&\quad \leq \exp\left(\frac{C + C(|x| + |z|) - C(|z| - |x|)_+^2}{\varepsilon} + \frac{1}{2\varepsilon}\int_0^{T_\varepsilon} C|\tilde{m}_s - X_1|^2 ds\right) \\
&\quad \leq \exp\left(\frac{C + C(|x| + |z|) - C(|z| - |x|)_+^2}{\varepsilon}\right),
\end{aligned}$$

where in the last inequality we have used the last part of Lemma 2.1. This completes the proof of (3.11).

The proof of (3.12) proceeds along similar lines. The starting point is the change of measure leading to (4.20). Define the function

$$\Psi_t = \begin{cases} x + 2(X_1 - x)t, & t \leq \frac{1}{2}, \\ X_1, & T - \frac{1}{2} > t \geq \frac{1}{2}, \\ z + 2(z - X_1)(t - T), & T \geq t \geq T - \frac{1}{2}. \end{cases}$$

Let D denote the event

$$D := \left\{ \sup_{t \le T} |\bar{Z}_t^{\varepsilon,x} - \Psi_t| < \sqrt{\varepsilon} \right\}.$$

We will prove below that, for $|x - X_1| \le 1$ and $T < T_\varepsilon$, there exists a constant C independent of T and ε such that

$$\mathbb{P}(D) \ge e^{-C/\varepsilon}. \tag{4.24}$$

We can clearly bound the right-hand side of (4.20) from below by

$$\begin{aligned}
\mathbb{E}\Bigg[& \mathbf{1}_{\{|\bar{Z}_T^{\varepsilon,x} - z| < \delta\}} \mathbf{1}_{\{||\bar{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon\}} \mathbf{1}_D \\
& \cdot \exp\left(\frac{1}{\varepsilon} \int_0^T \left[-h(\bar{Z}_t^{\varepsilon,x}) + \tilde{m}_s h'(\bar{Z}_s^{\varepsilon,x}) - \varepsilon b(\bar{Z}_s^{\varepsilon,x}) \right] d\bar{Z}_s^{\varepsilon,x} \right. \\
& \qquad - \frac{1}{\varepsilon} \int_0^T \left(\frac{[h(\bar{Z}_t^{\varepsilon,x}) - h(\tilde{m}_t)]^2}{2} + \frac{b^2(\bar{Z}_t^{\varepsilon,x})\varepsilon^2}{2} + \varepsilon b(\bar{Z}_s^{\varepsilon,x}) h(\bar{Z}_s^{\varepsilon,x}) \right. \\
& \qquad\qquad \left. \left. - \varepsilon h'(\bar{Z}_s^{\varepsilon,x}) b(\bar{Z}_s^{\varepsilon,x}) \tilde{m}_s - \varepsilon g_1(\bar{Z}_s^{\varepsilon,x}, \tilde{m}_s) \right) ds \right) \Bigg].
\end{aligned}$$

We now assume that (4.24) and $|z - X_1| \le 1$ hold. Then using the same integration by parts as in the proof of the upper bound, one concludes that the right-hand side of (4.20) is bounded from below by

$$\mathbb{E}\left[\mathbf{1}_D \exp\left(\frac{-C}{\varepsilon} + \frac{1}{\varepsilon} \int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,x}) d\bar{Z}_s^{\varepsilon,x} \right) \right]. \tag{4.25}$$

However, since

$$\mathrm{Var}\left(\int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,x}) d\bar{Z}_s^{\varepsilon,x} \right) \le C\varepsilon,$$

one gets, using Chebyshev's inequality, that

$$\mathbb{P}\left[\int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,x}) d\bar{Z}_s^{\varepsilon,x} < -c \right] \le \exp\left(-\frac{C_2 c^2}{\varepsilon} \right).$$

Hence,

$$\mathbb{P}\left[\int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,x}) d\bar{Z}_s^{\varepsilon,x} < -c | D \right] \le \frac{\exp\left(-\frac{C_2 c^2}{\varepsilon} \right)}{\mathbb{P}(D)} \le \frac{1}{2}$$

if c is chosen large, where in the last inequality we used (4.24). In particular, it follows that

$$\mathbb{E}\left[\exp\left(\frac{1}{\varepsilon} \int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,x}) d\bar{Z}_s^{\varepsilon,x} \right) \,\middle|\, D \right] \ge \exp\left(-\frac{C}{\varepsilon} \right)$$

for some $C > 0$. Substituting back into (4.25), the required lower bound follows.

It thus remains only to prove (4.24). This, however, is immediate from a martingale argument: first, perform the change of measure making $S_t := \bar{Z}_t^{\varepsilon,x} - \Psi_t$ into a Brownian motion of variance ε. Then, for $1 \le T \le T_\varepsilon$,

$$\mathbb{P}(D) = \mathbb{E}\left(\mathbf{1}_{\{\sup_{t\le T}|S_t|\le\sqrt{\varepsilon}\}} \exp\left(-\frac{1}{\varepsilon}\int_0^T \dot{\Psi}_t dS_t - \frac{1}{2\varepsilon}\int_0^T \dot{\Psi}_t{}^2 dt\right)\right).$$

Integrating the stochastic integral by parts and using that $\dot{\Psi}(t) = 0$ for $t \in (1/2, T - 1/2)$, (4.24) follows, which completes the proof of the lemma. □

Proof of (3.26). We let $\eta > 0$ as before. Note first that, by (4.5) and (4.6), there is a constant M depending on $|||\tilde{m}|||$ only such that

$$\limsup_{\varepsilon\to 0} \varepsilon \log \int_{[-M/\sqrt{\varepsilon}, M/\sqrt{\varepsilon}]^c} q_1^\varepsilon(x)dx = -\infty. \tag{4.26}$$

We may and will in what follows assume that $M = M_1$, where M_1 is defined in Lemma 3.3, and we use M_3 and M_2 as in Lemma 3.4.

Next, set ε_4 such that $\varepsilon_4 \log 2 < \eta/8$ and $\varepsilon \log(2M_3/\varepsilon\delta) \le \eta/8$ for $\varepsilon < \varepsilon_4$. Repeating the arguments in (3.21), without using the compact set $\mathcal{K}_1$, one has for $\varepsilon < \varepsilon_4$ and $|x| \le M_1/\sqrt{\varepsilon}$,

$$\begin{aligned}
\varepsilon \log \rho_1^\varepsilon(x) &\le -F(x,\tilde{m}_0) + \varepsilon \log \tilde{J}_\varepsilon(x) + \frac{\eta}{4} \quad \texttt{as in (3.21)} \\
&\le -F(x,\tilde{m}_0) + \varepsilon \log \sup_{|z|\le M_3/\varepsilon} \hat{J}_{\varepsilon,T}(x,z) + \frac{\eta}{2} \quad \texttt{by (3.13) and (3.15)} \\
&\le -F(x,\tilde{m}_0) + \frac{\eta}{2} + C_2 - C_3(|z|-|x|)_+^2 + C_5(|x|+|z|) \\
&\quad + \varepsilon \log \mathbb{E}\left[L_\varepsilon\left(X_1, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon - T} \le M_2/\varepsilon\}}\right].
\end{aligned} \tag{4.27}$$

A similar argument shows that for $|x - X_1| < 1$ and some constant C_6 depending only on $X, |||\tilde{m}|||$,

$$\begin{aligned}
\varepsilon \log \rho_1^\varepsilon(x) \ge &-F(X_1,X_1) - C_6 \\
&+ \varepsilon \log \mathbb{E}\left[L_\varepsilon\left(X_1, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon - T} \le M_2/\varepsilon\}}\right].
\end{aligned} \tag{4.28}$$

Fixing now an L, and using as in (3.18) the uniform quadratic growth of $F(x,m)$ as $|x| \to \infty$ and $|m| < |||\tilde{m}|||$, one finds a compact set $\mathcal{K}^L$ such that

$$\begin{aligned}
&\sup_{|m|<|||\tilde{m}|||} \sup_{x\in(\mathcal{K}^L)^c, z\in\mathbb{R}} \frac{C_2}{\varepsilon} - \frac{C_3(|z|-|x|)_+^2}{\varepsilon} + \frac{C_5(|x|+|z|)}{\varepsilon} - F(x,m) \\
&\qquad \le -F(X_1,X_1) - \frac{C_6 + L}{\varepsilon},
\end{aligned} \tag{4.29}$$

and hence, from (4.27) and (4.28), for $x \in (\mathcal{K}^L)^c \cap [-M_1/\sqrt{\varepsilon}, M_1/\sqrt{\varepsilon}]$,

$$\varepsilon \log \rho_1^\varepsilon(x) \le \inf_{|y - X_1|\le 1} \varepsilon \log \rho_1^\varepsilon(y) - L. \tag{4.30}$$

Hence,

(4.31)

$$\begin{aligned}
\limsup_{\varepsilon\to 0}\varepsilon\log\int_{(\mathcal{K}^L)^c} q_1^\varepsilon(x)dx &= \limsup_{\varepsilon\to 0}\varepsilon\log\int_{(\mathcal{K}^L)^c\cap[-M_1/\sqrt{\varepsilon},M_1/\sqrt{\varepsilon}]} q_1^\varepsilon(x)dx \quad \texttt{by (4.26)}\\
&\le \limsup_{\varepsilon\to 0}\left[\varepsilon\log\int_{(\mathcal{K}^L)^c\cap[-M_1/\sqrt{\varepsilon},M_1/\sqrt{\varepsilon}]}\rho_1^\varepsilon(x)dx - \varepsilon\log\int_{[X_1-1,X_1+1]}\rho_1^\varepsilon(x)dx\right]\\
&\le \limsup_{\varepsilon\to 0}\left[\varepsilon\log\left(\frac{2M_1}{\sqrt{\varepsilon}}\right) + \inf_{|y-X_1|\le 1}\varepsilon\log\rho_1^\varepsilon(y) - L - \inf_{|y-X_1|\le 1}\varepsilon\log\rho_1^\varepsilon(y)\varepsilon\log 2\right]\\
&\qquad\qquad \texttt{by (4.30)}\\
&\le -L\,.
\end{aligned}$$

This completes the proof. □

Appendix. Derivation of (2.1). We first recall Picard's theorem [7, Proposition 4.2]: under the assumptions of the current paper and with the same notation, a version of the conditional unnormalized density is given by

$$\tilde{q}(1,x) = \exp\left\{\frac{1}{2\varepsilon^2}\int_0^1 h^2(\bar{m}_s)ds - \frac{1}{\varepsilon}F(x,\tilde{m}_0)\right\}\tilde{\mathbb{E}}'\left[\exp\rho_1^{y,x}\right], \tag{A.1}$$

where

$$\begin{aligned}
\rho_1^{x,y} &= \log p_0(\bar{X}_1^x) + \frac{1}{\varepsilon}F(\bar{X}_1^x,0) - \frac{1}{\varepsilon}\int_0^1 h(\bar{m}_s)d\bar{X}_s^x - \frac{1}{\varepsilon}\int_0^1 h(\bar{X}_s^x)b(\bar{m}_s)ds\\
&\quad + \frac{1}{\varepsilon}\int_0^1 \bar{m}_s h'(\bar{X}_s^x)d\bar{X}_s^x + \frac{1}{2\varepsilon}\int_0^1 \bar{m}_s h''(\bar{X}_s^x)ds\\
&\quad + \frac{1}{\varepsilon}\int_0^1\left[b(\bar{X}_s^x)(h(\bar{X}_s^x)-h(\bar{m}_s)) - \frac{1}{2}h'(\bar{X}_s^x) - \varepsilon b'(\bar{X}_s^x)\right]ds,\\
d\bar{X}_s^x &= -\frac{1}{\varepsilon}(h(\bar{X}_s^x)-h(\bar{m}_s))ds - b(\bar{X}_s^x)ds + dW_s, \quad \bar{X}_0^x = x,
\end{aligned}$$

$W_\cdot$ is a Brownian motion, and $\tilde{\mathbb{E}}'$ denotes expectation with respect to this Brownian motion. Performing a time change $t\mapsto\varepsilon t$ and setting $\tilde{W}_t = \frac{1}{\sqrt{\varepsilon}}W_{\varepsilon t}$, we have that $\tilde{W}_t$ is again a standard Brownian motion and, with $\bar{X}_t^{\varepsilon,x} = \bar{X}_{\varepsilon t}^x$,

$$\begin{aligned}
\rho_1^{x,y} &= \log p_0(\bar{X}_{1/\varepsilon}^{\varepsilon,x}) + \frac{1}{\varepsilon}F(\bar{X}_{1/\varepsilon}^{\varepsilon,x},0) - \frac{1}{\varepsilon}\int_0^{1/\varepsilon} h(\tilde{m}_s)d\bar{X}_s^{\varepsilon,x} - \int_0^{1/\varepsilon} h(\bar{X}_s^{\varepsilon,x})b(\tilde{m}_s)ds\\
&\quad + \frac{1}{\varepsilon}\int_0^{1/\varepsilon}\tilde{m}_s h'(\bar{X}_s^{\varepsilon,x})d\bar{X}_s^{\varepsilon,x} + \frac{1}{2}\int_0^{1/\varepsilon}\tilde{m}_s h''(\bar{X}_s^{\varepsilon,x})ds\\
&\quad + \int_0^{1/\varepsilon}\left[b(\bar{X}_s^{\varepsilon,x})(h(\bar{X}_s^{\varepsilon,x})-h(\tilde{m}_s)) - \frac{1}{2}h'(\bar{X}_s^{\varepsilon,x}) - \varepsilon b'(\bar{X}_s^{\varepsilon,x})\right]ds,\\
d\bar{X}_s^{\varepsilon,x} &= -(h(\bar{X}_s^{\varepsilon,x})-h(\tilde{m}_s))ds - \varepsilon b(\bar{X}_s^{\varepsilon,x})ds + \sqrt{\varepsilon}d\tilde{W}_s\,, \quad \bar{X}_0^{\varepsilon,x} = x,
\end{aligned}$$

and

$$\tilde{q}(1,x) = \exp\left\{\frac{1}{2\varepsilon}\int_0^{1/\varepsilon} h^2(\tilde{m}_s))ds - \frac{1}{\varepsilon}F(x,\tilde{m}_0)\right\}\tilde{\mathbb{E}}\left[\exp\rho_1^{y,x}\right], \tag{A.2}$$

where the expectation now is with respect to the Brownian motion $\tilde{W}_t$.

Observe next that, by Girsanov's theorem, the law of the process $\bar{X}_t^{\varepsilon,x}$ is absolutely continuous with respect to that of the process $\tilde{Z}_t^{\varepsilon,x}$, with the Radon–Nikodym derivative given by

$$
\begin{aligned}
e^{\Lambda} = \exp\Bigg[& \frac{1}{\varepsilon}\int_0^{1/\varepsilon} [h(\tilde{m}_s) - \tilde{m}_s h'(\tilde{Z}_s^{\varepsilon,x})] d\tilde{Z}_s^{\varepsilon,x} \\
& - \frac{1}{2\varepsilon}\int_0^{1/\varepsilon} [h(\tilde{Z}_s^{\varepsilon,x}) - h(\tilde{m}_s) + \varepsilon b(\tilde{Z}_s^{\varepsilon,x})]^2 ds \\
& + \frac{1}{2\varepsilon}\int_0^{1/\varepsilon} [h(\tilde{Z}_s^{\varepsilon,x}) - \tilde{m}_s h'(\tilde{Z}_s^{\varepsilon,x}) + \varepsilon b(\tilde{Z}_s^{\varepsilon,x})]^2 ds \Bigg].
\end{aligned} \tag{A.3}
$$

Hence, with $\mathbb{E}$ denoting expectations with respect to the Brownian motion $\tilde{W}_t$ appearing in the definition of $\tilde{Z}_t^{\varepsilon,x}$, (A.2) transforms to

$$
\tilde{q}(1,x) = \exp\left\{ \frac{1}{2\varepsilon}\int_0^{1/\varepsilon} h^2(\tilde{m}_s))ds - \frac{1}{\varepsilon}F(x,\tilde{m}_0) \right\} \mathbb{E}\exp[\Lambda_1(x)],
$$

where

$$
\begin{aligned}
\Lambda_1(x) = {} & \Lambda + \log p_0(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) + \frac{1}{\varepsilon}F(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x},0) - \frac{1}{\varepsilon}\int_0^{1/\varepsilon} h(\tilde{m}_s) d\tilde{Z}_s^{\varepsilon,x} - \int_0^{1/\varepsilon} h(\tilde{Z}^{\varepsilon,x}) b(\tilde{m}_s) ds \\
& + \frac{1}{\varepsilon}\int_0^{1/\varepsilon} \tilde{m}_s h'(\tilde{Z}_s^{\varepsilon,x}) d\tilde{Z}_s^{\varepsilon,x} + \frac{1}{2}\int_0^{1/\varepsilon} \tilde{m}_s h''(\tilde{Z}_s^{\varepsilon,x}) ds \\
& + \int_0^{1/\varepsilon} \left[b(\tilde{Z}_s^{\varepsilon,x})(h(\tilde{Z}_s^{\varepsilon,x}) - h(\tilde{m}_s)) - \frac{1}{2}h'(\tilde{Z}_s^{\varepsilon,x}) - \varepsilon b'(\tilde{Z}_s^{\varepsilon,x}) \right] ds \\
= {} & \log p_0(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) + \frac{1}{\varepsilon}F(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x},0) + \int_0^{1/\varepsilon} g_1(\tilde{Z}_s^{1/\varepsilon},\tilde{m}_s) ds + \frac{1}{\varepsilon}\int_0^{1/\varepsilon} g_2(\tilde{Z}_s^{1/\varepsilon},\tilde{m}_s) ds.
\end{aligned}
$$

Since $\int_0^{1/\varepsilon} h^2(\tilde{m}_s)ds$ does not depend on x, taking

$$
\rho_1^{\varepsilon}(x) = \tilde{q}(1,x)\exp\left\{ -\frac{1}{2\varepsilon}\int_0^{1/\varepsilon} h^2(\tilde{m}_s))ds \right\}
$$

gives a version of the unnormalized conditional density that coincides with (2.2). □

Acknowledgment. We thank Ki-Jung Lee for a careful reading of a preliminary version of this paper. We also thank an anonymous referee for a detailed reading of the paper and many useful and important comments.

WELL-POSEDNESS OF NONCONVEX INTEGRAL FUNCTIONALS*

SILVIA VILLA†

Abstract. We find a sufficient condition which does not involve global convexity, guaranteeing well-posedness in a strong sense of the minimization of a multiple integral on the Sobolev space $W^{1,1}(\Omega;\mathbb{R}^m)$ with boundary datum equal to zero. In particular we apply our result to some nonconvex problems recently studied: functionals depending only on the gradient and radially symmetric functionals.

Key words. calculus of variations, well-posedness, nonconvex integrals, extreme points

AMS subject classifications. 49K40, 49A50

DOI. 10.1137/S0363012903437289

1. Introduction.

We consider well-posedness properties of the problem of minimizing the integral

$$J(u) = \int_\Omega L(x, u(x), Du(x))\, dx \tag{1.1}$$

in some class of vector-valued Sobolev functions with boundary datum equal to zero.

There are at least two different concepts of well-posedness. We recall that a minimization problem is called Tikhonov well-posed if there exists a unique minimizer to which every minimizing sequence converges. On the other hand, a problem is well-posed by perturbations if the solution depends continuously on the problem's data: the idea is to embed the given minimization problem J defined by (1.1) in a suitable family of problems of the same kind depending on a parameter which varies in a convenient topological space $\mathcal{A}$. In this manner, the functional that we are minimizing corresponds to a fixed parameter $a \in \mathcal{A}$, and we can denote it by J_a. For every sequence $a_n \in \mathcal{A}$ such that $a_n \to a$ we consider the corresponding functional J_{a_n}, assuming that $\inf J_a$ and $\inf J_{a_n}$ are finite. We say that a sequence u_n is asymptotically minimizing for J_{a_n} if $J_{a_n}(u_n) - \inf J_{a_n} \to 0$. Now, more precisely, well-posedness by perturbations of J_a means that J_a has a unique minimizer u_0, that any asymptotically minimizing sequence converges to u_0, and that $\inf J_{a_n} \to \inf J_a$ for any $a_n \to a$. We observe in particular that if a minimization problem is well-posed by perturbations, it is also Tikhonov well-posed. See section 4 for rigorous definitions, [12] for a survey, and [24]. In our context we deal with perturbations of the integrand (see Corollary 4.12) and, in section 5, with perturbations of the boundary data, as was done in [8] and [23].

In the recent work [15] Ioffe and Zaslavski proved a variational principle, thanks to which it is possible to show that well-posedness by perturbations with respect to a suitable topology on the space of the integrands is a generic property. Moreover, in [22] a stronger result is proved: the set of ill-posed problems of the calculus of variations is not only of the first category, but it is also σ-porous.

Surprisingly, the classical hypotheses of convexity and superlinearity at infinity are not needed generically to have well-posedness, and therefore existence and uniqueness of the minimizer, for an integral functional.

In this context it is useful to find a characterization of well-posed problems, or at least some sufficient conditions which imply well-posedness without involving global convexity. We note that uniqueness of the solution does not imply well-posedness of classical problems of the calculus of variations: examples of ill-posed problems with a unique solution can be found in [8].

There are not many well-posedness results in the classical calculus of variations; however, results on this subject are proved in [4], [8], [12], [23], and [24] with respect to different types of perturbations.

In [4] a Tikhonov well-posed one-dimensional integral functional is considered. In particular it is proved that under suitable hypotheses this is enough to get the strong convergence in some Sobolev space of the asymptotically minimizing sequences corresponding to perturbations of the integrand with respect to the variational convergence not involving the derivative.

In [23] sufficient and necessary conditions are obtained for well-posedness by perturbations of the boundary data for integral functionals depending only on the gradient. The integrand is assumed to be continuous in the one-dimensional case and, moreover, to have polynomial growth in the multidimensional one.

We find a sufficient condition of local character for Tikhonov well-posedness of an integral functional defined on the Sobolev space $W_0^{1,1}(\Omega;\mathbb{R}^m)$ by extending some results of [18] and [21]. More precisely we extend the definition of strict convexity at a point given by Sychev for continuous functions to the case of lower semicontinuous functions. Then we use this local definition to generalize the results of Visintin in [21] without global strict convexity assumptions, and to get new well-posedness results. We also remark that results analogous to the ones contained in [21] were obtained by Olech in [17].

The strategy of the proof is completely different from that in [18]; in fact, we investigate the geometric properties of the point at which the function is strictly convex, and this fact allows us to drop out the hypothesis of continuity of the integrand. This is remarkable because in this way it is possible to consider integrands also assuming the value $+\infty$ and therefore to treat problems with constraints.

Well-posedness by perturbations of the same problem follows from [19], where the equivalence between Tikhonov well-posedness and well-posedness by perturbations is proved under suitable hypotheses.

This paper is organized as follows. After introducing in section 2 definitions and preliminaries, in section 3 we state some properties of convex and strictly convex functions at a point. In fact we require these hypotheses on the integrand in order to get well-posedness of the integral functional.

In particular, Lemma 3.4 is useful because it relates different hypotheses made in the literature in order to obtain strong convergence of a sequence which is only weakly convergent.

In section 4 we obtain the main result, Corollary 4.11, which establishes in particular that if the integrand is strictly convex at the point $Du(x)$ for almost every $x \in \Omega$ (where u is the minimizer), then the minimizing sequences are in fact strongly convergent to u in $W_0^{1,1}(\Omega;\mathbb{R}^m)$. This is a consequence of Theorem 4.2, which partially extends Theorem 2 of [18] to lower semicontinuous integrands. In other words we get that every coercive integral functional with a unique minimizer u is Tikhonov

well-posed and well-posed by perturbations if the integrand is strictly convex at the point $Du(x)$ for almost every $x \in \Omega$. Moreover, as a consequence of the representation formula for the relaxed functional given, for instance, in [16], we give a sufficient condition for well-posedness which depends only on the problem's data, namely, on the integrand L and on its convex regularization with respect to the last variable, denoted by L^{**}. More precisely in Theorem 4.13 we prove that an integral functional is Tikhonov well-posed if it has a unique minimizer and it is strictly convex at every point belonging to the set where the integrands L and L^{**} coincide.

Finally, in section 5, we apply our results to study well-posedness of two classes of integral functionals. The first is the case of integrands depending only on the gradient, and with linear boundary datum: for this class we extend a previous result of [8] and we prove stability of the solution by perturbations of the boundary data. The second is the case of radially symmetric functionals, treated, for instance, in [7] and [10]. For this class we prove that the hypotheses which ensure existence and uniqueness of the solution guarantee also well-posedness in the sense of Tikhonov and therefore also well-posedness by perturbations with respect to the bounded Hausdorff topology (which we review in section 4).

2. Definitions and preliminaries. As we said in the introduction, very few results, not only regarding well-posedness but also existence and uniqueness of the minimizer of an integral functional, are known without the classical hypotheses of convexity and superlinearity of the integrand. As is well known, these hypotheses guarantee lower semicontinuity of the functional (1.1) and compactness of its sublevel sets with respect to the weak topology of the relevant Sobolev space.

Since we aim to avoid the global convexity requirement and to replace it with a local property, we start with the following definition, which is equivalent to the one given in [18] in the case of continuous functions.

DEFINITION 2.1. *Let U be a closed convex subset of $\mathbb{R}^n$ and $u_0 \in U$. We say that a function $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is* convex at u_0 *with respect to the set U if*

$$\sum_{i=1}^{m} c_i f(v_i) \geq f(u_0) \tag{2.1}$$

for every $m > 0$, and for every $v_i \neq u_0$ and $c_i > 0$ such that $v_i \in U$, $\sum_{i=1}^m c_i = 1$, and $\sum_{i=1}^m c_i v_i = u_0$.

If inequality (2.1) *is always strict, we say that the function f is* strictly convex at u_0 *with respect to U.*

It is very easy to find examples of convex and strictly convex functions at a point which are not globally convex: e.g., the function $x \mapsto \sqrt{|x|}$ is convex at the point 0 with respect to $\mathbb{R}$.

In the case that $U = \mathbb{R}^n$ we do not specify the set with respect to which f is convex.

Remark 2.2. In the definition of strict convexity at a point we require

(a) $\sum_{i=1}^m c_i f(v_i) > f(u_0)$ for every $m > 0$, and for every $v_i \neq u_0$ and $c_i > 0$ such that $\sum_{i=1}^m c_i = 1$ and $\sum_{i=1}^m c_i v_i = u_0$. We observe that it would be equivalent to require that

(b) $\sum_{i=1}^m c_i f(v_i) > f(u_0)$ for every $m > 0$, for every v_i, $i = 1, \ldots, m$, such that there exists at least some $v_j \neq u_0$, and for every $c_i > 0$ such that $\sum_{i=1}^m c_i = 1$ and $\sum_{i=1}^m c_i v_i = u_0$.

The existence theory of minimizers for nonconvex integrands is based on the idea of relaxation (see, e.g., [16]). In this context we recall the definition of the convex regularization, or the second conjugate, of a given function f.

DEFINITION 2.3. *Let $f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$. The* convex regularization of f *(or* second conjugate *of f) is the function f^{**} defined by*

$$f^{**}(x) = \sup\{g(x) \mid g : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\},\ g \text{ l.s.c. and convex},\ g \le f\}.$$

If the function f^{**} is proper, the following equality holds (see Proposition 3.2 of [13]):

$$\overline{\text{co}}(\text{epi} f) = \text{epi} f^{**}. \tag{2.2}$$

Here $\overline{\text{co}}$ denotes the closed convex hull. See [13] for further properties of f^{**}.

3. Properties of convex functions at a point. In this section we collect some general results about convex and strictly convex functions at a point that we will need later in the case of integrands arising in the calculus of variations.

We begin with a lemma which establishes a formula for computing the convex regularization of the restriction to an arbitrary closed ball of a given function defined on $\mathbb{R}^n$, useful in characterizing the points where f and f^{**} coincide, according to the following corollary. In the following we denote by f_r the function defined on $\mathbb{R}^n$ by setting $f_r = f$ on the closed ball $\overline{B}(u_0, r)$ with center u_0 and radius r and $f_r = +\infty$ otherwise.

LEMMA 3.1. *Let $f : \mathbb{R}^n \to [0, +\infty]$ be lower semicontinuous. Then the following formula holds:*

$$(f_r)^{**}(u) = \min\left\{ \sum_{i=1}^{m} c_i f(v_i) \;\middle|\; m \in \mathbb{N}; c_i > 0; v_i \in \overline{B}(u_0, r); \sum_{i=1}^{m} c_i = 1; \sum_{i=1}^{m} c_i v_i = u \right\} \tag{3.1}$$

for every $u_0 \in \mathbb{R}^n$ and for every $r > 0$.

Proof. Fix $u_0 \in \mathbb{R}^n$ and $r > 0$. Since f is lower semicontinuous, then f_r is lower semicontinuous too. In addition f_r is a superlinear function. From [13, Lemma 3.3, p. 280], it follows that formula (3.1) holds. □

A direct consequence of the preceding lemma is the following corollary.

COROLLARY 3.2. *Let $f : \mathbb{R}^n \to [0, +\infty]$ be lower semicontinuous. Then f is convex at $u_0 \in \mathbb{R}^n$ if and only if $f(u_0) = f^{**}(u_0)$.*

Proof. Suppose that f is convex at $u_0 \in \mathbb{R}^n$. Fix $r > 0$ and let $m \in \mathbb{N}$, $c_i > 0$, and $v_i \in \overline{B}(u_0, r)$ such that $\sum_{i=1}^m c_i = 1$ and $\sum_{i=1}^m c_i v_i = u_0$. Then by the definition of convexity at a point we get $f(u_0) \le \sum_{i=1}^m c_i f(v_i)$. Passing to the infimum on the convex combinations of points lying in $\overline{B}(u_0, r)$ and using Lemma 3.1, we obtain the inequality $f(u_0) \le (f_r)^{**}(u_0)$. Passing to the limit for $r \to +\infty$ (see, for instance, [13, Lemma 3.1, p. 329]), we get $f(u_0) \le f^{**}(u_0)$. Since $f^{**} \le f$, we conclude that $f(u_0) = f^{**}(u_0)$.

The other implication follows immediately from Lemma 3.1. □

We now recall the definition of an extreme point, since we will need this concept in what follows.

DEFINITION 3.3. *Let C be a convex subset of $\mathbb{R}^n$ and let $z \in C$. We say that z is an* extreme point of C *if $\lambda x + (1-\lambda)y = z$ for $\lambda \in (0,1)$ and $x, y \in C$ imply $x = y = z$.*

It's easy to verify that

$$z \text{ is an extreme point of } C \iff C \setminus \{z\} \text{ is convex.} \tag{3.2}$$

The next lemma shows the relation between strict convexity of a function at a point u_0 and extremality of the corresponding point of $(u_0, f(u_0))$ with respect to the epigraph of the second conjugate of f.

One implication is always true: if the point $(u_0, f^{**}(u_0))$ is extremal for $\mathrm{epi}f^{**}$, then the function f is strictly convex at the point u_0.

The converse does not hold in general, although it is true that the point $(u_0, f(u_0))$ is extremal for the epigraph of the convex regularization of the function f restricted to any closed ball of center u_0 and arbitrary radius.

LEMMA 3.4. *Let $f : \mathbb{R}^n \to [0, +\infty]$ be lower semicontinuous and proper. Then the following hold:*

1. *If $(u_0, f^{**}(u_0))$ is an extreme point of $\mathrm{epi}f^{**}$, then f is strictly convex at u_0.*
2. *If f is strictly convex at u_0, then $(u_0, f(u_0))$ is an extreme point of $\mathrm{epi}(f_r)^{**}$ for all $r > 0$.*

Proof. Suppose that $(u_0, f^{**}(u_0))$ is an extreme point of $\mathrm{epi}f^{**}$. By Remark 5.3 of [10] we get $f(u_0) = f^{**}(u_0)$.

Let $v_i \in \mathbb{R}^n$, $c_i > 0$ for $i = 1, \dots, m$ such that $\sum_{i=1}^m c_i v_i = u_0$. Since $f^{**} \le f$ we have that $(v_i, f(v_i)) \in \mathrm{epi}f^{**}$, and by the convexity of $\mathrm{epi}f^{**}$ it follows that

$$\sum_{i=1}^{m} c_i f(v_i) \ge f(u_0).$$

If the equality occurs, we get $v_i = u_0$ for every i, because $(u_0, f(u_0))$ is an extreme point. This implies that f is strictly convex at u_0.

Conversely, suppose that f is strictly convex at u_0. By definition we immediately obtain that also f_r is strictly convex at u_0 for every $r > 0$. According to (3.2) it's enough to prove that the set $\mathrm{epi}(f_r)^{**} \setminus (u_0, f(u_0))$ is a convex set. We will show that

(i) $\mathrm{co}(\mathrm{epi}f_r) \setminus (u_0, f(u_0))$ is a convex set;
(ii) $\mathrm{co}(\mathrm{epi}f_r)$ is closed.

Then the thesis will follow from the equality $\mathrm{epi}(f_r)^{**} = \overline{\mathrm{co}}(\mathrm{epi}f_r)$.

Let us first prove assertion (i). Fix $(v, s), (w, t) \in \mathrm{co}(\mathrm{epi}f_r) \setminus (u_0, f(u_0))$ and let $\lambda \in (0, 1)$. Since (v, s) and (w, t) are in the convex envelope of a subset of $\mathbb{R}^{n+1}$, by Carathéodory's theorem (see [11, p. 42]) they can be written as a convex combination of $(n + 2)$ points of $\mathrm{epi}f_r$:

$$(v, s) = \sum_{i=1}^{n+2} c_i(v_i, s_i); \quad (w, t) = \sum_{i=1}^{n+2} d_i(w_i, t_i). \tag{3.3}$$

Now consider the point $\lambda(v, s) + (1 - \lambda)(w, t)$. Certainly this point is in $\mathrm{co}(\mathrm{epi}f_r)$ by the definition of a convex envelope. We have to prove that it is not $(u_0, f(u_0))$. For this purpose assume that $\lambda v + (1 - \lambda)w = u_0$; we are going to show that $\lambda s + (1 - \lambda)t \ne f(u_0)$. From (3.3) we get

$$\sum_{i=1}^{n+2} \lambda c_i v_i + (1 - \lambda) d_i w_i = u_0; \tag{3.4}$$

i.e., u_0 is a convex combination of the points v_i and w_i, which are not all equal to u_0.

Recalling the strict convexity at the point u_0 and Remark 2.2, by (3.4) it follows that

$$\begin{aligned} f(u_0) &< \sum_{i=1}^{n+2} \lambda c_i f(v_i) + (1-\lambda) d_i f(w_i) \\ &\le \sum_{i=1}^{n+2} \lambda c_i s_i + (1-\lambda) d_i t_i \\ &= \lambda s + (1-\lambda) t. \end{aligned}$$

We obtain therefore that $\lambda(v,s) + (1-\lambda)(w,t)$ is in $\operatorname{co}(\operatorname{epi} f_r) \setminus \{(u_0, f(u_0))\}$ and assertion (i) is proved.

Now, it is enough to show that assertion (ii) holds.

Since f_r is lower semicontinuous and superlinear, (ii) is a consequence of [13, Lemma 3.3, p. 280] and the proof is complete. □

Remark 3.5. As we observed before, the converse of the first statement of the previous lemma is not true in general. Consider, for instance, the function $f : \mathbb{R} \to \mathbb{R}$ defined by

$$f(x) = \begin{cases} |x| & \text{if } |x| \le 1, \\ 1 & \text{if } |x| > 1. \end{cases}$$

Clearly f is strictly convex at 0, but $(0,0)$ is not extremal for $\operatorname{epi} f^{**} = \mathbb{R} \times [0, +\infty]$.

4. Well-posedness results. In this section we obtain a sufficient condition that guarantees well-posedness of the minimization problem of an integral functional. First of all we recall the definition of a normal integral.

DEFINITION 4.1. *Let $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^l \to [-\infty, +\infty]$, with Ω an open subset of $\mathbb{R}^n$. We say that g is a* normal integrand *if*

(i) *for almost every $x \in \Omega$, $g(x, \cdot, \cdot)$ is lower semicontinuous;*

(ii) *there exists a Borel function $\hat{g} : \Omega \times \mathbb{R}^m \times \mathbb{R}^l \to [-\infty, +\infty]$ such that $\hat{g}(x, \cdot, \cdot) = g(x, \cdot, \cdot)$ for almost every $x \in \Omega$.*

More precisely we consider the problem cited in the introduction of minimizing the functional

$$J(u) = \int_\Omega L(x, Du(x))\, dx \tag{4.1}$$

in the class of functions $u \in W_0^{1,1}(\Omega; \mathbb{R}^m)$.

We always assume that Ω is an open and bounded subset of $\mathbb{R}^n$ and that $L : \Omega \times \mathbb{R}^{nm} \to [0, +\infty]$ is a normal integrand possibly taking the value $+\infty$. When the integrand is not summable, we define $J(u) = +\infty$.

In order to study the semicontinuity of (4.1) at a point and the convergence of minimizing sequences, we also deal with the more general functional

$$G(u, \xi) = \int_\Omega g(x, u(x), \xi(x))\, dx, \tag{4.2}$$

where $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^l \to [0, +\infty]$ is a normal integrand, $u \in L^1(\Omega; \mathbb{R}^m)$, and $\xi \in L^1(\Omega; \mathbb{R}^l)$. In the rest of the paper we will denote by $\rightharpoonup$ the weak convergence in the spaces $L^1(\Omega; \mathbb{R}^m)$ and $W^{1,1}(\Omega; \mathbb{R}^m)$.

Now we are able to state a partial generalization of Theorem 2 of [18] to the case of lower semicontinuous integrands.

THEOREM 4.2. *Let $L_1 : \Omega \times \mathbb{R}^l \to [0, +\infty]$ be a normal integrand and let J_1 be defined by $J_1(\xi) := \int_\Omega L_1(x, \xi(x))\,dx$. Consider $\xi_h, \xi_0 \in L^1(\Omega; \mathbb{R}^l)$ and suppose that the function $v \mapsto L_1(x, v)$ is strictly convex at the point $\xi_0(x)$ for almost every $x \in \Omega$.*

If $\xi_h \rightharpoonup \xi_0$ in $L^1(\Omega; \mathbb{R}^l)$ and $J_1(\xi_h) \to J_1(\xi_0)$, then

$$\|\xi_h - \xi_0\| \to 0 \ \text{ in } L^1(\Omega; \mathbb{R}^l).$$

We will apply Theorem 4.2 in order to obtain well-posedness results in the two senses mentioned in the introduction, namely, Tikhonov well-posedness and well-posedness by perturbations. We also remark that the integrand can assume the value $+\infty$: we emphasize that in this way Theorem 4.2 can be applied also to constrained problems. The strategy of the proof is different from the one adopted by Sychev in [18] for the case of Carathéodory integrands. In fact Sychev's proof is based on the compactness (which fails in our hypotheses) of the union of the subdifferentials with respect to the last variable evaluated at some special points.

First we prove a semicontinuity result, using the equality furnished by Corollary 3.2, and then, extending some results of [21], we obtain Theorem 4.2.

Results of strong convergence implied by weak were obtained also in [21] and in [17]. We remark that Theorem 3 of [21] is a special case of Theorem 4.2 under the more restrictive hypothesis of global strict convexity. The proof of Theorem 3 of [21] relies on Theorem 1 of the same paper, which states that a sequence weakly convergent to an extreme point of the convex hull of the whole sequence is in fact strongly convergent. The proof of Theorem 3 is thus reduced to show that from strict convexity, the extremality of the corresponding point for the epigraph of the second conjugate follows. If we do not require global strict convexity, but only strict convexity at a point, as we saw in Remark 3.5, this point is in general not extremal for epif^{**}. Moreover, it is not easy to check the extremality of a point for epif^{**}, since it is already difficult to calculate f^{**}. But reviewing the proof of Theorem 1 of [21] it turns out that for some special sequences the thesis is still valid under less restrictive hypotheses (see Lemma 4.5).

Before proving Theorem 4.2, we need some preliminary lemmas.

LEMMA 4.3. *Let $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^l \to [0, +\infty]$ be a normal integrand and let G be defined as in (4.2). Consider $u_h, u_0 \in L^1(\Omega; \mathbb{R}^m)$, $\xi_h, \xi_0 \in L^1(\Omega; \mathbb{R}^l)$, and suppose that the function $v \mapsto g(x, u_0(x), v)$ is convex at the point $\xi_0(x)$ for almost every $x \in \Omega$.*

If $\|u_h - u_0\| \to 0$ in $L^1(\Omega; \mathbb{R}^m)$ and $\xi_h \rightharpoonup \xi_0$ in $L^1(\Omega; \mathbb{R}^l)$, then

$$\liminf G(u_h, \xi_h) \geq G(u_0, \xi_0).$$

Proof. First of all, by the convexity at the point $\xi_0(x)$ and by Corollary 3.2, we obtain

$$g^{**}(x, u_0(x), \xi_0(x)) = g(x, u_0(x), \xi_0(x))$$

for almost every $x \in \Omega$, where g^{**} is the convex regularization of g with respect to the last variable. We also note that by standard facts (see, for instance, [13, Proposition 1.3, p. 238]) the function $(x, u, v) \mapsto g^{**}(x, u, v)$ is a normal integrand, and therefore the functional

$$\hat{G}(u, \xi) := \int_\Omega g^{**}(x, u(x), \xi(x))\,dx$$

is well defined and takes values in $[0, +\infty]$.

Moreover $\hat{G}$ verifies

$$\hat{G}(u, \xi) \leq G(u, \xi)$$

for every $u \in L^1(\Omega; \mathbb{R}^m)$ and $\xi \in L^1(\Omega; \mathbb{R}^l)$. Finally we observe that $\hat{G}$ is sequentially lower semicontinuous with respect to the weak topology at every point because g^{**} is convex with respect to the last variable, so

$$\liminf_{n \to +\infty} G(u_h, \xi_h) \geq \liminf \hat{G}(u_h, \xi_h) \geq \hat{G}(u_0, \xi_0) = G(u_0, \xi_0),$$

and this concludes the proof. □

If g and L_1 are normal integrands as before, and $u \in L^1(\Omega; \mathbb{R}^m)$, $\xi \in L^1(\Omega; \mathbb{R}^l)$, we write

$$g \circ (u, \xi) \quad \text{and} \quad L_1 \circ \xi$$

for the maps $x \mapsto g(x, u(x), \xi(x))$ and $x \mapsto L_1(x, \xi(x))$, respectively.

LEMMA 4.4. *Let $g : \Omega \times \mathbb{R}^m \times \mathbb{R}^l \to [0, +\infty]$ be a normal integrand and let $u_h, u_0 \in L^1(\Omega; \mathbb{R}^m)$, $\xi_h, \xi_0 \in L^1(\Omega; \mathbb{R}^l)$. Suppose that the function $v \mapsto g(x, u_0(x), v)$ is convex at the point $\xi_0(x)$ for almost every $x \in \Omega$.*

If $\|u_h - u_0\|_{L^1} \to 0$, $\xi_h \rightharpoonup \xi_0$, and $G(u_h, \xi_h) \to G(u_0, \xi_0)$, then $g \circ (u_h, \xi_h) \rightharpoonup g \circ (u_0, \xi_0)$ in $L^1(\Omega; \mathbb{R})$.

Proof. Using Lemma 4.3 the proof goes exactly as that of Lemma 3 of [21], since the only property that is used there is the semicontinuity of the functional G at the point (u_0, ξ_0) and not the semicontinuity at every point. □

LEMMA 4.5. *Assume that $\xi_h \rightharpoonup \xi$ and $L_1 \circ \xi_h \rightharpoonup L_1 \circ \xi$ in $L^1(\Omega; \mathbb{R}^l)$, where L_1 is defined as above. Set $K(x) = \mathrm{epi} L_1(x, \cdot)$ and $C(x, r) = \overline{B}(\xi(x), r) \times \mathbb{R}$ for almost every $x \in \Omega$. Suppose that $(\xi(x), L_1(x, \xi(x)))$ is an extremal point of $\overline{\mathrm{co}}(K(x) \cap C(x, r))$ for almost every $x \in \Omega$ and for all $0 < r < R$ for some fixed $R > 0$.*

Then $\xi_h \to \xi$ strongly in $L^1(\Omega; \mathbb{R}^l)$.

Proof. Without loss of generality we can suppose that $\xi(x) = 0$ and $L_1(x, \xi(x)) = 0$ for almost every $x \in \Omega$; in fact it is always possible to reduce the problem to this case simply by substituting $\mathrm{epi} L_1^{**}(x, \cdot)$ with the set $\mathrm{epi} L_1^{**}(x, \cdot) - (\xi(x), L_1(x, \xi(x)))$.

Mimicking the proof of Theorem 1 of [21], fix any ϵ such that $0 < \epsilon < R$.

Set

$$w_h^\epsilon(x) = \begin{cases} \xi_h(x) & \text{if } |\xi_h(x)| \leq \epsilon, \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad t_h^\epsilon(x) = \begin{cases} L(x, \xi_h(x)) & \text{if } |\xi_h(x)| \leq \epsilon, \\ 0 & \text{otherwise.} \end{cases}$$

From the definition, we have $(w_h^\epsilon(x), t_h^\epsilon(x)) \in K(x)$ for almost every $x \in \Omega$.

Define also $v_h^\epsilon = \xi_h - w_h^\epsilon$ and $s_h^\epsilon = L_1 \circ \xi_h - t_h^\epsilon$; it follows that also $(v_h^\epsilon(x), s_h^\epsilon(x))$ is in $K(x)$ for almost every $x \in \Omega$.

Since w_h^ϵ is bounded in the L^∞-norm, there exists a subsequence $w_{h'}^\epsilon$ and w^ϵ such that $w_{h'}^\epsilon \rightharpoonup w^\epsilon$ in $L^1(\Omega)$; hence $v_{h'}^\epsilon \rightharpoonup -w^\epsilon := v^\epsilon$ in $L^1(\Omega)$. Moreover, by hypothesis, we also have

$$t_h^\epsilon \rightharpoonup 0 \quad \text{and} \quad s_h^\epsilon \rightharpoonup 0.$$

As in Theorem 1 of [21] we get $\frac{(v^\epsilon, 0)}{2} + \frac{(w^\epsilon, 0)}{2} = (0, 0)$ almost everywhere in Ω and $(v^\epsilon(x), 0), (w^\epsilon(x), 0) \in \overline{\mathrm{co}}[K(x) \cap C(0, r)]$ for almost every $x \in \Omega$. Since $(0, 0)$ is

an extremal point of $\overline{\text{co}}[K(x) \cap C(0,r)]$, it follows that $v^\epsilon = w^\epsilon = 0$ and the whole sequence v_h^ϵ converges.

From now on, exactly as in [21] we obtain that $\|\xi_h\| \to 0$. □

Now we are able to prove the theorem stated at the beginning of this section.

Proof of Theorem 4.2. From Lemma 3.4, the point $(\xi_0(x), L_1(x, \xi_0(x)))$ is extremal for $\text{epi}(L_1)_r^{**}(x,\cdot)$, where $(L_1)_r(x,\cdot)$ is the function $L_1(x,\cdot)$ restricted to the closed ball of center $\xi_0(x)$ and radius r for every $r > 0$.

Consider the sequence $(\xi_h, L_1 \circ \xi_h)$. By Lemma 4.4 we have

$$(\xi_h, L_1 \circ \xi_h) \rightharpoonup (\xi_0, L_1 \circ \xi_0)$$

in $L^1(\Omega;\mathbb{R}^m) \times L^1(\Omega;\mathbb{R})$. Then the conclusion follows from Lemma 4.5. □

Theorem 4.2 can be applied to the functional (4.1).

COROLLARY 4.6. *Let $L : \Omega \times \mathbb{R}^{nm} \to [0, +\infty]$ be a normal integrand and let J be defined as in* (4.1).

Let $u_h, u \in W_0^{1,1}(\Omega;\mathbb{R}^m)$ be such that $Du_h \rightharpoonup Du$ in $L^1(\Omega;\mathbb{R}^{nm})$.

Suppose that the function $v \mapsto L(x,v)$ is strictly convex at the point $Du(x)$ for almost every $x \in \Omega$ and further that $J(u_h) \to J(u)$. Then

$$\|Du_h - Du\| \to 0$$

in $L^1(\Omega;\mathbb{R}^{mn})$.

Now we apply Theorem 4.2 to the special case of minimizing sequences in order to obtain a sufficient condition for Tikhonov well-posedness of a nonconvex integral functional. Finally, using the results of [19] we will also get a corollary about well-posedness by perturbations. More precisely, we deal with perturbations of the integrand, and in this framework it is reasonable to use the so-called variational convergences. In particular our result deals with the bounded Hausdorff convergence. See [1], [2], [3] for the properties of this convergence. We start by giving the definitions that we need.

Let X be a normed space.

DEFINITION 4.7. *We say that the problem of minimizing $J : X \to (-\infty, +\infty]$ is Tikhonov well-posed if it satisfies the following conditions:*

1. *There exists a unique global minimum point x_0 for J.*
2. *If x_h is any minimizing sequence, i.e., a sequence in X such that $J(x_h) \to J(x_0)$, then $\|x_h - x_0\| \to 0$.*

Let $J_h : X \to (-\infty, +\infty]$ be a sequence of functions. We say that J_h is equicoercive if there exists $\phi : [0, +\infty) \to \mathbb{R}$ such that

$$\lim_{y \to +\infty} \phi(y) = +\infty \quad \text{and} \quad J_h(x) \geq \phi(|x|)$$

for every $x \in X$.

Now we give the definition of well-posedness by perturbations for an abstract global minimization problem (see [24]).

We consider metric spaces X and $\mathcal{A}$, a fixed point $a_0 \in \mathcal{A}$, and $B(a_0, R)$, a given ball around a_0 with positive radius R in $\mathcal{A}$. We are given the proper extended real-valued functions

$$J : X \to (-\infty, +\infty], \quad F : B(a_0, R) \times X \to (-\infty, +\infty]$$

such that

$$J(x) = F(a_0, x), \ x \in X.$$

The corresponding value function is given by

$$V(a) = \inf\{F(a,x) \,|\, x \in X\},\ a \in \mathcal{A}.$$

DEFINITION 4.8. *The problem of minimizing J on X is called* well-posed by perturbations *(with respect to the embedding defined by F) if and only if*

1. *$V(a) > -\infty$ for all $a \in B(a_0, R)$;*
2. *there exists a unique global minimizer x_0 for J;*
3. *for every sequence $a_h \to a_0$ in $\mathcal{A}$ such that*

$$F(a_h, x_h) - V(a_h) \to 0 \text{ as } n \to +\infty \tag{4.3}$$

we have $x_h \to x_0$ in X.

Sequences as in (4.3) will be called asymptotically minimizing corresponding to the sequence a_h.

Now for $A, C \subset X$, the excess of A on C is given by

$$e(A,C) := \sup_{x \in A} d(x,C),$$

with the convention that $e(A,C) = 0$ if $A = \emptyset$ and $e(A,C) = +\infty$ if $C = \emptyset$. Then the ρ-Hausdorff distance between A and C is defined by

$$\mathrm{haus}_\rho(A,C) := \max\{e(A \cap B(0,\rho), C), e(C \cap B(0,\rho), A)\}.$$

DEFINITION 4.9. *For $\rho \geq 0$, the ρ-(Hausdorff) distance between $f, g : X \to \mathbb{R} \cup \{+\infty\}$ is*

$$\mathrm{haus}_\rho(f,g) := \mathrm{haus}_\rho(\mathrm{epi} f, \mathrm{epi} g),$$

where the unit ball of $X \times \mathbb{R}$ is the set $B(0,1) := \{(x,\alpha) : \|x\| \leq 1, |\alpha| \leq 1\}$.

DEFINITION 4.10. *Let $f, f_h : X \to [-\infty, +\infty]$ be lower semicontinuous functions. We say that f_h converges to f with respect to the bounded Hausdorff convergence (or in the sense of Attouch–Wets), and we write $f = \tau_{aw} - \lim f_h$ if and only if*

$$\exists \rho_0 > 0 \text{ such that } \mathrm{haus}_\rho(f, f_h) \to 0 \text{ as } h \to +\infty \ \ \forall \rho > \rho_0.$$

Examples of sequences of functionals of the calculus of variations converging with respect to the bounded Hausdorff convergence can be found in [9]. Now we are able to prove the main results of the paper, which are in fact corollaries of Theorem 4.2.

COROLLARY 4.11. *Let L and J be defined as in Corollary* 4.6. *Suppose that J is coercive having a unique minimum point $u_0 \in W_0^{1,1}(\Omega; \mathbb{R}^m)$.*

Moreover, assume that $v \mapsto L(x,v)$ is strictly convex at the point $Du_0(x)$ for almost every $x \in \Omega$. Then J is Tikhonov well-posed in $W_0^{1,1}(\Omega; \mathbb{R}^m)$.

Equivalently, if $u_h \in W_0^{1,1}(\Omega; \mathbb{R}^m)$ is any minimizing sequence, then

$$\|u_h - u_0\| \to 0 \ \text{ in } W_0^{1,1}(\Omega; \mathbb{R}^m).$$

Proof. Let $u_h \in W_0^{1,1}(\Omega; \mathbb{R}^m)$ be a minimizing sequence for J. Up to subsequences, from the coercivity hypothesis it follows that u_h is weakly convergent in $W_0^{1,1}(\Omega; \mathbb{R}^m)$ to a function v. Since the functional J is lower semicontinuous, v is a minimizer of J, and therefore we get $v = u_0$.

Now, applying Theorem 4.2, we obtain that the weakly convergent sequence Du_h is actually strongly convergent in $L^1(\Omega;\mathbb{R}^{nm})$ to Du_0, and therefore

$$\|u_h - u_0\| \to 0 \text{ in } W_0^{1,1}(\Omega;\mathbb{R}^m). \qquad \square$$

See, for instance, [11] for the hypotheses which ensure coercivity of an integral functional.

The last corollary is about well-posedness by perturbations, and it follows directly from Theorem 3.5 of [19].

COROLLARY 4.12. *Let $L, L_h : \Omega \times \mathbb{R}^{nm} \to [0,+\infty]$ be normal integrands and let J be defined as in* (4.1). *Suppose that J is coercive having a unique minimum point $u_0 \in W_0^{1,1}(\Omega;\mathbb{R}^m)$.*

Moreover, assume that $v \mapsto L(x,v)$ is strictly convex at the point $Du_0(x)$ for almost every $x \in \Omega$. Consider the sequence J_h defined by $J_h(u) := \int_\Omega L_h(x, Du(x))\,dx$ on $W_0^{1,1}(\Omega,\ \mathbb{R}^m)$. Assume that

(i) *$J_h \to J$ with respect to the bounded Hausdorff convergence on $W_0^{1,1}(\Omega;\mathbb{R}^m)$;*

(ii) *J_h is equicoercive.*

Then

$$\|u_h - u_0\| \to 0 \text{ in } W_0^{1,1}(\Omega;\mathbb{R}^m)$$

for every asymptotically minimizing sequence u_h.

In some cases it is possible to put some natural topology on the space of integrands and to relate the convergence of the sequence of integrands with the bounded Hausdorff convergence of the sequence of the associated integral functionals. Results on this subject can be found in [9] for quadratic integrals of elliptic type and in [19] and [20] in a more general setting.

We observe that the condition imposed on the integrand in Corollary 4.11 is very precise but not easy to check: if we want to know that the integral functional is well-posed, we first have to find out the minimizer u_0 and then prove that the integrand is strictly convex at the point $Du_0(x)$. But under the conditions that allow us to represent J^{**} as an integral functional, it is possible to state a result which is less precise but depends only on the integrand L and on L^{**}, the convex regularization of L with respect to the second variable.

We shall deal with scalar functions; therefore we can use the fact that $J^{**}(u)$ is given by $\int_\Omega L^{**}(x, Du(x))\,dx$. Hence, from now on, we consider only the case $m = 1$ and the functional J defined on the space $W_0^{1,1}(\Omega;\mathbb{R})$ by (4.1).

Let us introduce the following set of points:

$$\mathcal{M}(x) := \{z \in \mathbb{R}^n \mid L(x,z) = L^{**}(x,z)\}.$$

THEOREM 4.13. *Let L and J be as in Corollary* 4.6, *with $m = 1$. Assume that $L(x,\cdot)$ has superlinear growth and that it is strictly convex at z for every $z \in \mathcal{M}(x)$ for almost every $x \in \Omega$. Suppose moreover that J has a unique minimizer on the space $W_0^{1,1}(\Omega;\mathbb{R})$.*

Then J is Tikhonov well-posed on $W_0^{1,1}(\Omega;\mathbb{R})$.

Proof. Let u be the unique minimizer for J. By Remark (iv) following Theorem 5.2 of [11], we obtain

$$L(x, Du(x)) = L^{**}(x, Du(x))$$

for almost every $x \in \Omega$, i.e., $Du(x) \in \mathcal{M}(x)$ for almost every x, and therefore $L(x,\cdot)$ is strictly convex at $Du(x)$. The thesis then follows from Corollary 4.11. $\square$

5. Two classes of well-posed functionals.

5.1. Functionals depending only on the gradient. In the papers [5], [6], [8], [14] the following problem of minimizing a functional of the gradient under linear boundary conditions is studied:

$$(P_a) \quad \text{Minimize} \int_\Omega L(Du(x))dx \quad \text{subject to } u \in u_a + W_0^{1,1}(\Omega).$$

Here $\Omega \subset \mathbb{R}^n$ is open, bounded, and with piecewise C^1 boundary, and $u_a(x) := \langle a, x\rangle$, where $a \in \mathbb{R}^n$ and $\langle\cdot,\cdot\rangle$ denotes the standard scalar product in $\mathbb{R}^n$. The function $L : \mathbb{R}^n \to \mathbb{R}$ is supposed to be lower semicontinuous and bounded from below. Moreover the function L satisfies the growth condition

$$(G) \qquad L(y) \geq \Phi(|y|) \text{ for any } y \in \mathbb{R}^n,$$

where $\Phi : [0, +\infty) \to \mathbb{R}$ is such that $\lim_{t\to+\infty} \frac{\Phi(t)}{t} = +\infty$.

In particular the paper [8] studies the continuous dependence of the solutions on the boundary data. For this purpose we need to introduce the problem

$$(P_a^{**}) \quad \text{Minimize} \int_\Omega L^{**}(Du(x))\,dx \quad \text{subject to } u \in u_a + W_0^{1,1}(\Omega).$$

As is well known (see Chapter X of [13]), it turns out that

$$\inf P_a = L^{**}(a)|\Omega| \tag{5.1}$$

and that the function u_a is a minimizer. The following theorem, which is a particular case of Theorem 4.1 of [8], holds.

THEOREM 5.1. *Let L be lower semicontinuous satisfying the growth condition (G). Suppose that $L(a) = L^{**}(a)$ and that $(a, L^{**}(a))$ belongs to the relative interior of a proper face F_1 of an n-dimensional face F of* epiL^{**}, *and let $\{a_k\}_{k\in\mathbb{N}}$ be any sequence such that $(a_k, L^{**}(a_k))$ belongs to the relative interior of F for any $k \in \mathbb{N}$ and $\lim_{k\to+\infty} a_k = a$.*

(i) *If any sequence u_k of solutions of P_{a_k} converges strongly to u_a in $W_0^{1,1}(\Omega)$, then $\dim(F_1) = 0$ and so $(a, L^{**}(a))$ is an extreme point of* epiL^{**}.

(ii) *If $(a, L^{**}(a))$ is an extreme point of* epiL^{**}, *then any sequence u_k of solutions of $P_{a_k}^{**}$ converges strongly to u_a in $W_0^{1,1}(\Omega)$.*

The previous theorem can be improved using the results of section 4. We establish the strong convergence also of asymptotically minimizing sequences without imposing constraints on the position of the sequence a_k with respect to epiL^{**}, and, according to the definition given in the introduction, this means that problem (P_a) is well-posed by perturbations of the boundary data.

THEOREM 5.2. *Let $L : \mathbb{R}^n \to \mathbb{R}$ be lower semicontinuous, bounded from below, and satisfying the growth condition (G). Suppose that $(a, L^{**}(a))$ is an extreme point of* epiL^{**}.

Then any asymptotically minimizing sequence of P_{a_k} converges strongly to u_a in $W^{1,1}(\Omega)$.

Proof. Since $(a, L^{**}(a))$ is an extreme point of epiL^{**} and L is lower semicontinuous, it follows that $L(a) = L^{**}(a)$ by Lemma 3.2. Then by [6] problem (P_a) has the only solution u_a. Let a_k be a sequence in $\mathbb{R}^n$ such that $a_k \to a$. We observe that problem (P_{a_k}) is equivalent to the following one:

$$(\hat{P}_{a_k}) \quad \text{Minimize} \quad G_k(u) := \int_\Omega L(Du(x) + a_k)dx \quad \text{subject to } u \in W_0^{1,1}(\Omega).$$

In fact $\int_\Omega L(Du(x))dx = \int_\Omega L(Dv(x)+a)dx$, where $u \in u_a + W_0^{1,1}(\Omega)$ and $v = u - u_a$, $v \in W_0^{1,1}(\Omega)$. In this manner we do not move the set on which we consider the minimization problems, and we can apply the previous results.

Now, if v_k is an asymptotically minimizing sequence for G_k and $u_k := v_k + u_{a_k}$, then there exists a sequence $\epsilon_k \to 0$ such that

$$G_k(v_k) \le \inf G_k + \epsilon_k = L^{**}(a_k)|\Omega| + \epsilon_k, \tag{5.2}$$

where the equality is a well-known fact in the calculus of variations as previously noted in (5.1). We observe that L^{**} is convex and finite, since L is finite, and therefore it is continuous at the point a. Hence the last quantity in (5.2) is bounded and this implies, by condition (G) and the Dunford–Pettis theorem, that the sequence Dv_k is weakly compact in $L^1(\Omega)$.

Let Dv_{k_h} be a weakly convergent subsequence and let U be its weak limit.

We aim to prove that there exists $v \in W_0^{1,1}(\Omega)$ such that $U = Dv$.

Since the sequence Dv_{k_h} is weakly convergent, there exists $M > 0$ such that

$$\|Dv_{k_h}\|_{L^1} \le M.$$

If the dimension of the space is $n = 1$, we are done. If $n > 1$, by the Sobolev embedding theorem (see, for instance, [11, p. 25]) we obtain

$$\|v_{k_h}\|_{L^{\frac{n}{n-1}}} \le C$$

for a suitable constant $C > 0$. Since $\frac{n}{n-1} > 1$ there exists a further subsequence of v_{k_h}, which we still denote by v_{k_h}, weakly convergent to a function v in $L^1(\Omega)$. We shall prove that $Dv = U$. To this purpose consider any function $\psi \in C_c^\infty(\Omega)$. By the definition of a weak derivative (denoted by ∂_i), the equality

$$\int_\Omega v_{k_h}(x)\partial_i\psi(x)\,dx = -\int_\Omega \partial_i v_{k_h}(x)\psi(x)\,dx$$

holds for every $i \in \{1,\dots,n\}$. Now, the right-hand side converges to $\int_\Omega v(x)\partial_i\psi(x)\,dx$, whereas the left-hand side converges to $-\int_\Omega U_i(x)\psi(x)\,dx$, and therefore

$$\int_\Omega v(x)\partial_i\psi(x)\,dx = -\int_\Omega U_i(x)\psi(x)\,dx \tag{5.3}$$

by the uniqueness of the limit. Since (5.3) holds for every $i \in \{1,\dots,n\}$ and for every $\psi \in C_c^\infty(\Omega)$, we get that $U = Dv$, and hence the function v is in $W^{1,1}(\Omega)$. In order to obtain that $v \in W_0^{1,1}(\Omega)$ it is enough to observe that $v_{k_h} \in W_0^{1,1}(\Omega)$, $v_{k_h} \rightharpoonup v$ in $W^{1,1}(\Omega)$ and $W_0^{1,1}(\Omega)$ is weakly closed.

Now define the functional

$$G^{**}(v) := \int_\Omega L^{**}(Dv + a)\,dx.$$

As a direct consequence of the Jensen inequality we know that

$$\inf_{v \in W_0^{1,1}(\Omega)} \int_\Omega L^{**}(Dv + a)\,dx = L^{**}(a)|\Omega|. \tag{5.4}$$

Since the functional G^{**} is lower semicontinuous on $W_0^{1,1}(\Omega)$ with respect to the weak convergence, by (5.4) we obtain

$$\begin{aligned}\inf P_a &= L^{**}(a)|\Omega| \\ &\le \int_\Omega L^{**}(Dv + a)dx \\ &\le \liminf \int_\Omega L(Dv_{k_h}(x) + a_{k_h}) \\ &\le \liminf L^{**}(a_{k_h})|\Omega| + \epsilon_{k_h} \\ &= L^{**}(a)|\Omega|.\end{aligned}$$

Then the function $v = 0$ because u_a is the unique minimizer of P_a.

Now using the fact that $(a, L^{**}(a))$ is an extreme point of epiL^{**}, by Lemma 3.4 and Theorem 4.2 of the preceding section, the subsequence Dv_{k_h} is actually strongly convergent to 0.

Since from any subsequence of Dv_k we can extract a strongly convergent subsequence with limit 0, then the whole sequence is strongly convergent to 0.

This means that the sequence u_k is strongly convergent to the function u_a, and this completes the proof. □

5.2. Radially symmetric functionals. In this section we consider the well-posedness of the variational problem

$$\text{(5.5)}\quad \text{Minimize } \int_{B(0,R)} [L(|Du(x)|) + h(u(x))]\,dx \quad \text{subject to } u \in W_0^{1,1}(B(0,R)),$$

where $B(0,R)$ is the ball of $\mathbb{R}^n$ of radius R centered at the origin; the function $L : [0,+\infty[\to [0,+\infty]$ is lower semicontinuous and $h : \mathbb{R} \to [0,+\infty[$ is a convex function.

Problems of this kind arise in various fields as nonlinear elasticity, fluid dynamics, and optimal design. We refer to [7] and [10] for results about existence and uniqueness of minimizers, and we remark that well-posedness was not considered there.

In order to prove well-posedness of (5.5) we need an elementary result about convergence of sequences.

LEMMA 5.3. *Let $\{a_h\}$, $\{b_h\}$ be two sequences and let $a, b \in [0,+\infty)$ such that*

(i) *$a_h \ge 0$, $b_h \ge 0$ for every n;*

(ii) *there exist $a, b \ge 0$ such that $\lim(a_h + b_h) = a + b$;*

(iii) *$\liminf a_h \ge a$; $\liminf b_h \ge b$.*

Then $\lim a_h = a$ and $\lim b_h = b$.

The proof of Lemma 5.3 is trivial, so we omit it.

Applying the results of [7] and Corollary 4.11 we obtain the following theorem.

THEOREM 5.4. *Assume that*

(h1) *$L : [0,+\infty[\to [0,+\infty]$ is lower semicontinuous and has superlinear growth;*

(h2) *$h : \mathbb{R} \to [0,+\infty[$ is convex and monotonic;*

and that either h or L^{**} is strictly monotonic. Then problem (5.5) *is well-posed in the sense of Tikhonov on the space $W_0^{1,1}(B(0,R))$.*

Proof. One of the steps of the proof of Theorem 5 of [7] consists in showing that if u is a solution of the minimum problem, then $(Du(x), L^{**}(Du(x)))$ is an extremal point of epiL^{**} for almost every $x \in B(0,R)$. Thus by Lemma 3.4 we deduce that L is strictly convex at the point $Du(x)$ for almost every $x \in \Omega$.

Now let u_h be a minimizing sequence; we want to apply Lemma 5.3 with $a_h = \int_\Omega L(|Du_h(x)|)\,dx$ and $b_h = \int_\Omega h(u_h(x))\,dx$. All the hypotheses are satisfied; in fact (i) is obvious; (ii) follows directly from the definition of minimizing sequence, with

$a = \int_\Omega L(|Du(x)|)\,dx$ and $b = \int_\Omega h(u(x))\,dx$; and (iii) comes from Lemma 4.3. We therefore obtain

$$\int_\Omega L(|Du_h(x)|)\,dx \to \int_\Omega L(|Du(x)|)\,dx.$$

Then the thesis follows from Corollary 4.11 of the preceding section. □

We remark that, applying Corollary 4.12, the problem defined by (5.5) is also well-posed by perturbations with respect to the bounded Hausdorff convergence.

NULL CONTROLLABILITY AND THE ALGEBRAIC RICCATI EQUATION IN BANACH SPACES*

J. M. A. M. VAN NEERVEN†

Abstract. By a recent result of Priola and Zabczyk, a null controllable linear system

$$y'(t) = Ay(t) + Bu(t)$$

in a Hilbert space E is null controllable with vanishing energy if and only if it is null controllable and the only positive self-adjoint solution of the associated algebraic Riccati equation

$$XA + A^*X - XBB^*X = 0$$

is the trivial solution $X = 0$. In this paper we extend this result to Banach spaces with an elementary proof which uses only reproducing kernel Hilbert space techniques. We also show that null controllability with vanishing energy implies null controllability.

Key words. null controllability with vanishing energy, algebraic Riccati equation, reproducing kernel Hilbert space

AMS subject classifications. Primary, 93B05; Secondary, 47D06, 93B03, 93C25

DOI. 10.1137/S0363012903437058

Let A be the generator of a C_0-semigroup on a real Banach space E and let B be a bounded linear operator from a real Hilbert space H into E. The pair (A, B) is said to be *null controllable with vanishing energy* if for all $x \in E$ and all $\varepsilon > 0$ there exists a time $t > 0$ and a function $u \in L^2(0, t; H)$ satisfying $\|u\|_{L^2(0,t;H)} < \varepsilon$ such that the mild solution $y^{u,x}$ of the linear control problem

$$\begin{aligned} y'(s) &= Ay(s) + Bu(s) \qquad (s \in [0, t]), \\ y(0) &= x \end{aligned} \tag{0.1}$$

satisfies $y^{u,x}(t) = 0$. The pair (A, B) is said to be *null controllable in finite time* if there exists a fixed time $t_0 > 0$ such that for all $x \in E$ there exists a function $u \in L^2(0, t_0; H)$ such that the mild solution of the problem (0.1) satisfies $y^{u,x}(t_0) = 0$.

For Hilbert spaces E, Priola and Zabczyk recently proved that a pair (A, B), which is null controllable in finite time, is null controllable with vanishing energy if and only if the only positive self-adjoint solution to the algebraic Riccati equation

$$XA + A^*X - XBB^*X = 0$$

is the trivial solution $X = 0$ [10]. One of the main ingredients of the proof is the fact that a certain differential Riccati equation is solved in terms of a minimal energy functional. In this paper we extend the Priola–Zabczyk result to Banach spaces with a different proof which is based on reproducing kernel Hilbert space techniques, and we

show that null controllability with vanishing energy in fact implies null controllability in finite time. Our approach relies upon the identification of the space H_t of points that are reachable in time t as the reproducing kernel Hilbert space associated with the operator $Q_t \in \mathcal{L}(E^*, E)$ defined by

$$Q_t x^* := \int_0^t S(s)BB^*S^*(s)x^*\,ds \qquad (x^* \in E^*).$$

The square norm $\|h\|_{H_t}^2$ can be interpreted as the minimal energy needed to reach the state $h \in H_t$ in time t starting from the origin. The basic problem is then to understand how this minimal energy varies with h and t. Our main result in this direction is Theorem 2.5, which describes the instantaneous rate of change of the minimal energy along curves in H_t as time progresses. It is used to obtain an explicit positive symmetric solution $X(t)$ for a differential Riccati equation. As in [10], the weak operator limit $X = \lim_{t\to\infty} X(t)$ then turns out to be the maximal positive symmetric solution of the algebraic Riccati equation, and null controllability with vanishing energy is equivalent to the condition that $X = 0$.

For more information about null controllability and Riccati equations as well as applications to various control systems we refer to [1, 2, 3, 4, 7, 8, 12, 13].

1. Reachable states and reproducing kernels. The mild solution of the problem (0.1) will be denoted by $y^{u,x}$. Thus,

$$y^{u,x}(s) := S(s)x + \int_0^s S(s-r)Bu(r)\,dr \qquad (s \in [0,t]).$$

An element $h \in E$ is *reachable in time* t if there exists a control $u \in L^2(0,t;H)$ such that $y^{u,0}(t) = h$. The collection H_t of all elements that are reachable in time t is a linear subspace of E which is a Hilbert space with norm

$$\|h\|_{H_t}^2 := \inf\big\{\|u\|_{L^2(0,t;H)}^2 :\ u \in L^2(0,t;H),\ y^{u,0}(t) = h\big\}.$$

Thus, $\|h\|_{H_t}^2$ is the minimal energy needed to steer the system from 0 to h in time t. Notice that H_t equals the range of the operator $L_t \in \mathcal{L}(L^2(0,t;H), E)$ defined by

$$L_t f := \int_0^t S(t-s)Bf(s)\,ds.$$

It is easy to check that $L_t^* x^* = B^*S^*(t-\cdot)x^*$ for all $x^* \in E^*$. Consequently, $L_t \circ L_t^* = Q_t$, where $Q_t \in \mathcal{L}(E^*, E)$ is defined by

$$Q_t x^* := \int_0^t S(s)BB^*S^*(s)x^*\,ds. \tag{1.1}$$

It follows from this that H_t can be identified with the reproducing kernel Hilbert space of Q_t. Denoting the inclusion operator $H_t \hookrightarrow E$ by i_t, we have the operator identity

$$i_t \circ i_t^* = Q_t. \tag{1.2}$$

Moreover, by general results on reproducing kernel Hilbert spaces, the range of i_t^* is dense in H_t.

We insert a simple result on controls with minimal energy. It will not be needed in what follows and is included for reasons of completeness only. We write Λ_t for the L_t when we regard it as an operator from $L^2(0,t;H)$ onto H_t.

PROPOSITION 1.1 (control with minimal energy). *For all $h \in H_t$ we have $\Lambda_t\Lambda_t^* h = h$ and $\|\Lambda_t^* h\|^2_{L^2(0,t;H)} = \|h\|^2_{H_t}$.*

Upon identifying $h \in H_t$ with $i_t h \in E$, we have $L_t(\Lambda_t^* h) = h$. Thus, the lemma states that the control $\Lambda_t^* h$ steers 0 to h in time t with minimal energy.

Proof. For all $x^* \in E^*$ we have $\Lambda_t^* i_t^* x^* = L_t^* x^* = B^* S^*(t-\cdot)x^*$. Hence,

$$i_t\Lambda_t\Lambda_t^* i_t^* x^* = L_t\Lambda_t^* i_t^* x^* = \int_0^t S(t-s)BB^*S^*(t-s)x^*\,ds = Q_t x^* = i_t i_t^* x^*.$$

Since i_t is injective and the range of i_t^* is dense in H_t, this implies that $\Lambda_t\Lambda_t^* h = h$ for all $h \in H_t$. This proves the first assertion. The second follows from

$$\|\Lambda_t^* i_t^* x^*\|^2_{L^2(0,t;H)} = \|L_t^* x^*\|^2_{L^2(0,t;H)} = \langle L_t L_t^* x^*, x^*\rangle = \langle Q_t x^*, x^*\rangle = \|i_t^* x^*\|^2_{H_t}$$

and another density argument. □

It will be helpful to recall some elementary facts about the spaces H_t; for the proofs we refer to [9, 13]. The inequality $\langle Q_t x^*, x^*\rangle \leqslant \langle Q_{t+s}x^*, x^*\rangle$, valid for all $x^* \in E^*$, $t > 0$ and $s \geqslant 0$, implies that $H_t \subseteq H_{t+s}$ (as subsets of E) with a contractive inclusion mapping

$$i_{t,t+s} : H_t \hookrightarrow H_{t+s}, \quad i_{t,t+s}h = h \quad (h \in H_t).$$

Moreover, $S(s)$ restricts to a contraction from H_t into H_{t+s}. We will denote this restriction by $S_{t,t+s}(s)$. Thus,

$$S_{t,t+s}(s) : H_t \to H_{t+s}, \quad S_{t,t+s}(s)h = S(s)h \quad (h \in H_t).$$

2. Null controllability. The pair (A,B) is said to be *null controllable in finite time* if there exists a time $t_0 > 0$ such that for any $x \in E$ there exists a control $u \in L^2(0,t_0;H)$ such that $y^{u,x}(t_0) = 0$. If we want to stress the role of t_0, we say that (A,B) is *null controllable in time t_0*.

From the trivial identity $y^{u,x}(t_0) = S(t_0)x + y^{u,0}(t_0)$ we see that (A,B) is null controllable in time t_0 if and only if

$$S(t_0)x \in H_{t_0} \quad \text{for all } x \in E.$$

As an operator from E into H_{t_0}, we shall denote $S(t_0)$ by $\Sigma(t_0)$. Thus,

$$S(t_0) = i_{t_0} \circ \Sigma(t_0). \tag{2.1}$$

If (A,B) is null controllable in time t_0, then (A,B) is null controllable in time t for all $t \geqslant t_0$. Indeed, from $S(t_0)x \in H_{t_0}$ and the fact that $S(t-t_0)$ maps H_{t_0} into H_t we see that $S(t)x \in H_t$ for all $x \in E$. As subsets of E, the spaces of reachable points agree:

$$H_t = H_{t_0} \quad \text{with equivalent norms.}$$

The inclusion $H_{t_0} \hookrightarrow H_t$ always holds. To prove the converse inclusion $H_t \hookrightarrow H_{t_0}$, we first note that (1.1) implies the operator identity

$$Q_t = Q_{t_0} + S(t_0)Q_{t-t_0}S^*(t_0) \qquad (t \geqslant t_0). \tag{2.2}$$

Using this identity, for all $t \geqslant t_0$ and $x^* \in E^*$ we have

$$\begin{aligned}\langle Q_t x^*, x^*\rangle &= \langle Q_{t_0} x^*, x^*\rangle + \langle Q_{t-t_0} S^*(t_0)x^*, S^*(t_0)x^*\rangle \\ &= \langle Q_{t_0} x^*, x^*\rangle + \langle Q_{t-t_0}\Sigma^*(t_0) i_{t_0}^* x^*, \Sigma^*(t_0) i_{t_0}^* x^*\rangle \\ &\leqslant \langle Q_{t_0} x^*, x^*\rangle + \|Q_{t-t_0}\| \cdot \|\Sigma(t_0)\|^2 \cdot \|i_{t_0}^* x^*\|_{H_{t_0}}^2 \\ &= \big(1 + \|Q_{t-t_0}\| \cdot \|\Sigma(t_0)\|^2\big) \cdot \langle Q_{t_0} x^*, x^*\rangle.\end{aligned}$$

The inclusion $H_t \hookrightarrow H_{t_0}$ now follows from [9, Proposition 1.1]. In general, H_{t_0} and H_t will be different as Hilbert spaces, and for this reason we will distinguish between these spaces carefully.

For the rest of this section we fix $t_0 > 0$ and assume that the pair (A, B) is null controllable in time t_0.

Since (A, B) is null controllable in any time $t \geqslant t_0$, for $t \geqslant t_0$ we define $\Sigma(t)$ as $S(t)$, regarded as an operator from E into H_t. Notice that $\|\Sigma(t)x\|_{H_t}^2$ is the minimal energy to steer from x to 0 in time t. The function $t \mapsto \|\Sigma(t)x\|_{H_t}^2$ is nonincreasing on $[t_0, \infty)$: this follows from

$$\|\Sigma(t+s)x\|_{H_{t+s}}^2 = \|S_{t,t+s}(s)\Sigma(t)x\|_{H_{t+s}}^2 \leqslant \|\Sigma(t)x\|_{H_t}^2. \tag{2.3}$$

By a similar argument, for each $t \geqslant t_0$ the function $s \mapsto \|i_{t,t+s}\Sigma(t)x\|_{H_{t+s}}^2$ is nonincreasing on $[0, \infty)$. The main result of this section, Theorem 2.5, will show that this function is in fact differentiable at $s = 0$, and its derivative will be computed explicitly.

To prepare for the proof we need a series of lemmas. The first uses the identity

$$i_{t+s}^* = i_{t,t+s} i_t^* + i_{t,t+s}\Sigma(t) Q_s \Sigma^*(t) i_t^*, \tag{2.4}$$

which follows from (2.2) by using (1.2), (2.1), the trivial identity $i_t = i_{t+s} \circ i_{t,t+s}$, and the injectivity of i_{t+s}.

LEMMA 2.1. *For all $h \in H_{t_0}$ the function $t \mapsto i_{t_0,t}^* i_{t_0,t} h$ is continuous on the interval $[t_0, \infty)$.*

Proof. Fix $t' \geqslant t \geqslant t_0$ arbitrary. Since $\|i_{t_0,t}\| \leqslant 1$, for all $h \in H_{t_0}$ we have

$$\|i_{t_0,t'}^* i_{t_0,t'} h - i_{t_0,t}^* i_{t_0,t} h\|_{H_{t_0}} = \|i_{t_0,t}^*(i_{t,t'}^* i_{t,t'} - I) i_{t_0,t} h\|_{H_{t_0}} \leqslant \|(i_{t,t'}^* i_{t,t'} - I) i_{t_0,t} h\|_{H_t}.$$

Hence it suffices to prove that $\lim_{t'-t\downarrow 0} \|i_{t,t'}^* i_{t,t'} g - g\|_{H_t} = 0$ for all $g \in H_t$. We first take $g = i_t^* x^*$ with $x^* \in E^*$. Then by (2.4),

$$i_{t,t'}^* i_{t,t'} g = i_{t,t'}^*\big(i_{t'}^* x^* - i_{t,t'}\Sigma(t) Q_{t'-t}\Sigma^*(t) i_t^* x^*\big) = g - i_{t,t'}^* i_{t,t'}\Sigma(t) Q_{t'-t}\Sigma^*(t) g.$$

Since the range of i_t^* is dense in H_t, a limiting argument shows that this identity holds for all $g \in H_t$. Using (2.3), for all $g \in H_t$ we have

$$\begin{aligned}\|i_{t,t'}^* i_{t,t'} g - g\|_{H_t} &= \|i_{t,t'}^* i_{t,t'}\Sigma(t) Q_{t'-t}\Sigma^*(t) g\|_{H_t} \\ &\leqslant \|\Sigma(t)\|^2 \, \|Q_{t'-t}\| \, \|g\|_{H_t} \leqslant \|\Sigma(t_0)\|^2 \, \|Q_{t'-t}\| \, \|g\|_{H_t}.\end{aligned}$$

Since $\lim_{t'-t\downarrow 0} \|Q_{t'-t}\| = 0$, this proves that $\lim_{t'\downarrow t} \|i_{t,t'}^* i_{t,t'} g - g\|_{H_t} = 0$. ∎

The adjoint T^* of a C_0-semigroup T on a Banach space X may fail to be strongly continuous on X^*. To overcome this problem, one defines

$$X^\odot := \Big\{x^* \in X^* : \lim_{t\downarrow 0} \|T^*(t)x^* - x^*\| = 0\Big\}.$$

This is a norm closed, weak*-dense, S^*-invariant subspace of X^*, and the restricted semigroup $T^\odot = T^*\big|_{X^\odot}$ is strongly continuous on $X^\odot$. If X is reflexive, then $X^\odot$ is norm closed and weakly dense in X^*, and therefore we have $X^\odot = X^*$.

LEMMA 2.2. *For all $t \geqslant t_0$ the space H_t is S-invariant and the restricted semigroup $S_t := S|_{H_t}$ is strongly continuous on H_t.*

Proof. Invariance follows from the fact that $S(s)$ maps H_t into H_{t+s} and the fact that both H_t and H_{t+s} equal H_{t_0} as subsets of E.

Let $\delta > 0$ be arbitrary and fixed. For all $x^* \in E^*$ and $s \in [0, \delta]$ we have

$$\begin{aligned}
\|S_t^*(s) i_t^* x^*\|_{H_t}^2 &= \|i_t^* S^*(s) x^*\|_{H_t}^2 \\
&= \langle Q_{t+s} x^*, x^* \rangle - \langle Q_s x^*, x^* \rangle \\
&\leqslant \langle Q_{t+s} x^*, x^* \rangle \\
&= \langle Q_t x^*, x^* \rangle + \int_0^s \langle BB^* S^*(t+r) x^*, S^*(t+r) x^* \rangle \, dr \\
&= \|i_t^* x^*\|_{H_t}^2 + \int_0^s \langle BB^* S^*(r) \Sigma^*(t) i_t^* x^*, S^*(r) \Sigma^*(t) i_t^* x^* \rangle \, dr \\
&\leqslant \left(1 + \delta \cdot \|BB^*\| \cdot \|\Sigma(t)\|^2 \cdot \sup_{r \in [0,\delta]} \|S(r)\|^2 \right) \cdot \|i_t^* x^*\|_{H_t}^2 .
\end{aligned}$$

Hence,

$$\limsup_{s \downarrow 0} \|S_t(s)\| \leqslant \left(1 + \delta \cdot \|BB^*\| \cdot \|\Sigma(t)\|^2 \cdot \sup_{r \in [0,\delta]} \|S(r)\|^2 \right).$$

On the other hand, for all $h \in H_t$ and $x^* \in E^*$ we have

$$\lim_{s \downarrow 0} [S_t(s) h - h, i_t^* x^*]_{H_t} = \lim_{s \downarrow 0} \langle S(t) i_t h - i_t h, x^* \rangle = 0.$$

It follows that S_t is weakly continuous. By a general result from semigroup theory, this implies that S_t is strongly continuous. □

We note two immediate consequences of this lemma.

LEMMA 2.3. *For all $x \in E$ the function $t \mapsto \Sigma^*(t)\Sigma(t)x$ is continuous on the interval $[t_0, \infty)$.*

Proof. By the observations preceding Lemma 2.2, the adjoint semigroup S_t^* is strongly continuous. The lemma now follows from the identity

$$\Sigma^*(t)\Sigma(t)x = \Sigma^*(t_0) S_{t_0}^*(t - t_0) i_{t_0,t}^* i_{t_0,t} S_{t_0}(t - t_0) \Sigma(t_0) x$$

and Lemmas 2.1 and 2.2. □

LEMMA 2.4. *For all $h \in H_t$ we have $\Sigma^*(t)h \in E^\odot$.*

Proof. This follows from

$$\lim_{s \downarrow 0} \|S^*(s)\Sigma^*(t)h - \Sigma^*(t)h\| = \lim_{s \downarrow 0} \big\| \Sigma^*(t) \big(S_t^*(s)h - h \big) \big\| = 0,$$

where we used again the strong continuity of S_t^*. □

We are now ready for the main result of this section, which describes the instantaneous rate of the change of the minimal energy along curves in the space of reachable states as time progresses.

THEOREM 2.5 (rate of change of minimal energy). *Let the pair (A,B) be null controllable in time t_0. Fix $t \geqslant t_0$ and let $f : [0,\infty) \to H_t$ be differentiable at 0. The function $\phi : [0,\infty) \to [0,\infty)$ defined by*

$$\phi(s) := \|i_{t,t+s} f(s)\|^2_{H_{t+s}}$$

is differentiable at 0, with derivative

$$\phi'(0) = 2[f'(0), f(0)]_{H_t} - \|B^*\Sigma^*(t)f(0)\|^2_H.$$

Notice that the first term on the right-hand side accounts for the speed and direction of leaving $f(0)$, while the second term describes the energy savings resulting from the extra time available.

Proof. Upon writing $f(s) = f(0) + sf'(0) + g(s)$ with $\lim_{s\downarrow 0} g(s)/s = 0$ we have

$$\begin{aligned}\lim_{s\downarrow 0} \frac{1}{s}\Big[\|f(s)\|^2_{H_t} - \|f(0)\|^2_{H_t}\Big] \\ = \lim_{s\downarrow 0} \frac{1}{s}\Big[2[sf'(0)+g(s), f(0)]_{H_t} + \|sf'(0)+g(s)\|^2_{H_t}\Big] = 2[f'(0), f(0)]_{H_t}.\end{aligned}$$

Consequently, it remains to prove that

$$\lim_{s\downarrow 0} \frac{1}{s}\Big[\|i_{t,t+s}f(s)\|^2_{H_{t+s}} - \|f(s)\|^2_{H_t}\Big] = -\|B^*\Sigma^*(t)f(0)\|^2_H.$$

Let $x^* \in E^*$ be fixed. Noting that

$$\|i^*_{t+s}x^*\|^2_{H_{t+s}} - \|i^*_t x^*\|^2_{H_t} = \langle Q_{t+s}x^*, x^*\rangle - \langle Q_t x^*, x^*\rangle = \langle Q_s\Sigma^*(t)i^*_t x^*, \Sigma^*(t)i^*_t x^*\rangle,$$

from identity (2.4) we have

$$\begin{aligned}&\|i_{t,t+s}i^*_t x^*\|^2_{H_{t+s}} - \|i^*_t x^*\|^2_{H_t} \\ &\quad = \|i^*_{t+s}x^*\|^2_{H_{t+s}} - \|i^*_t x^*\|^2_{H_t} \\ &\qquad - 2[i^*_{t+s}x^*, i_{t,t+s}\Sigma(t)Q_s\Sigma^*(t)i^*_t x^*]_{H_{t+s}} + \|i_{t,t+s}\Sigma(t)Q_s\Sigma^*(t)i^*_t x^*\|^2_{H_{t+s}} \\ &\quad = \langle Q_s\Sigma^*(t)i^*_t x^*, \Sigma^*(t)i^*_t x^*\rangle \\ &\qquad - 2[i^*_t x^*, \Sigma(t)Q_s\Sigma^*(t)i^*_t x^*]_{H_t} + \|i_{t,t+s}\Sigma(t)Q_s\Sigma^*(t)i^*_t x^*\|^2_{H_{t+s}}.\end{aligned}$$

By approximation, for all $s \geqslant 0$ we obtain

$$\begin{aligned}&\|i_{t,t+s}f(s)\|^2_{H_{t+s}} - \|f(s)\|^2_{H_t} \\ &\quad = \langle Q_s\Sigma^*(t)f(s), \Sigma^*(t)f(s)\rangle \\ &\qquad - 2[f(s), \Sigma(t)Q_s\Sigma^*(t)f(s)]_{H_t} + \|i_{t,t+s}\Sigma(t)Q_s\Sigma^*(t)f(s)\|^2_{H_{t+s}}.\end{aligned}$$

Next, for any $y^\odot \in E^\odot$ we have, by strong continuity,

$$\lim_{s\downarrow 0} \frac{1}{s} Q_s y^\odot = \lim_{s\downarrow 0} \frac{1}{s}\int_0^s S(r)BB^*S^*(r)y^\odot\, dr = BB^*y^\odot.$$

Hence, using the continuity of f at 0, the fact that $\limsup_{s\downarrow 0} \frac{1}{s}\|Q_s\| < \infty$, and the fact that $\Sigma^*(t)f(0) \in E^{\odot}$ by Lemma 2.4, we obtain

$$\begin{aligned}
&\limsup_{s\downarrow 0} \left\| \frac{1}{s} Q_s \Sigma^*(t) f(s) - BB^* \Sigma^*(t) f(0) \right\| \\
&\quad \leqslant \limsup_{s\downarrow 0} \left\| \frac{1}{s} Q_s \Sigma^*(t) f(s) - \frac{1}{s} Q_s \Sigma^*(t) f(0) \right\| \\
&\qquad\qquad + \limsup_{s\downarrow 0} \left\| \frac{1}{s} Q_s \Sigma^*(t) f(0) - BB^* \Sigma^*(t) f(0) \right\| \\
&\quad \leqslant \|\Sigma^*(t)\| \cdot \limsup_{s\downarrow 0} \left(\frac{1}{s} \|Q_s\| \right) \cdot \limsup_{s\downarrow 0} \|f(s) - f(0)\| \\
&\qquad\qquad + \limsup_{s\downarrow 0} \left\| \frac{1}{s} Q_s \Sigma^*(t) f(0) - BB^* \Sigma^*(t) f(0) \right\| = 0.
\end{aligned}$$

It follows that

$$\lim_{s\downarrow 0} \frac{1}{s} Q_s \Sigma^*(t) f(s) = BB^* \Sigma^*(t) f(0).$$

As a consequence,

$$\begin{aligned}
&\lim_{s\downarrow 0} \frac{1}{s} \Big[\langle Q_s \Sigma^*(t) f(s), \Sigma^*(t) f(s) \rangle - 2[f(s), \Sigma(t) Q_s \Sigma^*(t) f(s)]_{H_t} \\
&\qquad\qquad + \|i_{t,t+s} \Sigma(t) Q_s \Sigma^*(t) f(s)\|^2_{H_{t+s}} \Big] \\
&= \lim_{s\downarrow 0} \left\langle \frac{1}{s} Q_s \Sigma^*(t) f(s), \Sigma^*(t) f(s) \right\rangle - 2 \lim_{s\downarrow 0} \left[f(s), \Sigma(t) \left(\frac{1}{s} Q_s \Sigma^*(t) f(s) \right) \right]_{H_t} \\
&\qquad\qquad + \lim_{s\downarrow 0} s \left\| i_{t,t+s} \Sigma(t) \left(\frac{1}{s} Q_s \Sigma^*(t) f(s) \right) \right\|^2_{H_{t+s}} \\
&= \langle BB^* \Sigma^*(t) f(0), \Sigma^*(t) f(0) \rangle - 2[f(0), \Sigma(t) BB^* \Sigma^*(t) f(0)]_{H_t} + 0 \\
&= -\|B^* \Sigma^*(t) f(0)\|^2_H;
\end{aligned}$$

in the next to last step we used that $\|i_{t,t+s}\| \leqslant 1$. □

For the convenience of those readers familiar with the Hilbert space formalism as used, e.g., in [10], we add a reformulation of Theorem 2.5 for Hilbert spaces E. In this setting we identify E and its dual in the usual way and identify Q_t with a positive self-adjoint operator on E. As is well known, the reproducing kernel Hilbert space of Q_t is then given by

$$i_t(H_t) = \operatorname{Im} Q_t^{1/2}. \tag{2.5}$$

In what follows we identify $i_t(H_t)$ and H_t and abuse notation by regarding both $Q_t^{1/2}$ and Q_t as operators from E to H_t whenever this is convenient. Denoting the closure of H_t in E by E_t, it follows from (2.5) and a standard argument that $Q_t^{1/2}$ is unitary as an operator from E_t to H_t.

By (2.5), the pair (A, B) is null controllable in time t_0 if and only if $\operatorname{Im} S(t_0) \subseteq \operatorname{Im} Q_{t_0}^{1/2}$. Since the restriction of $Q_{t_0}^{1/2}$ to E_{t_0} is injective, the inverse $Q_{t_0}^{-1/2}$ is well-defined on the linear subspace H_{t_0} of E. Then by null controllability, the operator

$\Gamma(t_0) := Q_{t_0}^{-1/2} S(t_0)$ is well-defined as a bounded operator from E to E_{t_0}. For all $h = Q_{t_0}^{1/2} y \in H_{t_0}$ we have

$$[\Gamma(t_0)x, h]_E = [S(t_0)x, y]_E = [x, S^*(t_0)y]_E = [x, S^*(t_0)Q_{t_0}^{-1/2}h]_E.$$

Since H_{t_0} is dense in E_{t_0} we see that $\Gamma^*(t_0) := (\Gamma(t_0))^*$ is the unique extension of $S^*(t_0)Q_{t_0}^{-1/2}$ to a bounded operator from E_{t_0} to E.

COROLLARY 2.6. *Let the pair (A, B) be null controllable in time t_0. Fix $t \geqslant t_0$ and let $g : [0, \infty) \to E_t$ be differentiable at 0. The function $\phi : [0, \infty) \to [0, \infty)$ defined by*

$$\phi(s) := \|Q_t^{1/2} g(s)\|^2_{H_{t+s}} \tag{2.6}$$

is differentiable at 0, with derivative

$$\phi'(0) = 2[g'(0), g(0)]_E - [Q\Gamma^*(t)g(0), \Gamma^*(t)g(0)]_E.$$

Note some further abuse of notation in (2.6), where $Q_t^{1/2} g(s)$ is regarded as an element of H_{t+s}.

Proof. Let $f : [0, \infty) \to H_t$ be defined by $f(s) = Q_t^{1/2} g(s)$. Since $Q_t^{1/2}$ is unitary as an operator from E_t to H_t, f is differentiable at 0 with derivative $f'(0) = Q_t^{1/2} g'(0)$. Let $Q := BB^*$. By Theorem 2.5,

$$\phi(s) := \|i_{t,t+s} f(s)\|^2_{H_{t+s}} = \|Q_t^{1/2} g(s)\|^2_{H_{t+s}}$$

is differentiable at 0 with derivative

$$\begin{aligned} \phi'(0) &= 2[f'(0), f(0)]_{H_t} - \|B^*\Sigma^*(t)f(0)\|^2_H \\ &= 2[Q_t^{1/2} g'(0), Q_t^{1/2} g(0)]_{H_t} - [Q\Gamma^*(t)g(0), \Gamma^*(t)g(0)]_E \\ &= 2[g'(0), g(0)]_E - [Q\Gamma^*(t)g(0), \Gamma^*(t)g(0)]_E. \end{aligned} \tag{2.7}$$

In the second identity of (2.7) we used that $\Gamma^*(t)$ extends $S^*(t)Q_t^{-1/2}$ on E_t and that for all $h = Q_t y \in H_t$ we have

$$[B^*\Sigma^*(t)h, B^*\Sigma^*(t)h]_H = [Q\Sigma^*(t)i_t^* y, \Sigma^*(t)i_t^* y]_E = [Q^* S(t)y, S^*(t)y]_E,$$

recalling that we identify $Q_t y = i_t i_t^* y$ and $i_t^* y$. In the third identity of (2.7) we used that $Q_t^{1/2}$ is unitary from E_t to H_t. ∎

3. Null controllability with vanishing energy. Following Priola and Zabczyk [10] we call the pair (A, B) *null controllable with vanishing energy* if for all $\varepsilon > 0$ and $x \in E$ there exists a time $t > 0$ and a control $u \in L^2(0, t; H)$ with $y^{u,x}(t) = 0$ and $\|u\|_{L^2(0,t;H)} < \varepsilon$. Clearly, null controllability with vanishing energy implies null controllability with bounded energy.

THEOREM 3.1. *If the pair (A, B) is null controllable with vanishing energy, then it is null controllable in finite time.*

Proof. For $n = 1, 2, \ldots$, let E_n denote the set of all $x \in E$ for which there exists a control $u \in L^2(0, n; H)$ with $y^{u,x}(n) = 0$ and $\|u\|_{L^2(0,n;H)} \leqslant 1$. Notice that $\bigcup_{n \geqslant 1} E_n = E$.

We claim that each E_n is closed. To see this, fix $n \geqslant 1$ and let $\lim_{k\to\infty} x_k = x$ in E with all $x_k \in E_n$. We must check that $x \in E_n$. For each k we choose a

control $u_k \in L^2(0,n;H)$ with $y^{u_k,x_k}(n) = 0$ and $\|u_k\|_{L^2(0,n;H)} \leqslant 1$. After passing to a subsequence, we may assume that there exists a control $u \in L^2(0,n;H)$ with $\|u\|_{L^2(0,n;H)} \leqslant 1$ such that $\lim_{k\to\infty} u_k = u$ weakly in $L^2(0,n;H)$. Then for all $x^* \in E^*$ we have

$$\begin{aligned}\langle y^{u,x}(n), x^*\rangle &= \langle S(n)x, x^*\rangle + \int_0^n [u(s), B^*S^*(n-s)x^*]_H\, ds \\ &= \lim_{k\to\infty}\left(\langle S(n)x_k, x^*\rangle + \int_0^n [u_k(s), B^*S^*(n-s)x^*]_H\, ds\right) \\ &= \lim_{k\to\infty}\langle y^{u_k,x_k}(n), x^*\rangle = 0.\end{aligned}$$

Hence $y^{u,x}(n) = 0$ and $x \in E_n$.

By the Baire category theorem, at least one E_{n_0} has a nonempty interior. Fix an arbitrary x_0 in the interior of E_{n_0} and consider the set $E_{n_0} - x_0$. This is a neighborhood of 0 consisting of elements that can be steered to 0 in time n_0. By linearity it follows that every $x \in E$ can be steered to 0 in time n_0. This means that the pair (A,B) is null controllable in time n_0. □

Recall that if (A,B) is null controllable in time t_0, then for all $t \geqslant t_0$ the square norm $\|\Sigma(t)x\|^2_{H_t}$ is the minimal energy to steer from x to 0 in time t. Hence the following observation is a straightforward consequence of (2.3) and the above theorem.

COROLLARY 3.2. *The following assertions are equivalent:*

1. *The pair (A,B) is null controllable with vanishing energy.*
2. *The pair (A,B) is null controllable in finite time and $\lim_{t\to\infty}\|\Sigma(t)x\|_{H_t} = 0$ for all $x \in E$.*

We proceed with two simple examples of systems that are null controllable with vanishing energy.

Example 3.3. If (A,B) is null controllable in finite time and the semigroup S generated by A is *strongly stable*, i.e., if $\lim_{t\to\infty} S(t)x = 0$ for all $x \in E$, then (A,B) is null controllable with vanishing energy. Indeed, if (A,B) is null controllable in time t_0, then for all $t \geqslant t_0$ we have

$$\|\Sigma(t)x\|_{H_t} = \|i_{t_0,t}\Sigma(t_0)S(t-t_0)x\|_{H_t} \leqslant \|\Sigma(t_0)\|\,\|S(t-t_0)x\|.$$

Example 3.4. The range of B is a Hilbert space with norm

$$\|Bh\|_{\operatorname{range} B} = \inf\bigl\{\|h'\|_H :\ Bh' = Bh\bigr\}.$$

With this norm, the range of B equals the reproducing kernel Hilbert space of the operator BB^*. Accordingly we shall denote the range of B by H_{BB^*}. If S restricts to a C_0-semigroup S_B on H_{BB^*}, then it follows from [6, Theorem 3.5] that the reachable spaces H_t for the pair (A,B) coincide with the reproducing kernel space of the operators $R_t \in \mathcal{L}(H_{BB^*})$ defined by

$$R_t h := \int_0^t S_B(s)S_B^*(s)h\, ds \qquad (h \in H_{BB^*}),$$

and the pair (S_B, I_B) is null controllable for all times $t > 0$. Here I_B denotes the identity operator on H_{BB^*}. It follows from the same reference that for all $h \in \operatorname{range} B$ and $t > 0$ we have an estimate

$$\|\Sigma_B(t)h\|^2_{H_t} \leqslant \frac{1}{t^2}\int_0^t \|S_B(s)h\|^2_{H_{BB^*}}\, ds \qquad (h \in H_{BB^*}).$$

Here, $\Sigma_B(t)$ denotes $S_B(t)$, regarded as an operator from H_{BB^*} into H_t. In particular the pair (S_B, I_B) is null controllable with vanishing energy if the semigroup S_B is uniformly bounded on H_{BB^*}.

In [10], under the assumption that E is a Hilbert space it was shown by control theoretic methods that a pair (A, B) which is null controllable in finite time is null controllable with vanishing energy if and only if the algebraic Riccati equation

$$XA + A^*X - XBB^*X = 0 \tag{3.1}$$

admits $X = 0$ as its only positive self-adjoint solution. A *solution* of (3.1) is a bounded operator $X \in \mathcal{L}(E)$ such that

$$\langle XAx, y\rangle + \langle Xx, Ay\rangle - \langle XBB^*Xx, y\rangle = 0 \quad \text{for all } x, y \in D(A). \tag{3.2}$$

In this identity the brackets denote the scalar product of E.

In this section we shall prove an extension of this result to Banach spaces E. It shares with [10] the strategy of first solving a differential Riccati equation and obtaining the final characterization from a maximality argument, but both steps are accomplished in a completely different way. In the Banach space setting, a *solution* of (3.1) is a bounded operator $X \in \mathcal{L}(E, E^*)$ such that (3.2) holds for all $x, y \in D(A)$; this time the brackets denote the duality pairing between E^* and E. The notions of positivity and self-adjointness extend as follows: we call $X \in \mathcal{L}(E, E^*)$ *positive* if $\langle Xx, x\rangle \geqslant 0$ for all $x \in E$ and *symmetric* if $\langle Xx, y\rangle = \langle Xy, x\rangle$ for all $x, y \in E$.

We begin with a result which states that the operator function $t \mapsto \Sigma^*(t)\Sigma(t)$ solves, in some appropriate sense, the differential Riccati equation

$$\frac{d}{dt}X(t) = X(t)A + A^*X(t) - X(t)BB^*X(t)$$

on the interval $[t_0, \infty)$.

In the Hilbert space literature, existence of a solution is usually derived from a fixed point argument. Here, we obtain it as a direct consequence of Theorem 2.5.

PROPOSITION 3.5. *Let the pair (A, B) be null controllable in time t_0. For all $x, y \in D(A)$ the function $t \mapsto \langle \Sigma^*(t)\Sigma(t)x, y\rangle$ is differentiable on the interval $[t_0, \infty)$, with derivative*

$$\begin{aligned}\frac{d}{dt}&\langle \Sigma^*(t)\Sigma(t)x, y\rangle \\ &= \langle \Sigma^*(t)\Sigma(t)Ax, y\rangle + \langle \Sigma^*(t)\Sigma(t)x, Ay\rangle - \langle BB^*\Sigma^*(t)\Sigma(t)x, \Sigma^*(t)\Sigma(t)y\rangle.\end{aligned}$$

Proof. Since both BB^* and $\Sigma^*(t)\Sigma(t)$ are symmetric operators, by polarization it suffices to prove that for all $x \in D(A)$ and $t \geqslant t_0$ we have

$$\frac{d}{dt}\langle \Sigma^*(t)\Sigma(t)x, x\rangle = 2\langle \Sigma^*(t)\Sigma(t)Ax, x\rangle - \langle BB^*\Sigma^*(t)\Sigma(t)x, \Sigma^*(t)\Sigma(t)x\rangle.$$

For this, in turn, it suffices to prove right differentiability. Indeed, by Lemma 2.3 the functions $\langle \Sigma^*(t)\Sigma(t)x, x\rangle$ and $2\langle \Sigma^*(t)\Sigma(t)Ax, x\rangle - \langle BB^*\Sigma^*(t)\Sigma(t)x, \Sigma^*(t)\Sigma(t)x\rangle$ are continuous functions of $t \in [t_0, \infty)$, and by elementary calculus a continuous function that is right differentiable with continuous right derivative is differentiable; cf. [13].

Fix $x \in D(A)$ and $t \geqslant t_0$. By Theorem 2.5 applied to $f(s) = \Sigma(t)S(s)x$ we have

$$\begin{aligned}\lim_{s\downarrow 0} \frac{1}{s}\Big(\langle \Sigma^*(t+s)\Sigma(t+s)x, x\rangle - \langle \Sigma^*(t)\Sigma(t)x, x\rangle\Big)\\ &= \lim_{s\downarrow 0} \frac{1}{s}\Big(\|i_{t,t+s}\Sigma(t)S(s)x\|^2_{H_{t+s}} - \|\Sigma(t)x\|^2_{H_t}\Big)\\ &= 2[\Sigma(t)Ax, \Sigma(t)x]_{H_t} - \|B^*\Sigma^*(t)\Sigma(t)x\|^2_H\\ &= 2\langle \Sigma^*(t)\Sigma(t)Ax, x\rangle - \langle BB^*\Sigma^*(t)\Sigma(t)x, \Sigma^*(t)\Sigma(t)x\rangle. \qquad \square\end{aligned}$$

Remark 3.6. In the special case where E is a Hilbert space, instead of using Theorem 2.5 we could apply Corollary 2.6 to the E_t-valued function $g(s) := \Gamma(t)S(s)$; note that $Q_t^{1/2} g(s) = \Sigma(t)S(s)x = f(s)$.

From Proposition 3.5 we obtain the following.

PROPOSITION 3.7. *Let the pair (A, B) be null controllable in time t_0. For all $x, y \in E$ the limit $\lim_{t\to\infty}\langle \Sigma^*(t)\Sigma(t)x, y\rangle$ exists, and the operator $X \in \mathcal{L}(E, E^*)$ defined by*

$$\langle Xx, y\rangle := \lim_{t\to\infty} \langle \Sigma^*(t)\Sigma(t)x, y\rangle \tag{3.3}$$

defines a positive symmetric solution of the algebraic Riccati equation

$$XA + A^*X - XBB^*X = 0.$$

Proof. For all $x \in E$ we have $\langle \Sigma^*(t)\Sigma(t)x, x\rangle = \|\Sigma(t)x\|^2_{H_t}$, which is a nonincreasing function of $t \geqslant t_0$. In particular, for all $x \in E$ the limit $\lim_{t\to\infty}\langle \Sigma^*(t)\Sigma(t)x, x\rangle$ exists. Since each $\Sigma^*(t)\Sigma(t)$ is positive and symmetric, by polarization it follows that for all $x, y \in E$ the limit $\lim_{t\to\infty}\langle \Sigma^*(t)\Sigma(t)x, y\rangle$ exists, and then (3.3) defines a positive and symmetric operator X.

Since $t \mapsto \Sigma^*(t)\Sigma(t)$ solves the differential Riccati equation, a standard argument implies that X solves the algebraic Riccati equation. $\square$

Our next aim is to show that the weak operator limit $X = \lim_{t\to\infty} \Sigma^*(t)\Sigma(t)$ is in fact the *maximal* symmetric solution of the algebraic Riccati equation. More precisely we have the following.

THEOREM 3.8. *Let the pair (A, B) be null controllable at time $t_0 > 0$. If Y is a symmetric solution of the algebraic Riccati equation, then for all $x \in E$ we have $\langle Yx, x\rangle \leqslant \langle Xx, x\rangle$.*

Proof. Fix $t \geqslant t_0$ and $x \in E$, and let $u \in L^2(0, t; H)$ be any control steering x to 0 in time t:

$$y^{u,x}(t) = S(t)x + \int_0^t S(t-s)Bu(s)\, ds = 0.$$

We will show that the function $f_u : [0, t] \to \mathbb{R}$ defined by

$$f_u(s) := \int_0^s \|u(r)\|^2_H\, dr + \langle Y y^{u,x}(s), y^{u,x}(s)\rangle$$

is nondecreasing. To prove this we shall show that f_u is almost everywhere differentiable with nonnegative derivative.

Let us first consider the function $g_u(s) := \langle Y y^{u,x}(s), y^{u,x}(s)\rangle$. In order to show that g_u is differentiable we introduce a regularization operator as follows. For $\lambda > 0$ large enough, put $E_\lambda := \lambda(\lambda - A)^{-1}$ and define

$$g_{u,\lambda}(s) := \langle Y E_\lambda y^{u,x}(s), E_\lambda y^{u,x}(s)\rangle.$$

Then, by the symmetry of Y and the fact that this operator solves the algebraic Riccati equation,

$$\begin{aligned}
g'_{u,\lambda}(s) &= 2\left\langle YE_\lambda y^{u,x}(s), \frac{d}{ds}E_\lambda y^{u,x}(s)\right\rangle \\
&= 2\left\langle YE_\lambda y^{u,x}(s), \frac{d}{ds}\left(S(s)E_\lambda x + \int_0^s S(s-r)E_\lambda Bu(r)\,dr\right)\right\rangle \\
&= 2\left\langle YE_\lambda y^{u,x}(s), A\left(S(s)E_\lambda x + \int_0^s S(s-r)E_\lambda Bu(r)\,dr\right) + E_\lambda Bu(s)\right\rangle \\
&= \langle YBB^*YE_\lambda y^{u,x}(s), E_\lambda y^{u,x}(s)\rangle + 2\langle YE_\lambda y^{u,x}(s), E_\lambda Bu(s)\rangle \\
&=: G_{u,\lambda}(s).
\end{aligned}$$

From $\lim_{\lambda\to\infty} E_\lambda = I$ strongly we have $\lim_{\lambda\to\infty} g_{u,\lambda} = g_u$ and

$$\lim_{\lambda\to\infty} G_{u,\lambda} = \langle YBB^*Yy^{u,x}(s), y^{u,x}(s)\rangle + 2\langle Yy^{u,x}(s), Bu(s)\rangle$$

uniformly on $[0,t]$ (notice that $y^{u,x}$ is continuous on $[0,t]$). The closedness of the first derivative now implies that g_u is differentiable, with derivative

$$g'_u(s) = \langle YBB^*Yy^{u,x}(s), y^{u,x}(s)\rangle + 2\langle Yy^{u,x}(s), Bu(s)\rangle.$$

It follows that f_u is almost everywhere differentiable, with derivative

$$\begin{aligned}
f'_u(s) &= \|u(s)\|_H^2 + \langle YBB^*Yy^{u,x}(s), y^{u,x}(s)\rangle + 2\langle Yy^{u,x}(s), Bu(s)\rangle \\
&= \|u(s)\|_H^2 + \|B^*Yy^{u,x}(s)\|_H^2 + 2[B^*Yy^{u,x}(s), u(s)]_H \\
&\geqslant \|u(s)\|_H^2 + \|B^*Yy^{u,x}(s)\|_H^2 - 2\|B^*Yy^{u,x}(s)\|_H\|u(s)\|_H \\
&= \big(\|u(s)\|_H - \|B^*Yy^{u,x}(s)\|_H\big)^2,
\end{aligned}$$

which is nonnegative.

By what has been shown so far, we have

$$\begin{aligned}
\|u\|^2_{L^2(0,t;H)} &= \int_0^t \|u(r)\|_H^2\,dr = \int_0^t \|u(r)\|_H^2\,dr + \langle Yy^{u,x}(t), y^{u,x}(t)\rangle \\
&= f_u(t) \geqslant f_u(0) = \langle Yy^{u,x}(0), y^{u,x}(0)\rangle = \langle Yx, x\rangle.
\end{aligned}$$

Taking the infimum over all admissible controls we obtain

$$\|\Sigma(t)x\|^2_{H_t} \geqslant \langle Yx, x\rangle.$$

Finally, letting $t\to\infty$, this gives

$$\langle Xx, x\rangle = \lim_{t\to\infty} \|\Sigma(t)x\|^2_{H_t} \geqslant \langle Yx, x\rangle. \qquad \square$$

The preceding two results may now be combined to prove the following characterization of null controllability with vanishing energy, which extends the corresponding Hilbert space result of [10] to Banach spaces.

THEOREM 3.9. *The following assertions are equivalent:*

1. *The pair (A,B) is null controllable with vanishing energy.*
2. *The pair (A,B) is null controllable in finite time and the only positive symmetric solution of the algebraic Riccati equation $XA + A^*X - XBB^*X = 0$ is the trivial solution $X = 0$.*

Proof. We will use Corollary 3.2.

(1)⇒(2): Let Y be any positive symmetric solution of the algebraic Riccati equation. Then for all $x \in E$ we have

$$0 \leqslant \langle Yx, x\rangle \leqslant \langle Xx, x\rangle = \lim_{t\to\infty} \|\Sigma(t)x\|_{H_t}^2 = 0,$$

which implies that $Y = 0$.

(2)⇒(1): Since $X = \lim_{t\to\infty} \Sigma^*(t)\Sigma(t)$ is a positive symmetric solution of the algebraic Riccati equation, it follows that $\lim_{t\to\infty} \|\Sigma(t)x\|_{H_t}^2 = \langle Xx, x\rangle = 0$ for all $x \in E$. □

Under additional spectral assumptions (which are satisfied, e.g., if S is eventually compact), it is shown in [10] that the pair (A, B) is null controllable with vanishing energy if and only if $\sup\{\operatorname{Re}\lambda : \lambda \in \sigma(A)\} \leqslant 0$. This result is applied in [11], where it is used to obtain necessary and sufficient conditions for the validity of Liouville's theorem for the Ornstein–Uhlenbeck operator associated with the pair (A, B).

As an application of Theorem 3.9 we give a sufficient condition for null controllability with vanishing energy in the symmetric case.

THEOREM 3.10. *Let the pair (A, B) be null controllable at time $t_0 > 0$. Assume furthermore that*

- *(nondegeneracy) B has dense range,*
- *(BB^*-symmetry) $S(t)BB^* = BB^*S^*(t)$ for all $t \geqslant 0$.*

If the limit $Q_\infty := \lim_{t\to\infty} Q_t$ exists in the weak operator topology, then (A, B) is null controllable with vanishing energy.

Without any nondegeneracy condition on B, the assumptions of the theorem imply that S restricts to a strongly stable C_0-semigroup of contractions S_B on the range of B [6, Theorem 4.5]. By Examples 3.3 and 3.4, the pair (S_B, I_B) is null controllable with vanishing energy.

Proof. We shall use the fact that $Q_\infty := \lim_{t\to\infty} Q_t$ exists in the weak operator topology if and only if there exists a positive symmetric solution in $\mathcal{L}(E^*, E)$ of the Lyapunov equation

$$AY + YA^* + BB^* = 0$$

and that in this case Q_∞ is the minimal positive symmetric solution of this equation [6, Theorem 4.4]. In this context, a bounded operator $Y \in \mathcal{L}(E^*, E)$ is called *positive* if $\langle Yx, x\rangle \geqslant 0$ for all $x \in E$ and *symmetric* if $\langle Yx, y\rangle = \langle Yy, x\rangle$ for all $x, y \in E$.

Assume now that $X \in \mathcal{L}(E, E^*)$ is a positive symmetric solution of the algebraic Riccati equation. We have to show that $X = 0$.

Since B is assumed to have dense range, it is an easy consequence of the Hahn–Banach theorem that BB^* is injective and has dense range as well. From this it follows that Q_∞ is injective and has dense range [5, Lemma 5.2].

By the same argument as in the proof of [6, Theorem 4.5], the assumption $S(t)BB^* = BB^*S(t)$ implies that the semigroup S_t on H_t is self-adjoint for all $t \geqslant t_0$. Moreover, for all $x \in D(A)$ we have $\Sigma(t)x \in D(A_t)$ and $A_t\Sigma(t)x = \Sigma(t)Ax$. Similarly, for all $h \in D(A_t^*)$ we have $\Sigma^*(t)h \in D(A^*)$ and $A^*\Sigma^*(t)h = \Sigma^*(t)A_t^*h$. Using these facts, for all $x, y \in D(A)$ we obtain

$$\begin{aligned}\langle Xx, Ay\rangle &= \lim_{t\to\infty} \langle \Sigma^*(t)\Sigma(t)x, Ay\rangle = \lim_{t\to\infty} \langle \Sigma^*(t)A_t^*\Sigma(t)x, y\rangle \\ &= \lim_{t\to\infty} \langle \Sigma^*(t)A_t\Sigma(t)x, y\rangle = \lim_{t\to\infty} \langle \Sigma^*(t)\Sigma(t)Ax, y\rangle = \langle XAx, y\rangle.\end{aligned}$$

It follows that $Xx \in D(A^*)$ and $A^*Xx = XAx$. Thus, $A^*X = XA$. Similarly one proves that $AQ_\infty = Q_\infty A^*$. As X and Q_∞ are symmetric and solve the algebraic Riccati equation and the Lyapunov equation, respectively, for all $x^*, y^* \in D(A^*)$ we obtain

$$\begin{aligned}
0 &= \langle A^*XQ_\infty x^*, Q_\infty y^*\rangle + \langle XAQ_\infty x^*, Q_\infty y^*\rangle - \langle XBB^*XQ_\infty x^*, Q_\infty y^*\rangle \\
&= \langle XQ_\infty A^* x^*, Q_\infty y^*\rangle + \langle XAQ_\infty y^*, Q_\infty x^*\rangle - \langle XBB^*XQ_\infty x^*, Q_\infty y^*\rangle \\
&= -\langle XBB^* x^*, Q_\infty y^*\rangle - \langle XBB^*XQ_\infty x^*, Q_\infty y^*\rangle \\
&= -\langle Q_\infty XBB^* x^*, y^*\rangle - \langle Q_\infty XBB^*XQ_\infty x^*, y^*\rangle.
\end{aligned}$$

Thus,

$$\langle Q_\infty XBB^*(I + XQ_\infty)x^*, y^*\rangle = 0 \tag{3.4}$$

for all $x^*, y^* \in D(A^*)$. Since $D(A^*)$ is weak*-dense, it follows that

$$Q_\infty XBB^*(I + XQ_\infty)x^* = 0 \tag{3.5}$$

for all $x^* \in D(A^*)$. Furthermore, by the symmetry of Q_∞, X, and BB^*, from (3.4) we obtain

$$\langle (I + Q_\infty X)BB^*XQ_\infty y^*, x^*\rangle = 0$$

for all $x^*, y^* \in D(A^*)$. Since $D(A^*)$ is weak*-dense, it follows that

$$(I + Q_\infty X)BB^*XQ_\infty y^* = 0 \tag{3.6}$$

for all $y^* \in D(A^*)$. Taking $y^* = x^*$ and subtracting (3.5) and (3.6), we find

$$BB^*XQ_\infty x^* = Q_\infty XBB^* x^*$$

for all $x^* \in D(A^*)$. Hence, by (3.6),

$$(I + Q_\infty X)Q_\infty XBB^* x^* = 0$$

for all $x^* \in D(A^*)$. Since $D(A^*)$ is weak*-dense and BB^* is weak*-to-weakly continuous and has weakly dense range, this implies that

$$(I + Q_\infty X)Q_\infty X = 0$$

or, equivalently, $P(I - P) = 0$, where $P := -Q_\infty X$. Thus, P is a projection in E.

For any $x \in \ker P$ we have $Q_\infty Xx = 0$ and therefore $Xx = 0$ by the injectivity of Q_∞.

For any $x \in \ker(I - P)$ we have $-Q_\infty Xx = x$ and therefore

$$0 \leqslant \langle Xx, x\rangle = -\langle Xx, Q_\infty Xx\rangle = -\langle Q_\infty Xx, Xx\rangle \leqslant 0$$

by the positivity of Q_∞. It follows that $\langle Q_\infty Xx, Xx\rangle = \|i_\infty^* Xx\|_{H_\infty}^2 = 0$, where $i_\infty : H_\infty \hookrightarrow E$ denotes the reproducing kernel Hilbert space of Q_∞. Since $Q_\infty = i_\infty \circ i_\infty^*$ is injective, i_∞^* is injective, and we conclude that $Xx = 0$.

Combining the facts just proved, we obtain that $Xx = 0$ for all $x \in E$, i.e., $X = 0$. □

It is worthwhile to point out that Theorem 3.10 is not covered by Example 3.3, since the existence of Q_∞ does not imply strong stability of the semigroup S.

Example 3.11. Let $E = \mathbb{R}^2$ and $S(t) = \left(\begin{smallmatrix} e^{-t} & 0 \\ 0 & 1 \end{smallmatrix}\right)$. The semigroup S is not strongly stable. Taking $H = \mathbb{R}$ and $Bh = (h, 0)$, the limit $Q_\infty = \lim_{t\to\infty} Q_t$ exists: we have

$$\lim_{t\to\infty} Q_t = \lim_{t\to\infty} \int_0^t \begin{pmatrix} e^{-2s} & 0 \\ 0 & 0 \end{pmatrix} ds = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & 0 \end{pmatrix}.$$

Let us finally observe that in Theorem 3.10 the condition on existence of Q_∞ is not a necessary one (take $E = H = \mathbb{R}$, $B = I$, and $S(t) = I$), nor can it be dropped (take $E = H = \mathbb{R}$, $B = I$, and $S(t) = e^t I$).

Acknowledgment. The author thanks Professors Jerzy Zabczyk and Ben Goldys for stimulating discussions and kind hospitality.

BOUNDS AND ASYMPTOTIC APPROXIMATIONS FOR UTILITY PRICES WHEN VOLATILITY IS RANDOM*

RONNIE SIRCAR† AND THALEIA ZARIPHOPOULOU‡

Abstract. This paper is a contribution to the valuation of derivative securities in a stochastic volatility framework, which is a central problem in financial mathematics. The derivatives to be priced are of European type with the payoff depending on both the stock and the volatility. The valuation approach uses utility-based criteria under the assumption of exponential risk preferences. This methodology yields the indifference prices as solutions to second order quasilinear PDEs. Two sets of price bounds are derived that highlight the important ingredients of the utility approach, namely, nonlinear pricing rules with dynamic certainty equivalent characteristics, and pricing measures depending on correlation and the Sharpe ratio of the traded asset. The problem is further analyzed by asymptotic methods in the limit of the volatility being a fast mean-reverting process. The analysis relates the traditional market-selected volatility risk premium approach and the preference-based valuation techniques.

Key words. financial mathematics, derivative pricing, stochastic volatility, utility indifference pricing

DOI. 10.1137/S0363012903409253

1. Introduction.

We study the utility indifference pricing mechanism for European derivative contracts in financial markets with uncertain volatility. As is well known, in such incomplete markets, there are many possible no-arbitrage pricing (or "risk-neutral") measures and typically an interval of arbitrage-free option prices. The traditional pricing methodology is that the market selects a pricing probability measure that is reflected in the prices of liquidly traded derivative contracts (for example, at-the-money call options). Indifference pricing is an alternative mechanism whereby a no-arbitrage price is selected according to investment optimality criteria of a risk-averse investor. Our analysis, using bounds and asymptotic approximations, sheds some light on the relation between the two. Specifically, Theorem 3.2 shows that the nonlinear utility pricing rule lies between a linear no-arbitrage pricing rule and an insurance-type certainty equivalent pricing rule.

Stochastic volatility models are popular because they capture the deviation of stock price data from the Black–Scholes geometric Brownian motion model in a parsimonious way. They were originally introduced in the late 1980's by Hull and White [22] and others for option pricing. Much of their success derives from their predicted option prices exhibiting the implied volatility skew that is observed in many options markets. See [17], for example, for details.

However, a market with stochastic volatility is incomplete in that volatility is a source of uncertainty that is not traded. Therefore, enforcement of *no arbitrage* does not lead to a unique derivative pricing rule. The usual way to "close" the model is

to assume the market chooses a pricing measure which is implicit in the prices of liquidly traded options. The indifference pricing mechanism is an alternative in which the price is uniquely (and endogenously) determined at the cost of depending on the preferences of the pricer. It has been studied in various incomplete market problems, for example, when there are transaction costs [6, 11, 21] or nontraded assets [10, 31], and under exponential utilities [33].

Our analysis is presented as follows. In section 2, we describe the mechanism in the context of a standard stochastic volatility model and characterize the indifference price in terms of solutions of related Hamilton–Jacobi–Bellman (HJB) equations. We derive a quasilinear PDE (2.32) that the pricing function satisfies. In addition, a specific measure, $\mathcal{Q}$ in Definition 2.7, emerges as a natural "prior" pricing measure, and the indifference price can be characterized as a worst-case expected payoff, penalized by relative entropy with respect to this prior (section 2.1).

In section 3, we derive two sets of bounds for the indifference price by analysis of the associated HJB equations. Section 4 presents asymptotic approximations that relate the indifference price to a particular *no-arbitrage* price. Finally, section 5 concludes and lists some remaining questions about the mechanism for future investigation.

2. Indifference prices. We assume a dynamic market setting with two assets, a riskless bond B, and a stock S. The stock price is modeled as a diffusion process satisfying

$$dS_s = \mu S_s\, ds + \sigma(Y_s, s) S_s\, dW_s^1, \qquad s \geq 0, \tag{2.1}$$

with $\mu > 0$. The volatility coefficient of the stock is driven by the stochastic factor $Y \in \mathbb{R}$ which is modeled as a correlated diffusion satisfying

$$dY_s = b(Y_s, s)\, ds + a(Y_s, s)\, (\rho\, dW_s^1 + \rho' dW_s^2), \tag{2.2}$$

with $\rho \in (-1, 1)$ the correlation coefficient and $\rho' = \sqrt{1 - \rho^2}$.

The processes W^1 and W^2 are independent standard Brownian motions defined on a probability space $(\Omega, \mathcal{F}, (\mathcal{F}_s), \mathbb{P})$, where $\mathcal{F}_s$ is the augmented σ-algebra generated by $((W_u^1, W_u^2);\, 0 \leq u \leq s)$. We assume that a riskless bond with maturity T is available for trading, yielding constant interest rate $r = 0$. The case $r \neq 0$ can be treated using standard discounting arguments and it is not presented herein. The derivative to be priced is of European type with payoff $g(S_T, Y_T)$ at expiration T. We make the following assumptions throughout.

Assumption 1.

1. *The volatility function $\sigma(\cdot)$ and the diffusion coefficient $a(\cdot, \cdot)$ are smooth and bounded above and below away from zero.*
2. *The drift coefficient $b(\cdot, \cdot)$ in (2.2) is Lipschitz continuous on $\mathbb{R} \times [0, T]$.*
3. *The payoff function $g(\cdot, \cdot)$ is smooth and bounded.*

Under these assumptions, (2.1) and (2.2) have a unique solution with $S_s \geq 0$ $\mathbb{P}$-a.s., $s \geq 0$ a.e. The assumption on the payoff excludes put options (whose payoff has discontinuous first derivative) and call options (which are unbounded). Handling these issues will require regularization methods (see, for example, [19]) which we do not address in this paper.

The utility-based valuation method relies on the comparison of maximal expected utilities corresponding to investment opportunities with and without the derivative. In both settings, trading takes place between the bond and the stock, and the objective

is to maximize the terminal utility of wealth. The investor starts, at time $t \geq 0$, with initial endowment x and dynamically rebalances his portfolio allocations, say, π_s^0 and π_s, representing the amounts invested at time $s \geq t$ in the bond and the stock accounts. It is assumed that no intermediate consumption or infusion of extraneous funds is allowed. The total current wealth satisfies

$$X_s = \pi_s^0 + \pi_s, \quad t \leq s \leq T, \tag{2.3}$$

and thus solves the state controlled diffusion equation

$$\begin{cases} dX_s = \mu\pi_s\, ds + \sigma(Y_s, s)\pi_s\, dW_s^1, & t \leq s \leq T, \\ X_t = x. \end{cases} \tag{2.4}$$

The above equation can be easily derived from (2.1) and the budget constraint (2.3) (see Merton [30]). Note that because the coefficients in (2.1) are linear in S, the latter does not appear explicitly in (2.4). Moreover, the budget constraint results in eliminating the first control variable π_s^0. The single control variable π_s is called admissible if it is $\mathcal{F}_s$-measurable and satisfies the integrability constraint $E\int_t^T \sigma(Y_s, s)^2\pi_s^2\, ds < +\infty$. The set of admissible policies is denoted by $\mathcal{A}$.

The next task is to introduce and analyze the three fundamental optimal investment problems via which the indifference prices for the writer and the buyer of the derivative will be constructed. Throughout the analysis, it is assumed that the individual preferences are modeled via an exponential utility function

$$U(x) = -e^{-\gamma x}, \qquad x \in \mathbb{R}, \tag{2.5}$$

with risk-aversion parameter $\gamma > 0$, and that they remain the same, independently of whether the derivative is written, bought, or not traded at all. The first is the classical Merton portfolio optimization problem, appropriately modified to accommodate stochastic volatility. Its value function is

$$V(x, y, t) = \sup_{\mathcal{A}} E(-e^{-\gamma X_T} \mid X_t = x,\ Y_t = y), \tag{2.6}$$

where X and Y solve (2.4) and (2.2), respectively. The investor seeks to maximize his terminal expected utility.

If the derivative with payoff $g(S_T, Y_T)$ is written, the *writer's* value function is

$$u^w(x, S, y, t) = \sup_{\mathcal{A}} E(-e^{-\gamma(X_T - g(S_T, Y_T))} \mid X_t = x,\ S_t = S,\ Y_t = y), \tag{2.7}$$

and if the derivative is bought, the *buyer's* value function is

$$u^b(x, S, y, t) = \sup_{\mathcal{A}} E(-e^{-\gamma(X_T + g(S_T, Y_T))} \mid X_t = x,\ S_t = S,\ Y_t = y). \tag{2.8}$$

It is immediate that

$$u^w(x, S, y, t; g) = u^b(x, S, y, t; -g). \tag{2.9}$$

The payoffs in (2.7) and (2.8) reflect, respectively, the obligation of the writer and the compensation of the buyer at expiration T.

A fundamental assumption is that both the writer and the buyer optimize over the same set of admissible strategies . Moreover, the traditional no-bankruptcy constraint $X_s \geq 0$ a.e. $t \leq s \leq T$ is not imposed herein due to the fact that exponential

utilities may allow for negative wealth levels. Imposing such constraints affects significantly the nature of the indifference prices and, in most cases, yields prices that are considerably high and not applicable. For models with transaction costs, such issues were studied by Constantinides and Zariphopoulou [6, 7].

We next review the definition of indifference prices (see Hodges and Neuberger [21]). The *writer's indifference price* of the European claim $g(S_T, Y_T)$ is defined as the amount $h^w = h^w(x, S, y, t)$, such that the writer is indifferent to the following two scenarios: optimize the utility payoff without writing the derivative and optimize the utility payoff with the *liability* $g(S_T, Y_T)$ at expiration, but with an initial *compensation* $h^w(x, S, y, t)$ at the time of inscription t. Similarly, the *indifference buyer's price* of the European claim $g(S_T, Y_T)$ is defined as the amount $h^b = h^b(x, S, y, t)$ such that the buyer is indifferent to the following two scenarios: optimize the utility payoff without buying the derivative and optimize the utility payoff with the *payoff* $g(S_T, Y_T)$ at expiration, but with the initial *cost* $h^b(x, S, y, t)$ at the time of inscription t.

DEFINITION 2.1. *The indifference prices h^w and h^b are defined by*

$$V(x, y, t) = u^w\Big(x + h^w(x, S, y, t), S, y, t\Big), \tag{2.10}$$

$$V(x, y, t) = u^b\Big(x - h^b(x, S, y, t), S, y, t\Big). \tag{2.11}$$

The above definition allows for derivative prices that depend on the investor's wealth, as reflected in their x-argument. Such dependence might look like an undesirable feature given the wealth-independent prices that arbitrage-free theory yields in complete markets. As the calculations below show, the choice of exponential utility leads to wealth-independent prices, at least for the case of European claims and in the absence of trading constraints. Wealth independence, however, might not hold for other choices of risk preferences and/or trading constraints. In such situations, universality may be achieved by relaxing the notion of indifference price to *reservation prices*. The latter prices are defined as wealth-independent price bounds for which the price equalities (2.10) and (2.11) hold as inequalities (see, for example, [6, 7]).

The value functions V, u^w, and u^b, whose arguments will yield the indifference prices, may be studied via their associated HJB equations. Although these equations are fully nonlinear, the convenience of the exponential utility function allows us to construct classical solutions after an initial separation of variables. It follows from a standard viscosity solution argument that these solutions coincide with the respective value functions.

To facilitate the presentation, we introduce the following operators and Hamiltonians:

$$\begin{aligned}\mathcal{A}^{(S,y)}u = {} & \frac{1}{2}\sigma(y,t)^2S^2u_{SS} + \rho\sigma(y,t)a(y,t)Su_{Sy} \\ & + \frac{1}{2}a(y,t)^2u_{yy} + \mu Su_S + b(y,t)u_y,\end{aligned} \tag{2.12}$$

$$\mathcal{A}^{(y)}u = \frac{1}{2}a(y,t)^2u_{yy} + b(y,t)u_y, \tag{2.13}$$

$$\begin{aligned}\mathcal{H}^{(S,y)}(u_{xx}, u_{xy}, u_{xS}, u_x) = {} & \max_{\pi}\bigg(\frac{1}{2}\sigma(y,t)^2\pi^2u_{xx} + \pi(\rho\sigma(y,t)a(y,t)u_{xy} \\ & + \sigma(y,t)^2Su_{xS} + \mu u_x)\bigg),\end{aligned} \tag{2.14}$$

$$\mathcal{H}^{(y)}(u_{xx}, u_{xy}, u_x) = \max_{\pi}\left(\frac{1}{2}\sigma(y,t)^2\pi^2u_{xx} + \pi(\rho\sigma(y,t)a(y,t)u_{xy} + \mu u_x)\right). \tag{2.15}$$

Note that $\mathcal{A}^{(S,y)}$ is the infinitesimal generator of the Markov process (S, Y), and $\mathcal{A}^{(y)}$ is the infinitesimal generator of Y, which is a Markov process by itself in our stochastic volatility models.

The HJB equation associated with the value function u^w defined in (2.7) is

$$\begin{aligned} &u_t + \mathcal{A}^{(S,y)}u + \mathcal{H}^{(S,y)}(u_{xx}, u_{xy}, u_{xS}, u_x) = 0, \\ &u(x, S, y, T) = -e^{-\gamma(x-g(S,y))}, \end{aligned} \tag{2.16}$$

on $D = \mathbb{R} \times \mathbb{R}^+ \times \mathbb{R} \times [0, T]$. The relevant PDE for u^b, defined in (2.8), is the same as (2.16), with the sign of g changed in the terminal condition. For V, defined in (2.6), we simply set g to zero and remove the S-derivatives from the equation (i.e., $\mathcal{A}^{(S,y)}$ and $\mathcal{H}^{(S,y)}$ are replaced by $\mathcal{A}^{(y)}$ and $\mathcal{H}^{(y)}$, respectively).

In the theorems below, we produce a closed form expression for the value function V and we provide regularity results for $u^{w,b}$. The proofs are based on the construction of a candidate solution that is actually smooth and therefore a classical solution of the HJB equation. We readily identify it also as the unique viscosity solution and, from there, by a standard argument, with the value function. The intermediate step is required because classical verification theorems require polynomial growth (in x) restrictions on the value functions, which do not hold with exponential utility.

For convenience, we introduce

$$\mathcal{L}^{(S,y)}u = \mathcal{A}^{(S,y)}u - \rho\frac{\mu}{\sigma(y,t)}a(y,t)u_y, \tag{2.17}$$

$$\mathcal{L}^{(y)}u = \mathcal{A}^{(y)}u - \rho\frac{\mu}{\sigma(y,t)}a(y,t)u_y, \tag{2.18}$$

$$\mathcal{M}(G_S, G_y, G) = \frac{1}{2}\sigma(y,t)^2S^2\frac{G_S^2}{G} + \rho\sigma(y,t)a(y,t)S\frac{G_SG_y}{G} + \frac{1}{2}\rho^2a(y,t)^2\frac{G_y^2}{G}. \tag{2.19}$$

THEOREM 2.2. *The value function V is given by*

$$V(x, y, t) = -e^{-\gamma x}f(y, t)^{\frac{1}{1-\rho^2}}, \tag{2.20}$$

where f solves

$$f_t + \mathcal{L}^{(y)}f = \frac{1}{2}(1-\rho^2)\frac{\mu^2}{\sigma(y,t)^2}f \tag{2.21}$$

in $y \in \mathbb{R}$, $t < T$, with $f(y, T) = 1$ for $y \in \mathbb{R}$.

Proof. We first consider a candidate solution of the form $\tilde{V}(x, y, t) = -e^{-\gamma x}F(y, t)$. This form is suggested by the scaling properties of the exponential utility. We recall that V solves the HJB equation (2.16) for $g = 0$ which reduces to

$$V_t + \mathcal{H}^{(y)}(V_{xx}, V_{xy}, V_x) + \mathcal{A}^{(y)}u = 0, \tag{2.22}$$

with $V(x, y, T) = -e^{-\gamma x}$. Evaluating this equation at the candidate solution $\tilde{V}$ yields that F must satisfy the quasilinear equation

$$F_t + \mathcal{L}^{(y)}F = \frac{1}{2}\frac{\mu^2}{\sigma(y,t)^2}F + \frac{1}{2}\rho^2a(y,t)^2\frac{F_y^2}{F}, \tag{2.23}$$

with $F(y, T) = 1$. A power transformation $F = f^\delta$ for $\delta = \frac{1}{1-\rho^2}$ yields that f must solve the linear PDE (2.21), with $f(y, T) = 1$. The fact that the linear equation

(2.21) has a unique smooth and bounded solution follows from Assumption 1 on the coefficients (see [26, Theorem 2.9.10], for example). We then deduce that the candidate $\tilde{V}$ satisfies the HJB equation (2.22), with terminal value $-e^{-\gamma x}$, and it is also smooth. Therefore, it is a classical solution of (2.22). To conclude, we use uniqueness results for viscosity solutions of the HJB equation. This approach has become by now familiar in incomplete market models (see [34] for an overview).

Following the arguments of Theorems 4.1 and 4.2 in [13], we deduce that the value function V defined in (2.6) is the *unique* viscosity solution of (2.22). Uniqueness holds in the class of functions that are concave and of exponential growth in the wealth argument and are uniformly bounded in the variable y. (We note that in the model analyzed in [13], market incompleteness was generated by stochastic labor income modeled as a correlated diffusion. The two associated HJB equations have similar nonlinearities, and the technical arguments work under rather minor modifications.) We next observe that the candidate $\tilde{V}$ is smooth and therefore a viscosity solution of (2.22). Moreover, the assumptions on the model coefficients yield that it belongs to the class of viscosity solutions in which uniqueness holds. Therefore, $\tilde{V} \equiv V$ and the result follows. Note that classical verification results (for instance, [14, Theorem III.8.1]) require more stringent polynomial growth conditions on the candidate solution, a requirement that is bypassed by the viscosity arguments. □

DEFINITION 2.3. *Let $\mathbb{P}$ be the historical measure. We define an equivalent measure $\widetilde{\mathbb{P}}$ by*

$$\frac{d\widetilde{\mathbb{P}}}{d\mathbb{P}} = \exp\left(- \int_0^T \frac{\mu}{\sigma(Y_s, s)}\, dW_s^1 - \frac{1}{2} \int_0^T \frac{\mu^2}{\sigma(Y_s, s)^2}\, ds \right).$$

By Girsanov's theorem, the dynamics of (S, Y) under $\widetilde{\mathbb{P}}$ are

$$dS_s = \sigma(Y_s, s) S_s\, d\widetilde{W}_s^1, \tag{2.24}$$

$$dY_s = \left(b(Y_s, s) - \rho \frac{\mu}{\sigma(Y_s, s)} a(Y_s, s) \right) ds + a(Y_s, s)\, (\rho\, d\widetilde{W}_s^1 + \rho' d\widetilde{W}_s^2), \tag{2.25}$$

where $\widetilde{W}_s^1 = W_s^1 + \int_0^s \frac{\mu}{\sigma(Y_u, u)}\, du$ and $\widetilde{W}_s^2 = W_s^2$ are independent $\widetilde{\mathbb{P}}$-Brownian motions. The measure $\widetilde{\mathbb{P}}$ is often known as the minimal martingale measure [16].

From the formula (2.20) for V, the Feynman–Kac representation of the solution to (2.21), and the definition of the measure $\widetilde{\mathbb{P}}$, we obtain the following proposition.

PROPOSITION 2.4. *The solution f of* (2.21) *admits the probabilistic representation*

$$f(y, t) = \mathbb{E}_{\widetilde{\mathbb{P}}} \left(e^{- \int_t^T \frac{\mu^2 (1 - \rho^2)}{2\sigma(Y_s, s)^2}\, ds} \mid Y_t = y \right), \tag{2.26}$$

where the process Y satisfies (2.25). *The value function V is then given by*

$$V(x, y, t) = -e^{-\gamma x} \left(\mathbb{E}_{\widetilde{\mathbb{P}}} \left(e^{- \int_t^T \frac{\mu^2 (1 - \rho^2)}{2\sigma(Y_s, s)^2}\, ds} \mid Y_t = y \right) \right)^{\frac{1}{1 - \rho^2}}. \tag{2.27}$$

THEOREM 2.5. *The writer's value function u^w is given by*

$$u^w(x, S, y, t) = -e^{-\gamma x} G(S, y, t), \tag{2.28}$$

where $G \in C^{2,2,1}(\mathbb{R}^+ \times \mathbb{R} \times [0,T])$ *is the unique bounded solution of the quasilinear equation*

$$G_t + \mathcal{L}^{(S,y)} G = \frac{1}{2} \frac{\mu^2}{\sigma(y,t)^2} G + \mathcal{M}(G_S, G_y, G), \tag{2.29}$$

with $G(S,y,T) = e^{\gamma g(S,y)}$.

Proof. We look at a candidate solution of the form $\tilde{u}(x,S,y,t) = -e^{-\gamma x} G(S,y,t)$. Straightforward calculations in (2.16) imply that G must satisfy the quasilinear equation (2.29). Note that G must be positive as u is negative.

A logarithmic transformation $G = e^{\phi}$ gives that ϕ should solve a quasilinear equation with quadratic nonlinearity, namely,

$$\phi_t + \mathcal{L}^{(S,y)} \phi + \frac{1}{2} a(y)^2 (1-\rho^2) \phi_y^2 = \frac{\mu^2}{2\sigma(y)^2}, \tag{2.30}$$

with $\phi(S,y,T) = \gamma g(S,y)$. Equation (2.30) is the familiar HJB equation of a *quadratic cost* stochastic control problem (see Fleming and Rishel [15, section VI.5]). Under Assumption 1, we obtain that ϕ is bounded, $\phi \in C^{2,2,1}(\mathbb{R}^+ \times \mathbb{R} \times [0,T])$, and that it is the unique solution in this class (see, for example, Ladyzenskaja, Solonnikov, and Uralceva [27], Fleming and Rishel [15], or Pham [32]). This in turn yields the same properties for G. Following similar arguments as in the proof of Theorem 2.2 to identify $\tilde{u}$ as the unique viscosity solution of (2.16) and therefore the value function, we conclude that $u^w = \tilde{u}$. □

We note that even though a simple power transformation can linearize the reduced equation (2.23) in the one dimensional case, quasilinear equations of the form (2.29) cannot be linearized in higher dimensional settings unless the nonlinearity is a quadratic in ∇G, where ∇ denotes the gradient with respect to the spatial variables, and there are no cross-derivative terms. Of course under a logarithmic transformation, one may reduce (2.29) to (2.30).

Before we construct the indifference prices, we introduce some convenient notation.

LEMMA 2.1. *Let*

$$L(y,t) = \frac{1}{\rho'} a(y,t) \frac{f_y(y,t)}{f(y,t)}, \tag{2.31}$$

with f *given in* (2.26). *Then under Assumption* 1, L *is smooth, and bounded.*

Proof. From (2.21), f is positive, smooth, and bounded for fixed $t < T$ under Assumption 1. To establish that $f_y(y,t)$ is also smooth and bounded, it suffices to differentiate (2.21) with respect to y and use the relevant probabilistic representation of f_y. □

THEOREM 2.6. (i) *The writer's indifference price* h^w *is the unique* $C^{2,2,1}(\mathbb{R}^+ \times \mathbb{R} \times [0,T])$ *bounded solution of the pricing equation*

$$h^w_t + \mathcal{L}^{(S,y)} h^w + \rho' a(y,t) L(y,t) h^w_y + \frac{1}{2} \gamma (1-\rho^2) a(y,t)^2 (h^w_y)^2 = 0 \tag{2.32}$$

with $h^w(S,y,T) = g(S,y)$.

(ii) *The buyer's indifference price satisfies*

$$h^w(S,y,t;g) = -h^b(S,y,t;-g) \tag{2.33}$$

and solves

$$h_t^b + \mathcal{L}^{(S,y)} h^b + \rho' a(y,t) L(y,t) h_y^b - \frac{1}{2}\gamma(1-\rho^2) a(y,t)^2 (h_y^b)^2 = 0 \tag{2.34}$$

with $h^b(S,y,T) = g(S,y)$.

Proof. We discuss only the arguments for h^w. To this end, we first observe that the pricing equality (2.10) together with the representations (2.20) and (2.28) of the value functions V and u^w yield that h^w is given by

$$h^w(S,y,t) = \frac{1}{\gamma} \ln \frac{G(S,y,t)}{f(y,t)^{1/(1-\rho^2)}}, \tag{2.35}$$

and as such is independent of x. Direct substitution shows that h^w solves the claimed quasilinear equation (2.32). It also satisfies the terminal condition $h^w(S,y,T) = g(S,y)$. In (2.32), the coefficient of the additional h_y^w term is smooth and bounded by Lemma 2.1. The uniqueness and regularity results for h^w follow from an appropriate adaptation of Theorem 4.1 in Pham [32], which utilizes that (2.32), like (2.30) for ϕ, is the HJB equation of a quadratic cost control problem. The parity property (2.33) follows from the definition of the indifference prices and the properties of the value functions u^w and u^b. □

The indifference price equation (2.32) indicates that a new measure, defined below, emerges from the utility-based valuation.

Definition 2.7. *We define* $\mathcal{Q}$ *by*

$$\frac{d\mathcal{Q}}{d\mathbb{P}} = \exp\left(- \int_0^T \frac{\mu}{\sigma(Y_s,s)}\, dW_s^1 + \int_0^T L(Y_s,s)\, dW_s^2 \right.$$
$$\left. - \frac{1}{2}\int_0^T \left(\frac{\mu^2}{\sigma(Y_s,s)^2} + L(Y_s,s)^2 \right) ds \right).$$

In the language of stochastic volatility models, the function $-L$ is a particular market price of volatility risk (and $\mathcal{Q}$ a particular equivalent martingale measure), as described in section 4.1.1. In fact, $\mathcal{Q}$ is the minimal relative entropy martingale measure, as we discuss in section 2.1.

It is worth observing that the price equation (2.32) does not have a zeroth order term or drift terms in S. It does not have a nonlinear term involving h_S either. This is an immediate consequence of the assumptions of zero interest rate and that the stock is tradeable. We also observe that the only place where the risk-aversion coefficient γ appears is in front of the non-linear term that directly reflects market incompleteness. The latter has also a fixed sign with respect to γ which, in turn, yields the following intuitive result.

Theorem 2.8. *The writer's (resp., buyer's) indifference price is nondecreasing (resp., nonincreasing) with respect to the risk-aversion parameter* γ. *As* $\gamma \to 0$, *the writer's and buyer's indifference prices satisfy*

$$\lim_{\gamma \downarrow 0} h^{w,b}(S,y,t) = \mathbb{E}_{\mathcal{Q}}(g(S_T,Y_T) \mid S_t = S, Y_t = y), \tag{2.36}$$

where the measure $\mathcal{Q}$ *is defined above.*

Proof. We denote by h^{γ_1} and h^{γ_2} the writer's indifference prices corresponding to risk-aversion coefficients γ_1 and γ_2 with $\gamma_1 < \gamma_2$. Straightforward calculations show

that h^{γ_1} is a subsolution of the indifference pricing equation that h^{γ_2} satisfies and that $h^{\gamma_1}(S,y,T) = h^{\gamma_2}(S,y,T)$. Using classical comparison results for (2.32), we conclude.

We observe that as $\gamma \to 0$, the indifference pricing equation (2.32) formally converges to the linear equation

$$h^0_t + \mathcal{L}^{(S,y)} h^0 + \rho' a(y,t) L(y,t) h^0_y = 0 \tag{2.37}$$

with terminal condition $h^0(S,y,T) = g(S,y)$. Under Assumption 1, the latter has a unique smooth (and thus viscosity) solution given by the Feynman–Kac formula

$$h^0(S,y,t) = \mathbb{E}_{\mathcal{Q}}(g(S_T, Y_T) \mid S_t = S, Y_t = y). \tag{2.38}$$

The stability properties of viscosity solutions (see Lions [29, Proposition I.3]) yield that $\{h^\gamma(S,y,t)\}$ converges, along subsequences, to the viscosity solution of (2.37) and, by uniqueness, we conclude.

The analogous result for the buyer's price follows from similar calculations. □

Expressions such as (2.38) have also been obtained in other utility-based pricing approaches [9, 25, 24]. It is well known that the indifference price (buyer's or writer's) of $\alpha > 0$ derivative contracts with bounded payoff g, written $h(\alpha;\gamma)$ as a function of the quantity and risk-aversion parameter, satisfies

$$h(\alpha;\gamma) = \alpha h(1;\alpha\gamma),$$

as is clear in the current context from the PDEs (2.32) and (2.34) by replacing g by αg in the terminal condition and making the change of variable $h = \alpha h'$. Therefore, taking the limit of zero risk-aversion is analogous to taking the limit of the price per unit $h(\alpha;\gamma)/\alpha$ as α goes to zero (with $\gamma > 0$ fixed). This is how the "fair" price is defined in [9], and the measure $\mathcal{Q}$ that arises in its characterization is labeled the neutral pricing measure in [24]. In the next section, we also point out that $\mathcal{Q}$ is in fact the minimal relative entropy measure.

2.1. Interpretation via relative entropy penalization. One way to interpret the utility-based valuation mechanism is in terms of relative entropy penalization. This is a specific example of the well-known connection between exponential utility and entropy as discussed, for example, in [12, 33].

Recall that $\mathcal{Q}$ denotes the probability measure under which the dynamics of (S,Y) are

$$\begin{aligned} dS_s &= \sigma(Y_s,s) S_s \, dW^{\mathcal{Q}(1)}_s, \\ dY_s &= \left(b(Y_s,s) - \rho \frac{\mu}{\sigma(Y_s,s)} a(Y_s,s) + \rho' a(Y_s,s) L(Y_s,s) \right) ds \\ &\quad + a(Y_s,s) \left(\rho \, dW^{\mathcal{Q}(1)}_s + \rho' dW^{\mathcal{Q}(2)}_s \right), \end{aligned} \tag{2.39}$$

where $W^{\mathcal{Q}(1)}_s = W^1_s + \int_0^s \frac{\mu}{\sigma(Y_u,u)} \, du$ and $W^{\mathcal{Q}(2)}_s = W^2_s - \int_0^s L(Y_u,u) \, du$ are independent $\mathcal{Q}$-Brownian motions. Note that $\mathcal{Q}$ is already a "risk-neutral" martingale measure because S is a $\mathcal{Q}$-martingale.

Then, let $\mathbb{P}^{(\lambda)}$ be any *equivalent local martingale measure*, which, in this context, is parameterized by an adapted process, λ, say, with $\int_0^T \lambda_s^2 \, ds < \infty$ a.s., such that

$$\frac{d\mathbb{P}^{(\lambda)}}{d\mathcal{Q}} = \exp\left(- \int_0^T \lambda_s \, dW^{\mathcal{Q}(2)}_s - \frac{1}{2} \int_0^T \lambda_s^2 \, ds \right).$$

That is, defining $W_s^{\lambda(2)} = W_s^{\mathcal{Q}(2)} + \int_0^s \lambda_u\, du$, $(W^{\mathcal{Q}(1)}, W^{\lambda(2)})$ are independent Brownian motions under $\mathbb{P}^{(\lambda)}$, and the dynamics of (S, Y) are described by (2.39) and

$$dY_s = \left(b(Y_s, s) - \rho \frac{\mu}{\sigma(Y_s, s)} a(Y_s, s) + \rho' a(Y_s, s)(L(Y_s, s) - \lambda_s) \right) ds \\ + a(Y_s, s)\,(\rho\, dW_s^{\mathcal{Q}(1)} + \rho' dW_s^{\lambda(2)}).$$

We can think of $\mathcal{Q}$ as a *prior* risk-neutral measure, and we define the relative entropy $H_t(\mathbb{P}^{(\lambda)} \mid \mathcal{Q})$ between the conditional laws on the process $\{(S_s, Y_s), t \le s \le T\}$ starting at the same point (S, y) at time t as follows. First, let (ξ_s) denote the Radon–Nikodym process

$$\xi_s = \mathbb{E}_{\mathcal{Q}} \left(\frac{d\mathbb{P}^{(\lambda)}}{d\mathcal{Q}} \mid \mathcal{F}_s \right).$$

We then define

$$H_t(\mathbb{P}^{(\lambda)} \mid \mathcal{Q}) = \mathbb{E}_{\mathbb{P}^{(\lambda)}} \left(\ln(\xi_T/\xi_t) \mid \mathcal{F}_t \right).$$

By direct calculation, this is a quadratic penalization on the "additional" volatility risk premium λ:

$$H_t(\mathbb{P}^{(\lambda)} \mid \mathcal{Q}) = \frac{1}{2} \mathbb{E}_{\mathbb{P}^{(\lambda)}} \left(\int_t^T \lambda_s^2\, ds \mid \mathcal{F}_t \right). \tag{2.40}$$

We denote by $\mathcal{M}_f$ the set of λ with

$$\mathbb{E}_{\mathbb{P}^{(\lambda)}} \left(\int_0^T \lambda_s^2\, ds \right) < \infty,$$

which guarantees finiteness of the relative entropies $H_t(\mathbb{P}^{(\lambda)} \mid \mathcal{Q})$.

Therefore, we can interpret the writer's indifference pricing mechanism as choosing a measure which tries to maximize the derivative's expected payout but is constrained from deviating too far from the prior in terms of relative entropy:

$$h^w = \sup_{\lambda \in \mathcal{M}_f} \left[\mathbb{E}_{\mathbb{P}^{(\lambda)}} \left(g(S_T, Y_T) \mid \mathcal{F}_t \right) - \frac{1}{\gamma} H_t(\mathbb{P}^{(\lambda)} \mid \mathcal{Q}) \right]. \tag{2.41}$$

This is because the HJB equation associated with this stochastic control problem is (2.32), as follows from using the formula (2.40). Notice that the upshot of the utility mechanism is to identify the prior $\mathcal{Q}$ which does not depend on the risk-aversion γ or the claim g being priced. The relative entropy arises naturally as the dual of the exponential utility, and γ^{-1} weights the penalty term.

In [12], the writer's indifference price (at time $t = 0$) is characterized as

$$h^w = \sup_{Q \in P_f} \left[\mathbb{E}_Q(g(S_T, Y_T)) - \frac{1}{\gamma} H_0(Q \mid \mathbb{P}) \right] - \sup_{Q \in P_f} \left[-\frac{1}{\gamma} H_0(Q \mid \mathbb{P}) \right] \tag{2.42}$$

(their equation (5.6)) under quite general conditions. The set P_f consists of measures Q that are absolutely continuous with respect to $\mathbb{P}$, such that the wealth process X is a $(Q, \mathcal{F})$-local martingale, and $H_0(Q \mid \mathbb{P}) < \infty$. In (2.42), the indifference price

is given as the difference between the solutions of two optimization problems, with $\mathbb{P}$ as the prior measure. Our expression (2.41) gives the indifference price under our diffusion stochastic volatility models as the solution of a single optimization problem with prior (risk-neutral) measure $\mathcal{Q}$ (which arises from the solution of the Merton problem).

In fact, it is easy to show from the associated HJB equations that $\mathcal{Q}$ is the minimal relative entropy martingale measure (see Fritelli [20]) solution of

$$\sup_{Q \in P_f} \left(-H_0(Q \mid \mathbb{P})\right)$$

and that

$$H_0(\mathcal{Q} \mid \mathbb{P}) = -\frac{1}{1-\rho^2} \ln f \mid_{t=0},$$
$$\sup_{Q \in P_f} \left[\mathbb{E}_Q(g(S_T, Y_T)) - \frac{1}{\gamma} H_0(Q \mid \mathbb{P})\right] = \frac{1}{\gamma} \ln G \mid_{t=0},$$

which connects (at time $t = 0$) our expression (2.35) with (2.42), which is taken from [12].

Relative entropy minimization has been extensively used for calibration from market data, with additional constraints that some benchmark derivative contracts are priced exactly [2, 4]. The prior measure $\mathcal{Q}$ will also emerge later in section 3.1 in obtaining bounds for the indifference prices.

3. Indifference price spreads. The indifference pricing equations (2.32) and (2.34) do not in general have explicit solutions. Given that risk aversion is taken into account in the utility-based valuation, one would naturally expect to recover indifference prices in terms of the so-called certainty equivalent pricing rule. This is in fact the classical risk-based pricing device used in the de facto incomplete insurance market (see, for example, Bowers et al. [3]). However, as simple calculations show, indifference prices do not correspond to straightforward generalizations of certainty equivalents given that they result from an interplay between dynamic optimization among investment opportunities and risk monitoring. We note that classical arbitrage-free financial markets use a risk-neutral measure and incomplete insurance markets use the historical one.

In what follows we aim at addressing some of the above issues by looking at price bounds. We derive bounds on the indifference prices that involve characteristics of linear and nonlinear prices, namely, expected payoffs, certainty equivalents, and related pricing measures.

PROPOSITION 3.1. *Let $\widetilde{\mathbb{P}}$ be the minimal martingale measure described in Definition* 2.3*, and define*

$$R(y,t) = \frac{1}{2\gamma} \left(\frac{\mu}{\sigma(y,t)}\right)^2,$$

with $\mu/\sigma(y,t)$ being the (time-varying) Sharpe ratio of the traded stock, and

$$\zeta(S,y,t) = \frac{1}{\gamma(1-\rho^2)} \ln \mathbb{E}_{\widetilde{\mathbb{P}}} \left(e^{-\gamma(1-\rho^2)\int_t^T R(Y_s,s)\,ds} \mid S_t = S,\, Y_t = y\right).$$

(i) *The writer's indifference price h^w satisfies*

$$h^w(S,y,t) \le \frac{1}{\gamma}\ln \mathbb{E}_{\widetilde{\mathbb{P}}}\left(e^{\gamma\left(g(S_T,Y_T)-\int_t^T R(Y_s,s)\,ds\right)} \mid S_t = S, Y_t = y\right) - \zeta(S,y,t), \tag{3.1}$$

$$h^w(S,y,t) \ge \mathbb{E}_{\widetilde{P}}\left(g(S_T,Y_T) - \int_t^T R(Y_s,s)\,ds \mid S_t = S,\, Y_t = y\right) - \zeta(S,y,t). \tag{3.2}$$

(ii) *The buyer's indifference price h^b satisfies*

$$h^b(S,y,t) \le \mathbb{E}_{\widetilde{\mathbb{P}}}\left(g(S_T,Y_T) + \int_t^T R(Y_s,s)\,ds \mid S_t = S, Y_t = y\right) + \zeta(S,y,t),$$

$$h^b(S,y,t) \ge -\frac{1}{\gamma}\ln \mathbb{E}_{\widetilde{\mathbb{P}}}\left(e^{-\gamma\left(g(S_T,Y_T)+\int_t^T R(Y_s,s)\,ds\right)} \mid S_t = S, Y_t = y\right) + \zeta(S,y,t).$$

Proof. We first present the arguments for the derivation of the lower bound (3.2). We recall that

$$h(S,y,t) = \frac{1}{\gamma}\ln\frac{G(S,y,t)}{V(y,t)} = \frac{1}{\gamma}\ln\frac{G(S,y,t)}{f(y,t)^{1/(1-\rho^2)}} \tag{3.3}$$

and that G solves (2.29). Because $\rho^2 \le 1$ and $G > 0$, we easily conclude that G is a supersolution of

$$\bar{G}_t + \mathcal{L}^{(S,y)}\bar{G} = \frac{1}{2}\frac{\mu^2}{\sigma(y,t)^2}\bar{G} + \frac{1}{2}a^2(y,t)\frac{\bar{G}_y^2}{\bar{G}} + \rho\sigma(y,t)a(y,t)S\frac{\bar{G}_S\bar{G}_y}{\bar{G}} + \frac{1}{2}\sigma^2(y,t)S^2\frac{\bar{G}_S^2}{\bar{G}} \tag{3.4}$$

and, thus,

$$G(S,y,t) \ge \bar{G}(S,y,t). \tag{3.5}$$

The solution $\bar{G}$ to (3.4) can be derived via an exponential transformation $\bar{G} = e^{\bar{\phi}}$, with $\bar{\phi}$ solving

$$\bar{\phi}_t + \mathcal{L}^{(S,y)}\bar{\phi} = \frac{\mu^2}{2\sigma^2(y,t)}, \qquad \bar{\phi}(S,y,T) = \gamma g(S,y). \tag{3.6}$$

Under the boundedness assumptions on the coefficients and payoff, (3.6) has a unique classical solution, and $\bar{\phi}$ has the probabilistic representation

$$\bar{\phi}(S,y,t) = \gamma\mathbb{E}_{\widetilde{P}}\left(g(S_T,Y_T) - \int_t^T R(Y_s,s)\,ds \mid S_t = S, Y_t = y\right). \tag{3.7}$$

Combining $G \ge e^{\bar{\phi}}$ with (3.3) and (2.26) gives the lower bound (3.2) for the writer's indifference price h^w.

Following similar arguments, we can derive the upper bound for the indifference price. In fact, from (2.19), $\mathcal{M}(G_S, G_y, G) \ge 0$, so (2.29) yields

$$G_t + \mathcal{L}^{(S,y)}G \ge \frac{\mu^2}{2\sigma^2(y,t)}G.$$

Therefore, G is a subsolution to

$$\hat{G}_t + \mathcal{L}^{(S,y)}\hat{G} = \frac{\mu^2}{2\sigma^2(y,t)}\hat{G}, \qquad \hat{G}(S,y,T) = e^{\gamma g(S,y)}. \tag{3.8}$$

This in turn yields $G(S,y,t) \leq \hat{G}(S,y,t)$, and, in view of the probabilistic representation of the solution of (3.8), gives

$$G(S,y,t) \leq \mathbb{E}^{\widetilde{\mathbb{P}}}_{\mathbb{P}}\left(e^{\gamma\left(g(S_T,Y_T)-\int_t^T R(Y_s,s)\,ds\right)} \mid S_t = S, Y_t = y\right).$$

The upper bound (3.1) follows easily. Part(ii) can be derived from the parity formula (2.33). □

3.1. Alternative bounds. We continue with the derivation of alternative reservation prices. We stress that the bounds derived below have rather natural and desirable properties. The lower bound is given by an *arbitrage-free–type* price of the payoff g. This price corresponds to the limiting case $\gamma \to 0$ described in Theorem 2.8. The upper bound is given in terms of a *certainty-equivalent–type* price of the payoff g. It corresponds to what the writer would charge under a pricing device based entirely on static certainty equivalent valuation without taking into account dynamic rebalancing and optimal investments. It is important to observe that all bounds are expressed in terms of the same measure $\mathcal{Q}$.

THEOREM 3.2. *Let $\mathcal{Q}$ be the measure introduced in Definition* 2.7.

(i) *The writer's indifference price satisfies*

$$\begin{aligned}\mathbb{E}_{\mathcal{Q}}\Big(g(S_T,Y_T) \mid S_t = S, Y_t = y\Big) &\leq h^w(S,y,t)\\ &\leq \frac{1}{\gamma}\ln \mathbb{E}_{\mathcal{Q}}\Big(e^{\gamma g(S_T,Y_T)} \mid S_t = S, Y_t = y\Big).\end{aligned} \tag{3.9}$$

(ii) *The buyer's indifference price satisfies*

$$\begin{aligned}-\frac{1}{\gamma}\ln \mathbb{E}_{\mathcal{Q}}\Big(e^{-\gamma g(S_T,Y_T)} \mid S_t = S, Y_t = y\Big) &\leq h^b(S,y,t)\\ &\leq \mathbb{E}_{\mathcal{Q}}\Big(g(S_T,Y_T) \mid S_t = S, Y_t = y\Big).\end{aligned}$$

Proof. We first construct appropriate sub- and supersolutions of (2.29). In particular, we look for sub- and supersolutions of the separable form $M(y,t)N(S,y,t)$. Inserting the above function in (2.29) yields

$$\begin{cases} N\left(M_t + \mathcal{L}^{(y)}M - \frac{1}{2}\rho^2 a^2(y,t)\frac{M_y^2}{M} - \frac{\mu^2}{2\sigma^2(y,t)}M\right)\\ \quad + M\left(N_t + \mathcal{L}^{(S,y)}N + (1-\rho^2)a^2(y,t)\frac{M_y}{M}N_y - \mathcal{M}(N_S,N_y,N)\right) = 0, \end{cases}$$

where $\mathcal{M}$ was defined in (2.19), and with $M(y,T)N(S,y,T) = e^{\gamma g(S,y)}$. Next, we choose M and N to solve, respectively,

$$M_t + \mathcal{L}^{(y)}M = \frac{\mu^2}{2\sigma^2(y,t)}M + \frac{1}{2}\rho^2 a^2(y,t)\frac{M_y^2}{M}, \tag{3.10}$$

with $M(y,T)=1$, and

$$N_t+\mathcal{L}^{(S,y)}N+(1-\rho^2)a^2(y,t)\frac{M_y}{M}N_y=\mathcal{M}(N_S,N_y,N), \tag{3.11}$$

with $N(S,y,T)=e^{\gamma g(S,y)}$. We observe that M and F solve the same equations, (3.10) and (2.23), and satisfy the same terminal condition. By uniqueness, we deduce that $M\equiv F$ or, equivalently,

$$M(y,t)=f(y,t)^{1/(1-\rho^2)}, \tag{3.12}$$

with f solving (2.21). Therefore, we can write the solution of (2.29) as $G(S,y,t)=f(y,t)^{1/(1-\rho^2)}N(S,y,t)$, with N solving (3.11). It is worth observing that N solves the quasilinear equation (3.11) that is similar to (2.29) but with two modifications; namely, (3.11) does not have a potential term, and, also, its first derivative coefficient contains the extra term $(1-\rho^2)a^2(y,t)\frac{M_y(y,t)}{M(y,t)}$.

Because of (3.12), we have

$$\frac{M_y(y,t)}{M(y,t)}=\frac{1}{1-\rho^2}\frac{f_y(y,t)}{f(y,t)}\ , \tag{3.13}$$

which is smooth and bounded as observed in Lemma 2.1. Therefore, (3.11) can be written as

$$\begin{cases} N_t+\mathcal{L}^{(S,y)}N+\rho' a(y,t)L(y,t)N_y=\mathcal{M}(N_S,N_y,N),\\ N(S,y,T)=e^{\gamma g(S,y)}, \end{cases} \tag{3.14}$$

where $L(y,t)$ was introduced in (2.31). Observing that $\mathcal{M}(N_S,N_y,N)\geq 0$ and that $\rho^2\leq 1$, by arguments similar to the ones used in the derivation of the lower and upper bounds, (3.2) and (3.1), respectively, we readily deduce that

$$\underline{N}(S,y,t)\leq N(S,y,t)\leq \bar{N}(S,y,t), \tag{3.15}$$

where $\underline{N}$ and $\bar{N}$ solve, respectively,

$$\bar{N}_t+\mathcal{L}^{(S,y)}\bar{N}+\rho' a(y,t)L(y,t)\bar{N}_y=0, \tag{3.16}$$

with $\bar{N}(S,y,T)=e^{\gamma g(S,y)}$, and

$$\begin{aligned}\underline{N}_t+\mathcal{L}^{(S,y)}\underline{N}+\rho' a(y,t)L(y,t)\underline{N}_y=\frac{1}{2}a^2(y,t)\frac{\underline{N}_y^2}{\underline{N}}+\rho a(y,t)\sigma(y,t)S\frac{\underline{N}_S\underline{N}_y}{\underline{N}}\\ +\frac{1}{2}\sigma^2(y,t)S^2\underline{N}_{SS},\end{aligned} \tag{3.17}$$

with $\underline{N}(S,y,T)=e^{\gamma g(S,y)}$. The linear equation (3.16) has a unique classical solution under Assumption 1, and the Feynman–Kac formula yields

$$\bar{N}(S,y,t)=\mathbb{E}_{\mathcal{Q}}\Big(e^{\gamma g(S_T,Y_T)}\mid S_t=S,Y_t=y\Big), \tag{3.18}$$

with $\mathcal{Q}$ given in Definition 2.7. Using an exponential transformation $\underline{N}(S,y,t)=e^{k(S,y,t)}$ gives that k must solve

$$k_t+\mathcal{L}^{(S,y)}k+\rho' a(y,t)L(y,t)k_y=0,$$

with $k(S,y,T) = \gamma g(S,y)$, which has a unique classical solution under our assumptions. The same then follows for (3.17). The probabilistic representation for k is

$$k(S,y,t) = \mathbb{E}_{\mathcal{Q}}\Big(\gamma g(S_T, Y_T) \mid S_t = S, Y_t = y\Big).$$

Using (3.12) and (3.3), we deduce

$$\frac{1}{\gamma}\ln \underline{N}(S,y,t) \le h^w(S,y,t) \le \frac{1}{\gamma}\ln \bar{N}(S,y,t),$$

which yields the desired upper and lower bounds (3.9). □

From these bounds, we easily obtain the following bounds on the *price spread*.

PROPOSITION 3.3. *The price spread $h^w - h^b$ is bounded by*

$$0 \le h^w - h^b \le \frac{1}{\gamma}\ln\left[\mathbb{E}_{\mathcal{Q}}\Big(e^{-\gamma g(S_T,Y_T)} \mid S_t = S, Y_t = y\Big)\mathbb{E}_{\mathcal{Q}}\Big(e^{\gamma g(S_T,Y_T)} \mid S_t = S, Y_t = y\Big)\right].$$

4. Fast mean-reverting stochastic volatility. We now study the indifference price using asymptotic approximations. In this section, we assume the European contract is a claim on S_T only and not on Y_T. That is, $g = g(S_T)$, as is usually the case.

4.1. Stochastic volatility framework. For clarity of exposition, we take the volatility-driving process (Y_t) to be an Ornstein–Uhlenbeck (OU) process, namely,

$$dY_t = \alpha(m - Y_t)\,dt + \beta\,(\rho\,dW_t^1 + \rho' dW_t^2),$$

where α is the rate of mean-reversion, m the long-run mean, and β the volatility of the volatility factor Y, which we shall call the "v-vol." In terms of the previous notation, we have $b(y) = \alpha(m-y)$ and $a(y) = \beta$. The process admits a unique invariant distribution, $\mathcal{N}(m,\nu^2)$, where $\nu^2 = \beta^2/(2\alpha)$. We also define at this stage the density of this distribution $\Phi(y)$ and the average $\langle\cdot\rangle$ with respect to this density:

$$\langle\chi\rangle = \int \chi\Phi.$$

In particular, we denote by $\bar{\sigma}$ the long-run (root-mean-square) volatility

$$\bar{\sigma} = \sqrt{\langle\sigma^2\rangle}. \tag{4.1}$$

The utility-based pricing equation (2.32) describes the indifference price h as the solution of a quasilinear differential equation depending on the risk-aversion parameter γ, the level of the volatility driving process y, and the parameters of this model α, β, m, ρ as well as the function $\sigma(\cdot)$. Given a fully specified model and parameters estimated from data, we could compute the utility price by numerically discretizing (2.32). Another approach is to use asymptotic approximations that are exact in some limit in which the problem simplifies. These can be used in certain parameter ranges which may be valid in some markets. They also give a deeper analytical understanding of the pricing mechanism and its relationship to modeling assumptions.

The limit we focus on here is fast mean-reversion of the volatility process, meaning that α is large. We write

$$\alpha = 1/\varepsilon, \qquad 0 < \varepsilon << 1,$$

and we are interested in the limit $\varepsilon \downarrow 0$ with the variance of the invariant distribution ν^2 fixed. This implies the scaling $\beta = \sqrt{2}\,\nu/\sqrt{\varepsilon}$. The choice of scaling is natural, because it allows us to pick up the effects of both mean-reversion and v-vol in the correction (first order) term of the approximation (4.10) below.

Evidence of a rapidly mean-reverting volatility factor in the S&P 500 is presented in the empirical study [18] of high-frequency data. Another recent empirical study [1] has found evidence of a fast volatility scale in exchange rate dynamics. Chernov et al. [5] propose and give evidence from data for two-factor stochastic volatility models in which one factor mean-reverts on a short time-scale. For present purposes, the method of this section can be regarded as yielding an approximation whose validity will depend on specific market conditions, in particular over time horizons when other slower factors can be considered effectively constant. The extension to incorporate slower scales using mixed singular and regular perturbation techniques is the subject of future investigation.

This method was previously used for *no-arbitrage* derivative pricing and hedging problems in Fouque, Papanicolaou, and Sircar [17]. The arguments were extended for stochastic control problems in [23]. We summarize the main findings from the former for *no-arbitrage* pricing and hedging European claims in order to compare the analogous results for the indifference pricing mechanism.

4.1.1. No-arbitrage pricing of European claims. Let $P(S, y, t)$ be the pricing function for a European claim with payoff $g(S_T)$. By *no-arbitrage* arguments, this price is given by

$$P(S, y, t) = \mathbb{E}^{(\lambda_m)}\{g(S_T) \mid S_t = S, Y_t = y\}, \tag{4.2}$$

where the expectation is taken with respect to the equivalent martingale measure $\mathbb{P}^{(\lambda_m)}$, and λ_m is the market price of volatility risk. We assume that $\lambda_m = \lambda_m(Y_t)$ in that it is a bounded function of Y_t only and therefore that (S, Y) is also a Markov process under $\mathbb{P}^{(\lambda_m)}$, which justifies the notation in (4.2). This premium is implicit in the prices of liquidly traded options or the market-set implied volatility skew. Under the measure $\mathbb{P}^{(\lambda_m)}$, the dynamics of (S, Y) can be written

$$\begin{aligned} dS_t &= \sigma(Y_t) S_t \, dW_t^\star, \\ dY_t &= \left[\frac{1}{\varepsilon}(m - Y_t) - \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}} \left(\rho \frac{\mu}{\sigma(Y_t)} - \rho' \lambda_m(Y_t) \right) \right] dt + \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}} \left(\rho \, dW_t^\star + \rho' dZ_t^\star \right), \end{aligned}$$

where $(W_t^\star)$ and $(Z_t^\star)$ are independent $\mathbb{P}^{(\lambda_m)}$-Brownian motions.

We make the following assumption.

ASSUMPTION 2. *The market price of volatility risk function $\lambda_m(\cdot)$ is smooth and bounded.*

The analysis of [17, Chapter 5] leads to the following approximation for P in the limit of fast mean-reversion:

$$P(S, y, t) \approx P^{(0)}(S, t) + \widetilde{P^{(1)}}(S, t), \tag{4.3}$$

where $P^{(0)}(S, t)$ is the Black–Scholes pricing function for the claim using the long-run average volatility parameter $\bar{\sigma}$ which is related to the original stochastic volatility model through (4.1). In other words, $P^{(0)}(S, t)$ solves the Black–Scholes PDE problem

$$\begin{aligned} \mathcal{L}_{BS}(\bar{\sigma}) P^{(0)} &= 0; \qquad t < T, \\ P^{(0)}(S, T) &= g(S), \end{aligned} \tag{4.4}$$

where

$$\mathcal{L}_{BS}(\bar{\sigma}) = \frac{\partial}{\partial t} + \frac{1}{2}\bar{\sigma}^2 S^2 \frac{\partial^2}{\partial S^2}, \tag{4.5}$$

the Black–Scholes differential operator at volatility level $\bar{\sigma}$. Under Assumptions 1 and 2, $P^{(0)}$ is smooth and bounded with bounded derivatives.

The correction term $\widetilde{P^{(1)}}$ accounting for stochastic volatility effects is given by

$$\widetilde{P^{(1)}}(S,t) = -(T-t)\left(V_2 S^2 P^{(0)}_{SS} + V_3 S^3 P^{(0)}_{SSS}\right) \tag{4.6}$$

for some constants V_2 and V_3 related to the original parameters and the functions σ and λ_m by formulas given below. In the case of smooth payoff g, we have the following convergence result, shown in [17]. We use the order notation

$$f(\varepsilon) = \mathcal{O}(g(\varepsilon)), \qquad \text{as } \varepsilon \downarrow 0 \qquad \Rightarrow \qquad \lim_{\varepsilon \downarrow 0} \frac{f(\varepsilon)}{g(\varepsilon)} = c,$$

for some constant c independent of ε, and $f(\varepsilon) = o(g(\varepsilon))$ if $c = 0$.

PROPOSITION 4.1. *Under Assumptions* 1 *and* 2*, for a fixed point* (S, y, t)*,*

$$|P(S,y,t) - (P^{(0)}(S,t) + \widetilde{P^{(1)}}(S,t))| = \mathcal{O}(\varepsilon). \tag{4.7}$$

For the case of call and put options when the payoff is only $\mathcal{C}^0$, the following convergence result is proved in [19] using a regularization technique.

PROPOSITION 4.2. *Under Assumptions* 1 *and* 2*, for a fixed point* (S, y, t)*,*

$$|P(S,y,t) - (P^{(0)}(S,t) + \widetilde{P^{(1)}}(S,t))| = o(\varepsilon|\log\varepsilon|^{1+p})$$

for any $p > 0$*.*

In Theorem 4.3 below, we prove the analogue of (4.7) for smooth and bounded g and the indifference pricing mechanism.

We note the following points about the approximation (4.3).

- To this level, namely, zeroth plus first order of approximation, the price is insensitive to the present level of the stochastic volatility process $\sigma(Y_t)$.
- The group parameters V_2 and V_3 are related to the original model as follows:

$$V_2 = \frac{\nu}{\sqrt{2\alpha}}\left(2\rho\langle\sigma\psi_1'\rangle - \left\langle\left(\frac{\mu\rho}{\sigma} + \rho'\lambda_m\right)\psi_1'\right\rangle\right), \tag{4.8}$$

$$V_3 = \frac{\rho\nu}{\sqrt{2\alpha}}\langle\sigma\psi_1'\rangle, \tag{4.9}$$

  where $\nu^2 = \beta^2/(2\alpha)$ and $\psi_1(y)$ is a solution of the Poisson equation (4.23) below. In practice, these relations are not used and V_2 and V_3 are estimated directly from the market-implied volatility skew and then can be used for pricing American and exotic claims to the same order of approximation.
- The formulas (4.8) and (4.9) show that V_2 and V_3 are of order $1/\sqrt{\alpha}$ and so are small under the assumption of fast mean-reversion. Moreover, V_3 is zero when $\rho = 0$ and in the case of nonzero correlation, the third-derivative term describes the leverage effect. In the case of equities, ρ is typically negative and returns distributions are asymmetric with a fatter left tail. The second-derivative term contains effects due to the extra kurtosis of stochastic volatility models over geometric Brownian motion, and the market price of volatility risk λ_m.

- Finally, the approximation is *robust* in the sense that it does not depend on specification of σ or λ_m within the class of functions described in Assumptions 1 and 2.

4.2. Approximation of indifference prices and interpretation. The main result of this section is the following theorem.

THEOREM 4.3. *Let h denote either the writer's or the buyer's indifference price, defined in* (2.10) *and* (2.11). *Under Assumption* 1, *for a fixed point* (S, y, t),

$$|h(S,y,t) - (P^{(0)}(S,t) - (T-t)(V_3 S^3 P^{(0)}_{SSS} + V_2^{(0)} S^2 P^{(0)}_{SS}))| = \mathcal{O}(\varepsilon). \tag{4.10}$$

Here, V_3 is defined in (4.9) *and $V_2^{(0)}$ denotes V_2 defined in* (4.8), *with $\lambda_m = 0$.*

Comparing with the *no-arbitrage* fast mean-reverting stochastic volatility approximation (4.6), we see from (4.8) that to this order of approximation, *the (writer's or buyer's) utility indifference price is exactly the no-arbitrage price in which there is zero risk premium from the second Brownian motion ($\lambda_m(\cdot) \equiv 0$). In particular, the risk-aversion coefficient γ does not appear in these first two terms of the approximation.*

The intuition for this is best understood from the relative entropy formulation of the indifference pricing mechanism discussed in section 2.1. Given a prior risk-neutral measure $\mathcal{Q}$ under which the volatility is *fast mean-reverting*, the utility pricer does not use his freedom to deviate from this belief up to the level of accuracy we have computed. In particular, he would have to choose a very large volatility risk premium λ in (2.41) for the asymptotics to lead to a different approximation in the first two terms, and this is penalized heavily by the entropy.

4.3. Expansions for indifference prices. To produce an asymptotic expansion for the indifference price, one may either analyze the indifference price equation (2.32) directly or, alternatively, approximate the value functions V and u involved in the pricing mechanism and, subsequently, approximate h via (2.10). We choose to proceed in the latter way because it also gives, as an intermediate output, useful results for the optimization problems that are interconnected with the utility-based prices.

We recall that the value functions u and V of the writer and the plain investor, respectively, can be written $u(x,S,y,t) = -e^{-\gamma x} G(S,y,t)$, with G solving (2.29), and $V(x,y,t) = -e^{-\gamma x} F(y,t)$, with F solving (2.23), and that the indifference price is given by

$$h(S,y,t) = \frac{1}{\gamma} \ln \frac{G(S,y,t)}{F(y,t)}. \tag{4.11}$$

It is convenient to work with the logarithmic transformations of G and F. To this end, we set

$$G = e^{\phi}, \qquad F = e^{\psi}, \tag{4.12}$$

where $\phi(S,y,t)$ solves (2.30) and $\psi(y,t)$ solves

$$\psi_t + \mathcal{L}^{(y)}\psi + \frac{1}{2} a(y)^2 (1-\rho^2) \psi_y^2 - \frac{\mu^2}{2\sigma(y)^2} = 0, \tag{4.13}$$

with $\psi(y,T) = 0$. In the latter case, we could as easily work with f, which solves the linear equation (2.21), but since we will need the expansion for ϕ, it is simpler to

construct that and then obtain the expansion for ψ by setting $g \equiv 0$ and removing the S dependence.

The first two terms of the asymptotic expansions of ϕ and ψ in powers of $\sqrt{\varepsilon}$ are summarized in the following proposition, which is proven in the following sections.

PROPOSITION 4.4. *Under Assumption* 1*, for a fixed point* (S, y, t) *the following hold.*

(i) *The first two terms of the expansion for* ϕ*, solution of* (2.30)*, lead to the approximation*

$$|\phi(S,y,t) - (\phi^{(0)}(S,t) + \widetilde{\phi^{(1)}}(S,t))| = \mathcal{O}(\varepsilon), \tag{4.14}$$

where

$$\phi^{(0)}(S,t) = \gamma P^{(0)}(S,t) - \frac{\mu^2}{2\sigma_\star^2}(T-t), \tag{4.15}$$

$$\widetilde{\phi^{(1)}}(S,t) = -\gamma(T-t)\left[V_3 S^3 P^{(0)}_{SSS}(S,t) + V_2^{(0)} S^2 P^{(0)}_{SS}(S,t) + \frac{\mu^3 C_4}{\gamma}\right]. \tag{4.16}$$

Here, V_3 *is defined in* (4.9)*,* $V_2^{(0)}$ *denotes* V_2 *defined in* (4.8)*, with* $\lambda_m = 0$*,* C_4 *is a market constant,* $C_4 = \frac{\rho\nu}{\sqrt{2\alpha}}\langle \frac{\psi_2'}{\sigma}\rangle$*, with* ψ_2 *defined below in* (4.24)*, and*

$$\bar{\sigma}^2 = \langle \sigma^2 \rangle, \qquad \frac{1}{\sigma_\star^2} = \left\langle \frac{1}{\sigma^2} \right\rangle. \tag{4.17}$$

(ii) *The first two terms of the expansion for* ψ*, solution of* (4.13)*, lead to the approximation*

$$|\psi(S,y,t) - (\psi^{(0)}(S,t) + \widetilde{\psi^{(1)}}(S,t))| = \mathcal{O}(\varepsilon), \tag{4.18}$$

where

$$\psi^{(0)}(S,t) = -\frac{\mu^2}{2\sigma_\star^2}(T-t), \qquad \widetilde{\psi^{(1)}}(S,t) = -(T-t)\mu^3 C_4.$$

Before we give the proof of Proposition 4.4, we introduce some convenient notation.

4.4. Operator notation. We write (2.30) in the compact form

$$\mathcal{L}^\varepsilon \phi + \frac{\nu^2}{\varepsilon}(1-\rho^2)\phi_y^2 = \frac{\mu^2}{2\sigma(y)^2}, \tag{4.19}$$

where we define

$$\begin{aligned}
\mathcal{L}^\varepsilon &= \frac{1}{\varepsilon}\mathcal{L}_0 + \frac{1}{\sqrt{\varepsilon}}\mathcal{L}_1 + \mathcal{L}_2,\\
\mathcal{L}_0 &= \nu^2 \frac{\partial^2}{\partial y^2} + (m-y)\frac{\partial}{\partial y},\\
\mathcal{L}_1 &= \sqrt{2}\,\rho\nu\left(\sigma(y) S \frac{\partial^2}{\partial S \partial y} - \frac{\mu}{\sigma(y)}\frac{\partial}{\partial y}\right),\\
\mathcal{L}_2 &= \frac{\partial}{\partial t} + \frac{1}{2}\sigma(y)^2 S^2 \frac{\partial^2}{\partial S^2}.
\end{aligned} \tag{4.20}$$

We notice that

1. $\mathcal{L}_0$ is the infinitesimal generator of the OU process with unit rate of mean-reversion;
2. $\mathcal{L}_1$ takes derivatives in y and so kills any function that does not depend on y; and
3. $\mathcal{L}_2 = \mathcal{L}_{BS}(\sigma(y))$, where $\mathcal{L}_{BS}(\cdot)$ is the Black–Scholes differential operator as a function of the volatility level defined in (4.5).

4.5. Proof of Proposition 4.4. We first describe an expansion of the form

$$\begin{aligned}\phi(S,y,t) = \phi^{(0)}(S,y,t) + \sqrt{\varepsilon}\phi^{(1)}(S,y,t) + \varepsilon\phi^{(2)}(S,y,t)\\ + \varepsilon^{3/2}\phi^{(2)}(S,y,t) - Z^{\varepsilon}(S,y,t),\end{aligned} \tag{4.21}$$

and write an equation for the *error term* Z^{ε}.

We define $\phi^{(0)}$ and $\sqrt{\varepsilon}\phi^{(1)} = \widetilde{\phi^{(1)}}$ by (4.15) and (4.16), respectively. In particular, $\phi^{(0)}$ and $\phi^{(1)}$ do not depend on y, and, by the smoothness assumptions on g, they are also smooth.

We define $\phi^{(2)}$ by

$$\phi^{(2)}(S,y,t) = -\frac{1}{2}\psi_1(y)S^2\phi^{(0)}_{SS} + \frac{\mu^2}{2}\psi_2(y), \tag{4.22}$$

where ψ_1 and ψ_2 are solutions of the Poisson equations

$$\mathcal{L}_0\psi_1 = \sigma(y)^2 - \bar{\sigma}^2, \tag{4.23}$$

$$\mathcal{L}_0\psi_2 = \frac{1}{\sigma(y)^2} - \frac{1}{\sigma_\star^2}. \tag{4.24}$$

The average volatilities $\bar{\sigma}$ and $\sigma_\star$ are defined in (4.17) and are finite as σ is bounded. The expressions (4.15), (4.16), and (4.22) are motivated by a formal expansion. Finally, we define $\phi^{(3)}(S,y,t)$ by

$$\phi^{(3)}(S,y,t) = \frac{\rho\nu}{\sqrt{2}}\left[\psi_3(y)(S^3\phi^{(0)}_{SSS} + 2S^2\phi^{(0)}_{SS}) - \mu\psi_4(y)S^2\phi^{(0)}_{SS} - \mu\psi_5(y)\right], \tag{4.25}$$

where ψ_3, ψ_4, and ψ_5 are solutions of the Poisson equations

$$\mathcal{L}_0\psi_3 = \sigma(y)\psi_1'(y) - \langle\sigma\psi_1'\rangle, \tag{4.26}$$

$$\mathcal{L}_0\psi_4 = \frac{\psi_1'(y)}{\sigma(y)} - \left\langle\frac{\psi_1'}{\sigma}\right\rangle, \tag{4.27}$$

$$\mathcal{L}_0\psi_5 = \frac{\psi_2'(y)}{\sigma(y)} - \left\langle\frac{\psi_2'}{\sigma}\right\rangle. \tag{4.28}$$

Here, $\phi^{(3)}$ has been chosen to be a solution of

$$\mathcal{L}_0\phi^{(3)} + \mathcal{L}_1\phi^{(2)} + \mathcal{L}_2\phi^{(1)} = 0,$$

which is a Poisson equation (in y). Its solvability condition (see [17, section 5.2.2]) is

$$\langle\mathcal{L}_2\phi^{(1)} + \mathcal{L}_1\phi^{(2)}\rangle = 0, \tag{4.29}$$

which is satisfied because that is how $\phi^{(1)}$ and $\phi^{(2)}$ were chosen.

LEMMA 4.1. *The functions $\phi^{(2)}$ and $\phi^{(3)}$ are smooth as functions of S and t and can be chosen to be at most logarithmically growing in y at infinity.*

Proof. As shown in [19, Appendix C], the boundedness assumption on σ implies that we can choose ψ_1 and ψ_2 to be at most logarithmically growing at infinity:

$$|\psi_{1,2}(y)| \leq c(1 + \ln(1 + |y|))$$

for some constant c. In particular, the derivatives $\psi'_{1,2}$ are bounded, and the right-hand sides of (4.26)–(4.28) are therefore bounded. Then we can also choose ψ_3, ψ_4, and ψ_5 to be at most logarithmically growing at infinity. Since $\phi^{(0)}(S,t)$ and $\phi^{(1)}(S,t)$ are smooth, the result follows from the explicit expressions (4.22) and (4.25). ∎

We assume hereon that $\phi^{(2)}$ and $\phi^{(3)}$ *are* chosen to be at most logarithmically growing in y at infinity.

Inserting the expansion (4.21) into the PDE (2.30), we obtain the following equation and terminal condition for Z^ε:

$$\mathcal{L}^\varepsilon Z^\varepsilon + 2\nu^2(1-\rho^2)(\phi_y^{(2)} + \sqrt{\varepsilon}\phi_y^{(3)})Z_y^\varepsilon - \frac{\nu^2}{\varepsilon}(1-\rho^2)(Z_y^\varepsilon)^2 = \varepsilon J, \tag{4.30}$$

$$Z^\varepsilon(S,y,T) = \varepsilon K(S,y). \tag{4.31}$$

In this calculation, we have used the fact that $\phi^{(0)}$, $\phi^{(1)}$, $\phi^{(2)}$, and $\phi^{(3)}$ satisfy

$$\mathcal{L}_0\phi^{(0)} + \nu^2(1-\rho^2)(\phi_y^{(0)})^2 = 0, \qquad \mathcal{L}_0\phi^{(1)} + \mathcal{L}_1\phi^{(0)} = 0,$$

$$\mathcal{L}_0\phi^{(2)} + \mathcal{L}_1\phi^{(1)} + \mathcal{L}_2\phi^{(0)} = \frac{\mu^2}{2\sigma(y)^2}, \tag{4.32}$$

as well as the solvability condition (4.29) for (4.32).

In (4.30) and (4.31), the source term J and terminal data K are given by

$$J = \mathcal{L}_1\phi^{(3)} + \mathcal{L}_2\phi^{(2)} + \sqrt{\varepsilon}\mathcal{L}_2\phi^{(3)} + \nu^2(1-\rho^2)\left(\phi_y^{(2)} + \sqrt{\varepsilon}\phi_y^{(3)}\right)^2, \tag{4.33}$$

$$K = \phi^{(2)}(S,y,T) + \sqrt{\varepsilon}\phi^{(3)}(S,y,T). \tag{4.34}$$

From Lemma 4.1, it follows that J and K are smooth and at most logarithmically growing in y at infinity. Notice that Z^ε is the unique classical solution of a quasilinear parabolic PDE problem. Defining

$$\theta(S,y,t) = 2\nu^2(1-\rho^2)\left(\phi_y^{(2)} + \sqrt{\varepsilon}\phi_y^{(3)}\right), \tag{4.35}$$

we can write (4.30) as

$$\hat{\mathcal{L}}^\varepsilon Z^\varepsilon = \varepsilon J + \frac{\nu^2}{\varepsilon}(1-\rho^2)(Z_y^\varepsilon)^2, \tag{4.36}$$

where $\hat{\mathcal{L}}^\varepsilon = \mathcal{L}^\varepsilon + \theta(S,y,t)\frac{\partial}{\partial y}$ is a linear parabolic operator. Notice that θ is bounded.

LEMMA 4.2. *Let $\bar{Z}^\varepsilon(S,y,t)$ be the unique classical solution of the linear PDE problem*

$$\begin{aligned} \hat{\mathcal{L}}^\varepsilon \bar{Z}^\varepsilon &= \varepsilon J, \\ \bar{Z}^\varepsilon(S,y,T) &= \varepsilon K(S,y). \end{aligned} \tag{4.37}$$

Then $Z^\varepsilon \leq \bar{Z}^\varepsilon$.

Proof. The result follows from the nonnegativity of the nonlinear term in (4.36) and classical comparison results for linear parabolic equations. □

LEMMA 4.3. *Define* $\underline{Z}^\varepsilon(S,y,t)$ *by* $\underline{Z}^\varepsilon = -\ln \bar{q}^\varepsilon$, *where* $\bar{q}^\varepsilon(S,y,t)$ *is the unique classical solution of the linear PDE problem*

$$\begin{aligned} \hat{\mathcal{L}}^\varepsilon \bar{q}^\varepsilon + \varepsilon J \bar{q}^\varepsilon &= 0, \\ \bar{q}^\varepsilon(S,y,T) &= e^{-\varepsilon K(S,y)}. \end{aligned} \tag{4.38}$$

Then $Z^\varepsilon \geq \underline{Z}^\varepsilon$.

Proof. We first observe that $q^\varepsilon = e^{-Z^\varepsilon}$ satisfies

$$\hat{\mathcal{L}}^\varepsilon q^\varepsilon + \varepsilon J q^\varepsilon = \frac{1}{2q^\varepsilon}\left(\frac{\rho\nu\sqrt{2}}{\sqrt{\varepsilon}} q_y^\varepsilon + \sigma(y) S q_S^\varepsilon\right)^2, \tag{4.39}$$

with terminal condition

$$q^\varepsilon(S,y,T) = e^{-\varepsilon K(S,y)}.$$

By the nonnegativity of the nonlinear term on the right-hand side of (4.39) and classical comparison results for linear parabolic equations, the result follows. □

We next need to show that the upper and lower bounds go to zero with ε.

LEMMA 4.4. *At fixed* (S,y,t),

$$\bar{Z}(S,y,t) = \mathcal{O}(\varepsilon).$$

Proof. We can write the probabilistic representation of (4.37),

$$\bar{Z}^\varepsilon(S,y,t) = \mathbb{E}^\star\left(\varepsilon K(\hat{S}_T, \hat{Y}_T) - \varepsilon \int_t^T J(\hat{S}_u, \hat{Y}_u, u)\, du \mid \hat{S}_t = S, \hat{Y}_t = y\right), \tag{4.40}$$

in terms of the processes $(\hat{S}, \hat{Y})$ defined by

$$\begin{aligned} d\hat{S} &= \sigma(\hat{Y})\hat{S}\left(\rho\, d\hat{B}^1 + \rho' d\hat{B}^2\right), \\ d\hat{Y} &= \frac{1}{\varepsilon}\left((m - \hat{Y}) - \sqrt{2\varepsilon}\frac{\rho\nu\mu}{\sigma(\hat{Y})} + \varepsilon\theta(\hat{S}, \hat{Y}, t)\right) dt + \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}}\, d\hat{B}^1, \end{aligned} \tag{4.41}$$

on some probability space $(\hat{\Omega}, \hat{\mathcal{F}}, (\hat{\mathcal{F}}_t), \hat{\mathbb{P}}^\star)$ where $\hat{B}^1$ and $\hat{B}^2$ are independent Brownian motions and where $\mathbb{E}^\star$ denotes expectation with respect to $\hat{\mathbb{P}}^\star$. This is because the infinitesimal generator of $(\hat{S}, \hat{Y})$ is $\hat{\mathcal{L}}^\varepsilon$.

We recall that $J(S,y,t)$ and $K(S,y)$ are at most logarithmically growing as functions of y and are bounded as functions of (S,t). Then the expectation (4.40) can be bounded by a combination of terms of the form $\varepsilon\mathbb{E}^\star\{\chi(\hat{Y}_u) \mid \hat{S}_t = S, \hat{Y}_t = y\}$, with $t < u \leq T$, for some logarithmically growing functions χ. Using Lemma 4.6 below, for ε sufficiently small, the terms $\mathbb{E}^\star\{\chi(\hat{Y}_u) \mid \hat{S}_t = S, \hat{Y}_t = y\}$ are bounded independent of ε. The result follows from (4.40). □

LEMMA 4.5. *At fixed* (S,y,t),

$$\underline{Z}(S,y,t) = \mathcal{O}(\varepsilon).$$

Proof. The solution of (4.38) has the probabilistic representation, via the Feynman–Kac formula

$$\bar{q}^{\varepsilon}(S,y,t) = \mathbb{E}^{\star}\left\{\exp\left(-\varepsilon K(\hat{S}_T,\hat{Y}_T) + \varepsilon\int_t^T J(\hat{S}_u,\hat{Y}_u,u)\,du\right) \mid \hat{S}_t = S, \hat{Y}_t = y\right\},$$

where $(\hat{S},\hat{Y})$ were defined in the previous lemma. From the properties of J and K, this can be bounded above by

$$\mathbb{E}^{\star}\left\{\exp\left(\varepsilon\chi(\hat{Y}_T,T) + \varepsilon\int_t^T \chi(\hat{Y}_u,u)\,du\right) \mid \hat{S}_t = S, \hat{Y}_t = y\right\}$$

for some functions χ at most logarithmically growing in $\hat{Y}$. From the ε-independent exponential moments of $\hat{Y}$ given in Lemma 4.6 below, it follows that

$$\bar{q}^{\varepsilon}(S,y,t) = 1 + \mathcal{O}(\varepsilon)$$

for fixed (S,y,t). The result follows from $\underline{Z}^{\varepsilon} = -\ln\bar{q}^{\varepsilon}$. □

LEMMA 4.6. *For $\hat{Y}$ defined in (4.41), there exist some $\varepsilon_0 > 0$ and a constant $C(t,T,v,y)$, independent of ε, such that for any $t \le s \le T$ and $0 < \varepsilon < \varepsilon_0$,*

$$\mathbb{E}^{\star}\{e^{v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y\} < C(t,T,v,y).$$

Proof. The proof is a modification of [8, Proposition 2]. We first rewrite (4.41) as

$$d\hat{Y}_t = \left(\frac{1}{\varepsilon}(m - \hat{Y}_t) - \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}}\Lambda(\hat{S},\hat{Y},t)\right)dt + \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}}\,d\hat{B}^1_t,$$

with

$$\Lambda(S,y,t) = \frac{\rho\mu}{\sigma(y)} - \sqrt{\varepsilon}\frac{\theta(S,y,t)}{\nu\sqrt{2}},$$

where θ was defined in (4.35). Since θ is bounded, for any $\varepsilon_0 > 0$ and $0 < \varepsilon < \varepsilon_0$, Λ is bounded independent of ε.

Next, using Girsanov's theorem, we define an equivalent measure $\hat{\mathbb{P}}$ under which $\hat{Y}$ is a standard OU process. Introducing $\hat{W}^1_t = \hat{B}^1_t - \int_0^t \Lambda(\hat{S}_u,\hat{Y}_u,u)\,du$, we define $\hat{\mathbb{P}}$ by

$$\frac{d\hat{\mathbb{P}}^{\star}}{d\hat{\mathbb{P}}} = M_T^{(\Lambda)},$$

where

$$M_s^{(\Lambda)} = e^{-\int_t^s \Lambda(\hat{S}_u,\hat{Y}_u,u)d\hat{W}^1_u - \frac{1}{2}\int_t^s \Lambda(\hat{S}_u,\hat{Y}_u,u)^2 du}.$$

Then $\hat{W}^1$ is a $\hat{\mathbb{P}}$-Brownian motion and $M^{(\Lambda)}$ is a $(\hat{\mathbb{P}},(\hat{\mathcal{F}}_t))$-martingale.

Now we have

$$\mathbb{E}^{\star}\{e^{v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y\} = \mathbb{E}\{e^{v\hat{Y}_s}M_s^{(\Lambda)} \mid \hat{S}_t = S, \hat{Y}_t = y\}, \tag{4.42}$$

where $\mathbb{E}$ denotes the expectation under $\hat{\mathbb{P}}$. We rewrite (4.42) as

$$\mathbb{E}\{e^{v\hat{Y}_s} M_s^{(\Lambda)} \mid \hat{S}_t = S, \hat{Y}_t = y\} = \mathbb{E}\left\{ e^{v\hat{Y}_s} e^{\frac{1}{2}\int_t^s \Lambda(\hat{S}_u, \hat{Y}_u, u)^2 du} \sqrt{M_s^{(2\Lambda)}} \mid \hat{S}_t = S, \hat{Y}_t = y \right\},$$

and, using the Cauchy–Schwarz inequality, we deduce that

$$\mathbb{E}^\star\{e^{v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y\} \le \sqrt{\mathbb{E}\left\{ e^{2v\hat{Y}_s} e^{\int_t^s \Lambda(\hat{S}_u, \hat{Y}_u, u)^2 du} \mid \hat{S}_t = S, \hat{Y}_t = y \right\}}, \tag{4.43}$$

since $M^{(2\Lambda)}$ is a martingale with expected value equal to one. Therefore,

$$\mathbb{E}^\star\{e^{v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y\} \le e^{\frac{1}{2}(s-t)||\Lambda||_\infty^2} \sqrt{\mathbb{E}\left\{ e^{2v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y \right\}}. \tag{4.44}$$

Under $\hat{\mathbb{P}}$, the dynamics of $\hat{Y}$ are given by

$$d\hat{Y}_t = \frac{1}{\varepsilon}(m - \hat{Y}_t)\, dt + \frac{\nu\sqrt{2}}{\sqrt{\varepsilon}}\, d\hat{W}_t^1.$$

That is, it is an autonomous standard OU process. From [8, Lemma 2], there exists a constant $c(v, y)$ such that for any $t \le s \le T$ and $\varepsilon > 0$ we have

$$\mathbb{E}\{e^{v\hat{Y}_s} \mid \hat{S}_t = S, \hat{Y}_t = y\} \le c(v, y).$$

The result follows by setting

$$C(t, T, v, y) = e^{\frac{1}{2}(T-t)||\lambda||_\infty^2} \sqrt{c(2v, y)}. \qquad \square$$

Combining these results, we have

$$\mathcal{O}(\varepsilon) = -\ln \bar{q}^\varepsilon(S, y, t) \le Z^\varepsilon(S, y, t) \le \bar{Z}^\varepsilon(S, y, t) = \mathcal{O}(\varepsilon)$$

for fixed (S, y, t). It follows that

$$Z^\varepsilon(S, y, t) \to 0 \qquad \text{as } \varepsilon \downarrow 0,$$

and part (i) of Proposition 4.4 follows from (4.21).

The proof of convergence of the approximation (4.18) for the solution ψ of (4.13) is a simpler version of the preceding, setting $g \equiv 0$ and thereby removing the S-dependences.

4.6. Proof of Theorem 4.3. From (4.11) and (4.12), we have that

$$h(S, y, t) = \frac{1}{\gamma}(\phi(S, y, t) - \psi(S, y, t)).$$

Using (4.14) and (4.18) and the triangle inequality trivially leads to (4.10), completing the proof.

5. Conclusions. The practical implications of the preceding analysis are pricing spreads in section 3 that can be tuned by the pricer's risk aversion; robust asymptotic approximations in section 4 that do not require precise specification of a stochastic volatility model; and analytical results for the problem of optimizing a portfolio consisting of dynamic positions in a liquid underlying asset combined with a static position in a derivative security. Such a problem is important in incomplete markets when investors would like to use derivatives to "trade volatility" indirectly but cannot rebalance frequently because of high transaction costs. Our results herein are applied to this problem in work in preparation.

Many questions about the utility pricing mechanism remain for future investigation: the implications for hedging derivative risk; the effect on implied volatilities, especially the term-structure, or variation with time-to-maturity; the multidimensional problem, meaning both the case of multifactor stochastic volatility models (where perhaps one factor is slow and another is fast mean-reverting), and the case of options on a basket of stocks. Mathematically, the main challenge is in extending the present analysis to the important cases of unbounded and nonsmooth payoffs.

NEUMANN BOUNDARY CONTROL OF HYPERBOLIC EQUATIONS WITH POINTWISE STATE CONSTRAINTS*

BORIS S. MORDUKHOVICH† AND JEAN-PIERRE RAYMOND‡

Abstract. We consider optimal control problems for hyperbolic equations with controls in Neumann boundary conditions with pointwise constraints on the control and state functions. Focusing on the multidimensional wave equation with a nonlinear term, we derive new necessary optimality conditions in the form of a pointwise Pontryagin maximum principle for the state-constrained problem under consideration. Our approach is based on modern methods of variational analysis that allow us to obtain refined necessary optimality conditions with no convexity assumptions on integrands in the minimizing cost functional.

Key words. optimal control, wave equation, Neumann boundary controls, state constraints, necessary optimality conditions, Pontryagin maximum principle

1. Introduction.

This paper is concerned with optimal control problems for hyperbolic equations with controls in Neumann boundary conditions in the presence of *pointwise* constraints on the control and state functions. It is well known that *state-constrained* control problems are among the most challenging and difficult in dynamic optimization; see, e.g., [2, 3, 4, 7, 9, 17, 22, 25] and their references for state-constrained problems governed by parabolic and elliptic partial differential equations. To the best of our knowledge, such optimal control problems have not been studied yet for semilinear *hyperbolic equations* with controls in *Neumann boundary conditions*, which is the objective of this paper. For problems with no state constraints we refer to [18], where an optimal control problem for a semilinear hyperbolic equation with controls in Neumann boundary conditions has been studied.

Let Ω be an open bounded domain in $\mathbb{R}^N$, with a boundary Γ of class C^2, and let T be a positive time. We mainly pay attention to the following optimal control problem governed by the *semilinear wave equation*: minimize

$$J(y,u)=\int_\Omega f(x,y(T))dx+\int_Q g(x,t,y)dxdt+\int_\Sigma h(s,t,u)dsdt$$

over admissible pairs (y,u) satisfying

$$\left\{\begin{array}{ll} y_{tt}-\Delta y+\Phi(\cdot,y)=0 & \text{in } Q:=\Omega\times(0,T),\\ \partial_\nu y=u & \text{on } \Sigma:=\Gamma\times(0,T),\\ y(0)=y_0,\quad y_t(0)=y_1 & \text{in } \Omega, \end{array}\right. \tag{1.1}$$

under the pointwise constraints on control and state functions

$$u\in U_{ad}\subset L^2(\Sigma),\qquad y\in\mathcal{C}\subset C([0,T];L^2(\Omega)).$$

‡Laboratoire MIP, Université Paul Sabatier, 31062 Toulouse Cedex 4, France (raymond@mip.ups-tlse.fr).

We denote this problem by (P) and write it as

$$\text{(P)} \qquad \inf\{J(y,u) \mid (y,u) \text{ satisfies (1.1)},\ u \in U_{ad},\ y \in \mathcal{C}\}.$$

Assumptions on the nonlinear function Φ, as well as on the integrands f, g, and h, are presented and discussed in section 2. The initial state $(y_0, y_1) \in H^1(\Omega) \times L^2(\Omega)$ is fixed. Note that the main constructions and results of the paper can be extended to hyperbolic equations governed by more general *strongly elliptic operators* in (1.1)—not just by the Laplacian Δ—with *time-independent and regular* coefficients.

As mentioned above, we are not familiar with any publications concerning state-constrained control problems with Neumann boundary controls for hyperbolic equations. Some results for *distributed controls* in state-constrained hyperbolic systems are obtained in [7, 9, 28, 29]. Our preceding paper [21] deals with necessary optimality conditions for state-constrained problems governed by the wave equation with *Dirichlet* boundary controls.

It has been well recognized that Neumann and Dirichlet boundary conditions are essentially different in both parabolic and hyperbolic dynamical settings. While for parabolic equations the Dirichlet boundary value problem is considerably more difficult than the Neumann one, this is not the case for the hyperbolic dynamics; see, e.g., [11, 12, 13, 15, 17, 22, 24] and the references therein. On the contrary, the fundamental *regularity theory* for hyperbolic equations with Dirichlet boundary conditions has come first; cf. [11] and [13]. The sharp regularity results developed by Lasiecka and Triggiani for hyperbolic equations with Neumann boundary conditions [13] play a crucial role in this paper.

The main goal of this paper is to establish *necessary optimality conditions* for the state-constrained Neumann boundary control problem (P), which will be derived under rather mild and natural assumptions. In contrast to the Dirichlet case [21], where the dynamics is linear and the initial condition is in $L^2(\Omega) \times H^{-1}(\Omega)$, here we consider the *nonlinear dynamics* in (1.1) and we require *stronger* regularity assumptions on the initial state: $(y_0, y_1) \in H^1(\Omega) \times L^2(\Omega)$ in (1.1). On the other hand, the Neumann case provides *more regularity* of the corresponding solutions to the boundary value problem in (1.1), which eventually allows us to entirely *avoid the convexity assumptions*—on the integrands in the cost functional $J(y,u)$—that play a crucial role in the Dirichlet control problem considered in [21]. Moreover, in this paper we are able to establish necessary optimality conditions for (P) in the *pointwise form* of the Pontryagin maximum principle in contrast to the weaker integral form of [21].

Our approach to deriving necessary optimality conditions in the Neumann problem (P) is completely different from the one in [21] developed for the Dirichlet case. Instead of reducing the original problem to an abstract optimization problem and then using a suitable version of the Lagrange multiplier rule as in [21], we now employ *perturbation methods of modern variational analysis* involving *penalizing* state constraints and then passing to the limit from necessary optimality conditions in unconstrained approximating problems. In the case of optimal control problems governed by ordinary differential systems with even nonsmooth data this approach was developed in the 1970s; see, e.g., [5, 20, 27]. For problems governed by partial differential equations the situation is more complicated, and the first results have been obtained in the 1990s for bounded controls [2, 4]; see also [17] and the references therein. As mentioned in [9, page 595], versions of the maximum principle for unbounded control operators in the case of problems governed by partial differential equations were discovered by Fattorini [8] and independently by Raymond and Zidani in [25]. Based on

Ekeland's variational principle [6] and the approach developed in [25], we derive necessary optimality conditions for the original state-constrained hyperbolic problem (P) in the pointwise form of the maximum (actually minimum) principle of Pontryagin's type. Note that the approach developed in this paper allows us to obtain necessary optimality conditions for a more general version of problem (P), where the integrand h also depends on the *state variable* y. We are not going to pursue this issue here for simplicity.

The rest of the paper is organized as follows. In section 2 we present and discuss the *basic assumptions* used throughout the paper and then formulate the *main result* giving necessary conditions for optimal solutions to (P). Section 3 is devoted to the proper definitions of solutions and the subsequent analysis of the *state system* (1.1) and in the corresponding *adjoint system* appearing in the necessary optimality conditions.

Section 4 contains preparatory material allowing us to derive in the concluding section necessary optimality conditions in the pointwise maximum principle form for approximating problems with no state constraints. Namely, we obtain the so-called *increment formula* for the minimizing functional with respect to *diffuse/needle variations* of controls. This technique, which is well known for the case of ordinary differential equations (see, e.g., [10, 20]), requires a more delicate analysis in the case of partial differential equations. Following the constructions developed in [25] for the control of parabolic equations, we obtain an increment formula for approximating hyperbolic problems based on suitable *Taylor expansions* of the problem data with respect to diffuse perturbations of reference controls.

In the final section 5 we give the proof of the main result of this paper that involves the three major steps of variational analysis: (a) *perturbation* of the original state-constrained problem by a family of approximating problems with *no state constraints* by using Ekeland's variational principle in an appropriate metric space, (b) deriving necessary optimality conditions in the *approximating problems* that provide *suboptimality conditions* for the original problem, and finally (c) *passing to the limit* from the approximating problems to obtain the desired necessary conditions for the reference optimal solution to the state-constrained problem (P).

2. Basic assumptions and statement of the main theorem. Throughout the paper we use standard notation. For the reader's convenience we recall that $\mathcal{M}([0,T];L^2(\Omega))$ is the space of measures on $[0,T]$ with values in $L^2(\Omega)$, which is the topological dual of $C([0,T];L^2(\Omega))$. The topological dual of

$$C_0(]0,T];L^2(\Omega)) := \big\{y \in C([0,T];L^2(\Omega)) \mid y(0)=0\big\}$$

is denoted by $\mathcal{M}_b(]0,T];L^2(\Omega))$, and, similarly, the topological dual of

$$C_0(]0,T[;L^2(\Omega)) = \big\{y \in C([0,T];L^2(\Omega)) \mid y(0)=0,\ y(T)=0\big\}$$

is denoted by $\mathcal{M}_b(]0,T[;L^2(\Omega))$. Note that, according to the usual notation, the space $C_0(]0,T];L^2(\Omega))$ (respectively $C_0(]0,T[;L^2(\Omega))$) consists of continuous mappings on the interval $]0,T]$ (respectively $]0,T[$), vanishing at infinity. In what follows we identify $]0,T]$ and $]0,T[$ with $(0,T]$ and $(0,T)$, respectively.

It is well known that every measure $\mu \in \mathcal{M}_b(]0,T];L^2(\Omega))$ can be identified with a measure $\tilde{\mu} \in \mathcal{M}([0,T];L^2(\Omega))$ such that $\tilde{\mu}(\{0\})=0$ and $\tilde{\mu}|_{]0,T]}=\mu$, where $\tilde{\mu}|_{]0,T]}$ denotes the restriction of $\tilde{\mu}$ to $]0,T]$. Therefore, if $y \in C([0,T];L^2(\Omega))$ and $\mu \in \mathcal{M}_b(]0,T];L^2(\Omega))$, we still use the notation

$$\langle y,\mu\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T];L^2(\Omega))} \quad \text{for} \quad \langle y,\tilde{\mu}\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}([0,T];L^2(\Omega))}.$$

Since we have to deal with equations satisfied in the sense of distributions in Q (see, e.g., (2.4)), it is also convenient to identify $\mathcal{M}_b(]0,T];L^2(\Omega))$ with a subspace of $\mathcal{M}_b(\Omega\times]0,T])$; this identification follows from the continuous and dense imbedding $C_0(\Omega\times]0,T]) \hookrightarrow C_0(]0,T];L^2(\Omega))$. Therefore, if $\mu \in \mathcal{M}_b(]0,T];L^2(\Omega))$, the notation $\mu|_Q$—the restriction of μ to Q—is meaningful if μ is considered as a bounded measure on $\Omega\times]0,T] = \Omega\times(0,T]$, and so $\mu|_{\Omega\times\{T\}}$ stands for $\mu(\{T\})$. The same kind of notation is used in the paper in similar settings. For $z \in L^2(Q)$ we denote by z_t (respectively by z_{tt}) the derivative (respectively, the second derivative) of z in t in the sense of distributions in Q.

Given a Banach space Z, the duality pairing between Z and Z' is denoted by $\langle\cdot,\cdot\rangle_{Z,Z'}$. When there is no ambiguity, we sometimes write $\langle\cdot,\cdot\rangle$ instead of $\langle\cdot,\cdot\rangle_{Z,Z'}$. To emphasize a specific kind of regularity of solutions to the hyperbolic equations under consideration, we may write, e.g., that $(y,y_t) \in C([0,T];X)\times C([0,T];Y)$ is a solution to (1.1) instead of just indicating that y is a solution to this system.

For the definition of the space $BV([0,T];(H^1(\Omega))')$—the space of functions of bounded variation on $[0,T]$ with values in $(H^1(\Omega))'$—we refer to [1, 19]. If $p \in BV([0,T];(H^1(\Omega))')$, one can define $p(t^-)$ and $p(t^+)$ for every $t \in (0,T)$ and also $p(0^+)$ and $p(T^-)$, while the values $p(0)$ and $p(T)$ may be generally different from $p(0^+)$ and $p(T^-)$. There is a unique Radon measure on $[0,T]$ with values in $(H^1(\Omega))'$, denoted by d_tp, such that the restriction of d_tp to $(0,T)$ is the vector-valued distributional derivative of p in $(0,T)$ with $d_tp(\{0\}) = (p(0^+) - p(0))$ and $d_tp(\{T\}) = (p(T) - p(T^-))$. Moreover, identifying p with its representative right-hand side continuous in $(0,T)$, one has

$$p(0^+) = p(0) + d_tp(\{0\}) \quad \text{and} \quad p(t) = p(0) + d_tp([0,t]) \quad \text{for every } t \in]0,T].$$

Recall that if $\{p_n\}$ is a bounded sequence in $BV([0,T];(H^1(\Omega))')$, then there is a subsequence $\{p_{n_k}\}$ and a function $p \in BV([0,T];(H^1(\Omega))')$ such that

$$p_{n_k}(t) \to p(t) \quad \text{weakly in } (H^1(\Omega))' \quad \text{for almost every (a.e.) } t \in [0,T].$$

Note that this convergence may hold for every $t \in [0,T]$ if the above representative right-hand side continuous in $(0,T)$ is not specified; see [1, Theorem 3.5] and [19, Proposition 16.1]. In particular,

$$p_{n_k}(T) \to p(T) \quad \text{weakly in } (H^1(\Omega))'.$$

Now let us formulate the standing *basic assumptions* on the initial data of problem (P) that are needed throughout this paper.

(A1) For every $y \in \mathbb{R}$, $\Phi(\cdot,\cdot,y)$ is measurable in Q. For a.e. pair $(x,t) \in Q$, $\Phi(x,t,\cdot)$ is of class C^1 on $\mathbb{R}$. Moreover, one has

$$\Phi(\cdot,0) \in L^1(0,T;L^2(\Omega)), \qquad |\Phi'_y(x,t,y)| \le M \quad \text{in } Q\times\mathbb{R}, \tag{2.1}$$

where M is a positive constant.

(A2) For every $y \in \mathbb{R}$, $f(\cdot,y)$ is measurable in Ω with $f(\cdot,0)$ belonging to $L^1(\Omega)$. For a.e. $x \in \Omega$, $f(x,\cdot)$ is a function of class C^1 on $\mathbb{R}$. Moreover, there is a constant $C > 0$ such that

$$|f'_y(x,y)| \le C(1+|y|) \quad \text{whenever } (x,y) \in \Omega\times\mathbb{R}.$$

(A3) For every $y \in \mathbb{R}$, $g(\cdot,\cdot,y)$ is measurable in Q with $g(\cdot,0)$ belonging to $L^1(Q)$. For a.e. $(x,t) \in Q$, $g(x,t,\cdot)$ is of class C^1. Moreover, there is a constant $C > 0$ such that

$$|g'_y(x,t,y)| \le C(1+|y|) \quad \text{whenever } (x,t,y) \in Q \times \mathbb{R}.$$

(A4) For every $u \in \mathbb{R}$, $h(\cdot,\cdot,u)$ is measurable on Σ with $h(\cdot,0)$ belonging to $L^1(\Sigma)$. For a.e. $(s,t) \in \Sigma$, $h(s,t,\cdot)$ is of class C^1. Moreover, there is a constant $C > 0$ such that

$$|h'_u(s,t,u)| \le C(1+|u|) \quad \text{whenever } (s,t,u) \in \Sigma \times \mathbb{R}.$$

(A5) The state constraint set $\mathcal{C} \subset C([0,T];L^2(\Omega))$ is closed and convex with $\operatorname{int}\mathcal{C} \neq \emptyset$. We suppose that the function defined by $\hat{y}_0(x,t) := y_0(x)$ belongs to the interior of $\mathcal{C}$ (y_0 denotes the initial state).

(A6) The control set U_{ad} is given in the form

$$U_{ad} := \{u \in L^2(\Sigma) \mid u(s,t) \in K(s,t) \text{ a.e. on } \Sigma\},$$

where K is a measurable multifunction whose values are nonempty and closed subsets of $\mathbb{R}$.

Of course, we suppose as usual that the set of *feasible pairs* (y,u) to (P) is *nonempty*, i.e., there is $u \in U_{ad}$ such that $J(y_u,u) < \infty$ and $y_u \in \mathcal{C}$, where y_u is the weak solution of system (1.1) corresponding to u; see section 3.

Observe that the above basic assumptions do *not* impose any *convexity* requirements on the integrands in the cost functional with respect to either state or control variables, as well as on the control set U_{ad}. This is different from the setting of [21] for the corresponding Dirichlet problem. The reason is that the Neumann boundary value problem offers *more regularity* in comparison with the Dirichlet one and allows us to employ powerful variational methods to prove necessary optimality conditions that *do not rely on weak convergences*. These methods applied to the Dirichlet boundary value problem definitely require full convexity for the limiting procedures to end up with pointwise results. On the other hand, in this paper we do not establish any existence theorems for optimal solutions, in contrast to [21]. In fact, in the Neumann setting under consideration it would be enough to assume convexity only with *respect to control* variables to justify the existence of optimal solutions by the so-called direct method. The stronger convexity assumptions imposed in [21] with respect to *both state and control* variables are due to the lack of regularity in the Dirichlet setting and are needed not only for the existence of optimal solutions but also for the proof of necessary optimality conditions as given in [21].

To formulate our main result, let us define the *Hamiltonian* function

$$H(s,t,u,p,\lambda) := pu + \lambda h(s,t,u)$$

for the control problem (P). The following theorem gives necessary conditions for optimal solutions to (P) that are a version of the *Pontryagin maximum principle* in pointwise form for the Neumann boundary control problem under consideration. Note that it is more convenient in our case to formulate this result with the *minimum* (not maximum) condition.

THEOREM 2.1 (pointwise necessary optimality conditions). *Let $(\bar{y},\bar{u})$ be an optimal solution to problem* (P) *satisfying assumptions* (A1)–(A6). *Then there exist $\lambda \in \mathbb{R}^+$, $\mu \in \mathcal{M}_b(]0,T];L^2(\Omega))$, and a measurable subset $\widetilde{\Sigma} \subset \Sigma$ such that*

$\mathcal{L}^N(\Sigma \setminus \widetilde{\Sigma}) = 0$,

$$(\lambda, \mu) \neq 0, \qquad \langle \mu, z - \bar{y} \rangle \leq 0 \quad \textit{for all } z \in \mathcal{C}, \quad \textit{and} \tag{2.2}$$

$$H(s,t,\bar{u}(s,t),p(s,t),\lambda) = \min_{u \in K(s,t)} H(s,t,u,p(s,t),\lambda) \quad \textit{for all } (s,t) \in \widetilde{\Sigma}, \tag{2.3}$$

where $\mathcal{L}^N$ denotes the N-dimensional Lebesgue measure, and p is the corresponding solution to the adjoint system

$$\begin{cases} p_{tt} - \Delta p + \Phi'_y(\cdot,\bar{y})p = \lambda g'_y(x,t,\bar{y}) + \mu|_Q & \textit{in } Q, \\ \partial_\nu p = 0 & \textit{on } \Sigma, \\ p(T) = y_0, \quad p_t(T) = -\lambda f'_y(x,\bar{y}(T)) - \mu|_{\Omega\times\{T\}} & \textit{in } \Omega. \end{cases} \tag{2.4}$$

The proof of Theorem 2.1 is conducted in section 5. The definitions of solutions to the state and adjoint systems in this theorem are given and discussed in the next section.

3. Analysis of the state and adjoint systems. Let us start with the Neumann boundary value problem for the *linear wave equation*

$$\begin{cases} y_{tt} - \Delta y = \phi & \text{in } Q, \\ \partial_\nu y = u & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega. \end{cases} \tag{3.1}$$

The following fundamental *regularity* result is established by Lasiecka and Triggiani [13]. Note that this result involves the space $C^1([0,T];(H^{1/2}(\Omega))')$ for weak solutions to (3.1) as stated in [14].

LEMMA 3.1 (basic regularity). *Assume that $(\phi, u, y_0, y_1) \in L^1(0,T;L^2(\Omega)) \times L^2(\Sigma) \times H^1(\Omega) \times L^2(\Omega)$ and let $y(\phi,u,y_0,y_1) \in C([0,T];L^2(\Omega)) \cap C^1([0,T];(H^1(\Omega))')$ be the unique weak solution to the linear Neumann boundary value problem* (3.1). *Then the mapping $u \mapsto y(0,u,0,0)$ is bounded from $L^2(\Sigma)$ to $C([0,T];H^{1/2}(\Omega)) \cap C^1([0,T];(H^{1/2}(\Omega))')$, and it is also bounded from $L^2(\Sigma)$ to $H^{3/5-\varepsilon}(Q)$ for all $\varepsilon > 0$. Furthermore, the mapping $(\phi, y_0, y_1) \mapsto y(\phi,0,y_0,y_1)$ is bounded from $L^1(0,T;L^2(\Omega)) \times H^1(\Omega) \times L^2(\Omega)$ to $C([0,T];H^1(\Omega)) \cap C^1([0,T];L^2(\Omega))$.*

Next we consider the Neumann boundary value problem for the linear wave equation with possibly *nonsmooth data*:

$$\begin{cases} y_{tt} - \Delta y + ay = \phi & \text{in } Q, \\ \partial_\nu y = u & \text{on } \Sigma, \\ y(0) = y_0, \quad y_t(0) = y_1 & \text{in } \Omega, \end{cases} \tag{3.2}$$

where the nonsmooth coefficient $a(x,t)$ belongs to $L^\infty(Q)$. The following estimate of solutions to the homogeneous problem in (3.2) is needed in what follows.

LEMMA 3.2 (solution estimate for the homogeneous Neumann problem). *Assume that $u = 0$ and that $(\phi, y_0, y_1) \in L^1(0,T;L^2(\Omega)) \times H^1(\Omega) \times L^2(\Omega)$. Equation* (3.2) *admits a unique weak solution in $C([0,T];L^2(\Omega)) \cap C^1([0,T];(H^1(\Omega))')$. This solution satisfies the estimate*

$$\|y\|_{C([0,T];H^1(\Omega))} + \|y_t\|_{C([0,T];L^2(\Omega))} \leq C(\|\phi\|_{L^1(0,T;L^2(\Omega))} + \|y_0\|_{H^1(\Omega)} + \|y_1\|_{L^2(\Omega)}),$$

where the constant C may depend on $\|a\|_{L^\infty(Q)}$ and $\|\phi\|_{L^1(0,T;L^2(\Omega))}$, but it is invariant with respect to all $a(x,t)$ having the same $L^\infty(Q)$-norm.

Proof. The proof is standard. It is sufficient to multiply the first equation in (3.2) by y_t, to integrate it over Ω, and then to use Gronwall's lemma (see, for example, [18, page 184]). ∎

LEMMA 3.3 (compactness of the solution operator). *Assume that* $(\phi, y_0, y_1) = (0,0,0)$ *and that* $u \in L^2(\Sigma)$. *Equation* (3.2) *admits a unique weak solution* $y(u)$ *in* $C([0,T];L^2(\Omega)) \cap C^1([0,T];(H^1(\Omega))')$. *The mapping* $u \mapsto (y(u), y_t(u))$ *is a bounded operator from* $L^2(\Sigma)$ *into* $C([0,T];H^{1/2}(\Omega)) \times C([0,T];(H^{1/2}(\Omega))')$, *and the mapping* $u \mapsto y(u)$ *is a compact operator from* $L^2(\Sigma)$ *into* $C([0,T];L^2(\Omega))$.

Proof. The existence and uniqueness of the corresponding solution to (3.2) can be deduced from the well-known result for (3.1) by using a fixed point method in $L^2(0,\bar{t};L^2(\Omega))$ as $\bar{t}$ is sufficiently small and then by iterating the process n times with $n\bar{t} > T$; cf. [23] for more details. Moreover, in this way we get the estimate

$$\|y\|_{C([0,T];H^{1/2}(\Omega))} + \|y_t\|_{C([0,T];(H^{1/2}(\Omega))')} \le C\|u\|_{L^2(\Sigma)},$$

where C depends on an upper bound for the *norm* $\|a\|_{L^\infty(Q)}$ but not on $a(\cdot)$ itself. Now the compactness result follows from [26, Corollary 5]. ∎

Our next goal is to study the Neumann boundary value problem (1.1), which is labelled as the *state system* for convenience. We first recall the notion of *weak solutions* to the Neumann problem in (1.1) that is appropriate for the purposes of this paper.

DEFINITION 3.4 (weak solutions to the state system). *A function* $(y, y_t) \in C([0,T];L^2(\Omega)) \times C([0,T];(H^1(\Omega))')$ *is a* weak solution *to system* (1.1) *if*

$$\begin{aligned} &\int_Q -\Phi(\cdot,y)z\,dxdt \\ &\quad = \int_Q y\varphi\,dxdt - \langle y_t(0), z(0)\rangle_{(H^1(\Omega))',H^1(\Omega)} + \int_\Omega y(0)z_t(0)\,dx + \int_\Sigma zu\,dsdt, \end{aligned} \tag{3.3}$$

for all $\varphi \in L^1(0,T;L^2(\Omega))$, *where* z *solves the homogeneous Neumann boundary value problem*

$$\begin{cases} z_{tt} - \Delta z = \varphi & \text{in } Q, \\ \partial_\nu z = 0 & \text{on } \Sigma, \\ z(T) = 0, \quad z_t(T) = 0 & \text{in } \Omega. \end{cases} \tag{3.4}$$

The advantage of the above definition is that it allows us to establish the existence, uniqueness, and regularity of weak solutions to the original state system under the standing assumptions made in section 2.

THEOREM 3.5 (existence, uniqueness, and regularity of weak solutions to the state system). *For every* $(u, y_0, y_1) \in L^2(\Sigma) \times H^1(\Omega) \times L^2(\Omega)$ *the state system* (1.1) *admits a unique weak solution* (y, y_t) *in* $C([0,T];L^2(\Omega)) \times C([0,T];(H^1(\Omega))')$. *This solution belongs to* $C([0,T];H^{1/2}(\Omega)) \times C([0,T];(H^{1/2}(\Omega))')$ *and satisfies the estimate*

$$\|y\|_{C([0,T];H^{1/2}(\Omega))} + \|y_t\|_{C([0,T];(H^{1/2}(\Omega))')} \le C(\|u\|_{L^2(\Sigma)} + \|y_0\|_{H^1(\Omega)} + \|y_1\|_{L^2(\Omega)} + 1)$$

with some constant $C > 0$. *Moreover, the mapping* $(u, y_0, y_1) \mapsto y$ *is continuous from* $(u, y_0, y_1) \in L^2(\Sigma) \times H^1(\Omega) \times L^2(\Omega)$ *into* $C([0,T];H^{1/2}(\Omega)) \cap C^1([0,T];(H^{1/2}(\Omega))')$.

Proof. The existence of solutions in the space $C([0,\bar{t}];L^2(\Omega)) \cap C^1([0,\bar{t}];(H^1(\Omega))')$ with $\bar{t}$ sufficiently small can be obtained by a standard fixed point method. Then assumption (A1) and the estimates in Lemmas 3.2 and 3.3 allow us to ensure the existence of solutions in the space given in the theorem. The proof of uniqueness is also

standard and is omitted for brevity. The estimate of (y, y_t) in $C([0,T]; H^{1/2}(\Omega)) \cap C^1([0,T]; (H^{1/2}(\Omega))')$ follows from the estimate of y in $C([0,T]; L^2(\Omega))$ due to the basic Lemma 3.1. To justify the continuity of the mapping $(u, y_0, y_1) \mapsto y$ from $(u, y_0, y_1) \in L^2(\Sigma) \times H^1(\Omega) \times L^2(\Omega)$ into $C([0,T]; H^{1/2}(\Omega)) \cap C^1([0,T]; (H^{1/2}(\Omega))')$, we again use assumption (A1) and the corresponding estimates for the linearized system (3.2) presented in Lemmas 3.2 and 3.3. □

Next we consider the *adjoint system* given by

$$\begin{cases} p_{tt} - \Delta p + ap = \mu|_Q & \text{in } Q, \\ \partial_\nu p = 0 & \text{on } \Sigma, \\ p(T) = 0, \quad p_t(T) = -\mu|_{\Omega \times \{T\}} & \text{in } \Omega, \end{cases} \tag{3.5}$$

where $\mu \in \mathcal{M}_b(]0,T]; L^2(\Omega))$, where $\mu|_Q$ and $\mu|_{\Omega\times\{T\}}$ denote the restriction of μ to Q and to $\Omega \times \{T\}$, respectively, and where $a \in L^\infty(Q)$.

In order to introduce and justify an appropriate definition of solutions to the adjoint system (3.5), we need the following lemma that is certainly of independent interest.

LEMMA 3.6 (divergence formula). *The space*

$$W := \{\vec{V} \in (L^2(Q))^{N+1} \mid \operatorname{div}(\vec{V}) \in \mathcal{M}_b(]0,T[; L^2(\Omega))\}$$

endowed with the norm $\|\vec{V}\|_W := \|\vec{V}\|_{(L^2(Q))^{N+1}} + \|\operatorname{div}(\vec{V})\|_{\mathcal{M}_b(]0,T[;L^2(\Omega))}$ *is a Banach space. There exists a unique continuous operator* γ_{ν_Q} *from* W *into* $H^{-1/2}(\partial Q)$ *satisfying*

$$\gamma_{\nu_Q}(\vec{V}) = \gamma_0(\vec{V}) \cdot \nu_Q$$

for every $\vec{V} \in (C^1(\overline{Q}))^{N+1}$ *and such that the divergence formula*

$$\begin{aligned} \int_Q \vec{V} \cdot \nabla\phi + \langle \phi, \operatorname{div}(\vec{V})\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T[;L^2(\Omega))} \\ = \langle \gamma_{\nu_Q}(\vec{V}), \gamma_0(\phi)\rangle_{H^{-1/2}(\partial Q), H^{1/2}(\partial Q)} \end{aligned} \tag{3.6}$$

holds for all $\phi \in H^1(Q)$.

Proof. It is easy to see that the space W is Banach. Let Λ be a continuous extension operator from $H^{1/2}(\partial Q)$ into $H^1(Q)$ that is a bounded linear operator from $H^{1/2}(\partial Q)$ into $H^1(Q)$ satisfying

$$\gamma_0 \Lambda\varphi = \varphi \quad \text{for all } \varphi \in H^{1/2}(\partial Q).$$

Taking $\vec{V} \in (C^1(\overline{Q}))^{N+1}$, observe that the functional

$$\varphi \longmapsto \int_Q \vec{V} \cdot \nabla \Lambda\varphi + \langle \Lambda\varphi, \operatorname{div}(\vec{V})\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T[;L^2(\Omega))}$$

is linear and bounded on $H^{1/2}(\partial Q)$. Denoting this functional by $\gamma_{\nu_Q}(\vec{V})$, we directly verify that

$$\gamma_{\nu_Q}(\vec{V}) = \gamma_0(\vec{V}) \cdot \nu_Q,$$

and that the divergence formula (3.6) is satisfied. This means that $\gamma_{\nu_Q}(\vec{V})$ does not depend on the extension operator Λ. Furthermore, one has

$$\left| \int_Q \vec{V} \cdot \nabla \Lambda\varphi + \langle \Lambda\varphi, \operatorname{div}(\vec{V}) \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T[;L^2(\Omega))} \right| \le C\|\varphi\|_{H^{1/2}(\partial Q)} \|\vec{V}\|_W,$$

which implies that

$$\|\gamma_{\nu_Q}(\vec{V})\|_{H^{-1/2}(\partial Q)} \le C\|\vec{V}\|_W \quad \text{for all } \vec{V} \in (C^1(\overline{Q}))^{N+1}.$$

Since $(C^1(\overline{Q}))^{N+1}$ is dense in W, the proof is complete. □

Next take $(p, p_t) \in L^2(0,T;H^1(\Omega)) \times L^2(0,T;L^2(\Omega))$ and assume that the combination $p_{tt} - \Delta p$, calculated in the sense of distributions on Q, belongs to $\mathcal{M}_b(]0,T[;L^2(\Omega))$. Employing Lemma 3.6, we define the *normal trace* on ∂Q of the vectorfield $(-\nabla p, p_t)$ as an element of $H^{-1/2}(\partial Q)$. Then one has the estimate

$$\begin{aligned} &\|\gamma_{\nu_Q}(-\nabla p, p_t)\|_{H^{-1/2}(\partial Q)} \\ &\quad \le C(\|p\|_{L^2(0,T;H^1(\Omega))} + \|p_t\|_{L^2(Q)} + \|p_{tt} - \Delta p\|_{\mathcal{M}_b(]0,T[;L^2(\Omega))}), \end{aligned}$$

where the constant $C > 0$ is independent of p. Since $\Omega \times \{0\}$ is an open subset in ∂Q, the restriction of $\gamma_{\nu_Q}(-\nabla p, p_t)$ to $\Omega \times \{0\}$ belongs to $H^{-1/2}(\Omega)$. Thus we get

$$\gamma_{\nu_Q}(-\nabla p, p_t)|_{\Omega\times\{0\}} = p_t(0) \in H^{-1/2}(\Omega).$$

Note that this result can be improved. We are going to show in Theorem 3.8 that a properly defined solution p to (3.5) actually has the property $p_t(0) \in L^2(\Omega)$.

Now we are ready to introduce an appropriate notion of *weak solutions* to the adjoint system (3.5) and justify their basic properties needed in what follows.

DEFINITION 3.7 (weak solutions to the adjoint system). *A function $p \in L^\infty(0,T;L^2(\Omega))$ is a* weak solution *to* (3.5) *if*

$$\langle y(\varphi), \mu \rangle_{C([0,T];L^2(\Omega))\times\mathcal{M}_b(]0,T];L^2(\Omega))} - \int_Q p\varphi \, dxdt = 0 \tag{3.7}$$

for all $\varphi \in L^1(0,T;L^2(\Omega))$, where $y(\varphi)$ is the solution to

$$\begin{cases} y_{tt} - \Delta y + ay = \varphi & \text{in } Q, \\ \partial_\nu y = 0 & \text{on } \Sigma, \\ y(0) = 0, \quad y_t(0) = 0 & \text{in } \Omega. \end{cases} \tag{3.8}$$

The next theorem establishes the existence, uniqueness, and regularity of weak solutions to the adjoint system under the standing assumptions made.

THEOREM 3.8 (existence, uniqueness, and regularity of weak solutions to the adjoint system). *The adjoint system* (3.5) *admits a unique weak solution $(p, p_t) \in L^\infty(0,T;H^1(\Omega)) \times L^\infty(0,T;L^2(\Omega))$. This solution satisfies $p_t \in BV([0,T];(H^1(\Omega))')$, $p \in C_w([0,T];H^1(\Omega))$, and*

$$p_t(\tau) \in L^2(\Omega) \quad \text{whenever } \tau \in \{t \in [0,T] \mid \mu(\{t\}) = 0\},$$

which implies that $p_t(0) \in L^2(\Omega)$ ($C_w([0,T];H^1(\Omega))$ denotes the space of continuous functions from $[0,T]$ into $H^1(\Omega)$ endowed with its weak topology). Moreover, one has the estimate

$$\|p\|_{L^\infty(0,T;H^1(\Omega))} + \|p_t\|_{L^\infty(0,T;L^2(\Omega))} \le C\|\mu\|_{\mathcal{M}_b(]0,T];L^2(\Omega))}, \tag{3.9}$$

where C depends on $\|a\|_{L^\infty(Q)}$ but is invariant with respect to the functions $a(x,t)$ having the same norm in the space $L^\infty(Q)$.

Proof. Observe that $p=0$ when the pair $(p,p_t)\in L^\infty(0,T;H^1(\Omega))\times L^\infty(0,T;L^2(\Omega))$ satisfies (3.7) with $\mu=0$. This implies that the adjoint system (3.5) *cannot admit more than one* weak solution. To prove the *existence* of a weak solution, we develop an approximation procedure. First build a sequence $\{\mu_n\}\subset L^1(0,T;L^2(\Omega))$ satisfying

$$\begin{aligned}\lim_{n\to\infty}\int_Q y\mu_n\,dxdt &= \langle y,\mu|_{]0,T[}\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T[;L^2(\Omega))}\\ &\text{for all } y\in C([0,T];L^2(\Omega)),\quad \text{and}\\ &\|\mu_n\|_{L^1(0,T;L^2(\Omega))}=\|\mu|_{]0,T[}\|_{\mathcal{M}_b(]0,T[;L^2(\Omega))}.\end{aligned}\tag{3.10}$$

To define μ_n, we follow the construction in the appendix of [24]. Let $\bar\mu$ be the extension of $\mu|_{]0,T[}$ by zero to $\mathbb{R}$, let $\{\rho_n\}$ be a sequence of nonnegative symmetric mollifiers on $\mathbb{R}$ with their supports in $(-1/n,1/n)$, and let S_0 and S_T be the functions on $\mathbb{R}$ defined by $S_0(t):=-t$ and $S_T(t):=2T-t$. Given $n\ge 2$, we set

$$\bar\mu_n(A):=(\bar\mu*\rho_n)(A)+(\bar\mu*\rho_n)(S_0(A))+(\bar\mu*\rho_n)(S_T(A))$$

for every Borel subset A in $\mathbb{R}$, and then construct the desired measure by

$$\mu_n:=\frac{\|\mu\|_{\mathcal{M}_b(]0,T[;L^2(\Omega))}}{\|\bar\mu_n|_{]0,T[}\|_{\mathcal{M}_b(]0,T[;L^2(\Omega))}}\bar\mu_n|_{]0,T[}.$$

Following [24, appendix], one can verify both relations formulated in (3.10).

Considering now the unique solution p_n to the system

$$\begin{cases} p_{tt}-\Delta p+ap=\mu_n & \text{in } Q,\\ \partial_\nu p=0 & \text{on } \Sigma,\\ p(T)=0,\quad p_t(T)=-\mu|_{\Omega\times\{T\}} & \text{in } \Omega\end{cases}\tag{3.11}$$

and applying Lemma 3.2, we get the estimate

$$\begin{aligned}&\|p_n\|_{L^\infty(0,T;H^1(\Omega))}+\|p_{nt}\|_{L^\infty(0,T;L^2(\Omega))}+\|p_n(0)\|_{H^1(\Omega)}+\|p_{nt}(0)\|_{L^2(\Omega)}\\ &\quad\le C\|\mu\|_{\mathcal{M}_b(]0,T];L^2(\Omega))}\end{aligned}\tag{3.12}$$

with a constant $C>0$ independent of n, where p_{nt} stands for the derivative of p_n with respect to t in $(0,T)$ in the sense of vector-valued distributions. Denoting by p_{ntt} the corresponding derivative of p_{nt} with respect to t in $(0,T)$ and using (3.11), we arrive at

$$p_{ntt}=\pi_n+\mu_n\in L^\infty(0,T;(H^1(\Omega))')+\mathcal{M}_b(]0,T[;L^2(\Omega))\subset\mathcal{M}_b(]0,T[;(H^1(\Omega))'),$$

where the operator π_n is defined by

$$\langle\pi_n,y\rangle_{L^\infty(0,T;(H^1(\Omega))'),L^1(0,T;H^1(\Omega))}:=\int_Q(\nabla p_n\cdot\nabla y-ap_ny)\,dxdt.$$

Therefore, in addition to (3.12), the sequences $\{p_{ntt}\}$ and $\{p_{nt}\}$ are bounded in the spaces $\mathcal{M}_b(]0,T[;(H^1(\Omega))')$ and $BV([0,T];(H^1(\Omega))')$, respectively. Observing that $\mathcal{M}_b(]0,T[;(H^1(\Omega))')$ is the dual of a *separable* Banach space, we select weak* convergent *subsequences* of the above sequences. The same *sequential compactness* property

holds also for the space $BV([0,T];(H^1(\Omega))')$; see section 2. In this way we find $p \in L^\infty(0,T;H^1(\Omega))$ with $p_t \in L^\infty(0,T;L^2(\Omega)) \cap BV([0,T];(H^1(\Omega))')$ and a subsequence $\{p_n\}$ converging to p in the weak* topology of $L^\infty(0,T;H^1(\Omega))$ and such that the corresponding subsequence $\{p_{nt}\}$ converges weak* in $L^\infty(0,T;L^2(\Omega))$ to p_t. Furthermore, since $\gamma_{\nu_Q}(-\nabla p_n, p_{nt})$ is bounded in $L^2(\partial Q)$, we can also deduce that the sequence of $\gamma_{\nu_Q}(-\nabla p_n, p_{nt})$ converges to $\gamma_{\nu_Q}(-\nabla p, p_t)$ in the weak topology of $L^2(\partial Q)$. Taking into account the relations

$$\gamma_{\nu_Q}(-\nabla p_n, p_{nt})|_{\Omega\times\{T\}} = \mu|_{\Omega\times\{T\}} \quad \text{and} \quad \gamma_{\nu_Q}(-\nabla p_n, p_{nt})|_\Sigma = 0,$$

one gets that $\gamma_{\nu_Q}(-\nabla p, p_t)|_\Sigma = -\partial_\nu p = 0$ and that

$$\gamma_{\nu_Q}(-\nabla p_n, p_{nt})|_{\Omega\times\{0\}} = p_{nt}(0) \rightharpoonup \gamma_{\nu_Q}(-\nabla p, p_t)|_{\Omega\times\{0\}} = p_t(0)$$

in the weak topology of $L^2(\Omega)$. Finally, by passing to the limit in the equality

$$\langle y(\varphi), \mu_n\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T];L^2(\Omega))} - \int_Q p_n\varphi = 0,$$

where $y(\varphi)$ is the solution of (3.8), we conclude that (p, p_t) is the desired weak solution to the adjoint system (3.5). The proof of the theorem is complete. ∎

The last result of this section gives a useful Green-type relationship between the corresponding solutions of the (linearized) state and adjoint systems.

THEOREM 3.9 (Green formula). *Assume that* $(\phi, y_0, y_1) = (0,0,0)$ *and that* $u \in L^2(\Sigma)$, *let* y *be the corresponding weak solution to system* (3.2), *and let* p *satisfy* (3.5). *Then*

$$\langle y, \mu\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T];L^2(\Omega))} - \int_Q p\varphi = \int_\Sigma up\, ds\, dt. \tag{3.13}$$

Proof. This formula can be proved for the pair (y, p_n), where p_n is the solution to the approximating adjoint system (3.11). Passing there to the limit as $n \to \infty$, we obtain the desired Green formula (3.13) as formulated in the theorem. ∎

4. Diffuse perturbations and increment formula. As mentioned in section 1, our approach to deriving necessary optimality conditions in the original state-constrained problem (P) includes an approximation procedure to penalize the state constraints. In this way we arrive at a family of Neumann boundary control problems for hyperbolic equations with pointwise (or hard) constraints on the control variable but with *no state constraints*. Although the latter approximating problems are essentially easier than the initial state-constrained problem (P), they still require a delicate variational analysis. As is well known in the control theory for ordinary differential equations, a key element in obtaining maximum-type conditions for problems with hard constraints on control but not on state variables is the so-called *increment formula* for the minimizing cost functional with respect to *needle variations* of reference controls; see, e.g., [10, 20]. In this section we obtain some counterparts of such results for the hyperbolic control problems under consideration, by using the so-called diffuse perturbations first introduced in [16] and then developed in [2, 3, 4, 25]; see also the references therein. Here we follow the construction developed in [25].

Given a reference control $\bar u \in U_{ad}$, an admissible control $u \in U_{ad}$, and a number $\rho \in (0,1)$, a *diffuse perturbation* of $\bar u$ is defined by

$$u_\rho(s,t) := \begin{cases} \bar u(s,t) & \text{on } \Sigma \setminus E_\rho, \\ u(s,t) & \text{on } E_\rho, \end{cases} \tag{4.1}$$

where E_ρ is a measurable subset of Σ. The next theorem can be viewed as an increment formula for the cost functional $J(y,u)$ with respect to diffuse perturbations of the reference control. Note that it also contains the corresponding Taylor expansion for state trajectory of (1.1), which is an essential ingredient of the increment formula.

THEOREM 4.1 (increment formula). *Given arbitrary controls $\bar{u}, u \in U_{ad}$ and a number $\rho \in (0,1)$, we consider the diffuse perturbation defined in* (4.1) *and the weak solutions $\bar{y}$ and y_ρ of system* (1.1) *corresponding to $\bar{u}$ and u_ρ, respectively. Then there exists a measurable subset $E_\rho \subset \Sigma$ such that the following hold:*

$$\mathcal{L}^N(E_\rho) = \rho \mathcal{L}^N(\Sigma), \tag{4.2}$$

$$\int_{E_\rho} (h(s,t,\bar{u}) - h(s,t,u))\, dsdt = \rho \int_\Sigma (h(s,t,\bar{u}) - h(s,t,u))\, dsdt, \tag{4.3}$$

$$y_\rho = \bar{y} + \rho z + \rho r_\rho \quad \text{with } \lim_{\rho \to 0} \|r_\rho\|_{C([0,T];L^2(\Omega))} = 0, \tag{4.4}$$

$$J(y_\rho, u_\rho) = J(\bar{y},\bar{u}) + \rho \Delta J + o(\rho) \quad \text{with } \Delta J := J'_y(\bar{y},\bar{u})z + J(\bar{y},u) - J(\bar{y},\bar{u}), \tag{4.5}$$

where z is the weak solution to the system

$$\begin{cases} z_{tt} - \Delta z + \Phi'_y(\cdot,\bar{y})z = 0 & \text{in } Q, \\ \partial_\nu z = \bar{u} - u & \text{on } \Sigma, \\ z(0) = 0, \quad z_t(0) = 0 & \text{in } \Omega. \end{cases} \tag{4.6}$$

The proof of the theorem given below relies on the following technical lemma, which follows from [25, Lemma 4.1].

LEMMA 4.2 (diffuse perturbations). *Let $\bar{u}, u \in U_{ad}$. For every $\rho \in (0,1)$ there is a sequence of measurable subsets E^n_ρ in Σ such that*

$$\mathcal{L}^N(E^n_\rho) = \rho \mathcal{L}^N(\Sigma), \tag{4.7}$$

$$\int_{E^n_\rho} (h(s,t,\bar{u}) - h(s,t,u))\, dsdt = \rho \int_\Sigma (h(s,t,\bar{u}) - h(s,t,u))\, dsdt, \tag{4.8}$$

$$\frac{1}{\rho}\chi_{E^n_\rho} \rightharpoonup 1 \quad \text{weak}^* \text{ in } L^\infty(\Sigma) \text{ as } n \to \infty, \tag{4.9}$$

where χ_E stands for the characteristic function of the set E.

Proof of Theorem 4.1. The existence of the subsets E_ρ satisfying (4.2) and (4.3) is an easy consequence of Lemma 4.2. The main issue is to justify the Taylor expansion (4.4) for the trajectories y_ρ of (1.1) corresponding to the diffuse control perturbations. One clearly sees that (4.4) and (4.3) imply the increment formula (4.5) due to the construction of diffuse perturbations.

To prove (4.4), we pick a number $\rho \in (0,1)$, take the sets E^n_ρ from Lemma 4.2, and build the diffuse control perturbations

$$u^n_\rho(s,t) := \begin{cases} \bar{u}(s,t) & \text{on } \Sigma \setminus E^n_\rho, \\ u(s,t) & \text{on } E^n_\rho. \end{cases}$$

Let y^n_ρ be the solution of (1.1) corresponding to u^n_ρ and let z be the (unique) weak solution of (4.6). It is easy to see that for all n the function $\xi^n_\rho := (y^n_\rho - \bar{y})/\rho - z$ is the unique weak solution to the system

$$\begin{cases} \xi_{tt} - \Delta \xi + a^n_\rho \xi = f^n_\rho & \text{in } Q, \\ \partial_\nu \xi = w^n_\rho & \text{on } \Sigma, \\ \xi(0) = 0, \quad \xi_t(0) = 0 & \text{in } \Omega, \end{cases}$$

with the following data:

$$a_\rho^n := \int_0^1 \Phi_y'(\cdot, \bar{y}+\theta(y_\rho^n-\bar{y}))\, d\theta, \quad f_\rho^n := (\Phi_y'(\cdot,\bar{y})-a_\rho^n)z, \quad w_\rho^n := \left(1-\frac{1}{\rho}\chi_{E_\rho^n}\right)(u-\bar{u}).$$

Denote by $\xi_\rho^{n,1}$ the solution to

$$\begin{cases} \xi_{tt} - \Delta\xi + a_\rho^n \xi = f_\rho^n & \text{in } Q, \\ \partial_\nu \xi = 0 & \text{on } \Sigma, \\ \xi(0) = 0, \quad \xi_t(0) = 0 & \text{in } \Omega, \end{cases}$$

by $\xi_\rho^{n,2}$ the solution to

$$\begin{cases} \xi_{tt} - \Delta\xi + a_\rho^n \xi = 0 & \text{in } Q, \\ \partial_\nu \xi = w_\rho^n & \text{on } \Sigma, \\ \xi(0) = 0, \quad \xi_t(0) = 0 & \text{in } \Omega, \end{cases}$$

and by ζ_ρ^n the solution to

$$\begin{cases} \zeta_{tt} - \Delta\zeta + a\zeta = 0 & \text{in } Q, \\ \partial_\nu \zeta = w_\rho^n & \text{on } \Sigma, \\ \zeta(0) = 0, \quad \zeta_t(0) = 0 & \text{in } \Omega, \end{cases}$$

where $a(x,t) := \Phi_y'(x,t,\bar{y}(x,t))$. One clearly has

$$\begin{gathered} (\xi_\rho^{n,2}-\zeta_\rho^n)_{tt} - \Delta(\xi_\rho^{n,2}-\zeta_\rho^n) + a_\rho^n(\xi_\rho^{n,2}-\zeta_\rho^n) = (a-a_\rho^n)\zeta_\rho^n \quad \text{in } Q, \\ \partial_\nu(\xi_\rho^{n,2}-\zeta_\rho^n) = 0 \quad \text{on } \Sigma, \\ (\xi_\rho^{n,2}-\zeta_\rho^n)(0) = 0, \qquad (\xi_\rho^{n,2}-\zeta_\rho^n)_t(0) = 0 \quad \text{in } \Omega. \end{gathered}$$

By Lemma 3.2, we find a constant $C > 0$, independent of n and ρ, ensuring the following estimates for all $n = 1, 2, \ldots$ and $0 < \rho < 1$:

$$\begin{aligned} \|\xi_\rho^{n,2}-\zeta_\rho^n\|_{C([0,T];L^2(\Omega))} &\le C\|a-a_\rho^n\|_{L^1(0,T;L^{2N}(\Omega))}\|\zeta_\rho^n\|_{L^\infty(0,T;L^{2N/(N-1)}(\Omega))} \\ &\le C\|a-a_\rho^n\|_{L^1(0,T;L^{2N}(\Omega))}\|\zeta_\rho^n\|_{L^\infty(0,T;H^{1/2}(\Omega))}, \end{aligned} \tag{4.10}$$

$$\|\xi_\rho^{n,1}\|_{C([0,T];L^2(\Omega))} \le C\|f_\rho^n\|_{L^1(0,T;L^2(\Omega))}, \tag{4.11}$$

where $\|\zeta_\rho^n\|_{L^\infty(0,T;L^{2N/(N-1)}(\Omega))}$ are uniformly bounded due to Lemma 3.1. Taking (4.9) into account, we conclude that for all $0 < \rho < 1$ the sequence of w_ρ^n converges to zero in the weak topology of $L^2(\Sigma)$ and, by Lemma 3.3, the sequence of ζ_ρ^n converges to zero in $C([0,T];L^2(\Omega))$. Thus there is an integer $n(\rho)$ such that

$$\|\zeta_\rho^{n(\rho)}\|_{C([0,T];L^2(\Omega))} \le \rho \quad \text{for all } 0 < \rho < 1. \tag{4.12}$$

Observe further that $u_\rho^{n(\rho)}$ converge to $\bar{u}$ in $L^2(\Sigma)$ as $\rho \downarrow 0$. It follows now from Theorem 3.5 that $y_\rho^{n(\rho)}$ converge to $\bar{y}$ in $C([0,T];L^2(\Omega))$ as $\rho \downarrow 0$. Invoking assumption (A1), one has that $f_\rho^{n(\rho)}$ converge to zero in $L^1(0,T;L^2(\Omega))$ and that $(a-a_\rho^{n(\rho)})$ converge to zero in $L^1(0,T;L^{2N}(\Omega))$ as $\rho \downarrow 0$. This, together with (4.10)–(4.12), implies that

$$\begin{aligned} \lim_{\rho\to 0}\|\xi_\rho^{n(\rho)}\|_{C([0,T];L^2(\Omega))} \le \lim_{\rho\to 0}(&\|\xi_\rho^{n(\rho),1}\|_{C([0,T];L^2(\Omega))} + \|\xi_\rho^{n(\rho),2} \\ &-\zeta_\rho^{n(\rho)}\|_{C([0,T];L^2(\Omega))} + \|\zeta_\rho^{n(\rho)}\|_{C([0,T];L^2(\Omega))}) = 0. \end{aligned}$$

Finally, setting $E_\rho := E_\rho^{n(\rho)}$, $u_\rho := u_\rho^{n(\rho)}$, and $\frac{1}{\rho}r_\rho := \xi_\rho^{n(\rho)}$, we end the proof of the theorem. ∎

5. Proof of necessary optimality conditions. As mentioned, in the proof of our main theorem we are going to use *Ekeland's variational principle* [6], which is one of the most powerful tools of nonlinear analysis and is especially important in applications of variational methods. In the framework of deriving necessary optimality conditions for the state-constrained problem (P), Ekeland's variational principle allows us to perform an efficient *strong approximation* of the given optimal solution to the original problem by some functions that happen to be optimal solutions to *perturbed* optimal control problems with *no state constraints*. To accomplish this procedure, we first describe a complete metric space and a lower semicontinuous functional, which are suitable for the application of Ekeland's principle to our problem.

Given $\bar{u} \in U_{ad}$ and a fixed positive number k, we define the set

$$U_{ad}(\bar{u}, k) := \{u \in U_{ad} \mid |u(s,t) - \bar{u}(s,t)| \le k \text{ for a.e. } (s,t) \in \Sigma\}$$

and endow this set with the metric, which goes back to Ekeland's seminal paper [6],

$$d(v,u) := \mathcal{L}^N(\{(s,t) \mid v(s,t) \ne u(s,t)\}),$$

where $\mathcal{L}^N(\Omega)$ denotes as before the N-dimensional Lebesgue measure of $\Omega \subset \mathbb{R}^N$. Observe that if $\{u_n\} \subset U_{ad}(\bar{u}, k)$ and $u \in U_{ad}(\bar{u}, k)$ are such that $\lim_{n\to\infty} d(u_n, u) = 0$, then the sequence $\{u_n\}$ *strongly* converges to u in the norm of $L^2(\Sigma)$. The next result provides more information about this space and about the cost functional of (P) on it, where y_u stands for the weak solution of (1.1) corresponding to u.

LEMMA 5.1 (proper setting for Ekeland's principle). *The metric space* $(U_{ad}(\bar{u}, k), d)$ *is complete, and the mapping* $u \mapsto (y_u, J(y_u, u))$ *is continuous from* $(U_{ad}(\bar{u}, k), d)$ *into* $C([0,T]; L^2(\Omega)) \times \mathbb{R}$.

Proof. The completeness of the space $(U_{ad}(\bar{u}, k), d)$ is a well-known fact; cf. [6, 25]. Let us prove the continuity statement of the lemma based on the regularity of weak solutions to the state system (1.1) established in section 3.

Take $\{u_n\} \subset U_{ad}(\bar{u}, k)$ and $u \in U_{ad}(\bar{u}, k)$ such that the control sequence $\{u_n\}$ converges to u in the above d-metric as $n \to \infty$. Denote by y and by y_n the weak solutions of (1.1) corresponding to u and to u_n, respectively. Since $u_n \to u$ strongly in $L^2(\Sigma)$, the corresponding trajectories y_n converge to y in $C([0,T]; L^2(\Omega))$ by Theorem 3.5. Furthermore, it follows from the estimates in assumptions (A2)–(A4) that the sequence of values $J(y_n, u_n)$ converges to $J(y,u)$ as $n \to \infty$, which ensures the desired continuity. □

Now using the classical results in the geometry of Banach spaces presented, e.g., in [17, Chapter 2] (see Theorem 2.18 and Proposition 2.20 therein), we conclude by the separability of $C([0,T]; L^2(\Omega))$ that there is an equivalent norm $|\cdot|_{C([0,T];L^2(\Omega))}$ on this space such that it is Gâteaux differentiable at any nonzero point and its dual norm on $\mathcal{M}([0,T]; L^2(\Omega))$—denoted by $|\cdot|_{\mathcal{M}([0,T];L^2(\Omega))}$—is *strictly convex*. Given the constraint set $\mathcal{C} \subset C([0,T]; L^2(\Omega))$ in the original problem (P), we define the *distance function*

$$d_{\mathcal{C}}(x) := \inf_{z \in \mathcal{C}} |x - z|_{C([0,T];L^2(\Omega))} \tag{5.1}$$

via the new norm $|\cdot|_{C([0,T];L^2(\Omega))}$ on $C([0,T]; L^2(\Omega))$. Since $\mathcal{C}$ is convex, the distance function (5.1) is also convex, and it is Lipschitz continuous on $C([0,T]; L^2(\Omega))$ with rank 1. As is well known,

$$|\xi|_{\mathcal{M}([0,T];L^2(\Omega))} \le 1 \quad \text{whenever } \xi \in \partial d_{\mathcal{C}}(x) \text{ with } x \in \mathcal{C};$$

moreover, one has

$$|\xi|_{\mathcal{M}([0,T];L^2(\Omega))} = 1 \quad \text{for every } \xi \in \partial d_{\mathcal{C}}(x) \text{ and } x \notin \mathcal{C},$$

where $\partial d_{\mathcal{C}}$ stands for the *subdifferential* of convex analysis. Taking into account that the dual norm $|\cdot|_{\mathcal{M}([0,T];L^2(\Omega))}$ is strictly convex on $\mathcal{M}([0,T];L^2(\Omega))$, we conclude that the subdifferential $\partial d_{\mathcal{C}}(x)$ is a *singleton*, and hence $d_{\mathcal{C}}$ is *Gâteaux differentiable* at x for every $x \notin \mathcal{C}$.

Let $(\bar{y},\bar{u})$ be an optimal solution to the original problem (P). Using the distance function (5.1), we define the *penalized functional* by

$$J_k(y,u) := \left[\left(J(y,u) - J(\bar{y},\bar{u}) + \frac{1}{k^2}\right)^+\right]^2 + d^2_{\mathcal{C}}(y), \quad k = 1,2,\dots,$$

where J is the cost functional in (P). Since $J_k(\bar{y},\bar{u}) = k^{-4}$, one has that

$$J_k(\bar{y},\bar{u}) < \inf\{J_k(y,u) \mid u \in U_{ad}(\bar{u},k^{1/3}),\ (y,u) \text{ satisfies (1.1)}\} + \frac{1}{k^2},$$

for all k, i.e., $(\bar{y},\bar{u})$ is a $\frac{1}{k^2}$-*optimal solution* to the penalized problem.

Notice that the functional J_k is *smooth* at points where it *does not vanish*, in the sense that it is Gâteaux differentiable at such points; cf. [20] in the case of control systems governed by ordinary differential equations. This follows from the construction of J_k, assumptions (A2)–(A4), and the above property of (5.1). Ekeland's principle allows us to *strongly* approximate $(\bar{y},\bar{u})$ by a pair (y_k,u_k) satisfying (1.1) in such a way that (y_k,u_k) is an *exact solution* to some *perturbed* optimal control problem for system (1.1) with the same control constraints and *no state constraints*.

Proof of Theorem 2.1. We divide the proof of this theorem into the three major steps.

Step 1. *Approximating problems via Ekeland's principle.* Given an optimal solution $(\bar{y},\bar{u})$ to the original problem (P), we fix a natural number $k = 1,2,\dots$ and get from Lemma 5.1 that the metric space $(U_{ad}(\bar{u},k^{1/3}),d)$ is complete, and that the functional $u \longmapsto J_k(y_u,u)$ is lower semicontinuous (even continuous) on this space. By the Ekeland variational principle [6] we find an admissible control u_k satisfying

$$\begin{aligned} &u_k \in U_{ad}(\bar{u},k^{1/3}), \qquad d(u_k,\bar{u}) \le \frac{1}{k}, \quad \text{and} \\ &J_k(y_k,u_k) \le J_k(y_u,u) + \frac{1}{k}d(u_k,u) \quad \text{for all } u \in U_{ad}(\bar{u},k^{1/3}), \end{aligned} \tag{5.2}$$

where y_k and y_u are the weak solutions of (1.1) corresponding to u_k and u, respectively. The latter means that, for all natural numbers k, u_k is an *optimal solution* to the *perturbed problem*

$$\inf\left\{J_k(y,u) + \frac{1}{k} \,\middle|\, u \in U_{ad}(\bar{u},k^{1/3}),\ (y,u) \text{ satisfies (1.1)}\right\}. \tag{P_k}$$

Step 2. *Necessary conditions in approximating problems.* First take an arbitrary $u_0 \in U_{ad}$ and construct the following modification of $\bar{u}$ feasible to (P_k) by

$$u_{0k}(s,t) := \begin{cases} u_0(s,t) & \text{if } |u_0(s,t) - \bar{u}(s,t)| \le k^{1/3}, \\ \bar{u}(s,t) & \text{otherwise.} \end{cases} \tag{5.3}$$

Then, given any $0 \le \rho < 1$, we define *diffuse perturbations* of the optimal control u_k in (P_k) as

$$u_\rho^k(s,t) := \begin{cases} u_k(s,t) & \text{on } \Sigma \setminus E_\rho^k, \\ u_{0k}(s,t) & \text{on } E_\rho^k. \end{cases} \tag{5.4}$$

Theorem 4.1 ensures the existence of measurable sets $E_\rho^k \subset \Sigma$ for which $\mathcal{L}^N(E_\rho^k) = \rho\mathcal{L}^N(\Sigma)$,

$$y_\rho^k = y_k + \rho z_k + \rho r_\rho^k, \qquad \lim_{\rho\to 0} \|r_\rho^k\|_{C([0,T];L^2(\Omega))} = 0, \quad \text{and} \tag{5.5}$$

$$J(y_\rho^k, u_\rho^k) = J(y_k, u_k) + \rho\Delta J^k + o(\rho), \tag{5.6}$$

where y_ρ^k is the weak solution of (1.1) corresponding to u_ρ^k, where z_k is the weak solution to

$$\begin{cases} z_{tt} - \Delta z + \Phi_y'(\cdot, y_k)z = 0 & \text{in } Q, \\ \partial_\nu z = u_k - u_{0k} & \text{on } \Sigma, \\ z(0) = 0, \quad z_t(0) = 0 & \text{in } \Omega, \end{cases}$$

and where ΔJ^k is defined by

$$\Delta J^k := \int_Q g_y'(\cdot, y_k)z_k \, dxdt + \int_\Omega f_y'(\cdot, y_k(T))z_k \, dx + \int_\Sigma (h(\cdot, u_{0k}) - h(\cdot, u_k)) \, dsdt.$$

Since each u_ρ^k is clearly feasible for (P_k), from (5.2) and the construction of the metric d, we deduce that

$$\lim_{\rho\to 0} \frac{J_k(y_k, u_k) - J_k(y_\rho^k, u_\rho^k)}{\rho} \le \frac{1}{k}\mathcal{L}^N(\Sigma). \tag{5.7}$$

Observe that $J_k(y_k, u_k) \ne 0$ for all k due to the optimality of u_k in (P_k) and the structure of J_k. Hence J_k is *Gâteaux differentiable* at (y_k, u_k) by the discussion above. Then it easily follows from (5.6) and (5.7) that

$$-\lambda_k\Delta J^k - \langle \mu_k, z_k \rangle \le \frac{1}{k}\mathcal{L}^N(\Sigma), \tag{5.8}$$

where the multipliers λ_k and μ_k are computed by

$$\lambda_k := \frac{(J(y_k, u_k) - J(\bar{y}, \bar{u}) + \frac{1}{k^2})^+}{J_k(y_k, u_k)}, \qquad \mu_k := \begin{cases} \dfrac{d_{\mathcal{C}}(y_k)\nabla d_{\mathcal{C}}(y_k)}{J_k(y_k, u_k)} & \text{if } y_k \notin \mathcal{C}, \\ 0 & \text{otherwise.} \end{cases}$$

Observe that $\mu_k \in \mathcal{M}([0,T]; L^2(\Omega))$. Now let p_k be the (unique) weak solution to the *adjoint system*

$$\begin{cases} p_{tt} - \Delta p + \Phi_y'(\cdot, y_k)p = \lambda_k g_y'(\cdot, y_k) + \mu_k|_Q & \text{in } Q, \\ \partial_\nu p = 0 & \text{on } \Sigma, \\ p(T) = 0, \quad p_t(T) = -\lambda_k f_y'(\cdot, y_k(T)) - \mu_k|_{\Omega\times\{T\}} & \text{in } \Omega, \end{cases} \tag{5.9}$$

where $\mu_k|_Q$ and $\mu_k|_{\Omega\times\{T\}}$ are the restrictions of μ_k to Q and $\Omega\times\{T\}$, respectively. Employing the Green formula in Theorem 3.9, we have

$$\begin{aligned}\lambda_k\int_Q g'_y(x,t,y_k)z_k\,dxdt+\lambda_k\int_\Omega f'_y(x,y_k(T))z_k(T)\,dx+\langle\mu_k,z_k\rangle\\ =\int_Q p_k(z_{ktt}-\Delta z_k+\Phi'_y(\cdot,y_k)z_k)\,dxdt+\int_\Sigma p_k\partial_\nu z_k\,dsdt\\ =\int_\Sigma p_k(u_k-u_{0k})\,dsdt.\end{aligned}$$

The latter implies, by (5.8) and the definition of ΔJ^k, that

$$\int_\Sigma(\lambda_k h(s,t,u_k)+p_k u_k)\,dsdt\le\int_\Sigma(\lambda_k h(s,t,u_{0k})+p_k u_{0k})\,dsdt+\frac{1}{k}\mathcal{L}^N(\Sigma) \tag{5.10}$$

for every $k=1,2,\dots$, which gives necessary optimality conditions for the solutions u_k to the approximating problems (P_k).

Step 3. *Passing to the limit.* To conclude the proof of the theorem, we need to pass to the limit in the above relations for the optimal solutions u_k to (P_k) as $k\to\infty$. First observe that

$$\lambda_k^2+|\mu_k|^2_{\mathcal{M}([0,T];L^2(\Omega))}=1\quad\text{for all } k=1,2,\dots.$$

Invoking basic functional analysis, we find an element $(\lambda,\bar\mu)\in\mathbb{R}\times\mathcal{M}([0,T];L^2(\Omega))$, with $\lambda\ge0$, and a subsequence of (λ_k,μ_k), still indexed by k, such that

$$\lambda_k\to\lambda\quad\text{in }\mathbb{R}\quad\text{and}\quad\mu_k\rightharpoonup\bar\mu\quad\text{weak}^*\text{ in }\mathcal{M}([0,T];L^2(\Omega)).$$

Furthermore, Theorem 3.8 ensures the estimate

$$\begin{aligned}&\|p_k\|_{L^\infty(0,T;H^1(\Omega))}+\|p_{kt}\|_{L^\infty(0,T;L^2(\Omega))}\\ &\quad\le C(\|\mu\|_{\mathcal{M}([0,T];L^2(\Omega))}+\|g'_y(\cdot,y_k)\|_{L^1(0,T;L^2(\Omega))}+\|f'_y(\cdot,y_k(T))\|_{L^2(\Omega)}).\end{aligned}$$

Since the sequences $\{\lambda_k\}\subset\mathbb{R}$, $\{\mu_k\}\subset\mathcal{M}([0,T];L^2(\Omega))$, $\{y_k\}\subset C([0,T];L^2(\Omega))$, and $\{u_k\}\subset L^2(\Sigma)$ are bounded, the sequence $\{(p_k,p_{kt})\}$ is bounded in $L^\infty(0,T;H^1(\Omega))\times L^\infty(0,T;L^2(\Omega))$. Then there is a subsequence of $\{(p_k,p_{kt})\}$ converging to some (p,p_t) in the weak* topology of $L^\infty(0,T;H^1(\Omega))\times L^\infty(0,T;L^2(\Omega))$ and a subsequence of $\{y_k\}$ converging to some $\bar y\in L^\infty(0,T;L^2(\Omega))$ in the weak* topology of $L^\infty(0,T;L^2(\Omega))$. We already know that $\{u_k\}$ tends to $\bar u$ in $L^2(\Sigma)$. Employing standard arguments, we prove that $(\bar y,\bar y_t)$ is the solution of (1.1) corresponding to $\bar u$, and that (p,p_t) is the (unique) weak solution of (2.4) corresponding to $\bar y$.

We choose $(\lambda,\mu)=(\lambda,\bar\mu|_{]0,T]})$ as the multipliers for the necessary optimality conditions stated in Theorem 2.1. Taking into account assumption (A5) on the convexity and nonemptiness interiority of the set $\mathcal{C}$, one has the necessary condition (2.2) for the limiting multipliers (λ,μ). In particular, let us verify that $(\lambda,\mu)\ne0$. Suppose the contrary, which gives

$$\lim_{k\to\infty}|\mu_k|^2_{\mathcal{M}([0,T];L^2(\Omega))}=1. \tag{5.11}$$

By assumption (A5) we have $\hat y_0\in\operatorname{int}\mathcal{C}$. Thus there exists a ball $B(\hat y_0,\rho)$ in $C([0,T];L^2(\Omega))$ centered at $\hat y_0$ with radius $\rho>0$ such that $B(\hat y_0,\rho)\subset\mathcal{C}$. Using (5.11) and taking any $k=1,2,\dots$, we find $z_k\in B(0,\rho)$ satisfying

$$\langle z_k,\mu_k\rangle_{C([0,T];L^2(\Omega)),\mathcal{M}([0,T];L^2(\Omega))}=\frac{\rho}{2}|\mu_k|_{\mathcal{M}([0,T];L^2(\Omega))}.$$

Since $\hat{y}_0 + z_k \in \mathcal{C}$, one has by definition of μ_k that

$$\langle \hat{y}_0 + z_k - y_k, \mu_k \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}([0,T];L^2(\Omega))} \leq 0 \quad \text{for all } k = 1, 2, \dots .$$

Passing to the limit as $k \to \infty$, we get

$$\frac{\rho}{2} + \langle \hat{y}_0 - \bar{y}, \bar{\mu} \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}([0,T];L^2(\Omega))} \leq 0.$$

Remember that $\bar{y}(x,0) = \hat{y}_0(x,0)$ and $\mu = \bar{\mu}|_{]0,T]}$; therefore

$$\langle \hat{y}_0 - \bar{y}, \bar{\mu} \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}([0,T];L^2(\Omega))} = \langle \hat{y}_0 - \bar{y}, \mu \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T];L^2(\Omega))},$$

which implies that

$$\langle \hat{y}_0 - \bar{y}, \mu \rangle_{C([0,T];L^2(\Omega)),\mathcal{M}_b(]0,T];L^2(\Omega))} \leq -\frac{\rho}{2} < 0.$$

The latter contradicts the assumption on $(\lambda, \mu) = 0$ and thus justifies the nontriviality condition in the theorem.

It remains to verify the minimum condition (2.3). To do this, recall that $u_k \to \bar{u}$ strongly in $L^2(\Sigma)$. Passing to the limit as $k \to \infty$ in (5.10), we get

$$\int_\Sigma (\lambda h(s,t,\bar{u}) + p\bar{u})\, dsdt \leq \int_\Sigma (\lambda h(s,t,u_0) + pu_0)\, dsdt \quad \text{for all } u_0 \in U_{ad}. \tag{5.12}$$

Finally, taking into account the structure of U_{ad} in (A6) and employing the standard arguments (see, e.g., [25, section 5.2]), we derive the pointwise condition (2.3) from the integral one in (5.12). □

OPTIMAL CONTROL OF UNCERTAIN SYSTEMS WITH INCOMPLETE INFORMATION FOR THE DISTURBANCES*

MARC QUINCAMPOIX† AND VLADIMIR M. VELIOV‡

Abstract. We investigate the problem of optimization of a terminal cost function for a system depending on a control, and on two disturbances for which a priori set membership is known. The disturbances are of different natures: One becomes known to the controller at the current time (we called it observable) while the other remains unknown. No state measurements are available. The problem can be viewed as a differential game of min-max type where the controller aims at minimization of the objective function by a strategy which depends only on the observable disturbance. Since the state of the system is not exactly known due to the presence of an unobservable disturbance, we reformulate the problem through a set-valued dynamics describing the evolution of the current set estimation of the state. To reduce the complexity of the problem, we pass to a suboptimal problem where the evolution of the state estimation is restricted to a prescribed collection of sets. The main result of the paper is a characterization of the value function of this problem through a Hamilton–Jacobi inequality in terms of Dini derivatives, which implies a convergent scheme for numerical computations. As necessary auxiliary tools, we provide new results on evolution and viability of tubes in a given collection of sets that may be of independent interest.

1. Introduction.

We consider the system

$$\dot{x} = f(x, u, y, v), \qquad x(0) = e \in E_0, \tag{1}$$

where $x \in \mathbf{R}^n$ is the state, $u \in U$ is the control, and $y \in Y$ and $v \in V(y)$ are disturbances (U, Y, and $V(y)$ are given subsets of finite dimensional spaces $E_0 \subset \mathbf{R}^n$). The main concern of the paper is the optimal control problem where the controller wants to minimize (by choosing u) the cost

$$g(T, x(T)) \tag{2}$$

against the worst case of disturbances y and v and initial state $e \in E_0$. We distinguish two types of disturbance:

- *observable uncertainty* y, for which the current realization $y(t) \in Y$ becomes known to the controller;
- *unobservable uncertainty* $v \in V(y)$, for which the realization of $v(t) \in V(y(t))$ remains unknown.

Thus we consider a min-max problem or a differential game where the second player wants to maximize (by choosing e, y, and v) the cost (2) while the first player—the controller—wants to minimize it (by choosing u). The information available to the controller implies that the control u should be considered in a feedback form which may depend on the current and the past values of y, but not on v.

For every given open-loop control $u(\cdot)$ and observable uncertainty $y(\cdot)$, the unobservable uncertainty $v(\cdot)$ gives rise to a differential inclusion

$$\dot{x} \in f(x, u(t), y(t), V(y(t))), \qquad x(0) \in E_0, \tag{3}$$

whose solution is a time-dependent tube providing the deterministic estimation of the trajectory. Notice that a (set-valued) tube starting from E_0 is involved even in the case of precisely known initial state $x(0)$, due to the unobservable uncertainty.

Let us formulate the problem in a more precise way. Let $\mathcal{U}_{[t,\theta]}$ be the set of all open-loop admissible controls on the interval $[t, \theta]$, that is, the measurable functions with values in U. Similarly, $\mathcal{Y}_{[t,\theta]}$ denotes the set of all measurable selections of Y on $[t, \theta]$, and $\mathcal{V}_{[t,\theta]}(y(\cdot))$ denotes the set of all measurable selections of the mapping $V(y(\cdot))$ (for a given $y(\cdot)$) on the same interval. The suppositions formulated in section 4 will imply that for any $t \in [0, T)$, $e \in \mathbf{R}^n$, $u \in \mathcal{U}_{[t,T]}$, $y \in \mathcal{Y}_{[t,T]}$, and $v \in \mathcal{V}_{[t,T]}(y)$ system (1) has a unique solution on $[t, T]$ starting from e, denoted by $x[t, e; u, y, v](\cdot)$.

To make use of the dynamic programming principle, we consider problem (1), (2) also for an arbitrary initial time t and initial set E, instead of the fixed $t = 0$ and $E = E_0$. The optimal control for initial time t and initial compact set E is sought as a *nonanticipative strategy* (called also a Varaiya–Roxin–Elliot–Kalton strategy [17]; cf. the definition in section 4), $\alpha : \mathcal{Y}_{[t,T]} \mapsto \mathcal{U}_{[t,T]}$. The guaranteed result obtained by using the strategy α for initial data (t, E) is

$$I(t, E; \alpha) \stackrel{def}{=} \sup\{g(T, x[t, e; \alpha(y), y, v](T));\ e \in E,\ y \in \mathcal{Y}_{[t,T]},\ v \in \mathcal{V}_{[t,T]}(y)\}.$$

Then

$$I(t, E) \stackrel{def}{=} \inf_{\alpha} I(t, E; \alpha) \tag{4}$$

is the minimal guaranteed (lower) value that can be achieved starting from the set E at time t.

As previous works indicate (see [7, 8, 6]), the optimal control problem in the case of incomplete/inexact information is qualitatively different compared with the perfect information case, since the corresponding Hamilton–Jacobi–Isaacs (HJI) equation for the value function becomes, essentially, infinite dimensional. It is shown in [8] that the problem with incomplete measurement can be reformulated as a problem with complete information in the *information space*, which, however, is infinite dimensional.[1] In contrast, in the present paper we reformulate the problem as such with complete information, but for a dynamic system in the *estimation space*, which, in principle, is also infinite dimensional, but in some cases can be equivalently replaced by a finite dimensional one. In this case the corresponding HJI equation is finite dimensional. (A finite dimensional HJI equation was derived in [30] for a specific game on the plane where the state information is incomplete by employing the certainty equivalence principle [7, 9].) If this is not the case, one can still formulate a "suboptimal"

[1] We stress the fact that the *state* is partially measured in these papers, while we suppose that the *disturbance* in the equation is partially measured, while state measurements are not available.

version of the problem by restricting the consideration to an estimation space, which is a finitely parametrized collection of sets. To develop the technique for passing to such a "suboptimal" problem and its analysis is one of our main goals.

To pass to a finitely parametrized estimation we recall in section 2 the concept of solution tubes in a given collection of compact sets developed in [29]. We restrict the presentation to more special collections than in [29] which are more convenient for the present paper, but we add some necessary new facts. In particular, we prove in section 2.2 the continuous dependence of the solution tubes on data, which is essential for the subsequent analysis. For $y(\cdot)$ fixed, (3) can be considered as a controlled differential inclusion whose solution tube takes values in the given collection. Therefore the next step is to develop the viability theory for collections of sets and controlled differential inclusions. In section 3 we extend some of our results from [28] to the case of controlled inclusions and to the concept of *viability with a target* introduced in [27], which is essential for the control problem considered here. To maintain the flow of the paper some technical proofs are postponed until the last section.

With the appropriate viability theory at hand, we cope with problem (2), (1) in section 4. We can consider the end time T as fixed but, in fact, in section 4 the end time is determined by a terminal condition, which, if certainly reached (that is, reached for all possible realizations of the unobservable uncertainty), then the control process terminates and the performance index is evaluated. This formulation includes minimal time problems.

Our main result extends that of [10], the latter concerning the "classical" case where unobservable uncertainty is not present and the initial state is precisely known. We prove that the value function of the problem is the unique minimal Dini supersolution of the respective HJI equation. The epigraph of the value function is characterized also as the maximal set that for every $y \in Y$ is a viability domain (in a specified collection of sets) for an auxiliary controlled inclusion depending on y. This makes it possible to apply an appropriate modification of the viability kernel algorithm (see [31, 11]) for numerical calculation. The applicability of such a modification is, in principle, shown in [25] (where, however, a discrete-time problem in a somewhat different setting is considered) including numerical schemes and examples. In the last part of section 4 we also discuss the suppositions and possible extensions.

We mention that the material in sections 2 and 3 is aimed at solving the control problem formulated above, but the results presented there could also be useful for other control/estimation problems for continuous-time uncertain systems.

2. Solution tubes in a collection of sets. The reachable set of a differential inclusion (the latter interpreted as an uncertain system, as in (3)) is the minimal guaranteed estimation of the current state. Therefore, to calculate reachable sets is a cornerstone of the deterministic estimation and control of uncertain systems (see, e.g., [21]) and a lot of work has been done toward developing numerical approximation methods (see, e.g., the surveys [15, 24]). Since the geometry of the reachable sets could be rather complicated, specific subclasses of sets are usually used as approximation tools: boxes, polyhedral sets, ellipsoids (see [12, 22, 13, 23]), box or polyhedral complexes (see [31, 19, 11, 20]), etc. In some cases convergence results are obtained, but usually, to achieve a good approximation, one has to use rather complex approximating sets. On the other hand, in problems of control of uncertain systems and differential games, where the state estimation is just an auxiliary tool, one has to employ only fairly simple sets. (The associated HJI equation, for example, has the dimension of the state estimators, and therefore the latter should not be too large.)

In such cases the issue of *approximation* is not that relevant. A different problem arises: to obtain inclusions of the reachable set in sets from a prescribed collection $\mathcal{E}$, that is, to replace the solution tube $X(t)$ of the differential inclusion by a tube $E(t)$ with values in $\mathcal{E}$. In doing this, one has to ensure at least $X(t) \subset E(t)$, but two more properties are also desirable: (i) the Markov property of the evolution of $E(\cdot)$, which, together with $X(t) \subset E(t)$, requires invariance of the tube $E(t)$ with respect to the differential inclusion, and (ii) minimality.

In this section we modify some results from our paper [29] (where more bibliographical data and examples are provided) and establish some new ones needed in the subsequent sections.

2.1. Definitions and main suppositions. We shall use the following notation: $\mathcal{B}$ is the Euclidean unit ball in $\mathbf{R}^n$, $\mathrm{comp}(\mathbf{R}^n)$ is the set of all nonempty compact subsets of $\mathbf{R}^n$, $\mathrm{dist}(X,Y) \stackrel{def}{=} \sup_{x\in X} \inf_{y\in Y} |x-y|$ is the distance from $X \in \mathrm{comp}(\mathbf{R}^n)$ to $Y \in \mathrm{comp}(\mathbf{R}^n)$, $|X| = \mathrm{dist}(X,\{0\})$, and $H(X,Y) = \max\{\mathrm{dist}(X,Y), \mathrm{dist}(Y,X)\}$ is the Hausdorff distance between X and Y. Multiplication of a set with a scalar and summation of sets are understood in the usual (Minkowski) sense. For a set X, $f(X)$ stays for $\{f(x);\ x \in X\}$. For a given closed $X \subset \mathbf{R}^n$, the set of all Hausdorff continuous mappings $X \mapsto \mathrm{comp}(\mathbf{R}^n)$ is a complete metric cone (with respect to the Minkowski operations), which will be denoted by $C(X; \mathrm{comp}(\mathbf{R}^n))$.

Definition. A set-valued map $E(\cdot) : [0,T] \Rightarrow \mathbf{R}^n$ is called a *tube*. Throughout this paper it would be convenient to use the term "tube" only for mappings $E(\cdot)$ that have nonempty compact values and a closed graph. A tube is *Lipschitz continuous* if there is a constant L such that

$$H(E(s), E(t)) \le L|t-s| \quad \text{for every } s,t \in [0,T].$$

We consider a differential inclusion

$$\dot{x} \in F(x,t), \quad x \in \mathbf{R}^n,\ t \in [0,T], \tag{5}$$

supposing the following.

Condition A. $F : \mathbf{R}^n \times [0,T] \Rightarrow \mathbf{R}^n$ is a set-valued mapping with nonempty convex, compact values, measurable in t for every fixed x, and locally Lipschitz continuous in x uniformly with respect to t. Moreover, F satisfies the linear growth condition

$$|F(x,t)| \le a(1+|x|) \quad \forall x \in \mathbf{R}^n,\ t \in [0,T].$$

As usual, a solution to (5) is any absolutely continuous function that satisfies (5) for a.e. t. Given a set of initial states $E_0 \subset \mathbf{R}^n$, the solution tube of (5) on $[0,T]$ is defined as

$$X(s) \stackrel{def}{=} X[0,E_0](s) \stackrel{def}{=} \{x(s);\ x(\cdot) - \text{solution of (5) on } [0,s] \quad \text{with } x(0) \in E_0\}.$$

This is the unique *minimal* tube that starts from E_0 at $t=0$ and is *invariant* with respect to (5), the latter meaning that

$$\forall s \in [0,T) \quad \forall\, x(\cdot) - \text{solution of (5) on } [s,T] \quad \text{with } x(s) \in X(s) \\ \Rightarrow x(t) \in X(t) \quad \forall t \in [s,T].$$

Here and below, "minimal," when applied to sets, means "minimal with respect to inclusion"; when applied to tubes, minimality is meant with respect to the partial ordering in which $E_1(\cdot) \prec E_2(\cdot)$ if and only if $E_1(t) \subset E_2(t)$ for every $t \in [0,T]$.

Definition. Let $\mathcal{E}$ be a given collection of compact sets in $\mathbf{R}^n$. The tube $E(\cdot) : [0,T] \mapsto \mathrm{comp}(\mathbf{R}^n)$ is called the *solution tube of* (5) *in the collection* $\mathcal{E}$ if and only if $E(\cdot)$ is a minimal invariant tube with values in $\mathcal{E}$.

The above definition meets the requirements (i) and (ii) formulated in the preamble of this section and extends the usual concept of a solution tube. Clearly, $X[0,E_0](\cdot)$ is the unique solution tube in the collection $\mathcal{E} = \mathrm{comp}(\mathbf{R}^n)$, starting from E_0. To ensure the existence of a solution tube in a more general collection $\mathcal{E}$ we introduce the following conditions for $\mathcal{E}$.

Condition B.1. The collection $\mathcal{E}$ consists of nonempty compact sets and is closed in the Hausdorff metric. For every compact Z there is some $E \in \mathcal{E}$ containing Z.

Condition B.2. There exists a constant $L_{\mathcal{E}}$ such that for each $\varepsilon > 0$ and each $E \in \mathcal{E}$ there exists $E' \in \mathcal{E}$ for which $E + \varepsilon\mathcal{B} \subset E' \subset E + \varepsilon L_{\mathcal{E}}\mathcal{B}$.

Obviously Conditions B.1 and B.2, together with the Zorn lemma, imply that for every $Z \in \mathrm{comp}(\mathbf{R}^n)$ there exists a minimal element of $\mathcal{E}$ containing Z.

Condition B.3. For every $Z \in \mathrm{comp}(\mathbf{R}^n)$ there is a unique minimal element of $\mathcal{E}$ containing Z.

The last condition is not necessary for many of the considerations below, including the existence, but it is convenient in the context of the optimal control problem investigated in the present paper.

2.2. Existence and continuity of the solution tubes.

THEOREM 2.1 (adapted from [29]). *Suppose that Conditions* A *and* B.1–B.3 *are fulfilled. Then for every* $E_0 \in \mathcal{E}$ *inclusion* (5) *has a unique solution tube in* $\mathcal{E}$ *starting from* E_0*, it satisfies the growth estimation*

$$E(t) \subset E_0 + (1 + |E_0|)(e^{2a(L_{\mathcal{E}}+1)t} - 1)\mathcal{B}, \tag{6}$$

and is Lipschitz continuous with Lipschitz constant $2a(1 + L_{\mathcal{E}})(1 + |E_0|)e^{2a(1+L_{\mathcal{E}})T}$.

COROLLARY 2.2. *For every* $E_0 \in \mathcal{E}$ *inclusion* (5) *has a unique solution tube in* $\mathcal{E}$ *on* $[0, +\infty)$*, starting from* E_0*. The solution tube is contained in every invariant tube of* (5) *starting from* E_0 *and taking values in* $\mathcal{E}$.

In the next sections we shall need the following continuity property of the solution tubes. Let us consider a sequence of differential inclusions of the form

$$\dot{x} \in F_0^k(x,s) + B^k(x,s)u_k(s), \tag{7}$$

where $F_0^k : \mathbf{R}^n \times [t_k, T] \Rightarrow \mathbf{R}^n$, $u_k : [t_k, T] \mapsto U$, U is a subset of a finite dimensional space, and B^k is a matrix function with appropriate size.

PROPOSITION 2.3. *Let the following conditions be fulfilled:*

(i) *For every* $k = 0, 1, \ldots$, *the mapping* $F^k(x,s) \stackrel{def}{=} F_0^k(x,s) + B^k(x,s)u_k(s)$ *satisfies Condition* A *with the growth constant* a *independent of* k; B^k *are measurable in* s*, locally Lipschitz continuous in* x*, uniformly in* s; U *is compact; the functions* $u_k(\cdot)$ *are measurable; and the collection* $\mathcal{E}$ *satisfies Condition* B.

(ii) $t_k \in [0,T]$ *and* $E_0^k \in \mathcal{E}$, $k = 0, 1, \ldots$, *are such that* $\lim_{k\to+\infty} t_k = t_0$, $\liminf_{k\to+\infty} \mathrm{dist}(E_0^0, E_0^k) = 0$ *and* $u_k(\cdot)$ *converges* L_1*-weakly to* $u_0(\cdot)$*; for every compact set* Z

$$\liminf_{k\to+\infty} \int_0^T \sup_{x\in Z} [\mathrm{dist}(F_0^0(x,s), F_0^k(x,s)) + |B^k(x,s) - B^0(x,s)|]\,\mathrm{d}s = 0.$$

Let $E_k(\cdot) : [t_k, T] \mapsto \mathcal{E}$ *be the solution tube in* $\mathcal{E}$ *of* (7), $k = 0, 1, \ldots$, *starting from* E_0^k *at time* t_k*. Then there is a subsequence of* $\{E_k(\cdot)\}$ *that converges uniformly to*

some tube $E(\cdot) : [t_0, T] \mapsto \mathcal{E}$. *Every such limit tube* $E(\cdot)$ *is Lipschitz continuous, and* $E_0(t) \subset E(t)$ *for all* $t \in [t_0, T]$.

Proof. To avoid the obvious extension/restriction technicalities needed to cope strictly with the case $t_k \neq t_0$, we assume that $t_k = t_0$ in the proof below. Since the growth constant a is the same for all k, from Theorem 2.1 it follows that the tubes $E_k(\cdot)$ are equi-Lipschitz, and therefore, also equibounded. According to the Arzelà–Ascoli theorem applied to the space $C([t, T]; \mathcal{E})$, there is a subsequence uniformly converging to a tube $E(\cdot)$. To avoid multiple indexes, we suppose that the whole sequence is convergent and that the two "liminf" in supposition (ii) of the proposition are "lim." We shall prove that $E(\cdot)$ is an invariant tube for (7) with $k = 0$, which implies the claim of the proposition according to Corollary 2.2.

To prove the invariance of $E(\cdot)$, we take an arbitrary $\tau \in [t_0, T)$ and an arbitrary trajectory $x(\cdot)$ of (7) with $k = 0$, starting from a point $x_0^0 \in E(\tau)$. Then we define the Carathéodory selection

$$\psi_k(x, s) = \mathcal{P}_{F_0^k(x,s)}(\dot{x}(s) - B^0(x(s), s)u_0(s))$$

of F_0^k (where $\mathcal{P}_Z(y)$ is the projection of y on the convex compact set Z) and consider the equation

$$\dot{x}_k(s) = \psi_k(x_k(s), s) + B^k(x_k(s), s)u_k(s), \qquad x_k(\tau) = x_k^0,$$

where x_k^0 is chosen from $E_k(\tau)$ in such a way that $|x_0^0 - x_k^0| \leq \operatorname{dist}(E(\tau), E_k(\tau)) \stackrel{def}{=} \rho_k$. Thus $\rho_k \to 0$. Moreover, obviously

$$\begin{aligned}
|\psi_k(x_k(s), s) - (\dot{x}(s) - B^0(x(s), s)u_0(s))| &\leq \operatorname{dist}(F_0^0(x(s), s), F_0^k(x_k(s), s)) \\
&\leq H(F_0^0(x(s), s), F_0^0(x_k(s), s)) + \operatorname{dist}(F_0^0(x_k(s), s), F_0^k(x_k(s), s)) \\
&= H(F_0^0(x(s), s), F_0^0(x_k(s), s)) + \gamma_k(s),
\end{aligned}$$

where $\gamma_k \stackrel{def}{=} \int_\tau^T \gamma_k(s)\,\mathrm{d}s \to 0$ due to (ii) and the uniform boundedness of $x_k(\cdot)$. For the same reason,

$$\delta_k \stackrel{def}{=} \int_\tau^T |B^k(x_k(s), s) - B^0(x_k(s), s)|\,\mathrm{d}s \to 0.$$

Then we have

$$\begin{aligned}
&|x_k(s) - x(s)| \\
&\quad \leq \rho_k + \gamma_k + \int_\tau^s H(F_0^0(x(\theta), \theta), F_0^0(x_k(\theta), \theta))\,\mathrm{d}\theta \\
&\qquad + \left| \int_\tau^s [B^k(x_k(\theta), \theta)u_k(\theta) - B^0(x(\theta), \theta)u_0(\theta)]\,\mathrm{d}\theta \right| \\
&\quad \leq \rho_k + \gamma_k + \int_\tau^s L|x_k(\theta) - x(\theta)|\,\mathrm{d}\theta + \delta_k + \int_\tau^s L|x_k(\theta) - x(\theta)||U|\,\mathrm{d}\theta \\
&\qquad + \left| \int_\tau^s [B^0(x(\theta), \theta)(u_k(\theta) - u_0(\theta))]\,\mathrm{d}\theta \right|,
\end{aligned}$$

where $|U| \stackrel{def}{=} \operatorname{dist}(U, \{0\})$, L is the Lipschitz constant of $F_0^0(\cdot, s)$, and $B^0(\cdot, s)$ in a compact set Z that contains all $x_k(s)$. Since the last term is continuous and tends to

zero with k, the Gronwall inequality implies that $x_k(s) \to x(s)$. From the invariance of $E_k(\cdot)$ we have $x_k(s) \in E_k(s)$ for every $s \in [\tau, T]$, and therefore $x(s) \in E(s)$. This proves the invariance of $E(\cdot)$, and thus the claim of the theorem thanks to Corollary 2.2. □

Remark 2.4. In the case of single-valued F_0^k and E_0, the above theorem holds without the supposition that the second summand in (7) is linear in u. An example showing that Proposition 2.3 is false for nonaffine inclusions (even with single-valued F_0^k and convex compact-valued $f_1^k(x, s, U)$) is given in the next subsection.

2.3. Particular cases and examples. Every collection of closed sets $\mathcal{E}$ can be represented as consisting of sublevel sets of a parametric family of Lipschitz functions. Namely, if we define

$$\varphi(E, x) = \operatorname{dist}(x, E), \quad E \in \mathcal{E},\ x \in \mathbf{R}^n,$$

and denote $P = \mathcal{E}$, then obviously

$$E \in \mathcal{E} \Leftrightarrow \exists p \in P :\ E = E(p), \quad \text{where } E(p) \stackrel{def}{=} \{x \in \mathbf{R}^n;\ \varphi(p, x) \le 0\}. \tag{8}$$

For practical reasons, however, we are mainly interested in collections $\mathcal{E}$ that admit a parameterization as in (8) with a set P being a subset of a finite dimensional space, as in the examples below, which are especially convenient and easy for calculation.

(a) Let us fix a finite or countable subset $L = \{l_1, l_2, \dots\}$ of the unit sphere $\partial\mathcal{B} \subset \mathbf{R}^n$ such that the convex cone spanned by L coincides with $\mathbf{R}^n$. With every $Z \in \operatorname{comp}(\mathbf{R}^n)$ we associate the sequence of numbers $p(Z) = (p_1, p_2, \dots)$, where $p_i = \max_{z \in Z} \langle l_i, z\rangle$. Denote $P \stackrel{def}{=} \{p(Z);\ Z \in \operatorname{comp}(\mathbf{R}^n)\}$.

It is easy to check that the corresponding collection $\mathcal{E}_L \stackrel{def}{=} \{E(p);\ p \in P\}$ satisfies Conditions B.1–B.3. It may consist of all convex compact subsets of $\mathbf{R}^n$ (if L is dense in $\partial\mathcal{B}$), of all "boxes" (if $L = \{\pm e_i\}_{i=1}^n$ with $\{e_i\}_i$—an orthogonal basis in $\mathbf{R}^n$), and of all polyhedrons with given normal vectors to the faces.

(b) The following is an alternative collection $\mathcal{E}$ that satisfies Conditions B.1–B.3. Let us fix the points $z_1, \dots, z_N \in \mathbf{R}^n$, $N \ge 1$, and define

$$\mathcal{E} \stackrel{def}{=} \left\{ \bigcap_{i=1,\dots,N} (z_i + s_i\mathcal{B}),\ s = (s_1, \dots, s_N) \in S \right\},$$

where S is the set of those s for which the intersection is nonempty. For every $Z \in \operatorname{comp}(\mathbf{R}^n)$, the unique minimal element from $\mathcal{E}$ that contains Z has

$$s_i = \operatorname{dist}(Z, z_i).$$

(c) Similarly, as in the collection in (b), instead of translated sublevel sets of the Euclidean norm, one may use sublevel sets of a collection of other functions defined in $\mathbf{R}^n$, caring that Conditions B.1–B.3 are satisfied. Such a collection may involve nonconvex sets and may be "adapted" to a given differential inclusion in such a way that reachable sets initiated from elements of the collection are well approximated (locally in time) by other elements of the collection.

Example 2.5 (proof of the negative claim in Remark 2.4). Consider the system

$$\begin{aligned} &\dot{x}_1 = u_1, \quad \dot{x}_2 = u_1^2 + (1 + x_3^2)u_2 - 1, \quad \dot{x}_3 = 0, \\ &U = \{(u_1, u_2);\ -1 \le u_1 \le 1,\ 0 \le u_2 \le 1 - u_1^2\}. \end{aligned} \tag{9}$$

Notice that the right-hand side of the corresponding differential inclusion is convex and compact for every x. Let us consider the collection $\mathcal{E} = \mathrm{comp}(\mathbf{R}^n)$ and the initial element $E_0 = (0, 0, [-1, 1])$. Define the sequence u_1^k on $[0, 1]$ such that u_1^k switches alternatively between -1 and 1 at times $t = i/k$, $i = 0, 1, \dots, k-1$, and define $u_2^k \equiv 0$. Then $E_k(t) = (x_1^k(t), 0, [-1, 1])$ with $x_1^k(t) = \int_0^t u_1^k(s)\,\mathrm{d}s$ is a solution tube of (9). Obviously $x_1^k(\cdot) \to 0$ and $E_k(\cdot) \to E_0$ (since u_1^k converges weakly to zero, $(u_1^k)^2 \equiv 1$, and $x_2(0) = 0$). The last set, however, is neither a solution tube nor contains such a tube starting from E_0. Indeed, if E_0 is a solution tube, then u_1 must be identically zero. Then the solution tube of (9) becomes

$$\left\{(0, (1 + x_3^2) \int_0^t u_2(s)\,\mathrm{d}s - t, x_3);\ x_3 \in [-1, 1]\right\},$$

and the second component cannot be identically zero independently of $x_3 \in [-1, 1]$, no matter what the control u_2 is. This proves the negative claim in Remark 2.4. The solution tube $E(t) = (0, 0, [-1, 1])$ is, in fact, realized by the Young measure $\mu(t) = 0.5\delta_{-1} + 0.5\delta_1$, where δ_u is the atomic measure concentrated at u. Any control $u(t)$, however, that realizes the same trajectory as μ has to depend on its initial state x_3, which is "unknown" in the context of the solution tubes.

3. Viability theory for collections of sets and solution tubes. The theory developed in the previous section extends the usual notion of trajectory of a control system to the notion of a solution tube (in a collection of sets) of an *uncertain* control system (controlled differential inclusion). Then the problem arises of how to build a viability theory for solution tubes similarly to the way it has been done for usual trajectories [2].

General theories for set-valued dynamical systems (in metric spaces) were developed in [3, 26, 4]. In particular, the viability theory was extended to more general dynamics in metric spaces in [16, 18, 4]. The dynamics of the solution tubes in a given collection of sets, however, does not fit within the above-mentioned framework. A relevant notion for contingency and viability for collections of sets was developed in [28], but it concerns standard (certain) control systems, where only the initial state is uncertain. Below we extend this theory in two directions: (i) to uncertain control systems, and (ii) to the concept of "viability with a target" introduced in [27].

3.1. Viability domains and kernels. Let a collection of compact sets $\mathcal{E}$ in $\mathbf{R}^n$ be fixed and let $Z \in \mathrm{comp}(\mathbf{R}^n)$.

Definition. A mapping $L(\cdot) \in C(Z, \mathrm{comp}(\mathbf{R}^n))$ is called a (continuous) contingent field to $\mathcal{E}$ at Z if

$$\liminf_{h \to 0+} \inf_{\tilde{E} \in \mathcal{E}} \sup_{x \in Z} \mathrm{dist}\left(L(x), \frac{\tilde{E} - x}{h}\right) = 0.$$

The set of all contingent fields to $\mathcal{E}$ at Z will be denoted by $\mathcal{T}_{\mathcal{E}}(Z)$. The following lemma is a straightforward consequence of the definition.

LEMMA 3.1. *The (set-valued) mapping $L(\cdot) \in C(Z; \mathrm{comp}(\mathbf{R}^n))$ belongs to $\mathcal{T}_{\mathcal{E}}(Z)$ if and only if there are sequences $h_k \to 0+$, $\gamma_k \to 0$, and $E_k \in \mathcal{E}$ such that*

$$(I + h_k L(\cdot))(Z) \subset E_k + h_k \gamma_k \mathcal{B} \quad \forall k$$

(here and below, I is the identity mapping).

In the particular case of the collection $\mathcal{E}_K = \{\{x\};\ x \in K\}$ of all single points from a given set $K \subset \mathbf{R}^n$, the set $\mathcal{T}_{\mathcal{E}}(Z)$ is nonempty if and only if $Z = \{x\}$ is a singleton and every contingent field is single-valued. In fact, the contingent field at $\{x\}$ is defined at the single point x only, and therefore can be identified with a vector $l \in \mathbf{R}^n$. It is straightforward that $l \in \mathcal{T}_{\mathcal{E}_K}(\{x\})$ if and only if $l \in T_K(x)$, where $T_K(x)$ is the usual (Bouligand) contingent cone[2] to K at x (see, e.g., [5]). In the case of collections that do not consist only of singletons, we use the term *contingent field* (in contrast to "contingent vector") to stress that *mappings* defined on Z are considered "tangent" objects, rather than constant vectors only. All properties of the contingent fields (similar to those for contingent vectors) obtained in [28, Proposition 1] in the case of single-valued fields apply also to set-valued fields.

Below $\mathcal{M}$ will be another (possibly empty) collection of compact sets in $\mathbf{R}^n$ that will be interpreted later as a "target." Let $\mathcal{L}$ be a family of mappings from $C(\mathbf{R}^n; \mathrm{comp}(\mathbf{R}^n))$. Then $\mathcal{L}_{|Z}$ will denote the set of restrictions of the mappings from $\mathcal{L}$ to the set $Z \in \mathrm{comp}(\mathbf{R}^n)$.

Definition. The collection $\mathcal{E}$ is called a *viability domain with target* $\mathcal{M}$ for $\mathcal{L}$ if

$$\mathcal{T}_{\mathcal{E}}(E) \cap \mathcal{L}_{|E} \neq \emptyset \quad \forall E \in \mathrm{cl}(\mathcal{E}) \setminus \mathcal{M}.$$

Obviously $\mathcal{E}$ is a viability domain if and only if $\mathrm{cl}(\mathcal{E})$ is a viability domain.

The following proposition plays a key role in the whole theory.[3] It claims that the sequences γ_k in Lemma 3.1 can be chosen to a certain extent independent of the particular $\mathcal{E}$, E, and L. The idea of the proof is the same as that of Lemma 2 in [28], obtained in the case of a family of single-valued fields $\mathcal{L}$ and $\mathcal{M} = \emptyset$. However, the suppositions in [28] are too restrictive in the present context, so the proof below is technically rather different from that in [28].

We shall use the notation

$$\rho(E, \mathcal{M}) \stackrel{def}{=} \inf_{M \in \mathcal{M}} \mathrm{dist}(E, M).$$

Definition. The subset $\mathcal{E}'$ of $\mathcal{E}$ is *inclusion-complete* (in $\mathcal{E}$) if the inclusions $E \in \mathcal{E}'$, $E' \subset E$, and $E' \in \mathcal{E}$ together imply $E' \in \mathcal{E}'$.

PROPOSITION 3.2. *Let the closed collections $\mathcal{E}$ and $\mathcal{M}$ of compact sets and the closed convex family $\mathcal{L} \subset C(\mathbf{R}^n; \mathrm{comp}(\mathbf{R}^n))$ be given. Suppose that $\mathcal{E}$ satisfies Conditions* B.1–B.3 *and that for every $Z \in \mathrm{comp}(\mathbf{R}^n)$, the family $\mathcal{L}_{|Z}$ is equi-Lipschitz and uniformly bounded.*

Then for every number R there exist positive numbers β, c, and C such that for every $h \in (0, \beta]$, for every $\mathcal{E}' \subset \mathcal{E}$ which is a closed inclusion-complete viability domain with target $\mathcal{M}$ for $\mathcal{L}$, and for every $E \in \mathcal{E}'$, for which $E \subset R\mathcal{B}$ and $\rho(E, \mathcal{M}) > ch$, there exist $L(\cdot) \in \mathcal{L}$ and $\tilde{E} \in \mathcal{E}'$, with $\tilde{E} \subset (R+1)\mathcal{B}$, such that

$$(I + hL(\cdot))(E) \subset \tilde{E} + Ch^2\mathcal{B}.$$

The proof is given in section 5.

[2] $T_K(x)$ is defined as the set of those $l \in \mathbf{R}^n$ for which $\liminf_{h \to 0+} \frac{1}{h} \mathrm{dist}(x + hl, K) = 0$.

[3] To our knowledge the proposition below is new also in the "classical" case of a collection of singletons and single-valued fields (in fact, vectors). Its claim seems to provide one deep reason for the Euler discretizability of Hamilton–Jacobi equations associated with optimal control, despite the fact that the derivatives in these equations do not exist in the classical sense and the solution can be even discontinuous.

If a collection $\mathcal{E} \subset \mathrm{comp}(\mathbf{R}^n)$ is not a viability domain for $\mathcal{L}$, then it may happen that it contains a collection $\mathcal{E}' \subset \mathcal{E}$ which is a viability domain.

THEOREM 3.3. *Let $\mathcal{E}$, $\mathcal{M}$, and $\mathcal{L}$ be as in Proposition* 3.2. *Then there exists a (possibly empty) closed collection $\mathcal{E}_0 \subset \mathcal{E}$ which is a viability domain for $\mathcal{L}$ with target $\mathcal{M}$ and which contains every other viability domain in $\mathcal{E}$ with target $\mathcal{M}$.*

Definition. The (possibly empty) collection $\mathcal{E}_0 \subset \mathcal{E}$ obtained in the above theorem is called the *viability kernel of $\mathcal{E}$ with target $\mathcal{M}$* for $\mathcal{L}$ and will be denoted by $\mathrm{Viab}_{\mathcal{L}}(\mathcal{E}; \mathcal{M})$.

Proof. If no subset of $\mathcal{E}$ is a viability domain (below, we skip mentioning $\mathcal{L}$ and $\mathcal{M}$), then $\mathrm{Viab}_{\mathcal{L}}(\mathcal{E}; \mathcal{M}) = \emptyset$. Otherwise we denote

$$\mathcal{E}_0 \stackrel{def}{=} \mathrm{cl} \cup \mathcal{E}',$$

where the union is taken with respect to all viability domains included in $\mathcal{E}$. However, the collection $\mathcal{E}_0$ would not change if we take in the above union only the closed inclusion-complete viability domains $\mathcal{E}'$. Indeed, the viability property is invariant with respect to taking closure or completing a collection $\mathcal{E}'$ by adding to it all subsets of elements of $\mathcal{E}'$ that belong to $\mathcal{E}$.

We shall prove that $\mathcal{E}_0$ is a viability domain with target $\mathcal{M}$. Take an arbitrary $E_0 \in \mathcal{E}_0 \backslash \mathcal{M}$. Let us denote $R = \mathrm{dist}(E_0, 0)+1$ and let β, c, and C be the corresponding numbers from Proposition 3.2. Let $h \in (0, 1]$ be arbitrary, but such that $2ch \leq \rho(E_0, \mathcal{M})$.

By the definition of $\mathcal{E}_0$ there is a viability domain $\mathcal{E}'_h \subset \mathcal{E}_0$ and $E_h \in \mathcal{E}'_h$ such that $H(E_h, E_0) \leq h \min\{1, ch\}$. We have $\mathrm{dist}(E_h, 0) \leq \mathrm{dist}(E_0, 0) + 1 \leq R$ and $\rho(E_h, \mathcal{M}) \geq \rho(E_0, \mathcal{M}) - ch \geq ch$. Then we can apply Proposition 3.2 to obtain $L_h(\cdot) \in \mathcal{L}$ and $\tilde{E}_h \in \mathcal{E}'_h$ such that

$$(I + hL_h(\cdot))(E_h) \subset \tilde{E}_h + Ch^2\mathcal{B}.$$

Let D be a Lipschitz constant of the mappings from $\mathcal{L}_{|Y}$, where $Y = E_0 + \mathcal{B}$. Then

$$\begin{aligned}(I + hL_h(\cdot))(E_0) &\subset (I + hL_h(\cdot))(E_h) + (1 + D)ch^2\mathcal{B} \subset \tilde{E}_h + [(1 + D)c + C]h^2\mathcal{B} \\ &= \tilde{E}_h + C_1h^2\mathcal{B}\end{aligned}$$

with $C_1 = (1 + D)c + C$. Since L_h are equi-Lipschitz and uniformly bounded on Y, there is a sequence $h_k \to 0$ such that L_{h_k} converges to some $L \in \mathcal{L}_{|Y}$ in $C(Y; \mathrm{comp}(\mathbf{R}^n))$. Then

$$(I + h_kL(\cdot))(E_0) \subset \tilde{E}_{h_k} + C_1h^2\mathcal{B} + h_k\|L(\cdot) - L_{h_k}(\cdot)\|_{C(Y;\mathrm{comp}(\mathbf{R}^n))}\mathcal{B}.$$

Since $\tilde{E}_{h_k} \in \mathcal{E}'_{h_k} \subset \mathcal{E}_0$, the last relation implies that $L(\cdot) \in \mathcal{T}_{\hat{\mathcal{E}}}(\hat{E})$ according to Lemma 3.1. Thus $\mathcal{E}_0$ is a viability domain with target $\mathcal{M}$. □

The following lemma is another direct consequence of Proposition 3.2.

LEMMA 3.4. *Let $\mathcal{E}$, $\mathcal{M}$, and $\mathcal{L}$ be as in Proposition* 3.2*, but with a compact family $\mathcal{L}$. Let $\mathcal{E}_k \in \mathcal{E}$, $k = 1, 2, \ldots$, be a sequence of closed inclusion-complete viability domains with target $\mathcal{M}$ for $\mathcal{L}$. Then the Kuratowski upper limit of $\{\mathcal{E}_k\}$ is a viability domain with target $\mathcal{M}$ for $\mathcal{L}$.*

3.2. Existence of a viable solution tube. In this subsection we address the key issue of the viability theory specified below in Theorem 3.5 in the present framework of collections of sets and solution tubes: the existence of a solution tube in a viability domain.

We consider a specific family of mappings $\mathcal{L} \subset C(\mathbf{R}^n; \mathrm{comp}(\mathbf{R}^n))$ having the affine form

$$\mathcal{L} = \{F_0(\cdot) + B(\cdot)u;\ u \in U\}, \tag{10}$$

where $F_0 \in C(\mathbf{R}^n; \mathrm{comp}(\mathbf{R}^n))$, $U \subset \mathbf{R}^r$, and $B(\cdot)$ is an $(n \times r)$-matrix function. Below in this section we suppose that

(11) $\mathcal{E} \subset \mathrm{comp}(\mathbf{R}^n)$ is a collection satisfying Conditions B.1–B.3;

(12) is convex and compact, $B(\cdot)$ is locally Lipschitz continuous;

(13) $F_u(x) \stackrel{def}{=} F_0(x) + B(x)u$ satisfies Condition A uniformly in $u \in U$.

With the family $\mathcal{L}$ we associate the controlled differential inclusion

$$\dot{x} \in F_0(x) + B(x)u(t), \quad u(t) \in U. \tag{14}$$

Let us denote by $\mathcal{U}_{[s,\tau]}$ the set of all measurable $u(\cdot) : [s, \tau] \mapsto U$. According to Corollary 2.2, for every $s \geq 0$, every $E \in \mathcal{E}$, and every $u(\cdot) \in \mathcal{U}_{[s,+\infty)}$, inclusion (14) has a unique solution tube $E_{u(\cdot)}[s, E](\cdot)$ in the collection $\mathcal{E}$ on $[0, +\infty)$, starting from E at time s. Similarly, as before, the solution tube in $\mathrm{comp}(\mathbf{R}^n)$ will be denoted by $X_{u(\cdot)}[s, E](\cdot)$.

The following definition adapts the terminology from [2].

Definition. Let $\mathcal{E}'$ and $\mathcal{M}$ be given closed subsets of $\mathcal{E}$. The collection $\mathcal{E}'$ enjoys the *viability property* with target $\mathcal{M}$ with respect to (14) if and only if for every $E \in \mathcal{E}' \setminus \mathcal{M}$ there exists $u(\cdot) \in \mathcal{U}_{[0,+\infty)}$ such that the solution tube $E_{u(\cdot)}(\cdot) = E_{u(\cdot)}[0, E](\cdot)$ either satisfies $E_{u(\cdot)}(t) \in \mathcal{E}'$ for all $t \geq 0$, or there is $T > 0$ such that $E_{u(\cdot)}(t) \in \mathcal{E}'$ on $[0, T]$ and $E_{u(\cdot)}(T) \in \mathcal{M}$.

THEOREM 3.5. *Let Conditions* (11)–(13) *hold. The closed inclusion-complete collection $\mathcal{E}' \subset \mathcal{E}$ enjoys the viability property with target $\mathcal{M}$ with respect to* (14) *if and only if it is a viability domain with target $\mathcal{M}$.*

The proof of this result is rather technical; therefore it is postponed to section 5.

Remark 3.6. We mention that in the "classical" viability theory (that is, with single-valued F_0) affineness with respect to u is not required. Without asserting that Theorem 3.5 does not hold under weaker assumptions for the dependence of F_u on u, we point out that in the case of a nonlinear dependence on u, some undesirable irregularities may take place. For example, in the "classical" case the intersection of a monotone decreasing sequence of viability domains is a viability domain, too. This is not the case for Example 2.5 in section 2.3. The collection $\mathcal{E}'_\alpha = \{([-a, a], 0, [-1, 1]);\ a \in [0, \alpha]\} \subset \mathcal{E} \stackrel{def}{=} \mathrm{comp}(\mathbf{R}^3)$ is easily seen to be a viability domain (with $\emptyset$ as a target) if $\alpha > 0$. On the other hand, it was shown there that $\mathcal{E}'_0 \stackrel{def}{=} \cap_\alpha \mathcal{E}'_\alpha = \{(0, 0, [-1, 1]\}$ fails to enjoy the viability property. We shall comment further on this effect in section 4.3.

3.3. Dini derivative and viability. In this subsection, $\mathcal{E}$ will always be a closed collection of nonempty compact sets in $\mathbf{R}^n$ and $J : \mathcal{E} \to \mathbf{R}$ will be a lower semicontinuous function (abbreviated as l.s.c.). Let $E \in \mathcal{E}$ be fixed and let $F : E \mapsto \mathrm{comp}(\mathbf{R}^n)$ be a set-valued field on E.

Definition. We define the lower Dini derivative of J at E in the direction of the field F as

$$D^-_{\mathcal{E}} J(E; F) \stackrel{def}{=} \liminf_{h,\delta \to 0+} \inf \left\{ \frac{J(E') - J(E)}{h};\ E' \in \mathcal{E},\ (I + hF)(E) \subset E' + h\delta\mathcal{B} \right\}.$$

Remark 3.7. If J is Lipschitz and the collection $\mathcal{E}$ satisfies Condition B.1, then one can equivalently take $\delta = 0$ in the above definition.

For $\mathcal{E}$ and J as above, we define as usual

$$\operatorname{epi} J \stackrel{def}{=} \{(E,\nu);\ E \in \mathcal{E},\ \nu \in \mathbf{R} :\ J(E) \le \nu\} \subset \mathcal{E} \times \mathbf{R},$$

which is also a closed collection of compact sets.

The following lemma follows easily from the definitions.

LEMMA 3.8. *For every $E \in \mathcal{E}$ and $F : E \mapsto \operatorname{comp}(\mathbf{R}^n)$, the following two conditions are equivalent:*

(i) $D^-_{\mathcal{E}} J(E;F) \le 0$;

(ii) $(F,0) \in \mathcal{T}_{\operatorname{epi} J}(E, J(E))$.

Let $\mathcal{M} \subset \mathcal{E}$ be closed and let $\mathcal{L}$ be a closed family of mappings $L : \mathbf{R}^n \Rightarrow \mathbf{R}^n$ such that, for every $Z \in \operatorname{comp}(\mathbf{R}^n)$, the family $\mathcal{L}_{|Z}$ is equi-Lipschitz and uniformly bounded. As a consequence of the above lemma, we obtain that

$$\inf_{L \in \mathcal{L}} D^-_{\mathcal{E}} J(E; L_{|E}) \le 0 \quad \forall E \in \mathcal{E} \setminus \mathcal{M}$$

is a necessary condition for the collection $\operatorname{epi} J$ to be a viability domain for $\mathcal{L} \times \{0\}$ with a target $\mathcal{M} \times \mathbf{R}$. The next lemma implies that the "inf" in the above inequality is attained.

LEMMA 3.9. *For every fixed $E \in \mathcal{E}$, the mapping*

$$L \to D^-_{\mathcal{E}} J(E;L) \tag{15}$$

defined in the space $C(E; \operatorname{comp}(\mathbf{R}^n))$ of continuous set-valued fields on E is l.s.c.

Proof. Let $L_k \to L$, that is, $\rho_k \stackrel{def}{=} \sup_{x \in E} H(L(x), L_k(x)) \to 0$. There exist sequences h_k, δ_k, and $E'_k \in \mathcal{E}$ such that $0 < h_k, \delta_k \le 1/k$,

$$(I + h_k L_k)(E) \subset E'_k + h_k \delta_k \mathcal{B} \quad \text{and} \quad \frac{J(E'_k) - J(E)}{h_k} \le D^-_{\mathcal{E}} J(E; L_k) + \frac{1}{k}. \tag{16}$$

Then

$$(I + h_k L)(E) \subset E'_k + h_k \rho_k \mathcal{B} + h_k \delta_k \mathcal{B}.$$

From here and the second relation in (16),

$$D^-_{\mathcal{E}} J(E;L) \le \liminf_{k \to +\infty} \left(D^-_{\mathcal{E}} J(E;L_k) + \frac{1}{k} \right),$$

which proves the lemma. ∎

COROLLARY 3.10. $\operatorname{epi} J$ *is a viability domain with a target $\mathcal{M} \times \mathbf{R}$ for $\mathcal{L} \times \{0\}$ if and only if*

$$\min_{L \in \mathcal{L}} D^-_{\mathcal{E}} J(E; L_{|E}) \le 0 \quad \forall E \in \mathcal{E} \setminus \mathcal{M}.$$

Notice that we have replaced "inf" with "min" in the above inequality, meaning that the infimum is attained.

4. Optimal control in the presence of observable and unobservable uncertainties. We consider the minimization problem for (1), (2) formulated in the introduction. In addition we introduce a set $M \subset [0,T] \times \mathbf{R}^n$, which will determine the termination time of the control process, as described below. The following suppositions will hold for the rest of the section.

Condition C.1. U, Y, and $\bar{V}$ are compact subsets of finite dimensional vector spaces, U is convex, and the mapping $y \to V(y) \subset \bar{V}$ is compact valued and Lipschitz continuous.

Condition C.2. The function $f : \mathbf{R}^n \times U \times Y \times \bar{V} \mapsto \mathbf{R}^n$ has the form

$$f(x,u,y,v) = f_0(x,y,v) + B(x,y)u,$$

where f_0 and B are continuous, locally Lipschitz in x uniformly with respect to the other variables. The sets $f_0(x,y,V(y))$ are convex. f has linear growth with respect to x, uniformly in u,y,v.

The admissible sets $\mathcal{U}_{[t,\theta]}$, $\mathcal{Y}_{[t,\theta]}$, and $\mathcal{V}_{[t,\theta]}(y(\cdot))$ are defined in the introduction. We recall the notion of *nonanticipative strategy* on $[t,\theta]$. This is any mapping $\alpha : \mathcal{Y}_{[t,\theta]} \mapsto \mathcal{U}_{[t,\theta]}$ that satisfies the nonanticipativity condition

$$\begin{aligned}&\forall\, y_1, y_2 \in \mathcal{Y}_{[t,\theta]},\ \forall\, \tau \in (t,\theta]\\ &\text{if } y_1(s) = y_2(s) \quad \text{for a.e. } s \in [t,\tau], \text{ then } \alpha(y_1)(s) = \alpha(y_2)(s) \quad \text{for a.e. } s \in [t,\tau].\end{aligned}$$

Let $\mathcal{A}_{[t,\theta]}$ denote the set of all such strategies on $[t,\theta]$.

Let us consider first the case of a fixed-end time T discussed in the introduction. With the system (1) and any fixed $u \in \mathcal{U}_{[t,T]}$ and $y \in \mathcal{Y}_{[t,T]}$, we associate the differential inclusion

$$\dot{x} \in f(x,u(s),y(s),V(y(s))). \tag{17}$$

Similarly, as before, we denote by $X_{u,y}[t,E](\cdot)$ the solution tube of (17) in $\mathrm{comp}(\mathbf{R}^n)$, starting from the set E at time t. Moreover, for a compact set $Z \subset \mathbf{R}^n$ we define $G : \mathrm{comp}(\mathbf{R}^n) \mapsto \mathbf{R}$ as

$$G(T,Z) = \sup_{z \in Z} g(T,z).$$

Then, obviously, definition (4) is equivalent to

$$I(t,E) = \inf_{\alpha \in \mathcal{A}_{[t,T]}} \sup_{y \in \mathcal{Y}_{[t,T]}} G(T, X_{\alpha(y),y}[t,E](T)). \tag{18}$$

In this formulation of the original problem there is no unobservable uncertainty. We passed to a problem with complete information (here y is an observable disturbance) but over the solution tubes to differential inclusion (17).

Because of the complexity of the problem so obtained, we can restrict the consideration to the solution tubes of (17) in a given collection of sets $\mathcal{E}$ instead of the whole $\mathrm{comp}(\mathbf{R}^n)$. Thus we come up with the more general problem, formulated below in the case of a target that determines the termination time. We also suppose the following condition.

Condition C.3. The collection $\mathcal{E}$ satisfies Conditions B.1–B.3. The set $M \subset [0,+\infty) \times \mathbf{R}^n$ is closed and contains $t \times \mathbf{R}^n$ for every $t \geq T$. The function $g(\cdot) : M \mapsto \mathbf{R}$ is l.s.c. Moreover, the following property holds: For every $(t,x_0) \in M$ with $t < T$,

for every $s \in (t,T]$, $y \in \mathcal{Y}_{[t,T]}$, and $u \in \mathcal{U}_{[t,T]}$, the inclusion (17) has a trajectory $x(\cdot)$ with $x(t) = x_0$ for which $g(s,x(s)) \geq g(t,x_0)$.

Formulation of the general problem. Let Conditions C.1–C.3 be satisfied. For any fixed $u \in \mathcal{U}_{[t,T]}$ and $y \in \mathcal{Y}_{[t,T]}$, we denote by $E_{u,y}[t,E](\cdot)$ the solution tube in the collection $\mathcal{E}$ starting from $E \in \mathcal{E}$ at time t. We define also the target collection $\mathcal{M} \stackrel{def}{=} \{(t,E);\ E \in \mathcal{E},\ (t,E) \subset M\}$, which is nonempty since $(T,\mathcal{E}) \subset \mathcal{M}$, closed, and inclusion complete in $\mathcal{E}$. For a given tube $E(\cdot) \in C([0,T];\mathcal{E})$ the termination time is determined as

$$T(E(\cdot)) = \min\{t \geq 0;\ (t,E(t)) \in \mathcal{M}\}.$$

We consider the following minimization problem for the initial pair $(t,E) \notin \mathcal{M}$:

$$\begin{aligned} &I_{\mathcal{E}}(t,E) \stackrel{def}{=} \inf_{\alpha \in \mathcal{A}_{[t,T]}} \sup_{y \in \mathcal{Y}_{[t,T]}} G(\tau, E(\tau)), \\ &\text{where } E(\cdot) \stackrel{def}{=} E_{\alpha(y),y}[t,E](\cdot),\ \tau = T(E(\cdot)). \end{aligned} \tag{19}$$

If $(t,E) \in \mathcal{M}$, then by definition $I_{\mathcal{E}}(t,E) = G(t,E)$. The role of the last part of Condition C.3 is to ensure that once the target is achieved, the continuation of the process would not lead to a better guaranteed result. This supposition is obviously fulfilled in the case $\mathcal{M} = \{T\} \times \mathcal{E}$ (fixed-end time) or $G(t,E) = t$ (minimal time problem). Obviously we have $I_{\mathcal{E}}(t,E) \geq I_{\mathrm{comp}(\mathbf{R}^n)}(t,E)$. The difference between these two values is the price for the simplification we make by passing to the collection $\mathcal{E}$. In some cases, however, equality may take place even for simple subcollections of $\mathrm{comp}(\mathbf{R}^n)$, as shown by a discrete-time example in [25].

4.1. Some basic properties. The proof of the following dynamic programming principle adapts standard arguments.

PROPOSITION 4.1. *Under Conditions* C.1–C.3*, for every $E \in \mathcal{E}$, $t \in [0,T)$, and $s \in (t,T]$,*

$$I_{\mathcal{E}}(t,E) = \inf_{\alpha \in \mathcal{A}_{[t,s]}} \sup_{y \in \mathcal{Y}_{[t,s]}} I_{\mathcal{E}}(\tau, E(\tau)),$$

$$\text{where } E(\cdot) \stackrel{def}{=} E_{\alpha(y),y}[t,E](\cdot),\ \tau \stackrel{def}{=} \min\{s, T(E(\cdot))\}.$$

PROPOSITION 4.2. *Under Conditions* C.1–C.3*, the value function $I_{\mathcal{E}} : [0,T] \times \mathcal{E}$ is l.s.c.*

PROPOSITION 4.3. *Under Conditions* C.1–C.3*, for every $(t,E) \in [0,T) \times \mathcal{E}$ there is $\alpha \in \mathcal{A}_{[t,T]}$ for which the infimum in* (19) *is attained (that is an optimal strategy).*

Proof. The proof of the second proposition[4] follows from the proof of Proposition 4.2, applied for $(t_k,E_k) \equiv (t,E)$.

Let the sequence $\{(t_k,E_k)\}$, with $t_k \in [0,T]$ and $E_k \in \mathcal{E}$, converge to (t,E). By the definition of $I_{\mathcal{E}}$, there is $\alpha_k \in \mathcal{A}_{[t_k,T]}$ such that

$$\sup_{y \in \mathcal{Y}_{[t_k,T]}} \{G(\tau,E(\tau));\ E(\cdot) = E_{\alpha_k(y),y}[t_k,E_k](\cdot),\ \tau = T(E(\cdot))\} \leq I_{\mathcal{E}}(t_k,E_k) + \frac{1}{k}. \tag{20}$$

[4]The existence of an optimal strategy can be obtained also by a slight modification of part 3 of the proof of Theorems 4.5 and 4.7 below. However, we give here a direct proof (not involving the viability theory), which applies also to Proposition 4.2.

We fix an infinite subset $\mathbf{N}_0 \subset \mathbf{N}$ such that $\lim_{k\in\mathbf{N}_0} I_{\mathcal{E}}(t_k, E_k) = \liminf_{k\in\mathbf{N}} I_{\mathcal{E}}(t_k, E_k)$. We fix also some $\bar{y} \in Y$. For an arbitrary $y \in \mathcal{Y}_{[t,T]}$ define $y_k \in \mathcal{Y}_{[t_k,T]}$ either by restricting y to $[t_k, T]$ (if $t < t_k$) or by concatenating $\bar{y}$ on $[t_k, t)$ (if $t > t_k$). Then we denote by $S(y)$ the set of all L_2-weak limits of the sequence $\{\alpha_k(y_k)\}_{k\in\mathbf{N}_0}$. Below we utilize the following form of the Cardaliaguet–Plaskacz lemma (see [10]).

LEMMA 4.4. *Let $S : \mathcal{Y}_{[t,T]} \Rightarrow U_{[t,T]}$ be a set-valued mapping with nonempty L_2-weakly compact images, having the following* nonanticipativity *property:*

For every $\theta \in (t, T]$, if $y', y'' \in \mathcal{Y}_{[t,T]}$ and $y'(s) = y''(s)$ almost everywhere in $[t, \theta]$, then, for every $u' \in S(y')$, there exists $u'' \in S(y'')$ such that $u'(s) = u'(s)$ almost everywhere in $[t, \theta]$.

Then there exists $\alpha \in \mathcal{A}_{[t,T]}$ such that $\alpha(y) \in S(y)$ for every $y \in \mathcal{Y}_{[t,T]}$.

Clearly our set $S(y)$ is L_2-weakly closed and thus also L_2-weakly compact, since it is contained in the L_2-weakly compact set $\mathcal{U}_{[t,T]}$. To prove the nonanticipativity of S we take y', y'', and u' as in Lemma 4.4. Denoting by y'_k and y''_k the corresponding extensions/restrictions defined above, we have $\alpha_k(y'_k)(s) = \alpha_k(y''_k)(s)$ for a.e. $s \in [t, \theta]$, since α_k is nonanticipative. If $\mathbf{N}' \subset \mathbf{N}_0$ is the subsequence of $\alpha_k(y'_k)$ convergent to u', then we define u'' as an arbitrary L_2-weak limit of $\{\alpha_k(y''_k)\}_{\mathbf{N}'}$. Then $u'' \in S(y'')$ and clearly $u''(s) = u'(s)$ a.e. in $[t, \theta]$.

From Lemma 4.4 we obtain an $\alpha(\cdot) \in \mathcal{A}_{[t,T]}$ which is a selection of S. In particular, for every $y \in \mathcal{Y}_{[t,T]}$, we fix an infinite subset $\mathbf{N}^y \subset \mathbf{N}_0$ such that $\{\alpha_k(y_k)\}_{k\in\mathbf{N}^y}$ converges L_2-weakly to $\alpha(y)$.

Let us fix an arbitrary $y \in \mathcal{Y}_{[t,T]}$. For the corresponding restricted/extended $y_k \in \mathcal{Y}_{[t_k,T]}$ we have, according to Proposition 2.3, that solution tubes $E_{\alpha_k(y_k),y_k}[t_k, E_k](\cdot)$ converge uniformly along some subsequence $\mathbf{N}' \subset \mathbf{N}^y$ to a tube $E(\cdot)$ in $\mathcal{E}$, and $E_{\alpha(y),y}[t, E](s) \subset E(s)$. Let $E_k(\cdot) \stackrel{def}{=} E_{\alpha_k(y_k),y_k}[t_k, E_k](\cdot)$, $\tau_k \stackrel{def}{=} T(E_k(\cdot))$. Denote $\tau_0 = \liminf_{k\in\mathbf{N}'} \tau_k$. Then from the closedness and the inclusion-completeness of $\mathcal{M}$, we have that $\hat{\tau} \stackrel{def}{=} T(E_{\alpha(y),y}[t, E](\cdot)) \le \tau_0$. From the lower semicontinuity and inclusion-monotonicity of G, and then by the choice of $\mathbf{N}^y \supset \mathbf{N}'$ and (20),

$$\begin{aligned} G(\tau_0, E_{\alpha(y),y}[t, E](\tau_0)) &\le G(\tau_0, E(\tau_0)) \le \limsup_{k\in\mathbf{N}'} G(\tau_k, E_k(\tau_k)) \\ &\le \lim_{k\in\mathbf{N}'} \left(I_{\mathcal{E}}(t_k, E_k) + \frac{1}{k} \right) = \liminf_{k\to+\infty} I_{\mathcal{E}}(t_k, E_k). \end{aligned}$$

Since $\hat{\tau} \le \tau_0$, the last part of Condition C.3 and the above inequality imply

$$G(\hat{\tau}, E_{\alpha(y),y}[t, E](\hat{\tau})) \le G(\tau_0, E_{\alpha(y),y}[t, E](\tau_0)) \le \liminf_{k\to+\infty} I_{\mathcal{E}}(t_k, E_k).$$

Since $y \in \mathcal{Y}_{[t,T]}$ was chosen arbitrarily, this completes the proof. □

4.2. Characterizations of the value function. The first theorem below gives a characterization of the value function as the unique minimal Dini supersolution of the associated HJI equation. Define the extended closed collection of compact sets $\hat{\mathcal{E}}$ in $\mathbf{R} \times \mathbf{R}^n$ as

$$\hat{\mathcal{E}} \stackrel{def}{=} \{(t, E);\ t \ge 0,\ E \in \mathcal{E}\}.$$

THEOREM 4.5. *Under Conditions* C.1–C.3*, the value function $I_{\mathcal{E}}$ is the unique minimal l.s.c. solution of the differential inequality*

$$\sup_{y\in Y}\min_{u\in U} D^-_{\hat{\mathcal{E}}} J(t,E;(1,f(\cdot,u,y,V(y)))) \le 0 \quad \forall\,(t,E)\in \hat{\mathcal{E}}\setminus\mathcal{M}, \tag{21}$$

with the side condition

$$J(t,E)\ge G(t,E) \quad \forall\,(t,E)\in\mathcal{M}. \tag{22}$$

That is,

$$I_{\mathcal{E}}(t,E)=\min\{J(t,E);\ J \text{ – } l.s.c.\ solution\ of\ (21),\ (22)\}.$$

Remark 4.6. We can write "min" instead of "inf" in (21) thanks to Lemma 3.9.

In parallel with Theorem 4.5 we shall prove also the next theorem, which extends the result in [10], the latter concerning the case of complete information (the disturbance v is not present). It shows that one can apply for calculation of $I_{\mathcal{E}}$ an extension, similar to that in [27], of the viability kernel algorithm [31, 11].

THEOREM 4.7. *Under Conditions* C.1–C.3*, denote*

$$\mathcal{E}^* \stackrel{def}{=} \hat{\mathcal{E}}\times\mathbf{R}, \qquad \mathcal{M}^* \stackrel{def}{=} \{(t,E,\nu);\ (t,E)\in\mathcal{M},\ \nu\ge G(t,E)\}.$$

Define $\mathcal{E}^*_1=\mathcal{E}^*$*, and recursively,*

$$\mathcal{E}^*_{k+1}=\bigcap_{y\in Y}\mathrm{Viab}_{\mathcal{L}_y}(\mathcal{E}^*_k;\mathcal{M}^*), \tag{23}$$

where $\mathcal{L}_y \stackrel{def}{=} \{(1,f(\cdot,u,y,V(y)),0);\ u\in U\}$*. Then*

$$\mathrm{epi}\, I_{\mathcal{E}}=\mathcal{E}_\infty \stackrel{def}{=} \bigcap_k \mathcal{E}^*_k.$$

Proof. We prove Theorems 4.5 and 4.7 in parallel.

1. First we shall prove that $I_{\mathcal{E}}$ is an l.s.c. solution of (21), (22). The function $I_{\mathcal{E}}$ is l.s.c. according to Proposition 4.2 and satisfies (22) as an equality by definition. To prove that it satisfies (21) we shall employ the dynamic programming principle in Proposition 4.1. Fix $(t,E)\in\hat{\mathcal{E}}\setminus\mathcal{M}$ and an arbitrary $y\in Y$. Since $\mathcal{M}$ is closed, there exists a sequence $h_k\to 0+$ such that for the sequence $t_k \stackrel{def}{=} t+h_k$ we have $(t_k,E_{u,y}[t,E](t_k))\notin\mathcal{M}$ for every $u\in\mathcal{U}_{[t,t_k]}$ and $y\in\mathcal{Y}_{[t,t_k]}$. Then $T(E_{u,y}[t,E](\cdot))>t_k$. According to Proposition 4.1 there is $\alpha_k\in\mathcal{A}_{[t,t_k]}$ such that

$$I_{\mathcal{E}}(t,E)\ge \sup_{y\in\mathcal{Y}_{[t,t_k]}} I_{\mathcal{E}}(t_k,E_{\alpha(y),y}[t,E](t_k))-\frac{h_k}{k}.$$

For $y\in Y$, denote $u_k(\cdot)\stackrel{def}{=}\alpha_k(y)(\cdot)$ (here the function y is identified with the constant value y), and $E_k(\cdot)=E_{u_k,y}[t,E](\cdot)$. We have

$$I_{\mathcal{E}}(t,E)\ge I_{\mathcal{E}}(t_k,E_k(t_k))-\frac{h_k}{k}. \tag{24}$$

Denote $\hat{E}_k\stackrel{def}{=}(t_k,E_k(t_k))\in\hat{\mathcal{E}}$ and

$$\bar{u}_k=\frac{1}{h_k}\int_t^{t_k} u_k(\tau)\,\mathrm{d}\tau.$$

Since U is compact we may assume that for some $\bar{u} \in U$ and for a subsequence, we have $\beta_k \overset{def}{=} |\bar{u}_k - \bar{u}| \to 0$. Thanks to the structural and convexity assumptions in C.1 and C.2, one can prove in a standard way that there is a constant C such that

$$H(X_{u_k(\cdot),y}[t,E](t_k), (I + h_k f(\cdot, \bar{u}, y, V))(E)) \leq Ch_k(h_k + \beta_k).$$

Since $X_{u_k(\cdot),y}[t,E](t_k) \subset E_k(t_k)$, we obtain

$$(I + h_k(1, f(\cdot, \bar{u}, y, V)))(t,E) \subset \hat{E}_k + Ch_k(h_k + \beta_k)\mathcal{B}.$$

This together with (24) implies

$$D^-_{\hat{\mathcal{E}}} J(t,E;(1, f(\cdot, \bar{u}, y, V))) \leq 0.$$

Then

$$\min_{u \in U} D^-_{\hat{\mathcal{E}}} J(t,E;(1, f(\cdot, u, y, V))) \leq 0,$$

which gives (21), since $y \in Y$ was arbitrarily chosen.

2. Now we shall prove that every l.s.c. solution J of (21), (22) satisfies the inclusion

$$\operatorname{epi} J \subset \mathcal{E}^*_\infty \overset{def}{=} \bigcap_k \mathcal{E}^*_k. \tag{25}$$

Thanks to (21), (22), and the definition of $\mathcal{M}^*$, we obtain from Corollary 3.10 that $\operatorname{epi} J$ is a viability domain with target $\mathcal{M}^*$ for each family $\mathcal{L}_y$ with $y \in Y$. Thus

$$\operatorname{epi} J \subset \bigcap_{y \in Y} \operatorname{Viab}_{\mathcal{L}_y}(\mathcal{E}^*_1; \mathcal{M}^*) = \mathcal{E}^*_2.$$

Repeating the same argument, we obtain that $\operatorname{epi} J \subset \mathcal{E}^*_k$ for every $k \geq 1$; hence (25).

3. It remains to prove that $\mathcal{E}^*_\infty \subset \operatorname{epi} I_{\mathcal{E}}$, which, in view of point 2, implies also the minimality of $I_{\mathcal{E}}$. To do this we consider the auxiliary differential inclusion

$$\begin{pmatrix} \dot{t} \\ \dot{x} \\ \dot{\nu} \end{pmatrix} \in \begin{pmatrix} 1 \\ f(x, u(s), y(s), V(y(s))) \\ 0 \end{pmatrix}, \tag{26}$$

which corresponds to the set-valued fields $\mathcal{L}_y$ involved in Theorem 4.7. Moreover, we fix an arbitrary $(t, E, \nu) \in \mathcal{E}^*_\infty$.

3.1. We shall prove that for every $y(\cdot) \in \mathcal{Y}_{[t,T]}$ there exists $u(\cdot) \in \mathcal{U}_{[t,T]}$ such that the corresponding solution tube $s \to (s, E(s), \nu)$ of (26), starting from (t, E, ν) at time $s = t$, satisfies

$$(s, E(s), \nu) \in \mathcal{E}^*_\infty \quad \text{as long as } s < T(E(\cdot)) \text{ or } \nu < G(s, E(s)). \tag{27}$$

Since for a fixed $y \in Y$ we have $\mathcal{E}_{k+1} \subset \operatorname{Viab}_{\mathcal{L}_y}(\mathcal{E}_k; \mathcal{M}^*) \subset \mathcal{E}_k$, one can write

$$\mathcal{E}_\infty = \bigcap_k \operatorname{Viab}_{\mathcal{L}_y}(\mathcal{E}_k; \mathcal{M}^*).$$

Since $\operatorname{Viab}_{\mathcal{L}_y}(\mathcal{E}_k; \mathcal{M}^*)$ is a viability domain with target $\mathcal{M}^*$ for $\mathcal{L}_y$, Lemma 3.4 implies the same for $\mathcal{E}^*_\infty$. Thus, for every fixed $y \in Y$ the collection $\mathcal{E}^*_\infty$ is a viability domain

with target $\mathcal{M}^*$ for (26). Then for the fixed $(t, E, \nu) \in \mathcal{E}^*_\infty$ and for every piecewise constant function $y(\cdot) \in \mathcal{Y}_{[t,T]}$ there exists $u(\cdot) \in \mathcal{U}_{[t,T]}$ such that the corresponding solution tube $(s, E(s), \nu)$ of (26) belongs to $\mathcal{E}^*_\infty$, as long as the target $\mathcal{M}^*$ is not reached. With the definition of the set $\mathcal{M}^*$ in mind, we obtain (27).

For any $y(\cdot) \in \mathcal{Y}_{[t,T]}$ we denote by $S(y(\cdot))$ the set of all $u(\cdot) \in \mathcal{U}_{[t,T]}$ for which (27) is satisfied. We have already proved that $S(y(\cdot))$ is nonempty for all piecewise constant $y(\cdot) \in \mathcal{Y}_{[t,T]}$. We shall prove that the mapping S has a closed graph with respect to the L_2-weak topology in $\mathcal{Y}_{[t,T]} \times \mathcal{U}_{[t,T]}$.

Let $(y_k, u_k) \to (y_0, u_0)$ weakly, and let $(\cdot, E_k(\cdot), \nu)$ be the solution tube of (26) corresponding to $u_k(\cdot)$ and $y_k(\cdot)$. Thanks to Conditions C.1–C.3, we may apply Proposition 2.3 and obtain that the solution tube $(\cdot, E_0(\cdot), \nu)$ corresponding to $y_0(\cdot)$ and $u_0(\cdot)$ is contained in a uniform limit of a subsequence of $(\cdot, E_k(\cdot), \nu)$. Denote this limit by $(\cdot, E(\cdot), \nu)$. Let s be such that

$$s < T(E_0(\cdot)) \quad \text{or} \quad \nu < G(s, E_0(s)).$$

From the inclusion-completeness of $\mathcal{M}$ and the inclusion monotonicity of G, we obtain that the same inclusion holds also for $E(s)$. From the closedness of $\mathcal{M}$ and the lower semicontinuity of G, we conclude that the above inequality is satisfied also by $E_k(s)$. Then from (27) (applied to $E_k(s)$) and the closedness of $\mathcal{E}^*_0$, we have $(s, E(s), \nu) \in \mathcal{E}^*_0$.

Moreover, if a set $\mathcal{E}^*_k$ is inclusion-complete in $\mathcal{E}^*$, then $\mathrm{Viab}_{\mathcal{L}_y}(\mathcal{E}^*_k; \mathcal{M}^*)$ is inclusion-complete, too, and also an arbitrary intersection of inclusion-complete collections is inclusion-complete. This implies inductively that $\mathcal{E}^*_\infty$ is inclusion-complete in $\mathcal{E}^*$. Then the inclusion $(s, E(s), \nu) \in \mathcal{E}^*_\infty$ obtained above, together with $E_0(s) \subset E(s)$ and $(s, E_0(s), \nu) \in \mathcal{E}^*$, imply $(s, E_0(s), \nu) \in \mathcal{E}^*_\infty$ on $[t, T(E_0)]$. Thus (27) is satisfied by u_0 and $(y, u_0) \in \operatorname{graph} S$. This proves the closedness of graph S in the L_2-weak topology in $\mathcal{Y}_{[t,T]} \times \mathcal{U}_{[t,T]}$.

From the closedness of graph S, together the compactness of $\mathcal{U}[t, T]$ and the proven fact that $S(y) \neq \emptyset$ for the piecewise constant functions y, we obtain that $S(y) \neq \emptyset$ for every $y \in \mathcal{Y}_{[t,T]}$.

3.2. To apply Lemma 4.4 to the mapping S, we first notice that $S(y(\cdot))$ is L_2-weakly closed (thanks to closedness of graph S) and therefore it is L_2-weakly compact, since $S(y(\cdot)) \subset \mathcal{U}_{[t,T]}$. Thanks to the claim in part 3.1, it is straightforward to prove that the mapping $S(\cdot)$ satisfies the nonanticipativity property in Lemma 4.4. Then there exists a nonanticipative selection $\alpha(\cdot)$ of $S(\cdot)$.

3.3. Let $y \in \mathcal{Y}_{[t,T]}$ be arbitrary, and let $(\cdot, E_y(\cdot), \nu)$ be the solution tube of (26) corresponding to $u(\cdot) \overset{def}{=} \alpha(y)(\cdot)$ and $y(\cdot)$. Since $u(\cdot) \in S(y(\cdot))$, we have that (27) is fulfilled for E_y. The set of those s for which

$$s < T(E_y(\cdot)) \quad \text{or} \quad \nu < G(s, E_y(s))$$

is bounded by T due to the definition of $\mathcal{M}$, and its supremum, $\bar{\tau}_y$, satisfies

$$\bar{\tau}_y \geq T(E_y(\cdot)) \quad \text{and} \quad \nu \geq G(\bar{\tau}_y, E_y(\bar{\tau}_y)).$$

The first inequality and the last part of Condition C.3 give

$$G(\tau_y, E_y(\tau_y)) \leq G(\bar{\tau}_y, E_y(\bar{\tau}_y)),$$

where $\tau_y \overset{def}{=} T(E_y(\cdot))$. Then

$$I_{\mathcal{E}}(t, E) \leq \sup_{y \in \mathcal{Y}_{[t,T]}} G(\tau_y, E_y(\tau_y)) \leq \sup_{y \in \mathcal{Y}_{[t,T]}} G(\bar{\tau}_y, E_y(\bar{\tau}_y)) \leq \nu.$$

This means $(t, E, \nu) \in \operatorname{epi} I_{\mathcal{E}}$, and proves $\mathcal{E}^*_\infty \subset \operatorname{epi} I_{\mathcal{E}}$. □

Remark 4.8 (on the implementation of Theorems 4.5 and 4.7). The last theorem shows that finding the value $I_{\mathcal{E}}$ is equivalent to the determination of suitable viability kernels. Notice that the viability kernels in (23) involve the complete information systems $\mathcal{L}_y$ only. The latter systems, however, are set-valued and the numerical algorithms developed in [31, 11, 27] (the last of which concerns also the case of viability with a target) are not directly applicable. At a conceptual level, we may summarize the algorithm for finding the viability kernel $\operatorname{Viab}_{\mathcal{L}}(\mathcal{E}; \mathcal{M})$ of a family of set-valued fields $\mathcal{L}$, with target $\mathcal{M}$ in the collection $\mathcal{E}$ (see subsection 3.1) as follows. For $h > 0$ and a natural number k, we define recursively

$$\mathcal{E}^h_{i+1} := \{E \in \mathcal{E}^h_i \setminus \mathcal{M};\ \exists L \in \mathcal{L}, \exists \widetilde{E} \in \mathcal{E}^h_i,\ (I + hL)(E) \subset \widetilde{E} + ch^2\mathcal{B}\} \cup \mathcal{M}, \quad \mathcal{E}^h_0 = \mathcal{E},$$

where $c \geq \lambda M/2$, and λ and M are local Lipschitz constant and bound for all $L \in \mathcal{L}$, respectively. Then

$$\operatorname{Viab}_{\mathcal{L}}(\mathcal{E}; \mathcal{M}) = \lim_{h \to 0+} \bigcap_i \mathcal{E}^h_i.$$

The above procedure should be applied to the family $\mathcal{L}_y = \{(1, f(\cdot, u, y, V(y)), 0);\ u \in U\}$ in (23) for each $y \in Y$.

The state-space discretization which certainly should be involved in a constructive procedure for approximating the viability kernel, as well as the corresponding convergence analysis, will not be discussed in the present paper.[5] Clearly, the algorithm has a high computational complexity, and to make it implementable, one has to choose a simple finitely parameterized collection $\mathcal{E}$.

We mention that Theorem 4.5 can also be used as a base for a numerical solution. The possibility of convergent time discretization is provided by the uniformity result in Proposition 3.2. In [25] we demonstrate the solvability of a discrete-time Hamilton–Jacobi–Bellman inequality of similar type, where sets of intervals were used for the collection $\mathcal{E}$. Essentially, the approach based on Theorem 4.5 coincides with a particular realization of the viability kernel algorithm.

4.3. Final discussions. 1. Since the control problem considered above includes minimal time problems, clearly the value function can be discontinuous, unless appropriate controllability conditions are fulfilled. If g is locally Lipschitz and the problem with fixed-end time is considered, then $I_{\mathcal{E}}$ is Lipschitz, provided that the solution tubes in $\mathcal{E}$ depend in a certain Lipschitz-like way on the data. Such dependence is established for some special collections in [29, Theorem 2].

2. Even in the case of a Lipschitz continuous value function, it may happen that (21) is not satisfied as an equality. To show this we adapt an example from [10]:

$$\dot{x} = u - y, \quad u, y \in [-1, 1], \quad g(x) = -|x|.$$

Here we may take $\mathcal{E} = \mathbf{R}^1$, since there are no unobservable uncertainties. From the consideration in [10], it follows that $I_{\mathcal{E}}(t, x) = -|x|$. The expression in the left-hand side of (21) equals zero for $x \neq 0$. For $x = 0$, however,

$$\begin{aligned} \sup_{y \in [-1,1]} \inf_{u \in [-1,1]} D^- I_{\mathcal{E}}(t, x; u - y) &= \sup_{y \in [-1,1]} \inf_{u \in [-1,1]} -|u - y| \\ &= \sup_{y \in [-1,1]} -(1 + |y|) = -1 < 0. \end{aligned}$$

[5] We refer to [31] for a state-space discretization technique and to [28] for a convergence analysis that could also be useful in the present context.

3. The consideration of the differential game in section 4 involves two conditions that need some more discussion. The first is Condition B.3, which significantly restricts the class of collections $\mathcal{E}$. In our opinion, the above theory can be developed also under weaker conditions for $\mathcal{E}$ (cf. [29]) which do not imply uniqueness of the solution tubes (in particular, including collections of ellipsoids). Such a consideration, however, would involve another "inf" (over the set of solution tubes, in the case of nonuniqueness) in the formulation (19) of the problem, and would bring essential technical complications that we choose to avoid in the present exposition.

The second "questionable" assumption is that equation (1) has the affine structure required in C.2. This assumption is, at least to a certain extent, essential. In particular, without affineness the existence of optimal strategy (Proposition 4.3) fails, even if the set $f(x, U, y, v)$ is convex. A counterexample can easily be constructed for the system in Example 2.5, section 2.3.

5. Proofs. In the proof of Proposition 3.2, we shall use the following lemma.

LEMMA 5.1. *Let the collection $\mathcal{E}$ satisfy Conditions* B.1–B.3*, and let $\mathcal{E}' \subset \mathcal{E}$ be inclusion-complete. Then for every $Z \in \mathrm{comp}(\mathbf{R}^n)$ and $E \in \mathcal{E}'$ there exists $E^* \in \mathcal{E}'$ such that*

$$\mathrm{dist}(Z, E^*) \le \mathrm{dist}(Z, E) \quad \textit{and} \quad \mathrm{dist}(E^*, Z) \le (L_{\mathcal{E}} + 1) d_H(Z, \mathcal{E}) + L_{\mathcal{E}} \,\mathrm{dist}(Z, E),$$

where

$$d_H(Z, \mathcal{E}) = \inf_{E \in \mathcal{E}} H(Z, E).$$

Proof. Let $E_0' \in \mathcal{E}$ be such that $H(Z, E_0') = d_H(Z, \mathcal{E})$. From Condition B.2 (with $\varepsilon = d_H(Z, \mathcal{E})$) there is $E_0 \in \mathcal{E}$ such that

$$Z \subset E_0' + d_H(Z, \mathcal{E})\mathcal{B} \subset E_0 \subset E_0' + L_{\mathcal{E}} d_H(Z, \mathcal{E})\mathcal{B}.$$

Then

$$Z \subset E_0 \subset E_0' + L_{\mathcal{E}} d_H(Z, \mathcal{E})\mathcal{B} \subset Z + (L_{\mathcal{E}} + 1) d_H(Z, \mathcal{E})\mathcal{B}. \tag{28}$$

Denote $Z' = \mathcal{P}_E(Z)$ (as before, $\mathcal{P}_E$ is the projection mapping over E). Since $Z' \subset Z + \mathrm{dist}(Z, E)\mathcal{B} \subset E_0 + \mathrm{dist}(Z, E)\mathcal{B}$, according to Condition B.2 there is $\tilde{E} \in \mathcal{E}$ such that

$$Z' \subset E_0 + \mathrm{dist}(Z, E)\mathcal{B} \subset \tilde{E} \subset E_0 + L_{\mathcal{E}} \,\mathrm{dist}(Z, E)\mathcal{B}. \tag{29}$$

We define $E^* = E \cap \tilde{E}$. Condition B.3 implies that the intersection of elements of $\mathcal{E}$ is also an element of $\mathcal{E}$. Hence $E^* \in \mathcal{E}$, but also $E^* \subset E \in \mathcal{E}'$, and the inclusion-completeness of $\mathcal{E}'$ implies $E^* \in \mathcal{E}'$.

Since Z' is contained both in E and in $\tilde{E}$, we have also $Z' \subset E^*$. Thus

$$\mathrm{dist}(Z, E^*) \le \mathrm{dist}(Z, Z') = \mathrm{dist}(Z, E).$$

Moreover, from (29) and (28),

$$\begin{aligned} \mathrm{dist}(E^*, Z) &\le \mathrm{dist}(\tilde{E}, Z) \le \mathrm{dist}(E_0, Z) + L_{\mathcal{E}} \,\mathrm{dist}(Z, E) \\ &\le (L_{\mathcal{E}} + 1) d_H(Z, \mathcal{E}) + L_{\mathcal{E}} \,\mathrm{dist}(Z, E). \end{aligned}$$

□

Now we prove Proposition 3.2.

Proof. 1. Let us fix the number R. Let L and M be a Lipschitz constant and a bound of $\mathcal{L}_{|(R+2)\mathcal{B}}$. We define

$$C = e^L(3 + LM) + M, \qquad c = M + 3, \qquad \beta = [M(L_{\mathcal{E}} + 1) + L_{\mathcal{E}} + 1]^{-1}. \tag{30}$$

2. Let us fix an arbitrary $\mathcal{E}'$ as in the formulation of the proposition. We fix also an arbitrary $h \in (0, \beta]$. According to Lemma 3.1, for every $E \in \mathcal{E}' \setminus \mathcal{M}$ there exist some $L_E(\cdot) \in \mathcal{L}$, $\sigma(E) \in (0, h^2]$ and $E' \in \mathcal{E}'$ such that

$$(I + \sigma(E)L_E(\cdot))(E) \subset E' + h\sigma(E)\mathcal{B}. \tag{31}$$

If $E \in \mathcal{M} \cap \mathcal{E}'$, we define $\sigma(E) = 0$.

For $Z \subset \mathbf{R}^n$ we denote similarly, as above,

$$\rho(Z, \mathcal{E}') = \inf_{E' \in \mathcal{E}'} \operatorname{dist}(Z, E').$$

For an arbitrary $Z \in \operatorname{comp}(\mathbf{R}^n)$, consider

$$\begin{aligned} \alpha(Z) = \sup\{\sigma(E);\ E \in \mathcal{E}',\ \operatorname{dist}(Z, E) \le \rho(Z, \mathcal{E}') + h\sigma(E), \quad \text{and} \\ \operatorname{dist}(E, Z) \le (L_{\mathcal{E}} + 1)d_H(Z, \mathcal{E}') + L_{\mathcal{E}}\rho(Z, \mathcal{E}') + \sigma(E)\}. \end{aligned} \tag{32}$$

First we shall prove that the set in the braces is nonempty. Let $E_k \in \mathcal{E}'$ be such that $\operatorname{dist}(Z, E_k) \le \rho(Z, \mathcal{E}') + 1/k$, $k = 1, 2, \ldots$. According to Lemma 5.1, there are $E_k^* \in \mathcal{E}'$ such that

$$\begin{aligned} \operatorname{dist}(Z, E_k^*) &\le \operatorname{dist}(Z, E_k) \le \rho(Z, \mathcal{E}') + \frac{1}{k}, \\ \operatorname{dist}(E_k^*, Z) &\le (L_{\mathcal{E}} + 1)d_H(Z, \mathcal{E}) + L_{\mathcal{E}} \operatorname{dist}(Z, E_k) \\ &\le (L_{\mathcal{E}} + 1)d_H(Z, \mathcal{E}) + L_{\mathcal{E}} \left(\rho(Z, \mathcal{E}') + \frac{1}{k} \right). \end{aligned}$$

The last inequality implies that the sequence E_k^* is bounded; therefore it has a convergent subsequence (indexed again by k) with limit E^* which belongs to $\mathcal{E}'$ since the latter is closed. Passing to a limit in the above two inequalities, we obtain (since $d_H(Z, \mathcal{E}) \le d_H(Z, \mathcal{E}')$)

$$\operatorname{dist}(Z, E^*) \le \rho(Z, \mathcal{E}') \quad \text{and} \quad \operatorname{dist}(E^*, Z) \le (L_{\mathcal{E}} + 1)d_H(Z, \mathcal{E}') + L_{\mathcal{E}}\rho(Z, \mathcal{E}').$$

Thus $\sigma(E^*)$ belongs to the set in the right-hand side of (32). Moreover, if $E^* \notin \mathcal{M}$, then $\alpha(Z) \ge \sigma(E^*) > 0$.

Then for every compact Z there exists $\mathcal{F}(Z) \in \mathcal{E}'$ such that

$$\operatorname{dist}(Z, \mathcal{F}(Z)) \le \rho(Z, \mathcal{E}') + h\sigma(\mathcal{F}(Z)), \tag{33}$$

$$\operatorname{dist}(\mathcal{F}(Z), Z) \le (L_{\mathcal{E}} + 1)d_H(Z, \mathcal{E}') + L_{\mathcal{E}}\rho(Z, \mathcal{E}') + \sigma(\mathcal{F}(Z)), \tag{34}$$

$$\sigma(\mathcal{F}(Z)) \ge \frac{1}{2}\alpha(Z). \tag{35}$$

3. Let us fix an arbitrary $E_0 \in \mathcal{E}'$ such that $E_0 \subset R\mathcal{B}$ and $\rho(E_0, \mathcal{M}) > ch$. We define a sequence $E_0, E_1, \ldots$ of elements of $\mathcal{E}'$ by

$$\sigma_k = \sigma(E_k), \quad Z_k = (I + \sigma_k L_{E_k}(\cdot))(E_k), \quad E_{k+1} = \mathcal{F}(Z_k).$$

We terminate the sequence at σ_{N-1}, Z_{N-1}, E_N if at least one of the following conditions fails to be fulfilled:

(i) $\sum_{i=0}^{N}\sigma_i \le h$;
(ii) $E_N \subset (R+1)\mathcal{B}$;
(iii) $E_N \notin \mathcal{M}$.

From (31) and from the definition of Z_k, we obtain, respectively,

$$\rho(Z_k,\mathcal{E}') \le \rho((I+\sigma_k L_{E_k}(\cdot))(E_k),\mathcal{E}') \le h\sigma_k, \tag{36}$$

$$H(Z_k,E_k) \le M\sigma_k, \quad d_H(Z_k,\mathcal{E}') \le M\sigma_k. \tag{37}$$

We shall prove that (ii) and (iii) cannot fail earlier than (i). Suppose that $E_i \subset (R+1)\mathcal{B}$ for all $i=0,\dots,k<N$, and let (i) be fulfilled for N. Then from (34), (36), and (37) we have

$$\begin{aligned} E_{k+1} = \mathcal{F}(Z_k) &\subset Z_k + (L_{\mathcal{E}}+1)d_H(Z_k,\mathcal{E}')\mathcal{B} + L_{\mathcal{E}}\rho(Z_k,\mathcal{E}')\mathcal{B} + \sigma_{k+1}\mathcal{B} \\ &\subset E_k + \sigma_k M\mathcal{B} + (L_{\mathcal{E}}+1)\sigma_k M\mathcal{B} + L_{\mathcal{E}}h\sigma_k\mathcal{B} + \sigma_{k+1}\mathcal{B} \\ &\subset E_k + [(L_{\mathcal{E}}+2)M + L_{\mathcal{E}}]\sigma_k\mathcal{B} + \sigma_{k+1}\mathcal{B}. \end{aligned}$$

From here and (i), we obtain, inductively,

$$E_{k+1} \subset E_0 + [(L_{\mathcal{E}}+2)M + L_{\mathcal{E}} + 1]\sum_{i=0}^{N}\sigma_i\mathcal{B} \subset E_0 + \frac{h}{\beta}\mathcal{B} \subset (R+1)\mathcal{B}. \tag{38}$$

Hence (ii) is satisfied as long as (i) holds.

Using (33) and (36), we obtain

$$Z_k \subset \mathcal{F}(Z_k) + (\rho(Z_k,\mathcal{E}') + h\sigma_{k+1})\mathcal{B} \subset E_{k+1} + (\sigma_k + \sigma_{k+1})h\mathcal{B}. \tag{39}$$

From (37) and (39),

$$E_k \subset Z_k + M\sigma_k\mathcal{B} \subset E_{k+1} + ((M+1)\sigma_k + \sigma_{k+1})\mathcal{B}$$

and, inductively,

$$E_0 \subset E_N + (M+2)\sum_{i=0}^{N}\sigma_i\mathcal{B} \subset E_N + h(M+2)\mathcal{B}.$$

If we assume that (iii) fails at N, then

$$\rho(E_0,\mathcal{M}) \le \rho(E_N,\mathcal{M}) + \operatorname{dist}(E_0,E_N) \le h(M+2) + \rho(E_N,\mathcal{M}) \le ch. \tag{40}$$

This contradicts the choice of E_0 with $\rho(E_0,\mathcal{M}) > ch$; therefore (iii) is fulfilled as long as (i) holds.

4. We shall prove that there is a smallest number N for which (i) fails. If such N does not exist, then $\sum_{i=0}^{\infty}\sigma_i$ is finite. In particular, $\sigma_k \to 0$, and according to (35), $\alpha(Z_k) \le 2\sigma_{k+1} \to 0$. Since E_k and Z_k are uniformly bounded (in the sets $(R+1)\mathcal{B}$ and $(R+2)\mathcal{B}$, correspondingly), there is a convergent subsequence (indexed again by k) $E_k \to \bar{E} \in \mathcal{E}'$ and $Z_k \to \bar{Z} \in \operatorname{comp}(\mathbf{R}^n)$. Since, from (40), we have

$$\rho(E_k,\mathcal{M}) \ge \rho(E_0,\mathcal{M}) - (M+2)h \ge (c-(M+2))h = h,$$

we obtain $\rho(\bar{E},\mathcal{M}) \ge h$; therefore $\sigma(\bar{E}) > 0$. Since $\alpha(Z_k) \to 0$, we have $\alpha(Z_k) \le \sigma(\bar{E})$ for all sufficiently large k. Hence from the definition of $\alpha(Z_k)$, we obtain that for all sufficiently large k at least one of the following relations holds:

$$\operatorname{dist}(Z_k,\bar{E}) > \rho(Z_k,\mathcal{E}') + h\sigma(\bar{E}),$$
$$\operatorname{dist}(\bar{E},Z_k) > (L_{\mathcal{E}}+1)d_H(Z_k,\mathcal{E}') + L_{\mathcal{E}}\rho(Z_k,\mathcal{E}') + \sigma(\bar{E}).$$

Passing to a limit, we obtain that $\operatorname{dist}(\bar{Z},\bar{E}) \geq h\sigma(\bar{E}) > 0$ or $\operatorname{dist}(\bar{E},\bar{Z}) \geq \sigma(\bar{E}) > 0$. On the other hand, passing to the limit in the inequality $H(Z_k, E_k) \leq \sigma_k M$, we obtain $\bar{E} = \bar{Z}$. This contradiction proves the existence of a smallest number N for which (i) fails.

5. If N is the number defined above, then

$$\sum_{i=0}^{N-1} \sigma_i \leq h, \quad h < \sum_{i=0}^{N} \sigma_i \leq h + h^2. \tag{41}$$

From (39) we have

$$Z_k = (I + \sigma_k L_{E_k}(\cdot))(E_k) \subset E_{k+1} + h(\sigma_k + \sigma_{k+1})\mathcal{B}.$$

Now we shall apply Lemma 4 of [28] for the sets E_k and $S = R\mathcal{B}$, and for $\delta = 1$. The conditions are fulfilled since $M\sum_{i=0}^{N-1} \sigma_i \leq Mh \leq 1$ (see (30)). The lemma gives

$$\begin{aligned}
&\left(I + \sum_{i=0}^{N-1} \sigma_i L_{E_i}(\cdot)\right)(E_0) \\
&\quad \subset E_N + e^{L\sum_{i=0}^{N-1}\sigma_i}\left(h\left(\sum_{i=0}^{N-1}\sigma_i + \sum_{i=1}^{N}\sigma_i\right) + LM\left(\sum_{i=0}^{N-1}\sigma_i\right)^2\right)\mathcal{B} \\
&\quad \subset E_N + h^2 e^L(3 + LM)\mathcal{B}.
\end{aligned}$$

Denote

$$L_h(\cdot) = \frac{1}{\sum_{i=0}^{N-1}\sigma_i} \sum_{i=0}^{N-1} \sigma_i L_{E_i}(\cdot) \in \mathcal{L}.$$

Then

$$\left(I + \left(\sum_{i=0}^{N-1}\sigma_i\right) L_h(\cdot)\right)(E_0) \subset E_N + h^2 e^L(3 + LM)\mathcal{B}.$$

Using (41), we obtain

$$\begin{aligned}
(I + hL_h(\cdot))(E_0) &\subset E_N + h^2 e^L(3 + LM)\mathcal{B} + \left(h - \sum_{i=0}^{N-1}\sigma_i\right) M\mathcal{B} \\
&\subset E_N + (h^2 e^L(3 + LM) + \sigma_N M)\mathcal{B} \\
&\subset E_N + (h^2 e^L(3 + LM) + h^2 M)\mathcal{B} \\
&= E_N + Ch^2\mathcal{B},
\end{aligned}$$

according to the definition of C. Notice that $E_N \subset (R+1)\mathcal{B}$ according to (38). The proof is complete since $E_N \in \mathcal{E}'$. □

The proof of Theorem 3.5 follows.

Proof. 1. Let $\mathcal{E}'$ enjoy the viability property with target $\mathcal{M}$. Let us fix an arbitrary $E \in \mathcal{E}' \setminus \mathcal{M}$. There exists $u(\cdot) \in \mathcal{U}_{[0,+\infty)}$ such that $E(t) \stackrel{def}{=} E_{u(\cdot)[0,E]}(t) \in \mathcal{E}'$ on some interval $[0,T]$ with $T > 0$. Then

$$X_{u(\cdot)}[0,E](t) \subset E(t) \in \mathcal{E}' \quad \forall t \in [0,T]. \tag{42}$$

Let us define $\bar{u} \in U$ as an arbitrary element from the set

$$\operatorname*{Limsup}_{h\to 0+} \frac{1}{h}\int_0^h u(s)\,\mathrm{d}s$$

and let $h_k \to 0+$ be the subsequence corresponding to $\bar{u}$. In a standard way, we obtain that

$$H(X_{\bar{u}}[0,E](h_k),\ (I + h_k F_{\bar{u}}(\cdot))(E)) \le C_1 h_k^2,$$

where C_1 is independent of k. On the other hand, it is also standard to prove (thanks to the convexity of $F_0(x)$ and the linear dependence on u) that

$$H(X_{u(\cdot)}[0,E](h_k), X_{\bar{u}}[0,E](h_k)) \le C_2 h_k^2 + C_3 h_k \left|\bar{u} - \frac{1}{h_k}\int_0^{h_k} u(s)\,\mathrm{d}s\right| = C_2 h_k^2 + h_k \gamma_k$$

with $\gamma_k \to 0$. Then

$$(I + h_k F_{\bar{u}}(\cdot))(E) \subset X_{u(\cdot)}[0,E](h_k) + h_k[(C_1 + C_2)h_k + \gamma_k]\mathcal{B},$$

which, together with (42) and Lemma 3.1, implies that $F_{\bar{u}}(\cdot) \in \mathcal{T}_{\mathcal{E}'}(E)$. Thus $\mathcal{E}'$ is a viability domain with target $\mathcal{M}$.

2. Now let $\mathcal{E}' \subset \mathcal{E}$ be an inclusion-complete viability domain with target $\mathcal{M}$. We fix an arbitrary $E_0 \in \mathcal{E}'$. According to Theorem 2.1, there is a number $R > 1$ such that $E_{u(\cdot)}[0,E_0](t) \subset (R-1)\mathcal{B}$ for every $u(\cdot) \in \mathcal{U}_{[0,1]}$ and $t \in [0,1]$. By a standard argument there exist constants S and $h^* > 0$ (depending only on the growth constant a and on the Lipschitz constant of F_u on $R\mathcal{B}$) such that

$$H(X_{u(\cdot)}[0,Z](h),\ (I + hF_{u(\cdot)}(\cdot))(Z)) \le Sh^2$$

for every $Z \subset R\mathcal{B}$ and $h \in [0,h^*]$. Moreover, the mapping $X_{u(\cdot)}[0,Z](\cdot)$ is Lipschitz continuous on $[0,h^*]$ with a Lipschitz constant L_x (depending on the data like S), provided that $Z \subset R\mathcal{B}$. We define also the constants $D \stackrel{def}{=} L_{\mathcal{E}}(L_x + 1)$ (where $L_{\mathcal{E}}$ is the constant from Condition B.2 for $\mathcal{E}$).

We apply Proposition 3.2 with the above number R and the fixed $\mathcal{E}'$. There exist positive β, c, and C such that for every $h \in (0,\beta]$ and for every $E \in \mathcal{E}'$, such that $E \subset R\mathcal{B}$ and $\rho(E,\mathcal{M}) \ge ch$, there exists $u = u[E,h] \in U$ and $\tilde{E} = \tilde{E}[E,h] \in \mathcal{E}'$ for which

$$(I + hF_u(\cdot))(E) \subset \tilde{E} + Ch^2\mathcal{B}.$$

Now we start proving the existence of a "viable" solution tube from E_0 with target $\mathcal{M}$. Clearly, if $E_0 \in \mathcal{M}$, there is nothing to prove. Below we shall let the positive number h vary between 0 and a number $\bar{h}$ chosen in such a way that $\bar{h} \le \beta$, $c\bar{h} < \rho(E_0,\mathcal{M})$, $\bar{h} \le h^*$, $2\bar{h} \le 1$, and $(C+S)\bar{h} \le 1$.

For a fixed (for the moment) $h \in (0,\bar{h}]$, we define

$$t_0 = 0, \quad t_0' = 0, \quad u_h(t_0') = \bar{u}, \quad Y_h(t_0') = E_0,$$

where $\bar{u}$ is an arbitrarily fixed element of U. Then we perform the following recursive construction starting with $i = 1$, and supposing that

(i) $t_{i-1}' + h + (C+S)h^2 \le 1$;

(ii) $E_{i-1} \subset R\mathcal{B}$;
(iii) $\rho(E_{i-1}, \mathcal{M}) \geq ch$;
(iv) $Y_h(t'_{i-1}) \subset E_{i-1} \subset \mathcal{E}'$.
Define

$$t_i = t'_{i-1} + h, \quad t'_i = t_i + (C+S)h^2, \quad u_h(t) = u[E_{i-1}, h], \quad Y_h(t) = X_{u_h}[t_{i-1}, E_{i-1}](t)$$

for $t \in [t'_{i-1}, t_i]$, which is possible thanks to (i)–(iii). Then, again using (ii),

$$Y_h(t_i) \subset (I + hF_{u_h}(\cdot))(E_{i-1}) + Sh^2\mathcal{B} \subset \tilde{E}[E_{i-1}, h] + h^2(C+S)\mathcal{B}. \tag{43}$$

Then we extend $u_h(\cdot)$ and the mapping Y_h for $t \in (t_i, t'_i]$ by the formula

$$u_h(t) = \bar{u}, \qquad Y_h(t) = \bigcup_{y \in Y_h(t_i)} \left(\frac{t'_i - t}{t'_i - t_i} y + \frac{t - t_i}{t'_i - t_i} \mathcal{P}_{\tilde{E}[E_{i-1}, h]}(y) \right),$$

where, as before, $\mathcal{P}$ is the projection operator. Obviously $Y_h(t'_i) = \mathcal{P}_{\tilde{E}[E_{i-1}, h]}(Y_h(t_i)) \subset \tilde{E}[E_{i-1}, h]$. It is easy to check that the mapping Y_h is Lipschitz continuous with constant 1 on $[t_i, t'_i]$, thanks to the inclusion (43) (this is, in fact, proven in [1], where the above "linear" interpolation was proposed). Thus Y_h is now Lipschitz on $[0, t'_i]$ with constant $L'_x = \max\{L_x, 1\}$, thanks to (ii). Moreover,

$$H(Y_h(t'_{i-1}), Y_h(t'_i)) \leq L_x h + (C+S)h^2.$$

Since, according to (iv), $Y_h(t'_{i-1}) \subset E_{i-1}$, Conditions B.2 and B.3 together imply that the minimal element E_i from $\mathcal{E}$ that contains $Y_h(t'_i)$ satisfies

$$Y_h(t'_i) \subset E_i \subset E_{i-1} + L_{\mathcal{E}}(L_x h + (C+S)h^2)\mathcal{B} \subset E_{i-1} + hD\mathcal{B}. \tag{44}$$

Since $Y_h(t'_i) \subset \tilde{E}[E_{i-1}, h] \in \mathcal{E}' \subset \mathcal{E}$, we have $E_i \subset \tilde{E}[E_{i-1}, h]$, and since the collection $\mathcal{E}'$ is inclusion-complete in $\mathcal{E}$, we obtain that $E_i \in \mathcal{E}'$. Thus we ensure (iv) for the next step.

This completes the description of the construction. Thanks to the suppositions for $\bar{h}$, one can perform at least one step. One can repeat the same procedure as long as the relations (i)–(iii) hold. Thus the procedure terminates when one of these relations is violated; let $i = N = N(h)$ be the last integer for which (i)–(iii) still hold (as obviously exists, since (i) is violated for $i > 1/h$). Inclusion (44) implies that either $t'_N \geq 1$, or $Nh \geq 1/D$, or $\rho(E_N, \mathcal{M}) \leq ch$. In each case, when $h \to 0$, the sequence $t'_{N(h)}$ has a strictly positive lower limit T, and either $T \geq T_0 \stackrel{def}{=} \min\{1, 1/D\}$ or $\rho(E^h_{N(h)}, \mathcal{M}) \to 0$ for a subsequence (here we add the superscript h to E_i to indicate the dependence on h).

The sequence $Y_h(\cdot)$ is equi-Lipschitz (with Lipschitz constant L'_x) and uniformly bounded; therefore there exists a subsequence (for which also $t'_{N(h)} \to T$) converging to some Lipschitz tube $Y(\cdot)$ on $[0, T]$. Because of (iv) and the closedness of $\mathcal{E}'$, we obtain that $Y(t) \subset \mathcal{E}'$ for every $t \in [0, T]$.

Since $\mathrm{meas}(\cup_i [t_i, t'_i]) \leq \mathrm{const}.h$ and on every $[t'_{i-1}, t_i]$ the tube Y_h is invariant with respect to (14) with $u(t) = u_h(t)$, one can prove that $Y(\cdot)$ is an invariant tube of (14) for some $u_0(\cdot) \in \mathcal{U}_{[0,T]}$ (which is an L_1-weak limit of a subsequence of $u_h(\cdot)$). This is proven in detail in [28, Lemma 7]. Thus we obtain that $Y(\cdot)$ is an invariant tube in $\mathcal{E}'$ starting from E_0; therefore it contains the solution tube $E_{u_0(\cdot)}(\cdot)$ in $\mathcal{E}$ starting

from E_0 (see Corollary 2.2). From the inclusion-completeness of $\mathcal{E}'$, we conclude that $E_{u_0(\cdot)}(\cdot)$ is a tube in $\mathcal{E}'$, and since it is the solution tube in the larger collection $\mathcal{E}$, it is the solution tube also in $\mathcal{E}'$.

If $T < 1$ and $E_{u_0(\cdot)}(T) \notin \mathcal{M}$, then by the definition of R, we see that $E_{u(\cdot)}[T, E_{u_0(\cdot)}(T)](t) \subset (R-1)\mathcal{B}$ for every $u(\cdot) \in \mathcal{U}_{[T,1]}$ and $t \in [T,1]$. Therefore the same construction can be repeated with the same constants. Thus in a finite number of steps, the solution tube $E_{u_0(\cdot)}(\cdot)$ will either satisfy $E_{u_0(\cdot)}(t) \in \mathcal{M}$ for some $t \in [0,1]$ or will be defined on $[0,1]$. This, together with the growth condition and the estimation in Theorem 2.1, implies the claim of the theorem. □

UNIQUE CONTINUATION AND CONTROL FOR THE HEAT EQUATION FROM AN OSCILLATING LOWER DIMENSIONAL MANIFOLD*

CARLOS CASTRO† AND ENRIQUE ZUAZUA‡

Abstract. We consider the linear heat equation with Dirichlet boundary conditions in a bounded domain of $\mathbb{R}^n$, $n \geq 1$, and with a control acting on a lower-dimensional time-dependent manifold of dimension $k \leq n-1$. We analyze the approximate controllability problem. This problem is equivalent to a suitable uniqueness or unique continuation property of solutions of the heat equation without control. More precisely, it consists of proving that the unique solution of the Dirichlet problem vanishing on the time-dependent manifold is identically zero. This uniqueness problem, however, does not fit in the class of classical Cauchy problems and therefore, the existing tools based on power series expansions, Carleman inequalities, and doubling properties do not seem to apply. We give sufficient conditions on the time-dependent manifold for this uniqueness property to hold. The techniques we employ combine the Fourier series representation and the time analyticity of solutions and allow us to reduce the problem to a uniqueness question for the eigenfunctions of the Laplacian. We then apply well-known results on the nodal sets of these eigenfunctions.

We also analyze the asymptotic behavior of the control when the time-oscillation of the manifold supporting the control increases. When the frequency of oscillation tends to infinity we prove that the controls converge to an approximate control for the same heat equation but on a manifold of dimension $k+1$ that is independent of time. This is done under suitable time-periodicity assumptions on the original manifold and confirms the fact that increasing time-oscillations of the support of the control increases the efficiency of the control mechanism.

Key words. approximate controllability, heat equation, lower-dimensional manifold

DOI. 10.1137/S0363012903430317

1. Introduction.

This paper is devoted to a study of the properties of approximate controllability for the linear, constant coefficient heat equation in a bounded domain of $\mathbb{R}^n$, $n \geq 1$, with Dirichlet boundary conditions and with a control acting on a time-dependent lower-dimensional manifold of dimension $k \leq n-1$.

The main novelty of the analysis carried out in this paper lies precisely in the fact that the control acts on a lower-dimensional manifold that moves in time.

The problem under consideration is rather natural. Indeed, in the ultimate goal of optimally controlling a given system with the minimal amount of control it is natural to consider controls located, for instance, in a single point or on a finite collection of points. This is the so-called pointwise control problem (see Lions [L3]). However, in that case the system may easily fail to be controllable. That is the case, for instance, when the support of the control is located on a nodal set of an eigenfunction of the Laplacian. As a consequence of that, the property of pointwise controllability, even if it holds on some geometric configurations (when the support is chosen in an appropriate way), is extremely sensitive to the location of the controller.

On the contrary, when the control is located on an open subset of the domain, approximate controllability holds as a consequence of Holmgren's uniqueness theorem without any geometric restriction. In fact, in that case, a much stronger property, the so-called null-controllability property, holds (see [FI], [LR], or [FZ] among others).

The case where the control is supported on a manifold of dimension $k \leq n-1$ is an intermediate situation between the problem of pointwise control and the control on an open subset. However, when the support of the control is independent of time the situation is quite similar to the one encountered when dealing with the pointwise control problem: If the manifold is contained on the nodal set of some eigenfunction, the approximate controllability property fails.

Berggrem [B] pointed out that a possible way of enhancing the control property when the control was supported in a manifold of dimension $k \leq n-1$ was to make this support oscillate in time more and more. In [B] some numerical evidence of this fact for the one-dimensional (1-d) case was also given.

This paper is devoted to analytically investigating this issue. We consider, in particular, the following two problems.

Problem 1*:* To give sufficient conditions on a time-dependent manifold to ensure the approximate controllability of the heat equation.

Problem 2*:* To analyze the asymptotic limit of the controllers when the time-frequency of the oscillations of their supports tends to infinity.

Let us briefly describe the results we obtain and the techniques we employ. Concerning the first problem, using the time-analyticity of solutions of the heat equation and the Fourier development of solutions, under suitable assumptions on the time-evolution of the manifolds where the control is supported, the problem is reduced to a unique continuation question on the eigenfunctions of the Laplacian that we solve applying classical results on its nodal sets. At this point, it should be noted that we do not fully use the existing results on the size of the nodal sets of eigenfunctions ([DF], [L], [JL]) whose consequences in the context of approximate control of the heat equation remain to be investigated.

Once the heat equation is known to be approximately controllable (i.e., once Problem 1 is solved) the control can be characterized as the minimum of a suitable quadratic functional over the set of solutions of the adjoint heat equation as in [FPZ].

We then address Problem 2. More precisely, assuming that the manifold in which the control is located is time-periodic and that it satisfies the requirements of Problem 1 to guarantee approximate controllability, we investigate the behavior of the controls as the time-frequency (described by a parameter $1/\varepsilon$) tends to infinity. The control then undergoes a *homogenization* process (see [DN] and [Z1] for similar situations in different problems). In the limit we get controls distributed on a time-independent manifold of dimension $k+1$ modulated by a density factor varying along the manifold. This result does show indeed that time oscillations on the support of the control enhance the controllability properties.

The proof of this second result uses the characterization of controls as minima of suitable quadratic functionals, Γ-convergence arguments, and a careful analysis of the behavior as $\varepsilon \to 0$ of traces of solutions of the heat equation along rapidly oscillating manifolds.

Let us now state more precisely the problems we shall address and introduce the notation we shall employ.

2. Problem formulation. Let Ω be a bounded smooth domain of $\mathbb{R}^n$ ($n = 1, 2, 3$), $\partial\Omega$ its boundary, $T > 0$, $Q = \Omega \times (0, T)$, and $\Sigma = \partial\Omega \times (0, T)$. We consider the linear heat equation with an interior control $f(x, t)$ which acts in an open subset $\omega \subset \Omega$:

$$\begin{cases} u_t - \Delta u = f(x,t)\chi_\omega(x) & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,0) = u^0(x) & \text{in } \Omega. \end{cases} \tag{2.1}$$

Here χ_ω represents the characteristic function of the region ω.

Given any $T > 0$ and any open subset $\omega \subset \Omega$, the following approximate controllability property is known to hold: *For any initial data $u^0 \in L^2(\Omega)$, any final data $u^1 \in L^2(\Omega)$, and any $\alpha > 0$ there exists a control $f(x, t) \in L^2(\omega \times (0, T))$ such that the solution u of system* (2.1) *satisfies*

$$\|u(x,T) - u^1\|_{L^2(\Omega)} \leq \alpha. \tag{2.2}$$

Moreover, it is known (see [FPZ]) that the optimal control (the one with minimal L^2-norm) can be obtained by minimizing a suitable continuous, convex, and coercive functional over the space of solutions of the following adjoint system endowed with the L^2-norm of its datum at $t = T$:

$$\begin{cases} -\varphi_t - \Delta\varphi = 0 & \text{in } \Omega \times (0,T), \\ \varphi(T) = \varphi^0 & \text{in } \Omega, \\ \varphi = 0 & \text{on } \partial\Omega \times (0,T). \end{cases} \tag{2.3}$$

On the other hand, it is well known that the approximate controllability property above is equivalent to the following uniqueness property of (2.3): If $\varphi = 0$ in $\omega \times (0, T)$, then $\varphi \equiv 0$. In this case, this uniqueness property does hold as a consequence of Holmgren's theorem.

This paper is devoted to analyzing these questions when the open subset ω of Ω is replaced by a lower dimensional continuous manifold $\gamma(t) \subset \Omega$. In fact, in view of the fact that, in practice, the support of the control needs to be very small compared to the total size of the domain Ω it is very natural to consider the control to be located in such lower-dimensional manifolds. When the manifold $\gamma \subset \Omega$ is independent of time the corresponding control system reads as follows:

$$\begin{cases} u_t - \Delta u = f(x,t)\delta_\gamma(x) & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,0) = u^0(x) & \text{in } \Omega, \end{cases} \tag{2.4}$$

where $\delta_\gamma(x)$ represents the Dirac measure on γ. Here γ can be a point, a curve if $n \geq 2$, or a surface if $n = 3$, for instance. When γ is a point we consider it as a manifold of dimension zero.

It turns out that the approximate controllability property of system (2.4) depends on the location of γ. Indeed, the problem of approximate controllability for system (2.4) can be reduced to a uniqueness problem for the adjoint system (2.3):

$$\varphi = 0 \text{ on } \gamma \Rightarrow \quad \varphi \equiv 0.$$

Using the Fourier series representation of solutions of system (2.3) it can be shown that these properties hold if and only if the only eigenfunction of the Laplacian with

homogeneous Dirichlet boundary conditions and vanishing on γ is the identically zero one. In what follows, the manifolds γ for which this spectral property is satisfied will be referred to as *strategic manifolds*.

The property of γ being strategic is difficult to establish in practice since it is extremely unstable. For example, if $\Omega = (0,1)$ with $n = 1$, then $\gamma = x_0 \in \Omega$ is strategic if and only if it is irrational. In general, k-dimensional manifolds in Ω with $k < n$ are generically strategic. But, by the contrary, γ fails to be strategic if it is contained in a nodal set of any of the eigenfunctions of the Laplacian. Consequently, controllability properties over low-dimensional manifolds are hard to use in practice. At this point it is worth noting that the strategic property for a k-dimensional manifold is obviously more likely to hold when the dimension k is larger.

To overcome this difficulty one may consider controls supported on moving (in time) manifolds $\{\gamma(t)\}_{0\leq t\leq T}$.

The main advantage of moving controls is that it is easy to construct families $\{\gamma(t)\}_{0\leq t\leq T}$ for which the strategic property holds for $\gamma(t)$ a.e. in $t \in [0,T]$. For example, this is the case in the 1-d example above when we assume that the control is located at a point that moves continuously in time. In this case, $\gamma(t)$ is irrational, and therefore strategic, a.e. in $t \in [0,T]$. Therefore, the approximate controllability is likely to hold for such moving controls. A previous result in this direction is given in [K] where the approximate controllability for the 1-d case is proved when considering two pointwise moving controls that meet at a time $t_0 > 0$.

However, even if the system can be controlled from a one-parameter family of lower-dimensional manifolds $\{\gamma(t)\}_{0\leq t\leq T}$, the control is expected to be singular because it acts in a very small part of the domain. Indeed, as it was pointed out in [B] for the 1-d case, the control exhibits, in general, a highly oscillatory behavior in time.

To improve the efficiency of these moving controls, the possibility of increasing the time oscillations of the curve $\{\gamma(t)\}_{0\leq t\leq T}$ was suggested in [B]. More precisely, a highly oscillating periodic family of manifolds of the form $\{\gamma(t/\varepsilon)\}_{0\leq t\leq T}$ was considered, $\{\gamma(t)\}_{0\leq t}$ being a $2\pi-$periodic in time family of manifolds. We refer to these controls as *rapidly oscillating controllers*. As $\varepsilon \to 0$ the control acts at any point of the range of $\{\gamma(s)\}_{s\in[0,2\pi)}$ for an increasing number of times. In this way, as $\varepsilon \to 0$, the controls are likely to be close, in some sense, to a control acting on the open set ω defined as the interior set of $P = \ range\ \{\gamma(s)\}_{s\in[0,2\pi)}$ with respect to the relative topology, which, typically, contains a manifold of dimension $k+1$. As we mentioned above, controls acting on higher dimensional manifolds are likely to be more efficient. In the particular case $k = n-1$, the limit set (as $\varepsilon \to 0$) ω is an open subset of Ω and the limit system is approximately controllable. Thus, in general, rapidly oscillating controllers should provide a more efficient way to control the system.

This paper is devoted to rigorously proving that both ideas presented before are correct. First we provide several controllability results of the heat equation for a large class of lower-dimensional *moving controls* and second, we prove the convergence of *rapidly oscillating controllers* as $\varepsilon \to 0$ to a certain class of controllers distributed on a $k+1$-dimensional manifold.

The rest of this paper is divided into four more sections. In section 3 we give the main approximate controllability results in this paper. We distinguish the case of one space dimension and the multidimensional one. We also state the main results on the asymptotic behavior of the controls on rapidly oscillating control regions. Section 4 is devoted to analyzing the problem of unique continuation which is equivalent to the approximate controllability one. We distinguish again the 1-d and the multidimensional cases. In section 5 we prove the convergence results for the rapidly oscillating

controllers as the oscillation parameter ϵ goes to zero. Finally, in section 6 we provide some comments and extensions.

3. Main results. In this paper we restrict ourselves to the case where Ω is an open set of $\mathbb{R}^n$ in dimensions $n = 1, 2, 3$, but the techniques we employ and the results we get can be easily generalized to higher dimensions.

We consider system (2.4) with a moving control

$$\begin{cases} u_t - \Delta u = f(x,t)\delta_{\gamma(t)}(x) & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,0) = u^0(x) & \text{in } \Omega. \end{cases} \tag{3.1}$$

We assume that $\gamma(t)$ satisfies the following hypotheses:

1. $\gamma(t)$ is a Lipschitz-continuous k-dimensional manifold in Ω with $0 \le k \le n-1$ for all $t \in [0,T]$.
2. The set $\gamma = \{\gamma(t)\}_{0\le t\le T}$ is a time-continuous family of manifolds in the sense of the following definition.

DEFINITION 3.1. *We say that $\{\gamma(t)\}_{0\le t\le T}$ is a C^s $(s \ge 0)$ (resp., analytic) family of k-dimensional manifolds when $\gamma(t)$ is a Lipschitz-continuous k-dimensional manifold for all $t \in [0,T]$ and there exists a finite family of functions $\{\psi_\alpha(x,t)\}_{\alpha=1}^A$, $A \ge 1$ being independent of t, such that*

1. *$\psi_\alpha : V_\alpha \times [0,T] \subset \mathbb{R}^k \times [0,T] \to \{\gamma(t)\}_{0\le t\le T}$, where V_α are compact sets of $\mathbb{R}^k$, for any $\alpha = 1, \dots, A$, and*

$$\{\gamma(t)\}_{0\le t\le T} \subset \bigcup_{\alpha=1}^{A} \psi_\alpha(V_\alpha, t) \quad \text{for all } 0 \le t \le T.$$

2. *$\psi_\alpha(y,t) \in C([0,T]; W^{1,\infty}(V_\alpha))$ for all $\alpha = 1, \dots, A$.*
3. *for any fixed $y \in V_\alpha$, $\psi_\alpha(y,t)$ is C^s (resp., analytic) in the time variable t.*

Remark 3.1. 1. Note that a C^s family of k-dimensional manifolds may be constituted by manifolds $\gamma(t)$ which are not C^s. More precisely, the condition of being of class C^s refers only to the regularity on the time variable.

2. The assumption on the Lipschitz-continuity in space of the manifolds $\gamma(t)$ is the minimal one to define the surface measure σ on $\gamma(t)$ (see [N, Chap. 4, sect. 7]). Thus, the measure of $\gamma(t)$, arising below, and the integral on $\gamma(t)$ are well defined for any $t \in [0,T]$.

3. The measure of $\gamma(t) \subset \Omega$ is finite for all $t \in [0,T]$. Moreover, hypothesis 2 in Definition 3.1 ensures the time-continuity of the total measure of $\gamma(t)$. Therefore the measure of $\gamma(t)$ is in fact uniformly bounded in $t \in [0,T]$.

4. The case $k = 0$ corresponds to that in which, for each $t \in [0,T]$, $\gamma(t)$ is reduced to a single point or a finite number of points. For instance, when $\gamma(t) = \{x(t)\}$ for all $t \in [0,T]$ the control in (3.1) takes the form $f(t)\delta_{x=\gamma(t)}$ and f is independent of x.

In Figure 1 we show some examples of time-continuous families of manifolds that satisfy the hypotheses in Definition 3.1.

The control $f(x,t)$ (resp., $f(t)$ if $k = 0$) in (3.1) is assumed to belong to $L^2(0,T; L^2(\gamma(t)))$ (resp., $L^2(0,T)$), i.e.,

$$\int_0^T \int_{\gamma(t)} |f(x,t)|^2 d\sigma\, dt < \infty \qquad \left(\text{resp.}, \int_0^T |f(t)|^2 dt < \infty\right). \tag{3.2}$$

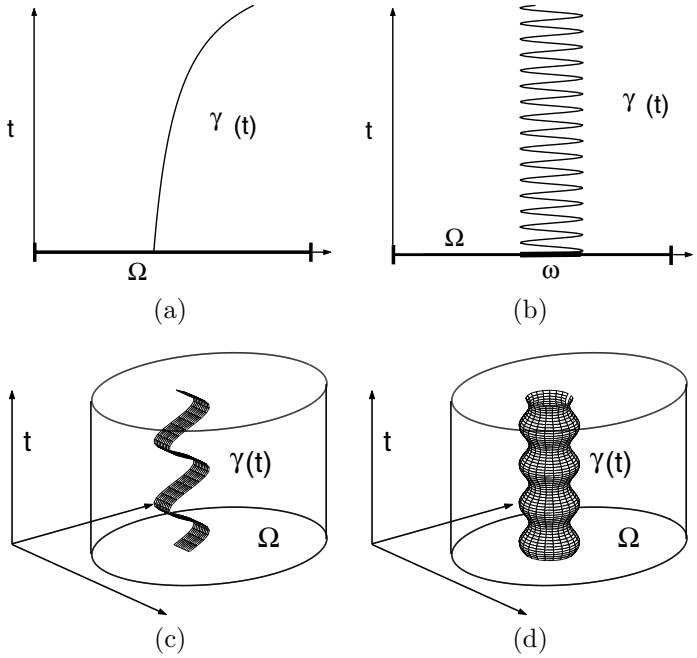

FIG. 1. *Examples of time-continuous families of manifolds that illustrate Definition* 3.1*:* (a) *and* (b)*, single point* ($k = 0$) *with nonregular and regular in time trajectories, respectively;* (c) *and* (d)*, curves* ($k = 1$) *with regular in time trajectories. Note that in case* (d) *the parametrization of* $\gamma(t)$*, for each* $t \in [0, T]$*, is a closed curve that requires at least two charts. Thus we have to consider* $A = 2$ *in Definition* 3.1.

Then, system (3.1) is well defined in different Sobolev spaces depending on the space dimension n and the dimension k of the manifold $\gamma(t)$. We introduce the spaces

$$H_{-1} = \begin{cases} H^{-1}(\Omega) & \text{if } n-k=1, \\ L^2(\Omega) & \text{if } n-k>1, \end{cases} \qquad H_0 = \begin{cases} L^2(\Omega) & \text{if } n-k=1, \\ H_0^1(\Omega) & \text{if } n-k>1, \end{cases}$$

$$H_1 = \begin{cases} H_0^1(\Omega) & \text{if } n-k=1, \\ H^2 \cap H_0^1(\Omega) & \text{if } n-k>1, \end{cases} \tag{3.3}$$

and we denote by H_i', $i = 1, 2, 3$, their duals. Recall that we are assuming the space dimension $n = 1, 2, 3$. Similar results can be proved for higher dimensions. But the choice of H_i, $i = 1, 2, 3$, has to be suitably modified for $n \geq 4$.

The term $f(x,t)\delta_{\gamma(t)}$ on the right-hand side of (3.1) clearly satisfies

$$f(x,t)\delta_{\gamma(t)} \in L^2(0,T;H_1'). \tag{3.4}$$

Indeed, if we denote by $\langle \cdot, \cdot \rangle$ the duality pairing between $L^2(0,T;H_1)$ and its dual we have

$$\langle f(x,t)\delta_{\gamma(t)}, \varphi \rangle = \begin{cases} \int_0^T \int_{\gamma(t)} f(x,t)\varphi(x,t)d\sigma\, dt & \text{if } k \geq 1, \\ \int_0^T f(t)\varphi(\gamma(t),t)dt, & \text{if } k = 0, \end{cases} \tag{3.5}$$

which is well defined under the assumptions above on $\gamma(t)$, since

$$\left|\int_0^T \int_{\gamma(t)} f(x,t)\varphi(x,t)d\sigma\, dt\right| \le \|f\|_{L^2(0,T;L^2(\gamma(t)))}\|\varphi\|_{L^2(0,T;L^2(\gamma(t)))} \quad \text{if } k \ge 1,$$
$$\left|\int_0^T f(t)\varphi(\gamma(t),t)dt\right| \le \|f\|_{L^2(0,T)}\|\varphi\|_{L^2(0,T;L^\infty(\Omega))}, \qquad \text{if } k = 0,$$

and

$$\|\varphi\|_{L^2(0,T;L^2(\gamma(t)))} \le \begin{cases} C(\gamma)\|\varphi\|_{L^2(0,T;L^\infty)} \le C(\gamma)\|\varphi\|_{L^2(0,T;H^2\cap H_0^1)} & \text{if } n=3 \text{ and } k=1,\\ C(\gamma)\|\varphi\|_{L^2(0,T;H_0^1(\Omega))} & \text{if } n=2,3 \text{ and } n-k=1, \end{cases}$$

$$\|\varphi\|_{L^2(0,T;L^\infty(\Omega))} \le \begin{cases} C(\gamma)\|\varphi\|_{L^2(0,T;H_0^1)} & \text{if } n=1,\\ C(\gamma)\|\varphi\|_{L^2(0,T;H^2\cap H_0^1)} & \text{if } n=2,3. \end{cases} \tag{3.6}$$

Here we have used the Sobolev embeddings

$$\begin{aligned} &H_0^1(\Omega) \subset C(\bar\Omega) && \text{if } n=1,\\ &H^2\cap H_0^1(\Omega) \subset C(\bar\Omega) && \text{if } n=2,3 \text{ and } n-k>1, \end{aligned}$$

and the trace theorem (see [N, Chap. 4, sect. 7]), in the case $n=2,3$ and $n-k=1$, guaranteeing that

$$\|\,\varphi|_{\gamma(t)}\,(\cdot,t)\|_{L^2(\gamma(t))} \le C(\gamma(t))\|\varphi(\cdot,t)\|_{H_0^1(\Omega)} \qquad \text{for } n=2,3 \text{ and } n-k=1.$$

The constant $C(\gamma(t))$ depends only on the measure of $\gamma(t)$. Thus, in view of the assumptions on γ, it can be chosen to be uniformly bounded in $t\in[0,T]$. Consequently (3.6) holds and therefore (3.4) holds too.

It is at this point where defining H_1 distinguishing the value of $n-k$ is needed. The same can be said about the assumptions we have made on the manifold γ.

We now define the weak solution of system (3.1) by transposition (see [LM]). Let $\psi\in L^2(0,T;H_{-1})$ and consider the adjoint heat equation

$$\begin{cases} -\varphi_t - \Delta\varphi = \psi & \text{in } Q,\\ \varphi = 0 & \text{on } \Sigma,\\ \varphi(x,T) = 0 & \text{in } \Omega. \end{cases} \tag{3.7}$$

Note that the unique solution of (3.7) belongs to the class

$$\varphi \in C([0,T];H_0)\cap L^2(0,T;H_1).$$

Multiplying the equation in (3.1) by φ and integrating by parts we obtain formally the following identity:

$$\int_0^T\int_{\gamma(t)} f\varphi d\sigma\, dt + \int_\Omega u^0\varphi(0)dx = \int_0^T\int_\Omega u\psi dx\, dt \quad \text{if } k\ge 1,$$
$$\int_0^T f(t)\varphi(\gamma(t),t)dt + \int_\Omega u^0\varphi(0)dx = \int_0^T\int_\Omega u\psi dx\, dt \quad \text{if } k=0.$$

This motivates the following definition: *We say that u is a solution of* (3.1), *in the sense of transposition, if*

$$\langle f\delta_{\gamma(t)},\varphi\rangle + \langle u^0,\varphi(0)\rangle_0 = \int_0^T \langle u,\psi\rangle_{-1}dt \qquad \forall\psi\in L^2(0,T;H_{-1}), \tag{3.8}$$

where $\langle\cdot,\cdot\rangle$ (resp., $\langle\cdot,\cdot\rangle_0$, $\langle\cdot,\cdot\rangle_{-1}$) is the duality pairing between $L^2(0,T;H_1)$ (resp., H_0, H_{-1}) and its dual space $L^2(0,T;H_1')$ (resp., H_0', H_{-1}).

It is easy to see that for any initial data $u^0\in H_0'$ there exists a unique solution of (3.1) in the sense of transposition in the class

$$u\in C\left([0,T];H_0'\right). \tag{3.9}$$

For example, if we consider the case $n-k>1$ (the case $n-k=1$ is even simpler), then $H_{-1}=L^2(\Omega)$ and $\psi\in L^2(0,T;L^2(\Omega))$. The solution φ of system (3.7) is in the class $\varphi\in L^2(0,T;H^2\cap H_0^1(\Omega))\cap C([0,T];H_0^1(\Omega))$, and then the map

$$\psi\to(\varphi(x,t),\varphi(x,0))$$

is linear and continuous from $L^2(0,T;L^2(\Omega))$ to $L^2(0,T;H^2\cap H_0^1(\Omega))\times H_0^1(\Omega)$. Therefore, for any initial data $u^0\in H^{-1}(\Omega)$, the left-hand side of (3.8) is linear and continuous from $\psi\in L^2(0,T;L^2(\Omega))$ to $\mathbb{R}$. Then, there exists a unique $u\in L^2(0,T;L^2(\Omega))$ satisfying (3.8), i.e., a solution of (3.1) in the sense of transposition. Moreover, it is easy to see that this solution u satisfies the first equation in system (3.1) in the sense of distributions, and then we deduce that $u_t\in L^2(0,T;(H^2\cap H_0^1(\Omega))')$. Consequently,

$$u\in C([0,T];H^{-1}(\Omega)),$$

and (3.9) holds for $n-k>1$.

We consider the following approximate controllability problem for system (3.1): *given u^0, $u^1\in H_0'$ and $\alpha>0$, to find a control $f\in L^2(0,T;L^2(\gamma(t)))$ such that the solution $u=u(x,t)$ of* (3.1) *satisfies*

$$\|u(T)-u^1\|_{H_0'}\le\alpha. \tag{3.10}$$

For the sake of clarity we divide the rest of this section into two subsections where we state separately the results for the 1-d case and those for higher space dimensions.

3.1. The one-dimensional case. We assume that $\Omega=(0,L)$ with $L>0$. Let $\gamma:[0,T]\to\Omega$ be any continuous curve. The following theorem holds.

THEOREM 3.1. *Let $\gamma(t):[0,T]\to\Omega$ be a nonconstant continuous curve satisfying at least one of the following conditions:*

1. *There exists an open subinterval $\mathcal{U}\subset[0,T]$ where γ is not analytic at any point $t\in\mathcal{U}$.*
2. *There exists $t_1\in(0,T)$ where $t\to\gamma(t)$ is not analytic and a subinterval $(t_1,t_2)\subset(0,T)$ where γ is analytic and can be extended analytically to a subinterval (t_0,t_2) with $t_1\in(t_0,t_2)$.*
3. *γ can be extended analytically to a curve $\bar\gamma(t):(-\infty,T]\to\mathbb{R}$ satisfying one of the following conditions:*
   (a) *$\bar\gamma(t)$ meets the boundary of Ω, i.e., there exists $t_0\in(-\infty,T]$ such that $\bar\gamma(t_0)\in\partial\Omega$.*
   (b) *The set of accumulation points of $\bar\gamma(t)$ as $t\to-\infty$ contains at least one point $x_0\in\Omega$ such that x_0/L is irrational.*

(c) *The set of accumulation points of* $\bar{\gamma}(t)$ *as* $t \to -\infty$ *is reduced to a unique* $x_0 \in \Omega$*, and there exists a sequence* $t_n \to -\infty$ *such that*

$$\lim_{t_n \to -\infty} (\bar{\gamma}(t_n) - x_0)^{-1} e^{t_n(\lambda_3 - \lambda_2)} = 0, \tag{3.11}$$

where $\lambda_3 - \lambda_2 = 5\pi^2/L^2$ *is the difference between the third and second eigenvalues of the Laplace operator in* Ω*.*

Then, for any $T > 0$*, system* (3.1) *is approximately controllable.*

Remark 3.2. The conditions on γ in Theorem 3.1 above do not characterize all possible curves for which approximate controllability holds. However, they may be considered sharp in different senses:

1. Condition 1 is sharp in the sense that if γ is analytic in one interval $(t_0, t_1) \subset [0, T]$, then the approximate controllability may fail. We can consider, for example, a curve $\gamma(t) = x_0$ with x_0 nonstrategic, i.e., x_0/L rational.
2. Condition 2 is sharp in the sense that if $\gamma : (t_1, t_2) \to \Omega$ is analytic but cannot be extended analytically to a subinterval (t_0, t_2) with $t_1 \in (t_0, t_2)$, then approximate controllability may fail (see example 1 in section 4.1 below).
3. Condition 3 is sharp in the sense that if $\gamma : [0, T] \to \Omega$ is analytic but cannot be extended analytically to $t \in (-\infty, T]$, then approximate controllability may fail (see example 2 in section 4.1 below).
4. Condition 3 is also sharp in the sense that if $\gamma : [0, T] \to \Omega$ is analytic and can be extended analytically to $\bar{\gamma} : (-\infty, T] \to \Omega$ in such a way that the set of accumulation points of $\bar{\gamma}(t)$ as $t \to -\infty$ is reduced to an unique nonstrategic point $x_0 \in \Omega$ that does not satisfy (3.11), then approximate controllability may fail (see example 3 in section 4.1 below).

We give now a number of examples showing that the conditions in Theorem 3.1 cover a large class of curves.

Examples.

1. *Weierstrass-type functions.* Let $\gamma(t) : [0, T] \to \Omega$ be a C^1 function with nowhere defined second derivative. Then $\gamma(t)$ is Lipschitz and satisfies condition 1 above. A function with this property can be constructed integrating the classical Weierstrass example of a continuous function that is nowhere differentiable (see [Pu, Chap. 4, sect. 7], for example).
2. *Piecewise analytic curves.* Let $\gamma_1, \gamma_2 : [0, T] \to \Omega$ be two analytic curves that meet at time t_0, i.e., there exists $t_0 \in (0, T)$, where $\gamma_1(t_0) = \gamma_2(t_0)$ and $\gamma_1'(t_0) \neq \gamma_2'(t_0)$. Then $\gamma : [0, T] \to \Omega$ defined as follows:

$$\gamma(t) = \begin{cases} \gamma_1(t) & \text{if } t \in [0, t_0], \\ \gamma_2(t) & \text{if } t \in [t_0, T] \end{cases}$$

   satisfies condition 2 in Theorem 3.1 (see Figure 1(a)).
3. *Constant velocity curves.* Let $\gamma(t) = x_0 + \alpha t$ with $x_0 \in \Omega$ (see Figure 2(a)). Then clearly γ satisfies condition 3(a) in Theorem 3.1.
4. *Periodic analytic curves.* Let $\gamma : \mathbb{R} \to \Omega$ be any nonconstant periodic analytic curve (see Figure 1(b)). In this case, the set of accumulation points of $\gamma(t)$ as $t \to -\infty$ is the range of γ over a period, which is an interval, and therefore it contains infinitely many points such that x_0/L is irrational. Then γ satisfies condition 3(b) in Theorem 3.1.

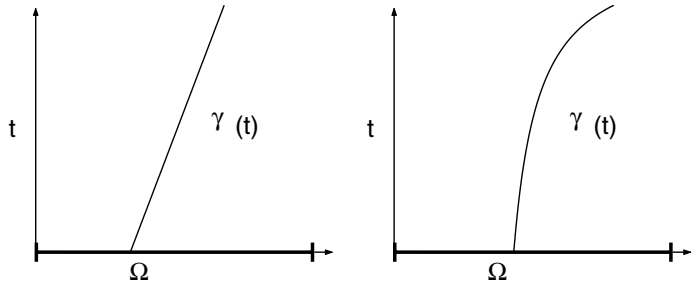

FIG. 2. *Trajectories of γ for which the approximate controllability property holds.*

5. *Curves that converge to a unique point as $t \to -\infty$ and satisfy* (3.11). For example, let $\gamma(t) = x_0 + \beta/t$ with $x_0 \in \Omega$ and let β be chosen in order to have $\gamma(t) \in \Omega$ for all $t \in [0, T]$. Then γ satisfies condition 3(c) in Theorem 3.1 (see Figure 2(b)).

3.2. The higher dimensional case. The situation is now more complex. We only consider nonconstant (in time) analytical families of k-dimensional manifolds $\{\gamma(t)\}_{0\le t\le T}$ satisfying, in particular, the following hypothesis:

$$\{\gamma(t)\}_{0\le t\le T} \quad \begin{array}{l}\text{can be extended to an analytical family } \{\bar\gamma(t)\}_{-\infty<t\le T}\\ \text{s.t. } \bar\gamma(t)\subset\Omega \quad \forall t\in(-\infty,T).\end{array} \tag{3.12}$$

Thus we are considering only the analogue of case 3 in the statement of Theorem 3.1.

In order to state our result let us introduce the eigenvalue problem associated to system (2.4):

$$\begin{cases} -\Delta w(x) = \lambda w(x), & x\in\Omega\\ w(x)=0, & x\in\partial\Omega. \end{cases} \tag{3.13}$$

The associated eigenvalues will be denoted by

$$0<\lambda_1<\lambda_2<\cdots<\lambda_j<\cdots$$

each one with finite multiplicity $l(j)\ge 1$.

We also introduce the following sets associated to the families $\{\gamma(t)\}_{0\le t\le T}$ satisfying (3.12).

DEFINITION 3.2. *Let $\{\gamma(t)\}_{0\le t\le T}$ be a family satisfying* (3.12). *We define the set of "accumulation points" of $\{\gamma(t)\}_{0\le t\le T}$ as*

$$P=\left\{x\in\overline{\Omega}\ s.t.\ \exists t_n\to-\infty,\ x_n\in\bar\gamma(t_n)\ with\ x_n\to x\right\}, \tag{3.14}$$

and for each $x\in P$, the set of "accumulation directions"

$$D_x=\left\{ v\in S^{n-1}\ s.t. \quad \begin{array}{c}\exists t_n\to-\infty,\ x_n\in\bar\gamma(t_n)\ with\ x_n\to x,\ \frac{x_n-x}{\|x_n-x\|}\to v\\ and\ \lim_{t_n\to-\infty}\|x_n-x\|^{-1}e^{ct_n}=0\ \forall c>0\end{array}\right\}. \tag{3.15}$$

Remark 3.3. Observe that D_x contains only those directions v for which $\|x_n - x\|$ converges to zero more slowly than any exponential as $t_n \to -\infty$. As indicated in Remark 3.2, in the 1-d case approximate controllability fails for some curves that converge to a unique accumulation point more rapidly than a certain exponential.

The following result reduces the approximate controllability property of system (3.1) to a suitable unique continuation property for the eigenfunctions of (3.13).

THEOREM 3.2. *Assume that* $\{\gamma(t)\}_{0\le t\le T}$ *satisfies the hypothesis* (3.12)*, and consider the sets* P *and* D_x *introduced in Definition* 3.2*. Assume also that the following spectral unique continuation property holds for the eigenfunctions of* (3.13)*:*

$$\begin{aligned} &\textit{The only eigenfunction } w \textit{ of } (3.13) \textit{ that satisfies}\\ &w(x_0+\mu v)=0,\ \forall x_0\in P,\ \forall v\in D_{x_0},\ \textit{and } \forall \mu\in\mathbb{R}\ \text{s.t. } x_0+\bar\mu v\in\bar\Omega,\\ &\forall \bar\mu\in[0,\mu],\ \textit{is the trivial one.} \end{aligned} \tag{3.16}$$

Then, for any $T>0$ *system* (2.4) *is approximately controllable.*

We observe that there are two special situations where the spectral unique continuation property (3.16) holds trivially:

1. P is not included in the zero set of any of the eigenfunctions of (3.13).
2. P is included in the zero set of some of the eigenfunctions of (3.13) but there exists $x_0\in P$ for which D_{x_0} contains an open set of S^{n-1}. Indeed, in this case if

$$w(x_0+\mu v)=0,\ \forall x_0\in P,\ \forall v\in D_{x_0},\ \text{and } \forall\mu\in\mathbb{R}\ \text{s.t. } x_0+\bar\mu v\in\overline{\Omega},\ \forall\bar\mu\in[0,\mu],$$

then $w=0$ on an open set of Ω and, by classical unique continuation for eigenfunctions (Holmgren's theorem), $w\equiv 0$.

Now, we give some examples where one of the above situations holds and therefore the approximate controllability property is satisfied.

Examples.

1. *Stationary control.* Assume that the control is located on a time-independent k-dimensional manifold γ. In this case, property (3.12) holds trivially. The set P coincides with γ, and D_x is empty for all $x\in P$. Therefore, the unique continuation property (3.16) is satisfied if and only if γ is not included in the nodal set of any of the eigenfunctions of (3.13).
2. *Time-periodic* $n-1$*-dimensional manifolds.* Assume that $\{\gamma(t)\}_{0\le t\le T}$ is a nonconstant periodic (in time) analytic (in time) family of $n-1$-dimensional manifolds. Then, $\{\gamma(t)\}_{0\le t\le T}$ satisfies property (3.12), and the set P is the range of $\gamma(t)$ over a period $[0,p]$, i.e.,

$$\bigcup_{t\in[0,p]}\gamma(t)=P\subset\Omega.$$

We observe that the dimension of P is n generically. However, this is not always the case. For example, if $n=2$ we may consider $\Omega=(-1,1)\times(-1,1)$ and $\gamma(t)$ the subinterval $[0,\frac{1}{2}+\frac{1}{4}\sin(t)]$ in the axis $y=0$.

When the dimension of P is n, it contains an open set of Ω. In this case, the unique continuation property (3.16) is a consequence of the unique continuation property for the eigenfunctions of (3.13).

We observe that, in general, the dimension of the set P is larger for periodic moving controls than for stationary ones. Therefore, the uniqueness property is much more likely to hold for moving controls.

3. *Pointwise control in* 2*-d.* We assume that $n = 2$, for instance, and $k = 0$. Here the control is localized on a continuous curve $\gamma(t) \subset \Omega \times [0, T]$. Consider the spiral curve around any point $x_0 \in \Omega$:

$$\gamma(t) = x_0 + \frac{\beta}{T + 1 - t}(\cos t, \sin t), \quad \beta > 0.$$

Here the parameter β must be chosen small enough to guarantee that $\gamma(t) \in \Omega$ for all $t \in (-\infty, T]$. In this case, $\gamma(t)$ is analytic and satisfies (3.12), and we have $P = \{x_0\}$ and $D_{x_0} = S^1$. Therefore, the unique continuation property (3.16) holds.

3.3. Rapidly oscillating controllers. Finally, we consider the case of rapidly oscillating controllers, i.e., where the control is located on a k-dimensional manifold $\{\gamma(t/\varepsilon)\}_{0 \le t \le T}$ with $\varepsilon > 0$ a small parameter and $\{\gamma(t)\}_{0 \le t}$ a time-dependent periodic and analytic family of k-dimensional manifolds. To simplify the presentation, we restrict ourselves to the case $k = n - 1$.

We assume without loss of generality that $\gamma(t)$ is periodic of period 2π.

We also assume that the range of $\gamma(t)$ over a period $[0, p]$, i.e., $\bigcup_{t \in [0,p]} \gamma(t) = P \subset \Omega$ has dimension n. As we pointed out in example 2 above (section 3.2) this is not always the case. However, for the purposes of this section, it is natural to consider the case where the supports of the controls scan a larger area.

In this case, system (3.1) reads as follows:

$$\begin{cases} u_t - \Delta u = f(x,t)\delta_{\gamma(t/\epsilon)}(x) & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,0) = u^0(x) & \text{in } \Omega. \end{cases} \tag{3.17}$$

We observe that, by hypothesis, the dimension of P (the range of $\gamma(t)$ over a period) is n and it contains an open set of Ω. Therefore, the unique continuation property (3.16) is a consequence of the unique continuation property for the eigenfunctions of the Laplace operator, and the approximate controllability of system (2.4) holds.

Let us introduce the limit problem

$$\begin{cases} u_t - \Delta u = f(x,t)m_\gamma(x) & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(x,0) = u^0(x) & \text{in } \Omega, \end{cases} \tag{3.18}$$

where $m_\gamma(x)$ is the limit of $\delta_{\gamma(t/\varepsilon)}(x)$ in the $L^\infty(0, T; H_1')$ weak-* topology as $\varepsilon \to 0$. As we will see, this limit measure $m_\gamma(x)$ is supported in the nonempty open set $\omega \subset \Omega$ defined as the interior set of P.

The following theorem holds.

THEOREM 3.3. *Let us assume that $\{\gamma(t)\}_{t \le T}$ is a nonconstant periodic analytic family of $(n-1)$-dimensional manifolds and $\varepsilon > 0$ is a small parameter.*

Given $T > 0$, $u^0, u^1 \in H_0'$, and $\alpha > 0$, there exists a sequence of approximate controls $f_\varepsilon \in L^2(0, T; L^2(\gamma(t/\varepsilon)))$ (resp., $f_\varepsilon \in L^2(0, T)$ if $n = 1$ and $k = 0$) of system (3.17)*, satisfying* (3.10)*, which is uniformly bounded in $L^2(0, T; L^2(\gamma(t/\varepsilon)))$ (resp., $L^2(0, T)$).*

Moreover, the controls f_ε can be chosen such that they strongly converge in the following sense:

$$f_\varepsilon(x,t)\delta_{\gamma(t/\varepsilon)}(x) \to f(x,t)m_\gamma(x) \text{ in } L^2(0, T; H_1') \quad \text{as } \varepsilon \to 0, \tag{3.19}$$

where f is an approximate control for the limit system (3.18) *so that* (3.10) *holds.*

The measure $m_\gamma(x)$ is the limit of $\delta_{\gamma(t/\varepsilon)}$ in the $L^\infty(0,T;H_1')$ weak- topology as $\varepsilon \to 0$. This limit measure m_γ is supported in the nonempty subset $\omega \subset \Omega$, the interior set of P, and it is characterized by*

$$\int_\omega \varphi(x) m_\gamma(x)\, d\sigma = \frac{1}{2\pi}\int_0^{2\pi}\int_{\gamma(s)} \varphi(x)\, d\sigma\, ds \quad \forall \varphi \in H_1 \text{ if } k \geq 1, \text{ i.e., } n \geq 2$$

$$\int_\omega \varphi(x) m_\gamma(x)\, d\sigma = \frac{1}{2\pi}\int_0^{2\pi} \varphi(\gamma(s))\, ds \quad \forall \varphi \in H_1 \text{ if } k = 0. \tag{3.20}$$

Here σ denotes the surface measure of ω. In the case $k = n-1$, ω is an open subset of Ω and $d\sigma = dx$.

On the other hand, with the above controls, the solutions u_ε of (2.4) *converge strongly in $C([0,T];H_0')$ as $\varepsilon \to 0$ to the solution u of the limit problem* (3.18). *This solution u satisfies* (3.10).

Remark 3.4. 1. As a consequence of the statement in Theorem 3.3, system (3.18) is approximately controllable. In fact, Theorem 3.3 guarantees that the control of (3.18) may be achieved as the limit (when $\varepsilon \to 0$) of the controls of (2.4) in the sense of (3.19).

Note, however, that one could prove directly the approximate controllability of (3.18) since the limit control f acts on an open set of Ω.

2. It is worth noting that for the limit system (3.18), where the control is located on an open subset of Ω, a stronger controllability property is known to hold: the so-called null-controllability property. This means that if $u^1 = 0$, then the control can be chosen to be exact, i.e., the solution of system (3.18) will satisfy $u(x,T) \equiv 0$. Whether this null-controllability property holds for the approximate systems (2.4) and the possible convergence of the controls as $\varepsilon \to 0$ are open problems.

3. When $k < n-1$, the set P will not contain an open subset of Ω but, generically, a $k+1$-dimensional manifold. Therefore, the approximate controllability property of both the approximate systems and the limit system will depend on whether the set ω, the interior of P with respect to the relative topology, belongs to the nodal set of any of the eigenfunctions of the Laplace operator.

If this approximate controllability property holds, then the analogue to Theorem 3.3 still holds. The limit density m_γ is then supported on the manifold ω of dimension $k+1 < n$ and takes the form

$$m_\gamma(x) = g(x)\delta_\omega(x),$$

where $g(x)$ is a density function defined on ω by (3.20).

4. In [B] the numerical approximation of the 1-d case $\Omega = (0,1)$ and $\gamma(t) = x_0 + \delta\cos(t)$ is addressed. Using the standard formal asymptotic expansion method in homogenization and the limit in the sense of distributions of the measure $\delta_{\gamma_\varepsilon(t)}$, the author obtains the first order approximation of a limit control when both ϵ and δ tend to zero ($\epsilon \ll \delta$). This first order approximation consists of two steady distributed controls, concentrated at the points $x = x_0 \pm \delta$, which depend only on the time variable t.

Here we prove that, when $\varepsilon \to 0$, $\delta > 0$ being fixed, the sequence of controls can be chosen to converge, in the sense stated in the above theorem, to a nonsteady distributed control (see (3.22) in example 1 below) acting on the range of $\gamma(t)$ over a period. Namely, the control may vary in x and t. The control obtained in [B]

corresponds to the first order approximation (as $\delta \to 0$) of the limit control, given in (3.22) below, obtained as the limit when $\varepsilon \to 0$ (see [B] for details).

The result above proves that, to some extent, the approximate controls depend continuously on ε. As $\varepsilon \to 0$ the transition is made from controls supported on a manifold of dimension $n-1$ to controls with support in an open subset of Ω.

We finish this section by showing several examples of limit densities $m_\gamma(x)$ in some particular cases.

Examples.

1. *Pointwise control, case* 1. We assume that $\gamma(t)$ is reduced to a unique point at each time $t \in [0,T]$. The trajectory of the control $x = x(t)$ is included in a simple curve $\omega \subset \Omega$, and the control moves forward and backward scanning the curve ω (see Figure 3(a)).

In this case, the integral in (3.20) can be simplified, studying separately the closed intervals where $\gamma(s)$ is one-to-one $\{I_h\}_{h=1}^H$. Note that the whole interval $[0,2\pi]$ is divided into the subintervals I_h. Indeed, if there is a subinterval $I \subset (0,2\pi)$ such that I is not included in $\bigcup_{h=1}^H I_h$, then $\gamma(s)$ must be constant on I and then constant everywhere because of the analyticity of γ.

Note also that the number H of subintervals $I_h \subset [0,2\pi]$ must be finite because of the analyticity of γ. Indeed, at the extremes of I_h, the control has a returning point where its trajectory changes direction and γ' vanishes. If there are infinitely many intervals I_h, there are infinitely many points in a period $[0,2\pi]$ where γ' vanishes. Thus, $\gamma(t)$ must be constant, and this is in contradiction with the hypotheses on $\gamma(t)$.

Let $\omega_h = \gamma(I_h) \subset \Omega$ and let $\gamma_h^{-1} : \omega_h \to I_h$ be the inverse function of ψ in each one of the sets ω_h. Then,

$$\begin{aligned} \frac{1}{2\pi}\int_0^{2\pi} \varphi(\gamma(s))\, ds &= \frac{1}{2\pi}\sum_{h=1}^{H}\int_{I_h} \varphi(\gamma(s))\, \frac{1}{|\gamma'(s)|}\,|\gamma'(s)|\, ds \\ &= \frac{1}{2\pi}\sum_{h=1}^{H}\int_{\omega_h} \varphi(x)\frac{1}{\left|\gamma'(\gamma_h^{-1}(x))\right|} d\omega_h. \end{aligned} \tag{3.21}$$

Then,

$$m_\gamma(x) = \begin{cases} \frac{1}{2\pi}\sum_{h=1}^{H} \frac{1}{|\gamma'(\gamma_h^{-1}(x))|}\delta_{\omega_h} & \text{if } n \geq 2, \\ \frac{1}{2\pi}\sum_{h=1}^{H} \frac{1}{|\gamma'(\gamma_h^{-1}(x))|}\chi_{\omega_h} & \text{if } n = 1. \end{cases}$$

Note that m_γ is defined over the whole curve ω since $\cup_h \omega_h = \omega$.

The function $m_\gamma(x)$ is singular at the extremes of the intervals I_h since $\gamma'(s) = 0$ for some points $s \in [0,2\pi]$. For example, in the 1-d case studied in [B], $\Omega = (0,1)$, $\gamma(t) = x_0 + \delta\cos(t)$, and

$$m_\gamma(x) = \begin{cases} \frac{1}{\pi\sqrt{\delta^2 - (x-x_0)^2}} & \text{if } |x - x_0| < \delta, \\ 0 & \text{otherwise,} \end{cases} \tag{3.22}$$

which is singular at $x = x_0 \pm \delta$. Observe, however, that $m_\gamma(x) \in L^1(\Omega)$ since the integral in (3.21) is well defined for all $\varphi \in H_1$ (see Figure 3).

2. *Pointwise control, case* 2. Now we assume that the trajectory of the control follows a simple closed curve without any returning point. This is only possible if $n \geq 2$ (see Figure 4(a)). In this case, $\gamma : [0,2\pi) \to \Omega$ is one-to-one and $\gamma'(s) \neq 0$ for any $s \in [0,2\pi)$. Then, we have

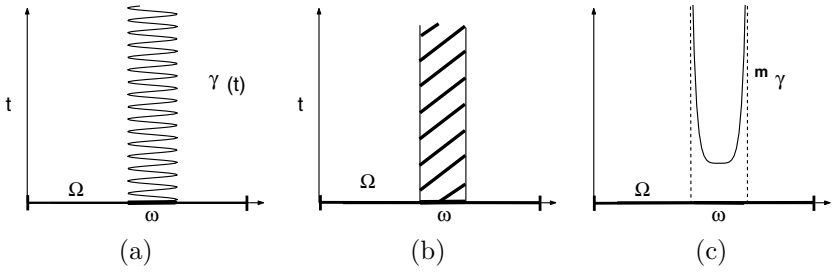

FIG. 3. *The sequence of controls acting on curves $\gamma(t/\varepsilon)$, with $\gamma(s)$ periodic (see* (a)*), converge as $\varepsilon \to 0$ to a control acting in the whole interval ω (see* (b)*) with a density $m_\gamma(x)$ which is singular at the extremes of ω (see* (c)*).*

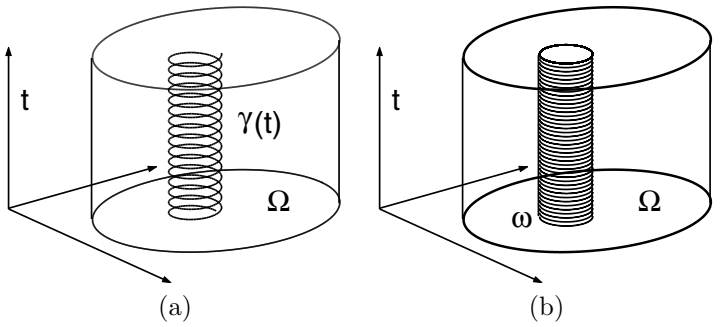

FIG. 4. *The pointwise control located on a periodic circular trajectory in time (see* (a)*) converges, as the period goes to zero, to a control acting on the lateral boundary of the space-time cylinder $\omega \times [0,T]$ (see* (b)*).*

$$m_\gamma(x) = \frac{1}{2\pi} \frac{1}{|\gamma'(\gamma^{-1}(x))|} \delta_\omega(x).$$

In particular, if γ follows a circular trajectory of radius R around $(x_0, y_0) \in \Omega \subset \mathbb{R}^2$, $\gamma(t) = (x_0, y_0) + R(\cos(t), \sin(t))$, then $|\gamma'(\gamma^{-1}(x))| = R$ and m_γ is given by $m_\gamma(x) = R\delta_\omega(x)$ (see Figure 4).

3. *Control on a curve in dimension $n = 2$.* Let $\gamma(t)$ be a curve for any $t \in [0,T]$. To simplify the presentation, we assume that $\{\gamma(t)\}_{0\le t\le T}$ can be described by a unique chart $\psi : V \times [0,T] \to \{\gamma(t)\}_{0\le t\le T}$, where V is an open and bounded subinterval of $\mathbb{R}$.

The measure m_γ satisfies (3.20). It can be computed studying separately the closed time intervals $\{I_h\}_{h=1}^H$, where $\psi(y,s) : V \times I_h \to \Omega$ is one-to-one. Let $\omega_h = \psi(V, I_h) \subset \Omega$ and $\psi_h^{-1} : \omega_h \to V \times I_h$ be the inverse function of ψ. Then,

$$\int_0^{2\pi} \int_{\gamma(s)} \varphi(x)\, d\sigma\, ds = \sum_{h=1}^H \int_{I_h} \int_V \varphi(\psi(y,s)) \frac{\left|\frac{\partial\psi}{\partial y}\right|}{\left|\frac{\partial\psi}{\partial y} \times \frac{\partial\psi}{\partial s}\right|} \left|\frac{\partial\psi}{\partial y} \times \frac{\partial\psi}{\partial s}\right| dy\, ds$$

$$= \sum_{h=1}^H \int_{\omega_h} \varphi(x) \frac{\left|\frac{\partial\psi}{\partial y}(\psi_h^{-1}(x))\right|}{\left|\frac{\partial\psi}{\partial y}(\psi_h^{-1}(x)) \times \frac{\partial\psi}{\partial s}(\psi_h^{-1}(x))\right|} dx. \tag{3.23}$$

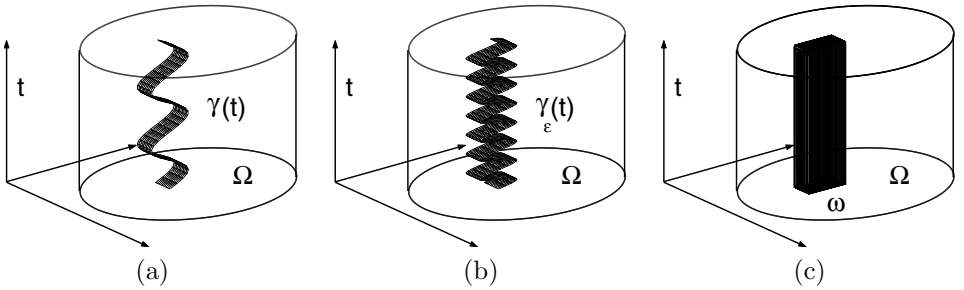

FIG. 5. *The control located on a curve with periodic trajectory in time (see* (a)*) converges, as the period goes to zero (see* (b)*), to a control acting on a* 2*-d domain* ω *for all time (see* (c)*).*

Then,

$$m_\gamma(x) = \frac{1}{2\pi} \sum_{h=1}^{H} \frac{\left|\frac{\partial \psi}{\partial y}(\psi_h^{-1}(x))\right|}{\left|\frac{\partial \psi}{\partial y}(\psi_h^{-1}(x)) \times \frac{\partial \psi}{\partial s}(\psi_h^{-1}(x))\right|} \chi_{\omega_h}.$$

Note that m_γ is defined over the whole ω since $\cup_h \omega_h = \omega$, which is a 2-d set (see Figure 5).

4. Unique continuation for the adjoint system. It is well known that the approximate controllability of system (2.4) is a consequence of the following unique continuation property for the adjoint system: *If* $\varphi \in C([0,T]; H_0)$ *solves*

$$\begin{cases} -\varphi_t - \Delta\varphi = 0 & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi(x,T) = \varphi^0(x) & \text{in } \Omega, \end{cases} \tag{4.1}$$

can we guarantee that

$$\varphi(x,t) = 0 \quad \forall t \in [0,T] \text{ and } \forall x \in \gamma(t) \quad \Rightarrow \quad \varphi \equiv 0? \tag{4.2}$$

In fact, as we will see later on, when this unique continuation property is satisfied, the control can be built as a minimizer of a quadratic, convex, continuous, and coercive functional in a Hilbert space, associated with the adjoint system (4.1).

This section is devoted to analyzing this uniqueness problem. We divide it into two subsections where we study separately the 1-d case and the higher dimensional one.

4.1. The one-dimensional case.

LEMMA 4.1. *Assume that* $\Omega = (0, L)$ *and* $\gamma : [0,T] \to \Omega$ *is a continuous curve which satisfies the hypotheses in the statement of Theorem* 3.1*. Then the unique continuation property* (4.2) *holds for the solutions of the adjoint problem* (4.1)*.*

As we stated in Remark 3.2, the conditions in Theorem 3.1 are sharp in different senses. This is so because these conditions are sharp in the context of Lemma 4.1. We present now three examples that illustrate this fact. After these examples we give the proof of Lemma 4.1.

Example 1. This example shows that condition 2 in Theorem 3.1 is sharp in the sense that if $\gamma : (t_1, T] \to \Omega$ cannot be extended analytically for $t < t_1$, then the

unique continuation property (4.2) for the solutions of the adjoint problem (4.1) may fail.

We consider $\Omega = (0,1)$ and the solution of the backward system (4.1) given by

$$\varphi(x,t) = e^{\lambda_2(t-T)}\sin(\sqrt{\lambda_2}x) + e^{\lambda_4(t-T)}\sin(\sqrt{\lambda_4}x) = e^{4\pi^2(t-T)}\sin(2\pi x) + e^{16\pi^2(t-T)}\sin(4\pi x).$$

For any $t \in [0,T]$ the points $x = x(t) \in \Omega$ for which $\varphi(x,t) = 0$ are characterized by

$$0 = \sin(2\pi x) + e^{12\pi^2(t-T)}\sin(4\pi x) = \sin(2\pi x)(1 + e^{12\pi^2(t-T)}2\cos(2\pi x)).$$

Thus, $\varphi(x(t),t) = 0$ if and only if $x(t) = 1/2 \in \Omega$ (for any $t \in [0,T]$) or $x(t) \in \Omega$ is any of the two roots of the equation

$$\cos(2\pi x(t)) = -\frac{1}{2}e^{-12\pi^2(t-T)} \quad \text{for } t \in (t_1, T], \tag{4.3}$$

where t_1 is defined as $t_1 = T - (\log 2)/(12\pi^2)$. Note that for $t < t_1$ the right-hand side term in (4.3) is smaller than -1 and therefore (4.3) has no roots for $t < t_1$.

We define $\gamma(t)$ as follows:

$$\gamma(t) = \begin{cases} 1/2 & \text{if } t \in [0,t_1], \\ x(t) = \frac{1}{2\pi}\arccos(-\frac{1}{2}e^{-12\pi^2(t-T)}) \text{ with } x(t) \in (0,\frac{1}{2}] & \text{if } t \in [t_1,T]. \end{cases}$$

Clearly $\gamma(t)$ is a continuous curve for which $\varphi(\gamma(t),t) = 0$ for all $t \in [0,T]$. Moreover, $\gamma(t)$ is analytic in $t \in [0,t_1) \cup (t_1,T]$ and it is easy to see (differentiating in (4.3)) that

$$\lim_{\substack{t \to t_1 \\ t > t_1}} \gamma'(t) = \infty.$$

This means that $\gamma : (t_1,T] \to \Omega$ cannot be analytically extended for $t < t_1$.

Thus, we have obtained a curve $\gamma(t)$ for which the unique continuation property (4.2) fails and that shows that condition 2 in Theorem 3.1 is sharp in the sense described above.

Example 2. This example shows that condition 3 is sharp in the sense that if γ cannot be extended analytically to a curve $\bar{\gamma} : (-\infty,T] \to \Omega$, then the unique continuation property (4.2) may fail.

We consider $\Omega = (0,1)$ and the solution of the backwards system (4.1) given by

$$\varphi(x,t) = c_1 e^{\lambda_1(t-T)}\sin(\sqrt{\lambda_1}x) + e^{\lambda_2(t-T)}\sin(\sqrt{\lambda_2}x) = c_1 e^{\pi^2(t-T)}\sin(\pi x) + e^{4\pi^2(t-T)}\sin(2\pi x),$$

with c_1 a constant to be chosen later.

For any $t \in [0,T]$ the points $x = x(t) \in \Omega$ for which $\varphi(x,t) = 0$ are characterized by

$$0 = c_1\sin(\pi x) + e^{3\pi^2(t-T)}\sin(2\pi x) = \sin(\pi x)(c_1 + e^{3\pi^2(t-T)}2\cos(\pi x)).$$

Thus, $\varphi(x(t),t) = 0$ if and only if $x(t) \in \Omega$ is a root of

$$\cos(\pi x(t)) = -\frac{c_1}{2}e^{-3\pi^2(t-T)}. \tag{4.4}$$

We choose $c_1 \in (0,2)$ in such a way that (4.4) has a unique root $x(t) \in \Omega$ for $t \in [0,T]$; i.e., the right-hand side of (4.4) is greater than -1.

Clearly $\gamma(t)$ is a continuous curve for which $\varphi(\gamma(t),t) = 0$ for all $t \in [0,T]$. Moreover, $\gamma(t)$ is analytic in $t \in [0,T]$ but cannot be extended to an analytic curve $\bar{\gamma} : (-\infty, T] \to \Omega$. In fact, its analytic extension is defined implicitly by (4.4), which has no roots if t is very (negatively) large.

Thus, we have obtained a curve $\gamma(t)$ for which the unique continuation property (4.2) fails and that shows that condition 3 in Theorem 3.1 is sharp in the sense described above.

Example 3. This example shows that condition 3 is also sharp in the sense that it is possible to construct solutions of the adjoint heat equation (4.1) that vanish at curves $\gamma(t)$ that do not satisfy (3.11). We consider $\Omega = (0,1)$ and the solution of the backward system (4.1) given by

$$\varphi(x,t) = e^{\lambda_2(t-T)}\sin(\sqrt{\lambda_2}x) - e^{\lambda_3(t-T)}\sin(\sqrt{\lambda_3}x) = e^{4\pi^2(t-T)}\sin(2\pi x) - e^{9\pi^2(t-T)}\sin(3\pi x).$$

It is easy to check that φ satisfies the following properties:

$$\begin{aligned} &\varphi(1/2,t) > 0 \quad \text{if } t \le T,\\ &\varphi(2/3,t) < 0 \quad \text{if } t \le T,\\ &\frac{\partial\varphi}{\partial x}(x,t) < 0 \quad \text{if } x \in [1/2,2/3] \text{ and } t \le T. \end{aligned}$$

Therefore, for any $t \le T$, $\varphi(x,t)$ has a unique zero in $x \in (1/2,2/3)$ at the point $\gamma(t)$, i.e.,

$$\varphi(\gamma(t),t) = 0 \text{ for all } t \le T.$$

On the other hand, by the analytic version of the implicit function theorem (see [H, p. 43], for example), the function $t \to \gamma(t)$ is analytic in $t \in (-\infty, T]$.

Moreover, as $\varphi(\gamma(t),t) = 0$ for all $t \in (-\infty, T]$,

$$\sin(2\pi\gamma(t)) = e^{5\pi^2(t-T)}\sin(3\pi\gamma(t)) \to 0 \text{ as } t \to -\infty.$$

Therefore $\gamma(t) \to 1/2$ as $t \to -\infty$ and, by the Taylor expansion of $\sin(2\pi x)$ and $\sin(3\pi x)$ near $x = 1/2$, we easily deduce that

$$\gamma(t) \sim \frac{1}{2} - \frac{1}{2\pi}e^{5\pi^2(t-T)} \quad \text{as } t \to -\infty.$$

In this way we have constructed an example of a nontrivial solution of (4.1) that vanishes at a nonconstant curve $\gamma(t)$ that does not satisfy (3.11).

Proof of Lemma 4.1. We divide the proof into different parts depending on the hypothesis we make on γ.

Part 1. Assume that γ satisfies hypothesis 1 in the statement of Theorem 3.1. Then there exists an open set $\mathcal{U} \subset (0,T)$ such that $\gamma : \mathcal{U} \to \Omega$ is not analytic at any point $t \in \mathcal{U}$. In this case, we prove the unique continuation property (4.2) by contradiction.

Assume that there exists a nontrivial solution $\varphi \in C([0,T]; H_0)$ of the heat equation (4.1) such that $\varphi(\gamma(t),t) = 0$ for all $t \in \mathcal{U}$. As the Laplace operator generates an

analytic semigroup (see, for example, [P, p. 211]), the solution $\varphi : \Omega \times (-\infty, T) \to \mathbb{R}$ of system (4.1) is analytic. By the analytic version of the implicit function theorem either $\frac{\partial \varphi}{\partial x}(\gamma(t_0), t_0) = 0$ or there exists a unique solution $x = \hat{\gamma}(t)$ of $\varphi(x,t) = 0$ near $(x,t) = (\gamma(t_0), t_0)$ with $\hat{\gamma}$ analytic. The latter is in contradiction with the hypothesis on $x = \gamma(t)$. Therefore, $\frac{\partial \varphi}{\partial x}(\gamma(t_0), t_0) = 0$ and this is true for all $t_0 \in \mathcal{U}$.

As $\gamma(t)$ is a noncharacteristic curve of the heat equation, Holmgren's uniqueness theorem asserts that the only solution φ of the heat equation with Cauchy data $\varphi(\gamma(t_0), t_0) = \frac{\partial \varphi}{\partial x}(\gamma(t_0), t_0) = 0$ on γ is $\varphi \equiv 0$. This is in contradiction with the hypothesis.

Part 2. Assume that γ satisfies hypothesis 2 in the statement of Theorem 3.1. Then there exists $t_1 \in (0,T)$ where $\gamma(t)$ is not analytic and a subinterval $(t_1, t_2) \subset (0,T)$ where γ is analytic and can be extended analytically to a subinterval (t_0, t_2) with $t_1 \in (t_0, t_2)$.

We continue $\gamma(t)$ analytically to $\bar{\gamma} : (t_0, t_2) \to \mathbb{R}$. Observe that the composition $\varphi(\bar{\gamma}(t), t)$ is analytic and therefore, in view of the fact that $\varphi(\bar{\gamma}(t), t) = \varphi(\gamma(t), t) = 0$ for $t \in (t_1, t_2)$,

$$\varphi(\bar{\gamma}(t), t) = 0 \qquad \forall t \in (t_0, t_2). \tag{4.5}$$

Let ω be the open region of $(x,t) \in \mathbb{R} \times (t_0, t_1)$ limited by the curves $x = \gamma(t)$, $x = \bar{\gamma}(t)$ and the horizontal line $t = t_0$. Note that φ vanishes at those parts of the boundary of ω constituted by γ and $\bar{\gamma}$.

Multiplying the adjoint heat equation (4.1) by the solution φ and integrating we easily obtain the following:

$$\begin{aligned} 0 = \int_{\bar{\gamma}(t)}^{\gamma(t)} (-\varphi_t - \varphi_{xx})\varphi \, dx &= -\frac{1}{2}\frac{d}{dt}\int_{\bar{\gamma}(t)}^{\gamma(t)} |\varphi|^2 dx + \int_{\bar{\gamma}(t)}^{\gamma(t)} |\varphi_x|^2 dx \\ &\geq -\frac{1}{2}\frac{d}{dt}\int_{\bar{\gamma}(t)}^{\gamma(t)} |\varphi|^2 dx. \end{aligned} \tag{4.6}$$

Thus, the function $\Phi(t) = \int_{\bar{\gamma}(t)}^{\gamma(t)} |\varphi|^2 dx$ is increasing and positive and vanishes at $t = t_1$ because γ and $\bar{\gamma}$ coincide for $t = t_1$. Therefore,

$$\int_{\bar{\gamma}(t)}^{\gamma(t)} |\varphi|^2 dx = 0 \quad \forall t \in [t_0, t_1],$$

and we deduce that φ must be zero in the open nonempty set ω. By Holmgren's uniqueness theorem we deduce that $\varphi \equiv 0$.

Part 3. Assume that γ satisfies hypothesis 3(a) in the statement of Theorem 3.1. Then, γ is analytic and can be extended analytically to a curve $\bar{\gamma}(t) : (-\infty, T] \to \mathbb{R}$ such that $\bar{\gamma}(t)$ meets the boundary of Ω, i.e., there exists $t_0 \in (-\infty, T]$ such that $\bar{\gamma}(t_0) \in \partial\Omega$.

The solution φ of (4.1) can be extended to all $x \in \mathbb{R}$ by odd extension and periodicity. The resulting φ satisfies the adjoint system (4.1) on $\mathbb{R} \times (-\infty, T)$. Observe that the composition $\varphi(\bar{\gamma}(t), t)$ is analytic and therefore

$$\varphi(\bar{\gamma}(t), t) = 0 \qquad \forall t \in (-\infty, T]. \tag{4.7}$$

By hypothesis, $\bar{\gamma}$ meets the boundary of Ω at $t_0 \in (-\infty, T]$ and $\gamma(t_0)$ must be one of the extremes of Ω, say, $x = 0$. Let ω be the open region of $(x,t) \in \mathbb{R} \times (t_0 - \alpha, t_0)$ with

$\alpha > 0$, bounded by $\bar{\gamma}$ and the axis $x = 0$. Note that ω cannot be an empty set because, in this case, $\bar{\gamma}$ and the axis $x = 0$ would coincide over the interval $(t_0 - \alpha, t_0)$ and, by the analyticity of $\bar{\gamma}$, they would coincide everywhere. This situation is excluded in our hypothesis on $\bar{\gamma}$.

Note also that φ vanishes on the subset of the boundary of ω constituted by $x = 0$ and $\bar{\gamma}$. Then we can argue as in Part 2 above to prove that $\varphi \equiv 0$ on ω and, therefore, $\varphi \equiv 0$.

Part 4. Assume that γ satisfies either hypothesis 3(b) or 3(c) in the statement of Theorem 3.1.

Let $\varphi \in C([0,T]; H_0)$ be a solution of (4.1) with $\varphi(\gamma(t), t) = 0$ for all $t \in [0,T]$. Obviously, this solution can be extended naturally to all $t \leq T$, and the extension is analytic.

On the other hand, by hypothesis, γ can be also extended to an analytic curve $\bar{\gamma} : (-\infty, T] \to \Omega$. Therefore, the composition $\varphi(\bar{\gamma}(t), t)$ is still analytic in $t \in (-\infty, T]$.

Now observe that $\bar{\gamma}$ and γ coincide in $t \in [0,T]$. Therefore, $\varphi(\bar{\gamma}(t), t) = \varphi(\gamma(t), t) = 0$ for any $t \in [0,T]$ and by the unique continuation of analytic functions we deduce that

$$\varphi(\bar{\gamma}(t), t) = 0 \qquad \forall t \in (-\infty, T]. \tag{4.8}$$

Let us introduce the Fourier representation of φ

$$\varphi(x,t) = \sum_{j=1}^{\infty} c_j e^{-\lambda_j (T-t)} w_j(x),$$

where

$$0 < \lambda_1 < \lambda_2 < \cdots < \lambda_j < \cdots$$

are the eigenvalues of (3.13), $w_j(x)$ is the eigenfunction associated to λ_j, and c_j is the Fourier coefficients. We choose $\{w_j(x)\}_{j \geq 1}$ to be orthonormal in $H_0^1(\Omega)$. Observe that $\varphi(T) = \varphi^0 \in H_0 = H_0^1(\Omega)$ and this implies that

$$\sum_{j \geq 1} |c_j|^2 < \infty.$$

From (4.8) we have

$$0 = \varphi(\bar{\gamma}(t), t) = \sum_{j=1}^{\infty} c_j e^{-\lambda_j (T-t)} w_j(\bar{\gamma}(t)) \quad \forall t \in (-\infty, T]. \tag{4.9}$$

We have to prove that this implies that $c_j = 0$ for all $j \geq 1$. We proceed by induction in j. We consider the case $j = 1$. Multiplying the series in (4.9) by $e^{\lambda_1 (T-t)}$ we obtain

$$c_1 w_1(\bar{\gamma}(t)) + \sum_{j=2}^{\infty} c_j e^{(\lambda_1 - \lambda_j)(T-t)} w_j(\bar{\gamma}(t)) = 0 \quad \forall t \in (-\infty, T]. \tag{4.10}$$

The second term on the left-hand side converges to zero as $t \to -\infty$. Indeed,

$$\begin{aligned}\left|\sum_{j=2}^{\infty} c_j e^{(\lambda_1-\lambda_j)(T-t)} w_j(\bar\gamma(t))\right|^2 &\le \left\|\sum_{j=2}^{\infty} c_j e^{(\lambda_1-\lambda_j)(T-t)} w_j\right\|^2_{L^\infty(\Omega)} \\ &\le C\left\|\sum_{j=2}^{\infty} c_j e^{(\lambda_1-\lambda_j)(T-t)} w_j\right\|^2_{H_0^1(\Omega)} = C\sum_{j=2}^{\infty} e^{2(\lambda_1-\lambda_j)(T-t)}|c_j|^2,\end{aligned} \tag{4.11}$$

which converges to zero as $t \to -\infty$. Consequently, the first term in (4.10) converges to zero, as $t \to -\infty$, too.

Assume that γ satisfies hypothesis 3(b) or 3(c) in the statement of Theorem 3.1. Let $x_0 \in \Omega$ be an accumulation point of $\bar\gamma(t)$ as $t \to -\infty$, and consider $t_n \to -\infty$ such that

$$\bar\gamma(t_n) \to x_0.$$

Passing to the limit as $(x_n, t_n) \to (x_0, -\infty)$ in (4.10) we obtain

$$c_1 w_1(x_0) = 0. \tag{4.12}$$

As the zeros of the first eigenfunction w_1 lie on the boundary of Ω we deduce that $c_1 = 0$.

Now we complete the induction argument in j. Assume that $c_j = 0$ for all $j < J$, $J \ge 2$, and let us prove that $c_J = 0$. First of all, we observe that (4.9) reads as follows:

$$0 = \varphi(\bar\gamma(t), t) = \sum_{j=J}^{\infty} c_j e^{-\lambda_j(T-t)} w_j(\bar\gamma(t)) \quad \forall t \in (-\infty, T]. \tag{4.13}$$

Multiplying now the series in (4.13) by $e^{\lambda_J(T-t)}$ we obtain

$$c_J w_J(\bar\gamma(t)) + \sum_{j=J+1}^{\infty} c_j e^{(\lambda_J-\lambda_j)(T-t)} w_j(\bar\gamma(t)) = 0 \quad \forall t \in (-\infty, T]. \tag{4.14}$$

Once again, it is easy to see that the second term on the left-hand side converges to zero as $t \to -\infty$.

Let $x_0 \in \Omega$ be an accumulation point of $\bar\gamma(t)$, as $t \to -\infty$, and consider $t_n \to -\infty$ such that

$$\bar\gamma(t_n) \to x_0.$$

Passing to the limit as $(x_n, t_n) \to (x_0, -\infty)$ in (4.10) we obtain

$$c_J w_J(x_0) = 0. \tag{4.15}$$

Now we distinguish the cases where γ satisfies hypothesis 3(b) or 3(c) in the statement of Theorem 3.1.

Assume that γ satisfies hypothesis 3(b). Then we can choose x_0 in such a way that x_0/L is irrational. As the zeros of the eigenfunctions w_j lie on points $x \in \Omega$ such that x/L is rational, we deduce that $c_J = 0$.

On the other hand, if γ satisfies hypothesis 3(c) in the statement of Theorem 3.1, then (4.15) is not enough to guarantee that $c_J = 0$ because the eigenfunction w_J may vanish at x_0.

Multiplying (4.14) by $(\bar\gamma(t) - x_0)^{-1}$ we obtain

$$0 = \frac{c_J w_J(\bar\gamma(t_n))}{\bar\gamma(t_n) - x_0} + \sum_{j=J+1}^{\infty} \frac{e^{(\lambda_J - \lambda_j)(T-t_n)}}{\bar\gamma(t_n) - x_0} c_j w_j(\bar\gamma(t_n)). \tag{4.16}$$

Due to (4.15), the first term on the right-hand side of (4.16) converges to $c_J w_J'(x_0)$ as $t_n \to -\infty$.

On the other hand, following the argument in (4.11) we easily find the following bound for the second term in (4.16):

$$\begin{aligned}\left| \sum_{j=J+1}^{\infty} \frac{e^{(\lambda_J - \lambda_j)(T-t_n)}}{\bar\gamma(t_n) - x_0} c_j w_j(\bar\gamma(t_n)) \right|^2 &\le \sum_{j=J+1}^{\infty} \frac{e^{-2(T-t_n)(\lambda_{J+1} - \lambda_J)}}{|\bar\gamma(t_n) - x_0|^2} |c_j|^2 \\ &\le \frac{e^{-2(T-t_n)(\lambda_3 - \lambda_2)}}{|\bar\gamma(t_n) - x_0|^2} \sum_{j=J+1}^{\infty} |c_j|^2,\end{aligned}$$

which converges to zero as $t_n \to -\infty$ by the hypothesis (3.11).

Therefore, passing to the limit as $t_n \to -\infty$ in (4.16) we obtain

$$c_J w_J'(x_0) = 0. \tag{4.17}$$

From (4.15), (4.17), and the fact that the eigenfunction w_J satisfies a linear second order ordinary differential equation we deduce that $c_J = 0$. □

4.2. The higher-dimensional case. The following lemma reduces the unique continuation problem (4.2) to a certain unique continuation property for the eigenfunctions of (3.13).

LEMMA 4.2. *Assume that $\{\gamma(t)\}_{0\le t\le T}$ is an analytic family of k-dimensional manifolds on Ω which satisfies the hypothesis* (3.12). *Let us consider the set of accumulation points P, and for each $x \in P$, the set of accumulation directions D_x, as defined in Definition* 3.2. *If the spectral unique continuation property* (3.16) *holds, then the unique continuation property* (4.2) *for the solutions of the adjoint problem* (4.1) *holds as well.*

Proof. Let $\varphi \in C([0,T]; H_0)$ be a solution of (4.1) with $\varphi(x,t) = 0$ for all $(x,t) \in \{\gamma(t)\}_{0\le t\le T}$. Obviously, this solution can be extended naturally to all $t \le T$ by solving (4.1). As the Laplace operator generates an analytic semigroup (see, for example, [P, p. 211]), the solution $\varphi : \Omega \times (-\infty, T) \to \mathbb{R}$ of system (4.1) is analytic.

On the other hand, the family $\{\gamma(t)\}_{0\le t\le T}$ can be extended to an analytic family of manifolds $\{\bar\gamma(t)\}_{-\infty<t\le T}$. Let $\{\psi_\alpha(y,t)\}_{\alpha=1}^{A}$ be a family of charts for $\{\bar\gamma(t)\}_{-\infty<t\le T}$, as in Definition 3.1. Then, for any $y \in V_\alpha$, $\psi_\alpha(y,t)$ is analytic in t and therefore, the composition $\varphi(\psi_\alpha(y,t),t)$ is still analytic in t.

Thus, the fact that $\varphi(x,t) = 0$ for all $(x,t) \in \{\gamma(t)\}_{0\le t\le T}$ implies that $\varphi(\psi_\alpha(y,t),t)$ vanishes for $t \in [0,T]$ and $y \in V_\alpha$ with $\alpha \in A$. Therefore, by the analyticity of $\varphi(\psi_\alpha(y,t),t)$ we have that

$$\varphi(\psi_\alpha(y,t),t) = 0 \quad \forall t \in (-\infty, T] \quad \text{and } \forall y \in V_\alpha \text{ with } \alpha = 1, \dots, A, \tag{4.18}$$

i.e.,

$$\varphi(x,t) = 0 \quad \forall (x,t) \in \{\bar{\gamma}(t)\}_{-\infty<t\leq T}. \tag{4.19}$$

Let us introduce the Fourier representation of φ:

$$\varphi(x,t) = \sum_{j=1}^{\infty} e^{-\lambda_j (T-t)} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x),$$

where

$$0 < \lambda_1 < \lambda_2 < \cdots < \lambda_j < \cdots$$

are the eigenvalues of (3.13), $\{l(j)\}_{j\geq 1}$ is their multiplicity, and $\{w_{j,k}(x)\}_{k=1,\ldots,l(j)}$ is a system of linear independent eigenfunctions associated to λ_j. We choose $\{w_{j,k}(x)\}_{j,k\geq 1}$ to be an orthonormal basis of H_0. Observe that $\varphi(T) = \varphi^0 \in H_0$ and this implies that

$$\sum_{j,k} |c_{j,k}|^2 < \infty.$$

From (4.19) we have

$$0 = \varphi(x,t) = \sum_{j=1}^{\infty} e^{-\lambda_j (T-t)} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x) \quad \forall (x,t) \in \{\gamma(t)\}_{-\infty<0\leq T}. \tag{4.20}$$

We have to prove that this implies that $c_{j,k} = 0$ for all $j \geq 1$ and $k = 1, \ldots, l(j)$. We proceed by induction in j.

First, we consider the case $j = 1$. Observe that the first eigenvalue of the Laplace operator λ_1 is simple. Then $l(1) = 1$ and we have to prove only that $c_{1,1} = 0$. Observe also that, from the spectral unique continuation property (3.16), it suffices to prove that

$$\begin{gathered} c_{1,1} w_{1,1}(x_0 + \mu v) = 0 \quad \forall x_0 \in P,\ \forall v \in D_{x_0}, \\ \text{and } \forall \mu \in \mathbb{R} \text{ s.t. } x_0 + \bar{\mu} v \in \Omega\ \forall \bar{\mu} \in [0,\mu]. \end{gathered} \tag{4.21}$$

Moreover, by the analyticity of the eigenfunction $c_{1,1} w_{1,1}$, this is equivalent to proving that the function $G_{x_0,v,1}(\mu) = c_{1,1} w_{1,1}(x_0 + \mu v)$ satisfies

$$G_{x_0,v,1}(0) = \frac{d^r G_{x_0,v,1}}{d\mu^r}(0) = 0 \quad \forall r \geq 1,\ \forall x_0 \in P, \text{ and } \forall v \in D_{x_0}. \tag{4.22}$$

We use an induction argument in r. We start by proving that $G_{x_0,v,1}(0) = c_{1,1} w_{1,1}(x_0) = 0$.

Multiplying the series in (4.20) by $e^{\lambda_1 (T-t)}$ and taking into account that λ_1 is simple we obtain

$$c_{1,1} w_{1,1}(x) + \sum_{j=2}^{\infty} e^{(\lambda_1 - \lambda_j)(T-t)} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x) = 0 \quad \forall (x,t) \in \{\gamma(t)\}_{-\infty<t\leq T}. \tag{4.23}$$

The second term on the left-hand side converges to zero as $t \to -\infty$ uniformly in $x \in \Omega$. Indeed,

$$\left|\sum_{j=2}^{\infty} e^{(\lambda_1-\lambda_j)(T-t)} \sum_{k=1}^{l(k)} c_{j,k} w_{j,k}(x)\right|^2 \le \left\|\sum_{j=2}^{\infty} e^{(\lambda_1-\lambda_j)(T-t)} \sum_{k=1}^{l(k)} c_{j,k} w_{j,k}\right\|^2_{L^\infty(\Omega)}$$
$$\le C \left\|\sum_{j=2}^{\infty} e^{(\lambda_1-\lambda_j)(T-t)} \sum_{k=1}^{l(k)} c_{j,k} w_{j,k}\right\|^2_{H_1} = C \sum_{j=2}^{\infty} e^{2(\lambda_1-\lambda_j)(T-t)} \sum_{k=1}^{l(k)} |c_{j,k}|^2,$$

which converges to zero as $t \to -\infty$.

Consider now $x_0 \in P$ and $v \in D_{x_0}$. There exists a sequence $(x_n, t_n) \in \{\bar\gamma(t)\}_{-\infty<t\le T}$ such that

$$x_n \to x_0, \quad \frac{x_n - x_0}{\|x_n - x_0\|} \to v, \quad \text{and} \quad t_n \to -\infty. \tag{4.24}$$

Passing to the limit as $(x_n, t_n) \to (x_0, -\infty)$ in (4.23) we obtain

$$G_{x_0,v,1}(0) = c_{1,1} w_{1,1}(x_0) = 0. \tag{4.25}$$

Now we complete the induction argument on r to prove (4.22). We assume that $\frac{d^r G_{x_0,v,1}}{d\mu^r}(0) = 0$ for $r \le R-1$. Then, from the Taylor expansion of $G_{x_0,v,1}$ at $\mu = 0$ we have

$$\frac{d^R G_{x_0,v,1}}{d\mu^R}(0) = \lim_{\mu\to 0} \frac{R!\, G_{x_0,v,1}(\mu)}{\mu^R} = \lim_{\mu_n\to 0} \frac{R!\, G_{x_0,v_n,1}(\mu_n)}{\mu_n^R}, \tag{4.26}$$

where we can choose x_n and v_n as in (4.24) and $\mu_n = \|x_n - x_0\|$.

On the other hand, we have

(4.27)

$$\left|\frac{G_{x_0,v_n,1}(\mu_n)}{\mu_n^R}\right|^2 = \left|c_{1,1}\frac{w_{1,1}(x_n)}{\|x_n - x_0\|^R}\right|^2 = \left|\sum_{j=2}^{\infty} \frac{e^{(\lambda_1-\lambda_j)(T-t_n)}}{\|x_n - x_0\|^R} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x_n)\right|^2$$
$$\le \left\|\sum_{j=2}^{\infty} \frac{e^{(\lambda_1-\lambda_j)(T-t_n)}}{\|x_n - x_0\|^R} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}\right\|^2_{L^\infty} \le C \left\|\sum_{j=2}^{\infty} \frac{e^{(\lambda_1-\lambda_j)(T-t_n)}}{\|x_n - x_0\|^R} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}\right\|^2_{H_1}$$
$$= C \sum_{j=2}^{\infty} \frac{e^{2(\lambda_1-\lambda_j)(T-t_n)}}{\|x_n - x_0\|^{2R}} \sum_{k=1}^{l(j)} |c_{j,k}|^2 \le C \frac{e^{-2(\lambda_2-\lambda_1)(T-t_n)}}{\|x_n - x_0\|^{2R}} \sum_{j=2}^{\infty} \sum_{k=1}^{l(j)} |c_{j,k}|^2,$$

which converges to zero as $t_n \to -\infty$ since the factor

$$\frac{e^{-2(\lambda_2-\lambda_1)(T-t_n)}}{\|x_n - x_0\|^{2R}} = \left(\frac{e^{-\frac{\lambda_2-\lambda_1}{R}(T-t_n)}}{\|x_n - x_0\|}\right)^{2R}$$

converges to zero as $t_n \to -\infty$, i.e., as $\mu \to 0$, due to the hypothesis on the accumulation directions given in (3.15).

Here we see why we include only "nonexponential directions" in the definition of D_{x_0} in (3.15).

This concludes the proof of (4.22). From (4.22) we deduce (4.21) and then

$$c_{1,1} = 0.$$

Following an induction argument in j we easily obtain

$$\frac{d^r G_{x_0,v,j}}{d\mu^r}(0) = 0 \quad \forall j \text{ and } \forall x_0 \in P,\ \forall v \in D_{x_0}, \tag{4.28}$$

where $G_{x_0,v,j}(\mu) = \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x_0 + \mu v)$.

From (4.28) and the analyticity of the eigenfunctions $w_{j,k}$ we have

$$\sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x_0 + \mu v) = 0 \quad \forall j,\ \forall x_0 \in P,\ \forall v \in D_{x_0},\ \text{and } \forall \mu \in \mathbb{R} \text{ s.t. } [x_0, x_0 + \mu v] \in \Omega. \tag{4.29}$$

On the other hand, taking into account the fact that $\sum_{k=1}^{l(j)} c_{j,k} w_{j,k}$ is an eigenfunction and by the unique continuation hypothesis (3.16) for the eigenfunctions we obtain

$$\sum_{k=1}^{l(j)} c_{j,k} w_{j,k} \equiv 0 \quad \forall j \geq 1.$$

Therefore $c_{j,k} = 0$ for all $k = 1, \ldots, l(j)$ because of the linear independence of $w_{j,k}$. This concludes the proof of the lemma. □

5. Averaging of rapidly oscillating controls. In this section we prove Theorem 3.3. We introduce the variational approach of the HUM method to characterize the controls f_ε of (3.17) of minimal norm (see [L1] and [L2]). Then we pass to the limit, as $\varepsilon \to 0$, in these equations to obtain the limit control. The main ingredient to establish the convergence is Lemma 5.1 below. The proof of Theorem 3.3 will be given after the proof of Lemma 5.1.

LEMMA 5.1. *Let $\{\gamma(t)\}_{0 \leq t \leq T}$ be an analytic 2π-periodic family of k-dimensional manifolds. Consider a sequence $u_\varepsilon^0 \rightharpoonup u^0$ that weakly converges in H_0. Let u_ε, u be the solutions of the homogeneous system* (3.1) *with $f = 0$, and initial data u_ε^0, u^0 respectively. Let $\gamma_\varepsilon(t) = \gamma(t/\varepsilon)$. Then*

$$\begin{aligned} &\int_0^T \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2 \, d\sigma \, dt \to \int_0^T \langle u(x,t) m_\gamma(x), u(x,t) \rangle_1 dt \quad \text{if } k \geq 1, \\ &\int_0^T |u_\varepsilon(\gamma_\varepsilon(t), t)|^2 \, dt \to \int_0^T \langle u(x,t) m_\gamma(x), u(x,t) \rangle_1 \quad \text{if } k = 0, \end{aligned} \tag{5.1}$$

where $m_\gamma(x)$ is the weak- limit of $\delta_{\gamma(t/\varepsilon)}$ in $L^\infty(0,T;H_1')$, and $\langle \cdot, \cdot \rangle_1$ denotes the duality pairing between H_1 and its dual.*

The density $m_\gamma(x)$ does not depend on the time variable t; it is supported on the nonempty open set ω, defined as the interior set, with respect to the relative topology, of the range of $\{\gamma(t)\}_{0 \leq t \leq 2\pi}$, and it is characterized by (3.20).

Moreover, if $\varphi \in C_0^\infty(\Omega \times (0,T))$, *then*

$$\int_0^T \int_{\gamma_\varepsilon(t)} u_\varepsilon(x,t)\varphi(x,t)\ d\sigma\ dt \to \int_0^T \langle u(x,t)m_\gamma(x), \varphi(x,t)\rangle_1 dt \quad if\ k \geq 1,$$

$$\int_0^T u_\varepsilon(\gamma_\varepsilon(t),t)\varphi(x,t)dt \to \int_0^T \langle u(x,t)m_\gamma(x), \varphi(x,t)\rangle_1 dt \quad if\ k = 0. \tag{5.2}$$

Proof of Lemma 5.1. To simplify the presentation we consider the case $k \geq 1$. The case $k = 0$ is analogous.

The sequence $u_\varepsilon(x,t)$ of solutions of the homogeneous system (3.1) with $f = 0$ and initial data u_ε^0 can be written in the Fourier representation

$$u_\varepsilon(x,t) = \sum_{j=1}^{\infty} e^{-\lambda_j t} \sum_{k=1}^{l(j)} c_{j,k}^\varepsilon w_{j,k}(x).$$

We assume that $(w_{j,k})_{j,k\geq 1}$ constitute an orthonormal basis in H_0. Analogously, the solution $u(x,t)$ of the homogeneous system (2.4) with $f = 0$ and initial data u^0, is

$$u(x,t) = \sum_{j=1}^{\infty} e^{-\lambda_j t} \sum_{k=1}^{l(j)} c_{j,k} w_{j,k}(x).$$

Due to the weak convergence of the initial data $u_\varepsilon^0 \rightharpoonup u^0$ in H_0 we have

$$\sum_{j,k\geq 1} |c_{j,k}^\varepsilon|^2 \leq C, \qquad \sum_{j,k\geq 1} |c_{j,k}|^2 \leq C, \tag{5.3}$$

with C independent of ε. Moreover,

$$c_{j,k}^\varepsilon \to c_{j,k} \qquad \text{as } \varepsilon \to 0 \qquad \forall j,k \geq 1.$$

Let us prove the convergence result stated in (5.1). To avoid the singularity of the solution u_ε at $t = 0$ we divide the left-hand side integral in (5.1) into two parts:

$$\begin{aligned} \int_0^T \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2\ d\sigma\ dt &= \int_0^\delta \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2\ d\sigma\ dt \\ &\quad + \int_\delta^T \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2\ d\sigma\ dt \end{aligned} \tag{5.4}$$

with $\delta > 0$ to be chosen later.

We first estimate the first integral in (5.4). By classical estimates on the heat kernel (see [CH, p. 44]) we know that

$$\|u_\varepsilon(\cdot,t)\|_{L^\infty(\Omega)} \leq Ct^{-\frac{n}{2q}} \left\|u_\varepsilon^0\right\|_{L^q(\Omega)}$$

with C a constant that does not depend on ε. Therefore the first integral in (5.4) can be estimated by

$$\begin{aligned} \int_0^\delta \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2\ d\sigma\ dt &\leq C \left\|u_\varepsilon^0\right\|_{L^q(\Omega)}^2 \int_0^\delta t^{-\frac{n}{q}} \int_{\gamma_\varepsilon(t)} d\sigma\ dt \\ &\leq C \left\|u_\varepsilon^0\right\|_{L^q(\Omega)}^2 \max_{t\in[0,\delta]} (\text{meas } (\gamma(t/\varepsilon))) \int_0^\delta t^{-\frac{n}{q}} dt \\ &= C \left\|u_\varepsilon^0\right\|_{L^q(\Omega)}^2 \frac{\delta^{1-\frac{n}{q}}}{1-\frac{n}{q}} \max_{t\in[0,2\pi]} \text{meas } (\gamma(t)). \end{aligned}$$

We set $q = 2$ if $n = 1$ and $q = 4$ if $n = 2, 3$. Then, by the continuous Sobolev embeddings $H_0^1(\Omega) \to L^\infty(\Omega)$ if $n = 1$ and $H_0^1(\Omega) \to L^4(\Omega)$ for $n = 2, 3$ we easily deduce the estimate

$$\int_0^\delta \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2 \, d\sigma \, dt \le C(\delta, n, \gamma) \left\| u_\varepsilon^0 \right\|_{H_0}^2 \tag{5.5}$$

with $C(\delta, n, \gamma)$ independent of ε and such that

$$C(\delta, n, \gamma) \to 0 \quad \text{as } \delta \to 0.$$

Note that the estimate above holds since the manifold γ is time-periodic and consequently

$$\max_{t\in[0,\delta]} (\text{meas } \gamma(t/\varepsilon)) = \max_{t\in[0,2\pi]} (\text{meas } \gamma(t/\varepsilon)) < \infty$$

as $\varepsilon \to 0$.

Thus, to prove the convergence result stated in (5.1), it suffices to show that the second integral in (5.4), for $\delta > 0$ fixed, tends to

$$\int_\delta^T \langle u(x,t) m_\gamma(x,t), u(x,t) \rangle_1 dt$$

as $\varepsilon \to 0$. Indeed, once this is proved, (5.1) is obtained passing to the limit, as $\delta \to 0$, in (5.4).

We have

$$\begin{aligned}\int_\delta^T \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2 \, d\sigma \, dt &= \int_\delta^T \int_{\gamma_\varepsilon(t)} \sum_{j,i=1}^{\infty} \sum_{k=1}^{l(j)} \sum_{m=1}^{l(i)} e^{-(\lambda_i+\lambda_j)t} c_{j,k}^\varepsilon c_{i,m}^\varepsilon w_{j,k}(x) w_{i,m}(x) d\sigma \, dt \\ &= \sum_{j,i=1}^{\infty} \sum_{k=1}^{l(j)} \sum_{m=1}^{l(i)} \int_\delta^T \int_{\gamma_\varepsilon(t)} e^{-(\lambda_i+\lambda_j)t} c_{j,k}^\varepsilon c_{i,m}^\varepsilon w_{j,k}(x) w_{i,m}(x) d\sigma \, dt.\end{aligned}$$

Now we take the limit as $\varepsilon \to 0$,

$$\begin{aligned}&\lim_{\varepsilon\to 0} \int_\delta^T \int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2 \, d\sigma \, dt \\ &\quad = \lim_{\varepsilon\to 0} \sum_{j,i=1}^{\infty} \sum_{k=1}^{l(j)} \sum_{m=1}^{l(i)} \int_\delta^T \int_{\gamma_\varepsilon(t)} e^{-(\lambda_i+\lambda_j)t} c_{j,k}^\varepsilon c_{i,m}^\varepsilon w_{j,k}(x) w_{i,m}(x) \, d\sigma \, dt \\ &\quad = \sum_{j,i=1}^{\infty} \sum_{k=1}^{l(j)} \sum_{m=1}^{l(i)} c_{j,k} c_{i,m} \lim_{\varepsilon\to 0} \int_\delta^T \int_{\gamma_\varepsilon(t)} e^{-(\lambda_i+\lambda_j)t} w_{j,k}(x) w_{i,m}(x) \, d\sigma \, dt. \qquad (5.6)\end{aligned}$$

Interchanging the sum and the limit is justified because of the dominated convergence

theorem. Indeed, each term of the series can be bounded above as follows:

$$\begin{aligned}
&\left| c^{\varepsilon}_{j,k} c^{\varepsilon}_{i,m} \int_{\delta}^{T} \int_{\gamma_\varepsilon(t)} e^{-(\lambda_i+\lambda_j)t} w_{j,k}(x) w_{i,m}(x)\, d\sigma\, dt \right| \\
&\quad \le |c^{\varepsilon}_{j,k} c^{\varepsilon}_{i,m}| \max_{t\in[\delta,T]} \left| \int_{\gamma_\varepsilon(t)} w_{j,k}(x) w_{i,m}(x)\, d\sigma \right| \int_{\delta}^{T} e^{-(\lambda_i+\lambda_j)t} dt \\
&\quad \le \left(\sum_{i=1}^{\infty} \sum_{m=1}^{l(i)} |c^{\varepsilon}_{i,m}|^2 \right) \max_{t\in[0,2\pi]} \left| \int_{\gamma(t)} w_{j,k}(x) w_{i,m}(x)\, d\sigma \right| \frac{e^{-(\lambda_i+\lambda_j)\delta} - e^{-(\lambda_i+\lambda_j)T}}{\lambda_i+\lambda_j} \\
&\quad \le \|u^{\varepsilon}_0\|^2_{H_0} \max_{t\in[0,2\pi]} \left| \int_{\gamma(t)} w_{j,k}(x) w_{i,m}(x)\, d\sigma \right| \frac{e^{-(\lambda_i+\lambda_j)\delta}}{\lambda_i+\lambda_j} \\
&\quad \le C \max_{t\in[0,2\pi]} \left| \int_{\gamma(t)} w_{j,k}(x) w_{i,m}(x)\, d\sigma \right| \frac{e^{-(\lambda_i+\lambda_j)\delta}}{\lambda_i+\lambda_j}, \qquad (5.7)
\end{aligned}$$

since, by hypothesis, the sequence of initial data u^0_ε is uniformly bounded in H_0 (see (5.3)). Now, by the Hölder inequality and the trace theorem,

$$\begin{aligned}
\left| \int_{\gamma(t)} w_{j,k}(x) w_{i,m}(x)\, d\sigma \right| &\le \|w_{j,k}\|_{L^2(\gamma(t))} \|w_{i,m}\|_{L^2(\gamma(t))} \\
&\le C(\gamma(t)) \|w_{j,k}\|_{H_1} \|w_{i,m}\|_{H_1}, \qquad (5.8)
\end{aligned}$$

where $C(\gamma(t))$ is a constant that depends only on the measure of $\gamma(t)$. Note that, in view of the hypothesis on $\gamma(t)$, this constant can be chosen independently of time; i.e., there exists $C(\gamma)$ independent of t such that $C(\gamma(t)) \le C(\gamma)$ for all $t \in [0, 2\pi]$. Moreover, taking into account the normalization of the eigenfunctions in H_0, we have

$$\|w_{j,k}\|_{H_1} \le C\sqrt{\lambda_j}\, \|w_{j,k}\|_{H_0} = C\sqrt{\lambda_j},$$

and the terms in (5.7) can be bounded above by

$$C(\gamma) \frac{\sqrt{\lambda_j}\sqrt{\lambda_i}}{\lambda_j+\lambda_i} e^{-(\lambda_j+\lambda_i)\delta} \le C(\gamma) e^{-(\lambda_j+\lambda_i)\delta} \qquad (5.9)$$

with $C(\gamma)$ a constant that does not depend on ε, i, j, k, m. The sum of all these terms in i, j, k, m is finite due to the well-known asymptotic behavior of the eigenvalues of the Laplace operator. Indeed,

$$\sum_{i,j\ge1} \sum_{m=1}^{l(i)} \sum_{k=1}^{l(j)} e^{-(\lambda_i+\lambda_j)\delta} = \left(\sum_{i\ge1} \sum_{m=1}^{l(i)} e^{-\lambda_i\delta} \right)^2.$$

The last sum is finite. Recall that the number of eigenvalues less than a constant λ, including multiplicity, is asymptotically equal to $\lambda|\Omega|/4\pi$ if $n = 2$, and $\lambda^{3/2}|\Omega|/6\pi^2$ if $n = 3$ (see [CoH, p. 442]). Then, for example, in the case $n = 3$ we have

$$\sum_{i\ge1} \sum_{m=1}^{l(i)} e^{-\lambda_i\delta} = \sum_{k=1}^{\infty} \sum_{k-1\le\lambda_i\le k} l(i) e^{-\lambda_i\delta} \le C \sum_{k=1}^{\infty} k^{3/2} e^{-(k-1)\delta} < \infty.$$

Once we have checked (5.6), we pass to the limit in each one of the terms in the right-hand side of (5.6). Then,

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_\delta^T\int_{\gamma_\varepsilon(t)} e^{-(\lambda_i+\lambda_j)t}w_{j,k}(x)w_{i,m}(x)\ d\sigma\ dt\\
&\quad=\lim_{\varepsilon\to 0}\int_\delta^T \langle \delta_{\gamma_\varepsilon(t)}, e^{-(\lambda_i+\lambda_j)t}w_{j,k}(x)w_{i,m}(x)\rangle_1\\
&\quad=\int_\delta^T \langle m_\gamma(x,t), e^{-(\lambda_j+\lambda_i)t}w_{j,k}(x)w_{i,m}(x)\rangle_1\ dt\\
&\quad=\int_\delta^T \langle e^{-\lambda_i t}w_{i,m}(x)m_\gamma(x,t), e^{-\lambda_j t}w_{j,k}(x)\rangle_1\ dt,
\end{aligned}$$

where $m_\gamma(x,t)$ is the weak-* limit of $\delta_{\gamma_\varepsilon(t)}$ in $L^\infty(0,T;H_1)$ and $\langle\cdot,\cdot\rangle_1$ is the duality pairing between H_1 and its dual space.

Thus,

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_\delta^T\int_{\gamma_\varepsilon(t)} |u_\varepsilon(x,t)|^2 d\sigma\ dt\\
&\quad=\sum_{j,i=1}^{\infty}\sum_{k=1}^{l(j)}\sum_{m=1}^{l(i)} c_{j,k}c_{i,m}\int_\delta^T \langle e^{-\lambda_i t}w_{i,m}(x)m_\gamma(x,t), e^{-\lambda_j t}w_{j,k}(x)\rangle_1\ dt\\
&\quad=\int_\delta^T \langle u(x,t)m_\gamma(x,t), u(x,t)\rangle_1 dt
\end{aligned}$$

for all $\delta>0$.

It remains to prove that the limit density $m_\gamma(x,t)$ does not depend on the time variable t and that it is supported on the region ω, constituted by the range of $\gamma(t)$ over the period $t\in[0,2\pi]$. In fact, the limit density m_γ is characterized by

$$\int_0^T \langle m_\gamma,\varphi\rangle_1 dt=\lim_{\varepsilon\to 0}\int_0^T\int_{\gamma(t/\varepsilon)}\varphi(x,t)d\sigma\ dt\quad\forall\varphi(x,t)\in L^1(0,T;H_1).$$

Taking into account that $C_0^\infty(\Omega)\times C_0^\infty(0,T)$ is sequentially dense in $C_0^\infty(\Omega\times(0,T))$, which is dense in $L^1(0,T;H_1)$, m_γ is also characterized by

$$\int_0^T \langle m_\gamma,\varphi\rangle_1 dt=\lim_{\varepsilon\to 0}\int_0^T\int_{\gamma(t/\varepsilon)}\varphi(x)\psi(t)d\sigma\ dt\quad\forall\varphi(x)\in H_1,\quad \psi(t)\in L^1(0,T).$$

Note that $F(s)=\int_{\gamma(t/\varepsilon)}\varphi(x)d\sigma$ is a 2π-periodic function and then $F(s/\varepsilon)$ converges weakly to its average in L^2_{loc} as $\varepsilon\to 0$. Therefore,

$$\lim_{\varepsilon\to 0}\int_0^T\int_{\gamma_\varepsilon(t)}\varphi(x)\psi(t)\ d\sigma\ dt=\frac{1}{2\pi}\int_0^{2\pi}\int_{\gamma(s)}\varphi(x)\ d\sigma\ ds\int_0^T\psi(t)\ dt. \tag{5.10}$$

This last integral can be written as an integral over the region $\omega\times(0,T)$, where ω is the interior set of the range of $\{\gamma(t)\}_{t\in[0,2\pi]}$. The control is weighted by a suitable density function m_γ, supported on ω, and independent of the time variable t. Moreover, this limit $m_\gamma(x)$ is characterized by

$$\int_\omega \varphi(x)m_\gamma(x)\ d\sigma=\frac{1}{2\pi}\int_0^{2\pi}\int_{\gamma(s)}\varphi(x)\ d\sigma\ ds\quad\forall\varphi\in H_1. \tag{5.11}$$

Note that m_γ depends, roughly, on the time derivative of $\gamma(t)$ over a period $[0, 2\pi]$.

The proof of (5.2) is similar. We have to take into account only that $C_0^\infty(\Omega) \times C_0^\infty(0,T)$ is sequentially dense in $C_0^\infty(\Omega \times (0,T))$ and then it suffices to check (5.2) for test functions in separated variables. This concludes the proof of the lemma. ∎

Proof of Theorem 3.3. We first restrict ourselves, without loss of generality, to the case where $u^0 = 0$ and $\|u^1\|_{H_0} \geq \alpha$.

Given $\varepsilon > 0$, system (3.1) is approximately controllable. Indeed according to Lemma 4.2 and, in view of the assumptions on the curve $\gamma(t)$, the unique continuation property (4.2) holds for $\gamma_\varepsilon(t) = \gamma(t/\varepsilon)$ for all $\varepsilon > 0$. Then the control that makes (3.10) hold is given by $f_\varepsilon = \overline{\varphi}_\varepsilon(\gamma_\varepsilon(t), t)$, where $\overline{\varphi}_\varepsilon$ solves (4.1), the initial data $\overline{\varphi}_\varepsilon^0$ being the minimizer of the functional

$$J_\varepsilon(\varphi^0) = \frac{1}{2}\int_0^T \int_{\gamma_\varepsilon(t)} |\varphi(x,t)|^2 \, d\sigma dt + \alpha \left\|\varphi^0\right\|_{H_0} - \langle u^1, \varphi^0 \rangle_{H_0', H_0} \tag{5.12}$$

over H_0. Note, in particular, that the coercivity of this functional is guaranteed by the unique continuation property (4.2) (see [FPZ]).

The adjoint system associated to the limit system (3.18) is also given by (4.1) and the corresponding functional associated to (3.18) is given by

$$J(\varphi^0) = \frac{1}{2}\int_0^T \int_\omega |\varphi(x,t)|^2 m_\gamma(x) d\sigma dt + \alpha \left\|\varphi^0\right\|_{H_0} - \langle u^1, \varphi^0 \rangle_{H_0', H_0}, \tag{5.13}$$

where φ is the solution of (4.1) with final data φ^0. Recall that Theorem 3.3 is stated for the particular case $k = n-1$ to simplify the presentation. In the general case $(0 \leq k \leq n-1)$, the first term in (5.13) would be

$$\frac{1}{2}\int_0^T \langle \varphi(x,t) m_\gamma(x), \varphi(x,t) \rangle_1 \, dt, \tag{5.14}$$

and the rest of this proof could be adapted in a straightforward manner. Note that when $k = n-1$, the weak limit of $\delta_{\gamma_\varepsilon(t)}$ is supported in an open subset $\omega \subset \Omega$ and then we can write (5.14) as in (5.13).

We set

$$M_\varepsilon = \inf_{\varphi^0 \in H_0} J_\varepsilon(\varphi^0). \tag{5.15}$$

For each $\varepsilon > 0$ the functional J_ε achieves its minimum M_ε in H_0. This is a consequence of the unique continuation property (4.2) which allows us to prove the coercivity of J_ε for each $\varepsilon > 0$. This unique continuation property is obtained applying the result of Lemma 4.2 to the curve $\gamma_\varepsilon(t) = \gamma(t/\varepsilon)$, which satisfies the hypotheses of Lemma 4.2.

Lemma 5.2 below establishes that the coercivity of J_ε is in fact uniform in ε. Moreover, if $f(t) = \overline{\varphi}_\varepsilon(\gamma(t/\varepsilon), t)$, where $\overline{\varphi}_\varepsilon$ solves (4.1) with data $\overline{\varphi}_\varepsilon^0$, the solution of (2.4) satisfies (3.10).

LEMMA 5.2. *We have*

$$\liminf_{\substack{\|\varphi^0\|_{H_0} \to \infty \\ \varepsilon \to 0}} \frac{J_\varepsilon(\varphi^0)}{\|\varphi^0\|_{H_0}} \geq \alpha. \tag{5.16}$$

Furthermore, the minimizers $\{\overline{\varphi_\varepsilon^0}\}_{\varepsilon \geq 0}$ *are uniformly bounded in* H_0.

Proof of Lemma 5.2. Let us consider sequences $\varepsilon_j \to 0$ and $\varphi^0_{\varepsilon_j} \in H_0$ such that $\|\varphi^0_{\varepsilon_j}\|_{H_0} \to \infty$ as $j \to \infty$.

Let us introduce the normalized data

$$\eta^0_{\varepsilon_j} = \frac{\varphi^0_{\varepsilon_j}}{\|\varphi^0_{\varepsilon_j}\|_{H_0}}$$

and the corresponding solutions of (4.1):

$$\eta_{\varepsilon_j} = \frac{\varphi_{\varepsilon_j}}{\|\varphi^0_{\varepsilon_j}\|_{H_0}}.$$

We have

$$I_j = \frac{J_{\varepsilon_j}(\varphi^0_{\varepsilon_j})}{\|\varphi^0_{\varepsilon_j}\|_{H_0}} = \frac{1}{2}\|\varphi^0_{\varepsilon_j}\|_{H_0} \int_0^T \int_{\gamma_{\epsilon_j}(t)} |\eta_{\varepsilon_j}(x,t)|^2 d\sigma dt + \alpha - \langle u^1, \psi^0_{\varepsilon_j}\rangle_{H_0',H_0}.$$

We distinguish the following two cases:

Case 1. $\liminf_{j\to\infty} \int_0^T \int_{\gamma_{\epsilon_j}(t)} |\eta_{\varepsilon_j}(x,t)|^2 d\gamma_\varepsilon dt > 0$. In this case, we have clearly $\liminf_{j\to\infty} I_j = \infty$.

Case 2. $\liminf_{j\to\infty} \int_0^T \int_{\gamma_{\epsilon_j}(t)} |\eta_{\varepsilon_j}(x,t)|^2 d\gamma_\varepsilon dt = 0$. In this case we argue by contradiction. Assume that there exists a subsequence, still denoted by the index j, such that

$$\int_0^T \int_{\gamma_{\epsilon_j}(t)} |\eta_{\varepsilon_j}(x,t)|^2 d\sigma dt \to 0 \tag{5.17}$$

and

$$\liminf_{j\to\infty} I_j < \alpha. \tag{5.18}$$

By extracting a subsequence, still denoted by the index j, we have

$$\eta^0_{\varepsilon_j} \rightharpoonup \eta^0 \text{ weakly in } H_0$$

and therefore

$$\eta_{\varepsilon_j} \rightharpoonup \eta \text{ weakly-* in } L^\infty(0,T;H_0),$$

where η is the solution of (4.1) with initial data η^0. By Lemma 5.1 we have

$$\eta = 0 \text{ in } \gamma_\varepsilon(t) \times (0,T).$$

Now, recall that, by hypothesis, γ_ε is a strategic curve and then Lemma 4.2 establishes that $\eta^0 = 0$. Thus

$$\eta^0_{\varepsilon_j} \rightharpoonup 0 \text{ weakly in } H_0$$

and therefore

$$\liminf_{j\to\infty} I_j \geq \liminf_{j\to\infty} (\alpha - \langle u^1, \eta^0_{\varepsilon_j}\rangle_{H_0',H_0}) = \alpha$$

since u_j^1 converges strongly in H_0. This is in contradiction with (5.18) and concludes the proof of (5.16).

On the other hand, it is obvious that $I_\varepsilon \leq 0$ for all $\varepsilon > 0$. Thus, (5.16) implies the uniform boundedness of the minimizers in H_0.

Concerning the convergence of the minimizers we have the following lemma.

LEMMA 5.3. *The minimizers $\overline{\varphi}_\varepsilon^0$ of J_ε converge strongly in H_0 as $\varepsilon \to 0$ to the minimizer $\overline{\varphi}^0$ of J in* (5.13) *and M_ε converges to*

$$M = \inf_{\overline{\varphi}^0 \in H_0} J(\overline{\varphi}^0). \tag{5.19}$$

Moreover, the corresponding solutions $\overline{\varphi}_\varepsilon$ of (4.1) *converge in $C([0,T];H_0)$ to the solution $\overline{\varphi}$ as $\varepsilon \to 0$.*

Proof of Lemma 5.3. We adapt a classical argument in Γ-convergence (see [DM]). By extracting a subsequence, which we still denote by ε, we have

$$\overline{\varphi}_\varepsilon^0 \rightharpoonup \eta^0 \text{ weakly in } H_0$$

as $\varepsilon \to 0$. It is sufficient to check that $\overline{\varphi}^0 = \eta^0$ or, equivalently, that η^0 is the minimizer of J, i.e.,

$$J(\eta^0) \leq J(\varphi^0) \quad \forall \varphi^0 \in H_0. \tag{5.20}$$

We know that

$$\overline{\varphi}_\varepsilon \rightharpoonup \eta \text{ weakly-* in } L^\infty(0,T;H_0),$$

where η is the solution of (4.1) with initial data ψ^0. By Lemma 5.1 we deduce that

$$J(\eta^0) = \lim_{\varepsilon \to 0} J_\varepsilon(\overline{\varphi}_\varepsilon^0). \tag{5.21}$$

On the other hand, for each $\varphi^0 \in H_0$ we have

$$\lim_{\varepsilon \to 0} J_\varepsilon(\overline{\varphi}_\varepsilon^0) \leq \lim_{\varepsilon \to 0} J_\varepsilon(\varphi^0). \tag{5.22}$$

Observe also that for $\varphi^0 \in H_0$ fixed, Lemma 5.1 ensures that

$$\lim_{\varepsilon \to 0} J_\varepsilon(\varphi^0) = J(\varphi^0). \tag{5.23}$$

Combining (5.21)–(5.23) it is easy to see that (5.20) holds.

This concludes the proof of the weak convergence of the minimizers and it also shows that

$$\liminf_{\varepsilon \to 0} M_\varepsilon \geq M = J(\bar{\varphi}^0) = \limsup_{\varepsilon \to 0} J_\varepsilon(\overline{\varphi}^0) \geq \limsup_{\varepsilon \to 0} J_\varepsilon(\overline{\varphi}_\varepsilon^0) = \limsup_{\varepsilon \to 0} M_\varepsilon. \tag{5.24}$$

Therefore we deduce that $M_\varepsilon \to M$.

Observe that (5.19), combined with the weak convergence of $\overline{\varphi}_\varepsilon^0$ in H_0, implies that

$$\lim_{\varepsilon \to 0} \left(\frac{1}{2} \int_0^T \int_{\gamma_\varepsilon(t)} |\overline{\varphi}_\varepsilon(x,t)|^2 d\sigma \, dt + \alpha \left\| \overline{\varphi}_\varepsilon^0 \right\|_{H_0} \right) = \frac{1}{2} \int_0^T \int_\omega |\overline{\varphi}|^2 m_\gamma(x) d\omega dt + \alpha \left\| \overline{\varphi}^0 \right\|_{H_0},$$

since the last term in $J_\varepsilon(\bar{\varphi}_\varepsilon^0)$, which is linear in $\bar{\varphi}_\varepsilon^0$, passes trivially to the limit.

This identity, combined with the weak convergence of $\overline{\varphi}_\varepsilon^0$ to $\overline{\varphi}^0$ in H_0 and Lemma 5.1, implies that

$$\overline{\varphi}_\varepsilon^0 \to \overline{\varphi}^0 \text{ strongly in } H_0. \tag{5.25}$$

Therefore, we have

$$\overline{\varphi}_\varepsilon \to \overline{\varphi} \text{ strongly in } C([0,T];H_0).$$

This concludes the proof of Theorem 3.3 when $u^0 = 0$ and $\|u^1\|_{L^2(\Omega)} \geq \alpha$.

Let us consider now the case where u^0 is nonzero. We set $v^1 = v(T)$ where v is the solution of (2.4) with $f = 0$. Now observe that the solution u of (2.4) can be written as $u = v + w$ where w is the solution of (2.4) with zero initial data that satisfies $w(T) = u(T) - v^1$. In this way, the controllability problem for u can be reduced to a controllability problem for w with zero initial data $w^0 = 0$. This is the problem we solved. The proof is now complete. □

Remark 5.1. The proof guarantees that the coercivity property (5.16) is also true for the limit functional J. This fact could also be proved arguing directly on J. In this case we would use the corresponding unique continuation property for the solutions of the adjoint limit system.

6. Further results and open problems. Let us describe briefly some generalizations and open problems related with the results in this paper.

1. In this paper we have restricted ourselves to space dimensions $n \leq 3$. However, only the results for space dimension $n = 1$, which was treated separately, are based on arguments that cannot be generalized to higher dimensions. The proofs given for the cases $n = 2, 3$ do not depend on the dimension and can be easily generalized to any space dimension n, for it is sufficient to make an appropriate choice of the Sobolev spaces (3.3) where system (3.1) is well-posed.

2. As we mentioned in the introduction, when the control acts on an open nonempty subset of the domain Ω for all $0 \leq t \leq T$ the heat equation is null-controllable. The problem of null-controllability for a system with a singular control concentrated on the curve γ is completely open. It is well known that the null-controllability of system (3.1) is equivalent to the following observability inequality for the solutions of the adjoint system (4.1):

$$\int_\Omega |\varphi(x,0)|^2 dx \leq C \int_0^T \int_{\gamma(s)} |\varphi(x,t)|^2 d\sigma\, ds \qquad \forall \varphi \text{ solution of (4.1).} \tag{6.1}$$

This observability inequality is much stronger than the unique continuation property (4.2). The arguments and techniques developed in this paper do not allow us to obtain (6.1). In recent years, Carleman estimates have been used systematically as the most efficient tool to obtain observability inequalities (see [FI] and [FZ]), but they do not seem to be sufficient to obtain quantitative results as (6.1) when $\gamma(t)$ is of dimension $k \leq n - 1$.

3. The results of this paper (Theorem 3.3) show that increasing the time-oscillations of the control region improves the controllability properties of the heat equation. It would be interesting to further analyze this property in the context of the cost of controlling the system. In other words, the initial and final data u^0, u^1 being fixed, as well as $\alpha > 0$, it would be interesting to analyze the size of the minimal control allowing us to achieve (3.10) and its behavior as $\varepsilon \to 0$. This was done in [FZ]

in the case of controls acting on open subsets of Ω independent of the time. But the techniques in [FZ], based on the use of Carleman inequalities, do not seem to apply in the present situation.

4. The results in Theorem 3.3 are also valid when considering controls that simultaneously guarantee the approximate control condition (2.2) and the exact control of a finite-dimensional projection (see [Z2] for details). In this case, the proof is very similar. We only have to replace the term $\alpha \left\|\varphi^0\right\|_{H_0}$ by $\alpha \left\|(I-\pi_E)\varphi^0\right\|_{H_0}$ in both the functionals J_ε and J, given in (5.12) and (5.13), respectively. Here, I represents the identity and π_E the orthogonal projection of H_0 on a finite-dimensional subspace E. It is not difficult to see that the arguments in the proof of Theorem 3.3 can be easily adapted to this situation.

5. The main ingredients to prove the approximate controllability results of this paper, and in particular Theorem 3.2, are the Fourier decomposition of solutions and the time-analyticity of the underlying semigroup. Therefore, we can easily extend the results to more general equations where these two properties hold. This is the case, for instance, in equations of the form

$$\rho(x)u_t - \ \text{div}\ (A(x)\nabla u) = 0,$$

with Dirichlet, Neuman, or mixed boundary conditions.

The situation is more complex when considering time-dependent coefficients. Then, in general, it is not possible to write the solutions in Fourier series. However, there are some particular cases where a certain decomposition is still possible. For example, consider the heat equation

$$\rho(t)u_t - \Delta u = 0$$

with $0 < \rho_m \leq \rho(t) \leq \rho_M < \infty$ and some boundary conditions. With the change of variable

$$s(t) = \int_0^t \rho^{-1}(r)dr,$$

the equation is transformed into the constant coefficient heat equation

$$u_s - \Delta u = 0,$$

for which a Fourier decomposition is known. Coming back to the original variable t we obtain a decomposition of the solutions that allows us to adapt the results of this paper.

But the problem is completely open for general linear equations with coefficients depending on both space and time.

6. The techniques used in this paper cannot be adapted to the semilinear case. Indeed, the approximate controllability of the semilinear heat equation is usually derived from the approximate controllability of the linearized equation with a potential. As this potential depends on both the space and time variables, our techniques do not apply, as pointed out above.

7. The techniques used in this paper cannot be adapted to wave or plate equations since the time-analyticity of the solutions fails. For the wave equation there are some partial controllability results, for the 1-d case, when the control acts on a point that follows particular time-dependent trajectories (see [K2]).

SPECTRAL FACTORIZATION BY SYMMETRIC EXTRACTION FOR DISTRIBUTED PARAMETER SYSTEMS*

J. J. WINKIN†, F. M. CALLIER†, B. JACOB‡, AND J. R. PARTINGTON§

Abstract. The spectral factorization problem of a scalar coercive spectral density is considered in the framework of the Callier–Desoer algebra of distributed parameter system transfer functions. Criteria are given for the infinite product representation of a meromorphic coercive spectral density of finite order and for the convergence of infinite product representations of spectral factors, i.e., for the convergence of the symmetric extraction method for solving the spectral factorization problem of such spectral density. These convergence criteria are applied to the solution of the linear-quadratic optimal control problem by spectral factorization for a specific class of semigroup Hilbert state-space systems with a Riesz-spectral generator. The speed of convergence of the symmetric extraction method is also considered. As an example a damped vibrating string model is handled.

Key words. distributed parameter systems, spectral factorization, coercivity, meromorphic function, entire function, finite order, infinite product, symmetric extraction, convergence analysis

1. Introduction.

The spectral factorization problem plays a central role in the framework of the fractional representation approach (which is also known in the literature as the "factorization approach") for feedback control system design; see, e.g., [8], [35]. In addition, spectral factorization constitutes an essential step in the solution of the linear-quadratic (LQ) optimal control problem for infinite-dimensional state-space systems; see, e.g., [9], [10], [18], [33], [36] and the references therein. The spectral factorization problem is also used as a main tool for solving linear operator inequalities (Lur'e equations); see, e.g., [16], [19]. As far as the LQ-optimal control problem is concerned, it is shown in [9] and [10] that the latter is solvable by spectral factorization for C_0-semigroup Hilbert state-space systems with bounded observation and control operators and with finite-dimensional output and input spaces. The philosophy developed in those papers has been extended, e.g., in [33] and [36] to C_0-semigroup Hilbert state-space systems with unbounded observation and control operators. In those references, the authors analyze spectral factorization problems of operator-valued Popov functions, giving an H^∞ spectral factor and showing notably the existence of solutions to related operator Riccati equations. However, they do not develop any method to perform the spectral factorization iteratively, which is done here similarly as on the heat diffusion model dealt with in [10].

Fundamental questions concerning the spectral factorization problem have been studied in the literature: in particular the existence and multiplicity of spectral factors and the continuity of the spectral factorization mapping have been analyzed; see, e.g., [12], [23], [22] and the references therein. As far as computational questions are

concerned, several methods have been developed and analyzed for the approximate computation of spectral factors or solutions of related operator Riccati equations for distributed parameter systems; see, e.g., the references cited in [9], [10], and [36]. The LQ-control based normalized coprime fraction spectral factorization problem considered in [10] was solved by an ad hoc iterative symmetric extraction method for a one-dimensional heat diffusion model, involving only elementary rational factors with real poles and zeros (first order case). The symmetric extraction method of spectral factorization was also studied in detail for multivariable finite-dimensional state-space systems in [4].

The major aim of this paper is to extend this method to a class of single-variable distributed parameter (i.e., in particular infinite-dimensional state-space) systems, including standard models like heat diffusion or wave propagation, and thereby involving the symmetric extraction of elementary rational factors with complex conjugate poles and zeros (second order case) as well. More specifically, this paper is devoted to the description and the convergence analysis of the symmetric extraction method for the spectral factorization of a scalar coercive spectral density, which is assumed to be a meromorphic function of finite order (see, e.g., [27]), in the framework of the Callier–Desoer algebra of distributed parameter system transfer functions (see, e.g., [5], [6], [11], [17]). Criteria for the infinite product representation of a meromorphic coercive spectral density of finite order and for the convergence of the symmetric extraction method of spectral factorization are developed, which extend some previous partial results (see [8], [10]). These criteria are mainly based on the knowledge of the comparative asymptotic behavior of the spectral density poles and zeros. Some comments concerning the speed of convergence of such a method are also given. Moreover, the symmetric extraction method is shown to work for the spectral factorization of a coprime fraction (coercive) spectral density. The analysis is performed in the framework of C_0-semigroup Hilbert state-space systems, whose infinitesimal generator is a Riesz-spectral operator, with eigenvalues satisfying some asymptotic conditions, and with transfer function in the Callier–Desoer algebra. The results are illustrated by an example, namely, the LQ-control based normalized coprime fraction spectral factorization problem for a vibrating string model. Some of these results were reported in [13], [14].

The methodology for the convergence analysis of the symmetric extraction method of spectral factorization which is used here is based on entire function theory; see, e.g., [37], [3], [26]. In particular, Hadamard's theorem on the infinite product representation of entire functions of finite order plays a central role here. Basically the analysis developed in this paper uses the material which is contained in [37] and which is paramount for the proof of a related important result, viz., Akhiezer's theorem, concerning the spectral factorization of entire functions of exponential type; see, e.g., [25, p. 567], [3, Theorem 7.5.1, p. 125].

Related results dealing with matrix-valued functions can also be found, e.g., in [29] and [30, Theorem 2.1]. These contributions do not deal with the symmetric case, whereas the present paper does. In addition, e.g., in [29], the starting point of the analysis is the function to be factorized (requiring a realization step in the analysis). Here the starting point of the analysis is basically a system transfer function, the main objective being to apply the methodology in a system theoretic framework.

The paper is organized as follows. Some preliminaries concerning the frequency domain framework, and properties of coercive spectral densities and invertible spectral factors are given in section 2. Fundamental results concerning the representation of a meromorphic coercive spectral density of finite order as an infinite product of

elementary rational spectral densities are developed in section 3. These results are used in section 4 in order to establish spectral criteria for the convergence of the symmetric extraction method for the computation of a spectral factor. Section 5 is devoted to the implementation of this method for solving the LQ-optimal control based spectral factorization problem for a vibrating string model. Finally, section 6 contains some concluding remarks and perspectives.

2. Preliminary concepts and results. The analysis of the symmetric extraction method of spectral factorization is performed in the framework of the Callier–Desoer transfer function algebra (see, e.g., [5], [6], [11], [17, section 7.1]). The latter is briefly described below.

Let $\sigma \leq 0$. An impulse response f is said to be in $\mathcal{A}(\sigma)$ if for $t < 0, f(t) = 0$, and for $t \geq 0, f(t) = f_a(t) + f_{sa}(t)$, where the regular functional part $f_a \in L^1_\sigma$, i.e., $\exp(-\sigma\cdot)\ f_a(\cdot)$ is in $L^1(0,\infty)$, and the singular atomic part $f_{sa} := \sum_{i=0}^{\infty}\ f_i\delta(.-t_i)$, where $t_0 = 0, t_i > 0$ for $i = 1, 2, \ldots$, and $f_i \in \mathbb{C}$ for $i = 0, 1, \ldots$ with $\sum_{i=0}^{\infty}\ |f_i| \exp(-\sigma t_i) < \infty$. The norm of a distribution f in $\mathcal{A}(\sigma)$ is defined by

$$||f||_{\mathcal{A}(\sigma)} := \int_0^\infty\ |f_a(t)|\ e^{-\sigma t}\ dt + \sum_{i=0}^{\infty}\ |f_i|\ e^{-\sigma t_i}\ .$$

The Laplace transform of a distribution f is denoted by $\hat{f}$, and the class of Laplace transforms of elements in $\mathcal{A}(\sigma)$ is denoted by $\hat{\mathcal{A}}(\sigma)$. The norm of $\hat{f}$ in $\hat{\mathcal{A}}(\sigma)$ is defined by

$$||\hat{f}||_{\hat{\mathcal{A}}(\sigma)} := ||f||_{\mathcal{A}(\sigma)}\ .$$

An impulse response f is said to be in $\mathcal{A}_-(\sigma)$ if $f \in \mathcal{A}(\sigma_1)$ for some $\sigma_1 < \sigma$. We write $\mathcal{A}_-$ for $\mathcal{A}_-(0)$. $\mathcal{A}(\sigma)$ and $\mathcal{A}_-$ are convolution algebras. By $\hat{\mathcal{A}}_-(\sigma)$ and $\hat{\mathcal{A}}_-$ we denote the classes of Laplace transforms of elements in $\mathcal{A}_-(\sigma)$ and $\mathcal{A}_-$, respectively. Then $\hat{\mathcal{A}}_-$ is our selected class of distributed proper-stable transfer functions. It contains the multiplicative subset $\hat{\mathcal{A}}_-^\infty$ of transfer functions that are bounded away from zero at infinity in $\mathbb{C}_+$, i.e., that are biproper-stable. The Callier–Desoer algebra $\hat{\mathcal{B}}$ of possibly unstable transfer functions consists of those $\hat{f}$ such that $\hat{f} = \hat{n}\hat{d}^{-1}$ with $\hat{n} \in \hat{\mathcal{A}}_-$ and $\hat{d} \in \hat{\mathcal{A}}_-^\infty$. A transfer function is in $\hat{\mathcal{B}}$ if and only if it is the sum of a completely unstable strictly proper rational function and a stable transfer function in $\hat{\mathcal{A}}_-$; hence $\hat{d}$ above can always be chosen biproper-stable *rational*; see [11], [17].

DEFINITION 2.1. *A complex–valued function f is said to be* (1) parahermitian *if* $f(s) \equiv f_*(s) := \overline{f(-\overline{s})}$, (2) real *if* $\overline{f(s)} \equiv f(\overline{s})$, *and* (3) real parahermitian *if* $\overline{f(s)} \equiv f(\overline{s})$ *and* $f(s) \equiv f_*(s)$.

A function $\hat{F}$ is said to be a (real) spectral density *if $\hat{F}$ is (real) parahermitian such that $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, where $\hat{G}$ is in $\hat{\mathcal{A}}_-$, and $\hat{F}$ is nonnegative on the imaginary axis, i.e., $\hat{F}(j\omega) \geq 0$ for all $\omega \in \mathbb{R}$. A spectral density $\hat{F}$ is said to be* coercive *if there exists $\eta > 0$ such that $\hat{F}(j\omega) \geq \eta$ for all $\omega \in \mathbb{R}$. A transfer function $\hat{R}$ in $\hat{\mathcal{A}}_-$ is said to be a* spectral factor *of a spectral density $\hat{F}$ if $\hat{F}(j\omega) = \hat{R}_*(j\omega)\hat{R}(j\omega)$ for all $\omega \in \mathbb{R}$. A spectral factor $\hat{R}$ is said to be* invertible *if $\hat{R}^{-1}$ is in $\hat{\mathcal{A}}_-$.*

A spectral density is also called a *Popov function* in the literature; see, e.g., [36] and the references therein. It is known that a spectral density has an invertible spectral factor if and only if it is coercive, and that spectral factors are unique up to multiplication by a constant of modulus one (see, e.g., [8], [9], [12]); furthermore,

to coercive real spectral densities correspond real spectral factors unique up to the $\pm$ sign. Moreover, a coercive spectral density $\hat{F}$ such that $\hat{F}(\infty) = 1$, i.e., $\hat{F} = \hat{G}_* + \hat{G}$ with $\hat{G} = G_0 + \hat{G}_a \in \hat{\mathcal{A}}_-$ and $\operatorname{Re} G_0 = 2^{-1}$, has a unique invertible *standard* spectral factor $\hat{R} = 1 + \hat{R}_a \in \hat{\mathcal{A}}_-$, i.e., such that $\hat{R}(\infty) = 1$. The following properties will be needed for the analysis of the following sections, especially in the proof of Theorem 3.4. The proof of the following lemma can be found in [8].

LEMMA 2.2 (algebraic properties of coercive spectral densities).

(a) *If $\hat{F}$ is a coercive (real) spectral density, then so is its inverse $\hat{F}^{-1}$.*

(b) *If $\hat{F}$ and $\hat{G}$ are coercive (real) spectral densities, then so is their product $\hat{F}\cdot\hat{G}$.*

Remark 2.1. All impulse responses f considered below have no delayed impulses (delays); i.e., their singular atomic part is of the form $f_{sa} = f_0\delta(\cdot)$.

In this paper we are essentially interested in meromorphic spectral densities. Recall that a function f is said to be *meromorphic* (in $\mathbb{C}$) if there exists a countable set $S \subset \mathbb{C}$ such that S has no limit point, f is holomorphic in S^c, and f has a pole at each point of S; see, e.g., [31, p. 241]. In particular a meromorphic coercive real spectral density $\hat{F}$ with a meromorphic inverse has a countable set of zeros $\mathcal{Z} \subset \mathbb{C}$ and a countable set of poles $\mathcal{P} \subset \mathbb{C}$ such that $\mathcal{Z}$ and $\mathcal{P}$ have no limit points, there exists a vertical strip S_δ, $\delta > 0$, such that $\mathcal{Z} \cap S_\delta = \emptyset$ and $\mathcal{P} \cap S_\delta = \emptyset$, and for any $z \in \mathcal{Z}$ and any $p \in \mathcal{P}$, $-z$, $\overline{z}$, $-\overline{z}$ are in $\mathcal{Z}$ and $-p$, $\overline{p}$, $-\overline{p}$ are in $\mathcal{P}$.

In addition, the order of a meromorphic function is defined as follows (see, e.g., [27, Chapters VI and VIII]): For a meromorphic function f, with no poles at $s = 0$, define the counting function $N(r, f)$ and the proximity function $m(r, f)$, where $r \geq 0$, respectively, by

$$N(r, f) \;:=\; \int_0^r \frac{n(t, f)}{t}\, dt,$$

where $n(t, f)$ denotes the number of poles of f (counting their multiplicities) in the closed disk $\{s \in \mathbb{C} : |s| \leq t\}$, and

$$m(r, f) \;:=\; \frac{1}{2\pi}\int_0^{2\pi} \log^+ |f(re^{j\theta})|\, d\theta,$$

where $\log^+ x := \max\{0, \log x\}$ and f is assumed to have no poles on the circle $\{s \in \mathbb{C} : |s| = r\}$. The function T which is given by

$$T(r) := T(r, f) := m(r, f) + N(r, f)$$

is called the *characteristic function* of f. Observe that T is positive and monotonically increasing for $r > 0$. The *order* of f is defined to be the order of its characteristic function T, viz.,

$$\rho \;:=\; \limsup_{r\to\infty} \frac{\log\, T(r)}{\log\, r}.$$

In particular, for an entire function f, let $M(r)$ be its maximum modulus defined by

$$M(r) \;:=\; \max\{|f(s)| : |s| = r\};$$

then the functions T and $\log\, M$ are of the same order, viz.,

$$\rho \;=\; \limsup_{r\to\infty} \frac{\log\, \log\, M(r)}{\log\, r}$$

(see, e.g., [27, p. 216] and [37]). Thus an entire function f is of finite order if and only if there exists a constant $k > 0$ such that $\max\{|f(s)| : |s| = r\} \leq \exp(r^k)$ for r large (see, e.g., [37]). Moreover, the sum, the product, and the quotient of two meromorphic functions of finite order are meromorphic functions of finite order as well; see, e.g., [27, p. 216]. The following concept will be very useful for the analysis of meromorphic spectral densities of finite order.

DEFINITION 2.3. *A* paraconjugate symmetric (ps-)family $\mathbf{M}$ with countably many defining parameters $\mu_n \in \mathbf{M}$ *is a countable family of complex numbers* (ρ_l), *containing* (μ_n) *as a subfamily, such that* (a) $\mathbf{M}$ *is paraconjugate symmetric, i.e., the* ρ_l*'s are either real such that* $\rho_l = \mu_n$ *and* $-\mu_n \in \mathbb{R}$, *with* $\mu_n < 0$, *or complex nonreal such that* $\rho_l = \mu_n, \overline{\mu_n}, -\mu_n$ *and* $-\overline{\mu_n} \in \mathbb{C}$, *with* $\operatorname{Re}\mu_n < 0$, $\operatorname{Im}\mu_n > 0$, $n \in \mathbb{N}$, (b) *the defining parameters may be finitely repeated in* $\mathbf{M}$, *i.e.,* (μ_n) *(or, equivalently,* (ρ_l)*) does not contain any constant subfamily, and* (c) *all the points* ρ_l *of* $\mathbf{M}$ *are located outside a vertical strip containing the imaginary axis in its interior, i.e., there exists some* $\kappa > 0$ *such that, for all* n, $|\operatorname{Re}\mu_n| \geq \kappa$.

It turns out that there is a strong connection between meromorphic real spectral densities and real parahermitian entire functions; see Lemma 2.5 below. This result is based on the following additional lemma concerning the infinite product representation of real parahermitian entire functions, which also will be needed in the proof of Theorem 3.4.

LEMMA 2.4 (infinite product representation of real parahermitian entire functions).

(1) *Consider a ps-family* $\mathbf{M}$ *with defining parameters* μ_n. *Assume that*

$$\sum_{n=1}^{\infty} \frac{1}{|\mu_n|^2} < \infty. \tag{2.1}$$

Then there exists an entire function P *of finite order such that* P *has a zero at each point of* $\mathbf{M}$ *and no other zero in* $\mathbb{C}$, *and such that* (a) P *has a product factorization of the form*

$$P(s) = \prod_{n=1}^{\infty} P_n(s), \tag{2.2}$$

where

$$P_n(s) = 1 - \left(\frac{s}{\mu_n}\right)^2, \quad \text{with } \mu_n \in \mathbb{R} \text{ such that } \mu_n < 0, \tag{2.3}$$

and

$$P_n(s) = \left(1 - \left(\frac{s}{\mu_n}\right)^2\right)\left(1 - \left(\frac{s}{\overline{\mu_n}}\right)^2\right), \quad \text{with } \mu_n \in \mathbb{C}\backslash\mathbb{R} \text{ such that } \operatorname{Re}\mu_n < 0, \tag{2.4}$$

whence, for all $\omega \in \mathbb{R}$, $P(j\omega) \geq 0$. *Moreover, the convergence of the infinite product in* (2.2) *is uniform and absolute on closed discs* $D(r) := \{s \in \mathbb{C} : |s| \leq r\}$, *and* (b) P *is real parahermitian, whence for all* $s \in \mathbb{C}$, $P(s) = P(-s)$, *and there exists* $\delta > 0$ *such that, for all* $s \in S_\delta$, $P(s) \neq 0$.

(2) *Let f be a real parahermitian entire function having zeros in $\mathbb{C}$ as described in part* (1)*; then $f(s)$ has the product representation*

$$f(s) = e^{g(s)}\, P(s), \tag{2.5}$$

where $P(s)$ is as in part (1) *and $g(s)$ is a real parahermitian entire function. If in addition f is of finite order ρ, then $g(s)$ is a polynomial of degree $\delta[g] \le \rho$.*

Proof. See, e.g., [37, pp. 54–57] for more detail.

Assume that $\mathbf{M} =: (\rho_l)_{l=1}^{\infty}$. Let p be the least nonnegative integer such that $\sum_{l=1}^{\infty} \frac{1}{|\rho_l|^{p+1}} < \infty$. It follows from (2.1) that p is 0 or 1. Then

$$P(s) := \prod_{l=1}^{\infty} E\left(\frac{s}{\rho_l}, p\right), \tag{2.6}$$

where

$$E\left(\frac{s}{\rho_l}, p\right) = \left(1 - \frac{s}{\rho_l}\right) e^{\frac{ps}{\rho_l}} \quad \text{for } p = 0, 1$$

is the *canonical product of genus* p associated with the sequence $(\rho_l)_{l=1}^{\infty}$. By the reasoning of [37, pp. 55–56] it is an entire function, which has a zero at each point ρ_l and no other zeros in $\mathbb{C}$. Moreover, the convergence of its infinite product is uniform and absolute on closed discs $D(r)$, whence it can be reordered arbitrarily. Now as the factors $E(\frac{s}{\rho_l}, p)$ can be grouped to form factors of the form (2.3) or (2.4) that have real coefficients and are invariant when s is exchanged for $-s$, there holds that in either case (i.e., $p = 0$ or $p = 1$), $P(s)$ is real parahermitian and can be rewritten as

$$P(s) = \prod_{n=1}^{\infty} P_n(s) = P(-s), \tag{2.7}$$

where the P_n's are the polynomial functions given by (2.3)–(2.4). In addition, the entire function P is of *finite order* $\rho \le 2$ (i.e., $|P(s)| \le e^{|s|^{\rho+\epsilon}}$ for $|s|$ large [37, pp. 63–64], for any $\epsilon > 0$). Indeed by [37, pp. 65–66], *the exponent of convergence of the zeros* ρ_l of the canonical product in (2.2)–(2.4) is the greatest lower bound of the nonnegative numbers α such that $\sum_{l=1}^{\infty} |\rho_l|^{-\alpha} < \infty$. By (2.1) it is less than or equal to 2. Then, by [37, Theorem 6, p. 69], the entire function P is of order $\rho \le 2$. Finally, the function $P(s)$ satisfies all conclusions of part (1) of the lemma.

Part (2) follows by the reasoning around Weierstrass's factorization theorem [37, pp. 55–57] and the reasoning of the proof of part (1). The last statement concerning an entire function f of finite order follows by Hadamard's theorem; see, e.g., [37, Theorem 9, p. 74]. □

Remark 2.2. Let f be a real parahermitian entire function of finite order $\rho < 2$ with zeros as in part (1) of Lemma 2.4, whence for some $\delta > 0$, for all $s \in S_\delta$, $f(s) \neq 0$, and for all $\omega \in \mathbb{R}$, $f(j\omega) \ge 0$. Then f has a product factorization of the form

$$f(s) = kP(s), \tag{2.8}$$

where k is a positive constant and $P(s)$ is of the form (2.2)–(2.4).

Indeed, f has the product factorization (2.5), where the entire function g is a polynomial of degree $\delta[g] \le \rho < 2$. Since g is a real coefficient polynomial function of $(-s^2)$, it should be a constant c, such that (2.8) holds with $k = e^c$.

It follows from the lemma above that a coercive real spectral density that is a meromorphic function of finite order can be written as a ratio of two real parahermitian entire functions of finite order, provided that its poles tend to infinity sufficiently fast: see the following lemma.

LEMMA 2.5. *Consider a coercive real spectral density $\hat{F}$ given by $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, where $\hat{G} \in \hat{\mathcal{A}}_-$ is such that $G_{sa} = G_0\delta(\cdot)$ for some $G_0 \in \mathbb{C}$, whence $\hat{F}$ is holomorphic in some open vertical strip containing the imaginary axis $S_\delta := \{s \in \mathbb{C} : \mathrm{Re}\ s \in (-\delta, \delta)\}$, where $\delta > 0$. Assume that $\hat{F}$ is a meromorphic function of finite order. Let the poles of $\hat{F}$ form a ps-family $\mathbf{P}$ with defining parameters p_n and let*

$$\sum_{n=1}^{\infty} \frac{1}{|p_n|^2} < \infty.$$

Then $\hat{F}$ can be written as a fraction

$$\hat{F}(s) = \frac{N(s)}{D(s)},$$

where the denominator D and numerator N are real parahermitian entire functions of finite order, such that $D(s) = D(-s)$, $N(s) = N(-s)$, and the zeros and poles of $\hat{F}$ are those of N and D, respectively.

Proof. Let the ps-family $\mathbf{P}$ be given by $\mathbf{P} =: (\pi_l)$. By Lemma 2.4 part (1), there exists a real parahermitian entire function D of finite order such that D has a zero at each pole π_l of $\hat{F}$ and no other zeros in $\mathbb{C}$. Now, as in the proof of [31, Theorem 15.12, p. 327], consider the function $N := \hat{F}\ D$, which is obviously real parahermitian and such that $\hat{F} = N\ D^{-1}$. Moreover, the singularities of N at the points π_l are removable, whence N can be extended such that it is holomorphic in $\mathbb{C}$, i.e., entire, and N and D have no common zeros in $\mathbb{C}$. Finally, $N = \hat{F}\ D$ is of finite order, since so are $\hat{F}$ and D. □

Remark 2.3. (α) The converse of Lemma 2.5 obviously holds: any coercive real spectral density whose poles satisfy the condition above and which can be written as a fraction as in the statement of Lemma 2.5 is a meromorphic function of finite order.

(β) The proof above contains the essential arguments of the proofs of [31, Theorems 15.11 and 15.12, pp. 326–327]). Lemma 2.5 will be used in the proof of Lemma 4.7.

(γ) Related results concerning the canonical representation of any meromorphic function of finite order are given in [27, pp. 218–221].

Later on, after having transformed the spectral density under study, we shall also need the following auxiliary technical result.

LEMMA 2.6 (entire coercive real spectral density of finite order without zeros). *Let $\hat{F}$ be a coercive real spectral density given by $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, where $\hat{G} \in \hat{\mathcal{A}}_-$ is such that $G_{sa} = G_0\delta(\cdot)$ for some $G_0 \in \mathbb{C}$. Assume that*

(2.9) *$\hat{F}$ is an entire function of finite order without zeros.*

In addition, assume that the limit of $\hat{F}$ at infinity exists on the imaginary axis such that

$$\hat{F}(\pm j\infty) := \lim_{|\omega| \to \infty} \hat{F}(j\omega) = 1, \tag{2.10}$$

(or, equivalently, Re $G_0 = 2^{-1}$*). Then* $\hat{F}$ *is a constant function, i.e.,* $\hat{F}(s) = 1$*, for all* $s \in \mathbb{C}$.

Proof. By Hadamard's theorem [37, Theorem 9, p. 74], $\hat{F}$ has the form

$$\hat{F}(s) = e^{g(s)}, \tag{2.11}$$

where $g(s)$ is a polynomial, i.e., $g(s) = \sum_{k=0}^{n} g_k s^k$. One has $\hat{F}(0) = e^{g(0)} = e^{g_0}$ is real and positive. Hence $g_0 = \log(\hat{F}(0))$ is real. Moreover, as $\hat{F}$ is real, i.e., $\hat{F}(\overline{s}) = \overline{\hat{F}(s)}$, there holds by (2.11) and the continuity of $g(s)$ that there exists a unique integer l such that $g(\overline{s}) = \overline{g(s)} + jl2\pi$, which for $s = 0$ reads $\mathrm{Im}(g_0) = l\pi$, whence $l = 0$ as g_0 is real. Thus $g(\overline{s}) = \overline{g(s)}$, i.e., g is a real polynomial or, equivalently, g has real coefficients.

In addition there holds that $\hat{F}$ is real parahermitian, whence $\hat{F}(s) = \hat{F}(-s)$. A similar reasoning using (2.11) shows then that g is a real polynomial in s^2, whence it can be rewritten as a real polynomial h in $-s^2$, i.e.,

$$g(s) = \sum_{k=0}^{m} g_{2k} s^{2k} = \sum_{k=0}^{m} h_{2k}(-s^2)^k =: h(-s^2) \in \mathbb{R}[-s^2] \quad \text{with} \quad h_{2k} = (-1)^k g_{2k}.$$

Observe now that, by the structure of $\hat{F}$, its coercivity, and (2.10), $\hat{F}(j\omega)$ is a real positive uniformly continuous function on $\omega \in \overline{\mathbb{R}}$ (i.e., the extended real line) and bounded as well as bounded away from zero on $\overline{\mathbb{R}}$. Hence $\log(\hat{F}(j\omega))$ is a real uniformly continuous function on $\omega \in \overline{\mathbb{R}}$ and bounded above and below on $\overline{\mathbb{R}}$; moreover, by (2.10), $\lim_{|\omega|\to\infty} \log(\hat{F}(j\omega)) = 0$. Furthermore, there holds that $\log(\hat{F}(j\omega)) = h(\omega^2)$ for all $\omega \in \mathbb{R}$, whence $\lim_{|\omega|\to\infty} h(\omega^2) = 0$ with $h(\omega^2) \in \mathbb{R}[\omega^2]$. As a consequence, the polynomial $h(\omega^2)$ is identical to $\log(\hat{F}(j\omega))$ on $\omega \in \overline{\mathbb{R}}$, bounded there above and below, and zero at infinity. Hence $h(\omega^2)$ must reduce to a constant polynomial which is identically zero, i.e., $g(s) \equiv 0$. Thus $\hat{F}(s) \equiv 1$. ∎

Remark 2.4. (α) Often (2.11) reads $\hat{F}(s) = ke^{g(s)}$, where k is a positive constant. Then with $k = e^c$, where $c \in \mathbb{R}$, one gets $\hat{F}(s) = e^{g(s)+c}$, where $g(s)+c$ is a polynomial. Hence (2.11) holds without loss of generality.

(β) Assumption (2.9) is realized for a meromorphic coercive real spectral density of finite order for which, "after the removal of the poles and zeros," there remains an entire function of finite order without zeros, or, equivalently, "after the removal of the poles" there remains an entire function of finite order (see Lemmas 2.5 and 2.4 (part 2)).

(γ) In Lemma 2.6, the assumption that the order of the spectral density $\hat{F}$ (as an entire function) is finite cannot be omitted. This fact is illustrated by the following simple example. Consider the function $\hat{F}$ given by

$$\hat{F}(s) := \exp\left(2 \cdot \frac{\sinh\ s}{s}\right).$$

Observe that $\hat{F}$ is a coercive real spectral density of the form $\hat{F} = \hat{G}_* + \hat{G}$, where $\hat{G} = G_0 + \hat{G}_a \in \hat{\mathcal{A}}_-$ and Re $G_0 = 2^{-1}$. Indeed, let $\hat{R}$ be the function defined by

$$\hat{R}(s) := \exp\left(\hat{g}(s)\right), \quad \text{where} \quad \hat{g}(s) := \frac{1 - e^{-s}}{s}.$$

Then $\hat{g}$ belongs to $\hat{\mathcal{A}}_-$ as the Laplace transform of the function of finite support $g := \chi_{[0,1]}$; i.e., $g(t) = 1$ if $0 \le t \le 1$ and $g(t) = 0$ elsewhere. Moreover, $\hat{g}$ is strictly

proper, i.e., $\hat{g}(\infty) = 0$, where $\hat{g}(\infty)$ should be interpreted as the limit of $\hat{g}(s)$ as $|s| \to \infty$ in any right half-plane strictly containing the closed right half-plane. Hence $\hat{R}$ is in $\hat{\mathcal{A}}_-$ together with its inverse $\hat{R}^{-1} = \exp(-\hat{g}(s))$, since they are exponentials of elements of a Banach algebra, viz., $\hat{\mathcal{A}}(\sigma) \subset \hat{\mathcal{A}}_-$, $\sigma < 0$; moreover, $\hat{R}(\pm j\infty) = 1$. Since $\hat{F}(s) = \hat{R}(-s)\cdot\hat{R}(s)$, it follows that $\hat{F}$ is a coercive real spectral density with invertible standard real spectral factor $\hat{R}$. In addition, $\hat{g}$ is an entire function, whence $\hat{R}$ is an entire function without zeros, and so is $\hat{F}$. However, $\hat{F}$ is not a constant function. Observe that there is no contradiction with Lemma 2.6, since $\hat{F}$ is of infinite order. Indeed, the function $2\cdot\frac{\sinh s}{s}$ is an entire function which is not a polynomial. Hence, in view of Hadamard's theorem (see, e.g., [37, p. 74]), $\hat{F}$ cannot be of finite order.

3. Meromorphic spectral densities of finite order. The main objective of this section is to show that, under certain conditions, a coercive real spectral density that is a meromorphic function of finite order can be written as an infinite product of coercive real rational spectral densities. First it is shown that, under certain technical conditions, such an infinite product is necessarily a coercive real spectral density.

3.1. Product of rational spectral densities.

THEOREM 3.1 (infinite product of coercive rational spectral densities). *Consider a function $\hat{F}$ given, for all s in some vertical strip symmetric with respect to the imaginary axis, by an infinite product of pole-zero pairs of the form*

$$\hat{F}(s) = \prod_{n=1}^{\infty} \hat{F}_n(s), \tag{3.1}$$

where the elementary factors $\hat{F}_n$ are coercive real rational spectral densities, which are given either by

$$\hat{F}_n(s) = \frac{z_n^2 - s^2}{p_n^2 - s^2}, \tag{3.2}$$

where z_n and $p_n \in \mathbb{R}$, with z_n and $p_n < 0$, or by

$$\hat{F}_n(s) = \frac{(z_n^2 - s^2)(\overline{z}_n^2 - s^2)}{(p_n^2 - s^2)(\overline{p}_n^2 - s^2)}, \tag{3.3}$$

where z_n and $p_n \in \mathbb{C}\backslash\mathbb{R}$, with Re z_n *and* Re $p_n < 0$. *Consider the standard invertible (real) spectral factors $\hat{R}_n$ of the spectral densities $\hat{F}_n$, which are such that $\hat{R}_n(\infty) = 1$ and which are given by*

$$\hat{R}_n(s) = \frac{z_n - s}{p_n - s} \tag{3.4}$$

(first order factor) when $\hat{F}_n$ is defined by (3.2) *and by*

$$\hat{R}_n(s) = \frac{(z_n - s)(\overline{z}_n - s)}{(p_n - s)(\overline{p}_n - s)} \tag{3.5}$$

(second order factor) when $\hat{F}_n$ is defined by (3.3)*, respectively. Assume that there exists a constant $\sigma < 0$ such that $\hat{R}_n$ and $\hat{R}_n^{-1}$ are in $\hat{\mathcal{A}}(\sigma)$, for all n, with*

$$\sum_{n=1}^{\infty} ||(R_n)_a||_{\mathcal{A}(\sigma)} < \infty \tag{3.6}$$

and

$$\sum_{i=1}^{\infty} ||(R_n^{-1})_a||_{\mathcal{A}(\sigma)} < \infty. \tag{3.7}$$

Then the following assertions hold:

(a) *The infinite product in* (3.1) *converges to* $\hat{F}$ *in the Banach algebra*

$$\widehat{L\Delta}(\sigma) := \{\hat{f} = \hat{f}_- + \hat{f}_+ \ : \ (f_-)_* \text{ and } f_+ \ \in \mathcal{A}(\sigma)\}$$

equipped with the norm

$$||\hat{f}||_\sigma := ||f||_\sigma := ||(f_-)_*||_{\mathcal{A}(\sigma)} + ||f_+||_{\mathcal{A}(\sigma)};$$

(b) *The function* $\hat{F}$ *is a coercive real spectral density such that* $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, *where* $\hat{G}$ *is in* $\hat{\mathcal{A}}(\sigma) \subset \hat{\mathcal{A}}_-$.

Proof. (a) The proof goes along the lines of [10, proof of Theorem 5].

(b) It follows from assertion (a) and from the fact that every elementary factor $\hat{F}_n$ is real parahermitian and positive semidefinite on the imaginary axis, that $\hat{F}$ is a real spectral density of the form $\hat{F} = \hat{G}_* + \hat{G}$ for some $\hat{G}$ in $\hat{\mathcal{A}}(\sigma)$. Finally observe that, by the fact that there exists a constant $\sigma < 0$ such that $\hat{R}_n$ and $\hat{R}_n^{-1}$ are in $\hat{\mathcal{A}}(\sigma)$ for all n, every elementary factor spectral density $\hat{F}_n$ is coercive such that, for some $\eta > 0$, $\prod_{n=1}^{N} \hat{F}_n(j\omega) \geq \eta$ for all $\omega \in \mathbb{R}$ and for all $N \geq 1$. Hence the spectral density $\hat{F}$ is coercive. ∎

Remark 3.1. Convergence in the $\widehat{L\Delta}(\sigma)$-norm implies convergence in the sup-norm on a vertical strip without singularities containing the $j\omega$-axis in its interior.

This result leads to a criterion for the convergence of an infinite product of coercive rational spectral densities, which is based on the knowledge of the spectrum, i.e., more precisely, on the knowledge of the comparative asymptotic behavior of the spectral density poles and zeros, p_n and z_n, as n tends to infinity; see Corollary 3.3 below. The proof of this spectral criterion is based on the following preliminary result.

LEMMA 3.2 (estimates of $||(R_n)_a||_{\mathcal{A}(\sigma)}$ and $||(R_n^{-1})_a||_{\mathcal{A}(\sigma)}$). *Consider the rational elementary factors* $\hat{R}_n$, $n = 1, 2, \ldots$, *given by* (3.4)–(3.5), *and assume that there exists a constant* $\sigma < 0$ *such that* $2 \cdot |\sigma| \leq \min(|\text{Re } p_n|, |\text{Re } z_n|)$ *for all* n. *Then* $\hat{R}_n$ *and* $\hat{R}_n^{-1}$ *are in* $\hat{\mathcal{A}}(\sigma)$ *for all* n *and the following inequalities hold for all* n: *when* $\hat{R}_n$ *is given by* (3.4), *then*

$$||(R_n)_a||_{\mathcal{A}(\sigma)} \leq 2 \, \frac{|z_n - p_n|}{|p_n|},$$

and

$$||(R_n^{-1})_a||_{\mathcal{A}(\sigma)} \leq 2 \, \frac{|z_n - p_n|}{|z_n|},$$

and when $\hat{R}_n$ *is given by* (3.5), *then*

$$||(R_n)_a||_{\mathcal{A}(\sigma)} \leq 4 \, \frac{|z_n - p_n|}{|\text{Re } p_n|} \left(1 + \frac{|z_n - p_n|}{|\text{Re } p_n|}\right),$$

and

$$||(R_n^{-1})_a||_{\mathcal{A}(\sigma)} \leq 4 \, \frac{|z_n - p_n|}{|\text{Re } z_n|} \left(1 + \frac{|z_n - p_n|}{|\text{Re } z_n|}\right).$$

Proof. For the case of a first order factor, see [10, Fact 1]. Concerning the case of a second order factor, we derive only the inequality for $(R_n)_a$. The other one can be proved similarly. Now, for all $t \geq 0$,

$$(R_n)_a(t) = (p_n - z_n) \cdot e^{p_n t} + (\overline{p_n - z_n}) \cdot e^{\overline{p_n} t} + \frac{|p_n - z_n|^2}{(\overline{p_n} - p_n)} \cdot (e^{\overline{p_n} t} - e^{p_n t}),$$

whence, upon noting that $|\overline{p_n} - p_n| = 2|\text{Im } p_n|$ and $|e^{\overline{p_n} t} - e^{p_n t}| = 2 \cdot e^{\text{Re } p_n t} \cdot |\sin(\text{Im } p_n t)|$, one obtains

$$|(R_n)_a(t)| \leq 2\ |z_n - p_n| \cdot e^{\text{Re } p_n t} + |z_n - p_n|^2 \cdot t \cdot e^{\text{Re } p_n t}.$$

By using the assumption that $|\text{Re } p_n| \geq 2 \cdot |\sigma|$, one gets

$$||e^{\text{Re } p_n t}||_{\mathcal{A}(\sigma)} = \int_0^\infty e^{(\text{Re } p_n - \sigma)t} dt = |\text{Re } p_n - \sigma|^{-1} \leq \frac{2}{|\text{Re } p_n|},$$

and

$$||t \cdot e^{\text{Re } p_n t}||_{\mathcal{A}(\sigma)} = \int_0^\infty t \cdot e^{(\text{Re } p_n - \sigma)t} dt = |\text{Re } p_n - \sigma|^{-2} \leq \frac{4}{|\text{Re } p_n|^2}.$$

As a result one gets

$$||(R_n)_a||_{\mathcal{A}(\sigma)} \leq 4\ \frac{|z_n - p_n|}{|\text{Re } p_n|} \left(1 + \frac{|z_n - p_n|}{|\text{Re } p_n|}\right). \qquad \square$$

COROLLARY 3.3 (spectral criterion for the convergence of an infinite product of coercive rational spectral densities). *Consider a function $\hat{F}$ given by* (3.1)–(3.3) *for all s in some vertical strip symmetric with respect to the imaginary axis. Let $\hat{R}_n$, $n = 1, 2, \ldots$, be the rational elementary factors defined by* (3.4)–(3.5), *with $2 \cdot |\sigma| \leq \min(|\text{Re } p_n|, |\text{Re } z_n|)$, for all n, for some $\sigma < 0$. Now assume that*

$$\sum_{n=1}^{\infty} \frac{|z_n - p_n|}{|\text{Re } p_n|} < \infty, \tag{3.8}$$

and

$$\sum_{n=1}^{\infty} \frac{|z_n - p_n|}{|\text{Re } z_n|} < \infty. \tag{3.9}$$

Then the conclusions of Theorem 3.1 *hold.*

Proof. Consider the series

$$\sum_{n=1}^{\infty} \frac{|z_n - p_n|}{|\text{Re } p_n|} \left(1 + \frac{|z_n - p_n|}{|\text{Re } p_n|}\right).$$

By (3.8) the sequence

$$\left(\frac{|z_n - p_n|}{|\text{Re } p_n|}\right)_{n=1}^{\infty}$$

is in l^1, hence also in l^∞, and thus also in l^2. Therefore the series above converges, and in view of Lemma 3.2, (3.6) holds. Moreover, by similar arguments (3.7) holds. Hence the conclusion follows by Theorem 3.1. □

Remark 3.2. The conclusions of Corollary 3.3 still hold if conditions (3.8) and (3.9) are replaced, respectively, by

$$\frac{|z_n - p_n|}{|\mathrm{Re}\ p_n|} = O\left(\frac{1}{n^\alpha}\right) \tag{3.10}$$

and

$$\frac{|z_n - p_n|}{|\mathrm{Re}\ z_n|} = O\left(\frac{1}{n^\alpha}\right) \tag{3.11}$$

for some exponent $\alpha > 1$.

3.2. Product representation of meromorphic spectral densities. The fact that a coercive real spectral density $\hat{F}$ has an infinite product representation of the form (3.1)–(3.3) is not automatically satisfied in applications. Typically one should check this by using the Weierstrass factorization theorem for entire functions and related results; see, e.g., [37, Chapter 2, part 1], [26, section 7.1, p. 343], and the references therein. This was done in [10, p. 765] for a heat diffusion example. In the following theorem, conditions on the poles and zeros of a meromorphic spectral density of finite order are derived, under which this methodology can be used.

THEOREM 3.4 (criterion for the infinite product representation of a meromorphic coercive spectral density of finite order). *Let $\hat{F}$ be a coercive real spectral density given by $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, where $\hat{G} \in \hat{\mathcal{A}}_-$ is such that $G_{sa} = G_0\delta(\cdot)$ for some $G_0 \in \mathbb{C}$; whence $\hat{F}$ is holomorphic in some open vertical strip containing the imaginary axis, namely, S_δ, where $\delta > 0$. Assume that the limit of $\hat{F}$ at infinity exists in this vertical strip such that*

$$\hat{F}(\infty) := \lim_{|s|\to\infty;\ s\in S_\delta} \hat{F}(s) = \lim_{|\omega|\to\infty;\ -\delta<\sigma<\delta} \hat{F}(\sigma + j\omega) = 1, \tag{3.12}$$

(or, equivalently, $\mathrm{Re}\ G_0 = 2^{-1}$*). In addition, assume that $\hat{F}$ is a meromorphic function of finite order such that*

(1) *the poles of $\hat{F}$ form a ps-family* $\mathbf{P}$ *with defining parameters p_n,*
(2) *the zeros of $\hat{F}$ form a ps-family* $\mathbf{Z}$ *with defining parameters z_n, and*
(3)

$$\sum_{n=1}^{\infty} \frac{1}{|p_n|^2} < \infty \qquad \text{and} \qquad \sum_{n=1}^{\infty} \frac{1}{|z_n|^2} < \infty. \tag{3.13}$$

Assume that the set of zeros (poles, respectively) of $\hat{F}$ consists of countably many real zeros (poles, respectively) and countably many complex zeros (poles, respectively) such that its zeros and poles can be associated by a one-to-one relationship, leading to elementary factors of the form (3.17)–(3.18). *Finally, assume that conditions* (3.8)–(3.9) *hold.*

Then (a) *$\hat{F}$ can be written as a fraction*

$$\hat{F}(s) = \frac{N(s)}{D(s)}, \tag{3.14}$$

where the denominator D and numerator N are real parahermitian entire functions of finite order such that $D(s) = D(-s)$ and $N(s) = N(-s)$ and the zeros and poles of $\hat{F}$ are those of N and D, respectively;

(b) *the spectral density $\hat{F}$ admits an infinite product representation of pole-zero pairs that is of the form*

$$\hat{F}(s) = \prod_{n=1}^{\infty} \hat{F}_n(s), \tag{3.15}$$

and the inverse spectral density $\hat{F}^{-1}$ admits the infinite product representation

$$\hat{F}(s)^{-1} = \prod_{n=1}^{\infty} \hat{F}_n(s)^{-1}, \tag{3.16}$$

where the elementary factors $\hat{F}_n$ are coercive real rational spectral densities that are given either by

$$\hat{F}_n(s) = \frac{z_n^2 - s^2}{p_n^2 - s^2} \tag{3.17}$$

if z_n and $p_n \in \mathbb{R}$, with z_n and $p_n < 0$, or by

$$\hat{F}_n(s) = \frac{(z_n^2 - s^2)(\overline{z}_n^2 - s^2)}{(p_n^2 - s^2)(\overline{p}_n^2 - s^2)} \tag{3.18}$$

if z_n and $p_n \in \mathbb{C}\backslash\mathbb{R}$, with Re z_n *and* Re $p_n < 0$.

Remark 3.3. (α) Conditions (3.13) are not the most general ones encountered in the theory of infinite product representation of entire functions; see, e.g., [26, p. 358] and [37, Theorem 1, pp. 55–56]. However, according to [26], these conditions are applicable to many problems. In addition these assumptions together with the fact that a spectral density is parahermitian lead to a simpler structure for the corresponding infinite product elementary factors.

(β) Concerning the definitions of the elementary factors (3.17)–(3.18), it is natural and usual to take the upper half-plane zeros and poles in increasing order of real part. This is done in this way in the application dealt with in this paper; see section 5.

Proof of Theorem 3.4. (a) follows from Lemma 2.5.

(b) *Step* 1. D and N have the infinite product representations

$$D(s) = e^{G_D(s)} \cdot \prod_{n=1}^{\infty} D_n(s), \tag{3.19}$$

and

$$N(s) = e^{G_N(s)} \cdot \prod_{n=1}^{\infty} N_n(s), \tag{3.20}$$

respectively, where G_D and G_N are polynomial functions and where D_n and N_n are the polynomial functions given by

$$D_n(s) = \begin{cases} 1 - (\frac{s}{p_n})^2 & \text{if } p_n \in \mathbb{R} \text{ with } p_n < 0, \\ (1 - (\frac{s}{p_n})^2) \cdot (1 - (\frac{s}{\overline{p}_n})^2) & \text{if } p_n \in \mathbb{C} \text{ with Re } p_n < 0 \end{cases} \tag{3.21}$$

and by

$$N_n(s) = \begin{cases} 1 - (\frac{s}{z_n})^2 & \text{if } z_n \in \mathbb{R} \text{ with } z_n < 0, \\ (1 - (\frac{s}{z_n})^2) \cdot (1 - (\frac{s}{\overline{z_n}})^2) & \text{if } z_n \in \mathbb{C} \text{ with } \operatorname{Re} z_n < 0, \end{cases} \tag{3.22}$$

respectively. Moreover, the convergence of the infinite products is uniform and absolute on any closed disc $D(r)$.

Indeed this follows from the data concerning D and N, where in particular (3.13) holds, and from Lemma 2.4, part (2).

Step 2. On closed discs $D(r)$ where small neighborhoods of the poles are omitted, the spectral density $\hat{F}$ has the infinite product representations

$$\hat{F}(s) \;=\; e^{H(s)} \cdot \prod_{n=1}^{\infty} \frac{N_n(s)}{D_n(s)} = \; e^{H(s)} \cdot \prod_{n=1}^{\infty} \phi_n \cdot \prod_{n=1}^{\infty} \hat{F}_n(s), \tag{3.23}$$

where $H := G_N - G_D$ is a polynomial function, the $\hat{F}_n(s)$ are given by (3.17)–(3.18), and where the constants ϕ_n are given by

$$\phi_n = \begin{cases} \left|\frac{p_n}{z_n}\right|^2 & \text{if } p_n,\ z_n \in \mathbb{R} \text{ with } p_n \text{ and } z_n < 0, \\ \left|\frac{p_n}{z_n}\right|^4 & \text{if } p_n,\ z_n \in \mathbb{C}\backslash\mathbb{R} \text{ with } \operatorname{Re} p_n \text{ and } \operatorname{Re} z_n < 0. \end{cases} \tag{3.24}$$

Moreover, the convergence of the s-dependent products is uniform and absolute on the aforementioned punctured discs.

Indeed this follows from identity (3.14), from (3.19)–(3.22), and from assumptions (3.8)–(3.9). First it can be shown that for n sufficiently large, for the case that $p_n,\ z_n \in \mathbb{R}$ with p_n and $z_n < 0$,

$$\left|\hat{F}_n(s) - 1\right| = \; O\left\{\left|1 - \left(\frac{z_n}{p_n}\right)^2\right|\right\},$$

and for the case that $p_n,\ z_n \in \mathbb{C}$ with $\operatorname{Re} p_n$ and $\operatorname{Re} z_n < 0$,

$$\left|\hat{F}_n(s) - 1\right| = \; O\left\{\left|1 - \left|\frac{z_n}{p_n}\right|^4\right| + 2\left|1 - \left(\frac{z_n}{p_n}\right)^2\right|\right\}.$$

In addition, observe that $\hat{F}(\infty) = 2 \cdot \operatorname{Re} G_0$; whence, by assumption (3.12), $\operatorname{Re} G_0 = 2^{-1}$. Moreover, it follows from (3.13) that $|p_n| \to \infty$ and $|z_n| \to \infty$ as $n \to \infty$. Finally by assumptions (3.8)–(3.9) and the inequalities

$$\left|1 - \left(\frac{z_n}{p_n}\right)\right| \leq \frac{|z_n - p_n|}{|\operatorname{Re} p_n|}$$

and

$$\left|1 - \left(\frac{p_n}{z_n}\right)\right| \leq \frac{|z_n - p_n|}{|\operatorname{Re} z_n|},$$

there holds that the spectral density poles and zeros will be asymptotically close (as $n \to \infty$), i.e.,

$$\lim_{n\to\infty} \left(\frac{z_n}{p_n}\right) = 1 \quad \text{and} \quad \lim_{n\to\infty} \left(\frac{p_n}{z_n}\right) = 1.$$

It then follows easily that

$$\sum_{n=1}^{\infty} \left| 1 - \left(\frac{z_n}{p_n} \right)^2 \right| < \infty \qquad \text{and} \qquad \sum_{n=1}^{\infty} \left| 1 - \left(\frac{p_n}{z_n} \right)^2 \right| < \infty. \tag{3.25}$$

Hence by (3.25), the infinite product $\prod_{n=1}^{\infty} \hat{F}_n(s)$ converges uniformly and absolutely in any closed disk $D(r)$ where small neighborhoods of the poles are omitted. Next by (3.25) it can also be shown that the infinite product $\prod_{n=1}^{\infty} \phi_n$ is well defined. Now, on closed discs $D(r)$ where small neighborhoods of the poles are omitted, there holds for any $M \in \mathbb{N}$

$$\frac{\prod_{n=1}^{M} N_n}{\prod_{n=1}^{M} D_n} = \prod_{n=1}^{M} \phi_n \cdot \prod_{n=1}^{M} F_n.$$

Hence, as the limits exist for $M \to \infty$ uniformly and absolutely on such discs, Step 2 follows.

Step 3. There holds that

$$e^{H(s)} \cdot \prod_{n=1}^{\infty} \phi_n \equiv 1, \tag{3.26}$$

whence, in view of (3.23), (3.15) and (3.17)–(3.18) hold.

Indeed observe that the infinite product $\prod_{n=1}^{\infty} \hat{F}_n(s)$ converges uniformly and absolutely in any closed disk not containing any of its poles and that $\prod_{n=1}^{\infty} \hat{F}_n(\infty) = 1$, such that $\prod_{n=1}^{\infty} \hat{F}_n(s)$ exists at infinity and converges uniformly in the vertical strip S_δ by Corollary 3.3 and (3.8)–(3.9). Thus

$$\prod_{n=1}^{\infty} \hat{F}_n(s) \to 1 \quad \text{as} \quad |s| \to \infty \quad \text{in} \quad S_\delta. \tag{3.27}$$

Since, by assumption, $\hat{F}(\infty) = 1$, it follows from (3.23) and (3.27) that

$$e^{H(\infty)} \cdot \prod_{n=1}^{\infty} \phi_n := \lim_{|s| \to \infty;\ s \in S_\delta} e^{H(s)} \cdot \prod_{n=1}^{\infty} \phi_n = 1. \tag{3.28}$$

Observe that, by Corollary 3.3, the function $\prod_{n=1}^{\infty} \hat{F}_n$ is a coercive real spectral density; whence, in view of Lemma 2.2, so is the function

$$e^{H(s)} \cdot \prod_{n=1}^{\infty} \phi_n = \hat{F}(s) \cdot \left(\prod_{n=1}^{\infty} \hat{F}_n(s) \right)^{-1},$$

which in addition, as H is a polynomial, is an entire function of finite order without zeros. Hence, by Lemma 2.6 (see also Remark 2.4 (α)), it follows from (3.28) that Step 3 holds.

Step 4. Observe that $\hat{F}^{-1}$ is a meromorphic function of finite order and mutatis mutandis satisfies the same conditions as $\hat{F}$. Hence, by reasoning similar to that above, (3.16) and (3.17)–(3.18) hold. □

4. Spectral factorization by symmetric extraction.

4.1. Main results. By the proof of [10, Theorem 5], the following result holds.

THEOREM 4.1 (criterion for infinite product representation of invertible spectral factors). *Consider a coercive real spectral density $\hat{F}$ given by* (3.1)–(3.3) *for all s in some vertical strip symmetric with respect to the imaginary axis. Let $\hat{R}_n$, $n = 1, 2, \dots$, be the rational elementary factors defined by* (3.4)–(3.5). *Assume that there exists a constant $\sigma < 0$ such that $\hat{R}_n$ and $\hat{R}_n^{-1}$ are in $\hat{\mathcal{A}}(\sigma)$, for all n, with*

$$\sum_{n=1}^{\infty} ||(R_n)_a||_{\mathcal{A}(\sigma)} < \infty \tag{4.1}$$

and

$$\sum_{i=1}^{\infty} ||(R_n^{-1})_a||_{\mathcal{A}(\sigma)} < \infty. \tag{4.2}$$

Then the invertible standard spectral factor $\hat{R}$ in $\hat{\mathcal{A}}_-$ of $\hat{F}$ is given by the infinite product representation

$$\hat{R}(s) = \prod_{n=1}^{\infty} \hat{R}_n(s) = \lim_{N\to\infty} \prod_{n=1}^{N} \hat{R}_n(s), \tag{4.3}$$

where the limit is taken in the framework of the topology induced by the norm $||\cdot||_{\hat{\mathcal{A}}(\sigma)}$ on the Banach algebra $\hat{\mathcal{A}}(\sigma)$.

We are now ready to get a spectral criterion for the convergence of the symmetric extraction method of spectral factorization: it is based on the knowledge of the comparative asymptotic behavior of the spectral density poles and zeros.

THEOREM 4.2 (spectral criterion for the convergence of the symmetric extraction method). *Consider a coercive real spectral density $\hat{F}$ given by* (3.1)–(3.3) *for all s in some vertical strip symmetric with respect to the imaginary axis. Let $\hat{R}_n$, $n = 1, 2, \dots$, be the rational elementary factors defined by* (3.4)–(3.5), *with $2 \cdot |\sigma| \leq \min(|\mathrm{Re}\ p_n|, |\mathrm{Re}\ z_n|)$, for all n, for some $\sigma < 0$. Now assume that $\hat{R}_n$ is a first order factor given by* (3.4) *or a second order factor given by* (3.5) *satisfying* (3.8) *and* (3.9). *Then* (a) *the conclusions of Theorem* 4.1 *hold. In particular, the sequence*

$$\left(\prod_{n=1}^{N} \hat{R}_n\right)_{N\geq 1} \tag{4.4}$$

of invertible approximate (rational) spectral factors converges to the invertible standard spectral factor $\hat{R} \in \hat{\mathcal{A}}_-$ of $\hat{F}$ in the $\hat{\mathcal{A}}(\sigma)$ norm, and the sequence

$$\left(\prod_{n=1}^{N} \hat{R}_n^{-1}\right)_{N\geq 1} \tag{4.5}$$

converges to the corresponding inverse spectral factor $\hat{R}^{-1} \in \hat{\mathcal{A}}_-$;

(b) *with $\hat{W}_N \in \widehat{L\Delta}^+(\sigma) \subset \hat{\mathcal{A}}_-$ denoting the approximate spectral factor defined by*

$$W_N := \prod_{i=1}^{N} R_i,$$

the spectral factor, inverse spectral factor, and spectral factorization relative errors *can be estimated for all* $N = 1, 2, \ldots$, *respectively, by the following inequalities:*

$$\|(W_N - R) * R^{-1}\|_\sigma \;\le\; \exp S_{N+1} - 1 \;\le\; 2S_{N+1}, \tag{4.6}$$

where the last inequality holds if

$$S_{N+1} \;:=\; 4 \sum_{i=N+1}^{\infty} \frac{|z_n - p_n|}{|\mathrm{Re}\ z_n|} \left(1 + \frac{|z_n - p_n|}{|\mathrm{Re}\ z_n|}\right) \;\le\; 1;$$

$$\|(W_N^{-1} - R^{-1}) * R\|_\sigma \;\le\; \exp T_{N+1} - 1 \;\le\; 2T_{N+1}, \tag{4.7}$$

where the last inequality holds if

$$T_{N+1} \;:=\; 4 \sum_{i=N+1}^{\infty} \frac{|z_n - p_n|}{|\mathrm{Re}\ p_n|} \left(1 + \frac{|z_n - p_n|}{|\mathrm{Re}\ p_n|}\right) \;\le 1;$$

and finally

$$\|((W_N)_* \cdot W_N - F) * F^{-1}\|_\sigma \;\le\; \exp(2S_{N+1}) - 1 \;\le\; 4S_{N+1}, \tag{4.8}$$

where the last inequality holds if $S_{N+1} \;\le\; 2^{-1}$.

Proof. (a) The conclusion follows directly from Theorem 4.1, by the proof of Corollary 3.3.

(b) The relative error estimates (4.6)–(4.8) can be derived by following the lines of the proof of [10, Theorem 5, pp. 766–767] and by using Lemma 3.2. □

Remark 4.1. (α) The conclusions of Theorem 4.2 still hold if conditions (3.8) and (3.9) are replaced by conditions (3.10) and (3.11). Note that this remark is also applicable to any other result that holds here under these conditions, e.g., Theorem 3.4.

(β) Typically, in applications, e.g., LQ-optimal control or spectral factorization of a normalized coprime fraction spectral density (see, e.g., [9], [10]) for an infinite-dimensional (without loss of generality) stable system, the p_n's and $\overline{p}_n$'s are the poles of the open-loop transfer function, and the z_n's and $\overline{z}_n$'s are the poles of the closed-loop transfer function.

(γ) The symmetric extraction method works very well for the heat diffusion equation; see [10], [7]. Indeed, in that case, the spectral density zeros and poles are all real, and the corresponding relative spectral errors $|z_n - p_n| \cdot |p_n|^{-1}$ and $|z_n - p_n| \cdot |z_n|^{-1}$ tend to zero exponentially fast as n tends to infinity, whence (3.10) and (3.11) obviously hold for $\alpha = \infty$, i.e., for any $\alpha > 1$.

(δ) The speed of convergence of the sequences (4.4) and (4.5) towards an invertible spectral factor $\hat{R}$ and its inverse $\hat{R}^{-1}$, respectively, is dictated by the magnitude of the parameter α of conditions (3.10) and (3.11). The larger it is, the better is the speed of convergence of the symmetric extraction method. However, this speed of convergence might not be as good as in the heat equation example mentioned above; see Example 4.1.

(ϵ) It is possible to compute absolute and relative error estimates, in the $\hat{\mathcal{A}}(\sigma)$-norm, for the spectral factor as well as for its inverse, especially when $||(R_n)_a||_{\mathcal{A}(\sigma)}$ and $||(R_n^{-1})_a||_{\mathcal{A}(\sigma)}$ are of the order of the general term of a converging power series; see [10].

Example 4.1. Consider the following coercive spectral density $\hat{F}(s)$ given by (3.1) with a countable number of elementary factors of the form (3.3) with complex conjugate poles and zeros such that

(1) for some $\sigma < 0$

$$2 \cdot |\sigma| \leq \min(|\text{Re } p_n|, |\text{Re } z_n|), \quad n = 1, 2, \dots ,$$

(2) for some constants $a > 0$ and $b > 0$

$$p_n = -a + j \cdot b \cdot n, \quad n = 1, 2, \dots ,$$

(3) for n sufficiently large,

$$|z_n - p_n| = O(\frac{1}{n^2}).$$

Then by Theorem 4.2 any invertible spectral factor of the spectral density $\hat{F}$ can be approximated arbitrarily precisely in the $\hat{\mathcal{A}}(\sigma)$-norm, by an invertible approximate (rational) spectral factor of the form (4.4). Here convergence is achieved but at a much slower speed ($\alpha = 2$) than in the heat equation example mentioned above ($\alpha = \infty$). Note that, in section 5, a physical example (vibrating string) is chosen to illustrate the possibility of slow convergence.

COROLLARY 4.3. *Let $\hat{F}$ be a coercive real spectral density satisfying the assumptions of Theorem* 3.4. *Then $\hat{F}$ admits an infinite product representation of pole-zero pairs that is of the form* (3.1)–(3.3) *for all s in some vertical strip symmetric with respect to the imaginary axis. Let $\hat{R}_n$, $n = 1, 2, \dots$, be the rational elementary factors defined by* (3.4)–(3.5), *with $2 \cdot |\sigma| \leq \min(|\text{Re } p_n|, |\text{Re } z_n|)$, for all n, for some $\sigma < 0$.*

Then the sequence

$$\left(\prod_{n=1}^{N} \hat{R}_n \right)_{N \geq 1} \tag{4.9}$$

of invertible approximate (rational) spectral factors converges to the invertible standard spectral factor $\hat{R} \in \hat{\mathcal{A}}_-$ of $\hat{F}$ in the $\hat{\mathcal{A}}(\sigma)$-norm, and the sequence

$$\left(\prod_{n=1}^{N} \hat{R}_n^{-1} \right)_{N \geq 1} \tag{4.10}$$

converges to the corresponding inverse spectral factor $\hat{R}^{-1} \in \hat{\mathcal{A}}_-$.

Proof. The conclusion follows from Theorems 3.4 and 4.2. □

We conclude this subsection by yet another spectral criterion for the convergence of the symmetric extraction spectral factorization method. Its sufficient conditions are stronger than those established in the previous results. However, they fit specific classes of systems quite well, as shown in the next subsection.

THEOREM 4.4 (spectral criterion for the convergence of the symmetric extraction method). *Let $\hat{F}$ be a coercive real spectral density given by $\hat{F} = \hat{F}_* = \hat{G}_* + \hat{G}$, where $\hat{G} \in \hat{\mathcal{A}}_-$ is such that $G_{sa} = G_0 \delta(\cdot)$ for some $G_0 \in \mathbb{C}$; whence $\hat{F}$ is holomorphic in some open vertical strip containing the imaginary axis, namely, $S_\delta := \{s \in \mathbb{C} : \text{Re } s \in (-\delta, \delta)\}$, where $\delta > 0$. Assume that the limit of $\hat{F}$ at infinity exists in this vertical strip such that*

$$\hat{F}(\infty) := \lim_{|s| \to \infty;\ s \in S_\delta} \hat{F}(s) = \lim_{|\omega| \to \infty;\ -\delta < \sigma < \delta} \hat{F}(\sigma + j\omega) = 1, \tag{4.11}$$

(or, equivalently, $\operatorname{Re} G_0 = 2^{-1}$*). In addition, assume that* $\hat{F}$ *is a meromorphic function of finite order and is given by the fraction*

$$\hat{F}(s) = \frac{N(s)}{D(s)}, \tag{4.12}$$

where the denominator D *and numerator* N *are real parahermitian entire functions of finite order such that* $D(s) = D(-s)$ *and* $N(s) = N(-s)$.

Moreover, (1) *the zeros of* D *form a ps-family* $\mathbf{P}$ *with defining parameters* p_n,

(2) *the zeros of* N *form a ps-family* $\mathbf{Z}$ *with defining parameters* z_n,

(3) *one assumes that*

$$\sum_{n=1}^{\infty} \frac{1}{|p_n|^2} < \infty, \tag{4.13}$$

and

(4) *the pole-zero absolute error sequence is absolutely summable; i.e.,*

$$\sum_{n=1}^{\infty} |z_n - p_n| < \infty. \tag{4.14}$$

Then (a) $\hat{F}$ *admits the infinite product representation of pole-zero pairs* (3.1)–(3.3).

(b) *In addition, let* $\hat{R}_n$, $n = 1, 2, \ldots$, *be the rational elementary factors defined by* (3.4)–(3.5), *with* $2 \cdot |\sigma| \le \min(|\operatorname{Re} p_n|, |\operatorname{Re} z_n|)$, *for all* n, *for some* $\sigma < 0$. *Then the sequence* $(\prod_{n=1}^{N} \hat{R}_n)_{N \ge 1}$ *of invertible approximate (rational) spectral factors converges to the exact invertible standard spectral factor* $\hat{R} \in \hat{\mathcal{A}}_-$ *of* $\hat{F}$ *in the* $\hat{\mathcal{A}}(\sigma)$*-norm, and the sequence* $(\prod_{n=1}^{N} \hat{R}_n^{-1})_{N \ge 1}$ *converges to the corresponding inverse spectral factor* $\hat{R}^{-1} \in \hat{\mathcal{A}}_-$.

Proof. In view of Corollary 4.3, it suffices to check that the assumptions of Theorem 3.4 hold. Since the spectral density $\hat{F}$ is coercive, there exists some $\gamma > 0$ such that, for all $n \ge 1$,

$$|\operatorname{Re} z_n| \ge \gamma.$$

Therefore by condition (4.14) there holds

$$\sum_{n=1}^{\infty} \frac{|z_n - p_n|}{|\operatorname{Re} z_n|} < \infty;$$

i.e., assumption (3.9) holds.

Now observe that

$$\sum_{n=1}^{\infty} \left| \frac{1}{z_n} - \frac{1}{p_n} \right| < \infty. \tag{4.15}$$

Indeed, for all $n \ge 1$,

$$\left| \frac{1}{z_n} - \frac{1}{p_n} \right| \le \gamma^{-1} \cdot |z_n - p_n| \cdot |p_n|^{-1},$$

where, by (4.13) and (4.14), the sequences $(|z_n - p_n|)$ and $(|p_n|^{-1})$ are, respectively, in l^1 and in l^∞. Whence (4.15) holds. It follows by (4.15) and (4.13) that (3.13)

holds. Finally observe that, by the holomorphicity of F in the strip S_δ, one has for all $n \geq 1$

$$|\mathrm{Re}\ p_n| \geq \delta.$$

This together with (4.14) implies

$$\sum_{n=1}^{\infty} \frac{|z_n - p_n|}{|\mathrm{Re}\ p_n|} < \infty,$$

i.e., assumption (3.8) holds. Hence all assumptions of Theorem 3.4 are valid and we are done. □

Remark 4.2. It can be shown that Theorem 4.4 can be applied to the heat diffusion model studied in [10], [7] (see Remark 4.1 (γ)). Actually this result is applicable to an important class of semigroup state-space systems in the framework of the LQ-optimal control problem for such systems. This question is addressed in the following subsection.

4.2. Semigroup state-space systems. Consider a single-input C_0-semigroup state-space system with bounded control and observation operators (see, e.g., [17], [28]), viz.,

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \quad y(t) = Cx(t), \quad t \geq 0, \tag{4.16}$$

where $x(t) \in \mathrm{H}$, with H a separable Hilbert state-space with inner product $\langle \cdot\ ,\ \cdot \rangle$, $u(t) \in \mathbb{R}$, $y(t) \in \mathbb{R}^p$, and

(1) $A : D(A) \subset \mathrm{H} \to \mathrm{H}$ is the generator of a C_0-semigroup $(e^{At})_{t \geq 0} \subset \mathbf{L}(\mathrm{H})$,

(2) $B \in \mathbf{L}(\mathbb{R}, \mathrm{H})$ is a bounded linear control operator given by

$$Bu = bu \quad \text{for all } u \in \mathbb{R}\ , \quad b \in \mathrm{H},$$

(3) $C \in \mathbf{L}(\mathrm{H}, \mathbb{R}^p)$ is a bounded linear observation operator.

Furthermore assume that A is a Riesz-spectral operator [17] with discrete spectrum

$$\sigma(A) = \sigma_p(A) = \{\lambda_n\ :\ n \in \mathbb{N}\} \subset \mathbb{C} \tag{4.17}$$

consisting of simple eigenvalues such that

$$\delta := \inf\ \{\ |\lambda_n - \lambda_m|\ :\ n, m \in \mathbb{N}\ ,\ n \neq m\} > 0 \tag{4.18}$$

and

$$\mu := \sup \left\{ \sum_{\substack{l=1 \\ l \neq n}}^{\infty} \frac{1}{|\lambda_l - \lambda_n|^2}\ :\ n \in \mathbb{N} \right\} < \infty. \tag{4.19}$$

Remark 4.3. Since the operator A is the (infinitesimal) generator of a C_0-semigroup of bounded linear operators $(e^{At})_{t \geq 0}$ on H, it holds (see [17]) that $\sup\ \{\mathrm{Re}\ \lambda_n\ :\ n \in \mathbb{N}\} < \infty$.

Finally assume that

(4.20) (A, B) is exponentially stabilizable and (C, A) is exponentially detectable.

Observe that, by (4.20), there exists some $\sigma < 0$ such that the spectrum of A can be decomposed according to

$$\sigma(A) \;=\; (\sigma(A) \cap \overset{o}{\mathbb{C}}_{\sigma-}) \;\dot\cup\; (\sigma(A) \;\cap\; \mathbb{C}_+), \tag{4.21}$$

where $\overset{o}{\mathbb{C}}_{\sigma-}$ denotes the open left half-plane $\{s \in \mathbb{C} \;:\; \mathrm{Re}\; s < \sigma\}$ and $\mathbb{C}_+$ denotes the closed right half-plane $\{s \in \mathbb{C} \;:\; \mathrm{Re}\; s \geq 0\}$. The two sets on the right-hand side of identity (4.21) are disjoint and the unstable spectrum $\sigma(A) \;\cap\; \mathbb{C}_+$ is a finite point set. Moreover, the following holds.

LEMMA 4.5. *The* nonzero *eigenvalues* $\lambda_n, n \in \mathbb{N}$, *of* A *satisfy*

$$\sum_{n=1,\lambda_n \neq 0}^{\infty} \;\frac{1}{|\lambda_n|^2} \;<\; \infty. \tag{4.22}$$

Proof. This follows immediately from (4.19). □

Now for system (4.16)–(4.20) consider the LQ-optimal control problem: for any initial state $x_0 \in \mathrm{H}$, find a square-integrable control $u_0 \in L^2(0,\infty;\mathbb{R})$ which minimizes the cost functional

$$J(x_0,u) := \int_0^\infty \;(\|Cx(t)\|^2 \;+\; \|u(t)\|^2)\;\, dt.$$

It is well known (see, e.g., [17] and the references cited therein) that the optimal control $u_0(t)$ is given by

$$u_0(t) = K_0\; x_0(t), \qquad x_0(t) = e^{(A+BK_0)t}x_0,$$

where the optimal feedback operator $K_0 \in \mathcal{L}(\mathrm{H},\mathbb{R})$ is given by

$$K_0 = -B^*\; Q_0,$$

where the operator $Q_0 \in \mathbf{L}(H)$ is the unique nonnegative self-adjoint solution of the operator Riccati equation on the domain of the operator A:

$$A^*Q_0 + Q_0A + C^*C - Q_0BB^*Q_0 = 0 \quad \text{on}\;\; D(A),$$

where $Q_0(D(A)) \subset D(A^*)$. Moreover, the optimal feedback K_0 is stabilizing; i.e., the feedback semigroup $(e^{(A+BK_0)t})_{t\geq 0}$ is exponentially stable, and $K_0 \in \mathbf{L}(\mathrm{H},\mathbb{R})$ is also given by

$$K_0\; x \;=\; \langle k_0\;,\; x\rangle \quad \text{for all } x \in \mathrm{H}, \quad k_0 \in \mathrm{H}. \tag{4.23}$$

We have then the following.

LEMMA 4.6. *Consider the* C_0*-semigroup state-space system given by* (4.16)–(4.20). *Let* $(\phi_n)_{n\in\mathbb{N}}$ *be a Riesz basis of eigenvectors of* A *(corresponding to the eigenvalues* λ_n*) and let* $(\psi_n)_{n\in\mathbb{N}}$ *be the corresponding biorthogonal dual Riesz basis of eigenvectors of the adjoint operator* A^*. *Consider the LQ-optimal feedback operator* $K_0 \in \mathcal{L}(H,\mathbb{R})$ *given by* (4.23). *Then the feedback semigroup generator*

$$A_c := A + BK_0 = A + b\;\langle k_0\;,\cdot\rangle \tag{4.24}$$

has a discrete spectrum of eigenvalues $\lambda_{cn}, n \in \mathbb{N}$, *with*

$$\sigma(A_c) = \sigma_p(A_c) = \{\lambda_{cn} \ : \ n \in \mathbb{N}\}, \tag{4.25}$$

and corresponding eigenvectors forming a Riesz basis of H. Moreover,

$$|\lambda_{cn} - \lambda_n| \ = \ O\left(\ |\langle k_0, \phi_n\rangle \cdot \langle b, \psi_n\rangle| \ \right) \quad \textit{for} \ \ n \ \textit{sufficiently large}, \tag{4.26}$$

whence

$$\sum_{n=1}^{\infty} |\lambda_{cn} - \lambda_n| < \infty. \tag{4.27}$$

Proof. Results (4.25)–(4.26), where $\{\lambda_{cn} : n \in \mathbb{N}\}$ is replaced by its closure, follow by (4.17)–(4.19), [34, Theorem 2.1], and [15, Appendix B, p. 66]. Now in (4.26) the sequences $(\langle k_0, \phi_n\rangle)$ and $(\langle b, \psi_n\rangle)$ are in l^2, whence the product sequence $(\langle k_0, \phi_n\rangle \cdot \langle b, \psi_n\rangle)$ is in l^1. Hence (4.27) holds. Furthermore, by Lemma 4.5, (4.22) holds.

Now as $(e^{(A+BK_0)t})_{t\geq 0}$ is exponentially stable and $\sigma(A)$ is as in (4.21), there exists some $\eta > 0$ and $M \in \mathbb{N}$ such that for all $n \geq M$, $\min(|\mathrm{Re}\lambda_n|, |\mathrm{Re}\lambda_{cn}|) \geq \eta$. This together with (4.27) and (4.22) and arguments similar to those in the proof of Theorem 4.4, gives

$$\sum_{n=M}^{\infty} \ \left| \frac{1}{\lambda_n} - \frac{1}{\lambda_{cn}} \right| < \infty.$$

Consequently

$$\sum_{n=1}^{\infty} \ \frac{1}{|\lambda_{cn}|^2} \ < \ \infty.$$

Hence $\sigma_p(A_c)$ cannot have limit points in $\mathbb{C}$, and the last equality of (4.25) holds. □

Remark 4.4. In view of [24, Corollary 4.6], the feedback semigroup generator A_c given by (4.24) is a *Riesz-spectral operator* [17, p. 41], whenever its eigenvalues $\lambda_{cn}, n \in \mathbb{N}$ are simple. *This will be tacitly assumed in what follows.*

It is also known (see [9], [10]) that the LQ-optimal control problem can be solved by the spectral factorization of a specific spectral density, whose spectral factor gives the state-feedback operator K_o via a Diophantine equation. In the sequel we shall concentrate upon that spectral factorization problem. More precisely, assuming that the operator pair (A, B) is exponentially stabilizable, there exists a stabilizing feedback operator $K \in \mathcal{L}(\mathrm{H}, \mathbb{R})$, i.e., such that the C_0-semigroup $(e^{(A+BK)t})_{t\geq 0}$ is exponentially stable. Moreover, with the spectrum of A as in (4.21), the feedback $K = [0 \ K_2]$ (K_2 = vector) can be chosen such that

$$\sigma(A + BK) \ = \ (\sigma(A) \cap \ \overset{o}{\mathbb{C}}_{\sigma-}) \ \dot{\cup} \ \Sigma, \tag{4.28}$$

where $\Sigma \subset \overset{o}{\mathbb{C}}_{\sigma-}$ is a finite set having the same number of elements as $\sigma(A) \ \cap \ \mathbb{C}_+$. Under these conditions the pair $(\hat{\mathcal{N}}, \hat{\mathcal{D}}) \in \hat{\mathcal{A}}_-^{p\times 1} \times \hat{\mathcal{A}}_-$ defined by

$$(\hat{\mathcal{N}}(s), \hat{\mathcal{D}}(s)) := (C(sI - A - BK)^{-1}B, \ 1 + K(sI - A - BK)^{-1}B) \tag{4.29}$$

generates a right fraction of the semigroup state-space system transfer function $\hat{G}(s) = C(sI - A)^{-1}B \in \hat{\mathcal{B}}^{p\times 1}$ with no common zeros in $\mathbb{C}_+$, where $\hat{\mathcal{D}}$ is a biproper stable rational function whose zeros are in $\sigma(A) \cap \mathbb{C}_+$ and whose poles are in Σ. Moreover, $\hat{\mathcal{D}}$ equals 1 at infinity.

Now consider the function $\hat{F}(s)$ defined by

$$\hat{F} := \hat{\mathcal{N}}_* \, \hat{\mathcal{N}} + \hat{\mathcal{D}}_* \, \hat{\mathcal{D}} = \hat{\mathcal{D}}_* \, (1 + \hat{G}_* \, \hat{G}) \, \hat{\mathcal{D}}. \tag{4.30}$$

It is shown in [9, Theorem 3, pp. 70–71] and [10, Theorem 3, pp. 761–762] that $\hat{F}$ is a coercive spectral density whose spectral factorization is the main step towards the solution of the LQ-optimal control problem, i.e., for the computation of the feedback operator K_0. Moreover for the specific case at hand one has the following.

LEMMA 4.7. *Under the assumptions of Lemma* 4.6, *let* $\hat{G}(s) = C(sI - A)^{-1}B$ *be the transfer function of the* C_0*-semigroup state-space system* (4.16)–(4.20). *Consider the real function* $\hat{F}$ *given by* (4.30), *where* $(\hat{\mathcal{N}}, \hat{\mathcal{D}})$ *is the right fraction* (4.29) *with no common zeros in* $\mathbb{C}_+$ *of* $\hat{G}(s)$, *where* $K \in \mathbf{L}(H, \mathbb{R})$ *is a stabilizing feedback operator such that* (4.28) *holds.*

Then $\hat{F}$ *is a coercive real spectral density such that* $\hat{F}$ *is holomorphic in a vertical strip* S_δ *for some* $\delta > 0$ *and such that* $\hat{F}(\infty) = 1$, *i.e.,* (4.11) *holds. Moreover,* $\hat{F}$ *is a meromorphic function of finite order* $\rho \leq 2$ *and can be described as a fraction of real parahermitian entire functions, i.e.,*

$$\hat{F}(s) = \frac{N(s)}{D(s)}, \tag{4.31}$$

where the functions $D = D_*$ *and* $N = N_*$ *are entire functions with countable zero sets* $\mathcal{Z}[D]$ *and* $\mathcal{Z}[N]$, *respectively, such that, with* $\mathcal{P}[\hat{F}]$ *denoting the set of poles of* $\hat{F}$ *and* $\sigma < 0$ *chosen such that* (4.21) *holds,*

$$\mathcal{Z}[D] = \mathcal{P}[\hat{F}] \subset \{p, -\overline{p} \, : \, p \in (\sigma(A) \cap \overset{o}{\mathbb{C}}_{\sigma-}) \, \dot{\cup} \, \Sigma\}, \tag{4.32}$$

and

$$\mathcal{Z}[N] = \mathcal{Z}[\hat{F}] \subset \{z, -\overline{z} \, : \, z \in \sigma(A_c) = \sigma(A + BK_0)\}. \tag{4.33}$$

Remark 4.5. (α) When the C_0-semigroup $(e^{At})_{t\geq 0}$ is exponentially stable, one can choose the feedback K to be zero. In this case, the right fraction $(\hat{\mathcal{N}}, \hat{\mathcal{D}})$ defined by (4.29) is given by $(\hat{\mathcal{N}}, \hat{\mathcal{D}}) = (\hat{G} \, , \, 1)$, and the spectral density reads

$$\hat{F} = 1 + \hat{G}_* \, \hat{G}. \tag{4.34}$$

Furthermore, the denominator entire function D in (4.31) is such that

$$\mathcal{Z}[D] = \mathcal{P}[\hat{F}] \subset \{p, -\overline{p} \, : \, p \in \sigma(A)\}. \tag{4.35}$$

(β) In general the inclusions in (4.32) and (4.33) are not equalities. This is due to the fact that the system is not necessarily approximately controllable and/or observable, whence the numerator and denominator can be simplified by common zero cancellations.

In standard examples, like the heat diffusion (see [10]) and the vibrating string (see below), the spectral density above is obtained (by applying the Laplace transform

to the PDE describing the system) as a fraction of entire functions where an infinite number of common zero cancellations may occur.

Proof of Lemma 4.7. Property (4.11) follows directly from (4.30) and (4.29), which ensure that $\hat{G}(s)$ is zero at infinity in $\mathbb{C}_{\sigma+}$ and that $\hat{\mathcal{D}}$ equals 1 at infinity. By [17, Lemma 4.3.10, p. 183], the transfer function $\hat{G}(s)$ is given by

$$\hat{G}(s) \;=\; \sum_{n=1}^{\infty} \; (C\phi_n) \;\; \overline{\langle b, \psi_n \rangle} \;\; (s-\lambda_n)^{-1}, \tag{4.36}$$

which is holomorphic in the resolvent set $\rho(A)$, whose complement $\sigma(A)$ is a pure point spectrum of isolated points by (4.18). It follows, using [31, Definition 10.41, p. 241]), that $\hat{G}(s)$ is meromorphic in $\mathbb{C}$ with poles contained in $\sigma(A)$. Thus, upon noting that in (4.30) $\hat{\mathcal{D}}$ is a biproper rational function, there holds that the spectral density $\hat{F}$ given by (4.30) is real parahermitian meromorphic in $\mathbb{C}$, with poles given by the inclusion in (4.32). Consequently, by Lemma 2.5, $\hat{F} = N/D$, where N and D are real parahermitian entire functions with no common zeros in $\mathbb{C}$; i.e., (4.31) holds with $\mathcal{Z}[D] = \mathcal{P}[\hat{F}]$ and $\mathcal{Z}[N] = \mathcal{Z}[\hat{F}]$. Hence (4.32) follows and we have to show that the inclusion of (4.33) holds. Now, by [9, Theorem 2, p. 67], the inverse spectral density $\hat{F}^{-1}$ can be written as

$$\hat{F}^{-1} \;=\; \hat{W}\, \hat{W}_*,$$

where

$$\hat{W}(s) \;=\; \hat{\mathcal{D}}(s)^{-1}\, [1 + K_0(sI - A - BK_0)^{-1}B] \;\in\; \hat{\mathcal{A}}_-.$$

Therefore the zero set of $\hat{F}$, i.e., the pole set of $\hat{F}^{-1}$, satisfies

$$\mathcal{Z}[\hat{F}] = \mathcal{P}[\hat{F}^{-1}] \;\subset\; \{z, -\overline{z} \;:\; z \in \sigma(A + BK_0)\},$$

and the inclusion in (4.33) holds. Finally $\hat{F}$ is holomorphic in a vertical strip S_δ for some $\delta > 0$ by its pole structure and because it is coercive.

It remains to be proved that the transfer function $\hat{G}(s) = C(sI - A)^{-1}B$ is a meromorphic function *of finite order*, whence so will be the spectral density $\hat{F}$ given by (4.30). Since C and B are bounded linear operators of finite-rank, and (ϕ_n) and (ψ_n) are Riesz bases, the sequences $((C\phi_n))$ and $(\overline{\langle b, \psi_n \rangle})$ are in l^2. It follows by (4.36) that

$$\hat{G}(s) = \sum_{n=1}^{\infty} \; d_n (s-\lambda_n)^{-1},$$

where the product sequence $(d_n) := ((C\phi_n)) \cdot \overline{\langle b, \psi_n \rangle})$ is in l^1, i.e., absolutely summable, and convergence is pointwise. It follows that

$$|\hat{G}(s)| \leq \frac{K}{d(s, \sigma(A))}, \tag{4.37}$$

for some constant K, where $d(s, \sigma(A))$ denotes the distance between s and $\sigma(A)$, which is given by

$$d(s, \sigma(A)) \;:=\; \inf \{|s - \lambda| \;:\; \lambda \in \sigma(A)\}.$$

In view of Lemma 4.5, $|\lambda_n| \longrightarrow \infty$ as $n \to \infty$. Hence, for any positive real number R, there exists a nonnegative integer $n(R)$ such that

$$|\lambda_n| > R \ \text{ for all } n > n(R).$$

Because of assumption (4.18), the maximum number of poles of the function $\hat{G}$ in a disc $\{s \in \mathbb{C} : |s| \leq R\}$ of arbitrarily large radius R, namely, $n(R)$, is such that

$$n(R) = O(R^2). \tag{4.38}$$

Moreover, in the annulus defined by the circles centered at the origin with radii R and $R+1$, respectively, the number of poles of $\hat{G}$ is $O(R)$, i.e., is equal to κR for some constant κ. These poles can be arranged in increasing order of modulus, say,

$$R_0 := R \leq R_1 \leq \cdots \leq R_{\kappa R} \leq R_{\kappa R+1} := R+1.$$

This set is formed of at most $\kappa R + 2$ numbers which are contained in an interval of length one. So the maximum gap between two consecutive numbers among them is at least $(\kappa R + 1)^{-1}$. Now if a point $s \in \mathbb{C}$ is such that $|s|$ lies in the middle of this gap, then the distance from s to the nearest pole of $\hat{G}$ is at least $(2(\kappa R + 1))^{-1}$, i.e., $O(R^{-1})$. Hence

$$d(s, \sigma(A)) = O\left(\frac{1}{R}\right) \text{ on a circle } C(0, r_R) := \{s \in \mathbb{C} : |s| = r_R\}, \text{ where } R < r_R < R+1.$$

Thus, by inequality (4.37),

$$|\hat{G}(s)| = O(R) \ \text{ on the circle } C(0, r_R). \tag{4.39}$$

It follows from (4.38) and (4.39) that the counting and proximity functions of $\hat{G}$ satisfy, respectively,

$$N(r_n, \hat{G}) = O(r_n^2) \ \text{ and } \ m(r_n, \hat{G}) = O(\log r_n) \ \text{ as } n \to \infty,$$

where the sequence of points (r_n) is such that, for all n, $n < r_n < n+1$; whence

$$T(r_n) = O\left(r_n^2\right) \quad \text{as } n \to \infty.$$

Since the characteristic function $T(r) := T(r, \hat{G})$ of $\hat{G}$ is a monotonically increasing function of $r > 0$, it follows that

$$T(r) = O(r^2) \ \text{ as } r \to \infty. \tag{4.40}$$

Observe that the order ρ of the meromorphic function $\hat{G}$ is the lower bound of all positive numbers k such that $T(r) = O(r^k)$ as $r \to \infty$. Hence, in view of (4.40), the function $\hat{G}$ is of finite order $\rho \leq 2$. □

We are now ready to show that the symmetric extraction method of spectral factorization works for such systems.

THEOREM 4.8. *Let the assumptions of Lemma* 4.6 *hold. Consider the coercive real spectral density* $\hat{F}$ *given by* (4.30), *where* $(\hat{\mathcal{N}}, \hat{\mathcal{D}})$ *is the right-coprime fraction of the transfer function* $\hat{G}(s) = C(sI - A)^{-1}B$, *which is given by* (4.29) *for some stabilizing feedback operator* $K \in \mathbf{L}(H, \mathbb{R})$ *such that* (4.28) *holds. Then the symmetric*

extraction method of spectral factorization of the spectral density $\hat{F}$ is convergent, i.e., the conclusions (a) *and* (b) *of Theorem* 4.4 *hold.*

Proof. From the initial stabilization procedure described above, it is clear that one may assume without loss of generality that the open-loop C_0-semigroup $(e^{At})_{t\geq 0}$ is exponentially stable. Hence without loss of generality, poles and zeros of $\hat{F}$ are a subset of, respectively, the λ_n and the λ_{cn} mentioned above. The conclusions then follow directly from Lemmas 4.5–4.7, by using Theorem 4.4. □

5. Example: Vibrating string with low damping. The main result of the last section, viz., Theorem 4.8, is now used in order to apply the symmetric extraction method to a lowly damped vibrating string model, with the purpose of illustrating a case of slow convergence.

In what follows $z(t,x)$ denotes the vertical position of a damped vibrating string at the place $x \in [0,1]$ and time $t \geq 0$ that is described by the PDE

$$z_{tt}(t,x) = z_{xx}(t,x) - 2\beta z_t(t,x) + b(x)u(t), \tag{5.1}$$

where the damping parameter $\beta \in (0,\pi)$ (low damping) and for all $t \geq 0$, $z(t,0) = z(t,1) = 0$; moreover, $u(t) \in \mathbb{R}$ is a scalar input, and $b(x)$ is a window function given for $\nu_i > 0$ small and $[x_i - \nu_i, x_i + \nu_i] \subset [0,1]$ by

$$b(x) := (2\nu_i)^{-1}\chi_{[x_i-\nu_i,x_i+\nu_i]}(x), \quad x \in [0,1]. \tag{5.2}$$

The scalar output $y(t) \in \mathbb{R}$ is given by

$$y(t) := \int_0^1 c(x)z(t,x)dx, \tag{5.3}$$

where $c(x)$ is a window function which for $\nu_o > 0$ small and $[x_o - \nu_o, x_o + \nu_o] \subset [0,1]$ reads

$$c(x) := (2\nu_o)^{-1}\chi_{[x_o-\nu_o,x_o+\nu_o]}(x), \quad x \in [0,1]. \tag{5.4}$$

It is moreover assumed that

$$x_i - \nu_i > 0, \quad x_o - \nu_o > x_i + \nu_i, \quad \text{and} \quad x_o + \nu_o < 1. \tag{5.5}$$

In order to show that the theory of subsection 4.2 applies to this example, we first derive a semigroup state-space model of the form (4.16) for this system. The reader is referred to [17, Examples 2.2.5 and 2.3.8] and [1, Example 3.5.3] for more detail. Consider the Hilbert space $\mathrm{H} = \mathrm{L}^2(0,1)$ with standard scalar product $\langle\cdot,\cdot\rangle_2$, which is antilinear in its second argument. Let $A:\ (D(A) \subset \mathrm{H}) \to \mathrm{H}$ be the generator of a C_0-semigroup $(e^{At})_{t\geq 0}$ on H given by

$$Az = z'', \qquad D(A) = \{z \in \mathrm{H}^2(0,1) :\ z(1) = 0,\ z(0) = 0\} = \mathrm{H}^2(0,1) \cap \mathrm{H}_0^1(0,1). \tag{5.6}$$

Since $A = A^* < 0$, A generates on H an analytic semigroup that is exponentially stable. Moreover, $D[(-A)^{\frac{1}{2}}]$ equipped with the graph norm of $(-A)^{\frac{1}{2}}$ is a Hilbert space that can be identified with $\mathrm{H}_0^1(0,1)$ equipped with the norm $||z'||_2$ for any $z \in \mathrm{H}_0^1(0,1)$ [1, Example 3.5.3]. In this sense it is possible to consider the Hilbert space

$$\mathcal{H} := D[(-A)^{\frac{1}{2}}] \oplus \mathrm{H} = \mathrm{H}_0^1(0,1) \oplus \mathrm{H}, \tag{5.7}$$

with scalar product

$$\langle \zeta, \eta \rangle_{\mathcal{H}} := \langle \zeta_1', \eta_1' \rangle_2 + \langle \zeta_2, \eta_2 \rangle_2 \qquad \forall\, \zeta = \begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix},\ \eta = \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix} \in \mathcal{H}. \tag{5.8}$$

Recall now $b(\cdot)$ and $c(\cdot)$ given by (5.2) and (5.4), and define $B \in \mathbf{L}(\mathbb{R}, \mathrm{H})$ and $C \in \mathbf{L}(\mathrm{H}, \mathbb{R})$ by, respectively,

$$Bu := b(\cdot)u \quad \forall\, u \in \mathbb{R} \quad \text{and} \quad Cz := \langle c(\cdot), z(\cdot) \rangle_2 = \int_0^1 c(x) z(x) dx \quad \forall\, z \in \mathrm{H}. \tag{5.9}$$

Consider now $\mathcal{A}:\ (D(\mathcal{A}) \subset \mathcal{H}) \to \mathcal{H}$ given by

$$\mathcal{A} := \begin{bmatrix} 0 & I \\ A & -2\beta I \end{bmatrix}, \qquad D(\mathcal{A}) = D(A) \oplus \mathrm{H}_0^1(0,1), \tag{5.10}$$

and $\mathcal{B} \in \mathbf{L}(\mathbb{R}, \mathcal{H})$ and $\mathcal{C} \in \mathbf{L}(\mathcal{H}, \mathbb{R})$ defined by

$$\mathcal{B}u := \begin{bmatrix} 0 \\ Bu \end{bmatrix} \quad \forall\, u \in \mathbb{R} \quad \text{and} \quad \mathcal{C}\zeta := \begin{bmatrix} C & 0 \end{bmatrix} \begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix} \quad \forall\, \zeta \in \mathcal{H}. \tag{5.11}$$

Observe that $\mathcal{C} \in \mathbf{L}(\mathcal{H}, \mathbb{R})$ because $\langle c(\cdot), z(\cdot) \rangle_2 = \langle -\int_0^{\cdot} c(\xi) d\xi, z'(\cdot) \rangle_2$ for any $z \in \mathrm{H}_0^1(0,1)$. It turns out that $\mathcal{A}$ is the generator of an exponentially stable C_0-semigroup $(e^{\mathcal{A}t})_{t \geq 0}$ of contraction on $\mathcal{H}$ [17, Example 2.2.5] and $\mathcal{A}$ is a Riesz-spectral operator [17, Definition 2.3.4, Example 2.3.8]. More precisely, $\mathcal{A}$ is a Riesz-spectral operator that has for $k \in \mathbb{Z}_0$ countably many complex eigenvalues λ_k given by

$$\lambda_k = -\beta + j \operatorname{sign}(k) \sqrt{(k\pi)^2 - \beta^2}, \tag{5.12}$$

with primal Riesz basis of eigenvectors

$$\phi_k(x) = \begin{bmatrix} \phi_{k1}(x) \\ \phi_{k2}(x) \end{bmatrix} = \begin{bmatrix} 1 \\ \lambda_k \end{bmatrix} \frac{\operatorname{sign}(k) \sin(k\pi x)}{\lambda_k} \quad x \in [0,1] \quad \forall k \in \mathbb{Z}_0, \tag{5.13}$$

and dual Riesz basis of eigenvectors

$$\psi_k(x) = \begin{bmatrix} \psi_{k1}(x) \\ \psi_{k2}(x) \end{bmatrix} = \begin{bmatrix} 1 \\ -\overline{\lambda_k} \end{bmatrix} \frac{\operatorname{sign}(k) \sin(k\pi x)}{j \operatorname{Im}(\lambda_k)} \quad x \in [0,1] \quad \forall k \in \mathbb{Z}_0, \tag{5.14}$$

such that

$$||\phi_k||_{\mathcal{H}}^2 = 1 \quad \text{and} \quad ||\psi_k||_{\mathcal{H}}^2 = \frac{(k\pi)^2}{(k\pi)^2 - \beta^2}.$$

Hence by [17, Theorem 2.3.5] the spectrum of $\mathcal{A}$ satisfies

$$\sigma(\mathcal{A}) = \overline{\{\lambda_k : k \in \mathbb{Z}_0\}},$$

where the eigenvalues λ_k are given by (5.12) and the growth constant of the semigroup $(e^{\mathcal{A}t})_{t \geq 0}$ generated by $\mathcal{A}$ is given by

$$\omega_0 := \inf_{t>0} \left(\frac{1}{t} \log ||e^{\mathcal{A}t}|| \right) = \sup_{k \in \mathbb{Z}_0} \operatorname{Re}\, \lambda_k = -\beta.$$

Thus, for $\sigma \in (-\beta, 0]$, $||e^{\mathcal{A}t}|| \leq M\ \exp(\sigma t)$ for all $t \geq 0$, and for such σ, $(e^{\mathcal{A}t})_{t\geq 0}$ is σ-exponentially stable [17, Definition 5.1.1].

Upon identifying $\zeta_1(t)(\cdot) := z(t,\cdot)$ and $\zeta_2(t)(\cdot) := z_t(t,\cdot)$, the PDE model described by (5.1)–(5.5) can be given an infinite-dimensional state-space description of the form (4.16) on the state-space $\zeta = [\zeta_1, \zeta_2]^T \in \mathcal{H}$ given by

$$\dot{\zeta} = \mathcal{A}\zeta + \mathcal{B}u(t) \quad \text{and} \quad y(t) = \mathcal{C}\zeta(t), \tag{5.15}$$

where one uses the mild solution of the state differential equation, viz.,

$$\zeta(t) = e^{\mathcal{A}t}\zeta(0) + \int_0^t e^{\mathcal{A}(t-\tau)}\mathcal{B}u(\tau)d\tau, \quad t \geq 0, \quad \zeta(0) \in \mathcal{H}, \tag{5.16}$$

and where $\mathcal{A}$ is a Riesz-spectral operator satisfying condition (4.17).

In addition, it follows from the fact that the semigroup $(e^{\mathcal{A}t})_{t\geq 0}$ is exponentially stable that (4.20) holds. Thus it remains to be proved that (4.18) and (4.19) hold. Now observe that, for all $k, l \in \mathbb{Z}_0$ such that $k \neq l$, there holds

$$|\lambda_k - \lambda_l| \ \geq \sqrt{\pi^2 - \beta^2};$$

whence (4.18) holds with

$$\delta = \inf\ \{\ |\lambda_k - \lambda_l|\ :\ k, l \in \mathbb{Z}_0\ ,\ k \neq l\}\ \geq \sqrt{\pi^2 - \beta^2}\ \ >\ 0.$$

Finally, for all k, l in $\mathbb{Z}_0$ such that $k \neq l$, there holds

$$|\lambda_l - \lambda_k|^2\ >\ (l\pi)^2 - \beta^2\ >\ 0,$$

when $\text{sign}(k) \neq \text{sign}(l)$, and

$$|\lambda_l - \lambda_k|^2\ =\ \left(\frac{\pi^2\ (k^2 - l^2)}{\sqrt{(k\pi)^2 - \beta^2} + \sqrt{(l\pi)^2 - \beta^2}}\right)^2\ >\ \pi^2\ (k-l)^2\ >\ 0,$$

when $\text{sign}(k) = \text{sign}(l)$. It follows that, for all k in $\mathbb{Z}_0$,

$$\sum_{\substack{l\ \in\ \mathbb{Z}_0 \\ l\neq k}} \frac{1}{|\lambda_l - \lambda_k|^2}\ \leq\ \sum_{l\ \in\ \mathbb{N}} \frac{1}{(l\pi)^2 - \beta^2} + \frac{1}{\pi^2} \cdot \sum_{\substack{l\ \in\ \mathbb{Z} \\ l\neq k}} \frac{1}{(l-k)^2}.$$

Hence condition (4.19) is satisfied with

$$\mu\ =\ \sup\ \left\{\ \sum_{\substack{l\ \in\ \mathbb{Z}_0 \\ l\neq k}} \frac{1}{|\lambda_l - \lambda_k|^2}\ :\ k \in \mathbb{Z}_0\right\}\ \leq\ \sum_{l\ \in\ \mathbb{N}} \frac{1}{(l\pi)^2 - \beta^2} + \frac{1}{\pi^2} \cdot \sum_{l\ \in\ \mathbb{Z}_0} \frac{1}{l^2} <\ \infty.$$

In view of Remark 4.5 (α), it follows from the exponential stability of the semigroup $(e^{\mathcal{A}t})_{t\geq 0}$ that the corresponding LQ-optimal control based (coercive) spectral density $\hat{F}$ to be factorized can without loss of generality be chosen to be

$$\hat{F} = 1 + \hat{g}_*\ \hat{g}, \tag{5.17}$$

where $\hat{g} \in \hat{\mathcal{A}}_-$ is the vibrating string model transfer function, which is given by

$$\hat{g}(s) = \frac{\sin(\sqrt{\rho_s}(1-x_o))}{\sin(\sqrt{\rho_s})} \cdot \frac{\sin(\sqrt{\rho_s}\nu_o)}{\sqrt{\rho_s}\nu_o} \cdot \frac{\sin(\sqrt{\rho_s}x_i)}{\sqrt{\rho_s}} \cdot \frac{\sin(\sqrt{\rho_s}\nu_i)}{\sqrt{\rho_s}\nu_i} \tag{5.18}$$

or, equivalently,

$$\hat{g}(s) = \frac{\sinh(\sqrt{r_s}(1-x_o))}{\sinh(\sqrt{r_s})} \cdot \frac{\sinh(\sqrt{r_s}\nu_o)}{\sqrt{r_s}\nu_o} \cdot \frac{\sinh(\sqrt{r_s}x_i)}{\sqrt{r_s}} \cdot \frac{\sinh(\sqrt{r_s}\nu_i)}{\sqrt{r_s}\nu_i}, \tag{5.19}$$

where $\rho_s := -s(2\beta + s)$ and $r_s := -\rho_s$.

Remark 5.1. As the semigroup $(e^{\mathcal{A}t})_{t\geq 0}$ generated by $\mathcal{A}$ is σ-exponentially stable for $\sigma \in (-\beta, 0]$, and $\mathcal{B} \in \mathbf{L}(\mathbb{R}, \mathcal{H})$ and $\mathcal{C} \in \mathbf{L}(\mathcal{H}, \mathbb{R})$, there holds by [17, Lemma 7.3.1] that the transfer function given above belongs to the class $\hat{\mathcal{A}}_-(\sigma)$ and to the class $\hat{\mathcal{A}}(\sigma)$ for $\sigma \in (-\beta, 0]$. As the corresponding impulse response $g(t)$ has no impulses, one has $\exp(-\sigma\cdot)g(\cdot) \in \mathrm{L}^1(0,\infty)$, $\sup_{\mathrm{Re}\ s\geq\sigma} |\hat{g}(s)| < \infty$, and $\hat{g}(s)$ is zero at infinity in $\mathbb{C}_{\sigma+} := \{s \in \mathbb{C} : \mathrm{Re}\ s \geq \sigma\}$.

Now observe that the spectral density $\hat{F}$ can be written as

$$\hat{F} \ = \ \frac{N}{D}, \tag{5.20}$$

where N and D are the real parahermitian entire functions given, respectively, by

$$N(s) \ := \ n(-s)\cdot n(s) + d(-s)\cdot d(s) \qquad \text{and} \qquad D(s) \ := \ d(-s)\cdot d(s), \tag{5.21}$$

where d and n are, respectively, the denominator and numerator of the transfer function $\hat{g}$, which are the entire functions given, respectively, by

$$d(s) \ := \ \frac{\sin(\sqrt{\rho_s})}{\sqrt{\rho_s}} \ = \ \frac{\sinh(\sqrt{r_s})}{\sqrt{r_s}}, \tag{5.22}$$

and

$$n(s) := \hat{g}(s)\ d(s), \tag{5.23}$$

where the zeros of d are exactly the open-loop eigenvalues λ_k, given by (5.12). Observe that the numerator N and denominator D of the spectral density $\hat{F}$ above may have infinitely many common zeros (see Remark 4.5 (β)). In addition observe that, in view of (5.21)–(5.22), the entire functions N and D are of finite order (see, e.g., [37, Example 1, p. 76]).

It follows from the analysis above that, by Theorem 4.8, the spectral factorization by symmetric extraction of the spectral density $\hat{F}$ given by (5.20)–(5.22) is convergent; i.e., the conclusions (a) and (b) of Theorem 4.4 hold.

Numerical results are presented in Table 5.1. These results were obtained for the following parameter values: $\beta = 2$, $x_i = 0.02$, $x_o = 1 - x_i = 0.98$, and $\nu_i = \nu_o = 0.01$. It is found that the closed-loop eigenvalues λ_{cn} have numerically a constant real part equal to -2 and hence are vertically distant from the open-loop ones by $|\lambda_n - \lambda_{cn}|$. One can observe that the convergence is slow. Moreover, the absolute and relative errors are overall decreasing in an oscillatory manner. Further numerical evidence leads us to conjecture that $|\lambda_n - \lambda_{cn}|$ is of order $n^{-\alpha}$, where α is slightly larger than one.

39	-2+122.51j	1.42e-7	5.56e-6	2.17e-4
40	-2+125.65j	9.26e-8	3.71e-6	1.48e-4

This is theoretically confirmed by the facts that (1) by Lemma 4.6, (5.11), and (5.14), $|\lambda_n - \lambda_{cn}| = O(\frac{x_n}{n})$, where (x_n) is a square-summable sequence, whence $\alpha > 1$, and (2) the linearized, i.e., Newton–Raphson, estimate of $|\lambda_n - \lambda_{cn}|$ is $O(\frac{1}{n^2})$. Thus as nonlinear perturbations do not improve the speed of convergence, one has $\alpha \in (1, 2]$: the situation is comparable with that of Example 4.1.

Notice further that the tail-sums used in (4.6)–(4.8) are here of order $\frac{1}{n^{\alpha-1}}$. Hence the error analysis of Theorem 4.2 reveals that approximate spectral factorization will be achieved very slowly, the main reason being the asymptotically linear distribution of the spectra along a vertical line in the open left half-plane. A better situation is to be expected when this is not the case, i.e., acceleration by the fact that the real parts of the closed-loop eigenvalues Re λ_{cn} tend to $-\infty$.

6. Conclusion. As we have seen, the symmetric extraction method may be applied to a wide class of distributed parameter systems, for which its convergence has been established theoretically.

Another example for which the symmetric extraction method is appropriate is the beam equation with structural damping (see, e.g., [32, pp. 131–133]), and in this case one would expect the convergence to be faster, since the real parts of the eigenvalues tend to $-\infty$. More generally, one would expect the convergence to be faster when the semigroup is analytic, since in that case the spectrum lies in a sector contained in some left half-plane; see, e.g., [2].

Other possible techniques for approaching the spectral factorization problem for distributed parameter systems include a direct approximation of the spectral density function, but this needs to be treated with caution, since the mapping from spectral density to spectral factor is discontinuous in the uniform norm (see, e.g., [22]). It would also be of interest to extend the present methods to multivariable systems (the finite-dimensional case was analyzed in [4]), but this introduces additional function-theoretic difficulties.

As a referee has observed, there may be connections between the factorization

approach taken here and the invariant subspace approach. This could be an interesting topic for further research, in particular for the special class of Riesz-spectral systems; see [24].

ERGODIC CONTROL FOR CONSTRAINED DIFFUSIONS: CHARACTERIZATION USING HJB EQUATIONS*

VIVEK BORKAR† AND AMARJIT BUDHIRAJA‡

Abstract. Recently in [A. Budhiraja, *SIAM J. Control Optim.*, 42 (2003), pp. 532–558] an ergodic control problem for a class of diffusion processes, constrained to take values in a polyhedral cone, was considered. The main result of that paper was that under appropriate conditions on the model, there is a Markov control for which the infimum of the cost function is attained. In the current work we characterize the value of the ergodic control problem via a suitable Hamilton–Jacobi–Bellman (HJB) equation. The theory of existence and uniqueness of classical solutions, for PDEs in domains with corners and reflection fields which are oblique, discontinuous, and multivalued on corners, is not available. We show that the natural HJB equation for the ergodic control problem admits a unique continuous viscosity solution which enables us to characterize the value function of the control problem. The existence of a solution to this HJB equation is established via the classical vanishing discount argument. The key step is proving the precompactness of the family of suitably renormalized discounted value functions. In this regard we use a recent technique, introduced in [V. S. Borkar, *Stochastic Process Appl.*, 103 (2003), pp. 293–310], of using the Athreya–Ney–Nummelin pseudoatom construction for obtaining a coupling of a pair of embedded, discrete time, controlled Markov chains.

1. Introduction.

In a recent work [10] an ergodic control problem for a class of constrained diffusion processes, in polyhedral cones, was studied. Such controlled constrained diffusion processes arise in the heavy traffic analysis of single class open queuing networks with state dependent arrival and service rates with control in the marginal service rates (cf. [24]). The study of optimal control of queuing networks in heavy traffic via the analysis of the control problem for a suitable limit controlled diffusion process is currently an active area of research (cf. [23], [21], [22], [20], [26], [13], [12], [24], [1]). The control problems considered in the above works (excepting the last two papers) are somewhat different from that in [10] (and the current work) in that they correspond to the control of sequencing and routing of jobs in the network. In the diffusion limit such control problems lead to rather nontrivial singular control problems with state constraints. In contrast, the current paper (and also [24], [1]) considers the problem of drift control for a diffusion which is constrained to take values in a polyhedral domain via the action of a suitable Skorohod map. The domain $G \subset \mathbb{R}^k$, which is the state space of the controlled Markov process, is given as an intersection of N half spaces G_i; $i = 1, \ldots, N$. Associated with each G_i is a vector d_i which defines the "direction of constraint" in the relative interior of ∂G_i. At a

point $x \in \partial G$ where several faces meet, there is more than one possible direction of constraint; in fact, the set of permissible directions is a cone denoted by $d(x)$. Roughly speaking, the constrained version of a given unrestricted trajectory in $\mathbb{R}^k$ is obtained by pushing back the trajectory, whenever it is about to exit the domain, in one of the permissible directions of constraint using the minimal force required to keep the trajectory inside the domain. Precise definitions will be given in section 2. The constraining mechanism is described via the notion of a Skorohod problem. Under appropriate conditions on $(d_i)_{i=1}^N$ it follows from the results in [16] that one can define the "Skorohod map," denoted as $\Gamma(\cdot)$, which takes an unrestricted trajectory $\psi(\cdot)$ and maps it to a trajectory $\phi(\cdot) \doteq \Gamma(\psi)(\cdot)$ such that $\phi(t) \in G$ for all $t \in (0, \infty)$.

The controlled constrained diffusion process that we will study is obtained as a solution to the equation

$$X(t) = \Gamma\left(X(0) + \int_0^{\cdot} b(X(s), u(s))ds + \int_0^{\cdot} \sigma(X(s))dW(s)\right)(t), \quad t \in [0, \infty), \tag{1.1}$$

where $W(\cdot)$ is a standard Wiener process, $b : G \times U \to \mathbb{R}^k$; $\sigma : G \to \mathbb{R}^{k\times k}$ are suitable coefficients, U is a given control set, and $u(\cdot)$ is a U valued "admissible" control process. The cost of interest is the ergodic cost criterion

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T k(X(s), u(s))ds, \tag{1.2}$$

where the limit above is taken almost surely (a.s.) and $k : G \times U \to \mathbb{R}$ is a suitable map.

In control theory, one of the most desirable features of a good control is that it should depend only on the current value of the state and not on the whole history of the state and/or the control process. Namely, one is interested in obtaining controls $u(\cdot)$ such that there exists some measurable map $v : G \to U$ satisfying $u(t) = v(X(t))$ a.s. for all $t \in [0, \infty)$. Under such a control the solution to (1.1) becomes a Markov process and for this reason the map $v(\cdot)$ is referred to as a "Markov control." The main result of [10] is that, under appropriate conditions on the model (Conditions 2.2, 2.4, 2.5, and 2.8 in section 2), there is a Markov control for which the infimum of the cost in (1.2) is attained.

The other important goal in stochastic control theory is the characterization of the value function of the control problem via a suitable Hamilton–Jacobi–Bellman (HJB) equation. For unconstrained diffusions this problem has been extensively studied and we refer the reader to [7] for a detailed account. For the controlled Markov processes in the present work, the problem is quite challenging since the domain in which the process is constrained to lie is not smooth (because of the corners where the faces meet) and the reflection field is oblique, discontinuous, and multivalued at the boundary points which lie on more than one face. The theory of existence and uniqueness of classical solutions for PDEs in such domains is not available. However, using the fundamental ideas of Crandall and Lions [15] and Lions [25], Dupuis and Ishii [17] have developed an existence and uniqueness theory of viscosity solutions for fully nonlinear second order elliptic PDEs on such domains. In this work we will show that the value of the ergodic control problem introduced above can be characterized via the unique viscosity solution of an appropriate HJB equation. The usual approach to the HJB equation for the ergodic control is via the "vanishing discount method" (cf. [14], [9], [7], [4], [27]). In this approach one first studies the value function $V_\alpha(x)$

of the discounted control problem

$$V_\alpha(x) = \inf_u \mathbb{E}\left(\int_0^\infty e^{-\alpha s} k(X^x(s), u(s))ds\right), \tag{1.3}$$

where $\alpha \in (0,\infty)$, the infimum is taken over all admissible controls u, and $X^x(\cdot)$ is the solution of (1.1) with $X(0) \equiv x$. For $f \in C_b^2(G)$ let $Lf : G \times U \to \mathbb{R}$ be defined as

$$(Lf)(x,u) \doteq \frac{1}{2}\sum_{i,j=1}^k a_{i,j}(x)\frac{\partial^2 f}{\partial x_i \partial x_j}(x) + \sum_{i=1}^k b_i(x,u)\frac{\partial f}{\partial x_i}(x), \quad (x,u) \in G \times U, \tag{1.4}$$

where $a_{ij}(x) \doteq \sigma(x)\sigma^T(x)$. Using results of [17] we will show that the value function $V_\alpha(x)$ is the unique viscosity solution (see Definition 3.3) of the following HJB equation:

$$\begin{aligned} \inf_{u\in U}\,(L\psi(x,u) + k(x,u) - \alpha\psi(x)) = 0, \quad x \in G, \\ \langle \nabla\psi(x), d_i\rangle = 0, \quad x \in \partial G,\ i \in \mathrm{In}(x), \end{aligned} \tag{1.5}$$

where $\mathrm{In}(x) \doteq \{i \in \{1,2,\ldots,N\} : x \in \partial G_i\}$. We remark that the work [17] considers the case where the domain is bounded; however, by a slight modification the techniques there can be used to cover the case in the present work.

In order to study the HJB equation of the ergodic control problem, we need to take the limit as $\alpha \to 0$. The key step in this program is to show that the family

$$\{\overline{V}_\alpha(\cdot) \doteq V_\alpha(\cdot) - V_\alpha(0),\ \alpha \in (0,\infty)\} \tag{1.6}$$

is precompact in $C(G)$. The classical derivation (see Theorem VI.3.1 of [7]) of such a result makes use of certain gradient estimates on $V_\alpha(x)$, uniform in α, which we are unable to prove for the model considered in the present work. Another approach based on viscosity solutions, taken in [4], proves the above precompactness by making some strong stability assumptions on the model (a restoring force toward bounded sets that grows without bound as $|x| \to \infty$) which are not natural for the constrained diffusion models that arise from the heavy traffic analysis of queuing networks. In the present work we prove the precompactness of the family in (1.6) by using the Athreya–Ney–Nummelin pseudoatom construction which was recently introduced in the context of partially observed ergodic control problems in [5]. The importance of pseudoatom construction ideas in ergodic control problems has also been pointed out in [28]. Using this construction, the precompactness of the family of (renormalized) discounted value functions for a partially observed control problem was proved in [8]. One of the key requirements for the coupling methods used in the above cited works to work, is the existence of a suitable Lyapunov function for the underlying controlled Markov processes. For the processes considered in the present work, the existence of such a Lyapunov function was proved in [2]. Using this Lyapunov function one can show that a Foster-type drift criterion is satisfied for an appropriate embedded discrete time controlled Markov chain. This, along with the pseudoatom construction, enables us to show that the coupling time, for two embedded controlled Markov chains driven by the same Markov control and independent noise processes but with two different initial conditions, has finite moments. The above step is the main ingredient to the proof of the precompactness of (1.6).

Once the precompactness is proved, one can take the limit of $(\alpha V_\alpha(0), \overline{V}_\alpha(\cdot))$, along a subsequence, as $\alpha \to 0$. Then by stability (under perturbations) properties of

viscosity solutions it follows that the limit, denoted as $(\rho, V(\cdot))$, is a viscosity solution of the HJB equation for the ergodic control problem (see (5.2)). The rest of the work involves showing that this equation admits a unique solution and that ρ is the infimum, over all admissible controls, of the cost function in (1.2).

The control problem considered in this work is motivated by average cost per unit time control problems for open queuing networks in heavy traffic. Consider a stochastic processing network consisting of k service stations each having input streams of jobs, possibly from outside and from other service stations in the network. The routing of the jobs in the network is probabilistic but uncontrolled and fixed (see [24]). More precisely, on completion of service at the ith station a customer is routed to station j with probability p_{ij}. The interarrival times of external streams of customers, in general, need not be independent, and their probability distribution could be state dependent. Here the state of the system is given by the vector of queue lengths at the various stations in the network. The system is "single class" in that the service rates at a given station do not depend on the customer type; however, the service rates could be state dependent. Furthermore, a system manager may exercise control to adjust the marginal service rates. This is the only mode of control in the system. The goal of the system manager is to control the marginal service rates in order to minimize a long term average cost per unit time where the cost function could depend on the queue lengths and the control process. Such a control problem was considered in [24] under a further restriction that the buffer lengths at all the service stations are finite. The authors showed that under appropriate assumptions on the arrival, service processes, routing probability matrix, and suitable heavy traffic conditions, such a control problem can be approximated by an ergodic control problem for certain controlled diffusions in compact polyhedral domains with control appearing only in the drift term. The compactness of the domain is a consequence of assumption of finite buffers at every station. More precisely, the authors show that the value function for the suitably scaled queuing network problem converges to the value function of the diffusion control problem as the scaling parameter approaches its limit. Furthermore, it is shown that an almost optimal solution for the limiting diffusion control problem can be used to obtain a near optimal solution to the network control problem when the network is close to heavy traffic. Thus it becomes of key importance to obtain methods for computing or numerically approximating controls for the limit diffusion control problem. In this work we consider the infinite buffer analogue of the control problem studied in [24]. Since in this setting one does not have the compactness of the state space which is critically exploited in the analysis of [24], the precise connection between the ergodic cost problem for the network and the corresponding control problem for the diffusion is still an open issue. Our goal in the current work is to take a first step in this direction by studying the properties of the formal diffusion control problem that arises in the heavy traffic analysis of the above described control problem. The main result of this work, namely, the characterization of the value function of the limit control problem as a unique solution of a suitable HJB equation, is the first step in numerically solving for an almost optimal control for the diffusion control problem. The eventual goal, of course, is to establish the convergence of the value function of the network control problem to the value function of the diffusion control problem and then obtain near optimal controls for the underlying queuing network. This will be studied in our future work.

The paper is organized as follows. In section 2 we present some preliminary definitions and known results that will be used in this work. Section 3 is devoted to showing that the value function of the discounted cost problem is the unique solution

of the HJB equation in (1.5). In section 4 we present the pseudoatom construction and use it to show the precompactness of the family in (1.6). In section 5, by taking the limit as $\alpha \to 0$ we obtain a viscosity solution of the HJB equation for the ergodic control problem. Finally, we characterize the value function by showing that the equation admits a unique viscosity solution.

2. Preliminaries and background results. Let $G \subset \mathbb{R}^k$ be a polyhedral cone with the vertex at the origin given as the intersection of half spaces G_i, $i = 1, \ldots, N$. Each half space G_i is associated with a unit vector n_i via the relation $G_i = \{x \in \mathbb{R}^k : \langle x, n_i \rangle \geq 0\}$, where $\langle \cdot, \cdot \rangle$ denotes the usual inner product in $\mathbb{R}^k$. Denote the boundary of a set $B \subset \mathbb{R}^k$ by ∂B. We will denote the set $\{x \in \partial G : \langle x, n_i \rangle = 0\}$ by F_i. For $x \in \partial G$, define the set, $n(x)$, of inward normals to G at x by $n(x) \doteq \{r : |r| = 1,\ \langle r, x - y \rangle \leq 0,\ \forall y \in G\}$. With each face F_i we associate a unit vector d_i such that $\langle d_i, n_i \rangle > 0$. This vector defines the *direction of constraint* associated with the face F_i. For $x \in \partial G$ define $d(x) \doteq \{d \in \mathbb{R}^k : d = \sum_{i \in \mathrm{In}(x)} \alpha_i d_i;\ \alpha_i \geq 0;\ \|d\| = 1\}$. We will denote the collection of all subsets of $\{1, \ldots, N\}$ by Λ.

Let $D([0, \infty) : \mathbb{R}^k)$ denote the set of functions mapping $[0, \infty)$ to $\mathbb{R}^k$ that are right continuous and have limits from the left. We endow $D([0, \infty) : \mathbb{R}^k)$ with the usual Skorohod topology. Let $D_G([0, \infty) : \mathbb{R}^k) \doteq \{\psi \in D([0, \infty) : \mathbb{R}^k) : \psi(0) \in G\}$. For $\eta \in D([0, \infty) : \mathbb{R}^k)$ let $|\eta|(T)$ denote the total variation of η on $[0, T]$ with respect to the Euclidean norm on $\mathbb{R}^k$.

DEFINITION 2.1. *Let $\psi \in D_G([0, \infty) : \mathbb{R}^k)$ be given. Then $(\phi, \eta) \in D([0, \infty) : \mathbb{R}^k) \times D([0, \infty) : \mathbb{R}^k)$ solves the Skorohod problem (SP) for ψ with respect to G and d if and only if $\phi(0) = \psi(0)$, and for all $t \in [0, \infty)$ (1) $\phi(t) = \psi(t) + \eta(t)$; (2) $\phi(t) \in G$; (3) $|\eta|(t) < \infty$; (4) $|\eta|(t) = \int_{[0,t]} I_{\{\phi(s) \in \partial G\}} d|\eta|(s)$; (5) There exists (Borel) measurable $\gamma : [0, \infty) \to \mathbb{R}^k$ such that $\gamma(t) \in d(\phi(t))$ ($d|\eta|$ almost everywhere (a.e.)) and $\eta(t) = \int_{[0,t]} \gamma(s) d|\eta|(s)$.*

On the domain $D \subset D_G([0, \infty) : \mathbb{R}^k)$ on which there is a unique solution to the SP we define the Skorohod map (SM) Γ as $\Gamma(\psi) \doteq \phi$, if $(\phi, \psi - \phi)$ is the unique solution of the SP posed by ψ. The following is the key assumption made in [10] on the data defining the SP.

Condition 2.2. (a) There exists a compact, convex set $B \in \mathbb{R}^k$ with $0 \in B^0$ such that if $v(z)$ denotes the set of inward normals to B at $z \in \partial B$, then for $i = 1, 2, \ldots, N$, $z \in \partial B$ and $|\langle z, n_i \rangle| < 1$ implies that $\langle v, d_i \rangle = 0$ for all $v \in v(z)$. (b) There exists a map $\pi : \mathbb{R}^k \to G$ such that if $y \in G$, then $\pi(y) = y$, and if $y \notin G$, then $\pi(y) \in \partial G$, and $y - \pi(y) = \alpha\gamma$ for some $\alpha \leq 0$ and $\gamma \in d(\pi(y))$. (c) For every $x \in \partial G$, there is $n \in n(x)$ such that $\langle d, n \rangle > 0$ for all $d \in d(x)$.

An important consequence of the above assumption is the regularity of the SM in the following sense.

THEOREM 2.3 (Dupuis and Ishii [16]). *Under Condition* 2.2 *the SM is well defined on all of $D_G([0, \infty) : \mathbb{R}^k)$, i.e., $D = D_G([0, \infty) : \mathbb{R}^k)$, and the SM is Lipschitz continuous in the following sense. There exists a $K < \infty$ such that for all $\phi_1, \phi_2 \in D_G([0, \infty) : \mathbb{R}^k)$*

$$\sup_{0 \leq t < \infty} |\Gamma(\phi_1)(t) - \Gamma(\phi_2)(t)| < K \sup_{0 \leq t < \infty} |\phi_1(t) - \phi_2(t)|. \tag{2.1}$$

In the rest of the paper Condition 2.2 will always be taken to hold. We refer the reader to [18] for sufficient conditions and examples for which the above condition holds. We will also assume without loss of generality that $K \geq 1$.

We now introduce the controlled constrained diffusion processes that will be studied in this paper. Throughout this paper we will assume the relaxed control framework; i.e., there is a compact metric space S such that the control set is $U \doteq \mathcal{P}(S)$ (the space of all probability measures on S endowed with the weak convergence topology). All topological spaces in this paper will be endowed with their natural Borel σ-field. For a topological space $\mathcal{K}$, we will denote its Borel σ-field by $\mathcal{B}(\mathcal{K})$. The space of all real, measurable and bounded functions defined on $\mathcal{K}$ will be denoted as $BM(\mathcal{K})$, the subset of $BM(\mathcal{K})$ consisting of continuous functions will be denoted by $C_b(\mathcal{K})$, and the space of all probability measures on $(\mathcal{K}, \mathcal{B}(\mathcal{K}))$ will be denoted by $\mathcal{P}(\mathcal{K})$. The space $\mathcal{P}(\mathcal{K})$ will be endowed with the weak convergence topology. For $A \in \mathcal{B}(\mathcal{K})$, $\mathcal{I}_A(\cdot)$ will denote the indicator function of the set A. Also, we will denote by $C_b^2(G)$ the space of real valued, bounded and twice continuously differentiable functions on G. By a filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$ we will mean a probability space $(\Omega, \mathcal{F}, P)$ endowed by a filtration $(\mathcal{F}_t)_{t\geq 0}$ satisfying the usual hypothesis. A pair of stochastic processes $(u(\cdot), W(\cdot))$ defined on some filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$ is said to be an admissible pair if $W(\cdot)$ is an $\mathcal{F}_t$-standard Wiener process and $u(\cdot)$ is a U valued, measurable, $\{\mathcal{F}_t\}$ adapted process.

We will consider controlled constrained diffusion processes of the form defined in (1.1), where for $(x, u) \in G \times U$, $b(x, u) \doteq \int_S \bar{b}(x, \alpha)u(d\alpha)$ and the coefficients $\sigma : G \to \mathbb{R}^{k\times k}$ and $\bar{b} : G \times S \to \mathbb{R}^k$ satisfy the following conditions.

Condition 2.4. There exists $r \in (0, \infty)$ such that

(i) $\bar{b}$ is a continuous map and for all $x, y \in G$ and $\alpha \in S$

$$\|\bar{b}(x, \alpha) - \bar{b}(y, \alpha)\| + \|\sigma(x) - \sigma(y)\| \leq r\|x - y\|.$$

(ii) For all $x \in G$ and $\alpha \in S$

$$\|\bar{b}(x, \alpha)\| + \|\sigma(x)\| \leq r.$$

We will also assume the following nondegeneracy assumption on σ.

Condition 2.5. There exists $c_0 \in (0, \infty)$ such that for all $x \in G$ and $\alpha \in \mathbb{R}^k$ $\alpha'(\sigma(x)\sigma'(x))\alpha \geq c_0\alpha'\alpha$.

In the rest of the paper, in addition to Condition 2.2, Conditions 2.4 and 2.5 will also be assumed to hold. Under these conditions, it follows, via the Lipschitz property of the SM and the usual fixed point arguments, that (1.1) admits a unique strong solution (cf. Theorem 2.6 of [10]). If $X(\cdot)$ solves (1.1), then (cf. Theorem 3.5.1 of [23]) there exist continuous, increasing $\mathcal{F}_t$ adapted processes $\{Y_i(\cdot);\ 1 \leq i \leq N\}$ such that

$$X(t) = X(0) + \int_0^t b(X(s), u(s))ds + \int_0^t \sigma(X(s))dW(s) + \sum_{i=1}^N d_i Y_i(t) \tag{2.2}$$

for all t, a.s. Furthermore, $Y_i(0) = 0$ and for all $t > 0$ $\int_0^t \mathcal{I}_{F_i}(X(s))dY_i(s) = Y_i(t)$, a.s., $i = 1, \ldots, N$. The following lemma essentially says that in considering admissible controls, we can without loss of generality restrict ourselves to controls that are adapted with respect to the filtration generated by $(X(\cdot), Y(\cdot))$. The proof is similar to Theorem 1.2.2, p. 18, of [7] and is therefore omitted.

LEMMA 2.6. *Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ be a filtered probability space on which is given an admissible pair $(u(\cdot), W(\cdot))$. Let $X(\cdot)$ be a solution to* (1.1) *with the corresponding boundary processes $\{Y_i(\cdot)\}_{i=1}^N$ as in* (2.2). *Then there exists an enlargement*

$(\overline{\Omega}, \overline{\mathcal{F}}, \{\overline{\mathcal{F}}_t\}, \overline{P})$ of the above probability space on which is given an $\{\overline{\mathcal{F}}_t\}$ Wiener process $\tilde{W}(\cdot)$ and $\mathcal{P}(S)$ valued measurable stochastic process $\tilde{u}(\cdot)$ such that for a.e. $t \in [0,\infty)$, $\tilde{u}(t)$ is $\mathcal{F}_t^{X,Y}$ measurable ($\tilde{u}$ is called a feedback control), where $\mathcal{F}_t^{X,Y}$ denotes the P completion of $\sigma\{X(s);\ \{Y_i(s)\}_{i=1}^N;\ 0 \le s \le t\}$, and $X(\cdot)$ solves

$$X(t) = X(0) + \int_0^t b(X(s), \tilde{u}(s))ds + \int_0^t \sigma(X(s))d\tilde{W}(s) + \sum_{i=1}^N d_i Y_i(t).$$

Henceforth, without loss of generality, we will assume that all controls are feedback controls. Next we introduce Markov controls. We begin with the following definition.

DEFINITION 2.7. *Let $v : G \to U$ be a measurable map. We say that the equation*

$$X(t) = \Gamma\left(X(0) + \int_0^{\cdot} b(X(s), v(X(s)))ds + \int_0^{\cdot} \sigma(X(s))dW(s)\right)(t), \quad X(0) \sim \mu, \tag{2.3}$$

admits a weak solution if there exists a filtered probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ on which is given an $\{\mathcal{F}_t\}$ Wiener process $W(\cdot)$ and an $\mathcal{F}_t$ adapted process $X(\cdot)$ with continuous paths such that $X(0)$ has the probability law μ and for all t the equality in (2.3) *holds a.s. We say that* (2.3) *admits a unique weak solution if whenever there are two sets of such spaces and processes denoted as $(\Omega^i, \mathcal{F}^i, P^i, \mathcal{F}_t^i)$, $(W^i(\cdot), X^i(\cdot))$, $i = 1, 2$, then the probability law of $X^1(\cdot)$ is the same as that of $X^2(\cdot)$.*

With an abuse of terminology, the map v will be referred to as a "Markov control." Under the standing assumptions of this paper there is a unique weak solution for (2.3), and denoting the law of the solution process $X(\cdot)$, when $X(0) = x$ a.s., by P_x^v it can be shown that $\{P_x^v\}_{x\in G}$ is a strongly Feller Markov family (cf. Theorem 2.9 of [10]).

We will call a Markov control v a stable Markov control (SMC) if the corresponding Markov family $\{P_x^v\}_{x\in G}$ is positive recurrent and has a unique invariant measure. We will now present the blanket stability condition, introduced in [10] under which all Markov controls are stable.

Define

$$\mathcal{C} \doteq \left\{ -\sum_{i=1}^N \alpha_i d_i : \alpha_i \ge 0;\ i \in \{1, \dots, N\} \right\}. \tag{2.4}$$

The cone $\mathcal{C}$ was used to characterize stability for a certain class of constrained diffusion processes in [11, 3].

Let $\delta \in (0,\infty)$ be fixed. Define the set

$$\mathcal{C}(\delta) \doteq \{v \in \mathcal{C} : \operatorname{dist}(v, \partial C) \ge \delta\}. \tag{2.5}$$

The blanket stability condition below, which will be assumed throughout this paper, stipulates the permissible drifts in the underlying diffusion.

Condition 2.8. There exists a $\delta \in (0,\infty)$ such that for all $(x,u) \in G \times U$, $b(x,u) \in \mathcal{C}(\delta)$.

Under the assumptions made above the results of [3] show that all Markov controls are SMC, namely, that the following theorem holds.

THEOREM 2.9. *The Markov family $\{P_x^v\}_{x\in G}$ defined above is positive recurrent and admits a unique invariant measure, denoted as η_v.*

In this work we are interested in a control problem with an ergodic cost criterion. Namely, we are interested in minimizing, over the class of all admissible controls, the cost

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t k(X(s),u(s))ds, \tag{2.6}$$

where $X(\cdot)$ is given as a solution of (2.2) on some filtered probability space with an admissible pair $(u(\cdot),W(\cdot))$, the limit above is taken a.s. on the corresponding probability space, and $k : G\times U \to \mathbb{R}$ is a map defined as follows. For $(x,u)\in G\times U$, $k(x,u) \doteq \int_S \overline{k}(x,\alpha)u(d\alpha)$, where $\overline{k}$ is in $C_b(G\times S)$.

Under the assumptions made above, the following result on the existence of an optimal Markov control was proved in [10].

THEOREM 2.10. *There exists a Markov control $\overline{v}(\cdot)$ such that if for some $\mu \in \mathcal{P}(G)$, $\overline{X}(\cdot)$ is the corresponding process solving* (2.3) *(with v there replaced by $\overline{v}$), on some filtered probability space, with the probability law of $\overline{X}(0)$ being μ, then*

$$\limsup_{T\to\infty} \frac{1}{T}\int_0^T k(\overline{X}(s),\overline{v}(\overline{X}(s)))ds = \inf \operatorname{ess\,inf} \limsup_{T\to\infty} \frac{1}{T}\int_0^T k(X(s),u(s))ds \tag{2.7}$$

a.s., where the outside infimum on the right-hand side above is taken over all controlled processes $X(\cdot)$ with an arbitrary initial distribution and solving (1.1) *over some filtered probability space with some admissible pair $(W(\cdot),u(\cdot))$.*

3. The discounted cost problem. One of the important goals in optimal control theory is to derive the HJB equation for the value function and characterize the value function as the unique solution (in an appropriate class) of the PDE.

The classical approach to the HJB equation for the ergodic control is by the "vanishing discount method" (cf. [14], [9], [7], [4]). In this approach the first step is to study the value function $V_\alpha(x)$ of the discounted control problem defined via (1.3). In this section we will characterize the value function $V_\alpha(x)$ via a suitable HJB equation.

With an abuse of notation, for $\alpha \in S$ we will write $(Lf)(x,\delta_{\{\alpha\}})$ merely as $(Lf)(x,\alpha)$, where $\delta_{\{\alpha\}}$ denotes the probability measure concentrated at the point α. Thus with this notation, for $(x,u)\in G\times U$, $(Lf)(x,u) = \int_S (Lf)(x,\alpha)u(d\alpha)$. For $i=1,2,\dots,N$ and $f\in C_b^2(G)$ let $D_if : G\to\mathbb{R}$ be defined as $(D_if)(x) \doteq \langle d_i, \nabla f(x)\rangle$, $x\in G$. The natural HJB equation associated with the control problem (1.3) is the one given in (1.5). A theory of classical solutions for such a PDE is not available, and therefore we will consider solutions in the viscosity sense [15], [25], [17]. We begin with the following proposition. The proof is identical to Theorem III.2.1 of [7] and, therefore, is omitted.

PROPOSITION 3.1. *Let $\alpha\in(0,\infty)$ and let V_α be defined by* (1.3). *Then $V_\alpha \in C_b(G)$.*

Now let $(X^x(\cdot),Y^x(\cdot))$ be given as a solution of (2.2) with $X(0)\equiv x$. Let η be stopping time with respect to the natural filtration of $(X^x(\cdot),Y^x(\cdot))$. Then one can prove the following dynamic programming principle, exactly along the lines of Theorem III.1.3 of [7] (cf. comments above equation (III.1.8) of [7]).

$$V_\alpha(x) = \inf \mathbb{E}\left(\int_0^\eta e^{-\alpha t}k(X^x(t),u(t))dt + e^{-\alpha\eta}V_\alpha(X^x(\eta))\right), \tag{3.1}$$

where the infimum is taken over all feedback controls u. The following lemma will be useful in controlling the reflection term $(Y(\cdot))$ in (2.2).

LEMMA 3.2. *Let $(X^x(\cdot),Y^x(\cdot))$ be given as a solution of* (2.2) *with $X(0)\equiv x$. Then for every $m\in\mathbb{N}$, there exists a $C_m\in(0,\infty)$, which is independent of the initial condition x, the control process u, and $t\in(0,\infty)$ such that*

$$\sup_{i\in\{1,2,\dots,N\}} \mathbb{E}(Y_i(t))^m \le C_m t^{\frac{m}{2}}.$$

Proof. From Lemma 4.2 of [10], there exists a $g \in C_b^2(G)$ such that

$$\langle \nabla g(x), d_i \rangle \geq 1, \quad \forall x \in F_i,\ i \in \{1, \ldots, N\}. \tag{3.2}$$

An application of Itô's formula yields that for all $i \in \{1, 2, \ldots, N\}$

$$Y_i(t) \leq \left| \int_0^t (Lg)(X(s), v(X(s)))ds \right| + \left| \int_0^t \langle \nabla g(X(s)), \sigma(X(s))dW(s) \rangle \right| + |g(X_t) - g(X_0)|.$$

The result now follows on recalling that g is in $C_b^2(G)$ and using the boundedness of b, σ, Burkholder–Gundy inequalities, the Lipschitz property of the SM, and Gronwall's inequality. □

Next we say what we mean by the viscosity solution of (1.5). Denote by S^k the space of $k \times k$ real symmetric matrices. Let $F_\alpha : G \times \mathbb{R} \times \mathbb{R}^k \times S^k \to \mathbb{R}$ be defined as

$$F_\alpha(x, r, p, M) \doteq -\frac{1}{2} \operatorname{Tr}(aM) + \alpha r - \inf_{u \in U} \{\langle b(x, u), p \rangle + k(x, u)\}. \tag{3.3}$$

Also, define $F_{\alpha,*}$ and F_α^* as maps from $G \times \mathbb{R} \times \mathbb{R}^k \times S^k$ to $\mathbb{R}$, as follows:

$$F_{\alpha,*}(x, r, p, M) = \begin{cases} F_\alpha(x, r, p, M) & \text{if } x \in G^o, \\ F_\alpha(x, r, p, M) \wedge \min\{-\langle d_i, p \rangle;\ i \in \mathrm{In}(x)\} & \text{if } x \in \partial G, \end{cases} \tag{3.4}$$

$$F_\alpha^*(x, r, p, M) = \begin{cases} F_\alpha(x, r, p, M) & \text{if } x \in G^o, \\ F_\alpha(x, r, p, M) \vee \max\{-\langle d_i, p \rangle;\ i \in \mathrm{In}(x)\} & \text{if } x \in \partial G. \end{cases} \tag{3.5}$$

DEFINITION 3.3. *We say that $\phi \in C_b(G)$ is a viscosity solution of* (1.5) *if and only if for all $x_0 \in G$ the following hold.*

1. *For all $\psi \in C^2(G)$, such that x_0 is a strict maximum point of $\phi - \psi$,*

$$F_{\alpha,*}(x_0, \phi(x_0), (D\psi)(x_0), (D^2\psi)(x_0)) \leq 0. \tag{3.6}$$

2. *For all $\psi \in C^2(G)$, such that x_0 is a strict minimum point of $\phi - \psi$,*

$$F_\alpha^*(x_0, \phi(x_0), (D\psi)(x_0), (D^2\psi)(x_0)) \geq 0. \tag{3.7}$$

We now have the following result.

THEOREM 3.4. *The value function V_α defined via* (1.3) *is a viscosity solution of* (1.5).

Proof. Let $x_0 \in G$ and $\psi \in C^2(G)$ be such that x_0 is a strict maximum point of $V_\alpha - \psi$. We will show that (3.6) holds with ϕ there replaced by V_α. Let $\kappa \doteq \psi(x_0) - V_\alpha(x_0)$ and fix $u \in U$. Then

$$\begin{aligned} \psi(x_0) &= V_\alpha(x_0) + \kappa \\ &\leq \mathbb{E}\left(\int_0^h e^{-\alpha s} k(X^{x_0}(s), u)ds + e^{-\alpha h} V_\alpha(X^{x_0}(h)) \right) + \kappa \\ &\leq \mathbb{E}\left(\int_0^h e^{-\alpha s} k(X^{x_0}(s), u)ds + (e^{-\alpha h} - 1) V_\alpha(X^{x_0}(h)) + \psi(X^{x_0}(h)) \right), \end{aligned}$$

where the first inequality follows from the dynamic programming principle (3.1) and the second inequality uses the minimality of κ. The above inequality yields

$$\begin{aligned} 0 \leq \frac{1}{h} \mathbb{E}\left(\int_0^h e^{-\alpha s} k(X^{x_0}(s), u)ds \right) + \frac{1}{h} \mathbb{E}(\psi(X^{x_0}(h)) - \psi(x_0)) \\ + \frac{(e^{-\alpha h} - 1)}{h} \mathbb{E}(V_\alpha(X^{x_0}(h))). \end{aligned}$$

Taking the limit as $h \to 0$ in the above inequality and using Proposition 3.1 and Itô's formula we have that

$$\begin{aligned} 0 &\le k(x_0,u) + (L\psi)(x_0,u) - \alpha V_\alpha(x_0) \\ &\quad + \limsup_{h\to 0} \sum_{i=1}^N \frac{1}{h}\mathbb{E}\bigg(\int_0^h \langle d_i, D\psi(X^{x_0}(s))\rangle dY_i(s)\bigg) \\ &= -F_\alpha(x_0, V_\alpha(x_0), D\psi(x_0), D^2\psi(x_0)) \\ &\quad + \limsup_{h\to 0} \sum_{i=1}^N \frac{1}{h}\mathbb{E}\bigg(\int_0^h \langle d_i, D\psi(X^{x_0}(s))\rangle dY_i(s)\bigg). \end{aligned} \tag{3.8}$$

We will now show that for every $i \in \{1,\dots,N\}$

$$\langle d_i, D\psi(x_0)\rangle < 0 \;\Rightarrow\; \limsup_{h\to 0} \frac{1}{h}\mathbb{E}\bigg(\int_0^h \langle d_i, D\psi(X^{x_0}(s))\rangle dY_i(s)\bigg) \le 0. \tag{3.9}$$

Clearly (3.8) and (3.9) will prove that (3.6) holds (with ϕ replaced by V_α). Now suppose that $i \in \{1,\dots,N\}$ is such that $\langle d_i, D\psi(x_0)\rangle < 0$. Then there exists $\epsilon > 0$ such that

$$\langle d_i, D\psi(y)\rangle < 0 \quad \forall y \in G \text{ satisfying } |x_0 - y| \le \epsilon. \tag{3.10}$$

Now

$$\begin{aligned} &\limsup_{h\to 0} \frac{1}{h}\mathbb{E}\bigg(\int_0^h \langle d_i, D\psi(X^{x_0}(s))\rangle dY_i(s)\bigg) \\ &\quad \le |D\psi|_\infty \limsup_{h\to 0} \frac{1}{h}\mathbb{E}(1_{\{\sup_{0\le s\le h}|X^{x_0}(s)-x_0|\ge\epsilon\}} Y_i(h)) \\ &\quad \le |D\psi|_\infty \limsup_{h\to 0} \sqrt{\mathbb{E}(Y_i^2(h))}\, \frac{\sqrt{\mathbb{E}(\sup_{0\le s\le h}|X^{x_0}(s)-x_0|^5)}}{h\epsilon^{5/2}} \\ &\quad \le C|D\psi|_\infty \sqrt{\mathbb{E}(Y_i^2(1))} \limsup_{h\to 0} \frac{h^{5/4}}{h\epsilon^{5/2}} \\ &\quad = 0 \end{aligned}$$

for a suitable constant C, where the second inequality follows on applying the Cauchy–Schwarz inequality and Chebyshev's inequality; the final inequality follows on using the Lipschitz property of the SM, boundedness of drift and diffusion coefficients, and Burkholder–Gundy inequalities. This proves (3.9) and hence part 1 of Definition 3.3.

Next let $\psi \in C^2(G)$ be such that x_0 is a strict minimum point of $V_\alpha - \psi$. To complete the proof we need to show that (3.7) holds with ϕ there replaced by V_α. From (3.1) we have that

$$V_\alpha(x_0) = \inf \mathbb{E}\left(\int_0^\epsilon e^{-\alpha t} k(X^{x_0}(t), u(t))dt + e^{-\alpha\epsilon} V(X^{x_0}(\epsilon))\right).$$

Let $u^\epsilon(\cdot)$ be a feedback control such that

$$V_\alpha(x_0) + \epsilon^2 \ge \mathbb{E}\left(\int_0^\epsilon e^{-\alpha t} k(X^{x_0,\epsilon}(t), u^\epsilon(t))dt + e^{-\alpha\epsilon} V(X^{x_0,\epsilon}(\epsilon))\right),$$

where $X^{x_0,\epsilon}(\cdot)$ solves (1.1) with $u(\cdot)$ there replaced by $u^\epsilon(\cdot)$ and $X(0) \equiv x$. Let κ be as before. Then

$$\psi(x_0) = V_\alpha(x_0) + \kappa \geq \mathbb{E}\left(\int_0^\epsilon e^{-\alpha t} k(X^{x_0,\epsilon}(t), u^\epsilon(t))dt \right.$$
$$\left. + (e^{-\alpha\epsilon} - 1)V(X^{x_0,\epsilon}(\epsilon)) + \psi(X^{x_0,\epsilon}(\epsilon))\right) - \epsilon^2.$$

Dividing by ϵ and taking the limit as $\epsilon \to 0$, we have

$$0 \geq \liminf_{\epsilon\to 0} \frac{1}{\epsilon}\mathbb{E}\left(\int_0^\epsilon e^{-\alpha t} k(X^{x_0,\epsilon}(t), u^\epsilon(t))dt \right.$$
$$\left. + (e^{-\alpha\epsilon} - 1)V(X^{x_0,\epsilon}(\epsilon)) + \psi(X^{x_0,\epsilon}(\epsilon)) - \psi(x_0)\right)$$
$$= \liminf_{\epsilon\to 0} \frac{1}{\epsilon}\mathbb{E}\left(\int_0^\epsilon e^{-\alpha t} k(x_0, u^\epsilon(t))dt \right.$$
$$\left. + \int_0^\epsilon (L\psi)(x_0, u^\epsilon(t))dt + \sum_{i=1}^N \int_0^\epsilon (D_i\psi)(X^{x_0,\epsilon}(t))dY_i(t)\right) - \alpha V_\alpha(x_0).$$

The last step follows on using the continuity and/or Lipschitz properties of k, $L\psi$, σ, and b and observing that

$$\limsup_{\epsilon\to 0} \mathbb{E}\left(\sup_{0\leq s\leq\epsilon} |X^{x_0,\epsilon}(s) - x_0|\right)^p \leq \limsup_{\epsilon\to 0} \sup \mathbb{E}\left(\sup_{0\leq s\leq\epsilon} |X^{x_0}(s) - x_0|\right)^p = 0,$$

where the supremum on the right-hand side is taken over all admissible controls. Thus we have that

$$0 \geq \liminf_{\epsilon\to 0} \frac{1}{\epsilon}\mathbb{E}\left(\int_0^\epsilon k(x_0, u^\epsilon(t))dt + \int_0^\epsilon (L\psi)(x_0, u^\epsilon(t))dt \right.$$
$$\left. + \sum_{i=1}^N \int_0^\epsilon (D_i\psi)(X^{x_0,\epsilon}(t))dY_i(t)\right) - \alpha V_\alpha(x_0)$$
$$\geq \inf_u (k(x_0, u) + (L\psi)(x_0, u)) - \alpha V_\alpha(x_0) + \liminf_{\epsilon\to 0} \sum_{i=1}^N \frac{1}{\epsilon}\mathbb{E}\left(\int_0^\epsilon (D_i\psi)(X^{x_0,\epsilon}(t))dY_i(t)\right)$$
$$= -F_\alpha(x_0, V_\alpha(x_0), D\psi(x_0), D^2\psi(x_0)) + \liminf_{\epsilon\to 0} \sum_{i=1}^N \frac{1}{\epsilon}\mathbb{E}\left(\int_0^\epsilon (D_i\psi)(X^{x_0,\epsilon}(t))dY_i(t)\right).$$

From the above inequality one can prove part 2 of Definition 3.3 exactly in the way part 1 was proved from (3.8). This proves the theorem. □

Next, we will show that under the standing assumptions of this paper, there is a unique viscosity solution of (1.5). For $n \in \mathbb{N}$, let $B_n \doteq \{x \in G \mid |x| < n\}$. Let $\psi \in C_b(G)$ be given. We begin by considering the following equation:

$$\begin{aligned} \inf_{u\in U} (L\phi(x, u) + k(x, u) - \alpha\phi(x)) &= 0, && x \in G \cap B_n, \\ \langle \nabla\phi(x), d_i\rangle &= 0, && x \in \partial G \cap B_n,\ i \in \mathrm{In}(x), \\ \phi(x) &= \psi(x), && x \in \partial B_n. \end{aligned} \tag{3.11}$$

DEFINITION 3.5. *We say that $\phi \in C_b(G)$ is a viscosity solution of* (3.11) *if* 1. *and* 2. *in Definition* 3.3 *hold for all $x_0 \in G \cap B_n$ and $\phi(x) = \psi(x)$ for all $x \in \partial B_n$.*

For $x \in \overline{B}_n$, let $X^x(\cdot)$ be given as a solution of (1.1) with $X(0) \equiv x$ and some admissible pair $(u(\cdot), W(\cdot))$. Let

$$\tau_n \equiv \tau_n(x) \doteq \inf\{t : X^x(t) \in B_n^c\} \tag{3.12}$$

and define

$$V^n(x) \doteq \inf \mathbb{E}\left(\int_0^{\tau_n} e^{-\alpha s} k(X^x(s), u(s))ds + e^{-\alpha\tau_n}\psi(X^x(\tau_n))\right), \tag{3.13}$$

where the infimum above is taken over all admissible controls.

The existence part of the following result is proved exactly as for Theorem 3.4. The proof of uniqueness, essentially, follows from results in [17]. A sketch of the argument is provided in the appendix for the reader's convenience.

THEOREM 3.6. *Let $\alpha \geq 0$ and let $V^n(\cdot)$ be defined via* (3.13). *Then $V^n(\cdot)$ is the unique viscosity solution of* (3.11).

An immediate consequence of the above theorem is the following result.

THEOREM 3.7. *Let $\alpha \in (0, \infty)$. Then $V_\alpha(\cdot)$ defined via* (1.3) *is the unique viscosity solution of* (1.5).

Proof. From Theorem 3.4 we know that $V_\alpha(\cdot)$ is a viscosity solution of (1.5). Now let $\tilde{V}$ be another viscosity solution of (1.5). Let $\tau_n(x)$ be defined via (3.12). Define

$$\phi(x) \doteq \inf \mathbb{E}\left(\int_0^{\tau_n(x)} e^{-\alpha s} k(X^x(s), u(s))ds + e^{-\alpha\tau_n(x)}\tilde{V}(X^x(\tau_n(x)))\right),$$

where the infimum is taken over all admissible controls. From Theorem 3.6, ϕ is the unique viscosity solution of (3.11), with ψ there replaced by $\tilde{V}$. However, since $\tilde{V}$ solves (1.5), clearly it is also a solution of (3.11) (once more with ψ there replaced by $\tilde{V}$). Thus we have that $\phi = \tilde{V}$ and so

$$\tilde{V}(x) = \inf \mathbb{E}\left(\int_0^{\tau_n(x)} e^{-\alpha t} k(X^x(t), u(t))dt + e^{-\alpha\tau_n(x)}\tilde{V}(X^x(\tau_n(x)))\right).$$

Also from (3.1) we have that the above equality holds with $\tilde{V}$ replaced by V_α. Thus we have that for $x \in G$ and n large enough so that $x \in B_n$,

$$\begin{aligned}|\tilde{V}(x) - V_\alpha(x)| &\leq \sup|\mathbb{E}(e^{-\alpha\tau_n(x)}\tilde{V}(X^x(\tau_n(x))) - e^{-\alpha\tau_n(x)}V_\alpha(X^x(\tau_n(x))))| \\ &\leq (|\tilde{V}|_\infty + |V_\alpha|_\infty)\sup\left(\mathbb{E}\big(e^{-\alpha\tau_n(x)}\big)\right),\end{aligned}$$

where the supremum in the above display is taken over all admissible controls. Using the boundedness of the drift and diffusion coefficients and the Lipschitz property of the Skorohod map, it follows that $\sup(\mathbb{E}(e^{-\alpha\tau_n(x)})) \to 0$ as $n \to \infty$. This shows that $\tilde{V}(x) = V_\alpha(x)$ for all $x \in G$. □

4. The vanishing discount limit. In this section we will show that if V_α is given via (1.3) and $\overline{V}_\alpha(x) \doteq V_\alpha(x) - V_\alpha(0)$, $x \in G$, then the family $\{\overline{V}_\alpha;\ \alpha \in (0, \infty)\}$ is precompact in $C(G)$. We begin with the following result, which says that the infimum of the cost in (1.3) over all admissible controls coincides with the infimum taken over all Markov controls. For the proof of this result for unconstrained diffusions, see Theorem II.4.2 of [7]. The result in the setting of constrained diffusions, of the form considered

in this work, is proved in a similar manner and therefore the proof is omitted. We refer the reader to [10] where the equivalence of infimum over all admissible controls and infimum over all Markov controls, under an ergodic cost criterion, is proved for constrained diffusions of the form considered in this work.

THEOREM 4.1. *For $\alpha \in (0,\infty)$ let $V_\alpha(\cdot)$ be defined via* (1.3). *Then for all $x \in G$*

$$V_\alpha(x) = \inf_v \mathbb{E}\left(\int_0^\infty e^{-\alpha s} k(X^x(s), v(X^x(s)))ds\right), \tag{4.1}$$

where $X^x(\cdot)$ is given as the unique weak solution of (2.3) *with $X(0) \equiv x$ and the infimum above is taken over all Markov controls v.*

We will also need the following "finite time horizon" equicontinuity result. For $M_0 \in (0,\infty)$ let

$$E_{M_0} \doteq \{x \in G : |x| \le M_0\}.$$

THEOREM 4.2. *Let $M, M_0, \epsilon \in (0,\infty)$. Define*

$$\begin{aligned}\Lambda(\epsilon, M, M_0) \doteq \sup_{x_1,x_2 \in E_{M_0},\, |x_1-x_2|\le\epsilon} \sup_v \int_0^M |&\mathbb{E}k(X^{x_1}(s), v(X^{x_1}(s))) \\ &-\mathbb{E}k(X^{x_2}(s), v(X^{x_2}(s)))|ds,\end{aligned} \tag{4.2}$$

where for $i = 1, 2$, $X^{x_i}(\cdot)$ is given as the unique weak solution of (2.3) *with $X(0) \equiv x_i$ and the inside supremum is taken over all Markov controls v. Then, for all $M, M_0 \in (0,\infty)$, $\Lambda(\epsilon, M, M_0) \to 0$ as $\epsilon \to 0$.*

The proof of the above theorem follows from results in [6]. We provide a sketch in the appendix.

Observe that, from Theorem 4.1, for all $x_1, x_2 \in G$ and $\alpha \in (0,\infty)$

$$\begin{aligned}|V_\alpha(x_1) - V_\alpha(x_2)| \le \sup_v \Big|&\mathbb{E}\int_0^\infty e^{-\alpha s} k(X^{x_1}(s), v(X^{x_1}(s)))ds \\ &- \mathbb{E}\int_0^\infty e^{-\alpha s} k(X^{x_2}(s), v(X^{x_2}(s)))ds\Big|,\end{aligned}$$

where for $i = 1, 2$, $X^{x_i}(\cdot)$ is given as the unique weak solution of (2.3) with $X(0) \equiv x_i$ and the inside supremum is taken over all Markov controls v. Now fix $\epsilon, M_0 \in (0,\infty)$ and let $M \in \mathbb{N}_0$. Suppose that $x_1, x_2 \in E_{M_0}$ and $|x_1 - x_2| \le \epsilon$. Then the expression on the right-hand side above can be bounded by

$$\begin{aligned}\sup_{x_1,x_2\in E_{M_0}} \sup_v \Big|&\mathbb{E}\int_M^\infty e^{-\alpha s} k(X^{x_1}(s), v(X^{x_1}(s)))ds \\ &- \mathbb{E}\int_M^\infty e^{-\alpha s} k(X^{x_2}(s), v(X^{x_2}(s)))ds\Big| + \Lambda(\epsilon, M, M_0).\end{aligned} \tag{4.3}$$

The main step in the proof of precompactness of $\{\overline{V}_\alpha;\ \alpha \in (0,\infty)\}$ is the following.

PROPOSITION 4.3. *For $M_0 \in (0,\infty)$ and $M \in \mathbb{N}$, let*

$$\begin{aligned}\Psi(M, M_0) \doteq \sup_{\alpha\in(0,\infty)} \sup_{x_1,x_2\in E_{M_0}} \sup_v \Big|&\mathbb{E}\int_M^\infty e^{-\alpha s} k(X^{x_1}(s), v(X^{x_1}(s)))ds \\ &- \mathbb{E}\int_M^\infty e^{-\alpha s} k(X^{x_2}(s), v(X^{x_2}(s)))ds\Big|.\end{aligned}$$

Then, for all $M_0 \in (0,\infty)$, $\Psi(M, M_0) \to 0$ as $M \to \infty$.

In order to prove the above proposition, we will need some stability properties of the underlying constrained diffusion process. Following [5], we begin by an embedding of the continuous time control problem in a discrete time control problem. Define

$$\mathcal{U} \doteq \{\theta : [0,1] \to U : \theta \text{ is a measurable map}\}.$$

We endow $\mathcal{U}$ with the coarsest topology under which, for every $e \in L^2[0,1]$ and $f \in C_b(S)$, the map $\Psi : \mathcal{U} \to \mathbb{R}$ defined as $\Psi(u) \doteq \int_0^1 e(t) \int_S f(\theta) u_t(d\theta)dt$ is continuous. Let $\hat{\Phi} \subset \mathcal{P}(C([0,1] : \mathbb{R}^k) \times \mathcal{U})$ be the class of all probability measures which correspond to the probability law of some admissible pair $(u(t), W(t))_{0 \le t \le 1}$. It follows from Chapter 1 of [7] that $\hat{\Phi}$ is a compact metric space.

Let $\phi \in \hat{\Phi}$ and let $(u(t), W(t))_{0 \le t \le 1}$ be the corresponding admissible pair on a filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$. Define

$$\hat{k}_\alpha(x, \phi) \doteq \mathbb{E}\left(\int_0^1 e^{-\alpha s} k(X^x(s), u(s))ds\right), \tag{4.4}$$

where $X^x(\cdot)$ is given as a solution of (1.1) with $X(0) \equiv x$. Let v be a Markov control. Define $\varrho_v : G \to \hat{\Phi}$ as follows. For $x \in G$, $\varrho_v(x)$ is defined as the probability law of $\{v(X^x(t)), W(t)\}_{0 \le t \le 1}$, where $W(\cdot)$ is a Wiener process and $X^x(\cdot)$ is given as the unique weak solution of (2.3) with $X(0) \equiv x$.

Setting $\hat{\alpha} \doteq e^{-\alpha}$ we have that for $M \in \mathbb{N}$

$$\begin{aligned} &\mathbb{E}\left(\int_M^\infty e^{-\alpha t} k(X^x(t), v(X^x(t)))dt\right) \\ &\quad = \sum_{n=M}^\infty \mathbb{E}\left(\mathbb{E}\left(\int_n^{n+1} e^{-\alpha t} k(X^x(t), v(X^x(t)))dt \mid \mathcal{F}_n^X\right)\right) \\ &\quad = \sum_{n=M}^\infty \hat{\alpha}^n \mathbb{E}(\hat{k}_\alpha(X_n^x, \varrho_v(X_n^x))), \end{aligned} \tag{4.5}$$

where $\mathcal{F}_n^X \doteq \sigma\{X(s) : 0 \le s \le n\}$ and $X_n^x \doteq X^x(n)$.

Note that $\{X_n^x\}$ is a controlled Markov chain with control set $\hat{\Phi}$, Markov control ϱ_v, and (controlled) transition probability kernel $\hat{p}(x_1, \phi, dy_1)$ given as follows:

$$\int_G f(y)\hat{p}(x, \phi, dy) \doteq \mathbb{E}(f(\xi)), \quad x \in G,\ f \in BM(G),\ \phi \in \hat{\Phi}, \tag{4.6}$$

where $\xi \doteq X(1)$ and $X(\cdot)$ is given via (1.1) with $X(0) \equiv x$ and the control pair $(u(t), W(t))_{0 \le t \le 1}$ having the probability law ϕ.

We now introduce a Lyapunov function for the controlled Markov chain $\{X_n^x\}$. This Lyapunov function was constructed in [2].

THEOREM 4.4 (see [2]). *There exists a function $F : G \to \mathbb{R}$ such that it is twice continuously differentiable on $G \setminus \{0\}$ and such that the following hold.*

(a) *There exist $c_1, c_2 \in (0, \infty)$ such that $c_1|x| \le F(x) \le c_2|x|$ for all $x \in G$.*

(b) *For all $\epsilon > 0$ there exists $M \in (0, \infty)$ such that $(x \in G,\ |x| \ge M)$ implies $\|D^2F(x)\| \le \epsilon$.*

(c) *There exists $c \in (0, \infty)$ such that $Df(x) \cdot r \le -c$, for $r \in \mathcal{C}(\delta)$ and $x \in G \setminus \{0\}$, and $Df(x) \cdot d \le -c$, for $d \in d(x)$ and $x \in \partial G \setminus \{0\}$.*

(d) *There exists* $L \in (0,\infty)$ *such that* $\sup_{x\in G}|Df(x)| \le L$.

The following theorem is an immediate consequence of the above theorem. For the sake of completeness we include a sketch in the appendix.

THEOREM 4.5. *There exist* $c_0, \ell_0, M_0 \in (0,\infty)$ *such that for any admissible pair* $(u(\cdot), W(\cdot))$ *on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$, $x \in G$, *and* $X^x(\cdot)$ *given by* (1.1), *we have that*

$$\mathbb{E}(F(X^x_{n+1}) \mid \mathcal{F}_n) - F(X^x_n) \le -c_0 1_{X^x_n \in B^c} + M_0 1_{X^x_n \in B}, \tag{4.7}$$

where $B \doteq \{x \in G \mid |x| \le \ell_0\}$ *and* $X^x_n \doteq X^x(n)$.

We now introduce a controlled probability transition kernel on $H \doteq G \times G$, with control set $\hat{\Phi} \times \hat{\Phi}$ defined as follows. For $\overline{x} \equiv (x_1, x_2) \in H$ and $\overline{\phi} \equiv (\phi_1, \phi_2) \in \hat{\Phi} \times \hat{\Phi}$, let $\overline{p}(\overline{x}, \overline{\phi}, d\overline{y}) \in \mathcal{P}(H)$ be defined as

$$\overline{p}(\overline{x}, \overline{\phi}, d\overline{y}) \doteq \hat{p}(x_1, \phi_1, dy_1)\hat{p}(x_2, \phi_2, dy_2). \tag{4.8}$$

Let v be a Markov control and for $x_1, x_2 \in G$, let $X^{x_i}(\cdot)$ be given via (2.3) with $X^{x_i}(0) \equiv x_i$ and driving Wiener process $W^{(i)}$, $i = 1, 2$. The Wiener processes $W^{(1)}$ and $W^{(2)}$ are taken to be independent of each other. Denote $X^{x_i}(n)$ by $X^{x_i}_n$. It is easy to see that if $\overline{x} \doteq (x_1, x_2)$, then $\{\overline{X}^{\overline{x}}_n\} \doteq \{(X^{x_1}_n, X^{x_2}_n)\}$ is an H valued controlled Markov chain, starting at $\overline{x}$, with the controlled probability transition kernel $\overline{p}(\overline{x}, \phi, d\overline{y})$ and the Markov control $\overline{\varrho}_v(\overline{x}) \equiv (\varrho_v(x_1), \varrho_v(x_2))$. Also, as noted earlier, for $i = 1, 2$, $X^{x_i}_n$ is a G valued controlled Markov chain, starting at x_i, with the controlled probability transition kernel $\hat{p}(x, \phi, dy)$ and the Markov control ϱ_v.

The pseudoatom construction. We will now proceed, as in [5], to adapt the Athreya–Ney–Nummelin construction of a pseudoatom to the current problem. Let $H \doteq G \times G$ and B be as in the statement of Theorem 4.5. Define $B^* \doteq B \times B$ and let $H^* \doteq H \times \{0, 1\} = G \times G \times \{0, 1\}$.

Let λ denote the Lebesgue measure on G. Define $\nu \in \mathcal{P}(H)$ as

$$\nu(A) \doteq \frac{(\lambda \times \lambda)(A \cap B^*)}{(\lambda(B))^2}. \tag{4.9}$$

Using the uniform nondegeneracy of the diffusion coefficient in (1.1), it follows that there exists $0 < \delta^* < 1$ such that

$$\overline{p}(x, \phi, A) \ge \delta^* 1_{B^*}(x)\nu(A), \quad \forall x \in H,\ A \in \mathcal{B}(H),\ \phi \in \hat{\Phi} \times \hat{\Phi}. \tag{4.10}$$

For a set $A \in \mathcal{B}(H)$ we let $A_0 \doteq A \times \{0\}$ and $A_1 \doteq A \times \{1\}$. For every $\mu \in \mathcal{P}(G \times G)$ we define a $\mu^* \in \mathcal{P}(H^*)$ as follows. For $A \in \mathcal{B}(H)$

$$\begin{aligned} \mu^*(A_0) &\doteq (1 - \delta^*)\mu(AB^*) + \mu(A(B^*)^c), \\ \mu^*(A_1) &\doteq \delta^* \mu(AB^*). \end{aligned} \tag{4.11}$$

Clearly, $\mu^*(A_0) + \mu^*(A_1) = \mu(A)$ and if $A \subset (B^*)^c$, then $\mu^*(A_0) = \mu(A)$.

Define $\varrho^*_v : H^* \to \hat{\Phi} \times \hat{\Phi}$ as follows. For $(x_1, x_2, i) \in H^*$, $\varrho^*_v(x_1, x_2, i) \doteq \overline{\varrho}_v(x_1, x_2)$. On a suitable probability space $(\Omega^*, \mathcal{F}^*, P^*)$, define an H^* valued controlled Markov chain $Z_n \equiv (X^*_n, i^*_n)$, where $X^*_n \equiv (X^{1,*}_n, X^{2,*}_n)$, with the control set $\hat{\Phi} \times \hat{\Phi}$ and the Markov control ϱ^*_v such that:

(1) The controlled transition kernel of Z_n is given as follows. For $\overline{z} \equiv (z,i) \in H^*$ and $\overline{\phi} \in \hat{\Phi} \times \hat{\Phi}$

$$q(\overline{z},\overline{\phi},d\overline{y}) = \begin{cases} \overline{p}^*(z,\overline{\phi},dy) & \text{if } \overline{z} \in H_0 \setminus B_0^*, \\ \dfrac{1}{1-\delta^*}(\overline{p}^*(z,\overline{\phi},dy) - \delta^*\nu^*(d\overline{y})) & \text{if } \overline{z} \in B_0^*, \\ \nu^*(d\overline{y}) & \text{if } \overline{z} \in H_1, \end{cases} \tag{4.12}$$

where $\overline{y} \equiv (y,j) \in H^*$.

(2) The initial distributions are given as follows. For $A \in \mathcal{B}(H)$

$$P^*(Z_0 \in A_0) \doteq ((1-\delta^*)1_{AB^*}(\overline{x}) + 1_{A(B^*)^c}(\overline{x})),$$
$$P^*(Z_0 \in A_1) \doteq \delta^* 1_{AB^*}(\overline{x}).$$

The above construction assures that the probability laws of $\{X_n^*, \varrho_v^*(X_n^*)\}_{n\in\mathbb{N}_0}$ and $\{\overline{X_n^{\overline{x}}}, \overline{\varrho}_v(\overline{X_n^{\overline{x}}})\}_{n\in\mathbb{N}_0}$ are the same. Using the Lyapunov function in (4.4) one can now show, in a similar manner as in Lemma 3.3 of [5], that the hitting time of B_1^* by the controlled Markov chain $\{Z_n\}$ has finite moments of all orders. Stability properties of the underlying (controlled) Markov processes using the Foster-type drift criterion in (4.7) are quite well studied in the literature. For example, [19] obtained functional central limit theorems for Markov processes and gives conditions under which the invariant distribution is a continuous function of its transition kernel. In [30], using Foster–Lyapunov inequalities the authors obtained criteria for Harris recurrence, ergodicity, and geometric ergodicity for general Right processes in terms of the underlying extended generator. See also [31] for more on regularity properties of Markov processes that follow from such a drift criterion. The following theorem is another standard consequence of the drift inequality (4.7) and thus we omit the proof.

THEOREM 4.6. *Let*

$$\tau(x_1,x_2) \doteq \inf\{n \in \mathbb{N}_0 : Z_n \in B_1^*\}.$$

Then there exists an $r \in (1,\infty)$ *such that for every* $M_0 \in (0,\infty)$,

$$\sup_{x_i\in G;\, |x_i|\le M_0;\, i=1,2} \sup \mathbb{E}^*(r^{\tau(x_1,x_2)}) < \infty,$$

where the inner supremum is taken over all Markov controls v.

The main idea in the proof is to show that one can find a small enough $\delta_0 \in (0,\infty)$ such that $\mathcal{V}(y) \doteq e^{\delta_0 F(y)}$, $y \in G$ satisfies the geometric drift condition (V4) of section 15.2.2 of [29]. (See Theorem 16.3.1 of [29].) Then define $\overline{\mathcal{V}} : H^* \to \mathbb{R}_+$ as $\overline{\mathcal{V}}(x_1,x_2,i) \doteq \mathcal{V}(x_1) + \mathcal{V}(x_2)$, where $(x_1,x_2,i) \in H^*$. And, for $n \in \mathbb{N}_0$, setting $\Gamma_n^* \doteq \sigma(X_m^*, i_m^*;\ m \le n)$, one can check that

$$\mathbb{E}^*(\overline{\mathcal{V}}(Z_{n+1}) \mid \Gamma_n^*) - \overline{\mathcal{V}}(Z_n) \le -\beta\overline{\mathcal{V}}(Z_n) + 2b$$

for some $\beta \in (0,1)$ and $b \in (0,\infty)$. The result now follows from Theorem 15.2.5 of [29].

We now prove Proposition 4.3.

Proof of Proposition 4.3. Let v be a Markov control and let $x_1, x_2 \in E_{M_0}$. Using the discrete time embedding introduced above, one has that

$$\left|\mathbb{E}\int_M^\infty e^{-\alpha s}k(X^{x_1}(s), v(X^{x_1}(s)))ds - \mathbb{E}\int_M^\infty e^{-\alpha s}k(X^{x_2}(s), v(X^{x_2}(s)))ds\right|$$

can be rewritten as

$$\left|\sum_{n=M}^{\infty}\hat{\alpha}^n\mathbb{E}(\hat{k}_\alpha(X_n^{x_1},\varrho_v(X_n^{x_1}))-\hat{k}_\alpha(X_n^{x_2},\varrho_v(X_n^{x_2})))\right|.$$

From the pseudoatom construction we have that $\{(X_n^{x_1},X_n^{x_2})\}_{n\in\mathbb{N}_0}$ has the same probability law as $\{(X_n^{1,*},X_n^{2,*})\}_{n\in\mathbb{N}_0}$. Thus the expression in the above display is the same as

$$\left|\sum_{n=M}^{\infty}\hat{\alpha}^n\mathbb{E}^*(\hat{k}_\alpha(X_n^{1,*},\varrho_v(X_n^{1,*}))-\hat{k}_\alpha(X_n^{2,*},\varrho_v(X_n^{2,*})))\right|.$$

Let $\tau\equiv\tau(x_1,x_2)$ be as in Theorem 4.6. Then the above expression can be written as

$$\begin{aligned}&\left|\sum_{n=M}^{\infty}\hat{\alpha}^n\mathbb{E}^*1_{\tau<n}(\hat{k}_\alpha(X_n^{1,*},\varrho_v(X_n^{1,*}))-\hat{k}_\alpha(X_n^{2,*},\varrho_v(X_n^{2,*})))\right|\\&\quad+\left|\sum_{n=M}^{\infty}\hat{\alpha}^n\mathbb{E}^*1_{\tau\geq n}(\hat{k}_\alpha(X_n^{1,*},\varrho_v(X_n^{1,*}))-\hat{k}_\alpha(X_n^{2,*},\varrho_v(X_n^{2,*})))\right|\\&\equiv T_1+T_2.\end{aligned}$$

Observing that for $m\in\mathbb{N}$, $X_{\tau+m}^{1,*}$ and $X_{\tau+m}^{2,*}$ have the same conditional law given Γ_τ^*, we have that $T_1=0$. Next, using the boundedness of $\hat{k}_\alpha$ we have that $T_2\leq\kappa\mathbb{E}^*(\tau-M)^+$ for a suitable constant κ. Note that $\kappa\mathbb{E}^*(\tau-M)^+$ can be bounded above by $\kappa\sup\frac{\mathbb{E}^*(\tau^2)}{M}$, where the supremum is taken over all $x_1,x_2\in E_{M_0}$ and Markov controls v. Combining the above observations we have that $\Psi(M,M_0)$ is bounded above by $\kappa\sup\frac{\mathbb{E}^*(\tau^2)}{M}$. The result now follows from Theorem 4.6. □

As an immediate consequence of the above proposition we have the following result.

THEOREM 4.7. *The family* $\{\overline{V}_\alpha(\cdot):\ \alpha\in(0,1)\}$ *is precompact in* $C(G)$.

Proof. Fix $M_0\in(0,\infty)$ and let $\delta>0$ be arbitrary. From Proposition 4.3 we can find $M\in\mathbb{N}$ large enough so that $\Psi(M,M_0)<\frac{\delta}{2}$. Next, from Theorem 4.2 find ϵ small enough so that $\Lambda(\epsilon,M,M_0)<\frac{\delta}{2}$. Using these bounds in (4.3) we have that for all $x_1,x_2\in E_{M_0}$ with $|x_1-x_2|\leq\epsilon$ and $\alpha\in(0,\infty)$, $|V_\alpha(x_1)-V_\alpha(x_2)|\leq\delta$. Since δ and M_0 are arbitrary, the result follows. □

Remark 4.8. By imitating the proof of Lemma 3.4 of [5] one can show that there is a $\varsigma\in(0,\infty)$ such that for $x\in G$

$$\begin{aligned}|\overline{V}_\alpha(x)|&\leq\varsigma F(x)\\&\leq\varsigma c_2|x|,\end{aligned}$$

where the last inequality follows from Theorem 4.4. This shows that if $V(\cdot)$ is any limit point of $\overline{V}_\alpha(\cdot)$, then $|V(x)|\leq\varsigma c_2|x|$ for all $x\in G$.

5. The HJB equation for the ergodic control problem. Let V_α and $\overline{V}_\alpha$ be as in the previous section. From (1.3) and the boundedness of k it follows that $\sup_{\alpha\in(0,1)}\alpha V_\alpha(0)<\infty$. This, along with Theorem 4.7, implies that there exists a sequence $\alpha_n\to0$ as $n\to\infty$ and $\rho\in(0,\infty)$, $V\in C(G)$ such that

$$\lim_{n\to\infty}\alpha_nV_{\alpha_n}(0)=\rho,\quad\lim_{n\to\infty}\overline{V}_{\alpha_n}=V,\tag{5.1}$$

where the second limit is taken uniformly on compact sets of G.

For $\rho^* \in [0,\infty)$, consider the following equation:

$$\begin{aligned} \inf_{u\in U}(L\psi(x,u)+k(x,u)-\rho^*) &= 0, \quad x\in G, \\ \langle \nabla\psi(x), d_i\rangle &= 0, \quad x\in \partial G,\ i\in \mathrm{In}(x). \end{aligned} \tag{5.2}$$

A viscosity solution to the above equation is defined in a similar manner as that defined for (1.5) in Definition 3.3. We begin with the following result.

THEOREM 5.1. *Let (V,ρ) be given via* (5.1). *Then V is a viscosity solution to* (5.2) *with $\rho^* = \rho$.*

Proof. The proof is a slight variation of the arguments in [25], [4]. Let $F : G\times\mathbb{R}\times\mathbb{R}^k\times S^k \to \mathbb{R}$ be defined as

$$F(x,r,p,M) \doteq -\frac{1}{2}\,\mathrm{Tr}(aM) + \rho - \inf_{u\in U}\{\langle b(x,u),p\rangle + k(x,u)\}. \tag{5.3}$$

Define F_* and F^* as maps from $G\times\mathbb{R}\times\mathbb{R}^k\times S^k$ to $\mathbb{R}$ via (3.4) and (3.5), with F_α there replaced by F. Fix $x_0\in G$ and let $\psi\in C^2(G)$ be such that x_0 is a strict maximum point of $V-\psi$. We would like to show that

$$F_*(x_0, V(x_0), (D\psi)(x_0), (D^2\psi)(x_0)) \le 0. \tag{5.4}$$

Define $V_n(\cdot) \doteq V_{\alpha_n}(\cdot)$, $\overline{V}_n(\cdot) \doteq \overline{V}_{\alpha_n}(\cdot)$, and $F_n(\cdot) \doteq F_{\alpha_n}(\cdot)$. Using the fact that $\overline{V}_n$ converges to V uniformly on compacts, we can find an $N_0\in(0,\infty)$ and a sequence $\{x_n\}\subset G$ such that $x_n\to x_0$ and x_n is a local maximum of $V_n(\cdot)-\psi(\cdot)$ for all $n\ge N_0$. From Theorem 3.4 we then have that

$$F_n(x_n, V_n(x_n), (D\psi)(x_n), (D^2\psi)(x_n)) \wedge \min\{-\langle D\psi(x_n), d_i\rangle;\ i\in \mathrm{In}(x_n)\} \le 0. \tag{5.5}$$

Define $\tilde{F}_n : G\times\mathbb{R}\times\mathbb{R}^k\times S^k\to\mathbb{R}$ as

$$\tilde{F}_n(x,r,p,M) \doteq -\frac{1}{2}\,\mathrm{Tr}(aM) + \alpha_n r - \alpha_n V_n(0) - \inf_{u\in U}\{\langle b(x,u),p\rangle + k(x,u)\}. \tag{5.6}$$

Then from (5.5) we have that

$$\tilde{F}_n(x_n, \overline{V}_n(x_n), (D\psi)(x_n), (D^2\psi)(x_n)) \wedge \min\{-\langle D\psi(x_n), d_i\rangle;\ i\in \mathrm{In}(x_n)\} \le 0. \tag{5.7}$$

Next note that, as $n\to\infty$, $x_n\to x_0$, $\overline{V}_n(x_n)\to V(x_0)$, $(D\psi)(x_n)\to(D\psi)(x_0)$, and $(D^2\psi)(x_n)\to(D\psi)(x_0)$. Furthermore, since as $n\to\infty$, $\tilde{F}_n(\cdot)\to F(\cdot)$ uniformly on compacts, we have that

$$\tilde{F}_n(x_n, \overline{V}_n(x_n), (D\psi)(x_n), (D^2\psi)(x_n)) \to F(x_0, V(x_0), (D\psi)(x_0), (D^2\psi)(x_0)).$$

Also the lower semicontinuity property of $\mathrm{In}(\cdot)$ implies that

$$\min\{-\langle D\psi(x_0), d_i\rangle;\ i\in \mathrm{In}(x_0)\} \le \liminf_{n\to\infty} \min\{-\langle D\psi(x_n), d_i\rangle;\ i\in \mathrm{In}(x_n)\}.$$

Using the above two displays in (5.5) we have (5.4).

In a similar manner one shows that for all $x_0\in G$ and $\psi\in C^2(G)$, such that x_0 is a strict maximum point of $V-\psi$, we have that

$$F^*(x_0, V(x_0), (D\psi)(x_0), (D^2\psi)(x_0)) \ge 0.$$

This proves the result. ∎

We now characterize the value of the ergodic cost problem via the solution of (5.2). We will denote the right-hand side of (2.7) by $\overline{\rho}$.

THEOREM 5.2. *Let $(V(\cdot),\rho)$ be a solution of* (5.2). *Then $\rho=\overline{\rho}$.*

Proof. We begin by noting that, for all $r\in(0,\infty)$, $V(\cdot)$ is a viscosity solution of

$$\begin{aligned}\inf_{u\in U}\left((L-r)\psi(x,u)+k(x,u)-\rho+rV(x)\right)=0,\quad x\in G,\\ \langle\nabla\psi(x),d_i\rangle=0,\quad x\in\partial G,\ i\in \mathrm{In}(x).\end{aligned}\tag{5.8}$$

This, in view of Theorem 3.7, implies that for all $x\in G$

$$V(x)=\inf\mathbb{E}\left(\int_0^\infty e^{-rt}(k(X^x(t),u(t))-\rho+rV(X^x(t)))dt\right),\tag{5.9}$$

where the infimum is taken over all admissible pairs $(u(\cdot),W(\cdot))$.

From the proof of Lemma 4.5 of [3] it follows that for all $M\in(0,\infty)$

$$\sup_{x\in G,\,|x|\le M,\,(u(\cdot),W(\cdot))\text{ admissible}}\ \sup_{t\in[0,\infty)}\mathbb{E}|X^x(t)|<\infty,\tag{5.10}$$

where $X^x(\cdot)$ is given as a solution of (1.1) with $X(0)\equiv x$ and the control pair $(u(\cdot),W(\cdot))$. From this bound it follows via a slight modification of the proof of Lemma 6.4 of [10] that

$$\sup_v\int_G|x|\eta_v(dx)<\infty,$$

where the supremum is taken over all Markov controls.

Next let $\overline{v}:G\to U$ be as in Theorem 2.10 and let $\eta_{\overline{v}}$ be as in Theorem 2.9. Then, in view of the above observation and Remark 4.8, we have that

$$\begin{aligned}r\int_G V(x)\eta_{\overline{v}}(dx)+\rho&\le r\int_G\left(\mathbb{E}\left(\int_0^\infty e^{-rt}(k(X^x(t),\overline{v}(X^x(t)))+rV(X^x(t)))dt\right)\right)\eta_{\overline{v}}(dx)\\&=\int_G k(x,\overline{v}(x))\eta_{\overline{v}}(dx)+r\int_G V(x)\eta_{\overline{v}}(dx).\end{aligned}$$

Thus we have that

$$\rho\le\int_G k(x,\overline{v}(x))\eta_{\overline{v}(dx)}=\overline{\rho},\tag{5.11}$$

where the last equality follows from Theorem 2.10.

Now we prove the reverse inequality. Let $(u^r(\cdot),W^r(\cdot))$ be an admissible control which is optimal for the cost function in (5.9). The existence of such a control follows via the usual compactness arguments (cf. Chapter 2 of [7]). We denote by $X^r(\cdot)$ the process defined via (1.1) with $X_0\equiv x$ and $(u(\cdot),W(\cdot))$ there replaced by $(u^r(\cdot),W^r(\cdot))$. Then for all $T\ge0$

$$V(x)=\mathbb{E}\left(\int_0^T e^{-rs}(k(X^r(t),u^r(t))-\rho+rV(X^r(t)))dt+e^{-rT}V(X^r(T))\right).\tag{5.12}$$

By picking a subsequence if necessary, we can assume, without loss of generality, that as $r\to0$, $(u^r(\cdot),W^r(\cdot),X^r(\cdot))$ converge weakly to some $(u^*(\cdot),W^*(\cdot),X^*(\cdot))$, where $u^*(\cdot)$, $W^*(\cdot)$ is an admissible pair and X^* is the corresponding controlled diffusion

starting at x. Using the continuity and boundedness of V and k, we then have by taking the limit as $r \to 0$ in (5.12) that

$$V(x) = \mathbb{E}\bigg(\int_0^T (k(X^*(t), u^*(t)) - \rho)dt + V(X^*(T)) \bigg).$$

Dividing by T and taking the limit as $T \to \infty$, we have, on recalling that $V(z) \le \varsigma c_2 |z|$ for all $z \in G$ and using (5.10), that

$$\rho = \lim_{T\to\infty} \frac{1}{T} \mathbb{E}\bigg(\int_0^T k(X^*(t), u^*(t))dt \bigg) \ge \overline{\rho},$$

where the last inequality once more follows from Theorem 2.10. Combining the above display with (5.11), we have the result. □

As an immediate consequence of the above, we have the following result which is proved exactly in the same way as Theorem 4.4 of [4].

THEOREM 5.3. *(V, ρ) given via (5.1) is the unique viscosity solution of (5.2) satisfying $V(0) = 0$ and the linear growth condition $|V(x)| \le c|x|$ for some $c \in (0, \infty)$.*

Appendix. In this section we sketch the proofs of Theorems 3.6, 4.2, and 4.5. We begin with Theorem 3.6. The proof is essentially taken from [17]; however, we reproduce it here for the reader's convenience. We begin with the following lemma, which is Lemma 3.1 of [17].

LEMMA A.1. *Let $u \in USC(G)$ and let $v \in LSC(G)$. Define $w \in USC(G \times G)$ by $w(x, y) = u(x) - v(y)$. For $x \in G$ and a real valued function f on G, define*

$$D^+ f(x) \doteq \{p \in \mathbb{R}^k : f(x + h) \le f(x) + \langle p, h\rangle + o(|h|) \text{ for } x + h \in G \text{ and as } h \to 0\},$$
$$D^- f(x) \doteq \{p \in \mathbb{R}^k : f(x + h) \ge f(x) + \langle p, h\rangle + o(|h|) \text{ for } x + h \in G \text{ and as } h \to 0\},$$
$$D^{2,+} f(x) \doteq \bigg\{ (p, A) \in \mathbb{R}^k \times S^k : f(x + h) \le f(x) + \langle p, h\rangle + \frac{1}{2}\langle Ah, h\rangle + o(|h|^2) \text{ for } x + h \in G \text{ and as } h \to 0 \bigg\}$$

and

$$D^{2,-} f(x) \doteq \bigg\{ (p, A) \in \mathbb{R}^k \times S^k : f(x + h) \ge f(x) + \langle p, h\rangle + \frac{1}{2}\langle Ah, h\rangle + o(|h|^2) \text{ for } x + h \in G \text{ and as } h \to 0 \bigg\}.$$

Also define $\overline{D}^{2,+} f(x)$ as the set of points $(r, p, A) \in \mathbb{R} \times \mathbb{R}^k \times S^k$ for which there is a sequence $\{(x_n, p_n, A_n)\} \subset G \times \mathbb{R}^k \times S^k$ such that $(p_n, A_n) \in D^{2,+} f(x_n)$ and such that $x_n \to x$, $u(x_n) \to r$, $p_n \to p$, and $A_n \to A$ as $n \to \infty$. Similarly define $\overline{D}^{2,-} f(x)$. Let $\alpha, \beta > 0$, $p, q \in \mathbb{R}^n$, and $x, y \in G$. Assume that

$$\bigg(p, q, \alpha \begin{pmatrix} I & -I \\ -I & I \end{pmatrix} + \beta \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \bigg) \in D^{2,+} w(x, y).$$

Then there are $X, Y \in S^k$ for which

$$-C\alpha \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \le \begin{pmatrix} X - \beta I & 0 \\ 0 & Y - \beta I \end{pmatrix} \le C\alpha \begin{pmatrix} I & -I \\ -I & I \end{pmatrix}$$

and

$$(u(x), p, X) \in \overline{D}^{2,+}u(x) \quad \textit{and} \quad (v(y), -q, -Y) \in \overline{D}^{2,-}v(y),$$

where $C \in (1, \infty)$ *is an absolute constant.*

Proof of Theorem 3.6. As stated above in Theorem 3.6, the proof that $V^n(\cdot)$ defined via (3.13) is a viscosity solution of (3.5) follows exactly as the proof of Theorem 3.4. Now let $V_1(\cdot)$ and $V_2(\cdot)$ be two viscosity solutions of (3.5). Let g be as in Lemma 4.2 of [10] (cf. (3.2)). For $\gamma, \beta \in (0, \infty)$ define

$$V_{\gamma\beta}(x) \doteq V_1(x) - \gamma g(x) + \beta \quad \text{and} \quad U_{\gamma\beta}(x) \doteq V_2(x) - \gamma g(x) - \beta, \quad x \in G.$$

Define $\tilde{F}_{\alpha,*}$ and $\tilde{F}^*_\alpha$ as maps from $G \times \mathbb{R} \times \mathbb{R}^k \times S^k$ to $\mathbb{R}$, via (3.4) and (3.5), respectively, by replacing the set $\{-\langle d_i, p\rangle;\ i \in \mathrm{In}(x)\}$ in (3.4) by the set $\{-\langle d_i, p\rangle + \gamma;\ i \in \mathrm{In}(x)\}$ and in (3.5) by the set $\{-\langle d_i, p\rangle - \gamma;\ i \in \mathrm{In}(x)\}$. Then as in Theorem 2.1 of [17], to every $\beta \in (0, \infty)$ there exists a $\gamma \equiv \gamma(\beta) \le \beta$ in $(0, \infty)$ such that

$$\tilde{F}_{\alpha,*}(x, U_{\gamma,\beta}(x), p, A) \le 0 \quad \text{for } x \in G \text{ and } (p, A) \in D^{2,+}U_{\gamma,\beta}(x), \tag{A.1}$$

$$\tilde{F}^*_\alpha(x, V_{\gamma,\beta}(x), p, A) \ge 0 \quad \text{for } x \in G \text{ and } (p, A) \in D^{2,-}V_{\gamma,\beta}(x). \tag{A.2}$$

Now fix a β and the corresponding γ in $(0, \infty)$. Suppose that

$$\kappa_0 \doteq \max_{x \in \overline{G} \cap B_n} (U_{\gamma\beta}(x) - V_{\gamma\beta}(x)) > 0. \tag{A.3}$$

Then noting that $U_{\gamma\beta}(x) - V_{\gamma\beta}(x) \le 0$ for all $x \in \partial B_n$, it follows through standard maximum principle arguments that

$$\kappa_0 = (U_{\gamma\beta}(z) - V_{\gamma\beta}(z)) \quad \text{for some } z \in \partial G \cap B_n. \tag{A.4}$$

We now show that (A.4) leads to a contradiction.

Let F be as in (3.3). Then by using the boundedness and Lipschitz property of the coefficients one can show that the following hold.

- There is a function $m_1 \in C([0, \infty))$ satisfying $m_1(0) = 0$ such that for all $\theta_0 \ge 1$, $x, y \in G \cap \overline{B}_n$, $r \in \mathbb{R}$, $P \in \mathbb{R}^k$, and $X, Y \in S^k$,

$$F_\alpha(y, r, p, -Y) - F_\alpha(x, r, p, X) \le m_1(|x - y|(|p| + 1) + \theta_0|x - y|^2)$$

whenever

$$-\theta_0 \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \le \begin{pmatrix} X & 0 \\ 0 & Y \end{pmatrix} \le \theta_0 \begin{pmatrix} I & -I \\ -I & I \end{pmatrix}.$$

- There is a neighborhood U of ∂G in $G \cap \overline{B}_n$ and a function $m_2 \in C([0, \infty))$ satisfying $m_2(0) = 0$ for which

$$|F(x, r, p, X) - F(x, r, q, Y)| \le m_2(|p - q| + \|X - Y\|) \tag{A.5}$$

for $x \in U$, $r \in \mathbb{R}$, $p, q \in \mathbb{R}^k$, and $X, Y \in S^k$.

Clearly, we can find an open neighborhood V of z (which is as small as we want) such that

$$\mathrm{In}(x) \subset \mathrm{In}(z) \quad \text{for } x \in V \cap \partial G,\ V \cap G \subset U, \tag{A.6}$$

and

$$\langle y-x, n_i\rangle \le \theta|x-y| \quad \text{for } i\in \mathrm{In}(z),\ x\in V\cap G_i, \text{ and } y\in V\cap \partial G_i. \tag{A.7}$$

Also, from Theorem 4.1 of [17] we can find a family $\{w_\epsilon\}_{\epsilon>0}$ of continuous functions on $\overline{V}\times\overline{V}$ and a positive constant θ having the following property: For any $\epsilon>0$ and $x,y\in V$, there are $p\equiv p(\epsilon,x,y), q\equiv q(\epsilon,x,y)\in\mathbb{R}^k$ such that for all $i\in \mathrm{In}(z)$, the following hold (cf. equations (3.15)–(3.19) of [17]):

$$w_\epsilon(x,x)=0, \qquad w_\epsilon(x,y)\ge \theta\frac{|x-y|^2}{\epsilon}, \tag{A.8}$$

$$\langle d_i, p\rangle \ge -\frac{|x-y|^2}{\epsilon} \quad \text{if } \langle y-x,n_i\rangle \ge -\theta|x-y|, \tag{A.9}$$

$$\langle d_i, q\rangle \ge -\frac{|x-y|^2}{\epsilon} \quad \text{if } \langle y-x,n_i\rangle \le \theta|x-y|, \tag{A.10}$$

$$|p+q|\le \frac{|x-y|^2}{\epsilon}, \quad |q|\le \frac{|x-y|}{\epsilon}, \tag{A.11}$$

and

$$\left(p, q, \frac{1}{\epsilon}\begin{pmatrix} I & -I\\ -I & I\end{pmatrix} + \frac{|x-y|^2}{\epsilon}\begin{pmatrix} I & 0\\ 0 & I\end{pmatrix}\right)\in D^{2,+}w_\epsilon(x,y). \tag{A.12}$$

Henceforth, we will write $U_{\gamma,\beta}$ as u and $V_{\gamma,\beta}$ as v. Now fix $\delta>0$ and define $\tilde{u}\in USC(G)$ by

$$\tilde{u}(x)\doteq u(x)-\frac{\delta}{2}|x-z|^2. \tag{A.13}$$

Clearly, z is the unique maximum point of $\tilde{u}-v$. Fix $\epsilon>0$ and define $\phi\in USC([\overline{V}\cap G]\times[\overline{V}\cap G])$ by

$$\phi(x,y)\doteq \tilde{u}(x)-v(y)-w_\epsilon(x,y).$$

Let $(\overline{x},\overline{y})\equiv(\overline{x}(\epsilon),\overline{y}(\epsilon))\in[\overline{V}\cap G]\times[\overline{V}\cap G]$ be a maximum point of ϕ. Then it follows exactly as in [17] (cf. equation (3.23) of that paper) that as $\epsilon\to 0$,

$$\frac{|\overline{x}-\overline{y}|^2}{\epsilon}\to 0, \quad \overline{x},\,\overline{y}\to z, \quad \tilde{u}(\overline{x})\to\tilde{u}(z), \quad \text{and} \quad v(\overline{y})\to v(z). \tag{A.14}$$

Now let ϵ be small enough so that $\overline{x},\overline{y}\in V$. Define $w(x,y)\doteq\tilde{u}(x)-v(y)$, $x,y\in G$. Let $p\doteq p(\epsilon,\overline{x},\overline{y})$, $q\doteq q(\epsilon,\overline{x},\overline{y})$. From (A.12) it follows that

$$\left(p, q, \frac{1}{\epsilon}\begin{pmatrix} I & -I\\ -I & I\end{pmatrix} + \frac{|\overline{x}-\overline{y}|^2}{\epsilon}\begin{pmatrix} I & 0\\ 0 & I\end{pmatrix}\right)\in D^{2,+}w_\epsilon(\overline{x},\overline{y})\subset D^{2,+}w(\overline{x},\overline{y}),$$

where the last inclusion follows on noting that $(\overline{x},\overline{y})$ is the maximum point of ϕ. Hereafter, denote $\frac{|\overline{x}-\overline{y}|^2}{\epsilon}$ by κ. From Lemma A.1 one can find matrices $X,Y\in S^k$ such that

$$-\frac{C}{\epsilon}\begin{pmatrix} I & 0\\ 0 & I\end{pmatrix}\le\begin{pmatrix} X & 0\\ 0 & Y\end{pmatrix}\le\frac{C}{\epsilon}\begin{pmatrix} I & -I\\ -I & I\end{pmatrix}+C\kappa\begin{pmatrix} I & 0\\ 0 & I\end{pmatrix}$$

and

$$(\tilde{u}(\overline{x}), p, X) \in \overline{D}^{2,+}\tilde{u}(\overline{x}) \quad \text{and} \quad (v(\overline{y}), -q, -Y) \in \overline{D}^{2,-}v(\overline{y}), \tag{A.15}$$

where C is as in Lemma A.1.

Using (A.13) one has that

$$(u(\overline{x}), p + \delta(\overline{x} - z), X + \delta I) \in \overline{D}^{2,+}u(\overline{x}). \tag{A.16}$$

Also, using (A.14) we have that for ϵ small enough and $i \in \mathrm{In}(z)$

$$\langle d_i, p + \delta(\overline{x} - z)\rangle + \gamma \geq \langle d_i, p\rangle + \frac{\gamma}{2}. \tag{A.17}$$

Using (A.9), (A.10), and (A.14) we have that for $i \in \mathrm{In}(z)$ and small enough ϵ

$$\langle d_i, p\rangle + \frac{\gamma}{2} > 0 \quad \text{if } \overline{x} \in \partial G_i, \quad \text{and} \quad -\langle d_i, q\rangle - \frac{\gamma}{2} < 0 \quad \text{if } \overline{y} \in \partial G_i. \tag{A.18}$$

From (A.6) we have that

$$V \cap \partial G \subset \bigcup_{i \in \mathrm{In}(z)} \partial G_i. \tag{A.19}$$

Combining (A.19), (A.18), and (A.17) we have that, for small enough ϵ,

$$\begin{aligned} &\langle d_i, p + \delta(\overline{x} - z)\rangle + \gamma > 0 \quad \text{if } \overline{x} \in \partial G \text{ and } i \in \mathrm{In}(\overline{x}) \quad \text{and} \\ &\langle d_i, -q\rangle - \gamma < 0 \quad \text{if } \overline{y} \in \partial G \text{ and } i \in \mathrm{In}(\overline{y}). \end{aligned} \tag{A.20}$$

This, along with (A.1), (A.2), (A.16), (A.15), shows that we can find $\epsilon_\delta \in (0, \infty)$ such that for all $0 \leq \epsilon \leq \epsilon_\delta$

$$F_\alpha(\overline{x}, u(\overline{x}), p + \delta(\overline{x} - z), X + \delta I) \leq 0 \leq F_\alpha(\overline{y}, v(\overline{y}), -q, -Y).$$

Thus we have that

$$\begin{aligned} 0 &\geq F_\alpha(\overline{x}, u(\overline{x}), p + \delta(\overline{x} - z), X + \delta I) - F_\alpha(\overline{y}, v(\overline{y}), -q, -Y) \\ &\geq F_\alpha(\overline{x}, u(\overline{x}), -q, X - C\kappa I) - F_\alpha(\overline{y}, u(\overline{x}), -q, -Y + C\kappa I) \\ &\quad + \alpha(u(\overline{x}) - v(\overline{y})) - m_2(\kappa + \delta|\overline{x} - z| + \delta + C\kappa) - m_2(C\kappa) \\ &\geq \alpha(u(\overline{x}) - v(\overline{y})) - m_1(|\overline{x} - \overline{y}| + 2C\kappa) - m_2(\kappa + \delta|\overline{x} - z| + \delta + C\kappa) - m_2(C\kappa), \end{aligned}$$

where the second inequality is obtained from (A.15), while the third inequality is obtained from (A.16). Taking the limit as $\epsilon \to 0$ we get that $\alpha(u(z) - v(z)) \leq 0$, which contradicts (A.3) and (A.4). This shows that $(U_{\gamma\beta}(x) - V_{\gamma\beta}(x)) \leq 0$ for all $x \in \overline{G \cap B_n}$. Taking the limit as $\beta \to 0$, we see that $V_2(x) \leq V_1(x)$ for all $x \in \overline{G \cap B_n}$. Reversing the roles of V_1 and V_2, we see that we must have $V_2(x) = V_1(x)$ for all $x \in \overline{G \cap B_n}$. □

Sketch of the proof of Theorem 4.2. Let $\mathrm{SM} \doteq \{v : G \to U \mid v \text{ is measurable}\}$ be the space of all Markov controls. Let $d(\cdot, \cdot)$ be the metric on SM introduced in [6] (see also Theorem II.2.2 of [7]). Then SM is compact under the metric topology of d.

Let $\Lambda(\epsilon, M, M_0)$ be as in the statement of the theorem and arguing via contradiction suppose that $\limsup_{\epsilon \to 0} \Lambda(\epsilon, M, M_0) \neq 0$. Then one can find $x_n, y_n, x \in E_{M_0}$ and $v_n, v \in \mathrm{SM}$ such that $x_n \to x$, $y_n \to x$, $v_n \to v$, and

$$\limsup_{n \to \infty} \int_0^M |\mathbb{E}k(X^{x_n}(s), v_n(X^{x_n}(s))) - \mathbb{E}k(X^{y_n}(s), v_n(X^{y_n}(s)))|\, ds \neq 0, \tag{A.21}$$

where $X^{x_n}(\cdot)$ (and $X^{y_n}(\cdot)$) are defined via (2.3) with $X(0) \equiv x_n$(resp., y_n) and the Markov control v^n. In a manner similar to Theorem II.2.3 of [7] one can show that for all $t \in (0,\infty)$ the probability laws of $X^{x_n}(t)$ and $X^{y_n}(t)$ converge in total variation from the probability law of $X(t)$, where $X(\cdot)$ is defined via (2.3) with $X(0) \equiv x$. From this and recalling that $k(x,v) \doteq \int_S \overline{k}(x,\alpha)v(d\alpha)$, where $\overline{k} \in C_b(G \times S)$, it then follows that for all $s \in (0,\infty)$

$$|\mathbb{E}k(X^{x_n}(s), v_n(X^{x_n}(s))) - \mathbb{E}k(X(s), v_n(X(s)))|$$

and

$$|\mathbb{E}k(X^{y_n}(s), v_n(X^{y_n}(s))) - \mathbb{E}k(X(s), v_n(X(s)))|$$

converge to 0 as $n \to \infty$. Combining the above displays we have that for all $s \in (0,\infty)$

$$|\mathbb{E}k(X^{x_n}(s), v_n(X^{x_n}(s))) - \mathbb{E}k(X^{y_n}(s), v_n(X^{y_n}(s)))|$$

converges to 0 as $s \to \infty$. Finally, an application of the dominated convergence theorem gives that

$$\int_0^M |\mathbb{E}k(X^{x_n}(s), v_n(X^{x_n}(s))) - \mathbb{E}k(X^{y_n}(s), v_n(X^{y_n}(s)))|ds$$

converges to 0 as $n \to \infty$. This contradicts (A.21), and thus the result follows. □

Proof of Theorem 4.5. An application of Itô's formula gives that

$$\begin{aligned} F(X^x_{n+1}) \le F(X^x_n) &+ \int_n^{n+1} \langle DF(X^x(s)), b(X^x(s), u(s))\rangle ds \\ &+ \sum_{i=1}^N \int_n^{n+1} \langle DF(X^x(s)), d_i\rangle dY_i(s) \\ &+ \frac{1}{2}\int_n^{n+1} \mathrm{tr}(\sigma^*(X^x(s))D^2F(X^x(s))\sigma(X^x(s)))ds \\ &+ \int_n^{n+1} \langle DF(X^x(s)), \sigma(X^x(s))dW(s)\rangle. \end{aligned}$$

Conditioning with respect to $\mathcal{F}_n$ and using parts (c) and (d) of Theorem 4.4, we have that

$$\begin{aligned} &\mathbb{E}(F(X^x_{n+1}) \mid \mathcal{F}_n) - F(X^x_n) \\ &\quad \le -c + \frac{1}{2}\mathbb{E}\left(\int_n^{n+1} \mathrm{tr}(\sigma^*(X^x(s))D^2F(X^x(s))\sigma(X^x(s)))ds \mid \mathcal{F}_n\right). \end{aligned} \tag{A.22}$$

Let $\tilde{g}(x) \doteq \frac{1}{2}\mathrm{tr}(\sigma^*(x)D^2F(x)\sigma(x))$. From part (b) of Theorem 4.4 we can find $\ell_0 \in (0,\infty)$ such that $|\tilde{g}(x)| \le \frac{c}{2}$ for all $x \in G$ such that $|x| > \frac{\ell_0}{2}$. This implies that

$$\begin{aligned} &\frac{1}{2}\int_n^{n+1} \mathrm{tr}(\sigma^*(X^x(s))D^2F(X^x(s))\sigma(X^x(s)))ds \\ &\quad \le |\tilde{g}|_\infty 1_{X^x_n \in B} + \left(|\tilde{g}|_\infty 1_{\sup_{n\le s\le n+1}|X^x(s)-X^x_n| > \frac{\ell_0}{2}} + \frac{c}{2}\right) 1_{X^x_n \in B^c}. \end{aligned}$$

From the above display and (A.22) we have that

$$\begin{aligned}
&\mathbb{E}(F(X_{n+1}^x) \mid \mathcal{F}_n) - F(X_n^x) \\
&\quad \le -c + \left(|\tilde{g}|_\infty \mathbb{E}(1_{\sup_{n\le s\le n+1} |X^x(s)-X_n^x| > \frac{\ell_0}{2}} \mid \mathcal{F}_n) + \frac{c}{2} \right) 1_{X_n^x \in B^c} + |\tilde{g}|_\infty 1_{X_n^x \in B} \\
&\quad \le \left(-\frac{c}{2} + |\tilde{g}|_\infty \frac{\mathbb{E}(\sup_{n\le s\le n+1} |X^x(s) - X_n^x| \mid \mathcal{F}_n)}{\ell_0/2} \right) 1_{X_n^x \in B^c} + |\tilde{g}|_\infty 1_{X_n^x \in B}.
\end{aligned}$$

Using the boundedness of the drift and diffusion coefficients we can find $\overline{\ell}$ such that

$$\mathbb{E}\left(\sup_{n\le s\le n+1} |X^x(s) - X_n^x| \mid \mathcal{F}_n \right) \le \overline{\ell},$$

and without loss of generality we can assume that ℓ_0 is large enough so that $\frac{2|\tilde{g}|_\infty \overline{\ell}}{\ell_0} < \frac{c}{4}$. Using these bounds in the above display, we have that

$$\mathbb{E}(F(X_{n+1}^x) \mid \mathcal{F}_n) - F(X_n^x) \le -\frac{c}{4} 1_{X_n^x \in B^c} + |\tilde{g}|_\infty 1_{X_n^x \in B}.$$

The result now follows on setting $c_0 = \frac{c}{4}$ and $M_0 = |\tilde{g}|_\infty$. □

Acknowledgments. We would like to thank the referee and an associate editor for several suggestions that led to improvements in the manuscript.

CAUSAL AND STABLE INPUT/OUTPUT STRUCTURES ON MULTIDIMENSIONAL BEHAVIORS*

J. WOOD†, V. R. SULE‡, AND E. ROGERS†

Abstract. In this work we study multidimensional (nD) linear differential behaviors with a distinguished independent variable, called "time." We define in a natural way causality and stability of input/output structures with respect to this distinguished direction. We make an extension of some results in the theory of partial differential equations, demonstrating that causality is equivalent to a property of the transfer matrix which is essentially hyperbolicity of the P^c operator defining the behavior $(\mathcal{B}^c)_{0,y}$. We also quote results which in effect characterize time-autonomy for the general systems case.

Stability is likewise characterized by a property of the transfer matrix. We prove this result for the 2D case and for the case of a single equation; for the general case it requires solution of an open problem concerning the geometry of a particular set in $\mathbb{C}^n$. In order to characterize input/output stability we also develop new results on inclusions of kernels, freeness of variables, and closure with respect to $\mathcal{S}, \mathcal{S}'$ and associated spaces, which are of independent interest. We also discuss stability of autonomous behaviors, which we believe to be governed by a corresponding condition.

Key words. stability, causality, partial differential equations, multidimensional systems, behavioral approach, hyperbolic systems, input/output structures, time-autonomy.

1. Introduction.

In this paper we are concerned with questions of causality and stability for systems defined by PDEs. We consider these problems in the framework of multidimensional (nD) behaviors (note that this is quite distinct from the infinite-dimensional systems framework of, e.g., [2]). To date, the theory of nD behaviors has almost entirely considered the independent variables on an equal footing. However, in an apparent majority of applications, particularly in the case of systems given by PDEs, one of the independent variables, "time," is distinguished and plays a special role. Recent work by Sasane [26, 24, 25] attempts to develop nD behavioral theory in this less symmetrical and more applicable situation.

This consideration is particularly significant when we discuss a concept such as stability, which is naturally associated with the passage of "time." Stability of course may be divided into two concepts: stability with respect to initial conditions (i.e., stability of an autonomous behavior) and input/output stability. The current work was motivated by consideration of the first concept but has led only to a (partial) characterization of the second!

We therefore begin our main exposition with a discussion of stability of autonomous behaviors in section 3. Our argument is motivated by the rough principle that a behavior should be classified as "unstable" only when it contains trajectories which are unstable (in whatever sense) but for which the corresponding initial conditions (whatever we may mean by these) are, nevertheless, (in some sense) stable. The two-dimensional (2D) discrete definition of stability by Valcher [33] applies this

principle. Unfortunately, for PDEs, "initial conditions" is a much harder concept to understand and work with. Section 3, however, proposes a possible condition for stability in this sense, which we call the characteristic variety (CV) condition. Roughly, the idea behind this condition is to classify trajectories as unstable only if they are both "blowing up" in the time direction and "physically reasonable" in the spatial direction. Section 3.1 brings hyperbolic systems into the discussion, since hyperbolicity is for certain important classes of systems a consequence of the CV condition. One particular property of hyperbolic systems is that they are time-autonomous as defined in [25]; we quote a result from the PDE literature which effectively characterizes this property for the general systems case.

The remainder of the paper is devoted to input/output stability and also input/output causality, on which the former concept rests. Essentially, a system (or rather, an input/output structure on a given behavior) is defined as causal if for any input with zero past, there exists a corresponding output with zero past. Strictly speaking, this definition only makes sense if the "past" contains an initial condition set for the zero-input behavior; we therefore restrict our attention to systems for which this behavior is time-autonomous. Bringing in some important results from the literature on PDEs, we demonstrate in section 4 that causality is a consequence of hyperbolicity of the P operator. More strongly, we show that causality is equivalent to a property of the transfer matrix of the system, which is in turn equivalent to hyperbolicity of the P^c operator in the description of the controllable part.

We then move on to stability, which is defined in terms of trajectories in $\mathcal{S}$ or in $\mathcal{S}'$ having support in the half-space $t \geq 0$. An input/output structure is defined as stable if any causal output response to an input of this type is also necessarily of this type. The growth restrictions on these trajectories in the spatial directions convey the notion that they are "physically reasonable," and the growth restrictions in the temporal direction suggest stability. In section 5, we give some background results from the PDE literature on convolution operators for these special cases; these results effectively characterize input/output stability in this sense for the special case $p(\delta)y = u$. The general case requires some "structure theory" for behaviors over $\mathcal{S}_+$ (signals of $\mathcal{S}$ with support in the half-plane) and its dual space, which we develop in section 6. For completeness, using the same methodology we also develop analogous results for the spaces $\mathcal{S}$ and $\mathcal{S}'$. In particular, for $n \leq 2$ and for the case where the P operator is a single polynomial (covering the single-input single-output case in particular), we characterize inclusion of behaviors over $\mathcal{S}'$ and freeness of variables over $\mathcal{S}$ (these being essentially dual problems). The more general case for $n > 2$ is not proved, since the arguments used depend critically on proving a geometric property "ideal-convexity" of a particular set (the "bad frequency" set) in $\mathbb{C}^n$. To date, we have not been able to prove this property for $n \geq 2$; this is discussed in section 5.3.

Section 7 finally defines input/output stability, and characterizes it, again for the cases $n \leq 2$ or P equal to a single polynomial (e.g., single-input single-output). It is shown that an input/output structure is both causal and stable (in terms of trajectories in $\mathcal{S}$ with zero past) if and only if the least common denominator of the transfer matrix satisfies the CV condition introduced in section 3, i.e., if and only if the system has no controllable unstable poles. Thus it appears that input/output stability may be equivalent to stability of the zero input behavior, as happens in the standard one-dimensional (1D) case. We also give a similar sufficient condition for stability with respect to trajectories in $\mathcal{S}'$ with zero past; this requires no prior assumptions on the system. Extension of all results to the general nD case requires only a proof that the set of unstable frequencies is ideal-convex. We summarize in section 8.

2. Behaviors, classical spaces, and pole structure. We begin by briefly reviewing some concepts and results from the theory of nD behaviors; see, e.g., [22, 34] for the 1D case and, e.g., [17, 20, 35, 40] for general background on the continuous nD case.

2.1. Classical and associated spaces. We consider solutions to behaviors in the classical spaces from the theory of distributions and so begin by recalling these and associated spaces. We denote the classical spaces by $\mathcal{C}^\infty$ (smooth functions), $\mathcal{D}'$ (distributions), $\mathcal{C}_0^\infty$ (compactly smooth functions), $\mathcal{E}'$ (compactly supported distributions), $\mathcal{S}$ (rapidly decreasing functions), and $\mathcal{S}'$ (tempered distributions). Here all functions and functionals are taken to be complex-valued. Recall (e.g., [23]) that rapidly decreasing functions are those functions which decay faster than any polynomial grows; a precise definition is given in section 5.1. The tempered distributions may be thought of as distributions that grow no faster than some polynomial (see, e.g., [8, sec. 7.1] for a detailed treatment of $\mathcal{S}$ and $\mathcal{S}'$). Following [4] we also define, for any of the classical spaces $\mathcal{W}$, the spaces [4],

$$\mathcal{W}_+ := \{w \in \mathcal{W} \mid \operatorname{supp} w \subseteq \mathbb{R}^n_+\}, \tag{1}$$

$$\mathcal{W}_- := \{w \in \mathcal{W} \mid \operatorname{supp} w \subseteq \mathbb{R}^n_-\}, \tag{2}$$

$$\mathcal{W}_\oplus := \mathcal{W}/\mathcal{W}_-, \tag{3}$$

$$\mathcal{W}_\ominus := \mathcal{W}/\mathcal{W}_+. \tag{4}$$

Here $\mathbb{R}_+ := \mathbb{R}^{n-1} \times [0, +\infty)$ and $\mathbb{R}_- := \mathbb{R}^{n-1} \times (-\infty, 0]$.

The spaces $\mathcal{S}_+$ and $\mathcal{S}'_\oplus$ will prove particularly important in what follows. It is clear that any element $f \in \mathcal{S}_\oplus$ may be regarded as an element of the dual of $\mathcal{S}_+$, according to

$$\langle f, \phi\rangle := \langle \overline{f}, \iota(\phi)\rangle,\ \phi \in \mathcal{S}_+, \tag{5}$$

where $\overline{f}$ is any element of $\mathcal{S}'$ which projects to f, and $\iota : \mathcal{S}_+ \to \mathcal{S}$ is the natural inclusion. As noted in [4], $\mathcal{S}'_\oplus$ is in fact equal to the dual space of $\mathcal{S}_+$.

Denote by $\mathbb{C}[s]$ the polynomial ring in n indeterminates $s = s_1, \ldots, s_n$ with complex coefficients. We associate with any polynomial matrix $R = R(s) \in \mathbb{C}^{g\times q}$ the differential operator $R(\delta) := R(\partial/\partial x_1, \ldots, \partial/\partial x_n)$, $x_1, \ldots, x_n$ being independent variables in the space $\mathbb{R}^n$. This operator maps $\mathcal{W}^q$ to $\mathcal{W}^g$ for any of the spaces $\mathcal{W}$ listed above (the action on factors $\mathcal{W}_\oplus$, $\mathcal{W}_\ominus$ being induced in the obvious way). We remark that in the theory of PDEs, it is more usual to consider operators in the form $w \mapsto R(1/\imath)\partial)w$. For this reason, certain results in the theory of PDEs concerning the algebraic structure of operators change form in a straightforward way when translated into the current framework.

Recall also that for any of the classical pairs of dual spaces $\mathcal{W}, \mathcal{W}'$, and any polynomial matrix $R \in \mathbb{C}[s]^{g\times q}$, the *adjoint matrix* $R^*(s) := R^T(-s)$ has the property that

$$\langle R(\partial)f, \phi\rangle = \langle f, R^*(\partial)\phi\rangle \tag{6}$$

for any $f \in \mathcal{W}^q$, $\phi \in (\mathcal{W}')^g$.

2.2. Behaviors, associated varieties, and time-autonomy. For any of the spaces $\mathcal{W}$ discussed in section 2.1, and for a polynomial matrix $R \in \mathbb{C}[s]^{g\times q}$,

denote as usual

$$\ker_{\mathcal{W}} R = \{w \in \mathcal{W}^q \mid R(\delta)w = 0\}, \tag{7}$$

$$\operatorname{im}_{\mathcal{W}} R = \{w \in \mathcal{W}^g \mid \exists\, l \in \mathcal{W}^q \text{ s.t. } w = R(\partial)l\}. \tag{8}$$

In this situation, we say that R is a *kernel representation matrix* of the behavior $\mathcal{B} = \ker_{\mathcal{R}} R$. $\mathcal{W}$ is referred to as the *the signal space;* the signal space of a behavior is taken to be $\mathcal{D}'$ unless otherwise specified.

For the operator $R(\partial)$ or behavior $\ker_{\mathcal{D}'} R$, the associated *system module* or *module of formal quantities* is defined as $\mathcal{M} := \mathbb{C}[s]^{1\times q}/\mathbb{C}[s]^{1\times g}R$. This object is also standard in PDE theory, and some relationships between $\mathcal{M}$ and $\mathcal{B}$ are drawn out in [35]. In particular, the behavior $\mathcal{B}$ (for any signal space $\mathcal{W}$) may be identified with $\operatorname{Hom}_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{W})$ [13, 17].

Given a polynomial matrix $R \in \mathbb{C}[s]^{g\times q}$, recall that a *universal or minimal left annihilator* is a matrix $L \in \mathbb{C}[s]^{h\times g}$ for some h, such that the rows of L generate the set of polynomial vectors v with $vR = 0$. Then the "fundamental principle" of Ehrenpreis–Palamodov states that $\operatorname{im}_{\mathcal{W}} R = \ker L$ for $\mathcal{W} = \mathcal{D}'$ or $\mathcal{W} = \mathcal{C}^\infty$. Equivalently, these two signal spaces (modules) are *injective.* This property is a major component of a very rich relationship between system modules $\mathcal{M}$ and behaviors $\mathcal{B}$, introduced into behavioral theory by Oberst [17]. We will also use standard facts and results concerning the *associated primes* of $\mathcal{M}$; see, e.g., [3] for the background here.

Let $\mathcal{B} = \ker_{\mathcal{D}'} R$ with $R \in \mathbb{C}[s]^{g\times q}$; denote by $\mathcal{V}(\mathcal{B})$ the *characteristic variety*

$$\mathcal{V}(\mathcal{B}) := \{\zeta \in \mathbb{C}^n \mid \operatorname{rank} R(\zeta) < q\} \tag{9}$$

which is well known to depend only on $\mathcal{B}$ and to be equal to the variety of the ideal

$$\operatorname{ann} \mathcal{M} := \{r \in \mathbb{C}[s] \mid rx = 0 \text{ for all } x \in \mathcal{M}\}. \tag{10}$$

The points of $\mathcal{V}(\mathcal{B})$ are precisely the frequencies ζ for which $\mathcal{B}$ admits *polynomial exponential trajectories* $p(x)\exp(\langle\zeta, x\rangle)$, p a polynomial function; see, e.g., [18, 37] for a discussion in the behavioral context. Since the associated primes of $\mathcal{M}$ include the primes minimal with respect to the property of including ann $\mathcal{M}$, $\mathcal{V}(\mathcal{B})$ is equal to the union of the varieties of the associated primes of $\mathcal{M}$.

We may further consider the *projective closure* $\overline{\mathcal{V}}$ of a variety $\mathcal{V} = \mathcal{V}(I)$ for some ideal I, which is the smallest projective variety containing $\mathcal{V}$ according to the inclusion $\mathbb{C}^n \to \mathbb{PC}^n$, $\zeta \mapsto (\zeta, 1)$. $\overline{\mathcal{V}}$ is the set of zeros of the homogeneous ideal equal to the set of all homogeneous polynomials in $\mathbb{C}[s, z]$ mapping I under $p(s, z) \mapsto p(s, 1)$. The *variety at infinity* $\tilde{\mathcal{V}}$ is defined as the intersection of $\tilde{\mathcal{V}}$ with the "hyperplane at infinity" $\mathbb{C}^n \times 0 \subseteq \mathbb{PC}^n$ (but $\tilde{\mathcal{V}}$ is regarded as an affine variety in $\mathbb{C}^n$). Since the hyperplane at infinity is defined by the additional equation $z = 0$, $\tilde{\mathcal{V}}$ may easily be seen to equal the set of zeros of the principal parts $pr(p)$ of all $p \in I$, where $pr(p)$ is the sum of all terms of p with the highest total degree. The variety at infinity may be computed, e.g., using Gröbner bases [3, sec. 15.10.5].

A vector $v \in \mathbb{R}^n\backslash 0$ is said to be a *characteristic direction* for $\mathcal{M}$ or for ann $\mathcal{M}$, or for the associated system of PDEs, if $v \in \tilde{\mathcal{V}}(\text{ann } \mathcal{M})$; otherwise it is said to be *noncharacteristic.* Recall now the definition of time-autonomy due to Sasane, Thomas, and Willems [25].

DEFINITION 2.1. *A behavior $\mathcal{B}$ is called* time-autonomous *if any trajectory is determined by its restriction to the half-space $\{x \in \mathbb{R}^n \mid x_n < 0.\}$ The behavior is autonomous if the characteristic variety is not all of $\mathbb{C}^n$.*

Thus for a behavior $\mathcal{B}$ with signal space $\mathcal{D}'$, time-autonomy is equivalent to the absence of nonzero solutions in $\mathcal{D}'_+$, so means that if a trajectory is zero in the "past" ($\mathbb{R}^n_-$) it must remain zero in the "future" ($\mathbb{R}^n_+$).

Nonzero solutions over $\mathcal{D}'_+$ or $\mathcal{C}^\infty_+$ (or more generally in a specified half-space) are *null solutions.* The following result characterizing their existence was first proved by Hormander [6] in the smooth, single polynomial case, and can be found in [15] for the smooth systems case and [16] for the distributional and smooth systems cases.

THEOREM 2.2. *A behavior $\mathcal{B}$ in $(\mathcal{D}')^q$ or in $(\mathcal{C}^\infty)^q$ has no null solutions, i.e., is time-autonomous, if and only if $(0,\dots,0,1)$ is a noncharacteristic direction for the system.*

Note. Recent work [27] has also given a characterization of time-autonomy for a class of 2D systems. Further consideration of how this relates to the above result is left as a topic for future research.

The *(Willems) closure* of a submodule $\mathcal{N}$ of $\mathbb{C}[s]^{1\times q}$ with respect to a signal space $\mathcal{W}$ is defined [20] as

$$\mathcal{N}^{\perp\perp} := \{v' \in \mathbb{C}[s]^{1\times q} \mid v'(\partial)w = 0 \text{ for all } w \in \mathcal{N}^\perp\}, \tag{11}$$

where

$$\mathcal{N}^\perp := \{w \in \mathcal{W}^q \mid v(\partial)w = 0 \text{ for all } v \in \mathcal{N}\}. \tag{12}$$

Notice that $\mathcal{N} \subseteq \mathcal{N}^{\perp\perp}$ and if $\mathcal{N}_1^\perp \subseteq \mathcal{N}_2^\perp$ are two behaviors, then $\mathcal{N}_2^{\perp\perp} \subseteq \mathcal{N}_1^{\perp\perp}$.

2.3. Pole structure. We now recall some results from [37] concerning the pole structure of nD behaviors. The material on input/output structures etc. may also be found in many other places in the literature.

Recall first that a *(free) input/output structure* (x, y) on a behavior $\mathcal{B}$ with a general signal space $\mathcal{W}$ is a partition of the system variables into m input variables u and p output variables y with the properties that

1. the projection of the behavior onto the u variables equals $\mathcal{W}^m$ (we say the variables u are *free over* $\mathcal{W}$), and
2. the *zero-input behavior*

$$\mathcal{B}_{0,y} := \{(u, y) \in \mathcal{B} \mid u = 0\} \tag{13}$$

is autonomous, i.e., has no free variables.

For a given kernel representation, by writing the system equations in the form

$$P(\partial)y = Q(\partial)u,$$

we equivalently have that P has full column rank and the rank of $(-Q, P)$ is equal to the rank of Q. When these conditions apply, there is a unique rational function matrix G with $PG = Q$, called the *transfer matrix.*

The *controllable part* $\mathcal{B}^c$ of $\mathcal{B}$ defined as the (unique) maximal controllable subbehavior of $\mathcal{B}$, possesses the same input/output structures as $\mathcal{B}$ and admits the same transfer matrix with respect to any such input/output structure. We do not define controllability here but refer the reader to [20]. The zero-input behavior $(\mathcal{B}^c)_{0,y}$ of the controllable part has a special structure.

LEMMA 2.3 (see [37, Thm. 5.3]). *Let $\mathcal{B}^c$ be a controllable behavior with given input/output structure (u, y). Let $\mathcal{M}'$ be the system module associated to the zero-input behavior $(\mathcal{B}^c)_{0,y}$. Then the associated primes of $\mathcal{M}'$ are all principal, and the ideal* ann $\mathcal{M}'$ *is generated by the least common denominator of the transfer matrix.*

For convenience, we will call a finitely generated module with the property that its associated primes are all principal a *principal module*; there is no standard term as far as we know.

The factor space $\mathcal{B}/\mathcal{B}^c$ has the structure of an "abstract behavior" as defined in [21]; it may be realized as any behavior of the form $R^c(\partial)(\mathcal{B})$, where R^c is a kernel representation matrix of $\mathcal{B}^c$. The behavior $\mathcal{B}/\mathcal{B}^c$ is autonomous and is the natural analogue of the autonomous part in 1D behavioral theory. It may be identified with the set of all classes of mutually concatenable trajectories in $\mathcal{B}$ [40], and so this behavior may be called the "obstruction to controllability."

The *pole variety*, *controllable pole variety*, and *uncontrollable pole variety* of $\mathcal{B}$ (with a specified input/output structure) are defined, respectively, as $\mathcal{V}(\mathcal{B}_{0,y})$, $\mathcal{V}((\mathcal{B}^c)_{0,y})$, and $\mathcal{V}(\mathcal{B}/\mathcal{B}^c)$. The points of the uncontrollable variety have an interpretation as input decoupling zeros, as discussed in [39]. The three sets are related as follows.

LEMMA 2.4. *We have*

$$\mathcal{V}(\mathcal{B}_{0,y}) = \mathcal{V}((\mathcal{B}^c)_{0,y}) \cup \mathcal{V}(\mathcal{B}/\mathcal{B}^c), \tag{14}$$

$$\widetilde{\mathcal{V}}(\mathcal{B}_{0,y}) = \widetilde{\mathcal{V}}((\mathcal{B}^c)_{0,y}) \cup \widetilde{\mathcal{V}}(\mathcal{B}/\mathcal{B}^c). \tag{15}$$

Proof. Equation (15) is derived in [37] from a standard general result. Equation (16) must also be a consequence of a standard result, but one that we have not found, so we derive it here. Let $\mathcal{M}, \mathcal{M}'$, and $\mathcal{M}''$ denote the system modules corresponding, respectively, to the behaviors $\mathcal{B}_{0,y}, \mathcal{B}/\mathcal{B}^c$, and $(\mathcal{B}^c)_{0,y}$; then $\mathcal{M}' \subseteq \mathcal{M}$ with factor $\mathcal{M}''$, and it is straightforward from this to see that

$$\operatorname{ann} \mathcal{M} \subseteq \operatorname{ann} \mathcal{M}' \cap \mathcal{M}'' \subseteq \operatorname{rad} \operatorname{ann} \mathcal{M}, \tag{16}$$

where rad denotes the radical of an ideal. Write

$$J := \{pr(d) \mid d \in \operatorname{ann} \mathcal{M}\}$$

and define J' and J'' analogously with respect to $\mathcal{M}'$ and $\mathcal{M}''$, respectively. Clearly, $J \subseteq J' \cap J''$. Moreover, if $r \in J' \cap J''$, say, $r = pr\ d_1 = pr\ d_2$ with $d_1 \in \operatorname{ann} \mathcal{M}'$, $d_2 \in \operatorname{ann} \mathcal{M}''$, then we find that $d_1 d_2 \in \operatorname{ann} \mathcal{M}$. We also see that for any two polynomials $p, q \in \mathbb{C}[s]$, $pr(p) \cdot pr(q) = pr(pq)$, and so $r^2 = pr(d_1 d_2) \in J$, and so $r \in \operatorname{rad} J$. This proves that

$$J \subseteq J' \cap J'' \subseteq \operatorname{rad} J.$$

Consequently, $\mathcal{V}(J) = \mathcal{V}(J') \cup \mathcal{V}(J'')$. However, $\mathcal{V}(J) = \tilde{\mathcal{J}}(\mathcal{B}_{0,y})$, etc., so we have proved (16). ∎

3. Stability of autonomous behaviors. In this section we consider an autonomous behavior $\mathcal{B}$ given by a kernel representation matrix R, which necessarily has full column rank q. Furthermore, we assume that one of the independent variables "time" (t) is distinguished; without loss of generality we will always take this to be the last variable listed in the coordinate system for $\mathbb{R}^n$. Under what conditions should $\mathcal{B}$ be referred to as a "stable" behavior?

Stability in this context should mean that $\mathcal{B}$ contains no physically reasonable trajectories which grow in time at an unacceptably fast rate in some sense (e.g., which are unbounded). We might call this "stability with respect to the initial conditions."

In [20, 30], $\mathcal{B}$ was defined to be *stable with respect to a cone* $C \subseteq \mathbb{R}^n$ if every smooth trajectory of $\mathcal{B}$ tends to 0 along every half-line in C. This is characterized in [20, 30], subject to some minor assumptions, by the condition that no projection onto the real space of $\mathcal{V}(\mathcal{B})$ should lie in the polar cone of C with positive distance from the boundary of this polar.

Let us consider the heat or diffusion equation in one spatial variable

$$\frac{\partial^2 w}{\partial x^2} = \frac{\partial w}{\partial t}. \tag{17}$$

This system was used recently by Sasane in [26, 24] to motivate an alternative signal space to $\mathcal{C}^\infty$, $\mathcal{D}'$; here we will consider it in a similar spirt. We find that the characteristic variety of the system (17) or of its behavior $\mathcal{B}$, is

$$\mathcal{V}(\mathcal{B}) = \{(\eta, \xi) \in \mathbb{C}^2 \mid \eta^2 = \xi\},$$

and the behavior contains trajectories of the form

$$\exp(\Re(\eta)x + \Re(\eta^2)t)\exp(\imath\Im(\eta)x + \imath\Im(\eta^2)t)$$

for all $\eta \in \mathbb{C}$. Hence $\mathcal{B}$ contains trajectories which are unbounded on the positive t-axis, corresponding to the choices $\Re(\eta^2) > 0$, and so is unstable in the sense introduced in [20, 30]. However, note that if $\Re(\eta^2) > 0$, then $\Re(\eta) \neq 0$; i.e., any solution which is unbounded on the $+t$-axis is also unbounded (indeed, exponentially growing) on the x-axis. In other words, the only way to get unbounded temporal behavior in this system is to start with exponentially growing initial spatial data! Indeed, we would prefer to consider the heat equation as "stable"; with no external input of heat, heat should diffuse in time and never blow up. In this paper, we take the view that the initial data and trajectories which are exponentially growing spatially are physically unrealistic. With these considerations in mind we introduce the following concept.

DEFINITION 3.1. *An autonomous behavior* $\mathcal{B}$, *or its characteristic variety* $\mathcal{V} = \mathcal{V}(\mathcal{B})$, *is said to* satisfy the CV condition *if*

$$\mathcal{V} \cap \mathcal{X}^+ = \emptyset, \mid \mathcal{X}^+ := \imath\mathbb{R}^{n-1} \times \overline{\mathbb{C}^+}, \tag{CV}$$

where $\overline{\mathbb{C}^+}$ *denotes the closed right-half plane. We say that* $\mathcal{B}$ *or* $\mathcal{V}$ *satisfies* the weak CV (WCV) condition *if the same holds but for the open right-half plane* $\mathbb{C}^+$ *instead of* $\overline{\mathbb{C}^+}$. *We also say that a polynomial or ideal* satisfies the CV condition *or* satisfies the WCV condition *if the corresponding condition is satisfied by the variety of the polynomial/ideal.*

For later use we also define

$$\mathcal{X}^- := \imath\mathbb{R}^{n-1} \times \overline{\mathbb{C}^-}, \tag{18}$$

where $\overline{\mathbb{C}^-}$ denotes the closed left-half plane.

Recalling the description of the points of the characteristic variety in terms of polynomial exponential trajectories, we note that a behavior satisfies the CV condition if and only if it contains no polynomial exponential trajectories which are bounded at $t = 0$ (corresponding to the spatial frequency components being imaginary) but which do not decay along the positive t-axis (corresponding to the temporal frequency components being in $\overline{\mathbb{C}^+}$). This observation applies equally well to both complex and real-valued trajectories. We therefore think of points of $\mathcal{X}^+$ as *unstable frequencies.*

Similarly, a behavior satisfies the WCV condition if and only if it contains no polynomial exponential trajectories which are bounded at $t = 0$ but grow faster than a polynomial in the $+t$-direction. Note that the behavior defined by the heat equation certainly satisfies the WCV condition, as if η is imaginary, then $\Re(\eta^2) < 0$ gives rise to a trajectory which is exponentially decaying in time.

As a working definition, we consider an autonomous behavior to be stable when it satisfies the CV condition. This attempts to capture the idea that a behavior is unstable when it contains trajectories which are well behaved at $t = 0$ but do not decay to 0 as $t \to +\infty$. The concept of "stability with respect to initial conditions" also lies behind the definition of stability for 2D discrete systems given by Valcher [33] (there is little parallel in the mathematics of the continuous and discrete cases, but the underlying philosophy is the same). As we have seen, in terms of polynomial exponential trajectories Definition 3.1 seems very appropriate, and by the same considerations the CV condition is certainly necessary for stability in the general sense we have been indicating. Moreover, since the polynomial exponential solutions of a system are dense in the smooth solutions, at least in the case of complex coefficients [7, Thm. 7.6.14], it is not unreasonable to conjecture that the CV condition is also sufficient for this type of stability. However, this important problem remains open, and we rely on later sections to fully motivate the CV condition.

Let us cover the other basic classical examples for general n. We have seen that the behavior of the heat equation satisfies the WCV condition, though it does not satisfy the CV condition; this holds in any number of spatial dimensions. This behavior of the wave equation and of the gradient operator also satisfy the WCV condition but not the CV condition. The kernel of the Laplace operator does not satisfy either.

3.1. Hyperbolic systems. It is also interesting to note that the WCV condition implies the *Gårding condition,* which is necessary for hyperbolicity of an autonomous system given by a single polynomial. Here is the condition,

$$\{\Re(\xi) \mid \exists \eta \in \imath\mathbb{R}^{n-1},\ \xi, \eta \in \mathcal{V}\} \subseteq \mathbb{R} \text{ is bounded above.} \tag{19}$$

We now discuss hyperbolicity, giving the definition for the systems case which is more complex than the better known definition for a single polynomial. The following definition is identical to one of the equivalent definitions given by Nacinovich [16], adjusted only in respect of the fact that our systems are defined via $P(\partial)w = 0$, whereas he uses the more standard $P((1/\imath)\partial)w = 0$. Also we have specialized the definition to hyperbolicity in a fixed direction.

DEFINITION 3.2. *A system $P(\partial)w = 0$, operator $P(\partial)$, associated system module $\mathcal{M}$, or behavior $\mathcal{B}$, is called* hyperbolic (in the direction t) *if for every associated prime I of $\mathcal{M}$ we can find a constant $0 < c < 1$ such that (where $\Re(\eta, \xi)$ denotes the real part vector of the complex $n + 1$ tuple (η, ξ))*

$$\Re(\xi) \leq c|\Re(\eta, \xi)| + c^{-1} \text{ for every } (\eta, \xi) \in \mathcal{V}(I). \tag{20}$$

The following result, also adapted from [16], links the definition to the more familiar one for a single polynomial.

THEOREM 3.3. *Let $P \in \mathbb{C}[s]^{g\times q}$, and let $\mathcal{M}$ be the system module, i.e., $\mathcal{M} = \mathbb{C}[s]^{1\times q}/\mathbb{C}[s]^{1\times g}P$. Suppose that $\mathcal{M}$ is principal. Then $P(\partial)$ is hyperbolic if and only if $(0, \ldots, 0, 1)$ is a noncharacteristic direction for the system $P(\partial)y = 0$, and the Gårding condition* (20) *holds for the characteristic variety of the system.*

Proof. We refer to the remark following [16, Prop. 6.1], which states that when the associated primes of $\mathcal{M}$ are all principal, hyperbolicity is equivalent to the requirement

that $(0, \dots, 0, 1)$ be noncharacteristic, together with the Gårding condition for each variety $\mathcal{V}(I)$, I an associated prime of $\mathcal{M}$. Since the number of associated primes is finite, the latter condition is, however, equivalent to the Gårding condition for the characteristic variety itself. □

It is easy to see that the conditions of Theorem 3.3 hold in particular when P is a single polynomial, as expected. Note from Lemma 2.3 that this condition is also met for the module corresponding to the zero-input behavior of any controllable behavior.

We remark that hyperbolicity is equivalent to solvability of the "noncharacteristic" Cauchy problem in many different formulations [9, 10], which is of great importance and deserves investigation in the context of control systems theory. Essentially, hyperbolicity allows the unique continuation of initial data in a large class on $t = 0$ to trajectories on the half-space $t \geq 0$. We will note in the next section its connections to causality.

Note also that hyperbolic behaviors are in particular time-autonomous (in the general case this is a consequence of Theorem 4.2 in the next section). Next, we link the WCV condition to hyperbolicity.

LEMMA 3.4. *Let $P(\partial)$ be a partial differential operator with kernel $\mathcal{B}$ and system module $\mathcal{M}$. Suppose that $\mathcal{M}$ is principal and that $\mathcal{B}$ satisfies the WCV condition and is time-autonomous. Then the system is hyperbolic and therefore admits a solution to the noncharacteristic Cauchy problem.*

In the case where $\mathcal{M}$ is principal, the CV property, together with time-autonomy, is of course a much stronger property than hyperbolicity; for example, in two dimensions the kernel of the operator $(\partial/\partial t - 1)$ is hyperbolic but does not satisfy the WCV condition. The relationship between these two properties will become clearer when we examine stable input/output structures. This, however, will require us to consider causality in the continuous space-time input/output framework.

4. Causal input/output structures. We are interested in this section with the question of when a given input/output structure is causal. Following Zampieri [38] for the discrete case (in which the past and future are defined with respect to a cone), we introduce the following definition of causality.

DEFINITION 4.1. *Suppose that (u, y) is an input/output structure on $\mathcal{B}$ and $\mathcal{B}_{0,y}$ is time-autonomous. Then the input/output structure is said to be* causal (with respect to $\mathcal{C}^\infty$) *if for any smooth input u with support in $\mathbb{R}^n_+$, there exists a smooth output y (necessarily unique) with support in $\mathbb{R}^n_+$, such that $(u, y) \in \mathcal{B}$.*

Causality with respect to $\mathcal{D}'$ may also be defined in the obvious way; where no solution type is specified, we take causality to be meant in the smooth sense.

Thus causality indicates that for any input u with zero past, there is a corresponding output y (intuitively, the output corresponding to zero initial conditions) with a past which is determined by that of u, and is therefore also zero. Notice that this interpretation of Definition 4.1 only makes complete sense if the complementary half-space $\mathbb{R}^n_-$ contains the domain of a complete set of Cauchy data for $\mathcal{B}_{0,y}$, and this is the reason for insisting a priori that $\mathcal{B}_{0,y}$ be time-autonomous. Time-autonomy of $\mathcal{B}_{0,y}$ clearly means that an output trajectory is entirely determined by its value in $\mathbb{R}^n_-$, together with the input trajectory. Physical systems should of course always be causal in the intuitive sense, but not all autonomous behaviors arising in the physical context are time-autonomous. For example, the behavior defined by the heat equation (18) is not time-autonomous, though in a more restricted and perhaps physically better motivated sense, it is (see [24]). A general solution of the heat equation is, however, not uniquely defined by its past!—essentially because an input may be supplied via

a boundary condition. For time-autonomous $\mathcal{B}_{0,y}$, however, causality in the sense of Definition 4.1 captures the intuitive concept.

Hyperbolicity is intimately connected to causality. To demonstrate this, we give some results essentially taken from [16]; these results are very well known in the PDE community for the case of a single polynomial operator (see, e.g., [9, Thm. 12.5.4]), in which case the matrix L below is 0.

THEOREM 4.2. *Let $P \in \mathbb{C}[s]^{g\times q}$ with universal left annihilator matrix $L \in \mathbb{C}[s]^{h\times g}$. The following are equivalent:*

1. *$P(\partial)$ is hyperbolic.*
2. *The system*

$$P(\partial)y = u \tag{21}$$

has a unique solution $y \in (\mathcal{C}_+^\infty)^p$ for all $u \in \ker_{\mathcal{C}_+^\infty} L$.

3. *The system (21) has a unique solution $y \in (\mathcal{D}'_+)^p$ for all $u \in \ker_{\mathcal{D}'_+} L$.*

Proof. In [16, Thm. 5.1], it is stated that $P(\partial)$ is hyperbolic if and only if $\operatorname{Ext}^i_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{C}_+^\infty) = 0$, $i = 0, 1$. For $i = 0$ this means that $P(\partial)$ admits no smooth null solutions; for $i = 1$ it means that the sequence

$$(\mathcal{C}'_+)^p \overset{P(\partial)}{\to} (\mathcal{C}_+^\infty)^g \overset{L(\partial)}{\to} (\mathcal{C}_+^\infty)^h$$

is exact, which together with condition 2 [16, Thm. 5.2] gives the result for distributions, which establishes the equivalence of 1–3. ∎

Notice that Theorem 4.2 in particular gives a restricted form of the "fundamental principle"—over $\mathcal{C}_+^\infty$ or $\mathcal{D}'_+$ when P (or its module) is hyperbolic, the system (21) has a solution y for given u if and only if u satisfies the necessary "compatibility conditions." Indeed, the results of Nacinovich characterize hyperbolicity in terms of the vanishing of $\operatorname{Ext}^i_{\mathbb{C}[s]}$, as indicated in the proof above.

Moreover, at least in the case of a single polynomial [9, Thm. 12.5.4], hyperbolicity guarantees the existence of a fundamental solution to the system (21) having support in $\mathbb{R}^n_+$, and in both smooth and distributional cases the causal input-to-output map is given simply by convolution with the fundamental solution, which in the current context we can also refer to as the impulse response. As discussed in [30], hyperbolic systems are in this sense, therefore, the natural analogue of standard 1D (lumped) systems.

In [30], Shankar considers causality in a slightly different sense, namely to mean the existence of a continuous linear shift-invariant map from the set of smooth inputs with support in some cone contained in $\mathbb{R}^n_+$, to the set of outputs of the same type. For the system (21) with P equal to a single polynomial p, he proves that the existence of such a causal input-to-output map guarantees time-autonomy of the zero-input behavior and thereby (using Theorem 4.2) hyperbolicity of p also.

It is easy to see that hyperbolicity is still sufficient for results of this type when a Q term is added to the equations.

COROLLARY 4.3. *Let $\mathcal{B}$ be a behavior defined by the equations*

$$P(\partial)y = Q(\partial)u$$

forming an input/output structure. If P is a hyperbolic operator, then $\mathcal{B}_{0,y}$ is time-autonomous and the input/output structure is causal.

Proof. Suppose that P is hyperbolic. Time-autonomy of $\mathcal{B}_{0,y}$ is immediate from the uniqueness of solutions y given in Theorem 4.2, and causality follows from this result also. ∎

It is open to discussion as to whether the converse of Corollary 4.3 holds. The next lemma shows that under a simple assumption, all the trajectories of $\mathcal{B}$ with support in $\mathcal{D}'_+$ are contained in the controllable part. We will then use this reasoning to demonstrate that $\mathcal{B}$ and $\mathcal{B}^c$ have the same causal input/output structures.

LEMMA 4.4. *Let $\mathcal{B}$ be a behavior in $(\mathcal{D}')^q$. If $\mathcal{B}/\mathcal{B}^c$ is time-autonomous, then $\mathcal{B} \cap (\mathcal{D}')^q = \mathcal{B}^c \cap (\mathcal{D}'_+)^q$.*

Proof. Suppose that $\mathcal{B}/\mathcal{B}^c$ is time-autonomous. The inclusion $\supseteq$ is trivial. Now suppose $w \in \mathcal{B} \cap (\mathcal{D}'_+)^q$, and let R^c be a kernel representation matrix of $\mathcal{B}^c$. Since $\mathcal{B}/\mathcal{B}^c$ is time-autonomous, $R^c(\partial)w \in R^c(\partial)(\mathcal{B}) \cong \mathcal{B}/\mathcal{B}^c$ must vanish, so $w \in \mathcal{B}^c$. ∎

An analogous argument may be used to generalize Zampieri's Lemma 3.3 and, hence, other results in [38] from the 2D to nD discrete case.

COROLLARY 4.5. *Let $\mathcal{B}$ be a behavior with controllable part $\mathcal{B}^c$ and a given input/output structure (u, y) (which is necessarily an input/output structure on $\mathcal{B}^c$ also). Then the following hold:*

1. *$\mathcal{B}_{0,y}$ is time-autonomous if and only if both $\mathcal{B}/\mathcal{B}^c$ and $(\mathcal{B}^c)_{0,y}$ are.*
2. *Under the equivalent conditions of claim 1, (u, y) is a causal input/output structure on $\mathcal{B}$ if and only if it is a causal input/output structure on $\mathcal{B}^c$.*

Proof.

1. This claim is immediate from Theorem 2.2 together with Lemma 2.4.
2. Suppose that the conditions of claim 1 hold. If (u, y) is causal for $\mathcal{B}^c$, then it is trivial that it is also causal for $\mathcal{B}$, and the converse follows directly from Lemma 4.4. ∎

Corollary 4.3, Lemma 4.4, and Corollary 4.5 apply to causality in both the smooth and distributional senses.

One consequence of Corollary 4.5 is that when causality of an input/output structure is defined (i.e., when the zero-input behavior is time-autonomous), whether or not it holds is determined purely by the controllable part of the behavior and therefore by the transfer matrix. This motivates the following definition.

DEFINITION 4.6. *Call a transfer matrix G* causal *if its least common denominator is hyperbolic,* stable *if this polynomial obeys the* CV *condition, and* weakly stable *if this polynomial obeys the WCV condition.*

Notice that for $n = 1$, stability of G agrees with the classical concept, and causality of G is automatic.

Suppose we are given a behavior $\mathcal{B}$ with input/output structure (u, y) and transfer matrix G. Due to Lemma 2.3, G is causal if and only if $(\mathcal{B}^c)_{0,y}$ is hyperbolic. Similarly, G is stable if and only if $(\mathcal{B}^c)_{0,y}$ obeys the CV condition. The following new result shows that causality of G corresponds to causality of the corresponding input/output structures when the latter are defined.

THEOREM 4.7. *Suppose that $\mathcal{B}$ is a behavior with an input/output structure such that $\mathcal{B}_{0,y}$ is time-autonomous. Then the input/output structure is causal with respect to $\mathcal{C}^\infty$ if and only if the associated transfer matrix is causal. These conditions imply that the input/output structure is causal with respect to $\mathcal{D}'$.*

Proof. Let $\mathcal{B}$ be given with $\mathcal{B}_{0,y}$ time-autonomous and let $P(\partial)y = Q^c(\partial)u$ be a description of the controllable part of $\mathcal{B}^c$. Write $\mathcal{M}$ for the system module of the behavior $\mathcal{B}^c$ and $\mathcal{M}'$ for the system module of the operator $P^c(\partial)$, corresponding to the behavior $(\mathcal{B}^c)_{0,y}$. We have an exact sequence (e.g., [37])

$$0 \to F \to \mathcal{M} \to \mathcal{M}' \to 0$$

for a free submodule F of $\mathcal{M}$, with rank equal to the number of inputs m. From this

we obtain the long exact sequence in Ext (see, e.g., [3]),

$$0 \to \mathrm{Hom}_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty) \to \mathrm{Hom}_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{C}_+^\infty) \xrightarrow{\rho} \mathrm{Hom}_{\mathbb{C}[s]}(F, \mathcal{C}_+^\infty)$$

$$\to \mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty) \to \mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{C}_+^\infty) \to 0, \tag{22}$$

the last "0" term occurring since F is free. Recall that $\mathrm{Hom}_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty)$ is identified with the $\mathcal{C}_+^\infty$ solutions in $(\mathcal{B}^c)_{0,y}$ and $\mathrm{Hom}_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{C}_+^\infty)$ with the $\mathcal{C}_+^\infty$ solutions in $\mathcal{B}^c$. Also, $\mathrm{Hom}_{\mathbb{C}[s]}(F, \mathcal{C}_+^\infty) = (\mathcal{C}_+^\infty)^m$ and the map ρ is the projection map $(u, y) \in (\mathcal{C}_+^\infty)^{m+p} \mapsto u$. Since $\mathcal{B}^c$ is controllable, $\mathcal{M}$ is torsionfree [20]. Furthermore, we have an exact sequence

$$0 \to \mathcal{C}_+^\infty \to \mathcal{C} \to \mathcal{C}_\ominus^\infty \to 0.$$

Note that $\mathcal{C}_\ominus^\infty$ is the set of restrictions of smooth functions to the set $\mathbb{R}^n_-$; it is therefore the direct limit as $\epsilon \mapsto 0$ of the sets $\mathcal{C}^\infty(H_\epsilon)$ on $H_\epsilon = \{x \in \mathbb{R}^n,\ x_n < \epsilon\}$ for $\epsilon > 0$. Since H_ϵ is convex, $\mathcal{C}^\infty(H_\epsilon)$ is known to be an injective module (e.g., [19, Cor. VII.8.4]), and now $\mathcal{C}_\ominus^\infty$ is injective as the direct limits of injectives (e.g., [11, Thm. (3.46)]). Therefore $\mathcal{C}_+^\infty$ has injective dimension 1, and so, $\mathcal{M}$ being torsionfree, $\mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}, \mathcal{C}_+^\infty) = 0$ by [36, Thm. 4.8]. From (22), we now see that the cokernel of ρ equals $\mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty)$.

Suppose now that (x, y) is causal for $\mathcal{B}$. Then by Corollary 4.5, it is also causal for $\mathcal{B}^c$, so the map ρ is surjective, due to which $\mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty) = 0$. Also, as $\mathcal{B}_{0,y}$ is time-autonomous, $(\mathcal{B})^c_{0,y}$ is time-autonomous by Corollary 4.5, and so $\mathrm{Ext}^0_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty) = 0$ also. By Theorem 4.2, $P^c(\partial)$ is hyperbolic, which means that G is causal.

Conversely, suppose that G is causal. As observed preceding the theorem, $P^c(\partial)$ is hyperbolic and so $\mathrm{Ext}^1_{\mathbb{C}[s]}(\mathcal{M}', \mathcal{C}_+^\infty)$ vanishes by Theorem 4.2. Thus the map ρ is surjective, so the variables u are free over $\mathcal{C}_+^\infty$, i.e., (u, y) is causal for $\mathcal{B}^c$ and so for $\mathcal{B}$ by Corollary 4.5. This converse argument also applies to distributional solutions. □

In particular, Theorem 4.7 establishes that causality of a given input/output structure may be tested (when it is defined) merely by looking at the least common denominator d of the transfer matrix G. In fact, since the prior condition of time-autonomy enforces that $(\mathcal{B}^c)_{0,y}$ be time-autonomous (by Corollary 4.5) and therefore that $(0, \ldots, 0, 1)$ be noncharacteristic for d, we have that (u, y) is causal if and only if d satisfies the Gårding condition. Unfortunately, it is not immediately clear how the condition may be tested. One possibly tractable necessary and sufficient condition is given in [16, Prop. 6.1]; $\mathcal{M}$ is hyperbolic if and only if $(0, \ldots, 0, -1)$ does not appear in any of the asymptotic cones (at infinity) of the real parts of the varieties of the associated primes of $\mathcal{M}$; for brevity we omit a precise description.

We remark also that a well-known necessary condition for hyperbolicity of d is that the principal part of $pr(d)$ of d itself be hyperbolic (e.g., [9, Thm. 12.4.2]). The Gårding condition on $pr(d)$ is equivalent to requiring that the roots ζ of $pr(d)(\nu, \zeta)$ all be real for any real $\nu \neq 0$ (e.g., [9, Thm. 12.4.3]). Any further analysis of computational issues is outside the scope of this paper.

5. Convolution operators and ideal convexity. Before we tackle the subject of stable input/output structures, we need to explore two areas of background material. This first is convolution operators and Fourier transforms on the classical and other related spaces, as developed by Gindikin and Volevich [4]. This will lead us to a necessary and sufficient condition for input/output stability of the system

$p(\partial)y = u$. The second area is "ideal-convexity" of a region in complex space, which is a necessary property for the extension of certain results from polynomials to ideals (and thereby general systems).

5.1. Convolution operators on $\mathcal{S}, \mathcal{S}'$. The following material is largely taken from [4, secs. 1.1–1.2]. For $s \in \mathbb{N}$ and $l \in \mathbb{R}$, let $\mathcal{C}^{(s)}_{(l)}$ denote the space of s-times continuously differentiable functions f on $\mathbb{R}^n$ with finite Hölder norm

$$|f|^{(s)}_{(l)} := \sup_{x\in\mathbb{R}^n, \alpha\in\mathbb{N}^n, |\alpha|\le s} (1+x^2)^{l/2} |\partial^\alpha f(x)|. \tag{23}$$

Here $|\alpha|$ denotes the total of the components of α, and δ^α is a shorthand for the operator $p(\partial)$, where $p = (s_1^{\alpha_1} s_2^{\alpha_2}, \ldots, s_n^{\alpha_n})$. The following elementary lemma is not in [4] but will prove useful.

LEMMA 5.1. *If $f, g \in \mathcal{C}^{(s)}_{l/2}$ for some s, l, then $fg \in \mathcal{C}^{(s)}_{l}$.*

Proof. Suppose that f and g are in $\mathcal{C}^{(s)}_{(l/2)}$. We have

$$\sup_{x\in\mathbb{R}^n,\ |\alpha|\le s} (1+x^2)^{l/2} \, |\partial^\alpha (fg)(x)| = \sup_{x\in\mathbb{R}^n,\ |\alpha|\le s} (1+x^2)^{l/2} \left| \sum_{i\le\alpha} \beta_{i,\alpha} (\partial^i f)(x) (\partial^{\alpha-i} g)(x) \right|,$$

where the sum on the right-hand side is taken over all multi-indices i which are, componentwise, less than or equal to α, and $\beta_{i,\alpha}$ are constants depending only on i, α. Hence we obtain

$$\begin{aligned}
\sup_{x\in\mathbb{R}^n,\ |\alpha|\le s} (1+x^2)^{l/2} \, |\partial^\alpha (fg)(x)| &\le \sup_{x\in\mathbb{R}^n,\ |\alpha|\le s} \sum_{i\le\alpha} (1+x^2)^{l/2} |\beta_{i,\alpha}| \, |(\partial^i f)(x)| \, |(\partial^{\alpha-i} g)(x)| \\
&\le \max_{|\alpha|\le s} \sum_{i\le\alpha} |\beta_{i,\alpha}| \left(\sup_{x\in\mathbb{R}^n} (1+x^2)^{l/4} |(\partial^i f)(x)| \right) \\
&\quad \times \left(\sup_{x\in\mathbb{R}^n} (1+x^2)^{l/4} |(\partial^{\alpha-i} g)(x)| \right),
\end{aligned}$$

which is finite since for any α the sum given is a finite linear combination of terms which are finite by supposition. Therefore $fg \in \mathcal{C}^{(s)}_{(l)}$ as required. ∎

Recall that $\mathcal{S}$ is defined as the intersection of all the spaces $\mathcal{C}^{(s)}_{(l)}$. Also of interest is the set

$$\mathcal{L} := \bigcap_s \bigcup_l \mathcal{C}^{(s)}_{(l)} \tag{24}$$

which is the set of all smooth functions, each derivative of which grows no faster than some power of x (which power may depend on the derivative), and

$$\mathcal{O} := \bigcup_l \bigcap_s \mathcal{C}^{(s)}_{(l)} \tag{25}$$

the set of all smooth functions, each derivative of which grows no faster than some power of x which is independent of the derivative. ("$\mathcal{M}$" is used rather than "$\mathcal{L}$" in [4].) $\mathcal{O}$ may be thought of as the set of (at most) slowly growing smooth functions; its dual space is denoted by $\mathcal{O}'$ and may be thought of as the space of rapidly decreasing distributions. Clearly $\mathcal{S} \subseteq \mathcal{O} \subseteq \mathcal{L} \subseteq \mathcal{C}^\infty$. We collect some basic facts and results from [4, sec. 1.1].

LEMMA 5.2.

1. *$\mathcal{L}$ is a ring with respect to multiplication.*
2. *$\mathcal{S}$ is closed under multiplication by elements of $\mathcal{L}$.*
3. *$\mathcal{F}(\mathcal{S}) = \mathcal{S}$, $\mathcal{F}(\mathcal{S}') = \mathcal{S}'$, and $\mathcal{F}(\mathcal{O}') = \mathcal{L}$, where $\mathcal{F}$ denotes Fourier transform.*
4. *Let p be a polynomial. The equation*

$$p(\partial)y = u$$

is uniquely solvable for $y \in \mathcal{S}$ (resp., $\mathcal{O}$, $\mathcal{S}'$, $\mathcal{O}'$) for any $u \in \mathcal{S}$ (resp., $\mathcal{O}$, $\mathcal{S}'$, $\mathcal{O}'$), if and only if p has no imaginary roots.
5. *Any polynomial p is in $\mathcal{L}$, and the function $p(\imath\zeta)$ of ζ has an inverse in $\mathcal{L}$ if and only if p has no imaginary roots.*

Proof. The last claim is not given explicitly in [4]; note that polynomials are contained in $\mathcal{O} \subseteq \mathcal{L}$. That the inverse of $p(\imath\zeta)$ of ζ is in $\mathcal{L}$ if and only if p has no imaginary roots is implicit in the argument of [4, sec. 1.1.5]; we provide an argument based on their explicit results. By claim 4, the polynomial p has no imaginary roots if and only if the convolutional equation $p(\partial)y = u$ is uniquely solvable for $y \in \mathcal{O}'$ for any $u \in \mathcal{O}'$. By [4, Thm. 1.1.5], this holds if and only if there is a fundamental solution $E \in \mathcal{O}'$ with $(p(\partial)\delta) * E = E * (p(\partial)\delta) = \delta$, where δ is the Dirac delta and $*$ denotes convolution. By Fourier transform (use claim 3), this is equivalent to invertibility of $p(\imath\zeta)$ in $\mathcal{L}$. ∎

5.2. Convolution operators on $\mathcal{S}_+$, $\mathcal{S}'_+$. Still following [4], we now introduce the spaces $\mathcal{C}^{(s)}_{(l)+}$ of all functions in $\mathcal{C}^{(s)}_{(l)}$ with support in $\mathbb{R}^n_+$ and define $\mathcal{S}_+$, $\mathcal{S}'_+$, $\mathcal{S}'_\oplus$, etc., as before. $\mathcal{O}_+$ and $\mathcal{O}'_+$ are defined analogously. We have that $\mathcal{S}'_\oplus$ is the dual space of $\mathcal{S}_+$ and $\mathcal{S}'_+$ is dual to $\mathcal{S}_\oplus$.

Now for any Banach space B of functions $(\nu, \sigma) \in \mathbb{R}^{(n-1)+1}$ with norm $\phi \mapsto |\phi|_B$, denote by B^+ the space of functions f of $(\nu, \xi) \in \mathbb{R}^{n-1} \times \mathbb{C}$, $\xi = \sigma + \imath\rho$, with the following properties:

1. For each $\rho \leq 0$, the functions $f_\rho = f(\cdot, \cdot + \imath\rho)$ are in B, and the map $(-\infty, 0] \mapsto B$, $\rho \mapsto f_\rho$ is continuous.
2. For each $\nu \in \mathbb{R}^{n-1}$, the functions $f_\nu = f(\nu, \cdot)$ are functions holomorphic in $\mathbb{C}_-$.
3. The norm $\sup_{\rho<0} |f_\rho|_B$ is finite.

A space B^- may be defined analogously by changing the sign of ρ in conditions 1 and 3 and changing $\mathbb{C}_-$ for $\mathbb{C}_+$ in condition 2. Note that if $f(s) \in B^+$, then $F(-s) \in B^-$ and vice versa, provided that B is preserved by the same operation.

Now we define

$$\mathcal{S}^+ := \bigcap_{s,l} \mathcal{C}^{(s)+}_{(l)}, \tag{26}$$

$$\mathcal{L}^+ := \bigcap_{s} \bigcup_{l} \mathcal{C}^{(s)+}_{(l)}. \tag{27}$$

Spaces $\mathcal{S}^-$ and $\mathcal{L}^-$ may be defined analogously, and again if $f(s) \in \mathcal{L}^+$, then $f(-s) \in \mathcal{L}^-$ and vice versa.

The interest in these spaces comes from the following collection of points, from [4] except where proof is given below.

LEMMA 5.3.

1. $\mathcal{L}^+$ *is closed under multiplication.*
2. $\mathcal{S}^+$ *is closed under multiplication by elements of* $\mathcal{L}^+$ *and this multiplication rule is associative.*
3. $\mathcal{F}(\mathcal{S}_+) = \mathcal{S}^+$ *and* $\mathcal{F}(\mathcal{O}'_+) = \mathcal{L}^+$.
4. *Let* p *be a polynomial. The equation*

$$p(\partial)y = u$$

is uniquely solvable for $y \in \mathcal{S}'_+$ *for any* $u \in \mathcal{S}'_+$ *if and only if* p *has no roots in* $\mathcal{X}^+ = \mathbb{R}^{n-1} \times \overline{\mathbb{C}_+}$.
5. *The equation*

$$p(\partial)y = u$$

is uniquely solvable for $y \in \mathcal{S}'_+$ *for any* $u \in \mathcal{S}'_+$ *if and only if* p *has no roots in* $\mathbb{R}^{n-1} \times \overline{\mathbb{C}_+}$.
6. *Any polynomial* p *is in* $\mathcal{L}^+$ *and the function* $1/p(\imath\zeta)$ *of* ζ *is in* $\mathcal{L}^+$ *if and only if* p *has no roots in* $\mathcal{X}^+$.

Proof.

1. Note that multiplication is defined since the elements of $\mathcal{L}^+$ are functions. It follows from Lemma 5.1 that if $f, g \in \mathcal{C}^{(s)+}_{(l/2)}$ for some $l \in \mathbb{R}$, then $fg \in \mathcal{C}^{(s)+}_{(l/2)}$. Hence if $f, g \in \mathcal{L}^+$, then for any s there exists l with $f, g \in \mathcal{C}^{(s)+}_{(l)}$, and so $fg \in \mathcal{C}^{(s)+}_{(l)}$. Therefore $fg \in \mathcal{L}^+$.
2. The first point is given in [4, sec. 1.2.2], and the second is immediate as $\mathcal{L}^+$, $\mathcal{S}^+ \subseteq \mathcal{C}^\infty$.
3. These identities are (21) and (24) in [4, sec. 1].
4. This is Theorem 2(i) in [4, sec. 1.2.5].
5. This is Theorem 2(ii) in [4, sec. 1.2.5].
6. That polynomials are in $\mathcal{L}^+$ follows from claim 3, as polynomials are Fourier transforms of distributions with support at 0, which are therefore in $\mathcal{O}'_+$. Also from [4, Thm. 2(i), sec. 1.2.5], p has no roots in $\mathcal{X}^+$ if and only if $p(\partial)y = u$ is uniquely solvable over $\mathcal{O}'_+$. By [4, Thm. 1, sec. 1.2.5], this is equivalent to the condition that $p(\imath\zeta)^{-1} \in \mathcal{F}(\mathcal{O}'_+) = \mathcal{L}^+$. □

Clearly all the claims of Lemma 5.3 can be "time-reversed" to give corresponding results for $\mathcal{L}^-, \mathcal{S}_-, \mathcal{X}^-$, etc.

Claims 4 and 5 of Lemma 5.3 are our first input/output stability results. Claim 4, for example, states that if the input is both spatially and temporally rapidly decreasing (the first condition being a reasonable prior assumption on physical signals and the second meaning that it is "stable") and has zero past, then there exists a causal response with the same properties if and only if a certain condition (in fact CV) holds on p. Moreover, by time-autonomy (which can be assumed a priori), there cannot be any different causal system response; i.e., all causal responses are stable. Our main goal in what follows will be to generalize this result to the general system case.

5.3. Ideal convexity. In order to generalize the results in the previous section to systems, we will need certain properties of polynomials with respect to the set $\mathcal{X}^+$ to extend to ideals.

DEFINITION 5.4. *We call a set $S \subseteq \mathbb{C}^n$* codimension $k-$convex, $k = 1, \ldots, n$, *if for any codimension k prime ideal J we have*

$$\mathcal{V}(J) \cap S = \emptyset \Rightarrow \exists\, f \in J : \mathcal{V}(f) \cap S = \emptyset. \tag{28}$$

We say that S is ideal-convex if property (28) *holds for any (not necessarily prime) ideal J.*

The first of these properties was introduced in [32], in which it is shown that the closed unit polydisc is codimension $k-$convex for all k. Codimension 1–convexity is trivial, since any prime ideal of codimension 1 in $\mathbb{C}[s]$ is principal (it must contain an irreducible polynomial and so must be equal to the codimension 1 prime ideal generated by that polynomial). It was also observed in [32] that if $\mathcal{S}$ is codimension $k-$convex for $k = 1, \ldots, n$, then S is ideal convex; this is essentially due to claim 2 of the following simple but important result.

THEOREM 5.5. *Let $S \subseteq \mathbb{C}^n$ be one of the sets: $\imath\mathbb{R}^n, \mathcal{X}^+, \mathcal{X}^-$. We have*

1. *S is codimension $n-$convex.*
2. *If the minimal prime divisors of an ideal satisfy* (28)*, then the ideal itself also does.*
3. *For $n = 2$, S is ideal-convex.*

Proof.

1. Suppose that J is a maximal ideal with variety not intersecting $\mathcal{X}^+$. Both real and complex coefficient polynomial rings are covered by the following argument. Let $(\alpha_1, \ldots, \alpha_{n-1}, \beta)$ be a point in $\mathcal{V}(J)$. Then either $\Re(\alpha_i) \neq 0$ for some $i = 1, \ldots, n-1$, or else $\Re(\beta) < 0$. In the first case, $f := (s_i - \alpha_i)(s_i - \overline{\alpha_i})$ is a suitable polynomial in J, where $\bar{\cdot}$ denotes complex conjugate. In the second case, $f := (s_n - \beta)(s_n - \overline{\beta})$ may be chosen. The argument for $\mathcal{X}^-$ is symmetric and that for $\imath\mathbb{R}^n$ similar but simpler.
2. This property holds for arbitrary S. For suppose that I is a given ideal such that $\mathcal{V}(I) \cap S = \emptyset$, and that $J_1, \ldots, J_l$ are prime divisors of I and satisfy property (28). Then the product f of the corresponding polynomials $f_i \in J_i$ is contained in the intersection of the J_i, which equals the radical of I, and therefore some power f^k of f is in I, and we have $\mathcal{V}(f^k) \cap S = \emptyset$ as required.
3. For $n = 2$, any nonzero prime ideal has codimension either 1 or n; using claim 1 we have that property (28) holds for all prime ideals. By claim 2, S is ideal-convex. ∎

An important open question is whether the sets S in the preceding theorem are actually ideal-convex for all n. We will see in section 7 that this question has major implications for input/output stability. Ideal-convexity can also be expressed (see also Proposition 1 in [28]) as a "(weak) Nullstellensatz"-type result for the localized ring $U^{-1}\mathbb{C}[s]$, where U is the multiplicatively closed set of all polynomials which do not vanish anywhere in the given domain.

In [33], Valcher characterizes stability of autonomous behaviors for "square" behaviors (those admitting a square kernel representation matrix) and finite-dimensional behaviors (those for which the corresponding system module has codimension n). These seem to correspond to principal modules/ideals and maximal ideals, respectively, and we suspect that the generalization of [33] to the nD case hits a problem analogous to proving ideal-convexity here.

6. Structure theory over $\mathcal{S}$, $\mathcal{S}'$, $\mathcal{S}_+$, $\mathcal{S}'_\oplus$. In this section, we will develop some basic but highly nontrivial results concerning the structure of behaviors over $\mathcal{S}$ and $\mathcal{S}'$, and then $\mathcal{S}_+$ and $\mathcal{S}'_\oplus$. The second set of results and proofs follow the structure

of the first. The results for $\mathcal{S}$ and $\mathcal{S}'$ are also included for independent interest. Many of the results in this section and section 7 are restricted to the case $n = 2$; this is due only to the lack of a proof that the sets S in Theorem 5.5 are ideal-convex for all n. The material in this section and section 7 is entirely new, barring Theorem 6.1.

We begin by recalling a result on (Willems) closure from [36], which, however, we state in the most general form as indicated in that paper.

THEOREM 6.1. *Let $\mathcal{W}$ be a module over $\mathbb{C}[s]$ and $\mathcal{N}$ a submodule of $\mathbb{C}[s]^{1\times q}$ for some q. Suppose that $\mathcal{N} = \cap_{i=1}^{t}\mathcal{N}_i$ is an irredundant decomposition of $\mathcal{N}$ in $\mathbb{C}[s]^{1\times q}$, where $\mathcal{N}_i$ is a J_i-primary submodule of $\mathbb{C}[s]^{1\times q}$ for some prime ideals $J_1, \dots, J_t$. Let the components be ordered so that for some $r \in 0, \dots, t$, $J_1, \dots, J_r$ each annihilate some nonzero element of $\mathcal{W}$, but $J_{r+1}, \dots, J_t$ do not. Assume that each of the primes J_i, $i = 1, \dots, r$, is contained in some prime K_i which also annihilates some nonzero element of $\mathcal{W}$, and for which*

$$(0 : K_i^{\infty})_{\mathcal{W}} := \{w \in \mathcal{W} \mid K_i^l w = 0 \text{ for some } l \in \mathcal{N}\}$$

is an injective $\mathbb{C}[s]$-module. Then the closure of $\mathcal{N}$ with respect to $\mathcal{W}$ is given by

$$\mathcal{N}^{\perp\perp} = \bigcap_{i=1}^{r} \mathcal{N}_i. \tag{29}$$

The assumption holds in particular whenever $\mathcal{W}$ is itself injective.

Proof. This result is a small refinement of [36, Thm. 3.9], as indicated in the comments following that result. For completeness, we sketch the necessary modifications to the proof given in [36] to achieve this refinement.

As shown in the original proof, the inclusion "$\supseteq$" in (29) does not require any assumption on the primes $J_1, \dots, J_r$. For the reverse inclusion, set $\mathcal{D} = \mathbb{C}[s]$, $\mathcal{M} = \mathcal{D}^{1\times q}/\mathcal{N}$, and $\mathcal{L} = \cap_{i=1}^{r}\mathcal{M}_i$, $\mathcal{M}_i = \mathcal{N}_i/\mathcal{N}$, as in the original proof. As in the original proof, if $x \in \mathcal{M}\backslash\mathcal{L}$, then there exist $i \in 1, \dots, r$ and $a \in \mathcal{D}$ with $\mathcal{D}(ax + \mathcal{M}_i) \cong \mathcal{D}/J_i$. Now by assumption, J_i is contained in K_i with $(0 : K_i^{\infty})_{\mathcal{W}}$ injective and also nonzero as K_i annihilates some nonzero element of $\mathcal{W}$. As in the argument for P_j in the original proof, K_i must be contained in some prime Q with a copy of the injective hull $E(\mathcal{D}/Q)$ of $\mathcal{D}/Q$ embedded in $(0 : K_i^{\infty})_{\mathcal{W}}$. We therefore have a sequence of maps of the form

$$\mathcal{D}(ax + \mathcal{M}_i) \xrightarrow{\cong} \mathcal{D}/J_i \xrightarrow{\rho_1} \mathcal{D}/K_i \xrightarrow{\rho_2} \mathcal{D}/Q \to E(\mathcal{D}/Q) \to (0 : K_i^{\infty})_{\mathcal{W}},$$

where ρ_1 and ρ_2 are the natural projections. Call the composition map w_1. As in the original proof, if $w_1(ax + \mathcal{M}_i) = 0$, then we must have $(\rho_2 \circ \rho_2)(1 + J_i) = 0$ in $\mathcal{D}/Q$, which entails that $1 \in Q$. This is impossible, so $w_1(ax + \mathcal{M}_i) \neq 0$ and w_1 is not the zero map. As in the original proof, w_1 can then be extended using injectivity of $(0 : K_i^{\infty})_{\mathcal{W}}$ to a nonzero map $w : \mathcal{M} \to \mathcal{W}$, which further is nonzero at x. This is enough to complete the proof, as explained in [36].

The final claim follows since injectivity of $\mathcal{W}$ guarantees injectivity of $(0 : I^{\infty})_{\mathcal{W}}$ for any ideal I [14]. ∎

6.1. Structure theory over $\mathcal{S}$, $\mathcal{S}'$. In particular, we may derive from Theorem 6.1 the characterization by Shankar of closure with respect to $\mathcal{S}'$ [29] (this latter result, however, preceded and motivated the theorem above). $\mathcal{S}'$ is injective, as proved originally by Malgrange [12] and more recently by Shankar [31], and therefore

Theorem 6.1 applies; a prime J kills some nonzero element of $\mathcal{S}'$ if and only if it vanishes at some imaginary point. We repeat Shankar's result from [29] here, together with an alternative form for a special case.

COROLLARY 6.2. *Suppose that $\mathcal{N} = \cap_{i=1}^{t} \mathcal{N}_i$ is an irredundant decomposition of a submodule $\mathcal{N}$ of $\mathbb{C}[s]^{1\times q}$, where $\mathcal{N}_i$ is J_i-primary. Let the components be ordered so that for some $r \in 0, \ldots, t$, $J_1, \ldots, J_r$ each vanish at some point $\imath\mathbb{R}^n$ but $J_{r+1}, \ldots, J_t$ do not. Then the closure of $\mathcal{N}$ with respect to $\mathcal{W}$ is equal to $\cap_{i=1}^{r} \mathcal{N}_i$. Moreover, in the case where the primes are minimal in the set $J_{r+1}, \ldots, J_t$ and each has codimension 1 or n (e.g., when $n \leq 2$), there exists a polynomial f with no imaginary roots such that the closure with respect to $\mathcal{W}$ may be written*

$$\mathcal{N}^{\perp\perp} = \{v \in \mathbb{C}[s]^{1\times q} \mid \exists k \in \mathbb{N},\ f^k v \in \mathcal{N}\}. \tag{30}$$

Proof. The equality

$$\mathcal{N}^{\perp\perp} = \bigcap_{i=1}^{r} \mathcal{N}_i \tag{31}$$

is already given [29]. Now suppose that the primes are minimal among $J_{r+1}, \ldots, J_t$ and each has codimension 1 or n. By Theorem 5.5 there then exists $f \in \cap_{i=r+1}^{t} J_i$ with no imaginary roots. Note that f is contained in $J_{r+1}, \ldots, J_t$ but not in any of $J_1, \ldots, J_r$ (since these do have imaginary roots). Hence by [3, Prop. 3.13], the module

$$H^0_{(f)}(\mathcal{M}) := \{v + \mathcal{N} \in \mathcal{M} \mid f^k v \in \mathcal{N} \text{ for some } k \in \mathcal{N}\}$$

agrees with $\cap_{i=1}^{r} \mathcal{N}_i/\mathcal{N}$, where $\mathcal{M} = \mathbb{C}[s]^{1\times q}/\mathcal{N}$. This together with (31) gives us the required result. ∎

Note from the proof that the assumptions in the second claim of the corollary may be dropped if it can be shown that $\imath\mathbb{R}^n$ is ideal-convex for any n. From the corollary we can give conditions for one behavior over $\mathcal{S}'$ to be contained in another (when the assumptions of Corollary 6.2 hold).

COROLLARY 6.3. *Let $\mathcal{B}_1 = \ker_{\mathcal{S}'} R_1$ and $\mathcal{B}_2 = \ker_{\mathcal{S}'} R_2$ be two behaviors contained in $(\mathcal{S}')^q$ for some q. Let $\mathcal{N}_1$ be the row span of R_1 over $\mathbb{C}[s]$. Suppose that the primes, minimal among those associated primes of the module $\mathbb{C}[s]^{1\times q}/\mathcal{N}_1$ with no imaginary points in their varieties, each have codimension 1 or n; this occurs, in particular, when $n \leq 2$. Then $\mathcal{B}_1 \subseteq \mathcal{B}_2$ if and only if there exist a polynomial f with no imaginary roots and a polynomial matrix L, such that $fR_2 = LR_1$.*

Proof. Suppose that such an f and L exist with $fR_2 = LR_1$. Then for any $w \in \ker_{\mathcal{S}'} R_1$, $f(\partial)(R_2(\partial)w) = 0$. Since f has no imaginary roots, by Corollary 6.2 the closure with respect to $\mathcal{S}'$ of the ideal generated by f is equal to $\mathbb{C}[s]$; i.e., f kills no nonzero element of $\mathcal{S}'$. Hence $R_2(\partial)w = 0$ as required.

Conversely, suppose that $\mathcal{B}_1 \subseteq \mathcal{B}_2$. Writing $\mathcal{N}_1$ and $\mathcal{N}_2$ for the row spans of R_1 and R_2, respectively, we have

$$\mathcal{N}_2 \subseteq \mathcal{N}_2^{\perp\perp} \subseteq \mathcal{N}_1^{\perp\perp},$$

where $\cdot^{\perp\perp}$ denotes closure with respect to $\mathcal{S}'$. By the second claim of Corollary 6.2 (which requires the given assumptions on $\mathbb{C}[s]^{1\times q}/\mathcal{N}_1$ or on n), there is a polynomial f with no imaginary roots such that for each row of R_2, f^k times that row is in $\mathcal{N}_1$ for sufficiently large k. Note that f^k also has no imaginary roots. The converse follows. ∎

Again, the assumptions in Corollary 6.3 are needed only because it has not been proven yet that $\imath\mathbb{R}^n$ is ideal-convex. These assumptions prove an obstacle to the next result, which for this reason only is restricted to the special cases when P is a polynomial or $n \leq 2$.

THEOREM 6.4. *Let*

$$\mathcal{B} := \{(u, y) \in (\mathcal{D}')^{m+p} \mid P(\partial)y = Q(\partial)u\}$$

be a behavior with the indicated input/output structure and corresponding transfer matrix G. Suppose that either P is a single polynomial or $n \leq 2$. Then the following are equivalent:

1. *The variables u are free over $\mathcal{S}$ in $\mathcal{B}$.*
2. $\ker_{\mathcal{S}'} P^* \subseteq \ker_{\mathcal{S}'} Q^*$.
3. *There exist a polynomial r with no imaginary roots and a polynomial matrix L, such that $G = \frac{1}{r}L$.*
4. *$\mathcal{B}$ has no imaginary controllable poles.*
5. $G(\imath\zeta) \in \mathcal{L}^{p\times m}$.

Proof. 5 $\Rightarrow$ 1: Suppose $G^*(\imath\zeta) \in \mathcal{L}^{p\times m}$. Then for any $u \in \mathcal{S}^m$ we have that $v(\zeta) := G^*(\imath\zeta)\hat{u}(\zeta) \in \mathcal{S}^p$, where $\hat{\cdot}$ denotes the Fourier transform, using claim 2 of Lemma 5.2. Now $P(\imath\zeta)v(\zeta) = Q(\imath\zeta)\hat{u}(\zeta)$, so the inverse Fourier transform of v is a solution y to $P(\partial)y = Q(\partial)u$.

1 $\Rightarrow$ 2: If the variables u are free over $\mathcal{S}$, then $\mathrm{im}_{\mathcal{S}}Q \subseteq \mathrm{im}_{\mathcal{S}}P$. Dualizing (in the distributional sense), we have condition 2.

2 $\Rightarrow$ 3: Suppose that condition 2 holds. If P is a single polynomial, then the associated primes of the system module of $P^*(\partial)$ all have codimension 1; thus in either this case or when $n \leq 2$, the conditions of Corollary 6.3 hold. Thus by this corollary, there exist a polynomial r with no imaginary roots and a polynomial matrix L, with $r^*Q^* = L^*P^*$, and hence $P(L/r) = Q$. Since P has full column rank, L/r equals G.

3 $\Rightarrow$ 4: This is immediate from Lemma 2.3.

4 $\Rightarrow$ 5: Suppose $\mathcal{B}$ has no imaginary controllable poles, and let r be the least common denominator of G. So, in particular, $G = (1/r)L$ for some polynomial matrix L, and r has no imaginary zeros. By claim 5 of Lemma 5.2, $(1/r)I_p \in \mathcal{L}^{p\times p}$, and now by claim 1 of Lemma 5.2, $G = (1/r)L \in \mathcal{L}^{p\times m}$. ∎

Similarly, we can also produce the following lemma.

LEMMA 6.5. *With the notation of Theorem 6.4 (but no assumptions on n or P are needed), the following are equivalent:*

1. *The variables u are free over $\mathcal{C}_0^\infty$ in $\mathcal{B}$.*
2. *The variables u are free over $\mathcal{E}'$ in $\mathcal{B}$.*
3. *$\mathcal{B}$ has no controllable poles or, equivalently, the outputs are observable from the inputs in $\mathcal{B}^c$.*
4. *G is a polynomial matrix.*

Proof. For either case $\mathcal{C}_0^\infty$, $\mathcal{E}'$, we use the same proof structure as for Theorem 6.4; dualizing condition 1 or 2 gives a condition for inclusion of behaviors over $\mathcal{D}'$ or over $\mathcal{C}^\infty$, which results in G being a polynomial matrix. Conversely, if G is a polynomial matrix, then with input $u \in (\mathcal{C}_0^\infty)^m$ or $u \in (\mathcal{E}')^m$ we can simply choose $y = G(\partial)u$. ∎

For completeness, we offer a result without prior assumption of an input/output structure.

COROLLARY 6.6. *Let a behavior $\mathcal{B}$ be given by*

$$\mathcal{B} := \{(u, y) \in (\mathcal{D}')^{m+p} \mid P(\partial)y = Q(\partial)u\},$$

where (u, y) is an arbitrary partition of the system variables. Then the following hold:

1. *The variables u are free over either $\mathcal{C}_0^\infty$ or $\mathcal{E}'$ in $\mathcal{B}$ if and only if there exists a polynomial matrix L with $PL = Q$. The maximum number of free variables over $\mathcal{C}_0^\infty$ or $\mathcal{E}'$ of a behavior $\mathcal{B}$ with kernel representation R equals the number of systems variables minus the minimum number of columns of R needed to generate column span over $\mathbb{C}[s]$.*
2. *Suppose $n \leq 2$. The variables u are free over $\mathcal{S}$ if and only if there exist a polynomial r and a polynomial matrix L, such that $PL = Qr$. The maximum number of free variables over $\mathcal{S}$ of a behavior $\mathcal{B}$ with kernel representation R equals the number of system variables minus the number of columns of R needed to generate the column span over the localized ring $U^{-1}\mathbb{C}[s]$, where U is the set of polynomials with no imaginary roots.*

Proof. We prove the second claim only, that u is free over $\mathcal{S}$ if and only if given that L, r exist follows entirely from the arguments $1 \Rightarrow 2 \Rightarrow 3,\ 5 \Rightarrow 1$, which do not require prior existence of an input/output structure. Finally, note that a given set of columns forming a submatrix P of R generates the column span of R over $U^{-1}\mathbb{C}[s]$ if and only if there exists a matrix K over $U^{-1}\mathbb{C}[s]$ with $PK = Q$, where Q consists of the complementary columns of R. This is clearly equivalent to the given condition for freeness over $\mathcal{S}$ of the variables corresponding to the columns of Q; the result follows. ∎

Recall that over $\mathcal{C}^\infty, \mathcal{D}'$, or $\mathcal{S}'$, a set of variables are free if and only if the corresponding elements in the system module are linearly independent over $\mathbb{C}[s]$ [35, Lem. 5.3]; this is due to injectivity of these three spaces. Equivalently, with the notation of Corollary 6.6, there exists a rational function matrix G with $PG = Q$. For $n \leq 2$, the corollary above completes the description of free variables over the classical spaces; the full generalization to $n > 2$ for $\mathcal{S}$ rests on proving ideal-convexity of $\imath\mathbb{R}^n$.

6.2. Structure theory over $\mathcal{S}_+, \mathcal{S}'_\oplus$. Our next aim is to repeat the pattern of Corollaries 6.2 and 6.3 and Theorem 6.4, but for $\mathcal{S}'_\oplus$ and $\mathcal{S}_+$ instead of $\mathcal{S}'$ and $\mathcal{S}$. This will give us results which we can then interpret in terms of stability. Notice that $\mathcal{S}'_\oplus := \mathcal{S}'/\mathcal{S}_-$ may be interpreted as the restriction of tempered distributions to $\mathbb{R}^n_+$.

To begin, we demonstrate that usual results on adjoint operators apply to the space $\mathcal{S}_+$ and dual $\mathcal{S}'_\oplus$.

LEMMA 6.7. *If $R \in \mathbb{C}[s]^{g\times q}$, then for any $f \in (\mathcal{S}'_\oplus)^q, \phi \in (\mathcal{S}_+)^g$ we have*

$$\langle R(\partial)f, \phi\rangle = \langle f, R^*(\delta)\phi\rangle. \tag{32}$$

Hence $f \in \ker'_{\mathcal{S}_\oplus} R$ if and only if f kills $\operatorname{im}_{\mathcal{S}_+} R^*$.

Proof. Let R, f, and ϕ be as given; denote by ι the natural inclusion $\mathcal{S}_+ \to \mathcal{S}$. Let $\overline{f} \in (\mathcal{S}')^q$ be some element such that its equivalence class in $\mathcal{S}'_+$ agrees with f, and let $\overline{h} = R(\partial)\overline{f} \in (\mathcal{S}')^g$; then $\overline{h} + (\mathcal{S}'_+)^g = R(\partial)f$ by definition of differentiation on a factor space such as $\mathcal{S}'_\oplus$. We now have

$$\begin{aligned}
\langle R(\partial)f, \phi\rangle &:= \langle \overline{h}, \iota(\phi)\rangle \\
&= \langle R(\partial)\overline{f}, \iota(\phi)\rangle \\
&= \langle \overline{f}, R^*(\partial)\iota(\phi)\rangle \\
&= \langle \overline{f}, \iota(R^*(\partial)\phi)\rangle \\
&= \langle f, R^*(\partial)\phi\rangle.
\end{aligned}$$

The second claim is immediate. ∎

We now provide some elementary results on the structure of $\mathcal{S}'_\oplus$ as a differential module.

LEMMA 6.8. *Let r be a polynomial. Then the differential operator $r(\partial)$ kills some nonzero element of $\mathcal{S}'_\oplus$ if and only if r has a root in $\mathcal{X}^-$.*

Proof. Suppose that r has no roots in $\mathcal{X}^-$ and let $\overline{w} = w + \mathcal{S}'_- \in \mathcal{S}'_\oplus$ be such that $r(\partial)\overline{w} = 0$. Then $r(\partial)w \in \mathcal{S}'_-$, so $r(\imath\zeta)\hat{w}(\zeta) \in \mathcal{F}(\mathcal{S}'_-)$, where $\mathcal{F}$ denotes Fourier transform, and by claim 3 of Lemma 5.3 this space equals $\mathcal{L}^-$. By claim 6 of Lemma 5.3, $1/r(\imath\zeta) \in \mathcal{L}^-$, and so by claim 1 of Lemma 5.3, $\hat{w}(\zeta) \in \mathcal{L}^- = \mathcal{F}(\mathcal{S}'_-)$ also. Hence $\overline{w} = 0$.

Conversely, suppose that r does not have a root $\zeta \in (\imath\mathbb{R}^{n-1} \times \overline{\mathbb{C}_-})$. Corresponding to this is a nonzero exponential trajectory u of frequency ζ which lies in $\mathcal{C}^\infty$. Multiplying it by a suitable "cut-off" function, we have a trajectory $w \in L^\infty \subseteq \mathcal{S}'$ which agrees with u on $\mathbb{R}^n_+$. As u is killed by $r(\partial)$, the support of $r(\partial)w$ lies in $\mathbb{R}^n_-$, and therefore $r(\partial)(w + \mathcal{S}'_-) = 0$, whereas $w + \mathcal{S}^+_- \neq 0$ because u is nonzero on $\mathbb{R}^n_+$. ∎

Next we generalize this to ideals, which requires ideal-convexity, and so is restricted to special cases, e.g., $n \leq 2$.

LEMMA 6.9. *If an ideal I kills some nonzero element of $\mathcal{S}'_\oplus$, then $\mathcal{V}(I) \cap \mathcal{X}^- \neq \emptyset$. The converse holds when the minimal primes containing I each have codimension 1 or n (e.g., when $n \leq 2$).*

Proof. Suppose that I vanishes at some point $\zeta \in (\imath\mathbb{R}^{n-1} \times \overline{\mathbb{C}_-})$. As in the proof of Lemma 6.8, we can construct a nonzero trajectory $w \in \mathcal{S}'_\oplus$ which is killed by the maximal ideal corresponding to ζ, and therefore killed by I.

Conversely, suppose that $\mathcal{V}(I) \cap \mathcal{X}^- = \emptyset$. By Theorem 5.5 (using the assumption on I), there exists $f \in I$ which has no roots in $\imath\mathbb{R}^{n-1} \times \overline{\mathbb{C}_-}$. Now if $Iw = 0$ for some $w \in \mathcal{S}'_\oplus$, then $f(\partial)w = 0$ in particular, so by Lemma 6.8, $w = 0$. ∎

Lemmas 6.8 and 6.9 are basic results on closure with respect to $\mathcal{S}'_\oplus$. In order to extend them to more general cases, we need some injectivity properties of certain modules associated to $\mathcal{S}'_\oplus$.

LEMMA 6.10. *For any maximal ideal I, $(0 : I^\infty)_{\mathcal{S}'_\oplus}$ is injective.*

Proof. In the case where I annihilates no nonzero element of $\mathcal{S}'_\oplus$, $(0 : I^\infty)_{\mathcal{S}'_\oplus} = 0$ is trivially injective. So suppose that I does annihilate some nonzero element of $\mathcal{S}'_\oplus$, which by Lemma 6.9 means that $\exists\, \zeta \in \mathcal{V}(I) \cap \mathcal{X}^-$; indeed we must have $\mathcal{V}(I) = \{\zeta\}$.

Now let $\Psi : (0 : I^\infty)_{\mathcal{D}'} \to (0 : I^\infty)_{\mathcal{D}'_\oplus}$ be the module homomorphism induced by the natural projection $\mathcal{D}' \to \mathcal{D}'_\oplus$. Since $(0 : I^\infty)_{\mathcal{D}'} = (0 : I^\infty)_{\mathcal{C}^\infty}$ is the set of polynomial exponentials with frequency ζ [18, 37], Ψ is clearly injective. Consider an arbitrary element $w \in (0 : I^\infty)_{\mathcal{D}'}$. We can write $w = pw'$, where p is a polynomial function and w' is an exponential trajectory of frequency ζ. Letting $f \in \mathcal{C}^\infty(\mathbb{R})$ be a "cut-off" function with $f(t) = 1$ for $t \geq 0$ and $f(t) = 0$ for $t \ll 0$, by the location of ζ we have that $f(t)w'(x,t) \in L^\infty \subseteq \mathcal{S}'$. Since by the Fourier transformation $\mathcal{S}'$ is closed under multiplication by polynomials, $fw = pfw' \in \mathcal{S}'$ also. Now fw agrees with w on $\mathbb{R}^n_+$, so $\Phi(w) = \Phi(fw) = fw + \mathcal{D}'_- \in \mathcal{D}'_\oplus$. It follows that

$$\text{im } \Psi \subseteq \frac{\mathcal{S}' + \mathcal{D}'_-}{\mathcal{D}'_-} \cong \frac{\mathcal{S}'}{\mathcal{S}' \cap \mathcal{D}'_-} = \mathcal{S}'_\oplus.$$

Hence we can construct another injective module homomorphism $\Phi : (0 : I^\infty)_{\mathcal{D}'} \to (0 : I^\infty)_{\mathcal{S}'_\oplus}$. The module $(0 : I^\infty)_{\mathcal{D}'}$ is injective because $\mathcal{D}'$ is injective [14], so it remains to show that Φ is surjective, or equivalently that the image of Ψ is $(0 : I^\infty)_{\mathcal{W}}$, where $\mathcal{W} = (\mathcal{S}' + \mathcal{D}'_-)/\mathcal{D}'$. However, if $\overline{w} = w + \mathcal{D}'$ with $w \in \mathcal{S}'$ and $I^k\overline{w} = 0$ for some k, we have that the support of $I^k w$ is in $\mathbb{R}^n_-$; i.e., w is a solution in $\mathbb{R}^n_+$ to the equations

of I^k. However, any distributional solution in $\mathbb{R}^n_+$ to the equations of I^k necessarily agrees in that region with a polynomial exponential of degree k, i.e., an element $\hat{w}$ of $(0 : I^k)_{\mathcal{D}'}$, as can be seen by induction on k (the base case $k = 1$ is clear as it reduces to the ODE case). Hence $\Psi(\hat{w}) = w$ as required. ∎

Lemma 6.10 leaves the important open question as to whether $\mathcal{S}'_\oplus$ itself is an injective module. We now provide a technical result, which sets up the conditions necessary to apply Theorem 6.1 over $\mathcal{S}'_\oplus$.

COROLLARY 6.11. *Any prime ideal which vanishes at some point of $\mathcal{X}^-$ is contained in a prime I which has the same property, and for which $(0 : I^\infty)_{\mathcal{S}'_\oplus}$ is injective.*

Proof. Let J be a prime for which $\mathcal{V}(J) \cap \mathcal{X}^- \neq \emptyset$. Thus there exists a maximal ideal I which vanishes at some point of $\mathcal{X}^-$ and for which $\mathcal{V}(I) \subseteq \mathcal{V}(J)$, so $J \subseteq I$. Lemma 6.10 now completes the proof. ∎

In certain special cases, e.g., $n \leq 2$, we can now characterize closure over $\mathcal{S}'_\oplus$.

COROLLARY 6.12. *Suppose that $\mathcal{N} = \cap_{i=1}^t \mathcal{N}_i$ is an irredundant primary decomposition of a submodule $\mathcal{N}$ of $\mathbb{C}[s]^{1\times q}$, where $\mathcal{N}_i$ is J_i-primary. Let the components be ordered so that for some $r \in 0, \ldots, t$, $J_1, \ldots, J_r$ each vanishes at some point of $\mathcal{X}^-$ but $J_{r+1}, \ldots, J_t$ do not. Suppose further that the primes $J_{r+1}, \ldots, J_t$ each have codimension 1 or n (e.g., $n \leq 2$). Then the closure of $\mathcal{N}$ with respect to $\mathcal{S}'_\oplus$ is equal to $\cap_{i=1}^r \mathcal{N}_i$, and, furthermore, there exists a polynomial f with no roots in $\mathcal{X}^-$ such that the closure with respect to $\mathcal{S}'_\oplus$ may be written*

$$\mathcal{N}^{\perp\perp} = \{v \in \mathbb{C}[s]^{1\times q} \mid \exists\, k \in \mathbb{N},\ f^k v \in \mathcal{N}\}. \tag{33}$$

Proof. Suppose that the primes $J_{r+1}, \ldots, J_t$ each has codimension 1 or n. Then by Lemma 6.9, $J_1, \ldots, J_r$ each annihilate a nonzero element of $\mathcal{S}'_\oplus$, whereas $J_{r+1}, \ldots, J_t$ do not. Using also Corollary 6.11, we have that $\mathcal{N}^{\perp\perp} = \cap_{i=1}^r \mathcal{N}_i$ by Theorem 6.1. Now by Theorem 5.5 there exists $f \in \cap_{i=r+1}^t J_i$ with no roots in $\mathcal{X}^-$. As in the proof of Corollary 6.2, we can now establish (33). ∎

Note that the codimension conditions in Corollary 6.12 in particular hold when $\mathcal{N}$ is equal to $\mathbb{C}[s] \cdot p(s)$ for p a single polynomial.

COROLLARY 6.13. *Let $\mathcal{B}_1 = \ker_{\mathcal{S}'_\oplus} R_1$ and $\mathcal{B}_2 = \ker_{\mathcal{S}'_\oplus} R_2$ be two behaviors contained in $(\mathcal{S}'_\oplus)^q$ for some q. Let $\mathcal{N}_1$ be the row span of R_1 over $\mathbb{C}[s]$. Suppose that those associated primes of $\mathbb{C}[s]^{1\times q}/\mathcal{N}_1$ with varieties not intersecting $\mathcal{X}^-$ each have codimension 1 or n (for example, $\mathbb{C}[s]^{1\times q}/\mathcal{N}_1$ is principal or $n \leq 2$). Then $\mathcal{B}_1 \subseteq \mathcal{B}_2$ if and only if there exist a polynomial f with no roots in $\mathcal{X}^-$ and a polynomial matrix L, such that $fR_2 = LR_1$.*

Proof. The proof uses exactly the same argument as for Corollary 6.3. ∎

It is the failure to prove ideal-convexity of $\mathcal{X}^-$ which prevents generalization of Corollaries 6.12 and 6.13 to the general nD case.

7. Stable input/output structures. Having finally done all the necessary groundwork, we can now consider input/output stability. We consider this only for input/output structures which are a priori causal (with respect to $\mathcal{C}^\infty$ or $\mathcal{D}'$ according to the type of stability required); thus, in particular, we assume that $\mathcal{B}_{0,y}$ is time-autonomous.

DEFINITION 7.1. *Let $\mathcal{B}$ be a behavior with associated input/output structure (u, y), where $\mathcal{B}_{0,y}$ is time-autonomous and the input/output structure is causal. Call this input/output structure* stable (with respect to $\mathcal{S}$ (resp., $\mathcal{S}'$)) *if for any $u \in (\mathcal{S}_+)^m$ (resp., $u \in (\mathcal{S}_+)^m$) and $y \in (\mathcal{C}^\infty_+)^p$ (resp., $y \in (\mathcal{D}'_+)^p$) for which $(u, y) \in \mathcal{B}$, we must have $y \in (\mathcal{S}_+)^p$ (resp., $y \in (\mathcal{S}'_+)^p$).*

Thus, roughly speaking, an input/output structure is stable if any causal output response to a stable input is itself stable. Since it is reasonable to assume a priori that our input/output structure is causal, the existence of a $y \in (\mathcal{C}_+^\infty)^p$ corresponding to a $u \in (\mathcal{S}_+)^m$ is guaranteed. Moreover, if $\mathcal{B}_{0,y}$ is a priori time-autonomous, this y is unique, and so in this case the input/output structure is stable with respect to $\mathcal{S}$ (resp., $\mathcal{S}'$) if and only if the variables u are free over the signal space $\mathcal{S}$ (resp., $\mathcal{S}'$). Fortunately, using methods analogous to those in the proof of Theorem 6.4, we can now characterize freeness of variables over $\mathcal{S}_+$ using the structure theory developed in the last section. The results for $\mathcal{S}_+$ are, however, restricted to the special cases when $n \leq 2$ or P is a single polynomial (i.e., there is a single system equation), due to the difficulty of proving ideal-convexity for $n > 2$, whereas those for $\mathcal{S}'_+$ give sufficient conditions for freeness only.

THEOREM 7.2. *Let*

$$\mathcal{B} := \{(u, y) \in (\mathcal{D}')^{m+p} \mid P(\partial)y = Q(\partial)u\}$$

be a behavior with given input/output structure, and transfer matrix G. Suppose that either P is a single polynomial or $n \leq 2$. Then the following are equivalent.

1. *The variables u are free over $\mathcal{S}_+$ in $\mathcal{B}$.*
2. $\ker_{\mathcal{S}'_\oplus} P^* \subseteq \ker_{\mathcal{S}'_\oplus} Q^*$.
3. *There exist a polynomial r with no roots in $\mathcal{X}^+$ and a polynomial matrix L, such that $G = \frac{1}{r}L$.*
4. *$\mathcal{B}$ has no controllable poles in $\mathcal{X}^+$.*
5. $G(\imath\zeta) \in (\mathcal{L}^+)^{p+m}$.

Proof. The proof has the same structure of that of Theorem 6.4.

5 $\Rightarrow$ 1: Suppose $G(\imath\zeta) \in (\mathcal{L}^+)^{p\times m}$. Then for any $u \in (\mathcal{S}_+)^m$ we have that $v(\zeta) := G(\imath\zeta)\hat{u}(\zeta) \in (\mathcal{S}^+)^p$, where $\hat{\cdot}$ denotes the Fourier transform, using claims 2 and 3 of Lemma 5.3. Now using claims 2 and 6 of Lemma 5.3, we have that $P(\imath\zeta)v(\zeta) = Q(\imath\zeta)\hat{u}(\zeta)$, so the inverse Fourier transform of v is a solution y to $P(\partial)y = Q(\partial)u$. By claim 3 of Lemma 5.3, $y \in (\mathcal{S}_+)^p$.

1 $\Rightarrow$ 2: Suppose the variables u are free over $\mathcal{S}_+$. Then $\mathrm{im}_{\mathcal{S}_+} Q \subseteq \mathrm{im}_{\mathcal{S}_+} P$. Using Lemma 6.7, we find the dual condition 2.

2 $\Rightarrow$ 3: Suppose that condition 2 holds. If P is a single polynomial, then the associated primes of the system module of $P^*(\partial)$ all have codimension 1; thus in either this case or when $n \leq 2$, the conditions of Corollary 6.13 hold. Thus by this corollary there exist a polynomial r^* with no roots in $\mathcal{X}^-$ and a polynomial matrix L^*, with $r^*Q^* = L^*P^*$. Hence $P(L/r) = Q$, where r has no roots in $\mathcal{X}^+$. Since P has full column rank, L/r equals G.

3 $\Rightarrow$ 4: This part of the proof is again immediate from the fact that the controllable pole variety of $\mathcal{B}$ is the variety of the least common denominator of G.

4 $\Rightarrow$ 5: Suppose $\mathcal{B}$ has no controllable poles in $\mathcal{X}^+$, and let r be the least common denominator of G, so in particular $G = (1/r)L$ for some polynomial matrix L, and r has no zeros in $\mathcal{X}^+$. By claim 6 of Lemma 5.3, $(1/r)I_p \in (\mathcal{L})^{p\times p}$, and now by claim 1 of Lemma 5.3, $G = (1/r)L \in (\mathcal{L}^+)^{p\times m}$. ∎

Note. A topic for future research is to seek further characterizations for a principal module, other than computing its associated primes. This could well lead to generalizations of Theorems 6.4 and 7.2 with less restrictive assumptions.

Let us consider the case of single polynomials in the equivalent conditions $2 \equiv 3 \equiv 5$ in Theorem 7.2; take q and $p \neq 0$ rather than their adjoints for ease of notation. We have that $\ker_{\mathcal{S}'_\oplus} p \subseteq \ker_{\mathcal{S}'_\oplus} q$ if and only if $p/\gcd(p, q)$ has no roots in $\mathcal{X}^-$ if and

only if $(q/p)(\imath\zeta) \in \mathcal{L}^-$. From this we may define an action of $\mathcal{L}^-$ on $\mathcal{S}'_\oplus$: given any $u \in \mathcal{S}'_\oplus$ we can choose an arbitrary $v \in \mathcal{S}'_\oplus$ with $u = p(\partial)v$; this is possible as $\mathcal{S}'_\oplus$ is a divisible $\mathbb{C}[s]$-module due to divisibility of $\mathcal{S}'$. Now $y := q(\partial)v \in \mathcal{S}_{\oplus'}$ is uniquely determined by u, due to the condition $\ker_{\mathcal{S}'_\oplus} p \subseteq \ker_{\mathcal{S}'_\oplus} q$, and we have $p(\partial)y = q(\partial)u$. Thus we have an extension of the operator ring on $\mathcal{S}'_\oplus$ from $\mathbb{C}[s]$ to $\mathcal{L}^-$, analogous to the construction of Glüsing-Lüerssen in [5] for delay-differential systems (however, in the current case, the extended ring is a localization, unlike in [5]). It may be profitable, as in the delay-differential case, to consider systems defined as equations over this extended ring. Analogous remarks apply to the signal space $\mathcal{S}'$ and ring $\mathcal{L}$.

We now give a generalization of claim 5 of Lemma 5.3, which gives sufficient conditions for freeness of variables over $\mathcal{S}'_+$. We suspect that these conditions are also necessary.

COROLLARY 7.3. *Let*

$$\mathcal{B} := \{(u, y) \in (\mathcal{D}')^{m+p} \mid P(\partial)y = Q(\partial)u\}$$

be a behavior with given input/output structure and transfer matrix G, and suppose that the denominators of G have no roots in $\mathbb{R}^{n-1} \times \mathbb{C}_+$. Then the variables u are free over $\mathcal{S}'_+$ in $\mathcal{B}$.

Proof. Let $\mathcal{B}, P, Q$, and G be as given. Let d be the least common denominator of G, so that $Gd = N$, a polynomial matrix, and d has no roots in $\mathbb{R}^{n-1} \times \mathbb{C}_+$. Let $u \in (\mathcal{S}'_+)^m$ be arbitrary. Then by claim 5 of Lemma 5.3, there exists $y \in (\mathcal{S}'_+)^p$ satisfying

$$d(\partial)y = N(\partial)u.$$

We now have that $P(\partial)d(\partial)y = P(\partial)N(\partial)u = Q(\partial)d(\partial)u$. Hence $d(\delta)$ kills $P(\partial)y - Q(\partial)u$. However, $d(\delta)$ can kill no elements of $\mathcal{S}'_+$, again by claim 5 of Lemma 5.3, and so $P(\partial)y = Q(\partial)u$. This proves that the variables u are free over $\mathcal{S}'_\oplus$. ∎

Note that the conditions of Corollary 7.3 are particularly met when the equivalent conditions of Theorem 7.2 are satisfied. One consequence of this corollary is that when G is as specified, given any input u which is a Dirac delta in one component and zero in the others (and so in $(\mathcal{S}'_+)^m$), there is a corresponding causal output in $(\mathcal{S}'_+)^p$. If we assume time-autonomy of $\mathcal{B}_{0,y}$, then these causal outputs are unique, and we may collect them into a matrix called the *impulse response matrix* H_{imp}. When G is further stable, the input-to-output map over $\mathcal{S}_+$, which exists due to Theorem 7.2, is then given by applying H_{imp} as a convolution operator. However, as shown in the proof $5 \Rightarrow 1$ of Theorem 7.2, it can also be given by Fourier transformation, multiplication by $G(\imath\zeta)$, and inverse Fourier transformation. Thus H_{imp} is indeed the inverse Fourier transform of the transfer matrix G. Moreover, by Lemma 5.3 we have $\mathcal{L}^+ = \mathcal{F}(\mathcal{O}'_+)$, so we have $H_{imp} \in (\mathcal{O}'_+)^{p \times m}$.

Our next result shows that, as for causality, when stability with respect to $\mathcal{S}$ of an input/output structure is defined, it is characterized purely in terms of the transfer matrix. This result is, however, restricted to the cases $n \leq 2$ or P is a single polynomial. For the case of stability with respect to $\mathcal{S}'$, no such restriction is needed, but only a sufficient condition is obtained.

THEOREM 7.4. *Let $\mathcal{B}$ be a behavior with a given input/output structure (u, y), such that $\mathcal{B}_{0,y}$ is time-autonomous, and associated transfer matrix G. If G is weakly stable, then (u, y) is causal with respect to $\mathcal{D}'$ and stable with respect to $\mathcal{S}'$. Moreover, suppose that either $n \leq 2$ or $\mathcal{B}_{0,y}$ is defined by a single polynomial. Then (u, y) is*

both causal with respect to $\mathcal{C}^\infty$ and stable with respect to $\mathcal{S}$ if and only if G is stable or, equivalently, if and only if $G(\imath\zeta) \in (\mathcal{L}^+)^{p\times m}$.

Proof. Let $\mathcal{B}$ be given with $\mathcal{B}_{0,y}$ time-autonomous. Suppose first that G is weakly stable or stable (the equivalent characterization of stability of G in terms of $\mathcal{L}^+$ is immediate from Theorem 7.2). Let d be the least common denominator of G, which satisfies the WCV condition and therefore obeys the Gårding condition (20). As $\mathcal{B}_{0,y}$ is time-autonomous, $(\mathcal{B}^c)_{0,y}$ is time-autonomous also by Corollary 4.5. Since $\mathcal{V}(d)$ is equal to the characteristic variety of $(\mathcal{B}^c)_{0,y}$ (Lemma 2.3), $(0, 0, \ldots, 1)$ is also a non-characteristic direction for $d(\partial)$; hence, being a single polynomial, d is hyperbolic by Theorem 3.3. In other words, G is causal. Now by Theorem 4.7, the input/output structure on $\mathcal{B}$ is causal with respect to both $\mathcal{C}^\infty$ and $\mathcal{D}'$.

When G is stable, then by Theorem 7.2 the variables u are free over $\mathcal{S}_+$, so each such input there corresponds to some output $y \in (\mathcal{S}_+)^p$, and by time-autonomy there cannot exist a different causal response, so all causal responses to u are in $(\mathcal{S}_+)^p$. In other words, (u, y) is stable with respect to $\mathcal{S}$. The same argument establishes stability with respect to $\mathcal{S}'$ on the condition that G is weakly stable.

Conversely, suppose the input/output structure is both causal with respect to $\mathcal{C}^\infty$ and stable with respect to $\mathcal{S}$. This shows that u is free over $\mathcal{S}_+$, so by Theorem 7.2 (this being the only point where we need assumptions on $\mathcal{B}_{0,y}$ or on n), G is stable, as required. ∎

Note that Theorem 7.4 effectively states that an input/output structure is both causal and stable (with respect to $\mathcal{C}^\infty$ and $\mathcal{S}$, respectively) if and only if the zero-input behavior $(\mathcal{B}^c)_{0,y}$ of the controllable part satisfies the CV condition, i.e., if and only if $\mathcal{B}$ has no controllable unstable poles. It is pleasing that input/output stability is determined by the poles of the system, as in the 1D case, and that the condition for input/output stability is precisely that which has been proposed for stability of the autonomous behavior $(\mathcal{B}^c)_{0,y}$. Also, observe that stability with respect to $\mathcal{S}$ is stronger than stability with respect to $\mathcal{S}'$.

While we have taken time-autonomy as a prior condition for the definition of causal and therefore stable (with respect to $\mathcal{S}$) input/output structures, it is in fact a consequence of these two properties. For if $y \in \mathcal{B}_{0,y}$ has support in $\mathbb{R}^n_+$, then by stability (0 being a stable input!), $y \in (\mathcal{S}_+)^p \subseteq \mathcal{S}^p$. If P is a kernel matrix representation matrix of $\mathcal{B}_{0,y}$, then it has a nonzero highest order minor r, and now we find that $r(\partial)y = 0$, which as $y \in \mathcal{S}$ necessitates $y = 0$ (e.g., by taking Fourier transforms). Thus $\mathcal{B}_{0,y}$ is time-autonomous.

As is the case for causality, Theorem 7.4 in particular implies that stability is determined by the properties of a single polynomial d, the least common denominator of the transfer matrix. To ascertain stability of the input/output structure with respect to $\mathcal{S}$, we need only test whether d obeys the CV condition, i.e., whether the roots of d intersect the set $\mathcal{X}^+$. This test amounts to checking whether a set of real algebraic equations and inequalities has a solution and so may be solved by quantifier elimination theory (e.g., [1]). An important open question is whether a simpler algorithm may be developed, making special use of the structure of $\mathcal{X}^+$.

We conclude with a final result which is a sufficient condition only but drops the restrictions $n \leq 2$ or P a single polynomial.

COROLLARY 7.5. *If $\mathcal{B}$ is a behavior with given input/output structure such that $\mathcal{B}_{0,y}$ is time-autonomous and G is stable, then the input/output structure is causal and stable with respect to $\mathcal{S}$. This occurs in particular when $\mathcal{B}_{0,y}$ is time-autonomous and satisfies the CV condition.*

Proof. The proof in Theorem 7.4 that G is stable implies (u, y) is causal and stable depends only on the proof $5 \Rightarrow 1$ of Theorem 7.2, which in turn does not require the assumptions $n \leq 2$ or P a single polynomial. The final claim is immediate from Lemma 2.4. ∎

8. Conclusions. We have defined causality and stability for input/output structures with the a priori property that $\mathcal{B}_{0,y}$ be time-autonomous. This property means that any output is determined by its own past together with the input. When this property does not hold (e.g., for the heat equation), our definitions do not apply, and we believe that an entirely different approach will be necessary to define and characterize these properties in that case.

We have shown that both causality and stability are characterized by properties of the system transfer matrix or, more precisely, its least common denominator d. Presupposing time-autonomy, the input/output structure is causal (with respect to $\mathcal{C}^\infty$) if and only if d is hyperbolic, and is stable (with respect to $\mathcal{S}$) if and only if d satisfies the CV condition. The CV condition is precisely that which we have proposed for stability of an autonomous behavior; establishing (or disproving) that the CV condition is equivalent to stability (in a suitable sense) for an autonomous behavior is an important open question.

The obstacle to generalizing the stability results for $\mathcal{S}$ to the general $n > 2$ case is in proving that the set $\mathcal{X}^-$ has the property of being ideal-convex. This seems difficult to establish, particularly since this set is noncompact (and so it is not clear that we can approximate holomorphic functions uniformly on $\mathcal{X}^-$ by polynomials). However, we note that $\mathcal{X}^-$ may be bilinearly transformed into the bounded set $(S^1)^{n-1} \times D$, where S^1 is the unit circle and D the unit disc. The stability results for S^1 require no prior assumptions but give sufficient conditions only.

Another open problem is the generalization of these results to the case of equations with real coefficients. We have used only complex coefficients here since we have applied many results from the theory of PDEs which have been developed for complex coefficients; but the real coefficient case will probably require close examination of the PDE literature.

Finally, we have developed some structure theory results for the sets $\mathcal{S}, \mathcal{S}', \mathcal{S}_+$, and $\mathcal{S}'_\oplus$. The use of algebraic "local cohomology" may prove a useful approach to characterizing (Willems) closures in other situations, particularly since when we apply this tool we immediately get, as a corollary, concrete characterizations of the inclusion of one behavior in another, as in Corollaries 6.3 and 6.13. We have also been able to characterize freeness of variables over $\mathcal{S}$ for $n \leq 2$ (and over $\mathcal{C}_0^\infty, \mathcal{E}'$ also); generalization to nD depends on establishing ideal-convexity of $\imath\mathbb{R}^n$. The question as to whether the space $\mathcal{S}'_\oplus$ is injective (and whether the space $\mathcal{S}_+$, to which it is dual, is flat) is also open.

WHAT IS THE BETTER SIGNAL SPACE FOR DISCRETE-TIME SYSTEMS: $\ell_2(\mathbb{Z})$ OR $\ell_2(\mathbb{N}_0)$?*

BIRGIT JACOB†

Abstract. In this paper a system is considered as a (possibly unbounded) linear operator between Hilbert spaces. As signal space we consider the spaces $\ell_2(\mathbb{Z})$ and $\ell_2(\mathbb{N}_0)$. Whereas the case $\ell_2(\mathbb{N}_0)$ has been well studied in the literature, the case $\ell_2(\mathbb{Z})$ has hardly been studied, and one goal of this paper is to study these systems from first principle. Further, we compare these two mathematical formalisms and show that the stabilizable systems and the stabilizing controllers are the same in both mathematical formalisms, provided that a suitable definition of stabilizability is used for systems over the signal space $\ell_2(\mathbb{Z})$.

Key words. linear systems, time-invariant systems, signal spaces, stabilizability, feedback systems

1. Introduction.

In this paper we consider an input-output approach to linear time-invariant discrete-time systems and, moreover, we do this quite generally, that is, without assuming specific system representations such as differential or integral equations. We have only two further basic requirements: First we assume that the input and output space are finite-dimensional, that is, input and output functions take values in $\mathbb{C}^p$, respectively, $\mathbb{C}^m$. Second, we assume that input and output functions are elements of Hilbert spaces. Under these assumptions a system can be seen as a (possibly) unbounded operator on Hilbert spaces. For the choice of the Hilbert spaces there are two natural possibilities: $\ell_2(\mathbb{Z})^n$ and $\ell_2(\mathbb{N}_0)^n$, depending on whether we consider as time axis $\mathbb{N}_0$ or $\mathbb{Z}$.

Systems with signal space $\ell_2(\mathbb{N}_0)$ have been studied from first principle in detail by Georgiou and Smith [5]. They discussed different system descriptions such as operators, transfer functions, and coprime factorizations, proved in which sense these representations are interchangeable, and discussed the question of how physically motivated properties such as causality and stabilizability should be defined in this mathematical formalism. Some of their results are reviewed in section 3. The input-output approach to systems is not new; it has been studied in [23], [21], [18], [2], [4], [22], and other works. However, systems are considered only as mappings, and equivalent conditions for some basic properties such as stabilizability and causality are missing. There are alternative approaches to systems, such as the algebraic/coprime factor theory approach [1], [19]. Using this approach a system is represented by its transfer function, which is in our case an element of the quotient field of H_∞. However, alternative approaches pay no attention to the signal space.

There are few results available concerning systems over the signal space $\ell_2(\mathbb{Z})$. Georgiou and Smith [5], [6] started to study these systems, and they discovered intrinsic difficulties: A causal system could have a noncausal closure, and a well-known stabilizable system seemed not to be stabilizable. The problem was analyzed further

by Mäkilä, who primarily studied in a series of papers [11], [12], [13] the question of whether the graphs of linear systems are in fact closable. In Jacob and Partington [10] and Jacob [7] these systems are considered in more detail: In these papers transfer functions and symbols are studied, and equivalent conditions for causality are given. One goal of this paper is to solve the problem concerning stabilizability for systems over the signal space $\ell_2(\mathbb{Z})$. Using an alternative definition of stabilizability in the mathematical formalism we are able to guarantee that all—from a physical point of view—stabilizable systems are actually stabilizable in the mathematical formalism. Further, we give equivalent conditions for stabilizability.

Once these two mathematical formalisms are available, the question arises which signal space—$\ell_2(\mathbb{N}_0)$ or $\ell_2(\mathbb{Z})$—should be used to model a system. The study of this question is the second goal of this paper. We show that the stabilizable systems and the stabilizing controllers are the same, and thus it does not really matter whether we work with $\ell_2(\mathbb{N}_0)$ or $\ell_2(\mathbb{Z})$ as signal space. Note that the results of this paper can also be found in the author's habilitation thesis [8], and for the single input-single output case in the conference paper [9].

We proceed as follows. First we review results on systems over the signal space $\ell_2(\mathbb{N}_0)$ (section 3) and $\ell_2(\mathbb{Z})$ (section 4). In section 5 we introduce and study an adapted notion of stabilizability for systems over the signal space $\ell_2(\mathbb{Z})$. Finally, in section 6 we compare these two mathematical formalisms.

2. Preliminaries. We introduce the following notation. We define $\mathbb{T} := \{z \in \mathbb{C} \mid |z| = 1\}$, and $\mathbb{D} := \{z \in \mathbb{C} \mid |z| < 1\}$. $H_\infty(\mathbb{D})$ denotes the Hardy space of bounded holomorphic function f on $\mathbb{D}$, and $L_\infty(\mathbb{T})$ denotes the space of all (equivalence classes of) measurable and essentially bounded functions on $\mathbb{T}$. Fatou's theorem (see, for example, Duren [3]) shows that to every $f \in H_\infty(\mathbb{D})$ there corresponds a function $\tilde{f} \in L_\infty(\mathbb{T})$, defined a.e. by $\tilde{f}(e^{it}) := \lim_{r\to 1} f(re^{it})$, $t \in [0, 2\pi]$. Note that $\tilde{f}(z) = 0$ on a set of positive measure implies that f equals the zero function. By means of the boundary function we can consider $H_\infty(\mathbb{D})$ as a subspace of $L_\infty(\mathbb{T})$. By $L_2(\mathbb{T})$ we denote the space of all (equivalence classes of) measurable and square integrable functions on $\mathbb{T}$, and $H_2(\mathbb{D})$ denotes the Hardy space of holomorphic functions f on $\mathbb{D}$ satisfying $\sup_{r\in(0,1)} \|f(r\cdot)\|_{L_2(\mathbb{T})} < \infty$. A similar argument as above shows that $H_2(\mathbb{D})$ can be considered as a subspace of $L_2(\mathbb{T})$. By $L_\infty(\mathbb{T})^{m\times n}$ we denote the set of all $m\times n$-matrices with elements in $L_\infty(\mathbb{T})$, and similar notations are used for $H_\infty(\mathbb{D})$, $L_2(\mathbb{T})$, and $H_2(\mathbb{D})$. If n equals 1, then we shorten this to $L_\infty(\mathbb{T})^m$, $H_\infty(\mathbb{D})^m$, $L_2(\mathbb{T})^m$, and $H_2(\mathbb{D})^m$.

By $\ell_2(\mathbb{Z})^n$, $n \in \mathbb{N}$, we denote the space of all vector valued square summable sequences on $\mathbb{Z}$. Similarly, we define $\ell_2(\mathbb{N}_0)^n$. We consider $\ell_2(\mathbb{N}_0)^n$ as a subset of $\ell_2(\mathbb{Z})^n$ by extending $x \in \ell_2(\mathbb{N}_0)^n$ to $\ell_2(\mathbb{Z})^n$ by defining the sequence to be zero outside $\mathbb{N}_0$. Moreover, $x \in \ell_2(\mathbb{Z})^n$ is an element of $\ell_2(\mathbb{N}_0)^n$ if $x(j) = 0$ for $j < 0$.

By S we denote the *right shift* on $\ell_2(\mathbb{Z})^n$, which is given by $(Sx)(j) := x(j-1)$, $j \in \mathbb{Z}$, as well as the *right shift* on $\ell_2(\mathbb{N}_0)^n$, which is given by $(Sx)(j) := x(j-1)$, $j \in \mathbb{N}$ and $(Sx)(0) := 0$. Thus the right shift on $\ell_2(\mathbb{Z})^n$ is bijective, whereas the right shift on $\ell_2(\mathbb{N}_0)^n$ is injective, but not surjective. By e_k, $k \in \mathbb{Z}$, we denote the kth unit vector of $\ell_2(\mathbb{Z})$, namely, $e_k(j) := \delta_{k,j}$, as well as the kth unit vector of $\mathbb{C}^n$, $n \geq k$. However, from the context it is always clear which space is meant. Finally, by $\hat{\cdot}$ we denote the *z-transform*, which is given by

$$\hat{u}(z) := \sum_{j\in\mathbb{Z}} u(j) z^j, \qquad u \in \ell_2(\mathbb{Z})^n.$$

The z-transform is an isometric isomorphism from $\ell_2(\mathbb{N}_0)^n$ onto $H_2(\mathbb{D})^n$, and from $\ell_2(\mathbb{Z})^n$ onto $L_2(\mathbb{T})^n$.

3. Review on LTI($\mathbb{N}_0$)-systems. Systems over the signal space $\ell_2(\mathbb{N}_0)$ are well studied in the literature; see [5] and the references therein. Transfer functions of these systems, which are matrices with entries in the quotient field of $H_\infty(\mathbb{D})$, are studied in even more detail. Following [5] we define a linear time-invariant system as follows.

DEFINITION 3.1. *A linear operator $P : D(P) \subset \ell_2(\mathbb{N}_0)^m \to \ell_2(\mathbb{N}_0)^p$ is called an* LTI$(\mathbb{N}_0)^{p\times m}$-system *if P is* shift-invariant, *i.e. $SG(P) \subset G(P)$, and $G(P)$ is a closed subspace of $\ell_2(\mathbb{N}_0)^{m+p}$.*

Here $D(P)$ denotes the *domain* of P, and $G(P) \subset \ell_2(\mathbb{N}_0)^{m+p}$ denotes the *graph* of P. If P is an LTI$(\mathbb{N}_0)^{p\times m}$-system and the dimensions of the input and output space are not important, we just say P is an LTI$(\mathbb{N}_0)$-*system*. An LTI$(\mathbb{N}_0)^{p\times m}$-system is called *stable* if $D(P) = \ell_2(\mathbb{N}_0)^m$. We stated the definition of an LTI$(\mathbb{N}_0)$-system in the time-domain. Using the z-transform and the fact that the z-transform is an isometric isomorphism from $\ell_2(\mathbb{N}_0)$ onto $H_2(\mathbb{D})$, we can interchangeably use the description of P in the frequency domain. By $\hat{P} : D(\hat{P}) \subset H_2(\mathbb{D})^p \to H_2(\mathbb{D})^m$ we denote the z-transform of P, that is, $\hat{P}\hat{u} = \widehat{Pu}$, $\hat{u} \in D(\hat{P}) = \widehat{D(P)}$.

DEFINITION 3.2. *We call an LTI$(\mathbb{N}_0)^{p\times m}$-system P* maximal *if for any LTI$(\mathbb{N}_0)^{p\times m}$-system $\tilde{P}$ with $G(P) \subset G(\tilde{P})$ we actually have $G(P) = G(\tilde{P})$. Further, an LTI$(\mathbb{N}_0)^{p\times m}$-system P is called* causal *if for every $u \in \ell_2(\mathbb{N}_0)^m$ and every $k \in \mathbb{N}_0$ with $S^k u \in D(P)$ there exists $v \in \ell_2(\mathbb{N}_0)^p$ such that $PS^k u = S^k v$.*

Causality guarantees that the previous output does not depend on the present and future input. Note that a stable LTI$(\mathbb{N}_0)$-system is always causal [5]. Next we show that every maximal LTI$(\mathbb{N}_0)^{p\times m}$-system is uniquely described by an element of $R(H_\infty(\mathbb{D}))^{p\times m}$. Here $R(H_\infty(\mathbb{D}))$ denotes the *quotient field of* $H_\infty(\mathbb{D})$, which is the set of equivalent classes of fractions $\frac{n}{m}$, where $n, m \in H_\infty(\mathbb{D})$ and $m \neq 0$.

THEOREM 3.3. *Any maximal LTI$(\mathbb{N}_0)^{p\times m}$-system P uniquely defines a function $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$ which determines the action of P in the frequency domain, that is, $\hat{P}\hat{x} = \mathcal{P}\hat{x}$, $\hat{x} \in D(\hat{P})$. Conversely, any matrix $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$ uniquely specifies a maximal LTI$(\mathbb{N}_0)^{p\times m}$-system P which satisfies $\hat{P}\hat{x} = \mathcal{P}\hat{x}$, $\hat{x} \in D(\hat{P})$.*

For the proof of this theorem we refer the reader to [5]. The function $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$, which is uniquely given by a maximal LTI$(\mathbb{N}_0)^{p\times m}$-system, is called a *transfer function*. Of special interest are left and right coprime factorizations of transfer functions. A function $\theta \in H_\infty(\mathbb{D})^{m\times r}$, $r \leq m$, is called *inner* if $\theta^*(z)\theta(z) = I_r$ for a.e. $z \in \mathbb{T}$ and $\|\theta(z)\| \leq 1$ for every $z \in \mathbb{D}$.

DEFINITION 3.4. *Let $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$. We say $\mathcal{P}$ has a* right coprime factorization (rcf) over $H_\infty(\mathbb{D})$ *if there exist $M \in H_\infty(\mathbb{D})^{m\times m}$ with $\det M \neq 0$, and $N \in H_\infty(\mathbb{D})^{p\times m}$ such that $\mathcal{P} = NM^{-1}$ and $\binom{M}{N}$ is left-invertible over $H_\infty(\mathbb{D})$. If additionally $\binom{M}{N}$ is inner, then we say $\mathcal{P}$ has a* normalized right coprime factorization (normalized rcf) over $H_\infty(\mathbb{D})$. *We say $\mathcal{P}$ has a* left coprime factorization (lcf) over $H_\infty(\mathbb{D})$ *if there exist $\tilde{M} \in H_\infty(\mathbb{D})^{p\times p}$ with $\det \tilde{M} \neq 0$, and $\tilde{N} \in H_\infty(\mathbb{D})^{p\times m}$ such that $\mathcal{P} = \tilde{M}^{-1}\tilde{N}$ and $(\tilde{M}\ \tilde{N})$ is right-invertible over $H_\infty(\mathbb{D})$. If additionally $\tilde{M}\tilde{M}^* + \tilde{N}\tilde{N}^* = I$, then we say $\mathcal{P}$ has a* normalized left coprime factorization (normalized lcf) over $H_\infty(\mathbb{D})$.

DEFINITION 3.5. *Let $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$. We say $\mathcal{P}$ has a* weak right coprime factorization (weak rcf) over $H_\infty(\mathbb{D})$ *if there exist $M \in H_\infty(\mathbb{D})^{m\times m}$ with $\det M \neq 0$, and $N \in H_\infty(\mathbb{D})^{p\times m}$ such that $\mathcal{P} = NM^{-1}$ and $\binom{M}{N}$ is irreducible over $H_\infty(\mathbb{D})$. Here a matrix Q with elements in $H_\infty(\mathbb{D})$ is* irreducible over $H_\infty(\mathbb{D})$ *if one (and hence all) gcd of all highest order minors of M are invertible in $H_\infty(\mathbb{D})$. We say $\mathcal{P}$ has a* weak

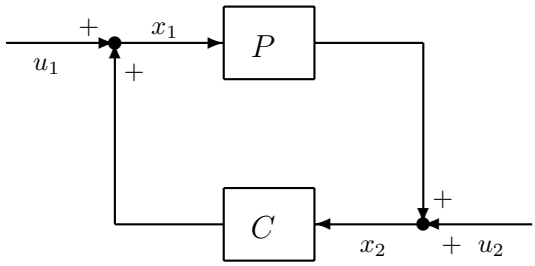

FIG. 3.1. *Standard feedback configuration.*

left coprime factorization (weak lcf) over $H_\infty(\mathbb{D})$, *if there exist* $\tilde{M} \in H_\infty(\mathbb{D})^{p\times p}$ *with* $\det \tilde{M} \neq 0$, *and* $\tilde{N} \in H_\infty(\mathbb{D})^{p\times m}$ *such that* $\mathcal{P} = \tilde{M}^{-1}\tilde{N}$ *and* $(\tilde{M}\ \tilde{N})$ *is irreducible over* $H_\infty(\mathbb{D})$.

It should be noted that not every transfer function of a maximal LTI$(\mathbb{N}_0)$-system possesses an rcf and lcf over $H_\infty(\mathbb{D})$. In general there exist only a weak rcf and weak lcf; see [5]. However, if P is a maximal LTI$(\mathbb{N}_0)^{p\times m}$-system and NM^{-1} is a (weak) rcf of the corresponding transfer function, then the graph of P is given by $G(P) = \binom{M}{N} H_2(\mathbb{D})^m$ (see [5]).We now consider feedback systems as given in Figure 3.1, which is the standard feedback configuration used in system and control theory; see Vidyasagar [19] for more details. We say that such a feedback system is stable if all the paths in the loop in Figure 3.1 are stable, or, more precisely, that Definition 3.6 holds.

DEFINITION 3.6. *Let* P *be an LTI*$(\mathbb{N}_0)^{p\times m}$*-system and let* C *be an LTI*$(\mathbb{N})^{m\times p}$*-system. We say that the feedback system* $[P, C]$, *as given by Figure* 3.1, *is stable if the mapping*

$$F_{[P,C]} := \begin{pmatrix} I & C \\ P & I \end{pmatrix} : D(P) \times D(C) \to \ell_2(\mathbb{N}_0)^{m+p}$$

has a bounded inverse, that is, if the operators $u_i \mapsto x_j$, $i, j = 1, 2$, *are well-defined and bounded. Further,* P *is called* stabilizable *if there is an LTI*$(\mathbb{N}_0)^{m\times p}$*-system* C *such that the feedback system* $[P, C]$ *is stable.*

If $[P, C]$ is stable, then $F^{-1}_{[P,C]}$ is a stable and causal LTI$(\mathbb{N}_0)^{(p+m)\times(p+m)}$-system. In [5], equivalent conditions for stable feedback systems as well as for stabilizable LTI$(\mathbb{N}_0)^{p\times m}$-systems are given. The following result will be of particular interest for us.

THEOREM 3.7. *Let* P *be an LTI*$(\mathbb{N}_0)^{p\times m}$*-system. Then* P *is stabilizable if and only if* P *is maximal and the transfer function* $\mathcal{P}$ *of* P *possesses (normalized) rcf over* $H_\infty(\mathbb{D})$.

The proof can be found in [5]. Further, it is shown in [5] that for every stabilizable LTI$(\mathbb{N}_0)$-system P there exists a causal system C which stabilizes P.

4. LTI$(\mathbb{Z})$-systems. In contrast to systems over the signal space $\ell_2(\mathbb{N}_0)$, systems with signals in $\ell_2(\mathbb{Z})$ are not that well studied. Following [7] we define a linear time-invariant system as follows.

DEFINITION 4.1. *A linear operator* $P : D(P) \subset \ell_2(\mathbb{Z})^m \to \ell_2(\mathbb{Z})^p$ *is called an* LTI$(\mathbb{Z})^{p\times m}$-system *if* P *is* shift-invariant, *i.e.,* $SG(P) = G(P)$, *and* $\overline{D(P)} = \ell_2(\mathbb{Z})^m$.

As above, $D(P)$ denotes the *domain* of P, and $G(P)$ denotes the *graph* of P. If P is an LTI$(\mathbb{Z})^{p\times m}$-system and the dimensions of the input and output space are not

important, we just say P is an *LTI($\mathbb{Z}$)-system*. Note that we do not assume that the graph of P is closed, because a lot of simple systems of relevance do not satisfy this assumption [6]. However, all those systems are densely defined [8] and thus we include this as a requirement in the definition.

DEFINITION 4.2. *We say an LTI($\mathbb{Z}$)$^{p\times m}$-system P is* closed *if the operator P is closed, that is, if $G(P)$ is a closed subspace of $\ell_2(\mathbb{Z})^{m+p}$, and we say an LTI($\mathbb{Z}$)$^{p\times m}$-system P is* closable *if the operator P is closable, i.e., if for every sequence $\{u_n\} \subseteq D(P)$ which tends to 0 and for which Pu_n tends to a function $y \in \ell_2(\mathbb{Z})^p$ we have $y = 0$. Further, P is called* causal *if $u \in \ell_2(\mathbb{N}_0)^m \cap D(P)$ implies $Pu \in \ell_2(\mathbb{N}_0)^p$.*

Closability means that there exists a closed LTI($\mathbb{Z}$)$^{p\times m}$-system $T : D(T) \subset \ell_2(\mathbb{Z})^m \to \ell_2(\mathbb{Z})^p$ such that $D(P) \subset D(T)$ and $Tu = Pu$ for every $u \in D(P)$. If P is closable, then the closure $\overline{P}$ of P is the smallest closed LTI($\mathbb{Z}$)$^{p\times m}$-system, which extends P. We stated the definition of an LTI($\mathbb{Z}$)-system in the time-domain. Using the z-transform and the fact that the z-transform is an isometric isomorphism, we can interchangeably use the description of P in the frequency domain. The z-transform of an LTI($\mathbb{Z}$)-system P is denoted by $\hat{P}$. In general, a causal LTI($\mathbb{Z}$)-system can have a noncausal closure; see [6], [7], [10]. This phenomenon is called the Georgiou–Smith paradox. In [7], closable causal systems with causal closure are studied and described via equivalent conditions. Next we introduce the notion of a transfer function of an LTI($\mathbb{Z}$)-system. The *total ring of fractions of* $L_\infty(\mathbb{T})$, denoted by $R(L_\infty(\mathbb{T}))$, is defined to be the set of equivalent classes of fractions $\frac{n}{m}$, where $n, m \in L_\infty(\mathbb{T})$ and $m(z) \neq 0$ a.e.

DEFINITION 4.3. *Let P be a closed LTI($\mathbb{Z}$)$^{p\times m}$-system. We call a function $\mathcal{P} \in R(L_\infty(\mathbb{T}))^{p\times m}$ the* transfer function *of P if $\hat{P}\hat{u} = \mathcal{P}\hat{u}$ for $\hat{u} \in D(\hat{P})$.*

A transfer function describes the action of the system P in the frequency domain. In [7] it is shown that every closed LTI($\mathbb{Z}$)-system possesses a transfer function, and a transfer function is uniquely determined. Further, a function $\mathcal{P} \in R(L_\infty(\mathbb{T}))^{p\times m}$ completely describes a closed LTI($\mathbb{Z}$)-system [7]. We say a matrix $M \in L_\infty(\mathbb{T})^{m\times m}$ is regular if $\det M(z) \neq 0$ for a.e. $z \in \mathbb{T}$. Of special interest are left and right coprime factorizations of transfer functions.

DEFINITION 4.4. *Let $\mathcal{P} \in R(L_\infty(\mathbb{T}))^{p\times m}$. We say $\mathcal{P}$ has a* right coprime factorization (rcf) over $L_\infty(\mathbb{T})$ *if there exist $M \in L_\infty(\mathbb{T})^{m\times m}$ regular and $N \in L_\infty(\mathbb{T})^{p\times m}$ such that $\mathcal{P} = NM^{-1}$ and $\binom{M}{N}$ is left-invertible over $L_\infty(\mathbb{T})$. If additionally $M^*M + N^*N = I$ holds, then we say that $\mathcal{P}$ has a* normalized rcf over $L_\infty(\mathbb{T})$. *We say $\mathcal{P}$ has a* left coprime factorization (lcf) over $L_\infty(\mathbb{T})$ *if there exist $\tilde{M} \in L_\infty(\mathbb{T})^{p\times p}$ regular and $\tilde{N} \in L_\infty(\mathbb{T})^{p\times m}$ such that $\mathcal{P} = \tilde{M}^{-1}\tilde{N}$ and $(\,\tilde{M}\ \tilde{N}\,)$ is right-invertible over $L_\infty(\mathbb{T})$. If additionally $\tilde{M}\tilde{M}^* + \tilde{N}\tilde{N}^* = I$ holds, then we say $\mathcal{P}$ has a* normalized lcf over $L_\infty(\mathbb{T})$.

In the following proposition it is shown that every $\mathcal{P} \in R(L_\infty(\mathbb{T}))^{p\times m}$ possesses normalized coprime factorizations over $L_\infty(\mathbb{T})$.

PROPOSITION 4.5. *Every $\mathcal{P} \in R(L_\infty(\mathbb{T}))^{p\times m}$ possesses a normalized lcf and a normalized rcf over $L_\infty(\mathbb{T})$. Moreover, an lcf and an rcf are unique up to an invertible element of $L_\infty(\mathbb{T})^{m\times m}$.*

Proof. It is easy to see that there exist matrices $N_1 \in L_\infty(\mathbb{T})^{p\times m}$ and $M_1 \in L_\infty(\mathbb{T})^{m\times m}$, M_1 diagonal and regular, such that $\mathcal{P} = N_1M_1^{-1}$. We define $G_1 \in L_\infty(\mathbb{T})^{(m+p)\times m}$ by $G_1 := \binom{M_1}{N_1}$. Using polar factorization (see, for example, Weidmann [20]), there exist $T \in L_\infty(\mathbb{T})^{m\times m}$ and $G \in L_\infty(\mathbb{T})^{(m+p)\times m}$ such that $G_1 = GT$, and $G^*G = I$. Actually, T is given by the square root of $G_1^*G_1$. Since M_1 is regular, T has to be regular as well. We split G as $G = \binom{M}{N}$ with $M \in L_\infty(\mathbb{T})^{m\times m}$ and

$N \in L_\infty(\mathbb{T})^{p\times m}$. Clearly, M is regular, $G^*G = I$, and $\mathcal{P} = NM^{-1}$. Thus $\mathcal{P}$ possesses a normalized rcf over $L_\infty(\mathbb{T})$.

Next we show the uniqueness of the rcf over $L_\infty(\mathbb{T})$. Let us consider two rcf's over $L_\infty(\mathbb{T})$ of $\mathcal{P}$, that is, $\mathcal{P} = N_1M_1^{-1} = N_2M_2^{-1}$ with $\binom{M_1}{N_1}, \binom{M_2}{N_2} \in L_\infty(\mathbb{T})^{(m+p)\times m}$ left-invertible over $L_\infty(\mathbb{T})$, and M_1, M_2 regular. This implies $\binom{M_1}{N_1} = \binom{M_2}{N_2}M_2^{-1}M_1$ and $\binom{M_2}{N_2} = \binom{M_1}{N_1}M_1^{-1}M_2$. Now Proposition 3.9 of [7] shows $M_2^{-1}M_1, M_1^{-1}M_2 \in L_\infty(\mathbb{T})^{m\times m}$, and since $(M_1^{-1}M_2)^{-1} = M_2^{-1}M_1$, the rcf over $L_\infty(\mathbb{T})$ is unique up to multiplication by an invertible matrix in $L_\infty(\mathbb{T})^{m\times m}$.

In order to show that $\mathcal{P}$ also possesses an lcf over $L_\infty(\mathbb{T})$, we proceed as follows. It is easy to see that we can write $\mathcal{P}$ as $\mathcal{P} = \tilde{M}_1^{-1}\tilde{N}_1$ with $\tilde{M}_1 \in L_\infty(\mathbb{T})^{p\times p}$ diagonal and regular, and $\tilde{N}_1 \in L_\infty(\mathbb{T})^{p\times m}$. We define G_1 by $G_1 := \binom{\tilde{M}_1^T}{\tilde{N}_1^T}$. Applying the same procedure as above we get that there exist matrices $\tilde{M}$ and $\tilde{N}$ of the required form, and that the lcf over $L_\infty(\mathbb{T})$ is unique up to multiplication by an invertible matrix in $L_\infty(\mathbb{T})^{m\times m}$. □

An LTI$(\mathbb{Z})^{p\times m}$-system P is *stable* if P is closed and $D(P) = \ell_2(\mathbb{Z})^m$. Using the closed graph theorem we see that P is stable if and only if P is a linear bounded operator from $\ell_2(\mathbb{Z})^m$ to $\ell_2(\mathbb{Z})^p$. In terms of the transfer function, a closed LTI$(\mathbb{Z})^{p\times m}$-system is stable if and only if the transfer function $\mathcal{P}$ satisfies $\mathcal{P} \in L_\infty(\mathbb{T})^{p\times m}$. We will see later on that a stable LTI$(\mathbb{Z})$-system is not automatically causal, as is the case for stable LTI$(\mathbb{N}_0)$-systems. Here a stable LTI$(\mathbb{Z})^{p\times m}$-system is causal if and only if its transfer function is an element of $H_\infty(\mathbb{D})^{p\times m}$.

We now consider feedback systems as given in Figure 3.1, which is the standard feedback configuration [19]. We say that such a feedback system is stable if all the paths in the loop in Figure 3.1 are stable, or, more precisely, that Definition 4.6 holds.

DEFINITION 4.6. *Let P be an LTI$(\mathbb{Z})^{p\times m}$-system, and let C be an LTI$(\mathbb{Z})^{m\times p}$-system. We say that the feedback system $[P, C]$, as given in Figure* 3.1, *is* stable *if*

$$F_{[P,C]} := \begin{pmatrix} I & C \\ P & I \end{pmatrix} : D(P) \times D(C) \to \ell_2(\mathbb{Z})^{p+m} : \begin{pmatrix} x_1 \\ -x_2 \end{pmatrix} \to \begin{pmatrix} u_1 \\ -u_2 \end{pmatrix}$$

has a bounded inverse, that is, the operators $u_i \to x_j$, $i, j = 1, 2$, are well defined and bounded. If $[P, C]$ is stable, then we denote the inverse of $F_{[P,C]}$ by $H_{[P,C]}$.

In Figure 3.1 we have

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + \begin{pmatrix} 0 & C \\ P & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}.$$

If the feedback system is stable, it is easy to see that the operators $I - PC : D(C) \to \ell_2(\mathbb{Z})^p$ and $I - CP : D(P) \to \ell_2(\mathbb{Z})^m$ are boundedly invertible, and that the inverse of $F_{[P,C]}$ is given by

$$\begin{aligned} H_{[P,C]} \begin{pmatrix} u_1 \\ -u_2 \end{pmatrix} &= \begin{pmatrix} (I-CP)^{-1} & -(I-CP)^{-1}C \\ -(I-PC)^{-1}P & (I-PC)^{-1} \end{pmatrix} \begin{pmatrix} u_1 \\ -u_2 \end{pmatrix} \\ &= \begin{pmatrix} (I-CP)^{-1} & -(I-CP)^{-1}C \\ -P(I-CP)^{-1} & I + P(I-CP)^{-1}C \end{pmatrix} \begin{pmatrix} u_1 \\ -u_2 \end{pmatrix}. \end{aligned} \tag{4.1}$$

The stability of $[P, C]$ implies that $H_{[P,C]}$ is a stable LTI$(\mathbb{Z})^{(m+p)\times(m+p)}$-system; that is, the transfer function of $H_{[P,C]}$, denoted by $\mathcal{H}_{[P,C]}$, satisfies $\mathcal{H}_{[P,C]} \in L_\infty(\mathbb{T})^{(m+p)\times(m+p)}$.

Further, we get that $\mathcal{H}_{[P,C]}$ is given by

$$\begin{aligned}\mathcal{H}_{[P,C]} &= \begin{pmatrix} (I-\mathcal{C}\mathcal{P})^{-1} & -(I-\mathcal{C}\mathcal{P})^{-1}\mathcal{C} \\ -(I-\mathcal{P}\mathcal{C})^{-1}\mathcal{P} & (I-\mathcal{P}\mathcal{C})^{-1} \end{pmatrix} \\ &= \begin{pmatrix} (I-\mathcal{C}\mathcal{P})^{-1} & -(I-\mathcal{C}\mathcal{P})^{-1}\mathcal{C} \\ -\mathcal{P}(I-\mathcal{C}\mathcal{P})^{-1} & I+\mathcal{P}(I-\mathcal{C}\mathcal{P})^{-1}\mathcal{C} \end{pmatrix}. \end{aligned} \tag{4.2}$$

The *inverse graph* of an LTI($\mathbb{Z}$)-system P is defined by $G^I(P) := \binom{P}{I} D(P)$. We have the following necessary conditions for stability of feedback systems. The proof follows Georgiou and Smith [5].

PROPOSITION 4.7. *Let P be an LTI$(\mathbb{Z})^{p\times m}$-system and let C be an LTI$(\mathbb{Z})^{m\times p}$-system. If $[P,C]$ is stable, then P and C are closed systems.*

Proof. Let $\{v_n\}_n \subset D(P)$ be a sequence which converges to v in $\ell_2(\mathbb{Z})^m$ and let $\{Pv_n\}_n$ converge to y in $\ell_2(\mathbb{Z})^p$. As n tends to ∞ in

$$\begin{pmatrix} v_n \\ 0 \end{pmatrix} = H_{[P,C]} \begin{pmatrix} v_n \\ Pv_n \end{pmatrix}$$

we get

$$\begin{pmatrix} v \\ 0 \end{pmatrix} = H_{[P,C]} \begin{pmatrix} v \\ y \end{pmatrix},$$

which implies $v \in D(P)$ and $y = Pv$. Thus P is closed. Similarly, it can be proved that C is closed. □

Next we characterize stable feedback systems $[P,C]$ by means of equivalent conditions. The proof of the equivalence of parts 1 and 2 follows Georgiou and Smith [5]. The equivalence of parts 1, 3, 4, 5, and 6 is standard using the coprime factorization approach (see Vidyasagar [19]), and the proof is based on these known results.

THEOREM 4.8. *Let P be a closed LTI$(\mathbb{Z})^{p\times m}$-system and let C be a closed LTI$(\mathbb{Z})^{m\times p}$-system. $\mathcal{P}$ denotes the transfer function of P with rcf $\mathcal{P} = NM^{-1}$ over $L_\infty(\mathbb{T})$ and lcf $\mathcal{P} = \tilde{M}^{-1}\tilde{N}$ over $L_\infty(\mathbb{T})$, and $\mathcal{C}$ denotes the transfer function of C with rcf $\mathcal{C} = TS^{-1}$ over $L_\infty(\mathbb{T})$ and lcf $\mathcal{C} = \tilde{S}^{-1}\tilde{T}$ over $L_\infty(\mathbb{T})$. Then the following statements are equivalent.*

1. *$[P,C]$ is stable.*
2. *$G(P) \cap G^I(C) = \{0\}$, and $G(P) + G^I(C) = \ell_2(\mathbb{Z})^{m+p}$.*
3. *$\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ is invertible over $L_\infty(\mathbb{T})$.*
4. *$\left(\begin{smallmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{smallmatrix}\right)^{-1} \in L_\infty(\mathbb{T})^{(m+p)\times(m+p)}$.*
5. *$\tilde{S}M - \tilde{T}N$ is invertible over $L_\infty(\mathbb{T})$.*
6. *$\tilde{M}S - \tilde{N}T$ is invertible over $L_\infty(\mathbb{T})$.*

It is easy to see that the inverse of $\left(\begin{smallmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{smallmatrix}\right)$, if it exists, is given by $\mathcal{H}_{[P,C]}$.

Proof.

1⇒2 The stability of $[P,C]$ implies $G(P) \cap G^I(C) = \{0\}$ and $G(P) + G^I(C) = \ell_2(\mathbb{Z})^{p+m}$.

2⇒3 We get

$$L_2(\mathbb{T})^{m+p} = G(\hat{P}) + G^I(\hat{C}) = \begin{pmatrix} M \\ N \end{pmatrix} L_2(\mathbb{T})^m + \begin{pmatrix} T \\ S \end{pmatrix} L_2(\mathbb{T})^p. \tag{4.3}$$

We define the multiplication operator $X : L_2(\mathbb{T})^m \to L_2(\mathbb{T})^m$ by $Xu := \left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right) u$, $u \in L_2(\mathbb{T})^m$. Equation (4.3) shows that X as well as $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)(z)$

is surjective for a.e. $z \in \mathbb{T}$, and hence $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)(z)$ is injective for a.e. $z \in \mathbb{T}$. This shows that X is injective. Finally, the invertibility of X (and hence the invertibility of $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ over $L_\infty(\mathbb{T})$) is implied by the open mapping theorem.

3⇒1 The invertibility of $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ over $L_\infty(\mathbb{T})$ implies that $G(P) \cap G^I(C) = \{0\}$ and $G(P) + G^I(C) = \ell_2(\mathbb{Z})^{m+p}$. This shows that $F_{[P,C]}$ is injective and surjective. Thus the inverse of $F_{[P,C]}$ exists, and it remains only to show that the inverse is bounded. Using the closed graph theorem, this holds if $F_{[P,C]}$ has a closed graph. The graph of $F_{[P,C]}$ is given by

$$\left\{ \begin{pmatrix} x_1 \\ -x_2 \\ x_1 - Cx_2 \\ Px_1 - x_2 \end{pmatrix} \;\middle|\; x_1 \in D(P), x_2 \in D(C) \right\},$$

and it is closed since P and C are closed.

3⇔4 The equation

$$\begin{pmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{pmatrix}^{-1} = \begin{pmatrix} M & 0 \\ 0 & S \end{pmatrix} \begin{pmatrix} M & T \\ N & S \end{pmatrix}^{-1}$$

shows that part 3 implies part 4. If $\left(\begin{smallmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{smallmatrix}\right)$ is invertible, we have

$$\begin{pmatrix} M & 0 \\ 0 & S \\ M & T \\ N & S \end{pmatrix} \begin{pmatrix} M & T \\ N & S \end{pmatrix}^{-1} = \begin{pmatrix} \begin{pmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{pmatrix}^{-1} \\ \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \end{pmatrix} \in L_\infty(\mathbb{T})^{(2m+2p)\times(m+p)}.$$

Using the fact that $\binom{M}{N}$ and $\binom{S}{T}$ are left-invertible over $L_\infty(\mathbb{T})$, Proposition 3.9 of [7] shows that

$$\begin{pmatrix} M & 0 \\ 0 & S \\ 0 & T \\ N & 0 \end{pmatrix}$$

is left-invertible over $L_\infty(\mathbb{T})$. Thus the matrix

$$\begin{pmatrix} M & 0 \\ 0 & S \\ M & T \\ N & S \end{pmatrix} = \begin{pmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ I & 0 & I & 0 \\ 0 & I & 0 & I \end{pmatrix} \begin{pmatrix} M & 0 \\ 0 & S \\ 0 & T \\ N & 0 \end{pmatrix}$$

is left-invertible over $L_\infty(\mathbb{T})$, and hence $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ is invertible over $L_\infty(\mathbb{T})$.

4⇔5 We define $D := \tilde{S}M - \tilde{T}N$. Clearly, $D = \tilde{S}(I - \mathcal{C}\mathcal{P})M$. Thus $D^{-1} = M^{-1}(I - \mathcal{C}\mathcal{P})^{-1}\tilde{S}^{-1}$ or, equivalently, $(I - \mathcal{C}\mathcal{P})^{-1} = MD^{-1}\tilde{S}$. We first assume that part 4 holds. An easy calculation shows that $\left(\begin{smallmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{smallmatrix}\right)^{-1}$ equals the matrix $\mathcal{H}_{[P,C]}$, given by (4.2). Thus the functions $(I - \mathcal{C}\mathcal{P})^{-1}$, $(I - \mathcal{C}\mathcal{P})^{-1}\mathcal{C}$, $\mathcal{P}(I - \mathcal{C}\mathcal{P})^{-1}$, and $\mathcal{P}(I - \mathcal{C}\mathcal{P})^{-1}\mathcal{C}$ are measurable and essentially bounded on $\mathbb{T}$. Using $(I - \mathcal{C}\mathcal{P})^{-1} = MD^{-1}\tilde{S}$, this shows that

$$MD^{-1}\tilde{S}, \quad MD^{-1}\tilde{T}, \quad ND^{-1}\tilde{S}, \quad \text{and} \quad ND^{-1}\tilde{T}$$

are measurable and essentially bounded on $\mathbb{T}$. By Proposition 3.9 in [7] we get that

$$D^{-1}\tilde{S} \quad \text{and} \quad D^{-1}\tilde{T}$$

are measurable and essentially bounded on $\mathbb{T}$. Using again Proposition 3.9 in [7] we see that $D^{-1} \in L_\infty(\mathbb{T})^{m\times m}$. Next we assume that part 5 holds. Thus D is invertible over $L_\infty(\mathbb{T})$. Using $(I-\mathcal{C}\mathcal{P})^{-1} = MD^{-1}\tilde{S}$, we get that

$$\begin{pmatrix} I & \mathcal{C} \\ \mathcal{P} & I \end{pmatrix}^{-1} \in L_\infty(\mathbb{T})^{(m+p)\times(m+p)}.$$

4⇔6 The proof of this equivalence is similar to the proof of 4⇔5. □

Beside stability another important property of a feedback system is causality, which is defined as follows.

DEFINITION 4.9. *Let P be an LTI$(\mathbb{Z})^{p\times m}$-system and let C be an LTI$(\mathbb{Z})^{m\times p}$-system such that the feedback system $[P,C]$ is stable. We say the feedback system $[P,C]$ is* causal *if $H_{[P,C]}$, as given in* (4.1)*, is causal.*

Equivalently, $[P,C]$ is causal if and only if $\mathcal{H}_{[P,C]} \in H_\infty(\mathbb{D})^{(m+p)\times(m+p)}$. Considering LTI$(\mathbb{N}_0)$-systems, we see that every stable feedback system is automatically causal [5]. Unfortunately, this is not the case for LTI$(\mathbb{Z})$-systems, as the following example shows. Note that in the example both systems P and C are causal, whereas the feedback system is not causal.

Example 4.10. We consider a feedback system $[P,C]$, which is given by

$$\begin{aligned} Pu &:= u, \quad u \in \ell_2(\mathbb{Z}), \\ (Cu)(t) &:= u(t) - u(t-1), \quad u \in \ell_2(\mathbb{Z}),\ t \in \mathbb{Z}. \end{aligned}$$

Clearly, P and C are stable, causal LTI$(\mathbb{Z})^{1\times 1}$-systems, and $G(\hat{P}) = \binom{1}{1}L_2(\mathbb{T})$ and $G(\hat{C}) = \binom{1}{1-z}L_2(\mathbb{T})$. Since $D := 1\cdot 1 - (1-z)\cdot 1 = z$ is invertible over $L_\infty(\mathbb{T})$, Theorem 4.8 shows that the feedback system $[P,C]$ is stable. In order to show that the feedback system is not causal, we choose the inputs $u_1 := (\dots,0,1,0,\dots)$, where the 1 stands at position 0, and $u_2 := 0$. This choice implies $x_1 = (\dots,0,1,0,\dots)$, where the 1 stands at position -1, and thus the feedback system is not causal.

Next we give a necessary condition for a feedback system to be causal.

PROPOSITION 4.11. *Let P be an LTI$(\mathbb{Z})^{p\times m}$-system and let C be an LTI$(\mathbb{Z})^{m\times p}$-system such that the feedback system $[P,C]$ is stable and causal. Then the transfer functions of P and C, denoted by $\mathcal{P}$ and $\mathcal{C}$, respectively, satisfy*

$$\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m} \quad \text{and} \quad \mathcal{C} \in R(H_\infty(\mathbb{D}))^{m\times p},$$

and $\mathcal{P}$ as well as $\mathcal{C}$ possesses normalized rcf's and normalized lcf's over $H_\infty(\mathbb{D})$.

Note that the stability of $[P,C]$ implies that the systems P and C are closed; see Proposition 4.7.

Proof. We define $u_1^{(1)}, u_1^{(2)}, \dots, u_1^{(p)} \in H_\infty(\mathbb{D})^m$ by $u_1^{(1)} = \cdots = u_1^{(p)} = 0$ and $u_2^{(1)}, u_2^{(2)}, \dots, u_2^{(p)} \in H_\infty(\mathbb{D})^p$ by $u_2^{(j)} = (0,\dots,0,1,0,\dots,0)^T$, $j \in \{1,\dots,p\}$, where the 1 stands at position j. Thus, the matrix $(u_2^{(1)},\dots,u_2^{(p)})$ is invertible over $H_\infty(\mathbb{D})$. Since the feedback system $[P,C]$ is stable and causal, there exist unique elements $x_1^{(1)},\dots,x_1^{(p)} \in H_2(\mathbb{D})^m$ and $x_2^{(1)},\dots,x_2^{(p)} \in H_2(\mathbb{D})^p$ such that

$$x_1^{(j)} = \mathcal{C}x_2^{(j)}, \qquad j \in \{1,\dots,p\}, \tag{4.4}$$

$$x_2^{(j)} = u_2^{(j)} + \mathcal{P}x_1^{(j)}, \qquad j \in \{1,\dots,p\}. \tag{4.5}$$

Using $x_1^{(j)} = (I - \mathcal{CP})^{-1}\mathcal{C}u_2^{(j)}$, $x_2^{(j)} = (I - \mathcal{PC})^{-1}u_2^{(j)}$, $(I - \mathcal{CP})^{-1}\mathcal{C} \in H_\infty(\mathbb{D})^{p\times m}$, $(I - \mathcal{PC})^{-1} \in H_\infty(\mathbb{D})^{p\times p}$, and $u_2^{(j)} \in H_\infty(\mathbb{D})^p$, we get $x_1^{(j)} \in H_\infty(\mathbb{D})^m$ and $x_2^{(j)} \in H_\infty(\mathbb{D})^p$, $j \in \{1,\dots,p\}$. Next we show that the determinant of $U := (x_2^{(1)},\dots,x_2^{(p)}) \in H_\infty(\mathbb{D})^{p\times p}$ is not zero. We assume that the determinant is zero. Similar to Proposition 3.12 in [7] it can be shown that there are functions $\alpha_1,\dots,\alpha_p \in H_\infty(\mathbb{D})$ such that $|\alpha_1|^2 + \cdots + |\alpha_p|^2 > 0$ and

$$\alpha_1 x_2^{(1)} + \cdots + \alpha_p x_2^{(p)} = 0.$$

Thus equation (4.4) implies

$$\alpha_1 x_1^{(1)} + \cdots + \alpha_p x_1^{(p)} = \mathcal{C}\left(\alpha_1 x_2^{(1)} + \cdots + \alpha_p x_2^{(p)}\right) = 0.$$

This shows, using equation (4.5),

$$\alpha_1 u_2^{(1)} + \cdots + \alpha_p u_2^{(p)} = \alpha_1 x_2^{(1)} + \cdots + \alpha_p x_2^{(p)} - \mathcal{P}\left(\alpha_1 x_1^{(1)} + \cdots + \alpha_p x_1^{(p)}\right) = 0.$$

However, this is in contradiction to the definition of $u_2^{(j)}$, $j = 1,\dots,p$. Thus $\det U \neq 0$, which implies $U^{-1} \in R(H_\infty(\mathbb{D}))^{p\times p}$.

Further, we define $V := \mathcal{C}U = (x_1^{(1)},\dots,x_1^{(j)}) \in H_\infty(\mathbb{D})^{m\times p}$, and thus $\mathcal{C} = VU^{-1} \in R(H_\infty(\mathbb{D}))^{m\times p}$. In a similar manner it can be proved that $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$.

The stability and causality of the feedback system show that the functions $(I-\mathcal{CP})^{-1}$, $(I - \mathcal{CP})^{-1}\mathcal{C}$, $\mathcal{P}(I - \mathcal{CP})^{-1}$, and $\mathcal{P}(I - \mathcal{CP})^{-1}\mathcal{C}$ are holomorphic and bounded on $\mathbb{D}$. Let $\mathcal{P} = NM^{-1}$ be a weak rcf over $H_\infty(\mathbb{D})$ of P and let $\mathcal{C} = \tilde{S}^{-1}\tilde{T}$ be a weak lcf over $H_\infty(\mathbb{D})$ of C. For the proof that every element of $H_\infty(\mathbb{D})^{m\times p}$ possesses a weak lcf and a weak rcf over $H_\infty(\mathbb{D})$ we refer the reader to [5] and [16]. Then we get that

$$M(\tilde{S}M - \tilde{T}N)^{-1}\tilde{S}, \qquad M(\tilde{S}M - \tilde{T}N)^{-1}\tilde{T}, \qquad N(\tilde{S}M - \tilde{T}N)^{-1}\tilde{S},$$
$$\text{and} \quad N(\tilde{S}M - \tilde{T}N)^{-1}\tilde{T}$$

are holomorphic and bounded on $\mathbb{D}$. By Lemma 4 of Smith [16] we get that

$$(\tilde{S}M - \tilde{T}N)^{-1}\tilde{S} \quad \text{and} \quad (\tilde{S}M - \tilde{T}N)^{-1}\tilde{T}$$

are holomorphic and bounded on $\mathbb{D}$. Using again Lemma 4 of Smith [16] we see that $(\tilde{S}M - \tilde{T}N)^{-1} \in H_\infty(\mathbb{D})^{m\times m}$. This shows that $\mathcal{P} = NM^{-1}$ is an rcf over $H_\infty(\mathbb{D})$ of P and that $\mathcal{C} = \tilde{S}^{-1}\tilde{T}$ is an lcf over $H_\infty(\mathbb{D})$ of C. In a similar manner it can be shown that $\mathcal{C}$ possesses an rcf over $H_\infty(\mathbb{D})$ and that $\mathcal{P}$ possesses an lcf over $H_\infty(\mathbb{D})$. Finally, the existence of normalized rcf's (lcf's) is shown in [5], [16]. □

Next we formulate equivalent conditions for a stable feedback system to be causal. The results are based on standard results using the coprime factorization approach (see Vidyasagar [19]). Similar results for systems over the signal space $\ell_2(\mathbb{N}_0)$ can be found in Georgiou and Smith [5].

THEOREM 4.12. *Let P be an $LTI(\mathbb{Z})^{p\times m}$-system and let C be an $LTI(\mathbb{Z})^{m\times p}$-system such that the feedback system $[P, C]$ is stable. We assume that the transfer functions of P and C, denoted by $\mathcal{P}$ and $\mathcal{C}$, respectively, satisfy $\mathcal{P} \in R(H_\infty(\mathbb{D}))^{p\times m}$ and $\mathcal{C} \in R(H_\infty(\mathbb{D}))^{m\times p}$ and that both transfer functions possess rcf's and lcf's over $H_\infty(\mathbb{D})$, denoted by $\mathcal{P} = NM^{-1} = \tilde{M}^{-1}\tilde{N}$ and $\mathcal{C} = TS^{-1} = \tilde{S}^{-1}\tilde{T}$. Then the following statements are equivalent.*

1. $[P, C]$ *is causal.*
2. $\left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ *is invertible over* $H_\infty(\mathbb{D})$.
3. $\left(\begin{smallmatrix} I & C \\ P & I \end{smallmatrix}\right)^{-1} \in H_\infty(\mathbb{D})^{(m+p)\times(m+p)}$.
4. $\tilde{S}M - \tilde{T}N$ *is invertible over* $H_\infty(\mathbb{D})$.
5. $\tilde{M}S - \tilde{N}T$ *is invertible over* $H_\infty(\mathbb{D})$.

Proof. The equivalence of parts 1 and 3 is easy to see, using the fact that $\left(\begin{smallmatrix} I & \mathcal{P} \\ C & I \end{smallmatrix}\right)^{-1}$ is the transfer function of the feedback system $H_{[P,C]}$. Moreover, the equivalence of parts 2 and 3, parts 3 and 4, and parts 3 and 5 can be proved similarly to Theorem 4.8, using Lemma 4 of Smith [16] instead of Proposition 3.9 of [7]. □

5. Stabilizable LTI($\mathbb{Z}$)-systems. The system C is called a *controller* of P. Note that a controller always is a closed LTI($\mathbb{Z}$)-system. There are different possibilities to define the notion of stabilizability for an LTI($\mathbb{Z}$)-system P. The simplest one would be to require that there exists an LTI($\mathbb{Z}$)-system C such that the feedback system $[P, C]$ is stable. This is the usual definition used in system and control theory. However, in our situation this definition is not suitable, since it would rule out a huge class of important systems from being stabilizable and this definition would not guarantee that the feedback system is causal. Thus we adapt the definition as follows.

DEFINITION 5.1. *An LTI($\mathbb{Z}$)-system P is called* stabilizable *if P is closable and if there exists an LTI($\mathbb{Z}$)-system C such that the feedback system $[\overline{P}, C]$ is stable and causal.*

We obtain the following equivalent condition for stabilizability.

THEOREM 5.2. *Let P be a closable LTI$(\mathbb{Z})^{p\times m}$-system. Then the following statements are equivalent.*

1. *P is stabilizable.*
2. *P is stabilizable by a causal controller.*
3. *The transfer function of $\overline{P}$, denoted by $\mathcal{P}$, possesses a normalized rcf as well as a normalized lcf over $H_\infty(\mathbb{D})$.*
4. *The transfer function of $\overline{P}$, denoted by $\mathcal{P}$, possesses an rcf over $H_\infty(\mathbb{D})$.*

Proof. Clearly, part 3 implies part 4, part 2 implies part 1, and the implication of part 1 to part 3 has been proved in Proposition 4.11.

Next we show that part 4 implies part 1. Part 4 implies that there exists a symbol $\binom{M}{N} \in H_\infty(\mathbb{D})^{(m+p)\times m}$ of $\overline{P}$ which is left-invertible over $H_\infty(\mathbb{D})$. Using Tolokonnikov's lemma (see, for example, Nikol′skiĭ [14, page 293]), there exist matrices $S \in H_\infty(\mathbb{D})^{p\times p}$ and $T \in H_\infty(\mathbb{D})^{m\times p}$ such that

$$X = \begin{pmatrix} M & T \\ N & S \end{pmatrix}$$

is invertible over $H_\infty(\mathbb{D})$. If $\det S \neq 0$, then we can define C via the graph $G(\hat{C}) = \binom{S}{T} L_2(\mathbb{T})^p$. The stability of $[P, C]$ is then implied by Theorem 4.8, since X is invertible over $H_\infty(\mathbb{D})$, and hence over $L_\infty(\mathbb{T})$, and the causality of $[P, C]$ is implied by Theorem 4.12. However it can happen that $\det S = 0$. Clearly, for every $Q \in H_\infty(\mathbb{D})^{m+p}$, the matrix $X_Q := \left(\begin{smallmatrix} M & T+MQ \\ N & S+NQ \end{smallmatrix}\right) = \left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)\left(\begin{smallmatrix} I & Q \\ 0 & I \end{smallmatrix}\right)$ is invertible over $H_\infty(\mathbb{D})$, and so it is enough to show that there is a matrix $Q \in H_\infty(\mathbb{D})^{m\times p}$ such that $\det(S + NQ) \neq 0$. We have that $(N\, S)$ is right-invertible over $H_\infty(\mathbb{D})$. Thus there exists at least one $p \times p$-minor of $(N\, S)$ which is nonzero. Let A be such a $p \times p$-submatrix of $(N\, S)$ with the fewest possible columns from N. We now define $Q \in H_\infty(\mathbb{D})^{m\times p}$ as follows. Suppose that we obtain A by excluding columns $j_1, \ldots, j_l$ of S and including columns $i_1, \ldots, i_l$ of N. Let now the i_kth row of Q be equal to the j_kth row of the identity

I_p on $\mathbb{C}^p$, $k = 1, \dots, l$, and be zero otherwise. It is easy to see that $Q \in H_\infty(\mathbb{D})^{m\times p}$. Moreover, since A possesses the fewest possible columns from N, we get that the determinant of $S + NQ = (S\ N)\binom{I_p}{Q}$ is nonzero. This shows that there is a controller which stabilizes P and the feedback system is causal; see Theorem 4.12.

Finally, it remains to show that part 1 implies part 2. Let $\mathcal{P}$ be the transfer function of $\overline{P}$, let $\mathcal{P} = NM^{-1}$ be an rcf over $H_\infty(\mathbb{D})$ of $\mathcal{P}$, and let C be a stabilizing controller with transfer function TS^{-1}. It remains to show that there exists a matrix $Q \in H_\infty(\mathbb{D})^{m\times p}$ such that $S + NQ$ is invertible over $H_\infty(\mathbb{D})$, because then P is causally stabilized by the controller C' with transfer function $(T+MQ)(S+NQ)^{-1} \in H^\infty(\mathbb{D})^{m\times p}$. By Theorem 4.12 the matrix $X = \left(\begin{smallmatrix} M & T \\ N & S \end{smallmatrix}\right)$ is invertible over $H_\infty(\mathbb{D})$. In particular, $(N\ \ S)$ is right-invertible over $H_\infty(\mathbb{D})$. This implies

$$\inf_{z\in\mathbb{D}} (\|N(z)\| + \|S(z)\|) > 0.$$

Now Quadrat [15] (see also Treil [17]) shows the existence of a matrix $Q \in H_\infty(\mathbb{D})^{m\times p}$ with the required properties, and thus the theorem is proved. □

The algorithm to stabilize an LTI($\mathbb{Z}$)-system can also be used for stable noncausal LTI($\mathbb{Z}$)-systems. In this case we obtain a stable and causal system.

6. Comparison: LTI($\mathbb{Z}$)-systems versus LTI($\mathbb{N}_0$)-systems. Every closable LTI($\mathbb{Z}$)-system can be *restricted* to an LTI($\mathbb{N}_0$)-system in the following way. Let P be a closable LTI$(\mathbb{Z})^{p\times m}$-system. Then we define $P_\mathbb{N} : D(P_\mathbb{N}) \subset \ell_2(\mathbb{N}_0)^m \to \ell_2(\mathbb{N}_0)^p$ as the closure of the operator $T : D(T) \subset \ell_2(\mathbb{N}_0)^m \to \ell_2(\mathbb{N}_0)^m$, which is given by

$$\begin{aligned} Tu &:= Pu, \quad u \in D(T), \\ D(T) &:= \{u \in D(P) \cap \ell_2(\mathbb{N}_0)^m \mid Pu \in \ell_2(\mathbb{N}_0)^p\}. \end{aligned}$$

By this definition $P_\mathbb{N}$ is an LTI$(\mathbb{N}_0)^{p\times m}$-system. Next we study the relation between the transfer function of $\overline{P}$ and $P_\mathbb{N}$. We show that if $P_\mathbb{N}$ is stabilizable, then P is stabilizable and both systems have the same transfer function. Moreover, if P is closed and stabilizable, then $P_\mathbb{N}$ is stabilizable and both systems have the same transfer function.

THEOREM 6.1. *Let P be a closable LTI$(\mathbb{Z})^{p\times m}$-system. If $P_\mathbb{N}$ is stabilizable, then P is stabilizable. Moreover, both systems have the same transfer function and they are stabilized by the same controllers.*

Proof. Let $\mathcal{P}_\mathbb{N}$ and $\mathcal{P}$ denote the transfer function of $P_\mathbb{N}$ and $\overline{P}$, respectively. Since $P_\mathbb{N}$ is stabilizable, $\mathcal{P}_\mathbb{N}$ possesses a normalized rcf $N_\mathbb{N}M_\mathbb{N}^{-1}$ over $H_\infty(\mathbb{D})$. Further, $\mathcal{P}$ possesses a normalized rcf NM^{-1} over $L_\infty(\mathbb{T})$. Since

$$\begin{pmatrix} M_\mathbb{N} \\ N_\mathbb{N} \end{pmatrix} H_2(\mathbb{D})^m = G(P_\mathbb{N}) \subset G(\overline{P}) = \begin{pmatrix} M \\ N \end{pmatrix} L_2(\mathbb{T})^m,$$

there exists a matrix $Q \in L_2(\mathbb{T})^{m\times p}$ such that

$$\begin{pmatrix} M_\mathbb{N} \\ N_\mathbb{N} \end{pmatrix} = \begin{pmatrix} M \\ N \end{pmatrix} Q.$$

$\binom{M}{N}^* \binom{M}{N} = I$ now implies $Q \in L_\infty(\mathbb{T})^{m\times m}$. Since $\binom{M_\mathbb{N}}{N_\mathbb{N}}$ is left-invertible over $H_\infty(\mathbb{D})$, there is a $Q_L \in L_\infty(\mathbb{T})^{m\times m}$ such that $Q_L Q = I$. Thus Q is invertible over $L_\infty(\mathbb{T})$, and $G(\overline{P}) = \binom{M_\mathbb{N}}{N_\mathbb{N}} L_2(\mathbb{T})^m$. This proves that P is stabilizable and $\mathcal{P} = N_\mathbb{N}M_\mathbb{N}^{-1} = NM^{-1}$.

That the sets of controllers coincide follows from Theorem 4.12 and Georgiou and Smith [5, Lemma 1]. □

THEOREM 6.2. *Let P be a closed LTI$(\mathbb{Z})^{p\times m}$-system. Then P is stabilizable if and only if $P_{\mathbb{N}}$ is stabilizable. Moreover, both systems have the same transfer function and they are stabilized by the same controllers.*

Proof. In view of the previous theorem it remains to show that when P is stabilizable it implies that $P_{\mathbb{N}}$ is stabilizable. As above, let $\mathcal{P}_{\mathbb{N}}$ and $\mathcal{P}$ denote the transfer function of $P_{\mathbb{N}}$ and P, respectively. Since P is stabilizable, $\mathcal{P}$ possesses a normalized rcf NM^{-1} over $H_\infty(\mathbb{D})$. Since

$$\begin{pmatrix} M \\ N \end{pmatrix} H_2(\mathbb{D})^m \subset G(P_{\mathbb{N}}) \subset G(P) = \begin{pmatrix} M \\ N \end{pmatrix} L_2(\mathbb{T})^m,$$

we get that NM^{-1} is the transfer function of a stabilizable and maximal LTI$(\mathbb{Z})^{p\times m}$-system T (see [5]) with the property $G(T) \subset G(P_{\mathbb{N}})$. Thus $T = P_{\mathbb{N}}$, and the theorem is proved. □

Conclusions. We studied discrete-time systems with signal space $\ell_2(\mathbb{Z})$ from first principal. For these systems Georgiou and Smith [5], [6] discovered that a well-known stabilizable system is not stabilizable when using the canonical definition of stabilizability. Using an adapted notion of stabilizability in the mathematical formalism we are able to guarantee that all—from a physical point of view—stabilizable systems are actually stabilizable in the mathematical formalism. Further, we give equivalent conditions for stabilizability.

In this paper we work with discrete-time LTI-systems only, and now is a good time to discuss how things change when we move to continuous-time LTI-systems. In fact, every result for discrete-time LTI-systems does have a counterpart for continuous-time LTI-systems, and the proofs are basically the same. Instead of using the z-transform, which is an isometric isomorphism between $\ell_2(\mathbb{Z})$ and $L_2(\mathbb{T})$, we use the Laplace transform, which is an isometric isomorphism between $L_2(\mathbb{R})$ and $L_2(i\mathbb{R})$. The subspace $L_2(0,\infty)$ then corresponds to the Hardy class $H_2(\mathbb{C}_+)$.

GAP METRICS, REPRESENTATIONS, AND NONLINEAR ROBUST STABILITY*

M. R. JAMES†, M. C. SMITH‡, AND G. VINNICOMBE‡

Abstract. Various alternative definitions for the nonlinear H_2-, L_2-, and ν-gap metrics are studied. The concept of β-conjugacy and multiplicative homogeneity are introduced to relate the metrics to each other and to compare the stability margins of nonlinear feedback loops expressed in terms of the norms of complementary parallel projections. Left and right representations for the graph of a nonlinear system are studied. A new definition of "normalized" is introduced for left representations. Formulas for the gap metrics as the norm of the product of left and right representations are derived. The problem of controller synthesis for input-affine nonlinear systems to achieve norm bounds on the parallel projection operators is studied for input-affine nonlinear systems. The duality between the optimization of the two parallel projections is highlighted. State-space realizations for the normalized left and right representations are derived using nonlinear H_∞ synthesis methods.

1. Introduction.

This paper is concerned with the approach to robust stability of nonlinear systems using gap metrics following the work of [1], [11], [30]. The paper considers several related issues surrounding the following basic robustness theorem: feedback stability is preserved if gap perturbations do not exceed the inverse of the norm of a nonlinear parallel projection operator associated with the feedback loop. The paper develops and unifies a number of concepts and results concerned with the definition and computation of gap metrics, graph representations, controller synthesis to achieve norm bounds on the parallel projection operators, and state-space realizations of graph representations.

The gap metric provides a measure of distance between dynamical systems which are not required to be stable in themselves. The original rationale for the (linear) gap metric was to provide a suitable topology in which small errors in the gap in open-loop systems would correspond to small errors in norm in the stable closed loop. In [9] the gap metric was shown to be exactly equal to the solution of a certain H_∞ optimization problem. Building on this work the optimal robustness problem in the gap metric was solved in [10] and connections emerged with H_∞ loop-shaping [20]. The stability margin for uncertainty in the gap metric was shown to be the norm of a certain parallel projection operator in [8]. In [29] the tightest possible metric for this stability margin, called the ν-gap metric, was derived.

An attempt to generalize the gap metric robust stability theory to nonlinear systems began in [5], where two complementary parallel projection operators of a

nonlinear feedback system were highlighted. In [11] the inverse of the induced norm of one of these projections was shown to define a guaranteed radius of stability for uncertainty in a nonlinear generalization of the gap metric. In [30] it was shown how to get a tighter version of the robustness theorem using ideas drawing on the linear ν-gap metric. These results showed in principle that the linear gap metric theory was capable of a powerful generalization to nonlinear systems. It is the purpose of this paper to refine and develop several aspects of this theory.

In [11], [30] several definitions of the gap and ν-gap were given which generalize definitions of the H_2-, L_2-, and ν-gap from the linear case. These, and some new definitions, will form a family of "δ-type" and "ρ-type" metrics which will be studied in section 4. Various versions of the main robustness theorem will be given involving the two complementary parallel projections of a feedback loop. In particular, the "δ-type" (respectively, "ρ-type") gap metrics are needed for results involving the parallel projection onto the plant (respectively, controller) graph. The δ-type and ρ-type gaps are shown to be equal subject to a certain conjugacy transformation on one of the systems (Lemma 4.1). Under similar conditions, the norms of the two complementary parallel projections are shown to be equal (Theorem 4.7).

The connection between gap metrics and representations of the graph is developed in this paper. Operators whose image (respectively, kernel) generates the graph are termed right (respectively, left) representations of the system. These operators, called graph symbols, generalize the usual notions of right and left coprime factorizations. As usual, we call a right representation normalized if the symbol is inner. We introduce a new definition of "normalized" for left representations, which requires that the "amplification" or "gain" of any L_2-function by the symbol is equal to the minimal distance to the graph (section 3.2). This allows formulas to be derived (Theorem 4.10), involving norms of products of the left and right symbols, for the various ρ-type gap metrics. This also allows versions of the robustness theorem to be obtained involving ∞-norm errors between the graph symbols to account for system uncertainty (Theorems 4.12 and 4.13).

The paper also considers the problem of controller synthesis to achieve norm bounds on each of the two complementary parallel projection operators. This problem is at the heart of H_∞ loop-shaping for linear systems and represents one of the most important "special" problems of H_∞ optimization. This problem is solved for the class of input-affine nonlinear systems in section 5. Applying the approach of [14] to the two corresponding generalized plants exposes notable simplifications in the information state dynamics and control laws compared to the usual case of H_∞-synthesis and highlights the duality between the two problems.

The circle of ideas explored in this paper is completed by considering state-space realizations for the graph representations defined in section 3. In the development of the theory of coprime factors and graph representations, state-space realizations have been important for computation and in studying the connection between existence of representations and stabilizability. Section 6.1 derives state-space realizations for the right graph representations in terms of the solution of a Hamilton–Jacobi–Bellman (HJB) equation and a state feedback. Realizations for the left graph representations are derived in the form of an information state system in section 6.2. A brief review of relevant facts from nonlinear H_∞ control which are relevant for sections 5 and 6 is given in the appendix.

We conclude the introduction by summarizing the main contributions of the paper.

- A unified set of definitions for the nonlinear gap metric is provided which highlights the natural linkage with the two fundamental parallel projection operators. Several versions of the fundamental robustness result are given in terms of these metrics. The notion of β-conjugacy is introduced to relate the norms of the two complementary parallel projection operators.
- A new definition of "normalized" for left graph representations is given, and robustness results are given in terms of the graph representations.
- A solution to the controller synthesis problem for a feedback system which optimizes the two fundamental parallel projection operators is given for input-affine nonlinear systems.
- A new realization theory for graph representations is given.

2. Preliminaries. This section provides the background on signal spaces, systems, and stability, which forms the basis for the rest of the paper. In the definitions to follow, n denotes the generic dimension of the range of the signals. Write

$$L_2 = L_2(-\infty,\infty) = \{w : (-\infty,\infty) \to \mathbf{R}^n \mid \| w \|_2 < \infty\}$$

for the Lebesgue space of signals on the doubly infinite time axis, where

$$\| w \|_2 = \| w \|_{L_2(-\infty,\infty)} \triangleq \left(\int_{-\infty}^{\infty} |w(s)|^2 ds \right)^{1/2}.$$

The signals in the following space are zero before a finite time and square integrable on each finite interval:

$$L_{2,ce} = L_{2,ce}(-\infty,\infty) = \{w : \quad (-\infty,\infty) \to \mathbf{R}^n \mid \mathbf{T}_T w = 0 \text{ for some } T \in (-\infty,\infty) \text{ and } \| \mathbf{T}_T w \|_2 < \infty \ \forall T > -\infty\},$$

where

$$(\mathbf{T}_T w)(s) = \begin{cases} w(s), & s \le T, \\ 0, & s > T. \end{cases}$$

The space of signals defined for positive times and square integrable on each finite interval is

$$L_{2,e} = L_{2,e}[0,\infty) = \{w : [0,\infty) \to \mathbf{R}^n \mid \| \mathbf{T}_T w \|_2 < \infty \ \forall T \ge 0\}.$$

We can regard $L_{2,e}$ as a subset of $L_{2,ce}$ by defining elements of $L_{2,e}$ to be 0 before time 0. For $w \in L_{2,ce}$ we write

$$\| w \|_T = \| \mathbf{T}_T w \|_2 .$$

The signal spaces $\mathcal{U}$, $\mathcal{Y}$, $\mathcal{W}$, etc., will be $L_{2,ce}$ spaces of suitable range dimension. The plant P and controller K will be operators defined on these spaces. We will also consider restrictions of these operators to $L_{2,e}$ and L_2.

We write

$$\begin{aligned} \| P \|_\infty &= \limsup_{T\to\infty} \sup_{u \in L_{2,ce}(-\infty,\infty), \|u\|_T \neq 0} \frac{\| Pu \|_T}{\| u \|_T} \\ &= \limsup_{T\to\infty} \sup_{u \in L_{2,e}(-\infty,\infty), \|u\|_T \neq 0} \frac{\| Pu \|_T}{\| u \|_T} \qquad (1) \\ &= \sup_{u \in L_2[0,\infty), u \neq 0} \frac{\| Pu \|_2}{\| u \|_2} \end{aligned}$$

for the induced norm for a causal, time-invariant operator $P : L_{2,ce} \to L_{2,ce}$; this is often called the H_∞ *norm* of P even if P is nonlinear. An operator P is defined to be *stable* if $\| P \|_\infty$ is finite. We sometimes use finite time restrictions $P|_{[T_0,T]}$ of operators, or operators defined on intervals $[T_0, T]$ (we can take $T_0 = -\infty$), and we define

$$\| P|_{[T_0,T]} u \|_{[T_0,T],\infty} = \sup_{u \in L_2[T_0,T], u \neq 0} \frac{\| P|_{[T_0,T]} u \|_T}{\| u \|_T}. \tag{2}$$

The feedback configuration of Figure 1 is denoted by $[P, K]$ and consists of a *plant* $P : \mathcal{U} \to \mathcal{Y}$ and a *controller* $K : \mathcal{Y} \to \mathcal{U}$, both causal, time-invariant maps defined on $L_{2,ce}$ signal spaces $\mathcal{U}$, $\mathcal{Y}$ and which satisfy $P0 = 0$ and $K0 = 0$.

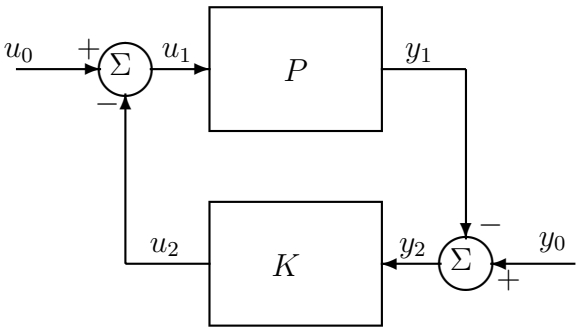

FIG. 1. *Feedback configuration* $[P, K]$.

In Figure 1, $u_i \in \mathcal{U}$ and $y_i \in \mathcal{Y}$ $(i = 0, 1, 2)$, and we write $\mathcal{W} = \mathcal{U} \times \mathcal{Y}$. The feedback system $[P, K]$ is assumed to be well-posed. Namely, for any $w = (u_0, y_0) \in \mathcal{W}$ there exist unique $u_1, u_2 \in \mathcal{U}$, $y_1, y_2 \in \mathcal{Y}$ such that the following closed-loop equations hold:

$$\begin{aligned} u_0 &= u_1 + u_2, \\ y_0 &= y_1 + y_2, \\ y_1 &= P u_1, \\ u_2 &= K y_2, \end{aligned} \tag{3}$$

and moreover, the map

$$\begin{aligned} H_{P,K} &: \mathcal{W} \to \mathcal{W} \times \mathcal{W}, \\ &: \begin{pmatrix} u_0 \\ y_0 \end{pmatrix} \mapsto \left(\begin{pmatrix} u_1 \\ y_1 \end{pmatrix} , \begin{pmatrix} u_2 \\ y_2 \end{pmatrix} \right) \end{aligned} \tag{4}$$

is causal.

Throughout the paper, it will be assumed that both the nominal feedback system as shown in Figure 1 and any perturbed feedback system (with P replaced by a perturbed plant P_1) are well-posed. The feedback system $[P, K]$ is defined to be *stable* if the operator from (u_0, y_0) to (u_1, y_1, u_2, y_2) has finite H^∞ norm, i.e., $\| H_{P,K} \|_\infty < \infty$.

It is convenient to consider *graphs* of operators. The graph of the plant P is

$$\mathcal{G}_P = \left\{ \begin{pmatrix} u \\ Pu \end{pmatrix} \ : \ u \in \mathcal{U}, Pu \in \mathcal{Y} \right\} \subset \mathcal{W},$$

and the graph of the controller K is

$$\mathcal{G}_K = \left\{ \begin{pmatrix} Ky \\ y \end{pmatrix} \ : \ y \in \mathcal{Y}, Ky \in \mathcal{U} \right\} \subset \mathcal{W}.$$

We often write

$$\mathcal{M} = \mathcal{G}_P, \quad \mathcal{N} = \mathcal{G}_K.$$

Of central importance to robustness of the feedback system $[P, K]$ are the *parallel projection* operators (see [5], [11])

$$\Pi_{\mathcal{M}\|\mathcal{N}} = \Pi_1 H_{P,K}, \quad \Pi_{\mathcal{N}\|\mathcal{M}} = \Pi_2 H_{P,K},$$

where $\Pi_i : \mathcal{W} \times \mathcal{W} \to \mathcal{W}$ denote the natural projections ($i = 1, 2$). The operators $\Pi_{\mathcal{M}\|\mathcal{N}}$, $\Pi_{\mathcal{N}\|\mathcal{M}}$ both enjoy the defining *parallel projection* property

$$\Pi(\Pi w_1 + (I - \Pi)w_2) = \Pi w_1 \tag{5}$$

for any w_1, $w_2 \in \mathcal{W}$, where I denotes the identity operator, and the following identities hold:

$$H_{P,K} = (\Pi_{\mathcal{M}\|\mathcal{N}}, \Pi_{\mathcal{N}\|\mathcal{M}}) \quad \text{and} \quad \Pi_{\mathcal{M}\|\mathcal{N}} + \Pi_{\mathcal{N}\|\mathcal{M}} = I. \tag{6}$$

Consequently, stability of the feedback system $[P, K]$, i.e., the finiteness of $\| H_{P,K} \|_\infty$, is equivalent to the stability of either parallel projection [11].

We note that the parallel projection operators can be represented as generalized plant and controller configurations as in Figures 2 and 3, where

$$\mathcal{P}_1 : \begin{pmatrix} u_0 \\ y_0 \\ u_2 \end{pmatrix} \mapsto \begin{pmatrix} u_1 \\ y_1 \\ y_2 \end{pmatrix} \quad \text{and } \mathcal{P}_2 : \begin{pmatrix} u_0 \\ y_0 \\ u_2 \end{pmatrix} \mapsto \begin{pmatrix} u_2 \\ y_2 \\ y_2 \end{pmatrix} \tag{7}$$

so that

$$\| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty = \| [\mathcal{P}_1, K] \|_\infty \quad \text{and} \quad \| \Pi_{\mathcal{N}\|\mathcal{M}} \|_\infty = \| [\mathcal{P}_2, K] \|_\infty \ . \tag{8}$$

Here, $[\mathcal{P}_1, K]$ and $[\mathcal{P}_2, K]$ refer to the closed-loop configurations of Figures 2 and 3, respectively. As we shall see in section 4, there are guaranteed bounds for robust stability in terms of the norms of these parallel projection operators. The synthesis problem of finding controllers to minimize either quantity is solved in section 5.

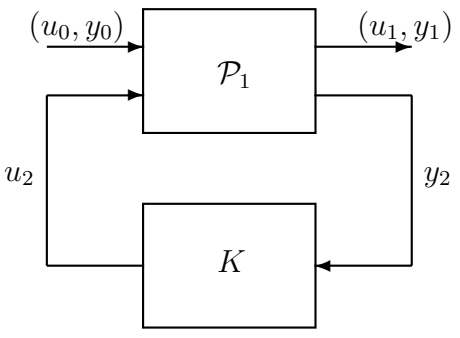

FIG. 2. *The parallel projection* $\Pi_{\mathcal{M}\|\mathcal{N}}$ *and generalized plant* $\mathcal{P}_1$.

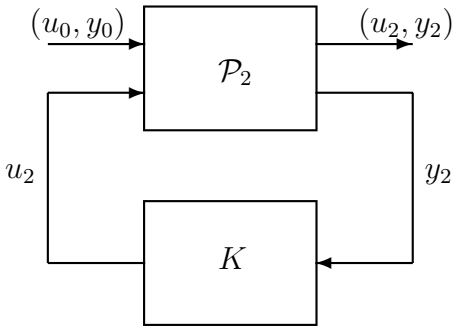

FIG. 3. *The parallel projection* $\Pi_{\mathcal{N}\|\mathcal{M}}$ *and generalized plant* $\mathcal{P}_2$.

3. Graph representations. The subject of right and left coprime factorizations has been fundamental in the development of the (linear) gap metric robustness theory. From an operator viewpoint these factorizations may be viewed as graph "symbols." A number of generalizations for nonlinear operators have been considered in the literature; see [24], [22], [27], [19]. In this section we propose a new approach which focuses on the essential energy balances related to a graph representation. This allows definitions to be made for both finite and infinite time horizons. More importantly, it allows a new definition of "co-innerness" for the left representations which appears to have significant advantages; in particular, it allows the left representations to be used for robustness analysis (section 4.5). The definition requires that the "amplification" of any L_2-function by the symbol be equal to the minimal distance of that function to the graph.

3.1. Right representations. Roughly speaking, we wish to generalize the idea that $P = NM^{-1}$ has a normalized coprime factorization, with

$$R = \begin{bmatrix} M \\ N \end{bmatrix}$$

defining a range representation of the graph of P:

$$\{w \in \mathcal{W} \mid w = R\psi, \text{ some } \psi \in \mathcal{U}\} = \mathcal{G}_P,$$

together with notions of the inner and coprime properties.

1. For any $T \in (-\infty, \infty)$ a causal operator

$$\mathsf{R}_{T,P} \ : \ \mathcal{U} \to \mathcal{W} \cap L_2(-\infty, T]$$

is called a *finite horizon right representation* of P provided it maps onto the graph:

$$\text{range}\, \mathsf{R}_{T,P}|_{[T_0,T]} = \mathcal{G}_P \cap L_2[T_0, T] \quad \forall T_0 \in (-\infty, T]. \tag{9}$$

(a) $\mathsf{R}_{T,P}$ is *contractive* if

$$\| \mathsf{R}_{T,P}\psi \|_T \leq \| \psi \|_T \quad \forall \psi \in \mathcal{U}; \tag{10}$$

(b) $\mathsf{R}_{T,P}$ is *finite time inner* (or *normalized*) if

$$\| \mathsf{R}_{T,P}\psi \|_T = \| \psi \|_T \tag{11}$$

for all $\psi \in \mathcal{U}$.

(c) A causal operator

$$\mathsf{R}_{T,P}^{-L} \ : \ \mathcal{W} \to \mathcal{U} \cap L_2(-\infty, T]$$

is called a *left inverse* of $\mathsf{R}_{T,P}$ if

$$\mathsf{R}_{T,P}^{-L}\mathsf{R}_{T,P} = I. \tag{12}$$

$\mathsf{R}_{T,P}^{-L}$ is norm bounded if there is some $c > 0$ such that

$$\| \mathsf{R}_{T,P}^{-L} w \|_T \leq c \, \| w \|_T \quad \forall w \in \mathcal{W}. \tag{13}$$

$\mathsf{R}_{T,P}$ is *finite time right coprime* if there exists a causal operator $\mathsf{R}_{T,P}^{-L}$ which is a left inverse of $\mathsf{R}_{T,P}$ and norm bounded.

2. A causal operator

$$\mathsf{R}_{eP} \ : \ \mathcal{U} \to \mathcal{W}$$

is called a *right representation* of P provided it maps onto the graph

$$\begin{aligned} \operatorname{range} \mathsf{R}_{eP} &= \mathcal{G}_P, \\ \operatorname{range} \mathsf{R}_{eP}|_{L_2} &= \mathcal{G}_P \cap L_2, \\ \operatorname{range} \mathsf{R}_{eP}|_{L_2[0,\infty)} &= \mathcal{G}_P \cap L_2[0,\infty). \end{aligned} \tag{14}$$

(a) R_{eP} is *contractive* if

$$\| \mathsf{R}_{eP}\psi \|_T \leq \| \psi \|_T \quad \forall \ T \in (-\infty, \infty), \psi \in \mathcal{U}; \tag{15}$$

(b) R_{eP} is *inner* (or *normalized*) if

$$\| \mathsf{R}_{eP}\psi \|_2 = \| \psi \|_2 \quad \forall \psi \in \mathcal{U} \cap L_2. \tag{16}$$

(c) A causal operator

$$\mathsf{R}_{eP}^{-L} \ : \ \mathcal{W} \to \mathcal{U}$$

is called a *left inverse* of R_{eP} if

$$\mathsf{R}_{eP}^{-L}\mathsf{R}_{eP} = I. \tag{17}$$

R_{eP}^{-L} is norm bounded if there is some $c > 0$ such that

$$\| \mathsf{R}_e{}^{-L} w \|_T \leq c \, \| w \|_T \quad \forall T \in (-\infty, \infty), \ w \in \mathcal{W}. \tag{18}$$

R_{eP} is *right coprime* if there exists a causal operator R_{eP}^{-L} which is a left inverse of R_{eP} and norm bounded.

3.2. Left representations. We next generalize the idea that $P = \tilde{M}^{-1}\tilde{N}$ has a normalized left coprime factorization, with

$$L = [-\tilde{N}, \ \tilde{M}]$$

defining a kernel representation of P:

$$\{w \in \mathcal{W} \mid Lw = 0\} = \mathcal{G}_P,$$

satisfying co-inner and coprime properties.

1. A causal operator

$$\mathsf{L}_{tvP} \ : \ \mathcal{W} \cap L_{2,e} \to \mathcal{Y} \cap L_{2,e}$$

is called a *finite horizon left representation* of P provided its kernel is the graph

$$\ker \mathsf{L}_{tvP} = \mathcal{G}_P \cap L_{2,e}. \tag{19}$$

(a) L_{tvP} is *contractive* if

$$\| \mathsf{L}_{tvP} w \|_T \leq \| w \|_T \quad \forall \ T \geq 0, w \in \mathcal{W} \cap L_{2,e}. \tag{20}$$

(b) L_{tvP} is *positive time co-inner* (or *normalized*) if

$$\| \mathsf{L}_{tvP} w \|_T = \inf \{ \| w - \tilde{w} \|_T \ | \ \tilde{w} \in \mathcal{G}_P \cap L_2[0,T] \} \tag{21}$$

for all $w \in \mathcal{W} \cap L_2[0,T]$, $T \geq 0$, and

$$\| \mathsf{L}_{tvP} w \|_2 = \inf \{ \| w - \tilde{w} \|_2 \ | \ \tilde{w} \in \mathcal{G}_P \cap L_2[0,\infty) \} \tag{22}$$

for all $w \in \mathcal{W} \cap L_2[0,\infty)$.

(c) A causal operator

$$\mathsf{L}_{tvP}^{-R} \ : \ \mathcal{Y} \cap L_{2,e} \to \mathcal{W} \cap L_{2,e}$$

is called a *right inverse* of L_{tvP} if

$$\mathsf{L}_{tvP} \mathsf{L}_{tvP}^{-R} = I. \tag{23}$$

L_{tvP}^{-R} is norm bounded if there is some $c > 0$ such that

$$\| \mathsf{L}_{tvP}^{-R} \phi \|_T \leq c \, \| \phi \|_T \quad \forall \phi \in \mathcal{Y} \cap L_{2,e}. \tag{24}$$

L_{tvP} is *finite time left coprime* if there exists a causal operator L_{tvP}^{-R} which is a right inverse of R_{tvP} and norm bounded.

2. A causal operator

$$\mathsf{L}_{eP} \ : \ \mathcal{W} \to \mathcal{Y}$$

is called a *left representation* of P provided its kernel is the graph

$$\ker \mathsf{L}_{eP} = \mathcal{G}_P. \tag{25}$$

(a) L_{eP} is *contractive* if

$$\| \mathsf{L}_{eP} w \|_T \leq \| w \|_T \quad \forall \ T \in (-\infty, \infty), w \in \mathcal{W}. \tag{26}$$

(b) L_{eP} is *co-inner* if

$$\| \mathsf{L}_{eP} w \|_T = \inf \{ \| w - \tilde{w} \|_T \ | \ \tilde{w} \in \mathcal{G}_P \} \ \forall T \in (-\infty, \infty), \tag{27}$$

for all $w \in \mathcal{W}$, $T \in (-\infty, \infty)$, and

$$\| \mathsf{L}_{eP} w \|_2 = \inf \{ \| w - \tilde{w} \|_2 \ | \ \tilde{w} \in \mathcal{G}_P \cap L_2 \} \tag{28}$$

for all $w \in L_2$.

(c) A causal operator

$$\mathsf{L}_{eP}^{-R}\colon \mathcal{Y} \to \mathcal{W}$$

is called a *right inverse* of L_{eP} if

$$\mathsf{L}_{eP}\mathsf{L}_{eP}^{-R} = I. \tag{29}$$

L_{eP}^{-R} is norm bounded if there is some $c > 0$ such that

$$\| \mathsf{L}_{eP}^{-R}\phi \|_T \leq c \| \phi \|_T \quad \forall\, T \in (-\infty, \infty), \phi \in \mathcal{Y}. \tag{30}$$

L_{eP} is *left coprime* if there exists a causal operator L_{eP}^{-R} which is a right inverse of L_{eP} and norm bounded.

Remark 3.1.

1. The definition proposed for the coinner property in 2b above agrees with the usual definition for linear, time-invariant (LTI) systems. In this case, L_{eP} can be interpreted as a normalized Kalman filter for P, with $\| \mathsf{L}_{eP} w \|_T$ the residual.
2. It is interesting to note that range and kernel representations do not behave in a completely analogous way with regard to the concept of coprimeness. If P is a finite-dimensional LTI system and G is *any* LTI system whose range is the graph, then G will be left invertible over H_∞, which is equivalent to coprimeness. The same is not true for kernel representations $\tilde{G}$, which may be freely multiplied by noninvertible factors on the left without changing the kernel. This situation does not change when the properties of inner/co-inner are added.
3. Representations satisfying the above properties can be constructed for input-affine systems subject to appropriate regularity assumptions. This is done in section 6.

4. Gap metrics and robust stability. The gap metric was introduced into the control literature by Zames and El-Sakkary [32], where it was defined as the norm of the difference of two orthogonal projection operators in Hilbert space. The result of Georgiou [9] that the gap metric was exactly equal to the solution of a certain H_∞ optimization problem opened up direct connections between uncertainty in gap metric and coprime fraction uncertainty and indeed proved the following formula for the (linear, directed) gap metric:

$$\vec{\rho}_{H_2}(P, P_1) = \inf_{\Delta_N, \Delta_M \in H_\infty} \left\{ \begin{bmatrix} \Delta_M \\ \Delta_N \end{bmatrix} \mid P_1 = (N + \Delta_N)(M + \Delta_M)^{-1} \right\},$$

where $P = NM^{-1}$ is a normalized right coprime factorization of the plant transfer-function. The basic gap metric robustness theorem can be expressed as follows [10]: if K stabilizes the nominal plant P, then it stabilizes all P_1 with $\vec{\rho}_{H_2}(P, P_1) < \gamma$ if and only if $\gamma \leq \| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty^{-1}$.

A smaller distance function can be defined by

$$\vec{\rho}_{L_2}(P, P_1) = \inf_{\Delta_N, \Delta_M \in L_\infty} \left\{ \begin{bmatrix} \Delta_M \\ \Delta_N \end{bmatrix} \mid P_1 = (N + \Delta_N)(M + \Delta_M)^{-1} \right\}$$

but proximity here does not guarantee robust stability by itself. However, if P and P_1 can both be approximated arbitrarily closely in the gap metric by finite-dimensional systems and $\vec{\rho}_{L_2}(P, P_1) < \| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty^{-1}$, then K stabilizes P_1 if and only

if $\operatorname{wno}\det(N_1^*N + M_1^*M) = 0$, where $P = NM^{-1}$ and $P_1 = N_1M_1^{-1}$ are any continuous right coprime factorizations (here, "wno" refers to the winding number). The ν-gap metric is obtained by setting it equal to $\vec{\rho}_{L_2}$ when this winding number test is satisfied and 1 otherwise, and is consequently less conservative than the gap metric [29].

For nonlinear systems $\vec{\rho}_{H_2}$ can be perfectly well defined (see below) but does not appear to give any robust stability guarantees. We shall consider two alternatives which do. The winding number test in the ν-gap definition can be viewed as implicitly checking for the existence of a homotopy linking P and P_1. In the nonlinear case this check appears in this form in Theorem 4.6.

4.1. Definitions and basic properties. There are a number of definitions for gap metrics in the literature. We now give the definitions of some of these together with some new ones.

We write $\mathcal{G}_0 = \mathcal{G}_{P_0}$, $\mathcal{G}_1 = \mathcal{G}_{P_1}$, for two plants P_0 and P_1. Define the δ-type "gap metrics"as follows:

(31)

$$\vec{\delta}_0(P_0,P_1) = \limsup_{T\to\infty} \sup_{x_1\in\mathcal{G}_1\cap L_{2,e}[0,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_{2,e}[0,\infty),x_0\neq 0} \frac{\| x_1 - x_0 \|_T}{\| x_0 \|_T},$$

$$\vec{\delta}_g(P_0,P_1) = \limsup_{T\to\infty} \sup_{x_1\in\mathcal{G}_1\cap L_{2,ce}(-\infty,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_{2,ce}(-\infty,\infty),x_0\neq 0} \frac{\| x_1 - x_0 \|_T}{\| x_0 \|_T},$$

$$\vec{\delta}_{H_2}(P_0,P_1) = \sup_{x_1\in\mathcal{G}_1\cap L_2[0,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_2[0,\infty),x_0\neq 0} \frac{\| x_1 - x_0 \|_2}{\| x_0 \|_2},$$

$$\vec{\delta}_{L_2}(P_0,P_1) = \sup_{x_1\in\mathcal{G}_1\cap L_2(-\infty,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_2(-\infty,\infty),x_0\neq 0} \frac{\| x_1 - x_0 \|_2}{\| x_0 \|_2},$$

and also define the ρ-gaps

(32)

$$\vec{\rho}_0(P_0,P_1) = \limsup_{T\to\infty} \sup_{x_1\in\mathcal{G}_1\cap L_{2,e}[0,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_{2,e}[0,\infty)} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T},$$

$$\vec{\rho}_g(P_0,P_1) = \limsup_{T\to\infty} \sup_{x_1\in\mathcal{G}_1\cap L_{2,ce}(-\infty,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_{2,ce}(-\infty,\infty)} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T},$$

$$\vec{\rho}_{H_2}(P_0,P_1) = \sup_{x_1\in\mathcal{G}_1\cap L_2[0,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_2[0,\infty)} \frac{\| x_1 - x_0 \|_2}{\| x_1 \|_2},$$

$$\vec{\rho}_{L_2}(P_0,P_1) = \sup_{x_1\in\mathcal{G}_1\cap L_2(-\infty,\infty),x_1\neq 0} \inf_{x_0\in\mathcal{G}_0\cap L_2(-\infty,\infty)} \frac{\| x_1 - x_0 \|_2}{\| x_1 \|_2}.$$

The definition of $\vec{\delta}_0$ is from [11] and those of $\vec{\delta}_g$ and $\vec{\delta}_{L_2}$ are taken from [30]. As pointed out in [30], for time-invariant systems, $\vec{\delta}_g(P_0,P_1) \le \vec{\delta}_0(P_0,P_1)$, since the extra freedom x_1 has in being shifted to the left is more than offset by a similar freedom in x_0. For the same reason $\vec{\delta}_{L_2}(P_0,P_1) \le \vec{\delta}_{H_2}(P_0,P_1)$, and the corresponding inequalities for the ρ-gaps, hold for time-invariant systems. For linear systems $\vec{\rho}_{H_2}(P_0,P_1)$ is the

usual directed gap over Hilbert spaces and is also equal to $\vec{\delta}_{H_2}(P_0, P_1)$ [11, proof of Proposition 5]. The same argument shows that each respective pair of δ and ρ gap metrics coincides. However, for nonlinear systems they need not be the same, though they are related as follows.

LEMMA 4.1. *Let $\gamma > 1$, and set $\beta = \sqrt{1-\gamma^{-2}}$. For each of the four cases $\vec{\delta} \in \{\vec{\delta}_0, \vec{\delta}_g, \vec{\delta}_{L_2}, \vec{\delta}_{H_2}\}$, with respective $\vec{\rho} \in \{\vec{\rho}_0, \vec{\rho}_g, \vec{\rho}_{L_2}, \vec{\rho}_{H_2}\}$, we have*

$$\vec{\delta}(P_0, P_1) < \gamma^{-1} \quad \textit{iff} \quad \vec{\rho}(P_0, \beta^{-2} P_1 \beta^2) < \gamma^{-1} \quad \textit{iff} \quad \vec{\rho}(\beta^2 P_0 \beta^{-2}, P_1) < \gamma^{-1}. \tag{33}$$

Similarly,

$$\vec{\rho}(P_0, P_1) < \gamma^{-1} \quad \textit{iff} \quad \vec{\delta}(P_0, \beta^2 P_1 \beta^{-2}) < \gamma^{-1} \quad \textit{iff} \quad \vec{\delta}(\beta^{-2} P_0 \beta^2, P_1) < \gamma^{-1}. \tag{34}$$

Proof. We give the proof for the case $\vec{\delta} = \vec{\delta}_{L_2}$ and $\vec{\rho} = \vec{\rho}_{L_2}$. Suppose

$$\vec{\delta}(P_0, P_1) < \gamma^{-1}.$$

Then for any $0 \neq x_1 \in \mathcal{G}_1 \cap L_2(-\infty, \infty)$ there exists $0 \neq x_0 \in \mathcal{G}_0 \cap L_2(-\infty, \infty)$ such that

$$\| x_1 - x_0 \|_2^2 < \gamma^{-2} \| x_0 \|_2^2 . \tag{35}$$

However, by expanding and completion of squares, this holds if and only if for any $0 \neq x_1 \in \mathcal{G}_1 \cap L_2(-\infty, \infty)$ there exists $0 \neq x_0 \in \mathcal{G}_0 \cap L_2(-\infty, \infty)$ such that

$$\| \beta^{-2} x_1 - x_0 \|_2^2 < \gamma^{-2} \| \beta^{-2} x_1 \|_2^2,$$

where $\beta = \sqrt{1-\gamma^{-2}}$. Since $\gamma > 1$, the condition that $x_0 \neq 0$ is redundant. Now $x_1 \in \mathcal{G}_1 \cap L_2(-\infty, \infty)$ iff $\beta^{-2} x_1 \in \tilde{\mathcal{G}}_1 \cap L_2(-\infty, \infty)$, where $\tilde{\mathcal{G}}_1 = \mathcal{G}_{\tilde{P}_1}$ and $\tilde{P}_1 = \beta^{-2} P_1 \beta^2$. Therefore, the last displayed equation holds if and only if for any $0 \neq \tilde{x}_1 \in \tilde{\mathcal{G}}_1 \cap L_2(-\infty, \infty)$, there exists $x_0 \in \mathcal{G}_0 \cap L_2(-\infty, \infty)$ such that

$$\| \tilde{x}_1 - x_0 \|_2^2 < \gamma^{-2} \| \tilde{x}_1 \|_2^2,$$

that is, if and only if

$$\vec{\rho}(P_0, \beta^{-2} P_1 \beta^2) < \gamma^{-1}.$$

Also, (35) holds if and only if for any $0 \neq x_1 \in \mathcal{G}_1 \cap L_2(-\infty, \infty)$, there exists $x_0 \in \mathcal{G}_0 \cap L_2(-\infty, \infty)$ such that

$$\| x_1 - \beta^2 x_0 \|_2^2 < \gamma^{-2} \| x_1 \|_2^2 .$$

Since $\gamma > 1$, then $x_0 \neq 0$. Thus the above equation holds if and only if for any $x_1 \in \mathcal{G}_1$ there exists $\tilde{x}_0 \in \tilde{\mathcal{G}}_0$ such that

$$\| x_1 - \tilde{x}_0 \|_2^2 < \gamma^{-2} \| x_1 \|_2^2,$$

where $\tilde{P}_0 = \beta^2 P_0 \beta^{-2}$. That is, (35) holds if and only if

$$\vec{\rho}(\beta^2 P_0 \beta^{-2}, P_1) < \gamma^{-1}. \qquad \square$$

We have the following result giving a class of systems for which the δ and ρ gaps are the same.

COROLLARY 4.2. *If P_0 and/or P_1 is homogeneous, then for each of the four cases $\vec{\delta} \in \{\vec{\delta}_0, \vec{\delta}_g, \vec{\delta}_{L_2}, \vec{\delta}_{H_2}\}$, with respective $\vec{\rho} \in \{\vec{\rho}_0, \vec{\rho}_g, \vec{\rho}_{L_2}, \vec{\rho}_{H_2}\}$,*

$$\min\left\{\vec{\delta}(P_0, P_1), \vec{\rho}(P_0, P_1)\right\} < 1 \tag{36}$$

implies

$$\vec{\delta}(P_0, P_1) = \vec{\rho}(P_0, P_1). \tag{37}$$

For any $\vec{\delta} \in \{\vec{\delta}_0, \vec{\delta}_g, \vec{\delta}_{L_2}, \vec{\delta}_{H_2}\}$, we define the corresponding symmetric quantities via

$$\delta(P_0, P_1) = \max\left\{\vec{\delta}(P_0, P_1), \vec{\delta}(P_1, P_0)\right\},$$

and similarly for any $\vec{\rho} \in \{\vec{\rho}_0, \vec{\rho}_g, \vec{\rho}_{L_2}, \vec{\rho}_{H_2}\}$, we define

$$\rho(P_0, P_1) = \max\left\{\vec{\rho}(P_0, P_1), \vec{\rho}(P_1, P_0)\right\}.$$

4.2. Robust stability. The $\vec{\delta}$, $\vec{\delta}_0$, $\vec{\delta}_g$, $\vec{\delta}_{L_2}$, and ν-gap metrics introduced in [11], [30], and [29] provide a maximum stability margin expressed as the inverse of the induced norm of the parallel projection operator $\Pi_{\mathcal{M}_0\|\mathcal{N}}$; a result of this type is quoted as Theorem 4.3.

THEOREM 4.3 ([30, Proposition 2.2], [11, Theorem 3]). *Assume $H_{P_0,K}$ is stable. If*

$$\vec{\delta}_g(P_0, P_1) < \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty^{-1}, \tag{38}$$

where $\mathcal{M}_0 = \mathcal{G}_{P_0}$ and $\mathcal{N} = \mathcal{G}_K$, then $H_{P_1,K}$ is stable and

$$\| \Pi_{\mathcal{M}_1\|\mathcal{N}} \|_\infty \leq \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty \frac{1 + \vec{\delta}_g(P_0, P_1)}{1 - \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty \vec{\delta}_g(P_0, P_1)}, \tag{39}$$

where $\mathcal{M}_1 = \mathcal{G}_{P_1}$.

The ρ-type gap metrics introduced above also lead to a natural stability margin, but this time it is expressed in terms of the inverse of the induced norm of the parallel projection operator $\Pi_{\mathcal{N}\|\mathcal{M}_0}$, revealing an interesting duality. This will be further explored below in section 4.5 in connection with uncertainty in the graph representations.

THEOREM 4.4. *Assume $H_{P_0,K}$ is stable. If*

$$\vec{\rho}_g(P_0, P_1) < \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty^{-1}, \tag{40}$$

where $\mathcal{M}_0 = \mathcal{G}_{P_0}$ and $\mathcal{N} = \mathcal{G}_K$, then $H_{P_1,K}$ is stable and

$$\| \Pi_{\mathcal{N}\|\mathcal{M}_1} \|_\infty \leq \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty \frac{1 + \vec{\rho}_g(P_0, P_1)}{1 - \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty \vec{\rho}_g(P_0, P_1)}, \tag{41}$$

where $\mathcal{M}_1 = \mathcal{G}_{P_1}$.

Proof. The proof is a modification of the proof of [11, Theorem 3].

Suppose $\vec{\rho}_g(P_0, P_1) < \alpha$, $\| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty < \gamma$. Let $w \in \mathcal{W}$. Since $[P_1, K]$ is well-posed by assumption, there exists $m_1 \in \mathcal{M}_1$, $n \in \mathcal{N}$ such that $w = m_1 + n$, so $\Pi_{\mathcal{N}\|\mathcal{M}_1}(w) = n$. Our goal is to bound the norm of n in terms of the norm of w.

There exists $T_0 > 0$ such that for all $T \geq T_0$

$$\inf_{x_0 \in \mathcal{M}_0} \frac{\| m_1 - x_0 \|_T}{\| m_1 \|_T} \leq \sup_{x_1 \in \mathcal{M}_1} \inf_{x_0 \in \mathcal{M}_0} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T} < \alpha.$$

Hence there exists $m_0 \in \mathcal{M}_0$ (depending on T) such that

$$\| m_1 - m_0 \|_T \leq \alpha \| m_1 \|_T .$$

Now $\Pi_{\mathcal{N}\|\mathcal{M}_0}(m_0 + n) = n$, and

$$\| n \|_T \leq \gamma \| m_0 + n \|_T .$$

Then

$$\begin{aligned} \| m_1 + n \|_T &\geq \| m_0 + n \|_T - \| m_1 - m_0 \|_T \\ &\geq \gamma^{-1} \| n \|_T - \alpha \| m_1 \|_T, \end{aligned}$$

and so

$$\begin{aligned} \gamma^{-1} \| n \|_T &\leq \| m_1 + n \|_T + \alpha \| m_1 \|_T \\ &\leq (1 + \alpha) \| m_1 + n \|_T + \alpha \| n \|_T . \end{aligned}$$

Therefore,

$$(\gamma^{-1} - \alpha) \| n \|_T \leq (1 + \alpha) \| m_1 + n \|_T$$

for all $T \geq T_0$. This is enough to prove the theorem. □

Note that both Theorems 4.3 and 4.4 also hold for $\vec{\delta}_0$ and $\vec{\rho}_0$, respectively, though the above are the stronger forms since $\vec{\delta}_g(P_0, P_1) \leq \vec{\delta}_0(P_0, P_1)$ and $\vec{\rho}_g(P_0, P_1) \leq \vec{\rho}_0(P_0, P_1)$. Interestingly, we are not able to give a robust stability theorem for $\vec{\delta}_{H_2}$ or $\vec{\rho}_{H_2}$ in spite of the fact that each is equal to the original definition of the gap metric for linear systems.

The L_2 gaps are not by themselves sufficient to prove stability. However, if stability is known for a plant P_1 near a nominal P_0, then the norms of the parallel projections can be estimated. This was done in [30, Theorem 2.1] for the $\vec{\delta}_{L_2}$ gap and the $\Pi_{\mathcal{M}\|\mathcal{N}}$ projection. The corresponding result for the $\vec{\rho}_{L_2}$ gap and the $\Pi_{\mathcal{N}\|\mathcal{M}}$ projection is as follows.

THEOREM 4.5. *Assume $H_{P_0,K}$ is stable. If $H_{P_1,K}$ is stable and*

$$\vec{\rho}_{L_2}(P_0, P_1) < \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty^{-1}, \tag{42}$$

where $\mathcal{M}_0 = \mathcal{G}_{P_0}$ and $\mathcal{N} = \mathcal{G}_K$, then

$$\| \Pi_{\mathcal{N}\|\mathcal{M}_1} \|_\infty \leq \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty \frac{1 + \vec{\rho}_{L_2}(P_0, P_1)}{1 - \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty \vec{\rho}_{L_2}(P_0, P_1)}, \tag{43}$$

where $\mathcal{M}_1 = \mathcal{G}_{P_1}$.

Proof. Suppose $\vec{\rho}_{L_2}(P_0, P_1) < \alpha$, $\| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty < \gamma$. Let $w \in \mathcal{W} \cap L_2(-\infty, \infty)$. Since $[P_1, K]$ is stable by assumption, there exists $m_1 \in \mathcal{M}_1 \cap L_2(-\infty, \infty)$, $n \in \mathcal{N} \cap L_2(-\infty, \infty)$ such that $w = m_1 + n$, so $\Pi_{\mathcal{N}\|\mathcal{M}_1}(w) = n$.

Note that there exists $m_0 \in \mathcal{M}_0 \cap L_2(-\infty, \infty)$ such that

$$\| m_1 - m_0 \|_2 \leq \alpha \| m_1 \|_2 .$$

Now $\Pi_{\mathcal{N}\|\mathcal{M}_0}(m_0+n)=n$, and

$$\| n \|_2 \leq \gamma \| m_0+n \|_2 .$$

Then, in a similar way to the proof of Theorem 4.4, we obtain

$$(\gamma^{-1}-\alpha)\| n \|_2 \leq (1+\alpha)\| m_1+n \|_2$$

as required. □

THEOREM 4.6. *Assume $H_{P_0,K}$ is stable. If*

$$\vec{\rho}_{L_2}(P_0,P_1) < \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty^{-1}, \tag{44}$$

where $\mathcal{M}_0=\mathcal{G}_{P_0}$ and $\mathcal{N}=\mathcal{G}_K$, then $H_{P_1,K}$ is stable if there exists a homotopy of plants $\{P_\lambda \mid 0<\lambda<1\}$ such that

1. *the mapping $\lambda \mapsto P_\lambda$ is ρ_g-continuous for $0\leq\lambda\leq 1$, and*
2. $$\vec{\rho}_{L_2}(P_0,P_\lambda) < \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty^{-1} - \varepsilon \tag{45}$$

   for some $\varepsilon>0$ and all $0\leq\lambda\leq 1$.

Proof. Assume $[P_{\lambda_0},K]$ is stable for some $\lambda_0\in[0,1]$. Then it must also be the case that $\| \Pi_{\mathcal{N}\|\mathcal{M}_{\lambda_0}} \|_\infty^{-1} > \epsilon' = \epsilon/(1+ \| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty^{-1} -\epsilon)$. By continuity there will exist a neighborhood $\mathcal{S}$ of λ_0, such that $\vec{\delta}_g(P_{\lambda_0},P_\lambda)<\epsilon'$ for all $\lambda\in\mathcal{S}$. It follows that $[P_\lambda,K]$ is stable for all $\lambda\in\mathcal{S}$ and hence that the set of $\lambda\in[0,1]$ for which $[P_\lambda,K]$ is stable is open. Conversely, let $\{\lambda_i\}\to\lambda$ and assume that $[P_{\lambda_i},K]$ is stable for all i. Then there must exist an i such that $\vec{\delta}_g(P_{\lambda_i},P_\lambda)<\epsilon'$, from which it follows that $[P_\lambda,K]$ is stable and hence that the set of $\lambda\in[0,1]$ for which $[P_\lambda,K]$ is stable is both open and closed, and since it includes the point $\lambda=0$ it must also include the whole interval $[0,1]$. □

4.3. Conjugate norm equivalence. For linear systems it is known that $\| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty = \| \Pi_{\mathcal{N}\|\mathcal{M}} \|_\infty$, and the inverse of this quantity is the stability margin for uncertainty in the gap metric [10]. This equality has several implications and interpretations. It means that the radius of gap metric uncertainty tolerated by the feedback system is the same for the plant and the controller. It also means that the radius of coprime factor balls of uncertainty tolerated by the feedback system is the same for both left and right coprime factors.

In the general nonlinear case it is known that $\| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty \neq \| \Pi_{\mathcal{N}\|\mathcal{M}} \|_\infty$ (see [7] for an example where both $\mathcal{M}$ and $\mathcal{N}$ are piecewise linear static functions). In this section we demonstrate a connection between these quantities under a certain scaling. This type of conjugacy transformation has also appeared in Lemma 4.1 in relating two different types of gap metrics. In this way, a new type of duality between the two complementary parallel projections is uncovered which is perhaps a more fundamental property.

For $\gamma>1$ let

$$\beta=\sqrt{1-\gamma^{-2}}<1. \tag{46}$$

We say that controllers K_1, K_2 are *β-conjugate* if

$$K_1=\beta^2 K_2 \beta^{-2}. \tag{47}$$

THEOREM 4.7. *Any plant P enjoys* conjugate norm equivalence,

$$\| \Pi_{\mathcal{M}\|\mathcal{N}_1} \|_\infty < \gamma \quad \textit{iff} \quad \| \Pi_{\mathcal{N}_2\|\mathcal{M}} \|_\infty < \gamma, \tag{48}$$

whenever K_1, K_2 are β-conjugate, where $\mathcal{M} = \mathcal{G}_P$, $\mathcal{N}_i = \mathcal{G}_{K_i}$ $(i = 1, 2)$.

Proof. We shall first show that, if K_2 satisfies $\| \Pi_{\mathcal{N}_2\|\mathcal{M}} \|_\infty < \gamma$ and K_1 is defined by (47), then $\| \Pi_{\mathcal{M}\|\mathcal{N}_1} \|_\infty < \gamma$. Then we shall show the converse.

Let $w \in \mathcal{W}$. Since $[P, K_1]$ is well-posed, there exists $m \in \mathcal{M}$, $n_1 \in \mathcal{N}_1$ such that $w = m + n_1$, so $\Pi_{\mathcal{M}\|\mathcal{N}_1}(w) = m$. Let $n_2 = \beta^{-2} n_1$ and note that $n_2 \in \mathcal{N}_2$. Now, $\| \Pi_{\mathcal{N}_2\|\mathcal{M}} \|_\infty < \gamma$ implies that $\|\beta^{-2} n_1 + m\|_T \geq \gamma^{-1} \|\beta^{-2} n_1\|_T$ for all T. However, squaring both sides, expanding, and completing the squares shows that this holds if and only if $\|n_1 + m\|_T \geq \gamma^{-1} \|m\|_T$ for all T as required.

Conversely, write $w = m + n_2$, so $\Pi_{\mathcal{N}_2\|\mathcal{M}}(w) = n_2$, and put $n_1 = \beta^2 n_2 \in \mathcal{N}_1$. $\| \Pi_{\mathcal{M}\|\mathcal{N}_1} \|_\infty < \gamma$ implies that $\|n_1 + m\|_T \geq \gamma^{-1} \|m\|_T$ for all T which is equivalent to $\|n_2 + m\|_T \geq \gamma^{-1} \|n_2\|_T$ as above. ∎

COROLLARY 4.8. *We have*

$$\inf_{K_1} \| \Pi_{\mathcal{M}\|\mathcal{N}_1} \|_\infty = \inf_{K_2} \| \Pi_{\mathcal{N}_2\|\mathcal{M}} \|_\infty . \tag{49}$$

Proof. Given any K_2 we can define K_1 beta-conjugate to K_2 as in (47) to achieve the same norm for the complementary parallel projection, and similarly with the roles of K_1 and K_2 interchanged. Hence the infimums must be equal. ∎

An operator P is *(positively, multiplicatively) homogeneous* if

$$\alpha P = P \alpha \tag{50}$$

for all real $\alpha > 0$. Linear systems, of course, enjoy this property.

COROLLARY 4.9. *If P and/or K is homogeneous, then*

$$\| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty = \| \Pi_{\mathcal{N}\|\mathcal{M}} \|_\infty . \tag{51}$$

Proof. Suppose $[P, K]$ is stable, $\| \Pi_{\mathcal{N}\|\mathcal{M}} \|_\infty < \gamma$, and K is homogeneous. Write $K_2 = K$, so $\mathcal{N}_2 = \mathcal{N}$, and put $K_1 = \beta^2 K_2 \beta^{-2}$, which gives $K_1 = K$ and $\mathcal{N}_1 = \mathcal{N}$, since K is homogeneous. It follows, from Theorem 4.7, that $\| \Pi_{\mathcal{M}\|\mathcal{N}} \|_\infty < \gamma$. The reverse may be established similarly, writing $K_1 = K$ and letting $K_2 = \beta^{-2} K_1 \beta^2 = K$. This establishes (51).

The same result will hold if P is homogeneous, since (51) is symmetric in $\mathcal{M}$ and $\mathcal{N}$. ∎

4.4. Evaluation. The following theorem shows how the ρ-gaps can be evaluated in terms of the right and left symbols from the plant representations.

THEOREM 4.10.

1. *Assume L_{tv0} is a positive time co-inner left representation for P_0 and $\mathsf{R}_{T,1}$ is a finite time inner right representation for P_1; then*

$$\vec{\rho}_0(P_0, P_1) = \limsup_{T \to \infty} \| \mathsf{L}_{tv0} \mathsf{R}_{T,1} \|_{[0,T],\infty} . \tag{52}$$

2. *Assume L_{e0} is a co-inner left representation for P_0 and $\mathsf{R}_{T,1}$ is a finite time inner right representation for P_1; then*

$$\vec{\rho}_g(P_0, P_1) = \limsup_{T \to \infty} \| \mathsf{L}_{e0} \mathsf{R}_{T,1} \|_{(-\infty,T],\infty} . \tag{53}$$

3. *Assume* L_{tv0} *is a positive time co-inner left representation for* P_0 *and* R_{e1} *is an inner right representation for* P_1*; then*

$$\vec{\rho}_{H_2}(P_0, P_1) = \| \mathsf{L}_{tv0}\mathsf{R}_{e1} \|_\infty . \tag{54}$$

4. *Assume* L_{e0} *is a co-inner left representation for* P_0 *and* R_{e1} *is an inner right representation for* P_1*; then*

$$\vec{\rho}_{L_2}(P_0, P_1) = \| \mathsf{L}_{e0}\mathsf{R}_{e1} \|_\infty . \tag{55}$$

Proof. 1. $\vec{\rho}_0(P_0, P_1)$. Let $T \geq 0$ and let $0 \neq x_1 \in \mathcal{G}_1 \cap L_2[0, T]$. Then by the positive time co-inner property (21)

$$\inf_{x_0 \in \mathcal{G}_0 \cap L_{2,e}} \| x_1 - x_0 \|_T = \| \mathsf{L}_{tv0} x_1 \|_T .$$

Now $x_1|_{[0,T]} = \mathsf{R}_{T,1}\psi$ for some $\psi \in L_2[0, T]$ by the onto property (9), and so the finite time inner property (11) implies

$$\| x_1 \|_T = \| \mathsf{R}_{T,1}\psi \|_T = \| \psi \|_T .$$

Then

$$\inf_{x_0 \in \mathcal{G}_0 \cap L_{2,e}} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T} = \frac{\| \mathsf{L}_{tv0}\mathsf{R}_{T,1}\psi \|_T}{\| \psi \|_T},$$

and so

$$\sup_{\substack{x_1 \in \mathcal{G}_1 \cap L_{2,e} \\ \|x_1\|_T \neq 0}} \inf_{x_0 \in \mathcal{G}_0 \cap L_{2,e}} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T} = \sup_{\substack{\psi \in L_{2,e} \\ \|\psi\|_T \neq 0}} \frac{\| \mathsf{L}_{tv0}\mathsf{R}_{T,1}\psi \|_T}{\| \psi \|_T} = \| \mathsf{L}_{tv0}\mathsf{R}_{T,1} \|_{[0,T],\infty} .$$

Taking the lim sup as $T \to \infty$ we obtain the formula (52) for $\vec{\rho}_0(P_0, P_1)$.

2. $\vec{\rho}_g(P_0, P_1)$. Let $T \in (-\infty, \infty)$ and let $x_1 \in \mathcal{G}_1$, $\|x_1\|_T \neq 0$. Then by the co-inner property (27),

$$\| \mathsf{L}_{eP} x_1 \|_T = \inf_{x_0 \in \mathcal{G}_0} \| x_1 - x_0 \|_T .$$

By the finite time inner property (11),

$$\| x_1 \|_T = \| \mathsf{R}_{T,1}\psi \|_T = \| \psi \|_T$$

for some $\psi \in \mathcal{U} \cap L_2(-\infty, T]$ (by (9), $T_0 = -\infty$). Then

$$\sup_{\substack{x_1 \in \mathcal{G}_1 \\ \|x_1\|_T \neq 0}} \inf_{x_0 \in \mathcal{G}_0} \frac{\| x_1 - x_0 \|_T}{\| x_1 \|_T} = \sup_{\substack{\psi \in \mathcal{U} \\ \|\psi\|_T \neq 0}} \frac{\| \mathsf{L}_{e0}\mathsf{R}_{T,1}\psi \|_T}{\| \psi \|_T} = \| \mathsf{L}_{e0}\mathsf{R}_{T,1} \|_{(-\infty,T],\infty} .$$

Taking the lim sup as $T \to \infty$ we obtain the formula (53) for $\vec{\rho}_g(P_0, P_1)$.

3. $\vec{\rho}_{H_2}(P_0, P_1)$. Let $0 \neq x_1 \in \mathcal{G}_1 \cap L_2[0, \infty)$. Then by the positive time co-inner property (22),

$$\inf_{x_0 \in \mathcal{G}_0 \cap L_2[0,\infty)} \| x_1 - x_0 \|_2 = \| \mathsf{L}_{tv0} x_1 \|_2 .$$

Now by the inner property (16)

$$\| x_1 \|_2 = \| \mathsf{R}_{e1}\psi \|_2 = \| \psi \|_2$$

for some $\psi \in \mathcal{U} \cap L_2[0,\infty)$, by (14). Then

$$\sup_{\substack{x_1 \in \mathcal{G}_1 \cap L_2[0,\infty) \\ x_1 \neq 0}} \inf_{x_0 \in \mathcal{G}_0 \cap L_2[0,\infty)} \frac{\| x_1 - x_0 \|_2}{\| x_1 \|_2} = \sup_{\substack{\psi \in L_2[0,\infty) \\ \psi \neq 0}} \frac{\| \mathsf{L}_{tv0}\mathsf{R}_{e1}\psi \|_2}{\| \psi \|_2} = \| \mathsf{L}_{tv0}\mathsf{R}_{e1} \|_\infty .$$

This gives the formula (54) for $\vec{\rho}_{H_2}(P_0, P_1)$.

4. $\vec{\rho}_{L_2}(P_0, P_1)$. Let $0 \neq x_1 \in \mathcal{G}_1 \cap L_2$. Then by the co-inner property (28)

$$\inf_{x_0 \in \mathcal{G}_0 \cap L_2} \| x_1 - x_0 \|_2 = \| \mathsf{L}_{e0}x_1 \|_2 .$$

Now by the inner property (16)

$$\| x_1 \|_2 = \| \mathsf{R}_{e1}\psi \|_2 = \| \psi \|_2$$

for some $\psi \in \mathcal{U} \cap L_2$, by (14). Then

$$\sup_{\substack{x_1 \in \mathcal{G}_1 \cap L_2 \\ x_1 \neq 0}} \inf_{x_0 \in \mathcal{G}_0 \cap L_2} \frac{\| x_1 - x_0 \|_2}{\| x_1 \|_2} = \sup_{\substack{\psi \in L_2 \\ \psi \neq 0}} \frac{\| \mathsf{L}_{e0}\mathsf{R}_{e1}\psi \|_2}{\| \psi \|_2} = \| \mathsf{L}_{e0}\mathsf{R}_{e1} \|_\infty .$$

This gives the formula (55) for $\vec{\rho}_{L_2}(P_0, P_1)$. □

4.5. Robust stability and representation uncertainty. The subject of coprime fraction uncertainty, and robustness for nonlinear systems has previously been considered in [1] and [25] and some partial results obtained. In this section we give two dual results relating uncertainty in the graph representations to gap balls of uncertainty for the new definitions given in this paper.

LEMMA 4.11.

1. *Let L_{e0} be a co-inner left representation of P_0, and let L_{e1} be a left representation of P_1 (not necessarily coinner); then*

$$\vec{\rho}_{L_2}(P_0, P_1) \leq \| \mathsf{L}_{e0} - \mathsf{L}_{e1} \|_\infty . \tag{56}$$

2. *Let R_{e0} be an inner right representation of P_0, and let R_{e1} be a right representation of P_1 (not necessarily inner) satisfying $\mathsf{R}_{e0}0 = 0$; then*

$$\vec{\delta}_{L_2}(P_0, P_1) \leq \| \mathsf{R}_{e0} - \mathsf{R}_{e1} \|_\infty . \tag{57}$$

Proof. Let $x_1 \in \mathcal{G}_1 \cap L_2(-\infty,\infty), x_1 \neq 0$. Then $\mathsf{L}_{e1}x_1 = 0$, and so

$$\mathsf{L}_{e0}x_1 + (\mathsf{L}_{e1} - \mathsf{L}_{e0})x_1 = 0.$$

Since L_{e0} is coinner, by (28) we have

$$\begin{aligned} \inf_{x_0 \in \mathcal{G}_0 \cap L_2(-\infty,\infty)} \| x_1 - x_0 \|_2 &= \| \mathsf{L}_{e0}x_1 \|_2 \\ &= \| (\mathsf{L}_{e1} - \mathsf{L}_{e0})x_1 \|_2 . \end{aligned}$$

Therefore,

$$\begin{aligned}\vec{\rho}_{L_2}(P_0,P_1) &= \sup_{x_1\in\mathcal{G}_1\cap L_2(-\infty,\infty),x_1\neq 0}\frac{\|\ (\mathsf{L}_{e1}-\mathsf{L}_{e0})x_1\ \|_2}{\|\ x_1\ \|_2}\\ &\leq \sup_{x_1\in L_2(-\infty,\infty),x_1\neq 0}\frac{\|\ (\mathsf{L}_{e1}-\mathsf{L}_{e0})x_1\ \|_2}{\|\ x_1\ \|_2}\\ &=\|\ \mathsf{L}_{e0}-\mathsf{L}_{e1}\ \|_\infty,\end{aligned}$$

establishing (56).

Again let $x_1 \in \mathcal{G}_1 \cap L_2(-\infty,\infty), x_1 \neq 0$. Then by (14) there exists $\psi_1 \in \mathcal{U}\cap L_2(-\infty,\infty)$, $\psi_1 \neq 0$, such that $x_1 = \mathsf{R}_{e1}\psi_1$ and $\psi_1 \neq 0$ since $\mathsf{L}_{e0}0 = 0$. Since R_{e0} is inner, by (16) we have

$$\|\ x_0\ \|_2=\|\ \psi_1\ \|_2,$$

where $x_0 = \mathsf{R}_{e0}\psi_1 \neq 0$, and also we have

$$\|\ x_1 - x_0\ \|_2=\|\ (\mathsf{R}_{e1}-\mathsf{R}_{e0})\psi_1\ \|_2\ .$$

Hence

$$\begin{aligned}\frac{\|\ x_1-x_0\ \|_2}{\|\ x_0\ \|_2} &= \frac{\|\ (\mathsf{R}_{e1}-\mathsf{R}_{e0})\psi_1\ \|_2}{\|\ \psi_1\ \|_2}\\ &\leq\|\ \mathsf{R}_{e0}-\mathsf{R}_{e1}\ \|_\infty,\end{aligned}$$

from which (57) follows. □

THEOREM 4.12. *Assume $H_{P_0,K}$ is stable. Let L_{e0} be a co-inner left representation of P_0, and let L_{e1} be a left representation of P_1 (not necessarily co-inner). If*

$$\|\ \mathsf{L}_{e0}-\mathsf{L}_{e1}\ \|_\infty<\|\ \Pi_{\mathcal{N}\|\mathcal{M}_0}\ \|_\infty^{-1}, \tag{58}$$

where $\mathcal{M}_0 = \mathcal{G}_{P_0}$ and $\mathcal{N} = \mathcal{G}_K$, then $H_{P_1,K}$ is stable,

$$\vec{\rho}_{L_2}(P_0,P_1) <\|\ \Pi_{\mathcal{N}\|\mathcal{M}_0}\ \|_\infty^{-1}, \tag{59}$$

and the norm bound (43) *of Theorem* 4.5 *applies.*

Proof. Assume $\|\ \mathsf{L}_{e0}-\mathsf{L}_{e1}\ \|_\infty< \alpha$, $\|\ \Pi_{\mathcal{N}\|\mathcal{M}_0}\ \|_\infty< \gamma$, and $\alpha\gamma < 1$. As in the proof of Theorem 4.4, let $w \in \mathcal{W}$. Since $[P_1, K]$ is well-posed by assumption, there exists $m_1 \in \mathcal{M}_1$, $n \in \mathcal{N}$ such that $w = m_1 + n$, so $\Pi_{\mathcal{N}\|\mathcal{M}_1}(w) = n$.

There exists $T_0 > 0$ such that for all $T \geq T_0$

$$\sup_{x\in L_{2,ce}(-\infty,\infty),x\neq 0}\frac{\|\ (\mathsf{L}_{e0}-\mathsf{L}_{e1})x\ \|_T}{\|\ x\ \|_T} < \alpha.$$

Then

$$\frac{\|\ (\mathsf{L}_{e0}-\mathsf{L}_{e1})m_1\ \|_T}{\|\ m_1\ \|_T} < \alpha,$$

and hence

$$\frac{\|\ \mathsf{L}_{e0}m_1\ \|_T}{\|\ m_1\ \|_T} < \alpha,$$

because $\mathsf{L}_{e1}m_1 = 0$ implies $\mathsf{L}_{e0}m_1 = (\mathsf{L}_{e0} - \mathsf{L}_{e1})m_1$. Since L_{e0} is co-inner, by (27) there exists $m_0 \in \mathcal{G}_0$ (depending on T) such that

$$\frac{\| m_1 - m_0 \|_T}{\| m_1 \|_T} < \alpha.$$

Also, we have $\Pi_{\mathcal{N}\|\mathcal{M}_0}(m_0 + n) = n$, and following the proof of Theorem 4.4, we find that

$$(\gamma^{-1} - \alpha) \| n \|_T \leq (1 + \alpha) \| m_1 + n \|_T$$

for all $T \geq T_0$. This is enough to prove $\| \Pi_{\mathcal{N}\|\mathcal{M}_0} \|_\infty < \infty$. Note that once stability of $H_{P_1,K}$ has been established, the bound (43) follows from Theorem 4.5 and Lemma 4.11. □

The corresponding result for right representations is not perfectly dual to Theorem 4.12 in that a left inverse for the representation appears to be required. This is perhaps not completely unexpected in the light of Remark 3.1(2).

THEOREM 4.13. *Assume $H_{P_0,K}$ is stable. Let R_{e0} be an inner, contractive right representation of P_0, with causal left inverse R_{e0}^{-L}, and let R_{e1} be a right representation of P_1 (not necessarily inner). If*

$$\| \mathsf{R}_{e0} - \mathsf{R}_{e1} \|_\infty < \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty^{-1}, \tag{60}$$

where $\mathcal{M}_0 = \mathcal{G}_{P_0}$ and $\mathcal{N} = \mathcal{G}_K$, then $H_{P_1,K}$ is stable,

$$\vec{\delta}_{L_2}(P_0, P_1) < \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty^{-1}, \tag{61}$$

and by [30, Theorem 2.1] *the norm bound*

$$\| \Pi_{\mathcal{M}_1\|\mathcal{N}} \|_\infty \leq \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty \frac{1 + \vec{\delta}_{L_2}(P_0, P_1)}{1 - \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty \vec{\delta}_{L_2}(P_0, P_1)} \tag{62}$$

holds, where $\mathcal{M}_1 = \mathcal{G}_{P_1}$.

Proof. Assume $\| \mathsf{R}_{e0} - \mathsf{R}_{e1} \|_\infty < \alpha$, $\| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty < \gamma$, and $\alpha\gamma < 1$. As in the proof of [11, Theorem 3], let $w \in \mathcal{W}$. Since $[P_1, K]$ is well-posed by assumption, there exists $m_1 \in \mathcal{M}_1$, $n \in \mathcal{N}$ such that $w = m_1 + n$, so $\Pi_{\mathcal{M}_1\|\mathcal{N}}(w) = m_1$.

Define an operator $\tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}} : \mathcal{W} \to \mathcal{U}$ by

$$\tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}} = \mathsf{R}_{e0}^{-L} \Pi_{\mathcal{M}_0\|\mathcal{N}},$$

so that $\mathsf{R}_{e0}^{-L}\mathsf{R}_{e0}\tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}} = \mathsf{R}_{e0}^{-L}\Pi_{\mathcal{M}_0\|\mathcal{N}}$. We can check that $\mathsf{R}_{e0}^{-L}w_1 = \mathsf{R}_{e0}^{-L}w_2$, for $w_1, w_2 \in \mathcal{M}_0$ implies $w_1 = w_2$, which gives $\Pi_{\mathcal{M}_0\|\mathcal{N}} = \mathsf{R}_{e0}\tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}}$. Then, since R_{e0} is inner, (16) implies

$$\| \tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}} \|_\infty = \| \Pi_{\mathcal{M}_0\|\mathcal{N}} \|_\infty < \gamma.$$

Since R_{e1} is a right representation of P_1, by (14) there exists $\psi_1 \in \mathcal{U}$ such that $m_1 = \mathsf{R}_{e1}\psi_1$. Set $m_0 = \mathsf{R}_{e0}\psi_1$, and note that $m_0 = \Pi_{\mathcal{M}_0\|\mathcal{N}}(m_0 + n)$. Then $\psi_1 = \tilde{\Pi}_{\mathcal{M}_0\|\mathcal{N}}(m_0 + n)$, and for sufficiently large T

$$\begin{aligned} \| \psi_1 \|_T &\leq \gamma \| m_0 + n \|_T \\ &\leq \gamma \| m_1 + n \|_T + \gamma \| m_0 - m_1 \|_T \\ &= \gamma \| m_1 + n \|_T + \gamma \| (\mathsf{R}_{e0} - \mathsf{R}_{e1})\psi_1 \|_T \\ &\leq \gamma \| m_1 + n \|_T + \gamma\alpha \| \psi_1 \|_T \end{aligned}$$

so that

$$\| \psi_1 \|_T \leq \frac{\gamma}{1-\alpha\gamma} \| w \|_T .$$

Next, since R_{e0} is contractive (see (15)) and from above we have

$$\begin{aligned} \| m_1 \|_T &\leq \| m_0 \|_T + \| m_1 - m_0 \|_T \\ &\leq \| \psi_1 \|_T + \alpha \| \psi_1 \|_T \\ &\leq \tfrac{\gamma(1+\alpha)}{1-\alpha\gamma} \| w \|_T, \end{aligned}$$

and the theorem follows. □

Other relationships among the ρ-gaps and representation uncertainties are as follows (L_{e0} and L_{tv} are co-inner):

$$\begin{aligned} \vec{\rho}_0(P_0, P_1) &\leq \| \mathsf{L}_{tv0} - \mathsf{L}_{tv1} \|_\infty, \\ \vec{\rho}_g(P_0, P_1) &\leq \| \mathsf{L}_{e0} - \mathsf{L}_{e1} \|_\infty, \\ \vec{\rho}_{H_2}(P_0, P_1) &\leq \| \mathsf{L}_{tv0} - \mathsf{L}_{tv1} \|_\infty . \end{aligned} \tag{63}$$

Similarly, for the δ-gaps we have (R_{e0} and $\mathsf{R}_{T,0}$ are inner)

$$\begin{aligned} \vec{\delta}_0(P_0, P_1) &\leq \| \mathsf{R}_{T,0} - \mathsf{R}_{T,1} \|_{[0,T],\infty}, \\ \vec{\delta}_g(P_0, P_1) &\leq \| \mathsf{R}_{T,0} - \mathsf{R}_{T,1} \|_{(-\infty,T],\infty}, \\ \vec{\delta}_{H_2}(P_0, P_1) &\leq \| \mathsf{R}_{e0} - \mathsf{R}_{e1} \|_\infty . \end{aligned} \tag{64}$$

It is possible to establish representation uncertainty stability results using these relationships, though we do not do so explicitly here.

5. Controller synthesis. We turn our attention to controller synthesis for the two H^∞ control problems which minimize the norms of the two parallel projections in (8). These two problems are identical for linear systems, and their special structure has made them amenable to computation and particularly useful in controller design. For this reason it is of interest to try to generalize them to nonlinear systems. This will be done here for input-affine systems.

We consider a plant $P : \mathcal{U} \to \mathcal{Y}$ with the following state space model:

$$P \ : \ \begin{cases} \dot{x} = A(x) + B(x)u \ \text{ on } (-\infty, \infty), \ x(-\infty) = 0, \\ y = C(x), \end{cases} \tag{65}$$

where $u \in \mathbf{R}^m$, $y \in \mathbf{R}^p$. We use the notation

$$P = \begin{bmatrix} A & B \\ C & 0 \end{bmatrix}$$

to mean P has a state space realization with matrix-valued functions A, B, and C.

Assumption 5.1. We assume A, B, C are of class C^1 with globally bounded derivatives, B is globally bounded, and 0 is an equilibrium: $A(0) = 0$, $C(0) = 0$.

The meaning of (65) is as follows. If $u \in \mathcal{U}$, then $u(t) = 0$ for all $t \leq T_0$, for some finite T_0, and since 0 is an equilibrium we must have $x(t) = 0$ for all $t \leq T_0$. For $t \geq T_0$, the differential equation is integrated as usual.

Our approach is to apply the information state framework of [17], [14] to this problem (see Appendix A for background information). We shall see that a single H_2 equation underlies the controllers:

$$\nabla V A - \tfrac{1}{2} \nabla V B B' \nabla V' + \tfrac{1}{2} |C|^2 = 0. \tag{66}$$

We denote by V_+ the unique smooth solution of (66) satisfying $V_+ \geq 0$, $V_+(0) = 0$, and

$$(A - BB'\nabla V_+') \quad \text{asymptotically stable,} \tag{67}$$

and by V_- the unique smooth solution of (66) satisfying $V_- \leq 0$, $V_-(0) = 0$, and

$$-(A - BB'\nabla V_-') \quad \text{asymptotically stable.} \tag{68}$$

Before applying this theory it will be useful to carry out some preliminary transformations on the generalized plants corresponding to the two parallel projection operators.

5.1. Generalized plant transformations. In this section we transform the generalized plants $\mathcal{P}_1$ and $\mathcal{P}_2$ in equation (7) into modified forms $\tilde{\mathcal{P}}_1$ and $\tilde{\mathcal{P}}_2$ which have "zero D_4 terms" in the standard terminology; see, e.g., [13], [1], [31] for background on the use of such transformations.

In terms of the state-space model (65) for the plant P, the generalized plants $\mathcal{P}_1$, $\mathcal{P}_2$ in (7) are given by

$$\mathcal{P}_1 = \left[\begin{array}{c|cc|c} A & B & 0 & -B \\ \hline 0 & I & 0 & -I \\ C & 0 & 0 & 0 \\ \hline -C & 0 & I & 0 \end{array}\right] \quad \text{and} \quad \mathcal{P}_2 = \left[\begin{array}{c|ccc} A & B & 0 & -B \\ \hline 0 & 0 & 0 & I \\ -C & 0 & I & 0 \\ \hline -C & 0 & I & 0 \end{array}\right]. \tag{69}$$

Now consider the following transformed plants:

$$\tilde{\mathcal{P}}_1 : \begin{pmatrix} \tilde{u}_0 \\ \tilde{y}_0 \\ \tilde{u}_2 \end{pmatrix} \mapsto \begin{pmatrix} \tilde{u}_1 \\ \tilde{y}_1 \\ y_2 \end{pmatrix} \quad \text{and} \quad \tilde{\mathcal{P}}_2 : \begin{pmatrix} \hat{u}_0 \\ \hat{y}_0 \\ u_2 \end{pmatrix} \mapsto \begin{pmatrix} \hat{u}_2 \\ \hat{y}_2 \\ \tilde{y}_2 \end{pmatrix},$$

defined by the block diagrams in Figures 4 and 5, where

$$\Theta_1 = \gamma^{-1} \left(\begin{array}{cc|cc} \gamma^{-1}I & 0 & \beta I & 0 \\ 0 & 0 & 0 & I \\ \hline -\beta I & 0 & \gamma^{-1}I & 0 \\ 0 & -I & 0 & 0 \end{array}\right) \quad \text{and} \quad \Theta_2 = \gamma^{-1} \left(\begin{array}{cc|cc} 0 & 0 & I & 0 \\ 0 & \gamma^{-1}I & 0 & \beta I \\ \hline -I & 0 & 0 & 0 \\ 0 & -\beta I & 0 & \gamma^{-1}I \end{array}\right), \tag{70}$$

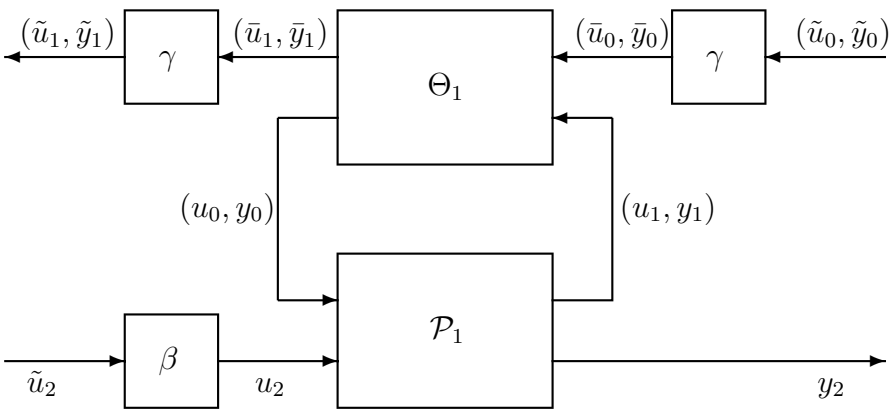

FIG. 4. *Construction of* $\tilde{\mathcal{P}}_1$.

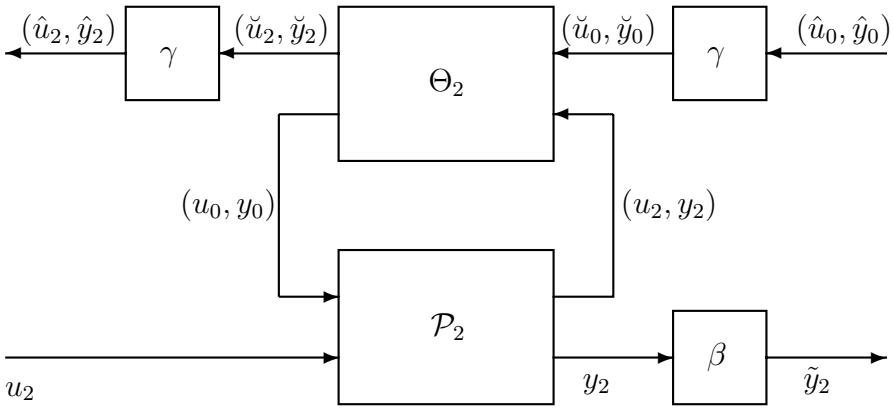

FIG. 5. *Construction of* $\tilde{\mathcal{P}}_2$.

and $\beta = \sqrt{1-\gamma^{-2}}$. It can be verified (see Lemma 5.2 below) that the plants have the following state-space realizations:

(71)
$$\tilde{\mathcal{P}}_1 = \left[\begin{array}{c|cc|c} A & -\beta^{-1}B & 0 & -\beta^{-1}B \\ \hline 0 & 0 & 0 & -I \\ C & 0 & 0 & 0 \\ \hline -C & 0 & -I & 0 \end{array}\right] \quad \text{and} \quad \tilde{\mathcal{P}}_2 = \left[\begin{array}{c|cc|c} A & -B & 0 & -B \\ \hline 0 & 0 & 0 & I \\ -\beta^{-1}C & 0 & 0 & 0 \\ \hline -\beta^{-1}C & 0 & -I & 0 \end{array}\right].$$

We also define the controllers K_1 and K_2:

$$\tilde{K}_1 = \beta^{-1}K_1, \quad \tilde{K}_2 = K_2\beta^{-1}. \tag{72}$$

The constructions of the transformed plants $\tilde{\mathcal{P}}_1$, $\tilde{\mathcal{P}}_2$ take the same form as in [13, p. 162] and yield the following result.

LEMMA 5.2. *The plants* $\tilde{\mathcal{P}}_1$ *and* $\tilde{\mathcal{P}}_1$ *defined in Figures* 4 *and* 5 *have the state-space realizations given by* (71) *and satisfy*

$$\begin{array}{l} \| (\mathcal{P}_1, K_1) \|_\infty < \gamma \quad \textit{iff} \quad \| (\tilde{\mathcal{P}}_1, \tilde{K}_1) \|_\infty < \gamma, \quad \textit{and} \\ \| (\mathcal{P}_2, K_2) \|_\infty < \gamma \quad \textit{iff} \quad \| (\tilde{\mathcal{P}}_2, \tilde{K}_2) \|_\infty < \gamma. \end{array} \tag{73}$$

Proof. The proof is substantially as in [13, p. 162], and we give some details here for completeness.

The plant $\mathcal{P}_1$ in state-space form reads (recall (69)):

$$\mathcal{P}_1 \ : \ \left\{ \begin{array}{l} \dot{x} = A(x) + B(x)(u_0 - u_2), \\ u_1 = u_0 - u_2, \\ y_1 = C(x), \\ y_2 = -C(x) + y_0. \end{array} \right. \tag{74}$$

We also have the relations

$$\begin{array}{r} u_0 = -\frac{\gamma^{-1}}{\beta}\bar{u}_0 - \frac{\gamma^{-2}}{\beta^2}u_2, \\ \bar{u}_1 = -\frac{\gamma^{-1}}{\beta}u_2, \\ u_0 - u_2 = -\frac{\gamma^{-1}}{\beta}\bar{u}_0 - \frac{1}{\beta^2}u_2. \end{array} \tag{75}$$

Then (74) and (75) imply

$$\begin{aligned} \dot{x} &= A(x) + B(x)(-\tfrac{\gamma^{-1}}{\beta}\bar{u}_0 - \tfrac{1}{\beta^2}u_2), \\ \bar{u}_1 &= -\tfrac{\gamma^{-1}}{\beta}u_2, \\ \bar{y}_1 &= \gamma^{-1}C(x), \\ y_2 &= -C(x) + y_0. \end{aligned} \tag{76}$$

Then by scaling (refer to Figure 4) we get

$$\tilde{\mathcal{P}}_1 \ : \ \begin{cases} \dot{x} = A(x) + B(x)(-\frac{1}{\beta}\tilde{u}_0 - \frac{1}{\beta}\tilde{u}_2), \\ \tilde{u}_1 = -\tilde{u}_2, \\ \tilde{y}_1 = C(x), \\ y_2 = -C(x) - \tilde{y}_0. \end{cases} \tag{77}$$

The construction of $\mathcal{P}_2$ is similar.

We claim that K_1 achieves

$$\| u_1 \|_{2,T}^2 + \| y_1 \|_{2,T}^2 \leq \gamma^2(\| u_0 \|_{2,T}^2 + \| y_0 \|_{2,T}^2) \tag{78}$$

for all $T \geq 0$ if and only if $\tilde{K}_1$ achieves

$$\| \tilde{u}_1 \|_{2,T}^2 + \| \tilde{y}_1 \|_{2,T}^2 \leq \gamma^2(\| \tilde{u}_0 \|_{2,T}^2 + \| \tilde{y}_0 \|_{2,T}^2) \tag{79}$$

for all $T \geq 0$.

Since $\Theta_1^*\Theta_1 = \gamma^{-2}I$ we have

$$\begin{aligned} &\| \bar{u}_1 \|_{2,T}^2 + \| \bar{y}_1 \|_{2,T}^2 + \| u_0 \|_{2,T}^2 + \| y_0 \|_{2,T}^2 \\ &\quad = \gamma^{-2}(\| \bar{u}_0 \|_{2,T}^2 + \| \bar{y}_0 \|_{2,T}^2 + \| u_1 \|_{2,T}^2 + \| y_1 \|_{2,T}^2). \end{aligned} \tag{80}$$

Then (78) holds if and only if

$$\| \bar{u}_1 \|_{2,T}^2 + \| \bar{y}_1 \|_{2,T}^2 \leq \gamma^{-2}(\| \bar{u}_0 \|_{2,T}^2 + \| \bar{y}_0 \|_{2,T}^2), \tag{81}$$

which is equivalent to (79)

Similarly, it can be checked that K_2 achieves

$$\| u_2 \|_{2,T}^2 + \| y_2 \|_{2,T}^2 \leq \gamma^2(\| u_0 \|_{2,T}^2 + \| y_0 \|_{2,T}^2) \tag{82}$$

for all $T \geq 0$ if and only if $\tilde{K}_2$ achieves

$$\| \hat{u}_2 \|_{2,T}^2 + \| \hat{y}_2 \|_{2,T}^2 \leq \gamma^2(\| \hat{u}_0 \|_{2,T}^2 + \| \hat{y}_0 \|_{2,T}^2) \tag{83}$$

for all $T \geq 0$. We omit the remaining details. □

5.2. Synthesis for $\Pi_{\mathcal{N}\|\mathcal{M}}$. We are now ready to apply the information state framework of [17] and [14] to the controller synthesis problem for $\Pi_{\mathcal{N}\|\mathcal{M}}$. Given $\gamma > 0$, we wish to find, if possible, a controller K_2 such that

$$\| \Pi_{\mathcal{N}_2\|\mathcal{M}} \|_\infty = \| (\mathcal{P}_2, K_2) \|_\infty < \gamma, \tag{84}$$

where $\mathcal{P}_2$ is given by (69). By Lemma 5.2, it is enough to find a controller $\tilde{K}_2$ such that

$$\| (\tilde{\mathcal{P}}_2, \tilde{K}_2) \|_\infty < \gamma, \tag{85}$$

and this is technically simpler since the D_{11} term is zero in $\tilde{\mathcal{P}}_2$.

The information state for $\tilde{\mathcal{P}}_2$ is denoted by p_{2t} and satisfies (from [14, eq. (3.9)] and (195) below)

$$\begin{aligned}\tfrac{\partial}{\partial t}p_2 \quad &= -\nabla p_2(A - Bu_2) + \gamma^{-2}\tfrac{1}{2}\nabla p_2 BB'\nabla p_2' - \gamma^2\tfrac{1}{2}|C|^2 \\ &\quad +\tfrac{1}{2}|u_2|^2 - \gamma^2\tfrac{1}{2}|\tilde{y}_2|^2 - \gamma^2\beta^{-1}C'\tilde{y}_2,\end{aligned} \tag{86}$$

or in shorthand,

$$\dot{p}_2 = \tilde{F}_2(p_2, u_2, \tilde{y}_2), \tag{87}$$

where $\tilde{F}_2(p_2, u_2, \tilde{y}_2)$ is the differential operator defined by the right-hand side of (86). The Hamilton–Jacoby–Bellman–Isaacs (HJBI) equation for the value function $W_2(p_2)$ is (from [14, eq. (4.16)] and (199) below)

$$\inf_{u_2\in\mathbf{R}^m}\sup_{\tilde{y}_2\in\mathbf{R}^p}\left\{\nabla W_2(p_2)[\tilde{F}_2(p_2, u_2, \tilde{y}_2)]\right\} = 0, \tag{88}$$

from which the optimal information state feedback function is (by [14, eq. (4.23)] and (200) below)

$$u_2^*(p_2) = -\nabla W_2(p_2)[B'\nabla p_2']. \tag{89}$$

The stationary information state for the control attractor p_{2e} is (from [14, eq. (3.28)] and (197) below)

$$0 = -\nabla p_{2e}A + \gamma^{-2}\tfrac{1}{2}\nabla p_{2e}BB'\nabla p_{2e}' - \gamma^2\tfrac{1}{2}|C|^2. \tag{90}$$

Now this must satisfy $p_{2e} \le 0$, $p_{2e}(0) = 0$, and

$$-(A - \gamma^{-2}BB'\nabla p_{2e}') \quad \text{asymptotically stable}, \tag{91}$$

and so we have, by uniqueness,

$$p_{2e} = \gamma^2 V_-. \tag{92}$$

Significantly, this says that the control attractor for the present H_∞ problem can be obtained from the antistable solution to an H_2 equation (66), which is straightforward to find since (66) is sign-definite and independent of γ (cf. [12], [1]).

The optimal information state controller $\tilde{K}_2^* : \tilde{y}_2 \mapsto u_2$ is given by (from [14, sec. 4.1] and (201) below)

$$\tilde{K}_2^* \;:\; \begin{cases} \dot{p}_2 = \tilde{F}_2(p_2, u_2, \tilde{y}_2), \quad p_{20} = \gamma^2 V_-, \\ u_2 = -\nabla W_2(p_2)[B'\nabla p_2']. \end{cases} \tag{93}$$

By a simple scaling, we obtain the desired controller $K_2^* : y_2 \mapsto u_2$ for $\mathcal{P}_2$ by

$$K_2^* = \tilde{K}_2^*\beta,$$

given by

$$K_2^* \;:\; \begin{cases} \dot{p}_2 = F_2(p_2, u_2, y_2), \quad p_{20} = \gamma^2 V_-, \\ u_2 = -\nabla W_2(p_2)[B'\nabla p_2'], \end{cases} \tag{94}$$

where

$$
\begin{aligned}
F_2(p_2,u_2,y_2) &= \tilde{F}_2(p_2,u_2,\beta y_2)\\
&= -\nabla p_2(A-Bu_2)+\gamma^{-2}\tfrac{1}{2}\nabla p_2 BB'\nabla p_2' \\
&\quad +\tfrac{1}{2}|u_2|^2+\tfrac{1}{2}|y_2|^2-\gamma^2\tfrac{1}{2}|y_2+C|^2.
\end{aligned}
\tag{95}
$$

In this form, it can be seen that $p_{2t}(x)$ has the representation

$$
\begin{aligned}
p_{2t}(x) = \sup_{v(\cdot)}\Big\{ & p_{20}(\xi(0))+\tfrac{1}{2}\int_0^t [|u_2(s)|^2+|y_2(s)|^2]ds \\
& -\gamma^2\tfrac{1}{2}\textstyle\int_0^t[|v(s)|^2+|y_2(s)+C(\xi(s))|^2]ds, \\
& \dot{\xi}=A(\xi)+B(\xi)(u_2+v),\ 0\le s\le t, \\
& \xi(t)=x\Big\}
\end{aligned}
\tag{96}
$$

and as a consequence is finite for all $t\ge 0$ and all $x\in\mathbf{R}^n$ for any finite $p_{20}\le 0$ and any pair $(u_2,y_2)\in\mathcal{W}$; this is again a consequence of the special structure of the present H_∞ problem.

The HJBI equation (88) can be written as

$$
\inf_{u_2\in\mathbf{R}^m}\sup_{y_2\in\mathbf{R}^p}\{\nabla W_2(p_2)[F_2(p_2,u_2,y_2)]\}=\inf_{u_2\in\mathbf{R}^m}\sup_{\tilde{y}_2\in\mathbf{R}^p}\left\{\nabla W_2(p_2)[\tilde{F}_2(p_2,u_2,\tilde{y}_2)]\right\}=0,
$$

or more explicitly, as

$$
\begin{aligned}
&\nabla W_2(p_2)[-\nabla p_2 A+\gamma^{-2}\tfrac{1}{2}\nabla p_2 BB'\nabla p_2'-\gamma^2\tfrac{1}{2}|C|^2] \\
&\quad -\tfrac{1}{2}|\nabla W_2(p_2)[\nabla p_2 B]|^2+\gamma^2\beta^{-2}|\nabla W_2(p_2)[C]|^2=0,
\end{aligned}
\tag{97}
$$

which is an infinite-dimensional nonlinear Riccati equation.

Of interest is the smallest value of $\gamma>1$ for which there exists a controller K_2 with the objective (84) satisfied. Let

$$
\gamma_2^*=\inf\left\{\gamma>1\ :\ p_{2e}\in\{p\in\mathcal{X}\ :\ \exists\varepsilon>0 \text{ with } p+\varepsilon|\cdot|^2\in \mathrm{dom}W_2\}\right\}. \tag{98}
$$

Then, for $\gamma>\gamma_2^*$, under the hypotheses of the sufficiency theorems of [14, Chapter 4], the controller K_2^* achieves the H_∞ norm objective (84). One of the key hypotheses concerning the so-called "quadratic upper limiting" property of the control attractor p_{2e} follows from a strengthened form of the antistability condition for V_- (68) (e.g., "incremental L_2 exponential antistability") and negative definiteness: $V_-(x)\le -c_-|x|^2$ ($c_->0$). Indeed, under these circumstances it will always be the case that

$$
p_{2t}\in\{p\in\mathcal{X}\ :\ \exists\varepsilon>0 \text{ with } p+\varepsilon|\cdot|^2\in\mathrm{dom}W_2\} \tag{99}
$$

whenever $(u_2,y_2)\in\mathcal{W}\cap L_2[0,\infty)$ (this is a coupling condition).

The state feedback HJBI equation for the state feedback H_∞ problem specified by $\mathcal{P}_2$ is (by [14, eq. (5.45)] and (193) below)

$$
\nabla V_2 A-\tfrac{1}{2}\beta^2\nabla V_2 BB'\nabla V_2'+\tfrac{1}{2}\beta^{-2}|C|^2=0 \tag{100}
$$

with $V_2\ge 0$, $V_2(0)=0$, and

$$
(A-\beta^2 BB'\nabla V_2') \quad \text{asymptotically stable.} \tag{101}
$$

Then by uniqueness,

$$V_2 = \beta^{-2} V_+. \tag{102}$$

Again, the present special structure leads to a considerable simplification since the state feedback H_∞ value function V_2 can be solved in terms of the stabilizing solution V_+ of the H_2 equation (66).

The certainty equivalence controller K_2^{ce} (under the standard certainty equivalence assumptions [4]) is given by

$$K_2^{ce}\colon \begin{cases} \dot{p}_2 = F_2(p_2, u_2, y_2), \quad p_{20} = \gamma^2 V_-, \\ u_2 = \beta^{-2} B(\bar{x})' \nabla V_+(\bar{x})', \end{cases} \tag{103}$$

where

$$\bar{x}(t) = \operatorname*{argmax}_{x \in \mathbf{R}^n} \{p_{2t}(x) + V_2(x)\}. \tag{104}$$

Remark 5.3. The results of this section are closely related to [1] and [25], which treated coprime factor uncertainty.

5.3. Synthesis for $\boldsymbol{\Pi_{\mathcal{M}\|\mathcal{N}}}$. For this second projection, given $\gamma > 0$, a controller K_1 can be found such that

$$\| \Pi_{\mathcal{M}\|\mathcal{N}_1} \|_\infty = \| (\mathcal{P}_1, K_1) \|_\infty < \gamma \tag{105}$$

using the controller K_2^* obtained above via conjugacy (see (47))

$$K_1^* = \beta^2 K_2^* \beta^{-2}. \tag{106}$$

However, it is instructive to do this directly, as we now show.

By Lemma 5.2, as above, it is enough to find a controller $\tilde{K}_1$ such that

$$\| (\tilde{\mathcal{P}}_1, \tilde{K}_1) \|_\infty < \gamma. \tag{107}$$

The information state equation for $p_{1t}(x) = p_1(x,t)$ is (from [14, eq. (3.9)] and (195) below)

$$\begin{aligned} \tfrac{\partial}{\partial t} p_1 &= -\nabla p_1 (A - \beta^{-1} B \tilde{u}_2) + \gamma^{-2} \beta^{-2} \tfrac{1}{2} \nabla p_2 B B' \nabla p_2' - \gamma^2 \beta^2 \tfrac{1}{2} |C|^2 \\ &\quad + \tfrac{1}{2} |\tilde{u}_2|^2 - \gamma^2 \tfrac{1}{2} |y_2|^2 - \gamma^2 C' y_2, \\ \dot{p}_1 &= \tilde{F}_1(p_1, \tilde{u}_2, y_2). \end{aligned} \tag{108}$$

The HJBI equation for the value function $W_1(p_1)$ is (from[14, eq. (4.16)] and (199) below)

$$\inf_{\tilde{u}_2 \in \mathbf{R}^m} \sup_{y_2 \in \mathbf{R}^p} \left\{ \nabla W_1(p_1) [\tilde{F}_1(p_1, \tilde{u}_2, y_2)] \right\} = 0, \tag{109}$$

from which the optimal information state feedback function is (by [14, eq. (4.23)] and (200) below)

$$\tilde{u}_2^*(p_1) = -\beta^{-1} \nabla W_1(p_1) [B' \nabla p_1']. \tag{110}$$

The stationary information state for the control attractor p_{1e} is (from [14, eq. (3.28)] and (197) below)

$$0 = -\nabla p_{1e} A + \gamma^{-2} \beta^{-2} \tfrac{1}{2} \nabla p_{1e} B B' \nabla p_{1e}' - \gamma^2 \beta^2 \tfrac{1}{2} |C|^2. \tag{111}$$

Now $p_{1e} \leq 0$, $p_{1e}(0) = 0$, and

$$-(A - \gamma^{-2}\beta^{-2}BB'\nabla p_{1e}') \quad \text{asymptotically stable,} \tag{112}$$

and so we have, by uniqueness,

$$p_{1e} = \gamma^2\beta^2 V_-. \tag{113}$$

The optimal information state controller $\tilde{K}_1^* : y_2 \mapsto \tilde{u}_2$ is given by (from [14, sec. 4.1] and (201) below)

$$\tilde{K}_1^* \ : \ \begin{cases} \dot{p}_1 = \tilde{F}_1(p_1, \tilde{u}_2, y_2), \quad p_{10} = \gamma^2\beta^2 V_-, \\ \tilde{u}_2 = -\beta^{-1}\nabla W_1(p_1)[B'\nabla p_1']. \end{cases} \tag{114}$$

The state feedback HJBI equation is (by [14, eq. (5.45)] and (193) below)

$$\nabla V_1 A - \tfrac{1}{2}\nabla V_1 BB'\nabla V_1' + \tfrac{1}{2}|C|^2 = 0 \tag{115}$$

with $V_1 \geq 0$, $V_1(0) = 0$, and

$$(A - BB'\nabla V_1') \quad \text{asymptotically stable.} \tag{116}$$

Then by uniqueness,

$$V_1 = V_+. \tag{117}$$

The controller $K_1^* : y_2 \mapsto u_2$ for $\mathcal{P}_1$ is given by

$$K_1^* = \beta\tilde{K}_1^*$$

so that

$$K_1^*: \ \begin{cases} \dot{p}_1 = F_1(p_1, u_2, y_2), \quad p_{10} = \gamma^2\beta^2 V_-, \\ u_2 = -\nabla W_1(p_1)[B'\nabla p_1'], \end{cases} \tag{118}$$

where

$$F_1(p_1, u_2, y_2) = \tilde{F}_1(p_1, \beta^{-1}u_2, y_2). \tag{119}$$

Remark 5.4. It can be checked that (106) (β-conjugacy) holds for the controllers K_1^* and K_2^* defined by (118) and (94), respectively.

Let

$$\gamma_1^* = \inf\left\{\gamma > 1 \ : \ p_{1e} \in \{p \in \mathcal{X} \ : \ \exists \varepsilon > 0 \text{ with } p + \varepsilon|\cdot|^2 \in \mathrm{dom} W_1\}\right\}. \tag{120}$$

Then as above we have

$$\gamma_1^* \geq (1 - \bar{\beta}^2)^{-1/2} \tag{121}$$

as in [1, Theorem 4.3].

5.4. A local controller. In this subsection we construct a local solution to the $\Pi_{\mathcal{N}\|\mathcal{M}}$ H_∞ problem using the results of [15] (see also [16], [2], [26], etc.). As in section 5.2, we consider the problem of finding $\tilde{K}_2$ such that (85) holds, in a local sense.

The controller can be obtained from two solutions to the H_2 PDE (66) or slightly more generally, from partial differential inequalities (PDIs) related to (66). Assume as follows.

1. There exists a C^3 positive definite function V_+ defined in a neighborhood of 0 and vanishing at 0 which satisfies
$$\nabla V_+ A - \tfrac{1}{2}\nabla V_+ BB'\nabla V_+' + \tfrac{1}{2}|C|^2 \le 0 \tag{122}$$
in the neighborhood.
2. There exists a C^3 negative definite function V_- defined in a neighborhood of 0 and vanishing at 0 which satisfies
$$\nabla V_- A - \tfrac{1}{2}\nabla V_- BB'\nabla V_-' + \tfrac{1}{2}|C|^2 \le 0 \tag{123}$$
in the neighborhood, and in addition
$$\begin{aligned}\nabla^2\{&-\nabla r_{2e}(A+\gamma^{-2}\beta^{-2}BB'\nabla V_+) + \gamma^{-2}\tfrac{1}{2}\nabla r_e BB'\nabla r_e' \\ &+\tfrac{1}{2}\beta^{-4}\nabla V_+ BB'\nabla V_+' - \gamma^2\tfrac{1}{2}|C|^2\} < 0\end{aligned} \tag{124}$$
in the neighborhood, where
$$r_{2e} = \gamma^2 V_- + \beta^{-2}V_+.$$
3. There exists a C^2 function G_2 such that
$$\nabla r_{2e}(x)G_2(x) = \gamma^2\beta^{-1}C(x)' \tag{125}$$
in a neighborhood of 0.

Consider the controller
$$\tilde{K}_2^\dagger\colon \left\{\begin{array}{l}\dot{\xi} = A(\xi) - B(\xi)B(\xi)'\nabla V_+(\xi)' + G_2(\xi)(\tilde{y} + \beta^{-1}C(\xi)),\\ u_2 = \beta^{-2}B(\xi)'\nabla V_+(\xi)'\end{array}\right. \tag{126}$$
defined locally in a neighborhood of 0 (the intersection defined by the assumptions).

Then by [15, Theorem 3.1], the controller $\tilde{K}_2^\dagger$ achieves local disturbance attenuation (dissipation) with stability. This means that the function
$$U(x,\xi) = \beta^{-2}V_+(x) - \gamma^2 V_-(x-\xi) - \beta^{-2}V_+(x-\xi)$$
is a storage function for the closed-loop system in a neighborhood of 0 and is a local Lyapunov function; in particular, for trajectories $(x(\cdot),\xi(\cdot))$ of $(\tilde{\mathcal{P}}_2, \tilde{K}_2^\dagger)$ staying near 0 one has
$$\begin{aligned}U(x(t),\xi(t)) + \tfrac{1}{2}\textstyle\int_0^t[|\hat{u}_1(s)|^2 + |\hat{y}_1(s)|^2]ds \\ \le U(x_0,\xi_0) + \tfrac{1}{2}\textstyle\int_0^t[|\hat{u}_0(s)|^2 + |\hat{y}_0(s)|^2]ds.\end{aligned} \tag{127}$$

Rescaling, one obtains a local controller $K_2^\dagger$ for $\mathcal{P}_2$, and via conjugation, one for $\mathcal{P}_1$.

6. State-space realizations of graph representations. The generalization of the well-known state-space formulae for normalized coprime factorizations of linear systems (see, e.g., [31] and the references therein) to nonlinear systems has been considered by a number of authors. In [22] and [27] the connection between existence of right representations and the existence of stabilizing feedbacks is explored. In [1], [24], [25], and [19], state-space realizations for image and kernel representations are considered, and definitions of normalized representations are proposed. In this section we rework the theory for the right representations according to our definitions and derive new realizations for normalized left representations.

Consider the state-space model (65) for the plant $P : \mathcal{U} \to \mathcal{Y}$. Using this model, we derive realizations of the right and left representations defined in section 3.

6.1. Right representations.

6.1.1. Preliminaries. Consider the finite horizon HJB:

(128)
$$\begin{aligned}\tfrac{\partial}{\partial t}V_T(t,x) + \nabla V_T(t,x)A(x)\\ -\tfrac{1}{2}\nabla V_T(t,x)B(x)B(x)'\nabla V_T(t,x)' + \tfrac{1}{2}|C(x)|^2 = 0 \ \text{ in } (-\infty,T)\times\mathbf{R}^n,\\ V_T(T,x) = 0 \ \text{ for } x\in\mathbf{R}^n.\end{aligned}$$

In general, this equation will have a unique viscosity solution, not necessarily smooth. However, for our purposes we make the following assumption.

Assumption 6.1. *There exists a unique smooth solution $V_T(t,x)$ to the HJB equation* (128), *with $\nabla V_T(t,x)$ globally Lipschitz in x.*

Define R_{tT}: $\mathcal{U}\cap L_2[t,T] \to \mathcal{W}\cap L_2[t,T]$ by

(129)
$$\mathsf{R}_{tT}\colon \begin{cases} \dot\xi(s) = A(\xi(s)) + B(\xi(s))(v_T^*(s)+\psi(s)), \quad t\le s\le T,\ \xi(t)=0,\\ \begin{bmatrix} u_T(s)\\ y_T(s)\end{bmatrix} = \begin{bmatrix} v_T^*(s)+\psi(s)\\ C(\xi(s))\end{bmatrix},\end{cases}$$

where

(130)
$$v_T^*(s) = -B(\xi(s))'\nabla V_T(s,\xi(s))'.$$

Lemma 6.2. *We have the following.*

1. *The solution of the HJB equation* (128) *is given by*

(131)
$$\begin{aligned}V_T(t,x) = \inf_{v\in\mathcal{U}}\{\tfrac{1}{2}\textstyle\int_t^T [|v(s)|^2 + |C(\xi(s))|^2]\,ds\\ \mid \dot\xi(s) = A(\xi(s)) + B(\xi(s))v(s), \quad t\le s\le T,\\ \xi(t) = x\}.\end{aligned}$$

2. *$V_T(t,x)\ge 0$ for all x and $V_T(t,0) = 0$ for all $t\ge 0$.*
3. *For $\psi\in L_2[t,T]$, the system R_{tT} defined by (129) satisfies the inner property*

(132)
$$\tfrac{1}{2}\int_t^T [|u_T(s)|^2 + |y_T(s)|^2]\,ds = V_T(t,x) + \tfrac{1}{2}\int_t^T |\psi(s)|^2\,ds.$$

Proof. The proof is based on a standard verification argument from optimal control (completion of squares). For any $v \in \mathcal{U}$, let $\xi(\cdot)$ denote the solution of

$$\dot{\xi}(s) = A(\xi(s)) + B(\xi(s))v(s),\ t \le s \le T,\ \xi(t) = x.$$

Then

$$\begin{aligned}
\tfrac{d}{ds}V_T(s,\xi(s)) &= \tfrac{\partial}{\partial s}V_T(s,\xi(s)) + \nabla V_T(s,\xi(s))[A(\xi(s)) + B(\xi(s))v(s)] \\
&= \tfrac{\partial}{\partial s}V_T(s,\xi(s)) + \nabla V_T(s,\xi(s))[A(\xi(s)) + B(\xi(s))v_T^*(s) \\
&\qquad + B(\xi(s))(v(s) - v_T^*(s))] \\
&= \tfrac{\partial}{\partial s}V_T(s,\xi(s)) + \nabla V_T(s,\xi(s))A(\xi(s)) \\
&\qquad - \tfrac{1}{2}\nabla V_T(s,\xi(s))B(\xi(s))B(\xi(s))'\nabla V_T(s,\xi(s))' \\
&\qquad - \tfrac{1}{2}|v_T^*(s)|^2 + \nabla V_T(s,\xi(s))B(\xi(s))(v(s) - v_T^*(s)) \\
&= \tfrac{1}{2}|v(s) - v_T^*(s)|^2 - \tfrac{1}{2}|v(s)|^2 - \tfrac{1}{2}|C(\xi(s))|^2,
\end{aligned}$$

and on integrating from t to T we get

$$\begin{aligned}
V_T(t,x) &= \tfrac{1}{2}\textstyle\int_t^T [|v(s)|^2 + |C(\xi(s))|^2]ds - \tfrac{1}{2}\int_t^T |v(s) - v_T^*(s)|^2 ds. \\
&\le \tfrac{1}{2}\textstyle\int_t^T [|v(s)|^2 + |C(\xi(s))|^2]ds.
\end{aligned} \tag{133}$$

For $v(s) = v_T^*(s)$ this gives the optimal value

$$V_T(t,x) = \tfrac{1}{2}\int_t^T [|v_T^*(s)|^2 + |C(\xi(s))|^2]ds.$$

This proves 1.

From the representation formula (131) it is clear that $V_T(t,x) \ge 0$. If $x = 0$ and $v(s) = 0$ on $[t,T]$, then the corresponding trajectory $\xi(s) = 0$ and $C(\xi(s)) = 0$ on $[t,T]$, and so $V_T(t,0) = 0$. This proves 2.

Now let $\psi \in \mathcal{U} \cap L_2[t,T]$, and define v by

$$v(s) = v_T^*(s) + \psi(s) \ \text{ on } [t,T].$$

Then $v \in \mathcal{U} \cap L_2[t,T]$, and so item 3 follows from the first line of (133). ∎

Consider next the infinite horizon HJB equation

$$\nabla V(x)A(x) - \tfrac{1}{2}\nabla V(x)B(x)B(x)'\nabla V(x)' + \tfrac{1}{2}|C(x)|^2 = 0 \ \text{ in } \mathbf{R}^n. \tag{134}$$

Assumption 6.3. *There exists a unique smooth solution to the HJB equation* (134), *with* $\nabla V(x)$ *globally Lipschitz, such that* $V \ge 0$, $V(0) = 0$, *and* V *stabilizing:*

$$(A - BB'\nabla V') \ \textit{ asymptotically stable.} \tag{135}$$

That is, for any $v \in \mathcal{U} \cap L_2[0,\infty)$, *if* ξ *is the solution on* $[0,\infty)$ *of*

$$\dot{\xi} = A(\xi) - B(\xi)B(\xi)\nabla V(\xi)' + B(\xi)v, \quad \xi(0) = x, \tag{136}$$

then $\xi \in L_2[0,\infty)$ *and* $\xi(t) \to 0$ *as* $t \to \infty$.

Define $\mathsf{R}_{[0,\infty)} : \mathcal{U} \cap L_{2,e} \to \mathcal{W} \cap L_{2,e}$ by

(137)
$$\mathsf{R}_{[0,\infty)}\colon \left\{ \begin{array}{c} \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(v^*(s) + \psi(s)), \quad 0 \le s < \infty,\ \xi(0) = 0, \\ \left[\begin{array}{c} u(s) \\ y(s) \end{array} \right] = \left[\begin{array}{c} v^*(s) + \psi(s) \\ C(\xi(s)) \end{array} \right], \end{array} \right.$$

where

$$v^*(s) = -B(\xi(s))' \nabla V(\xi(s))'. \tag{138}$$

LEMMA 6.4. *We have the following.*

1. *The solution of the HJB equation* (134) *is given by*

$$\begin{array}{l} V(x) = \inf_{v \in \mathcal{U} \cap L_2} \{ \frac{1}{2} \int_0^\infty [|v(s)|^2 + |C(\xi(s))|^2]\, ds \\ \qquad\qquad \mid \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))v(s), \quad 0 \le s < \infty, \\ \qquad\qquad\quad \xi(0) = x, \ \textit{and}\ \xi \in L_2 \}. \end{array} \tag{139}$$

2. *For $\psi \in L_{2,e}$ and all $t \ge 0$ we have*

$$V(\xi(t)) + \tfrac{1}{2} \int_0^t [|u(s)|^2 + |y(s)|^2]\, ds = V(x) + \tfrac{1}{2} \int_0^t |\psi(s)|^2\, ds \tag{140}$$

for the system $\mathsf{R}_{[0,\infty)}$.

3. *For $\psi \in L_2$ we have*

$$\tfrac{1}{2} \int_0^\infty [|u(s)|^2 + |y(s)|^2]\, ds = V(x) + \tfrac{1}{2} \int_0^\infty |\psi(s)|^2\, ds. \tag{141}$$

Proof. The proof is similar to that of Lemma 6.2 and we indicate only the main changes. For any $v \in \mathcal{U} \cap L_{2,e}$, let $\xi(\cdot)$ denote the solution of

$$\dot{\xi}(s) = A(\xi(s)) + B(\xi(s))v(s), \ s \ge 0, \ \xi(0) = x.$$

Then

$$\frac{d}{ds} V(\xi(s)) = \tfrac{1}{2}|v(s) - v^*(s)|^2 - \tfrac{1}{2}|v(s)|^2 - \tfrac{1}{2}|C(\xi(s))|^2,$$

and on integrating from 0 to t we have

$$V(x) = V(\xi(t)) + \tfrac{1}{2} \int_0^t [|v(s)|^2 + |C(\xi(s))|^2] ds - \tfrac{1}{2} \int_0^t |v(s) - v_T^*(s)|^2 ds. \tag{142}$$

Now if $v \in \mathcal{U} \cap L_2$ is such that the trajectory $\xi(\cdot) \in L_2$ and $\xi(t) \to 0$ as $t \to \infty$, then $V(\xi(t)) \to 0$ as $t \to \infty$ and the integrands in (142) are integrable on $[0, \infty)$; hence

$$\begin{array}{l} V(x) = \frac{1}{2} \int_0^\infty [|v(s)|^2 + |C(\xi(s))|^2] ds - \frac{1}{2} \int_0^\infty |v(s) - v_T^*(s)|^2 ds \\ \qquad \le \frac{1}{2} \int_0^\infty [|v(s)|^2 + |C(\xi(s))|^2] ds. \end{array} \tag{143}$$

The stability property in Assumption 6.3 implies that $v = v^*$ is a valid (admissible) control in the representation (139), and (143) implies

$$V(x) = \tfrac{1}{2} \int_0^\infty [|v^*(s)|^2 + |C(\xi(s))|^2] ds,$$

and so v^* is optimal. This proves item 1.

Let $\psi \in \mathcal{U} \cap L_{2,e}$ and define

$$v(s) = v^*(s) + \psi(s) \quad \text{on } [0, \infty).$$

Then $v \in \mathcal{U} \cap L_{2,e}$, and item 2 follows from (142).

If $\psi \in \mathcal{U} \cap L_2$, Assumption 6.3 and (143) imply item 3. ∎

6.1.2. Finite horizon right representation: $\mathsf{R}_{T,P}$. Define $\mathsf{R}_{T,P} : \mathcal{U} \to \mathcal{W} \cap L_2(-\infty, T]$ by

(144)

$$\mathsf{R}_{T,P}\colon \left\{ \begin{array}{c} \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(v_T^*(s) + \psi(s)), \quad s \le T,\ \xi(-\infty) = 0, \\ \left[\begin{array}{c} u_T(s) \\ y_T(s) \end{array} \right] = \left[\begin{array}{c} v_T^*(s) + \psi(s) \\ C(\xi(s)) \end{array} \right], \end{array} \right.$$

where $v_T^*(s)$ is given by (130).

THEOREM 6.5. *The operator $\mathsf{R}_{T,P}$ defined by* (144) *is a finite horizon right representation of the plant P given by* (65) *and is contractive and finite time inner. A left inverse of $\mathsf{R}_{T,P}$ is given by*

$$\mathsf{R}_{T,P}^{-L}\colon \left\{ \begin{array}{l} \dot{\xi}(s) = A(\xi(s)) + \left[\begin{array}{cc} B(\xi(s)) & 0 \end{array} \right] \left[\begin{array}{c} u \\ y \end{array} \right], \quad s \le T,\ \xi(-\infty) = 0, \\ \psi(s) = u(s) - v_T^*(s), \end{array} \right. \tag{145}$$

where $v_T^*(s)$ is given by (130).

Proof. We must check that the operator $\mathsf{R}_{T,P}$ defined by (144) satisfies the definitions given in section 3.1, part 1.

Let $(u, y) \in \operatorname{range} \mathsf{R}_{T,P}|_{[T_0,T]}$. Then

$$u(s) = v_T^*(s) + \psi(s) \text{ and } y(s) = C(\xi(s))$$

for some $\psi \in \mathcal{U}$, where

$$\dot{\xi} = A(\xi) + B(\xi)u \text{ on } [T_0, T],\ \xi(T_0) = 0.$$

Then clearly $(u, y) \in \mathcal{G}_P \cap L_2[T_0, T]$, and so $\operatorname{range} \mathsf{R}_{T,P}|_{[T_0,T]} \subset \mathcal{G}_P \cap L_2[T_0, T]$. It can similarly be checked that $\mathcal{G}_P \cap L_2[T_0, T] \subset \operatorname{range} \mathsf{R}_{T,P}|_{[T_0,T]}$, proving that $\mathsf{R}_{T,P}$ is a finite horizon right representation.

Let $\psi \in \mathcal{U}$. Then $\psi(t) = 0$ for all $t \le T_0$, some $-\infty < T_0$. We suppose $T_0 < T$. Now item 3 of Lemma 6.2, i.e., (132), implies

$$\int_{T_0}^{T} |\mathsf{R}_{T,P}(\psi)(s)|^2 ds = \int_{T_0}^{T} |\psi(s)|^2 ds.$$

From this we see that $\mathsf{R}_{T,P}$ is finite time inner and contractive.

Next we check that $\mathsf{R}_{T,P}^{-L} : \mathcal{W} \to \mathcal{U} \cap L_2(-\infty, T]$ defined by (145) is a left inverse of $\mathsf{R}_{T,P}$. Let $\psi \in \mathcal{U} \cap L_2(-\infty, T]$, $\psi(t) = 0$ for all $t \le T_0$, some $-\infty < T_0 < T$, and $(u, y) = \mathsf{R}_{T,P}(\psi)$. Then

$$\dot{\xi} = A(\xi) + B(\xi)(v_T^* + \psi) \text{ on } [T_0, T],\ \xi(T_0) = 0.$$

Now $u = v_T^* + \psi$, $y = C(\xi)$ on $[T_0, T]$, and so this same trajectory satisfies

$$\dot{\xi} = A(\xi) + B(\xi)u \text{ on } [T_0, T],\ \xi(T_0) = 0.$$

Hence we must have

$$\psi = \mathsf{R}_{T,P}^{-L}(u, y),$$

showing that $\mathsf{R}_{T,P}^{-L}$ is a left inverse of $\mathsf{R}_{T,P}$. ∎

6.1.3. Right representation: R_{eP}. Define $\mathsf{R}_{eP} : \mathcal{U} \to \mathcal{W}$ by

$$\mathsf{R}_{eP}\colon \left\{ \begin{array}{rl} \dot{\xi}(s) & = A(\xi(s)) + B(\xi(s))(v^*(s) + \psi(s)),\ \xi(-\infty) = 0, \\ \left[\begin{array}{c} u(s) \\ y(s) \end{array} \right] & = \left[\begin{array}{c} v^*(s) + \psi(s) \\ C(\xi(s)) \end{array} \right], \end{array} \right. \tag{146}$$

where $v^*(s)$ is given by (138).

A state space realization (A, B, C) of a plant P is said to be *L_2-detectable* if $(u, y) \in \mathcal{G}_P \cap L_2$ implies that the corresponding state $\xi \in L_2$.

THEOREM 6.6. *The operator R_{eP} defined by* (146) *is a right representation of the plant P given by* (65) *(assumed L_2-detectable) and is contractive and inner. A left inverse of R_{eP} is given by*

(147)

$$\mathsf{R}_{eP}^{-L}\colon \left\{ \begin{array}{l} \dot{\xi}(s) = A(\xi(s)) + \left[\begin{array}{cc} B(\xi(s)) & 0 \end{array} \right] \left[\begin{array}{c} u \\ y \end{array} \right], \quad s \geq -\infty,\ \xi(-\infty) = 0, \\ \psi(s) = u(s) - v^*(s), \end{array} \right.$$

where $v^*(s)$ is given by (138). *The system R_{eP}^{-L} has asymptotically stable zero dynamics.*

Proof. We must check that the operator R_{eP} defined by (144) satisfies the definitions given in section 3.1, part 2.

Let $(u, y) \in \operatorname{range} \mathsf{R}_{eP}$. Then

$$u(s) = v^*(s) + \psi(s) \text{ and } y(s) = C(\xi(s))$$

for some $\psi \in \mathcal{U}$, where

$$\dot{\xi} = A(\xi) + B(\xi)u \text{ on } (-\infty, \infty),\ \xi(-\infty) = 0.$$

Then clearly $(u, y) \in \mathcal{G}_P$, and so $\operatorname{range} \mathsf{R}_{eP} \subset \mathcal{G}_P$. If $(u, y) \in \operatorname{range} \mathsf{R}_{eP}|_{L_2}$, then $\psi \in \mathcal{U} \cap L_2$. The proof is similar for the $L_2[0, \infty)$ case.

Now suppose $(u, y) \in \mathcal{G}_P$. Reversing the above argument, with $\psi = u - v^* \in \mathcal{U}$, we see that $(u, y) \in \operatorname{range} \mathsf{R}_{eP}$. If $(u, y) \in \mathcal{G}_P \cap L_2$, L_2-detectability ensures $\psi = u - v^* \in \mathcal{U} \cap L_2$. Similarly for the $L_2[0, \infty)$ case. This shows that R_{eP} is a right representation of P.

The contractive and inner properties of R_{eP} follow from Lemma 6.4, items 2 and 3, respectively.

Next we check that $\mathsf{R}_{eP}^{-L} : \mathcal{W} \to \mathcal{U}$ defined by (147) is a left inverse of R_{eP}. Let $\psi \in \mathcal{U}$ and $(u, y) = \mathsf{R}_{eP}(\psi)$. Then

$$\dot{\xi} = A(\xi) + B(\xi)(v^* + \psi) \text{ on } (-\infty, \infty),\ \xi(-\infty) = 0.$$

Now $u = v^* + \psi$, $y = C(\xi)$, and so this same trajectory satisfies

$$\dot{\xi} = A(\xi) + B(\xi)u \text{ on } (-\infty, \infty),\ \xi(-\infty) = 0.$$

Hence we must have

$$\psi = \mathsf{R}_{eP}^{-L}(u, y),$$

showing that R_{eP}^{-L} is a left inverse of R_{eP} on $\mathcal{U}$.

If $\psi \in \mathcal{U} \cap L_2$, Assumption 6.3 ensures $(u, y) = \mathsf{R}_{eP}(\psi) \in \mathcal{W} \cap L_2$. The argument just done for the case $\psi \in \mathcal{U}$ implies here that $\psi = \mathsf{R}_{eP}^{-L}(u, y)$. (We do not use or assert norm boundedness of R_{eP}^{-L} on $\mathcal{W}$.) So R_{eP}^{-L} is a left inverse of R_{eP} on $\mathcal{U} \cap L_2$. The case $\psi \in \mathcal{U} \cap L_2[0, \infty)$ is similar.

Finally, let $(u, y) \in \ker \mathsf{R}_{eP}^{-L}$ and consider the associated dynamics of (147). Then $\psi \equiv 0$, so $u(s) = v^*(s)$ for all $s > 0$. By Assumption 6.3, we see that the trajectory $\xi(\cdot)$ of (147) tends to zero asymptotically for any initial condition. This proves the stability of the zero dynamics. □

6.2. Left representations.

6.2.1. Preliminaries. Let $\mathcal{X}$ be the Banach space of real-valued continuous functions on $\mathbf{R}^n$ with at most quadratic growth with norm

$$\| p \|_{\mathcal{X}} = \sup_{x \neq 0} \frac{|p(x)|}{1 + |x|^2}.$$

Write

$$\langle p \rangle = \sup_{x \in \mathbf{R}^n} \{p(x)\}.$$

Let $p_0 \in \mathcal{X}$ be strictly negative definite:

$$p_0(x) < -c|x|^2 \ \forall x \in \mathbf{R}^n, \tag{148}$$

with $c = c[p_0] > 0$ and $p_0(0) = 0$.

Define a system evolving in $\mathcal{X}$ for $t \geq 0$ with state $p_t(x) = p(t, x)$ by

$$\mathsf{L}(0, p_0)\colon \begin{cases} \dot{p} = F(p, u, y), \quad p|_{t=0} = p_0, \\ \phi = C(\hat{x}) + \begin{bmatrix} 0 & -I \end{bmatrix} \begin{bmatrix} u \\ y \end{bmatrix}, \end{cases} \tag{149}$$

where $\dot{p} = \frac{\partial}{\partial t} p$, and $F(p, u, y)$ is the differential operator

$$F(p, u, y) = -\nabla p(A + Bu) + \tfrac{1}{2} \nabla p B B' \nabla p' - \tfrac{1}{2} |y - C|^2, \tag{150}$$

and

$$\hat{x} \in [[p]] \stackrel{\triangle}{=} \operatorname*{argmax}_{x \in \mathbf{R}^n} \{p(x)\} \tag{151}$$

is specified by

$$\tfrac{1}{2} |y - C(\hat{x})|^2 = \min_{x \in [[p]]} \{\tfrac{1}{2} |y - C(x)|^2\}. \tag{152}$$

We will also have occasion to use functions belonging to an extension $\mathcal{X}_e$ of the space $\mathcal{X}$. For instance,

$$\mathbf{\Delta}_{x_0}(x) = \begin{cases} 0 & \text{if } x = x_0, \\ -\infty & \text{if } x \neq x_0. \end{cases} \tag{153}$$

This function belongs to $\mathcal{X}_e$ and can be viewed as a limit $\mathbf{\Delta}_{x_0}(x) = \lim_{N \to \infty} -N|x - x_0|^2$. More generally, elements of $\mathcal{X}_e$ can be viewed as max-plus measures [14].

We make the following representation and regularity assumption concerning the PDE in the system (149).

Assumption 6.7. *Let the initial condition p_0 belong to $\mathcal{X}$ and satisfy* (148), $p_0(0) = 0$, *or let $p_0 = \mathbf{\Delta}_0$. For $(u, y) \in \mathcal{W}$ we assume as follows.*

1. *The HJB equation in* (149) *has a unique solution given by*

$$\begin{aligned} p_t(x) = \sup_{v \in \mathcal{U} \cap L_{2,e}} \{ & p_0(\xi(0)) - \tfrac{1}{2} \textstyle\int_0^t [|v(s)|^2 + |y(s) - C(\xi(s))|^2]\, ds \\ & \mid \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(u(s) + v(s)), \quad 0 \le s \le t, \\ & \xi(t) = x \}. \end{aligned} \tag{154}$$

2. *The map $t \mapsto \langle p_t \rangle$ is absolutely continuous, and*

$$\frac{d}{dt}\langle p_t \rangle = - \inf_{\hat{x} \in [[p_t]]} \{ \tfrac{1}{2} |y(t) - C(\hat{x})|^2 \} \quad a.e. \tag{155}$$

Remark 6.8. If the information state p_t were smooth, the representation would follow from classical optimal control, and the derivative (155) would follow from Danskin's Theorem [4, Theorem 10.1] (see also [14, Theorem 10.3.4]). To gain some heuristic understanding of (155), suppose the maximum $\hat{x}(t)$ in (151) is unique for each t, and then

$$\begin{aligned} \tfrac{d}{dt}\langle p_t \rangle &= \tfrac{\partial}{\partial t} p_t(\hat{x}(t)) + \nabla p_t(\hat{x}(t)) \dot{\hat{x}}(t) \\ &= \tfrac{\partial}{\partial t} p_t(\hat{x}(t)) \\ &= F(p_t, u(t), y(t))(\hat{x}(t)) \\ &= -\tfrac{1}{2} |y(t) - C(\hat{x}(t))|^2 \end{aligned}$$

using $\nabla p_t(\hat{x}(t)) = 0$ (because by definition $\hat{x}(t)$ maximizes $p_t(\cdot)$).

We also need an assumption concerning the existence of an equilibrium for the PDE in (149), and stability of this system:

Assumption 6.9. *There exists a unique smooth solution $p_e \in \mathcal{X}$ of the stationary HJB equation*

$$0 = F(p_e, 0, 0) \tag{156}$$

such that p_e is strictly negative definite ($p_e(x) \le -c_e |x|^2$, $c_e > 0$), $p_e(0) = 0$, and antistable (essentially $-(A - BB'\nabla p_e')$ asymptotically stable) in the following sense:

1. *For any $v \in L_2[0, \infty)$, if $\xi_t(\cdot)$ is the solution on $[0, t]$ of*

$$\dot{\xi}_t(s) = A(\xi_t(s)) - B(\xi_t(s))B(\xi_t(s))\nabla p_e(\xi_t(s))' + B(\xi_t(s))v(s), \quad 0 \le s \le t, \ \xi(t) = x, \tag{157}$$

then

$$\int_0^t |\xi_t(s)|^2 ds \le c_0 |x|^2 + c_1 \int_0^t |v(s)|^2 \, ds \quad \forall t \ge 0. \tag{158}$$

2. *For any $(u, y) \in \mathcal{W}$, the information state p_t given by* (149) *with $p_0 = p_e$ or $p_0 = \mathbf{\Delta}_0$ satisfies*

$$p_t \to p_e + c(u, y) \tag{159}$$

as $t \to \infty$, where $c(u, y) \in \mathbf{R}$ is a constant depending on (u, y).

3. *In addition, p_t is uniformly bounded above as follows (tight):*

$$p_t(x) < -c_2|x|^2 + c_3 \ \forall x \in \mathbf{R}^n, \tag{160}$$

with $c_2 = c_2(u,y) > 0$, $c_3 = c_3(u,y) \geq 0$.

4. *There exists $T(x) \geq 0$ and $k(x) \geq 0$ such that for any $w = (u,y) \in \mathcal{W} \cap L_2[0,\infty)$, the information state p_t given by (149) with $p_0 = p_e$ or $p_0 = \mathbf{\Delta}_0$ satisfies*

$$-k(x)(1+ \parallel w \parallel^2_{L_2[0,\infty)}) \leq p_t(x) \quad \forall t \geq T(x). \tag{161}$$

The function p_e is given by

$$\begin{aligned} p_e(x) &= \sup_{v\in\mathcal{U}}\{-\lim_{T\to\infty} \tfrac{1}{2}\int_{-T}^0 [|v(s)|^2 + |C(\xi(s))|^2]\,ds \\ &\qquad | \ \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))v(s), \quad -T \leq s \leq 0, \\ &\qquad \lim_{T\to\infty} \xi(-T) = 0, \quad \xi(0) = x\} \\ &= \lim_{T\to\infty} \sup_{v\in\mathcal{U}\cap L_2[-T,0]}\{-\tfrac{1}{2}\int_{-T}^0 [|v(s)|^2 + |C(\xi(s))|^2]\,ds \\ &\qquad | \ \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))v(s), \quad -T \leq s \leq 0, \\ &\qquad \xi(-T) = 0, \quad \xi(0) = x\}. \end{aligned} \tag{162}$$

Remark 6.10. Assumption 6.9 is essentially an H_2 filter assumption together with stability consequences [14, section 11.4], [24, section 4.2]. Item 4 also involves controllability.

LEMMA 6.11. *Given $(u,y) \in \mathcal{W} \cap L_{2,e}$,*

1. *the set $[[p_t]]$ is compact for each $t \geq 0$;*
2. *for each $t \geq 0$ we have*

$$\langle p_t \rangle + \tfrac{1}{2}\int_0^t |\phi(s)|^2\,ds = \langle p_0 \rangle = 0; \tag{163}$$

3. *for some constant $c(u,y)$,*

$$\lim_{t\to\infty} \langle p_t \rangle = c(u,y) = -\tfrac{1}{2}\int_0^\infty |\phi(s)|^2\,ds, \tag{164}$$

whenever $(u,y) \in \mathcal{W} \cap L_2[0,\infty)$.

Proof. Item 1 follows from the upper bound (160) by Assumption 6.9. The equality (163) of item 2 follows by integrating the derivative (155) by Assumption 6.7, and the definition of ϕ, (149).

We turn now to item 3; this will follow from Assumption 6.9. Let $t > 0$ and combine the bound (161) with item 2, (163), to give

$$-k(x)(1+ \parallel w \parallel^2_{L_2[0,\infty)}) + \tfrac{1}{2}\int_0^t |\phi(s)|^2 ds \leq 0.$$

This shows that the monotone nondecreasing map $t \mapsto \frac{1}{2}\int_0^t |\phi(s)|^2 ds$ is bounded, and hence the following limits exist and are equal:

$$-\lim_{t\to\infty} \langle p_t \rangle = \tfrac{1}{2}\int_0^\infty |\phi(s)|^2 ds. \tag{165}$$

This proves item 3, (164). In fact, it follows from [14, Appendix C] that $\lim_{t\to\infty} \langle p_t \rangle = \langle p_e + c(u,y) \rangle = c(u,y)$. ∎

6.2.2. Finite horizon left representation: L_{tvP}. We set $p_0 = \mathbf{\Delta}_0$ to define $\mathsf{L}_{tvP} : \mathcal{W} \cap L_{2,e} \to \mathcal{Y} \cap L_{2,e}$ by

$$\mathsf{L}_{tvP}\colon \begin{cases} \dot{p} = F(p,u,y), \quad p|_{t=0} = \mathbf{\Delta}_0, \\ \phi = C(\hat{x}) + \begin{bmatrix} 0 & -I \end{bmatrix} \begin{bmatrix} u \\ y \end{bmatrix}. \end{cases} \tag{166}$$

THEOREM 6.12. *The system L_{tvP} defined by* (166) *is a finite time left representation for the plant P given by* (65) *and is contractive and co-inner.*

Proof. We must check that the operator L_{tvP} defined by (166) satisfies the definitions given in section 3.2, part 1.

Let $(u,y) \in \mathcal{G}_P \cap L_{2,e}$, so that $y = Pu$. Let ξ be the solution of

$$\dot{\xi} = A(\xi) + B(\xi)u, \quad \xi(0) = 0,$$

on $[0,\infty)$. Then $y = C(\xi)$ and by the representation (154), we have

$$p_t(\xi(t)) = 0 \quad \text{for all} \quad t \geq 0$$

using $v(\cdot) = 0$. This implies $\hat{x}(t) = \xi(t)$, $t \geq 0$, and $\phi(\cdot) = 0$. Hence $(u,y) \in \ker \mathsf{L}_{tvP}$.

Let $(u,y) \in \ker \mathsf{L}_{tvP}$. Then

$$\mathsf{L}_{tvP}(u,y) = \phi = 0,$$

and by (163) we have

$$p_t(\hat{x}(t)) = \langle p_t \rangle = 0 \tag{167}$$

for all $t \geq 0$. In the representation (154), let $v_t^*(\cdot)$ and $\xi_t^*(\cdot)$ be optimal on $[0,t]$ with end condition $x = \hat{x}(t)$, so that

$$\dot{\xi}_t^*(s) = A(\xi_t^*(s)) + B(\xi_t^*(s))(u(s) + v_t^*(s)), \quad 0 \leq s \leq t, \quad \xi_t^*(t) = \hat{x}(t).$$

Then (167) and (154) imply

$$0 = p_t(\hat{x}(t)) = p_0(\xi_t^*(0)) - \tfrac{1}{2}\int_0^t [|v_t^*(s)|^2 + |y(s) - C(\xi_t^*(s))|^2] ds,$$

which implies

$$\begin{aligned} p_0(\xi_t^*(0)) = 0, &\quad \text{which implies} \quad \xi_t^*(0) = 0; \\ \textstyle\int_0^t |v_t^*(s)|^2 ds = 0, &\quad \text{which implies} \quad v_t^*(\cdot) = 0; \\ \textstyle\int_0^t |y(s) - C(\xi_t^*(s))|^2 ds = 0, &\quad \text{which implies} \quad y(\cdot) = C(\xi_t^*(\cdot)). \end{aligned}$$

This implies $y = Pu$ on $[0,\infty)$ and so $(u,y) \in \mathcal{G}_P \cap L_{2,e}$. Consequently, L_{tvP} is a finite horizon left representation of P.

Next, let $w = (u,y) \in \mathcal{W} \cap L_{2,e}$. By (163), Lemma 6.11, we have

$$\tfrac{1}{2}\int_0^T |\phi(s)|^2 \, ds = -\langle p_T \rangle,$$

which implies, by (154) and the definition (153) of $p_o = \mathbf{\Delta}_0$,

$$\begin{aligned} \tfrac{1}{2}\textstyle\int_0^T |\mathsf{L}_{tvP}(w)(s)|^2 ds = \inf_{v \in \mathcal{U} \cap L_{2,e}} \{ & \tfrac{1}{2}\textstyle\int_0^T [|v(s)|^2 + |y(s) - C(\xi(s))|^2] \, ds \\ & \mid \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(u(s) + v(s)), \quad 0 \leq s \leq T, \\ & \xi(0) = 0\}. \end{aligned} \tag{168}$$

Let $\tilde{w} = (\tilde{u}, \tilde{y}) \in \mathcal{G}_P \cap L_{2,e}$, so that $\tilde{y} = P\tilde{u}$, with state $\tilde{\xi}$, and

$$\dot{\tilde{\xi}} = A(\tilde{\xi}) + B(\tilde{\xi})\tilde{u}, \quad \tilde{\xi}(0) = 0, \quad \tilde{y} = C(\tilde{\xi})$$

on $[0, \infty)$. Set $v = \tilde{u} - u$ in (168) to obtain

$$\tfrac{1}{2}\int_0^T |\mathsf{L}_{tvP}(w)(s)|^2 ds \le \tfrac{1}{2}\int_0^T \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds.$$

This holds for all $(\tilde{u}, \tilde{y}) \in \mathcal{G}_P \cap L_{2,e}$, and so

(169)

$$\tfrac{1}{2}\int_0^T |\mathsf{L}_{tvP}(w)(s)|^2 ds \le \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P\cap L_{2,e}} \left\{ \tfrac{1}{2}\int_0^T \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds \right\}.$$

Setting $(\tilde{u}, \tilde{y}) = (0, 0)$ in (169) gives the contractive property (20).

Given any $v \in \mathcal{U} \cap L_{2,e}$, set $\tilde{u} = u + v$, $\tilde{y} = P\tilde{u}$, and we see from (168) that equality holds in (169):

(170)

$$\tfrac{1}{2}\int_0^T |\mathsf{L}_{tvP}(w)(s)|^2 ds = \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P\cap L_{2,e}} \left\{ \tfrac{1}{2}\int_0^T \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds \right\};$$

this establishes (21) of the positive time co-inner property.

Now suppose $w = (u, y) \in \mathcal{G}_P \cap L_2[0, \infty)$. By Lemma 6.11, item 3, (164), we know that the limits as $T \to \infty$ of both sides of (170) exist and are equal. We need to show that this value is given by the right-hand side of (22), the second part of the positive time co-inner property.

Let $\tilde{w} = (\tilde{u}, \tilde{y}) \in \mathcal{W} \cap L_2[0, \infty)$. Then by (170) we have

$$\tfrac{1}{2}\int_0^T |\mathsf{L}_{tvP}(w)(s)|^2 ds \le \tfrac{1}{2}\int_0^\infty \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds$$

and hence

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \le \tfrac{1}{2}\int_0^\infty \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds.$$

This implies

(171)

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \le \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P\cap L_2[0,\infty)} \left\{ \tfrac{1}{2}\int_0^\infty \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds \right\}.$$

Also, by (170) we have

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \ge \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P\cap L_{2,e}} \left\{ \tfrac{1}{2}\int_0^T \left[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2\right] ds \right\}$$

for all $T \ge 0$. Let $\varepsilon > 0$. Then for each $T \ge 0$, select $\tilde{w}^T = (\tilde{u}^T, \tilde{y}^T) \in \mathcal{G}_P \cap L_2[0, T]$ such that

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \ge \tfrac{1}{2}\int_0^T |w(s) - \tilde{w}^T(s)|^2 \, ds - \varepsilon.$$

Set $v^T = \tilde{u}^T - u$ on $[0,T]$, and $v^T = 0$ on (T,∞). Then we have

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \tfrac{1}{2}\int_0^T [|v^T(s)|^2 + |y(s) - \tilde{y}^T(s)|^2]\, ds - \varepsilon \tag{172}$$

and

$$\begin{aligned} \dot{\tilde{\xi}}^T &= A(\tilde{\xi}^T) + B(\tilde{\xi}^T)(u + v^T), \quad \tilde{\xi}^T(0) = 0, \\ \tilde{y}^T &= C(\xi^T) \end{aligned} \tag{173}$$

on $[0,T]$. Now inequality (172) implies that $\{v^T\}_{T>0}$ is bounded in $L_2[0,\infty)$. By weak compactness, let $\{v^{T_i}\}$ denote a weakly convergent subsequence, with weak limit $v^* \in L_2[0,\infty)$. Similarly, $\{\tilde{y}^T\}_{T>0}$ is bounded in $L_2[0,\infty)$, with weak limit $\tilde{y}^* \in L_2[0,\infty)$ (use the same index T_i for the convergent subsequence, without loss of generality).

Let $S > 0$ be arbitrary. Then for any $T \geq S$ inequality (172) implies

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \tfrac{1}{2}\int_0^S [|v^T(s)|^2 + |y(s) - \tilde{y}^T(s)|^2]\, ds - \varepsilon. \tag{174}$$

Let $T = T_i$ in (174) and send $i \to \infty$, to obtain

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \tfrac{1}{2}\int_0^S [|v^*(s)|^2 + |y(s) - \tilde{y}^*(s)|^2]\, ds - \varepsilon \tag{175}$$

by weak lower semicontinuity. Let $S \to \infty$ in (175) to obtain

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \tfrac{1}{2}\int_0^\infty [|v^*(s)|^2 + |y(s) - \tilde{y}^*(s)|^2]\, ds - \varepsilon. \tag{176}$$

Next set $\tilde{w}^* = (\tilde{u}^*, \tilde{y}^*) = (u + v^*, \tilde{y}^*) \in L_2[0,\infty)$, so that

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \tfrac{1}{2}\int_0^\infty |w(s) - \tilde{w}^*(s)|^2\, ds - \varepsilon. \tag{177}$$

It remains to check that $\tilde{w}^* \in \mathcal{G}_P$. Again let $S > 0$ be arbitrary and consider the system (173) on $[0,S]$ for $T = T_i > S$. Let $\tilde{\xi}^*$ be the solution of

$$\dot{\tilde{\xi}}^* = A(\tilde{\xi}^*) + B(\tilde{\xi}^*)(u + v^*) \tag{178}$$

on $[0,S]$. Then by standard ODE estimates (using the Holder and Jensen inequalities), for $t \in [0,S]$,

$$|\tilde{\xi}^{T_i}(t) - \tilde{\xi}^*(t)|^2 \leq K\int_0^t |\tilde{\xi}^{T_i}(s) - \tilde{\xi}^*(s)|^2 ds + K\left|\int_0^t B(\tilde{\xi}^*(s))(v^{T_i}(s) - v^*(s))ds\right|^2 \tag{179}$$

for a suitable constant $K > 0$. Note that by weak convergence, the second term in the right-hand side of (179) tends to zero as $i \to \infty$ (since $s \mapsto B(\tilde{\xi}^*(s)) \in L_2[0,\infty)$ by our hypotheses on B). Then an application of Gronwall's inequality allows us to conclude that $\tilde{\xi}^{T_i}(t) \to \tilde{\xi}^*(t)$ as $i \to \infty$ uniformly in $t \in [0,S]$. Moreover, we have $\tilde{y}^*(t) = C(\tilde{\xi}^*(t))$ for $t \in [0,S]$, and hence $\tilde{w}^* \in \mathcal{G}_P \cap L_2[0,S]$. But $S > 0$ was arbitrary, and we saw earlier that $\tilde{w}^* \in L_2[0,\infty)$, so we have shown that $\tilde{w}^* \in \mathcal{G}_P \cap L_2[0,\infty)$.

Therefore

$$\tfrac{1}{2}\int_0^\infty |\mathsf{L}_{tvP}(w)(s)|^2 ds \geq \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P\cap L_2[0,\infty)} \left\{\tfrac{1}{2}\int_0^\infty |w(s) - \tilde{w}^*(s)|^2\, ds\right\} - \varepsilon. \tag{180}$$

Inequalities (171) and (180) now imply (22). ∎

6.2.3. Left representation: L_{eP}. We set $p_0 = p_e$ to define $\mathsf{L}_{eP} : \mathcal{W} \to \mathcal{Y}$ by

$$\mathsf{L}_{eP}\colon \begin{cases} \dot{p} = F(p,u,y), \quad p|_{t=-\infty} = p_e, \\ \phi = C(\hat{x}) + \begin{bmatrix} 0 & -I \end{bmatrix} \begin{bmatrix} u \\ y \end{bmatrix}. \end{cases} \tag{181}$$

THEOREM 6.13. *The system L_{eP} defined by* (181) *is a left representation of the plant P given by* (65) *and is contractive and co-inner.*

Proof. We must check that the operator L_{eP} defined by (166) satisfies the definitions given in section 3.2, part 2.

Let $(u,y) \in \mathcal{G}_P$, so that $y = Pu$. Since $u \in L_{2,ce}$, there exists T_0 finite such that $u(t) = 0$, $y(t) = 0$, and $p_t = p_e$ for all $t \le T_0$. Let ξ be the solution of

$$\dot{\xi} = A(\xi) + B(\xi)u, \quad \xi(T_0) = 0,$$

on $[T_0, \infty)$. Then $y = C(\xi)$ and by the representation (154), which here takes the form

$$\begin{aligned} p_t(x) = \sup_{v \in \mathcal{U} \cap L_2[T_0,t]} \{ & p_e(\xi(T_0)) - \tfrac{1}{2}\textstyle\int_{T_0}^{t} [|v(s)|^2 + |y(s) - C(\xi(s))|^2]\, ds \\ & \mid \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(u(s) + v(s)), \quad T_0 \le s \le t, \\ & \xi(t) = x \}, \end{aligned} \tag{182}$$

we have

$$p_t(\xi(t)) = 0 \quad \text{for all} \quad t \ge T_0$$

using $v(\cdot) = 0$. This implies $\hat{x}(t) = \xi(t)$, $t \ge T_0$, and $\phi(\cdot) = 0$. Hence $(u,y) \in \ker \mathsf{L}_{eP}$.

Let $(u,y) \in \ker \mathsf{L}_{eP}$. Since $u \in L_{2,ce}$, there exists T_0 finite such that $u(t) = 0$, $y(t) = 0$, and $p_t = p_e$ for all $t \le T_0$. Then

$$\mathsf{L}_{eP}(u,y) = \phi = 0,$$

and by (163) (with 0 replaced by T_0) we have

$$p_t(\hat{x}(t)) = \langle p_t \rangle = 0 \tag{183}$$

for all $t \ge T_0$. In the representation (182), let $v_t^*(\cdot)$ and $\xi_t^*(\cdot)$ be optimal on $[T_0, t]$ with end condition $x = \hat{x}(t)$, so that

$$\dot{\xi}_t^*(s) = A(\xi_t^*(s)) + B(\xi_t^*(s))(u(s) + v_t^*(s)), \quad T_0 \le s \le t, \quad \xi_t^*(t) = \hat{x}(t).$$

Then (183) and (182) imply

$$0 = p_t(\hat{x}(t)) = p_e(\xi_t^*(T_0)) - \tfrac{1}{2}\int_{T_0}^{t} [|v_t^*(s)|^2 + |y(s) - C(\xi_t^*(s))|^2] ds,$$

which implies

$$\begin{aligned} p_e(\xi_t^*(T_0)) = 0, \quad & \text{which implies} \quad \xi_t^*(T_0) = 0; \\ \textstyle\int_{T_0}^{t} |v_t^*(s)|^2 ds = 0, \quad & \text{which implies} \quad v_t^*(\cdot) = 0; \\ \textstyle\int_{T_0}^{t} |y(s) - C(\xi_t^*(s))|^2 ds = 0, \quad & \text{which implies} \quad y(\cdot) = C(\xi_t^*(\cdot)). \end{aligned}$$

This implies $y = Pu$ on $[T_0, \infty)$ and so $(u,y) \in \mathcal{G}_P$. Consequently, L_{eP} is a left representation of P.

Next, let $w = (u, y) \in \mathcal{W}$. Since $w \in L_{2,ce}$, there exists T_0 finite such that $u(t) = 0$, $y(t) = 0$ and $p_t = p_e$, $\phi(t) = 0$ for all $t \le T_0$. By (163), Lemma 6.11 (with 0 replaced by T_0, and $p_{T_0} = p_e$), we have

$$\tfrac{1}{2}\int_{T_0}^{T} |\phi(s)|^2\, ds = -\langle p_T \rangle,$$

which implies, by (182),

(184)

$$\tfrac{1}{2}\textstyle\int_{T_0}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds = \inf_{v\in\mathcal{U}\cap L_2[T_0,T]}\{-p_e(\xi(T_0)) + \tfrac{1}{2}\int_{T_0}^{T}[|v(s)|^2 + |y(s) - C(\xi(s))|^2]\, ds \\ |\ \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(u(s) + v(s)),\quad T_0 \le s \le T\}$$

(the infimum is over all possible trajectories ξ and controls v, with no end point constraint). Let $\tilde{w} = (\tilde{u}, \tilde{y}) \in \mathcal{G}_P$, so that $\tilde{y} = P\tilde{u}$. Since $\tilde{w} \in L_{2,ce}$, there exists T_1 finite such that $\tilde{u}(t) = 0$, $\tilde{y}(t) = 0$ for all $t \le T_1$. Let $T_2 = \min(T_1, T_0)$. Now (184) holds with T_0 replaced by T_2:

(185)

$$\tfrac{1}{2}\textstyle\int_{T_2}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds = \inf_{v\in\mathcal{U}\cap L_2[T_0,T]}\{-p_e(\xi(T_2)) + \tfrac{1}{2}\int_{T_2}^{T}[|v(s)|^2 + |y(s) - C(\xi(s))|^2]\, ds \\ |\ \dot{\xi}(s) = A(\xi(s)) + B(\xi(s))(u(s) + v(s)),\quad T_2 \le s \le T\}.$$

The state $\tilde{\xi}$ corresponding to $\tilde{w}$ satisfies

$$\dot{\tilde{\xi}} = A(\tilde{\xi}) + B(\tilde{\xi})\tilde{u},\quad \tilde{\xi}(T_2) = 0,\quad \tilde{y} = C(\tilde{\xi})$$

on $[T_2, \infty)$. Set $v = \tilde{u} - u$ in (185) to obtain

$$\tfrac{1}{2}\int_{T_2}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds \le \tfrac{1}{2}\int_{T_2}^{T} [|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2]\, ds$$

(since $p_e(\xi(T_2)) = 0$). This holds for all $(\tilde{u}, \tilde{y}) \in \mathcal{G}_P$, and so

(186)

$$\tfrac{1}{2}\int_{-\infty}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds \le \inf_{(\tilde{u},\tilde{y})\in\mathcal{G}_P}\left\{\tfrac{1}{2}\int_{-\infty}^{T}[|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2]\, ds\right\}.$$

Setting $(\tilde{u}, \tilde{y}) = (0, 0)$ in (186) gives the contractive property (26).

In order to prove the co-inner property (27), we must show that (186) holds with equality. To this end, let $\varepsilon > 0$. Let v_1 and ξ_1 be ε-optimal in (184), so that

$$\tfrac{1}{2}\int_{T_0}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds \ge -p_e(\xi_1(T_0)) + \tfrac{1}{2}\int_{T_0}^{T} [|v_1(s)|^2 + |y(s) - C(\xi_1(s))|^2]\, ds - \varepsilon,$$

where

$$\dot{\xi}_1(s) = A(\xi_1(s)) + B(\xi_1(s))(u(s) + v_1(s)),\quad T_0 \le s \le T.$$

Next, using the representation (162) for $p_e(x)$ with $x = \xi_1(T_0)$, select $S \ge 0$ and v_2 so that

$$-p_e(\xi_1(T_0)) \ge \tfrac{1}{2}\int_{-S}^{T_0} [|v_2(s)|^2 + |C(\xi_2(s))|^2]\, ds - \varepsilon,$$

where

$$\dot{\xi}_2(s) = A(\xi_2(s)) + B(\xi_2(s))v_2(s), \quad -S \le s \le T_0, \quad \xi_2(T_0) = \xi_1(T_0).$$

Set

$$v(s) = \begin{cases} v_1(s) & \text{on } [T_0, T], \\ v_2(s) & \text{on } [-S, T_0), \\ 0 & \text{on } (-\infty, -S), \end{cases}$$

with associated state trajectory ξ. Then combining the above, we see that

$$\begin{aligned} \textstyle\int_{T_0}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds &\ge \tfrac{1}{2} \textstyle\int_{-S}^{T} [|v(s)|^2 + |y(s) - C(\xi(s))|^2]\, ds - 2\varepsilon \\ &\ge \inf_{(\tilde{u},\tilde{y}) \in \mathcal{G}_P} \left\{ \tfrac{1}{2} \textstyle\int_{-\infty}^{T} [|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2]\, ds \right\} - 2\varepsilon \end{aligned}$$

with $\tilde{u} = u + v$, etc. This proves equality in (186),

(187)
$$\int_{-\infty}^{T} |\mathsf{L}_{eP}(w)(s)|^2 ds = \inf_{(\tilde{u},\tilde{y}) \in \mathcal{G}_P} \left\{ \tfrac{1}{2} \int_{-\infty}^{T} [|u(s) - \tilde{u}(s)|^2 + |y(s) - \tilde{y}(s)|^2]\, ds \right\},$$

and hence (27).

The second part (28) of the co-inner property can be proved using (184), (187), and the techniques used in the proof of Theorem 6.12. □

6.2.4. Special case. To relate our state-space realizations (166), (181) for the left representations with other results in the nonlinear literature [24, Theorem 13 and equation (40)], [25, Theorem 2.1 and equation (9)], we present the following discussion.

Consider the information state p_t, the state in the realizations (166), (181) with suitable initialization. Let us suppose that $\hat{x}(t)$, the maximizer of $p_t(\cdot)$, is unique. Then given appropriate differentiability, we can perform the following calculations. Since $\hat{x}(t)$ maximizes $p_t(\cdot)$, we have (as mentioned earlier)

$$\nabla p_t(\hat{x}(t)) = 0 \quad \text{for all} \quad t > 0.$$

Differentiate this with respect to t to obtain

$$\frac{d}{dt} p_t(\hat{x}(t)) = \frac{\partial}{\partial t} \nabla p_t(\hat{x}(t)) + \nabla^2 p_t(\hat{x}(t)) \dot{\hat{x}}(t) = 0.$$

Now we suppose that the Hessian is positive definite:

$$-\nabla^2 p_t(\hat{x}(t)) > 0$$

for all $t > 0$. Then

$$\dot{\hat{x}}(t) = [-\nabla^2 p_t(\hat{x}(t))]^{-1} \frac{\partial}{\partial t} \nabla p_t(\hat{x}(t)),$$

and taking the gradient of $\dot{p} = F(p, u, y)$ with respect to x and using the fact that $\nabla p_t(\hat{x}(t)) = 0$ we obtain

(188)
$$\begin{aligned} \dot{\hat{x}}(t) \;&= \big(A(\hat{x}(t)) - [-\nabla^2 p_t(\hat{x}(t))]^{-1} \nabla C(\hat{x}(t))' C(\hat{x}(t))\big) \\ &\quad + B(\hat{x}(t))u(t) + [-\nabla^2 p_t(\hat{x}(t))]^{-1} \nabla C(\hat{x}(t))' y(t). \end{aligned}$$

Associated with this equation is the error quantity

$$\phi(t) = C(\hat{x}(t)) - y(t) \tag{189}$$

from (166), (181). The pair of equations (188), (189), is similar to the state space realizations [24, equation (40)], [25, equation (9)] if $[-\nabla^2 p_t(\hat{x}(t))]^{-1}\nabla C(\hat{x}(t))'$ takes the place of $k(x)$ in [24, equation (40)] or if $[-\nabla^2 p_t(\hat{x}(t))]$ replaces $M(x)$ in [25, equation (9)]. We remark that in the linear case $p_t(x)$ is a quadratic form with quadratic term $-\frac{1}{2}x'Y_e^{-1}x$ and so $[-\nabla^2 p_t(\hat{x}(t))] = Y_e^{-1}$ and the state-space realizations (188) and (189) reduce to the well-known linear equations.

We remark also that the co-inner definition introduced in this paper (section 3.2) differs from the one used in [25]; there the co-inner property is defined in terms of a Hamiltonian system of equations [24, Definition 7 and equation (34)], and it appears that these equations are related to the Pontryagin equations associated with the optimal control representation of $p_t(x)$ (recall (154)).

7. Concluding remarks. This paper has been concerned with robustness of nonlinear systems using the closely related gap metric and coprime factor approaches to uncertainty. There have been two main streams of thought running through the paper:

(i) signal-based definitions of the gap metric, robustness results in terms of the parallel projection operators, and synthesis of controllers based on minimizing the induced norms of the parallel projections (sections 4.1, 4.2, 4.3, 4.4, 5);

(ii) graph representations, robustness of feedback systems in terms of perturbations of the graph "symbols," and state-space realizations of graph symbols (sections 3, 4.4, 4.5, 6).

For linear systems, (ii) was the earliest to develop fully, and technical results there provided an important resource for the development of a more operator-based approach along the lines of (i). For nonlinear systems there have been several approaches to (ii) which potentially pave the way for a full robustness theory. Our contention here is that the complete working out of (i) in this paper has shed new light on how to develop (ii) in a way that closely matches the needs of the robustness theory.

The two streams of thought have by no means been independent in this paper—they touch one another most closely in section 4.4 and in the commonality of the nonlinear H_∞ control techniques used in sections 5 and 6. It is interesting to note that the realization theory for graph representations has been presented as the final topic of the paper (section 6), with its importance being a proof of existence of the graph representations defined here. In contrast, this topic was an essential early building block in the development of the linear coprime factorization theory.

Appendix A. Nonlinear H_∞ control. We will now review the nonlinear H_∞ controller synthesis theory developed in [17], [14] for the class of nonlinear systems or *generalized plants*:

$$\begin{aligned} \dot{x} &= A(x) + B_1(x)w + B_2(x)u, & x(0) &= x_0, \\ z &= C_1(x) + D_{12}u, & D_{12}'D_{12} &= I_m, \\ y &= C_2(x) + D_{21}w, & D_{21}D_{21}' &= I_q. \end{aligned} \tag{190}$$

In these equations $x(t) \in \mathbf{R}^n$ denotes the state of the system and $y(t) \in \mathbf{R}^q$ is the measurement signal. The output to be regulated is $z(t) \in \mathbf{R}^p$. The control input is $u(t) \in \mathbf{R}^m$, while $w(t) \in \mathbf{R}^l$ is an exogenous disturbance input. We assume that all the problem data are smooth functions of x with bounded first derivatives, that B_1

and B_2 are bounded, and that the origin is an equilibrium state: $A(0) = 0, C_1(0) = 0$, and $C_2(0) = 0$. In brief, the generalized plant is

$$\left[\begin{array}{c|c|c} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ \hline C_2 & D_{21} & 0 \end{array}\right].$$

The (output feedback) controller K is assumed to be a causal mapping $y \in \mathcal{Y} \mapsto u \in \mathcal{U}$, where $\mathcal{U}$ and $\mathcal{Y}$ are signal spaces as described in section 2. Such a controller is called admissible if the closed-loop equations associated with K and (190) are well-defined in the sense that they have unique solutions in $L_{2,e}$.

A controller K is said to solve the H_∞ control problem provided the closed-loop system is γ-dissipative and internally stable. The closed-loop system is γ-*dissipative* if

$$\tfrac{1}{2}\int_0^T |z(s)|^2 ds \le \tfrac{1}{2}\gamma^2 \int_0^T |w(s)|^2 ds + \beta(x(0)) \tag{191}$$

for some nonnegative function β with $\beta(0) = 0$ and every $w \in L_2[0,T]$ for all $T \ge 0$. *Internal stability* means that if $w \in L_2$, then $u(\cdot), y(\cdot), z(\cdot), x(\cdot) \in L_2$, and consequently $x(t) \to 0$ as $t \to \infty$.

A.1. The state feedback problem. Let us consider static state feedback controllers of the form

$$u = u(x),$$

where $u : \mathbf{R}^n \to \mathbf{R}^m$. Combining this with (190) gives the following closed-loop system:

$$\begin{aligned} \dot{x} &= A(x) + B_2(x)u(x) + B_1(x)w, \\ z &= C_1(x) + D_{12}(x)u(x). \end{aligned} \tag{192}$$

If there exists a static state feedback controller $u(x)$ such that this closed-loop system is γ-dissipative, we know that there exists a storage function $V(x) \ge 0$ which satisfies $V(0) = 0$ and the HJBI equation

$$\nabla V(A - B_2E_1^{-1}D_{12}'C_1) - \tfrac{1}{2}\nabla V(B_2E_2^{-1}B_2' - \gamma^{-2}B_1B_1')\nabla V' + \tfrac{1}{2}C_1'(I - D_{12}E_1^{-1}D_{12}')C_1 = 0 \tag{193}$$

(here $E_1 = D_{12}'D_{12} > 0$); the function $V(x)$ need not necessarily be smooth, in which case the PDE (193) can be interpreted in the viscosity sense [23, Theorem 3.4]; see also [14, section 5.4].

Conversely, if (193) has a smooth solution $V(x) > 0$ if $x \ne 0$, $V(0) = 0$, then the state feedback controller

$$u^*_{state}(x) = -(D_{12}'C_1(x) + B_2(x)'\nabla V(x)') \tag{194}$$

renders the closed loop γ-dissipative. Since the control law depends on ∇V, we assume that $V(\cdot)$ is differentiable in some sense (C^1 with globally Lipschitz derivative is enough). The stability of the closed loop follows from strict positive definiteness of V and the zero state detectability of $((A + B_2u^*_{state})(x), (C_1 + D_{12}u^*_{state})(x))$; see, e.g., [26, section 6.1].

A.2. The information state. We will now consider the case of output feedback controllers of the form $K : y \mapsto u$. We transform the output feedback problem to a new state feedback problem using the information state $p_t(x) = p(x,t)$ defined by the equation

$$\begin{aligned}\frac{\partial}{\partial t}p = &-\nabla p(A + B_1 D_{21}'(y - C_2) + B_2 u) + \gamma^{-2}\tfrac{1}{2}\nabla p B_1(I - D_{21}' D_{21})B_1'\nabla p' \\ &-\gamma^2\tfrac{1}{2}|y - C_2|^2 + \tfrac{1}{2}|C_1 + D_{12}u|^2.\end{aligned} \tag{195}$$

In shorthand notation, we write $p_t(\cdot) = p(\cdot, t)$ and regard p_t as the state of a new dynamical system with state equations

$$\dot{p} = F(p, u, y), \tag{196}$$

where $F(p,u,y)$ is the nonlinear differential operator defined in (195). The state space is an appropriate function space $\mathcal{X}$ (e.g., the Banach space of continuous functions with at most quadratic growth with the norm $\| p \|_{\mathcal{X}} = \sup_{x\in\mathbf{R}^n} \frac{|p(x)|}{1+|x|^2}$). It is known (see [14, Section 3.1]) that if a controller $K : y \mapsto u$ exists such that the closed loop is γ-dissipative, then (195) has a solution. If the solution is not smooth, it can be interpreted in the viscosity sense [3], [6]. However, we will assume it to be smooth.

In the equilibrium (or steady-state) case ($u \equiv 0$ and $y \equiv 0$), this equation reduces to

$$\nabla p_\infty(A - B_1 D_{21}' C_2) - \gamma^{-2}\tfrac{1}{2}\nabla p_\infty B_1(I - D_{21}' D_{21})B_1'\nabla p_\infty' + \gamma^2\tfrac{1}{2}|C_2|^2 - \tfrac{1}{2}|C_1|^2 = 0, \tag{197}$$

or in shorthand, $F(p_\infty, 0, 0) = 0$. A particular equilibrium solution p_e of (197), called a *control attractor*, is important. The present context is nonsingular in the sense of [14], meaning p_e is everywhere finite. The control attractor satisfies $p_e \le 0$, $p_e(0) = 0$, and

$$-(A - B_1 D_{21}' C_2 - \gamma^{-2} B_1[I - D_{21}' D_{21}]B_1'\nabla p_e') \quad \text{asymptotically stable} \tag{198}$$

(it is the unique such function). Convergence of p_t (when driven by $L_2[0,\infty)$ signals u, y) to a solution $p_\infty = p_e + c$ of (197) as $t \to \infty$ is discussed in [14] ($c = c(u,y) \in \mathbf{R}$ is a constant independent of x but depending on the signals u, y). To be precise, the particular type of stability (198) required is referred to in [14] as *incremental L_2 exponential antistability*.

A.3. Information state controller. In the output feedback case, the transformation afforded by the information state gives rise to a nonlinear PDE on an infinite-dimensional (Banach) space $\mathcal{X}$ (the analog of the PDE (193)), viz.

$$\inf_{u\in\mathbf{R}^m} \sup_{y\in\mathbf{R}^p} \{\nabla W(p)[F(p,u,y)]\} = 0, \tag{199}$$

where $\nabla W(p)$ is a linear operator (Frechet derivative). It is known that there exists a value function $W(p)$ solving this equation in a suitable sense [17], [18], [14]. In general it cannot be expected that W is smooth, and in fact at present there is no adequate theory for PDEs of the type (199); however, it can be interpreted in an integrated form, and various notions of smoothness of solution have been considered [18], [14]. We assume that smoothness facilitates system-theoretic interpretation and remark that smoothness issues do not arise in discrete time [17]. The value function

W should satisfy a number of properties in addition to (199): (i) $W(p) \geq \sup_x\{p(x)\}$, (ii) $p_1 \geq p_2$ implies $W(p_1) \geq W(p_2)$, and (iii) $W(p+c) = W(p)+c$ for all $c \in \mathbf{R}$. Also, in general, W has a nontrivial domain of finiteness dom$W$. For full details, see [18], [14]. Here, it is sufficient to note that a smooth solution of (199) defines an output feedback controller K^* via the optimal feedback function obtained by evaluating the infimum in (199) (cf. (194)):

$$u^*(p) = \nabla W(p)[-D_{12}'C_1 + B_2'\nabla p']. \tag{200}$$

The optimal information state controller is given by

$$K^*: \begin{cases} \dot{p} = F(p,u,y), & p_0 = p_e, \\ u = u^*(p). \end{cases} \tag{201}$$

This controller feeds back the information state, initialized at the control attractor p_e, and produces a γ-dissipative closed loop. For precise statements and stability results, see [14]. It turns out that $p_e \in \text{dom}W$ (in fact, $W(p_e) = 0$), and the antistabilizing property of p_e ensures that $p_t \in \text{dom}W$ for all $t \geq 0$ when driven by $L_2[0,\infty)$ signals u, y, and this will be the case provided p_t remains in a region relating to the smoothness of W [14, Chapter 4].

Further, the function $W(p)$ is related to the state feedback function $V(x)$ by

$$\max_x\{p(x) + V(x)\} \leq W(p), \tag{202}$$

and in particular

$$\max_x\{p_e(x) + V(x)\} \leq W(p_e) = 0 < +\infty. \tag{203}$$

Equation (203) is a necessary condition which holds irrespective of the smoothness of $W(p)$, and in fact does not depend on the existence of the optimal feedback $u^*(p)$ [14].

A.4. Certainty equivalence. Under certain conditions, the optimal information state controller simplifies to a controller which is equivalent to the certainty equivalence controller of [4]. Let $u^*_{state}(x)$ denote the optimal state feedback control, given by (194). Assume that the minimum stress state estimate

$$\bar{x}(t) = \arg\max_x\{p(x,t) + V(x)\} \tag{204}$$

is unique. Then the certainty equivalence controller exists and is given by

$$u^{ce}(t) = u^*_{state}(\bar{x}(t)), \tag{205}$$

giving a γ-dissipative closed loop [4], [18], [14]. If a certainty equivalence controller does not exist, it is necessary to solve (199) for the optimal information state controller (200). When the certainty equivalence assumptions are valid, essentially one can take

$$\hat{W}(p) = \max_x\{p(x) + V(x)\} \tag{206}$$

as a solution of (199) [18], [14].

AN INVERSE PROBLEM FOR A PARABOLIC VARIATIONAL INEQUALITY ARISING IN VOLATILITY CALIBRATION WITH AMERICAN OPTIONS*

YVES ACHDOU†

Abstract. In finance, the price of an American option is obtained from the price of the underlying asset by solving a parabolic variational inequality. The free boundary associated with this variational inequality can be interpreted as the price for which the option should be exercised. The calibration of volatility from the observations of the prices of an American option yields an inverse problem for the previously mentioned parabolic variational inequality. After studying the variational inequality and the exercise price, we give results concerning the sensitivity of the option price and of the exercise price with respect to the variations of the volatility. The inverse problem is addressed by a least square method, with suitable regularization terms. We give necessary optimality conditions involving an adjoint state for a simplified inverse problem and we study the differentiability of the cost function. Optimality conditions are also given for the genuine calibration problem.

Key words. variational inequalities, inverse problems, American options, calibration in finance

1. Introduction.

A *European vanilla call (resp., put) option is a contract giving its owner the right to buy (resp., sell) a share of a specific common stock at a fixed price K at a certain date T*. The specific stock is called *the underlying asset*. The fixed price K is termed *the strike*, and T is termed *the maturity*. The term *vanilla* is used to notify that this kind of option is the simplest one: indeed, there may be more complicated contracts. The price of the underlying asset at time t will be referred to as the *spot price* and will be noted x_t. Assuming that the market rules out arbitrage (the possibility to make an instantaneous risk-free benefit), it is very easy to see that the price of a call (resp., put) option at maturity is $u_\circ(x_T) = (x_T - K)_+$ (resp., $u_\circ(x_T) = (K - x_T)_+$). The function $u_\circ$ is called the payoff function.

In order to price the option before maturity, some assumptions have to be made on the spot price x_t: the Black–Scholes model involves the above mentioned underlying asset and a risk-free asset whose price at time t is $S_t^0 = e^{rt}$, where r is the interest rate; it assumes that the price of the risky asset is a solution to the following stochastic differential equation:

$$dx_t = x_t(\mu dt + \sqrt{\eta_t} dB_t), \tag{1.1}$$

where B_t is a standard Brownian motion on a probability space $(\Omega, \mathcal{A}, \mathbb{P})$. Here η_t is a positive number, and $\sqrt{\eta_t}$ is called the *volatility*. With the Black–Scholes assumptions, it is possible to prove that the option's price at time t is given by

$$P_t = u_e(t, x_t) \equiv \mathbb{E}^*(e^{-r(T-t)} u_\circ(x_T) | F_t), \tag{1.2}$$

where the expectation $\mathbb{E}^*$ is taken with respect to the so-called risk-neutral probability $\mathbb{P}^*$ (equivalent to $\mathbb{P}$ and under which $dx_t = x_t(rdt + \sqrt{\eta_t}dW_t)$, W_t being a standard Brownian motion under $\mathbb{P}^*$ and F_t being the natural filtration of W_t). Assuming that $\eta_t = \eta(t, x_t)$, where η is a smooth enough function, it can be seen that the pricing function u_e solves the parabolic PDE

$$\frac{\partial u_e}{\partial t} + \frac{\eta(t,x)x^2}{2}\frac{\partial^2 u_e}{\partial x^2} + rx\frac{\partial u_e}{\partial x} - ru_e = 0. \tag{1.3}$$

In contrast with European options, American options can be exercised any time before maturity: *An American vanilla call (resp., put) option is a contract giving its owner the right to buy (resp., sell) a share of a specific common stock at a fixed price K before a certain date T.* More generally, for a payoff function $u_\circ$, the American option with payoff $u_\circ$ and maturity T can be exercised at any $t < T$, yielding the payoff $u_\circ(x_t)$. Since the American option gives its owner more rights than the corresponding European option, its price should be higher.

Consider an American vanilla put. If its price P_t were less than $K - x_t$, then one could buy a put and a share of the underlying asset and exercise immediately the option, making a risk-free immediate benefit of $K - x_t - P_t > 0$: this is ruled out by the no arbitrage assumption, so we see that $P_t \geq (K - x_t)_+$. For a general payoff $u_\circ$, we have $P_t > u_\circ(x_t)$. Using the notion of strategy with consumption, the Black–Scholes model leads to the following formula for pricing an American option with payoff $u_\circ$: under the risk-neutral probability,

$$P_t = u(t, x_t) \equiv \sup_{\tau \in \mathcal{T}_{t,T}} \mathbb{E}^* \left(e^{-r(\tau - t)} u_\circ(x_\tau) \middle| F_t \right), \tag{1.4}$$

where $\mathcal{T}_{t,T}$ denotes the set of stopping times in $[t, T]$ (see [23] for the proof of this formula). It can be seen that for an American vanilla call, formula (1.4) coincides with (1.2), so American and European vanilla calls have the same price. This means that an American vanilla call should not be exercised before maturity.

It can be shown that the price u of the American put of strike K and maturity T is given as a solution to

$$\begin{aligned} &\frac{\partial u}{\partial t} + \frac{\eta x^2}{2}\frac{\partial^2 u}{\partial x^2} + rx\frac{\partial u}{\partial x} - ru \leq 0, \quad u(t,x) \geq (K-x)_+, \quad t \in [0,T),\ x > 0, \\ &\left(\frac{\partial u}{\partial t} + \frac{\eta x^2}{2}\frac{\partial^2 u}{\partial x^2} + rx\frac{\partial u}{\partial x} - ru \right)(u - (K-x)_+) = 0, \quad t \in [0,T),\ x > 0, \\ &u(t = T, x) = (K - x)_+; \end{aligned} \tag{1.5}$$

see [31] for a formal derivation of (1.5).

By using suitable Sobolev spaces, it is possible to use now well-known variational procedures for (1.5) (see Kinderlehrer and Stampacchia [19]) and prove the existence and uniqueness of u, under mild assumptions on η.

The volatility is the difficult parameter of the Black–Scholes model. It is convenient to take it to be constant, but then the computed options' prices do not match the prices given by the market. There are essentially three ways to improve on the Black-Scholes model with a constant volatility:

- Use a local volatility; i.e., assume that the volatility is a function of time and of the stock price. Then one has *to calibrate the volatility* from the market data, i.e., to find a volatility function which permits one to recover the prices of the options available on the market.

- Assume that the volatility is itself a stochastic process; see, for example, [14, 11].
- Generalize the Black–Scholes model by assuming that the spot price is, for example, a Lévy process; see [9] and references therein.

There is much discussion among specialists in finance on comparing the merits of the three kinds of models above. Here, we will focus on the first one and we will deal with the calibration of the local volatility.

In mathematical finance there have been a number of valuable studies on calibration with European options for which it is difficult to make a complete account: Avellaneda et al. [3] proposed a procedure based on the maximization of an entropy function via dynamic programming. Lagnado and Osher [21, 22], Jackson, Süli, and Howison [17], Coleman, Li, and Verma [8], and Achdou and Pironneau [2] used, as we do here, a least square fit to the financial data. Calibration with European options is made easier thanks to the linear character of the equations; see [10].

Concerning calibration with American options, we are not aware of any published articles; in this paper, we focus on American vanilla put options and study theoretically the least square optimization problem arising when one tries to calibrate the volatility from the observed prices of the option. Mathematically, it is an inverse problem in order to find the coefficient of a parabolic variational inequality.

The aim is to find a function $\eta(t,x)$ such that the price of the option computed by (1.5) fits some observations of the price of the American put for different maturities T and stroke K (the number of observed prices is finite). In this paper, we will first replace this inverse problem by a simpler one, i.e., with a single maturity T, and assume that the observation is made for all times t in $[0,T]$ and every price x (complete observation). From the theoretical point of view, this inverse problem retains the essential difficulties of the original one. We are going to use a least square approach, and the problem will somehow resemble optimal control problems studied in [28, 16, 5]. Let us mention especially the work of Hintermüller [15] on an inverse problem for an elliptic variational inequality, which has inspired the present work. Finally, we will investigate the genuine inverse problem for the calibration of volatility with a discrete set of observations.

The main results of the paper are:

1. Theorem 6.4 in section 6.2, where first order necessary optimality conditions are given for the least square inverse problem essentially under the assumption that no observed prices lie on the free boundary, i.e., the curve limiting the zone where the option should be exercised.
2. Theorem 5.4 in section 5.3, which states that the least square functional is differentiable with respect to η, under more restrictive assumptions, and which gives the derivative. This result is stated for the simpler least square problem mentioned above, but it holds for the genuine one with obvious modifications.
3. A careful study of the free boundary; see section 3.

The numerical counterpart of the present work has been carried out successfully (see [1]), and software has been written for the calibration of American options: it uses a discrete analogue of Theorem 5.4 for computing descent directions. Alternatively, an optimization method based on a least square version of the optimality conditions given by Theorem 6.4 is possible; see [15].

The paper is organized as follows. In section 2, we study carefully the variational inequality satisfied by the price of the American option. Section 3 is devoted to

the free boundary: under some assumptions on the volatility, we prove that the free boundary is the graph of a continuous function of time. In section 4, we investigate the sensitivity of u and the free boundary with respect to variations of the volatility. An inverse problem (simpler than the original one) is introduced in section 5, and we give some necessary optimality conditions. We also address the differentiability issue: is the cost function differentiable with respect to the volatility, and can we compute a gradient? We give a partial positive answer for volatilities such that the corresponding state function and free boundary are regular enough. Section 6 is devoted to the genuine calibration problem: necessary optimality conditions are given.

2. The variational inequality. Changing t into the time to maturity $T-t$, (1.5) becomes

(2.1)
$$\begin{aligned} \frac{\partial u}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 u}{\partial x^2} - rx\frac{\partial u}{\partial x} + ru \geq 0, \qquad u(t,x) &\geq u_\circ(x), \qquad t\in(0,T],\ x>0,\\ \left(\frac{\partial u}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 u}{\partial x^2} - rx\frac{\partial u}{\partial x} + ru\right)(u-u_\circ) &= 0, \qquad t\in(0,T],\ x>0,\\ u(t=0,x) &= u_\circ(x), \qquad x>0, \end{aligned}$$

where $\eta : [0,T]\times\mathbb{R}_+ \to \mathbb{R}_+$ is a positive function and

$$u_\circ(x) = (K-x)_+. \tag{2.2}$$

The pricing function u_e for the corresponding European put solves $u_e|_{t=0} = u_\circ$ and for $0 < t \leq T$,

$$\frac{\partial u_e}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 u_e}{\partial x^2} - rx\frac{\partial u_e}{\partial x} + ru_e = 0. \tag{2.3}$$

Although (2.1) may be tackled with the results of [12], we prefer to study it completely in order to make the presentation self-contained. For what follows, we introduce the weighted Sobolev space

$$V = \left\{ v\in L^2(\mathbb{R}_+), x\frac{\partial v}{\partial x}\in L^2(\mathbb{R}_+)\right\}, \tag{2.4}$$

which is a Hilbert space for the norm $\|v\|_V = \left(\|v\|^2_{L^2(\mathbb{R}_+)} + \|x\frac{\partial v}{\partial x}\|^2_{L^2(\mathbb{R}_+)}\right)^{\frac{1}{2}}$. The space V is clearly separable, and $\mathcal{D}(\mathbb{R}_+)$ is a dense subspace of V.

Assumption 1. We assume that for two fixed positive constants $\underline{\eta}$ and $\overline{\eta}$, $0 < \underline{\eta} \leq \eta \leq \overline{\eta}$ a.e. in $(0,T)\times\mathbb{R}_+$, and for a positive constant M, $|x\frac{\partial \eta}{\partial x}| \leq M$ a.e in $(0,T)\times\mathbb{R}_+$.

Remark 1. The assumption $|x\frac{\partial\eta}{\partial x}| \leq M$ is necessary for the variational formulation of (2.1): using viscosity solutions techniques (see the article by Friedman and Shen [13] on a closely related variational inequality and the references therein), one can do without it. It is also possible to obtain many results on (2.1) from the probability theory; see [18]. With Assumption 1, we can consider the family of linear operators $A(t) : V \to V'$ defined, for $v, w \in V$, by

$$\langle A(t)v, w\rangle = \int_{\mathbb{R}_+}\left(\frac{\eta(t)}{2}x^2\frac{\partial v}{\partial x}\frac{\partial w}{\partial x} + \left(\eta(t) + \frac{x}{2}\frac{\partial\eta}{\partial x} - r\right)x\frac{\partial v}{\partial x}w + rvw\right)dx. \tag{2.5}$$

From the assumptions on η, there exists a nonnegative constant α such that, for a.e. $t \in (0,T)$ and for any $v \in V$,

$$\langle A(t)v, v\rangle \geq \frac{1}{4}\underline{\eta}\|v\|_V^2 - \alpha\|v\|^2_{L^2(\mathbb{R}_+)}. \tag{2.6}$$

We introduce the closed subset of $L^2(0,T;V)$:

$$\mathcal{K} = \{v \in L^2(0,T;V), v \geq u_\circ \text{ a.e. in } (0,T)\times\mathbb{R}_+\}. \tag{2.7}$$

The variational formulation of (2.1) is as follows: find $u \in \mathcal{K} \cap C^0([0,T];L^2(\mathbb{R}_+))$, with $\frac{\partial u}{\partial t} \in L^2(0,T;V')$ such that for all $v \in \mathcal{K}$,

$$\left\langle \frac{\partial u}{\partial t} + A(t)u, v-u \right\rangle \geq 0 \quad \text{for } t>0 \quad \text{and} \quad u(t=0) = u_\circ. \tag{2.8}$$

In order to prove the existence for u, we make two observations:

1. The price of the American put is larger than that of the European put given by (2.3), which is itself positive for any $t \in (0,T]$ (we shall justify this by using the maximum principle; see below).
2. The function $u_\circ$ satisfies, for $t \in [0,T]$,

$$\left(\frac{\partial u_\circ}{\partial t} + A(t)u_\circ\right)\Big|_{x<K} = rK, \qquad \left(\frac{\partial u_\circ}{\partial t} + A(t)u_\circ\right)\Big|_{x>K} = 0. \tag{2.9}$$

Therefore, following [19], we introduce the penalized problem: find u_ϵ such that

$$\begin{aligned} \frac{\partial u_\epsilon}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 u_\epsilon}{\partial x^2} - rx\frac{\partial u_\epsilon}{\partial x} + ru_\epsilon - rK1_{\{x<K\}}\mathcal{V}_\epsilon(u_\epsilon - u_\circ) &= 0 \quad \begin{cases} t \in (0,T], \\ x>0, \end{cases} \\ u_\epsilon(t=0,x) &= u_\circ(x), \end{aligned} \tag{2.10}$$

where $\mathcal{V}_\epsilon(u) = \mathcal{V}(\frac{u}{\epsilon})$ and $\mathcal{V}$ is a smooth nonincreasing convex function such that

$$\mathcal{V}(0) = 1, \qquad \mathcal{V}(u) = 0 \quad \text{for } u \geq 1, \qquad 0 \geq \mathcal{V}'(u) \geq -2 \quad \text{for } 0 \leq u \leq 1. \tag{2.11}$$

THEOREM 2.1. *Under Assumption* 1, (2.10) *has a unique weak solution* $u_\epsilon \in L^2(0,T;V) \cap C^0([0,T];L^2(\mathbb{R}_+))$ *which belongs to* $\mathcal{K}$. *Also,* $x\frac{\partial u_\epsilon}{\partial x}$ *and* $\frac{\partial u_\epsilon}{\partial x}$ *belong to* $L^2(0,T;V) \cap C^0([0,T];L^2(\mathbb{R}_+))$, *and* u_ϵ *is continuous in* $[0,T]\times[0,+\infty]$. *Moreover,* $\frac{\partial u_\epsilon}{\partial t} \in L^2((0,T)\times\mathbb{R}_+)$. *The quantities* $\|u_\epsilon\|_{L^2(0,T;V)}$, $\|u_\epsilon\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, $\|x\frac{\partial u_\epsilon}{\partial x}\|_{L^2(0,T;V)}$, $\|\frac{\partial u_\epsilon}{\partial x}\|_{L^2(0,T;V)}$, $\|x\frac{\partial u_\epsilon}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, $\|\frac{\partial u_\epsilon}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, *and* $\|\frac{\partial u_\epsilon}{\partial t}\|_{L^2((0,T)\times\mathbb{R}_+)}$ *are bounded independently of* ϵ.

Furthermore, there exists a function $\hat{z}_\epsilon \in L^2(0,T;V) \cap C^0([0,T];L^2(\mathbb{R}_+))$ *such that*

$$\|\hat{z}_\epsilon\|_{L^2(0,T;V)} + \|\hat{z}_\epsilon\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} \to 0$$

and

$$-1 - \hat{z}_\epsilon \leq \frac{\partial u_\epsilon}{\partial x} \leq 0 \quad \forall t \in (0,T], \text{ a.e. } x>0. \tag{2.12}$$

Finally, u_ϵ *is greater than* u_e, *the price of the European put (given by* (2.3)*).*

Proof. By using results on parabolic equations with monotone operators [26, page 156], it is possible to prove that (2.10) has a unique weak solution in $L^2(0,T;V)\cap C^0([0,T];L^2(\mathbb{R}_+))$, with $\frac{\partial u_\epsilon}{\partial t}\in L^2(0,T;V')$, and that $\|u_\epsilon\|_{L^2(0,T;V)}$ and $\|u_\epsilon\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$ are bounded independently of ϵ. Furthermore, the weak maximum principle for parabolic equations leads to

$$0\le u_\epsilon(t,x)\le K\quad \forall t\in(0,T],\ \text{a.e. } x>0. \tag{2.13}$$

With u_e given by (2.3), we have, again by the maximum principle,

$$0<u_e(t,x)\le u_\epsilon(t,x)\quad \forall t\in(0,T],\ \text{a.e. } x>0, \tag{2.14}$$

and we can also compare the function u_ϵ with the function $K-x$:

$$K-x\le u_\epsilon(t,x)\quad \forall t\in(0,T],\ \text{a.e. } x>0. \tag{2.15}$$

From estimates (2.14) and (2.15), $u_\epsilon\in\mathcal{K}$.

By taking the derivative of (2.10) with respect to x, we obtain that $z_\epsilon=\frac{\partial u_\epsilon}{\partial x}$ satisfies

$$\begin{aligned}&\frac{\partial z_\epsilon}{\partial t}-\frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial z_\epsilon}{\partial x}\right)-rx\frac{\partial z_\epsilon}{\partial x}-rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon-u_\circ)(z_\epsilon+1)\\&=-rK\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K},\\&z_\epsilon(t=0,x)=-1_{\{x<K\}},\end{aligned} \tag{2.16}$$

which also has a variational formulation in $L^2(0,T;V)$ because

$$-\frac{2}{\epsilon}\le\mathcal{V}'_\epsilon(u_\epsilon-u_\circ)\le 0$$

and $-rK\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K}\in L^2((0,T),V')$; we can easily obtain that

$$\frac{\partial u_\epsilon}{\partial x}\in L^2(0,T,V)\cap C^0([0,T];L^2(\mathbb{R}_+)),$$

with no additional assumption on η. This proves that u_ϵ is actually continuous and that (2.13), (2.14), (2.15) hold pointwise. From (2.16), it is possible to prove that $\|\frac{\partial u_\epsilon}{\partial x}\|_{L^2(0,T;V)}$ and $\|\frac{\partial u_\epsilon}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$ are bounded independently of ϵ, and that $\frac{\partial u_\epsilon}{\partial x}\le 0$ for all t and a.e. in x. From (2.16), we deduce that $z_\epsilon(t=0,x)+1=1_{\{x\ge K\}}$ and for $t\in(0,T],\ x>0$,

$$\begin{aligned}&\frac{\partial(z_\epsilon+1)}{\partial t}-\frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial(z_\epsilon+1)}{\partial x}\right)-rx\frac{\partial(z_\epsilon+1)}{\partial x}-rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon-u_\circ)(z_\epsilon+1)\\&\qquad=-rK\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K}.\end{aligned} \tag{2.17}$$

The function $z_\epsilon+1$ is the sum of two functions $\tilde z_\epsilon+1$ and $\hat z_\epsilon$ which satisfy, respectively,

$$\begin{aligned}&\frac{\partial(\tilde z_\epsilon+1)}{\partial t}-\frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial(\tilde z_\epsilon+1)}{\partial x}\right)-rx\frac{\partial(\tilde z_\epsilon+1)}{\partial x}-rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon-u_\circ)(\tilde z_\epsilon+1)\\&\qquad=0,\quad t>0,\\&\tilde z_\epsilon(t=0,x)+1=1_{\{x\ge K\}}\end{aligned} \tag{2.18}$$

and

$$\begin{aligned}\frac{\partial \hat{z}_\epsilon}{\partial t} - \frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial \hat{z}_\epsilon}{\partial x}\right) - rx\frac{\partial \hat{z}_\epsilon}{\partial x} - rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon - u_\circ)\hat{z}_\epsilon \\ = -rK\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K}, \quad t>0, \\ \hat{z}_\epsilon(t=0,x) = 0.\end{aligned} \tag{2.19}$$

Since $u_\epsilon \geq u_e$, we know that $\lim_{\epsilon\to 0}\|\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K}\|_{L^2(0,T;V')} = 0$.

Thus, $\lim_{\epsilon\to 0}\|\hat{z}_\epsilon\|_{L^2(0,T;V)} = 0$. On the other hand, $\tilde{z}_\epsilon \geq -1$. Thus, $\frac{\partial u_\epsilon}{\partial x} \geq -1 - \hat{z}_\epsilon$ for all t and for a.e. x.

Finally, we can check that $w_\epsilon = x\frac{\partial u_\epsilon}{\partial x}$ satisfies $w_\epsilon(t=0,x) = -x1_{\{x<K\}}$ and for $t\in(0,T]$, $x>0$,

$$\begin{aligned}\frac{\partial w_\epsilon}{\partial t} - \frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial w_\epsilon}{\partial x}\right) + (\eta - r)x\frac{\partial w_\epsilon}{\partial x} + \left(r + \frac{x}{2}\frac{\partial \eta}{\partial x}\right)w_\epsilon \\ -rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon - u_\circ)(w_\epsilon + x) = -rK^2\mathcal{V}_\epsilon(u_\epsilon(K))\delta_{x=K},\end{aligned} \tag{2.20}$$

so $x\frac{\partial u_\epsilon}{\partial x} \in L^2(0,T;V)\cap C^0([0,T],L^2(\mathbb{R}_+))$, and it is possible to prove that $\|x\frac{\partial u_\epsilon}{\partial x}\|_{L^2(0,T;V)}$, $\|x\frac{\partial u_\epsilon}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, and thus $\|x^2\frac{\partial^2 u_\epsilon}{\partial x^2}\|_{L^2((0,T)\times\mathbb{R}_+)}$ are bounded independently of ϵ. Therefore, so is $\|\frac{\partial u_\epsilon}{\partial t}\|_{L^2((0,T)\times\mathbb{R}_+)}$, from (2.10). ∎

THEOREM 2.2. *With η satisfying Assumption* 1*, problem* (2.8) *has a unique solution u which belongs to $C^0([0,T]\times[0,+\infty))$ with $u(t,0) = K$, for all $t\in[0,T]$, and is such that $x\frac{\partial u}{\partial x}, \frac{\partial u}{\partial x} \in L^2(0,T;V)$, $\frac{\partial u}{\partial x}$ and $x\frac{\partial u}{\partial x}$ belong to $C^0([0,T];L^2(\mathbb{R}_+))$, and $\frac{\partial u}{\partial t}\in L^2((0,T)\times\mathbb{R}_+)$. The function u is also greater than u_e, the price of the European put, solution to* (2.3).

The quantities $\|u\|_{L^2(0,T;V)}$, $\|u\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, $\|x\frac{\partial u}{\partial x}\|_{L^2(0,T;V)}$, $\|\frac{\partial u}{\partial x}\|_{L^2(0,T;V)}$, $\|x\frac{\partial u}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, $\|\frac{\partial u}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, and $\|\frac{\partial u}{\partial t}\|_{L^2((0,T)\times\mathbb{R}_+)}$ are bounded independently of η in the class defined in Assumption 1.

We have that

$$-1 \leq \frac{\partial u}{\partial x} \leq 0 \quad \forall t\in(0,T],\ \text{a.e. } x>0. \tag{2.21}$$

Proof. The proof consists of passing to the limit in (2.10) as $\epsilon\to 0$ and proving that the solution to (2.8) is unique. We skip it since it is rather classical: it can be found in [19]. The entire sequence u_ϵ converges weakly to u in $L^2(0,T,V)$. All the bounds on u_ϵ hold for u and they are independent of η in the class defined by Assumption 1. The bounds (2.21) are obtained by passing to the limit in (2.12). From the fact that $\frac{\partial u}{\partial t} + A(t)u \in L^2((0,T)\times\mathbb{R}_+)$, we deduce that, for $w = x\frac{\partial u}{\partial x}$,

$$\frac{\partial w}{\partial t} - \frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial w}{\partial x}\right) + (\eta - r)x\frac{\partial w}{\partial x} + \left(r + \frac{x}{2}\frac{\partial \eta}{\partial x}\right)w \in L^2(0,T;V'),$$

and $w(t=0)\in L^2(\mathbb{R}_+)$. So from classical results on linear parabolic equations [27], we know that $w = x\frac{\partial u}{\partial x} \in C^0([0,T];L^2(\mathbb{R}_+))$. This implies that the function xu is continuous in $[0,T]\times[0,+\infty)$ and the bounds $K - x \leq u(t,x) \leq K$ hold pointwise for $x>0$, so we have $u(t,x=0) = K$ and u is continuous in $[0,T]\times[0,+\infty)$. Therefore the region where $u = u_\circ$ is a closed subset of $[0,T]\times[0,+\infty)$. ∎

PROPOSITION 2.3. *For any $t \geq 0$ and any $x \in [0, +\infty)$,*

$$u_\epsilon(t,x) - \epsilon \leq u(t,x) \leq u_\epsilon(t,x), \tag{2.22}$$

and u_ϵ converges to u in $C^0([0,T] \times [0,+\infty))$.

Proof. Let $\epsilon' < \epsilon$ be two positive numbers, and consider u_ϵ and $u_{\epsilon'}$ the two solutions to (2.10) corresponding to ϵ and ϵ'. Calling $e_{\epsilon,\epsilon'} = u_{\epsilon'} - u_\epsilon$,

$$\begin{aligned} &\frac{\partial e_{\epsilon,\epsilon'}}{\partial t} + A(t) e_{\epsilon,\epsilon'} - rK1_{x<K}(\mathcal{V}_{\epsilon'}(u_{\epsilon'} - u_\circ) - \mathcal{V}_{\epsilon'}(u_\epsilon - u_\circ)) \\ &= - rK1_{x<K}(\mathcal{V}_\epsilon(u_\epsilon - u_\circ) - \mathcal{V}_{\epsilon'}(u_\epsilon - u_\circ)) \leq 0. \end{aligned}$$

Thanks to the nonincreasing character of $\mathcal{V}_{\epsilon'}$, we can use the weak maximum principle and prove that $e_{\epsilon,\epsilon'} \leq 0$, a.e. Then passing to the limit as $\epsilon' \to 0$ (for a converging subsequence), we deduce that $u \leq u_\epsilon$.

Calling v_ϵ the function $u + \epsilon$, we have that $v_\epsilon(t=0) = u_\circ + \epsilon \geq u_\epsilon$ and, with $\mu = \frac{\partial u}{\partial t} + A(t)u$, that

$$\frac{\partial v_\epsilon}{\partial t} + A(t) v_\epsilon - rK1_{x<K}\mathcal{V}_\epsilon(v_\epsilon - u_\circ) = r\epsilon + \mu \geq 0,$$

because $\mathcal{V}_\epsilon(v_\epsilon - u_\circ) = 0$. The maximum principle shows that $v_\epsilon \geq u_\epsilon$. We have proved (2.22) and therefore the convergence of u_ϵ to u in $C^0([0,T] \times [0,+\infty))$. ∎

LEMMA 2.4. *Let u be the solution to (2.8). There exists a function $\gamma : (0,T] \to [0,K)$, such that for all $t \in (0,T)$, $\{x \text{ s.t. } u(t,x) = u_\circ(x)\} = [0, \gamma(t)]$.*

Calling

$$\mu = \frac{\partial u}{\partial t} + A(t)u, \tag{2.23}$$

we have a.e.

$$0 \leq \mu \leq rK1_{\{u=u_\circ\}} = rK1_{\{x \leq \gamma(t)\}}. \tag{2.24}$$

Proof. The function $x\frac{\partial u}{\partial x}$ belongs to $C^0([0,T]; L^2(\mathbb{R}_+))$, and, for any t, we have that $x\frac{\partial u}{\partial x}(t,x) \geq -x$ a.e. in x. Let us prove Lemma 2.4 by contradiction: if the set $\{x; u(t,x) = u_\circ(x)\}$ were not connected, then there would exist an interval where $\frac{\partial u}{\partial x}(t,x) < -1$ a.e., but this contradicts the bound on $x\frac{\partial u}{\partial x}(t,\cdot)$.

On the other hand, we know that $u(t,0) = K = u_\circ(0)$.

This proves that at each time t, the set where $u(t,x)$ coincides with $u_\circ$ is an interval $[0, \gamma(t)]$. Note that $\gamma(t) \leq K$ for $t > 0$ because $u(t,K) \geq u_e(t,K) > 0 = u_\circ(K)$.

With $\mu \in L^2((0,T) \times \mathbb{R}_+)$ given by (2.23), we have $\mu = 0$ a.e. in the open region where $u > u_\circ$ and $\mu = rK$ in the interior of the region where $u = u_\circ$. Now, μ is the weak limit of $rK1_{x<K}\mathcal{V}_\epsilon(u_\epsilon - u_\circ)$ in $L^2((0,T) \times \mathbb{R}_+)$. From (2.22), we deduce that $rK1_{x<K}\mathcal{V}_\epsilon(u_\epsilon - u_\circ) \leq rK1_{x<K}\mathcal{V}_\epsilon(u - u_\circ)$, and $1_{x<K}\mathcal{V}_\epsilon(u - u_\circ)$ converges pointwise to $1_{\{u=u_\circ\}}$. Therefore, $\mu \leq rK1_{\{u=u_\circ\}}$. ∎

The free boundary $\{x = \gamma(t),\ t \in (0,T)\}$ is called the exercise boundary.

Remark 2. Consider a sequence of penalty parameters $(\epsilon_n)_{n\in\mathbb{N}}$ with $\epsilon_n \to 0$ as $n \to +\infty$, a function η, and a sequence of functions $(\eta_n)_{n\in\mathbb{N}}$ in the class defined by Assumption 1 such that $\|\eta_n - \eta\|_{L^\infty((0,T)\times\mathbb{R}_+)} \to 0$ as $n \to +\infty$. Then it can be

proved (the proof is exactly the same as that of Theorem 2.2) that the solution u_n of the problem

$$\frac{\partial u_n}{\partial t} - \frac{\eta_n x^2}{2}\frac{\partial^2 u_n}{\partial x^2} - rx\frac{\partial u_n}{\partial x} + ru_n - rK1_{\{x<K\}}\mathcal{V}_{\epsilon_n}(u_n - u_\circ) = 0, \quad \begin{cases} t \in (0,T], \\ x > 0, \end{cases}$$

$$u_n(t=0,x) = u_\circ(x)$$

converges weakly in $L^2(0,T;V)$ to the solution u of (2.1), and that $\frac{\partial u_n}{\partial x}$ (resp., $x\frac{\partial u_n}{\partial x}$) converges weakly to $\frac{\partial u}{\partial x}$ (resp., $x\frac{\partial u}{\partial x}$) in $L^2(0,T;V)$. We also have that $\frac{\partial u_n}{\partial t}$ converges weakly to $\frac{\partial u}{\partial t}$ in $L^2((0,T)\times\mathbb{R}_+)$.

LEMMA 2.5. *There exists a real number $q_{\max} > 2$ such that, for any real q, $2 \le q < q_{\max}$, and for any interval (x_1,x_2), $0 < x_1 < x_2 < +\infty$, there exists a constant C independent of η in the class defined by Assumption* 1 *such that*

$$\left\|\frac{\partial u}{\partial t}\right\|_{L^q((0,T)\times(x_1,x_2))} + \left\|\frac{\partial^2 u}{\partial x^2}\right\|_{L^q((0,T)\times(x_1,x_2))} \le C. \tag{2.25}$$

Proof (sketch of the proof). There exists $q_{\max} > 2$ such that, for any real q, $2 \le q < q_{\max}$, $u(t=0) \in W^{2-\frac{2}{q},q}(\mathbb{R}_+)$. Moreover, from (2.24), the left-hand side of (2.23) belongs to $L^\infty((0,T)\times\mathbb{R}_+)$. Then the result follows by applying locally [20, Theorem 9.1, page 340]. ∎

3. The free boundary. With stronger assumptions on η, we can prove some additional regularity, thanks to the convexity of the penalty function $\mathcal{V}_\epsilon$.

Assumption 2. We assume for the constant M introduced in Assumption 1 that we also have

$$\left|x^2\frac{\partial^2\eta}{\partial x^2}\right| + \left|\frac{\partial\eta}{\partial t}\right| + \left|x\frac{\partial^2\eta}{\partial x\partial t}\right| \le M \quad \textit{a.e. in } (0,T)\times\mathbb{R}_+.$$

LEMMA 3.1. *Under Assumptions* 1 *and* 2 *(in fact it is enough to assume that $|x^2\frac{\partial^2\eta}{\partial x^2}| \le M$ for a given constant M), the solution of* (2.8) *satisfies $\frac{\partial^2 u}{\partial x^2} \ge 0$ a.e.*

Proof. Calling u_ϵ the solution to (2.10) and $z_\epsilon = \frac{\partial u_\epsilon}{\partial x}$, we recall that $z_\epsilon = \tilde{z}_\epsilon + \hat{z}_\epsilon$, where $\lim_{\epsilon\to 0}\|\hat{z}_\epsilon\|_{L^2(0,T;V)} = 0$ and where $\tilde{z}_\epsilon$ satisfies (2.18). We derive (2.18) with respect to x. Setting $y_\epsilon = \frac{\partial\tilde{z}_\epsilon}{\partial x}$, we have $y_\epsilon(t=0,x) = \delta_{x=K}$, and for $t \in (0,T]$ and $x > 0$,

$$\begin{aligned} &\frac{\partial y_\epsilon}{\partial t} - \frac{\partial^2}{\partial x^2}\left(\frac{\eta x^2}{2}y_\epsilon\right) - \frac{\partial}{\partial x}(rxy_\epsilon) - rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon - u_\circ)y_\epsilon \\ &= rK1_{\{x<K\}}\mathcal{V}''_\epsilon(u_\epsilon - u_\circ)(\tilde{z}_\epsilon + 1)^2 - rK\mathcal{V}'_\epsilon(u_\epsilon - u_\circ)(\tilde{z}_\epsilon + 1)\delta_{x=K}. \end{aligned} \tag{3.1}$$

From Assumptions 1 and 2, the monotonicity and the convexity of $\mathcal{V}_\epsilon$, and the fact that $\tilde{z}_\epsilon + 1 \ge 0$, we obtain that $y_\epsilon \ge 0$. On the other hand, we know that $x^2 y_\epsilon$ converges weakly to $x^2\frac{\partial^2 u}{\partial x^2}$ in $L^2((0,T)\times\mathbb{R}_+)$. By passing to the limit, we obtain that $\frac{\partial^2 u}{\partial x^2} \ge 0$ in the sense of distributions and a.e. since $x^2\frac{\partial^2 u}{\partial x^2} \in L^2((0,T)\times\mathbb{R}_+)$. ∎

LEMMA 3.2. *Under Assumptions* 1 *and* 2, *there exists a constant C_1 such that the solution u to* (2.8) *satisfies, for any τ, $0 < \tau \le T$, $\|\frac{\partial u}{\partial t}\|_{L^\infty([\tau,T];L^2(\mathbb{R}_+))} \le \frac{C_1}{\sqrt{\tau}}$ and $\|\frac{\partial u}{\partial t}\|_{L^2([\tau,T];V)} \le \frac{C_1}{\sqrt{\tau}}$.*

Proof. By calling y_ϵ the time derivative of u_ϵ and deriving (2.10) with respect to t, we obtain that

$$\frac{\partial y_\epsilon}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 y_\epsilon}{\partial x^2} - rx\frac{\partial y_\epsilon}{\partial x} + ry_\epsilon - rK1_{\{x<K\}}\mathcal{V}'_\epsilon(u_\epsilon - u_\circ)y_\epsilon = \frac{x^2}{2}\frac{\partial \eta}{\partial t}\frac{\partial^2 u_\epsilon}{\partial x^2}. \tag{3.2}$$

We can check that there exists a constant C independent of ϵ such that, for all $\tau > s > 0$,

$$\int_{\mathbb{R}_+} y_\epsilon(\tau,x)^2 dx + \int_s^\tau \|y_\epsilon(t)\|_V^2 dt \le C\left(\int_{\mathbb{R}_+} y_\epsilon(s,x)^2 dx + 1\right) \tag{3.3}$$

because $\|\frac{\partial \eta}{\partial t}\|_{L^\infty} \le M$, $x^2\frac{\partial^2 u_\epsilon}{\partial x^2}$ is bounded independently of ϵ, and $\mathcal{V}'_\epsilon \le 0$. Integrating with respect to s between 0 and τ, and using the fact that $\|y_\epsilon\|_{L^2((0,T)\times\mathbb{R}_+)}$ is bounded independently of ϵ leads to $\int_{\mathbb{R}_+} y_\epsilon(\tau,x)^2 dx \le \frac{C}{\tau}$, and using again (3.3), $\int_s^T \|y_\epsilon(t)\|_V^2 dt \le \frac{C}{s}$. The same estimates hold for $\frac{\partial u}{\partial t}$, by passing to the limit. ∎

We can also prove that γ is bounded from below by a positive constant depending only on $\bar\eta$. For that, we use a preliminary lemma.

LEMMA 3.3. *For two positive constants $\tilde\eta$ and K, call $\tilde A_t$ the operator $\tilde A_t v = -\frac{\tilde\eta x^2}{2}\frac{\partial^2 v}{\partial x^2} - rx\frac{\partial v}{\partial x} + rv$, and let $u^{\tilde\eta,K}$ be the solution of*

$$\begin{aligned}
&\frac{\partial \tilde u^{\tilde\eta,K}}{\partial t} + \tilde A_t u^{\tilde\eta,K} \ge 0, \qquad \tilde u^{\tilde\eta,K}(t,x) \ge (K-x)_+, \quad t\in(0,T],\ x>0,\\
&(\tfrac{\partial \tilde u^{\tilde\eta,K}}{\partial t} + \tilde A_t u^{\tilde\eta,K})(\tilde u^{\tilde\eta,K} - (K-x)_+) = 0, \quad t\in(0,T],\ x>0,\\
&\tilde u^{\tilde\eta,K}(t=0,x) = (K-x)_+.
\end{aligned} \tag{3.4}$$

The function $\tilde u^{\tilde\eta,K}$ is a nondecreasing function of time and satisfies $\frac{\partial^2 \tilde u^{\tilde\eta,K}}{\partial x^2} \ge 0$. The function $\tilde\gamma : [0,T] \mapsto [0,K]$ such that $\{x>0 : \tilde u^{\tilde\eta,K}(t,x) = (K-x)_+\} = [0,\tilde\gamma]$ is nonincreasing and continuous and

$$\frac{\partial \tilde u^{\tilde\eta,K}}{\partial t} + \tilde A_t u^{\tilde\eta,K} = rK1_{\{\tilde u^{\tilde\eta,K} = (K-x)_+\}}. \tag{3.5}$$

Proof. Since the coefficient $\tilde\eta$ is constant, we know that $\frac{\partial^2 \tilde u^{\tilde\eta,K}}{\partial x^2} \ge 0$ (from Lemma 3.1). We can also prove that $\tilde u^{\tilde\eta,K}$ is a nondecreasing function of time (one checks first the property on the corresponding penalized problem (analogue to (2.10)) and then passes to the limit). Then, obviously, $\tilde\gamma$ is a nonincreasing function of time. Also, as proved in [19, page 288], $\tilde\gamma$ is continuous. This implies that the boundary of the set $\{t>0, 0\le x\le\gamma(t)\}$ is the graph of $\tilde\gamma$. In other words, the set $\partial\{\tilde u^{\tilde\eta,K} = (K-x)_+\} \cap \{t>0\}$ is the graph of $\tilde\gamma$ so it is measurable and has zero measure. Therefore, $\frac{\partial \tilde u^{\tilde\eta,K}}{\partial t} + \tilde A_t \tilde u^{\tilde\eta,K} = rK1_{x\le\tilde\gamma(t)}$ in $L^2((0,T)\times\mathbb{R}_+)$. ∎

THEOREM 3.4. *Under Assumption 1, there exists $\gamma_0 > 0$ depending only on $\bar\eta$ such that*

$$\gamma(t) \ge \gamma_0 \quad \forall t\in[0,T]. \tag{3.6}$$

Proof. Let $\tilde u = \tilde u^{\bar\eta,K}$ as defined in Lemma 3.3. We have $u \le \tilde u$. Indeed, calling $e = \tilde u - u$,

$$\begin{aligned}
&\frac{\partial e}{\partial t} - \frac{\eta(t,x)x^2}{2}\frac{\partial^2 e}{\partial x^2} - rx\frac{\partial e}{\partial x} + re - rK\left(1_{\{\tilde u\le u_\circ\}} - 1_{\{u\le u_\circ\}}\right)\\
&= \left(\frac{x^2}{2}(\bar\eta-\eta)\frac{\partial^2 \tilde u}{\partial x^2}\right) + \left(rK(1_{u\le u_\circ}) - \mu\right).
\end{aligned}$$

The two terms in the right-hand side are nonnegative, thanks to Lemma 3.1 and to (2.24). Therefore, a weak maximum principle can be applied, thanks to the monotonicity of $z \mapsto 1_{\{z \le u_\circ(x)\}}$, and we see that $e_- = 0$ (everywhere since u and $\tilde{u}$ are continuous).

Since $u \le \tilde{u}$, we know that $\tilde{\gamma} \le \gamma$. Therefore, if there exists $t_0 < T$ such that $\gamma(t_0) = 0$, then $\tilde{\gamma}(t_0) = 0$ and $\tilde{\gamma}(t) = 0$, for $t \ge t_0$, because $\tilde{\gamma}$ is nonincreasing from Lemma 3.3. It follows that $\tilde{u}$ solves the Black–Scholes equation for $t > t_0$, i.e., $\frac{\partial \tilde{u}}{\partial t} - \frac{\bar{\eta} x^2}{2} \frac{\partial^2 \tilde{u}}{\partial x^2} - rx \frac{\partial \tilde{u}}{\partial x} + r\tilde{u} = 0$ and $\tilde{u}(t_0) \le K$: the maximum principle indicates that $\tilde{u}(t) \le K e^{-r(t-t_0)}$ for $t > t_0$. This is in contradiction to the fact that $\tilde{u} \ge u_\circ$. The assertion $\gamma(T) = 0$ is also impossible, because we can always look for $\tilde{u}$ in a larger time interval. Since $\tilde{\gamma}$ is continuous on $[0, T]$, there exists $\gamma_0 > 0$ such that (3.6) is satisfied. ∎

The next results deal with the regularity of the function γ.

LEMMA 3.5. *Under Assumption* 1*, the function* γ *defined in Lemma* 2.4 *is such that for all* $t > 0$*,* $\limsup_{\tau \to t} \gamma(\tau) \le \gamma(t)$*; i.e.,* γ *is upper semicontinuous.*

Proof. The intersection of the epigraph of $t \mapsto -\gamma(t)$ with $[0, T] \times \mathbb{R}_-$ is the region $\{(t, x) \in [0, T] \times \mathbb{R}_-;\, u(t, -x) = u_\circ(-x)\}$. From the continuity of u, this region is closed. This and Theorem 3.4 imply that γ is upper semicontinuous. ∎

LEMMA 3.6. *Under Assumption* 1*, the function* γ *defined in Lemma* 2.4 *is such that for all* $t > 0$*,*

$$\liminf_{\tau \to t^+} \gamma(\tau) = \gamma(t), \quad \textit{and} \quad \liminf_{\tau \to t^-} \gamma(\tau) = \limsup_{\tau \to t^-} \gamma(\tau) \le \gamma(t).$$

Proof. The idea is to compare u for $\tau > t$ with $K - \gamma(t) + \tilde{u}$, where $\tilde{u}(\tau, x) = \tilde{u}^{\bar{\eta}, \gamma(t)}(\tau - t, x)$ and $\tilde{u}^{\bar{\eta}, \gamma(t)}$ is defined in Lemma 3.3. We have from Lemma 3.3 that $\frac{\partial \tilde{u}}{\partial \tau} - \bar{\eta} \frac{x^2}{2} \frac{\partial^2 \tilde{u}}{\partial x^2} - rx \frac{\partial \tilde{u}}{\partial x} + r\tilde{u} = r\gamma(t) 1_{\{\tilde{u}(\tau, x) = (\gamma(t) - x)_+\}}$. Therefore,

$$\begin{aligned} & \frac{\partial \tilde{u}}{\partial \tau} - \frac{\eta x^2}{2} \frac{\partial^2 \tilde{u}}{\partial x^2} - rx \frac{\partial \tilde{u}}{\partial x} + r\tilde{u} \\ = \;& (\bar{\eta} - \eta) \frac{x^2}{2} \frac{\partial^2 \tilde{u}}{\partial x^2} + r\gamma(t) 1_{\{K - \gamma(t) + \tilde{u} = K - \gamma(t) + (\gamma(t) - x)_+\}}, \end{aligned} \tag{3.7}$$

which implies that the error $e = K - \gamma(t) + \tilde{u} - u$ satisfies

$$\begin{aligned} & \frac{\partial e}{\partial \tau} - \eta \frac{x^2}{2} \frac{\partial^2 e}{\partial x^2} - rx \frac{\partial e}{\partial x} + re - rK(1_{\{u+e \le u_\circ\}} - 1_{\{u \le u_\circ\}}) \\ & = r(K - \gamma(t)) 1_{\{u+e > u_\circ\}} + (\bar{\eta} - \eta) \frac{x^2}{2} \frac{\partial^2 \tilde{u}}{\partial x^2} + (rK 1_{\{u \le u_\circ\}} - \mu) \\ & + r\gamma(t) \left(1_{\{u+e \le K - \gamma(t) + (\gamma(t) - x)_+\}} - 1_{\{u+e \le u_\circ\}} \right). \end{aligned} \tag{3.8}$$

From Lemma 3.3 and $\bar{\eta} \ge \eta$, all the terms in the right-hand side of (3.8) are nonnegative, so the maximum principle indicates that $0 \le e$ for $\tau \ge t$. This implies that $\tilde{\gamma}(\tau) \le \gamma(\tau)$ for $\tau > t$.

From $\tilde{\gamma}(\tau) \le \gamma(\tau)$, we deduce that $\lim_{\tau \to t^+} \tilde{\gamma}(\tau) \le \liminf_{\tau \to t^+} \gamma(\tau)$.

But $\lim_{\tau \to t^+} \tilde{\gamma}(\tau) = \gamma(t)$. Therefore $\liminf_{\tau \to t^+} \gamma(\tau) \ge \gamma(t)$, and using Lemma 3.5, we obtain that $\liminf_{\tau \to t^+} \gamma(\tau) = \gamma(t)$. The idea for proving that $\liminf_{\tau \to t^-} \gamma(\tau) = \limsup_{\tau \to t^-} \gamma(\tau)$ is somewhat similar: assume that $s < \limsup_{\tau \to t^-} \gamma(\tau)$, so there exists a sequence of times t_k smaller than t, converging to t and such that $\gamma(t_k) > s$. We construct $\tilde{u}_k(\tau, x) = K - s + \tilde{u}^{\bar{\eta}, s}(\tau - t_k, x)$, where $\tilde{u}^{\bar{\eta}, s}$ is defined in Lemma 3.3, and we define $\tilde{\gamma}_k$ by $\{x : \tilde{u}_k(\tau, x) = K - s + (s - x)_+\} = [0, \tilde{\gamma}_k(\tau)]$. As above,

$\tilde{\gamma}_k$ is a nonincreasing and continuous function of time. From the continuity of $\tilde{\gamma}_k$, we deduce that

$$\lim_{k\to\infty} \inf_{t_k\le\tau\le t} \tilde{\gamma}_k(\tau) = s.$$

The same arguments as above show that for $t_k \le \tau \le t$, $\tilde{u}_k(\tau, x) \ge u(\tau)$ and $\gamma(\tau) \ge \tilde{\gamma}_k(\tau)$. Therefore $\liminf_{\tau\to t_-} \gamma(\tau) \ge \lim_{k\to\infty} \inf_{t_k\le\tau\le t} \tilde{\gamma}_k(\tau) = s$, which shows that $\liminf_{\tau\to t^-} \gamma(\tau) = \limsup_{\tau\to t^-} \gamma(\tau)$. ∎

Remark 3. Lemmas 3.5 and 3.6 indicate that under Assumption 1, the function γ is right continuous in $[0, T)$ and, for each $t \in (0, T]$, γ has a left-limit at t. As a consequence, we have the following theorem.

THEOREM 3.7. *For η satisfying Assumption* 1*, the function $\mu = \frac{\partial u}{\partial t} + A_t u$ is*

$$\mu = rK1_{\{u=u_\circ\}} = rK1_{\{x\le\gamma(t)\}}. \tag{3.9}$$

In other words, a.e. one of the two conditions $u = u_\circ$ and $\mu = 0$ is not satisfied: we see that there is strict complementarity in (2.1).

Proof. For any time t, both $\lim_{\tau<t} \gamma(\tau)$ and $\lim_{\tau>t} \gamma(\tau)$ exist. Therefore, the function γ is the uniform limit of a sequence of piecewise constant functions γ_k (i.e., γ_k is constant on a finite number of intervals). Thus, calling $\mathcal{J}$ (resp., $\mathcal{J}_k$) the set of points where γ (resp., γ_k) jumps, we have $\mathcal{J} \subset \cup_{k\in\mathbb{N}}\mathcal{J}_k$ because of the uniform convergence and $\mathcal{J}_k$ is finite. Thus the set $\mathcal{J}$ is countable.

Consider now the boundary Γ of the set $\{u = u_\circ\} = \{x \le \gamma(t), t \in [0, T]\}$: we have

$$\Gamma = (\Gamma \cap \{(x, t), t \in [0, T]\backslash\mathcal{J}\}) \cup (\Gamma \cap \{(x, t), t \in \mathcal{J}\}).$$

The second set is negligible, since $\mathcal{J}$ is countable. For the first set, we have

$$\Gamma \cap \{(x, t), t \in [0, T]\backslash\mathcal{J}\} = \{(\gamma(t), t), t \in [0, T]\backslash\mathcal{J}\},$$

so it is also negligible.

Therefore, Γ is negligible, and the set $\{u = u_\circ\}$ has the same measure as its interior, on which $\mu = rK$. This proves (3.9). ∎

PROPOSITION 3.8. *Under Assumption* 1*, and with μ defined in* (2.23)*, the sequence*

$$\mu_\epsilon = rK1_{x<K}\mathcal{V}_\epsilon(u_\epsilon - u_\circ), \quad \text{with } u_\epsilon \text{ solution to } (2.10),$$

converges to μ in $L^p((0, T) \times \mathbb{R}_+)$ as $\epsilon \to 0$, for any real number $p \ge 1$.

Proof. We know that the functions μ_ϵ satisfy $0 \le \mu_\epsilon \le rK$ and are supported in $[0, T] \times [0, K]$. We also know that the sequence μ_ϵ converges weakly to μ in L^2. But μ takes only the two values 0 and rK. This implies easily that $\mu_\epsilon \to \mu$ in L^1, and in every $L^p((0, T) \times \mathbb{R}_+)$, $1 \le p < +\infty$, because $\|\mu_\epsilon\|_{L^\infty} \le rK$ and $\|\mu\|_{L^\infty} \le rK$ and the functions are supported in $[0, T] \times [0, K]$. ∎

PROPOSITION 3.9. *Under Assumption* 1*, the sequence $x\frac{\partial u_\epsilon}{\partial x}$ (u_ϵ solution to* (2.10)*) converges to $x\frac{\partial u}{\partial x}$ in $C^0([0, T], L^2(\mathbb{R}_+))$.*

Proof. Calling $w_\epsilon = x\frac{\partial u_\epsilon}{\partial x}$, we have

$$\frac{\partial w_\epsilon}{\partial t} - \frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\frac{\partial w_\epsilon}{\partial x}\right) + (\eta - r)x\frac{\partial w_\epsilon}{\partial x} + \left(r + \frac{x}{2}\frac{\partial \eta}{\partial x}\right) w_\epsilon = x\frac{\partial \mu_\epsilon}{\partial x},$$

and $w_\epsilon(t = 0) = x\frac{\partial u_\circ}{\partial x} \in L^2(\mathbb{R}_+)$. From Proposition 3.8, $x\frac{\partial \mu_\epsilon}{\partial x}$ converges to $x\frac{\partial \mu}{\partial x}$ strongly in $L^2(0, T; V')$. This implies that $w_\epsilon \to w$ in $C^0([0, T], L^2(\mathbb{R}_+))$, where $w = x\frac{\partial u}{\partial x}$. ∎

It is possible to prove that the function γ is continuous, under stronger assumptions on η as follows.

LEMMA 3.10. *Under Assumptions* 1 *and* 2, *the function* γ *defined in Lemma* 2.4 *is such that* $\lim_{\tau\to t^-}\gamma(\tau)=\gamma(t)$.

Proof. Assume that $s=\lim_{\tau\to t_-}\gamma(\tau)<\gamma(t)$. Then there exists a positive number ϵ such that $u(\tau,x)>u_\circ(x)$ in the region $Q=[t-\epsilon,t)\times(\tilde{s},\gamma(t))$, where $\tilde{s}=\max_{t-\epsilon\le\tau<t}\gamma(\tau)=\gamma(\tilde{\tau})$ (this maximum is attained at $t-\epsilon\le\tilde{\tau}<t$ because γ is upper semicontinuous). In this region, the function satisfies the parabolic PDE

$$\frac{\partial u}{\partial t}+A(t)u=0, \tag{3.10}$$

and u is a regular function. Therefore, we can derive the equation twice with respect to x and we obtain that $y=\frac{\partial^2 u}{\partial x^2}$ satisfies

$$\frac{\partial y}{\partial t}-\frac{\eta x^2}{2}\frac{\partial^2 y}{\partial x^2}+\left(2x\eta+x^2\frac{\partial\eta}{\partial x}-rx\right)\frac{\partial y}{\partial x}-\left(r+\frac{x^2}{2}\frac{\partial^2\eta}{\partial x^2}+2x\frac{\partial\eta}{\partial x}+\eta\right)y=0. \tag{3.11}$$

We have that $y\ge 0$ on the parabolic boundary of Q, whereas $y=0$ on $\tau=t$. The strong maximum principle [30] implies that $y=0$ in Q, so $u(\tau,\cdot)$ is an affine function in Q with respect to the variable x. We can look for $u(\tau,x)$ as $u(\tau,x)=a(\tau)x+\beta(\tau)$. Plugging this into (3.10), we obtain easily that $a(\tau)=-1$ and $b(\tau)=Ke^{r(t-\tau)}$. This means that $u(\tilde{\tau},\tilde{s})=Ke^{r(t-\tilde{\tau})}-\tilde{s}$, so u jumps across the graph of γ, which is in contradiction with the continuity of u. □

From Lemmas 3.5, 3.6, and 3.10, we have proved the following theorem.

THEOREM 3.11. *Under Assumptions* 1 *and* 2, *the function* γ *defined in Lemma* 2.4 *is continuous. The function* μ *defined by* (2.23) *belongs to* $C^0([0,T];L^p((0,T)\times\mathbb{R}_+))$, $1\le p<+\infty$, *and* $\frac{\partial u}{\partial t}\in C^0([0,T];V')$. We define by Γ the free boundary

$$\Gamma=\{(t,\gamma(t)),0<t\le T\} \tag{3.12}$$

and by Ω^+ the set

$$\Omega^+=\{(t,x),x>\gamma(t),0<t\le T\}=\{(t,x)\in(0,T]\times\mathbb{R}_+,u(t,x)>u_\circ(x)\}. \tag{3.13}$$

Remark 4. It is possible, by extending the results of Lamberton [24], to prove that the function $\gamma-K$ is more singular than $\sqrt{t}$ as t tends to 0. Therefore, the function γ is not Lipschitz continuous in $[0,T]$. However, depending on η, γ may be Lipschitz continuous in $[t,T]$, for all $t>0$. In particular, if η is a nondecreasing function of time, it is possible to prove such a regularity by adapting the proofs in [19] for the Stefan problem. Under some additional regularity assumptions on Γ and u, it is possible to prove that $\frac{\partial^2 u}{\partial x^2}$ stays bounded away from zero in $\Omega_t^+\cap\{x<K\}$, for $t>0$.

PROPOSITION 3.12. *Assume that the solution* u *of* (2.1) *is such that for all times* t, $0<t\le T$,

- $\gamma|_{[t,T]}$ *is a Lipschitz function;*
- $\frac{\partial u}{\partial t}\in H^1(\Omega_t^+)$, *where* Ω_t^+ *is the region* $\Omega_t^+=\{u(\tau,x)>u_0,\tau\ge t\}$.

In this case, for t, $0<t<T$, *there exists a positive constant* $m_t>0$ *such that* $\frac{\partial^2 u}{\partial x^2}\ge m_t$ *in the region* $\Omega_t^+\cap\{x<K\}$.

Proof. We take $t>0$ and we call $\Gamma_t=\Gamma\cap\{\tau>t\}$. We know from Theorem 2.2 and Lemma 3.2 that $x\frac{\partial u}{\partial x}\in H^1((t,T)\times\mathbb{R}_+)$, and from Theorem 3.4 that $\frac{\partial u}{\partial x}$ does not jump across Γ_t, so $\frac{\partial u}{\partial x}|_{\Gamma_t}=-1$.

The assumptions also ensure that $\frac{\partial u}{\partial t}|_{\Omega_t^+}$ has a trace on Γ_t. From the fact that $u(\tau,\gamma(\tau)) = K - \gamma(\tau)$ and the Lipschitz regularity of γ, we obtain that

$$\frac{\partial u}{\partial t}(\tau,\gamma(\tau)) + \frac{\partial u}{\partial x}(\tau,\gamma(\tau))\frac{d\gamma}{dt}(\tau) = -\frac{d\gamma}{dt}(\tau) \quad \text{a.e. } \tau > t,$$

which yields $\frac{\partial u}{\partial t}|_{\Gamma_t} = 0$. From these results and the PDE satisfied by u in the region Ω_t^+, we obtain that the trace of $\eta x^2 \frac{\partial^2 u}{\partial x^2})|_{\Omega_t^+}$ on Γ_t is rK.

The function $y = \frac{\partial^2 u}{\partial x^2}$ satisfies the parabolic PDE (3.11) in Ω_+. The coefficients of the PDE are bounded thanks to Assumptions 1 and 2, and the operator $-\frac{\eta x^2}{2}\frac{\partial^2 y}{\partial x^2}$ is uniformly elliptic in Ω_t^+ thanks to Assumption 1 and Theorem 3.4. We also know from Lemma 3.1 that $y \geq 0$. So it is possible to use the strong maximum principle for y in Ω_t^+ (see [30, page 168]): if there exists a point $(t_1,\xi) \in \Omega^+$ such that $y = 0$, then for all $t, 0 < t \leq t_1$, $y = 0$ in $\Omega_t^+ \cap \{\tau \leq t_1\}$. But this is in contradiction with the fact that $y|_{\Gamma_t} = rK$. Therefore, for $t > 0$, the infimum of y in $\Omega_t^+ \cap \{x \leq K\}$ is positive. ∎

4. Sensitivity analysis. Here, we aim at understanding the sensitivity of u with respect to variations of η. For η satisfying Assumption 1, we call $u(\eta)$ the solution to problem (2.8), with $A = A_\eta$ given by (2.5).

PROPOSITION 4.1. *There exists a positive constant C such that, for η and η' satisfying Assumption* 1*,*

(4.1)
$$\|u(\eta) - u(\eta')\|_{L^2(0,T;V)} + \|u(\eta) - u(\eta')\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} \leq C\|\eta - \eta'\|_{L^\infty((0,T)\times\mathbb{R}_+)}$$

and

(4.2)
$$\int_0^T \int_0^K 1_{\{u(\eta)=u_\circ\}}(u(\eta') - u_\circ) + 1_{\{u(\eta')=u_\circ\}}(u(\eta) - u_\circ)dtdx \leq C\|\eta - \eta'\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}.$$

Proof. For all $v \in L^2(0,T,V)$,

$$\begin{aligned}
\left\langle \frac{\partial u(\eta)}{\partial t} + A_\eta(t)u(\eta), v \right\rangle &= rK\langle 1_{\{u(\eta)=u_\circ\}}, v\rangle, \\
\left\langle \frac{\partial u(\eta')}{\partial t} + A_{\eta'}(t)u(\eta'), v \right\rangle &= rK\langle 1_{\{u(\eta')=u_\circ\}}, v\rangle.
\end{aligned}$$

Calling $\delta u = u(\eta) - u(\eta')$, we subtract the two equations above and take $\delta u\, e^{-2\alpha t}$ as a test function, where α is the constant appearing in (2.6):

$$\begin{aligned}
&\left\langle \frac{\partial \delta u}{\partial t} + A_\eta(t)\delta u, \delta u e^{-2\alpha t} \right\rangle \\
&+ rK\int_0^T \int_0^K \left(1_{\{u(\eta)=u_\circ\}}(u(\eta') - u_\circ) + 1_{\{u(\eta')=u_\circ\}}(u(\eta) - u_\circ)\right) e^{-2\alpha t}dtdx \\
&= \int_0^T \langle (A_{\eta'}(t) - A_\eta(t))u(\eta'), \delta u e^{-2\alpha t}\rangle dt.
\end{aligned} \tag{4.3}$$

This implies that, for all $t \in [0,T]$,

$$\begin{aligned}(4.4)\quad &\frac{1}{2}\|\delta u(t)e^{-\alpha t}\|^2_{L^2(\mathbb{R}_+)} + \int_0^T \langle A_\eta(s)\delta u, \delta u\rangle e^{-2\alpha s}ds + \alpha\|\delta u e^{-\alpha t}\|^2_{L^2((0,T)\times\mathbb{R}_+)}\\ &\quad + rK\int_0^T\int_0^K \left(1_{\{u(\eta)=u_\circ\}}(u(\eta')-u_\circ) + 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)\right)e^{-2\alpha s}dsdx\\ &\le \int_0^T \langle (A_{\eta'}(s)-A_\eta(s))u(\eta'), \delta u e^{-2\alpha s}\rangle ds\end{aligned}$$

because $\delta u(t=0)=0$. From the Gårding inequality (2.6), we deduce from (4.4) that for all $t \in (0,T]$,

$$\begin{aligned}(4.5)\quad &\frac{1}{2}\|\delta u(t)\|^2_{L^2(\mathbb{R}_+)} + \frac{1}{4}\underline{\eta}\|\delta u\|^2_{L^2(0,T;V)}\\ &\quad + rK\int_0^T\int_0^K \left(1_{\{u(\eta)=u_\circ\}}(u(\eta')-g) + 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)\right)dsdx\\ &\le e^{2\alpha T}\int_0^T \langle (A_{\eta'}(s)-A_\eta(s))u(\eta'), \delta u e^{-2\alpha s}\rangle ds.\end{aligned}$$

But

$$\begin{aligned}(4.6)\quad &\int_0^T \left|\langle (A_{\eta'}(s)-A_\eta(s))u(\eta'), \delta u e^{-2\alpha s}\rangle\right| ds\\ &\le \|\eta-\eta'\|_{L^\infty((0,T)\times\mathbb{R}_+)}\left\|x^2\frac{\partial^2 u(\eta')}{\partial x^2}\right\|_{L^2((0,T)\times\mathbb{R}_+)}\|\delta u\|_{L^2((0,T)\times\mathbb{R}_+)}.\end{aligned}$$

Note also that

$$(4.7)\qquad \int_0^T\int_0^K \left(1_{\{u(\eta)=u_\circ\}}(u(\eta')-u_\circ) + 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)\right)dsdx \ge 0.$$

The bound (4.1) follows from (4.5), (4.7), and (4.6). The bound (4.2) follows from (4.5), (4.1), and (4.6). □

PROPOSITION 4.2. *Let η and $(\eta_k)_{k\in\mathbb{N}}$ be, respectively, a function and a sequence of functions satisfying Assumption* 1*, such that*

$$(4.8)\qquad \lim_{k\to+\infty}\|\eta_k-\eta\|_{L^\infty((0,T)\times\mathbb{R}_+)} = 0.$$

Then $1_{\{u(\eta_k)=u_\circ\}}$ tends to $1_{\{u(\eta)=u_\circ\}}$ strongly in $L^p((0,T)\times\mathbb{R}_+)$, $1\le p<+\infty$.

Proof. From Proposition 4.1, we know that the sequence $u(\eta_k)$ converges to $u(\eta)$ in $L^2(0,T;V)$ and in $L^\infty(0,T;L^2(\mathbb{R}_+))$. Moreover, we know from Theorem 2.2 that the quantities $\|(x+1)\frac{\partial u(\eta_k)}{\partial x}\|_{L^2(0,T;V)}$, $\|x\frac{\partial u(\eta_k)}{\partial x}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$, $\|\frac{\partial u(\eta_k)}{\partial t}\|_{L^2((0,T)\times\mathbb{R}_+)}$ are bounded independently of η. Therefore, $u(\eta_k)$ tends to $u(\eta)$ in $L^2(0,T;V)$ and in $L^\infty(0,T;L^2(\mathbb{R}_+))$ strongly, $\frac{\partial u(\eta_k)}{\partial t}$ tends weakly to $\frac{\partial u(\eta)}{\partial t}$ in $L^2((0,T)\times\mathbb{R}_+)$, and $x^2\frac{\partial^2 u(\eta_k)}{\partial x^2}$ tends weakly to $x^2\frac{\partial^2 u(\eta)}{\partial x^2}$ in $L^2((0,T)\times\mathbb{R}_+)$. This implies that $\mu(\eta_k)$ tends weakly to $\mu(\eta)$ in $L^2((0,T)\times\mathbb{R}_+)$, and in every $L^p((0,T)\times\mathbb{R}_+)$, $1\le p<\infty$, because $\mu(\eta_k) = rK1_{\{u(\eta_k)=u_\circ\}}$ is bounded and has a limited support. Thus the sequence $1_{\{u(\eta_k)=u_\circ\}}$ converges weakly in $L^p((0,T)\times\mathbb{R}_+)$, $1\le p<+\infty$, to a function which can take only two values, 0 and 1, and which has a bounded support. Hence, the convergence must be strong. □

PROPOSITION 4.3. *Let η and $(\eta_k)_{k\in\mathbb{N}}$ be, respectively, a function and a sequence of functions satisfying Assumption 1, such that $\lim_{k\to+\infty}\|\eta_k-\eta\|_{L^\infty((0,T)\times\mathbb{R}_+)}=0$. Then for any interval $[x_1,x_2]$, $0<x_1<x_2<+\infty$,*

$$\lim_{k\to+\infty}\|u(\eta_k)-u(\eta)\|_{L^\infty((0,T)\times(x_1,x_2))}=0. \tag{4.9}$$

Proof. Noting $\delta u=u(\eta)-u(\eta_k)$, we have that

$$\frac{\partial\delta u}{\partial t}+A_\eta(t)\delta u=-(\eta-\eta_k)\frac{x^2}{2}\frac{\partial^2u(\eta_k)}{\partial x^2}+rK(1_{\{u(\eta)=u_\circ\}}-1_{\{u(\eta_k)=u_\circ\}}).$$

But from Lemma 2.5, for any compact ω strictly contained in $\mathbb{R}_+$, there exist a real number $q>2$ and a constant C independent of η_k such that

$$\left\|\frac{\partial^2u(\eta_k)}{\partial x^2}\right\|_{L^q((0,T)\times\omega)}\le C.$$

Therefore,

$$\left\|(\eta-\eta_k)\frac{x^2}{2}\frac{\partial^2u(\eta_k)}{\partial x^2}\right\|_{L^q((0,T)\times\omega)}\to 0.$$

From this and (4.8), and by applying locally [20, Theorem 9.1, page 340], we obtain that

$$\lim_{k\to\infty}\left\|\frac{\partial\delta u}{\partial t}\right\|_{L^q((0,T))\times(x_1,x_2)}+\left\|\frac{\partial\delta u}{\partial x}\right\|_{L^q((0,T))\times(x_1,x_2)}+\left\|\frac{\partial^2\delta u}{\partial x^2}\right\|_{L^q((0,T))\times(x_1,x_2)}=0,$$

which implies (4.9) by Sobolev injections. □

Under additional regularity assumptions on Γ and u, it is possible to find estimates on the variation of Γ as follows.

PROPOSITION 4.4. *Let η and η' satisfy Assumptions 1 and 2.*

Assume that the solution $u(\eta)$ of (2.1) is such that, for all times t, $0<t\le T$,

- *$\gamma(\eta)|_{[t,T]}$ is a Lipschitz function;*
- *$\frac{\partial u(\eta)}{\partial t}\in H^1(\Omega_t^+)$, where Ω_t^+ is the region $\Omega_t^+=\{u(\tau,x)>u_0,\tau\ge t\}$.*

In this case, for t, $0<t\le T$, there exists a positive constant $c_t>0$ such that

$$\|(\gamma(\eta')-\gamma(\eta))^+\|^3_{L^3(t,T)}\le c_t\|\eta-\eta'\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}. \tag{4.10}$$

Proof. We know from (4.2) that $\int_0^T\int_0^K 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)dtdx\le C\|\eta-\eta'\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}$. But

$$\begin{aligned}&\int_t^T\int_0^K 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)d\tau dx\\ =\;&\int_t^T 1_{\{\gamma(\eta')>\gamma(\eta)\}}d\tau\int_{\gamma(\eta)(\tau)}^{\gamma(\eta')(\tau)}dx\int_{\gamma(\eta)(\tau)}^{x}dy\int_{\gamma(\eta)(\tau)}^{y}\frac{\partial^2u}{\partial x^2}(\tau,s)ds.\end{aligned}$$

From Proposition 3.12, there exists a positive constant $m_t>0$ such that $\frac{\partial^2u}{\partial x^2}\ge m_t$ in the region $(t,T]\times[0,K]\cap\{(\tau,x):u(\tau,x)>u_0\}$. Therefore,

$$\int_t^T\int_0^K 1_{\{u(\eta')=u_\circ\}}(u(\eta)-u_\circ)d\tau dx\;\ge\;\frac{m_t}{6}\int_t^T\left((\gamma(\eta')(\tau)-\gamma(\eta)(\tau))^+\right)^3d\tau,$$

which proves the desired result. □

Remark 5. We believe that the estimate

$$\|(\gamma(\eta') - \gamma(\eta))^+\|^3_{L^3(0,T)} \leq c\|\eta - \eta'\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}$$

is true.

5. A first least square problem.

5.1. Description of the problem. Let X be the space

$$X = \left\{\eta \in L^2(\mathbb{R}_+); (x+1)\frac{\partial \eta}{\partial x} \in L^2(\mathbb{R}_+)\right\}. \tag{5.1}$$

We can easily check the Sobolev type embedding $X \subset L^\infty(\mathbb{R}_+) \cap C^0(\mathbb{R}_+)$ with continuous injection. This comes from the facts that $H^1(I) \subset C^0(I)$ for any compact interval and that $x\eta(x) = \int_0^x s\frac{\partial \eta}{\partial x}(s)ds - \int_0^x \eta(s)ds$, and the Cauchy–Schwarz inequality yields that for all $x > 0$, $|\eta(x)|^2 \leq \frac{2}{x}\int_0^x \left(|s\frac{\partial \eta}{\partial x}(s)|^2 + \eta^2(s)\right) ds$. In fact, from this inequality, we deduce that the embedding $X \subset L^\infty(\mathbb{R}_+)$ is also compact, because it is possible to approximate a function $\eta \in X$ by means of a piecewise constant function η_N, with

- $\eta_N(x) = 0$ for $x \geq N$,
- $\eta_N(x) = \frac{1}{N}\int_{i+\frac{j}{N}}^{i+\frac{j+1}{N}} \eta(s)ds$ for $i + \frac{j}{N} \leq x < i + \frac{j+1}{N}$, $0 \leq i,\, j \leq N-1$,

and prove that there exists a positive constant C such that

$$\|\eta - \eta_N\|_{L^\infty(\mathbb{R}_+)} \leq \frac{C}{\sqrt{N}}\|\eta\|_X.$$

We denote by Y the space

$$Y = \left\{\eta : \eta, x\frac{\partial \eta}{\partial x} \in H^1(0,T;X)\right\}. \tag{5.2}$$

We have that $Y \subset \{\eta : \eta, x\frac{\partial \eta}{\partial x} \in L^\infty((0,T)\times\mathbb{R}_+)\}$. We call $\mathcal{H}$ the set of the functions $\eta \in Y$ satisfying Assumption 1. The set $\mathcal{H}$ is a closed and convex subset of Y, compactly embedded in $L^\infty((0,T); W^{1,\infty}(\mathbb{R}_+))$.

Let J_R be a Fréchet differentiable, coercive and convex functional on Y, and let J be a Fréchet differentiable functional defined on $L^2(0,T;V)$.

Remark 6. The discussion below may be generalized to functionals J defined on $C^0((0,T)\times\mathbb{R}_+)$. We are interested in the following minimizing problem:

$$\min_{\substack{\eta\in\mathcal{H}\\ u \text{ satisfies (2.1)}}} \left(J(u) + J_R(\eta)\right). \tag{5.3}$$

For simplifying the discussion below, we make some assumptions on J, but generalizations are possible.

Assumption 3. We assume that $J(u)$ has the form

$$J(u) = \int_{t_1}^{t_2}\int_{x_1}^{x_2} (u(t,x) - u_g(t,x))^2 dtdx, \tag{5.4}$$

where $0 \leq t_1 < t_2 \leq T$ and $0 \leq x_1 < x_2 < \infty$ and $u_g \in L^2((0,T)\times\mathbb{R}_+) \cap L^\infty((0,T)\times\mathbb{R}_+)$. With this special choice,

$$DJ(u) = 2(u - u_g)1_{(t_1,t_2)\times(x_1,x_2)}. \tag{5.5}$$

By using the results of the previous sections, it is fairly easy to prove that (5.3) has solutions.

It is also possible to consider the optimization problem for the penalized problem

$$\min_{\substack{\eta\in\mathcal{H}\\ u \text{ satisfies (2.10)}}} \left(J(u_\epsilon)+J_R(\eta)\right). \tag{5.6}$$

Again, one may prove that this problem has solutions and the following result.

LEMMA 5.1. *Let $(\epsilon_n)_n$ be a sequence of penalty parameters such that $\epsilon_n \to 0$ as $n\to\infty$, and let $\eta^*_{\epsilon_n}, u^*_{\epsilon_n}$ be a solution of the problem* (5.6). *Consider a subsequence such that $\eta^*_{\epsilon_n}\to\eta^*$ weakly in Y and strongly in $L^\infty(0,T,W^{1,\infty}(\mathbb{R}_+))$, and $u^*_{\epsilon_n}\to u^*$ weakly in $L^2(0,T;V)$. Then η^*, u^* is a solution to* (5.3) *and we have for any x_1, x_2, $0<x_1<x_2<+\infty$,*

$$\lim_{n\to\infty} \|u^*_{\epsilon_n}-u^*\|_{L^\infty((0,T)\times(x_1,x_2))}=0. \tag{5.7}$$

Calling $\mu^* = rK1_{\{u^*=u_\circ\}}$,

$$\lim_{n\to\infty} \|rK1_{\{x<K\}}\mathcal{V}_{\epsilon^*_n}(u^*_{\epsilon_n}-u_\circ)-\mu^*\|_{L^p((0,T)\times\mathbb{R}_+)} = 0 \quad \forall p,\ 1\le p<+\infty. \tag{5.8}$$

Finally,

$$\lim_{n\to\infty} \left\| x\frac{\partial u^*_{\epsilon_n}}{\partial x} - x\frac{\partial u^*}{\partial x}\right\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} = 0. \tag{5.9}$$

Proof. The proof that u^* satisfies (2.1) with $\eta=\eta^*$ follows the same lines as that of Theorem 2.2, because $\eta^*_{\epsilon_n}\to\eta^*$ strongly in L^∞; see Remark 2. The convergence of $\eta^*_{\epsilon_n}$ and of $u^*_{\epsilon_n}$ imply that $J(u^*_{\epsilon_n})\to J(u^*)$ and that $J_R(\eta^*)\le \liminf_{n\to\infty} J_R(\eta^*_{\epsilon_n})$.

We have that

$$J(u^*_{\epsilon_n})+J_R(\eta^*_{\epsilon_n}) \le J(u_{\epsilon_n}(\eta))+J_R(\eta) \quad \forall \eta\in\mathcal{H},$$

which yields by passing to the limit

$$J(u^*)+J_R(\eta^*)\le J(u(\eta))+J_R(\eta) \quad \forall\eta\in\mathcal{H}.$$

In order to prove (5.7), we notice that $u(\eta^*_{\epsilon_n})\le u^*_{\epsilon_n}\le u(\eta^*_{\epsilon_n})+\epsilon_n$ from Proposition 2.3 and that $\lim_{n\to\infty}\|u(\eta^*_{\epsilon_n})-u^*\|_{L^\infty((0,T)\times(x_1,x_2))}=0$ from Proposition 4.3. Combining these two results yields (5.7).

The proof of (5.8) is exactly the same as for Proposition 3.8. The proof of (5.9) is exactly the same as for Proposition 3.9. ∎

5.2. First order optimality conditions. It is possible to formulate the variational inequality (2.1) as the identity $\frac{\partial u}{\partial t}+A(t)u=\mu$, with additional constraints on u and μ: $u\ge u_\circ$, $\mu\ge 0$ and $\langle \mu, u-u_\circ\rangle=0$. It is then tempting to use the Lagrange machinery for the least square problem. However, as observed by Bergounioux and

Kunisch [5] for optimal control of obstacle problems, it is generally not possible to find a necessary optimality condition with as many Lagrange multipliers as there are constraints, because the Lagrange system that one would obtain has no solutions. So it is not easy to derive suitable optimality conditions from the variational inequality itself. Instead, we are going to work on the penalized problem (2.10) first, as in [16] and [15].

It is classical to find the first order conditions for a solution $(\eta_\epsilon^*, u_\epsilon^*)$ of (5.6):

- u_ϵ^* satisfies (2.10) for $\eta = \eta_\epsilon^*$;
- there exists an adjoint state $p_\epsilon^* \in L^2(0,T;V) \cap C^0((0,T];L^2(\mathbb{R}_+))$ solution of the problem

(5.10)
$$\left.\begin{array}{l} \dfrac{\partial p_\epsilon^*}{\partial t} + \dfrac{\partial^2}{\partial x^2}\left(\dfrac{\eta_\epsilon^* x^2}{2} p_\epsilon^*\right) - \dfrac{\partial}{\partial x}(rx p_\epsilon^*) - r p_\epsilon^* \\ +rK1_{\{x<K\}} \mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ) p_\epsilon^* \end{array}\right\} = -DJ(u_\epsilon^*), \quad \left\{\begin{array}{l} t \in [0,T), \\ x > 0, \end{array}\right.$$
$$p_\epsilon^*(T) = 0;$$

- $\forall \eta \in \mathcal{H}$,

$$\langle DJ_R(\eta_\epsilon^*), \eta - \eta_\epsilon^* \rangle + \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}(\eta - \eta_\epsilon^*) p_\epsilon^* \frac{\partial^2 u_\epsilon^*}{\partial x^2}\, dt\, dx \geq 0. \tag{5.11}$$

We will use the above first order conditions and let ϵ tend to zero, in order to obtain first order conditions for problem (5.3). Such a program has already been applied by Hintermüller [15] and Ito and Künisch [16] for elliptic variational inequalities. At this point, we should also mention Mignot and Puel [28], who applied an elegant method for finding optimality conditions for a special control problem for a parabolic variational inequality.

Before stating the result, we introduce, for a given η satisfying Assumption 1, the Hilbert spaces

$$\begin{aligned} \tilde{Z}_\eta &= \left\{ v \in L^2(0,T;V); \frac{\partial v}{\partial t} - \frac{\eta x^2}{2}\frac{\partial^2 v}{\partial x^2} \in L^2((0,T)\times\mathbb{R}_+) \right\}, \\ Z_\eta &= \left\{ v \in \tilde{Z}_\eta; v(t=0) = 0 \right\}. \end{aligned} \tag{5.12}$$

It is easy to prove that a function $v \in \tilde{Z}_\eta$ belongs to $H^1(0,T;V')$, so the condition $v(t=0)=0$ has a meaning and defines a closed subspace of $\tilde{Z}_\eta$.

It can be shown by studying the properties of $x\frac{\partial v}{\partial x}$ for $v \in Z_\eta$ that

$$x\frac{\partial v}{\partial x} \in L^2(0,T;V) \cap \mathcal{C}^0(0,T;L^2(\mathbb{R}_+)),$$

which implies that both $\frac{\partial v}{\partial t}$ and $\frac{\eta x^2}{2}\frac{\partial^2 v}{\partial x^2}$ belong to $L^2((0,T)\times\mathbb{R}_+)$, and that v is continuous in $[0,T]\times\mathbb{R}_+$. We have that Z_η does not depend on η in the class defined by Assumption 1, so we call this space Z.

THEOREM 5.2. *Let ϵ_n be a sequence of penalty parameters going to zero, and let $(\eta_{\epsilon_n}^*, u_{\epsilon_n}^*)$ be a sequence of solutions to* (5.6) *converging to (η^*, u^*) as in Lemma* 5.1. *There exists a subsequence denoted n_k such that $p_{\epsilon_{n_k}}^*$ converges weakly to p^* in*

$L^2(0,T,V)$. Moreover, there exists a Radon measure α^* such that, in the sense of distributions,

$$\frac{\partial p^*}{\partial t} + \frac{\partial^2}{\partial x^2}\left(\frac{\eta^* x^2}{2} p^*\right) - \frac{\partial}{\partial x}(rxp^*) - rp^* - \alpha^* = -DJ(u^*) \quad \begin{cases} t \in (0,T), \\ x > 0, \end{cases} \tag{5.13}$$

and for all functions $v \in Z$,

$$\int_0^T \int_{\mathbb{R}_+} \left(\frac{\partial v}{\partial t} - \frac{\eta^* x^2}{2}\frac{\partial^2 v}{\partial x^2} - rx\frac{\partial v}{\partial x} + rv\right) p^* + \langle \alpha^*, v\rangle = \langle DJ(u^*), v\rangle. \tag{5.14}$$

Furthermore we have

$$\mu^* |p^*| = 0, \tag{5.15}$$

and, for any $x_1 > 0$ and any function $\phi \in C^0([0,T]\times\mathbb{R}_+)$ such that $\phi(t,x) = 0$ if $x \le x_1$,

$$\langle \alpha^*, |u^* - u_\circ|\phi\rangle = 0. \tag{5.16}$$

Finally, for any $\eta \in \mathcal{H}$,

$$\langle DJ_R(\eta^*), \eta - \eta^*\rangle + \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}(\eta - \eta^*) p^* \frac{\partial^2 u^*}{\partial x^2}\, dt\, dx \ge 0. \tag{5.17}$$

Proof. For simplicity, we drop the index n in ϵ_n.

The first thing to do is to obtain estimates on p_ϵ^*: multiplying (5.11) by $p_\epsilon^* e^{\zeta t}$ and integrating leads to

$$\begin{aligned} &\int_{\mathbb{R}_+} \frac{1}{2}(p_\epsilon^*(t,x)e^{\frac{\zeta}{2}t})^2 dx + \int_t^T \int_{\mathbb{R}_+} \frac{\eta_\epsilon^* x^2}{2}\left(\frac{\partial p_\epsilon^*}{\partial x}\right)^2 e^{\zeta s} ds dx \\ &\quad + \int_t^T \int_{\mathbb{R}_+} \left(\frac{\partial}{\partial x}\left(\frac{\eta_\epsilon^* x^2}{2}\right) + rx\right) p_\epsilon^* \frac{\partial p_\epsilon^*}{\partial x} e^{\zeta s} ds dx \\ &\quad + \left(\frac{\zeta}{2} + 2r\right)\int_t^T \int_{\mathbb{R}_+} (p_\epsilon^* e^{\frac{\zeta}{2}s})^2 ds dx - rK \int_t^T \int_0^K \mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ)(p_\epsilon^*)^2 e^{\zeta s} ds dx \\ &= \int_t^T \int_{\mathbb{R}_+} DJ(u_\epsilon^*) p_\epsilon^* e^{\zeta s} ds dx. \end{aligned} \tag{5.18}$$

Taking ζ large enough, one obtains, thanks to the decreasing character of $\mathcal{V}_\epsilon$, that there exists a positive constant C independent of ϵ such that $\|p_\epsilon^*\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} + \|p_\epsilon^*\|_{L^2(0,T;V)} \le C$. Then, for a positive parameter δ, we introduce the nondecreasing function $\rho_\delta : \mathbb{R} \to \mathbb{R}$:

$$\rho_\delta(p) = \left| \begin{array}{cc} -1 & \text{for } p \le -\delta, \\ \frac{p}{\delta} & \text{for } -\delta \le p \le \delta, \\ 1 & \text{for } p \ge \delta. \end{array} \right. \tag{5.19}$$

We also have the nonnegative function $G_\delta(p) = \int_0^p \rho_\delta(q) dq$. For $\bar{K} > K$, we also introduce a smooth cut-off function $\Phi : \mathbb{R}_+ \to [0,1]$, taking the value 1 for $x \le \bar{K}$ and

0 for $x \geq 2\bar{K}$. We multiply (5.18) by $\rho_\delta(p^*_\epsilon)\Phi(x)$ and integrate. We obtain that there exists a constant $C_{\bar{K}}$ independent of δ and ϵ such that

$$\int_{\mathbb{R}_+}\int_t^T\int_{\mathbb{R}_+}\left(\frac{\eta^*_\epsilon x^2}{2}\rho'_\delta(p^*_\epsilon)\left(\frac{\partial p^*_\epsilon}{\partial x}\right)^2\Phi(x) - rK\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)p^*_\epsilon\rho_\delta(p^*_\epsilon)\right)dsdx \\ + G_\delta(p^*_\epsilon(t,x))\Phi(x)dx \quad \leq C_{\bar{K}}.$$

One can easily check that all the terms in the left-hand side are nonnegative and that a.e. $p^*_\epsilon\rho_\delta(p^*_\epsilon)$ is an increasing sequence with respect to δ, which converges to $|p^*_\epsilon|$. So the Beppo Levi theorem tells us that

$$-rK\int_t^T\int_0^K \mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)p^*_\epsilon\rho_\delta(p^*_\epsilon) \to -rK\int_t^T\int_0^K \mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)|p^*_\epsilon| \quad \text{as} \quad \delta \to 0.$$

Therefore, there exists a positive constant C such that

$$rK\int_0^T\int_0^K |\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)p^*_\epsilon|dtdx \leq C, \tag{5.20}$$

and it is possible to extract a subsequence ϵ_{n_k} such that $p^*_{\epsilon_{n_k}} \to p^*$ weakly in $L^2(0,T;V)$,

$$-rK1_{\{x\leq K\}}\mathcal{V}'_{\epsilon_{n_k}}(u^*_{\epsilon_{n_k}} - u_\circ)p^*_{\epsilon_{n_k}} \to \alpha^* \text{ weakly}^* \text{ in } (L^\infty((0,T)\times\mathbb{R}_+))^*.$$

Equation (5.13) is satisfied in the sense of distributions, and (5.14) is obtained by passing to the limit.

For proving (5.15), we use the convexity of $\mathcal{V}_\epsilon$ (still dropping the index n_k in ϵ_{n_k}): since $\mathcal{V}_\epsilon(\epsilon) = 0$, we have that for all $u \in [0,\epsilon]$,

$$\mathcal{V}_\epsilon(u) \leq -\mathcal{V}'_\epsilon(u)(\epsilon - u) \leq -\epsilon\mathcal{V}'_\epsilon(u).$$

This implies that $\mathcal{V}_\epsilon(u^*_\epsilon - u_\circ) \leq -\epsilon\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)$ because we also know that $\mathcal{V}_\epsilon(u^*_\epsilon - u_\circ) = 0$ if $u^*_\epsilon - u_\circ \geq \epsilon$. Thus, calling $\mu^*_\epsilon = rK1_{\{x<K\}}\mathcal{V}_\epsilon(u^*_\epsilon - u_\circ)$, we have that

$$\int_0^T\int_{\mathbb{R}_+}\mu^*_\epsilon|p^*_\epsilon| \leq -\epsilon rK\int_0^T\int_{\mathbb{R}_+}\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)|p^*_\epsilon| \to 0 \tag{5.21}$$

from (5.20). But we also know that $p^*_\epsilon \to p^*$ weakly in $L^2(0,T;V)$ and that $\mu^*_\epsilon \to \mu^*$ strongly in $L^2((0,T)\times\mathbb{R}_+)$ from Lemma 5.1. Therefore

$$\int_0^T\int_{\mathbb{R}_+}\mu^*_\epsilon|p^*_\epsilon| \to \int_0^T\int_{\mathbb{R}_+}\mu^*|p^*|,$$

and (5.15) is proved.

Let us call $\alpha^*_\epsilon = -rK1_{\{x<K\}}\,\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)p^*_\epsilon$, let $x_1 < x_2$ be two positive numbers, and let ϕ be a continuous function supported in $[0,T]\times[x_1,+\infty)$,

$$\int_0^T\int_{\mathbb{R}_+}|\alpha^*_\epsilon||(u^*_\epsilon - u_\circ)\phi| \\ \leq rK\left(\int_0^T\int_{\mathbb{R}_+}|\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)||p^*_\epsilon|^2\right)^{\frac{1}{2}}\left(\int_0^T\int_0^K|\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)||(u^*_\epsilon - u_\circ)\phi|^2\right)^{\frac{1}{2}}$$

from the Cauchy–Schwarz inequality. But it can be checked that

$$|\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)||(u^*_\epsilon - u_\circ)\phi|^2 \leq C\epsilon,$$

so $\int_0^T \int_0^K |\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)||(u^*_\epsilon - u_\circ)\phi|^2 \leq C\epsilon$, and from (5.18),

$$\int_0^T \int_0^K |\mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ)||p^*_\epsilon|^2 \leq C.$$

Therefore, $\int_0^T \int_{\mathbb{R}_+} \alpha^*_\epsilon |u^*_\epsilon - u_\circ|\phi \to 0$ as $\epsilon \to 0$. We know that $\alpha^*_\epsilon \to \alpha^*$ weakly* in $(L^\infty)^*$ and that $|u^*_\epsilon - u_\circ|\phi \to |u^* - u_\circ|\phi$ in $C^0([0,T]\times\mathbb{R}_+)$ from (5.7). We can pass to the limit as $\epsilon \to 0$ and (5.16) is proved.

There remains to prove (5.17). For that, we remark that (5.11) is equivalent to, for all $\eta \in \mathcal{H}$,

$$\begin{aligned} &J_R(\eta^*_\epsilon) - J_R(\eta) + \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}(\eta - \eta^*_\epsilon)\frac{\partial p^*_\epsilon}{\partial x}\frac{\partial u^*_\epsilon}{\partial x}\, dt\, dx \\ &+ \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}\frac{\partial}{\partial x}(\eta - \eta^*_\epsilon)\frac{\partial u^*_\epsilon}{\partial x}p^*_\epsilon - \int_0^T \int_{\mathbb{R}_+} u^*_\epsilon \frac{\partial}{\partial x}(x(\eta - \eta^*_\epsilon)p^*_\epsilon) \leq 0, \end{aligned}$$

thanks to the convexity of J_R and of $\mathcal{H}$. We can pass to the limit in the first term thanks to the weak convergence of η^*_ϵ to η^* in Y and the fact that J_R is convex and continuous, therefore weakly lower semicontinuous in Y. We can pass to the limit in the other terms from the facts that

- $x\frac{\partial u^*_\epsilon}{\partial x} \to x\frac{\partial u^*}{\partial x}$ in $L^\infty(0,T;L^2(\mathbb{R}_+))$,
- $\eta^*_\epsilon \to \eta^*$ in $L^\infty([0,T];W^{1,\infty}(\mathbb{R}_+))$,
- $p^*_\epsilon \to p^*$ in $L^2(0,T;V)$ weakly,

and we obtain

$$\begin{aligned} &J_R(\eta^*) - J_R(\eta) + \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}(\eta - \eta^*)\frac{\partial p^*}{\partial x}\frac{\partial u^*}{\partial x}\, dt\, dx \\ &+ \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}\frac{\partial}{\partial x}(\eta - \eta^*)\frac{\partial u^*}{\partial x}p^* - \int_0^T \int_{\mathbb{R}_+} u^* \frac{\partial}{\partial x}(x(\eta - \eta^*)p^*) \leq 0, \end{aligned}$$

which yields (5.17), since J_R is differentiable. □

Remark 7. For a given Radon measure α^*, the problem (5.14) has a unique solution (see the proof of Lemma 6.2 below and also the article by Bergounioux and Kunisch [4]). Under some assumptions, it is possible to give an interpretation of the adjoint problem (5.14), (5.15), (5.16): if η^* satisfies Assumptions 1 and 2, there exists a free boundary Γ^* which can be written $\{x = \gamma^*(t), 0 < t < T\}$, where γ^* is a continuous function from $[0,T]$ with values in $(0,K]$. We call Ω^+ the domain $\Omega^+ = \{(t,x),\ 0 \leq t \leq T,\ x > \gamma^*(t)\}$.

Equation (5.15) tells us that $p^* = 0$ a.e. in the region $\{x < \gamma^*(t)\}$. Equation (5.16) tells us that α^* is supported in the region $\{x \leq \gamma^*(t)\}$. From this, (5.13) tells us that α^* can be written

$$\alpha^* = \alpha^*_s + DJ(u^*)1_{\{x<\gamma^*(t)\}},$$

where the measure α^*_s is a Radon measure supported by Γ (singular with respect to the Lebesgue measure).

5.3. Partial results on differentiability. The aim of this section is to prove that the functional $\eta \mapsto J(u(\eta))$ is Fréchet-differentiable at the points η such that $u(\eta)$ and $\gamma(\eta)$ are smooth enough, and to compute its differential. For that, we will define first an adjoint state, which will be given as a solution of a problem close to (but stronger than) (5.14), (5.15), (5.16). This adjoint state will permit us to build an ansatz for the differential. To prove that this ansatz is actually the Fréchet differential, we will make use of the sensitivity results proved in section 4.

The solution of problem (2.1) is singular at $t = 0$. This causes technical difficulties when trying to see if J is differentiable. To avoid these difficulties, we modify the definition of $\mathcal{H}$: we choose a positive time t_0, $0 < t_0 < T$ (which can be taken as small as desired), and η_0, a smooth bounded function satisfying assumptions 1 and 2. We restrict Y to be

$$Y = \left\{ \eta : \eta, x\frac{\partial \eta}{\partial x}, x^2\frac{\partial^2 \eta}{\partial x^2}, \frac{\partial \eta}{\partial t}, x\frac{\partial^2 \eta}{\partial t \partial x} \in H^1(0,T;X), \qquad \eta|_{t<t_0} = \eta_0 \right\}. \tag{5.22}$$

We call $\mathcal{H}$ the set of the functions $\eta \in Y$ satisfying Assumptions 1 and 2.

Remark 8. If the inequality stated in Remark 5 were proven, the restriction $\eta|_{t<t_0} = \eta_0$ would become unnecessary. We believe that this is indeed unnecessary. For η in $\mathcal{H}$, we call $u(\eta)$ the solution of (2.1), or simply u when no ambiguity is possible. The free boundary Γ is described by the equation $x = \gamma(\tau)$, $0 \le \tau \le T$, with γ a continuous function bounded away from 0. We call Ω^+ the domain $\Omega^+ = \{(\tau, x), 0 \le \tau \le T, x > \gamma(\tau)\}$ and $\Omega_t^+ = \Omega^+ \cap \{\tau \ge t\}$. We call $\Gamma_t = \Gamma \cap \{\tau \ge t\}$.

Consider the backward parabolic problem in the noncylindrical domain Ω^+: find $\tilde{p}$ such that

$$\frac{\partial \tilde{p}}{\partial t} + \frac{\partial^2}{\partial x^2}\left(\frac{\eta x^2}{2}\tilde{p}\right) - \frac{\partial}{\partial x}(rx\tilde{p}) - r\tilde{p} = -DJ(u), \quad (t,x) \in \Omega^+, \tag{5.23}$$

$$\tilde{p} = 0, \quad t = T,\ \gamma(T) < x, \tag{5.24}$$

$$\tilde{p} = 0, \quad x = \gamma(t),\ 0 < t < T. \tag{5.25}$$

Assuming that the function γ is Hölder continuous with power $\frac{1}{2}$, and since η satisfies Assumptions 1 and 2, it is possible to find a weak solution of (5.23)–(5.25); see the work of Brown, Hu, and Lieberman [7]. Following these authors, we call $C_S^1(\Omega^+)$ the space of the functions v whose support is bounded in the variable x and such that v, $\frac{\partial v}{\partial x}$, and $\frac{\partial v}{\partial t}$ are uniformly continuous and v satisfies (5.24), (5.25). We consider the closure $Z(\Omega^+)$ of $C_S^1(\Omega^+)$ with respect to the norm

$$|||v||| = \sup_{t\in(0,T)} \left(\int_{x>\gamma(t)} v(t,x)^2 dx \right)^{\frac{1}{2}} + \left(\int_{\Omega^+} \left| x\frac{\partial v}{\partial x} \right|^2 \right)^{\frac{1}{2}}. \tag{5.26}$$

Following [7], there exists a unique $\tilde{p} \in Z(\Omega_+)$ such that for all $\phi \in C_S^1(\Omega^+)$,

$$\begin{aligned} &- \int_{\Omega_t^+} \tilde{p}\frac{\partial \phi}{\partial t} - \int_{\Omega_t^+} \frac{\eta x^2}{2}\frac{\partial \tilde{p}}{\partial x}\frac{\partial \phi}{\partial x} - \int_{\Omega_t^+} \left(\frac{\partial}{\partial x}\left(\frac{\eta x^2}{2}\right) - rx \right) \tilde{p}\frac{\partial \phi}{\partial x} - r\int_{\Omega_t^+} \tilde{p}\phi \\ &= - \int_{\Omega_t^+} DJ(u)\phi. \end{aligned} \tag{5.27}$$

Remark 9. Among the works on parabolic equations in noncylindrical domains (in any space dimension), let us mention articles by Lions [25] and by Oleĭnik [29] for classes of boundaries smaller than the class considered in [7]. To obtain further results, we need a further assumption on the regularity of the free boundary and u, as in Propositions 3.12 and 4.4.

Assumption 4 (on $\gamma(\eta)$ and $u(\eta)$). For all $t>0$, $\gamma|_{(t,T]}$ is a Lipschitz function, so $\tilde p$ has a trace on Γ_t (because $\frac{\partial \tilde p}{\partial x}\in L^2(\Omega_t^+)$), and we have $\tilde p|_{\Gamma_t}=0$. We also assume that $\frac{\partial u(\eta)}{\partial \tau}\in H^1(\Omega_t^+)$, so the result of Proposition 4.4 holds.

LEMMA 5.3. *For $\eta\in\mathcal{H}$, and under the previous assumption, the solution $\tilde p$ of (5.27) satisfies $x^2\frac{\partial^2\tilde p}{\partial x^2}\in L^2(\Omega_t^+)$ and that $\frac{\partial\tilde p}{\partial\tau}\in L^2(\Omega_t^+)$ for all $t>0$.*

Proof. Since γ is a Lipschitz function, it is possible by a simple change of variables to transform (5.23), (5.24), (5.25) in a problem posed in a cylindrical domain, and then to apply standard regularity results. A similar program has already been carried out in, e.g., [6].

We know that there exists a positive constant γ_0 such that $\gamma_0<\gamma(\tau)\le K$ for all times τ, $0\le\tau\le T$. We make the change of variables $(\tau,x)\mapsto(\tau,\xi)$, with

$$\xi = 2K+\frac{2K-\gamma_0}{2K-\gamma(\tau)}(x-2K) \quad \text{if } \gamma(\tau)\le x\le 2K, \qquad \xi = x \quad \text{if } 2K\le x. \tag{5.28}$$

This a Lipschitz mapping from Ω_t^+ onto $(t,T)\times(\gamma_0,+\infty)$, with a Lipschitz inverse. Its Jacobian matrix is

$$\begin{pmatrix} 1 & \dfrac{(2K-\gamma_0)\gamma'(t)}{(2K-\gamma(\tau))^2}(x-2K) \\ 0 & \dfrac{2K-\gamma_0}{2K-\gamma(\tau)} \end{pmatrix} \quad \text{if } x<2K.$$

As for the inverse mapping, we have

$$x(\tau,\xi)=2K+\frac{2K-\gamma(\tau)}{2K-\gamma_0}(\xi-2K) \quad \text{for} \quad \gamma_0<\xi<2K.$$

With this change of variable, the parabolic equation (5.23) is transformed into a parabolic equation in the variables (τ,ξ):

(5.29)

$$\frac{\partial\hat p}{\partial\tau}-\frac{2K-\xi}{2K-\gamma(\tau)}\gamma'(\tau)\frac{\partial\hat p}{\partial\xi}+\left(\frac{2K-\gamma_0}{2K-\gamma(\tau)}\right)^2\frac{\partial^2}{\partial\xi^2}\left(\frac{\hat\eta x^2}{2}\hat p\right)-\frac{2K-\gamma_0}{2K-\gamma(\tau)}\frac{\partial}{\partial\xi}(rx\hat p)-r\hat p$$
$$=-\widehat{DJ(u)}, \qquad t<\tau<T,\ \gamma_0<\xi<2K,$$

$$\frac{\partial\hat p}{\partial\tau}+\frac{\partial^2}{\partial\xi^2}\left(\frac{\eta\xi^2}{2}\hat p\right)-\frac{\partial}{\partial\xi}(r\xi\hat p)-r\hat p=-DJ(u), \qquad t<\tau<T,\ 2K<\xi,$$

$$\hat p=0, \quad \tau=T,\ \xi>\gamma_0,$$

$$\hat p=0, \quad \xi=\gamma_0,\ t<\tau<T,$$

where for a function u defined in Ω_t^+, the function $\hat u$ is defined in $(t,T)\times(\gamma_0,+\infty)$ by $\hat u(\tau,\xi)=u(t,x)$.

It is possible to use standard results on parabolic equations and prove that problem (5.29) has a unique solution in $L^2((t,T);\hat{V}) \cap C^0([t,T];L^2(\gamma_0,+\infty))$, with $\frac{\partial \hat{p}}{\partial \tau} \in L^2((t,T);\hat{V}')$, where

$$\hat{V} = \left\{ v \in L^2(\gamma_0,+\infty),\ \xi \frac{\partial v}{\partial \xi} \in L^2(\gamma_0,+\infty) \right\}.$$

Furthermore, thanks to Assumptions 1 and 2 and the Lipschitz regularity of γ, we have in fact that $\frac{\partial \hat{p}}{\partial \tau} \in L^2((t,T)\times(\gamma_0,+\infty))$ and $\xi^2 \frac{\partial^2 \hat{p}}{\partial \xi^2} \in L^2((t,T)\times(\gamma_0,+\infty))$. The desired result on $\tilde{p}$ follows easily. □

For any $\tau > 0$, it is possible to extend $\tilde{p}$ by 0 in $(\tau,T)\times\mathbb{R}_+$. Calling p this extension, $\frac{\partial p}{\partial t} \in L^2((\tau,T)\times\mathbb{R}_+)$ (resp., $\frac{\partial p}{\partial x} \in L^2((\tau,T)\times\mathbb{R}_+)$) is the extension of $\frac{\partial \tilde{p}}{\partial t}$ (resp., $\frac{\partial \tilde{p}}{\partial x}$) by 0 in $(\tau,T)\times\mathbb{R}_+$. We define $\alpha \in L^2((\tau,T),V')$ by

$$\langle \alpha, v\rangle = \int_{\{x<\gamma(t)\}} DJ(u)v + \frac{1}{2}\int_\Gamma \eta x^2 \frac{\partial \tilde{p}}{\partial x}|_\Gamma v|_\Gamma n_\Gamma ds,$$

where $n_\Gamma(t,\gamma(t)) = \frac{1}{\sqrt{1+(\gamma'(t))^2}}$. Note that $n_\Gamma ds = dt$. We have

$$\begin{array}{rcl} \frac{\partial p}{\partial t} + \frac{\partial^2}{\partial x^2}(\frac{\eta x^2}{2}p) - \frac{\partial}{\partial x}(rxp) - rp - \alpha &=& -DJ(u), \quad t\in(0,T),\ x>0, \\ p(T) &=& 0, \\ p &=& 0, \quad 0<t<T,\ x<\gamma(t), \end{array}$$

or in other words, for all $w \in L^2(0,T;V)\cap C^0([0,T]\times\mathbb{R}_+)$, with $\frac{\partial w}{\partial t} \in L^2(0,T;V')$ and $w(t)=0$ for $t<t_0$,

$$\begin{array}{l} \left\langle \dfrac{\partial w}{\partial t} + A_\eta(t)w, p \right\rangle + \langle DJ(u(\eta)) - \alpha, w\rangle = 0, \\ p = 0 \quad \text{a.e. in } \{u(\eta)=u_\circ\}, \\ \langle \alpha, w\rangle = 0 \quad \text{if } w \text{ satisfies } w=0 \text{ in } \{u(\eta)=u_\circ\}. \end{array} \tag{5.30}$$

THEOREM 5.4. *If $\eta \in \mathcal{H}$ such that the regularity Assumption 4 on $u(\eta)$ and on the free boundary is fulfilled, then the functional $\xi \mapsto J(u(\xi))$ is differentiable in $\mathcal{H}$ at η, and with p given by* (5.30)*, its differential is*

$$\xi \mapsto \int \frac{x^2}{2}\xi \frac{\partial u(\eta)}{\partial x}\frac{\partial p}{\partial x} + \left(x\xi + \frac{x^2}{2}\frac{\partial \xi}{\partial x}\right)\frac{\partial u(\eta)}{\partial x}p. \tag{5.31}$$

Proof. Let $\delta\eta$ be a small variation of η in Y, such that $\min \eta+\delta\eta > 0$. We note that $\delta u = u(\eta+\delta\eta)-u(\eta)$, $\delta\mu = \mu(\eta+\delta\eta)-\mu(\eta)$, and $\delta J = J(u(\eta+\delta\eta))-J(u(\eta))$. We know from Proposition 4.1 that $\|\delta u\|_{L^2(0,T;V)} + \|\delta u\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} \le C\|\delta\eta\|_{L^\infty((0,T)\times\mathbb{R}_+)}$, so $\delta J = \langle DJ(u(\eta)), \delta u\rangle + o(\delta\eta)$, where the notation $o(\delta\eta)$ is used for a function of $\delta\eta$ such that

$$\lim_{\|\delta\eta\|_{L^\infty((0,T)\times\mathbb{R}_+)} + \|x\frac{\partial\delta\eta}{\partial x}\|_{L^\infty((0,T)\times\mathbb{R}_+)}\to 0} \frac{|o(\delta\eta)|}{\|\delta\eta\|_{L^\infty((0,T)\times\mathbb{R}_+)} + \|x\frac{\partial\delta\eta}{\partial x}\|_{L^\infty((0,T)\times\mathbb{R}_+)}} = 0.$$

Subtracting the equation satisfied by $(u(\eta),\mu(\eta))$ from the one satisfied by $(u(\eta)+\delta u, \mu(\eta)+\delta\mu)$, we obtain that

$$\begin{array}{l} \left\langle \dfrac{\partial \delta u}{\partial t} + A_{\eta+\delta\eta}(t)\delta u, w \right\rangle \\ \qquad + \displaystyle\int \frac{x^2}{2}\delta\eta \frac{\partial u(\eta)}{\partial x}\frac{\partial w}{\partial x} + \left(x\delta\eta + \frac{x^2}{2}\frac{\partial\delta\eta}{\partial x}\right)\frac{\partial u(\eta)}{\partial x}w - \langle \delta\mu, w\rangle = 0, \end{array} \tag{5.32}$$

because A_η is linear with respect to η. From estimate (4.1), we deduce from (5.32) that

$$\left\langle \frac{\partial \delta u}{\partial t} + A_\eta(t)\delta u, w \right\rangle + \int \frac{x^2}{2}\delta\eta \frac{\partial u(\eta)}{\partial x}\frac{\partial w}{\partial x} + \left(x\delta\eta + \frac{x^2}{2}\frac{\partial \delta\eta}{\partial x}\right)\frac{\partial u(\eta)}{\partial x} w - \langle \delta\mu, w\rangle = o(\delta\eta). \tag{5.33}$$

We have also

$$\langle \mu, \delta u\rangle + \langle \delta\mu, u(\eta) - u_\circ\rangle + \langle \delta\mu, \delta u\rangle = 0, \tag{5.34}$$

and estimate (4.2) indicates that $\langle \delta\mu, \delta u\rangle \leq C\|\delta\eta\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}$.

Since $\delta\eta = 0$ for $t < t_0$, we have that $\delta u = 0$ for $t < t_0$. We deduce from (5.30) that

$$\begin{array}{l}\langle DJ(u(\eta)), \delta u\rangle = \\ \displaystyle\int \frac{x^2}{2}\delta\eta\frac{\partial u(\eta)}{\partial x}\frac{\partial p}{\partial x} + \left(x\delta\eta + \frac{x^2}{2}\frac{\partial\delta\eta}{\partial x}\right)\frac{\partial u(\eta)}{\partial x}p - \langle\delta\mu, p\rangle + \langle\alpha, \delta u\rangle + o(\delta\eta).\end{array} \tag{5.35}$$

We aim at proving that the terms $\langle\alpha, \delta u\rangle$ and $\langle\delta\mu, p\rangle$ are $o(\delta\eta)$.

Let us start with the term $\langle\alpha, \delta u\rangle$. The measure α can be written as the sum of two terms:

(1) A measure $\alpha_a = 1_{\{u(\eta)=u_\circ\}}DJ(u(\eta))$ which is absolutely continuous with respect to the Lebesgue measure, and supported in the region $\{u(\eta) = u_\circ\}$. From Assumption 3, we see that

$$\alpha_a = 1_{\{u(\eta)=u_\circ\}}2(u_\circ - u_g). \tag{5.36}$$

We know that $\langle\alpha_a, \delta u\rangle = 2\int 1_{\{u(\eta)=u_\circ\}}(u_\circ - u_g)(u(\eta+\delta\eta) - u_\circ)$. Therefore from (4.2),

$$\begin{array}{l}|\langle\alpha_a, \delta u\rangle| \leq 2(K + \|u_g\|_{L^\infty((0,T)\times\mathbb{R}_+)})\displaystyle\int 1_{\{u(\eta)=u_\circ\}}(u(\eta+\delta\eta) - u_\circ) \\ \leq C\|\eta\|^2_{L^\infty((0,T)\times\mathbb{R}_+)}.\end{array}$$

(2) A singular measure $\alpha_s \in L^2(0,T;V')$ supported by Γ:

$$\langle\alpha_s, \delta u\rangle = \int_{t=t_0}^T h(t)\gamma(t)\delta u(t,\gamma(t))dt, \qquad h(t) = \eta(t,\gamma(t))\gamma(t)\frac{\partial\tilde{p}}{\partial x}(t,\gamma(t)). \tag{5.37}$$

So

$$\begin{array}{rcl}|\langle\alpha_s, \delta u\rangle| = & \left|\displaystyle\int_{t=t_0}^T h(t)\gamma(t)\delta u(t,\gamma(t))dt\right| \\ = & \left|\displaystyle\int_{t=t_0}^T h(t)1_{\delta\gamma(t)<0}\int_{\gamma(t)+\delta\gamma(t)}^{\gamma(t)}\frac{\partial}{\partial x}(x\delta u)dx\right| \\ \leq & \|h\sqrt{(\delta\gamma)_-}\|_{L^2(t_0,T)}\left(\displaystyle\int_{t=t_0}^T 1_{\delta\gamma(t)<0}\int_{\gamma(t)+\delta\gamma(t)}^{\gamma(t)}\left(\frac{\partial}{\partial x}(x\delta u)\right)^2 dx\right)^{\frac{1}{2}}.\end{array}$$

But from Proposition 4.2, $(\delta\gamma)_-$ converges to 0 in $L^1(t_0,T)$. Consider a subsequence $(\delta\eta_n,\delta\gamma_n)$ such that $\|h\sqrt{(\delta\gamma_n)_-}\|_{L^2(t_0,T)} \to \ell$. It is possible to extract a second subsequence still called $(\delta\eta_n,\delta\gamma_n)$ such that $(\delta\gamma_n)_- \to 0$ a.e., but we know that $0 \le (\delta\gamma)_- \le K$, so Lebesgue's theorem tells us that $\ell = 0$. Therefore, we have that $\lim_{\delta\eta\to 0} \|h\sqrt{(\delta\gamma_n)_-}\|_{L^2(t_0,T)} = 0$. From this and (4.1), we conclude that $\langle \alpha_s, \delta u\rangle = o(\delta\eta)$.

We have proved that $\langle \alpha, \delta u\rangle = o(\delta\eta)$. There remains to study the term $\langle \delta\mu, p\rangle$:

$$\begin{aligned}
|\langle \delta\mu, p\rangle| &= rK \left| \int_{t=t_0}^{T} 1_{\delta\gamma(t)>0} \int_{\gamma(t)}^{\gamma(t)+\delta\gamma(t)} p \right| \\
&\le \int_{t=t_0}^{T} 1_{\delta\gamma(t)>0} \sqrt{\delta\gamma(t)} \sqrt{\int_{\gamma(t)}^{\gamma(t)+\delta\gamma(t)} p^2} \\
&\le \int_{t=t_0}^{T} 1_{\delta\gamma(t)>0} (\delta\gamma(t))^{\frac{3}{2}} \sqrt{\int_{\gamma(t)}^{\gamma(t)+\delta\gamma(t)} \left(\frac{\partial p}{\partial x}\right)^2},
\end{aligned}$$

and we deduce from Proposition 4.4 and from the argument based on Lebesgue's theorem, which is detailed above, that $\langle \delta\mu, p\rangle = o(\delta\eta)$.

We have proved Theorem 5.4. □

6. The calibration problem.

6.1. Toward the calibration problem. A first step toward the calibration problem is to consider problem (5.3), where $\mathcal{H}$ and J_R are defined in section 5.1, and where J is now

$$J(u) = (u(T,x_{ob}) - \bar{u})^2, \tag{6.1}$$

where x_{ob} and $\bar{u}$ are positive numbers. Of course, for any penalty parameter ϵ, it is possible to consider problem (5.6). For this new choice of J, a result similar to Lemma 5.1 holds.

LEMMA 6.1. *Let $(\epsilon_n)_n$ be a sequence of penalty parameters such that $\epsilon_n \to 0$ as $n \to \infty$, and let $\eta^*_{\epsilon_n}, u^*_{\epsilon_n}$ be a solution of the problem* (5.6). *Consider a subsequence such that $\eta^*_{\epsilon_n} \to \eta^*$ weakly in Y and strongly in $L^\infty(0,T,W^{1,\infty}(\mathbb{R}_+))$, and $u^*_{\epsilon_n} \to u^*$ weakly in $L^2(0,T;V)$. We have for any x_1, x_2, $0 < x_1 < x_2 < +\infty$,*

$$\lim_{n\to\infty} \|u^*_{\epsilon_n} - u^*\|_{L^\infty((0,T)\times(x_1,x_2))} = 0. \tag{6.2}$$

Moreover, η^*, u^* is a solution to (5.3) *and, calling $\mu^* = rK1_{\{u^*=u_\circ\}}$,*

$$\lim_{n\to\infty} \|rK1_{\{x<K\}}\mathcal{V}_{\epsilon^*_n}(u^*_{\epsilon_n} - u_\circ) - \mu^*\|_{L^p((0,T)\times\mathbb{R}_+)} = 0 \quad \forall p,\ 1 \le p < +\infty, \tag{6.3}$$

and

$$\lim_{n\to\infty} \left\| x\frac{\partial u^*_{\epsilon_n}}{\partial x} - x\frac{\partial u^*}{\partial x} \right\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} = 0. \tag{6.4}$$

Proof. It can be shown exactly as in the proof of Lemma 5.1 that u^* satisfies (2.1) with $\eta = \eta^*$. Moreover, from Proposition 4.3,

$$\lim_{n\to\infty} \|u(\eta_{\epsilon^*_n}) - u^*\|_{L^\infty((0,T)\times(x_1,x_2))} = 0.$$

Combining this with the fact that $u(\eta^*_{\epsilon_n}) \leq u^*_{\epsilon_n} \leq u(\eta^*_{\epsilon_n}) + \epsilon_n$ yields that $u^*_{\epsilon_n}$ converges uniformly to u^* in $[0,T] \times [x_1, x_2]$. This proves that $\lim_{n\to\infty} J(u^*_{\epsilon_n}) = J(u^*)$ and we conclude as in the proof of Lemma 5.1 that (η^*, u^*) is a solution to (5.3). We prove (6.3) and (6.4) as in the proof of Lemma 5.1. □

Remark 10. Let $(\eta^*_{\epsilon_n}, u^*_{\epsilon_n})$ be a subsequence converging to (η^*, u^*) as in Lemma 6.1. It is clear from the continuity of u^* and from (6.2) that if $u^*(T, x_{ob}) > u_\circ(x_{ob})$, then there exists a positive real number a and an integer N such that for $n > N$, $u^*_{\epsilon_n}(t,x) > u_\circ(x) + \epsilon_n$ for all (t,x) with $|x - x_{ob}| \leq a$ and $t > T - a$. Let $(\eta^*_{\epsilon_n}, u^*_{\epsilon_n})$ be a subsequence converging to (η^*, u^*) as in Lemma 6.1. Assume that $u^*(T, x_{ob}) > u_\circ(x_{ob})$ and let a and N be as in Remark 10. It is possible to derive necessary optimality conditions for problem (5.6) for $n > N$. We drop the index n to simplify the notation.

LEMMA 6.2. *Assume that there exits a positive number a such that $u^*_\epsilon(t,x) > u_\circ(x) + \epsilon$ for all (t,x) with $|x - x_{ob}| \leq a$ and $T - t \leq a$. There exists a unique $p^*_\epsilon \in L^2((0,T) \times \mathbb{R}_+)$ such that, for all $v \in Z$ (the space Z is defined in* (5.12)*),*

$$\int_0^T \int_{\mathbb{R}_+} \left(\frac{\partial v}{\partial t} - \frac{\eta^*_\epsilon x^2}{2} \frac{\partial^2 v}{\partial x^2} - rx \frac{\partial v}{\partial x} + rv - rK 1_{\{x<K\}} \mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ) v \right) p^*_\epsilon \tag{6.5}$$
$$= 2(u^*_\epsilon(T, x_{ob}) - \bar{u}) v((T, x_{ob})),$$

and $\|p^*_\epsilon\|_{L^2((0,T)\times\mathbb{R}_+)}$ is bounded by a constant independent of ϵ in the subsequence.

Moreover, we have, in the sense of distributions in the domain $t < T$, $x > 0$,

$$\frac{\partial p^*_\epsilon}{\partial t} + \frac{\partial^2}{\partial x^2} \left(\frac{\eta^*_\epsilon x^2}{2} p^*_\epsilon \right) - \frac{\partial}{\partial x}(rx p^*_\epsilon) - r p^*_\epsilon + rK 1_{\{x<K\}} \mathcal{V}'_\epsilon(u^*_\epsilon - u_\circ) p^*_\epsilon = 0, \tag{6.6}$$

and for a smooth function ϕ taking the value 1 for $|x - x_{ob}| \geq \frac{a}{2}$, $T - t \geq \frac{a}{2}$ and vanishing in a neighborhood of (T, x_{ob}), we have that $\phi p^*_\epsilon \in L^2(0,T;V) \cap \mathcal{C}^0([0,T]; L^2(\mathbb{R}_+))$, with norms bounded independently of ϵ.

Proof. We call b the bilinear form on $L^2((0,T) \times \mathbb{R}_+) \times Z$ defined by

$$b(q,v) = \int_0^T \int_{\mathbb{R}_+} \left(\frac{\partial v}{\partial t} - \frac{\eta^*_\epsilon x^2}{2} \frac{\partial^2 v}{\partial x^2} - rx \frac{\partial v}{\partial x} + rv \right) q.$$

It is clear that b is continuous and that there exists a positive constant c, independent of η^*_ϵ in the class defined by Assumption 1, such that

$$\inf_{q \in L^2((0,T)\times\mathbb{R}_+)} \sup_{v \in Z} \frac{b(q,v)}{\|q\|_{L^2((0,T)\times\mathbb{R}_+)} \|v\|_Z} \geq c.$$

To prove this inf-sup condition, take $v \in L^2(0,T;V) \cap H^1(0,T;L^2(R_+))$ as the weak solution of

$$\frac{\partial v}{\partial t} - \frac{\eta^*_\epsilon x^2}{2} \frac{\partial^2 v}{\partial x^2} - rx \frac{\partial v}{\partial x} + rv = q, \quad t > 0, \qquad v(0,\cdot) = 0.$$

It can be proved that $x \frac{\partial v}{\partial x} \in L^2(0,T;V)$ and that $\|v\|_{L^2(0,T;V)}$ and $\|x \frac{\partial v}{\partial x}\|_{L^2(0,T;V)}$ are bounded by $C\|q\|_{L^2(0,T;L^2(R_+))}$ with C independent of η^*_ϵ in the class defined by Assumption 1. Therefore $\|\frac{x^2}{2} \frac{\partial^2 v}{\partial x^2}\|_{L^2(0,T;L^2(R_+))} \leq C\|q\|_{L^2(0,T;L^2(R_+))}$ and from

the equation satisfied by v, $\|\frac{\partial v}{\partial t}\|_{L^2(0,T;L^2(R_+))} \le C\|q\|_{L^2(0,T;L^2(R_+))}$. Hence, $\|v\|_Z \le C\|q\|_{L^2(0,T;L^2(R_+))}$, and the inf-sup condition above is proved. In other words, calling B the continuous linear operator from $L^2(0,T;L^2(\mathbb{R}_+)$ to the dual of Z defined by $\langle Bp, v\rangle = b(p,v)$, the range of B is closed. Also, it is clear that B^T is injective, so B is surjective. Using again the inf-sup condition, we have that B is an isomorphism from $L^2((0,T)\times\mathbb{R}_+)$ onto the dual of Z, and its inverse is continuous with a norm independent of η_ϵ^*.

Therefore, there exists a unique $g_\epsilon \in L^2(0,T;L^2(\mathbb{R}_+))$ such that for all $v \in Z$,

$$b(g_\epsilon, v) = 2(u_\epsilon^*(T,x_{ob}) - \bar{u})v((T,x_{ob}))$$

and $\|g_\epsilon\|_{L^2(0,T;L^2(R_+))}$ is bounded independently of η_ϵ^*. Furthermore, for any smooth function ϕ vanishing near (T,x_{ob}), $\phi g_\epsilon \in L^2(0,T;V)$ with a norm bounded independently of ϵ.

Call now $\tilde{p}_\epsilon \in L^2(0,T;V)\cap \mathcal{C}^0([0,T];L^2(\mathbb{R}_+))$ the weak solution of the following problem:

(6.7)
$$\begin{aligned}
&\frac{\partial \tilde{p}_\epsilon}{\partial t} + \frac{\partial^2}{\partial x^2}\left(\frac{\eta_\epsilon^* x^2}{2}\tilde{p}_\epsilon\right) - \frac{\partial}{\partial x}(rx\tilde{p}_\epsilon) - r\tilde{p}_\epsilon + rK1_{\{x<K\}}\mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ)\tilde{p}_\epsilon \\
&\qquad = -rK1_{\{x<K\}}\mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ)g_\epsilon = -rK1_{\{x<K\}}\mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ)\phi g_\epsilon, \quad t<T,\ x>0, \\
&\tilde{p}_\epsilon(T) = 0,
\end{aligned}$$

where ϕ is the smooth function introduced in the statement of Lemma 6.2. By looking at the equation satisfied by $\tilde{p}_\epsilon + \phi g_\epsilon$, we see that $\|\tilde{p}_\epsilon + \phi g_\epsilon\|_{L^2(0,T;V)}$ is bounded independently of ϵ. It is clear that $p_\epsilon^* = \tilde{p}_\epsilon + g_\epsilon$ satisfies (6.5). By using now the bilinear form

$$\tilde{b}(q,v) = \int_0^T \int_{\mathbb{R}_+} \left(\frac{\partial v}{\partial t} - \frac{\eta_\epsilon^* x^2}{2}\frac{\partial^2 v}{\partial x^2} - rx\frac{\partial v}{\partial x} + rv - rK1_{\{x<K\}}\mathcal{V}_\epsilon'(u_\epsilon^* - u_\circ)v\right) q,$$

and repeating the same argument as for b (using the monotonicity properties of $\mathcal{V}_\epsilon$), the solution of (6.5) is clearly unique.

We have also proved that $\|p_\epsilon\|_{L^2((0,T)\times\mathbb{R}_+)}$ and $\|\phi p_\epsilon\|_{L^2(0,T;V)}$ are bounded independently of ϵ. □

The optimality conditions for problem (5.6) are the following:

1. u_ϵ^* satisfies (2.10) for $\eta = \eta_\epsilon^*$.
2. There exists an adjoint state $p_\epsilon^* \in L^2((0,T)\times\mathbb{R}_+)$ solution of the problem (6.5).
3. For all $\eta \in \mathcal{H}$,

$$\langle DJ_R(\eta_\epsilon^*), \eta - \eta_\epsilon^*\rangle + \int_0^T \int_{\mathbb{R}_+} \frac{x^2}{2}(\eta - \eta_\epsilon^*)p_\epsilon^* \frac{\partial^2 u_\epsilon^*}{\partial x^2}\, dt\, dx \ge 0. \tag{6.8}$$

The next step is to pass to the limit when $\epsilon \to 0$.

THEOREM 6.3. *Let ϵ_n be a sequence of penalty parameters going to zero, and let $(\eta_{\epsilon_n}^*, u_{\epsilon_n}^*)$ be a sequence of solutions to* (5.6) *converging to (η^*, u^*) as in Lemma* 6.1. *Assume that there exits a positive number a such that $u_{\epsilon_n}^*(t,x) > u_\circ(x) + \epsilon_n$ for all*

(t,x) with $|x-x_{ob}|\leq a$ and $T-t\leq a$. There exists a subsequence denoted n_k such that $p^*_{\epsilon_{n_k}}$ converges weakly to p^* in $L^2(0,T,L^2(\mathbb{R}_+))$ and $\phi p^*_{\epsilon_{n_k}}$ converges weakly to ϕp^* in $L^2(0,T;V)$, where ϕ is given in Lemma 6.2. Moreover, there exists a Radon measure α^* such that for all $v\in Z$ (the space Z is defined in (5.12)),

$$\int_0^T\int_{\mathbb{R}_+}\left(\frac{\partial v}{\partial t}-\frac{\eta^* x^2}{2}\frac{\partial^2 v}{\partial x^2}-rx\frac{\partial v}{\partial x}+rv\right)p^*+\langle\alpha^*,v\rangle = 2(u^*(T,x_{ob})-\bar u)v((T,x_{ob})). \tag{6.9}$$

The function p^* satisfies

$$\frac{\partial p^*}{\partial t}+\frac{\partial^2}{\partial x^2}\left(\frac{\eta^* x^2}{2}p^*\right)-\frac{\partial}{\partial x}(rxp^*)-rp^*-\alpha^*=0 \tag{6.10}$$

in the sense of distributions. Furthermore we have

$$\mu^*|p^*|=0, \tag{6.11}$$

and, for any $x_1>0$ and any function $\psi\in C^0([0,T]\times\mathbb{R}_+)$ such that $\psi(t,x)=0$ if $x\leq x_1$,

$$\langle\alpha^*,|u^*-u_\circ|\psi\rangle=0. \tag{6.12}$$

Finally, for any $\eta\in\mathcal{H}$,

$$\langle DJ_R(\eta^*),\eta-\eta^*\rangle+\int_0^T\int_{\mathbb{R}_+}\frac{x^2}{2}(\eta-\eta^*)p^*\frac{\partial^2 u^*}{\partial x^2}\,dt\,dx\geq 0. \tag{6.13}$$

Proof. We follow essentially the proof of Theorem 5.2, but we have to take into account the singular behavior of p^*_ϵ at (T,x_{ob}) which necessitates additional technicalities. For ϕ introduced in Lemma 6.2, we consider the parabolic PDE satisfied by p^*_ϵ and we take as a test function $\rho_\delta(p^*_\epsilon)\chi(x)\phi(t,x)$, where ρ is defined in (5.30) and where χ is a smooth cut-off function $\chi:\mathbb{R}_+\to[0,1]$, taking the value 1 for $x\leq\bar K$ and 0 for $x\geq 2\bar K$. Calling $G_\delta(p)=\int_0^p\rho_\delta(q)dq$, we obtain that there exists a constant $C_{\bar K}$ independent of δ and ϵ such that

$$\int_t^T\int_{\mathbb{R}_+}\left(\frac{\eta^*_\epsilon x^2}{2}\rho'_\delta(p^*_\epsilon)\left(\frac{\partial p^*_\epsilon}{\partial x}\right)^2\phi(s,x)\chi(x)-rK\mathcal{V}'_\epsilon(u^*_\epsilon-u_\circ)p^*_\epsilon\rho_\delta(p^*_\epsilon)\right)dsdx + \int_{\mathbb{R}_+}G_\delta(p^*_\epsilon(t,x))\phi(t,x)\chi(x)dx\leq C_{\bar K}.$$

From this, we infer that there exists a positive constant C such that

$$rK\int_0^T\int_0^K|\mathcal{V}'_\epsilon(u^*_\epsilon-u_\circ)p^*_\epsilon|dtdx\leq C,$$

and it is possible to extract a subsequence ϵ_{n_k} such that $p^*_{\epsilon_{n_k}}\to p^*$ weakly in $L^2((0,T)\times\mathbb{R}_+)$, $\phi p^*_{\epsilon_{n_k}}\to p^*$ weakly in $L^2(0,T;V)$, and $-rK1_{\{x\leq K\}}\mathcal{V}'_{\epsilon_{n_k}}(u^*_{\epsilon_{n_k}}-u_\circ)p^*_{\epsilon_{n_k}}\to\alpha^*$ weakly* in $(L^\infty((0,T)\times\mathbb{R}_+))^*$. Equation (6.10) is satisfied in the sense of distributions and (6.9) is obtained as well by passing to the limit. The proofs of (6.11) and (6.12) follow the same line as in the proof of Theorem 5.2.

There remains to prove (6.13).

For that we write $p_{\epsilon^*}\frac{\partial^2}{\partial x^2}u_{\epsilon^*}$ as $\phi p_{\epsilon^*}\frac{\partial^2}{\partial x^2}u_{\epsilon^*}+p_{\epsilon^*}(1-\phi)\frac{\partial^2}{\partial x^2}u_{\epsilon^*}$ and we use the fact that for a subsequence,

- $\phi p_{\epsilon^*}\to\phi p^*$ in $L^2(0,T;V)$ weakly and $p^*_\epsilon\to p^*$ in $L^2((0,T)\times\mathbb{R}_+)$ weakly,
- $x\frac{\partial u^*_\epsilon}{\partial x}\to x\frac{\partial u^*}{\partial x}$ in $L^\infty(0,T;L^2(\mathbb{R}_+))$,
- $x^2(1-\phi)\frac{\partial^2 u^*_\epsilon}{\partial x^2}\to x^2(1-\phi)\frac{\partial^2 u^*}{\partial x^2}$ in $L^2(0,T;L^2(\mathbb{R}_+))$,
- $\eta^*_\epsilon\to\eta^*$ in $L^\infty([0,T];W^{1,\infty}(\mathbb{R}_+))$.

The decomposition of $p_{\epsilon^*}\frac{\partial^2}{\partial x^2}u_{\epsilon^*}$ and these convergence properties enable us to pass to the limit in $\int_0^T\int_{\mathbb{R}_+}\frac{x^2}{2}(\eta-\eta^*_\epsilon)p^*_\epsilon\frac{\partial^2 u^*_\epsilon}{\partial x^2}\,dt\,dx$ and to obtain (6.13). ∎

6.2. The calibration problem. The calibration problem consists of finding η from the observations of

- the price x_o of the underlying asset today,
- the prices $(\bar u_i)_{i\in I}$ of a family of American puts with different maturities and different strikes $(T_i,K_i)_{i\in I}$.

We call $T=\max_{i\in I}T_i$. For $\mathcal{H}$ and J_R given in section 5.1, we consider the least square problem: find $\eta\in\mathcal{H}$ minimizing

$$J(\eta)+J_R(\eta),\qquad J(\eta)=\sum_{i\in I}|u_i(T_i,x_\circ)-\bar u_i|^2, \tag{6.14}$$

where

(6.15)
$$\left.\begin{aligned}
&\frac{\partial u_i}{\partial t}-\frac{\eta(T_i-t,x)x^2}{2}\frac{\partial^2 u_i}{\partial x^2}-rx\frac{\partial u_i}{\partial x}+ru_i\ge 0,\\
&u_i\ge(K_i-x)_+\\
&\left(\frac{\partial u_i}{\partial t}-\frac{\eta(T_i-t,x)x^2}{2}\frac{\partial^2 u_i}{\partial x^2}-rx\frac{\partial u_i}{\partial x}+ru_i\right)(u_i-(K_i-x)_+)=0,
\end{aligned}\right\}\quad \begin{array}{l}t<T_i,\\ x>0,\end{array}$$
$$u_i(t=0,x)=(K_i-x)_+,\quad x>0,$$

Note that we have changed the time variable so that the expiration date of all the options becomes 0.

THEOREM 6.4. *Assuming that η_* is a minimum of* (6.14), (6.15) *obtained as the limit of a sequence of minimizers for the corresponding penalized problems as the penalty parameter goes to* 0, *and such that for all $i\in I$, (T_i,x_i) lies in the zone where $u_i^*>(K_i-x)_+$ (where u_i^* is the solution of* (6.15) *with $\eta=\eta^*$), we have the following necessary condition of optimality: for $i\in I$, there exists p_i in $L^2(0,T_i,L^2(\mathbb{R}_+))$ and a Radon measure α_i such that for all $v\in Z_i$,*

$$\begin{aligned}&\int_0^{T_i}\int_{\mathbb{R}_+}\left(\frac{\partial v}{\partial t}-\frac{\eta^*(T_i-t)x^2}{2}\frac{\partial^2 v}{\partial x^2}-rx\frac{\partial v}{\partial x}+rv\right)p_i+\langle\alpha_i,v\rangle\\ &\quad=2(u_i^*(T_i,x_i)-\bar u_i)v((T_i,x_i)),\end{aligned} \tag{6.16}$$

with

$$1_{\{u_i^*=(K_i-x)_+\}}|p_i|=0, \tag{6.17}$$

and, for any $x_1 > 0$ *and any function* $\psi \in C^0([0,T_i]\times\mathbb{R}_+)$ *such that* $\psi(t,x)=0$ *if* $x \le x_1$,

$$\langle \alpha_i, |u_i^* - (K_i - x)_+|\psi\rangle = 0. \tag{6.18}$$

For any $\eta \in \mathcal{H}$,

$$\langle DJ_R(\eta^*), \eta-\eta^*\rangle + \sum_{i\in I}\int_0^{T_i}\int_{\mathbb{R}_+} \frac{x^2}{2}(\eta-\eta^*)(T_i-t,x)p_i\frac{\partial^2 u_i^*}{\partial x^2}\,dt\,dx \ge 0. \tag{6.19}$$

CONTROLS INSENSITIZING THE OBSERVATION OF A QUASI-GEOSTROPHIC OCEAN MODEL*

ENRIQUE FERNÁNDEZ-CARA†, GALINA C. GARCIA‡, AND AXEL OSSES§

Abstract. We consider a linear quasi-geostrophic ocean model with partially known initial conditions. We search for controls that make the observation locally insensitive to the perturbations of the initial data. Their existence is equivalent to the null controllability property for an associated cascade Stokes-like system. Thanks to the presence of the Coriolis term, we are able to prove the existence of such controls. Our strategy is the following. First, we prove a unique continuation property for the adjoint of the state system that leads to approximate controllability; then, under certain assumptions, an observability inequality is established for the adjoint. The proof is inspired by the arguments leading to the unique continuation property. This inequality leads to the desired null controllability result.

Key words. insensitizing controls, Carleman inequalities, unique continuation, null controllability, ocean model

1. Introduction and main results.

1.1. Incomplete initial data ocean model. Let Ω be a nonempty open bounded and connected subset of $\mathbb{R}^2$, with boundary Γ of class $\mathcal{C}^2$ and outwards unit normal vector $\nu = \nu(x)$. Let ω be a nonempty open subset of Ω, $T > 0$, $Q = \Omega \times (0,T)$, and $\Sigma = \Gamma \times (0,T)$. In this paper, we will consider a linear quasi-geostrophic ocean model [1, 15, 16] described by the following equations:

$$\begin{cases} u_t - A\Delta u + \gamma u + (f_0 + \beta x_2)\,\mathrm{k} \wedge u + \dfrac{1}{\rho_0}\nabla p = \mathcal{T} + h1_\omega & \text{in } Q, \\ \operatorname{div} u = 0 & \text{in } Q, \\ u = 0 & \text{on } \Sigma, \\ u(0) = u_0 + \tau\widehat{u}_0 & \text{in } \Omega, \end{cases} \tag{1.1}$$

where $u(x,t)$ and $p(x,t)$, respectively, denote the velocity and the pressure of the fluid at $(x,t) = (x_1, x_2, t) \in \mathbb{R}^2 \times \mathbb{R}_+$. In this model, A represents the horizontal *eddy viscosity* coefficient, γ is the bottom *friction* coefficient, ρ_0 is the fluid density, and $(f_0 + \beta x_2)\mathrm{k} \wedge u$ is the Coriolis term, with $\mathrm{k} \wedge u = (-u_2, u_1)$. In the right-hand side, 1_ω denotes the characteristic function of ω and $\mathcal{T}$ is a given source in $L^2(Q)^2$. The term

$\tau\widehat{u}_0$, where $\tau \in \mathbb{R}$, represents a small unknown perturbation of the initial velocity field u_0, and $h = h(x,t)$ is a control function to be determined.

Notice that the Coriolis force is represented by a zero order coupling term in the equations. It introduces a different behavior of the system depending on the direction in space. To simplify the presentation of the results, we will assume that $A = 1$, $\gamma = 1$, $f_0 = 1$, $\beta = 1$, and $\rho_0 = 1$.

We introduce the following spaces, which are usual in the analysis of Stokes systems:

$$H = \{v \in L^2(\Omega)^2 : \ \operatorname{div} v = 0 \text{ in } \Omega, \ v \cdot \nu = 0 \text{ on } \Gamma\},$$
$$V = \{v \in H_0^1(\Omega)^2 : \ \operatorname{div} v = 0 \text{ in } \Omega\}, \qquad W = H^2(\Omega)^2 \cap V.$$

Recall that

$$W \hookrightarrow V \hookrightarrow H \equiv H' \hookrightarrow V' \hookrightarrow W',$$

where the embeddings are dense and compact.

For any given $u_0, \tau\widehat{u}_0 \in H$ with $\|\widehat{u}_0\|_{0,\Omega} = 1$, any $\mathcal{T} \in L^2(Q)^2$, and any $h \in L^2(\omega \times (0,T))^2$, the linear system (1.1) possesses a unique solution (u,p), with $u \in L^2(0,T;V) \cap H^1(0,T;V')$ and $p \in W^{-1,\infty}(0,T;L^2(\Omega))$. ($p$ is unique up to an additive distribution only depending on t.) This is easily proved by adapting the arguments of [17] to the presence of a skew-symmetric Coriolis term in the equations. Notice that if we had $u_0 + \tau\widehat{u}_0 \in V$, then the couple (u,p) would satisfy $u \in L^2(0,T;W) \cap H^1(0,T;H)$ and $p \in L^2(0,T;H^1(\Omega))$.

We will be concerned with the search of controls such that the velocity measurements over an observation set are either insensitive or almost insensitive to small variations of the initial conditions. To do this, we will use *insensitizing control theory*.

1.2. Insensitizing controls and controllability. Let $\mathcal{O}$ be an open nonempty subset of Ω and let us introduce the following functional, defined on the family of solutions to (1.1):

$$\Phi(u) = \frac{1}{2}\int_0^T \int_{\mathcal{O}} |u(x,t)|^2 \, dx \, dt. \tag{1.2}$$

The notion of *insensitizing controls* was introduced by Lions [13]. In the context of (1.1)–(1.2), it reads as follows.

DEFINITION 1.1. *We say that the control $h \in L^2(\omega \times (0,T))^2$ is Φ insensitizing if*

$$\frac{d}{d\tau}\Phi(u)\Big|_{\tau=0} = 0 \qquad \forall \widehat{u}_0 \in H \quad \text{with} \quad \|\widehat{u}_0\|_{0,\Omega} = 1. \tag{1.3}$$

On the other hand, we say that $h \in L^2(\omega \times (0,T))^2$ is Φ ε-insensitizing if

$$\left|\frac{d}{d\tau}\Phi(u)\Big|_{\tau=0}\right| \le \varepsilon \qquad \forall \widehat{u}_0 \in H \quad \text{with} \quad \|\widehat{u}_0\|_{0,\Omega} = 1. \tag{1.4}$$

Of course, in (1.3) and in (1.4) u is, together with p, the solution to (1.1).

The Φ insensitizing (resp., Φ ε-insensitizing) controls h must be interpreted as those leading to an observation $\Phi(u)$ that is locally independent (resp., almost independent) at the initial perturbation $\tau\widehat{u}_0$. The existence of such controls is a pertinent

question, since it is realistic to assume that the true initial conditions for (1.1) are unknown. In fact, as noticed in [13], it would be more convenient to search for Ψ insensitizing (or Ψ ε-insensitizing) controls, where

$$\Psi(u) = \frac{1}{2}\int_0^T \int_{\mathcal{O}} |\operatorname{curl} u(x,t)|^2 \, dx\, dt,$$

but this is beyond the scope of this article and will be the subject of future work.

It is easy to characterize the insensitivity (resp., ε-insensitivity) property in terms of exact null controllability (resp., approximate controllability) of a related cascade system. Indeed, let $(\bar{u}, \bar{p})$ and (q, r) be the solutions of the following systems:

$$\begin{cases} \bar{u}_t - \Delta \bar{u} + \bar{u} + (1 + x_2)\, k \wedge \bar{u} + \nabla \bar{p} = \mathcal{T} + h 1_\omega & \text{in } Q, \\ \operatorname{div} \bar{u} = 0 & \text{in } Q, \\ \bar{u} = 0 & \text{on } \Sigma, \\ \bar{u}(0) = u_0 & \text{in } \Omega, \end{cases} \tag{1.5}$$

$$\begin{cases} -q_t - \Delta q + q - (1 + x_2)\, k \wedge q + \nabla \pi = \bar{u} 1_{\mathcal{O}} & \text{in } Q, \\ \operatorname{div} q = 0 & \text{in } Q, \\ q = 0 & \text{on } \Sigma, \\ q(T) = 0 & \text{in } \Omega. \end{cases} \tag{1.6}$$

Then the control h is Φ insensitizing (resp., Φ ε-insensitizing) if and only if

$$q(0) = 0 \qquad (\text{resp., } \ \|q(0)\|_{0,\Omega} \leq \varepsilon). \tag{1.7}$$

Indeed, in view of (1.2), condition (1.3) is equivalent to

$$\int_0^T \int_{\mathcal{O}} \bar{u} \cdot u_\tau \, dx\, dt = 0 \quad \left(\text{resp., (1.4) is equivalent to } \left| \int_0^T \int_{\mathcal{O}} \bar{u} \cdot u_\tau \, dx\, dt \right| \leq \varepsilon \right),$$

where $\bar{u}$ is the solution of (1.5) and u_τ is the solution of (1.1) differentiated with respect to τ. Using the definition of (q, π) and integrating by parts, we obtain

$$\int_\Omega q(0) \cdot \widehat{u}_0 \, dx = 0 \quad \left(\text{resp., } \left| \int_\Omega q(0) \cdot \widehat{u}_0 \, dx \right| \leq \varepsilon \right) \quad \forall \widehat{u}_0 \in H \ \text{ with } \|\widehat{u}_0\|_{0,\Omega} = 1.$$

This is equivalent to (1.7). See [18] for more detail.

Notice that since $\bar{u} \in L^2(0,T;V)$, we also have $q \in L^2(0,T;W) \cap H^1(0,T;H)$ and $\pi \in L^2(0,T;H^1(\Omega))$.

We are thus in the presence of a null controllability problem (resp., an approximate controllability problem) for a cascade system, where the control h is not acting directly in the system satisfied by q (the function we want to drive to zero after a time interval of length T) but indirectly, through $\bar{u}1_{\mathcal{O}}$.

1.3. Main results. There have been several recent results concerning the existence of insensitizing and ε-insensitizing controls for parabolic problems.

Thus, in [2] the existence of ε-insensitizing controls for linear heat equations with partially known initial and boundary conditions was established. The same was also obtained for semilinear heat equations with globally Lipschitz-continuous nonlinearities. Since then, it has been proved in [18] that insensitizing controls exist for the same equations completed with zero initial data, under suitable assumptions

on the source term. In [3], the authors extended these results to other more general (slightly superlinear) nonlinearities.

In this paper, we deal with the insensitizing and ε-insensitizing problems for the case of the Stokes-type equations (1.1). Our results were sketched in [7]. These are the first insensitivity results in the literature for equations of this type, as far as we know.

We will assume that the following geometrical hypothesis is satisfied, as in the previous references:

$$\omega \cap \mathcal{O} \neq \emptyset. \tag{1.8}$$

Our main results are the following.

THEOREM 1.2. *Let $T > 0$ and assume that (1.8) is satisfied. Then, for each $\varepsilon > 0$ there exists a control $h \in L^2(\omega \times (0,T))^2$ which is Φ ε-insensitizing.*

THEOREM 1.3. *Under the assumptions of Theorem 1.2, if we also have $u_0 = 0$ and*

$$\int_0^T \int_\Omega \exp\left(Mt^{-4}\right) \mathcal{T}^2 \, dx \, dt < +\infty \tag{1.9}$$

for an appropriate constant M depending on Ω, ω, $\mathcal{O}$, and T, then there exists a control $h \in L^2(\omega \times (0,T))^2$ which is Φ insensitizing.

It was proved in [18] for the linear heat equation that, in general, we cannot expect the existence of insensitizing controls for nonvanishing initial data in $L^2(\Omega)$ when $\Omega \setminus \overline{\omega} \neq \emptyset$. The proof of this result is based on a counterexample for which the appropriate *observability inequality* fails when the initial data belong to $L^2(\Omega)$. Similar arguments could be used for Stokes systems. In view of this, it is reasonable to impose in Theorem 1.3 that $u_0 = 0$.

This paper is organized as follows. In section 2, we prove Theorem 1.2, where we obtain a unique continuation result for an adjoint cascade system thanks to the presence of the Coriolis term. In section 3, we prove Theorem 1.3. In this section, we show that insensitizing controls do exist if an appropriate observability inequality holds. We deduce this observability inequality in section 3.2 by means of an appropriate global Carleman inequality for the same adjoint cascade system. The proof of this global Carleman inequality is given in section 3.1 and follows a chain of estimates based on the steps of the unique continuation proof. At the end of this section and to be self-contained, we give the proof of a standard global Carleman estimate for Stokes-like systems that is needed in section 3.1. Finally, in section 4, we summarize the key points of this article in some final remarks.

2. Proof of Theorem 1.2. We can assume without loss of generality that $\mathcal{T} = 0$ and $u_0 = 0$ in (1.5)–(1.6). It is well known that the existence of ε-insensitizing controls for (1.5)–(1.6) is equivalent to a *unique continuation property* of the associate adjoint system

$$\begin{cases} \phi_t - \Delta\phi + \phi + (1 + x_2)\, k \wedge \phi + \nabla\theta = 0 \quad \text{in } Q, \\ \operatorname{div} \phi = 0 \quad \text{in } Q, \\ \phi = 0 \quad \text{on } \Sigma, \\ \phi(0) = \phi_0 \quad \text{in } \Omega, \end{cases} \tag{2.1}$$

$$\begin{cases} -z_t - \Delta z + z - (1 + x_2)\, k \wedge z + \nabla r = \phi 1_{\mathcal{O}} \quad \text{in } Q, \\ \operatorname{div} z = 0 \quad \text{in } Q, \\ z = 0 \quad \text{on } \Sigma, \\ z(T) = 0 \quad \text{in } \Omega \end{cases} \tag{2.2}$$

for a given $\phi_0 \in H$. This coupled system possesses a unique solution (ϕ, θ), (z, r), with at least $\phi, z \in L^2(0,T;V) \cap H^1(0,T;V')$ and $\theta, r \in W^{-1,\infty}(0,T;L^2(\Omega))$. (Again, θ and r are unique up to a distribution depending only on t.)

Using (1.5)–(1.6) and (2.1)–(2.2) the following duality identity is easily deduced:

$$\int_0^T \int_\omega h \cdot z \, dx \, dt = \int_\Omega q(0) \cdot \phi_0 \, dx \qquad \forall h \in L^2(\omega \times (0,T))^2.$$

It is clear from this last identity that the set $\{ q(0) : h \in L^2(\omega \times (0,T))^2 \}$ is dense in H if the following unique continuation result holds.

LEMMA 2.1. *Assume* (1.8). *Let* (ϕ, θ), (z, r) *be the solution to* (2.1)–(2.2) *with* $\phi_0 \in H$. *Then, if* $z = 0$ *in* $\omega \times (0,T)$, *we necessarily have* $z \equiv \phi \equiv 0$ *and* $\nabla r \equiv \nabla \theta \equiv 0$ *in* Q.

Proof. This is a direct consequence of a more general unique continuation result. To state this result precisely, let $\widetilde{\omega} = \omega \cap \mathcal{O} \neq \emptyset$ and let us set

$$C_1(\widetilde{\omega}) = \{(x_1, x_2) \in \Omega \,:\, \exists x_1^0 \ \text{ s.t. } (x_1^0, x_2) \in \widetilde{\omega}\}, \quad \Sigma_1(\widetilde{\omega}) = (\Gamma \cap \overline{C}_1) \times (0,T). \tag{2.3}$$

($C_1(\widetilde{\omega})$ is the horizontal component of $\widetilde{\omega}$.) We will prove that if $\phi = (\phi_1, \phi_2)$ is together with θ, z, and r a solution of

$$\begin{cases} \phi_t - \Delta\phi + \phi + (1 + x_2)\, k \wedge \phi + \nabla\theta = 0 \quad \text{in } Q, \\ \operatorname{div} \phi = 0 \quad \text{in } Q, \\ \phi_1 = 0 \quad \text{on } \Sigma_1, \end{cases} \tag{2.4}$$

$$\begin{cases} -z_t - \Delta z + z - (1 + x_2)\, k \wedge z + \nabla r = \phi 1_{\widetilde{\omega}} \quad \text{in } Q, \\ \operatorname{div} z = 0 \quad \text{in } Q, \end{cases}$$

and $z = 0$ in $\widetilde{\omega} \times (0,T)$, then $\phi \equiv 0$.

To prove this assertion, we divide the proof into two steps. Without loss of generality, we can assume that $\widetilde{\omega}$ is connected; otherwise we would replace $\widetilde{\omega}$ by one of its connected components.

In a first step, we deduce from the fact that $z = 0$ in $\widetilde{\omega} \times (0,T)$ that $\phi_2 = 0$ and ϕ_1 is constant if they are restricted to $\widetilde{\omega} \times (0,T)$. Thus, since $z = 0$ in $\widetilde{\omega} \times (0,T)$ we notice that $\operatorname{curl} \phi = 0$ in $\widetilde{\omega} \times (0,T)$ by applying the curl operator in the equation of z in (2.4). Using this fact, if we now apply the curl operator to the first equation in (2.4), thanks to the presence of the Coriolis term we obtain that

$$\operatorname{curl}\left((1 + x_2)\, k \wedge \phi\right) = \phi_2 + \operatorname{div} \phi = \phi_2 = 0$$

in $\widetilde{\omega} \times (0,T)$. Now, since $\operatorname{div} \phi = 0$ and $\operatorname{curl} \phi = 0$ in $\widetilde{\omega} \times (0,T)$, we have $\nabla \phi_1 = 0$ in $\widetilde{\omega} \times (0,T)$. Therefore ϕ_1 is constant in $\widetilde{\omega} \times (0,T)$ and we certainly obtain $\phi = (\text{Const.}, 0)$ in $\widetilde{\omega} \times (0,T)$.

In a second step, let us introduce

$$\psi = \frac{\partial \phi}{\partial x_1}, \quad \pi = \frac{\partial \theta}{\partial x_1} \tag{2.5}$$

and the coefficient matrix:

$$a = \begin{bmatrix} 1 & -(1 + x_2) \\ (1 + x_2) & 1 \end{bmatrix} \in L^\infty_{loc}(Q). \tag{2.6}$$

Then we have

$$\begin{cases} \psi_t - \Delta\psi + a\psi + \nabla\pi = 0 \quad \text{in } Q, \\ \operatorname{div}\psi = 0 \quad \text{in } Q, \end{cases} \tag{2.7}$$

$$(\psi, \pi) \in L^2_{loc}(Q)^2 \times \mathcal{D}'(Q) \tag{2.8}$$

with $\psi = 0$ in $\widetilde{\omega} \times (0,T)$. Here, we use a sharp uniqueness property for the Stokes system (2.7) proved in [5] that says that, under the regularity determined by (2.6) and (2.8), one has $\psi \equiv 0$ in Q. Now, from (2.5) we obtain $\partial\phi_i/\partial x_1 \equiv 0$ for $i = 1, 2$ in Q. Since $\operatorname{div}\phi = 0$ in Q we also have $\nabla\phi_2 = 0$ in Q and, from the fact that $\phi_2 = 0$ in $\widetilde{\omega} \times (0,T)$, we deduce that $\phi_2 \equiv 0$ in Q (recall that Ω is connected).

On the other hand, since $\partial\phi_1/\partial x_1 = 0$ in Q and $\phi_1 = 0$ on Σ_1 , we see that $\phi_1 = 0$ in $C_1 \times (0,T)$. Finally we have $\phi = (\phi_1, \phi_2) = 0$ in $C_1 \times (0,T)$, which is an open subset of Q. We can conclude that $\phi \equiv 0$ in Q using again the uniqueness property of [5]. (We can also use here the weaker result proved in [4].) □

Remark 1. The method used in the second part of the proof of Lemma 2.1 leads to the following uniqueness property in any dimension n. Let (ϕ, θ) be the solution of

$$\begin{cases} \phi_t - \Delta\phi + a\,\phi + \nabla\theta = 0 \quad \text{in } Q, \\ \operatorname{div}\phi = 0 \quad \text{in } Q, \\ \phi = 0 \quad \text{on } \Sigma_1(\omega), \end{cases} \tag{2.9}$$

where $Q = \Omega \times (0,T)$, Ω is a nonempty open bounded connected subset of $\mathbb{R}^n$, ω is an open nonempty subset of Ω, Σ_1 and C_1 are as defined in (2.3), and $a \in L^\infty(Q)$. If a is a function independent of x_1 in Q and ϕ is independent of x_1 in $\omega \times (0,T)$, then ϕ vanishes in Q. Indeed, let us introduce $\psi = \partial\phi/\partial x_1$, $\pi = \partial\theta/\partial x_1$, which satisfy a Stokes problem similar to (2.9), and this problem does not involve ϕ explicitly since a is independent of x_1. Now, from the uniqueness property in [5], $\psi \equiv 0$ in Q. Consequently $\partial\phi/\partial x_1 = 0$ in Q and $\phi = 0$ on Σ_1, so we have $\phi = 0$ in $C_1 \times (0,T)$. Using the unique continuation property in [5] once again, we obtain that $\phi \equiv 0$ in Q.

Remark 2. The previous remark shows that the Coriolis term plays a crucial role only in the first part of the proof of Lemma 2.1. In fact, the presence of the Coriolis term allows us to prove that $\operatorname{curl}\phi = 0$ in $\widetilde{\omega} \times (0,T)$ implies that the second component of ϕ vanishes in $\widetilde{\omega} \times (0,T)$. This will also be important in the deduction of the Carleman inequality later.

Remark 3. In the proof of the previous lemma, it is not possible to use the results of [4] concerning uniqueness properties of the Stokes system when one of the components of ϕ vanishes in $\widetilde{\omega} \times (0,T)$. This is because the results in [4] require that the coefficient a, introduced in (2.6), satisfy $a_{12} = 0$.

3. Proof of Theorem 1.3. The proof of the existence of insensitizing controls for (1.1), i.e., the exact null controllability for (1.5)–(1.6), relies on the following observability result for the cascade adjoint system (2.1)–(2.2).

PROPOSITION 3.1. *Assume that $\omega \cap \mathcal{O} \neq \emptyset$. There exist positive constants M and K, depending only on Ω, ω, $\mathcal{O}$, and T, such that the inequality*

$$\int_0^T \int_\Omega \exp\left(-Mt^{-4}\right)|z|^2\,dx\,dt \leq K \int_0^T \int_\omega |z|^2\,dx\,dt \tag{3.1}$$

holds for every solution of (2.1)–(2.2) *with $\phi_0 \in H$.*

The proof of this result is based on a global Carleman inequality (see Theorem 3.3), as will be seen in section 3.2. This Carleman inequality will be proved in section 3.1.

Let us now give the proof of Theorem 1.3 using Proposition 3.1. Thus, let us assume that (1.8) is satisfied, $u_0 = 0$, and (1.9) holds with M being the constant furnished by Proposition 3.1.

The approximate control h of minimal norm in $L^2(\omega \times (0,T))^2$ corresponding to $u_0 = 0$, a source term $\mathcal{T}$ satisfying (1.9), and tolerance $\varepsilon > 0$ can be obtained by minimizing in $L^2(\Omega)^2$ the following convex functional [6, 14]:

$$J_\varepsilon(\phi_0) = \frac{1}{2}\int_0^T\int_\omega |z|^2\,dx\,dt + \int_0^T\int_\Omega \mathcal{T}\cdot z\,dx\,dt + \varepsilon\|\phi_0\|_{0,\Omega}. \tag{3.2}$$

Thus, the minimum of J_ε is attained at some $\widehat{\phi}_{0\varepsilon} \in L^2(\Omega)^2$. We denote by $(\widehat{\phi}_\varepsilon, \widehat{\theta}_\varepsilon)$, $(\widehat{z}_\varepsilon, \widehat{r}_\varepsilon)$ the corresponding solution to (2.1)–(2.2) with $\phi_0 = \widehat{\phi}_{0\varepsilon}$; then the control function defined as

$$h_\varepsilon = \widehat{z}_\varepsilon 1_\omega \tag{3.3}$$

is such that the associated solution $(\bar{u}_\varepsilon, \bar{p}_\varepsilon)$, $(q_\varepsilon, \pi_\varepsilon)$ to (1.5)–(1.6) with $u_0 = 0$ satisfies $\|q_\varepsilon(0)\|_{0,\Omega} \le \varepsilon$.

It is not difficult to see that

$$\liminf_{\|\phi_0\|_{0,\Omega}\to\infty} \frac{J_\varepsilon(\phi_0)}{\|\phi_0\|_{0,\Omega}} \ge \varepsilon.$$

The proof of this inequality is classical; see [6]. It is implied by the unique continuation property for the cascade adjoint system that we presented above (see Lemma 2.1).

Furthermore, the following optimality condition must be satisfied at $\widehat{\phi}_{0\varepsilon}$:

$$\int_0^T\int_\omega |\widehat{z}_\varepsilon|^2\,dx\,dt + \int_0^T\int_\Omega \mathcal{T}\cdot\widehat{z}_\varepsilon\,dx\,dt + \varepsilon\|\widehat{\phi}_{0\varepsilon}\|_{0,\Omega} = 0. \tag{3.4}$$

By replacing (3.3) in (3.4), introducing the weight $e^{Mt^{-4}}$, and using (3.1) and Young's inequality, we easily deduce that

$$\int_0^T\int_\omega |h_\varepsilon|^2\,dx\,dt \le K^2\int_0^T\int_\Omega \exp(Mt^{-4})|\mathcal{T}|^2\,dx\,dt.$$

Since $\{h_\varepsilon\}$ is uniformly bounded in $L^2(\omega\times(0,T))^2$, then up to a subsequence, still denoted $\{h_\varepsilon\}$, we have

$$\begin{aligned} &h_\varepsilon \rightharpoonup h \quad \text{weakly in} \quad L^2(\omega\times(0,T))^2,\\ &\bar{u}_\varepsilon \to \bar{u} \quad \text{strongly in} \quad L^2(Q)^2, \quad \text{and}\\ &q_\varepsilon \to q \quad \text{strongly in} \quad L^2(Q)^2, \end{aligned}$$

as $\varepsilon \to 0$. Of course, we have denoted here by $(\bar{u}_\varepsilon, \bar{p}_\varepsilon)$, $(q_\varepsilon, \pi_\varepsilon)$ and $(\bar{u}, \bar{p})$, (q, π) the solutions to (1.5)–(1.6) associated with h_ε and h, respectively. Notice that $\|q_\varepsilon(0)\|_{0,\Omega} \le \varepsilon$ and consequently we have $q(0) = 0$. This ends the proof of Theorem 1.3.

3.1. A global Carleman estimate. The goal of this section is to present an estimate of the Carleman kind for the solutions to the adjoint cascade system (2.1)–(2.2). As mentioned above, this estimate will be crucial for the proof of Proposition 3.1.

Let us first introduce an open ball B_0 such that $B_0 \subset\subset \omega \cap \mathcal{O}$ and an auxiliary function $\eta_0 \in \mathcal{C}^2(\overline{\Omega})$ satisfying

$$\eta_0(x) > 0 \ \ \forall x \in \Omega, \quad \eta_0 = 0 \ \text{ on } \partial\Omega, \quad |\nabla \eta_0(x)| > 0 \ \ \forall x \in \overline{\Omega \setminus B_0}\,. \tag{3.5}$$

The existence of such a function is proved in [9].

Let us also introduce the weight functions

$$\alpha(x,t) = \frac{e^{2\lambda\|\eta_0\|_\infty} - e^{\lambda\eta_0}}{t^4(T-t)^4}, \quad \widehat{\alpha}(t) = \min_{\overline{\Omega}} \alpha(x,t), \quad \alpha^*(t) = \max_{\overline{\Omega}} \alpha(x,t),$$
$$\varphi(x,t) = \frac{e^{\lambda\eta_0}}{t^4(T-t)^4}, \qquad \widehat{\varphi}(t) = \max_{\overline{\Omega}} \varphi(x,t), \quad \varphi^*(t) = \min_{\overline{\Omega}} \varphi(x,t).$$

The following property of the functions α^* and $\widehat{\alpha}$ will be needed later.

LEMMA 3.2. *For any $a > 1$ there exists $\lambda_a > 0$ such that*

$$a\,\widehat{\alpha}(t) > \alpha^*(t) \quad \forall \lambda > \lambda_a\,, \quad \forall t \in (0,T).$$

Proof. The proof is elementary. It suffices to notice that we have $a(e^{2x} - e^x) > e^{2x} - 1$ if $a > 1$ and x is sufficiently large. ∎

The main result in this section is the following.

THEOREM 3.3. *Assume that $\omega \cap \mathcal{O} \neq \emptyset$ and let the functions α, φ, $\widehat{\alpha}$, and $\widehat{\varphi}$ be as above. For each $\widehat{\gamma} \in (0,1)$, there exist constants $\widehat{s}$, $\widehat{\lambda}$, and $\widehat{C}$ depending on Ω, ω, $\mathcal{O}$, T, and $\widehat{\gamma}$ such that one has*

$$\begin{aligned}
&\int_0^T\!\!\int_\Omega e^{-2s\alpha}\left(\frac{1}{s\varphi}(|z_t|^2 + |\Delta z|^2) + s\lambda^2\varphi|\nabla z|^2 + s^3\lambda^4\varphi^3|z|^2\right) dx\,dt \\
&\quad + \int_0^T\!\!\int_\Omega e^{-2s\alpha}\left(\frac{1}{s\varphi}(|\phi_t|^2 + |\Delta\phi|^2) + s\lambda^2\varphi|\nabla\phi|^2 + s^3\lambda^4\varphi^3|\phi|^2\right) dx\,dt \\
&\quad \le \widehat{C}\int_0^T\!\!\int_\omega e^{-(1+\widehat{\gamma})s\widehat{\alpha}} s^{63}\lambda^{32}\widehat{\varphi}^{67}|z|^2\,dx\,dt
\end{aligned} \tag{3.6}$$

for any $s > \widehat{s}$ and $\lambda > \widehat{\lambda}$ and for every solution (ϕ,θ), (z,r) to (2.1)–(2.2) associated with initial data $\phi_0 \in H$.

The proof will be divided in several steps and will be given in the following subsections. First, we will apply a global Carleman estimate for the Stokes system to (2.1) and (2.2). This will lead to the estimate (3.10). Then, to deduce (3.6), we will have to estimate the integral in the right-hand side of (3.10) containing ϕ in terms of z. To this end, we will follow the steps of the proof of Lemma 2.1 in reverse order.

3.1.1. Step 1: A first direct Carleman estimate. Let $I(s,\lambda;v)$ stand for the quantity

$$I(s,\lambda;v) = \int_0^T\!\!\int_\Omega e^{-2s\alpha}\left(\frac{1}{s\varphi}(|v_t|^2 + |\Delta v|^2) + s\lambda^2\varphi|\nabla v|^2 + s^3\lambda^4\varphi^3|v|^2\right) dx\,dt \tag{3.7}$$

for any positive s and λ and any sufficiently regular function $v = v(x,t)$. We then have the following.

LEMMA 3.4. *For each $\gamma_1 \in (0,1)$ there exist positive constants s_1, λ_1, and C_1, depending on Ω, ω, $\mathcal{O}$, T, and γ_1, with the following properties:*

$$
\begin{aligned}
I(s,\lambda;z) \le C_1 \Bigg\{ & \int_0^T \int_{B_0} e^{-(1+\gamma_1)s\widehat{\alpha}} s^7 \lambda^4 \widehat{\varphi}^{15/2} |z|^2 \, dx\, dt \\
& + \int_0^T \int_{B_0} e^{-2s\widehat{\alpha}} (s\lambda\widehat{\varphi})^2 |\phi|^2 \, dx\, dt \\
& + \int_0^T \int_{\mathcal{O}} e^{-2s\alpha} \left((s\varphi)^{1/2} |\phi|^2 + \frac{1}{s^3\varphi^{7/2}} |\phi_t|^2 \right) dx\, dt \Bigg\}
\end{aligned} \tag{3.8}
$$

and

$$
I(s,\lambda;\phi) \le C_1 \int_0^T \int_{B_0} e^{-(1+\gamma_1)s\widehat{\alpha}} s^7 \lambda^4 \widehat{\varphi}^{15/2} |\phi|^2 \, dx\, dt \tag{3.9}
$$

for any $s > s_1$ and $\lambda > \lambda_1$ and for every solution of (2.1)–(2.2) *with $\phi_0 \in H$.*

The proof of Lemma 3.4 is similar to the proof of other recent global Carleman inequalities for the Stokes system. The main ideas are due to Imanuvilov [10, 11]; also see [8] for other related results. The proof is presented in the appendix.

Let us fix $\widehat{\gamma}$, with $0 < \widehat{\gamma} < 1$. We are now going to deduce several estimates that hold for "sufficiently large s and λ." By this we mean that they are satisfied for any $s > \bar{s}$ and any $\lambda > \bar{\lambda}$, where $\bar{s}$ and $\bar{\lambda}$ are (large) positive constants depending only on Ω, ω, $\mathcal{O}$, T, and $\widehat{\gamma}$.

In what follows, C denotes a generic constant, not necessarily the same at each occurrence, depending on Ω, ω, $\mathcal{O}$, T, and (possibly) $\widehat{\gamma}$.

Let γ_1 be given in $(\widehat{\gamma}, 1)$. In view of Lemma 3.4 applied to γ_1, we get

$$
I(s,\lambda;z) + I(s,\lambda;\phi) \le C \int_0^T \int_{B_0} e^{-(1+\gamma_1)s\widehat{\alpha}} s^7 \lambda^4 \widehat{\varphi}^{15/2} (|z|^2 + |\phi|^2) \, dx\, dt \tag{3.10}
$$

for s and λ large enough.

Indeed, the last two integrals in (3.8) can be absorbed by the left-hand side of $I(s,\lambda;\phi)$, since

$$
Cs^{-3}\varphi^{-7/2} \le \frac{1}{2}(s\varphi)^{-1} \quad \text{and} \quad C(s\varphi)^{1/2} \le \frac{1}{2} s^3 \varphi^3
$$

for sufficiently large s.

3.1.2. Step 2: An estimate of ϕ in terms of curl ϕ. To simplify the notation, let us set $a = 7$ and $b = 15/2$. Then

$$
I(s,\lambda;z) + I(s,\lambda;\phi) \le C \int_0^T \int_{B_0} e^{-(1+\gamma_1)s\widehat{\alpha}} s^a \lambda^4 \widehat{\varphi}^b (|z|^2 + |\phi|^2) \, dx\, dt. \tag{3.11}
$$

We will denote by $B_1, B_2, \ldots$ a sequence of balls centered at the same point as B_0 and satisfying

$$
B_0 \subset\subset B_1 \subset\subset \cdots \subset\subset \omega \cap \mathcal{O}.
$$

It is not a restriction to assume that their common center is the origin. This will be supposed in what follows for simplicity. We will consider some functions $\xi_i \in \mathcal{C}_0^\infty(B_i)$ satisfying

$$\begin{gathered} 0 \le \xi_i \le 1, \quad \xi_i(x) = 1 \text{ in } B_{i-1}\,, \\ \xi_i^{-1/2}\nabla\xi_i \in L^\infty(\Omega), \quad \xi_i^{-1/2}\Delta\xi_i \in L^\infty(\Omega). \end{gathered} \tag{3.12}$$

(See [18] for a justification of the existence of these ξ_i.)

Since $\operatorname{div}\phi = 0$, $\phi = 0$ on Σ, and Ω is connected, we can introduce the stream function ψ satisfying

$$\phi = \operatorname{curl}\psi \equiv \left(\frac{\partial\psi}{\partial x_2}, -\frac{\partial\psi}{\partial x_1}\right),$$

with $\psi = 0$ on one connected component of Σ and $\frac{\partial\psi}{\partial n} = 0$ on Σ.

Let us set $\rho_1(t) = e^{-(1+\gamma_1)s\widehat{\alpha}}s^a\lambda^4\widehat{\varphi}^b$. Then we have

$$\int_0^T\int_{B_0}\rho_1|\phi|^2\,dx\,dt \le \int_0^T\int_{B_1}\rho_1\xi_1|\nabla\psi|^2\,dx\,dt.$$

We will now give an estimate of the last integral in terms of $|\operatorname{curl}\phi|^2$. To this end, let us introduce the vorticity w, given by

$$w = \operatorname{curl}\phi = \frac{\partial\phi_2}{\partial x_1} - \frac{\partial\phi_1}{\partial x_2}.$$

Applying the curl operator to (2.1), we obtain

$$\begin{cases} w_t - \Delta w + w - \dfrac{\partial\psi}{\partial x_1} = 0 \quad \text{in } Q, \\ \Delta\psi + w = 0 \quad \text{in } Q. \end{cases} \tag{3.13}$$

To estimate $|\nabla\psi|^2$, we multiply by $\rho_1\xi_1\psi$ the second equation of (3.13). Then, we integrate by parts with respect to the space variable x and we get

$$\int_0^T\int_{B_1}\rho_1\xi_1|\nabla\psi|^2\,dx\,dt = \int_0^T\int_{B_1}\rho_1\xi_1\psi w\,dx\,dt + \frac{1}{2}\int_0^T\int_{B_1}\rho_1(\Delta\xi_1)|\psi|^2\,dx\,dt. \tag{3.14}$$

Notice that using $I(s,\lambda;\phi)$, we can get upper bounds for $|\psi|^2$, $|\nabla\psi|^2$, and $|\psi_t|^2$. Indeed, from the definition of α^*, φ^*, and $\widehat{\varphi}$, we have

$$\begin{aligned} I(s,\lambda;\phi) &\ge \int_0^T\int_\Omega e^{-2s\alpha}\left(\frac{1}{s\varphi}|\nabla\psi_t|^2 + s^3\lambda^4\varphi^3|\nabla\psi|^2\right)dx\,dt \\ &\ge \int_0^T\int_\Omega e^{-2s\alpha^*}\left(\frac{1}{s\widehat{\varphi}}|\nabla\psi_t|^2 + s^3\lambda^4(\varphi^*)^3|\nabla\psi|^2\right)dx\,dt \\ &\ge C\int_0^T\int_\Omega e^{-2s\alpha^*}\left(\frac{1}{s\widehat{\varphi}}|\psi_t|^2 + s^3\lambda^4(\varphi^*)^3\left(|\psi|^2 + |\nabla\psi|^2\right)\right)dx\,dt. \end{aligned} \tag{3.15}$$

Here we have used the fact that $\psi = 0$ on one of the connected components of Σ to apply Poincaré's inequality.

With this information, we will be able to absorb the first integral in (3.14). Indeed, after using Young's inequality, we can estimate this term as follows:

$$\int_0^T\int_{B_1}\rho_1\xi_1\psi w\,dx\,dt \le \delta\int_0^T\int_\Omega e^{-2s\alpha^*}s^3\lambda^4(\varphi^*)^3|\psi|^2\,dx\,dt + C_\delta\int_0^T\int_{B_1} e^{-2(1+\gamma_1)s\widehat{\alpha}+2s\alpha^*}s^{2a-3}\lambda^4\widehat{\varphi}^{2b-3}|w|^2\,dx\,dt. \tag{3.16}$$

Now, if we introduce γ_2 with $0<\gamma_2<2\gamma_1-1$, then $(1+2\gamma_1-\gamma_2)/2>1$ and, from Lemma 3.2, we see that $(1+2\gamma_1-\gamma_2)\widehat{\alpha}/2>\alpha^*$ for λ sufficiently large. Consequently, it can be assumed that

$$-2(1+\gamma_1)\widehat{\alpha}+2\alpha^*<-(1+\gamma_2)\widehat{\alpha}$$

and we can replace $e^{-2(1+\gamma_1)s\widehat{\alpha}+2s\alpha^*}$ by $e^{-(1+\gamma_2)s\widehat{\alpha}}$ in the last integral in (3.16):

$$\int_0^T\int_{B_1}\rho_1\xi_1\psi w\,dx\,dt \le \delta\int_0^T\int_\Omega e^{-2s\alpha^*}s^3\lambda^4(\varphi^*)^3|\psi|^2\,dx\,dt + C_\delta\int_0^T\int_{B_1} e^{-(1+\gamma_2)s\widehat{\alpha}}s^{2a-3}\lambda^4\widehat{\varphi}^{2b-3}|w|^2\,dx\,dt. \tag{3.17}$$

Notice that if we had chosen γ_1 sufficiently close to 1 before, then we would still have the possibility of choosing γ_2 satisfying $\widehat{\gamma}<\gamma_2<2\gamma_1-1$.

On the other hand, by choosing δ sufficiently small, we can absorb the first term in the right-hand side of (3.17) with $I(s,\lambda;\phi)$.

It remains in this step to estimate the last integral in (3.14). Assume that ξ_1 has been constructed as before but also satisfying

$$\xi_1(x)=\begin{cases}1 & \text{in } |x|<r_0,\\ \widehat{\Psi}\left(\frac{|x|-r_0}{r_1-a-r_0}\right) & \text{in } r_0\le|x|\le r_1-a,\\ 0 & \text{in } |x|>r_1-a,\end{cases}$$

where r_i denotes the radius of B_i, a is small enough, and $\widehat{\Psi}$ is a function satisfying $\widehat{\Psi}\in\mathcal{C}^\infty([0,1])$,

$$\widehat{\Psi}(0)=1,\quad \widehat{\Psi}(1)=0,\quad \text{and}\quad \widehat{\Psi}^{(n)}(0)=\widehat{\Psi}^{(n)}(1)=0\quad\forall n\ge1.$$

Let us set

$$\eta(x)=\int_{\bar{x}_1}^{x_1}\Delta\xi_1(y_1,x_2)\,dy_1$$

where for each $x=(x_1,x_2)\in\bar{B}_1$ we take $\bar{x}_1<x_1$ and $(\bar{x}_1,x_2)\in\partial B_1$. Notice that $\frac{\partial\eta}{\partial x_1}=\Delta\xi_1$. It is also easy to see that Supp $\eta\subset\bar{B}_1(0;r_1-a)$. And now, using the first equation in (3.13), we observe that

$$\begin{aligned}\frac{1}{2}\int_0^T\int_{B_1}\rho_1(\Delta\xi_1)|\psi|^2\,dx\,dt &= \frac{1}{2}\int_0^T\int_{B_1}\rho_1\frac{\partial\eta}{\partial x_1}|\psi|^2\,dx\,dt\\ &= -\int_0^T\int_{B_1}\rho_1\eta\psi\frac{\partial\psi}{\partial x_1}\,dx\,dt\\ &= -\int_0^T\int_{B_1}\rho_1\eta\psi(w_t-\Delta w+w)\,dx\,dt.\end{aligned} \tag{3.18}$$

Remark 4. Notice that we used the term $\frac{\partial \psi}{\partial x_1}$ in equation (3.13) to estimate $|\psi|^2$ over B_1. The term comes from Coriolis force and it is absent in the Stokes system.

We will now estimate this last integral in the right-hand side of (3.18). Concerning the product $\rho_1 \eta \psi w_t$, we can integrate by parts with respect to time in $B_1 \times (0,T)$ and then apply Young's inequality to deduce that

$$\begin{aligned}\int_0^T\!\!\int_{B_1} \rho_1 \eta \psi w_t \, dx\, dt &= -\int_0^T\!\!\int_{B_1} (\rho_1 \eta \psi_t w + \rho_1' \eta \psi w)\, dx\, dt \\ &\le \delta \int_0^T\!\!\int_\Omega e^{-2s\alpha^*} \left(\frac{1}{s\widehat{\varphi}} |\psi_t|^2 + s^3 \lambda^4 (\varphi^*)^3 |\psi|^2 \right) dx\, dt \\ &\quad + C_\delta \int_0^T\!\!\int_{B_1} e^{-(1+\gamma_2)s\widehat{\alpha}} (s^{2a+1}\lambda^8 \widehat{\varphi}^{2b+1} + s^{2a-1}\lambda^4 \widehat{\varphi}^{2b-1/2}) |w|^2 \, dx\, dt \end{aligned} \tag{3.19}$$

for sufficiently large s and λ.

To obtain this inequality, we first used that

$$|\rho_1'| = \left| (e^{-(1+\gamma_1)s\widehat{\alpha}} s^a \lambda^4 \widehat{\varphi}^b)_t \right| \le C e^{-(1+\gamma_1)s\widehat{\alpha}} s^{a+1} \lambda^4 \widehat{\varphi}^{b+5/4}.$$

Then, we noticed that

$$\begin{aligned}&\int_0^T\!\!\int_{B_1} \rho_1' \eta \psi w \, dx\, dt \\ &\quad \le \delta \int_0^T\!\!\int_\Omega e^{-2s\alpha^*} s^3 \lambda^4 (\varphi^*)^3 |\psi|^2 \, dx\, dt \\ &\quad + C_\delta \int_0^T\!\!\int_{B_1} e^{-2(1+\gamma_1)s\widehat{\alpha} + 2s\alpha^*} s^{2a-1} \lambda^4 \widehat{\varphi}^{2b+5/2} (\varphi^*)^{-3} |w|^2 \, dx\, dt, \end{aligned}$$

and, finally, we took s and λ large enough to have

$$e^{-2(1+\gamma_1)s\widehat{\alpha} + 2s\alpha^*} \widehat{\varphi}^{2b+5/2} (\varphi^*)^{-3} \le e^{-(1+\gamma_2)s\widehat{\alpha}} \widehat{\varphi}^{2b-1/2}.$$

We can simplify the estimate (3.19) by using the inequality

$$s^{2a-1} \widehat{\varphi}^{2b-1/2} \le C s^{2a+1} \widehat{\varphi}^{2b+1},$$

which must hold for large s. Thus, we obtain

$$\begin{aligned}&\int_0^T\!\!\int_{B_1} \rho_1 \eta \psi w_t \, dx\, dt \\ &\quad \le \delta \int_0^T\!\!\int_\Omega e^{-2s\alpha^*} \left(\frac{1}{s\widehat{\varphi}} |\psi_t|^2 + s^3 \lambda^4 (\varphi^*)^3 |\psi|^2 \right) dx\, dt \\ &\quad + C_\delta \int_0^T\!\!\int_{B_1} e^{-(1+\gamma_2)s\widehat{\alpha}} s^{2a+1} \lambda^8 \widehat{\varphi}^{2b+1} |w|^2 \, dx\, dt. \end{aligned} \tag{3.20}$$

Notice that the first integral in the right-hand side of (3.20) also appears in (3.15) and can be absorbed later by choosing δ small enough.

Let us now consider the term $\rho_1 \eta \psi (\Delta w)$ in the last integral of (3.18). Let us integrate by parts with respect to the space variable x, let us use the identity $\Delta \psi = w$,

and let us apply Young's inequality. Arguing as before, we obtain

$$\begin{aligned}\int_0^T\int_{B_1}\rho_1\eta\psi(\Delta w)\,dx\,dt &= \int_0^T\int_{B_1}\rho_1\left((\Delta\eta)\psi w+2\nabla\eta\cdot\nabla\psi\, w+\eta|w|^2\right)\,dx\,dt\\ &\le \delta\int_0^T\int_\Omega e^{-2s\alpha^*}s^3\lambda^4(\varphi^*)^3(|\psi|^2+|\nabla\psi|^2)\,dx\,dt\\ &\quad + C_\delta\int_0^T\int_{B_1}e^{-(1+\gamma_2)s\widehat{\alpha}}s^{2a-3}\lambda^4\widehat{\varphi}^{\,2b-3}|w|^2\,dx\,dt \qquad (3.21)\end{aligned}$$

for any sufficiently large s and λ.

Finally, arguing in a similar way, we can also estimate the last term $\rho_1\eta\psi w$ in (3.18):

$$\begin{aligned}\int_0^T\int_{B_1}\rho_1\eta\psi w\,dx\,dt &\le \delta\int_0^T\int_{B_1}e^{-2s\alpha^*}s^3\lambda^4(\varphi^*)^3|\psi|^2\,dx\,dt\\ &\quad + C_\delta\int_0^T\int_{B_1}e^{-(1+\gamma_2)s\widehat{\alpha}}s^{2a-3}\lambda^4\widehat{\varphi}^{\,2b-3}|w|^2\,dx\,dt. \qquad (3.22)\end{aligned}$$

From (3.18) and (3.20)–(3.22), we find that

$$\begin{aligned}&\frac12\int_0^T\int_{B_1}\rho_1(\Delta\xi_1)|\psi|^2\,dx\,dt\\ &\qquad\le 3\delta\int_0^T\int_\Omega e^{-2s\alpha^*}\left(\frac{1}{s\widehat{\varphi}}|\psi_t|^2+s^3\lambda^4(\varphi^*)^3(|\psi|^2+|\nabla\psi|^2)\right)\,dx\,dt\\ &\qquad\quad + C_\delta\int_0^T\int_{B_1}\rho_2|w|^2\,dx\,dt, \qquad (3.23)\end{aligned}$$

where

$$\rho_2(t)=e^{-(1+\gamma_2)s\widehat{\alpha}}s^{2a+1}\lambda^8\widehat{\varphi}^{\,2b+1}.$$

Replacing the estimates (3.16) and (3.23) in (3.10), with $\delta>0$ sufficiently small, we obtain

$$I(s,\lambda;z)+I(s,\lambda;\phi)\le C\left\{\int_0^T\int_{B_0}\rho_1|z|^2\,dx\,dt+\int_0^T\int_{B_1}\rho_2|\operatorname{curl}\phi|^2\,dx\,dt\right\}. \qquad (3.24)$$

3.1.3. Step 3: An estimate of $\operatorname{curl}\phi$ in terms of z. Let us apply the curl operator to (2.2). For $\zeta=\operatorname{curl} z$, we obtain the following:

$$-\zeta_t-\Delta\zeta+\zeta-z_2=w1_{\mathcal{O}}\quad\text{in }\mathcal{O}\times(0,T).$$

Recall that $\xi_2\in\mathcal{C}_0^\infty(B_2)$ satisfies (3.12) and $B_1\subset\subset B_2\subset\subset\omega\cap\mathcal{O}$. After multiplying the above equation by $\rho_2\xi_2 w$, integrating by parts in Q, and using (3.13), it follows that

$$\begin{aligned}\int_0^T\int_{B_2}\rho_2\xi_2|w|^2\,dx\,dt &= -\int_0^T\int_{B_2}\rho_2\xi_2\phi_2\zeta\,dx\,dt+\int_0^T\int_{B_2}\rho_2'\xi_2 w\zeta\,dx\,dt\\ &\quad -\int_0^T\int_{B_2}\rho_2((\Delta\xi_2)w\zeta+2(\nabla\xi_2\cdot\nabla w)\zeta+\xi_2 wz_2)\,dx\,dt. \qquad (3.25)\end{aligned}$$

As before, we choose γ_3 satisfying $0 < \gamma_3 < 2\gamma_2 - 1$. Then, for sufficiently large λ we have $(1 + 2\gamma_2 - \gamma_3)\widehat{\alpha}/2 > \alpha^*$ and, consequently,

$$-2(1+\gamma_2)\widehat{\alpha} + 2s\alpha < -2(1+\gamma_2)\widehat{\alpha} + 2s\alpha^* < -(1+\gamma_3)\widehat{\alpha}.$$

Notice once more that if γ_1 is sufficiently close to 1, then we can choose γ_3 in $(\widehat{\gamma}, 1)$.

Now, proceeding as in the previous step, we see that

$$\left|\int_0^T\int_{B_2} \rho_2\xi_2\phi_2\zeta\,dx\,dt\right| \le \delta\int_0^T\int_\Omega e^{-2s\alpha}s^3\lambda^4\varphi^3|\phi_2|^2\,dx\,dt + C_\delta\int_0^T\int_{B_2}\rho_3\frac{1}{s^4\lambda^4\widehat{\varphi}^4}\xi_2^2|\zeta|^2\,dx\,dt$$

for any small $\delta > 0$ (to be fixed later). Here, ρ_3 stands for the function

$$\rho_3(t) = e^{-(1+\gamma_3)s\widehat{\alpha}(t)}s^{4a+3}\lambda^{16}\widehat{\varphi}^{4b+3}(t).$$

We also have

$$\int_0^T\int_{B_2}\rho_2'\xi_2 w\zeta\,dx\,dt \le \delta\int_0^T\int_{B_2}\rho_2\xi_2|w|^2\,dx\,dt + C_\delta\int_0^T\int_{B_2}\rho_2 s^2\widehat{\varphi}^{5/2}\xi_2|\zeta|^2\,dx\,dt.$$

Furthermore, after separating the terms in the last integral in (3.25), we find that

$$\left|\int_0^T\int_{B_2}\rho_2(\Delta\xi_2)w\zeta\,dx\,dt\right| \le \delta\int_0^T\int_{B_2}\rho_2\xi_2|w|^2\,dx\,dt + C_\delta\int_0^T\int_{B_2}\rho_2\frac{|\Delta\xi_2|^2}{\xi_2}|\zeta|^2\,dx\,dt$$

and

$$\left|\int_0^T\int_{B_2}\rho_2(\nabla\xi_2\cdot\nabla w)\,\zeta\,dx\,dt\right| \le \delta\int_0^T\int_\Omega e^{-2s\alpha}\frac{1}{s\varphi}|\Delta\phi|^2\,dx\,dt + C_\delta\int_0^T\int_{B_2}\rho_3|\nabla\xi_2|^2|\zeta|^2\,dx\,dt.$$

In this last estimate we have used that $|\nabla w|^2 = |\Delta\phi|^2$. Finally,

$$\left|\int_0^T\int_{B_2}\rho_2\xi_2 w z_2\,dx\,dt\right| \le \delta\int_0^T\int_{B_2}\rho_2\xi_2|w|^2\,dx\,dt + C_\delta\int_0^T\int_{B_2}\rho_2\xi_2|z_2|^2\,dx\,dt.$$

In view of (3.25) and all these inequalities, we obtain

$$\begin{aligned}\int_0^T\int_{B_2}\rho_2\xi_2|\mathrm{curl}\,\phi|^2\,dx\,dt &\le \frac{\delta}{1-3\delta}\int_0^T\int_\Omega e^{-2s\alpha}\left(\frac{1}{s\varphi}|\Delta\phi|^2 + s^3\lambda^4\varphi^3|\phi_2|^2\right)dx\,dt\\ &\quad + C_\delta\int_0^T\int_{B_2}\left(\rho_2|z_2|^2 + \rho_3\bar{\xi}_2|\mathrm{curl}\,z|^2\right)dx\,dt \qquad (3.26)\end{aligned}$$

for some $\bar{\xi}_2 \in \mathcal{C}_0^\infty(B_2)$.

It remains to estimate the previous integral of $\rho_3\bar{\xi}_2|\mathrm{curl}\, z|^2$. Arguing as above, we see that

$$\begin{aligned}\int_0^T\int_{B_2}\rho_3\bar{\xi}_2|\mathrm{curl}\, z|^2\,dx\,dt &\le 2\int_0^T\int_{B_2}\rho_3\bar{\xi}_2|\nabla z|^2\,dx\,dt\\ &= -2\int_0^T\int_{B_2}\rho_3(\nabla\bar{\xi}_2\cdot\nabla z+\bar{\xi}_2(\Delta z))z\,dx\,dt\\ &\le \delta\int_0^T\int_\Omega e^{-2s\alpha}\left(s\lambda^2\varphi|\nabla z|^2+\frac{1}{s\varphi}|\Delta z|^2\right)dx\,dt\\ &\quad + C_\delta\int_0^T\int_{B_2}\rho_4|z|^2\,dx\,dt, \end{aligned}\tag{3.27}$$

where

$$\rho_4(t)=e^{-(1+\gamma_4)s\widehat{\alpha}}s^{8a+7}\lambda^{32}\widehat{\varphi}^{8b+7}$$

for some γ_4 satisfying $0<\gamma_4<2\gamma_3-1$. For the reasons stated above, it is clear that γ_4 can be assumed to satisfy $\widehat{\gamma}<\gamma_4<1$.

Choosing $\delta>0$ small enough and replacing the estimates (3.26) and (3.27) in (3.24), we obtain

$$I(s,\lambda;z)+I(s,\lambda;\phi)\le C\int_0^T\int_\omega\rho_4|z|^2\,dx\,dt\tag{3.28}$$

for all large s and λ. Taking into account the definition of ρ_4, that $\gamma_4>\widehat{\gamma}$, $a=7$, and $b=15/2$, we see that (3.6) holds.

This ends the proof of Theorem 3.3.

3.2. Proof of Proposition 3.1. Let us now give the proof of the observability inequality (3.1) for solutions of system (2.1)–(2.2), which relies on the above result. First, we observe that from the continuous dependence of the solution of (2.2), we have

$$\int_{T/2}^T\int_\Omega|z|^2\,dx\,dt\le C\int_{T/2}^T\int_{\mathcal{O}}|\phi|^2\,dx\,dt,\tag{3.29}$$

and from classical energy estimates for system (2.1), using the fact that $(k\wedge\phi)\cdot\phi=0$, we obtain an energy decreasing property:

$$\|\phi(t+T/4)\|_{0,\Omega}^2\le C\|\phi(t)\|_{0,\Omega}^2\qquad\forall t\in(T/4,3T/4)\,.$$

If we integrate the last inequality over the time interval $(T/4,3T/4)$ and change the integral variable $t\to t+T/4$ on the left-hand integral, we can easily deduce that

$$\int_{T/2}^T\int_\Omega|\phi|^2\,dx\,dt\le C\int_{T/4}^{3T/4}\int_\Omega|\phi|^2\,dx\,dt,\tag{3.30}$$

where C is independent of ϕ.

In what follows, we will fix s, λ, and $\widehat{\gamma}$ as in Theorem 3.3, depending on Ω, ω, $\mathcal{O}$, and T, such that (3.6) is satisfied.

Let us first prove that there exist positive constants M, C_1 such that

$$\int_0^{T/2}\int_\Omega \exp(-Mt^{-4})|z|^2\,dx\,dt + \int_{T/2}^{T}\int_\Omega |\phi|^2\,dx\,dt \le C_1\int_0^T\int_\omega |z|^2\,dx\,dt. \tag{3.31}$$

For this estimate, let us first notice that for some constants M and C, one has

$$e^{-2s\alpha(x,t)}\varphi(x,t)^3 \ge Ce^{-Mt^{-4}} \quad \forall (x,t)\in \overline{\Omega}\times(0,T/2);$$

this is easy to see, in view of the definitions of α and φ. Now, using (3.6), we get

$$\begin{aligned}\int_0^{T/2}\int_\Omega \exp(-Mt^{-4})|z|^2\,dx\,dt &\le \frac{1}{s^3\lambda^4}\,I(s,\lambda;z)\\ &\le CK\int_0^T\int_\omega e^{-(1+\widehat{\gamma})s\widehat{\alpha}}s^{63}\widehat{\varphi}^{67}|z|^2\,dx\,dt,\end{aligned}$$

and since the weight $e^{-(1+\widehat{\gamma})s\widehat{\alpha}}\widehat{\varphi}^{67}$ is bounded, we can estimate the first term in the left-hand side of (3.31). On the other hand, to obtain an estimate of ϕ in terms of z, let us recall the inequality (3.6). Since $e^{-2s\alpha}t^{-12}(T-t)^{-12}$ is bounded from below far from $t=0$ and $t=T$, in view of (3.30), we have

$$\begin{aligned}\int_{T/2}^T\int_\Omega |\phi|^2\,dx\,dt &\le \int_{T/4}^{3T/4}\int_\Omega |\phi|^2\,dx\,dt\\ &\le C\int_{T/4}^{3T/4}\int_\Omega e^{-2s\alpha}s^3\lambda^4\varphi^3|\phi|^2\,dx\,dt \le C\int_0^T\int_\omega e^{-(1+\widehat{\gamma})s\widehat{\alpha}}\widehat{\varphi}^{67}|z|^2\,dx\,dt.\end{aligned}$$

As before, from the fact that $e^{-(1+\widehat{\gamma})s\widehat{\alpha}}\widehat{\varphi}^{67}$ is bounded, we are able to estimate the second term in the left-hand side of (3.31).

Finally, the desired observability inequality (3.1) is obtained using the energy estimate (3.29) and (3.31):

$$\begin{aligned}\int_0^T\int_\Omega \exp(-Mt^{-4})|z|^2\,dx\,dt &\le \int_0^{T/2}\int_\Omega \exp(-Mt^{-4})|z|^2\,dx\,dt + \int_{T/2}^T\int_\Omega |z|^2\,dx\,dt\\ &\le C\left(\int_0^{T/2}\int_\Omega \exp(-Mt^{-4})|z|^2\,dx\,dt + \int_{T/2}^T\int_\Omega |\phi|^2\,dx\,dt\right)\\ &\le C\int_0^T\int_\omega |z|^2\,dx\,dt.\end{aligned}$$

Appendix. Proof of Lemma 3.4. Let us recall that this proof is given for the sake of completeness, but it is essentially an adaptation to our framework of the arguments presented in [8] and [11]. Let us consider the system

$$\begin{cases} -z_t - \Delta z + z - (1+x_2)\,\mathrm{k}\wedge z + \nabla r = \phi 1_{\mathcal{O}} \quad \text{in } Q,\\ \operatorname{div} z = 0 \quad \text{in } Q,\\ z = 0 \quad \text{on } \Sigma,\\ z(T) = 0 \quad \text{in } \Omega,\end{cases} \tag{3.32}$$

where $\phi \in L^2(0,T;W)\cap H^1(0,T;H)$.

Recall that B_0 is an open ball satisfying $B_0 \subset\subset \omega \cap \mathcal{O}$ and the auxiliary function η_0 satisfies $\eta_0 \in \mathcal{C}^2(\overline{\Omega})$,

$$\eta_0(x) > 0 \ \ \forall x \in \Omega, \quad \eta_0 = 0 \ \text{ on } \partial\Omega, \quad |\nabla \eta_0(x)| > 0 \ \ \forall x \in \overline{\Omega \setminus B_0}\,.$$

We will need an additional open ball $B_{00} \subset\subset B_0$, such that we still have

$$|\nabla \eta_0(x)| > 0 \ \ \forall x \in \overline{\Omega \setminus B_{00}}\,.$$

We will divide the proof of Lemma 3.4 into several steps.

Step 1. Following [8], we apply some well-known Carleman estimates for the heat equation to (3.32). Thus, there exist constants s_0, λ_0, and $C > 0$ depending on Ω, ω, and T such that for every $\lambda > \lambda_0$ and $s > s_0$, the following estimate holds:

$$\begin{aligned} I(s,\lambda;z) \le C\Bigg\{ &\int_0^T \int_{B_{00}} e^{-2s\alpha} s^3\lambda^4\varphi^3 |z|^2 \,dx\,dt \\ &+ \int_0^T \int_\Omega e^{-2s\alpha} \left(|\nabla r|^2 + |(1+x_2)k \wedge z|^2 + |\phi 1_{\mathcal{O}}|^2 \right) dx\,dt \Bigg\}. \end{aligned} \tag{3.33}$$

Recall that the definitions of $I(s,\lambda;z)$ and the weights α and φ are given in section 3.1.

Of course, we can choose s large enough to absorb the previous term $|(1+x_2)k \wedge z|^2$ with the left-hand side (3.33). We then have

$$\begin{aligned} I(s,\lambda;z) \le C\Bigg\{ &\int_0^T \int_{B_{00}} e^{-2s\alpha} s^3\lambda^4\varphi^3 |z|^2 \,dx\,dt \\ &+ \int_0^T \int_\Omega e^{-2s\alpha} |\nabla r|^2 \,dx\,dt + \int_0^T \int_{\mathcal{O}} e^{-2s\alpha} |\phi|^2 \,dx\,dt \Bigg\} \end{aligned} \tag{3.34}$$

for any $\lambda > \lambda_0$ and any $s > s_{01}$.

Step 2. To estimate the pressure gradient ∇r in (3.34), we first apply the divergence operator to (3.32), i.e., we write

$$\Delta r(t) = \operatorname{div}((1+x_2)\mathrm{k} \wedge z)(t) \quad \text{in } \ \Omega, \qquad t \in (0,T), \tag{3.35}$$

and then we use the following result by Imanuvilov and Puel [12], which is satisfied by weak solutions to second order elliptic equations.

LEMMA 3.5. *Let us set $\beta(x) = e^{\lambda\eta_0(x)}$ and let $v \in H^1(\Omega)$ be a solution of*

$$\Delta v = \operatorname{div} h \quad \text{in} \quad \Omega, \tag{3.36}$$

where $h \in L^2(\Omega)^2$. Then there exist positive constants τ_2, λ_{01}, and C such that

$$\begin{aligned} \int_\Omega e^{2\tau\beta} |\nabla v|^2 \,dx \le C\Bigg\{ &\tau \int_\Omega e^{2\tau\beta} \beta |h|^2 \,dx + \tau^{1/2} e^{2\tau} \|g\|^2_{1/2,\partial\Omega} \\ &+ \tau^2\lambda^2 \int_{B_{00}} e^{2\tau\beta} \beta^2 |v|^2 \,dx + \int_{B_{00}} e^{2\tau\beta} |\nabla v|^2 \,dx \Bigg\} \end{aligned} \tag{3.37}$$

for any $\tau > \tau_2$ and any $\lambda > \lambda_{01}$, where $g = v|_{\partial\Omega}$. ∎

In particular, we have the following for $r(t)$ and $g(t) = r(t)|_{\partial\Omega}$:

$$\int_\Omega e^{2\tau\beta}|\nabla r(t)|^2\,dx \le C\Big\{\tau\int_\Omega e^{2\tau\beta}\beta|(1+x_2)k\wedge z(t)|^2\,dx + \tau^{1/2}e^{2\tau}\|g(t)\|^2_{1/2,\partial\Omega} + \tau^2\lambda^2\int_{B_{00}} e^{2\tau\beta}\beta^2|r(t)|^2\,dx + \int_{B_{00}} e^{2\tau\beta}|\nabla r(t)|^2\,dx\Big\}. \tag{3.38}$$

To estimate the last integral in (3.38), let us introduce an open set B_{01} such that $B_{00}\subset\subset B_{01}\subset\subset B_0$ and a function $\xi_{01}\in\mathcal{C}_0^2(B_{01})$ such that

$$0\le\xi_{01}\le 1 \quad\text{and}\quad \xi_{01}=1 \text{ in } B_{00}\,.$$

Integrating by parts, it follows from (3.35) that

$$\begin{aligned}\int_{B_{00}} e^{2\tau\beta}|\nabla r(t)|^2\,dx &\le \int_{B_{01}} e^{2\tau\beta}\xi_{01}|\nabla r(t)|^2\,dx\\ &= -\int_{B_{01}} e^{2\tau\beta}\xi_{01}\,\mathrm{div}((1+x_2)\mathrm{k}\wedge z)(t)r(t)\,dx\\ &\quad -\frac{1}{2}\int_{B_{01}} e^{2\tau\beta}\nabla\xi_{01}\cdot\nabla|r(t)|^2\,dx - \int_{B_{01}}\xi_{01}\nabla e^{2\tau\beta}\cdot\nabla|r(t)|^2\,dx.\end{aligned}$$

Integrating again by parts, applying Young's inequality, and taking into account that $|\Delta(e^{2\tau\beta}\xi_{01})|\le C\tau^2\lambda^2\beta^2e^{2\tau\beta}$ for some positive constant C, after some straightforward computations we deduce that

$$\int_{B_{00}} e^{2\tau\beta}|\nabla r(t)|^2\,dx \le C\Big\{\tau^2\lambda^2\int_{B_{01}} e^{2\tau\beta}\beta^2|r(t)|^2\,dx + \int_{B_{01}} e^{2\tau\beta}|z(t)|^2\,dx\Big\}.$$

Replacing this inequality in (3.38), we obtain the following for each $t\in(0,T)$:

$$\int_\Omega e^{2\tau\beta}|\nabla r(t)|^2\,dx \le C\Big\{\tau\int_\Omega e^{2\tau\beta}\beta|z(t)|^2\,dx + \tau^{1/2}e^{2\tau}\|g(t)\|^2_{1/2,\partial\Omega} + \tau^2\lambda^2\int_{B_{01}} e^{2\tau\beta}\beta^2|r(t)|^2\,dx\Big\}.$$

Now, let us put $\tau = s/(t^4(T-t)^4)$ and let us choose $s > s_{02} = \max(s_{01}\,, \tau_2(T/2)^8)$. Then $\tau > \tau_2$. Let us multiply by $\exp(-2s\exp(2\lambda\|\eta_0\|_\infty)/(t^4(T-t)^4))$ the previous inequality and let us integrate with respect to t in $(0,T)$. This leads to the estimate

$$\int_0^T\int_\Omega e^{-2s\alpha}|\nabla r|^2\,dx\,dt \le C\Big\{\int_0^T\int_\Omega e^{-2s\alpha}s\varphi|z|^2\,dx\,dt + \int_0^T e^{-2s\alpha^*}(s\varphi^*)^{1/2}\|g(t)\|^2_{1/2,\partial\Omega}\,dt + \int_0^T\int_{\omega_1} e^{-2s\alpha}(s\lambda\varphi)^2|r|^2\,dx\,dt\Big\}, \tag{3.39}$$

where α^* and φ^* were introduced in section 3.1.

The first term in the right-hand side of (3.39) can be absorbed by the left-hand side $I(s,\lambda;z)$ in (3.33) for s large enough. Hence, we obtain

$$I(s,\lambda;z) \le C\left\{\int_0^T\int_{\omega_0} e^{-2s\alpha}s^3\lambda^4\varphi^3|z|^2\,dx\,dt + \int_0^T e^{-2s\alpha^*}(s\varphi^*)^{1/2}\|g(t)\|^2_{1/2,\partial\Omega}\,dt\right.$$
$$\left. + \int_0^T\int_{\omega_1} e^{-2s\alpha}(s\lambda\varphi)^2|r|^2\,dx\,dt + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha}|\phi|^2\,dx\,dt\right\} \tag{3.40}$$

for any $\lambda > \lambda_{01}$ and any $s > s_{03}$.

Step 3. Step 3 estimates the norm of the trace of the pressure on the boundary. To this end, we introduce three new functions:

$$\chi(t) = e^{-s\alpha^*(t)}(s\varphi^*(t))^{1/4}, \quad \tilde z = \chi(t)z, \qquad \tilde r = \chi(t)r.$$

From (3.32), we see that $(\tilde z,\tilde r)$ satisfies

$$\begin{cases} -\tilde z_t - \Delta\tilde z + \tilde z + \nabla\tilde r = -\chi' z + \chi(1+x_2)\,\mathrm{k}\wedge z + \chi\phi 1_{\mathcal{O}} & \text{in } Q,\\ \operatorname{div}\tilde z = 0 & \text{in } Q,\\ \tilde z = 0 & \text{on } \Sigma,\\ \tilde z(T) = 0 & \text{in } \Omega. \end{cases}$$

Using the continuity of the trace operator and standard a priori estimates for the pressure, we deduce that

$$\begin{aligned}\int_0^T \|\tilde r(t)\|^2_{1/2,\partial\Omega}\,dt &\le \int_0^T \|\tilde r(t)\|^2_{1,\Omega}\,dt\\ &\le C\left\{\int_0^T\int_\Omega e^{-2s\alpha^*}s^{5/2}(\varphi^*)^3|z|^2\,dx\,dt\right.\\ &\qquad \left. + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}(s\varphi^*)^{1/2}|\phi|^2\,dx\,dt\right\}.\end{aligned}$$

We have used here that $|\chi'(t)|^2 \le Ce^{-2s\alpha^*}s^{5/2}(\varphi^*(t))^3$ for all $t\in(0,T)$. We thus obtain a new estimate from (3.40):

$$I(s,\lambda;z) \le C\left\{\int_0^T\int_{B_{00}} e^{-2s\alpha}s^3\lambda^4\varphi^3|z|^2\,dx\,dt + \int_0^T\int_{B_{01}} e^{-2s\alpha}(s\lambda\varphi)^2|r|^2\,dx\,dt\right.$$
$$\left. + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha}(s\varphi)^{1/2}|\phi|^2\,dx\,dt\right\} \tag{3.41}$$

for any $\lambda > \lambda_{01}$ and any $s > s_{04}$.

Step 4. It remains to estimate the local term in the right-hand side of (3.41) containing $|r|^2$ in terms of z and ϕ.

Assume that the pressure r has been normalized in such a way that

$$\int_{B_{01}} r(t)\,dx = 0 \quad \forall t\in(0,T).$$

Then there exists $C>0$ such that

$$\int_{B_{01}} |r(t)|^2\,dx \le C\int_{B_{01}} |\nabla r(t)|^2\,dx \quad \forall t\in(0,T)$$

and also

$$\int_0^T\int_{B_{01}} e^{-2s\alpha}(s\lambda\varphi)^2|r|^2\,dx\,dt \le C\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\nabla r|^2\,dx\,dt,$$

where the functions $\widehat{\alpha}=\widehat{\alpha}(t)$ and $\widehat{\varphi}=\widehat{\varphi}(t)$ were introduced in section 3.1.

From (3.32), we see that

$$\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\nabla r|^2\,dx\,dt \le C\Bigg\{\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2(|z|^2+|\phi|^2)\,dx\,dt + \int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2(|z_t|^2+|\Delta z|^2)\,dx\,dt\Bigg\}.$$

Therefore, in view of (3.41), we obtain

$$\begin{aligned} I(s,\lambda;z) \le C\Bigg\{&\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}\left(s^3\lambda^4\widehat{\varphi}^3|z|^2+(s\lambda\widehat{\varphi})^2|\phi|^2\right)\,dx\,dt\\ &+\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2(|z_t|^2+|\Delta z|^2)\,dx\,dt\\ &+\int_0^T\int_{\mathcal{O}} e^{-2s\alpha}(s\varphi)^{1/2}|\phi|^2\,dx\,dt\Bigg\}. \end{aligned} \tag{3.42}$$

Step 5. The rest of the proof deals with the estimates of the local integrals containing $|\Delta z|^2$ and $|z_t|^2$. First, we will be concerned with $|\Delta z|^2$.

Let us introduce a function $\xi_0\in\mathcal{C}_0^4(B_0)$ such that

$$0\le\xi_0\le 1 \quad\text{and}\quad \xi_0=1 \text{ in } B_{01}\,.$$

Let us set $\widehat{z}(x,t)=e^{-s\widehat{\alpha}}\widehat{\varphi}\,\xi_0\Delta z(T-t)$. We want to estimate the norm $\|\widehat{z}\|_{L^2(B_{01}\times(0,T))^2}$. Following the arguments in [8] (see Step 4), we can deduce that

$$\begin{aligned} &\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\Delta z|^2\,dx\,dt = \int_0^T\int_{B_{01}} s^2\lambda^2|\widehat{z}|^2\,dx\,dt\\ &\le C\left(\int_0^T\int_{B_0} e^{-2s\widehat{\alpha}}s^4\lambda^2\widehat{\varphi}^{9/2}|z|^2\,dx\,dt+\int_0^T\int_{B_0} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\phi|^2\,dx\,dt\right). \end{aligned} \tag{3.43}$$

Thus, from (3.42) we have

$$\begin{aligned} &I(s,\lambda;z)\\ &\le C\Bigg(\int_0^T\int_{B_0} e^{-2s\widehat{\alpha}}s^4\lambda^4\widehat{\varphi}^{9/2}|z|^2\,dx\,dt+\int_0^T\int_{B_0} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\phi|^2\,dx\,dt\\ &\qquad+\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|z_t|^2\,dx\,dt+\int_0^T\int_{\mathcal{O}} e^{-2s\alpha}(s\varphi)^{1/2}|\phi|^2\,dx\,dt\Bigg). \end{aligned} \tag{3.44}$$

Step 6. Now we want to estimate $|z_t|^2$. Due to the regularity properties of ϕ, we can use here a more straightforward argument than in [8], where the right-hand side belongs only to $L^2(Q)^2$.

First, notice that

$$\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|z_t|^2\,dx\,dt \le \delta\int_0^T\int_{B_{01}} e^{-2s\alpha}\frac{1}{s\varphi}|z_t|^2\,dx\,dt + \delta\int_0^T\int_{B_{01}} e^{-2s\alpha^*}\frac{1}{s^3(\varphi^*)^{7/2}}|z_{tt}|^2\,dx\,dt + C_\delta\int_0^T\int_{B_{01}} e^{-4s\alpha^*+2s\alpha^*}s^7\lambda^4\widehat{\varphi}^{15/2}|z|^2\,dx\,dt.$$

This is easily obtained by integrating by parts in time. We will later choose $\delta > 0$ small enough.

We have the following auxiliary result.

LEMMA 3.6. *Let (z, r) be the solution of* (3.32). *Then the following estimate holds:*

$$\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s^3(\varphi^*)^{7/2}}|z_{tt}|^2\,dx\,dt \le C\left(I(s,\lambda;z) + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}\left(\frac{1}{s\varphi^*}|\phi|^2 + \frac{1}{s^3(\varphi^*)^{7/2}}|\phi_t|^2\right)dx\,dt\right). \tag{3.45}$$

Proof. Multiply (3.32) by $e^{-2s\alpha^*}s^{-2}(\varphi^*)^{-9/4}z_{tt}$ and integrate in Q. Noticing that

$$\left|(e^{-2s\alpha^*}(\varphi^*)^{-9/4})_t\right| \le Ce^{-2s\alpha^*}s(\varphi^*)^{-1},$$

after some computations we deduce that

$$\begin{aligned}\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s^2(\varphi^*)^{9/4}}|\nabla z_t|^2\,dx\,dt &\le C\left\{\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s\varphi^*}(|z|^2+|z_t|^2)\,dx\,dt\right.\\ &\quad\left.+\int_0^T\int_\Omega e^{-2s\alpha^*}s(\varphi^*)^{1/4}|\nabla z|^2\,dx\,dt + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}\frac{1}{s\varphi^*}|\phi|^2\,dx\,dt\right\}\\ &\quad+\frac{1}{2}\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s^3(\varphi^*)^{7/2}}|z_{tt}|^2\,dx\,dt.\end{aligned} \tag{3.46}$$

On the other hand, if we compute the time derivative of (3.32) and then we multiply the result by $e^{-2s\alpha^*}s^{-3}(\varphi^*)^{-7/2}z_{tt}$, we find that

$$\begin{aligned}\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s^3(\varphi^*)^{7/2}}|z_{tt}|^2\,dx\,dt &\le \int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s^2(\varphi^*)^{9/4}}|\nabla z_t|^2\,dx\,dt\\ &\quad+C\left(\int_0^T\int_\Omega e^{-2s\alpha^*}\frac{1}{s\varphi^*}|z_t|^2\,dx\,dt + \int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}\frac{1}{s^3(\varphi^*)^{7/2}}|\phi_t|^2\,dx\,dt\right).\end{aligned} \tag{3.47}$$

From (3.46) and (3.47), we see that (3.45) holds. ∎

In view of this lemma, we have

$$\begin{aligned}
&\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|z_t|^2\,dx\,dt\\
&\quad\le C\delta\left(I(s,\lambda;z)+\int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}\left(\frac{1}{s\varphi^*}|\phi|^2+\frac{1}{s^3(\varphi^*)^{7/2}}|\phi_t|^2\right)dx\,dt\right)\\
&\quad+C_\delta\int_0^T\int_{B_{01}} e^{-4s\alpha^*+2s\alpha^*}s^7\lambda^4\widehat{\varphi}^{15/2}|z|^2\,dx\,dt.
\end{aligned}$$

If we assume that $\gamma_1<1$, then $(3-\gamma_1)/2>1$, and from Lemma 3.2 we deduce that $(3-\gamma_1)\widehat{\alpha}/2>\alpha^*$ for sufficiently large λ, say, $\lambda>\lambda_{02}$. Consequently, $-4\widehat{\alpha}+2\alpha^*<-(1+\gamma_1)\widehat{\alpha}$ and

$$\begin{aligned}
&\int_0^T\int_{B_{01}} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|z_t|^2\,dx\,dt\\
&\quad\le C\delta\left(I(s,\lambda;z)+\int_0^T\int_{\mathcal{O}} e^{-2s\alpha^*}\left(\frac{1}{s\varphi^*}|\phi|^2+\frac{1}{s^3(\varphi^*)^{7/2}}|\phi_t|^2\right)dx\,dt\right)\\
&\quad+C_\delta\int_0^T\int_{B_{01}} e^{-(1+\gamma_1)s\widehat{\alpha}}s^7\lambda^4\widehat{\varphi}^{15/2}|z|^2\,dx\,dt
\end{aligned}$$

for any $\lambda>\lambda_{02}$ and any $s>s_{04}$.

From (3.44) and this estimate, choosing $\delta>0$ small enough, we find

$$\begin{aligned}
&I(s,\lambda;z)\\
&\quad\le C\left\{\int_0^T\int_{B_0} e^{-(1+\gamma_1)s\widehat{\alpha}}s^7\lambda^4\widehat{\varphi}^{15/2}|z|^2\,dx\,dt+\int_0^T\int_{B_0} e^{-2s\widehat{\alpha}}(s\lambda\widehat{\varphi})^2|\phi|^2\,dx\,dt\right.\\
&\qquad\left.+\int_0^T\int_{\mathcal{O}} e^{-2s\alpha}\left((s\varphi)^{1/2}|\phi|^2+\frac{1}{s^3(\varphi^*)^{7/2}}|\phi_t|^2\right)dx\,dt\right\}
\end{aligned}$$

for all $\lambda>\lambda_{02}$ and $s>s_{04}$.

Obviously, this yields (3.8). The proof of (3.9) is very similar and in fact much simpler, since the left-hand side of (2.1) is zero.

Thus, we have proved Lemma 3.4 for $\lambda_1=\lambda_{02}$ and $s_1=s_{04}$ (two parameters depending on Ω, ω, $\mathcal{O}$, and T).

4. Some final remarks. The geometrical hypothesis $\omega\cap\mathcal{O}\neq\emptyset$ is required to prove the existence of both ε-insensitizing and insensitizing controls. In the first case, this assumption is used to prove a unique continuation property (Lemma 2.1). In the case of insensitizing controls, it is used to prove an observability inequality. The problem is completely open when $\omega\cap\mathcal{O}=\emptyset$ (see [18]).

The existence of insensitizing controls is guaranteed by the null controllability property of a cascade system of quasi-geostrophic equations (1.5)–(1.6). In this case, the control acts indirectly on one variable through the other one. Of course, this controllability property is stronger than the null controllability of a single quasi-geostrophic system.

To prove the null controllability property of the cascade system, there are two main difficulties.

First is the need for a unique continuation result for the adjoint system (2.2)–(2.1). The presence of the Coriolis term permits us to relate the second component of the velocity and its associated vorticity, and this is a key point in the proof of uniqueness (see Remark 2).

The second problem is the need for an observability inequality for the adjoint. This inequality comes from an appropriate (global) Carleman estimate. The main idea is to estimate ϕ in terms of $\operatorname{curl}\phi$ in a ball contained in $\omega \cap \mathcal{O}$ in the right-hand side of (3.10). This is possible again due to the presence of the Coriolis term (in fact, our method does not work in the case of the usual Stokes equations). We rewrite the system using the stream function and the vorticity and we see that the Coriolis term leads to an expression of the horizontal derivative of the stream function in terms of the vorticity. In this way, we are able to avoid estimates of pressure terms, which are in general very hard to deduce (see the appendix in section 3). Moreover, the weight in the right-hand side of (3.10) is larger than the weight in the left-hand side. Accordingly, the terms in the right cannot be absorbed directly as in the case of the heat equation (see [18]) and this fact requires some additional work.

Acknowledgments. The authors wish to thank J.-P. Puel of the Laboratoire de Mathématiques Appliquées, Université Versailles/Saint Quentin-en-Yvelines (France) and S. Guerrero of the Departamento de Ecuaciones Diferenciales y Análisis Numérico, Universidad de Sevilla (Spain), for very useful discussions.

ADAPTIVE WAVELET METHODS FOR LINEAR-QUADRATIC ELLIPTIC CONTROL PROBLEMS: CONVERGENCE RATES*

WOLFGANG DAHMEN† AND ANGELA KUNOTH‡

Abstract. We propose an adaptive algorithm based on wavelets for the fast numerical solution of control problems governed by elliptic boundary value problems with distributed or Neumann boundary control. A quadratic cost functional that may involve fractional Sobolev norms of the state and the control is to be minimized subject to linear constraints in weak form. Placing the problem into the framework of (biorthogonal) wavelets allows us to formulate the functional and the constraints equivalently in terms of ℓ_2-norms of wavelet expansion coefficients and constraints in the form of an ℓ_2 automorphism. The resulting first order necessary conditions are then derived as a (still infinite) system in ℓ_2. Applying the machinery developed in [A. Cohen, W. Dahmen, and R. DeVore, *Math. Comp.*, 70 (2001), pp. 27–75; A. Cohen, W. Dahmen, and R. DeVore, *Found. Comput. Math.*, 2 (2002), pp. 203–245], we propose an adaptive method which can be interpreted as an inexact gradient descent method, where in each iteration step the primal and the adjoint system need to be solved up to a prescribed accuracy. Convergence of the adaptive algorithm is proved. In addition, we show that the adaptive algorithm is asymptotically optimal, that is, the convergence rate achieved for computing the solution up to a desired target tolerance is asymptotically the same as the wavelet-best N-term approximation of the solution, and the total computational work is proportional to the number of computational unknowns.

1. Introduction.

A new type of adaptive wavelet method for the numerical solution of a wide class of variational problems has been developed and analyzed in a series of papers [CDD1, CDD2, CDD3]. These methods have been shown to exhibit asymptotically computational complexity in the following sense. If the solution can be approximated (using ideal complete information) by N terms from the underlying wavelet basis with accuracy $\mathcal{O}(N^{-s})$ (in the energy norm), then the scheme recovers for a certain range of decay rates s, depending on the wavelet basis, the solution with any desired target accuracy ε at a computational expense that stays proportional to $\varepsilon^{-1/s}$, uniformly in ε, and matches in this sense the optimal work/accuracy rate of best *N-term approximation*.

Moreover, the underlying analysis has lead to a new algorithmic paradigm that can be summarized as follows:

(i) Establish *well-posedness* of the underlying variational problem, which is to identify a Hilbert space (energy space) for which the operator induced by the

variational problem is boundedly invertible as a mapping from this Hilbert space onto its dual.

(ii) Transform the original problem into an equivalent one that is now well posed in the Euclidean metric ℓ_2. This is usually done by finding a *wavelet basis* that is a Riesz basis for the energy space.

(iii) Exploit (ii) so as to devise an iterative scheme for the (still infinite dimensional) transformed problem on ℓ_2 that has a fixed error reduction per step.

(iv) Perform the ideal iteration from (iii) approximately by *adaptively* applying the involved operators in wavelet coordinates within suitable dynamically updated accuracy tolerances.

The objective for this paper is to explore the use of such concepts in the context of *optimal control problems* with PDE constraints. We are primarily motivated by the following two aspects. By their very nature, such control problems tend to have a rather demanding computational complexity, so that the use of schemes that minimize computational complexity is very tempting. Second, since the above paradigm tries to stay with the infinite dimensional well-posed problem as long as possible, it turns out to inherit the stability of the infinite dimensional problem in the following sense. Compatibility conditions on finite dimensional trial spaces that may arise in coupled problems, such as in the form of the LBB condition for saddle point problems, do not arise in the adaptive context; see [CDD2, DDU]. Moreover, the fact that suitable scalings of one and the same wavelet basis form Riesz bases for a whole range of Sobolev spaces allows one to treat in a convenient way (at least up to equivalence) a variety of such norms in the objective functional whose realization (of any equivalent version) poses severe difficulties in conventional settings. We view the fact that the use of such norms (even when realized only up to equivalence) offers greater flexibility in balancing data and regularization as an additional *modeling* tool. We shall further comment on this point below.

To bring out the basic mechanisms, we deliberately confine the discussion to rather simple types of control problems with linear constraints, including Dirichlet and Neumann problems with distributed or Neumann boundary controls. The setting will be described in section 2, along with some examples that will guide the subsequent developments. While the above paradigm was developed mainly for PDEs or singular integral equations, the first issue will be to formulate the optimal control problem in a way that allows us to branch into the above road map. This will be done in section 3, which provides the background for (ii). These formulations also shed some light on principal preferences concerning the formulation of reduced minimization problems through elimination of the state variable. Moreover, whether the penalty term in the cost functional is needed for regularization becomes obvious; see sections 3.4 and 3.5. These issues might be less apparent when working from the outset with a finite dimensional discretized problem.

To understand the potential but also the limitations of the concepts developed in this paper, it is important to distinguish two slightly different problem scenarios. In the first, a specific cost functional is imposed by the (physical) problem background, and it is mandatory to compute an optimal solution with respect to this special objective function. The quadratic forms appearing in this case induce typically (weighted) L_2-norms or first order Sobolev norms (with possibly varying diffusion coefficients). We shall refer to this case in the following as the *mandatory case*.

On the other hand, in particular, when the cost functional involves a regularization term, the purpose of formulating an optimal control problem is often to accom-

plish a possibly good compromise between fitting the data under the given constraints and a necessary regularization. One usually has only estimates for the regularization parameter and, in principle, one obtains different optimal solutions when varying this parameter slightly. In such a case there is possibly no *unique* optimization problem associated with the underlying task, but the formulation of the objective functional becomes part of the modeling process; see, e.g., [BBDM]. An interesting way to enrich this modeling process, beyond varying a single scale weight, is to incorporate mechanisms that allow one to affect contributions with different characteristic length scales in a different way when searching for a good compromise between data fit and regularization. This could help, for instance, to exploit best a possibly higher regularity of the observed data to suppress unwanted undulations in the final solution. Moreover, imposing more regularity on the control might significantly improve its practical executability in applications. While this is not possible by a global weight (or weight function implanted in a single norm), smoothness norms of Sobolev or Besov type would serve that purpose. (See, e.g., [CDLL] for application of such norms in image compression or, e.g., [CK] in the context of scattered data fitting.) Such norms, especially when the smoothness order is not an integer, typically do not have any canonical, physically motivated representer. Using extensions combined with Fourier transforms, or interpolation between integer order cases, or intrinsic norms defined by double integrals of difference quotients, or factor norms when dealing with traces, one obtains different variants whose common feature is the above-mentioned weighting of different length scales. Lacking an a priori physical reason for employing any specific version of such a norm, it is natural to choose one that supports the numerical treatment best. We shall refer to this scenario (typically associated with noninteger smoothness norms) when no physically mandatory optimal solution can be identified as the *ambiguous case*.

Unfortunately, not much is known about this latter scenario, primarily because in conventional discretization settings none of the above-mentioned equivalent norms is easily (or is not at all) realized in practice. In the ambiguous case, when in principle any *representer* can be used, wavelet concepts offer a promising alternative that renders such mechanisms feasible. In fact, norm equivalences based on simple scalings suggest themselves and, in particular, support (iii) and (iv). Of course, preferring one equivalent norm in the objective functional over another one will change the solution, although the constraints remain unchanged. However, in the case of compatible data, the same solution is obtained for all equivalent representers of the chosen norm. Moreover, it will be seen that the well-posedness of the corresponding variational problem remains invariant.

We present here for the first time to our knowledge rigorous convergence and complexity estimates for adaptive methods for optimal control problems that treat in full generality the ambiguous case and also, for certain naturally arising objective functionals, the mandatory case.

Therefore, the general control problem described initially in section 2.1 is to be viewed only as a *reference model*, where in the ambiguous case the involved norms are specified only up to equivalence. To facilitate a possibly unified treatment of both scenarios, we employ the concept of *Riesz operators* when formulating the problem in wavelet coordinates. This enables us to retain formally the same cost functional when dealing with the mandatory case. In favor of a unified treatment and to keep technicalities at a manageable level, we present a detailed description and analysis of the adaptive concept first in the ambiguous case. We sketch at the end the modifications

needed to address the mandatory case for certain naturally arising norms.

In section 4 we briefly collect some relevant facts from [CDD2, CDD3] that will later be used for (iv). One major task in the present context is the formulation of a convergent (ideal) iteration (iii) and a way that makes (iv) feasible. This is the objective of section 5. Having started out from a rather general setting we will have by then narrowed, step by step, requirements on the computational ingredients that will imply optimal complexity at the end and guide the construction of the scheme. The complexity analysis in section 6 will finally allow us to identify specific evaluation schemes that will be seen to render our adaptive solver for the optimal control problems under consideration to have optimal work/accuracy rates in the above sense. It is perhaps worth noting that the analysis brings out some distinctions between the inherent computational complexity of problems with distributed versus Neumann boundary control. In section 7 we address some special cases regarding simplifications of the scheme. Moreover, we indicate for natural objective functionals ways of treating the mandatory case. Finally, in section 8 some concluding remarks are made.

Throughout the paper, we use the following notational conventions, unless specific constants have to be identified. The relation $a \sim b$ stands for $a \lesssim b$ and $a \gtrsim b$, where the latter relation means that b can be estimated from above by a constant multiple of a independent of all parameters on which a or b may depend.

2. Problems in optimal control. We shall be concerned with the following abstract class of problems in optimal control that will serve as a first simple model for studying adaptive solution concepts in such a context. Several specifications will guide the subsequent analysis.

2.1. Abstract linear-quadratic control problems. Let Y and Q denote the *state* and the *control space*, respectively, which are assumed to be (closed subspaces of) Hilbert spaces, with topological duals Y', Q' and associated dual forms $\langle\cdot,\cdot\rangle_{Y'\times Y}$, $\langle\cdot,\cdot\rangle_{Q'\times Q}$. When there is no risk of confusion we write briefly $\langle\cdot,\cdot\rangle$.

In many applications the *states* y are measured in a weaker norm corresponding here to a Hilbert space Z hosting the observed data y_*. Specifically, suppose that $T : Y \to R$ is a continuous linear operator from Y onto its range R

$$\|Tv\|_R \lesssim \|v\|_Y, \quad v \in Y, \tag{2.1}$$

and that R is continuously embedded in Z. We shall always identify norms by using the respective space as a subscript. In contrast, the regularity imposed on the *control* u, represented here by a Hilbert space U, is often higher than that required in a natural variational formulation. Thus, in summary we shall assume the validity of the continuous embeddings

$$\|w\|_Z \lesssim \|w\|_R, \quad w \in R, \qquad \|v\|_Q \lesssim \|v\|_U, \quad v \in U. \tag{2.2}$$

Our objective is to minimize quadratic functionals of the form

$$J(y,u) = \frac{1}{2}\|Ty - y_*\|_Z^2 + \frac{\omega}{2}\|u\|_U^2, \tag{2.3}$$

subject to linear constraints, that will be described next. We shall assume that $a(\cdot,\cdot) : Y \times Y \to \mathbb{R}$ is a bilinear continuous Y-*elliptic* form, i.e.,

$$a(v,v) \sim \|v\|_Y^2, \qquad v \in Y. \tag{2.4}$$

It will sometimes be convenient to refer to the linear operator $A : Y \to Y'$ defined by $\langle Aw, v\rangle = a(w, v)$, $w, v \in Y$.

The last ingredient is a linear continuous operator $E : Q \to Y'$, describing an action on the control.

The abstract *linear-quadratic control problem* can now be formulated as follows.

(CP). *For given observations $y_* \in Z$, a right-hand side $f \in Y'$, and a weight parameter $\omega > 0$, minimize the quadratic functional* (2.3) *over $(y, u) \in Y \times Q$ subject to the linear constraints*

$$a(y, v) = \langle f + Eu, v\rangle, \quad v \in Y. \tag{2.5}$$

Remark 2.1. Of course, when the observed data are *compatible* in the sense that $y_* \equiv TA^{-1}f$, (CP) has the trivial solution $u \equiv 0$ yielding $J(y, u) \equiv 0$.

2.2. Some examples. In all the following, $\Omega \subset \mathbb{R}^d$ denotes a bounded Lipschitz domain. The choice $Z = U = L_2(\Omega)$ in the functional (2.3) is classical (see [Li]), perhaps partly due to the difficulty of evaluating the norms that could be termed *natural* (such as fractional trace norms) with regard to the underlying variational formulation, namely, the norms $\|\cdot\|_Y, \|\cdot\|_Q$. Here we explicitly allow for use also of natural norms for observing the state y, unless, for statistical reasons, measurements are meaningful only in weaker norms, such as L_2. It will be shown below that Sobolev or even Besov norms on Ω or (part of) its boundary $\partial\Omega$ for a certain range of regularity scales can be dealt with by our approach.

Although the problems with *distributed control* are perhaps of a rather academic nature, they serve as good illustrations for the essential mechanisms.

2.2.1. Dirichlet problem with distributed control. In our first example we consider such a distributed control problem with the following identification of the above ingredients:

$$a(v, w) := \int_\Omega \nabla v \cdot \nabla w \, dx, \quad Y = H_0^1(\Omega),\ Q = H^{-1}(\Omega) = Y'. \tag{2.6}$$

This gives rise to constraints whose strong form is given by the standard second order Dirichlet problem with distributed control,

$$\begin{aligned} -\Delta y &= f + u && \text{in } \Omega, \\ y &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{2.7}$$

Admissible choices for Z, U, satisfying (2.2), are then

$$Z := H_{00}^{1-\gamma}(\Omega), \quad U = H^{\beta-1}(\Omega) := (H_{00}^{1-\beta}(\Omega))', \quad 0 \le \gamma, \beta \le 1, \tag{2.8}$$

where $H_{00}^\gamma(\Omega)$ consists of those elements in $H^\gamma(\Omega)$ whose trivial extension by zero belongs to $H^\gamma(\mathbb{R}^d)$. Thus, for $\gamma > 0$ states are measured in a weaker norm, while for $\beta > 0$ additional smoothness is imposed on the control when compared with the natural norms. In particular, the classical case $U = Z = L_2(\Omega)$ is covered. In all these cases the operators T, E are the canonical injections $T = I$, $E = I$, which, for the regularity scales in (2.8), are indeed bounded.

2.2.2. Neumann problem with distributed control. Choosing

$$a(v,w) := \int_\Omega (\nabla v \cdot \nabla w + vw)dx, \quad Y := H^1(\Omega), \quad Q = (H^1(\Omega))' = Y', \tag{2.9}$$

(2.4) holds. Denoting by ι the trace operator to $\partial\Omega$, mapping functions in $Y = H^1(\Omega)$ to $H^{1/2}(\partial\Omega)$, we consider next the constraint

$$a(y,v) = \langle \tilde{f}, v\rangle + \int_{\partial\Omega} g(\iota v)\, ds + \langle u, v\rangle \qquad \text{for all } v \in Y \tag{2.10}$$

and for given $\tilde{f} \in Y'$, $g \in H^{-1/2}(\partial\Omega)$. Its strong form is the second order nonhomogeneous Neumann problem with distributed control

$$\begin{aligned} -\Delta y + y &= \tilde{f} + u && \text{in } \Omega, \\ \frac{\partial y}{\partial n} &= g && \text{on } \partial\Omega, \end{aligned} \tag{2.11}$$

where $\frac{\partial}{\partial n}$ is the normal derivative in the direction of the outward normal. The constraints (2.10) can be formulated as an operator equation

$$Ay = f + u, \tag{2.12}$$

where the data f are defined by $\langle f, v\rangle := \langle \tilde{f}, v\rangle + \int_{\partial\Omega} g(\iota v)\, ds$ and A is boundedly invertible from Y to Y'.

In analogy to (2.8) we can take here

$$Z = H^{1-\gamma}(\Omega), \quad U = (H^{1-\beta}(\Omega))', \quad 0 \le \gamma, \beta \le 1. \tag{2.13}$$

Again $T = I$ and $E = I$ are then the canonical injections.

One can also prescribe as observations boundary conditions of Dirichlet type y_* on $\partial\Omega$, in which case the range of T is $R = H^{1/2}(\partial\Omega)$, which will be referred to as the natural observation space. In this case $Z = H^{1/2-\gamma}(\partial\Omega)$ are admissible observation spaces for $\gamma \ge 0$. Here $T : H^1(\Omega) \to H^{1/2}(\partial\Omega)$ coincides with the trace operator. Hence, the optimal control problem is to steer the states toward Dirichlet boundary conditions, while the constraints (2.11) involve Neumann boundary conditions.

2.2.3. Neumann problem with Neumann boundary control. Now let the boundary $\partial\Omega$ be decomposed into two parts, $\overline{\partial\Omega} = \overline{\Gamma_N} \cup \overline{\Gamma_c}$, where Γ_c has nonvanishing $d-1$ dimensional measure. For $a(\cdot,\cdot)$ from (2.9), consider the constraint

$$a(y,v) = \langle \tilde{f}, v\rangle + \int_{\Gamma_c} g(\iota v)\, ds + \int_{\Gamma_c} u(\iota v)\, ds \qquad \text{for all } v \in Y := H^1(\Omega) \tag{2.14}$$

and given $\tilde{f} \in Y'$, $g \in (H^{1/2}(\Gamma_c))'$, whose strong form is the second order Neumann problem

$$\begin{aligned} -\Delta y + y &= \tilde{f} && \text{in } \Omega, \\ \frac{\partial y}{\partial n} &= \begin{cases} 0 & \text{on } \Gamma_N, \\ g + u & \text{on } \Gamma_c. \end{cases} \end{aligned} \tag{2.15}$$

To identify the remaining ingredients, note first that for the right-hand side of (2.14) to be well defined, the control must belong to $Q = (H^{1/2}(\Gamma_c))'$. Thus, the operator E is the adjoint of the trace operator ι to the *control boundary* Γ_c, defined as

$$\langle Eq, w\rangle_{(H^1(\Omega))'\times H^1(\Omega)} := \int_{\Gamma_c} q(\iota w)\, ds. \tag{2.16}$$

That is, $E : (H^{1/2}(\Gamma_c))' \to (H^1(\Omega))'$ is an extension operator to Ω. Thus, the formulation of the constraint as an operator equation reads in this case

$$Ay = f + Eu. \tag{2.17}$$

As in the previous cases, one could choose Z to be a space defined on Ω. A more frequent practical situation is to approximate prescribed conditions for the state on some part of the boundary.

To this end, denote by $\Gamma_\circ \subseteq \partial\Omega$ an *observation boundary* (again with strictly positive measure) and by $T : H^1(\Omega) \to H^{1/2}(\Gamma_\circ) =: R$ the trace operator to this part of the boundary. Then admissible choices for Z are $H^{1/2-\gamma}(\Gamma_\circ)$, $\gamma \geq 0$. For the control, we have $Q = (H^{1/2}(\Gamma_c))'$ so that $U = L_2(\Gamma_c)$ would require the optimal control to be somewhat smoother. For these choices, the functional (2.3) is of the form

$$J(y,u) = \frac{1}{2}\|Ty - y_*\|^2_{H^{1/2}(\Gamma_\circ)} + \frac{\omega}{2}\|u\|^2_{L_2(\Gamma_c)}. \tag{2.18}$$

Again we could take $Z = H^{1/2-\gamma}(\Gamma_\circ)$ for $0 \leq \gamma$ instead. For the choice $Z = L_2(\Gamma_\circ)$ and $U = L_2(\Gamma_c)$, the functional (2.3) with constraints (2.14) was treated in [BKR] by employing an adaptive finite element solver. The case $\Gamma_\circ = \Gamma_c = \partial\Omega$ and $Z = U = L_2(\partial\Omega)$ is classical [Li].

Remark 2.2. Note that the choice of a specific representer of the broken trace norms (that arise above as *natural norms*) and of any other smoothness norm of noninteger order (that enable scale-dependent fitting criteria) is ambiguous. Whether one uses, for instance, a factor norm or an intrinsic norm based on a parametrization of the boundary manifold in the case of trace norms is neither essential nor physically predetermined.

Remark 2.3. For linear-quadratic elliptic problems with Dirichlet boundary controls the constraints are usually formulated as saddle point problems (see, e.g., [K2]), which no longer satisfy the ellipticity condition (2.4). The techniques developed below can also be extended to this situation; see [CDD2, K3]. However, to make the basic mechanisms as transparent as possible, we confine the present discussion to the case of elliptic constraints.

3. Reformulation of (CP). The standard approach to control problems like (CP) would be to derive the necessary conditions for optimality in terms of an adjoint equation in the functional analytic setting (see, e.g., [Li]) and to discretize the resulting conditions by choosing suitable *finite dimensional* trial spaces. Here we will deviate from such a procedure in several ways. The first step is to transform the original problem (CP) into an *equivalent* (hence still infinite dimensional) problem, which is now formulated entirely in ℓ_2. The use of appropriate Riesz operators allows us to leave the original reference objective functional unchanged and to treat the mandatory case. However, in the ambiguous case associated with smoothness norms of noninteger order, these norms are only given up to equivalence (see Remark 2.2)

and consequently the Riesz maps are unspecified. Furthermore, their numerical realization would generally be practically infeasible, except when using one specific norm equivalence induced by wavelet expansions. Therefore we shall specify the objective functionals by employing norm equivalences induced by scaled wavelet expansions. This particular reformulation will be seen to offer the following advantages:

- All the previous special cases take on a *unified format*. All norms (including those with negative order or fractional trace norms) are represented by ℓ_2-norms. In particular, the more flexible options of balancing the observation part against the regularization part in the cost functional with the aid of different regularity requirements are retained and become computationally feasible.
- There is no need for inverting ill-conditioned linear systems.
- It provides the foundation for adaptive solution strategies.
- Aside from complexity issues, such adaptive strategies have stabilizing effects in cases where discretizations usually have to obey compatibility constraints, such as the LBB-condition for saddle point problems.

The transformation hinges on the availability of appropriate *wavelet bases*, which are described next.

3.1. Wavelet coordinates. In the following we shall assume that for each Hilbert space $H \in \{Y, Z, R, Q, U\}$ we have a collection of functions

$$\Psi_H = \{\psi_{H,\lambda} : \lambda \in \mathbb{I}_H\} \subset H \tag{3.1}$$

—a *wavelet basis*—with the following properties at our disposal. $\mathbb{I}_H$ is an infinite index set whose elements λ encode different features such as *scale* $|\lambda|$ and spatial location $k = k(\lambda)$. In the simplest case of wavelets on the real line one has $\psi_{H,\lambda} = 2^{j/2}\psi(2^j \cdot -k)$, $j, k \in \mathbb{Z}$, normalized in L_2. Thus λ represents (j, k) and $|\lambda| = j$. We dispense at this point with further technical details about the actual construction of such wavelet bases but collect only those properties that are relevant in the present context.

Locality (L). The functions $\psi_{H,\lambda}$ are local, and the widths of their support are decreasing with growing discretization level $|\lambda|$,

$$\operatorname{diam}(\operatorname{supp}\psi_{H,\lambda}) \sim 2^{-|\lambda|}. \tag{3.2}$$

Cancellation property (CanP). There exists an integer $\tilde{m} = \tilde{m}_H$ such that

$$\langle v, \psi_{H,\lambda}\rangle \lesssim 2^{-|\lambda|(d/2+\tilde{m})}|v|_{W^{\tilde{m}}_\infty(\operatorname{supp}\,\psi_{H,\lambda})}, \tag{3.3}$$

where d is the dimension of the underlying domain or manifold. Thus, integrating against a wavelet has the effect of taking an $\tilde{m}$th order difference which annihilates the smooth part of v. In fact, this is typically realized (for wavelets defined on Euclidean domains) by constructing Ψ_H in such a way that it possesses a *dual* or *biorthogonal* basis $\tilde{\Psi}_H \subset H'$ such that the multiresolution spaces $\tilde{S}_j := \operatorname{span}\{\tilde{\psi}_{H,\lambda} : |\lambda| < j\}$ contain all polynomials of order $\tilde{m}$. Here *dual basis* means that $\langle \psi_{H,\lambda}, \tilde{\psi}_{H,\nu}\rangle = \delta_{\lambda,\nu}$, $\lambda, \nu \in \mathbb{I}_H$. Here and in what follows the tilde is to express that the collection is a dual basis to a primal one for the space identified by the subscript. The role of dual bases will be addressed again below.

This cancellation property entails quasi-sparse representations of a wide class of operators.

Riesz basis property (R). This is perhaps the most crucial requirement. Every $v \in H$ has a unique expansion in terms of Ψ_H,

$$v = \sum_{\lambda \in \mathbb{I}_H} v_\lambda \, \psi_{H,\lambda} =: \mathbf{v}^T \, \Psi_H, \quad \mathbf{v} := (v_\lambda)_{\lambda \in \mathbb{I}_H}, \tag{3.4}$$

and its expansion coefficients satisfy the following *norm equivalence*: There exist finite positive constants c_H, C_H such that

$$c_H \|\mathbf{v}\|_{\ell_2(\mathbb{I}_H)} \le \|\mathbf{v}^T \Psi_H\|_H \le C_H \|\mathbf{v}\|_{\ell_2(\mathbb{I}_H)}, \quad \mathbf{v} \in \ell_2(\mathbb{I}_H). \tag{3.5}$$

Thus, wavelet expansions induce isomorphisms between certain function and sequence spaces.

By duality arguments one can show that (3.5) is equivalent to the existence of a biorthogonal collection

$$\tilde{\Psi}_H := \{\tilde{\psi}_{H,\lambda} : \lambda \in \mathbb{I}_H\} \subset H', \quad \langle \psi_{H,\lambda}, \tilde{\psi}_{H,\mu} \rangle = \delta_{\lambda,\mu}, \qquad \lambda, \mu \in \mathbb{I}_H, \tag{3.6}$$

which is a Riesz basis in H', i.e.,

$$C_H^{-1} \|\tilde{\mathbf{v}}\|_{\ell_2(\mathbb{I}_H)} \le \|\tilde{\mathbf{v}}^T \tilde{\Psi}_H\|_{H'} \le c_H^{-1} \|\tilde{\mathbf{v}}\|_{\ell_2(\mathbb{I}_H)} \tag{3.7}$$

holds for any $\tilde{v} = \tilde{\mathbf{v}}^T \, \tilde{\Psi}_H \in H'$; see, e.g., [D1, D3, D4, K1].

We shall need a little more information about how bases with the above properties are constructed. In all our examples the Hilbert space $H \in \{Y, Q, R, Z, U\}$ is actually (a closed subspace of) a Sobolev space $H^s = H^s(G)$ or its dual (possibly determined by homogeneous boundary conditions), where G is either the domain Ω or (part of) its boundary. The basis Ψ_H for H is then typically obtained from an *anchor* basis $\Psi = \{\psi_\lambda : \lambda \in \mathbb{I} = \mathbb{I}_H\}$, which is a Riesz basis for $L_2(G)$, i.e., $\|\psi_\lambda\|_{L_2(G)} \sim 1$, whose dual basis $\tilde{\Psi}$ is therefore also a Riesz basis for $L_2(G)$. In fact, Ψ and $\tilde{\Psi}$ are constructed in such a way that rescaled versions of *both bases* $\Psi, \tilde{\Psi}$ form Riesz bases for a whole range of Sobolev (sub-)spaces H^s, for $0 < s < \gamma, \tilde{\gamma}$, respectively. From this fact one derives then that for each $s \in (-\tilde{\gamma}, \gamma)$ the collection

$$\Psi_s := \{2^{-s|\lambda|} \psi_\lambda : \lambda \in \mathbb{I}\} =: \mathbf{D}^{-s} \Psi \tag{3.8}$$

is a Riesz basis for H^s (with the above interpretation of H^s as a dual when s is negative) [D1]; i.e., there exist positive constants c_s, C_s such that

$$c_s \, \|\mathbf{v}\|_{\ell_2(\mathbb{I})} \le \|\mathbf{v}^T \Psi_s\|_{H^s} \le C_s \, \|\mathbf{v}\|_{\ell_2(\mathbb{I})}, \quad \mathbf{v} \in \ell_2(\mathbb{I}), \tag{3.9}$$

holds for each $s \in (-\tilde{\gamma}, \gamma)$. Analogous relations hold for $\tilde{\Psi}$ with reversed roles of γ and $\tilde{\gamma}$. We shall make use of the following consequence of this fact. For $t \in (-\tilde{\gamma}, \gamma)$ the mapping

$$D^t : v = \mathbf{v}^T \Psi \mapsto (\mathbf{D}^t \mathbf{v})^T \Psi = \mathbf{v}^T \mathbf{D}^t \Psi = \sum_{\lambda \in \mathbb{I}} v_\lambda \, 2^{t|\lambda|} \psi_\lambda \tag{3.10}$$

acts as a shift operator between Sobolev scales, i.e.,

$$\|D^t v\|_{H^s} \sim \|v\|_{H^{s+t}} \sim \|\mathbf{D}^{s+t} \mathbf{v}\|_{\ell_2(\mathbb{I})}, \quad \text{provided that} \quad s, \; s+t \in (-\tilde{\gamma}, \gamma). \tag{3.11}$$

Concrete constructions of wavelet bases with the above properties for parameters $\gamma, \tilde{\gamma}$ ranging in most cases up to $3/2$ on bounded Euclidean domains and also on closed

piecewise parametrically defined manifolds can be found in [CTU, CM, DKU, DS1, DS2, DSt]. Note that in the above examples the relevant Sobolev regularity indices range then between -1 and 1 so that these bases allow us to exploit relations like (3.11) when the metrics in the spaces Z and U differ from the natural norms in the way indicated above. Thus we shall henceforth assume the validity of the above properties (L), (CanP), and (R) in appropriate ranges, as detailed in the next section.

It should be noted, however, that such norm equivalences are by no means restricted to simple Sobolev spaces, as indicated by the following example.

Remark 3.1. Let H be the Hilbert space endowed with the norm $\|v\|_H^2 := \langle \nabla v, a\nabla v\rangle + \langle wv, v\rangle =: a(v,v)$, where a is a uniformly positive definite but possibly spatially varying diffusion matrix and w is a nonnegative spatially varying weight function. Starting with a basis Ψ for $L_2(\Omega)$, say, the matrix $\mathbf{D}^{-s}$ in (3.8) (for $s=1$) should then be replaced by $\mathbf{D}^{-1}$, where $\mathbf{D}$ now has the diagonal entries $a(\psi_\lambda,\psi_\lambda)^{1/2}$. This automatically incorporates spatially varying weights or diffusion terms in the normalization of the wavelet basis.

In what follows, it will be convenient to make systematic use of the following shorthand notation that already has been used to some extent above. We will view Ψ both as in (3.1) as a *collection* of functions as well as a (possibly infinite) (column) *vector* containing all functions always assembled in some fixed order. For a countable collection of functions Θ and some single function σ, the quantities $\langle\Theta,\sigma\rangle$ and $\langle\sigma,\Theta\rangle$ are to be understood as the column, respectively, row, vector with entries $\langle\theta,\sigma\rangle$, respectively, $\langle\sigma,\theta\rangle$, $\theta\in\Theta$. For two collections Θ,Σ, the term $\langle\Theta,\Sigma\rangle$ is then a (possibly infinite) matrix with entries $(\langle\theta,\sigma\rangle)_{\theta\in\Theta,\ \sigma\in\Sigma}$ for which $\langle\Theta,\Sigma\rangle = \langle\Sigma,\Theta\rangle^T$. This also implies for a (possibly infinite) matrix $\mathbf{C}$ that $\langle\mathbf{C}\Theta,\Sigma\rangle = \mathbf{C}\langle\Theta,\Sigma\rangle$ and $\langle\Theta,\mathbf{C}\Sigma\rangle = \langle\Theta,\Sigma\rangle\mathbf{C}^T$. In this notation, the expansion coefficients in (3.4) and (3.7) can explicitly be expressed as $\mathbf{v}^T = \langle v,\tilde\Psi\rangle$ and $\tilde{\mathbf{v}} = \langle\Psi,\tilde v\rangle$. Furthermore, the *biorthogonality* or *duality conditions* (3.6) can be reexpressed as $\langle\Psi,\tilde\Psi\rangle = \mathbf{I}$ with the infinite identity matrix.

3.2. Wavelet representation of operators. The last important ingredient concerns *wavelet representations* of operators. Suppose that Ψ_H,Ψ_M are Riesz bases for Hilbert spaces H,M. As before, we shall always denote by $\tilde\Psi_H,\tilde\Psi_M$ the respective dual bases, i.e., $\langle\Psi_V,\tilde\Psi_V\rangle = \mathbf{I}$, $V\in\{H,M\}$, where $\langle\cdot,\cdot\rangle$ is the corresponding duality. Suppose $L: H\to M$ is a linear operator. Any image $Lv\in M$ is naturally expanded with respect to Ψ_M as $Lv = \langle Lv,\tilde\Psi_M\rangle\Psi_M$. Inserting the expansion $v=\mathbf{v}^T\Psi_H$ with respect to Ψ_H yields

$$Lv = \mathbf{v}^T\langle L\Psi_H,\tilde\Psi_M\rangle\Psi_M = (\langle\tilde\Psi_M, L\Psi_H\rangle\mathbf{v})^T\Psi_M. \tag{3.12}$$

Since we shall make frequent use of this operation, we record the relevant facts in the following remark.

Remark 3.2. The wavelet representation of $L: H\to M$ (with respect to the bases $\Psi_H,\tilde\Psi_M$ of H, M', respectively) is given by

$$\mathbf{L} := \langle\tilde\Psi_M, L\Psi_H\rangle, \qquad Lv = (\mathbf{L}\mathbf{v})^T\Psi_M. \tag{3.13}$$

Thus, the expansion coefficients of Lv (in the basis that spans the range space of L) are obtained by applying the *infinite* matrix $\mathbf{L} = \langle\tilde\Psi_M, L\Psi_H\rangle$ to the coefficient vector of v. Moreover, boundedness of L implies boundedness of $\mathbf{L}$ in ℓ_2, i.e.,

$$\|Lv\|_M \lesssim \|v\|_H, \quad v\in H, \quad \text{implies} \quad \|\mathbf{L}\| := \sup_{\|\mathbf{v}\|_{\ell_2(\mathbb{I}_H)}\le 1}\|\mathbf{L}\mathbf{v}\|_{\ell_2(\mathbb{I}_M)} \lesssim 1. \tag{3.14}$$

Proof. The first part of the assertion was established by the preceding observations. For (3.14), one infers from (3.5) and (3.13) that

$$\|\mathbf{Lv}\|_{\ell_2(\mathbb{I}_M)} \sim \|(\mathbf{Lv})^T\Psi_M\|_M = \|Lv\|_M \lesssim \|v\|_H \sim \|\mathbf{v}\|_{\ell_2(\mathbb{I}_H)},$$

which confirms the claim. □

We shall employ *Riesz operators* $R_H : H \to H'$ defined by

$$(v,w)_H = \langle v, R_H w\rangle, \quad v,w \in H, \tag{3.15}$$

where $(\cdot,\cdot)_H$ denotes the inner product in H. Thus, R_H maps H boundedly invertibly onto its dual H'. By Remark 3.2, we therefore have (with the role of M being played now by H')

$$\mathbf{R}_H := \langle \Psi_H, R_H\Psi_H\rangle = (\Psi_H,\Psi_H)_H \tag{3.16}$$

and

$$\|\mathbf{R}_H\|,\ \|\mathbf{R}_H^{-1}\| \lesssim 1. \tag{3.17}$$

For general surveys on the application of wavelets to operator equations, we refer to [Co, D2, D3].

3.3. Equivalent control problems in ℓ_2. Now we are in the position to transform the abstract control problem (CP) into wavelet coordinates. We begin with the constraints (2.5). Following the above recipe (3.12), we expand y in Ψ_Y and u in a wavelet basis Ψ_U for $U \subset Q$; see (2.2). As explained in section 3.1, the basis Ψ_U is conveniently obtained as a scaled version of a basis for Q, i.e.,

$$\mathbf{D}_Q\Psi_U = \Psi_Q, \tag{3.18}$$

where the diagonal elements of $\mathbf{D}_Q$ are nondecreasing. Hence, expanding $u = \mathbf{u}^T\Psi_U$ in terms of Ψ_Q, gives

$$u = \mathbf{u}^T\Psi_U = (\mathbf{D}_Q^{-1}\mathbf{u})^T\Psi_Q. \tag{3.19}$$

The operators A and E, in turn, are bounded operators from Y, respectively, Q, to Y'. By Remark 3.2, their wavelet representations and that of $f \in Y'$ are therefore given by

$$\mathbf{A} := a(\Psi_Y,\Psi_Y), \quad \mathbf{E} := \langle \Psi_Y, E\Psi_Q\rangle, \quad \boldsymbol{f} := \langle \Psi_Y, f\rangle. \tag{3.20}$$

Since $\mathbf{E}$ acts on coordinates relative to Ψ_Q we can express Eu in (2.5) as $Eu = (\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u})^T\tilde{\Psi}_Y$. Thus, the constraints (2.5) take on the form

$$\mathbf{A}\mathbf{y} = \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}. \tag{3.21}$$

To simplify the notation we shall suppress in the following the subscripts $\ell_2(\mathbb{I})$ and write briefly $\|\cdot\| := \|\cdot\|_{\ell_2(\mathbb{I})}$ because we shall be dealing with only Euclidean norms, and the ranges of indices $\mathbb{I}$ will always be clear from the context.

It is well known that the ellipticity (2.4) and the Riesz basis property (R) (3.5) (for $H = Y$) imply the following fact; see, e.g., [D2].

Remark 3.3. The matrix $\mathbf{A}$ is a boundedly invertible mapping of $\ell_2(\mathbb{I}_Y)$ onto itself, i.e., $\mathbf{A}$ is onto $\ell_2(\mathbb{I}_Y)$ and there exist finite positive constants $c_{\mathbf{A}}, C_{\mathbf{A}}$ such that

$$c_{\mathbf{A}}\|\mathbf{v}\| \le \|\mathbf{A}\mathbf{v}\| \le C_{\mathbf{A}}\|\mathbf{v}\|, \qquad \mathbf{v} \in \ell_2(\mathbb{I}_Y). \tag{3.22}$$

Similarly, since the operator T is bounded as a mapping from Y to R, it is natural to represent it with respect to a pair of bases $\Psi_Y, \tilde{\Psi}_R$, i.e.,

$$\mathbf{T} = \langle \tilde{\Psi}_R, T\Psi_Y \rangle. \tag{3.23}$$

We infer from Remark 3.2 that there exist finite positive constants $C_{\mathbf{T}}, C_{\mathbf{E}}$ such that

$$\|\mathbf{T}\mathbf{v}\| \le C_{\mathbf{T}}\|\mathbf{v}\|, \qquad \|\mathbf{E}\mathbf{v}\| \le C_{\mathbf{E}}\|\mathbf{v}\| \tag{3.24}$$

for $\mathbf{v} \in \ell_2(\mathbb{I}_Y)$ and $\mathbf{v} \in \ell_2(\mathbb{I}_Q)$, respectively.

In general, R is a continuously embedded subspace of Z, and the dual pair of bases $\Psi_R, \tilde{\Psi}_R$ are scaled versions of a corresponding pair $\Psi_Z, \tilde{\Psi}_Z$; i.e., there is a diagonal matrix $\mathbf{D}_Z$ with nondecreasing diagonal entries such that

$$\Psi_Z = \mathbf{D}_Z\Psi_R, \quad \tilde{\Psi}_Z = \mathbf{D}_Z^{-1}\tilde{\Psi}_R. \tag{3.25}$$

We shall make frequent use of the fact that

$$\|\mathbf{D}_Q^{-1}\|, \ \|\mathbf{D}_Z^{-1}\| \le 1, \tag{3.26}$$

where we assume without loss of generality that all entries on the respective diagonals are bounded by one.

The observed data have to be expanded in Ψ_Z. By (2.2), T is also continuous as an operator from Y to Z. Thus the representations of T with respect to $\Psi_Y, \tilde{\Psi}_Z$ and of y_* are given by

$$\mathbf{D}_Z^{-1}\mathbf{T} = \langle \tilde{\Psi}_Z, T\Psi_Y \rangle, \qquad \mathbf{y}_* := \mathbf{D}_Z\langle \tilde{\Psi}_Z, y_* \rangle. \tag{3.27}$$

We are now in a position to express the functional $J(y,u)$ in (2.3) in terms of wavelet coordinates. On account of (3.15) and (3.16), we have the exact representation

$$J(y,u) = \frac{1}{2}\|\mathbf{R}_Z^{1/2}\mathbf{D}_Z^{-1}(\mathbf{T}\mathbf{y} - \mathbf{y}_*)\|^2 + \frac{\omega}{2}\|\mathbf{R}_U^{1/2}\mathbf{u}\|^2. \tag{3.28}$$

A few comments on possible interrelations on the various involved bases are in order. The spaces Z and U may be defined over domains different from Ω, such as traces as explained at the end of section 2.2.2 and in section 2.2.3. In these cases T is a trace operator and E an extension. Here we cannot simply interrelate Ψ_Z and Ψ_Y since traces of wavelets generally are not wavelets. Thus, the bases for Z and U have to be provided independently.

This is different, however, in the following special case.

Special case (SC). Suppose that the space Z belongs to the Sobolev scale over Ω; see (2.8), (2.13). In this case T is the identity and $R = Y$. Hence, (3.25) becomes

$$\Psi_Z = \mathbf{D}_Z\Psi_Y, \qquad \tilde{\Psi}_Z = \mathbf{D}_Z^{-1}\tilde{\Psi}_Y, \tag{3.29}$$

which clearly forms a dual pair for Z. As a mapping into Z, T is the canonical injection so that, according to (3.27),

$$\mathbf{D}_Z^{-1}\mathbf{T} = \mathbf{D}_Z^{-1}, \quad \text{i.e.,} \quad \mathbf{T} = \mathbf{I}. \tag{3.30}$$

If Z does not coincide with Y, Z induces a weaker topology than Y so that the entries of the diagonal matrix $\mathbf{D}_Z$ increase in scale. For instance, for $Y = H^t$, $Z = H^{t-\gamma}$, $0 \le \gamma$, one has $(\mathbf{D}_Z)_{\lambda,\lambda} \sim 2^{\gamma|\lambda|}$. Recall that in this case the mapping E is also just the identity ((2.7), (2.12)), i.e., $Q = Y'$ and Ψ_Q should span the range of A. So we may as well take

$$\Psi_Q := \tilde{\Psi}_Y, \quad \mathbf{E} = \mathbf{I}, \tag{3.31}$$

in this case.

In summary, we have shown that the solution to the abstract control problem (CP) is equivalent to finding the coefficient arrays $\mathbf{y}, \mathbf{u}$ of $y \in Y, u \in U$, that solve the following *abstract control problem in wavelet coordinates.*

(CPW). *Given data* $\mathbf{y}_* \in \ell_2(\mathbb{I}_Z)$, $\boldsymbol{f} \in \ell_2(\mathbb{I}_Y)$ *and a weight parameter* $\omega > 0$, *minimize the quadratic functional*

$$\widetilde{\mathbf{J}}(\mathbf{y}, \mathbf{u}) := \frac{1}{2}\|\mathbf{R}_Z^{1/2}\mathbf{D}_Z^{-1}(\mathbf{T}\mathbf{y} - \mathbf{y}_*)\|^2 + \frac{\omega}{2}\|\mathbf{R}_U^{1/2}\mathbf{u}\|^2 \quad (= J(y,u)) \tag{3.32}$$

over $(\mathbf{y}, \mathbf{u}) \in \ell_2(\mathbb{I}_Y) \times \ell_2(\mathbb{I}_Q)$ *subject to the linear constraints* (3.21)

$$\mathbf{A}\mathbf{y} = \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}.$$

3.4. Further auxiliary formulations. Next we shall derive equivalent formulations of (CPW), on which the subsequent numerical treatment will be based. By standard arguments (see, e.g., [Li]), the unique minimum for (CPW) is obtained by solving the first order necessary conditions for $\widetilde{\mathbf{J}}$ which can, e.g., be derived by first eliminating $\mathbf{y}$ in (3.32). In view of (3.22), we can invert (3.21) to obtain $\mathbf{y} = \mathbf{A}^{-1}\boldsymbol{f} + \mathbf{A}^{-1}\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}$. Substituting this into (3.32) yields a functional that depends only on $\mathbf{u}$,

$$\widetilde{\mathbf{J}}(\mathbf{u}) \;=\; \frac{1}{2}\|\mathbf{R}_Z^{1/2}\mathbf{D}_Z^{-1}\left(\mathbf{T}\mathbf{A}^{-1}\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u} - (\mathbf{y}_* - \mathbf{T}\mathbf{A}^{-1}\boldsymbol{f})\right)\|^2 + \frac{\omega}{2}\|\mathbf{R}_U^{1/2}\mathbf{u}\|^2. \tag{3.33}$$

Abbreviating

$$\mathbf{Z} := \mathbf{D}_Z^{-1}\mathbf{T}\mathbf{A}^{-1}\mathbf{E}\mathbf{D}_Q^{-1}, \quad \mathbf{G} := \mathbf{D}_Z^{-1}(\mathbf{y}_* - \mathbf{T}\mathbf{A}^{-1}\boldsymbol{f}), \tag{3.34}$$

$\widetilde{\mathbf{J}}$ is of the form

$$\widetilde{\mathbf{J}}(\mathbf{u}) \;=\; \frac{1}{2}\|\mathbf{R}_Z^{1/2}(\mathbf{Z}\mathbf{u} - \mathbf{G})\|^2 + \frac{\omega}{2}\|\mathbf{R}_U^{1/2}\mathbf{u}\|^2. \tag{3.35}$$

This is a standard least squares functional whose minimizer is characterized by the normal equations that were in the present format derived in [K2].

PROPOSITION 3.4. *The functional* $\widetilde{\mathbf{J}}$ *is twice differentiable on* $\ell_2(\mathbb{I}_Q)$ *with first and second variation given by*

$$\delta\widetilde{\mathbf{J}}(\mathbf{u}) = (\mathbf{Z}^T\mathbf{R}_Z\mathbf{Z} + \omega\mathbf{R}_U)\mathbf{u} - \mathbf{Z}^T\mathbf{R}_Z\mathbf{G}, \qquad \delta^2\widetilde{\mathbf{J}}(\mathbf{u}) = \mathbf{Z}^T\mathbf{R}_Z\mathbf{Z} + \omega\mathbf{R}_U. \tag{3.36}$$

Thus, $\widetilde{\mathbf{J}}$ *is strictly convex so that a unique minimizer exists.*

Proof. By (3.24), (3.22), (3.17), and the fact that the scaling matrices $\mathbf{D}_Z, \mathbf{D}_Q$ have nondecreasing diagonal entries (3.26), we conclude that

$$\widetilde{\mathbf{Q}} := \mathbf{Z}^T\mathbf{R}_Z\mathbf{Z} + \omega\mathbf{R}_U \tag{3.37}$$

is bounded on $\ell_2(\mathbb{I}_Q)$. Moreover, $\widetilde{\mathbf{Q}}$ is positive definite since $\mathbf{Z}^T\mathbf{R}_Z\mathbf{Z}$ is at least positive semidefinite and, by (3.17), we have $\|\mathbf{R}_U\mathbf{v}\| \sim \|\mathbf{v}\|$. Hence, for any fixed $\omega > 0$ there exist finite positive constants $c_{\widetilde{\mathbf{Q}}}, C_{\widetilde{\mathbf{Q}}}$ such that

$$c_{\widetilde{\mathbf{Q}}}\|\mathbf{v}\| \le \|\widetilde{\mathbf{Q}}\mathbf{v}\| \le C_{\widetilde{\mathbf{Q}}}\|\mathbf{v}\|, \qquad \mathbf{v} \in \ell_2(\mathbb{I}_Q). \tag{3.38}$$

This confirms the claim. ∎

In summary, the solution of (CPW) is uniquely determined by solving $\delta\widetilde{\mathbf{J}}(\mathbf{u}) = 0$, i.e., the system

$$\widetilde{\mathbf{Q}}\mathbf{u} = \widetilde{\mathbf{g}} \qquad \text{where} \qquad \widetilde{\mathbf{g}} := \mathbf{Z}^T\mathbf{R}_Z\mathbf{G}. \tag{3.39}$$

The above argument reveals also the following facts concerning the necessity of regularization.

Remark 3.5. The operator $\widetilde{\mathbf{Q}}$ is well conditioned in the sense of (3.38), uniformly in $\omega \ge 0$, if and only if $\mathbf{Z}$ is a topological automorphism on ℓ_2. Obviously this prohibits the appearance of nontrivial scalings and requires $\mathbf{E}, \mathbf{T}$ to be boundedly invertible and hence excludes trace operators.

Specifically, in the situation (SC), i.e., $\mathbf{E} = \mathbf{T} = \mathbf{I}$, $\widetilde{\mathbf{Q}}$ takes on the form

$$\widetilde{\mathbf{Q}} = \mathbf{D}_Q^{-1}\mathbf{A}^{-T}\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{A}^{-1}\mathbf{D}_Q^{-1} + \omega\mathbf{R}_U. \tag{3.40}$$

Note that when employing natural norms, i.e., $\mathbf{D}_Q = \mathbf{D}_Z = \mathbf{I}$,

$$\widetilde{\mathbf{Q}} = \mathbf{A}^{-T}\mathbf{R}_Z\mathbf{A}^{-1} + \omega\mathbf{R}_U$$

obviously satisfies (3.38) also for $\omega = 0$, which means that in this case regularization is not necessary. Moreover, (3.39) is equivalent to

$$(\mathbf{I} + \omega\mathbf{D}_Q\mathbf{A}\mathbf{D}_Z\mathbf{R}_Z^{-1}\mathbf{D}_Z\mathbf{A}^T\mathbf{D}_Q\mathbf{R}_U)\mathbf{u} = \mathbf{D}_Q(\mathbf{A}\mathbf{y}_* - \boldsymbol{f}). \tag{3.41}$$

Proof. The first part, especially (3.40), follows from substituting the definition of $\mathbf{Z}$. (3.41) is obtained by multiplying (3.39) with $\mathbf{Z}^{-1}\mathbf{R}_Z^{-1}\mathbf{Z}^{-T}$ from the left. ∎

The system (3.39) would offer a natural link to the setting in [CDD1] because it is symmetric positive definite and, thus, invites the application of gradient iterations which could then be carried out approximately by adaptive applications of $\widetilde{\mathbf{Q}}$. However, even when approximate evaluation schemes for infinite matrices like $\mathbf{A}$ were available, one immediately encounters some severe obstructions in applying $\widetilde{\mathbf{Q}}$ and evaluating the right-hand side, due to the appearance of (a) the Riesz operators and (b) the inverses involved in the definition of $\mathbf{Z}$ and $\mathbf{G}$.

To this end, the formulation (3.41) looks tempting since it no longer involves the inverse of $\mathbf{A}$ but requires only inverting a Riesz map. However, it is not very helpful unless in (SC) one employs only the natural norms $Z = Y, U = Q$ since otherwise the matrices $\mathbf{D}_Z, \mathbf{D}_Q$ are not bounded in ℓ_2. In this latter very special case $\mathbf{D}_Z = \mathbf{I}$, $\mathbf{D}_Q = \mathbf{I}$ so that (3.41) becomes

$$(\mathbf{I} + \omega\mathbf{A}\mathbf{R}_Z^{-1}\mathbf{A}^T\mathbf{R}_U)\mathbf{u} = \mathbf{A}\mathbf{y}_* - \boldsymbol{f}. \tag{3.42}$$

In the example discussed in section 2.2.1 we have $Y = Z = H_0^1(\Omega)$, $U = Q = H^{-1}(\Omega)$. When $\|\cdot\|_Z$ is the first order Sobolev seminorm, $\mathbf{R}_Z$ is the wavelet representation $\boldsymbol{\Delta} = \langle\nabla\Psi_Y, \nabla\Psi_Y\rangle$ of the Laplacian, while $\mathbf{R}_U = \boldsymbol{\Delta}^{-1}$. Thus (3.42) provides

$$(\mathbf{I} + \omega\mathbf{A}\boldsymbol{\Delta}^{-1}\mathbf{A}^T\boldsymbol{\Delta}^{-1})\mathbf{u} = \mathbf{A}\mathbf{y}_* - \boldsymbol{f}. \tag{3.43}$$

We shall discuss the advantage of this formulation later in more detail but must concede that, for the reasons mentioned above, it is not appropriate for more general situations because, in contrast to (3.39), (3.41) is generally ill conditioned on the infinite dimensional level.

To facilitate nevertheless the application of $\widetilde{\mathbf{Q}}$ for the above general scope of problems we shall employ further auxiliary reformulations of (CPW) to be derived next.

3.5. The Euler equations. We define the Lagrangian and introduce as an additional variable the Lagrange parameter $\mathbf{p} \in \ell_2(\mathbb{I}_Y)$,

$$\mathrm{Lagr}(\mathbf{y},\mathbf{p},\mathbf{u}) := \widetilde{\mathbf{J}}(\mathbf{y},\mathbf{u}) + \langle \mathbf{p}, \mathbf{A}\mathbf{y} - \boldsymbol{f} - \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}\rangle, \tag{3.44}$$

where $\widetilde{\mathbf{J}}(\mathbf{y},\mathbf{u})$ has been defined in (3.32). Straightforward calculations yield the first order Euler–Lagrange equations whose solution also yields the minimizer of (3.32); see, e.g., [Z] or [K2].

Remark 3.6. The solution $\mathbf{u}$ of the system (3.39) is a component of the solution $(\mathbf{y},\mathbf{p},\mathbf{u})$ of the weakly coupled system of Euler equations in wavelet coordinates

$$\begin{aligned} \mathbf{A}\mathbf{y} &= \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}, \\ \mathbf{A}^T\mathbf{p} &= -\mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\left(\mathbf{T}\mathbf{y} - \mathbf{y}_*\right), \qquad \text{(EE)} \\ \omega\mathbf{R}_U\mathbf{u} &= \mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}. \end{aligned} \tag{3.45}$$

(3.46)

The first equation of (EE) is often denoted as the *state* or *primal equation*, while the second equation is called the *costate* or *adjoint equation*.

The system (EE) can, of course, be reformulated as a saddle point problem

$$\begin{pmatrix} \omega\mathbf{R}_U & \mathbf{0} & -\mathbf{D}_Q^{-1}\mathbf{E}^T \\ \mathbf{0} & \mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{T} & \mathbf{A}^T \\ -\mathbf{E}\mathbf{D}_Q^{-1} & \mathbf{A} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{y} \\ \mathbf{p} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{y}_* \\ \boldsymbol{f} \end{pmatrix}. \tag{3.47}$$

In particular, in the case (SC) when using natural norms in (2.3), i.e., $\mathbf{D}_Q = \mathbf{D}_Z = \mathbf{I}$, we have

$$\begin{pmatrix} \omega\mathbf{R}_U & \mathbf{0} & -\mathbf{I} \\ \mathbf{0} & \mathbf{R}_Z & \mathbf{A}^T \\ -\mathbf{I} & \mathbf{A} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{y} \\ \mathbf{p} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{R}_Z\mathbf{y}_* \\ \boldsymbol{f} \end{pmatrix}. \tag{3.48}$$

Due to the appearance of the isomorphisms $\mathbf{R}_U, \mathbf{R}_Z$ on the diagonal of the upper left two-by-two block, this system satisfies the *inf-sup* condition and, therefore, defines a boundedly invertible mapping on $\ell_2(\mathbb{I}_Q) \times \ell_2(\mathbb{I}_Y)^2$. Thus, one can immediately apply the results from [DDU] on adaptive Uzawa iterations for well-posed saddle point problems. Corresponding optimal complexity estimates apply whenever the matrix $\mathbf{A}$ is compressible, which is the case in all the above examples.

In general, however, when $\mathbf{T}$ is a trace operator, the block $\mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{T}$ has a nontrivial kernel. To apply the Uzawa strategy, one first must use an augmented Lagrangian formulation so as to have a well-defined Schur complement. This can be done along the lines described in [DDU].

Here we prefer the formally somewhat different approach based on the system (EE). This approach also applies, in principle, to constraints in the form of a saddle point system, as pointed out in Remark 2.3; see [K3].

Our strategy will be to solve (3.39) with the aid of a (perturbed) descent scheme which requires approximating at each stage the *residual* $\widetilde{\mathbf{g}} - \widetilde{\mathbf{Q}}\mathbf{u}^k$. Such an approximation will be based on the following observation, namely, that the residual of (3.39) is just the residual of the third equation in (EE), sometimes referred to as the *design equation*.

LEMMA 3.7. *For any* $\mathbf{v} \in \ell_2(\mathbb{I}_Q)$, *one has the representation*

$$\widetilde{\mathbf{Q}}\mathbf{v} - \widetilde{\mathbf{g}} = \omega \mathbf{R}_U \mathbf{v} - \mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}, \tag{3.49}$$

where $\mathbf{p}$ *is the solution of the first two equations in* (EE). *Thus, for any given* $\mathbf{v}$, *the sequence* $\mathbf{p}$ *is determined by solving*

$$\mathbf{A}^T\mathbf{p} = -\mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}\left(\mathbf{T}\mathbf{y} - \mathbf{y}_*\right), \quad \textit{where} \quad \mathbf{A}\mathbf{y} = \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v}. \tag{3.50}$$

Proof. By definition we infer from (3.34), (3.37), and (3.39) that

$$\widetilde{\mathbf{Q}}\mathbf{v} - \widetilde{\mathbf{g}} = \omega \mathbf{R}_U \mathbf{v} + \mathbf{Z}^T\mathbf{R}_Z(\mathbf{Z}\mathbf{v} - \mathbf{D}_Z^{-1}(\mathbf{y}_* - \mathbf{T}\mathbf{A}^{-1}\boldsymbol{f})).$$

The second term on the right-hand side of this equality can be written as

$$\begin{aligned}\mathbf{Z}^T\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{T}\mathbf{A}^{-1}\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v} - \mathbf{Z}^T\mathbf{R}_Z\mathbf{D}_Z^{-1}(\mathbf{y}_* - \mathbf{T}\mathbf{A}^{-1}\boldsymbol{f}) \\ = \mathbf{Z}^T\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{T}\mathbf{A}^{-1}(\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v} + \boldsymbol{f}) - \mathbf{Z}^T\mathbf{R}_Z\mathbf{D}_Z^{-1}\mathbf{y}_*.\end{aligned}$$

Thus, taking $\mathbf{y}$ as the solution of the second equation in (3.50), this reduces to

$$-\mathbf{Z}^T\mathbf{R}_Z\mathbf{D}_Z^{-1}(\mathbf{y}_* - \mathbf{T}\mathbf{y}) = -\mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{A}^{-T}\mathbf{T}^T\mathbf{D}_Z^{-1}\mathbf{R}_Z\mathbf{D}_Z^{-1}(\mathbf{y}_* - \mathbf{T}\mathbf{y}) = -\mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p},$$

where we have used the first equation in (3.50). This finishes the proof. ∎

Note that one immediately infers from (3.24) and (3.26) that one still has

$$\|\mathbf{D}_Z^{-1}\mathbf{T}\mathbf{v}\| \le C_{\mathbf{T}}\|\mathbf{v}\|, \quad \|\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v}\| \le C_{\mathbf{E}}\|\mathbf{v}\|. \tag{3.51}$$

3.6. Special cost functionals: A scaling model. We have succeeded so far in realizing steps (i) and (ii) of the paradigm described in the introduction, namely, to reformulate (CP) as an equivalent well-posed problem over ℓ_2. The realization of step (iii) will be based on the residual representation (3.49). Lemma 3.7 suggests approximating the residual with the aid of approximate solutions of the equations (3.50). This, in turn, will be done iteratively as well. Aside from approximately applying the infinite matrices $\mathbf{A}, \mathbf{A}^T$, this also requires the application of the Riesz matrices $\mathbf{R}_Z, \mathbf{R}_U$.

Remark 3.8. When $Z, U \in \{H^1, L_2\}$, the matrices $\mathbf{R}_H$ are for $H = Z, U$ of the form $\langle \Psi_H, \Psi_H\rangle$, $\langle \nabla\Psi_H, \nabla\Psi_H\rangle$ or $c_1\langle \Psi_H, \Psi_H\rangle + c_2\langle \nabla\Psi_H, \nabla\Psi_H\rangle$; see Remark 3.1. In this case, $\mathbf{R}_H$ can be shown to be compressible in the sense of [CDD1]; see also section 5.1 concerning the application of $\mathbf{A}, \mathbf{A}^T$. Thus, the efficient approximate application of such matrices can be carried out with the aid of the schemes developed in [BCDU, CDD1]. Similarly, when $U = H^{-1}$ we have $\mathbf{R}_U = \boldsymbol{\Delta}^{-1}$, in which case the design equation (3.46) becomes

$$\omega\mathbf{u} = \boldsymbol{\Delta}\mathbf{D}_Q^{-1}\mathbf{p}, \tag{3.52}$$

which corresponds to the application of the Laplacian; see section 2.2.1. We shall discuss the consequences of these facts in more detail later.

As explained in Remark 2.2, in the ambiguous case associated with Sobolev spaces Z, U of noninteger order the corresponding Riesz operators $\mathbf{R}_Z, \mathbf{R}_U$ are not specified.

In conventional discretization settings, the evaluation of neither representer of such a norm is practically feasible. In the present framework, however, we can resort to one specific representer which supports the numerical treatment best. As explained earlier, the rational, of course, is that changing the regularity scales in the different parts of the cost functional has a much more subtle effect than changing the (single scale) weight ω and that this effect is realized by any equivalent norm; see [BK] for numerical explorations of this issue. Formally, this amounts to expressing Sobolev norms as sequence norms, based on (3.9). In the present framework this means to replace the norm automorphisms $\mathbf{R}_Z, \mathbf{R}_U$ (see (3.17)) simply by the identity $\mathbf{I}$ in the definition of $\widetilde{\mathbf{J}}$ in (3.32). This leads us to consider the following *specified abstract control problem in wavelet coordinates.*

(SCPW). *Given data* $\mathbf{y}_* \in \ell_2(\mathbb{I}_Z)$, $\boldsymbol{f} \in \ell_2(\mathbb{I}_Y)$, *and a weight parameter* $\omega > 0$, *minimize the quadratic functional*

$$\mathbf{J}(\mathbf{y}, \mathbf{u}) := \frac{1}{2}\|\mathbf{D}_Z^{-1}(\mathbf{T}\mathbf{y} - \mathbf{y}_*)\|^2 + \frac{\omega}{2}\|\mathbf{u}\|^2 \tag{3.53}$$

over $(\mathbf{y}, \mathbf{u}) \in \ell_2(\mathbb{I}_Y) \times \ell_2(\mathbb{I}_Q)$ *subject to the linear constraints* (3.21)

$$\mathbf{A}\mathbf{y} = \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u}.$$

Remark 3.9. Problem (SCPW) is related to the reference problem (CPW) (respectively, (CP)) as follows. The constraints remain unchanged as (3.21) is the exact wavelet representation of (2.5). Furthermore, there exist finite positive constants c_J, C_J such that for any $y = \mathbf{y}^T\Psi_Y \in Y$, and any $u = \mathbf{u}^T\Psi_U \in U$, one has

$$c_J\, \mathbf{J}(\mathbf{y}, \mathbf{u}) \le J(y, u) \le C_J\, \mathbf{J}(\mathbf{y}, \mathbf{u}). \tag{3.54}$$

Moreover, in the case of *compatible data* $y_* = TA^{-1}f$, the respective minimizers coincide.

Proof. The fact that $\|\mathbf{D}_Z^{-1}(\mathbf{y} - \mathbf{y}_*)\| \sim \|\mathbf{R}_Z^{1/2}\mathbf{D}_Z^{-1}(\mathbf{y} - \mathbf{y}_*)\| = \|Ty - y_*\|_Z$ follows immediately from (3.17). This proves (3.54), which, in turn, implies the rest of the assertion. ∎

In case of incompatible data, the solution of (SCPW) may certainly depend on the specific equivalent norm although the constraints remain unchanged. Thus, in the mandatory case the formulation (SCPW) may not yield a solution that could be termed optimal. On the other hand, in the ambiguous case (see the scenario described in Remark 2.2) (SCPW) may very well be expected to capture the essential features of the original extremal problem reflecting the mutual effect of different regularity scales in the cost functional. Specifically, realizing more regular controls should support their practical executability. In this case, we shall refer to $\mathbf{J}(\cdot, \cdot)$ as a *representer* of $J(\cdot, \cdot)$ from (2.3).

The situation that a specific norm in the cost functional is essential arises most likely for the norms described in Remark 3.1. As pointed out in Remark 3.8, the corresponding Riesz operators are then numerically accessible. In favor of a unified and clearer treatment we shall focus first entirely on (SCPW), however. Later we shall indicate the necessary modifications for dealing with the mandatory situation (CPW) when the involved Riesz operators are accessible in the sense of Remark 3.8.

For the representer defined in (3.53) the reduced cost functional takes on the form

$$\mathbf{J}(\mathbf{u}) := \frac{1}{2}\|\mathbf{Z}\mathbf{u}-\mathbf{G}\|^2+\frac{\omega}{2}\|\mathbf{u}\|^2, \tag{3.55}$$

whose minimization is equivalent to solving

$$\mathbf{Q}\mathbf{u}=\mathbf{g}, \quad \text{where} \quad \mathbf{Q}:=\mathbf{Z}^T\mathbf{Z}+\omega\mathbf{I},\ \mathbf{g}:=\mathbf{Z}^T\mathbf{G}, \tag{3.56}$$

where $\mathbf{G},\mathbf{Z}$ are defined in (3.34). By the same reasoning as before we still have

$$c_{\mathbf{Q}}\|\mathbf{v}\|\le\|\mathbf{Q}\mathbf{v}\|\le C_{\mathbf{Q}}\|\mathbf{v}\|, \qquad \mathbf{v}\in\ell_2(\mathbb{I}_Q), \tag{3.57}$$

with finite positive constants $c_{\mathbf{Q}},C_{\mathbf{Q}}$ that may depend on ω under the same circumstances described in Remark 3.5. Thus, in principle, the well-posedness of the optimal control problem is not affected by exchanging equivalent norms.

In view of (3.57), there exists a fixed positive parameter α such that the *descent iteration*

$$\mathbf{u}^{k+1}=\mathbf{u}^k+\alpha(\mathbf{g}-\mathbf{Q}\mathbf{u}^k) \tag{3.58}$$

reduces the error in each step by at least a factor $\rho<1$, i.e.,

$$\|\mathbf{u}-\mathbf{u}^{k+1}\|\le\rho\|\mathbf{u}-\mathbf{u}^k\|, \quad k=0,1,2,\dots, \tag{3.59}$$

where $\mathbf{u}$ is the exact solution of (3.56). Our ultimate goal is to carry out this iteration approximately with dynamically updated accuracy tolerances.

The application of $\mathbf{Q}$ will be facilitated by the following obvious modification of Remark 3.6. The solution $\mathbf{u}$ of the system (3.56) results from the following Euler equations in wavelet coordinates:

$$\begin{aligned}
&\mathbf{A}\mathbf{y}=\boldsymbol{f}+\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u},\\
&\mathbf{A}^T\mathbf{p}=-\mathbf{T}^T\mathbf{D}_Z^{-2}\left(\mathbf{T}\mathbf{y}-\mathbf{y}_*\right), &\text{(EE}')\quad (3.60)\\
&\omega\mathbf{u}=\mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}. &(3.61)
\end{aligned}$$

Likewise, according to Lemma 3.7, one has for any $\mathbf{v}\in\ell_2(\mathbb{I}_Q)$, the representation

$$\mathbf{Q}\mathbf{v}-\mathbf{g}=\omega\mathbf{v}-\mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}, \tag{3.62}$$

where $\mathbf{p}$ is the solution of the first two equations in (EE′). Thus, for any given $\mathbf{v}$, the sequence $\mathbf{p}$ is given by solving

$$\mathbf{A}^T\mathbf{p}=-\mathbf{T}^T\mathbf{D}_Z^{-2}\left(\mathbf{T}\mathbf{y}-\mathbf{y}_*\right), \quad \text{where} \quad \mathbf{A}\mathbf{y}=\boldsymbol{f}+\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v}. \tag{3.63}$$

4. Basic concepts. In this section we collect the main conceptual tools from [CDD1, CDD2, CDD3] that will be needed to treat, in the general situation, first (3.56) for the numerical solution of (SCPW). The core issue will be the application of $\mathbf{Q}$ and the evaluation of the right-hand-side $\mathbf{g}$ (which will be easier than that of $\widetilde{\mathbf{Q}}$ and $\widetilde{\mathbf{g}}$).

4.1. Perturbed iterations. The basic strategy applies, in principle, to any system of the form

$$\mathbf{Mq} = \mathbf{z}, \tag{4.1}$$

where $\mathbf{M} : \ell_2 \to \ell_2$ is a (possibly) infinite matrix satisfying

$$c_{\mathbf{M}}\|\mathbf{v}\| \le \|\mathbf{Mv}\| \le C_{\mathbf{M}}\|\mathbf{v}\|, \quad \mathbf{v} \in \ell_2, \tag{4.2}$$

for some finite positive constants $c_{\mathbf{M}}, C_{\mathbf{M}}$, as well as

$$\rho := \|\mathbf{I} - \alpha\mathbf{M}\| < 1 \tag{4.3}$$

for some positive number α. Clearly, due to the positive definiteness of $\mathbf{Q}$ and by (3.57), $\mathbf{M} = \mathbf{Q}$ falls into this category.

Given (4.3), the gradient descent iteration

$$\mathbf{q}^{k+1} = \mathbf{q}^k + \alpha(\mathbf{z} - \mathbf{Mq}^k), \quad k = 0, 1, 2, \dots, \tag{4.4}$$

will converge with a fixed error reduction rate $\rho < 1$ per step. Of course, this iteration cannot be carried out exactly because $\mathbf{M}$ is an infinite matrix and the data $\mathbf{z}$ could be an infinite array. However, one can hope that perturbed iterations with dynamical accuracy tolerances, that are suitably updated in the course of the iteration, will still converge. Thus, we need a routine with the following property.

RES $[\eta, \mathbf{M}, \mathbf{z}, \mathbf{v}] \to \mathbf{r}_\eta$ determines for a given tolerance $\eta > 0$ a finitely supported sequence $\mathbf{r}_\eta$ satisfying

$$\|\mathbf{z} - \mathbf{Mv} - \mathbf{r}_\eta\| \le \eta. \tag{4.5}$$

There is a further ingredient whose role is at this stage not apparent yet but which will eventually play a crucial role in controlling the complexity of the scheme.

COARSE $[\eta, \mathbf{w}] \to \mathbf{w}_\eta$ determines for any finitely supported input vector $\mathbf{w}$ a vector $\mathbf{w}_\eta$ with smallest possible support such that

$$\|\mathbf{w} - \mathbf{w}_\eta\| \le \eta. \tag{4.6}$$

The precise description of COARSE can be found in [CDD1]. The idea is to sort the entries of $\mathbf{w}$ by size and to subtract squares of their moduli starting from the smallest one until the sum reaches η^2. The sorting usually introduces a logarithmic term of the size of $\mathbf{w}$. A quasi-sorting based on binary binning can be shown to avoid the logarithmic term at the expense of the resulting support size being at most a fixed constant of the minimal size; see [B]. This will suffice for the subsequent analysis so that it is justified to suppress logarithmic terms in what follows.

Let us suppose for the moment that the routine RES is already at our disposal. We shall first devise the precise form of a perturbed iteration that converges in the following sense. For every target accuracy ε it produces after finitely many steps a finitely supported approximate solution with accuracy ε.

Following [CDD2], to arrive at the right interplay between the routines RES and COARSE, we need the following control parameter. Given (an estimate of) the reduction rate ρ and the step size parameter α from (4.3), fix any constant $a > 1$ and let

$$K := \min\{\ell \in \mathbb{N} : \rho^{\ell-1}(\alpha\ell + \rho) \le \tfrac{1}{2(1+a)}\}. \tag{4.7}$$

(Here the upper bound $(2+2a)^{-1}$ stems from the analysis in [CDD3] and will be used again below.) Denoting in the following always by $\mathbf{q}$ the exact solution of (4.1), a perturbed version of (4.4) can now be formulated as follows.

SOLVE $[\varepsilon, \mathbf{M}, \mathbf{z}, \overline{\mathbf{q}}^0, \varepsilon_0] \to \overline{\mathbf{q}}_\varepsilon$.

(i) Fix a target accuracy $\varepsilon > 0$. Given an initial guess $\overline{\mathbf{q}}^0$ along with an error bound $\|\mathbf{q} - \overline{\mathbf{q}}^0\| \le \varepsilon_0$, set $j = 0$.

(ii) If $\varepsilon_j \le \varepsilon$, stop and set $\overline{\mathbf{q}}_\varepsilon := \overline{\mathbf{q}}^j$. Otherwise set $\mathbf{v}^0 := \overline{\mathbf{q}}^j$.

(ii.1) For $k = 0, \dots, K-1$ compute RES $[\rho^k \varepsilon_j, \mathbf{M}, \mathbf{z}, \mathbf{v}^k] \to \mathbf{r}^k$ and

$$\mathbf{v}^{k+1} := \mathbf{v}^k + \alpha \mathbf{r}^k. \tag{4.8}$$

(ii.2) Apply COARSE $[\frac{a\varepsilon_j}{2(1+a)}, \mathbf{v}^K] \to \overline{\mathbf{q}}^{j+1}$; set $\varepsilon_{j+1} := \frac{1}{2}\varepsilon_j$, $j+1 \to j$ and go to (ii).

In the case that no particular initial guess is known, step (i) is replaced by the default

(i)′ Fix a target accuracy $\varepsilon > 0$. Set $j = 0$ and

$$\overline{\mathbf{q}}^0 = \mathbf{0}, \quad \varepsilon_0 := c_{\mathbf{M}}^{-1} \|\mathbf{z}\|. \tag{4.9}$$

In this case we use the short notation SOLVE $[\varepsilon, \mathbf{M}, \mathbf{z}] \to \overline{\mathbf{q}}_\varepsilon$.

The choice of the interior tolerance $\rho^k \varepsilon_j$ in step (ii.1) yields the following estimate from [CDD2] regarding the final iterate $\mathbf{v}^K$ resulting from step (ii.1). Inserting the exact iterate of (4.4) with initial value $\overline{\mathbf{w}}^j$ denoted by $\overline{\mathbf{v}}^K(\overline{\mathbf{w}}^j)$, we get

$$\begin{aligned} \|\mathbf{v}^K - \mathbf{q}\| &\le \|\mathbf{v}^K - \overline{\mathbf{v}}^K(\overline{\mathbf{w}}^j)\| + \|\overline{\mathbf{v}}^K(\overline{\mathbf{w}}^j) - \mathbf{q}\| \\ &\le \alpha K \rho^{K-1} \varepsilon_j + \rho^K \|\overline{\mathbf{w}}^j - \mathbf{q}\| \le (\alpha K + \rho) \rho^{K-1} \varepsilon_j. \end{aligned} \tag{4.10}$$

Employing the choice of K in (4.7), this yields

$$\|\mathbf{v}^K - \mathbf{q}\| \le \frac{\varepsilon_j}{2(1+a)}. \tag{4.11}$$

The particular form of the constants for the interior estimates that can be seen in (4.10) will be employed later in section 5.

Straightforward perturbation arguments reveal the following result; see [CDD2, CDD3].

PROPOSITION 4.1. *The iterates* $\overline{\mathbf{q}}^j$ *generated by* SOLVE $[\varepsilon, \mathbf{M}, \mathbf{z}]$ *satisfy*

$$\|\mathbf{q} - \overline{\mathbf{q}}^j\| \le \varepsilon_j, \qquad j \in \mathbb{N}_0, \tag{4.12}$$

where $\varepsilon_j = 2^{-j}\varepsilon_0$.

Of course, the estimates for α rely on the constants in the norm equivalences (3.5) and in the relation (4.2). Thus there may be only a poor estimate for ρ, which, in turn, gives rise to an overly pessimistic choice for the number K defined in (4.7) of perturbed iterations in each block (ii) of SOLVE prior to a coarsening step. Therefore, we recall from [CDD3] that step (ii) can be terminated based on monitoring the approximate residuals as follows. By (4.2), we have

$$\|\mathbf{q} - \mathbf{v}\| \le c_{\mathbf{M}}^{-1} \|\mathbf{z} - \mathbf{M}\mathbf{v}\|. \tag{4.13}$$

Choose any $\bar{\rho} < 1$ and define $\bar{K}$ by (4.7) with respect to $\bar{\rho}$. Replacing ρ by $\bar{\rho}$ in the definition of the tolerances in step (ii) of SOLVE would take $M := \max\{K, \bar{K}\}$ steps to ensure that in the $(j+1)$st call of (ii) $\|\mathbf{q} - \mathbf{v}^M\| \le \varepsilon_j/10$. Now suppose that the

ρ is expected to be a too-pessimistic estimate of the true reduction rate. Choosing, e.g., $\bar{\rho} := 1/2$ and setting $\eta_k := 2^{-k}\varepsilon_j = \bar{\rho}^{-k}\varepsilon_j$ as tolerances in the $(j+1)$st call of (ii), we infer from (4.13) and (4.5) that

$$\|\mathbf{q} - \mathbf{v}^k\| \le c_{\mathbf{M}}^{-1}\|\mathbf{z} - \mathbf{M}\mathbf{v}^k\| \le c_{\mathbf{M}}^{-1}\left(\eta_k + \|\mathbf{r}^k\|\right) =: \delta_k,$$

where $\mathbf{r}^k$ is the approximate residual produced in step (ii.1) of SOLVE. By the previous remarks, we can terminate the iteration in step (ii) of SOLVE when either $k = K-1$ or the *computable a posteriori bound* δ_k satisfies $\delta_k \le \varepsilon_j/2(1+a)$, which might happen much earlier than predicted by (4.7). In fact, a refined argument reveals that a weaker error reduction in (4.11) suffices; see [CDD3]. Of course, the constant $c_{\mathbf{M}}$ is usually also only estimated. However, a poor estimate enters the above a posteriori termination criterion in a less severe way than a poor estimate for ρ. Nevertheless, to keep the exposition as simple as possible, we confine the subsequent discussion to the above version of SOLVE, bearing in mind that variants of the above sort are automatically covered by the complexity analysis.

4.2. Complexity analysis. Of course, the main issues are the actual realization of the routine RES and to understand its complexity. The realization will depend on the concrete application, which here will be the control problem (SCPW). Here we outline first a suitable framework for the complexity analysis. Striving for schemes that are in some sense *optimal*, the meaning of optimality must first be clarified.

We say that the scheme SOLVE has an *optimal work/accuracy rate* s if the following is true: whenever the error of best N-term approximation

$$\sigma_N(\mathbf{q}) := \|\mathbf{q} - \mathbf{q}_N\| := \min_{\#\operatorname{supp}\mathbf{v}\le N}\|\mathbf{q} - \mathbf{v}\| \tag{4.14}$$

decays like $\mathcal{O}(N^{-s})$, then the solution $\overline{\mathbf{q}}_\varepsilon$ is produced by SOLVE at an expense that also stays proportional to $\varepsilon^{-1/s}$ and in that sense matches the best N-term rate. Clearly this implies that $\#\operatorname{supp}\overline{\mathbf{q}}_\varepsilon$ also stays proportional to $\varepsilon^{-1/s}$. Thus, our benchmark is "best N-term approximation," which is obviously the best one can hope for.

Clearly this best N-term approximation $\mathbf{q}_N$ of $\mathbf{q}$ is given by taking the N largest terms in modulus from $\mathbf{q}$. When $\mathbf{q}$ is the (unknown) solution of (4.1), this knowledge is certainly not available. Nevertheless, the formulation of appropriate complexity criteria will be based on a characterization of those sequences $\mathbf{v}$ for which the best N-term approximation error decays at a particular rate (*Lorentz spaces*). Following [CDD1], consider sequences that are *sparse* in the sense that for any given threshold $0 < \eta \le 1$, say, the number of terms exceeding that threshold is controlled by some function of this threshold. Specifically, set for some $0 < \tau < 2$

$$\ell_\tau^w := \{\mathbf{v} \in \ell_2 :\ \#\{\lambda \in \mathbb{I} : |v_\lambda| > \eta\} \le C_{\mathbf{v}}\,\eta^{-\tau} \text{ for all } 0 < \eta \le 1\}, \tag{4.15}$$

i.e., the set ℓ_τ^w consists of all those sequences $\mathbf{v} \in \ell_2$ for which there exists a constant $C_{\mathbf{v}}$ such that for all $0 < \eta \le 1$ the number of terms v_λ whose moduli exceed the threshold η is bounded by $C_{\mathbf{v}}\eta^{-\tau}$. Note that this determines a strict subspace of ℓ_2 only when $\tau < 2$, and the sequence is sparser the smaller τ is. Denote for a given $\mathbf{v} \in \ell_\tau^w$ by $C_{\mathbf{v}}$ the smallest constant for which (4.15) holds. Then one has

$$|\mathbf{v}|_{\ell_\tau^w} := \sup_{n\in\mathbb{N}} n^{1/\tau} v_n^* = C_{\mathbf{v}}^{1/\tau}, \tag{4.16}$$

where $\mathbf{v}^* = (v_n^*)_{n\in\mathbb{N}}$ is a nondecreasing rearrangement of $\mathbf{v}$. The quantity

$$\|\mathbf{v}\|_{\ell_\tau^w} := \|\mathbf{v}\| + |\mathbf{v}|_{\ell_\tau^w} \tag{4.17}$$

can be shown to be a quasi-norm for ℓ_τ^w [CDD1]. Furthermore, because of the continuous embeddings

$$\ell_\tau \hookrightarrow \ell_\tau^w \hookrightarrow \ell_{\tau+\varepsilon} \hookrightarrow \ell_2 \qquad \text{for } \tau < \tau + \varepsilon < 2, \tag{4.18}$$

ℓ_τ^w is very close to ℓ_τ, which justifies calling it *weak* ℓ_τ. Now we can recall the following result from [CDD1], which relates the sequences in ℓ_τ^w to best N-term approximation.

PROPOSITION 4.2. *Let positive real numbers s and τ be related by*

$$\frac{1}{\tau} = s + \frac{1}{2}. \tag{4.19}$$

Then a sequence $\mathbf{v}$ belongs to ℓ_τ^w if and only if

$$\|\mathbf{v} - \mathbf{v}_N\| \lesssim N^{-s} \qquad \text{and} \qquad \sigma_N(\mathbf{v}) \lesssim N^{-s}\,\|\mathbf{v}\|_{\ell_\tau^w}, \tag{4.20}$$

where as before $\mathbf{v}_N$ denotes a best N-term approximation of $\mathbf{v}$.

Depending on the space H which is characterized by the wavelet basis Ψ_H, the fact that an array of wavelet coefficients satisfies $\mathbf{v} \in \ell_\tau$ is typically equivalent to the fact that the expansion $\mathbf{v}^T\Psi_H$ belongs to a certain Besov space which describes a much weaker regularity measure than a Sobolev space of corresponding order. In view of (4.18), Proposition 4.2 therefore expresses how much loss of regularity can be *compensated* by best N-term approximation, i.e., by judiciously placing the degrees of freedom in a nonlinear way to retain a certain optimal order of error decay. We shall return to this issue later.

As will be seen in Theorem 4.3, a key criterion for a scheme SOLVE to exhibit an optimal work/accuracy rate can be formulated through the following property of the respective residual approximation.

τ^*-sparsity. *The routine* RES *is called τ^*-sparse for some $0 < \tau^* < 2$ if the following holds: whenever the solution $\mathbf{q}$ of (4.1) belongs to ℓ_τ^w for some $\tau^* < \tau < 2$, then for any $\mathbf{v}$ with finite support the output $\mathbf{r}_\eta$ of* RES $[\eta, \mathbf{M}, \mathbf{z}, \mathbf{v}]$ *satisfies*

(i)
$$\begin{aligned} \|\mathbf{r}_\eta\|_{\ell_\tau^w} &\lesssim \max\{\|\mathbf{v}\|_{\ell_\tau^w}, \|\mathbf{q}\|_{\ell_\tau^w}\}, \\ \#\operatorname{supp}\mathbf{r}_\eta &\lesssim \eta^{-1/s}\max\{\|\mathbf{v}\|_{\ell_\tau^w}^{1/s}, \|\mathbf{q}\|_{\ell_\tau^w}^{1/s}\}, \end{aligned} \tag{4.21}$$

where s and τ are related as before by (4.19);

(ii) *the number of floating point operations needed to compute $\mathbf{r}_\eta$ stays proportional to $\#\operatorname{supp}\mathbf{r}_\eta$.*

Furthermore, the constants in (i), (ii) *depend only on τ as $\tau \to \tau^*$.*

In this context we shall always make the following tacit assumption. Given data are always to be considered completely accessible. In practical terms this may mean that depending on some final target accuracy (in view of (3.38)) sufficiently many of the corresponding coefficients of explicitly given data are determined in a preprocessing step and then ordered by size, so that COARSE can be applied to a finitely supported array. For notational simplicity we shall not distinguish between the ideal exact data and such an approximation.

The following result can then be extracted from the analysis in [CDD2] (see also [CDD3] for nonlinear problems) and was used in [DUV].

THEOREM 4.3. *If* RES *is τ^*-sparse and if the exact solution $\mathbf{q}$ of* (4.1) *belongs to ℓ_τ^w for some $\tau > \tau^*$, then for every $\varepsilon > 0$ algorithm* SOLVE $[\varepsilon, \mathbf{M}, \mathbf{z}]$ *produces after*

finitely many steps an output $\overline{\mathbf{q}}_\varepsilon$ *(which, according to Proposition* 4.1*, always satisfies* $\|\mathbf{q}-\overline{\mathbf{q}}_\varepsilon\|<\varepsilon$*) with the following properties: for* s *and* τ *related by* (4.19)*, one has*

$$\#\operatorname{supp}\overline{\mathbf{q}}_\varepsilon \lesssim \varepsilon^{-1/s}\|\mathbf{q}\|_{\ell^w_\tau}^{1/s}, \qquad \|\overline{\mathbf{q}}_\varepsilon\|_{\ell^w_\tau} \lesssim \|\mathbf{q}\|_{\ell^w_\tau}, \tag{4.22}$$

and the number of floating point operations needed to compute $\overline{\mathbf{q}}_\varepsilon$ *remains proportional to* $\#\operatorname{supp}\overline{\mathbf{q}}_\varepsilon$.

Thus, τ^*-sparsity of the routine RES implies asymptotically optimal work/accuracy rates of the scheme SOLVE for a certain range of decay rates given by τ^*. We stress that the algorithm itself does *not* require any a priori knowledge about the solution such as its actual best N-term approximation rate. Theorem 4.3 also shows that controlling the ℓ^w_τ-norm of the quantities generated in the course of the computation is crucial. This finally explains the role of COARSE in step (ii.2) of SOLVE through the following result; see, e.g., [CDD3].

LEMMA 4.4 (coarsening lemma). *Let* $\mathbf{v}\in\ell^w_\tau$ *and let* $\mathbf{w}$ *be any finitely supported approximation such that* $\|\mathbf{v}-\mathbf{w}\|\le\eta$*. Then, for any fixed* $a>1$*, the output* $\mathbf{w}_\eta$ *of* COARSE$\,[a\eta,\mathbf{w}]$ *satisfies*

$$\#\operatorname{supp}\mathbf{w}_\eta \lesssim \|\mathbf{v}\|_{\ell^w_\tau}^{1/\tau}\,\eta^{-1/s}, \quad \|\mathbf{v}-\mathbf{w}_\eta\|\le(1+a)\eta, \qquad \|\mathbf{w}_\eta\|_{\ell^w_\tau}\lesssim\|\mathbf{v}\|_{\ell^w_\tau}, \tag{4.23}$$

where the constants in the first and third estimate depend on a *when* $a\to 1$.

Thus, knowing an error bound for a given finitely supported approximation $\mathbf{w}$, a certain coarsening using only knowledge about $\mathbf{w}$, produces a new approximation to (the possibly unknown) $\mathbf{v}$ which gives rise to a slightly larger error but realizes up to a uniform constant the optimal relation between support and accuracy. In the scheme SOLVE this means that by the coarsening step, the ℓ^w_τ-norms of the iterates $\mathbf{v}^K$ are controlled. Recall from (4.11) that the choice of the constant K in (4.7), which controls the number of iterations in step (ii.1), guarantees that in the $(j+1)$st outer iteration of SOLVE the iterate $\mathbf{v}^K$ satisfies $\|\mathbf{q}-\mathbf{v}^K\|\le\frac{1}{2(1+a)}\varepsilon_j$. The threshold $\frac{a\varepsilon_j}{2(1+a)}$ in step (ii.2) ensures, on account of (4.23), that the error after coarsening is still bounded by $\frac{1}{2}\varepsilon_j$. At the same time, if $\mathbf{q}\in\ell^w_\tau$, then $\|\overline{\mathbf{q}}^j\|_{\ell^w_\tau}$ remains bounded and $\#\operatorname{supp}\overline{\mathbf{q}}^j$ increases at most like $\varepsilon_j^{-1/s}$, which is the best possible N-term rate for sequences in ℓ^w_τ. Thus to ensure an overall optimal work/accuracy rate, one has to show that the ℓ^w_τ-norms of the intermediate iterates $\mathbf{v}^k$ in step (ii.1) of SOLVE cannot grow too much, which is indeed guaranteed by τ^*-sparsity.

The proportionally constants in the above complexity estimates can, in principle, be assessed or at least estimated in any concrete case. They will depend on the Riesz constants of the employed wavelet bases, on the ellipticity and continuity constants in the operator equation (which determine the constants in (4.2) and (4.3)), on the choice of the constant a in the coarsening step, and on the concrete realization of the approximate application of matrices like $\mathbf{A}$; see section 5.1.

The remainder of this paper is now devoted to the construction and analysis of a concrete realization of SOLVE—termed $\text{SOLVE}_{\text{SCPW}}$—for the problem (SCPW) such that the corresponding routine RES_{SCPW} is τ^*-sparse.

5. The scheme $\text{SOLVE}_{\text{SCPW}}$.

Since $\mathbf{Q}$ from (3.56) still involves several inverses of matrices it is not so clear how to realize a residual approximation in an economical way—recall obstruction (b) in section 3.4.

5.1. Realization of the routine RES_{SCPW}.

The realization of the routine RES_{SCPW} for the problem (3.56) will be based on the residual representation (3.62);

see also Lemma 3.7. However, this requires solving the two auxiliary systems (3.21), (3.60) in (EE′). Since the residual has to be only approximated, these systems will have to be solved only approximately. These approximate solutions, in turn, will be provided again by calls of the scheme SOLVE but this time with respect to suitable residual schemes tailored to the systems in (EE′). In all our examples the matrix $\mathbf{A}$ appearing in (EE′) is symmetric positive definite and the choice of wavelet bases ensures the validity of (3.22). Hence, (4.2) and (4.3) hold for $\mathbf{M} = \mathbf{A}$ and $\mathbf{M} = \mathbf{A}^T$ so that the scheme SOLVE can indeed be invoked. We hasten to mention, however, that the symmetry and positive definiteness of $\mathbf{A}$ is not essential. As long as (3.22) holds, which means that the operator equation induced by the constraints is well posed (which is still the case, e.g., for many saddle point problems), we can multiply the systems in (EE′) by $\mathbf{A}^T$, respectively, $\mathbf{A}$, to arrive at a least squares formulation with $\mathbf{M} = \mathbf{A}^T\mathbf{A}$ or $\mathbf{M} = \mathbf{A}\mathbf{A}^T$, still satisfying (4.2) but now yielding symmetric positive definite systems to ensure (4.3). However, to keep the exposition as simple as possible, we confine the following discussion to the case that $\mathbf{A}$ already satisfies (in addition to (3.22)) (4.3).

Note also that although we conceptually use the fact that a gradient descent for the reduced problem (3.56) reduces the error for $\mathbf{u}$ in each step by a fixed amount, the use of (EE′) for the evaluation of the residuals will generate as byproducts approximate solutions to the full Euler–Lagrange system, i.e., we shall obtain approximations to the exact solution triple $(\mathbf{y}, \mathbf{p}, \mathbf{u})$ of (EE′).

Under this hypothesis, we have to formulate next the ingredients for suitable versions $\text{SOLVE}_{\text{PRM}}$ and $\text{SOLVE}_{\text{ADJ}}$ of SOLVE for the systems in (EE′). Specifically, this requires identifying residual schemes RES_{PRM} and RES_{ADJ} for the systems $\text{SOLVE}_{\text{PRM}}$ and $\text{SOLVE}_{\text{ADJ}}$. The main task in both cases is to apply scaling matrices and operators $\mathbf{A}, \mathbf{T}, \mathbf{E}$ along with their transposes. Of course, the application of a scaling matrix can be done exactly and hence is easily realized. To ease notation we may therefore combine conceptually the application of $\mathbf{T}$ followed by $\mathbf{D}_Z^{-1}$ in a single operator application, which will be reflected by the notation

$$\mathbf{T}_Z := \mathbf{D}_Z^{-1}\mathbf{T}, \quad \mathbf{y}_Z := \mathbf{D}_Z^{-1}\mathbf{y}_*. \tag{5.1}$$

Again we assume for the moment that routines for the application of these operators are available, i.e., that for any $\mathbf{L} \in \{\mathbf{A}, \mathbf{A}^T, \mathbf{T}_Z, \mathbf{T}_Z^T, \mathbf{E}, \mathbf{E}^T\}$ we have a scheme with the following property at our disposal. We shall later discuss their concrete realization.

$\text{APPLY}[\eta, \mathbf{L}, \mathbf{v}] \to \mathbf{w}_\eta$ determines for any finitely supported input vector $\mathbf{v}$ and any tolerance $\eta > 0$ a finitely supported output $\mathbf{w}_\eta$ which satisfies

$$\|\mathbf{L}\mathbf{v} - \mathbf{w}_\eta\| \le \eta. \tag{5.2}$$

The scheme $\text{SOLVE}_{\text{PRM}}$ for the first system in (EE′) is now defined by

$$\text{SOLVE}_{\text{PRM}}[\eta, \mathbf{A}, \mathbf{E}, \mathbf{D}_Q, \boldsymbol{f}, \mathbf{v}, \overline{\mathbf{y}}^0, \varepsilon_0] := \text{SOLVE}[\eta, \mathbf{A}, \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v}, \overline{\mathbf{y}}^0, \varepsilon_0], \tag{5.3}$$

where $\overline{\mathbf{y}}^0$ is an initial guess for the solution $\mathbf{y}$ of $\mathbf{A}\mathbf{y} = \boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v}$ with accuracy ε_0 and where the scheme RES for step (ii) in SOLVE is in this case realized by a new routine RES_{PRM}, which is defined as follows.

$\text{RES}_{\text{PRM}}[\eta, \mathbf{A}, \mathbf{E}, \mathbf{D}_Q, \boldsymbol{f}, \mathbf{v}, \overline{\mathbf{y}}] \to \mathbf{r}_\eta$ determines for any positive tolerance η a given finitely supported $\mathbf{v}$ and any finitely supported input $\overline{\mathbf{y}}$ a finitely supported approximate residual $\mathbf{r}_\eta$ satisfying (4.5), that is,

$$\|\boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v} - \mathbf{A}\overline{\mathbf{y}} - \mathbf{r}_\eta\| \le \eta, \tag{5.4}$$

as follows:

(i) $\text{APPLY}[\frac{1}{3}\eta, \mathbf{A}, \overline{\mathbf{y}}] \to \mathbf{w}_\eta$;
(ii) $\text{COARSE}[\frac{1}{3}\eta, \boldsymbol{f}] \to \boldsymbol{f}_\eta$;
$\text{APPLY}[\frac{1}{3}\eta, \mathbf{E}, \mathbf{D}_Q^{-1}\mathbf{v}] \to \mathbf{z}_\eta$;
(iii) set $\mathbf{r}_\eta := \boldsymbol{f}_\eta + \mathbf{z}_\eta - \mathbf{w}_\eta$.

In fact, noting that $\boldsymbol{f} + \mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v} - \mathbf{A}\overline{\mathbf{y}} - \mathbf{r}_\eta = (\boldsymbol{f} - \boldsymbol{f}_\eta) + (\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{v} - \mathbf{z}_\eta) + (\mathbf{w}_\eta - \mathbf{A}\overline{\mathbf{y}})$, by triangle inequality (5.4) is an immediate consequence of the choice of the tolerances in steps (i)–(iii) of RES_{PRM}.

Similarly, we need a version of SOLVE for the approximate solution of the second system in (EE′), which with the notation (5.1) now reads $\mathbf{A}^T\mathbf{p} = -\mathbf{T}_Z^T(\mathbf{T}_Z\mathbf{y} - \mathbf{y}_Z)$. This depends therefore on $\mathbf{y}_Z = \mathbf{D}_Z^{-1}\mathbf{y}_*$, an approximate solution $\overline{\mathbf{y}}$ of the primal system, and possibly on some initial guess $\overline{\mathbf{p}}^0$ with accuracy ε_0. Specifically, we set here

$$\text{SOLVE}_{\text{ADJ}}[\eta, \mathbf{A}, \mathbf{T}_Z, \mathbf{y}_Z, \overline{\mathbf{y}}, \overline{\mathbf{p}}^0, \varepsilon_0] := \text{SOLVE}[\eta, \mathbf{A}^T, -\mathbf{T}_Z^T(\mathbf{T}_Z\overline{\mathbf{y}} - \mathbf{y}_Z), \overline{\mathbf{p}}^0, \varepsilon_0]. \tag{5.5}$$

As usual we will assume that the data $\boldsymbol{f}, \mathbf{y}_Z$ are approximated in a preprocessing step with sufficient accuracy (depending on the final target accuracy for solving (3.56)) by finite arrays whose entries are ordered by size and hence can be treated by COARSE.

Again we have to identify a suitable residual approximation scheme RES_{ADJ} for step (ii) of this version of SOLVE where the main issue is the approximate evaluation of the right-hand side. The routine RES_{ADJ} is defined as follows.

$\text{RES}_{\text{ADJ}}[\eta, \mathbf{A}, \mathbf{T}_Z, \mathbf{y}_Z, \overline{\mathbf{y}}, \overline{\mathbf{p}}] \to \mathbf{r}_\eta$ determines for any positive tolerance η, given finitely supported data $\overline{\mathbf{y}}, \mathbf{y}_Z$ and any finitely supported input $\overline{\mathbf{p}}$ an approximate residual $\mathbf{r}_\eta$ satisfying (4.5), i.e.,

$$\| - \mathbf{T}_Z^T(\mathbf{T}_Z\overline{\mathbf{y}} - \mathbf{y}_Z) - \mathbf{A}^T\overline{\mathbf{p}} - \mathbf{r}_\eta\| \le \eta, \tag{5.6}$$

as follows:

(i) $\text{APPLY}[\frac{1}{3}\eta, \mathbf{A}^T, \overline{\mathbf{p}}] \to \mathbf{w}_\eta$;
(ii) $\text{APPLY}[\frac{1}{6\,C_{\mathbf{T}}}\eta, \mathbf{T}_Z, \overline{\mathbf{y}}] \to \mathbf{z}_\eta$ with $C_{\mathbf{T}}$ from (3.51);
$\text{COARSE}[\frac{1}{6\,C_{\mathbf{T}}}\eta, \mathbf{y}_Z] \to (\mathbf{y}_Z)_\eta$; set $\mathbf{d}_\eta := (\mathbf{y}_Z)_\eta - \mathbf{z}_\eta$;
$\text{APPLY}[\frac{1}{3}\eta, \mathbf{T}_Z^T, \mathbf{d}_\eta] \to \mathbf{v}_\eta$;
(iii) set $\mathbf{r}_\eta := \mathbf{v}_\eta - \mathbf{w}_\eta$.

To confirm the validity of (5.6), note that by steps (i)–(iii) of RES_{ADJ}

$$\begin{aligned} - \mathbf{T}_Z^T(\mathbf{T}_Z\overline{\mathbf{y}} - \mathbf{y}_Z) - \mathbf{A}^T\overline{\mathbf{p}} - \mathbf{r}_\eta \\ = -\mathbf{T}_Z^T\left((\mathbf{T}_Z\overline{\mathbf{y}} - \mathbf{y}_Z) - \mathbf{d}_\eta\right) + (\mathbf{T}_Z^T\mathbf{d}_\eta - \mathbf{v}_\eta) + (\mathbf{w}_\eta - \mathbf{A}^T\overline{\mathbf{p}}), \end{aligned}$$

so that (5.6) follows, in view of (3.51) and the tolerances above, by triangle inequality.

Recall that the exact solution $\mathbf{u}$ of (3.56) is the third component of the solution triple $(\mathbf{y}, \mathbf{p}, \mathbf{u})$ of the Euler–Lagrange system (EE′). We shall consistently use this notation for the exact solutions of the respective systems.

We are now in a position to define the residual scheme for the version of SOLVE applied to (3.56). We shall refer to this specification as $\text{SOLVE}_{\text{SCPW}}$. Likewise the corresponding residual scheme is denoted by RES_{SCPW}. We shall use the constants from (3.22) and (3.51). Since the scheme is based on (3.62) (see also Lemma 3.7), it will therefore involve several parameters stemming from the auxiliary systems (EE′).

$\text{RES}_{\text{SCPW}}[\eta, \mathbf{Q}, \mathbf{g}, \tilde{\mathbf{y}}, \delta_y, \tilde{\mathbf{p}}, \delta_p, \mathbf{v}, \delta_v] \to (\mathbf{r}_\eta, \tilde{\mathbf{y}}, \delta_y, \tilde{\mathbf{p}}, \delta_p)$ determines for any approximate solution triple $(\tilde{\mathbf{y}}, \tilde{\mathbf{p}}, \mathbf{v})$ of the system (EE′) satisfying

$$\|\mathbf{y} - \tilde{\mathbf{y}}\| \le \delta_y, \quad \|\mathbf{p} - \tilde{\mathbf{p}}\| \le \delta_p, \quad \|\mathbf{u} - \mathbf{v}\| \le \delta_v, \tag{5.7}$$

an approximate residual $\mathbf{r}_\eta$ such that

$$\|\mathbf{g} - \mathbf{Q}\mathbf{v} - \mathbf{r}_\eta\| \le \eta. \tag{5.8}$$

Moreover, the initial approximations $\tilde{\mathbf{y}}, \tilde{\mathbf{p}}$ are overwritten by new approximations $\tilde{\mathbf{y}}, \tilde{\mathbf{p}}$ satisfying (5.7) with new bounds δ_y and δ_p defined in (5.10), as follows:

(i) $\textsc{Solve}_{\textsc{prm}}[\frac{c_{\mathbf{A}}\eta}{3C_{\mathbf{E}}C_{\mathbf{T}}^2}, \mathbf{A}, \boldsymbol{f}, \mathbf{v}, \tilde{\mathbf{y}}, \delta_y] \to \mathbf{y}_\eta$;
(ii) $\textsc{Solve}_{\textsc{adj}}[\frac{\eta}{3C_{\mathbf{E}}}, \mathbf{A}, \mathbf{T}_Z, \mathbf{y}_Z, \mathbf{y}_\eta, \tilde{\mathbf{p}}, \delta_p] \to \mathbf{p}_\eta$;
(iii) $\textsc{Apply}[\frac{\eta}{3}, \mathbf{D}_Q^{-1}\mathbf{E}^T, \mathbf{p}_\eta] \to \mathbf{q}_\eta$;
(iv) set $\mathbf{r}_\eta := \mathbf{q}_\eta - \omega\mathbf{v}$;
(v) set

$$\xi_y := \frac{C_{\mathbf{E}}}{c_{\mathbf{A}}}\,\delta_v + \frac{c_{\mathbf{A}}}{3C_{\mathbf{E}}C_{\mathbf{T}}^2}\,\eta, \quad \xi_p := \frac{C_{\mathbf{T}}^2 C_{\mathbf{E}}}{c_{\mathbf{A}}^2}\,\delta_v + \frac{2}{3C_{\mathbf{E}}}\,\eta, \tag{5.9}$$

and replace $\tilde{\mathbf{y}}, \delta_y$ as well as $\tilde{\mathbf{p}}, \delta_p$ by the new values

$$\begin{aligned} \tilde{\mathbf{y}} &:= \textsc{Coarse}[a\xi_y, \mathbf{y}_\eta], \qquad \delta_y := (1+a)\,\xi_y, \\ \tilde{\mathbf{p}} &:= \textsc{Coarse}[a\xi_p, \mathbf{p}_\eta], \qquad \delta_p := (1+a)\,\xi_p. \end{aligned} \tag{5.10}$$

((5.9) already indicates the conditions on the tolerance η and the accuracy bound δ_v under which the new error bounds in (5.10) are actually tighter. The precise relation between η and δ_v in the context of $\textsc{Solve}_{\textsc{scpw}}$ will emerge from the complexity analysis in section 6; see (6.2).) Let us confirm the claimed estimates (5.8) and (5.10). To this end, let for any given input $\mathbf{v}$ the exact solution to the first system in (EE′) be denoted by $\mathbf{y}_\mathbf{v}$. Moreover, let $\mathbf{p}_\mathbf{v}$ be the exact solution of the second system in (EE′) with $\mathbf{y}$ replaced by $\mathbf{y}_\mathbf{v}$. Finally, let $\hat{\mathbf{p}}$ be the exact solution of the second system but with $\mathbf{y}$ replaced by the approximate solution $\mathbf{y}_\eta$ of the first equation in (EE′). By step (iv) in $\textsc{Res}_{\textsc{scpw}}$ and (3.49), we have

$$\mathbf{g} - \mathbf{Q}\mathbf{v} - \mathbf{r}_\eta = \mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}_\mathbf{v} - \mathbf{q}_\eta = \mathbf{D}_Q^{-1}\mathbf{E}^T(\mathbf{p}_\mathbf{v} - \mathbf{p}_\eta) + \mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{p}_\eta - \mathbf{q}_\eta.$$

Hence it follows that

$$\|\mathbf{g} - \mathbf{Q}\mathbf{v} - \mathbf{r}_\eta\| \le \frac{\eta}{3} + C_{\mathbf{E}}\|\mathbf{p}_\eta - \mathbf{p}_\mathbf{v}\|. \tag{5.11}$$

To estimate the second term, note that

$$\mathbf{p}_\mathbf{v} - \hat{\mathbf{p}} = \mathbf{A}^{-T}\mathbf{T}_Z^T\mathbf{T}_Z(\mathbf{y}_\mathbf{v} - \mathbf{y}_\eta),$$

and therefore, by (3.22), (3.51), and step (i),

$$\|\mathbf{p}_\mathbf{v} - \hat{\mathbf{p}}\| \le c_{\mathbf{A}}^{-1}C_{\mathbf{T}}^2\|\mathbf{y}_\mathbf{v} - \mathbf{y}_\eta\| \le \frac{\eta}{3C_{\mathbf{E}}}. \tag{5.12}$$

Thus, by step (ii) and (5.12), $\|\mathbf{p}_\eta - \mathbf{p}_\mathbf{v}\| \le \frac{2\eta}{3C_{\mathbf{E}}}$, which together with (5.11) confirms (5.8).

Adhering to the above notational conventions, the first system in (EE′) yields $\mathbf{y} - \mathbf{y}_\mathbf{v} = \mathbf{A}^{-1}\mathbf{E}\mathbf{D}_Q^{-1}(\mathbf{w} - \mathbf{v})$ so that by (5.7), (3.22), and (3.51),

$$\|\mathbf{y} - \mathbf{y}_\eta\| \le \|\mathbf{y} - \mathbf{y}_\mathbf{v}\| + \|\mathbf{y}_\mathbf{v} - \mathbf{y}_\eta\| \le \frac{C_{\mathbf{E}}}{c_{\mathbf{A}}}\,\delta_v + \frac{c_{\mathbf{A}}}{3C_{\mathbf{E}}C_{\mathbf{T}}^2}\,\eta, \tag{5.13}$$

which is the value of ξ_y in step (v). Likewise we infer from the second system in (EE′) that

$$\mathbf{p}-\mathbf{p}_\eta=\mathbf{p}-\hat{\mathbf{p}}+\hat{\mathbf{p}}-\mathbf{p}_\eta=\mathbf{A}^{-T}\mathbf{T}_Z^T\mathbf{T}_Z(\mathbf{y}-\mathbf{y}_\eta)+\hat{\mathbf{p}}-\mathbf{p}_\eta.$$

Hence, by (3.22), (3.24), and step (ii), we obtain

$$\|\mathbf{p}-\mathbf{p}_\eta\|\le\frac{C_{\mathbf{T}}^2}{c_{\mathbf{A}}}\,\xi_y+\frac{\eta}{3C_{\mathbf{E}}}=\frac{C_{\mathbf{T}}^2C_{\mathbf{E}}}{c_{\mathbf{A}}^2}\,\delta_v+\frac{2}{3C_{\mathbf{E}}}\,\eta, \tag{5.14}$$

which is the value of ξ_p in step (v). The estimates (5.7) with the new bounds defined in (5.10) are now an immediate consequence of the coarsening step in (v) and the triangle inequality. This concludes the confirmation of all estimates stated in RES_{SCPW}.

It remains to initialize the scheme $\text{SOLVE}_{\text{SCPW}}$. Again we assume that $\boldsymbol{f}$ and $\mathbf{y}_Z$ are given and fully accessible. Choosing $\overline{\mathbf{u}}^0\equiv\mathbf{0}$ we infer from (3.38), (3.34), and (3.39) that

$$\begin{aligned}\|\overline{\mathbf{u}}^0-\mathbf{u}\|&\le c_{\mathbf{Q}}^{-1}\|\mathbf{Q}\overline{\mathbf{w}}^0-\mathbf{g}\|=c_{\mathbf{Q}}^{-1}\|\mathbf{g}\|\\&=c_{\mathbf{Q}}^{-1}\|\mathbf{D}_Q^{-1}\mathbf{E}^T\mathbf{A}^{-T}\mathbf{T}_Z^T(\mathbf{y}_Z-\mathbf{T}_Z\mathbf{A}^{-1}\boldsymbol{f})\|\\&\le\frac{C_{\mathbf{E}}C_{\mathbf{T}}}{c_{\mathbf{A}}}\left(\|\mathbf{y}_Z\|+\frac{C_{\mathbf{T}}}{c_{\mathbf{A}}}\|\boldsymbol{f}\|\right)\\&=:\varepsilon_0.\end{aligned} \tag{5.15}$$

Moreover, for $\tilde{\mathbf{y}}^0:=\mathbf{0}$ one has

$$\begin{aligned}\|\mathbf{y}-\tilde{\mathbf{y}}^0\|=\|\mathbf{A}^{-1}(\boldsymbol{f}+\mathbf{E}\mathbf{D}_Q^{-1}\mathbf{u})\|&\le c_{\mathbf{A}}^{-1}\left(\|\boldsymbol{f}\|+C_{\mathbf{E}}c_{\mathbf{Q}}^{-1}\|\mathbf{g}\|\right)\\&\le c_{\mathbf{A}}^{-1}\left(\|\boldsymbol{f}\|+C_{\mathbf{E}}\varepsilon_0\right)=:\delta_{y,0}.\end{aligned} \tag{5.16}$$

Similarly, for $\tilde{\mathbf{p}}^0:=\mathbf{0}$ we obtain

$$\|\tilde{\mathbf{p}}^0-\mathbf{p}\|=\|\mathbf{A}^{-T}\mathbf{T}_Z^T(\mathbf{T}_Z\mathbf{y}-\mathbf{y}_Z)\|\le c_{\mathbf{A}}^{-1}(C_{\mathbf{T}}^2\delta_{y,0}+C_{\mathbf{T}}\|\mathbf{y}_Z\|)=:\delta_{p,0}. \tag{5.17}$$

The scheme $\text{SOLVE}_{\text{SCPW}}$ takes now the following form with the error reduction factor $\rho=\rho(\mathbf{Q})$ from (3.59) and K given by (4.7) with α from (3.58).

$\text{SOLVE}_{\text{SCPW}}[\varepsilon,\mathbf{Q},\mathbf{g}]\to(\overline{\mathbf{u}}_\varepsilon,\overline{\mathbf{y}}_\varepsilon,\overline{\mathbf{p}}_\varepsilon)$.

(i) Let $\overline{\mathbf{q}}^0:=\mathbf{0}$ and let ε_0 be given by (5.15). Moreover, let $\tilde{\mathbf{y}}:=\mathbf{0}$, $\tilde{\mathbf{p}}:=\mathbf{0}$ and set $j=0$. Finally, let $\delta_y:=\delta_{y,0},\delta_p:=\delta_{p,0}$ be defined by (5.16), (5.17), respectively.

(ii) If $\varepsilon_j\le\varepsilon$, stop and set $\overline{\mathbf{u}}_\varepsilon:=\overline{\mathbf{u}}^j$, $\overline{\mathbf{y}}_\varepsilon=\tilde{\mathbf{y}}$, $\overline{\mathbf{p}}_\varepsilon=\tilde{\mathbf{p}}$.
Otherwise set $\mathbf{v}^0:=\overline{\mathbf{u}}^j$.

(ii.1) For $k=0,\dots,K-1$, compute
$\text{RES}_{\text{SCPW}}[\rho^k\varepsilon_j,\mathbf{Q},\mathbf{g},\tilde{\mathbf{y}},\delta_y,\tilde{\mathbf{p}},\delta_p,\mathbf{v}^k,\delta_k]\to(\mathbf{r}^k,\tilde{\mathbf{y}},\delta_y,\tilde{\mathbf{p}},\delta_p)$,
where $\delta_0:=\varepsilon_j$ and $\delta_k:=\rho^{k-1}(\alpha k+\rho)\varepsilon_j$;
set

$$\mathbf{v}^{k+1}:=\mathbf{v}^k+\alpha\mathbf{r}^k. \tag{5.18}$$

(ii.2) Apply $\text{COARSE}[\frac{a\varepsilon_j}{2(1+a)},\mathbf{v}^K]\to\overline{\mathbf{u}}^{j+1}$; set $\varepsilon_{j+1}:=\frac{1}{2}\varepsilon_j$, $j+1\to j$ and go to (ii).

(The particular choice of the interior tolerance δ_k in step (ii.1) is based on the estimate (4.10).) Since when overwriting $\tilde{\mathbf{y}}$, $\tilde{\mathbf{p}}$ at the last stage before termination of $\text{SOLVE}_{\text{SCPW}}$ one has $\delta_k \le \varepsilon$, $\eta \le \varepsilon$, the following fact is an immediate consequence of (5.10).

Remark 5.1. The outputs $\overline{\mathbf{y}}_\varepsilon$ and $\overline{\mathbf{p}}_\varepsilon$ produced by $\text{SOLVE}_{\text{SCPW}}$ in addition to $\overline{\mathbf{u}}_\varepsilon$ are approximations to the exact solutions $\mathbf{y}, \mathbf{p}$ of (EE) satisfying

$$\|\mathbf{y} - \overline{\mathbf{y}}_\varepsilon\| \le (1+a)\varepsilon \left(\frac{C_{\mathbf{E}}}{c_{\mathbf{A}}} + \frac{c_{\mathbf{A}}}{3C_{\mathbf{E}}C_{\mathbf{T}}^2} \right), \tag{5.19}$$

$$\|\mathbf{p} - \overline{\mathbf{p}}_\varepsilon\| \le (1+a)\varepsilon \left(\frac{C_{\mathbf{T}}^2 C_{\mathbf{E}}}{c_{\mathbf{A}}^2} + \frac{2}{3C_{\mathbf{E}}} \right). \tag{5.20}$$

6. The complexity of $\text{SOLVE}_{\text{SCPW}}$. In view of the definition of RES_{PRM} and RES_{ADJ} entering RES_{SCPW}, the scheme $\text{SOLVE}_{\text{SCPW}}$ ultimately hinges on the availability of suitable schemes APPLY for the operators $\mathbf{L} \in \{\mathbf{A}, \mathbf{A}^T, \mathbf{T}_Z, \mathbf{T}_Z^T, \mathbf{E}, \mathbf{E}^T\}$. We shall adhere to our strategy of narrowing down step by step the requirements on our algorithmic ingredients, and we first identify conditions on the APPLY schemes that ensure τ^*-sparsity of RES_{SCPW} as formulated in section 4.2. It is no surprise that the key requirement is that the approximate application of each of these operators has a work/accuracy rate that is within some range comparable to best N-term approximation. Precisely, we say that $\text{APPLY}[\cdot, \mathbf{L}, \cdot]$ is τ^*-*efficient* for some $0 < \tau^* < 2$ if for any finitely supported $\mathbf{v} \in \ell_\tau^w$, for $0 < \tau^* < \tau < 2$, the output $\mathbf{w}_\eta$ of $\text{APPLY}[\eta, \mathbf{L}, \mathbf{v}]$ satisfies

$$\|\mathbf{w}_\eta\|_{\ell_\tau^w} \lesssim \|\mathbf{v}\|_{\ell_\tau^w}, \quad \#\text{supp}\, \mathbf{w}_\eta \lesssim \eta^{-1/s} \|\mathbf{v}\|_{\ell_\tau^w}^{1/s} \quad \eta \to 0, \tag{6.1}$$

where the constants depend only on τ as $\tau \to \tau^*$ and where s is related to τ by (4.19). Moreover, the number of floating point operations needed to compute $\mathbf{w}_\eta$ is to remain proportional to $\#\text{supp}\, \mathbf{w}_\eta$.

One should note that the existence of a τ^*-efficient scheme for an operator $\mathbf{L}$ has the following important implication that follows immediately from Proposition 4.2.

Remark 6.1. If one can find a τ^*-efficient scheme for $\mathbf{L}$, then $\mathbf{L}$ is bounded on ℓ_τ^w for every $\tau > \tau^*$.

Proof. For convenience, the proof from [CDD1] is included here. For $\mathbf{v} \in \ell_\tau^w$ and $\eta > 0$ there exists a $\tilde{\mathbf{v}}$ with $\|\mathbf{v} - \tilde{\mathbf{v}}\| \le \eta/(2\|\mathbf{L}\|)$ and $\#\text{supp}\, \tilde{\mathbf{v}} \lesssim \eta^{-1/s} \|\mathbf{v}\|_{\ell_\tau^w}^{1/s}$. Now by definition of $\mathbf{w}_\eta = \text{APPLY}\,[\eta/2, \mathbf{L}, \tilde{\mathbf{v}}]$ and τ^*-efficiency of $\mathbf{L}$ (6.1), one has for $\tau > \tau^*$, the estimate $\|\mathbf{L}\tilde{\mathbf{v}} - \mathbf{w}_\eta\| \le \eta/2$ while $\#\text{supp}\, \mathbf{w}_\eta \lesssim \eta^{-1/s} \|\tilde{\mathbf{v}}\|_{\ell_\tau^w}^{1/s} \le \eta^{-1/s} \|\mathbf{v}\|_{\ell_\tau^w}^{1/s}$. Since $\|\mathbf{L}\mathbf{v} - \mathbf{w}_\eta\| \le \eta$, we have identified a vector $\mathbf{w}_\eta$ with support $\lesssim \eta^{-1/s}$ that approximates $\mathbf{L}\mathbf{v}$ within accuracy η. Hence we can invoke Proposition 4.2 to conclude that $\|\mathbf{L}\mathbf{v}\|_{\ell_\tau^w} \lesssim \|\mathbf{v}\|_{\ell_\tau^w}$ as claimed. ∎

PROPOSITION 6.2. *If the* APPLY *schemes in* RES_{PRM} *and* RES_{ADJ} *are* τ^**-efficient for some* $\tau^* < 2$*, then* RES_{SCPW} *is* τ^**-sparse whenever there exists a constant* C *such that*

$$C\eta \ge \delta_v, \tag{6.2}$$

$$\max\{\|\tilde{\mathbf{y}}\|_{\ell_\tau^w}, \|\tilde{\mathbf{p}}\|_{\ell_\tau^w}, \|\mathbf{v}\|_{\ell_\tau^w}\} \le C\left(\|\mathbf{y}\|_{\ell_\tau^w} + \|\mathbf{p}\|_{\ell_\tau^w} + \|\mathbf{u}\|_{\ell_\tau^w}\right), \tag{6.3}$$

where $\mathbf{v}$ *is the current finitely supported input and where* $\tilde{\mathbf{y}}, \tilde{\mathbf{p}}$ *are the initial guesses for the exact solution components* $(\mathbf{y}, \mathbf{p})$.

Proof. Since $\text{SOLVE}_{\text{SCPW}}$ actually determines an approximation to the full triple $(\mathbf{y}, \mathbf{p}, \mathbf{u})$, the notion of τ^*-sparseness of RES_{SCPW} refers to properties of the whole triple. Thus, we have to assume that each of the solution components belongs to ℓ_τ^w for some $\tau > \tau^*$. By Remark 6.1 and our hypothesis on τ^*-efficiency, each $\mathbf{L} \in \{\mathbf{A}, \mathbf{A}^T, \mathbf{T}_Z, \mathbf{T}_Z^T, \mathbf{E}\mathbf{D}_Q^{-1}, \mathbf{D}_Q^{-1}\mathbf{E}^T\}$ is bounded on ℓ_τ^w for $\tau > \tau^*$. Thus, for the first system in (EE′) this implies

$$\|\boldsymbol{f}\|_{\ell_\tau^w} \lesssim \|\mathbf{y}\|_{\ell_\tau^w} + \|\mathbf{u}\|_{\ell_\tau^w}. \tag{6.4}$$

Likewise we have

$$\|\mathbf{T}_Z^T \mathbf{y}_Z\|_{\ell_\tau^w} \lesssim \|\mathbf{p}\|_{\ell_\tau^w} + \|\mathbf{y}\|_{\ell_\tau^w}. \tag{6.5}$$

Now, by the assumption (6.2), the quotients δ_v/η, δ_y/η, and δ_p/η are bounded. Therefore, according to step (i) in RES_{SCPW}, the scheme $\text{SOLVE}_{\text{PRM}}$ will invoke only a uniformly bounded finite number of iteration blocks (ii) with corresponding residual approximations RES_{PRM}. From the τ^*-efficiency of $\mathbf{A}$ and $\mathbf{E}\mathbf{D}_Q^{-1}$ and Remark 6.1, we infer that

$$\|\mathbf{y}_\eta\|_{\ell_\tau^w} \lesssim \|\boldsymbol{f}\|_{\ell_\tau^w} + \|\mathbf{v}\|_{\ell_\tau^w} + \|\tilde{\mathbf{y}}\|_{\ell_\tau^w} \lesssim \|\mathbf{y}\|_{\ell_\tau^w} + \|\mathbf{u}\|_{\ell_\tau^w} + \|\mathbf{v}\|_{\ell_\tau^w} + \|\tilde{\mathbf{y}}\|_{\ell_\tau^w}, \tag{6.6}$$

where we used (6.4). Likewise one concludes that the output $\mathbf{p}_\eta$ of step (ii) of RES_{SCPW} satisfies

$$\begin{aligned} \|\mathbf{p}_\eta\|_{\ell_\tau^w} &\lesssim \|\tilde{\mathbf{p}}\|_{\ell_\tau^w} + \|\mathbf{T}_Z^T \mathbf{y}_Z\|_{\ell_\tau^w} + \|\tilde{\mathbf{y}}\|_{\ell_\tau^w} \\ &\lesssim \|\tilde{\mathbf{p}}\|_{\ell_\tau^w} + \|\tilde{\mathbf{y}}\|_{\ell_\tau^w} + \|\mathbf{p}\|_{\ell_\tau^w} + \|\mathbf{y}\|_{\ell_\tau^w}, \end{aligned} \tag{6.7}$$

where we used (6.5) in the last step. (4.21) follows now from (6.6), (6.7), and (6.3). The second part of (4.21) and (ii) of the τ^*-sparseness of RES_{SCPW} can be concluded from τ^*-efficiency of the APPLY schemes in RES_{PRM} and RES_{ADJ}. This confirms the claim. ∎

THEOREM 6.3. *Assume that the* APPLY *schemes appearing in* RES_{PRM} *and* RES_{ADJ} *are* τ^**-efficient for some* $\tau^* < 2$ *and that the components of the solution* $(\mathbf{y}, \mathbf{p}, \mathbf{u})$ *of* (EE) *all belong to the respective space* ℓ_τ^w *for some* $\tau > \tau^*$. *Then the approximate solutions* $\mathbf{y}_\varepsilon, \mathbf{p}_\varepsilon, \mathbf{u}_\varepsilon$, *produced by* $\text{SOLVE}_{\text{SCPW}}$ *for any target accuracy* ε, *satisfy*

$$\|\mathbf{y}_\varepsilon\|_{\ell_\tau^w} + \|\mathbf{p}_\varepsilon\|_{\ell_\tau^w} + \|\mathbf{u}_\varepsilon\|_{\ell_\tau^w} \lesssim \|\mathbf{y}\|_{\ell_\tau^w} + \|\mathbf{p}\|_{\ell_\tau^w} + \|\mathbf{u}\|_{\ell_\tau^w} \tag{6.8}$$

and

$$(\#\operatorname{supp} \mathbf{y}_\varepsilon) + (\#\operatorname{supp} \mathbf{p}_\varepsilon) + (\#\operatorname{supp} \mathbf{u}_\varepsilon) \lesssim \left(\|\mathbf{y}\|_{\ell_\tau^w}^{1/s} + \|\mathbf{p}\|_{\ell_\tau^w}^{1/s} + \|\mathbf{u}\|_{\ell_\tau^w}^{1/s}\right) \varepsilon^{-1/s}, \tag{6.9}$$

where the constants depend only on τ *when* τ *approaches* τ^*. *Moreover, the number of floating point operations required during the execution of* $\text{SOLVE}_{\text{SCPW}}$ *remains proportional to the right-hand side of* (6.9).

Proof. According to Theorem 4.3, it remains to show that at each stage when RES_{SCPW} is called in step (ii.1) of $\text{SOLVE}_{\text{SCPW}}$, the hypotheses (6.2) and (6.3) in Proposition 6.2 are satisfied for some fixed constant C. The claim follows then from Theorem 4.3.

The validity of (6.2) is a consequence of the bounds (5.10) for the initial guesses, the values of η and δ_k in the kth perturbed iteration of the $(j+1)$st call of step (ii.1) of

$\text{SOLVE}_{\text{SCPW}}$, and the initialization bounds (5.15), (5.16), and (5.17). By the coarsening Lemma 4.4 and the coarsening in step (v) of RES_{SCPW}, we know that

$$\|\tilde{\mathbf{y}}\|_{\ell_\tau^w} \lesssim \|\mathbf{y}\|_{\ell_\tau^w}, \quad \|\tilde{\mathbf{p}}\|_{\ell_\tau^w} \lesssim \|\mathbf{p}\|_{\ell_\tau^w}. \tag{6.10}$$

Moreover, since in the $(j+1)$st call of step (ii) in $\text{SOLVE}_{\text{SCPW}}$ $\mathbf{v}^K$ satisfies $\|\mathbf{u}-\mathbf{v}^K\| \le \varepsilon_j/2(1+a)$ (see [CDD3] or (4.10)), we conclude from step (ii.2) in $\text{SOLVE}_{\text{SCPW}}$ and Lemma 4.4 that

$$\|\overline{\mathbf{u}}^j\|_{\ell_\tau^w} \lesssim \|\mathbf{u}\|_{\ell_\tau^w}, \quad j \in \mathbb{N}_0. \tag{6.11}$$

Combining (6.10) and (6.11) confirms the validity of (6.3). ∎

Thus the practical realization of $\text{SOLVE}_{\text{SCPW}}$ providing optimal work/accuracy rates for a possibly large range of decay rates of the error of best N-term approximation hinges on the availability of τ^*-efficient APPLY schemes with possibly small τ^* for the involved operators.

Distributed control. In this regard we discuss first the example in section 2.2.1 for *natural norms*, i.e., $Z = H_0^1(\Omega)$ and $U = Y' = Q = H^{-1}(\Omega)$. In this case, one has $\mathbf{E} = \mathbf{T} = \mathbf{D}_Z = \mathbf{D}_Q = \mathbf{I}$ and $\mathbf{A} = \mathbf{A}^T$. Since the identity mapping is τ^*-efficient for any $\tau^* < 2$, we only have to discuss the τ^*-efficiency of $\mathbf{A}$ defined by (3.20). The fact that one can indeed devise efficient schemes for the approximate application of wavelet representations of a wide class of operators, including differential operators, is a consequence of the cancellation properties (3.3) of wavelets together with the norm equivalences (3.5) for the relevant function spaces. In fact, such representations turn out to be *quasi-sparse* in the following sense. Recall that a matrix $\mathbf{A}$ is called *s^*-compressible* if for any $0 < s < s^*$ there exists a matrix $\mathbf{A}_j$ with at most $\le \alpha_j 2^j$ nonzero entries per row and column such that

$$\|\mathbf{A} - \mathbf{A}_j\| \le \alpha_j 2^{-sj}, \qquad j \in \mathbb{N}_0, \tag{6.12}$$

where $\{\alpha_j\}_{j\in\mathbb{N}_0}$ is any summable sequence.

Denote for a finitely supported vector $\mathbf{v}$ its best 2^j-approximations (given by the 2^j largest wavelet coefficients) by $\mathbf{v}_{[j]} := \mathbf{v}_{2^j}$. Following [CDD1], the expansion

$$\mathbf{w}_j := \mathbf{A}_j\mathbf{v}_{[0]} + \mathbf{A}_{j-1}(\mathbf{v}_{[1]} - \mathbf{v}_{[0]}) + \cdots + \mathbf{A}_0(\mathbf{v}_{[j]} - \mathbf{v}_{[j-1]}) \tag{6.13}$$

approximates $\mathbf{A}\mathbf{v}$. In fact, combining the a priori knowledge (6.12) with the a posteriori information $\|\mathbf{v}_{[k]} - \mathbf{v}_{[k-1]}\|$, one can see that for any finitely supported input $\mathbf{v}$ the error $\|\mathbf{A}\mathbf{v} - \mathbf{w}_j\|$ tends to zero when j grows. Thus, given a tolerance $\eta > 0$, one chooses the smallest j so that the bound for $\|\mathbf{A}\mathbf{v} - \mathbf{w}_j\|$ is less than or equal to η. This leads to a concrete scheme with the following properties.

$\text{APPLY}\,[\eta, \mathbf{A}, \mathbf{v}] \to \mathbf{w}_\eta$ computes for a given tolerance $\eta > 0$ a finitely supported sequence $\mathbf{w}_\eta$ satisfying

$$\|\mathbf{A}\mathbf{v} - \mathbf{w}_\eta\| \le \eta. \tag{6.14}$$

A detailed description and analysis of this routine can be found in [CDD1]. Its implementation has been discussed in [BCDU]. The following essential complexity estimate is taken from [CDD1].

THEOREM 6.4. *If $\mathbf{A}$ is s^*-compressible, then $\mathbf{A}$ is bounded on ℓ_τ^w for $s < s^*$, where τ and s are related by* (4.19), $\frac{1}{\tau} = s + \frac{1}{2}$. *Moreover, for a finitely supported vector $\mathbf{v}$ the output $\mathbf{w}_\eta$ of* $\text{APPLY}\,[\eta, \mathbf{A}, \mathbf{v}]$ *satisfies*

$$\|\mathbf{w}_\eta\|_{\ell_\tau^w} \lesssim \|\mathbf{v}\|_{\ell_\tau^w}, \qquad \#\operatorname{supp}\mathbf{w}_\eta,\ \#\text{flops} \lesssim \eta^{-1/s}\|\mathbf{v}\|_{\ell_\tau^w}^{1/s}. \tag{6.15}$$

Thus, the above scheme APPLY is τ^*-efficient for $\tau^* = (s^* + 1/2)^{-1}$ whenever $\mathbf{A}$ is s^*-compressible. It is known that s^* is larger the higher the regularity and the order of cancellation properties of the wavelets are for all the differential operators considered in section 2. Bounds for s^* in terms of these quantities for families of spline wavelets can be found, e.g., in [BCDU]. Hence, Theorem 6.3 ensures asymptotically optimal complexity bounds in the range $\tau > \tau^*$, i.e., the scheme $\text{SOLVE}_{\text{SCPW}}$ recovers rates of the error of best N-term approximation of order N^{-s} for $s < s^*$.

Now consider the same example but with a strictly larger space $Z \supset Y$ and a strictly smaller space $U \subset Q = Y'$. While one still has $\mathbf{E} = \mathbf{T} = \mathbf{I}$, the matrices $\mathbf{D}_Z, \mathbf{D}_Q$ are nontrivial scalings of the form $\mathbf{D}_Z = \mathbf{D}^\gamma$, i.e., $(\mathbf{D}_Z)_{\lambda,\nu} = 2^{\gamma|\lambda|}\delta_{\lambda,\nu}$, and $\mathbf{D}_Q = \mathbf{D}^\beta$ for some positive numbers $\gamma, \beta > 0$. The system (EE′) then takes the form

$$\begin{aligned} \mathbf{A}\mathbf{y} &= \boldsymbol{f} + \mathbf{D}^{-\beta}\mathbf{u}, \\ \mathbf{A}^T\mathbf{p} &= -\mathbf{D}^{-2\gamma}(\mathbf{y} - \mathbf{y}_*), \\ \omega\mathbf{u} &= \mathbf{D}^{-\beta}\mathbf{p}. \end{aligned} \tag{6.16}$$

First, the scaling smoothes the right-hand sides of the first two equations and favors their sparsity. Since it is important to understand the effect of such scalings in the present context, in particular in connection with the application of the operators $\mathbf{T}, \mathbf{E}$, we shall next make this point more precise. It is perhaps instructive to relate this first briefly to regularity issues. To this end, suppose that Ψ_H is a Riesz basis for a Sobolev space $H = H^t$ with respect to a bounded domain in $\mathbb{R}^d$. Besov spaces $B_p^{t+\gamma}(L_p)$, measuring smoothness in L_p, are then known, by the Sobolev embedding theorem, to be embedded in H^t whenever $p^{-1} \le \gamma/d + 1/2$. The smaller p is, the larger is $B_p^{t+\gamma}(L_p)$, which admits more singularities compared with the space $H^{t+\gamma}$ of the same smoothness level but measured in L_2. For a certain range of smoothness indices γ, depending on the regularity of the wavelets, an equivalent seminorm for $B_p^{t+\gamma}(L_p)$ can be given as a weighted sequence norm of wavelet coefficients (see, e.g., [D2, DeV]),

$$|v|^p_{B_p^{t+\gamma}(L_p)} := \sum_{\lambda\in\mathbb{I}} 2^{|\lambda| p d\left(\frac{\gamma}{d} + \frac{1}{2} - \frac{1}{p}\right)} |v_\lambda|^p. \tag{6.17}$$

Note that the scaling for t is already incorporated in the normalization of the wavelet basis. Specifically, when $\tau^{-1} = \gamma/d + 1/2$, the Besov norm $\|\cdot\|_{B_\tau^{t+\gamma}(L_\tau)}$ is equivalent to the ℓ_τ-norm of the wavelet coefficients. Therefore, the membership to such a Besov space on the Sobolev embedding line is, in view of (4.18), *almost* equivalent to saying that the sequence of wavelet coefficients belongs to the corresponding weak ℓ_τ-space and hence has a best N-term approximation rate of $N^{-\gamma/d}$; see Proposition 4.2. This means that nonlinear approximation, like best N-term approximation, compensates for the loss of regularity between $H^{t+\gamma}$ and $B_\tau^{t+\gamma}(L_\tau)$ in that the same approximation rate (in terms of degrees of freedoms) is preserved for $B_\tau^{t+\gamma}(L_\tau)$, that would be achievable in the smaller space $H^{t+\gamma}$ with the aid of uniform mesh refinements. It immediately follows now from (6.17) that

$$v = \mathbf{v}^T\Psi_H \in B_\tau^{t+\gamma}(L_\tau) \quad \text{implies} \quad w = (\mathbf{D}^{-\beta}\mathbf{v})^T\Psi_H \in B_\tau^{t+\gamma+\beta}(L_\tau) \subset B_{\tau'}^{t+\gamma}(L_{\tau'}), \tag{6.18}$$

where τ' is the critical index for the higher smoothness level $\gamma + \beta$.

$$\frac{1}{\tau'} = \frac{\gamma+\beta}{d} + \frac{1}{2}. \tag{6.19}$$

Note that τ' and τ are related by $\frac{1}{\tau'} - \frac{1}{\tau} = \frac{\beta}{d}$. The next observation says that scaling by $\mathbf{D}^{-\beta}$ effects exactly the same shift also between *weak* ℓ_τ-spaces that *precisely* characterize best N-term approximation whose order therefore grows, on account of Proposition 4.2 by β/d.

PROPOSITION 6.5. *One has that*

$$\mathbf{p} \in \ell^w_\tau \quad \textit{implies} \quad \mathbf{D}^{-\beta}\mathbf{p} \in \ell^w_{\tau'}, \quad \textit{where} \quad \frac{1}{\tau'} := \frac{1}{\tau} + \frac{\beta}{d}. \tag{6.20}$$

Moreover, this result is sharp in the sense that for no $\tau'' < \tau'$ there holds $\mathbf{D}^{-\beta}\mathbf{p} \in \ell^w_{\tau''}$ for all $\mathbf{p} \in \ell^w_\tau$.

Proof. Let $C > 1$ be a fixed constant that later will be chosen at our convenience. Let $\mathcal{P}$ be the class of those $\mathbf{p} \in \ell^w_\tau$ with $\|\mathbf{p}\|_{\ell^w_\tau} \le C^{1/\tau}$ and let $\tilde{\mathbf{p}} := \mathbf{D}^{-\beta}\mathbf{p}$. Consider the set

$$\tilde{\Lambda}_{(J)} := \{\lambda : |\tilde{p}_\lambda| \ge \eta_J\}, \qquad \text{where } \eta_J := 2^{-J\tau/\tau'}.$$

In view of the definition of $\ell^w_{\tau'}$ in (4.15), we have to show that the cardinality of $\tilde{\Lambda}_{(J)}$ increases at most like $2^{J\tau}$. (Standard arguments imply then that $\#\{\lambda : |\tilde{p}_\lambda| \ge \eta\} \lesssim \eta^{-\tilde{\tau}}$ for any $\eta \le 1$.) To this end, we determine first which of the sets

$$\Lambda_j := \{\lambda : 2^{-j} \le |p_\lambda| < 2^{-j+1}\}$$

is always fully contained in $\tilde{\Lambda}_{(J)}$. We know from [CDD1] that $\#\Lambda_j \le C2^{j\tau}$. Without loss of generality we may assume that $\#\Lambda_j = C2^{j\tau}$ to cover the largest possible sets. Since the entries of $\tilde{\mathbf{p}}$ arise from those of $\mathbf{p}$ by scaling with the weights $2^{-\beta|\lambda|} \le 1$, the smaller the levels $|\lambda|$ in these weights, the better the chance for $\lambda \in \Lambda_j$ to belong to $\tilde{\Lambda}_{(J)}$. Thus, to ensure that for any $\mathbf{p} \in \mathcal{P}$ the set Λ_j is contained in $\tilde{\Lambda}_{(J)}$, we must be able to find $C2^{j\tau}$ indices λ with possibly small $|\lambda|$ such that $2^{-\beta|\lambda|}2^{-j} \ge \eta_J$. This count clearly involves the spatial dimension d since $c2^{jd}$ indices λ of level $|\lambda| = j$ can occur. Here the constant c depends on the spatial dimension of the functions whose wavelet coefficients are considered. Thus, the smallest possible maximum level L_j of these indices is therefore determined by $c2^{dL_j} = C2^{j\tau}$, i.e., $L_j = j\tau/d + \left(\log_2 \frac{C}{c}\right)/d$. Assume for convenience that $C/c \ge 1$. Then, for $\lambda \in \Lambda_j$ we conclude

$$|\tilde{p}_\lambda| \ge 2^{-\beta|\lambda|}2^{-j} \ge 2^{-(\beta L_j + j)} = 2^{-j\left(\frac{d+\beta\tau}{d}\right)}(C/c)^{\beta/d} \ge 2^{-j\tau/\tau'}. \tag{6.21}$$

Thus, $\Lambda_j \subset \tilde{\Lambda}_{(J)}$ for $j \le J$. On the other hand, since for $\lambda \in \Lambda_j$ one also has $|\tilde{p}_\lambda| \le 2^{-\beta|\lambda|-j+1}$, not all the indices in Λ_j can always be contained in $\tilde{\Lambda}_{(J)}$ for $j \ge J$ and any choice of $\mathbf{p} \in \mathcal{P}$. To determine the maximum number of $\lambda \in \Lambda_{J+k}$ for $k \in \mathbb{N}$ that can belong to $\tilde{\Lambda}_{(J)}$ for any $\mathbf{p} \in \mathcal{P}$, we must have in view of (6.21) $|\lambda| \le \ell_k$, where $\beta\ell_k + J + k \le J\tau/\tau'$. Using that $(\tau/\tau') - 1 = \beta\tau/d$, straightforward calculations yield $\ell_k \le \frac{J\tau}{d} - \frac{k}{\beta}$. Thus, we can assign at most $2^{d\ell_k}$ scaling weights to Λ_j to keep $|\tilde{p}_\lambda| \ge \eta_J$ for that many $\lambda \in \Lambda_{J+k}$. Moreover, the set Λ_{J+k} is disjoint from $\tilde{\Lambda}_{(J)}$ whenever $2^{-(J+k)+1} \le \eta_J$, which is the case when $k \ge 1 + J\tau\beta/d$. Hence, we have

$$\sum_{k\in\mathbb{N}} \#(\Lambda_{J+k} \cap \tilde{\Lambda}_{(J)}) \le \sum_{k=1}^{J\tau\beta/d} 2^{d\ell_k} = \sum_{k=1}^{J\tau\beta/d} 2^{\frac{d}{\beta}\left(\frac{J\tau\beta}{d} - k\right)} \lesssim 2^{J\tau}. \tag{6.22}$$

Since $\mathbb{I} = \bigcup_{j\ge 0} \Lambda_j$ and $\sum_{j\le J} \#\Lambda_j \lesssim 2^{J\tau}$, we conclude from (6.22) that $\#\tilde{\Lambda}_{(J)} \lesssim 2^{J\tau} = \eta^{-\tau'}$ for $\eta = 2^{-J\tau/\tau'}$. This confirms (6.20).

To verify the rest of the assertion, consider $\mathbf{p}$, whose decreasing rearrangement is given by $p_n^* = n^{-1/\tau}$ while $\tilde{p}_n^* = 2^{-\beta(j+1)} n^{-1/\tau}$ for $2^{dj} < n \le 2^{d(j+1)}$. Then

$$\begin{aligned}\sigma_{2^{dj}}(\tilde{\mathbf{p}})^2 &= \sum_{n>2^{dj}} (\tilde{p}_n^*)^2 \gtrsim \sum_{j=J}^{\infty} \sum_{2^{jd}<n\le 2^{d(j+1)}} n^{-2/\tau} 2^{-2\beta(j+1)} \\ &\gtrsim \sum_{j=J}^{\infty} 2^{-2dj\left(\frac{1}{\tau}+\frac{\beta}{d}-\frac{1}{2}\right)} \gtrsim \left(2^{-dJs'}\right)^2,\end{aligned}$$

where $s' = \frac{1}{\tau'} - \frac{1}{2}$. Thus, by Proposition 4.2, $\mathbf{p} \notin \ell_{\tau''}^w$ for any $\tau'' < \tau'$, which finishes the proof. □

Therefore, whatever the sparsity class of the adjoint variable $\mathbf{p}$, the third equation in (6.16) says, in view of Proposition 6.5, that the control $\mathbf{u}$ is even sparser. Thus, although the control $\mathbf{u}$ may be accurately recovered with relatively few degrees of freedom, the overall solution complexity in the above case is bounded from below by the (perhaps) less sparse auxiliary variable $\mathbf{p}$.

As a possible remedy one might think of introducing the variable $\tilde{\mathbf{p}} = \mathbf{D}^{-\beta}\mathbf{p}$ (to replace $\mathbf{p}$ by a sparser variable) and rewrite the second system in (6.16) as

$$\tilde{\mathbf{A}}^T \tilde{\mathbf{p}} = \mathbf{D}^{-\beta}\mathbf{D}^{-2\gamma}(\mathbf{y}_* - \mathbf{y}), \quad \tilde{\mathbf{A}} := \mathbf{D}^{\beta}\mathbf{A}\mathbf{D}^{-\beta}.$$

To apply our complexity analysis we could assume now that $\tilde{\mathbf{p}}$ has a certain sparsity which would then naturally be the same as the sparsity of $\mathbf{u}$. But although the matrix $\tilde{\mathbf{A}}$ has still the same spectrum as $\mathbf{A}$ and hence is an ℓ_2-automorphism for which the gradient iteration would still converge, it is presumably less compressible. In fact, the unsymmetric scaling means that we only have an estimate of the form

$$|(\tilde{\mathbf{A}})_{\lambda,\nu}| \lesssim 2^{\beta(|\nu|-|\lambda|)} 2^{-\sigma||\lambda|-|\nu||},$$

where σ results from the regularity of the wavelets and determines the original compressibility of $\mathbf{A}$.

So, in summary, in the case of a distributed control the solution complexity is determined not by the sparseness of the control but by that of the remaining variables in (EE′).

Boundary control. The situation is different for the example from section 2.2.3. Recall that in this case $Y = H^1(\Omega)$, $Q = (H^{1/2}(\Gamma_c))'$ so that $E : (H^{1/2}(\Gamma_c))' \to (H^1(\Omega))'$ is the extension operator defined by (2.16). Choosing $Z = H^{1-\gamma}(\Omega)$ for $0 \le \gamma \le 1$ as the observation space, T is the canonical injection and

$$\mathbf{T} = \mathbf{I}, \qquad \mathbf{T}_Z = \mathbf{D}^{\gamma} = \mathbf{D}_Z. \tag{6.23}$$

Choosing bases $\Psi_Q \subset Q = (H^{1/2}(\Gamma_c))'$, $\tilde{\Psi}_Q \subset Q' = H^{1/2}(\Gamma_c)$, and $\Psi_Y \subset Y = H^1(\Omega)$, $\tilde{\Psi}_Y \subset (H^1(\Omega))'$, (2.16), and (3.20) say that $\mathbf{E}$ is given by

$$\mathbf{E} = \langle \iota\Psi_Y, \tilde{\Psi}_Q \rangle, \quad \mathbf{E}^T = \langle \tilde{\Psi}_Q, \iota\Psi_Y \rangle. \tag{6.24}$$

Thus, the entries of $\mathbf{E}$ are inner products of traces of wavelets on Ω with wavelets on the control boundary Γ_c. Choosing $U = L_2(\Gamma_c)$, the Euler–Lagrange system (EE′) now reads

$$\begin{aligned}\mathbf{A}\mathbf{y} &= \boldsymbol{f} + \mathbf{E}\mathbf{D}^{-1/2}\mathbf{u}, \\ \mathbf{A}^T\mathbf{p} &= -\mathbf{D}^{-2\gamma}(\mathbf{y} - \mathbf{y}_*), \\ \omega\mathbf{u} &= \mathbf{D}^{-1/2}\mathbf{E}^T\mathbf{p}.\end{aligned} \tag{6.25}$$

Recall that the sparsity of solutions of the first two systems in (6.25) is exploited by the compressibility of $\mathbf{A}$ up to the limiting index s^* which depends only on the cancellation properties and the regularity of Ψ_Y and not on the particular differential operator. In contrast, as shown in [M], $\mathbf{E}$ is τ^*-efficient only for $\tau^* \geq 1$, i.e., $\mathbf{E}^T$ is not bounded on ℓ_τ^w for $\tau < 1$. In other words, $\mathbf{E}^T$ is at most s^*-compressible for $s^* = 1/2$. This is because traces of wavelets are in general no longer wavelets, so this factor does not have any cancellation properties that help keep the entries of $\mathbf{E}$ small. Thus, in this case, even when $\mathbf{p}$ is highly sparse in the sense that $\mathbf{p}$ belongs to ℓ_τ^w for τ much smaller than 1, the application of $\mathbf{E}^T$ in the third equation of (6.25) reduces that sparsity when computing the control $\mathbf{u}$. However, the scaling $\mathbf{D}_Q^{-1} = \mathbf{D}^{-1/2}$ raises the order of compressibility by Proposition 6.5 to $s^* = 1$. This also can be seen directly because it enhances the decay of the entries of $\mathbf{E}^T$ along each row. Without the attenuation caused by the scaling, the latter decay is weak due to the lack of vanishing moments of the traces of domain wavelets.

7. Special cases and alternatives. We address in this section some special issues concerning alternative solution strategies as well as the mandatory case when retaining the exact reference objective functional (CP), respectively, (CPW). Several cases arise.

(I) Recall from Remark 3.5 that in the special situation (SC) with natural norms, (3.56) is equivalent to the equation

$$\mathbf{M}\mathbf{u} := (\mathbf{I} + \omega \mathbf{A}\mathbf{A}^T)\mathbf{u} = \mathbf{A}\mathbf{y}_* - \boldsymbol{f}. \tag{7.1}$$

A twofold application of the scheme APPLY to $\mathbf{A}$, $\mathbf{A}^T$ immediately yields a τ^*-efficient evaluation scheme for $\mathbf{M}$. Thus we can apply here the scheme SOLVE introduced in section 4.1 directly without any inner iterations. Moreover, the solution complexity is now completely governed by the compressibility of $\mathbf{A}$ and by the sparsity of the control $\mathbf{u}$.

In this case one can therefore still efficiently solve the exact reference problem (CPW) that involves the Riesz maps. This is illustrated best by the example (3.43). Using appropriate wavelet bases, $\mathbf{A}, \boldsymbol{\Delta}$ are ℓ_2-automorphisms, so that the application of SOLVE to $\mathbf{M}\mathbf{u} = \mathbf{A}\mathbf{y}_* - \boldsymbol{f}$ with $\mathbf{M} := (\mathbf{I} + \omega \mathbf{A}\boldsymbol{\Delta}^{-1}\mathbf{A}^T\boldsymbol{\Delta}^{-1})$ is feasible. The application of $\mathbf{M}$ can then be realized in a way similar to $\text{SOLVE}_{\text{SCPW}}$ through suitable inner iterations. An advantage is that now only systems involving the Laplacian have to be solved instead of possibly more complicated operator equations with variable coefficients.

(II) So far $\text{SOLVE}_{\text{SCPW}}$ has been confined to the problem (3.56), which is only a representer of (CP) in the ambiguous case. However, at least for the cases listed in Remark 3.8 (where the necessity for realizing a specific norm is more conceivable), we can extend $\text{SOLVE}_{\text{SCPW}}$ so as to apply it to the original reference formulation (CPW). In this case, one could solve (3.39) based on the system (EE) and Lemma 3.7. In view of (3.45) and (3.46) in the system (EE), this now requires the additional application of $\mathbf{R}_Z$ and $\mathbf{R}_U$ in the scheme $\text{SOLVE}_{\text{ADJ}}$. This is feasible for the cases listed in Remark 3.8. The scheme APPLY can then be applied with optimal complexity. This requires an evaluation of the Riesz operators within suitable dynamically updated tolerances which have to be taken into proper account. Since the reasoning is completely analogous to the previous case, we omit the details.

Nevertheless, the question remains how to extend the scheme $\text{SOLVE}_{\text{SCPW}}$ to scenarios where a specific cost functional should be kept although the norms do not fall

into the category described in Remark 3.1 and therefore usually do not have canonical representers. One could then strive for representers of (CP) that approximate the specific reference formulation in a quantitatively better way. This could be done by using better approximations to $\mathbf{R}_Z, \mathbf{R}_U$ which are still efficiently applicable. These applications have to be incorporated in $\text{SOLVE}_{\text{SCPW}}$ as explained above. In a nonadaptive context the effect of such strategies is investigated in [BK], where $\mathbf{R}_Z, \mathbf{R}_U$ are replaced by scaled L_2-mass matrices of the respective wavelet bases.

8. Concluding remarks. We have developed a class of fully adaptive schemes for the solution of optimal control problems with elliptic boundary problems as constraints. The approach is based on a gradient descent iteration for the corresponding full infinite dimensional variational problem in wavelet coordinates. The various possible ways of formulating this infinite dimensional variational problem through elimination of the state variable reveal preferences with regard to well-posedness that would perhaps not be so apparent when working from the beginning with a finite dimensional discretization. The numerical realization of the adaptive solution concepts relies on the adaptive application of the involved operators within stage-dependent dynamically updated tolerances. The complexity of such schemes is shown to hinge on the properties of these application routines. Concrete realizations of such schemes are exhibited in several simple cases. This sheds some light on the different inherent complexity properties of distributed versus boundary control problems also in connection with different choices of norms in the objective functional. We refer to [BK] for first numerical experiments with algorithms of the above form with uniform refinements where the influence of different norms as a modeling tool is explored.

We have not considered here so far the quantitative role of the regularization parameter ω in (2.3), (6.16), or (6.25). Its variation affects all scales simultaneously, while the diagonal scalings representing different smoothness norms treat high and low frequencies differently. The concepts presented here unfold their full potential when the problem context allows one to modify the cost functional within classes of equivalent norms. We have indicated the limitations when this is not the case, as well as possible remedies. This issue is also addressed in the experiments in [BK]. It turns out that when no regularization is needed, the scheme is robust when ω tends to zero and produces the correct solution. Corresponding numerical experiments for the above adaptive version will be presented and discussed in a forthcoming paper.

Acknowledgments. We are indebted to the referees for valuable comments and suggestions that helped us improve the presentation of the material. A comment in one of the reports motivated part of the material presented in section 7.

SENSITIVITY ANALYSIS USING ITÔ–MALLIAVIN CALCULUS AND MARTINGALES, AND APPLICATION TO STOCHASTIC OPTIMAL CONTROL*

EMMANUEL GOBET† AND RÉMI MUNOS†

Abstract. We consider a multidimensional diffusion process $(X_t^\alpha)_{0\le t\le T}$ whose dynamics depends on a parameter α. Our first purpose is to write as an expectation the sensitivity $\nabla_\alpha J(\alpha)$ for the expected cost $J(\alpha) = \mathbb{E}(f(X_T^\alpha))$, in order to evaluate it using Monte Carlo simulations. This issue arises, for example, from stochastic control problems (where the controller is parameterized, which reduces the control problem to a parametric optimization one) or from model misspecifications in finance. Previous evaluations of $\nabla_\alpha J(\alpha)$ using simulations were limited to smooth cost functions f or to diffusion coefficients not depending on α (see Yang and Kushner, *SIAM J. Control Optim.*, 29 (1991), pp. 1216–1249). In this paper, we cover the general case, deriving three new approaches to evaluate $\nabla_\alpha J(\alpha)$, which we call the *Malliavin calculus approach*, the *adjoint approach*, and the *martingale approach*. To accomplish this, we leverage Itô calculus, Malliavin calculus, and martingale arguments. In the second part of this work, we provide discretization procedures to simulate the relevant random variables; then we analyze their respective errors. This analysis proves that the discretization error is essentially linear with respect to the time step. This result, which was already known in some specific situations, appears to be true in this much wider context. Finally, we provide numerical experiments in random mechanics and finance and compare the different methods in terms of variance, complexity, computational time, and time discretization error.

Key words. sensitivity analysis, parameterized control, Malliavin calculus, weak approximation

DOI. 10.1137/S0363012902419059

1. Introduction.

We consider a d-dimensional stochastic differential equation (SDE) defined by

$$X_t = x + \int_0^t b(s, X_s, \alpha)\, ds + \sum_{j=1}^{q} \int_0^t \sigma_j(s, X_s, \alpha)\, dW_s^j, \tag{1.1}$$

where α is a parameter (taking values in $\mathcal{A} \subset \mathbb{R}^m$) and $(W_t)_{0\le t\le T}$ is a standard Brownian motion in $\mathbb{R}^q$ on a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{0\le t\le T}, \mathbb{P})$, with the usual assumptions on the filtration $(\mathcal{F}_t)_{0\le t\le T}$.

We first aim at evaluating the sensitivity w.r.t. α of the expected cost

$$J(\alpha) = \mathbb{E}\left(f(X_T)\right), \tag{1.2}$$

for a given terminal cost f and for a fixed time T. The sensitivity of more general functionals including instantaneous costs like $\mathbb{E}\big(\int_0^T g(t, X_t)dt + f(X_T)\big) = \int_0^T \mathbb{E}(g(t, X_t))dt + \mathbb{E}(f(X_T))$ will follow by discretizing the integral and applying the sensitivity estimator for each time.

This evaluation is a typical issue raised in various applications. A first example is the analysis of the impact on the expected cost $J(\alpha)$ of a misspecification of a stochastic model (defined by a SDE with coefficients $\bar{b}(t, x)$ and $(\bar{\sigma}_j(t, x))_{1\le j\le q}$). The issue

*Received by the editors December 3, 2002; accepted for publication (in revised form) July 5, 2004; published electronically March 11, 2005.

†Centre de Mathématiques Appliquées, Ecole Polytechnique, 91128 Palaiseau Cedex, France (emmanuel.gobet@polytechnique.fr, remi.munos@polytechnique.fr).

may be formulated by setting $b(t,x,\alpha) = \bar{b}(t,x) + \sum_{i=1}^{m} \alpha_i \phi_i(t,x)$ (and analogously for $(\sigma_j(t,x,\alpha))_{1\le j\le q}$), then computing the sensitivities at the point $\alpha = 0$. In finance, misspecifications in option pricing procedures usually concern the diffusion coefficients $(\bar{\sigma}_j(t,x))_{1\le j\le q}$ (the *volatility* of the assets). There are also some connections with the so-called model risk problem (see Cvitanić and Karatzas [CK99]).

Stochastic control is another field requiring sensitivity analysis. For instance, if the controlled SDE is defined by $dX_t = \bar{b}(t,X_t,u_t)\ dt + \sum_{j=1}^{q} \bar{\sigma}_j(t,X_t,u_t) dW_t^j$, the problem is to find the maximal value of $\mathbb{E}(f(X_T))$ among the admissible policies $(u_t)_{0\le t\le T}$. In low dimensions (say 1 or 2), numerical methods based on the dynamic programming principle can be successfully implemented (see Kushner and Dupuis [KD01] for some references), but they become inefficient in higher dimensions. Alternatively, one can use *policy search* algorithms (see [BB01] and references therein). It consists in seeking a *good* policy in a feedback form using a parametric representation, that is, $u_t = u(t,X_t,\alpha)$: in that case, one puts $b(t,x,\alpha) = \bar{b}(t,x,u(t,x,\alpha))$ and $\sigma_j(t,x,\alpha) = \bar{\sigma}_j(t,x,u(t,x,\alpha))$. The policy function $u(t,x,\alpha)$ can be parameterized through a linear approximation (a linear combination of basis functions) or through a nonlinear one (e.g., with neural networks, see Rumelhart and McClelland [RM86] or Haykin [Hay94] for general references). Then, one might use a standard parametric optimization procedure such as the stochastic gradient method or other stochastic approximation algorithms (see Polyak [Pol87]; Benveniste, Metivier, and Priouret [BMP90]; Kushner and Yin [KY97]), which require sensitivity estimations of $J(\alpha)$ w.r.t. α, such as $\nabla_\alpha J(\alpha)$. This gradient is the quantity we will focus on in this paper.

Since the setting is a priori multidimensional, we propose a Monte Carlo approach for the numerical computations. The evaluation of $J(\alpha)$ is standard and has been widely studied. For an introduction to numerical approximations of SDEs, we refer the reader to Kloeden and Platen [KP95], for instance. To our knowledge, there are three different approaches to compute $\nabla_\alpha J(\alpha)$ in our context:

1. The *resampling method* (see Glasserman and Yao [GY92], L'Ecuyer and Perron [LP94] for instance), which consists in computing different values of $J(\alpha)$ for some close values of the parameter α and then forming some appropriate differences to approximate the derivatives. However, not only is it costly when the dimension of the parameter α is large, but it also provides biased estimators.
2. The *pathwise method* (proposed in our context by Yang and Kushner [YK91]), which consists in putting the gradient inside the expectation, involving ∇f and $\nabla_\alpha X_T$. Then, $\nabla_\alpha J(\alpha)$ is expressed as an expectation (see Proposition 1.1 below) and Monte Carlo methods can be used. One limitation of this method is that the cost function f has to be smooth.
3. The so-called *likelihood method* or *score method* (introduced by Glynn [Gly86, Gly87], Reiman and Weiss [RW86]; see also Broadie and Glasserman [BG96] for applications to the computation of Greeks in finance), in which the gradient is rewritten as $\mathbb{E}(f(X_T)H)$ for some random variable H. There is no uniqueness in this representation, since we can add to H any random variables orthogonal to X_T. Unlike the pathwise method, this method is not limited to smooth cost functions. Usually, H is equal to $\nabla_\alpha(\log(p(\alpha,X_T)))$, where $p(\alpha,.)$ is the density w.r.t. the Lebesgue measure of the law of X_T. This has some strong limitations in our context since this quantity is generally unknown. However, Yang and Kushner [YK91] provide explicit weights H, under the restrictions that α concerns only b (and not σ_j) and that the diffusion coefficient is elliptic, using the Girsanov theorem (see Proposition 2.6).

A **first purpose** of this work is to handle more general situations where both coefficients defining the SDE (1.1) depend on α. To address this issue, we provide three new approaches to express the sensitivity of $J(\alpha)$ with respect to α.

1. The first one is an extension of the likelihood approach method to the case of diffusion coefficients depending on α. It uses a direct integration-by-parts formula of the Malliavin calculus. This idea has been used recently in a financial context in the paper by Fournié et al. [FLL$^+$99] to compute option prices' sensitivities. These techniques have also been used efficiently by the first author to derive asymptotic properties of statistical procedures when we estimate parameters defining a SDE (see [Gob01b, Gob02]). Actually, our true contribution concerns essentially a situation where ellipticity is replaced by a weaker (but standard) nondegeneracy condition, which addresses random mechanics problems or portfolio optimization problems in finance.
2. The second approach is rather different from previous methods. Indeed, we initially focus on the adjoint point of view (see Bensoussan [Ben88] or Peng [Pen90]) to finally derive new formulae, involving again some integration-by-parts formula, but written in a simple way (using only Itô's calculus). In stochastic control problems, adjoint processes are related to backward SDEs (see Yong and Zhou [YZ99], e.g.), and their simulation is an extremely difficult and costly task. Here, we circumvent this difficulty since we only need to express them as explicit conditional expectations, which is feasible.
3. The third approach follows from martingale arguments applied to the expected cost and leads to an original representation, which appears to be surprisingly simple.

To compare these new methods with the previous ones, we will measure in section 5, on the one hand, the variance of the random variables involved in the resulting formulae for $\nabla_\alpha J(\alpha)$, and on the other hand, the computational time. Surprisingly, the three methods that we propose behave similarly in terms of variance, but the most efficient in terms of computational time is certainly the *martingale approach* (see Tables 5.1, 5.2, 5.3, 5.4, and 5.5).

Another element of comparison is the influence of the time step h, which is used to approximately simulate the random variables. The analysis of these discretization errors is the second significant part of this work. The relevant random variables are essentially written as the product of the cost function $f(X_T)$ by a random variable H, and simulations are based on Euler schemes. Although H has a complex form, we first propose an approximation algorithm and then we analyze the induced error w.r.t. the time step h. This part of the paper is original: previous results in the literature concern the approximation of $\mathbb{E}(f(X_T))$ (see Bally and Talay [BT96a]) or more generally of some smooth functionals of X (see Kohatsu-Higa and Pettersson [KHP00], [KHP02]). Here, regarding the techniques, we improve estimates given in [KHP00] since we do not need to add a small perturbation to the processes. Our multidimensional framework also raises extra difficulties compared to [KHP02], and we develop specific localization techniques that are interesting for themselves.

Outline of the paper. In the following, we make some assumptions and define the notations which will be used throughout the paper. We also recall the *pathwise* approach in Proposition 1.1. In section 2, after giving some standard facts on the Malliavin calculus, we develop our three approaches to computing the sensitivity of $J(\alpha)$ w.r.t. α: these are the so-called *Malliavin calculus* approach (Propositions 2.5 and 2.8), the *adjoint* approach (Theorem 2.11), and the *martingale* approach (Theorem 2.12). In section 3, we provide simulation procedures to compute $\nabla_\alpha J(\alpha)$ by

the usual Monte Carlo approach using the methods developed before and analyze the influence of the time step h used for Euler-type schemes. A significant part of the paper covers these analyses which have never been developed before in the literature. The approximation results are stated in Theorems 3.1, 3.2, 3.4, and 3.5, while their proofs are postponed to section 4. Finally, numerical experiments in section 5 illustrate the developed methods: we compare the computational time, the complexity, the variance, and the time discretization error of the estimators on many examples borrowed from finance and control.

Assumptions. In our applications, the parameter is a priori multidimensional, but since in the following we will look at sensitivities w.r.t. α coordinatewise, it is not a restriction to assume that the parameter space $\mathcal{A}$ is a subset of $\mathbb{R}$ ($m = 1$).

The process defined in (1.1) depends on the parameter α, but we deliberately omit this dependence in the notation. Furthermore, the initial condition $X_0 = x$ is fixed throughout the paper. We note σ_j, the jth column vector of σ.

To study the sensitivity of J (defined in (1.2)) w.r.t. α, we may assume that coefficients are smooth enough: in what follows, k is an integer greater than 2.

ASSUMPTION (R_k). *The functions b and σ are of class C^1 w.r.t. the variables t, x, α, and for some $\eta > 0$, the following Hölder continuity condition holds:*

$$\sup_{(t,x,\alpha,\alpha')\in[0,T]\times\mathbb{R}^d\times\mathcal{A}\times\mathcal{A}} \frac{|g(t,x,\alpha) - g(t,x,\alpha')|}{|\alpha - \alpha'|^\eta} < \infty$$

for $g = \partial_\alpha b$ and $g = \partial_\alpha \sigma$. Furthermore, for any $\alpha \in \mathcal{A}$, the functions $b(\cdot,\cdot,\alpha)$, $\sigma(\cdot,\cdot,\alpha)$, $\partial_\alpha b(\cdot,\cdot,\alpha)$, and $\partial_\alpha\sigma(\cdot,\cdot,\alpha)$ are of class $C^{\lfloor k/2\rfloor,k}$ w.r.t. (t,x); the functions $\partial_\alpha b$ and $\partial_\alpha\sigma$ are uniformly bounded in (t,x,α), and the derivatives of b, σ, $\partial_\alpha b$, and $\partial_\alpha\sigma$ w.r.t. (t,x) are uniformly bounded as well.

Note that b and σ may be unbounded. We do not assert that the assumption above is the weakest possible, but it is sufficient for our purpose. At several places, the diffusion coefficient will be required to be uniformly elliptic, in the following sense.

ASSUMPTION (E). *σ is a squared matrix ($q = d$) such that the matrix $\sigma\sigma^*$ satisfies a uniform ellipticity condition:*

$$\forall (t,x) \in [0,T]\times\mathbb{R}^d, \qquad [\sigma\sigma^*](t,x,\alpha) \geq \mu_{\min}\, \mathrm{I}_d$$

for a real number $\mu_{\min} > 0$.

Notation.

- *Sensitivity estimators.* To clarify the connection between our methods and the estimators H which are derived, we will write $H_T^{Path.}$ for the pathwise approach (Proposition 1.1), $H_T^{Mall.Ell.}$ (resp., $H_T^{Mall.Gen.}$) for the Malliavin calculus approach in the elliptic case (resp., in the general case) (Propositions 2.5 and 2.8), $H_T^{b,Adj.}$ and $H_T^{\sigma,Adj.}$ for the adjoint approach (Theorem 2.11), and $H_T^{Mart.}$ for the martingale approach (Theorem 2.12). The subscript T refers to the time in the expected cost (1.2). Their approximations using some discretization procedure with N time steps will be denoted $H_T^{Path.,N}$, $H_T^{Mall.Ell.,N}$, and so on.
- *Differentiation.* As usual, derivatives w.r.t. α will be simply denoted with a dot, for instance, $\partial_\alpha J = \dot{J}$. If no ambiguity is possible, we will omit to write explicitly the parameter α in b, $\sigma_j \cdots$. We adopt the following usual convention on the gradients: if $\psi : \mathbb{R}^{p_2} \mapsto \mathbb{R}^{p_1}$ is a differentiable function, its gradient $\nabla_x\psi(x) = (\partial_{x_1}\psi(x), \ldots, \partial_{x_{p_2}}\psi(x))$ takes values in $\mathbb{R}^{p_1}\otimes\mathbb{R}^{p_2}$. At many places, $\nabla_x\psi(x)$ will simply be denoted $\psi'(x)$.

- *Linear algebra.* The rth column of a matrix A will be denoted A_r (or $A_{r,t}$ if A is a time dependent matrix), and the rth element of a vector a will be denoted a_r (or $a_{r,t}$ if a is a time dependent vector). A^* stands for the transpose of A. For a matrix A, the matrix obtained by keeping only the last r rows (resp., the last r columns) will be denoted $\Pi_r^R(A)$ (resp., $\Pi_r^C(A)$). For $i \in \{1, \dots, d\}$, we set $e^i = (0 \cdots 0\ 1\ 0 \cdots 0)^*$, where 1 is the ith coordinate.
- *Constants.* We will keep the same notation $K(T)$ for all finite, nonnegative, and nondecreasing functions: they do not depend on x, the function f, or further discretization steps h, but they may depend on the coefficients $b(\cdot)$ and $\sigma(\cdot)$. The generic notation $K(x,T)$ stands for any function bounded by $K(T)(1+|x|^Q)$ for $Q \geq 0$.

When a function $g(s,x,\alpha)$ is evaluated at $x = X_s^\alpha$, we may sometimes use the short notation g_s if no ambiguity is possible. For instance, (1.1) may be written as $X_t = x + \int_0^t b_s ds + \sum_{j=1}^q \int_0^t \sigma_{j,s} dW_s^j$.

Other processes related to $(X_t)_{0\leq t\leq T}$. To the diffusion X under (R_2), we may associate its flow, i.e., the Jacobian matrix $Y_t := \nabla_x X_t$, the inverse of its flow $Z_t = {Y_t}^{-1}$, and the pathwise derivative of X_t w.r.t. α, which we denote $\dot{X}_t$ (see Kunita [Kun84]). These processes solve

$$Y_t = \mathrm{I}_d + \int_0^t b'_s\, Y_s\, ds + \sum_{j=1}^q \int_0^t \sigma'_{j,s}\, Y_s\, dW_s^j, \tag{1.3}$$

$$Z_t = \mathrm{I}_d - \int_0^t Z_s (b'_s - \sum_{j=1}^q (\sigma'_{j,s})^2)\, ds - \sum_{j=1}^q \int_0^t Z_s \sigma'_{j,s}\, dW_s^j, \tag{1.4}$$

$$\dot{X}_t = \int_0^t \left(\dot{b}_s + b'_s\, \dot{X}_s\right) ds + \sum_{j=1}^q \int_0^t \left(\dot{\sigma}_{j,s} + \sigma'_{j,s}\, \dot{X}_s\right) dW_s^j. \tag{1.5}$$

Actually, since the process $(\dot{X}_t)_{0\leq t\leq T}$ satisfies a linear equation, it can also simply be written using Y_t and Z_t (apply Theorem 56 from p. 271 of Protter [Pro90]):

$$\dot{X}_t = Y_t \int_0^t Z_s \left[\left(\dot{b}_s - \sum_{j=1}^q \sigma'_{j,s} \dot{\sigma}_{j,s} \right) ds + \sum_{j=1}^q \dot{\sigma}_{j,s} dW_s^j \right]. \tag{1.6}$$

If f is continuously differentiable with an appropriate growth condition (in order to apply the Lebesgue differentiation theorem), one immediately obtains the following result (see also Yang and Kushner [YK91]), which we call the *pathwise approach*.

PROPOSITION 1.1. *Assume* (R_2). *One has* $\dot{J}(\alpha) = \mathbb{E}\big(H_T^{Path.}\big)$ *with*

$$H_T^{Path.} = f'(X_T)\dot{X}_T.$$

Hence, the gradient can still be written as an expectation, which is crucial for a Monte Carlo evaluation. One purpose of the paper is to extend this result to the case of nondifferentiable functions, by essentially writing $\dot{J}(\alpha) = \mathbb{E}\left(f(X_T)H\right)$ for some random variable H.

In what follows, we will make two types of assumption on f.

ASSUMPTION (H). *f is a bounded measurable function.*

Actually, the above boundedness property of f is not important, since in what follows, we essentially use the fact that the random variable $f(X_T)$ belongs to any $\mathbf{L}^p$. However, this assumption simplifies the analysis.

ASSUMPTION (H′). *f is a bounded measurable function and satisfies the following continuity estimate for $p_0 > 1$:*

$$\int_0^T \frac{\|f(X_T) - f(X_t)\|_{\mathbf{L}^{p_0}}}{T-t}\, dt < +\infty.$$

This $\mathbf{L}^p$-smoothness assumption of $f(X_T) - f(X_t)$ is obviously satisfied for uniformly Hölder functions with exponent β, but also for some nonsmooth functions, such as the indicator function of a domain.

PROPOSITION 1.2. *Let D be a domain of $\mathbb{R}^d$: suppose that either it has a compact and smooth boundary (say, of class C^2; see* [GT77]*), or it is a convex polyhedron ($D = \cap_{i=1}^I D_i$, where $(D_i)_{1\le i\le I}$ are half-spaces). Assume* (E), (R$_2$), *and bounded coefficients b and σ. Then, the function $f = \mathbf{1}_D$ satisfies the assumption* (H′) *(for any $p_0 > 1$).*

Proof. Since $\|f(X_T) - f(X_t)\|_{\mathbf{L}^p}^p \le \mathbb{E}|\mathbf{1}_D(X_T) - \mathbf{1}_D(X_t)| \le \mathbb{P}(X_T \in D, X_t \notin D) + \mathbb{P}(X_T \notin D, X_t \in D)$, we only need to prove that $\mathbb{P}(X_T \in D, X_t \notin D) \le K(T)(T-t)^\beta$ with $\beta > 0$. Now, recall the standard exponential inequality $\mathbb{P}(\|X_u - x\| \ge \delta) \le K(T)\exp(-c\frac{\delta^2}{u})$ (with $c > 0$) available for $u \in]0, T]$ and $\delta \ge 0$ (see, e.g., Lemma 4.1 in [Gob00]). Combining this with the Markov property, it follows that $\mathbb{P}(X_T \in D, X_t \notin D) \le K(T)\mathbb{E}(\mathbf{1}_{X_t \notin D}\exp(-c\frac{d^2(X_t, D^c)}{(T-t)}))$. Then, a direct estimation of the above expectation using in particular a Gaussian upper bound for the density of the law of X_t (see Friedman [Fri64]) yields easily the required estimate with $\beta = \frac{1}{2}$ (see Lemma 2.8 in [Gob01a] for details). □

2. Sensitivity formulae. In this section, we present three different approaches to evaluate $\dot{J}(\alpha)$. Before this, we introduce the Malliavin calculus material necessary to our computations.

2.1. Some basic results on the Malliavin calculus. The reader may refer to Nualart [Nua95] (section 2.2 for the case of diffusion processes) for a detailed exposition of this section.

Put $\mathcal{H} = \mathbf{L}^2([0,T], \mathbb{R}^q)$: we will consider elements of $\mathcal{H}$ written as a row vector. For $h(.) \in \mathcal{H}$, denote by $W(h)$ the Wiener stochastic integral $\int_0^T h(t)\, dW_t$.

Let $\mathcal{S}$ denote the class of random variables of the form $F = f(W(h_1), \dots, W(h_N))$, where f is a C^∞-function with derivatives having a polynomial growth, $(h_1, \dots, h_N) \in \mathcal{H}^N$ and $N \ge 1$. For $F \in \mathcal{S}$, we define $\mathcal{D}F = (\mathcal{D}_t F := (\mathcal{D}_t^1 F, \dots, \mathcal{D}_t^q F))_{t\in[0,T]}$, its derivative, as the $\mathcal{H}$-valued random variable given by $\mathcal{D}_t F = \sum_{i=1}^N \partial_{x_i} f(W(h_1), \dots, W(h_N))\ \ h_i(t)$. The operator $\mathcal{D}$ is closable as an operator from $\mathbf{L}^p(\Omega)$ to $\mathbf{L}^p(\Omega, \mathcal{H})$, for any $p \ge 1$. Its domain is denoted by $\mathbb{D}^{1,p}$ w.r.t. the norm $\|F\|_{1,p} = [\mathbb{E}|F|^p + \mathbb{E}(\|\mathcal{D}F\|_{\mathcal{H}}^p)]^{1/p}$. We can define the iteration of the operator $\mathcal{D}$ in such a way that for a smooth random variable F, the derivative $\mathcal{D}^k F$ is a random variable with values on $\mathcal{H}^{\otimes k}$. As in the case $k = 1$, the operator $\mathcal{D}^k$ is closable from $S \subset \mathbf{L}^p(\Omega)$ into $\mathbf{L}^p(\Omega; \mathcal{H}^{\otimes k})$, $p \ge 1$. If we define the norm $\|F\|_{k,p} = [\mathbb{E}|F|^p + \sum_{j=1}^k \mathbb{E}(\|\mathcal{D}^j F\|_{\mathcal{H}^{\otimes j}}^p)]^{1/p}$, we denote its domain by $\mathbb{D}^{k,p}$. Finally, set $\mathbb{D}^{k,\infty} = \cap_{p\ge1}\mathbb{D}^{k,p}$ and $\mathbb{D}^\infty = \cap_{k,p\ge1}\mathbb{D}^{k,p}$. One has the following chain rule property.

PROPOSITION 2.1. *Fix $p \ge 1$. For $f \in C_b^1(\mathbb{R}^d, \mathbb{R})$ and $F = (F_1, \dots, F_d)^*$ a random vector whose components belong to $\mathbb{D}^{1,p}$, $f(F) \in \mathbb{D}^{1,p}$ and for $t \ge 0$, one has*

$\mathcal{D}_t(f(F)) = f'(F)\mathcal{D}_t F$, *with the notation*

$$\mathcal{D}_t F = \begin{pmatrix} \mathcal{D}_t F_1 \\ \vdots \\ \mathcal{D}_t F_d \end{pmatrix} \in \mathbb{R}^d \otimes \mathbb{R}^q.$$

We now introduce δ, the Skorohod integral, defined as the adjoint operator of $\mathcal{D}$.

DEFINITION 2.2. *δ is a linear operator on $\mathbf{L}^2([0,T]\times\Omega,\mathbb{R}^q)$ with values in $\mathbf{L}^2(\Omega)$ such that*

1. *the domain of δ (denoted by $\mathrm{Dom}(\delta)$) is the set of processes $u \in \mathbf{L}^2([0,T]\times\Omega,\mathbb{R}^q)$ such that $\left|\mathbb{E}\big(\int_0^T \mathcal{D}_t F \cdot u_t\, dt\big)\right| \le c(u)\,\|F\|_{\mathbf{L}^2}$ for any $F \in \mathbb{D}^{1,2}$.*
2. *if u belongs to $\mathrm{Dom}(\delta)$, then $\delta(u)$ is the element of $\mathbf{L}^2(\Omega)$ characterized by the integration-by-parts formula*

$$\forall F \in \mathbb{D}^{1,2}, \qquad \mathbb{E}\big(F\ \delta(u)\big) = \mathbb{E}\left(\int_0^T \mathcal{D}_t F \cdot u_t\ dt\right). \tag{2.1}$$

In the following proposition, we outline a few properties of the Skorohod integral.

PROPOSITION 2.3.

1. *The space of weakly differentiable $\mathcal{H}$-valued variables $\mathbb{D}^{1,2}(\mathcal{H})$ belongs to $\mathrm{Dom}(\delta)$.*
2. *If u is an adapted process belonging to $\mathbf{L}^2([0,T]\times\Omega,\mathbb{R}^q)$, then the Skorohod integral and the Itô integral coincide: $\delta(u) = \int_0^T u_t\, dW_t$.*
3. *If F belongs to $\mathbb{D}^{1,2}$, then for any $u \in \mathrm{Dom}(\delta)$ such that $\mathbb{E}(F^2 \int_0^T \|u_t\|^2\, dt) < +\infty$, one has*

$$\delta(F\ u) = F\ \delta(u) - \int_0^T \mathcal{D}_t F \cdot u_t\ dt, \tag{2.2}$$

whenever the right-hand side above belongs to $\mathbf{L}^2(\Omega)$.

Concerning the solution of SDEs, it is well known that under (R_k) $(k \ge 2)$ for any $t \ge 0$, the random variable X_t (resp., Y_t, Z_t, and $\dot{X}_t$) belongs to $\mathbb{D}^{k,\infty}$ (resp., $\mathbb{D}^{k-1,\infty}$). Furthermore, one has the following estimates: $\mathbb{E}\left(\sup_{0\le t\le T} \|\mathcal{D}_{r_1,\dots,r_{k'}} U_t\|^p\right) \le K(T,x)$ for $U_t = X_t$ with $1 \le k' \le k$ or $U_t = Y_t, Z_t, \dot{X}_t$ with $1 \le k' \le k-1$. Besides, $\mathcal{D}_s X_t$ is given by

$$\mathcal{D}_s X_t = Y_t\ Z_s \sigma(s, X_s)\ \mathbf{1}_{s\le t}. \tag{2.3}$$

Finally, we recall some standard results related to the integration-by-parts formulae. The Malliavin covariance matrix of a smooth random variable F is defined by

$$\gamma^F = \int_0^T \mathcal{D}_t F\ [\mathcal{D}_t F]^*\ dt. \tag{2.4}$$

PROPOSITION 2.4. *Let $\bar{\gamma}$ be a multi-index, F be a random variable in $\mathbb{D}^{k_1,\infty}$ such that $\det(\gamma^F)$ is almost surely positive with $1/\det(\gamma^F) \in \cap_{p\ge1}\mathbf{L}^p$ and G belongs to $\mathbb{D}^{k_2,\infty}$. Then for any smooth function g with polynomial growth, provided that k_1 and k_2 are large enough (depending on $\bar{\gamma}$), there exists a random variable $H_{\bar{\gamma}}(F,G)$ in any $\mathbf{L}^p$ such that*

$$\mathbb{E}[\partial^{\bar{\gamma}} g(F) G] = \mathbb{E}[g(F) H_{\bar{\gamma}}(F,G)].$$

Moreover, for any arbitrary event A we have

$$\|H_{\bar\gamma}(F,G)\mathbf{1}_A\|_{\mathbf{L}^p} \le C\|[\gamma^F]^{-1}\mathbf{1}_A\|_{\mathbf{L}^{q_3}}^{p_3}\|F\|_{k_1,q_1}^{p_1}\|G\|_{k_2,q_2}$$

for some constants $C, p_1, p_3, q_1, q_2, q_3$ depending on p and $\bar\gamma$.

Proof. See Propositions 3.2.1 and 3.2.2 in Nualart [Nua98, pp. 160–161] when $A = \Omega$. For any other event A, see Proposition 2.4 from Bally and Talay [BT96a]. □

The construction of $H_{\bar\gamma}(F,G)$ is based on the equality (2.1) and involves iterated Skorohod integrals. We do not really need to make it explicit at this stage.

2.2. First approach: Direct Malliavin calculus computations. Here, the guiding idea is to start from Proposition 1.1 and apply results like Proposition 2.4 to get $\dot J(\alpha) = \mathbb{E}(f(X_T)H)$. Nevertheless, there are several ways to do this, depending on whether the diffusion coefficient is elliptic (see also [FLL+99] in that situation) or not.

2.2.1. Elliptic case. Consider first that the assumption (E) is fulfilled.

PROPOSITION 2.5. *Assume* (R_2), (E), *and* (H). *One has* $\dot J(\alpha) = \mathbb{E}\big(H_T^{Mall.Ell.}\big)$, *where*

$$H_T^{Mall.Ell.} = \frac{1}{T} f(X_T)\delta\big([\sigma_\cdot^{-1}\, Y_\cdot\, Z_T\, \dot X_T]^*\big)$$

belongs to $\cap_{p\ge1}\mathbf{L}^p$.

Proof. We can consider that f is smooth, the general case being obtained using an $\mathbf{L}^2$-approximation of f with some smooth and compactly supported functions. As a consequence of (2.3) and Assumption (E), $\mathcal{D}_t X_T$ is invertible for any $t \in [0,T]$: thus, for such t, using the chain rule (Proposition 2.1), one gets that $f'(X_T) = \mathcal{D}_t(f(X_T))\sigma_t^{-1}\, Y_t\, Z_T$. Integrating in time over $[0,T]$ and using Proposition 1.1, one gets that $\dot J(\alpha) = \frac{1}{T}\int_0^T dt\, \mathbb{E}(\mathcal{D}_t(f(X_T))\sigma_t^{-1}\, Y_t\, Z_T\, \dot X_T)$. An application of the relation (2.1) completes the proof of Proposition 2.5 (the $\mathbf{L}^p$-estimates follow from Proposition 2.4). □

When the parameter enters the drift coefficient only, the laws of $(X_t)_{0\le t\le T}$ for two different values of α are equivalent owing to the Girsanov theorem. Exploiting this possible change of measure directly, a simplified expression for $\dot J(\alpha)$ can be found: this is the *likelihood ratio method* or *score method* from Kushner and Yang [YK91].

PROPOSITION 2.6. *Assume* (R_2), (E), *and* (H). *Suppose that the parameter of interest α is not in the diffusion coefficient. Then, one has*

$$\dot J(\alpha) = \mathbb{E}\left(f(X_T)\int_0^T [\sigma_t^{-1}\dot b_t]^* dW_t\right).$$

Proof. Instead of using the Girsanov theorem, we leverage the particular form of $\dot X_T$ given in (1.6) to prove this. Indeed, $f'(X_T)\dot X_T = f'(X_T)Y_T\int_0^T Z_t\dot b_t dt = \int_0^T dt\, \mathcal{D}_t(f(X_T))[\sigma_t^{-1}\dot b_t]$, and the result follows using (2.1). □

2.2.2. General nondegenerate case. There are many situations where the ellipticity Assumption (E) is too stringent and cannot be fulfilled. To illustrate this, let us rewrite the SDE in the following way, splitting its structure into two parts:

$$dX_t = \begin{pmatrix} dS_t \\ dV_t \end{pmatrix} = \begin{pmatrix} b_S(t,X_t,\alpha) \\ b_V(t,X_t,\alpha) \end{pmatrix} dt + \begin{pmatrix} \sigma_S(t,X_t,\alpha) \\ \sigma_V(t,X_t,\alpha) \end{pmatrix} dW_t. \tag{2.5}$$

Here, $(S_t)_{t\geq 0}$ is $(d-r)$-dimensional, $(V_t)_{t\geq 0}$ r-dimensional, and the dimension of W is arbitrary. The cost function of interest may involve only the value of V_T: $J(\alpha) = \mathbb{E}(f(V_T))$. Note that considering $r = d$ reduces to the previous situation. We now give two examples that motivate the statement of Proposition 2.7 below.

(a) In random mechanics (see Krée and Soize [KS86]), the pair position/velocity $dX_t = \begin{pmatrix} dx_t \\ dv_t \end{pmatrix} = \begin{pmatrix} v_t dt \\ \cdots \end{pmatrix}$ cannot satisfy an ellipticity condition, but weaker assumptions such as hypoellipticity are more realistic.

(b) For portfolio optimization in finance (for a recent review, see, e.g., Runggaldier [Run02]), r usually equals 1. $(S_t)_{t\geq 0}$ describes the dynamic of the risky assets, while $(V_t)_{t\geq 0}$ is the wealth process, corresponding to the value of a self-financed portfolio invested in a nonrisky asset with instantaneous return $r(t, S_t)$ and in the assets $(S_t)_{t\geq 0}$ w.r.t. the strategy $(\xi_t = \{\xi_i(t, X_t) : 1 \leq i \leq d-1\})_{t\geq 0}$: $dV_t = \xi(t, X_t) \cdot dS_t + (V_t - \xi(t, X_t) \cdot S_t) r(t, S_t) dt$ (see e.g. Karatzas and Shreve [KS98]). It is clear that the resulting diffusion coefficient for the whole process $X_t = \begin{pmatrix} S_t \\ V_t \end{pmatrix}$ cannot satisfy an ellipticity condition. Nevertheless, requiring that the matrix $\sigma_V \sigma_V^*(t, x)$ satisfy an ellipticity type condition is not very restricting in that framework.

We set γ_T for the Malliavin covariance matrix of V_T: $\gamma_T = \int_0^T \mathcal{D}_t V_T \, [\mathcal{D}_t V_T]^* \, dt$. This allows to reformulate Assumption (E) as the following.

ASSUMPTION (E′). $\det(\gamma_T)$ *is almost surely positive and for any* $p \geq 1$, *one has*

$$\|1/\det(\gamma_T)\|_{\mathbf{L}^p} < +\infty.$$

We now bring together standard results related to Assumption (E′).

PROPOSITION 2.7. *Assumption* (E′) *is fulfilled in the following situations.*

1. Hypoelliptic case *(with* $r = d$*) under* (R_∞). *The Lie algebra generated by the vector fields* $\partial_t + A_0(t, x) := \partial_t + \sum_{i=1}^d (b - \frac{1}{2} \sum_{j=1}^q \sigma_j' \sigma_j)_i(t, x) \partial_{x_i}$, $A_j(t, x) := \sum_{i=1}^d \sigma_{i,j}(t, x) \partial_{x_i}$ *for* $1 \leq j \leq q$ *spans* $\mathbb{R}^{d+1}$ *at the point* $(0, X_0)$*:*

$$\dim \operatorname{span} \operatorname{Lie}(\partial_t + A_0, A_j, 1 \leq j \leq q)(0, X_0) = d + 1.$$

2. Partially elliptic case *(with* $r \geq 1$*) under* (R_2). *For a real number* $\mu_{\min} > 0$, *one has*

$$\forall x \in \mathbb{R}^d, \qquad [\sigma_V \sigma_V^*](T, x, \alpha) \geq \mu_{\min} \, \mathrm{I}_d.$$

Proof. The statement 1 is standard and we refer to Cattiaux and Mesnager [CM02] for a recent account on the subject. The statement 2 is also standard: see, for instance, the arguments in Nualart [Nua98, pp. 158–159]. □

Now, we are in a position to give a sensitivity formula under (E′).

PROPOSITION 2.8. *Assume* (R_2), (E′), *and* (H). *One has* $\dot{J}(\alpha) = \mathbb{E}\big(H_T^{Mall.Gen.}\big)$ *where*

$$H_T^{Mall.Gen.} = f(V_T) \, \delta\big(\dot{V}_T^* \gamma_T^{-1} \mathcal{D}.V_T\big)$$

belongs to $\cap_{p\geq 1} \mathbf{L}^p$.

Proof. Assumption (E′) validates (see Nualart [Nua98, Proposition 3.2.1]) the following computations, adapted from the ones used for Proposition 2.5. The chain

rule property yields $f'(V_T) = \int_0^T \mathcal{D}_t(f(V_T))[\mathcal{D}_t V_T]^* \gamma_T^{-1}\, dt$, and thus $\mathbb{E}(f'(V_T)\dot{V}_T) = \mathbb{E}(\int_0^T \mathcal{D}_t(f(V_T))[\mathcal{D}_t V_T]^* \gamma_T^{-1}\dot{V}_T\, dt)$. Proposition 2.8 now follows from (2.1). □

Proposition 2.8 is also valid under (E) in the case $r = d$, but the formula in Proposition 2.5 is actually a bit simpler to implement.

2.3. A second approach based on the adjoint point of view.

2.3.1. Another representation of the sensitivity of $J(\alpha)$. If we set $u(t,x) = \mathbb{E}\big(f(X_T)|X_t = x\big)$, omitting to indicate the dependence w.r.t. α, we have that $J(\alpha)$ defined in (1.2) equals $u(0, X_0)$. Under smoothness assumptions on b and σ and the nondegeneracy hypothesis on the infinitesimal generator of $(X_t)_{t\geq 0}$, it is well known (see Cattiaux and Mesnager [CM02]) that u is the smooth solution of the partial differential equation (PDE)

$$\begin{cases} \partial_t u(t,x) + \sum_{i=1}^d b_i(t,x)\partial_{x_i} u(t,x) + \frac{1}{2}\sum_{i,j=1}^d [\sigma\sigma^*]_{i,j}(t,x)\partial^2_{x_i,x_j} u(t,x) = 0 \ \text{ for } t < T, \\ u(T,x) = f(x). \end{cases}$$

Our purpose is to give another expression for $\dot{J}(\alpha)$ of Proposition 1.1. The idea is simple: it consists in formally differentiating the PDE above w.r.t. α and in reinterpreting the derivative as an expectation. This is now stated and justified rigorously.

LEMMA 2.9. *Assume* (R_3), (E), *and* (H). *One has*

$$\dot{J}(\alpha) = \int_0^T \mathbb{E}\left(\sum_{i=1}^d \dot{b}_{i,t}\partial_{x_i} u(t, X_t) + \frac{1}{2}\sum_{i,j=1}^d [\dot{\sigma\sigma^*}]_{i,j,t}\partial^2_{x_i,x_j} u(t, X_t)\right) dt.$$

Proof. This is a standard fact that under (R_3) and (E), u is twice differentiable w.r.t. x (see the arguments of Lemma 2.10 below, where the proof is sketched). The technical difficulty in the following computations comes from the possible explosion of derivatives of u for t close to T, when f is nonsmooth. For this reason, we first prove useful uniform estimates: for any multi-index $\bar{\gamma}$ with $|\bar{\gamma}| \leq 2$, any smooth random variable $G \in \mathbb{D}^{2,\infty}$ and any parameters α and α', one has

$$\sup_{t\in[0,T[} |\mathbb{E}[G\, \partial_x^{\bar{\gamma}} u(t, X_t^{\alpha'})]| \leq K(T,x)\frac{\|f\|_\infty}{T^{\frac{|\bar{\gamma}|}{2}}}\|G\|_{|\bar{\gamma}|,p'}. \tag{2.6}$$

Indeed, for $t \geq T/2$, first apply Proposition 2.4: then, use $|u(t,x)| \leq \|f\|_\infty$ combined with some specific estimates for $\|H_{\bar{\gamma}}(X_t^{\alpha'}, G)\|_{\mathbf{L}^p} \leq \frac{K(T,x)}{t^{\frac{|\bar{\gamma}|}{2}}}\|G\|_{|\bar{\gamma}|,p'}$ available under the ellipticity condition (E) (see Theorem 1.20 and Corollary 3.7 in Kusuoka and Stroock [KS84], or section 4.1. in [Gob00] for a brief review). For $t \leq T/2$, note that using the Markov property, one has $\partial_x^{\bar{\gamma}} u(t,x) = \partial_x^{\bar{\gamma}}\mathbb{E}\big(u(\frac{T+t}{2}, X_{\frac{T+t}{2}}^{t,x})\big) = \sum_{1\leq|\gamma'|\leq|\bar{\gamma}|}\mathbb{E}\big(\partial_x^{\gamma'} u(\frac{T+t}{2}, X_{\frac{T+t}{2}}^{t,x}) G_{\frac{T+t}{2}}^{\gamma'}\big)$ with $G_{\frac{T+t}{2}}^{\gamma'} \in \mathbb{D}^{2+|\gamma'|-|\bar{\gamma}|,\infty}$ and $(X_s^{t,y})_{s\geq t}$ standing for the process starting from y at time t. Again applying the integration-by-parts formula with the elliptic estimates gives $|\partial_x^{\bar{\gamma}} u(t,x)| \leq \frac{K(T,x)}{[\frac{T+t}{2}-t]^{\frac{|\bar{\gamma}|}{2}}}\|f\|_\infty$ and (2.6) follows

since $\frac{T+t}{2} - t \geq \frac{T}{4}$. Now, for $\epsilon \in \mathbb{R}$, the difference $J(\alpha+\epsilon) - J(\alpha)$ equals

$$\begin{aligned}
&\mathbb{E}\left(f(X_T^{\alpha+\epsilon}) - f(X_T^{\alpha})\right) = \mathbb{E}\left(u(T, X_T^{\alpha+\epsilon}) - u(0, X_0^{\alpha+\epsilon})\right) \\
&= \int_0^T \mathbb{E}\left(\partial_t u(t, X_t^{\alpha+\epsilon}) + \sum_{i=1}^d b_i(t, X_t^{\alpha+\epsilon}, \alpha+\epsilon) \partial_{x_i} u(t, X_t^{\alpha+\epsilon}) \right. \\
&\qquad \left. + \frac{1}{2} \sum_{i,j=1}^d [\sigma\sigma^*]_{i,j}(t, X_t^{\alpha+\epsilon}, \alpha+\epsilon) \partial^2_{x_i,x_j} u(t, X_t^{\alpha+\epsilon}) \right) dt \\
&= \int_0^T \mathbb{E}\left(\sum_{i=1}^d (b_i(t, X_t^{\alpha+\epsilon}, \alpha+\epsilon) - b_i(t, X_t^{\alpha+\epsilon}, \alpha)) \partial_{x_i} u(t, X_t^{\alpha+\epsilon}) \right. \\
&\qquad \left. + \frac{1}{2} \sum_{i,j=1}^d ([\sigma\sigma^*]_{i,j}(t, X_t^{\alpha+\epsilon}, \alpha+\epsilon) - [\sigma\sigma^*]_{i,j}(t, X_t^{\alpha+\epsilon}, \alpha)) \partial^2_{x_i,x_j} u(t, X_t^{\alpha+\epsilon}) \right) dt,
\end{aligned}$$

where at the last equality we used the PDE solved by u to remove the term $\partial_t u$. Now, divide by ϵ and take its limit to 0: the result follows owing to the uniform estimates (2.6). □

Note that the formulation of Lemma 2.9 is strongly related to a form of the stochastic maximum principle (the Pontryagin principle) for optimal control problems: the processes $([\partial_{x_i} u(t, X_t)]_i)_{0 \leq t < T}$ and $([\partial^2_{x_i,x_j} u(t, X_t)]_{i,j})_{0 \leq t < T}$ are the so-called adjoint processes (see Bensoussan [Ben88] for convex control domains, or more generally Peng [Pen90]) and solve backward SDEs. Usually in these problems, the function f is smooth. Here, since the law of X_t has a smooth density w.r.t. the Lebesgue measure, we can remove the regularity condition on f.

Note also that Lemma 2.9 remains valid under a hypoellipticity hypothesis (condition 1 in Proposition 2.7). However, the derivation of tractable formulae below relies strongly on the ellipticity property.

2.3.2. Transformation using Itô–Malliavin integration-by-parts formulae. The aim of this section is to transform the expression for $\dot{J}(\alpha)$ in terms of explicit quantities. To remove the nonexplicit terms $\partial_{x_i} u$ and $\partial^2_{x_i,x_j} u$, we may use some integration-by-parts formulae, but here, to keep more tractable expressions, we are going to derive Bismut-type formulae, i.e., involving only Itô integrals instead of Skorohod integrals (see Bismut [Bis84]; Elworthy, Le Jan, and Li [EJL99]; and references therein), using a martingale argument (see also Thalmaier [Tha97] or, more recently, Picard [Pic02]). In the cited references, this approach has been used to compute estimates of the gradient of u. Here, we extend it to support higher derivatives. The basic tool is given by the following lemma.

LEMMA 2.10. *Assume* (R_2), (E), *and* (H) *and define* $M_t = u'(t, X_t) Y_t$ *for* $t < T$. *Then* $M = (M_t)_{0 \leq t < T}$ *is an* $\mathbb{R}^1 \otimes \mathbb{R}^d$*-valued martingale.*

Proof. First, we justify that u is continuously differentiable w.r.t x under (R_2) and (E). If f is smooth, this is clear (even without (E)), but (2.10) below also shows that under (E), u' can be expressed without the derivative of f. This easily leads to our assertion (see the proof of Proposition 3.2 in [FLL+99]). Now, the Markov property ensures that $(u(t, X_t^{0,x}))_{0 \leq t < T}$ is a martingale for any $x \in \mathbb{R}^d$. Hence, its derivative w.r.t. x (i.e., $(M_t)_{0 \leq t < T}$) is also a martingale (see Arnaudon and Thalmaier [AT98]). □

We now state a theorem which, if combined with Lemma 2.9, leads to an alternative representation for $\dot{J}(\alpha)$.

THEOREM 2.11. *Assume* (R_3) *and* (E).

Under (H), *one has*

$$\int_0^T \mathbb{E}\Big(\sum_{i=1}^d \dot{b}_{i,t}\partial_{x_i}u(t,X_t)\Big)dt = \mathbb{E}(H_T^{b,Adj.}), \tag{2.7}$$

where $H_T^{b,Adj.} = f(X_T)\displaystyle\int_0^T dt\ \dot{b}_t \cdot \frac{Z_t^*}{T-t}\int_t^T [\sigma_s^{-1}\ Y_s]^*\ dW_s$ *belongs to* $\bigcap_{p\geq 1}\mathbf{L}^p$.

Under (H′), *one has*

$$\int_0^T \mathbb{E}\Big(\sum_{i,j=1}^d [\sigma\dot{\sigma}^*]_{i,j,t}\partial^2_{x_i,x_j}u(t,X_t)\Big)dt = \mathbb{E}(H_T^{\sigma,Adj.}), \tag{2.8}$$

where

$$H_T^{\sigma,Adj.} = \int_0^T dt\ \sum_{i,j=1}^d [\sigma\dot{\sigma}^*]_{i,j,t}[f(X_T)-f(X_t)]\left(\frac{2e^j}{T-t}\cdot\left[Z_t^*\int_{\frac{T+t}{2}}^T [\sigma_s^{-1}Y_s]^* dW_s\right]\right.$$
$$\left.\times\ \frac{2e^i}{T-t}\cdot\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^*dW_s\right] + \frac{2e^i}{T-t}\cdot\left\{\nabla_x\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^*dW_s\right]Z_t e^j\right\}\right)$$

belongs to $\bigcap_{p<p_0}\mathbf{L}^p$.

Proof. Equality (2.7). First, Clark and Ocone's formula [Nua95, p. 42] gives $u(\tau,X_\tau) = u(t,X_t) + \int_t^\tau \mathbb{E}(\mathcal{D}_s[u(\tau,X_\tau)]|\mathcal{F}_s)dW_s$ for $0\leq t\leq\tau<T$. Using (2.3) and the martingale property of Lemma 2.10, we get $\mathbb{E}(\mathcal{D}_s[u(\tau,X_\tau)]|\mathcal{F}_s) = \mathbb{E}(u'(\tau,X_\tau)Y_\tau Z_s\sigma_s|\mathcal{F}_s) = u'(s,X_s)\sigma_s$. Hence, it gives an explicit form to the predictable representation theorem:

$$\forall\ 0\leq t\leq\tau\leq T \qquad u(\tau,X_\tau) = u(t,X_t) + \int_t^\tau u'(s,X_s)\sigma_s dW_s \tag{2.9}$$

(the case $\tau = T$ is obtained by passing to the limit). Note that this representation holds under (R_2). Since $(u'(t,X_t)Y_t)_{0\leq t<T}$ is a martingale, we obtain that

$$\begin{aligned}
u'(t,X_t)Y_t &= \mathbb{E}\left(\frac{1}{T-t}\int_t^T u'(s,X_s)Y_s\ ds|\mathcal{F}_t\right)\\
&= \mathbb{E}\left(\frac{1}{T-t}\left[\int_t^T u'(s,X_s)\sigma_s dW_s\right]\left[\int_t^T[\sigma_s^{-1}Y_s]^*dW_s\right]^*|\mathcal{F}_t\right)\\
&= \mathbb{E}\left(\frac{f(X_T)-u(t,X_t)}{T-t}\left[\int_t^T[\sigma_s^{-1}Y_s]^*dW_s\right]^*|\mathcal{F}_t\right)\\
&= \mathbb{E}\left(\frac{f(X_T)}{T-t}\left[\int_t^T[\sigma_s^{-1}Y_s]^*dW_s\right]^*|\mathcal{F}_t\right),
\end{aligned} \tag{2.10}$$

where for the third equality we used (2.9) with $\tau = T$ and $u(T, X_T) = f(X_T)$. Now the proof of (2.7) is straightforward.

Equality (2.8). Note that a slight modification of the preceding arguments (namely, integrating over $[t,(T+t)/2]$ instead of $[t,T]$ and applying (2.9) with $\tau = (t+T)/2$) leads to $\partial_{x_i} u(t,X_t) = \mathbb{E}\big(u\big(\frac{T+t}{2}, X_{\frac{T+t}{2}}\big)\frac{2e^i}{T-t}\cdot\big[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^* dW_s\big]|\mathcal{F}_t\big)$. Differentiating w.r.t. x on both sides and using (2.10) yields

$$
\begin{aligned}
(\partial_{x_i} u)'(t,X_t)Y_t &= \mathbb{E}\left(u'\left(\frac{T+t}{2}, X_{\frac{T+t}{2}}\right) Y_{\frac{T+t}{2}} \frac{2e^i}{T-t}\cdot\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^* dW_s\right]|\mathcal{F}_t\right)\\
&\quad+\mathbb{E}\left(u\left(\frac{T+t}{2}, X_{\frac{T+t}{2}}\right)\frac{2e^i}{T-t}\cdot\nabla_x\left\{\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^* dW_s\right]\right\}|\mathcal{F}_t\right)\\
&= \mathbb{E}\left([f(X_T)-f(X_t)]\frac{2}{T-t}\left[\int_{\frac{T+t}{2}}^T[\sigma_s^{-1}Y_s]^* dW_s\right]^*\frac{2e^i}{T-t}\cdot\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^* dW_s\right]\right.\\
&\quad\left.+[f(X_T)-f(X_t)]\frac{2e^i}{T-t}\cdot\nabla_x\left\{\left[Z_t^*\int_t^{\frac{T+t}{2}}[\sigma_s^{-1}Y_s]^* dW_s\right]\right\}|\mathcal{F}_t\right)
\end{aligned}
$$

(note that the $f(X_t)$ terms have no contribution in the expectation). Rearranging this last expression leads to (2.8).

The $\mathbf{L}^p$-estimates can be justified using the generalized Minkowski inequality and standard estimates from the stochastic calculus:

(2.11)

$$
\begin{aligned}
&\|H_T^{b,Adj.}\|_{\mathbf{L}^p} \le \int_0^T \frac{\|f\|_\infty}{T-t}\left\|\dot b(t,X_t)\cdot Z_t^*\int_t^T[\sigma_s^{-1}Y_s]^* dW_s\right\|_{\mathbf{L}^p} dt \le K(T,x)\int_0^T\frac{\|f\|_\infty}{\sqrt{T-t}}dt,\\
&\|H_T^{\sigma,Adj.}\|_{\mathbf{L}^p} \le K(T,x)\int_0^T\frac{\|f(X_T)-f(X_t)\|_{\mathbf{L}^{p'}}}{T-t}\,dt
\end{aligned}
$$

for $p < p' < p_0$. □

Remark 2.1. The $f(X_t)$ terms in $H_T^{\sigma,Adj.}$ seem to be crucial to ensure its $\mathbf{L}^p$ integrability: numerical experiments in section 5 illustrate this fact.

2.4. A third approach using martingales. We emphasize the dependence on α of the expected cost by denoting $u(\alpha,t,x) = \mathbb{E}(f(X_T^\alpha)|X_t^\alpha = x)$: hence, $J(\alpha) = u(\alpha,0,X_0)$. From the estimates proved in Lemma 2.9, this is a differentiable function w.r.t. α and one has $|\dot u(\alpha,t,x)| \le K(T,x)\|f\|_\infty$ and $|u'(\alpha,t,x)| \le \frac{K(T,x)}{\sqrt{T-t}}\|f\|_\infty$. Furthermore, using Theorem 2.11 and the $\mathbf{L}^p$-estimates (2.11) under (H′), one gets

$$
|\dot u(\alpha,t,x)| \le K(T,x)\left[\|f\|_\infty\sqrt{T-t} + \int_t^T\frac{\|f(X_T^{t,x})-f(X_s^{t,x})\|_{\mathbf{L}^{p'}}}{T-s}\,ds\right]
$$

for $p' < p_0$. Consequently, if we put $g(r) = \mathbb{E}\,(\dot u(\alpha,r,X_r))$, we easily obtain $|g(r)| \le K(T,x)[\|f\|_\infty\sqrt{T-r} + \int_r^T \frac{\|f(X_T)-f(X_s)\|_{\mathbf{L}^{p_0}}}{T-s}\,ds]$ and thus, $\lim_{r\to T} g(r) = 0$. For any $0 \le r \le s \le T$, one has $\mathbb{E}(u(\alpha,r,X_r)) = \mathbb{E}(u(\alpha,s,X_s)) = \frac{1}{T-r}\int_r^T \mathbb{E}(u(\alpha,s,X_s))\,ds$

using the Markov property; hence, by differentiation w.r.t. α, one gets

(2.12)
$$\begin{aligned}\mathbb{E}\big(\dot{u}(\alpha,r,X_r)\big) &= \frac{1}{T-r}\int_r^T ds\,\mathbb{E}\big(\dot{u}(\alpha,s,X_s)+u'(\alpha,s,X_s)\dot{X}_s - u'(\alpha,r,X_r)\dot{X}_r\big)\\ &= \frac{1}{T-r}\int_r^T ds\,\mathbb{E}\big(\dot{u}(\alpha,s,X_s)+u'(\alpha,s,X_s)[\dot{X}_s - Y_sZ_r\dot{X}_r]\big),\end{aligned}$$

where we used at the last equality the martingale property of $M_t = u'(\alpha,t,X_t)Y_t$ between $t=s$ and $t=r$ (see Lemma 2.10).

Now, put $h(r) = \frac{1}{T-r}\int_r^T ds\,\mathbb{E}\left(u'(\alpha,s,X_s)[\dot{X}_s - Y_sZ_r\dot{X}_r]\right)$: one has derived the following integral equation:

$$g(t) = \frac{1}{T-t}\int_t^T g(s)\,ds + h(t). \tag{2.13}$$

Before solving it, we express $h(r)$ using only f: for this, we use the predictable representation (2.9), which immediately gives

$$h(r) = \frac{1}{T-r}\mathbb{E}\left((f(X_T)-f(X_r))\int_r^T [\sigma_s^{-1}(\dot{X}_s - Y_sZ_r\dot{X}_r)]^* dW_s\right). \tag{2.14}$$

Note again that the term with $f(X_r)$ has no contribution and is put only to justify that $|h(r)| \le K(T,x)\|f(X_T)-f(X_r)\|_{\mathbf{L}^{p_0}}$ (use the Burkholder–Davis–Gundy inequalities and straightforward upper bounds for $\|\dot{X}_s - Y_sZ_r\dot{X}_r\|_{\mathbf{L}^q} \le K(T,x)\sqrt{s-r}$), from which we deduce that the integral $\int_0^T \frac{h(t)}{T-t}\,dt$ is convergent because of (H′). To solve the integral equation above, note that $[\frac{1}{T-t}\int_t^T g(s)\,ds]' = -\frac{h(t)}{T-t}$, and thus by integration, we have $\frac{1}{T-t}\int_t^T g(s)\,ds = C - \int_t^T \frac{h(r)}{T-r}dr$. The constant C equals 0 since both integrals in the previous equality converge to 0 when t goes to T (use $\lim_{t\to T} g(t) = 0$ and (H′)). Plug this new equality into (2.13), use (2.14), and take $t=0$ (with $\dot{X}_0 = 0$) to get the following representation for $\dot{J}(\alpha)$: this is the main result of this section.

THEOREM 2.12. *Assume* (R_2), (E), *and* (H′). *Then, one has* $\dot{J}(\alpha) = \mathbb{E}(H_T^{Mart.})$ *with*

$$\begin{aligned}H_T^{Mart.} &= \frac{f(X_T)}{T}\int_0^T [\sigma_s^{-1}\dot{X}_s]^* dW_s\\ &\quad + \int_0^T dr\,\frac{[f(X_T)-f(X_r)]}{(T-r)^2}\int_r^T [\sigma_s^{-1}(\dot{X}_s - Y_sZ_r\dot{X}_r)]^* dW_s.\end{aligned} \tag{2.15}$$

Furthermore, the random variable $H_T^{Mart.}$ *belongs to* $\bigcap_{p<p_0}\mathbf{L}^p$.

This method is called the *martingale approach* because it is based on the equality (2.12), which is a consequence of the martingale property of

$$[\dot{u}(\alpha,s,X_s) + u'(\alpha,s,X_s)\dot{X}_s]_{0\le s<T}.$$

Proof. What remains to be proved is the $\mathbf{L}^p$ estimate of $H_T^{Mart.}$: this can be easily obtained by combining Minkowski's inequality, Hölder's inequality, Assumption (H′), and standard stochastic calculus inequalities as before. □

Remark 2.2. When the parameter is not involved in the diffusion coefficient, it is easy to see that the improved estimate $\|\dot{X}_s - Y_s Z_r \dot{X}_r\|_{L_q} \leq K(T,x)(s-r)$ is available: thus, this allows us to remove $f(X_r)$ terms in the expression of $H_T^{Mart.}$ without changing the finiteness of the $\mathbf{L}^p$-norm of the new $H_T^{Mart.}$. In other words, only Assumption (H) is needed.

Besides, when α is only in the drift coefficient and these $f(X_r)$ terms are suppressed, this representation coincides with that of Theorem 2.11. Indeed, let us write $P_r = \int_r^T [\sigma_s^{-1}(\dot{X}_s - Y_s Z_r \dot{X}_r)]^* dW_s = \int_r^T [\sigma_s^{-1}\dot{X}_s]^* dW_s - [Z_r \dot{X}_r]^* \int_r^T [\sigma_s^{-1} Y_s]^* dW_s := P_{1,r} - P_{2,r}$, where $P_{1,r} = \int_0^T [\sigma_s^{-1}\dot{X}_s]^* dW_s - [Z_r\dot{X}_r]^* \int_0^T [\sigma_s^{-1}Y_s]^* dW_s$ and $P_{2,r} = \int_0^r [\sigma_s^{-1}\dot{X}_s]^* dW_s - [Z_r\dot{X}_r]^* \int_0^r [\sigma_s^{-1}Y_s]^* dW_s$. From the fact that $Z_r\dot{X}_r = \int_0^r Z_s \dot{b}_s ds$ (see (1.6)), one gets $dP_{2,r} = [Z_r \dot{b}_r]^* (\int_0^r [\sigma_t^{-1} Y_t]^* dW_t) dr$, hence $P_{2,r}$ is of bounded variation. $P_{1,r}$ is also of bounded variation, since $Z_r\dot{X}_r$ is. Thus, one obtains $dP_r = -\dot{b}_r \cdot Z_r^* (\int_r^T [\sigma_t^{-1} Y_t]^* dW_t) dr$: furthermore, since $P_T = 0$, one has $\|P_r\|_{\mathbf{L}^p} \leq K(T,x)(T-r)^{3/2}$. Using an integration-by-parts formula in (2.15) finally completes our assertion: $H_T^{Mart.} = f(X_T)\big(\frac{1}{T}P_0 + \int_0^T \frac{P_r}{(T-r)^2} dr\big) = f(X_T)\big(-\int_0^T \frac{dP_r}{(T-r)}\big) = H_T^{b,Adj.}$.

Consequently, this martingale approach does not provide any new elements when the parameter is not in the diffusion coefficient. On the contrary, if σ depends on α, the representation with the adjoint point of view is different from the martingale one (see numerical experiments). However, we must admit that this martingale approach remains somewhat mysterious to us.

3. Monte Carlo simulation and analysis of the discretization error. In this section, we discuss the numerical implementation of the formulae derived in this paper to compute the sensitivity of $J(\alpha)$ w.r.t. α. These formulae are written as expectations of some functionals of the process $(X_t)_{0\leq t\leq T}$ and related ones: a standard way to proceed consists in drawing independent simulations, approximating the functional using Euler schemes, and averaging independent samples of the resulting functional to get an estimation of the expectation (see section 5).

Here, we focus on the impact of the time step $h = T/N$ (N is the number of discretization times in the regular mesh of the interval $[0,T]$) in the simulation of the functional: it is well known that for the evaluation of $\mathbb{E}(f(X_T))$, the discretization error using an Euler scheme is of order h (see Bally and Talay [BT96a] for measurable functions f, or Kohatsu-Higa and Pettersson [KHP02] if f is a distribution and for more general discretization schemes). We recall that the error on the processes (called the *strong* error) is much easier to analyze than the one on the expectations (the *weak* error): the first one is essentially of order $\sqrt{h}$ (see [KP95]) but this is not relevant for the current issues.

Besides, the quantity of interest here has a more complex structure that is essentially $\mathbb{E}(f(X_T)H)$, where H is one of the random variables resulting from our computations. In general, H involves Itô or Skorohod integrals: our first purpose is to give some approximation procedure to simulate these weights using only the increments of the Brownian motion computed along the regular mesh with time step h.

Our second purpose is to analyze the error induced by this discretization procedure: generally speaking, the weak error is still at most linear w.r.t. h, as for $\mathbb{E}(f(X_T))$. The proofs are quite intricate and we postpone them to section 4. For the sake of clarity, we assume (R_∞), that is, b and σ of class C^∞, but approximation results only depend on a finite number of coefficients' derivatives.

Approximation procedure. We consider a regular mesh of the interval $[0,T]$, with N discretization times $t_i = ih$, where $h = T/N$ is the time step. Denote $\phi(t) = \sup\{t_i : t_i \le t\}$. The processes we need to simulate are essentially $(X_t)_{0\le t\le T}$, $(Y_t)_{0\le t\le T}$, $(Z_t)_{0\le t\le T}$, $(\dot X_t)_{0\le t\le T}$, and we approximate them using a standard Euler scheme as follows:

(3.1)
$$X_t^N = x + \int_0^t b(\phi(s), X_{\phi(s)}^N)\, ds + \sum_{j=1}^q \int_0^t \sigma_j(\phi(s), X_{\phi(s)}^N)\, dW_s^j,$$

(3.2)
$$Y_t^N = \mathrm{I}_d + \int_0^t b'(\phi(s), X_{\phi(s)}^N)\, Y_{\phi(s)}^N\, ds + \sum_{j=1}^q \int_0^t \sigma_j'(\phi(s), X_{\phi(s)}^N)\, Y_{\phi(s)}^N\, dW_s^j,$$

(3.3)
$$Z_t^N = \mathrm{I}_d - \int_0^t Z_{\phi(s)}^N (b' - \sum_{j=1}^q (\sigma_j')^2)(\phi(s), X_{\phi(s)}^N)\, ds - \sum_{j=1}^q \int_0^t Z_{\phi(s)}^N \sigma_j'(\phi(s), X_{\phi(s)}^N)\, dW_s^j,$$

(3.4)
$$\begin{aligned}\dot X_t^N = {} & \int_0^t \left(\dot b(\phi(s), X_{\phi(s)}^N) + b'(\phi(s), X_{\phi(s)}^N)\, \dot X_{\phi(s)}^N\right) ds \\ & + \sum_{j=1}^q \int_0^t \left(\dot\sigma_j(\phi(s), X_{\phi(s)}^N) + \sigma_j'(\phi(s), X_{\phi(s)}^N)\, \dot X_{\phi(s)}^N\right) dW_s^j.\end{aligned}$$

Note that only the increments $(W_{t_{i+1}}^j - W_{t_i}^j; 1 \le j \le q)_{0\le i\le N-1}$ of the Brownian motion are needed to get values of X^N, Z^N, Y^N, $\dot X^N$ at times $(t_i)_{0\le i\le N}$.

3.1. Pathwise approach.

THEOREM 3.1. *Assume* (R_∞). *Then, one has*

$$\left|\dot J(\alpha) - \mathbb{E}\left(f'(X_T^N)\dot X_T^N\right)\right| \le C(T,x,f)h,$$

under either one of the two following assumptions on f and X:

(A1) *f is of class C_b^4: one may put $C(T,x,f) = K(T,x)\sum_{1\le|\alpha|\le 4}\|\partial^\alpha f\|_\infty$ in that case.*

(A2) *f is continuously differentiable with a bounded gradient and the nondegeneracy condition* (E′) *holds: in that case, $C(T,x,f)$ may be set to*

$$K(T,x)\|f'\|_\infty \|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q$$

for some positive numbers p and q.

Note that in the case (A1), only three additional derivatives of the function f' are required to get the order 1 w.r.t. h: this is a slight improvement compared to results in Talay and Tubaro [TL90], where four derivatives are needed.

3.2. Malliavin calculus approach.

3.2.1. Elliptic case. One needs to define the approximation for the random variable $H_T^{Mall.Ell.} := \delta\big([\sigma^{-1}(\cdot, X.)\ Y.\ Z_T\ \dot X_T]^*\big)$ involved in Proposition 2.5. Basic

algebra using the equality (2.2) gives

$$H_T^{Mall.Ell.} = \sum_{i=1}^{d} \delta\big([\sigma^{-1}(\cdot, X_\cdot)\, Y_\cdot]_i^* \, [Z_T \; \dot{X}_T]_i\big)$$
$$= \sum_{i=1}^{d} [Z_T \; \dot{X}_T]_i \int_0^T [\sigma^{-1}(s, X_s)\, Y_s]_i^* \, dW_s - \sum_{i=1}^{d} \int_0^T \mathcal{D}_s([Z_T \; \dot{X}_T]_i)[\sigma^{-1}(s, X_s)\, Y_s]_i \, ds.$$

The new quantities involved are $\mathcal{D}_s Z_{j,k,T}$ and $\mathcal{D}_s \dot{X}_{k,T}$. We now indicate how to simulate them. The $\mathbb{R}^{2d}$-valued process $\binom{X_t}{\dot{X}_t}_{t\geq 0}$ forms a new stochastic differential equation (see (1.5)): we denote the flow of this extended system by $\hat{Y}_t$ and its inverse by $\hat{Z}_t$. As we did for Y_t and Z_t, we can define their Euler scheme (as in (3.2) and (3.3)), which we denote $\hat{Y}_t^N$ and $\hat{Z}_t^N$. The Malliavin derivative of this system follows from (2.3). Hence, one has

$$\mathcal{D}_s \dot{X}_T = \Pi_d^R \left(\hat{Y_T} \hat{Z}_s \begin{pmatrix} \vdots & \sigma_j(s, X_s) & \vdots \\ \vdots & \dot{\sigma}_j(s, X_s) + \sigma_j'(s, X_s)\, \dot{X}_s & \vdots \end{pmatrix} \right), \tag{3.5}$$

and we naturally approximate it by

$$[\mathcal{D}_s \dot{X}_T]^N = \Pi_d^R \left(\hat{Y}_T^N \hat{Z}_s^N \begin{pmatrix} \vdots & \sigma_j(s, X_s^N) & \vdots \\ \vdots & \dot{\sigma}_j(s, X_s^N) + \sigma_j'(s, X_s^N)\, \dot{X}_s^N & \vdots \end{pmatrix} \right). \tag{3.6}$$

The same approach can be developed for the cth column of the transpose of Z_T, since $\binom{X_t}{(Z_t{}^*)_c}_{t\geq 0}$ forms a new SDE (see (1.4)): the associated flow and its inverse, respectively denoted $\hat{Y}_t^c$ and $\hat{Z}_t^c$, enable us to derive a simple expression for $\mathcal{D}_s[(Z_t{}^*)_c]$ analogously to (3.5) and (3.6). As a consequence, one gets

$$\mathcal{D}_s([Z_T \; \dot{X}_T]_i) = \mathbf{1}_{s\leq T} \sum_j A_{\beta(j,i),T} B_{\beta(j,i),s}, \tag{3.7}$$

where $A_{\beta(j,i),T}$ and $B_{\beta(j,i),s}$ are given by some appropriate coordinates of the processes $\hat{Y}_T$, $(\hat{Y}_T^c)_{1\leq c\leq d}$ on one hand; and $\hat{Z}_s$, $(\hat{Z}_s^c)_{1\leq c\leq d}$, $\sigma_j(s, X_s)$, $\dot{\sigma}_j(s, X_s)$, $\sigma_j'(s, X_s)$, $\dot{X}_s$, Z_s on the other hand; in order to keep things clear, we do not develop their expression further (we refer to a technical report [GM03] for full details). Finally, we approximate $H_T^{Mall.Ell.}$ by

$$H_T^{Mall.Ell.,N} = \sum_{i=1}^{d} [Z_T^N \; \dot{X}_T^N]_i \int_0^T [\sigma^{-1}(\phi(s), X_{\phi(s)}^N)\, Y_{\phi(s)}^N]_i^* \, dW_s$$
$$- \sum_{i=1}^{d} \int_0^T \left(\sum_j A_{\beta(j,i),T}^N B_{\beta(j,i),\phi(s)}^N \right) [\sigma^{-1}(\phi(s), X_{\phi(s)}^N)\, Y_{\phi(s)}^N]_i \, ds,$$

which can be simulated using only the Brownian increments as before. We now state that the approximation above converges at order 1 w.r.t. the time step.

THEOREM 3.2. *Assume* (R_∞), (E), *and* (H). *For some* $q \geq 0$, *one has*

$$\left| \dot{J}(\alpha) - \mathbb{E}\left(f(X_T^N) H_T^{Mall.Ell.,N} \right) \right| \leq K(T, x) \frac{\|f\|_\infty}{T^q} h.$$

Remark 3.1. Instead of basing the computations of Malliavin derivatives for different adapted processes U, $(\mathcal{D}_{t_i}U_{t_j})_{0\le i\le j\le N}$, on the equality (2.3), an alternative approach would be to derive equations solved by $(\mathcal{D}_{t_i}U_t)_{t_i\le t\le T}$ and then approximate them with a discretization scheme (for each t_i). However, this approach would require essentially $O(N^2)$ operations, instead of $O(N)$ in our case.

3.2.2. General nondegenerate case. Denote by $0_{d_1,d_2}$ the $d_1\times d_2$ matrix with 0 for each element. Simple algebra yields that $\dot{V}_T^*\gamma_T^{-1}\mathcal{D}_sV_T$ is equal to

$$\dot{V}_T^*\gamma_T^{-1}\Pi_r^R(Y_TZ_s\sigma(s,X_s)) = (0_{1,d-r}\dot{V}_T^*)\begin{pmatrix} 0_{d-r,d-r} & 0_{d-r,r} \\ 0_{r,d-r} & \gamma_T^{-1}\end{pmatrix} Y_TZ_s\sigma(s,X_s)$$
$$= \sum_{i=1}^d F_i[(Z_s\sigma(s,X_s))^*]_i,$$

where

$$F_i = \left(Y_T^*\begin{pmatrix} 0_{d-r,d-r} & 0_{d-r,r} \\ 0_{r,d-r} & \gamma_T^{-1}\end{pmatrix}\begin{pmatrix} 0_{d-r,1} \\ \dot{V}_T\end{pmatrix}\right)_i = \sum_j U_{\kappa(i,j),T}(\gamma_T^{-1})_{\beta(i,j),\gamma(i,j)},$$

with the random variables $(U_{\kappa(i,j),T})_{i,j}$ being expressed as a product of coordinates of Y_T and $\dot{V}_T$. As before, we do not develop their expression to keep the formulae easy to manipulate, and we refer to [GM03] for more details.

Hence, the random variable of interest in Proposition 2.8, i.e., $H_T^{Mall.Gen.}$, is

$$\delta\left(\dot{V}_T^*\gamma_T^{-1}\mathcal{D}_{\cdot}V_T\right) = \sum_{i=1}^d F_i\int_0^T[(Z_s\sigma(s,X_s))^*]_i^*dW_s - \sum_{i=1}^d\int_0^T\mathcal{D}_sF_i[(Z_s\sigma(s,X_s))^*]_ids.$$

By the chain rule, the Malliavin derivative of F_i is related to that of $U_{\kappa(i,j),T}$ (i.e., coordinates of Y_T and $\dot{V}_T$) and that of $(\gamma_T^{-1})_{\beta(i,j),\gamma(i,j)}$: the latter can be expressed in terms of γ_T^{-1} and $\mathcal{D}_s\gamma_T$ (see Lemma 2.1.6 in Nualart [Nua95, p. 89]) and we obtain

$$H_T^{Mall.Gen.} = \sum_{i,j}U_{\kappa(i,j),T}(\gamma_T^{-1})_{\beta(i,j),\gamma(i,j)}\int_0^T[(Z_s\sigma(s,X_s))^*]_i^*dW_s \tag{3.8}$$

$$-\sum_{i,j}(\gamma_T^{-1})_{\beta(i,j),\gamma(i,j)}\int_0^T\mathcal{D}_sU_{\kappa(i,j),T}[(Z_s\sigma(s,X_s))^*]_ids \tag{3.9}$$

$$+\sum_{i,j,k,l}U_{\kappa(i,j),T}(\gamma_T^{-1})_{\beta(i,j),k}(\gamma_T^{-1})_{l,\gamma(i,j)}\int_0^T\mathcal{D}_s(\gamma_{k,l,T})[(Z_s\sigma(s,X_s))^*]_ids. \tag{3.10}$$

Analogously to the elliptic case, the integrals above may be discretized. Furthermore, the random variables $U_{\kappa(i,j),T}$ may be approximated by $U^N_{\kappa(i,j),T}$, defined by the same product of coordinates of Y_T^N and $\dot{V}_T^N$ as the one defining $U_{\kappa(i,j),T}$. Its weak derivative can be computed as in (3.7): indeed, with the same arguments, one may prove that

$$\mathcal{D}_sU_{\kappa(i,j),T} = \mathbf{1}_{s\le T}\sum_k\hat{U}_{\kappa(i,j,k),T}\check{U}_{\beta(i,j,k),s}, \tag{3.11}$$

where $(\hat{U}_{\kappa(i,j,k),T})_{i,j,k}$ (resp., $(\check{U}_{\beta(i,j,k),s})_{i,j,k}$) are appropriate real values (resp., vectors) at time T (resp., at time s) of some extended systems of SDEs. Then, the

natural approximation is

$$[\mathcal{D}_s U_{\kappa(i,j),T}]^N = \mathbf{1}_{s\le T} \sum_k \hat{U}^N_{\kappa(i,j,k),T} \check{U}^N_{\beta(i,j,k),s}. \tag{3.12}$$

Actually, what differs from the elliptic case are the Malliavin covariance matrix γ_T and its weak derivative. Even if $\gamma_T = \int_0^T \Pi^R_r(Y_T Z_s \sigma(s, X_s))[\Pi^R_r(Y_T Z_s \sigma(s, X_s))]^* ds$ is almost surely invertible with an inverse in any $\mathbf{L}^p$, a naive approximation may not satisfy these invertibility properties: for this reason, we add a small perturbation in its discretization as follows:

$$\gamma^N_T = \int_0^T \Pi^R_r(Y^N_T Z^N_{\phi(s)} \sigma(\phi(s), X^N_{\phi(s)}))[\Pi^R_r(Y^N_T Z^N_{\phi(s)} \sigma(\phi(s), X^N_{\phi(s)}))]^* ds + \frac{T}{N} \mathrm{I}_d. \tag{3.13}$$

This allows us to state the following result.

LEMMA 3.3. *Assume* (R_∞) *and* (E'). *Then, for any* $p \ge 1$, *one has for some positive numbers* p_1 *and* q_1: $\|1/\det(\gamma^N_T)\|_{\mathbf{L}^p} \le K(T,x) \|1/\det(\gamma_T)\|^{q_1}_{\mathbf{L}^{p_1}}$ *with a constant* $K(T,x)$ *independent of* N.

Proof. It is easy to check that $\|\gamma^N_T - \gamma_T\|_{\mathbf{L}^p} \le K(T,x)\sqrt{h}$ (use Lemma 4.3 below). Moreover, the eigenvalues of γ^N_T are all greater than h; hence $\det(\gamma^N_T) \ge h^r$, and one deduces

$$\begin{aligned}
\mathbb{E}(\det(\gamma^N_T)^{-p}) &= \mathbb{E}\left(\det(\gamma^N_T)^{-p} \mathbf{1}_{\det(\gamma^N_T) \le \frac{1}{2}\det(\gamma_T)}\right) + \mathbb{E}\left(\det(\gamma^N_T)^{-p} \mathbf{1}_{\det(\gamma^N_T) > \frac{1}{2}\det(\gamma_T)}\right) \\
&\le h^{-rp} \mathbb{P}\left(\frac{\det(\gamma_T) - \det(\gamma^N_T)}{\det(\gamma_T)} \ge \frac{1}{2}\right) + 2^p \mathbb{E}(\det(\gamma_T)^{-p}) \\
&\le h^{-rp} 2^q \| \, |\det(\gamma_T) - \det(\gamma^N_T)|^q \|_{\mathbf{L}^{p_1}} \|\det(\gamma_T)^{-q}\|_{\mathbf{L}^{p_2}} + 2^p \mathbb{E}(\det(\gamma_T)^{-p})
\end{aligned}$$

where p_1 and p_2 are conjugate numbers. Take $q = 2rp$ to get the result. ∎

To deal with the weak derivative of γ_T, one needs to rewrite

$$\gamma_{k,l,T} = \sum_{i'} A_{\epsilon(k,l,i'),T} \int_0^T B_{\eta(k,l,i'),u} du,$$

where $A_{\epsilon(k,l,i'),T}$ (resp., $B_{\eta(k,l,i'),u}$) are products of coordinates of Y_T (resp., Z_u and $\sigma(u, X_u)$). As for (3.7), the Malliavin derivative of $A_{\epsilon(k,l,i'),T}$ and $B_{\eta(k,l,i'),u}$ can be expressed as

$$\begin{aligned}
\mathcal{D}_s A_{\epsilon(k,l,i'),T} &= \mathbf{1}_{s\le T} \sum_{j'} C_{\epsilon(k,l,i',j'),T} D_{\epsilon(k,l,i',j'),s}, \\
\mathcal{D}_s B_{\eta(k,l,i'),u} &= \mathbf{1}_{s\le u} \sum_{j'} E_{\eta(k,l,i',j'),u} F_{\eta(k,l,i',j'),s}.
\end{aligned}$$

Hence, for $s \le T$, one has

$$\begin{aligned}
\mathcal{D}_s \gamma_{k,l,T} = &\sum_{i',j'} C_{\epsilon(k,l,i',j'),T} \left(\int_0^T B_{\eta(k,l,i'),u} du\right) D_{\epsilon(k,l,i',j'),s} \\
&+ \sum_{i',j'} A_{\epsilon(k,l,i'),T} F_{\eta(k,l,i',j'),s} \int_s^T E_{\eta(k,l,i',j'),u} du,
\end{aligned} \tag{3.14}$$

which can be approximated by

$$[\mathcal{D}_s\gamma_{k,l,T}]^N = \sum_{i',j'} C^N_{\epsilon(k,l,i',j'),T}\left(\int_0^T B^N_{\eta(k,l,i'),\phi(u)}du\right) D^N_{\epsilon(k,l,i',j'),s}$$

$$+\sum_{i',j'} A^N_{\epsilon(k,l,i'),T}\; F^N_{\eta(k,l,i',j'),s}\int_s^T E^N_{\eta(k,l,i',j'),\phi(u)}du. \tag{3.15}$$

We now turn to the global approximation of the weight $H_T^{Mall.Gen.}$:

(3.16)

$$H_T^{Mall.Gen.,N} = \sum_{i,j} U^N_{\kappa(i,j),T}[(\gamma_T^N)^{-1}]_{\beta(i,j),\gamma(i,j)}\int_0^T [(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]^*_i dW_s$$

$$-\sum_{i,j}[(\gamma_T^N)^{-1}]_{\beta(i,j),\gamma(i,j)}\int_0^T [\mathcal{D}_{\phi(s)}U_{\kappa(i,j),T}]^N[(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i ds \tag{3.17}$$

$$+\sum_{i,j,k,l} U^N_{\kappa(i,j),T}[(\gamma_T^N)^{-1}]_{\beta(i,j),k}[(\gamma_T^N)^{-1}]_{l,\gamma(i,j)}$$

$$\int_0^T [\mathcal{D}_{\phi(s)}(\gamma_{k,l,T})]^N[(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i ds. \tag{3.18}$$

We are now in a position to state the following approximation result.

THEOREM 3.4. *Assume* (R_∞), (E′), *and* (H). *For some positive numbers* p *and* q, *one has:*

$$\left|\dot{J}(\alpha) - \mathbb{E}(f(V_T^N)H_T^{Mall.Gen.,N})\right| \le K(T,x)\|f\|_\infty \|1/\det(\gamma_T)\|^q_{\mathbf{L}^p} h.$$

In the hypoelliptic case (case 1) in Proposition 2.7), note that the weak approximation result above holds true under a nondegeneracy condition stated only at the initial point $(0, X_0)$, which is a significant improvement compared to [BT96a] (or more recently in [TZ04]), where the condition was stated in the whole space.

3.3. Adjoint approach. To approximate $H_T^{b,Adj.}$ and $H_T^{\sigma,Adj.}$ from Theorem 2.11, we propose the following natural estimates:

(3.19)

$$H_T^{b,Adj.,N} = f(X_T^N)h\sum_{k=0}^{N-1}\dot{b}(t_k,X^N_{t_k})\cdot\frac{Z^{N*}_{t_k}}{T-t_k}\int_{t_k}^T [\sigma^{-1}(\phi(s),X^N_{\phi(s)})\; Y^N_{\phi(s)}]^*\; dW_s,$$

$$H_T^{\sigma,Adj.,N} = h\sum_{k=0}^{N-1}\sum_{i,j=1}^d [\sigma\dot{\sigma}^*]_{i,j}(t_k,X^N_{t_k})[f(X_T^N)-f(X^N_{t_k})]$$

$$\times\left(\frac{2e^j}{T-t_k}\cdot\left[Z^{N*}_{t_k}\int_{\phi(\frac{T+t_k}{2})}^T [\sigma^{-1}(\phi(s),X^N_{\phi(s)})Y^N_{\phi(s)}]^* dW_s\right]\right.$$

$$\left.\times\frac{2e^i}{T-t_k}\cdot\left[Z^{N*}_{t_k}\int_{t_k}^{\phi(\frac{T+t_k}{2})} [\sigma^{-1}(\phi(s),X^N_{\phi(s)})Y^N_{\phi(s)}]^* dW_s\right]\right.$$

$$\left.+\frac{2e^i}{T-t_k}\cdot\left\{\nabla_x\left[Z^{N*}_{t_k}\int_{t_k}^{\phi(\frac{T+t_k}{2})} [\sigma^{-1}(\phi(s),X^N_{\phi(s)})Y^N_{\phi(s)}]^* dW_s\right]Z^N_{t_k}e^j\right\}\right). \tag{3.20}$$

Derivatives $\nabla_x Y^N_{\phi(s)}$ and $\nabla_x Z^N_{t_k}$ are obtained by a direct differentiation in (3.2) and (3.3): we do not make the equations explicit; they coincide with those of the Euler procedure applied to $\nabla_x Y_t$ and $\nabla_x Z_t$ defined in (1.3) and (1.4).

These approximations also induce a discretization error in the computation of $\dot{J}(\alpha)$ of order 1 w.r.t. h.

THEOREM 3.5. *Assume* (R_∞), (E), *and* (H). *For some* $p \geq 0$, *one has*

$$\left| \dot{J}(\alpha) - \mathbb{E}\left(H_T^{b,Adj.,N} + H_T^{\sigma,Adj.,N} \right) \right| \leq K(T,x) \frac{\|f\|_\infty}{T^p} h.$$

The proof is postponed to section 4.4.

3.4. Martingale approach. The natural approximation of $H_T^{Mart.}$ defined in Theorem 2.12 may be given by

$$H_T^{Mart.,N} = \frac{f(X_T^N)}{T} \int_0^T [\sigma^{-1}(\phi(s), X^N_{\phi(s)}) \dot{X}^N_{\phi(s)}]^* dW_s + \int_0^T dr \, \frac{[f(X_T^N) - f(X^N_{\phi(r)})]}{(T-\phi(r))^2}$$

$$\times \int_{\phi(r)}^T [\sigma^{-1}(\phi(s), X^N_{\phi(s)})(\dot{X}^N_{\phi(s)} - Y^N_{\phi(s)} Z^N_{\phi(r)} \dot{X}^N_{\phi(r)})]^* dW_s.$$

Unfortunately, we have not been able to analyze the approximation error $\dot{J}(\alpha) - \mathbb{E}(H_T^{Mart.,N})$ under the fairly general assumption (H′). Indeed, an immediate issue to handle would be to quantify the quality of the approximation of $\int_0^T dr \, \mathbb{E}\big(\frac{[f(X_T) - f(X_r)]}{(T-r)^2} \int_r^T [\sigma_s^{-1}(\dot{X}_s - Y_s Z_r \dot{X}_r)]^* dW_s \big)$ by its Riemann sum, which seems to be far from obvious under (H′).

4. Proof of the results on the discretization error analysis. This section is devoted to the proof of section 3's theorems analyzing the discretization error.

The trick to prove these estimates for $\mathbb{E}(f(X_T))$ usually relies on the Markov property: one decomposes the error using the PDE solved by the function $(t,x) \mapsto \mathbb{E}(f(X^x_{T-t}))$ (see Bally and Talay [BT96a]), but this makes no sense in our situation. Another way to proceed consists in cleverly using the duality relationship (2.1) with some stochastic expansion to get the right order (see Kohatsu-Higa [KH01] or [KHP02]). During the revision of this work, Kohatsu-Higa brought to our attention another paper [KHP00] where the approximation of some smooth functionals of SDEs is successfully analyzed in this way. Here, we also adopt this approach. However, the functionals of interest are much more complex. Moreover, extra technicalities compared to [KHP02] are required, because of the necessity for our Malliavin calculus computations to introduce a localization factor $\psi_T^{N,\epsilon}$.

To clarify the arguments, we first state a quite general result, whose statement enables us to reduce the proof of our theorems to check that a stochastic expansion holds true.

4.1. A more general result. By convention, we set $dW_s^0 = ds$. First, we need to define some particular forms of stochastic expansions.

DEFINITION 4.1. *The real random variable U_T (which in general depends on N) satisfies property $(\mathcal{P})$ if it can be written as*

$$U_T = \sum_{i,j=0}^{q} c_{i,j}^{U,0}(T) \int_0^T c_{i,j}^{U,1}(t) \left(\int_{\phi(t)}^t c_{i,j}^{U,2}(s) dW_s^i \right) dW_t^j + \sum_{i,j,k=0}^{q} c_{i,j,k}^{U,0}(T) \int_0^T c_{i,j,k}^{U,1}(t) \left[\int_0^t c_{i,j,k}^{U,2}(s) \left(\int_{\phi(s)}^s c_{i,j,k}^{U,3}(u) dW_u^i \right) dW_s^j \right] dW_t^k$$

for some adapted processes $\{(c_{i,j}^{U,i_1}(t), c_{i,j,k}^{U,i_2}(t))_{t\geq 0}\colon\ 0 \leq i,j,k \leq q, 0 \leq i_1 \leq 2, 0 \leq i_2 \leq 3\}$ (possibly depending on N) and if, for each $t \in [0,T]$, they belong to $\mathbb{D}^\infty$ with Sobolev norms satisfying $\sup_{N,t\in[0,T]} \left(\|c_{i,j}^{U,i_1}(t)\|_{k',p} + \|c_{i,j,k}^{U,i_2}(t)\|_{k',p} \right) < \infty$ for any $k', p \geq 1$.

THEOREM 4.2. *Assume* (R_∞) *and that $H_T^N - H_T$ satisfies property $(\mathcal{P})$. Then,*

1. *if f is of class C_b^3, one has*

$$\left| \mathbb{E}(f(V_T)H_T) - \mathbb{E}(f(V_T^N)H_T^N) \right| \leq K(T,x) \Big(\sum_{0\leq|\alpha|\leq 3} \|\partial^\alpha f\|_\infty \Big) h;$$

2. *under* (E') *and* (H), *one has*

$$\left| \mathbb{E}(f(V_T)H_T) - \mathbb{E}(f(V_T^N)H_T^N) \right| \leq K(T,x)\ \|f\|_\infty\ \|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q\ h.$$

In the statement above, $(V_t)_{0\leq t\leq T}$ corresponds to some coordinates of a SDE $(X_t)_{0\leq t\leq T}$ as it is defined in (2.5), but we can also simply consider $V = X$.

Theorem 4.2 is proved at the end of this section, and for a while, we focus on its applications to derive the announced results about the discretization errors. Remember that the approximation of the weights H is essentially based on an Euler scheme applied to a system of SDEs. For this reason, the verification of property $(\mathcal{P})$ is tightly connected to the decomposition of the error, between a Brownian SDE and its Euler approximation, in terms of a stochastic expansion. This is the purpose of the following standard lemma (for more general driven semimartingales, see Jacod and Protter [JP98]).

LEMMA 4.3. *Consider a general d'-dimensional SDE $(\bar{X}_t)_{t\geq 0}$ defined by C^∞ coefficients with bounded derivatives, and $(\bar{X}_t^N)_{t\geq 0}$ its Euler approximation:*

$$\bar{X}_t = x + \int_0^t \bar{b}(s, \bar{X}_s)\ ds + \sum_{j=1}^q \int_0^t \bar{\sigma}_j(s, \bar{X}_s)\ dW_s^j,$$

$$\bar{X}_t^N = x + \int_0^t \bar{b}(\phi(s), \bar{X}_{\phi(s)}^N)\ ds + \sum_{j=1}^q \int_0^t \bar{\sigma}_j(\phi(s), \bar{X}_{\phi(s)}^N)\ dW_s^j.$$

Then, for each t, each component of $\bar{X}_t - \bar{X}_t^N$ satisfies $(\mathcal{P})$. Namely, for $1 \leq k \leq d'$, one has

$$\bar{X}_{k,t} - \bar{X}_{k,t}^N = \sum_{i,j=0}^q c_{i,j,k}^{\bar{X},0}(t) \int_0^t c_{i,j,k}^{\bar{X},1}(s) \Big(\int_{\phi(s)}^s c_{i,j,k}^{\bar{X},2}(u) dW_u^i \Big) dW_s^j$$

for some adapted processes $\{(c_{i,j,k}^{\bar{X},i_1}(t))_{t\geq 0} : 0 \leq i,j \leq q, 1 \leq k \leq d', 0 \leq i_1 \leq 2\}$ satisfying $\sup_{N,t\in[0,T]} \|c_{i,j,k}^{\bar{X},i_1}(t)\|_{k',p} < \infty$ for any $k', p \geq 1$.

Proof. One has $\bar{X}_t - \bar{X}_t^N = \int_0^t \bar{b}'(s)(\bar{X}_s - \bar{X}_s^N)\,ds + \sum_{j=1}^q \int_0^t \bar{\sigma}_j'(s)(\bar{X}_s - \bar{X}_s^N)\,dW_s^j + \int_0^t [\bar{b}(s,\bar{X}_s^N) - \bar{b}(\phi(s),\bar{X}_{\phi(s)}^N)]\,ds + \sum_{j=1}^q \int_0^t [\bar{\sigma}_j(s,\bar{X}_s^N) - \bar{\sigma}_j(\phi(s),\bar{X}_{\phi(s)}^N)]\,dW_s^j$ with $a'(s) = \int_0^1 \nabla_x a(s, \bar{X}_s^N + \lambda(\bar{X}_s - \bar{X}_s^N))d\lambda$ for $a = \bar{b}$ or $a = \bar{\sigma}_j$. Now, consider the unique solution of the linear equation $\mathcal{E}_t = \mathrm{I}_d + \int_0^t \bar{b}'(s)\mathcal{E}_s\,ds + \sum_{j=1}^q \int_0^t \bar{\sigma}_j'(s)\mathcal{E}_s\,dW_s^j$. From Theorem 56 p. 271 in Protter [Pro90], one deduces that

$$\begin{aligned}\bar{X}_t - \bar{X}_t^N = \mathcal{E}_t \int_0^t {\mathcal{E}_s}^{-1} \Bigg\{ & [\bar{b}(s,\bar{X}_s^N) - \bar{b}(\phi(s),\bar{X}_{\phi(s)}^N)] \\ & - \sum_{j=1}^q \bar{\sigma}_j'(s)[\bar{\sigma}_j(s,\bar{X}_s^N) - \bar{\sigma}_j(\phi(s),\bar{X}_{\phi(s)}^N)] \Bigg\} ds \\ + \sum_{j=1}^q \mathcal{E}_t \int_0^t {\mathcal{E}_s}^{-1} & [\bar{\sigma}_j(s,\bar{X}_s^N) - \bar{\sigma}_j(\phi(s),\bar{X}_{\phi(s)}^N)]\,dW_s^j;\end{aligned}$$

then, by applying Itô's formula between $\phi(s)$ and s, we can easily complete the proof of Lemma 4.3. □

4.2. Proof of Theorem 3.4 (general nondegenerate case). Owing to Theorem 4.2, we only have to prove that $H_T^{Mall.Gen.} - H_T^{Mall.Gen.,N}$ satisfies property $(\mathcal{P})$. Thus, it is enough to separately look at each factor in $H_T^{Mall.Gen.}$ and $H_T^{Mall.Gen.,N}$, by proving that their difference is of the form $c_{i,j}^{U,0}(T)\int_0^T c_{i,j}^{U,1}(t)\big(\int_{\phi(t)}^t c_{i,j}^{U,2}(s)dW_s^i\big)dW_t^j$ or $c_{i,j,k}^{U,0}(T)\int_0^T c_{i,j,k}^{U,1}(t)\big[\int_0^t c_{i,j,k}^{U,2}(s)\big(\int_{\phi(s)}^s c_{i,j,k}^{U,3}(u)dW_u^i\big)dW_s^j\big]dW_t^k$, while the other factors just belong to $\mathbb{D}^\infty$ with uniformly bounded Sobolev norms.

(a) The fact that the difference $U_{\kappa(i,j),T} - U_{\kappa(i,j),T}^N$ (involved in (3.8), (3.10), (3.16), and (3.18)) satisfies $(\mathcal{P})$ can be derived from an application of Lemma 4.3 by noticing that $U_{\kappa(i,j),T}$ is the product of coordinates of Y_T and $\dot{V}_T$.

(b) Using the expressions of γ_T and γ_T^N, one gets $\gamma_{k,l,T} - \gamma_{k,l,T}^N = -\delta_{k,l}h + \mathcal{E}_{3,1,k,l} + \mathcal{E}_{3,2,k,l}$ with

$$\begin{aligned}\mathcal{E}_{3,1,k,l} &= \int_0^T \big[\Pi_r^R(Y_T Z_s \sigma(s,X_s))[\Pi_r^R(Y_T Z_s \sigma(s,X_s))]^*\big]_{k,l}\,ds \\ &\quad - \int_0^T \big[\Pi_r^R(Y_T^N Z_s^N \sigma(s,X_s^N))[\Pi_r^R(Y_T^N Z_s^N \sigma(s,X_s^N))]^*\big]_{k,l}\,ds, \\ \mathcal{E}_{3,2,k,l} &= \int_0^T \big[\Pi_r^R(Y_T^N Z_s^N \sigma(s,X_s^N))[\Pi_r^R(Y_T^N Z_s^N \sigma(s,X_s^N))]^*\big]_{k,l}\,ds \\ &\quad - \int_0^T \Big[\Pi_r^R(Y_T^N Z_{\phi(s)}^N \sigma(\phi(s),X_{\phi(s)}^N))[\Pi_r^R(Y_T^N Z_{\phi(s)}^N \sigma(\phi(s),X_{\phi(s)}^N))]^*\Big]_{k,l}\,ds.\end{aligned}$$

Using Lemma 4.3 and the relation $a(s,X_s) - a(s,X_s^N) = a'(s)(X_s - X_s^N)$ with $a'(s) = \int_0^1 \nabla_x a(s, X_s^N + \lambda(X_s - X_s^N))d\lambda$ available for smooth functions a, it is straightforward to see that $\mathcal{E}_{3,1,k,l}$ can be written as a sum of terms satisfying $(\mathcal{P})$. The same conclusion holds for $\mathcal{E}_{3,2,k,l}$ if we apply Itô's formula between $\phi(s)$ and s.

Finally, as $1/\det(\gamma_T)$ and $1/\det(\gamma_T^N)$ belong to any $\mathbf{L}^p$ $(p \geq 1)$ according to Lemma 3.3, it follows that the difference $[\gamma_T^{-1}]_{k',l'} - [(\gamma_T^N)^{-1}]_{k',l'}$ (involved in (3.8), (3.9), (3.10), (3.16), (3.17), and (3.18)) satisfies $(\mathcal{P})$.

(c) Concerning (3.8) and (3.16), the difference $\int_0^T [(Z_s\sigma(s,X_s))^*]_i^* dW_s - \int_0^T [(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i^* dW_s$ is equal to a sum of two terms:

$$\int_0^T [(Z_s\sigma(s,X_s))^*]_i^* dW_s - \int_0^T [(Z^N_s\sigma(s,X^N_s))^*]_i^* dW_s,$$

$$\int_0^T [(Z^N_s\sigma(s,X^N_s))^*]_i^* dW_s - \int_0^T [(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i^* dW_s.$$

It is straightforward to check that both contributions satisfy $(\mathcal{P})$, the first one because of Lemma 4.3 and the second one as an application of Itô's formula.

(d) The approximation error between terms (3.9) and (3.17) also comes from the difference $\int_0^T \mathcal{D}_s U_{\kappa(i,j),T}[(Z_s\sigma(s,X_s))^*]_i ds - \int_0^T [\mathcal{D}_{\phi(s)}U_{\kappa(i,j),T}]^N[(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i ds := \mathcal{E}_{4,1,i,j} + \mathcal{E}_{4,2,i,j}$, where

$$\begin{aligned}\mathcal{E}_{4,1,i,j} &= \int_0^T \mathcal{D}_s U_{\kappa(i,j),T}[(Z_s\sigma(s,X_s))^*]_i ds \\ &\qquad - \int_0^T [\mathcal{D}_s U_{\kappa(i,j),T}]^N[(Z^N_s\sigma(s,X^N_s))^*]_i ds, \\ \mathcal{E}_{4,2,i,j} &= \int_0^T [\mathcal{D}_s U_{\kappa(i,j),T}]^N[(Z^N_s\sigma(s,X^N_s))^*]_i ds \\ &\qquad - \int_0^T [\mathcal{D}_{\phi(s)}U_{\kappa(i,j),T}]^N[(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i ds.\end{aligned}$$

The error induced by the approximation between $Z_s\sigma(s,X_s)$, $Z^N_s\sigma(s,X^N_s)$, and $Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)})$ can be handled as before using Lemma 4.3 and Itô's formula. To deal with $\mathcal{D}_s U_{\kappa(i,j),T}$, $[\mathcal{D}_s U_{\kappa(i,j),T}]^N$ and $[\mathcal{D}_{\phi(s)}U_{\kappa(i,j),T}]^N$, we may recall their particular forms given by equations (3.11) and (3.12). Again, Lemma 4.3 applies to the extended systems which help in defining $\mathcal{D}_s U_{\kappa(i,j),T}$. This provides a contribution error equal to a sum of terms satisfying $(\mathcal{P})$.

(e) The difference $\int_0^T \mathcal{D}_s(\gamma_{k,l,T})[(Z_s\sigma(s,X_s))^*]_i ds - \int_0^T [\mathcal{D}_{\phi(s)}(\gamma_{k,l,T})]^N [(Z^N_{\phi(s)}\sigma(\phi(s),X^N_{\phi(s)}))^*]_i ds$ coming from (3.10) and (3.18) can be analyzed with the same arguments as before, if we take into account the specific form of the derivative $\mathcal{D}_s(\gamma_{k,l,T})$ and its approximation given by (3.14) and (3.15).

The proof of Theorem 3.4 is complete.

4.3. Proof of Theorems 3.1 (pathwise approach) and 3.2 (elliptic case).

Proof of Theorem 3.1. By an application of Theorem 4.2, it is enough to check that $\dot{X}_T - \dot{X}^N_T$ satisfies $(\mathcal{P})$, which is actually a direct consequence of Lemma 4.3.

Proof of Theorem 3.2. As for Theorem 3.4, we can check that $H_T^{Mall.Ell.} - H_T^{Mall.Ell.,N}$ satisfies $(\mathcal{P})$. Thus, Theorem 4.2 with $V_T = X_T$ and $V^N_T = X^N_T$ yields $\left|\dot{J}(\alpha) - \mathbb{E}(f(X^N_T)H_T^{Mall.Ell.,N})\right| \le \frac{K(T,x)}{T}\ \|f\|_\infty\ \|1/\det(\gamma_T)\|^q_{\mathbf{L}^p}\ h$, for some positive numbers p and q. Invoking the following well-known upper bound (see Theorem 3.5 in [KS84]) $\|1/\det(\gamma_T)\|_{\mathbf{L}^p} \le K(T,x)/T^d$ completes the estimate given in Theorem 3.2.

4.4. Theorem 3.5 (adjoint approach). The first approximation which is easy to justify is the time discretization of the integral involved in Lemma 2.9. For this, note that the function $t \mapsto \mathbb{E}(\sum_{i=1}^d \dot{b}_i(t,X_t)\partial_{x_i}u(t,X_t) + \frac{1}{2}\sum_{i,j=1}^d [\sigma\dot{\sigma}^*]_{i,j}(t,X_t)\partial^2_{x_i,x_j}u(t,X_t))$

is of class $C_b^1([0,T],\mathbb{R})$: indeed, it is a smooth function in particular because u is, and its derivatives are uniformly bounded thanks to estimates of type (2.6). Hence, it remains to prove the following upper bounds, uniformly in i,j:

(4.1)
$$\left|\mathbb{E}\left(f(X_T)\dot{b}(t_k,X_{t_k})\cdot {Z_{t_k}}^* \int_{t_k}^T [\sigma^{-1}(s,X_s)\, Y_s]^*\, dW_s - f(X_T^N)\dot{b}(t_k,X_{t_k}^N)\cdot Z_{t_k}^{N*}\right.\right.$$
$$\left.\left.\times \int_{t_k}^T [\sigma^{-1}(\phi(s),X_{\phi(s)}^N)\, Y_{\phi(s)}^N]^*\, dW_s\right)\right| \le K(T,x)\frac{\|f\|_\infty}{T^q}(T-t_k)h,$$

(4.2)
$$\left|\mathbb{E}\left([\sigma\dot{\sigma}^*]_{i,j}(t_k,X_{t_k})f(X_T)e^j\cdot\left[{Z_{t_k}}^*\int_{\frac{T+t_k}{2}}^T[\sigma^{-1}(s,X_s)Y_s]^*dW_s\right]\right.\right.$$
$$\times\, e^i\cdot\left[{Z_{t_k}}^*\int_{t_k}^{\frac{T+t_k}{2}}[\sigma^{-1}(s,X_s)Y_s]^*dW_s\right] - [\sigma\dot{\sigma}^*]_{i,j}(t_k,X_{t_k}^N)f(X_T^N)$$
$$\times\, e^j\cdot\left[Z_{t_k}^{N*}\int_{\phi(\frac{T+t_k}{2})}^T[\sigma^{-1}(\phi(s),X_{\phi(s)}^N)Y_{\phi(s)}^N]^*dW_s\right]$$
$$\left.\left.\times\, e^i\cdot\left[Z_{t_k}^{N*}\int_{t_k}^{\phi(\frac{T+t_k}{2})}[\sigma^{-1}(\phi(s),X_{\phi(s)}^N)Y_{\phi(s)}^N]^*dW_s\right]\right)\right| \le K(T,x)\frac{\|f\|_\infty}{T^q}(T-t_k)^2h,$$

(4.3)
$$\left|\mathbb{E}\left([\sigma\dot{\sigma}^*]_{i,j}(t_k,X_{t_k})f(X_T)e^i\cdot\left\{\nabla_x\left[{Z_{t_k}}^*\int_{t_k}^{\frac{T+t_k}{2}}[\sigma^{-1}(s,X_s)Y_s]^*dW_s\right]Z_{t_k}e^j\right\}\right.\right.$$
$$- [\sigma\dot{\sigma}^*]_{i,j}(t_k,X_{t_k}^N)f(X_T^N)e^i$$
$$\left.\left.\cdot\left\{\nabla_x\left[Z_{t_k}^{N*}\int_{t_k}^{\phi(\frac{T+t_k}{2})}[\sigma^{-1}(\phi(s),X_{\phi(s)}^N)Y_{\phi(s)}^N]^*dW_s\right]Z_{t_k}^Ne^j\right\}\right)\right|$$
$$\le K(T,x)\frac{\|f\|_\infty}{T^q}(T-t_k)h.$$

Note that terms with $f(X_{t_k})$ and $f(X_{t_k}^N)$ have been removed since they do not contribute in the expectation. The three errors above can be analyzed by applying Theorem 4.2, except that the upper bounds have to include factors $(T-t_k)$ or $(T-t_k)^2$: this is a simple improvement that we won't detail here. □

4.5. Proof of Theorem 4.2.

4.5.1. When f is of class C_b^3. Set $V_T^{\lambda,N} = V_T^N + \lambda(V_T - V_T^N)$ for $\lambda\in[0,1]$. Then, the error to analyze is

(4.4)
$$\mathbb{E}(f(V_T)H_T) - \mathbb{E}(f(V_T^N)H_T^N) = \mathbb{E}([f(V_T)-f(V_T^N)]H_T) + \mathbb{E}(f(V_T^N)[H_T - H_T^N]).$$

Note that the difference $V_T - V_T^N$ can be expressed componentwise using Lemma 4.3; using a Taylor expansion, it follows that the first contribution in the right-hand side

above can be split in a sum of terms

$$\mathcal{E}_{i,j,k} = \int_0^1 d\lambda\, \mathbb{E}\left(\partial_{x_k} f(V_T^{\lambda,N}) H_T c_{i,j,k}^0(T) \int_0^T c_{i,j,k}^1(t) \left[\left(\int_{\phi(t)}^t c_{i,j,k}^2(s) dW_s^i\right) dW_t^j\right]\right),$$

for $0 \le i,j \le q$. If i and j are different from 0, we twice apply the duality relation (2.1) combined with Fubini's theorem to obtain that $\mathcal{E}_{i,j,k}$ equals

$$\begin{aligned}
&\int_0^1 d\lambda \int_0^T dt\, \mathbb{E}\left(\mathcal{D}_t^j\left[\partial_{x_k} f(V_T^{\lambda,N}) H_T c_{i,j,k}^0(T)\right] c_{i,j,k}^1(t) \left(\int_{\phi(t)}^t c_{i,j,k}^2(s) dW_s^i\right)\right)\\
&= \int_0^1 d\lambda \int_0^T dt \int_{\phi(t)}^t ds\, \mathbb{E}\big(\mathcal{D}_s^i\big\{\mathcal{D}_t^j\left[\partial_{x_k} f(V_T^{\lambda,N}) H_T c_{i,j,k}^0(T)\right] c_{i,j,k}^1(t)\big\} c_{i,j,k}^2(s)\big)\\
&= \sum_l \int_0^1 d\lambda \int_0^T dt \int_{\phi(t)}^t ds\, \mathbb{E}\big(\partial_x^{\gamma_1(l)} f(V_T^{\lambda,N}) G_{s,t,T}^{1,l,\lambda,N}\big), \qquad (4.5)
\end{aligned}$$

where the length of the differentiation index $\gamma_1(l)$ is less than 3. If i and/or j equals 0, an analogous formula holds with $|\gamma_1(l)| \le 2$. The random variable $G_{s,t,T}^{1,l,\lambda,N}$ is integrable with an $\mathbf{L}^1$-norm uniformly bounded w.r.t. λ, N, s, t. We have proved that this first contribution in the right-hand side of (4.4) meets the estimate of Theorem 4.2.

For the second contribution, taking into account that $H_T - H_T^N$ satisfies $(\mathcal{P})$ and using the same techniques as before, we obtain that $\mathbb{E}(f(V_T^N)[H_T - H_T^N])$ can be decomposed as a sum of terms of type

(4.6)
$$\int_0^T dt \int_{\phi(t)}^t ds \mathbb{E}\big(\partial_x^{\gamma_2} f(V_T^N) G_{s,t,T}^{\gamma_2,N}\big) \text{ and } \int_0^T dt \int_0^t ds \int_{\phi(s)}^s du \mathbb{E}\big(\partial_x^{\gamma_3} f(V_T^N) G_{u,s,t,T}^{\gamma_3,N}\big)$$

with $|\gamma_2| \le 2$ and $|\gamma_3| \le 3$. Uniform $\mathbf{L}^p$ estimates are available for $G_{s,t,T}^{\gamma_2,N}$ and $G_{u,s,t,T}^{\gamma_3,N}$ and the proof is complete for the case of functions f of class C_b^3.

4.5.2. When f is only measurable. Formally, techniques are identical, but to remove the *derivatives* of f in (4.5) and (4.6), we may integrate by parts. This step is not directly possible since the Malliavin covariance matrix of V_T^N or $V_T^{\lambda,N}$ may have bad properties, even under Assumption (E′). We do not encounter this problem in the one-dimensional elliptic case developed in [KHP02], since the convex combination of positive diffusion coefficients is still positive: this argument fails in higher dimensions with elliptic matrices, and a fortiori in a hypoelliptic framework. To circumvent this difficulty, we introduce a series of localization and approximation arguments, which unfortunately make the reading more tedious.

We put $V_T^\epsilon = V_T + \epsilon \tilde{W}_T$ and $V_T^{N,\epsilon} = V_T^N + \epsilon \tilde{W}_T$, where $(\tilde{W}_T)_{t\ge 0}$ is an extra independent r-dimensional Brownian motion and we define $V_T^{\lambda,N,\epsilon} = V_T^{N,\epsilon} + \lambda(V_T^\epsilon - V_T^{N,\epsilon})$ for $\lambda \in [0,1]$. In the following computations, the Malliavin calculus will be made w.r.t. the $(q+r)$-dimensional Brownian motion $\binom{W_t}{\tilde{W}_t}_{0\le t\le T}$.

Denote by $\bar{\mu}$ the measure defined by $\int_{\mathbb{R}^r} g(x)\bar{\mu}(dx) = \mathbb{E}(g(V_T^{0,N,0})) + \mathbb{E}(g(V_T^{1,N,0})) + \int_0^1 \mathbb{E}(g(V_T^{\lambda,N,0}))d\lambda$ and consider $(f_m)_{m\ge 1}$ a sequence of smooth functions with compact support, which converges to f in $\mathbf{L}^2(\bar{\mu})$. Thus, one easily gets that

$$\lim_{m\uparrow\infty} \lim_{\epsilon\downarrow 0} \|f_m(V_T^{\lambda,N,\epsilon})\|_{\mathbf{L}^2} = \lim_{m\uparrow\infty} \|f_m(V_T^{\lambda,N,0})\|_{\mathbf{L}^2} = \|f(V_T^{\lambda,N,0})\|_{\mathbf{L}^2} \le \|f\|_\infty \qquad (4.7)$$

for $\lambda = 0$ or 1, and

$$\lim_{m\uparrow\infty}\lim_{\epsilon\downarrow 0}\left(\int_0^1 \|f_m(V_T^{\lambda,N,\epsilon})\|_{\mathbf{L}^2}d\lambda\right) = \lim_{m\uparrow\infty}\left(\int_0^1 \|f_m(V_T^{\lambda,N})\|_{\mathbf{L}^2}d\lambda\right)$$

$$\leq \lim_{m\uparrow\infty}\sqrt{\int_0^1 \mathbb{E}(f_m^2(V_T^{\lambda,N}))d\lambda} = \sqrt{\int_0^1 \mathbb{E}(f^2(V_T^{\lambda,N,0}))d\lambda} \leq \|f\|_\infty. \tag{4.8}$$

Then, the error to analyze is equal to $\mathbb{E}(f(V_T)H_T) - \mathbb{E}(f(V_T^N)H_T^N) = \lim_{m\uparrow\infty,\epsilon\downarrow 0}[\mathcal{E}_1(m,\epsilon) + \mathcal{E}_2(m,\epsilon)]$ with

$$\mathcal{E}_1(m,\epsilon) = \mathbb{E}\left(f_m(V_T^\epsilon)H_T - f_m(V_T^{N,\epsilon})H_T\right),$$
$$\mathcal{E}_2(m,\epsilon) = \mathbb{E}\left(f_m(V_T^{N,\epsilon})H_T - f_m(V_T^{N,\epsilon})H_T^N\right).$$

In view of (4.7) and (4.8), it is enough to prove the following estimates, with some constants $K(T,x)$, p and q uniform in m, and $\epsilon \leq 1$:

$$|\mathcal{E}_1(m,\epsilon)| \leq K(T,x)\bigg(\|f_m(V_T^{0,N,\epsilon})\|_{\mathbf{L}^2} + \|f_m(V_T^{1,N,\epsilon})\|_{\mathbf{L}^2}$$
$$+ \int_0^1 \|f_m(V_T^{\lambda,N,\epsilon})\|_{\mathbf{L}^2}d\lambda\bigg)\|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q h, \tag{4.9}$$

$$|\mathcal{E}_2(m,\epsilon)| \leq K(T,x)\left(\|f_m(V_T^{0,N,\epsilon})\|_{\mathbf{L}^2} + \|f_m(V_T^{1,N,\epsilon})\|_{\mathbf{L}^2}\right)\|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q h. \tag{4.10}$$

We introduce a localization factor $\psi_T^{N,\epsilon} \in [0,1]$, satisfying the following properties:

(a) $\psi_T^{N,\epsilon} \in \mathbb{D}^\infty$ and $\sup_{N,\epsilon}\|\psi_T^{N,\epsilon}\|_{k,p} \leq K(T,x)\|1/\det(\gamma_T)\|_{\mathbf{L}^{q_1}}^{q_2}$ for any integers k,p;

(b) $\mathbb{P}(\psi_T^{N,\epsilon} \neq 1) \leq K(T,x)\|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q h^k$ for any $k \geq 1$, uniformly in ϵ;

(c) $\{\psi_T^{N,\epsilon} \neq 0\} \subset \{\forall\lambda \in [0,1] : \det(\gamma^{V_T^{\lambda,N,\epsilon}}) \geq \frac{1}{2}\det(\gamma^{V_T})\}$.

Its construction is given at the end of this section.

Error $\boldsymbol{\mathcal{E}_1(m,\epsilon)}$. Clearly, one has $\mathcal{E}_1(m,\epsilon) = \mathcal{E}_{1,1}(m,\epsilon) + \mathcal{E}_{1,2}(m,\epsilon)$ with

$$\mathcal{E}_{1,1}(m,\epsilon) = \mathbb{E}\left([f_m(V_T^\epsilon) - f_m(V_T^{N,\epsilon})](1-\psi_T^{N,\epsilon})H_T\right), \tag{4.11}$$

$$\mathcal{E}_{1,2}(m,\epsilon) = \mathbb{E}\left([f_m(V_T^\epsilon) - f_m(V_T^{N,\epsilon})]\psi_T^{N,\epsilon}H_T\right). \tag{4.12}$$

The first term can easily be bounded by $K(T,x)\big(\|f_m(V_T^{0,N,\epsilon})\|_{\mathbf{L}^2} + \|f_m(V_T^{1,N,\epsilon})\|_{\mathbf{L}^2}\big)$ $\|1/\det(\gamma_T)\|_{\mathbf{L}^p}^q h^k$ for any $k \geq 1$, using property (b) of $\psi_T^{N,\epsilon}$.

Now, to deal with the term $\mathcal{E}_{1,2}(m,\epsilon)$, we proceed as for the first term of the right-hand side of (4.4), that is, by decomposing $V_T^\epsilon - V_T^{N,\epsilon} = V_T - V_T^N$ using Lemma 4.3 and applying the duality relationship. Consequently, $\mathcal{E}_{1,2}(m,\epsilon)$ can be written as a sum of terms

$$\mathcal{E}_{1,2,\gamma_1}(m,\epsilon) = \int_0^1 d\lambda \int_0^T dt \int_{\phi(t)}^t ds\, \mathbb{E}\big(\partial_x^{\gamma_1} f_m(V_T^{\lambda,N,\epsilon})G_{s,t,T}^{\gamma_1,\lambda,N}\big) \tag{4.13}$$

with $|\gamma_1| \leq 3$. The random variable $G_{s,t,T}^{\gamma_1,\lambda,N}$ does not depend on ϵ and belongs to $\mathbb{D}^\infty$ with Sobolev norms uniformly bounded w.r.t. λ, N, s, t. Owing to the factor $\psi_T^{N,\epsilon}$,

note that $G^{\gamma_1,\lambda,N}_{s,t,T} = 0$ when $\psi^{N,\epsilon}_T = 0$, because of the local property of the derivative operator (see Proposition 1.3.7 in [Nua95, p. 44]). Since $\det(\gamma^{V^{\lambda,N,\epsilon}_T}) \geq \epsilon^{2r}$, one can apply Proposition 2.4, which yields

$$\mathbb{E}\big(\partial^{\gamma_1}_x f_m(V^{\lambda,N,\epsilon}_T) G^{\gamma_1,\lambda,N}_{s,t,T}\big) = \mathbb{E}\big(f_m(V^{\lambda,N,\epsilon}_T) H_{\gamma_1}(V^{\lambda,N,\epsilon}_T, G^{\gamma_1,\lambda,N}_{s,t,T})\big)$$

for some iterated Skorohod integral $H_{\gamma_1}(V^{\lambda,N,\epsilon}_T, G^{\gamma_1,\lambda,N}_{s,t,T})$. Due to the local property of the Skorohod integral (see Proposition 1.3.6 in [Nua95, p. 43]), one has $H_{\gamma_1}(V^{\lambda,N,\epsilon}_T, G^{\gamma_1,\lambda,N}_{s,t,T}) = H_{\gamma_1}(V^{\lambda,N,\epsilon}_T, G^{\gamma_1,\lambda,N}_{s,t,T})\mathbf{1}_{\psi^{N,\epsilon}_T \neq 0}$, and applying the estimate from Proposition 2.4, one gets

$$\|H_{\gamma_1}(V^{\lambda,N,\epsilon}_T, G^{\gamma_1,\lambda,N}_{s,t,T})\|_{\mathbf{L}^2} \leq C \|[\gamma^{V^{\lambda,N,\epsilon}_T}]^{-1} \mathbf{1}_{\psi^{N,\epsilon}_T \neq 0}\|^{p_3}_{\mathbf{L}^{q_3}} \|V^{\lambda,N,\epsilon}_T\|^{p_1}_{k_1,q_1} \|G^{\gamma_1,\lambda,N}_{s,t,T}\|_{k_2,q_2}$$

for some integers $p_1, p_3, q_1, q_2, q_3, k_1, k_2$. It is easy to upper bound $\|V^{\lambda,N,\epsilon}_T\|_{k_1,q_1}$ and $\|G^{\gamma_1,\lambda,N}_{s,t,T}\|_{k_2,q_2}$, uniformly in λ, N, s, t, and $\epsilon \leq 1$. It is straightforward to derive the estimation of $\|[\gamma^{V^{\lambda,N,\epsilon}_T}]^{-1} \mathbf{1}_{\psi^{N,\epsilon}_T \neq 0}\|_{\mathbf{L}^{q_3}}$ since on $\{\psi^{N,\epsilon}_T \neq 0\}$, $\det(\gamma^{V^{\lambda,N,\epsilon}_T}) \geq \frac{1}{2}\det(\gamma^{V_T})$, which has an inverse in any $\mathbf{L}^p$. One has proved that

$$|\mathcal{E}_{1,2,\gamma_1}(m,\epsilon)| \leq K(T,x) \left(\int_0^1 \|f_m(V^{\lambda,N,\epsilon}_T)\|_{\mathbf{L}^2} d\lambda \right) \|1/\det(\gamma_T)\|^q_{\mathbf{L}^p} h;$$

this completes the estimation (4.9).

Error $\boldsymbol{\mathcal{E}_2(m,\epsilon)}$. As before, this error can be split into two parts $\mathcal{E}_2(m,\epsilon) = \mathbb{E}\big(f_m(V^{N,\epsilon}_T)(1-\psi^{N,\epsilon}_T)(H_T - H^N_T)\big) + \mathbb{E}\big(f_m(V^{N,\epsilon}_T)\psi^{N,\epsilon}_T(H_T - H^N_T)\big)$. The first contribution can be neglected using property (b) about $\psi^{N,\epsilon}_T$. The other contribution is analyzed as the second term in the right-hand side of (4.4): it gives a sum of terms of type (4.6) with $V^{N,\epsilon}_T$ instead of V^N_T and some random variables $G^{\gamma_2,N}_{s,t,T}$ and $G^{\gamma_3,N}_{u,s,t,T}$ vanishing when $\psi^{N,\epsilon}_T = 0$. Then, the rest of the proof is identical to that for (4.13); we omit details. The inequality (4.10) follows and Theorem 4.2 is proved.

Construction of $\boldsymbol{\psi^{N,\epsilon}_T}$. Set $d(\mu) = \det(\gamma^{V^\epsilon_T + \mu(V^N_T - V_T)})$ for $\mu \in [0,1]$. Since $\det(\gamma^{V^{\lambda,N,\epsilon}_T}) = d(1-\lambda)$, one has

$$\det(\gamma^{V^{\lambda,N,\epsilon}_T}) = \det(\gamma^{V^\epsilon_T}) - \int_{1-\lambda}^1 d'(\mu) d\mu. \tag{4.14}$$

Assume that for some $C > 0$, one has for any $\mu \in [0,1]$, $|d'(\mu)|^2 \leq R^N_T$ with

$$R^N_T := C \left(\int_0^T \|\mathcal{D}_t(V^N_T - V_T)\|^2 dt \right) \left(\int_0^T \big[\|\mathcal{D}_t V^\epsilon_T\|^2 + \|\mathcal{D}_t(V^N_T - V_T)\|^2\big] dt \right)^3. \tag{4.15}$$

Then, if we put $\psi^{N,\epsilon}_T = \psi(\frac{R^N_T}{\det^2(\gamma^{V^\epsilon_T})})$ with $\psi \in C^\infty_b(\mathbb{R},\mathbb{R})$ such that $\mathbf{1}_{[0,\frac{1}{8}]} \leq \psi \leq \mathbf{1}_{[0,\frac{1}{4}]}$, it is now clear that statement (a) is fulfilled using $\gamma^{V^\epsilon_T} = \gamma^{V_T} + \epsilon^2 \mathrm{I}_d$. Besides, $\psi^{N,\epsilon}_T \neq 1 \Rightarrow R^N_T > \frac{1}{8}\det^2(\gamma^{V^\epsilon_T})$, and thus estimates (b) follow using techniques of Lemma 3.3. Finally, $\psi^{N,\epsilon}_T \neq 0 \Rightarrow R^N_T < \frac{1}{4}\det^2(\gamma^{V^\epsilon_T}) \Rightarrow \det(\gamma^{V^{\lambda,N,\epsilon}_T}) \geq \frac{1}{2}\det(\gamma^{V^\epsilon_T}) \geq \frac{1}{2}\det(\gamma^{V_T})$ using (4.14) and (c) holds true.

It remains to prove (4.15). For this, using for any invertible matrix A the relations $\partial_A \det(A) = \det(A)[A^*]^{-1}$ (see Theorem A.98 of [RT99]) and $A^{-1} = \frac{1}{\det(A)}[\mathrm{Cof}(A)]^*$ ($\mathrm{Cof}(A)$ being the matrix of cofactors of A), one gets

$$\begin{aligned}[\det(A(\mu))]' &= \sum_{i,j} \partial_{a_{i,j}}[\det(A)] a'_{i,j}(\mu) = \sum_{i,j} \det(A)[(A^*)^{-1}]_{i,j} a'_{i,j}(\mu) \\ &= \mathrm{Tr}\big(\mathrm{Cof}(A(\mu)) A'^*(\mu)\big).\end{aligned}$$

Put $A(\mu) = \gamma^{V_T^\epsilon + \mu(V_T^N - V_T)} = \gamma^{V_T^\epsilon} + \mu\big(\int_0^T \mathcal{D}_t V_T^\epsilon [\mathcal{D}_t(V_T^N - V_T)]^* dt + \int_0^T \mathcal{D}_t(V_T^N - V_T)[\mathcal{D}_t V_T^\epsilon]^* dt\big) + \mu^2 \gamma^{V_T^N - V_T}$. We now easily prove that

$$[(\mathrm{Cof}(A))_{i,j}(\mu)]^2 \le C_1 \left(\int_0^T \big[\|\mathcal{D}_t V_T^\epsilon\|^2 + \|\mathcal{D}_t(V_T^N - V_T)\|^2 \big] dt \right)^2,$$

$$[(A'_{i,j})(\mu)]^2 \le C_2 \left(\int_0^T \|\mathcal{D}_t(V_T^N - V_T)\|^2 dt \right) \left(\int_0^T \big[\|\mathcal{D}_t(V_T^N - V_T)\|^2 + \|\mathcal{D}_t V_T^\epsilon\|^2 \big] dt \right).$$

Thus, (4.15) immediately follows using $d'(\mu) = [\det(A(\mu))]'$.

5. Numerical experiments.

5.1. Analysis of computational complexity. In this paragraph we indicate the first-order approximation of the number of elementary operations (multiplications) needed for computing the different estimators w.r.t. the quantities m (number of parameters), d (dimension of the space), q (dimension of the Brownian motion), and N (number of discretization times).

In previous sections we derived estimators of the gradient of the performance measure $J(\alpha)$ w.r.t. α when J is defined by a terminal cost (see (1.2)). However, these results may be extended to functionals with instantaneous costs such as $J(\alpha) = \mathbb{E}\left(\int_0^T g(t, X_t) dt + f(X_T)\right)$ for which an estimator of the gradient may be $\frac{T}{N}\sum_{i=1}^N H_{t_i}^N(g) + H_T^N(f)$, where $H_{t_i}^N(g)$ (resp., $H_T^N(f)$) is an approximated estimator of the gradient of $\mathbb{E}(g(t_i, X_{t_i}))$ (resp., $\mathbb{E}(f(X_T))$). This case is illustrated in the first numerical experiment considered below.

The computational complexity of the different estimators depends on whether the payoff has instantaneous costs (in which case an estimator $H_{t_i}^N(g)$ for all $i \in \{1, \dots, N\}$ is needed) or if it has only a terminal cost (for which only $H_T^N(f)$ is needed). In the pathwise and Malliavin calculus methods, the cost of computing $H_{t_i}^N(g)$ for all $i \in \{1, \dots, N\}$ is the same as just computing $H_T^N(f)$, whereas in the adjoint and martingale methods, there is an additional computational burden.

- Complexity of the pathwise method: $d^2 qmN$ operations for computing the pathwise estimator $H_{t_i}^{Path.,N}(g)$ (see Proposition 1.1) for all $i \in \{1, \dots, N\}$ (required for computing $\dot{X}_{t_i}^N$, for all $i \in \{1, \dots, N\}$ and all m parameters).
- Complexity of the Malliavin calculus method, in the elliptic case ($q = d$): $3d^4(d + m)N$ operations, for computing the Malliavin calculus estimator $H_{t_i}^{Mall.Ell.,N}(g)$ (see Proposition 2.5) for all $i \in \{1, \dots, N\}$. Indeed, the complexity of computing the Malliavin derivative of each column c (among d) of Z_{c,t_i}^N is $3d^4 N$ and computing the Malliavin derivative of $\dot{X}_{t_i}^N$ for all m parameters requires $3d^3 mN$ operations.

- Complexity of the adjoint method: $d^4N^2 + d^2mN^2/2$ operations are needed to compute the adjoint estimator $H_{t_i}^{Adj.,N}(g) = H_{t_i}^{b,Adj.,N}(g) + \frac{1}{2}H_{t_i}^{\sigma,Adj.,N}(g)$ (see Lemma 2.9 and Theorem 2.11) for all $i \in \{1,\dots,N\}$. Our implementation memorizes $Z_{t_i}^N$ (and other data) along the trajectory and computes $H_{t_i}^{b,Adj.,N}(g)$ and $H_{t_i}^{\sigma,Adj.,N}(g)$ for all $i \in \{1,\dots,N\}$ afterwards. Such an implementation allows to treat problems with instantaneous costs. If we consider a problem with a terminal cost only, the complexity is reduced to $4d^4N + 3d^2mN$.
- Complexity of the martingale method: $d^2N^2/2 + dmN^2/2 + d^3mN$ for computing the martingale estimator $H_{t_i}^{Mart.,N}(g)$ (see Theorem 2.12) for all $i \in \{1,\dots,N\}$. For problems with terminal cost only the complexity of computing $H_T^{Mart.,N}(f)$ is d^3mN.

These results are summarized in Table 5.1. Note that they are strongly related to the way we have implemented the methods and they are not guaranteed to be optimal.

TABLE 5.1
Complexity (in terms of number of elementary operations) of the different estimators for payoff with instantaneous costs or with terminal cost only.

	Pathwise	Malliavin	Adjoint	Martingale
Instantaneous costs	d^3mN	$3d^4(d+m)N$	$d^4N^2 + d^2m\frac{N^2}{2}$	$d(d+m)\frac{N^2}{2} + d^3mN$
Terminal cost	Same	Same	$4d^4N + 3d^2mN$	$d^2N + d^3mN$

5.2. Stochastic linear quadratic optimal control. We consider a simple one-dimensional stochastic linear quadratic (SLQ) control problems (see [CY01] and [YZ99] for an extensive study on SLQ problems) for which the control $u(\cdot)$ appears in particular in the diffusion term: $dX_t = u(t)dt + \delta u(t)dW_t$. The cost functional to be minimized is $J(u(\cdot)) = \mathbb{E}\big[\int_0^1 X_t^2 dt\big]$. This problem admits an optimal control (see references above) given by the state feedback $u^*(t) = -\frac{X_t}{\delta^2}$.

We consider a class of feedback controllers $u(t,x,\alpha)$ linearly parameterized by a three-dimensional vector α with basis functions 1, x, and t (i.e., $u(t,x,\alpha) = \alpha_1 + \alpha_2 x + \alpha_3 t$) and we write $J(\alpha)$ for $J(u(\cdot,X_\cdot,\alpha))$. In that case, the optimal control u^* belongs to the class of parameterized feedback controllers and corresponds to the parameter $\alpha^* = (0, -1/\delta^2, 0)$.

As explained before, since the payoff involves instantaneous costs, we evaluate $\nabla_\alpha J(\alpha)$ using a quantity of type $\frac{T}{N}\sum_{i=1}^N H_{t_i}^N(x^2)$. We check that the different estimators (pathwise, Malliavin calculus, adjoint, martingale) return a zero gradient for the value α^* of the parameter and we compare their variance and time for computation. Table 5.2 shows the empirical variance of the different estimators obtained for 1000 trajectories, with $h = 0.05$, $\delta = 1$. These simulations have been performed on a Pentium III, 700Mhz processor.

TABLE 5.2
Variance of the estimators $H^{Path.}$, $H^{Mall.Ell.}$, $H^{Adj.}$, and $H^{Mart.}$ of $\nabla_\alpha J(\alpha)$ at the optimal setting of the parameter: $\alpha_1 = 0$, $\alpha_2 = -1$, $\alpha_3 = 0$.

Var(H)	Pathwise	Malliavin	Adjoint	Martingale
α_1	0.1346	0.3754	0.6669	0.1653
α_2	0.0525	0.1188	0.1707	0.0480
α_3	0.0136	0.0446	0.0612	0.0148
CPU time	0.44s	1.95s	2.89s	0.89s

Note that the estimator used in the adjoint approach includes the term $f(X_T) - f(X_t)$ in the computation of $H_T^{\sigma,Adj.}$. Table 5.3 shows similar results for a suboptimal setting of the parameter (here α_1, α_2, and α_3 are chosen randomly within the range $[-0.1, 0.1]$). The columns Adjoint2 and Martingale2 describe simulations of the adjoint and martingale methods when the term $f(X_t)$ is omitted from the computation of the estimators $H_T^{\sigma,Adj.}$ and $H_T^{Mart.}$. We note that the variance of these estimators is significantly larger than when the term $f(X_t)$ is included, which corroborates Remark 2.1.

TABLE 5.3
Variance of the different estimators of $\nabla_\alpha J(\alpha)$ *for* $\alpha_1 = -0.0789$, $\alpha_2 = 0.0156$, $\alpha_3 = 0.0648$.

Var(H)	Pathwise	Malliavin	Adjoint	Adjoint2	Mart.	Mart.2
α_1	0.2005	4.0347	1.0287	9.5535	1.5085	4.6029
α_2	0.0252	0.6597	0.1433	1.6781	0.2360	0.7894
α_3	0.0174	0.3869	0.1051	2.2337	0.1407	1.0185
CPU time	0.44s	1.97s	2.94s	2.94s	0.90s	0.90s

For this problem with smooth cost functions, the pathwise approach provides the best performance in terms of the estimator's variance. This nice behavior for smooth costs compared to other methods has been previously observed in [FLL+99].

5.2.1. Stochastic approximation algorithm. The computation of an estimator H of $\nabla_\alpha J(\alpha)$ may be used in a stochastic approximation algorithm (see, e.g., [KY97] or [BMP90]) to search a locally optimal parameterization of the controller. The algorithm begins with an initial setting of the parameter α^0. Then, if α^k denotes the value of the parameter at iteration k, the algorithm proceeds by computing an estimator $\widehat{\nabla_\alpha J(\alpha^k)}$ of $\nabla_\alpha J(\alpha^k)$ and then by performing a stochastic gradient ascent

$$\alpha^{k+1} = \alpha^k + \eta_k \widehat{\nabla_\alpha J(\alpha^k)}, \tag{5.1}$$

where the learning steps η_k satisfy a decreasing condition (for example, $\sum_k \eta_k = \infty$ and $\sum_k \eta_k^2 < \infty$; see [Pol87]). Assuming smoothness conditions on $J(\alpha)$ and a bounded variance for $\widehat{\nabla_\alpha J(\alpha^k)}$, one proves that if α^k converges, then the limit is a point of local minimum for $J(\alpha)$ (see references above for several sets of hypotheses for which the convergence is guaranteed).

Figure 5.1 illustrates this algorithm on the SLQ problem described previously, where the initial parameter is chosen randomly (same value as in Table 5.3). At iteration k, one trajectory is simulated using the controller parameterized by α^k, and an estimation $\widehat{\nabla_\alpha J(\alpha^k)}$ of $\nabla J(\alpha_k)$ (using the pathwise method) is obtained. The parameter is updated according to (5.1) with a learning step $\eta_k = \frac{K}{K+k}$. We take $K = 200$ to avoid a too rapid decreasing of $(\eta_k)_k$ at the beginning: this trick usually speeds up the numerical optimization as mentioned in [BT96b]. We note that the parameter converges to $\alpha^* = (0, -1, 0)$.

The speed of convergence for such algorithms is closely related to the gradient estimator's variance, which motivates our variance analysis for the different estimators.

5.2.2. Discretization error. Here, we report the impact of the number of discretization times in the regular mesh of the interval $[0, T]$, in the computation of the gradient $\nabla_\alpha J(\alpha)$ for the SLQ problem. Figure 5.2 reports the sensitivity of

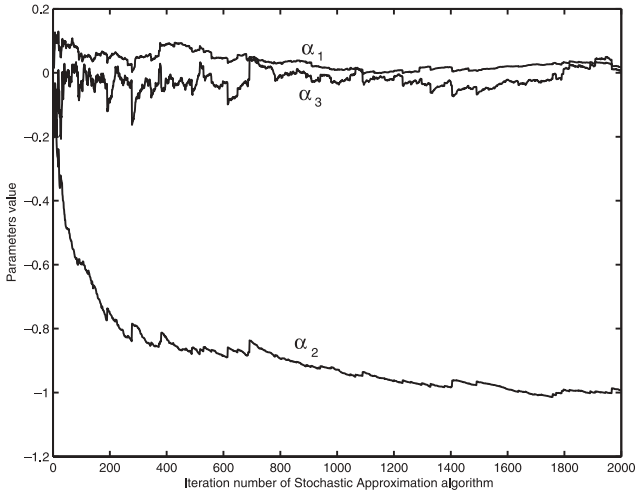

FIG. 5.1. *Stochastic approximation of the control parameters. The gradient* $\nabla_\alpha J(\alpha_k)$ *is estimated using the pathwise method.*

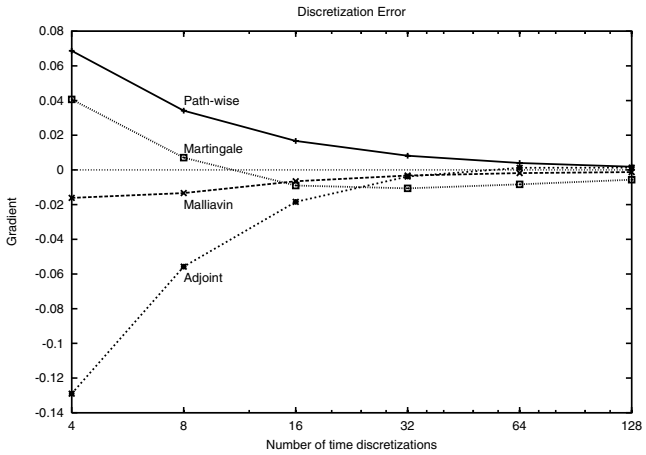

FIG. 5.2. *Discretization error as a function of the number of discretization times.*

$J(\alpha)$ (for $\alpha = \alpha^*$) w.r.t. the parameter α_1, computed with different estimators, with $N = 8, 16, 32, 64$, and 128 discretization times. Recall that, for this setting of the parameter, the true gradient is zero. To get relevant results, we have run 10^7 sample paths, which ensures that the confidence interval's width is less than 10^{-3} for all methods. We can empirically check that the convergence holds at rate $1/N$ (as previously proved), except for the martingale method, for which the rate of convergence is not clear because of the sign change (more discretization times would be needed to clarify the speed of approximation). Note that the discretization error for the Malliavin calculus estimator is smaller than for the other ones, although we have not found any explanation for this.

5.3. Sensitivity analysis in a financial market. We consider two risky assets with price process evolving according to the following SDE under the so-called risk-

neutral probability:

$$\frac{dS_t^1}{S_t^1} = r\,dt + \sigma(S_t^1, \lambda_1)\,dW_t^1,$$
$$\frac{dS_t^2}{S_t^2} = r\,dt + \sigma(S_t^2, \lambda_2)\left(\rho\,dW_t^1 + \sqrt{1-\rho^2}\,dW_t^2\right),$$

with constant interest rate r and volatility function $\sigma(x,\lambda) = 0.25(1 + \frac{1}{1+e^{-\lambda x}})$. The parameters of this dynamics are λ_1, λ_2, and the correlation coefficient ρ. Suppose that the true model is given by a set of parameters and that we are interested in the impact of the inaccuracy on these parameters (due to a previous statistical procedure) on option prices. For instance, we may consider digital options with payoff $\chi(S_T^1 - S_T^2)$ (where $\chi(x) = \mathbf{1}_{x\geq 0}$) whose prices are given by $J(\lambda_1,\lambda_2,\rho) = \mathbb{E}[\chi(S_T^1 - S_T^2)]$ up to the discount factor.

TABLE 5.4
Variance of the estimators $H_T^{Mall.Ell.}$, $H_T^{Adj.}$, $H_T^{Mart.}$, $H_T^{\varepsilon,Path.}$.

Var(H) or Var(H^ε)	Malliavin	Adjoint	Martingale	Pathwise $\varepsilon = 10^{-2}$	Pathwise $\varepsilon = 10^{-3}$	Pathwise $\varepsilon = 10^{-4}$
λ_1	0.0011	0.0022	0.0012	0.0053	0.0378	3.8951
λ_2	0.0048	0.0030	0.0018	0.0042	0.0296	4.9427
ρ	1.5788	2.0829	1.4323	1.6523	14.923	100.86
CPU time	20.8s	18.6s	7.31s	2.97s	2.97s	2.97s

We estimate the sensitivity of J w.r.t. the parameters λ_1, λ_2, and ρ. Table 5.4 reports the empirical variance of the estimators ($H_T^{Mall.Ell.}$, $H_T^{Adj.}$, and $H_T^{Mart.}$) of the sensitivity of J w.r.t. the parameters for the Malliavin calculus, adjoint, and martingale methods. Since the payoff function is not differentiable, we cannot directly apply the pathwise method; instead, we use χ^ε, a regularization of χ defined by $\chi^\varepsilon(x) = 1$ if $x > \varepsilon$, 0 if $x < -\varepsilon$, and $(x+\varepsilon)/(2\varepsilon)$ otherwise. Note that this induces a bias on the true value of the gradient, bias which vanishes when ε goes to 0. The pathwise estimator that we obtain with this regularization is denoted by $H^{\varepsilon,Path.}$ and Table 5.4 also reports its variance for different values of ε.

For this experiment, we ran 1000 trajectories with initial values $S_0^1 = S_0^2 = 1$, $r = 0.04$, $T = 1$, $h = 0.01$ and parameters setting $\lambda_1 = 2$, $\lambda_2 = 2$, and $\rho = 0.6$.

We note that the variance obtained by the pathwise methods is significantly larger than those obtained by the other methods (especially when ε is small), which motivates the use of the Malliavin calculus, adjoint, or martingale estimators for non-smooth cost functions. To further reduce the variance in the case of piecewise smooth cost functions, we could combine two methods as suggested in [FLL$^+$99]: the pathwise method where the cost function is smooth and one of the other methods where it is not.

5.4. Neurocontrol for a stochastic target problem. We consider a two-dimensional stochastic target (for example, that models the displacement of a fly) moving according to a diffusion. We control a squared fly-swatter with a two-dimensional bounded force $(b(u_1), b(u_2))$ (where $u = (u_1, u_2)$ is the control), and our goal is to hit the fly at time T. Let $X = (X_1, X_2)$ be the relative coordinates of

the fly w.r.t. the fly-swatter, and $V = (V_1, V_2)$ be the velocity of the fly-swatter. A simple model of the dynamics is

$$\begin{aligned} dX_{1,t} &= V_{1,t}dt + \sigma_{fly}dW_t^1, \\ dX_{2,t} &= V_{2,t}dt + \sigma_{fly}dW_t^2, \\ dV_{1,t} &= b(u_{1,t})dt + \sigma_{swat}(1 + ||u_t||)dW_t^3, \\ dV_{2,t} &= b(u_{2,t})dt + \sigma_{swat}(1 + ||u_t||)dW_t^4, \end{aligned}$$

where $b(x) = [1 - e^{-x}]/[1 + e^{-x}]$. $[(W_t^i)_{t\geq 0}]_i$ are independent standard Brownian motions; the coefficients σ_{fly} and σ_{swat} are constant. The factor $(1 + ||u||)$ (where $||u|| = \sqrt{u_1^2 + u_2^2}$) adds uncertainty on highly forced movements. The goal is to reach the fly with the fly-swatter at time T: hence, $J(u(\cdot); X_0, V_0) = \mathbb{E}[\mathbf{1}_{(X_{1,T}, X_{2,T})\in A}]$, where $A = [-a, a] \times [-a, a]$ is the squared fly-swatter.

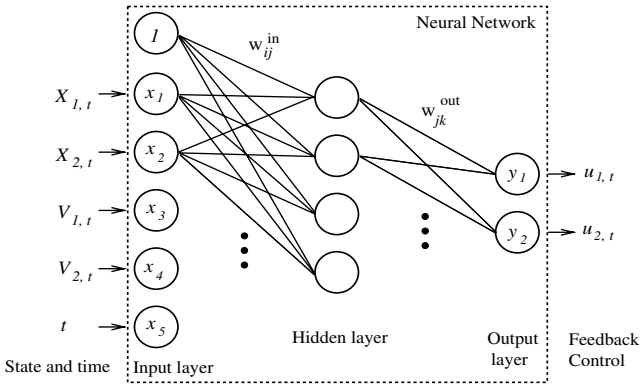

FIG. 5.3. *The architecture of the network.*

We implement the feedback controller using a one-hidden-layer neural network (see [Hay94] or [RM86] for general references on neural networks) whose architecture is given in Figure 5.3. The input layer $(x_i)_{1\leq 5}$ is connected to the state and time variables: $x_1 = X_{1,t}$, $x_2 = X_{2,t}$, $x_3 = V_{1,t}$, $x_4 = V_{2,t}$, and $x_5 = t$. There is one hidden layer with n neurons, and the output layer $(y_k)_{1\leq k\leq 2}$ returns the feedback control $y_1 = u_1(t)$, $y_2 = u_2(t)$. The network is defined by two matrices of weights (the parameters): the *input weights* $\{w_{ij}^{in}\}$ and the *output weights* $\{w_{jk}^{out}\}$. The network's output is given by $y_k = \sum_{j=1}^n w_{jk}^{out}\varphi(\sum_{i=0}^5 w_{ij}^{in}x_i)$ (for $1 \leq k \leq 2$), where the w_{0j}^{in}'s are the *bias weights* (and we set $x_0 = 1$) and $\varphi(s) = 1/(1 + e^{-s})$ is the sigmoid function.

In this experiment, we use a hidden layer with four neurons (thus there are $6 \times 4 + 4 \times 2 = 32$ control parameters); we have run 1000 trajectories with initial values of the weights chosen randomly within the range $[-0.1, 0.1]$. Here, $T = 1$, $h = 0.05$, $\sigma_{fly} = \sigma_{swat} = 0.1$, and $a = 0.1$. Each trajectory starts from a initial state chosen randomly within the range $\Omega = [-0.5, 0.5]^4$. Thus, we actually estimate $\nabla_w \mathbb{E}[J(\cdot; X_0, V_0) \mid (X_0, V_0) \sim \frac{1}{|\Omega|}\mathbf{1}_\Omega(d\omega)]$, for each weight w.

Table 5.5 reports the empirical variance of the estimators ($H^{Mall.Ell.}$, $H^{Adj.}$, and $H^{Mart.}$) of the gradient of J w.r.t. the parameters (the set of input and output weights). Here again, the function to be maximized is not differentiable and to apply the pathwise method, we use a regularization of the indicator function of A (i.e., $J^\varepsilon(\alpha) = \mathbb{E}[(\chi^\varepsilon(X_{1,T}+a)-\chi^\varepsilon(X_{1,T}-a))(\chi^\varepsilon(X_{2,T}+a)-\chi^\varepsilon(X_{2,T}-a))]$). The associated

TABLE 5.5
Variance of the estimators of the gradient of $\mathbb{E}[J(\cdot; X_0, V_0)|(X_0, V_0) \sim \frac{1}{|\Omega|}\mathbf{1}_\Omega(d\omega)]$ *w.r.t. the weights. The values provided are the averaged variances over all* 32 *parameters.*

Var(H) or Var($H_\varepsilon^{Path.}$)	Malliavin	Adjoint	Martingale	Pathwise $\varepsilon = 10^{-3}$	Pathwise $\varepsilon = 10^{-4}$
Average over all parameters	0.1917	0.2550	0.1701	3.364	187.48

pathwise estimator is denoted $H_T^{\varepsilon,Path.}$: its variance for some values of ε is also given in Table 5.5. Although its computational time is the lowest one, the pathwise approach is not appropriate because of its large variance. On the other hand, the martingale method is the most attractive.

Stochastic approximation of an optimal controller. We run a stochastic approximation algorithm (5.1) with a learning rate $\eta_k = \frac{K}{K+k}$ (with $K = 1000$) using a neural network with four hidden neurons. At each iteration, the SA algorithm uses an estimator of the gradient of J w.r.t. the weights, which averages 50 samples of the martingale estimator.

On Figure 5.4, we plot the parameter and performance evolutions w.r.t. the iteration number: we obtain a series of weights that provide a locally optimal performance, although there is no guarantee of global optimality of the controller.

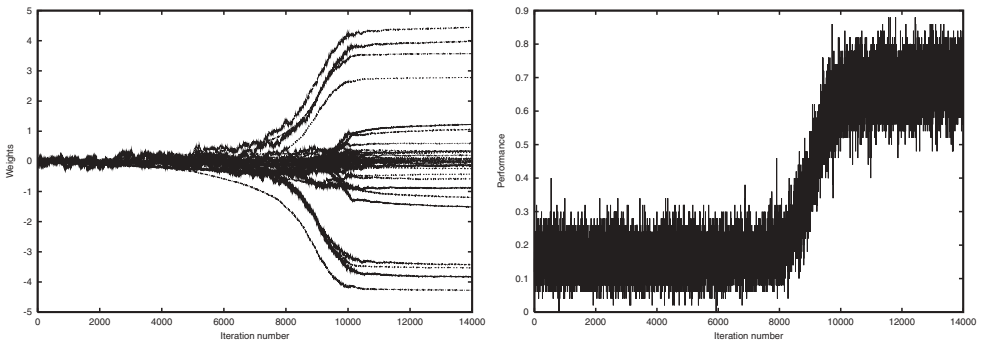

FIG. 5.4. *Stochastic approximation of the parameters (the weights of the neural network) and performance of the parameterized controller. The gradient is estimated using the martingale method.*

This stochastic gradient algorithm in the space of parameterized policies is often called *policy search* (about which an abundant literature exists in the discrete-time case; see, e.g., [BB01]), as opposed to *value search* for which some approximate dynamic programming algorithm is performed on a parameterized value function (see, e.g., [BT96b]). One may also combine these approaches and learn an approximate value function to perform a policy search (the so-called *Actor-Critic* algorithms, see e.g. [KB99]).

6. Conclusion. In this work, we have derived three new types of formulae to compute $\nabla_\alpha \mathbb{E}(f(X_T^\alpha))$ or $\nabla_\alpha \mathbb{E}(\int_0^T g(t, X_t^\alpha)dt + f(X_T^\alpha))$ using Monte Carlo methods. Our computations rely on Itô–Malliavin calculus and martingale techniques: the representations derived are simple to implement using Euler-type schemes and the associate weak error is in most of the cases linear w.r.t. the time step. We have assumed that f is bounded, but all results remain valid if f satisfies some polynomial growth.

The numerical experiments enable us to draw the following conclusions on how to select the appropriate method to use.

1. *Pathwise approach.* This can be used only if the instantaneous and terminal costs are differentiable. Otherwise, regularization procedures lead to high variances. It provides the smallest computational time. Note also that no condition on the nondegeneracy of the diffusion coefficient is needed. For the implementation, only the first derivatives of the coefficient are required.
2. *Malliavin calculus approach.* This handles the case of nonsmooth costs, but the computational time is rather large. A nondegeneracy assumption has to be satisfied but it may be not stringent (hypoellipticity, e.g.). Note that the simulation procedures require the computations of the second derivatives $\partial^2_{x,x}$ and $\partial^2_{x,\alpha}$ of the coefficients.
3. *Adjoint approach.* It can be applied in the elliptic case and is particularly efficient in terms of computational time for a large number of parameters. However, it is quite slow, especially when there are instantaneous costs (because of double time integrals and a possible large number of discretization times). The second derivatives required for the simulations concern only $\partial^2_{x,x}$.
4. *Martingale approach.* The diffusion coefficient has to be elliptic. As for the adjoint approach, it handles situations with nonsmooth costs. It appears to be very fast (almost as fast as the pathwise approach), but it is slower for instantaneous cost problems (same reason as for the adjoint approach). Note also that only the first derivatives of the coefficient are needed.

In future research, we will consider the analysis of the weak error for the martingale method and numerical optimizations in the general nondegenerate case (such as portfolio optimization problems in finance).

Acknowledgment. We thank the two referees and the associate editor for their remarks and suggestions, which helped to improve the clarity of the paper.

A REAL-TIME ITERATION SCHEME FOR NONLINEAR OPTIMIZATION IN OPTIMAL FEEDBACK CONTROL*

MORITZ DIEHL†, HANS GEORG BOCK†, AND JOHANNES P. SCHLÖDER†

Abstract. An efficient Newton-type scheme for the approximate on-line solution of optimization problems as they occur in optimal feedback control is presented. The scheme allows a fast reaction to disturbances by delivering approximations of the exact optimal feedback control which are iteratively refined *during the runtime* of the controlled process. The contractivity of this *real-time iteration* scheme is proven, and a bound on the loss of optimality—compared with the theoretical optimal solution—is given. The robustness and excellent real-time performance of the method is demonstrated in a numerical experiment, the control of an unstable system, namely, an airborne kite that shall fly loops.

Key words. direct multiple shooting, Newton-type optimization, optimal feedback control, nonlinear model predictive control, ordinary differential equations, real-time optimization

1. Introduction.

Feedback control based on the real-time optimization of nonlinear dynamic process models, also referred to as *nonlinear model predictive control (NMPC)*, has attracted increasing attention over the past decade, particularly in chemical engineering [4, 27, 1, 28]. Based on the current system state, feedback is provided by an online optimization of the predicted system behavior, using the mathematical model. The first part of the optimized control trajectory is implemented at the real system, and a sampling time later the optimization procedure is repeated. Among the advantages of this approach are the flexibility provided in formulating the objective and in modeling the process using ordinary or partial differential equations (ODEs or PDEs), the capability of directly handling equality and inequality constraints, and the possibility of treating large disturbances quickly.

One important precondition, however, is the availability of reliable and efficient numerical optimal control algorithms. One particularly successful algorithm that is designed to achieve this aim, the recently developed *real-time iteration* scheme, will be the focus of this paper. In the literature, several suggestions have been made on how to adapt off-line optimal control algorithms for use in on-line optimization. For an overview and comparison of important approaches, see, e.g., Binder et al. [6]. We particularly mention here the "Newton-type control algorithm" proposed by Li and Biegler [32] and de Oliveira and Biegler [15] and the "feasibility-perturbed SQP" approach to NMPC by Tenny, Wright, and Rawlings [38]. Both approaches keep even intermediate optimization iterates feasible. This is in contrast to the *simultaneous* dynamic optimization methods, as the collocation method proposed in Biegler [5] or the direct multiple shooting method in Bock et al. [7] and in Santos [37], which allow

infeasible state trajectories and are more suitable for trajectory following problems and problems with final state constraints. The real-time iteration scheme belongs to this latter class.

Most approaches in the literature try to solve quickly but exactly an optimal control problem. However, if the time scale for feedback is too short for exact computation, some approximations must be made: for this aim an "instantaneous control" technique has been proposed in the context of PDE models that approximates the optimal feedback control problem by regarding one future time step only (Choi et al. [14, 13]). By construction, this "greedy" approach to optimal control is based on immediate gains only and neglects future costs; thus it may result in poor performance when future costs matter. A somewhat opposed approach to derive a feedback approximation (formulated for ODE models) is based on a system linearization along a fixed optimal trajectory over the whole time horizon and can, e.g., be found in Krämer-Eis and Bock [29] or Kugelmann and Pesch [30]. The approach works well when the nonlinear system is not too largely disturbed and stays close to the nominal trajectory.

The real-time iteration scheme presented in this paper is a different approximation technique for optimal feedback control. It regards the complete time horizon and performs successive linearizations along (approximately) optimal trajectories to provide feedback approximations. Using these linearizations, it iterates toward the rigorous optimal solutions *during the runtime of the process*. In this way a truly nonlinear optimal feedback control is provided whose accuracy is limited, however, by the time needed to converge to the current optimal solutions. In contrast to a somewhat similar idea mentioned in [32], the real-time iteration scheme is based on the direct multiple shooting method [12], a simultaneous optimization technique, which offers excellent convergence properties, particularly for tracking problems and problems with state constraints.

The scheme was introduced in its present form in Diehl et al. [19] going back to ideas presented in Bock et al. [10]. In its actual implementation it is able to treat *differential algebraic equation (DAE)* models (Leineweber [31]), as they often arise in practical applications. It has already been successfully tested for the feedback control of large-scale DAE models with inequality constraints, particularly a binary distillation column [11, 33, 19]. Moreover, it has been applied for the NMPC of a real pilot plant distillation column situated at the *Institut für Systemdynamik und Regelungstechnik (ISR)* of the University of Stuttgart [25, 16, 21].

However, to concentrate on the essential features of the method and on a new proof of contractivity of the scheme, we will restrict the presentation in this paper to ODE models and optimization problems of a simplified type. Moreover, we will start the paper by regarding (nonlinear) *discrete*-time systems first; the multiple shooting technique, which allows us to formulate a discrete-time system from an ODE system, is only introduced later, and very briefly, when the numerical example is presented. Part of the material is also covered in [18]; for technical details about the real-time iteration scheme we refer to [16, 20].

1.1. Real-time optimal feedback control. Throughout this paper, let us consider the simplified nonlinear controlled discrete-time system

$$x_{k+1} = f_k(x_k, u_k), \quad k = 0, \dots, N-1, \tag{1.1}$$

with system states $x_k \in \mathbb{R}^{n_x}$ and controls $u_k \in \mathbb{R}^{n_u}$. The aim of optimal feedback control is to find controls u_k that depend on the current system state x_k and that are

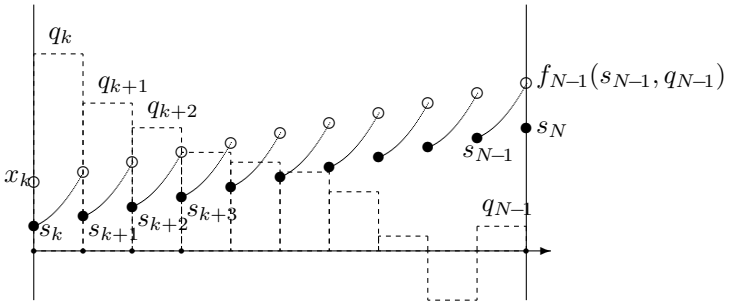

FIG. 1.1. *Problem $P_k(x_k)$: Initial value x_k and problem variables $s_k, \dots, s_N$ and $q_k, \dots, q_{N-1}$.*

optimal with respect to a specified objective. As time advances, we proceed by solving a sequence of nonlinear programming problems $P_k(x_k)$ on shrinking horizons, each with the current system state x_k as initial value (for a visualization, see Figure 1.1). Let us define $P_k(x_k)$ to be the problem

$$\min_{\substack{s_k,\dots,s_N,\\ q_k,\dots,q_{N-1}}} \quad \sum_{i=k}^{N-1} L_i(s_i, q_i) + E(s_N) \tag{1.2a}$$

subject to

$$x_k - s_k = 0, \tag{1.2b}$$

$$f_i(s_i, q_i) - s_{i+1} = 0, \quad i = k, \dots, N-1. \tag{1.2c}$$

The control part $(q_k^*, \dots, q_{N-1}^*)$ of the solution of problem $P_k(x_k)$ allows us to define the optimal feedback control

$$u_k := q_k^*.$$

Note that, due to the dynamic programming property, the optimal control trajectory $(q_0^*, \dots, q_{N-1}^*)$ of the first problem $P_0(x_0)$ would already give all later closed-loop controls $u_0, u_1, \dots u_{N-1}$, if the system behaves as predicted by the model. The practical reason to introduce the closed-loop optimal feedback control is, of course, that it allows us to optimally respond to disturbances.

We will now assume that we know each initial value x_k only at the time when the corresponding control u_k is already needed for application to the real process, and that the solution time for each problem $P_k(x_k)$ is not negligible compared with the runtime of the process. This is a typical situation in realistic applications: ideally, we would like to have the solution of each problem $P_k(x_k)$ instantaneously, but due to finite computing power this usually cannot be accomplished in practice. In this paper we propose and investigate an efficient Newton-type scheme that allows us to approximately solve the optimization problems $P_k(x_k)$ *during the runtime of the real process*.

Remark. In practical applications, inequality path constraints of the form $h(s_i, q_i) \geq 0$, like bounds on controls or states, are of major interest and are usually present in the formulation of the optimization problems $P_k(x_k)$. For the purpose of this paper we leave such constraints unconsidered, since general convergence results for Newton-type methods with changing active sets are difficult to establish. However, we note that in the practical implementation of the real-time iteration scheme they are included and pose no difficulty for the performance of the algorithm.

1.2. Overview. The paper is organized as follows:

- In section 2 we give a review of Newton-type optimization methods for the solution of optimal control problems of type (1.2) and discuss the problem structure.
- The real-time iteration scheme is presented in section 3 building on the previously introduced Newton-type methods. It performs only one Newton-type iteration per optimization problem $P_k(x_k)$, applies the obtained feedback control to the real system, and then proceeds already to the following problem, $P_{k+1}(x_{k+1})$, until the end of the horizon is reached. This allows a particularly fast reaction to disturbances.
- A new contractivity result for the scheme is presented and proven in section 4. The theorem guarantees that the real-time iteration scheme is contracting under mild conditions and delivers approximations to the optimal feedback control with diminishing error.
- Based on the contractivity result, a bound on the loss of optimality of the scheme compared to exact optimal feedback control is established in section 5.
- In section 6 we finally present a numerical example, the real-time control of a kite that shall start to fly loops. A new kite model is developed and a periodic reference orbit is defined. The optimal control problem is to steer the kite into the periodic orbit, starting at an a priori unknown initial value. This example, though of small state dimension, is particularly challenging, because the system is highly nonlinear and unstable.

2. Newton-type optimization methods. In order to solve an optimization problem $P_k(x_k)$, let us first introduce the Lagrange multipliers $\lambda_k, \dots, \lambda_N$ and define the Lagrangian function $\mathcal{L}^k(\lambda_k, s_k, q_k, \dots)$ of problem $P_k(x_k)$ to be

$$\mathcal{L}^k(\cdot) = \sum_{i=k}^{N-1} L_i(s_i, q_i) + E(s_N) + {\lambda_k}^T(x_k - s_k) + \sum_{i=k}^{N-1} {\lambda_{i+1}}^T(f_i(s_i, q_i) - s_{i+1}).$$

Summarizing all variables in a vector $y := (\lambda_k, s_k, q_k, \lambda_{k+1}, s_{k+1}, q_{k+1}, \dots, \lambda_N, s_N) \in \mathbb{R}^{n_k}$,[1] we can formulate necessary optimality conditions of first order (also called *Karush–Kuhn–Tucker* conditions):

$$\nabla_y \mathcal{L}^k(y) = 0. \tag{2.1}$$

To solve this system, the exact full-step Newton–Raphson method would start at an initial guess y_0 and compute a sequence of iterates $y_1, y_2, \dots$ according to

$$y_{i+1} = y_i + \Delta y_i, \tag{2.2}$$

where each Δy_i is the solution of the linearized system

$$\nabla_y \mathcal{L}^k(y_i) + \nabla_y^2 \mathcal{L}^k(y_i)\Delta y_i = 0. \tag{2.3}$$

The Newton-type methods considered in this paper differ from the exact Newton–Raphson method in the way that a part of the exact second derivative $\nabla_y^2 \mathcal{L}^k$, namely, the Hessian $\nabla^2_{(q,s)} \mathcal{L}^k$, is replaced by a (symmetric) approximation. We denote the resulting approximation of $\nabla_y^2 \mathcal{L}^k(y)$ by $J^k(y)$. For our Newton-type method, (2.3) is replaced by the approximation

$$\nabla_y \mathcal{L}^k(y_i) + J^k(y_i)\Delta y_i = 0. \tag{2.4}$$

[1] For simplicity, we omit the index k for the variable y and implicitly assume that $y \in \mathbb{R}^{n_k}$ when not specified otherwise. Note that $n_k = (2n_x + n_u)(N - k) + 2n_x$.

The matrix $\nabla_y^2 \mathcal{L}^k$, respectively, its approximation J^k, is often referred to as the *Karush–Kuhn–Tucker (KKT)* matrix.

2.1. Structure of the Karush–Kuhn–Tucker matrix. The Lagrangian function $\mathcal{L}^k$ of the optimal control problem is *partially separable* [12], and its second derivative has a block diagonal structure:

$$\nabla_y^2 \mathcal{L}^k(y) = \begin{pmatrix}
 & -\mathbb{I} & & & & & & & & & \\
-\mathbb{I} & Q_k & M_k & A_k^T & & & & & & & \\
 & M_k^T & R_k & B_k^T & & & & & & & \\
 & A_k & B_k & & -\mathbb{I} & & & & & & \\
 & & & -\mathbb{I} & Q_{k+1} & M_{k+1} & A_{k+1}^T & & & & \\
 & & & & M_{k+1}^T & R_{k+1} & B_{k+1}^T & & & & \\
 & & & & A_{k+1} & B_{k+1} & & & & & \\
 & & & & & & & \ddots & & & \\
 & & & & & & \ddots & Q_{N-1} & M_{N-1} & A_{N-1}^T & \\
 & & & & & & & M_{N-1}^T & R_{N-1} & B_{N-1}^T & \\
 & & & & & & & A_{N-1} & B_{N-1} & & -\mathbb{I} \\
 & & & & & & & & & -\mathbb{I} & Q_N
\end{pmatrix},$$

where we have set

$$A_i := \frac{\partial f_i}{\partial s_i}, \quad B_i := \frac{\partial f_i}{\partial q_i}, \quad \begin{pmatrix} Q_i & M_i \\ M_i^T & R_i \end{pmatrix} := \nabla^2_{(s_i,q_i)} \mathcal{L}^k, \quad \text{and} \quad Q_N := \nabla^2_{s_N} \mathcal{L}^k.$$

In the approximation $J^k(y)$ of this second derivative, we replace Q_i, M_i, and R_i by approximations $Q_i^H(s_i, q_i, \lambda_{k+1}), M_i^H(s_i, q_i, \lambda_{k+1})$, and $R_i^H(s_i, q_i, \lambda_{k+1})$.

Remark 1. Note that the KKT matrix of each problem $P_k(x_k)$ is completely independent of the value of x_k.

Remark 2. If we split the variables $y = (\lambda_k, s_k, q_k, \dots) = (\lambda_k, s_k, q_k, \tilde{y})$ into a first and a second part, the second part $\tilde{y} \in \mathbb{R}^{n_{k+1}}$ corresponds directly to the variable space of the next, shrunken problem $P_{k+1}(x_{k+1})$, and we can see that the KKT matrix contains the KKT matrix of the next problem as a submatrix, as

$$\nabla_y^2 \mathcal{L}^k(y) = \left(\begin{array}{ccc|c}
 & -\mathbb{I} & & \\
-\mathbb{I} & Q_k & M_k & A_k^T \\
 & M_k^T & R_k & B_k^T \\
\hline
 & A_k & B_k & \\
 & & & \nabla_{\tilde{y}}^2 \mathcal{L}^{k+1}(\tilde{y}) \\
 & & &
\end{array}\right).$$

Remark 3. The favorable structure of the matrix $\nabla_y^2 \mathcal{L}^k(y)$, respectively, its approximation $J^k(y)$, allows an efficient solution of the linear system $J^k(y)x = b$ by a Riccati recursion proposed independently by Pantoja [34] and Dunn and Bertsekas [26]; cf. also [36, 16].

2.2. The constrained Gauss–Newton method. An important special case of the Newton-type methods considered in this paper is the constrained Gauss–Newton method, which is applicable for problems with a least squares form of the objective function

$$\sum_{i=k}^{N-1} \frac{1}{2} \|l_i(s_i, q_i)\|_2^2 + \frac{1}{2} \|e(s_N)\|_2^2. \tag{2.5}$$

For this case, the Hessian block approximations Q_i^H, M_i^H, and R_i^H are defined to be

$$\begin{pmatrix} Q_i^H & M_i^H \\ (M_i^H)^T & R_i^H \end{pmatrix} := \left(\frac{\partial l_i(s_i,q_i)}{\partial(s_i,q_i)}\right)^T \frac{\partial l_i(s_i,q_i)}{\partial(s_i,q_i)}, \quad Q_N^H := \left(\frac{\partial e(s_N)}{\partial s_N}\right)^T \frac{\partial e(s_N)}{\partial s_N}. \tag{2.6}$$

Note that these Hessian block approximations do not depend on the values of the Lagrange multipliers.

2.3. Local convergence. It is well known that the Newton-type scheme (2.4) for the solution of (2.1) converges in a neighborhood $D_k \subset \mathbb{R}^{n_k}$ of a solution y_*^k that satisfies the second order sufficient conditions for optimality of problem $P_k(x_k)$ if $J^k(y)$ approximates $\nabla_y^2 \mathcal{L}^k(y)$ sufficiently well on D_k.

3. Real-time iterations. Let us now go back to the real-time scenario described in section 1.1, where we want to solve the sequence of optimization problems $P_k(x_k)$, but where we do not have the time to iterate each problem to convergence. Let us more specifically assume that each Newton-type iteration needs exactly as much computation time as corresponds to the time that the real process needs for the transition from one system state to the next. Thus, we can only perform *one single Newton-type iteration* for each problem $P_k(x_k)$, and then we have to proceed already to the next problem $P_{k+1}(x_{k+1})$. The *real-time iteration* scheme that we will investigate here is based on a carefully designed transition between subsequent problems. After an initial disturbance, it subsequently delivers approximations u_k for the optimal feedback control that become better and better if no further disturbance occurs, as will be shown in section 4.

It turns out that the computations of the real-time iteration belonging to problem $P_k(x_k)$ can largely be prepared *without knowledge of the value of* x_k so that we can assume that the approximation u_k of the optimal feedback control is instantly available at the time that x_k is known. However, after this feedback has been delivered, we need to *prepare* the next real-time iteration (belonging to problem $P_{k+1}(x_{k+1})$) which needs the full computing time.

In the framework for optimal feedback control on shrinking horizons (1.2), we reduce the number of remaining intervals from one problem $P_k(x_k)$ to the next $P_{k+1}(x_{k+1})$, in order to keep pace with the process development. Therefore, we have to perform real-time iterates in primal-dual variable spaces $\mathbb{R}^{n_0} \supset \cdots \supset \mathbb{R}^{n_k} \supset \mathbb{R}^{n_{k+1}} \supset \cdots \supset \mathbb{R}^{n_{N-1}}$ of different sizes. Let us denote by Π^{k+1} the projection from $\mathbb{R}^{n_k}$ onto $\mathbb{R}^{n_{k+1}}$; i.e., if $y = (\lambda_k, s_k, q_k, \tilde{y}) \in \mathbb{R}^{n_k}$, then $\Pi^{k+1} y = \tilde{y} \in \mathbb{R}^{n_{k+1}}$.

3.1. The real-time iteration algorithm. Let us assume that we have an initial guess $y^0 \in \mathbb{R}^{n_0}$ for the primal-dual variables of problem $P_0(\cdot)$. We set the iteration index k to zero and perform the following steps:

1. Preparation. Based on the initial guess $y^k \in \mathbb{R}^{n_k}$, compute the vector $\nabla_y \mathcal{L}^k(y^k)$ and the matrix $J^k(y^k)$: Note that $J^k(y^k)$ is completely independent of the value of x_k, and that of the vector $\nabla_y \mathcal{L}^k(y^k)$ only the first component $(\nabla_{\lambda_k} \mathcal{L}^k = x_k - s_k)$ depends on x_k. This component will only be needed in the second step. Therefore, prepare the linear algebra computation of $J^k(y^k)^{-1} \nabla_y \mathcal{L}^k(y^k)$ as much as possible without knowledge of the value of x_k (a detailed description how this can be achieved is given in [19] or [16]).
2. Feedback response. At the time when x_k is exactly known, finish the computation of the step vector $\Delta y^k = -J^k(y)^{-1} \nabla_y \mathcal{L}^k(y^k)$ and give the control $u_k := q_k + \Delta q_k$ immediately to the real system.

3. Transition. If $k = N-1$, stop. Otherwise, compute the next initial guess y^{k+1} by adding the step vector to y^k and "shrinking" the resulting variable vector onto $\mathbb{R}^{n_{k+1}}$; i.e., $y^{k+1} := \Pi^{k+1}(y^k + \Delta y^k)$. Set $k = k+1$ and go to 1.

Note that after one iteration belonging to system state x_k we expect the next system state to be $x_{k+1} = f_k(x_k, u_k)$, but this may not be true due to disturbances. The scheme allows an immediate feedback to such disturbances, due to the separation of steps 1 and 2. This separation is only possible because we do *not* require the guess of initial value, s_k, to be equal to the real initial value, x_k. This formulation may be regarded as an *initial value embedding* of each problem into the manifold of perturbed problems. Though this formulation comes quite naturally in the framework of an *infeasible path* (also *simultaneous*) solution strategy, as presented, where optimality and constraints are treated simultaneously, it deserves strong emphasis as it is a feature that is crucial for the success of the method in practice.

We will in the following investigate the contraction properties of the real-time iteration scheme. Though a principal advantage of the scheme lies in this immediate response to disturbances, we will investigate contractivity only under the assumption that after an initial disturbance the system behaves according to the model. This is analogous to the notion of "nominal stability" for an infinite horizon steady state tracking problem.

4. Contractivity of the real-time iterations. In this subsection we investigate the contraction properties of the real-time iteration scheme. The system starts at an initial state x_0, and the real-time algorithm is initialized with an initial guess $y^0 \in D_0 \subset \mathbb{R}^{n_0}$. Let us define the projections D_k of the neighborhood D_0 onto the primal-dual subspaces $\mathbb{R}^{n_k}$; i.e., $D_{k+1} := \Pi^{k+1} D_k$.

We will in the following make use of vector and corresponding matrix norms $\|\cdot\|_k$ defined on the subspaces $\mathbb{R}^{n_k}$. These norms are assumed to be compatible in the sense that $\|\Pi^{k+1} y\|_{k+1} \le \|y\|_k$ and that $\|{\Pi^{k+1}}^T \tilde{y}\|_k = \|\tilde{y}\|_{k+1}$.

THEOREM 4.1 (local contractivity of the real-time iterations). *Let us assume that the Lagrangian functions $\mathcal{L}^k : D_k \to \mathbb{R}$ for all $k = 0, \dots, N$ are twice continuously differentiable and that their second derivative approximations $J^k : D_k \to \mathbb{R}^{n_k \times n_k}$ are continuous and have a bounded inverse $(J^k)^{-1} : D_k \to \mathbb{R}^{n_k \times n_k}$.*

Furthermore, let us assume that there exist a $\kappa < 1$ and an $\omega < \infty$ such that for each $k = 0, \dots, N$ and all $y', y \in D_k$, $\Delta y = y' - y$, and all $t \in [0,1]$ it holds that

$$\left\| \left(J^k(y')\right)^{-1} \left(J^k(y + t\Delta y) - \nabla_y^2 \mathcal{L}^k(y + t\Delta y)\right) \Delta y \right\|_k \le \kappa \|\Delta y\|_k \tag{4.1a}$$

and that

$$\left\| \left(J^k(y')\right)^{-1} \left(J^k(y + t\Delta y) - J^k(y)\right) \Delta y \right\|_k \le \omega t \|\Delta y\|_k^2, \tag{4.1b}$$

and such that for each $k = 0, \dots, N-1$ it additionally holds that

$$\left\| \left(J^{k+1}(\Pi^{k+1} y')\right)^{-1} \Pi^{k+1} \left(J^k(y + t\Delta y) - J^k(y)\right) \Delta y \right\|_{k+1} \le \omega t \|\Delta y\|_k^2. \tag{4.1c}$$

We suppose that the first step $\Delta y^0 := J^0(y^0)^{-1} \nabla_y \mathcal{L}^0(y^0)$ starting at the initial guess y^0 is sufficiently small so that

$$\delta_0 := \kappa + \frac{\omega}{2} \|\Delta y^0\|_0 < 1 \tag{4.1d}$$

and that the ball

$$B_0 := \left\{ y \in \mathbb{R}^{n_0} \,|\, \|y - y^0\|_0 \le \frac{\|\Delta y^0\|_0}{1-\delta_0} \right\} \tag{4.1e}$$

is completely contained in D_0. Under these conditions the real-time iterates $y^0, \dots, y^N$ defined by

$$\Delta y^k := -J^k(y^k)^{-1} \nabla_y \mathcal{L}^k(y^k), \quad y^{k+1} := \Pi^{k+1}(y^k + \Delta y^k)$$

(where $\mathcal{L}^k$ is the Lagrangian function corresponding to problem $P_k(x_k)$ with the system state obtained according to the closed-loop dynamics $x_{k+1} = f_k(x_k, u_k)$, $u_k := q_k^k + \Delta q_k^k$) are well defined and stay in the projections of the ball B_0, i.e.,

$$y^k \in \Pi^k \cdots \Pi^1 B_0 \subset D_k, \tag{4.2}$$

and satisfy the contraction condition

$$\|\Delta y^{k+1}\|_{k+1} \le \left(\kappa + \frac{\omega}{2} \|\Delta y^k\|_k \right) \|\Delta y^k\|_k =: \delta_k \|\Delta y^k\|_k \le \delta_0 \|\Delta y^k\|_k. \tag{4.3}$$

Furthermore, the iterates y^k approach the exact stationary points y_*^k of the corresponding problems $P_k(x_k)$:

$$\|y^k - y_*^k\|_k \le \frac{\|\Delta y^k\|_k}{1-\delta_k} \le \frac{(\delta_0)^k \|\Delta y^0\|_0}{1-\delta_0}. \tag{4.4}$$

Proof. We divide the proof into three parts, corresponding to the properties (4.3), (4.2), and (4.4).

Contraction property. We will first show that the contraction property (4.3) holds. By adding zero to the defining equation of Δy^{k+1} we get

$$\begin{aligned} -\Delta y^{k+1} &= J^{k+1}(y^{k+1})^{-1} \nabla_y \mathcal{L}^{k+1}(y^{k+1}) \\ &= J^{k+1}(y^{k+1})^{-1} \left(\nabla_y \mathcal{L}^{k+1}(y^{k+1}) - \Pi^{k+1} \left(\nabla_y \mathcal{L}^k(y^k) + J^k(y^k) \Delta y^k \right) \right). \end{aligned} \tag{4.5}$$

Using the notation $y^k = (\lambda_k^k, s_k^k, q_k^k, \lambda_{k+1}^k, s_{k+1}^k, q_{k+1}^k, \dots)$ we observe that

$$\begin{aligned} \nabla_y \mathcal{L}^{k+1}(y^{k+1}) &= \nabla_y \mathcal{L}^{k+1}(\Pi^{k+1}(y^k + \Delta y^k)) = \begin{pmatrix} x_{k+1} - (s_{k+1}^k + \Delta s_{k+1}^k) \\ \vdots \end{pmatrix} \\ &= \begin{pmatrix} f_k(s_k^k + \Delta s_k^k, q_k^k + \Delta q_k^k) - (s_{k+1}^k + \Delta s_{k+1}^k) \\ \vdots \end{pmatrix} \\ &= \Pi^{k+1} \nabla_y \mathcal{L}^k(y^k + \Delta y^k), \end{aligned}$$

because $x_{k+1} = f_k(x_k, u_k) = f_k(s_k^k + \Delta s_k^k, q_k^k + \Delta q_k^k)$ if the system was undisturbed.[2] Therefore, we can continue to transform Δy^{k+1} and write

$$\begin{aligned} -\Delta y^{k+1} &= J^{k+1}(y^{k+1})^{-1} \Pi^{k+1} \left(\nabla_y \mathcal{L}^k(y^k + \Delta y^k) - \nabla_y \mathcal{L}^k(y^k) - J^k(y^k) \Delta y^k \right) \\ &= J^{k+1}(y^{k+1})^{-1} \Pi^{k+1} \int_0^1 (\nabla_y^2 \mathcal{L}^k(y^k + t\Delta y^k) - J^k(y^k)) \Delta y^k \, dt \\ &= J^{k+1}(y^{k+1})^{-1} \Pi^{k+1} \int_0^1 (\nabla_y^2 \mathcal{L}^k(y^k + t\Delta y^k) - J^k(y^k + t\Delta y^k)) \Delta y^k \, dt \\ &\quad + J^{k+1}(y^{k+1})^{-1} \Pi^{k+1} \int_0^1 (J^k(y^k + t\Delta y^k) - J^k(y^k)) \Delta y^k \, dt. \end{aligned} \tag{4.6}$$

[2] Note that $s_k^k + \Delta s_k^k = x_k$ due to the linearity of the constraint $x_k - s_k = 0$ and that $u_k = q_k^k + \Delta q_k^k$ by definition.

Noting that, with $\tilde{y} := \Pi^{k+1} y$,

$$\begin{aligned}\Pi^{k+1}\left(\nabla_y^2 \mathcal{L}^k(y) - J^k(y)\right) &= \Pi^{k+1}\left(\begin{array}{ccc|c} & 0 & & \\ 0 & \Delta Q_k & \Delta M_k & 0 \\ & \Delta M_k^T & \Delta R_k & 0 \\ \hline & 0 & 0 & \\ & & & \nabla_{\tilde{y}}^2 \mathcal{L}^{k+1}(\tilde{y}) - J^{k+1}(\tilde{y}) \end{array}\right) \\ &= \left(\begin{array}{ccc|c} 0 & 0 & 0 & \\ \vdots & \vdots & \vdots & \nabla_{\tilde{y}}^2 \mathcal{L}^{k+1}(\tilde{y}) - J^{k+1}(\tilde{y}) \\ 0 & 0 & 0 & \end{array}\right)\end{aligned}$$

and abbreviating $\tilde{y}^k := \Pi^{k+1} y^k$, $\Delta\tilde{y}^k := \Pi^{k+1}\Delta y^k$, we can exploit assumption (4.1a) to obtain

$$\begin{aligned}&\|J^{k+1}(y^{k+1})^{-1}\,\Pi^{k+1}(\nabla_y^2 \mathcal{L}^k(y^k + t\Delta y^k) - J^k(y^k + t\Delta y^k))\Delta y^k\|_{k+1} \\ &\quad = \|J^{k+1}(y^{k+1})^{-1}(\nabla_y^2 \mathcal{L}^{k+1}(\tilde{y}^k + t\Delta\tilde{y}^k) - J^{k+1}(\tilde{y}^k + t\Delta\tilde{y}^k))\Delta\tilde{y}^k\|_{k+1} \\ &\quad \le \kappa\|\Delta\tilde{y}^k\|_{k+1} = \kappa\|\Pi^{k+1}\Delta y^k\|_{k+1} \le \kappa\|\Delta y^k\|_k.\end{aligned}$$

Making also use of assumption (4.1c), we can, building on (4.6), prove the left inequality of the contraction property (4.3):

$$\|\Delta y^{k+1}\|_{k+1} \le \kappa\|\Delta y^k\|_k + \int_0^1 \omega t\|\Delta y^k\|_k^2\, dt. = \kappa\|\Delta y^k\|_k + \frac{1}{2}\omega\|\Delta y^k\|_k^2 =: \delta_k\|\Delta y^k\|_k.$$

With the help of condition (4.1d) ($\delta_0 < 1$) it is straightforward to deduce inductively that

$$\delta_{k+1} = \kappa + \frac{\omega}{2}\|\Delta y^{k+1}\|_{k+1} \le \kappa + \frac{\omega}{2}\delta_k\|\Delta y^k\|_k \le \delta_k \le \delta_0,$$

which proves the remaining part of (4.3).

Well definedness. To show that the iterates remain inside the domains of definition as stated in (4.2) we first observe that

$$\|\Delta y^k\|_k \le \delta_{k-1}\delta_{k-2}\dots\delta_0\|\Delta y^0\|_0 \le (\delta_0)^k\|\Delta y^0\|_0.$$

Using the representation

$$\begin{aligned}y^k &= \Pi^k(y^{k-1} + \Delta y^{k-1}) = \Pi^k(\Pi^{k-1}(y^{k-2} + \Delta y^{k-2}) + \Delta y^{k-1}) \\ &= \Pi^k(\Pi^{k-1}(\dots\Pi^1(y^0 + \Delta y^0)\dots) + \Delta y^{k-1}) \\ &= \Pi^k\cdots\Pi^1 y^0 + \Pi^k\cdots\Pi^1\Delta y^0 + \cdots + \Pi^k\Delta y^{k-1},\end{aligned}$$

we can find $y' := y^0 + (\Pi^k\cdots\Pi^1)^T(y^k - \Pi^k\cdots\Pi^1 y^0)$ such that

$$\begin{aligned}\|y' - y^0\|_0 &= \|(\Pi^k\cdots\Pi^1)^T(y^k - \Pi^k\cdots\Pi^1 y^0)\|_0 = \|y^k - \Pi^k\cdots\Pi^1 y^0\|_k \\ &\le \textstyle\sum_{i=0}^{k-1}\|\Delta y^i\|_i \le \|\Delta y^0\|_0\sum_{i=0}^{k-1}(\delta_0)^i \le \frac{\|\Delta y^0\|_0}{1-\delta_0},\end{aligned}$$

i.e., $y' \in B_0$ and $y^k = \Pi^k\dots\Pi^1 y'$, i.e., $y^k \in \Pi^k\dots\Pi^1 B_0$, as desired.

Distance to optimal solutions. It remains to be shown that the iterates y^k approach the exact solutions of the corresponding problems $P_k(x_k)$ as stated in (4.4). For this aim we devise a hypothetical standard Newton-type algorithm as introduced in (2.4) that allows us to compute the exact solution y_*^k of $P_k(x_k)$. As a by-product, we obtain a bound on the distance of y_*^k from y^k.

The hypothetical algorithm would proceed by starting at $y_0^k := y^k$ and iterating with iterates $y_1^k, y_2^k, \dots$ according to

$$y_{i+1}^k := y_i^k + \Delta y_i^k, \quad \Delta y_i^k := -J^k(y_i^k)^{-1} \nabla_y \mathcal{L}^k(y_i^k).$$

Note that the first step Δy_0^k is identical to Δy^k. It is for this hypothetical algorithm only that we need assumption (4.1b). Due to this condition and (4.1a), we have the contraction property

$$\|\Delta y_{i+1}^k\|_k \le \left(\kappa + \frac{\omega}{2}\|\Delta y_i^k\|_k\right) \|\Delta y_i^k\|_k$$

as can be shown by a well-known technique for Newton-type methods (see, e.g., [9]):

(4.7)

$$\begin{aligned}
\|\Delta y_{i+1}^k\|_k &= \|J^k(y_{i+1}^k)^{-1} \cdot \nabla_y \mathcal{L}^k(y_{i+1}^k)\|_k \\
&= \|J^k(y_{i+1}^k)^{-1} \cdot (\nabla_y \mathcal{L}^k(y_{i+1}^k) - \nabla_y \mathcal{L}^k(y_i^k) - J^k(y_i^k) \cdot \Delta y_i^k)\|_k \\
&= \|J^k(y_{i+1}^k)^{-1} \cdot \textstyle\int_0^1 (\nabla_y^2 \mathcal{L}^k(y_i^k + t\Delta y_i^k) - J^k(y_i^k)) \cdot \Delta y_i^k \, dt\|_k \\
&= \|J^k(y_{i+1}^k)^{-1} \cdot \textstyle\int_0^1 (\nabla_y^2 \mathcal{L}^k(y_i^k + t\Delta y_i^k) - J^k(y_i^k + t\Delta y_i^k))\Delta y_i^k \, dt \\
&\quad + J^k(y_{i+1}^k)^{-1} \cdot \textstyle\int_0^1 (J^k(y_i^k + t\Delta y_i^k) - J^k(y_i^k))\Delta y_i^k \, dt\|_k \\
&\le \textstyle\int_0^1 \|J^k(y_{i+1}^k)^{-1} (\nabla_y^2 \mathcal{L}^k(y_i^k + t\Delta y_i^k) - J^k(y_i^k + t\Delta y_i^k))\Delta y_i^k\|_k \, dt \\
&\quad + \textstyle\int_0^1 \|J^k(y_{i+1}^k)^{-1} (J^k(y_i^k + t\Delta y_i^k) - J^k(y_i^k))\Delta y_i^k\|_k \, dt \\
&\le \kappa\|\Delta y_i^k\|_k + \textstyle\int_0^1 \omega t \|\Delta y_i^k\|_k^2 \, dt \\
&= \left(\kappa + \tfrac{\omega}{2}\|\Delta y_i^k\|_k\right) \|\Delta y_i^k\|_k.
\end{aligned}$$

Together with the property

$$\kappa + \frac{\omega}{2}\|\Delta y_0^k\|_k = \kappa + \frac{\omega}{2}\|\Delta y^k\|_k = \delta_k < 1,$$

this leads again to the conclusion that $\|\Delta y_i^k\|_k \le (\delta_k)^i \|\Delta y^k\|_k$, so that $y_0^k, y_1^k, y_2^k, \dots$ is a Cauchy sequence and remains in the ball

$$B_k := \left\{ y \in \mathbb{R}^{n_k} \,|\, \|y - y^k\|_k \le \frac{\|\Delta y^k\|_k}{1 - \delta_k} \right\}$$

and thus converges toward a point $y_*^k \in B_k$, which satisfies $\nabla_y \mathcal{L}^k(y_*^k) = 0$ due to the boundedness of J^k on the (compact) ball B_k, as $\nabla_y \mathcal{L}^k(y_i^k) = -J^k(y_i^k)\Delta y_i^k \to 0$ for $i \to \infty$. ∎

5. Comparison with optimal feedback control. To assess the performance of the proposed real-time iteration scheme, we will compare the resulting system trajectory with the one which would have been obtained by exact optimal feedback control. For this aim, we denote by $u_0, \dots, u_{N-1}$ and $x_1, \dots, x_N$ the control and system state trajectories obtained by an application of the real-time iteration scheme to the system starting at the state x_0, when the iteration scheme was initialized with an initial guess $y^0 = (\lambda_0^0, s_0^0, q_0^0, \dots, \lambda_N^0, s_N^0)$, as in Theorem 4.1. On the other hand,

we denote by $q_0^*, \dots, q_{N-1}^*$ and $s_1^*, \dots, s_N^*$ the corresponding trajectories which would have been obtained by an application of exact optimal feedback control, starting at the same initial state x_0. Note that this trajectory is contained in the exact primal-dual solution vector $y_*^0 = (\lambda_0^*, s_0^*, q_0^*, \lambda_1^*, s_1^*, q_1^*, \dots, \lambda_N^*, s_N^*)$ of problem $P_0(x_0)$, as already pointed out in section 1.1.

THEOREM 5.1 (loss of optimality). *Let us in addition to the assumptions of Theorem* 4.1 *suppose that the Hessian of the Lagrangian $\mathcal{L}^0(\cdot)$ of problem $P_0(\cdot)$ is bounded on B_0, i.e.,*

$$\|\nabla_y^2 \mathcal{L}^0(y)\|_0 \le C \quad \forall y \in B_0. \tag{5.1}$$

Then the objective values, on the one hand evaluated at the closed-loop trajectory resulting from the real-time iteration scheme and on the other hand at the trajectory resulting from optimal feedback control

$$F_{\text{real}} := \sum_{i=k}^{N-1} L_i(x_i, u_i) + E(x_N) \quad \textit{and} \quad F_{\text{opt}} := \sum_{i=k}^{N-1} L_i(s_i^*, q_i^*) + E(s_N^*),$$

can be compared by

$$F_{\text{real}} \le F_{\text{opt}} + 2C \left(\frac{\delta_0}{1-\delta_0} \right)^2 \|\Delta y^0\|_0^2. \tag{5.2}$$

In particular, if $\kappa = 0$ (as for the exact Newton method), the loss of optimality is of fourth order in the size of the first step Δy^0:

$$F_{\text{real}} \le F_{\text{opt}} + \frac{C}{2} \left(\frac{\omega}{1 - \frac{\omega}{2}\|\Delta y^0\|_0} \right)^2 \|\Delta y^0\|_0^4. \tag{5.3}$$

Proof. First note that both the real-time iteration trajectory $(x_0, u_0, x_1, \dots, x_N)$ and the optimal feedback control trajectory $(s_0^*, q_0^*, s_1^*, \dots) = (x_0, q_0^*, s_1^*, \dots)$ are feasible "points" for the optimization problem $P_0(x_0)$. Let us augment the real-time iteration trajectory to a primal-dual point $y_{\text{real}} := (\lambda_0, x_0, u_0, \dots, \lambda_N, x_N)$, which is obtained by

$$y_{\text{real}} := y^0 + \Delta y^0 + {\Pi^1}^T \Delta y^1 + (\Pi^2 \Pi^1)^T \Delta y^2 + \cdots + (\Pi^N \cdots \Pi^1)^T \Delta y^N.$$

From the contractivity condition (4.3), it can easily be verified that $\|y_{\text{real}} - y^0\|_0 \le \frac{\|\Delta y^0\|_0}{1-\delta_0}$, i.e., that $y_{\text{real}} \in B_0$. We similarly see that

$$\|y_{\text{real}} - (y^0 + \Delta y^0)\|_0 \le \frac{\delta_0 \|\Delta y^0\|_0}{1-\delta_0} \quad \text{and that} \quad \|y_*^0 - (y^0 + \Delta y^0)\|_0 \le \frac{\delta_0 \|\Delta y^0\|_0}{1-\delta_0},$$

where the latter bound is due to contraction property (4.7) for the hypothetical Newton-type iterations toward the solution of $P_0(x_0)$, and the fact that the first step Δy_0^0 of these iterations coincides with the step vector Δy^0 of the real-time iterations. We can conclude that

$$\|y_{\text{real}} - y_*^0\|_0 \le \|y_{\text{real}} - (y^0 + \Delta y^0)\|_0 + \|y_*^0 - (y^0 + \Delta y^0)\|_0 \le 2 \frac{\delta_0 \|\Delta y^0\|_0}{1-\delta_0}. \tag{5.4}$$

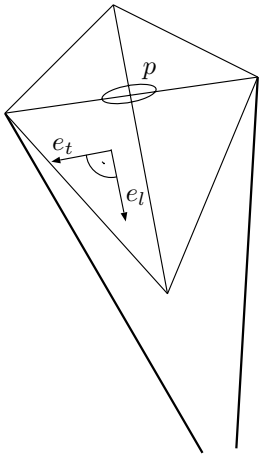

FIG. 6.1. *A picture of the kite from the pilot's point of view.*

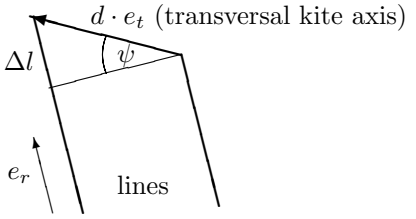

FIG. 6.2. *The kite seen from the top and visualization of the roll angle ψ.*

Because of feasibility of the primal-dual points y_{real} and y_*^0 the values of the Lagrangian function coincide with those of the objective, so that we can deduce

$$\begin{aligned} F_{\text{real}} - F_{\text{opt}} &= \mathcal{L}^0(y_{\text{real}}) - \mathcal{L}^0(y_*^0) = \int_0^1 \nabla_y \mathcal{L}^0(y_*^0 + t_1(y_{\text{real}} - y_*^0))^T \, (y_{\text{real}} - y_*^0) \, dt_1 \\ &= \int_0^1 \Big(\int_0^{t_1} \nabla_y^2 \mathcal{L}^0(y_*^0 + t_2(y_{\text{real}} - y_*^0))(y_{\text{real}} - y_*^0) \, dt_2 \Big)^T (y_{\text{real}} - y_*^0) \, dt_1 \\ &= (y_{\text{real}} - y_*^0)^T \Big(\int_0^1 \int_0^{t_1} \nabla_y^2 \mathcal{L}^0(y_*^0 + t_2(y_{\text{real}} - y_*^0)) \, dt_2 \, dt_1 \Big)^T (y_{\text{real}} - y_*^0), \end{aligned}$$

where we have used the fact that $\nabla_y \mathcal{L}^0(y_*^0) = 0$. We conclude with (5.1) and (5.4) that

$$F_{\text{real}} - F_{\text{opt}} \le \frac{1}{2} C \| y_{\text{real}} - y_*^0 \|_0^2 \le \frac{1}{2} C \left(2 \frac{\delta_0 \| \Delta y^0 \|_0}{1 - \delta_0} \right)^2 . \qquad \square$$

6. Numerical example: Control of a looping kite. In order to demonstrate the versatility of the proposed real-time iteration scheme we present here the control of an airborne kite as a periodic control example. The kite is held by two lines which allow control of the roll angle of the kite; see Figures 6.1 and 6.2. By pulling one line the kite will turn in the direction of the line being pulled. This allows an experienced kite pilot to fly loops or similar figures. The aim of our automatic control is to make the kite fly a figure that may be called a "lying eight," with a cycle time of 8 seconds (see Figure 6.3). The corresponding orbit is not open-loop stable, so that feedback has to be applied during the flight; we will show simulation results where our proposed real-time iteration scheme is used to control the kite, starting at a largely disturbed initial state x_0, over three periods, with a sampling time of one second.

6.1. The dual line kite model. The movement of the kite in the sky can be modeled by Newton's laws of motion and a suitable model for the aerodynamic force. The most difficulty lies in the determination of suitable coordinate systems; we will first describe the kite's motion in polar coordinates, and second we will determine the direction of the aerodynamic forces.

6.1.1. Newton's laws of motion in polar coordinates. The position $p \in \mathbb{R}^3$ of the kite can be modeled in three-dimensional Euclidean space, choosing the position of the kite pilot as the origin, and the third component p_3 to be the height of the kite above the ground. With m denoting the mass of the kite and $F \in \mathbb{R}^3$ the total force acting on the kite, Newton's law of motion reads

$$\ddot{p} = \frac{d^2 p}{dt^2} = \frac{F}{m}.$$

Let us introduce polar coordinates θ, ϕ, r:

$$p = \begin{pmatrix} p_1 \\ p_2 \\ p_3 \end{pmatrix} = \begin{pmatrix} r\sin(\theta)\cos(\phi) \\ r\sin(\theta)\sin(\phi) \\ r\cos(\theta) \end{pmatrix}.$$

Note that the distance r between pilot and kite is usually constant during flight, and θ is the angle that the lines form with the vertical. Let us introduce a local right-handed coordinate system with the three basis vectors

$$e_\theta = \begin{pmatrix} \cos(\theta)\cos(\phi) \\ \cos(\theta)\sin(\phi) \\ -\sin(\theta) \end{pmatrix}, \quad e_\phi = \begin{pmatrix} -\sin(\phi) \\ \cos(\phi) \\ 0 \end{pmatrix}, \quad \text{and} \quad e_r = \begin{pmatrix} \sin(\theta)\cos(\phi) \\ \sin(\theta)\sin(\phi) \\ \cos(\theta) \end{pmatrix}.$$

Defining $F_\theta := F \cdot e_\theta, F_\phi := F \cdot e_\phi$, and $F_r := F \cdot e_r$, we can write Newton's laws of motion in the form

$$\begin{aligned} r\ddot{\theta} - r\sin(\theta)\cos(\theta)\dot{\phi}^2 + 2\dot{r}\dot{\theta} &= \frac{F_\theta}{m}, \\ r\sin(\theta)\ddot{\phi} + 2r\cos(\theta)\dot{\phi}\dot{\theta} + 2\sin(\theta)\dot{r}\dot{\phi} &= \frac{F_\phi}{m}, \\ \ddot{r} - r\dot{\theta}^2 - r\sin^2(\theta)\dot{\phi}^2 &= \frac{F_r}{m}. \end{aligned} \tag{6.1}$$

If the length of the lines, denoted by r, is kept constant, all terms involving time derivatives of r will drop out. Furthermore, the last equation (6.1) will become redundant, as any acting force F_r' in the radial direction will automatically be augmented by a constraint force contribution $F_c := F_r + mr\dot{\theta}^2 + mr\sin^2(\theta)\dot{\phi}^2$ so that (6.1) is satisfied with $F_r := F_r' - F_c$. In this case we can regard only the components F_θ and F_ϕ which are not changed by the constraint force. The equations of motion[3] simplify to

$$\ddot{\theta} = \frac{F_\theta}{rm} + \sin(\theta)\cos(\theta)\dot{\phi}^2, \tag{6.2}$$

$$\ddot{\phi} = \frac{F_\phi}{rm\sin(\theta)} - 2\cot(\theta)\dot{\phi}\dot{\theta}. \tag{6.3}$$

In our model, the force F acting on the kite consists of three contributions, constraint force $-F_c e_r$, gravitational force F^{gra}, and aerodynamic force F^{aer}. In Cartesian coordinates, $F^{\text{gra}} = (0, 0, -mg)^T$ with $g = 9.81$ m s^{-2} being the earth's gravitational acceleration. In local coordinates we therefore have

$$F_\theta = F_\theta^{\text{gra}} + F_\theta^{\text{aer}} = \sin(\theta)mg + F_\theta^{\text{aer}} \quad \text{and} \quad F_\phi = F_\phi^{\text{aer}}.$$

It remains to derive an expression for the aerodynamic force F^{aer}.

[3]Note that the validity of these equations requires that $F_c \geq 0$, as a line can only pull and not push.

6.1.2. Kite orientation and the aerodynamic force. To model the aerodynamic force that is acting on the kite, we first assume that the kite's trailing edge is always pulled by the tail into the direction of the effective wind, as seen from the kite's body-fixed frame. This assumption can be regarded as the limiting case of very large tail force. It crucially simplifies the model by allowing us to disregard angular momentum and the moments acting on the kite. Under this assumption we are able to determine the kite orientation as an explicit function of position and velocity only, as shown in the following.

By the large tail force assumption, the kite's longitudinal axis is always in line with the effective wind vector $w_e := w - \dot{p}$, where $w = (v_w, 0, 0)^T$ is the wind as seen from the earth system, and $\dot{p}$ is the kite velocity. If we introduce a unit vector e_l pointing from the front toward the trailing edge of the kite (cf. Figure 6.1), we therefore assume that

$$e_l = \frac{w_e}{\|w_e\|}.$$

The transversal axis of the kite can be described by a perpendicular unit vector e_t that is pointing from the left to the right wing tip. Clearly, it is orthogonal to the longitudinal axis, i.e.,

$$e_t \cdot e_l = \frac{e_t \cdot w_e}{\|w_e\|} = 0. \tag{6.4}$$

The orientation of the transversal axis e_t against the lines' axis (which is given by the vector e_r) can be influenced by the length difference Δl of the two lines. If the distance between the two lines' fixing points on the kite is d, then the vector from the left to the right fixing point is de_t, and the projection of this vector onto the lines' axis should equal $\Delta l = d\, e_t \cdot e_r$, being positive if the left hand's lines wingtip is farther away from the pilot; cf. Figure 6.2. Let us define the *roll angle* ψ to be

$$\psi = \arcsin\left(\frac{\Delta l}{d}\right).$$

We will assume that we control this angle ψ directly. It determines the orientation of e_t which has to satisfy

$$e_t \cdot e_r = \frac{\Delta l}{d} = \sin(\psi). \tag{6.5}$$

A third requirement that e_t should satisfy is that

$$(e_l \times e_t) \cdot e_r = \frac{w_e \times e_t}{\|w_e\|} \cdot e_r > 0, \tag{6.6}$$

which takes account of the fact that the kite is always in the same orientation with respect to the lines.

How does one find a unit vector e_t that satisfies these requirements (6.4)–(6.6)? Using the projection w_e^p of the effective wind vector w_e onto the tangent plane spanned by e_θ and e_ϕ,

$$w_e^p := e_\theta(e_\theta \cdot w_e) + e_\phi(e_\phi \cdot w_e) = w_e - e_r(e_r \cdot w_e),$$

we can define the orthogonal unit vectors

$$e_w := \frac{w_e^p}{\|w_e^p\|} \quad \text{and} \quad e_o := e_r \times e_w,$$

so that (e_w, e_o, e_r) forms an orthogonal right-handed coordinate basis. Note that in this basis the effective wind w_e has no component in the e_o direction, as $w_e = \|w_e^p\| e_w + (w_e \cdot e_r) e_r$. We will show that the definition

$$e_t := e_w(-\cos(\psi)\sin(\eta)) + e_o(\cos(\psi)\cos(\eta)) + e_r \sin(\psi) \tag{6.7}$$

with

$$\eta := \arcsin\left(\frac{w_e \cdot e_r}{\|w_e^p\|} \tan(\psi)\right)$$

satisfies the requirements (6.4)–(6.6).[4] Equation (6.4) can be verified by substitution of the definition of η into

$$e_t \cdot w_e = -\cos(\psi)\sin(\eta)\|w_e^p\| + \sin(\psi)(w_e \cdot e_r) = 0.$$

Equation (6.5) is trivially satisfied, and (6.6) can be verified by calculation of

$$\begin{aligned}(w_e \times e_t) \cdot e_r &= (w_e \cdot e_w)\cos(\psi)\cos(\eta) - (w_e \cdot e_o)(-\cos(\psi)\sin(\eta)) \\ &= \|w_e^p\| \cos(\psi)\cos(\eta)\end{aligned}$$

(where we used the fact that $w_e \cdot e_o = 0$). For angles ψ and η in the range from $-\pi/2$ to $\pi/2$ this expression is always positive. The above considerations allow us to determine the orientation of the kite depending on the control ψ and the effective wind w_e only. Note that the considerations would break down if the projection of the effective wind w_e^p would be equal to zero, if $|\psi| \geq \frac{\pi}{2}$, or if

$$\left|\frac{w_e \cdot e_r}{\|w_e^p\|} \tan(\psi)\right| > 1.$$

The two vectors $e_n := e_l \times e_t$ and e_l are the directions of aerodynamic lift and drag, respectively. To compute the magnitudes F_{L} and F_{D} of lift and drag we assume that the lift and drag coefficients C_{L} and C_{D} are constant, so that we have

$$F_{\mathrm{L}} = \frac{1}{2}\rho\|w_e\|^2 A C_{\mathrm{L}} \quad \text{and} \quad F_{\mathrm{D}} = \frac{1}{2}\rho\|w_e\|^2 A C_{\mathrm{D}},$$

with ρ being the density of air and A being the characteristic area of the kite. Given the directions and magnitudes of lift and drag, we can compute F^{aer} as their sum, yielding $F^{\mathrm{aer}} = F_{\mathrm{L}} e_n + F_{\mathrm{D}} e_l$, or, in the local coordinate system,

$$F_\theta^{\mathrm{aer}} = F_{\mathrm{L}}(e_n \cdot e_\theta) + F_{\mathrm{D}}(e_l \cdot e_\theta) \;\text{ and }\; F_\phi^{\mathrm{aer}} = F_{\mathrm{L}}(e_n \cdot e_\phi) + F_{\mathrm{D}}(e_l \cdot e_\phi).$$

The system parameters that have been chosen for the simulation model are listed in Table 6.1. Defining the system state $\xi := (\theta, \phi, \dot\theta, \dot\phi)^T$ and the control $u := \psi$, we can summarize the four system equations, i.e., (6.2)–(6.3) and the trivial equations $\frac{\partial\theta}{\partial t} = \dot\theta$, $\frac{\partial\phi}{\partial t} = \dot\phi$, in the short form

$$\dot\xi = \hat f(\xi, u).$$

[4] It is interesting to note that the assignment of e_t can be made more transparent by considering a rotation from the (e_w, e_o, e_r) tangential frame to the body frame (e_l, e_t, e_n), with $e_n := e_l \times e_t$. Specifically, starting from (e_w, e_o, e_r), we rotate about the e_r-axis through the *yaw* angle $-\eta$ and then *roll* through the angle ψ about the e_l-axis. From this we find that e_t as the second basis vector of the body frame is represented by (6.7) in the tangential frame (e_w, e_o, e_r).

TABLE 6.1
The kite parameters.

Name	Symbol	Value
Line length	r	50 m
Kite mass	m	1 kg
Wind velocity	v_w	6 m/s
Density of air	ρ	1.2 kg/m^3
Characteristic area	A	0.5 m^2
Lift coefficient	C_{L}	1.5
Drag coefficient	C_{D}	0.29

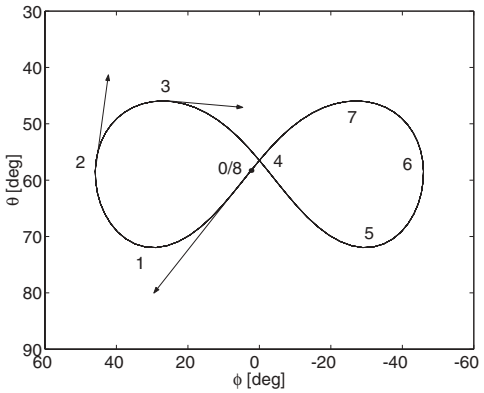

FIG. 6.3. *Periodic orbit plotted in the (ϕ, θ)-plane, as seen by the kite pilot. The dots separate intervals of one second.*

6.2. A periodic orbit. Using the above system model, a periodic orbit was determined that can be characterized as a "lying eight" and which is depicted as a (ϕ, θ)-plot in Figure 6.3. The wind is assumed to blow in the direction of the p_1-axis ($\theta = 90^o$ and $\phi = 0^o$). The periodic solution was computed using an off-line variant of the direct multiple shooting method (MUSCOD-II, due to Leineweber [31, 22, 23]), imposing periodicity conditions with period $T = 8$ seconds and suitable state bounds and a suitable objective function in order to yield a solution that was considered to be a meaningful reference orbit. We will denote the periodic reference solution by $\xi_r(t)$ and $u_r(t)$. This solution is defined for all $t \in (-\infty, \infty)$ and satisfies the periodicity condition $\xi_r(t+T) = \xi_r(t)$ and $u_r(t+T) = u_r(t)$. It is interesting to note that small errors accumulate very quickly so that the uncontrolled system will not stay in the periodic orbit very long during a numerical simulation; this observation can be confirmed by investigating the asymptotic stability properties of the periodic orbit [16], which shows that local errors are amplified by a factor of more than 5 during each period. Thus, the open-loop system is highly unstable in the periodic orbit.

We want to mention that the kite model and the periodic orbit may serve as a challenging benchmark problem for nonlinear periodic control and are available in MATLAB/SIMULINK format [17].

6.3. The optimal control problem. Given an arbitrary initial state x_0 (that we do not know in advance) we want the kite to fly three times the figure of Figure 6.3, on a time horizon of $3T = 24$ seconds. By using the figure as a reference orbit, we

formulate an optimal control problem which has the objective of bringing the system close to the reference orbit. For this aim we define a Lagrange term of least squares type

$$L(\xi, u, t) := \frac{1}{2}(\xi - \xi_r(t))^T Q(\xi - \xi_r(t)) + \frac{1}{2}(u - u_r(t))^T R(u - u_r(t))$$

with diagonal weighting matrices

$$Q := \mathrm{diag}(0.4,\ 1,\ \mathrm{s}^2,\ \mathrm{s}^2)\frac{1}{\mathrm{s}} \quad \text{and} \quad R := 1.0 \cdot 10^{-2}\mathrm{deg}^{-2}\mathrm{s}^{-1}.$$

Using these definitions, we formulate the following optimal control problem on the time horizon of interest $[0, 3T]$:

$$\begin{aligned} &\min_{u(\cdot),\xi(\cdot)} \int_0^{3T} L(\xi(t), u(t), t)\, dt \\ &\text{subject to} \\ &\qquad \dot{\xi}(t) = \hat{f}(\xi(t), u(t)) \qquad \forall t \in [0, 3T], \\ &\qquad \xi(0) = x_0. \end{aligned} \tag{6.8}$$

6.4. Direct multiple shooting formulation. In order to reformulate the above continuous optimal control problem into a discrete-time optimal control problem, we use the *direct multiple shooting* technique, originally due to Plitt and Bock [35, 12]: We divide the time horizon into $N = 24$ invervals $[t_i, t_{i+1}]$, each of one second length, and introduce a locally constant control representation $q_0, q_1, \ldots, q_{N-1}$, as well as artificial initial values $s_0, \ldots, s_N$, as depicted in Figure 1.1. On each of these intervals we solve the following initial value problem:

$$\begin{aligned} \dot{\xi}_i(t; s_i, q_i) &= \hat{f}\left(\xi_i(t; s_i, q_i), q_i\right), \quad t \in [t_i, t_{i+1}], \\ \xi_i(t_i; s_i, q_i) &= s_i, \end{aligned} \tag{6.9}$$

yielding a trajectory piece $\xi_i(t; s_i, q_i)$ for $t \in [t_i, t_{i+1}]$. This allows us to conveniently define a discrete-time system as in (1.2c) with transition function

$$f_i(s_i, q_i) := \xi_i(t_{i+1}; s_i, q_i).$$

Analogously, we define the objective contributions in (1.2a) by

$$L_i(s_i, q_i) := \int_{t_i}^{t_{i+1}} L(\xi_i(t; s_i, q_i), q_i, t)dt.$$

The main difficulty of the direct multiple shooting method lies in the efficient solution of the initial value problems (6.9) and in the sensitivity computation. For this aim we use the advanced backward differentiation formula (BDF) code DAESOL (Bauer, Bock, and Schlöder [3], Bauer [2]), which is especially suited for stiff problems, as the above kite model. It uses the principle of internal numerical differentiation (IND) as introduced by Bock [8].

Using the multiple shooting formulation, we have transformed the continuous-time optimization problem (6.8) into a nonlinear programming problem $P_0(x_0)$ of exactly the type (1.2).

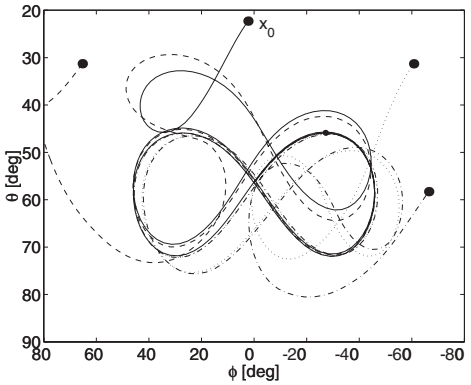

FIG. 6.4. *Closed-loop trajectories resulting from the real-time iteration scheme for different initial values x_0. The kite never crashes onto the ground ($\theta = 90$ degrees).*

6.4.1. Generation of the Gauss–Newton Hessian blocks. The efficient generation of a Gauss–Newton approximation for continuous least squares terms deserves some attention: the Hessian approximations (2.6) are determined according to

$$\begin{pmatrix} Q_i^H & M_i^H \\ (M_i^H)^T & R_i^H \end{pmatrix} := \int_{t_i}^{t_{i+1}} \left(\frac{\partial \xi_i(t; s_i, q_i)}{\partial (s_i, q_i)} \right)^T Q \; \frac{\partial \xi_i(t; s_i, q_i)}{\partial (s_i, q_i)} + \begin{pmatrix} 0 & 0 \\ 0 & R \end{pmatrix} dt.$$

These integrals are efficiently computed during the sensitivity computation using a specially adapted version of the integrator DAESOL [16, 25].

6.5. A real-time scenario. In the following real-time scenario we assume that the Newton-type optimizer is initialized with the reference trajectory itself, i.e., $y^0 := (\lambda_0^0, s_0^0, q_0^0, \ldots, \lambda_N^0, s_N^0)$, where $\lambda_i^0 := 0$, and $s_i^0 := \xi_r(t_i)$ and $q_i^0 := \frac{1}{t_{i+1}-t_i} \int_{t_i}^{t_{i+1}} u_r(t)\, dt$ are the corresponding values of the periodic reference solution. This y^0 is (nearly) identical to the solution of the problem $P_0(\xi_r(t_0))$. At the time $t_0 = 0$, when the actual value of x_0 is known, we start the iterations as described in section 3.1 by solving the first prepared linear system $\Delta y^0 = -J^0(y^0)^{-1} \nabla_y \mathcal{L}^0(y^0)$ (step 2) and give the first control $u_0 := q_0^0 + \Delta q_0^0$ immediately to the system. Then we shrink the problem (step 3) and prepare the iteration for the following one (step 1). As we assume no further disturbances, the new initial value is $x_1 = f_0(x_0, u_0) = \xi_0(t_1; x_0, u_0)$ resulting from the (continuous) system dynamics. This cycle is repeated until the $N = 24$ intervals are over.

The corresponding trajectory resulting from the real-time iteration scheme for different initial values x_0 is shown in Figure 6.4 as (ϕ, θ)-plots. For all scenarios, the third loop is already close to the reference trajectory.

In Figure 6.5 we compare the result of the real-time iteration scheme with the open-loop system dynamics without feedback (dash-dotted line) and with a hypothetical optimal feedback control (dashed line) for one initial value x_0. The open-loop system, where the controls are simply taken from the reference (and initialization) trajectory ($u_k := q_k^0$), crashes after seven seconds onto the ground.

Note that the computation of the hypothetical optimal feedback control needs about eight seconds on a Compaq Alpha XP1000 workstation. This delay means that

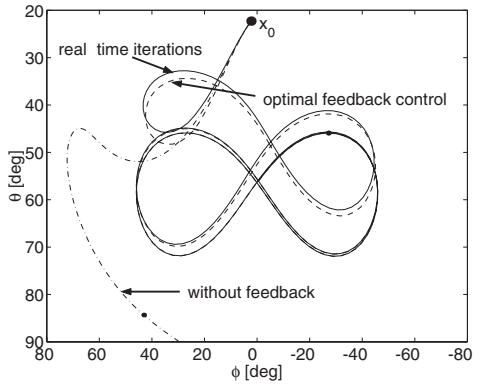

FIG. 6.5. *Comparison of trajectories resulting from the real-time iteration scheme (solid line), the open-loop controls without feedback (dash-dotted line, crashing onto the ground), and a hypothetical optimal feedback control (dashed line).*

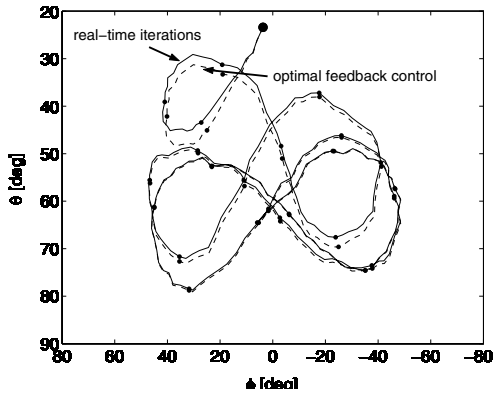

FIG. 6.6. *Disturbance scenario: Closed-loop response resulting from real-time iteration scheme (solid line) and a hypothetical optimal feedback control (dashed line). After a large initial disturbance, the state is additionally disturbed each* 0.1 *second by independent Gaussian noise. The disturbance sequence for both trajectories is identical.*

no feedback can be applied in the meantime, so the kite would have crashed onto the ground before the first response would have been computed.

In contrast to this, the first feedback control u_0 of the real-time iteration scheme was available within only 0.05 seconds delay after time t_0 (for the computations of step 2). The sampling time of one second until the next feedback can be applied was necessary to prepare the following real-time iteration (to be exact, step 1 always needed under 0.8 seconds). The comparison with the hypothetical optimal feedback control shows that the real-time iteration scheme delivers a quite good approximation even for this challenging nonlinear and unstable test example with largely disturbed initial values.

6.5.1. High frequency disturbances. In a third feedback simulation scenario shown in Figure 6.6 we test the performance of the real-time iteration scheme in the

presence of random disturbances with a frequency higher than the sampling time: each tenth of a second the state $(\theta, \phi, \dot{\theta}, \dot{\phi})$ is randomly disturbed by independent Gaussian noise of standard deviation $0.01 \cdot (1, 1, \mathrm{s}^{-1}, \mathrm{s}^{-1})$. Because feedback is provided only once a second, the kite flies open-loop during one second before feedback can be provided to the accumulated result of the disturbances. The initial state was much more strongly disturbed, in the same way as in the scenario of Figure 6.5. Despite these combined disturbances the scheme is able to lead the kite efficiently into the reference orbit. Again, it compares well with optimal feedback control. Note, however, that the results of Theorems 4.1 and 5.1 are not directly applicable to this third scenario as these theorems assume undisturbed system behavior after one initial disturbance.

For feedback control simulations of the kite using a moving horizon framework including also state constraints, we refer to [16, 24].

7. Conclusions. We have presented a recently developed Newton-type method for the real-time optimization of nonlinear processes and have given a new contractivity result and a bound on the loss of optimality when compared to optimal feedback control. In a numerical case study, the real-time control of an airborne kite, we have demonstrated the practical applicability of the method for a challenging nonlinear control example.

The "real-time iteration" scheme is based on the direct multiple shooting method, which offers several advantages in the context of real-time optimal control, among them the ability to efficiently initialize subsequent optimization problems, to treat highly nonlinear and unstable systems, and to deal efficiently with path constraints. The most important feature of the real-time iteration scheme is a dovetailing of the solution iterations with the process development which allows us to reduce sampling times to a minimum but maintains all advantages of a fully nonlinear treatment of the optimization problems. A separation of the computations in each real-time iteration into a *preparation phase* and a *feedback response phase* can be realized. The feedback phase is typically orders of magnitude shorter than the preparation phase and allows us to obtain an immediate feedback that takes all linearized constraints into account.

The contractivity of the scheme is proven under mild conditions that are nearly identical to the sufficient conditions for convergence of off-line Newton-type methods. Iterates on different horizon lengths have to be compared. The result is that the real-time iterates, after an initial disturbance, geometrically approach the exact optimal solutions during the runtime of the process. When the resulting closed-loop trajectory is compared to optimal feedback control, a bound on the loss of optimality has been established, which is of fourth order in the initial disturbance if an exact Newton–Raphson method is used.

A newly developed kite model is presented. The control aim is, starting from an arbitrary initial state, to steer the kite into a periodic orbit, a "lying eight" with a period duration of eight seconds. We consider a time horizon of 24 seconds. The initial state is only known at the moment that the first control needs already to be applied; the real-time iteration scheme delivers linearized feedback nearly without delay and provides a newly linearized feedback after each sampling time of one second, leading to a fully nonlinear optimization, and is always prepared to react to further disturbances. The scheme shows an excellent closed-loop performance for this highly nonlinear and unstable system and compares well to a hypothetical exact optimal feedback control.

The real-time iteration scheme has also been applied for NMPC of a real pilot plant distillation column described by a stiff DAE model with over 200 system states, allowing feedback sampling times of only 20 seconds [21].

STOCHASTIC DIFFERENTIAL GAMES IN A NON-MARKOVIAN SETTING*

ERHAN BAYRAKTAR† AND H. VINCENT POOR‡

Abstract. Stochastic differential games are considered in a non-Markovian setting. Typically, in stochastic differential games the modulating process of the diffusion equation describing the state flow is taken to be Markovian. Then Nash equilibria or other types of solutions such as Pareto equilibria are constructed using Hamilton–Jacobi–Bellman (HJB) equations. But in a non-Markovian setting the HJB method is not applicable. To examine the non-Markovian case, this paper considers the situation in which the modulating process is a fractional Brownian motion. Fractional noise calculus is used for such models to find the Nash equilibria explicitly. Although fractional Brownian motion is taken as the modulating process because of its versatility in modeling in the fields of finance and networks, the approach in this paper has the merit of being applicable to more general Gaussian stochastic differential games with only slight conceptual modifications. This work has applications in finance to stock price modeling which incorporates the effect of institutional investors, and to stochastic differential portfolio games in markets in which the stock prices follow diffusions modulated with fractional Brownian motion.

Key words. stochastic differential games, non-Markovian games, fractional Brownian motion, fractional noise theory

1. Introduction.

The study of stochastic differential games with controls is a part of game theory that is relatively unknown, even though it has significant potential for application as noted by Øksendal and Reikvam [27]. Prior work in this area has focused on the examination of such games in a Markovian setting (see below). In this paper we will study a type of non-Markovian stochastic differential game. In particular, we will consider a game in which the one-dimensional state X_t follows the following stochastic differential equation:

$$dX_t = \mu(t, X_t, \upsilon_1, \dots, \upsilon_N)dt + \sigma(t, X_t, \upsilon_1, \dots, \upsilon_N)dB_t^{(H)}, \tag{1}$$

$$\mu : [0,T] \times \mathbb{R} \times \Upsilon_1 \times \cdots \times \Upsilon_N \to \mathbb{R}, \tag{2}$$

$$\sigma : [0,T] \times \mathbb{R} \times \Upsilon_1 \times \cdots \times \Upsilon_N \to \mathbb{R}, \tag{3}$$

where $\upsilon_i \in \Upsilon_i \subset \mathbb{R}^{\nu_i}$ is the control of the ith player over the state and is adapted to the natural filtration of B^H. Here T is the expiration date of the game, and B^H is a fractional Brownian motion (fBm) with Hurst parameter $H \in (\frac{1}{2}, 1)$. B^H is

defined as an almost surely (a.s.) continuous zero-mean Gaussian process having the autocorrelation structure given by

$$E\left\{B_t^H B_s^H\right\} = \frac{1}{2}\left\{|s|^{2H} + |t|^{2H} - |t-s|^{2H}\right\}. \tag{4}$$

Each agent wants to maximize its own pay-off (with this feature the problem differs from the usual optimal control problem):

$$J_i(x) = E^x\left\{\int_0^T f_i(t, X_t, \upsilon_t)dt + K_i(T, X_T)\right\}, \tag{5}$$

where $E^x\{\cdot\}$ denotes conditional expectation given $X_0 = x$. In this paper we consider only the case in which the state and the source of randomness are one-dimensional. The results can be extended to the case in which there are multiple sources of randomness and multiple controlled states (see [4]).

Typically in this type of setting the modulating process in (1) is taken to be Brownian motion, i.e., $H = 1/2$, and the controls of the players are Markovian. Then Nash equilibria or other types of solutions such as Pareto equilibria are constructed using the Hamilton–Jacobi–Bellman (HJB) equations (see, e.g., Friedman [9], Gaidov [11], [12], [10], Nilakantan [23], Øksendal and Reikvam [27], and Varaiya [32]). However, fBm is not a Markov process for any H other than $\frac{1}{2}$, and therefore this approach does not work for the general case of (1). Here we will develop a quasi-martingale approach to the solution of this problem using the fractional noise calculus developed by Duncan, Hu, and Pasik-Duncan [7], and the work of Hu and Øksendal [16], which generalizes white noise calculus (see [1]) to develop an integration theory with respect to fBm. The key to our solution will be the fractional Clark–Ocone formula developed by Hu and Øksendal [16]. The integrals in (1) are Wick type integrals (see Definition 3.3) rather than Stieltjes integrals (defined pathwise; see, e.g., [33]). The motivation for using Wick type integrals is as follows: The pathwise integral $\int_0^t f_s \delta B_s^H$ with respect to fBm does not in general have a zero mean; i.e., $E\{\int_0^t f_s \delta B_s^H\} \neq 0$. However, the Wick type integral $\int_0^t f_s dB_s^H$ has zero mean; i.e., $E\{\int_0^t f_s dB_s^H\} = 0$. Therefore in a stochastic differential equation (SDE) of the form

$$dX_t = b(X_t)dt + \sigma(X_t)dB_t^H, \tag{6}$$

the volatility term $\sigma(X_t)dB_t^H$ does not contribute to the mean rate of change, as it does with SDEs with pathwise integrals. Since separating the random fluctuations from the mean rate of change is desirable for our purposes, we prefer to use Wick type integrals for defining the integrals with respect to fBm (see [7]). (Note also that only in the Wick type calculus are the standard tools of Itô calculus such as an Itô representation theorem available.) See [5] for applications of Wick calculus to pricing weather derivatives and [8] and [16] for further applications of Wick type calculus, particularly in finance.

Fractional noise calculus reduces to white noise calculus when H is replaced by $\frac{1}{2}$. Moreover the integrals of adapted processes in this framework are equal to the Itô integrals of these processes with respect to Brownian motion. Hence our results hold in particular for the standard framework, i.e., when the modulator is a Brownian motion, and the integrals in (1) are taken to be Itô integrals.

This work has an immediate application in finance, to stock price modeling when long-range dependence is accounted for in the model. The stock prices are considered

to be states in this setting, while the agents are *not price takers*; i.e., their trading changes the price level. This models a market with institutional investors who make large transactions and therefore influence the prices of the stocks. These investors find themselves in a random environment due to the existence of small investors. The small investors are typically inert; i.e., they do not trade for long time intervals. A microstructure model taking the inertness of the agents into account is constructed in [3]. It is shown that the prices arising from the interaction of the small agents can be approximated by geometric fractional Brownian motion. The game theoretic setting in this paper is an extension to the results of [3] in the sense that we start by assuming that the noise in the environment can be modeled by an fBm differential in the controlled stochastic differential equation (1), which is the noise due to the trades of the small investors.

Another possible application is in stochastic differential portfolio games, which are studied by Browne in a Brownian motion setting in [6]. This formulation is applicable to the analysis of traders who are competing for a bonus, or to fund managers whose funds are invested in different markets and who achieve rewards based on the relative performance of their funds. Yet another possible application is in stochastic goodwill problems (finding the optimal advertising policy for the maximization of the product image) in advertising when there are more than one good of the same kind in competition. (See [22] for stochastic goodwill problems in a stochastic optimal control setting.)

By adapting the fractional noise machinery, we will see that our results can be shown to hold for more general Gaussian modulators in the state flow dynamics. However, we state the results in terms of fBm to emphasize the fact that the game under consideration becomes non-Markovian and also because this case admits an explicit equilibrium. Another motivation for this model is the fact that fBm is frequently used in modeling in various areas of research (see [2], [31], [24], [25], and [26] for applications other than finance).

The rest of the paper is organized as follows. In section 2 we give a Nash equilibrium theorem. In section 3 we introduce the necessary tools from the fractional noise calculus that we use in the proof of the equilibrium theorem that is carried out in section 4. Finally in section 5 we give a sketch of how to extend the fractional noise machinery to more general Gaussian modulation processes.

2. Nash equilibrium in a linear game of N players. For ease of exposition we consider first a one-dimensional state equation, with the drift and diffusion coefficients controlled linearly by the players:

$$dX_t = rX_t dt + \sum_{i=1}^{N} \alpha_i(t)u_i(t)dt + C\sum_{i=1}^{N} \beta_i(t)v_i(t)dt + \sum_{i=1}^{N} \beta_i(t)v_i(t)dB^H(t), \tag{7}$$

where B^H denotes the one-dimensional version of $B^{(H)}$ with $H_1 = H$. The initial state will be denoted by $X_0 = x$. The pay-off function of player i will be of the form

$$J_i(x) = E_\mu^x\left\{ \int_0^T \frac{c_i u_i^{\gamma_i}(t)}{\gamma_i} dt + \frac{b_i X_T^{\gamma_i'}}{\gamma_i'} \right\}; \tag{8}$$

that is, players are constant relative risk averse (CRRA). Here μ is the measure on the sample space under which the canonical process is an fBm. Player i controls the state by its choice of actions (u_i, v_i). We assume that $\alpha_i : [0,T] \to \mathbb{R}$ is bounded

for each $i \in \{1, \dots, N\}$. The coefficient functions $\beta_i : [0,T] \to \mathbb{R}$ will appear in the definition of admissible strategies.

Since this game is in a non-Markovian setting, it cannot be solved via the HJB method. Instead we will employ the recently developed fractional Wick calculus, which we describe briefly in section 3, and the fractional Clark–Ocone formula (which is given along with the proof of the equilibrium theorem) to find Nash equilibria for this game. Observe that u_i affects the drift of the state and also appears in the pay-off function. It can be interpreted as a cost for the player; i.e., for gaining a certain amount of riskless increase the player pays an associated cost. Whereas by choice of v_i, the player does not have to pay a cost for an associated gain (since this action does not appear in the pay-off function), but is taking some risk (since v_i affects the diffusion coefficient in addition to the drift).

Let us introduce the following notation that is necessary to define the admissible strategies and for the statement of the theorem.

Define K as

$$K(t) = \frac{C(Tt - t^2)^{\frac{1}{2}-H}}{2H(2H-1)\Gamma(2H-1)\Gamma(2-2H)\cos(\pi(H-\frac{1}{2}))} \quad \text{for } t \in [0,T], \tag{9}$$

and define ζ by

$$\begin{aligned} \big((-\Delta)^{-(H-1/2)}\zeta_t\big)(s) &= \big((-\Delta)^{-(H-1/2)}K\big)(s), \quad 0 \le s \le t, \\ \zeta_t(s) &= 0, \quad s < 0 \quad \text{or} \quad s > t, \end{aligned} \tag{10}$$

where the action of the operator $(-\Delta)^{-(H-1/2)}$ on a test function f is defined by

$$\big((-\Delta)^{-(H-1/2)}f\big)(x) = \frac{1}{2\Gamma(2H-1)\cos(\pi(H-1/2))}\int_{-\infty}^{\infty} |x-t|^{2H-2} f(t)dt, \tag{11}$$

where Γ is the Gamma function and is given by $\Gamma(x) = \int_0^\infty t^{x-1}e^{-t}dt$ for $x > 0$. The existence of such ζ is guaranteed by [15].

Define $\hat{\mu}$ and η by

$$\eta(T) := \frac{d\hat{\mu}}{d\mu} := \exp\left(-\int_0^T K(s)dB_s^H - \frac{1}{2}|K|_\phi^2\right), \tag{12}$$

with $|K|_\phi^2$ given by $|K|_\phi^2 = \int_{\mathbb{R}_+^2} K(s)K(t)\phi(s,t)dsdt$, where

$$\phi(s,t) = H(2H-1)|s-t|^{2H-2}; \quad s,t \in \mathbb{R}_+. \tag{13}$$

Here μ denotes the probability measure under which B^H is an fBm with Hurst parameter H. Note that integrals of deterministic functions w.r.t. fBm are well defined, as will become clear in section 3.

And finally define ρ by $\rho(t,w) := E_\mu\big\{\eta(T)\big|\mathcal{F}_t\big\}$, where $\mathcal{F}_t$ is the σ-algebra generated by $\{B_s^H, s \le t\}$.

Now we will introduce the solution concept of Nash equilibrium in our context. We consider a set $\mathcal{A} = \mathcal{A}_1 \times \cdots \times \mathcal{A}_N$ of admissible strategies for which the admissibility conditions are adaptedness w.r.t. the filtration generated by fBm and the following integrability condition:

$$\beta_i v_i \in \mathcal{L}_\phi^{1,2}(\hat{\mu}), \tag{14}$$

where $\mathcal{L}_\phi^{1,2}(\hat{\mu})$ denotes the completion of the set of all $\mathcal{F}_t$ adapted processes f such that

$$\| f \|_{\mathcal{L}_\phi^{1,2}(\hat{\mu})} := E_{\hat{\mu}}\left\{\int_{\mathbb{R}}\int_{\mathbb{R}} f(s)f(t)\phi(s,t)dsdt\right\} + E_{\hat{\mu}}\left\{\left(\int_{\mathbb{R}} D_s^\phi f(s)ds\right)^2\right\} < \infty. \tag{15}$$

Here $D_s^\phi F = \int_{\mathbb{R}} \phi(s,t) D_t F dt$, where $D_s F$ denotes the Hida–Malliavin derivative of F, which will be introduced in section 3.

DEFINITION 2.1. *The strategy $z^e = (u^e, v^e) \in \mathcal{A}$ is called a Nash equilibrium strategy if, for each i, player i's action $z_i^e = (u_i, v_i) \in \mathcal{A}_i$ is a best response to its opponents'; i.e.,*

$$J_i^x(z_1^e, \dots, z_{i-1}^e, z_i, z_{i+1}^e, \dots, z_N^e) \le J_i^x(z^e) \tag{16}$$

for all x, for each player i, and for all $z_i \in \mathcal{A}_i$.

Then we have the following Nash equilibrium theorem.

THEOREM 2.2. *Consider the game given by* (7) *and* (8). *Then conditions* (17) and (18) *are necessary and sufficient for the existence of a Nash equilibrium:*

$$\gamma_i' = \gamma' \quad \textit{for } i = 1, \dots, N, \quad \textit{and} \tag{17}$$

$$\begin{aligned}\sum_{i=1}^N \int_0^T m^{\frac{1}{\gamma_i - 1}} b_i^{\frac{1}{\gamma_i - 1}} \alpha_i(t)^{\frac{\gamma_i}{\gamma_i - 1}} e^{-rt\frac{\gamma_i}{\gamma_i - 1}} \exp\left(\frac{\gamma_i}{2(1-\gamma_i)^2}|\zeta_t|_\phi\right)dt \\ + m^{\frac{1}{\gamma' - 1}} e^{-rT\frac{\gamma'}{\gamma' - 1}} \exp\left(\frac{2\gamma'|K|_\phi}{2(1-\gamma')^2}\right) = x\end{aligned} \tag{18}$$

has a solution $m^* \in \mathbb{R}$.

Let $\big((u_1^e, v_1^e), \dots, (u_N^e, v_N^e)\big)$ denote the agents' Nash equilibrium strategies. The first components of the equilibrium strategies are uniquely determined by

$$u_i^e(t) = \left(\frac{m^* b_i \alpha_i(t)}{c_i} e^{-rt}\rho(t,w)\right)^{\frac{1}{\gamma_i - 1}} \quad \textit{for } i = 1, \dots, N, \tag{19}$$

while the second component of the players' strategies will be any adapted (to the filtration of fBm) processes satisfying the following constraint:

$$\begin{aligned} e^{-rt}\sum_{i=1}^N \beta_i v_i^e(t) = (m^*)^{\frac{1}{\gamma' - 1}} \frac{K(t)}{1-\gamma'} \exp\left(\frac{1}{1-\gamma'}\int_0^t K(s)dB_s^H - \frac{C}{1-\gamma'}\int_t^T K(s)ds\right. \\ \left. + \frac{2-\gamma}{2(1-\gamma^2)}|K|_\phi^2 - \frac{1}{1-\gamma}|K1_{[0,t]}|_\phi^2 - rT\frac{\gamma'}{\gamma' - 1}\right) \\ - \int_0^T \sum_{i=1}^N \alpha_i(u)^{\frac{\gamma_i}{\gamma_i - 1}} \big(\frac{m^* b_i}{c_i}\big)^{\frac{1}{\gamma_i - 1}} \times \frac{\zeta_u(t)}{1-\gamma_i} e^{-ru\frac{\gamma_i}{\gamma_i - 1}} \\ \times \exp\left(\frac{1}{1-\gamma_i}\int_0^t \zeta_u(s)dB_s^H - \frac{C}{1-\gamma_i}\int_t^u \zeta_u(s)ds\right. \\ \left. + \frac{2-\gamma_i}{2(1-\gamma_i)^2}|\zeta_u|_\phi^2 - \frac{1}{1-\gamma_i}|\zeta_u 1_{[0,t]}|_\phi^2\right)du, \end{aligned} \tag{20}$$

where 1 *stands for the indicator function. Finally, the state at time* T *at Nash equilibrium is given by*

$$F^e = (m^*)^{\frac{1}{\gamma'-1}} \eta(T)^{\frac{1}{\gamma'-1}} e^{\frac{-rT}{\gamma'-1}}. \tag{21}$$

These results can be extended to games with multiple controlled states and multiple sources of randomness (see [4]).

Before proving Theorem 2.2, in the next section we will give a brief review of the facts from fractional noise calculus, largely following the treatment by Hu and Øksendal [16]. (An extended version of the following section can be found in [4].)[1]

3. Fractional noise calculus. We start this section by introducing the necessary ingredients for the definition of the stochastic integral in (1). In what follows $L^2_\phi(\mathbb{R})$ will denote the completion of the set of measurable functions satisfying

$$|f|^2_\phi := \int_{\mathbb{R}^2} f(s)f(t)\phi(s,t)dsdt < \infty. \tag{22}$$

Remark. It is shown by Pipiras and Taqqu [28] that the set of functions satisfying (22) is not a complete space.

The stochastic integral of deterministic functions in $L^2_\phi(\mathbb{R})$ w.r.t. fBm is well defined (see [13]). For $f \in L^2_\phi(\mathbb{R})$, we will denote its integral w.r.t. fBm by $\langle w, f\rangle := \int_{\mathbb{R}} f(t)dB^H_t$.

The probability space in our game will be $\Omega = \mathcal{S}'(R)$, the space of tempered distributions (the dual space of $\mathcal{S}(\mathbb{R})$, the Schwartz space of rapidly decreasing functions) equipped with the weak-star topology. And we will take the events to be Borel subsets of $\mathcal{S}'(R)$. By the Bochner–Minlos theorem there exists a probability measure μ on Ω such that $\langle \cdot, f\rangle \colon \Omega \to \mathbb{R}$ is a Gaussian random variable with mean 0 and variance $|f|^2_\phi$ (see [16]).

We will now introduce the Wiener chaos expansion of random variables in $L^2(\mu)$. One first has to find the orthonormal basis for $L^2_\phi(\mathbb{R})$. Recall that the Hermite functions (see, e.g., Appendix C of [14]), which we will denote by (z_n), form an orthonormal basis for $L^2(\mathbb{R})$.

Let us define the map from the space of functions satisfying (22) into $L^2(\mathbb{R})$ by

$$(I_\phi f)(u) = c_H \int_u^\infty (t-u)^{H-\frac{3}{2}} f(t)dt, \tag{23}$$

where $c_H = \sqrt{\frac{H(2H-1)\Gamma(\frac{3}{2}-H)}{\Gamma(H-\frac{1}{2})\Gamma(2-2H)}}$ (here Γ denotes the Gamma function). This map preserves the inner product, and the Hermite functions are in the range of this map. Let I^{-1}_ϕ denote the inverse map of I_ϕ. (For summable functions this inverse exists and is proportional to the Liouville differential of order $H - \frac{1}{2}$ [30], since $I_\phi(f)$ is proportional to the fractional integral of f of order $H - \frac{1}{2}$.) Now we see that the set $(e_n = I^{-1}_\phi(z_n))_{n=1,2,\ldots}$ constitutes an orthonormal basis for $L^2_\phi(\mathbb{R})$.

[1] Although the original name given by Hu and Øksendal in [16] to this kind of calculus was fractional white noise calculus, we prefer to omit "white" from the name since white suggests independence at each point in time, and here the noise considered is far from it.

Let $\mathcal{J}$ denote the set of all (finite) multi-indices of nonnegative integers. Then for $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_m) \in \mathcal{J}$, define

$$H_\alpha(w) := h_{\alpha_1}(\langle w, e_1\rangle) \cdots h_{\alpha_m}(\langle w, e_m\rangle). \tag{24}$$

Note that $E_\mu\{H_\alpha H_\beta\} = 0$ if $\alpha \neq \beta$, and $E_\mu\{H_\alpha^2\} = \alpha!$. Now we can state what is known as the chaos decomposition for the elements of $L^2(\mu)$ (see [16]): Every $F \in L^2(\mu)$ can be decomposed uniquely as $F(w) = \sum_{\alpha\in\mathcal{J}} c_\alpha H_\alpha(w)$, where $c_\alpha \in \mathbb{R}$ for all $\alpha \in \mathcal{J}$.

For defining the integration w.r.t. fBm of random functions we will make use of the Hida test function space (a subspace of $L^2(\mu)$) and Hida distribution space (a superset of $L^2(\mu)$), which we denote by $(\mathcal{S})_H$ and $(\mathcal{S})_H^*$, respectively (see [34] for their definitions). Let $\psi(w) = \sum_{\alpha\in\mathcal{J}} a_\alpha H_\alpha(w) \in (\mathcal{S})_H$ and let $G(w) = \sum_{\beta\in\mathcal{J}} b_\beta H_\beta(w)$; then we denote the action of G on ψ by $\langle\langle G, \psi\rangle\rangle := \sum_{\alpha\in\mathcal{J}} \alpha! a_\alpha b_\alpha$.

For defining the integral w.r.t. fBm it is necessary to define $(\mathcal{S})_H^*$-valued Pettis integrals as follows.

DEFINITION 3.1. *A function $Z : \mathbb{R} \to (\mathcal{S})_H^*$ is $(\mathcal{S})_H^*$ integrable if $\langle\langle Z(t), \psi\rangle\rangle \in L^1(\mathbb{R})$ for all $\psi \in (\mathcal{S})_H$. Then the $(\mathcal{S})_H^*$ integral of Z denoted by $\int_{\mathbb{R}} Z(t)dt$ is the unique element in $(\mathcal{S})_H^*$ such that*

$$\left\langle\left\langle \int_{\mathbb{R}} Z(t)dt, \psi \right\rangle\right\rangle = \int_{\mathbb{R}} \langle\langle Z(t), \psi\rangle\rangle \, dt \quad \text{for all } \psi \in (\mathcal{S})_H. \tag{25}$$

Remark. $t \to B_t^H$ is differentiable in $(\mathcal{S})_H^*$; i.e., fractional noise is a well-defined object and we denote it by (W_t^H).

Below we describe the Wick product which is the last ingredient necessary for describing the integration w.r.t. fBm.

DEFINITION 3.2. *Suppose $F, G \in (\mathcal{S})_H^*$ are given by*

$$F(w) = \sum_{\alpha\in\mathcal{J}} a_\alpha H_\alpha(w) \quad \text{and} \quad G(w) = \sum_{\beta\in\mathcal{J}} b_\beta H_\beta(w). \tag{26}$$

Then the Wick product $F \diamond G$ of F and G is defined as

$$(F \diamond G)(w) = \sum_{\alpha,\beta\in\mathcal{J}} a_\alpha b_\beta H_{\alpha+\beta}(w). \tag{27}$$

Remark. $(\mathcal{S})_H$ and $(\mathcal{S})_H^*$ are closed under the Wick product.

The Wick exponential $\exp^\diamond$ is defined as $\exp^\diamond(X) = \sum_{n=0}^\infty \frac{X^{\diamond n}}{n!}$, provided the series converges in $(\mathcal{S})_H^*$, where $X^{\diamond n} = X \diamond \cdots \diamond X$ (n factors). And we have that $\exp^\diamond(\langle w, f\rangle) = \exp(\langle w, f\rangle - \frac{1}{2}|f|_\phi^2)$ for $f \in L_\phi^2(\mathbb{R})$ (see [16]).

DEFINITION 3.3. *Suppose $Y : \mathbb{R} \to (\mathcal{S})_H^*$ is such that $Y(t) \diamond W_t^H$ is integrable in $(\mathcal{S})_H^*$. Then $\int_{\mathbb{R}} Y(t)dB_t^H$ is defined by*

$$\int_{\mathbb{R}} Y(t)dB_t^H := \int_{\mathbb{R}} Y(t) \diamond W_t^H dt. \tag{28}$$

LEMMA 3.4. *Let $\mathcal{L}_\phi^{1,2}(\mu)$ be as in (15). If $Y \in \mathcal{L}_\phi^{1,2}(\mu)$, then $\int_{\mathbb{R}} Y_t dB_t^H$ exists as an element of $L^2(\mu)$ and its norm is given by $\| Y \|_{\mathcal{L}_\phi^{1,2}(\mu)}$.*

For finding the equilibrium strategies we also make use of the Hida derivative (which is called the Malliavin derivative in the context of Wiener space), which we will define below. We first define the directional derivative.

DEFINITION 3.5. *Suppose that $F : \mathcal{S}' \to \mathbb{R}$ and $\gamma \in \mathcal{S}'$. Then the directional (Gateaux) derivative of F in the direction of γ is given by*

$$D_\gamma F(w) := \lim_{\epsilon \to 0} \frac{F(w + \epsilon\gamma) - F(w)}{\epsilon} \quad \text{if it exists in } (\mathcal{S})_H^*. \tag{29}$$

DEFINITION 3.6. *$F : \mathcal{S}' \to \mathbb{R}$ is said to be differentiable if there is a map $K : \mathbb{R} \to (\mathcal{S})_H^*$ such that*

$$\begin{aligned} &K(t,w)\gamma(t) \text{ is } (\mathcal{S})_H^* \text{ integrable} \\ &\text{and} \quad D_\gamma F(w) = \int_{\mathbb{R}} K(t,w)\gamma(t)dt \text{ for all } \gamma \in L^2(\mathbb{R}). \end{aligned} \tag{30}$$

Then $D_t F(w) := K(t,w)$ is said to be the Hida derivative of F.

We will make use of the Pothoff–Timpel test functions and distributions (see [29] for the definitions) to define quasi-conditional expectation in the following sections. We denote these spaces by $\mathcal{G}$ and $\mathcal{G}^*$, respectively. The Hida derivative of the random variables in $\mathcal{G}^*$ exists.

Let $F = \sum_\alpha c_\alpha H_\alpha(w) \in \mathcal{G}^*$. Then the Hida derivative exists and is given by

$$D_t F(w) = \sum_\alpha c_\alpha \sum_i \alpha_i H_{\alpha - \varepsilon^i}(w) e_i(t), \tag{31}$$

where $\varepsilon^i = (0, \dots, 0, 1, 0, \dots, 0)$ with the 1 in the ith component.

We proceed by defining the quasi-conditional expectation and then introducing the fractional Clark–Ocone theorem which will be crucial in reducing the dynamic optimization problems of the next section into static optimization problems.

DEFINITION 3.7 (see [16]). *If $F \in \mathcal{G}^*(\mu)$ has the expansion*

$$F(w) = \sum_{n=0}^{\infty} \int_{[0,T]^n} f_n (dB^H)^{\otimes n}, \tag{32}$$

then its quasi-conditional expectation is given by

$$\tilde{E}_\mu\{F|\mathcal{F}_t\} = \sum_{n=0}^{\infty} \int_{[0,t]^n} f_n (dB^H)^{\otimes n}. \tag{33}$$

Note that $\tilde{E}_\mu\{F|\mathcal{F}_t\} \neq E_\mu\{F|\mathcal{F}_t\}$ in general. (Only for $H = \frac{1}{2}$ is the quasi-conditional expectation operator the same as the conditional expectation operator on $L^2(\mu)$.) However, the following holds: $\tilde{E}\{F|\mathcal{F}_t\} = F$ a.s. $\Leftrightarrow F$ is $\mathcal{F}_t$ measurable.

The following feature of the quasi-conditional expectation will be helpful in the computations in the next section:

$$\tilde{E}\{F \diamond G|\mathcal{F}_t\} = \tilde{E}\{F|\mathcal{F}_t\} \diamond \tilde{E}\{G|\mathcal{F}_t\} \quad \text{for } F, G \in \mathcal{G}^*. \tag{34}$$

We will also need the notion of a quasi martingale which is defined as follows.

DEFINITION 3.8. *Suppose M_t is an $(\mathcal{F}_t)$ adapted process in $\mathcal{G}^*$. It is called a quasi martingale if*

$$\tilde{E}\{M_t|\mathcal{F}_s\} = M_s \quad \text{for all } t \geq s. \tag{35}$$

LEMMA 3.9 (see [17]). *Let $F \in \mathcal{L}_\phi^{1,2}(\mu)$. Then $M_t = \int_0^t F_s dB_s^H$ is a quasi martingale.*

Now we will state the fractional Clark–Ocone theorem.

THEOREM 3.10 (see [16]). *Suppose $G(w) \in L^2(\mu)$ is $\mathcal{F}_T$ measurable. Define $\psi(t,w) = \tilde{E}_\mu\{D_t G | \mathcal{F}_t\}$, where $D_t G$ is the Hida derivative of G at t, which exists as an element of $\mathcal{G}^*(\mu)$. Then $\psi \in \mathcal{L}_\phi^{1,2}(\mu)$ and*

$$G(w) = E_\mu\{G\} + \int_0^T \psi(t,w) dB_t^H. \tag{36}$$

4. Proof of Theorem 2.2. Recall that in Theorem 2.2, we consider the one-dimensional state equation (7) where the pay-off function of player i is of the form (8).

As noted previously, we will employ the fractional Clark–Ocone formula and the Wick calculus introduced in section 3 to find Nash equilibria for this type of game. We begin this development by stating a fractional version of the Girsanov theorem, which is given by [16].

THEOREM 4.1 (see [16]). *Suppose $T > 0$ and $u : [0,T] \to \mathbb{R}$ is continuous. Suppose further that $K : [0,T] \to \mathbb{R}$ satisfies the equation*

$$\int_0^T K(s)\phi(s,t) ds = u(t), \quad 0 \le t \le T, \tag{37}$$

where ϕ is given by (13). *Extend K to $\mathbb{R}$ by putting $K(s) = 0$ outside $[0,T]$. Define the probability measure $\hat{\mu}$ on F_T by*

$$\frac{d\hat{\mu}(w)}{d\mu(w)} = \exp\left(- \int_0^T K(s) dB_s^H - \frac{1}{2}|K|_\phi^2 \right). \tag{38}$$

Then $\hat{B}_t^H = \int_0^t u(s) ds + B_t^H$ is an fBm with respect to $\hat{\mu}$.

The dynamics of the state (7) can be written as

$$d(e^{-rt} X_t) - e^{-rt} \sum_{i=1}^N \alpha_i(t) u_i(t) dt = e^{-rt} \sum_{i=1}^N \beta_i(t) v_i(t) (C dt + dB_t^H). \tag{39}$$

Let η and $\hat{\mu}$ be defined as in (12); i.e.,

$$\begin{aligned} \eta(T) = \frac{d\hat{\mu}}{d\mu} &= \exp\left(- \int_0^T K(s) dB_s^H - \frac{1}{2}|K|_\phi^2 \right) \\ &= \exp^\diamond\left(- \int_0^T K(s) dB_s^H \right), \end{aligned} \tag{40}$$

where K is from (9). Then since K solves (37) for $u(t) = C$ (see Lemma 7.1) and by the fractional Girsanov formula, the process

$$\hat{B}_t^H = Ct + B_t^H \tag{41}$$

is an fBm with respect to $\hat{\mu}$ having the same Hurst parameter as the modulating process in (7). Thus, the differential equation describing the flow of the state is

given in terms of $\hat{B}^H$ as

$$e^{-rt}X_t - \int_0^t e^{-rs}\sum_{i=1}^N \alpha_i(s)u_i(s)dt = x + \int_0^t e^{-rs}\sum_{i=1}^N \beta_i(s)v_i(s)d\hat{B}_s^H. \tag{42}$$

To be able to find a Nash equilibrium, we will use the quasi-martingale approach to stochastic control in the proof. (For another application of this approach see [17].) We first find the best response of a player to the given strategies of other players and for that we will use the fractional Clark–Ocone theorem (Theorem 3.10).

By (14) we have that $e^{-rt}X_t - \int_0^t e^{-rs}\sum_{i=1}^N \alpha_i(s)u_i(s)dt \in L^2(\hat{\mu})$. And note that by Lemma 3.9 and (14), $\int_0^t e^{-rs}\sum_{i=1}^N \beta_i(s)v_i(s)d\hat{B}_s^H$ is a quasi martingale. Therefore we have

$$E_{\hat{\mu}}\left\{e^{-rt}X_t - \int_0^t e^{-rs}\sum_{i=1}^N \alpha_i(s)u_i(s)dt\right\} = x.$$

Now let G be given by

$$G = e^{-rT}F_i - \int_0^T e^{-rs}\sum_{j=1}^N \alpha_j(s)u_j(s)ds. \tag{43}$$

Assume $G \in L^2(\hat{\mu})$. Then if

$$E_{\hat{\mu}}\{G\} = x, \tag{44}$$

by the fractional Clark–Ocone formula (36) we have

$$G = x + \int_0^T \tilde{E}_{\hat{\mu}}\left\{D_sG\middle|\mathcal{F}_s\right\}d\hat{B}_s^H. \tag{45}$$

If we choose v_i in (42) such that

$$v_i(s) = \frac{-\sum_{j\neq i}\beta_j(s)v_j(s) + e^{rs}\tilde{E}_{\hat{\mu}}\left\{D_sG\middle|\mathcal{F}_s\right\}}{\beta_i(s)}, \tag{46}$$

then from (45) we see that $X_T = F_i$.

By the above argument we can change the dynamic optimization problem of maximizing (8) under the dynamics (7) into a static optimization problem. In particular, given the other players' strategies, player i wishes to solve the following maximization problem:

$$\begin{aligned} K_i(x) = \sup_{u_i,F_i}\Bigg\{&E_\mu\left\{\int_0^T \frac{c_iu_i(t)^{\gamma_i}}{\gamma_i}dt + \frac{b_iF_i^{\gamma_i'}}{\gamma_i'}\right\};\ \text{given that} \\ &E_{\hat{\mu}}\left\{-\int_0^T e^{-rs}\sum_{j=1}^N \alpha_j(s)u_j(s)ds + e^{-rT}F_i\right\} = x\Bigg\}, \end{aligned} \tag{47}$$

where the supremum is taken over F_i and (u_i) such that

$$e^{-rT}F_i - \int_0^T e^{-rs}\sum_{j=1}^N \alpha_j(s)u_j(s)ds \in L^2(\hat{\mu}). \tag{48}$$

This optimization problem can be solved by first considering for each $\lambda_i > 0$ the unconstrained problem

$$C_i(x,\lambda) = \sup_{u_i,F_i} \left\{ E_\mu \left\{ \int_0^T \frac{c_i u_i(t)^{\gamma_i}}{\gamma_i} dt + \frac{b_i F_i^{\gamma_i'}}{\gamma_i'} \right\} \right.$$

(49)

$$\left. + \lambda_i E_{\hat{\mu}} \left\{ -\int_0^T e^{-rs} \sum_{j=1}^N \alpha_j(s) u_j(s) ds + e^{-rT} F_i \right\} \right\},$$

and then solving for λ_i from the slackness condition

$$E_{\hat{\mu}} \left\{ -\int_0^T e^{-rs} \sum_{j=1}^N \alpha_j(s) u_j(s) ds + e^{-rT} F_i \right\} = x. \tag{50}$$

Let us define, as before, the following random variable:

$$\rho(t,w) = E_\mu \big\{ \eta(T) \big| \mathcal{F}_t \big\}, \tag{51}$$

where η is from (40). Using the fact that

$$E_\mu\{\eta(T) u_i(t)\} = E_\mu\{\rho(t) u_i(t)\}, \tag{52}$$

we can solve (4) by maximizing pointwise, i.e., for each t and w, the functions

$$g_i(u_i) = \frac{c_i u_i^{\gamma_i}}{\gamma_i} - \lambda_i \rho(t,w) e^{-rt} \sum_{j=1}^N \alpha_j(t) u_j \tag{53}$$

$$\text{and} \quad h_i(F_i) = \frac{b_i F_i^{\gamma_i'}}{\gamma_i'} - \lambda_i \eta(T,w) e^{-rT} F_i. \tag{54}$$

Since $0 < \gamma_i < 1$, these functions are concave, and therefore we can solve $g_i'(u_i) = 0$ and $h_i'(F_i) = 0$ to find the maximum points, which are given by

$$u_i(t) = \left(\frac{\lambda_i \rho(t,w) e^{-rt} \alpha_i(t)}{c_i} \right)^{\frac{1}{\gamma_i - 1}}, \tag{55}$$

$$\text{and} \quad F_i = \left(\frac{\lambda_i \eta(T,w) e^{-rT}}{b_i} \right)^{\frac{1}{\gamma_i' - 1}}. \tag{56}$$

Since $\alpha_i(t)$ is bounded by assumption, (48) is satisfied. Note that at the Nash equilibrium F_i is independent from the player index i, i.e., $F_i = F^e$ for all i. We will use this condition to show that the Lagrange multipliers at the equilibrium are necessarily linear in b_i and then use the slackness condition to actually find their value. First we will find $E_\mu\{\eta(T)^{\frac{1}{\gamma_i' - 1}}\}$. Note that

(57)

$$\begin{aligned} \eta(T)^{\frac{1}{\gamma_i' - 1}} &= \exp\left(\frac{1}{1-\gamma_i'} \int_0^T K(s) dB_s^H + \frac{1}{2(1-\gamma_i')} |K|_\phi^2 \right) \\ &= \exp\left(\frac{1}{1-\gamma_i'} \int_0^T K(s) dB_s^H - \frac{1}{2(1-\gamma_i')^2} |K|_\phi^2 \right) \exp\left(\frac{2-\gamma_i'}{2(1-\gamma_i')^2} |K|_\phi^2 \right). \end{aligned}$$

$$\text{Since} \quad E\left\{\exp^{\diamond}\left(\int_0^T f(s)dB_s^H\right)\right\} = 1, \tag{58}$$

for all $f \in L^2(\mu)$, we have

$$E\left\{\eta(T)^{\frac{1}{\gamma_i'-1}}\right\} = \exp\left(\frac{2-\gamma_i'}{2(1-\gamma_i')^2}|K|_\phi^2\right). \tag{59}$$

Therefore using (56) we obtain

$$EF_i = \left(\frac{\lambda_i}{b_i}\right)^{\frac{1}{\gamma_i'-1}} \exp\left(\frac{2-\gamma_i'}{2(1-\gamma_i')^2}|K|_\phi^2 - \frac{rT}{\gamma_i'-1}\right). \tag{60}$$

It follows that

$$F_i = E\{F_i\}\exp^{\diamond}\left(\frac{1}{1-\gamma_i'}\int_0^T K(s)dB_s^H\right). \tag{61}$$

From (61) we see that for a Nash equilibrium to exist, it is necessary that we have $\gamma_i' = \gamma'$ and $\lambda_i^e = mb_i$. From (4) we see that m is to be found from the slackness condition:

$$\begin{aligned} E_\mu\Bigg\{ &\int_0^T e^{-rt}\rho(t)\left(\sum_{i=1}^N \alpha_i(t)\left(\frac{\lambda_i^e\rho(t)e^{-rt}\alpha_i(t)}{c_i}\right)^{\frac{1}{\gamma_i-1}}\right)dt \\ &+ e^{-rT}\eta(T)\left(\frac{\lambda_i^e\eta(T)e^{-rT}}{b_i}\right)^{\frac{1}{\gamma_i'-1}}\Bigg\} = x. \end{aligned} \tag{62}$$

Note that by (40) we have the following:

$$\begin{aligned} \eta(T)^{\frac{\gamma'}{\gamma'-1}} &= \exp\left(\frac{\gamma'}{1-\gamma'}\int_0^T K(s)dB_s^H + \frac{\gamma'}{2(1-\gamma')}|K|_\phi^2\right) \\ &= \exp^{\diamond}\left(\frac{\gamma'}{1-\gamma'}\int_0^T K(s)dB_s^H\right)\exp\left(\frac{\gamma'}{2(1-\gamma')^2}|K|_\phi^2\right), \end{aligned} \tag{63}$$

$$E\left\{\eta(T)^{\frac{\gamma'}{\gamma'-1}}\right\} = \exp\left(\frac{\gamma'}{2(\gamma'-1)^2}|K|_\phi^2\right). \tag{64}$$

Using Theorem 3.2 of [15], $\rho(t,w)$ can be written as

$$\rho(t,w) = \exp\left(-\int_0^t \zeta_t(s)dB_s^H - \frac{1}{2}|\zeta_t|_\phi^2\right), \tag{65}$$

where ζ_t is given by

$$\begin{aligned} \big((-\Delta)^{-(H-1/2)}\zeta_t\big)(s) &= \big((-\Delta)^{-(H-1/2)}K\big)(s), \quad 0 \le s \le t, \\ \zeta_t(s) &= 0, \quad s < 0 \quad \text{or} \quad s > t, \end{aligned} \tag{66}$$

with the operator $(-\Delta)^{-(H-1/2)}$ on $L^2(\mu)$ defined by (11).

Thus

$$E\left\{\rho_t^{\frac{\gamma_i}{\gamma_i-1}}\right\} = E\Bigg\{\exp\left(\frac{\gamma_i}{1-\gamma_i}\int_0^T \zeta_t(s)dB_s^H - \frac{\gamma_i^2}{2(1-\gamma_i)^2}|\zeta_t|_\phi^2 + \frac{\gamma_i}{2(1-\gamma_i)}|\zeta_t|_\phi^2 + \frac{\gamma_i^2}{2(1-\gamma_i)^2}|\zeta_t|_\phi^2\right)\Bigg\}, \tag{67}$$

from which we conclude that

$$E\left\{\rho(t)^{\frac{\gamma_i}{\gamma_i-1}}\right\} = \exp\left(\frac{\gamma_i}{2(1-\gamma_i)^2}|\zeta_t|_\phi\right), \tag{68}$$

so that m can be solved from (62), which leads to the following equation:

$$\sum_{i=1}^N \int_0^T m^{\frac{1}{\gamma_i-1}} b_i^{\frac{1}{\gamma_i-1}} \alpha_i(t)^{\frac{\gamma_i}{\gamma_i-1}} e^{-rt\frac{\gamma_i}{\gamma_i-1}} \exp\left(\frac{\gamma_i}{2(1-\gamma_i)^2}|\zeta_t|_\phi\right) dt + m^{\frac{1}{\gamma'-1}} e^{-rT\frac{\gamma'}{\gamma'-1}} \exp\left(\frac{2\gamma'|K|_\phi}{2(1-\gamma')^2}\right) = x. \tag{69}$$

After solving for m using (69), then by (55) and (56) we have the final state at the equilibrium and strategy u_i for player i leading to that state, given, respectively, by

$$F^e = m^{\frac{1}{\gamma'-1}}\eta(T)^{\frac{1}{\gamma'-1}} e^{\frac{-rT}{\gamma'-1}} \tag{70}$$

and

$$u_i^e(t) = \left(\frac{mb_i\alpha_i(t)}{c_i}e^{-rt}\rho(t,w)\right)^{\frac{1}{\gamma_i-1}}. \tag{71}$$

Observe that these controls are not Markovian. (In a Brownian motion setting the controls were assumed to be Markovian at the outset so that the HJB equations for an equilibrium solution can be developed [6], [11], and [27].)

Now we will proceed to find (v_i) at the equilibrium, which is the second component of the players' strategies. For this we will again make use of the fractional Clark–Ocone formula.

Suppose G^e is given by

$$G^e = e^{-rT}F^e - \int_0^T e^{-rs}\sum_{i=1}^N \alpha_i u_i^e(s)ds. \tag{72}$$

Since there is a unique adapted process $\psi(t,w)$ such that

$$G^e = E_\mu\{G^e\} + \int_0^T \psi(t,w)d\hat{B}_t^H, \tag{73}$$

which, from the Clark–Ocone formula, is given by

$$\psi(t,w) = \tilde{E}_{\hat{\mu}}\big\{D_tG^e\big|\mathcal{F}_t\big\}, \tag{74}$$

it can now be seen immediately that any adapted (v_i^e) that satisfies

$$\tilde{E}_\mu\{D_t G^e|\mathcal{F}_t\} = e^{-rt}\sum_{i=1}^N \beta_i v_i^e(t) \tag{75}$$

is an equilibrium strategy.

To obtain a more explicit expression, we will compute $\tilde{E}_{\hat{\mu}}\{D_t G^e|\mathcal{F}_t\}$. Using (70) and (71), G^e is given by

$$\begin{aligned} G^e(T,w) &= m^{\frac{1}{\gamma'-1}} e^{-rT\frac{\gamma'}{\gamma'-1}} \eta(T,w)^{\frac{1}{\gamma'-1}} \\ &\quad - \int_0^T \sum_{i=1}^N \alpha_i(t)^{\frac{\gamma_i}{\gamma_i-1}} \left(\frac{mb_i}{c_i}\right)^{\frac{1}{\gamma_i-1}} e^{-rt\frac{\gamma_i}{\gamma_i-1}} \rho(t,w)^{\frac{1}{\gamma_i-1}} dt. \end{aligned} \tag{76}$$

To calculate the quasi-conditional expectation of the Hida derivative of G^e we will first find it for the stochastic part of the first term on the right-hand side of (76). Define R as

$$R = \exp\left(\frac{2-\gamma'}{(1-\gamma')^2}|K|_\phi^2 - \frac{C}{1-\gamma'}\int_0^T K(s)ds\right). \tag{77}$$

Using the chain rule, (41), and (33), we have

$$\begin{aligned} \tilde{E}_{\hat{\mu}}\left\{D_t\eta(T)^{\frac{1}{\gamma'-1}}|\mathcal{F}_t\right\} &= \tilde{E}_{\hat{\mu}}\left\{\frac{K(t)}{1-\gamma'}\eta(T)^{\frac{1}{\gamma'-1}}|\mathcal{F}_t\right\} \\ &= \frac{K(t)}{1-\gamma'}R\tilde{E}_{\hat{\mu}}\left\{\exp^\diamond\left(\frac{1}{1-\gamma'}\int_0^T K(s)d\hat{B}_s^H\right)|\mathcal{F}_t\right\} \\ &= \frac{K(t)}{1-\gamma'}R\exp^\diamond\left(\frac{1}{1-\gamma'}\int_0^t K(s)d\hat{B}_s^H\right) \\ &= \frac{K(t)}{1-\gamma'}\exp\left(\frac{1}{1-\gamma'}\int_0^T K(s)dB_s^H - \frac{C}{1-\gamma'}\int_t^T K(s)ds\right. \\ &\qquad \left. + \frac{2-\gamma}{2(1-\gamma^2)}|K|_\phi^2 - \frac{1}{1-\gamma}|K1_{[0,t]}|_\phi^2\right). \end{aligned} \tag{78}$$

Now we will find the quasi-conditional expectation of the Hida derivative of the stochastic part of second term on the right-hand side of (76) using (65), i.e.,

$$\begin{aligned} &\tilde{E}_{\hat{\mu}}\left\{D_t\left(e^{-ru\frac{\gamma_i}{\gamma_i-1}}\rho(u)^{\frac{1}{\gamma_i-1}}\right)|\mathcal{F}_t\right\} = \\ &\frac{\zeta_u(t)}{1-\gamma_i}e^{-ru\frac{\gamma_i}{\gamma_i-1}}\exp\left(\frac{1}{1-\gamma_i}\int_0^t \zeta_u(s)dB_s^H - \frac{C}{1-\gamma_i}\int_t^u \zeta_u(s)ds\right. \\ &\qquad \left. + \frac{2-\gamma_i}{2(1-\gamma_i)^2}|\zeta_u|_\phi^2 - \frac{1}{1-\gamma_i}|\zeta_u 1_{[0,t]}|_\phi^2\right). \end{aligned} \tag{79}$$

Using (75) and (76), we have the result for the second component for the players' equilibrium strategies, and this concludes the proof of Theorem 2.2. □

5. Extension of the Wick calculus to arbitrary Gaussian processes. Although the results of the preceding sections have considered the explicit case in which the modulator in (1) is fBm, these results can be extended to the situation in which the modulator is a more general Gaussian process within sufficient regularity. This requires the extension of the Wick calculus to more general Gaussian processes. In this section, we sketch how this extension can be accomplished. The first step in extending the fractional noise machinery introduced in section 3 to more general Gaussian processes is the following theorem due to Loève [21] for integrating deterministic functions with respect to second-order processes.

THEOREM 5.1 (see [21]). *Suppose that X is a zero-mean process such that $E\{X_t^2\} < \infty$ for all t, and denote its covariance function by R. Then, for $-\infty<a<b<\infty$,*

$$\int_a^b f(t)dX_t \tag{80}$$

exists as the L^2-limit of Riemann sums if and only if

$$|f|_R^2 := \int_a^b \int_a^b f(t)f(s)d^2R(s,t) < \infty. \tag{81}$$

Henceforth X will denote a Gaussian process. By the Bochner–Minlos theorem, there exists a unique probability measure on the space of tempered distributions such that $\langle \cdot, f\rangle : \Omega \to \mathbb{R}$ is a Gaussian random variable with mean 0 and variance $|f|_R^2$.

We will denote $L^2(\mu)$ by $L^2(X)$, and $H(X)$ will denote the linear space of X, i.e., the closed subspace of $L^2(X)$ spanned by X_t for all $t \in [a,b]$ (i.e., the first Wiener chaos). As in [18] we construct $\Lambda(R)$, a Hilbert space of deterministic integrable "functions" isomorphic to $H(X)$ by completing the pre-Hilbert space of step functions $\mathbb{S}$ with the inner product

$$\langle f, g\rangle_{\mathbb{S}} = \int\int f(t)g(s)d^2R(t,s) \tag{82}$$

for any $f, g \in \mathbb{S}$. Then the integration operator defined on the set of step functions (the integration with respect to X) can be extended to an isomorphism between $H(X)$ and $\Lambda(R)$. (The elements of $\Lambda(R)$ are generalized functions, i.e., distributions [28].)

As a second step we will define the Wick-integrability of a random process with respect to a Gaussian process. This is done by utilizing the tensor product structure of the space $L^2(X)$. Let us define the tensor product of Hilbert spaces.

DEFINITION 5.2. *The algebraic tensor product $H_1 \otimes H_2$ of Hilbert spaces H_1 and H_2 is a pre-Hilbert space with the following inner product:*

$$\langle h_1 \otimes h_2, g_1 \otimes g_2\rangle_{H_1\otimes H_2} := \langle h_1, g_1\rangle_{H_1}\langle h_2, g_2\rangle_{H_2} \tag{83}$$

for $g_i, h_i \in H_i$ and $i = 1, 2$. The closure of this pre-Hilbert space is the tensor product of Hilbert spaces, which will still be denoted by $H_1 \otimes H_2$. $H_1 \tilde{\otimes} H_2$ will denote the symmetrized tensor product.

Then we have the following Wiener chaos isomorphism theorem.

THEOREM 5.3 (see [19]). *$\oplus_{p\geq 0} H^{\tilde{\otimes} p}(X)$ is isomorphic to $L^2(X)$ with the unique isomorphism Φ defined by*

$$\Phi(\xi_1^{\tilde{\otimes}\alpha_1} \tilde{\otimes} \cdots \tilde{\otimes} \xi_k^{\tilde{\otimes}\alpha_k}) = \frac{1}{\sqrt{p!}} \prod_{j=1}^{k} h_{\alpha_j}(\xi_j), \tag{84}$$

where $\xi_i \in H(X)$ for all i are orthonormal; $p = |\alpha| = \alpha_1 + \cdots + \alpha_k$. Here h_n is the Hermite polynomial of degree n (see Appendix C of [14]*).*

Note that for a random variable $\xi \in H(X)$ with unit variance we have

$$\Phi(e^{\tilde{\otimes}\xi}) = \exp\left(\xi - \frac{1}{2}\right), \tag{85}$$

where the exponential is defined by $e^{\tilde{\otimes}\xi} = \sum_{p\geq 0} \frac{\xi^{\tilde{\otimes}p}}{\sqrt{p!}}$.

We proceed as in [18] and in order to define the integral of a stochastic process with respect to X, we first define a tensor product integral, denoted by $\int F_t \otimes dX_t$, and its domain, denoted by $\Lambda(R)_{L^2(X)}$.

Suppose $\mathbb{S}_{L^2(X)}$ is the pre-Hilbert space of the $L^2(X)$-valued step functions F_t,

$$F_t = \sum_{i=1}^{N} F_i 1_{(t_i, t_{i+1}]}, \tag{86}$$

for $(t_i, t_{i+1}] \in [a, b]$, and $F_i \in L^2(X)$, equipped with the inner product

$$\langle F, G\rangle = \int\int \langle F_t, G_s\rangle_{L^2(X)} d^2R(t, s). \tag{87}$$

Let $\Lambda(R)_{L^2(X)}$ denote the completion of $\mathbb{S}_{L^2(X)}$. For the $F \in \mathbb{S}_{L^2(X)}$ given in (86) define the integral $I_\otimes$ as

$$\int F_t \otimes dX_t = \sum_{i=1}^{N} F_{t_i} \otimes (X_{t_{i+1}} - X_{t_i}). \tag{88}$$

Since this integral is a norm-preserving linear map, it has a unique extension to an isomorphism from $\Lambda(R)_{L^2(X)}$ into $L^2(X) \otimes H(X)$. We will construct a map Ψ from $L^2(X) \otimes H(X)$ into $L^2(X)$ and call the composition of the two maps, $\Psi(I_\otimes)$, the stochastic integral. We start by defining the linear map

$$\Psi_p : H^{\tilde{\otimes}p}(X) \otimes H(X) \to H^{\tilde{\otimes}p+1}(X) \tag{89}$$

by

$$\Psi_p\left(\left(\xi_1^{\tilde{\otimes}\alpha_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_k^{\tilde{\otimes}\alpha_k}\right)\otimes\xi_l\right) = (p+1)^{\frac{1}{2}}\xi_1^{\tilde{\otimes}\alpha_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_k^{\tilde{\otimes}\alpha_k}\tilde{\otimes}\xi_l, \tag{90}$$

where $(\xi_i) \in H(X)$ is an orthonormal set of random variables, $\alpha_1 + \cdots + \alpha_k = p$. Ψ_p can be extended uniquely to a bounded linear map with norm $(p+1)^{1/2}$ from $H^{\tilde{\otimes}p}(X) \otimes H(X)$ onto $H^{\tilde{\otimes}p+1}(X)$.

Now define Ψ^* as the map from $\oplus_{p\geq 0} H^{\tilde{\otimes}p}(X) \otimes H(x)$ onto $\oplus_{p\geq 1} H^{\tilde{\otimes}p}(X)$, by $\Psi^* = \oplus_{p\geq 0}\Psi_p$, viz., the restriction of Ψ^* to $H^{\tilde{\otimes}p}(X) \otimes H(X)$ is Ψ_p. The domain of the operator Ψ^* is given by

$$\mathcal{D}^* = \left\{\eta \in \left(H^{\tilde{\otimes}\alpha_1}(X) \oplus \cdots \oplus H^{\tilde{\otimes}\alpha_m}(X)\right) \otimes H(X) : \alpha_1 + \cdots + \alpha_m < \infty\right\}, \tag{91}$$

so that $\sum_{p\geq 0} \|\Psi_p(\eta_p)\|^2 < \infty$, where η_p is the projection of η on $H^{\tilde{\otimes}p}(X) \otimes H(X)$.

By Theorem 5.3, $\oplus_{p\geq 0}H^{\tilde{\otimes}p}(X)$ is isomorphic to $L^2(X)$. Therefore $(\oplus_{p\geq 0}H^{\tilde{\otimes}p}(X))\otimes H(X)$ is isomorphic to $L^2(X)\otimes H(X)$. Denote this isomorphism by Φ_0. Let $\mathcal{D}=\Phi_0(\mathcal{D}^*)$, which is a proper subset of $L^2(X)\otimes H(X)$. Then define Ψ by

$$\Psi=\Phi\circ\Psi^*\circ\Phi_0^{-1}. \tag{92}$$

We define the Wick product of $V\in L^2(X)$ and $W\in H(X)$ as

$$V\diamond W:=\Psi(V\otimes W). \tag{93}$$

Note that $V\diamond W$ is in $L^2(X)$ if and only if $V\otimes W\in\mathcal{D}\otimes H(X)$.

The integral $\int F_t\diamond dX_t$ is then defined by

$$\int_a^b F_t\diamond dX_t=\Psi\circ I_{\otimes}(F) \tag{94}$$

for all F such that $I_{\otimes}(F)=\int F_t\otimes dX_t\in\mathcal{D}$. The set of all F's in the domain of integration is denoted by $\Lambda(R)^*_{L^2(X)}$. Then we have the Itô representation formula as a result of the multiple Wiener integral (MWI) representation of the random variables in $L^2(X)$ [18] and the fact that each MWI can be written as an iterated integral.

THEOREM 5.4 (see [18]). *Every $\theta\in L^2(X)$ has the representation*

$$\theta=E\{\theta\}+\int_a^b F_t\diamond dX_t \tag{95}$$

for an $F\in\Lambda(R)^*_{L^2(X)}$ that is adapted to the filtration generated by X.

Now let us define the Wick product of two elements in $L^2(X)$. As a first step we define $\Upsilon_{p,q}$,

$$\Upsilon_{p,q}:H^{\tilde{\otimes}p}(X)\otimes H^{\tilde{\otimes}q}(X)\to H^{\tilde{\otimes}p+q}(X), \tag{96}$$

as

$$\begin{aligned}&\Upsilon_{p,q}\left(\left(\xi_{\gamma_1}^{\tilde{\otimes}\alpha_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_{\gamma_k}^{\tilde{\otimes}\alpha_k}\right)\otimes\left(\xi_{\lambda_1}^{\tilde{\otimes}\beta_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_{\lambda_l}^{\tilde{\otimes}\beta_l}\right)\right)\\&\quad=\sqrt{\frac{(p+q)!}{p!q!}}\xi_{\gamma_1}^{\tilde{\otimes}\alpha_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_{\gamma_k}^{\tilde{\otimes}\alpha_k}\tilde{\otimes}\xi_{\lambda_1}^{\tilde{\otimes}\beta_1}\tilde{\otimes}\cdots\tilde{\otimes}\xi_{\lambda_l}^{\tilde{\otimes}\beta_l}\end{aligned} \tag{97}$$

for any (ξ_γ) that is an orthonormal set in $H(X)$.

Let $\Upsilon=\oplus_{p\geq 0}\oplus_{q\geq 0}\Upsilon_{p,q}$; then we define the Wick product of the $W,V\in L^2(X)$ as

$$W\diamond V:=\Phi\left(\Upsilon\left(\Phi^{-1}(W)\otimes\Phi^{-1}(V)\right)\right). \tag{98}$$

Note that $L^2(X)$ is not closed under $\diamond$, since the tensor product of the random variables may not be in the domain of Υ. Then one can define the Hida distribution space, use (98) as the definition of the Wick product over this space, and see that the Wick product so defined is closed over these spaces.

The main machinery we use to develop strategies leading to a Nash equilibrium are the Girsanov formula (the absolute continuity of the translated measure w.r.t. the original measure) and the Clark–Ocone formula. These can be extended to a more general Gaussian modulator with regularity. The Girsanov theorem, Theorem 4.1,

can be stated for sufficiently regular Gaussian processes. (The proof of the Girsanov theorem in [16] does not make use of the explicit expression for ϕ.) The derivation of the Clark–Ocone theorem (Theorem 3.10) is done by using only the tensor product structure of the space L^2 (Theorem 5.3) and the spaces of generalized random variables. Defining the Hida derivative and the quasi-conditional expectation operator (w.r.t. which X is a quasi martingale) for the Gaussian process X, we can restate the Clark–Ocone theorem. Now replacing ζ_t in Theorem 2.2 by ϑ_t such that

$$E\left\{\int_0^T K(s)dX_s\Big|\mathcal{F}_t\right\} = \int_0^t \vartheta_t(s)dX_s, \tag{99}$$

we have a Nash equilibrium theorem for a general Gaussian process. Note that unlike the case of fBm, we cannot in general write ϑ explicitly in terms of K.

Hence, we cannot give an explicit solution for the Nash equilibrium. A general multidimensional theorem can also be restated for a multidimensional Gaussian process with independent components (the components do not have to be identical) by making the conceptual modifications as in the one-dimensional case.

6. Conclusion. In this paper we have explicitly found Nash equilibria for a stochastic differential game in a non-Markovian setting. In this game, the agents modify the dynamics of a common observable state by modifying its drift and volatility. The agents are heterogeneous in their controls and utility functions. We have taken the modulating process to be fractional Brownian motion, since fBm is versatile in modeling long-range dependence phenomena in finance and networks.

Since the diffusion is modulated by a non-Markovian process, the usual way of finding Nash equilibria via HJB equations is not available. Therefore we have made use of the fractional noise calculus to calculate the agents' Nash equilibrium strategies. Although we have taken the modulating process of the diffusions to be fBm, our results hold for more general Gaussian modulating processes with only slight modifications to the white noise machinery.

Our results are applicable to financial markets in which stock price dynamics are modulated with fractional Brownian motion. One of the candidate applications is stock price modeling when each agent's activities in the market affect the price flow (institutional investors are such examples) or if there are transaction costs. This work is also applicable to stochastic portfolio games, in which agents compete for a bonus.

7. Appendix.

LEMMA 7.1 (see [20]). *Let $f : [0,T] \to \mathbb{R}$ be a continuous function and introduce the following integral equation:*

$$\int_0^T \hat{f}(s)\phi(s,t)ds = f(t) \quad \textit{for } t \in [0,T], \tag{100}$$

where ϕ is given by (13)*. The solution to this equation is given by*

(101)
$$\hat{f}(t) = -\frac{1}{d_H} t^{\frac{1}{2}-H} \frac{d}{ds} \int_t^T dw w^{2H-1}(w-t)^{\frac{1}{2}-H} \frac{d}{dw} \int_0^w dz z^{\frac{1}{2}-H}(w-z)^{\frac{1}{2}-H} f(z),$$

where

$$d_H = 2H(2H-1)\left(\Gamma\left(\frac{3}{2}-H\right)\right)^2 \Gamma(2H-1)\cos\left(\pi\left(H-\frac{1}{2}\right)\right). \tag{102}$$

COROLLARY 7.2. *If we take* $f(t) = C$ *on* $[0, T]$ *in the integral equation given by* (100)*, then the solution* $\hat{f}(t)$ *is given by*

$$\hat{f}(t) = \frac{C}{k_H} t^{\frac{1}{2}-H} (T-t)^{\frac{1}{2}-H}, \tag{103}$$

where

$$k_H = 2H(2H-1)\Gamma(2-2H)\Gamma(2H-1)\cos\left(\pi\left(H-\frac{1}{2}\right)\right). \tag{104}$$

Proof. The proof can be found in [16], but we present it here for the sake of completeness:

$$\hat{f}(t) = -\frac{1}{d_H} C t^{\frac{1}{2}-H} \frac{d}{ds} \int_t^T dw w^{2H-1} (w-t)^{\frac{1}{2}-H} \frac{d}{dw} \int_0^w dz z^{\frac{1}{2}-H} (w-z)^{\frac{1}{2}-H}. \tag{105}$$

Note that

$$\frac{\int_0^w z^{\frac{1}{2}-H}(w-z)^{\frac{1}{2}-H} dz}{w^{2-2H}} = B\left(\frac{3}{2}, \frac{3}{2}\right) = \frac{\Gamma\left(\frac{3}{2}-H\right)^2}{\Gamma(3-H)}, \tag{106}$$

where $B(\cdot,\cdot)$ is the beta function given by

$$B(x,y) = \int_0^1 t^{x-1}(1-t)^{y-1} dt. \tag{107}$$

Hence

$$\frac{d}{dw} \int_0^w z^{\frac{1}{2}-H}(w-z)^{\frac{1}{2}-H} dz = \frac{\Gamma\left(\frac{3}{2}-H\right)^2}{\Gamma(2-H)} w^{1-2H}. \tag{108}$$

Using (108) it is not hard to evaluate (105) to get (103). □

THE INSTABILITY OF OPTIMAL CONTROL PROBLEMS TO TIME DELAY*

ALEXEY S. MATVEEV†

Abstract. This paper considers a general optimal control problem with a small time delay Δ in both the state and control. The objective is to find a correct way to neglect the delay or, in other words, to construct a well-posed instantaneous approximation of the delayed problem. The natural way to do so is by merely ignoring the delay in the model. It is shown that this way is almost always incorrect: it gives rise to an error that does not vanish as $\Delta \to +0$, and so results in an ill-posed model. A proper approximation of the delayed problem is offered.

Key words. optimal control, time delay, stability, well-posedness

1. Introduction.

The time delay optimal control problem is a good model of a wide range of real-life phenomena. Unfortunately, the solution of such problems encounters considerable troubles in even the simplest cases. This impels one to employ instantaneous models whenever the delay is small. The conventional way to construct such a model is via merely ignoring the delay. Is this correct? To get an answer, we consider infinitely small delays and analyze the error that accrues from neglecting them. At first sight, the outcome of such an analysis can be easily foreseen and comes to the platitude: the error must be infinitely small as well. This is true indeed if the delay occurs only in the state. However, in the case of the delayed control, this platitudinous property fails to be true not only in general but also "almost always." Therefore the natural way to ignore the delay results in an ill-posed model and so is not acceptable. The objective of this research is to justify these claims and offer well-posed instantaneous approximations of optimization problems with small delays.

The motivation of the issues addressed in this paper comes from many sources. For example, due to the recent growth in communication technology, it is becoming more common to employ digital finite capacity channels for communicating information from controllers to actuators. Not only quantization but also time delay is inherent in transmission via such channels. Moreover, serial digital networks have become popular to serve complex systems with spatially distributed components like advanced aircraft, spacecraft, automotive, industrial and defense systems, arrays of microactuators, power control in mobile communication, multiagent mobile robots, etc. The delay effects are typically enhanced in networks. Indeed, then transmission delays are combined with those induced by the protocol to resolve conflicts between several data sources sharing a common channel [11]. These communication delays are usually small. So as a rule, they are ignored at the theoretical stage of controller design. There are two more reasons to do so. First, in many cases the communication delays are irregular and a priori unknown [11]. Second, ironically, the smaller the delay the harder the delayed optimization from the computational point of view.

*Received by the editors February 15, 2003; accepted for publication (in revised form) May 3, 2004; published electronically March 22, 2005.

In this paper, we consider an optimal control problem in the situation where controls are transmitted to the actuators over two channels. One of them is instantaneous whereas the other provides a constant delay $\Delta \approx 0$. Modulo a shift of the time, this also includes the case where the delays in both channels are nonzero and close to each other. All measurable controls are admissible. This situation is the simplest among those worth studying. However, it is enough to reveal all major points and so is a good option to start with.

We compare the delayed problem with its *natural limit model* (*problem*) that results from putting $\Delta := 0$. We show that in general this problem is not a proper (well-posed) approximation of the delayed one: the optimal value of the cost functional in the latter does not converge to that in the former as $\Delta \to +0$. Moreover, this phenomenon is robust and occurs for almost all delayed problems; the corresponding problems constitute an open and dense subset in the space of all problems. (Any problem is identified with its data.)

Thus the natural way to neglect the delay is almost always incorrect. What is the correct one? As an answer to this question, a proper "limit" (as $\Delta \to 0$) of the delayed problem is found. In brief, this is an instantaneous ($\Delta = 0$) optimal control problem well posed by perturbation [4, 24] of the delay. Here the perturbed problem is the original Δ-delayed one. More specifically, the minimum values of the cost functionals in the limit and Δ-delayed problems, respectively, are close: the latter converges to the former as $\Delta \to 0$. Moreover, solution of the limit problem gives an exhaustive description of the asymptotically optimal Δ-parametric control sequences. For the Δ-delayed problem, the control from such a sequence provides the level of performance, which differs from the optimal one by a vanishing (as $\Delta \to 0$) quantity. The above description is given by the fact that a sequence is asymptotically optimal if and only if it converges to the set of all optimal controls in the limit problem.

The proper limit problem is not standard, in contrast with the natural limit model. This promotes the interest to the cases where the natural model is yet well-posed. Such a case occurs if and only if the optimal values of the cost functionals in the two concerned problems coincide. This criterion is exhaustive but not relevant in the current context since it employs the proper limit problem. We show that the wellposedness of the natural model is not recognizable if the knowledge about the system is confined to only this model. Moreover, then it is impossible to estimate to which extent this model may be ill-posed. Thus information is required about the delayed model, though not the values of the delays. We also offer a simple sufficient criterion. It is far from being exhaustive but deals with a popular situation where the system's equations and the cost functional are linear and convex, respectively, in controls, and the domain of admissible controls is also convex.

As will be shown, the defect of the natural limit model is that it conceals certain possibilities to improve the performance. What is their source? We show that they are due to chattering controls. To this end, we examine the level of performance attainable under constraints on the rate of chattering. More precisely, we consider optimization in a class of sampled controls. The above constraints are given by the lower bound q of the sample period, which is commensurable with the delay: $q/\Delta \to N \in [0, \infty]$ as $\Delta \to +0$.

Optimization over sampled controls is of interest in its own right. For example, sampling of controls is typical for computer controlled systems. The sample period is usually commensurable with transmission delays in digital channels communicating information from controllers to actuators. Then the class of all measurable controls is

not relevant; it can be accepted only if the delays are much greater than the sample period.

We show that the harder the constraint on the rate of chattering (i.e., the larger the N), the worse the limit (as $\Delta \to 0$) optimal performance, and so the smaller the "gap" between the delayed problem and its natural limit model. For $N = \infty$ (the sample period is much greater than the delay), the gap disappears; i.e., the natural limit model becomes proper in the class of sampled controls. Typically, this is the only case where this model is proper. The limit problem that is proper in the class of all measurable controls remains proper for sampled ones if and only if the lower bound of the sample period does not exceed the delay $N \leq 1$. At the same time, neither of these two problems is proper if $1 < N < \infty$. Moreover, no pair $N_1 \neq N_2$ can be served by a common proper limit problem. So the parameter N is essential for construction of a well-posed limit problem. This problem is also explicitly described.

Up to now, not much attention was given to stability (wellposedness) of optimal control problems with respect to perturbation of the delay. The research activity was focused on the case where the delay occurs in the state alone. It was shown in [3, 20] that the trajectory of an uncontrolled delayed equation depends on the delay continuously. Conditions under which such an equation exhibits the same asymptotic behavior as that without delay were offered in [8]. An optimal control problem with time delay in the state was studied in [7]. It was shown that a small perturbation of the delay causes a small disturbance of the optimum. The bounds for certain Dini derivatives of the cost functional optimal value with respect to the delay were also established. By the author's knowledge, the current paper pioneers an analysis of stability with respect to the delay in control.

An introduction to delayed optimal control problems can be found in [16, 17, 22]. The study of the maximum principle for such problems was initiated in [12] and continued in [1, 2, 5, 6, 13, 14, 15, 22]. Relaxation issues were addressed in [18, 19, 22, 23].

The paper is organized as follows. Sections 2 and 3 offer the statement of the optimization problem and a simple example illustrating illposedness of the natural limit problem, respectively. Section 4 shows that this problem is almost always ill-posed. In section 6, we discuss when this problem is yet proper. The well-posed limit problem is presented in section 5. Section 7 discusses optimization in the class of sampled controls. The remainder of the paper is devoted to proofs. They employ certain limits of the set of admissible controls, which are introduced in section 8. Section 9 reveals their general properties. Computation of these limits in section 11 is based upon calculation of extremal points of a polygon in the space of matrices, which is done in section 10. Finally, sections 12, 13, and 14 contain the proofs of the results stated in sections 5, 4, and 6, respectively.

2. The problem statement and assumptions. We consider time delay optimal control problems of the form

$$\text{minimize} \quad \int_T \varphi\left[t, x(t), x(t-\Delta), u(t), u(t-\Delta)\right] \, dt \qquad \text{subject to} \tag{2.1}$$

$$\dot{x}(t) = f\left[t, x(t), x(t-\Delta), u(t), u(t-\Delta)\right] \quad \text{a.a.} \quad t \in T := [t_0, t_1]\,, \tag{2.2}$$

$$x(t) = a(t) \quad \text{for} \quad t \in [t_0 - \Delta, t_0]\,, \tag{2.3}$$

$$u(t) \in \Omega \quad \text{a.a.} \quad t \in [t_0 - \Delta, t_1]\,. \tag{2.4}$$

Here "a.a." means "for almost all." The state $x = x(t) \in \mathbb{R}^n$ and the control $u = u(t) \in \mathbb{R}^m$ are absolutely continuous and measurable functions of time $t \in [t_0 - \Delta, t_1]$, respectively. We interpret the delay $\Delta > 0$ as the parameter of the problem, which is denoted by $\mathfrak{P}(\Delta)$.

DEFINITION 2.1. *The* natural limit problem *is the problem* $\mathfrak{P}(0)$ *obtained by ignoring the delay in* (2.1)–(2.4)

$$\text{minimize} \quad \int_{t_0}^{t_1} \overline{\varphi}\,[t, x(t), u(t)]\,dt \quad \text{subject to} \tag{2.5}$$

$$\dot{x}(t) = \overline{f}\,[t, x(t), u(t)]\,, \quad u(t) \in \Omega \quad \text{a.a.} \quad t \in T, \quad x(t_0) = a_0, \quad \text{where} \tag{2.6}$$

$$\overline{\varphi}(t, x, u) := \varphi(t, x, x, u, u), \quad \overline{f}(t, x, u) := f(t, x, x, u, u), \quad a_0 := a(t_0). \tag{2.7}$$

Can this problem be considered as a proper (well-posed) instantaneous approximation of the delayed one $\mathfrak{P}(\Delta)$ with $\Delta \approx 0$? The answer is in the affirmative only if

$$\lim_{\Delta \to +0} \mathfrak{I}_{opt}(\Delta) = \mathfrak{I}_{opt}(0), \tag{2.8}$$

where $\mathfrak{I}_{opt}(\Delta)$ is the infimum of the cost functional in the problem $\mathfrak{P}(\Delta)$. Our first objective is to check whether relation (2.8) is true or not.

For definiteness, we consider delays $\Delta \in (0, 1)$. Suppose that in (2.1)–(2.4),

(i) the set $\Omega \subset \mathbb{R}^m$ is compact and contains at least two points;

(ii) the functions $f(t, x_1, x_2, u_1, u_2) \in \mathbb{R}^n$ and $\varphi(t, x_1, x_2, u_1, u_2) \in \mathbb{R}$ of the variables $t \in T = [t_0, t_1]$, $x_1, x_2 \in \mathbb{R}^n$, and $u_1, u_2 \in \Omega$ are continuous and continuously differentiable with respect to x_1 and x_2;

(iii) the function $a(\cdot) : [t_0 - 1, t_0] \to \mathbb{R}^n$ is absolutely continuous;

(iv) for any $\Delta \in [0, 1)$ and any measurable control $u(\cdot) : [t_0 - \Delta, t_1] \to \Omega$, the Cauchy problem (2.2), (2.3) has a solution $x(\cdot) : [t_0 - \Delta, t_1] \to \mathbb{R}^n$ such that $|x(t)| \le k < \infty$, where the constant k does not depend on $t \in [t_0 - \Delta, t_1]$, $u(\cdot)$, or $\Delta \in [0, 1)$.

It follows from (i)–(iv) that $\mathfrak{I}_{opt}(\Delta) > -\infty$.

3. Example. We start with a simple example of the situation where the natural limit model is not a proper approximation of the delayed problem. This example is as follows:

$$\text{minimize} \quad I := x_1(1)^2 + x_2(1)^2 \quad \text{subject to} \quad x_1(0) = x_2(0) = 0, \tag{3.1}$$
$$\begin{matrix} \dot{x}_1(t) = \min\{u(t), u(t-\Delta)\} \\ \dot{x}_2(t) = 1 - \max\{u(t), u(t-\Delta)\} \end{matrix}, \ 0 \le t \le 1, \quad 0 \le u(t) \le 1, \ -\Delta \le t \le 1.$$

The natural limit problem results from putting $\Delta := 0$ here is

$$\text{minimize} \quad x_1(1)^2 + x_2(1)^2 \quad \text{subject to} \tag{3.2}$$
$$\dot{x}_1 = u, \dot{x}_2 = 1 - u, \quad 0 \le u = u(t) \le 1, \quad t \in [0, 1], \quad x_1(0) = x_2(0) = 0.$$

In this problem, the trajectories obey the relation $x_1(t) + x_2(t) = t$. So it is easy to see that the states attainable at time $t = 1$ constitute the segment $S = \{(x_1, x_2) = (\theta, 1 - \theta) : 0 \le \theta \le 1\}$. Hence *the minimum of the cost functional in the natural limit problem equals* $1/2$.

At the same time, *the minimum of the cost functional in the original* Δ*-delayed problem is* 0 *irrespective of the delay value* $\Delta > 0$. This minimum is attained at the control

$$u(t) = \begin{cases} 0 & \text{for } t \in [(i-1)\Delta, i\Delta) \cap [0,1], \quad i = 0,2,4,\dots, \\ 1 & \text{for } t \in [i\Delta, (i+1)\Delta) \cap [0,1], \quad i = 0,2,4,\dots. \end{cases} \tag{3.3}$$

Indeed this control is such that for almost all t, one of the numbers $u(t)$, $u(t-\Delta)$ equals 0 whereas the other is 1. Hence $\dot{x}_1(t) = \dot{x}_2(t) = 0 \Rightarrow x_1(\cdot) \equiv x_2(\cdot) \equiv 0$ and so $I = 0$.

Thus in this example, *the natural limit problem is not a proper approximation of the delayed problem with* $\Delta \approx 0$. The "gap" (i.e., the discrepancy between the optimal values of the cost functionals) between these problems amounts to 1/2 and does not depend on Δ.

Formula (3.3) resembles that giving the standard chattering control sequence [18, 19, 22], i.e., a sequence of ordinary controls approximating a randomized one. Such sequences are used in studies of optimal control existence. As is known, there may be no ordinary optimal control. However, for a wide class of problems, the optimum is necessarily attained at some randomized control. Approximation of this control by the above sequence yields a minimizing sequence of ordinary controls, i.e., an asymptotic solution of the original problem.

It should be stressed that in the current context, the situation is different. Formula (3.3) associates not a sequence but a single control with a given Δ-delayed problem. There is no problem with existence of optimal controls; they exist in problems (3.1) and (3.2).

Illposedness of the problem (3.2) is due to the fact that even if $\Delta \approx 0$, the set $\mathcal{X}(\Delta)$ of trajectories $\mathfrak{x} = [x_1(\cdot), x_2(\cdot)]$ generated in the delayed model (3.1) sufficiently differs from that $\mathcal{X}(0)$ related to the natural limit problem (3.2). Indeed, it is easy to see that

$$\mathcal{X}(0) = \Big\{\mathfrak{x} : \dot{x}_1(t) + \dot{x}_2(t) = 1 \quad 0 \le \dot{x}_i(t) \le 1 \quad \text{a.a. } t, \quad x_i(0) = 0,\ i = 1,2\Big\}.$$

At the same time, $\mathcal{X}(\Delta)$ contains the zero trajectory $x_1(\cdot) \equiv x_2(\cdot) \equiv 0$, which does not belong to the closed convex set $\mathcal{X}(0)$. Thus $\mathcal{X}(\Delta) \not\to \mathcal{X}(0)$ (in any reasonable sense) as $\Delta \to 0$. It can be shown that in fact $\mathcal{X}(\Delta) \approx \mathcal{X}_{\lim}$ for $\Delta \approx 0$, where $\mathcal{X}_{\lim}$ results from putting $\dot{x}_1(t) + \dot{x}_2(t) \le 1$ in place of $\dot{x}_1(t) + \dot{x}_2(t) = 1$ in the formulas for $\mathcal{X}(0)$. (We do not prove this fact since it is not used further. It easily follows from the results of sections 8–11.) Thus $\mathcal{X}(\Delta)$ with $\Delta \approx 0$ is sufficiently larger than $\mathcal{X}(0)$.

Unlike (2.1), we considered a terminal cost functional in this section to underscore that the phenomenon of illposedness is not caused by the form of this functional.

4. Illposedness of the natural limit model. Now we revert to the problem (2.1)–(2.4).

LEMMA 4.1. *The limit* $\lim_{\Delta\to+0} \mathfrak{I}_{opt}(\Delta)$ *in* (2.8) *exists and is finite.*

The proofs of the results presented in this section will be given in section 13.

Our first theorem shows that in general the natural limit problem is ill-posed.

THEOREM 4.2. *Given an interval* $T = [t_0, t_1]$ *and a set* Ω *satisfying* (i), *there exists problem* (2.1)–(2.4) *for which the properties* (ii)–(iv) *hold and relation* (2.8) *violates*

$$\lim_{\Delta\to+0} \mathfrak{I}_{opt}(\Delta) < \mathfrak{I}_{opt}(0). \tag{4.1}$$

This inequality means that the natural limit problem conceals certain possibilities of improving the performance.

Now we are going to analyze whether the property (4.1) is typical or not. In doing so, it is natural to compare the variety of all of problem (2.1)–(2.4) with the set of those for which (4.1) holds. To this end, we fix the interval T and the set Ω. We also identify the problem (2.1)–(2.4) with the triplet of functions $\xi := [f(\cdot), \varphi(\cdot), a(\cdot)]$. The linear space Ξ of all such triplets ξ satisfying (ii) and (iii) is equipped with the locally convex topology generated by the following c-parametric ($c > 0$) family of hemi-norms:

(4.2)
$$\mathfrak{H}_c(\xi) := \sum_{r=f,\varphi,\partial f/\partial x_i,\partial\varphi/\partial x_i,i=1,2} \max |r(t,x_1,x_2,u_1,u_2)| + \max_{t\in T^0} |a(t)| + |\dot a(\cdot)|_1,$$

where the first maximum is over $t \in T, |x_i| \le c, u_i \in \Omega$, and $T^0 := [t_0 - 1, t_0], |\dot a(\cdot)|_1 := \int_{T^0} |\dot a(t)|\, dt$. As can be shown, the set $\Xi_{(iv)} \subset \Xi$ of all triplets $\xi \in \Xi$ satisfying (iv) is open.

THEOREM 4.3. *Given an interval $T = [t_0, t_1]$ and a set Ω satisfying* (i)*, consider the set $\Xi_{(4.1)}$ of all triplets $\xi \in \Xi_{(iv)}$ for which* (4.1) *is valid. The set $\Xi_{(4.1)}$ is nonempty and open. If the domain Ω is connected, then the set $\Xi_{(4.1)}$ is dense in $\Xi_{(iv)}$.*

The second claim means that the phenomenon (4.1) is typical.

5. The proper instantaneous (limit) model of the delayed optimal control problem. We recall that this is an instantaneous (undelayed) optimal control problem $\mathcal{P}$ such that first, the minimum of the cost functional in $\mathcal{P}$ equals the limit from (4.1) and second, the solution of this problem provides a complete characterization of *asymptotically optimal sequences* of controls in the original Δ-parametric family of problem (2.1)–(2.4). These sequences $\{u_\Delta(\cdot)\}$ are those for which $u_\Delta(\cdot)$ is "almost optimal" in $\mathfrak{P}(\Delta)$ for $\Delta \approx 0$,

$$I_\Delta\,[u_\Delta(\cdot)] - \mathfrak{I}_{opt}(\Delta) \to 0 \quad \text{as} \quad \Delta \to +0. \tag{5.1}$$

Here $I_\Delta\,[u_\Delta(\cdot)]$ is the value of the cost functional from (2.1). More specifically, the sequence is asymptotically optimal if and only if it converges to the optimal control in the proper limit problem $\mathcal{P}$ if this control is unique, and to the set of all such controls otherwise.

To introduce $\mathcal{P}$, we need some notation. Following [22], we denote by $\mathbf{frm}(\Omega^2)$ the collection of all Radon (finite regular Borel) measures in $\Omega^2 := \Omega \times \Omega$ and put

$$\mathbf{srpm}(\Omega^2) := \Big\{\eta \in \mathbf{frm}\,(\Omega^2) : \eta(du_1, du_2) \ge 0, \quad \eta(\Omega^2) = 1, \\ \text{and the measure } \eta \text{ is symmetric:} \quad \eta\,(du, \Omega) = \eta\,(\Omega, du)\Big\}. \tag{5.2}$$

(The last relation means that $\eta(E \times \Omega) = \eta(\Omega \times E)$ for any Borel set $E \subset \Omega$.) By the Riesz theorem, $\mathbf{frm}(\Omega^2)$ is the topological dual to the space $\mathbb{C}(\Omega^2)$ of continuous functions $g : \Omega^2 \to \mathbb{R}$. We endow $\mathbf{frm}(\Omega^2)$ and, thereby, $\mathbf{srpm}(\Omega^2)$ with the corresponding weak star topology. Denote by $\mathfrak{G}^s$ the set of all measurable maps $\nu : T \to \mathbf{srpm}(\Omega^2)$. They are controls in the *proper limit problem*, which is as follows:

$$\text{minimize} \quad \int_T dt \int_{\Omega^2} \varphi\,[t, x(t), x(t), w]\,\nu(t, dw) \quad \text{subject to} \quad \nu \in \mathfrak{G}^s, \tag{5.3}$$

$$\dot x(t) = \int_{\Omega^2} f\,[t, x(t), x(t), w]\,\nu(t, dw), \qquad x(t_0) = a_0 := a(t_0). \tag{5.4}$$

THEOREM 5.1. *Let the hypotheses* (i)–(iv) *be fulfilled. In the problem* (5.3), (5.4), *the minimum of the cost functional is archived and equals* $\lim_{\Delta\to+0}\mathfrak{I}_{opt}(\Delta)$.

The proofs of the results presented in this section will be given in section 12.

The problem (5.3), (5.4) has several advantages over (2.1)–(2.4). For example, along the lines of the theory of functional differential equations [10], the state space in the latter should be viewed as infinite dimensional in contrast with the former. Though another approach [21] reduces the problem (2.1)–(2.4) to one without delay and with the state space of finite dimension k, this dimension is much greater $k \geq n(t_1-t_0)/\Delta \ggg n$ than that in (5.3), (5.4) if $\Delta \approx 0$. Both interpretations reflect the point of the matter and affect the formulations of basic optimization results such as the maximum or dynamic programming principles [22].

The problem (5.3), (5.4) has deeper relations to the primal one, (2.1)–(2.4), as compared with those indicated in Theorem 5.1. For example, the set $\mathfrak{R}_\Delta$ of admissible controls $u:[t_0-\Delta,t_1]\to\Omega$ in the problem (2.1)–(2.4) converges to the set $\mathfrak{G}^s$ from (5.3) as $\Delta\to 0$. To elucidate this claim, we need to embed both $\mathfrak{G}^s$ and $\mathfrak{R}_\Delta$ into a common enveloping space. To this end, we denote by $\mathbb{L}_1\big[T,\mathbb{C}(K)\big]$ (where K is a compact topological space) the Banach space of the equivalence classes of maps $g:T\times K\to\mathbb{R}$ such that the function $g(\cdot,\varkappa)$ is measurable for all $\varkappa\in K$, the function $g(t,\cdot)$ is continuous for almost all $t\in T$, and

$$\|g\| := \int_T \max_{\varkappa\in K}|g(t,\varkappa)|\,dt < \infty. \tag{5.5}$$

The above equivalence $g_1 \backsim g_2$ holds if and only if $g_1(t,\cdot)\equiv g_2(t,\cdot)$ for almost all $t\in T$. The norm in $\mathbb{L}_1\big[T,\mathbb{C}(K)\big]$ is given by (5.5). We also denote by $\mathbf{frm}(K)$ and $\mathbf{rpm}(K)$ the collections of all the Radon and Radon probability measures in K, respectively, and put

$$\|\nu\| := \sup\int g(\varkappa)\nu(d\varkappa) \qquad \forall\,\nu\in\mathbf{frm}(K),$$

where sup is over $g(\cdot)\in\mathbb{C}(K)$ with $\max_\varkappa|g(\varkappa)|\leq 1$. Denote by $\boldsymbol{\mathcal{N}}(T,K)$ the space of equivalence classes of measurable functions $\nu:T\to\mathbf{frm}(K)$ such that $\operatorname{ess\,sup}_t\|\nu(t)\|<\infty$. This space can be put in duality to $\mathbb{L}_1\big[T,\mathbb{C}(K)\big]=\{g(\cdot)\}$ by setting

$$\langle\nu,g\rangle := \int_T dt\int_K g(t,\varkappa)\nu(t,d\varkappa) \tag{5.6}$$

(see [22]). By the Bishop and Dunford–Pettis theorems, the relativization to $\mathfrak{G}(T,K) := \{\nu(\cdot)\in\boldsymbol{\mathcal{N}}(T,K):\nu(t)\in\mathbf{rpm}(K)\ \text{a.a.}\ t\in T\}$ of the weak topology generated on $\boldsymbol{\mathcal{N}}(T,K)$ by the above duality is induced on $\mathfrak{G}(T,K)$ by a certain norm $\|\cdot\|_w$ in $\boldsymbol{\mathcal{N}}(T,K)$ (weak norm). The space $\mathfrak{G}:=\mathfrak{G}(T,\Omega^2)$ will be of further special interest. We denote by $\operatorname{dist}(A,B)$ the Hausdorff distance between the sets $A,B\subset\mathfrak{G}$, i.e.,

$$\operatorname{dist}(A,B) := \max\left\{\sup_{\nu\in A}\inf_{\mu\in B}\|\nu-\mu\|_w;\sup_{\mu\in B}\inf_{\nu\in A}\|\nu-\mu\|_w\right\}. \tag{5.7}$$

Given $\Delta\in(0,1)$, we embed $\mathfrak{R}_\Delta$ into $\mathfrak{G}$ by identifying $u(\cdot)\in\mathfrak{R}_\Delta$ with the function $\nu:T\to\mathbf{rpm}(\Omega^2)$, where $\nu(t)$ is the Dirac measure at the point $[u(t),u(t-\Delta)]\in\Omega^2$, i.e.,

$$\int r(u',u'')\nu(t,du',du'') := r[u(t),u(t-\Delta)] \tag{5.8}$$

for any $r(\cdot)\in\mathbb{C}(\Omega^2)$. Thus $\mathfrak{R}_\Delta\subset\mathfrak{G}$. The inclusion $\mathfrak{G}^s\subset\mathfrak{G}$ is obvious.

LEMMA 5.2. *The Hausdorff distance between* $\mathcal{G}^s$ *and* $\mathcal{R}_\Delta$ *converges to* 0 *as* $\Delta \to +0$.

It readily follows from this lemma that any $\nu^0(\cdot) \in \mathcal{G}^s$ can be approximated

$$u_\Delta(\cdot) \to \nu^0(\cdot) \quad \text{as} \quad \Delta \to +0 \tag{5.9}$$

by "regular" controls $u_\Delta(\cdot) \in \mathcal{R}_\Delta$. A number of algorithms can be proposed to construct such a sequence $\{u_\Delta(\cdot)\}$ explicitly. Its importance is demonstrated by the following theorem.

THEOREM 5.3. *Let the hypotheses* (i)–(iv) *be fulfilled and* $\nu^0(\cdot)$ *be an optimal control in the problem* (5.3), (5.4). *Consider a sequence* $\{u_\Delta(\cdot)\}_{\Delta\in(0,1)}$ *of "regular" controls* $u_\Delta(\cdot) \in \mathcal{R}_\Delta$, *the solution* $x_\Delta(\cdot)$ *of the Cauchy problem* (2.2), (2.3) *for* $u(\cdot) := u_\Delta(\cdot)$, *and the trajectory* $x^0(\cdot)$ *of the system* (5.4) *related to the control* $\nu^0(\cdot)$.

If (5.9) *is true, the sequence* $\{u_\Delta(\cdot)\}$ *is asymptotically optimal, i.e.,* (5.1) *holds, and*

$$\max_{t\in T} \left|x_\Delta(t) - x^0(t)\right| \to 0 \quad \textit{as} \quad \Delta \to 0.$$

The last theorem shows that a sequence is asymptotically optimal only if (5.9) holds.

THEOREM 5.4. *Let the optimal control* $\nu^0(\cdot)$ *in the problem* (5.3), (5.4) *be unique. A sequence* $\{u_\Delta(\cdot)\}_{\Delta\in(0,1)}$ *of "regular" controls* $u_\Delta(\cdot) \in \mathcal{R}_\Delta$ *is asymptotically optimal if and only if it converges to* $\nu^0(\cdot)$, *i.e.,* (5.9) *holds.*

In general, such a sequence is asymptotically optimal if and only if it converges to the set $\mathfrak{OC}$ *of all optimal controls* $\nu^0(\cdot)$ *in the problem* (5.3), (5.4), *i.e.,*

$$\textit{dist}\,[u_\Delta(\cdot), \mathfrak{OC}] := \inf_{\nu^0(\cdot)\in\mathfrak{OC}} \|u_\Delta(\cdot) - \nu^0(\cdot)\|_w \to 0 \quad \textit{as} \quad \Delta \to +0. \tag{5.10}$$

Theorems 5.1 and 5.4 mean that the problem $\mathcal{P}$ is well posed by perturbation of the delay [4, 24], provided (2.1)–(2.4) is interpreted as the perturbed problem.

6. Problems for which the natural limit model is proper. In this section, we discuss how to recognize problems for which (2.8) is true. This remains of interest despite the fact that by Theorem 4.3, relation (2.8) is likely to be violated because of errors in our knowledge of ξ. However, it can be shown that both quantities in (2.8) depend on ξ continuously. So whenever (2.8) holds for the nominal model, small errors in the knowledge of ξ cannot spoil (2.8) much. Furthermore, the following lemma shows that in the case (2.8), the control optimal for the natural limit problem is suboptimal for the delayed one.

LEMMA 6.1. *Let the hypotheses* (i)–(iv) *be fulfilled and a measurable function* $u(\cdot) : [t_0 - 1, t_1] \to \Omega$ *be given. If the control* $u|_{[t_0,t_1]}$ *is optimal in the natural limit problem* $\mathfrak{P}(0)$, *the control* $u|_{[t_0-\Delta,t_1]}$ *is* $\mu(\Delta)$*-suboptimal in the primal one* (2.1)–(2.4). *More precisely, the corresponding value of the cost functional does not exceed* $\mathfrak{I}_{opt}(\Delta) + \mu(\Delta)$, *where*

$$\mu(\Delta) \le \left|\lim_{\Delta\to+0} \mathfrak{I}_{opt}(\Delta) - \mathfrak{I}_{opt}(0)\right| + \varepsilon(\Delta) \quad \textit{and} \quad \varepsilon(\Delta) \to 0 \qquad \textit{as} \quad \Delta \to +0. \tag{6.1}$$

The proofs of this lemma and Theorem 6.3 (stated below) will be given in section 14.

DEFINITION 6.2. *If* (2.8) *is true, the problem* (2.1)–(2.4) *is said to be* stable to the delay.

Now we show that it is impossible to recognize such a stability and estimate the discrepancy between the left- and right-hand sides of (2.8) if only the natural limit model is known.

THEOREM 6.3. *Consider the problem* (2.5), (2.6)*, where the vector* $a_0 \in \mathbb{R}^n$*, the set* $\Omega \subset \mathbb{R}^m$*, and the functions* $\overline{\varphi}(\cdot), \overline{f}(\cdot)$ *are given and satisfy* (i), (ii), (iv) *(where* $f(t, x_1, x_2, u_1, u_2) := \overline{f}(t, x_1, u_1)$ *and* $\varphi(t, x_1, x_2, u_1, u_2) := \overline{\varphi}(t, x_1, u_1)$*).*

Given $A > 0$*, there exists a problem* (2.1)–(2.4) *satisfying* (i)–(iv) *and such that the original problem* (2.5), (2.6) *is its natural limit case (i.e.,* (2.7) *is true) and*

$$\left| \lim_{\Delta \to +0} \mathfrak{I}_{opt}(\Delta) - \mathfrak{I}_{opt}(0) \right| > A. \tag{6.2}$$

An exhaustive criterion of stability to the delay is immediate from Theorem 5.1.

COROLLARY 6.4. *The problem* (2.1)–(2.4) *is stable to the delay if and only if the infimum value of the cost functional in the problem* (2.5), (2.6) *equals that in* (5.3), (5.4).

This criterion is technical and rather complicated. The next theorem offers particular and simple sufficient conditions for stability to the delay, which readily follow from Corollary 6.4.

THEOREM 6.5. *Let* (i)–(iv) *from section* 2 *be valid. Suppose also that the set* Ω *is convex, the function* $\varphi(t, x_1, x_2, u_1, u_2)$ *is convex in* (u_1, u_2)*, and the function* $f(\cdot)$ *is linear* $f_i(t, x_1, x_2, u_1, u_2) = A_1(t, x_1, x_2)u_1 + A_2(t, x_1, x_2)u_2$ *in controls. Then the problem* (2.1)–(2.4) *is stable to the delay.*

Proof. Let $[x(\cdot), \nu]$ be a process in the problem (5.3), (5.4). Thanks to the symmetry condition from (5.2),

$$u(t) := \int_\Omega u\, \nu(t, du, \Omega) = \int_\Omega u\, \nu(t, \Omega, du).$$

Since the set Ω is convex and compact, $u(t) \in \Omega$. Furthermore, (5.4) implies that

$$\begin{aligned} \dot{x}(t) &= \int_{\Omega^2} \Big\{ A_1[t, x(t), x(t)]u' + A_2[t, x(t), x(t)]u'' \Big\}\, \nu(t, du', du'') \\ &= \sum_{i=1}^{2} A_i[t, x(t), x(t)]u(t) = f[t, x(t), x(t), u(t), u(t)] \overset{(2.7)}{=\!=} \overline{f}[t, x(t), u(t)], \end{aligned}$$

and $x(0) = a(0)$. Thus (2.6) holds, and $[x(\cdot), u(\cdot)]$ is a process in the problem (2.5), (2.6). So far as the function $\varphi(\cdot)$ is convex in controls, the following relations hold (see, e.g., [9, p. 402]):

$$\begin{aligned} \int_T dt \int_{\Omega^2} &\varphi[t, x(t), x(t), u', u'']\, \nu(t, du', du'') \\ &\geq \int_T \varphi \left\{ t, x(t), x(t), \int_{\Omega^2} [u', u'']\ \nu(t, du', du'') \right\} dt \\ &= \int_T \varphi[t, x(t), x(t), u(t), u(t)]\, dt \overset{(2.7)}{=\!=} \int_T \overline{\varphi}[t, x(t), u(t)]\, dt. \end{aligned}$$

Summarizing, we see that the infimum of the cost functional in the problem (5.3), (5.4) is not less than that in the problem (2.5), (2.6). At the same time, putting the elements ν of the form (5.8) with $\Delta := 0$ in (5.3), (5.4) assures that the first infimum does not exceed the second one. Thus these infima coincide. Corollary 6.4 completes the proof. □

7. Optimization in the class of sampled controls. By (4.1), the optimal value of the cost functional in the Δ-delayed problem with $\Delta \approx 0$ is typically less than that in the natural limit problem. In this section, we show that this is due to chattering controls. We also estimate the rate of chattering that is required for the above phenomenon to take place. To this end, we focus attention on sampled controls modelled as piecewise constant functions. Then the available rate of chattering is given by the lower bound on the sample period.

Now we consider the following class of admissible controls:

(7.1)
$$u(\cdot) \in \mathfrak{R}^{\rm sam}_\Delta := \bigcup_{q \geq q(\Delta)} \mathfrak{R}^q_\Delta\,, \text{ where } \mathfrak{R}^q_\Delta := \Big\{u(\cdot) : u(t) \in \Omega \text{ a.a. } t \in T_\Delta := [t_0 - \Delta, t_1]$$
$$\text{and the control } u = u(t) \in \mathbb{R}^m \text{ is constant on any time interval}$$
$$\text{of the form } \big[t_0 - \Delta + iq, t_0 - \Delta + (i+1)q\big) \cap T_\Delta, i = 0, 1, 2, \dots\Big\}.$$

Here the lower bound $q(\Delta) > 0$ on the sample period q is a given function of the delay. In this section, we study the optimization problem $\mathfrak{P}^{\rm sam}(\Delta)$ described by (2.1)–(2.4) and (7.1). Note that in this problem, the sample period is optimized above the bound $q(\Delta)$. Many of the results to follow remain true if this period is given a priori, i.e., $\mathfrak{R}^{\rm sam}_\Delta := \mathfrak{R}^{q(\Delta)}_\Delta$.

The goal is to find a proper limit model $\mathcal{P}^{\rm sam}$ of $\mathfrak{P}^{\rm sam}(\Delta)$ as $\Delta \to 0$. In this model, the set of admissible controls $\mathcal{G}^s_N$ depends on the parameter $N = \lim q/\Delta \in [0, +\infty]$ and is the set of all measurable maps $\nu : T \to \mathbf{srpm}_N(\Omega^2)$. The set $\mathbf{srpm}_N(\Omega^2)$ of controls admissible at a given time is obtained by restricting the similar set (5.2) serving the problem (5.3), (5.4),

$$\mathbf{srpm}_N(\Omega^2) := \Big\{\eta \in \mathbf{srpm}(\Omega^2) : (N-1)\,[\eta(du, \Omega) - \eta_d(du)] \leq \eta_d(du)\Big\}. \tag{7.2}$$

Here $\eta_d(du)$ is the component of η concentrated on the diagonal $D := \{(u, u) : u \in \Omega\}$,

$$\eta_d(E) := \eta(E_d), \quad \text{where} \quad E_d := \{w = (u, u) : u \in E\}. \tag{7.3}$$

Remark 7.1. In (7.2), $\eta_-(du) := \eta(du, \Omega) - \eta_d(du) \geq 0$.

Indeed in (7.3), $E_d \subset E \times \Omega$ and so $\eta_-(E) = \eta(E \times \Omega) - \eta(E_d) \geq 0$ for any Borel set E.

Hence for $N \in [0, 1]$, the inequality from (7.2) is true and $\mathcal{G}^s_N$ equals the set $\mathcal{G}^s$ of controls in the limit problem (5.3), (5.4). For $N \in (1, \infty)$, the inequality means that η is concentrated mainly on the diagonal D. The set $\mathcal{G}^s_\infty$ consists of all probability measures η concentrated on the diagonal since $\infty - 1 := \infty$ and $\infty \cdot b := \infty\ \forall b > 0$. It is clear that

$$\mathcal{G}^s_1 \supset \mathcal{G}^s_{N_1} \supset \mathcal{G}^s_{N_2} \supset \bigcap_{N>1} \mathcal{G}^s_N = \mathcal{G}^s_\infty \quad \text{if} \quad 1 < N_1 < N_2 < \infty. \tag{7.4}$$

Now we are in a position to state the main result of this section.

THEOREM 7.2. *Let the hypotheses* (i)–(iv) *from section* 2 *be fulfilled. Suppose also that*

$$\textit{either} \quad \frac{q(\Delta)}{\Delta} \to N \in [1, \infty] \textit{ as } \Delta \to +0 \qquad \textit{or} \quad \varlimsup_{\Delta \to +0} \frac{q(\Delta)}{\Delta} \leq 1\ (=: N), \tag{7.5}$$

and $q(\Delta) \to 0$ *as* $\Delta \to +0$ *if* $N = \infty$. *Then the problem* $\mathcal{P}^{sam}$ *that results from* (5.3), (5.4) *by putting* $\mathcal{G}^s_N$ *in place of* $\mathcal{G}^s$ *in* (5.3) *is the proper limit model for the* Δ*-delayed problem* $\mathfrak{P}^{sam}(\Delta)$ *given by* (2.1)–(2.4) *and* (7.1). *In other words, the following statements hold:*

(i) *In the problem* $\mathcal{P}^{sam}$, *the minimum value of the cost functional is archived and equals* $\lim_{\Delta\to+0} \mathfrak{I}^{sam}_{opt}(\Delta)$, *where* $\mathfrak{I}^{sam}_{opt}(\Delta)$ *is the infimum of the cost functional in* $\mathfrak{P}^{sam}(\Delta)$.

(ii) *A sequence* $\{u_\Delta(\cdot)\}_{\Delta\in(0,1)}, u_\Delta(\cdot) \in \mathfrak{R}^{sam}_\Delta$ *is asymptotically optimal if and only if it approaches the set* $\mathfrak{OC}$ *of all optimal controls in the problem* $\mathcal{P}^{sam}$, *i.e.,* (5.10) *holds.*

(iii) *The set* $\mathfrak{R}^{sam}_\Delta$ *of "regular" controls defined by* (7.1) *approximates the set of "generalized" ones* $\mathcal{G}^s_N$: *the distance* (5.7) *between them converges to zero as* $\Delta \to +0$.

The proof of this theorem will be given in section 12.

Remark 7.3. The problem (5.3), (5.4) with $\mathcal{G}^s := \mathcal{G}^s_\infty$ is in fact the relaxation [22] of the natural limit problem (2.5), (2.6) that results from merely ignoring the delay in (2.1)–(2.4).

Indeed this relaxation is as follows [22]:

$$\text{(7.6)}\quad \text{minimize} \quad \int_T dt \int_\Omega \overline{\varphi}\,[t, x(t), u]\,\mu(t, du) \quad \text{subject to} \quad \mu \in \mathcal{G}(T, \Omega),$$
$$\dot{x}(t) = \int_\Omega \overline{f}\,[t, x(t), u]\,\mu(t, du), \quad x(t_0) = a_0 := a(0).$$

Here $\overline{\varphi}(\cdot)$ and $\overline{f}(\cdot)$ are given by (2.7), and $\mathcal{G}(T, \Omega)$ is the set of all measurable maps from T to the space $\mathbf{rpm}(\Omega)$ of probability measures in Ω. The isomorphism $u \in \Omega \leftrightarrow (u, u) \in D$ establishes a one-to-one correspondence between $\mu \in \mathbf{rpm}(\Omega)$ and $\zeta \in \mathbf{rpm}(D)$. At the same time, the elements ζ can be identified with probability measures η in Ω^2 concentrated on the diagonal. Thus the elements ζ constitute $\mathbf{srpm}_\infty(\Omega^2)$, and there is a one-to-one correspondence $\mu \in \mathcal{G}(T, \Omega) \leftrightarrow \nu \in \mathcal{G}^s_\infty$. It is straightforward to check that whenever $\mu \leftrightarrow \nu$,

$$\int_\Omega \overline{r}\,[t, x(t), u]\,\mu(t, du) = \int_{\Omega^2} r\,[t, x(t), x(t), u_1, u_2]\,\nu(t, du_1, du_2) \quad \text{for} \quad r := f, \varphi.$$

This implies that the relaxation (7.6) of (2.5), (2.6) does reduce to (5.3), (5.4) with $\mathcal{G}^s := \mathcal{G}^s_\infty$.

Hence relations (7.4) mean that for $1 < N < \infty$, the proper limit problem (5.3), (5.4) (where $\mathcal{G}^s := \mathcal{G}^s_N$) in the class of sampled controls is intermediate between the natural limit one (2.5), (2.6) and the proper limit problem (5.3), (5.4) in the class of all measurable controls.

Now we are going to show that the natural limit problem is typically ill-posed in the class of sampled controls unless the sample period greatly exceeds the delay. We also demonstrate that the parameter $N = \lim q/\Delta$ is essential for construction of a proper limit problem $\mathcal{P}^{\mathrm{sam}}$. Strictly speaking, this does not follow from the fact that $\mathcal{P}^{\mathrm{sam}}$ formally depends on N. This will follow from the fact that the limit optimal cost $\lim_{\Delta\to+0} \mathfrak{I}^{\mathrm{sam}}_{\mathrm{opt}}(\Delta)$ strictly increases as N grows. So different N cannot be served by a common limit problem.

We recall that problem (2.1)–(2.4) is identified with the triplet $\xi := [f(\cdot), \varphi(\cdot), a(\cdot)]$; the space Ξ of all such triplets ξ satisfying (ii) and (iii) from section 2 is equipped with the topology generated by the hemi-norms (4.2), and $\Xi_{(iv)}$ denotes the set of all

$\xi \in \Xi$ satisfying (iv). The space Ξ is complete and metricizible, and the set $\Xi_{(iv)}$ is open. We recall that a subset $\Upsilon \subset \Xi_{(iv)}$ is said to be *residual* if it is representative as the intersection of a countable collection of open dense (in $\Xi_{(iv)}$) sets. For $\xi \in \Xi_{(iv)}$, (i) of Theorem 5.1 ensures that

$$\frac{q(\Delta)}{\Delta} \to N \in [1,+\infty] \text{ as } \Delta \to +0 \Big| \Rightarrow \exists \lim_{\Delta\to+0} \mathfrak{I}^{\rm sam}_{\rm opt}(\Delta) =: \boldsymbol{\mathfrak{J}}^{\rm sam}_{\rm opt}[N,\xi]. \tag{7.7}$$

THEOREM 7.4. *Let* (i) *from section* 2 *be true and the set* Ω *be connected. Then there exists a residual subset* $\Upsilon \subset \Xi_{(iv)}$ *consisting of delayed problem* (2.1)–(2.4) *for which*

(i) *the minimum of the cost functional* $\mathfrak{I}^{sam}_{opt}(\Delta)$ *obeys the bound*

$$\overline{\lim_{\Delta\to+0}}\, \mathfrak{I}^{sam}_{opt}(\Delta) < \mathfrak{I}_{opt}(0) \quad \textit{whenever} \quad \overline{\lim_{\Delta\to+0}}\, q(\Delta)/\Delta < \infty; \tag{7.8}$$

(ii) *the limit optimal cost* $\boldsymbol{\mathfrak{J}}^{sam}_{opt}[N,\xi]$ *defined in* (7.7) *is a strictly increasing function of the parameter* $N = \lim_{\Delta\to+0} q(\Delta)/\Delta \in [1,\infty]$.

Moreover, given $1 < N_- < N_+ < \infty$, *there exists an open and dense subset* $\Xi_-(N_-,N_+) \subset \Xi_{(iv)}$ *such that for* $\xi \in \Xi_-(N_-,N_+)$, *the limit optimal cost* $\boldsymbol{\mathfrak{J}}^{sam}_{opt}[N,\xi]$ *strictly increases on the interval* $[N_-,N_+]$. *If the set* Ω *is not connected, there exists an open, nonempty, but not necessarily dense such a subset* $\Xi_-(N_-,N_+)$.

The proof of this theorem will be given in section 13.

Remark 7.5. In general, the function $\boldsymbol{\mathfrak{J}}^{\rm sam}_{\rm opt}[N,\xi]$ of N does not decrease.

This assertion follows from (7.7), (i) of Theorem 5.1, and (7.4).

By the first claim of the theorem, it is typical that the natural limit problem is ill-posed in the class of sampled controls, provided the set Ω is connected and $N < \infty$.

8. Limits of the set of admissible controls. In the remainder of the paper, we prove the results stated above. The key to the proofs is studying some limits of Δ-parametric sets $\mathfrak{R}_\Delta$ of measurable controls $u(\cdot) : [t_0-\Delta, t_1] \to \Omega$ as $\Delta \to 0$. (Here and throughout, $\Delta \in (0,1)$.)

In this section, we introduce these limits and reveal their role. Furthermore, we employ the notation introduced before Lemma 5.2 and embed $\mathfrak{R}_\Delta$ into $\mathcal{G}$ by identifying $u(\cdot) \in \mathfrak{R}_\Delta$ with the function $\nu : T \to \mathbf{rpm}(\Omega^2)$ given by (5.8). We also introduce the following "limits":

$$\begin{aligned}\mathrm{LIM}_{\Delta\to0}\mathfrak{R}_\Delta := \big\{\nu \in \mathcal{G} :\ &\text{there exists a sequence } \{u_\Delta(\cdot)\} \text{ of "regular" controls}\\ &u_\Delta(\cdot) \in \mathfrak{R}_\Delta\ \forall\Delta \text{ such that } u_\Delta(\cdot) \to \nu \text{ as } \Delta \to 0\big\},\end{aligned} \tag{8.1}$$

$$\begin{aligned}\mathrm{LIM}^{\rm seq}_{\Delta\to0}\mathfrak{R}_\Delta := \big\{\nu \in \mathcal{G} :\ &\text{there exist sequences } \{\Delta_i\}_{i=1}^\infty \subset (0,1) \text{ and } \{u_i(\cdot)\}_{i=1}^\infty\\ &\text{such that}\quad u_i(\cdot) \in \boldsymbol{\mathfrak{R}}_{\Delta_i}\ \forall i \text{ and } \Delta_i \to 0, u_i(\cdot) \to \nu \text{ as } i \to \infty\big\}.\end{aligned} \tag{8.2}$$

(The space $\mathcal{G}$ is endowed with the week topology generated by the duality (5.6).)

DEFINITION 8.1. Modified *problems* (2.1)–(2.4) *and* (5.3), (5.4) *are defined to be those resulting from the original problems* (2.1)–(2.4) *and* (5.3), (5.4) *by substitution of the inclusion* $u(\cdot) \in \mathfrak{R}_\Delta$ *in place of* (2.4) *and the set* $\mathrm{LIM}_{\Delta\to0}\mathfrak{R}_\Delta$ *in place of* $\mathcal{G}^s$ *in* (5.3), *respectively.*

In this section, we show that under natural assumptions, the proper limit (as $\Delta \to 0$) of the first modified problem is the second one. To this end, we start with two technical facts.

LEMMA 8.2. *Both sets* (8.1) *and* (8.2) *are closed in* $\mathfrak{G}$.

Proof. Let $\mathfrak{S}$ denote the set (8.1) and $\nu \in \overline{\mathfrak{S}}$. Then $\|\nu - \nu_j\|_w < j^{-1}$ for some $\nu_j \in \mathfrak{S}$ for $j = 1, 2, \ldots$. By (8.1), there exist sequences $\{u_\Delta^{(j)}\}$ of controls $u_\Delta^{(j)} \in \mathfrak{R}_\Delta$ such that $u_\Delta^{(j)} \to \nu_j$ as $\Delta \to +0$ for $j = 1, 2, \ldots$. Hence $\|\nu_j - u_\Delta^{(j)}\|_w < j^{-1}$ whenever $\Delta < \Delta_j$ and $\Delta_j > 0$ is small enough. Without loss of generality, we can assume that $\Delta_{j+1} < \Delta_j \ \forall j$ and $\Delta_j \to 0$ as $j \to \infty$. Putting $u_\Delta := u_\Delta^{(j)} \in \mathfrak{R}_\Delta$ for $\Delta \in (\Delta_{j+1}, \Delta_j]$, we get

$$\|\nu - u_\Delta\|_w \le \|\nu - \nu_j\|_w + \|\nu_j - u_\Delta\|_w \le 2j^{-1} \to 0 \quad \text{as} \quad \Delta \to +0.$$

Therefore, $\nu \in \mathfrak{S}$ and $\overline{\mathfrak{S}} = \mathfrak{S}$. The closedness of the set (8.2) is established likewise. □

Remark 8.3. Since $\mathfrak{G}$ is compact, so are the sets (8.1) and (8.2) by Lemma 8.2.

LEMMA 8.4. *For any* $\nu \in \mathfrak{S} := \mathrm{LIM}_{\Delta \to 0}^{seq} \mathfrak{R}_\Delta$, *the Cauchy problem* (5.4) *has a unique solution* $x(\cdot|\nu) : T \to \mathbb{R}^n$. *This solution obeys the estimation* $|x(\cdot|\nu)| \le k \ \forall t \in T$, *where* k *is taken from* (iv) *in section* 2. *Let* $\{\Delta_i\}_{i=1}^\infty \subset (0,1)$ *and* $\{u_i\}_{i=1}^\infty$ *be two sequences such that* $u_i \in \mathfrak{R}_{\Delta_i} \ \forall i$ *and* $\Delta_i \to 0, u_i \to \nu$ *as* $i \to \infty$. *Then,*

$$\max_{t \in T} |x_i(t) - x(t|\nu)| \to 0 \quad \textit{and} \quad I_{\Delta_i}(u_i) \to I(\nu) \quad \textit{as} \quad i \to \infty. \tag{8.3}$$

Here $x_i(\cdot)$ *is the solution of the Cauchy problem* (2.2), (2.3) *with* $\Delta := \Delta_i$, $u := u_i$, *whereas* $I_\Delta(u)$ *and* $I(\nu)$ *are the values of the cost functionals generated by* $u \in \mathfrak{R}_\Delta$ *and* $\nu \in \mathfrak{S}$ *in the problems* (2.1)–(2.4) *and* (5.3), (5.4), *respectively. The map* $\nu \in \mathfrak{S} \mapsto I(\nu)$ *is continuous.*

Proof. By (8.2), any $\nu \in \mathfrak{S}$ is related to sequences $\{\Delta_i\}$ and $\{u_i\}$ with the properties given by the third sentence of the lemma. The Arzela theorem and (iv) from section 2 imply that $x_i(\cdot)$ is defined on $[t_0 - \Delta_i, t_1]$ and $|x_i(t)| \le k \ \forall t \in T, i = 1, 2, \ldots$, and also that the sequence $\{x_i|_T\}$ is precompact in $\mathbb{C}(T, \mathbb{R}^n)$. It is easy to check (see, e.g., [22, Theorem VII.1.2]) that each of its limit points satisfies (5.4). Thus relations (5.4) do have a solution such that $|x(t|\nu)| \le k \ \forall t$. Its uniqueness results from (ii) in section 2. In particular, all limit points of the precompact sequence $\{x_i(\cdot)\}$ equal $x(\cdot|\nu)$, which implies the first relation from (8.3). We recall that the control $u_i(\cdot) \in \mathfrak{R}_{\Delta_i} \subset \boldsymbol{\mathfrak{R}}_{\Delta_i}$ is identified with the element $\nu_i(t, du_1, du_2) = \delta_{[u_i(t), u_i(t-\Delta_i)]}(du_1, du_2)$ of $\mathfrak{G}$, where δ_ω is the Dirac measure at the point ω. Denote $\widetilde{\Delta}_i := \Delta_i$. By (2.1) and (5.3), the quantity $I_{\Delta_i}(u_i) - I(\nu)$ amounts to

$$\begin{aligned} \int_T dt \int_{\Omega^2} \Big\{ \varphi \left[t, x_i(t), x_i(t - \widetilde{\Delta}_i), w \right] - \varphi \left[t, x(t|\nu), x(t|\nu), w \right] \Big\} \nu_i(t, dw) \\ + \int_T dt \int_{\Omega^2} \underbrace{\varphi \left[t, x(t|\nu), x(t|\nu), w \right]}_{\eta(t,w)} \Big[\nu_i(t, dw) - \nu(t, d\omega) \Big]. \end{aligned} \tag{8.4}$$

The integrand in the first integral converges to 0 uniformly over $t \in T, w \in \Omega^2$ by the first relation from (8.3). By (5.6), the second summand equals $\langle \nu_i - \nu, \eta \rangle$. Hence (8.3) does hold.

Now let $\{\nu_i\} \subset \mathfrak{S}$ and $\nu_i \to \nu \in \mathfrak{S}$ as $i \to \infty$. Denote $x_i(\cdot) := x(\cdot|\nu_i)$. Retracing the above arguments ensures consecutively that the sequence $\{x_i(\cdot)\}$ is precompact in $\mathbb{C}(T, \mathbb{R}^n)$, each of its limit points satisfies (5.4) and so equals $x(\cdot|\nu)$, and hence $\max_{t \in T} |x_i(t) - x(t|\nu)| \to 0$ as $i \to \infty$. Then the last claim of the lemma is proved like the second relation from (8.3) since the quantity $I(\nu_i) - I(\nu)$ has the form (8.4) with $\widetilde{\Delta}_i := 0$. □

In fact, the following three theorems mean that one of the modified problems introduced by Definition 8.1 is the proper limit as $\Delta \to +0$ of the other.

THEOREM 8.5. *Suppose that* $\mathfrak{S} := \mathrm{LIM}^{seq}_{\Delta\to 0}\mathfrak{R}_\Delta = \mathrm{LIM}_{\Delta\to 0}\mathfrak{R}_\Delta$ *for some* Δ*-parametric set* $\mathfrak{R}_\Delta$ *of controls, where the limits are defined by* (8.1) *and* (8.2). *Denote by* $\mathfrak{I}^m_{opt}(\Delta)$ *the infimum of the cost functional in the modified problem* (2.1)–(2.4). *The minimum of the cost functional in the modified problem* (5.3), (5.4) *is attained and equals* $\lim_{\Delta\to+0}\mathfrak{I}^m_{opt}(\Delta)$.

Proof. By Remark 8.3, the set $\mathfrak{S}$ is compact. So thanks to the last claim from Lemma 8.4, $\inf_{\nu\in\mathfrak{S}} I(\nu)$ is attained at a control $\nu^0 \in \mathfrak{S}$. Due to (8.1), there exists a sequence $\{u_\Delta\}$ such that $u_\Delta \in \mathfrak{R}_\Delta$ and $u_\Delta \to \nu^0$ as $\Delta \to +0$. By (8.3), $\mathfrak{I}^m_{opt}(\Delta) \le I_\Delta(u_\Delta) \to I(\nu^0)$ and so

$$\overline{\lim_{\Delta\to+0}}\,\mathfrak{I}^m_{opt}(\Delta) \le I(\nu^0).$$

On the other hand, there apparently exist sequences $\{\Delta_i\}$ and $\{v_i\}$ such that $v_i \in \mathfrak{R}_{\Delta_i}\ \forall i$ and $\Delta_i \to 0, I_{\Delta_i}(v_i) \to \underline{\lim}_{\Delta\to+0}\mathfrak{I}^m_{opt}(\Delta)$ as $i \to \infty$. So far as the space $\mathfrak{G} \supset \{v_i\}$ is compact, passing to a subsequence ensures that $v_i \to \nu$ as $i \to \infty$, where $\nu \in \mathrm{LIM}^{\mathrm{seq}}_{\Delta\to+0}\mathfrak{R}_\Delta = \mathfrak{S}$ in correspondence with (8.2). By invoking (8.3), we get

$$\overline{\lim_{\Delta\to+0}}\,\mathfrak{I}^m_{opt}(\Delta) = \lim_{i\to\infty} I_{\Delta_i}(v_i) = I(\nu) \ge I(\nu^0).$$

Thus $\mathfrak{I}^m_{opt}(\Delta) \to I(\nu^0)$ as $\Delta \to +0$, which completes the proof. □

THEOREM 8.6. *Suppose that the assumption of Theorem* 8.5 *is fulfilled. The Hausdorff distance* (5.7) *between the sets* $\mathfrak{S} := \mathrm{LIM}_{\Delta\to+0}\mathfrak{R}_\Delta$ *and* $\mathfrak{R}_\Delta$ *vanishes as* $\Delta \to +0$.

Proof. Suppose the contrary. Then due to (5.7), there exist $\delta > 0$ and a sequence $\{\Delta_i\} \subset (0,1)$ such that $\Delta_i \to 0$ as $i \to \infty$ and either

(i) $\inf_{u\in\mathfrak{R}_{\Delta_i}}\|\nu_i - u\|_w \ge \delta\ \forall i$ for some sequence $\{\nu_i\} \subset \mathfrak{S}$ or

(ii) $\inf_{\mu\in\mathfrak{S}}\|\mu - u_i\|_w \ge \delta\ \forall i$ for some sequence $\{u_i\}, u_i \in \mathfrak{R}_{\Delta_i}\ \forall i$.

By Remark 8.3, both sets $\mathfrak{G}$ and $\mathfrak{S}$ are compact. So passing to subsequences ensures that $\nu_i \to \nu \in \mathfrak{S}, u_i \to \xi \in \mathfrak{G}$ as $i \to \infty$. Due to (8.2), $\xi \in \mathfrak{S}$, which implies that (ii) cannot be true and (i) thereby holds. By (8.1), $\nu = \lim_{i\to\infty} w_i$ for some $w_i \in \mathfrak{R}_{\Delta_i}, i = 1, 2, \ldots$. So

$$\inf_{u\in\mathfrak{R}_{\Delta_i}}\|\nu_i - u\|_w \le \|\nu_i - w_i\|_w \le \|\nu_i - \nu\|_w + \|\nu - w_i\|_w \to 0 \quad \text{as} \quad i \to \infty$$

in violation of (i). The contradiction obtained proves the theorem. □

THEOREM 8.7. *Let the assumption of Theorem* 8.5 *be true. Employ the notation* $\mathfrak{I}^m_{opt}(\Delta)$ *from it. A sequence* $\{u_\Delta(\cdot)\}$ *of controls* $u_\Delta(\cdot) \in \mathfrak{R}_\Delta$ *is asymptotically optimal in the modified problem* (2.1)–(2.4), *i.e.,* $I_\Delta[u_\Delta] - \mathfrak{I}^m_{opt}(\Delta) \to 0$ *as* $\Delta \to +0$, *if and only if it converges to the set* $\mathfrak{OC}$ *of all optimal controls in the modified problem* (5.3), (5.4), *i.e.,* (5.10) *holds.*

Proof. Let (5.10) be true. Suppose that the sequence $\{u_\Delta\}$ is not asymptotically optimal. With regard to Theorem 8.5, we see that there exist $\delta > 0$ and a sequence $\{\Delta_i\}$ for which $I_{\Delta_i}(u_{\Delta_i}) \ge \delta + \min_{\mu\in\mathfrak{S}} I(\mu)\ \forall i$ and $\Delta_i \to 0$ as $i \to \infty$. Since the space $\mathfrak{G} \supset \{u_{\Delta_i}\}$ is compact, passing to a subsequence ensures that $u_{\Delta_i} \to \nu$ as $i \to \infty$, where $\nu \in \mathfrak{S}$ by (8.2). In view of (5.10), $\mathrm{dist}[\nu, \mathfrak{OC}] \le \|\nu - u_{\Delta_i}\|_w + \mathrm{dist}[u_{\Delta_i}, \mathfrak{OC}] \to 0$ as $i \to \infty$, where the set $\mathfrak{OC}$ is closed due to the last claim from Lemma 8.4. Hence $\nu \in \mathfrak{OC}$. Due to (8.3), we have

$$\delta + \min_{\mu\in\mathfrak{S}} I(\mu) \le I_{\Delta_i}(u_{\Delta_i}) \to I(\nu) = \min_{\mu\in\mathfrak{S}} I(\mu) \quad \text{as} \quad i \to \infty.$$

The contradiction obtained proves that the sequence $\{u_\Delta\}$ is asymptotically optimal.

Conversely, consider such a sequence $\{u_\Delta\}$. Suppose that (5.10) is violated. Then there exist $\delta > 0$ and a sequence $\{\Delta_i\}$ such that $\operatorname{dist}[u_{\Delta_i}, \mathfrak{OC}] \geq \delta\ \forall i$ and $\Delta_i \to 0$ as $i \to \infty$. As above, it can be assumed that $u_{\Delta_i} \to \nu \in \mathfrak{S}$ as $i \to \infty$. By (8.3), $\lim_{\Delta\to+0} \mathfrak{I}^m_{opt}(\Delta) = \lim_{i\to\infty} I_{\Delta_i}(u_{\Delta_i}) = I(\nu)$. So Theorem 8.5 yields $\nu \in \mathfrak{OC}$ in violation of the above relation $\operatorname{dist}[u_{\Delta_i}, \mathfrak{OC}] \geq \delta\ \forall i$. Thus (5.10) does hold. ∎

9. General properties of the limit (8.1). The previous section shows that proofs of the results from sections 5 and 7 are reduced to calculating the limits (8.1) and (8.2) for $\mathfrak{R}_\Delta := \mathfrak{R}_\Delta, \mathfrak{R}^{\mathrm{sam}}_\Delta$. In doing so, some general properties of the limit (8.1) are helpful. In this section, we reveal them. They follow from the single property introduced by the following definition.

DEFINITION 9.1. *A subset $\mathfrak{S} \subset \mathfrak{G}$ is said to be* permutable *if for any $\nu_1, \nu_2 \in \mathfrak{S}$ and $\tau \in (t_0, t_1)$, it contains the element given by the following formula (where $E := [t_0, \tau)$):*

$$\nu_E(t, du_1, du_2) := \begin{cases} \nu_1(t, du_1, du_2) & \text{whenever } t \in E, \\ \nu_2(t, du_1, du_2) & \text{otherwise.} \end{cases} \tag{9.1}$$

The next lemma shows that this property holds in the cases of our primal interest.

LEMMA 9.2. *If either $\mathfrak{R}_\Delta := \mathfrak{R}_\Delta \forall \Delta$ or $\mathfrak{R}_\Delta := \mathfrak{R}^{sam}_\Delta\ \forall \Delta$, the set* (8.1) *is permutable.*

Proof. Let $\mathfrak{R}_\Delta := \mathfrak{R}^{\mathrm{sam}}_\Delta\ \forall \Delta$, $\nu_1, \nu_2 \in \mathfrak{S} := \mathrm{LIM}_{\Delta\to 0}\mathfrak{R}_\Delta$, and $\tau \in (t_0, t_1)$. For $i = 1, 2$, consider a sequence $\{u^{(i)}_\Delta\}$ associated with ν_i by (8.1). Let $\mathfrak{D}^{(i)}_\Delta$ denote the set of the points where $u^{(i)}_\Delta(\cdot)$ is not continuous, and $D^{(i)}_\Delta := \mathfrak{D}^{(i)}_\Delta \cup \{t_0 - \Delta, t_1\}$. We put $\tau^{(1)}_\Delta := \max\{t = s + jq(\Delta) : t < \tau, s \in D^{(1)}_\Delta, j = 0, 1, \dots\} \geq \tau - q(\Delta), \tau^{(2)}_\Delta := \min\{t = s - jq(\Delta) : t > \tau, s \in D^{(2)}_\Delta, j = 0, 1, \dots\} \leq \tau + q(\Delta)$, and $v_\Delta := u^{(2)}_\Delta(\tau^{(2)}_\Delta + 0)$. Setting $u_\Delta(t) := u^{(1)}_\Delta(t)$ for $t < \tau^{(1)}_\Delta$, $u_\Delta(t) := u^{(2)}_\Delta(t)$ for $t \geq \tau^{(2)}_\Delta$, and $u_\Delta(t) := v_\Delta$ for $t \in [\tau^{(1)}_\Delta, \tau^{(2)}_\Delta)$ gives a control $u_\Delta(\cdot) \in \mathfrak{R}^{\mathrm{sam}}_\Delta$. For $\eta \in \mathbb{L}_1\big[T, \mathbb{C}(\Omega^2)\big]$, we put $\eta_1(t, w) := \eta(t, w), \eta_2(t, w) := 0$ if $t < \tau$ and $\eta_2(t, w) := \eta(t, w), \eta_1(t, w) := 0$ if $t \geq \tau$. Then (5.6) and (5.8) yield

$$\begin{aligned}
\langle \eta; u_\Delta \rangle &= \int_T \eta\left[t, u_\Delta(t), u_\Delta(t-\Delta)\right] dt = \int_{\tau+\Delta+q(\Delta)}^{t_1} \eta\left[t, u^{(2)}_\Delta(t), u^{(2)}_\Delta(t-\Delta)\right] dt \\
&+ \underbrace{\int_{\tau-q(\Delta)}^{\tau+\Delta+q(\Delta)} \eta\left[t, u_\Delta(t), u_\Delta(t-\Delta)\right] dt}_{\alpha^{(1)}(\Delta)} + \int_{t_0}^{\tau-q(\Delta)} \eta\left[t, u^{(1)}_\Delta(t), u^{(1)}_\Delta(t-\Delta)\right] dt \\
&= \int_\tau^{t_1} \eta\left[t, u^{(2)}_\Delta(t), u^{(2)}_\Delta(t-\Delta)\right] dt - \underbrace{\int_\tau^{\tau+\Delta+q(\Delta)} \eta\left[t, u^{(2)}_\Delta(t), u^{(2)}_\Delta(t-\Delta)\right] dt}_{\alpha^{(2)}(\Delta)} + \alpha^{(1)}(\Delta) \\
&+ \int_{t_0}^{\tau} \eta\left[t, u^{(1)}_\Delta(t), u^{(1)}_\Delta(t-\Delta)\right] dt - \underbrace{\int_{\tau-q(\Delta)}^{\tau} \eta\left[t, u^{(1)}_\Delta(t), u^{(1)}_\Delta(t-\Delta)\right] dt}_{\alpha^{(3)}(\Delta)} \\
&= \left\langle \eta_2; u^{(2)}_\Delta \right\rangle + \left\langle \eta_1; u^{(1)}_\Delta \right\rangle + \alpha^{(1)}(\Delta) - \alpha^{(2)}(\Delta) - \alpha^{(3)}(\Delta).
\end{aligned}$$

In view of (5.5),

$$\left|\alpha^{(i)}(\Delta)\right| \le \int_{\tau-q(\Delta)}^{\tau+\Delta+q(\Delta)} \max_{u_1,u_2\in\Omega} \left|\eta\,[t,u_1,u_2]\right|\,dt \to 0 \quad \text{as} \quad \Delta\to 0.$$

So letting $\Delta\to 0$ gives $\langle u_\Delta;\eta\rangle \to \langle\nu_1;\eta_1\rangle + \langle\nu_2;\eta_2\rangle =: \chi$, where

$$\chi = \int_T dt \int_{\Omega^2} \eta_1(t,w)\nu_1(t,dw) + \int_T dt \int_{\Omega^2} \eta_2(t,w)\nu_2(t,dw) = \langle\nu_E;\eta\rangle$$

and $\eta\in\mathbb{L}_1\big[T,\mathbb{C}(\Omega^2)\big]$ is arbitrary. Thus $u_\Delta\to\nu_E$, and so $\nu_E\in\mathfrak{S}$ by (8.1). The case $\mathfrak{R}_\Delta := \boldsymbol{\mathcal{R}}_\Delta\ \forall\Delta$ is considered likewise. □

In the remainder of this section, we reveal consequences of permutability and closedness.

LEMMA 9.3. *Suppose that the set $\mathfrak{S}\subset\mathfrak{G}$ is closed and permutable. Given $\nu_1,\nu_2\in\mathfrak{S}$, the element* (9.1) *belongs to $\mathfrak{S}$ for any Borel set E.*

Proof. The claim is immediate from Definition 9.1 in the case where E is the union of a finite number of intervals. As is well known, any Borel set E can be approximated by such unions $E^{(1)},E^{(2)},\dots$, in the sense that $\mathrm{mes}(E^{(i)}\triangle E)\to 0$ as $i\to\infty$. Here and throughout, the symbol **mes** stands for the Lebesgue measure and $A\triangle B := \big(A\setminus B\big)\cup\big(B\setminus A\big)$. For any function $\eta\in\mathbb{L}_1\big[T,\mathbb{C}(\Omega^2)\big]$, we have due to (9.1),

$$\begin{aligned}\langle\nu_{E^{(i)}};\eta\rangle - \langle\nu_E;\eta\rangle &= \int_T dt\int_{\Omega^2}\eta(t,u_1,u_2)\,[\nu_{E^{(i)}}(t,du_1,du_2)-\nu_E(t,du_1,du_2)]\\ &= \underbrace{\int\limits_{E\setminus E^{(i)}} dt \int\limits_{\Omega^2}\eta(t,u_1,u_2)\nu_{21}(t,du_1,du_2)}_{\beta(1,i)} + \underbrace{\int\limits_{E^{(i)}\setminus E} dt\int\limits_{\Omega^2}\eta(t,u_1,u_2)\nu_{12}(t,du_1,du_2)}_{\beta(2,i)}.\end{aligned}$$

Here $\nu_{sl} := \nu_s-\nu_l$ for $s,l=1,2$ and thanks to (5.5),

$$\begin{aligned}|\beta(j,i)| &\le \int_{E^{(i)}\triangle E} dt\int_{\Omega^2}|\eta(t,u_1,u_2)|\Big[\nu_1(t,du_1,du_2)+\nu_2(t,du_1,du_2)\Big]\\ &\le 2\int_{E^{(i)}\triangle E}\max_{u_1,u_2\in\Omega}|\eta(t,u_1,u_2)|\,dt\to 0 \quad\text{as}\quad i\to\infty.\end{aligned}$$

Hence $\langle\nu_{E^{(i)}};\eta\rangle\to\langle\nu_E;\eta\rangle$ as $i\to\infty\ \forall\eta\in\mathbb{L}_1\big[T,\mathbb{C}(\Omega^2)\big]$ or in other words, $\nu_{E^{(i)}}\to\nu_E$ as $i\to\infty$. Thus, $\nu_E\in\overline{\mathfrak{S}}=\mathfrak{S}$. □

Lemma 9.3 easily implies the following claim.

COROLLARY 9.4. *Suppose that the assumptions of Lemma* 9.3 *are true, $\nu_1,\dots,\nu_s\in\mathfrak{S}$, and $E_1,\dots,E_s$ are Borel sets constituting a partition of T. Put $\nu(t,dw) := \nu_i(t,dw)$ whenever $t\in E_i$ and $i=1,\dots,s$. Then $\nu\in\mathfrak{S}$.*

Though the next fact is well known, we offer its proof for the convenience of the reader.

LEMMA 9.5. *Any closed and permutable set $\mathfrak{S}\subset\mathfrak{G}$ is convex.*

Proof. Let $\nu_1,\nu_2\in\mathfrak{S},\theta_1,\theta_2>0$, and $\theta_1+\theta_2=1$. We put $\nu_{(r)}(t,dw) := \nu_i(t,dw)$ whenever $t\in T_i(j,r)$ for some $i=1,2$ and $j=0,\dots,2^r-1$, where $r=1,2,\dots$,

$$\begin{aligned}T_1(j,r) &:= \big[t_0+j2^{-r}|T|,\,t_0+j2^{-r}|T|+\theta_1 2^{-r}|T|\big),\\ T_2(j,r) &:= \big[t_0+j2^{-r}|T|+\theta_1 2^{-r}|T|,\,t_0+(j+1)2^{-r}|T|\big),\end{aligned}$$

and $|T| := t_1 - t_0$. For any $\eta(\cdot) \in \mathbb{L}_1\big[T, \mathbb{C}(\Omega^2)\big]$, relation (5.6) yields

$$\big\langle \nu_{(r)}; \eta \big\rangle = \int_T dt \int_{\Omega^2} \eta(t,w)\nu_{(r)}(t,dw) = \mathcal{A}_r(\mathfrak{f}_1, \mathfrak{f}_2) := \sum_{j=0}^{2^r-1} \sum_{i=1,2} \int_{T_i(j,r)} \mathfrak{f}_i(t)\, dt,$$

where $\mathfrak{f}_i(t) := \int_{\Omega^2} \eta(t,w)\nu_i(t,dw)$. For any $\chi_1(\cdot), \chi_2(\cdot) \in \mathbb{L}_1(T)$,

$$|\mathcal{A}_r(\chi_1, \chi_2)| \le \sum_{j=0}^{2^r-1} \sum_{i=1,2} \int_{T_i(j,r)} |\chi_i(t)|\ dt \le \sum_{i=1,2} \int_T |\chi_i(t)|\ dt = |(\chi_1, \chi_2)|.$$

Denote by S_r the set of functions $\chi(\cdot) : T \to \mathbb{R}$ that are constant on any interval $T(j,r) := T_1(j,r) \cup T_2(j,r)$. It is easy to see that $\int_{T_i(j,r')} \chi(t)dt = \theta_i \int_{T(j,r')} \chi(t)dt$, $i = 1,2$ for $\chi(\cdot) \in S_r$ and $r' \ge r$. Hence $\mathcal{A}_r(\chi_1, \chi_2) = \mathcal{A}(\chi_1, \chi_2) := \sum_{i=1,2} \theta_i \int_T \chi_i(t)dt$ for large $r \ge \overline{r}(\chi_1, \chi_2)$ whenever $\chi_1(\cdot), \chi_2(\cdot) \in S := \bigcup_{r=1}^{\infty} S_r$. The set S is dense in $\mathbb{L}_1(T)$. So given $\varepsilon > 0$, there exist $\chi_1(\cdot), \chi_2(\cdot) \in S$ such that $|\mathfrak{f}_i - \chi_i| < \varepsilon$ for $i = 1,2$. Whence

$$\begin{aligned}
\overline{\lim_{r\to\infty}} \left|\left(\mathcal{A}_r - \mathcal{A}\right)(\mathfrak{f}_1, \mathfrak{f}_2)\right| &= \overline{\lim_{r\to\infty}} \left|\left(\mathcal{A}_r - \mathcal{A}\right)\left[(\mathfrak{f}_1, \mathfrak{f}_2) - (\chi_1, \chi_2)\right]\right| \\
&\le \overline{\lim_{r\to\infty}} \left|\mathcal{A}_r\left[(\mathfrak{f}_1, \mathfrak{f}_2) - (\chi_1, \chi_2)\right]\right| + \left|\mathcal{A}\left[(\mathfrak{f}_1, \mathfrak{f}_2) - (\chi_1, \chi_2)\right]\right| \\
&\le \left(1 + \|\mathcal{A}\|\right) \left|(\mathfrak{f}_1, \mathfrak{f}_2) - (\chi_1, \chi_2)\right| \le 2\varepsilon\left(1 + \|\mathcal{A}\|\right) \quad \forall \varepsilon > 0.
\end{aligned}$$

Thus we see that $\lim_{r\to\infty} \big\langle \nu_{(r)}; \eta \big\rangle = \mathcal{A}(\mathfrak{f}_1, \mathfrak{f}_2) = \theta_1 \int_T \mathfrak{f}_1(t)dt + \theta_2 \int_T \mathfrak{f}_2(t)dt = \int_T dt \int_{\Omega^2} \eta(t,w)[\theta_1\nu_1(t,dw) + \theta_2\nu_2(t,dw)] = \langle \theta_1\nu_1 + \theta_2\nu_2; \eta \rangle\ \forall \eta$, i.e., $\nu_{(r)} \to \theta_1\nu_1 + \theta_2\nu_2$ as $r \to \infty$. Since $\nu_{(r)} \in \mathfrak{S}\ \forall r$ by Lemma 9.3, we get $\theta_1\nu_1 + \theta_2\nu_2 \in \overline{\mathfrak{S}} = \mathfrak{S}$. □

Now we are in a position to prove the main result of this section.

THEOREM 9.6. *Let a set $\mathfrak{S} \subset \mathfrak{G}$ be closed and permutable. Whenever*

(9.2)

$$\mu_j \in \mathfrak{S}, \alpha_j(\cdot) \in \mathbb{L}_\infty(T)\ j = 1, \dots, l,\ \textit{and}\ \alpha_1(t) \ge 0, \dots, \alpha_l(t) \ge 0,\ \sum_{j=1}^{l} \alpha_j(t) = 1$$

for almost all $t \in T$, the set $\mathfrak{S}$ contains the element $\nu(t,dw) := \sum_{j=1}^{l} \alpha_j(t)\mu_j(t,dw)$.

Proof. The functions $\alpha_j(\cdot)$ can be uniformly approximated by step functions, i.e., measurable functions taking a finite number of values. These step functions can be chosen to satisfy (9.2). Since $\overline{\mathfrak{S}} = \mathfrak{S}$, this implies that it suffices to prove Lemma 9.6 in the case where $\alpha_1(t), \dots, \alpha_l(t)$ are step functions. Then there exists a Borel partition $E_1 \cup \dots \cup E_s = T$ of T such that $\alpha_j(t) = \alpha_j^{(i)}$ a.a. $t \in E_i$ and all j, i. By Lemma 9.5, $\nu_i := \sum_{j=1}^{l} \alpha_j^{(i)}\mu_j \in \mathfrak{S}\ \forall i$. It remains to note that $\nu(t,dw) = \nu_i(t,dw)$ whenever $t \in E_i$, and apply Corollary 9.4. □

Lemmas 8.2 and 9.2 and Theorem 9.6 give rise to the following claim.

COROLLARY 9.7. *The conclusion of Theorem* 9.6 *is true for the limits* (8.1) *of both $\mathfrak{R}_\Delta \equiv \mathcal{R}_\Delta$ and $\mathfrak{R}_\Delta \equiv \mathcal{R}_\Delta^{sam}$.*

10. Extremal points of a polygon in the space of matrices. Now we show that

(10.1)

$$\mathfrak{S} = \mathfrak{S}^{\mathrm{seq}} = \begin{cases} \mathfrak{G}^s & \text{if } \mathfrak{R}_\Delta \equiv \mathcal{R}_\Delta, \\ \mathfrak{G}_N^s & \text{if } \mathfrak{R}_\Delta \equiv \mathcal{R}_\Delta^{\mathrm{sam}}, \end{cases} \quad \text{where } \mathfrak{S} := \operatorname*{LIM}_{\Delta\to 0} \mathfrak{R}_\Delta,\ \mathfrak{S}^{\mathrm{seq}} := \operatorname*{LIM}_{\Delta\to 0}^{\mathrm{seq}} \mathfrak{R}_\Delta,$$

and the limits are defined by (8.1), (8.2). We recall that $\mathfrak{G}^s = \mathfrak{G}^s_1$ and $\mathfrak{G}^s_N$ stands for the set of all measurable maps $\nu : T \to \mathbf{srpm}_N(\Omega^2)$, whereas $\mathbf{srpm}_N(\Omega^2)$ is given by (5.2) and (7.2).

To show that $\nu \in \mathfrak{G}^s_N \Rightarrow \nu \in \mathfrak{S}$, we shall start with the elements ν of the form

$$\nu(t, du', du'') = \sum_{i,j=1}^{l} p_{ij}(t)\delta_{u_i}(du')\delta_{u_j}(du''), \quad \Big(p_{ij}(t)\Big)_{i,j=1}^{l} =: P(t) \in \mathbb{R}^{l\times l}, \tag{10.2}$$

where $u_1, \dots, u_l \in \Omega$, $u_i \neq u_j$ whenever $i \neq j$, and $\delta_v(du)$ is the Dirac measure at the point $v \in \Omega$. It is easy to see that $\nu \in \mathfrak{G}^s_N \Leftrightarrow P(t) \in \mathcal{M}_l(N-1)$ a.a. $t \in T$, where

$$\mathcal{M}_l(\varkappa) := \Bigg\{ P = \Big(p_{ij}\Big)_{i,j=1}^{l} : p_{i,j} \geq 0 \ \forall i,j, \quad \sum_{i,j=1}^{l} p_{i,j} = 1, \\ \sum_{j=1}^{l} p_{i,j} = \sum_{j=1}^{l} p_{j,i}, \quad \varkappa \sum_{j:j\neq i} p_{i,j} \leq p_{i,i} \ \forall i \Bigg\} \qquad (\varkappa \in [0, +\infty]). \tag{10.3}$$

(The sum over the empty set is 0 and $\infty \cdot 0 := 0$.) Since $\mathcal{M}_l(\varkappa)$ is a polygon, it is the convex hull of the set $\mathcal{M}^{\mathrm{ext}}_l(\varkappa)$ of its extremal points. By Corollary 9.7, this means that any element $\nu \in \mathfrak{G}^s_N$ of the form (10.2) belongs to $\mathfrak{S}$ if so do the elements (10.2) with the matrix $P(t)$ constant and from the set $\mathcal{M}^{\mathrm{ext}}_l(N-1)$. In this section, we compute this set.

LEMMA 10.1. *Suppose that* $\widetilde{P} = (\widetilde{p}_{ij}) \in \mathcal{M}^{ext}_l(\varkappa)$, $\varkappa \in [0, \infty]$, $P = (p_{ij}) \in \mathcal{M}_l(\varkappa)$, $\varkappa \sum_{j:j\neq i} p_{i,j} = p_{i,i}$ $\forall i$ *if* $\varkappa < \infty$, *and* $\widetilde{p}_{ij} \geq \theta p_{ij}$ $\forall i,j$, *where* $\theta > 0$. *Then* $\widetilde{P} = P$.

Proof. Reducing $\theta > 0$ yields that $\widetilde{p}_{i'j'} > \theta p_{i'j'}$ for some i', j'. By (10.3), $1 = \sum_{i,j=1}^{l} \widetilde{p}_{ij} > \theta \sum_{i,j=1}^{l} p_{ij} = \theta$, i.e., $0 < \theta < 1$. Put $p'_{ij} := (1-\theta)^{-1}(\widetilde{p}_{ij} - \theta p_{ij})$. It is easy to see that $P' := (p'_{ij})_{i,j=1}^{l} \in \mathcal{M}_l(\varkappa)$ and $\widetilde{P} = \theta P + (1-\theta)P'$. This implies $\widetilde{P} = P$ by the definition of the extremal point. □

DEFINITION 10.2. *An* $l \times l$*-matrix* P *is said to be* cyclic $\varkappa$-subdiagonal *if there exists a sequence of integers* $1 \leq i_1, i_2, \dots, i_s \leq l$ *such that* $i_h \neq i_d$ *for* $h \neq d$ *and* $s = 1$ *if* $\varkappa = \infty$,

$$\begin{array}{c} p_{hd} = 0 \quad \textit{whenever} \quad (h,d) \neq (i_\sigma, i_{\sigma-1}), (i_\sigma, i_\sigma) \quad \forall \sigma = 1, \dots, s \quad (i_0 := i_s), \\ p_{i_\sigma i_{\sigma-1}} = \frac{1}{(\varkappa+1)s},\ p_{i_\sigma i_\sigma} = \frac{\varkappa}{(\varkappa+1)s}\ \forall \sigma \quad \textit{if } s > 1, \quad \textit{otherwise} \quad p_{i_1,i_1} = 1. \end{array} \tag{10.4}$$

Any such matrix clearly belongs to $\mathcal{M}_l(\varkappa)$. Now we state the main result of this section.

LEMMA 10.3. *Any extremal point of* $\mathcal{M}_l(\varkappa)$ *is a cyclic* $\varkappa$*-subdiagonal matrix.*

Proof. Let $\widetilde{P} = (\widetilde{p}_{ij}) \in \mathcal{M}^{\mathrm{ext}}_l(\varkappa)$. Suppose first that $\widetilde{p}_{ij} = 0$ if $i \neq j$. For $d \in \Upsilon := \{d : \widetilde{p}_{dd} > 0\}$, we put $p^{\langle d\rangle}_{ij} := 1$ if $i = j = d$ and $p^{\langle d\rangle}_{ij} := 0$ otherwise. Since $P^{\langle d\rangle} := (p^{\langle d\rangle}_{ij}) \in \mathcal{M}_l(\varkappa)$, $\widetilde{P} = \sum_{d\in\Upsilon} \widetilde{p}_{dd} P^{\langle d\rangle}$, and the point $\widetilde{P}$ is extremal, the set Υ contains only one element d. So $\widetilde{P} = P^{\langle d\rangle}$, where the matrix $P^{\langle d\rangle}$ is cyclic $\varkappa$-subdiagonal.

Now suppose that $\widetilde{p}_{d_1 d_2} > 0$ for some indices $d_1 \neq d_2$. Then $\varkappa < \infty$ and $\sum_{j=1}^{l} \widetilde{p}_{jd_2} > \widetilde{p}_{d_2 d_2}$. By (10.3), $\sum_{j=1}^{l} \widetilde{p}_{d_2 j} = \sum_{j=1}^{l} \widetilde{p}_{jd_2} > \widetilde{p}_{d_2 d_2}$ and so $\widetilde{p}_{d_2 d_3} > 0$ for some $d_3 \neq d_2$. Continuing likewise, we get a sequence $d_1, d_2, d_3, \dots$, such that $d_{j+1} \neq d_j$ and $\widetilde{p}_{d_j d_{j+1}} > 0$ $\forall j$. We terminate it when some index repeats, i.e.,

$d_i \neq d_j$ whenever $i < j \leq q$ and $d_{q+1} = d_r$ for some $r = 1, \ldots, q$. Here $r \leq q-1$ since $d_q \neq d_{q+1}$. Put $s := q-r+1 \geq 2$ and $i_j := d_{s+r-j}$ for $j = 1, \ldots, s$. Then $i_j \neq i_{j'}$ whenever $j < j' \leq s$ and $\widetilde{p}_{i_j i_{j-1}} > 0$ for $j = 1, \ldots, s$, where $i_0 := d_{s+r} = d_{q+1} = d_r = i_s$. Define the cyclic $\varkappa$-subdiagonal matrix $P = (p_{ij})_{i,j=1}^{l}$ in correspondence with (10.4) and denote $\theta := s(\varkappa+1)\min_{j=1,\ldots,s} \widetilde{p}_{i_j i_{j-1}}$. With regard to (10.3), we conclude that $\widetilde{p}_{ij} \geq \theta p_{ij}$ for all i, j. Lemma 10.1 completes the proof. □

In fact, the set $\mathcal{M}_l^{\rm ext}(\varkappa)$ consists of all cyclic $\varkappa$-subdiagonal matrices. However, we do not need this strengthening of Lemma 10.3 to prove the results of this paper.

11. Proof of (10.1).

LEMMA 11.1. *For any Δ-parametric set $\mathfrak{R}_\Delta$, the following inclusions hold $\mathfrak{S} \subset \mathfrak{S}^{seq} \subset \mathfrak{G}^s (= \mathfrak{G}_1^s)$.*

Proof. The first of them is immediate from (8.1) and (8.2). To prove the second one, consider an element $\nu \in \mathfrak{S}^{\rm seq}$ and the corresponding sequences $\{\Delta_i\}$ and $\{u_i\}$ from (8.2). Given two functions $\zeta(\cdot) \in \mathbb{L}_1(T)$ and $\rho(\cdot) \in \mathbb{C}(\Omega)$, we put $\eta_j(t, u_1, u_2) := \zeta(t)\rho(u_j)$ $(j = 1, 2)$ for all $t \in T$ and $u_1, u_2 \in \Omega$. By (5.6) and (5.8),

$$\begin{aligned}\langle u_i; \eta_2\rangle - \langle u_i; \eta_1\rangle &= \int_T \rho\left[u_i(t-\Delta_i)\right]\zeta(t)\,dt - \int_T \rho\left[u_i(t)\right]\zeta(t)\,dt \\ &= \int_{t_0-\Delta_i}^{t_1-\Delta_i} \rho\left[u_i(t)\right]\zeta(t+\Delta_i)\,dt - \int_{t_0}^{t_1} \rho\left[u_i(t)\right]\zeta(t)\,dt.\end{aligned}$$

Letting $i \to \infty$ gives

$$0 = \langle \nu; \eta_2\rangle - \langle \nu; \eta_1\rangle = \int_T \zeta(t)\,dt \int_{\Omega^2} \left[\rho(u_2) - \rho(u_1)\right]\nu(t, du_1, du_2).$$

So far as the function $\zeta(\cdot) \in \mathbb{L}_1(T)$ is arbitrary, we have for almost all $t \in T$,

$$0 = \int_{\Omega^2} \left[\rho(u_2) - \rho(u_1)\right]\nu(t, du_1, du_2) = \int_\Omega \rho(u)\nu(t, du, \Omega) - \int_\Omega \rho(u)\nu(t, \Omega, du)$$

for all $\rho(\cdot) \in \mathbb{C}(\Omega)$. So $\nu(t, du, \Omega) = \nu(t, \Omega, du)$ and thus $\nu \in \mathfrak{G}^s$. □

LEMMA 11.2. *Let $\mathfrak{R}_\Delta \equiv \mathfrak{R}_\Delta^{sam}$, $q(\Delta) \to 0$, and $\frac{q(\Delta)}{\Delta} \to N \in (1, \infty]$ as $\Delta \to 0$. Then*

$$\mathfrak{S}^{seq} \subset \mathfrak{G}_N^s. \tag{11.1}$$

Proof. Consider an element $\nu \in \mathfrak{S}^{\rm seq}$ and the corresponding sequences $\{\Delta_i\}$ and $\{u_i\}$ from (8.2). Due to (7.1), the inclusion $u_i \in \mathfrak{R}_{\Delta_i}^{\rm sam}$ implies that

$$u_i(t) = u_i^{(j)}\ \forall\, t_i^{(j)} \leq t < t_i^{(j+1)},\ j = 0, \ldots, s_i, \qquad t_i^{(r+1)} - t_i^{(r)} \geq q(\Delta_i), \tag{11.2}$$

where $r = 0, \ldots, s_i - 1$, $t_i^{(0)} = t_0 - \Delta_i$, and $t_i^{(s_i+1)} = t_1$. Put

$$E_i^{[1]} := T \cap \bigcup_{j=0}^{s_i} \left[t_i^{(j)}, t_i^{(j)} + \Delta_i\right),\ E_i^{[2]} := T \setminus E_i^{[1]},\ \chi_i^{[p]}(t) := \begin{cases} 1 \text{ if } t \in E_i^{[p]} \\ 0 \text{ if } t \notin E_i^{[p]} \end{cases}. \tag{11.3}$$

Invoke the space $\boldsymbol{\mathcal{N}}(T, K)$ introduced in section 5. Passing to subsequences ensures that there exist limits in the weak topologies of $\boldsymbol{\mathcal{N}}(T, \Omega^2)$ and $\boldsymbol{\mathcal{N}}(T, \Omega)$, respectively,

$$\nu^{[1]}(t, dw) := \lim_{i\to\infty} \chi_i^{[1]}(t)\delta_{[u_i(t), u_i(t-\Delta_i)]}(dw), \mu(t, du) := \lim_{i\to\infty} \chi_i^{[2]}(t)\delta_{u_i(t)}(du). \tag{11.4}$$

We recall that δ_a is the Dirac measure at the point a. Here μ can be interpreted as an element $\nu^{[2]}$ of $\boldsymbol{\mathcal{N}}(T,\Omega^2)$ concentrated on the diagonal $D:=\{(u,u):u\in\Omega\}$. More precisely,

$$\nu^{[2]}(t,E):=\mu\big(t,E\pitchfork D\big),\quad \text{where}\quad E\pitchfork D:=\{u:(u,u)\in E\}. \tag{11.5}$$

Since $u_i(t-\Delta_i)=u_i(t)$ whenever $t\in E_i^{[2]}$, we have for any $g(\cdot)\in\mathbb{L}_1\big[T,\mathbb{C}(\Omega^2)\big]$,

$$\begin{aligned}\langle\nu,g\rangle&=\lim_{i\to\infty}\int_T g\left[t,u_i(t),u_i(t-\Delta_i)\right]\,dt\\&=\lim_{i\to\infty}\int_{E_i^{[1]}} g\left[t,u_i(t),u_i(t-\Delta_i)\right]\,dt+\lim_{i\to\infty}\int_{E_i^{[2]}} g\left[t,u_i(t),u_i(t)\right]\,dt\\&=\int_T dt\int_{\Omega^2} g(t,w)\nu^{[1]}(t,dw)+\int_T dt\int_\Omega g(t,u,u)\mu(t,du)\\&=\int_T dt\int_{\Omega^2} g(t,w)\left[\nu^{[1]}(t,dw)+\nu^{[2]}(t,dw)\right].\end{aligned}$$

Thus $\nu=\nu^{[1]}+\nu^{[2]}$. By (7.3) and (11.5), $\nu_d^{[2]}(t,du)=\mu(t,du)=\nu^{[2]}(t,du,\Omega)$. Hence

$$\nu_d(t,du)=\nu_d^{[1]}(t,du)+\mu(t,du)\geq\mu(t,du) \tag{11.6}$$

and $\nu_-(t,du):=\nu(t,du,\Omega)-\nu_d(t,du)=\nu^{[1]}(t,du,\Omega)-\nu_d^{[1]}(t,du)\leq\nu^{[1]}(t,du,\Omega)=\int_\Omega\nu^{[1]}(t,du,du_2)$. This means that for any functions $\zeta(\cdot)\in\mathbb{C}(T)$ and $\rho(\cdot)\in\mathbb{C}(\Omega)$ such that $\zeta(\cdot)\geq 0,\rho(\cdot)\geq 0$, and $\zeta(t)=0\ \forall t\in[t_1-\varepsilon,t_1]$ for some $\varepsilon\approx 0,\varepsilon>0$, we have

$$\begin{aligned}\sigma:=\int_T\zeta(t)dt\int_\Omega\rho(u_1)\nu_-(t,du_1)&\leq\int_T\zeta(t)dt\int_{\Omega^2}\rho(u_1)\nu^{[1]}(t,du_1,du_2)\\&\overset{(11.4)}{=\!=}\lim_{i\to\infty}\int_{E_i^{[1]}}\zeta(t)\rho[u_i(t)]dt=\lim_{i\to\infty}\sum_{j=0}^{\widehat{s}_i}\int_{t_i^{(j)}}^{t_i^{(j)}+\Delta_i}\zeta(t)\rho[u_i(t)]dt.\end{aligned} \tag{11.7}$$

Here $\widehat{s}_i:=\max\{j:t_i^{(j)}\leq t_1-\varepsilon\}$. For $j\leq\widehat{s}_i$ and i sufficiently large, $[t_i^{(j)}+\Delta_i,t_i^{(j)}+q(\Delta_i)]\subset T$ and $u_i(t)$ is constant on $[t_i^{(j)},t_i^{(j)}+q(\Delta_i)]$ due to (11.2). Therefore

$$\begin{aligned}&\left|\int_{t_i^{(j)}}^{t_i^{(j)}+\Delta_i}\zeta(t)\rho[u_i(t)]dt-\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\int_{t_i^{(j)}+\Delta_i}^{t_i^{(j)}+q(\Delta_i)}\zeta(t)\rho[u_i(t)]dt\right|\\&=\left|\int_{t_i^{(j)}}^{t_i^{(j)}+\Delta_i}\underbrace{\Big(\zeta[t]-\zeta\left[t_i^{(j)}+\Delta_i\right]\Big)}_{\varkappa(t)}\rho[u_i(t)]dt-\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\int_{t_i^{(j)}+\Delta_i}^{t_i^{(j)}+q(\Delta_i)}\varkappa(t)\rho[u_i(t)]dt\right|\\&\leq\int_{t_i^{(j)}}^{t_i^{(j)}+\Delta_i}|\varkappa(t)|\rho[u_i(t)]dt+\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\int_{t_i^{(j)}+\Delta_i}^{t_i^{(j)}+q(\Delta_i)}|\varkappa(t)|\rho[u_i(t)]dt\\&\leq 2\Delta_i\Gamma_\zeta\left[q(\Delta_i)\right]c_\rho,\end{aligned}$$

where $\Gamma_\zeta(\delta):=\max_{|t_2-t_1|\leq\delta}|\zeta(t_1)-\zeta(t_2)|\to 0$ as $\delta\to 0$ and $c_\rho:=\max_{u\in\Omega}\rho(u)$.

Hence the discrepancy between the sum from (11.7) and $\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\sum_{j=0}^{\widehat{s}_i}\int_{t_i^{(j)}+\Delta_i}^{t_i^{(j)}+q(\Delta_i)}\zeta(t)\rho[u_i(t)]dt$ does not exceed $2c_\rho\Gamma_\zeta\big[q(\Delta_i)\big]\sum_{j=1}^{\widehat{s}_i}\Delta_i \le 2c_\rho\Gamma_\zeta\big[q(\Delta_i)\big](t_1-t_0)$ thanks to (11.2). Thus this discrepancy converges to zero as $i\to\infty$, and (11.7) can be continued as follows:

$$\begin{aligned}\sigma &\le \lim_{i\to\infty}\sum_{j=1}^{\widehat{s}_i}\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\int_{t_i^{(j)}+\Delta_i}^{t_i^{(j)}+q(\Delta_i)}\zeta(t)\rho[u_i(t)]dt\\ &\overset{(11.3)}{\le} \lim_{i\to\infty}\frac{\Delta_i}{q(\Delta_i)-\Delta_i}\int_{E_i^{[2]}}\zeta(t)\rho[u_i(t)]dt\end{aligned}$$

$$\overset{(11.3),\,(11.4)}{=\!=\!=} \frac{1}{N-1}\int_T\zeta(t)dt\int_\Omega\rho(u)\mu(t,du)\overset{(11.6)}{\le}\frac{1}{N-1}\int_T\zeta(t)dt\int_\Omega\rho(u)\nu_d(t,du).$$

(We put $1/\infty := 0$.) Since the nonnegative functions $\zeta(\cdot),\rho(\cdot)$ are arbitrary, we get $\nu(t,du,\Omega)-\nu_d(t,du)=\nu_-(t,du)\le(N-1)^{-1}\nu_d(t,du)$ a.a. $t\in T$, which completes the proof in view of (7.2) and Lemma 11.1 (and Remark 7.2 in the case $N=\infty$). □

LEMMA 11.3. *Let the assumptions of Lemma* 11.2 *be true. Suppose also that in* (10.2)*, the matrix $P(t)$ is cyclic $(N-1)$-subdiagonal and does not depend on t, i.e., $P(t)=P$ a.a. $t\in T=[t_0,t_1]$. Then the element ν given by* (10.2) *belongs to* $\mathfrak{S}=\mathrm{LIM}_{\Delta\to+0}\mathfrak{R}_\Delta^{sam}$.

Proof. Consider the sequence $1\le i_1,\dots,i_s\le l$ associated with P by (10.4) and denote

$$t_\Delta(r,j):=t_0-\Delta+srq(\Delta)+jq(\Delta),\quad T_\Delta(r,j):=\Big[t_\Delta(r,j-1)\,;t_\Delta(r,j)\Big)\cap[t_0-\Delta,t_1],$$
$$u_\Delta(t):=u_{i_j}\quad\text{whenever}\quad t\in T_\Delta(r,j)\quad\text{for some}\quad r=0,1,\dots,\ j=1,\dots,s.$$

Then $u_\Delta\in\mathfrak{R}_\Delta^{\mathrm{sam}}$. By (8.1), it suffices to show that $u_\Delta\to\nu$ as $\Delta\to+0$, i.e., $\langle u_\Delta;\eta\rangle\to\langle\nu;\eta\rangle$ as $\Delta\to+0$ for any $\eta\in\mathbb{L}_1\big[T,\mathbb{C}(\Omega^2)\big]$. By [22, Lemma IV.2.4], one can focus on the functions η of the form $\eta(t,u_1,u_2)=\chi_E(t)\rho(u_1,u_2)$, where $\rho(\cdot)\in\mathbb{C}(\Omega\times\Omega), E=[\tau_1,\tau_2], t_0<\tau_1<\tau_2<t_1$, and $\chi_E(t):=1$ for $t\in E$ whereas $\chi_E(t):=0$ if $t\notin E$. Put

$$A_\Delta:=\Big\{\alpha=0,1,\cdots:T_\Delta(\alpha):=\Big[t_\Delta(0,0)+s\alpha q(\Delta);\,t_\Delta(0,0)+s(\alpha+1)q(\Delta)\Big]\subset[\tau_1,\tau_2]\Big\},\quad \alpha_\Delta^-:=\min\{\alpha:\alpha\in A_\Delta\},\quad \alpha_\Delta^+:=\max\{\alpha:\alpha\in A_\Delta\}.$$

Then by (5.6) and (5.8),

$$\langle u_\Delta;\eta\rangle=\int_T\chi_E(t)\underbrace{\rho\,[u_\Delta(t),u_\Delta(t-\Delta)]}_{\varkappa(t)}\,dt=\int_{\tau_1}^{\tau_2}\varkappa(t)\,dt$$
$$=\underbrace{\int_{T_\Delta(\alpha_\Delta^--1)\cap[\tau_1,\tau_2]}\varkappa(t)\,dt}_{\omega^-(\Delta)}+\underbrace{\int_{T_\Delta(\alpha_\Delta^++1)\cap[\tau_1,\tau_2]}\varkappa(t)\,dt}_{\omega^+(\Delta)}+\underbrace{\sum_{r=\alpha_\Delta^-}^{\alpha_\Delta^+}\sum_{j=1}^{s}\int_{T_\Delta(r,j)}\varkappa(t)\,dt}_{\omega(\Delta)}.$$

Here $\mathrm{mes}T_\Delta(\alpha^\pm_\Delta \pm 1) = sq(\Delta)$, and so $|\omega^\pm(\Delta)| \le c_\rho sq(\Delta)$, where $c_\rho := \max_{u',u''\in\Omega}|\rho(u', u'')|$. Thus $\omega^\pm(\Delta) \to 0$ as $\Delta \to +0$. For the indices r, j involved in the last sum and $\Delta \approx 0$,

$$\int_{T_\Delta(r,j)} \varkappa(t)dt = \int_{t_\Delta(r,j-1)}^{t_\Delta(r,j-1)+\Delta} \rho\big(u_{i_j}, u_{i_{j-1}}\big)dt + \int_{t_\Delta(r,j-1)+\Delta}^{t_\Delta(r,j)} \rho\big(u_{i_j}, u_{i_j}\big)dt$$
$$= \Delta\rho\big(u_{i_j}, u_{i_{j-1}}\big) + \big[q(\Delta) - \Delta\big]\rho\big(u_{i_j}, u_{i_j}\big).$$

Note that $q(\Delta) = \mathrm{mes}T_\Delta(r, j)$. Hence

$$\omega(\Delta) = \frac{1}{s}\sum_{j=1}^{s}\left[\frac{\Delta}{q(\Delta)}\rho\big(u_{i_j}, u_{i_{j-1}}\big) + \left(1 - \frac{\Delta}{q(\Delta)}\right)\rho\big(u_{i_j}, u_{i_j}\big)\right]\sum_{r=\alpha^-_\Delta}^{\alpha^+_\Delta}\sum_{j=1}^{s}\mathrm{mes}T_\Delta(r, j).$$

The last double sum equals $\mathrm{mes}\mathcal{T}_\Delta$: $\mathcal{T}_\Delta := \bigcup_{r=\alpha^-_\Delta}^{\alpha^+_\Delta}\bigcup_{j=1}^{s} T_\Delta(r, j) \subset [\tau_1, \tau_2]$, $[\tau_1, \tau_2] \setminus \mathcal{T}_\Delta \subset \mathfrak{T}_\Delta := T_\Delta(\alpha^-_\Delta - 1) \cup T_\Delta(\alpha^+_\Delta + 1)$, and $\mathrm{mes}\mathfrak{T}_\Delta \to 0$ as $\Delta \to +0$ by the foregoing. So

$$\langle u_\Delta; \eta\rangle \to \Gamma := s^{-1}(\tau_2 - \tau_1)\sum_{j=1}^{s}\left[\frac{1}{N}\rho\big(u_{i_j}, u_{i_{j-1}}\big) + \left(1 - \frac{1}{N}\right)\rho\big(u_{i_j}, u_{i_j}\big)\right].$$

At the same time, (5.6), (10.2), and (10.4) (where $\varkappa := N - 1$) yield $\Gamma = \int_{\tau_1}^{\tau_2} dt\sum_{i,j=1}^{l} p_{ij}\rho(u_i, u_j) = \langle\nu; \eta\rangle$, which completes the proof. □

LEMMA 11.4. *Lemma* 11.3 *remains true for* $N = 1$.

Proof. Let $P \in \mathcal{M}_l(0)$ and I denote the unit $l \times l$-matrix. Given $\varkappa > 0$, it follows from (10.3) that $P_\varkappa := \frac{1}{l\varkappa+1}P + \frac{\varkappa}{(l\varkappa+1)}I \in \mathcal{M}_l(\varkappa)$. The corresponding element $\nu_\varkappa$ given by (10.2) (where $P(t) := P_\varkappa$) belongs to the set $\mathrm{LIM}_{\Delta\to+0}\mathfrak{R}^{\mathrm{sam}}_{\Delta,\varkappa}$ defined by (8.1) due to Lemma 11.3. Here the set $\mathfrak{R}^{\mathrm{sam}}_{\Delta,\varkappa}$ is defined by (7.1) with $q(\Delta) := (1 + \varkappa)\Delta$. Since $\frac{q(\Delta)}{\Delta} \to N = 1$ as $\Delta \to +0$, we have $\mathfrak{R}^{\mathrm{sam}}_{\Delta,\varkappa} \subset \mathfrak{R}^{\mathrm{sam}}_\Delta$ for $\Delta \approx 0$. So $\mathrm{LIM}_{\Delta\to+0}\mathfrak{R}^{\mathrm{sam}}_{\Delta,\varkappa} \subset \mathrm{LIM}_{\Delta\to+0}\mathfrak{R}^{\mathrm{sam}}_\Delta = \mathfrak{S}$ and thus $\nu_\varkappa \in \mathfrak{S}$. It remains to note that $\nu_\varkappa \to \nu$ as $\varkappa \to +0$ and employ Lemma 8.2. □

LEMMA 11.5. *Suppose that* $\mathfrak{R}_\Delta \equiv \mathfrak{R}^{sam}_\Delta$ *and the first relation from* (7.5) *is true. The set* $\mathfrak{S}$ *defined in* (10.1) *contains any element* (10.2) *such that* $P(t) \in \mathcal{M}_l(N - 1)$ *a.a.* $t \in T$.

Proof. Put $\mathfrak{A} := \{\alpha : \mathcal{M}_l^{\mathrm{ext}}(N - 1) \to [0, \infty) : \sum_{P\in\mathcal{M}_l^{\mathrm{ext}}(N-1)}\alpha(P) = 1\}$ and $\Lambda\big[\alpha(\cdot)\big] := \sum_{P\in\mathcal{M}_l^{\mathrm{ext}}(N-1)}\alpha(P)P$, where $\mathcal{M}_l^{\mathrm{ext}}(N - 1)$ is the set of the extremal points of $\mathcal{M}_l(N - 1)$. By the Krein–Milman theorem, $\Lambda(\mathfrak{A}) \supset \mathcal{M}_l(N - 1)$. Then Theorems I.7.6 and I.7.7 in [22] imply that $P(t) = \Lambda\big[\alpha(t, \cdot)\big]$ for a measurable function $t \mapsto \alpha(t, \cdot) \in \mathfrak{A}$. Lemmas 10.3, 11.3, and 11.4 and Corollary 9.7 complete the proof. □

Now we are in a position to prove the main result of this section.

THEOREM 11.6. *The relationships* (10.1) *are true whenever* (7.5) *is valid.*

Proof. Suppose that $\mathfrak{R}_\Delta \equiv \mathfrak{R}^{\mathrm{sam}}_\Delta$ and the first relation from (7.5) is true. Due to Lemma 11.1 and (11.1), it suffices to show that $\mathfrak{G}^s_N \subset \mathfrak{S}$. Let $\nu \in \mathfrak{G}^s_N$. Given $\delta > 0$, we introduce a Borel partition $\Omega = \Omega^\delta(1)\cup\cdots\cup\Omega^\delta(l_\delta)$ such that $\sup_{u\in\Omega^\delta(i)}|u - u^\delta_i| < \delta$ for some $u^\delta_i \in \Omega^\delta(i)$ for all i. For

$$p_{ij} := p^\delta_{ij}(t) := \nu\left[t, \Omega^\delta(i) \times \Omega^\delta(j)\right], \quad i, j = 1, \ldots, l_\delta, \qquad \text{and} \qquad l := l_\delta,$$

all relations in (10.3) except for the last one are immediate from (5.2) and (7.2). To prove the last relation, we put $\Omega_d^\delta(i) := \{w = (u,u) : u \in \Omega^\delta(i)\}$. By (7.2), we have for $N < \infty$

$$(N-1)\sum_{j=1}^{l_\delta} p_{ij} = (N-1)\nu\Big[t, \Omega^\delta(i)\times\Omega\Big] \le N\nu_d\Big[t,\Omega^\delta(i)\Big] \overset{(7.3)}{=\!=} N\nu\Big[t, \underbrace{\Omega_d^\delta(i)}_{\subset\Omega^\delta(i)\times\Omega^\delta(i)}\Big]$$
$$\le N\nu\Big[t,\Omega^\delta(i)\times\Omega^\delta(i)\Big] = Np_{ii}.$$

Hence $P(t) := \big(p_{ij}^\delta(t)\big)_{i,j=1}^{l_\delta} \in \mathcal{M}_{l_\delta}(N-1)$ a.a. t, where $\mathcal{M}_{l_\delta}(N-1)$ is given by (10.3). If $N=\infty$, then (7.4) $\Rightarrow \nu \in \mathcal{G}_\infty^s = \bigcap_{N'>1}\mathcal{G}_{N'}^s$. Thus $P(t) \in \bigcap_{N'=1,2,\ldots,} \mathcal{M}_{l_\delta}(N'-1) = \mathcal{M}_{l_\delta}(\infty) = \mathcal{M}_{l_\delta}(N-1)$ a.a. t. So Lemma 11.5 ensures that the element ν_δ defined by (10.2) (where $l := l_\delta,\ p_{ij} := p_{ij}^\delta(t),\ u_i := u_i^\delta$) belongs to $\mathfrak{S}$. For any $\rho \in \mathbb{C}(\Omega^2)$ and a.a. $t \in T$,

$$\text{(11.8)}\quad \left|\int_{\Omega^2}\rho(u',u'')\nu_\delta(t,du',du'') - \int_{\Omega^2}\rho(u',u'')\nu(t,du',du'')\right|$$
$$= \left|\sum_{i,j=1}^{l_\delta}\rho\left(u_i^\delta,u_j^\delta\right)p_{ij}^\delta(t) - \sum_{i,j=1}^{l_\delta}\int_{\Omega^\delta(i)\times\Omega^\delta(j)}\rho(u',u'')\nu(t,du',du'')\right|$$
$$\le \sum_{i,j=1}^{l_\delta}\int_{\Omega^\delta(i)\times\Omega^\delta(j)}\left|\rho\left(u_i^\delta,u_j^\delta\right)-\rho(u',u'')\right|\nu(t,du',du'') \le q_\delta[\rho(\cdot)].$$

Here $q_\delta[\rho(\cdot)] := \max|\rho(v_1,v_2)-\rho(u_1,u_2)|$, where max is over $(v_1,v_2),(u_1,u_2)\in\Omega^2$ such that $|v_1-u_1|\le\delta, |v_2-u_2|\le\delta$. Pick $\eta\in\mathbb{C}(T)$. Then

$$\left|\int_T\eta(t)\,dt\int_{\Omega^2}\rho(u',u'')\nu_\delta(t,du',du'') - \int_T\eta(t)\,dt\int_{\Omega^2}\rho(u',u'')\nu(t,du',du'')\right|$$
$$\le q_\delta[\rho(\cdot)]\int_T|\eta(t)|\,dt.$$

Let $\delta\to+0$. Since $q_\delta[\rho(\cdot)]\to 0$, then $\nu_\delta\to\nu$ by [22, Theorem IV.2.4]. As was shown, $\nu_\delta\in\mathfrak{S}$. Then Lemma 8.2 yields $\nu\in\mathfrak{S}$, $\mathcal{G}_N^s\subset\mathfrak{S}$, which implies (10.1) for the case at hand.

Now let the second relation from (7.5) hold. By Lemma 11.1, it suffices to show that $\mathcal{G}_1^s\subset\mathfrak{S}$. For the set $\mathcal{R}_\Delta^{\mathrm{sam}*}$ defined by (7.1) with $q(\Delta) := \max\{q(\Delta),\Delta\}$, the first relation from (7.5) is true with $N=1$. So $\mathcal{G}_1^s = \mathrm{LIM}_{\Delta\to0}\mathcal{R}_\Delta^{\mathrm{sam}*}$ by the foregoing. At the same time, $\mathcal{R}_\Delta^{\mathrm{sam}*}\subset\mathfrak{R}_\Delta \overset{(8.1)}{\Rightarrow} \mathrm{LIM}_{\Delta\to0}\mathcal{R}_\Delta^{\mathrm{sam}*}\subset\mathrm{LIM}_{\Delta\to0}\mathfrak{R}_\Delta = \mathfrak{S}$, which completes the proof.

For $\mathfrak{R}_\Delta\equiv\mathcal{R}_\Delta$, the proof comes to retracing the arguments from the previous paragraph for $\mathcal{R}_\Delta^{\mathrm{sam}*}$ given by (7.1) with $q(\Delta):=\Delta$. □

12. Proofs of Theorem 7.2 and the claims from section 5. Theorem 5.1 is immediate from Theorems 8.5 and 11.6. Lemma 5.2 follows from Theorems 8.6 and 11.6. Theorem 5.3 results from Theorems 8.7, 11.6, and the first relation from (8.3). Theorem 5.4 is justified by Theorems 8.7 and 11.6. Theorem 7.2 follows from Theorems 8.5, 8.6, 8.7, and 11.6.

13. Proofs of Theorem 7.4 and the claims from section 4.

Proof of Lemma 4.1. This is immediate from Theorem 5.1. □

Proof of Theorem 4.2. Put in (2.1)–(2.4) $f(\cdot)\equiv 0, a(\cdot)\equiv 0, \varphi(t,x_1,x_2,\,u_1,u_2):=-(t_1-t_0)^{-1}|u_1-u_2|^2$, where $|\cdot|$ is the Euclidean norm in $\mathbb{R}^m$. Then due to (2.7), $\overline{\varphi}(t,x,u)=0$ and so $\mathfrak{I}_{opt}(0)=0$, where $\mathfrak{I}_{opt}(0)$ is the infimum of the cost functional in the problem (2.5), (2.6). By (i) from section 4, the set Ω contains two points $u_1\neq u_2$. Put

$$\nu(t,dw):=\eta(dw):=\frac{1}{2}\Big[\delta_{(u_1,u_2)}(dw)+\delta_{(u_2,u_1)}(dw)\Big], \tag{13.1}$$

where $w=(u',u'')\in\Omega^2$ and $\delta_\omega(dw)$ is the Dirac measure at the point $\omega\in\Omega^2$. Then η satisfies the relations from (5.2) and hence $\nu\in\mathfrak{G}^s$. As a result, Theorem 5.1 yields

$$\lim_{\Delta\to+0}\mathfrak{I}_{opt}(\Delta)\leq-\int_T dt\int_{\Omega^2}\frac{|u'-u''|^2}{t_1-t_0}\nu(t,du',du'')=-|u_1-u_2|^2<0=\mathfrak{I}_{opt}(0). \quad \square$$

In the remainder of the section, we prove Theorems 4.3 and 7.4. The attention is focused on Theorem 7.4 since it and Remark 7.5 imply Theorem 4.3. We start with a technical fact.

LEMMA 13.1. *There exist $\delta=\delta_0>0, \varkappa\in(0,1)$, and a map $\chi_\delta(\cdot):\Omega\to\Omega$ such that*

$$\varkappa\delta\leq|\chi_\delta(u)-u|\leq\delta\ \forall u\in\Omega,\quad \chi_\delta(u)=\mathrm{const}=v_i\ \forall u\in W_i, i=1,\dots,k, \tag{13.2}$$

$$\text{where}\quad W_i=\begin{cases}V_1 & \text{if } i=1\\ V_i\setminus(V_{i-1}\cup\dots\cup V_1) & \text{if } i>1,\end{cases}$$

$V_1,\dots,V_k\subset\Omega$ are some open (in Ω) sets, and $V_1\cup\dots\cup V_k=\Omega$. If the set Ω is connected, the numbers δ_0 and $\varkappa$ can be chosen so that such a function $\chi_\delta(\cdot)$ exists for all $\delta\in(0,\delta_0]$.

Proof. If the set Ω is not connected, we put $\delta:=\delta_0>m_+, \varkappa:=1/2\delta^{-1}m_-$, where $m_+:=\max_{u\in\Omega}m(u)$, $m_-:=\min_{u\in\Omega}m(u)$, and $m(u):=\max_{v\in\Omega}|u-v|=|v(u)-u|$ for some $v(u)\in\Omega$. Then $\varkappa\delta<m_-\leq|v(u)-u|\leq m_+<\delta$. Hence for some $\varepsilon_\delta>0$,

$$\varkappa\delta+\varepsilon_\delta\leq|v(u)-u|\leq\delta-\varepsilon_\delta\qquad\forall u\in\Omega. \tag{13.3}$$

If the set Ω is connected, we set $\delta_0:=m_-, \varkappa:=1/2$, and $\varepsilon_\delta:=1/5\delta$ for $\delta\in(0,\delta_0]$. The connected set Ω is not covered by the disjoint sets $\{v:|v-u|\leq 7/10\delta\}$ and $\{v:|v-u|\geq 4/5\delta\}$. So $7/10\delta<|v-u|<4/5\delta$ for some $v=v(u)\in\Omega$, i.e., (13.3) still holds.

In any case for $u'\in\Omega(u):=\{u'\in\Omega:|u'-u|<\varepsilon_\delta\}$, we have $|u'-v(u)|\leq|u'-u|+|u-v(u)|<\varepsilon_\delta+\delta-\varepsilon_\delta=\delta$, $|u'-v(u)|\geq|u-v(u)|-|u'-u|>\varkappa\delta$. Since the set Ω is compact by (i) from section 2, there exist points $u_1,\dots,u_k$ such that $\Omega=V_1\cup\dots\cup V_k, V_i:=\Omega(u_i)$. It remains to define $\chi_\delta(\cdot)$ by (13.2), where $v_i:=v(u_i)$. □

From now on, we fix $\delta,\varkappa$, and $\chi_\delta(\cdot)$ from (13.2). To prove Theorem 7.4, we show that $\mathcal{J}^{\mathrm{sam}}_{\mathrm{opt}}[N-\varepsilon,\xi]<\mathcal{J}^{\mathrm{sam}}_{\mathrm{opt}}[N,\xi]$ if $\varepsilon>0,\varepsilon\approx 0$. To this end, we find a variation $\nu(\varepsilon)\in\mathfrak{G}^s_{N-\varepsilon}$ of the optimal control ν in (5.3), (5.4) (where $\mathfrak{G}^s:=\mathfrak{G}^s_N$) that decreases the cost. It is obtained by "spraying" a small portion of the diagonal component of ν outside the diagonal D of Ω^2. This is possible since, due to (7.2), the lesser the N, the lesser this component may be.

Now we introduce a "dispersion" of a measure $\eta \in \mathbf{frm}(\Omega^2)$ concentrated on D. The isomorphism $u \in \Omega \leftrightarrow (u,u) \in D$ identifies η with an element of $\mathbf{frm}(\Omega)$, which is denoted by the same symbol. For any Borel subsets $E \subset \Omega^2$ and $\mathcal{E} \subset \Omega$, we put

$$\eta^{\langle\delta\rangle}(E) := 1/2\left(\eta\left\{u : [u, \chi_\delta(u)] \in E\right\} + \eta\left\{u : [\chi_\delta(u), u] \in E\right\}\right), \tag{13.4}$$

$$\widehat{\eta}^{\langle\delta\rangle}(\mathcal{E}) := 1/2\left[\eta(\mathcal{E}) + \eta\{u : \chi_\delta(u) \in \mathcal{E}\}\right]. \tag{13.5}$$

For $\eta \in \mathbf{rpm}(\Omega^2)$, we consider the diagonal component η_d given by (7.3), and put

$$\widehat{\eta}_N^{\langle\delta,\varepsilon\rangle} := \tau(\eta_d)^{\langle\delta\rangle} + (1-\tau)\widehat{(\eta_d)}^{\langle\delta\rangle}, \quad \text{where} \quad \tau := \frac{1}{N-\varepsilon}, \tag{13.6}$$

$$\eta_N^{\langle\delta,\varepsilon\rangle} := \underbrace{\eta - \eta_d}_{=:\eta^-} + (1-\theta)\,\eta_d + \theta\widehat{\eta}_N^{\langle\delta,\varepsilon\rangle}, \quad \text{where} \quad \theta := \frac{\varepsilon}{N-1}. \tag{13.7}$$

LEMMA 13.2. *Suppose that $N \in (1,\infty), \varepsilon \in (0, N-1)$, and $\eta \in \mathbf{srpm}_N(\Omega^2)$, where $\mathbf{srpm}_N(\Omega^2)$ is given by* (7.2) *and* (5.2). *Then $\eta_N^{\langle\delta,\varepsilon\rangle} \in \mathbf{srpm}_{N-\varepsilon}(\Omega^2)$.*

Proof. The first two relations from (5.2) are clearly true for $\eta := \eta_N^{\langle\delta,\varepsilon\rangle}$. By (13.4), (13.5),

$$(\eta_d)^{\langle\delta\rangle}(du,\Omega) = \widehat{(\eta_d)}^{\langle\delta\rangle}(du) = (\eta_d)^{\langle\delta\rangle}(\Omega, du). \tag{13.8}$$

Thus $(\eta_d)^{\langle\delta\rangle}$ meets the third requirement from (5.2). So do the measures $\widehat{(\eta_d)}^{\langle\delta\rangle}$ and η_d, since they are concentrated on the diagonal D, and η since $\eta \in \mathbf{srpm}_N(\Omega^2)$. It follows that the measure (13.7) satisfies the third condition from (5.2) as well.

Due to (13.2), (13.4), (13.7), the diagonal components of $\eta^{\langle\delta\rangle}$ and η^- are zero. Hence

$$\left[\eta_N^{\langle\delta,\varepsilon\rangle}\right]_d \overset{(13.7)}{=\!=} (1-\theta)\,\eta_d + \theta\left[\widehat{\eta}_N^{\langle\delta,\varepsilon\rangle}\right]_d \overset{(13.5),\,(13.6)}{=\!=\!=} (1-\theta)\,\eta_d + \theta(1-\tau)\widehat{(\eta_d)}^{\langle\delta\rangle}. \tag{13.9}$$

Note that $\mu(du,\Omega) = \mu(du,du) = \mu(du)$ for any measure μ in Ω^2 concentrated on the diagonal D, and by (7.2), $\eta \in \mathbf{srpm}_N(\Omega^2) \Rightarrow \eta^-(du,\Omega) \le (N-1)^{-1}\eta_d(du)$. So

$$\begin{aligned}
&\eta_N^{\langle\delta,\varepsilon\rangle}(du,\Omega) \overset{(13.6),\,(13.7)}{=\!=\!=} \eta^-(du,\Omega) + (1-\theta)\eta_d(du) + \theta\left[\tau(\eta_d)^{\langle\delta\rangle}(du,\Omega) + (1-\tau)\widehat{(\eta_d)}^{\langle\delta\rangle}(du)\right] \\
&\overset{(13.8)}{=\!=} \eta^-(du,\Omega) + (1-\theta)\eta_d(du) + \theta\widehat{(\eta_d)}^{\langle\delta\rangle}(du);\ (N-\varepsilon-1)\left(\eta_N^{\langle\delta,\varepsilon\rangle}(du,\Omega) - \left[\eta_N^{\langle\delta,\varepsilon\rangle}\right]_d(du)\right) \\
&\le (N-\varepsilon-1)\left\{\left(\frac{1}{N-1} + 1 - \theta\right)\eta_d(du) + \theta\widehat{(\eta_d)}^{\langle\delta\rangle}(du) - \left[\eta_N^{\langle\delta,\varepsilon\rangle}\right]_d(du)\right\} \overset{(13.6),\,(13.7)}{=\!=\!=} \\
&(N-\varepsilon)\left[(1-\theta)\eta_d + \theta(1-\tau)\widehat{(\eta_d)}^{\langle\delta\rangle}(du)\right] - (N-\varepsilon-1)\left[\eta_N^{\langle\delta,\varepsilon\rangle}\right]_d(du) \overset{(13.9)}{=\!=} \left[\eta_N^{\langle\delta,\varepsilon\rangle}\right]_d(du).
\end{aligned}$$

Thus $\eta_N^{\langle\delta,\varepsilon\rangle} \in \mathbf{srpm}_{N-\varepsilon}(\Omega^2)$ by (7.2). □

LEMMA 13.3. *Let $\mu \in \mathfrak{N}(T,\Omega), \nu \in \mathfrak{N}(T,\Omega^2)$, and $\mu(t,du) \ge 0, \nu(t,dw) \ge 0, \mu(t,\Omega) \le 1, \nu(t,\Omega^2) \le 1$ a.a. $t \in T$. Then the maps $t \in T \mapsto \mu^{\langle\delta\rangle}(t) := [\mu(t)]^{\langle\delta\rangle} \in \mathbf{frm}(\Omega^2), t \mapsto \widehat{\mu}^{\langle\delta\rangle}(t) := \widehat{[\mu(t)]}^{\langle\delta\rangle} \in \mathbf{frm}(\Omega)$ and $t \mapsto \nu_d(t) := [\nu(t)]_d \in \mathbf{frm}(\Omega^2)$ are measurable.*

Proof. For $u\in\Omega, w\in\Omega^2, j=1,2,\dots$, we put $\omega^i_j(u):=\min\big\{j\cdot\mathrm{dist}\big(u;\Omega\setminus V_i\big);1\big\}$, $\omega_j(w):=\min\big\{[j\cdot\mathrm{dist}\big(w,D\big)]^{-1};1\big\}$, where D is the diagonal of Ω^2, $0^{-1}:=\infty$, and $V_i, i=1,\dots,k$ are the open sets from (13.2). Then $0\le\omega^i_j(u),\omega_j(w)\le 1$ for all u,w; $\omega^i_j(u)=0$ for all $u\notin V_i$, $\omega_j(w)=1$ for all $w\in D$, and $\omega^i_j(u)\to 1$ for all $u\in V_i, \omega_j(w)\to 0$ for all $w\notin D$ as $j\to\infty$. We also set $\omega^0_j(u):=0$. For any $\rho(\cdot)\in\mathbb{C}(\Omega^2), g(\cdot)\in\mathbb{C}(\Omega)$, we have by (13.4),

$$\sigma_\mu(t):=2\int_{\Omega^2}\rho(w)\mu^{\langle\delta\rangle}(t,dw)=\int_\Omega\big(\rho[u,\chi_\delta(u)]+\rho[\chi_\delta(u),u]\big)\mu(t,du)\overset{(13.2)}{=\!=}$$

$$\sum_{i=1}^k\int_{W_i}\underbrace{\big[\rho(u,v_i)+\rho(v_i,u)\big]}_{\rho_i(u)}\mu(t,du)=\sum_{i=1}^k\lim_{j\to\infty}\int_\Omega\omega^i_j(u)\Big[1-\max_{r=0,\dots,i-1}\omega^r_j(u)\Big]\rho_i(u)\mu(t,du)$$

$$\sigma_\nu(t):=\int_\Omega g(u)\nu_d(t,du)=\lim_{j\to\infty}\int_{\Omega^2}g(u_1)\omega_j(u_1,u_2)\nu(t,du_1,du_2).$$

The integrands in both final expressions are continuous. By the definition of $\mathfrak{N}(T,K)$, $K=\Omega,\Omega^2$, this means that the corresponding integrals are measurable functions of t. Hence so are their limits $\sigma_\mu(t)$ and $\sigma_\nu(t)$. This proves that the maps $\mu^{\langle\delta\rangle}$ and ν_d are measurable. The measurability of $\widehat{\mu}^{\langle\delta\rangle}$ is established likewise. □

By combining Lemmas 13.2 and 13.3 with (13.6) and (13.7), we arrive at the following corollary.

COROLLARY 13.4. *If $\nu\in\mathfrak{G}^s_N, N\in(1,\infty)$, $\varepsilon\in(0,N-1)$, then $\nu^{\langle\delta,\varepsilon\rangle}_N\in\mathfrak{G}^s_{N-\varepsilon}$.*

LEMMA 13.5. *For $\xi=[f(\cdot),\varphi(\cdot),a(\cdot)]\in\Xi_{(iv)}$, $N\in(1,\infty)$, and $\nu\in\mathfrak{G}^s_N$, we put $\widetilde{r}(t,x,w):=r(t,x,x,w)$, $r^{\blacktriangledown}(t,\xi,\nu,N,\delta):=\int_{\Omega^2}\widetilde{r}\,[t,x(t),w]\nu^{\langle\delta\rangle}_N(t,dw)$, where $r=f,\varphi$,*

$$\nu^{\langle\delta\rangle}_N:=\frac{1}{N-1}\left(\frac{1}{N}\left[(\nu_d)^{\langle\delta\rangle}+(N-1)\widehat{(\nu_d)}^{\langle\delta\rangle}\right]-\nu_d\right),\tag{13.10}$$

and $x(\cdot)$ is the solution of (5.4). *Let $J(\nu)$ denote the value of the cost functional from* (5.3). *Consider the constant k from* (iv) *in section* 2 *and the hemi-norm $\mathfrak{H}_k(\cdot)$ given by* (4.2). *Then*

$$\lim_{\varepsilon\to+0}\varepsilon^{-1}\left[J\left(\nu^{\langle\delta,\varepsilon\rangle}_N\right)-J(\nu)\right]=\sigma(\xi,\nu,N,\delta)+\int_T\varphi^{\blacktriangledown}(t,\xi,\nu,N,\delta)dt,\tag{13.11}$$

$$|\sigma(\xi,\nu,N,\delta)|\le|T|\mathfrak{H}_k(\xi)e^{\mathfrak{H}_k(\xi)|T|}\max_{t\in T}\left|\int_{t_0}^t f^{\blacktriangledown}(\theta,\xi,\nu,N,\delta)d\theta\right|,|T|:=t_1-t_0.\tag{13.12}$$

Proof. As follows from (13.6), (13.7), (13.10), $\frac{d}{d\varepsilon}\nu^{\langle\delta,\varepsilon\rangle}_N|_{\varepsilon=0}=\nu^{\langle\delta\rangle}_N$. Then (5.3), (5.4) imply via the standard arguments (see, e.g., the proof of Theorem II.4.11 in [22]) (13.11) with

$$\sigma(\xi,\nu,N,\delta):=\int_T\breve{\varphi}_\partial(t)y(t)dt,\quad\text{where}\quad y(t)=\int_{t_0}^t\breve{f}_\partial(\theta)y(\theta)d\theta+z(t),\tag{13.13}$$

$\breve{r}_\partial(t):=\int_{\Omega^2}\frac{\partial\widetilde{r}}{\partial x}[t,x(t),w]\nu(t,dw)$ for $r=\varphi,f$, and $z(t)$ is the integral embraced by $|\cdot|$ in (13.12). Due to Lemma 8.4, $|x(t)|\le k$ for all $t\in T$. So (4.2) yields $|\breve{r}_\partial(t)|\le c:=\mathfrak{H}_k(\xi), r=f,\varphi$. Thus $|y(t)|\le c\int_{t_0}^t|y(\theta)|d\theta+|z(t)|$ for all t, and Theorem II.4.4 [22] gives $|y(t)|\le|z(t)|+c\int_{t_0}^t e^{c(t-\theta)}|z(\theta)|d\theta\le e^{c(t_1-t_0)}\max_t|z(t)|$. Then (13.13) ⇒ (13.12). □

LEMMA 13.6. *We employ the notation from Lemmas* 13.1 *and* 13.5 *and put for* $r = f, \varphi$,

(13.14)
$$\alpha_r^k(\delta) := \max_{\substack{t\in T,|x|\le k,\\ u,v\in\Omega,|u-v|\le\delta}} \left\{\widetilde{r}(t,x,v,v) - \widetilde{r}(t,x,u,u)\right\}_r, \quad \{b\}_r := \begin{cases} b & \text{for } r=\varphi,\\ |b| & \text{for } r=f,\end{cases}$$

$$\beta_r^k(\delta) := \max_{t\in T,|x|\le k,u,v\in\Omega,\varkappa\delta\le|u-v|\le\delta} \max_{w=(u,v),(v,u)} \left\{\widetilde{r}(t,x,w) - \widetilde{r}(t,x,u,u)\right\}_r. \tag{13.15}$$

Suppose that $1 < N_- \le N \le N_+ < \infty$ *and denote* $\lambda_r^k(\delta, N_+) := 2\beta_r^k(\delta) + N_+\alpha_r^k(\delta)$. *Then*

$$\left\{r^{\blacktriangledown}(t,\xi,\nu,N,\delta)\right\}_r \le \lambda_r^k(\delta,N_+) \times \begin{cases} 1/2(N_--1)^{-2} & \text{if } r=f,\\ 1/2N_+^{-2} & \text{if } r=\varphi \text{ and } \lambda_\varphi^k(\delta,N_+)\le 0.\end{cases}$$

Proof. The definition of $r^{\blacktriangledown}(\cdot)$ given in Lemma 13.5 and (13.4), (13.5), and (13.10) imply that

$$\begin{aligned}\left\{r^{\blacktriangledown}(t,\xi,\nu,N,\delta)\right\}_r \le \int_\Omega \Big\{ &\frac{1}{2N(N-1)}\Big[\left\{\widetilde{r}[t,x(t),u,\chi_\delta(u)] - \widetilde{r}[t,x(t),u,u]\right\}_r\\ &+\left\{\widetilde{r}[t,x(t),\chi_\delta(u),u] - \widetilde{r}[t,x(t),u,u]\right\}_r\Big]\\ &+\frac{1}{2N}\Big[\left\{\widetilde{r}[t,x(t),\chi_\delta(u),\chi_\delta(u)] - \widetilde{r}[t,x(t),u,u]\right\}_r\Big]\Big\}\nu_d(t,du) \overset{(13.2),\,(13.14),\,(13.15)}{\le}\\ \frac{1}{2N(N-1)}\left[2\beta_r^k(\delta) + (N-1)\alpha_r^k(\delta)\right]&\int_\Omega \nu_d(t,du) \le \frac{1}{2N(N-1)}\lambda_r^k(\delta,N_+)\nu_d(t,\Omega).\end{aligned}$$

Here $\lambda_f^k(\delta,N_+) \ge 0$ by (13.14), (13.15), whereas (7.3), (7.2), and (5.2) yield $\nu_d(t,\Omega) = \nu(t,D) \le \nu(t,\Omega^2) \le 1$. Since $2N(N-1) \ge 2(N_--1)^2$, this completes the proof for $r := f$. Now let $r = \varphi$ and $\lambda_\varphi^k(\delta,N_+) \le 0$. The last relation from (7.2) gives

$$(N-1)[\nu(t,\Omega^2) - \nu_d(t,\Omega)] \le \nu_d(t,\Omega) \Rightarrow \nu_d(t,\Omega) \ge (N-1)/N\nu(t,\Omega^2) = (N-1)/N,$$
$$\left\{\varphi^{\blacktriangledown}(t,\xi,\nu,N,\delta)\right\}_r \le \frac{1}{2N^2}\lambda_\varphi^k(\delta,N_+) \le \frac{1}{2N_+^2}\lambda_\varphi^k(\delta,N_+). \qquad \square$$

LEMMA 13.7. *Given* $1 < N_- < N_+ < \infty$, *the following set is open and nonempty:*

$$\Xi[\delta,N_-,N_+] := \left\{\xi = [f(\cdot),\varphi(\cdot),a(\cdot)] \in \Xi_{(iv)} : \gamma_\xi(\delta,N_-,N_+) < 0\right\}, \quad \text{where} \tag{13.16}$$
$$\gamma_\xi(\delta,N_-,N_+) := \frac{|T|^2}{2(N_--1)^2}\lambda_f^k(\delta,N_+)\mathfrak{H}_k(\xi)e^{\mathfrak{H}_k(\xi)|T|} + \frac{|T|}{2N_+^2}\lambda_\varphi^k(\delta,N_+).$$

Whenever $\xi \in \Xi[\delta,N_-,N_+]$, *the limit optimal cost* $\mathfrak{J}_{opt}^{sam}[N,\xi]$ *defined in* (7.7) *strictly increases on the interval* $[N_-,N_+]$.

Proof. In the topology generated by the family of hemi-norms (4.2), the hemi-norm $\mathfrak{H}_k(\cdot)$ is evidently continuous. Due to (13.14), (13.15), so is the function $\xi \mapsto \lambda_r^k(\delta,N_+)$ for $r = f,\varphi$ and thus $\xi \mapsto \gamma_\xi(\delta,N_-,N_+)$. It follows that the set $\Xi[\delta,N_-,N_+]$ is open. For $f(\cdot) \equiv 0, a(\cdot) \equiv 0, \varphi(t,x_1,x_2,u,v) := -|u-v|, \xi := [f(\cdot),\varphi(\cdot),a(\cdot)]$,

we have by (13.14), (13.15), $\alpha^k_f(\delta)=\alpha^k_\varphi(\delta)=\beta^k_f(\delta)=0,\beta^k_\varphi(\delta)\le-\varkappa\delta<0$. So $\lambda^k_f(\delta,N_+)=0,\lambda^k_\varphi(\delta,N_+)<0$. Hence $\xi\in\Xi[\delta,N_-,N_+]$ by (13.16), i.e., $\Xi[\delta,N_-,N_+]\neq\emptyset$.

Now let $N\in(N_-,N_+]$, $\xi\in\Xi[\delta,N_-,N_+]$, and $J(\cdot)$ denote the functional from (5.3). Due to Theorem 7.2, there is an optimal control $\nu\in\mathfrak{G}^s_N$ in the problem (5.3), (5.4) with $\mathfrak{G}^s:=\mathfrak{G}^s_N$, and $J(\nu)=\mathcal{J}^{\rm sam}_{\rm opt}[N,\xi]$. By Corollary 13.4, $\nu^{\langle\delta,\varepsilon\rangle}_N\in\mathfrak{G}^s_{N-\varepsilon}$ for all $\varepsilon>0,\varepsilon\approx0$. So

$$\overline{\lim_{\varepsilon\to+0}}\,\varepsilon^{-1}\left[\mathcal{J}^{\rm sam}_{\rm opt}(N-\varepsilon,\xi)-\mathcal{J}^{\rm sam}_{\rm opt}(N,\xi)\right]\le\lim_{\varepsilon\to+0}\varepsilon^{-1}\left[J\left(\nu^{\langle\delta,\varepsilon\rangle}_N\right)-J(\nu)\right]. \tag{13.17}$$

In (13.14), (13.15), $\nmid b\nmid_f\ge0$. Hence $\lambda^k_f(\delta,N_+)\ge0$, and the inequality from (13.16) yields $\lambda^k_\varphi(\delta,N_+)<0$. This permits us to employ Lemma 13.6. Combining it with (13.11) and (13.12) shows that the right-hand side of (13.17) does not exceed $\gamma_\xi(\delta,N_-,N_+)$. So it is negative by (13.16). At the same time, the function $\mathcal{J}^{\rm sam}_{\rm opt}[N,\xi]$ of N does not decrease by Remark 7.5. So if it does not strictly increase on $[N_-,N_+]$, there would be a nontrivial interval $[N'_-,N'_+]\subset[N_-,N_+]$ on which this function would be constant in violation of (13.17) with $N\in(N'_-,N'_+)$. Thus we see that $\mathcal{J}^{\rm sam}_{\rm opt}[N,\xi]$ strictly increases on $[N_-,N_+]$. □

LEMMA 13.8. *If the set Ω is connected, the following set is open and dense in $\Xi_{(iv)}$:*

$$\Xi[N_-,N_+]:=\bigcup_{\delta\in(0,\delta_0]}\Xi[\delta,N_-,N_+]. \tag{13.18}$$

Proof. The set (13.18) is open as the union of the open sets. Let $\xi=[f(\cdot),\varphi(\cdot),a(\cdot)]\in\Xi_{(iv)}$. Define $\gamma(\delta)$ to be the right-hand side of the last formula from (13.16), where $\mathfrak{H}_k(\xi)+1$ is put in place of $\mathfrak{H}_k(\xi)$. Due to (13.14) and (13.15), $\gamma(\delta)\to0$ as $\delta\to+0$. For $z=(t,x_1,x_2)\in T\times\mathbb{R}^n\times\mathbb{R}^n$ and $u,v\in\Omega$, we put $\varphi^\delta(z,u,v):=\varphi(z,u,v)-|T|N^2_+[\gamma(\delta)+\delta]\min\left\{\frac{1}{\varkappa\delta}|u-v|,1\right\}$, $\xi^\delta:=[f(\cdot),\varphi^\delta(\cdot),a(\cdot)]$, where $\varkappa$ is taken from Lemma 13.1. By (13.14), (13.15), $\alpha^k_{\varphi^\delta}(\delta)=\alpha^k_\varphi(\delta)$, $\beta^k_{\varphi^\delta}(\delta)\le\beta^k_\varphi(\delta)-|T|N^2_+[\gamma(\delta)+\delta]$, and so $\lambda^k_{\varphi^\delta}(\delta,N_+)\le\lambda^k_\varphi(\delta,N_+)-2|T|N^2_+[\gamma(\delta)+\delta]$. Furthermore, $\xi^\delta\to\xi$ as $\delta\to+0$ owing to (4.2) and hence $\mathfrak{H}_k(\xi^\delta)\le\mathfrak{H}_k(\xi^\delta-\xi)+\mathfrak{H}_k(\xi)\le\mathfrak{H}_k(\xi)+1$ for $\delta\approx0$. This, the definition of $\gamma(\cdot)$, and (13.16) imply that $\gamma_{\xi^\delta}(\delta,N_-,N_+)\le\gamma(\delta)-[\gamma(\delta)+\delta]<0$. Thus $\xi^\delta\in\Xi[\delta,N_-,N_+]\subset\Xi[N_-,N_+]$ for all $\delta\approx0$. It remains to be noted that $\xi^\delta\to\xi$ as $\delta\to0$. □

Proof of Theorem 7.4. By Lemma 13.8, the set $\Upsilon:=\bigcap_{N_-<N_+}\Xi[N_-,N_+]$ is residual in $\Xi_{(iv)}$ if the set Ω is connected. For $\xi\in\Upsilon$, (ii) of Theorem 7.4 is immediate from Lemma 13.7. To prove (i), we pick N that exceeds the second $\overline{\lim}$ from (7.8) and consider the set $\mathfrak{R}^{\rm sam*}_\Delta$ defined by (7.1), where $q(\Delta)$ is replaced by $N\Delta$. Since $q(\Delta)\le N\Delta$ for all $\Delta\approx0$, then $\mathfrak{R}^{\rm sam}_\Delta\supset\mathfrak{R}^{\rm sam*}_\Delta$. So $\mathfrak{I}_{opt}(\Delta)\le\mathfrak{I}^*_{opt}(\Delta)$, where $\mathfrak{I}_{opt}(\Delta)$ and $\mathfrak{I}^*_{opt}(\Delta)$ are the infima of the cost functionals in problem (2.1)–(2.4) related to the classes $\mathfrak{R}^{\rm sam}_\Delta$ and $\mathfrak{R}^{\rm sam*}_\Delta$, respectively. With regard to (7.7) and (ii) of the theorem, letting $\Delta\to+0$ shows that the first $\overline{\lim}$ from (7.8) does not exceed $\mathcal{J}^{\rm sam}_{\rm opt}[N,\xi]$. Then (i) of Theorem 7.4 follows from (ii) since $\mathfrak{I}_{opt}(0)=\mathcal{J}^{\rm sam}_{\rm opt}[\infty,\xi]$ due to Remark 7.3 and (i) of Theorem 7.2.

The second and third claims of Theorem 7.4 follow from Lemmas 13.7 and 13.8. □

Proof of Theorem 4.3. This is stated by the results from Theorem 7.4, Remarks 7.3 and 7.5, and (i) of Theorem 7.2. □

14. Proofs of the statements from section 6.

Proof of Theorem 6.3. Consider the problem (2.1)–(2.4) with $f(t,x_1,x_2,u_1,u_2) := \overline{f}(t,x_1,u_1), a(t) := a_0, \varphi(t,x_1,x_2,u_1,u_2) := \overline{\varphi}(t,x_1,u_1) - B|u_1-u_2|$, where B will be specified later. This problem meets the requirements (i)–(iv) from section 2 and its natural "limit" case equals the original problem (2.5), (2.6) (i.e., (2.7) is true). By invoking Theorem 5.1 and employing the element (13.1), we get

$$\lim_{\Delta\to+0}\mathfrak{I}_{opt}(\Delta) \le \int_T dt \int_{\Omega\times\Omega} \left(\overline{\varphi}[t,x(t),u'] - B|u'-u''|\right)\,\nu(t,du',du'')$$
$$= \frac{1}{2}\int_T \left(\overline{\varphi}[t,x(t),u_1] + \overline{\varphi}[t,x(t),u_2]\right)\,dt - B(t_1-t_0)|u_1-u_2|.$$

Here $x(\cdot)$ is the solution of (5.4). Due to Lemma 8.4, $|x(t)| \le k$ for all $t \in [t_0,t_1]$. Hence

$$\lim_{\Delta\to+0}\mathfrak{I}_{opt}(\Delta) \le \overbrace{\max_{t\in[t_0,t_1],u\in\Omega,|x|\le k}|\overline{\varphi}(t,x,u)|}^{\varkappa} - B\overbrace{(t_1-t_0)|u_1-u_2|}^{\delta}.$$

By picking $B > \delta^{-1}(\varkappa - \mathfrak{I}_{opt}(0) + A)$, we arrive at (6.2) and complete the proof. □

The proof of Lemma 6.1 is prefaced by the following technical fact.

LEMMA 14.1. *Given $u(\cdot) \in \mathbb{L}_\infty([t_0-1,t_1] \to \Omega)$ and $\Delta \in [0,1]$, the symbol ν_Δ stands for the element given by* (5.8). *The function $\Delta \mapsto \nu_\Delta \in \mathfrak{G}$ is continuous.*

Proof. By [22, Theorem IV.2.4], it suffices to show that for any $\zeta(\cdot) \in \mathbb{C}(T), \rho(\cdot) \in \mathbb{Y} := \mathbb{C}(\Omega^2)$, and $\Delta \in [0,1]$,

$$\Lambda_{\Delta',\Delta}[\rho(\cdot)] := \int_T \zeta(t)\left\{\rho[u(t),u(t-\Delta')] - \rho[u(t),u(t-\Delta)]\right\}\,dt \to 0 \tag{14.1}$$

as $\Delta' \to \Delta$. Fix Δ and $\zeta(\cdot)$. All $\rho(\cdot) \in \mathbb{Y}$ such that (14.1) is true and constitute a linear subspace $\mathbb{Y}_\rho$ of $\mathbb{Y}$. We are going to show that it is closed. Indeed, let $\rho_*(\cdot) \in \overline{\mathbb{Y}_\rho}$. For any $\varepsilon > 0$, there exists $\rho(\cdot) \in \mathbb{Y}_\rho$ such that $\varkappa := \max_{\omega\in\Omega^2}|\rho(\omega)-\rho_*(\omega)| \le \varepsilon$. Then

$$|\Lambda_{\Delta',\Delta}[\rho_*(\cdot)]| \le |\Lambda_{\Delta',\Delta}[\rho_*(\cdot)-\rho(\cdot)]| + |\Lambda_{\Delta',\Delta}[\rho(\cdot)]| \le 2\varkappa\int_T|\zeta(t)|\,dt + |\Lambda_{\Delta',\Delta}[\rho(\cdot)]|;$$
$$\overline{\lim_{\Delta'\to\Delta}}\,|\Lambda_{\Delta',\Delta}[\rho_*(\cdot)]| \le 2\varepsilon\int_T|\zeta(t)|\,dt + \lim_{\Delta'\to\Delta}|\Lambda_{\Delta',\Delta}[\rho(\cdot)]| = 2\varepsilon\int_T|\zeta(t)|\,dt.$$

Letting $\varepsilon \to +0$ shows that $\rho_*(\cdot) \in \mathbb{Y}_\rho$, i.e., $\mathbb{Y}_\rho = \overline{\mathbb{Y}_\rho}$. So it suffices to prove (14.1) for $\rho(\cdot) \in \mathcal{E}$, where $\mathcal{E}$ is an arbitrary set whose linear hull is dense in $\mathbb{Y}$. This permits us to focus on the functions $\rho(\cdot)$ of the form $\rho(u',u'') = \rho_1(u')\rho_2(u''), \rho_1(\cdot),\rho_2(\cdot) \in \mathbb{C}(\Omega)$. For them,

$$|\Lambda_{\Delta',\Delta}[\rho(\cdot)]| = \left|\int_T \underbrace{\zeta(t)\rho_1[u(t)]}_{\chi(t)}\left\{\rho_2[u(t-\Delta')] - \rho_2[u(t-\Delta)]\right\}\,dt\right|$$
$$\le \operatorname{ess\,sup}_{t\in T}|\chi(t)|\int_T|r(t-\Delta')-r(t-\Delta)|\,dt, \to 0 \quad \text{as} \quad \Delta' \to \Delta,$$

where $r(t) := \rho_2[u(t)]$. Thus (14.1) is valid. □

Proof of Lemma 6.1. We denote $u_\Delta(\cdot) := u|_{[t_0-\Delta,t_1]}(\cdot) \in \mathfrak{R}_\Delta$, $\mu(\Delta) := I_\Delta(u_\Delta) - \mathfrak{I}_{opt}(\Delta)$, and employ the notation ν_Δ introduced in Lemma 14.1. Then $I_\Delta(u_\Delta) = \mathfrak{I}_{opt}(\Delta) + \mu(\Delta)$, i.e., the control u_Δ is $\mu(\Delta)$-suboptimal. Furthermore, thanks to Lemmas 8.4 and 14.1,

$$\lim_{\Delta\to 0}\mu(\Delta) = \lim_{\Delta\to 0} I_\Delta(u_\Delta) - \lim_{\Delta\to 0}\mathfrak{I}_{opt}(\Delta) = I(\nu_0) - \lim_{\Delta\to 0}\mathfrak{I}_{opt}(\Delta) = \mathfrak{I}_{opt}(0) - \lim_{\Delta\to 0}\mathfrak{I}_{opt}(\Delta),$$

which implies (6.1) and completes the proof. □

CONVEX OPTIMAL CONTROL PROBLEMS WITH SMOOTH HAMILTONIANS*

RAFAL GOEBEL†

Abstract. Optimal control problems with convex costs, for which Hamiltonians have Lipschitz continuous gradients, are considered. Examples of such problems, including extensions of the linear-quadratic regulator with hard and possibly state-dependent control constraints, and piecewise linear-quadratic penalties are given. Lipschitz continuous differentiability and strong convexity of the terminal cost are shown to be inherited by the value function, leading to Lipschitz continuity of the optimal feedback. With no regularity assumptions on the limiting problem, epi-convergence of costs, which can be equivalently described by pointwise convergence of Hamiltonians, is shown to guarantee epi-convergence of value functions. Resulting schemes of approximating any concave-convex Hamiltonian by continuously differentiable ones are displayed. Auxiliary results about existence and stability of saddle points of quadratic functions over polyhedral sets are also proved. Tools used are based on duality theory of convex and saddle functions.

Key words. optimal control, differentiable Hamiltonian, convex value function, optimal feedback regularity, conjugate duality, epi-convergence, piecewise linear-quadratic function, saddle function

1. Introduction.

Given a point $(\tau, \xi) \in (-\infty, T] \times \mathbb{R}^n$, a *terminal cost* $g : \mathbb{R}^n \mapsto \overline{\mathbb{R}}$ and a *Lagrangian* $L : \mathbb{R}^{2n} \mapsto \overline{\mathbb{R}}$, consider the generalized problem of Bolza:

$$\mathcal{P}(\tau, \xi): \quad \text{minimize } \int_{\tau}^{T} L(x(t), \dot{x}(t))\, dt + g(x(T)) \text{ subject to } x(\tau) = \xi, \tag{1}$$

with the minimization carried out over all absolutely continuous arcs $x : [\tau, T] \mapsto \mathbb{R}^n$. While it is well known that a smooth Lagrangian need not lead to a regular (maximized) *Hamiltonian*, which is defined by

$$H(x, y) = \sup_{v \in \mathbb{R}^n} \{y \cdot v - L(x, v)\}, \tag{2}$$

it is less appreciated that nonsmooth and infinite-valued L may give rise to a smooth H. We explore this fact here, focusing on problems with convex g and L, and with Hamiltonians for which ∇H is Lipschitz continuous.

Optimal control problems with explicit linear dynamics, hard and possibly state-dependent control constraints, and state and control penalties can be reformulated in Bolza format; see Clarke [10] or Rockafellar [18]. In section 2 we show that a broad range of optimal control problems, including various extensions of the classical linear-quadratic regulator, can lead to a smooth Hamiltonian. This makes the results of section 3 applicable to the control framework.

Section 3 studies regularity of the *value function* $V : (-\infty, T] \times \mathbb{R}^n \mapsto \overline{\mathbb{R}}$, defined as the optimal value in $\mathcal{P}(\tau, \xi)$ parameterized by the initial condition. Lipschitz continuity of ∇g and ∇H is shown to lead to Lipschitz ∇V; explicit bounds on the constants are given. We stress that no smoothness or even finiteness assumptions are made on L. For comparison, in a nonconvex setting, if the method of characteristics associated with the Hamilton–Jacobi equation has no shocks (in our setting, this automatically holds; see Goebel [14]), the value function inherits continuous differentiability from that of the terminal cost, under further regularity assumptions on L; see Byrnes and Frankowska [7] and also Caroff and Frankowska [8]. We note that while we work with continuously differentiable Hamiltonians, we do not require them to be C^2. This raises an obstacle to Riccati-like descriptions of V as given by Byrnes [6] and Caroff and Frankowska [9] but allows for treatment of problems discussed in section 2 (for those, hard constraints or piecewise linear-quadratic penalties exclude C^2 smoothness of the Hamiltonian).

Our interest in Lipschitz continuity of ∇V comes from the role the gradient plays in constructing optimal feedback. With the regularity of H and V as just mentioned, the adjoint variable to an optimal arc $x(t)$ is just $-\nabla V(t, x(t))$, and the resulting optimal feedback mapping is continuous and Lipschitz in the state variable. Consequently, the classical differential equation tools and existence and uniqueness results apply. This is not the case for the general convex but nonsmooth setting—there, the resulting set-valued feedback may be highly irregular, even for piecewise linear-quadratic costs; see Goebel [14].

In section 4 we show that regular Bolza problems—those with Lipschitz ∇g and ∇H—can approximate any convex problem fitting our mild growth conditions. The approximations are explicit and, together with direct proofs in section 3, they should yield insights to numerical implementation of the method of characteristics. The approximations rely on a more general result concluding the convergence of value functions, defined by any converging to g and L sequences of initial costs and Lagrangians. As the functions in question need not be finite, we rely on the concept of epi-convergence. Its extensions to infinite dimensions, where various topologies have to be considered, have been used to study control problems; see Buttazzo and Dal Maso [5] and Briani [4]. These works, while not requiring full convexity, had stricter growth assumptions and finite cost functions, and dealt, respectively, with convergence of optimal solutions and pointwise convergence of value functions. Moreover, methods used here are significantly different; we employ a dual problem leading to a dual value function, as described by Rockafellar and Wolenski [27]. The symmetry between the primal and dual problem, and the fact that epi-convergence is preserved by convex conjugacy (vaguely speaking, the "lower half" of epi-convergence dualizes to the "upper" and vice-versa), requires us to show just one side (the easier one) of epi-convergence. A similar idea was employed by Joly and Thelin [17] in the study of convex integral functionals; here we keep to a minimum the discussion of such issues, preferring to work with functions on finite-dimensional spaces.

Some of our results are most conveniently handled with the tools related to conjugacy and epi/hypo-convergence of saddle functions; see, respectively, chapters 33–37 in Rockafellar [19], Attouch and Wets [2], and Attouch, Azé, and Wets [1]. We present the necessary background in section 5. In particular, our results on finiteness and differentiability of piecewise linear-quadratic Hamiltonians are closely related to existence and uniqueness of saddle points of an auxiliary quadratic function defined on a product of polyhedral sets. Such a function also appears as a Lagrangian in ex-

tended linear-quadratic programming; see Rockafellar [25]. (In convex optimization, Lagrangians are saddle functions used, in particular, to express optimality conditions.)

2. Extended piecewise linear-quadratic optimal control. In this section we illustrate that control problems with constraints and nondifferentiable costs can possess Hamiltonians with desirable smoothness properties. Let us start with the following example.

Example 2.1 (separable smooth Hamiltonian). Suppose that $L(x,v) = k(x) + l(v)$, and l is a convex function. Then the Hamiltonian $H(x,y)$ is differentiable and ∇H is (globally) Lipschitz continuous if and only if k has this property and l is strongly convex (that is, $v \mapsto l(v) - \rho\|v\|^2$ is convex for some $\rho > 0$). Indeed, $H(x,y) = -k(x) + l^*(y)$, where $l^*(y) = \sup_v \{y \cdot v - l(v)\}$ is the convex function conjugate to l. The statement about differentiability of l^*, and the bound $(2\rho)^{-1}$ on its Lipschitz constant, can be found in [26, Proposition 12.60]. Strongly convex functions include functions of the form $l(v) = v \cdot Pv$ for $v \in C$ while $l(v) = +\infty$ for $v \notin C$, where P is a symmetric positive definite matrix and C is any convex set, but the (piecewise) quadratic structure is not necessary. For example, the "barrier function" $l(v) = -\log(1 - |v|)$ for $v \in (-1,1)$, $l(v) = +\infty$ otherwise, is strongly convex (note the nondifferentiability at the origin), we have $l^*(y) = 0$ for $y \in [-1,1]$, $l^*(y) = |y| - \log|y| - 1$ otherwise, and l^* has a Lipschitz continuous gradient.

In the remainder of this section, we discuss control problems with explicit mention of controls, dynamics, constraints, and penalties. Translating such problems to the generalized format of Bolza (1) is possible; see Clarke [10] for a general exposition or Rockafellar [18] for details in the convex case. This enables the translation of results of sections 3 and 4 to the control setting. As finiteness of the Hamiltonian and of the value function implies that an optimal arc $x(\cdot)$ has a bounded derivative—in the control setting below, $u(\cdot)$ is bounded—the potential discrepancy between minimizing over absolutely continuous arcs in $\mathcal{P}(\tau,\xi)$ and over L^2 controls in the linear-quadratic regulator is avoided in most cases under discussion.

Separable Hamiltonians of Example 2.1, and their biaffine perturbations given by $H(x,y) = y \cdot Ax - k(x) + l^*(y)$, appear, for example, in the linear-quadratic regulator with control constraints of the type $u(t) \in U$. However, state-dependent constraints $u(t) \le Cx(t) + d$ or mixed control and state penalties call for the analysis of a more general class of Hamiltonians.

Given vectors p, q; matrices A, B, C, D, P, Q; and sets U, V of appropriate dimensions, consider the following control problem $\mathcal{C}(\tau,\xi)$:

$$\begin{aligned} &\min \int_\tau^T \left[p \cdot u(t) + \frac{1}{2} u(t) \cdot Pu(t) + \rho_{V,Q}(q - Cx(t) - Du(t)) \right] dt + g(x(T)) \\ &\text{s.t.} \qquad \dot{x}(t) = Ax(t) + Bu(t), \quad u(t) \in U \text{ a.e.}, \quad x(\tau) = \xi, \end{aligned} \tag{3}$$

with the minimization carried out over all integrable controls $u : [\tau, T] \mapsto \mathbb{R}^k$. The convex and possibly infinite-valued penalty function $\rho_{V,Q}(\cdot)$ is given by

$$\rho_{V,Q}(s) = \sup_{v \in V} \left\{ s \cdot v - \frac{1}{2} v \cdot Qv \right\}. \tag{4}$$

The key assumptions, guaranteeing not only the convex structure of the problem, but also the piecewise linear-quadratic structure of the resulting Hamiltonian, is stated below. We recall that a set is polyhedral if it is the intersection of finitely many

closed half-spaces; consequently, a polyhedral set is always closed and convex (but not necessarily bounded).

$$\begin{array}{c}\text{Matrices } P \text{ and } Q \text{ are symmetric positive semidefinite.}\\ \text{Sets } U \text{ and } V \text{ are nonempty and polyhedral.}\end{array} \tag{5}$$

Such *extended piecewise linear-quadratic optimal control* format was proposed by Rockafellar [22]. Therein, optimality conditions taking advantage of duality were stated. Their minimax form (related to the structure of the Hamiltonian as outlined in Example 5.1 and the surrounding discussion) facilitates the use of various primal-dual optimization methods to discretized problems; see Rockafellar and Zhu [28], Wright [29], and Zhu [30].

Here, we begin by describing when the control problem (3) fits the convex duality framework of Rockafellar and Wolenski [27], we call upon some of their results in later sections. The Hamiltonian for $\mathcal{C}(\tau,\xi)$ (see Rockafellar [23] or apply (2) to the Lagrangian (11)) is

$$H(x,y) = y\cdot Ax + J^*(B^*y, Cx), \tag{6}$$

where the function J^*, convex in a and concave in b, is given by

$$J^*(a,b) = \sup_{u\in U}\inf_{v\in V}\left\{a\cdot u + b\cdot v - p\cdot u - \frac{1}{2}u\cdot Pu + q\cdot v + \frac{1}{2}v\cdot Qv + v\cdot Du\right\}. \tag{7}$$

Here and in what follows, B^* denotes the transpose of B. The Hamiltonian (and the Lagrangian (11)) are piecewise linear-quadratic: their effective domains are unions of finitely many polyhedral sets, relative to each of which the functions are linear-quadratic (Goebel [12]). Goebel and Rockafellar [15] showed that if a piecewise linear-quadratic Hamiltonian is finite, the control problem fits the framework of [27]. A particular consequence of such a structure of the Hamiltonian, shown in [15], is that the knowledge of $V(\overline{\tau},\cdot)$ at any particular $\overline{\tau}\in(-\infty,T]$ determines V (uniquely) for all times $\tau\in(-\infty,T]$.

In our setting, the finiteness of J^*, which implies that of the Hamiltonian, is described by the following result. For a given set S, the *recession cone* S^∞ consists of all z such that $S+z\subset S$, while for a cone K, the polar cone K^* is $\{w \mid w\cdot z\le 0 \text{ for all } z\in K\}$.

THEOREM 2.2 (finiteness of J^*). *Assume that* (5) *holds. Then, the function J^* is finite if and only if the following is satisfied:*

$$\begin{cases} U^\infty\cap\ker P\cap(-D^*V^\infty)^* = \{0\},\\ V^\infty\cap\ker Q\cap(DU^\infty)^* = \{0\}.\end{cases} \tag{8}$$

Above, $(DU^\infty)^* = \{w \mid D^*w\in U^{\infty *}\}$ and $(-D^*V^\infty) = \{z \mid -Dz\in V^{\infty *}\}$, this comes directly from the definitions. The proof of Theorem 2.2, as well as that of Theorem 2.4, requires some notions of saddle function theory. We present them and the proofs in section 5. Note that if D is the zero matrix (which excludes many modeling options), the function J^* is separable: $J^*(a,b) = \sup_{u\in U}\{a\cdot u - \frac{1}{2}u\cdot Pu\} - \sup_{v\in V}\{-b\cdot v - \frac{1}{2}v\cdot Qv\}$, and (8) reduce to known conditions on recession cones and kernels, we mention them in the discussion preceding Example 3.8.

COROLLARY 2.3. *Assume that* (5) *holds.*

(a) *If U is a bounded set, J^* is finite if and only if $V^\infty\cap\ker Q = \{0\}$ (and this holds in particular when V is bounded or Q is positive definite).*

(b) *When sets U and V are cones, J^* is finite if and only if*

$$\begin{cases} U \cap \ker P \cap (-D^*V)^* = \{0\}, \\ V \cap \ker Q \cap (DU)^* = \{0\}. \end{cases}$$

Arguments of Example 2.1 imply that in the separable case, as described before Corollary 2.3, positive definiteness of P and Q is equivalent to the differentiability of J^*. Below, we give a sufficient condition for differentiability, applicable to cases where $D \neq 0$ and not requiring the positive definiteness of P and Q. A somewhat extreme example, showing that this last property is not necessary, is as follows. For a and b one-dimensional, consider J^* with $p = q = P = Q = 0$, $D = 1$, and $U = V = \mathbb{R}$. Direct calculation shows that $J^*(a, b) = ab$.

THEOREM 2.4 (differentiability of J^*). *Assume that the following condition holds:*

$$\begin{cases} \ker P \cap [D^*(V^\infty \cap -V^\infty)]^\perp = \{0\}, \\ \ker Q \cap [D(U^\infty \cap -U^\infty)]^\perp = \{0\}. \end{cases} \tag{9}$$

Then J^* is differentiable and ∇J^* is Lipschitz continuous.

Lipschitz continuity of ∇J^*, while guaranteed by the proof, is automatic in the presence of differentiability of J^*. This is thanks to the piecewise linear-quadratic structure; if J^* is differentiable, then ∇J^* is piecewise affine (and there is finitely many pieces). The piecewise linear-quadratic structure furthermore implies that J^* is not C^2, unless it is in fact quadratic (and this excludes any hard constraints or piecewise linear-quadratic penalties in the underlying problem).

In the remainder of this section, we illustrate the modeling capabilities of the extended piecewise linear-quadratic control, and use Theorem 2.4 to conclude the differentiability of the Hamiltonian for various extensions of the linear-quadratic regulator. Computational methods for such problems in discrete time are of great interest in the engineering literature; see Bemporad et al. [3] and the references therein.

Given symmetric positive semidefinite matrices E and G and a symmetric and positive definite F, this classical problem is as follows:

$$\begin{aligned} &\min \int_\tau^T \frac{1}{2}\left(x(t) \cdot Ex(t) + u(t) \cdot Fu(t)\right) dt + \frac{1}{2} x(T) \cdot Gx(T), \\ &\text{s.t.} \qquad \dot{x}(t) = Ax(t) + Bu(t), \quad x(\tau) = \xi. \end{aligned} \tag{10}$$

Minimization is carried out over all L^2 controls $u(\cdot)$ on $[\tau, T]$ (optimal controls turn out to be bounded, and in fact continuous). The value function for (10) is $V(\tau, \xi) = \frac{1}{2}\xi \cdot S(\tau)\xi$, where the matrix $S(\cdot)$ solves the associated Riccati equation, the Hamiltonian is quadratic, and the optimal feedback is linear in the state. Results of section 3 will show that while constraints and penalties destroy the linear structure, the optimal feedback may still be Lipschitz continuous. Here, we focus on the regularity of the Hamiltonian.

The linear-quadratic regulator can of course be cast in the format (3), by taking

$$P = F,\ Q = I,\ U = \mathbb{R}^k,\ V = \mathbb{R}^n,\ C = \sqrt{E},\ D = 0,\ p = 0,\ q = 0.$$

Indeed, we obtain $\rho_{V,Q}(q - Cu - Dv) = \sup_v\{(-\sqrt{E}u) \cdot v - \frac{1}{2}v \cdot v\} = \frac{1}{2}u \cdot \sqrt{E}^* \sqrt{E}u$. It can be easily verified that conditions (8) and (9) are (obviously) satisfied.

Example 2.5 (fixed control constraints). A linear-quadratic regulator with a constraint $u(t) \in U$, for a nonempty polyhedral set U, certainly fits the format (3).

Thanks to the positive definiteness of $P = F$ and $Q = I$, conditions (8) and (9) hold, and thus the Hamiltonian is finite and differentiable (if U is bounded, the Hamiltonian remains finite but not differentiable if the matrix F is just positive-semidefinite). Direct calculation yields $J^*(a,b) = \rho_{U,F}(a) - \frac{1}{2}\|b\|^2$, and thus the Hamiltonian is $H(x,y) = y \cdot Ax - \frac{1}{2}x \cdot Ex + \rho_{U,F}(B^*y)$. Note that H is not C^2.

Example 2.6 (state-dependent inequality constraints on controls). Consider (10) with the following constraint on the control:

$$u(t) \le C_0 x(t) - q_0,$$

for some matrix C_0. Taking $U = \mathbb{R}^k,\ V = \mathbb{R}^n \times \mathbb{R}^k_+,\ P = F,\ p = 0$, and

$$Q = \begin{bmatrix} I_{n\times n} & 0_{n\times k} \\ 0_{k\times n} & 0_{k\times k} \end{bmatrix},\ q = \begin{bmatrix} 0_{n\times n} \\ q_0 \end{bmatrix},\ C = \begin{bmatrix} \sqrt{E} \\ C_0 \end{bmatrix},\ D = \begin{bmatrix} 0_{n\times k} \\ -I_{k\times k} \end{bmatrix},$$

where 0_n is a zero vector in $\mathbb{R}^n$, $0_{n\times k}$ is the zero matrix of appropriate dimension, etc., casts the problem in the framework of (3). We get, for $s = \begin{pmatrix} s_1 \\ s_2 \end{pmatrix}$ with $s_1 \in \mathbb{R}^n$, $s_2 \in \mathbb{R}^k$,

$$\begin{aligned}\rho_{V,Q}(s) &= \sup_{v\in V}\left\{s\cdot v - \frac{1}{2}v\cdot Qv\right\} = \sup_{v_1\in\mathbb{R}^n, v_2\in\mathbb{R}^k_+}\left\{s_1\cdot v_1 + s_2\cdot v_2 - \frac{1}{2}v_1\cdot v_1\right\} \\ &= \sup_{v_1\in\mathbb{R}^n}\left\{s_1\cdot v_1 - \frac{1}{2}v_1\cdot v_1\right\} + \sup_{v_2\in\mathbb{R}^k_+}\{s_2\cdot v_2\} = \frac{1}{2}|s_1|^2 + \delta_{\mathbb{R}^k_-}(s_2),\end{aligned}$$

and thus, since

$$q - Cx - Du = \begin{pmatrix} -\sqrt{E}x \\ q_0 - C_0x + u \end{pmatrix},$$

expression $\rho_{V,Q}(q - Cu - Dv)$ equals

$$\frac{1}{2}x\cdot Ex + \delta_{\mathbb{R}^k_-}(q_0 - C_0x + u) = \frac{1}{2}x\cdot Ex + \begin{cases} 0 & \text{if } u \le C_0x - q_0, \\ +\infty & \text{otherwise.}\end{cases}$$

As desired, the penalty function enforces the inequality constraint.

We now check the finiteness and differentiability of the Hamiltonian. First, conditions in both (8) and (9) are satisfied since P is positive definite. We have $V^\infty = V$, $\ker Q = \{0_n\}\times\mathbb{R}^k$, and, since $U^{\infty *} = 0_n$, $(DU^\infty)^* = \{w \mid [0_{n\times n}, I_{k\times k}]w = 0\} = \mathbb{R}^n \times 0_k$; thus the second condition for finiteness is satisfied. Similarly, $[D(U^\infty \cap -U^\infty)]^\perp = \mathbb{R}^n \times 0_k$, and the Hamiltonian is differentiable.

Example 2.7 (state-dependent control constraints through quadratic penalties). Adding to the integrand in (10) the penalty function

$$\sum_{i=1}^{s}\begin{cases} 0 & \text{if } q_i - c_i\cdot x(t) - d_i\cdot u(t) \le 0, \\ \frac{1}{2}\lambda_i\left(q_i - c_i\cdot x(t) - d_i\cdot u(t)\right)^2 & \text{if } q_i - c_i\cdot x(t) - d_i\cdot u(t) > 0,\end{cases}$$

with $\lambda_i > 0$ leads to another problem in the extended piecewise linear-quadratic format. Indeed, set $U = \mathbb{R}^k,\ V = \mathbb{R}^n \times \mathbb{R}^s_+,\ P = F,\ p = 0$, and

$$Q = \begin{bmatrix} I_{n\times n} & 0_{n\times s} \\ 0_{s\times n} & \Lambda^{-1} \end{bmatrix},\ q = \begin{bmatrix} 0_{n\times n} \\ q_1 \\ \vdots \\ q_s \end{bmatrix},\ C = \begin{bmatrix} \sqrt{E} \\ c_1 \\ \vdots \\ c_s \end{bmatrix},\ D = \begin{bmatrix} 0_{n\times k} \\ d_1 \\ \cdots \\ d_s \end{bmatrix},$$

where Λ is a diagonal matrix with diagonal entries λ_i. It can be verified that the corresponding Hamiltonian function is finite and continuously differentiable (but not C^2).

We add that combining penalty functions from Example 2.7, with constraints of either Example 2.5 or 2.6, is possible in the extended piecewise linear-quadratic format. Moreover, these suggested combinations will lead to a differentiable Hamiltonian. In section 3 we will return to the examples above to describe the corresponding optimal feedback mappings.

3. Value function regularity. Techniques used in this and the following sections will rely in part on the Hamilton–Jacobi and duality theories developed for convex control problems in Rockafellar and Wolenski [27]. The required assumptions on the problem $\mathcal{P}(\tau,\xi)$ defined in (1), which we pose throughout this section, are stated below. The growth conditions in (A2), (A3) are quite mild, their detailed discussions can be found in [27] and also Goebel [14].

Assumption 3.1 (basic assumptions).

(A1) The functions $g:\mathbb{R}^n \mapsto \overline{\mathbb{R}}$ and $L:\mathbb{R}^{2n} \mapsto \overline{\mathbb{R}}$ are proper, l.s.c., and convex.

(A2) The set $F(x) = \{v \mid L(x,v) < \infty\}$ is nonempty for all x, and there is a constant ρ such that $\operatorname{dist}(0,F(x)) \le \rho(1+|x|)$ for all x.

(A3) There exist constants α, β and a coercive, proper, nondecreasing function $\theta(\cdot)$ on $[0,\infty)$ such that $L(x,v) \ge \theta(\max\{0,|v|-\alpha|x|\}) - \beta|x|$ for all x and v.

The symbol $\overline{\mathbb{R}}$ stands for the interval $[-\infty,+\infty]$, a function $f:\mathbb{R}^n \mapsto \overline{\mathbb{R}}$ is said to be proper if it does not take on the value $-\infty$, and its effective domain $\operatorname{dom} f = \{x \mid f(x) < +\infty\}$ is nonempty; a function f is called coercive if $\lim_{|x|\to+\infty} \frac{f(x)}{|x|} = +\infty$.

Example 3.2 (piecewise linear-quadratic Lagrangian). Translating the control problem $\mathcal{C}(\tau,\xi)$ discussed in section 2 to the format of Bolza (1) (see [10] or [18]) leads to the Lagrangian

$$L(x,v) = \inf_u \left\{ p\cdot u + \frac{1}{2}u\cdot Pu + \rho_{V,Q}(q - Cx - Du) \mid v = Ax + Bu, u \in U \right\}. \tag{11}$$

In particular, the value function defined by (1) with the Lagrangian (11) is the same as that defined by (3). If (5) holds and the corresponding Hamiltonian (6) is finite (as is always the case if conditions (8) are in place), then the Lagrangian above satisfies Assumption 3.1; see [15, Corollary 4.5].

A key tool for the analysis of the regularity of the value function V is the global description of the graph of $\partial_\xi V(\tau,\cdot)$ as the image of $\operatorname{gph}\partial g$ under a certain flow mapping. Here, and in what follows, $\partial_\xi V$ denotes the subdifferential in the sense of convex analysis, of the convex function $\xi \mapsto V(\tau,\xi)$; the subdifferentials ∂g and $\partial_y H$ should also be understood in the convex sense; see Rockafellar [19, section 23]. The subdifferential $\tilde{\partial}_x H(x,y)$ of the concave function $H(\cdot,y)$ equals $-\partial_x(-H(x,y))$. If any of the mentioned functions are differentiable, the subdifferential reduces to the gradient. Consider the Hamiltonian inclusion

$$-\dot{y}(t) \in \tilde{\partial}_x H(x(t),y(t)), \quad \dot{x}(t) \in \partial_y H(x(t),y(t)). \tag{12}$$

A pair of absolutely continuous arcs $(x(\cdot),y(\cdot))$ on $[a,b]$ will be called a *Hamiltonian trajectory* if it satisfies (12) for almost all $t \in [a,b]$.

THEOREM 3.3 (flow of the value function). *One has $\eta \in \partial_\xi V(\tau,\xi)$ if and only if, for some $\eta^T \in \partial g(\xi^T)$, there is a Hamiltonian trajectory on $[T-\tau,T]$ from $(\xi,-\eta)$ to $(\xi^T,-\eta^T)$.*

The above result was shown by Rockafellar and Wolenski [27], as Theorem 2.4, in the setting of control problems with an initial cost function, and for which the value function is parameterized by a terminal constraint. A change of variables in the expression for the value function yields the result as described above.

In a less convex setting, descriptions of the (appropriately understood) subdifferential of the value function in the flavor of Theorem 3.3 are possible in some local sense, as long as the image of the subdifferential of the terminal cost under the Hamiltonian flow remains a subdifferential of a function—this is the case in our convex setting for any length of the time interval $[\tau, T]$. Under stronger smoothness assumptions than used here, the Hessian of the value function may then turn out to be a solution of an appropriate matrix Riccati differential equation; see Byrnes [6] and Caroff and Frankowska [9].

To illustrate Theorem 3.3, we show that a piecewise linear-quadratic problem need not yield a piecewise linear-quadratic value function. This is in contrast to discrete time problems.

Example 3.4 (loss of piecewise linear-quadratic structure). Consider a one-dimensional problem of Bolza with the cost functions

$$L(x,v) = \frac{1}{2}v^2 + \begin{cases} 0, & x<0,\\ \frac{1}{2}x^2, & x\geq 0,\end{cases} \qquad g(x) = \frac{1}{2}(x+3)^2.$$

The corresponding Hamiltonian is piecewise linear-quadratic and differentiable, and its gradient is piecewise linear:

$$H(x,y) = \begin{cases} \frac{1}{2}y^2, & x<0,\\ -\frac{1}{2}x^2+\frac{1}{2}y^2, & x\geq 0,\end{cases} \qquad \nabla H(x,y) = \begin{cases} (0,y), & x<0,\\ (-x,y), & x\geq 0.\end{cases}$$

A Hamiltonian trajectory $(x(\cdot), y(\cdot))$ must satisfy $\dot{x}(t) = y(t) = const$ when $x(t) < 0$, and $x(t) = \alpha e^t + \beta e^{-t}$, $y(t) = \alpha e^t - \beta e^{-t}$ for suitably chosen α, β when $x(t) > 0$.

The segment between $(-2,-1)$ and $(-1,-2)$ is contained in $\operatorname{gph}(-\nabla g)$. Parameterize the segment by $(x_s(T), y_s(T)) = (s-2, -s-1)$ with $s \in [0,1]$. Hamiltonian trajectories terminating at $(x_s(T), y_s(T))$ are given by

$$(x_s(t), y_s(t)) = \begin{cases} \Big((s+1)(T-t)+s-2, -s-1\Big), & 0\leq T-t\leq \frac{2-s}{s+1},\\ (s+1)\Big(\sinh(T-t-\frac{2-s}{s+1}), -\cosh(T-t-\frac{2-s}{s+1})\Big), & T-t\geq \frac{2-s}{s+1}.\end{cases}$$

It is easy to check that for any $t < T-1$, the set $\{(x_s(t), y_s(t)), s\in[0,1]\}$ is not a straight line segment, nor is it a union of segments. But $\{(x_s(t), y_s(t)), s\in[0,1]\} \subset \operatorname{gph} -\partial_\xi V(T-t,\cdot)$, and consequently, $V(T-t,\cdot)$ is not piecewise linear-quadratic.

LEMMA 3.5. *Suppose that H is differentiable and ∇H is Lipschitz continuous with constant K. Let $g(x) = \frac{1}{2}a\|x\|^2 + b\cdot x + c$, with $a>0$. Then, for all $\tau \leq T$,*

(a) *$V(\tau,\cdot)$ is differentiable with $\nabla_\xi V(\tau,\cdot)$ Lipschitz continuous, with constant*

$$a\left[1+\left(e^{K(T-\tau)}-1\right)\sqrt{1+a^{-2}}\right]^2;$$

(b) *$V(\tau,\cdot)$ is strongly convex with constant*

$$a\left[1+\left(e^{K(T-\tau)}-1\right)\sqrt{1+a^{2}}\right]^{-2}.$$

Proof. Fix $\tau \le T$. Pick two points, $\xi_1^T \ne \xi_2^T$ in $\mathbb{R}^n$, and let $\eta_i^T = \nabla g(\xi_i^T) = a\,\xi_i^T + b$, $i = 1, 2$. Let $(x_i(\cdot), y_i(\cdot))$ be the Hamiltonian trajectory on $[\tau, T]$ with $(x_i(T), y_i(T)) = (\xi_i^T, -\eta_i^T)$ for $i = 1, 2$. As ∇H is Lipschitz continuous, the Hamiltonian trajectories and the endpoints just mentioned are well defined. To shorten the notation, let $\alpha(t) = x_1(t) - x_2(t)$, $\beta(t) = y_1(t) - y_2(t)$.

The monotone structure of ∇H implies that $\alpha(t) \cdot \beta(t)$ is a nondecreasing function of t; see Theorem 4 in [20]—this is a distinguishing feature of a convex problem. Consequently,

$$-\|\alpha(\tau)\|\,\|\beta(\tau)\| \le \alpha(\tau) \cdot \beta(\tau) \le \alpha(T) \cdot \beta(T) = -a\|\alpha(T)\|^2,$$

and thus $\|\alpha(\tau)\|\,\|\beta(\tau)\| \ge a\|\alpha(T)\|^2$. Lipschitz continuity of ∇H implies that

$$\|\beta(\tau)\| \le \|\beta(T)\| + \left(e^{K(T-\tau)} - 1\right) \|(a(T), b(T))\|. \tag{13}$$

Maximizing $\|\beta(\tau)\|/\|\alpha(\tau)\|$ subject to the last two inequalities (this is a simple two-dimensional calculus problem) yields

$$\frac{\|\beta(\tau)\|}{\|\alpha(\tau)\|} \le \frac{\|\beta(T)\| + \left(e^{K(T-\tau)} - 1\right) \|(a(T), b(T))\|}{a\|\alpha(T)\|^2 \Big/ \left[\|\beta(T)\| + \left(e^{K(T-\tau)} - 1\right) \|(a(T), b(T))\|\right]},$$

which simplifies to $\|\beta(\tau)\|/\|\alpha(\tau)\| \le a\left[1 + \left(e^{K(T-\tau)} - 1\right)\sqrt{1 + a^{-2}}\right]^2$, since $\beta(T) = -a\,\alpha(T)$. Thanks to Theorem 3.3, the last bound is in fact a bound on $\|\eta_1 - \eta_2\|/\|\xi_1 - \xi_2\|$ over all (ξ_i, η_i) such that $\eta_i \in \partial_\xi V(\tau, \xi_i)$, $i = 1, 2$. This shows (a).

A lower bound on $\|\eta_1 - \eta_2\|/\|\xi_1 - \xi_2\|$ and the relationship between strong convexity of a convex function and the Lipschitz continuity of the gradient of its conjugate [26, Proposition 12.60] yield (b); see also Example 4.2. □

THEOREM 3.6 (Lipschitz gradient). *Assume that H is differentiable and ∇H is Lipschitz continuous with constant K.*

(a) *Suppose that g is differentiable and ∇g is Lipschitz with constant γ_0. Then $V(\tau, \cdot)$ is differentiable for all $\tau < T$, and there exists a continuous function $\gamma : (-\infty, T] \mapsto \mathbb{R}$ with $\gamma(T) = \gamma_0$ such that $\nabla_\xi V(\tau, \cdot)$ is Lipschitz with constant $\gamma(\tau)$.*

(b) *Suppose that g is strongly convex with constant δ_0. Then there exists a continuous (and positive) function $\delta : (-\infty, T] \mapsto \mathbb{R}$ with $\delta(T) = \delta_0$ such that for all $\tau < T$, $V(\tau, \cdot)$ is strongly convex with constant $\delta(\tau)$.*

In fact, one can choose $\gamma(\tau) = \frac{c^2-1}{2c}$ with $c = (\gamma_0 + \sqrt{1 + \gamma_0^2})e^{2K(T-\tau)}$, and $\delta(\tau) = \frac{2d}{d^2-1}$ with $d = \left(\delta_0^{-1} + \sqrt{1 + \delta_0^{-2}}\right)e^{2K(T-\tau)}$. In particular, $\gamma(\tau) \le (\gamma_0 + \frac{1}{2})e^{2K(T-\tau)}$ and $\delta(\tau) \ge \frac{2\delta_0}{2+\delta_0}e^{-2K(T-\tau)}$.

Proof. The gradient of a differentiable convex function f is Lipschitz continuous with constant a if and only if, for all x, x',

$$f(x') \le f(x) + \nabla f(x) \cdot (x' - x) + \frac{1}{2}a\|x' - x\|^2; \tag{14}$$

see Proposition 12.60 in [26]. If g is as assumed in (a), we have for any x, x', $g(x') \le \overline{g}^x(x')$, where $\overline{g}^x(x') = g(x) + \nabla g(x) \cdot (x' - x) + \frac{1}{2}\gamma_0\|x' - x\|^2$. Then for any $\tau \le T$, $V(\tau, \xi) \le \overline{V}^x(\tau, \xi)$, where $\overline{V}^x(\tau, \cdot)$ is the value function corresponding to the initial cost g_x. The latter value function is differentiable, as shown in Lemma

3.5. Also, $V(\tau,\xi_x) = \overline{V}^x(\tau,\xi_x)$, where ξ_x is the first coordinate of the initial point of the Hamiltonian trajectory on $[\tau,T]$ terminating at $(x,-\nabla g(x))$; this follows from Theorem 3.3 and from the optimality of the first arc constituting the mentioned Hamiltonian trajectory in the definition of both value functions. Consequently, $V(\tau,\cdot)$ is also differentiable at ξ_x, and $\nabla_\xi V(\tau,\xi_x) = \nabla_\xi \overline{V}^x(\tau,\xi_x)$. Now, Lemma 3.5 implies that the gradient of $\overline{V}^x(\tau,\cdot)$ is Lipschitz continuous with constant γ' as described in (a) of the lemma. Combining this, the inequality (14), and the comparison between $V(\tau,\cdot)$ and $\overline{V}^x(\tau,\cdot)$ yields

$$V(\tau,\xi) \le V(\tau,\xi_x) + \nabla_\xi V(\tau,\xi_x) + \frac{1}{2}\gamma'\|\xi-\xi_x\|^2.$$

In light of Theorem 3.3 this bound holds for any ξ, ξ', and thus $\nabla_\xi V(\tau,\cdot)$ is Lipschitz continuous with constant γ'.

The Optimality Principle and time-invariance of the Hamiltonian allow us to derive, through arguments similar to those above, a Lipschitz constant for $\nabla_\xi V(\tau',\cdot)$ given a constant for $\nabla_\xi V(\tau,\cdot)$, with $\tau' < \tau$. Let $\gamma(t)$ denote the (smallest possible) Lipschitz constant for $\nabla_\xi V(t,\cdot)$. Then $\gamma(\tau') \le \gamma(\tau)[1+(e^{K(\tau-\tau')}-1)\sqrt{1+\gamma(\tau)^{-2}}]^2$ whenever $\gamma(\tau) > 0$; a similar bound can be obtained for the case of $\gamma(\tau) = 0$ for small values of $\tau-\tau'$ (by estimating $\|a(\tau')\|$, $\|b(\tau')\|$ from the proof of Lemma 3.5 as in (13)). Consequently, we can show that

$$\liminf_{\tau'\to\tau} \frac{\gamma(\tau')-\gamma(\tau)}{\tau'-\tau} \ge -2K\sqrt{1+\gamma^2(\tau)}.$$

Thus $\gamma(\tau) \le \phi(\tau)$, where ϕ is the solution of $\phi'(t) = -2K\sqrt{1+\phi^2(t)}$, $\phi(T) = \gamma_0$. This yields the bound at the end of Theorem 3.6 and proves (a).

A direct proof of (b) is symmetrical to the one just presented for (a), and an alternate approach is explained in Example 4.2. □

The factor 2 in the exponent in formulas for c and d at the end of Theorem 3.6 is not surprising. Consider $H(x,y) = x\cdot y$ corresponding to $L(x,v) = \delta_x(v)$. Then for any g, $V(\tau,\xi) = g(e^{T-\tau}\xi)$ and the Lipschitz constant for $\nabla V(\tau,\cdot)$ is $e^{2(T-\tau)}$ times that of ∇g.

Under the assumptions of Theorem 3.6 (a), an arc $x(\cdot)$ is optimal for $\mathcal{P}(\tau,\xi)$ in (1) if and only if

$$x(\tau) = \xi, \quad \dot{x}(t) = \nabla_y H(x(t), -\nabla_\xi V(t,x(t))) \text{ for almost all } t\in[\tau,T]. \tag{15}$$

The properties of the optimal feedback mapping $\Phi : (-\infty,T]\times\mathbb{R}^n$, defined by $\Phi(t,x) = \nabla_y H(x,-\nabla_\xi V(t,x))$, are summarized below. Continuity of ϕ in both variables follows from that of $\nabla_\xi V$, which in turn is a consequence of graphical continuity of $\nabla_\xi V(t,\cdot)$ in t, as stated in [27, Corollary 2.2]; details were worked out in Goebel [14].

Corollary 3.7 (Lipschitz optimal feedback). *Suppose that H and g are differentiable and their gradients are Lipschitz continuous. Then the optimal feedback mapping Φ is continuous on $(-\infty,T]\times\mathbb{R}^n$, and there exists a continuous function $\mu : (-\infty,T]\mapsto\mathbb{R}$ such that for all $t\le T$, $\Phi(t,\cdot)$ is Lipschitz continuous with constant $\mu(t)$.*

If the problem of Bolza $\mathcal{P}(\tau,\xi)$ represents a control problem $\mathcal{C}(\tau,\xi)$ in (3) via the transformation (11), an optimal control minimizes the right-hand side in (11). This translates (15) to necessary and sufficient optimality conditions for $\mathcal{C}(\tau,\xi)$ (general

case with no smoothness present was discussed in [14]), $x(\tau) = \xi$, $\dot{x}(t) = Ax(t)+Bu(t)$, and

$$u(t) = \nabla_1 J^*(-B^*\nabla_\xi V(t, x(t)), Cx(t)) \text{ for almost all } t \in [\tau, T]. \tag{16}$$

Under the assumptions of Theorem 2.4, conclusions similar to those in Corollary 3.7 can be made about $\phi(t, x) = \nabla_1 J^*(-B^*\nabla_\xi V(t, x), Cx)$. In particular, optimal controls turn out to be continuous. To finish this section, we calculate ϕ for some of the examples of section 2.

We will need some properties of $\rho_{V,Q}$ defined in (4) (recall that Q is positive semidefinite and V is polyhedral). The function $\rho_{V,Q}$ is proper, convex, and piecewise linear-quadratic; $\operatorname{dom} \rho_{V,Q} = (V^\infty \cap \ker Q)^*$ and, in particular, $\rho_{V,Q}$ is finite-valued if and only if $V^\infty \cap \ker Q = \{0\}$ (Theorem 2.2 generalizes this fact). If this condition holds, then

$$\partial\rho_{V,Q}(s) = \operatorname*{argmax}_{v\in V}\left\{s \cdot v - \frac{1}{2}v \cdot Qv\right\} = \{v \mid s - Qv \in N_V(v)\} = (Q + N_V)^{-1}(s),$$

where $N_V(v)$ is the normal cone to the set V at v. For details, see Example 11.18 in Rockafellar and Wets [26]. If Q is actually positive definite, and thus invertible, we have, with $\operatorname{proj}_{\sqrt{V}Q}$ being the projection onto $\sqrt{Q}V$,

$$\partial\rho_{Q,V}(s) = \left(\sqrt{Q}\right)^{-1} \operatorname{proj}_{\sqrt{Q}V}\left(\left(\sqrt{Q}\right)^{-1} s\right).$$

Indeed for any convex set C, $(\operatorname{proj}_C)^{-1} = I + N_C$. Then

$$\left[\left(\sqrt{Q}\right)^{-1} \operatorname{proj}_{\sqrt{Q}V}\left(\sqrt{Q}\right)^{-1}\right]^{-1} = \sqrt{Q}\left(\operatorname{proj}_{\sqrt{Q}V}\right)^{-1}\sqrt{Q} = \sqrt{Q}\left(I + N_{\sqrt{Q}V}\right)\sqrt{Q}.$$

The last expression equals $Q+N_V$. It follows from the fact that $\sqrt{Q}N_{\sqrt{Q}V}\sqrt{Q} = N_V$, and this can be deduced from the properties of the normal cone under a change of coordinates.

Example 3.8 (optimal controls in feedback form). The linear-quadratic regulator (10) with a constraint $u(t) \in U$ (Example 2.5) has the following feedback mapping:

$$\phi(t, x) = (F + N_U)^{-1}(-B^*\nabla_\xi V(t, x)) = \sqrt{F}^{-1} \operatorname{proj}_{\sqrt{F}U}\left(-\sqrt{F}^{-1}B^*\nabla_\xi V(t, x)\right).$$

A similar formula was obtained by Heemels, Van Eijndhoven, and Stoorvogel [16] for a conical U; our regularity results are also stronger than those therein.

Example 2.6 discussed (10) with a constraint $u(t) \le C_0x(t) - q_0$. With the matrices as defined in the mentioned example, we obtain

$$\begin{aligned}
J^*(a, b) &= \sup_{u\in U}\inf_{v\in V}\left\{a \cdot u + b \cdot v - \frac{1}{2}u \cdot Pu + \frac{1}{2}v \cdot Qv + v \cdot Du\right\} \\
&= \inf_{v\in V}\left\{b \cdot v + \frac{1}{2}v \cdot Qv + \sup_{u\in\mathbb{R}^k}\left\{(a + D^*v) \cdot u - \frac{1}{2}u \cdot Pu\right\}\right\} \\
&= \inf_{v\in V}\left\{b \cdot v + \frac{1}{2}v \cdot Qv + \frac{1}{2}(a + D^*v) \cdot P^{-1}(a + D^*v)\right\} \\
&= \frac{1}{2}a \cdot P^{-1}a - \sup_{v\in V}\left\{(-b - DP^{-1}a) \cdot v - \frac{1}{2}v \cdot (Q + DP^{-1}D^*)v\right\}.
\end{aligned}$$

The matrix $Q + DP^{-1}D^*$ equals $\left[\begin{smallmatrix} I_{n\times n} & 0_{n\times k} \\ 0_{k\times n} & F^{-1} \end{smallmatrix}\right]$, and thus the sup expression above is separable. Also, $DP^{-1} = \left[\begin{smallmatrix} 0_{k\times k} \\ -F^{-1} \end{smallmatrix}\right]$, so $(-b - DP^{-1}a)_1 = -b_1$, $(-b - DP^{-1}a)_2 = -b_2 - F^{-1}a$. Then $J^*(a,b)$ equals

$$\begin{aligned}\frac{1}{2}a\cdot F^{-1}a - \frac{1}{2}\left\|(-b-DF^{-1}a)_1\right\|^2 - \sup_{v_2\in\mathbb{R}^k_+}\left\{(-b-DF^{-1}a)_2\cdot v_2 - v_2\cdot F^{-1}v_2\right\}\\ = \frac{1}{2}a\cdot F^{-1}a - \frac{1}{2}\left\|b_1\right\|^2 - \rho_{\mathbb{R}^k_-,F^{-1}}\left(-b_2 - F^{-1}a\right)\end{aligned}$$

and thus $\nabla_1 J^*(a,b) = F^{-1}\left[a + (N_{\mathbb{R}^k_-} + F^{-1})^{-1}(-b_2 - F^{-1}a)\right]$. Since for $b = Cx$ we have $b_1 = \sqrt{E}x$, $b_2 = C_2x$, the optimal feedback map is

$$\phi(t,x) = -F^{-1}\left[B^*\nabla_\xi V(t,x) - \left(N_{\mathbb{R}^k_-} + F^{-1}\right)^{-1}\left(F^{-1}B^*\nabla_\xi V(t,x) - C_2x\right)\right].$$

4. Convergence and approximation of value functions. In this section we study the convergence of value functions defined by sequences of converging costs $\{g_i\}$ and $\{L_i\}$,

$$V_i(\tau,\xi) = \inf\left\{g_i(x(0)) + \int_0^\tau L_i(x(t),\dot{x}(t))\,dt \;\middle|\; x(\tau) = \xi\right\}, \tag{17}$$

to $V(\tau,\xi)$ defined in (1). To treat sequences of possibly infinite-valued functions we use the well appreciated in optimization notion of epi-convergence. A sequence of functions $f_i : \mathbb{R}^n \to \overline{\mathbb{R}}$, $i = 1,2,\ldots$, is said to *epi-converge* to f ($\text{e-lim}_i f_i = f$ for short) if, for every point $x \in \mathbb{R}^n$,

(a) $\liminf_i f_i(x_i) \geq f(x)$ for every sequence $x_i \to x$,

(b) $\limsup_i f_i(x_i) \leq f(x)$ for some sequence $x_i \to x$.

For details, consult Rockafellar and Wets [26, Chapter 7]. We will only need to directly show the "lower" part of epi-convergence of value functions and rely on duality results to complete the argument. Let us briefly introduce the needed concepts.

For a function $f : \mathbb{R}^n \mapsto \overline{\mathbb{R}}$ its convex conjugate is defined by

$$f^*(y) = \sup_{x\in\mathbb{R}^n}\{y\cdot x - f(x)\}.$$

If f is proper, l.s.c., and convex, then so is f^*, and the conjugate of f^* equals f (that is, $f(x) = \sup_{y\in\mathbb{R}^n}\{x\cdot y - f^*(y)\}$). For details, consult Rockafellar [19, section 12]. Relations of certain properties of f to some other properties of f^*, say of coercivity and finiteness, were alluded to in the previous sections; in Example 4.2 we discuss the symmetry between strong convexity of f and Lipschitz continuity of ∇f^*, and revisit Lemma 3.5 and Theorem 3.6. Epi-convergence of a sequence of convex function is equivalent to that of the sequence of conjugates; we will need the following related facts. Below, $\text{e-lim}\inf_i f_i \geq f$ means that condition (a) in the definition of epi-convergence holds. A sequence $\{f_i\}$ is said to escape epigraphically to the horizon if the epigraphical limit of f_i is equal to $+\infty$ everywhere.

LEMMA 4.1. *Suppose that functions $f : \mathbb{R}^n \mapsto \overline{\mathbb{R}}$ and $f_i : \mathbb{R}^n \mapsto \overline{\mathbb{R}}$, $i = 1,2,\ldots$, are proper, l.s.c., and convex.*

(a) *If $\text{e-lim}\inf_i f_i \geq f$ and $\text{e-lim}\inf_i f_i^* \geq f^*$ and neither sequence escapes epigraphically to the horizon, then $\text{e-lim}_i f_i = f$ and $\text{e-lim}_i f_i^* = f^*$.*

(b) *Neither of the sequences f_i, f_i^* escapes epigraphically to the horizon provided there exists a constant $\rho > 0$ such that $f_i(x) \geq -\rho(\|x\| + 1)$ and $f_i^*(x) \geq -\rho(\|x\| + 1)$ for all x and $i = 1, 2, \ldots$.*

Proof. Statement (a) essentially follows from the statement and proof of Theorem 11.34 in [26]. We show (b). An application of a separation principle (for example, Theorem 11.3 in [19]) implies that for every $i = 1, 2, \ldots$, there exist $\alpha_i \in \mathbb{R}^n$, $\beta_i \in \mathbb{R}$ such that $f_i(x) \geq \alpha_i \cdot x + \beta_i \geq -\rho(\|x\| + 1)$ for every $x \in \mathbb{R}^n$. It must be the case that $\|\alpha_i\| \leq \rho$ while $\beta_i \geq -\rho$. We then obtain

$$f_i^*(\alpha_i) = \sup_x\{\alpha_i \cdot x - f(x)\} \leq \sup_x\{\alpha_i \cdot x - \alpha_i \cdot x - \beta_i\} = -\beta_i \leq \rho.$$

Thus $f_i^*(\alpha_i) \leq \rho$ while by assumption, $f_i^*(\alpha_i) \geq -\rho(\|\alpha_i\| + 1)$. As $\|\alpha_i\| \leq \rho$, there exists a convergent subsequence of $(\alpha_i, f_i^*(\alpha_i))$, and, consequently, the sequence f_i^* cannot escape to the horizon. A symmetric argument shows the corresponding fact for the sequence f_i. ∎

For a given initial cost g and Lagrangian L, the *dual value function* $\widetilde{V} : (-\infty, T] \times \mathbb{R}^n \mapsto \mathbb{R}$ is defined in a fashion similar to V,

$$\widetilde{V}(\tau, \eta) = \inf\left\{g^*(y(0)) + \int_0^\tau \widetilde{L}(y(t), \dot{y}(t))\, dt \;\middle|\; y(\tau) = \eta\right\}, \tag{18}$$

where the dual Lagrangian is

$$\widetilde{L}(y, w) = L^*(w, y) = \sup_{(x,v)\in\mathbb{R}^{2n}} \{w \cdot x + y \cdot v - L(x, v)\}. \tag{19}$$

If L satisfies Assumption 3.1, then so does $\widetilde{L}$ (and consequently $\widetilde{V}(\tau, \cdot)$ is proper, l.s.c., and convex for every $\tau \leq T$), and in fact for any $\tau \leq T$, the functions $V(\tau, \cdot)$ and $\widetilde{V}(\tau, \cdot)$ are conjugate to each other:

$$\widetilde{V}(\tau, \eta) = \sup_{\xi\in\mathbb{R}^n} \big\{\eta \cdot \xi - V(\tau, \xi)\big\}, \qquad V(\tau, \xi) = \sup_{\eta\in\mathbb{R}^n} \big\{\xi \cdot \eta - \widetilde{V}(\tau, \eta)\big\}. \tag{20}$$

These results were shown by Rockafellar and Wolenski [27]. The Hamiltonian $\widetilde{H}$ associated with a dual Lagrangian $\widetilde{L}$ is exactly $\widetilde{H}(y, x) = -H(x, y)$, and thus it has the same smoothness properties as H. Note also that the Lagrangian dual to $\widetilde{L}$ is the original L.

Example 4.2 (strong convexity and Lipschitz differentiability). A convex function f is differentiable and ∇f is Lipschitz continuous with constant σ if and only if f^* is strongly convex with constant $1/\sigma$. This and (20) automatically proves one of the statements (a), (b) of Theorem 3.6 once the other is in place and similarly for Lemma 3.5. For example, we show (b) of 3.6 with the help of (a). Suppose g is strongly convex with constant δ_0, and ∇H is Lipschitz with constant K. Then ∇g^* is Lipschitz with constant $\gamma_0 = 1/\delta_0$, while the dual Hamiltonian $\widetilde{H}$ also has a Lipschitz gradient, with constant K. Application of (a) shows that the dual value function $\widetilde{V}(\tau, \cdot)$ is differentiable, with $\nabla_\eta \widetilde{V}(\tau, \cdot)$ Lipschitz with constant $\gamma(\tau)$ as described at the end of Theorem 3.6. Now (20) implies that $V(\tau, \cdot)$ is strongly convex, with constant $\delta(\tau) = 1/\gamma(\tau)$. This yields the expression for $\delta(\tau)$ as described in the other formula at the end of Theorem 3.6. The lower bound on $\delta(\tau)$ can be obtained in a similar fashion from the upper bound on $\gamma(\tau)$.

We now focus on sequences of Bolza problems. Given a sequence of Lagrangians $\{L_i\}$, for each i we let $\widetilde{L}_i$ be the Lagrangian dual to L_i as described in (19), and H_i be the Hamiltonian corresponding to L_i as suggested by (2). The value function V_i is defined by (17), while $\widetilde{V}_i$ is defined similarly in terms of g_i^* and $\widetilde{L}_i$.

Assumption 4.3 (uniform growth assumption). Each of the functions g_i and L_i, $i = 1, 2, \ldots$, is proper, l.s.c., and convex. There exist functions $\underline{L}$ and $\overline{L}$, each satisfying Assumption 3.1, such that, for every $i = 1, 2, \ldots$,

$$\underline{L} \le L_i \le \overline{L}.$$

As L satisfies Assumption 3.1 if and only if $\widetilde{L}$ does, the second condition above is equivalent to the existence of $\underline{M}$ and $\overline{M}$, each satisfying Assumption 3.1, such that $\underline{M} \le \widetilde{L}_i \le \overline{M}$; take $\underline{M}$ to be the Lagrangian dual to $\overline{L}$, $\overline{M}$ dual to $\underline{L}$.

LEMMA 4.4 (convergence equivalence). *If Assumption* 4.3 *holds, the following statements are equivalent:*

(a) *Lagrangians L_i epi-converge to L,*

(b) *dual Lagrangians $\widetilde{L}_i$ epi-converge to $\widetilde{L}$,*

(c) *Hamiltonians H_i converge pointwise to H.*

The proof is postponed until section 5. Also there we discuss the convergence of Lagrangians (11) and Hamiltonians (6) corresponding to extended piecewise linear-quadratic functions under perturbations of all defining data; see Theorem 5.6.

Assumption 4.5 (epi-convergence of cost functions). Sequences $\{g_i\}$, $\{L_i\}$ epi-converge, respectively, to g and L.

Equivalently, we could assume that sequences $\{g_i^*\}$ and $\{\widetilde{L}_i\}$ epi-converge, respectively, to g^* and $\widetilde{L}$. We are now ready to state the main result of this section.

THEOREM 4.6 (value function epi-convergence). *Let Assumptions* 4.3 *and* 4.5 *hold. For any $\tau \le T$ and a sequence $\tau_i \to \tau$ (in particular for $\tau_i = \tau$) we have*

$$\text{e-lim}\, V_i(\tau_i, \cdot) = V(\tau, \cdot). \tag{21}$$

Equivalently, $\text{e-lim}\, \widetilde{V}_i(\tau_i, \cdot) = \widetilde{V}(\tau, \cdot)$. *This implies* $\text{e-lim}\, V_i = V$ *and* $\text{e-lim}\, \widetilde{V}_i = \widetilde{V}$.

We prove the theorem by taking advantage of the representation

$$V(\tau, \xi) = \inf_{\xi' \in \mathbb{R}^n} \{E(\tau, \xi, \xi') + g(\xi')\}, \tag{22}$$

where the *fundamental kernel* $E : (-\infty, T] \times \mathbb{R}^n \times \mathbb{R}^n$ is given by

$$E(\tau, \xi, \xi') = \inf \left\{ \int_\tau^T L(x(t), \dot{x}(t))\, dt \mid x(\tau) = \xi,\ x(T) = \xi' \right\},$$

with the infimum taken over all arcs with prescribed endpoints. A symmetric representation of $\widetilde{V}(\tau, \eta)$ is available, with $\widetilde{E}(\tau, \eta, \eta')$ defined in terms of $\widetilde{L}$. The following conjugacy relationship is a direct consequence of (20); to see this, consider $E(\cdot, \cdot, \xi')$ as the value function associated with the terminal cost $g(x) = \delta_{\xi'}(x)$ and use the fact that $g^*(y) = \xi' \cdot y_0$:

$$\widetilde{E}(\tau, \eta, \eta') = \sup_{\xi, \xi'} \{\eta \cdot \xi - \eta' \cdot \xi' - E(\tau, \xi, \xi')\},$$
$$E(\tau, \xi, \xi') = \sup_{\eta, \eta'} \left\{\xi \cdot \eta - \xi' \cdot \eta' - \widetilde{E}(\tau, \eta, \eta')\right\}.$$

We will need some facts about continuity and convergence of integral functionals. It is known that for a fixed $\tau > 0$, the functional $\Phi(\tau, \cdot)$ defined on the space of absolutely continuous arcs on $[0, \tau]$ by $\Phi(\tau, z(\cdot)) = \int_0^\tau L(z(t), \dot{z}(t))dt$ is weakly sequentially lower semicontinuous. This can be shown as a consequence of the conjugacy between L and H, and by interchanging the integration and maximization,

$$\int_0^\tau \sup_w \{w \cdot \dot{z}(t) - H(z(t), w)\}\, dt = \sup_{w(\cdot)} \int_0^\tau \{w(t) \cdot \dot{z}(t) - H(z(t), w(t))\}\, dt, \tag{23}$$

where the latter supremum is taken over all arcs w in $L^\infty[0, T]$ (see, for example, [26, Theorem 14.60]). Now consider a sequence of functionals $\Phi_i(\tau, z(\cdot)) = \int_0^\tau L_i(z(t), \dot{z}(t))dt$ a sequence of arcs x_i on $[0, \tau]$ weakly convergent to an arc x (meaning that $\dot{x}_i$ converge weakly to $\dot{x}$ in L^1 and $x_i(0)$ converge to $x(0)$). Then

$$\liminf_i \Phi_i(\tau, x_i(\cdot)) \geq \Phi(\tau, x(\cdot)). \tag{24}$$

We only need to consider the case where $\liminf \Phi_i(\tau, x_i(\cdot)) < +\infty$. As in (23), we have, for any w in $L^\infty[0, T]$, $\Phi_i(\tau, x_i(\cdot)) \geq \int_0^\tau \{w(t) \cdot \dot{x}_i(t) - H_i(x_i(t), w(t))\}\, dt$. Then, as $\dot{x}_i(\cdot)$ converge weakly in L^1 to $\dot{x}(\cdot)$, $x_i(\cdot)$ converge pointwise to $x(\cdot)$, and H_i converge to H pointwise and also uniformly on compact sets (Lemma 5.4), we get $\liminf \Phi_i(\tau, x_i(\cdot)) \geq \int_0^\tau \{w(t) \cdot \dot{x}(t) - H(x(t), w(t))\}\, dt$, and this holds for any w in $L^\infty[0, T]$. By (23), we conclude (24). In the proof of Lemma 4.7 we extend these arguments to varying time intervals.

LEMMA 4.7 (fundamental kernel epi-convergence). *Let E_i and $\widetilde{E}_i$ be the fundamental kernels associated, respectively, with L_i and $\widetilde{L}_i$. Under assumptions of Theorem* 4.6*, for any $\tau < T$ and a sequence $\tau_i \to \tau$ (in particular for $\tau_i = \tau$) we have*

$$\text{e-lim}\, E_i(\tau_i, \cdot, \cdot) = E(\tau, \cdot, \cdot). \tag{25}$$

Equivalently, $\text{e-lim}\, \widetilde{E}_i(\tau_i, \cdot, \cdot) = \widetilde{E}(\tau, \cdot, \cdot)$. *Consequently,* $\text{e-lim}\, E_i = E$ *and* $\text{e-lim}\, \widetilde{E}_i = \widetilde{E}$.

Proof. Fix $\tau < T$ and $\tau_i \to \tau$. First, we show that $\text{e-lim inf}_i\, E_i(\tau_i, \cdot, \cdot) \geq E(\tau, \cdot, \cdot)$, that is, for any point $(\xi, \xi') \in \mathbb{R}^{2n}$ and a sequence $(\xi_i, \xi_i') \to (\tau, \xi, \xi')$, we have

$$\liminf_{i \to \infty} E_i(\tau_i, \xi_i, \xi_i') \geq E(\tau, \xi, \xi'). \tag{26}$$

We only need to consider the case where $\liminf_{i\to\infty} E_i(\tau_i, \xi_i, \xi_i') = m < +\infty$, and if necessary we pass to a subsequence so that $E_i(\tau_i, \xi_i, \xi_i') \to m$. There exist arcs x_i on $[\tau_i, T]$ such that $E_i(\tau_i, \xi_i, \xi_i') = \Phi_i(\tau_i, x_i(\cdot)) = \int_0^{\tau_i} L_i(x_i(t), \dot{x}_i(t))dt$. Setting $a_i = (T - \tau_i)/(T - \tau)$ and defining $x_i^0(\tau + s) = x_i(\tau_i + a_i s)$, $L_i^0(x, v) = a_i L_i(x, v/a_i)$ leads to

$$\Phi_i(\tau_i, x_i(\cdot)) = \int_{\tau_i}^T L_i(x_i(t), \dot{x}_i(t))dt = \int_\tau^T L_i^0(x_i^0(t), \dot{x}_i^0(t))dt = \Phi_i^0(\tau, x_i^0(\cdot)),$$

with L_i^0 epiconverging to L [26, Exercise 7.47]. Corresponding Hamiltonians are $H_i^0(x, y) = a_i H(x, y)$, while the dual Lagrangians are $\tilde{L}_i^0(x, v) = a_i \widetilde{L}_i(x, v/a_i)$. As $\{L_i\}$ satisfies Assumption 4.3, so does $\{L_i^0\}$; this is a direct calculation. Consequent uniform growth assumptions imply in particular that some subsequence of rescaled arcs x_i^0 on $[0, \tau]$ weakly converges to an arc x on $[0, \tau]$ with $x(\tau) = \xi$,

$x(T) = \xi'$ (this follows from Theorem 1 in [21]). Moreover, as in (24), we have $\lim_i \Phi_i(\tau_i, x_i(\cdot)) = \lim_i \Phi_i^0(\tau, x_i^0(\cdot)) \geq \Phi(\tau, x(\cdot))$. But the arc x is feasible for the problem defining $E(\tau, \xi, \xi')$, and (26) follows.

The same argument applied to dual problems gives e-$\liminf \widetilde{E}_i(\tau_i, \cdot, \cdot) \geq \widetilde{E}(\tau, \cdot, \cdot)$. Lemma 4.1 (a) will conclude (25) (and the equivalent dual statement) if we show that neither $E_i(\tau_i, \cdot, \cdot)$ nor $\widetilde{E}_i(\tau_i, \cdot, \cdot)$ escapes to the horizon. Uniform growth in Assumption 4.3 and the rescaling arguments above imply that $\{E_i(\tau_i, \cdot, \cdot)\}$ is uniformly bounded below by $\widehat{E}(\tau, \cdot, \cdot)$, a fundamental function corresponding to some Lagrangian satisfying Assumption 3.1. As the latter function is proper and convex, it is bounded below by an affine function. A similar bound is in place for $\widetilde{E}_i(\tau_i, \cdot, \cdot)$, and thus the desired conclusions hold.

Lastly, the very definition of epi-convergence explains that (25) implies e-$\lim E_i = E$. □

Proof (Theorem 4.6). As in Lemma 4.7, we begin by showing that for any $(\tau, \xi) \in (0, +\infty) \times \mathbb{R}^n$ and a sequence $(\tau_i, \xi_i) \to (\tau, \xi)$, we have

$$\liminf_i V_i(\tau_i, \xi_i) \geq V(\tau, \xi). \tag{27}$$

It suffices to consider, passing to a subsequence if necessary, the case of $\lim_i V_i(\tau_i, \xi_i) < +\infty$. Recall (22). Functions g_i epi-converge to g by assumption, while Lemma 4.7 and the definition of epi-convergence yield e-$\liminf_i E_i(\tau_i, \xi_i, \cdot) \geq E(\tau, \xi, \cdot)$. Now by Theorem 7.46 of [26], we obtain

$$\text{e-}\liminf_i \{E_i(\tau_i, \xi_i, \cdot) + g_i(\cdot)\} \geq E(\tau, \xi, \cdot) + g(\cdot). \tag{28}$$

As mentioned in the proof of Lemma 4.7, $\{E_i(\tau_i, \cdot, \cdot)\}$ is uniformly bounded below by $\widehat{E}(\tau, \cdot, \cdot)$, a fundamental kernel corresponding to some Lagrangian satisfying Assumption 3.1. Proposition 4.2 in [27] implies that

$$E_i(\tau_i, \xi_i, \xi') \geq \widehat{E}(\tau, \xi_i, \xi') \geq \theta\left(\max\{0, |\xi'| - \alpha|\xi_i|\}\right) - \beta|\xi_i| \tag{29}$$

for a proper, nondecreasing, and coercive $\theta : [0, +\infty) \mapsto \mathbb{R}$ and constants α, β. As ξ_i converge, there exist a, b such that $\widehat{E}(\tau_i, \xi, \xi') \geq \theta(\max\{0, |\xi'| - a\}) - b$. A similar bound is in place for $E(\tau, \cdot, \cdot)$, and consequently, $E_i(\tau_i, \xi_i, \cdot)$ and $E(\tau, \xi, \cdot)$ are bounded below by a coercive function. Convexity and epi-convergence of g_i to g implies, by 7.34 in [26], that g_i and g are bounded below (uniformly in i) by $-\rho(|\cdot| + 1)$, for some constant ρ. As $\inf_{\xi'}\{E_i(\tau_i, \xi_i, \xi') + g_i(\xi')\}$ converge to a finite value, there exists a compact set S such that

$$\inf_{\xi'} \{E_i(\tau_i, \xi', \xi_i) + g_i(\xi')\} = \inf_{\xi' \in S} \{f_i(\xi') + E_i(\tau_i, \xi', \xi_i)\},$$

and a similar condition holds for $E(\tau, \xi, \xi') + g(\xi')$. Consequently, infimum in (22) can be taken over S, similarly for $V_i(\tau_i, \cdot)$. Now (28) and Proposition 7.29 in [26] yield (27).

Growth conditions $g_i(\xi') \geq -\rho(|\xi'| + 1)$, (29), and the fact that since θ in (29) is coercive, there exists $\gamma > 0$ such that $\theta \geq \rho|\cdot| - \gamma$ imply that

$$\begin{aligned} V_i(\tau_i, \xi) &\geq \inf_{\xi'} \{-\rho(|\xi'| + 1) + \rho \max\{0, |\xi'| - \alpha|\xi|\} - \gamma - \beta|\xi|\} \\ &\geq -(\alpha\rho + \beta)|\xi| - (\rho + \gamma). \end{aligned}$$

A similar bound holds for $\widetilde{V}_i(\tau_i,\cdot)$. This and (27) show the desired epi-convergence of $V_i(\tau_i,\cdot)$ as well as $\widetilde{V}_i(\tau_i,\cdot)$, by Lemma 4.1 (b). Epi-convergence of V_i and $\widetilde{V}_i$ follows directly from the definition of epi-convergence. □

We now describe how any problems fitting the general Assumption 3.1 can be approximated by problems with value functions possessing regularity as discussed in section 3. We will rely on Moreau–Yosida envelopes of convex and saddle functions. For any proper, l.s.c., and convex f and $\lambda > 0$, $e_\lambda f(x) = \inf_q \left\{ f(q) + \frac{1}{2\lambda}\|x-q\|^2 \right\}$ is finite and differentiable; see [26, Theorem 2.26]. A generalization of this smoothing technique to saddle functions was introduced by Attouch and Wets [2]. Applied to a concave-convex Hamiltonian H (and simplified to single parameter λ vs. the original two), it yields a differentiable concave-convex function

$$e_\lambda H(x,y) = \sup_p \inf_q \left\{ H(p,q) - \frac{1}{2\lambda}\|x-p\|^2 + \frac{1}{2\lambda}\|y-q\|^2 \right\}. \tag{30}$$

(We use the same notation for Moreau–Yosida regularization of convex and saddle functions; it should be clear which one is considered.) The key fact is that $\nabla e_\lambda f$ and $\nabla e_\lambda H$ are globally Lipschitz with constant $1/\lambda$. This is the case since $\nabla e_\lambda f$ is the Yosida regularization of the monotone subdifferential ∂f (see Exercise 12.23 in [26]), while $(x,y) \mapsto (-\nabla_x e_\lambda H(x,y), \nabla_y e_\lambda H(x,y))$ is the Yosida regularization of the monotone mapping $(x,y) \mapsto (-\tilde{\partial}_x H(x,y), \partial_y H(x,y))$.

COROLLARY 4.8 (regularization of value functions). *Let L be any Lagrangian satisfying Assumption* 3.1*; $\widetilde{L}$ be the associated dual Lagrangian; g be any proper, l.s.c., and convex function; and V, $\widetilde{V}$ be the associated value functions. There exists a sequence of finite convex functions g_i and a sequence of Lagrangians L_i satisfying Assumption* 4.3 *such that the following hold.*

(a) *Conclusions of Theorem* 4.6 *hold for sequences $\{V_i\}$, $\{\widetilde{V}_i\}$ of value functions corresponding, respectively, to L_i, g_i and their dual costs g_i^*, $\widetilde{L}_i$.*

(b) *For each i, V_i and $\widetilde{V}_i$ are continuously differentiable, and there exist continuous and positive functions $\gamma_i : (-\infty, T] \mapsto \mathbb{R}$, $\delta : (-\infty, T] \mapsto \mathbb{R}$ such that*

(i) *$\nabla_\xi V_i(\tau,\cdot)$ and $\nabla_\xi \widetilde{V}_i(\tau,\cdot)$ are Lipschitz with constant $\gamma(\tau)$,*

(ii) *$V(\tau,\cdot)$ and $\widetilde{V}(\tau,\cdot)$ are strongly convex with constant $\delta(\tau)$.*

This can be achieved by considering (with H associated to L)

$$g_i(x) = e_{1/i}\, g(x) + \|x\|^2/i, \qquad H_i(x,y) = e_{1/i}\, H(x,y),$$

and letting L_i and $\widetilde{L}_i$ be the Lagrangians associated with H_i.

Proof. Condition ($A3$) in Assumption 3.1 (by the proof of Theorem 2.3 in [27]) and the definition of H_i imply, respectively, that

$$H(x,y) \le \theta^*(\|y\|) + (\alpha\|y\| + \beta)\,\|x\|, \quad H_i(x,y) \le \sup_p \left\{ H(p,y) - \frac{1}{2\lambda}\|p-x\|^2 \right\}.$$

Combining the two inequalities yields

$$\begin{aligned} H_i(x,y) &\le \theta^*(\|y\|) + \sup_p \left\{ (\alpha\|y\| + \beta)\,\|p\| - \frac{1}{2\lambda}\|p-x\|^2 \right\} \\ &= \theta^*(\|y\|) + \frac{\lambda}{2}\,(\alpha\|y\| + \beta)^2 + (\alpha\|y\| + \beta)\,\|x\|. \end{aligned}$$

This in turn implies that $(A3)$ holds for L_i, with θ replaced by

$$\theta'(r) = \inf_{s\in[0,r]} \left\{ \theta^*(s) + \frac{\lambda}{2}(\alpha s + \beta)^2 \right\}.$$

Coercivity of both θ^* and the quadratic implies that of θ', which is obviously nondecreasing. A symmetric argument shows that $\widetilde{L}_i$ satisfies $(A3)$ uniformly, and consequently, Assumption 4.3 is satisfied. Moreau–Yosida approximations of H hypo/epi-converge to H, and as all these functions are finite, the convergence is pointwise (Lemma 5.4). Functions g_i epi-converge to g by Theorem 1.25 and Exercise 7.47 in [26]. This shows (a).

To see (b), note that g has a Lipschitz gradient (with constant i) as well as strongly convex (with constant $1/i$). Now, invoke Theorem 3.6 and the symmetry between strong convexity and Lipschitz continuity of the gradient of the dual as outlined in Example 4.2. □

Example 4.9 (regularization of control problems). Recall that the Hamiltonian (6) corresponding to an extended piecewise linear-quadratic problem (3) had the special structure $H(x,y) = y \cdot Ax + J^*(B^*y, Cx)$. The regularization, as described in Corollary 4.8, can be applied to such H, but a more explicit smoothing technique is available. One may regularize J^* directly, using the convex-concave counterpart of (30)—the infimum is to be taken over the first variable, supremum over the second. Such regularization, with parameter $1/i$ can be equivalently obtained by defining functions J_i^* in (7) with matrices P and Q replaced, respectively, by positive definite $P + I/i$, $Q + I/i$. (Here I denotes an identity matrix of appropriate size.)

5. Convex analysis tools. We say that a function $K : \mathbb{R}^k \times \mathbb{R}^l \mapsto [-\infty, +\infty]$ is convex-concave if, for any fixed $z \in \mathbb{R}^l$, the function $K(\cdot, z)$ is convex, while for any fixed $w \in \mathbb{R}^k$, $K(w, \cdot)$ is concave. We call a convex-concave function K proper if the effective domain of K, defined as

$$\operatorname{dom} K = \left\{ w \in \mathbb{R}^k \mid K(w,z) < +\infty \ \forall z \in \mathbb{R}^l \right\} \times \left\{ z \in \mathbb{R}^l \mid -\infty < K(w,z) \ \forall w \in \mathbb{R}^k \right\},$$

is nonempty.

Convex function duality gives a one-to-one correspondence between a proper lsc convex function and its conjugate (also proper and l.s.c.). Saddle function duality describes a one-to-one correspondence between *equivalence classes* of proper *closed* saddle functions. Closedness is a notion corresponding, in a sense, to lower semicontinuity of convex functions. For the somewhat technical definition, and the reasons for considering equivalence classes, see Rockafellar [19]. Here, we limit ourselves to the facts crucial to the developments in what follows.

Any equivalence class $[K]$ of closed saddle functions contains the lowest and the highest element, denoted $\underline{K}$ and $\overline{K}$, and consists of all closed saddle functions K such that $\underline{K} \le K \le \overline{K}$. If a saddle function K is finite, then it is closed, $K = \underline{K} = \overline{K}$, and the class $[K]$ of all closed functions equivalent to K is just $\{K\}$. A saddle function k, defined on $W \times Z$, for some nonempty closed convex sets $W \subset \mathbb{R}^K$, $Z \subset \mathbb{R}^L$, gives rise to an equivalence class $[K]$ of saddle functions on $\mathbb{R}^K \times \mathbb{R}^l$, whose lowest and highest elements, $\underline{K}$, $\overline{K}$, are given by

$$\underline{K}(w,z) = \begin{cases} k(w,z) & \text{for } w \in W, z \in Z, \\ -\infty & \text{for } z \notin Z, \\ +\infty & \text{for } w \notin W, z \in Z; \end{cases} \qquad \overline{K}(w,z) = \begin{cases} k(w,z) & \text{for } w \in W, z \in Z, \\ +\infty & \text{for } w \notin W, \\ -\infty & \text{for } w \in W, z \notin Z. \end{cases}$$

Equivalent saddle functions have the same effective domains, on the relative interior of which they are equal to each other (and finite).

For a given saddle function K, the lower conjugate $\underline{K^*}$ and the upper conjugate $\overline{K^*}$ are defined by

$$\underline{K^*}(a,b) = \sup_{u\in\mathbb{R}^k}\inf_{v\in\mathbb{R}^l}\{a\cdot u+b\cdot v-K(u,v)\},\quad \overline{K^*}(a,b) = \inf_{v\in\mathbb{R}^l}\sup_{u\in\mathbb{R}^k}\{a\cdot u+b\cdot v-K(u,v)\}. \tag{31}$$

The lower and upper conjugate functions are equivalent to each other and are, respectively, the lowest and the highest elements of $[K^*]$, the class of saddle functions conjugate to K. In fact, $\underline{K^*}$, $\overline{K^*}$ do not depend on the choice of $K \in [K]$, so $[K^*]$ should be thought of as conjugate to $[K]$. The lower and upper conjugates of any $K^* \in [K^*]$ are, in turn, the lowest and highest elements of $[K]$.

Example 5.1 (Hamiltonian in terms of a conjugate function). Recall that the Hamiltonian (6) was expressed in terms of a function J^*, which can be viewed as a conjugate of J (a unique conjugate, if we request that J^* be finite), where

$$J(u,v) = p\cdot u + \frac{1}{2}u\cdot Pu + q\cdot v - \frac{1}{2}v\cdot Qv - v\cdot Du \quad \text{for } (u,v)\in U\times V, \tag{32}$$

and has appropriately assigned $\pm\infty$ values outside $U\times V$.

Subdifferentials of K^* are exactly the saddle points in the expressions in (31); see Rockafellar [19, Theorem 37.2]. In particular, as finite saddle functions have nonempty subdifferentials, Theorem 2.2 can be viewed as saying that J has a saddle point on $U\times V$ for any (p,q). In other words, the function J_0 below has a saddle point under any affine perturbation. Similarly, Theorem 2.4 states the Lipschitz continuity of saddle points of J^* under perturbations. From a numerical viewpoint, finding the gradients of the Hamiltonian (6) amounts to solving a quadratic minimax problem.

As the linear terms $p\cdot u$ and $q\cdot v$ in (32) do not influence the finiteness and differentiability of $J^*(\cdot,\cdot)$, in proofs of Theorems 2.2 and 2.4 we work with

$$J_0(u,v) = \frac{1}{2}u\cdot Pu - \frac{1}{2}v\cdot Qv - v\cdot Du.$$

(From (7), we get that $J^*(a,b) = J_0^*(a-p,b+q)$.) We will need the following technical lemma.

LEMMA 5.2. *Assume that sets W and Z in $\mathbb{R}^n$ are polyhedral. Then $W+Z=\mathbb{R}^n$ is equivalent to $W^\infty+Z^\infty=\mathbb{R}^n$. For a linear mapping L we have $(LW)^\infty = LW^\infty$.*

Proof. For a polyhedral set W we can conclude that $W\subset W^\infty+\epsilon_w\mathbb{B}$ for some $\epsilon>0$, this follows for example from Corollary 3.53 in [26]. Thus if $W+Z=\mathbb{R}^n$, then $W^\infty+Z^\infty+(\epsilon_w+\epsilon_z)\mathbb{B}=\mathbb{R}^n$. But since $W^\infty+Z^\infty$ is a cone, we must have $W^\infty+Z^\infty=\mathbb{R}^n$. Now assume the latter. We have $W^\infty\subset W-w$ for any $w\in W$. Similarly for Z. Then $W^\infty+Z^\infty\subset W+Z-(w+z)$, which shows that $W+Z=\mathbb{R}^n$. The fact about linear mappings follows directly from the representation of a polyhedral set in Corollary 3.53 in [26]. ∎

For a proper lsc and convex function f, finiteness of f^* is equivalent to coercivity of f. Generalization of this fact to saddle functions, shown by Goebel [13, Proposition 2.7], states that for a proper closed convex-concave function $K:\mathbb{R}^k\times\mathbb{R}^l\mapsto[-\infty,\infty]$, the following conditions are equivalent:

(a) The class $[K^*]$ of convex-concave functions conjugate to K consists of a unique finite-valued function.

(b) The convex function $\alpha(u) = \sup_v K(u,v)$ and the concave $\beta(v) = \inf_u K(u,v)$ are both proper and coercive (respectively, in the convex and concave sense).

A concave function g is coercive (in the concave sense) if $-g$ is coercive as a convex function. Condition (a) can be translated to the following: for every $(a,b) \in \mathbb{R}^k \times \mathbb{R}^l$, $\underline{K^*}(a,b) = \overline{K^*}(a,b)$, and the common value is finite).

Proof (Theorem 2.2). By the result quoted above, $J_0^*(\cdot,\cdot)$ is finite if and only if the convex function

$$\phi(u) = \sup_{v \in V} \left\{ \frac{1}{2} u \cdot Pu - \frac{1}{2} v \cdot Qv - v \cdot Du + \delta_U(u) \right\}$$

and the concave function

$$\psi(v) = \inf_{u \in U} \left\{ \frac{1}{2} u \cdot Pu - \frac{1}{2} v \cdot Qv - v \cdot Du - \delta_V(v) \right\}$$

are proper and coercive. By symmetry, it will suffice to analyze $\phi(\cdot)$. We have

$$\phi(u) = \frac{1}{2} u \cdot Pu + \delta_U(u) + \sup_{v \in V} \left\{ v \cdot (-Du) - \frac{1}{2} v \cdot Qv \right\}.$$

Let $\phi_1(u) = \frac{1}{2} u \cdot Pu + \delta_U(u)$ and $\phi_2(u) = \sup_{v \in V} \left\{ v \cdot (u) - \frac{1}{2} v \cdot Qv \right\}$. Properness of $\phi(\cdot)$ is equivalent to the existence of some $u \in U$ with $\phi_2(-Du)$ finite. As $\operatorname{dom} \phi_2 = (V^\infty \cap \ker Q)^*$ [26, Example 11.18], we get that $\phi(\cdot)$ is proper if and only if $-DU \cap (V^\infty \cap \ker Q)^* \neq \emptyset$. Assuming that this holds, we obtain, through Corollary 11.33 in [26], that the conjugate of the function $u \mapsto \phi_2(-Du)$ at a point w is given by

$$\inf_{v \in V} \left\{ \frac{1}{2} v \cdot Qv \mid w = -D^* v \right\}$$

and the domain of this function is $-D^*V$. The domain of $\phi_1^*(\cdot)$ is $(U^\infty \cap \ker P)^*$. Then the domain of $\phi^*(\cdot)$ is $(U^\infty \cap \ker P)^* + (-D^*V)$. Now the properness and coercivity of $\phi(\cdot)$ is equivalent to $\operatorname{dom} \phi^*(\cdot) = \mathbb{R}^k$. We get that $\phi(\cdot)$ is proper and coercive if and only if

$$-DU \cap (V^\infty \cap \ker Q)^* \neq \emptyset, \qquad -D^*V + (U^\infty \cap \ker P)^* = \mathbb{R}^k.$$

Analogous statements for $\psi(\cdot)$ follow after analyzing the convex function $-\psi(\cdot)$ in the above way. We obtain

$$D^*V \cap (U^\infty \cap \ker P)^* \neq \emptyset, \qquad DU + (V^\infty \cap \ker Q)^* = \mathbb{R}^l.$$

Now note that $-D^*V + (U^\infty \cap \ker P)^* = \mathbb{R}^k$ implies $D^*V \cap (U^\infty \cap \ker P)^* \neq \emptyset$. Indeed, since $0 \in \mathbb{R}^k$, there exists a $v \in V$ such that $0 \in -D^*v + (U^\infty \cap \ker P)^*$. But this means that $D^*v \in (U^\infty \cap \ker P)^*$, so $D^*V \cap (U^\infty \cap \ker P)^* \neq \emptyset$. The latter condition is then superfluous, and a similar statement can be made about $-DU \cap (V^\infty \cap \ker Q)^* \neq \emptyset$.

Using the properties of polyhedral sets in Lemma 5.2, we can translate the condition $DU + (V^\infty \cap \ker Q)^* = \mathbb{R}^l$ to

$$DU^\infty + (V^\infty \cap \ker Q)^* = \mathbb{R}^l.$$

By polarizing both sides of this equation according to the rules in Corollary 11.25 in [26], we get one of the conditions in (8). The other one is obtained symmetrically

from $-D^*V + (U^\infty \cap \ker P)^* = \mathbb{R}^k$. The expression for $(DU^\infty)^*$ and $(-D^*V^\infty)^*$ also come from Corollary 11.25. ∎

Saddle points in the definition (7) of J^* are exactly the subgradients of that function. This allows us to use a result of Dontchev and Rockafellar [11] on the stability of saddle points; we quote it below in a form specialized for our current setting. By $(a,b) \in \partial^s K(w,z)$ we mean that $a \in \partial_w K(w,z)$, $b \in \tilde{\partial}_z K(w,z)$.

LEMMA 5.3 (see [11, Theorem 3.2]). *Assume that $(\bar{u},\bar{v}) \in \partial^s J_0^*(a,b)$. Then a necessary and sufficient condition for $\partial^s J_0^*$ to be single-valued and Lipschitz continuous on a neighborhood of (a,b) is the following:*

$$\begin{cases} u \in U_0 - U_0, \quad Pu = 0, \quad Du \in [V_0 \cap -V_0]^\perp & \Rightarrow \quad u = 0, \\ v \in V_0 - V_0, \quad Qv = 0, \quad D^*v \in [U_0 \cap -U_0]^\perp & \Rightarrow \quad v = 0, \end{cases} \tag{33}$$

where $U_0 = T_U(\bar{u}) \cap (a - P\bar{u} + R^*\bar{v})^\perp$ and $V_0 = T_V(\bar{v}) \cap (b + Q\bar{v} + R\bar{u})^\perp$.

The subspace $U_0 - U_0$ is the smallest subspace containing U_0, whereas $U_0 \cap -U_0$ is the largest subspace contained in the cone U_0. Similarly for V_0.

Proof (Theorem 2.4). For a convex set S, the lineality space S_l of S is the set of all those vectors y, such that for all $x \in S$, the line from x in the direction of y is contained in S. If S is a polyhedral set, $S_l = S^\infty \cap -S^\infty$. Using this notation,

$$[D^*(V^\infty \cap -V^\infty)]^\perp = \left\{u \mid Du \in V_l^\perp\right\},$$

and similarly for the other similar expression in condition (9). Thus, this condition can be restated as

$$\begin{cases} Pu = 0, Du \in V_l^\perp \Rightarrow u = 0, \\ Qv = 0, D^*v \in U_l^\perp \Rightarrow v = 0. \end{cases}$$

We first show that for a closed convex set S and any $w \in N_S(s)$, $S_l \subset w^\perp$. The condition for $w \in N_S(s)$ is that for all $x' \in S$, $(x' - x) \cdot w \le 0$, in particular, for every $l \in S_l$, $l \cdot w \le 0$. But S_l is a subspace, so it must be that $l \cdot w = 0$. This shows that $S_l \subset w^\perp$. Also note that $S_l \subset T_S(s)$.

Pick any (a,b) with $J_0^*(a,b)$ finite. As J_0^* is piecewise linear-quadratic, $\partial^s J_0^*(a,b)$ is nonempty. Pick any $(\bar{u},\bar{v}) \in \partial^s J_0^*(a,b)$. This is equivalent to $(a,b) \in \partial^s J_0(\bar{u},\bar{v})$, meaning $a - P\bar{u} + D^*\bar{v} \in N_U(\bar{u})$ and $b + Q\bar{v} + D\bar{u} \in -N_V(\bar{v})$, and consequently $U_l \subset (a - P\bar{u} + D^*\bar{v})^\perp$ and $V_l \in (b + Q\bar{v} + D\bar{u})^\perp$. This implies that $U_l \subset U_0$ and $V_l \subset V_0$, so then $U_l \subset U_0 \cap -U_0$, $V_l \subset V_0 \cap -V_0$ and also $U_l^\perp \supset (U_0 \cap -U_0)^\perp$, $V_l^\perp \supset (V_0 \cap -V_0)^\perp$.

In view of the above inclusions, condition (9) implies that (33) holds everywhere. That is, in the neighborhood of every point where J^* is finite, this function is also differentiable—therefore, in particular, finite. But the domain of J_0^* is a polyhedral, so also closed, set. Then J_0^* is finite and differentiable everywhere. ∎

A corresponding notion of convergence for convex-concave functions is that of epi/hypo-convergence. We will only use it for sequences of convex-concave functions which are modulated (in the sense of Rockafellar [24]), that is, for sequences which satisfy the following: for some $\rho \ge 0$ and some i_0, we have, for all $i > i_0$,

$$\inf_{|w| \le \rho} \overline{K_i}(w,z) \le \rho(1 + |z|) \quad \forall z, \qquad \sup_{|z| \le \rho} \underline{K_i}(w,z) \ge -\rho(1 + |w|) \quad \forall w. \tag{34}$$

Under Assumption 4.3, the sequence of functions $(y,x) \to H_i(x,y)$ is modulated. This can be seen by looking at the equivalent to Assumption 3.1 growth conditions

on the Hamiltonian, as described in Rockafellar and Wolenski [27], Theorem 2.3; see also our proof of Corollary 4.8. A sequence of (equivalence classes of) convex-concave functions K_i is said to *epi/hypo-converge* to K if

$$\lim_{\epsilon\searrow 0}\left[\limsup_{z_i\to z,i\to\infty}\left(\inf_{|w_i-w|\le\epsilon}\overline{K_i}(w_i,z_i)\right)\right]\le\overline{K}(w,z), \tag{35}$$

$$\lim_{\epsilon\searrow 0}\left[\liminf_{w_i\to w,i\to\infty}\left(\sup_{|z_i-z|\le\epsilon}\underline{K_i}(w_i,z_i)\right)\right]\ge\underline{K}(w,z). \tag{36}$$

LEMMA 5.4 (convergence of finite saddle functions). *Let K_i, $i=1,2,\dots$ and K be finite-valued convex-concave functions on $\mathbb{R}^k\times\mathbb{R}^l$. The following are equivalent:*

(a) *K_i converge epi/hypo-graphically to k,*

(b) *K_i converge pointwise to k,*

(c) *K_i converge uniformly to k on every compact subset of $\mathbb{R}^k\times\mathbb{R}^l$.*

Proof. Assume (a). Subdifferentials of K_i converge graphically to that of K, this follows from an extension of Attouch's theorem for convex functions; see [24, Theorem 4.3]. As subdifferentials of K are convex-valued, Exercise 5.34 in [26] implies the existence of $N>0$, $\epsilon_0>0$ such that, $\|\partial_w K_i(w',z')\|<N$ for $(w',z')\in(w,z)+\epsilon_0\mathbb{B}$. For $\epsilon<\epsilon_0$ we have $\inf_{|w_i-w|\le\epsilon}K_i(w_i,z_i)\ge K_i(w,z_i)-\epsilon N$. Using this in (35) we get

$$\begin{aligned}K(w,z)&\ge\lim_{\epsilon\searrow 0}\left[\limsup_{z_i\to z,i\to\infty}\left(K_i(w,z_i)-\epsilon N\right)\right]\\&\ge\lim_{\epsilon\searrow 0}\left[\limsup_{i\to\infty}\left(K_i(w,z)-\epsilon N\right)\right]=\limsup_{i\to\infty}K_i(w,z).\end{aligned}$$

Symmetric argument shows that $K(w,z)\le\liminf_{i\to\infty}K_i(w,z)$, and thus K_i converge to K pointwise. Implication (b)⇒(c) was shown in [19, Theorem 35.1], while (c)⇒ (a) is simple—it follows from the uniform continuity of K and the definition of epi/hypo-convergence. □

Proof (Lemma 4.4). The equivalence of (a) and (b) follows from the definitions of $\widetilde{L}_i$, $\widetilde{L}$ and the fact that convex conjugacy preserves epi-convergence; see, for example, Theorem 11.34 in [26]. An extension of this fact to partial conjugacy, first shown by Attouch, Aze, and Wets [1] and specialized to modulated sequences in [24, Theorem 4.1], implies that (a) is equivalent to the "hypo/epi-convergence" of H_i to H. As the Hamiltonians are finite, hypo/epi-convergence is equivalent to their pointwise convergence. □

We conclude by discussing the convergence of extended piecewise linear-quadratic problems. Let $\mathcal{C}_i(\tau,\xi)$ be defined as in (3) by matrices A_i, B_i, C_i, D_i, P_i, Q_i, vectors p_i, q_i and sets U_i, V_i. To study the convergence of $\{\mathcal{C}_i(\tau,\xi)\}$ to $\mathcal{C}(\tau,\xi)$ one could analyze the sequence of Lagrangians $\{L_i\}$ defined as in (11), with the help of the calculus of epi-convergence, as described for example in [26, Chapter 7]. We propose an alternate way, suggested by Lemma 4.4 and Example 5.1—we focus on Hamiltonians and rely on the lemma below.

LEMMA 5.5 (convergence of constrained saddle functions and their conjugates). *Suppose that*

(a) *$k_i:\mathbb{R}^k\times\mathbb{R}^l\mapsto\mathbb{R}$, $i=1,2,\dots$, are convex-concave functions converging pointwise to a finite-valued convex-concave function k;*

(b) *$W_i\in\mathbb{R}^k$, $Z_i\in\mathbb{R}^l$, $i=1,2,\dots$, are nonempty closed convex sets converging, respectively, to nonempty closed convex sets W, Z.*

Let $[K_i]$ be the equivalence class of convex-concave functions determined by k_i and $W_i \times Z_i$, similarly define $[K]$ by k and $W \times Z$, and assume that $\{[K_i]\}$ is modulated. Then the sequence $\{[K_i]\}$ epi/hypo-converges to K. Consequently, the sequence $\{[M_i]\}$ given by

$$\underline{M_i}(a,b) = \sup_{w\in W_i}\inf_{z\in Z_i}\{a\cdot w+b\cdot z-k_i(w,z)\},\ \overline{M_i}(a,b) = \inf_{z\in Z_i}\sup_{w\in W_i}\{a\cdot w+b\cdot z-k_i(w,z)\}$$

epi/hypo-converges to $[M]$ described by

$$\underline{M}(a,b) = \sup_{w\in W}\inf_{z\in Z}\{a\cdot w+b\cdot z-k(w,z)\},\ \overline{M}(a,b) = \inf_{z\in Z}\sup_{w\in W}\{a\cdot w+b\cdot z-k(w,z)\}.$$

If all four of the functions above are finite-valued, the equivalence classes $[M_i]$ and $[M]$ consist of just one function each, and the convergence is pointwise.

Proof. We show that (35) holds for $\{K_i\}$ and K; the argument for (36) is symmetrical. When $w \notin W$, there is nothing to prove, as $K(w,z) = +\infty$. Suppose that $w \in W$ and fix $\epsilon > 0$. There exists a sequence $\bar{w}_i \to w$ with $\bar{w}_i \in W_n$, and we have

$$\limsup_{z_i\to z, i\to\infty}\left(\inf_{|w_i-w|\le\epsilon}\overline{K_i}(w_i,z_i)\right) \le \limsup_{z_i\to z,i\to\infty}\overline{K_i}(\bar{w}_i,z_i).$$

If $z \notin Z$, any sequence $z_i \to z$ must eventually satisfy $z_i \notin Z_i$, and thus $\overline{K_i}(\bar{w}_i, z_i) = -\infty$. Thus

$$\limsup_{z_i\to z, i\to\infty}\left(\inf_{|w_i-w|\le\epsilon}\overline{K_i}(w_i,z_i)\right) = -\infty = \overline{K}(w,z).$$

Now note that

$$\begin{aligned}\limsup_{z_i\to z, i\to\infty}\left(\inf_{|w_i-w|\le\epsilon}\overline{K_i}(w_i,z_i)\right) &\le \limsup_{z_i\to z,i\to\infty}\overline{K_i}(\bar{w}_i,z_i)\\ &\le \limsup_{z_n\to z,n\to\infty} k_n(\bar{w}_n,z_n) = k(w,z),\end{aligned}$$

where the equality follows from the fact that k_i converge to k uniformly on any compact neighborhood of (w,z) (Lemma 5.4). If $z \in Z$, $k(w,z) = \overline{K}(w,z)$, and this shows the epi/hypo-convergence of $\{K_i\}$ to K.

Epi/hypo-convergence is preserved under saddle function conjugacy [24, Theorem 4.2]. As $\{M_i\}$ are saddle conjugates of $\{K_i\}$ (in (31) the infimum and supremum need to be taken only over the sets where the function values are finite), epi/hypo-convergence of $\{K_i\}$ to K implies that of $\{M_i\}$ to M. The last statement follows from Lemma 5.4. □

A related result was shown by Wright [29]. It concluded the convergence of $\{K_i\}$, if each K_i had the form $k_i'(w) - k_i''(z) - w \cdot Dz$ (separable saddle function plus a constant biaffine term); convergence of M_i was not addressed there. Also in [29], epi/hypo-convergence was employed to study discrete approximations of $C(\tau,\xi)$.

THEOREM 5.6 (convergence of piecewise linear-quadratic Hamiltonians). *Assume that matrices A_i, B_i, C_i, D_i, P_i, Q_i, vectors p_i, q_i and sets U_i, V_i defining the problem $\mathcal{C}_i(\tau,\xi)$ converge, respectively, to A, B, C, D, P, Q, p, q, U, V defining $\mathcal{C}(\tau,\xi)$. Suppose also that the data in $\mathcal{C}_i(\tau,\xi)$, $i = 1,2,\ldots$, and $C(\tau,\xi)$ satisfies the conditions of Theorem 2.2. Then Hamiltonians H_i converge pointwise to H.*

Proof. The sequence of functions J_i corresponding to $\mathcal{C}_i(\tau,\xi)$ as in (32) is modulated (too see this, note that there exist $u_i \in U_i$ converging to some $u \in U$, and for

some $\rho > 0$, $\inf_{|u|\le\rho} \overline{J}_i(u,v)$ is bounded above by $p_i \cdot u_i + \frac{1}{2} u_i \cdot P_i u_i + q_i \cdot v - v \cdot D_i u_i$; this shows the first inequality in (34)). The quadratic expressions defining J_i in (32) converge pointwise (on the whole space) to that of J. Lemma 5.5 guarantees that $\{J_i\}$ as well as $\{J_i^*\}$ epi/hypo-converge to, respectively, J and J^*. As the functions J_i^* and J^* are finite, their convergence is uniform on compact sets by Lemma 5.4. But then, it also implies the pointwise convergence of Hamiltonians H_i. □

A NONDEGENERATE MAXIMUM PRINCIPLE FOR THE IMPULSE CONTROL PROBLEM WITH STATE CONSTRAINTS*

A. ARUTYUNOV†, D. KARAMZIN‡, AND F. PEREIRA§

Abstract. In this article, a free-time impulsive control problem with state constraints and equality and inequality constraints on the trajectory endpoints is considered. A weakened maximum principle is obtained for problems with data measurable in the time variable, being the time transversality conditions deduced with the help of some extra convexity assumption on the state constraints. In the case of smooth problems a nondegenerate maximum principle is derived by using a penalty function method.

Key words. optimal control, impulsive control, maximum principle, state constraints, nonfixed time, time transversality conditions, nondegeneracy

1. Statement of the problem.

We shall address the following impulse control optimization problem:

$$J(p,u,\mu) = e_0(p) \to \min, \tag{1.1}$$

$$dx = f(x,u,t)dt + g(x,t)d\mu, \quad t \in [t_0,t_1], \tag{1.2}$$

$$e_1(p) \le 0, \quad e_2(p) = 0, \tag{1.3}$$

$$\varphi(x,t) \le 0, \quad t \in [t_0,t_1], \tag{1.4}$$

$$u(t) \in U(t) \quad [t_0,t_1]\text{-a.e.}, \quad \mu \ge 0, \tag{1.5}$$

$$p = (x_0,x_1,t_0,t_1), \quad x_0 = x(t_0),\ x_1 = x(t_1).$$

Here e_1, e_2, φ are given vector-functions with values in $\Re^{k_j}$, $j = 1,2,3$, respectively, $t \in \Re^1$ is the time variable, μ is a nonnegative scalar valued Borel measure on time interval $[t_0,t_1]$, referred to by impulse control, and x is the state variable with values in $\Re^n$. The notation a.e. stands for almost all $t \in [t_0,t_1]$ with respect to Lebesgue measure. The vector u with values in $\Re^m$ is called control. An admissible control is an essentially bounded measurable function $u(t)$ such that $u(t) \in U(t)$ a.e. The vector $p \in \Re^{2n+2}$ is called an endpoint.

The functions e_0, e_1, e_2, φ, g, defining the minimizing functional, endpoint, and state constraints, and the impulse driven dynamics are continuously differentiable in all their arguments. The vector function f is linear in u, i.e.,

$$f(t,x,u) = f_0(t,x) + F(t,x)u, \tag{1.6}$$

continuously differentiable in x for almost all t, and, together with its partial derivatives in x, is measurable in t for all fixed (x,u). Both f and its partial derivatives in x are bounded on any bounded set and continuous in (x,u) uniformly in t. The set-valued mapping U is measurable in t and bounded, i.e., $\exists\ c > 0$, s.t. $|U(t)| \leq c$ $\forall t$. The set $U(t)$ is convex and closed for almost all t.

The triple (p,u,μ) is said to be a *control process* if $\exists\ x(t) : x(t_0) = x_0$, $x(t_1) = x_1$ and x,u,μ satisfy (1.2). A control process is called *admissible* if it satisfies all constraints of the considered problem. The admissible process (p^*,u^*,μ^*) is said to be *optimal* if for any admissible process (p,u,μ), the inequality $e_0(p^*) \leq e_0(p)$ is true.

The goal for this article is to derive necessary conditions for optimality in the form of a nondegenerate maximum principle for the free-time impulsive control problem (1.1)–(1.5) with control constraints. The maximum principle is said to degenerate if condition (4.3) in our main result, Theorem 4.1, does not hold.

If condition (4.3) does not hold, then it can be easily seen that the maximum condition may not be informative in the sense that it holds for any admissible controls (u,μ). Indeed, that is so when $\psi(t) = 0$ a.e., $\sigma_r(s) = 0$ a.e. (see Theorem 4.1). For example, we may point to a specific class of problems for which the classical maximum principle always degenerates: the autonomous time-optimal problem with state constraints and fixed endpoints which belong to the boundary of the state constraints.

This article pertains to the significant effort made over the years to extend the conventional optimal control theory, addressing systems with trajectories which are continuous, more precisely, absolutely continuous, to systems whose trajectories might present discontinuities.

Despite the already significant body of theory addressing optimal impulsive control problems developed during the last two decades (consider, for example, [2, 4, 5, 7, 13, 10, 14, 15, 16, 17, 18, 20, 21, 22, 23], none of the authors that derived necessary conditions of optimality for impulsive control problems with state constraints, namely, [4, 15, 17], addressed the issue of nondegeneracy of the optimality conditions.

The issue of nondegeneracy is an important one in optimal control and, for conventional optimal control problems with state constraints, it was addressed by, among others, [1, 3, 6]. Furthermore, a weakened maximum principle (Theorem 7.1) for free-time impulsive control problems with data merely measurable in the time variable was derived, being the time transversality conditions obtained with the help of some extra convexity assumption on the state constraints. This result is also new.

This article is organized as follows. After addressing in the next section the set of hypotheses under which our results are proved, we present and discuss some preliminary concepts. In section 4, we state our main result and present some remarks as well as an illustrative example. Then, some auxiliary results are stated in section 5. Their proof is presented in the appendix. In section 6, we state and prove two results of increasing order of complexity. While in the first result we consider the free-time impulsive optimal control problem without constraints, in the second result only add endpoint state constraints. The weakened version of our main result is stated and proved for the full problem in section 7. Finally, in section 8, we derive our main result.

2. Hypotheses. Let us formulate basic definitions and assumptions.

DEFINITION 2.1. *Endpoint constraints are said to be* regular *if, for any endpoint vector* $p = (x_0, x_1, t_0, t_1)$ *satisfying* (1.3),

(1) *the vectors* $\frac{\partial e_2^j}{\partial p}(p)$, $j = 1, \dots, k_2$, *are linearly independent;*

(2) *there exists vector* $\bar{p} \in \Re^{2n+2}$ *such that*

$$\frac{\partial e_2}{\partial p}(p)\bar{p} = 0, \qquad \left\langle \frac{\partial e_1^j}{\partial p}(p), \bar{p} \right\rangle > 0 \quad \forall j \ \textit{s.t.}\ e_1^j(p) = 0.$$

DEFINITION 2.2. *State constraints are said to be* regular *if, for any* (x, t) *satisfying* (1.4), *there exists vector* $q = q(x, t) \in \Re^n$ *such that*

$$\langle \varphi_x^j(x, t), q \rangle > 0 \quad \forall j \ \textit{s.t.}\ \varphi^j(x, t) = 0.$$

DEFINITION 2.3. *Let vector* $p^* = (x_0^*, x_1^*, t_0^*, t_1^*)$ *satisfy endpoint constraints* (1.3) *and* $\varphi(x_k^*, t_k^*) \le 0$, $k = 0, 1$. *We say that state constraints are* compatible *with endpoint constraints at* p^* *if there exists* $\varepsilon > 0$ *such that*

$$\{p \in \Re^{2n+2} : |p - p^*| \le \varepsilon,\ e_1(p) \le 0,\ e_2(p) = 0\} \subseteq \{p : \varphi(x_k, t_k) \le 0,\ k = 0, 1\}.$$

Assumption S. The function f is continuously differentiable in all arguments, and the set-valued map $U(\cdot)$ is constant. To be more precise, $U(t) \equiv U$, being U convex and compact.

DEFINITION 2.4. *Let Assumption* S *be in force. The admissible trajectory* $x(t)$, $t \in [t_0, t_1]$, *is called* controllable *at the endpoints (with regard to state constraints) if there exist* $u_k \in U$ *and* $m_k \in [0, +\infty)$, $k = 0, 1$, *such that*

$$(-1)^k[\langle f(x_k, u_k, t_k) + g(x_k, t_k)m_k, \varphi_x^j(x_k, t_k)\rangle + \varphi_t^j(x_k, t_k)] < 0$$

for all j *such that* $\varphi^j(x_k, t_k) = 0$. *Here* $x_k = x(t_k)$, $k = 0, 1$.

When $g \equiv 0$ or μ is in class of absolutely continuous measures having density in L_∞, then Definition 2.4 becomes a definition of controllability for the associated conventional control optimization problem [1]. A simple argument gives the following sufficient condition for controllability: a trajectory $x(\cdot)$ is controllable at the endpoints if at least one of the two following conditions holds:

- There exists $u_k \in U$ such that $\forall j$ satisfying $\varphi^j(x_k, t_k) = 0$,

$$(-1)^k[\langle f(x_k, u_k, t_k), \varphi_x^j(x_k, t_k)\rangle + \varphi_t^j(x_k, t_k)] < 0.$$

- $(-1)^k W^j(x_k, t_k) < 0$ $\forall j$ satisfying $\varphi^j(x_k, t_k) = 0$.

From now on, let $W^j(x, t) = \langle \varphi_x^j(x, t), g(x, t)\rangle$, $j = 1, \dots, k_3$.

We need Definitions 2.1–2.4 and Assumption S to prove nondegeneracy (Theorem 4.1).

The following *convexity* assumption is used along with Definition 2.3 to obtain time transversality conditions for problems with data measurable in t and state constraints (Theorem 7.1).

Assumption C. Let $x^*(\cdot)$ be the reference optimal trajectory on $[t_0^*, t_1^*]$ and $E_0^* = (x_0^{*+}, t_0^*)$, $E_1^* = (x_1^{*-}, t_1^*)$. Let the function φ be twice continuously differentiable.

There exists $\delta > 0$ such that

$$\dot{W}^j(E) \geq 0 \quad \forall E \in \Re^n \times \Re \text{ s.t. } |E - E_k^*| \leq \delta \quad \forall j,k \text{ s.t. } \varphi^j(E_k^*) = W^j(E_k^*) = 0, \tag{2.1}$$

where $\dot{W}^j = \langle g_x g, \varphi_x^j \rangle + \langle g, \varphi_{xx}^j g \rangle$ is the evolution derivative of W^j at any point of the arc joining the jump endpoints.

Here are a few comments about condition (2.1). It always holds when $W^j(E_k^*) \neq 0$. If $\varphi^j(E_k^*) = W^j(E_k^*) = 0$, then (2.1) means that function φ^j is convex along jump evolutions in some neighborhood of the endpoint. In this case, examples where (2.1) holds are

- linear systems—g does not depend on x, and φ is linear in x;
- conventional system—$g \equiv 0$ (then in both cases $\dot{W}^j \equiv 0$); and
- the function g does not depend on x, and the matrix φ_{xx}^j is nonnegative defined.

Finally, (2.1) is true when $\dot{W}^j(E_k^*) > 0$.

3. Preliminaries. Let us introduce the adopted notation and present the main concepts to be used in this article.

Denote by $T = [t_0, t_1]$ the time interval and by $C(T)$ the Banach space of continuous functions $f : T \to \Re^1$ with the usual norm $\|f\|_C = \max_{t \in T} |f(t)|$. Let $V(T)$ be the linear space of functions of bounded variation on T, right continuous on interval (t_0, t_1), and $V^n(T)$ be the space of n-vector valued functions $x(t) = (x^1(t), \ldots, x^n(t))$ such that $x^j \in V(T)$, $j = 1, \ldots, n$. Denote by $C^*(T)$ the topologically dual space to $C(T)$ (its elements are Borel measures on T) and by $C_+^*(T)$ the class of nonnegative Borel measures on T.

Given $\mu \in C^*(T)$, let the distribution function $F(t;\mu)$ of the Borel measure μ be defined by

$$F(t;\mu) = \int_{[0,t]} d\mu = \mu([0,t]), \quad t \in (0,1], \qquad F(0;\mu) = 0.$$

The variation of μ is an element in $C_+^*(T)$ defined as the Borel measure $\operatorname{Var}\mu = \mu^+ + \mu^-$, where $\mu = \mu^+ - \mu^-$ is the Jordan decomposition of μ. The total variation of μ is given by the number $|\mu| = \operatorname{Var}\mu(T)$. The variation of a vector-measure (vector-function) is defined as the sum of the variation of its components.

We denote by μ_d and μ_c, respectively, the discrete and the continuous part of the measure μ. Let us put $\operatorname{Ds}(\mu) = \{r \in T : \operatorname{Var}\mu(\{r\}) > 0\}$, $\operatorname{Cont}(\mu) = [T \setminus \operatorname{Ds}(\mu)] \cup \{t_0\} \cup \{t_1\}$. By $\mu_1 \leq \mu_2$ it is meant that $\mu_2 - \mu_1 \in C_+^*(T)$. The weak star convergence of a sequence of measures $\{\mu_i\}$ to μ is represented by $\mu_i \xrightarrow{w} \mu$.

Given $g \in V(T)$, let $g(s^+) = \lim_{t \to s,\, t > s} g(t)$, $g(s^-) = \lim_{t \to s,\, t < s} g(t)$ be, respectively, the right and the left limits of g at point s. Function g defines the Borel measure $\nu[g]$ by the formula

$$\nu[g]([0,t]) = g(t^+) - g(0), \quad t \in [0,1].$$

Thus, according to our notation, $\nu[F(t;\mu)] = \mu$. The measure corresponding to the length is denoted by $\mathcal{L}$, $\mathcal{L} = \nu[t]$. If $x \in V^n(T)$, then $\nu[x]$ is a vector measure with components $\nu[x^j]$, $j = 1, \ldots, n$. $\operatorname{Var}|_a^b[g]$ denotes the variation of the measure $\nu[g]$ on $[a,b]$.

We present the concept of the solution to (1.2), following the one given first in [8, 9] and later completed and further discussed in [2, 13, 11, 12, 20, 23, 5, 16, 19]. Let

us consider the function $\xi(x,r,\Delta):\Re^n\times\Re^1\times\Re^1\to\Re^n$, with $\xi(x,r,\Delta)=\alpha_r(1)$, being $\alpha_r(s)=\alpha_r(s;x,\Delta)$ the solution to the following conventional differential equation:

$$\dot\alpha_r=g(\alpha_r,r)\Delta,\qquad s\in[0,1],\qquad \alpha_r(0)=x.$$

DEFINITION 3.1. *The function $x(t)$ is called the solution to* (1.2) *if $x(t_0)=x_0$ and, $\forall t>t_0$,*

$$x(t)=x_0+\int_{t_0}^{t}f(x,u,s)ds+\int_{[t_0,t]}g(x,s)d\mu_c+\sum_{r\in\mathrm{Ds}(\mu),\ r\le t}[\xi(x(r^-),r,\mu(\{r\}))-x(r^-)].$$

Here, $\mu(\{r\})$ is the atom of μ at point r.

Let $\phi(x,t)$ be a scalar continuous function on $\Re^n\times\Re^1$ and consider the following concept of graph completion supremum:

$$\operatorname*{gc\,sup}_{t\in T}\phi(x,t)=\max_{t\in T}\max_{s\in[0,1]}\phi(\alpha_t(s;x(t^-),\mu(\{t\})),t).$$

Now, we are in position to precise the definition of trajectory admissability introduced in section 1.

DEFINITION 3.2. *Inequality* (1.4), *i.e., $\varphi(x,t)\le 0$, is understood in the sense that for $j=1,\dots,k_3$, $\operatorname{gc\,sup}\varphi^j(x,t)\le 0$. This means that the trajectory $x(t)$ satisfies the state constraints* (1.4) *if and only if*

(1) $\varphi(x(t),t)\le 0\ \forall t\in[t_0,t_1]$, *and*
(2) $\varphi(\alpha_r(s),r)\le 0\ \forall s\in[0,1]$ *and* $\forall r\in\mathrm{Ds}(\mu)$.

4. The main result. In this section, we state nondegenerate necessary conditions for optimal control problems with state constraints and equality and inequality endpoint constraints derived in its full generality.

Let $\lambda=(\lambda_0,\lambda_1,\lambda_2)$ and consider the following scalar functions:

$$H(x,u,\psi,t)=\langle f(x,u,t),\psi\rangle,$$
$$Q(x,\psi,t)=\langle g(x,t),\psi\rangle,$$
$$l(p,\lambda)=\sum_{j=0}^{2}\langle e_j(p),\lambda_j\rangle.$$

THEOREM 4.1. *Let (p^*,u^*,μ^*) be a solution to problem* (1.1)–(1.5). *Suppose that Assumption* S *is in force, the state constraints are compatible with endpoint constraints, the state and endpoint constraints are regular, and the optimal trajectory is controllable.*

Then, there exist

- *number $\lambda_0\ge 0$, vectors $\lambda_1\in\Re^{k_1}$, $\lambda_1\ge 0$, $\lambda_2\in\Re^{k_2}$,*
- *vector function $\psi\in V^n(T^*)$,*
- *scalar function $\phi\in V(T^*)$,*
- *vector measure $\eta=(\eta^1,\dots,\eta^{k_3})$, $\eta^j\in C_+^*(T^*)$, s.t. $\mathrm{Ds}(\mu^*)\cap\mathrm{Ds}(\eta^j)=\emptyset\ \forall j$,*

and

- *for every atom $r\in\mathrm{Ds}(\mu^*)$, there exist its own*
  - *vector function $\sigma_r\in V^n([0,1])$,*
  - *scalar function $\theta_r\in V([0,1])$, and*
  - *vector measure $\eta_r=(\eta_r^1,\dots,\eta_r^{k_3})$, $\eta_r^j\in C_+^*([0,1])$, $j=1,\dots,k_3$,*

such that, for all $t \in (t_0^*, t_1^*]$ *and all* $s \in [0,1]$,

$$\psi(t) = \psi_0 - \int_{t_0^*}^{t} H_x(s)ds - \int_{[t_0^*,t]} Q_x(s)d\mu_c^* + \int_{[t_0^*,t]} \varphi_x^\top(x^*,s)d\eta + \Sigma(\psi,t),$$

$$\Sigma(\psi,t) = \sum_{r\in \mathrm{Ds}(\mu^*),\ r\le t} [\sigma_r(1) - \psi(r^-)],$$

$$\phi(t) = \phi_0 + \int_{t_0^*}^{t} H_t(s)ds + \int_{[t_0^*,t]} Q_t(s)d\mu_c^* - \int_{[t_0^*,t]} \varphi_t^\top(x^*,s)d\eta + \Theta(\phi,t), \tag{4.1}$$

$$\Theta(\phi,t) = \sum_{r\in \mathrm{Ds}(\mu^*),\ r\le t} [\theta_r(1) - \phi(r^-)],$$

$$\begin{cases} d\alpha_r^*(s) = g(\alpha_r^*(s),r)\Delta_r^* ds, \\ d\sigma_r(s) = -g_x^\top(\alpha_r^*(s),r)\sigma_r(s)\Delta_r^* ds + \varphi_x^\top(\alpha_r^*(s),r)d\eta_r, \\ d\theta_r(s) = \langle g_t(\alpha_r^*(s),r),\sigma_r(s)\rangle \Delta_r^* ds - \varphi_t^\top(\alpha_r^*(s),r)d\eta_r, \\ \alpha_r^*(0) = x^*(r^-), \qquad \sigma_r(0) = \psi(r^-), \qquad \theta_r(0) = \phi(r^-), \qquad \Delta_r^* = \mu^*(\{r\}), \end{cases}$$

$$\psi_0 = \frac{\partial l}{\partial x_0}(p^*,\lambda), \qquad \psi_1 = -\frac{\partial l}{\partial x_1}(p^*,\lambda),$$

$$\phi_0 = -\frac{\partial l}{\partial t_0}(p^*,\lambda), \qquad \phi_1 = \frac{\partial l}{\partial t_1}(p^*,\lambda),$$

$$\langle g(\alpha_r^*(s),r),\sigma_r(s)\rangle = 0 \quad \forall r \in \mathrm{Ds}(\mu^*),$$

$$\mathrm{supp}(\eta_r^j) \subseteq \{s\in[0,1] : \varphi^j(\alpha_r^*(s),r) = W^j(\alpha_r^*(s),r) = 0\} \quad \forall j,$$

$$\langle \lambda_1, e_1(p^*)\rangle = 0,$$

$$\varphi^j(x^*(t),t) = 0 \ \ \eta^j\text{-a.e.} \quad \forall j,$$

$$\max_{u\in U} H(u,t) = H(t) \ \ a.e., \qquad \max_{u\in U} H(u,t) = \phi(t) \quad \forall t \in (t_0^*, t_1^*), \tag{4.2}$$

$$Q(t) \le 0 \quad \forall t, \qquad Q(t) = 0 \quad \mu^*\text{-a.e.},$$

$$\lambda_0 + \mathcal{L}(\{t : |\psi(t)| > 0\}) + \sum_{r\in \mathrm{Ds}(\mu^*)} \mathcal{L}(\{s : |\sigma_r(s)| > 0\})\Delta_r^* = 1. \tag{4.3}$$

In this result and from now on, we adopt the following short notation: $T^* = [t_0^*, t_1^*]$, $\psi_k = \psi(t_k^*)$, $\phi_k = \phi(t_k^*)$, $\Delta_k^* = \mu^*(\{t_k^*\})$, $k = 0,1$, $H(t,u) = H(x^*(t),u,\psi(t),t)$, $H(t) = H(t,u^*(t))$, $Q(t) = Q(x^*(t),\psi(t),t)$, $H_x(t) = H_x(x^*(t),u^*(t),\psi(t),t)$, ..., etc. In other words, if H, Q, or their partial derivatives miss some of arguments x, ψ, u, then it is understood that the values $x^*(t)$, $\psi(t)$, and $u^*(t)$ are considered in their place.

The proof is presented in sections 6, 7, and 8. It is based on a penalty function method [1], results from [16, 20], and on the reduction to the so-called v-problem (Proposition 5.7).

Remark 1. From Theorem 4.1, we deduce $\mathrm{Var}\,\nu[Q] \le \mathrm{const}(\mathrm{Var}\,\eta + \mathcal{L})$. This implies that the function $Q(t)$ is continuous on $\mathrm{Ds}(\mu^*)$.

Remark 2. The time transversality conditions in Theorem 4.1 can be rewritten as follows:

$$\begin{aligned} \max_{u\in U} H(\beta_k^*,u,\gamma_k,t_k^*) + (-1)^{k+1}\Bigg[\Delta_k^* \int_0^1 \langle g_t(\alpha_k^*(s),t_k^*),\sigma_k(s)\rangle ds \\ - \int_{[0,1]} \varphi_t^\top(\alpha_k^*(s),t_k^*)d\eta_k - \varphi_t^\top(x_k^*,t_k^*)\eta(\{t_k^*\}) \\ - \frac{\partial l}{\partial t_k}(p^*,\lambda)\Bigg] = 0, \quad k = 0,1. \end{aligned} \tag{4.4}$$

From now on, $\beta_0^* = x^*(t_0^{*+})$, $\beta_1^* = x^*(t_1^{*-})$, $\gamma_0^* = \psi(t_0^{*+})$, $\gamma_1^* = \psi(t_1^{*-})$, $\Delta_k^* = \mu^*(\{t_k^*\})$, $k = 0, 1$, being α_k^*, σ_k, and η_k, the jump evolution elements at point t_k^*, $k = 0, 1$.

Below, we give a simple example showing that the maximum principle proved in Theorem 4.1 may degenerate when the controllability condition (Definition 2.4) does not hold.

Example 4.2. Consider optimal problem

$$dx = 2td\mu, \quad t \in [0,1]; \qquad x_0 = 0, \qquad x_1 = 1;$$
$$x \geq t^2, \qquad \int_{[0,1]} 1 d\mu \to \min.$$

Now, we show that minimum is reached for the Lebesgue measure $\mu^* = \mathcal{L}$. The corresponding optimal trajectory is the parabola $x^*(t) = t^2$. In fact, this statement is a consequence of the inequality $F(t;\mu) \geq t \ \forall t \in [0,1]$, which holds for any admissible measure μ. Let us prove it. We have

$$x(t) \geq t^2 \ \Rightarrow \ \int_{[0,t]} 2td\mu \geq t^2.$$

By integrating by parts, we have $2F(t;\mu)t \geq t^2 + 2\int_{[0,t]} F(s;\mu)ds$ and, thus,

$$F(t;\mu) \geq \frac{t}{2} + \frac{1}{t}\int_{[0,t]} F(s;\mu)ds.$$

It follows that $F(t;\mu) \geq t/2$. By substituting in the right part of the obtained inequality, we arrive at the more precise estimate $F(t;\mu) \geq 3t/4$. By repeating the procedure, we get, for step n, $F(t;\mu) \geq (2^n - 1)t/2^n$, and, by passing to the limit as $n \to \infty$, we establish $F(t;\mu) \geq t$. Thus $\mu^* = \mathcal{L}$.

However, the maximum principle proved in Theorem 4.1 degenerates for this problem. Indeed, the impulsive maximum condition yields $2t\psi(t) - \lambda_0 = 0$ for a.e. $t \in [0,1]$. By passing to the limit when $t \to 0$ and by bearing in mind that $\psi(t)$ is bounded, we conclude that $\lambda_0 = 0$. Hence, $\psi(t) = 0 \ \forall t \in (0,1)$. It follows that (4.3) does not hold. This happens because the optimal trajectory is not controllable.

5. Lemmas and propositions. In this section, we compile a set of auxiliary lemmas and propositions that we will use in the proof of the main result. Their proofs appear in the appendix. While Lemmas 5.1 to 5.5 are of independent interest in themselves, Propositions 5.6 and 5.7 support the progressive reduction strategy adopted in the proof of Theorems 4.1, 6.1, 6.2, and 7.1.

LEMMA 5.1. *Given a sequence of measures $\mu_i \in C_+^*(T)$, $\mu_i \xrightarrow{w} \mu$, and a sequence of functions $f_i \in C(T)$, such that*

(1) *there exists a sequence of absolutely continuous measures $\eta_i \in C_+^*(T)$, $\eta_i \xrightarrow{w} \eta$ such that $\mathrm{Ds}(\mu) \cap \mathrm{Ds}(\eta) = \emptyset$ and $\mathrm{Var}\,\nu[f_i] \leq c\eta_i \ \forall i$;*

(2) *$f_i(t) \to f(t) \ \forall t \in \mathrm{Cont}(\eta)$, where $f \in V(T)$.*

Then

$$\int_{[t_0,t_1]} f_i(t) d\mu_i \to \int_{[t_0,t_1]} f(t) d\mu.$$

Remark 3. The following example shows that we cannot omit requirement (1) in Lemma 5.1.

Example 5.2. Let $T = [0,1]$, and $d\mu_i = \delta_{t_i}(t)$ is the sequence of Dirac's measures, concentrated at points $t_i = \frac{1}{i}$. Consider the following sequence of (bump) functions $\{f_i\}$:

$$f_i(t) = \begin{cases} it, & t \in [0, i^{-1}], \\ 2 - it, & t \in [i^{-1}, 2i^{-1}], \\ 0, & t \in [2i^{-1}, 1]. \end{cases}$$

It is clear that $\mu_i \xrightarrow{w} \mu$, where $d\mu = \delta_0(t)$, and $f_i(t) \to 0\ \forall t \in [0,1]$. Nevertheless $\int_{[0,1]} f_i(t)d\mu_i = 1\ \forall i$, while $\int_{[0,1]} f(t)d\mu = 0$. The fact is that for the sequences $\{\mu_i\}$ and $\{f_i\}$ constructed above, there is no sequence $\{\eta_i\}$ satisfying the requirements of Lemma 5.1. Indeed, $\operatorname{Var}\nu[f_i] \xrightarrow{w} \eta$ with $d\eta = 2\delta_0(t)$, but $\operatorname{Ds}(\mu) \cap \operatorname{Ds}(\eta) = \{0\} \neq \emptyset$.

LEMMA 5.3. *Let all the hypotheses of Lemma* 5.1 *hold. Let* $x_i(t_0) = x(t_0) = 0,\ i \in \mathbf{N}$, *and* $\forall t \in (t_0, t_1]$,

$$x_i(t) = \int_{[t_0,t]} f_i(s)d\mu_i, \qquad x(t) = \int_{[t_0,t]} f(s)d\mu.$$

For any given convergent sequence $\{t_i\}$, $t_i \to s \in T$, *where* $s \notin \operatorname{Ds}(\mu)$, *we have that* $x_i(t_i) \to x(s)$.

LEMMA 5.4. *Let* $\mu_i \in C_+^*(T)$, $\mu_i \xrightarrow{w} \mu$, $u_i \xrightarrow{w} u$ *weakly in* $L_2(T)$, $u_i(t) \in U(t)$ *a.e.,* $x_{0,i} \to x_0$, *and given a sequence of vector-functions* $x_i \in V^n(T)$ *such that*

$$dx_i = f(x_i, u_i, t)dt + g(x_i, t)d\mu_i, \quad t \in T,\ x_i(t_0) = x_{0,i}.$$

If $\operatorname{gc\,sup}_{t\in T} |x_i(t)| \leq \text{const}\ \forall i$, *then* $x_i(t) \to x(t)\ \forall t \in \operatorname{Cont}(\mu)$, *where* $x(t)$ *is the solution to* (1.2). *Furthermore,* $\operatorname{gc\,sup}_{t\in T} |x_i(t)| \to \operatorname{gc\,sup}_{t\in T} |x(t)|$.

LEMMA 5.5. *Let the sequences* $\{f_i\}$ *and* $\{\eta_i\}$ *be such that* $f_i \in C(T)$, $\eta_i \in C_+^*(T)$, *and* $f_i \to f \in C(T)$ *uniformly and* $\eta_i \xrightarrow{w} \eta \in C_+^*(T)$, *respectively. Assume also that* $\operatorname{supp}(\eta) \subset W_0 = \{t : f(t) = 0\}$. *Consider the sequence of functions* $\{x_i\}$ *defined by*

$$x_i(t) = \int_{[t_0,t]} f_i(s)d\eta_i, \quad t > t_0, \qquad x_i(t_0) = 0.$$

If the function f *is Lipschitz continuous, then* $\operatorname{Var}|_{\tau}[x_i] \to 0$.

Reduction R_1. In parallel with initial problem (1.1)–(1.4), denoted (P), we shall consider problem (P_1):

$$(P_1): \quad \begin{cases} e_0(p) \to \min, \\ dx = f(x,u,t)dt + g(x,t)d\mu, \\ d\alpha_k = g(\alpha_k, \theta_k)d\upsilon_k, \quad \alpha_k(t_{1-k}) = x_k, \\ d\theta_k = 0, \quad \theta_k = t_k,\ k = 0,1,\ t \in [t_0, t_1], \\ e_1(p) \leq 0, \quad e_2(p) = 0, \\ \varphi(x,t) \leq 0, \quad \varphi(\alpha_k, \theta_k) \leq 0, \quad k = 0,1, \\ u(t) \in U(t) \text{ a.e.}, \quad \mu, \upsilon_k \geq 0,\ k = 0,1, \\ p = (\xi_0, \xi_1, t_0, t_1), \quad x_k = x(t_k), \quad \xi_k = \alpha_k(t_k), \quad k = 0,1. \end{cases}$$

PROPOSITION 5.6. *Problems* (P) *and* (P_1) *are equivalent. This means that for every admissible process* (p, u, μ) *of* (P), *there exists an admissible process* $(\tilde{p}, \tilde{u}, \tilde{\mu}, \upsilon_0, \upsilon_1)$ *of* (P_1) *such that* $e_0(p) = e_0(\tilde{p})$, *and, conversely, for each admissible process of* (P_1), *there exists one of* (P) *yielding the same cost.*

Reduction R_1 permits us to focus on simpler problems in which the control measure has no atoms at the initial and the final points of the time interval.

Remark 4. All the results obtained in this paper for problem (P) can easily be written to problem (P_1) because the systems corresponding to measures μ, υ_0, and υ_1 are dynamically independent.

Reduction R_2. This is a reduction to the so-called v-problem [1]. Let Assumption S be in force. Consider problem (P_2) (v-problem).

$$(P_2): \quad \begin{cases} e_0(p) \to \min, \\ dx = (v+1)f(x,u,\chi)dt + g(x,\chi)d\mu, \quad t \in [t_0,t_1], \\ d\chi = (v+1)dt, \\ e_1(p) \le 0, \quad e_2(p) = 0, \quad p = (x_0,x_1,\chi_0,\chi_1), \quad \varphi(x,\chi) \le 0, \\ u(t) \in U, \quad |v(t)| \le 1/2 \text{ a.e.}, \quad \mu \ge 0. \end{cases}$$

PROPOSITION 5.7. *Problems* (P) *and* (P_2) *are equivalent.*

6. Primary problems. We start by considering the optimal control problem without state and endpoint constraints, i.e., (1.1)–(1.2) and (1.5), for which a maximum principle is given in Theorem 6.1. Then, the complexity of the problem is increased by adding endpoint constraints (1.3), and the necessary conditions of optimality presented in Theorem 6.2 are derived. State constraints will not be considered in this section.

THEOREM 6.1. *Let* (p^*,u^*,μ^*) *be an optimal process for the problem specified by* (1.1), (1.2) *and* (1.5). *Then, there exists a function* $\psi \in V^n(T^*)$ *such that*

$$\begin{cases} dx^* = H_\psi(t)dt + Q_\psi(t)d\mu^*, \\ d\psi = -H_x(t)dt - Q_x(t)d\mu^*, \end{cases} \qquad t \in T^*, \tag{6.1}$$

$$\psi_0 = \frac{\partial e_0}{\partial x_0}(p^*), \qquad \psi_1 = -\frac{\partial e_0}{\partial x_1}(p^*), \tag{6.2}$$

$$\max_{u\in U(t)} H(u,t) = H(t) \ \textit{a.e.}, \tag{6.3}$$

$$Q(t) \le 0 \quad \forall t, \qquad Q(t) = 0 \quad \forall t \in \operatorname{supp}(\mu^*), \tag{6.4}$$

$$\begin{cases} \operatorname{ess\,lim\,sup}\limits_{t\to t_k^*} \max\limits_{u\in U(t)} H(\beta_k^*,u,\gamma_k,t) \\ \quad +(-1)^{k+1}\left[\Delta_k^* \displaystyle\int_0^1 \langle g_t(\alpha_k^*,t_k^*),\sigma_k\rangle ds - \frac{\partial e_0}{\partial t_k}(p^*)\right] \ge 0, \\ \operatorname{ess\,lim\,inf}\limits_{t\to t_k^*} \max\limits_{u\in U(t)} H(\beta_k^*,u,\gamma_k,t) \\ \quad +(-1)^{k+1}\left[\Delta_k^* \displaystyle\int_0^1 \langle g_t(\alpha_k^*,t_k^*),\sigma_k\rangle ds - \frac{\partial e_0}{\partial t_k}(p^*)\right] \le 0, \end{cases} \qquad k = 0,1, \tag{6.5}$$

$$\operatorname*{ess\,lim\,inf}_{t\to t_k^*} \max_{u\in U(t)} H(x_k^*,u,\psi_k,t) + (-1)^k \frac{\partial e_0}{\partial t_k}(p^*) \le 0. \tag{6.6}$$

Here, $\beta_0^* = x^*(t_0^{*+})$, $\beta_1^* = x^*(t_1^{*-})$, $\gamma_0 = \psi(t_0^{*+})$, $\gamma_1 = \psi(t_1^{*-})$, $\Delta_k^* = \mu^*(\{t_k^*\})$, $k = 0,1$, *are the control atoms at the time endpoints (see last remark in section* 4*), and the pair* (α_k^*,σ_k), $k = 0,1$, *in* (6.5) *corresponds to the solution* (6.1) *in atom* t_k^*. *According to our solution concept, this means that the pair* (α_k^*,σ_k) *satisfies*

$$\begin{cases} \dot\alpha_k^* = g(\alpha_k^*,t_k^*)\Delta_k^*, \quad \alpha_k^*(0) = x^*(t_k^{*-}), \\ \dot\sigma_k = -g_x^\top(\alpha_k^*,t_k^*)\sigma_k\Delta_k^*, \quad \sigma_k(0) = \psi(t_k^{*-}), \end{cases} \qquad s \in [0,1], \quad k = 0,1. \tag{6.7}$$

Proof. The proof of (6.1)–(6.4) is given in [16, 20]. So we only have to show that the time-transversality conditions (6.5) hold. We shall do it using the scheme from [1].

We start by assuming that measure μ^* has no atoms at points t_k^*, i.e., $\Delta_k^* = 0$, $k = 0, 1$. Let us prove (6.5) when $k = 1$.

Fix $\varepsilon > 0$ such that $t_1^* - \varepsilon \in \mathrm{Cont}(\mu^*)$ and let $T_\varepsilon = [t_1^* - \varepsilon, t_1^*]$. Define the measure $\mu_\varepsilon := \mu^* + \mu^*(T_\varepsilon)\delta(t_1^* - \varepsilon)$ on $[t_0^*, t_1^* - \varepsilon]$. Let $p_\varepsilon = (x_0^*, x_\varepsilon(t_1^* - \varepsilon), t_0^*, t_1^* - \varepsilon)$, where x_ε is the trajectory associated to $(x_0^*, u^*, \mu_\varepsilon)$. For ε sufficiently small and from the optimality of the process (p^*, u^*, μ^*), i.e.,

$$e_0(p_\varepsilon) - e_0(p^*) \geq 0 \quad \forall \varepsilon > 0,$$

we have that

$$\left\langle \frac{\partial e_0}{\partial x_1}(p^*), \Delta x_\varepsilon \right\rangle - \varepsilon \frac{\partial e_0}{\partial t_1}(p^*) + o(|\Delta x_\varepsilon|) + o(\varepsilon) \geq 0, \tag{6.8}$$

where $\Delta x_\varepsilon = x_\varepsilon(t_1^* - \varepsilon) - x_1^*$.

Let $\xi_\varepsilon^* = \xi(x^*(t_1^* - \varepsilon), t_1^* - \varepsilon, \mu^*(T_\varepsilon))$. Then, by definition $\Delta x_\varepsilon = \Delta x_\varepsilon^1 + \Delta x_\varepsilon^2$, where

$$\Delta x_\varepsilon^1 = -\int_{T_\varepsilon} f(x^*, u^*, t)dt, \qquad \Delta x_\varepsilon^2 = \xi_\varepsilon^* - \left(x^*(t_1^* - \varepsilon) + \int_{T_\varepsilon} g(x^*, t)d\mu^* \right).$$

The estimate $|\Delta x_\varepsilon^1| \leq \mathrm{const}\, \varepsilon$ is obvious. Let us show that $|\Delta x_\varepsilon^2| \leq \mathrm{const}\, \varepsilon \mu^*(T_\varepsilon)$. Since $|\Delta x_\varepsilon^2| = 0$ whenever $\mu^*(T_\varepsilon) = 0$, we assume that $\mu^*(T_\varepsilon) > 0$ $\forall \varepsilon > 0$.

Let us construct a sequence of absolutely continuous measures $\{\mu_i\}$ having density $\dot{\mu}_i = m_i > 0$ a.e., defined on the segment T_ε such that $\mu_i \xrightarrow{w} \mu^*$ weakly* on T_ε, $\mu_i(T_\varepsilon) = \mu^*(T_\varepsilon)$. Let x_i be a continuation of the solution x^* on segment T_ε, corresponding to the measure μ_i (such a continuation exists when i is sufficient large). By Lemma 5.4, $x_i(t) \to x^*(t)$ $\forall t \in \mathrm{Cont}(\mu^*)$. Then, $\Delta x_{\varepsilon,i} = x_\varepsilon(t_1^* - \varepsilon) - x_i(t_1^*) \to \Delta x_\varepsilon$ as $i \to \infty$. Furthermore, $\Delta x_{\varepsilon,i}^1 \to \Delta x_\varepsilon^1$ and $\Delta x_{\varepsilon,i}^2 \to \Delta x_\varepsilon^2$, being

$$\Delta x_{\varepsilon,i}^1 = -\int_{T_\varepsilon} f(x_i, u^*, t)dt, \qquad \Delta x_{\varepsilon,i}^2 = \xi_\varepsilon^* - \left(x^*(t_1^* - \varepsilon) + \int_{T_\varepsilon} g(x_i, t)m_i dt \right).$$

To estimate $|\Delta x_{\varepsilon,i}^2|$, let us consider the equation

$$\dot{x}_{2,i} = g(x_{1,i} + x_{2,i}, t)m_i, \quad t \in T_\varepsilon, \qquad x_{2,i}(t_1^* - \varepsilon) = x^*(t_1^* - \varepsilon). \tag{6.9}$$

Here, $x_{1,i}(t) = \int_{t_1^* - \varepsilon}^t f(x_i, u^*, \tau)d\tau$ and $x_i = x_{1,i} + x_{2,i}$.

Define the functions $\pi_i : T_\varepsilon \to [0, 1]$ as follows:

$$\pi_i(t) = \frac{F(t; \mu_i) - F(t_1^* - \varepsilon; \mu_i)}{\mu^*(T_\varepsilon)}, \quad t \in T_\varepsilon.$$

Obviously, π_i is absolutely continuous and $\frac{d\pi_i}{dt} > 0$ a.e. Therefore, there exists the inverse function $\pi_i^{-1} : [0, 1] \to T_\varepsilon$ which is also strictly monotone and absolutely continuous. By the change of variable $s = \pi_i(t)$ in (6.9), and by putting $\alpha_i(s) = x_{2,i}(\pi_i^{-1}(s))$, we arrive at the equation

$$\dot{\alpha}_i = g(x_{1,i}(\pi_i^{-1}(s)) + \alpha_i, \pi_i^{-1}(s))\mu^*(T_\varepsilon), \quad s \in [0, 1], \qquad \alpha_i(0) = x^*(t_1^* - \varepsilon).$$

By definition $\xi_\varepsilon^* = \alpha(1)$, where $\alpha(s)$ satisfies

$$\dot\alpha = g(\alpha, t_1^* - \varepsilon)\mu^*(T_\varepsilon), \quad s \in [0,1], \qquad \alpha(0) = x^*(t_1^* - \varepsilon).$$

From here, $|\alpha_i(s) - \alpha(s)| \le \mu^*(T_\varepsilon) \int_0^s c(|\alpha_i(\tau) - \alpha(\tau)| + \int_{T_\varepsilon} |f(x_i, u^*, \theta)| d\theta + \varepsilon) d\tau \ \forall s$.

From Gronwall's inequality, $|\Delta x^2_{\varepsilon,i}| = |\alpha_i(1) - \alpha(1)| \le \text{const}\, \varepsilon \mu^*(T_\varepsilon)$ and, therefore,

$$|\Delta x^2_\varepsilon| \le \text{const}\, \varepsilon \mu^*(T_\varepsilon) = o(\varepsilon).$$

The last equality holds from the fact that $\mu^*(T_\varepsilon) \to 0$ as $\varepsilon \to 0$.

In view of the obtained estimates and the already proved transversality conditions (6.2), inequality (6.8) becomes

$$\left\langle \psi_1, \int_{T_\varepsilon} f(x^*, u^*, t) dt \right\rangle - \varepsilon \frac{\partial e_0}{\partial t_1}(p^*) + o(\varepsilon) \ge 0.$$

From here, we may write

$$\int_{t_1^* - \varepsilon}^{t_1^*} \max_{u \in U(t)} H(u, \psi_1, t) dt - \varepsilon \frac{\partial e_0}{\partial t_1}(p^*) + o(\varepsilon) \ge 0,$$

and, by dividing the last inequality by $\varepsilon > 0$ and taking the limit as ε goes to zero, we obtain

$$\operatorname{ess\,lim\,sup}_{t \to t_1^*} \max_{u \in U(t)} H(x_1^*, u, \psi_1, t) - \frac{\partial e_0}{\partial t_1}(p^*) \ge 0.$$

This corresponds to the first inequality in (6.5).

Now, we consider the other inequality for the final endpoint. Let us put $\mu^*([t_1^*, +\infty)) = 0$. The control function u^* is continued to the right beyond t_1^* as follows:

$$u^*(t) \in \operatorname*{Arg\,max}_{u \in U(t)} H(x_1^*, u, \psi_1, t), \quad t > t_1^*.$$

The trajectory x^* is continued as a solution to (1.2), corresponding to the constructed u^*, on the segment $[t_1^*, t_1^* + \delta]$ for a sufficient small $\delta > 0$. For $\varepsilon \in (0, \delta]$, let $p_\varepsilon = (x_0^*, x^*(t_1^* + \varepsilon), t_0^*, t_1^* + \varepsilon)$. By using the same arguments as above, we arrive at the second inequality in (6.5) for $k = 1$. Similar arguments allow us to show these inequalities for $k = 0$.

Now, let us show that conditions (6.5) hold when $\Delta_k^* > 0$, $k = 0, 1$. For this purpose let us consider the problem (P_1) as a reduction (via R_1) of (P).[1]

If the process (p^*, u^*, μ^*) is a solution to (P), then the process $(\beta_0^*, \beta_1^*, t_0^*, t_1^*, u^*, \Delta_0^*, \Delta_1^*, \tilde\mu)$ is a solution to (P_1). Here, $\tilde\mu = \mu^* - \sum_{k=0}^1 \Delta_k^* \delta_{t_k^*}(t)$, and β_0^*, and β_1^* are as defined above. The measure $\tilde\mu$ has no atoms in t_k^*, $k = 0, 1$, and the maximum principle for this problem has just been proved.

[1]Here, (P) and (P_1) are considered as in section 5 but without constraints. To be more precise, if (P) is a problem without constraints, then (P_1) is defined as follows (equivalent definition):

$$(P_1): \begin{cases} e_0(p) \to \min, \\ dx = f(x,u,t)dt + g(x,t)d\mu, \ d\Delta_k = 0, \ \Delta_k \ge 0, \ k = 0,1, \\ p = (\xi_0, \xi_1, t_0, t_1), \ \xi_k = \xi(x_k, t_k, (-1)^{k+1}\Delta_k). \end{cases}$$

By applying this maximum principle to (P_1) and decoding its conditions in terms of the data of problem (1.1)–(1.2), we conclude the existence of a function $\psi^R \in V^n(T^*)$ such that

$$
\begin{aligned}
&d\psi^R = -H_x(\tilde{x},\psi^R,t)dt - Q_x(\tilde{x},\psi^R,t)d\tilde{\mu}, \quad t \in T^*,\\
&\begin{cases} \psi_0^R = \xi_x^\top(\beta_0^*,t_0^*,-\Delta_0^*)\dfrac{\partial e_0}{\partial x_0}(p^*),\\ \psi_1^R = -\xi_x^\top(\beta_1^*,t_1^*,\Delta_1^*)\dfrac{\partial e_0}{\partial x_1}(p^*), \end{cases} \qquad (6.10)\\
&\left\langle \xi_\Delta(\beta_k^*,t_k^*,(-1)^{k+1}\Delta_k^*), \frac{\partial e_0}{\partial x_k}(p^*)\right\rangle = 0, \quad k=0,1, \qquad (6.11)\\
&\max_{u\in U(t)} H(\tilde{x}(t),u,\psi^R(t),t) = H(\tilde{x}(t),u^*(t),\psi^R(t),t), \quad \text{a.e.},\\
&Q(\tilde{x}(t),\psi^R(t),t) \le 0, \quad t \in T^*,\\
&Q(\tilde{x}(t),\psi^R(t),t) = 0 \quad \forall t \in \operatorname{supp}(\tilde{\mu}),\\
&\begin{cases} \operatorname{ess\,lim\,sup}\limits_{t\to t_k^*} \max\limits_{u\in U(t)} H(\beta_k^*,u,\psi_k^R,t)\\ \quad +(-1)^k\left[\dfrac{\partial e_0}{\partial t_k}(p^*) + \left\langle \xi_t(\beta_k^*,t_k^*,(-1)^{k+1}\Delta_k^*), \dfrac{\partial e_0}{\partial x_k}(p^*)\right\rangle\right] \ge 0,\\ \operatorname{ess\,lim\,inf}\limits_{t\to t_k^*} \max\limits_{u\in U(t)} H(\beta_k^*,u,\psi_k^R,t)\\ \quad +(-1)^k\left[\dfrac{\partial e_0}{\partial t_k}(p^*) + \left\langle \xi_t(\beta_k^*,t_k^*,(-1)^{k+1}\Delta_k^*), \dfrac{\partial e_0}{\partial x_k}(p^*)\right\rangle\right] \le 0, \end{cases} \qquad k=0,1. \end{aligned}
$$

Here, $\tilde{x}$ is the optimal trajectory for problem (P_1), and the matrix function ξ_x and the vector functions ξ_Δ, ξ_t are the derivatives of ξ with respect to, respectively, x, Δ, and t.

Clearly, $\tilde{x}(t) = x^*(t)$ $\forall t \in (t_0^*, t_1^*)$, and $\tilde{x}(t_k^*) = \beta_k^*$, $k = 0, 1$. Let us take $\psi(t) = \psi^R(t)$ $\forall t \in (t_0^*, t_1^*)$, $\psi(t_k^*) = (-1)^k \frac{\partial e_0}{\partial x_k}(p^*)$, $k = 0, 1$, and show that ψ satisfies (6.1)–(6.5). Clearly, we need to verify them only at the two endpoints t_k^*, $k = 0, 1$.

Consider the case $k = 1$ (the case $k = 0$ is similar). Let (α_1^*, σ_1) be a solution to (6.7). It is straightforward to verify that function $(\xi_x, \xi_\Delta, \xi_t)$ is given by

$$(\xi_x, \xi_\Delta, \xi_t)(\beta_1^*, t_1^*, \Delta_1^*) = (\bar{\xi}_x, \bar{\xi}_\Delta, \bar{\xi}_t)(1),$$

where $(\bar{\xi}_x, \bar{\xi}_\Delta, \bar{\xi}_t)(0) = (E, 0, 0)$ (E is the n-dimensional identity matrix) and, for $s \in [0, 1]$,

$$
\begin{cases} \dot{\bar{\xi}}_x(s) = g_x(\alpha_1^*(s), t_1^*)\bar{\xi}_x(s)\Delta_1^*,\\ \dot{\bar{\xi}}_\Delta(s) = g_x(\alpha_1^*(s), t_1^*)\bar{\xi}_\Delta(s)\Delta_1^* + g(\alpha_1^*(s), t_1^*),\\ \dot{\bar{\xi}}_t(s) = g_x(\alpha_1^*(s), t_1^*)\bar{\xi}_t(s)\Delta_1^* + g_t(\alpha_1^*(s), t_1^*)\Delta_1^*. \end{cases}
$$

From (6.10) we get $\sigma_1(1) = \psi_1$. Thus (6.1)–(6.3) are proved.

To prove (6.4), we will show that $\langle \sigma_1, g(\alpha_1^*, t_1^*)\rangle \equiv 0$. Indeed, by direct computation and by using the fact that $\frac{d}{ds}\langle \sigma_1, g(\alpha_1, t_1^*)\rangle = 0$ $\forall s \in [0, 1]$, we have that $\frac{d}{ds}\langle \sigma_1, \bar{\xi}_\Delta\rangle = \langle \sigma_1, g(\alpha_1^*, t_1^*)\rangle = \text{const}$ $\forall s \in [0, 1]$. On the other hand, from (6.11) and the definition of ξ_Δ, we conclude that $\langle \sigma_1(0), \bar{\xi}_\Delta(0)\rangle = \langle \sigma_1(1), \bar{\xi}_\Delta(1)\rangle = 0$.

Hence, $\langle \sigma_1, \bar{\xi}_\Delta\rangle \equiv 0$ and, as consequence, $\langle \sigma_1, g(\alpha_1^*, t_1^*)\rangle \equiv 0$ on $[0, 1]$, i.e., condition (6.4) is proved.

To obtain inequalities in (6.5), note that these follow from the fact that

$$\frac{d}{ds}\langle \sigma_1, \bar{\xi}_t \rangle = \langle \sigma_1, g_t(\alpha_1^*, t_1^*)\rangle \Delta_1^*.$$

The condition (6.6) can be easily deduced as its analogue in (6.5).

The proof is complete. □

THEOREM 6.2. *Let (p^*, u^*, μ^*) be an optimal process for the problem specified by (1.1)–(1.3) and (1.5). Then, there exist a number $\lambda_0 \geq 0$, vectors $\lambda_j \in \Re^{k_j}$, $j = 1, 2$, with $|\lambda| = 1$, and a function $\psi \in V^n(T^*)$ satisfying*

$$\begin{aligned}
&d\psi = -H_x(t)dt - Q_x(t)d\mu^*, \quad t \in T^*,\\
&\psi_0 = \frac{\partial l}{\partial x_0}(p^*, \lambda), \quad \psi_1 = -\frac{\partial l}{\partial x_1}(p^*, \lambda),\\
&\lambda_1 \geq 0, \quad \langle \lambda_1, e_1(p^*)\rangle = 0;\\
&\max_{u \in U(t)} H(u, t) = H(t) \ \textit{a.e.},\\
&Q(t) \leq 0 \quad \forall t, \qquad Q(t) = 0 \quad \forall t \in \operatorname{supp}(\mu^*),
\end{aligned}$$

$$\begin{cases}
\operatorname{ess\,lim\,sup}\limits_{t \to t_k^*} \max\limits_{u \in U(t)} H(\beta_k^*, u, \gamma_k, t)\\
\quad +(-1)^{k+1}\left[\Delta_k^* \int_0^1 \langle g_t(\alpha_k^*, t_k^*), \sigma_k\rangle ds - \frac{\partial l}{\partial t_k}(p^*, \lambda)\right] \geq 0,\\
\operatorname{ess\,lim\,inf}\limits_{t \to t_k^*} \max\limits_{u \in U(t)} H(\beta_k^*, u, \gamma_k, t)\\
\quad +(-1)^{k+1}\left[\Delta_k^* \int_0^1 \langle g_t(\alpha_k^*, t_k^*), \sigma_k\rangle ds - \frac{\partial l}{\partial t_k}(p^*, \lambda)\right] \leq 0,
\end{cases} \qquad k = 0, 1. \tag{6.12}$$

Furthermore, inequalities (6.12) *may be replaced by*

$$\operatorname{ess\,lim\,inf}_{t \to t_k^*} \max_{u \in U(t)} H(x_k^*, u, \psi_k, t) + (-1)^k \frac{\partial l}{\partial t_k}(p^*) \leq 0, \ \ k = 0, 1. \tag{6.13}$$

However, we cannot guarantee that both conditions (6.12) *and* (6.13) *hold at the same time, i.e., we have two different versions of the maximum principle.*

Proof. The proof is based on the penalty function method [1]. Assume, first, that $\Delta_k^* = 0$, $k = 0, 1$. Take any natural i and define the function $e_{0,i}$ as follows:

$$e_{0,i}(p) = e_0(p) + |p - p^*|^2 + i(|e_1^+(p)|^2 + |e_2(p)|^2).$$

Here, for a given vector $a = (a^1, \ldots, a^k)$, a^+ stands for the vector with components $(a^j)^+ = \max\{0, a^j\}$, $j = 1, \ldots, k$.

Let $F(t) = F(t; \mu^*)$ be the distribution function of the optimal measure. Take $c = \operatorname{gc\,sup}_{t \in T^*} |x^*(t)| + |\mu^*| + |p^*| + 1$ and a sufficiently small $\varepsilon > 0$. Consider, for each $i \in \mathbf{N}$, the following penalty problem:

$$\begin{cases}
J_i(p, u, \mu) = e_{0,i}(p) + |y_1 - F(t_1^*)|^2\\
\qquad\qquad +\varepsilon \int_{t_0}^{t_1} [|u - u^*(t)|^2 + |y - F(t)|^2]dt \to \min,\\
dx = f(x, u, t)dt + g(x, t)d\mu, \quad t \in [t_0, t_1],\\
dy = d\mu, \qquad y_0 = 0, \qquad t \in [t_0, t_1],\\
\max\{|p|, \operatorname{gc\,sup}|x|, y_1\} \leq c,\\
u(t) \in U(t) \text{ a.e.}, \quad \mu \geq 0.
\end{cases} \tag{6.14}$$

This problem is called the *i-problem.*

For every i-problem, there exists a solution (p_i, u_i, μ_i).[2] By using compactness and by extracting a subsequence, we obtain a process (p, u, μ) such that $p_i \to p$, $u_i \xrightarrow{w} u$ weakly in $L_2^m(T_c)$, $\mu_i \xrightarrow{w} \mu$ weakly* in $C^*(T_c)$.[3] It is a straightforward task to establish that $p = p^*$, $u = u^*$, and $\mu = \mu^*$. Moreover, from the penalty method we conclude that indeed $u_i \to u^*$ in $L_2^m(T_c)$. Then, by extracting a subsequence if necessary, we conclude that $u_i(t) \to u^*(t)$ a.e.

All inequality constraints of problem (6.14) become strict for i sufficiently large. For this reason we can apply Theorem 6.1 to the i-problem. By writing down the necessary conditions of Theorem 6.1 and bearing in mind that $i \to \infty$, we conclude Theorem 6.2 when $\Delta_k^* = 0$, $k = 0, 1$. If $\Delta_k^* > 0$, then, by using reduction R_1 (the same way as in Theorem 6.1), we obtain the time-transversality conditions in the conventional case. To prove (6.13) we do not need to use reduction R_1.

The proof is complete. □

7. The problem with state constraints. In this section, we prove a *weakened* maximum principle for problems with state and endpoint constraints.

THEOREM 7.1. *Consider the optimal control problem* (1.1)–(1.5) *with compatible state and endpoint constraints and let triple* (p^*, u^*, μ^*) *be its solution.*

Then, there exist a number $\lambda_0 \geq 0$, *vectors* $\lambda_1 \in \Re^{k_1}$, $\lambda_1 \geq 0$, $\lambda_2 \in \Re^{k_2}$, *a vector function* $\psi \in V^n(T^*)$, *a vector measure* $\eta = (\eta^1, \dots, \eta^{k_3})$, $\eta^j \in C_+^*(T^*)$ *such that* $\mathrm{Ds}(\mu^*) \cap \mathrm{Ds}(\eta^j) = \emptyset$ $\forall j$, *and, for every atom* $r \in \mathrm{Ds}(\mu^*)$, *there exist its own vector function* $\sigma_r \in V^n([0,1])$ *and its own vector measure* $\eta_r = (\eta_r^1, \dots, \eta_r^{k_3})$, $\eta_r^j \in C_+^*([0,1])$, $j = 1, \dots, k_3$, *such that*

$$\psi(t) = \psi_0 - \int_{t_0^*}^{t} H_x(s)ds - \int_{[t_0^*,t]} Q_x(s)d\mu_c^* + \int_{[t_0^*,t]} \varphi_x^\top(x^*, s)d\eta + \Sigma(\psi, t), \quad t \in (t_0^*, t_1^*], \tag{7.1}$$

$$\Sigma(\psi, t) = \sum_{r \in \mathrm{Ds}(\mu^*),\ r \leq t} [\sigma_r(1) - \psi(r^-)],$$

$$\begin{cases} \dot{\alpha}_r^*(s) &= g(\alpha_r^*(s), r)\Delta_r^*, \quad s \in [0,1], \\ d\sigma_r(s) &= -g_x^\top(\alpha_r^*(s), r)\sigma_r(s)\Delta_r^* ds + \varphi_x^\top(\alpha_r^*(s), r)d\eta_r, \quad s \in [0,1], \\ \alpha_r^*(0) &= x^*(r^-), \\ \sigma_r(0) &= \psi(r^-), \\ \Delta_r^* &= \mu^*(\{r\}), \end{cases}$$

$$\psi_0 = \frac{\partial l}{\partial x_0}(p^*, \lambda), \qquad \psi_1 = -\frac{\partial l}{\partial x_1}(p^*, \lambda), \tag{7.2}$$

$$\langle g(\alpha_r^*(s), r), \sigma_r(s)\rangle = 0 \quad \forall s \in [0,1],\ \forall r \in \mathrm{Ds}(\mu^*) \tag{7.3}$$

$$\mathrm{supp}(\eta_r^j) \subseteq \{s \in [0,1] : \varphi^j(\alpha_r^*(s), r) = W^j(\alpha_r^*(s), r) = 0\} \quad \forall j, \tag{7.4}$$

$$\langle \lambda_1, e_1(p^*)\rangle = 0,$$

$$\varphi^j(x^*(t), t) = 0 \ \ \eta^j\text{-a.e.} \quad \forall j \tag{7.5}$$

$$\max_{u \in U(t)} H(u, t) = H(t) \quad \text{a.e.}, \tag{7.6}$$

[2] This is due to the compactness and Lemma 5.4. In fact, since $x(t)$ are bounded uniformly (due to $\mathrm{gc}\sup|x| \leq$ const and by using $|\mu| \leq$ const) and $\mathrm{Var}\,|_a^b[x_i(t)] \leq \sup_{s\in[a,b]}|f_i(s)| \times |\mu_i|([a,b])$ $\forall a, b \in T$ (from the uniform bound of (u_i, μ_i)), we can use Helly's theorem and extract appropriate subsequences.

[3] Here, $T_c = [-c, c]$.

$$Q(t) \le 0 \quad \forall t, \qquad Q(t) = 0 \quad \mu^*\text{-a.e.}, \tag{7.7}$$

$$\operatorname{ess}\liminf_{t\to t_k^*} \max_{u\in U(t)} H(x_k^*, u, \psi_k, t) + (-1)^k \frac{\partial l}{\partial t_k}(p^*, \lambda) \le 0, \quad k = 0, 1, \tag{7.8}$$

$$|\lambda| + |\eta| + \sum_{r\in \mathrm{Ds}(\mu^*)} |\eta_r| = 1. \tag{7.9}$$

Furthermore, when Assumption C *is in force, then in place of* (7.8) *we can obtain* time transversality conditions, *which are written as follows for the case where* $\Delta_k^* = 0$:[4]

$$\begin{cases} \operatorname{ess}\limsup_{t\to t_k^*} \max_{u\in U(t)} H(x_k^*, u, \psi_k, t) + (-1)^k \dfrac{\partial l}{\partial t_k}(p^*, \lambda) \ge 0, \\ \operatorname{ess}\liminf_{t\to t_k^*} \max_{u\in U(t)} H(x_k^*, u, \psi_k, t) + (-1)^k \dfrac{\partial l}{\partial t_k}(p^*, \lambda) \le 0, \end{cases} \quad k = 0, 1. \tag{7.10}$$

Besides, as in Theorem 6.2, *we cannot guarantee that* (7.8) *and* (7.10) *are satisfied at the same time, so again we have two readings of the theorem.*

Proof. The proof is based on a penalty function method [1].

Let us start by proving this result for the most difficult case, i.e., to consider the second variant of the theorem with time transversality conditions (7.10).

Bearing in mind Assumption C and Definition 2.3, let us take a sufficiently small $\delta > 0$. Since μ^* is continuous at t_k^*, $k = 0, 1$, there are points $t_{0,\delta} > t_0^*$, $t_{1,\delta} < t_1^*$, and a small number $\varepsilon > 0$ such that $(\mu^* + \mathcal{L})([t_0^*, t_{0,\delta} + \varepsilon] \cup [t_{1,\delta} - \varepsilon, t_1^*]) < \delta$. Define the function φ_δ^+ as follows:

$$\varphi_\delta^+(x,t) = \begin{cases} \varphi^+(x,t), & t_{0,\delta} < t < t_{1,\delta}, \\ 0 \quad \text{otherwise.} \end{cases}$$

The components of φ_δ^+ are nonnegative and lower semicontinuous.

Let $F(t) = F(t; \mu^*)$ and $c = \operatorname{gc\,sup} |x^*| + |p^*| + |\mu^*| + 1$. Take any $i, A \in \mathbf{N}$ and construct the following auxiliary penalty problem:

$$\begin{cases} J_{i,A}(p,u,\mu) = e_0(p) + |p - p^*|^2 + |y_1 - F(t_1^*)|^2 \\ \qquad\qquad + A\displaystyle\int_{t_0}^{t_1} |\varphi^+(x,t)|^2 dt + A \int_{[t_0,t_1]} |\varphi_\delta^+(x,t)|^2 d\mu \\ \qquad\qquad + i^{-1} \displaystyle\int_{t_0}^{t_1} [|u - u^*(t)|^2 + |y - F(t)|^2] dt \to \min, \\ \qquad\qquad dx = f(x,u,t)dt + g(x,t)d\mu, \quad dy = d\mu, \ t \in [t_0, t_1], \\ \qquad\qquad y_0 = 0, \qquad e_1(p) \le 0, \qquad e_2(p) = 0, \\ \qquad\qquad |p - p^*| \le \delta, \quad \mu([t_0, t_{0,\delta} + \varepsilon) \cup (t_{1,\delta} - \varepsilon, t_1]) \le \delta, \\ \qquad\qquad \max\{\operatorname{gc\,sup} |x|, y_1\} \le c, \qquad u(t) \in U(t) \text{ a.e.}, \quad \mu \ge 0. \end{cases} \tag{7.11}$$

The functional $J_{i,A}$ is weakly lower semicontinuous in (u, μ) and, thus, for every $i, A \in \mathbf{N}$, the problem (7.11) has a solution. Denote it by $(p_{i,A}, u_{i,A}, \mu_{i,A})$ and let $(x_{i,A}, y_{i,A})$ be the corresponding optimal trajectory. By using compactness, extract a subsequence as i is fixed and obtain a process (p, u, μ) satisfying $p_{i,A} \to p$, $u_{i,A} \xrightarrow{w} u$ weakly in $L_2^m(T_c)$, $\mu_{i,A} \xrightarrow{w} \mu$ weakly* in $C^*(T_c)$[5] as $A \to \infty$. Furthermore, $x_{i,A}(t) \to x(t)$ $\forall t \in \mathrm{Cont}(\mu)$. We proceed by showing that $p = p^*$, $u = u^*$, $\mu = \mu^*$ (for every fixed i).

[4] Case $\Delta_k^* > 0$ may be researched with the help of reduction R_1.

[5] Again, $T_c = [-c, c]$.

Let us first show that (p, u, μ) is an admissible process. In fact, from (7.11), we have

$$\int_{T_{i,A}} |\varphi^+(x_{i,A}, t)|^2 dt + \int_{T_{i,A}} |\varphi_\delta^+(x_{i,A}, t)|^2 d\mu_{i,A} \le \frac{\text{const}}{A},$$

and, by passing to the limit (with the help of Lemma 5.4) as $A \to \infty$, we obtain

$$\int_{t_0}^{t_1} |\varphi^+(x, t)|^2 dt + \int_{[t_0,t_1]} |\varphi_\delta^+(x, t)|^2 d\mu = 0.$$

From here, and by using Assumption C and the compatibility condition, we deduce that $\operatorname{gc}\sup \varphi^j(x) \le 0$, $j = 1, \dots, k_3$. Thus, (p, u, μ) is an admissible process. Hence, $e_0(p) \ge e_0(p^*)$. Furthermore, since

$$J_{i,A}(p_{i,A}, u_{i,A}, \mu_{i,A}) \le J_{i,A}(p^*, u^*, \mu^*) = e_0(p^*),$$

we have that

$$e_0(p_{i,A}) + |p_{i,A} - p^*|^2 + |y_{1,i,A} - F(t_1^*)|^2 + A \int_{T_{i,A}} |\varphi^+(x_{i,A}, t)|^2 dt$$
$$+ A \int_{T_{i,A}} |\varphi_\delta^+(x_{i,A}, t)|^2 d\mu_{i,A} + \frac{1}{i} \int_{T_{i,A}} (|u_{i,A} - u^*(t)|^2 + |y_{i,A} - F(t)|^2) dt \le e_0(p^*).$$

By passing to the limit in this inequality as $A \to \infty$, and by using the weak lower semicontinuity of the left part in u, we obtain

$$e_0(p) + |p - p^*|^2 + |y_1 - F(t_1^*)|^2 + \frac{1}{i} \int_{t_0}^{t_1} (|u - u^*(t)|^2 + |y - F(t)|^2) dt$$
$$+ \limsup_{A \to \infty} \left[A \int_{T_{i,A}} |\varphi^+(x_{i,A}, t)|^2 dt + A \int_{T_{i,A}} |\varphi_\delta^+(x_{i,A}, t)|^2 d\mu_{i,A} \right] \le e_0(p^*).$$

Since $e_0(p) \ge e_0(p^*)$, we conclude immediately that $p = p^*$, $u = u^*$, $\mu = \mu^*$, and

$$\lim_{A \to \infty} A \int_{T_{i,A}} |\varphi^+(x_{i,A}, t)|^2 dt + A \int_{T_{i,A}} |\varphi_\delta^+(x_{i,A}, t)|^2 d\mu_{i,A} = 0 \quad \forall i.$$

So, for every i, we can take a number A_i satisfying

$$|p_{i,A_i} - p^*|^2 + \|u_{i,A_i} - u^*\|_{L_2}^2 + \|y_{i,A_i} - F(t)\|_{L_2}^2$$
$$+ A_i \int_{T_{i,A_i}} |\varphi^+(x_{i,A_i}, t)|^2 dt + A_i \int_{T_{i,A_i}} |\varphi_\delta^+(x_{i,A_i}, t)|^2 d\mu_{i,A_i} \le \frac{1}{i}$$

and define a new diagonal sequence denoted by (p_i, u_i, μ_i), i.e.,

$$p_i = p_{i,A_i}, \qquad u_i = u_{i,A_i}, \qquad \mu_i = \mu_{i,A_i}. \tag{7.12}$$

By extracting a subsequence, we obtain $p_i \to p^*$, $u_i \to u^*$ a.e., $\mu_i \xrightarrow{w} \mu^*$ as $i \to \infty$. For this sequence, we have $x_i(t) = x_{i,A_i}(t) \to x^*(t)$ $\forall t \in \operatorname{Cont}(\mu^*)$. By replacing A in problem (7.11) by this specially chosen A_i, a new problem, called *i-problem*, is obtained.

All the additional inequality constraints of i-problem become strict inequalities for i sufficiently large. Therefore, Theorem 6.2 can be applied to the i-problem. It states that for every such i, there are functions $\psi_i \in V^n(T_i)$, $\zeta_i \in C(T_i)$, a number $\lambda_{0,i} \geq 0$, and vectors $\lambda_{1,i}$ and $\lambda_{2,i}$ such that

$$d\psi_i = -H^i_x(t)dt - Q^i_x(t)d\mu_i + \varphi^\top_x(x_i,t)d\eta_i, \quad t \in T_i, \tag{7.13}$$

$$\psi_{0,i} = \frac{\partial l}{\partial x_0}(p_i,\lambda_i) + 2\lambda_{0,i}(x_{0,i} - x^*_0), \quad \psi_{1,i} = -\frac{\partial l}{\partial x_1}(p_i,\lambda_i) - 2\lambda_{0,i}(x_{1,i} - x^*_1), \tag{7.14}$$

$$d\zeta_i = \frac{2\lambda_{0,i}}{i}[y_i - F(t)]dt, \qquad \zeta_i(t_{1,i}) = -2\lambda_{0,i}[y_{1,i} - F(t^*_1)],$$

$$\lambda_{1,i} \geq 0, \quad \langle e_1(p_i), \lambda_{1,i}\rangle = 0,$$

$$\max_{u\in U(t)}[H_i(u,t) - \lambda_{0,i}i^{-1}|u - u^*(t)|^2] = H_i(t) - \lambda_{0,i}i^{-1}|u_i(t) - u^*(t)|^2 \text{ a.e.}, \tag{7.15}$$

$$Q_i(t) + \zeta_i(t) - \lambda_{0,i}A_i|\varphi^+_\delta(x_i(t),t)|^2 \leq 0 \quad \forall t, \tag{7.16}$$

$$Q_i(t) + \zeta_i(t) - \lambda_{0,i}A_i|\varphi^+_\delta(x_i(t),t)|^2 = 0 \quad \forall t \in \operatorname{supp}(\mu_i), \tag{7.17}$$

$$\left\{\begin{array}{l} \operatorname{ess\,lim\,sup}\limits_{t\to t_{k,i}} \max\limits_{u\in U(t)}[H(\beta_{k,i},u,\gamma_{k,i},t) - \lambda_{0,i}i^{-1}|u - u^*(t)|^2] \\ \quad -\lambda_{0,i}A_i|\varphi^+(\beta_{k,i},t_{k,i})|^2 + (-1)^k\left[\dfrac{\partial l}{\partial t_k}(p_i,\lambda_i) + 2\lambda_{0,i}(t_{k,i} - t^*_k)\right] \geq 1(i), \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad k = 0,1, \\ \operatorname{ess\,lim\,inf}\limits_{t\to t_{k,i}} \max\limits_{u\in U(t)}[H(\beta_{k,i},u,\gamma_{k,i},t) - \lambda_{0,i}i^{-1}|u - u^*(t)|^2] \\ \quad -\lambda_{0,i}A_i|\varphi^+(\beta_{k,i},t_{k,i})|^2 + (-1)^k\left[\dfrac{\partial l}{\partial t_k}(p_i,\lambda_i) + 2\lambda_{0,i}(t_{k,i} - t^*_k)\right] \leq 1(i), \end{array}\right. \tag{7.18}$$

$$|\lambda_i| + \operatorname{gc\,sup}_{t\in T_i}|\psi_i(t)| + |\eta_i| = 1. \tag{7.19}$$

Here, $T_i = [t_{0,i}, t_{1,i}]$, $\lambda_i = (\lambda_{0,i}, \lambda_{1,i}, \lambda_{2,i})$, $\beta_{0,i} = x_i(t^+_{0,i})$, $\beta_{1,i} = x_i(t^-_{1,i})$, $\gamma_{0,i} = \psi_i(t^+_{0,i})$, $\gamma_{1,i} = \psi_i(t^-_{1,i})$, and $\eta_i = (\eta^1_i, \dots, \eta^{k_3}_i)$ is a vector measure whose components are defined, $j = 1, \dots, k_3$, by the distribution functions

$$F(t;\eta^j_i) = 2\lambda_{0,i}A_i\int_{[t_{0,i},t]}[\varphi^j(x_i,t)]^+ds + 2\lambda_{0,i}A_i\int_{[t_{0,i},t]}[\varphi^j_\delta(x_i,t)]^+d\mu_i, \quad t > t_{0,i}.$$

The expression $1(i)$ denotes a sequence of numbers converging to zero as $i \to \infty$, and the index i in H and Q (and its partial derivatives) indicates that they are evaluated at $x_i(t)$, $u_i(t)$, and $\psi_i(t)$, whenever the corresponding arguments x, u, and ψ are missing.

Note that because the function φ^+_δ is discontinuous, the i-problem is a nonstandard one. However, Theorem 6.2 applies in the same way for this problem. Furthermore, conditions (7.13)–(7.19) hold independently of the values $\mu_i(\{t_{k,\delta}\})$, $k = 0, 1$. This is so due to the nonnegativity and lower semicontinuity of the function $|\varphi^+_\delta|^2$ and also to the following fact: if $|\varphi^+|^2$ is zero at some point (x,t), then its derivative is zero at this point.

From (7.19), we get that $\zeta_i \to 0$ uniformly. Again from (7.19), and by using compactness, we conclude that, after subsequence extraction, $\lambda_i \to \lambda$, and $\eta^j_i \overset{w}{\to} \tilde\eta^j$, $j = 1, \dots, k_3$, as $i \to \infty$. Let, for every Borel set $B \subseteq \Re^1$, $\eta(B) = \tilde\eta(B) - \tilde\eta(B \cap \operatorname{Ds}(\mu^*))$, where $\tilde\eta = (\tilde\eta^1, \dots, \tilde\eta^{k_3})$. Thus, $\eta = (\eta^1, \dots, \eta^{k_3})$ is a vector measure satisfying $\operatorname{Ds}(\mu^*) \cap \operatorname{Ds}(\eta^j) = \emptyset$ $\forall j$.

Also from (7.19), it follows that the variation of ψ_i is bounded uniformly in i. By using the second Helly theorem and by extracting a subsequence, we obtain a function ψ_H such that $\psi_i(t) \to \psi_H(t)\ \forall t \in T^*$ as $i \to \infty$. Let us find $\psi \in V^n(T^*)$ such that $\psi(t) = \psi_H(t)\ \forall t \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$.[6] Such function $\psi(t)$ exists because of the estimate $\mathrm{Var}\,|_a^b[\psi_H] \le c(\mu^* + \mathrm{Var}\,\tilde{\eta} + \mathcal{L})([a,b])\ \forall a \le b$, which follows from the inequality $\mathrm{Var}\,\nu[\psi_i] \le c(\mu_i + \mathrm{Var}\,\eta_i + \mathcal{L})$ as $i \to \infty$.

Let us prove that $\psi(t)$ satisfies the conditions of our theorem. For this purpose, let us construct a countable family of absolutely continuous measures $\{\hat{\mu}_i\}$, $i \in \mathbf{N}$, which approximately satisfies all the conditions (except, possibly, the ones concerning time transversality (7.18)) of the maximum principle for the i-problem, as follows.

Let $\{t_k\}$, $k \in \mathbf{N}$, be a countable set of points everywhere dense in T^* such that $t_k \in X = \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta) \cap [\bigcap_{i=1}^{\infty} \mathrm{Cont}(\mu_i)]$,[7] and let $\{\phi_k\}$ be a countable set of functions everywhere dense in $C(T_c)$. For every i sufficiently large, there exists a sequence of absolutely continuous measures $\mu_{i,\tau}$ having densities $m_{i,\tau} > 0$ a.e., such that $\mu_{i,\tau} \xrightarrow{w} \mu_i$ on T_i, $\mu_{i,\tau} \xrightarrow{w} \mu_i$ on $[t_{0,i}, t_{0,\delta}]$, $\mu_{i,\tau} \xrightarrow{w} \mu_i$ on $[t_{1,\delta}, t_{1,i}]$ as $\tau \to \infty$ for all τ.

Let the pair $(x_{i,\tau}, \psi_{i,\tau})$ satisfy the following differential system:[8]

$$\begin{cases} dx_{i,\tau} = f(x_{i,\tau}, u_i, t)dt + g(x_{i,\tau}, t)d\mu_{i,\tau}, \\ d\psi_{i,\tau} = -H_x(x_{i,\tau}, u_i, \psi_{i,\tau}, t)dt - Q_x(x_{i,\tau}, \psi_{i,\tau}, t)d\mu_{i,\tau} + \varphi_x^{\top}(x_{i,\tau}, t)d\eta_{i,\tau}, \\ x_{i,\tau}(t_{0,i}) = x_i(t_{0,i}),\ \ \psi_{i,\tau}(t_{0,i}) = \psi_i(t_{0,i}), \end{cases}$$

where the measure $\eta_{i,\tau}^j$ is given by its distribution function

$$\begin{aligned} F(t; \eta_{i,\tau}^j) = {} & 2\lambda_{0,i}A_i \int_{[t_{0,i},t]} [\varphi^j(x_{i,\tau}, t)]^+ ds \\ & + 2\lambda_{0,i}A_i \int_{[t_{0,i},t]} [\varphi_\delta^j(x_{i,\tau}, t)]^+ d\mu_{i,\tau}, \quad j = 1, \dots, k_3. \end{aligned}$$

By using Lemma 5.4, choose a number τ_i such that

$$\begin{cases} \displaystyle\sum_{j=1}^{k_3} \sum_{k=1}^{i} \left[\left| \int_{T_i} \phi_k(t) d(\mu_{i,\tau_i} - \mu_i) \right| + \left| \int_{T_i} \phi_k(t) d(\eta_{i,\tau_i}^j - \eta_i^j) \right| \right] \le \frac{1}{i}, \\ \displaystyle\sum_{k=1}^{i} |\psi_{i,\tau_i}(t_k) - \psi_i(t_k)| + \left| \operatorname{gc}\sup_{t \in T_i} |\psi_i(t)| - \max_{t \in T_i} |\psi_{i,\tau_i}(t)| \right| \le \frac{1}{i}, \\ \displaystyle\left| \int_{T_i} \tilde{Q}_i(x_{i,\tau_i}, \psi_{i,\tau_i}, t) d\mu_{i,\tau_i} - \int_{T_i} \tilde{Q}_i(x_i, \psi_i, t) d\mu_i \right| \\ \qquad \displaystyle + \sum_{j=1}^{k_3} \left| \int_{T_i} \varphi^j(x_{i,\tau_i}, t) d\eta_{i,\tau_i}^j - \int_{T_i} \varphi^j(x_i, t) d\eta_i^j \right| \le \frac{1}{i}, \\ |\psi_{i,\tau_i}(t_{1,i}) - \psi_i(t_{1,i})| + \max_{t \in T_i} |\tilde{Q}_i(x_{i,\tau_i}, \psi_{i,\tau_i}, t) - \tilde{Q}_i(x_i, \psi_i, t)| \le \frac{1}{i}, \end{cases} \tag{7.20}$$

where $\tilde{Q}_i(x, \psi, t) = Q(x, \psi, t) - \lambda_{0,i}A_i|\varphi_\delta^+(x, t)|^2$.

[6] From now on, $\mathrm{Cont}(\eta) = \bigcap_{j=1}^{k_3} \mathrm{Cont}(\eta^j)$.

[7] Such an everywhere dense set exists, because, being a countable union of countable sets, $T^* \setminus X$ is countable.

[8] For every i, the solution of this system exists as τ becomes sufficiently large.

Put $\hat{\psi}_i = \psi_{i,\tau_i}$, $\hat{x}_i = x_{i,\tau_i}$, $\hat{\mu}_i = \mu_{i,\tau_i}$, $\hat{\eta}_i = \eta_{i,\tau_i}$. By extracting a subsequence, we have that $\hat{\psi}_i(t) \to \psi_A(t)$ $\forall t \in T^*$.

Now, we show that $\psi_A(t) = \psi(t)$ $\forall t \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$. Indeed, since $\mathrm{Var}\,\nu[\psi_i] \le c(\mu_i + \mathrm{Var}\,\eta_i + \mathcal{L})$, $\psi(t)$ is continuous on the set $\mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta) \setminus \{t_0^*, t_1^*\}$. The same can be said about ψ_A. Then, it follows from (7.20) that $\psi_A(t) = \psi(t)$ $\forall t \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$. For such a sequence, $\hat{x}_i(t) \to x^*(t)$, $\forall t \in \mathrm{Cont}(\mu^*)$, $\hat{\mu}_i \xrightarrow{w} \mu^*$, $\hat{\eta}_i^j \xrightarrow{w} \tilde{\eta}^j$, $j = 1, \dots, k_3$, as $i \to \infty$.

Let us prove (7.1). We start by showing that there are sequences of absolutely continuous measures $\{\bar{\mu}_i\}$, $\{\bar{\eta}_i^j\}$, $j = 1, \dots, k_3$, and also a sequence of natural numbers $k_i \ge i$ such that

(1) $\bar{\mu}_i \xrightarrow{w} \mu_d^*$, and, $\forall j$, $\bar{\eta}_i^j \xrightarrow{w} \tilde{\eta}^j - \eta^j$ as $i \to \infty$,

(2) $\hat{\mu}_{k_i} \ge \bar{\mu}_i$, $\hat{\eta}_{k_i}^j \ge \bar{\eta}_i^j$ $\forall i, j$.

If $\mathrm{Ds}(\mu^*) = \emptyset$, then we put $\bar{\mu}_i = \bar{\eta}_i^j = 0$, $k_i = i$, $\forall i, j$.

Let $\mathrm{Ds}(\mu^*) \ne \emptyset$. Consider the chain of sets D_i such that $D_0 = \emptyset$, $D_{i-1} \subseteq D_i \subseteq \mathrm{Ds}(\mu^*)$ and $\sum_{r \in \mathrm{Ds}(\mu^*) \setminus D_i} \mu^*(\{r\}) \le \frac{1}{i}$, $i \in \mathbf{N}$. Define sets $S_{r,i} = [r - \rho_i, r + \rho_i]$, $r \in D_i$, as a system of pairwise disjoint closed neighborhoods of points r such that

(i) $\rho_i > 0$, $\rho_i \to 0$ as $i \to \infty$,

(ii) $|\mu^*(S_i) - \sum_{r \in D_i} \mu^*(\{r\})| + \sum_{j=1}^{k_3} |\tilde{\eta}^j(S_i) - \sum_{r \in D_i} \tilde{\eta}^j(\{r\})| \le \frac{1}{i}$, where $S_i = \bigcup_{r \in D_i} S_{r,i}$,

(iii) $r \pm \rho_i \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$.

The existence of such sets S_i follows from the regularity of Borel measures $\mu^*, \tilde{\eta}^j$, $j = 1, \dots, k_3$. Due to the weak star convergence of the considered sequences of measures, it is possible to take a natural number $k_i \ge i$ such that

$$\sum_{r \in D_i} \left(\left| \hat{\mu}_{k_i}(S_{r,i}) - \mu^*(S_{r,i}) \right| + \sum_{j=1}^{k_3} \left| \hat{\eta}_{k_i}^j(S_{r,i}) - \tilde{\eta}^j(S_{r,i}) \right| \right) \le \frac{1}{i}.$$

Define $\bar{\mu}_i$ and $\bar{\eta}_i = \{\bar{\eta}_i^1, \dots, \bar{\eta}_i^{k_3}\}$, respectively, by $\bar{\mu}_i(B) := \hat{\mu}_{k_i}(B \cap S_i)$, and $\bar{\eta}_i(B) := \hat{\eta}_{k_i}(B \cap S_i)$, for any Borel set $B \subseteq \Re^1$. Clearly, $\bar{\mu}_i \xrightarrow{w} \mu_d^*$, $\bar{\eta}_i^j \xrightarrow{w} \tilde{\eta}^j - \eta^j$ as $i \to \infty$ (and, hence, $\hat{\mu}_{k_i} - \bar{\mu}_i \xrightarrow{w} \mu_c^*$, $\hat{\eta}_{k_i}^j - \bar{\eta}_i^j \xrightarrow{w} \eta^j$) for $j = 1, \dots, k_3$. It is also clear that $\hat{\mu}_{k_i} - \bar{\mu}_i \in C_+^*(T_c)$, $\hat{\eta}_{k_i}^j - \bar{\eta}_i^j \in C_+^*(T_c)$ $\forall i, j$.

From now on, consider subsequences extracted from $\{\hat{\mu}_i\}$, $\{\hat{\eta}_i\}$, $\{\hat{x}_i\}$, $\{\hat{\psi}_i\}$, $\{u_i\}$, and $\{T_i\}$ (denote them again by the old index i) according to the constructed sequence $\{k_i\}$ and let us rewrite (1.2), (7.13) as follows:

$$\begin{cases} \hat{x}_i(t) = x_{0,i} + \displaystyle\int_{t_{0,i}}^{t} f(\hat{x}_i, u_i, s)ds + \int_{[t_{0,i},t]} g(\hat{x}_i, s)d(\hat{\mu}_i - \bar{\mu}_i) + \int_{[t_{0,i},t]} g(\hat{x}_i, s)d\bar{\mu}_i, \\ \hat{\psi}_i(t) = \psi_{0,i} - \displaystyle\int_{t_{0,i}}^{t} \hat{H}_x^i(s)ds - \int_{[t_{0,i},t]} \hat{Q}_x^i(s)d(\hat{\mu}_i - \bar{\mu}_i) - \int_{[t_{0,i},t]} \hat{Q}_x^i(s)d\bar{\mu}_i \\ \qquad + \displaystyle\int_{[t_{0,i},t]} \varphi_x^\top(\hat{x}_i, s)d(\hat{\eta}_i - \bar{\eta}_i) + \int_{[t_{0,i},t]} \varphi_x^\top(\hat{x}_i, s)d\bar{\eta}_i, \quad t \in T_i. \end{cases}$$

From now on, the index i and the sign hat in H and Q (and also its partial derivatives) stand for their values when $\hat{x}_i(t)$, $u_i(t)$, and $\hat{\psi}_i(t)$ replace the omitted arguments x,

u, and ψ respectively. Put, $\forall t \in T_i$,

$$\hat{x}_i^c(t) = x_{0,i} + \int_{t_{0,i}}^{t} f(\hat{x}_i, u_i, s)ds + \int_{[t_{0,i},t]} g(\hat{x}_i, s)d(\hat{\mu}_i - \bar{\mu}_i),$$

$$\hat{x}_i^d(t) = \int_{[t_{0,i},t]} g(\hat{x}_i, s)d\bar{\mu}_i,$$

$$\hat{\psi}_i^{\eta}(t) = \psi_{0,i} - \int_{t_{0,i}}^{t} \hat{H}_x^i(s)ds - \int_{[t_{0,i},t]} \hat{Q}_x^i(s)d(\hat{\mu}_i - \bar{\mu}_i) + \int_{[t_{0,i},t]} \varphi_x^{\top}(\hat{x}_i, s)d(\hat{\eta}_i - \bar{\eta}_i),$$

$$\hat{\psi}_i^{d}(t) = -\int_{[t_{0,i},t]} \hat{Q}_x^i(s)d\bar{\mu}_i + \int_{[t_{0,i},t]} \varphi_x^{\top}(\hat{x}_i, s)d\bar{\eta}_i.$$

Thus, $\hat{x}_i(t) = \hat{x}_i^c(t) + \hat{x}_i^d(t)$, $\hat{\psi}_i(t) = \hat{\psi}_i^{\eta}(t) + \hat{\psi}_i^d(t)$ $\forall t \in T_i$. Bearing in mind that $\hat{x}_i(t) \to x^*(t)$ $\forall t \in \mathrm{Cont}(\mu^*)$, by Lebesgue theorem and Lemma 5.1, we deduce that

$$\hat{x}_i^c(t) \to x_c^*(t) = x_0^* + \int_{t_0^*}^{t} f(x^*, u^*, s)ds + \int_{[t_0^*,t]} g(x^*, s)d\mu_c^* \quad \forall t \in T^*,\ i \to \infty.$$

In a similar way, from Lemma 5.1, we conclude that $\forall t \in \mathrm{Cont}(\eta)$,

$$\hat{\psi}_i^{\eta}(t) \to \psi_{\eta}(t) = \psi_0 - \int_{t_0^*}^{t} H_x(s)ds - \int_{[t_0^*,t]} Q_x(s)d\mu_c^* + \int_{[t_0^*,t]} \varphi_x^{\top}(x^*, s)d\eta$$

as $i \to \infty$. Let $\psi_d = \psi - \psi_{\eta}$. Then, $\hat{\psi}_i^d(t) \to \psi_d(t)$ $\forall t \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$.

Let us show $\psi_d = \Sigma(\psi, t)$. In fact, fix $t \in \mathrm{Cont}(\mu^*) \cap \mathrm{Cont}(\eta)$ and $\varepsilon > 0$. Take a number $N = N(\varepsilon)$ such that $\sum_{r \in \mathrm{Ds}(\mu^*) \setminus D_N} [\mu^*(\{r\}) + \mathrm{Var}\, \tilde{\eta}(\{r\})] \le \varepsilon$. In this case, then

$$\limsup_{i \to \infty} \left| \sum_{r \in D(N,t)} \left[\int_{S_{r,i}} -\hat{Q}_x^i(s)d\bar{\mu}_i + \int_{S_{r,i}} \varphi_x^{\top}(\hat{x}_i, s)d\bar{\eta}_i \right] - \hat{\psi}_i^d(t) \right| \le \mathrm{const}\, \varepsilon, \tag{7.21}$$

where, from now on, $D(N,t) = \{r \in D_N : r \le t\}$.

Let $r_i^- = r - \rho_i$ and, for $r \in D(N,t)$, consider, on segment $S_{r,i}$, the system

$$\begin{cases} \hat{x}_i^d(s) = \hat{x}_i^d(r_i^-) + \displaystyle\int_{[r_i^-,s]} g(\hat{x}_i(\tau), \tau)d\bar{\mu}_i, \\ \hat{\psi}_i^d(s) = \hat{\psi}_i^d(r_i^-) - \displaystyle\int_{[r_i^-,s]} g_x^{\top}(\hat{x}_i(\tau), \tau)\hat{\psi}_i(\tau)d\bar{\mu}_i + \int_{[r_i^-,s]} \varphi_x^{\top}(\hat{x}_i(\tau), \tau)d\bar{\eta}_i. \end{cases} \tag{7.22}$$

For each i sufficiently large, we define the function[9]

$$\pi_{r,i}(\tau) = \frac{F(\tau; \bar{\mu}_i) - F(r_i^-; \bar{\mu}_i)}{\bar{\mu}_i(S_{r,i})}, \quad r \in D(N,t),\ \tau \in S_{r,i}.$$

The function $\pi_{r,i} : S_{r,i} \to [0,1]$ is absolutely continuous and strictly increasing, $\frac{d\pi_{r,i}}{d\tau} = \frac{\bar{m}_i(\tau)}{\bar{\mu}_i(S_{r,i})} > 0$ ($\bar{m}_i(\tau)$ is the density of measure $\bar{\mu}_i$). Hence, there exists an inverse mapping, $\theta_{r,i} : [0,1] \to S_{r,i}$, $\theta_{r,i} = (\pi_{r,i})^{-1}$, which is also absolutely continuous and

[9]Let us take numbers i such that $t \notin S_{r,i}$ $\forall i \ge i_0$, $r \in D(N,t)$, where i_0 is sufficiently large.

strictly increasing. By performing the change of variable $\omega = \pi_{r,i}(\tau)$ in (7.22), we obtain the system defined for all $s \in [0,1]$, and $r \in D(N,t)$,

$$\alpha_{r,i}(s) = \hat{x}_i^d(r_i^-) + \hat{x}_i^c(\theta_{r,i}(s)) + \bar{\mu}_i(S_{r,i}) \int_0^s g(\alpha_{r,i}(\omega), \theta_{r,i}(\omega))d\omega,$$
$$\sigma_{r,i}(s) = \hat{\psi}_i^d(r_i^-) + \hat{\psi}_i^\eta(\theta_{r,i}(s)) - \bar{\mu}_i(S_{r,i}) \int_0^s g_x^\top(\alpha_{r,i}(\omega), \theta_{r,i}(\omega))\sigma_{r,i}(\omega)d\omega$$
$$+ \int_{[0,s]} \varphi_x^\top(\alpha_{r,i}(\omega), \theta_{r,i}(\omega))d\eta_{r,i},$$

where

$$\alpha_{r,i}(\omega) = \hat{x}_i(\theta_{r,i}(\omega)), \quad \sigma_{r,i}(\omega) = \hat{\psi}_i(\theta_{r,i}(\omega)),$$
$$F(\omega; \eta_{r,i}^j) = F(\theta_{r,i}(\omega); \bar{\eta}_i^j), \quad j = 1, \dots, k_3.$$

Clearly, $\theta_{r,i}(\omega) \to r$ uniformly on $[0,1]$, and, by Lemma 5.3, $\hat{x}_i^c(\theta_{r,i}(\omega)) \to x_c^*(r)$, and $\hat{\psi}_i^\eta(\theta_{r,i}(\omega)) \to \psi_\eta(r)$ uniformly on $[0,1]$ as $i \to \infty$. From Gronwall's inequality, it follows that $\alpha_{r,i}$ is a Cauchy sequence. Its limit is α_r^*.[10] Compactness yields the existence of measures η_r^j and of a function $\sigma_r \in V^n([0,1])$ such that, after subsequence extraction, $\hat{\eta}_{r,i}^j \xrightarrow{w} \eta_r^j$, $j = 1, \dots, k_3$, $\sigma_{r,i}(s) \to \sigma_r(s)$, $\forall s \in \bigcap_{j=1}^{k_3} \mathrm{Cont}(\eta_r^j)$. By passing to the limit in the last system as $i \to \infty$, we deduce that[11] $\forall s \in [0,1]$ and $r \in D(N,t)$,

$$\alpha_r^*(s) = x^*(r^-) + \mu^*(\{r\}) \int_0^s g(\alpha_r^*, r)d\omega,$$
$$\sigma_r(s) = \psi(r^-) - \mu^*(\{r\}) \int_0^s g_x^\top(\alpha_r^*, r)\sigma_r d\omega + \int_{[0,s]} \varphi_x^\top(\alpha_r^*, r)d\eta_r.$$

From here and from (7.21), we have

$$\left| \psi_d(t) - \sum_{r \in D(N,t)} [\sigma_r(1) - \psi(r^-)] \right| \le \mathrm{const}\, \varepsilon.$$

But $\varepsilon > 0$ is arbitrary. Then, by definition of Σ, this means $\psi_d(t) = \Sigma(\psi, t)$. Thus, (7.1) and (7.2) are proved.

A simple contradiction argument implies (7.9). In fact if $|\lambda_i| \to 0$, $|\hat{\eta}_i| \to 0$, then $\max_{t \in T_i} |\hat{\psi}_i(t)| \to 0$ as $i \to \infty$, and (7.19) does not hold.

Let us prove (7.3), and (7.4). Fix $r \in \mathrm{Ds}(\mu^*)$, $j = 1, \dots, k_3$. From the penalty method and (7.20), we have that

$$A_i \int_{T_i} |\varphi^+(\hat{x}_i, t)|^2 dt + A_i \int_{T_i} |\varphi_\delta^+(\hat{x}_i, t)|^2 d\hat{\mu}_i \to 0. \tag{7.23}$$

Furthermore,

$$2A_i \int_{T_i} |\varphi^+(\hat{x}_i, t)|^2 dt + 2A_i \int_{T_i} |\varphi_\delta^+(\hat{x}_i, t)|^2 d\hat{\mu}_i$$
$$\ge 2\lambda_{0,i} A_i \left(\int_{T_i} \varphi^j(\hat{x}_i, t)[\varphi^j(\hat{x}_i, t)]^+ dt + \int_{T_i} \varphi_\delta^j(\hat{x}_i, t)[\varphi_\delta^j(\hat{x}_i, t)]^+ d\hat{\mu}_i \right)$$
$$= \int_{T_i} \varphi^j(\hat{x}_i, t) d\hat{\eta}_i^j \ge 0.$$

[10] This is the corollary of the uniqueness of the solution [23].

[11] Here, we used the fact that by construction, $\hat{x}_i^d(r_i^-) \to x^*(r^-) - x_c^*(r)$ and $\hat{\psi}_i^d(r_i^-) \to \psi_d(r^-)$.

Then, from (7.23), $\int_{S_{r,i}} \varphi^j(\hat{x}_i,t)d\hat{\eta}_i^j \to 0$ as $i \to \infty$. By changing variable $s = \pi_{r,i}(t)$ and by passing to the limit we get $\int_0^1 \varphi^j(\alpha_r^*,r)d\eta_r^j = 0$. Since $\varphi^j(\alpha_r^*(s),r) \le 0$, we conclude that $\varphi^j(\alpha_r^*(s),r) = 0\ \forall s \in \mathrm{supp}(\eta_r^j)$.

Next, we show that $Q(t) = Q(x^*(t),\psi(t),t) \le 0$, $\forall t \in T^*$. Indeed, $\zeta_i \to 0$ uniformly on T^*. Let $\hat{\kappa}_i(t) = \lambda_{0,i}A_i|\varphi_\delta^+(\hat{x}_i(t),t)|^2$. From (7.23), $\hat{\kappa}_i(t) \to 0$ strongly in $L_1(T^*)$, and, by extracting subsequences, $\hat{\kappa}_i(t) \to 0$ a.e. From (7.16), (7.20), and the right continuity of $Q(t)$ on interval $[t_{0,\delta},t_{1,\delta}]$, we establish that $Q(t) \le 0\ \forall t \in T^*$.

From (7.17), (7.20), and $\int_{T_i} \hat{Q}_i(t)d\hat{\mu}_i \to 0$, we have that $\int_0^1 \langle g(\alpha_r^*,r),\sigma_r\rangle ds = 0$. From (7.16), (7.20), (7.23), and $Q(t) \le 0\ \forall t$, it is not hard to deduce by arguments analogous to the ones that show $\varphi^j(\alpha_r^*(s),r) = 0\ \forall s \in \mathrm{supp}(\eta_r^j)$ that $q_r(s) = \langle g(\alpha_r^*(s),r),\sigma_r(s)\rangle \le 0\ \forall s \in [0,1]$. Thus, $q_r(s) = 0\ \forall s \in (0,1)$. Let us show that $q_r(0) = q_r(1) = 0$. Indeed, if $\eta_r(\{0\}) = 0$, then $q_r(0) = 0$. Let $\eta_r^j(\{0\}) > 0$ for some $j = 1,\dots,k_3$. Then, $\varphi^j(\alpha_r^*(0),r) = 0$ and $W^j(\alpha_r^*(0),r) \le 0$. Otherwise the state constraint would not be satisfied. Thus, $q_r(0) \ge 0$. But, at the same time, the complementary inequality is true. Hence, $q_r(0) = W^j(\alpha_r^*(0),r) = 0$. Similarly, $q_r(1) = 0$. We proved statements (7.3), and (7.4).

Let us prove (7.5). Since $\mathrm{Var}\,\nu[\varphi^j(\hat{x}_i,t)] \le c(\hat{\mu}_i + \mathcal{L})$, we have, by Lemma 5.1, that

$$\int_{T_i} \varphi^j(\hat{x}_i,t)d[\hat{\eta}_i^j - \bar{\eta}_i^j] \to \int_{T^*} \varphi^j(x^*,t)d\eta^j, \quad i \to \infty,\ j = 1,\dots,k_3.$$

On the other hand, it follows from (7.23) that $\int_{T_i} \varphi^j(\hat{x}_i,t)d[\hat{\eta}_i^j - \bar{\eta}_i^j] \to 0$. Now, (7.5) follows from nonpositivity of $\varphi^j(x^*,t)$, $j = 1,\dots,k_3$.

By passing to the limit in (7.15), we establish (7.6).

Let us show how to prove (7.7) with the help of Lemma 5.1. It has already been asserted that $\mathrm{Ds}(\nu[Q]) \cap \mathrm{Ds}(\mu^*) = \emptyset$. However, it is not enough to use Lemma 5.1 to obtain the desired conclusion. Next, we show that $\forall r \in \mathrm{Ds}(\mu^*)$, $\mathrm{Var}\,|_0^1[q_{r,i}] \to 0$ as $i \to \infty$, where $q_{r,i}(s) = \langle \sigma_{r,i}(s), g(\alpha_{r,i}(s),\theta_{r,i}(s))\rangle$, $s \in [0,1]$. In fact,

$$q_{r,i}(s) = q_{r,i}(0) + \sum_{j=1}^{k_3} \int_0^s W^j(\alpha_{r,i},\theta_{r,i})d\eta_{r,i}^j + \int_0^s \langle \sigma_{r,i}, g_t(\alpha_{r,i},\theta_{r,i})\rangle d\theta_{r,i}, \quad s \in [0,1].$$

From this we conclude that

$$\mathrm{Var}\,|_0^1[q_{r,i}] \le \sum_{j=1}^{k_3} \mathrm{Var}\,|_0^1 \left[\int_0^s W^j(\alpha_{r,i},\theta_{r,i})d\eta_{r,i}^j\right] + 1(i).$$

Since $W^j(\alpha_{r,i},\theta_{r,i}) \to W^j(\alpha_r^*,r)$ uniformly on $[0,1]$ as $i \to \infty$, and since $\eta_{r,i}^j \xrightarrow{w} \eta_r^j$, we have that $\mathrm{supp}(\eta_r^j) \subseteq \{s : W^j(\alpha_r^*(s),r) = 0\}\ \forall j$. From Lemma 5.5, $\mathrm{Var}\,|_0^1[q_{r,i}] \to 0$. Hence,

$$\mathrm{Var}\,\nu[\hat{Q}_i] \le c([\hat{\mu}_i - \bar{\mu}_i] + \mathrm{Var}[\hat{\eta}_i - \bar{\eta}_i] + \mathcal{L}) + 1(i).$$

By using Lemma 5.1, (7.17), (7.20), and (7.23), we deduce that

$$1(i) = \int_{T_i} \hat{Q}_i(t)d\hat{\mu}_i + \int_{T_i} \hat{\kappa}_i(t)d\hat{\mu}_i \to \int_{T^*} Q(t)d\mu^*$$

and, therefore, $\int_{T^*} Q(t)d\mu^* = 0$. Bearing in mind that $Q(t) \le 0\ \forall t$, we conclude (7.7).

Let us prove (7.10). We consider $k = 0$.

We return to the initial sequence of solutions (7.12) and consider conditions (7.18). Note that $\Delta_{0,i} = \mu_i(\{t_{0,i}\}) \to 0$ since μ^* is continuous at t_0^*. Hence, $x_{0,i}^+ = \beta_{0,i} \to x_0^*$ and $\psi_{0,i}^+ = \gamma_{0,i} \to \psi_0$ as $i \to \infty$. We put $\kappa_i = \lambda_{0,i} A_i[\varphi^+(x_{0,i}^+, t_{0,i})]^2$ and show that $\kappa_i \to 0$ as $i \to \infty$. Two cases can be considered:

(1) The sequence $\Delta_{0,i}$ has a zero subsequence.

(2) $\Delta_{0,i} > 0$ for all i greater some i_0.

By extracting a subsequence we have, in the first case, that $x_{0,i}^+ = x_{0,i}$ and, from the compatibility between state and endpoint constraints, $\kappa_i = 0$.

Let us consider the second case. When i is sufficiently large, the function $Q_i(t)$ is absolutely continuous in some neighborhood of point $t_{0,i}$ and its derivative in this set is given by

$$\dot{Q}_i(t) = \sum_{j=1}^{k_3} 2\lambda_{0,i} A_i [\varphi^j(x_i(t), t)]^+ W^j(x_i(t), t) + \omega_i(t), \tag{7.24}$$

where $\omega_i(t)$ is an essentially bounded measurable function, $\|\omega_i\|_{L_\infty} \le \text{const}\ \forall i$.

Since $\Delta_{0,i} > 0$, we have, from (7.17), $Q_i(t_{0,i}) + \zeta_{0,i} = 0$. By using this and (7.16), we conclude by integrating (7.24) with the Newton–Leibnitz formula that

$$\sum_{j=1}^{k_3} \int_{t_{0,i}}^{t_{0,i}+\Delta} 2\lambda_{0,i} A_i [\varphi^j(x_i, s)]^+ W^j(x_i, s) ds \le \text{const}\, \Delta.$$

By dividing both sides by $\Delta > 0$ and passing to the limit as $\Delta \to 0$, we obtain

$$\sum_{j=1}^{k_3} \lambda_{0,i} A_i [\varphi^j(x_{0,i}^+, t_{0,i})]^+ W^j(x_{0,i}^+, t_{0,i}) \le \text{const}. \tag{7.25}$$

From Assumption C and the compatibility of state and endpoint constraints, it follows that if $W^j(x_{0,i}^+, t_{0,i}) \le 0$, then $[\varphi^j(x_{0,i}^+, t_{0,i})]^+ = 0$. In this way, from (7.25), we conclude that

$$\lambda_{0,i} A_i [\varphi^j(x_{0,i}^+, t_{0,i})]^+ W^j(x_{0,i}^+, t_{0,i}) \le \text{const}, \quad j = 1, \dots, k_3. \tag{7.26}$$

Let $\kappa_i^j = \lambda_{0,i} A_i [\varphi^{j+}(x_{0,i}^+, t_{0,i})]^2$. Notice that $\kappa_i = \sum_{j=1}^{k_3} \kappa_i^j$. If $W^j(x_{0,i}^+, t_{0,i}) \le 0$, then, as it was seen above, $\kappa_i^j = 0$. Suppose that $\kappa_i^j > 0$. Then, $W^j(x_{0,i}^+, t_{0,i}) > 0$. Furthermore,

$$\begin{aligned}
\kappa_i^j &= \lambda_{0,i} A_i [\varphi^+(x_{0,i}^+, t_{0,i})]^2 \\
&= \lambda_{0,i} A_i \left[\varphi^+(x_{0,i}, t_{0,i}) + \Delta_{0,i} \int_0^1 h[\varphi^j(\alpha_{0,i}, t_{0,i})] W^j(\alpha_{0,i}, t_{0,i}) ds \right]^2,
\end{aligned}$$

where $h(t)$ is the Heavyside function, i.e., $h(t) = 0$ when $t \le 0$ and $h(t) = 1$ otherwise. From the last equality, we have, by the constraints compatibility assumption and Assumption C, that for sufficiently large i,

$$\kappa_i^j \le 2\lambda_{0,i} A_i \Delta_{0,i}^2 [W^j(x_{0,i}^+, t_{0,i})]^2.$$

Now, from (7.26), we have

$$\kappa_i^j \le \text{const}\, \frac{\lambda_{0,i} A_i \Delta_{0,i}^2}{[\lambda_{0,i} A_i \varphi^{j+}(x_{0,i}^+, t_{0,i})]^2} = \text{const}\, \frac{\Delta_{0,i}^2}{\kappa_i^j},$$

and, from this, we conclude that

$$(\kappa_i^j)^2 \le \text{const}\, \Delta_{0,i}^2 \to 0.$$

Now, by passing to the limit in (7.18), we obtain (7.10).

Now note that Assumption C and the requirement $\Delta_k^* = 0$, $k = 0, 1$, are used only to obtain the time transversality conditions and, therefore, can be omitted in the remaining parts of the proof. Indeed, let us modify the penalty term in (7.11) $\int_T [\varphi_\delta^+(x,t)]^2 d\mu$ onto $\int_T [\varphi^+(x,t)]^2 d\mu$. It is clear that such a transformation of the function φ_δ^+ into φ^+ does not invalidate the arguments proving (7.1)–(7.9). The only issue here is to ensure that the compatibility of state and endpoint constraints stays in force and cannot be omitted. Indeed, we use it to prove (a) the maximum condition for the impulsive component (more precisely, to get inequalities $Q(t_k^*) \le 0$, $k = 0, 1$) and (b) inequalities (7.8).

The proof is complete. □

8. Nondegenerate maximum principle. Here we prove our main result, Theorem 4.1. This theorem is formulated under the smooth Assumption S. Therefore, we shall need the following.

Remark 5. Under Assumption S, inequalities (7.8) in Theorem 7.1 become

$$\max_{u \in U} H(x_k^*, u, \psi_k, t_k^*) + (-1)^k \frac{\partial l}{\partial t_k}(p^*, \lambda) \le 0, \quad k = 0, 1. \tag{8.1}$$

Proof of Theorem 4.1. Let us verify the technique suggested in [1]. For this, we shall use the first statement of Theorem 7.1, i.e., conditions (7.1)–(7.9).

Equations (4.2) can be obtained by applying Theorem 7.1 to v-problem.[12] This proof is absolutely analogous to the corresponding one in [1].

We shall consider the case $\Delta_k^* = 0$[13] and use a contradiction argument to show (4.3). Assume that (4.3) does not hold. Then, because of the right continuity of ψ on $B^* = (t_0^*, t_1^*)$, we have that $\lambda_0 = 0$, $\psi(t) = 0$ $\forall t \in B^*$ and, therefore, $\sigma_r(s) = 0$, $\forall s \in [0,1]$, $\forall r \in \mathrm{Ds}(\mu^*)$. By using the regularity of state constraints, we conclude that $\eta(B^*) = 0$, $\eta_r = 0$ $\forall r \in \mathrm{Ds}(\mu^*)$. Furthermore, from the maximum principle,

$$\varphi_x^\top(x_k^*, t_k^*)\eta(\{t_k^*\}) = -\frac{\partial l}{\partial x_k}(p^*, \lambda), \quad k = 0, 1.$$

In the same way, from (4.2) we obtain

$$\langle \varphi_t(x_k^*, t_k^*), \eta(\{t_k^*\})\rangle = -\frac{\partial l}{\partial t_k}(p^*, \lambda), \quad k = 0, 1.$$

By substituting these expressions into (8.1), we deduce that for $k = 0, 1$,

$$\max_{u \in U} H(x_k^*, u, (-1)^{k+1}\varphi_x^\top(x_k^*, t_k^*)\eta(\{t_k^*\}), t_k^*) + (-1)^{k+1}\langle \varphi_t(x_k^*, t_k^*), \eta(\{t_k^*\})\rangle \le 0.$$

Analogously, by substituting in inequalities $Q(t_k^*) \le 0$, $k = 0, 1$, we deduce, for $k = 0, 1$,

$$\langle g(x_k^*, t_k^*), (-1)^{k+1}\varphi_x^\top(x_k^*, t_k^*)\eta(\{t_k^*\})\rangle \le 0.$$

[12] This is obtained by reduction R_2. The equivalence is guaranteed by Proposition 5.7.

[13] The case $\Delta_k^* > 0$ is dealt with in a similar way.

From the controllability of $x^*(t)$, we conclude that $\eta(\{t_k^*\}) = 0$, $k = 0, 1$, and, therefore, $\frac{\partial l}{\partial p}(p^*, \lambda) = 0$. From the regularity of endpoint constraints, we get $\lambda = 0$. Thus, we obtain a contradiction with (7.9).

The proof is complete. □

Remark 6. Here, we want to emphasize the following important class of problems. Suppose that all state constraints are convex along the jump evolutions (i.e., $\dot{W}^j \geq 0$ $\forall j$). For such problems, we have the following.

(1) The controllability concept can be simplified as follows. An optimal trajectory $x^*(t)$ is controllable if there exist points $s_k \in [0, 1]$, $k = 0, 1$, such that Definition 2.4 holds at $(\tilde{x}_k, t_k^*)$, where $\tilde{x}_k = \alpha_k^*(s_k)$. This can be proved because of the reduction R_1 (where the extra state constraints can be omitted for the considered class of problems).

(2) Assumption C always holds under mentioned convexity supposition, hence for such problems we may obtain the time transversality conditions for problems merely measurable in t problem (Theorem 7.1). Note that, here, time transversality conditions can always be derived with the help of reduction R_2 (see Remark 2 in section 4). However, we need smooth Assumption S to use this reduction.

A simple example of the problem with pointed convexity properties is given by linear systems: g does not depend on x, φ is linear in x. Furthermore for linear problems, (4.3) becomes

$$\lambda_0 + \mathcal{L}(\{t : |\psi(t)| > 0\}) = 1.$$

In conclusion, we say that the following question pertaining to Assumption C remains open: *How do we get time transversality conditions for the case when data of the problem is measurable in t without any convexity assumptions on state constraints?*

9. Appendix. *Proof of Lemma* 5.1. We start by noting that if $s \in T$ and $t_i \to s$ as $i \to \infty$, then

$$F(s^-; \mu) \leq \liminf_{t_i \to s} F(t_i; \mu_i) \leq \limsup_{t_i \to s} F(t_i; \mu_i) \leq F(s^+; \mu).$$

This statement can be easily obtained with the help of Lemma 7.1 in [1] and with a simple contradiction arguments. By using the last statement, it is not hard to establish that

$$\limsup_{i \to \infty} \sup_{t \in K} |F(t; \mu_i) - F(t; \mu)| \leq \varepsilon, \tag{9.1}$$

where K is a closed subset of T such that $\mu(\{t\}) \leq \varepsilon$ $\forall t \in K$ $\varepsilon \geq 0$.

Furthermore, the triangle inequality gives

$$\left| \int_T f_i(t) d\mu_i - \int_T f(t) d\mu \right| \leq \left| \int_T f_i(t) d(\mu_i - \mu) \right| + \left| \int_T [f_i(t) - f(t)] d\mu \right|. \tag{9.2}$$

By the Lebesgue theorem, the second term in the right-hand side converges to zero. In fact, $f_i(t) \to f(t)$, μ-a.e. Furthermore, the f_i are uniformly bounded.

Thus, we have to show that $\int_T f_i(t) d(\mu_i - \mu) \to 0$. Let $F_i(t) = F(t; \mu_i)$ and $F(t) = F(t; \mu)$. By integrating by parts, we deduce

$$\int_T f_i(t) d(\mu_i - \mu) = f_i(t_1)[F_i(t_1) - F(t_1)] - \int_T [F_i(t) - F(t)] d\nu[f_i].$$

From the weak convergence $F_i(t_1) \to F(t_1)$. Let us show that $\int_T [F_i(t) - F(t)] d\nu[f_i] \to 0$.

There are two cases: either $\mathrm{Ds}(\mu) = \emptyset$ or $\mathrm{Ds}(\mu) \neq \emptyset$. If $\mathrm{Ds}(\mu) = \emptyset$, then this means that measure μ is continuous, and, by using (9.1) (with $\varepsilon = 0$, $K = T$), we conclude the proof. Let $\mathrm{Ds}(\mu) \neq \emptyset$ and fix $\varepsilon > 0$ sufficiently small. There exists a finite, not empty set of points $t_j \in \mathrm{Ds}(\mu)$, $j = 1, \ldots, N$, $N = N(\varepsilon) \geq 1$, such that $\mu(\{t_j\}) \geq \varepsilon$. Since $\mathrm{Ds}(\mu) \cap \mathrm{Ds}(\eta) = \emptyset$, then $\forall j \leq N$, $\exists \delta_j > 0$ such that $\eta(C_j) \leq \varepsilon N^{-1}$, where $C_j = [t_j - \delta_j, t_j + \delta_j]$, $t_j \pm \delta_j \in \mathrm{Cont}(\eta)$ and C_j are pairwise disjoint. Let O_j be a neighborhood of t_j such that $O_j \subset C_j$. Set $O = \bigcup_{j=1}^N O_j$ is open. Hence, $K = T \setminus O$ is closed. For such $O \subset C$, $\eta(O) \leq \eta(C) \leq \varepsilon$, where $C = \bigcup_{j=1}^N C_j$. From this, we conclude that

$$\left| \int_T [F_i(t) - F(t)] d\nu[f_i] \right| \leq \int_K |F_i(t) - F(t)| d \operatorname{Var} \nu[f_i] + \int_C |F_i(t) - F(t)| d \operatorname{Var} \nu[f_i].$$

By using (9.1) and $\operatorname{Var} \nu[f_i] \leq c\eta_i$ $\forall i$, we deduce that

$$\begin{aligned} \limsup_{i \to \infty} \left| \int_T [F_i(t) - F(t)] d\nu[f_i] \right| &\leq \limsup_{i \to \infty} \left(\sup_{t \in K} \left| F_i(t) - F(t) \right| \operatorname{Var} \nu[f_i](K) \right) \\ &\quad + \limsup_{i \to \infty} \left(\sup_{t \in C} \left| F_i(t) - F(t) \right| \operatorname{Var} \nu[f_i](C) \right) \\ &\leq \varepsilon c |\eta| + 2\varepsilon c |\mu| \leq c_1 \varepsilon. \end{aligned}$$

Since $\varepsilon > 0$ is arbitrary, the right-hand part of (9.2) converges to zero. The proof is complete. □

Proof of Lemma 5.3. Fix $\varepsilon > 0$ such that $s \pm \varepsilon \in \mathrm{Cont}(\mu)$. Furthermore,

$$x_i(s + \varepsilon) - x_i(t_i) = \int_{[t_i, s+\varepsilon]} f_i(t) d\mu_i = A_{i,\varepsilon}.$$

Clearly, $|A_{i,\varepsilon}| \leq c\mu_i([t_i, s + \varepsilon])$ $\forall i$. By passing to the limit,

$$-c\mu([s, s+\varepsilon]) \leq \liminf_{i \to \infty} [x_i(s+\varepsilon) - x_i(t_i)] \leq \limsup_{i \to \infty} [x_i(s+\varepsilon) - x_i(t_i)] \leq c\mu([s, s+\varepsilon]).$$

By Lemma 5.1, $x_i(s + \varepsilon) \to x(s + \varepsilon)$ as $i \to \infty$, and, therefore,

$$x(s+\varepsilon) - c\mu([s, s+\varepsilon]) \leq \liminf_{i \to \infty} x_i(t_i) \leq \limsup_{i \to \infty} x_i(t_i) \leq x(s+\varepsilon) + c\mu([s, s+\varepsilon]).$$

Bearing in mind that $c\mu([s, s+\varepsilon]) \to 0$ as $\varepsilon \to 0$ (indeed, $s \notin \mathrm{Ds}(\mu)$), we conclude the proof. □

To prove Lemma 5.4, we need the following propositions.

PROPOSITION 9.1. *Let $x \in V^n(T)$, $\operatorname{Var} \nu[x] \leq c\mu$. Then, if function $h(x,t)$ is Lipschitz continuous in (x,t), there exists a constant denoted* const *such that* $\operatorname{Var} \nu[h(x, \cdot)] \leq \mathrm{const}(\mu + \mathcal{L})$.

Proof. By definition of the variation

$$\operatorname{Var}|_a^b [h(x(t), t)] = \sup_{T_N} \sum_{k=1}^N |h(x(s_k), s_k) - h(x(s_{k-1}), s_{k-1})|,$$

where supremum is considered in every possible finite partitions of segment $[a,b]$. By using the Lipschitz continuity of h and condition $\operatorname{Var}\nu[x] \le c\mu$, we deduce that

$$\sum_{k=1}^{N} |h(x^1(s_k),\dots,x^n(s_k),s_k) - h(x^1(s_{k-1}),\dots,x^n(s_{k-1}),s_{k-1})|$$
$$\le \operatorname{const}\left(\sum_{j=1}^{n} \operatorname{Var}|_a^b[x^j] + a - b\right) \le \operatorname{const}[\mu([a,b]) + \mathcal{L}([a,b])].$$

The proof is complete. □

PROPOSITION 9.2. *If the solution to* (1.2) *exists, then it is unique.*

Proof. Suppose that there are functions $x, y \in V^n(T)$ such that $x \ne y$, and x, and y do satisfy (1.2). From Definition 3.1, we have

$$|x(t) - y(t)| \le \int_{t_0}^{t} |f(x,u,s) - f(y,u,s)|ds + \int_{[t_0,t]} |g(x,s) - g(y,s)|d\mu_c$$
$$+ |\Phi(x,t) - \Phi(y,t)| \quad \forall t \in T.$$

Here and from now on, $\Phi(x,t)$ denotes the last item in formula specifying $x(t)$ in Definition 3.1. By using Gronwall's inequality, we arrive at the estimate

$$\sup_{s\in[t_0,t]} |x(s) - y(s)| \le \int_{[t_0,t]} c|x(s) - y(s)|(d\mu_c + ds)$$
$$+ \sum_{s\in D(t)} c\mu(\{s\})e^{c\mu(\{s\})}|x(s^-) - y(s^-)|$$
$$\le c \sup_{s\in[t_0,t]} |x(s) - y(s)| \times (\mu_c([t_0,t]) + t - t_0) + c_1 \sum_{s\in D(t)} \mu(\{s\})A_s,$$

where $A_s = |x(s^-) - y(s^-)|$, $s \in D(t)$, $D(t) = \operatorname{Ds}(\mu) \cap [t_0,t]$, and $c_1 = ce^{c|\mu|}$. Let $\phi(t) = \sup_{s\in[t_0,t]} |x(s) - y(s)|$, and $\gamma(t) = c(\mu_c([t_0,t]) + t - t_0)$. Let us enumerate the atoms of the measure μ in $[t_0,t]$ by the decreasing order of its values and denote by $\{a_j\}$ such a sequence, $a_j = \mu(\{s_j\})$, $s_j \in D(t)$, $j = 1,2,\dots$. In this constructive process, it may happen that the measure μ has no atoms or only a finite number of atoms s_j, $j = 1,\dots,r$, $r \ge 1$ on $[t_0,t]$. In the first case, we put $a_j = 0\ \forall j$, and in the second case, we let $a_j = 0\ \forall j > r$. By construction, $a_{j+1} \le a_j$, $a_j \to 0+$, as $j \to \infty$, and $\sum_{j=1}^{\infty} a_j = \mu_d([t_0,t])$. Now, we can write the inequality obtained above as

$$\phi(t) \le \phi(t)\gamma(t) + c_1 \sum_{j=1}^{\infty} a_j A_{s_j}. \tag{9.3}$$

Now, let us estimate an upper bound of the series $\sum_{j=1}^{\infty} a_j A_{s_j}$. Fix $\varepsilon > 0$. Since, $\forall j$, $A_{s_j} \le \phi(t)$, there exists a number $N = N(\varepsilon)$ such that $\sum_{j=N+1}^{\infty} a_j A_{s_j} \le \varepsilon\phi(t)$. To evaluate the partial sum $S_N = \sum_{j=1}^{N} a_j A_{s_j}$, let us consider $s_j < s_{j+1}$, $j = 1,\dots,N-1$. (If this is not the case, then we may renumber the finite set of a_j and s_j, $j = 1,\dots,N-1$. It is not hard to see that this relabeling does not affect the proof.) Let $Q(t) = \phi(t)\gamma(t) + c_1\varepsilon\phi(t)$. From (9.3), it follows that $A_{s_1} \le Q(t)$, $A_{s_2} \le Q(t) + a_1 A_{s_1} \le Q(t)(1 + a_1)$, $A_{s_3} \le Q(t) + a_1 A_{s_1} + a_2 A_{s_2} \le Q(t)(1 + a_1)(1 + a_2), \dots$, and so on,

until we get

$$A_{s_N} \le Q(t) \prod_{j=1}^{N-1} (1 + a_j).$$

Thus $S_N \le Q(t) \sum_{j=1}^{N} a_j \prod_{i=1}^{j-1}(1+a_i)$. Since the series $\sum_{j=1}^{\infty} \ln(1+a_j) \le \sum_{j=1}^{\infty} a_j \le |\mu|$ converges, the infinite product $\prod_{j=1}^{\infty}(1 + a_j)$ also converges. Then, $S_N \le Q(t)$ $\sum_{j=1}^{N} a_j e^{|\mu|} \le Q(t)|\mu|e^{|\mu|}$. Now, from (9.3), we obtain

$$\phi(t) \le \phi(t)\gamma(t) + c_1[\varepsilon\phi(t) + Q(t)|\mu|e^{|\mu|}],$$

and hence

$$\phi(t) \le \phi(t)[\gamma(t) + \varepsilon c_1][1 + c_1|\mu|e^{|\mu|}].$$

By letting $\varepsilon \to 0$, we finally arrive at

$$\phi(t) \le c[1 + c|\mu|e^{c(1+|\mu|)}](\mu_c([t_0, t]) + t - t_0)\phi(t) \quad \forall t \in T. \tag{9.4}$$

The uniqueness follows from the continuity of the Borel measure μ_c. Indeed, there exists τ_1 such that $c[1+c|\mu|e^{c(1+|\mu|)}](\mu_c([t_0, \tau_1]) + \tau_1 - t_0) < 1$. Hence $\phi(\tau_1) = 0$, and, on the segment $[t_0, \tau_1]$, the solutions $x(t)$ and $y(t)$ are congruent. All the conditions of the proposition are satisfied on the segment $[\tau_1, t_1]$. By applying the described procedure to $[\tau_1, t_1]$, we find τ_2 such that $x(t) = y(t)$ $\forall t \in [\tau_1, \tau_2]$, and so on. It is obvious that we may cover the whole segment T in a finite number of steps. Therefore, $x(t) \equiv y(t)$ and the proof is complete. □

PROPOSITION 9.3. *Consider a sequence of absolutely continuous measures* $\{\mu_i\}$, $\mu_i \in C_+^*(T)$, $i = 1, 2, \ldots$, *converging weakly star to* μ, *a sequence of controls* $\{u_i\}$, $u_i \xrightarrow{w} u$ *weakly in* $L_2(T)$, $u_i(t) \in U(t)$ *a.e., a sequence of vectors* $\{x_{0,i}\}$, $x_{0,i} \to x_0 \in \mathbf{R}^n$, *and the corresponding sequence of vector functions* $\{x_i\}$, $x_i \in V^n(T)$, *satisfying*

$$x_i(t) = x_{0,i} + \int_{t_0}^{t} f(x_i, u_i, s)ds + \int_{[t_0,t]} g(x_i, s)d\mu_i, \quad t \in T. \tag{9.5}$$

Then, if $|x_i(t)| \le \text{const}$, $x_i(t) \to x(t)$ $\forall t \in \text{Cont}(\mu)$, *where* $x(t)$ *is the solution to* (1.2). *Furthermore,* $\max_{t\in T} |x_i(t)| \to \text{gc}\sup_{t\in T} |x(t)|$.

Proof. Since x_i are solutions to (9.5) and are uniformly bounded, it follows that $\text{Var}\, \nu[x_i] \le \text{const}(\mu_i + \mathcal{L})$. From Proposition 9.1, $\text{Var}\, \nu[g(x_i, t)] \le \text{const}(\mu_i + \mathcal{L})$ and from Helly's second theorem, we may extract a subsequence so that $x_i(t) \to \tilde{x}(t)$ $\forall t \in T$ for some $\tilde{x} \in V^n(T)$.

Let the function $x \in V^n(T)$ be such that $x(t) = \tilde{x}(t)$ $\forall t \in \text{Cont}(\mu)$. The function $x(t)$ exists since $\text{Var}\,|_a^b[\tilde{x}] \le c(\mu+\mathcal{L})([a, b])$ $\forall a \le b$. Now, let us show that $x(t)$ satisfies (1.2).

Without any loss of generality, we may consider that $\frac{dF(t;\mu_i)}{dt} > 0$ a.e. on T, $i = 1, 2, \ldots$.[14]

[14]Otherwise, we can consider the sequence $\tilde{\mu}_i = \mu_i + i^{-1}\mathcal{L}$, and, from (9.5), we obtain

$$x_i(t) = x_{0,i} + \int_{t_0}^{t} f(x_i, u_i, s)ds + \int_{t_0}^{t} g(x_i, s)d\tilde{\mu}_i - p_i(t),$$

where $p_i(t) := \frac{1}{i}\int_{t_0}^{t} g(x_i, s)ds$ clearly converges to 0 uniformly on T, thus preserving all the required reasoning.

We start by showing that there exist sequences of absolutely continuous measures $\{\bar\mu_k\}$ and of numbers $k_i \geq i$ such that $\bar\mu_k \xrightarrow{w} \mu_d$ and $\mu_{i_k} - \bar\mu_k \xrightarrow{w} \mu_c$ on T.

If $\mathrm{Ds}(\mu) = \emptyset$, we put $\bar\mu_i = 0$, $k_i = i$, $\forall i$.

Let $\mathrm{Ds}(\mu) \neq \emptyset$. Consider the chain of sets D_i such that $D_{i-1} \subseteq D_i \subseteq \mathrm{Ds}(\mu)$ and $\sum_{r\in \mathrm{Ds}(\mu)\setminus D_i} \mu(\{r\}) \leq i^{-1}$, being $D_0 = \emptyset$. Define the sets $S_{r,i} = [r-\rho_i, r+\rho_i]$, $r \in D_i$ as a system of closed pairwise disjoint neighborhoods of points r, such that

(1) $\rho_i > 0$, $\rho_i \to 0$ as $i \to \infty$,
(2) $|\mu(S_i) - \sum_{r\in D_i} \mu(\{r\})| \leq \frac{1}{i}$, where $S_i = \bigcup_{r\in D_i} S_{r,i}$, and
(3) $r \pm \rho_i \in \mathrm{Cont}(\mu)$.

The existence of such sets S_i follows from the regularity of μ. Take $k_i \geq i$ such that $\sum_{r\in D_i} |\mu_{k_i}(S_{r,i}) - \mu(S_{r,i})| \leq \frac{1}{i}$. This is possible because $\mu_i \xrightarrow{w} \mu$. Let $\bar\mu_k(B) = \mu_{k_i}(B \cap S_i)$ for any Borel set $B \subset \mathbf{R}^1$. It is easy to verify that $\bar\mu_i \xrightarrow{w} \mu_d$. Hence, $\mu_{k_i} - \bar\mu_i \xrightarrow{w} \mu_c$. Note also that $\mu_{k_i} - \bar\mu_i \in C_+^*(T)$.

From now on we shall relabel the subsequence extracted (with the help of the sequence k_i) as the initial one (by index i) and rewrite (9.5) as

$$x_i(t) = x_{0,i} + \int_{t_0}^t f(x_i,u_i,s)ds + \int_{[t_0,t]} g(x_i,s)(d\mu_i - d\bar\mu_i) + \int_{[t_0,t]} g(x_i,s)d\bar\mu_i,\ t\in T, \quad \forall i.$$

Let $x_i^c(t) = x_{0,i} + \int_{t_0}^t f(x_i,u_i,s)ds + \int_{[t_0,t]} g(x_i,s)(d\mu_i - d\bar\mu_i)$, and $x_i^d(t) = \int_{[t_0,t]} g(x_i,s)d\bar\mu_i$, $t \in T$.

Thus, $x_i(t) = x_i^c(t) + x_i^d(t)$ $\forall t \in T$. By the Lebesgue theorem, the weak-L_2 convergence of controls u_i, formula (1.6), the weak star convergence of μ_i, and Lemma 5.1, $x_i^c(t) \to x_c(t) = x_0 + \int_{t_0}^t f(x,u,s)ds + \int_{[t_0,t]} g(x,s)d\mu_c$ $\forall t \in T$, $i \to \infty$. Then, $x_i^d(t) \to x(t) - x_c(t) = x_d(t)$ $\forall t \in \mathrm{Cont}(\mu)$, being $x_d \in V^n(T)$.

Next, we show that $x_d = \Phi(x,t)$ with Φ defined as in Proposition 9.2 above. Let $t \in \mathrm{Cont}(\mu)$. Fix $\varepsilon > 0$, and take a number $N = N(\varepsilon)$ such that $\sum_{r\in \mathrm{Ds}(\mu)\setminus D_N} \mu(\{r\}) \leq \varepsilon$.

Then,

$$\limsup_{i\to\infty} \left| \sum_{r\in D(N,t)} \int_{S_{r,i}} g(x_i,s)m_i(s)ds - x_i^d(t) \right| \leq \mathrm{const}\,\varepsilon. \tag{9.6}$$

Here and from now on, $D(N,t) = \{r \in D_N : r \leq t\}$, and $m_i(s)$ is the density of μ_i.

For $r \in D(N,t)$ consider, on $S_{r,i}$, the system

$$x_i^d(s) = x_i^d(r-\rho_i) + \int_{r-\rho_i}^s g(x_i,\sigma)m_i(\sigma)d\sigma, \quad s \in S_{r,i}. \tag{9.7}$$

For all sufficiently large i, define the functions

$$\pi_{r,i}(\sigma) = \frac{F(\sigma;\mu_i) - F(r-\rho_i;\mu_i)}{\mu_i(S_{r,i})}, \quad r \in D(N,t).$$

The function $\pi_{r,i} : S_{r,i} \to [0,1]$, is absolutely continuous and strictly increasing. Moreover, $\frac{d\pi_{r,i}}{d\sigma} = \frac{m_i(\sigma)}{\mu_i(S_{r,i})} > 0$ a.e. Hence, there exists an inverse map $\theta_{r,i} : [0,1] \to S_{r,i}$, $\theta_{r,i} = (\pi_{r,i})^{-1}$. Let us perform the change of variables $\tau = \pi_{r,i}(\sigma)$ in (9.7). We have, for $s \in [0,1]$, and $r \in D(N,t)$,

$$\alpha_{r,i}(s) = x_i^d(r-\rho_i) + x_i^c(\theta_{r,i}(s)) + \mu_i(S_{r,i}) \int_0^s g(\alpha_{r,i}(\tau),\theta_{r,i}(\tau))d\tau,$$

where $\alpha_{r,i}(\tau) = x_i(\theta_{r,i}(\tau))$. It is clear that $\theta_{r,i}(\tau) \to r$ uniformly on $[0,1]$, and, from Lemma 5.3, $x_i^c(\theta_{r,i}(\tau)) \to x_c(r)$ uniformly on $[0,1]$, as $i \to \infty$. It is straightforward to show that $\alpha_{r,i}$ is in $C([0,1])$.

Denote its limit as in i by α_r. By passing to the limit in the last formula as $i \to \infty$, we deduce

$$\alpha_r(s) = x(r^-) + \mu(\{r\}) \int_0^s g(\alpha_r, r)d\tau, \ s \in [0,1], \ r \in D(N,t).$$

(Here we use the fact that by construction, $x_i^d(r-\rho_i) \to x_d(r^-)$.) From this and from (9.6), we have

$$\left| x_d(t) - \sum_{r \in D(N,t)} [\alpha_r(1) - x(r^-)] \right| \le \text{const}\, \varepsilon.$$

By taking the limit as $\varepsilon \to 0$, we obtain, from the definition of Φ, that $x_d(t) = \Phi(x(t), t)$. The statement of the proposition is proved for some subsequence. However, Proposition 9.2 allows its extension to the whole sequence $\{x_i\}$.

It remains to verify that $\max_{t\in T} |x_i(t)| \to \operatorname{gc\,sup}_{t\in T} |x(t)|$. Clearly, this follows from Lemma 5.3, the reasoning presented above, and a simple contradiction argument. The proof is complete. □

Proof of Lemma 5.4. Since the x_i are solutions to (1.2) and are uniformly bounded, it follows that $\operatorname{Var} \nu[x_i] \le \text{const}(\mu_i + \mathcal{L})$. From Proposition 9.1, we have that $\operatorname{Var} \nu[g(x_i,t)] \le \text{const}(\mu_i + \mathcal{L})$, and by applying Helly's second theorem, we may extract a subsequence so that $x_i(t) \to \tilde{x}(t)$ $\forall t \in T$. Let $x \in V^n(T)$ be a function such that $x(t) = \tilde{x}(t)$ $\forall t \in \text{Cont}(\mu)$. Such a function $x(t)$ exists since $\operatorname{Var}|_a^b[\tilde{x}] \le c(\mu + \mathcal{L})([a,b])$, $\forall a \le b$. Let us show that $x(t)$ satisfies (1.2).

For each number i, let us construct a sequence of absolutely continuous measures $\mu_{i,j} \in C_+^*(T)$ such that $\mu_{i,j} \xrightarrow{w} \mu_i$ on T, as $j \to \infty$. Let $\{\phi_k : k \in \mathbf{N}\}$ be a countable everywhere dense subset of $C(T)$ set of functions, and let $\{t_k : k \in \mathbf{N}\}$ be countable everywhere dense subset of points of T set such that $t_k \in \text{Cont}(\mu) \cap [\bigcap_{i=1}^\infty \text{Cont}(\mu_i)]$.

By using Proposition 9.3, we find, for each i, a number $j = j(i)$ so that, for $k = 1, \dots, i$,

$$\max\left\{ \left| \int_T \phi_k d\mu_{i,j} - \int_T \phi_k d\mu_i \right|, |x_i(t_k) - x_{i,j}(t_k)| \right\} \le \frac{1}{i},$$

$$\left| \max_{t\in T} |x_{i,j}(t)| - \operatorname{gc\,sup}_{t\in T} |x_i(t)| \right| \le \frac{1}{i},$$

where $x_{i,j}$ is the solution to the equation

$$x_{i,j}(t) = x_{0,i} + \int_{t_0}^t f(x_{i,j}, u_i, s)ds + \int_{[t_0,t]} g(x_{i,j}, s)d\mu_{i,j}, \quad t \in T. \tag{9.8}$$

Let us show that this solution exists for j sufficiently large. Assume $c = \operatorname{gc\,sup}_{t\in T} |x_i(t)| + 1$. Consider functions

$$\tilde{f}(x,u,t) = \begin{cases} f(x,u,t), & |x| \le c, \\ f(p_c(x),u,t), & |x| > c, \end{cases} \qquad \tilde{g}(x,t) = \begin{cases} g(x,t), & |x| \le c, \\ g(p_c(x),t), & |x| > c, \end{cases}$$

where $p_c(x)$ is the projection of vector x on the sphere $|x| = c$. Note that $\tilde{f}$ and $\tilde{g}$ are Lipschitz continuous in x uniformly in (x,u,t). This is why, for each j, there exists

a solution $x_{i,j}$ to (9.8), with functions $\tilde{f}$ and $\tilde{g}$ replacing f and g, respectively. This is so due to a theorem of existence of solution for convenient differential equations. From (9.4) it is not hard to deduce that the $x_{i,j}$ are uniformly bounded in j. By using Propositions 9.2 and 9.3 for large j we conclude that $\max_{t\in T}|x_{i,j}(t)| \le c$, and hence the solution to (9.8) exists.

Let $\mu_i^a = \mu_{i,j}$, and $x_i^a = x_{i,j}$. By construction $\mu_i^a \xrightarrow{w} \mu$. By Proposition 9.3, there exists a solution $\bar{x}$ of (1.2) on T and $x_i^a(t) \to \bar{x}(t)$ $\forall t \in \mathrm{Cont}(\mu)$. But, on the other hand, $\forall k$, $x_i^a(t_k) \to x(t_k)$, as $i \to \infty$. Then, from inequality $\mathrm{Var}\,\nu[x_i^a] \le \mathrm{const}(\mu_i^a + \mathcal{L})$, it follows that $x_i^a(t) \to x(t)$ $\forall t \in \mathrm{Cont}(\mu)$. Hence, $x(t)$ is a solution to (1.2).

The lemma is proved for some subsequence. However, by using Proposition 9.2, we extend it to the whole sequence $\{x_i\}$. The proof is complete. □

Proof of Lemma 5.5. Fix any $\varepsilon > 0$ and consider the set $S(W_0,\varepsilon)$, the ε-neighborhood of W_0. Since f is Lipschitz continuous, $|f(t)| \le \mathrm{const}\,\varepsilon$ $\forall t \in S(W_0,\varepsilon)$. From the weak convergence $\eta_i(T \setminus S(W_0,\varepsilon)) \to 0$ as $i \to \infty$. From uniform convergence, we conclude that $\|f_i - f\|_C \le \varepsilon$ for i sufficiently large. Then, for any $a < b$,

$$\left|\int_{[a,b)} f_i(s)d\eta_i\right| \le c[\varepsilon\eta_i([a,b)) + \eta_i([a,b) \cap [T \setminus S(W_0,\varepsilon)])].$$

By definition of variation of a function $\limsup_{i\to\infty} \mathrm{Var}\,|_\tau[x_i] \le \mathrm{const}\,\varepsilon$. But $\varepsilon > 0$ is arbitrary, and hence, $\mathrm{Var}\,|_\tau[x_i] \to 0$. The proof is complete. □

Proof of Proposition 5.6. Let (p,u,μ) be an admissible process in problem (P). Associated with it, let us construct an admissible process $(\tilde{p},\tilde{u},\tilde{\mu},\upsilon_0,\upsilon_1)$ for problem (P_1). Let $\tilde{u} = u$, $\tilde{\mu} = \mu - \sum_{k=0,1}\mu(\{t_k\})\delta_{t_k}$,[15] $\tilde{x}_0 = x(t_0^+)$, $\tilde{x}_1 = x(t_1^-)$, $\upsilon_k = \mu(\{t_k\})(t_1-t_0)^{-1}\mathcal{L}$, $\tilde{t}_k = t_k$, $k = 0,1$. Clearly, $(\tilde{p},\tilde{u},\tilde{\mu},\upsilon_0,\upsilon_1)$ is an admissible process for (P_1), and $e_0(p) = e_0(\tilde{p})$.

Conversely, let $(\tilde{p},\tilde{u},\tilde{\mu},\upsilon_0,\upsilon_1)$ be an admissible process in (P_1) and take $u = \tilde{u}$, $\mu = \tilde{\mu} + \sum_{k=0,1}|\upsilon_k|\delta(t_k)$, $x_k = \xi_k = \xi(\tilde{x}_k,t_k,(-1)^{k+1}|\upsilon_k|)$, $t_k = \tilde{t}_k$, $k = 0,1$. Then, the process (p,u,μ) is admissible for (P), and $e_0(p) = e_0(\tilde{p})$. The proof is complete. □

Proof of Proposition 5.7. Let $(\tilde{x}_0,\tilde{x}_1,\chi_0,\chi_1,\tilde{t}_0,\tilde{t}_1,\tilde{u},v,\tilde{\mu})$ be an admissible process for (P_2). Since $\frac{3}{2} \ge \dot{\chi} \ge \frac{1}{2} > 0$ a.e., χ strictly increases on $[\tilde{t}_0,\tilde{t}_1]$. Hence, there exists inverse mapping $\pi(t) = \chi^{-1}(t)$, $t \in [\chi(\tilde{t}_0),\chi(\tilde{t}_1)]$, which is also strictly increasing and absolutely continuous. Let $t_0 = \chi(\tilde{t}_0)$, $t_1 = \chi(\tilde{t}_1)$, $x_0 = \tilde{x}_0$, $u(t) = \tilde{u}(\pi(t))$, and $F(t;\mu) = F(\pi(t);\tilde{\mu})$. We show that $x(t) = \tilde{x}(\pi(t))$. In fact, by changing variable $\tau = \pi(s)$, deduce

$$\begin{aligned}\tilde{x}(\pi(t)) &= \tilde{x}_0 + \int_{\tilde{t}_0}^{\pi(t)}(v+1)f(\tilde{x},\tilde{u},\chi)d\tau + \int_{[\tilde{t}_0,\pi(t)]} g(\tilde{x},\chi)d\tilde{\mu}\\ &= x_0 + \int_{t_0}^{t} f(x,u,s)ds + \int_{[t_0,t]} g(x,s)d\mu\\ &= x(t), \quad t \in [t_0,t_1].\end{aligned}$$

From here, it follows that (p,u,μ) is an admissible process for (P), and $e_0(p) = e_0(\tilde{p})$.

Conversely, let (p,u,μ) be an admissible process for (P) and consider $v = 0$. Then, $(p,t_0,t_1,u,0,\mu)$ is admissible for (P_2). The proof is complete. □

QUOTIENTS OF FULLY NONLINEAR CONTROL SYSTEMS*

PAULO TABUADA† AND GEORGE J. PAPPAS‡

Abstract. In this paper, we introduce and study quotients of fully nonlinear control systems. Our definition is inspired by categorical definitions of quotients as well as recent work on abstractions of affine control systems. We show that quotients exist under mild regularity assumptions and characterize the structure of the quotient state/input space. This allows one to understand how states and inputs of the quotient system are related to states and inputs of the original system. We also introduce a notion of projectability which turns out to be equivalent to controlled invariance. This allows one to regard previous work on symmetries, partial symmetries, and controlled invariance as leading to special types of quotients. We also show the existence of quotients that are not induced by symmetries or controlled invariance. Such decompositions have a potential use in a theory of hierarchical control based on quotients.

Key words. quotient control systems, control systems category, controlled invariance, symmetries

1. Introduction.

The analysis and synthesis problems for nonlinear control systems are often very difficult due to the size and complicated nature of the equations describing the processes to be controlled. It is therefore desirable to have a methodology that decomposes control systems into smaller subsystems while preserving the properties relevant for analysis or synthesis. From a theoretical point of view, the problem of decomposing control systems is also extremely interesting since it reveals system structure that must be understood and exploited.

In this paper we will focus on the study of quotient control systems since they can be seen as lower dimensional models that may still carry enough information about the original system. We will build on several accumulated results of different authors that in one way or another have made contributions to this problem. One of the first approaches was given in [17] were the analysis of the Lie algebra of a control system lead to a decomposition into smaller systems. At the same time in [35], quotients of control systems induced by observability equivalence relations where introduced in the more general context of realization theory. In [31], Lie algebraic conditions are formulated for the parallel and cascade decomposition of nonlinear control systems, while the feedback version of the same problem was addressed in [24]. A different approach was based on reduction of mechanical systems by symmetries. In [39], symmetries were introduced for mechanical control systems and further developed in [9] for general control systems. The existence of such symmetries was then used to decompose control systems as the interconnection of lower dimensionality subsystems. The notion of symmetry was further generalized in [26], where it was shown that the existence of symmetries implies that a certain distribution associated with the

symmetries was controlled invariant. This related the notion of symmetry with the notion of controlled invariance for nonlinear systems. Controlled invariance [23, 12] was also used to decompose systems into smaller components. A different approach was taken in [22] where it was shown how to study controllability of systems evolving on principle fiber bundles through their projection on the base space. More recently, a modular approach to the modeling of mechanical systems has been proposed in [40], by studying how the interconnection of Hamiltonian control systems can still be regarded as a Hamiltonian control system. A different research direction was taken in [29], where instead of using structural properties of control systems, a constructive procedure was proposed to compute smaller control systems called abstractions.

In several of the above approaches, some notion of quotienting is involved. When symmetries exist, one of the blocks of the decompositions introduced in [9] is simply the original control system factored by the action of a Lie group representing the symmetry. If a control system admits a controlled invariant distribution, it is shown in [23, 12] that it has a simpler local representation. This simpler representation can be obtained by factoring the original control system by the equivalence relation defined by considering the leaves of the foliation induced by the controlled invariant distribution, equivalence classes. The notion of abstraction introduced in [29] can also be seen as a quotient since the abstraction is a control system on a smaller dimensional state space defined by an equivalence relation on the state space of the original control system. These facts motivate fundamental questions such as existence and characterization of quotient systems. Existence questions have already been addressed in [35] but in a different setting. Only specific equivalence relations were considered (those induced by indistinguishability), and the input space remained unaltered by the factorization process. Furthermore, the quotients discussed in [35] are of a particular nature being characterized by the notion of projectability introduced in section 6.

A thorough understanding of quotient systems also has important consequences for hierarchical control, since the construction of quotients proposed in [29] implicitly indicates that certain states of the original system may become inputs on the quotient control system. It is perhaps surprising that this methodology interchanges the role of state and input. However, this fact is the crucial factor that allows the development of a hierarchical control theory based on quotients. Since states of the original system may become inputs of the quotient system, a control design performed on a quotient system can serve as a design specification for the original system. We can therefore regard a control design as a *specification* for the evolution of certain state variables on the more detailed model. A complete and thorough understanding of how the states and inputs propagate from control systems to their quotients will enable such a hierarchical design scheme. Preliminary work exploiting such a hierarchical approach has been reported in [37].

In this paper, we take a new approach to the study of quotients by introducing the category of control systems as the natural setting for such problems in systems theory. The use of category theory for the study of problems in system theory also has a long history which can be traced back to the works of Arbib and Manes (see [2] for an introduction). More recently, several authors have also adopted a categorical approach as in [19], where the category of affine control systems is investigated. We also mention [33], where a categorical approach has been used to provide a general theory of systems.

We define the category of control systems whose objects are fully (nonaffine) nonlinear control systems and morphisms map trajectories between objects. The

morphisms in this category extend the notion of ϕ-related systems from [28]. In this categorical setting we formulate the notion of quotient control systems and show, in one of the main results, that

under some regularity (constant rank) assumptions quotient control systems always exist.

This result implies that, given a nonlinear projection map from the state space to some reduced state space, we can always construct a new control system on the reduced state space with the property that the nonlinear projection map carries trajectories of the original system into trajectories of the reduced system. This should be contrasted with several other approaches which rely on the existence of symmetries or controlled invariance to assert the existence of quotients. We also introduce the notion of projectable control sections, which will be a fundamental ingredient to characterize the structure of quotients. This notion is in fact equivalent to controlled invariance, and this allows one to regard quotients based on symmetries or controlled invariance as a special type of quotients. General quotients, however, are not necessarily induced by symmetries or controlled invariance and have the property that some of their inputs are related to states of the original model. This fact, implicit in [29], is explicitly characterized in this paper by understanding how the state and input space of the quotient is related to the state and input space of the original control system. In particular, this paper's main contribution states that

in the absence of symmetries, states that are factored out in the quotient construction can be regarded as inputs of the quotient control system.

This result clearly distinguishes general quotients from previously studied quotients based on symmetries or partial symmetries in which inputs of the quotient system are the inputs (or a quotient) of the original system inputs. Since existence of symmetries can be regarded as rare phenomena,[1] as shown in [32] for single-input systems, construction of quotients enables a widely applicable hierarchical approach to control design based on reconstruction of trajectories for the original system from quotient trajectories [37].

The outline of the paper is as follows. We start by introducing the relevant notions from differential geometry and control theory in section 2. We then review the notion of ϕ-related control systems in section 3 which was originally introduced in [28] and will motivate the definition of the category of control systems presented in section 4. In section 5, we introduce the notion of quotient control systems and prove an existence and uniqueness result regarding quotients which roughly asserts that given a regular equivalence relation on the state space of a control system a quotient system exists (under some regularity conditions) and is unique up to isomorphism. The characterization of quotients will be the goal of the remaining sections of the paper. We first introduce the notion of projectable control section in section 6 and prove the main result of the paper characterizing the structure of the quotient state/input space in section 7. We end with conclusions and some open questions for further research in section 8.

2. Control systems. In this section we introduce all the relevant notions from differential geometry and control systems necessary for the remainder of the paper. The reader may wish to consult numerous books on these subjects, such as [1] for differential geometry and [14, 27] for control theory.

[1] We thank one of the anonymous reviewers for bringing this fact to our attention.

2.1. Differential geometry. We will consider that all the manifolds will be C^∞ and that all the maps will be smooth. Let M be a manifold and T_xM its tangent space at $x \in M$. The tangent bundle of M is denoted by $TM = \cup_{x\in M} T_xM$, and π_M is the canonical projection map $\pi_M : TM \longrightarrow M$ taking a tangent vector $X(x) \in T_xM \subset TM$ to the base point $x \in M$. Now, letting M and N be manifolds and $\phi : M \longrightarrow N$ a map, we denote by $T_x\phi : T_xM \longrightarrow T_{\phi(x)}N$ the induced tangent map which maps tangent vectors X at T_xM to tangent vectors $T_x\phi \cdot X$ at $T_{\phi(x)}N$. If ϕ is such that $T_x\phi$ is surjective at $x \in M$, then we say that ϕ is a submersion at x. When ϕ is a submersion at every $x \in M$ we simply say that it is a submersion. Similarly, we say that ϕ has constant rank if the rank of the pointwise linear map $T_x\phi$ is constant for every $x \in M$. When ϕ has an inverse which is also smooth we call ϕ a diffeomorphism. We say that a manifold M is diffeomorphic to a manifold N, denoted by $M \cong N$, when there is a diffeomorphism between M and N. When this is the case we can use $\phi^{-1} : N \longrightarrow M$ to define a vector field on M from a vector field $Y \in TN$, denoted by $\phi^*Y = (\phi^{-1})_*Y$ and defined by $T_{\phi(x)}\phi^{-1} \cdot Y(\phi(x))$.

A fibered manifold is a manifold B equipped with a surjective submersion $\pi_B : B \longrightarrow M$. Manifolds B and M are called the total space and the base space, respectively. The surjection π_B defines a submanifold $\pi_B^{-1}(x) = \{b \in B : \pi_B(b) = x\} \subseteq B$ for every $x \in M$ called the fiber at $x \in M$. We will usually denote a fibered manifold simply by $\pi_B : B \longrightarrow M$. Since a surjective submersion is locally the canonical projection from $\mathbb{R}^i$ to $\mathbb{R}^j$, $i = \dim(B)$ and $j = \dim(M)$, we can always find local coordinates (x, y), where x are coordinates for the base space and y are coordinates for the fibers over the base space. We shall call these coordinates adapted coordinates.

A map $\varphi : B_1 \longrightarrow B_2$ between two fibered manifolds is fiber preserving iff there exists a map $\phi : M_1 \longrightarrow M_2$ between the base spaces such that the following diagram commutes:

$$\begin{array}{ccc} B_1 & \xrightarrow{\varphi} & B_2 \\ {\scriptstyle \pi_{B_1}}\downarrow & & \downarrow{\scriptstyle \pi_{B_2}} \\ M_1 & \xrightarrow[\phi]{} & M_2 \end{array} , \tag{2.1}$$

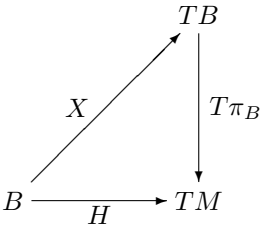
that is to say, iff $\pi_{B_2} \circ \varphi = \phi \circ \pi_{B_1}$. In such a case we also refer to φ as a fiber preserving lift of ϕ. Given fibered manifolds B_1 and B_2, we will say that B_1 is a fibered submanifold of B_2 if the inclusion map $i : B_1 \hookrightarrow B_2$ is fiber preserving.

Given a map $h : M \longrightarrow N$ defined on the base space of a fibered manifold, its extension to the total space B is given by $\pi_B^* h = h \circ \pi_B$. We now consider the extension of a map $H : B \longrightarrow TM$ to a vector field in B. We will define local and global extensions of H. Globally, we define H^e as the set of all vector fields[2] $X : B$

[2]Global existence of such vector fields X follows from the existence of a horizontal space $\mathcal{H} \subseteq TB$, $\mathcal{H} \cong TM$ that allows the decomposition of TB as $TB = \mathcal{H} \oplus \ker(T\pi_B)$. A global extension of a map $H : B \longrightarrow TM$ to a vector field $X : B \longrightarrow TB$ is now uniquely defined as the vector field $X = H : B \longrightarrow TM \cong \mathcal{H} \subseteq TB$. Such horizontal space can be obtained, for example, as the orthogonal complement to $\ker(T\pi_B)$ given by a Riemannian metric on B.

$\longrightarrow TB$ such that the following diagram commutes:

(2.2)



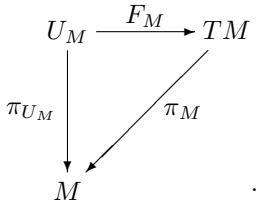
that is, $T\pi_B(X) = H$. When working locally, one can be more specific and select a distinguished element of H^e, denoted by H^l, which satisfies in adapted local coordinates (x, y), $H^l = H\frac{\partial}{\partial x} + 0\frac{\partial}{\partial y}$. A vector field $Y : M \longrightarrow TM$ on the base space M of a fibered manifold can also be extended to a vector field on the total space. It suffices to compose Y with the projection $\pi_B : B \longrightarrow M$ and recover the previous situation since $Y \circ \pi_B$ is a map from B to TM.

2.2. Control systems. Since the early days of control theory it was clear that in order to give a global definition of control systems the notion of input could not be decoupled from the notion of state [4, 41]. Although the coupling between states and inputs is usually modeled through the use of fiber bundles, we shall consider more general spaces.

In any case a control system can be globally defined as follows.

DEFINITION 2.1 (control system). *A control system $\Sigma_M = (U_M, F_M)$ consists of a fibered manifold $\pi_{U_M} : U_M \longrightarrow M$ called the control bundle and a map $F_M : U_M \longrightarrow TM$ making the following diagram commutative:*

(2.3)



That is, $\pi_M \circ F_M = \pi_{U_M}$, where $\pi_M : TM \longrightarrow M$ is the tangent bundle projection.

The input space U_M is modeled as a fibered manifold since in general the available control inputs may depend on the current state of the system. In adapted coordinates (x, v), Definition 2.1 reduces to the familiar expression $\dot{x} = f(x, v)$ with $v \in \pi^{-1}_{U_M}(x)$. The lack of local triviality assumptions on π_{U_M} is motivated by the need to model the construction of abstractions of control affine systems, as described in [29], in a fully nonlinear context. As the following example illustrates, even in simple situations the inputs of a control system resulting from an abstraction or quotient process can depend on the states in a way that cannot be modeled by a fiber bundle.

Consider control system $F_M : U_M \longrightarrow TM$ with $U_M = M \times U$, $M = \mathbb{R}^3$, $U =]0, 1[$ defined by:

$$F_M(x, y, z, u) = \left(x\frac{\partial}{\partial x} + y\frac{\partial}{\partial y} + z\frac{\partial}{\partial z} \right) u.$$

On the state space we define the following map $\phi : \mathbb{R}^3 \longrightarrow \mathbb{R}$ based on Reeb's foliation:

$$\phi(x, y, z) = (1 - r^2)e^z, \quad r = x^2 + y^2. \tag{2.4}$$

Computing the derivative of ϕ,

$$\mathrm{d}\phi = e^z(-4rx\,\mathrm{d}x - 4ry\,\mathrm{d}y + (1-r^2)\,\mathrm{d}z),$$

we see that ϕ is a submersion since $1-r^2=0$ for $r^2=1$, which implies that $x\neq 0$ or $y\neq 0$, and this in turn implies that $\mathrm{d}\phi\neq 0$. This shows that we can see $\phi:\mathbb{R}^3\longrightarrow\mathbb{R}$ as a fibered manifold. If we now compute the projection of F_M on $\mathbb{R}$ by ϕ, we obtain

$$\mathrm{d}\phi\cdot F_M = e^z(-4rx^2-4ry^2+(1-r^2)z)u.$$

The set of vectors defined by the previous expression can be seen as a control system on $\mathbb{R}$ up to control parameterization, as it defines the possible directions of motion achievable by control. This is the principle underlying the notion of abstraction described in [29]. Such a collection of vector fields admits the natural parameterization $\pi^{-1}_{U_M}(\phi^{-1}(w))$ for every $w\in\mathbb{R}$. However, such a set of inputs cannot be given the structure of a fiber bundle. To see this, it suffices to note that the fibers $\phi^{-1}(w)$ are not homeomorphic for $w>0$ and $w=0$. For $w>0$ we can solve $\phi(x,y,z)=w$ to obtain $z=\log\frac{w}{1-r^2}$ which defines $\phi^{-1}(w)$ as

$$\left\{(x,y,z)\in\mathbb{R}^3 \;:\; z=\log\frac{w}{1-r^2} \quad\wedge\quad 0\leq r^2<1\right\}$$

and which is homeomorphic to the open unit disk in $\mathbb{R}^2$. If $w=0$, solving $\phi(x,y,z)=0$, we obtain $r=1$ which is diffeomorphic to a cylinder. We thus see that for any open set O in $\mathbb{R}$ containing 0, $\pi_{U_M}(\phi^{-1}(0))$ cannot be diffeomorphic to $O\times L$ for some manifold L describing the typical fibers of $\phi\circ\pi_{U_M}$ as they are not diffeomorphic for different points in O. It is precisely the need to capture and analyze situations like this that forces one to consider models for the state/input space other than fiber bundles. The need to model these and other couplings between states and inputs has led to alternative approaches where the notion of control system and its properties are defined independently of states and inputs as in Willem's behavioral theory [30] and Fliess' differential algebraic approach [7].

We now return to our discussion of control systems by introducing the notion of control section[3] that is closely related to control systems and which will be fundamental in our study of quotients.

Definition 2.2 (control section). *Given a manifold M, a control section on M is a fibered submanifold $\pi_{\mathcal{S}_M}:\mathcal{S}_M\longrightarrow M$ of TM.*

We denote by $\mathcal{S}_M(x)$ the set of vectors $X\in T_xM$ such that $X\in\pi^{-1}_{\mathcal{S}_M}(x)$. We now see that under certain regularity assumptions, a control system (U_M,F_M) defines a control section by the pointwise assignment $\mathcal{S}_M(x)=F_M(\pi^{-1}_{U_M}(x))$. Conversely, a control section also defines a control system as we shall see in detail in section 4. The notion of a control section allows one to refer in a concise way to the set of all tangent vectors that belong to the image of F_M by saying that $X\in T_xM$ belongs to $\mathcal{S}_M(x)$ iff there exists a $u\in U_M$ such that $\pi_M(u)=x$ and $F_M(u)=X$. When $\mathcal{S}_M(x)$ defines an affine distribution on TM, we call control system F_M control affine and fully nonlinear otherwise.

Having defined control systems the concept of trajectories or solutions of a control system is naturally expressed by the following definition.

[3]In some literature this notion is also known as the field of admissible velocities.

DEFINITION 2.3 (trajectories of control systems). *A smooth curve $c : I \longrightarrow M$, $I \subseteq \mathbb{R}^+_0$, is called a trajectory of control system $\Sigma_M = (U_M, F_M)$ if there exists a (not necessarily smooth) curve $c^U : I \longrightarrow U_M$ making the following diagrams commutative:*

$$\begin{array}{ccc} & & U_M \\ & \overset{c^U}{\nearrow} & \downarrow \pi_{U_M} \\ I & \xrightarrow[c]{} & M \end{array} \qquad \begin{array}{ccc} & & U_M \\ & \overset{c^U}{\nearrow} & \downarrow F_M \\ I & \xrightarrow[Tc]{} & TM \end{array} \quad , \tag{2.5}$$

where we have identified I with TI.

The above commutative diagrams are equivalent to the following equalities:

$$\begin{aligned} \pi_{U_M} \circ c^U &= c, \\ Tc &= F_M(c^U), \end{aligned}$$

which mean in adapted coordinates that $x(t)$ is a trajectory of a control system if there exists an input $v(t)$ such that $x(t)$ satisfies $\dot{x}(t) = f(x(t), v(t))$ and $v(t) \in \pi^{-1}_{U_M}(x(t))$ for all $t \in I$.

3. ϕ-related control systems. We start by reviewing the notion of ϕ-related control systems originally introduced in [28] and which motivates the construction of the category of control systems to be later presented.

DEFINITION 3.1 (ϕ-related control systems). *Let Σ_M and Σ_N be two control systems defined on manifolds M and N, respectively. Given a map $\phi : M \longrightarrow N$ we say that Σ_N is ϕ-related to Σ_M iff for every $x \in M$,*

$$T_x\phi(\mathcal{S}_M(x)) \subseteq \mathcal{S}_N \circ \phi(x). \tag{3.1}$$

In [28] it is shown that this notion is equivalent to a more intuitive relation between Σ_M and Σ_N.

PROPOSITION 3.2 (see [28]). *Let Σ_M and Σ_N be two control systems defined on manifolds M and N, respectively, and let $\phi : M \longrightarrow N$ be a map. Control system Σ_N is ϕ-related to Σ_M iff for every trajectory $c(t)$ of Σ_M, $\phi(c(t))$ is a trajectory of Σ_N.*

Propagating trajectories from one system to another is clearly desirable. Since most control system properties are properties of its trajectories, relating trajectories of different control systems also allows one to relate the corresponding properties. If, in fact, system Σ_N is lower dimensional than system Σ_M, then we are clearly reducing the complexity of Σ_M. We can therefore regard Σ_N as an *abstraction* of Σ_M in the sense that some aspects of Σ_M have been collapsed or abstracted away, while others remain in Σ_N. This motivated the notion of abstraction based on trajectory propagation in [28], which defined an abstraction of a control system Σ_M as a ϕ-related control system Σ_N by a surjective submersion ϕ.

The idea of sending trajectories from one system to trajectories of another system has been used many times in control theory to study equivalence of control systems. We mention, for example, linearization by diffeomorphism [16] or feedback linearization [5, 10, 13]. In these examples the maps ϕ relating the control systems were in fact diffeomorphisms so that no aggregation or abstraction was involved. Related to the feedback linearization problem is the partial feedback linearization problem where only partial linearization is thought of. Such a problem can be reduced to the feedback linearization problem by considering feedback linearization of a subsystem of

the original control system [20]. The notion of a subsystem can also be described by defining how subsystem trajectories relate to the original system trajectories. In this case, we require the existence of a map (satisfying certain injectivity assumptions) transforming subsystem trajectories into trajectories of the original system. The use of trajectory propagating maps can already be traced back to the works of Arbib and Manesl (see [2] for an introduction), where by the use of category theoretic ideas it is shown that (discrete time) control systems and finite state automata are just different manifestations of the same phenomena.

4. The category of control systems. Informally speaking, a category is a collection of *objects* and *morphisms* between the objects that relate to the structure of the objects. If one is interested in understanding vector spaces, it is natural to consider vector spaces as objects and linear maps as morphisms, since they preserve the vector space structure. This choice for objects and morphisms defines **Vect**, the category of vector spaces. Choosing manifolds for objects leads to the natural choice of smooth maps for morphisms and defines **Man**, the category of smooth manifolds. In this section we introduce the category of control systems which we regard as the natural framework to study quotients of control systems. Besides providing an elegant language to describe the constructions to be presented, category theory also offers a conceptual methodology for the study of objects, control systems in this case. We refer the reader to [18] and [3] for further details on the elementary notions of category theory used throughout the paper.

The category of control systems, denoted by **Con**, has as objects control systems as described in Definition 2.1. The morphisms in this category extend the concept of ϕ-related control systems described by Definition 3.1. Since the notion of ϕ-related control systems relates control sections and these can be parameterized by controls, the lifted notion should relate control sections as well as its parameterizations by inputs.

DEFINITION 4.1 (morphisms of control systems). *Let Σ_M and Σ_N be two control systems defined on manifolds M and N, respectively. A morphism f from Σ_M to Σ_N is a pair of maps $f = (\phi, \varphi)$, $\phi : M \longrightarrow N$ and $\varphi : U_M \longrightarrow U_N$ making the following diagrams commutative:*

(4.1)
$$\begin{array}{ccc} U_M & \xrightarrow{\varphi} & U_N \\ {\scriptstyle \pi_{U_M}}\downarrow & & \downarrow{\scriptstyle \pi_{U_N}} \\ M & \xrightarrow[\phi]{} & N \end{array} \qquad \begin{array}{ccc} U_M & \xrightarrow{\varphi} & U_N \\ {\scriptstyle F_M}\downarrow & & \downarrow{\scriptstyle F_N} \\ TM & \xrightarrow[T\phi]{} & TN \end{array}$$

It will be important for later use to also define isomorphisms.

DEFINITION 4.2 (isomorphisms of control systems). *Let Σ_M and Σ_N be two control systems defined on manifolds M and N, respectively. System Σ_M is isomorphic to system Σ_N iff there exist morphisms f_1 from Σ_M to Σ_N and f_2 from Σ_N to Σ_M such that $f_1 \circ f_2 = (id_N, id_{U_N})$ and $f_2 \circ f_1 = (id_M, id_{U_M})$.*

In this setting, feedback transformations[4] can be seen as special isomorphisms. Consider an isomorphism (ϕ, φ) with $\varphi : U_M \longrightarrow U_M$ such that $\phi = id_M$. In adapted

[4]Some authors use the expression feedback transformation to denote any isomorphism in **Con**. We consider the more restrictive use where changes of coordinates in the state space are disallowed as they cannot be realized by feedback.

coordinates (x, v), where x represents the base coordinates (the state) and v the coordinates on the fibers (the inputs), the isomorphism has a coordinate expression for φ of the form $\varphi = (x, \beta(x, v))$. The fiber term $\beta(x, v)$ representing the new control inputs is interpreted as a feedback transformation since it depends on the state at the current location as well as the former inputs v. We shall therefore refer to feedback transformations as isomorphisms over the identity since we have $\phi = id_M$. The control theoretic notion of feedback equivalence is captured in this framework by noting that two control systems are feedback equivalent iff there exists an isomorphism (although not necessarily a feedback transformation) between the two systems. A related notion is that of system immersion. Although we cannot capture such a notion in our framework, as we have not equipped control systems with observation maps, a restricted version of system immersion can still be defined within our framework. Recall that, according to [6], system Σ_M is said to be immersed in system Σ_N if there exists an injective map $\phi : M \longrightarrow N$ such that the input-output behavior of Σ_M, when initialized at x, equals the input-output behavior of Σ_N, when initialized at $\phi(x)$. If we assume that $U_M = U \times M$ and $U_N = U \times N$ for some common input manifold U, that M is a submanifold of N, and that i is the canonical injection of M into N, then Σ_M is immersed into Σ_N, when (id_U, i) is a morphism from Σ_M to Σ_N. Note that the existence of morphism (id_U, i) implies that $F_M(x, u) = Ti \cdot F_M(x, u) = F_N(i(x), id_U(u)) = F_N(x, u)$ for local coordinates $(x, u) \in U \times M \subseteq U \times N$, and this implies that Σ_M and Σ_N have the same input-output behavior when initialized at x and $i(x)$, respectively.

A control system can alternatively be defined by a control section $\mathcal{S}_M$ on M in the sense that at each point $x \in M$, $\mathcal{S}_M(x)$ defines all the possible directions along which we can flow or steer our system. However, there can be several control parameterizations for $\mathcal{S}_M$ and it is important to understand in what sense all those parameterizations represent the same control system. In order to obtain such equivalence we make the following assumptions about control systems that will be explicitly mentioned when needed:

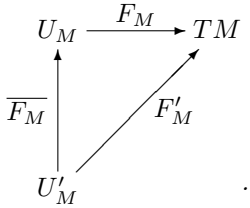
AI: The fibers $\pi_{U_M}^{-1}(x)$ are connected for every $x \in M$.

AII: The map $F_M : U_M \longrightarrow T_M$ is an embedding.

Control systems satisfying assumption **AII** enjoy the following property.

PROPOSITION 4.3. *Let (U_M, F_M) be a control system on manifold M satisfying* **AII** *and let (U'_M, F'_M) be any control system on manifold M such that $\mathcal{S}'_M(x) \subseteq \mathcal{S}_M(x)$ for every $x \in M$. Then, there exists a unique fiber preserving map $\overline{F_M}$ making the following diagram commutative:*

(4.2)



The previous result is an immediate consequence of the fact that $F_M(U_M)$ is an embedded submanifold of TM. This is sufficient for the previous result to hold but not necessary. In fact, the existence of a unique map $\overline{F_M}$ is the property of interest and could be used as a definition. However, it would be difficult to check in concrete examples if a given control system would satisfy such a property. A different approach

would relax the requirement that $F_M(U_M)$ is an embedded submanifold by the weaker assumption of initial submanifold (see [15] for the definition of initial submanifolds and its properties).

Since assumption **AII** implies the universal property [18] stated in Proposition 4.3, any two control systems satisfying **AII** and defining the same control section are isomorphic. It is in this sense that we do not need to distinguish between different parameterizations of the same control section. They are the same control system, up to a change of control coordinates, that is, up to an isomorphism over the identity. This will be important when considering the effect of feedback since, as we have already seen, this change of control coordinates can be regarded as a feedback transformation.

The relation between the notions of ϕ-related control systems (3.1) and **Con** morphisms (4.1) is stated in the next proposition.

PROPOSITION 4.4. *Let Σ_M and Σ_N be two control systems defined on M and N, respectively. If $f = (\phi, \varphi)$ is a* **Con** *morphism from Σ_M to Σ_N, then Σ_N is ϕ-related to Σ_M. Conversely, if Σ_N satisfies* **AII** *and Σ_N is ϕ-related to Σ_M by a smooth map $\phi : M \longrightarrow N$, then there exists a unique fiber preserving lift φ of ϕ such that $f = (\phi, \varphi)$ is a* **Con** *morphism from Σ_M to Σ_N.*

Proof. Definition 4.1 trivially implies Definition 3.1, so let us prove that Definition 3.1 implies Definition 4.1. If Σ_N is ϕ-related to Σ_M, then by Definition 3.1, $T_x\phi(\mathcal{S}_M(x)) \subseteq \mathcal{S}_N \circ \phi(x)$. But $\mathcal{S}_M$ is parameterized by U_M, so that the map $T\phi \circ F_M : U_M \longrightarrow TN$ (see the diagram below) satisfies $T\phi \circ F_M(U_M) \subseteq \mathcal{S}_N$. Therefore, by Proposition 4.3, there is a unique fiber preserving map $\overline{F_N}$ such that

$$\begin{array}{ccc} U_M & \xrightarrow{\overline{F_N}} & U_N \\ {\scriptstyle F_M}\downarrow & & \downarrow{\scriptstyle F_N} \\ TM & \xrightarrow{T\phi} & TN \\ {\scriptstyle \pi_M}\downarrow & & \downarrow{\scriptstyle \pi_N} \\ M & \xrightarrow[\phi]{} & N \end{array}$$

commutes. By taking $\varphi = \overline{F_N}$, $\pi_{U_M} = \pi_M \circ F_M$, and $\pi_{U_N} = \pi_N \circ F_N$ one recovers Definition 4.1 and the equivalence is proved. □

The previous result shows that there is an equivalence between smooth maps ϕ relating control systems and **Con** morphisms provided that we work on a suitable subcategory (where assumption **AII** holds). This means that many properties of nonlinear control systems can be characterized by working with $\mathcal{S}_M$ instead of F_M. We also see that if there is a morphism f from Σ_M to Σ_N, then this morphism carries trajectories of Σ_M to trajectories of Σ_N in virtue of Proposition 3.2.

5. Quotients of control systems. Given a control system Σ_M and an equivalence relation on the manifold M, we can regard the quotient control system as an abstraction since some modeling details propagate from Σ_M to the quotient while other modeling details disappear in the factorization process. This fact motivates the study of quotient control systems as they represent lower complexity (dimension) objects that can be used to verify properties of the original control system. Quotients are also important from a design perspective since a control law for the quotient object can be regarded as a specification for the desired behavior of the original control

system. In this spirit we will address the following questions.

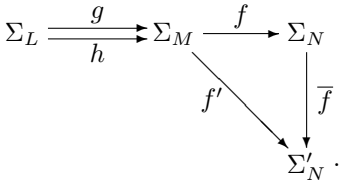
1. *Existence.* Given a control system Σ_M defined on a manifold M and an equivalence relation $\sim_M$ on M, when does there exist a control system on $M/\sim_M$, the quotient manifold, and a fiber preserving lift p_U of the projection $p_M : M \longrightarrow M/\sim_M$ such that (p_M, p_U) is a **Con** morphism?

2. *Uniqueness.* Is the lift p_U of p_M, when it exists, unique?

3. *Structure of the quotient state/input space.* What is the structure of the fibers (input space) of the quotient control system?

To clarify our discussion we formalize the notion of quotient control systems.

DEFINITION 5.1 (quotient control system). *Let Σ_L, Σ_M, Σ_N be control systems defined on manifolds L, M, and N, respectively, and g, h two morphisms from Σ_L to Σ_M. The pair (f, Σ_N), where f is a morphism and Σ_N a control system, is a quotient control system of Σ_M if $f \circ g = f \circ h$ and for any other pair (f', Σ'_N) such that $f' \circ g = f' \circ h$ there exists one and only one morphism $\overline{f}$ from Σ_N to Σ'_N such that the following diagram commutes:*



(5.1)

That is, $f' = \overline{f} \circ f$.

Intuitively, we can read diagram (5.1) as follows. Assume that the set $\sim = \{(u, v) \in U_M \times U_M \;:\; (u, v) = (g(l), h(l)) \text{ for some } l \in U_L\}$ is a regular equivalence relation [1]. Then, the condition $f \circ g = f \circ h$ simply means that f respects the equivalence relation, that is, $u \sim v \;\Rightarrow\; f(u) = f(v)$. Furthermore, it asks that for any other map f' respecting relation $\sim$, there exists a unique map $\overline{f}$ such that $f' = \overline{f} \circ f$. This is a usual characterization of quotient manifolds [1] that we use here as a definition. The same chain of reasoning shows that if we replace control systems by the corresponding state space and the morphisms by the maps between the state spaces, then diagram (5.1) asks for N to also be quotient manifold obtained by factoring M by a regular equivalence relation $\sim_M$ on M defined by g and h. The same idea must therefore hold for control systems. This means that control system Σ_N must also satisfy a unique factorization property in order to be a quotient control system.

From the above discussion it is clear that a necessary condition for the existence of the quotient control system is the existence of the quotient manifold $M/\sim_M$. When $\sim_M$ is a regular equivalence relation the quotient space $M/\sim_M$ will be a manifold [1] and the equivalence relation can be equivalently described by a surjective submersion. We will therefore assume that the regular equivalence relation $\sim_M$ is given by a surjective submersion $\phi : M \longrightarrow N$. Similarly, the fiber preserving lift φ of ϕ will also have to be a surjective submersion. We now consider the following assumption which will be explicitly stated when required.

AIII: The map $T\phi \circ F_M : U_M \longrightarrow TN$ has constant rank and connected fibers.

The first two questions of the previous list are answered in the next theorem which asserts that quotients exist under moderate conditions.

THEOREM 5.2. *Let Σ_M be a control system on a manifold M and $\phi : M \longrightarrow N$ a surjective submersion, and assume that* **AIII** *holds. Then there exist,*

1. *a control system Σ_N on N,*

2. *a* unique *fiber preserving lift* $\varphi : U_M \longrightarrow U_N$ *of* ϕ *such that the pair* $((\phi, \varphi), \Sigma_N)$ *is a quotient control system of* Σ_M.

Proof. By assumption **AIII**, the map $T\phi \circ F_M$ has constant rank and we can define a regular and involutive distribution $\mathcal{D}$ on TU_M by $\mathcal{D} = \ker(TT\phi \circ TF_M)$. Furthermore, as $T\phi \circ F_M$ has connected fibers, also by assumption **AIII**, these are described by the integral manifolds of $\mathcal{D}$. We thus have a regular equivalence relation $\sim \subseteq U_M \times U_M$ obtained by declaring two points equivalent if they lie on the same integral manifold of $\mathcal{D}$. We now consider the manifold $U_M/\sim$ obtained as the quotient of U_M by $\sim$ and denote by $\pi : U_M \longrightarrow U_M/\sim$ the canonical projection. Since $T\phi \circ F_M(u) = T\phi \circ F_M(u')$ iff $\pi(u) = \pi(u')$, it follows from the properties of quotient manifolds [1] that there exists a unique map $\alpha : U_M/\sim \longrightarrow TN$ such that $\alpha \circ \pi = T\phi \circ F_M$. We now define U_N as $U_M/\sim$, π_{U_N} as $\pi_N \circ \alpha$, F_N as α, and φ as π. We note that φ is unique and claim that $((\phi, \varphi), U_M/\sim)$ is a quotient of Σ_M. The pair of maps (ϕ, φ) is a morphism from Σ_M to Σ_N since $T\phi \circ F_M = F_N \circ \varphi$ as required by the second diagram in (4.1), and composing $T\phi \circ F_M = F_N \circ \varphi$ with π_N, we obtain,

$$\begin{aligned}
\pi_N \circ T\phi \circ F_M &= \pi_N \circ F_N \circ \varphi \\
\Leftrightarrow \phi \circ \pi_M \circ F_M &= \pi_N \circ F_N \circ \varphi && \text{since } \pi_N \circ T\phi = \phi \circ \pi_M \\
\Leftrightarrow \phi \circ \pi_{U_M} &= \pi_N \circ F_N \circ \varphi && \text{by commutativity of diagram (2.3)} \\
\Leftrightarrow \phi \circ \pi_{U_M} &= \pi_{U_N} \circ \varphi && \text{by definition of } \pi_{U_N},
\end{aligned}$$

which shows that the first diagram in (4.1) also commutes.

It remains to show that any other morphism $f' = (\phi', \varphi')$ such that ϕ' is compatible with the equivalence relation defined by ϕ factors uniquely through f. Since the equivalence relation defined by ϕ on M induces the equivalence relation $\sim$ on U_M, we see that $\varphi(u) = \varphi(u')$ implies $\varphi'(u) = \varphi'(u')$. It then follows from the universality of φ that φ' factors uniquely through φ; that is, there exists a unique map $\overline{\varphi}$ such that $\varphi' = \overline{\varphi} \circ \varphi$. Similarly, ϕ' factors uniquely trough ϕ via $\overline{\phi}$. It then remains to show that $(\overline{\phi}, \overline{\varphi})$ is a morphism from Σ_N to Σ'_N.

We first show that diagram (4.1) commutes. Let $u_n \in U_N$, as φ is a surjective map; there is a $u_m \in U_M$ such that $\varphi(u_m) = u_n$. We now have, by diagram chasing,

$$\begin{aligned}
F'_N \circ \overline{\varphi} \circ \varphi(u_m) &= F'_N \circ \varphi'(u_m) && \text{since } \varphi' \text{ factors on } \varphi \\
&= T\phi' \circ F_M(u_m) && \text{by commutativity of the 2nd diagram in (4.1)} \\
&= T\overline{\phi} \circ T\phi \circ F_M(u_m) && \text{since } \phi' \text{ factors on } \phi \\
&= T\overline{\phi} \circ F_N \circ \varphi(u_m) && \text{by commutativity of the 2nd diagram in (4.1),}
\end{aligned}$$

and replacing $\varphi(u_m)$ by u_n we see that $\overline{f}$ satisfies the second diagram in (4.1). Commutativity of the first diagram in (4.1) can be obtained similarly by diagram chasing. □

This result provides the first characterization of quotient objects in **Con**. It shows that given a regular equivalence relation on the base (state) space of a control system and a mild regularity condition, there exists a quotient control system on the quotient manifold. Furthermore, it also shows that the regular equivalence relation on M or the map ϕ uniquely determines a fiber preserving lift φ which describes how the state/input pairs of the control system on M relate to the state/input pairs of the quotient control system. Furthermore, we also see that the map F_N is an injective immersion, a fact we will use several times in the remainder of this paper.

Existence of quotients under such weak conditions is perhaps surprising given the fact that in other contexts, quotients exist only in very specific situations. A quotient

group can only be obtained by factoring a group by a normal subgroup and not by a general equivalence relation, a quotient linear space can only be obtained by factoring a linear space by a linear subsubspace and not by a general equivalence relation, etc. This fact highlights the relevance of Theorem 5.2 at the theoretical level but also at the practical level since quotients can be constructively used to hierarchically design trajectories [37].

Having answered the first two questions from the previous list (existence and uniqueness), we concentrate on the characterization of the quotient control system input space. This problem requires a deeper understanding of how ϕ determines φ and will be the goal of the remainder of this paper. Since **Con** was defined over **Man**, that is, morphisms in **Con** are smooth maps and control systems are defined on manifolds, the characterization of φ will require an interplay of tools from differential geometry and category theory.

6. Projectable control sections. We now extend the notion of projectable vector fields from [21] and of projectable families of vector fields from [22] to control sections. The notion of projectable control sections is weaker than projectable vector field or families of vector fields but nonetheless stronger than **Con** morphisms. The motivation for introducing this notion comes from the fact that projectability of control sections will be a fundamental ingredient in characterizing the structure of the quotient system input space . Furthermore, we will also see that projectability, as defined in this categorical setting, will correspond to the well-known notion of controlled invariance.

Given a vector field X on M and a surjective submersion $\phi : M \longrightarrow N$ we say that X is projectable with respect to ϕ when $Y = T\phi \cdot X$, the projection of X, is a well-defined vector field on N that satisfies $T\phi \cdot X = Y \circ \phi$ [21]. The vector field Y is also called ϕ-related to X [1]. This notion was extended to families of vector fields in [22] by requiring that the projection of each vector field in the family is a well-defined vector field on N. However, when working with control sections, which can be regarded as *sets* of vectors at each base point $x \in M$, one should require only that the projection of these *sets* of vectors is the same *set* when the base points on M project on the same base point on N. Intuitively, we are asking for control sections that behave well under the projection defined by ϕ. This is formalized as follows.

DEFINITION 6.1. *Let M be a manifold, $\mathcal{S}_M$ a control section on M, and $\phi : M \longrightarrow N$ a surjective submersion. We say that $\mathcal{S}_M$ is projectable with respect to ϕ iff $\mathcal{S}_M$ induces a control section $\mathcal{S}_N$ on N such that the following diagram commutes:*

$$\begin{array}{ccc} \mathcal{P}(TM) & \xrightarrow{T\phi} & \mathcal{P}(TN) \\ \uparrow{\scriptstyle \mathcal{S}_M} & & \uparrow{\scriptstyle \mathcal{S}_N} \\ M & \xrightarrow[\phi]{} & N \end{array} \quad , \tag{6.1}$$

where $\mathcal{P}(TM)$ denotes the powerset of T_xM for every $x \in M$.

We see that if $\mathcal{S}_M$ is in fact a vector field we recover the notion of projectable vector fields. The notion of projectable control sections is stronger then the notion of **Con** morphism since for any $x_1, x_2 \in M$ such that $\phi(x_1) = \phi(x_2)$ we necessarily have $T\phi(\mathcal{S}_M(x_1)) = \mathcal{S}_N \circ \phi(x_1) = T\phi(\mathcal{S}_M(x_2))$ if $\mathcal{S}_M$ is projectable. On the other hand, if (ϕ, φ) is a **Con** morphism for a fiber preserving lift φ of ϕ, we only have the inclusions $T\phi(\mathcal{S}_M(x_1)) \subseteq \mathcal{S}_N \circ \phi(x_1)$ and $T\phi(\mathcal{S}_M(x_2)) \subseteq \mathcal{S}_N \circ \phi(x_1)$. Therefore, projectability

with respect to ϕ and **AII** implies that ϕ can be extended to a **Con** morphism but given a **Con** morphism $f = (\phi, \varphi)$ from Σ_M to Σ_N it is not true, in general, that $\mathcal{S}_M$ is projectable with respect to ϕ.

To determine the relevant conditions on $\mathcal{S}_M$ that ensure projectability we will need an auxiliary result.

LEMMA 6.2. *Let $f : M \longrightarrow N$ be a map between manifolds and let X_t be the flow of a vector field $X \in TM$ such that $f \circ X_t = f$. Then the following equality holds for every $x \in M$:*

$$T_x f \, T_{X_t(x)} X_{-t} = T_{X_t(x)} f. \tag{6.2}$$

Proof. The equality $f \circ X_t = f$ is equivalent to

$$\begin{aligned} & f \circ X_t(x) = f(x) \\ \Leftrightarrow\ & f(X_t(x)) = f \circ (X_t)^{-1} \circ X_t(x) \\ \Leftrightarrow\ & f(X_t(x)) = f \circ X_{-t}(X_t(x)), \end{aligned} \tag{6.3}$$

and by differentiation of the previous expression we arrive at the desired equality

$$T_{X_t(x)} f = T_x f \, T_{X_t(x)} X_{-t}. \qquad \square \tag{6.4}$$

We can now give sufficient and necessary conditions for projectability of control sections.

PROPOSITION 6.3 (projectable control sections). *Let M be a manifold, $\mathcal{S}_M$ a control section on M, and $\phi : M \longrightarrow N$ a surjective submersion with connected fibers. Given any control system (U_M, F_M) satisfying* **AI** *and defining $\mathcal{S}_M$, and any $\widehat{F_M} \in F_M^e$, $\mathcal{S}_M$ is projectable with respect to ϕ iff*

$$[\widehat{F_M}, \ker(T\pi_{U_M}^* \phi)] \subseteq \ker(T\pi_{U_M}^* \phi) + [\widehat{F_M}, \ker(T\pi_{U_M})]. \tag{6.5}$$

Proof. We show necessity first. Assume that diagram (6.1) commutes. Then we have

$$T_x \phi(\mathcal{S}_M(x)) = T_{x'} \phi(\mathcal{S}_M(x')) \tag{6.6}$$

for all $x, x' \in M$ such that $\phi(x) = \phi(x')$, that is, for any x and x' on the same leaf of the foliation induced by $\ker(T\phi)$. If we denote by K_t the flow of any vector field $K \in \ker(T\pi_{U_M}^* \phi)$, expression (6.6) implies that

$$T_{\pi_{U_M} \circ K_t(u)} \phi(F_M \circ K_t(u)) \in T_x \phi(\mathcal{S}_M(x)) \tag{6.7}$$

for every $t \in \mathbb{R}$ such that K_t is defined and for every $u \in \pi_{U_M}^{-1}(x)$. Since the left-hand side of (6.7) belongs to the right-hand side and $\pi_{U_M}^{-1}(x)$ is connected by **AI**, we can always find a $Y \in \ker(T\pi_{U_M})$ such that its flow Y_t will parameterize the image of the left-hand side. That is

$$T_{\pi_{U_M} \circ K_t(u)} \phi(F_M \circ K_t(u)) = T_{\pi_{U_M} \circ Y_t(u)} \phi(F_M \circ Y_t(u)). \tag{6.8}$$

The previous equality implies that for any $\widehat{F_M} \in F_M^e$ we have

$$T_{K_t(u)} \pi_{U_M}^* \phi(\widehat{F_M} \circ K_t(u)) = T_{Y_t(u)} \pi_{U_M}^* \phi(\widehat{F_M} \circ Y_t(u)); \tag{6.9}$$

however, the equalities $\pi^*_{U_M}\phi \circ K_t = K_t$, $\pi^*_{U_M}\phi \circ Y_t = Y_t$ and Lemma 6.2 allow one to rewrite (6.9) as

$$\begin{aligned} & T_u\pi^*_{U_M}\phi(T_{K_t(u)}K_{-t} \circ \widehat{F_M} \circ K_t(u)) = T_u\pi^*_{U_M}\phi(T_{Y_t(u)}Y_{-t} \circ \widehat{F_M} \circ Y_t(u)) \\ \Leftrightarrow \quad & T_u\pi^*_{U_M}\phi(K_t(u)^*\widehat{F_M}) = T_u\pi^*_{U_M}\phi(Y_t(u)^*\widehat{F_M}). \end{aligned} \tag{6.10}$$

Time differentiation at $t = 0$ now implies

$$\begin{aligned} & T_u\pi^*_{U_M}\phi([K(u), \widehat{F_M}(u)]) = T_u\pi^*_{U_M}\phi([Y(u), \widehat{F_M}(u)]) \\ & \Rightarrow [K, \widehat{F_M}] \in [Y, \widehat{F_M}] + \ker(T\pi^*_{U_M}\phi), \end{aligned} \tag{6.11}$$

which trivially implies inclusion (6.5).

To show sufficiency we use a similar argument. Assume that (6.5) holds; then for any $K \in \ker(T\pi^*_{U_M}\phi)$ there exists a $Y \in \ker(T\pi_{U_M})$ such that

$$\begin{aligned} & T_u\pi^*_{U_M}\phi([\widehat{F_M}(u), K(u)]) = T_u\pi^*_{U_M}\phi([\widehat{F_M}(u), Y(u)]) \\ \Leftrightarrow\ & T_u\pi^*_{U_M}\phi([\widehat{F_M}(u), K(u) - Y(u)]) = 0. \end{aligned} \tag{6.12}$$

Consider now the regular and involutive distribution $\ker(T\pi^*_{U_M}\phi)$. Involutivity and regularity imply that $Z_t^*W \in \ker(T\pi^*_{U_M}\phi)$ for any $W \in \ker(T\pi^*_{U_M}\phi)$ and the flow Z_t of any vector field $Z \in \ker(T\pi^*_{U_M}\phi)$ [34]. Since $K \in \ker(T\pi^*_{U_M}\phi)$ and $Y \in \ker(T\pi^*_{U_M}\phi)$, it follows that $K - Y \in \ker(T\pi^*_{U_M}\phi)$, but from (6.12), $[\widehat{F_M}, K - Y]$ also belongs to $\ker(T\pi^*_{U_M}\phi)$ so that we conclude

$$T_u\pi^*_{U_M}\phi((K-Y)_t(u)^*[\widehat{F_M}, K - Y]) = 0, \tag{6.13}$$

where $(K - Y)_t$ denotes the flow of the vector field $K - Y$. However, the previous expression is equivalent to

$$\begin{aligned} & T_u\pi^*_{U_M}\phi\left(\frac{d}{dt}(K-Y)_t(u)^*\widehat{F_M}\right) = 0 \\ \Leftrightarrow\ & \frac{d}{dt}T_u\pi^*_{U_M}\phi((K-Y)_t(u)^*\widehat{F_M}) = 0, \end{aligned} \tag{6.14}$$

where the last equality follows from the fact that $T\phi$ is a linear map. Since the time derivative is zero, we must have

$$T_u\pi^*_{U_M}\phi((K-Y)_t(u)^*\widehat{F_M}) = T_u\pi^*_{U_M}\phi((K-Y)_0(u)^*\widehat{F_M}) = T_u\pi^*_{U_M}\phi(\widehat{F_M}(u)). \tag{6.15}$$

From the equality $\pi^*_{U_M}\phi = \pi^*_{U_M}\phi \circ (K-Y)_t$ we conclude that $T_u\pi^*_{U_M}\phi T_{(K-Y)_t(u)}(K - Y)_{-t} = T_{(K-Y)_t(u)}\pi^*_{U_M}\phi$ by Lemma 6.2 so that (6.15) can be written as

$$T_{(K-Y)_t(u)}\pi^*_{U_M}\phi(\widehat{F_M} \circ (K-Y)_t(u)) = T_u\pi^*_{U_M}\phi(\widehat{F_M}(u)) \tag{6.16}$$

and projecting on TM we get

$$T_{\pi_{U_M}(K'_t(u))}\phi(F_M \circ (K')_t(u)) = T_x\phi(F_M(u)) \tag{6.17}$$

with $K' = K - Y$. This equality shows that for any $X \in \mathcal{S}_M(x)$, $T_x\phi \cdot X \in T_{x'}\phi(\mathcal{S}_M(x'))$; therefore, $T_x\phi(\mathcal{S}_M(x)) \subseteq T_{x'}\phi(\mathcal{S}_M(x'))$. However, replacing x by x' and K by $-K$ on (6.17), we get $T_{x'}\phi(\mathcal{S}_M(x')) \subseteq T_x\phi(\mathcal{S}_M(x))$ so that we conclude the equality

$$T_x\phi(\mathcal{S}_M(x)) = T_{x'}\phi(\mathcal{S}_M(x')). \tag{6.18}$$

By connectedness of the fibers $\phi^{-1}(y)$ any point x'' satisfying $\phi(x'') = \phi(x)$ can be reached by a concatenation of flows induced by vector fields in $\ker(T\phi)$. Transitivity of equality between sets implies that (6.18) holds for any two points $x, x' \in M$ such that $\phi(x) = \phi(x')$ from which commutativity of diagram (6.1) readily follows. □

By now it is already clear that projectability and local controlled invariance are equivalent concepts. We recall the notion of locally controlled invariant distribution.

DEFINITION 6.4 (locally controlled invariant distributions [27]). *Let $\Sigma_M = (U_M, F_M)$ be a control system on manifold M and let $\mathcal{D}$ be a distribution on M. Distribution $\mathcal{D}$ is locally controlled invariant for F_M if for every $x \in M$ there exist an open set $O \subseteq M$ containing x and a local (feedback) isomorphism over the identity α such that in adapted coordinates (x, v) the new control system $F_M \circ \alpha$ satisfies*

$$[F_M \circ \alpha(x, v), \mathcal{D}(x)] \subseteq \mathcal{D}(x) \tag{6.19}$$

for every (x, v) in the domain of α.

If a control section is projectable, then locally we can always choose $\widehat{F_M} = F_M^l$ and therefore recover the conditions for local controlled invariance from [8].

THEOREM 6.5 (see [8]). *Let Σ_M be a control system on manifold M satisfying* **AI** *and $\phi : M \longrightarrow N$ a surjective submersion with connected fibers. The distribution $\ker(T\phi)$ is locally controlled invariant for F_M iff $\mathcal{S}_M$ is projectable with respect to ϕ.*

Even though controlled invariance and projectability are equivalent concepts, we shall use the notion of projectability to describe control sections that behave well under projection instead of controlled invariance which was introduced to describe certain control enforced invariance properties of control systems [42].

From the study of symmetries of nonlinear control systems [9, 26] it was already known that the existence of symmetries or partial symmetries implies controlled invariance of a certain distribution associated with the symmetries. This shows that control systems that are projectable comprise quotients by symmetry and controlled invariance. Furthermore, quotients induced by indistinguishability, as discussed in [35], are also of this type. However, there are also quotients for which projectability does not hold as we describe in the next section. Furthermore, as the existence of symmetries can be considered a rare phenomena [32], it is especially important to understand the structure of general nonprojectable quotients.

7. The structure of quotient control systems. We have already seen that the notion of **Con** morphisms generalizes the notion of projectable control sections. This shows that it is possible to quotient control systems whose control sections are nonprojectable. In this situation the map φ and the input space of the quotient control system will be significantly different from the projectable case. To understand this difference we start characterizing the fiber preserving lift φ of ϕ. Recall that if $f = (\phi, \varphi)$ is a morphism from Σ_M to Σ_N, we have the following commutative diagram:

$$\begin{array}{ccc} U_M & \xrightarrow{\varphi} & U_N \\ {\scriptstyle F_M}\downarrow & & \downarrow{\scriptstyle F_N} \\ TM & \xrightarrow[T\phi]{} & TN \end{array} \quad . \tag{7.1}$$

Since φ is a surjective submersion, we know that U_N is diffeomorphic to $U_M/\sim$, where $\sim$ is the regular equivalence relation induced by φ. This means that to understand the structure of U_N it is enough to determine the regular and involutive distribution on U_M given by $\ker(T\varphi)$. However, the map φ is completely unknown, so we will resort to the elements that are available, namely, F_M and ϕ, to determine $\ker(T\varphi)$. Differentiating[5] diagram (7.1) we get

$$\begin{array}{ccc} TU_M & \xrightarrow{T\varphi} & TU_N \\ {\scriptstyle TF_M}\downarrow & & \downarrow{\scriptstyle TF_N} \\ TTM & \xrightarrow[TT\phi]{} & TTN \end{array} \tag{7.2}$$

from which we conclude that

$$\ker(TT\phi \circ TF_M) = \ker(TF_N \circ T\varphi) = \ker(T\varphi), \tag{7.3}$$

where the last equality holds since F_N is an immersion, provided that assumption **AIII** holds. We can now attempt to understand what is factored away and what is propagated from U_M to U_N since $\ker(T\varphi)$ is expressible in terms of F_M and ϕ. The first step is to clarify the relation between $\ker(T\varphi)$ and $\ker(T\phi)$. Since φ is a fiber preserving lift of ϕ, the following diagram commutes:

$$\begin{array}{ccc} TU_M & \xrightarrow{T\varphi} & TU_N \\ {\scriptstyle T\pi_{U_M}}\downarrow & & \downarrow{\scriptstyle T\pi_{U_N}} \\ TM & \xrightarrow[T\phi]{} & TN \end{array} \quad , \tag{7.4}$$

which implies that

$$T\pi_{U_M}(\ker(T\varphi)) \subseteq \ker(T\phi). \tag{7.5}$$

However, this only tells us that the reduction on M due to ϕ cannot be "smaller" than the reduction on the base space of U_M due to φ. This leads to the interesting phenomena which occurs when, e.g.,

$$T\pi_{U_M}(\ker(T\varphi)) = \{0\} \subseteq \ker(T\phi). \tag{7.6}$$

[5]The operator sending manifolds to their tangent manifolds and maps to their tangent maps is an endofunctor on **Man**, also called the tangent functor [15].

The above expression implies that the base space of U_M is not reduced by φ. However, U_N is a fibered manifold with base space N and therefore the points reduced by ϕ must necessarily move to the fibers of U_N. This means that points $u, u' \in U_M$ satisfying $\pi_{U_M}(u) \neq \pi_{U_M}(u')$ will be mapped by φ to points satisfying $\pi_{U_N} \circ \varphi(u) = \pi_{U_N} \circ \varphi(u')$ and $\varphi(u) \neq \varphi(u')$. This will not happen if we can ensure the existence of a distribution $\mathcal{D} \subseteq \ker(T\varphi)$ such that $T\pi_{U_M}(\mathcal{D}) = \ker(T\phi)$. The existence of such a distribution turns out to be related with projectability. To show such a fact we need the following characterization of $\ker(T\varphi)$.

LEMMA 7.1. *Let $\Sigma_M = (U_M, F_M)$ be a control system on manifold M, $\phi : M \longrightarrow N$ a surjective submersion and $\varphi : U_M \longrightarrow U_N$ a fiber preserving lift of ϕ which is also a submersion, and assume that* **AIII** *holds. Under these assumptions, a regular distribution $\mathcal{D} \subseteq TU_M$ belongs to* $\ker(T\varphi)$ *iff*

$$[\widehat{F_M}, \mathcal{D}]; \subseteq \ker(T\pi^*_{U_M}), \tag{7.7}$$

where $\widehat{F_M}$ is any vector field in F^e_M.

Proof. Assume the existence of the distribution $\mathcal{D}$; then $\mathcal{D} \subseteq \ker(T\varphi)$ is equivalent to

$$TT\phi \circ TF_M(\mathcal{D}) = \{0\} \tag{7.8}$$

since **AIII** holds. Let $Z \in \mathcal{D}$ and denote by Z_t the flow of Z. Expression (7.8) implies that

$$\frac{d}{dt}\Big|_{t=0} T_{\pi_{U_M} \circ Z_t(u)}\phi(F_M \circ Z_t(u)) = 0 \quad \Rightarrow \quad \frac{d}{dt}\Big|_{t=0} T_{Z_t(u)}\pi^*_{U_M}\phi(\widehat{F_M} \circ Z_t(u)) = 0 \tag{7.9}$$

for any $\widehat{F_M} \in F^e_M$ and for all $t \in \mathbb{R}$ such that Z_t is defined.

Noticing that $Z \in \mathcal{D} \subseteq \ker(T\varphi)$ implies $\varphi = \varphi \circ Z_t$ (since φ is constant on the leaves of the foliation induced by $\ker(T\varphi)$) and $\pi_{U_N} \circ \varphi = \phi \circ \pi_{U_M}$ by commutativity of diagram (4.1), we conclude that $\pi^*_{U_M}\phi$ is also Z_t invariant:

$$\pi^*_{U_M}\phi \circ Z_t = \phi \circ \pi_{U_M} \circ Z_t = (\pi_{U_N} \circ \varphi) \circ Z_t = \pi_{U_N} \circ \varphi = \phi \circ \pi_{U_M} = \pi^*_{U_M}\phi. \tag{7.10}$$

Lemma 6.2 now ensures that

$$T_{Z_t(u)}\pi^*_{U_M}\phi = T_u\pi^*_{U_M}\phi \circ T_{Z_t(u)}Z_{-t}, \tag{7.11}$$

and expression (7.11) allows one to rewrite (7.9) as

$$\begin{aligned}
\frac{d}{dt}\Big|_{t=0} T_{Z_t(u)}\pi^*_{U_M}\phi(\widehat{F_M} \circ Z_t(u)) = 0 &\Leftrightarrow \frac{d}{dt}\Big|_{t=0} T_u\pi^*_{U_M}\phi(T_{Z_t(u)}Z_{-t} \circ \widehat{F_M} \circ Z_t(u)) = 0 \\
&\Leftrightarrow \frac{d}{dt}\Big|_{t=0} T_u\pi^*_{U_M}\phi(Z_t(u)^*\widehat{F_M}) = 0 \\
&\Leftrightarrow T_u\pi^*_{U_M}\phi([Z(u), \widehat{F_M}(u)]) = 0
\end{aligned} \tag{7.12}$$

or, equivalently, $[Z, \widehat{F_M}] \in \ker(T\pi^*_{U_M}\phi)$. Since Z is any vector field in $\mathcal{D}$ it follows that $[\widehat{F_M}, \mathcal{D}] \subseteq \ker(T\pi^*_{U_M}\phi)$ as desired.

The converse is similarly proved. ∎

Using Lemma 7.1, we can now characterize the existence of a distribution $\mathcal{D} \subseteq \ker(T\varphi)$ projecting on $\ker(T\phi)$.

PROPOSITION 7.2. *Let $\Sigma_M = (U_M, F_M)$ be a control system on manifold M satisfying* **AI**, *$\phi : M \longrightarrow N$ a surjective submersion, and $\varphi : U_M \longrightarrow U_N$ a fiber preserving lift of ϕ which is also a submersion. There exists a regular distribution $\mathcal{D}$ on U_M satisfying $\mathcal{D} \subseteq \ker(T\varphi)$ and $T\pi_{U_M}(\mathcal{D}) = \ker(T\phi)$ iff $\mathcal{S}_M$ is projectable with respect to ϕ.*

Proof. We start by showing that projectability implies the existence of $\mathcal{D}$. If $\mathcal{S}_M$ is projectable with respect to ϕ, then for every $x, x' \in M$ such that $\phi(x) = \phi(x')$ we have that $T_x\phi(\mathcal{S}_M(x)) = T_{x'}\phi(\mathcal{S}_M(x'))$. This means that for any $x \in M$, $u \in \pi^{-1}_{U_M}(x)$, and $X \in \ker(T\pi^*_{U_M}\phi)$, there exists a $Y \in \ker(T\pi_{U_M})$ (recall that $\pi^{-1}_{U_M}(x)$ is connected by **AI**) such that

$$T_{\pi_{U_M}\circ X_t(u)}\phi(F_M \circ X_t(u)) = T_x\phi(F_M \circ Y_t(u)) \tag{7.13}$$

for all $t \in \mathbb{R}$ such that the flows X_t and Y_t of X and Y are defined. Considering now $T\phi$ as a map between the manifolds TM and TN, the time derivative of $T_{\alpha(t)}\phi(\beta(t))$ for $(\alpha, \beta) : \mathbb{R} \longrightarrow TM$ provides $T_{(\alpha(t),\beta(t))}T_{\alpha(t)}\phi(T\beta(t))$. The same considerations applied to (7.13) at $t = 0$ give

$$T_{(x,F_M(u))}T_x\phi \circ T_uF_M(X(u)) = T_{(x,F_M(u))}T_x\phi \circ T_uF_M(Y(u)), \tag{7.14}$$

which we rewrite as

$$T_{(x,F_M(u))}T_x\phi \circ T_uF_M(X(u) - Y(u)) = 0 \tag{7.15}$$

by linearity of the involved maps. Since (7.15) is true for any $X \in \ker(T\pi^*_{U_M}\phi)$, we can define the distribution

$$\mathcal{D} = \bigcup_{K \in \ker(T\phi)} \{Z = X - Y \ : \ X \in K^e \ \wedge \ Y \in \ker(T\pi_{U_M}) \text{ is such that (7.15) holds}\}. \tag{7.16}$$

This distribution clearly satisfies

$$TT\phi \circ TF_M(\mathcal{D}) = \{0\} \quad \Leftrightarrow \quad \mathcal{D} \subseteq \ker(T\varphi), \tag{7.17}$$

is regular since $\dim(\mathcal{D}) = \dim(\ker(T\phi))$ by construction, satisfies $T\pi_{U_M}(\mathcal{D}) = \ker(T\phi)$ also by construction, and is therefore the desired distribution.

The converse is proved as follows. Assume the existence of the distribution $\mathcal{D} \subseteq \ker(T\varphi)$. By Lemma 7.1 we have

$$[\widehat{F_M}, \mathcal{D}] \subseteq \ker(T\pi^*_{U_M}).$$

Since $T\pi_{U_M}(\mathcal{D}) = \ker(T\phi)$ it follows that $\mathcal{D} + T\pi_{U_M} = T\pi^*_{U_M}\phi$ and

$$\begin{aligned} & [\widehat{F_M}, \mathcal{D}] \subseteq \ker(T\pi^*_{U_M}) \\ \Rightarrow\ & [\widehat{F_M}, \mathcal{D} + \ker(T\pi_{U_M})] \subseteq \ker(T\pi^*_{U_M}) + [\widehat{F_M}, \ker(T\pi_{U_M})] \\ \Rightarrow\ & [\widehat{F_M}, \ker(T\pi^*_{U_M}\phi)] \subseteq \ker(T\pi^*_{U_M}) + [\widehat{F_M}, \ker(T\pi_{U_M})], \end{aligned}$$

which combined with Proposition 6.3 shows that $\mathcal{S}_M$ is projectable with respect to ϕ as desired. ∎

Collecting the results given by Lemma 7.1 and Proposition 7.2 we can now characterize both φ and U_N. Intuitively, we will use projectability to determine if the fibers of the quotient control system will receive states from M and Lemma 7.1 to characterize the amount of reduction induced by φ on the fibers of π_{U_M}.

THEOREM 7.3 (structure of control systems quotients). *Consider a control system $\Sigma_M = (U_M, F_M)$ over a manifold M satisfying* **AI**, *let $(f, \Sigma_N) = ((\phi, \varphi), (U_N, F_N))$ be a quotient of Σ_M where ϕ has connected fibers, and assume that* **AIII** *holds. Let $\mathcal{E}$ be the involutive distribution defined by $\mathcal{E} = \{X \in \ker(T\pi_{U_M}) : [\widehat{F_M}, X] \in \ker(T\pi^*_{U_M}\phi)\}$, which we assume to be regular, denote by $R_{\mathcal{E}}$ the regular equivalence relation induced by $\mathcal{E}$, and let $\widehat{F_M}$ be any vector field in F^e_M. Under these assumptions the following can be stated:*

1. Reduction from states to states and no reduction on inputs. *Fibered manifold U_N has base space diffeomorphic to N, and fibers $\pi^{-1}_{U_N}(y)$ diffeomorphic to $\pi^{-1}_{U_M}(x)$, $\phi(x) = y$ iff*

(i) *$\mathcal{S}_M$ is projectable with respect to ϕ;*

(ii) *$\mathcal{E} = \{0\}$.*

2. Reduction from states to states and from inputs to inputs. *Fibered manifold U_N has base space diffeomorphic to N, and fibers $\pi^{-1}_{U_N}(y)$ diffeomorphic to $\pi^{-1}_{U_M}(x)/R_{\mathcal{E}}$, $\phi(x) = y$ iff*

(i) *$\mathcal{S}_M$ is projectable with respect to ϕ;*

(ii) *$\mathcal{E} \neq \{0\}$.*

3. Reduction from states to inputs and no reduction on inputs. *Fibered manifold U_N has base space diffeomorphic to N, and fibers $\pi^{-1}_{U_N}(y)$ diffeomorphic to $\pi^{-1}_{U_M}(\phi^{-1}(y))$, $\phi(x) = y$ iff*

(i) *for all $K \in \ker(T\pi^*_{U_M}\phi)$, $\quad [\widehat{F_M}, K] \notin \ker(T\pi^*_{U_M}\phi)$;*

(ii) *$\mathcal{E} = \{0\}$.*

4. Reduction from states to inputs and from inputs to inputs. Fibered manifold U_N has base space diffeomorphic to N, and fibers $\pi^{-1}_{U_N}(y)$ diffeomorphic to $(\pi^{-1}_{U_M}/R_{\mathcal{E}})(\phi^{-1}(y))$, $\phi(x) = y$ iff

(i) for all $K \in ker(T\pi^*_{U_M}\phi)$, $\quad [\widehat{F_M}, K] \notin ker(T\pi^*_{U_M}\phi)$;

(ii) $\mathcal{E} \neq \{0\}$.

Proof. We note that in all four cases the base space of U_N is diffeomorphic to N, since U_N is equipped with a surjective submersion $\pi_{U_N} : U_N \longrightarrow N$. We will, therefore, only discuss the characterization of fibers of π_{U_N}. We follow the enumeration of the theorem.

1 and 2: Since φ is fiber preserving, we denote by $\varphi_x : \pi^{-1}_{U_M}(x) \longrightarrow \pi^{-1}_{U_N}(\phi(x))$ the restriction of φ to the fibers $\pi^{-1}_{U_M}(x)$, $x \in M$. We now claim that projectability implies $\varphi_x(\pi^{-1}_{U_M}(x)) = \varphi_{x'}(\pi^{-1}_{U_M}(x'))$ for every $x, x' \in M$ such that $\phi(x) = \phi(x')$. Recall that by definition of projectability, we have $T_x\phi(\mathcal{S}_M(x)) = T_{x'}\phi(\mathcal{S}_M(x'))$. However, $\mathcal{S}_M(x) = F_M(\pi^{-1}_{U_M}(x))$ so that we conclude $T_x\phi \circ F_M(\pi^{-1}_{U_M}(x)) = T_{x'}\phi \circ F_M(\pi^{-1}_{U_M}(x'))$. From assumption **AIII** follows injectivity of F_N, which combined with commutativity of the second diagram in (4.1) leads to $\varphi_x(\pi^{-1}_M(x)) = \varphi_{x'}(\pi^{-1}_M(x'))$, as desired. This equality also shows that φ_x is surjective since φ is. Furthermore, we conclude that to characterize $\pi^{-1}_{U_N}(y)$ it suffices to characterize the image of φ_x for some $x \in \phi^{-1}(y)$. We now consider $\ker(T\varphi(x)) \cap \ker(T\pi^{-1}_{U_M}(x))$, which by Lemma 7.1 is equal to $\mathcal{E}$ and is regular by assumption. Fields in $\pi^{-1}_{U_M}(x)$ and the equivalence relation $R_{\mathcal{E}}$ can be identified with an equivalence relation on $\pi^{-1}_{U_M}(x)$. We first note that projectability implies via Proposition 7.2 and (7.5) that $T\pi_{U_M}(\ker(T\varphi)) = \ker(T\phi)$. This shows

that

$$\dim(\ker(T\varphi)) = \dim(\ker(T\phi)) + \dim(\mathcal{E}). \tag{7.18}$$

On the other hand,

$$\begin{aligned}
\dim(\pi_{U_N}^{-1}(y)) &= \dim(U_N) - \dim(N) \\
&= \dim(U_M) - \dim(\ker(T\varphi)) - \dim(N) \\
&= \dim(U_M) - \dim(\ker(T\phi)) - \dim(\mathcal{E}) - \dim(N) \qquad \text{by (7.18)} \\
&= \dim(U_M) - \dim(\ker(T\phi)) - \dim(\mathcal{E}) - \dim(M) + \dim(\ker(T\phi)) \\
&= \dim(U_M) - \dim(\mathcal{E}) - \dim(M) \\
&= \dim(\pi_{U_M}^{-1}(x)) - \dim(\mathcal{E}) = \operatorname{rank}(\varphi_x), \qquad (7.19)
\end{aligned}$$

which shows that φ_x is a submersion. We thus see that $\pi_{U_N}^{-1}(y)$ can now be identified with $\pi_{U_M}^{-1}(x)/R_{\mathcal{E}}$ since every vector field $X \in \mathcal{E}$ satisfies $T\pi_{U_M}(X) = 0$ and therefore induces a vector field on $\pi_{U_M}^{-1}(x)$. If $\mathcal{E} = \{0\}$, it follows that $\pi_{U_N}^{-1}(y) \cong \pi_{U_M}^{-1}(x)/R_{\mathcal{E}} \cong \pi_{U_M}^{-1}(x)$ as required by case 1.

Conversely, since the base of U_N is diffeomorphic to the quotient of M by the regular equivalence relation induced by $\ker(T\phi)$ and the fibers of π_{U_N} diffeomorphic to $\pi_{U_M}/R_{\mathcal{E}}$, it follows that $\ker(T\varphi)$ can be locally described by $\mathcal{D} \oplus \mathcal{E}$ for $\mathcal{D} = \ker(T\phi)^l$ and $T\pi_{U_M}(\mathcal{E}) = \{0\}$. From the existence of $\mathcal{D}$ and Proposition 6.3 follows projectability of $\mathcal{S}_M(x)$. Furthermore, if the fibers of π_{U_M} are diffeomorphic to the fibers of π_{U_N}, we have $\mathcal{E} = \{0\}$ (case 1) and otherwise $\mathcal{E} \neq \{0\}$ (case 2).

3 and 4: From assumption (i) and Lemma 7.1 we conclude that there exists no $X \neq 0$ belonging to $K(T\varphi)$ such that $T\pi_{U_M}(X) \in \ker(T\phi)$. Since $T\pi_{U_M}(\ker(T\varphi)) \subseteq \ker(T\phi)$ (see the discussion before (7.5)), it follows that $T\pi_{U_M}(\ker(T\varphi)) = \{0\}$. Consequently, every $X \in \ker(T\varphi)$ is tangent to $\pi_{U_M}^{-1}(x)$ and $\varphi(U_M)$ is diffeomorphic to a fibered manifold with base space M and fibers $\pi_{U_M}^{-1}(x)/R_{\mathcal{E}}$. Let us denote by $\pi : \varphi(U_M) \longrightarrow M$ the projection from total space to base space which clearly satisfies $\pi_{U_M} = \pi \circ \varphi$. We now use the fact $\pi_{U_N} \circ \varphi = \phi \circ \pi_{U_M}$ with $\pi_{U_M} = \pi \circ \varphi$ to get $\pi_{U_N} \circ \varphi = \phi \circ \pi \circ \varphi$ and by surjectivity of φ we finally conclude the equality $\pi_{U_N} = \phi \circ \pi$. It is now clear that $\pi_{U_N}^{-1}(y) \cong \pi^{-1}(\phi^{-1}(y)) \cong (\pi_{U_M}^{-1}/R_{\mathcal{E}})(\phi^{-1}(y))$ as required by case 4. Case 3 is obtained by setting $\mathcal{E} = \{0\}$ and obtaining $\pi_{U_N}^{-1}(y) \cong (\pi_{U_M}^{-1}/R_{\mathcal{E}})(\phi^{-1}(y)) \cong \pi_{U_M}^{-1}(\phi^{-1}(y))$.

The converse is proved as follows. Since the fibers of π_{U_N} are diffeomorphic to $(\pi_{U_M}^{-1}/R_{\mathcal{E}})(\phi^{-1}(y))$, we see that points $u, u' \in U_M$ satisfying $\pi_{U_M}(u) \neq \pi_{U_M}(u')$ and $\phi \circ \pi_{U_M}(u) = \phi \circ \pi_{U_M}(u')$ also satisfy $\varphi(u) \neq \varphi(u')$. This shows that no vector field $X \neq 0$ in $\ker(T\pi_{U_M}^*\phi)$ belongs to $\ker(T\varphi)$ since otherwise different points in a trajectory of X would violate the above remark. The nonexistence of such vectors X implies, via Lemma 7.1, condition (i) and also implies that $\ker(T\varphi) = \mathcal{E}$. It then follows that if $\pi_{U_N}^{-1}(y) \cong \pi_{U_M}^{-1}(\phi^{-1}(y))$, then $\mathcal{E} = 0$ (case 3) and $\mathcal{E} \neq 0$ otherwise (case 4). □

We see that the notion of projectability is fundamentally related to the structure of quotient control systems. If the controlled section $\mathcal{S}_M$ is projectable, then the inputs of the quotient control system are the same or a quotient of the original inputs. Projectability can therefore be seen as a structural property of a control system in the sense that it admits special decompositions [11, 27]. However, for general systems not admitting this special structure, that is, for systems that are not projectable, it is still

possible to construct quotients by moving the neglected state information to the fibers. The states of the original system that are factored out by ϕ are regarded as control inputs in the quotient control system. This shows that from a hierarchical synthesis point of view, control systems that are not projectable are much more appealing since one can design control laws for the abstracted system that when pulled-down to the original one are regarded as specifications for the dynamics on the neglected states [37].

8. Conclusions. In this paper quotients of fully nonlinear control systems were investigated. We showed that under mild conditions quotients exist, and we characterized the structure of the quotient state/input space. This was achieved by introducing the category of control systems which was the natural framework to discuss quotients of control systems. One of the important ingredients of the characterization of quotients was the notion of a projectable control section, which being equivalent to controlled invariance allowed one to understand the difference between general quotients and those induced by symmetries, partial symmetries, or controlled invariance.

There are still innumerous directions to be explored. The correct relations of the results presented in this work with the notion of extended control system [25] are not yet understood. This seems to lead to a possible generalization of the constructive procedures presented in [29] to compute quotients of nonlinear control affine systems to fully nonlinear control systems. Other directions being currently investigated include similar results for mechanical control systems where the Hamiltonian structure is preserved by the factorization process [36] as well as hybrid control systems [38].

Acknowledgments. The authors would like to acknowledge the innumerous enlightening discussions with Gonçalo Tabuada, Esfandiar Hagverdi, and Slobodan Simic on categorical interpretations of dynamical and control systems. Equally appreciated were the constructive comments provided by the anonymous reviewers.

HYBRID NECESSARY PRINCIPLE*

MAURO GARAVELLO† AND BENEDETTO PICCOLI†

Abstract. We consider a hybrid control system and general optimal control problems for this system. We suppose that the switching strategy imposes restrictions on control sets and we provide necessary conditions for an optimal hybrid trajectory, stating a hybrid necessary principle (HNP). Our result generalizes various necessary principles available in the literature.

Key words. optimal control, necessary conditions, switching strategy

1. Introduction.

This paper deals with optimal control problems for hybrid systems. Our definition of a hybrid system is the one used in [20]. Roughly speaking, a hybrid system is a collection of control systems called locations, possibly defined on different manifolds, and an automaton that rules the switchings between locations. The term hybrid is commonly used to indicate the presence of both continuous and discrete dynamics, and in our case the continuous part is given by location controlled dynamics and the discrete part by the automaton. An optimal control problem is obtained assigning Lagrangian running costs on each location and final and switching costs.

Recently optimization problems for hybrid systems have attracted a lot of attention; thus both theoretical results and applications were developed (see [6, 10, 11, 12, 14, 17, 23, 29]). For general theory of hybrid systems we refer to [3, 15, 19].

For an optimal (classical) control problem, the main tool for the construction of optimal trajectories, and then optimal synthesis, is the celebrated Pontryagin maximum principle (PMP). The strength of PMP is evident when it permits us to describe completely the structure of optimal trajectories and obtain a finite dimensional reduction of the problem; see, for example, [5, 8, 24]. A hybrid maximum principle (HMP) was developed in [26]; see also [20, 21]. A key role is played by the switching mechanism that permits us to pass from one location to another with possible restrictions on state, time to spend in the next location, and feasible controls for the next location. The first two kinds of restrictions do not affect the general strategy of PMP, and an HMP can be proved in a similar way. However, the restriction on usable controls, after location switchings, dramatically changes the possibility of constructing "needle variations" that are the basic ingredient to prove PMP, and HMP is no more applicable. More precisely, a classical needle variation is no longer prolongable after a location switching time; therefore a new class of "admissible needle variations" must be introduced. As a first example (in section 3), to construct this kind of variation, one can prolong the family of trajectories, originating from a needle variation, via the choice of a suitable family of controls having continuity and weak differentiability (in L^1) properties.

*Received by the editors August 20, 2003; accepted for publication (in revised form) June 14, 2004; published electronically March 22, 2005.

†IAC, Viale del Policlinico 137, 00161 Roma, Italy (m.garavello@iac.rm.cnr.it, piccoli@iac.rm.cnr.it).

The problem of producing variations more general than needle variations has been extensively considered in the literature for the classical (not hybrid) setting (see [1, 2, 4, 7, 18, 25]), and more recently also for the hybrid settings; see [27].

In section 4 we introduce a general concept of "map of variations." The basic request is again to have weak differentiability properties, but now in the space of bounded Radon measures, seen as the dual of the space of continuous functions. We are then able to prove the hybrid necessary principle (HNP), using results from [22, 27, 28]. The word maximum in this context disappears, since necessary conditions are no longer written in a supremum form.

Section 2 gives basic definitions of *hybrid systems* and states HMP, section 3 deals with *admissible needle variations,* and section 4 deals with the *map of variations.* Finally, an appendix, with two technical lemmas on weak convergence in L^1 and for measures, concludes the paper.

2. Basic definitions and HMP. We start by introducing the definition of a hybrid system.

DEFINITION 2.1. A *hybrid control system* is a 7-tuple $\Sigma = (\mathcal{Q}, M, U, f, \mathcal{U}, J, \mathcal{S})$ such that

- H1 $\mathcal{Q}$ is a finite set;
- H2 $M = \{M_q\}_{q\in\mathcal{Q}}$ is a family of smooth manifolds, indexed by $\mathcal{Q}$;
- H3 $U = \{U_q\}_{q\in\mathcal{Q}}$ is a family of sets;
- H4 $f = \{f_q\}_{q\in\mathcal{Q}}$ is a family of maps $f_q : M_q \times U_q \mapsto TM_q$ (TM_q is the tangent bundle of M_q), such that $f_q(x,u) \in T_xM_q$ for every $(x,u) \in M_q \times U_q$;
- H5 $\mathcal{U} = \{\mathcal{U}_q\}_{q\in\mathcal{Q}}$ is a family of sets $\mathcal{U}_q$ whose members are maps $u : \mathrm{Dom}(u) \to U_q$, defined on some interval $\mathrm{Dom}(u) \subset \mathbb{R}$;
- H6 $J = \{J_q\}_{q\in\mathcal{Q}}$ is a family of subintervals of $\mathbb{R}^+$;
- H7 $\mathcal{S}$ is a subset of $\mathrm{Switch}(\Sigma)$, where

$$\mathrm{Switch}(\Sigma) \stackrel{\mathrm{def}}{=} \{(q,x,q',x',u(\cdot),\tau) : q,q' \in \mathcal{Q}, x \in M_q, x' \in M_{q'}, u(\cdot) \in \mathcal{U}_{q'}, \tau \in J_{q'}\}.$$

The members of $\mathcal{Q}$ are called *locations* and represent the states of the automaton. The families M, U are, respectively, the *family of state spaces* and the *family of control spaces* of Σ. For each q, the manifold M_q, the set U_q, the map f_q, and the set $\mathcal{U}_q$ are, respectively, the *state space*, the *control space*, the *controlled dynamical law*, and the *class of admissible controls* at location q.

The system evolves in a location q according to the corresponding controlled dynamic and then switches as prescribed by $\mathcal{S}$. The intervals J_q indicate the lengths of time intervals on which the system can stay in location q. So, for example, if $J_q = [0, +\infty[$, then the system can evolve in location q on every interval of time.

For $q, q' \in \mathcal{Q}$, we write

$$\mathcal{S}_{q,q'} \stackrel{\mathrm{def}}{=} \{(x,x') \in M_q \times M_{q'} : (q,x,q',x',u(\cdot),\tau) \in \mathcal{S} \text{ for some } u(\cdot) \in \mathcal{U}_{q'} \text{ and } \tau \in J_{q'}\}.$$

The sets $\mathcal{S}_{q,q'}$ are called the *switching sets* of Σ from location q to location q'. Moreover, for $q, q' \in \mathcal{Q}$ and $x \in M_q$, $x' \in M_{q'}$, we write

$$\mathcal{U}_{q,x,q',x'} \stackrel{\mathrm{def}}{=} \{u(\cdot) \in \mathcal{U}_{q'} : (q,x,q',x',u(\cdot),\tau) \in \mathcal{S} \text{ for some } \tau \in J_{q'}\}.$$

The set $\mathcal{U}_{q,x,q',x'}$ is formed by the controls we can use at location q' if there is a switching from the point x of M_q to the point x' of $M_{q'}$.

DEFINITION 2.2. *A hybrid state is a triplet (q, x, τ), where $q \in \mathcal{Q}$ is the location, $x \in M_q$ is the state of the control system, and $\tau \in [0, \sup J_q)$ is the time since last switching. We denote by $\mathcal{HS}$ the set of all hybrid states.*

The evolution of the hybrid system is as follows. Given a hybrid initial state $(q_1, x_0, 0)$, at time t_0, on some time interval $[t_0, t_1[$, with $t_1 - t_0 \in J_{q_1}$, the system evolves solving

$$\begin{cases} q(t) \equiv q_1, \\ \dot{x}(t) = f_{q_1}(x(t), u_1(t)), & x(t_0) = x_0, \\ \dot{\tau}(t) = 1, & \tau(t_0) = 0 \end{cases}$$

for some $u_1(\cdot) \in \mathcal{U}_{q_1}$ such that $\mathrm{Dom}(u_1) \supset [t_0, t_1]$. This means that the system remains in location q_1 until $\tau = t_1 - t_0$ and it evolves on M_{q_1} according to the dynamic $f_{q_1}(x(t), u_1(t))$ for the control $u_1(\cdot) \in \mathcal{U}_{q_1}$. If the solution to the previous system can be prolonged on the whole interval $[t_0, t_1]$, then we can choose another hybrid state $(q_2, x_1, 0)$, a control $u_2(\cdot) \in \mathcal{U}_{q_2}$, and t_2 such that $(q_1, x(t_1), q_2, x_1, u_2(\cdot), t_2 - t_1) \in \mathcal{S}$ and let the system evolve in location q_2 following the corresponding controlled dynamics on the interval $[t_1, t_2]$:

$$\begin{cases} q(t) \equiv q_2, \\ \dot{x}(t) = f_{q_2}(x(t), u_2(t)), & x(t_1) = x_1, \\ \dot{\tau}(t) = 1, & \tau(t_1) = 0. \end{cases}$$

We say that a location switching from q_1 to q_2 occurs at time t_1. Then we can proceed in the same way with a location switching and so on. Notice that the time t_1 (t_2 and so on) can be chosen freely in J_{q_1} (respectively, J_{q_2} and so on); hence it represents a control for the hybrid system.

We assume that if $u \in \mathcal{U}_q$, then every time translation of u is in $\mathcal{U}_q$; more precisely, we assume

(A1) If $u \in \mathcal{U}_q$ for some $q \in \mathcal{Q}$, then for every $\sigma \in \mathbb{R}$ the control $\tilde{u}(t) = u(t + \sigma)$ satisfies $\tilde{u} \in \mathcal{U}_q$.

Hence we can always assume that $t_0 = 0$.

Let us now give a precise definition of trajectories, cost functionals, and optimal control problems.

DEFINITION 2.3. *A trajectory is a map $\boldsymbol{X} : [0, T] \to \mathcal{HS}$, $\boldsymbol{X}(t) = (q(t), x(t), \tau(t))$ such that the following holds. There exist $0 = t_0 < t_1 < \cdots < t_\nu = T$ such that if $i \in \{1, \dots, \nu\}$, then $q(\cdot)$ is constant in $[t_{i-1}, t_i[$ and equal to $q_i \in \mathcal{Q}$, $\tau(t) = t - t_{i-1}$ on $[t_{i-1}, t_i[$, $t_i - t_{i-1} \in J_{q_i}$. Moreover, for every $i \in \{1, \dots, \nu\}$, there exists $u_i \in \mathcal{U}_{q_i}$ such that*

- *$x_i(\cdot) := x|_{]t_{i-1}, t_i[}(\cdot)$ is an absolutely continuous function in $]t_{i-1}, t_i[$, continuously prolongable to $[t_{i-1}, t_i]$;*
- *$\frac{d}{dt} x_i(t) = f_{q_i}(x_i(t), u_i(t))$ for a.e. $t \in]t_{i-1}, t_i[$;*
- *$(x_i(t_i), x_{i+1}(t_i)) \in \mathcal{S}_{q_i, q_{i+1}}$ if $i = 1, \dots, \nu - 1$;*
- *$u_{i+1} \in \mathcal{U}_{q_i, x_i(t_i), q_{i+1}, x_{i+1}(t_i)}$ if $i = 1, \dots, \nu - 1$.*

Remark 1. In this setting, for a Cauchy type problem, it is not appropriate to first choose a sequence of controls and then determine the trajectory associated to it, because a priori the sequence could not be admissible, in the sense that there could exist no trajectory corresponding to it. This is due to the fact that in every location q, it is possible to use as controls only a subset of $\mathcal{U}_q$, depending on the switching strategy.

DEFINITION 2.4. *If Σ is a hybrid system, then a Lagrangian for Σ is a family $L = \{L_q\}_{q\in Q}$, $L_q : M_q \times U_q \to \mathbb{R}$ such that, for every trajectory $\boldsymbol{X}$, for every $i \in \{1,\dots,\nu\}$, and for every control u_i associated to x_i, the function $t \mapsto L_{q_i}(x_i(t), u_i(t))$ is integrable in $]t_{i-1}, t_i[$.*

DEFINITION 2.5. *If Σ is a hybrid system, then a switching cost function is a family $\Phi = \{\Phi_{q,q'}\}_{(q,q')\in\mathcal{Q}\times\mathcal{Q}}$ such that each $\Phi_{q,q'}$ is a real valued function defined on $\mathcal{S}_{q,q'}$.*

DEFINITION 2.6. *If Σ is a hybrid system, then an endpoint cost function is a family $\varphi = \{\varphi_{q,q'}\}_{(q,q')\in\mathcal{Q}\times\mathcal{Q}}$ such that each $\varphi_{q,q'}$ is a real valued function defined on $M_q \times M_{q'}$.*

If $L = \{L_q\}_{q\in\mathcal{Q}}$ is a Lagrangian, $\Phi = \{\Phi_{q,q'}\}_{(q,q')\in\mathcal{Q}\times\mathcal{Q}}$ is a switching cost function, and $\varphi = \{\varphi_{q,q'}\}_{(q,q')\in\mathcal{Q}\times\mathcal{Q}}$ is an endpoint cost function for the hybrid control system Σ, then we can define the corresponding *cost functional* C by letting

$$C(\mathbf{X}) = \sum_{j=1}^{\nu} \int_{t_{j-1}}^{t_j} L_{q_j}(x_j(t), u_j(t))\, dt + \sum_{j=1}^{\nu-1} \Phi_{q_j,q_{j+1}}(x_j(t_j), x_{j+1}(t_j)) + \varphi_{q_1,q_\nu}(x_1(t_0), x_\nu(t_\nu)),$$

where $\mathbf{X}$ is a trajectory for Σ.

DEFINITION 2.7. *Given a hybrid control system Σ, a cost functional C, and two nonempty subsets $\mathcal{N}_{in}, \mathcal{N}_{fin}$ of $\mathcal{HS}$, we call with $\mathcal{P}$ the problem of minimizing $C(\boldsymbol{X})$ over all trajectories $\boldsymbol{X}$ for Σ such that*

(i) $(q_1, x_1(t_0), 0) \in \mathcal{N}_{in}$;

(ii) $(q_\nu, x_\nu(t_\nu), t_\nu - t_{\nu-1}) \in \mathcal{N}_{fin}$.

Remark 2. Note that there could be no trajectory satisfying boundary data. However, we expect that in many applications the set $\mathcal{N}_{fin}$ should be chosen to impose restrictions only on the final location q and point x. So if $(q, x, t) \in \mathcal{N}_{fin}$, then $\mathcal{N}_{fin}$ should also contain all the points (q, x, s) with $s \le \sup J_{q_\nu}$ (with possible equality only if $\sup J_{q_\nu} \in J_{q_\nu}$).

The *maximum principle* gives a necessary condition for a trajectory $\mathbf{X}$ to be a solution of $\mathcal{P}$. The set of variations involves trajectories having the same *history* (see [20]) as the candidate optimal one, that is, having the same switching strategy. As suggested in [20], if there is a finite number of possible switching strategies for the optimization problem $\mathcal{P}$, then the maximum principle can sometimes single out the optimal trajectory.

DEFINITION 2.8. *If Σ is a hybrid system and L is a Lagrangian for Σ, then we say that (ψ, ψ_0) is an adjoint pair along a trajectory $\boldsymbol{X}$ if*

1. *$\psi = (\psi_1, \dots, \psi_\nu)$ is such that, for every $i \in \{1,\dots,\nu\}$, $\psi_i : [t_{i-1}, t_i] \to T^*M_{q_i}$ is an absolutely continuous function, $\psi_i(t) \in T^*_{x_i(t)}M_{q_i}$, and*

$$\dot\psi_i(t) = - < \psi_i(t), \frac{\partial}{\partial x} f_{q_i}(x_i(t), u_i(t)) > + \psi_0 \frac{\partial}{\partial x} L_{q_i}(x_i(t), u_i(t))$$

for a.e. $t \in [t_{i-1}, t_i]$;

2. *$\psi_0 \in \mathbb{R}^+$.*

In order to state the switching condition, we need a concept of a tangent cone. In this paper, as in [27], we use the notion of a Boltyanskiĭ approximating cone.

DEFINITION 2.9. *Let S be a subset of a smooth manifold $\mathcal{X}$ and let $\bar s \in S$. A Boltyanskiĭ approximating cone to S at $\bar s$ is a closed convex cone K in the tangent space $T_{\bar s}\mathcal{X}$ such that there exist a neighborhood W of 0 in $T_{\bar s}\mathcal{X}$ and a continuous map*

$\omega : W \cap K \to S$ with the property that $\omega(0) = \bar{s}$ and $\omega(w) = \bar{s} + w + o(\|w\|)$ as $w \to 0$ via values in $W \cap K$.

DEFINITION 2.10. *If Σ is a hybrid system, L is a Lagrangian, and Φ is a switching cost function, then we say that an adjoint pair (ψ, ψ_0) along a trajectory $\boldsymbol{X}$ satisfies the switching condition if*

$$(-\psi_i(t_i), \psi_{i+1}(t_i)) - \psi_0 \nabla \Phi_{q_i, q_{i+1}}(x_i(t_i), x_{i+1}(t_i)) \in K_i^{\perp}$$

for every $i \in \{1, \dots, \nu - 1\}$, where K_i is a Boltyanskiĭ approximating cone to the set $\mathcal{S}_{q_i, q_{i+1}}$ at the point $(x_i(t_i), x_{i+1}(t_i))$ and $K_i^{\perp}$ is its polar cone.

DEFINITION 2.11. *If (ψ, ψ_0) is an adjoint pair along $\boldsymbol{X}$, and*

$$H_i := \sup\{< \psi_i(t), f_{q_i}(x_i(t), u) > -\psi_0 L_{q_i}(x_i(t), u) : u \in U_{q_i}\},$$

then we say that (ψ, ψ_0) satisfies the Hamiltonian value condition *if, for every $i \in \{1, \dots, \nu - 1\}$,*

- *if $t_i - t_{i-1} \in \mathrm{Int}(J_{q_i})$, then $H_i = H_\nu = 0$;*
- *if $t_i - t_{i-1}$ is the left endpoint of J_{q_i}, but J_{q_i} is nontrivial, then $H_i \le 0$;*
- *if $t_i - t_{i-1}$ is the right endpoint of J_{q_i}, but J_{q_i} is nontrivial, then $H_i \ge 0$.*

As explained in the introduction for "simple" switching constraints an HMP is valid. The condition ensuring this is precisely the following:

Assumption (H). For every fixed $q, q' \in \mathcal{Q}$, $x \in M_q$, $x' \in M_{q'}$, we have $\mathcal{U}_{q,x,q',x'} = \mathcal{U}_{q'}$.

Assumption (H) says that in every location $q \in \mathcal{Q}$ we can always use all the controls which are in $\mathcal{U}_q$. Thus the admissible controls do not depend on the location switchings. In particular, the classical "needle variations" are still admissible variations.

HYBRID MAXIMUM PRINCIPLE. *Consider the problem $\mathcal{P}$ and assume* (H). *Let $\boldsymbol{X}$ be a solution for $\mathcal{P}$. Then, under suitable assumptions, there exists an adjoint pair (ψ, ψ_0) along $\boldsymbol{X}$ that satisfies the switching condition, the Hamiltonian maximization, nontriviality, transversality, and Hamiltonian value conditions for $\mathcal{P}$.*

There are some technical assumptions that are necessary for the HMP to hold true. These are specified in [21], [26], [27].

3. Simple necessary conditions. In this section we present some introductory results about necessary conditions for optimality for hybrid systems that do not satisfy assumption (H). We postpone to the next section the statement and the proof of the HNP, the main result of this paper. So this section is intended as a clarifying introduction to the subject of the next section.

Assumption (H) is not verified by many mechanical control systems. For example, to describe a car with gears, one can use a hybrid system, where each location corresponds to a gear of the car and the control is the acceleration. In this case it is clear that when switching from a low gear to a higher one, not all the controls can be used; see [13].

Here we suppose that every M_q is equal to $\mathbb{R}^{d_q}$ for some $d_q \in \mathbb{N}$, $d_q \ge 1$, and that every U_q is a compact subset of $\mathbb{R}^l$ for some $l \in \mathbb{N}$, $l \ge 1$. So $f_q : \mathbb{R}^{d_q} \times U_q \to \mathbb{R}^{d_q}$ and we assume that

$$f_q \in C^2(\mathbb{R}^{d_q} \times U_q; \mathbb{R}^{d_q}); \tag{3.1}$$

hence, for every compact $K \subseteq \mathbb{R}^{d_q}$ there exists a constant $\Gamma_K > 0$ such that

$$\begin{cases} |f_q(x,u) - f_q(y,u)| \le \Gamma_K |x - y| & \forall x, y \in K, \quad \forall u \in U_q, \\ |f_q(x,u) - f_q(x,v)| \le \Gamma_K |u - v| & \forall x \in K, \quad \forall u, v \in U_q. \end{cases} \tag{3.2}$$

In addition, we consider the case $\mathcal{U}_q = L^{p_q}_{loc}(\mathbb{R}; U_q)$ for some $1 \le p_q \le +\infty$ and $L_q \in C^2(\mathbb{R}^{d_q} \times U_q; \mathbb{R})$. The symbol $L^{p_q}_{loc}(\mathbb{R}; U_q)$ denotes the set of functions from $\mathbb{R}$ to U_q belonging to $L^{p_q}(K; U_q)$ for every compact subset K of $\mathbb{R}$. Therefore we are in the situation of local existence and uniqueness for every Cauchy problem.

Remark 3. In order to avoid too many technicalities, in this paper we prefer to consider simplified hypotheses about the manifolds, the vector fields, and the Lagrangians. However, it is possible to prove all the results of this paper in a similar way using weaker assumptions.

Needle variations are the basic tool to prove the PMP in nonhybrid settings and the HMP in hybrid settings. Needle variations consist of modifying the supposed optimal control in a small interval of times and to understand how the trajectory and the cost vary in this way. Unfortunately, under our hypotheses, since the choice of admissible controls depends on the switching strategy, needle variations do not produce admissible trajectories. Therefore, it is necessary to modify the notion of needle variation.

For the aim of simplicity, we consider only admissible needle variations of the following type: the control is the same as that of the candidate optimal trajectory until a certain time $\bar\tau$; then we produce a constant variation for a small interval of times and finally, in the following locations, we consider controls satisfying the switching conditions and some continuity and differentiability properties. More precisely, we have the following definition.

DEFINITION 3.1. *Let us fix a trajectory* $\boldsymbol{X}$ *and* $i \in \{1, \dots, \nu\}$. *We say that the family of trajectories* $\boldsymbol{X}^\varepsilon = (q, x^\varepsilon, \tau)$, $\boldsymbol{X}^\varepsilon : [0, T] \to \mathcal{HS}$ $(\varepsilon > 0)$ *is an* admissible needle variation *at location* i *if*

1. $\boldsymbol{X}^0 \equiv \boldsymbol{X}$;
2. $\boldsymbol{X}^\varepsilon(t) = \boldsymbol{X}(t)$ *for every* $t \in [0, t_{i-1}]$;
3. *the curves* $\varepsilon \mapsto x^\varepsilon_j(t_{j-1})$ *are differentiable at* $\varepsilon = 0^+$ *for every* $j \in \{1, \dots, \nu\}$;
4. *there exists a time* $\bar\tau \in [t_{i-1} + \varepsilon, t_i]$ *such that*

$$u^\varepsilon_i(t) = \begin{cases} u_i(t), & t \in [t_{i-1}, \bar\tau - \varepsilon[, \\ \omega, & t \in [\bar\tau - \varepsilon, \bar\tau[, \\ u_i(t), & t \in [\bar\tau, t_i] \end{cases} \tag{3.3}$$

for some $\omega \in U_{q_i}$, *where the symbol* u^ε_j $(j \in \{1, \dots, \nu\})$ *denotes the control at location* j *of* x^ε_j;

5. *for every* $j \in \{i+1, \dots, \nu\}$, $u^\varepsilon_j \to u_j$ *strongly in* $L^1([t_{j-1}, t_j])$ *as* $\varepsilon \to 0^+$ *and* $\frac{u^\varepsilon_j - u_j}{\varepsilon} \rightharpoonup \theta_j$ *weakly in* $L^1([t_{j-1}, t_j])$ *as* $\varepsilon \to 0^+$ *for some* $\theta_j \in L^1([t_{j-1}, t_j])$.

Remark 4. Notice that in Definition 3.1 we require that $\mathbf{X}^\varepsilon$, when $\varepsilon > 0$, be a family of trajectories. This means that, for a fixed $\varepsilon > 0$, $\mathbf{X}^\varepsilon$ is a trajectory and hence, by Definition 2.3,

$$(x^\varepsilon_j(t_j), x^\varepsilon_{j+1}(t_j)) \in \mathcal{S}_{q_j, q_{j+1}}$$

for every $j \in \{1, \dots, \nu - 1\}$ *and*

$$u^\varepsilon_{j+1} \in \mathcal{U}_{q_j, x_j(t_j), q_{j+1}, x_{j+1}(t_j)}$$

for every $j \in \{1, \dots, \nu - 1\}$.

Moreover, we require the existence of a location q_i, $i \in \{1, \dots, \nu\}$, in which a variation originates. In particular we demand that, in the fixed location q_i, the variation is a classical needle variation and so the expression of the control u^ε_i is

given in (3.3). In another location q_j, $j \in \{1, \dots, \nu\}$, $j \neq i$, we have the following possibilities.

1. *If $j < i$, then $u_j^\varepsilon = u_j$ and $x_j^\varepsilon = x_j$ since the variation originates in location q_i.*

2. *If $j > i$, then we need some regularity properties of the control with respect to the parameter ε. These properties are described in* 5 *of Definition* 3.1. *Recall that for HMP we may choose $u_j^\varepsilon = u_j$ so that* 5 *is trivially satisfied.*

For a needle variation $\mathbf{X}^\varepsilon$ we define

$$v_j(t) = \frac{d}{d\varepsilon} x_j^\varepsilon(t)\big|_{\varepsilon=0}. \tag{3.4}$$

We have the following lemmas.

LEMMA 3.2. *Let us assume* (3.2). *Let $\boldsymbol{X}^\varepsilon$ be an admissible needle variation. Then x^ε converges to x uniformly as ε goes to* 0.

Proof. It is sufficient to prove that, for every $j \in \{1, \dots, \nu\}$, x_j^ε converges uniformly to x_j in $[t_{j-1}, t_j]$ as $\varepsilon \to 0$.

Obviously, if $1 \leq j < i$, then $x_j^\varepsilon = x_j$ and so the conclusion is true. Therefore we can treat the case $j \geq i$. For $t \in [t_{j-1}, t_j]$, we have, for some $\Gamma > 0$,

$$\begin{aligned}
\left|x_j^\varepsilon(t) - x_j(t)\right| &\leq \left|x_j^\varepsilon(t_{j-1}) - x_j(t_{j-1})\right| \\
&+ \left| \int_{t_{j-1}}^t \left[f_{q_j}(x_j^\varepsilon(s), u_j^\varepsilon(s)) - f_{q_j}(x_j(s), u_j(s)) \right] ds \right| \\
&\leq \left|x_j^\varepsilon(t_{j-1}) - x_j(t_{j-1})\right| + \Gamma \int_{t_{j-1}}^t \left|x_j^\varepsilon(s) - x_j(s)\right| ds + \Gamma \int_{t_{j-1}}^t \left|u_j^\varepsilon(s) - u_j(s)\right| ds.
\end{aligned}$$

Now, using the Gronwall lemma, we obtain

$$\begin{aligned}
\left|x_j^\varepsilon(t) - x_j(t)\right| &\leq \left|x_j^\varepsilon(t_{j-1}) - x_j(t_{j-1})\right| e^{\Gamma(t_j - t_{j-1})} \\
&+ \Gamma \int_{t_{j-1}}^{t_j} \left|u_j^\varepsilon(s) - u_j(s)\right| ds\, e^{\Gamma(t_j - t_{j-1})}.
\end{aligned}$$

Obviously, by definition of admissible needle variation, the term $\left|x_j^\varepsilon(t_{j-1}) - x_j(t_{j-1})\right|$ tends to 0 as $\varepsilon \to 0$ and also the last term goes to 0 as $\varepsilon \to 0$. So we have obtained the thesis. □

LEMMA 3.3. *Let us assume* (3.1). *Let $\boldsymbol{X}^\varepsilon$ be an admissible needle variation. Then $v_j \equiv 0$ if $j < i$, $v_i(t) = 0$ if $t_{i-1} \leq t < \bar{\tau}$, and*

$$\begin{cases} \dot{v}_i(t) = D_x f_{q_i}(x_i(t), u_i(t)) v_i(t), \\ v_i(\bar{\tau}) = f_{q_i}(x_i(\bar{\tau}), \omega) - f_{q_i}(x_i(\bar{\tau}, u_i(\bar{\tau}))) \end{cases} \tag{3.5}$$

in the i-location if $\bar{\tau} \leq t \leq t_i$, while

$$\begin{cases} \dot{v}_j(t) = D_u f_{q_j}(x_j(t), u_j(t)) \theta_j(t) + D_x f_{q_j}(x_j(t), u_j(t)) v_j(t), \\ v_j(t_{j-1}) = \frac{d}{d\varepsilon} x_j^\varepsilon(t_{j-1})\big|_{\varepsilon=0} \end{cases} \tag{3.6}$$

if $j > i$.

Proof. Clearly, if $j < i$, then $v_j \equiv 0$. The case $j = i$ is well known, so we consider only the case $j > i$. In particular we prove the case $j = i + 1$, the other cases being similar.

For simplicity, let us denote with f, x, u, respectively, $f_{q_{i+1}}$, x_{i+1}, u_{i+1}. So, it is sufficient to prove that, if z in $[t_i, t_{i+1}]$ is the solution to

$$\begin{cases} \dot z(t) = D_u f(x(t), u(t))\theta_{i+1}(t) + D_x f(x(t), u(t))z(t), \\ z(t_i) = \frac{d}{d\varepsilon} x^\varepsilon_{i+1}(t_i)\big|_{\varepsilon=0}, \end{cases}$$

then $z(t) = \frac{d}{d\varepsilon} x^\varepsilon_{i+1}(t)\big|_{\varepsilon=0}$ for almost every $t \in [t_i, t_{i+1}]$. In order to prove this, for $t \in [t_i, t_{i+1}]$, we estimate

$$\begin{aligned} \left| \frac{x^\varepsilon_{i+1}(t) - x(t)}{\varepsilon} - z(t) \right| &\le \left| \frac{x^\varepsilon_{i+1}(t_i) - x(t_i)}{\varepsilon} - z(t_i) \right| \\ &+ \frac{1}{\varepsilon} \left| \int_{t_i}^t \left[f(x^\varepsilon_{i+1}(s), u^\varepsilon_{i+1}(s)) - f(x(s), u(s)) \right] ds \right. \\ &\left. - \varepsilon \int_{t_i}^t D_u f(x(s), u(s))\theta_{i+1}(s) ds - \varepsilon \int_{t_i}^t D_x f(x(s), u(s)) z(s) ds \right|. \end{aligned}$$

Fix $\delta > 0$. Then for ε sufficiently small (depending on δ), the first term of the right-hand side is less than δ. Using Taylor's expansion,

$$\begin{aligned} \left| \frac{x^\varepsilon_{i+1}(t) - x(t)}{\varepsilon} - z(t) \right| &\le \delta + \left| \int_{t_i}^t D_x f(x(s), u(s)) \cdot \left[\frac{x^\varepsilon_{i+1}(s) - x(s)}{\varepsilon} - z(s) \right] ds \right| \\ &+ \left| \int_{t_i}^t D_u f(x(s), u(s)) \cdot \left[\frac{u^\varepsilon_{i+1}(s) - u(s)}{\varepsilon} - \theta_{i+1}(s) \right] ds \right| \\ &+ \frac{c}{\varepsilon} \int_{t_i}^t \left[\left| x^\varepsilon_{i+1}(s) - x(s) \right| + \left| u^\varepsilon_{i+1}(s) - u(s) \right| \right]^2 ds, \end{aligned} \tag{3.7}$$

where c is a positive constant, depending on the second derivatives of f. Now $x^\varepsilon_{i+1} \to x$ uniformly, so for ε sufficiently small it holds that

$$\begin{aligned} \frac{c}{\varepsilon} \int_{t_i}^t \left| x^\varepsilon_{i+1}(s) - x(s) \right|^2 ds &\le c\delta \int_{t_i}^t \frac{\left| x^\varepsilon_{i+1}(s) - x(s) \right|}{\varepsilon} ds \\ &\le c\delta \int_{t_i}^t \left| \frac{x^\varepsilon_{i+1}(s) - x(s)}{\varepsilon} - z(s) \right| ds + c\delta \int_{t_i}^t |z(s)|\, ds \\ &\le c\delta \int_{t_i}^t \left| \frac{x^\varepsilon_{i+1}(s) - x(s)}{\varepsilon} - z(s) \right| ds + c_1 \delta \end{aligned}$$

with c_1 a positive constant. Moreover,

$$\frac{c}{\varepsilon} \int_{t_i}^t \left| u^\varepsilon_{i+1}(s) - u(s) \right|^2 ds \le c_2 \delta$$

with c_2 a positive constant, since $\frac{u^\varepsilon_{i+1} - u}{\varepsilon}$ converges weakly in $L^1([t_i, t_{i+1}])$ and $u^\varepsilon_{i+1} - u$ converges strongly to 0 in $L^1([t_i, t_{i+1}])$. For a detailed proof of this fact see the appendix. Analogously,

$$\frac{2c}{\varepsilon} \int_{t_i}^t \left| u^\varepsilon_{i+1}(s) - u(s) \right| \left| x^\varepsilon_{i+1}(s) - x(s) \right| ds \le c_2 \delta.$$

The third addend of the right-hand side of (3.7) is estimated similarly, since $\frac{u^\varepsilon_{i+1}-u}{\varepsilon} \rightharpoonup \theta_{i+1}$ weakly in $L^1([t_i, t_{i+1}])$. Thus,

$$\left|\frac{x^\varepsilon_{i+1}(t)-x(t)}{\varepsilon} - z(t)\right| \le M_1\delta + (M_2+c\delta)\int_{t_i}^{t}\left|\frac{x^\varepsilon_{i+1}(s)-x(s)}{\varepsilon} - z(t)\right| ds,$$

where M_1, M_2 are positive constants, depending on f and $U_{q_{i+1}}$. Using the Gronwall lemma we conclude that

$$\left|\frac{x^\varepsilon_{i+1}(t)-x(t)}{\varepsilon} - z(t)\right| \le M_1\delta e^{(M_2+c\delta)(t_{i+1}-t_i)} \tag{3.8}$$

and so the lemma is proved, by the arbitrariness of $\delta > 0$. □

Remark 5. From the last result, we note that the evolution equation for v_j in general is an affine equation, since a term depending on θ_j appears. This is due to the definition of admissible needle variation. For hybrid systems with assumption (H), we may consider usual needle variations and so the resulting equation for v_j is linear, without the term containing θ_j.

Remark 6. It is useful to recall that (3.6) is valid only if $j > i$, i.e., only if the variation is originated in a previous location. Therefore, to prove (3.6) we do not consider expression (3.3), but we use properties 3 and 5 of Definition 3.1.

Now, we want to evaluate how the Lagrangian cost varies for an admissible needle variation. If we define

$$G_\varepsilon(t) := \sum_{h=1}^{j-1}\int_{t_{h-1}}^{t_h} L_{q_h}(x^\varepsilon_h(s), u^\varepsilon_h(s))ds + \int_{t_{j-1}}^{t} L_{q_j}(x^\varepsilon_j(s), u^\varepsilon_j(s))ds$$

when $t_{j-1} \le t < t_j$ and set $w(t) := \frac{d}{d\varepsilon}G_\varepsilon(t)\big|_{\varepsilon=0^+}$, then we can get the following result.

LEMMA 3.4. *Let $\bar\tau \in]t_{i-1}, t_i[$ be the time at which an admissible needle variation originates. If $t \in]\bar\tau, t_i[$, then w satisfies the following differential equation:*

$$\begin{cases} \dot w(t) = \dfrac{\partial}{\partial x}L_{q_i}(x_i(t), u_i(t))v_i(t), \\ w(\bar\tau) = L_{q_i}(x_i(\bar\tau), \omega) - L_{q_i}(x_i(\bar\tau), u_i(\bar\tau)). \end{cases}$$

Moreover, if $i < j \le \nu$, then we have

$$\begin{cases} \dot w(t) = \dfrac{\partial}{\partial x}L_{q_j}(x_j(t), u_j(t))v_j(t) + \dfrac{\partial}{\partial u}L_{q_j}(x_j(t), u_j(t))\theta_j(t), \ t_{j-1} < t < t_j, \\ w(t_{j-1}) = \lim_{t\to t^-_{j-1}} w(t). \end{cases}$$

Proof. First we evaluate $w(\bar\tau)$. By definition

$$w(\bar\tau) = \frac{d}{d\varepsilon}G_\varepsilon(\bar\tau)\big|_{\varepsilon=0^+} = \lim_{\varepsilon=0^+}\frac{G_\varepsilon(\bar\tau) - G_0(\bar\tau)}{\varepsilon},$$

and, by the fact that x^ε and u^ε coincide, respectively, with x and u before $\bar\tau - \varepsilon$, we conclude that

$$\begin{aligned} w(\bar\tau) &= \lim_{\varepsilon\to 0^+}\frac{1}{\varepsilon}\int_{\bar\tau-\varepsilon}^{\bar\tau}\left[L_{q_i}(x^\varepsilon_i(s), \omega) - L_{q_i}(x_i(s), u_i(s))\right] ds \\ &= L_{q_i}(x_i(\bar\tau), \omega) - L_{q_i}(x_i(\bar\tau), u_i(\bar\tau)). \end{aligned}$$

Now suppose that $\bar\tau < t < t_i$. In this case we have

$$\begin{aligned} w(t) &= \lim_{\varepsilon\to 0^+} \left\{ \frac{1}{\varepsilon} \int_{\bar\tau-\varepsilon}^{\bar\tau} [L_{q_i}(x_i^\varepsilon(s),\omega) - L_{q_i}(x_i^\varepsilon(s),u_i(s))]\,ds \right. \\ &\qquad \left. + \frac{1}{\varepsilon}\int_{\bar\tau}^{t} [L_{q_i}(x_i^\varepsilon(s),u_i(s)) - L_{q_i}(x_i(s),u_i(s))]\,ds \right\} \\ &= L_{q_i}(x_i(\bar\tau),\omega) - L_{q_i}(x_i(\bar\tau),u_i(\bar\tau)) \\ &\quad + \lim_{\varepsilon\to 0^+} \left\{ \int_{\bar\tau}^{t} \frac{\partial}{\partial x} L_{q_i}(x_i(s),u_i(s)) \frac{x_i^\varepsilon(s)-x_i(s)}{\varepsilon} ds \right. \\ &\qquad \left. + \int_{\bar\tau}^{t} \frac{\partial^2}{\partial x^2} L_{q_i}(\tilde x_i(s),\tilde u(s)) \frac{(x_i^\varepsilon(s)-x_i(s))^2}{2\varepsilon} ds \right\}. \end{aligned}$$

Using estimate (3.8) we conclude by the Lebesgue theorem that

$$w(t) = L_{q_i}(x_i(\bar\tau),\omega) - L_{q_i}(x_i(\bar\tau),u_i(\bar\tau)) + \int_{\bar\tau}^{t} \frac{\partial}{\partial x} L_{q_i}(x_i(s),u_i(s)) v_i(s) ds.$$

So the first part of the lemma is proved.

In order to prove the last statement, we claim that, if $t_{j-1} < t < t_j$, then $w(t)$ is equal to

$$\begin{aligned} w(t) &= [L_{q_i}(x_i(\bar\tau),\omega) - L_{q_i}(x_i(\bar\tau),u_i(\bar\tau))] \\ &+ \int_{\bar\tau}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(s),u_i(s)) v_i(s) ds + \sum_{l=i+1}^{j-1} \int_{t_{l-1}}^{t_l} \frac{\partial}{\partial x} L_{q_l}(x_l(s),u_l(s)) v_l(s) ds \\ &+ \sum_{l=i+1}^{j-1} \int_{t_{l-1}}^{t_l} \frac{\partial}{\partial u} L_{q_l}(x_l(s),u_l(s)) \theta_l(s) ds \\ &+ \int_{t_{j-1}}^{t} \frac{\partial}{\partial x} L_{q_j}(x_j(s),u_j(s)) v_j(s) ds + \int_{t_{j-1}}^{t} \frac{\partial}{\partial u} L_{q_j}(x_j(s),u_j(s)) \theta_j(s) ds. \end{aligned}$$

In fact, if $l \in \{i+1,\dots,j\}$, then we have for $t \in [t_{l-1}, t_l]$ that

$$\begin{aligned} &\lim_{\varepsilon\to 0^+} \int_{t_{l-1}}^{t} \frac{L_{q_l}(x_l^\varepsilon(s),u_l^\varepsilon(s)) - L_{q_l}(x_l(s),u_l(s))}{\varepsilon} ds \\ &\quad = \lim_{\varepsilon\to 0^+} \left\{ \int_{t_{l-1}}^{t} \frac{L_{q_l}(x_l^\varepsilon(s),u_l^\varepsilon(s)) - L_{q_l}(x_l(s),u_l^\varepsilon(s))}{\varepsilon} ds \right. \\ &\qquad \left. + \int_{t_{l-1}}^{t} \frac{L_{q_l}(x_l(s),u_l^\varepsilon(s)) - L_{q_l}(x_l(s),u_l(s))}{\varepsilon} ds \right\} \\ &\quad = \int_{t_{l-1}}^{t} \frac{\partial}{\partial x} L_{q_l}(x_l(s),u_l(s)) v_l(s) ds \\ &\qquad + \lim_{\varepsilon\to 0^+} \int_{t_{l-1}}^{t} \frac{L_{q_l}(x_l(s),u_l^\varepsilon(s)) - L_{q_l}(x_l(s),u_l(s))}{\varepsilon} ds. \end{aligned}$$

Now the last term is equal to

$$\begin{aligned}
&\lim_{\varepsilon\to 0^+}\int_{t_{l-1}}^{t}\frac{L_{q_l}(x_l(s),u_l^\varepsilon(s))-L_{q_l}(x_l(s),u_l(s))}{\varepsilon}ds\\
&\quad=\lim_{\varepsilon\to 0^+}\left\{\int_{t_{l-1}}^{t}\frac{\partial}{\partial u}L_{q_l}(x_l(s),u_l(s))\frac{u_l^\varepsilon(s)-u_l(s)}{\varepsilon}ds\right.\\
&\qquad\qquad\left.+\int_{t_{l-1}}^{t}\frac{\partial^2}{\partial u^2}L_{q_l}(\tilde{x}_l(s),\tilde{u}_l(s))\frac{u_l^\varepsilon(s)-u_l(s)}{\varepsilon}(u_l^\varepsilon(s)-u_l(s))ds\right\}\\
&\quad=\int_{t_{l-1}}^{t}\frac{\partial}{\partial u}L_{q_l}(x_l(s),u_l(s))\theta_l(s)ds\\
&\qquad+\lim_{\varepsilon\to 0^+}\int_{t_{l-1}}^{t}\frac{\partial^2}{\partial u^2}L_{q_l}(\tilde{x}_l(s),\tilde{u}_l(s))\frac{u_l^\varepsilon(s)-u_l(s)}{\varepsilon}(u_l^\varepsilon(s)-u_l(s))ds
\end{aligned}$$

by definition of admissible needle variation. The last integral converges to 0 since $\frac{u_l^\varepsilon(s)-u_l(s)}{\varepsilon}$ converges weakly in $L^1([t_{l-1},t_l])$ and $u_l^\varepsilon(s)-u_l(s)$ converges to 0 strongly in $L^1([t_{l-1},t_l])$ and so the product converges to 0 weakly in $L^1([t_{l-1},t_l])$; see the appendix. □

Putting together all the previous results we have the following proposition.

PROPOSITION 3.5. *Let $\boldsymbol{X}$ be a trajectory and let $\boldsymbol{X}^\varepsilon$ be an admissible needle variation. Then, for every adjoint pair (ψ,ψ_0) along $\boldsymbol{X}$ and for every $j\in\{1,\dots,\nu\}$ the function*

$$\psi_j(t)\cdot v_j(t)-\psi_0 w(t)+q_j(t) \tag{3.9}$$

is constant in $[t_{j-1},t_j]$, where v_j is defined by (3.4) *and q_j is any function defined by*

$$\dot{q}_j(t)=-\psi_j(t)\frac{\partial}{\partial u}f_{q_j}(x_j(t),u_j(t))\theta_j(t)+\psi_0\frac{\partial}{\partial u}L_{q_j}(x_j(t),u_j(t))\theta_j(t) \tag{3.10}$$

if $j>i$, while $q_j\equiv 0$ otherwise.

Proof. It is a simple consequence of Lemmas 3.3 and 3.4. If $j<i$, then $v_j\equiv 0$, $q_j\equiv 0$, and $w(t)=0$ for every $t\in[0,t_j]$.

If $j=i$, where q_i is the location at which the admissible needle variation originates, then we have

$$\begin{aligned}
&\frac{d}{dt}\left[\psi_i(t)\cdot v_i(t)-\psi_0 w(t)\right]=\dot{\psi}_i(t)\cdot v_i(t)+\psi_i(t)\cdot\dot{v}_i(t)-\psi_0\dot{w}(t)\\
&\quad=-\psi_i(t)D_x f_{q_i}(x_i(t),u_i(t))v_i(t)+\psi_0\frac{\partial}{\partial x}L_{q_i}(x_i(t),u_i(t))v_i(t)\\
&\quad+\psi_i(t)D_x f_{q_i}(x_i(t),u_i(t))v_i(t)-\psi_0\frac{\partial}{\partial x}L_{q_i}(x_i(t),u_i(t))v_i(t)=0
\end{aligned}$$

and so we have the thesis when $j=i$.

Now if $j > i$, then

$$\begin{aligned}
&\frac{d}{dt}\left[\psi_j(t)\cdot v_j(t) - \psi_0 w(t) + q_j(t)\right] = \dot\psi_j(t)\cdot v_j(t) + \psi_j(t)\cdot \dot v_j(t) - \psi_0 \dot w(t) + \dot q_j(t)\\
&\quad = -\psi_j(t) D_x f_{q_j}(x_j(t),u_j(t))v_j(t) + \psi_0 \frac{\partial}{\partial x} L_{q_j}(x_j(t),u_j(t))v_j(t)\\
&\quad + \psi_j(t) D_u f_{q_j}(x_j(t),u_j(t))\theta_j(t) + \psi_j(t) D_x f_{q_j}(x_j(t),u_j(t))v_j(t)\\
&\quad - \psi_0 \frac{\partial}{\partial x} L_{q_j}(x_j(t),u_j(t))v_j(t) - \psi_0 \frac{\partial}{\partial u} L_{q_j}(x_j(t),u_j(t))\theta_j(t)\\
&\quad - \psi_j(t)\cdot D_u f_{q_j}(x_j(t),u_j(t))\theta_j(t) + \psi_0 \frac{\partial}{\partial u} L_{q_j}(x_j(t),u_j(t))\theta_j(t) = 0.
\end{aligned}$$

This completes the proof. □

Now, we study how to deduce some necessary conditions from the previous analysis. For clarity, we consider optimal control problems where the cost is formed only by the Lagrangian part; that is, the switching cost and the endpoint cost vanish. We suppose that $\mathbf{X}$ is an optimal trajectory and we consider an admissible needle variation $\mathbf{X}^\varepsilon$. Clearly, by optimality, $C(\mathbf{X}) \le C(\mathbf{X}^\varepsilon)$. This implies that $w(T) \ge 0$. Let us consider an adjoint pair (ψ, ψ_0) along $\mathbf{X}$ with the property that, for every $j \in \{1,\dots,\nu\}$,

$$\psi_j(t_j)\cdot v_j(t_j) \le 0. \tag{3.11}$$

Thus

$$\psi_\nu(t_\nu)\cdot v_\nu(t_\nu) - \psi_0 w(t_\nu) \le 0. \tag{3.12}$$

This implies that, for every $q_\nu(\cdot)$ defined as in Proposition 3.5 with $q_\nu(t_\nu) \le 0$, it holds that

$$\psi_\nu(t)\cdot v_\nu(t) - \psi_0 w(t) + q_\nu(t) \le 0 \tag{3.13}$$

for every $t \in [t_{\nu-1}, t_\nu]$. Therefore in the $\nu - 1$ location we have

$$\psi_{\nu-1}(t_{\nu-1})\cdot v_{\nu-1}(t_{\nu-1}) - \psi_0 w(t_{\nu-1}) + q_\nu(t_{\nu-1}) \le 0 \tag{3.14}$$

and so

$$\psi_{\nu-1}(t)\cdot v_{\nu-1}(t) - \psi_0 w(t) + q_\nu(t_{\nu-1}) + q_{\nu-1}(t) \le 0 \tag{3.15}$$

for every $q_{\nu-1}$ with $q_{\nu-1}(t_{\nu-1}) \le 0$ and for every $t \in [t_{\nu-2}, t_{\nu-1}]$.

Iterating this argument we conclude that

$$\psi_j(t)\cdot v_j(t) - \psi_0 w(t) + \sum_{l=j+1}^{\nu} q_l(t_{l-1}) + q_j(t) \le 0 \tag{3.16}$$

for every $j \in \{1,\dots,\nu\}$, $t \in [t_{j-1}, t_j]$ and for every function q_l with $q_l(t_l) \le 0$.

Equation (3.16) gives a necessary condition for optimality when the hybrid system does not satisfy assumption (H). In the next section we generalize this approach.

4. Hybrid necessary principle. This section is devoted to the statement and proof of a general HNP in the case where the lack of Assumption (H) generalizes some previous results in [27]. Again for sake of simplicity we assume (3.1) and (3.2).

We recall first some basic facts about measure theory and in particular about Radon measures; see [16].

DEFINITION 4.1. *Let $a, b \in \mathbb{R}$, $a < b$. If $\mathcal{B}_{(a,b)}$ denotes the Borel σ-algebra on (a, b), then a signed measure $\mu : \mathcal{B}_{(a,b)} \to \overline{\mathbb{R}}$ is called a Radon measure if*

1. *$|\mu(K)| < +\infty$ for every K, compact set in (a, b);*
2. *$\mu(E) = \inf\{\mu(U) : E \subseteq U, U$ open set in $(a, b)\}$ for every $E \in \mathcal{B}_{(a,b)}$;*
3. *$\mu(E) = \sup\{\mu(K) : K \subseteq E, K$ compact set in $(a, b)\}$ for every $E \in \mathcal{B}_{(a,b)}$.*

Moreover, if $|\mu|$ is finite, then μ is said to be bounded. We denote by $\mathfrak{M}_b(a, b; \mathbb{R})$ the set of bounded Radon measures on (a, b).

If $a, b \in \mathbb{R}$, $a < b$, then $L^1(a, b)$ is contained in $\mathfrak{M}_b(a, b; \mathbb{R})$. The inclusion is intended in the following way: to every function $f \in L^1(a, b)$ we associate a measure μ defined by

$$\mu(A) := \int_A f(t)dt, \tag{4.1}$$

where A is a Borel subset of (a, b). The space $\mathfrak{M}_b(a, b; \mathbb{R})$, equipped with the norm $\|\mu\| := |\mu|(a, b)$, is equal to $(C(a, b))'$ (see [16]). So in $\mathfrak{M}_b(a, b; \mathbb{R})$ we may consider the weak* topology. We have that $\mu_n \rightharpoonup^* \mu$ as $n \to +\infty$ if and only if, for every $g \in C(a, b)$,

$$\int_a^b g(t)d\mu_n(t) \to \int_a^b g(t)d\mu(t) \qquad \text{as } n \to +\infty.$$

In the same way, we consider the space of bounded Radon measures on (a, b) with values in $\mathbb{R}^n$ and we indicate them by $\mathfrak{M}_b(a, b; \mathbb{R}^n)$.

Remark 7. The measure μ defined in (4.1) is clearly a signed measure. In fact if the function f is strictly negative in a Borel set E, whose Lebesgue measure is strictly positive, then $\mu(E) < 0$.

All the properties of Radon measures are clearly satisfied by any measure defined as in (4.1). Moreover, equation (4.1) says that $\mu \ll m$; that is, μ is an absolutely continuous measure with respect to the Lebesgue measure.

Now we recall a result about the differentiability of a trajectory with respect to a parameter, used to prove the main result.

DEFINITION 4.2. *Let P be a normed space, let $\{\bar{x}^p\}_{p\in P}$ be a family in $\mathbb{R}^n$, and let $\boldsymbol{f} = \{\boldsymbol{f}_p\}_{p\in P}$ be a family of time-varying vector fields on $\mathbb{R}^n$. For every $p \in P$, we denote with $x^p : [a, b] \to \mathbb{R}^n$ a solution to*

$$\begin{cases} \dot{x}^p(t) = \boldsymbol{f}_p(t, x^p(t)) & a.e.\ t \in [a, b], \\ x^p(a) = \bar{x}^p. \end{cases}$$

Let us fix an element $p_0 \in P$. We say that $\boldsymbol{f}$ is weakly differentiable at $p_0 \in P$ along $x^{p_0}(\cdot)$ if there exists $\bar{\varepsilon} > 0$ such that

1. *for every p such that $\|p - p_0\| \le \bar{\varepsilon}$ and for every $\xi : [a, b[\to \mathbb{R}^{d_q}$, solution to $\dot{\xi}(t) = \boldsymbol{f}_p(t, \xi(t))$, with $\|\xi(t) - x^{p_0}(t)\| \le \bar{\varepsilon}$ for every $t \in [a, b[$, the limit $\lim_{t\to b^-} \xi(t)$ exists;*

2. *for every p such that $\|p-p_0\| \le \bar\varepsilon$ and for every x such that $\|x-x^{p_0}(t)\| < \bar\varepsilon$ for some $a \le t < b$, there exists a local forward solution to*

$$\begin{cases} \dot\xi = \boldsymbol{f}_p(t,\xi), \\ \xi(t) = x; \end{cases}$$

3. *there exist $A \in L^1([a,b];\mathbb{R}^{n\times n})$ and positive functions $\zeta_\varepsilon \in L^1([a,b];\mathbb{R}^+)$ for every $\varepsilon \in]0,\bar\varepsilon]$, such that*

$$\begin{aligned} &\|\boldsymbol{f}_p(t,x) - \boldsymbol{f}_p(t,x^{p_0}(t)) - A(t)(x-x^{p_0}(t))\| \\ &\qquad \le \zeta_\varepsilon(t)(\|x-x^{p_0}(t)\| + \|p-p_0\|) \end{aligned}$$

whenever $a \le t \le b$, $\|x-x^{p_0}(t)\| \le \varepsilon$, $\|p-p_0\| \le \varepsilon$, and

$$\lim_{\varepsilon\to 0^+} \int_a^b \zeta_\varepsilon(t)dt = 0;$$

4. *the function $\tilde w_p(t) := \boldsymbol{f}_p(t,x^{p_0}(t)) - \boldsymbol{f}_{p_0}(t,x^{p_0}(t))$ is integrable in $[a,b]$ for every $\|p-p_0\| \le \bar\varepsilon$;*

5. *for every $\alpha \in C([a,b];\mathbb{R}^n)$ the map*

$$p \mapsto \int_{[a,b]} \alpha(t)\, d\left(\int_a^t \tilde w_p(s)ds\right)$$

is Fréchet differentiable at p_0.

PROPOSITION 4.3. *We use here the notation of Definition* 4.2. *Fix $p_0 \in P$, let $v \in P$, and assume that*

$$\lim_{\varepsilon\to 0^+} \frac{\bar x^{p_0+\varepsilon v} - \bar x^{p_0}}{\varepsilon}$$

exists in $\mathbb{R}^n$ and moreover that there exists $\alpha_{p_0,v}(\cdot) \in \mathfrak{M}_b(a,b;\mathbb{R}^n)$ such that

$$\frac{\boldsymbol{f}_{p_0+\varepsilon v}(t,x^{p_0}(t)) - \boldsymbol{f}_{p_0}(t,x^{p_0}(t))}{\varepsilon} \rightharpoonup^* \alpha_{p_0,v}(t) \tag{4.2}$$

as $\varepsilon \to 0^+$. If we denote by $y_{p_0,v}(t)$ the derivative of $x^{p_0}(t)$ in the v-direction evaluated at p_0, then we have that

$$\dot y_{p_0,v}(t) = \frac{\partial}{\partial x}\boldsymbol{f}_{p_0}(t,x^{p_0}(t)) \cdot y_{p_0,v}(t) + \alpha_{p_0,v}(t), \tag{4.3}$$

where the last equation is to be intended in the integral sense. Moreover, if $\boldsymbol{f}$ is weakly differentiable at p_0 along $x^{p_0}(\cdot)$, then $x^p(\cdot) \to x^{p_0}(\cdot)$ uniformly on $[a,b]$ when $p \to p_0$ in P.

For a proof, see [22, Appendix A].

Remark 8. The previous proposition gives us a tool to evaluate the evolution of the derivative of a trajectory of an ODE with respect to a parameter. In particular, it is useful in order to understand the behavior of modifications due to "variations" on a supposed optimal trajectory. We apply the previous proposition in the case where the time-varying vector fields are the coupled dynamic-Lagrangian functions evaluated on controls produced by a variation. Notice that the limit in (4.2) is in the weak star topology of Radon measures.

DEFINITION 4.4. *Let X, Y be finite dimensional vector spaces over $\mathbb{R}$ and let Λ be a cone in X. Consider a function $f : x + \Lambda \to Y$ for some $x \in X$. We say that f is differentiable at x in the direction Λ if there exists a linear map $D_\Lambda f(x) : X \to Y$ such that*

$$f(x+\lambda) = f(x) + D_\Lambda f(x)\cdot\lambda + o(\|\lambda\|) \quad \text{as } \lambda \to 0,\ \lambda \in \Lambda. \tag{4.4}$$

Obviously the map $D_\Lambda f(x)$ is uniquely determined on $\operatorname{span}\{\Lambda\}$.

Let $\mathbf{X}$ be an optimal trajectory for the problem $\mathcal{P}$ and let $\bar\varepsilon > 0$. We denote with K a cone in $\mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_\nu}$, with $v = (v_1, \dots, v_\nu)$ an element of K and with $(u_1, \dots, u_\nu)$ the controls of the candidate optimal hybrid trajectory $\mathbf{X}$. The aim of next definition is to give a rigorous description of all variations we are able to consider. Analogously to [27], we treat variations depending on two parameters: ε and v. ε is a real positive number, while v belongs to a cone in a finite dimensional manifold. The reader can think of v as the parameter responsible for the variation of the initial points of each trajectory x_j, $j \in \{1, \dots, \nu\}$, and ε as parameterizing the control variation.

DEFINITION 4.5 (map of variations). *A map V defined on $[0, \bar\varepsilon] \times K$, $V(\varepsilon, v) = (x_1^{(\varepsilon,v)}, u_1^{(\varepsilon,v)}, \dots, x_\nu^{(\varepsilon,v)}, u_\nu^{(\varepsilon,v)})$, is called a map of variations if, for every $(\varepsilon, v) \in [0, \bar\varepsilon] \times K$, the following hold:*

1. *for every $i \in \{1, \dots, \nu\}$, $u_i^{(\varepsilon,v)} \in \mathcal{U}_{q_i}$ and $u_i^{(\delta\varepsilon,\delta v)} \to u_i$ in $L^1(t_{i-1}, t_i)$ as $\delta \to 0^+$;*
2. *for every $i \in \{1, \dots, \nu\}$, $x_i^{(\varepsilon,v)} :]t_{i-1}, t_i[\to \mathbb{R}^{d_i}$ is an absolutely continuous function continuously prolongable to $[t_{i-1}, t_i]$ such that $\frac{d}{d\delta} x_i^{(\delta\varepsilon,\delta v)}(t_{i-1})\big|_{\delta=0} = v_i$ and*

$$\frac{d}{dt} x_i^{(\varepsilon,v)}(t) = f_{q_i}(x_i^{(\varepsilon,v)}(t), u_i^{(\varepsilon,v)}(t)) \quad \text{for a.e. } t \in [t_{i-1}, t_i]; \tag{4.5}$$

3. *for every $i \in \{1, \dots, \nu - 1\}$, $u_{i+1}^{(\varepsilon,v)} \in \mathcal{U}_{q_i, x_i^{(\varepsilon,v)}(t_i), q_{i+1}, x_{i+1}^{(\varepsilon,v)}(t_i)}$;*
4. *the map*

$$\begin{aligned} \widetilde{C}_V : [0,\bar\varepsilon]\times K &\to (\mathbb{R}^{d_1}\times\mathbb{R}^{d_2})\times\cdots\times(\mathbb{R}^{d_\nu}\times\mathbb{R}^{d_1})\times\mathbb{R} \\ (\varepsilon, v) &\mapsto ((x_1^{(\varepsilon,v)}(t_1), x_2^{(\varepsilon,v)}(t_1)), \dots, (x_\nu^{(\varepsilon,v)}(t_\nu), x_1^{(\varepsilon,v)}(t_0)), \gamma(\varepsilon, v)) \end{aligned} \tag{4.6}$$

with

$$\gamma(\varepsilon, v) = \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} L_{q_i}(x_i^{(\varepsilon,v)}(t), u_i^{(\varepsilon,v)}(t))dt$$

is differentiable at 0 in the direction $\mathbb{R}^+ \times K$;

5. *for every $i \in \{1, \dots, \nu\}$, there exist $\alpha_{i,f,V}^{(\varepsilon,v)} \in \mathfrak{M}_b(t_{i-1}, t_i; \mathbb{R}^{d_i})$ and $\alpha_{i,L,V}^{(\varepsilon,v)} \in \mathfrak{M}_b(t_{i-1}, t_i; \mathbb{R})$ such that*

$$\frac{f_{q_i}(x_i(t), u_i^{(\delta\varepsilon,\delta v)}(t)) - f_{q_i}(x_i(t), u_i(t))}{\delta} \rightharpoonup^* \alpha_{i,f,V}^{(\varepsilon,v)}(t) \tag{4.7}$$

and

$$\frac{L_{q_i}(x_i(t), u_i^{(\delta\varepsilon,\delta v)}(t)) - L_{q_i}(x_i(t), u_i(t))}{\delta} \rightharpoonup^* \alpha_{i,L,V}^{(\varepsilon,v)}(t) \tag{4.8}$$

as $\delta \downarrow 0$.

We denote by $\mathcal{V}$ the set of all maps of variations.

Remark 9. The main reasoning in the proof of the HNP follows the classical approach. We consider *feasible* cones generated by final points of admissible variations and *profitable* cones formed by points that realize a cost lower than that of the candidate trajectory. To have optimality these two cones must be separated; i.e., there exists a hyperplane that separates the cones. From these considerations we deduce necessary conditions.

In Definition 3.1 (map of variations), we require various assumptions. In particular, the assumptions 1, 2, and 3 guarantee that maps of variations produce admissible trajectories for our hybrid system. Moreover assumption 4 implies the existence of the cone generated by the variations and, finally, assumption 5 is necessary in order to apply Proposition 4.3.

Remark 10. Notice that in order to have the differentiability of the function $\widetilde{C}_V$, the Radon measures $\alpha_{i,f,V}^{(\varepsilon,v)}$ and $\alpha_{i,L,V}^{(\varepsilon,v)}$ must depend continuously on the parameters (ε, v). This is guaranteed if $\alpha_{i,f,V}^{(\varepsilon,v)}$ and $\alpha_{i,L,V}^{(\varepsilon,v)}$ are linear with respect to the parameters (ε, v), and if $(\varepsilon_n, v_n) \in \mathbb{R}^+ \times K$ with $(\varepsilon_n, v_n) \to (\varepsilon, v) \in \mathbb{R}^+ \times K$, then $\alpha_{i,f,V}^{(\varepsilon_n,v_n)} \rightharpoonup^* \alpha_{i,f,V}^{(\varepsilon,v)}$ in $\mathfrak{M}_b(t_{i-1}, t_i; \mathbb{R}^{d_i})$ for every $i = 1, \dots, \nu$ and $\alpha_{i,L,V}^{(\varepsilon_n,v_n)} \rightharpoonup^* \alpha_{i,L,V}^{(\varepsilon,v)}$ in $\mathfrak{M}_b(t_{i-1}, t_i; \mathbb{R})$ for every $i = 1, \dots, \nu$.

Now, if $V \in \mathcal{V}$, then we have that

$$D\widetilde{C}_V(0) : \mathbb{R}^+ \times K \to (\mathbb{R}^{d_1} \times \mathbb{R}^{d_2}) \times \cdots \times (\mathbb{R}^{d_\nu} \times \mathbb{R}^{d_1}) \times \mathbb{R}$$

and if $\varepsilon \in [0, \bar{\varepsilon}]$, then

$$D\widetilde{C}_V(0)(\varepsilon, v) = ((w_1, v_2), \dots, (w_\nu, v_1), \beta(\varepsilon, v)), \tag{4.9}$$

where

$$\begin{aligned}\beta(\varepsilon, v) = &\sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(s), u_i(s)) M_i(s, t_{i-1}) v_i \, ds \\ &+ \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(s), u_i(s)) \int_{t_{i-1}}^{s} M_i(s, r) \, d\alpha_{i,f,V}^{(\varepsilon,v)}(r) \, ds \\ &+ \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} d\alpha_{i,L,V}^{(\varepsilon,v)}(s), \end{aligned} \tag{4.10}$$

$$w_i = M_i(t_i, t_{i-1}) v_i + \int_{t_{i-1}}^{t_i} M_i(t_i, s) d\alpha_{i,f,V}^{(\varepsilon,v)}(s), \tag{4.11}$$

and $M_i(t, s)$ $(i = 1, \dots, \nu)$ is the fundamental matrix solution for the linear system

$$\dot{y}(t) = \frac{\partial}{\partial x} f_{q_i}(x_i(t), u_i(t)) y(t).$$

Indeed, the differential of the components $x_i^{(\varepsilon,v)}(t_{i-1})$ is equal to v_i by hypothesis 2 of the definition of map of variations. For the differential of the components $x_i^{(\varepsilon,v)}(t_i)$ we use Proposition 4.3, while for the differential of $\gamma(\varepsilon, v)$ we have to estimate, for

every $i = 1, \dots, \nu$, the limit as $\delta \to 0^+$ of the expression

$$\begin{aligned}&\int_{t_{i-1}}^{t_i} \frac{L_{q_i}(x_i^{(\delta\varepsilon,\delta v)}(t), u_i^{(\delta\varepsilon,\delta v)}(t)) - L_{q_i}(x_i(t), u_i(t))}{\delta} dt \\ &= \int_{t_{i-1}}^{t_i} \frac{L_{q_i}(x_i^{(\delta\varepsilon,\delta v)}(t), u_i^{(\delta\varepsilon,\delta v)}(t)) - L_{q_i}(x_i(t), u_i^{(\delta\varepsilon,\delta v)}(t))}{\delta} dt \\ &\quad + \int_{t_{i-1}}^{t_i} \frac{L_{q_i}(x_i(t), u_i^{(\delta\varepsilon,\delta v)}(t)) - L_{q_i}(x_i(t), u_i(t))}{\delta} dt.\end{aligned}$$

For the last addend we use hypothesis 5 of the definition of map of variations, while for the other term we have to use Proposition 4.3 and Lemma A.2 of the appendix.

Let us denote by $\mathbf{X}^{(\varepsilon,v)}(\cdot)$ the candidate hybrid trajectory obtained by piecing together $x_i^{(\varepsilon,v)}$, $i = 1, \dots, \nu$. Then $\mathbf{X}^{(\varepsilon,v)}(\cdot)$ is a trajectory if and only if

- $(x_i^{(\varepsilon,v)}(t_i), x_{i+1}^{(\varepsilon,v)}(t_i)) \in \mathcal{S}_{q_i,q_{i+1}}$ for $i = 1, \dots, \nu - 1$;
- $(q_1, x_1^{(\varepsilon,v)}(t_0), 0) \in \mathcal{N}_{in}$;
- $(q_\nu, x_\nu^{(\varepsilon,v)}(t_\nu), t_\nu - t_{\nu-1}) \in \mathcal{N}_{fin}$.

Since $\mathbf{X}$ is optimal we have that

$$C(\mathbf{X}^{(\varepsilon,v)}) \geq C(\mathbf{X}) \tag{4.12}$$

whenever the previous conditions hold.

In what follows we identify, for simplicity, $x_{\nu+1}(t_\nu)$ with $x_1(t_0)$ and $\mathbb{R}^{d_{\nu+1}}$ with $\mathbb{R}^{d_1}$. Moreover,

$$\mathcal{S}_{q_\nu,q_{\nu+1}} := \{(z, z') \in \mathbb{R}^{d_\nu} \times \mathbb{R}^{d_1} : (q_1, z', 0) \in \mathcal{N}_{in}, (q_\nu, z, t_\nu - t_{\nu-1}) \in \mathcal{N}_{fin}\}.$$

Now, fix smooth functions $\sigma_i : \mathbb{R}^{d_i} \times \mathbb{R}^{d_{i+1}} \to \mathbb{R}$ $(i = 1, \dots, \nu)$ such that

$$\sigma_i(x_i(t_i), x_{i+1}(t_i)) = 0$$

and $\sigma_i(z_i, z_i') > 0$ if $(z_i, z_i') \in \mathbb{R}^{d_i} \times \mathbb{R}^{d_{i+1}} \setminus \{(x_i(t_i), x_{i+1}(t_i))\}$. Let P be the set of points $((z_1, z_1'), \dots, (z_\nu, z_\nu'), r)$ of $(\mathbb{R}^{d_1} \times \mathbb{R}^{d_2}) \times \cdots \times (\mathbb{R}^{d_\nu} \times \mathbb{R}^{d_1}) \times \mathbb{R}$ such that $(z_i, z_i') \in \mathcal{S}_{q_i,q_{i+1}}$ $(i = 1, \dots, \nu)$ and

$$r \leq C(\mathbf{X}) - \sum_{i=1}^{\nu-1} \Phi_{q_i,q_{i+1}}(z_i, z_i') - \widetilde{\varphi}_{q_1,q_\nu}(z_\nu, z_\nu') - \sum_{i=1}^{\nu} \sigma_i(z_i, z_i'),$$

where $\widetilde{\varphi}_{q_1,q_\nu}(z_\nu, z_\nu') = \varphi_{q_1,q_\nu}(z_\nu', z_\nu)$. Notice that if $\widetilde{C}_V(\varepsilon, v) \in P$, then $\mathbf{X}^{(\varepsilon,v)}$ is a hybrid trajectory and $C(\mathbf{X}^{(\varepsilon,v)}) \leq C(\mathbf{X})$ with strict inequality if $\mathbf{X}^{(\varepsilon,v)} \not\equiv \mathbf{X}$; then from (4.12), we get $\widetilde{C}_V([0, \bar{\varepsilon}] \times K) \cap P = \{p_*\}$, where

$$p_* = ((x_1(t_1), x_2(t_1)), \dots, (x_\nu(t_\nu), x_1(t_0)), C_L(\mathbf{X})).$$

Define

$$K_V = D\widetilde{C}_V(0)([0, \bar{\varepsilon}] \times K). \tag{4.13}$$

Let K_P be the set of all $((z_1, z_1'), \dots, (z_\nu, z_\nu'), r)$ such that (z_i, z_i'), for $i = 1, \dots, \nu$, belongs to a Boltyanskiĭ approximating cone to $\mathcal{S}_{q_i,q_{i+1}}$ at the point $(x_i(t_i), x_{i+1}(t_i))$

and

$$r \le -\sum_{i=1}^{\nu-1} \nabla\Phi_{q_i,q_{i+1}}(x_i(t_i), x_{i+1}(t_i)) \cdot (z_i, z_i') - \nabla\widetilde{\varphi}_{q_1,q_\nu}(x_\nu(t_\nu), x_1(t_0)) \cdot (z_\nu, z_\nu').$$

Then K_P is a Boltyanskiĭ approximating cone to P at p_* and is not a linear subspace. By a general separation theorem (see [28]), for every convex cone $\widehat{K} \subseteq \bigcup_{V\in\mathcal{V}} K_V$, there exists an element $\psi \in (\mathbb{R}^{d_1} \times \mathbb{R}^{d_2}) \times \cdots \times (\mathbb{R}^{d_\nu} \times \mathbb{R}^{d_1}) \times \mathbb{R}$ such that it weakly separates K_P from $\widehat{K}$. In particular we may suppose that

$$(\psi, k) \ge 0 \quad \forall k \in K_P$$

and

$$(\psi, k') \le 0 \quad \forall k' \in \widehat{K},$$

where $(\cdot,\cdot)$ denotes the usual scalar product in $\mathbb{R}^n$. We may write

$$\psi = ((\psi_1^+, \psi_2^-), \dots, (\psi_\nu^+, \psi_1^-), -\psi_0).$$

We note that $(0, \dots, 0, -1) \in K_P$ and so $\psi_0 \ge 0$.

If $V \in \mathcal{V}$ and $(\varepsilon, v) \in [0, \bar{\varepsilon}] \times K$ is such that $D\widetilde{C}_V(0)(\varepsilon, v) \in \widehat{K}$, then

$$\begin{aligned}
&\sum_{i=1}^{\nu} \left(\psi_i^- \cdot v_i + \psi_i^+ \cdot M_i(t_i, t_{i-1}) \cdot v_i + \psi_i^+ \int_{t_{i-1}}^{t_i} M_i(t_i, s) d\alpha_{i,f,V}^{(\varepsilon,v)}(s) \right) \\
&\quad - \psi_0 \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(s), u_i(s)) M_i(s, t_{i-1}) v_i ds \\
&\quad - \psi_0 \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(s), u_i(s)) \int_{t_{i-1}}^{s} M_i(s, r) d\alpha_{i,f,V}^{(\varepsilon,v)}(r) ds \\
&\quad - \psi_0 \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} d\alpha_{i,L,V}^{(\varepsilon,v)}(s) \le 0.
\end{aligned}$$

Hence, if we define, for every $i = 1, \dots, \nu$, $\psi_i : [t_{i-1}, t_i] \to \mathbb{R}^{d_i}$ to be the Carathéodory solution to

$$\begin{cases} \dot{\psi}_i(t) = -\psi_i(t) \dfrac{\partial}{\partial x} f_{q_i}(x_i(t), u_i(t)) + \psi_0 \dfrac{\partial}{\partial x} L_{q_i}(x_i(t), u_i(t)), \\ \psi_i(t_i) = \psi_i^+, \end{cases}$$

then we obtain that

$$\begin{aligned}
&\sum_{i=1}^{\nu} \left(\psi_i^- \cdot v_i + \psi_i(t_i) \int_{t_{i-1}}^{t_i} M_i(t_i, s) d\alpha_{i,f,V}^{(\varepsilon,v)}(s) \right) \\
&\qquad + \sum_{i=1}^{\nu} \psi_i(t_{i-1}) v_i - \psi_0 \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} d\alpha_{i,L,V}^{(\varepsilon,v)}(s) \\
&\quad - \psi_0 \sum_{i=1}^{\nu} \int_{t_{i-1}}^{t_i} \frac{\partial}{\partial x} L_{q_i}(x_i(t), u_i(t)) \int_{t_{i-1}}^{s} M_i(s, r) d\alpha_{i,f,V}^{(\varepsilon,v)}(r) ds \le 0.
\end{aligned} \tag{4.14}$$

Fix $i \in \{1, \dots, \nu - 1\}$ and a point $(z, z') \in K_i$, where K_i is a Boltyanskiĭ approximating cone to $\mathcal{S}_{q_i,q_{i+1}}$ at the point $(x_i(t_i), x_{i+1}(t_i))$. Let us consider

$$\mathbf{z} = ((0,0), \dots, (z, z'), \dots, (0,0), r)$$

with $r = -\nabla\Phi_{q_i,q_{i+1}}(x_i(t_i), x_{i+1}(t_i)) \cdot (z, z')$. Obviously $\mathbf{z} \in K_P$ and so

$$\psi_i^+ \cdot z + \psi_{i+1}^- \cdot z' - \psi_0 r \geq 0;$$

that is,

$$((\psi_i(t_i), \psi_{i+1}^-) + \psi_0 \nabla\Phi_{q_i,q_{i+1}}(x_i(t_i), x_{i+1}(t_i))) \cdot (z, z') \geq 0$$

and so

$$((-\psi_i(t_i), -\psi_{i+1}^-) - \psi_0 \nabla\Phi_{q_i,q_{i+1}}(x_i(t_i), x_{i+1}(t_i))) \in K_i^\perp, \tag{4.15}$$

where $K_i^\perp$ is the polar of the cone K_i.

Now take a point $(z, z') \in K_\nu$, where K_ν is a Boltyanskiĭ approximating cone to $\mathcal{S}_{q_\nu,q_{\nu+1}}$ at the point $(x_\nu(t_\nu), x_1(t_0))$. Let us consider

$$\mathbf{z} = ((0,0), \dots, (0,0), (z, z'), r)$$

with $r = -\nabla\widetilde{\varphi}_{q_1,q_\nu}(x_\nu(t_\nu), x_1(t_0)) \cdot (z, z')$. Analogously we obtain that

$$((-\psi_\nu(t_\nu), -\psi_1^-) - \psi_0 \nabla\widetilde{\varphi}_{q_\nu,q_1}(x_\nu(t_\nu), x_1(t_0))) \in K_\nu^\perp, \tag{4.16}$$

where $K_\nu^\perp$ is the polar of the cone K_ν.

So we have just proved the following theorem.

THEOREM 4.6 (hybrid necessary principle). *Let $\boldsymbol{X}$ be an optimal trajectory for problem $\mathcal{P}$. For every convex cone $\widehat{K}$ contained in $\cup_{V \in \mathcal{V}} K_V$, where K_V is defined in* (4.13)*, there exist an adjoint pair (ψ, ψ_0) along $\boldsymbol{X}$ and $(\psi_1^-, \dots, \psi_\nu^-) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_\nu}$ such that* (4.14) *holds for every $V \in \mathcal{V}$, $(\varepsilon, v) \in [0, \bar{\varepsilon}] \times K$ such that $D\widetilde{C}_V(0)(\varepsilon, v) \in \widehat{K}$. Moreover,* (4.15) *and* (4.16) *hold.*

Remark 11. Notice that in the previous theorem we have implicitly supposed that the times of switchings are fixed. Obviously it is possible to consider variations of these times as in [27], using a more complicated covector. We obtain analogous necessary conditions that are more complicated and less readable.

Remark 12. If assumption (H) holds and if we can take $(0, \dots, v_i, \dots, 0) \in K$, then from the previous theorem we can obtain the same result as in [27, Theorem 1.4.1].

Appendix. A lemma on integrable functions.

LEMMA A.1. *Let I be a compact interval of $\mathbb{R}$, and let f_n, f be functions of $L^\infty(I)$ such that $\|f_n\|_\infty \leq c < +\infty$ and $f_n \to f$ strongly in $L^1(I)$. Moreover, let g_n be a sequence such that $g_n \rightharpoonup g$ weakly in $L^1(I)$. Then $f_n g_n \rightharpoonup fg$ weakly in $L^1(I)$.*

Proof. Let $\varphi \in L^\infty(I)$. We have to prove that

$$\int_I \varphi(s)(f_n(s)g_n(s) - f(s)g(s))ds \to 0$$

as $n \to +\infty$. We have that

$$\int_I \varphi(s)(f_n(s)g_n(s) - f(s)g(s))ds = \int_I \varphi(s)(f_n(s) - f(s))g_n(s)ds + \int_I \varphi(s)f(s)(g_n(s) - g(s))ds.$$

The last integral goes to 0 since $g_n \rightharpoonup g$. Fix $\varepsilon > 0$. Then we can write

$$\int_I \varphi(s)(f_n(s) - f(s))g_n(s)ds$$
$$= \int_{|f_n - f| \geq \varepsilon} \varphi(s)(f_n(s) - f(s))g_n(s)ds + \int_{|f_n - f| < \varepsilon} \varphi(s)(f_n(s) - f(s))g_n(s)ds.$$

Moreover,

$$\left| \int_{|f_n - f| < \varepsilon} \varphi(s)(f_n(s) - f(s))g_n(s)ds \right| \leq \varepsilon \|\varphi\|_\infty \int_I |g_n(s)|\, ds \leq M\varepsilon,$$

where M is a positive constant. Besides,

$$\left| \int_{|f_n - f| \geq \varepsilon} \varphi(s)(f_n(s) - f(s))g_n(s)ds \right| \leq \|\varphi\|_\infty M_1 \int_{|f_n - f| \geq \varepsilon} |g_n(s)|\, ds$$

with M_1 a positive constant. Since $f_n \to f$ strongly in $L^1(I)$, f_n converges to f in measure. Moreover g_n is equi-integrable by the Dunford–Pettis theorem (see [9]); hence we can find $\bar{n} \in \mathbb{N}$ such that

$$\left| \int_I \varphi(s)(f_n(s) - f(s))g_n(s)ds \right| \leq (M + M_1\|\varphi\|_\infty)\varepsilon$$

for every $n \geq \bar{n}$ and we conclude by the arbitrariness of ε. □

With an analogous proof, which we omit here, we can generalize the previous lemma to the case of Radon measures in the following way.

LEMMA A.2. *Let I be a compact interval of $\mathbb{R}$, and let f_n, f be functions of $C(I)$ such that $f_n \to f$ uniformly on I as $n \to +\infty$. Moreover, let g_n be a sequence in $\mathfrak{M}_b(I)$ such that $g_n \rightharpoonup^* g$ in $\mathfrak{M}_b(I)$, where $g \in \mathfrak{M}_b(I)$. Then $f_n g_n \rightharpoonup^* fg$ in $\mathfrak{M}_b(I)$.*

ASYMPTOTIC CONTROLLABILITY AND ROBUST ASYMPTOTIC STABILIZABILITY*

CHRISTOPHE PRIEUR†

Abstract. This paper deals with asymptotically controllable systems for which there exists no smooth stabilizing state feedback. To investigate the robustness asymptotic stabilization property, a new class of hybrid feedbacks (with a continuous component and a discrete one) is introduced: the hybrid patchy feedbacks. The notion of solutions is a generalization of π-solutions and Euler solutions. It is proved that the origin of all globally asymptotically controllable systems can be globally asymptotically stabilized via a hybrid feedback with robustness with respect to measurement noise, actuator errors, and external disturbances.

Key words. control systems, feedback stabilization, controllability, measurement noise

1. Introduction.

Let us consider the system

$$\dot{x} = f(x, u), \tag{1}$$

assuming that the control set $K \subset \mathbb{R}^m$ is a compact subset of $\mathbb{R}^m$ and that the map $f : \mathbb{R}^n \times K \to \mathbb{R}^n$ is locally Lipschitz in x, uniformly with respect to u, and continuous in u. We focus our study on systems that are asymptotically controllable, i.e., that satisfy, for every initial point x_0 in $\mathbb{R}^n$, there exists a measurable $u : [0, +\infty) \to K$ such that the (Carathéodory) solution of

$$\dot{x} = f(x, u(t)), \qquad x(0) = x_0,$$

is defined for all $t \geq 0$ and tends to the origin as t tends to infinity; and that satisfy a stability property (see Definition 2.5).

The general problem under consideration in this paper is the asymptotic stabilization via state feedback. Let us recall that *asymptotic stabilization* means that the following two properties hold:

- stability of the origin of the closed-loop system and
- convergence to the origin of all the solutions.

There exists a necessary condition [6, Theorem 1, (iii)] for the existence of a continuous control law which makes the origin globally asymptotically stable. But there are asymptotically controllable systems which do not satisfy this necessary condition and hence for which there does not exist a continuous stabilizing feedback [23, 6] (consider, e.g., the so-called Brockett's example).

Therefore we must consider discontinuous controllers to stabilize all asymptotically controllable systems. The first result concerning the use of such controllers is [24], but the author assumes that the system is analytic and completely controllable. The following property is proved in [8]:

*Received by the editors February 23, 2001; accepted for publication (in revised form) July 27, 2004; published electronically March 22, 2005.

($\mathcal{P}$) Any asymptotically controllable systems can be asymptotically stabilized by a discontinuous controller.

The notion of solutions used by the authors is the notion of π-solutions (i.e., solutions with a feedback computed with an arbitrary small sampling schedule) [19]. In [1], the authors prove the property ($\mathcal{P}$) for all Carathéodory solutions by exhibiting a patchy feedback.

The controllers in [8, 1] are robust with respect to actuator and external disturbances (i.e., all systems perturbed by small actuator and external disturbances are asymptotically stable) but are not robust with respect to arbitrary small measurement noise. One way to robustly stabilize the system (1) is to enlarge the class of controllers as in [14], where the authors introduced the notion of a dynamic hybrid controller, which is computed with an external model. This controller compares, at suitable sampling times, the predicted state with the measured state. Due to the measurement noise these can differ substantially; therefore, as remarked in [21], it requires a resetting of the controller which may be difficult to construct. Moreover, with this controller, the origin is a robustly globally asymptotically stable equilibrium for π-solutions only. Here we prove also the existence of a hybrid controller (in the sense that it has a continuous component and a discrete one) which renders the origin a robustly globally asymptotically stable equilibrium for a *larger* class of solutions and, moreover, our feedback does not need a *resetting*.

In [21, 7], the authors proved the existence, for all asymptotically controllable systems, of a controller that is robust with respect to measurement noise and makes the origin of system (1) be a semiglobal *practical* stable equilibrium (i.e., driving all states in a given compact set of initial conditions into a specified neighborhood of the origin). (The case of the state-constraint stabilization is studied separately in [10].) It is proved in [22, section 5.4] that one can get a more general result: one can prove the existence of a sampling feedback making the origin be a robust global asymptotically stable equilibrium for all π-solutions with a sampling rate *sufficiently slow*. We exhibit in this paper a robust global asymptotically stabilizing controller for π-solutions with *any fast enough* sampling schedule, so for a larger class of solutions than those considered in [22].

The main result of this paper is Theorem 2.7: if (1) is asymptotically controllable, then there exists a hybrid feedback which makes the origin be a globally asymptotically stable equilibrium and with robustness with respect to measurement noise, actuator errors, and external disturbances. The class of solutions under consideration in this result includes π-solutions, Euler solutions (i.e., the limit of π-solutions as the sampling schedules tend to zero), and the *generalized* solutions (defined in [11, 12]).

To prove this result, we use some techniques of [1] to deduce from the asymptotic controllability a family of nested patchy vector fields, and we introduce hysteresis between an infinite number of controllers as it is done in [16] for two controllers. This allows us to define a *hybrid patchy feedback*. This gives rise to a hybrid system for which we rewrite the notion of solutions of [5] in the context of π-solutions (see Definition 2.1).

Note that this method was used in [18], where the authors used the special geometry of the chained system in dimension n. (In dimension 3 it is equivalent to the Brockett's example by a change of coordinates.) They exhibit a simple hybrid feedback (with only one discrete variable) making the origin of the chained system be a globally *exponentially* stable equilibrium with a robustness with respect to noise.

The paper is organized as follows. In section 2 we introduce the class of solutions

of a system in closed loop with a hybrid feedback and we state our main result. In section 3 we define the class of hybrid patchy feedbacks and we give properties of π-solutions of systems in closed loop with such a feedback in section 4. Finally we prove our main result in section 5.

2. Definitions and statement of the main result. In this section we make more precise the notions of controller and solutions under consideration.

Let $\mathcal{A}$ be a nonempty totally ordered index set. The controllers under consideration in this paper admit the following description (see [25, 5]):

$$u = u(x, s_d), \qquad s_d = k_d(x, s_d^-), \tag{2}$$

where s_d evolves in the set $\{1,2\}^{\mathcal{A}}$, $u : \mathbb{R}^n \times \{1,2\}^{\mathcal{A}} \to K$ is continuous in x for each fixed s_d, $k_d : \mathbb{R}^n \times \{1,2\}^{\mathcal{A}} \to \{1,2\}^{\mathcal{A}}$ is a function, and s_d^- is defined, at this stage only formally, as

$$s_d^-(t) = \lim_{s<t,\ s\to t} s_d(s). \tag{3}$$

For this to make sense, we equip $\{1,2\}^{\mathcal{A}}$ with the discrete topology, i.e., every set is an open set. We say that the above controller is hybrid because it has a continuous component and a discrete one. Moreover, there is a delay since to evaluate $s_d^-(t)$ at time t, we need to know the past values of $s_d(t)$. Note that time cannot be reversed.

In this paper we are interested in a notion of robustness with respect to small noise. To this end, consider three functions satisfying our *standing regularity assumptions*, i.e.,

- ξ and ζ in $\mathcal{L}^\infty_{loc}(\mathbb{R}^n \times \mathbb{R}_{\geq 0}; \mathbb{R}^n)$ which are continuous in x in $\mathbb{R}^n$ for each t in $\mathbb{R}_{\geq 0}$,
- ψ in $\mathcal{L}^\infty_{loc}(\mathbb{R}^n \times \mathbb{R}_{\geq 0}; \mathbb{R}^m)$ which is continuous in x in $\mathbb{R}^n$ for each t in $\mathbb{R}_{\geq 0}$.

We introduce these functions as a measurement noise ξ, an actuator noise ψ, and an external noise ζ of (1) and study the following perturbed system:

$$\begin{cases} \dot{x}(t) = f(x(t), u(x(t) + \xi(x,t), s_d(t)) + \psi(x,t)) + \zeta(x,t), \\ s_d(t) = k_d(x(t) + \xi(x,t), s_d^-(t)). \end{cases} \tag{4}$$

As noted in [14, Remark 1.4], with the presence of ζ and the continuity of f in u, we can omit any explicit reference to actuator errors. So in the following we suppose that, for all x in $\mathbb{R}^n$ and for all $t \geq 0$, we have

$$\psi(x,t) = 0.$$

We have to clarify what we mean by a solution of the corresponding differential equation. The notion of solution is given in detail in [5] but, here, we want to study the implementation of the controller (2). Therefore we consider π-solutions that have a meaningful physical interpretation: it is an accurate model of the process in computer control. These π-solutions are studied in [8, 21, 15, 22, 13] in the case of an ordinary differential equation. Let π be a sampling schedule of $\mathbb{R}$, i.e., a sequence $(t_n)_{n\in\mathbb{Z}}$ such that, for all n in $\mathbb{Z}$, we have $t_n < t_{n+1}$ and $\lim_{n\to+\infty} t_n = \lim_{n\to-\infty} -t_n = +\infty$. Note that the upper and lower diameters of the sampling schedule are defined by (see [21])

$$\overline{d}(\pi) = \sup_{i\in\mathbb{Z}}(t_{i+1} - t_i), \qquad \underline{d}(\pi) = \inf_{i\in\mathbb{Z}}(t_{i+1} - t_i).$$

We rewrite the notion of solution given in [5] in the context of π-solutions.

DEFINITION 2.1. *Let π be a sampling schedule of $\mathbb{R}$, t_0 in π, $T > t_0$, and $(x_0, s_0) \in \mathbb{R}^n \times \{1,2\}^{\mathcal{A}}$. We say that $(X, S_d) : [t_0, T) \to \mathbb{R}^n \times \{1,2\}^{\mathcal{A}}$ is a* π-solution *of* (4) *on $[t_0, T)$ with initial condition (x_0, s_0) if*

1. *The map X is absolutely continuous on $[t_0, T)$.*
2. *We have, for all t in $[t_0, \min(t_1, T))$,*

$$S_d(t) = S_d(t_0), \tag{5}$$

for all i in $\mathbb{N}_{>0}$ and for all t in $[\min(t_i, T), \min(t_{i+1}, T))$,

$$S_d(t) = k_d(X(t_i) + \xi(X(t_i), t_i), S_d(t_{i-1})). \tag{6}$$

3. *We have, for all i in $\mathbb{N}$ and for almost all t in $[\min(t_i, T), \min(t_{i+1}, T))$,*

$$\dot{X}(t) = f\left(X(t), u(X(t_i) + \xi(X(t_i), t_i), S_d(t_i))\right) + \zeta(X(t), t).$$

4. *We have*

$$X(t_0) = x_0, \qquad S_d(t_0) = k_d(x_0 + \xi(x_0, t_0), s_0). \tag{7}$$

As usual we define Euler solutions as the limits of π-solutions as the sampling schedules tend to zero. More precisely, we have the following definition.

DEFINITION 2.2. *Given t_0 in $\mathbb{R}$, $T > t_0$ and $x_0 \in \mathbb{R}^n$, we say that $X : [t_0, T) \to \mathbb{R}^n$ is an* Euler solution *starting from x_0 of* (4) *on $[t_0, T)$ if, for each compact subinterval J of $[t_0, T)$, there exists a sequence π^n of sampling schedules of $\mathbb{R}$ and a sequence (X^n, S_d^n) of π^n-solutions of* (4) *defined on J such that*

$$\lim_{n \to \infty} \left(\sup_J |X^n - X| + \overline{d}(\pi^n) \right) = 0$$

and such that we have

$$X(t_0) = x_0. \tag{8}$$

Actually we are interested in a notion of solutions which is robust with respect to disturbances. For this reason we introduce a notion of generalized solutions (see [11, 12, 17]).

DEFINITION 2.3. *Let t_0 in $\mathbb{R}$, $T > t_0$ and x_0 in $\mathbb{R}^n$. We say that $X : [t_0, T) \to \mathbb{R}^n$ is a* generalized solution *starting from x_0 of* (4) *if we have* (8) *and if, for each J compact subinterval of $[t_0, T)$, there exist two sequences $(e^n)_{n \in \mathbb{N}}$ and $(d^n)_{n \in \mathbb{N}}$ of measurable functions $[t_0, +\infty) \to \mathbb{R}^n$ and a sequence $(X^n, S_d^n)_{n \in \mathbb{N}}$ of π-solutions of*

$$\begin{cases} \dot{x}(t) = f(x(t), u(x(t) + \xi(x(t), t), s_d(t)) + \zeta(x, t) + d^n(t), \\ s_d(t) = k_d(x(t) + \xi(x, t) + e^n(t), s_d^-(t)) \end{cases} \tag{9}$$

such that we have

$$\lim_{n \to +\infty} \left(\sup_J |X^n - X| + \sup_J |e^n| + \operatorname*{esssup}_J |d^n| \right) = 0. \tag{10}$$

By invoking Zorn's lemma exactly as in the proof of [20, Proposition 1], one can prove that every π-solution can be extended to a maximal solution. More precisely, we define the maximal extension taking account of all sufficiently fast sampling schedules π of $[0, +\infty)$.

DEFINITION 2.4. *Let t_0 in $\mathbb{R}$, $T > t_0$, (x_0, s_0) in $\mathbb{R}^n \times \{1,2\}^{\mathcal{A}}$ and $d_0 > 0$. We say that $(X, S_d) : [t_0, T) \to \mathbb{R}^n \times \{1,2\}^{\mathcal{A}}$ is a* d_0-maximal solution *starting from (x_0, s_0) of (4) on $[t_0, T)$, if the following properties hold:*

- *For all $T' < T$, there exists a sampling schedule π of $[0, +\infty)$ such that*

$$\overline{d}(\pi) \leq d_0 \tag{11}$$

and such that (X, S_d) is a π-solution starting from x_0 of (4) on $[t_0, T')$.

- *For all $T' > T$ and for all sampling schedules π of $[0, +\infty)$ such that (11), there does not exist any π-solution (X', S'_d) starting from (x_0, s_0) and defined on $[t_0, T')$ such that the restriction of (X', S'_d) to $[t_0, T)$ is (X, S_d).*

We say that $X : [t_0, T) \to \mathbb{R}^n$ is a maximal Euler solution *starting from x_0 of (4) on $[t_0, T)$ if the following properties hold:*

- *For all $T' < T$, X is an Euler solution starting from x_0 of (4) on $[t_0, T')$.*
- *For all $T' > T$, there does not exist any Euler solution X' starting from x_0 of (4) on $[t_0, T')$ such that the restriction of X' to $[t_0, T)$ is X.*

We say that $X : [t_0, T) \to \mathbb{R}^n$ is a d_0-maximal generalized solution *starting from x_0 of (4) on $[t_0, T)$ if the following properties hold:*

- *For all $T' < T$, X is a generalized solution obtained as limit of π-solutions whose sampling schedule satisfies (11) starting from x_0 of (4) on $[t_0, T')$.*
- *For all $T' > T$, there does not exist any generalized solution X' obtained as limit of π-solutions whose sampling schedule satisfies (11) starting from x_0 of (4) on $[t_0, T')$ and such that the restriction of X' to $[t_0, T)$ is X.*

Let us recall that a function of class $\mathcal{K}_\infty$ is a function $\delta : [0, +\infty) \to [0, +\infty)$ which is continuous, strictly increasing, satisfying $\delta(0) = 0$ and $\lim_{\varepsilon \to +\infty} \delta(\varepsilon) = +\infty$. In the following we denote the closed ball centered at $x \in \mathbb{R}^n$ with radius $r > 0$ by $B(x, r)$. In our context our definition of robust global asymptotic stability is as follows (see [3]).

DEFINITION 2.5. *The origin is said to be a* robustly globally asymptotically stable equilibrium *of the system (4) if the following properties hold:*

1. Existence of solutions: *For all $C > 0$, there exists $\chi_0 = \chi_0(C) > 0$ such that for all ξ, ζ satisfying our regularity assumptions and such that*

$$\sup_{x \in \mathbb{R}^n,\, t \geq 0} |\xi(x,t)| \leq \chi_0, \qquad \operatorname*{esssup}_{x \in \mathbb{R}^n,\, t \geq 0} |\zeta(x,t)| \leq \chi_0, \tag{12}$$

for all (x_0, s_0) in $B(0, C) \times \{1,2\}^{\mathcal{A}}$, and for all sampling schedules π of $\mathbb{R}$, there exists a π-solution of (4) (resp., an Euler solution, resp., a generalized solution) starting from (x_0, s_0) (resp., starting from x_0) at $t_0 = 0$.

2. Completeness: *Moreover, there exists $d_0 = d_0(C)$ such that all the d_0-maximal solutions (resp., maximal Euler solutions, resp., d_0-maximal generalized solutions) of (4) are defined on $[0, +\infty)$.*

3. Global stability: *There exists δ of class $\mathcal{K}_\infty$ such that, for all $\varepsilon > 0$, there exist $\chi_0 = \chi_0(\varepsilon) > 0$ and $d_0 = d_0(\varepsilon) > 0$ such that, for all ξ, ζ satisfying our regularity assumptions and (12), for all (x_0, s_0) in $B(0, \delta(\varepsilon)) \times \{1,2\}^{\mathcal{A}}$, and for every d_0-maximal solution (X, S_d) of (4) (resp., maximal Euler solution X, resp., d_0-maximal generalized solution) starting from (x_0, s_0) (resp., starting from x_0) at $t_0 = 0$, one has*

$$X(t) \in B(0, \varepsilon) \quad \forall t \geq 0. \tag{13}$$

4. Global attractivity: *For all $\varepsilon > 0$ and for all $C > 0$, there exist $T > 0$, $\chi_0 > 0$, and $d_0 > 0$ such that, for all ξ, ζ satisfying our regularity assumptions and* (12)*, for each (x_0, s_0) in $B(0, C) \times \{1, 2\}^{\mathcal{A}}$, and for d_0-every maximal solution (X, S_d) of* (4) *(resp., maximal Euler solution X, resp., d_0-maximal generalized solution) starting from (x_0, s_0) (resp., starting from x_0) at $t_0 = 0$, one has*

$$X(t) \in B(0, \varepsilon) \quad \forall t \geq T. \tag{14}$$

We recall the definition of global asymptotic controllability of the system (1).

DEFINITION 2.6. *The system* (1) *is said to be* globally asymptotically controllable to the origin *if the following properties hold:*

1. *For each x_0 in $\mathbb{R}^n$, there exists an admissible control u_0 (i.e., a measurable function $[0, +\infty) \to K$) such that the maximal Carathéodory solution X starting from x_0 of*

$$\dot{x} = f(x, u_0) \tag{15}$$

is defined for all $t \geq 0$ and satisfies $X(t) \to 0$ as $t \to +\infty$.

2. *For each $\varepsilon > 0$ there exists $C > 0$ such that for each x_0 in $B(0, C)$, there is an admissible control u_0 as in* 1 *such that*

$$X(t) \in B(0, \varepsilon) \quad \forall t \geq 0.$$

Our main result is as follows.

THEOREM 2.7. *Let* (1) *be a globally asymptotically controllable system to the origin. Then there exists a feedback control, $u : \mathbb{R}^n \times \{1, 2\}^{\mathbb{N}} \to K$, $k_d : \mathbb{R}^n \times \{1, 2\}^{\mathbb{N}} \to \{1, 2\}^{\mathbb{N}}$ such that the origin is a robustly globally asymptotically stable equilibrium for the system* (4).

Remark 2.8.

1. Note that in Theorem 2.7 we have the robust global asymptotic stability for π-solutions for *any fast enough* sampling rate since the only constraint on the sampling schedule is (11).

In [21, 7], only for the π-solutions with a sampling rate *sufficiently slow* are considered since, in these papers, it is assumed moreover that the lower diameters of the sampling schedules have a strictly positive lower bound.

See in particular the assumption in [21, Theorem 1],

$$|\xi(t)| \leq \underline{d}(\pi) \quad \forall t \geq 0. \tag{16}$$

Thus the class of solutions under consideration in Theorem 2.7 is *larger* than those considered in [21, 7].

Let us compare (12) and the inequality (16). Given a sampling schedule whose lower diameter is close to zero, this restriction forces the measurement noise to be close to zero. In our context the measurement noise and the lower diameter are completely independent.

Note that the controller given by [21] is not robust with respect to noise which does not satisfy (16) (consider the example of Artstein's circles). See also the discussion given in [22, section 4].

2. Note that Theorem 2.7 is false if in (12) the supremum *sup* is relaxed by *esssup*. See [17, Theorem 4.2], where it is proved, in an analogous situation, that there exists a noise ξ such that $\operatorname{esssup} |\xi| = 0$, $\sup |\xi| \neq 0$ and such that the origin of the perturbed closed-loop system is not an attractive equilibrium.

To prove Theorem 2.7 we need to introduce a class of hybrid patchy feedbacks (see section 3) whose continuous component is derived from a family of nested patchy vector fields (a slight generalization of patchy vector fields defined in [1]) and whose discrete component allows us to unite vector fields, as done in [17] for two vector fields, with robustness with respect to noise. Then we give basic properties of π-solutions of system (1) with a hybrid patchy feedback in section 4 and we prove Theorem 2.7 in section 5.

3. Definition of the hybrid patchy feedbacks. Let Ω be a nonempty open connected subset of $\mathbb{R}^n$. The closure, the interior, and the boundary of Ω are written as $\mathrm{clos}(\Omega)$, $\mathrm{int}(\Omega)$, and $\partial\Omega$, respectively. We define the set $\mathcal{F} = \{1, \dots, 7\}$. Let $\mathcal{A}$ be a nonempty totally ordered index set. Given a set-valued map $F : \mathbb{R}^n \to 2^{\mathbb{R}^n}$, we can define the solutions X of the differential inclusion

$$\dot{x} \in F(x)$$

as all absolutely continuous functions satisfying $\dot{X}(t) \in F(X(t))$ almost everywhere. We follow the ideas of [1, Definition 2.1], but we extend the definition to allow nested sets (as in [16]).

DEFINITION 3.1. *We say that* $(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$ *is a* family of nested patchy vector fields *if*

1. *for all* $(\alpha, l) \in \mathcal{A} \times \mathcal{F}$; $\Omega_{\alpha,l}$ *is an open bounded subset of* $\mathbb{R}^n$,
2. *for all* $\alpha \in \mathcal{A}$ *and for all* $m > l \in \mathcal{F}$

$$\Omega_{\alpha,l} \subsetneq \mathrm{clos}(\Omega_{\alpha,l}) \subsetneq \Omega_{\alpha,m}; \tag{17}$$

3. *for all* α *in* $\mathcal{A}$, g_α *is a smooth vector field defined in a neighborhood of* $\mathrm{clos}(\Omega_{\alpha,7})$ *taking values in* $\mathbb{R}^n$;
4. *for all compact subsets* C *of* $\mathbb{R}^n$, *there exist* $r = r(C) > 0$ *and* $T = T(C) > 0$ *such that for all* $(\alpha, l) \in \mathcal{A} \times \mathcal{F}$ *satisfying* $\Omega_{\alpha,l} \subset C$, *all solutions* X *of*

$$\dot{x} \in g_\alpha(x) + B(0, r) \tag{18}$$

starting in $\partial\Omega_{\alpha,l} \setminus \bigcup_{\beta>\alpha} \Omega_{\beta,1}$ *are such that*

$$X(t) \in \mathrm{clos}(\Omega_{\alpha,l}) \quad \forall t \in [0, T].$$

5. *The sets* $(\Omega_{\alpha,1})_{\alpha\in\mathcal{A}}$ *form a locally finite covering of* Ω.

Remark 3.2. Some observations are in order.

- Roughly speaking, property 4 states that a part of $\mathrm{clos}(\Omega_{\alpha,l})$ is positively invariant in $[0, T]$ relative to the system (18). Note that we can characterize this property in terms of proximal normal by [9, Theorem 4.3.8] and we can redefine the notion of the patchy vector fields by using this concept of nonsmooth analysis as done in [4].
- On the one hand, given any compact set C, the positive real number $r(C)$ allows us to get robustness with respect to external disturbances. On the other hand, the gap between the different patches given by (17) allow us to get robustness with respect to measurement noise. See Definition 3.7 for a precise statement of admissible radius of measurement noise and external disturbances.
- Let us explain shortly why, to state our main result, we need to consider a family of seven nested patchy vector fields. Patches 2 and 6 define the dynamics of the discrete component of our hybrid controller (see Definition 3.4). Due to the

measurement noise, the switches (this notion will be precisely introduced in Definition 4.1) of the discrete variable can be located only in a neighborhood of Ω_2 and Ω_6 which are described by patches 1-3 and 5-7 (see Lemma 4.2). Patch 4 is only needed to describe π-solutions after the first switch (see Lemma 4.11). These seven patches are enough to state our main result and we show, for Artstein's circles, that we need to use so many patches (see Example 4.10).

EXAMPLE 3.3. *Let us give an example of such a family of nested patchy vector fields.*

We can construct a family of nested patchy vector fields for Artstein's circles. This system is one of the simplest which is not stabilizable by a continuous feedback and which admits a (nonrobust) discontinuous stabilizing feedback. This system is studied in several papers (see, e.g., [2, 21, 22, 16]*) and is defined by*

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} -x_1^2 + x_2^2 \\ -2x_1x_2 \end{pmatrix}. \tag{19}$$

The integral curves of (19) *are*

- *the origin,*
- *the circles centered on the x_2-axis and tangent to the x_1-axis,*
- *the x_1-axis.*

Let us define the three smooth vector fields g_a, g_b, and $g_c : \mathbb{R}^2 \to \mathbb{R}^2$ by

$$\begin{aligned} g_a(x_1, x_2) &= (-x_1^2 + x_2^2, -2x_1x_2)', \\ g_b(x_1, x_2) &= -g_a(x_1, x_2), \\ g_c(x_1, x_2) &= (0, 0). \end{aligned}$$

Let θ be in $\mathbb{R}$ the polar angle of a point $(x_1, x_2) \neq (0, 0)$. For all l in $\mathcal{F}$, let us define the open bounded sets $\Omega_{a,l}$, $\Omega_{b,l}$, and $\Omega_{c,l} \subset \mathbb{R}^2$ by

$$\begin{aligned} \Omega_{a,l} = &\left\{ x \in \mathbb{R}^2, -\frac{3\pi}{4} - \frac{l\pi}{30} < \theta < \frac{3\pi}{4} l + \frac{l\pi}{30} \right\} \cap \left\{ |x| > 1 - \frac{l}{14} \right\} \\ &\cap \left\{ \left(x_1 < 0 \text{ and } x_1^2 + \left(x_2 - 10 - \frac{l}{14} \right)^2 < \left(10 + \frac{l}{14} \right)^2 \right) \right. \\ &\qquad \left. \text{or } \left(x_1 \geq 0 \text{ and } x_1^2 + x_2^2 < \left(20 + \frac{l}{7} \right)^2 \right) \right\}, \\ \Omega_{b,l} = &\operatorname{sym}_{x_2}(\Omega_{a,l}), \\ \Omega_{c,l} = &\left\{ x \in \mathbb{R}^2, |x| < 1 + \frac{l}{7} \right\}, \end{aligned}$$

where sym_{x_2} is the symmetry with respect to the x_2-axis. Let $\mathcal{A} = \{a, b, c\}$ be lexicographically ordered ($a < b < c$) and $\Omega = \operatorname{int}(B(0, 10))$. It is easy to prove that

$$\left(\Omega, \left((\Omega_{\alpha,l})_{l \in \mathcal{F}}, g_\alpha \right)_{\alpha \in \mathcal{A}} \right) \tag{20}$$

is a family of nested patchy vector fields. This is depicted in Figure 3.1*. To make the figure clearer, only two open sets and some values of the vector field g_a are shown.*

With such a family of nested patchy vector fields, we can define a class of hybrid controllers as those considered in section 2. To do this, we denote for all $s_d \in \{1, 2\}^{\mathcal{A}}$ the αth element of s_d by $s_{d,\alpha}$.

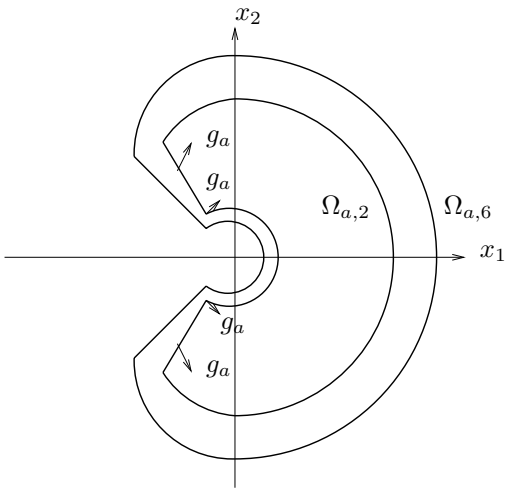

FIG. 3.1. *Artstein's circles as a family of nested patchy vector fields.*

DEFINITION 3.4. *Let* $(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$ *be a family of nested patchy vector fields. Assume that for each* α *in* $\mathcal{A}$*, we can find a point* k_α *in* K *such that for each* x *in* $\Omega_{\alpha,7}$*, we have*

$$g_\alpha(x) = f(x, k_\alpha). \tag{21}$$

Let k_0 *be an arbitrary point in* K*. Let* (u, k_d) *be the map defined by*

$$\begin{array}{rcll} u : \{1,2\}^{\mathcal{A}} & \to & K, & \\ s_d & \mapsto & k_0 & \text{if } \{\beta \in \mathcal{A},\ s_{d,\beta} = 1\} \text{ is empty or infinite,} \\ & & k_\alpha & \text{if } \alpha = \max\{\beta \in \mathcal{A}, s_{d,\beta} = 1\}, \end{array} \tag{22}$$

and

$$\begin{array}{rcl} k_d : \mathbb{R}^n \times \{1,2\}^{\mathcal{A}} & \to & \{1,2\}^{\mathcal{A}}, \\ (x, s_d) & \mapsto & t_d, \end{array} \tag{23}$$

where t_d *is the sequence defined, for all* α *in* $\mathcal{A}$*, by*

$$\begin{array}{rl} t_{d,\alpha} = 1 & \text{if } x \in \operatorname{clos}(\Omega_{\alpha,2}), \\ t_{d,\alpha} = s_{d,\alpha} & \text{if } x \in \Omega_{\alpha,6} \setminus \operatorname{clos}(\Omega_{\alpha,2}), \\ t_{d,\alpha} = 2 & \text{if } x \notin \Omega_{\alpha,6}. \end{array} \tag{24}$$

We say that (u, k_d) *is a* hybrid patchy feedback *on* Ω*.*

Remark 3.5. This hybrid controller takes advantage of the existence of regions where different controllers k_α exist and, roughly speaking, allows the hybrid variable to choose between the different controllers. This is the main idea of the hysteresis as done in [17] to unite two controllers. Moreover, for any s_d in $\{1,2\}^{\mathcal{A}}$, the function $k_d(., s_d)$ is continuous except on the boundary of the sets defining the hysteresis. This remark is very helpful in particular to establish Lemma 4.2.

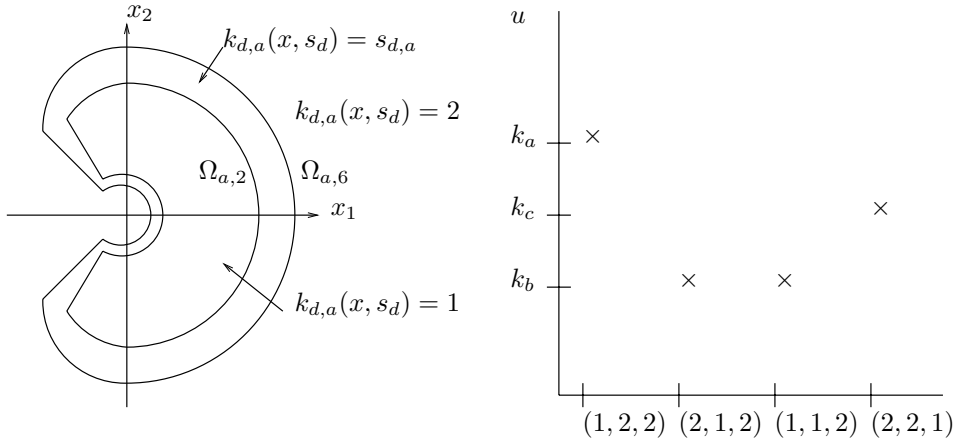

FIG. 3.2. *A hybrid patchy feedback. On the left is the $k_{d,a}$-component and on the right is the u-component.*

EXAMPLE 3.6. *Let us use the family of nested patchy vector fields* (20) *to define a hybrid patchy feedback for Artstein's circles.*

Let us define the controlled Artstein's circles by

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} u(-x_1^2 + x_2^2) \\ -2ux_1x_2 \end{pmatrix} = f((x_1, x_2), u) \tag{25}$$

with u in $\mathbb{R}$. We remark that by denoting $k_a = 1$, $k_b = -1$, and $k_c = 0$, we have (21) *and thus we can define a hybrid patchy feedback, depicted in Figure* 3.2. *The $k_{d,a}$ component is on the left and the u-component (for some values) is on the right.*

Given a family of nested patchy vector fields $(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$ it is easy to check from Definition 3.1 that for all x in $\mathbb{R}^n$, the set $C_x \subset \mathbb{R}^n$ defined by

$$C_x = \operatorname{clos}\left(\bigcup_{\alpha\in\mathcal{A},\ x\in\Omega_{\alpha,7}} \Omega_{\alpha,7} \right) \tag{26}$$
