TOPOLOGICAL SENSITIVITY AND SHAPE OPTIMIZATION FOR THE STOKES EQUATIONS*

PH. GUILLAUME† AND K. SID IDRIS†

Abstract. The topological sensitivity analysis provides an asymptotic expansion of a shape function with respect to the insertion of a small hole or obstacle inside a domain. This expansion can then be used for shape optimization. In this paper, such an expansion is obtained for the Stokes equations with general shape functions and arbitrarily shaped holes. A numerical example illustrates the use of the topological sensitivity in a shape optimization problem.

1. Introduction.

The topological sensitivity analysis consists of studying the variation of a cost function with respect to a modification of the topology of a domain. It is a basic tool for topological shape optimization, in that it provides a "descent direction" for updating the shape of the domain. In this paper, we consider the case of the Stokes equations. The shape optimization problem consists of minimizing a function $j(\Omega) = J(\Omega, u_\Omega)$ where the solution u_Ω to the Stokes equations (2.1) is defined on a variable open and bounded subset Ω of $\mathbb{R}^n$. For $\varepsilon > 0$, let $\Omega_\varepsilon = \Omega \backslash (\overline{x_0 + \varepsilon\omega})$ be the subset obtained by inserting a small obstacle $\overline{x_0 + \varepsilon\omega}$ into Ω, where $x_0 \in \Omega$ and $\omega \subset \mathbb{R}^n$ is a fixed open and bounded subset containing the origin. Then, an asymptotic expansion of function j is obtained in the following form:

$$j(\Omega_\varepsilon) = j(\Omega) + \varepsilon \delta j(x_0) + o(\varepsilon).$$

The "topological sensitivity" $\delta j(x_0)$ provides information for inserting a small obstacle at x_0: if $\delta j(x_0) < 0$, then $j(\Omega_\varepsilon) < j(\Omega)$ for small ε. More generally, function δj can be used like a descent direction in an optimization process. The step length then consists of choosing the size of the obstacle which is added, located where $\delta j(x)$ is the most negative. For example, in the case of a circular obstacle and $n = 3$, if the cost function involves u_Ω but not Du_Ω, then the first variation of function j reads

$$j(\Omega_\varepsilon) = j(\Omega) + 6\pi\nu\varepsilon\, u_\Omega(x_0).v_\Omega(x_0) + o(\varepsilon),$$

where v_Ω is the adjoint state (see Proposition 4.3). It is interesting to observe that the resulting optimality condition $u_\Omega.v_\Omega \geq 0$ is almost the same as the one given by Buttazzo and Dal Maso [4] in the case of the Laplace equation. When the cost function involves Du_Ω, there is an additional term (see Proposition 4.4).

An asymptotic theory for partial differential equations defined on a singular perturbed domain has been developed by several authors; see, for example, [12]. In the context of shape optimization, the topological sensitivity was introduced by Schumacher [14] followed by Sokolowski and Zochowski [15], who studied the effect of

removing a small part of material in structural mechanics. A topological sensitivity framework using an adaptation of the adjoint method [5] and a truncation technique was then introduced by Masmoudi [11] in the case of the Laplace equation with a circular hole and a Dirichlet condition on the boundary of the hole. It was generalized in [9] to the elasticity equations in the case of arbitrarily shaped holes and a Neumann boundary condition. In [10], we have analyzed the case of Poisson's Equation with noncircular holes (with a Dirichlet boundary condition), arbitrary right-hand sides, and cost functions. These results are generalized here to the Stokes equations which have some similar properties: in the three-dimensional case, one observes that the topological sensitivity $\delta j(x_0)$ depends on the shape of the obstacle, whereas it is independent of the shape in the two-dimensional case. This comes from the Stokes paradox, and was already observed by Allaire [1] in the case of periodically distributed holes. There is, however, a difference with Poisson's equation in the three-dimensional case: in the Stokes equations, the topological sensitivity $\delta j(x_0)$ may also depend on the orientation of the obstacle, whereas it was independent of the orientation in the (scalar) Poisson's equation.

First, the formulation of the problem is presented in section 2, and its truncated version is described in section 3. Section 4 presents the main results whose proofs are given in section 6. In the case of a circular obstacle, explicit expressions of the topological sensitivity are given for Dirichlet boundary conditions and for dimensions $n = 2$ or 3. Finally, numerical examples in section 5 illustrate the use of the topological sensitivity in shape optimization.

2. Formulation of the problem. Let Ω be an open and bounded subset of $\mathbb{R}^n$ with boundary Γ, $n = 2$ or 3. The Stokes equations [16] with homogeneous Dirichlet boundary conditions read

$$\left\{\begin{array}{rl} -\nu\Delta u_\Omega + \nabla p_\Omega = f & \text{in } \Omega, \\ \operatorname{div} u_\Omega = 0 & \text{in } \Omega, \\ u_\Omega = 0 & \text{on } \Gamma, \end{array}\right. \tag{2.1}$$

with $\nu > 0$. The case of an inhomogeneous boundary condition on Γ can be treated in a similar way by using a suitable change of the unknown velocity field, of the form $u_\Omega^r = u_\Omega + \mu$, where μ satisfies the given boundary condition. We suppose throughout this paper that $f \in L^q(\Omega)^n$ with $q > n/2$. These equations have a unique solution in $H_0^1(\Omega)^n \times L^2(\Omega)/\mathbb{R}$, and due to the regularity of f, the velocity field u_Ω is continuous in Ω [16, 3]. For a given $x_0 \in \Omega$, consider the modified open subset $\Omega_\varepsilon = \Omega \backslash \overline{\omega_\varepsilon}$, $\omega_\varepsilon = x_0 + \varepsilon\omega$, where ω is a fixed open and bounded subset of $\mathbb{R}^n$ containing the origin ($\omega_\varepsilon = \emptyset$ if $\varepsilon = 0$), whose boundary $\partial\omega$ is connected and piecewise of class $\mathcal{C}^1$ (cf. Figure 1). It is supposed that ε is small enough so that $\overline{\omega_\varepsilon} \subset \Omega$. The modified solution u_{Ω_ε}, p_{Ω_ε} satisfies

$$\left\{\begin{array}{rl} -\nu\Delta u_{\Omega_\varepsilon} + \nabla p_{\Omega_\varepsilon} = f & \text{in } \Omega_\varepsilon, \\ \operatorname{div} u_{\Omega_\varepsilon} = 0 & \text{in } \Omega_\varepsilon, \\ u_{\Omega_\varepsilon} = 0 & \text{on } \Gamma \cup \partial\omega_\varepsilon. \end{array}\right. \tag{2.2}$$

Note that for $\varepsilon = 0$, one has $u_{\Omega_0} = u_\Omega$ and $p_{\Omega_0} = p_\Omega$.

Consider now a cost function $j(\varepsilon)$ of the form

$$j(\varepsilon) = \widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) \tag{2.3}$$

where $\widetilde{J}_\varepsilon$ is defined on $H_0^1(\Omega_\varepsilon)^n$ for $\varepsilon \geq 0$. We aim to obtain an asymptotic expansion of j with respect to ε. The velocity field u_{Ω_ε} is defined on the variable open subset Ω_ε;

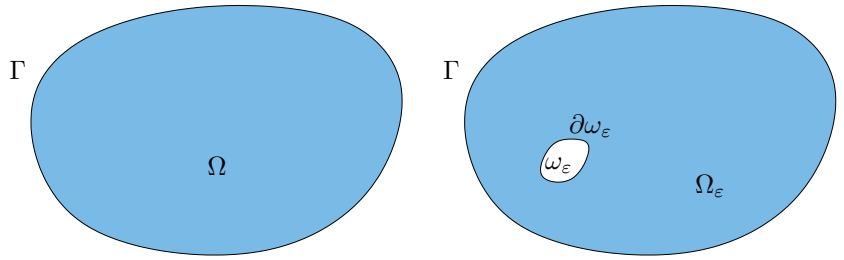

FIG. 1. *The initial domain and the same domain after inclusion of an obstacle.*

thus it belongs to a functional space which depends on ε. In order to obtain an asymptotic expansion of j, we need to work on a fixed functional space (cf. Lemma 6.1). Such a functional space can be constructed by using the domain truncation technique described in the next section (see also [11] and [9]). This truncation is needed only for analysis, and will never be used for practical computations. During the optimization process, the two systems which have to be solved at each step are (2.1) and (4.14).

3. The truncated problem. Let $R > 0$ be such that the closed ball $\overline{B}(x_0, R)$ is included in Ω. The truncated open subset Ω_R and D_ε (cf. Figure 2) are defined by

$$\Omega_R = \Omega \backslash \overline{B}(x_0, R), \quad D_\varepsilon = B(x_0, R) \backslash \overline{\omega_\varepsilon}.$$

Let Γ_R be the boundary of the ball $B(x_0, R)$. We will use the following space of traces on Γ_R:

$$H_V^{1/2}(\Gamma_R)^n = \left\{ \varphi \in H^{1/2}(\Gamma_R)^n ; \int_{\Gamma_R} \varphi . \mathbf{n} \, d\gamma(x) = 0 \right\}, \tag{3.1}$$

where $d\gamma(x)$ denotes the Lebesgue measure on the boundary. The normal $\mathbf{n}$ is chosen outward to D_ε on Γ_R and $\partial\omega_\varepsilon$, regardless of whether D_ε or Ω_R are considered. The dual space of $H_V^{1/2}(\Gamma_R)^n$ is denoted $H_V^{-1/2}(\Gamma_R)^n$. Here $x.y$ denotes the usual dot product of $\mathbb{R}^n$.

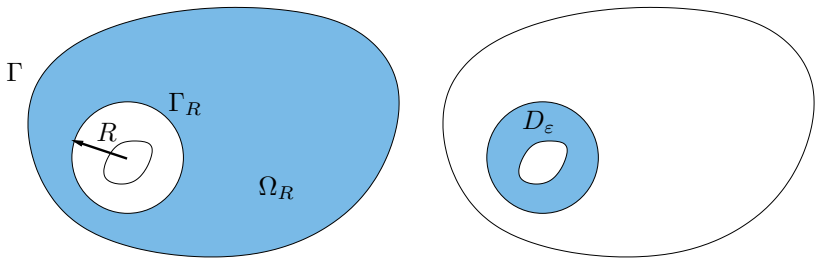

FIG. 2. *The truncated domain.*

For $\varphi \in H_V^{1/2}(\Gamma_R)^n$ and $\varepsilon > 0$, let $(u_\varepsilon^{f,\varphi}, p_\varepsilon^{f,\varphi}) \in H^1(D_\varepsilon)^n \times L_0^2(D_\varepsilon)$ be the solution to the following problem: find $u_\varepsilon^{f,\varphi}$, $p_\varepsilon^{f,\varphi}$ such that

$$\left\{ \begin{array}{rcl} -\nu\Delta u_\varepsilon^{f,\varphi} + \nabla p_\varepsilon^{f,\varphi} = f & \text{in} & D_\varepsilon, \\ \operatorname{div} u_\varepsilon^{f,\varphi} = 0 & \text{in} & D_\varepsilon, \\ u_\varepsilon^{f,\varphi} = \varphi & \text{on} & \Gamma_R, \\ u_\varepsilon^{f,\varphi} = 0 & \text{on} & \partial\omega_\varepsilon. \end{array} \right. \tag{3.2}$$

As usual, the space $L^2(D_\varepsilon)/\mathbb{R}$ is identified to $L^2_0(D_\varepsilon) = \{p \in L^2(D_\varepsilon)\,;\, \int_{D_\varepsilon} p\,dx = 0\}$. This problem has a unique solution [16]. For $\varepsilon = 0$, $(u_0^{f,\varphi}, p_0^{f,\varphi})$ is the solution to

$$\left\{\begin{array}{rcl} -\nu\Delta u_0^{f,\varphi} + \nabla p_0^{f,\varphi} = f & \text{in} & D_0, \\ \operatorname{div} u_0^{f,\varphi} = 0 & \text{in} & D_0, \\ u_0^{f,\varphi} = \varphi & \text{on} & \Gamma_R. \end{array}\right. \tag{3.3}$$

Clearly we have

$$u_\varepsilon^{f,\varphi} = u_\varepsilon^{f,0} + u_\varepsilon^{0,\varphi}, \quad p_\varepsilon^{f,\varphi} = p_\varepsilon^{f,0} + p_\varepsilon^{0,\varphi}. \tag{3.4}$$

For $\varepsilon \geq 0$, the Dirichlet-to-Neumann operator T_ε is defined by

$$\begin{array}{rcl} T_\varepsilon : H_V^{1/2}(\Gamma_R)^n & \longrightarrow & H_V^{-1/2}(\Gamma_R)^n, \\ \varphi & \longmapsto & T_\varepsilon\varphi = (\nu Du_\varepsilon^{0,\varphi} - p_\varepsilon^{0,\varphi} I)\mathbf{n}; \end{array}$$

that is,

$$\langle T_\varepsilon\varphi, \psi\rangle_{-1/2,1/2} = \nu \int_{D_\varepsilon} Du_\varepsilon^{0,\varphi} : Du_\varepsilon^{0,\psi}\,dx. \tag{3.5}$$

Here and in what follows, I denotes the identity matrix, $A : B = \sum_{ij} A_{ij}B_{ij}$ for $A,\ B \in \mathcal{M}_n(\mathbb{R})$, and $Du = (\partial_j u_i)_{i,j=1,n}$ denotes the Jacobian matrix of u. One can observe that $T_\varepsilon\varphi$ is completely determined by $u_\varepsilon^{0,\varphi}$.

Function $f_\varepsilon \in H_V^{-1/2}(\Gamma_R)^n$ is defined by

$$f_\varepsilon = (-\nu Du_\varepsilon^{f,0} + p_\varepsilon^{f,0} I)\mathbf{n};$$

that is,

$$\langle f_\varepsilon, \psi\rangle_{-1/2,1/2} = \int_{D_\varepsilon} f.u_\varepsilon^{0,\psi}\,dx. \tag{3.6}$$

Notice that

$$\int_{D_\varepsilon} Du_\varepsilon^{f,0} : Du_\varepsilon^{0,\psi}\,dx = 0. \tag{3.7}$$

Hence, we have

$$(\nu Du_\varepsilon^{f,\varphi} - p_\varepsilon^{f,\varphi} I)\mathbf{n} = T_\varepsilon\varphi - f_\varepsilon.$$

For $\varepsilon \geq 0$, we can now define the solution $(u_\varepsilon,\, p_\varepsilon) \in H^1(\Omega_R)^n \times L^2(\Omega_R)$ to the truncated problem

$$\left\{\begin{array}{rcl} -\nu\Delta u_\varepsilon + \nabla p_\varepsilon = f & \text{in} & \Omega_R, \\ \operatorname{div} u_\varepsilon = 0 & \text{in} & \Omega_R, \\ u_\varepsilon = 0 & \text{on} & \Gamma, \\ -(\nu Du_\varepsilon - p_\varepsilon I)\mathbf{n} + T_\varepsilon u_\varepsilon = f_\varepsilon & \text{on} & \Gamma_R. \end{array}\right. \tag{3.8}$$

The associated variational formulation is as follows: find $u_\varepsilon \in \mathcal{V}_R$ such that

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \qquad \forall v \in \mathcal{V}_R, \tag{3.9}$$

where the functional space $\mathcal{V}_R$, the bilinear form a_ε, and the linear form l_ε are defined by

$$\mathcal{V}_R = \left\{ u \in H^1(\Omega_R)^n;\ \operatorname{div} u = 0,\ u = 0 \text{ on } \Gamma \right\},$$

$$a_\varepsilon(u,v) = \nu \int_{\Omega_R} Du : Dv\ dx + \int_{\Gamma_R} T_\varepsilon u.v\ d\gamma(x), \tag{3.10}$$

$$l_\varepsilon(v) = \int_{\Omega_R} f.v\ dx + \int_{\Gamma_R} f_\varepsilon.v\ d\gamma(x). \tag{3.11}$$

Symmetry, continuity, and coercivity of a_ε and continuity of l_ε follow directly from (3.5) and (3.6). We suppose that the pressure p_{Ω_ε} solution to (2.2) is chosen in such a way that $\int_{D_\varepsilon} p_{\Omega_\varepsilon}\ dx = 0$. Recall that $f \in L^q(\Omega)^n$ with $q > n/2$.

PROPOSITION 3.1. *Let $\varepsilon \geq 0$. Problems* (2.2) *and* (3.8) *have a unique solution. Moreover, the restriction to Ω_R of the solution u_{Ω_ε}, p_{Ω_ε} to* (2.2) *is the solution u_ε, p_ε to* (3.8)*, and we have on D_ε*

$$(u_{\Omega_\varepsilon})_{|D_\varepsilon} = u_\varepsilon^{f,\varphi}, \quad (p_{\Omega_\varepsilon})_{|D_\varepsilon} = p_\varepsilon^{f,\varphi}, \tag{3.12}$$

where φ is the trace of u_ε on Γ_R.

Proof. Problem (2.2) has a unique solution u_{Ω_ε} [16], and it follows from Lax–Milgram's theorem and [16] that Problem (3.8) has a unique solution u_ε. Let $\varphi = (u_{\Omega_\varepsilon})_{|\Gamma_R}$ and $u_R = (u_{\Omega_\varepsilon})_{|\Omega_R}$. Clearly (3.12) holds for this φ, and it remains to prove that $u_R = u_\varepsilon$. Let $v \in \mathcal{V}_R$ and $\psi = v_{|\Gamma_R}$. Its extension by $u^{0,\psi}$ on D_ε is still denoted by v, and it is divergence free on D_ε. Using (3.5), (3.6), (3.7), and the definition of u_{Ω_ε}, we have

$$\begin{aligned}
\nu \int_{\Omega_R} Du_R\ :\ Dv\ dx &+ \int_{\Gamma_R} (T_\varepsilon u_R - f_\varepsilon).v\ d\gamma(x) \\
&= \nu \int_{\Omega_R} Du_R : Dv\ dx + \int_{D_\varepsilon} \nu Du^{0,\varphi} : Du^{0,\psi} - f.u^{0,\psi}\ dx \\
&= \nu \int_{\Omega_R} Du_R : Dv\ dx + \int_{D_\varepsilon} \nu(Du^{f,\varphi} - Du^{f,0}) : Du^{0,\psi} - f.u^{0,\psi}\ dx \\
&= \nu \int_{\Omega_\varepsilon} Du_{\Omega_\varepsilon} : Dv\ dx - \int_{D_\varepsilon} f.u^{0,\psi}\ dx \\
&= \int_{\Omega_\varepsilon} f.v\ dx - \int_{D_\varepsilon} f.v\ dx = \int_{\Omega_R} f.v\ dx.
\end{aligned}$$

This proves that u_R is a solution to (3.9), and $u_R = u_\varepsilon$ follows from uniqueness of this solution. ∎

We now have at our disposal the fixed functional space $\mathcal{V}_R$ (independent of ε) required by Lemma 6.1. The cost function (2.3) can be redefined in the following way: for $u \in \mathcal{V}_R$, let $\widetilde{u}_\varepsilon \in H^1(\Omega_\varepsilon)^n$ be the extension of u which coincides with u on Ω_R and with $u_\varepsilon^{f,\varphi}$ on D_ε for $\varphi = u_{|\Gamma_R}$. Then, a function J_ε can be defined on $\mathcal{V}_R$ by

$$J_\varepsilon(u) = \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon). \tag{3.13}$$

Particularly, it follows from the previous proposition that

$$j(\varepsilon) = \widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) = J_\varepsilon(u_\varepsilon). \tag{3.14}$$

Notice that $J_\varepsilon(u_\varepsilon)$ is independent of the choice of R. For example, for a given target function u_d, if

$$\widetilde{J}_\varepsilon(u_{\Omega_\varepsilon}) = \int_{\Omega_\varepsilon} |u_{\Omega_\varepsilon} - u_\mathrm{d}|^2 dx,$$

then we have

$$J_\varepsilon(u) = \int_{\Omega_R} |u - u_\mathrm{d}|^2 dx + \int_{D_\varepsilon} |u_\varepsilon^{f,\varphi} - u_\mathrm{d}|^2 dx, \quad u \in \mathcal{V}_R \text{ and } \varphi = u_{|\Gamma_R}.$$

4. Asymptotic expansion of the cost function. This section presents the main results of the paper. All asymptotic expansions concern the homogeneous problem (2.1) and involve its solution u_Ω, a cost function J_ε (or $\widetilde{J}_\varepsilon$), and the associated adjoint state v_Ω solution to (4.14). However, they remain valid for inhomogeneous problems (on Γ), provided that all data are written with respect to the inhomogeneous formulation: u_Ω has to be replaced by the inhomogeneous solution u_Ω^r and J_ε by the cost function depending on this solution u_Ω^r. The adjoint state corresponding to the inhomogeneous problem is the same as the one corresponding to the associated homogeneous problem.

A general statement (Theorem 4.1) is followed by applications to two classes of cost functions, the first one involving u, the second one involving Du. Most proofs are reported in section 6. Henceforth we have to distinguish the cases $n = 2$ and $n = 3$. This is due to the fact that the fundamental solutions to the Stokes equations in $\mathbb{R}^2$ and $\mathbb{R}^3$ have an essentially different asymptotic behavior at infinity, and Problem (4.1) generally has no solution if $n = 2$.

4.1. The three-dimensional case. Possibly changing the coordinate system, we can suppose for convenience that $x_0 = 0$. Let v_ω, p_ω be the solution to the exterior problem

$$\left\{\begin{array}{rl} -\nu\Delta v_\omega + \nabla p_\omega = 0 & \text{in} \quad \mathbb{R}^3\backslash\overline{\omega}, \\ \operatorname{div} v_\omega = 0 & \text{in} \quad \mathbb{R}^3\backslash\overline{\omega}, \\ v_\omega = 0 & \text{at infinity}, \\ v_\omega = u_\Omega(x_0) & \text{on} \quad \partial\omega, \end{array}\right. \tag{4.1}$$

where u_Ω is the solution to (2.1). Due to $f \in L^q(\Omega)^n$ with $q > n/2$, u_Ω is continuous in Ω and the above boundary condition is well defined.

Functions v_ω, p_ω can be expressed by a single layer potential on $\partial\omega$. For $y \in \mathbb{R}^3\backslash\{0\}$, let

$$E(y) = \frac{1}{8\pi\nu r}\left(I + \mathbf{e}_r\mathbf{e}_r^T\right), \; P(y) = \frac{y}{4\pi r^3}, \tag{4.2}$$

with $r = \|y\|$ and $\mathbf{e}_r = y/\|y\|$. It is a fundamental solution system to the Stokes equations in $\mathbb{R}^3$; that is

$$-\nu\Delta E_j + \nabla P_j = \delta\mathbf{e}_j, \tag{4.3}$$

where E_j denotes the jth column of E, $(\mathbf{e}_j)_{j=1}^3$ is the canonical basis of $\mathbb{R}^3$, and δ is the Dirac distribution. Then, functions v_ω, p_ω read (recall that $x.y$ denotes the usual dot product of $\mathbb{R}^3$) as follows:

$$\begin{aligned} v_\omega(y) &= \int_{\partial\omega} E(y-x)t_\omega(x)\, d\gamma(x), \quad y \in \mathbb{R}^3\backslash\overline{\omega}, \\ p_\omega(y) &= \int_{\partial\omega} P(y-x).t_\omega(x)\, d\gamma(x), \quad y \in \mathbb{R}^3\backslash\overline{\omega}, \end{aligned} \tag{4.4}$$

where $t_\omega \in H^{-1/2}(\partial\omega)^3$ is a solution to the boundary integral equation (see [8], Chap. XI-B, sect. 5)

$$\int_{\partial\omega} E(y-x)t_\omega(x)\,d\gamma(x) = u_\Omega(x_0) \quad \forall y \in \partial\omega. \tag{4.5}$$

Function t_ω is determined up to a function proportional to the normal; hence it is unique in $H^{-1/2}(\partial\omega)^3/\mathbb{R}\mathbf{n}$, which can be identified to $H_V^{-1/2}(\partial\omega)^3 = (\ker l_\mathbf{n})'$ for $l_\mathbf{n}(\varphi) = \int_{\partial\omega} \varphi.\mathbf{n}\,d\gamma(x)$.

For x bounded (and $r = \|y\|$), we have

$$E(y-x) = E(y) + O\left(\frac{1}{r^2}\right), \quad P(y-x) = P(y) + O\left(\frac{1}{r^3}\right),$$

from which follows the asymptotic expansion at infinity of functions v_ω and p_ω:

$$v_\omega(y) = V_\omega(y) + R_\omega(y),\ p_\omega(y) = P_\omega(y) + S_\omega(y), \tag{4.6}$$

$$V_\omega(y) = E(y)A_\omega(u_\Omega(x_0)), \quad P_\omega(y) = P(y).A_\omega(u_\Omega(x_0)), \tag{4.7}$$

$$A_\omega(u_\Omega(x_0)) = \int_{\partial\omega} t_\omega(x)\,d\gamma(x) \in \mathbb{R}^3, \tag{4.8}$$

$$R_\omega(y) = O\left(\frac{1}{r^2}\right), \quad S_\omega(y) = O\left(\frac{1}{r^3}\right).$$

Notice that $V_\omega \in L^m_{\mathrm{loc}}(\mathbb{R}^3)^3$ for all $m < 3$. Clearly, the function $\alpha \longmapsto A_\omega(\alpha)$ is linear on $\mathbb{R}^3$, and the vector $A_\omega(\alpha)$ depends on the shape of ω. For example, if ω is changed in $k\omega$, $k > 0$, then $v_{k\omega}(ky) = v_\omega(y)$ in (4.1), and it follows from (4.5) that $kt_{k\omega}(kx) = t_\omega(x)$ for $x \in \partial\omega$. Then using (4.8) we obtain $A_{k\omega}(u_\Omega(x_0)) = kA_\omega(u_\Omega(x_0))$. More generally, $A_\omega(\alpha)$ may depend on the orientation of ω, contrary to the scalar case like Poisson's equations [10]. Next we consider W_ω, Q_ω the solution to

$$\begin{cases} -\nu\Delta W_\omega + \nabla Q_\omega = 0 & \text{in} \quad D_0, \\ \operatorname{div} W_\omega = 0 & \text{in} \quad D_0, \\ W_\omega = V_\omega & \text{on} \quad \Gamma_R. \end{cases} \tag{4.9}$$

The main result is the following. It is based on the fact that

$$\varepsilon(W_\omega - V_\omega)_{|D_\varepsilon} \tag{4.10}$$

is the "first order approximation" of $(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})_{|D_\varepsilon}$ with $\varphi = (u_\Omega)_{|\Gamma_R}$, in a sense which will be stated precisely in section 6. The stronger hypothesis $f \in L^q(\Omega)^n$, $q > n$, is used in the study of the variation of the linear form l_ε (3.11) (cf. Proposition 6.8), which involves the $\mathcal{C}^1$ norm of u_0 around x_0. If l_ε does not depend on ε (which happens, for example, if f vanishes on D_0), then $f \in L^q(\Omega)^n$, $q > n/2$ is sufficient.

THEOREM 4.1. *Let $f \in L^q(\Omega)^n$ with $q > n$ and let J_ε be a function defined on $\mathcal{V}_R$ for all $\varepsilon \geq 0$. Suppose that for all $v \in \mathcal{V}_R$ and $\varepsilon > 0$, one has*

$$J_\varepsilon(v) - J_0(u_0) = DJ_0(u_0)(v-u_0) + \varepsilon\,\delta J(u_0) + o(\varepsilon + \|v-u_0\|_{\mathcal{V}_R}), \tag{4.11}$$

where $DJ_0(u_0)$ is linear and continuous on $\mathcal{V}_R$, and u_ε, $\varepsilon \geq 0$, is the solution to (3.9). *Let $v_0 \in \mathcal{V}_R$ be the solution to the adjoint equation*

$$a_0(w, v_0) = -DJ_0(u_0)w \quad \forall w \in \mathcal{V}_R. \tag{4.12}$$

Let $j(\varepsilon) = J_\varepsilon(u_\varepsilon)$ for $\varepsilon \geq 0$. Then function j has the following asymptotic expansion:

$$j(\varepsilon) = j(0) + \varepsilon\, \delta j(x_0) + o(\varepsilon)$$

with

$$\delta j(x_0) = \int_{\Gamma_R} ((\nu DW_\omega - Q_\omega I) - (\nu DV_\omega - P_\omega I))\, \mathbf{n}.v_0\, d\gamma(x) + \delta J(u_0). \tag{4.13}$$

Function $\delta j(x_0)$ is called the "topological sensitivity" or the "topological gradient." As j is usually independent of R (at least when it is of the form (3.14), which is the "natural" way of posing the problem) and $\delta j(x_0)$ is independent of ε, it follows from the uniqueness of an asymptotic expansion that $\delta j(x_0)$ is also usually independent of R. This is not necessarily true for the terms $\delta a(u_0, v_0)$, $\delta l(v_0)$ (see section 6), or $\delta J(u_0)$ considered separately, because a, l, and J do depend on R.

During an optimization process, what is in fact computed is the solution u_Ω to (2.1) and the adjoint state $v_\Omega \in \mathcal{V}_0$, which is the solution to

$$\nu \int_\Omega Dw : Dv_\Omega\, dx = -D\widetilde{J}_0(u_\Omega)w, \quad \forall w \in \mathcal{V}_0, \tag{4.14}$$

with $\mathcal{V}_0 = \{v \in H_0^1(\Omega)^3;\, \operatorname{div} v = 0 \text{ in } \Omega\}$. As observed in Proposition 3.1, u_0 is the restriction to Ω_R of u_Ω. Similarly, v_0 is the restriction to Ω_R of v_Ω, which can be proved in the same way as in [9]. Hence, the basic property of an adjoint technique is here satisfied, in that function u_Ω (or u_0) and the adjoint state v_Ω (or v_0) do not depend on x_0. Thus *only two systems must be solved* in order to compute the topological sensitivity $\delta j(x)$ for all $x \in \Omega$. Moreover, there exists a unique $q_\Omega \in L^2(\Omega)/\mathbb{R}$ such that

$$\nu \int_\Omega Dw : Dv_\Omega - \int_\Omega q_\Omega \operatorname{div} w = -D\widetilde{J}_0(u_\Omega)\, w, \qquad \forall w \in H_0^1(\Omega)^3, \tag{4.15}$$

and (4.13) can be expressed in the following way (see Corollary 4.2). Proposition 4.3 will show that in fact the two last terms in the right-hand side of (4.16) cancel each other for a large class of cost functions which do not involve Du_Ω. The regularity of $\nu\Delta v_\Omega - \nabla q_\Omega$ depends on u_Ω and on the cost function J; some examples are provided in sections 4.1.1 and 4.1.2.

COROLLARY 4.2. *Under the assumptions of Theorem* 4.1*, if $\nu\Delta v_\Omega - \nabla q_\Omega \in L^q(D_0)^n$ with $q > n/2$, then*

$$\delta j(x_0) = A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \int_{D_0} (\nu\Delta v_\Omega - \nabla q_\Omega).(V_\omega - W_\omega)\, dx + \delta J(u_0). \tag{4.16}$$

If ω is the unit ball $B(0,1)$, then $v_\omega(y)$, $t_\omega(y)$, and $A_\omega(u_\Omega(x_0))$ are given explicitly by

$$\begin{aligned} v_\omega(y) &= \pi\nu(6E + \Delta E)u_\Omega(x_0), \\ t_\omega(y) &= \frac{3\nu}{2} u_\Omega(x_0), \quad \forall y \in \partial\omega, \\ A_\omega(u_\Omega(x_0)) &= 6\pi\nu u_\Omega(x_0). \end{aligned}$$

Proof. Thanks to Green's formula and (4.9) (with $V_\omega = W_\omega$ on Γ_R), (4.13) also

reads as follows:

$$\begin{aligned}\delta j(x_0) &= \int_{\Gamma_R} ((\nu DW_\omega - Q_\omega I) - (\nu DV_\omega - P_\omega I))\,\mathbf{n}.v_\Omega\, d\gamma(x) + \delta J(u_0)\\ &= \int_{\Gamma_R} (\nu Dv_\Omega - q_\Omega I)\mathbf{n}.V_\omega\, d\gamma(x) - \int_{\Gamma_R} (\nu DV_\omega - P_\omega I)\mathbf{n}.v_\Omega\, d\gamma(x)\\ &\quad - \int_{D_0} (\nu \Delta v_\Omega - \nabla q_\Omega)\mathbf{n}.W_\omega\, dx + \delta J(u_0).\end{aligned}$$

Through a regularization and localization technique, it can be shown that

$$\begin{aligned}&\int_{\Gamma_R} (\nu Dv_\Omega - q_\Omega I)\mathbf{n}.V_\omega\, d\gamma(x) - \int_{\Gamma_R} (\nu DV_\omega - P_\omega I)\mathbf{n}.v_\Omega\, d\gamma(x)\\ &= \int_{D_0} (\nu \Delta v_\Omega - \nabla q_\Omega).V_\omega\, dx - \langle \nu \Delta V_\omega - \nabla P_\omega, \varphi v_\Omega\rangle,\end{aligned}$$

where $\varphi \in \mathcal{D}(D_0)^3$ satisfies $\varphi(x_0) = 1$. It follows from (4.7) and (4.3) that

$$\begin{aligned}\langle -\nu\Delta V_\omega + \nabla P_\omega, \varphi v_\Omega\rangle &= \langle -\nu\Delta(EA_\omega(u_\Omega(x_0))) + \nabla(P.A_\omega(u_\Omega(x_0))), \varphi v_\Omega\rangle\\ &= \sum_j A_\omega(u_\Omega(x_0))_j \,\langle -\nu\Delta E_j + \nabla P_j, \varphi v_\Omega\rangle\\ &= \sum_j A_\omega(u_\Omega(x_0))_j \,\langle \delta \mathbf{e}_j, \varphi v_\Omega\rangle\\ &= A_\omega(u_\Omega(x_0)).\, v_\Omega(x_0).\end{aligned}$$

This proves (4.16). For $\omega = B(0,1)$, function v_ω can be computed explicitly. For $y \neq 0$, we have

$$\begin{aligned}E(y) &= \frac{1}{8\pi\nu r}(I + \mathbf{e}_r\mathbf{e}_r^T),\\ \Delta E(y) &= \frac{1}{4\pi\nu r^3}(I - 3\,\mathbf{e}_r\mathbf{e}_r^T),\\ \pi\nu(6E + \Delta E)(y) &= \frac{1}{4}\left(\frac{3}{r} + \frac{1}{r^3}\right) I + \frac{1}{4}\left(\frac{3}{r} - \frac{3}{r^3}\right)\mathbf{e}_r\mathbf{e}_r^T.\end{aligned}$$

Hence $\pi\nu(6E+\Delta E)(y) = I$ on $\partial B(0,1)$, and it follows from the uniqueness of v_ω that

$$v_\omega(y) = \pi\nu(6E + \Delta E)(y)u_\Omega(x_0).$$

The expressions of $t_\omega(y)$ and $A_\omega(u_\Omega(x_0))$ follow straightforwardly from (4.5) and

$$\int_{\partial B(0,1)} E(y-x)\, d\gamma(x) = \frac{2}{3\nu} I \quad \forall y \in \partial B(0,1). \qquad \square$$

We now examine two classes of cost functions.

4.1.1. First example. It consists of functions of the form

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega_\varepsilon} g(x, u(x))\, dx, \quad u \in H^1(\Omega_\varepsilon)^3. \tag{4.17}$$

The hypotheses on g are the following:

- For all $x \in \Omega$, function $s \mapsto g(x,s)$ is of class $\mathcal{C}^1$ on $\mathbb{R}^3$, its gradient being denoted by $\nabla_s g(x,s)$.
- For all $x \in \Omega$, function $s \mapsto \nabla_s g(x,s)$ is Lipschitz continuous, and there exists a constant M such that

$$|\nabla_s g(x,t) - \nabla_s g(x,s)| \leq M\,|t-s|\,, \quad \forall (x,s,t) \in \Omega \times \mathbb{R}^3 \times \mathbb{R}^3, \tag{4.18}$$

  where $|t|$ denotes the usual norm on $\mathbb{R}^n$.
- Function $x \mapsto \nabla_s g(x,0)$ belongs to $L^2(\Omega)^3$ and $x \mapsto g(x,0)$ belongs to $L^{3/2}(\Omega)$.

These hypotheses imply that for all $(x,s) \in \Omega \times \mathbb{R}^3$

$$|g(x,s)| \leq |g(x,0)| + |\nabla_s g(x,0).s| + \frac{M}{2}\,|s|^2\,, \tag{4.19}$$

$$|\nabla_s g(x,s)| \leq |\nabla_s g(x,0)| + M\,|s|\,, \tag{4.20}$$

and functions $x \mapsto g(x,u(x))$ and $x \mapsto |\nabla_s g(x,u(x))|^2$ are integrable on Ω for all $u \in L^2(\Omega)^3$. If $u \in L^6(\mathcal{O})^3$, $\mathcal{O} \subset\Omega$, then function $x \mapsto g(x,u(x))$ belongs to $L^{3/2}(\mathcal{O})$. The standard example

$$g(x,s) = |s - u_{\rm d}(x)|^2$$

satisfies these hypotheses if $u_{\rm d} \in L^3(\Omega)^3$.

PROPOSITION 4.3. *If these hypotheses are satisfied and if $f \in L^q(\Omega)^n$ with $q > n$, then*

$$\delta J(u_0) = \int_{D_0} \nabla_s g(x,u_\Omega).(W_\omega - V_\omega)\,dx,$$

the adjoint state $(v_\Omega,\, q_\Omega) \in \mathcal{V}_0 \times L^2(\Omega)/\mathbb{R}$ is the solution to

$$-\nu\Delta v_\Omega + \nabla q_\Omega = -\nabla_s g(x,u_\Omega),$$

and function j has the asymptotic expansion

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + o(\varepsilon).$$

If ω is the unit ball $B(0,1)$, then

$$j(\varepsilon) = j(0) + 6\pi\nu\varepsilon\, u_\Omega(x_0).v_\Omega(x_0) + o(\varepsilon).$$

4.1.2. Second example. It consists of functions of the form

$$\widetilde{J}_\varepsilon(u) = \frac{1}{2}\int_{\Omega_\varepsilon} BD(u-u_{\rm d}) : D(u-u_{\rm d})\,dx, \quad u \in H^1(\Omega_\varepsilon)^3, \tag{4.21}$$

where $B \in W^{1,\infty}(\Omega, \mathbb{R}^{9\times 9})$ with $(BM)_{ij}(x) = \sum_{kl} b_{ijkl}(x) M_{kl}$ for $M \in \mathcal{M}_3(\mathbb{R})$, and $u_{\rm d} \in H^1(\Omega)^3$. The operator B is supposed to be symmetric; that is, $b_{ijkl} = b_{klij}$, or equivalently $BM : N = M : BN$ for all M, $N \in \mathcal{M}_3(\mathbb{R})$.

PROPOSITION 4.4. *If these hypotheses are satisfied and if f and $\Delta u_{\rm d}$ belong to $L^q(\Omega)^n$, $q > n$, then the adjoint state $(v_\Omega,\ q_\Omega) \in \mathcal{V}_0 \times L^2(\Omega)/\mathbb{R}$ is the solution to*

$$-\nu\Delta v_\Omega + \nabla q_\Omega = \operatorname{div}\left[BD(u_\Omega - u_{\rm d})\right],$$

the variation of J is given by

$$\delta J(u_0) = \int_{D_0} (\nu\Delta v_\Omega - \nabla q_\Omega).(W_\omega - V_\omega) + \frac{1}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)Dv_\omega(y) : Dv_\omega(y)\,dy,$$

and function j has the asymptotic expansion

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \frac{\varepsilon}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0)Dv_\omega(y) : Dv_\omega(y)\,dy + o(\varepsilon).$$

If ω is the unit ball, then

$$v_\omega = \pi\nu(6E + \Delta E)u_\Omega(x_0) = \frac{3r^2+1}{4r^3}u_\Omega(x_0) + \frac{(3r^2-3)u_\Omega(x_0).\mathbf{e}_r}{4r^3}\mathbf{e}_r,$$

and the integral can be computed explicitly.

If $\overline{\omega}$ is the unit ball $\overline{B}(0,1)$, the integral has the form

$$\begin{aligned}&\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} B(x_0)Dv_\omega(y) : Dv_\omega(y)\,dy\\ &= \sum_{ijklmn} (B_{ijkl}u_m u_n)(x_0)\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} (\pi\nu)^2\partial_j(6E+\Delta E)_{im}\partial_l(6E+\Delta E)_{kn}\,dy,\end{aligned}$$

where $u_\Omega = (u_1, u_2, u_3)$, each term in $\partial_j(6E_{im} + \Delta E_{im})\partial_l(6E_{kn} + \Delta E_{kn})$ is of the form y^α/r^s with $s = |\alpha| + p$, $p = 4, 6$, or 8, and each y^α is of the form y_i^2, $y_i^2y_j^2$, or $y_i^2y_j^2y_k^2$ (the other integrals vanish). Then one can use the following formulas:

$$\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} \frac{y_i^2}{r^s}dy = \frac{1}{3}\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} \frac{1}{r^p}dy = \frac{4\pi}{3(p-3)}$$

$$\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} \frac{y_i^2y_j^2}{r^s}dy = \begin{cases} \frac{4\pi}{5(p-3)} & \text{if } i = j,\\ \frac{4\pi}{15(p-3)} & \text{if } i \neq j,\end{cases}$$

$$\int_{\mathbb{R}^3\setminus\overline{B}(0,1)} \frac{y_i^2y_j^2y_k^2}{r^s}dy = \begin{cases} \frac{4\pi}{7(p-3)} & \text{if } i = j = k,\\ \frac{4\pi}{35(p-3)} & \text{if } i = j \neq k,\\ \frac{4\pi}{105(p-3)} & \text{if } i \neq j \neq k \neq i.\end{cases}$$

For example, if $BM(x) = C(x)M$ where $C(x) \in \mathcal{M}_3(\mathbb{R})$ is a symmetric matrix, then

$$j(\varepsilon) = j(0) + \varepsilon[6\pi\nu u_\Omega.v_\Omega + \frac{3\pi}{10}\operatorname{tr} C|u_\Omega|^2 + \frac{21\pi}{10}Cu_\Omega.u_\Omega](x_0) + o(\varepsilon).$$

4.2. The two-dimensional case. We briefly describe the transposition of the previous results to the two-dimensional case. As before, u_Ω and the adjoint state v_Ω, respectively, are the solutions to (2.1) and (4.14). A fundamental solution system to the Stokes equations in $\mathbb{R}^2$ is given here by

$$E(y) = \frac{1}{4\pi\nu}\left(-\log r I + \mathbf{e}_r\mathbf{e}_r^T\right), \quad P(y) = \frac{y}{2\pi r^2}.$$

The exterior problem must now be defined differently than in (4.1), which generally has no solution in the two-dimensional case (Stokes paradox). Let v_ω be the solution to

$$\begin{cases} -\nu\Delta v_\omega + \nabla p_\omega = 0 & \text{in } \mathbb{R}^2\setminus\overline{\omega},\\ \operatorname{div} v_\omega = 0 & \text{in } \mathbb{R}^2\setminus\overline{\omega},\\ v_\omega/\log\|y\| = u_\Omega(x_0) & \text{at } \infty,\\ v_\omega = 0 & \text{on } \partial\omega.\end{cases}$$

Functions v_ω and p_ω have the following asymptotic expansion at infinity:

$$v_\omega(y) = -4\pi\nu E(y)u_\Omega(x_0) + V_\omega + R_\omega(y), \quad R_\omega(y) = O(1/r),$$
$$p_\omega(y) = -4\pi\nu P(y).u_\Omega(x_0) + S_\omega(y), \quad S_\omega(y) = O(1/r^2),$$

where $V_\omega \in \mathbb{R}^2$ is *constant* (it follows from the fact that any tempered distribution solution to the homogeneous Stokes equations in $\mathbb{R}^n$ is a polynomial, which can be proved as in [8, Chap. II, sect. 2, Prop. 3]). The principal part of v_ω is $-4\pi\nu E(y)u_\Omega(x_0)+V_\omega$ and, because V_ω is constant, its derivative is independent of ω. The consequence is that, in contrast to the three-dimensional case, the topological sensitivity does not depend on the shape of ω (cf. Propositions 4.5 and 4.6).

If $\omega = B(0,1)$, then function v_ω can be computed explicitly as follows: for $y \neq 0$, we have

$$E(y) = \frac{1}{4\pi\nu}(-\log r I + \mathbf{e}_r\mathbf{e}_r^T),$$
$$\Delta E(y) = \frac{1}{2\pi\nu r^2}(I - 2\mathbf{e}_r\mathbf{e}_r^T),$$
$$\pi\nu(4E + \Delta E)(y) = \left(-\log r + \frac{1}{2r^2}\right) I + \left(1 - \frac{1}{r^2}\right)\mathbf{e}_r\mathbf{e}_r^T.$$

Hence $\pi\nu(4E + \Delta E)(y) = I/2$ on $\partial B(0,1)$, and it follows from the uniqueness of v_ω that

$$v_\omega(y) = -\pi\nu(4E + \Delta E)(y)u_\Omega(x_0) + \frac{1}{2}u_\Omega(x_0).$$

Next we consider the solution W_ω, Q_ω to the interior problem

$$\begin{cases} -\nu\Delta W_\omega + \nabla Q_\omega = 0 & \text{in } D_0, \\ \operatorname{div} W_\omega = 0 & \text{in } D_0, \\ W_\omega = -4\pi\nu E u_\Omega(x_0) + V_\omega & \text{on } \Gamma_R. \end{cases}$$

The "first order approximation" of $(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})_{|D_\varepsilon}$ with $\varphi = (u_\Omega)_{|\Gamma_R}$ now becomes (compare with (4.10))

$$\frac{-1}{\log\varepsilon}\left(-4\pi\nu E(x)u_\Omega(x_0) + V_\omega - W_\omega(x)\right)_{|D_\varepsilon}.$$

PROPOSITION 4.5. *The assumptions are the same as in Proposition* 4.3*, with* $\widetilde{J}_\varepsilon$ *of the form*

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega_\varepsilon} g(x, u(x))\,dx, \quad u \in H^1(\Omega_\varepsilon)^2.$$

Then function j *has the following asymptotic expansion:*

$$j(\varepsilon) = j(0) - \frac{4\pi\nu u_\Omega(x_0).v_\Omega(x_0)}{\log\varepsilon} + o\left(\frac{-1}{\log\varepsilon}\right). \tag{4.22}$$

In the next proposition, the first expression of $j(\varepsilon)$ is given for comparison with the three-dimensional case.

PROPOSITION 4.6. *The assumptions are the same as in Proposition* 4.4, *with* $\widetilde{J}_\varepsilon$ *of the form*

$$\widetilde{J}_\varepsilon(u) = \frac{1}{2}\int_{\Omega_\varepsilon} BD(u-u_{\rm d}) : D(u-u_{\rm d})\,dx, \quad u \in H^1(\Omega_\varepsilon)^2.$$

Then function j *has the following asymptotic expansion (with* $D_\varepsilon/\varepsilon = B(0,R/\varepsilon)/\overline{\omega}$*):*

$$\begin{aligned} j(\varepsilon) &= j(0) - \frac{4\pi\nu}{\log\varepsilon} u_\Omega(x_0).v_\Omega(x_0) + \frac{1}{2\log^2\varepsilon}\int_{D_\varepsilon/\varepsilon} B(x_0)Dv_\omega : Dv_\omega\,dy + o\left(\frac{-1}{\log\varepsilon}\right) \\ &= j(0) - \frac{4\pi\nu}{\log\varepsilon} u_\Omega(x_0).v_\Omega(x_0) + \frac{(4\pi\nu)^2}{2\log^2\varepsilon}\int_{D_\varepsilon/\varepsilon} B(x_0)D(Eu_\Omega(x_0)) : D(Eu_\Omega(x_0))\,dy \\ &\quad + o\left(\frac{-1}{\log\varepsilon}\right) \\ &= j(0) - \frac{\pi}{4\log\varepsilon}[16\nu u_\Omega.v_\Omega + (b_{1111}+b_{2222}+b_{1212}+b_{2121}-2b_{2112}-2b_{1122})|u_\Omega|^2 \\ &\quad + 4b_{1212}u_1^2 + 4b_{2121}u_2^2 + 4(-b_{1112}+b_{1222}-b_{2122}+b_{1121})u_1u_2](x_0) + o\left(\frac{-1}{\log\varepsilon}\right), \end{aligned}$$

where $u_\Omega = (u_1, u_2)$.

The proofs use the same tools as for the three-dimensional case (see section 6) and will not be repeated for the two-dimensional case.

5. A numerical example. The example presented in this section shows how topological sensitivity can be used to improve a given criterion. Although the obtained result indicates that the problem may not have a "classical solution," which is quite common in shape optimization, such a result may still have some practical interest for situations where the user does not necessarily need the "best solution," but only an improved design. A classical approach used for obtaining existence of an optimal solution is to use homogeneization [1, 4, 7, 13]. For a review on recent advances in shape optimization methods and existence of an optimal solution (either through penalization or relaxation), we refer the reader to [2] and references therein.

We consider the case of a tank filled with an incompressible fluid, in which some obstacles can be inserted in order to approximate a target flow $u_{\rm d}$. The velocity and the pressure are the solution to

$$-\nu\Delta u_\Omega + \nabla p_\Omega = 0 \ \text{ in } \Omega = [0,1.4]\times[-1.2,1.2], \tag{5.1}$$

where the domain Ω and the boundary conditions are illustrated by Figure 3.

The cost function is defined by (see also Figure 3)

$$\begin{aligned} J(u) &= \int_{\Omega_d} ||u-u_{\rm d}||^2\,dx, \\ u_{\rm d} &= \left(\frac{y+1.2}{2.4^2}, 0\right), \quad \Omega_{\rm d} = \{(x,y)\in\Omega;\ |x|<0.8\}. \end{aligned}$$

The subset $\Omega\backslash\overline{\Omega_{\rm d}}$ is the location where some obstacles can be inserted. For that function, the adjoint equation (4.15) reads

$$\begin{cases} -\nu\Delta v_\Omega + \nabla q_\Omega = -2(u_\Omega - u_{\rm d}) \text{ in } \Omega, \\ v_\Omega = 0 \text{ on } \Gamma, \end{cases}$$

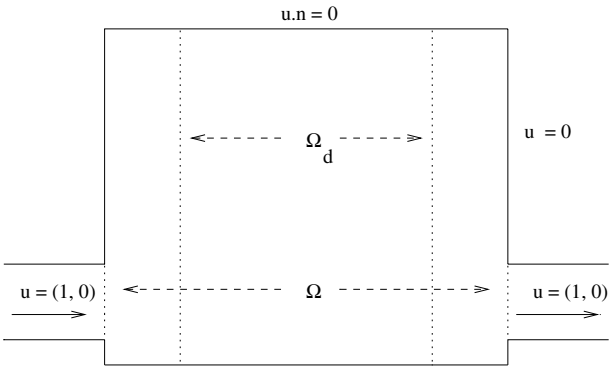

FIG. 3. *The domain Ω and the boundary conditions.*

and we obtain from (4.22) the topological sensitivity

$$j(\varepsilon) = j(0) - \frac{4\pi\nu}{\log \varepsilon} u_\Omega(x_0).v_\Omega(x_0) + o\left(\frac{-1}{\log \varepsilon}\right).$$

For completeness, we recall here the topology optimization algorithm described in [9], which was inspired by the original work of Céa [6]. Let $(m_k)_{k\geq 0}$ be an increasing sequence of volume constraints, with $m_0 = \text{meas}(\Omega_\text{d})$. For example, a geometrical sequence may be chosen. At the kth iteration, the topological sensitivity is denoted by $\delta j_k(x)$, and a small obstacle is added at the point where δj is the most negative. The algorithm is the following [9]:

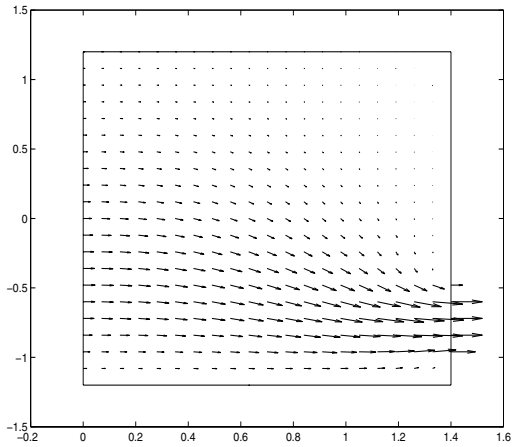
- Initialization: choose $\Omega_0 = \Omega_\text{d}$, and set $k = 0$.
- Repeat until target is reached:
  1. solve (5.1) in Ω_k,
  2. compute the topological sensitivity δj_k,
  3. set $\Omega_{k+1} = \{x \in \Omega_k;\, \delta j_k(x) \geq c_{k+1}\}$, where c_{k+1} is chosen in such a way that $\text{meas}(\Omega_{k+1}) = m_{k+1}$,
  4. $k \leftarrow k + 1$.

Figures 4(a) and 4(b) show the initial flow and the objective flow that we want to obtain after optimization. Only half of the tank is represented. The results after optimization (obstacles and obtained flow) are presented in Figures 4(c) and 4(d). The plotting function of MATLAB normalizes the sizes of the arrows, which is the reason why we show in Figure 4(d) the restriction of the flow (Figure 4(c)) to Ω_d. That allows a better comparison between the objective flow and the obtained flow. The value of the cost function at each iteration is presented in Figure 4(f).

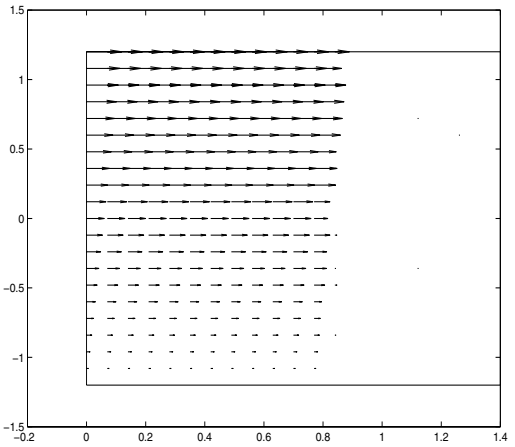
6. Proofs. This section consists of the proofs of Theorem 4.1 and Propositions 4.3 and 4.4. They use the fundamental result from [11], [9] which is recalled here.

LEMMA 6.1. *Let $\mathcal{V}$ be a Hilbert space. For $\varepsilon \geq 0$, let a_ε be a bilinear and symmetric form on $\mathcal{V}$ and l_ε be a linear form on $\mathcal{V}$, such that for all $\varepsilon \geq 0$,*

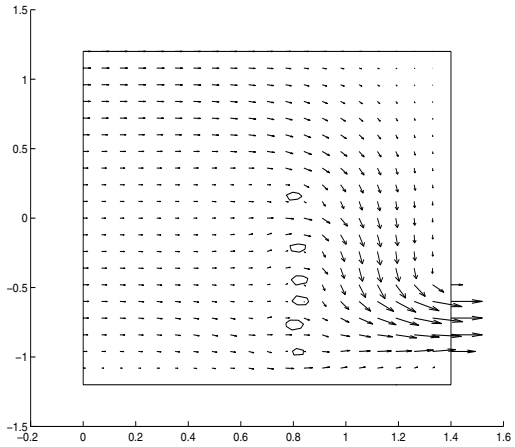
$$\begin{aligned} a_\varepsilon(u,v) &\leq M_1\|u\|\,\|v\|, \quad \forall u,\, v \in \mathcal{V}, \\ a_\varepsilon(u,u) &\geq \alpha\|u\|^2, \quad \forall u \in \mathcal{V}, \\ |l_\varepsilon(v)| &\leq M_2\|v\|, \quad \forall v \in \mathcal{V}. \end{aligned}$$



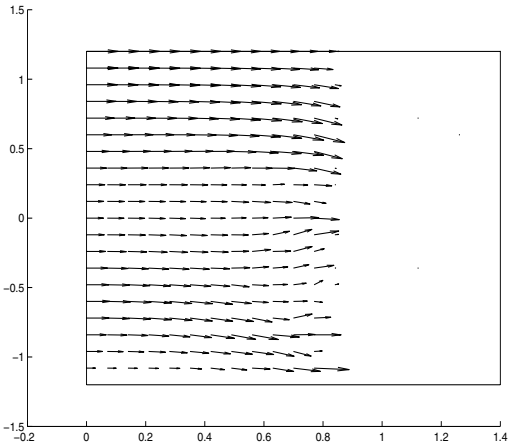
(a) initial flow



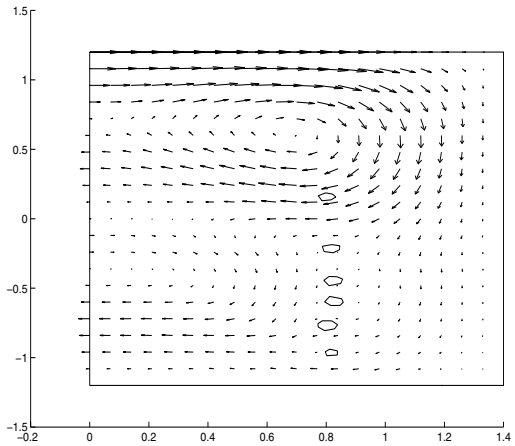
(b) objective flow



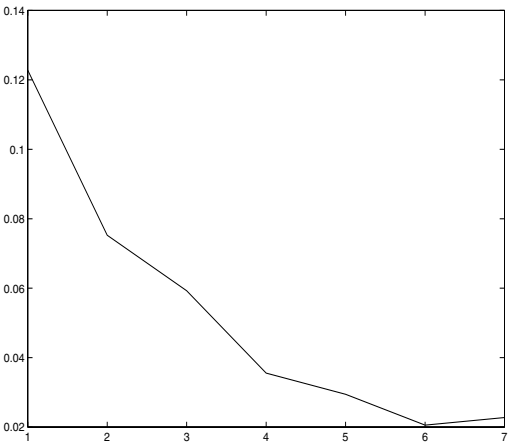
(c) obtained flow on Ω



(d) obtained flow on Ω_d



(e) adjoint flow



(f) cost function

FIG. 4.

We suppose that there exists a bilinear and continuous form δa, a linear and continuous form δl, and a real function $f(\varepsilon) > 0$ defined on $\mathbb{R}_+$ such that

$$\begin{aligned} ||a_\varepsilon - a_0 - f(\varepsilon)\delta a||_{\mathcal{L}_2(\mathcal{V})} &= o(f(\varepsilon)), \\ ||l_\varepsilon - l_0 - f(\varepsilon)\delta l||_{\mathcal{L}(\mathcal{V})} &= o(f(\varepsilon)), \\ \lim_{\varepsilon \to 0} f(\varepsilon) &= 0. \end{aligned}$$

For $\varepsilon \geq 0$, let u_ε be the solution to

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \quad \forall v \in \mathcal{V}.$$

Then

$$\|u_\varepsilon - u_0\|_{\mathcal{V}} = O(f(\varepsilon)).$$

Consider next a cost function of the form $j(\varepsilon) = J_\varepsilon(u_\varepsilon)$, where J_ε is defined on $\mathcal{V}$ and J_0 is differentiable with respect to u, its derivative being denoted by $DJ_0(u)$. Suppose that there exists a function δJ defined on $\mathcal{V}$ such that for all $v \in \mathcal{V}$ and all $\varepsilon > 0$

$$J_\varepsilon(v) - J_0(u) = DJ_0(u)(v-u) + f(\varepsilon)\delta J(u) + o(\|v-u\|_{\mathcal{V}} + f(\varepsilon)).$$

Then j has the asymptotic expansion

$$j(\varepsilon) = j(0) + f(\varepsilon)[\delta a(u_0, v_0) - \delta l(v_0) + \delta J_0(u_0)] + o(f(\varepsilon)),$$

where $v_0 \in \mathcal{V}$ is the solution to the adjoint problem

$$a_0(w, v_0) = -DJ_0(u_0)w \quad \forall w \in \mathcal{V}.$$

Here, the variations of the bilinear form a_ε and the linear form l_ε (see (3.10) and (3.11)) read

$$\begin{aligned} a_\varepsilon(u,v) - a_0(u,v) &= \int_{\Gamma_R} (T_\varepsilon - T_0)u.v \, d\gamma(x), \\ l_\varepsilon(v) - l_0(v) &= \int_{\Gamma_R} (f_\varepsilon - f_0).v \, d\gamma(x). \end{aligned}$$

Hence, the problem reduces to the analysis of $(T_\varepsilon - T_0)\varphi$ for $\varphi \in H_V^{1/2}(\Gamma_R)^3$ and of $f_\varepsilon - f_0$ in $H_V^{-1/2}(\Gamma_R)$. More precisely, it will be shown in sections 6.3 and 6.4 that there exists an operator $\delta T \in \mathcal{L}(H_V^{1/2}(\Gamma_R)^3; H_V^{-1/2}(\Gamma_R)^3)$ and a function $\delta f \in H^{-1/2}(\Gamma_R)$ such that

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H_V^{1/2}(\Gamma_R)^3;\, H_V^{-1/2}(\Gamma_R)^3)} = O(\varepsilon^2), \tag{6.1}$$

$$\|f_\varepsilon - f_0 - \varepsilon\delta f\|_{H_V^{-1/2}(\Gamma_R)} = O(\varepsilon^2). \tag{6.2}$$

Consequently, defining δa and δl by

$$\begin{aligned} \delta a(u,v) &= \int_{\Gamma_R} \delta T u.v \, d\gamma(x), \quad u,\, v \in \mathcal{V}_R, \\ \delta l(v) &= \int_{\Gamma_R} \delta f.v \, d\gamma(x), \quad v \in \mathcal{V}_R, \end{aligned}$$

will yield straightforwardly

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}_2(\mathcal{V}_R)} = O(\varepsilon^2),$$
$$\|l_\varepsilon - l_0 - \varepsilon\delta l\|_{\mathcal{L}(\mathcal{V}_R)} = O(\varepsilon^2),$$

and Lemma 6.1 can be applied. In order to derive (6.1)–(6.2), we need some definitions and preliminary lemmas.

6.1. Definitions. This section describes the functional spaces and norms which will be used in the proofs.

- For a bounded and open subset $\mathcal{O} \subset \mathbb{R}^3$ and $m \geq 0$, the Sobolev space $H^m(\mathcal{O})^3$ is equipped with the norm defined by

$$\|u\|^2_{m,\mathcal{O}} = \sum_{k=0}^{m} |u|^2_{k,\mathcal{O}}\,,$$

where the seminorms $|u|^2_{k,\mathcal{O}}$ are given by

$$|u|^2_{k,\mathcal{O}} := \sum_{|\alpha|=k} ||D^\alpha u||^2_{L^2(\mathcal{O})}. \tag{6.3}$$

The usual space of traces on the boundary of $\mathcal{O}$ is denoted by $H^{1/2}(\partial\mathcal{O})$, and its norm is denoted by $||\cdot||_{1/2,\partial\mathcal{O}}$. The subspace

$$H^{1/2}_V(\partial\mathcal{O})^3 = \left\{\varphi \in H^{1/2}(\partial\mathcal{O})^3;\ \int_{\Gamma_R} \varphi.\mathbf{n}\, d\gamma(x) = 0\right\}$$

is equipped with the norm induced by $H^{1/2}(\partial\mathcal{O})^3$, and $H^{-1/2}_V(\partial\mathcal{O})^3$ denotes its dual space. A special case is when $\psi = (\nu Du - pI)\mathbf{n}$ on Γ_R with $-\nu\Delta u + \nabla p = 0$ in $C(R/2, R)$. For $\varphi \in H^{1/2}_V(\Gamma_R)^3$, let $v \in H^1(C(R/2,R))$ solve the Stokes equations with a null right-hand side, $v = \varphi$ on Γ_R and $v = 0$ on $\Gamma_{R/2}$. Using the well-posedness of the Stokes equations, we have

$$\begin{aligned}\langle(\nu Du - pI)\mathbf{n},\varphi\rangle_{-1/2,1/2} &= \nu \int_{C(R/2,R)} Du : Dv\, dx \\ &\leq \nu|u|_{1,C(R/2,R)}|v|_{1,C(R/2,R)} \\ &\leq c|u|_{1,C(R/2,R)}||\varphi||_{1/2},\end{aligned}$$

which proves that

$$\|(\nu Du - pI)\mathbf{n}\|_{-1/2,\Gamma_R} \leq c|u|_{1,C(R/2,R)}. \tag{6.4}$$

As usual in PDEs, letter c denotes a positive constant independent of the data (e.g., on ε).

- Finally, the space $L^2(\mathcal{O})/\mathbb{R}$ is identified with

$$L^2_0(\mathcal{O}) = \left\{p \in L^2(\mathcal{O});\ \int_{\mathcal{O}} p\, dx = 0\right\}.$$

6.2. Preliminary lemmas. Recall that $x_0 = 0$. We will use extensively the following change of variable. For a given function u defined on a subset $\mathcal{O}$, function $\widetilde{u}$ is defined on $\widetilde{\mathcal{O}} := \mathcal{O}/\varepsilon$ by

$$\widetilde{u}(y) = u(x), \quad y = x/\varepsilon.$$

Due to $Du(x) = D\widetilde{u}(y)/\varepsilon$ and to Definition (6.3), we have

$$|u|^2_{1,\mathcal{O}} = \int_{\mathcal{O}} |Du|^2 \, dx = \frac{1}{\varepsilon^2} \int_{\widetilde{\mathcal{O}}} |D\widetilde{u}|^2 \, \varepsilon^3 dy;$$

hence

$$|u|_{1,\mathcal{O}} = \varepsilon^{1/2} \, |\widetilde{u}|_{1,\widetilde{\mathcal{O}}} \, . \tag{6.5}$$

Similarly, we have

$$||u||_{0,\mathcal{O}} = \varepsilon^{3/2} ||\widetilde{u}||_{0,\widetilde{\mathcal{O}}}. \tag{6.6}$$

LEMMA 6.2. *For $\varphi \in H_V^{1/2}(\partial\omega)$, let v_ω, q_ω be the solution to the problem*

$$\left\{ \begin{array}{rl} -\nu\Delta v_\omega + \nabla q_\omega = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ \operatorname{div} v_\omega = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ v_\omega = 0 & \text{at } \infty, \\ v_\omega = \varphi & \text{on } \partial\omega. \end{array} \right. \tag{6.7}$$

Function v_ω is split into

$$\begin{aligned} v_\omega(y) &= V_\omega(y) + R_\omega(y), \\ V_\omega(y) &= E(y) \int_{\partial\omega} t_\omega(x) \, d\gamma(x), \end{aligned}$$

where $E(y)$ is defined in (4.2) and $t_\omega \in H_V^{-1/2}(\partial\omega)^3$ is the unique solution to

$$\int_{\partial\omega} E(y-x) t_\omega(x) d\gamma(x) = \varphi(y) \quad \forall y \in \partial\omega. \tag{6.8}$$

There exists a constant $c > 0$ (independent of φ and ε) such that

$$\begin{aligned} \|V_\omega\|_{0,C(R/(2\varepsilon),R/\varepsilon)} &\leq c\varepsilon^{-1/2} \|\varphi\|_{1/2,\partial\omega}, \\ |V_\omega|_{1,C(R/(2\varepsilon),R/\varepsilon)} &\leq c\varepsilon^{1/2} \|\varphi\|_{1/2,\partial\omega}, \\ \|V_\omega\|_{0,D_\varepsilon/\varepsilon} &\leq c\varepsilon^{-1/2} \|\varphi\|_{1/2,\partial\omega}, \\ |V_\omega|_{1,D_\varepsilon/\varepsilon} &\leq c||\varphi||_{1/2,\partial\omega}, \\ \|R_\omega\|_{0,C(R/(2\varepsilon),R/\varepsilon)} &\leq c\varepsilon^{1/2} \|\varphi\|_{1/2,\partial\omega}, \\ |R_\omega|_{1,C(R/(2\varepsilon),R/\varepsilon)} &\leq c\varepsilon^{3/2} \|\varphi\|_{1/2,\partial\omega}, \\ \|R_\omega\|_{1,D_\varepsilon/\varepsilon} &\leq c\|\varphi\|_{1/2,\partial\omega}. \end{aligned}$$

Proof. Function v_ω reads

$$v_\omega(y) = \int_{\partial\omega} E(y-x) t_\omega(x) \, d\gamma(x), \quad y \in \mathbb{R}^3\backslash\overline{\omega}.$$

Using a Taylor expansion of E computed at the point y and the well-posedness of (6.8) we have for large $r = ||y||$

$$|V_\omega(y)| \leq \frac{c}{r}\|\varphi\|_{1/2,\partial\omega},\ |R_\omega(y)| \leq \frac{c}{r^2}\|\varphi\|_{1/2,\partial\omega},$$
$$|DV_\omega(y)| \leq \frac{c}{r^2}\|\varphi\|_{1/2,\partial\omega},\ |DR_\omega(y)| \leq \frac{c}{r^3}\|\varphi\|_{1/2,\partial\omega},$$

from which the above inequalities follow straightforwardly. □

LEMMA 6.3. *For $\varepsilon > 0$ and $\varphi \in H_V^{1/2}(\Gamma_R)^3$, let v_ε, q_ε be the solution to the problem*

$$\left\{\begin{array}{rl} -\nu\Delta v_\varepsilon + \nabla q_\varepsilon = 0 & \text{in } D_\varepsilon, \\ \operatorname{div} v_\varepsilon = 0 & \text{in } D_\varepsilon, \\ v_\varepsilon = \varphi & \text{on } \Gamma_R, \\ v_\varepsilon = 0 & \text{on } \partial\omega_\varepsilon. \end{array}\right. \tag{6.9}$$

There exist a constant $c > 0$ (independent of φ and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\|v_\varepsilon\|_{1,D_\varepsilon} \leq c\,\|\varphi\|_{1/2,\Gamma_R}.$$

Proof. Let $\varepsilon_0 > 0$. Problem (6.9) is well-posed; hence there exists a constant c such that

$$|v_{\varepsilon_0}|_{1,D_{\varepsilon_0}} \leq c\|\varphi\|_{1/2,\Gamma_R}.$$

Let $\varepsilon_1 \leq \varepsilon_0$ be such that $D_{\varepsilon_0} \subset D_\varepsilon$ for all $\varepsilon < \varepsilon_1$. Let $\widehat{v}_{\varepsilon_0}$ be the extension of v_{ε_0} to D_ε by 0. Function v_ε minimizes the energy $|v|_{1,D_\varepsilon}$ over the affine space

$$\left\{v \in H^1(D_\varepsilon)^3;\ v = \varphi \text{ on } \Gamma_R,\ \operatorname{div} v = 0 \text{ and } v = 0 \text{ on } \partial\omega\right\};$$

hence, for all $\varepsilon \leq \varepsilon_1$ we have

$$|v_\varepsilon|_{1,D_\varepsilon} \leq |\widehat{v}_{\varepsilon_0}|_{1,D_\varepsilon} = |v_{\varepsilon_0}|_{1,D_{\varepsilon_0}} \leq c\|\varphi\|_{1/2,\Gamma_R}.$$

We also have

$$\|v_0\|_{0,D_0} \leq c\,\|\varphi\|_{1/2,\Gamma_R}.$$

Then, denoting by $\widehat{v}_\varepsilon$ the extension by 0 of v_ε to D_0 and using Poincaré's inequality on D_0 yields

$$\begin{aligned}\|v_\varepsilon\|_{0,D_\varepsilon} = \|\widehat{v}_\varepsilon\|_{0,D_0} &\leq \|\widehat{v}_\varepsilon - v_0\|_{0,D_0} + \|v_0\|_{0,D_0} \\ &\leq c\,|\widehat{v}_\varepsilon - v_0|_{1,D_0} + \|v_0\|_{0,D_0} \\ &\leq c\,|\widehat{v}_\varepsilon|_{1,D_0} + c\,\|v_0\|_{1,D_0} = c\,|v_\varepsilon|_{1,D_\varepsilon} + c\,\|v_0\|_{1,D_0} \\ &\leq c\,\|\varphi\|_{1/2,\Gamma_R}.\end{aligned}$$ □

LEMMA 6.4. *For $\varepsilon > 0$ and $\psi \in H^1(D_0)^3$ such that $\operatorname{div}\psi = 0$, let u_ε, p_ε be the solution to the problem*

$$\left\{\begin{array}{rl} -\nu\Delta u_\varepsilon + \nabla p_\varepsilon &= 0 \quad \text{in } D_\varepsilon, \\ \operatorname{div} u_\varepsilon &= 0 \quad \text{in } D_\varepsilon, \\ u_\varepsilon &= 0 \quad \text{on } \Gamma_R, \\ u_\varepsilon &= \psi \quad \text{on } \partial\omega_\varepsilon. \end{array}\right. \tag{6.10}$$

There exist a constant $c > 0$ (independent of ψ and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned} |u_\varepsilon|_{1,C(R/2,R)} &\le c\varepsilon \|\psi(\varepsilon y)\|_{1/2,\partial\omega}, \\ \|u_\varepsilon\|_{0,D_\varepsilon} &\le c\varepsilon \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}, \\ |u_\varepsilon|_{1,D_\varepsilon} &\le c\varepsilon^{1/2} \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}. \end{aligned}$$

Proof. Let $\widetilde{v}_\varepsilon$, $\widetilde{q}_\varepsilon$ be the solution to the exterior problem

$$\left\{ \begin{array}{rl} -\nu\Delta\widetilde{v}_\varepsilon + \nabla\widetilde{q}_\varepsilon = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ \operatorname{div}\widetilde{v}_\varepsilon = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ \widetilde{v}_\varepsilon = 0 & \text{at infinity}, \\ \widetilde{v}_\varepsilon = \psi(\varepsilon y) & \text{on } \partial\omega. \end{array} \right.$$

Function u_ε can be written

$$u_\varepsilon = v_\varepsilon - w_\varepsilon$$

where $v_\varepsilon(x) = \widetilde{v}_\varepsilon(x/\varepsilon)$. Function w_ε itself is the solution to

$$\left\{ \begin{array}{rl} -\nu\Delta w_\varepsilon + \nabla s_\varepsilon = 0 & \text{in } D_\varepsilon, \\ \operatorname{div} w_\varepsilon = 0 & \text{in } D_\varepsilon, \\ w_\varepsilon = v_\varepsilon & \text{on } \Gamma_R, \\ w_\varepsilon = 0 & \text{on } \partial\omega_\varepsilon. \end{array} \right.$$

It follows from Lemma 6.3, (6.5), (6.6), and Lemma 6.2 that there exist $c > 0$ and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned} \|w_\varepsilon\|_{1,D_\varepsilon} &\le c \|v_\varepsilon\|_{1/2,\Gamma_R} \\ &\le c \|v_\varepsilon\|_{1,C(R/2,R)} \\ &\le c(|v_\varepsilon|_{0,C(R/2,R)} + |v_\varepsilon|_{1,C(R/2,R)}) \\ &= c(\varepsilon^{3/2}|\widetilde{v}_\varepsilon|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2}|\widetilde{v}_\varepsilon|_{1,C(R/2\varepsilon,R/\varepsilon)}) \\ &\le c\varepsilon \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}. \end{aligned} \tag{6.11}$$

Hence

$$\begin{aligned} |u_\varepsilon|_{1,C(R/2,R)} = |v_\varepsilon - w_\varepsilon|_{1,C(R/2,R)} &\le |v_\varepsilon|_{1,C(R/2,R)} + |w_\varepsilon|_{1,D_\varepsilon} \\ &\le c\varepsilon \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}. \end{aligned}$$

Similarly we have

$$\begin{aligned} \|v_\varepsilon\|_{0,D_\varepsilon} &= \varepsilon^{3/2} \left\|\tilde{v}_\varepsilon\right\|_{0,D_\varepsilon/\varepsilon} \le c\varepsilon \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}, \\ |v_\varepsilon|_{1,D_\varepsilon} &= \varepsilon^{1/2} \left|\tilde{v}_\varepsilon\right|_{1,D_\varepsilon/\varepsilon} \le c\varepsilon^{1/2} \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega} \end{aligned}$$

and

$$\begin{aligned} \|u_\varepsilon\|_{0,D_\varepsilon} &\le c\varepsilon \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}, \\ |u_\varepsilon|_{1,D_\varepsilon} &\le c\varepsilon^{1/2} \left\|\psi(\varepsilon y)\right\|_{1/2,\partial\omega}. \end{aligned}$$

□

Lemmas 6.3 and 6.4 are summarized in the following lemma.

LEMMA 6.5. *For $\varepsilon > 0$, $\varphi \in H_V^{1/2}(\Gamma_R)^3$, and $\psi \in H^1(D_0)^3$ such that* $\operatorname{div}\psi = 0$, *let v_ε, q_ε be the solution to the problem*

$$\begin{cases} -\nu\Delta v_\varepsilon + \nabla q_\varepsilon = 0 & \text{in } D_\varepsilon, \\ \operatorname{div} v_\varepsilon = 0 & \text{in } D_\varepsilon, \\ v_\varepsilon = \varphi & \text{on } \Gamma_R, \\ v_\varepsilon = \psi & \text{on } \partial\omega_\varepsilon. \end{cases}$$

There exist a constant $c > 0$ (independent of φ, ψ and ε) and $\varepsilon_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_1$,

$$\begin{aligned} |v_\varepsilon|_{1,C(R/2,R)} &\le c\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right), \\ ||v_\varepsilon||_{0,D_\varepsilon} &\le c\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right), \\ |v_\varepsilon|_{1,D_\varepsilon} &\le c\left(\|\varphi\|_{1/2,\Gamma_R} + \varepsilon^{1/2}\,\|\psi(\varepsilon y)\|_{1/2,\partial\omega}\right). \end{aligned}$$

6.3. Variation of the bilinear form. The variation of the bilinear form a_ε reads

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Gamma_R} (T_\varepsilon - T_0)u.v\, d\gamma(x).$$

For $\varphi \in H_V^{1/2}(\Gamma_R)^3$, recall that $u_\varepsilon^{0,\varphi}$ is the solution to (3.2) or (3.3) if $\varepsilon = 0$. Let $v_\omega^{0,\varphi}$, $p_\omega^{0,\varphi}$ be the solution to

$$\begin{cases} -\nu\Delta v_\omega^{0,\varphi} + \nabla p_\omega^{0,\varphi} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ \operatorname{div} v_\omega^{0,\varphi} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ v_\omega^{0,\varphi} = 0 & \text{at } \infty, \\ v_\omega^{0,\varphi} = u_0^{0,\varphi}(x_0) & \text{on } \partial\omega. \end{cases} \tag{6.12}$$

As in (4.6), let $V_\omega^{0,\varphi}(y) = E(y)A_\omega(u_0^{0,\varphi}(x_0))$ be the dominant part of $v_\omega^{0,\varphi}$, and let $W_\omega^{0,\varphi}$, $Q_\omega^{0,\varphi}$ be the associated solution to (4.9) with $W_\omega^{0,\varphi} = V_\omega^{0,\varphi}$ on Γ_R. The linear operator δT (independent of ε) is defined as

(6.13)
$$\begin{aligned} \delta T : H_V^{1/2}(\Gamma_R)^3 &\longrightarrow H_V^{-1/2}(\Gamma_R)^3, \\ \varphi &\longmapsto \delta T\varphi := [(\nu DW_\omega^{0,\varphi} - Q_\omega^{0,\varphi} I) - (\nu DV_\omega^{0,\varphi} - P_\omega^{0,\varphi} I)]\mathbf{n}. \end{aligned}$$

PROPOSITION 6.6. *The asymptotic expansion of T_ε is*

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H_V^{1/2}(\Gamma_R)^3;\, H_V^{-1/2}(\Gamma_R)^3)} = O(\varepsilon^2). \tag{6.14}$$

Proof. Let $\varphi \in H_V^{1/2}(\Gamma_R)^3$. For simplicity we may drop the subscripts $(.)^{0,\varphi}$. For $y = x/\varepsilon$, we have $v_\omega(y) = V_\omega(y) + R_\omega(y)$ with $V_\omega(x/\varepsilon) = \varepsilon V_\omega(x)$; $p_\omega(y) = P_\omega(y) + S_\omega(y)$ with $P_\omega(x/\varepsilon) = \varepsilon^2 P_\omega(x)$; and $R_\omega(y) = O(1/||y||^2)$, $S_\omega(y) = O(1/||y||^3)$ (see (4.2), (4.6), (4.7)). Let

$$\psi_\varepsilon(x) = (T_\varepsilon - T_0 - \varepsilon\delta T)\varphi(x).$$

We have

$$\begin{aligned} \psi_\varepsilon(x) &= (\nu Du_\varepsilon - p_\varepsilon I)\mathbf{n} - (\nu Du_0 - p_0 I)\mathbf{n} - \varepsilon[(\nu DW_\omega - Q_\omega I)\mathbf{n} - (\nu DV_\omega - P_\omega I)\mathbf{n}] \\ &= \nu D(w_\varepsilon(x) - R_\omega(x/\varepsilon))\mathbf{n} - \left(s_\varepsilon(x) - \frac{1}{\varepsilon}S_\omega(x/\varepsilon)\right)\mathbf{n}, \end{aligned}$$

where w_ε, s_ε is defined by

$$w_\varepsilon(x) = u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon W_\omega(x),$$
$$s_\varepsilon(x) = p_\varepsilon(x) - p_0(x) + \frac{1}{\varepsilon} p_\omega(x/\varepsilon) - \varepsilon\, Q_\omega(x).$$

Functions w_ε, s_ε are solutions to

$$\left\{\begin{array}{rcll} -\nu\Delta w_\varepsilon + \nabla s_\varepsilon = & 0 & & \text{in } D_\varepsilon, \\ \operatorname{div} w_\varepsilon = & 0 & & \text{in } D_\varepsilon, \\ w_\varepsilon = & v_\omega(x/\varepsilon) - \varepsilon W_\omega(x) & & \text{on } \Gamma_R, \\ w_\varepsilon = & [-u_0(x) + u_0(x_0) - \varepsilon W_\omega(x)] & & \text{on } \partial\omega_\varepsilon. \end{array}\right.$$

In order to apply Lemma 6.5, we have to estimate the two right-hand sides.

On Γ_R, due to $W_\omega(x) = V_\omega(x)$, we have

$$v_\omega(x/\varepsilon) - \varepsilon W_\omega(x) = R_\omega(x/\varepsilon).$$

Due to the definition of v_ω and W_ω, we have

$$\int_{\Gamma_R} (v_\omega(x/\varepsilon) - \varepsilon W_\omega(x))\mathbf{n}\, d\gamma(x) = 0.$$

Using (6.5), (6.6), Lemma 6.2, and elliptic regularity we obtain

$$\begin{aligned} \|v_\omega(x/\varepsilon) - \varepsilon W_\omega\|_{1/2,\Gamma_R} &= \|R_\omega(x/\varepsilon)\|_{1/2,\Gamma_R} \\ &\le c\|R_\omega(x/\varepsilon)\|_{1,C(R/2,R)} \\ &\le c(\|R_\omega(x/\varepsilon)\|_{0,C(R/2,R)} + |R_\omega(x/\varepsilon)|_{1,C(R/2,R)}) \\ &= c(\varepsilon^{3/2}|R_\omega(y)|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2}|R_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)}) \\ &\le c\varepsilon^2\, \|u_0(x_0)\|_{1/2,\partial\omega} \\ &\le c\varepsilon^2 ||\varphi||_{1/2,\Gamma_R}. \end{aligned}$$

On $\partial\omega_\varepsilon$, putting $\theta_\varepsilon(x) := (-u_0(x) + u(x_0) - \varepsilon W_\omega(x))/\varepsilon$, we have $\operatorname{div}\theta_\varepsilon = 0$ in D_0, and for small ε,

$$\begin{aligned} \|\theta_\varepsilon(\varepsilon y)\|_{1/2,\partial\omega} &\le c\|\theta_\varepsilon(\varepsilon y)\|_{1,\omega} \\ &= c\left\|\frac{u_0(\varepsilon y) - u_0(x_0)}{\varepsilon} + W_\omega(\varepsilon y)\right\|_{1,\omega} \\ &\le c(||u_0||_{\mathcal{C}^2(B(0,R/2))} + ||W_\omega||_{\mathcal{C}^1(B(0,R/2))}) \\ &\le c(||\varphi||_{1/2,\Gamma_R} + ||V_\omega||_{1/2,\Gamma_R}) \\ &\le c||\varphi||_{1/2,\Gamma_R}. \end{aligned}$$

We can now apply Lemma 6.5, which gives

$$\begin{aligned} |w_\varepsilon(x)|_{1,C(R/2,R)} &\le c(\varepsilon^2||\varphi||_{1/2,\Gamma_R} + \varepsilon||\varepsilon\theta_\varepsilon(\varepsilon y)||_{1/2,\partial\omega}) \\ &\le c\varepsilon^2\, ||\varphi||_{1/2,\Gamma_R}. \end{aligned}$$

Finally, observing that $-\nu\Delta V_\omega + \nabla P_\omega = 0$ in $C(R/2, R)$, which implies that $-\nu\Delta(w_\varepsilon(x) - R(x/\varepsilon)) + \nabla(s_\varepsilon(x) - S_\omega(x/\varepsilon)/\varepsilon) = 0$ in $C(R/2, R)$, it follows from (6.4), (6.5), and

Lemma 6.2 that

$$\begin{aligned}||\psi||_{-1/2,\Gamma_R} &= \|\nu D(w_\varepsilon(x) - R(x/\varepsilon))\mathbf{n} - (s_\varepsilon(x) - S_\omega(x/\varepsilon)/\varepsilon)\mathbf{n}\|_{-1/2,\Gamma_R} \\ &\le c(|w_\varepsilon|_{1,C(R/2,R)} + |R_\omega(x/\varepsilon)|_{1,C(R/2,R)}) \\ &= c(|w_\varepsilon|_{1,C(R/2,R)} + \varepsilon^{1/2}|R_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)}) \\ &\le c\varepsilon^2\|\varphi\|_{1/2,\Gamma_R}.\end{aligned}$$

Hence

$$\|(T_\varepsilon - T_0 - \varepsilon\delta T)\varphi\|_{-1/2,\Gamma_R} = O(\varepsilon^2). \qquad \square$$

The asymptotic expansion of the bilinear form a_ε now follows straightforwardly.

PROPOSITION 6.7. *Let*

$$\delta a(u,v) = \int_{\Gamma_R} \delta T u.v \, d\gamma(x), \quad u,\, v \in \mathcal{V}_R.$$

Then the asymptotic expansion of the bilinear form a_ε is given by

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}_2(\mathcal{V}_R)} = O(\varepsilon^2).$$

6.4. Variation of the linear form. The technique is the same as in section 6.3. The difference comes from the boundary condition imposed on $\partial\omega$ to the solution of the exterior problem: $v_\omega^{0,\varphi} = u_0^{0,\varphi}(x_0)$ in (6.12) for the study of the bilinear form; $v_\omega^{f,0} = u_0^{f,0}(x_0)$ in (6.15) for the study of the linear form. Hence estimations involving $\|\varphi\|_{1/2,\Gamma_R}$ are replaced by estimations involving $\|f\|_{L^q}$. The variation of the linear form l_ε reads

$$l_\varepsilon(v) - l_0(v) = \int_{\Gamma_R} (f_\varepsilon - f_0).v \, d\gamma(x).$$

Recall that $u_\varepsilon^{f,0}$ is the solution to (3.2) or (3.3) if $\varepsilon = 0$. Let $v_\omega^{f,0}$, $p_\omega^{f,0}$ be the solution to

$$\left\{\begin{array}{rl} -\nu\Delta v_\omega^{f,0} + \nabla p_\omega^{f,0} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ \operatorname{div} v_\omega^{f,0} = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ v_\omega^{f,0} = 0 & \text{at } \infty, \\ v_\omega^{f,0} = u_0^{f,0}(x_0) & \text{on } \partial\omega. \end{array}\right. \tag{6.15}$$

As in (4.6), let $V_\omega^{f,0}(y) = E(y)A_\omega(u_0^{f,0}(x_0))$ be the dominant part of $v_\omega^{f,0}$, and let $W_\omega^{f,0}$, $Q_\omega^{f,0}$ be the associated solution to (4.9) with $W_\omega^{f,0} = V_\omega^{f,0}$ on Γ_R. Function $\delta f \in H_V^{-1/2}(\Gamma_R)^3$ (independent of ε) is defined by

$$\delta f = [-(\nu D W_\omega^{f,0} - Q_\omega^{f,0} I) + (\nu D V_\omega^{f,0} - P_\omega^{f,0} I)]\mathbf{n}. \tag{6.16}$$

PROPOSITION 6.8. *Let $f \in L^q(\Omega)^n$, $q > n$. The asymptotic expansion of f_ε is*

$$\|f_\varepsilon - f_0 - \varepsilon\delta f\|_{-1/2,\Gamma_R} = O(\varepsilon^2).$$

Proof. The proof runs as in Proposition 6.6 (we drop the subscripts $(.)^{f,0}$) with w_ε and θ_ε defined by

$$\begin{aligned} w_\varepsilon(x) &= u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon W_\omega(x), \\ \theta_\varepsilon(x) &= (-u_0(x) + u_0(x_0) - \varepsilon W_\omega(x))/\varepsilon. \end{aligned}$$

The only difference lies in the elliptic regularity estimates

$$|u_0(x_0)| \leq \|u_0\|_{\mathcal{C}^0(D_0)} \leq c\,\|f\|_{L^q},$$

and for small ε

$$\begin{aligned}
\|\theta_\varepsilon(\varepsilon y)\|_{1/2,\partial\omega} &\leq c\,\|\theta_\varepsilon(\varepsilon y)\|_{1,\omega} \\
&\leq c\,\left\|\frac{u_0(\varepsilon y)-u_0(x_0)}{\varepsilon}+W_\omega(\varepsilon y)\right\|_{1,\omega} \\
&\leq c\,(\|u_0\|_{\mathcal{C}^1(B(0,R/2))}+||W_\omega||_{\mathcal{C}^1(B(0,R/2))}) \\
&\leq c\,(\|f\|_{L^q}+||V_\omega||_{1/2,\Gamma_R}) \\
&\leq c\,\|f\|_{L^q}. \qquad \square
\end{aligned}$$

The asymptotic expansion of the linear form l_ε now follows straightforwardly.

PROPOSITION 6.9. *Let*

$$\delta l(v)=\int_{\Gamma_R}\delta f.v\,d\gamma(x),\quad v\in\mathcal{V}_R.$$

Then the asymptotic expansion of linear form l_ε is given by

$$\|l_\varepsilon-l_0-\varepsilon\delta l\|_{\mathcal{L}(\mathcal{V}_R)}=O(\varepsilon^2).$$

6.5. Proof of Theorem 4.1. It follows from Propositions 6.7 and 6.8 and Lemma 6.1 that

$$j(\varepsilon)=j(0)+(\delta a(u_0,v_0)-\delta l(v_0)+\delta J(u_0))\varepsilon+o(\varepsilon).$$

With $\varphi=u_{0|\Gamma_R}$, it follows from (3.4), (3.12), (4.1), (6.12), and (6.15) that

$$v_\omega=v_\omega^{f,0}+v_\omega^{0,\varphi},$$

which implies

$$\begin{aligned}
V_\omega &= V_\omega^{f,0}+V_\omega^{0,\varphi}, \\
W_\omega &= W_\omega^{f,0}+W_\omega^{0,\varphi}.
\end{aligned}$$

Then, using (6.13), (6.16), and Propositions 6.7 and 6.9, we obtain

$$\begin{aligned}
\delta a(u_0,v_0)-\delta l(v_0) &= \int_{\Gamma_R}[(\nu DW_\omega^{0,\varphi}-Q_\omega^{0,\varphi}I)-(\nu DV_\omega^{0,\varphi}-P_\omega^{0,\varphi}I)]\mathbf{n}.v_0\;d\gamma(x) \\
&\quad+\int_{\Gamma_R}[(\nu DW_\omega^{f,0}-Q_\omega^{f,0}I)-(\nu DV_\omega^{f,0}-P_\omega^{f,0}I)]\mathbf{n}.v_0\;d\gamma(x) \\
&= \int_{\Gamma_R}[(\nu DW_\omega^{f,\varphi}-Q_\omega^{f,\varphi}I)-(\nu DV_\omega^{f,\varphi}-P_\omega^{f,\varphi}I)]\mathbf{n}.v_0\;d\gamma(x),
\end{aligned}$$

which achieves the proof of Theorem 4.1.

6.6. Proof of Proposition 4.3. This section describes the variations of $J_\varepsilon(u) = \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon)$ (see (3.13)) when $\widetilde{J}_\varepsilon$ is of the form (4.17)

$$\widetilde{J}_\varepsilon(u) = \int_{\Omega_\varepsilon} g(x, u(x))\, dx, \quad u \in H^1(\Omega_\varepsilon)^3.$$

The hypotheses on g (4.18)–(4.20) described in section 4 are supposed to be satisfied. Throughout the two next sections, $\widetilde{u}_\varepsilon \in H^1(\Omega_\varepsilon)^3$, $\varepsilon \geq 0$, denotes the extension of $u \in \mathcal{V}_R$ which coincides with u on Ω_R and with $u_\varepsilon^{f,\varphi}$ on D_ε for $\varphi = u_{|\Gamma_R}$.

LEMMA 6.10. *Let $\varphi \in H_V^{1/2}(\Gamma_R)^3$ and $f \in L^q(\Omega)^3$, $q > n$. Let $u_\varepsilon^{f,\varphi}$ and $u_0^{f,\varphi}$ be, respectively, the solutions to* (3.2) *and* (3.3)*. Then*

$$||u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(W_\omega^{f,\varphi} - V_\omega^{f,\varphi})||_{0,D_\varepsilon} = O(\varepsilon^{3/2}), \tag{6.17}$$

$$||u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon W_\omega^{f,\varphi} + v_\omega^{f,\varphi}(x/\varepsilon)||_{1,D_\varepsilon} = O(\varepsilon^{3/2}), \tag{6.18}$$

where $V_\omega^{f,\varphi}$ is the dominant part (4.6) *of the solution $v_\omega^{f,\varphi}$ to the exterior problem* (4.1) *with $u_0^{f,\varphi}(x_0)$ substituted for $u_\Omega(x_0)$, and $W_\omega^{f,\varphi}$ is the associated solution to* (4.9)*.*

Proof. Recall that $v_\omega = V_\omega + R_\omega$ (4.6) with $V_\omega(x/\varepsilon) = \varepsilon V_\omega(x)$ and $R_\omega(y) = O(1/||y||^2)$ (we drop the subscripts $(.)^{f,\varphi}$). Let

$$\begin{aligned} w_\varepsilon(x) &= \left(u_\varepsilon - u_0 - \varepsilon(W_\omega - V_\omega)\right)(x) + R_\omega(x/\varepsilon) \\ &= u_\varepsilon(x) - u_0(x) + v_\omega(x/\varepsilon) - \varepsilon W_\omega(x). \end{aligned} \tag{6.19}$$

Function w_ε (with the appropriate s_ε) is the solution to

$$\left\{ \begin{array}{rcll} -\nu\Delta w_\varepsilon + \nabla s_\varepsilon = & 0 & & \text{in } D_\varepsilon, \\ \operatorname{div} w_\varepsilon = & 0 & & \text{in } D_\varepsilon, \\ w_\varepsilon = & v_\omega(x/\varepsilon) - \varepsilon W_\omega(x) & & \text{on } \Gamma_R, \\ w_\varepsilon = & -u_0(x) + u_0(x_0) - \varepsilon W_\omega(x) & & \text{on } \partial\omega_\varepsilon. \end{array} \right.$$

Using the same arguments as in the proofs of Proposition 6.6 and 6.8 we obtain

$$\begin{aligned} \|v_\omega(x/\varepsilon) - \varepsilon Q_\omega\|_{1/2,\Gamma_R} &\leq c\varepsilon^2 \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right), \\ \| - u_0(\varepsilon y) + u_0(x_0) - \varepsilon Q_\omega)\|_{1/2,\partial\omega} &\leq c\varepsilon \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right). \end{aligned}$$

It follows from Lemma 6.5 that

$$\begin{aligned} ||w_\varepsilon||_{0,D_\varepsilon} &\leq c\varepsilon^2 \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right), \\ ||w_\varepsilon||_{1,D_\varepsilon} &\leq c\varepsilon^{3/2} \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right). \end{aligned}$$

The second equation proves (6.18). Due to (6.6), Lemma 6.2, and elliptic regularity we also have

$$\|R_\omega(x/\varepsilon)\|_{0,D_\varepsilon} = \varepsilon^{3/2} \|R_\omega\|_{0,D_\varepsilon/\varepsilon} \leq c\varepsilon^{3/2} \left(\|\varphi\|_{1/2,\Gamma_R} + \|f\|_{L^q} \right).$$

We conclude by using $u_\varepsilon - u_0 - \varepsilon(W_\omega - V_\omega) = w_\varepsilon(x) - R_\omega(x/\varepsilon)$. ∎

The variation $J_\varepsilon(u) - J_0(u)$ is given by the next lemma.

LEMMA 6.11. *For $u \in \mathcal{V}_R$ we have*

$$\begin{aligned} J_\varepsilon(u) &= J_0(u) + \varepsilon\delta J(u) + o(\varepsilon), \\ \delta J(u) &= \int_{D_0} \nabla_s g(x, \widetilde{u}_0(x)).(W_\omega - V_\omega)\, dx, \end{aligned}$$

where W_ω and V_ω are defined as in Lemma 6.10, with $\varphi = u_{|\Gamma_R}$.

Proof. Let

$$I_\varepsilon = J_\varepsilon(u) - J_0(u) - \varepsilon \int_{D_0} \nabla_s g(x, \widetilde{u}_0).(W_\omega - V_\omega)\, dx.$$

On D_ε we have $\widetilde{u}_\varepsilon = u_\varepsilon^{f,\varphi}$ for $\varepsilon \geq 0$, $\varphi = u$ on Γ_R, and on Ω_R we have $\widetilde{u}_\varepsilon = \widetilde{u}_0$. Hence

$$\begin{aligned} I_\varepsilon &= \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon) - \widetilde{J}_0(\widetilde{u}_0) - \varepsilon \int_{D_0} \nabla_s g(x, \widetilde{u}_0).(W_\omega - V_\omega)\, dx \\ &= \int_{\Omega\varepsilon} g(x, \widetilde{u}_\varepsilon)\, dx - \int_\Omega g(x, \widetilde{u}_0)\, dx - \varepsilon \int_{D_0} \nabla_s g(x, \widetilde{u}_0).(W_\omega - V_\omega)\, dx \\ &= \int_{D_\varepsilon} g(x, u_\varepsilon^{f,\varphi}) - g(x, u_0^{f,\varphi})\, dx - \int_{\omega_\varepsilon} g(x, u_0^{f,\varphi})\, dx - \varepsilon \int_{D_0} \nabla_s g(x, u_0^{f,\varphi}).(W_\omega - V_\omega)\, dx. \end{aligned}$$

Due to the hypotheses on g (4.18) and (4.19), we have, for all $(x, s, t) \in \Omega \times \mathbb{R}^3 \times \mathbb{R}^3$,

$$\begin{aligned} &g(x,t) - g(x,s) = \nabla_s g(x,s).(t-s) + \theta(x,s,t)(t-s).(t-s), \\ &\|\theta(x,s,t)\|_{\mathcal{L}(\mathbb{R}^3)} \leq \frac{M}{2}. \end{aligned}$$

Then

$$\begin{aligned} I_\varepsilon = &\int_{D_\varepsilon} \nabla_s g(x, u_0^{f,\varphi}).\left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(W_\omega - V_\omega)\right)\, dx \\ &-\varepsilon \int_{\omega_\varepsilon} \nabla_s g(x, u_0^{f,\varphi}).(W_\omega - V_\omega)\, dx - \int_{\omega_\varepsilon} g(x, u_0^{f,\varphi})\, dx \\ &+ \int_{D_\varepsilon} \theta(x, u_0^{f,\varphi}, u_\varepsilon^{f,\varphi})(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi}).(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi})\, dx, \end{aligned}$$

and

$$\begin{aligned} |I_\varepsilon| \leq &\int_{D_\varepsilon} \left|\nabla_s g(x, u_0^{f,\varphi}).\left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(W_\omega - V_\omega)\right)\right|\, dx \\ &+\varepsilon \int_{\omega_\varepsilon} \left|\nabla_s g(x, u_0^{f,\varphi}).(W_\omega - V_\omega)\right|\, dx + \int_{\omega_\varepsilon} \left|g(x, u_0^{f,\varphi})\right|\, dx + \int_{D_\varepsilon} \frac{M}{2}|u_\varepsilon^{f,\varphi} - u_0^{f,\varphi}|^2\, dx. \end{aligned}$$

It follows from the hypotheses on g (4.18)–(4.20), Lemma 6.10, the regularity of $u_0^{f,\varphi}$ (which implies that $x \mapsto g(x, u_0^{f,\varphi}(x))$ is in $L^{3/2}(D_{R/2})$), $||V_\omega||_{0,\omega_\varepsilon} = c\varepsilon^{1/2}$, and $||\nabla_s g(., u_0^{f,\varphi}(.))||_{0,\omega_\varepsilon} = o(1)$ that

$$\begin{aligned} \int_{D_\varepsilon} \left|\nabla_s g(x, u_0^{f,\varphi}).\left(u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(W_\omega - V_\omega)\right)\right|\, dx &\leq c||u_\varepsilon^{f,\varphi} - u_0^{f,\varphi} - \varepsilon(W_\omega - V_\omega)||_{0,D_\varepsilon} \\ &= O(\varepsilon^{3/2}), \\ \int_{D_\varepsilon} \frac{M}{2}|u_\varepsilon^{f,\varphi} - u_0^{f,\varphi}|^2\, dx &= O(\varepsilon^2), \\ \varepsilon \int_{\omega_\varepsilon} \left|\nabla_s g(x, u_0^{f,\varphi}).(W_\omega - V_\omega)\right|\, dx &\leq \varepsilon||\nabla_s g(., u_0^{f,\varphi}(.))||_{0,\omega_\varepsilon}||W_\omega - V_\omega||_{0,\omega_\varepsilon} \\ &= o(\varepsilon^{3/2}), \end{aligned}$$

$$\int_{\omega_\varepsilon} \left| g(x, u_0^{f,\varphi}) \right| \, dx \leq \left(\int_{\omega_\varepsilon} \left| g(x, u_0^{f,\varphi}) \right|^{3/2} \, dx \right)^{2/3} \left(\int_{\omega_\varepsilon} dx \right)^{1/3} = o(\varepsilon). \tag{6.20}$$

Hence

$$I_\varepsilon = o(\varepsilon). \qquad \square$$

We can now check hypothesis (4.11) involved in Theorem 4.1.

PROPOSITION 6.12. *Function J_0 is differentiable on $\mathcal{V}_R$ and we have, for all $u, v \in \mathcal{V}_R$,*

$$J_\varepsilon(v) - J_0(u) = \varepsilon \delta J(u) + DJ_0(u)(v-u) + o(\varepsilon + \|v-u\|_{\mathcal{V}_R}).$$

Proof. We have

$$J_0(u) = \widetilde{J}_0(\widetilde{u}) = \int_\Omega g(x, \widetilde{u}(x)) \, dx.$$

It follows from the hypotheses on g (4.18) that function $\widetilde{J}_0$ is differentiable on $H^1(\Omega)^3$ with

$$D\widetilde{J}_0(\widetilde{u}_0)w = \int_\Omega \nabla_s g(x, \widetilde{u}_0).w \, dx, \quad w \in H^1(\Omega)^3.$$

Thus J_0 is differentiable on $\mathcal{V}_R$, and for $w \in \mathcal{V}_R$ extended by $\widehat{w} \in H^1(\Omega)^3$ with $-\nu\Delta\widehat{w} + \nabla\widehat{q} = 0$ in D_0 and $\operatorname{div}\widehat{w} = 0$, we have

$$DJ_0(u)w = D\widetilde{J}_0(\widetilde{u}_0)\widehat{w}.$$

Hence, applying Lemma 6.11 yields

$$\begin{aligned} J_\varepsilon(v) - J_0(u) &= J_\varepsilon(v) - J_0(v) + J_0(v) - J_0(u) \\ &= \varepsilon\delta J(v) + o(\varepsilon) + DJ_0(u)(v-u) + o(\|v-u\|_{\mathcal{V}_R}) \\ &= \varepsilon\delta J(u) + DJ_0(u)(v-u) + o(\varepsilon + \|v-u\|_{\mathcal{V}_R}) \\ &\quad + \varepsilon(\delta J(v) - \delta J(u)). \end{aligned}$$

It remains to prove that $\varepsilon(\delta J(v) - \delta J(u)) = o(\varepsilon + \|v-u\|_{\mathcal{V}_R})$. For this it is sufficient to prove that $\delta J(v) - \delta J(u) = O(\|v-u\|_{\mathcal{V}_R})$. With the notation defined below in (6.21) and (6.22), it follows from Lemma 6.11 that

$$\begin{aligned} \delta J(v) - \delta J(u) &= \int_{D_0} \nabla_s g(x, \widetilde{v}_0).(W_\omega^v - V_\omega^v) - \nabla_s g(x, \widetilde{u}_0).(W_\omega^u - V_\omega^u) \, dx \\ &= \int_{D_0} \left[\nabla_s g(x, \widetilde{v}_0) - \nabla_s g(x, \widetilde{u}_0) \right].(W_\omega^v - V_\omega^v) \, dx \\ &\quad + \int_{D_0} \nabla_s g(x, \widetilde{u}_0).\left[(W_\omega^v - V_\omega^v) - (W_\omega^u - V_\omega^u) \right] \, dx. \end{aligned}$$

Hence, using the hypotheses on g (4.18)–(4.19) we obtain

$$\begin{aligned} |\delta J(v) - \delta J(u)| &\leq \int_{D_0} M|\widetilde{v}_0 - \widetilde{u}_0||W_\omega^v - V_\omega^v| \, dx \\ &\quad + \int_{D_0} \left(|\nabla_s g(x,0)| + M|\widetilde{u}_0| \right) \left(|W_\omega^v - W_\omega^u| + |V_\omega^v - V_\omega^u| \right) \, dx. \end{aligned}$$

We conclude by using linearity and continuity of

$$\begin{array}{ccccccc} \mathcal{V}_R & \to & H_V^{1/2}(\Gamma_R)^3 & \to & H^1(D_0)^3 & \to & L^2(D_0)^3, \\ u & \mapsto & \varphi := u_{|\Gamma_R} & \mapsto & u_0^{f,\varphi} & \mapsto & V_\omega^u := EA_\omega(u_0^{f,\varphi}(x_0)) \end{array} \tag{6.21}$$

and

$$\begin{array}{ccccccc} \mathcal{V}_R & \to & H^{1/2}(\Gamma_R)^3 & \to & \mathbb{R}, \\ u & \mapsto & (V_\omega^u)_{|\Gamma_R} & \mapsto & W_\omega^u. \end{array} \tag{6.22}$$

□

Hence, hypothesis (4.11) is fulfilled and we can apply Theorem 4.1. The adjoint equation (4.14) reads

$$\nu \int_\Omega Dw : Dv_\Omega \, dx = -\int_\Omega \nabla_s g(x, u_\Omega).w \, dx;$$

hence

$$-\nu\Delta v_\Omega + \nabla q_\Omega = -\nabla_s g(x, u_\Omega). \tag{6.23}$$

It follows from (4.16), Proposition 6.11, and (6.23) that

$$\begin{aligned} \delta j(x_0) &= A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \int_{D_0} (\nu\Delta v_\Omega - \nabla q_\Omega).(V_\omega - W_\omega) \, dx + \delta J(u_0) \\ &= A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \int_{D_0} (\nu\Delta v_\Omega - \nabla q_\Omega)(V_\omega - W_\omega) \, dx \\ &\quad + \int_{D_0} \nabla_s g(x, u_\Omega)(W_\omega - V_\omega) \, dx \\ &= A_\omega(u_\Omega(x_0)).v_\Omega(x_0), \end{aligned}$$

which achieves the proof of Proposition 4.3.

6.7. Proof of Proposition 4.4. Here $\widetilde{J}_\varepsilon$ is of the form (4.21)

$$\widetilde{J}_\varepsilon(u) = \frac{1}{2} \int_{\Omega_\varepsilon} BD(u - u_{\mathrm{d}}) : D(u - u_{\mathrm{d}}) \, dx, \quad u \in H^1(\Omega_\varepsilon)^3.$$

The notation is the same as in section 6.6. For $u \in \mathcal{V}_R$, we have

$$J_\varepsilon(u) = \widetilde{J}_\varepsilon(\widetilde{u}_\varepsilon) = \frac{1}{2} \int_{\Omega_\varepsilon} BD(\widetilde{u}_\varepsilon - u_{\mathrm{d}}) : D(\widetilde{u}_\varepsilon - u_{\mathrm{d}}) \, dx.$$

Due to the assumptions Δu_{d}, $f \in L^q(\Omega)^3$ with $q > n$, we have Du_{d}, $D\,\widetilde{u}_0 \in \mathcal{C}^0(\overline{B}(0, R/2))^9$ (see [8, Chap. II, sect. 3, Prop. 6]); hence

$$\int_{\omega_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D(\widetilde{u}_0 - u_{\mathrm{d}}) \, dx = O(\varepsilon^3).$$

This and the fact that $b_{ijkl}(x) = b_{klij}(x)$ yield

$$J_\varepsilon(u) - J_0(u) = \frac{1}{2} \int_{D_\varepsilon} 2\, BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D(\widetilde{u}_\varepsilon - \widetilde{u}_0) + BD(\widetilde{u}_\varepsilon - \widetilde{u}_0) : D(\widetilde{u}_\varepsilon - \widetilde{u}_0) \, dx + o(\varepsilon).$$

Equation (6.19) reads here as

$$w_\varepsilon(x) = \widetilde{u}_\varepsilon(x) - \widetilde{u}_0(x) + v_\omega(x/\varepsilon) - \varepsilon W_\omega(x)$$

and

$$\begin{aligned} J_\varepsilon(u) - J_0(u) = &\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D(\varepsilon W_\omega - v_\omega(x/\varepsilon) + w_\varepsilon)\,dx \\ &+\frac{1}{2}\int_{D_\varepsilon} BD(\varepsilon W_\omega - v_\omega(x/\varepsilon) + w_\varepsilon) : D(\varepsilon W_\omega - v_\omega(x/\varepsilon) + w_\varepsilon)\,dx + o(\varepsilon). \end{aligned}$$

Recall that $v_\omega = V_\omega + R_\omega$ (4.6) with $V_\omega(x/\varepsilon) = \varepsilon V_\omega(x)$ and $R_\omega(y) = O(1/||y||^2)$. Then

$$\begin{aligned} J_\varepsilon(u) - J_0(u) = &\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D(\varepsilon W_\omega(x) - \varepsilon V_\omega(x))\,dx \\ &-\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D_x R_\omega(x/\varepsilon)\,dx \\ &+\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : Dw_\varepsilon(x)\,dx + \frac{\varepsilon^2}{2}\int_{D_\varepsilon} BDW_\omega : DW_\omega\,dx \\ &+\frac{1}{2}\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : D_x v_\omega(x/\varepsilon)\,dx - \varepsilon\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : DW_\omega\,dx \\ &+\int_{D_\varepsilon} BD(\varepsilon W_\omega - v_\omega(x/\varepsilon)) : Dw_\varepsilon\,dx + \frac{1}{2}\int_{D_\varepsilon} BDw_\varepsilon : Dw_\varepsilon\,dx + o(\varepsilon). \end{aligned}$$

Here D_x denotes the derivative with respect to x, and particularly $D(v(x/\varepsilon)) = D_x v(x/\varepsilon) = Dv(x/\varepsilon)/\varepsilon$. We have $||D_x R_\omega(x/\varepsilon)||_{L^1(D_\varepsilon)} = \varepsilon^2 ||DR_\omega||_{L^1(D_\varepsilon/\varepsilon)} = O(\varepsilon^2|\log\varepsilon|)$; hence

$$\begin{aligned} \left|\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : D_x R_\omega(x/\varepsilon)\,dx\right| &\le ||BD(\widetilde{u}_0 - u_{\mathrm{d}})||_\infty ||D_x R_\omega(x/\varepsilon)||_{L^1(D_\varepsilon)} \\ &\le (||\widetilde{u}_0||_{3,D_0} + ||u_{\mathrm{d}}||_{1,\infty,D_0})||D_x R_\omega(x/\varepsilon)||_{L^1(D_\varepsilon)} \\ &= o(\varepsilon). \end{aligned}$$

It follows from the regularity of W_ω and Lemmas 6.2 and 6.10 that

$$\int_{D_\varepsilon} BD(\widetilde{u}_0 - u_{\mathrm{d}}) : Dw_\varepsilon(x)\,dx = O(\varepsilon^{3/2}),$$

$$\int_{D_\varepsilon} \varepsilon^2 BDW_\omega : DW_\omega\,dx = O(\varepsilon^2),$$

$$\varepsilon\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : DW_\omega\,dx = O(\varepsilon^{3/2}),$$

$$\int_{D_\varepsilon} BD(\varepsilon W_\omega - v_\omega(x/\varepsilon)) : Dw_\varepsilon\,dx = O(\varepsilon^2),$$

$$\int_{D_\varepsilon} BDw_\varepsilon : Dw_\varepsilon\,dx = O(\varepsilon^3).$$

Hence, using $DV_\omega = O(1/r^2)$, which implies that $\int_{\omega_\varepsilon} BD(\widetilde{u}_0 - u_\mathrm{d}) : D(W_\omega - V_\omega)\,dx = O(\varepsilon)$, we obtain

$$J_\varepsilon(u) - J_0(u) = \varepsilon \int_{D_0} BD(\widetilde{u}_0 - u_\mathrm{d}) : D(W_\omega - V_\omega)\,dx + \frac{1}{2}\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : D_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

The adjoint equation reads for $\varphi \in \mathcal{D}^3(D_0)$ as

$$\int_{D_0} (-\nu\Delta v_\Omega + \nabla q_\Omega).\varphi\,dx = -\int_{D_0} BD(u_\Omega - u_\mathrm{d}) : D\varphi\,dx. \tag{6.24}$$

Due to $B \in W^{1,\infty}(\Omega)^{9\times 9}$ and Δu_d, $f \in L^q(\Omega)^3$ (thus $D^2 u_\mathrm{d}$, $D^2 u_\Omega \in L^q(D_0)$; cf. the Calderon–Zygmund theorem [8, Chap. II, sect. 3, Prop. 8]), we have $-\nu\Delta v_\Omega + \nabla q_\Omega = \mathrm{div}\,[BD(u_\Omega - u_\mathrm{d})] \in L^q(D_0)^3$. Moreover, $q > n/2$ and $W_\omega - V_\omega \in L^m(D_0)^3$ for all $m < 3$; thus $(-\nu\Delta v_\Omega + \nabla q_\Omega).(P_\omega - Q_\omega) \in L^1(D_0)$. Hence, as $W_\omega - V_\omega$ vanishes on Γ_R, (6.24) still holds for $\varphi = W_\omega - V_\omega$, and

$$J_\varepsilon(u_0) - J_0(u_0) = \int_{D_0} \varepsilon(\nu\Delta v_\Omega - \nabla q_\Omega).(W_\omega - V_\omega) + \frac{1}{2}\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : D_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

Then the proof can be achieved as in section 6.6. It follows from Corollary 4.2 that

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \frac{1}{2}\int_{D_\varepsilon} BD_x v_\omega(x/\varepsilon) : D_x v_\omega(x/\varepsilon)\,dx + o(\varepsilon).$$

Using Lebesgue's convergence theorem, we deduce that

$$\int_{D_\varepsilon} B(x) D_x v_\omega(x/\varepsilon) : D_x v_\omega(x/\varepsilon)\,dx = \varepsilon \int_{D_\varepsilon/\varepsilon} B(\varepsilon y) Dv_\omega(y) : Dv_\omega(y)\,dy = \varepsilon \int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0) Dv_\omega(y) : Dv_\omega(y)\,dy + o(\varepsilon),$$

which proves that

$$j(\varepsilon) = j(0) + \varepsilon A_\omega(u_\Omega(x_0)).v_\Omega(x_0) + \frac{\varepsilon}{2}\int_{\mathbb{R}^3\setminus\overline{\omega}} B(x_0) Dv_\omega(y) : Dv_\omega(y)\,dy + o(\varepsilon)$$

and completes the proof of Proposition 4.4.

Acknowledgment. The authors are grateful to the referees for their careful reading and their valuable suggestions concerning the presentation.

PRACTICAL AND ASYMPTOTIC STABILIZATION OF CHAINED SYSTEMS BY THE TRANSVERSE FUNCTION CONTROL APPROACH*

PASCAL MORIN† AND CLAUDE SAMSON†

Abstract. A control approach for the practical and asymptotic stabilization of nonlinear driftless systems subjected to additive perturbations is proposed. Such perturbations arise naturally, for instance, in the modeling of trajectory stabilization problems for controllable driftless systems on Lie groups. The objective of the approach is to provide practical stability of an arbitrary given point in the state space, whatever the perturbations, and asymptotic stability (resp., convergence to the point) when the perturbations are absent (resp., tend to zero). A general framework is presented in this paper, and a control solution is proposed for the class of the chained systems.

Key words. nonlinear systems, stabilization, feedback control, Lie groups

1. Introduction.

The development of the transverse function (t.f.) approach [18] finds its original motivation in the problem of *practical* stabilization of the origin of a control system in the form

$$\mathcal{S}: \qquad \dot{x} = \sum_{i=1}^{m} u_i X_i(x) + P(x,t), \tag{1}$$

with $x \in \mathbb{R}^n$, $n > m$, $\{X_1, \ldots, X_m\}$ a set of smooth vector fields (v.f.) that satisfy the Lie algebra rank condition (LARC) on an open ball centered at $x = 0$, and P an additive perturbation, continuous in x and t but otherwise *arbitrary*. Note that such a perturbation may well forbid the existence of any equilibrium point for the controlled system. The t.f. approach provides a general solution to this problem. Up to now, and to our knowledge, this solution is unique in its class, even though several other methods and many control laws have been devised during the last decade to address the stabilization problem when $P \equiv 0$. These studies were motivated in the first place by Brockett's theorem [5] according to which, if $m < n$ and the control v.f. evaluated at $x = 0$ are linearly independent, no smooth or even continuous pure state feedback can make the origin of the system asymptotically stable. Different types of feedback laws have been considered to circumvent this difficulty, although not all of them guarantee Lyapunov stability. Discontinuous feedback [1, 3, 6, 11] and hybrid feedback [2, 15, 23] are two possibilities. Another one, more related to the present approach, consists of using continuous time-varying feedback [21, 7, 20, 27, 22, 13, 19, 16, 14]. An early survey on the control of nonholonomic systems, whose kinematic models are nonlinear driftless systems, can also be found in [4]. The importance of considering the perturbed case in association with the objective of practical stabilization is well illustrated when $\mathcal{S}$ is a system on a Lie group and the control objective consists of tracking a trajectory. Indeed, it is shown in [18] that the *error system* associated with

†INRIA, 2004 Route des Lucioles, B. P. 93, 06902 Sophia-Antipolis Cedex, France (Pascal.Morin@inria.fr, Claude.Samson@inria.fr)

this problem is in the same form as the original system, except for the presence of a perturbation P. Moreover, when the trajectory is not a solution of the control system, asymptotic stabilization is not possible. Other reasons for considering practical stabilization as a reasonable control objective, in the case of nonlinear driftless systems, are also pointed out in [18]: lack of robustness of exponential (continuous/time-varying or discontinuous) stabilizers, nonexistence of feedback controllers capable of stabilizing asymptotically every feasible trajectory [12], and incapacity of most existing asymptotic stabilizers to ensure ε-ultimate boundedness of the closed-loop trajectories when a destabilizing perturbation P is present. However, it is important to realize that practical stabilization is by no means opposed to asymptotic stabilization. It is merely a weaker requirement, whose interest resides precisely in the fact that it is weaker and thus applicable to more numerous situations. Once practical stabilization is granted, it may still be possible, and desirable in some cases, to achieve asymptotic stabilization, or at least convergence to zero—when, for instance, P vanishes after some time. For the same reasons, feedback controllers derived with the t.f. approach should not be considered as antagonistic to other controllers proposed for nonlinear driftless systems—asymptotic stabilizers, in particular. A more pertinent issue is the possibility of deriving a practical stabilizer which also ensures asymptotic stabilization when the perturbation P allows for it. For instance, can the t.f. approach be used for this purpose?

This question is addressed in the present paper, and a partial positive answer is obtained. More precisely, an extension of the approach in [18] is proposed in order to achieve asymptotic stabilization of the origin of $\mathcal{S}$ when $P \equiv 0$, and asymptotic convergence to the origin when P tends to zero as time tends to infinity. The main ingredient of this extension is the concept of a *generalized* t.f. introduced in section 2. The principles of the t.f. approach and design of stabilizers are also laid out in this section. A solution to the problem of practical and asymptotic stabilization for the popular class of the chained systems is proposed in section 3, and illustrated by simulation results in section 4. The practical relevance of this case comes from the widespread use of chained systems to model the kinematic equations of various mechanical systems subjected to nonholonomic constraints (unicycle and car-like mobile robots, for instance) and also the possibility of using them as homogeneous approximations of dynamics involved in several other physical systems (ships, induction motors, etc.). Finding a more general solution, which applies to a broader class of systems, remains an open subject of research. In order to facilitate the reading of the paper, we have distributed the proofs of our results into two sections: the cores are given in section 5, whereas intermediate technical results of lesser conceptual significance are regrouped in the appendix.

Since the t.f. approach finds its most natural exposition in the context of systems which are invariant on Lie groups, we have chosen to recast the systems and control problems evoked above in this framework. Let us recall the prominent role played by Lie groups in control theory [26, 10]. In particular, controllable driftless systems can always be approximated by controllable driftless homogeneous systems which are, after a possible dynamic extension, systems on Lie groups. The chained systems, which are more specifically addressed here, are systems on Lie groups.

The following notation is used throughout the paper. The tangent space of a manifold M at a point p is denoted as T_pM. The differential of a smooth mapping f between manifolds, at a point p, is denoted as $df(p)$. The torus of dimension $p \in \mathbb{N}$ is $\mathbb{T}^p$ with $\mathbb{T} \triangleq \mathbb{R}/2\pi\mathbb{Z}$. An element $\theta \in \mathbb{T}$ is identified with the real number in $(-\pi, +\pi]$ which belongs to the class of equivalence of θ. Addition of angles makes $\mathbb{T}^p$

a Lie group. The ith component of $\sigma \in \mathbb{T}^p$ is denoted as σ_i, i.e., $\sigma = (\sigma_1, \ldots, \sigma_p)$. The canonical basis of $\mathbb{R}^p$ is the set of unitary vectors $\{e_i\}_{i=1,\ldots,p}$. Since this set is also the natural basis of the Lie algebra of $\mathbb{T}^p$, a vector field v on $\mathbb{T}^p$ is identified with its vector of coordinates in this basis, i.e., $v = (v_1, \ldots, v_p)'$ if $v = \sum_{i=1}^p v_i e_i$. If $\sigma(.)$ is a smooth curve on $\mathbb{T}^p$, this identification allows us to view $\dot{\sigma}(t)$ as a vector in $\mathbb{R}^p$. Consider a differentiable mapping f from $\mathbb{T}^p$ to a manifold M. By a slight abuse of notation, and for the sake of simplifying the writing of several forthcoming equations, we write the Lie derivative of f along e_i at σ as $\frac{\partial f}{\partial \sigma_i}(\sigma)$, or $\frac{\partial f}{\partial \sigma}(\sigma)e_i$, instead of $df(\sigma)(e_i)$ (or $L_{e_i} f(\sigma)$), even though the normal use of the partial derivative symbol refers to a system of coordinates on M. Accordingly, along an arbitrary v.f. v on $\mathbb{T}^p$, we write $\frac{\partial f}{\partial \sigma}(\sigma)v \triangleq df(\sigma)(v)$. We also use standard notation for Lie groups—see, e.g., [8] for more details on this topic. G denotes a Lie group of dimension n, with Lie algebra (of left-invariant v.f.) $\mathfrak{g}$. For simplicity, we assume that G is connected so that there exists a globally defined left-invariant distance d_G on G. The identity element of G is denoted by e. Left and right translations are denoted by l and r, respectively, i.e., $l_\sigma(\tau) = r_\tau(\sigma) = \sigma\tau$. As usual, if $X \in \mathfrak{g}$, then $\exp tX$ is the solution at time t of $\dot{g} = X(g)$ with initial condition $g(0) = e$. The adjoint representation of G is Ad; i.e., for $\sigma \in G$, $\mathrm{Ad}(\sigma) = dI_\sigma(e)$ with $I_\sigma : G \longrightarrow G$ defined by $I_\sigma(g) = \sigma g \sigma^{-1}$. By extension we define the v.f. $\mathrm{Ad}(\sigma)X$ on G by $\mathrm{Ad}(\sigma)X(g) = dl_g(e)(\mathrm{Ad}(\sigma)X(e))$. The differential of Ad is ad, and $(\mathrm{ad}X, Y) = [X, Y]$, the Lie bracket of X and Y.

2. Control of perturbed driftless systems by the t.f. approach. Consider a control system

$$\mathcal{S}(g): \qquad \dot{g} = \sum_{i=1}^m u_i X_i(g) + P(g,t) \tag{2}$$

on a Lie group G, with $X_1, \ldots, X_m$ independent left-invariant smooth v.f. that satisfy the LARC. We assume that the drift term $P(g,t)$ is a continuous function of g and t, and that[1]

$$\forall (g,t) \in G \times \mathbb{R}, \qquad P(g,t) \in \mathrm{span}\{X_1(g), \ldots, X_m(g)\}^\perp, \tag{3}$$

where orthogonality refers to an arbitrary Riemannian metric on G. The definition of a *transverse function*, as originally given in [17] for v.f. on an arbitrary manifold—i.e., not necessarily on a Lie group—is now recalled.

DEFINITION 1. *Let $X_1, \ldots, X_m$ denote smooth v.f. on a manifold M. A function $f \in \mathcal{C}^\infty(\mathbb{T}^p; M)$ is called a* transverse function *(for the v.f. $X_1, \ldots, X_m$) if*

$$\forall \sigma \in \mathbb{T}^p, \quad \mathrm{span}\{X_1(f(\sigma)), \ldots, X_m(f(\sigma))\} + df(\sigma)(T_\sigma \mathbb{T}^p) = T_{f(\sigma)} M. \tag{4}$$

Another way of writing the above relation (with the notation explained before) is

$$\forall \sigma \in \mathbb{T}^p, \quad \mathrm{span}\left\{X_1(f(\sigma)), \ldots, X_m(f(\sigma)), \frac{\partial f}{\partial \sigma_1}(\sigma), \ldots, \frac{\partial f}{\partial \sigma_p}(\sigma)\right\} = T_{f(\sigma)} M. \tag{5}$$

Note that, by this definition, the image set $\mathrm{Im}(f) = f(\mathbb{T}^p)$ is compact. The main contribution of [17] was to show that if a set of v.f. $X_1, \ldots, X_m$ satisfies the LARC at some point $q \in M$, then for any neighborhood $\mathcal{U}$ of q there exists a transverse function with values in $\mathcal{U}$.

[1] Note that (3) can always be obtained after the application of a suitable preliminary feedback.

In the context of stabilization, transverse functions allow to use $\dot{\sigma}$ as a new—virtual—control input vector. This leads us to introduce the following dynamic extension of $\mathcal{S}(g)$, which evolves on $G \times \mathbb{T}^p$:

$$\mathcal{S}(g,\sigma): \quad \begin{cases} \dot{g} = \sum_{i=1}^{m} u_i X_i(g) + P(g,t), \\ \dot{\sigma} = u_\sigma, \end{cases} \tag{6}$$

where (u, u_σ) is viewed as an extended control vector. In the following subsection, the practical stabilization of $g = e$ for $\mathcal{S}(g)$, based on the t.f. approach, is addressed. More details on the approach, as well as several examples with explicit derivations of t.f., can be found in [18].

2.1. Practical stabilization. The formulation of a general practical stabilization problem which can be associated with $\mathcal{S}(g)$ is as follows: given an arbitrary neighborhood $\mathcal{U}_G(e)$ of e, determine a (smooth, or at least continuous) feedback control (which depends on g and, eventually, on other variables) which asymptotically stabilizes some compact set $\mathcal{D}_G \subset \mathcal{U}_G(e)$. The t.f. control approach provides a solution to this problem. This solution is now recalled.

Consider the change of variables on $G \times \mathbb{T}^p$ defined by $\Psi_f(g,\sigma) = (f(\sigma)g^{-1}, \sigma)$, with f a t.f. such that $f(\mathbb{T}^p) \subset \mathcal{U}_G(e)$. From now on, in order to ease the notation, the element $f(\sigma)g^{-1} \in G$ associated with g and $f(\sigma)$ will be abbreviated as z, i.e., $z \triangleq f(\sigma)g^{-1}$. By differentiating both members of the equality $zg = f(\sigma)$, one easily verifies that, along any trajectory $(g,\sigma)(.)$ of $\mathcal{S}(g,\sigma)$,

$$\dot{z} = -dr_{g^{-1}}(f(\sigma))\left(\sum_{i=1}^{m} u_i X_i(f(\sigma)) - \frac{\partial f}{\partial \sigma}(\sigma)\dot{\sigma} + dl_z(g)P(g,t)\right). \tag{7}$$

Therefore, $\mathcal{S}(g,\sigma)$ is equivalent to the control system

$$\bar{\mathcal{S}}(z,\sigma): \begin{cases} \dot{z} = -dr_{g^{-1}}(f(\sigma))\left(\sum_{i=1}^{m} u_i X_i(f(\sigma)) - \frac{\partial f}{\partial \sigma}(\sigma)u_\sigma + dl_z(g)P(g,t)\right), \\ \dot{\sigma} = u_\sigma. \end{cases} \tag{8}$$

From the definition of Ψ_f, the asymptotic stability of $\{e\} \times \mathbb{T}^p$ for $\bar{\mathcal{S}}(z,\sigma)$ is equivalent to the asymptotic stability of $\{(f(\sigma),\sigma) : \sigma \in \mathbb{T}^p\}$ for $\mathcal{S}(g,\sigma)$. It is also equivalent to the asymptotic stability of $f(\mathbb{T}^p)$ for $\mathcal{S}(g)$, provided that, for some left-invariant distance on G, the initial value $\sigma(0)$ of σ is chosen so as to minimize the distance between $z(0) = f(\sigma(0))g(0)^{-1}$ and e.

Now, for any v.f. Z on G, the property of transversality of f ensures that the equation

$$\sum_{i=1}^{m} u_i X_i(f(\sigma)) - \frac{\partial f}{\partial \sigma}(\sigma)u_\sigma = -dl_z(g)P(g,t) - dr_g(z)Z(z) \tag{9}$$

admits a feedback solution $(u, u_\sigma)(g,\sigma,t)$. Applying any[2] such feedback law to $\bar{\mathcal{S}}(z,\sigma)$, and using the fact that $(dr_g(z))^{-1} = dr_{g^{-1}}(f)$, it follows from (7) that

$$\dot{z} = Z(z). \tag{10}$$

[2]The only (weak) requirement is that the solutions of $\mathcal{S}(g,\sigma)$ must be well defined for $t \in [0,\infty)$.

Therefore, provided that Z is chosen so as to asymptotically stabilize e for system (10), the feedback law (u, u_σ) defined by (9) makes the set $\{e\} \times \mathbb{T}^p$ asymptotically stable for $\bar{\mathcal{S}}(z, \sigma)$.

In general, the solution (u, u_σ) of (9) is not unique. It is shown in [18], however, that one can always find[3] t.f. $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m}; G)$, i.e., such that $p = n - m$ with the notation of Definition 1. It is clear from the transversality condition (4) that this value of p is minimal and that the solution (u, u_σ) of (9), given f, is unique in this case. Allowing the t.f. f to depend on a larger number of variables provides complementary control inputs which can be used to guarantee complementary control objectives. The asymptotic stabilization of e for $\mathcal{S}(g)$ when $P \equiv 0$ will, for instance, be addressed in this way.

2.2. A framework for asymptotic stabilization. Let us introduce, in the framework of Lie groups, the following specific class of transverse functions.

DEFINITION 2. *Consider a function $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m} \times \mathbb{T}^{n-m}; G)$ and the associated family of functions $\{f_\beta\}_{\beta \in \mathbb{T}^{n-m}}$ defined by $f_\beta(\theta) = f(\theta, \beta)$. The function f is called a* generalized *t.f. for the v.f. $X_1, \ldots, X_m$ on the Lie group G if*

$$\begin{aligned} &\forall \sigma = (\theta, \beta) \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}, \\ &\operatorname{span}\{X_1(f(\sigma)), \ldots, X_m(f(\sigma))\} + df_\beta(\theta)(T_\theta \mathbb{T}^{n-m}) = T_{f(\sigma)} G \end{aligned} \tag{11}$$

and

$$\forall \beta \in \mathbb{T}^{n-m}, \quad f(0, \beta) = e. \tag{12}$$

From now on, variables in $\mathbb{T}^{n-m}$ will be indexed starting from $m + 1$; i.e., if $\theta \in \mathbb{T}^{n-m}$, then $\theta = (\theta_{m+1}, \ldots, \theta_n)$. With the notation specified in the introduction, another way of writing relation (11) is

$$\begin{aligned} &\forall \sigma = (\theta, \beta) \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}, \\ &\operatorname{span}\left\{X_1(f(\sigma)), \ldots, X_m(f(\sigma)), \frac{\partial f}{\partial \theta_{m+1}}(\sigma), \ldots, \frac{\partial f}{\partial \theta_n}(\sigma)\right\} = T_{f(\sigma)} G. \end{aligned} \tag{13}$$

It is clear that any generalized t.f. is a t.f. It is also quite simple to build a generalized t.f. $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m} \times \mathbb{T}^{n-m}; G)$ from a t.f. $\bar{f} \in \mathcal{C}^\infty(\mathbb{T}^{n-m}; G)$. For example, define

$$\forall (\theta, \beta) \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}, \quad f(\theta, \beta) = (\bar{f}(\beta))^{-1} \bar{f}(\theta + \beta).$$

Let us now consider any generalized t.f. We let

$$\dot{\theta} = v, \qquad \dot{\beta} = w, \tag{14}$$

so that $\dot{\sigma} = u_\sigma = (v, w)$. With this notation, (9)—whose satisfaction yields $\dot{z} = Z(z)$—is equivalent to

$$\sum_{i=1}^{m} u_i X_i(f(\sigma)) - \frac{\partial f}{\partial \theta}(\sigma) v = \frac{\partial f}{\partial \beta}(\sigma) w - dl_z(g) P(g, t) - dr_g(z) Z(z). \tag{15}$$

From (11), this equation has a unique feedback solution $(u, v)(g, \sigma, t)$ for any function w. The v.f. Z is again chosen so as to make $z = e$ asymptotically stable. Now the

[3] Expressions of such functions are given in that paper—see also the next subsection.

objective is to determine w in order to make θ tend to zero. Indeed, this latter property implies, in view of (12), that f tends to e so that, from the fact that $z = f(\sigma)g^{-1}$ tends to e, the asymptotic convergence of g to e follows. Note that such a convergence cannot be obtained without the drift term P satisfying some extra conditions. For instance, if $P(e,t)$ is periodically different from zero, then it follows from (3) that e cannot be an equilibrium for system (2), whatever the control u. Moreover, under mild complementary regularity conditions upon the function P, convergence of $P(g,t)$ to zero when g tends to e and t tends to infinity is necessary to the convergence of the system's solutions to e.

The feedback law (u,v) defined by (15) ensures the convergence of z to e independently of w. Hence, the asymptotic behavior of $\theta(t)$ and $\beta(t)$, for the controlled system, is described by the *zero-dynamics* obtained by setting $z = e$ in (15), i.e.,

$$\sum_{i=1}^{m} u_i(g,\sigma,t)X_i(f(\sigma)) - \frac{\partial f}{\partial \theta}(\sigma)v(g,\sigma,t) = \frac{\partial f}{\partial \beta}(\sigma)w - P(f(\sigma),t). \tag{16}$$

From the initial assumption that the v.f. $X_1,\ldots,X_m$ are independent, there exist v.f. $X_{m+1},\ldots,X_n$ such that $\operatorname{span}\{X_1,\ldots,X_n\} = \mathfrak{g}$. For any such set of v.f., there exist smooth functions $a_{i,j}$ and $b_{i,j}$ such that

(17)
$$\forall j = m+1,\ldots,n\,, \quad \frac{\partial f}{\partial \theta_j}(\sigma) = \sum_{i=1}^{n} a_{i,j}(\sigma)X_i(f(\sigma))\,, \quad \frac{\partial f}{\partial \beta_j}(\sigma) = \sum_{i=1}^{n} b_{i,j}(\sigma)X_i(f(\sigma)).$$

With d_i $(i = m+1,\ldots,n)$ denoting the one-forms defined by $\langle d_i, X_k\rangle = \delta_{i,k}$ (the Kronecker delta), the application of d_i to each side of (16) yields, since $\dot\theta = v$,

$$A(\sigma)\dot\theta = -B(\sigma)w + \sum_{i=m+1}^{n} \langle d_i(f(\sigma)), P(f(\sigma),t)\rangle e_i \tag{18}$$

with

$$A(\sigma) \triangleq (a_{i,j}(\sigma))_{i,j=m+1,\ldots,n}, \qquad B(\sigma) \triangleq (b_{i,j}(\sigma))_{i,j=m+1,\ldots,n}, \tag{19}$$

and e_i the $(i-m)$th unit vector in $\mathbb{R}^{n-m}$. Note that the transversality condition (11) is equivalent to the matrix $A(\sigma)$ being invertible for any σ.

Equation (18) is important because it explicitly relates the control w (the time-derivative of β) to the variation of θ. In particular, the simplification obtained when $P \equiv 0$, i.e.,

$$\dot\theta = -A^{-1}(\sigma)B(\sigma)w, \tag{20}$$

suggests some ways of choosing w to make $|\theta(t)|$ nonincreasing on the zero-dynamics. However, a difficulty arising at this stage, to ensure the convergence of $\theta(t)$ to zero, comes from the fact that $B(\sigma)$ tends to the null matrix when θ tends to zero, since $f(0,\beta) = e\ \forall\beta \Rightarrow \frac{\partial f}{\partial \beta}(0,\beta) = 0,\ \forall\beta$. This difficulty is itself related to the well-known impossibility of ensuring *exponential* stabilization of e by means of a *smooth* feedback [13, Thm. 3]. The matter would still be easily settled if $B(\sigma)$ were invertible everywhere except at $\theta = 0$. Unfortunately, this is not true in general, and further inspection of this matrix, in relation to the way the structure of f combines with the

structure of the Lie algebra $\mathfrak{g}$, is required. Although we do not know whether a solution always exists, we were able to use the specific structure of the Lie algebra associated with the chained systems and derive a solution in this case. Prior to reporting it in the next section, we propose below a formulation of the problem which, whereas it is restricted to the zero-dynamics (20), simplifies the search for a solution for the complete system.

PROBLEM 1. *Given a neighborhood $\mathcal{U}_G(e)$ of e, determine a triplet (f, w, V) consisting of*

(i) *a generalized t.f. $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m} \times \mathbb{T}^{n-m}; \mathcal{U}_G(e))$,*

(ii) *a function $w \in \mathcal{C}^1(\mathcal{U}_{\mathbb{T}^{n-m}}(0); \mathbb{R}^{n-m})$,*

(iii) *a function $V \in \mathcal{C}^1(\mathcal{U}_{\mathbb{T}^{n-m}}(0); \mathbb{R})$ with bounded first-order partial derivatives such that*

1. *$\forall \theta \in V^{-1}([0, V_{\max}))$, $h_{V_m}(|\theta|) \leq V(\theta) \leq h_{V_M}(|\theta|)$ with h_{V_m} and h_{V_M} two $\mathcal{K}$-functions, and $V_{\max} > 0$ a real number such that $V^{-1}([0, V_{\max})) \subset \mathcal{U}_{\mathbb{T}^{n-m}}(0)$;*
2. *the following proposition is true:*

$$\forall \beta \in \mathbb{T}^{n-m},\ \forall \theta \in V^{-1}([0, V_{\max})), \quad L_F(\pi^* V)(\sigma) \leq -\gamma V(\theta)^l, \quad \gamma, l > 0, \tag{21}$$

with π and F defined by

$$\forall \sigma = (\theta, \beta), \quad \pi(\sigma) = \theta,\ F(\sigma) = -A^{-1}(\sigma) B(\sigma) w(\theta). \tag{22}$$

Note that (21) clearly implies that $\theta = 0$ is locally asymptotically stable for the system (20). Note also that the inclusion $\mathcal{U}_{\mathbb{T}^{n-m}}(0) \subset \mathbb{T}^{n-m}$ has to be strict since (21) would otherwise contradict the known nonexistence of global asymptotic stabilizers on $\mathbb{T}^{n-m}$. Once the above problem is solved, it is not difficult to infer a solution to the problem of asymptotic stabilization of e for system $\mathcal{S}(g)$ when $P \equiv 0$. Such a solution is pointed out in the following proposition.

PROPOSITION 1. *Let Z denote a smooth v.f. which asymptotically stabilizes e for the system $\dot{z} = Z(z)$. Assume that Problem 1 is solved by a triplet $(f, w^\star, V)$, and consider for $\mathcal{S}(g, \sigma)$ the feedback control (u, v, w) with (u, v) defined by (15) and w defined by*

$$w(\theta) = k\left(\frac{1}{V_{\max} - V(\theta)}\right) w^\star(\theta), \tag{23}$$

with k denoting any $\mathcal{K}_\infty$-function. Assume also that the initial condition $\theta(0)$ is chosen in $V^{-1}([0, V_{\max}))$. Then

1. *whatever P, the above-defined feedback control asymptotically stabilizes the set $\{(f(\sigma), \sigma) : \sigma \in V^{-1}([0, V_{\max})) \times \mathbb{T}^{n-m}\}$ for $\mathcal{S}(g, \sigma)$;*
2. *if $P \equiv 0$, then this control asymptotically stabilizes the set $\{e\} \times \{0\} \times \mathbb{T}^{n-m}$ for $\mathcal{S}(g, \sigma)$;*
3. *if $P(g, t)$ tends to zero as $t \longrightarrow +\infty$, uniformly w.r.t. g in compact sets, then $(g, \theta)(t) \longrightarrow (e, 0)$ as $t \longrightarrow +\infty$.*

Note that when P, Z, and k are differentiable, the stabilizing feedback control (u, v, w) so obtained is also differentiable. When $P \equiv 0$ and $\theta(0) = 0$, this control asymptotically stabilizes e for $\mathcal{S}(g)$. However, as in the case of a time-periodic Lipschitz-continuous asymptotic stabilizer of $\mathcal{S}(g)$, the control's differentiability rules out the possibility of a uniform convergence rate as fast as exponential. On the other hand, while the frequency of a time-periodic stabilizer is constant, the time-derivatives of θ and β, which may be interpreted as self-adapting frequencies in the case of a stabilizer derived with the t.f. approach, asymptotically tend to zero.

2.3. A class of generalized t.f. In this section, we introduce a class of generalized t.f. which is instrumental in solving Problem 1 for the class of the chained systems. First, we need to recall the definition of a graded basis of $\mathfrak{g}$ (see [18]). This definition is similar to the one of a *basis adapted to the control filtration* [9, 25]; a complementary requirement is that some elements of the basis be expressed as Lie brackets of other elements of the basis.

DEFINITION 3. *Let* $X_1, \ldots, X_m \in \mathfrak{g}$ *denote independent v.f. such that* $\mathrm{Lie}(X_1, \ldots, X_m) = \mathfrak{g}$. *Let* $\mathfrak{u} = \mathrm{span}\{X_1, \ldots, X_m\}$, *and define inductively, for* $k = 2, \ldots, K$, $\mathfrak{u}^k = \mathfrak{u}^{k-1} + [\mathfrak{u}, \mathfrak{u}^{k-1}]$ *with* $K = \min\{k : \mathfrak{u}^k = \mathfrak{g}\}$. *A* graded basis *of* $\mathfrak{g}$ *associated with* $X_1, \ldots, X_m$ *is an ordered basis* $\{X_1, \ldots, X_n\}$ *of* $\mathfrak{g}$ *associated with two mappings* $\lambda, \rho : \{m+1, \ldots, n\} \longrightarrow \{1, \ldots, n\}$ *such that*

1. *for any* $k \in \{1, \ldots, K\}$, $\mathfrak{u}^k = \mathrm{span}\{X_1, X_2, \ldots, X_{\dim \mathfrak{u}^k}\}$;
2. *for* $k \geq 2$ *and* $\dim \mathfrak{u}^{k-1} < i \leq \dim \mathfrak{u}^k$, $X_i = [X_{\lambda(i)}, X_{\rho(i)}]$ *with* $X_{\lambda(i)} \in \mathfrak{u}^a$, $X_{\rho(i)} \in \mathfrak{u}^b$, *and* $a + b = k$.

With any graded basis of $\mathfrak{g}$, one can associate a *weight-vector* $(r_1, \ldots, r_n)$ defined by

$$r_i = k \Longleftrightarrow X_i \in \mathfrak{u}^k \setminus \mathfrak{u}^{k-1} \Longleftrightarrow \dim \mathfrak{u}^{k-1} < i \leq \dim \mathfrak{u}^k.$$

Note that $1 = r_1 \leq r_2 \leq \cdots \leq r_n = K$, and, from Definition 3, $\forall i > m$, $r_i = r_{\lambda(i)} + r_{\rho(i)}$.

With $\{X_1, \ldots, X_n\}$ any graded basis of $\mathfrak{g}$, let us define $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m} \times \mathbb{T}^{n-m}; G)$ by

$$\forall \sigma = (\theta, \beta) \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}, \quad f(\sigma) = f_n(\sigma_n) \cdots f_{m+1}(\sigma_{m+1}), \tag{24}$$

with $f_j : \mathbb{T} \times \mathbb{T} \longrightarrow G$ defined by

$$\forall \sigma_j = (\theta_j, \beta_j), \quad f_j(\sigma_j) = \exp\left(\alpha_j(\sigma_j) X_j\right) \exp\left(\alpha_{j,\lambda}(\sigma_j) X_{\lambda(j)} + \alpha_{j,\rho}(\sigma_j) X_{\rho(j)}\right), \tag{25}$$

where

$$\alpha_{j,\lambda}(\sigma_j) = \varepsilon_j^{r_{\lambda(j)}} (\sin(\theta_j + \beta_j) - \sin \beta_j), \qquad \alpha_{j,\rho}(\sigma_j) = \varepsilon_j^{r_{\rho(j)}} (\cos(\theta_j + \beta_j) - \cos \beta_j),$$

$$\alpha_j(\sigma_j) = \frac{\varepsilon_j^{r_j}}{2} \sin \theta_j, \tag{26}$$

and the ε_j's are positive real numbers. This function obviously satisfies (12). As for the transversality condition (11), we have the following result.

PROPOSITION 2. *Let* $X_1, \ldots, X_m$ *denote independent v.f. on a Lie group* G *of dimension* n. *Assume that* $\mathrm{Lie}(X_1, \ldots, X_m) = \mathfrak{g}$. *Let* $f \in \mathcal{C}^\infty(\mathbb{T}^{n-m} \times \mathbb{T}^{n-m}; G)$ *be defined by* (24), (25), (26), *with* $\{X_1, \ldots, X_n\}$ *a graded basis of* $\mathfrak{g}$. *Then there exist real positive numbers* $\eta_{m+1}, \ldots, \eta_n$ *and* ε_0 *such that, for* $(\varepsilon_{m+1}, \ldots, \varepsilon_n) = \varepsilon(\eta_{m+1}, \ldots, \eta_n)$ *with* $\varepsilon \in (0, \varepsilon_0)$, f *satisfies* (11). *More precisely, the* η_k*'s can be defined recursively by choosing any* $\eta_{m+1} > 0$ *and for* $k = m+2, \ldots, n$, *choosing* η_k *large enough w.r.t.* $\eta_{m+1}, \ldots, \eta_{k-1}$.

3. Asymptotic stabilization of chained systems. A solution to Problem 1 is provided in the case where $G = \mathbb{R}^n$, $m = 2$, and the control v.f. X_1, X_2 are defined by

$$X_1(x) = (1, 0, x_2, \ldots, x_{n-1})', \quad X_2 = (0, 1, 0, \ldots, 0)' \tag{27}$$

with $g = x = (x_1, \ldots, x_n)'$ and $e = 0$.

The v.f. X_1 and X_2 defined by (27) are left-invariant w.r.t. the group operation

$$(xy)_i = \begin{cases} x_i + y_i & \text{if } i = 1, 2, \\ x_i + y_i + \displaystyle\sum_{j=2}^{i-1} \frac{y_1^{i-j}}{(i-j)!} x_j & \text{otherwise,} \end{cases}$$

with $x, y \in \mathbb{R}^n$ (see [24], for instance). Furthermore, $\mathrm{Lie}(X_1, X_2) = \mathfrak{g}$, so that chained systems (with $P \equiv 0$) are controllable, and the v.f.

$$X_1, X_2, X_k \triangleq [X_1, X_{k-1}] \quad (k = 3, \ldots, n) \tag{28}$$

define a graded basis. The associated weight-vector r is given by

$$r_1 = r_2 = 1, \qquad r_k = k - 1 \quad (k = 3, \ldots, n). \tag{29}$$

Since the underlying Lie group G is $\mathbb{R}^n$, a simple example of v.f. which globally exponentially stabilizes the origin of $\dot{z} = Z(z)$ on $\mathbb{R}^n$ is defined by $Z(z) = Kz$, with K denoting any $n \times n$ Hurwitz-stable matrix. The main result is stated next.

THEOREM 1. *When $m = 2$ and the v.f. X_1, X_2 are given by* (27)*, there exist real positive numbers $\eta_{m+1}, \ldots, \eta_n$ such that a solution to Problem* 1 *is the triplet (f, w, V) consisting of*

1. *the candidate generalized t.f. defined by* (24)–(26) *with $(\varepsilon_{m+1}, \ldots, \varepsilon_n) = \varepsilon(\eta_{m+1}, \ldots, \eta_n)$ and $\varepsilon > 0$ chosen small enough so that f ranges in $\mathcal{U}_{\mathbb{R}^n}(0)$,*
2. *the function $w \in \mathcal{C}^1((-\pi, \pi)^{n-2}; \mathbb{R}^{n-2})$ defined by*

$$w_i(\theta_i) = \frac{1}{\eta_i^{i-2}} |\theta_i|^{(i-3)} \theta_i \qquad (i = 3, \ldots, n), \tag{30}$$

3. *the function $V \in \mathcal{C}^1((-\pi, \pi)^{n-2}; \mathbb{R})$ defined by*

$$V(\theta) \triangleq \sum_{i=3}^{n} \eta_i^{i-3/2} |\theta_i|^{n+2-i} \quad \text{with} \quad V_{\max} = \min_{i=3,\ldots,n} \{\eta_i^{i-3/2} \pi^{n+2-i}\}.$$

Remark 1. The proof of this theorem in section 5.3 involves a recursive procedure for the determination of the numbers $\eta_{m+1}, \ldots, \eta_n$, which is similar to the one indicated in Proposition 2.

Remark 2. The solution to Problem 1 given in Theorem 1 applies also to a unicycle-like mobile robot without having to transform its kinematic equations into the chain form—the only restriction is that ε must be smaller than some finite upper bound $\varepsilon_0 > 0$, whatever $\mathcal{U}_G(e)$, whereas, in the case of a chained system, $\varepsilon_0 = +\infty$. One only has to check that the proof of Theorem 1 works as well in this case with $n = 3$, $G = \mathbb{R}^2 \times S^1$, $g = (x, y, \alpha)'$, and the system's control v.f. defined by

$$X_1(g) = (\cos\alpha, \sin\alpha, 0)', \quad X_2(g) = (0, 0, 1)'. \tag{31}$$

These v.f. are left-invariant w.r.t. the group operation

$$g_1 g_2 = \begin{pmatrix} \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} + R(\alpha_1) \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} \\ \alpha_1 + \alpha_2 \end{pmatrix}$$

with $g_i = (x_i, y_i, \alpha_i)'$ and $R(\alpha_1)$ the rotation matrix of angle α_1. Also, $\mathrm{Lie}(X_1, X_2) = \mathfrak{g}$ and $\{X_1, X_2, X_3 = [X_1, X_2]\}$ constitutes a graded basis of $\mathfrak{g}$ with weight vector $(r_1 = r_2 = 1, r_3 = 2)$.

Let us comment on the rate of convergence provided by a feedback control derived according to Proposition 1 and Theorem 1 when $P \equiv 0$. This will be the starting point of a more general discussion about what the t.f. approach can offer in comparison with other control design methods, its limitations and assets. Assuming that the v.f. Z used in the expression of (u, v) is chosen so as to stabilize the origin of $\dot{z} = Z(z)$ exponentially, the rate of convergence of $g(t)$ to e coincides with the slower rate of convergence of $\theta(t)$ to zero on the zero-dynamics. This latter rate is itself given by the rate of convergence of $V(\theta(t))$ to zero, and is thus related to the integer l in relation (21). From (47) in the proof of Theorem 1, we have $l = \frac{n+1}{2}$, and one deduces that $V(\theta(t))$ tends to zero as quickly as $t^{-\frac{2}{n-1}}$. In fact, a complementary analysis would show that $V(\theta(t))$ cannot tend to zero faster. Now, since $k_1|\theta|^{n-1} \leq V(\theta) \leq k_2|\theta|^2$ in the neighborhood of $\theta = 0$, this in turn implies that $|\theta(t)|$ may (and will usually) not tend to zero faster than $t^{-\frac{2}{(n-1)^2}}$. The same rate holds for the convergence of $|g(t)|$ towards e. This polynomial rate of convergence is similar to the one which can be obtained by applying a smooth time-periodic stabilizer to $\mathcal{S}(g)$. Therefore, one can conclude that, as far as asymptotic stabilization is concerned, no clear advantage results from designing a stabilizer with the t.f. approach. In the authors' opinion this conclusion is correct, but it conveys only a partial picture of the properties granted by the approach. Indeed, the primary feature of such a controller, which motivated the development of the t.f. approach in the first place, is the capacity of ensuring practical stabilization, with easily tunable arbitrary small ultimate bound of the state error, independently of the "perturbation" P acting on the system. As shown in [18], this allows, for example, the tracking of *any* trajectory in the state space (it does not have to be a solution to the system's equations) with arbitrarily good precision, in the sense that tracking errors are ultimately bounded by a prespecified (nonzero, but otherwise as small as desired) threshold. To our knowledge, no other controller proposed so far in the literature has this capacity. Our motivation for the present paper was to show that such a controller can also be endowed with the extra property of ensuring asymptotic point-stabilization when such a feature is desirable. This is achieved via the concept of a generalized t.f. depending upon two sets of variables whose time-derivatives are used as extra control inputs. Transversality is maintained with respect to the first set θ, while the second set β is used to enforce some type of "phase-tuning," which allows us to reduce the size of the t.f. when the perturbation P vanishes.

4. Simulation results. The control law proposed in the previous section has been tested by simulation on the four-dimensional (4d) chained system. The following parameters for the definition of the transverse function have been used: $\varepsilon = 0.2$, $\eta_3 = 1, \eta_4 = 8$. The v.f. $Z(z)$ in (15) has been chosen as $Z(z) = -0.3z$. Finally, the $\mathcal{K}_\infty$-function k in (23) has been defined by $k(s) = 10V_{\max}s$, with $V_{\max}$ as specified in Theorem 1. The initial condition for the simulation was $x(0) = (0, 0, 0, 10)'$, and $\sigma(0) = 0$. Figure 1 displays the state variables versus time. As discussed in the previous section, the convergence rate to zero is slow. For comparison, Figure 2 displays the same variables when no attempt is made to achieve convergence to zero, i.e., with $w = 0$ and $\beta = 0$ in the control law defined by (15). In this case $\theta(t)$ exponentially converges to some $\theta_{\lim} \in \mathbb{T}^{n-m}$, and $x(t)$ exponentially converges to $f(\theta_{\lim}, 0)$. Note that the solution to Problem 1 given by Theorem 1 is only one of its kind, and that much room is left for improving the proposed stabilization method.

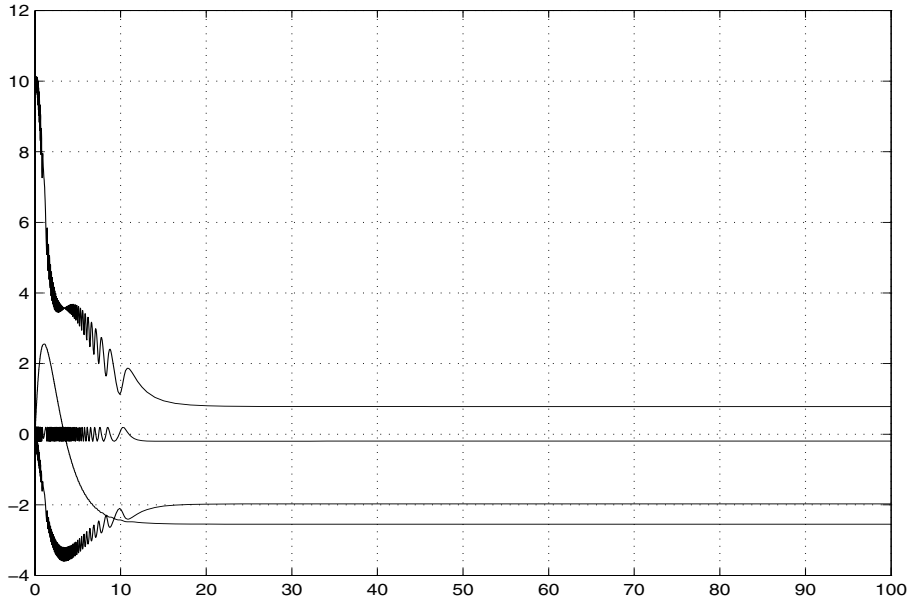

FIG. 2. *State variables for the* 4*d chained system, practical stabilization.*

5. Proofs.

5.1. Proof of Proposition 1. Let us first recall, as shown in section 2.2, that the control $(u, v)(g, \sigma, t)$ defined by (15) yields

$$\dot{z} = Z(z), \tag{32}$$

with $z = fg^{-1}$ and Z chosen so as to ensure the asymptotic stability of e for the above system. Now, applying the one-forms d_i $(i = m+1, \ldots, n)$ to each side of the equality (15) yields (compare with (18))

$$\dot{\theta} = -A^{-1}(\sigma)B(\sigma)w(\theta) + A^{-1}(\sigma) \sum_{i=m+1}^{n} \langle d_i(f), dl_z(g)P(g,t) + dr_g(z)Z(z)\rangle e_i, \tag{33}$$

where we have used the same notation as in section 2.2. Using the fact that $z = fg^{-1}$, we rewrite this equation as

$$\begin{aligned} \dot{\theta} = -A^{-1}(\sigma)B(\sigma)w(\theta) + A^{-1}(\sigma) \sum_{i=m+1}^{n} \langle d_i(f), dl_z(z^{-1}f)P(z^{-1}f,t) \\ + dr_{z^{-1}f}(z)Z(z)\rangle e_i. \end{aligned} \tag{34}$$

By using (23), this in turn implies that, along a solution of the controlled system,

$$\frac{d}{dt}V(\theta) = k\left(\frac{1}{V_{\max} - V(\theta)}\right) L_F(\pi^* V)(\sigma) + Q(g,\sigma,t),$$

with

$$F(\sigma) \triangleq -A^{-1}(\sigma)B(\sigma)w^\star(\theta),$$

$$Q(g,\sigma,t) \triangleq \frac{\partial V}{\partial \theta}(\theta)A^{-1}(\sigma) \sum_{i=m+1}^{n} \langle d_i(f), dl_z(z^{-1}f)P(z^{-1}f,t) + dr_{z^{-1}f}(z)Z(z)\rangle e_i.$$

Therefore, in view of (21),

$$\frac{d}{dt}V(\theta) \le -\xi(V(\theta)) + Q(g,\sigma,t), \qquad \xi(V) \triangleq k\left(\frac{1}{V_{\max} - V}\right)\gamma V^l. \tag{35}$$

Let us show that $\theta(t)$ cannot leave the set $V^{-1}([0, V_{\max}))$. We first remark that, on any time-interval $[0,T)$ such that $\theta(t)$ stays in this set, there exists a constant M_T, independent of the trajectory $\theta(.)$, such that $|Q(g(t),\sigma(t),t)| \le M_T$ because (i) by assumption, $\frac{\partial V}{\partial \theta}$ is bounded on $\mathcal{U}_{\mathbb{T}^{n-m}}(0) \supset V^{-1}([0, V_{\max}))$; (ii) z, and subsequently z^{-1}, are bounded due to the asymptotic stability of e for the system (32); (iii) P is continuous. Since, by (35), ξ is a bijective increasing function from $[0, V_{\max})$ to $[0, +\infty)$, we deduce from (35) that on any such interval $[0,T)$

$$V(\theta(t)) \le \max\{\xi^{-1}(M_T), V(\theta(0))\} < V_{\max}.$$

This implies that $V(\theta(t))$ cannot tend to $V_{\max}$ in finite time, so that $\theta(t)$ remains in the set $V^{-1}([0, V_{\max}))$. This in turn implies that the control law is well defined along any trajectory of the closed-loop system with initial conditions $(g(0), \theta(0), \beta(0))$ such that $z(0) = f(\sigma(0))g(0)^{-1}$ is in the stability domain of e for the system $\dot{z} = Z(z)$ and $\theta(0) \in V^{-1}([0, V_{\max}))$, and that such a trajectory is complete. Point 1 of Proposition 1 then follows directly from the asymptotic stability of $z = e$, as ensured by (32), and the invariance of the set $V^{-1}([0, V_{\max}))$ for the variable θ.

As for point 2, which assumes that $P \equiv 0$, it is sufficient to consider trajectories with initial conditions $(z(0), \theta(0))$ in a small neighborhood of the point $(e, 0)$. From the definition of Q, the asymptotic stability of $z = e$, combined with the invariance

of the set $V^{-1}([0, V_{\max}))$ for the variable θ and the fact that V has bounded partial derivatives on this set, yields the existence of a $\mathcal{K}$-function h_z such that

$$\forall t \geq 0, \qquad |Q(g(t), \sigma(t), t)| \leq h_z(d_G(z(0), e)).$$

Therefore, in view of (35),

$$\forall t \geq 0, \qquad \frac{d}{dt} V(\theta(t)) \leq -k_V V(\theta(t))^l + h_z(d_G(z(0), e)),$$

with $k_V = k(\frac{1}{V_{\max}})\gamma(> 0)$. This in turn implies

$$\forall t \geq 0, \qquad V(\theta(t)) \leq \left(\frac{h_z(d_G(z(0), e))}{k_V} \right)^{1/l} + V(\theta(0)). \tag{36}$$

In view of (36) and property 1 in Problem 1,

$$\forall t \geq 0, \qquad |\theta(t)| \leq h_{V_m}^{-1} \left(\left(\frac{h_z(d_G(z(0), e))}{k_V} \right)^{1/l} + h_{V_M}(|\theta(0)|) \right).$$

This relation, combined with the asymptotic stability of $z = e$, implies the stability of the set $\{e\} \times \{0\} \times \mathbb{T}^{n-m}$ for $\mathcal{S}(g, \sigma)$. The convergence of the closed-loop trajectories to this set simply results from the convergence of $Q(g(t), \sigma(t), t)$ to zero when $z(t)$ tends to e, since $Z(z(t))$ then converges to zero. In view of (35), this yields the convergence of $V(\theta(t))$ to zero.

When it is assumed only that $P(g, t)$ tends to zero when t tends to infinity—uniformly w.r.t. g in compact sets—the term $Q(g(t), \sigma(t), t)$ in (35) still converges to zero, because the asymptotic stability of $z = e$ implies that $Z(z(t))$ converges to $Z(e) = 0$. Hence, the convergence of $V(\theta(t))$ to zero is still ensured, so that $\theta(t)$ tends to zero and $f(\sigma(t))$ tends to e (using the property (12) of a generalized t.f.). Therefore $(g, \theta)(t)$ tends to the point $(e, 0)$, as announced in point 3 of the proposition.

5.2. Proof of Proposition 2. The following notation is used in the forthcoming proofs. With v denoting a smooth function of the real variables x and y—possibly vector-valued—we write $v = \mathrm{o}(x^k)$ (resp., $v = \mathrm{O}(x^k)$) if $(|v(x, y)|/|x|^k) \longrightarrow 0$ as $|x| \longrightarrow 0$ (resp., if $(|v(x, y)|/|x|^k) \leq K < \infty$ in some neighborhood of $x = 0$) uniformly w.r.t. the y variable which takes values in a compact set. Finally, for indexed variables x_i with $i = k, \ldots, n$, we define the set of indexed vectors $\{\bar{x}_p\}_{p \in \{k, \ldots, n\}}$ by setting $\bar{x}_p = (x_k, \ldots, x_p)$.

Remark 3. Various results in the paper, starting with Proposition 2, refer to t.f. which depend on a vector of parameters $\varepsilon \in \mathbb{R}^{n-m}$, used as a means to monitor the "size" of the functions. Relations (24)–(26) define such a family of transverse functions. A member of this family could have been denoted as f_ε or $f(\varepsilon, .)$ in order to point out the functional dependence upon ε explicitly. However, for the sake of simplifying the (already cumbersome) notation used in the paper, we have chosen to systematically omit the argument ε when referring to t.f. It is nonetheless important to keep this dependence in mind when reading the forthcoming proofs. In particular, several functions associated with an arbitrary member of the family of t.f. defined by (24)–(26) will be introduced in Lemmas 1 and 2. Each of them is thus also a function of ε. For the sake of keeping the notation coherent throughout the paper, the index is again omitted when referring to such a function.

The proof of Proposition 2 consists of three steps summarized in the form of three lemmas, which are proved in the appendix.

LEMMA 1. *Assume that the assumptions of Proposition* 2 *are satisfied. Then, for each* $j \in \{m+1, \dots, n\}$ *and* $i \in \{1, \dots, n\}$, *there exist analytic functions* $v_{i,j}$ *and* $w_{i,j}$ *of* $\varepsilon_j \in \mathbb{R}$ *and* $\sigma_j \in \mathbb{T} \times \mathbb{T}$ *such that*

$$\frac{\partial f_j}{\partial \theta_j}(\sigma_j) = \sum_{i=1}^{n} v_{i,j}(\sigma_j) X_i(f_j(\sigma_j)), \quad \frac{\partial f_j}{\partial \beta_j}(\sigma_j) = \sum_{i=1}^{n} w_{i,j}(\sigma_j) X_i(f_j(\sigma_j)), \tag{37}$$

with

$$v_{i,j} = \begin{cases} \mathrm{O}(\varepsilon_j^{r_i}) & \forall i, \\ \mathrm{o}(\varepsilon_j^{r_i}) & \text{if } i < j \text{ and } r_i = r_j, \\ \dfrac{\varepsilon_j^{r_j}}{2} + \mathrm{o}(\varepsilon_j^{r_j}) & \text{if } i = j, \end{cases} \tag{38}$$

and

$$w_{i,j} = \begin{cases} \mathrm{O}(\varepsilon_j^{r_i})\mathrm{O}(\theta_j) & \forall i, \\ \varepsilon_j^{r_j}(1 - \cos\theta_j) + \mathrm{o}(\varepsilon_j^{r_j})\mathrm{o}(\theta_j^2) & \text{if } i = j. \end{cases} \tag{39}$$

In the following lemma, $\mathrm{O}(\bar{\varepsilon}_m)$ formally appears when setting $j = m+1$ in $\mathrm{O}(\bar{\varepsilon}_{j-1})$, although ε_m has not been defined previously. The lemma's statement is nonetheless valid, provided that $\mathrm{O}(\bar{\varepsilon}_m)$ is identified with the null function.

LEMMA 2. *Assume that the assumptions of Proposition* 2 *are satisfied. Then, for each* $j \in \{m+1, \dots, n\}$ *and* $i \in \{1, \dots, n\}$, *there exist analytic functions* $a_{i,j}$ *and* $b_{i,j}$ *of* $\bar{\varepsilon}_j \in \mathbb{R}^{j-m}$ *and* $\sigma \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}$ *such that*

$$\frac{\partial f}{\partial \theta_j}(\sigma) = \sum_{i=1}^{n} a_{i,j}(\sigma) X_i(f(\sigma)), \quad \frac{\partial f}{\partial \beta_j}(\sigma) = \sum_{i=1}^{n} b_{i,j}(\sigma) X_i(f(\sigma)), \tag{40}$$

with

$$a_{i,j} = \begin{cases} \mathrm{O}(\bar{\varepsilon}_j^{r_i}) & \forall i, \\ \mathrm{O}(\bar{\varepsilon}_{j-1})\mathrm{O}(\bar{\varepsilon}_j^{r_i - 1}) + \mathrm{o}(\bar{\varepsilon}_j^{r_i}) & \text{if } i < j \text{ and } r_i = r_j, \\ \dfrac{\varepsilon_j^{r_j}}{2} + \mathrm{O}(\bar{\varepsilon}_{j-1})\mathrm{O}(\bar{\varepsilon}_j^{r_j - 1}) + \mathrm{o}(\bar{\varepsilon}_j^{r_j}) & \text{if } i = j, \end{cases} \tag{41}$$

and

$$b_{i,j} = \begin{cases} \mathrm{O}(\bar{\varepsilon}_j^{r_i})\mathrm{O}(\bar{\theta}_j) & \forall i, \\ \varepsilon_j^{r_j}(1 - \cos\theta_j) + \mathrm{O}(\bar{\varepsilon}_{j-1})\mathrm{O}(\bar{\varepsilon}_j^{r_j - 1})\mathrm{O}(\theta_j)\mathrm{O}(\bar{\theta}_{j-1}) + \mathrm{o}(\bar{\varepsilon}_j^{r_j})\mathrm{o}(\bar{\theta}_j^2) & \text{if } i = j. \end{cases} \tag{42}$$

Note that, if all O and o terms in the above expressions were equal to zero, then the transversality property would simply follow from (40)–(41) and the fact that $\{X_1, \dots, X_n\}$ is a basis of $\mathfrak{g}$. Although this is not the case, one can show that these terms can be neglected, provided that the ε_j's are adequately chosen.

LEMMA 3. *Assume that the assumptions of Proposition* 2 *are satisfied. Then there exist* $n - m$ *numbers* $\eta_{m+1}, \dots, \eta_n$ *and* $\varepsilon_0 > 0$ *such that choosing*

$$(\varepsilon_{m+1}, \dots, \varepsilon_n) = \varepsilon(\eta_{m+1}, \dots, \eta_n)$$

with $\varepsilon \in (0, \varepsilon_0)$ *yields*

$$\forall \sigma \in \mathbb{T}^{n-m} \times \mathbb{T}^{n-m}, \quad \mathrm{Det}\, A(\sigma) \neq 0 \quad \textit{with } A(\sigma) = (a_{i,j}(\sigma))_{i,j=m+1,\ldots,n}. \tag{43}$$

5.3. Proof of Theorem 1. One easily verifies that for any positive real numbers $\eta_3, \ldots, \eta_n$ the functions w and V satisfy (ii) and (iii) of Problem 1 with $\mathcal{U}_{\mathbb{T}^{n-m}}(0) = (-\pi, \pi)^{n-m}$. It is also clear that property 1 of Problem 1 is verified. We show below that, for an adequate choice of positive $\eta_3, \ldots, \eta_n$, properties (i) and 2 are also satisfied. The proof relies on the following lemma, proved in the appendix, which points out complementary properties of the functions $a_{i,j}$ and $b_{i,j}$ in Lemma 2 in the case of the chained systems.

LEMMA 4. *In the case of chained systems, the functions* $a_{i,j}$ *and* $b_{i,j}$ $(i = 1, \ldots, n,$ $j = 3, \ldots, n)$ *are homogeneous polynomials of degree* r_i *in* $\varepsilon_3, \ldots, \varepsilon_j$. *Furthermore,*

$$a_{i,j} = \mathrm{O}(\bar{\theta}_j^{r_i - r_j}), \quad b_{i,j} = \mathrm{O}(\bar{\theta}_j^{\max(1, r_i - r_j + 2)}). \tag{44}$$

Let

$$A_p(\sigma) \triangleq (a_{i,j}(\sigma))_{i,j=3,\ldots,p}, \quad B_p(\sigma) \triangleq (b_{i,j}(\sigma))_{i,j=3,\ldots,p}, \tag{45}$$

and note that $A_n = A$ and $B_n = B$, with A and B defined by (19).

PROPOSITION 3. *For any* $p = 3, \ldots, n$, *there exists a set of positive numbers* $\{\eta_3, \ldots, \eta_p\}$ *such that setting* $(\varepsilon_3, \ldots, \varepsilon_p) = \varepsilon(\eta_3, \ldots, \eta_p)$ *with* $\varepsilon > 0$ *implies that*

(i) *the matrix* $A_p(\sigma)$ *is invertible for any* σ, *and*

$$\forall i, j = 3, \ldots, p, \quad (A_p^{-1}(\sigma))_{i,j} = \mathrm{O}(\bar{\theta}_p^{r_i - r_j}); \tag{46}$$

(ii) *the following is true:*

$$V_p(\bar{\theta}_p) < V_{p,max} \Longrightarrow L_{F_p} V_p(\sigma) \leq -\alpha_p |\bar{\theta}_p|^{n+1} \quad (\alpha_p > 0) \tag{47}$$

with

$$V_p(\bar{\theta}_p) \triangleq \sum_{i=3}^{p} \eta_i^{i-3/2} |\theta_i|^{n+2-i}, \qquad V_{p,max} = \min_{i=3,\ldots,p} \{\eta_i^{i-3/2} \pi^{n+2-i}\} \tag{48}$$

and

$$F_p(\sigma) = -A_p^{-1}(\sigma) B_p(\sigma) \bar{w}_p(\bar{\theta}_p). \tag{49}$$

With $p = n$, property (i) of this proposition implies that the function f satisfies the transversality condition (11). Since (12) is trivially verified from (24), (25), (26), property (i) of Problem 1 follows. As for property 2 in Problem 1, it is true by (ii) in the above proposition. Note that, to be fully precise, in (47) one should write $L_{F_p}(\pi_p^* V_p)(\sigma)$ instead of $L_{F_p} V_p(\sigma)$, with $\pi_p(\sigma) = \bar{\theta}_p$ (compare with (21)). For the sake of simplifying the notation in the forthcoming proof, we have chosen to keep this small abuse of notation.

Proof of Proposition 3. We proceed by induction. For $p = 3$, it follows from (29) and Lemma 2 that

$$a_{3,3}(\sigma) = \frac{\varepsilon_3^2}{2} + \mathrm{o}(\varepsilon_3^2), \quad b_{3,3}(\sigma) = \varepsilon_3^2 (1 - \cos\theta_3) + \mathrm{o}(\varepsilon_3^2)\mathrm{o}({\theta_3}^2). \tag{50}$$

Lemma 4 implies that the o terms in the above equation are identically equal to zero, since $a_{3,3}$ and $b_{3,3}$ are homogeneous polynomials of degree $r_3 = 2$ in ε_3. Therefore, $a_{3,3}(\sigma) > 0$ for any $\varepsilon_3 > 0$, and the point (i) of the proposition is verified.

Take $\eta_3 = 1$. From (30), (49), (50), and the fact that the o terms in (50) are equal to zero,

$$F_3(\sigma) = -a_{3,3}^{-1}(\sigma)\left(\varepsilon_3^2(1-\cos\theta_3)\right)\theta_3 = -2(1-\cos\theta_3)\theta_3. \tag{51}$$

From (48), one easily checks that

$$L_{F_3}V_3(\sigma) = -2(n-1)(1-\cos\theta_3)|\theta_3|^{n-1}. \tag{52}$$

Since $V_3(\theta_3) = |\theta_3|^{n-1}$ and $V_{3,max} = \pi^{n-1}$, we deduce from (52) that

$$V_3(\theta_3) < \pi^{n-1} \Longrightarrow \qquad L_{F_3}V_3(\sigma) \leq -\alpha_3|\theta_3|^{n+1}$$

for some $\alpha_3 > 0$. Point (ii) of the proposition is thus verified with $\eta_3 = 1$ and $\varepsilon = \varepsilon_3 > 0$, and this concludes the proof of Proposition 3 for $p = 3$.

Let us now assume that points (i) and (ii) of the proposition hold true up to some $p < n$, with $\bar{\varepsilon}_p = \bar{\eta}_p$, and show that they are also true for $p+1$, with $\bar{\varepsilon}_{p+1} = \bar{\eta}_{p+1}$. This will in turn imply that they are true when $\bar{\varepsilon}_{p+1} = \varepsilon\bar{\eta}_{p+1}$ with $\varepsilon > 0$, thanks to the homogeneity properties of the $a_{i,j}$'s and $b_{i,j}$'s—see Lemma 4. Indeed, when $\bar{\eta}_{p+1}$ is multiplied by ε, then A_{p+1} and B_{p+1} are just premultiplied by the diagonal matrix $\mathrm{Diag}(\varepsilon^{r_3}, \ldots, \varepsilon^{r_{p+1}})$, thus leaving $F_{p+1}(\sigma)$ and the subsequent analysis unchanged.

From (45), A_{p+1} and B_{p+1} can be written as

$$A_{p+1} = \begin{pmatrix} A_p & a_{*,p+1} \\ a_{p+1,*} & a_{p+1,p+1} \end{pmatrix}, \quad B_{p+1} = \begin{pmatrix} B_p & b_{*,p+1} \\ b_{p+1,*} & b_{p+1,p+1} \end{pmatrix}, \tag{53}$$

with the star denoting the indexes from 1 to p, i.e., $a_{p+1,*} = (a_{p+1,1}, \ldots, a_{p+1,p})$ and $a_{*,p+1} = (a_{1,p+1}, \ldots, a_{p,p+1})'$. Let us recall (see, e.g., [29, Chap. 2]) that if A_{11} and A_{22} are square matrices with A_{11} nonsingular, the matrix

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}$$

is invertible if and only if the Schur complement $S \triangleq A_{22} - A_{21}A_{11}^{-1}A_{12}$ of A_{11} in A is invertible. Then

$$A^{-1} = \begin{pmatrix} A_{11}^{-1} + A_{11}^{-1}A_{12}S^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1}A_{21}A_{11}^{-1} & S^{-1} \end{pmatrix}. \tag{54}$$

From (53), the Schur complement of A_p in A_{p+1} is $S = a_{p+1,p+1} - a_{p+1,*}A_p^{-1}a_{*,p+1}$, and, in view of (29) and Lemmas 2 and 4,

$$S = \frac{\varepsilon_{p+1}^p}{2} + q^{p-1}(\varepsilon_{p+1}), \tag{55}$$

with $q^{p-1}(\varepsilon_{p+1})$ a polynomial of degree $p-1$ in ε_{p+1}. (Note, from the domain definition of the functions $a_{i,j}$ in Lemma 2, that the term $a_{p+1,*}A_p^{-1}a_{*,p+1}$ depends on ε_{p+1} only through $a_{*,p+1}$ so that, by Lemma 4, it is a polynomial of degree $r_p = p-1$ in ε_{p+1}.) This implies that S, and thus A_{p+1}, are invertible for ε_{p+1} large enough. In order to prove (i), it remains to show that (46) holds true for $p+1$. Since (46) is true for p,

for any $p = 3, \dots, n-1$ and $\varepsilon_3, \dots, \varepsilon_{p+1}$ such that A_p and A_{p+1} are invertible, let us use (54) to decompose A_{p+1}^{-1} as follows:

$$A_{p+1}^{-1} = \begin{pmatrix} A_p^{-1} & 0 \\ 0 & S^{-1} \end{pmatrix} + \begin{pmatrix} \Xi_{11} & \Xi_{12} \\ \Xi_{21} & 0 \end{pmatrix} \triangleq \begin{pmatrix} A_p^{-1} & 0 \\ 0 & S^{-1} \end{pmatrix} + \Xi, \tag{56}$$

with

$$\begin{aligned} \Xi_{11} &= A_p^{-1} a_{*,p+1} S^{-1} a_{p+1,*} A_p^{-1}, \\ \Xi_{12} &= -A_p^{-1} a_{*,p+1} S^{-1}, \\ \Xi_{21} &= -S^{-1} a_{p+1,*} A_p^{-1}. \end{aligned}$$

By Lemma 4, $a_{i,j}$ is a homogeneous polynomial in $\varepsilon_3, \dots, \varepsilon_j$ of degree r_i and satisfies (44). Therefore, there exists a constant C such that

$$\forall \sigma, \quad |a_{i,j}(\sigma)| \leq C |\bar{\varepsilon}_j|^{r_i} |\bar{\theta}_j|^{r_i - r_j}. \tag{57}$$

Then, from Lemma 4, relations (46), (55), and (57), and using the fact that neither A_p nor $a_{p+1,*}$ depend on ε_{p+1}, one infers that

$$\varepsilon_{p+1} \geq 1 \Longrightarrow \begin{cases} |\xi_{i,j}| \leq C \varepsilon_{p+1}^{-1} |\bar{\theta}_{p+1}|^{r_i - r_j} & \text{for } i \leq p, \\ |\xi_{i,j}| \leq C \varepsilon_{p+1}^{-p} |\bar{\theta}_{p+1}|^{r_i - r_j} & \text{for } i = p+1, \end{cases} \tag{58}$$

with $\Xi = \{\xi_{i,j}\}_{i,j=3,\dots,p+1}$. The fact that (46) holds true for $p+1$, provided that it is true up to p, directly follows from (56) and (58). Note that a relation similar to (57) holds for $b_{i,j}$, i.e.,

$$\forall \sigma, \quad |b_{i,j}(\sigma)| \leq C |\bar{\varepsilon}_j|^{r_i} |\bar{\theta}_j|^{\max(1, r_i - r_j + 2)}. \tag{59}$$

This relation will be used later on.

Let us now examine the case of (ii). Throughout the rest of the proof, we assume that $\varepsilon_{p+1} \geq 1$. From (53) and (56),

$$A_{p+1}^{-1} B_{p+1} \bar{w}_{p+1} = \begin{pmatrix} A_p^{-1} B_p \bar{w}_p \\ S^{-1} b_{p+1,p+1} w_{p+1} \end{pmatrix} + D_2, \tag{60}$$

with

$$D_2 = \Xi B_{p+1} \bar{w}_{p+1} + \begin{pmatrix} A_p^{-1} b_{*,p+1} w_{p+1} \\ S^{-1} b_{p+1,*} \bar{w}_p \end{pmatrix}. \tag{61}$$

From (42) and Lemma 4, it is not difficult to deduce that

$$b_{p+1,p+1} = \varepsilon_{p+1}^p (1 - \cos \theta_{p+1}) + R_b, \tag{62}$$

with

$$|R_b| \leq C \varepsilon_{p+1}^{p-1} |\bar{\theta}_{p+1}|^2 \tag{63}$$

for some constant C—recall that $\varepsilon_{p+1} \geq 1$. From the definition of $F_{p+1}(\sigma)$ in Proposition 3 and from relations (60) and (62),

$$F_{p+1}(\sigma) = \underbrace{\begin{pmatrix} F_p(\sigma) \\ -S^{-1} \varepsilon_{p+1}^p (1 - \cos \theta_{p+1}) w_{p+1}(\theta) \end{pmatrix}}_{D_0} - \underbrace{\begin{pmatrix} 0 \\ S^{-1} R_b w_{p+1}(\theta) \end{pmatrix}}_{D_1} - D_2. \tag{64}$$

We claim that the Lie derivative $L_{D_0}V_{p+1}$ of V_{p+1} along D_0 defined by (64) satisfies

$$L_{D_0}V_{p+1}(\sigma) \leq -\alpha_p|\bar{\theta}_p|^{n+1} - \alpha_1\varepsilon_{p+1}^{1/2}|\theta_{p+1}|^{n+1} \quad (\alpha_p, \alpha_1 > 0). \tag{65}$$

Indeed, by (48), $V_{p+1} = V_p + \varepsilon_{p+1}^{p-1/2}|\theta_{p+1}|^{n-p+1}$ (recall that $\bar{\varepsilon}_{p+1} = \bar{\eta}_{p+1}$), and it follows from (64) that

$$L_{D_0}V_{p+1}(\sigma) = L_{F_p}V_p(\sigma) - (n-p+1)S^{-1}\varepsilon_{p+1}^{2p-1/2}(1-\cos\theta_{p+1})w_{p+1}(\theta)\theta_{p+1}^{\{n-p\}}, \tag{66}$$

with the notation $x^{\{n\}} = |x|^{n-1}x$, also used in subsequent relations. From (47),

$$L_{F_p}V_p(\sigma) \leq -\alpha_p|\bar{\theta}_p|^{n+1}, \tag{67}$$

and, proceeding as for $a_{3,3}$, it is simple to verify, by using (30), (55), and the fact that $\varepsilon_{p+1} = \eta_{p+1} \geq 1$, that

$$-(n-p+1)S^{-1}\varepsilon_{p+1}^{2p-1/2}(1-\cos\theta_{p+1})w_{p+1}(\theta)\theta_{p+1}^{\{n-p\}} \leq -\alpha_1\varepsilon_{p+1}^{1/2}|\theta_{p+1}|^{n+1}. \tag{68}$$

Then, (65) follows from (66), (67), and (68).

From (30), (55), (63), and (64), it is straightforward to verify—by again using the condition $\varepsilon_{p+1} \geq 1$—that

$$|L_{D_1}V_{p+1}(\sigma)| \leq \alpha_2\varepsilon_{p+1}^{-1/2}|\bar{\theta}_p|^{n+1} + \alpha_2|\theta_{p+1}|^{n+1}. \tag{69}$$

Finally, we claim that

$$|L_{D_2}V_{p+1}(\sigma)| \leq \left(\frac{\alpha_p}{2} + \alpha_3\varepsilon_{p+1}^{-1/2}\right)|\bar{\theta}_p|^{n+1} + \alpha_4|\theta_{p+1}|^{n+1}. \tag{70}$$

Indeed, from (53), (56), and (61),

$$D_2 = \begin{pmatrix} (\Xi_{11}B_p + \Xi_{12}b_{p+1,*})\bar{w}_p + (\Xi_{11}b_{*,p+1} + \Xi_{12}b_{p+1,p+1})w_{p+1} + A_p^{-1}b_{*,p+1}w_{p+1} \\ \Xi_{21}B_p\bar{w}_p + \Xi_{21}b_{*,p+1}w_{p+1} + S^{-1}b_{p+1,*}\bar{w}_p \end{pmatrix}.$$

By using (29), (30), (46), (57), (58), and (59), it is tedious but not difficult to show that

$$\begin{cases} |(D_2)_i| \leq C\varepsilon_{p+1}^{-1}|\bar{\theta}_{p+1}|^i + C|\bar{\theta}_{p+1}|^{i-p+1}|\theta_{p+1}|^{p-1} & \text{for } i = 3, \ldots, p, \\ |(D_2)_{p+1}| \leq C\varepsilon_{p+1}^{-p}|\bar{\theta}_{p+1}|^{p+1}. \end{cases} \tag{71}$$

We infer from (48) and (71) that

$$|L_{D_2}V_p(\sigma)| \leq \alpha_5\varepsilon_{p+1}^{-1}|\bar{\theta}_{p+1}|^{n+1} + \alpha_6|\bar{\theta}_{p+1}|^{n-p+2}|\theta_{p+1}|^{p-1}. \tag{72}$$

By using Young's inequality, one shows that

$$\begin{aligned} \alpha_6|\bar{\theta}_{p+1}|^{n-p+2}|\theta_{p+1}|^{p-1} &\leq \frac{\alpha_p}{2}|\bar{\theta}_{p+1}|^{n+1} + \alpha_7|\theta_{p+1}|^{n+1} \\ &\leq \frac{\alpha_p}{2}|\bar{\theta}_p|^{n+1} + \alpha_8|\theta_{p+1}|^{n+1} \end{aligned} \tag{73}$$

for other constants α_7, α_8. We deduce from (72) and (73) that

$$|L_{D_2}V_p(\sigma)| \leq \left(\frac{\alpha_p}{2} + \alpha_9\varepsilon_{p+1}^{-1}\right)|\bar{\theta}_p|^{n+1} + \alpha_{10}|\theta_{p+1}|^{n+1}. \tag{74}$$

We also deduce from (71) that

$$|L_{D_2}(V_{p+1} - V_p)(\sigma)| \leq \alpha_{11}\varepsilon_{p+1}^{-1/2}|\bar{\theta}_{p+1}|^{n+1}, \tag{75}$$

and (70) then follows from (74), (75), and the condition $\varepsilon_{p+1} \geq 1$.

Let us now use (65), (69), and (70) to get an upper bound for $L_{F_{p+1}}V_{p+1}$. We obtain

$$\begin{aligned} L_{F_{p+1}}V_{p+1}(\sigma) &= (L_{D_0}V_{p+1} - L_{D_1}V_{p+1} - L_{D_2}V_{p+1})(\sigma) \\ &\leq -\left(\frac{\alpha_p}{2} - \alpha_{12}\varepsilon_{p+1}^{-1/2}\right)|\bar{\theta}_p|^{n+1} - \left(\alpha_1\varepsilon_{p+1}^{1/2} - \alpha_{13}\right)|\theta_{p+1}|^{n+1}. \end{aligned}$$

Since, by (65), α_p and α_1 are strictly positive, for ε_{p+1} large enough there exists $\alpha_{p+1} > 0$ such that

$$L_{F_{p+1}}V_{p+1}(\sigma) \leq -\alpha_{p+1}|\bar{\theta}_{p+1}|^{n+1}.$$

This concludes the proofs of Proposition 3 and Theorem 1.

Appendix: Proofs of Lemmas 1–4. The proofs of these lemmas rely on the following two properties.

Claim 1. *Let Y and Z denote two time-dependent left-invariant v.f. on G, and g, h solutions of $\dot{g} = Y(g,t)$ and $\dot{h} = Z(h,t)$, respectively. Then $\nu \triangleq gh$ is a solution of $\dot{\nu} = \mathrm{Ad}(h^{-1})Y(\nu,t) + Z(\nu,t)$.*

This is simple to verify. Indeed one has

$$\begin{aligned} \tfrac{d}{dt}(gh) &= dl_g(h)\dot{h} + dr_h(g)\dot{g} \\ &= dl_g(h)Z(h,t) + dr_h(g)Y(g,t) \\ &= Z(gh,t) + dr_h(g)dl_g(e)Y(e,t), \end{aligned}$$

so that one has to show only that $dr_h(g)dl_g(e) = dl_{gh}(e)\mathrm{Ad}(h^{-1})$. For this purpose, it suffices to use the definition of the Ad operator, i.e.,

$$\begin{aligned} \mathrm{Ad}(h) &= d(l_h \circ r_{h^{-1}})(e) \\ &= dl_h(r_{h^{-1}}(e))dr_{h^{-1}}(e) \\ &= dl_h(h^{-1})dr_{h^{-1}}(e), \end{aligned}$$

and well-known relations obtained by differentiating both members of the identities $l_g \circ r_h = r_h \circ l_g$, $l_g \circ l_{g^{-1}} = i_d$, and $l_{gh} = l_g \circ l_h$. The desired result is then obtained as follows:

$$\begin{aligned} dr_h(g)dl_g(e) &= dl_g(h)dr_h(e) \\ &= dl_g(h)dl_h(e)dl_{h^{-1}}(h)dr_h(e) \\ &= dl_{gh}(e)dl_{h^{-1}}(h)dr_h(e) \\ &= dl_{gh}(e)\mathrm{Ad}(h^{-1}). \end{aligned}$$

Claim 2. *Let $\{X_1, \ldots, X_n\}$ denote a graded basis of the Lie algebra $\mathfrak{g}$ of a Lie group G. Let $\lambda, \rho, q \in \{1, \ldots, n\}$, $\alpha_p \in \mathbb{R}$, and $s \in \mathbb{N}$. Then, there exist analytic functions $g_1, \ldots, g_n$ such that, for any $\alpha_\lambda, \alpha_\rho \in \mathbb{R}$,*

$$\sum_{j=s}^{\infty} \frac{1}{j!}(\mathrm{ad}^j(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho), X_q) = \sum_{k=1}^{n} g_k(\alpha_\lambda, \alpha_\rho)X_k.$$

Furthermore, if $\alpha_\lambda, \alpha_\rho$ are analytic functions of x and y such that $\alpha_\lambda = \mathrm{O}(x^{r_\lambda})$ and $\alpha_\rho = \mathrm{O}(x^{r_\rho})$, then $g_k(\alpha_\lambda, \alpha_\rho)$ is an analytic function of x and y and $g_k(\alpha_\lambda, \alpha_\rho) = \mathrm{O}(x^{\max\{s\ \min\{r_\lambda, r_\rho\}, r_k - r_q\}})$.

The proof of this claim, which can be viewed as a direct adaptation of [28, sect. 2], is given in [18, App. A, Claim 2].

Proof of Lemma 1. In order to simplify the notation, let

$$X_\lambda = X_{\lambda(j)}\,,\ X_\rho = X_{\rho(j)}\,,\ \ \alpha_\lambda = \alpha_{j,\lambda}\,,\ \alpha_\rho = \alpha_{j,\rho}. \tag{76}$$

With this notation, it follows from (25) that $f_j(\sigma_j) = g_j(\sigma_j)h_j(\sigma_j)$, with $g_j(\sigma_j) = \exp(\alpha_j(\sigma_j)X_j)$ and $h_j(\sigma_j) = \exp(\alpha_\lambda(\sigma_j)X_\lambda + \alpha_\rho(\sigma_j)X_\rho)$.

Let $\sigma_j(.)$ denote an arbitrary smooth curve on $\mathbb{T}^2$. By using the fact that $\frac{d}{dt}\exp X(t) = \frac{d}{ds}\exp(X(t) + s\frac{d}{dt}X(t))_{|s=0}$ and that (see, e.g., [8, p. 105])

$$\frac{d}{ds}\exp(X + sY)_{|s=0} = (\phi(\mathrm{ad}X), Y)(\exp X)\,, \quad \phi(z) \triangleq \sum_{k=0}^{\infty} \frac{(-1)^k}{(k+1)!} z^k,$$

one infers that

$$\begin{aligned}
\dot{h}_j &\triangleq \frac{d}{dt} h_j(\sigma_j(t)) \\
&= \frac{d}{ds} \exp\left(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho + s\frac{d}{dt}(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho)\right)_{|s=0} \\
&= (\phi(\mathrm{ad}(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho)), \dot{\alpha}_\lambda X_\lambda + \dot{\alpha}_\rho X_\rho)(h_j).
\end{aligned}$$

One has also $\dot{g}_j = \dot{\alpha}_j X_j(g_j)$. The application of Claim 1 then yields

$$\dot{f}_j = (\phi(\mathrm{ad}(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho)), \dot{\alpha}_\lambda X_\lambda + \dot{\alpha}_\rho X_\rho)(f_j) + \dot{\alpha}_j \mathrm{Ad}(\exp(-\alpha_\lambda X_\lambda - \alpha_\rho X_\rho))X_j(f_j). \tag{77}$$

Let us now use the fact (see, e.g., [8, p. 128]) that $\mathrm{Ad}(\exp Y)Z = (\exp \mathrm{ad}Y, Z)$. From (77),

$$\begin{aligned}
\dot{f}_j \ &= (\phi(\mathrm{ad}(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho)), \dot{\alpha}_\lambda X_\lambda + \dot{\alpha}_\rho X_\rho)(f_j) \\
&\quad + \dot{\alpha}_j(\exp \mathrm{ad}(-\alpha_\lambda X_\lambda - \alpha_\rho X_\rho), X_j)(f_j) \\
&= \dot{\alpha}_\lambda X_\lambda(f_j) + \dot{\alpha}_\rho X_\rho(f_j) - \frac{1}{2}[\alpha_\lambda X_\lambda + \alpha_\rho X_\rho, \dot{\alpha}_\lambda X_\lambda + \dot{\alpha}_\rho X_\rho](f_j) \\
&\quad + \sum_{k=2}^{\infty} \frac{(-1)^k}{(k+1)!}(\mathrm{ad}^k(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho), \dot{\alpha}_\lambda X_\lambda + \dot{\alpha}_\rho X_\rho)(f_j) \\
&\quad + \dot{\alpha}_j X_j(f_j) + \dot{\alpha}_j \sum_{k=1}^{\infty} \frac{1}{k!}(\mathrm{ad}^k(-\alpha_\lambda X_\lambda - \alpha_\rho X_\rho), X_j)(f_j).
\end{aligned} \tag{78}$$

Since $X_j = [X_\lambda, X_\rho]$ by Definition 3, it comes from (78) that

$$\begin{aligned}
\dot{f}_j = \dot{\alpha}_\lambda X_\lambda(f_j) + \dot{\alpha}_\rho X_\rho(f_j) + \left(\dot{\alpha}_j - \frac{1}{2}(\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda)\right) X_j(f_j) \\
+ (\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda) \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{(k+2)!}(\mathrm{ad}^k(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho), X_j)(f_j) \\
+ \dot{\alpha}_j \sum_{k=1}^{\infty} \frac{1}{k!}(\mathrm{ad}^k(-\alpha_\lambda X_\lambda - \alpha_\rho X_\rho), X_j)(f_j).
\end{aligned} \tag{79}$$

It follows from (26) that

$$\alpha_\lambda, \frac{\partial \alpha_\lambda}{\partial \theta_j}, \frac{\partial \alpha_\lambda}{\partial \beta_j} = \mathrm{O}(\varepsilon_j^{r_\lambda}); \quad \alpha_\rho, \frac{\partial \alpha_\rho}{\partial \theta_j}, \frac{\partial \alpha_\rho}{\partial \beta_j} = \mathrm{O}(\varepsilon_j^{r_\rho}); \quad \alpha_j, \frac{\partial \alpha_j}{\partial \theta_j}, \frac{\partial \alpha_j}{\partial \beta_j} = \mathrm{O}(\varepsilon_j^{r_j}). \tag{80}$$

Therefore, by application of Claim 2 (with $x = \varepsilon_j$ and $y = \theta_j$),

$$\sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{(k+2)!} (\mathrm{ad}^k(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho), X_j)(f_j) = \sum_{k=1}^{n} g_k(\alpha_\lambda, \alpha_\rho) X_k(f_j) \tag{81}$$

for some analytic functions $g_1, \ldots, g_n$ which verify

$$g_k(\alpha_\lambda, \alpha_\rho) = \mathrm{O}(\varepsilon_j^{\max\{1, r_k - r_j\}}). \tag{82}$$

Similarly, by applying Claim 2 again,

$$\sum_{k=1}^{\infty} \frac{1}{k!} (\mathrm{ad}^k(-\alpha_\lambda X_\lambda - \alpha_\rho X_\rho), X_j)(f_j) = \sum_{k=1}^{n} h_k(\alpha_\lambda, \alpha_\rho) X_k, \tag{83}$$

with

$$h_k(\alpha_\lambda, \alpha_\rho) = \mathrm{O}(\varepsilon_j^{\max\{1, r_k - r_j\}}). \tag{84}$$

From (79), (81), and (83), we get

(85)

$$\begin{aligned}
\dot{f}_j = &\left(\dot{\alpha}_\lambda + (\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda)\, g_\lambda(\alpha_\lambda, \alpha_\rho) + \dot{\alpha}_j\, h_\lambda(\alpha_\lambda, \alpha_\rho)\right) X_\lambda(f_j) \\
&+ \left(\dot{\alpha}_\rho + (\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda)\, g_\rho(\alpha_\lambda, \alpha_\rho) + \dot{\alpha}_j\, h_\rho(\alpha_\lambda, \alpha_\rho)\right) X_\rho(f_j) \\
&+ \left(\dot{\alpha}_j - \frac{1}{2}(\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda) + (\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda)\, g_j(\alpha_\lambda, \alpha_\rho) + \dot{\alpha}_j\, h_j(\alpha_\lambda, \alpha_\rho)\right) X_j(f_j) \\
&+ \sum_{k \notin \{\lambda, \rho, j\}} \left((\alpha_\lambda \dot{\alpha}_\rho - \alpha_\rho \dot{\alpha}_\lambda)\, g_k(\alpha_\lambda, \alpha_\rho) + \dot{\alpha}_j\, h_k(\alpha_\lambda, \alpha_\rho)\right) X_k(f_j).
\end{aligned}$$

Since this equality holds along any smooth curve $\sigma_j(.)$ on $\mathbb{T}^2$, it is also true when the time-derivatives are replaced by partial derivatives w.r.t. either θ_j or β_j.

Now, it follows from (26) that

$$d\alpha_j - \frac{1}{2}(\alpha_\lambda d\alpha_\rho - \alpha_\rho d\alpha_\lambda) = \frac{\varepsilon_j^{r_j}}{2} d\theta_j + \varepsilon_j^{r_j}(1 - \cos\theta_j) d\beta_j \tag{86}$$

and

$$\alpha_\lambda, \ \frac{\partial \alpha_\lambda}{\partial \beta_j}, \ \alpha_\rho, \ \frac{\partial \alpha_\rho}{\partial \beta_j}, \ \alpha_j = \mathrm{O}(\theta_j); \quad \frac{\partial \alpha_j}{\partial \beta_j} = 0. \tag{87}$$

Furthermore, if f is an analytic function of ε and θ such that $f = \mathrm{O}(|\varepsilon|^p)$ and $f = \mathrm{O}(|\theta|^q)$, then $f = \mathrm{O}(|\varepsilon|^p)\mathrm{O}(|\theta|^q)$. Therefore, by using (80), (82), (84), (86), and (87) in (85), it is tedious but simple to recover all relations in Lemma 1. (For the last relation of (39), note that g_j in (85) is an $\mathrm{O}(\theta_j)$ because it is a function of α_λ and α_ρ, which vanishes when $\alpha_\lambda = \alpha_\rho = 0$).

Proof of Lemma 2. From Claim 1 and relations (24) and (37),

(88)
$$\frac{\partial f}{\partial \theta_j} = \sum_{k=1}^{n} v_{k,j} \mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) X_k(f)\,, \quad \frac{\partial f}{\partial \beta_j} = \sum_{k=1}^{n} w_{k,j} \mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) X_k(f).$$

From the fact that $\mathrm{Ad}(g_1 g_2) = \mathrm{Ad}(g_1)\mathrm{Ad}(g_2)$ and (25),

(89)
$$\begin{aligned} \mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) &= \prod_{p=m+1}^{j-1} \mathrm{Ad}(f_p^{-1}) \\ &= \prod_{p=m+1}^{j-1} \mathrm{Ad}(\exp(-\alpha_{p,\lambda} X_{\lambda(p)} - \alpha_{p,\rho} X_{\rho(p)}))\mathrm{Ad}(\exp -\alpha_p X_p). \end{aligned}$$

By application of Claim 2, for any $p, q, k = 1, \ldots, n$ and $(\alpha_p, \alpha_q) \in \mathbb{R}^2$,

$$\mathrm{Ad}(\exp -\alpha_p X_p - \alpha_q X_q) X_k = X_k + \sum_{i=1}^{n} h_{p,q}^i(\alpha_p, \alpha_q) X_i$$

for some analytic functions $h_{p,q}^i$. Moreover, if $\alpha_p = \mathrm{O}(\varepsilon^{r_p})$ and $\alpha_q = \mathrm{O}(\varepsilon^{r_q})$ are analytic functions, then $h_{p,q}^i(\alpha_p, \alpha_q) = \mathrm{O}(\varepsilon^{\max(1, r_i - r_k)})$. This is used to infer from (80) and (89) that

$$\mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) X_k = X_k + \sum_i g_{j,k}^i X_i \quad \text{with } g_{j,k}^i = \mathrm{O}(\bar{\varepsilon}_{j-1}^{\max(1, r_i - r_k)}). \tag{90}$$

From (90),

$$\sum_{k=1}^{n} v_{k,j} \mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) X_k(f) = \sum_{i=1}^{n} \left(v_{i,j} + \sum_{k=1}^{n} v_{k,j} g_{j,k}^i \right) X_i(f),$$

and a similar expression holds when replacing v by w. Therefore, in view of (88), equation (40) holds with

$$a_{i,j} \triangleq v_{i,j} + \sum_{k=1}^{n} v_{k,j}\, g_{j,k}^i = A + B + C\,, \tag{91}$$
$$A = \sum_{r_k \le r_i} v_{k,j}\, g_{j,k}^i\,,\ B = v_{i,j}\,,\ C = \sum_{r_k > r_i} v_{k,j}\, g_{j,k}^i,$$

and

$$b_{i,j} \triangleq w_{i,j} + \sum_{k=1}^{n} w_{k,j}\, g_{j,k}^i = D + E + F\,, \tag{92}$$
$$D = \sum_{r_k \le r_i} w_{k,j}\, g_{j,k}^i\,,\ E = w_{i,j}\,,\ F = \sum_{r_k > r_i} w_{k,j}\, g_{j,k}^i.$$

Lemma 2 follows from this decomposition. Let us first show how (41) is obtained. From (38) and (90), A, B, and C in (91) are $\mathrm{O}(\bar{\varepsilon}_j^{r_i})$. This gives the first relation of (41).

For $i < j$ and $r_i = r_j$, A vanishes at $\bar{\varepsilon}_{j-1} = 0$ because of (90), and in view of (38), $B = \mathrm{o}(\bar{\varepsilon}_j^{r_i})$ and $C = \mathrm{o}(\bar{\varepsilon}_j^{r_i})$. This gives the second relation of (41).

For $i = j$, the only difference with the previous case comes from the B term, which, in view of (38), is equal to $\varepsilon_j^{r_j}/2 + \mathrm{o}(\varepsilon_j^{r_j})$. This gives the third relation of (41).

Let us now show how (42) is obtained. From (90),

$$g^i_{j,k} = \mathrm{O}(\bar{\theta}_{j-1}) \tag{93}$$

because, by (25) and (26),

$$\bar{\theta}_{j-1} = 0 \Longrightarrow f_{m+1} = \cdots = f_{j-1} = e \Longrightarrow \mathrm{Ad}(f_{m+1}^{-1} \cdots f_{j-1}^{-1}) X_k = X_k.$$

The first relation of (42) is then simply obtained from (39), (90), (92), and (93).

For $i = j$, E in (92) accounts for the term $\varepsilon_j^{r_j}(1 - \cos\theta_j)$—up to higher order terms—in the second relation of (42), whereas D and F account for the remaining term by inspection of (39), (90), and (93).

Proof of Lemma 3. The lemma is a direct consequence of the following property, which can be proved by induction exactly as in the proof of [18, Lem. 3]:

$$\begin{array}{l} \forall k = m+1, \ldots, n,\ \exists \bar{\eta}_k \in \mathbb{R}^{k-m},\ \exists \alpha_k > 0\ : \\ \bar{\varepsilon}_k = \varepsilon_k \bar{\eta}_k \Rightarrow D_k \geq \alpha_k \varepsilon_k^{\bar{r}_k} + o(|\varepsilon_k|^{\bar{r}_k}), \end{array} \tag{94}$$

with $\bar{r}_k = r_{m+1} + \cdots + r_k$ and D_k the function defined by

$$D_k(\sigma) \triangleq \mathrm{Det}(a_{i,j}(\sigma))_{i,j=m+1,\ldots,k}.$$

The first step consists of showing that (94) holds for $k = m+1$. From relation (41) in Lemma 2, $a_{m+1,m+1} = \frac{1}{2}\varepsilon_{m+1}^{r_{m+1}} + o(\varepsilon_{m+1}^{r_{m+1}})$. Since $D_{m+1} = a_{m+1,m+1}$ and $\bar{r}_{m+1} = r_{m+1}$, (94) is verified with $\eta_{m+1} = 1$ and $\alpha_{m+1} = \frac{1}{2}$. For the subsequent steps of the proof, the reader is referred to [18].

Proof of Lemma 4. Let us first show how Lemma 4—relation (44), in particular—is obtained from the following two claims.

Claim 3. *For any i, j,*

$$\left\{ \begin{array}{ll} v_{i,j} = \varepsilon_j^{r_i} \tilde{v}_{i,j} & \textit{with}\ \ \tilde{v}_{i,j} = \mathrm{O}(\theta_j^{r_i - r_j}), \\ w_{i,j} = \varepsilon_j^{r_i} \tilde{w}_{i,j} & \textit{with}\ \ \tilde{w}_{i,j} = \mathrm{O}(\theta_j^{\max(1, r_i - r_j + 2)}), \end{array} \right. \tag{95}$$

where the functions $\tilde{v}_{i,j}$ and $\tilde{w}_{i,j}$ do not depend on the ε_k's.

Claim 4. *Each function $g^i_{j,k}$ in* (90) *is a polynomial in $\varepsilon_3, \ldots, \varepsilon_{j-1}$ homogeneous of degree $r_i - r_k$. Furthermore,*

$$g^i_{j,k} = \left\{ \begin{array}{ll} \mathrm{O}(\bar{\theta}_{j-1}^{r_i - r_k}) & \textit{if}\ r_j \leq r_k < r_i, \\ \mathrm{O}(\bar{\theta}_{j-1}^{r_i - r_j + 1}) & \textit{if}\ r_k < r_j < r_i. \end{array} \right. \tag{96}$$

From these claims, and from (91) and (92), it is straightforward to show that $a_{i,j}$ and $b_{i,j}$ are polynomials homogeneous of degree r_i in $\varepsilon_3, \ldots, \varepsilon_j$. Then, by (95), E and F in (92) are $\mathrm{O}(\bar{\theta}_j^{\max(1, r_i - r_j + 2)})$. As for the term D, it can be decomposed as

$$D = \sum_{r_k < r_i} w_{k,j}\, g^i_{j,k} + \sum_{r_k = r_i} w_{k,j}\, g^i_{j,k}. \tag{97}$$

From (95) and (96), the first sum in (97) is an $\mathrm{O}(\theta_j^{\max(1,r_k-r_j+2)})\mathrm{O}(\bar\theta_{j-1}^{r_i-r_k})$ if $r_j \le r_k < r_i$, and an $\mathrm{O}(\theta_j)\mathrm{O}(\bar\theta_{j-1}^{r_i-r_j+1})$ if $r_k < r_j < r_i$. Therefore, in both cases, it is an $\mathrm{O}(\bar\theta_j^{\max(1,r_i-r_j+2)})$. As for the second sum in (97), it follows from (95) that it is an $\mathrm{O}(\bar\theta_j^{\max(1,r_i-r_j+2)})$. This proves (44) for the term $b_{i,j}$. The proof for $a_{i,j}$ is similar.

It remains to prove Claims 3 and 4. In the case of a chained system, each element X_j of the graded basis, for $j = 3, \dots, n$, is equal to $[X_{\lambda(j)}, X_{\rho(j)}]$ with $\lambda(j) = 1$ and $\rho(j) = j-1$. It is also a constant v.f. With the notation used in the proof of Lemma 1, these two facts imply that

$$(\mathrm{ad}(\alpha_\lambda X_\lambda + \alpha_\rho X_\rho), X_j) = \begin{cases} \alpha_\lambda X_{j+1} & \text{if } j < n, \\ 0 & \text{if } j = n. \end{cases}$$

Relation (79) in Lemma 1 then becomes

$$\dot f_j = \dot\alpha_\lambda X_\lambda(f_j) + \dot\alpha_\rho X_\rho(f_j) + \left(\dot\alpha_j - \frac{1}{2}(\alpha_\lambda\dot\alpha_\rho - \alpha_\rho\dot\alpha_\lambda)\right) X_j(f_j)$$
$$+ (\alpha_\lambda\dot\alpha_\rho - \alpha_\rho\dot\alpha_\lambda)\sum_{k=1}^{n-j}\frac{(-1)^{k+1}}{(k+2)!}\alpha_\lambda^k X_{j+k}(f_j) + \dot\alpha_j\sum_{k=1}^{n-j}\frac{(-\alpha_\lambda)^k}{k!}X_{j+k}(f_j).$$

Claim 3 is easily obtained by identifying this equality with (37), and by using (26) and (29).

Let us now prove Claim 4 by showing how relation (96) is obtained. The first step involves the evaluation of $\mathrm{Ad}(f_p^{-1})X_k$, for $p \in \{3, \dots, n-1\}$ and $k \in \{1, \dots, n\}$. We distinguish two cases.

Case 1. $k \ne 1$. From the definition (28) of $X_1, \dots, X_n$ and from (25),

$$\begin{aligned} \mathrm{Ad}(f_p^{-1})X_k &= \mathrm{Ad}(\exp(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}))\mathrm{Ad}(\exp -\alpha_p X_p)X_k \\ &= \mathrm{Ad}(\exp(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}))X_k \\ &= X_k + \sum_{j=1}^{n-k}\frac{(-\alpha_{p,\lambda})^j}{j!}X_{k+j} \\ &= X_k + \sum_{j=1}^{n-k}\varepsilon_p^j\, h_{p,k}^{k+j}X_{k+j} \quad \text{with } h_{p,k}^{k+j} = \mathrm{O}(\theta_p^j), \end{aligned} \tag{98}$$

where the last equality comes from (26) and (29), and $h_{p,k}^{k+j}$ is a function which does not depend on ε_p. From (29), $r_{k+j} = r_k + j$ for $k > 1$ and $0 \le j \le n-k$. Therefore, from (26) and (98),

$$\mathrm{Ad}(f_p^{-1})X_k = X_k + \sum_{i>k}\varepsilon_p^{r_i-r_k}h_{p,k}^i X_i \quad \text{with } h_{p,k}^i = \mathrm{O}(\theta_p^{r_i-r_k}). \tag{99}$$

By applying (99) recursively, it follows that, for any $k \ne 1$,

$$\mathrm{Ad}(f_3^{-1}\cdots f_{j-1}^{-1})X_k = X_k + \sum_{i>k} g_{j,k}^i X_i \quad \text{with } g_{j,k}^i = \mathrm{O}(\bar\theta_{j-1}^{r_i-r_k}), \tag{100}$$

where each $g_{j,k}^i$ is a polynomial homogeneous of degree $r_i - r_k$ in $\varepsilon_3, \dots, \varepsilon_{j-1}$. This yields (96) for $r_j \le r_k \le r_i$, and also for $r_k < r_j < r_i$ (and $k \ne 1$) after noticing that, in this case, $r_i - r_k \ge r_i - r_j + 1$.

Case 2. $k = 1$. We have

(101)
$$\begin{aligned}
\mathrm{Ad}(f_p^{-1})X_1 &= \mathrm{Ad}(\exp(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}))\mathrm{Ad}(\exp -\alpha_p X_p)X_1 \\
&= \mathrm{Ad}(\exp(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}))(X_1 + \alpha_p X_{p+1}) \\
&= X_1 + \alpha_p X_{p+1} + [-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}, X_1 + \alpha_p X_{p+1}] \\
&\quad + \sum_{k=2}^{\infty} \frac{1}{k!}\Big(\mathrm{ad}^{k-1}(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}), \\
&\qquad\qquad [-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}, X_1 + \alpha_p X_{p+1}]\Big) \\
&= X_1 + \alpha_p X_{p+1} - \alpha_{p,\lambda}\alpha_p X_{p+2} + \alpha_{p,\rho}X_p \\
&\quad + \sum_{k=2}^{\infty} \frac{1}{k!}(\mathrm{ad}^{k-1}(-\alpha_{p,\lambda}X_1 - \alpha_{p,\rho}X_{p-1}), -\alpha_{p,\lambda}\alpha_p X_{p+2} + \alpha_{p,\rho}X_p) \\
&= X_1 + \alpha_p X_{p+1} - \alpha_{p,\lambda}\alpha_p X_{p+2} + \alpha_{p,\rho}X_p \\
&\quad - \alpha_{p,\lambda}\alpha_p \sum_{k=2}^{\infty} \frac{(-\alpha_{p,\lambda})^{k-1}}{k!} X_{p+2+k-1} + \alpha_{p,\rho} \sum_{k=2}^{\infty} \frac{(-\alpha_{p,\lambda})^{k-1}}{k!} X_{p+k-1}.
\end{aligned}$$

It follows from (26) and (101) that

$$\mathrm{Ad}(f_p^{-1})X_1 = X_1 + \sum_{i>1} \varepsilon_p^{r_i - r_1} h_p^i X_i \quad \text{with } h_p^i = \mathrm{O}(\theta_p^{r_i - r_p}), \tag{102}$$

and h_p^i does not depend on ε_p. By applying (102) recursively and by using (100), it follows that

$$\mathrm{Ad}(f_3^{-1} \cdots f_{j-1}^{-1})X_1 = X_1 + \sum_{i>1} g_{j,1}^i X_i \quad \text{with } g_{j,1}^i = \mathrm{O}(\bar{\theta}_{j-1}^{r_i - r_{j-1}}) = \mathrm{O}(\bar{\theta}_{j-1}^{r_i - r_j + 1}),$$

where each $g_{j,1}^i$ is polynomial homogeneous of degree $r_i - r_1$ in $\varepsilon_3, \ldots, \varepsilon_{j-1}$. This concludes the proof of Claim 4.

Acknowledgments. The authors wish to thank the anonymous reviewers who read the first version of the paper in depth and provided numerous relevant remarks and suggestions to improve the presentation.

PERPETUAL CONVERTIBLE BONDS*

MIHAI SÎRBU†, IGOR PIKOVSKY‡, AND STEVEN E. SHREVE†

Abstract. A firm issues a convertible bond. At each subsequent time, the bondholder must decide whether to continue to hold the bond, thereby collecting coupons, or to convert it to stock. The firm may at any time call the bond. Because calls and conversions often occur far from maturity, it is not unreasonable to model this situation with a perpetual convertible bond, i.e., a convertible coupon-paying bond without maturity. This model admits a relatively simple solution, under which the value of the perpetual convertible bond, as a function of the value of the underlying firm, is determined by a nonlinear ordinary differential equation.

Key words. convertible bonds, stochastic calculus, viscosity solutions

1. Introduction.

Firms raise capital by issuing debt (bonds) and equity (shares of stock). The convertible bond is intermediate between these two instruments. A convertible is a bond in the sense that it entitles its owner to receive coupons plus the return of the principle at maturity. However, prior to maturity, the holder may "convert" the bond, surrendering it for a preset number of shares of stock. The price of the bond is thus dependent on the price of the firm's stock. Finally, prior to maturity, the firm may "call" the bond, forcing the bondholder to either surrender it to the firm for a previously agreed price or else convert it for stock as above.

After issuing a convertible bond, the firm's objective is to exercise its call option in order to maximize the value of shareholder equity. The bondholder's objective is to exercise his conversion option in order to maximize the value of the bond. If stock and convertible bonds are the only assets issued by a firm, then the value of the firm is the sum of the value of these two types of assets. In idealized markets where the Miller–Modigliani [17], [18] assumptions hold, changes in corporate capital structure do not affect firm value. In particular, the value of the firm does not change at the time of conversion, and the only change in the value of the firm at the time of call is a reduction by the call price paid to the bondholder if the bondholder surrenders rather than converts the bond. By acting to maximize the value of equity, the firm is in fact minimizing the value of the convertible bond. By acting to maximize the value of the bond, the bondholder is in fact minimizing the value of equity. This creates a two-person, zero-sum game.

Brennan and Schwartz [5] and Ingersoll [11] address the convertible bond pricing problem via the arbitrage pricing theory developed by Merton [16] and underlying the option pricing formula of Black and Scholes [4]. This leads to the conclusion that the firm should call as soon as the conversion value of the bond (the value the bondholder would receive if he converts the bond to stock) rises to the call price. There has been

considerable discussion whether firms call bonds at this time; see, e.g., [1], [2], [8], [12].

In the Brennan and Schwartz [5] model, dividends and coupons are paid at discrete dates. Between these dates the value of the firm is a geometric Brownian motion and the price of the convertible bond is governed by the linear second-order partial differential equation developed by Black and Scholes [4]. Brennan and Schwartz [6] generalize that model to allow random interest rates and debt senior to the convertible bond. In Ingersoll [11], coupons are paid out continuously, and for most of the results obtained, dividends are zero. Again, the bond price is governed by a linear second-order partial differential equation. In [5] the bond should not be converted except possibly immediately prior to a dividend payment; in [11] the bond should not be converted except possibly at maturity. Therefore, neither of these papers needs to address the free boundary problem which would arise if early conversion were optimal.

The present paper assumes that a firm's value comprises equity and convertible bonds. To simplify the discussion, we assume the equity is in the form of a single share of stock, and there is a single convertible bond. We assume the value of the issuing firm has constant volatility, the bond continuously pays a coupon at a fixed rate, and the firm equity pays a dividend at a rate which is a fixed fraction of the equity value. In particular, payments are always up to date and there is no issue of accrued interest at the time of a call, default, or conversion. Default occurs if the coupon payments cause the firm value to fall to zero, in which case the bond has zero recovery. In this model, both the bond price and the stock price are functions of the underlying firm value. As pointed out by [3], this means that the stock price does not have constant volatility. Furthermore, because the stock price is the difference between firm value and bond price and because dividends are paid proportionally to the stock price, the differential equation characterizing the bond price as a function of the firm value is *nonlinear*. The development of a mathematical methodology to treat this nonlinearity is the rationale for this paper.

To simplify the analysis, we assume the bond is *perpetual*, i.e., it never matures. This removes the time parameter from the problem, and the free boundary problems associated with optimal call and optimal conversion become "free point" problems. Perpetual bonds are the asymptotic case of finite-maturity bonds; work along the lines of this paper on these bonds is forthcoming. Also, as noted by Ingersoll [11], perpetual convertible bonds are unknown in the market, but they are close relatives of preferred stock, which does trade. Preferred stock does not mature, it can often be called by the issuing firm, and it can be converted to common stock by its owner.

In the time-independent setting of this paper, it is possible to place the convertible bond pricing problem on a firm theoretical foundation. Indeed, the price we obtain is shown to be the only arbitrage-free price in a perfectly liquid market in which the bond, the stock, and a constant-interest-rate money market can be traded. To establish this we first make the assumption that the respective parties adopt not necessarily optimal call and conversion strategies and derive the corresponding no-arbitrage bond price (Theorem 2.1). We then pose the determination of optimal call and conversion strategies as a two-person, zero-sum game and show that the game has a value (Theorem 2.4). We give a full description of the bond price as a function of the firm value in Theorem 2.5. One of the conclusions of that theorem is that it can be optimal to call the bond before the conversion price has reached the call price.

2. The model. We consider a firm whose value at time $t \geq 0$ is denoted by $X(t)$. We assume that prior to call or conversion of the convertible bond, the evolution of

$X(t)$ is governed by the stochastic differential equation

$$dX(t) = h(X(t))\,dt - c\,dt + \sigma X(t)\,dW(t), \tag{2.1}$$

where W is a one-dimensional Brownian motion on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$, h is a Lipschitz continuous function satisfying $h(0) = 0$, and c and σ are positive constants. We denote by $\{\mathcal{F}(t); t \geq 0\}$ the filtration generated by the Brownian motion W, augmented by the null sets in $\mathcal{F}$.

At time t, the firm has a debt $D(t)$, and so the equity value is

$$S(t) = X(t) - D(t). \tag{2.2}$$

The debt is in the nature of a convertible bond, which pays coupons at the constant rate c. The bond never matures. The firm's dividend policy is to pay continuously to shareholders at a rate δ times the equity, where $\delta > 0$.

At any time, the owner of the convertible bond may *convert* it for stock. Upon conversion the bondholder will be issued new stock so that his share of the total equity of the company is the *conversion factor* γ, where $0 < \gamma < 1$. To simplify the discussion, let us assume that before conversion the firm has one share of stock outstanding. We are denoting by $X(t)$ the value of the firm and by $D(t)$ the size of the debt before conversion. Therefore, (2.2) gives the price of firm's single share of stock before conversion. Upon conversion, the firm issues new stock and the former bondholder becomes a stockholder. The total value of the firm's outstanding stock is $X(t)$, and the value of the stock owned by the former bondholder is $\gamma X(t)$. Therefore, the price of the share of the stock outstanding before conversion is now $(1-\gamma)X(t)$.

At any time, the firm may *call* the bond, which requires the bondholder to either immediately surrender it for the fixed *conversion price* $K > 0$ or else immediately convert it as described above. If the bond is surrendered, no new stock is issued and the price of the firm's single outstanding share becomes $X(t) - K$. In this model the firm may not call the bond if $X(t) < K$; i.e., there is no provision for reissuing debt.

Equation (2.1) describes the evolution of $X(t)$ only before call or conversion. Prior to conversion or call, the firm value $X(t)$ may drop to zero, in which case the firm declares bankruptcy and coupons and dividends cease.

There is a constant interest rate r, and we assume $\delta < r$. Prior to call or conversion of the bond, there are three tradable assets: the firm's stock, the convertible bond, and a money market paying interest r. We assume that all these are infinitely divisible and there are no transaction costs. Thus, the value $V(t)$ of a portfolio which holds $\Delta_1(t)$ shares of stock and $\Delta_2(t)$ convertible bonds at time t and finances this by investing or borrowing at interest rate r evolves according to the stochastic differential equation

$$\begin{aligned} dV(t) = {} & \Delta_1(t)\big(dS(t) + \delta S(t)\big) + \Delta_2(t)\big(dD(t) + c\,dt\big) \\ & + r\big(V(t) - \Delta_1(t)S(t) - \Delta_2(t)D(t)\big)\,dt. \end{aligned} \tag{2.3}$$

An arbitrage arises if one can begin with $V(0) = 0$ and use $\{\mathcal{F}(t)\}$-adapted processes Δ_1 and Δ_2 so that at some bounded stopping time τ at or before the minimum of the time of call, the time of conversion and the time of bankruptcy, $V(\tau) \geq 0$ almost surely and $V(\tau) > 0$ with positive probability. We restrict ourselves to trading strategies $\Delta_1(t)$, $\Delta_2(t)$ which cause $V(t)$ to be uniformly bounded from below for $0 \leq t \leq \tau$. Our goal is to price the convertible bond, under the assumption that the firm issuing the bond and the bondholder behave optimally, in a way which precludes arbitrage.

If the bond is called, the bondholder surrenders it for the call price K if K exceeds the conversion value $\gamma X(t)$ and converts it if $\gamma X(t) > K$. If $\gamma X(t) = K$, the bondholder is indifferent between surrender and conversion. Thus, if the bond is called when the firm value is $X(t)$, then the value of the bond is $\max\{K, \gamma X(t)\}$. If the bond has not been called, we assume the bondholder adopts a rule of the form: "convert as soon as the value of the firm equals or exceeds C_o." For the firm, we consider call strategies of the form "call the first time the value of the firm equals or exceeds C_a." The firm must choose $C_a \geq K$; if $C_a < K$, the firm would call when the firm value was insufficient to pay the call price. The firm and bondholder each choose a strategy, characterized by positive constants $C_a \geq K$ and $C_o > 0$. Once C_a, C_o are chosen, we want to find the price of the bond as a smooth function of the value of the firm such that no arbitrage can occur.

To set the notation, for an arbitrary number $a > 0$ we define the *nonlinear* differential operator acting on functions $f \in C[0,a] \cap C^2(0,a)$ by

$$\mathcal{N}f(x) \triangleq rf(x) - (rx - c)f'(x) + \delta(x - f(x))f'(x) - \frac{1}{2}\sigma^2 x^2 f''(x). \tag{2.4}$$

We shall see that this differential operator corresponds to the stochastic differential equation for the firm value

$$dX(t) = \big(rX(t) - c\big)\,dt - \delta\big(X(t) - f(X(t))\big)\,dt + \sigma X(t)\,dW(t), \tag{2.5}$$

rather than (2.1) posited above. This turns out to be the so-called *risk-neutral* evolution of the value of the firm. Under the risk-neutral evolution, the firm value has mean rate of change r reduced by the coupon and dividend payments. The volatility σ is the same as in (2.1). An interesting feature of this model is that the function f appearing in (2.5), which determines the evolution of the "state" under the risk neutral measure for this problem, must be determined by optimality considerations. It is not known a priori.

THEOREM 2.1. *Suppose $C_a \geq K$ and $C_o > 0$ are chosen (not necessarily optimally) by the firm and bondholder, respectively, and set*

$$a_* \triangleq \min\{C_a, C_o\}, \quad \tau_* \triangleq \inf\{t \geq 0; X(t) \notin (0, a_*)\}. \tag{2.6}$$

Assume $X(0) \in (0, a_*)$ and

$$D(t) = f(X(t)), \qquad 0 \leq t \leq \tau_*, \tag{2.7}$$

for a function $f \in C[0,a_*] \cap C^2(0,a_*)$ satisfying the boundary conditions

$$f(0) = 0, \quad f(a_*) = \begin{cases} \gamma a_* & \text{if } 0 < C_o < C_a, \\ \max\{K, \gamma a_*\} & \text{if } K \leq C_a \leq C_o. \end{cases} \tag{2.8}$$

If there is no arbitrage, then

$$\mathcal{N}f(x) = c \text{ for } 0 < x < a_*. \tag{2.9}$$

Conversely, if the function f satisfies (2.8) *and* (2.9) *and the derivative f' is bounded on $(0, a_*)$, then there is no arbitrage.*

Proof. Assume that the price of the bond is $D(t) = f(X(t))$ for a function $f \in C[0,a_*] \cap C^2(0,a_*)$ satisfying (2.8). In particular, the value of the equity is $S(t) = X(t) - f(X(t))$ for $0 \leq t \leq \tau_*$. Taking (2.3) into account, we see that the value

$V(t)$ of a self-financing portfolio starting with initial capital $V(0) = 0$ and containing $\Delta_1(t)$ shares of stock and $\Delta_2(t)$ units of convertible bond evolves according to

$$\begin{aligned} dV(t) = {} & \Delta_1(t)\big[d\big(X(t) - f(X(t))\big) + \delta\big(X(t) - f(X(t))\big)dt\big] \\ & + \Delta_2(t)\big[df(X(t)) + c\,dt\big] \\ & + r\big[V(t) - \Delta_1(t)\big(X(t) - f(X(t))\big) - \Delta_2(t)f(X(t))\big]dt. \end{aligned}$$

Therefore,

$$\begin{aligned} & d(e^{-rt}V(t)) \\ & = e^{-rt}\big[\Delta_1(t)\big(1 - f'(X(t))\big) + \Delta_2(t)f'(X(t))\big]dX(t) \\ & \quad + e^{-rt}\Delta_1(t)\left[-\frac{1}{2}\sigma^2X^2(t)f''(X(t)) - (r-\delta)X(t) + (r-\delta)f(X(t))\right]dt \\ & \quad + e^{-rt}\Delta_2(t)\left[\frac{1}{2}\sigma^2X^2(t)f''(X(t)) + c - rf(X(t))\right]dt. \end{aligned} \tag{2.10}$$

We choose $\Delta_1(t) = f'(X(t))\text{sgn}(\mathcal{N}f(X(t)) - c)$ and $\Delta_2(t) = -(1 - f'(X(t)))$ sgn $(\mathcal{N}f(X(t)) - c)$, so that $\Delta_1(t)(1 - f'(X(t))) + \Delta_2(t)f'(X(t)) = 0$. With these choices (2.10) becomes $d(e^{-rt}V(t)) = |\mathcal{N}f(X(t)) - c|\,dt$. This equation shows that the portfolio value $V(t)$ is bounded from below by $V(0) = 0$ and provides an arbitrage unless $\mathcal{N}f(x) = c$ for $0 < x < a_*$.

We now prove the converse. Assume $D(t) = f(X(t))$ for $0 \le t \le \tau_*$, and f satisfies (2.8) and (2.9). Let $\tau \le \tau_*$ be a bounded stopping time. Since $\frac{h(X(t))}{X(t)}$ and $\frac{f(X(t))}{X(t)}$ are bounded for $0 \le t \le \tau_*$, we can use Girsanov's theorem to construct an equivalent probability measure $\widetilde{\mathbb{P}}$ such that

$$\int_0^t \frac{h(X(s))}{X(s)}ds + \sigma W(t) = rt - \delta\int_0^t \left(1 - \frac{f(X(s))}{X(s)}\right)ds + \sigma\widetilde{W}(t) \tag{2.11}$$

for $0 \le t \le \tau$, where $\widetilde{W}$ is a Brownian motion under $\widetilde{\mathbb{P}}$. The differential of the value of the firm may be rewritten as

$$dX(t) = rX(t)dt - \delta(X(t) - f(X(t)))dt - cdt + \sigma X(t)d\widetilde{W}(t), \qquad 0 \le t \le \tau. \tag{2.12}$$

Let us consider the value $V(t)$ starting with initial capital $V(0) = 0$ corresponding to a self-financing trading strategy $\Delta_1(t)$, $\Delta_2(t)$ for $0 \le t \le \tau$. We can write the evolution of $V(t)$ as

$$\begin{aligned} d(e^{-rt}V(t)) = {} & \Delta_1(t)\big(d(e^{-rt}S(t)) + \delta e^{-rt}S(t)dt\big) \\ & + \Delta_2(t)\big(d(e^{-rt}D(t)) + ce^{-rt}dt\big). \end{aligned} \tag{2.13}$$

Since $D(t) = f(X(t))$, $S(t) = X(t) - f(X(t))$, and the function f is smooth, we can apply Itô's formula to obtain

$$\begin{aligned} & d(e^{-rt}S(t)) + \delta e^{-rt}S(t)dt \\ & \qquad = e^{-rt}\left(\mathcal{N}f(X(t)) - c\right)dt + e^{-rt}(1 - f'(X(t)))\sigma X(t)d\widetilde{W}(t), \end{aligned} \tag{2.14}$$

$$\begin{aligned} & d(e^{-rt}D(t)) + ce^{-rt}dt \\ & \qquad = -e^{-rt}\left(\mathcal{N}f(X(t)) - c\right) + e^{-rt}f'(X(t))\sigma X(t)d\widetilde{W}(t). \end{aligned} \tag{2.15}$$

We assume $\mathcal{N}f(x) - c = 0$ for $0 < x < a_*$, and taking into account (2.14), (2.15), and (2.13), we conclude that $e^{-r(t\wedge\tau)}V(t\wedge\tau)$ is a local martingale under $\widetilde{\mathbb{P}}$. But V is uniformly bounded below, and Fatou's lemma implies $\widetilde{\mathbb{E}}[e^{-r\tau}V(\tau)] \le V(0) = 0$. This means it is impossible to have $\widetilde{\mathbb{P}}\{V(\tau) \ge 0\} = 1$ and $\widetilde{\mathbb{P}}\{V(\tau) > 0\} > 0$. Since $\widetilde{\mathbb{P}}$ is equivalent to the probability measure $\mathbb{P}$, no arbitrage exists. □

In the remainder of this section we state the principal results of the paper. Their proofs are provided in section 7.

To compute the "no arbitrage" price of the convertible bond for some (not necessarily optimal) call and conversion levels, we need an existence and uniqueness result for boundary value problems associated with (2.9).

THEOREM 2.2. *Let y_1 be a positive number and $0 < y_1 \le x_1$. Then there exists a unique solution $f \in C[0,x_1] \cap C^2(0,x_1)$ of the boundary value problem*

$$\begin{cases} \mathcal{N}f(x) = c \text{ for } x \in (0,x_1), \\ f(0) = 0,\ f(x_1) = y_1. \end{cases} \tag{2.16}$$

Furthermore, the derivative f' is bounded on $(0,x_1)$. If $y_1 < x_1$, then $f'(x) < 1$ for all $x \in (0,x_1)$.

Taking into account Theorem 2.1, Theorem 2.2, and the discussion regarding the price of the bond at call or conversion time, we see that once the call and conversion levels have been set, the "no-arbitrage" price of the convertible bond is

$$D(t) = f(X(t), C_a, C_o), \tag{2.17}$$

where the function $f(x, C_a, C_o)$ is given in the next definition.

DEFINITION 2.3.

(i) *If $0 < C_o < C_a$, define $f(x, C_a, C_o)$ for $0 \le x \le C_o$ to be the unique solution of the equation $\mathcal{N}f = c$ on $(0, C_o)$ satisfying the boundary conditions $f(0) = 0$, $f(C_o) = \gamma C_o$. For $x \ge C_o$, define*

$$f(x, C_a, C_o) = \begin{cases} \gamma x, & C_o \le x < C_a, \\ \max\{K, \gamma x\}, & x \ge C_a. \end{cases}$$

(ii) *If $K \le C_a \le C_o$, define $f(x, C_a, C_o)$ for $0 \le x \le C_a$ to be the unique solution of the equation $\mathcal{N}f = c$ on $(0, C_a)$ satisfying the boundary conditions $f(0) = 0$, $f(C_a) = \max\{K, \gamma C_a\}$. For $x \ge C_a$, define $f(x, C_a, C_o) = \max\{K, \gamma x\}$.*

Equation (2.17) provides a bond price once the call and conversion levels C_a and C_o have been chosen. The firm wishes to minimize the value of the bond (in order to maximize the value of equity), and the bondholder wishes to maximize the value of the bond. This creates a two-person game, and according to the next theorem, this game has a value.

THEOREM 2.4. *There exist $C_a^* \ge K$ and $C_o^* > 0$ such that for each $x \ge 0$, we have*

$$f(x, C_a^*, C_o^*) = \inf_{C_a \ge K} f(x, C_a, C_o^*) = \sup_{C_o > 0} f(x, C_a^*, C_o). \tag{2.18}$$

Equation (2.18) implies the following equalities, so we can define

$$f_*(x) \triangleq f(x, C_a^*, C_o^*) = \sup_{C_o>0} \inf_{C_a \ge K} f(x, C_a, C_o) = \inf_{C_a \ge K} \sup_{C_o > 0} f(x, C_a, C_o). \tag{2.19}$$

This is the price of the bond as a function of the underlying firm value x, and C_a^* and C_o^* are the optimal call and optimal conversion levels, respectively.

THEOREM 2.5. *The function f_* is in $C[0,\infty)$ and is described by one of three cases. There are two constants $0 \le K_1 < K_2$ depending on r, δ, σ, c, and γ.*

(i) *If $K > K_2$, then $f_* \in C^1(0,\infty)$ and satisfies*

$$0 < f_*'(x) < 1 \text{ for } x > 0. \tag{2.20}$$

In this case,

$$C_o^* = \min\{x > 0; f_*(x) = \gamma x\} = \frac{K_2}{\gamma},$$

f_* restricted to $(0, C_o^*)$ is the unique classical solution of $\mathcal{N}f_* = c$ on $(0, C_o^*)$ with boundary conditions $f_*(0) = 0$ and $f_*(C_o^*) = \gamma C_o^*$,

$$f_*(x) = \gamma x \text{ for } x \ge C_o^*, \tag{2.21}$$

and $C_a^* = \frac{K}{\gamma} > C_o^* = \frac{K_2}{\gamma}$.

(ii) *If $K_1 \le K \le K_2$, then f_* restricted to $(0, K/\gamma)$ is the unique classical solution of $\mathcal{N}f_* = c$ on $(0, K/\gamma)$ with the boundary conditions $f_*(0) = 0$ and $f_*(K/\gamma) = K$. We have*

$$0 < f_*'(x) < 1 \text{ for } 0 < x < \frac{K}{\gamma}, \tag{2.22}$$

$$f_*(x) = \gamma x \text{ for } x \ge \frac{K}{\gamma}. \tag{2.23}$$

In this case, $C_o^* = C_a^* = \frac{K}{\gamma}$.

(iii) *If $K_1 > 0$, there is a third case. A sufficient condition for $K_1 > 0$ is $0 < \gamma < \frac{1}{2}$. In the third case, $0 < K < K_1$, f_* restricted to $(0, K/\gamma)$ is continuously differentiable, $C_a^* \in (K, K/\gamma)$, and f_* restricted to $(0, C_a^*)$ is the unique solution of $\mathcal{N}f_* = c$ on $(0, C_a^*)$ with the boundary conditions $f_*(0) = 0$, $f_*(C_a) = K$. We have*

$$0 < f_*'(x) < 1 \text{ for } 0 < x < C_a^*, \tag{2.24}$$

$$f_*(x) = \begin{cases} K, & C_a^* \le x \le \frac{K}{\gamma}, \\ \gamma x, & x \ge \frac{K}{\gamma}. \end{cases} \tag{2.25}$$

In particular, $f_*'(C_a^*-) = 0$ and $K < C_a^* < C_o^* = \frac{K}{\gamma}$.

From Theorem 2.5 we see that the firm debt at time t is $D(t) = f_*(X(t))$, and (2.2) becomes

$$S(t) = X(t) - f_*(X(t)). \tag{2.26}$$

So long as $x \in (0, C_a^* \wedge C_o^*)$, the function $F(x) \triangleq x - f_*(x)$ is strictly increasing because of (2.20), (2.22), and (2.24) and hence has an inverse F^{-1}. We may invert (2.26) to obtain $X(t) = F^{-1}(S(t))$, and thereby obtain a formula for the market price of the convertible bond in terms of the equity of the firm: $D(t) = f_*(F^{-1}(S(t)))$. In all three cases of Theorem 2.5, the firm should call as soon as $D(t)$ rises to the call price K. In cases (i) and (ii), this is the first time the conversion value of the bond rises to the call price. In case (iii), the call should occur before the conversion value rises to the call price. The owner of the bond should convert as soon as $D(t) - \gamma F^{-1}(S(t))$ falls to zero, i.e., as soon as the difference between the bond price and the bond's conversion value falls to zero.

3. Generation of candidate functions. Theorem 2.5 asserts that for small values of x, the value $f_*(x)$ of the convertible bond satisfies the second-order ordinary differential equation $\mathcal{N}f(x) = c$. Not only is this equation nonlinear, it is also singular at $x = 0$. Rather than solving the differential equation $\mathcal{N}f(x) = c$ directly, we generate a one-parameter family of solutions to the variational inequality

$$\min\{\mathcal{N}f(x) - c, f(x) - \gamma x\} = 0. \tag{3.1}$$

To do this, we first construct for a fixed function $g \in C[0,a]$, a solution to the variational inequality

$$\min\{\mathcal{L}_g f(x) - c, f(x) - \gamma x\} = 0, \tag{3.2}$$

subject to boundary conditions $f(0) = 0,\ f(a) = \gamma a$. Here, the *linear* differential operator $\mathcal{L}_g$ is defined by

$$\mathcal{L}_g f(x) \triangleq rf(x) - (rx - c)f'(x) + \delta(x - g(x))f'(x) - \frac{1}{2}\sigma^2 x^2 f''(x). \tag{3.3}$$

In section 6 we prove existence of a function g for which the solution to this equation is g itself.

DEFINITION 3.1. *Let $a \in (0,\infty)$ be given. Denote $\mathcal{D}_a = [0,a]$ and let $\mathcal{G}_a$ be the set of continuous functions $g\colon \mathcal{D}_a \to \mathbb{R}$ which are continuously differentiable on $(0,a)$ and satisfy*

$$\begin{aligned} &g(0) = 0, \quad g(a) = \gamma a, \\ &g(x) \geq \gamma x, \quad -M_a \leq g'(x) < 1 \quad \forall x \in (0,a), \end{aligned}$$

where M_a will be defined in Proposition 5.6. We denote by $\overline{\mathcal{G}}_a$ the closure of $\mathcal{G}_a$ with respect to the supremum norm in $C[0,a]$.

Denote $\mathcal{D}_\infty = [0,\infty)$ and let $\mathcal{G}_\infty$ be the set of continuous functions $g\colon \mathcal{D}_\infty \to \mathbb{R}$ which are continuously differentiable on $(0,\infty)$ and satisfy

$$\begin{aligned} &g(0) = 0, \quad g(x) = \gamma x \quad \forall x \in [b_g,\infty), \\ &g(x) \geq \gamma x, \quad 0 \leq g'(x) < 1 \quad \forall x \in (0,\infty), \end{aligned}$$

where b_g is a finite number depending on the function g. Let (C_γ, d) be the complete metric space of continuous functions on $\mathcal{D}_\infty$ which satisfy $\lim_{x\to\infty}[g(x) - \gamma x] = 0$, and d is the supremum metric. We denote by $\overline{\mathcal{G}}_\infty$ the closure of $\mathcal{G}_\infty$ in (C_γ, d).

For $a \in (0,\infty]$, $g \in \overline{\mathcal{G}}_a$, and $x \in \mathcal{D}_a$, we define $X^x(t)$ by $X^x(0) = x$ and

$$dX^x(t) = rX^x(t)\,dt - \delta\left(X^x(t) - g(X^x(t))\right)\,dt - c\,dt + \sigma X^x(t)\,dW(t) \tag{3.4}$$

for $0 \leq t \leq \tau_0^x \wedge \tau_a^x$, where $\tau_y^x \triangleq \inf\{t \geq 0; X^x(t) = y\}$. We then set

$$T_a g(x) \triangleq \sup_{0\leq\tau\leq\tau_0^x\wedge\tau_a^x} \mathbb{E}\left[\int_0^\tau e^{-ru}c\,du + \mathbb{I}_{\{\tau<\infty\}}e^{-r\tau}\gamma X^x(\tau)\right], \tag{3.5}$$

where the supremum is over stopping times τ which satisfy $0 \leq \tau \leq \tau_0^x \wedge \tau_a^x$.

We interpret the objects in Definition 3.1 as follows. Suppose we have a function g which maps the value of the firm into the value of convertible bond. Then $S(t)$ in (2.2) is given by $S(t) = X(t) - g(X(t))$. As we have already seen in the proof of

Theorem 2.1 (see (2.12)), under a "risk-neutral" measure, we expect the value of the firm to have mean rate of growth equal to the interest rate r, reduced by the dividend and coupon payments. In other words, if $g(x)$ is the value of the bond when x is the value of the firm, then the evolution of the value of the firm should be given by (3.4).

The fortunes of the firm, which depend on the function g and the initial condition x, may result in bankruptcy at time τ_0^x. If bankruptcy never occurs, then $\tau_0^x = \infty$. The bondholder collects dividends at rate c until bankruptcy occurs or until he converts the bond to stock. He may convert at any stopping time $\tau \le \tau_a^x$; if he has not converted by the time τ_a, he must do so at this time. The parameter a in this restriction on the stopping time τ will allow us to construct a one-parameter family of solutions to (2.4), and we shall later see that the correct choice of the parameter a depends on the call price K. However, in this interpretation of the function $T_a g$, we do not permit the firm to call. Since the conversion option is worthless after bankruptcy, we assume without loss of generality that $0 \le \tau \le \tau_0^x$. Upon conversion, the bondholder receives stock valued at $\gamma X^x(\tau)$. It follows that the risk-neutral value of a conversion strategy τ is $\mathbb{E}\left[\int_0^\tau e^{-ru} c\, du + \mathbb{I}_{\{\tau<\infty\}} e^{-r\tau}\gamma X^x(\tau)\right]$, and $T_a g(x)$ is the value of the optimal conversion strategy, if it exists.

We began this discussion with the supposition that $g(x)$ is the value of the convertible bond when x is the value of the firm. But the value of the convertible bond should be the risk-neutral discounted value of coupons collected plus the risk-neutral discounted value of the stock received upon conversion. In other words, we seek a function $f \in \overline{\mathcal{G}}_a$ such that $T_a f = f$. Such a function will satisfy (2.9), at least for small values of x.

In section 4 we prove continuity of the function $T_a g$. In section 5 we show that, like g, the function $T_a g$ is in $\overline{\mathcal{G}}_a$, and we state the *Hamilton–Jacobi–Bellman equation* (3.2) satisfied by $T_a g$. In section 6, we show that the mapping $T_a \colon \overline{\mathcal{G}}_a \to \overline{\mathcal{G}}_a$ has a unique fixed point, which we call f_a. Section 7 shows that for each call price K, there is a value of a so that f_a is a part of the function described in Theorem 2.5. This enables us to prove Theorems 2.4 and 2.5. Finally, at the end of section 7 we also prove Theorem 2.2.

4. Continuity of candidate functions. Let $a \in (0,\infty]$ and $g \in \overline{\mathcal{G}}_a$ be given, and define $T_a g$ by (3.5). If a is finite, we extend g to be constant on $(-\infty, 0]$ and on $[a,\infty)$. Since the extended g is Lipschitz, we may use (3.4) to define $X^x(t)$ for all $t \ge 0$. The assumptions on g ensure that for some $\eta > 0$, $\delta(x - g(x)) + c \ge \eta x$ for all $x \ge 0$. We now set $Z(t) = \exp\left\{-\sigma W(t) - \frac{1}{2}\sigma^2 t\right\}$, so that $d(Z(t)X^x(t)) \le (r - \sigma^2 - \eta) Z(t) X^x(t)\, dt$ for all $0 \le t \le \tau_0^x$. Integration yields

$$Z(t)X^x(t) \le x + \left(r - \sigma^2 - \eta\right) \int_0^t Z(u)X^x(u)\, du, \quad 0 \le t \le \tau_0^x,$$

and an application of Gronwall's inequality gives the bound

$$X^x(t) \le \frac{x}{Z(t)} e^{\left(r-\sigma^2-\eta\right)t} = x \exp\left\{\sigma W(t) + \left(r - \frac{1}{2}\sigma^2 - \eta\right) t\right\}, \ 0 \le t \le \tau_0^x. \tag{4.1}$$

LEMMA 4.1. *The function $T_a g$ satisfies the bounds*

$$\gamma x \le T_a g(x) \le \frac{c}{r} + \gamma x \quad \forall x \in \mathcal{D}_a. \tag{4.2}$$

Proof. The lower bound in (4.2) follows from taking $\tau \equiv 0$ in (3.5). For the upper bound, we apply the optional sampling theorem and Fatou's lemma to the martingale

$\exp\left\{\sigma W(t) - \frac{1}{2}\sigma^2 t\right\}$ and use (4.1) to obtain for any stopping time τ satisfying $0 \leq \tau \leq \tau_0^x$

$$\begin{aligned}(4.3)\qquad \mathbb{E}e^{-r\tau}X^x(\tau) &\leq x\mathbb{E}\exp\left\{\sigma W(\tau) - \frac{1}{2}\sigma^2\tau\right\} \\ &\leq x\liminf_{t\to\infty}\mathbb{E}\exp\left\{\sigma W(t\wedge\tau) - \frac{1}{2}\sigma^2(t\wedge\tau)\right\} \;=\; x.\end{aligned}$$

Therefore,

$$T_a g(x) \leq \int_0^\infty e^{-ru}c\,du + \gamma \sup_{0\leq\tau\leq\tau_0^x}\mathbb{E}e^{-r\tau}X^x(\tau) \leq \frac{c}{r} + \gamma x.$$

LEMMA 4.2. *For all $y \geq 0$, τ_y^x is almost surely continuous in x at all $x \geq 0$.*

Proof. It is possible to choose for each initial condition a version of the process $X^x(t)$, $t \geq 0$, such that $X^x(t)$ is jointly continuous in (t,x), almost surely (see [15, Theorem 4.2.5]). Because of the uniqueness of the solution to (3.4), we have for $0 \leq \xi < x \leq y$ that $X^\xi(t) \leq X^x(t)$, $0 \leq t < \infty$, almost surely; if these processes ever coalesce, they would henceforth coincide. This implies that $\lim_{\xi\uparrow x}\tau_y^\xi \geq \tau_y^x$. On the other hand, $\tau_y^x = \inf\{t \geq 0; X^x(t) > y\}$, which implies that $\lim_{\xi\uparrow x}\tau_y^\xi \leq \tau_y^x$. Therefore,

$$(4.4)\qquad \lim_{\xi\uparrow x}\tau_y^\xi = \tau_y^x.$$

By a similar argument, we conclude

$$(4.5)\qquad \lim_{\xi\downarrow x}\tau_y^\xi = \tau_y^x.$$

Combining (4.4) and (4.5), we see that, almost surely, $\lim_{\xi\to x}\tau_y^\xi = \tau_y^x$, $0 \leq x < y$, and (4.4) holds for $x = y$. A similar argument shows that $\lim_{\xi\to x}\tau_y^\xi = \tau_y^x$, $0 \leq y < x$, and (4.5) holds for $x = y$. □

Using (4.1) to bound $e^{-rt}X^x(t)$, $\lim_{t\to\infty}\exp\{\sigma W(t) - \frac{1}{2}\sigma^2 t\} = 0$, joint continuity of $X^x(t)$ in (t,x), and Lemma 4.2, we conclude that the process

$$(4.6)\qquad Y^x(t) \triangleq \int_0^{t\wedge\tau_0^x\wedge\tau_a^x} e^{-ru}c\,du + \mathbb{I}_{\{t\wedge\tau_0^x\wedge\tau_a^x<\infty\}}e^{-r(t\wedge\tau_0^x\wedge\tau_a^x)}\gamma X^x(t\wedge\tau_0^x\wedge\tau_a^x)$$

is jointly continuous in $(t,x) \in [0,\infty] \times \mathcal{D}_a$, almost surely. In particular, we have continuity at time $t = \infty$, where

$$Y^x(\infty) \triangleq \int_0^{\tau_0^x\wedge\tau_a^x} e^{-ru}c\,du + \mathbb{I}_{\{\tau_0^x\wedge\tau_a^x<\infty\}}e^{-r(\tau_0^x\wedge\tau_a^x)}\gamma X^x(\tau_0^x\wedge\tau_a^x).$$

LEMMA 4.3. *The function $T_a g$ is lower semicontinuous on $\mathcal{D}_a$.*

Let τ be any nonnegative stopping time. Lemma 4.2 implies that $\tau\wedge\tau_0^x\wedge\tau_a^x$ is almost surely continuous in x. The function

$$h_{\tau,a} = \mathbb{E}\left[\int_0^{\tau\wedge\tau_0^x\wedge\tau_a^x} e^{-ru}c\,du + \mathbb{I}_{\{\tau\wedge\tau_0^x\wedge\tau_a^x<\infty\}}e^{-r(\tau\wedge\tau_0^x\wedge\tau_a^x)}\gamma X^x(\tau\wedge\tau_0^x\wedge\tau_a^x)\right]$$

is thus lower semicontinuous (Fatou's lemma), and $T_a g(x) = \sup_\tau h_{\tau,a}(x)$, the supremum of lower semicontinuous functions, is lower semicontinuous. □

We know from inequality (4.1) that

$$\sup_{0\leq t\leq\infty} Y^x(t) \leq \frac{c}{r} + \gamma x \sup_{t\geq 0} \exp\left\{\sigma W(t) - \left(\eta + \frac{1}{2}\sigma^2\right)t\right\} = \frac{c}{r} + \gamma x e^{\sigma W^*}, \tag{4.7}$$

where $W^* = \sup_{t\geq 0}\left[W(t) - \left(\frac{\sigma}{2} + \frac{\eta}{\sigma}\right)t\right]$. According to [13, Exercise 5.9, Chapter 3], W^* has density

$$\mathbb{P}\{W^* \in db\} = 2\left(\frac{\sigma}{2} + \frac{\eta}{\sigma}\right)\exp\left\{-2\left(\frac{\sigma}{2} + \frac{\eta}{\sigma}\right)b\right\} db, \qquad b > 0. \tag{4.8}$$

This means that $\mathbb{E}e^{\sigma W^*} < \infty$, so we obtain

$$\mathbb{E}\sup_{0\leq t\leq\infty} Y^x(t) < \infty. \tag{4.9}$$

In light of Lemmas 4.1 and 4.3, the set

$$\mathcal{S}_g \triangleq \{x \in \mathcal{D}_a; T_a g(x) = \gamma x\} = \{x \in \mathcal{D}_a : T_a g(x) \leq \gamma x\}$$

is closed, contains the origin, and contains a if a is finite. We define

$$\tau_*^x \triangleq \inf\{t \geq 0; X^x(t) \in \mathcal{S}_g\}, \tag{4.10}$$

a stopping time satisfying $\tau_*^x \leq \tau_0^x \wedge \tau_a^x$. Since inequality (4.9) holds, it is known from the general theory of optimal stopping that the process

$$Z^x(t) \triangleq \int_0^{t\wedge\tau_0^x\wedge\tau_a^x} e^{-ru} c\, du + \mathbb{I}_{\{t\wedge\tau_0^x\wedge\tau_a^x<\infty\}} e^{-r(t\wedge\tau_0^x\wedge\tau_a^x)} T_a g(X^x(t\wedge\tau_0^x\wedge\tau_a^x)) \tag{4.11}$$

is a supermartingale for $0 \leq t \leq \infty$; the stopped process $Z^x(t\wedge\tau_*^x)$, $0 \leq t \leq \infty$, is a martingale; and τ_*^x is an optimal stopping time, i.e.,

$$T_a g(x) = \mathbb{E}\left[\int_0^{\tau_*^x} e^{-ru} c du + \mathbb{I}_{\{\tau_*^x<\infty\}} e^{-r\tau_*^x}\gamma X^x(\tau_*^x)\right] = \mathbb{E}Y^x(\tau_*^x). \tag{4.12}$$

To prove this, one can first show, using the Markov property, that the process $\{Z^x(t)\}_{0\leq t\leq\infty}$ is the *Snell envelope* of $\{Y^x(t)\}_{0\leq t\leq\infty}$, i.e.,

$$Z^x(t) = \operatorname{ess\,sup}_{\tau\geq t}\mathbb{E}\left[Y^x(\tau)|\mathcal{F}_t\right], \tag{4.13}$$

and then appeal to [14, Appendix D] . Another way to prove it is to combine Theorem 1, page 124, and Theorem 3, page 127, from [20].

LEMMA 4.4. *Assume $a = \infty$. We have*

$$\gamma x \leq T_\infty g(x) \leq x \quad \forall x \in \mathcal{D}_\infty, \tag{4.14}$$

and there is a number $b > 0$ such that

$$T_\infty g(x) = \gamma x \quad \forall x \in [b, \infty). \tag{4.15}$$

If $a \in (0, \infty)$, we have

$$\gamma x \leq T_a g(x) \leq x \quad \forall x \in \mathcal{D}_a. \tag{4.16}$$

Proof. We shall construct a number $b > 0$ and a function $\varphi\colon [0,\infty) \mapsto \mathbb{R}$ such that

$$\gamma x \le \varphi(x) \le x \ \forall x \in [0,b], \quad \varphi(x) = \gamma x \ \forall x \in [b,\infty); \tag{4.17}$$

φ'' is defined and continuous on $[0,\infty)$, except at $\sqrt{b}$ and b, but has one-sided derivatives at these points; φ' is defined, bounded, and continuous on $[0,\infty)$ except at $\sqrt{b}$, but has one-sided derivatives at this point which satisfy

$$D^-\varphi(\sqrt{b}) - D^+\varphi(\sqrt{b}) > 0, \tag{4.18}$$

$$\mathcal{L}_g\varphi(x) \ge c \quad \forall x \in [0,\infty) \setminus \{\sqrt{b}, b\}. \tag{4.19}$$

Once b and φ are constructed, we choose an arbitrary $x \ge 0$. With $X(t) = X^x(t)$, the extension of Itô's rule to continuous, piecewise C^2 functions [13, Chapter 3, Theorem 7.1 and Corollary 7.2] implies that

$$\begin{aligned} d\left(e^{-rt}\varphi(X(t))\right) = -e^{-rt}\mathcal{L}_g\varphi(X(t))\,dt - e^{-rt}\left(D^-\varphi(\sqrt{b}) - D^+\varphi(\sqrt{b})\right)d\Lambda(t) \\ + e^{-rt}\sigma X(t)\varphi'(X(t))\,dW(t), \end{aligned}$$

where $\Lambda(t)$ is the (nondecreasing) local time of X at $\sqrt{b}$. From (4.18) and (4.19), we see that

$$d\left(e^{-rt}\varphi(X(t))\right) \le -e^{-rt}c\,dt + e^{-rt}\sigma X(t)\varphi'(X(t))\,dW(t).$$

Hence, for any stopping time $\tau \le \tau_0^x$ and any deterministic time T, we have

$$\mathbb{E}e^{-r(\tau\wedge T)}\varphi(X(\tau\wedge T)) \le \varphi(x) - \mathbb{E}\int_0^{\tau\wedge T} e^{-rt}c\,dt,$$

where we have used the boundedness of φ' and (4.1) to ensure that the expectation of the Itô integral is zero. This last inequality implies

$$\varphi(x) \ge \mathbb{E}\left[\int_0^{\tau\wedge T} e^{-rt}c\,dt + \mathbb{I}_{\{\tau<\infty\}}e^{-r(\tau\wedge T)}\gamma X(\tau\wedge T)\right].$$

Letting $T \to \infty$ and using Fatou's lemma, then maximizing over τ, we obtain $\varphi(x) \ge T_a g(x)$. Relations (4.14), (4.15) follow from (4.2) and (4.17).

If $a \in (0,\infty)$, then the function $h(x) = x$ on $[0,a]$ is two times continuously differentiable on $(0,a)$ and satisfies $\mathcal{L}_g h(x) \ge c$. Since $h(x) \ge \gamma x$ for each $0 \le x \le a$, we can do the same computation as above for the function h instead of φ and obtain (4.16).

The remainder of the proof is the construction of b and φ. For $b > e^2$, define the positive function $\eta(b) \triangleq (1-\gamma)/\left(\frac{1}{2}\log b + \frac{1}{\sqrt{b}} - 1\right)$. Consider the function

$$k(b) \triangleq c\,[\gamma - \eta(b) - 1] + \frac{1}{2}\delta\sqrt{b}(1-\gamma)\,(\gamma - \eta(b)) - \frac{1}{2}\sigma^2\eta(b)\sqrt{b}.$$

Since $\lim_{b\to\infty}\eta(b) = 0$, we have $\lim_{b\to\infty}k(b) = \infty$. We fix a value $b > e^2$ for which $k(b) > 0,\ \eta(b) < \gamma$. For any $g \in \overline{\mathcal{G}}_a$ we know that $\lim_{x\to\infty}[g(x) - \gamma x] = 0$, so for b

sufficiently large, we also have

$$x - g(x) \geq \frac{1}{2}(1-\gamma)\sqrt{b} \quad \forall x \in [\sqrt{b}, \infty), \tag{4.20}$$

$$\delta(x - g(x)) \geq \frac{(1-\gamma)c}{\gamma} \quad \forall x \in [b, \infty). \tag{4.21}$$

With b chosen to satisfy all the above properties, we set

$$\varphi(x) = \begin{cases} x, & 0 \leq x \leq \sqrt{b}, \\ \gamma x + \eta(b)\sqrt{b}\left(\frac{x}{b} - \log\frac{x}{b} - 1\right), & \sqrt{b} < x < b, \\ \gamma x, & x \geq b. \end{cases} \tag{4.22}$$

A straightforward computation verifies that φ has the desired properties.

COROLLARY 4.5. *The function $T_a g$ is continuous on $\mathcal{D}_a$.*

Proof. Recall from the proof of Lemma 4.3 that for each $y \geq 0$, the stopping time τ_y^x is a continuous function of x. The complement of the closed set $\mathcal{S}_g$,

$$\mathcal{C}_g \triangleq \{x \in \mathcal{D}_a; T_a g(x) > \gamma x\},$$

is a countable union of disjoint open intervals, and on each of these intervals (α, β), we have $\tau_*^x = \tau_\alpha^x \wedge \tau_\beta^x$, which is a continuous function of $x \in [\alpha, \beta]$. On the set $\mathcal{S}_g$, $\tau_*^x \equiv 0$. Hence, τ_*^x is continuous on both $\mathcal{S}_g$ and its complement $\mathcal{C}_g$. To show that τ_*^x is continuous on $\mathcal{D}_a = \mathcal{C}_g \cup \mathcal{S}_g$, it remains only to show that if $\{x_n\}_{n=1}^\infty$ is a sequence in $\mathcal{C}_g$ converging to $x \in \mathcal{S}_g$, then $\tau_*^{x_n} \to \tau_*^x = 0$. But $\tau_*^{x_n} \leq \tau_x^{x_n}$ and $\tau_x^{x_n} \to \tau_x^x = 0$, almost surely (Lemma 4.2), so the desired result holds.

For $a < \infty$ we have $0 \leq X^x(t \wedge \tau_*^x) \leq a$. For $a = \infty$, Lemma 4.4 implies there exists $b > 0$ such that $[b, \infty) \subset \mathcal{S}_g$. In this case, $0 \leq X^x(t \wedge \tau_*^x) \leq \max\{x, b\}$. The continuity of $T_a g$ follows from the representation (4.12), the continuity of τ_*^x, the joint continuity of $Y^x(t)$ on $[0, \infty] \times \mathcal{D}_a$, and the dominated convergence theorem. ∎

PROPOSITION 4.6. *The function $T_a g$ is twice continuously differentiable on $\mathcal{C}_g$ and satisfies the equation*

$$\mathcal{L}_g T_a g = c \text{ on } \mathcal{C}_g. \tag{4.23}$$

If $g \in \mathcal{G}_a$, then $T_a g$ is three times continuously differentiable on $\mathcal{C}_g$.

Proof. Let $x \in \mathcal{C}_g$ be given, and choose $0 < \alpha < x < \beta$ such that $(\alpha, \beta) \subset \mathcal{C}_g$. Consider the linear, second-order ordinary differential equation

$$\mathcal{L}_g h(x) = c \quad \forall x \in (\alpha, \beta), \tag{4.24}$$

with the boundary conditions $h(\alpha) = T_a g(\alpha)$, $h(\beta) = T_a g(\beta)$. Because the coefficients of (4.24) are continuous, the equation has a twice continuously differentiable solution h satisfying these boundary conditions. If $g \in \mathcal{G}_a$, so that the coefficients of (4.24) are continuously differentiable, then h is three times continuously differentiable. Itô's formula implies that

$$\begin{aligned} d\left[e^{-rt}h(X^x(t))\right] &= e^{-rt}\left[-\mathcal{L}_g h(X^x(t))\,dt + \sigma X^x(t) h'(X^x(t))\,dW(t)\right] \\ &= -e^{-rt}c\,dt + e^{-rt}\sigma X^x(t)h'(X^x(t))\,dW(t). \end{aligned}$$

Integrating this equation from $t = 0$ to $t = \tau_\alpha^x \wedge \tau_\beta^x$ and taking expectations, we obtain

$$\begin{aligned} h(x) &= \mathbb{E}\left[\int_0^{\tau_\alpha^x \wedge \tau_\beta^x} e^{-rt} c\, dt + e^{-r(\tau_\alpha^x \wedge \tau_\beta^x)} h(X^x(\tau_\alpha^x \wedge \tau_\beta^x))\right] \\ &= \mathbb{E}\left[\int_0^{\tau_\alpha^x \wedge \tau_\beta^x} e^{-rt} c\, dt + e^{-r(\tau_\alpha^x \wedge \tau_\beta^x)} T_a g(X^x(\tau_\alpha^x \wedge \tau_\beta^x))\right] \\ &= \mathbb{E} Z^x(\tau_\alpha^x \wedge \tau_\beta^x) \;=\; Z^x(0) \;=\; T_a g(x), \end{aligned}$$

where we have used the fact that $Z^x(t \wedge \tau_\alpha^x \wedge \tau_\beta^x)$ is a bounded martingale, since $\tau_\alpha^x \wedge \tau_\beta^x \le \tau_*^x$. □

Remark 4.7. Let us denote by $D^{\pm} T_a g$ the derivatives from the right and left of $T_a g$, when these one-sided derivatives exist. We likewise denote by $DT_a g$ the derivative of $T_a g$, when the derivative exists. Because it is open, the set $\mathcal{C}_g$ is a countable union of disjoint open intervals, which we call the *components* of $\mathcal{C}_g$. Let (α, β) be one of these components. The second-order differential operator $\mathcal{L}_g$ does not degenerate to a first-order operator at any point in $[\alpha, \beta]$, except at α when $\alpha = 0$. Therefore, the function h in the proof of Proposition 4.6 is twice continuously differentiable at the endpoint β and also at α provided that $\alpha > 0$. We conclude that $D^- T_a g(\beta) = \lim_{x \uparrow \beta} DT_a g(x)$ exists. If $\alpha > 0$, then $D^+ T_a g(\alpha) = \lim_{x \downarrow \alpha} DT_a g(x)$ also exists.

5. The invariance property of T_a. As in the previous section, let $a \in (0, \infty]$ and $g \in \overline{\mathcal{G}}_a$ be given, and define $T_a g$ by (3.5). In this section we show that T_a maps $\mathcal{G}_a$ into itself. For this we use the theory of viscosity solutions of Hamilton–Jacobi–Bellman equations developed by Crandall and Lions (see [7], [9]). The proof of Proposition 5.1 below is standard, so we omit it. See [19] for a similar proof.

PROPOSITION 5.1. *The function $T_a g$ is a viscosity solution of the Hamilton–Jacobi–Bellman equation*

$$\min\{\mathcal{L}_g h(x) - c, h(x) - \gamma x\} = 0 \quad \forall x \in \mathcal{D}_a. \tag{5.1}$$

We use Proposition 5.1 to deduce other information about $T_a g$.

COROLLARY 5.2. *Given any $b \in (0, a)$, the set $\mathcal{C}_g \cap (0, b)$ is nonempty.*

Proof. Suppose $T_a g(x) = \gamma x$ for all $x \in [0, b]$. Then

$$\mathcal{L}_g T_a g(x) - c = (\gamma - 1)c + \delta\gamma(x - g(x)),$$

which is strictly negative for $x > 0$ sufficiently small. This violates the viscosity supersolution property of $T_a g$. □

LEMMA 5.3. *If $(0, a) \cap \mathcal{S}_g$ contains a point b, then $[b, \infty) \cap \mathcal{D}_a \subset \mathcal{S}_g$.*

Proof. Assume $b \in (0, a) \cap \mathcal{S}_g$ and denote $\overline{\varphi}(x) = \gamma x$. Because $T_a g(b) = \overline{\varphi}(b)$ and $T_a g \ge \overline{\varphi}$, the viscosity supersolution property for $T_a g$ implies

$$c \le \mathcal{L}_g \overline{\varphi}(b) = c\gamma + \delta\gamma(b - g(b)).$$

But the function $x \to x - g(x)$ is nondecreasing on $\mathcal{D}_a$. Therefore

$$c \le c\gamma + \delta\gamma(x - g(x)) \quad \forall x \in [b, \infty) \cap \mathcal{D}_a.$$

We must show that $T_a g(x) \le \overline{\varphi}(x)$ for all $x \in [b, \infty) \cap \mathcal{D}_a$. Assume on the contrary that $\eta \triangleq \sup\{T_a g(x) - \overline{\varphi}(x); x \in [b, \infty) \cap \mathcal{D}_a\}$ is positive and let x_0 attain

the supremum in the definition of η. (The supremum is attained because both $T_a g$ and $\overline{\varphi}$ are continuous, and if $a = \infty$, then $T_a g(x) = \overline{\varphi}(x)$ for all sufficiently large x.)

We take $\varphi(x) = \overline{\varphi}(x) + \eta$ for $x \in [b, \infty) \cap \mathcal{D}_a$, so that $\varphi(x) \geq T_a g(x)$ for $x \in [b, \infty) \cap \mathcal{D}_a$ and $\varphi(x_0) = T_a g(x_0)$. We have $\varphi(b) > T_a g(b)$ and can choose φ on $(0, b)$ so that it is twice continuously differentiable and dominates $T_a g$ on all of $(0, a)$. Because $T_a g$ is a viscosity subsolution of (5.1) and $\varphi(x_0) = T_a g(x_0) > \gamma x_0$, we obtain

$$\mathcal{L}_g \varphi(x_0) = r T_a g(x_0) - \gamma(r x_0 - c) + \delta\gamma(x_0 - g(x_0)) \leq c \leq \gamma c + \delta\gamma(x_0 - g(x_0)),$$

and hence $T_a g(x_0) \leq \gamma x_0$, a contradiction to the choice of x_0. We conclude that $T_a g(x) \leq \overline{\varphi}(x)$ for $x \in [b, \infty) \cap \mathcal{D}_a$. □

From Corollary 5.2 and Lemmas 5.3 and 4.4, we have the following.

PROPOSITION 5.4. *If a is finite, then $\mathcal{C}_g = (0, b)$ for some $b \in (0, a]$ and $\mathcal{S}_g = \{0\} \cup [b, a]$. If $a = \infty$, then $\mathcal{C}_g = (0, b)$ for some $b \in (0, \infty)$ and $\mathcal{S}_g = \{0\} \cup [b, \infty)$.*

Let b be as in Proposition 5.4. We have already seen that $T_a g$ is twice continuously differentiable on $\mathcal{C}_g = (0, b)$ with a one-sided derivative $D^- T_a g(b)$ at b. Since $T_a g(x) = \gamma x$ on $\mathcal{S}_g$, this function is clearly differentiable on the set (b, a) if $b < a$, with one-sided derivative $D^+ T_a g(b) = \gamma$. It remains to examine the differentiability of $T_a g$ at the point b.

PROPOSITION 5.5 (smooth pasting). *The function $T_a g$ is continuously differentiable on $(0, a)$.*

Proof. It suffices to show in the case that $b < a$ that $D^- T_a g(b) = D^+ T_a g(b)$. Because $T_a g(x) \geq \gamma x$ for all $x \in \mathcal{D}_a$ and $T_a g(b) = \gamma b$, we must have $D^- T_a g(b) \leq \gamma$. If $D^- T_a g(b) < \gamma$, we choose $m \in (D^- T_a g(b), D^+ T_a g(b))$, $k > 0$, and define $\varphi(x) = \gamma b + m(x - b) + k(x - b)^2$ for x in an open interval containing b. Note that $\varphi(b) = T_a g(b)$ and $\varphi'(b) = m$. Therefore, $\varphi(x) < T_a g(x)$ for $x \neq b$ in a sufficiently small neighborhood of b (whose size depends on k). We construct φ outside this neighborhood so that φ is twice continuously differentiable on $(0, a)$ and $\varphi(x) \leq T_a g(x)$ for all $x \in (0, a)$. Because $T_a g$ is a viscosity supersolution of (5.1), the inequality

$$0 \leq \mathcal{L}_g \varphi(b) - c = r\gamma b - (rb - c)m + \delta(b - g(b))m - \sigma^2 b^2 k - c$$

must hold. Since $k > 0$ is arbitrary, this is impossible. □

We have proved so far the following properties of the value function $T_a g$: for any $g \in \overline{\mathcal{G}}_a$, $T_a g$ is a continuous function on $\mathcal{D}_a$ and it has a continuous derivative on $(0, a)$, $T_a g(0) = 0$ and $T_a g(x) \geq \gamma x$ for all $x \in \mathcal{D}_a$. If a is finite, then $T_a g(x) = \gamma a$; if $a = \infty$, then $T_\infty g(x) = \gamma x$ for x sufficiently large.

We now need to prove an invariance property for the operator T_a. Up to this point, we have taken g to be an arbitrary function in $\overline{\mathcal{G}}_a$. For the next proposition, we must restrict our attention to $g \in \mathcal{G}_a$.

PROPOSITION 5.6. *Let $a \in (0, \infty]$ be given. Then T_a maps $\mathcal{G}_a$ into $\mathcal{G}_a$.*

Proof. Assume that $g \in \mathcal{G}_a$. By the above remark, it remains only to show that $-M_a \leq D T_a g < 1$ on $(0, a)$ if a is finite and $0 \leq D T_a g < 1$ if $a = \infty$.

First we claim that the function $\psi = D T_a g$ (defined on $(0, a)$) cannot attain a positive local maximum or a negative local minimum in $\mathcal{C}_g$. By Proposition 4.6, ψ is C^2 on $\mathcal{C}_g$. Assume that ψ has a positive local maximum at $x_* \in \mathcal{C}_g$. Thus, we have $\psi'(x_*) = 0$. In particular,

$$\frac{d}{dx}(T_a g(x) - x\psi(x))\Big|_{x = x_*} = -x_* \psi'(x_*) = 0.$$

Equation (4.23) implies for $x \in \mathcal{C}_g$ that

$$\begin{aligned} c &= \mathcal{L}_g T_a g(x) \\ &= r(T_a g(x) - x\psi(x)) + c\psi(x) + \delta(x - g(x))\psi(x) - \frac{1}{2}\sigma^2 x^2 \psi'(x), \end{aligned}$$

and thus

$$0 = \frac{d}{dx}\mathcal{L}_g T_a g(x)\Big|_{x=x_*} = \delta(1 - g'(x_*))\psi(x_*) - \frac{1}{2}\sigma^2 x_*^2 \psi''(x_*).$$

Because ψ has a local maximum at x_*, $\psi''(x_*) \le 0$. But $1 - g'(x_*)$ is positive, and $\psi(x_*) > 0$. We have a contradiction, and hence ψ cannot have a positive local maximum in $\mathcal{C}_g$. If ψ has a negative local minimum at x_*, we likewise have a contradiction.

We consider now the case that $a = \infty$. For $x < y$ we have $X^x(t) \le X^y(t)$ almost surely and $\tau_0^x \le \tau_0^y$ almost surely. It follows from (3.5) that $T_\infty g$ is nondecreasing. The lower bound $DT_\infty g \ge 0$ is established. For the upper bound, $DT_\infty g(x) < 1$, we recall that $\mathcal{C}_g = (0, b)$ for some $b \in (0, \infty)$. Assume there were a point $x_0 \in (0, b)$ where $DT_\infty g(x_0) \ge 1$. We know that $DT_\infty g(b) = \gamma < 1$. Now consider a point $x_1 \in (0, x_0)$. If $DT_\infty g(x_1) < 1$, then $DT_\infty g$ would have a positive local maximum in the interval (x_1, b), which is impossible. We conclude that $DT_\infty g(x_1) \ge 1$. In other words, if there were a point $x_0 \in (0, b)$ where $DT_\infty g(x_0) \ge 1$, then $DT_\infty g \ge 1$ on the whole interval $(0, x_0)$. The upper bound in (4.14) would immediately imply that $T_\infty g(x) = x$ for $0 \le x \le x_0$, and once again $DT_\infty g$ would have a positive local maximum in $(0, b)$. We conclude that $DT_\infty g(x_0) < 1$ for all $x_0 \in (0, b)$.

If a is finite, we can modify the above argument, using (4.16) in place of (4.14) and $D^- T_a g(b) \le \gamma$ (in case $\mathcal{C}_g = (0, a)$), to obtain the upper bound $DT_a g < 1$ on $(0, a)$.

The proof of the lower bound $DT_a g(x) \ge -M_a$ for the case $a < \infty$ is more involved. Again using the notation $\mathcal{C}_g = (0, b)$, we assume there is $x_0 \in (0, b)$ such that $DT_a g(x_0) < 0$. Let $x_1 \in (0, x_0)$. The continuous function $DT_a g$ attains its minimum on $[x_1, b]$ at x_1 or b, since it cannot attain a negative interior minimum. In case the minimum is attained at x_1, this means that $DT_a g(x_1) < DT_a(x_0) < 0$. For any $0 < x_2 < x_1$, DT_g cannot attain a negative interior minimum on $[x_2, x_0]$, so we can conclude that $DT_a g(x_2) < DT_a g(x_1) < 0$. This should hold for any $0 < x_2 < x_1$, which is in contradiction to $T_a g(0) = 0$, $T_a g(x) \ge \gamma x$. So if $DT_a g(x_0) < 0$, then for any $x_1 \in (0, x_0)$, $DT_a g$ attains its negative minimum on $[x_1, b]$ at b. This means that

$$D^- T_a g(b) \le \inf_{0 < x \le b} D_a T g(x) < 0. \tag{5.2}$$

In other words, the derivative $D_a T g$ either is nonnegative or, if it has negative values, is bounded below by $DT_a^- g(b)$. Of course, the latter case can only happen for $b = a$. The first case satisfies the conclusion, so we assume

$$D^- T_a g(a) = \min_{x \in (0, a]} DT_a g(x) < 0. \tag{5.3}$$

This means that $\mathcal{C}_g = (0, a)$ and hence $\mathcal{L}_g T_a g(x) = c$ for all $x \in (0, a)$. Let h satisfy $\mathcal{L}_g h(x) = c$ for $x \in (\gamma a, a)$ and $h(\gamma a) = \gamma a$, $h(a) = \gamma a$. Since $T_a g(\gamma a) \le \gamma a = h(\gamma a)$, $T_a g(a) = \gamma a = h(a)$ and $\mathcal{L}_g T_a g(x) = \mathcal{L}_g h(x)$ for all $x \in (0, a)$, the usual comparison argument based on the maximum principle yields $T_a g(x) \le h(x)$ for all $x \in [\gamma a, a]$. But $T_a g(a) = h(a)$, and this implies

$$D^- T_a g(a) \ge D^- h(a). \tag{5.4}$$

It suffices to find a lower bound on $D^- h(a)$. We have $0 \le \gamma x \le T_a g(x) \le h(x)$ for $x \in [\gamma a, a]$. In order to find an upper bound on h, we let $x^* \in [\gamma a, a]$ be such that $h(x^*) = \max_{x\in[\gamma a,a]} h(x)$. If x^* is an interior point of $[\gamma a, a]$, then $h'(x^*) = 0$ and $h''(x^*) \le 0$. But $\mathcal{L}_g h(x^*) = c$ from which we conclude that $\max_{x\in[\gamma a,a]} h(x) = h(x^*) \le \frac{c}{r}$. If x^* is not an interior point of $[\gamma a, a]$, then $\max_{x\in[\gamma a,a]} h(x) \le h(\gamma a) = h(a) = \gamma a$. In either case, we have

$$0 \le h(x) \le \max\left\{\gamma a, \frac{c}{r}\right\} \quad \forall x \in [\gamma a, a]. \tag{5.5}$$

We know that

$$0 \le g(x) \le a \quad \forall\ x \in [\gamma a, a]. \tag{5.6}$$

Neither (5.5) nor (5.6) depends on the lower bound $-M_a \le g'(x)$ satisfied by functions g in $\mathcal{C}_a$ when a is finite.

Since $h(\gamma a) = h(a)$, there exists $x_0 \in (\gamma a, a)$ such that $h'(x_0) = 0$. We solve the equation $\mathcal{L}_g h = c$ on $(\gamma a, a)$ for h'' and then integrate to obtain

$$h'(x) = \int_{x_0}^{x} \frac{2}{\sigma^2 y^2}\big[rh(y) - (ry - c)h'(y) + \delta(y - g(y))h'(y) - c\big]\, dy \tag{5.7}$$

for all $x \in [x_0, a]$. Taking into account the bounds (5.5) and (5.6), we may use Gronwall's inequality to obtain $|h'(a)| \le M_a$ for some constant M_a depending only on the bounds $\max\{\gamma a, \frac{c}{r}\}$ and a appearing in (5.5) and (5.6) and also depending on the interval $[\gamma a, a]$. From (5.3), (5.4) we conclude that $DT_a g(x) \ge -M_a$ for all $x \in (0, a)$. □

Remark 5.7. M_a is bounded in a as long as a is bounded away from 0.

6. The fixed point property. For $a = \infty$ we recall that $\overline{\mathcal{G}}_\infty$ is a closed subset of the complete metric space (C_γ, d) (see Definition 3.1). For $a < \infty$, the set $\overline{\mathcal{G}}_a$ is a closed convex subset of the Banach space $C[0, a]$ endowed with the supremum norm. We denote by $d(f, g)$ the metric associated with the supremum norm. We have proved that $T_\infty(\overline{\mathcal{G}}_\infty) \subset C_\gamma$ and $T_a(\overline{\mathcal{G}}_a) \subset C[0, a]$ for $a < \infty$. We also know (in both cases $a = \infty$ and $a < \infty$) that $T_a(\mathcal{G}_a) \subset \mathcal{G}_a$. In this section we prove that $T_a(\overline{\mathcal{G}}_a) \subset \overline{\mathcal{G}}_a$ and the operator T_a has a unique fixed point in $\overline{\mathcal{G}}_a$. Many of the arguments in the rest of the paper are based on the following lemma.

LEMMA 6.1 (comparison). *Let $0 \le \alpha < \beta$ and $f, g \in C(\alpha, \beta)$ be given. Consider $\varphi \in C^1(\alpha, \beta)$ a viscosity subsolution of $\mathcal{L}_f \varphi(x) \le c$ on (α, β) and $\psi \in C^1(\alpha, \beta)$ a viscosity supersolution of $\mathcal{L}_g \psi(x) \ge c$ on (α, β). Assume that at least one of the functions is a classical ($C^2(\alpha, \beta)$) solution of the corresponding differential inequality and that the function $\varphi - \psi$ attains a local maximum at $x_* \in (\alpha, \beta)$. Then*

$$r(\varphi(x_*) - \psi(x_*)) \le \delta(f(x_*) - g(x_*))\varphi'(x_*) = \delta(f(x_*) - g(x_*))\psi'(x_*).$$

Proof. Let us assume that $\varphi \in C^2(\alpha, \beta)$ is a classical solution of $\mathcal{L}_f \varphi(x) \le c$. (The argument in the other case is identical.) This means that

$$r\varphi(x_*) - (rx_* - c)\varphi'(x_*) + \delta(x_* - f(x_*))\varphi'(x_*) - \frac{1}{2}\sigma^2 x_*^2 \varphi''(x_*) \le c.$$

The function $\psi - \varphi$ attains a local minimum at x_*, and since φ is C^2 in a neighborhood of x_*, we can consider φ as a test function when we apply the definition of the viscosity supersolution ψ. We obtain the inequality

$$r\psi(x_*) - (rx_* - c)\varphi'(x_*) + \delta(x_* - g(x_*))\varphi'(x_*) - \frac{1}{2}\sigma^2 x_*^2 \varphi''(x_*) \ge c.$$

Comparing the above results, we conclude that

$$r(\varphi(x_*) - \psi(x_*)) \le \delta(f(x_*) - g(x_*))\varphi'(x_*).$$

Since x_* is a point of interior maximum for $\varphi - \psi$, and both φ and ψ have continuous derivatives on $(0, \alpha)$, we have that $\varphi'(x_*) = \psi'(x_*)$. □

PROPOSITION 6.2. *For $0 < a \le \infty$, we have $T_a(\overline{\mathcal{G}}_a) \subset \overline{\mathcal{G}}_a$, and the mapping T_a has a unique fixed point in $\overline{\mathcal{G}}_a$.*

Proof. Let $f, g \in \overline{\mathcal{G}}_a$ be given. We denote $\varphi = T_a f$ and $\psi = T_a g$. Since $\varphi(0) = \psi(0) = 0$, we know that $\sup_{x\in\mathcal{D}_a}(\varphi(x) - \psi(x)) \ge 0$. We recall that φ, ψ are continuous on $[0, a]$ for finite a (or they are continuous on $[0, \infty)$ and equal to γx for x large enough if $a = \infty$). Thus there exists x_* such that $\varphi(x_*) - \psi(x_*) = \max_{x\in[0,a]}(\varphi(x) - \psi(x))$. If $\varphi(x_*) - \psi(x_*) = 0$, then

$$\sup_{x\in\mathcal{D}_a}(\varphi(x) - \psi(x)) \le \varphi(x_*) - \psi(x_*) = 0 \le \frac{\delta}{r}\max\{M_a, 1\}d(f, g).$$

Assume that $\varphi(x_*) - \psi(x_*) > 0$. Since $\varphi(0) = \psi(0)$ and $\varphi(a) = \psi(a)$ (or $\varphi(x) = \psi(x)$ for all x large enough if $a = \infty$), we see that $0 < x_* < a$. Moreover, since $\varphi(x_*) > \psi(x_*) \ge \gamma x_*$, we know $x_* \in \mathcal{C}_f = \{x : \ \varphi(x) > \gamma x\}$.

We remember that φ is a C^2 function on the open set $\mathcal{C}_f$, it is a classical solution of $\mathcal{L}_f\varphi = c$ on $\mathcal{C}_f$, and ψ is a viscosity supersolution of $\mathcal{L}_g\psi \ge c$. Lemma 6.1 implies $r(\varphi(x_*) - \psi(x_*)) \le \delta(f(x_*) - g(x_*))\varphi'(x_*)$. Therefore,

$$\sup_{x\in[0,a]}\big(\varphi(x) - \psi(x)\big) \le \varphi(x_*) - \psi(x_*) \le \frac{\delta}{r}|f(x_*) - g(x_*)||\varphi'(x_*)|.$$

Since $\varphi'(x_*) = \psi'(x_*)$, it is enough to assume that at least one of the functions f and g is an element of $\mathcal{G}_a$ to conclude that $|\varphi'(x_*)| \le \max\{M_a, 1\}$, where $M_a = 0$ for $a = \infty$. Consequently, we obtain

$$\sup_{x\in[0,a]}\big(\varphi(x) - \psi(x)\big) \le \frac{\delta}{r}\max\{M_a, 1\}d(f, g).$$

We can switch φ and ψ in the argument above and obtain a similar inequality for $\psi - \varphi$. In other words, we have proved that

$$d(T_a f, T_a g) \le \frac{\delta}{r}\max\{M_a, 1\}d(f, g), \tag{6.1}$$

provided that at least one of the functions f and g is an element of $\mathcal{G}_a$.

We now choose $f \in \overline{\mathcal{G}}_a$, and let $f_n \in \mathcal{G}_a$ be such that $d(f_n, f) \to 0$ as $n \to \infty$. Using (6.1) we immediately obtain $d(T_a f_n, T_a f) \to 0$ as $n \to \infty$, and since $T_a f_n \in \mathcal{G}_a$ for all n, we conclude that $T_a f \in \overline{\mathcal{G}}_a$.

A similar approximation argument ($f_n \to f,\ g_n \to g,\ f_n, g_n \in \mathcal{G}_a$), together with

$$d(T_a f, T_a g) \le d(T_a f, T_a f_n) + d(T_a f_n, T_a g_n) + d(T_a g_n, T_a g)$$

yields

$$d(T_a f, T_a g) \le \frac{\delta}{r}\max\{M_a, 1\}d(f, g) \quad \forall f, g \in \overline{\mathcal{G}}_a.$$

We consider separately the two cases $a = \infty$ and $a < \infty$. If $a = \infty$, then $M_\infty = 0$. Since $\delta < r$, T_a is a contraction on the complete metric space $(\overline{\mathcal{G}}_\infty, d)$. Applying the Banach fixed point theorem, we conclude that T_a has a unique fixed point in $\overline{\mathcal{G}}_\infty$.

If $a < \infty$, the Arzela–Ascoli theorem implies that $\overline{\mathcal{G}}_a$ is a convex and compact subset of the Banach space $C[0, a]$. Since $T_a : \overline{\mathcal{G}}_a \to \overline{\mathcal{G}}_a$ is a continuous mapping with respect to the norm of $C[0, a]$, Schauder's fixed point theorem implies that there exists a fixed point of T_a in $\overline{\mathcal{G}}_a$. Suppose there were two fixed points of T_a, namely f and g. Assume without loss of generality that

$$f(x_*) - g(x_*) = \max_{x\in[0,a]} \big(f(x) - g(x)\big) > 0,$$

so $x_* \in \mathcal{C}_f$. We apply Lemma 6.1 to conclude

$$r(f(x_*) - g(x_*)) \le \delta f'(x_*)(f(x_*) - g(x_*)),$$

which is impossible since $f(x_*) - g(x_*) > 0$, $\delta < r$, and $f'(x_*) \le 1$. (We use here the fact that f has a continuous derivative on $(0, a)$ and $f \in \overline{\mathcal{G}}_a$ to conclude $f'(x_*) \le 1$.) This means that $f \le g$ on $[0, a]$. Interchanging f and g, we obtain $f = g$, so the fixed point is unique. □

We denote by f_a the unique fixed point of T_a in $\overline{\mathcal{G}}_a$. The function f_a is continuous on $\mathcal{D}_a$ and continuously differentiable on $(0, a)$. Associated with the function f_a is a number $b_a \in (0, a]$ such that

$$\mathcal{L}_{f_a} f_a(x) = c, \quad f_a(x) > \gamma x, \quad 0 < x < b_a, \tag{6.2}$$

$$\mathcal{L}_{f_a} f_a(x) \ge c, \quad f_a(x) = \gamma x, \quad b_a < x \le a. \tag{6.3}$$

Even if $a = \infty$, b_∞ is finite.

PROPOSITION 6.3. *The number b_a is given by*

$$b_a = \begin{cases} a & \text{if } a \le b_\infty, \\ b_\infty & \text{if } a \ge b_\infty. \end{cases} \tag{6.4}$$

Proof. The proof is based on the same comparison argument for viscosity solutions that allowed us to conclude that the fixed point is unique in Proposition 6.2, namely an application of Lemma 6.1.

Consider first the case $a \le b_\infty$, and suppose $b_a < a$. The function f_a is defined only on $[0, a]$, but we may extend it by the formula

$$\overline{f}_a(x) = \begin{cases} f_a(x) & \text{if } 0 \le x \le a, \\ \gamma x & \text{if } x \ge a. \end{cases} \tag{6.5}$$

It is apparent from (6.3) that $\overline{f}_a$ is continuous on $[0, \infty)$ and continuously differentiable on $(0, \infty)$. Furthermore, for $x \ge a$ we have

$$c \le \mathcal{L}_{\overline{f}_a} \overline{f}_a(a) = c\gamma + \delta\gamma(1 - \gamma)a \le c\gamma + \delta\gamma(1 - \gamma)x = \mathcal{L}_{\overline{f}_a} \overline{f}_a(x). \tag{6.6}$$

Using (6.6) we conclude that $\overline{f}_a$ is a viscosity solution of the equation $\min\{\mathcal{L}_f f(x) - c, f(x) - \gamma x\} = 0$ on $(0, \infty)$. Furthermore, $\overline{f}_a$ has a continuous derivative on $(0, \infty)$ and $\overline{f}_a(x) = \gamma x$ for large x. We can now compare $\overline{f}_a$ and f_∞. We know that either

$$\sup_{x\in[0,\infty)} (\overline{f}_a(x) - f_\infty(x)) \le 0$$

or there exists $x_* \in (0, b_\infty)$ such that

$$\overline{f}_a(x_*) - f_\infty(x_*) = \sup_{x\in[0,\infty)} (\overline{f}_a(x) - f_\infty(x)) > 0.$$

In the latter case, $x_* \in \mathcal{C}_{\overline{f}_a}$ and Lemma 6.1 implies

$$r(\overline{f}_a(x_*) - f_\infty(x_*)) \le \delta f'_\infty(x_*)(\overline{f}_a(x_*) - f_\infty(x_*)),$$

which is impossible since $r < \delta$ and $f'_\infty(x_*) \le 1$. This means that the only possibility is $\overline{f}_a \le f_\infty$. In the same way we prove that $f_\infty \le \overline{f}_a$, so $\overline{f}_a = f_\infty$. This implies that $b_a = b_\infty$, which contradicts the hypothesis $b_a < a \le b_\infty$.

The case $a > b_\infty$ is similar since $f_a(a) = \gamma a = f_\infty(a)$, and the restriction of f_∞ to $[0, a]$ is a viscosity solution of (3.1) on $(0, a)$. We can use the same comparison argument to conclude that $f_\infty|_{[0,a]} = f_a$, which implies $b_a = b_\infty$.

COROLLARY 6.4. *For $0 < a \le \infty$, the function f_a is in $\mathcal{G}_a$.*

Proof. We have already seen that f_a is continuously differentiable, and since $f_a \in \overline{\mathcal{G}}_a$, we conclude that $-M_a \le f'_a(x) \le 1$ for $0 < x < a$. It remains only to prove that the derivative f'_a cannot attain the value 1.

Assume, by contradiction, that $f'_a(x_0) = 1$ for some $x_0 \in (0, a)$. This means f'_a has a maximum at x_0 and $x_0 \in \mathcal{C}_{f_a}$, where f_a is two times continuously differentiable. Hence, $f''_a(x_0) = 0$. Moreover, $\mathcal{L}_{f_a} f_a(x_0) = c$, so $(r - \delta)(x_0 - f_a(x_0)) = 0$. Since $r - \delta > 0$ we see that $f_a(x_0) = x_0$. The function f_a is thus a solution of the ordinary differential equation $\mathcal{L}_f f(x) = c$ with initial conditions $f(x_0) = x_0$, $f'(x_0) = 1$ on the interval $[x_0, b_a]$. However, the only such solution to this equation is $f(x) = x$, and we conclude that $f_a(x) = x$ for $x_0 \le x \le b_a$. This contradicts the fact that $f_a(b_a) = \gamma b_a < b_a$.

COROLLARY 6.5. *For every $0 < a \le \infty$, the function f_a is concave for small values of x, it has a right derivative at $x = 0$, and $D^+ f_a(0) \le 1$.*

Proof. Since $f_a = T_a f_a$ and we just proved that $f_a \in \mathcal{G}_a$, we know from the first part of the proof of Proposition 5.6 that the derivative $f'_a = DT_a f_a$ cannot attain a positive local maximum in $(0, b_a)$. Since $f_a(0) = 0$, $f_a(b_a) = \gamma b_a$, and f_a is differentiable on $(0, b_a)$, we can conclude from the mean-value theorem that there exists $x_\gamma \in (0, b_a)$ with $f'_a(x_\gamma) = \gamma$. Since $D^- f_a(b_a) \le \gamma$, we can argue that for any $x_1 < x_2 \le x_\gamma$ we have $f'_a(x_1) > f'_a(x_2)$. To do this, we first use the fact that f'_a cannot attain a positive interior maximum on $[x_2, b_a]$ to conclude that $f'_a(x_2) > f'_a(x_\gamma) = \gamma$ and then use the fact that f'_a cannot attain a positive interior maximum on $[x_1, x_\gamma]$ to further conclude that $f'_a(x_1) > f'_a(x_2)$. In other words, the derivative f'_a is strictly decreasing on $(0, x_\gamma)$. This means that the function f_a is concave on $[0, x_\gamma]$ and

$$D^+ f_a(0) \triangleq \lim_{x\to 0} \frac{f_a(x) - 0}{x - 0} = \lim_{x\to 0} f'_a(x) \tag{6.7}$$

is well defined. It is obvious that $D^+ f_a(0) \le 1$.

7. Proofs of Theorems 2.2, 2.4, and 2.5. For each call price K we construct a function f^* so that $f^*(x)$ is the value of the convertible bond when the value of the firm is x. For small values of x, the function $f^*(x)$ agrees with $f_a(x)$ for an appropriately chosen a, depending on K. In order to proceed, we must first understand the dependence of f_a on the parameter a. For this purpose, we define $m\colon (0,\infty) \to (0,\infty)$ by

$$m(a) = \max_{x\in[0,a]} f_a(x). \tag{7.1}$$

Because $f_a = f_\infty|_{[0,a]}$ for $a \geq b_\infty$ and f_∞ is nondecreasing by virtue of its membership in $\overline{\mathcal{G}}_\infty$, we have

$$m(a) = \gamma a \quad \forall a \geq b_\infty. \tag{7.2}$$

For $a < b_\infty$ and $x \in (0, a)$, we have $f_a(x) > \gamma x$ (Proposition 6.3 and the inequality in (6.2)), and so it is possible that $m(a) > \gamma a$ for $0 < a < b_\infty$. We shall in fact discover that there is a number $b_0 \in [0, b_\infty)$ such that $m(a) > \gamma a$ for $0 < a < b_0$, whereas $m(a) = \gamma a$ for $a \geq b_0$ (see Remark 7.3).

LEMMA 7.1. *The function $m\colon (0,\infty) \to (0,\infty)$ is strictly increasing and continuous and satisfies $\lim_{a \downarrow 0} m(a) = 0$.*

Proof. It is clear from (7.2) that m is strictly increasing on $[b_\infty, \infty)$. We first show that m is nondecreasing on $(0, b_\infty]$. Let $0 < a_1 < a_2 \leq b_\infty$ be given. Since $f_{a_1}(0) = 0 = f_{a_2}(0)$ and $f_{a_1}(a_1) = \gamma a_1 < f_{a_2}(a_1)$, if the function $f_{a_1} - f_{a_2}$ attains a positive maximum over $[0, a_1]$ it must be at an interior point $x_* \in (0, a_1)$. But $\mathcal{L}_{f_{a_1}} f_{a_1}(x) = c = \mathcal{L}_{f_{a_2}} f_{a_2}(x)$ for $0 < x < a_1$, and $x \in \mathcal{C}_{f_{a_1}}$, where f_{a_1} is C^2. Lemma 6.1 implies that

$$r\big(f_{a_1}(x_*) - f_{a_2}(x_*)\big) \leq \delta\big(f_{a_1}(x_*) - f_{a_2}(x_*)\big) f'_{a_1}(x_*),$$

which is impossible because $\delta < r$ and $f'_{a_1}(x_*) \leq 1$. We conclude that $f_{a_1}(x) \leq f_{a_2}(x)$ for all $x \in [0, a_1]$. Therefore m is nondecreasing on $(0, b_\infty]$.

By the same comparison argument, the function $f_{a_2} - f_{a_1}$ cannot attain a positive maximum in $(0, a_1)$, so $f_{a_2}(x) - f_{a_1}(x) \leq f_{a_2}(a_1) - \gamma a_1$ for $0 \leq x \leq a_1$. It follows that

$$\begin{aligned} m(a_2) - m(a_1) &= \max\Big\{ \max_{x\in[0,a_1]} f_{a_2}(x), \max_{x\in[a_1,a_2]} f_{a_2}(x)\Big\} - m(a_1) \\ &\leq \max\Big\{ \max_{x\in[0,a_1]} \big(f_{a_2}(x) - f_{a_1}(x)\big), \max_{x\in[a_1,a_2]} \big(f_{a_2}(x) - \gamma a_1\big)\Big\} \\ &= \max\Big\{ f_{a_2}(a_1) - \gamma a_1, \max_{x\in[a_1,a_2]} \big(f_{a_2}(x) - \gamma a_1\big)\Big\} \\ &= -\gamma a_1 + \max_{x\in[a_1,a_2]} f_{a_2}(x). \end{aligned} \tag{7.3}$$

By virtue of its membership in $\overline{\mathcal{G}}_{a_2}$ and Remark 5.7, the function f_{a_2} satisfies $f'_{a_2}(x) \geq -C$ for all $x \in (0, a_2)$ and some positive constant C which is bounded away from zero so long as a_2 is bounded away from zero. Thus, for $x \in [a_1, a_2]$,

$$f_{a_2}(x) = f_{a_2}(a_2) - \int_x^{a_2} f'_{a_2}(y)\, dy \leq \gamma a_2 + C(a_2 - x) \leq \gamma a_2 + C(a_2 - a_1).$$

Substituting this into (7.3), we conclude that

$$0 \leq m(a_2) - m(a_1) \leq (C + \gamma)(a_2 - a_1), \tag{7.4}$$

so long as a_2 is bounded away from zero. The function m is thus continuous.

We now prove that $m(a_1) < m(a_2)$. Assume, by contradiction, that $m(a_1) = m(a_2)$. Let $x_0 \in [0, a_1]$ be such that $f_{a_1}(x_0) = m(a_1)$. We must actually have $x_0 \in (0, a_1)$ because $m(a_1) = m(a_2) \geq \gamma a_2 > \gamma a_1 = f_{a_1}(a_1) > 0 = f_{a_1}(0)$. We have already shown that f_{a_2} dominates f_{a_1} on $[0, a_1]$, and hence we must have $f_{a_1}(x_0) = f_{a_2}(x_0)$. The comparison argument using Lemma 6.1 shows that neither $f_{a_2} - f_{a_1}$ nor $f_{a_1} - f_{a_2}$ can have a positive maximum in the open interval $(0, x_0)$; we conclude that

$$f_{a_1}(x) = f_{a_2}(x) \quad \forall x \in [0, x_0]. \tag{7.5}$$

Both f_{a_1} and f_{a_2} are solutions of the ordinary differential equation $\mathcal{L}_f f(x) = c$ on $[x_0, a_1]$ and have the same initial conditions $f_{a_1}(x_0) = f_{a_2}(x_0)$, $f'_{a_1}(x_0) = f'_{a_2}(x_0)$. It follows that

$$f_{a_1}(x) = f_{a_2}(x) \quad \forall x \in [x_0, a_1]. \tag{7.6}$$

This implies that $f_{a_2}(a_1) = f_{a_1}(a_1) = \gamma a_1$, which contradicts Proposition 6.3. We conclude that m is strictly increasing on $(0, b_\infty]$.

Finally, since $f_a(x) \le x$ for $0 \le x \le a$, we see that $0 \le m(a) \le a$, and consequently $\lim_{a \downarrow 0} m(a) = 0$. □

LEMMA 7.2.

(i) *Assume $m(\overline{a}) > \gamma \overline{a}$ for some $\overline{a} > 0$. Then $\overline{a} < \frac{c}{r\gamma}$ and $m(a) > \gamma a$ for all $a \in (0, \overline{a})$.*

(ii) *If $m(a) > \gamma a$, the function f_a attains its maximum over $[0, a]$ at a unique point $x_a \in (0, a)$.*

Proof. (i) If $a \ge \frac{c}{r\gamma}$, we define $h(x) = \gamma a \ge \frac{c}{r}$ for $x \in [0, a]$. Then $\mathcal{L}_{f_a} h(x) \ge c$ for $0 < x < a$. Lemma 6.1 shows that $f_a - h$ cannot have a positive maximum in $(0, a)$, and since $f_a(0) = 0 \le h(0)$ and $f_a(a) = \gamma a = h(x)$, we conclude that $f_a(x) \le h(a)$ for all $0 \le x \le a$. Consequently, the maximum of f_a is $m(a) = \gamma a$.

Assume now that $m(\overline{a}) > \gamma \overline{a}$ for some $\overline{a} > 0$. We have just seen that $\overline{a} < \frac{c}{r\gamma}$. Let $a \in (0, \overline{a})$ be given. Define $\ell = a/\overline{a} < 1$ and rescale the function $f_{\overline{a}}$ by setting $f(x) = \ell f_{\overline{a}}(\frac{x}{\ell})$ for all $x \in [0, a]$. We compute $f'(x) = f'_{\overline{a}}(\frac{x}{\ell})$ and $f''(x) = \frac{1}{\ell} f''_{\overline{a}}(\frac{x}{l})$, from which we conclude that

$$\mathcal{L}_f f(x) = \ell \mathcal{L}_{f_{\overline{a}}} f_{\overline{a}} \left(\frac{x}{l}\right) + c(1-l) f'_{\overline{a}} \left(\frac{x}{l}\right) \le \ell c + c(1-\ell) = c \quad \forall x \in (0, a).$$

Lemma 6.1 shows that $f - f_a$ cannot have a positive maximum over $[0, a]$ at a point in $(0, a)$. But $f(0) = f_a(0) = 0$ and $f(a) = f_a(a) = \gamma a$, and therefore $f_a(x) \ge f(x)$ for all $x \in [0, a]$. In particular,

$$m(a) = \max_{x \in [0,a]} f_a(x) \ge \max_{x \in [0,a]} f(x) = \ell m(\overline{a}) > \ell \gamma \overline{a} = \gamma a. \tag{7.7}$$

(ii) Let us assume now that $m(a) > \gamma a$ and there exist $0 < x_0 < y_0 < a$ such that $f_a(x_0) = f_a(y_0) = m(a)$. Since $f_a(x) \le m(a)$ for $x_0 \le x \le y_0$ we see that f_a has a local minimum at some point $x_1 \in (x_0, y_0)$. Then $f'_a(x_1) = 0$, $f''_a(x_1) \ge 0$, and we may use the equation $\mathcal{L}_{f_a} f_a(x_1) = c$ to obtain $r f_a(x_1) \ge c$. This is impossible because $f_a(x_1) \le m(a) < m(\frac{c}{\gamma r}) = \frac{c}{r}$.

Remark 7.3. We define $b_0 \triangleq \sup\{a > 0, m(a) > \gamma a\}$, where we set $b_0 = 0$ if $m(a) = \gamma a$ for all $a > 0$. Lemma 7.2 shows that $m(a) > \gamma a$ for all $a \in (0, b_0)$. This lemma further shows that $b_0 \le \frac{c}{\gamma r}$. Since for $x \ge b_\infty$ we have $f_\infty(x) = \gamma x$ and $\mathcal{L}_{f_\infty} f_\infty(x) \ge c$, we conclude that

$$r\gamma b_\infty - (r b_\infty - c)\gamma + \delta(b_\infty - \gamma b_\infty)\gamma \ge c,$$

which implies $\delta(1-\gamma) b_\infty \gamma \ge c(1-\gamma)$, and consequently $b_\infty \ge \frac{c}{\gamma \delta}$. In summary,

$$0 \le b_0 \le \frac{c}{\gamma r} < \frac{c}{\gamma \delta} \le b_\infty. \tag{7.8}$$

LEMMA 7.4. *If $0 < \gamma < \frac{1}{2}$, then $b_0 > 0$.*

Proof. For small values of a, we construct a quadratic subsolution of

$$\begin{cases} \mathcal{L}_g g(x) \le c \text{ for } 0 < x < a, \\ g(0) = 0,\ g(a) = \gamma a, \end{cases} \tag{7.9}$$

which satisfies $\max_{x\in[0,a]} g(x) > \gamma a$. According to Lemma 6.1, $g - f_a$ cannot have a positive maximum over $[0,a]$ in $(0,a)$, and since $g(0) = f_a(0) = 0$, $g(a) = f_a(a) = \gamma a$, we see that $f_a \ge g$ on $[0,a]$. It follows that $m(a) > \gamma a$.

The remainder of the proof is the construction of g. We define

$$g(x) = -\frac{x^2}{2a} + \left(\gamma + \frac{1}{2}\right) x,$$

so that $g(0) = 0$ and $g(a) = \gamma a$. Direct computation results in

$$\begin{aligned} &\mathcal{L}_g g(x) \\ &= \frac{rx^2}{2a} - \frac{cx}{a} + \left(\gamma + \frac{1}{2}\right) c - \frac{\delta x^3}{2a^2} + \frac{3\delta\gamma x^2}{2a} - \frac{\delta x^2}{4a} - \delta\gamma^2 x + \frac{\delta x}{4} + \frac{\sigma^2 x^2}{2a} \\ &\le \frac{ra}{2} + \left(\gamma + \frac{1}{2}\right) c + \frac{3\delta\gamma a}{2} + \frac{\delta a}{4} + \frac{\sigma^2 a}{2} \quad \forall x \in [0,a]. \end{aligned}$$

Since $\left(\gamma + \frac{1}{2}\right) c < c$, we have $\sup_{x\in[0,a]} \mathcal{L}_g g(x) \le c$ for sufficiently small a. ∎

We summarize what has so far been established.

(a) For $a > b_\infty$ we have $f_a = f_\infty|_{[0,a]}$ and the maximum $m(a) = \gamma a$ of f_a over $[0,a]$ is attained at the right endpoint a. We have $f_a(x) > \gamma x$ for $x \in (0, b_\infty)$ and $f_a(x) = \gamma x$ for $x \in [b_\infty, a]$.

(b) For $b_0 \le a \le b_\infty$, the maximum $m(a) = \gamma a$ of f_a over $[0,a]$ is attained at the right endpoint a and $f_a(x) > \gamma x$ for all $x \in (0,a)$.

(c) If $b_0 > 0$ (a sufficient condition for this is $0 < \gamma < \frac{1}{2}$), then for $0 < a < b_0$, we have $f_a(x) > \gamma x$ for all $x \in (0,a)$ and the maximum $m(a) > \gamma a$ of f_a over $[0,a]$ is attained at a unique point $x_a \in (0,a)$.

For a fixed call price K we want to define $f^*(x)$ to be $f_a(x)$ for small values of x, where a is the unique parameter such that $m(a) = K$. Denoting

$$K_1 = \gamma b_0, \quad K_2 = \gamma b_\infty,$$

we have the following three situations corresponding to the three cases of Theorem 2.5.

(i) If $K > K_2$, we set $a = \frac{K}{\gamma}$. We define

$$f_*(x) = \begin{cases} f_a(x) = f_\infty(x) & \text{if } 0 \le x \le a, \\ \gamma x & \text{if } x \ge a. \end{cases} \tag{7.10}$$

We see that $f_*(x) = f(x, C_a^*, C_o^*)$ for $C_a^* = \frac{K}{\gamma}$ and $C_o^* = b_\infty < C_a^*$.

(ii) If $K_1 \le K \le K_2$, then again we set $a = \frac{K}{\gamma}$. We define

$$f_*(x) = \begin{cases} f_a(x) & \text{if } 0 \le x \le a, \\ \gamma x & \text{if } x \ge a. \end{cases} \tag{7.11}$$

In this case, $f_*(x) = f(x, C_a^*, C_o^*)$ for $C_a^* = C_o^* = \frac{K}{\gamma}$.

(iii) Assume $K_1 > 0$ and $0 < K < K_1$. Because $m(b_0) = K_1$, there exists a unique $a = m^{-1}(K) < b_0$ such that $m(a) = K$. Since $K < K_1$, Lemma 7.2 implies

that $K = m(a) > \gamma a$ and there exists a unique $x_a \in (0, a)$ such that $f_a(x_a) = m(a)$. Since $f_a' < 1$, we obtain that $K = m(a) = f_a(x_a) < x_a$, so $K < x_a < a < \frac{K}{\gamma}$. We now take $C_a^* = x_a$, $C_o = \frac{K}{\gamma}$ and define

$$f^*(x) = \begin{cases} f_a(x) & \text{for } 0 \le x \le C_a^*, \\ K & \text{for } C_a^* \le x \le C_o^*, \\ \gamma x & \text{for } x \ge C_o^*. \end{cases} \tag{7.12}$$

Again we have $f_*(x) = f(x, C_a^*, C_o^*)$. Since $f_a'(C_a^*) = 0$, f_* is a C^1 function on $(0, \frac{K}{\gamma})$.

It is apparent that the function f_* and the numbers C_o^*, C_a^* just defined have all the properties set forth in Theorem 2.5. The uniqueness of solutions to $\mathcal{N}f = c$ in that theorem follows from Lemma 6.1. We now accept Theorem 2.2, whose proof will be given later in this section, and show that the function f_* defined by (7.10)–(7.12) is indeed the function f_* given by (2.19), and the numbers C_o^* and C_a^* defined above satisfy (2.18). Using f_*, C_o^*, and C_a^* just defined in this way means that the proof of Theorem 2.4 given below also completes the proof of Theorem 2.5.

Proof of Theorem 2.4. We need to prove that

$$f(x, C_a^*, C_o^*) \le f(x, C_a, C_o^*) \text{ for each } C_a \ge K,\ x \in (0, \infty), \tag{7.13}$$

$$f(x, C_a^*, C_o^*) \ge f(x, C_a^*, C_o) \text{ for each } C_o > 0,\ x \in (0, \infty). \tag{7.14}$$

Case (i). $K > K_2 = \gamma b_\infty$.

If $C_a \ge C_a^* = \frac{K}{\gamma}$, then clearly $f(x, C_a^*, C_o^*) = f(x, C_a, C_o^*)$ for $x \in (0, \infty)$.

If $C_o^* < C_a \le \frac{K}{\gamma}$, according to Definition 2.3(i) we have $f(x, C_a, C_o^*) = f(x, C_a^*, C_o^*)$ for $0 \le x < C_a$, and $f(x, C_a, C_o^*) = K \ge f(x, C_a^*, C_a^*)$ for $C_a \le x \le \frac{K}{\gamma}$. For $x \ge \frac{K}{\gamma}$, we have $f(x, C_a^*, C_o^*) = f(x, C_a, C_o^*) = \gamma x$.

Finally, consider the case $K \le C_a \le C_o^* = b_\infty$. Using the Case (i) assumption, we have $K > K_2 = \gamma b_\infty = \gamma C_o^* \ge \gamma C_a$. From Definition 2.3(ii),

$$f(C_a, C_a, C_o^*) = \max\{K, \gamma C_a\} = K \ge \gamma C_a = f_*(C_a).$$

Since $f(\cdot) = f(\cdot, C_a, C_o^*)$ satisfies $\mathcal{L}_f f(x) = c$ on $(0, C_a)$ and $\mathcal{L}_{f_*} f_*(x) = c$ on $(0, C_a)$, an application of Lemma 6.1 yields

$$f(x, C_a^*, C_o^*) = f_*(x) \le f(x, C_a, C_o^*) \text{ for } 0 \le x \le C_a.$$

For $C_a \le x \le \frac{K}{\gamma}$, we have

$$f(x, C_a, C_o^*) = \max\{K, \gamma x\} = K = f_*\Big(\frac{K}{\gamma}\Big) \ge f_*(x) = f(x, C_a^*, C_o^*).$$

For $x > \frac{K}{\gamma}$, we have $f(x, C_a^*, C_o^*) = \gamma x = f(x, C_a, C_o^*)$. This completes the proof of (7.13) in Case (i).

To establish (7.14), we let $C_o > 0$ be given. If $C_o \le C_o^*$, then $f(C_o, C_a^*, C_o) = \gamma C_o \le f_*(C_o)$. Applying Lemma 6.1, we get

$$f(x, C_a^*, C_o) \le f_*(x) = f(x, C_a^*, C_o^*) \text{ for } 0 \le x \le C_o. \tag{7.15}$$

The same inequality is easily verified for $C_o \le x < \infty$.

The case $C_o^* < C_o \leq C_a^*$ is the most interesting. We know that the function $f(\cdot) = f(\cdot, C_a^*, C_o)$ satisfies

$$\begin{cases} \mathcal{L}_f f(x) = c \text{ for } 0 < x < C_o, \\ f(0) = 0,\ f(C_o) = \gamma C_o = f^*(C_o) \text{ (since } C_o > C_o^* = b_\infty). \end{cases}$$

We recall that f_* is a C^1 viscosity supersolution of $\mathcal{L}_{f_*} f_*(x) = c$ on $(0, C_o)$, so Lemma 6.1 can be again used to obtain

$$f(x, C_a^*, C_o) = f(x) \leq f^*(x) = f(x, C_a^*, C_o^*) \text{ for } 0 \leq x \leq C_o.$$

For $C_o \leq x$, we have

$$f(x, C_a^*, C_o) = \gamma x = f^*(x) = f(x, C_a^*, C_o^*).$$

If $C_o \geq C_a^* = \frac{K}{\gamma}$, we just observe that $f(x, C_a^*, C_o) = f(x, C_a^*, \frac{K}{\gamma})$, so we can reduce this case to the case $C_o = C_a^*$ already considered. This completes the proof of (7.14) in Case (i).

Case (ii). $\gamma b_0 = K_1 \leq K \leq K_2 = \gamma b_\infty$.

This is the simplest case, all proofs being based on comparison arguments for C^2 solutions of the equation $\mathcal{L}_f f(x) = c$. The details are left to the reader.

Case (iii). $0 < K < K_1 = \gamma b_o$.

If $C_a^* < C_o < \infty$, there is no change:

$$f(x, C_a^*, C_o) = f(x, C_a^*, C_o^*) \text{ for } 0 \leq x < \infty.$$

If $0 < C_o \leq C_a^*$, then $f(C_o, C_a^*, C_o) = \gamma C_o \leq f_*(C_o)$. The Comparison Lemma 6.1 implies

$$f(x, C_a^*, C_o) \leq f(x, C_a^*, C_o^*) \text{ for } 0 \leq x \leq C_o.$$

For $C_o < x < C_a^*$, we have $f(x, C_a^*, C_o) = \gamma x \leq f(x, C_a^*, C_o^*)$, and for $C_a^* \leq x$ we know that $f(x, C_a^*, C_o) = f(x, C_a^*, C_o^*) = \max\{K, \gamma x\}$. This completes the proof of (7.14) in Case (iii).

We consider (7.13). If $K \leq C_a \leq C_a^*$, then $f(C_a, C_a, C_o^*) = K \geq f(C_a, C_a^*, C_o^*)$. The Comparison Lemma 6.1 implies $f(x, C_a, C_o^*) \geq f(x, C_a^*, C_o^*)$ for $0 \leq x \leq C_a$. For $x \geq C_a$, we have $f(x, C_a, C_o^*) = \max\{K, \gamma x\} \geq f(x, C_a^*, C_o^*)$.

The case $C_a \geq C_o^*$ can be reduced to the case $C_a = C_o^*$ since $f(x, C_a, C_o^*) = f(x, C_a^*, C_o^*)$ for all $x \geq 0$ if $C_a \geq C_o^*$. We do that case now.

Assume $C_a^* < C_a \leq C_o^*$. First we claim that $f_*(\cdot) = f(\cdot, C_a^*, C_o^*)$ is a C^1 viscosity subsolution of

$$\mathcal{L}_{f_*} f_*(x) \leq c \text{ on } \left(0, \frac{K}{\gamma}\right), \tag{7.16}$$

and then we use the Comparison Lemma 6.1 (the difference $f_*(\cdot) - f(\cdot, C_a, C_o^*)$ cannot have a positive maximum in $(0, C_a)$) to conclude that

$$f_*(x) \leq f(x, C_a, C_o^*) \text{ for } 0 \leq x \leq C_a.$$

In the comparison argument we also use the fact that $f(\cdot) = f(\cdot, C_a, C_o^*)$ satisfies $\mathcal{L}_f f(x) = c$ for $0 < x < C_a$, and

$$f_*(0) = 0 = f(0, C_a, C_o^*), \quad f_*(C_a) = K = f(C_a, C_a, C_o^*).$$

For $C_a \le x \le \frac{K}{\gamma}$, we have $f_*(x) = K = f(x, C_a, C_o^*)$, and for $x > \frac{K}{\gamma}$ we know that $f_*(x) = \gamma x = f(x, C_a, C_o^*)$.

This means that the proof of (7.14) is complete, provided we can show that f_* is a viscosity subsolution of (7.16). We know that $\mathcal{L}_{f_*} f_*(x) = c$ for $0 < x < C_a^*$, f_* being a C^2 function on $(0, C_a^*)$. From (7.8) and the Case (iii) assumption, we see that $rK \le c$. Furthermore, $f_*(x) = K$ for $C_o^* \le x \le \frac{K}{\gamma}$. We conclude that $\mathcal{L}_{f_*} f_*(x) \le c$ on $(C_a^*, \frac{K}{\gamma})$.

It remains to show that if $\psi \in C^2(0, C_o^*)$ dominates f^* on $(0, C_o^*)$ and agrees with f^* at C_a^*, then

$$r\psi(C_a^*) - (rC_a^* - c)\psi'(C_a^*) + \delta(C_a^* - \psi(C_a^*))\psi'(C_a^*) - \frac{1}{2}\sigma^2 (C_a^*)^2 \psi''(C_a^*) \le c. \tag{7.17}$$

Since $f_* \in C^1(0, \frac{K}{\gamma})$ and $f_*'(C_a^*) = 0$, we have $\psi'(C_a^*) = 0$. Since $0 < C_a^* < a$, we know $\mathcal{L}_{f_a} f_a(C_a^*) = c$, and since $f_a(C_a^*) = K$ and $f_a'(C_a^*) = 0$, we obtain

$$rK - \frac{1}{2}\sigma^2 (C_a^*)^2 f_a''(C_a^*) = c. \tag{7.18}$$

However, since $\psi(C_a^*) = f_a(C_a^*)$, $\psi'(C_a^*) = f_a'(C_a^*) = 0$, and ψ dominates f_a on $[0, C_a^*]$ (because $f_*(x) = f_a(x)$ on $[0, C_a^*]$), we conclude that

$$f_a''(C_a^*) \le \psi''(C_a^*). \tag{7.19}$$

Substituting this into (7.18), we obtain (7.17). □

Remark 7.5. The proof of the last claim is based on the elementary observation that for a C^2 function, a one-sided maximum is enough to conclude that the second derivative is not positive, provided that the first derivative vanishes. Furthermore, we have proved that f_* is a viscosity solution of the variational inequality $\max\{\mathcal{N} f_*(x) - c, f_*(x) - K\} = 0$ on $(0, \frac{K}{\gamma})$.

Proof of Theorem 2.2. For $y_1 = x_1$, it is easily verified that $f(x) = x$ is a solution of (2.16), and the Comparison Lemma 6.1 establishes uniqueness.

For $0 < y_1 < x_1$, uniqueness again follows from Lemma 6.1 once we have a solution satisfying $f' \le 1$ on $(0, x_1)$. The proof of existence is based on a fixed point argument similar to the proof of Proposition 6.2 with $a < \infty$. In fact, the argument here is simpler, since we deal only with C^2 solutions of the differential equation $\mathcal{L}_g f(x) = c$ rather then viscosity solutions of the variational inequality $\min\{\mathcal{L}_g f(x) - c, f(x) - \gamma x\} = 0$.

For $0 < y_1 < x_1$, we set $A = x_1 - y_1$ and define $\mathcal{G}$ to be the set of all functions $g \in C[0, x_1] \cap C^2(0, x_1)$ such that $g(0) = 0$, $g(x_1) = y_1$, and

$$g(x) \ge \max\{x - A, 0\}, \quad -M(x_1, y_1) \le g'(x) < 1 \quad \forall x \in (0, x_1),$$

where $M(x_1, y_1)$ is a constant to be determined later but depending on only x_1 and y_1. We further define $\overline{\mathcal{G}}$ to be the closure of $\mathcal{G}$ in $C[0, x_1]$ with respect to the supremum norm $\|\cdot\|$. For $g \in \overline{\mathcal{G}}$, we set

$$Tg(x) = \mathbb{E}\left[\int_0^{\tau_0^x \wedge \tau_{x_1}^x} ce^{-ru} du + \mathbb{I}_{\{\tau_{x_1}^x < \tau_0^x\}} e^{-r(\tau_0^x \wedge \tau_{x_1}^x)} y_1\right], \tag{7.20}$$

where $X^x(t)$ is given by (3.4) with $X^x(0) = x$. It is clear from its definition that $Tg \ge 0$ for every $g \in \overline{\mathcal{G}}$. We use the argument in the proof of Proposition 4.6 to

conclude that for $g \in \overline{\mathcal{G}}$ the function Tg is of class C^2 on $(0, x_1)$ and $\mathcal{L}_g Tg(x) = c$ for $0 < x < x_1$. The continuity of Tg at 0 and x_1 follows from Lemma 4.2. The functions $\max\{x - A, 0\}$ and x are respective sub- and supersolutions of $\mathcal{L}_g f = c$ which lie respectively below and above Tg at the endpoints 0 and x_1. Lemma 6.1 implies that for all $g, h \in \overline{\mathcal{G}}$,

$$\max\{x - A, 0\} \le Tg(x) \le x \text{ for } 0 \le x \le x_1, \tag{7.21}$$

$$\|Tg - Th\| \le \sup_{0<x<x_1} |DTg(x)| \|g - h\|. \tag{7.22}$$

We now prove that $T(\mathcal{G}) \subset \mathcal{G}$, the analogue of Proposition 5.6. For $g \in \mathcal{G}$, the first part of the proof of Theorem 5.6 shows that DTg cannot attain a positive local maximum nor a negative local minimum in $(0, x_1)$. This implies that either DTg is nonnegative on $(0, x_1)$ or else $D^- Tg(x_1) \le DTg(x)$ for $0 < x < x_1$. To show that $DTg(x) \ge -M(x_1, y_1)$, it suffices to find a lower bound on $D^- Tg(x_1)$ which may depend on x_1 and y_1 but not on g. For this purpose, we let h be the solution on $[y_1, x_1]$ of the equation $\mathcal{L}_g h = c$ with boundary conditions $h(y_1) = h(x_1) = y_1$. Lemma 6.1 shows that h is nonnegative and dominates Tg on $[y_1, x_1]$, and hence $D^- h(x_1) \le D^- Tg(x_1)$. If h attains a maximum at some point $x_* \in (y_1, x_1)$, the equation $\mathcal{L}_g h(x_*) = c$ implies $h(x_*) \le \frac{c}{r}$. If h does not attain a maximum in (y_1, x_1), then h is dominated by its value y_1 at the endpoints of this interval. In either case, we obtain a bound on $|h|$ which is independent of g. Furthermore, there must be some point $x_0 \in (y_1, x_1)$ where h' vanishes. We solve the equation $\mathcal{L}_g h = c$ for h'' and integrate from x_0 to obtain (5.7). We then use Gronwall's inequality to obtain a bound on $|h'|$ independent of g.

We need also to obtain the upper bound $DTg < 1$. We observe first that since $Tg(x) \ge \max\{x - A, 0\}$ and these two functions agree at $x = x_1$, we must have $D^- Tg(x_1) \le 1$. We use the same arguments used to prove $DT_a g < 1$ if $g \in \mathcal{G}_a$ to conclude that $DTg < 1$ on $(0, x_1)$. This completes the proof that $T(\mathcal{G}) \subset \mathcal{G}$. A relation similar to (6.1) shows that the operator T is continuous on $\overline{\mathcal{G}}$, and hence $T(\overline{\mathcal{G}}) \subset \overline{\mathcal{G}}$. Schauder's fixed point theorem implies the existence of a function $f \in \overline{\mathcal{G}}$ satisfying $Tf = f$. This means, in particular, that $f \in C[0, x_1] \cap C^2(0, x_1)$ and $\mathcal{L}_f f = c$, so f is a solution of (2.16). Since f is differentiable and $f \in \overline{\mathcal{G}}$, we know that $f' \le 1$ on $(0, x_1)$. In fact, $f' < 1$. The proof is identical to the proof of $f'_a < 1$. □

STOCHASTIC GAMES WITH A SINGLE CONTROLLER AND INCOMPLETE INFORMATION*

DINAH ROSENBERG†, EILON SOLAN‡, AND NICOLAS VIEILLE§

Abstract. We study stochastic games with incomplete information on one side, in which the transition is controlled by one of the players.

We prove that if the informed player also controls the transitions, the game has a value, whereas if the uninformed player controls the transitions, the max-min value as well as the min-max value exist, but they may differ.

We discuss the structure of the optimal strategies, and provide extensions to the case of incomplete information on both sides.

Key words. stochastic games, incomplete information, single controller

1. Introduction. In a seminal work, Aumann and Maschler [1, 2] introduced infinitely repeated two-player zero-sum games with incomplete information on one side. Those are repeated games where the payoff matrix is known to one player, say player 1, but is not known to the other player—all player 2 knows is that the payoff matrix was drawn according to some known probability distribution from a finite set of possible matrices. Aumann and Maschler proved that those games have a value.

The issue faced by player 1 is the optimal use of information. On the one hand, player 1 needs to reveal his information (at least partially) in order to make use of it. On the other hand, any piece of information that is revealed to player 2 can later be exploited against player 1.

In the optimal strategies devised by Aumann and Maschler, player 1 reveals part of his information at the first stage, but no further information is revealed during the game. Player 2, on the other hand, has to play optimally whatever the actual payoff matrix may be. Aumann and Maschler achieved this by using Blackwell's approachability strategies.

When the underlying game is a stochastic game rather than a repeated one, the difficulties the players face are more serious.

Is it optimal for player 1 to reveal information only once in every state, or will he reveal information several times in each state? In repeated games, it does not help to dilute the revelation of information over time, since player 2 would wait until player 1 has revealed all the information he will ever reveal, and since interim payoffs are irrelevant in the long run. In stochastic games, by contrast, the game can move to a different state that can be more or less favorable to the informed player. By

giving away some information about the true game at the initial stage, player 1 might induce player 2 to adapt in an adverse way, while postponing this disclosure might allow player 1 to escape from specific states. This is a crude explanation for why it may help player 1 to conceal his information for a while.

For player 2 the issue is to devise the analog of Blackwell's approachability strategies for stochastic games.

Sorin [20, 21] and Sorin and Zamir [23] studied classes of stochastic games with incomplete information on one side that have a single nonabsorbing state, and proved that these games have a min-max value, a max-min value, and that the values of the n-stage (resp., λ-discounted) games converge as n goes to infinity (resp., as λ goes to 0) to the max-min value. Rosenberg and Vieille [17] studied recursive games with incomplete information on one side, and proved that the max-min value exists and is equal to the limit of the values of n-stage games (resp., λ-discounted games) as n goes to infinity (resp., as λ goes to 0).

In the present paper we study stochastic games in which one player controls the transitions; that is, the evolution of the stochastic state depends on the actions of one player but is independent of the actions of his opponent.

We show that if player 1 (who is the informed player) controls the transitions, then the game admits a value. We also propose a specific optimal strategy for player 1 and explain the way this strategy uses the additional information he possesses. Roughly speaking, the state space is partitioned into disjoint sets, which are called communicating sets. Whenever the play enters a communicating set, player 1 chooses a stationary nonrevealing strategy, and he plays this strategy until a new communicating set is visited. The random choice of the stationary strategy itself may be revealing, in that the distribution used at stage n to select a stationary strategy depends on the actual payoff function.

If player 2 controls the transitions, then the game admits a min-max value and a max-min value. We use an example to show that the two values may differ.

The techniques and the characterizations we provide extend the ideas of Aumann and Maschler for incomplete information games to our framework.

In the last section of the paper we extend the existence results to the case of stochastic games with a single controller and incomplete information on both sides; that is, to the case when each of the players has some partial private information about the true stochastic game being played.

2. The model and the main results.

2.1. The model. A *two-player zero-sum stochastic game* G is described by (i) a finite set Ω of states, and an initial state $\omega \in \Omega$; (ii) finite action sets I and J for the two players; (iii) a transition rule $q : \Omega \times I \times J \to \Delta(\Omega)$, where $\Delta(\Omega)$ is the simplex of probability distributions over Ω; and (iv) a reward function $g : \Omega \times I \times J \to \mathbf{R}$.

A *two-player zero-sum stochastic game with incomplete information* is described by a finite collection $(G_k)_{k\in K}$ of stochastic games, together with a distribution $p \in \Delta(K)$ over K. We assume that the games G_k differ only through their reward functions g^k, but they all have the same sets of states and actions, and the same transition rule. We denote the common transition rule by q.

The game is played in stages. An element $k \in K$ is chosen according to p. Player 1 is informed of k, while player 2 is not. At every stage $n \in \mathbf{N}$, the two players choose simultaneously actions $i_n \in I$ and $j_n \in J$, and ω_{n+1} is drawn according to $q(\cdot \mid \omega_n, i_n, j_n)$. Both players are informed of (i_n, j_n, ω_{n+1}). We stress that the actual reward $g^k(\omega_n, i_n, j_n)$ is not told to player 2 (but is known to player 1).

We parametrize the game by the initial distribution p and by the initial state ω, and denote it by $\Gamma(p,\omega)$. We write Γ for $(\Gamma(p,\omega))_{(p,\omega)\in\Delta(K)\times\Omega}$.

A few remarks are in order. This model is an extension of the classical model of zero-sum stochastic games. It is also an extension of Aumann and Maschler's model of repeated games with incomplete information, where a zero-sum matrix game is first drawn using p, then played repeatedly over time. Here, nature chooses a stochastic game that is then played over time.

We assume without loss of generality (w.l.o.g.) that $0 \le g^k \le 1$ for every $k \in K$, and we identify each $k \in K$ with the probability measure over K that gives weight 1 to k.

2.2. Strategies and values. Players may base their choices on the stochastic states the play has visited so far, as well as on past choices of actions (of the two players). Player 1 can base his choices also on the state of the world k.

The space of histories of length n is $H_n = (\Omega \times I \times J)^{n-1} \times \Omega$, the space of finite histories is $H = \cup_{n\in\mathbf{N}} H_n$, and the space of plays (infinite histories) is $H_\infty = (\Omega \times I \times J)^\infty$. H_n defines naturally a finite algebra $\mathcal{H}_n$ over H_∞. We equip H_∞ with the σ-algebra $\vee_{n\in\mathbf{N}}\mathcal{H}_n$ spanned by all cylinder sets. A (behavioral) *strategy* of player 1 is a function $\sigma : K \times H \to \Delta(I)$. A strategy for player 2 is a function $\tau : H \to \Delta(J)$. A strategy $\sigma = (\sigma_k)_{k\in K}$ of player 1 is *nonrevealing* if σ_k is independent of $k \in K$.[1]

A strategy σ is stationary if the mixed action played at every stage depends only on the current state. We identify each vector $x = (x_\omega)_{\omega\in\Omega} \in (\Delta(I))^\Omega$ with the stationary strategy that plays the mixed action x_ω whenever the game visits ω. Stationary strategies of player 2 are defined analogously.

Every distribution p, every initial stochastic state ω, and every pair of strategies (σ,τ) induce a probability measure $\mathbf{P}_{p,\omega,\sigma,\tau}$ over $K \times H_\infty$ (equipped with the product σ-algebra). We denote by $\mathbf{E}_{p,\omega,\sigma,\tau}$ the corresponding expectation operator.

We let k, ω_n, i_n and j_n denote, respectively, the actual game being played, the current state at stage n, and the actions played at stage n. These are random variables.

Define the expected average payoff up to stage N by

$$\gamma_N(p,\omega,\sigma,\tau) = \mathbf{E}_{p,\omega,\sigma,\tau}\left[\overline{g}_N\right],$$

where $\overline{g}_N = \frac{1}{N}\sum_{n=1}^N g^k(\omega_n, i_n, j_n)$. For fixed strategies σ,τ, $\gamma_N(p,\omega,\sigma,\tau)$ is linear in p and 1-Lipshitz.

We recall the definitions of the max-min value, the min-max value, and the (uniform) value.

DEFINITION 1. *Player* 1 *can* guarantee $\phi \in \mathbf{R}$ *in the game* $\Gamma(p,\omega)$ *if, for every* $\epsilon > 0$*, there exists a strategy* σ *of player* 1 *and* $N \in \mathbf{N}$ *such that*

$$\forall \tau, \forall n \ge N, \quad \gamma_n(p,\omega,\sigma,\tau) \ge \phi - \epsilon.$$

We then say that the strategy σ guarantees $\phi - \epsilon$ *in* $\Gamma(p,\omega)$.

Player 1 *can guarantee a function* $\phi : \Delta(K) \times \Omega \to \mathbf{R}$ *if player* 1 *can guarantee* $\phi(p,\omega)$ *in the game* $\Gamma(p,\omega)$*, for every* $(p,\omega) \in \Delta(K) \times \Omega$.

Note that, due to the Lipshitz property on payoffs and the compactness of $\Delta(K)$, the integer N in Definition 1 can be chosen to be independent of (p,ω). The definition

[1] The strategy is nonrevealing in the sense that knowledge of the strategy σ and of past play does not enable player 2 to gain information on k. This property relies on the fact that transitions are independent of k.

of a function that is guaranteed by player 2 is similar, with the roles of the two players exchanged.

DEFINITION 2. *Player* 2 *can* defend $\phi \in \mathbf{R}$ *in the game* $\Gamma(p,\omega)$ *if, for every* $\epsilon > 0$ *and every strategy* σ *of player* 1*, there exists a strategy* τ *of player* 2 *and* $N \in \mathbf{N}$ *such that*

$$\forall n \geq N, \quad \gamma_n(p,\omega,\sigma,\tau) \leq \phi + \epsilon. \tag{1}$$

We say that such a strategy τ defends $\phi + \epsilon$ *against* σ *in* $\Gamma(p,\omega)$.

Player 2 *can defend a function* $\phi : \Delta(K) \times \Omega \to \mathbf{R}$ *if player* 2 *can defend* $\phi(p,\omega)$ *in the game* $\Gamma(p,\omega)$*, for every* $(p,\omega) \in \Delta(K) \times \Omega$.

The definition of a function that is defended by player 1 is similar, with the roles of the two players exchanged. The following lemma follows from the definitions.

LEMMA 3. *Player* 1 *can guarantee (resp., defend)* $\max\{\phi,\phi'\}$ *as soon as he can guarantee (resp., defend) both* ϕ *and* ϕ'*. Player* 2 *can guarantee (resp., defend)* $\min\{\phi,\phi'\}$ *as soon as he can guarantee (resp., defend) both* ϕ *and* ϕ'.

DEFINITION 4. *A function* $\phi : \Delta(K) \times \Omega \to \mathbf{R}$ *is*

- *the* (uniform) value *of* Γ *if both players can guarantee* ϕ*;*
- *the* max-min value *of* Γ *if player* 1 *can guarantee* ϕ *and player* 2 *can defend* ϕ*;*
- *the* min-max value *of* Γ *if player* 1 *can defend* ϕ *and player* 2 *can guarantee* ϕ.

Note that the value exists if and only if the max-min value and min-max value exist and coincide.

The value (resp., max-min value, min-max value) is denoted by v (resp., $\underline{v}, \bar{v}$) when it exists. Observe that $\underline{v} \leq \bar{v}$ whenever the two exist. Note that each of the functions $\underline{v}$ and $\bar{v}$ is 1-Lipshitz in p as soon as it exists. When the value v exists, any strategy that guarantees v up to ε is ε-*optimal*. Strategies that are ε-optimal for each $\varepsilon > 0$ are also termed *optimal*.

2.3. Related literature. Most of the literature deals with the polar cases where either Ω or K is a singleton. In the former case, the game is a repeated game with incomplete information. Such games have a value; see Aumann and Maschler [2]. Moreover, an explicit formula for the value exists. Letting $u^*(p)$ be the value of the matrix game with payoff function $\sum_k p_k g^k(\cdot,\cdot)$, the value of the repeated game with incomplete information is the concavification cav u^* of u^* (see section 3.1 for definitions).

When K is a singleton the game is a standard stochastic game. Such games have a value; see Mertens and Neyman [9].

For general stochastic games with incomplete information, little is known, but some classes were studied in the literature. For "Big Match" games Sorin [20, 21] and Sorin and Zamir [23] proved the existence of the max-min value and of the min-max value. These values may differ.

For recursive games, Rosenberg and Vieille [17] proved that the max-min value exists and provided an example where the value does not exist.

Parthasarathy and Raghavan [14] were the first to study the class of stochastic games in which one player controls the transitions. They proved that in this class the value exists, and both players have optimal stationary strategies. They also studied the two-player non-zero-sum game. Filar [5] studied the situation in which states are partitioned into two subsets, and each player controls the transitions from states in his subset of the partition. Several finite-stage algorithms that calculate the value

and optimal stationary strategies were proposed in the literature (see the survey by Raghavan and Filar [15] and the references therein).

Recently Renault [16] studied games where transitions do not depend on the actions chosen by the players and only player 1 observes the current state of the world. All that player 2 observes are the actions of player 1.

2.4. Statements of the results. In the present paper we consider games where a single player controls the transitions.

DEFINITION 5. *Player* 1 controls the transitions *if, for every* $\omega \in \Omega$ *and every* $i \in I$, *the transition* $q(\cdot \mid \omega, i, j)$ *does not depend on* j. *Player* 2 *controls the transitions if the symmetric property holds. We then simply write* $q(\cdot \mid \omega, i)$ *or* $q(\cdot \mid \omega, j)$ *depending on who controls the transitions.*

We prove the following two results.

THEOREM 6. *If player* 1 *controls the transitions, the value exists.*

THEOREM 7. *If player* 2 *controls the transitions, both the min-max value and max-min value exist.*

We provide an example of a game where player 2 controls the transitions and $\overline{v} \neq \underline{v}$. We also provide a characterization of $\overline{v}$ and $\underline{v}$ as a unique solution to a functional equation, and we study the structure of simple optimal strategies of player 1.

We prove no result on the existence of the limit of the values of the finitely repeated games. In the games analyzed so far (see section 2.3), this limit is known to exist and coincides with $\underline{v}$. This property is conjectured to hold in general by Mertens [8].

3. Various tools. This section gathers a few results that we use in subsequent sections. The first three subsections introduce a few extensions of tools used in the analysis of games with incomplete information.

For three vectors $a, b, c \in \mathbf{R}^K$, $c = a + b$ if and only if $c_k = a_k + b_k$ for every $k \in K$, $c = \max\{a, b\}$ if and only if $c_k = \max\{a_k, b_k\}$ for every $k = 1, \ldots, K$, and $a \geq b$ if and only if $a_k \geq b_k$ for every $k = 1, \ldots, K$. For a scalar $r \in \mathbf{R}$, $c = a + r$ if and only if $c_k = a_k + r$ for every $k = 1, \ldots, K$, and $c = ra$ if and only if $c_k = ra_k$ for every $k = 1, \ldots, K$. Finally, the L_1-norm and L_∞-norm will be denoted by $\|\cdot\|_1$ and $\|\cdot\|_\infty$, respectively.

3.1. Concavification. Given a continuous function $u : \Delta(K) \to \mathbf{R}$, we denote by cav u its concavification, namely, the least concave function v defined over $\Delta(K)$, such that $v \geq u$. It is the function whose hypograph is the convex hull of the hypograph of u. Similarly, we denote by vex u its convexification, namely, the largest convex function v such that $v \leq u$. Both cav u and vex u are well defined. Thus, cav and vex are functional operators that act on real-valued functions defined on $\Delta(K)$.

LEMMA 8 (see, e.g., Laraki [7]). *When* $\Delta(K)$ *is endowed with the* L_1*-norm, the two operators* cav *and* vex *map* C*-Lipshitz functions into* C*-Lipshitz functions.*

LEMMA 9. *When the set of functions* $u : \Delta(K) \to \mathbf{R}$ *is endowed with the* L_∞*-norm, the two operators* cav *and* vex *are nonexpansive.*

Proof. For any two real-valued continuous functions over $\Delta(K)$, u, and v, one has

$$\|u^{**} - v^{**}\|_\infty \leq \|u^* - v^*\|_\infty \leq \|u - v\|_\infty,$$

where $u^*(x) = \inf\{\langle y, x\rangle - u(y), y \in \mathbf{R}^K\}$ is the conjugate of u. Since $u^{**} = \text{cav } u$, the result follows.

The argument for the operator vex is analogous. ∎

The following lemma is classical (see, e.g., Mertens, Sorin, and Zamir [10, Corollary V.1.3], or the discussion in Zamir [24, p. 118]).

LEMMA 10. *Assume that player* 1 *can guarantee* u. *Then player* 1 *can guarantee* cav u.

Proof. We briefly recall the main ideas of the proof. Prior to the first stage, player 1 performs a state-dependent lottery, designed as follows. By the Carathéodory theorem there exist $p_e \in \Delta(K), \alpha_e \in [0,1]$, for $e = 1, \ldots, |K|+1$, such that $\sum_e \alpha_e = 1$, $\sum_e \alpha_e p_e = p$, and

$$\text{cav } u(p) \leq \sum_e \alpha_e u(p_e) + \varepsilon. \tag{2}$$

If u is continuous, ε may be set to zero in (2). To guarantee cav $u(p)$ in $\Gamma(p,\omega)$, player 1 chooses a fictitious distribution p_e, and he plays optimally in $\Gamma(p_e,\omega)$. The distributions (p_e) must satisfy that their average is p. We now provide one mechanism player 1 can employ.

For each e set $\mu^k(e) = \alpha_e p_e^k / p^k$ if $p^k > 0$, and we let μ^k be arbitrary if $p^k = 0$. Observe that $\sum_e p^k \mu^k(e) = \sum_e \alpha_e p_e^k = p^k$. The following strategy of player 1 guarantees cav $u(p) - 2\varepsilon$: given k, choose e according to μ^k, and play a strategy σ_e that guarantees $u(p_e) - \varepsilon$. □

The following result will be useful later.

LEMMA 11. *Let* $(\mathcal{A}_i)_{i\in I}$ *be a finite collection of convex closed upwards comprehensive sets, and let* $\mathcal{A}$ *be the set* $\left\{a \in R^K : a = \max_{i\in I} a_i, a_i \in \mathcal{A}_i\right\}$. *Then*

$$f_{\mathcal{A}}(p) = (\text{cav } \max_{i\in I} f_{\mathcal{A}_i})(p),$$

where, for any convex upwards comprehensive set $\mathcal{B}$, $f_{\mathcal{B}}(p) = \inf_{a\in\mathcal{B}} \langle a, p\rangle$.

Proof. Since each $\mathcal{A}_i$ is upwards comprehensive, $\mathcal{A}$ coincides with $\cap_i \mathcal{A}_i$. Therefore $f_{\mathcal{A}} \geq f_{\mathcal{A}_i}$ for each i. In particular $f_{\mathcal{A}} \geq \max_{i\in I} f_{\mathcal{A}_i}$. Since $f_{\mathcal{A}}$ is concave, $f_{\mathcal{A}} \geq \text{cav } \max_{i\in I} f_{\mathcal{A}_i}$.

To prove the opposite inequality, we first observe that if $\mathcal{B}$ is convex, closed, and upwards comprehensive, one has

$$\mathcal{B} = \left\{a \in \mathbf{R}^K : \langle a, p\rangle \geq f_{\mathcal{B}}(p) \text{ for each } p \in \Delta(K)\right\}. \tag{3}$$

Set $g = \text{cav } \max_{i\in I} f_{\mathcal{A}_i}$, and

$$\mathcal{D} = \left\{a \in \mathbf{R}^K : \langle a, p\rangle \geq g(p) \text{ for each } p \in \Delta(K)\right\}.$$

Since $g \geq f_{\mathcal{A}_i}$ for each $i \in I$, and using (3) with $\mathcal{B} = \mathcal{A}_i$, one has $\mathcal{D} \subseteq \mathcal{A}_i$. Therefore, $\mathcal{D} \subseteq \mathcal{A}$, which readily implies $g \geq f_{\mathcal{A}}$. □

3.2. Approachability. We present here the basic approachability result of Blackwell [4], in the framework of stochastic games. Let G be a stochastic game with payoffs in $\mathbf{R}^K$. The description of such a game is the same as that of a two-player zero-sum stochastic game given in section 2.1, except that the reward function g now takes values in $\mathbf{R}^K$. The definition of strategies in this framework is similar to that given in section 2.2.

We denote $\bar{g}_N = \frac{1}{N}\sum_{n=1}^N g(\omega_n, i_n, j_n) \in \mathbf{R}^K$, the average vector payoff in the first N stages.

DEFINITION 12. *A vector $a \in \mathbf{R}^K$ is* approachable *by player 2 at ω if, for every $\varepsilon > 0$, there is a strategy τ of player 2 and $N \in \mathbf{N}$ such that*[2]

$$\forall \sigma, \mathbf{E}_{\omega,\sigma,\tau}\left[\sup_{n \geq N} (\bar{g}_n - a)^+\right] \leq \varepsilon.$$

We say that such a strategy τ approaches $a + \varepsilon$ *at ω.*

In other words, for every ε player 2 has a strategy such that the average payoff vector will eventually not exceed $a + \varepsilon$. Note that a is approachable if and only if $a + \varepsilon$ is approachable for every $\varepsilon > 0$, so that the set of approachable vectors is closed and upwards comprehensive.

Our definition differs slightly from that of Blackwell [4], where the strategy τ is required to be independent of ε (i.e., the original definition of Blackwell reads as $\exists \tau, \forall \varepsilon > 0$, etc.). Any vector a that is approachable in Blackwell's sense is also approachable in our sense. The two definitions are not equivalent. However, it is easily checked that, if a is approachable (in our sense) at each state, it is also approachable in Blackwell's sense.

Every stochastic game with incomplete information $\Gamma(p, \omega)$ induces a stochastic game with vector payoffs $\Gamma^V(\omega)$, in which the payoff coordinates are given by the reward functions of the component games (G_k) of $\Gamma(p, \omega)$. The next lemma relates the two games. Its proof is straightforward.

LEMMA 13. *If $a \in \mathbf{R}^K$ is approachable at ω in the game Γ^V, then player 2 can guarantee $\langle a, p \rangle$ in $\Gamma(p, \omega)$ for every $p \in \Delta(K)$.*

We now state Blackwell's sufficient condition for approachability in this context. Denote by $u_\infty(p, \omega)$ the uniform value of the two-player zero-sum stochastic game with reward function $\sum_{k \in K} p_k g^k(\omega, \cdot, \cdot)$. The existence of u_∞ follows, by Mertens and Neyman [9] or by Parthasarathy and Raghavan [14]. We also denote by $u_n(p, \omega)$ the value of the n-stage version of that game (thus, $\lim_{n \to \infty} u_n = u_\infty$, and the limit is uniform in p).

PROPOSITION 14. *If* cav $u_\infty(p, \omega) \leq \langle a, p \rangle$ *for every $(p, \omega) \in \Delta(K) \times \Omega$, then a is approachable in Γ^V by player 2 at ω, for each $\omega \in \Omega$.*

In this statement (and in later ones), cav u_∞ is the concavification of u_∞ with respect to the first variable, p: cav $u_\infty(p, \omega) = (\text{cav } u_\infty(\cdot, \omega))(p)$.

Sketch of the proof. Let $\varepsilon > 0$, and choose N such that $\|u_N - u_\infty\| \leq \varepsilon$, so that cav $u_N(p, \omega) \leq \langle a + \varepsilon, p \rangle$. We define an auxiliary game with vector payoffs, where each stage corresponds to N stages in the original game. We apply Blackwell's result to the auxiliary game, noting that Blackwell's proof still holds when the stage game changes from stage to stage, with payoffs remaining bounded. □

A more precise result was proved by Milman [13, Theorem 2.1.1]. For results with similar flavor, see Shimkin and Shwartz [19].

3.3. Information revelation. Let σ be a given strategy of player 1. For $n \in \mathbf{N}$, we denote by p_n the conditional distribution over K given $\mathcal{H}_n$: it is the belief held by player 2 about the true game being played.[3] The difference $\|p_n - p_{n+1}\|_1$ may be interpreted as the amount of information that is revealed at stage n.

It is well known (see, e.g., Sorin [22, Lemma 3.4] or Mertens, Sorin, and Zamir

[2] For every real $c \in \mathbf{R}$, $c^+ = \max\{c, 0\}$.

[3] The value of p_n at a specific atom of $\mathcal{H}_n$ depends on σ but not on τ. Since the distribution on $\mathcal{H}_n$ depends on τ, the law of p_n depends on both σ and τ.

[24, Lemma IV.2.1]) that, for each τ,

$$\mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{n=1}^{\infty}\|p_n-p_{n+1}\|_2^2\right]\leq|K|\,. \tag{4}$$

Given $p\in\Delta(K)$, we denote by σ^p the average nonrevealing strategy defined by $\sigma^p(h)=\sum_{k\in K}p(k)\sigma(k,h)$ for each finite history h. It is convenient to relate the benefit derived by player 1 from using his information at a given stage to the amount of information revealed at that stage. Let $n\in\mathbf{N}$ be given. The expected payoff at stage n, conditional on past play, is

$$\mathbf{E}_{p,\omega,\sigma,\tau}\left[g_n|\mathcal{H}_n\right]=\sum_{k\in K}p_n(k)g^k(\omega_n,\sigma(k,h_n),\tau(h_n)),$$

where $\sigma(k,h_n)$ and $\tau(h_n)$ are the mixed moves used by the two players at that stage.[4] By Proposition 3.2 and Lemma 3.13 in Sorin [22],

$$\left|\mathbf{E}_{p,\omega,\sigma,\tau}\left[g_n|\mathcal{H}_n\right]-\langle p_n,g(\omega_n,\sigma^{p_n}(h_n),\tau(h_n))\rangle\right|\leq\mathbf{E}\left[\|p_n-p_{n+1}\|_1\,|\mathcal{H}_n\right]. \tag{5}$$

Definition 15. *Let $\widetilde{\mathcal{T}}$ be a set of strategies of player 2. Let $\varepsilon>0$ and σ be given. The strategy $\widetilde{\tau}\in\widetilde{\mathcal{T}}$ is* ε-exhausting information *given (p,ω) and σ if $\widetilde{\tau}$ maximizes $\mathbf{E}_{p,\omega,\sigma,\tau}[\sum_{n=1}^{\infty}\|p_n-p_{n+1}\|_2^2]$ up to ε over $\widetilde{\mathcal{T}}$.*

This notion is relative to the class $\widetilde{\mathcal{T}}$. Which class of strategies is meant will always be clear from the context.

Lemma 16. *Let $\widetilde{\mathcal{T}},\varepsilon,\sigma,(p,\omega)$ as in Definition 15. Let $\widetilde{\tau}\in\widetilde{\mathcal{T}}$ be an ε-exhausting strategy given (p,ω) and σ, and let $N\in\mathbf{N}$ be such that $\mathbf{E}_{p,\omega,\sigma,\widetilde{\tau}}[\sum_{n=N}^{\infty}\|p_n-p_{n+1}\|_2^2]\leq\varepsilon$. Then for each strategy $\tau\in\widetilde{\mathcal{T}}$ that coincides with $\widetilde{\tau}$ until stage N, one has*

$$\mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{n=N}^{\infty}\|p_n-p_{n+1}\|_1\right]\leq\sqrt{2\varepsilon},\ \text{and}\ \mathbf{E}_{p,\omega,\sigma,\tau}\left[\|p_l-p_N\|_2\right]\leq\sqrt{2\varepsilon}\ \text{for each}\ l\geq N.$$

Proof. By Jensen's inequality and since (p_n) is a martingale, for every $l\geq N$ one has

$$\left(\mathbf{E}_{p,\omega,\sigma,\tau}\left[\|p_l-p_N\|_2\right]\right)^2\leq\mathbf{E}_{p,\omega,\sigma,\tau}\left[\|p_l-p_N\|_2^2\right]=\mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{n=N}^{l-1}\|p_n-p_{n+1}\|_2^2\right]. \tag{6}$$

The equality in (6) is a standard result for martingales; see, e.g., Karatzas and Shreve [6, p. 32]. The second inequality follows. The first inequality follows using Jensen's inequality (applied to each stage independently) and since $\|\cdot\|_1\leq\|\cdot\|_2$. □

The next lemma is specific to stochastic games with incomplete information. In effect, it proves that the amount of information revealed by player 1 up to stage $l\in\mathbf{N}$ is an upper bound on the excess gain from the private information.

Lemma 17. *Let (σ,τ) be given. For every $p\in\Delta(K)$, every $\omega\in\Omega$, and every $l\in\mathbf{N}$, one has*

$$\left|\mathbf{E}_{p,\omega,\sigma,\tau}\left[\overline{g}_l\right]-\mathbf{E}_{p,\omega,\sigma^p,\tau}\left[\overline{g}_l\right]\right|\leq4\mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{m=1}^{l}\|p_m-p_{m+1}\|_1\right].$$

[4] There is a small notational inconsistency here, since the right-hand side is the value of the left-hand side on a typical atom of $\mathcal{H}_n$.

Proof. To distinguish between $\mathbf{E}_{p,\omega,\sigma,\tau}$ and $\mathbf{E}_{p,\omega,\sigma^p,\tau}$, we denote the latter by $\widetilde{\mathbf{E}}_{p,\omega,\sigma^p,\tau}$. Let $n \leq l$ be given. Since σ^p is nonrevealing, and by the Lipshitz property,

$$\begin{aligned}
&\left|\langle p_n, g(\omega_n, \sigma^{p_n}(h_n), \tau(h_n))\rangle - \widetilde{\mathbf{E}}_{p,\omega,\sigma^p,\tau}\left[g_n|\mathcal{H}_n\right]\right| \\
&\quad = \left|\langle p_n, g(\omega_n, \sigma^{p_n}(h_n), \tau(h_n))\rangle - \langle p, g(\omega_n, \sigma^{p}(h_n), \tau(h_n))\rangle\right| \\
&\quad \leq 2\left\|p_n - p\right\|_1. \qquad (7)
\end{aligned}$$

By (5), it follows that

$$\left|\mathbf{E}_{p,\omega,\sigma,\tau}\left[g_n|\mathcal{H}_n\right] - \widetilde{\mathbf{E}}_{p,\omega,\sigma^p,\tau}\left[g_n|\mathcal{H}_n\right]\right| \leq 2\left\|p_n - p\right\|_1 + \mathbf{E}_{p,\omega,\sigma,\tau}\left[\left\|p_n - p_{n+1}\right\|_1 |\mathcal{H}_n\right]. \qquad (8)$$

On the other hand, it is easily checked that the probabilities $\mathbf{P}^n_{p,\omega,\sigma,\tau}$ and $\widetilde{\mathbf{P}}^n_{p,\omega,\sigma^p,\tau}$ induced by $\mathbf{P}$ and $\mathbf{P}_{p,\omega,\sigma^p,\tau}$ on $\mathcal{H}_n$ satisfy

$$\left\|\mathbf{P}^n_{p,\omega,\sigma,\tau} - \widetilde{\mathbf{P}}^n_{p,\omega,\sigma^p,\tau}\right\|_1 \leq \mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{m=1}^{n}\left\|p_m - p_{m+1}\right\|_1\right]. \qquad (9)$$

By (8) and (9),

$$\left|\mathbf{E}_{p,\omega,\sigma,\tau}\left[g_n\right] - \widetilde{\mathbf{E}}_{p,\omega,\sigma^p,\tau}\left[g_n\right]\right| \leq 4\mathbf{E}_{p,\omega,\sigma,\tau}\left[\sum_{m=1}^{n}\left\|p_m - p_{m+1}\right\|_1\right],$$

which implies the result. □

3.4. A partition of states. In this section we define a partition of the set of states that will be extensively used in what follows. It hinges on the fact that a single player controls the transitions, but it does not matter who is the controller. The partition is similar to the one defined by Ross and Varadarajan [18] for Markov decision processes, who also provide an algorithm to calculate it.

We assume that player 1 controls the transitions. The partition when player 2 controls the transitions is defined analogously. Since transitions are independent of player 2's actions, we here omit player 2's strategy from the notations.

Given $\omega \in \Omega$, we denote by

$$r_\omega \ = \min\{n \in \mathbf{N}, \omega_n = \omega\}$$

the stage of the first visit to ω. By convention, the minimum over an empty set is $+\infty$.

Definition 18. *Let $\omega_1, \omega_2 \in \Omega$. We say that* ω_1 leads to ω_2 *if $\omega_1 = \omega_2$, or if $\mathbf{P}_{\omega_1,\sigma}(r_{\omega_2} < +\infty) = 1$ for some strategy σ of player* 1.

Note that the relation *leads to* is reflexive and transitive.

We define an equivalence relation over Ω by

$$\omega \leftrightarrow \omega' \text{ if and only if } \omega \text{ leads to } \omega' \text{ and } \omega' \text{ leads to } \omega.$$

The equivalence classes of this relation are called *communicating sets.* Given $\omega \in \Omega$, we let C_ω denote the communicating set that contains ω, and we define

$$I_\omega = \{i \in I\colon q(C_\omega \mid \omega, i) = 1\}.$$

Thus, whenever C_ω contains at least two elements, by properly selecting actions in $(I_{\omega'})_{\omega' \in C_\omega}$ player 1 can ensure that the play reaches any state in C_ω infinitely often, provided the play starts in C_ω.

The set I_ω may (but does not have to) be empty only if $|C_\omega| = 1$. Actions in I_ω are called *stay* actions, and any state ω such that $I_\omega = \emptyset$ is a *null* state. The set of nonnull states is denoted by Ω_c. Note that $C_\omega \subseteq \Omega_c$ whenever $\omega \in \Omega_c$.

LEMMA 19. *$\omega \in \Omega_c$ if and only if there is a stationary strategy x_{C_ω} such that C_ω is a recurrent set for x.*

Thus, a state is null if it is visited only finitely many times, whatever player 1 plays: $I_\omega = \emptyset$ if and only if ω is transient for every stationary strategy x.

Proof. We start with the direct implication. Let $\omega \in \Omega_c$. For $\omega' \in C_\omega$, define $x_{\omega'} \in \Delta(A)$ by

$$x_{\omega'}[i] = \begin{cases} 0, & i \notin I_{\omega'}, \\ 1/|I_{\omega'}|, & i \in I_{\omega'}, \end{cases}$$

and let x be any stationary strategy that coincides with $x_{\omega'}$ in each state $\omega' \in C_\omega$. It is easy to show that C_ω is recurrent under x.

The reverse implication is straightforward. □

Some communicating sets are absorbing, in the sense that once entered, the play remains there forever. We now single them out. Let x^* be a fully mixed stationary strategy, i.e., $x^*_\omega[i] > 0$ for every $\omega \in \Omega$ and every $i \in I$. If $R \subseteq \Omega$ is a recurrent set for x^*, then R is a communicating set, and $I_\omega = I$ for every $\omega \in R$.

We denote by Ω_0 the union of these sets:

$$\Omega_0 = \cup\{R : R \text{ recurrent for } x^*\} = \{\omega \in \Omega : I_{\omega'} = I \text{ for every } \omega' \in C_\omega\}.$$

The following lemma implies that the max-min value and the min-max value are constant over C_ω for every $\omega \in \Omega_0$, provided they exist.

LEMMA 20. *Assume player 1 controls transitions. Let $\omega \in \Omega$ and $\omega' \in C_\omega$. If one of the players can guarantee ϕ in $\Gamma(p, \omega)$, he can also guarantee ϕ in $\Gamma(p, \omega')$.*

Proof. Assume first that player 1 can guarantee ϕ in $\Gamma(p, \omega)$. Let σ be a strategy that guarantees $\phi - \varepsilon$ in $\Gamma(p, \omega)$, and let σ^* be the strategy that plays x_{C_ω} until r_ω, then switches to σ. In the game $\Gamma(p, \omega')$, the strategy σ^* guarantees $\phi - \varepsilon'$ for each $\varepsilon' > \varepsilon$.

Assume now that player 2 can guarantee ϕ in $\Gamma(p, \omega)$, but assume to the contrary that he *cannot* guarantee ϕ in $\Gamma(p, \omega')$ for some $\omega' \in C_\omega$. We argue that player 2 cannot guarantee ϕ in $\Gamma(p, \omega)$, a contradiction. Since player 2 cannot guarantee ϕ in $\Gamma(p, \omega')$, there is $\varepsilon > 0$ such that for every strategy τ of player 2 and every $N \in \mathbf{N}$ there is a strategy $\sigma_{\tau,N}$ of player 1 and an integer $n_{\tau,N} \geq N$ such that $\gamma_{n_{\tau,N}}(p, \omega', \sigma_{\tau,N}, \tau) > \phi + \varepsilon$. Let τ and N be given. Let σ^* be the strategy of player 1 defined as follows. Play x_{C_ω} until stage $r_{\omega'}$, then switch to $\sigma_{\tau_\nu,M}$, where τ_ν is the strategy induced by τ after stage ν, and M is sufficiently large so that $\mathbf{P}_{\omega,x_{C_\omega}}(r_{\omega'} < M) > 1 - \frac{\varepsilon}{2}$. One can verify that there is $n' \geq N$ such that $\gamma_{n'}(p, \omega, \sigma^*, \tau) > \phi + \varepsilon/2$, a contradiction. □

When player 2 controls the transitions, we denote by J_ω the set of stay actions at ω:

$$J_\omega = \{j \in J : q(C_\omega \mid \omega, j) = 1\}.$$

3.5. Auxiliary games. As for the analysis of zero-sum repeated games with incomplete information on one side, it is convenient to introduce an average game in which no player is informed of the realization of k.

For notational ease, assume that player 1 is the controller. For every $p \in \Delta(K)$ and every nonnull state $\omega \in \Omega$, we denote by $\widetilde{\Gamma}_R(p,\omega)$ the zero-sum stochastic game with (i) initial state ω, (ii) state space C_ω, (iii) reward function $\sum_k p_k g^k$, (iv) action sets $I_{\omega'}$ and J at each state $\omega' \in C_\omega$, and (v) transition function induced by q.

In the case where player 2 is the controller, the game $\widetilde{\Gamma}_R(p,\omega)$ is defined by restricting player 2's action set to $J_{\omega'}$ in each state $\omega' \in C_\omega$.

Thus, $\widetilde{\Gamma}_R(p,\omega)$ is the stochastic game in which player 1 is not informed of the realization of k (or does not use his information), and the controller is restricted to stay actions. In particular, the game remains in C_ω forever. The letter R is a symbol for *restricted*, while the symbol $\widetilde{\ }$ stands for average.

Note that $\widetilde{\Gamma}_R(p,\omega)$ is a single controller game, so that both players have optimal stationary strategies. Denote by $\widetilde{u}(p,\omega)$ its value. Note that $\widetilde{u}(p,\omega) = u_\infty(p,\omega)$ for each $\omega \in \Omega_0$.

By convention, if ω is a null state, we set $\widetilde{u}(p,\omega) = -\infty$ if player 1 controls the transitions, and $\widetilde{u}(p,\omega) = +\infty$ if player 2 controls the transitions. By Lemma 20, for every communicating set C, $\widetilde{u}(p,\omega)$ is independent of $\omega \in C$.

PROPOSITION 21. *For every $\omega \in \Omega_0$ and every $p \in \Delta(K)$ the value $v(p,\omega)$ of $\Gamma(p,\omega)$ exists and is equal to* cav $\widetilde{u}(p,\omega)(=$ cav $u_\infty(p,\omega))$.

Thus, restricted to Ω_0, the game is similar to a standard repeated game with incomplete information.

Proof. The proof of this lemma is similar to the proof for repeated games with incomplete information on one side. Let $p \in \Delta(K)$ and $\omega \in \Omega_0$ be given. Clearly player 1, by not using his information, can guarantee $\widetilde{u}(p,\omega)$. By Lemma 10, player 1 can guarantee cav $\widetilde{u}(p,\omega)$.

The proof that player 2 can guarantee cav $\widetilde{u}$ is based on approachability results, and closely follows classical lines. Let $a \in \mathbf{R}^K$ be such that

$$\langle a, p\rangle = \text{cav } \widetilde{u}(p,\omega),$$
$$\langle a, q\rangle \geq \text{cav } \widetilde{u}(q,\omega) \text{ for every } q \in \Delta(K).$$

If cav $\widetilde{u}(\cdot,\omega)$ is differentiable at p, then a is defined by the hyperplane tangent to cav $\widetilde{u}(\cdot,\omega)$ at p. By Proposition 14, a is approachable. By Lemma 13, player 2 can guarantee cav $\widetilde{u}(p,\omega)$. □

Let $\Gamma_R(p,\omega)$ be a game similar to $\widetilde{\Gamma}_R(p,\omega)$, but in which player 1 is informed of k. Thus, $\Gamma_R(p,\omega)$ differs from $\Gamma(p,\omega)$ only in that actions of the controller are restricted.

Since in Γ_R, for each nonnull state ω the game cannot leave C_ω, Proposition 21 yields the following.

LEMMA 22. *Let ω be a nonnull state. Then $\Gamma_R(p,\omega)$ has a value, which is* cav $\widetilde{u}(p,\omega)$.

We denote by Γ_R^V the stochastic game with vector payoffs in which the controller is restricted to stay actions.

3.6. Functional equations. Let $\mathcal{B}$ denote the set of functions $\phi\colon \Delta(K) \times \Omega \to [0,1]$ that are 1-Lipshitz with respect to p, when $\Delta(K)$ is endowed with the L_1-norm. We here define three operators on $\mathcal{B}$ that will be used to characterize the solutions of the game.

When transitions are controlled by player 1, we define the operator T_1 by

$$T_1\phi(p,\omega) = \text{cav max}\left\{ \widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}\left[\phi \mid \omega', i\right]\right\}(p,\omega). \tag{10}$$

By convention, a maximum over an empty set is $-\infty$. In this expression, $\mathbf{E}\left[\phi \mid \omega', i\right]$ stands for the expectation of ϕ under $q(\cdot \mid \omega', i)$.

Note that $T_1\phi(p,\omega)$ is equal to $\text{cav max}\left\{\text{cav } \widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}\left[\phi \mid \omega', i\right]\right\}(p,\omega)$ as well.

When transitions are controlled by player 2, we define the operators T_2 and T_3 by

$$T_2\phi(p,\omega) = \text{cav min}\left\{\widetilde{u}, \min_{\omega'\in C_\omega, j\notin J_{\omega'}} \mathbf{E}\left[\phi \mid \omega', j\right]\right\}(p,\omega),$$

$$T_3\phi(p,\omega) = \min\left\{\text{cav } \widetilde{u}, \min_{\omega'\in C_\omega, j\notin J_{\omega'}} \mathbf{E}\left[\phi \mid \omega', j\right]\right\}(p,\omega).$$

Since the maximum (or minimum) of a finite number of elements of $\mathcal{B}$ belongs to $\mathcal{B}$, and since by Lemma 8 concavification preserves Lipshitz properties when $\Delta(K)$ is endowed with the L_1-norm, all three operators T_1, T_2, and T_3 map $\mathcal{B}$ into $\mathcal{B}$. Note that for each $i = 1, 2, 3$ the operator T_i is monotonic: $\phi_1 \leq \phi_2$ implies $T_i\phi_1 \leq T_i\phi_2$. Moreover, for every $\phi \in \mathcal{B}$, $T_i\phi$ is constant over C_ω, for each $\omega \in \Omega$.

We now assume that player 1 controls transitions, and prove a few results on T_1. When transitions are controlled by player 2, identical results hold for both T_2 and T_3. Since the proofs are similar, they are omitted.

PROPOSITION 23.

1. *T_1 has a unique fixed point ϕ.*
2. *The sequences (ϕ_n^0) and (ϕ_n^1) defined by $\phi_0^j = j$, $\phi_{n+1}^j = T_1\phi_n^j$ for $j = 0, 1$, are monotonic and converge uniformly to ϕ.*
3. *ϕ coincides with* cav $\widetilde{u}$ *on Ω_0.*
4. *If $f \in \mathcal{B}$ satisfies $f \leq T_1 f$ (resp., $f \geq T_1 f$), then $f \leq \phi$ (resp., $f \geq \phi$).*

Since $T_1\phi$ and $T_2\phi$ are concave for every $\phi \in \mathcal{B}$, the fixed points of those operators are concave functions. Since 0 is concave, and since T_3 maps concave functions to concave functions, the analog of Proposition 23 for T_3 implies that the fixed point of T_3 is concave as well.

Proof. By monotonicity of T_1, item 2 follows from item 1. Since cav $\widetilde{u}(p,\omega)$ is constant on every communicating set, so is $T_1\phi(p,\omega)$ for every $\phi \in \mathcal{B}$. Since $I_\omega = I$ for every $\omega \in \Omega_0$, $T_1\phi(p,\omega) = \text{cav } \widetilde{u}(p,\omega)$ for every $\phi \in \mathcal{B}$, every $\omega \in \Omega_0$, and every $p \in \Delta(K)$. Thus, item 3 will follow from item 1. We now prove item 1. By Ascoli's characterization, $\mathcal{B}$ is a compact metric space when endowed with the L_∞-norm. By Lemma 9, T_1 is nonexpansive, so that it is continuous on $\mathcal{B}$. Hence T_1 has a fixed point.

We prove uniqueness by contradiction. Let ϕ_1 and ϕ_2 be two distinct fixed points of T_1, and assume w.l.o.g. that $\delta := \max_{(p,\omega)\in\Delta(K)\times\Omega}(\phi_1(p,\omega) - \phi_2(p,\omega)) > 0$. Let

$$D = \{\omega \in \Omega, \phi_1(p,\omega) - \phi_2(p,\omega) = \delta \text{ for some } p \in \Delta(K)\}$$

contain those states where the difference is maximal. Since both $\phi_1(p,\cdot)$ and $\phi_2(p,\cdot)$ are constant on each communicating set, $C_\omega \subseteq D$ whenever $\omega \in D$.

Since $\phi_1 = \phi_2$ on Ω_0, $D \subseteq \Omega \setminus \Omega_0$. Let $\omega \in D$ be given, and let $p_0 \in \Delta(K)$ be an extreme point of the convex hull of the set $\{p \in \Delta(K) : \phi_1(p,\omega) - \phi_2(p,\omega) = \delta\}$.

Thus, $\phi_1(p_0,\omega) - \phi_2(p_0,\omega) = \delta > 0$. Since $\phi_1(\cdot,\omega)$ and $\phi_2(\cdot,\omega)$ are concave, it also follows that $(p_0, \phi_1(p_0,\omega))$ is an extreme point of the hypograph of the concave function $\phi_1(\cdot,\omega)$. This implies

$$\phi_1(p_0,\omega) = \max\left\{\text{cav } \widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_\omega} \mathbf{E}\left[\phi_1|\omega', i\right]\right\}(p_0,\omega).$$

Since $\phi_1(p_0,\omega) > \phi_2(p_0,\omega) \geq \text{cav } \widetilde{u}(p_0,\omega)$, one has $\phi_1(p_0,\omega) = \mathbf{E}\left[\phi_1(p_0,\cdot) \mid \omega', i\right]$ for some $\omega' \in C_\omega$ and $i \notin I_{\omega'}$. Since $T_1\phi_2 = \phi_2$, $\phi_2(p_0,\omega) \geq \mathbf{E}\left[\phi_2(p_0,\cdot) \mid \omega', i\right]$, and therefore

$$\delta = \phi_1(p_0,\omega) - \phi_2(p_0,\omega) \leq \mathbf{E}\left[\phi_1(p_0,\cdot) - \phi_2(p_0,\cdot) \mid \omega', i\right].$$

By the definition of D, this implies that $q(D \mid \omega', i) = 1$.

Thus, for every $\omega \in D$ there exists $\omega' \in C_\omega$ and $i \notin I_{\omega'}$ that satisfy $q(D \mid \omega', i) = 1$. This implies the existence of $\omega_1, \omega_2 \in D$ such that $C_{\omega_1} \neq C_{\omega_2}$ and $\omega_1 \leftrightarrow \omega_2$, a contradiction. This proves 1.

To prove 4, we assume that $\delta = \max_{(p,\omega)\in\Delta(K)\times\Omega}(f(p,\omega) - \phi(p,\omega)) > 0$, and repeat the second part of the proof of 1 to obtain a contradiction. □

4. Incomplete information on one side.

4.1. Preliminaries. We here single out a useful lemma. The lemma concerns a standard two-player zero-sum stochastic game G and its version G_R in which player 1 is restricted to stay actions. Thus, K is a singleton.

LEMMA 24. *Let G be a two-player zero-sum stochastic game with transitions controlled by player* 1*, and let $\omega \in \Omega$. If player* 2 *can guarantee that $\alpha \in \mathbf{R}$ in $G_R(\omega)$ and he can guarantee that $\phi : \Omega \to \mathbf{R}$ in G, then he can also guarantee* $\max\{\alpha, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\phi|\omega', i]\}$ *in $G(\omega)$.*

Proof. By Lemma 20 player 2 can guarantee α in $G_R(\omega')$ for every $\omega' \in C_\omega$. Let τ_1 be a strategy that guarantees $\alpha+\varepsilon$ in $G_R(\omega')$ for every $\omega' \in C_\omega$, and let τ_2 be a strategy that guarantees $\phi+\varepsilon$ in G. Let $N \in \mathbf{N}$ be such that for every $n \geq N$, every $\omega' \in C_\omega$, and every σ in $G_R(\omega)$, $\gamma_n(\omega', \sigma, \tau_1) \leq \alpha + \varepsilon$, and for every σ in G, $\gamma_n(\omega', \sigma, \tau_2) \leq \phi(\omega') + \varepsilon$.

Define $\nu = 1 + \inf\{n \geq 1, i_n \notin I_{\omega_n}\}$. Define a strategy τ for player 2 as follows.

- Until stage ν, τ plays in blocks of size N (the last block may be shorter). In block $l \geq 0$, where $lN < \nu$, τ forgets past play and follows $\tau_1(\omega_{lN+1})$ for N stages.
- At stage ν, τ forgets past play and starts following τ_2.

Let σ be an arbitrary pure strategy. We will compute an upper bound on $\mathbf{E}_{\omega,\sigma,\tau}[\overline{g}_n]$ for n sufficiently large. Set $L_* = \lceil \frac{\ln\varepsilon}{\ln(1-\varepsilon)} \rceil$[5] and take $n \geq N_1 := \lceil L_* N/\varepsilon^2 \rceil$. Denote by $\overline{g}_{m_1\to m_2}$ the average payoff from stage m_1 to stage m_2. With $\theta^* := N \times \lceil \frac{\nu}{N} \rceil$, since payoffs are nonnegative one has

$$\overline{g}_n \leq \frac{\theta^*}{n}\overline{g}_{\theta^*} + \frac{n+1-\nu}{n}\overline{g}_{\nu\to n}. \tag{11}$$

On the event $\nu \leq n - N$, one has

$$\mathbf{E}_{\omega,\sigma,\tau}\left[\overline{g}_{\nu\to n}|\mathcal{H}_\nu\right] = \mathbf{E}_{\omega_\nu,\sigma_\nu,\tau_2}\left[\overline{g}_{n-\nu+1}\right] \leq \phi(\omega_\nu) + \varepsilon, \tag{12}$$

[5]For every real c, $\lceil c \rceil$ is the smallest integer larger than or equal to c.

where σ_ν is the strategy induced by σ after ν. Since σ is pure, $\nu - 1$ is a stopping time and, using (12),

$$\begin{aligned}\mathbf{E}_{\omega,\sigma,\tau}\left[\overline{g}_{\nu\to n}|\mathcal{H}_{\nu-1}\right] &\leq \mathbf{E}\left[\phi|\omega_{\nu-1}, i_{\nu-1}\right] + \varepsilon \\ &\leq \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}\left[\phi|\omega', i\right] + \varepsilon.\end{aligned} \tag{13}$$

On the other hand, on the event $\nu > n - N$,

$$\frac{n+1-\nu}{n} \leq \varepsilon. \tag{14}$$

We now proceed to the first term in the decomposition (11) of $\overline{g}_n$. For each l, we let $\pi_l = \mathbf{P}_{\omega,\sigma,\tau}\left(\nu \leq (l+1)N \mid \mathcal{H}_{lN+1}\right)$. By the choice of N,

$$\mathbf{E}_{\omega,\sigma,\tau}\left[\overline{g}_{lN+1\to(l+1)N}|\mathcal{H}_{lN+1}\right] \leq \alpha + \varepsilon \ + \mathbf{P}_{\omega,\sigma,\tau}\left(\nu \leq (l+1)N \mid \mathcal{H}_{lN+1}\right)$$

on the event $lN + 1 < \nu$. By taking expectations, this yields

$$\mathbf{E}_{\omega,\sigma,\tau}\left[\overline{g}_{lN+1\to(l+1)N}\mathbf{1}_{lN+1<\nu}\right] \leq (\alpha+\varepsilon)\mathbf{P}_{\omega,\sigma,\tau}(lN+1<\nu) + \mathbf{P}_{\omega,\sigma,\tau}((l+1)N \geq \nu).$$

By summation over l, and using the definition of θ^*, this yields

$$\mathbf{E}_{\omega,\sigma,\tau}\left[\sum_{l=0}^{\theta^*-1} \overline{g}_{lN+1\to(l+1)N}\right] \leq (\alpha+\varepsilon)\mathbf{E}_{\omega,\sigma,\tau}\left[\theta^*\right] + 1,$$

hence

$$\mathbf{E}_{\omega,\sigma,\tau}\left[\frac{N\theta^*}{n}\overline{g}_{N\theta^*}\right] \leq (\alpha+\varepsilon)\mathbf{E}_{\omega,\sigma,\tau}\left[\frac{N\theta^*}{n}\right] + \frac{N}{n}. \tag{15}$$

The result follows by (11), (13), (14), and (15). □

We shall need a variant of the previous result whose proof is identical to the previous proof. Consider the stochastic game with incomplete information $\Gamma(p,\omega)$ where ω is a nonnull state and assume that transitions are controlled by player 2. Assume that player 1 can guarantee a function ϕ. Then player 1 can also guarantee $\min\left\{\widetilde{u}, \min_{\omega'\in C_\omega, j\notin J_{\omega'}} \mathbf{E}\left[\phi|\omega', j\right]\right\}(p,\omega)$ in $\Gamma(p,\omega)$.

4.2. Transitions controlled by player 1. In this section we assume that transitions are controlled by player 1.

4.2.1. Existence of the value.

PROPOSITION 25. *The unique fixed point of T_1 is the value of Γ.*

Proof. Let ϕ be the unique fixed point of T_1, and fix $\epsilon > 0$ once and for all.

Step 1. Player 1 can guarantee ϕ in Γ. By Lemma 22 player 1 can guarantee cav $\widetilde{u}$. Set $\phi_0^0 = 0$, and, for $n \geq 0$, define $\phi_{n+1}^0 = T_1\phi_n^0$. Assume that player 1 can guarantee ϕ_n^0 for some $n \in \mathbf{N}$. Let $p \in \Delta(K)$ and $\omega \in \Omega$ be given. Plainly, for every $\omega' \in C_\omega$ and every $i \notin I_\omega$, player 1 can guarantee $\mathbf{E}\left[\phi_n^0 \mid \omega', i\right](p,\omega)$ in $\Gamma(p,\omega')$; first he plays the action i at ω', and then a strategy that guarantees $\phi_n^0(p,\cdot)$ (up to ε). By Lemma 20, he can guarantee $\mathbf{E}\left[\phi_n^0 \mid \omega', i\right]$ (p,ω) in $\Gamma(p,\omega)$. By Lemmas 3 and 10 he can guarantee $T_1\phi_n^0 = \phi_{n+1}^0$ in Γ. Since player 1 can guarantee $\phi_0^0 = 0$, and since $\lim_{n\to\infty}\phi_n^0 = \phi$, the result follows.

We now prove that player 2 can guarantee ϕ.

Step 2. Definition of approachable sets. For $\omega \in \Omega$, let $\mathcal{B}_\omega$ be the set of vectors approachable in Γ^V by player 2 at ω. We also define

$$\mathcal{A}_\omega = \left\{a \in \mathbf{R}^K \colon \langle a, p\rangle \geq \operatorname{cav} \widetilde{u}(p,\omega) \text{ for every } p\right\}.$$

By Proposition 14 and Lemma 22, $\mathcal{A}_\omega$ is the set of vectors approachable by player 2 at ω in the stochastic game with vector payoffs Γ_R^V. Both sets $\mathcal{A}_\omega$ and $\mathcal{B}_\omega$ are nonempty, closed, convex, and upwards comprehensive.

For every $\omega \in \Omega$ define

$$\mathcal{D}_\omega = \left\{d = \max\left\{a, \max_{\omega' \in C_\omega, i \notin I_{\omega'}} \mathbf{E}\left[b(\cdot) \mid \omega', i\right]\right\} : a \in \mathcal{A}_\omega, b(\omega'') \in \mathcal{B}_{\omega''} \text{ for every } \omega'' \in \Omega\right\}.$$

Step 3. $\mathcal{D}_\omega \subseteq \mathcal{B}_\omega$. Fix $d \in \mathcal{D}_\omega$. Let τ_1 be a strategy that approaches $a + \varepsilon$ at ω, and let τ_2 be a strategy that approaches $b(\omega'') + \varepsilon$ at each state ω''. For each k the strategy τ_1 guarantees $a^k + \varepsilon$ in the game $\Gamma(k,\omega)$, and τ_2 has a similar property. By Lemma 24, applied independently to each G^k, the strategy obtained by concatenation of τ_1 and τ_2 guarantees $\max\left\{a^k, \max_{\omega' \in C_\omega, i \notin I_{\omega'}} \mathbf{E}\left[b^k(\cdot) \mid \omega', i\right]\right\} + 3\varepsilon = d^k + 3\varepsilon$ in G^k. Lemma 13 implies that $d \in \mathcal{B}_\omega$.

Step 4. Player 2 can guarantee ϕ. Let $f(p,\omega) = \inf_{a \in \mathcal{B}_\omega} \langle a, p\rangle$ and $h(p,\omega) = \inf_{a \in \mathcal{D}_\omega} \langle a, p\rangle$, so that by Step 3 $f \leq h$. By Lemma 13 player 2 can guarantee $\langle a, p\rangle$ in $\Gamma(p,\omega)$ for every $a \in \mathcal{B}_\omega$. Therefore he can guarantee $f(p,\omega)$ as well. By Lemma 11, the definition of $\mathcal{D}_\omega$ may be rephrased as

$$h = \operatorname{cav}\ \max\left\{\operatorname{cav}\ \widetilde{u}, \max_{\omega' \in C_\omega, i \notin I_{\omega'}} \mathbf{E}\left[f \mid \omega', i\right]\right\} = T_1 f.$$

Thus, $f \leq T_1 f$. By item 4 in Proposition 23, $f \leq \phi$. Therefore, player 2 can guarantee ϕ. □

4.2.2. Optimal strategies. The proof of Proposition 25 yields no information on ε-optimal strategies for player 1. We argue here that player 1 has an optimal strategy σ of a simple type. In effect, σ has the following structure. Whenever the play enters a communicating set, say at stage $n \geq 0$, σ randomly selects a nonrevealing stationary strategy that is used until the play moves to a new communicating set, if ever. The random choice of the stationary strategy may itself be revealing, in that the distribution used at stage n to select a stationary strategy depends both on p_n and on k. We describe below such a strategy in more detail.

Let v be the value of the game. Let $(p,\omega) \in \Delta(K) \times \Omega$ be given. Upon entering a communicating set at stage $n \geq 0$, player 1 computes $v(p_n) = \operatorname{cav} \max\{\widetilde{u}, \max_{\omega' \in C_{\omega_n}, i \notin I_{\omega'}} \mathbf{E}[v \mid \omega', i]\}(p_n, \omega_n)$, and performs a state-dependent lottery, as described in the proof of Lemma 10. To be specific, one determines $\widetilde{p}_e \in \Delta(K), \alpha_e \in [0,1]$, for $e = 1, \ldots, |K| + 1$, such that $\sum_e \alpha_e = 1$, $\sum_e \alpha_e \widetilde{p}_e = p_n$, and

$$v(p_n) = \sum_e \alpha_e \max\left\{\widetilde{u}, \max_{\omega' \in C_{\omega_n}, i \notin I_{\omega'}} \mathbf{E}\left[v \mid \omega', i\right]\right\}(\widetilde{p}_e, \omega_n).$$

If G^k is the actual game that is played, player 1 chooses e according to a state-dependent lottery μ^k, where $\mu^k(e) = \alpha_e \widetilde{p}_e^k / p_n^k$.

If $\max\left\{\widetilde{u}, \max_{\omega' \in C_{\omega_n}, i \notin I_{\omega'}} \mathbf{E}\left[v \mid \omega', i\right]\right\}(p^e, \omega_n) = \widetilde{u}(p^e, \omega_n)$, player 1 plays a stationary (nonrevealing) strategy which guarantees $\widetilde{u}(p^e, \omega_n)$ in the restricted game $\widetilde{\Gamma}_R(p^e, \omega_n)$. Recall that there are finite-stage algorithms that compute this strategy.

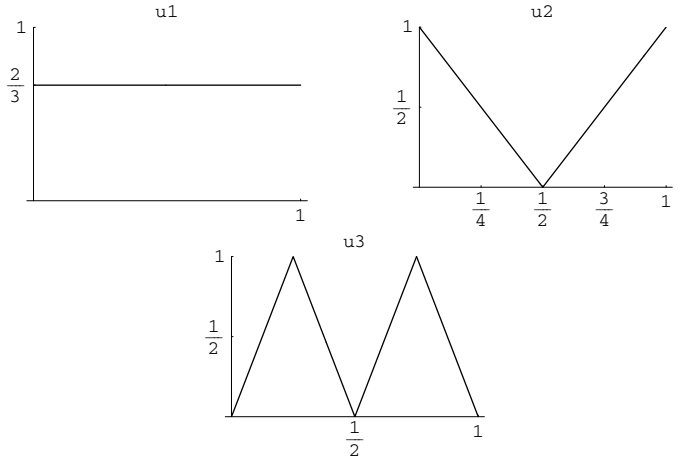

FIG. 1. *The value of the restricted games* $\widetilde{\Gamma}_R(p, \omega_i)$.

If, on the other hand, $\max\left\{\widetilde{u}, \max_{\omega' \in C_{\omega_n}, i \notin I_{\omega'}} \mathbf{E}\left[v \mid \omega', i\right]\right\}(p^e, \omega_n) = \mathbf{E}[v(p^e, \cdot) \mid \omega', i]$ for some $\omega' \in C_{\omega_n}$ and $i \notin I_{\omega'}$, player 1 plays the stationary strategy $x_{C_{\omega_n}}$ until the play reaches ω', and at ω' he plays the action i. He then recursively switches to a strategy that guarantees $v(p^e, \cdot)$.

Under σ, player 1 will end up in finite time playing an optimal stationary strategy in some restricted game $\widetilde{\Gamma}_R(p', \omega')$, with $p' \in \Delta(K)$ and $\omega' \in \Omega$. It can be checked that σ guarantees $v(p, \omega) - \varepsilon$ for every $\varepsilon > 0$. In that sense, σ is optimal. The proof is standard and therefore omitted.

4.2.3. An example. We here provide a simple example that illustrates the basic issues of splitting and information revelation. In particular, in this example the informed player will perform two state-dependent lotteries and therefore reveal information in two different stages of the game, unlike what happens in standard repeated games with incomplete information. The game has three states $\Omega = \{\omega_1, \omega_2, \omega_3\}$, where ω_2 and ω_3 are absorbing. There are two possible payoff functions, so that $K = \{1, 2\}$. A distribution over K is identified with the probability $p \in [0, 1]$ assigned to $k = 2$.

We first describe the main features of the example before providing the payoff and transition matrices of the game.

All actions of player 1 at state ω_1 are stay actions, except one, which leads to either state ω_2 and ω_3 with equal probability.

The value $u_i(p)$ of the restricted game $\widetilde{\Gamma}_R(p, \omega_i)$ is given by (see Figure 1)

$$u_1(p) = 2/3,$$

$$u_2(p) = \max\{1 - 2p, 2p - 1\},$$

$$u_3(p) = \begin{cases} 4p & 0 \le p \le 1/4, \\ 2 - 4p & 1/4 \le p \le 1/2, \\ 4p - 2 & 1/2 \le p \le 3/4, \\ 4 - 4p & 3/4 \le p \le 1. \end{cases}$$

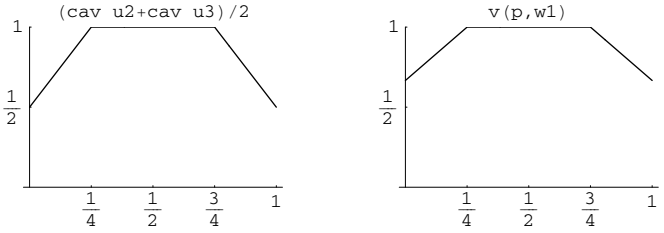

FIG. 2.

Note that $1/2(\text{cav } u_2 + \text{cav } u_3)$ is given by (see Figure 2)

$$1/2(\text{cav } u_2 + \text{cav } u_3)(p) = \begin{cases} 2p + 1/2 & 0 \le p \le 1/4, \\ 1 & 1/4 \le p \le 3/4, \\ 5/2 - 2p & 3/4 \le p \le 1. \end{cases}$$

It is the payoff that is guaranteed by player 1, when starting at (p, ω_1), and exiting from ω_1 without revealing any information. Indeed, once in ω_2 or in ω_3, the game will stay there and therefore the value is given by cav u_2 and cav u_3, respectively.

By section 4.2, the value $v(p, \omega_1) = \text{cav } \max\left\{\frac{2}{3}, \frac{1}{2}(\text{cav } u_2 + \text{cav } u_3)\right\}$ is given by (see Figure 2)

$$v(p, \omega_1) = \begin{cases} (2 + 4p)/3 & 0 \le p \le 1/4, \\ 1 & 1/4 \le p \le 3/4, \\ 2 - 4p/3 & 3/4 \le p \le 1. \end{cases}$$

Assume that the game starts in state ω_1, with $p = 1/8$. Note that $v(1/8, \omega_1) = \frac{1}{2}u_1(0) + \frac{1}{2}(\text{cav } u_2(1/4) + \text{cav } u_3(1/4))$, and that cav $u_3(1/4) = \frac{3}{4}u_3(0) + \frac{1}{4}u_3(1)$, while cav $u_2(1/4) = u_2(1/4)$.

The optimal strategy described in section 4.2.2 is as follows. Player 1 starts by tossing a state-dependent coin. If the coin comes up heads, player 1 plays forever an optimal stationary strategy in the game $k = 1$. If the coin comes up tails, player 1 first plays the nonstay action. The game then moves with equal probability to states ω_2 and ω_3. In the former case, player 1 continues with an optimal nonrevealing stationary strategy in the average game $\tilde{\Gamma}_R(1/4, \omega_2)$. In the latter case, player 2 again tosses a (degenerate) state-dependent coin. If $k = 1$ (resp., $k = 2$), player 1 continues with an optimal strategy in the game $\tilde{\Gamma}_R(0, \omega_3)$ (resp., $\tilde{\Gamma}_R(1, \omega_3)$).

Note that the amount of information revealed by player 1 depends on the actual play.

To complete the example, we provide in Figure 3 payoff matrices that satisfy the required specifications. The vertical arrows that appear in the bottom row of the two top matrices stand for the random transition to either ω_2 or ω_3.

In both states ω_1 and ω_2, player 2 is a dummy. The incomplete information game that corresponds to the game of state ω_3 coincides with example 1.3 in Zamir [24].

4.3. Transitions controlled by player 2. In this section we assume that transitions are controlled by player 2. We prove that both the min-max value and the max-min value exist, but that they may differ.

4.3.1. The max-min value.

LEMMA 26. *The unique fixed point of T_2 is the max-min value of Γ .*

$k=1$

	j_1	j_2	j_3
T	2/3	2/3	2/3
B	↓	↓	↓

$k=2$

	j_1	j_2	j_3	
T	2/3	2/3	2/3	ω_1
B	↓	↓	↓	

	j_1	j_2	j_3
T	1	1	1
B	-1	-1	-1

	j_1	j_2	j_3	
T	-1	-1	-1	ω_2
B	1	1	1	

	j_1	j_2	j_3
T	4	0	2
B	4	0	-2

	j_1	j_2	j_3	
T	0	4	-2	ω_3
B	0	4	2	

FIG. 3. *The payoff matrices.*

Proof. Let ϕ be the unique fixed point of T_2, and fix $\varepsilon > 0$.

Step 1. Player 1 can guarantee ϕ. Set ϕ_0^0 and, for $m \geq 0$, set $\phi_{m+1}^0 = T_2\phi_m^0$. Assume that player 1 can guarantee ϕ_m^0 for some $m \in \mathbf{N}$. By the remark following Lemma 24, player 1 can guarantee $\min\{\widetilde{u}, \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}[\phi_m^0 \mid \omega', j]\}$. Hence player 1 can also guarantee $\operatorname{cav}\ \min\{\widetilde{u}, \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}[\phi_m^0 \mid \omega', j]\} = \phi_{m+1}^0$. Since player 1 can guarantee $\phi_0^0 \equiv 0$, and since $\phi = \lim_{m\to\infty} \phi_m^0$, the result follows.

We now prove that player 2 can defend ϕ. Assume that player 2 can defend ϕ_m^1 for some $m \in \mathbf{N}$, and let σ be an arbitrary strategy of player 1. We prove in Steps 2 and 3 below that in this case player 2 can defend ϕ_{m+1}^1. Since $\phi = \lim_{m\to\infty} \phi_m^1$, and since player 2 can defend $\phi_0^1 \equiv 1$, he can defend ϕ as well.

Step 2. Definition of a reply. Given (p, ω), we let $\tau_1(p, \omega)$ be a (stationary) strategy that guarantees $\widetilde{u}(p, \omega) + \varepsilon$ in $\widetilde{\Gamma}_R(p, \omega)$. Choose $N_1 \in \mathbf{N}$ such that $\gamma_n(p, \omega, \widetilde{\sigma}, \tau_1(p, \omega)) \leq \widetilde{u}(p, \omega) + 2\varepsilon$ for every $n \geq N_1$ and every nonrevealing strategy $\widetilde{\sigma}$ of player 1.

By the remark that follows Definition 1, N_1 can be chosen independently of (p, ω). Let $\widetilde{\mathcal{T}}$ be the set of strategies of player 2 in $\widetilde{\Gamma}_R(p, \omega)$, and let $\widetilde{\tau} \in \widetilde{\mathcal{T}}$ be an $\varepsilon^2/32N_1^2$-exhausting information strategy given σ and (p, ω). Choose $N \in \mathbf{N}$ such that

$$\mathbf{E}_{p,\omega,\sigma,\widetilde{\tau}}\left[\sum_{n=N}^{+\infty} \|p_n - p_{n+1}\|_2^2\right] \leq \frac{\varepsilon^2}{32N_1^2}.$$

By Lemma 16,

$$\mathbf{E}_{p,\omega,\sigma,\widetilde{\tau}}\left[\sum_{n=N}^{+\infty} \|p_n - p_{n+1}\|_1\right] \leq \frac{\varepsilon}{\sqrt{32}N_1} \leq \frac{\varepsilon}{4}. \tag{16}$$

We define τ as follows.

- Play $\widetilde{\tau}$ up to stage N.

- At stage N compute $\beta_N := \min\left\{\widetilde{u}, \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}\left[\phi^1_m \mid \omega', j\right]\right\}(p_N, \omega_N)$.
  - If $\beta_N = \widetilde{u}(p_N, \omega_N)$, play by successive blocks of length N_1: in the $b+1$th block play the strategy $\tau_1(p_{N+bN_1}, \omega_{N+bN_1})$.
  - Otherwise, switch to a strategy that defends the quantity $\min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}\left[\phi^1_m \mid \omega', j\right](p_N, \omega_N) + \varepsilon$ against σ_N, where σ_N is the strategy induced by σ after stage N.

Step 3. The computation. We here prove that τ defends $\phi^1_{m+1}(p,\omega) + 8\sqrt{\varepsilon}$ in $\Gamma(p,\omega)$. We abbreviate $\mathbf{E}_{p,\omega,\sigma,\tau}$ to $\mathbf{E}$. First, we provide an upper bound on the average payoff $\mathbf{E}\left[\overline{g}_{N\to N+n-1}|\mathcal{H}_N\right]$ between stages N and $N+n$ on the event

$$A := \{\beta_N = \widetilde{u}(p_N, \omega_N)\}. \tag{17}$$

First take $n = N_1$. By definition,

$$\mathbf{E}\left[\overline{g}_{N\to N+N_1-1}|\mathcal{H}_N\right] = \mathbf{E}_{p_N,\omega_N,\sigma_N,\tau_1(p_N,\omega_N)}\left[\overline{g}_{N_1}\right].$$

By the choice of N_1,

$$\mathbf{E}_{p_N,\omega_N,\sigma_N^{p_N},\tau_1(p_N,\omega_N)}\left[\overline{g}_{N_1}\right] \le \widetilde{u}(p_N,\omega_N) + 2\varepsilon. \tag{18}$$

On the other hand, by Lemma 17,

$$\begin{aligned}\left|\mathbf{E}_{p_N,\omega_N,\sigma_N^{p_N},\tau_1(p_N,\omega_N)}\left[\overline{g}_{N_1}\right] - \mathbf{E}_{p_N,\omega_N,\sigma_N,\tau_1(p_N,\omega_N)}\left[\overline{g}_{N_1}\right]\right| \\ \le 4\mathbf{E}_{p_N,\omega_N,\sigma_N,\tau_1(p_N,\omega_N)}\left[\sum_{m=1}^{N_1}\|p_m - p_{m+1}\|_1\right].\end{aligned}$$

Thus, using (18),

$$\mathbf{E}\left[\overline{g}_{N\to N+N_1-1}|\mathcal{H}_N\right] \le \widetilde{u}(p_N,\omega_N) + 2\varepsilon + 4\mathbf{E}\left[\sum_{m=N}^{N+N_1-1}\|p_m - p_{m+1}\|_1 |\mathcal{H}_N\right].$$

The same computation applies to any block of N_1 stages. Specifically, for each $b \ge 0$,

$$\begin{aligned}\mathbf{E}\left[\overline{g}_{N+bN_1\to N+(b+1)N_1-1}|\mathcal{H}_{N+bN_1}\right] &\le \widetilde{u}(p_{N+bN_1},\omega_{N+bN_1}) + 2\varepsilon \\ &\quad + 4\mathbf{E}\left[\sum_{m=N+bN_1}^{N+(b+1)N_1-1}\|p_m - p_{m+1}\|_1 |\mathcal{H}_{N+bN_1}\right].\end{aligned}$$

Since $\widetilde{u}(p,\cdot)$ is constant on every communicating set, and since $\widetilde{u}(\cdot,\omega)$ is 1-Lipshitz, $\widetilde{u}(p_{N+bN_1},\omega_{N+bN_1}) \le \widetilde{u}(p_N,\omega_N) + \|p_{N+bN_1} - p_N\|_1$. By taking expectations on the event A (defined by (17)), one gets, by Lemma 16, (16), and since $\|\cdot\|_1 \le \|\cdot\|_2$,

$$\begin{aligned}\mathbf{E}\left[\mathbf{1}_A\overline{g}_{N+bN_1\to N+(b+1)N_1-1}\right] &\le \mathbf{E}\left[\mathbf{1}_A\widetilde{u}(p_N,\omega_N)\right] + 2\varepsilon + \mathbf{E}\left[\mathbf{1}_A\|p_{N+bN_1} - p_N\|_2\right] \\ &\quad + 4\mathbf{E}\left[\mathbf{1}_A\sum_{m=N+bN_1}^{N+(b+1)N_1-1}\|p_m - p_{m+1}\|_2\right] \\ &\le \mathbf{E}\left[\mathbf{1}_A\widetilde{u}(p_N,\omega_N)\right] + 5\sqrt{\varepsilon}.\end{aligned}$$

By averaging over blocks, one obtains for every $n \geq \frac{2}{\varepsilon}(N+N_1)$

$$\mathbf{E}\left[\mathbf{1}_A \overline{g}_n\right] \leq \mathbf{E}\left[\mathbf{1}_A \widetilde{u}(p_N,\omega_N)\right] + 6\sqrt{\varepsilon}. \tag{19}$$

On the other hand, there is $N_2 \in \mathbf{N}$ such that for every $n \geq N_2$,

$$\mathbf{E}\left[\overline{g}_n|\mathcal{H}_N\right] \leq \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}\left[\phi_m^1 \mid \omega', j\right](p_N,\omega_N) + 2\varepsilon \text{ on the event } \overline{A}. \tag{20}$$

By taking expectations, (19) and (20) yield

$$\begin{aligned}\mathbf{E}\left[\overline{g}_n\right] &\leq \mathbf{E}\left[\min\left\{\widetilde{u}, \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}\left[\phi_m^1 \mid \omega', j\right]\right\}(p_N,\omega_N)\right] + 8\sqrt{\varepsilon} \\ &\leq \operatorname{cav}\ \min\left\{\widetilde{u}, \min_{\omega' \in C_\omega, j \notin J_{\omega'}} \mathbf{E}\left[\phi_m^1 \mid \omega', j\right]\right\}(p,\omega) + 8\sqrt{\varepsilon}\end{aligned}$$

for every $n \geq \max\{N_2, \frac{2}{\varepsilon}(N+N_1)\}$. □

Let $\underline{v}$ denote the max-min of the game, and let (p,ω) be given. Similar to the discussion in section 4.2.2, it can be checked that there is a simple strategy for player 1 that guarantees $\underline{v}(p,\omega) - \varepsilon$ for each $\varepsilon > 0$. Under this strategy, player 1 chooses at random a nonrevealing stationary strategy whenever the play enters a communicating set, and uses it until the play moves to a new communicating set.

4.4. The min-max value.

LEMMA 27. *The unique fixed point of T_3 is the min-max value of* Γ.

Proof. Let ϕ be the unique fixed point of T_3, and fix $\varepsilon > 0$.

We first prove by induction that player 2 can guarantee ϕ. Set $\phi_0^1 \equiv 1$ and, for $m \geq 0$, set $\phi_{m+1}^1 = T_3\phi_m^1$. Assume that player 2 can guarantee ϕ_m^1 for some $m \in \mathbf{N}$, and let (p,ω) be given. Plainly, for each $\omega' \in C_\omega, j \notin J_{\omega'}$, player 2 can guarantee $\mathbf{E}\left[\phi_m^1 \mid \omega', j\right]$ in $\Gamma(p,\omega')$ by first playing j at ω', and then a strategy that guarantees ϕ_m^1 (up to ε). By Lemma 20, he can guarantee $\mathbf{E}\left[\phi_m^1 \mid \omega', j\right]$ in $\Gamma(p,\omega)$ as well. By Lemma 22, player 2 can guarantee cav $\widetilde{u}$. Thus, he can guarantee $T_3\phi_m^1 = \phi_{m+1}^1$. Since he can guarantee ϕ_0^1, and since $\phi = \lim_{m\to\infty} \phi_m^1$, the result follows.

We now prove that player 1 can defend ϕ_m^0 for each $m \in \mathbf{N}$. Clearly, player 1 can defend $\phi_0^0 \equiv 0$. Assume that player 1 can defend ϕ_m^0 for some $m \in \mathbf{N}$. Let a strategy τ of player 2 and $(p,\omega) \in \Delta(K) \times \Omega$ be given. Set $\nu = 1 + \inf\{n \geq 1, j_n \notin J_{\omega_n}\}$. The supremum of $\mathbf{P}_{p,\omega,\sigma,\tau}(\nu < \infty)$ over all strategies σ coincides with the supremum over all nonrevealing strategies σ.[6] Denote by σ^* a *nonrevealing* strategy that achieves the supremum up to ε. We choose N such that $\mathbf{P}_{p,\omega,\sigma^*,\tau}(\nu > N) \leq \varepsilon$. The strategy σ^* thus exhausts the probability of leaving the initial communicating set. Denote by $\tau_{\min\{\nu,N\}}$ the strategy induced by τ after stage $\min\{\nu,N\}$.

On the event $\nu > N$, there is a strategy $\widetilde{\tau}$ in $\Gamma_R(p,\omega)$ such that $\|\mathbf{P}_{p,\omega_N,\sigma,\widetilde{\tau}} - \mathbf{P}_{p,\omega_N,\sigma,\tau_N}\| \leq \mathbf{P}_{p,\omega_N,\sigma,\tau_N}(\nu < +\infty)$ for every nonrevealing strategy σ in $\Gamma_R(p,\omega)$. This strategy depends on the history up to stage N.

We now define the reply σ of player 1 to τ as follows: play σ^* up to stage $\min\{\nu,N\}$.

- If $\nu > N$, switch to a strategy that defends cav $\widetilde{u}(p,\omega) + \varepsilon$ in $\Gamma_R(p,\omega_N)$ against $\widetilde{\tau}$.

[6] Indeed, for every strategy $\sigma = (\sigma^k)_k$, one has $\mathbf{P}_{p,\omega,(\sigma^k)_k,\tau}(\nu < +\infty) = \sum_k p_k \mathbf{P}_{k,\omega,\sigma^k,\tau}(\nu < +\infty) \leq \max_k \mathbf{P}_{k,\omega,\sigma^k,\tau}(\nu < +\infty)$. Let k_0 achieve the maximum, and let σ' be the nonrevealing strategy that plays σ_{k_0} irrespective of k. Since transitions are independent of k, one has $\mathbf{P}_{p,\omega,\sigma,\tau}(\nu < +\infty) \leq \mathbf{P}_{p,\omega,\sigma',\tau}(\nu < +\infty)$.

$k=1$

	j_1	j_2	j_3	j_4	j_5
T	4	0	0	0	0

FIG. 4. *The payoff matrices.*

- If $\nu \leq N$, switch to a strategy that defends $\phi^0_m(p,\omega_\nu)+\varepsilon$ against τ_ν.

Since there are finitely many histories of length N, the set of strategies $(\tau_{\min\{\nu,N\}})$ is finite. It is straightforward to check that σ defends

$$\min\left\{\operatorname{cav}\,\widetilde{u}, \min_{\omega'\in C_\omega, j\notin J_{\omega'}} \mathbf{E}\left[\phi^0_m \mid \omega', i\right]\right\}(p,\omega)+2\varepsilon = \phi^0_{m+1}(p,\omega)+2\varepsilon$$

against τ. □

4.5. An example. Here we provide an example where $\min\{\operatorname{cav} f, g\}$ is strictly larger than $\operatorname{cav}\,\min\{f,g\}$, so that the max-min value and the min-max value differ.

Consider the game depicted in Figure 4, where player 2 controls the transitions, and $|\Omega|=|K|=2$, $|I|=2$, and $|J|=5$. The initial state is ω_1 (bottom two matrices). If in ω_1 player 2 chooses j_5, the game moves to ω_2, which is absorbing. If player 2 chooses another action in ω_1, the game remains in ω_1. Payoffs are as depicted in Figure 4 (the definition of $g^k(\omega_1,\cdot,j_5)$ is irrelevant).

Note that $I_{\omega_1}=\{j_1,j_2,j_3,j_4\}$, $\Omega_0=\{\omega_2\}$, and $C_{\omega_1}=\{\omega_1\}$.

The game $\Gamma_R(p,\omega_1)$ is similar to Example 3.3 in Aumann and Maschler [2]. As calculated in Aumann and Maschler,

$$f(p)=\widetilde{u}(p,\omega_1)=\begin{cases} 3p & 0\leq p\leq 2-\sqrt{3},\\ 1-p(1-p) & 2-\sqrt{3}\leq p\leq \sqrt{3}-1,\\ 3(1-p) & \sqrt{3}-1\leq p\leq 1\end{cases}$$

(see Figure 5). Note that $\operatorname{cav} f \neq f$.

The game $\Gamma_R(p,\omega_2)$ is similar to the game presented in Aumann and Maschler [2, I.2], with all payoffs multiplied by 4.[7] As calculated in Aumann and Maschler,

$$g(p)=\widetilde{u}(p,\omega_2)=4p(1-p).$$

As proved above, the max-min value when the initial state is ω_1 is $(\operatorname{cav}\,\min\{f,g\})(p)$, while the min-max value is $\min\{\operatorname{cav} f, g\}(p)$. A straightforward calculation shows that $\min\{\operatorname{cav} f,g\}(1/2)=3(2-\sqrt{3})$ while $\operatorname{cav}\,\min\{f,g\}(1/2)=4/5$, so the two functions differ. The graphs of the two functions appear in Figure 6.

[7] We added the actions j_3,j_4,j_5, which do not change the calculation of the value. For our purposes, we could have multiplied all payoffs by any α, $3<\alpha<3/(\sqrt{3}-1)$.

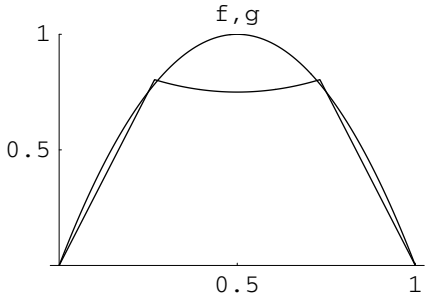

FIG. 5. *The value functions of the restricted games* $\widetilde{\Gamma}_R(p, \omega_i)$.

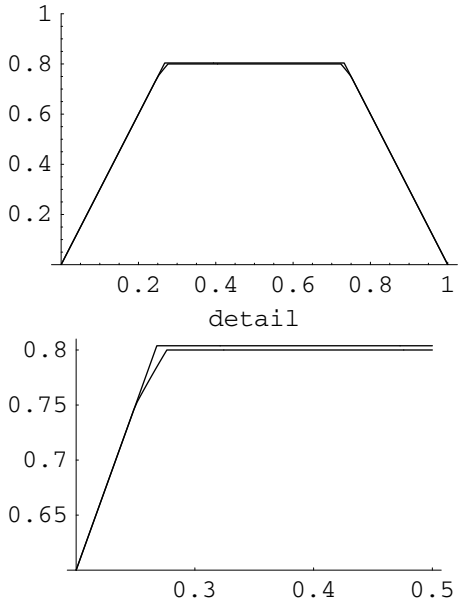

FIG. 6. *The functions* $\min\{\text{cav } f, g\}$ *and* $\text{cav } \min\{f, g\}$.

5. Incomplete information on both sides.

5.1. The model. We now extend our model to the case of incomplete information on both sides; that is, each player has some private information on the game that is to be played. Formally the model is extended as follows. For more details we refer to Mertens, Sorin, and Zamir [10] or Sorin [22].

A *two-player zero-sum stochastic game with incomplete information on both sides* is described by a finite collection $(G_{k,l})_{k\in K, l\in L}$ of stochastic games, together with a distribution $p \in \Delta(K)$ and a distribution $s \in \Delta(L)$. We assume that the games $G_{k,l}$ differ only through their reward functions $g^{k,l}$, but they all have the same sets of states Ω and actions I and J, and the same transition rule q.

The game is played in stages. At the outset of the game a pair $(k, l) \in K \times L$ is chosen according to $p \otimes s$. Player 1 is informed of k, and player 2 of l. At every stage n, the two players choose simultaneously actions $i_n \in I$ and $j_n \in J$, and ω_{n+1} is drawn according to $q(\cdot \mid \omega_n, i_n, j_n)$. Both players are informed of (i_n, j_n, ω_{n+1}).

W.l.o.g. we assume throughout this section that transitions are controlled by player 1. We will only sketch the proofs, since none of them involves any new idea.

5.2. Related literature. The main results in this framework are related to the case $|\Omega| = 1$ (repeated games with incomplete information) and are due to Aumann, Maschler, and Stearns [3] (see also Aumann and Maschler [2]) and Mertens and Zamir [11, 12]. As in the case of incomplete information on one side, we denote by $u(p,s)$ the value of the matrix game with action sets I and J and matrix payoff $(\sum_{k\in K,l\in L} p^k s^l g^{k,l}(i,j))_{i,j}$. Given $f : \Delta(K)\times\Delta(L) \to \mathbf{R}$, we let $\mathrm{cav}_p f$ denote the smallest function that is above f and concave in p, and $\mathrm{vex}_s f$ denotes the largest function that is below f and convex in s.

The min-max value of a repeated game with incomplete information exists and is equal to $\mathrm{vex}_s\mathrm{cav}_p u(p,s)$. The max-min value exists and is equal to $\mathrm{cav}_p\mathrm{vex}_s u(p,s)$.

5.3. Partitioning the states and the average restricted game. Since player 1 controls transitions, the partition defined in section 4 extends to this case, as well as the definition of the average restricted game $\widetilde{\Gamma}_R(p,s,\omega)$ in which none of the players has any information. Denote by $\widetilde{u}(p,s,\omega)$ the value of $\widetilde{\Gamma}_R(p,s,\omega)$. In addition, we define the average restricted game $\widetilde{\Gamma}^1_R(p,s,\omega)$ (resp., $\widetilde{\Gamma}^2_R(p,s,\omega)$) in which player 1 (resp., player 2) is informed of k (resp., l) while his opponent gets no information. Our first goal is to extend Proposition 21.

PROPOSITION 28. *For every $(\omega,p,s)\in\Omega_0\times\Delta(K)\times\Delta(L)$, the min-max value of $\Gamma(p,s,\omega)$ exists and is equal to $\mathrm{vex}_s\mathrm{cav}_p\widetilde{u}(p,s,\omega)$. Similarly the max-min value exists and is equal to $\mathrm{cav}_p\mathrm{vex}_s\widetilde{u}(p,s,\omega)$.*

Proof. The proof follows the proof for repeated games with incomplete information, using the tools developed in the previous sections. We shall only sketch the arguments for the min-max value, and refer for details to Zamir [24].

First, we explain how player 2 can guarantee $\mathrm{vex}_s\mathrm{cav}_p\widetilde{u}(p,s,\omega)$. When player 2 ignores his information, he faces a game with incomplete information on one side with parameter set K and payoffs $\sum_{l\in L} s^l g^{k,l}$. By Proposition 21, player 2 can guarantee $\mathrm{cav}_p\widetilde{u}(p,s,\omega)$ in this game. Therefore by Lemma 10 (with the roles of the two players exchanged) he can also guarantee $\mathrm{vex}_s\mathrm{cav}_p\widetilde{u}(p,s,\omega)$.

To prove that player 1 can defend $\mathrm{vex}_s\mathrm{cav}_p\widetilde{u}(p,s,\omega)$, we adapt Zamir [24, Theorem 4.1]. Let τ be a given strategy of player 2. As in Step 2 of the proof of Lemma 26, we let player 1 play first an ε-exhausting strategy $\widetilde{\sigma}$ given τ. This strategy may be chosen to be nonrevealing (see, e.g., Sorin [22, Lemma IV.4.1]). Player 1 switches at some stage N to a strategy that defends $\mathrm{cav}_p\widetilde{u}(p,s_N,\omega_N)$ (up to ε) in $\Gamma(p,s_N,\omega_N)$ against the continuation strategy τ_N (see Step 3 of Lemma 26). Since $\widetilde{u}(\cdot,\cdot,\omega) = \widetilde{u}(\cdot,\cdot,\omega_N)$, $\mathrm{cav}_p\widetilde{u}(p,s_N,\omega_N) = \mathrm{cav}_p\widetilde{u}(p,s_N,\omega)$. Therefore player 1 defends $\mathbf{E}_{p,s,\omega,\widetilde{\sigma},\tau}\left[\mathrm{cav}_p\widetilde{u}(p,s_N,\omega)\right] \geq \mathrm{vex}_s\mathrm{cav}_p\widetilde{u}(p,s,\omega)$. □

5.4. The max-min value and the min-max value. Let $\mathcal{B}$ denote the set of all functions $\phi : \Delta(K)\times\Delta(L)\times\Omega \to [0,1]$ that are 1-Lipshitz with respect to p and s. Denote by T_4 and T_5 the operators on $\mathcal{B}$ defined by

$$T_4\phi(p,s,\omega) = \mathrm{cav}_p \max\left\{\mathrm{cav}_p\mathrm{vex}_s\widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\phi \mid \omega', i]\right\}(p,s,\omega) \tag{21}$$

and

$$T_5\phi(p,s,\omega) = \mathrm{vex}_s\mathrm{cav}_p \max\left\{\mathrm{cav}_p\widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\phi \mid \omega', i]\right\}(p,s,\omega). \tag{22}$$

Our main result is the following.

THEOREM 29.

1. *The mappings T_4 and T_5 have unique fixed points, denoted respectively by $\underline{v}$ and $\overline{v}$.*
2. *The function $\underline{v}$ is the max-min value of the game.*
3. *The function $\overline{v}$ is the min-max value of the game.*

Note that if player 2 has no information, there is no vex operator in (21) and (22), and both T_4 and T_5 reduce to T_1. If player 1 has no information, there is no cav operator in (21) and (22), and T_4 and T_5 reduce respectively to T_3 and T_2 with the roles of the players reversed.

Proof. The first assertion follows the same lines as the proof of Proposition 23.

We now prove the second assertion. For $j = 0, 1$, we define the sequence $(\phi_n^j)_{n\geq 0}$ by $\phi_0^j = j$ and $\phi_{n+1}^j = T_4\phi_n^j$. We follow the inductive proof of Proposition 25, Step 1, or the first part of Lemma 27.

The sequence (ϕ_n^0) is increasing and converges uniformly to $\underline{v}$. It is clear that player 1 can guarantee ϕ_0^0. Assuming player 1 can guarantee ϕ_n^0, we prove that he can guarantee ϕ_{n+1}^0. By Lemma 10 it is sufficient to show that he can guarantee both $\mathrm{cav}_p\mathrm{vex}_s\widetilde{u}(p,s,\omega)$ and $\max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\phi_n^0 \mid \omega', i]$, which is true by Proposition 28 and by Step 1 of Proposition 25.

To prove that player 2 can defend $\underline{v}$, we combine several ideas from the preceding sections. Let σ be given, and let $\widetilde{T}$ be the set of nonrevealing strategies of player 2. We let τ_σ be a nonrevealing strategy that ε-exhausts the information contained in σ, and choose N as in Step 2 of Lemma 26. Denote by $\nu = 1 + \min\{n \geq 1, i_n \notin I_{\omega_n}\}$. Player 2 plays according to τ_σ up to stage $\min\{\nu, N\}$.

- If $\nu \leq N$, from stage ν on he defends $\phi_n^1(p_\nu, s, \omega_\nu)$.
- If $\nu > N$, we first use the idea of Lemma 27, with the roles of the two players exchanged. Specifically, we define a nonrevealing strategy τ_N^σ that exhausts the probability of leaving the initial communicating set, given the strategy σ_N induced by σ after stage N. Choose N' such that $\mathbf{P}_{p_N,s,\omega_N,\sigma_N,\tau_N^\sigma}(\nu > N') \leq \varepsilon$. Player 2 plays τ_N^σ up to stage $\min\{\nu, N + N'\}$.
  - If $\nu \leq N+N'$, player 2 switches to a strategy that defends $\phi_n(p_\nu, s, \omega_\nu)+\varepsilon$.
  - If $\nu > N + N'$, following Steps 2 and 3 of Lemma 26, player 2 starts to play in blocks of length N_1. In the bth block he forgets past play and follows a strategy that defends $\mathrm{vex}_s\widetilde{u}(p_{N+N'+bN_1}, s, \omega_{N+N'+bN_1})$ in the restricted game $\widetilde{\Gamma}_R^2(p_{N+N'+bN_1}, s, \omega_{N+N'+bN_1})$ against the average continuation strategy $\sigma_{N+N'+bN_1}^{p_{N+N'+bN_1}}$ of player 1.

We now turn to the third assertion. We first prove that player 2 can guarantee $\overline{v}$. By following Steps 2, 3, and 4 of Lemma 25, one proves that player 2 guarantees $\mathrm{cav}_p \max\{\mathrm{cav}_p\widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\overline{v} \mid \omega', i]\}(p,s,\omega)$. Hence, by Lemma 10 (with the roles of the two players exchanged), he can guarantee $\mathrm{vex}_s\mathrm{cav}_p \max\{\mathrm{cav}_p\widetilde{u}, \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\overline{v} \mid \omega', i]\} = \overline{v}$.

We now prove that player 1 can defend $\overline{v}$. We first follow Step 2 of Lemma 26. Given τ, we let σ^τ be a strategy in $\widetilde{\Gamma}_R^2(p,s,\omega)$ that exhausts the information contained in τ, and we choose N such that $\mathbf{E}_{p,s,\omega,\sigma^\tau,\tau}[\sum_{n=N}^\infty \|p_n - p_{n+1}\|_1^2] \leq \varepsilon$. Player 1 plays σ^τ up to stage N. He then switches to a strategy that guarantees $\mathrm{cav}_p \max\left\{\mathrm{cav}_p\widetilde{u}(\cdot, s_N, \omega), \max_{\omega'\in C_\omega, i\notin I_{\omega'}} \mathbf{E}[\overline{v} \mid \omega', i]\right\}(p, s_N)$ in $\widetilde{\Gamma}_R^1(p, s_N, \omega_N)$, as in the proof of Proposition 25. The result follows. ∎

OPTIMAL CONTROL OF NEUTRAL FUNCTIONAL-DIFFERENTIAL INCLUSIONS*

BORIS S. MORDUKHOVICH† AND LIANWEN WANG‡

Dedicated to Jack Warga in honor of his 80th birthday

Abstract. This paper deals with optimal control problems for dynamical systems governed by constrained functional-differential inclusions of neutral type. Such control systems contain time delays not only in state variables but also in velocity variables, which make them essentially more complicated than delay-differential (or differential-difference) inclusions. Our main goal is to derive necessary optimality conditions for general optimal control problems governed by neutral functional-differential inclusions with endpoint constraints. While some results are available for smooth control systems governed by neutral functional-differential equations, we are not familiar with any results for neutral functional-differential inclusions, even with smooth cost functionals in the absence of endpoint constraints. Developing the method of discrete approximations (which is certainly of independent interest) and employing advanced tools of generalized differentiation, we conduct a variational analysis of neutral functional-differential inclusions and obtain new necessary optimality conditions of both Euler–Lagrange and Hamiltonian types.

Key words. optimal control, functional-differential inclusions of neutral type, variational analysis, discrete approximations, generalized differentiation, necessary optimality conditions

1. Introduction.

This paper concerns the study of optimal control problems for the so-called *neutral functional-differential inclusions*, which contain time delays in both state and velocity variables. Such inclusions belong to the broad class of *hereditary* systems known also as systems with *memory* or *aftereffect*. They have been investigated in the form of controlled functional-differential *equations* being important for various practical applications, particularly to problems of automatic control, economic dynamics, modeling of ecological, biological, and chemical processes, etc.; see examples and discussions in [1, 4, 10, 12, 14, 15, 19] and their references. Note that some classes of *hyperbolic PDEs* (e.g., the so-called telegraph equations) can be reduced to neutral functional-differential equations, as shown in the above references.

To our knowledge, control problems for neutral functional-differential *inclusions* have not been sufficiently studied in the literature. We are only familiar with results concerning the existence of optimal solutions, local controllability, and relaxation procedures mostly collected in [14].

In this paper we consider the following dynamic optimization (generalized optimal control) problem (P):

$$\text{minimize} \quad J[x] := \varphi(x(a), x(b)) + \int_a^b f(x(t), x(t-\Delta), t)\, dt \tag{1.1}$$

over feasible arcs $x : [a-\Delta, b] \to \mathbb{R}^n$, which are continuous on $[a-\Delta, a)$ and $[a, b]$ (with a possible *jump* at $t = a$) and are such that the combination $x(\cdot) - Ax(\cdot - \Delta)$ is absolutely continuous on $[a, b]$, satisfying the *neutral functional-differential inclusion*

$$\frac{d}{dt}[x(t) - Ax(t-\Delta)] \in F(x(t), x(t-\Delta), t) \quad \text{for a.e. } t \in [a, b], \tag{1.2}$$

$$x(t) = c(t), \quad t \in [a-\Delta, a), \tag{1.3}$$

with the endpoint constraints

$$(x(a), x(b)) \in \Omega \subset \mathbb{R}^{2n}. \tag{1.4}$$

We always assume that $F : \mathbb{R}^n \times \mathbb{R}^n \times [a, b] \rightrightarrows \mathbb{R}^n$ is a set-valued mapping of closed graph, Ω is a closed set, $\Delta > 0$ is a constant delay, and A is a constant $n \times n$ matrix.

Note that the neutral-type operator on the left-hand side of (1.2) is given in the *Hale form* [10], which seems to be essential for our consideration. Observe to this end that trajectories $x(t)$ of (1.2) are generally *discontinuous* on $[a-\Delta, b]$ while their linear combinations $x(t) - Ax(t-\Delta)$ behave nicely on $[a, b]$. Note also that trajectories of the neutral inclusion may be assumed to be discontinuous not only at $t = a$ but also at the points $t = a + j\Delta \in [a, b]$, $j = 1, 2, \ldots$. Moreover, the results obtained in this paper can be easily extended to problems with the cost function φ depending on $x(a + j\Delta)$, the constraints (1.4) given at these intermediate points, and the integrand f in (1.1) depending on the velocity $\dot{z}(t)$ for $z(t) := x(t) - Ax(t-\Delta)$, $t \in [a, b]$. We can also consider the cases of *multiple delays* $\Delta_1 \geq \Delta_2 \geq \cdots \geq \Delta_m > 0$ as well as *variable delays* $\Delta(t)$, where $\Delta(\cdot)$ is a Lipschitz continuous (hence almost everywhere differentiable) function satisfying the assumption

$$|\dot{\Delta}(t)| < \alpha \in (0, 1) \quad \text{for a.e. } t \in [a, b],$$

which ensures that the function $t - \Delta(t)$ is invertible on $[a, b]$. For simplicity we focus in what follows on problem (P) formulated in (1.1)–(1.4).

Our primary goal is to derive *necessary optimality conditions* for problem (P) under general assumptions on the initial data. For *nondelayed* systems governed by differential inclusions ($\Delta = 0, A = 0$) necessary optimality conditions have been studied intensively during recent years; see [5, 11, 16, 21, 27, 28, 29, 31] and the references therein. Some results are known for *delay-differential* (or differential-difference) inclusions corresponding to $A = 0$ in (1.2); see [6, 7, 17, 23, 24]. We are not familiar with any necessary optimality conditions obtained for problem (P) governed by neutral functional-differential inclusions with $A \neq 0$ in (1.2) besides the case of *smooth* control systems corresponding to

$$F(x, y, t) = \{v \in \mathbb{R}^n \mid v = g(x, y, u, t), u \in U\} \tag{1.5}$$

with continuously differentiable functions φ, f, g in (1.1) and (1.2) as well as those describing endpoint constraints; see [3, 9, 13, 19] and their references.

Observe that neutral-type systems are essentially different from their counterparts with $A = 0$. In particular, it is well known that an analog of the Pontryagin maximum principle does *not* generally hold for neutral systems, even in the classical smooth framework of (1.5), with *no convexity* assumptions; see, e.g., [9, 15]. In a sense, neutral-type systems combine properties of continuous-time and discrete-time

control systems; indeed, they can be treated as discrete-time systems regarding velocity variables. On the other hand, neutral systems have some similarities with the so-called *hybrid* and *differential-algebraic* equations that are important in engineering control applications.

In this paper we derive necessary optimality conditions for the neutral-type control problem (P) under general assumptions on its initial data involving nonsmooth functions and nonconvex sets. These conditions are obtained in extended *Euler–Lagrange* and *Hamiltonian* forms involving advanced generalized differential constructions of variational analysis; see section 4. Note that the results obtained seem to be new even in the case of nondelayed problems with $A \neq 0$ corresponding to *implicit* differential inclusions.

Our approach is based on the *method of discrete approximations*, in the manner developed in [19, 21] for nondelayed differential inclusions and in [23, 24] for delay-differential systems with $A = 0$. This method, which is certainly of independent interest from both qualitative and numerical viewpoints, allows us to construct a *well-posed* parametric family of optimal control problems for approximating systems governed by *discrete-time* analogs of neutral functional-differential inclusions. A crucial issue is to establish *stability* of such approximations that ensures an appropriate *strong convergence* of optimal solutions. Convergence analysis of this method and its application to necessary optimality conditions for neutral systems are essentially more involved in comparison with the cases of differential and delay-differential inclusions.

The approximating discrete-time control problems can be reduced to special *finite-dimensional* problems of *nonsmooth programming* with an increasing number of *geometric constraints* that may have empty interiors. To handle such problems, we use suitable generalized differential tools of variational analysis satisfying a comprehensive calculus that allows us to derive general necessary optimality conditions for finite-difference analogs of neutral functional-differential inclusions. Then passing to the limit from well-posed discrete approximations with the strong convergence of optimal solutions and employing generalized differential calculus, we obtain necessary optimality conditions for the original problem (P).

The rest of the paper is organized as follows. In section 2 we show that some combination built upon a given admissible trajectory of the neutral inclusion (1.2) can be *strongly approximated* by the corresponding combination built upon admissible trajectories of discrete-time systems. This result, important for its own sake, plays a crucial role in the construction of well-posed discrete approximations to the original problem (P) and in the subsequent justification of a strong convergence of their optimal solutions to the given optimal trajectory for (P).

Such a convergence analysis is conducted in section 3 for a sequence of well-posed discrete approximations to (P) involving an appropriate perturbation of the endpoint constraints (1.4) that is *consistent* with the step of discretization. The required strong convergence of optimal solutions is established under an intrinsic property of the original problem (P) called *relaxation stability*. This property, imposing the equality between the optimal values in (P) and its relaxation (convexification), goes far beyond the convexity assumption on the velocity sets $F(x, y, t)$.

Section 4 contains the basic constructions and required material on generalized differentiation needed for performing a variational analysis of discrete-time and continuous-time optimal control problems in the subsequent sections. These constructions and calculus rules are used in section 5 for deriving general necessary optimality conditions for nonconvex discrete-time inclusions arising in discrete approximations

of the original problem (P). The main results on the extended Euler–Lagrange and Hamiltonian conditions for neutral functional-differential inclusions are derived in section 6 via passing to the limit from discrete approximations.

Our notation is basically standard; cf. [21] and [26]. Recall that, given a set-valued mapping (multifunction) $F : X \rightrightarrows Y$ between finite-dimensional spaces, the *Painlevé–Kuratowski upper/outer limit* of $F(x)$ as $x \to \bar{x}$ is defined by

$$\operatorname*{Lim\,sup}_{x\to\bar{x}} F(x) := \{y \in Y \mid \exists\, x_k \to \bar{x},\ \exists\, y_k \to y \text{ with } y_k \in F(x_k) \text{ for all } k \in \mathbb{N}\},$$

where $\mathbb{N}$ stands for the collection of all natural numbers.

2. Discrete approximations of neutral inclusions. This section concerns the study of discrete approximations of an *arbitrary* admissible trajectory to the neutral functional-differential inclusion (1.2) with the initial condition (1.3). We show that, under fairly general assumptions, any admissible trajectory to (1.2) and (1.3) can be *strongly approximated*, in the sense indicated below, by the corresponding trajectories to finite-difference inclusions obtained from (1.2) by the Euler scheme. This result is constructive, providing efficient estimates for the approximation rate, and hence it is certainly of independent interest for numerical analysis and applications.

Let $\bar{x}(\cdot)$ be an *admissible trajectory* in (P), i.e., it is continuous on $[a-\Delta, a)$ and $[a, b]$ (with a possible jump at $t = a$), the combination $x(\cdot) - Ax(\cdot - \Delta)$ is absolutely continuous on $[a, b]$, and relations (1.2) and (1.3) are satisfied. Note that the endpoint constraints (1.4) may not hold for $\bar{x}(\cdot)$; if they do hold, $\bar{x}(\cdot)$ is *feasible* to (P). The following *standing assumptions* are imposed throughout the paper.

(H1) There are an open set $U \subset \mathbb{R}^n$ and two positive numbers l_F and m_F such that $\bar{x}(t) \in U$ for all $t \in [a-\Delta, b]$, the sets $F(x, y, t)$ are closed, and one has

$$\begin{aligned} F(x, y, t) &\subset m_F\mathbb{B} \quad \text{for all } (x, y, t) \in U \times U \times [a, b],\\ F(x_1, y_1, t) &\subset F(x_2, y_2, t) + \ell_F(|x_1 - x_2| + |y_1 - y_2|)\mathbb{B} \end{aligned}$$

if $(x_1, y_1), (x_2, y_2) \in U \times U$ and $t \in [a, b]$, where $\mathbb{B}$ stands for the closed unit ball in $\mathbb{R}^n$.

(H2) $F(x, y, t)$ is Hausdorff continuous for a.e. $t \in [a, b]$ uniformly in $(x, y) \in U \times U$.

(H3) The function $c(\cdot)$ is continuous on $[a-\Delta, a]$.

Following [8], we consider the so-called *averaged modulus of continuity* for the multifunction $F(x, y, t)$ with $(x, y) \in U \times U$ and $t \in [a, b]$ that is defined by

$$\tau(F; h) := \int_a^b \sigma(F; t, h)\, dt,$$

where $\sigma(F; t, h) := \sup\{\vartheta(F; x, y, t, h) \mid (x, y) \in U \times U\}$ with

$$\vartheta(F; x, y, t, h) := \sup\left\{\operatorname{haus}(F(x, y, t_1), F(x, y, t_2)) \mid (t_1, t_2) \in \left[t - \frac{h}{2}, t + \frac{h}{2}\right] \cap [a, b]\right\},$$

and where $\operatorname{haus}(\cdot, \cdot)$ stands for the Hausdorff distance between two compact sets. It is proved in [8] that if $F(x, y, t)$ is Hausdorff continuous for a.e. $t \in [a, b]$ uniformly in $(x, y) \in U \times U$, then $\tau(F; h) \to 0$ as $h \to 0$. This fact is essentially used in what follows.

Let us construct a sequence of discrete approximations of the given neutral-differential inclusion replacing the derivative in (1.2) by the *Euler finite difference*

$$\frac{d}{dt}[x(t)-Ax(t-\Delta)]\approx\frac{x(t+h)-Ax(t+h-\Delta)-x(t)+Ax(t-\Delta)}{h}.$$

For any $N\in\mathbb{N}:=\{1,2,\dots\}$ we consider the *step of discretization* $h_N:=\frac{\Delta}{N}$ and define the *discrete grid/partition* $t_j:=a+jh_N$ as $j=-N,\dots,k$ and $t_{k+1}:=b$, where k is a natural number determined from $a+kh_N\le b<a+(k+1)h_N$. One clearly has $t_{-N}=a-\Delta$, $t_0=a$, and $h_N\to 0$ as $N\to\infty$. Then the corresponding *neutral functional-difference inclusions* associated with (1.2) and (1.3) are given by

$$\begin{cases}x_N(t_{j+1})-Ax_N(t_{j+1}-\Delta)\in x_N(t_j)-Ax_N(t_j-\Delta),\\ +h_NF(x_N(t_j),x_N(t_j-\Delta),t_j)\quad\text{for } j=0,\dots,k,\\ x_N(t_j)=c(t_j)\quad\text{for } j=-N,\dots,-1.\end{cases}\tag{2.1}$$

A collection of vectors $\{x_N(t_j)\mid j=-N,\dots,k+1\}$ satisfying (2.1) is a *discrete trajectory* and the corresponding collection

$$\left\{\frac{x_N(t_{j+1})-Ax_N(t_{j+1}-\Delta)-x_N(t_j)+Ax_N(t_j-\Delta)}{h_N}\mid j=0,\dots,k\right\}$$

is a *combined discrete velocity* for (2.1). We consider *extensions* $x_N(t)$ *of discrete trajectories* to the continuous-time interval $[a-\Delta,b]$ defined piecewise linearly on $[a,b]$ and piecewise constantly, continuously from the right on $[a-\Delta,a)$. We also define piecewise constant *extensions of combined discrete velocities* on $[a,b]$ by

$$v_N(t):=\frac{x_N(t_{j+1})-Ax_N(t_{j+1}-\Delta)-x_N(t_j)+Ax_N(t_j-\Delta)}{h_N}$$

for $t\in[t_j,t_{j+1})$, $j=0,\dots,k$. It is easy to verify that

$$x_N(t)-Ax_N(t-\Delta)=x_N(a)-Ax_N(a-\Delta)+\int_a^t v_N(s)\,ds\quad\text{for } t\in[a,b]\quad\text{and}$$

$$\frac{d}{dt}[x_N(t)-Ax_N(t-\Delta)]=v_N(t)\quad\text{for a.e. } t\in[a,b].$$

Let $W^{1,2}[a,b]$ be a standard Sobolev space of absolutely continuous functions $x:[a,b]\to\mathbb{R}^n$ with the norm

$$\|x(\cdot)\|_{W^{1,2}}:=\max_{t\in[a,b]}|x(t)|+\left(\int_a^b|\dot{x}(t)|^2dt\right)^{1/2}.$$

The next theorem, important in what follows, establishes a *strong approximation* of any admissible trajectory for the given neutral functional-differential inclusion by solutions corresponding to discrete approximations (2.1).

THEOREM 2.1. *Let* $\bar{x}(\cdot)$ *be an admissible trajectory for* (1.2) *and* (1.3) *under hypotheses* (H1)–(H3). *Then there is a sequence* $\{z_N(t_j)\mid j=-N,\dots,k+1\}$, $N\in\mathbb{N}$, *of solutions to discrete inclusions* (2.1) *such that* $z_N(t_0)=\bar{x}(a)$ *for all* $N\in\mathbb{N}$, *the extended discrete trajectories* $z_N(t)$, $a-\Delta\le t\le b$, *converge uniformly to* $\bar{x}(\cdot)$ *on*

$[a-\Delta, b]$, and their extended combinations $z_N(t) - Az_N(t-\Delta)$ converge to $\bar{x}(t) - A\bar{x}(t-\Delta)$ in the $W^{1,2}$-norm on $[a,b]$ as $N \to \infty$. In particular, some subsequence of $\{\frac{d}{dt}[z_N(t) - Az_N(t-\Delta)]\}$ converges pointwisely to $\frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)]$ for a.e. $t \in [a,b]$.

Proof. Using the density of step functions in $L^1[a,b]$, we first select a sequence $\{\omega_N(\cdot)\}$, $N \in \mathbb{N}$, such that each $\omega_N(t)$ is constant on the interval $[t_j, t_{j+1})$ for $j = 0, \ldots, k$ and that $\omega_N(\cdot)$ converge to $\frac{d}{dt}[\bar{x}(\cdot) - A\bar{x}(\cdot - \Delta)]$ as $N \to \infty$ in the norm topology of $L^1[a,b]$. It follows from (H1) that

$$|\omega_N(t)| \le \left|\omega_N(t) - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)]\right| + \left|\frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)]\right| \le 1 + m_F$$

for all $t \in [a,b]$ and $N \in \mathbb{N}$. In the estimates below we use the sequence

$$\xi_N := \int_a^b \left|\frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] - \omega_N(t)\right| dt \to 0 \quad \text{as } N \to \infty.$$

Denote $\omega_{N_j} := \omega_N(t_j)$ and define discrete functions $\{u_N(t_j) \mid j = -N, \ldots, k+1\}$ recurrently by

$$\begin{cases} u_N(t_j) := \bar{x}(t_j) \quad \text{for } j = -N, \ldots, 0, \\ u_N(t_{j+1}) := Au_N(t_{j+1} - \Delta) + u_N(t_j) - Au_N(t_j - \Delta) \\ \qquad\qquad + h_N\omega_{N_j} \quad \text{for } j = 0, \ldots, k. \end{cases}$$

Then the extended (in the above way) discrete functions satisfy

$$\begin{cases} u_N(t) = \bar{x}(t_j) \quad \text{for } t \in [t_j, t_{j+1}),\ j = -N, \ldots, -1, \\ u_N(t) - Au_N(t-\Delta) = \bar{x}(a) - A\bar{x}(a-\Delta) + \displaystyle\int_a^t \omega_N(s)\, ds \quad \text{for } t \in [a,b]. \end{cases}$$

Next we denote $r_N(t) := u_N(t) - \bar{x}(t)$, $y_N(t) := |r_N(t) - Ar_N(t-\Delta)|$ and prove that $|r_N(t)| \to 0$ uniformly in $[a,b]$ as $N \to \infty$. Indeed, for any $t \in [a,b]$ one has

$$\begin{aligned} y_N(t) :&= |u_N(t) - Au_N(t-\Delta) - [\bar{x}(t) - A\bar{x}(t-\Delta)]| \\ &\le \int_a^t \left|\omega_N(s) - \frac{d}{dt}[\bar{x}(s) - A\bar{x}(s-\Delta)]\right| ds \le \xi_N, \end{aligned}$$

which implies the estimates

$$\begin{aligned} |r_N(t)| &\le y_N(t) + |A| \cdot |r_N(t-\Delta)| \\ &\le y_N(t) + |A| y_N(t-\Delta) + |A|^2 |r_N(t-2\Delta)| \le \cdots \\ &\le y_N(t) + |A| y_N(t-\Delta) + \cdots + |A|^m y_N(t-m\Delta) \\ &\quad + |A|^{m+1} |r_N(t-(m+1)\Delta)|. \end{aligned}$$

Observe that $c(\cdot)$ is *uniformly continuous* on $[a-\Delta, a]$ due to assumption (H3). Picking an arbitrary sequence $\beta_N \downarrow 0$ as $N \to \infty$, we therefore have

$$|c(t') - c(t'')| \le \beta_N \quad \text{whenever } t', t'' \in [t_j, t_{j+1}],\ j = -N, \ldots, -1.$$

Choose an integer number m such that $a - \Delta \le b - (m+1)\Delta < a$. Then $t - (m+1)\Delta \in [t_j, t_{j+1})$ for some $j \in \{-N, \ldots, -1\}$, which implies that

$$|r_N(t-(m+1)\Delta)| \le |c(t_j) - c(t-(m+1)\Delta)| \le \beta_N.$$

Since $m \in \mathbb{N}$ does not depend on N, this gives

$$|r_N(t)| \le \xi_N(1 + |A| + \cdots + |A|^m) + |A|^{m+1}\beta_N \to 0 \quad \text{as } N \to \infty. \tag{2.2}$$

Now consider a sequence $\{\zeta_N\}$ defined by

$$\zeta_N := h_N \sum_{j=0}^{k} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t_j))$$

and show that $\zeta_N \downarrow 0$ as $N \to \infty$. By construction of ζ_N and the averaged modulus of continuity $\tau(F; h)$ we get the following estimates:

$$\begin{aligned}
\zeta_N &= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t_j))\, dt \\
&= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t))\, dt \\
&\quad + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} [\operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t_j)) \\
&\qquad\qquad - \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t))]\, dt \\
&\le \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t))\, dt + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \sigma(F; t, h_N)\, dt \\
&\le \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t))\, dt + \tau(F; h_N).
\end{aligned}$$

Further, assumption (H1) implies that for any $t \in [t_j, t_{j+1})$ with $j = 0, \dots, k$ one has

$$\begin{aligned}
&\operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t)) - \operatorname{dist}(\omega_{N_j}; F(u_N(t), u_N(t - \Delta), t)) \\
&\quad \le \operatorname{dist}(F(u_N(t_j), u_N(t_j - \Delta), t), F(u_N(t), u_N(t - \Delta), t)) \\
&\quad \le \ell_F(|u_N(t_j) - u_N(t)| + |u_N(t_j - \Delta) - u_N(t - \Delta)|).
\end{aligned}$$

Taking into account that

$$\begin{aligned}
&|u_N(t_j) - Au_N(t_j - \Delta) - [u_N(t) - Au_N(t - \Delta)]| \\
&\quad = \left| \int_{t_j}^{t} \omega_N(s)\, ds \right| \le (1 + m_F)(t_{j+1} - t_j) = (1 + m_F)h_N := a_N \downarrow 0,
\end{aligned}$$

we arrive at

$$\begin{aligned}
|u_N(t) - u_N(t_j)| &\le a_N + |A| \cdot |u_N(t - \Delta) - u_N(t_j - \Delta)| \\
&\le a_N(1 + |A| + \cdots + |A|^m) + |A|^{m+1}|u_N(t - (m+1)\Delta) - u_N(t_j - (m+1)\Delta)| \\
&\le a_N(1 + |A| + \cdots + |A|^m) + |A|^{m+1}\beta_N := b_N \downarrow 0 \quad \text{as } N \to \infty
\end{aligned}$$

and hence ensure that

$$\operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t)) - \operatorname{dist}(\omega_{N_j}; F(u_N(t), u_N(t - \Delta), t)) \le 2\ell_F b_N.$$

It follows from (H1) and (2.2) that for any $t \in [t_j, t_{j+1})$ and $j = 0, \ldots, k$ one has

$$\begin{aligned}
&\operatorname{dist}(\omega_{N_j}; F(u_N(t), u_N(t-\Delta), t)) - \operatorname{dist}(\omega_N(t); F(\bar{x}(t), \bar{x}(t-\Delta), t)) \\
&\quad \le \operatorname{dist}(F(u_N(t), u_N(t-\Delta), t),\ F(\bar{x}(t), \bar{x}(t-\Delta), t)) \\
&\quad \le \ell_F(|u_N(t) - \bar{x}(t)| + |u_N(t-\Delta) - \bar{x}(t-\Delta)|) \\
&\quad \le 2\ell_F \xi_N (1 + |A| + \cdots + |A|^m) + 2\ell_F |A|^{m+1} \beta_N.
\end{aligned}$$

Combining the above estimates and denoting

$$\mu_N := 2b_N + 2\xi_N(1 + |A| + \cdots + |A|^m) + 2|A|^{m+1}\beta_N,$$

we arrive at

$$\begin{aligned}
\operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j-\Delta), t)) &\le\ 2\ell_F b_N + \operatorname{dist}(\omega_{N_j}; F(u_N(t), u_N(t-\Delta), t)) \\
&\le 2\ell_F b_N + 2\ell_F \xi_N (1 + |A| + \cdots + |A|^m) + 2\ell_F |A|^{m+1}\beta_N \\
&\quad + \operatorname{dist}(\omega_{N_j}; F(\bar{x}(t), \bar{x}(t-\Delta), t)) \le \ell_F \mu_N + \left| \omega_{N_j} - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|
\end{aligned}$$

and finally conclude that

$$\begin{aligned}
\zeta_N &\le \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left(\left| \omega_{N_j} - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right| + \ell_F \mu_N \right) dt + \tau(F; h_N) \\
&= \xi_N + \ell_F \mu_N (b-a) + \tau(F; h_N) := \gamma_N \downarrow 0 \quad \text{as } N \to \infty.
\end{aligned} \tag{2.3}$$

Note that the discrete functions $\{u_N(t_j) \mid j = -N, \ldots, k+1\}$ may *not* be trajectories for (2.1), since one does not generally have $\omega_{N_i} \in F(u_N(t_j), u_N(t_j - \Delta), t_j)$ for $j = 0, \ldots, k$. Let us construct the desired trajectories $\{z_N(t_j) \mid j = -N, \ldots, k+1\}$ by the following *proximal algorithm*:

$$\begin{cases}
z_N(t_j) = c(t_j) \quad \text{for } j = -N, \ldots, -1,\ z_N(t_0) = \bar{x}(a), \\
z_N(t_{j+1}) - A z_N(t_{j+1} - \Delta) \\
\qquad = z_N(t_j) - A z_N(t_j - \Delta) + h_N v_{N_j} \quad \text{for } j = 0, \ldots, k, \\
v_{N_j} \in F(z_N(t_j), z_N(t_j - \Delta), t_j) \quad \text{with} \\
|v_{N_j} - \omega_{N_j}| = \operatorname{dist}(\omega_{N_j}; F(z_N(t_j), z_N(t_j - \Delta), t_j)) \quad \text{for } j = 0, \ldots, k.
\end{cases} \tag{2.4}$$

It follows from construction (2.4) that $z_N(t_j)$ is a feasible trajectory to the discrete inclusion (2.1) for each $N \in \mathbb{N}$. Note that

$$|z_N(t) - \bar{x}(t)| = |z_N(t_j) - \bar{x}(t)| = |c(t_j) - c(t)| < \beta_N$$

for $t \in [t_j, t_{j+1})$, $j = -N, \dots, -1$, which implies that the extensions of $z_N(\cdot)$ converge to $\bar{x}(t)$ uniformly on $[a - \Delta, a)$. Let us analyze the situation on $[a, b]$.

First we claim that $z_N(t_j) \in U$ for $j = 0, \dots, k+1$, where $U \subset \mathbb{R}^n$ is a neighborhood of $\bar{x}(\cdot)$ given in (H1). Arguing by induction, we obviously have $z_N(t_0) \in U$ and assume that $z_N(t_j) \in U$ for all $j = 1, \dots, m$ with some fixed $m \in \{1, \dots, k\}$. Then

$$\begin{aligned}
&|z_N(t_{m+1}) - u_N(t_{m+1})| \\
&\quad = |Az_N(t_{m+1} - \Delta) + z_N(t_m) - Az_N(t_m - \Delta) + h_N v_{N_m} \\
&\qquad -(Au_N(t_{m+1} - \Delta) + u_N(t_m) - Au_N(t_m - \Delta) + h_N \omega_{N_m})| \\
&\quad \le |A| \cdot |z_N(t_{m+1} - \Delta) - u_N(t_{m+1} - \Delta)| + |A| \cdot |z_N(t_m - \Delta) - u_N(t_m - \Delta)| \\
&\qquad + |z_N(t_m) - u_N(t_m)| + h_N \operatorname{dist}(\omega_{N_m}; F(z_N(t_m), z_N(t_m - \Delta), t_m)).
\end{aligned}$$

Taking into account that

$$\begin{aligned}
|z_N(t_m) - u_N(t_m)| &\le |z_N(t_{m-1}) - u_N(t_{m-1})| \\
&\quad + |A||z_N(t_{m-1-N}) - u_N(t_{m-1-N})| + |A||z_N(t_{m-N}) - u_N(t_{m-N})| \\
&\quad + h_N \operatorname{dist}(\omega_{N_{m-1}}; F(z_N(t_{m-1}), z_N(t_{m-1} - \Delta), t_{m-1}))
\end{aligned}$$

and that $|z_N(t_j) - u_N(t_j)| = 0$ for $j \le 0$, one has

$$\begin{aligned}
&|z_N(t_{m+1}) - u_N(t_{m+1})| \\
&\qquad \le M h_N \sum_{j=0}^{m} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t_j)) \le M\gamma_N
\end{aligned} \tag{2.5}$$

with some constant $M > 0$. Now invoking (2.2) and increasing M if necessary, we arrive at

$$|z_N(t_{m+1}) - \bar{x}(t_{m+1})| \le \xi_N + M\gamma_N \to 0 \quad \text{as } N \to \infty.$$

It remains to prove that the extended combinations $z_N(t) - Az_N(t - \Delta)$ converge to $\bar{x}(t) - A\bar{x}(t - \Delta)$ in the $W^{1,2}$-norm on $[a, b]$, which means that

$$\begin{aligned}
&\max_{t \in [a,b]} |z_N(t) - Az_N(t - \Delta) - [\bar{x}(t) - A\bar{x}(t - \Delta)]| \\
&\qquad + \int_a^b \left| \frac{d}{dt}[z_N(t) - Az_N(t - \Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t - \Delta)] \right|^2 dt \to 0
\end{aligned} \tag{2.6}$$

as $N \to \infty$. To furnish this, we use (2.5) and get the estimate

$$\begin{aligned}
\sum_{j=0}^{k+1} |z_N(t_j) - u_N(t_j)| &\le \sum_{j=0}^{k+1} M \sum_{m=0}^{j-1} h_N \operatorname{dist}(\omega_{N_m}; F(u_N(t_m), u_N(t_m - \Delta), t_m)) \\
&\le M(b - a) \sum_{j=0}^{k} \operatorname{dist}(\omega_{N_j}; F(u_N(t_j), u_N(t_j - \Delta), t_j)),
\end{aligned}$$

which by (H1) implies that

$$
\begin{aligned}
&\int_a^b \left|\frac{d}{dt}[z_N(t)-Az_N(t-\Delta)]-\omega_N(t)\right| dt\\
&\quad=\sum_{j=0}^{k}\int_{t_j}^{t_{j+1}}\left|\frac{d}{dt}[z_N(t)-Az_N(t-\Delta)]-\omega_N(t)\right| dt\\
&\quad=\sum_{j=0}^{k}\int_{t_j}^{t_{j+1}}|v_{N_j}-\omega_{N_j}|\,dt\\
&\quad=\sum_{j=0}^{k}h_N\,\mathrm{dist}(\omega_{N_j};F(z_N(t_j),z_N(t_j-\Delta),t_j))\\
&\quad=\sum_{j=0}^{k}h_N\,\mathrm{dist}(\omega_{N_j};F(u_N(t_j),u_N(t_j-\Delta),t_j))\\
&\qquad+\sum_{j=0}^{k}h_N[\mathrm{dist}(\omega_{N_j};F(z_N(t_j),z_N(t_j-\Delta),t_j))\\
&\qquad\qquad-\mathrm{dist}(\omega_{N_j};F(u_N(t_j),u_N(t_j-\Delta),t_j))]\\
&\quad\le\sum_{j=0}^{k}h_N\,\mathrm{dist}(\omega_{N_j};F(u_N(t_j),u_N(t_j-\Delta),t_j))\\
&\qquad+\sum_{j=0}^{k}\ell_F h_N[|z_N(t_j)-u_N(t_j)|+|z_N(t_j-\Delta)-u_N(t_j-\Delta)|]\\
&\quad\le\gamma_N+\sum_{j=0}^{k}\ell_F h_N[|z_N(t_j)-u_N(t_j)|+|z_N(t_j-\Delta)-u_N(t_j-\Delta)|]\\
&\quad\le\gamma_N+2M(b-a)\ell_F\sum_{j=0}^{k}h_N\,\mathrm{dist}(\omega_{N_j};F(u_N(t_j),u_N(t_j-\Delta),t_j))\\
&\quad\le\gamma_N+2M\ell_F(b-a)\gamma_N.
\end{aligned}
$$

The latter ensures the estimate

$$
\begin{aligned}
&\int_a^b\left|\frac{d}{dt}[z_N(t)-Az_N(t-\Delta)]-\frac{d}{dt}[\bar{x}(t)-A\bar{x}(t-\Delta)]\right| dt\\
&\qquad\le\int_a^b\left|\frac{d}{dt}[z_N(t)-Az_N(t-\Delta)]-\omega_N(t)\right| dt\\
&\qquad\quad+\int_a^b\left|\omega_N(t)-\frac{d}{dt}[\bar{x}(t)-A\bar{x}(t-\Delta)]\right| dt\\
&\qquad\le\gamma_N(1+2M(b-a)\ell_F)+\xi_N.
\end{aligned}
$$

Since $z_N(t)\in U$, it follows from (H1) by (1.2) and (2.4) that $|\frac{d}{dt}[z_N(t)-Az_N(t-\Delta)]|\le$

m_F, $|\frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)]| \le m_F$, and hence

$$\begin{aligned}
&\int_a^b \left| \frac{d}{dt}[z_N(t) - Az_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt \\
&\quad = \int_a^b \left| \frac{d}{dt}[z_N(t) - Az_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right| \\
&\qquad \times \left| \frac{d}{dt}[z_N(t) - Az_N(t-\Delta)] + \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right| dt \\
&\quad \le 2m_F[\gamma_N(1 + 2M(b-a)\ell_F) + \xi_N] \downarrow 0 \quad \text{as } N \to \infty.
\end{aligned}$$

Observing that

$$\begin{aligned}
&\max_{t\in[a,b]} |z_N(t) - Az_N(t-\Delta) - [\bar{x}(t) - A\bar{x}(t-\Delta)]| \\
&\quad \le \int_a^b \left| \frac{d}{dt}[z_N(t) - Az_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt,
\end{aligned}$$

we arrive at (2.6) and complete the proof of the theorem. □

3. Strong convergence of discrete optimal solutions. Our next goal is to construct a sequence of *well-posed* discrete approximations of the whole dynamic optimization problem (P) given in (1.1)–(1.4) such that optimal solutions to discrete approximation problems *strongly converge*, in the sense described below, to a *given* optimal solution $\bar{x}(\cdot)$ to the original optimization problem governed by neutral functional-differential inclusions. The following construction explicitly involves the optimal solution $\bar{x}(\cdot)$ to the problem (P) under consideration, for which we aim to derive necessary optimality conditions in the subsequent sections.

Given $\bar{x}(t)$, $a - \Delta \le t \le b$, take its approximation $z_N(t)$ from Theorem 2.1 and denote $\eta_N := |z_N(t_{k+1}) - \bar{x}(b)|$. For any natural number N we consider the following *discrete-time* dynamic optimization problem (P_N):

(3.1)

$$\begin{aligned}
\text{minimize} \quad J_N[x_N] &:= \varphi(x_N(t_0), x_N(t_{k+1})) + |x_N(t_0) - \bar{x}(a)|^2 \\
&\quad + h_N \sum_{j=0}^{k} f(x_N(t_j), x_N(t_j - \Delta), t_j) \\
&\quad + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left| \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right. \\
&\quad \left. - \frac{x_N(t_{j+1}) - Ax_N(t_{j+1} - \Delta) - x_N(t_j) + Ax_N(t_j - \Delta)}{h_N} \right|^2 dt
\end{aligned}$$

subject to the *dynamic constraints* governed by neutral functional-difference inclusions (2.1), the *endpoint constraints*

$$(x_N(t_0), x_N(t_{k+1})) \in \Omega_N := \Omega + \eta_N \mathbb{B}, \tag{3.2}$$

which are η_N-*perturbations* of the original endpoint constraints (1.4), and the auxiliary constraints

$$|x_N(t_j) - \bar{x}(t_j)| \le \varepsilon, \quad j = 1, \dots, k+1, \tag{3.3}$$

with some $\varepsilon > 0$. The latter auxiliary constraints are needed to guarantee the existence of optimal solutions in (P_N) and can be ignored in the derivation of necessary optimality conditions; see below.

In what follows we select $\varepsilon > 0$ in (3.3) such that $\bar{x}(t) + \varepsilon\mathbb{B} \subset U$ for all $t \in [a - \Delta, b]$ and take sufficiently large N ensuring that $\eta_N < \varepsilon$. Note that problems (P_N) have *feasible* solutions, since the trajectories z_N from Theorem 2.1 satisfy all the constraints (2.1), (3.2), and (3.3). Therefore, by the classical Weierstrass theorem in finite dimensions, each (P_N) admits an *optimal* solution $\bar{x}_N(\cdot)$ under the following assumption imposed in addition to (H1)–(H3), where U stands for a neighborhood of the optimal trajectory $\bar{x}(\cdot)$ to (P).

(H4) φ is continuous on $U \times U$, $f(x, y, \cdot)$ is continuous for a.e. $t \in [a, b]$ uniformly in $(x, y) \in U \times U$, $f(\cdot, \cdot, t)$ is continuous on $U \times U$ uniformly in $t \in [a, b]$, and Ω is locally closed around $(\bar{x}(a), \bar{x}(b))$.

We are going to justify the strong convergence of $\bar{x}_N(\cdot) \to \bar{x}(\cdot)$ in the sense of Theorem 2.1. To proceed, we need to involve an important intrinsic property of the original problem (P) called *relaxation stability*. Following the line originated by Jack Warga in optimal control theory (see the book [30] and its references), we consider the *relaxed* problem (R) of minimizing the cost functional (1.1) on admissible trajectories of the *convexified* functional-differential inclusion of the neutral type

$$\frac{d}{dt}[x(t) - Ax(t - \Delta)] \in \operatorname{co} F(x(t), x(t - \Delta), t) \quad \text{for a.e. } t \in [a, b] \tag{3.4}$$

with the initial "tail" condition (1.3) and the endpoint constraints (1.4). Any admissible trajectory for (3.4) satisfying (1.3) is called a *relaxed trajectory* for (1.2).

One clearly has $\inf(\mathrm{R}) \le \inf(\mathrm{P})$ for the optimal values of the cost functionals in the relaxed and original problems. We say that the original problem (P) is *stable with respect to relaxation* if

$$\inf(\mathrm{P}) = \inf(\mathrm{R}).$$

This property, which obviously holds under the convexity assumption on the sets $F(x, y, t)$, goes far beyond the convexity. General sufficient conditions for the relaxation stability of the neutral-type problem (P) follow from [14]. We also refer the reader to [2, 21, 23, 30] for more detailed discussions on the validity of the relaxation stability property for various classes of differential, functional-differential, and functional-integral control systems.

Now we are ready to establish the following strong convergence theorem for optimal solutions to discrete approximations, which makes a *bridge* between optimal control problems governed by neutral functional-differential and functional-difference inclusions.

THEOREM 3.1. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (P)*, which is assumed to be stable with respect to relaxation. Suppose also that hypotheses* (H1)–(H4) *hold. Then any sequence $\{\bar{x}_N(\cdot)\}$, $N \in \mathbb{N}$, of optimal solutions to (P_N) extended to the continuous interval $[a-\Delta, b]$ converges uniformly to $\bar{x}(\cdot)$ on $[a-\Delta, b]$, and the sequence of their combinations $\bar{x}_N(\cdot) - A\bar{x}_N(\cdot - \Delta)$ converges to $\bar{x}(\cdot) - A\bar{x}(\cdot - \Delta)$ in the $W^{1,2}$-norm on $[a, b]$ as $N \to \infty$.*

Proof. We know from the above discussion that (P_N) has an optimal solution $\bar{x}_N(\cdot)$ for all N sufficiently large; suppose that it happens for all $N \in \mathbb{N}$ without loss of generality. Given $\bar{x}(\cdot)$, we consider the sequence $\{z_N(\cdot)\}$ strongly approximating

$\bar{x}(\cdot)$ by Theorem 2.1. Since each z_N is feasible to (P_N), one has

$$J_N[\bar{x}_N] \le J_N[z_N] \quad \text{for all } N \in \mathbb{N}.$$

For convenience we represent $J_N[z_N]$ as the sum of three terms:

$$\begin{aligned} J_N[z_N] &= \varphi(z_N(t_0), z_N(t_{k+1})) + h_N \sum_{j=0}^{k} f(z_N(t_j), z_N(t_j-\Delta), t_j) \\ &\quad + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left| \frac{z_N(t_{j+1}) - Az_N(t_{j+1}-\Delta) - z_N(t_j) + Az_N(t_j-\Delta)}{h_N} \right. \\ &\qquad \left. - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt := I_{1N} + I_{2N} + I_{3N}. \end{aligned}$$

It follows from Theorem 2.1 and the assumption on φ in (H4) that

$$I_{1N} \to \varphi(\bar{x}(a), \bar{x}(b)) \quad \text{as } N \to \infty$$

and that, using the sign $\approx$ for expressions that are equivalent as $N \to \infty$,

$$\begin{aligned} I_{2N} &= h_N \sum_{j=0}^{k} f(z_N(t_j), z_N(t_j-\Delta), t_j) \\ &= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} f(z_N(t_j), z_N(t_j-\Delta), t)\, dt \\ &\quad + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} [f(z_N(t_j), z_N(t_j-\Delta), t_j) - f(z_N(t_j), z_N(t_j-\Delta), t)]\, dt \\ &= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} f(z_N(t_j), z_N(t_j-\Delta), t)\, dt + \tau(f; h_N) \\ &\approx \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} f(z_N(t_j), z_N(t_j-\Delta), t)\, dt \\ &\approx \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} f(\bar{x}(t_j), \bar{x}(t_j-\Delta), t)\, dt \\ &\to \int_a^b f(\bar{x}(t), \bar{x}(t-\Delta), t)\, dt \quad \text{as } N \to \infty, \\ I_{3N} &= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left| v_N(t) - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt \\ &= \int_a^b \left| v_N(t) - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt \\ &= \int_a^b \left| \frac{d}{dt}[z_N(t) - Az_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt \to 0 \quad \text{as } N \to \infty, \end{aligned}$$

where $v_N(t)$ stands for the extensions of combined discrete velocities for $z_N(\cdot)$; see

section 2. This implies that $J_N[z_N] \to J[\bar{x}]$ as $N \to \infty$, and therefore

$$\limsup_{N\to\infty} J_N[\bar{x}_N] \le J[\bar{x}]. \tag{3.5}$$

It is easy to observe that the strong convergence claimed in the theorem follows from

$$\rho_N := |\bar{x}_N(a) - \bar{x}(a)|^2 + \int_a^b \left| \frac{d}{dt}[\bar{x}_N(t) - A\bar{x}_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt \to 0 \quad \text{as } N \to \infty.$$

On the contrary, suppose that the latter does not hold. Then there are a constant $\alpha > 0$ and a subsequence $\{N_m\} \subset \mathbb{N}$ for which $\rho_{N_m} \to \alpha$ as $m \to \infty$. Employing the standard compactness arguments based on (2.1) and the boundedness assumption in (H1), we find an absolutely continuous function $\widetilde{z} : [a,b] \to \mathbb{R}^n$ and a function $\widetilde{x} : [a-\Delta, b]$ continuous on $[a-\Delta, a)$ and $[a,b]$ such that

$$\frac{d}{dt}[\bar{x}_N(t) - A\bar{x}_N(t-\Delta)] \to \dot{\widetilde{z}}(t) \quad \text{weakly in } L^2[a,b],$$

that $\bar{x}_N(t) \to \widetilde{x}(t)$ uniformly on $[a-\Delta, b]$ as $N \to \infty$ (without loss of generality), and that $\widetilde{z}(t) = \widetilde{x}(t) - A\widetilde{x}(t-\Delta)$ for $t \in [a,b]$. By the classical Mazur theorem, there is a sequence of *convex combinations* of $\frac{d}{dt}[\bar{x}_N(t) - A\bar{x}_N(t-\Delta)]$ that converges to $\frac{d}{dt}[\widetilde{x}(t) - A\widetilde{x}(t-\Delta)]$ in the norm topology of $L^2[a,b]$ and hence *pointwisely* for a.e. $t \in [a,b]$ along some subsequence. Therefore

$$\frac{d}{dt}[\widetilde{x}(t) - A\widetilde{x}(t-\Delta)] \in \operatorname{co} F(\widetilde{x}(t), \widetilde{x}(t-\Delta), t) \quad \text{for a.e. } t \in [a,b].$$

Since $\widetilde{x}(\cdot)$ obviously satisfies the tail condition (1.3) and the endpoint constraints (1.4), it is a feasible solution to the relaxed problem (R). Note that

$$\begin{aligned} h_N \sum_{j=0}^{k} f(\bar{x}_N(t_j), \bar{x}_N(t_j-\Delta), t_j) &= \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} f(\bar{x}_N(t_j), \bar{x}_N(t_j-\Delta), t_j)dt \\ &\to \int_a^b f(\widetilde{x}(t), \widetilde{x}(t-\Delta), t)dt \end{aligned}$$

as $N \to \infty$ due to the assumptions made. Observe also that the integral functional

$$I[v] := \int_a^b \left| v(t) - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt$$

is lower semicontinuous in the weak topology of $L^2[a,b]$ by the *convexity* of the integrand in v. Since one has

$$\begin{aligned} \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \Bigg| &\frac{\bar{x}_N(t_{j+1}) - A\bar{x}_N(t_{j+1}-\Delta) - [\bar{x}_N(t_j) - A\bar{x}_N(t_j-\Delta)]}{h_N} \\ &- \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \Bigg|^2 dt \\ = \int_a^b &\left| \frac{d}{dt}[\bar{x}_N(t) - A\bar{x}_N(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt, \end{aligned}$$

the latter implies that

$$\int_a^b \left| \frac{d}{dt}[\widetilde{x}(t) - A\widetilde{x}(t-\Delta)] - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt$$
$$\le \liminf_{N\to\infty} \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left| \frac{\bar{x}_N(t_{j+1}) - A\bar{x}_N(t_{j+1}-\Delta) - [\bar{x}_N(t_j) - A\bar{x}_N(t_j-\Delta)]}{h_N} \right.$$
$$\left. - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt.$$

Using the above relationships and passing to the limit in the expression (3.1) for $J_N[\bar{x}_N]$, we get

$$J[\widetilde{x}] + \alpha \le \lim_{N\to\infty} J_N[\bar{x}_N].$$

By (3.5) one therefore has

$$J[\widetilde{x}] \le J[\bar{x}] - \alpha < J[\bar{x}] \quad \text{if } \alpha > 0.$$

This clearly contradicts the optimality of $\bar{x}(\cdot)$ in the relaxed problem (R) due to the assumption on relaxation stability. Thus $\alpha = 0$, which completes the proof of the theorem. □

4. Tools of variational analysis. Convegence/stability results of the previous section allow us to make a bridge between the original infinite-dimensional optimization problem (P) for neutral functional-differential inclusions and the sequence of finite-dimensional dynamic optimization problems (P_N) for neutral functional-difference inclusions. Our strategy is first to obtain necessary optimality conditions for the latter finite-dimensional problems and then to derive necessary optimality conditions for the original problem (P) by passing to the limit from the ones for (P_N) as $N \to \infty$.

Observe that problems (P_N) are essentially *nonsmooth*, even in the case of smooth functions φ and f in the cost functional and the absence of endpoint constraints. The main source of nonsmoothness comes from the (increasing number of) geometric constraints in (2.1), which reflect the discrete dynamics and may have empty interiors. To conduct a variational analysis of such problems, we use appropriate tools of generalized differentiation introduced in [18] and then developed and applied in many publications; see, in particular, the books [19, 26, 29] for detailed treatments and further references.

Recall that the *basic/limiting normal cone* to the set $\Omega \subset \mathbb{R}^n$ at the point $\bar{x} \in \Omega$ is

$$N(\bar{x};\Omega) := \operatorname*{Limsup}_{x \overset{\Omega}{\to} \bar{x}} \widehat{N}(x;\Omega), \tag{4.1}$$

where $x \overset{\Omega}{\to} \bar{x}$ means that $x \to \bar{x}$ with $x \in \Omega$, and where

$$\widehat{N}(\bar{x};\Omega) := \left\{ x^* \in \mathbb{R}^n \mid \limsup_{x \overset{\Omega}{\to} \bar{x}} \frac{\langle x^*, x - \bar{x}\rangle}{|x - \bar{x}|} \le 0 \right\} \tag{4.2}$$

is the cone of Fréchet (or regular) normals to Ω at $\bar{x}$. For convex sets Ω both cones

$N(\bar{x};\Omega)$ and $\widehat{N}(\bar{x};\Omega)$ reduce to the normal cone of convex analysis. Note that the basic normal cone (4.1) is often *nonconvex* while satisfying a comprehensive calculus, in contrast to (4.2).

Given an extended real-valued function $\varphi : \mathbb{R}^n \to \overline{\mathbb{R}} := [-\infty, \infty]$ finite at $\bar{x}$, the *subdifferential* of φ at $\bar{x}$ is defined geometrically as

$$\partial\varphi(\bar{x}) := \{x^* \in \mathbb{R}^n \mid (x^*, -1) \in N((\bar{x}, \varphi(\bar{x})); \operatorname{epi}\varphi)\} \tag{4.3}$$

via basic normals to the epigraph $\operatorname{epi}\varphi := \{(x,\mu) \in \mathbb{R}^{n+1} \mid \mu \geq \varphi(x)\}$; equivalent analytic representations of (4.3) can be found in [19, 26, 29].

Given a set-valued mapping $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ with the graph $\operatorname{gph} F := \{(x,y) \in \mathbb{R}^n \times \mathbb{R}^m \mid y \in F(x)\}$, the *coderivative* $D^*F(\bar{x},\bar{y}) : \mathbb{R}^m \rightrightarrows \mathbb{R}^n$ of F at $(\bar{x},\bar{y}) \in \operatorname{gph} F$ is defined by

$$D^*F(\bar{x},\bar{y})(y^*) := \{x^* \in \mathbb{R}^n \mid (x^*, -y^*) \in N((\bar{x},\bar{y}); \operatorname{gph} F)\}. \tag{4.4}$$

Note the useful relationships

$$\partial\varphi(\bar{x}) = D^*E_\varphi(\bar{x}, \varphi(\bar{x}))(1) \qquad \text{and} \qquad D^*g(\bar{x})(y^*) = \partial\langle y^*, g\rangle(\bar{x}), \quad y^* \in \mathbb{R}^m,$$

between the subdifferential and coderivative introduced, where $E_\varphi(x) := \{\mu \in \mathbb{R} \mid \mu \geq \varphi(x)\}$ is the epigraphical multifunctions associated with $\varphi : \mathbb{R}^n \to \overline{\mathbb{R}}$ and where $\langle y^*, g\rangle(x) := \langle y^*, g(x)\rangle$ is the scalarized function associated with a locally Lipschitzian mapping $g : \mathbb{R}^n \to \mathbb{R}^m$.

The subdifferential/coderivative constructions (4.3) and (4.4) enjoy a variety of useful calculus rules that can be found in the books mentioned above and their references. Let us formulate two results crucial in what follows. The first one gives a complete coderivative characterization of the classical local Lipschitzian property of multifunctions imposed in our standing assumption (H1); cf. [20, Theorem 5.11] and [26, Theorem 9.40].

THEOREM 4.1. *Let $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ be a closed-graph multifunction locally bounded around $\bar{x}$. Then the following conditions are equivalent.*

(i) *F is locally Lipschitzian around $\bar{x}$.*

(ii) *There exist a neighborhood U of $\bar{x}$ and a number $\ell > 0$ such that*

$$\sup\{|x^*| \mid x^* \in D^*F(x,y)(y^*)\} \leq \ell|y^*| \quad \text{for all } x \in U,\ y \in F(x),\ y^* \in \mathbb{R}^m.$$

The next result taken from [19, Corollary 7.5] provides necessary optimality conditions for a general problem (MP) of *nonsmooth mathematical programming* with many geometric constraints:

$$\begin{cases} \text{minimize } \phi_0(z) & \text{subject to} \\ \phi_j(z) \leq 0, & j = 1, \ldots, r, \\ g_j(z) = 0, & j = 0, \ldots, m, \\ z \in \Lambda_j, & j = 0, \ldots, l, \end{cases}$$

where $\phi_j : \mathbb{R}^d \to \mathbb{R}$, $g_j : \mathbb{R}^d \to \mathbb{R}^n$, and $\Lambda_j \subset \mathbb{R}^d$.

THEOREM 4.2. *Let $\bar{z}$ be an optimal solution to* (MP). *Assume that all ϕ_i are Lipschitz continuous, that g_j are continuously differentiable, and that Λ_j are locally*

closed near $\bar{z}$. *Then there exist real numbers* $\{\mu_j \mid j = 0, \dots, r\}$ *as well as vectors* $\{\psi_j \in \mathbb{R}^n \mid j = 0, \dots, m\}$ *and* $\{z_j^* \in \mathbb{R}^d \mid j = 0, \dots, l\}$, *not all zero, such that*

$$\mu_j \geq 0 \quad \text{for } j = 0, \dots, r, \tag{4.5}$$

$$\mu_j \phi_j(\bar{z}) = 0 \quad \text{for } j = 1, \dots, r, \tag{4.6}$$

$$z_j^* \in N(\bar{z}; \Lambda_j) \quad \text{for } j = 0, \dots, l, \tag{4.7}$$

$$-\sum_{j=0}^{l} z_j^* \in \partial\left(\sum_{j=0}^{r} \mu_j \phi_j\right)(\bar{z}) + \sum_{j=0}^{m} \nabla g_j(\bar{z})^* \psi_j. \tag{4.8}$$

For applications in this paper in the case of nonautonomous continuous-time systems we need the following modifications of the basic constructions (4.1), (4.3), and (4.4) for sets, functions, and set-valued mappings *depending on a parameter* t from a topological space T (in our case $T = [a, b]$).

Given $\Omega : T \rightrightarrows \mathbb{R}^n$ and $\bar{x} \in \Omega(\bar{t})$, we define the *extended normal cone* to $\Omega(\bar{t})$ at $\bar{x}$ by

$$\widetilde{N}(\bar{x}; \Omega(\bar{t})) := \operatorname*{Limsup}_{(t,x) \overset{\text{gph}\Omega}{\to} (\bar{t},\bar{x})} \widehat{N}(x; \Omega(t)). \tag{4.9}$$

For $\varphi : \mathbb{R}^n \times T \to \overline{\mathbb{R}}$ finite at $(\bar{x}, \bar{t})$ and for $F : \mathbb{R}^n \times T \rightrightarrows \mathbb{R}^m$ with $\bar{y} \in F(\bar{x}, \bar{t})$, the *extended subdifferential* of φ at $(\bar{x}, \bar{t})$ and the *extended coderivative* of F at $(\bar{x}, \bar{y}, \bar{t})$ with respect to x are given, respectively, by

$$\widetilde{\partial}_x \varphi(\bar{x}, \bar{t}) := \{x^* \in \mathbb{R}^n \mid (x^*, -1) \in \widetilde{N}((\bar{x}, \varphi(\bar{x}, \bar{t})); \operatorname{epi} \varphi(\cdot, \bar{t}))\} \tag{4.10}$$

and, whenever $y^* \in \mathbb{R}^m$, by

$$\widetilde{D}_x^* F(\bar{x}, \bar{y}, \bar{t})(y^*) := \{x^* \in \mathbb{R}^n \mid (x^*, -y^*) \in \widetilde{N}((\bar{x}, \bar{y}); \operatorname{gph} F(\cdot, \bar{t}))\}. \tag{4.11}$$

Note that the sets (4.9)–(4.11) may be bigger in some situations than the corresponding sets $N(\bar{x}; \Omega(\bar{t}))$, $\partial_x \varphi(\bar{x}, \bar{t})$, and $D_x^* F(\bar{x}, \bar{y}, \bar{t})(y^*)$, where the latter two sets stand for the subdifferential (4.3) of $\varphi(\cdot, \bar{t})$ at $\bar{x}$ and the coderivative (4.4) of $F(\cdot, \bar{t})$ at $(\bar{x}, \bar{y}, \bar{t})$, respectively. Efficient conditions ensuring equalities for these sets are discussed in [21, 22, 24].

It is not hard to check that the extended constructions (4.9)–(4.11) are *robust* with respect to their variables, which is important for performing limiting procedures in what follows. In particular,

$$\widetilde{N}(\bar{x}; \Omega(\bar{t})) = \operatorname*{Lim\,sup}_{(t,x) \overset{\text{gph}\Omega}{\to} (\bar{t},\bar{x})} \widetilde{N}(x; \Omega(t)). \tag{4.12}$$

Note also that the constructions (4.9)–(4.11) enjoy a full generalized differential calculus similar to (4.1), (4.3), and (4.4). We are not going to use this calculus in the present paper.

5. Necessary optimality conditions for discrete approximations. This section concerns necessary optimality conditions for discrete approximation problems (P_N) governed by neutral functional-difference inclusions. We derive such conditions in the extended Euler–Lagrange form by reducing (P_N) to nonsmooth mathematical

programs with many geometric constraints and employing generalized differential calculus for the basic constructions (4.1), (4.3), and (4.4).

Let us reduce the dynamic optimization problem (P_N) for each $N \in \mathbb{N}$ to the mathematical programming problem (MP) considered in section 4 with the decision vector

$$z := (x_0^N, x_1^N, \dots, x_{k+1}^N, v_0^N, v_1^N, \dots, v_k^N) \in \mathbb{R}^{n(2k+3)}$$

and the following data:

$$\begin{aligned}
\phi_0(z) :&= \varphi(x_0^N, x_{k+1}^N) + |x_0^N - \bar{x}(a)|^2 + h_N \sum_{j=0}^{k} f(x_j^N, x_{j-N}^N, t_j) \\
&\quad + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} \left| v_j^N - \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \right|^2 dt, \\
\phi_j(z) :&= |x_j^N - \bar{x}(t_j)| - \varepsilon, \quad j = 1, \dots, k+1, \\
\Lambda_j :&= \{(x_0^N, \dots, v_k^N) \mid v_j^N \in F(x_j^N, x_{j-N}^N, t_j)\}, \quad j = 0, \dots, k, \\
\Lambda_{k+1} :&= \{(x_0^N, \dots, v_k^N) \mid (x_0^N, x_{k+1}^N) \in \Omega_N\}, \\
g_j(z) :&= x_{j+1}^N - Ax_{j+1-N}^N - x_j^N + Ax_{j-N}^N - h_N v_j^N, \quad j = 0, \dots, k,
\end{aligned} \tag{5.1}$$

where $x_j^N := c(t_j)$ for $j < 0$. Let $\bar{z}^N = (\bar{x}_0^N, \dots, \bar{x}_{k+1}^N, \bar{v}_0^N, \dots, \bar{v}_k^N)$ be an optimal solution to (MP). Applying Theorem 4.2, we find real numbers μ_j^N and vectors $z_j^* \in \mathbb{R}^{n(2k+3)}$ for $j = 0, \dots, k+1$ as well as vectors $\psi_j^N \in \mathbb{R}^n$ for $j = 0, \dots, k$, not all zero, such that conditions (4.5)–(4.8) are satisfied.

Taking $z_j^* = (x_{0,j}^*, \dots, x_{k+1,j}^*, v_{0,j}^*, \dots, v_{k,j}^*) \in N(\bar{z}^N; \Lambda_j)$ for $j = 0, \dots, k$, we observe that all components of z_j^* are zero except one, and the remaining one satisfies

$$(x_{j,j}^*, x_{j-N,j}^*, v_{j,j}^*) \in N((\bar{x}_j^N, \bar{x}_{j-N}^N, \bar{v}_j^N); \operatorname{gph} F(\cdot, \cdot, t_j)), \quad j = 0, \dots, k.$$

Similarly, the condition $z_{k+1}^* \in N(\bar{z}^N; \Lambda_{k+1})$ is equivalent to

$$(x_{0,k+1}^*, x_{k+1,k+1}^*) \in N((\bar{x}_0^N, \bar{x}_{k+1}^N); \Omega_N),$$

with all the other components of z_{k+1}^* equal to zero. Applying Theorem 3.1 to the convergence of discrete approximations, we have $\phi_j(\bar{z}^N) < 0$ for $j = 1, \dots, k+1$ whenever N is sufficiently large. Thus $\mu_j^N = 0$ for these indexes due to the complementary slackness conditions (4.6). Let $\lambda^N := \mu_0^N \geq 0$. Observe further that

$$\begin{aligned}
&\sum_{j=0}^{k} (\nabla g_j(\bar{z}^N))^* \psi_j^N \\
&\quad = \big(-\psi_0 + A^*(\psi_N^N - \psi_{N-1}^N), \psi_0 - \psi_1 + A^*(\psi_{N+1}^N - \psi_N^N), \dots, \\
&\qquad \psi_{k-N-1} - \psi_{k-N} + A^*(\psi_k^N - \psi_{k-1}^N), \psi_{k-N} - \psi_{k-N+1} + A^*\psi_k^N, \dots, \\
&\qquad \psi_{k-1}^N - \psi_k^N, \psi_k^N, -h_N\psi_0^N, \dots, -h_N\psi_k^N\big).
\end{aligned}$$

From the subdifferential sum rule for ϕ_0 in (5.1) one has

$$\partial\phi(\bar z^N) \subset \partial\varphi(\bar x_0^N, \bar x_{k+1}^N) + 2(\bar x_0^N - \bar x(a)) + h_N \sum_{j=0}^{k} \partial f(\bar x_j^N, \bar x_{j-N}^N, t_j) + \sum_{j=0}^{k} \int_{t_j}^{t_{j+1}} 2\left(\bar v_j^N - \frac{d}{dt}[\bar x(t) - A\bar x(t-\Delta)]\right) dt,$$

with ∂f standing here and in what follows for the basic subdifferential of f with respect to the first two variables. Thus the inclusion (4.8) in Theorem 4.2 is equivalent to the relationships

$$\begin{aligned}
-x_{0,0}^* - x_{0,N}^* - x_{0,k+1}^* &= \lambda^N u_0^N + \lambda^N h_N \vartheta_0^N + \lambda^N h_N \kappa_0^N + 2\lambda^N(\bar x_0^N - \bar x(a)) \\
&\quad -\psi_0^N - A^*(\psi_{N-1}^N - \psi_N^N), \\
-x_{j,j}^* - x_{j,j+N}^* &= \lambda^N h_N \kappa_j^N + \lambda^N h_N \vartheta_j^N + \psi_{j-1}^N - \psi_j^N \\
&\quad -A^*(\psi_{j+N-1}^N - \psi_{j+N}^N), \quad j = 1, \dots, k-N, \\
-x_{k-N+1,k-N+1}^* &= \lambda^N h_N v_{k-N+1}^N + \psi_{k-N}^N - \psi_{k-N+1}^N + A^*\psi_k^N, \\
-x_{j,j}^* &= \lambda^N h_N \vartheta_j^N + \psi_{j-1}^N - \psi_j^N, \quad j = k-N+2, \dots, k, \\
-x_{k+1,k+1}^* &= \lambda^N u_{k+1}^N + \psi_k^N, \\
-v_{j,j}^* &= \lambda^N \theta_j^N - h_N \psi_j^N, \quad j = 0, \dots, k,
\end{aligned}$$

with the notation

$$(u_0^N, u_{k+1}^N) \in \partial\varphi(\bar x_0^N, \bar x_{k+1}^N), \qquad (\vartheta_j^N, \kappa_{j-N}^N) \in \partial f(\bar x_j^N, \bar x_{j-N}^N, t_j),$$
$$\theta_j^N := -2\int_{t_j}^{t_{j+1}} \left(\frac{d}{dt}[\bar x(t) - A\bar x(t-\Delta)] - \bar v_j^N\right) dt.$$

Based on the above relationships, we arrive at the following necessary optimality conditions for discrete-time problems (P_N), where $f_j(\cdot,\cdot) := f(\cdot,\cdot,t_j)$ and $F_j(\cdot,\cdot) := F(\cdot,\cdot,t_j)$.

THEOREM 5.1. *Let $\bar z^N$ be an optimal solution to problem (P_N). Assume that the sets Ω and $\operatorname{gph} F_j$ are closed and that the functions φ and f_j are Lipschitz continuous around the points $(\bar x_0^N, \bar x_{k+1}^N)$ and $(\bar x_j^N, \bar x_{j-N}^N)$, respectively, for all $j = 0, \dots, k$. Then there exist $\lambda^N \ge 0$, p_j^N $(j = 0, \dots, k+N+1)$, and q_j^N $(j = -N, \dots, k+1)$, not all zero, such that*

$$p_j^N = 0, \quad j = k+2, \dots, k+N+1, \tag{5.2}$$

$$q_j^N = 0, \quad j = k-N+1, \dots, k+1, \tag{5.3}$$

$$(p_0^N + q_0^N, -p_{k+1}^N) \in \lambda^N \partial\varphi(\bar x_0^N, \bar x_{k+1}^N) + N((\bar x_0^N, \bar x_{k+1}^N); \Omega_N), \tag{5.4}$$

$$\begin{aligned}
&\left(\frac{P_{j+1}^N - P_j^N}{h_N}, \frac{Q_{j-N+1}^N - Q_{j-N}^N}{h_N}, -\frac{\lambda^N \theta_j^N}{h_N} + p_{j+1}^N + q_{j+1}^N\right) \\
&\quad \in \lambda^N(\partial f_j(\bar x_j^N, \bar x_{j-N}^N), 0) + N((\bar x_j^N, \bar x_{j-N}^N, \bar v_j^N); \operatorname{gph} F_j), \quad j = 0, \dots, k,
\end{aligned} \tag{5.5}$$

with the notation

$$P_j^N := p_j^N - A^* p_{j+N}^N, \qquad Q_j^N := q_j^N - A^* q_{j+N}^N,$$
$$\bar{v}_j^N := \frac{(\bar{x}_{j+1}^N - \bar{x}_j^N) + A(x_{j-N}^N - x_{j-N+1}^N)}{h_N}.$$

Proof. Actually, most of the proof has been done above—we just need to change notation in the relationships formulated right before the theorem. First let

$$\widetilde{p}_j^N := \begin{cases} \psi_{j-1}^N & \text{for } j = 1, \dots, k+1, \\ 0 & \text{for } j = k+2, \dots, k+N+1, \end{cases}$$
$$\widetilde{q}_j^N := \begin{cases} x_{j,j+N}^*/h_N & \text{for } j = -N, \dots, -1, \\ \lambda^N \kappa_j^N + x_{j,j+N}^*/h_N & \text{for } j = 0, \dots, k-N, \\ 0 & \text{for } j = k-N+1, \dots, k+1, \end{cases}$$

and then define q_j^N for $j = -N, \dots, k+1$ by the recurrent formula

$$q_j^N := q_{j+1}^N - A^*(q_{j+N+1}^N + q_{j+N}^N) - h_N \widetilde{q}_j^N,$$

where we put $q_j^N := 0$ for $j > k+1$. Observe that

$$\left(\frac{(\widetilde{p}_{j+1}^N - q_{j+1}^N) - A^*(\widetilde{p}_{j+N+1}^N - q_{j+N+1}^N) - (\widetilde{p}_j^N - q_j^N) + A^*(\widetilde{p}_{j+N}^N - q_{j+N}^N)}{h_N}, \right.$$
$$\left. \frac{(q_{j-N+1}^N - A^* q_{j+1}^N) - (q_{j-N}^N - A^* q_j^N)}{h_N}, -\frac{\lambda^N \theta_j^N}{h_N} + \widetilde{p}_{j+1}^N \right)$$
$$\in \lambda^N(\partial f_j(\bar{x}_j^N, \bar{x}_{j-N}^N), 0) + N((\bar{x}_j^N, \bar{x}_{j-N}^N, \bar{v}_j^N); \operatorname{gph} F_j), \quad j = 0, \dots, k.$$

Finally letting

$$p_0^N := \lambda^N u_0^N + x_{0,k+1}^* - q_0^N, \qquad p_j^N := \widetilde{p}_j^N - q_j^N \quad \text{for } j = 1, \dots, k+N+1,$$

we can easily check that all the relationships (5.2)–(5.5) hold. □

Corollary 5.2. *In addition to the assumptions of Theorem* 5.1*, suppose that the mapping F_j is bounded and Lipschitz continuous around $(\bar{x}_j^N, \bar{x}_{j-N}^N)$ for each $j = 0, \dots, k$. Then conditions $\lambda^N \ge 0$ and* (5.2)–(5.5) *hold with $(\lambda^N, p_{k+1}^N) \ne 0$; i.e., one can let*

$$(\lambda^N)^2 + |p_{k+1}^N|^2 = 1. \tag{5.6}$$

Proof. If $\lambda^N = 0$, then (5.5) together with (5.2) and (5.3) imply that

$$\left(\frac{p_{k+1}^N - p_k^N}{h_N}, \frac{-q_{k-N}^N}{h_N} \right) \in D^* F_k(\bar{x}_k^N, \bar{x}_{k-N}^N, \bar{v}_k^N)(-p_{k+1}^N).$$

Assuming now that $p_{k+1}^N = 0$, we get

$$\left(\frac{-p_k^N}{h_N}, \frac{-q_{k-N}^N}{h_N} \right) \in D^* F_k(\bar{x}_k^N, \bar{x}_{k-N}^N, \bar{v}_k^N)(0),$$

which yield $p_k^N = q_{k-N}^N = 0$ by Theorem 4.1. Repeating the above procedure, we arrive at a contradiction with the nontriviality assertion in Theorem 5.1. □

6. Optimality conditions for functional-differential inclusions. In this section we obtain the main results of the paper, providing necessary optimality conditions for the original dynamic optimization problem (P) in both extended Euler–Lagrange and Hamiltonian forms involving generalized differential constructions of section 4. Our major theorem establishes the following conditions of the Euler–Lagrange type derived by the limiting procedure from discrete approximations. Note that here $\Delta > 0$ as was assumed in section 2.

THEOREM 6.1. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (P) *under hypotheses* (H1)–(H4)*, where φ and $f(\cdot,\cdot,t)$ are assumed to be Lipschitz continuous instead of the plain continuity. Suppose also that* (P) *is stable with respect to relaxation. Then there exist a number $\lambda \ge 0$ and piecewise continuous functions $p : [a, b+\Delta] \to \mathbb{R}^n$ and $q : [a-\Delta, b] \to \mathbb{R}^n$ (whose points of discontinuity are confined to multiples of the delay time Δ) such that $p(t) - A^*p(t+\Delta)$ and $q(t-\Delta) - A^*q(t)$ are absolutely continuous on $[a,b]$ and the following conditions hold:*

$$\lambda + |p(b)| = 1, \tag{6.1}$$

$$p(t) = 0 \quad \text{for } t \in (b, b+\Delta], \qquad q(t) = 0 \quad \text{for } t \in (b-\Delta, b], \tag{6.2}$$

$$(p(a) + q(a), -p(b)) \in \lambda \partial \varphi(\bar{x}(a), \bar{x}(b)) + N((\bar{x}(a), \bar{x}(b)); \Omega), \tag{6.3}$$

$$\begin{aligned} &\left(\frac{d}{dt}[p(t) - A^*p(t+\Delta)], \frac{d}{dt}[q(t-\Delta) - A^*q(t)] \right) \\ &\quad \in \operatorname{co} \Big\{ (u, w, p(t) + q(t)) \in \lambda(\widetilde{\partial} f(\bar{x}(t), \bar{x}(t-\Delta), t), 0) \\ &\qquad + \widetilde{N}\Big(\Big(\bar{x}(t), \bar{x}(t-\Delta), \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \Big); \\ &\qquad\qquad \operatorname{gph} F(\cdot,\cdot,t) \Big) \Big\} \quad \text{for a.e. } t \in [a,b]. \end{aligned} \tag{6.4}$$

Proof. To prove this theorem by the method of discrete approximations, we first construct a sequence of discrete-time problems (P_N) whose optimal solutions $\bar{x}_N$ strongly approximate $\bar{x}(\cdot)$ in the sense of Theorem 2.1. By necessary optimality conditions for $\bar{x}_N$ from Corollary 5.2 we find $\lambda_N \ge 0$, p_j^N, and q_j^N satisfying relationships (5.2)–(5.6) for all $N \in \mathbb{N}$.

Without loss of generality we suppose that $\lambda^N \to \lambda$ as $N \to \infty$ for some $\lambda \ge 0$. As usual, the symbols $\bar{x}^N(t)$, $p^N(t)$, $q^N(t-\Delta)$, $P^N(t)$, and $Q^N(t)$ stand for the piecewise linear extensions of the corresponding discrete functions from Theorem 5.1 with their piecewise constant derivatives on the continuous-time interval $[a,b]$.

Considering θ_j from Theorem 5.1, we define $\theta^N(t) := \theta_j^N / h_N$ for $t \in [t_j, t_{j+1})$ as $j = 0, \dots, k$ and conclude by Theorem 2.1 that

$$\begin{aligned} \int_a^b |\theta^N(t)|\, dt &= \sum_{j=0}^k |\theta_j^N| \le 2 \sum_{j=0}^k \int_{t_j}^{t_{j+1}} \left| \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] - \bar{v}_j^N \right| dt \\ &= 2 \int_a^b \left| \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] - \frac{d}{dt}[\bar{x}^N(t) - A\bar{x}^N(t-\Delta)] \right| dt := \nu_N \to 0 \end{aligned}$$

as $N \to \infty$. We may assume without loss of generality that

$$\bar{v}^N(t) := \frac{d}{dt}[\bar{x}^N(t) - A\bar{x}^N(t-\Delta)] \to \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)] \qquad \text{and} \qquad \theta^N(t) \to 0$$

for a.e. $t \in [a,b]$ as $N \to \infty$; such a *pointwise* convergence plays a significant role in what follows.

Let us estimate $(p^N(t), q^N(t-\Delta))$ for large N. Using (5.2) and (5.3), we derive from (5.5) that

$$\left(\frac{p^N_{j+1}-p^N_j}{h_N} - \lambda^N\vartheta^N_j, \frac{q^N_{j-N+1}-q^N_{j-N}}{h_N} - \lambda^N\kappa^N_{j-N}, -\frac{\lambda^N\theta^N_j}{h_N} + p^N_{j+1}\right)$$
$$\in N((\bar{x}^N_j, \bar{x}^N_{j-N}, \bar{v}^N_j); \operatorname{gph} F_j) \quad \text{with some } (\vartheta^N_j, \kappa^N_{j-N}) \in \partial f_j(\bar{x}^N_j, \bar{x}^N_{j-N})$$

for $j = k-N+2, \ldots, k+N+1$. This means, by definition of the coderivative (4.4), that

$$\left(\frac{p^N_{j+1}-p^N_j}{h_N} - \lambda^N\vartheta^N_j, \frac{q^N_{j-N+1}-q^N_{j-N}}{h_N} - \lambda^N\kappa^N_{j-N}\right)$$
$$\in D^*F_j(\bar{x}^N_j, \bar{x}^N_{j-N}, \bar{v}^N_j)\left(\frac{\lambda^N\theta^N_j}{h_N} - p^N_{j+1}\right)$$

for such j. Thus it follows from Theorem 4.1 that

$$\left|\left(\frac{p^N_{j+1}-p^N_j}{h_N} - \lambda^N\vartheta^N_j, \frac{q^N_{j-N+1}-q^N_{j-N}}{h_N} - \lambda^N\kappa^N_{j-N}\right)\right| \le \ell_F\left|\frac{\lambda^N\theta^N_j}{h_N} - p^N_{j+1}\right|$$

for $j = k-N+2, \ldots, k+N+1$. Since $|(\vartheta^N_j, \kappa^N_{j-N})| \le \ell_f$ due to the Lipschitz continuity of f with modulus ℓ_f, we derive from the above that

$$\begin{aligned}
&|(p^N_j, q^N_{j-N})| \\
&\quad \le \ell_F|\theta^N_j| + (\ell_F+1)h_N\ell_f + (\ell_F h_N+1)|(p^N_{j+1}, q^N_{j-N+1})| \\
&\quad \le \ell_F|\theta^N_j| + (\ell_F h_N+1)\ell_F|\theta^N_{j+1}| + (\ell_F+1)h_N\ell_f \\
&\qquad + (\ell_F h_N+1)(\ell_F+1)h_N\ell_f + (\ell_F h_N+1)^2|(p^N_{j+2}, q^N_{j-N+2})| \le \cdots \\
&\quad \le \exp[\ell_F(b-a)](1+\ell_f(\ell_F+1)/\ell_F + \ell_F\nu_N), \quad j = k-N+2, \ldots, k+N+1,
\end{aligned}$$

which implies the uniform boundedness of $\{(p^N_j, q^N_{j-N}) \mid j = k-N+2, \ldots, k+N+1\}$ and hence of $(p^N(t), q^N(t-\Delta))$ on $[b-\Delta, b]$.

Next we consider $j = k-2N+2, \ldots, k+1$ and derive from (5.5) that

$$\left|\left(\frac{p^N_{j+1}-p^N_j}{h_N} - \lambda^N\vartheta^N_j, \frac{q^N_{j-N+1}-q^N_{j-N}}{h_N} - \lambda^N\kappa^N_{j-N}\right)\right|$$
$$\le \ell_F\left|\frac{\lambda^N\theta^N_j}{h_N} - p^N_{j+1} - q^N_{j+1}\right| + \left|\left(\frac{A^*p^N_{j+N+1} - A^*p^N_{j+N}}{h_N}, \frac{A^*q^N_{j+1} - A^*q^N_j}{h_N}\right)\right|.$$

This implies, due to Theorem 4.1 and the uniform boundedness of p^N_{j+N} and q^N_j by some constant $\alpha > 0$ for such j, that

$$\left|\left(\frac{p^N_{j+1}-p^N_j}{h_N} - \lambda^N\vartheta^N_j, \frac{q^N_{j-N+1}-q^N_{j-N}}{h_N} - \lambda^N\kappa^N_{j-N}\right)\right|$$
$$\le \ell_F\left|\frac{\lambda^N\theta^N_j}{h_N} - p^N_{j+1} - q^N_{j+1}\right| + \frac{\alpha}{h_N}$$

for $j = k - 2N + 2, \dots, k + 1$. Therefore

$$\begin{aligned}
&|(p_j^N, q_{j-N}^N)| \\
&\quad \le \ell_F|\theta_j^N| + (\ell_F + 1)h_N\ell_f + (\ell_F h_N + 1)|(p_{j+1}^N, q_{j-N+1}^N)| + (\ell_F h_N + 1)\alpha \\
&\quad \le \ell_F|\theta_j^N| + (\ell_F h_N + 1)\ell_F|\theta_{j+1}^N| + (\ell_F + 1)h_N\ell_f + (\ell_F h_N + 1)(\ell_F + 1)h_N\ell_f \\
&\qquad + (\ell_F h_N + 1)(\ell_F + 1)\alpha + (\ell_F h_N + 1)^2|(p_{j+2}^N, q_{j-N+2}^N)| \le \cdots \\
&\quad \le \exp[\ell_F(b-a)](1 + (\ell_f + \alpha)(\ell_F + 1)/\ell_F + \ell_F\nu_N), \quad j = k - 2N + 2, \dots, k + 1.
\end{aligned}$$

This shows that p_j^N and q_{j-N}^N are uniformly bounded for $j = k - 2N + 2, \dots, k + 1$, and hence the sequence $\{p^N(t), q^N(t - \Delta)\}$ is uniformly bounded on $[b - 2\Delta, b - \Delta]$. Repeating the above procedure, we conclude that both sequences $\{p^N(t), q^N(t - \Delta)\}$ and $\{P^N(t), Q^N(t - \Delta)\}$ are uniformly bounded on the whole interval $[a, b]$.

Next we estimate $(\dot{P}^N(t), \dot{Q}^N(t - \Delta))$ on $[a, b]$ using (5.5) and Theorem 4.1. This yields, for $t_j \le t < t_{j+1}$ with $j = 0, \dots, k$, that

$$\begin{aligned}
&|(\dot{P}^N(t), \dot{Q}^N(t - \Delta))| \\
&\qquad = \left| \left(\frac{P_{j+1}^N - P_j^N}{h_N}, \frac{Q_{j-N+1}^N - Q_{j-N}^N}{h_N} \right) \right| \\
&\qquad \le \ell_F \left| \frac{\lambda^N\theta_j^N}{h_N} - p_{j+1}^N - q_{j+1}^N \right| + \ell_f \le \ell_F|\theta_j^N| + \ell_F|p_{j+1}^N| + \ell_F|q_{j+1}^N| + \ell_f.
\end{aligned}$$

Thus the sequence $\{\dot{P}^N(t), \dot{Q}^N(t - \Delta)\}$ is weakly compact in $L^1[a, b]$. Taking the whole sequence of $N \in \mathbb{N}$ without loss of generality, we find two absolutely continuous functions $P(\cdot)$ and $Q(\cdot - \Delta)$ on $[a, b]$ such that

$$\dot{P}^N(t) \to \dot{P}(t), \quad \dot{Q}^N(t - \Delta) \to \dot{Q}(t - \Delta) \quad \text{weakly in } L^1[a, b]$$

and $P^N(t) \to P(t)$, $Q^N(t - \Delta) \to Q(t - \Delta)$ uniformly on $[a, b]$ as $N \to \infty$. Since $p^N(t)$ and $q^N(t - \Delta)$ are uniformly bounded on $[a, b + \Delta]$, they surely converge to some functions $p(t)$ and $q(t - \Delta)$ weakly in $L^1[a, b + \Delta]$. Taking into account the above convergence of $P^N(t)$ and $Q^N(t - \Delta)$, we get that $p(\cdot)$ and $q(\cdot)$ satisfy (6.2), that

$$P(t) = p(t) - A^*p(t + \Delta), \quad Q(t - \Delta) = q(t - \Delta) - A^*q(t), \quad t \in [a, b],$$

and that $p(t)$ and $q(t)$ are piecewise continuous on $[a, b+\Delta]$ and $[a-\Delta, b]$, respectively, with possible discontinuity (from the right) at the points $b - i\Delta$ at $i = 0, 1, \dots$. Conditions (6.1) and (6.3) follow by passing to the limit from (5.6) and (5.4), respectively, taking into account the robustness of the basic subdifferential (4.3) and the normal cone (4.1).

It remains to justify the Euler–Lagrange inclusion (6.4). To furnish this, we rewrite the discrete Euler–Lagrange inclusion (5.5) in the form

$$\begin{aligned}
&(\dot{P}^N(t), \dot{Q}^N(t - \Delta)) \\
&\qquad \in \left\{ (u, w) \mid \left(u, w, p^N(t_{j+1}) + q^N(t_{j+1}) - \frac{\lambda^N\theta_j^N}{h_N} \right) \right. \\
&\qquad\qquad \left. \in \lambda^N(\partial f(\bar{x}(t_j), \bar{x}(t_j - \Delta), t_j), 0) + (N(\bar{x}_j^N, \bar{x}_{j-N}^N, \bar{v}_j^N); \operatorname{gph} F_j) \right\}
\end{aligned} \tag{6.5}$$

for $t \in [t_j, t_{j+1}]$ with $j = 0, \ldots, k$. By the classical Mazur theorem there is a sequence of convex combinations of the functions $(\dot{P}^N(t), \dot{Q}^N(t-\Delta))$ that converges to $(\dot{P}(t), \dot{Q}(t-\Delta))$ for a.e. $t \in [a,b]$. Passing the limit in (6.5), taking into account the pointwise convergence of $\theta^N(t)$ and $\bar{v}^N(t)$ established above, as well as the constructions of the extended normal cone (4.9) and the extended subdifferential (4.10) and their robustness property (4.12) with respect to all variables and parameters, we arrive at (6.4) and complete the proof of the theorem. □

Observe that for the *Mayer problem* (P_M), which is (1.1)–(1.4) with $f = 0$, the generalized Euler–Lagrange inclusion (6.4) is equivalently expressed in terms of the extended coderivative (4.11) with respect to the first two variables of $F = F(x,y,t)$, i.e., in the form

$$\begin{aligned} &\left(\frac{d}{dt}[p(t) - A^*p(t+\Delta)], \frac{d}{dt}[q(t-\Delta) - A^*q(t)]\right) \\ &\qquad \in \operatorname{co} \widetilde{D}^*_{x,y} F\left(\bar{x}(t), \bar{x}(t-\Delta), \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)], t\right)(-p(t) - q(t)) \end{aligned} \tag{6.6}$$

for almost all $t \in [a,b]$. It turns out that the extended Euler–Lagrange inclusion obtained above implies, under the *relaxation stability* of the original problems, two other principal optimality conditions expressed in terms of the Hamiltonian function built on the mapping F in (1.2). The first condition called the extended *Hamiltonian inclusion* is given below in terms of a *partial convexification* of the basic subdifferential (4.3) for the Hamiltonian function. The second is an analog of the classical *Weierstrass–Pontryagin maximum condition* (maximum principle) for neutral functional-differential inclusions. Recall that an analog of the maximum principle does *not generally hold* even in the case of optimal control problems governed by smooth functional-differential equations of neutral type.

The following relationships between the extended Euler–Lagrange and Hamiltonian inclusions are based on Rockafellar's dualization theorem [25] (see also [29, section 7.6]) that concerns subgradients of abstract Lagrangians and Hamiltonians associated with set-valued mappings regardless of the dynamics in (1.2). For simplicity we consider the case of the Mayer problem (P_M) for autonomous functional-differential inclusions of neutral type. Then the *Hamiltonian* function for F in (1.2) is defined by

$$H(x,y,p) := \sup\{\langle p, v\rangle \mid v \in F(x,y)\}. \tag{6.7}$$

Corollary 6.2. *Let $\bar{x}(\cdot)$ be an optimal solution to the Mayer problem (P_M) for the autonomous neutral functional-differential inclusion (1.2) under the assumptions of Theorem 6.1. Then there exist a number $\lambda \ge 0$ and piecewise continuous functions $p : [a, b+\Delta] \to \mathbb{R}^n$ and $q : [a-\Delta, b] \to \mathbb{R}^n$ such that $p(t) - A^*p(t+\Delta)$ and $q(t-\Delta) - A^*q(t)$ are absolutely continuous on $[a,b]$ and, besides (6.1)–(6.4), one has the extended Hamiltonian inclusion*

$$\begin{aligned} &\left(\frac{d}{dt}[p(t) - A^*p(t+\Delta)], \frac{d}{dt}[q(t-\Delta) - A^*q(t)]\right) \\ &\qquad \in \operatorname{co}\left\{(u,w) \mid \left(-u, -w, \frac{d}{dt}[\bar{x}(t) - A\bar{x}(t-\Delta)]\right)\right. \\ &\qquad\qquad \left. \in \partial H\left(\bar{x}(t), \bar{x}(t-\Delta), p(t) + q(t)\right)\right\} \end{aligned} \tag{6.8}$$

and the maximum condition

$$\left\langle p(t)+q(t),\frac{d}{dt}[\bar{x}(t)-A\bar{x}(t-\Delta)]\right\rangle = H(\bar{x}(t),\bar{x}(t-\Delta),p(t)+q(t)) \tag{6.9}$$

for almost all $t\in[a,b]$. *If, moreover,* F *is convex-valued around* $(\bar{x}(t),\bar{x}(t-\Delta))$, *then* (6.8) *is equivalent to the Euler–Lagrange inclusion*

$$\begin{aligned}&\left(\frac{d}{dt}[p(t)-A^*p(t+\Delta)],\frac{d}{dt}[q(t-\Delta)-A^*q(t)]\right)\\ &\quad\in \operatorname{co} D^*F\left(\bar{x}(t),\bar{x}(t-\Delta),\frac{d}{dt}[\bar{x}(t)-A\bar{x}(t-\Delta)]\right)(-p(t)-q(t)) \quad \textit{for a.e. } t\in[a,b],\end{aligned} \tag{6.10}$$

which in this case automatically implies the maximum condition (6.9).

Proof. Since (P_M) is stable with respect to relaxation, $\bar{x}(\cdot)$ is an optimal solution to the relaxed problem (R_M), whose only difference from (P_M) is that the neutral functional-differential inclusion (1.2) is replaced by its convexification (3.4). By Theorem 6.1 the optimal solution $\bar{x}(\cdot)$ satisfies conditions (6.1)–(6.4) and the relaxed counterpart of (6.6), which is the same as (6.10) in this case with F replaced by $\operatorname{co} F$. According to [25, Theorem 3.3] one has

$$\begin{aligned}&\operatorname{co}\{(u,v)\mid (u,w,p)\in N((x,y,v);\operatorname{gph}(\operatorname{co}F)\}\\ &\qquad=\operatorname{co}\{(u,w)\mid(-u,-w,v)\in\partial H_R(x,y,p)\},\end{aligned}$$

where H_R stands for the Hamiltonian (6.7) of the relaxed system, i.e., with F replaced by $\operatorname{co} F$. It is easy to check that $H_R=H$. Thus the extended Euler–Lagrange inclusion for the relaxed system implies the extended Hamiltonian inclusion (6.8), which surely yields the maximum condition (6.9). When F is *convex-valued*, (6.8) and (6.10) are *equivalent* due to the mentioned result of [25]. This completes the proof of the corollary. □

COUNTEREXAMPLES CONCERNING OBSERVATION OPERATORS FOR C_0-SEMIGROUPS*

BIRGIT JACOB† AND HANS ZWART‡

Abstract. This paper concerns systems of the form $\dot{x}(t) = Ax(t)$, $y(t) = Cx(t)$, where A generates a C_0-semigroup. Two conjectures which were posed in 1991 and 1994 are shown not to hold. The first conjecture (by G. Weiss) states that if the range of C is one-dimensional, then C is admissible if and only if a certain resolvent estimate holds. The second conjecture (by D. Russell and G. Weiss) states that a system is exactly observable if and only if a test similar to the Hautus test for finite-dimensional systems holds. The C_0-semigroup in both counterexamples is analytic and possesses a basis of eigenfunctions. Using the (A, C)-pair from the second counterexample, we construct a generator A_e on a Hilbert space such that $(sI - A_e)$ is uniformly left-invertible, but its semigroup does not have this property.

Key words. infinite-dimensional system, admissible observation operator, exact observability, conditional basis, C_0-semigroup, left-invertibility

1. Introduction.

Consider the abstract system

$$\dot{x}(t) = Ax(t), \qquad y(t) = Cx(t), \qquad x(0) = x_0 \tag{1.1}$$

with $x(t) \in H$ and $y(t) \in Y$, where H and Y are Hilbert spaces. For this abstract differential equation one would like to obtain conditions in terms of A and C such that it has a solution with certain properties. If one only considers the differential equation $\dot{x}(t) = Ax(t)$, then it is well known that it has a unique (weak) solution which is strongly continuous and depends continuously on the initial state $x(0) = x_0 \in H$ if and only if A satisfies the estimates of the Hille–Yosida theorem (see, e.g., [4, Theorem 2.1.12]). Since $\dot{x}(t) = Ax(t)$ is a part of (1.1) we have to assume that A satisfies the estimates of the Hille–Yosida theorem, or equivalently, that A generates a C_0-semigroup. If in addition C is a bounded linear operator from H to Y, then it is straightforward to see that $y(\cdot)$ in (1.1) is well defined and continuous. However, many PDEs rewritten in the form (1.1) do not have a bounded operator C, although the output is a well-defined square integrable function. We assume that C is a bounded operator from $D(A)$ (with the graph norm) to a Hilbert space Y. If the output is locally square integrable, then C is called an *admissible observation operator* (see Weiss [20] and the survey article by Jacob and Partington [7]). In other words, C is an admissible observation operator if and only if for some $t_0 > 0$ (and hence any $t_0 > 0$) there exists a constant $L > 0$ such that

$$\int_0^{t_0} \|CT(t)x\|^2 \, dt \le L\|x\|^2, \qquad x \in D(A).$$

Here $(T(t))_{t\geq 0}$ is the C_0-semigroup generated by A. If the C_0-semigroup is exponentially stable, then t_0 can be replaced by ∞. Now an interesting question is if there are simple conditions on C (and A) such that C is an admissible observation operator.

Dual to the concept of admissible observation operator is the concept of admissible control operator. An operator B is said to be an admissible control operator if $\dot{x}(t) = Ax(t) + Bu(t)$ has a continuous (weak) solution for every locally square integrable input u. It is well known that C is an admissible observation operator for A if and only if C^* is an admissible control operator for A^*; see [20] for a proof of this statement. Here $*$ denotes the adjoint operator. Because of this duality any result for admissible observation operators has an equivalent counterpart for admissible control operators, and vice versa. Hence if we refer to a paper which only deals with control operators, we trust that the reader can make the equivalent statement for observation operators. Basically, it boils down to replacing B by C^* and replacing the infinitesimal generator by its dual one.

In Weiss [21] it is shown that if C is admissible, then there exists a constant $M > 0$ such that

$$\|C(sI - A)^{-1}\| \leq \frac{M}{\sqrt{\mathrm{Re}(s)}} \tag{1.2}$$

for all s in some right-half plane. He conjectured in [21] (see also [22]) that this condition is also sufficient. The sufficiency of condition (1.2) was proved for surjective semigroups in Weiss [21], for normal, analytic semigroups in Weiss [21, 22], for the right shift semigroup with scalar output in Partington and Weiss [15], for contraction semigroups with scalar output by Jacob and Partington [6], and for analytic contraction semigroups by Le Merdy [12]. Recently, Zwart, Jacob, and Staffans [26] and Jacob, Partington, and Pott [8] showed that in general estimate (1.2) is not sufficient. Their observation operator is infinite-dimensional. Here we use techniques similar to those in [26] to show that (1.2) is not sufficient for scalar outputs. Note that in [5] a necessary and sufficient condition has been obtained. This condition involves all powers of the resolvent, as in the Hille–Yosida theorem. Some sufficient conditions for admissibility can be found in [24].

Apart from the well-posedness of the abstract differential equation (1.1) one would like to characterize other properties in terms of the pair (A, C). One property that has received a lot of attention is the property of exact observability. Assuming that the observation operator C is admissible, the system (1.1) is said to be exactly observable if there is a bounded mapping from the output trajectory to the initial condition, that is, for some $t_0 > 0$ (and hence any $t_0 > 0$) there exists a constant $l > 0$ such that

$$\int_0^{t_0} \|CT(t)x\|^2 \, dt \geq l\|x\|^2, \qquad x \in D(A).$$

If the C_0-semigroup is exponentially stable, then t_0 can be replaced by ∞. Note that admissibility gives that the mapping from initial condition to output trajectory is bounded. If the state space H is finite-dimensional, and thus A and C are just matrices, then it is well known that (1.1) is exactly observable if and only if

$$\mathrm{rank} \begin{bmatrix} C \\ sI - A \end{bmatrix}$$

is full for all complex s. For infinite-dimensional systems, Russell and Weiss [17], proposed the following test for exact observability of an exponentially stable system:

$$\|(sI - A)x_0\|^2 + |\mathrm{Re}(s)|\|Cx_0\|^2 \geq m|\mathrm{Re}(s)|^2\|x_0\|^2 \tag{1.3}$$

for all complex s with negative real part, for all $x_0 \in D(A)$, and for some positive m independent of s and x_0. In [17] they proved that this condition is always necessary, and that for A and C bounded this condition is sufficient as well. In the same paper they showed that if A has a Riesz basis of eigenfunctions and an extra condition on the eigenvalues is satisfied, then (1.3) is sufficient. In Zhou and Yamamoto [23] it was shown that (1.3) is sufficient if A is skew adjoint and C is bounded. For Riesz spectral systems with finite-dimensional output space Y inequality (1.3) is sufficient as well; see Jacob and Zwart [9, 10]. Grabowski and Callier [5] proved that if m in (1.3) is equal to one, then this estimate implies exact observability. In section 3 we show that for general m estimate (1.3) is not sufficient. Note that in our counterexample the output is one-dimensional and that A generates an analytic semigroup. In [11] we give a refined version of this conjecture.

We conclude this paper with a section on left-invertibility of C_0-semigroups. It is known that uniform left-invertibility of the semigroup implies uniform left-invertibility of the generator on the open left-half plane. We show that in general the inverse implication does not hold.

2. General results. Let H be a separable Hilbert space with a conditional basis $\{\varphi_n\}_{n\in\mathbb{N}}$. Since $\{\varphi_n\}_{n\in\mathbb{N}}$ is a conditional basis, we have that for every $x \in H$ there exists a unique sequence of complex numbers α_n such that

$$x = \lim_{k\to\infty} \sum_{n=1}^{k} \alpha_n \varphi_n. \tag{2.1}$$

Hence, we can write

$$x = \sum_{n=1}^{\infty} \alpha_n \varphi_n.$$

Using (2.1) it is not hard to see that the following holds (see also Singer [18, pages 18–20]).

LEMMA 2.1. *If $\{\varphi_n\}_{n\in\mathbb{N}}$ is a conditional basis, then the following mappings are uniformly bounded:*

$$P_n x = \sum_{k=1}^{n} \alpha_k \varphi_k \tag{2.2}$$

and

$$\tilde{P}_n x = \alpha_n \varphi_n, \tag{2.3}$$

where $x = \sum_{n=1}^{\infty} \alpha_n \varphi_n$.

Furthermore, if $\inf_{n\in\mathbb{N}} \|\varphi_n\| > 0$, then

$$\sup_{n\in\mathbb{N}} |\alpha_n| \le \kappa \|x\| \tag{2.4}$$

for some $\kappa > 0$ independent of x.

The following two properties of a conditional basis are important for the construction of our counterexamples.

DEFINITION 2.2. *Let $\{\varphi_n\}_{n\in\mathbb{N}}$ be a conditional basis.*

1. $\{\varphi_n\}_{n\in\mathbb{N}}$ *is* Besselian *if there exists a constant* $c > 0$ *such that*

$$\sum_{k=1}^{n} |a_k|^2 \leq c \left\| \sum_{k=1}^{n} a_k \varphi_k \right\|^2$$

for all finite sequences of scalars $a_1, \ldots, a_n$.

2. $\{\varphi_n\}_{n\in\mathbb{N}}$ *is* Hilbertian *if there exists a constant* $c > 0$ *such that*

$$\left\| \sum_{k=1}^{n} a_k \varphi_k \right\|^2 \leq c \sum_{k=1}^{n} |a_k|^2$$

for all finite sequences of scalars $a_1, \ldots, a_n$.

Equivalently, $\{\varphi_n\}_{n\in\mathbb{N}}$ is Besselian if and only if there exists a bounded linear operator S such that $v_n := S\varphi_n$ is an orthonormal basis for H. More information on conditional bases can be found in Singer [18].

For diagonal operators on a conditional basis of H there is the following nice result, which can be found in Benamara and Nikolski [1, Lemma 3.2.5].

LEMMA 2.3. *Let* $\{\varphi_n\}_n$ *be a conditional basis of* H. *If* Q *is defined as*

$$Q\varphi_n = q_n \varphi_n$$

with $\{q_n\}_{n\in\mathbb{N}} \subset \mathbb{C}$, *and the total variation of the sequence* $\{q_n\}$ *is finite, i.e.,*

$$Var(q_n) := \sum_{n=1}^{\infty} |q_{n+1} - q_n| < \infty,$$

then Q *can be extended to a linear bounded operator on* H, *and*

$$\|Q\| \leq K(Var(q_n) + \limsup |q_n|), \tag{2.5}$$

where K *is the supremum of* $\|P_n\|$; *see Lemma* 2.1.

In order to calculate the total variation, the following observation is useful. If f is a continuous function which is nondecreasing or nonincreasing on the interval (a, b), and if the sequence $\{q_n\}_n \subset (a, b)$ is nondecreasing or nonincreasing, then

$$Var(f(q_n)) \leq |f(a) - f(b)|.$$

In [26] the following useful result can be found.

LEMMA 2.4. *Let* $\{\mu_n\}_n \subset (-\infty, -1]$ *be a monotonically decreasing sequence with* $\lim_{n\to\infty} \mu_n = -\infty$. *Furthermore, let* $\{\varphi_n\}_{n\in\mathbb{N}}$ *be a conditional basis for the Hilbert space* H.

For $t \geq 0$, *we define* $(T(t))_{t\geq 0}$ *by*

$$T(t)\varphi_n := e^{\mu_n t}\varphi_n, \qquad n \in \mathbb{N}. \tag{2.6}$$

The operator valued function $(T(t))_{t\geq 0}$ *defines an analytic, exponentially stable* C_0*-semigroup on* H.

3. Counterexample on admissibility. In this section we show that the conjecture of George Weiss for admissibility of scalar observation operators (see [21, 22]) does not hold. That means we construct an exponentially stable C_0-semigroup $(T(t))_{t\geq 0}$ on H with infinitesimal generator A and an operator $C \in \mathcal{L}(D(A), \mathbb{C})$ such that

$$\|C(sI - A)^{-1}\| \leq \frac{M}{\sqrt{\mathrm{Re}(s)}}$$

for all s in some right-half plane and some constant $M > 0$, but C is not an admissible observation operator for $(T(t))_{t\geq 0}$.

Let $\{e_n\}_{n\in\mathbb{N}}$ be a conditional basis on H which has the following properties:

1. $\inf_{n\in\mathbb{N}} \|e_n\| > 0$.
2. $\{e_n\}_{n\in\mathbb{N}}$ is not Besselian.

Such Hilbert spaces and bases do exist; see, for example, Singer [18, page 351, example 11.2].

We define the sequence μ_n as

$$\mu_n := -4^n, \qquad n \in \mathbb{N}, \tag{3.1}$$

and the C_0-semigroup $(T(t))_{t\geq 0}$ as

$$T(t)e_n = e^{\mu_n t} e_n. \tag{3.2}$$

By Lemma 2.4 we know that $(T(t))_{t\geq 0}$ is an exponentially stable analytic semigroup. By A we denote the infinitesimal generator of $(T(t))_{t\geq 0}$. It is easy to see that A satisfies

$$Ae_n = \mu_n e_n, \qquad n \in \mathbb{N}.$$

For $x \in D(A)$, $x = \sum_{n=1}^{\infty} x_n e_n$, we further define

$$Cx = \sum_{n=1}^{\infty} \sqrt{-\mu_n}\, x_n. \tag{3.3}$$

First of all we show that C is a bounded linear operator from the domain of A into $\mathbb{C}$.

PROPOSITION 3.1. *Let C be given as in* (3.3) *and let A be the infinitesimal generator of the C_0-semigroup* (3.2). *Then we have $C \in \mathcal{L}(D(A), \mathbb{C})$.*

Proof. It is enough to show that there exists a constant $c > 0$ such that

$$|CA^{-1}x| \leq c, \qquad x \in H, \|x\| = 1.$$

Let $x \in H$ with $\|x\| = 1$. Then there exist scalars x_n, $n \in \mathbb{N}$, such that

$$x = \sum_{n=1}^{\infty} x_n e_n.$$

Using that $\inf_{n\in\mathbb{N}} \|e_n\| > 0$, we get from Lemma 2.1 that $\sup_{n\in\mathbb{N}} |x_n| \leq \kappa < \infty$. Note that κ is independent of $x \in H$ with $\|x\| = 1$. Now we have

$$|CA^{-1}x| = \left| \sum_{n=1}^{\infty} \frac{x_n}{\sqrt{-\mu_n}} \right| \leq \kappa \sum_{n=1}^{\infty} 2^{-n} = \kappa.$$

Thus the proposition is proved. □

Next we show that C satisfies the estimate (1.2).

PROPOSITION 3.2. *For C given by* (3.3) *and A as the infinitesimal generator of the semigroup* (3.2) *the following holds. There exists a constant $M > 0$ such that*

$$\|C(sI - A)^{-1}\| \leq \frac{M}{\sqrt{\operatorname{Re}(s)}}, \qquad s \in \mathbb{C}_+.$$

Proof. Let s be an element of $\mathbb{C}_+$, and let $x \in H$ have norm one. We have the following estimate:

$$\begin{aligned}\sqrt{\operatorname{Re}(s)}|C(sI - A)^{-1}x| &= \sqrt{\operatorname{Re}(s)}\left|\sum_{k=1}^{\infty}\frac{2^k}{s+4^k}x_k\right| \\ &\leq \sqrt{\operatorname{Re}(s)}\sum_{k=1}^{\infty}\frac{2^k}{|\operatorname{Re}(s)+4^k|}|x_k| \\ &\leq \kappa\sqrt{\operatorname{Re}(s)}\sum_{k=1}^{\infty}\frac{2^k}{\operatorname{Re}(s)+4^k},\end{aligned}$$

where we have used Lemma 2.1. Note that κ is independent of x. In order to estimate this last expression we introduce the monotonically decreasing sequence $a_k := \frac{1}{\operatorname{Re}(s)+k^2}$. Then for $N \geq 2^K$ we have

$$\begin{aligned}\sum_{k=1}^{N} a_k &\geq a_1 + a_2 + (a_3 + a_4) + \cdots + (a_{2^{K-1}+1} + \cdots + a_{2^K}) \\ &\geq a_2 + 2a_4 + \cdots + 2^{K-1}a_{2^K} \\ &= \frac{1}{2}\sum_{k=1}^{K} 2^k a_{2^k},\end{aligned}$$

and so

$$\sum_{k=1}^{\infty}\frac{2^k}{\operatorname{Re}(s)+4^k} \leq 2\sum_{k=1}^{\infty}\frac{1}{\operatorname{Re}(s)+k^2}.$$

Using this in our estimate of $\sqrt{\operatorname{Re}(s)}|C(sI - A)^{-1}x|$, we obtain that

$$\begin{aligned}\sqrt{\operatorname{Re}(s)}|C(sI - A)^{-1}x| &\leq 2\kappa\sqrt{\operatorname{Re}(s)}\sum_{k=1}^{\infty}\frac{1}{\operatorname{Re}(s)+k^2} \\ &\leq 2\kappa\sqrt{\operatorname{Re}(s)}\int_0^{\infty}\frac{1}{\operatorname{Re}(s)+t^2}\,dt \\ &\leq 2\kappa\sqrt{\operatorname{Re}(s)}\left(\frac{1}{\sqrt{\operatorname{Re}(s)}}\arctan\left(\frac{t}{\sqrt{\operatorname{Re}(s)}}\right)\Bigg|_0^{\infty}\right) \\ &\leq 2\kappa\frac{\pi}{2} = \kappa\pi,\end{aligned}$$

which proves our assertion. □

PROPOSITION 3.3. *If C given by* (3.3) *is an admissible observation operator for the C_0-semigroup given by* (3.2)*, then $\{e_n\}$ is Besselian.*

Proof. If C is an admissible observation operator for $(T(t))_{t\geq 0}$, then there would exist a constant $L > 0$ such that

$$\int_0^\infty |CT(t)x|^2 dt \leq L\|x\|^2, \qquad x \in D(A).$$

Now take a finite sequence of α_k's and consider

$$x := \sum_{k=1}^{n} \alpha_k e_k.$$

Then the above estimate gives

$$\int_0^\infty \left| \sum_{k=1}^{n} \sqrt{-\mu_k} e^{\mu_k t} \alpha_k \right|^2 dt \leq L\|x\|^2.$$

However, from Nikolski and Pavlov [14] (see also Jacob and Zwart [10]), we know that there exists a constant $L_1 > 0$, independent of x, such that

$$\int_0^\infty \left| \sum_{k=1}^{n} \sqrt{-\mu_k} e^{\mu_k t} \alpha_k \right|^2 dt \geq L_1 \sum_{k=1}^{n} |\alpha_k|^2.$$

Thus we have that for any finite sequence

$$\|x\|^2 \geq \frac{L_1}{L} \sum_{k=1}^{n} |\alpha_k|^2,$$

which shows that $\{e_n\}$ is Besselian. □

Thus we have disproved the scalar admissibility conjecture of George Weiss.

4. Counterexample on exact observability. In this section we use the operators A and C constructed in section 3 with different assumptions on the basis to settle another question about operator semigroups.

We disprove the conjecture of Russell and Weiss [17] on exact observability. That means we construct an exponentially stable C_0-semigroup $(T(t))_{t\geq 0}$ with infinitesimal generator A and an operator $C \in \mathcal{L}(D(A), \mathbb{C})$ such that

$$\|(sI - A)x_0\|^2 + |\mathrm{Re}(s)|\|Cx_0\|^2 \geq m|\mathrm{Re}(s)|^2\|x_0\|^2, \quad s \in \mathbb{C}_-, x_0 \in D(A),$$

for some constant $m > 0$, but the pair (A, C) is not exactly observable.

Let $\{e_n\}_{n\in\mathbb{N}}$ be a conditional basis on H which is Besselian, normalized—that is, $\|e_n\| = 1$, but not Hilbertian. Such Hilbert spaces and bases do exist; see, for example, Singer [18, page 351, example 11.2].

We define the sequence μ_n as

$$\mu_n := -4^n, \qquad n \in \mathbb{N}, \tag{4.1}$$

and the C_0-semigroup as

$$T(t)e_n = e^{\mu_n t} e_n. \tag{4.2}$$

By Lemma 2.4 we know that this is an exponentially stable analytic C_0-semigroup. By A we denote the infinitesimal generator of $(T(t))_{t\geq 0}$. It is easy to see that A satisfies

$$Ae_n = \mu_n e_n, \qquad n \in \mathbb{N}.$$

Since $\{e_n\}_{n\in\mathbb{N}}$ is Besselian, we know that there exists a bounded linear operator S such that $v_n := Se_n$ is an orthonormal basis for H. On this new basis we define

$$\tilde{A}v_n = \mu_n v_n.$$

It is easy to see that $\tilde{A}$ generates a C_0-semigroup $(\tilde{T}(t))_{t\geq 0}$, and that

$$ST(t) = \tilde{T}(t)S. \tag{4.3}$$

Now define the operator $\tilde{C}$ as

$$\tilde{C}v_n = \sqrt{-\mu_n}.$$

It is easy to see that we can extend $\tilde{C}$ as a bounded operator from the domain of $\tilde{A}$ to $\mathbb{C}$. We denote this extension again by $\tilde{C}$. We shall prove that $\tilde{C}$ is an admissible observation operator for $(\tilde{T}(t))_{t\geq 0}$. Since $(\tilde{T}(t))_{t\geq 0}$ has an orthonormal basis of eigenfunctions, we can use the result of Weiss [19], which tells us that $\tilde{C}$ is admissible if and only if

$$\sum_{-\mu_n \in R(h,\omega)} |\mu_n| \leq \beta h,$$

where

$$R(h,\omega) := \{s \in \mathbb{C}_+ \mid \operatorname{Re}(s) \leq h, |\operatorname{Im}(s) - \omega| \leq h\}$$

and β is independent of h. Using the definition of μ_n this is easy to prove. Now we define for $x \in D(A)$,

$$Cx = \tilde{C}Sx. \tag{4.4}$$

From this and (4.3) we see that for $x \in D(A)$

$$CT(t)x = \tilde{C}\tilde{T}(t)Sx.$$

Since S is bounded and since $\tilde{C}$ is admissible for $(\tilde{T}(t))_{t\geq 0}$, we obtain that C is an admissible output operator for $(T(t))_{t\geq 0}$.

In several steps we shall prove that the pair (A, C) satisfies the estimate of Russell and Weiss, but that it is not exactly observable. In our proof we follow closely the proof of Theorem 4.4 of Russell and Weiss [17]. As in [17] we define $N : \mathbb{C}_- \to \mathbb{N}$ as the integer such that

$$|s - \mu_{N(s)}| = \min_{k\in\mathbb{N}} |s - \mu_k|. \tag{4.5}$$

This number is well defined if the real part of s is unequal to $(\mu_k + \mu_{k+1})/2$ for all k. We define the set for which this mapping is well defined as $\mathbb{C}_g$.

LEMMA 4.1. *There exists a constant $c > 0$ such that, for all $s \in \mathbb{C}_g$, we have that*

$$\left|\frac{\operatorname{Re}(s)}{s-\mu_k}\right| \leq c, \qquad s \in \mathbb{C}_g, k \neq N(s),$$

and

$$\left|\frac{\operatorname{Re}(s)}{\operatorname{Re}(s)-\mu_k}\right| \leq c, \qquad s \in \mathbb{C}_g, k \neq N(s).$$

Proof. In Weiss and Russell [17] it is shown that the first estimate holds. Since $\{\mu_k\}$ is a real sequence, it is easy to see that $N(s) = N(\operatorname{Re}(s))$. Taking s to be real in the first inequality, and using this observation, proves the second inequality. □

For $s \in \mathbb{C}_g$, we define

$$V(s) := \overline{\operatorname{span}_{n \neq N(s)}\{e_n\}}. \tag{4.6}$$

Clearly, $V(s)$ is again a Hilbert space and in Singer [18, page 26, Proposition 4.1] it is shown that $\{e_n\}_{n\neq N(s)}$ is a conditional basis of $V(s)$. By $P_{V(s)}$ we denote the projection from H onto $V(s)$ given by

$$P_{V(s)} := I - \tilde{P}_{N(s)}.$$

Using Lemma 2.1 we see that the projections $P_{V(s)}$ are uniformly bounded. For $s \in \mathbb{C}_g$, we introduce the notation

$$e_n^s := \begin{cases} e_n, & n < N(s), \\ e_{n+1}, & n \geq N(s), \end{cases} \tag{4.7}$$

and

$$\mu_n^s := \begin{cases} \mu_n, & n < N(s), \\ \mu_{n+1}, & n \geq N(s). \end{cases} \tag{4.8}$$

The constant K in Lemma 2.3 is given by $K := \sup_{n\in\mathbb{N}} \|P_n\|$. Let $K(s)$ be the corresponding constant for $V(s)$ with conditional basis $\{e_n^s\}$, for $s \in \mathbb{C}_g$. Then it follows easily that $K(s) \leq K$.

Let $s \in \mathbb{C}_g$. We denote by A_s the part of A in $V(s)$, that is,

$$A_s x := Ax, \qquad x \in D(A_s),$$

and $D(A_s) := D(A) \cap V(s)$. Note that $V(s)$ is a $T(t)$-invariant subspace. Thus it is easy to see that C_s, defined by

$$C_s x := Cx, \qquad x \in D(A_s),$$

is an admissible observation operator for $(T_s(t))_{t\geq 0}$. Here $(T_s(t))_{t\geq 0}$ is the C_0-semigroup generated by A_s. Now we shall prove two important estimates.

LEMMA 4.2. *Let A_s, C_s, and $V(s)$ denote the objects defined above. The following two estimates hold.*

1. *There exists a constant $M > 0$ such that*

$$\|(sI - A_s)^{-1}\|_{V(s)} \leq \frac{M}{|\operatorname{Re}(s)|}, \qquad s \in \mathbb{C}_g.$$

2. *There exists a constant $d > 0$ such that*

$$\|C_s(sI - A_s)^{-1}\| \leq \frac{d}{\sqrt{|\operatorname{Re}(s)|}}, \qquad s \in \mathbb{C}_g.$$

Proof. Part 1. Let $s = s_r + is_i \in \mathbb{C}_g$. Clearly,

$$(sI - A_s)^{-1} e_n^s = \frac{1}{s - \mu_n^s} e_n^s, \qquad n \in \mathbb{N}.$$

This is an operator of the form as discussed in Lemma 2.3, and thus we have to show that $1/(s - \mu_n^s)$ is of bounded variation. We begin with the following simple observation:

$$\begin{aligned} \left| \frac{1}{s - \mu_{n+1}^s} - \frac{1}{s - \mu_n^s} \right| &= \left| \frac{\mu_{n+1}^s - \mu_n^s}{(s - \mu_{n+1}^s)(s - \mu_n^s)} \right| \\ &\leq \left| \frac{\mu_{n+1}^s - \mu_n^s}{(s_r - \mu_{n+1}^s)(s_r - \mu_n^s)} \right| \\ &= \left| \frac{1}{s_r - \mu_{n+1}^s} - \frac{1}{s_r - \mu_n^s} \right|, \end{aligned} \tag{4.9}$$

where we have used the fact that μ_n^s is real.

Next we define

$$h : \mathbb{R}_- \setminus \{s_r\} \to \mathbb{R}, \qquad h(x) := \frac{1}{s_r - x}.$$

Then we have $h(-\infty) = 0$, $h(0) = \frac{1}{s_r}$, and h is monotonically increasing on $(-\infty, s_r)$ and on $(s_r, 0)$. Combining the above results with Lemma 2.3 we get the following estimate for $\|(sI - A_s)^{-1}\|$:

$$\begin{aligned} &\|(sI - A_s)^{-1}\| \\ &\leq K \left(\operatorname{Var} \left(\frac{1}{s - \mu_n^s} \right) + \left| \lim_{n \to \infty} \frac{1}{s - \mu_n^s} \right| \right) = K \sum_{n=1}^{\infty} \left| \frac{1}{s - \mu_{n+1}^s} - \frac{1}{s - \mu_n^s} \right| \\ &\leq K \sum_{n=1}^{\infty} \left| \frac{1}{s_r - \mu_{n+1}^s} - \frac{1}{s_r - \mu_n^s} \right| \\ &\leq K \left[\left[0 + \frac{1}{s_r - \mu_{N(s)+1}} \right] + \left[\frac{1}{s_r - \mu_{N(s)+1}} - \frac{1}{s_r - \mu_{N(s)-1}} \right] \right. \\ &\quad \left. + \left[\frac{1}{s_r} - \frac{1}{s_r - \mu_{N(s)-1}} \right] \right] \\ &\leq \frac{(4c+1)K}{|\operatorname{Re}(s)|}, \end{aligned}$$

where we have used Lemmas 2.3 and 4.1 and (4.9). Since c and K are independent of s we have proved the statement.

Part 2. In order to prove this statement we follow Lemma 4.6 of Russell and Weiss [17]. Let $s \in \mathbb{C}_g$. Using the resolvent identity, we have

$$C_s(sI - A_s)^{-1} = C_s(-\bar{s}I - A_s)^{-1}[I - (\bar{s} + s)(sI - A_s)^{-1}].$$

Since C_s is an admissible observation operator for $(T_s(t))_{t\geq 0}$ there exists a constant $\tilde{d} > 0$, independent of s, such that

$$\|C_s(-\bar{s}I - A_s)^{-1}\| \leq \frac{\tilde{d}}{\sqrt{|\operatorname{Re}(s)|}}$$

(see, e.g., Weiss [22]). Combining this with Part 1, the statement is proved. □

Now we can prove the estimate of Russell and Weiss [17].

LEMMA 4.3. *For C defined by* (4.4) *and A as the infinitesimal generator of* (4.2) *the following holds. There exists a constant $m > 0$ such that, for every $s \in \mathbb{C}_-$ and every $x \in D(A)$, we have*

$$\frac{1}{|\operatorname{Re}(s)|^2}\|(sI - A)x\|^2 + \frac{1}{|\operatorname{Re}(s)|}\|Cx\|^2 \geq m\|x\|^2. \tag{4.10}$$

Proof. The proof of this lemma is divided into two steps. First, we show that the estimate holds for $s \in \mathbb{C}_- \setminus \mathbb{C}_g$. Second, we prove the estimate for $s \in \mathbb{C}_g$.

Part 1. If s is not in $\mathbb{C}_g$, then there exists an $k_0 \in \mathbb{N}$ such that $\operatorname{Re}(s) = (\mu_{k_0+1} + \mu_{k_0})/2$. It is easy to see that

$$(sI - A)^{-1}e_n = \frac{1}{s - \mu_n}e_n.$$

We use Lemma 2.3 to estimate the norm of this operator. Using (4.9) we see that it is sufficient to show that $\{\frac{1}{\operatorname{Re}(s)-\mu_n}\}$ is of bounded variation. Similar to the proof of Part 1 of Lemma 4.2, we obtain that

$$\|(sI - A)^{-1}\| \leq K\sum_{n=1}^{\infty}\left|\frac{1}{\operatorname{Re}(s) - \mu_{n+1}} - \frac{1}{\operatorname{Re}(s) - \mu_n}\right|.$$

Now we have that $\operatorname{Re}(s) = (\mu_{k_0+1} + \mu_{k_0})/2$, and thus we obtain

$$\begin{aligned}
&\|(sI - A)^{-1}\| \\
&\leq K\left[\left[0 + \frac{1}{\operatorname{Re}(s) - \mu_{k_0+1}}\right] + \left[\frac{1}{\operatorname{Re}(s) - \mu_{k_0+1}} - \frac{1}{\operatorname{Re}(s) - \mu_{k_0}}\right]\right. \\
&\quad \left. + \left[\frac{1}{\operatorname{Re}(s)} - \frac{1}{\operatorname{Re}(s) - \mu_{k_0}}\right]\right] \\
&\leq K\left[\frac{8}{\mu_{k_0} - \mu_{k_0+1}} + \frac{1}{|\operatorname{Re}(s)|}\right].
\end{aligned}$$

Now the sequence $\{\mu_n\} = \{-4^n\}$ satisfies

$$\frac{1}{\mu_n - \mu_{n+1}} = \frac{5/3}{|\mu_n + \mu_{n+1}|}.$$

So we see that

$$\|(sI - A)^{-1}\| \leq \frac{40K}{3|\mu_{k_0} + \mu_{k_0+1}|} + \frac{K}{|\operatorname{Re}(s)|} = \frac{23K}{3|\operatorname{Re}(s)|}.$$

This is equivalent to

$$|\operatorname{Re}(s)|^{-1}\|(sI - A)x\| \geq \frac{3}{23K}\|x\|,$$

and so (4.10) holds for $s \in \mathbb{C}_- \setminus \mathbb{C}_g$.

Part 2. In order to prove this statement we follow Theorem 4.4 of Russell and Weiss.

If (4.10) would not hold, then there would exist sequences $\{s_n\}$ and $\{z^n\}$ such that $s_n \in \mathbb{C}_g$, $z^n \in D(A)$, $\|z^n\| = 1$, and

$$\frac{1}{|\operatorname{Re}(s_n)|^2}\|(s_nI - A)z^n\|^2 + \frac{1}{|\operatorname{Re}(s_n)|}|Cz^n|^2 = \varepsilon_n^2, \tag{4.11}$$

where $\varepsilon_n \geq 0$ and $\varepsilon_n \to 0$.

Now define

$$q^n := \frac{1}{|\operatorname{Re}(s_n)|}(s_nI - A_{s_n})P_{V(s_n)}z^n$$

and the scalar α_n such that

$$\alpha_n e_{N(s_n)} = \tilde{P}_{N(s_n)}z^n = (I - P_{V(s_n)})z^n.$$

Thus we have that

$$\frac{1}{|\operatorname{Re}(s_n)|}(s_nI - A)z^n = \frac{s_n - \mu_{N(s_n)}}{|\operatorname{Re}(s_n)|}\alpha_n e_{N(s_n)} + q_n.$$

Now we have that

$$\|q^n\| = \left\|P_{V(s_n)}\frac{1}{|\operatorname{Re}(s_n)|}(s_nI - A)z^n\right\| \leq K\frac{1}{|\operatorname{Re}(s_n)|}\|(s_nI - A)z^n\| \leq K\varepsilon_n \tag{4.12}$$

by (4.11). For α_n, we obtain

$$\begin{aligned}\left|\frac{s_n - \mu_{N(s_n)}}{\operatorname{Re}(s_n)}\alpha_n\right| &= \left\|\frac{s_n - \mu_{N(s_n)}}{\operatorname{Re}(s_n)}\alpha_n e_{N(s_n)}\right\| = \left\|\frac{s_n - \mu_{N(s_n)}}{\operatorname{Re}(s_n)}\tilde{P}_{N(s_n)}z^n\right\| \\ &= \frac{1}{|\operatorname{Re}(s_n)|}\|\tilde{P}_{N(s_n)}(s_n - A)z^n\| \\ &\leq 2K\frac{1}{|\operatorname{Re}(s_n)|}\|(s_n - A)z^n\| \leq 2K\varepsilon_n. \qquad (4.13)\end{aligned}$$

By definition of q^n, we have that

$$P_{V(s_n)}z^n = |\operatorname{Re}(s_n)|(s_nI - A_{s_n})^{-1}q^n.$$

Using (4.12) and Lemma 4.2, we get

$$\|P_{V(s_n)}z^n\| \leq MK\varepsilon_n,$$

whence $P_{V(s_n)}z^n \to 0$. Since $\|z^n\| = 1$, it follows that $\|(I - P_{V(s_n)})z^n\| \to 1$, i.e.,

$$\lim_{n\to\infty}|\alpha_n| = 1. \tag{4.14}$$

Together with (4.13) this implies that

$$\lim_{n\to\infty}\left|\frac{s_n - \mu_{N(s_n)}}{\operatorname{Re}(s_n)}\right| = 0.$$

It is now easy to see that

$$\lim_{n\to\infty}\left|\frac{\mu_{N(s_n)}}{\operatorname{Re}(s_n)}\right| = 1. \tag{4.15}$$

Now we turn our attention to the second term of (4.11). We have

$$\begin{aligned} Cz^n &= C(I - P_{V(s_n)})z^n + CP_{V(s_n)}z^n \\ &= \alpha_n Ce_{N(s_n)} + C_{s_n}(s_nI - A_{s_n})^{-1}(s_nI - A_{s_n})P_{V(s_n)}z^n \\ &= \alpha_n\sqrt{-\mu_{N(s_n)}} + |\operatorname{Re}(s_n)|C_{s_n}(s_nI - A_{s_n})^{-1}q^n. \end{aligned}$$

Thus we can estimate the norm of this number as

$$|Cz^n| \geq |\alpha_n\sqrt{-\mu_{N(s_n)}}| - |\operatorname{Re}(s_n)||C_s(s_nI - A_{s_n})^{-1}q^n|.$$

Hence using Lemma 4.2, Part 2, we obtain that

$$\frac{1}{\sqrt{|\operatorname{Re}(s_n)|}}|Cz^n| \geq |\alpha_n|\left|\frac{\mu_{N(s_n)}}{\operatorname{Re}(s_n)}\right|^{\frac{1}{2}} - d\|q^n\|. \tag{4.16}$$

By (4.12) and (4.14)–(4.16), we conclude that there exists a positive number κ such that for n sufficiently large,

$$\frac{1}{|\operatorname{Re}(s_n)|}|Cz^n|^2 \geq \kappa.$$

On the other hand, (4.11) implies that for each $n \in \mathbb{N}$,

$$\frac{1}{|\operatorname{Re}(s_n)|}|Cz^n|^2 \leq \varepsilon_n^2,$$

which is a contradiction. Therefore, (4.10) must be true. □

So we know that the system (A, C) as defined in the beginning of this section satisfies the estimate of Russell and Weiss. Suppose now that the pair would be exactly observable. Then there would exist a constant $l > 0$ such that

$$\int_0^\infty |CT(t)x|^2 dt \geq l\|x\|^2, \qquad x \in D(A).$$

Now take a finite sequence of α_k's and consider

$$x := \sum_{k=1}^n \alpha_k e_k.$$

Then the above estimate gives

$$\int_0^\infty \left|\sum_{k=1}^n \sqrt{-\mu_k}e^{\mu_k t}\alpha_k\right|^2 dt \geq l\|x\|^2.$$

However, from Nikolski and Pavlov [14] (see also Russell and Weiss [17]) we know

that there exists a constant $l_1 > 0$ such that

$$\int_0^\infty \left| \sum_{k=1}^n \sqrt{-\mu_k} e^{\mu_k t} \alpha_k \right|^2 dt \leq l_1 \sum_{k=1}^n |\alpha_k|^2.$$

Thus we have that for any finite sequence,

$$\|x\|^2 \leq \frac{l_1}{l} \sum_{k=1}^n |\alpha_k|^2.$$

However, this implies that $\{e_n\}$ is Hilbertian, providing the contradiction.

Thus we have disproved the conjecture of Russell and Weiss on exact observability.

5. On left-invertibility of C_0-semigroups. We consider a bounded C_0-semigroup $(T_e(t))_{t\geq 0}$ with infinitesimal generator A_e on a separable Hilbert space Z. A natural question is whether uniform left-invertibility of the C_0-semigroup, that is,

$$\|T_e(t)x\| \geq c_1 \|x\|, \quad x \in Z, \tag{5.1}$$

for some $c_1 > 0$, is equivalent to uniform left-invertibility of $sI - A_e$ on the open left-half plane, that is,

$$\|(sI - A_e)x\| \geq c_2 |\operatorname{Re}(s)| \, \|x\|, \quad x \in D(A_e), s \in \mathbb{C}_-, \tag{5.2}$$

for some constant $c_2 > 0$.

In van Neerven [13] it is shown that (5.1) implies (5.2). Van Neerven considered only the case of a semigroup of isometries, but the general case can be proved in a similar way. If $(T_e(t))_{t\geq 0}$ can be extended to a group or if $\mathbb{C}_-$ is contained in the resolvent set of A, then (5.2) implies (5.1); see van Casteren [2, 3] or Zwart [25].

We now show that in general (5.2) does not imply (5.1). Consider the operators A and C of section 3, and let $(T(t))_{t\geq 0}$ denote the exponentially stable C_0-semigroup generated by A. We now define the semigroup $(T_e(t))_{t\geq 0}$ on $H \oplus L^2(0,\infty)$ by

$$T_e(t) \begin{pmatrix} x \\ f \end{pmatrix} := \begin{pmatrix} T(t)x \\ CT(t-\cdot)x|_{[0,t]} + f(\cdot - t)|_{[t,\infty)} \end{pmatrix}.$$

In Grabowski and Callier [5] it is shown that $(T_e(t))_{t\geq 0}$ is a uniformly bounded C_0-semigroup on $H \oplus L^2(0,\infty)$, and that the infinitesimal generator A_e of $(T_e(t))_{t\geq 0}$ is given by

$$A_e \begin{pmatrix} x \\ f \end{pmatrix} := \begin{pmatrix} Ax \\ -\dot{f} \end{pmatrix}, \quad \begin{pmatrix} x \\ f \end{pmatrix} \in D(A_e),$$

$$D(A_e) := \left\{ \begin{pmatrix} x \\ f \end{pmatrix} \mid x \in D(A), f, \dot{f} \in L^2(0,\infty), \right.$$
$$\left. f \text{ is absolutely continuous and } f(0) = Cx \right\}.$$

Next we calculate the norm of $\|(sI - A_e)\binom{x}{f}\|$. For $s = s_r + is_i \in \mathbb{C}_-$ we have

$$\begin{aligned}
&\left\|(sI - A_e)\begin{pmatrix} x \\ f \end{pmatrix}\right\|^2 \\
&\quad = \|(sI - A)x\|^2 + \|sf + \dot{f}\|^2_{L^2(0,\infty)} \\
&\quad = \|(sI - A)x\|^2 + |s|^2\|f\|^2_{L^2(0,\infty)} + \|\dot{f}\|^2_{L^2(0,\infty)} \\
&\qquad +2s_r \operatorname{Re}(\langle f, \dot{f}\rangle_{L^2(0,\infty)}) + is_i(\langle f, \dot{f}\rangle_{L^2(0,\infty)} - \langle \dot{f}, f\rangle_{L^2(0,\infty)}) \\
&\quad = \|(sI - A)x\|^2 + \|is_i f + \dot{f}\|^2_{L^2(0,\infty)} + s_r^2\|f\|^2_{L^2(0,\infty)} + 2s_r \operatorname{Re}(\langle f, \dot{f}\rangle_{L^2(0,\infty)}) \\
&\quad = \|(sI - A)x\|^2 + \|is_i f + \dot{f}\|^2_{L^2(0,\infty)} + s_r^2\|f\|^2_{L^2(0,\infty)} \\
&\qquad +s_r \int_0^\infty \frac{d}{dt}\langle f(t), f(t)\rangle \, dt \\
&\quad = \|(sI - A)x\|^2 + \|is_i f + \dot{f}\|^2_{L^2(0,\infty)} + s_r^2\|f\|^2_{L^2(0,\infty)} - s_r\|Cx\|^2,
\end{aligned}$$

because $f(0) = Cx$ and $f, \dot{f} \in L^2(0,\infty)$. Thus

$$\begin{aligned}
&\left\|(sI - A_e)\begin{pmatrix} x \\ f \end{pmatrix}\right\|^2 \\
&\geq \|(sI - A)x\|^2 + |\operatorname{Re}(s)|^2\|f\|^2_{L^2(0,\infty)} + |\operatorname{Re}(s)|\|Cx\|^2 \\
&\geq c_2|\operatorname{Re}(s)|^2 \left\|\begin{pmatrix} x \\ f \end{pmatrix}\right\|^2 \qquad \text{(using Lemma 4.3)},
\end{aligned}$$

where c_2 is independent of x and f. This shows that (5.2) holds. Assuming (5.1) holds as well, we get

$$\left\|T_e(t)\begin{pmatrix} x \\ f \end{pmatrix}\right\| \geq c_1 \left\|\begin{pmatrix} x \\ f \end{pmatrix}\right\|, \qquad t \geq 0, x \in H, f \in L^2(0,\infty),$$

for some constant $c_1 > 0$. Thus

$$\|T(t)x\|^2 + \|CT(\cdot)x\|^2_{L^2(0,t)} = \left\|T_e(t)\begin{pmatrix} x \\ 0 \end{pmatrix}\right\| \geq c_1\|x\|^2, \qquad x \in H, t \geq 0. \tag{5.3}$$

Using that $(T(t))_{t\geq 0}$ is exponentially stable, we get $\lim_{t\to\infty}\|T(t)x\|^2 = 0$, and so letting t to infinity in (5.3) gives

$$\|CT(\cdot)x\|_{L^2(0,\infty)} \geq \sqrt{c_1}\|x\|, \qquad x \in H,$$

which says that the pair (A, C) is exactly observable. However, this is in contradiction with section 3, where we showed that the pair (A, C) is not exactly observable. Thus (5.2) holds, but (5.1) is not valid.

We conclude this section with a positive result; it shows that (5.2) implies (5.1) if the constant c_2 satisfies $c_2 \geq 1$.

PROPOSITION 5.1. *Let $(T_e(t))_{t\geq 0}$ be a bounded C_0-semigroup with infinitesimal generator A_e on a separable Hilbert space Z. If (5.2) holds with $c_2 \geq 1$, then (5.1) holds as well.*

Proof. If $c_2 \geq 1$, then it is easy to see that (5.2) implies that

$$\|(sI - A_e)x\| \geq |\operatorname{Re} s|\|x\|, \quad s \in \mathbb{C}_-,$$

for all $x \in D(A)$. Choosing $s < 0$ and taking the square of the above equation gives

$$\|(sI - A_e)x\|^2 \geq s^2\|x\|^2.$$

Using the fact that Z is a Hilbert space gives that the above inequality is equivalent to

$$s^2\|x\|^2 - 2s\,\mathrm{Re}\langle x, A_e x\rangle + \|A_e x\|^2 \geq s^2\|x\|^2,$$

which is equivalent to

$$-2s\,\mathrm{Re}\langle x, A_e x\rangle + \|A_e x\|^2 \geq 0.$$

Since this must hold for all negative s, we see that

$$\mathrm{Re}\langle x, A_e x\rangle \geq 0.$$

We now consider the function $f(t) := \|T_e(t)x\|^2$. Taking the derivative of f gives

$$\dot{f}(t) = 2\,\mathrm{Re}\langle T_e(t)x, A_e T_e(t)x\rangle \geq 0.$$

Hence f is nondecreasing, and thus

$$\|T_e(t)x\|^2 = f(t) \geq f(0) = \|x\|^2.$$

Since x was arbitrary, we have shown the result. □

INPUT CONSTRAINED ADAPTIVE TRACKING WITH APPLICATIONS TO EXOTHERMIC CHEMICAL REACTION MODELS*

ACHIM ILCHMANN†, MOSALAGAE THUTO‡, AND STUART TOWNLEY§

Abstract. We consider input constrained adaptive output feedback control for a class of nonlinear systems which are prototype models for controlled exothermic chemical reactions. Our objective is set-point control of the output, i.e., the temperature of the reaction. In the context of chemical reactions, practical considerations lead us to work in the presence of input constraints. We adopt an approach based on modified λ-tracking controllers, whereby prespecified asymptotic tracking accuracy, quantified by $\lambda > 0$ set by the designer, is ensured. The adaptive control strategy does not require any knowledge of the system's parameters and does not invoke an internal model. Only a feasibility assumption in terms of the reference temperature and the input constraints is assumed.

Key words. adaptive control, exothermic chemical reaction models, global stabilization, input saturation, tracking

1. Introduction.

In this paper, we consider input constrained adaptive output feedback control for a class of nonlinear systems which arise as prototype models for controlled exothermic chemical reactions. The output of the system is the reaction temperature, and primarily we control the rate of change of reaction temperature. Secondary control is achieved via dilution, specifically by feedrate control of reactants. Our objective is set-point control of the output, i.e., the temperature of the reaction. In the context of chemical reactions, since the rate of conversion of product into reactant should be economically profitable, this set-point temperature is often close to a hyperbolic equilibrium of the open-loop system. Additional practical considerations lead us also to work in the presence of input constraints. We adopt an approach based on modified λ-tracking controllers [7]. We are motivated by results obtained by Viel, Jadot, and Bastin [12] for similar prototype chemical reaction models. Our aims are two-fold: to show that the λ-tracking approach can be developed for this relevant class of nonlinear systems, and moreover to show that input constraints are allowed. Of particular interest is the interplay between the input constraints, the specific nature of the nonlinearities in chemical reaction models, and the set-point to be tracked.

In chemical engineering, the analysis and control of exothermic continuous stirred tank reactors (ExCSTRs) originated in [2]. They have subsequently been used extensively as models in several industries including continuous polymerization reactors, distillation columns, biochemical fermentation, and biological processes. More recently, for the prototype class of chemical reaction models used in this paper, various

nonadaptive control theory approaches have been developed for the set-point control of temperature. Specifically, in [12] a state feedback controller, with observer, was proposed for globally stabilizing the temperature of ExCSTRs; in [9] (adaptive) dynamic output PI type controllers were derived, and similar stabilization results were obtained in [1].

Whilst we are motivated by the issues raised and the results in [12, 9, 1], we adopt a different approach based on adaptive λ-tracking. This means that asymptotically a prespecified, arbitrarily small accuracy $\lambda > 0$ of the tracking error is ensured; see [6, 7]. This λ-tracking technique is well suited to classes of systems with "strict relative-degree" one, which include models for temperature control in the prototype exothermic reactions. It is therefore reasonable to expect that λ-trackers would be well-suited in this context of exothermic reactions. However, their direct application is not so straightforward because of the input constraints and also the need to find alternatives to the "minimum phase assumptions" typical in λ-tracking. In fact, instead of "minimum phase assumptions" we need a certain feasibility assumption which essentially captures the interplay between the input constraints, the specific nonlinearity in the exothermic reaction model, and the set-point (temperature) to be tracked. In the case of global set-point control, we also need to accommodate more ad hoc, non–relative-degree one, control action via dilution rates. To some extent, in modifying the λ-tracking technique, we are guided by the developments in [12]. However, our results actually go further in that we tolerate disturbances to the temperature measurement and also parameters of the system model are not invoked in the controller. We also overcome some of the drawbacks in the previous approaches in [12], and also [9] and [1], which need state feedback, or have complicated controller structure, or else require the system to be minimum phase (i.e., have exponentially stable zero dynamics).

We consider the following class of nonlinear systems:

$$(1)\qquad \begin{cases} \dot{x}(t) = C\, r\big(x(t), T(t)\big) + d\,[x^{\mathrm{in}} - x(t)], & x(0) = x^0 \in \mathbb{R}^n_{\geq 0}, \\ \dot{T}(t) = b^T\, r\big(x(t), T(t)\big) - q\, T(t) \;+\; u(t), & T(0) = T^0 \in \mathbb{R}_{>0}. \end{cases}$$

In (1), $n \in \mathbb{N}$ and the constants and variables represent the following for $m \in \mathbb{N}$ with $n > m$:

$x(t) \in \mathbb{R}^n_{\geq 0}$	concentrations of n chemical species,
$T(t) \in \mathbb{R}_{>0}$	temperature of the reactor,
$u(t) \in \mathbb{R}_{\geq 0}$	control, a combination of the temperatures of reactant feed and coolant,
$x^{\mathrm{in}} \in \mathbb{R}^n_{\geq 0}$	constant feed concentrations,
$C = [c_1, \ldots, c_m] \in \mathbb{R}^{n \times m}$	stoichiometric matrix,
$b \in \mathbb{R}^m_{\geq 0}$	coefficients of the exothermicity,
$d > 0$	dilution rate,
$q > 0$	heat transfer rate between heat exchanger and reactor.

The function

$$(2)\qquad r(\cdot,\cdot) : \mathbb{R}^n_{\geq 0} \times \mathbb{R}_{>0} \to \mathbb{R}^m_{\geq 0}$$

is locally Lipschitz with $r(0, T) = 0$ for all $T > 0$ and models the reaction kinetics.

In the context of chemical reactions, practical considerations lead us to assume that the control input $u(\cdot)$ is constrained so that there exist $\underline{u}$ and $\overline{u}$ with $0 < \underline{u} < \overline{u}$

so that

$$\underline{u} \le u(t) \le \overline{u} \qquad \text{for all} \qquad t \ge 0\,. \tag{3}$$

Remark 1.

(i) Nonlinear systems of the form (1) have been used extensively in the last thirty years as simplified models for ExCSTR models, both mathematically and in industrial applications. Their relevance was established in [3].

(ii) The values of $\underline{u}$ and $\overline{u}$ will depend on the specific application. In our work, and also in [12] and [9], they are fixed numbers which then feature strongly in the assumptions needed so as to prove convergence for the control schemes.

To make sense of (1) as a model for exothermic reactions, we make the following assumptions.

(A1) $\mathbb{R}^n_{\ge 0} \times \mathbb{R}_{>0}$ is positively invariant under (1) for any bounded, nonnegative, locally integrable $u(\cdot) : \mathbb{R}_{\ge 0} \to \mathbb{R}_{\ge 0}$.

(A2) There exists $\gamma \in \mathbb{R}^n_{>0}$ such that $\gamma^T c_i \le 0$ for all columns $c_1, \dots, c_m$ of the stoichiometric matrix C.

(A3) For $T^* > 0$ there exist $0 \le \underline{u} < \overline{u}$ such that

$$\underline{u} < q T^* - b^T r(x, T^*) < \overline{u} \quad \text{for all} \quad x \in \Omega(\gamma, x^{\text{in}}) := \left\{ x \in \mathbb{R}^n_{\ge 0} \,\middle|\, \gamma^T x < \gamma^T x^{\text{in}} \right\}.$$

Remark 2.

(i) The system (1) and assumptions (A1)–(A3) capture the essential features of ExCSTRs. They give rise to a class of nonlinear systems for which a λ-tracking approach seems plausible, whilst the interplay between the nonlinearity, input constraints, and the feasibility assumption provides novelty in controller design and convergence proofs.

(ii) The assumption (A1) is natural for exothermic reactions. Indeed, concentrations and temperature should not become zero once they are positive. In fact, since $r(\cdot,\cdot)$ is nonnegative, if $u(\cdot)$ is nonnegative, then it is clear that $T(t) > 0$ whenever $T^0 > 0$. It is easy to show that the remainder of (A1) holds automatically when $n = 2$, i.e., in the case of a single reaction. For multiple reactions, there are various conditions (see, e.g., [8, Proposition 6]) in terms of specific rates which imply that (A1) holds.
(A1) has been formulated for the closed positive orthant $\mathbb{R}^n_{\ge 0}$ of the concentrations and the open half line for the temperature. The latter is natural since the reactor should not operate with zero or negative temperature; the former could also be assumed for the open positive orthant $\mathbb{R}^n_{>0}$; the analysis goes through without any changes.

(iii) (A2) holds if (1) satisfies the law of conservation of mass, which means that there exists $\gamma \in \mathbb{R}^n_{>0}$ with $\gamma^T C = 0$. This can be found implicitly in [4], and it is also assumed in [12]. If C does not represent exactly the stoichiometric relationships between all species, then conservation of mass need not be satisfied. Nevertheless, the reaction model might still be relevant provided that all essential reactions are obeyed. This approach was adopted in [3] and also in [8]. In [8] a concept of a noncyclic process was developed and shown to ensure dissipativity of mass and hence that (A2) is satisfied.

(iv) (A3) is simply a feasibility assumption arising because of the saturation of the nonnegative input $u(\cdot)$ at $\underline{u}$ and $\overline{u}$. Assumption (A3) coincides with (H3) in [12].

Note that, by continuity of $r(\cdot,\cdot)$, assumption (A3) implies, for some $\underline{T}$, $\overline{T}$, and small enough $\rho > 0$, the assumption

(A3′) For $T^* > 0$ there exist $0 < \underline{T} < T^* < \overline{T}$, $\rho > 0$, $0 < \underline{u} < \overline{u}$, such that

$$0 < \underline{u} + \rho < qT - b^T r(x,T) < \overline{u} - \rho \qquad \text{for all} \quad (x,T) \in \Omega(\gamma, x^{\text{in}}) \times [\underline{T}, \overline{T}].$$

We will work with (A3′) rather than with the weaker (A3) for the following two reasons: The explicit introduction of ρ makes the exposition in the proofs clearer, and in some of the results we need to use explicit knowledge of $[\underline{T}, \overline{T}]$ so that (A3′) holds for a given ρ.

The control objective is to regulate the temperature $T(t)$ toward a prespecified neighborhood of a given reference temperature T^*. In specific applications, T^* would correspond to a desirable, but possibly unstable, set-point temperature.

The actual error between T^* and $T(t)$ is denoted by

$$\hat{e}(t) = T^* - T(t),$$

and, since the temperature measurement may be corrupted by disturbances, we denote by $e(t)$ the measured error, i.e.,

$$e(t) \;=\; T^* - T(t) + \xi(t).$$

We assume that the disturbance signal $\xi(\cdot) : \mathbb{R}_{\geq 0} \to \mathbb{R}$ is a continuous bounded function.

To achieve the control objective, we use a λ-tracking controller

$$\boxed{\begin{aligned} e(t) &= T^* - T(t) + \xi(t), \\ u(t) &= \operatorname{sat}_{[\underline{u},\overline{u}]}\big(\beta(t)\, e(t) \,+\, u^*\big), \\ \dot{\beta}(t) &= \kappa \begin{cases} (|e(t)| - \lambda)^l & \text{if} \quad |e(t)| > \lambda, \\ 0 & \text{if} \quad |e(t)| \leq \lambda, \end{cases} \qquad \beta(0) = \beta^0, \end{aligned}} \tag{4}$$

and variations thereof. Here $\lambda > 0$ specifies the tolerance of the tracking error; $l \geq 1, \kappa, \beta^0 > 0$ are design parameters, and $u^* \in (\underline{u}, \overline{u})$ is a constant offset. Significantly, the controller involves a saturation function

$$\operatorname{sat}_{[\underline{u},\overline{u}]}(\eta) \;:=\; \begin{cases} \underline{u} & \text{if} \quad \eta < \underline{u}, \\ \eta & \text{if} \quad \eta \in [\underline{u}, \overline{u}], \\ \overline{u} & \text{if} \quad \eta > \overline{u}. \end{cases}$$

Remark 3. Note the simplicity of the adaptive λ-tracker. It consists of a proportional error feedback with saturation and a time-varying proportional gain $\beta(\cdot)$ determined adaptively by the error measurement alone. However, the design parameters should be carefully chosen when the feedback controller is applied to a real process. The upper bound $\overline{u}$ depends not only on the feasibility condition (A3′) but also on the physical limitations of the actuator. When both conditions are compatible, i.e., the actuator limit is higher than the bound in (A3′), one should choose $\overline{u}$ close to the actuator upper bound to avoid unnecessary cut off by the saturation bound.

To specify λ appropriately, one needs to know in advance an estimate of the upper bound for the magnitude of the measurement accuracy and disturbance signal. The power l in the gain adaptation influences the speed of the adaptation. If the difference $(|e(t)| - \lambda)$ is smaller than 1, then a bigger $l \geq 1$ gives a slower increase in $\beta(t)$; if the difference is bigger than 1, then the bigger l is the faster $\beta(t)$ increases. Similar effects can be achieved by varying κ or the initial gain β^0. The constant u^* is an input reference, an appropriate choice for which might be known from experiments with constant feedback. Note also that in applications any information specific to the chemical reaction of interest would be used to make additional modifications to the λ-tracking controller so as to fine-tune the performance.

Although our emphasis is on the adaptive controller (4), we also consider the nonadaptive version

$$\boxed{u(t) \;=\; \mathrm{sat}_{[\underline{u},\overline{u}]}\big(\beta(t)\, e(t) \,+\, u^*\big), \qquad \beta(\cdot) : \mathbb{R}_{\geq 0} \to [\beta^*, \infty) \quad \text{continuous.}} \tag{5}$$

Although the gain $\beta(t) \geq \beta^*$ in this nonadaptive controller might be conservatively too large, this nonadaptive controller is useful because it is even simpler than the already simple (4). We give explicit lower bounds for β^* in terms of weak conditions on the system data.

Throughout the paper we assume that the saturation bounds, the offset, the temperature set-point, and λ satisfy

$$0 < \underline{u} < u^* < \overline{u}, \qquad 0 < \lambda < \overline{T} - T^*, \qquad 0 < \underline{T} < T^* < \overline{T}. \tag{6}$$

The paper is organized as follows. In section 2 we consider local (adaptive and nonadaptive) λ-set-point control in the sense that the initial temperature T^0 belongs to $(0, \overline{T})$. We prove additional properties of the closed-loop system in the special case of a single reactant and a single product. In section 3 we consider the global tracking problem in the sense that we assume only $T^0 > 0$. This problem is solved by introducing a feedback control for the feedrate of reactants which has the effect of reducing the concentration of the reactants if the temperature of the reaction is too high. We make some conclusions in section 4. To help the presentation flow, we prove most of the results in the appendix.

2. λ-set-point control for $T^0 \in (0, \overline{T})$. In this section we consider local λ-set-point control in the sense that the initial temperature T^0 is constrained in the interval $(0, \overline{T})$. We present two feedback strategies which force the temperature into a λ-neighborhood of the given setpoint. The first is nonadaptive, whilst the second is adaptive.

PROPOSITION 4. *Suppose* (6), (A1), (A2), (A3′) *hold, and the continuous disturbance satisfies*

$$\sup_{t \geq 0} \{|\xi(t)|\} =: \|\xi\|_\infty < \overline{T} - T^* \,. \tag{7}$$

If the initial data of (1) *satisfy* $(x^0, T^0) \in \Omega(\gamma, x^{\mathrm{in}}) \times (0, \overline{T})$*, then the feedback* (5) *with*

$$\beta^* \geq [u^* - \underline{u}]/[\overline{T} - T^* - \|\xi\|_\infty] \tag{8}$$

applied to (1) *yields a unique solution*

$$(x(\cdot), T(\cdot)) : \mathbb{R}_{\geq 0} \to \Omega(\gamma, x^{\mathrm{in}}) \times (0, \overline{T}), \quad t \mapsto (x(t), T(t)). \tag{9}$$

If (8) *is strengthened to*

$$\beta^* \geq \max\left\{\frac{u^* - \underline{u}}{\overline{T} - T^* - \|\xi\|_\infty}, \frac{\overline{u} - u^*}{\lambda}, \frac{u^* - \underline{u}}{\lambda}\right\}, \tag{10}$$

then there exists $t' \geq 0$ *such that*

$$T(t) \in [T^* - \lambda - \|\xi\|_\infty, T^* + \lambda + \|\xi\|_\infty] \qquad \textit{for all } \ t \geq t'. \tag{11}$$

Proposition 4 is proved in the appendix.

Remark 5. In Proposition 4, it is ensured that the set $\Omega(\gamma, x^{\text{in}}) \times (0, \overline{T})$ (where $\Omega(\gamma, x^{\text{in}})$ denotes the generalized triangle as defined in (A3)) remains positively invariant under the closed-loop system (1), (5); more importantly, after some finite time, the temperature $T(t)$ is within the $(\lambda + \|\xi\|_\infty)$-neighborhood of the reference temperature. The width $\lambda > 0$ of the strip around the reference temperature is prespecified, but the neighborhood is corrupted by $\|\xi\|_\infty$. The condition in (7) requires that the amplitude of the measurement disturbance must be sufficiently small when compared to $\overline{T} - T^*$. Note also that the feedback gain $\beta(\cdot)$ must be large enough.

The following remark provides some intuition behind the dynamics of the closed-loop system (1), (5).

Remark 6. Consider the closed-loop system (1), (5). For any initial condition $(x^0, T^0) \in \mathbb{R}^n_{\geq 0} \times \mathbb{R}_{>0}$, there exists a unique continuously differentiable solution on a maximally extended interval $[0, \omega)$, $\omega \in (0, \infty]$. This is a standard result of the theory of ordinary differential equations following from (2).

In the following we show that $\Omega(\gamma, x^{\text{in}}) \times (0, \overline{T})$, where $\Omega(\gamma, x^{\text{in}})$ denotes the generalized triangle as defined in (A3), is invariant under (1), (5). Therefore, boundedness of $(x(\cdot), T(\cdot))$ yields $\omega = \infty$; i.e., finite escape time cannot occur.

(i) Suppose (A1), (A2) hold. We show that for any initial data $(x^0, T^0) \in \Omega(\gamma, x^{\text{in}}) \times (0, \overline{T})$, the $x(t)$ component of the solution (1), (5) remains in $\Omega(\gamma, x^{\text{in}})$ for all $t \in [0, \omega)$. In particular, $x(\cdot)$ is bounded on $[0, \omega)$.
To see this, we note from (A1) that we need only to show that $\gamma^T x(t) < \gamma^T x^{\text{in}}$ for all $t \in [0, \omega)$. This follows from integration of

$$\frac{d}{dt}\gamma^T x(t) \ = \ \gamma^T C r(x(t), T(t)) + d\,\gamma^T [x^{\text{in}} - x(t)],$$

which yields, by invoking (A2) and $\gamma^T x(0) < \gamma^T x^{\text{in}}$, for all $t \in [0, \omega)$,

$$\gamma^T x(t) \leq e^{-dt}\gamma^T x(0) + d\int_0^t e^{-d(t-\tau)} d\tau\, \gamma^T x^{\text{in}} = \gamma^T x^{\text{in}} - e^{-dt}[\gamma^T x^{\text{in}} - \gamma^T x(0)] \leq \gamma^T x^{\text{in}}.$$

(ii) From Remark 2(i), if $T^0 > 0$, then $T(t) > 0$ for all $t \in [0, \omega)$. Now suppose that (A1), (A2), (A3′), (7), and (8) hold. Now to see that $T(t) < \overline{T}$ for all $t \in [0, \omega)$, first note that from (i) we have that $x(t) \in \Omega(\gamma, x^{\text{in}})$ for all $t \in [0, \omega)$. Seeking a contradiction, suppose there exists $t' \in [0, \omega)$ such that $T(t') = \overline{T}$ and $T(t) < \overline{T}$ for all $t \in [0, t')$.
Then by (8) we have that

$$\beta(t')e(t') \ \leq \ \beta(t')[T^* - \overline{T} + \|\xi\|_\infty] \ \leq \ \underline{u} - u^*,$$

and hence $u(t') = \underline{u}$. Using the feasibility condition (A3′) yields

$$\dot{T}(t') \ = \ b^T r(x(t'), \overline{T}) - q\overline{T} + \underline{u} \ < \ -\rho,$$

and this contradicts the assumption. It follows that if $T^0 \in (0, \overline{T})$, then $T(t) \in (0, \overline{T})$ for all $t \in [0, \omega)$.

In the following theorem, we show that it is possible to determine a sufficiently large $\beta(\cdot)$ in (5) adaptively.

THEOREM 7. *Suppose* (6), (A1), (A2), (A3′) *hold, and the continuous disturbance satisfies*

$$\sup_{t\geq 0}\{|\xi(t)|\} \;=:\; \|\xi\|_\infty \;<\; \lambda/2\,. \tag{12}$$

Then an application of the λ*-tracker* (4) *to any system* (1) *yields, for any initial data*

$$(x^0, T^0) \in \Omega(\gamma, x^{\text{in}}) \times (0, \overline{T}), \qquad \beta^0 \geq [u^* - \underline{u}]/[\overline{T} - T^* - \|\xi\|_\infty], \tag{13}$$

a closed-loop system with unique solution

$$\big(x(\cdot), T(\cdot), \beta(\cdot)\big) \;:\; \mathbb{R}_{\geq 0} \;\longrightarrow\; \Omega(\gamma, x^{\text{in}}) \times (0, \overline{T}) \times \mathbb{R}_{>0} \tag{14}$$

defined on the whole time axis $\mathbb{R}_{\geq 0}$ *and, moreover,*

(i) $\lim_{t\to\infty} \beta(t) = \beta_\infty \in \mathbb{R}_{\geq 0}$*, i.e., adaptation of the gain is convergent,*

(ii) $\lim_{t\to\infty} \operatorname{dist}(|T^* - T(t)|,\ [0, \lambda + \|\xi\|_\infty]) = 0$*, i.e., the temperature* $T(t)$ *tends to the* $[\lambda + \|\xi\|_\infty]$*-strip* $\big[T^* - [\lambda + \|\xi\|_\infty],\, T^* + [\lambda + \|\xi\|_\infty]\big]$ *as* $t \to \infty$*.*

Theorem 7 is proved in the appendix.

Note that the only information needed for the λ-tracker (4) to work is that the initial gain parameter $\beta(0)$ is sufficiently large as determined from knowledge of the upper feasibility bound $\overline{T}$ and $\|\xi\|_\infty$; see (13). This has advantages when compared to the nonadaptive controller (5) in Proposition 4, which requires the stronger condition (10). The nonadaptive result in Proposition 4 guarantees that the temperature $T(t)$ remains in the $[\lambda + \|\xi\|_\infty]$-strip after some finite time, but this time is unknown, whereas Theorem 7 ensures that $T(t)$ approaches the $[\lambda + \|\xi\|_\infty]$-strip asymptotically.

To conclude this section, we consider the special case of (1) with only a single reaction. Specifically, we assume a model for a single reaction of the form

$$\left\{\begin{array}{rcrcl} \dot{x}_1(t) &=& -k\big(T(t)\big)\, x_1(t) &+& d\,[x_1^{\text{in}} - x_1(t)], \\ \dot{x}_2(t) &=& k\big(T(t)\big)\, x_1(t) &-& d\, x_2(t), \\ \dot{T}(t) &=& b\, k\big(T(t)\big)\, x_1(t) &-& q\, T(t) \;+\; u(t). \end{array}\right. \tag{15}$$

Here $b > 0$ denotes the exothermicity of a reaction $A \longrightarrow B$, $x^{\text{in}} = (x_1^{\text{in}}, 0)^T$, where x_1^{in} is the constant feed rate of reactant A, and the reaction kinetics are given by a locally Lipschitz function $k(\cdot) : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ with $k(0) = 0$. A typical example of $k(\cdot)$ is the Arrhenius law $k(T) = k_0 e^{-\frac{E}{RT}}$ (extended to zero by continuity), where k_0 is a constant, E is the activation energy, and R is the Joule constant. The function $k(\cdot)$ and the positive constants d, q, and b are typically unknown.

In this case $\gamma = (1, 1)^T$ and the feasibility assumption (A3′) becomes the following:

(A3″) There exist $\rho > 0$ and $0 < \underline{T} < T^* < \overline{T}$ such that
$$0 < \underline{u} + \rho < q\,T - b\,k(T)\,x_1 < \overline{u} - \rho \quad \text{for all} \quad (x_1, T) \in [0, x_1^{\text{in}}] \times [\underline{T}, \overline{T}].$$

In [12] it is shown that the nonadaptive feedback law (5) with "sufficiently large" and constant $\beta(\cdot) \equiv \beta^*$ ensures that $(x_1(t), x_2(t))$ tends to an asymptotically stable equilibrium of the closed-loop reactor dynamics. The corresponding result for λ-tracking is stated as follows.

PROPOSITION 8. *Suppose* (6), (13), $\xi(\cdot) \equiv 0$, *and* (A3″) *hold. Define*

$$x_1^* := \frac{d\, x_1^{\text{in}}}{k(T^*) + d} \qquad \textit{and} \qquad x_2^* := \frac{k(T^*)\, x_1^{\text{in}}}{k(T^*) + d}.$$

Then the solution of the closed-loop system (4), (15), *parametrized by* λ, *satisfies*

$$\lim_{\lambda \to 0} \limsup_{t \to \infty} (|x_1(t) - x_1^*|) = 0 \qquad \textit{and} \qquad \lim_{\lambda \to 0} \limsup_{t \to \infty} (|x_2(t) - x_2^*|) = 0; \tag{16}$$

i.e., the narrower the λ*-strip (i.e., smaller* λ*) is, then the closer* $(x_1(t), x_2(t))$ *is, eventually, to* (x_1^*, x_2^*).

Note that (x_1^*, x_2^*) *is an equilibrium of* (15) *for* $T(\cdot) \equiv T^*$ *and so* $(x_1^*, x_2^*) \in \partial\Omega\big((1,1), (x_1^{\text{in}}, 0)\big)$.

The proof of Proposition 8 is given in the appendix.

In the remainder of this section, we illustrate previous results by some simulations. In the simulations we use a prototype model for a single exothermic chemical reaction as was also used in [12]. By using the same model, we can at least check that the performance of the λ-tracker is not out of line with a controller which actually relies on more system information. Specifically we consider (15) with reaction kinetics modelled by the Arrhenius law $k(T) = k_0 e^{-k_1 T}$. As in [12], we use the following system parameters:

(17)
$$k_0 = e^{25},\ d = 1.1,\ q = 1.25\,[\text{min}^{-1}],\ k_1 = 8700\,[\text{K}],\ x_i^{\text{in}} = 1\,[\text{mol/l}],\ b = 209.2\,[\text{Kl/mol}].$$

These parameter values are consistent with a laboratory-scale reaction vessel of approximately 100 liters [5].

The objective is to regulate the temperature to a neighborhood of $T^* = 337.1$[K]. Our constraints for the input $u(\cdot)$ are similar to those in [12]. Specifically we suppose that

$$\underline{u} = 295, \quad \overline{u} = 505. \tag{18}$$

It is easy to see that the feasibility assumption (A3″) is satisfied in this case if

$$\underline{T} = 240, \quad \overline{T} = 339.65\ [\text{K}], \quad \rho = 5. \tag{19}$$

We assume in this simulation that the error is disturbance free, i.e., $\xi \equiv 0$, and aim for a tracking error of within 1%. This leads us to choose the following parameters in the λ-tracker (4):

$$\lambda = 2.85, \quad u^* = 330, \quad T^* = 337.1\,[\text{K}], \quad l = 2. \tag{20}$$

In the simulations we choose $\beta^0 = 12$, which satisfies (13), and we consider three different initial conditions $T^0 = 270$, $T^0 = 320$, and $T^0 = 390$. As in [12], we choose $x_1(0) = 0.02$ and $x_2(0) = 1.07$ for the initial conditions of the single reactor (15).

For the two initial conditions $T^0 = 270$ and $T^0 = 320$, we see from Figure 1 that λ-tracking of T^* by $T(t)$ is achieved in 1 minute. Note that in both cases the transient behavior of the input hits the saturation values only for a short period at the beginning of the simulation. Otherwise the input behaves smoothly. The simulation results are similar to those in [12].

The λ-tracker (4) does not work for $T^0 = 390$, which is outside the interval $[0, \overline{T}]$. As shown by the dotted line in Figure 1, a thermal runaway occurs and the

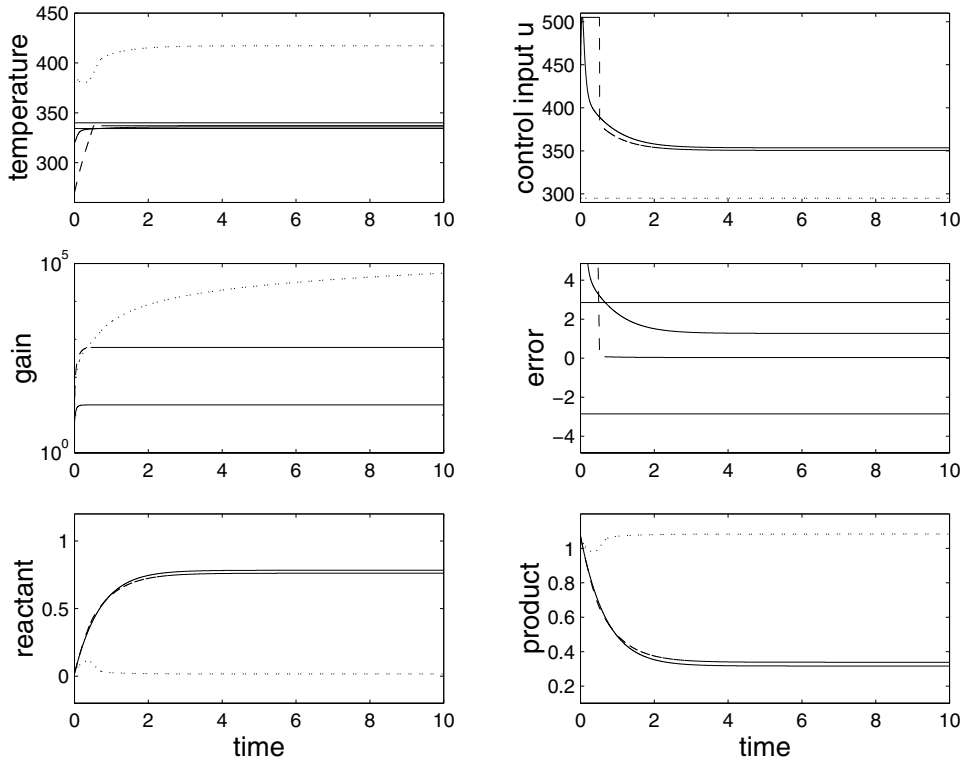

FIG. 1. *Closed-loop behavior of the adaptive λ-tracker* (4) *for local set-point control without measurement disturbance with parameters* (20) *applied to the single reaction* (15) *with parameters* (17)*, input constraints* (18)*, feasibility bounds* (19)*,* $T^0 = 270$ *(dashed),* $T^0 = 320$ *(solid),* $T^0 = 390$ *(dotted). The latter exhibits a thermal runaway.*

temperature is attracted to a stable but undesirably high temperature. As a result, the reaction becomes overheated, the reactant burns out, and there is a rapid growth of the product. Furthermore, the control input saturates at its lower limit throughout the simulation and the gain increases unboundedly.

3. Global tracking. The main result of the previous section, i.e., Theorem 7, has the shortcoming in that it is local in the sense that the initial temperature must lie inside $(0, \overline{T})$. This shortcoming can, under adverse temporary disturbances to the reaction, lead to a problem of thermal runaway in that the reaction dynamics are attracted to an undesirable equilibrium. See the simulations in Figure 1. Due to the given input saturations, it may even be impossible to reduce the temperature of the reaction from such equilibria by any type of control of the temperature alone. To overcome this problem, we borrow an idea from [12] and introduce an additional input action which has a cooling effect if the temperature is too large. To see the idea, consider the modification of the single reaction model (15) of the form

$$\left\{\begin{array}{rcrcl} \dot{x}_1(t) &=& -k\big(T(t)\big)\, x_1(t) &+& d\,[v(t) - x_1(t)], \\ \dot{x}_2(t) &=& k\big(T(t)\big)\, x_1(t) &-& d\, x_2(t), \\ \dot{T}(t) &=& b\, k\big(T(t)\big)\, x_1(t) &-& q\, T(t) \;+\; u(t), \end{array}\right. \tag{21}$$

with constant feedrate x_1^{in} replaced by $v(\cdot)$, an additional open-loop control of the feedrate of reactant. In [12] a choice of v as feedback control is

$$v(T) \;=\; \begin{cases} x_1^{\text{in}} & \text{if} \quad T \in (0, \overline{T}), \\ 0 & \text{if} \quad T \in [\overline{T}, \infty)\,. \end{cases} \tag{22}$$

The additional feedback (22) has the following beneficial effect: if $T(t) \geq \overline{T}$, then $\dot{x}_1(t) \leq -d\, x_1(t)$ and hence $x_1(\cdot)$ decreases; if $T(t) \geq \overline{T}$ is maintained, then $x_1(t)$ is eventually small enough to yield a decrease in temperature.

It is not clear to us whether the resulting discontinuous closed-loop system has a solution. It seems that the discontinuity should be harmless if the intervals in (22) are replaced by $(0, \overline{T}]$ and $(\overline{T}, \infty)$. However, since we also assume that the temperature measurement is corrupted by measurement disturbance, this discontinuity will be difficult to handle rigorously. To circumvent this technical difficulty, we replace the discontinuity in (22) by a simple piecewise linear control for $v(\cdot) : \mathbb{R} \to [0, x_1^{\text{in}}]$ given by

$$v(\beta e) \;=\; \begin{cases} 0 & \text{if} \quad \beta e \in (-\infty, \underline{u} - u^*], \\ (\beta e + u^* - \underline{u})\, x_1^{\text{in}}/\delta & \text{if} \quad \beta e \in (\underline{u} - u^*, \underline{u} - u^* + \delta), \\ x_1^{\text{in}} & \text{if} \quad \beta e \in [\underline{u} - u^* + \delta, \infty). \end{cases} \tag{23}$$

Here $\delta > 0$ would be small.

The additional feedrate control action (23) can also be introduced for multiple reactions as follows. We divide the state $x(t)$ into two substates $x_1(t)$ and $x_2(t)$ so that all reactants are collected in x_1. Applying a permutation of coordinates to (1) yields a system of the form

$$\begin{aligned} \dot{x}_1(t) &= C_1\, r\big(x(t), T(t)\big) + d\,[x_1^{\text{in}} - x_1(t)], \\ \dot{x}_2(t) &= C_2\, r\big(x(t), T(t)\big) + d\,[x_2^{\text{in}} - x_2(t)], \\ \dot{T}(t) &= b^T\, r\big(x(t), T(t)\big) - q\,T(t) + u(t), \end{aligned}$$

where $C_1 \in \mathbb{R}^{(n-m)\times m}$, $C_2 \in \mathbb{R}^{m\times m}$, $x_1^{\text{in}} \in \mathbb{R}^{n-m}_{\geq 0}$, and $x_2^{\text{in}} \in \mathbb{R}^{m}_{\geq 0}$. Since x_1 represents the reactants of the chemical reactor, it follows that each entry of C_1 is nonpositive, i.e., $C_1 \in \mathbb{R}^{(n-m)\times m}_{\leq 0}$. In this multireaction global case, the assumption (2) on the reaction kinetics must be strengthened to

$$\text{(A4)} \quad \|r(x,T)\| \leq \hat{r}(x_1)\, T \qquad \text{for all} \quad (x,T) = (x_1^T, x_2^T)^T, T) \in \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}_{>0}$$

for some locally Lipschitz function $\hat{r} : \mathbb{R}^{n-m}_{\geq 0} \to \mathbb{R}_{\geq 0}$ with $\lim_{x_1 \to 0} \hat{r}(x_1) = 0$.

Remark 9. Note that (A4) encompasses the class of functions considered in [12], where $b^T\, r(x,T) = \sum_{i=1}^m b_i\, k_i(T)\, \varphi_i(x)$, each $b_i > 0$, each function $T \mapsto k_i(T)$ is positive, bounded, and globally Lipschitz, and each function $x \mapsto \varphi_i(x)$ is nonnegative and continuous and vanishes if any component of x is zero for $i = 1, \ldots, m$, respectively.

The constant concentration of reactants in the feed flow x_1^{in} is replaced by an $(n-m)$-dimensional feedback term $v(\beta(\cdot)e(\cdot))$ given by (23) and the overall model becomes (compare [12, eq. (20)])

$$\begin{cases} \dot{x}_1(t) &= C_1\, r\big(x(t), T(t)\big) + d\,[v(\beta(t)e(t)) - x_1(t)], \\ \dot{x}_2(t) &= C_2\, r\big(x(t), T(t)\big) + d\,[x_2^{\text{in}} - x_2(t)], \\ \dot{T}(t) &= b^T\, r\big(x(t), T(t)\big) - q\,T(t) + u(t). \end{cases} \tag{24}$$

To proceed, we need to ensure that if the control $u(\cdot)$ and concentration of reactant $\nu(\cdot)$ in the feed of (24) are nonnegative, then the solution takes values in the positive orthant. To do this, we replace (A1) with the following:

(A1′) $\mathbb{R}^n_{\geq 0} \times \mathbb{R}_{>0}$ is positively invariant under

$$\begin{aligned} \dot{x}_1(t) &= C_1\, r\big(x(t), T(t)\big) + d\,[\nu(t) - x_1(t)], \\ \dot{x}_2(t) &= C_2\, r\big(x(t), T(t)\big) + d\,[x_2^{\text{in}} - x_2(t)], \\ \dot{T}(t) &= b^T\, r\big(x(t), T(t)\big) - q\,T(t) \;+\; u(t) \end{aligned}$$

for any bounded, nonnegative, locally integrable functions $u(\cdot) : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ and $\nu(\cdot) : \mathbb{R} \to [0, x_1^{\text{in}}]$.

As we pointed out in Remark 2(i), $T(t) > 0$ for all $t \geq 0$ is immediate and is only included in (A1′) for a less technical presentation. For the same reason, we have stated (A1′) for $\nu(\cdot)$, whereas it is only needed for $t \mapsto v(\beta(t)e(t))$.

Note that the comments we made for Assumption (A1) in Remark 2 apply here also. If we are in the situation described in Remark 9, then (A1′) holds.

We are now in a position to state the main result of this paper.

THEOREM 10 (adaptive tracking with measurement disturbance). *Suppose* (6), (A1′), (A2), (A3′), (A4) *hold and that the continuous disturbance satisfies*

$$\sup_{t\geq 0} \{|\xi(t)|\} \;=:\; \|\xi\|_\infty \;<\; \min\{T^* - \underline{T},\, \lambda/2\}\,. \tag{25}$$

Then an application of the λ*-tracker* (4) *combined with* (23) *to any system* (24) *yields, for any initial data* $(x^0, T^0, \beta^0) \in \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}^2_{>0}$*, a closed-loop system with unique solution* $\big(x(\cdot), T(\cdot), \beta(\cdot)\big) : \mathbb{R}_{\geq 0} \longrightarrow \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}^2_{>0}$ *defined on the whole time axis* $\mathbb{R}_{\geq 0}$*. Moreover,*

(i) $\lim_{t\to\infty} \beta(t) = \beta_\infty \in \mathbb{R}_{\geq 0}$*, i.e., the gain adaptation is convergent,*

(ii) $\lim_{t\to\infty} \operatorname{dist}(|T^* - T(t)|,\ [0, \lambda + \|\xi\|_\infty]) = 0$*; i.e., the temperature* $T(t)$ *tends to the* $[\lambda + \|\xi\|_\infty]$*-strip* $[T^* - [\lambda + \|\xi\|_\infty],\ T^* + [\lambda + \|\xi\|_\infty]]$ *as* $t \to \infty$*.*

The proof of Theorem 10 relies on the following high-gain lemma. This lemma is of interest in its own right, as it also gives insight into essential structural properties of the system class (24). It also shows that for sufficiently large gain, after some finite time the error enters and remains in the λ-strip.

LEMMA 11. *Suppose* (6), (A1′), (A2), (A3′), (A4), (25) *hold. Then an application to any system* (24) *of the nonadaptive feedback*

$$u(t) \;=\; sat_{[\underline{u},\overline{u}]}(\beta(t)e(t) + u^*), \qquad e(t) = T^* - T(t) + \xi(t), \tag{26}$$

combined with (23)*, yields, for any continuous* $\beta(\cdot) : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0}$ *satisfying, for some* $t' \geq 0$*,*

$$\beta(t) \;\geq\; \beta' \;:=\; \max\left\{\frac{\overline{u} - u^*}{\lambda - 2\|\xi\|_\infty}, \frac{u^* - \underline{u}}{\lambda - 2\|\xi\|_\infty}\right\} \qquad \textit{for all} \qquad t \geq t' \tag{27}$$

and any initial data $(x^0, T^0) \in \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}_{>0}$*, a closed-loop system with unique solution*

$$\big(x(\cdot), T(\cdot)\big) \;:\; \mathbb{R}_{\geq 0} \quad\longrightarrow\quad \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}_{>0}$$

on the whole time axis $\mathbb{R}_{\geq 0}$*. Moreover, there exists a time* $t_1 \geq t'$ *such that*

$$e(t) \;\in\; (-\lambda, \lambda) \qquad \textit{for all} \qquad t \geq t_1. \tag{28}$$

Theorem 10 and Lemma 11 are proved in the appendix.

A simple consequence of Lemma 11 is the following theorem, which shows that tracking can be achieved by the nonadaptive feedback (5) if the constant gain parameter β^* is sufficiently large (depending on the feasibility bounds). This feedback is simpler than (19) in [12], and we give an explicit lower bound for the gain in terms of weak conditions on the system.

THEOREM 12 (nonadaptive tracking with measurement disturbance). *Suppose* (6), (A1′), (A2), (A3′), (A4), (25) *hold, and* $\beta^* \geq \beta'$ *as defined in* (27). *Then an application of the nonadaptive output feedback*

$$u(t) \;=\; sat_{[\underline{u},\overline{u}]}\big(\beta^*\, e(t) \,+\, u^*\big), \qquad e(t) \;=\; T^* - T(t) + \xi(t), \tag{29}$$

combined with (23) *to any system* (24) *yields, for any initial data* $(x^0, T^0) \in \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}_{>0}$, *a closed-loop system with a unique solution*

$$\big(x(\cdot), T(\cdot)\big) \;:\; \mathbb{R}_{\geq 0} \quad \longrightarrow \quad \Omega(\gamma, x^{\text{in}}) \times \mathbb{R}_{>0}$$

on the whole time axis $\mathbb{R}_{\geq 0}$, *and moreover, there exists a time* $t_1 \geq t'$ *such that* (28) *is satisfied.*

Remark 13. If $\xi(\cdot) \equiv 0$, then (25) holds trivially, and so the adaptive gain feedback controller (4) can be applied without restriction, whereas the constant gain feedback controller (29) needs $\beta^* \geq \beta'$. If $\xi(\cdot) \not\equiv 0$, then in applying either the nonadaptive or the adaptive controller, we need to check conditions involving $\underline{T}$ and $\overline{T}$. Although this suggests that we might just as well use the simpler nonadaptive controller, in practice the adaptive gain is less conservative and the adaptive controller produces better results.

Figure 2 shows that the problem of thermal runaway above, exhibited for the local λ-set-point controller with $T^0 = 390$, is overcome by incorporating into the λ-tracker (4) the additional feedrate control via (23). Indeed, when $T^0 = 390$ the input v is switched off, i.e., $v(0) = 0$, and consumption of reactant is increased. This causes the temperature to drop, and λ-tracking is achieved. On the other hand, for $T^0 = 270$ and $T^0 = 320$, $v(\cdot) \equiv x_1^{\text{in}}$ and the response curves are the same as in Figure 1.

To illustrate the effectiveness of the controller in the presence of temperature measurement disturbances, we consider a disturbance signal

$$\xi(t) = \frac{1}{12} q_1(t), \tag{30}$$

where $q_1(\cdot)$ is the first component of the Lorenz equation

$$\begin{aligned}
\dot{q}_1(t) &= 10[q_2(t) - q_1(t)], & q_1(0) &= 1,\\
\dot{q}_2(t) &= 28q_1(t) - q_2(t) - q_1(t)q_3(t), & q_2(0) &= 0,\\
\dot{q}_3(t) &= q_1(t)q_2(t) - \tfrac{8}{3}q_3(t), & q_3(0) &= 3.
\end{aligned}$$

This Lorenz equation is known [11] to exhibit chaotic but bounded behavior. In this case $|\xi(t)| \leq 1.42$ for all $t \geq 0$. Hence, $\xi(\cdot)$ satisfies (25) for the data given in (18), (19), and (20).

Looking at Figures 3 and 4, we see that the error $T^* - T(t)$ is forced into the $[\lambda + \|\xi\|_\infty]$-strip $[-4.27, 4.27]$ despite the chaotic behavior of the disturbance signal (30). Since the constant gain in (5) is at all time equal to $\beta' = 6619$, unlike the adaptive gain in (4), which can be less than $\beta' = 6619$, the error in Figure 4 tends

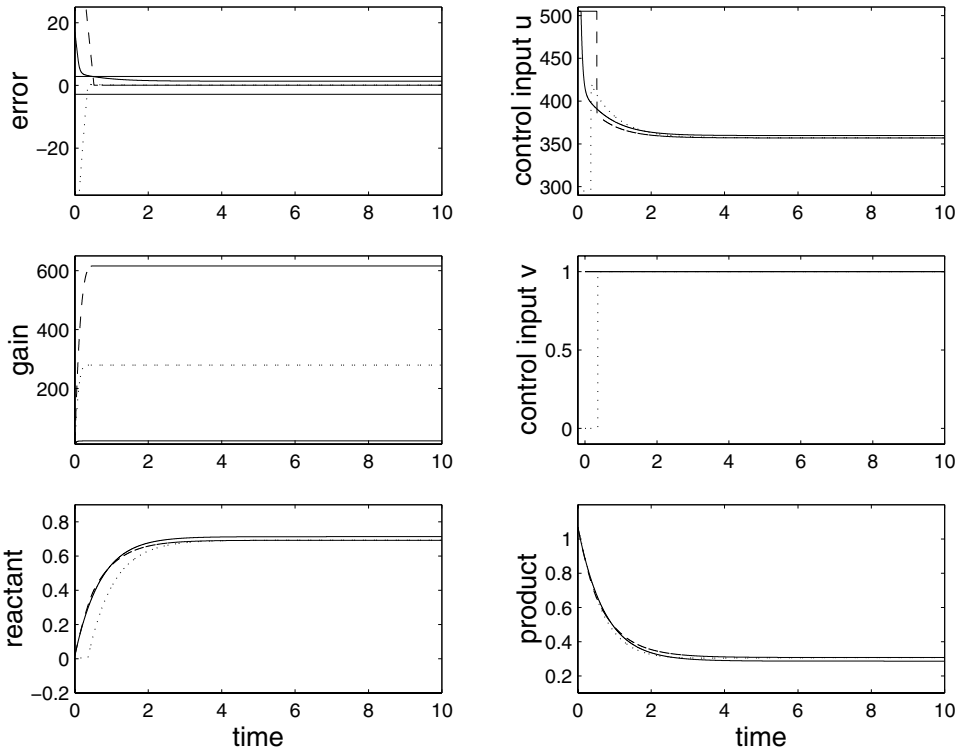

FIG. 2. *Closed-loop behavior of the adaptive λ-tracker* (4) *combined with cooling action* (23) *for global setpoint control without disturbance with parameters* (20) *applied to the single reaction* (21) *with parameters* (17), *input constraints* (18), *feasibility bounds* (19), $T^0 = 270$ *(dashed),* $T^0 = 320$ *(solid),* $T^0 = 390$ *(dotted). to a smaller strip than that of the error in Figure 4. Note that there is considerably more control action for the fixed gain controller than for the adaptive gain controller, even after the control objective has been met. This increased control action is bang-bang in nature, leads to a repeated switching on and off of the control action, and is therefore undesirable from a practical point of view. This observation provides some justification for the use of the adaptive gain controller in preference to the fixed gain controller. In this group of simulations, we have omitted the graphs corresponding to the initial temperature $T^0 = 270$ since they are similar to those for $T^0 = 320$. Moreover, we have replaced the graph of the product in Figure 3 (which is close to that in Figure 4) by that of an error in a longer simulation time to show that λ-tracking is indeed achieved.

4. Conclusion. In the present paper we have developed a λ-tracking approach to the set-point control of the temperature for a class of nonlinear systems arising as models in chemical reactor control. The novelty in this development is the need to carefully consider the interplay between the reaction dynamics, input constraints, and feasibility. The application of λ-trackers requires only limited information concerning the system. In addition, the λ-trackers quite readily tolerate bounded temperature measurement disturbances. In many respects they generalize the controllers developed by [12]. It is worth noting that the minimum phase assumption usually needed for

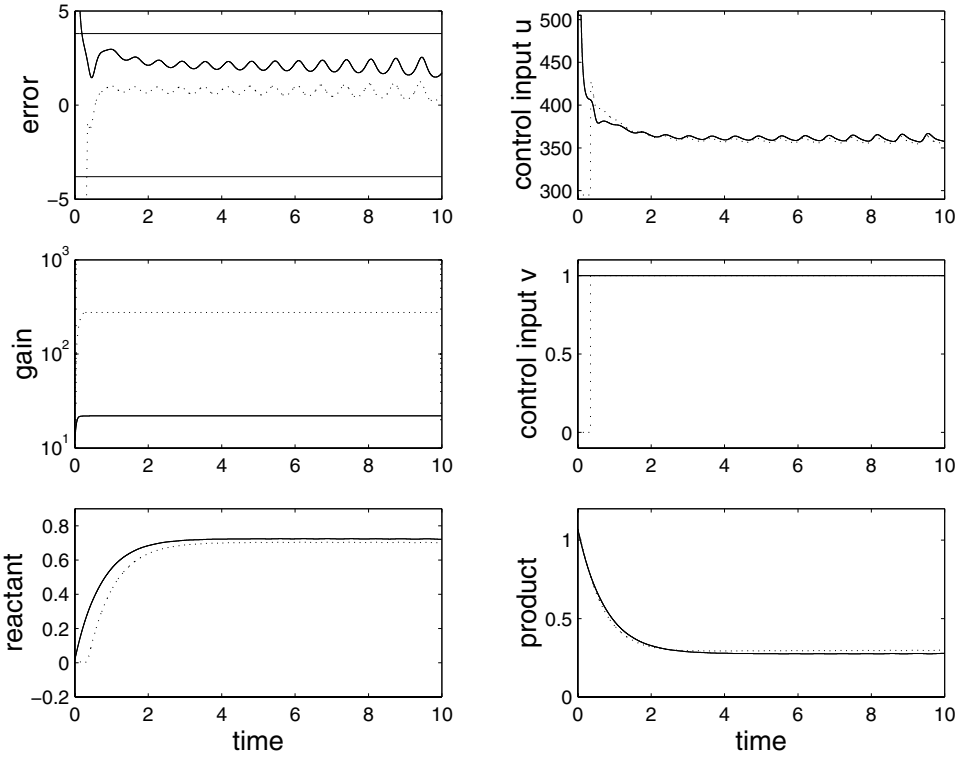

FIG. 3. *Closed-loop behavior of the adaptive λ-tracker* (4) *combined with cooling action* (23) *for global setpoint control with measurement disturbance with parameters* (20) *and disturbance signal given by* (30)*, applied to the single reaction* (21) *with parameters* (17)*, input constraints* (18)*, feasibility bounds* (19)*,* $T^0 = 320$ *(solid),* $T^0 = 390$ *(dotted).*

λ-tracking is not needed here. Instead, we exploit the natural property of chemical reactions that the internal state, i.e., the concentrations, is bounded.

Appendix. Proofs. For the sake of presentation, we define, for arbitrary $\Lambda > 0$, the distance function

$$d_\Lambda(\eta) \;:=\; \max\{|\eta| - \Lambda, 0\} \qquad \text{for all } \; \eta \in \mathbb{R}.$$

Note that for every solution (x, T) of (1) or (21) on $\mathbb{R}_{\geq 0}$ and $\hat{e}(t) = T^* - T(t)$, differentiation of

$$V_\Lambda(t) \;:=\; d_\Lambda(\hat{e}(t))^2 \qquad \text{for all } t \geq 0, \tag{31}$$

along (1) or (21) satisfies

$$\dot{V}_\Lambda(t) \;=\; \begin{cases} 2\sqrt{V_\Lambda(t)}\,\big[-b^T r\big(x(t),T(t)\big) + q\,T(t) - u(t)\big]\,, & \hat{e}(t) > 0, \\ 0, & \hat{e}(t) = 0, \\ -2\sqrt{V_\Lambda(t)}\,\big[-b^T r\big(x(t),T(t)\big) + q\,T(t) - u(t)\big]\,, & \hat{e}(t) < 0, \end{cases} \qquad \text{for all } t \geq 0. \tag{32}$$

Proof of Proposition 4. Existence and uniqueness of the solution (9) follow from Remark 6.

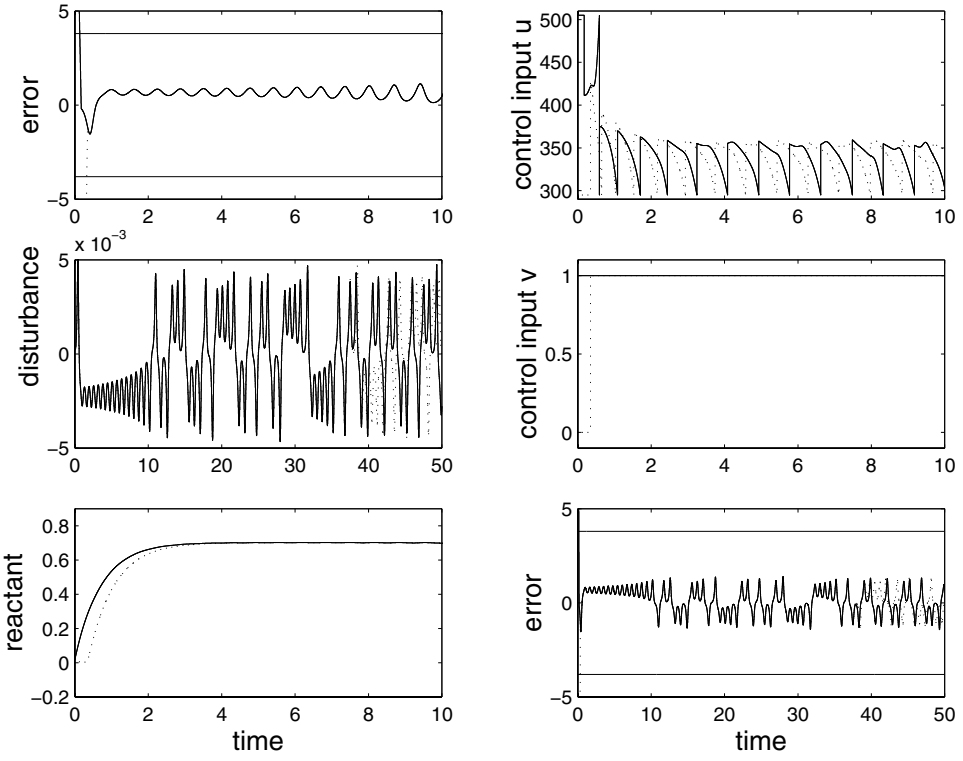

FIG. 4. *Closed-loop behavior of the constant gain controller* (5) *combined with cooling action* (23) *for global set-point control with measurement disturbance with parameters* (20) *and disturbance signal given by* (30)*, applied to the single reaction* (21) *with parameters* (17)*, input constraints* (18)*, feasibility bounds* (19)*,* $T^0 = 320$ *(solid),* $T^0 = 390$ *(dotted).*

Set $\Lambda := \lambda + \|\xi\|_\infty$ and consider, for all $t \geq 0$, the evolution of the actual error $\hat{e}(t) = T^* - T(t)$ with respect to V_Λ as in (31):

$$
\begin{aligned}
\hat{e}(t) \in [-\Lambda, \Lambda] \quad &\Longrightarrow \quad V_\Lambda(t) = 0 \ ; \\
\hat{e}(t) > \Lambda \quad &\Longrightarrow \quad \beta(t)\, e(t) + u^* \ = \ \beta(t)\, [\hat{e}(t) + \xi(t)] + u^* \\
&\qquad \overset{(5)}{>} \ \beta^* \, [\Lambda - \|\xi\|_\infty] \ + u^* = \beta^* \lambda + u^* \ \overset{(10)}{\geq} \ \bar{u} \ \overset{(5)}{=} \ u(t) \\
&\qquad \overset{(A3') \,\&\, (32)}{\Longrightarrow} \quad \dot{V}_\Lambda(t) \leq -2\rho \sqrt{V_\Lambda(t)} \, ; \\
\hat{e}(t) < -\Lambda \quad &\Longrightarrow \quad \beta(t)\, e(t) + u^* \ = \ \beta(t)\, [\hat{e}(t) + \xi(t)] + u^* \\
&\qquad < \ \beta(t)\, [-\Lambda + \|\xi\|_\infty] + u^* \ \overset{(5)}{\leq} \ -\beta^* \lambda + u^* \ \overset{(10)}{\leq} \ \underline{u} \ \overset{(5)}{=} \ u(t) \\
&\qquad \overset{(A3') \,\&\, (32)}{\Longrightarrow} \quad \dot{V}_\Lambda(t) \leq -2\rho \sqrt{V_\Lambda(t)} \, .
\end{aligned}
$$

Summarizing, we have, for all $t \geq 0$, $\dot{V}_\Lambda(t) \leq -2\rho \sqrt{V_\Lambda(t)}$, and so there exists $t' \geq 0$ such that $\hat{e}(t) \in [-\Lambda, \Lambda]$ for all $t \geq t'$, whence (11).

Proof of Theorem 7. Existence and uniqueness of the initial value problem (1), (4), (13) on a maximally extended interval $[0, \omega)$, $\omega \in (0, \infty]$, follows from the

theory of ordinary differential equations. Monotonicity of $t \mapsto \beta(t)$ and (13) yield $\beta(t) \geq \beta^*$ with β^* satisfying (8). Therefore Proposition 4 applies and $\Omega(\gamma, x^{\text{in}}) \times (0, \overline{T})$ is positively invariant. Now the gain adaptation (4) yields that $\beta(\cdot)$ cannot exhibit a finite escape time on $[0, \omega)$ and hence $\omega = \infty$.

For the remainder of the proof, consider the unique solution $\big(x(\cdot), T(\cdot), \beta(\cdot)\big)$ of (14).

We show assertion (i). Seeking a contradiction, suppose that β is unbounded. Then

$$\text{(33)} \qquad \text{there exists } \hat{t} \geq 0 \ : \ \text{for all } t \geq \hat{t} \quad : \qquad \beta(t) \ \geq \ \frac{\max\big\{u^* - \underline{u},\, \overline{u} - u^*\big\}}{\lambda - 2\,\|\xi\|_\infty}\,.$$

Set $\Lambda := \lambda - \|\xi\|_\infty$. By (12) $\Lambda > \|\xi\|_\infty$. Now consider, for all $t \geq \hat{t}$, the evolution of the actual error $\hat{e}(t) = T^* - T(t)$ with V_Λ as in (31):

$$\begin{aligned}
\hat{e}(t) \in [-\Lambda, \Lambda] \qquad &\Longrightarrow \qquad V_\Lambda(t) = 0\ ; \\
\hat{e}(t) > \Lambda \qquad &\Longrightarrow \qquad \beta(t)\, e(t) + u^* \ = \ \beta(t)\,[\hat{e}(t) + \xi(t)] + u^* \\
&\qquad\qquad > \ \beta(t)\,[\Lambda - \|\xi\|_\infty] + u^* = \ \beta(t)\,[\lambda - 2\|\xi\|_\infty] + u^* \\
&\qquad\qquad \overset{(33)}{\geq} \ \beta^*\big[\lambda - 2\|\xi\|_\infty\big] + u^* \ \geq \ \bar{u} \ \overset{(5)}{=} \ u(t) \\
&\overset{(A3')\,\&\,(32)}{\Longrightarrow} \qquad \dot{V}_\Lambda(t) \leq -2\rho\,\sqrt{V_\Lambda(t)}; \\
\hat{e}(t) < -\Lambda \qquad &\Longrightarrow \qquad \beta(t)\, e(t) + u^* \ = \ \beta(t)\,[\hat{e}(t) + \xi(t)] + u^* \\
&\qquad\qquad < \ \beta(t)\,[-\Lambda + \|\xi\|_\infty] + u^* \\
&\qquad\qquad \overset{(33)}{\leq} \ -\beta^*\big[\lambda - 2\|\xi\|_\infty\big] + u^* \ \leq \ \underline{u} \overset{(5)}{=} u(t) \\
&\overset{(A3')\,\&\,(32)}{\Longrightarrow} \qquad \dot{V}_\Lambda(t) \leq -2\rho\,\sqrt{V_\Lambda(t)}.
\end{aligned}$$

Summarizing, we have, for all $t \geq \hat{t}$, $\dot{V}_\Lambda(t) \leq -2\rho\,\sqrt{V_\Lambda(t)}$, and so there exists $t' \geq \hat{t}$ such that $\hat{e}(t) \in [-\Lambda, \Lambda]$ for all $t \geq t'$, whence $\beta(t) = 0$ for all $t \geq t'$, which contradicts the supposition of unboundedness of β. Therefore, β is bounded and assertion (i) follows by monotonicity of β.

Finally, we show assertion (ii). It is easy to see that

$$\kappa \int_0^t d_{\lambda + \|\xi\|_\infty}\big(\hat{e}(\tau)\big)^l \,\mathrm{d}\tau \ \leq \ \kappa \int_0^t d_\lambda\big(e(\tau)\big)^l \,\mathrm{d}\tau \ = \ \beta(t) - \beta^0 \qquad \text{for all } t \geq 0,$$

and hence assertion (i) yields $d_{\lambda+\|\xi\|_\infty}\big(\hat{e}(\cdot)\big)^l \in \mathcal{L}^1([0,\infty); \mathbb{R})$. Since continuity of $\eta \mapsto d_\lambda(\eta)$, together with boundedness and uniform continuity of $t \mapsto \hat{e}(t)$, yields uniform continuity of the composition $t \mapsto d_\lambda(\hat{e}(t))$, we may apply Barbălat's lemma (see, e.g., [10]) to conclude

$$\lim_{t\to\infty} \operatorname{dist}\Big(|\hat{e}(t)|,\ [0, \lambda + \|\xi\|_\infty]\Big) = 0.$$

This proves assertion (ii) and completes the proof of the theorem.

Proof of Proposition 8. By Theorem 7, there exist $t_0 \geq 0$ such that, for all $t \geq t_0$, $T(t) \in [T^* - 2\lambda, T^* + 2\lambda]$, and so, for all $t \geq t_0$,

$$\begin{aligned}
\text{(34)} \quad \inf\Big\{k(T)\Big|\ T \in [T^* - 2\lambda, T^* + 2\lambda]\Big\} \ &=: \ k_1(\lambda) \ \leq \ k(T(t)) \\
&\leq \ k_2(\lambda) \ := \ \sup\Big\{k(T)\Big|\ T \in [T^* - 2\lambda, T^* + 2\lambda]\Big\},
\end{aligned}$$

whence, by the continuity of $k(\cdot)$,

$$\lim_{\lambda\to 0} k_1(\lambda) = \lim_{\lambda\to 0} k_2(\lambda) = k(T^*). \tag{35}$$

Integrating the first equation in (15) yields

$$x_1(t) = e^{-\int_{t_0}^t (k(T(\tau))+d)\,\mathrm{d}\tau}\, x_1(t_0) + \int_{t_0}^t e^{-\int_s^t (k(T(\tau))+d)\,\mathrm{d}\tau} d\, x_1^{\mathrm{in}}\,\mathrm{d}s.$$

So, applying (34), we obtain

$$\frac{d\, x_1^{\mathrm{in}}}{k_2(\lambda)+d} \;\le\; \liminf_{t\to\infty} x_1(t) \;\le\; \limsup_{t\to\infty} x_1(t) \;\le\; \frac{d\, x_1^{\mathrm{in}}}{k_1(\lambda)+d}. \tag{36}$$

Therefore the first equation in (16) follows from (36) and (35). Integrating the second equation in (15) yields

$$x_2(t) = e^{-d\,(t-t_0)}\, x_2(t_0) + \int_{t_0}^t e^{-d(t-s)} k\big(T(s)\big)\, x_1(s)\,\mathrm{d}s.$$

Now applying (34) and (36), we obtain

$$\frac{k_1(\lambda)\, x_1^{\mathrm{in}}}{k_2(\lambda)+d} \;\le\; \liminf_{t\to\infty} x_2(t) \;\le\; \limsup_{t\to\infty} x_2(t) \;\le\; \frac{k_2(\lambda)\, x_1^{\mathrm{in}}}{k_1(\lambda)+d}, \tag{37}$$

and so the second equation in (16) follows from (37) and (35). This completes the proof.

Proof of Lemma 11. We proceed in several steps.

Step 1. The right-hand side of the closed-loop system is locally Lipschitz, and so the existence and uniqueness of the solution on a maximally extended interval $[0,\omega)$, $\omega \in (0,\infty]$, follow from the theory of ordinary differential equations.

Step 2. We show positive invariance of $\Omega(\gamma, x^{\mathrm{in}}) \times (0,\infty)$. Note that (A2) yields, for $x^{\mathrm{in}} = (x_1^{\mathrm{in}^T}, x_2^{\mathrm{in}^T})^T$, $\frac{d}{dt}\gamma^T x(t) \le -d\gamma^T x(t) + d\gamma^T x^{\mathrm{in}}$, and hence by integration

$$\gamma^T x(t) \le e^{-dt}\gamma^T x(0) + \gamma^T x^{\mathrm{in}}[1 - e^{-dt}] \qquad \text{for all } \; t \in [0,\omega).$$

If $x(0) \in \Omega(\gamma, x^{\mathrm{in}})$, then $\gamma^T x(0) < \gamma^T x^{\mathrm{in}}$, and so this inequality together with assumption (A1′) proves $x(t) \in \Omega(\gamma, x^{\mathrm{in}})$ for all $t \in [0,\omega)$. To see that $T(t)$ is positive, note that if we had $T(t) = 0$, then, by (1) and (6), $\dot{T}(t) \ge u(t) \ge \underline{u} > 0$.

Step 3. We show $\omega = \infty$. Since $x(\cdot)$ and $u(\cdot)$ are bounded, (A4) ensures that the right-hand side of $\dot{T}$ in (24) is affine linearly bounded in T and hence $T(\cdot)$ cannot escape in finite time. Applying the boundedness of $x(\cdot)$ and the maximality of ω yields the claim.

Step 4. We show that there exists $t_1 \ge t'$ such that $T(t) \in (0, \overline{T})$ for all $t \ge t_1$. Recall that, by Step 2, $T(t) > 0$ for all $t \in [0,\omega)$.

(4a) We claim that $T(s) \le \overline{T}$, for some $s \in [0,\omega)$, implies $T(t) \in (0,\overline{T})$ for all $t \in (s,\omega)$. This follows from (24) and (A3′), which give, in the case of $T(t) = \overline{T}$, that

$$\dot{T}(t) \;=\; b^T\, r\big(x(t), \overline{T}\big) - q\,\overline{T} + \underline{u} \;<\; -\rho\,.$$

(4b) It remains to be shown that if $T(t') > \overline{T}$, then $T(t) = \overline{T}$ for some $t > t'$. Seeking a contradiction, suppose

$$T(t) \;>\; \overline{T} \qquad \text{for all} \qquad t \ge t'\,. \tag{38}$$

Then (38) together with (27) gives

$$\beta(t)e(t) + u^* \;\le\; \beta(t)\,[T^* + \|\xi\|_\infty - \overline{T}] + u^* \;\le\; \underline{u} \qquad \text{for all} \qquad t \ge t', \tag{39}$$

and hence, by (23), $v(\beta(t)e(t)) = 0$ for all $t \ge t'$. Therefore, (24) and the fact that all entries of C_1 are nonpositive yield

$$\tfrac{\mathrm{d}}{\mathrm{d}t}\,\|x_1(t)\|^2 = 2\,x_1(t)^T\,\big[C_1\,r\big(x(t),T(t)\big) - d\,x_1(t)\big] \le -2\,d\,\|x_1(t)\|^2,$$

and it follows that

$$\|x_1(t)\| \;\le\; e^{-d(t-t')}\|x_1(t')\| \qquad \text{for all} \quad t \ge t'\,. \tag{40}$$

By (A3′), we may choose $\varepsilon \in (0,q)$ sufficiently small so that

$$-\,[q-\varepsilon]\,\overline{T} + \underline{u} \;<\; -\,\rho/2\,. \tag{41}$$

By (A4) and (40), there exists $t_1 \ge t'$ such that

$$\hat{r}(x_1(t)) \;\le\; \varepsilon/\|b\| \qquad \text{for all} \quad t \ge t_1\,. \tag{42}$$

Finally, applying (39), (24), (A4), (42), (38), and (41) yields

$$\begin{aligned}\dot{T}(t) \;&\le\; b\,r\big(x(t),T(t)\big) - qT(t) + \underline{u} \;\le\; \|b\|\,\hat{r}(x_1(t))\,T(t) - qT(t) + \underline{u}\\ &\le\; -\,[q-\varepsilon]\,T(t) + \underline{u} \;\le\; -\,[q-\varepsilon]\,\overline{T} + \underline{u} \;<\; -\,\rho/2 \qquad \text{for all} \qquad t \ge t_1\,.\end{aligned}$$

It then follows that there exists $t_2 \ge t_1$ such that $T(t_2) = \overline{T}$, which contradicts (38). This completes the proof of Step 4.

Step 5. Finally, we prove the existence of some $t_1 \ge t'$ such that (28) holds. Note that it suffices to show that there exists $t_2 \ge t_1$, t_1 as in Step 4, such that the actual error satisfies

$$\hat{e}(t) \in (-\lambda + \|\xi\|_\infty, \lambda - \|\xi\|_\infty) \qquad \text{for all} \qquad t \ge t_2\,, \tag{43}$$

since then (25) yields (28).

Set $\Lambda := \lambda - \|\xi\|_\infty$ and consider, for all $t \ge t_1$, the evolution of the actual error $\hat{e}(t) = T^* - T(t)$ with respect to V_Λ as in (31). Then, for all $t \ge t_1$,

$$\begin{aligned}
&\hat{e}(t) \in [-\Lambda,\Lambda] \quad &&\Longrightarrow \quad V_\Lambda(t) = 0\;;\\
&\hat{e}(t) > \Lambda \quad &&\Longrightarrow \quad \beta(t)\,e(t) + u^* \;=\; \beta(t)\,[\hat{e}(t) + \xi(t)] + u^*\\
&&&\qquad > \beta(t)\,[\Lambda - \|\xi\|_\infty] + u^* \;=\; \beta(t)\,[\lambda - 2\|\xi\|_\infty] + u^*\\
&&&\qquad \overset{(25,27)}{\ge} \beta'\,[\lambda - 2\|\xi\|_\infty] + u^* \overset{(5,27)}{\ge} \bar{u} \;=\; u(t)\\
&&&\overset{(A3')\,\&\,(32)}{\Longrightarrow} \quad \dot{V}_\Lambda(t) \le -2\rho\,\sqrt{V_\Lambda(t)};\\
&\hat{e}(t) < -\Lambda \quad &&\Longrightarrow \quad \beta(t)\,e(t) + u^* \;=\; \beta(t)\,[\hat{e}(t) + \xi(t)] + u^*\\
&&&\qquad <\; \beta(t)\,[-\Lambda + \|\xi\|_\infty] + u^* \;= \beta(t)\,[\lambda - 2\|\xi\|_\infty] + u^*\\
&&&\qquad \overset{(25,27)}{\le} -\beta'\,[\lambda - 2\|\xi\|_\infty] + u^* \overset{(5,27)}{\le} \underline{u} \;=\; u(t)\\
&&&\overset{(A3')\,\&\,(32)}{\Longrightarrow} \quad \dot{V}_\Lambda(t) \le -2\rho\,\sqrt{V_\Lambda(t)}.
\end{aligned}$$

Summarizing, we have, for all $t \geq t_1$, $\dot{V}_\Lambda(t) \leq -2\rho\sqrt{V_\Lambda(t)}$, and so there exists $t_2 \geq \hat{t}$ such that $\hat{e}(t) \in [-\Lambda, \Lambda]$ for all $t \geq t_2$, whence (43). This completes the proof of the lemma.

Proof of Theorem 10.

Steps 1–3. These steps are the same as in the proof of Lemma 11. The only addition to the proofs is that $\beta(\cdot)$ does not have a finite escape time if $T(\cdot)$ does not have a finite escape time.

Step 4. We prove (i). Note that $t \mapsto \beta(t)$ is monotonically nondecreasing. Then either (27) is not satisfied, in which case (i) is immediate, or (27) is satisfied. However, the latter yields by Lemma 11 that (28) holds, and thus the "dead zone" in the adaptation law (4) guarantees boundedness of $\beta(\cdot)$.

Step 5. We prove boundedness of $T(\cdot)$. Seeking a contradiction, suppose that $T(\cdot)$ is unbounded. Then there exists a sequence of disjoint intervals $I_m = (a_m, b_m)$, $m \in N$, with

$$T(a_m) = T^0 + T^* + \|\xi\|_\infty + \lambda + m < T(t) < T(b_m) = T^0 + T^* + \|\xi\|_\infty + \lambda + m + 1$$

for all $t \in I_m$. It follows that

$$|e(t)| = |T(t) - T^* - \xi(t)| \geq T(t) - T^* - \|\xi\|_\infty > \lambda + 1\,,$$

and hence $d_\lambda(e(t)) = |e(t)| - \lambda > 1$ for all $t \in \bigcup_{m\in\mathbb{N}} I_m$. Furthermore, we have, with $d := c[T^0 + T^* + \|\xi\|_\infty + \lambda + 1] + \overline{u}$ and for all $m \in \mathbb{N}$,

$$1 \;=\; T(b_m) - T(a_m) \;=\; \int_{a_m}^{b_m} \dot{T}(t)dt \;<\; \int_{a_m}^{b_m} [cT(b_m) + \overline{u}]dt \;=\; [c\,m + d]\,[b_m - a_m]\,.$$

This leads to the contradiction

$$\infty \;=\; \sum_{m\in\mathbb{N}} \frac{1}{c\,m + d} \;<\; \sum_{m\in\mathbb{N}} |b_m - a_m| \;<\; \sum_{m\in\mathbb{N}} \int_{a_m}^{b_m} d_\lambda(|e(t)|)^l dt \;\leq\; \frac{\beta_\infty}{\kappa} \;<\; \infty\,.$$

Step 6. Since all variables of the closed-loop system are bounded, the proof of (ii) is identical to Step 6 in the proof of Theorem 7. This completes the proof of the theorem.

Acknowledgments. We are indebted to an anonymous referee for several constructive comments which have helped to improve the paper. We add special thanks to Petia Georgieva (Bulgarian Academy of Sciences, Sofia) for a number of remarks on the modelling of exothermic chemical reactions.

$C^{2,\alpha}$ EXISTENCE RESULT FOR A CLASS OF SHAPE OPTIMIZATION PROBLEMS*

ARIAN NOVRUZI†

Abstract. In this paper we give a sufficient condition for the existence of regular optimal domains for a class of shape optimization problems. This consists of finding a $C^{2,\alpha}$ domain minimizing locally a shape functional depending on the perimeter of the domain and on a general term, which in most PDE applications represents the energy associated with the state equation, under the constraint that the measure of the domain is given. The proof of this result is based on another existence result for $C^{2,\alpha}$ solutions for a class of free boundary problems that are critical domains for the shape functionals considered previously. A key point is the introduction of a special domain transformation, which has a separate term responsible for the domain translation and another which is basically only responsible for "pure" deformation of the domain. As an application, a typical example involving the Dirichlet problem in R^N is considered.

1. Introduction.

In this paper we present a sufficient condition for the existence of $C^{2,\alpha}$ *optimal domains* which minimize locally a shape functional $E(\Omega) = e(\Omega) + \frac{1}{\sigma^2}P(\Omega)$ under the constraint that the measure $m(\Omega)$ of Ω is given, where $\Omega \subset R^N$ is a $C^{2,\alpha}$ open set, $e(\Omega)$ is a shape functional satisfying some hypotheses given later, $P(\Omega)$ is the perimeter of Ω, and $\sigma \in R\backslash\{0\}$.

Let $N \geq 2$, $0 < \alpha < 1$, $\mathcal{O} = \{\Omega \subset R^N,\ C^{2,\alpha}$ *open simply connected bounded set*$\}$, and let us consider the following problem:

$$\text{Find } \Omega_\sigma \in \mathcal{O} \mid E(\Omega_\sigma) = \min_{\text{loc}}\{E(\Omega),\ \Omega \in \mathcal{O},\ m(\Omega) = m_0\}, \quad m_0 > 0 \text{ given.} \tag{1.1}$$

The existence of solutions of (1.1) is proven in two steps: first we prove that there exist $C^{2,\alpha}$ *critical domains*, which are solutions of free boundary problems associated with (1.1), and second, based on this result, we prove that these critical domains are optimal domains.

For a particular $e(\Omega)$ and in two- and three-dimensional cases this problem has been studied in [3], [6], [7], [8], [9], and [11]. In [6] is given a sufficient existence condition for C^2 critical domains in dimension two with a particular $e(\Omega)$.

In this paper we prove an existence result for the existence of optimal domains of E for $|\sigma| << 1$, under some "reasonable assumptions" on $e(\Omega)$. Compared with the work presented in [6], in this paper there are two main contributions:

(i) the existence result is proven for both the minimization problem (1.1) and the free boundary problem rather than only for the free boundary problem associated with (1.1), and

(ii) the results are in dimension $N \geq 2$.

†Department of Mathematics and Statistics, University of Ottawa, 585 King Edward Ave., Ottawa, ON K1N 6N5, Canada (novruzi@uottawa.ca).

To solve (1.1), in addition to some conditions on $e(\Omega)$ required to solve the free boundary problem (hypotheses (1.2), (1.5), (1.6)), we need an interesting new condition concerning H^1 continuity of second shape derivative of $e(\Omega)$ (hypothesis (1.10)).

Usually, the necessary condition for the existence of Ω_σ is obtained by differentiating the functional $E(\Omega)$ with respect to the shape (we assume that the reader is familiar with shape derivatives; see, for example, [12], [13]); if not, most information is given here: for given $\Omega_0 \in \mathcal{O}$, let $\Gamma_0 = \partial\Omega_0$, $\Theta := C^{2,\alpha}(\Gamma_0; R^N)$, and $\theta \in \Theta$ with $\|\theta\|_\Theta$ small enough. Let us consider the domain $\Omega_\theta = \{x + \overset{*}{\theta}(x),\ x \in \Omega_0\} \in \mathcal{O}$, where $\overset{*}{\cdot} : \Theta \mapsto C^{2,\alpha}(\overline{\Omega}_0; R^N)$ is a $C^{2,\alpha}$ linear extension operator; see, for example, [4]. Then the shape derivative of e at Ω_θ is defined as the usual derivative at θ of the function $\theta \mapsto e(\Omega_\theta)$, considered as a function from Θ into R. Its value at θ evaluated at $\xi \in \Theta$ is denoted by $\partial_\theta e(\Omega_\theta)(\xi)$.

We make this general assumption for the functional $e(\Omega)$:

$$\forall\theta \in \Theta \ \text{ small}, \exists\ b(\theta) \in C^{0,\alpha}(\Gamma_\theta) \mid \forall\xi \in \Theta,\ \partial_\theta e(\theta)(\xi) = \int_{\partial\Omega_\theta} b(\theta)(\check{\xi} \cdot \nu_\theta), \tag{1.2}$$

where ν_θ is the outward normal unit vector to $\partial\Omega_\theta$, $\check{\xi} = \xi \circ (I + \theta)^{-1}$, and $\cdot$ is the inner product in R^N.

We will look for Ω_σ of the form Ω_θ, $\theta \in \Theta$. Knowing that (see, for example, [5], [9], [13])

$$\partial_\theta P(\Omega_\theta)(\xi) = \int_{\partial\Omega_\theta} \mathcal{H}_\theta(\check{\xi} \cdot \nu_\theta), \quad \partial_\theta m(\Omega_\theta)(\xi) = \int_{\partial\Omega_\theta} (\check{\xi} \cdot \nu_\theta),$$

where $\mathcal{H}_\theta$ is the mean curvature of $\partial\Omega_\theta$ (defined as the sum of principal curvatures), the necessary condition for the optimal domain Ω_σ is the existence of a θ_σ such that

$$\begin{cases} b(\theta_\sigma) + \frac{1}{\sigma^2}\mathcal{H}_{\theta_\sigma} + \Lambda_\sigma = 0 \quad \textit{on } \partial\Omega_\sigma, \\ m(\Omega_{\theta_\sigma}) = m_0, \end{cases} \tag{1.3}$$

where $\Lambda_\sigma \in R$ is a Lagrange multiplier due to the constraint $m(\Omega) = m_0$.

Let us explain first how we find a necessary condition for the existence of solutions of (1.3) in terms of $e(\Omega)$. From (1.1) it follows that $\mathbf{x} \in R^N \mapsto e(\Omega_{\sigma,\mathbf{x}})$, where $\Omega_{\sigma,\mathbf{x}} = (I + \mathbf{x})(\Omega_\sigma)$, has a minimum at $\mathbf{x} = 0$. Formally, it is expected that when σ tends to 0, Ω_σ should tend to a ball $B_{\mathbf{x}_0}$ of measure m_0. This allows thinking that the map $\mathbf{x} \to e(B_\mathbf{x})$, where $B_\mathbf{x} = \{\mathbf{y} \in R^N, |\mathbf{y} - \mathbf{x}| < r_0\}$, $m(B_\mathbf{x}) = m_0$, should also have a minimum at $\mathbf{x}_0$. To prove this let us make the following general assumptions:

(i) for any $\sigma^2 << 1$ there exists a Ω_σ solution of (1.1) in $\{B_\mathbf{x},\ \mathbf{x} \in R^N\}$;
(ii) $\Omega_\sigma \subset B_R := \{\mathbf{x} \in R^N, |\mathbf{x}| < R\}$ for some $R > 0$;
(iii) $\Omega \mapsto e(\Omega)$ is semicontinuous for $BV(B_R)$ weak topology; and
(iv) $\inf\{e(\Omega),\ \Omega \subset B_R,\ \Omega \in \mathcal{O}\} > -\infty$.

Then we may prove the following.

LEMMA 1.1. *Under assumptions* (i)–(iv) *there exists* $\mathbf{x}_0 \in R^N$ *such that* $\mathbf{x} \in R^N \to e(B_\mathbf{x}) \in R$ *has a minimum at* $\mathbf{x}_0$.

Proof. As $m(\Omega_\sigma) = m_0$, from isoperimetric inequality it follows that $P(\Omega_\sigma) = P(B_\mathbf{0}) + \epsilon_\sigma$, where $\epsilon_\sigma \geq 0$ and $B_\mathbf{0}$ is the ball with its center at origin and measure m_0. From (i) we have $E(\Omega_\sigma) \leq E(B_\mathbf{x})$. It follows that

$$e(\Omega_\sigma) + \frac{\epsilon_\sigma}{\sigma^2} \leq e(B_\mathbf{x}) \ \ \forall\mathbf{x} \in R^N. \tag{1.4}$$

From (iv) one obtains $\lim_{\sigma\to 0}\epsilon_\sigma = 0$. Thus $\{\Omega_\sigma, \sigma^2 << 1\}$ is bounded in $BV(B_R)$. Then there exists a subsequence of $\{\Omega_\sigma, \sigma^2 << 1\}$ denoted again by $\{\Omega_\sigma, \sigma^2 << 1\}$ such that $\lim_{\sigma\to 0}\Omega_\sigma = \Omega_0$ in $BV(B_R)$ weakly. As Ω_σ converges in L^1 we have $m(\Omega_0) = m_0$. From semicontinuity of the $BV(B_R)$ norm and $\lim_{\sigma\to 0}\epsilon_\sigma = 0$ it follows that $P(\Omega_0) \le P(B_{\mathbf{0}})$. Then from isoperimetric inequality (for Ω_0 it becomes equality) it follows that $\Omega_0 = B_{\mathbf{x}_0} \subset B_R$ for any $\mathbf{x}_0 \in R^N$. On the other hand from (iii) we have $e(B_{\mathbf{x}_0}) \le \liminf_{\sigma\to 0} e(\Omega_\sigma)$. Taking $\mathbf{x} = \mathbf{x}_0$ in (1.4) and letting σ tend to 0 gives $\lim_{\sigma\to 0}\frac{\epsilon_\sigma}{\sigma^2} = 0$. Letting once again σ tend to zero in (1.4) yields $e(B_{\mathbf{x}_0}) \le e(B_{\mathbf{x}})$ for all $\mathbf{x} \in R^N$. This proves the lemma. □

COROLLARY 1.2. *Assuming* (i)–(iv) *and* C^2 *regularity for* $e(B_{\mathbf{x}})$ *we have* $\nabla e(B_{\mathbf{x}})|_{\mathbf{x}_0} = 0$, *where* $\nabla = (\partial_1, \dots, \partial_N)$, ∂_i *denotes the* x_i *partial derivative. Moreover, if* $e(B_{\mathbf{x}})$ *has a minimum at* $\mathbf{x}_0$, *we have also* $\nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}_0} \ge 0$, *where* $\nabla^2 = [\partial_i\partial_j]$. *Lemma* 1.1 *may be useful to find counterexamples for the existence of optimal domains of* (1.1). *For example, if* $\nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}_0}$ *has any negative eigenvalue, then* (1.1) *cannot have solutions for* $\sigma^2 << 1$ *satisfying* (i)–(iv).

Let ν_0 denote the outward unitary normal vector to Γ_0. We will make these assumptions for the functional $e(\Omega)$:

$$\theta \mapsto b(\theta)\circ(I+\theta) \text{ is a } C^1 \text{ function near 0 from } \Theta \text{ into } C^{0,\alpha}(\Gamma_0), \tag{1.5}$$

$$\nabla e(B_{\mathbf{x}})|_{\mathbf{x}_0} = (0,\dots,0), \quad \nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}_0}, \text{ is positive.} \tag{1.6}$$

While (1.5) is a quite general assumption often satisfied, (1.6) has to be checked for any particular $e(\Omega)$. In section 4 we give an example for which we show that the hypothesis (1.6) is satisfied under some conditions that may be checked.

We think of the solutions Ω_σ of (1.1) and (1.3) as perturbations of the domain $\Omega_0 = B_{\mathbf{x}_0}$. While the perimeter $P(\Omega_\theta)$ is invariant by translation, the term $e(\Omega_\theta)$ is not. But $e(\Omega_\theta)$ has a minimum at $\theta = 0$ in the set $\{\theta \in R^N\}$ (from hypothesis (1.6)). This suggests for us to consider domain transformations having an explicit translation like

$$T : \begin{cases} R\times C^{2,\alpha}(\Gamma_0) & \longrightarrow \quad C^{2,\alpha}(\Gamma_0; R^N), \\ (\sigma,\varphi) & \longmapsto \quad I + u(\sigma,\varphi) := I + \mathbf{t}(\varphi) + \sigma\varphi\nu_0, \end{cases} \tag{1.7}$$

where $\mathbf{t}(\varphi) = \int_{\Gamma_0}\varphi\nu_0\, d\Gamma_0$.

It is clear that for (σ,φ) small in $R\times C^{2,\alpha}(\Gamma_0)$, $\Omega_{u(\sigma,\varphi)}$ is a $C^{2,\alpha}$ open set, denoted by $\Omega(\sigma,\varphi)$. Let $\Gamma(\sigma,\varphi) = \partial\Omega(\sigma,\varphi)$ be its boundary and $d\Gamma(\sigma,\varphi)$ its element area. Moreover, let $\nu(\sigma,\varphi)$ denote the outward unitary normal vector to $\Gamma(\sigma,\varphi)$, let $\mathcal{H}(\sigma,\varphi)$ denote the curvature of $\Gamma(\sigma,\varphi)$, and let $\mathcal{H}_0$ denote the curvature of Γ_0.

Let us also set $\mathbf{E}(\sigma,\varphi) = E(\Omega(\sigma,\varphi))$, $\mathbf{e}(\sigma,\varphi) = e(\Omega(\sigma,\varphi))$, $\mathbf{b}(\sigma,\varphi) = b(\Omega(\sigma,\varphi))$, $\mathbf{P}(\sigma,\varphi) = P(\Omega(\sigma,\varphi))$, and $\mathbf{m}(\sigma,\varphi) = m(\Omega(\sigma,\varphi))$.

REMARK 1.3. *A main part of the paper deals with the solution of* (1.3). *The difficulty in solving it comes from the singularity in* σ^{-2} *of* (1.3). *Let us first point out that from* (1.3) *it is expected that the leading term of* Λ_σ *should be* $-\frac{\mathcal{H}_0}{\sigma^2}$ *(this follows from the regularity of* $b(\theta)$ *and* $\mathcal{H}_\theta$*); thus* $\Lambda_\sigma = \frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}$ *for any* $\Lambda \in R$. *Then one may prove (we will see throughout this paper) that the first and second* φ *derivatives of* $\mathbf{E}(\sigma,\varphi) + \left(\frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right)\mathbf{m}(\sigma,\varphi)$ *are no longer singular. This is the first main advantage of having* σ *in* (1.7) *(see also Remark* 2.8).

In the case when (1.1) has a solution in the set $\{\Omega(\sigma,\varphi),\ \varphi \in C^{2,\alpha}(\Gamma_0)\}$, a priori, this is not a solution of (1.1). A key point is to show that for $(\sigma,\varphi) \in R\times C^{2,\alpha}(\Gamma_0)$, if $\mathbf{t}(\varphi) + \sigma\varphi\nu_0$ is small in Θ, then for every $\xi \in \Theta$ small, there exists a small $\phi \in$

$C^{2,\alpha}(\Gamma_0)$ such that $\Omega_{u(\sigma,\varphi)+\xi} = \Omega(\sigma, \varphi + \phi)$ (Proposition 2.6). Thus if $\Omega(\sigma, \varphi_\sigma)$ for any $(\sigma, \varphi_\sigma) \in R \times C^{2,\alpha}(\Gamma_0)$ is the solution of (1.1) in the set $\{\Omega(\sigma, \varphi), \varphi \in C^{2,\alpha}(\Gamma_0)\}$, then $\Omega(\sigma, \varphi_\sigma)$ is the solution of (1.1) too.

The main results we prove are the following two theorems.

THEOREM 1.4. *Under the hypotheses* (1.2), (1.5), *and* (1.6) *there exist* $\sigma^* > 0$ *and a unique* C^1 *map* $\sigma \in (-\sigma^*, \sigma^*) \longmapsto (\varphi_\sigma, \Lambda_\sigma) \in C^{2,\alpha}(\Gamma_0) \times R$ *such that for all* $\sigma \in (-\sigma^*, \sigma^*)\backslash\{0\}$ *we have*

$$\mathbf{b}(\sigma, \varphi_\sigma) + \frac{1}{\sigma^2}\mathcal{H}(\sigma, \varphi_\sigma) + \left(\frac{\Lambda_\sigma}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right) = 0 \quad on \quad \Gamma(\sigma, \varphi_\sigma), \tag{1.8}$$

$$\mathbf{m}(\sigma, \varphi_\sigma) - m_0 = 0. \tag{1.9}$$

Thus $\left(\Omega(\sigma, \varphi_\sigma), \frac{\Lambda_\sigma}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right)$ *is the solution of* (1.3).

REMARK 1.5.

(i) *We emphasize that* (1.8) *is equivalent to* $\partial_\varphi \mathbf{L}(\sigma, \varphi_\sigma, \Lambda_\sigma) = 0$ *(Remark* 3.1, *Lemma* 3.2) *where*

$$\mathbf{L}(\sigma, \varphi, \Lambda) = \mathbf{e}(\sigma, \varphi) + \frac{1}{\sigma^2}\mathbf{P}(\sigma, \varphi) + \left(\frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right)\mathbf{m}(\sigma, \varphi).$$

The form of $\mathbf{L}(\sigma, \varphi, \Lambda)$ *is* $\mathbf{E}(\sigma, \varphi)$ *plus the last term, which is related to the constraint that the measure is fixed. The coefficient* $\frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}$ *is the Lagrange multiplier in* (1.3). *Its coefficient near* σ^{-2} *is such that* $\partial_\varphi \mathbf{L}$ *is a* C^1 *function (see the discussion before Theorem* 1.4 *and Lemma* 3.3).

(ii) *Rather than the positiveness of* $\nabla^2 e(B_\mathbf{x})|_{\mathbf{x}_0}$, *what is essential for the existence of critical points is* $\det(\nabla^2 e(B_\mathbf{x})|_{\mathbf{x}_0}) \neq 0$. *Indeed, to prove Theorem* 1.4 *it is required that only* $\nabla^2 e(B_\mathbf{x})|_{\mathbf{x}_0}$ *have nonzero eigenvalues.*

THEOREM 1.6. *Let us assume that the hypotheses* (1.2), (1.5), *and* (1.6) *are satisfied and the maps*

$$\theta \mapsto \partial_\theta^2 e(\Omega_\theta), \quad \theta \mapsto \partial_\theta^2 P(\Omega_\theta), \quad \theta \mapsto \partial_\theta^2 m(\Omega_\theta)$$
$$\text{are continuous from } \Theta \text{ to } H^1(\Gamma_0; R^N) \times H^1(\Gamma_0; R^N). \tag{1.10}$$

Then there exist $\sigma^* > 0$ *and a unique* C^1 *map* $\sigma \in (-\sigma^*, \sigma^*) \longmapsto (\varphi_\sigma, \Lambda_\sigma) \in C^{2,\alpha}(\Gamma_0) \times R$ *such that for all* $\sigma \in (-\sigma^*, \sigma^*)\backslash\{0\}$, $\Omega(\sigma, \varphi_\sigma)$ *is the solution of* (1.1).

REMARK 1.7. *Although the condition* (1.10) *seems a "nonnatural hypothesis," because we have chosen* $C^{2,\alpha}$ *as the framework and* (1.10) *involves* H^1 *norms, it is quite reasonable in a shape optimization context. Indeed, in* [10] *is given the precise structure of shape derivatives. In particular, there is shown that the second shape derivative applied to* (ξ, η) *depends only on the* $C^1(\Gamma_0)$ *norm of* ξ *and* η, *which makes it quite reasonable to expect a control of* $\partial_\theta^2 e(\Omega_\theta)(\xi, \eta)$ *through the* $H^1(\Gamma_0)$ *norm of* ξ *and* η. *The perimeter* $P(\Omega_\theta)$ *and the measure* $m(\Omega_\theta)$ *satisfy the condition* (1.10), *thus the condition* (1.10) *directly concerns* $e(\Omega_\theta)$.

In section 4 *we will give an example satisfying all the hypotheses of Theorem* 1.6. *A condition similar to* (1.10) *for a class of energy functionals associated with a general second order elliptic operator is proven in* [2].

2. Some shape derivatives results. In this section we deal with some results that will be very useful throughout this paper. We start with the derivative of $\mathcal{H}(\sigma, \varphi) \circ T(\sigma, \varphi)$ and of $\frac{1}{\sigma}(\mathcal{H}(\sigma, \varphi) \circ T(\sigma, \varphi) - \mathcal{H}_0)$. In order to make full use of a particular structure of the transformation (1.7) we will make the computations by hand. Later on we show some results related to the domain transformations.

Throughout this paper we set $\mathbf{x}_0 = \mathbf{0}$, $\Omega_0 = B_{r_0}(\mathbf{x}_0)$, and $\Gamma_0 = \partial\Omega_0$. For $\sigma \neq 0$ given and $\varphi \in C^{2,\alpha}(\Gamma_0)$, let $\mathbf{y} : R^N \mapsto R$ be defined by

$$\mathbf{y}(y) = |y - \mathbf{t}(\varphi)| - \sigma\varphi\left(r_0 \frac{y - \mathbf{t}(\varphi)}{|y - \mathbf{t}(\varphi)|}\right) - r_0.$$

It is clear that for $y \in \Gamma(\sigma, \varphi)$, $\mathbf{y}(y) = 0$ and $\nu(\sigma, \varphi)(y) = \frac{\nabla_y \mathbf{y}(y)}{|\nabla_y \mathbf{y}(y)|}$. Thus we obtain

$$\nu(\sigma,\varphi)(y) = \frac{z - \sigma r_0 \overline{\nabla}\varphi(x)}{|z - \sigma r_0 \overline{\nabla}\varphi(x)|}, \quad \text{where} \quad z = y - \mathbf{t}(\varphi), \quad x = r_0 \frac{z}{|z|}, \quad x \in \Gamma_0, \tag{2.1}$$
$$\overline{\nabla} = (\overline{\partial}_1, \ldots, \overline{\partial}_N), \quad \overline{\partial}_i\varphi = \partial_i\varphi - (\nabla\varphi \cdot \nu_0)\nu_0^i, \quad \text{(the tangential gradient)}.$$

It is clear also that for $\sigma\varphi$ small, $\nu(\sigma, \varphi)$ is a $C^{1,\alpha}(\Gamma_0)$ well-defined function. Indeed, we have $|z - \sigma r_0 \overline{\nabla}\varphi(x)| = [(r_0 + \sigma\varphi)^2 + r_0^2\sigma^2|\overline{\nabla}\varphi|^2]^{1/2}$, which shows that for $\sigma\varphi$ small, for example, $\|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \leq \frac{r_0}{2}$, the denominator in the expression of $\nu(\sigma, \varphi)(y)$ is greater than $\frac{r_0}{2}$ and of course implies $C^{1,\alpha}$ regularity of $\nu(\sigma, \varphi)$.

LEMMA 2.1. *The curvature of* $\Gamma(\sigma, \varphi)$ *is given by*

$$\mathcal{H}(\sigma,\varphi) \circ T(\sigma,\varphi) = \mathcal{H}_0 \frac{r_0}{|(r_0 + \sigma\varphi)\nu_0 - \sigma r_0 \overline{\nabla}\varphi|} - \frac{r_0}{|r_0 + \sigma\varphi|}\left[\frac{\sigma r_0 \ \underline{\Delta}\varphi}{|(r_0 + \sigma\varphi)\nu_0 - \sigma r_0 \overline{\nabla}\varphi|}\right.$$
$$\left. - \frac{\sigma^3 r_0^3 \ \overline{\nabla}\varphi \cdot \overline{\nabla}^2\varphi \cdot \overline{\nabla}\varphi}{|(r_0 + \sigma\varphi)\nu_0 - \sigma r_0 \overline{\nabla}\varphi|^3}\right], \tag{2.2}$$

where $\overline{\nabla}^2\varphi$ *is the matrix* $[\overline{\partial}_i\overline{\partial}_j\varphi]$ *and* $\underline{\Delta}\varphi = tr[\overline{\nabla}^2\varphi]$ *is the Laplace–Beltrami operator on* Γ_0.

Proof. Because $\mathcal{H}(\sigma, \varphi) = \sum_{i=1}^N \overline{\partial}_i \nu^i(\sigma, \varphi)$, where

$$\overline{\partial}_i \nu^i(\sigma,\varphi) = \partial_{y_i} \overset{*}{\nu}{}^i(\sigma,\varphi) - (\nu(\sigma,\varphi) \cdot \nabla_y \overset{*}{\nu}(\sigma,\varphi))\nu^i(\sigma,\varphi),$$

we have to compute the terms $\overline{\partial}_{y_i}\nu^i(\sigma, \varphi)$. It is easy to verify the relations

$$\overline{\partial}_{y_i} z_i = \delta_{ij} - \nu^i(\sigma,\varphi)\nu^j(\sigma,\varphi), \qquad \overline{\partial}_{y_i}\phi(x) = \frac{r_0}{|z|}\overline{\partial}_i\phi(x), \qquad \phi \in C^1(\Gamma_0),$$

where δ_{ij} is the Kronecker's symbol. For simplicity, let's set $\phi = \sigma r_0 \varphi$. Then

$$\begin{aligned}
\mathcal{H}(\sigma,\varphi) \circ T(\sigma,\varphi) &= \overline{\partial}_{y_i}\nu^i(\sigma,\varphi) \\
&= \frac{\overline{\partial}_{y_i} z_i - \overline{\partial}_{y_i}\overline{\partial}_i\phi(x)}{|z - \overline{\nabla}\phi(x)} \\
&\quad - \frac{(z_i - \overline{\partial}_i\phi(x))(z_j - \overline{\partial}_j\phi(x)}{|z - \overline{\nabla}\phi(x)|^3}(\delta_{ij} - \nu^i(\sigma,\varphi)\nu^j(\sigma,\varphi) - \frac{r_0}{|z|}\overline{\partial}_i\overline{\partial}_j\phi(x)) \\
&= \frac{N-1}{|z - \overline{\nabla}\phi(x)|} - \frac{r_0}{|z|}\frac{\underline{\Delta}\phi(x)}{|z - \overline{\nabla}\phi(x)|} + \frac{r_0}{|z|}\frac{\overline{\nabla}\phi(x) \cdot \overline{\nabla}^2\phi(x) \cdot \overline{\nabla}\phi(x)}{|z - \overline{\nabla}\phi(x)|^3},
\end{aligned}$$

because $x \cdot \overline{\nabla}^2\phi(x) = 0$. From $\mathcal{H}_0 = \frac{N-1}{r_0}$, $|z| = |r_0 + \sigma\varphi|$, and $|z - \overline{\nabla}\varphi| = |(r_0 + \sigma\varphi)\nu_0 - \sigma r_0 \overline{\nabla}\varphi|$ we obtain immediately the expression for $\mathcal{H}(\sigma, \varphi) \circ T(\sigma, \varphi)$. ∎

As a simple corollary of this lemma we have the following.

COROLLARY 2.2. *The map* $(\sigma,\varphi)\mapsto \mathcal{H}(\sigma,\varphi)\circ T(\sigma,\varphi)$ *from* $R\times C^{2,\alpha}(\Gamma_0)$ *into* $C^{0,\alpha}(\Gamma_0)$ *is of class* C^1 *near* $(0,0)$.

Proof. First, we point out that $\mathcal{H}(\sigma,\varphi)\circ T(\sigma,\varphi)\in C^{0,\alpha}(\Gamma_0)$. This is a simple consequence of the fact that $\mathcal{H}(\sigma,\varphi)\circ T(\sigma,\varphi)$ is a simple algebraic expression depending on $C^{0,\alpha}(\Gamma_0)$ functions. We emphasize that its denominator is strictly greater than, say, $r_0/2$ for $\sigma\varphi$ small. Then its differentiability with respect to (σ,φ) is clear for $\sigma\varphi$ small. □

COROLLARY 2.3. *The map* $(\sigma,\varphi)\mapsto \mathcal{K}(\sigma,\varphi):=\frac{\mathcal{H}(\sigma,\varphi)\circ T(\sigma,\varphi)-\mathcal{H}_0}{\sigma}$ *from* $R\times C^{2,\alpha}(\Gamma_0)$ *into* $C^{0,\alpha}(\Gamma_0)$ *is of class* C^1 *near* $(0,0)$. *Moreover, its derivative with respect to* φ *at* $(0,0)$ *is given by*

$$\partial_\varphi \mathcal{K}(0,0)(\phi)=-\underline{\Delta}\phi-\frac{\mathcal{H}_0^2}{N-1}\phi. \tag{2.3}$$

Proof. By direct computations and using (2.2) one may easily find that

$$\begin{aligned}\mathcal{K}(\sigma,\varphi)=&-\mathcal{H}_0\frac{2r_0\varphi+\sigma\varphi^2+\sigma r_0^2|\overline{\nabla}\varphi|^2}{|(r_0+\sigma\varphi)\nu_0-\sigma r_0\overline{\nabla}\varphi|(r_0+|(r_0+\sigma\varphi)\nu_0-\sigma r_0\overline{\nabla}\varphi|)}\\ &-\frac{r_0^2}{|r_0+\sigma\varphi|}\left[\frac{\underline{\Delta}\varphi}{|(r_0+\sigma\varphi)\nu_0-\sigma r_0\overline{\nabla}\varphi|}-\frac{\sigma^2 r_0^2\ \overline{\nabla}\varphi\cdot\overline{\nabla}^2\varphi\cdot\overline{\nabla}\varphi}{|(r_0+\sigma\varphi)\nu_0-\sigma r_0\overline{\nabla}\varphi|^3},\right],\end{aligned} \tag{2.4}$$

which shows that $\mathcal{K}(\sigma,\varphi)$ is of class C^1 near $(0,0)$, for example, for $\|\sigma\varphi\|_{C^{2,\alpha}(\Gamma)}<r_0/2$. The expression of $\mathcal{K}(\sigma,\varphi)$ also gives immediately the value of $\partial_\varphi\mathcal{K}(0,0)(\varphi)$. □

As we mentioned in the introduction, we will prove first that the problem (1.1) has a solution $\Omega(\sigma,\varphi_\sigma)$ in the set of domains $\{\Omega(\sigma,\varphi),\varphi\in C^{2,\alpha}(\Gamma_0)\}$. Then a key point is to prove that $\Omega(\sigma,\varphi)$ is the solution of (1.1) in Θ. For this it is sufficient to show that for any $\xi\in\Theta$ small, there exists a $\phi\in C^{2,\alpha}(\Gamma_0)$ such that $\Omega_{u(\sigma,\varphi_\sigma)+\xi}=\Omega(\sigma,\varphi_\sigma+\phi)$. Let us prove first the following important lemma.

LEMMA 2.4. *Let* $\sigma\neq 0$, $\sigma\le\frac{P(\Omega_0)}{2N}$. *There exist* Θ_0, *a small neighborhood of* 0 *in* Θ *not depending on* σ, *and two* C^1 *functions*

$$\theta\in\Theta_0\mapsto\varphi=\boldsymbol{\varphi}(\theta)\in C^{2,\alpha}(\Gamma_0)\quad\text{and}\quad\theta\in\Theta_0\mapsto g=\mathbf{g}(\theta)\in C^{2,\alpha}(\Gamma_0;\Gamma_0),$$

with g *invertible, such that*

$$(I+\theta)\circ g=I+\mathbf{t}(\varphi)+\sigma\varphi\nu_0\quad\text{on }\Gamma_0. \tag{2.5}$$

Moreover, there exist $C>0$ *not depending on* σ *such that for* $\theta\in\Theta_0$, *we have*

$$\|\mathbf{g}(\theta)\|_\Theta\le C, \tag{2.6}$$

$$\|\mathbf{g}^{-1}(\theta)-I\|_\Theta\le C\|\theta\|_\Theta. \tag{2.7}$$

Proof. Let $t\in R^N$, and for $y\in\Gamma_0$ set $x=r_0\frac{(I+\theta)(y)-t}{|(I+\theta)(y)-t|}\in\Gamma_0$ and $g(\theta,t):\Gamma_0\mapsto\Gamma_0$, $g(\theta,t)(x)=y$. For $(\theta,t)\in\Theta_1\times\mathcal{U}_1$, a small neighborhood of $(0,0)$ in $\Theta\times R^N$, the function $g(\theta,t)$ is a $C^{2,\alpha}(\Gamma_0;\Gamma_0)$ well-defined invertible function. Indeed, for $(\theta,t)=(0,0)$ we have $g(0,0)(x)=x$. Then the inversibility of $g(\theta,t)$ for (θ,t) small follows from C^1 regularity of $(\theta,t)\mapsto g(\theta,t)$.

Now let us introduce the function $\varphi(\theta,t):\Gamma_0\mapsto R$ by

$$\sigma\varphi(\theta,t)(x)=|(I+\theta)\circ g(\theta,t)(x)-t|-r_0. \tag{2.8}$$

We look for t such that $t = \mathbf{t}(\varphi(\theta, t))$. For this, let us consider the equation

$$\sigma t = \int_{\Gamma_0} (|(I+\theta)\circ g(\theta,t)(x) - t| - r_0)\nu_0(x)dx. \tag{2.9}$$

The function

$$\begin{aligned} f : (\theta, t) \in \Theta \times R^N \mapsto \sigma t - \int_{\Gamma_0} (|(I+\theta)\circ g(\theta,t)(x) - t| - r_0)\nu_0(x)dx \in R^N \\ = \sigma t - \int_{\Gamma_0} (I+\theta)\circ g(\theta,t)(x) - t - xdx \end{aligned}$$

is of class C^1, $f(0,0) = 0$, and for $s \in R^N$, $\partial_t f(0,0)(s) = (\sigma + \frac{P(\Omega_0)}{N})s$.

Let us prove the expression of $\partial_t f(0,0)(s)$. For $\theta = 0$, we have $\frac{g(0,t)-t}{|g(0,t)-t|} = \nu_0$. This gives $(|g(0,t) - t|\nu_0 + t)^2 = r_0^2$ because $|g(\theta,t)| = r_0$. Then we may find that

$$|g(0,t) - t| = [(\nu_0 \cdot t)^2 - t^2 + r_0^2]^{1/2} - (\nu_0 \cdot t).$$

It follows that

$$g(0,t) = t + [(\nu_0 \cdot t)^2 - t^2 + r_0^2]^{1/2}\nu_0 - (\nu_0 \cdot t)\nu_0, \quad \partial_t g(0,0)(s) = s - (\nu_0 \cdot s)\nu_0,$$

and we obtain

$$\begin{aligned} \partial_t f(0,0)(s) &= \sigma s - \int_{\Gamma_0} \partial_t g(0,0)(s)(x) - s dx \\ &= \sigma s + \int_{\Gamma_0} (\nu_0(x)\cdot s)\nu_0(x)dx = \left(\sigma + \frac{P(\Omega_0)}{N}\right)s. \end{aligned}$$

From the implicit function theorem it follows that we have the existence of Θ_2, a neighborhood of 0 in Θ, and a map $\theta \in \Theta_2 \mapsto t_\theta \in R^N$ such that $t_\theta|_{\theta=0} = \mathbf{0}$ and t_θ satisfies (2.9). Taking σ small, say, $|\sigma| < \frac{P(\Omega_0)}{2N}$, allows us to choose Θ_2 independent of σ.

Now, putting $t = t_\theta$ in (2.8), multiplying by $\nu_0(x)$, and integrating on Γ_0, from (2.9) it follows that $\mathbf{t}(\varphi(\theta, t_\theta)) = t_\theta$. Finally, let $\Theta_0 = \Theta_1 \cap \Theta_2$. For $\theta \in \Theta_0$ let's set $\mathbf{g}(\theta) = g(\theta, t_\theta)$, $\boldsymbol{\varphi}(\theta) = \varphi(\theta, t_\theta)$. These functions satisfy the lemma. Indeed, for θ and $t = t_\theta$, from the construction of $g(\theta,t)$, $\varphi(\theta,t)$, and (2.8) we have

$$\begin{aligned} (I+\theta)\circ g(\theta,t_\theta) &= |(I+\theta)\circ g(\theta,t_\theta) - t_\theta|\nu_0 + t_\theta = (r_0 + \sigma\varphi(\theta,t_\theta))\nu_0 + t_\theta \\ &= I + \mathbf{t}(\varphi(\theta,t_\theta)) + \sigma\varphi(\theta,t_\theta)\nu_0. \end{aligned}$$

The C^1 regularity of the functions $\boldsymbol{\varphi}$ and $\mathbf{g}$ follows immediately from the formula giving $g(\theta,t_\theta)$, $\varphi(\theta,t_\theta)$ and from the C^1 regularity of $\theta \mapsto t_\theta$.

The estimation (2.6) follows from the fact that $\mathbf{g}^{-1}(\theta) = r_0\frac{I+\theta-t_\theta}{|I+\theta-t_\theta|}$ and that $\theta \mapsto t_\theta$ is a uniformly C^1 function (with respect to σ) from Θ to itself.

For (2.7) we write

$$\begin{aligned} \mathbf{g}^{-1}(\theta) - I &= \frac{1}{|I+\theta-t_\theta|}\left[r_0(\theta - t_\theta) + \frac{r_0^2 - |r_0\nu_0 + \theta - t_\theta|^2}{r_0 + |r_0\nu_0 + \theta - t_\theta|}I\right] \\ &= \frac{1}{|I+\theta-t_\theta|}\left[r_0(\theta - t_\theta) - \frac{\theta^2 + t_\theta^2 + 2r_0(\nu_0\cdot\theta) - 2r_0(\nu_0\cdot t_\theta) - 2(\theta\cdot t_\theta)}{r_0 + |r_0\nu_0 + \theta - t_\theta|}I\right]. \end{aligned}$$

This equality, together with the facts $t_\theta|_{\theta=0} = 0$ and C^1 continuity of $\theta \to t_\theta$, gives $|t_\theta| \le C\|\theta\|_\Theta$. It follows that $\|\mathbf{g}^{-1}(\theta) - I\|_\Theta \le C\|\theta\|_\Theta$, which proves (2.7). □

COROLLARY 2.5. *For any $\varphi_\sigma \in C^{2,\alpha}(\Gamma_0)$, let's set $\theta = u(\sigma, \varphi_\sigma)$. Then $\boldsymbol{\varphi}(\theta) = \varphi_\sigma$.*

Proof. First we show that $t_\theta = \mathbf{t}(\varphi_\sigma)$. Indeed, as we have $g(\theta, \mathbf{t}(\varphi_\sigma)) = I$, it follows that $\mathbf{t}(\varphi_\sigma)$ satisfies (2.9). From uniqueness of t satisfying (2.9), we obtain $t_\theta = \mathbf{t}(\varphi_\sigma)$. Then from the formula defining $\varphi(\theta, t)$, by direct verification, we obtain $\boldsymbol{\varphi}(\theta) = \varphi(\theta, t_\theta) = \varphi_\sigma$. □

PROPOSITION 2.6. *Let's assume that for any σ small, there exists $\varphi_\sigma \in C^{2,\alpha}(\Gamma_0)$ such that $\Omega(\sigma, \varphi_\sigma)$ is the solution of* (1.1) *in $\{\Omega(\sigma, \varphi), \varphi \in C^{2,\alpha}(\Gamma_0)\}$. If $u(\sigma, \varphi_\sigma) \in \Theta_0$, where Θ_0 is given by Lemma* 2.4, *then $\Omega(\sigma, \varphi_\sigma)$ is the solution of* (1.1) *in Θ.*

Proof. As σ is small, it follows that $u(\sigma, \varphi_\sigma) \in \Theta_0$. Then there exists a ball $B(0, \epsilon) = \{\|\theta\|_\Theta < \epsilon\}$ such that $u(\sigma, \varphi_\sigma) + B(0, \epsilon) \subset \Theta_0$. From Lemma 2.4, $\Omega_{u(\sigma,\varphi_\sigma)+\xi}$ $= \Omega(\sigma, \boldsymbol{\varphi}(u(\sigma, \varphi_\sigma) + \xi))$ for all $\xi \in B(0, \epsilon)$. Then the proposition follows from the C^1 regularity of $\boldsymbol{\varphi}$ and $\boldsymbol{\varphi}(u(\sigma, \varphi_\sigma)) = \varphi_\sigma$ (Corollary 2.5). □

LEMMA 2.7. *For $\theta \in \Theta_0$, let φ and g be as in Lemma* 2.4, *$(I + \theta) \circ g = I + \mathbf{t}(\varphi) + \sigma\varphi\nu_0$. Then there exist two constants C_1, C_2 not depending on σ such that*

$$\|\theta\|_\Theta \le \delta \Longrightarrow \|\mathbf{t}(\varphi) + \sigma\varphi\nu_0\|_\Theta \le C_1\delta, \tag{2.10}$$

$$\|\mathbf{t}(\varphi) + \sigma\varphi\nu_0\|_\Theta \le \delta \Longrightarrow |\mathbf{t}(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \le C_2\delta. \tag{2.11}$$

Proof. Let us first prove (2.10). From (2.8) we have $\mathbf{t}(\varphi) + \sigma\varphi\nu_0 = (I + \theta) \circ \mathbf{g}(\theta) - I = \theta \circ \mathbf{g}(\theta) - \mathbf{g}(\theta) \circ (\mathbf{g}^{-1}(\theta) - I)$. From (2.6) and (2.7), we get

$$\|\mathbf{t}(\varphi) + \sigma\varphi\nu_0\|_\Theta \le C\|\mathbf{g}(\theta)\|_\Theta\|\theta\|_\Theta + \|\mathbf{g}(\theta)\|_\Theta\|\mathbf{g}^{-1}(\theta) - I\|_\Theta \le C\|\theta\|_\Theta,$$

which proves (2.10).

Now, let's prove (2.11). As each component of ν_0 becomes 0 for any $|\mathbf{x}| = r_0$, it follows that $|\mathbf{t}(\varphi)| \le \delta$. This implies $\|\sigma\varphi\nu_0\|_\Theta \le 2\delta$, and

$$\|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} = \|\sigma\varphi\nu_0 \cdot \nu_0\|_{C^{2,\alpha}(\Gamma_0)} \le \nu_0\|_\Theta\|\sigma\varphi\nu_0\|_\Theta \le 2\|\nu_0\|_\Theta\delta,$$

which proves (2.11) with $C_2 = 1 + 2\|\nu_0\|_\Theta$. □

REMARK 2.8. *Proposition* 2.6 *and Lemma* 2.7 *are very important, in particular for proving Theorem* 1.6. *Indeed, let $\Omega(\sigma, \varphi_\sigma)$ be the solution of* (1.3). *To prove that $\Omega(\sigma, \varphi_\sigma)$ is the solution of* (1.1), *from Lemma* 2.4 *it follows that it is enough to consider perturbations of the form $I + \mathbf{t}(\varphi) + \sigma\varphi\nu_0$. Moreover, from Proposition* 2.6 *and Lemma* 2.7, *it is enough to consider perturbation of $\Omega(\sigma, \varphi_\sigma)$ of the form $I + \mathbf{t}(\varphi) + \sigma\varphi\nu_0$ with φ satisfying $|\mathbf{t}(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \le \delta$. Thus, φ may be large but $\sigma\varphi$ must be of order δ. Thus, if*

$$\varphi = \sum_{i,j} \varphi_{ij}u_{ij} = \sum_{j=1,n} \varphi_{1j}u_{1j} + \sum_{i\ne1,j} \varphi_{ij}u_{ij} =: \varphi_1 + \varphi_1^c,$$

where u_{ij} are the eigenfunctions of $\underline{\Delta}$, from

$$\|\varphi\|^2_{H^1(\Gamma_0)} = \|\varphi_1\|^2_{H^1(\Gamma_0)} + \|\varphi_1^c\|^2_{H^1(\Gamma_0)},$$

$$\|\varphi_1\|^2_{H^1(\Gamma_0)} = \left(1 + \frac{\mathcal{H}_0^2}{N-1}\right) \sum_{j=1,N} \varphi_{1j}^2 = \frac{N}{|\Gamma_0|}\left(1 + \frac{\mathcal{H}_0^2}{N-1}\right)|\mathbf{t}(\varphi)|^2, \tag{2.12}$$

it follows that

$$\|\varphi_1\|^2_{H^1(\Gamma_0)} + \|\sigma\varphi_1^c\|^2_{H^1(\Gamma_0)} \le C\delta. \tag{2.13}$$

From (2.5) *and* (2.12) *it follows that* φ_1 *is responsible for the domain translation* $\mathbf{t}(\varphi)$. *The "pure" deformation of the domain is basically due to* φ_1^c *because the contribution of* φ_1 *is of order* $\sigma\delta$ *(for the* $H^1(\Gamma_0)$ *norm).*

Writing the domain perturbation as the sum of two terms involving φ_1 *and* φ_1^c *with* φ_1^c *multiplied by* σ *is very important. Indeed, if one considers* $E(\Omega_{\theta+\varphi\nu_0})-E(\Omega_\theta)$ *(instead of* $E(\Omega_{\theta+\mathbf{t}(\varphi)+\sigma\varphi\nu_0})-E(\Omega_\theta)$*), its main part is*

$$\frac{1}{\sigma^2}\int_{\Gamma_0}|\overline{\nabla}\varphi|^2-\frac{\mathcal{H}_0^2}{N-1}\varphi^2+\frac{o(1)}{\sigma^2}\|\phi\|_{H^1(\Gamma_0)}+\mathbf{t}(\varphi)\cdot\nabla^2 e(B_{\mathbf{x}_0})\cdot\mathbf{t}(\varphi).$$

The integral term has no φ_1 *contribution, but it is positive (greater than* $C\|\varphi_1^c\|^2_{H^1(\Gamma_0)}$*). The term with* φ_1 *appears only near to the* $o(1)$ *term and the* $e(\Omega)$ *derivative. In general, it is difficult to control the residue* $o(1)\|\varphi\|^2_{H^1(\Gamma_0)}$*, and here the transformation* $\mathbf{t}(\varphi)+\sigma\varphi\nu_0$ *is of interest, because in this case one would have* $o(1)\|\varphi\|_{H^1(\Gamma_0)}$ *instead of* $\frac{o(1)}{\sigma^2}\|\varphi\|_{H^1(\Gamma_0)}$. *The* $\|\varphi_1\|_{H^1(\Gamma_0)}$ *part of the* $o(1)$ *term may be controlled by the* $e(\Omega)$ *derivative term (and here the hypothesis* (1.6) *intervenes crucially), while the* $\|\varphi_1^c\|_{H^1(\Gamma_0)}$ *part of the* $o(1)$ *term is controlled by the integral term.*

LEMMA 2.9. *Let* $K_0=\{\varphi,\partial_\theta m(\Omega_0)(\varphi\nu_0)=0\}$. *There exists a* C^2 *function* $q: dom(q)\subset K_0\mapsto C^{2,\alpha}(\Gamma_0)$ *where* $dom(q)$ *is an open neighborhood of* 0 *in* K_0 *such that* $m(\Omega_{q(\varphi)\nu_0})=m_0$, $q(\varphi)=\varphi+\beta(\varphi)$ *with* β *a* C^2 *function, and* $\beta(0)=0$. *Moreover,*

$$\partial_\varphi\beta(0)(\phi)=0, \tag{2.14}$$

$$\partial_\theta m(\Omega_{q(\varphi)\nu_0})(\partial^2_\varphi\beta(\varphi)(\phi,\phi))+\partial^2_\theta m(\Omega_{q(\varphi)\nu_0})(\partial_\varphi\beta(\varphi)(\phi),\partial_\varphi\beta(\varphi)(\phi))=0, \tag{2.15}$$

$$\varphi\mapsto\partial_\varphi\beta \quad \textit{is continuous from} \quad C^{2,\alpha}(\Gamma_0) \textit{ to } H^1(\Gamma_0),$$

$$\varphi\mapsto\partial^2_\varphi\beta \quad \textit{is continuous from} \quad C^{2,\alpha}(\Gamma_0) \textit{ to } H^1(\Gamma_0)\times H^1(\Gamma_0).$$

Proof. The existence of β and q as well as (2.14) and (2.15) are classical results and may be proven easily by direct computations and applying the implicit function theorem to $(\varphi,t)\in K_0\times R\mapsto m(\Omega_{(\varphi+t)\nu_0})-m_0\in R$ at $(0,0)$ (although a proof of it is presented in [9]).

Here, we will not present the complete proof. Instead, we will prove the regularity for $\partial_\varphi\beta$ and $\partial^2_\varphi\beta$. Indeed, differentiating one and two times with respect to φ, the equation $m(\Omega_{q(\varphi)\nu_0})-m_0=0$ gives

$$\begin{aligned}
0&=\int_{\partial\Omega_{q(\varphi)\nu_0}}(\phi+\partial_\varphi\beta(\varphi)(\phi))(\nu_0\cdot\nu_{q(\varphi)\nu_0})\\
&=\int_{\Gamma_0}(\phi+\partial_\varphi\beta(\varphi)(\phi))(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0),\\
0&=\int_{\Gamma_0}\partial^2_\varphi\beta(\varphi)(\phi,\phi)(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0)\\
&\quad+\int_{\Gamma_0}(\phi+\partial_\varphi\beta(\varphi)(\phi))\partial_\varphi[(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0)](\phi).
\end{aligned}$$

It follows that

$$\partial_\varphi\beta(\varphi)(\phi)=\frac{\int_{\Gamma_0}\phi(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0)d\Gamma_0}{\int_{\Gamma_0}(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0)},$$

$$\partial^2_\varphi\beta(\varphi)(\phi,\phi)=\frac{\int_{\Gamma_0}(\phi+\partial_\varphi\beta(\varphi)(\phi))\partial_\varphi[(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_\Gamma(I+q(\varphi)\nu_0)](\phi)}{\int_{\Gamma_0}(\nu_0\cdot\nu_{q(\varphi)\nu_0})Jac_{\Gamma_0}(I+q(\varphi)\nu_0)}.$$

From the C^1 continuity of $\varphi \mapsto \partial_\varphi \beta$ and of the maps $\theta \mapsto \nu_\theta \circ (I+\theta)$ and $\theta \mapsto Jac_\Gamma(I+\theta)$, the regularity claimed for the maps $\varphi \mapsto \partial_\varphi \beta(\varphi)$ and $\varphi \mapsto \partial^2_\varphi \beta(\varphi)$ follows. □

3. Proof of the main results. Let F be the function

$$F : R \times C^{2,\alpha}(\Gamma_0) \times R \longmapsto C^{0,\alpha}(\Gamma_0) \times R,$$
$$(\sigma, \varphi, \Lambda) \longmapsto \big(F_1(\sigma,\varphi,\Lambda), F_2(\sigma,\varphi,\Lambda)\big),$$

where F_1, F_2 are defined by

$$(3.1)\quad F_1(\sigma,\varphi,\Lambda) = \nu_0 \cdot \int_{\Gamma(\sigma,\varphi)} \mathbf{b}(\sigma,\varphi)\nu(\sigma,\varphi)d\Gamma + [\sigma \mathbf{b}(\sigma,\varphi)\circ T(\sigma,\varphi) + \mathcal{K}(\sigma,\varphi) - \Lambda](\nu(\sigma,\varphi)\circ T(\sigma,\varphi)\cdot\nu_0) J_{\Gamma_0} T(\sigma,\varphi),$$

$$(3.2)\quad F_2(\sigma,\varphi,\Lambda) = [\mathbf{m}(\sigma,\varphi) - \mathbf{m}(0,0)]/\sigma.$$

Here $J_{\Gamma_0}T(\sigma,\varphi) = |^t[DT(\sigma,\varphi)]^{-1}\cdot\nu_0| JT(\sigma,\varphi)$ is the tangential Jacobian of $T(\sigma,\varphi)$ and $JT(\sigma,\varphi)$ is the usual Jacobian of $T(\sigma,\varphi)$.

REMARK 3.1. *Note that F_1/σ differs from the left-hand side of* (1.8) *basically by the term $\sigma^{-1}\nu_0 \cdot \int_\Gamma \mathbf{b}(\sigma,\varphi)\nu(\sigma,\varphi)d\Gamma$. F_1 is the $C^{0,\alpha}(\Gamma)$ representation of $\partial_\varphi \mathbf{L}(\sigma,\varphi,\Lambda)$. The function $F_1(\sigma,\varphi,\Lambda)$ is defined explicitly, while $F_2(\sigma,\varphi,\Lambda)$ initially is defined implicitly. In* (3.6) *is given the explicit form of $F_2(\sigma,\varphi,\Lambda)$. It is clear that in particular $F(0,\varphi,\Lambda)$ is well defined. See Remark* 3.4 *for more discussion about $F(0,\varphi,\Lambda)$.*

LEMMA 3.2. *For $(\sigma,\varphi) \in (R\backslash\{0\}) \times C^{2,\alpha}(\Gamma_0)$ small such that $u(\sigma,\varphi) \in \Theta_0$, $F_1(\sigma,\varphi,\Lambda) = 0$ is equivalent to* (1.8).

Proof. It is enough to prove that $\partial_\varphi \mathbf{L}(\sigma,\varphi,\Lambda) = 0$ implies

$$\partial_\theta E(\Omega_{u(\sigma,\varphi)}) + \left(\frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right)\partial_\theta m(\Omega_{u(\sigma,\varphi)}) = 0.$$

(See the introduction for the difference between ∂_θ and ∂_φ.)

Let $s \in R$ be small such that $u(\sigma,\varphi) + s\xi \in \Theta_0$. From Lemma 2.4, $\Omega_{u(\sigma,\varphi)+s\xi} = \Omega(\sigma, \boldsymbol{\varphi}(u(\sigma,\varphi)+s\xi))$. But

$$\partial_\theta E(\Omega_{u(\sigma,\varphi)})(\xi) = \partial_s \mathbf{E}(\sigma, \boldsymbol{\varphi}(u(\sigma,\varphi)+s\xi)) = \partial_\varphi \mathbf{E}(\sigma,\varphi)(\partial_\theta \boldsymbol{\varphi}(u(\sigma,\varphi))(\xi)),$$
$$\partial_\theta m(\Omega_{u(\sigma,\varphi)})(\xi) = \partial_s \mathbf{m}(\sigma, \boldsymbol{\varphi}(u(\sigma,\varphi)+s\xi)) = \partial_\varphi \mathbf{m}(\sigma,\varphi)(\partial_\theta \boldsymbol{\varphi}(u(\sigma,\varphi))(\xi)),$$

which leads to

$$\partial_\theta E(\Omega_{u(\sigma,\varphi)})(\xi) + \left(\frac{\Lambda}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2}\right)\partial_\theta m(\Omega_{u(\sigma,\varphi)})(\xi) = \partial_\varphi \mathbf{L}(\sigma,\varphi,\Lambda)(\partial_\theta \boldsymbol{\varphi}(u(\sigma,\varphi))(\xi)) = 0$$

and finishes the proof. □

LEMMA 3.3. *The function $F : R \times C^{2,\alpha}(\Gamma_0) \times R \to C^{0,\alpha}(\Gamma_0) \times R$ is of class C^1 near $(0,0,0)$. Moreover, the derivative of F with respect to (φ,Λ) at $(0,0,0)$ is given by*

$$(3.3)\quad \partial_{\varphi,\Lambda} F_1(0,0,0)(\varphi,\lambda) = -\underline{\Delta}\varphi - \frac{\mathcal{H}_0^2}{N-1}\varphi + \lambda + \nu_0 \cdot \nabla^2 e(B_x)|_{\mathbf{x}_0} \cdot \mathbf{t}(\varphi),$$

$$(3.4)\quad \partial_{\varphi,\Lambda} F_2(0,0,0)(\varphi,\lambda) = \int_{\Gamma_0} \varphi d\Gamma_0.$$

Proof. Taking into account (3.1), the C^1 regularity of F_1 near $(0,0)$ follows from the hypothesis (1.5), the regularity result of Corollary 2.3, and the classical regularity results of the maps $(\sigma,\varphi)\mapsto \nu(\sigma,\varphi)\circ T(\sigma,\varphi)$ and $J_{\Gamma_0}T(\sigma,\varphi)$; see, for example, [12].

Let $F_{11}(\sigma,\varphi)$ be the first term of $F_1(\sigma,\varphi,\Lambda)$. It is easy to verify that

$$\begin{aligned} F_{11}(0,\varphi) &= \sum_{i=1,N} \nu_0^i \int_{\Gamma(0,\varphi)} \mathbf{b}(0,\varphi)\nu^i(0,\varphi) \\ &= \frac{N}{P(\Omega_0)} \sum_{i=1,N} \nu_0^i \int_{\Gamma(0,\varphi)} \mathbf{b}(0,\varphi)(\nu(0,\varphi)\cdot \mathbf{t}(\nu_0^i)) \\ &= \frac{N}{P(\Omega_0)} \sum_{i=1,N} \nu_0^i \partial_\varphi \mathbf{e}(0,\varphi)(\nu_0^i). \end{aligned}$$

As we also have $\mathbf{e}(0,\varphi)=e(B_{\mathbf{x}_0+\mathbf{t}(\varphi)})$, it follows that

$$\begin{aligned} \partial_\varphi F_{11}(0,0)(\varphi) &= \frac{N}{P(\Omega_0)} \sum_{i=1,N} \nu_0^i\ \partial_\varphi^2 \mathbf{e}(0,0)(\nu_0^i,\varphi) \\ &= \frac{N}{P(\Omega_0)} \sum_{i=1,N} \nu_0^i\ \mathbf{t}(\nu_0^i)\cdot \nabla^2 e(B_x)|_{\mathbf{x}_0}\cdot \mathbf{t}(\varphi) = \nu_0\cdot \nabla^2 e(B_x)|_{\mathbf{x}_0}\cdot \mathbf{t}(\varphi). \end{aligned}$$

The expression of $\partial_{\varphi,\Lambda}F_1(0,0,0)$ is completed then by Corollary 2.3.

The C^1 regularity of F_2 is a classical result. However, the proof is simple. Indeed, we have

$$\mathbf{m}(\sigma,\varphi)=\int_{\Omega_0} JT(\sigma,\varphi))d\Omega_0 = \int_{\Omega_0} det[\delta_{ij}+\sigma\partial_j(\overset{*}{\varphi}\overset{*}{\nu}{}_0^i)]d\Omega_0. \tag{3.5}$$

Thus we obtain

$$F_2(\sigma,\varphi,\Lambda)=\int_{\Omega_0}\sum_{i=1,N}\partial_i(\overset{*}{\varphi}\overset{*}{\nu}{}_0^i)d\Omega_0+\sum_{k=2,N}\sigma^{k-1}\int_{\Omega_0}Q_k d\Omega_0, \tag{3.6}$$

where Q_k is a homogeneous polynomial of order N depending on the first derivatives of $\overset{*}{\varphi}\overset{*}{\nu}{}_0^i$. Then it is clear that F_2 is a C^1 function and

$$\partial_\varphi F_2(0,0,0)(\varphi)=\int_{\Omega_0}\sum_{i=1,N}\partial_i(\overset{*}{\varphi}\overset{*}{\nu}{}_0^i)d\Omega_0=\int_{\Gamma_0}\varphi d\Gamma_0,$$

which achieves the proof of the lemma. □

Remark 3.4. *In the next theorem we will apply the implicit function theorem near* $(0,0,0)$ *to the function* F. *Let us emphasize that* $F_1(0,0,0)=0$ *is ensured by the first part of* (1.6) *and* (2.4), *while* $F_2(0,0,0)=0$ *is guaranteed by* (3.6). *Also, from* (2.4) *and* (3.6), *it follows that*

$$F(0,\varphi,\Lambda)=\begin{pmatrix} -\underline{\Delta}\varphi-\frac{\mathcal{H}_0^2}{N-1}\varphi-\Lambda+\nu_0\cdot\int_{\Gamma_{\mathbf{t}(\varphi)}}\mathbf{b}(0,\varphi)\nu_0 d\Gamma_0 \\ \int_{\Gamma_0}\varphi \end{pmatrix}.$$

This implies $F(0,\varphi,\Lambda)\neq(0,0)$ *iff* $(\varphi,\Lambda)\neq 0$. *Indeed, if* $F(0,\varphi,\Lambda)=(0,0)$, *then* $\varphi=\boldsymbol{\alpha}\cdot\nu_0$, *for any* $\boldsymbol{\alpha}\in R^N$. *It follows that* $\Lambda=\nu_0\cdot\int_{\Gamma_{\mathbf{t}(\varphi)}}\mathbf{b}(0,\varphi)\nu_0 d\Gamma_0$. *From the second part of* (1.6), $\nu_0\cdot\int_{\Gamma_{\mathbf{t}(\varphi)}}\mathbf{b}(0,\varphi)\nu_0 d\Gamma_0\neq 0$ *iff* $\mathbf{t}(\varphi)\neq\mathbf{0}$. *As* $\mathbf{t}(\varphi)=\boldsymbol{\alpha}\frac{P(\Omega_0)}{N}$ *it follows that* $\boldsymbol{\alpha}=\mathbf{0}$ *and* $(\varphi,\Lambda)=(0,0)$.

Proof of Theorem 1.4. As we mentioned in the introduction, the main tool of the proof is the implicit function theorem applied to the function F near $(0,0,0)$. The only thing we have to prove is that the application $(\phi,\lambda) \in C^{2,\alpha}(\Gamma_0) \times R \mapsto \partial_{\varphi,\Lambda} F(0,0,0)(\phi,\lambda) \in C^{0,\alpha}(\Gamma_0) \times R$ defines an isomorphism. Then it would follow that there exist $\sigma^* > 0$ and a unique C^1 map

$$\Phi : (-\sigma^*, \sigma^*) \mapsto (C^{2,\alpha}(\Gamma_0), R), \quad \Phi(\sigma) = (\varphi_\sigma, \Lambda_\sigma),$$

such that $F(\sigma, \varphi_\sigma, \Lambda_\sigma) = 0$. Lemma 3.2 shows that for $\sigma \neq 0$, $(\varphi_\sigma, \Lambda_\sigma)$ satisfies Theorem 1.4. Thus $\Omega(\sigma, \varphi_\sigma)$ is the solution of the free boundary problem (1.3).

Let $(f,\mu) \in C^{0,\alpha}(\Gamma_0) \times R$ and look for the $(\varphi,\lambda) \in C^{2,\alpha}(\Gamma_0) \times R$ solution of

$$\partial_{\varphi,\Lambda} F(0,0,0)(\varphi,\lambda) = (f,\mu). \tag{3.7}$$

Let us prove first that this equation can have only one solution. Indeed, the eigenvalues of $\underline{\Delta}$ (if $\underline{\Delta}$ is considered as an operator in $H^2(\Gamma_0)$) are $\{\lambda_k = -k\frac{(N+k-2)}{(N-1)^2}\mathcal{H}_0^2, k = 0,1,\dots\}$. Let $\mathcal{U}_k = \{u_{ki},\ i = 1,\dots,i_k\}$ be the orthonormal family (with respect to $L^2(\Gamma_0)$ norm) of eigenfunctions associated to λ_k and $\mathcal{U} = \cup_{k=0}^{\infty}\mathcal{U}_k$. From [1], for example, we know completely $\mathcal{U}$: $\mathcal{U}_k$ is the trace on Γ_0 of kth order harmonic homogeneous polynomials in R^N. For example, we have

$$\mathcal{U}_0 = \left\{\frac{1}{P(\Omega_0)}\right\},\ \mathcal{U}_1 = \left\{\frac{x_1}{r_0}\sqrt{\frac{N}{P(\Omega_0)}}, \dots, \frac{x_N}{r_0}\sqrt{\frac{N}{P(\Omega_0)}}\right\},\ \dots .$$

As $\mathcal{U}$ is a base for $L^2(\Gamma_0)$, f can be written in the form $f = \sum_{k,i} f_{ki}u_{ki}$. Writing φ, the solution of (3.7), in the form $\varphi = \sum_{k,i}\varphi_{ki}u_{ki}$ and replacing it in (3.7) allows us to identify its coefficients

$$\begin{aligned}
&\varphi_{00} = \mu,\\
&\sum_{i=1,N} \partial^2_{ki} e(B_{\mathbf{x}})|_{\mathbf{x}_0}\varphi_{1i} = \frac{N}{P(\Omega_0)}f_{1i}, \qquad k = 1,\\
&\varphi_{ki} = \frac{1}{\mathcal{H}_0^2}\frac{(N-1)^2}{k(N+k-2)(N-1)}f_{ki}, \quad k \geq 2,\ i = 1,\dots,i_k,\\
&\lambda = \frac{f_0}{P(\Omega_0)} + \frac{\mu}{P(\Omega_0)}\frac{\mathcal{H}_0^2}{N-1}.
\end{aligned}$$

This system defines uniquely all the coefficients φ_{ki} and λ in terms of f_{ki} and μ, which together with the second part of (1.6) (in fact, only nonzero eigenvalues of $\nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}_0}$ are required) proves the uniqueness of the solution of (3.7). We emphasize that the hypothesis (1.6) is essential for the proof of the uniqueness.

Now let us prove the existence of the solution of (3.7). Let $C_0^{0,\alpha}(\Gamma_0)$, respectively, $C_0^{2,\alpha}(\Gamma_0)$, be the space of $C^{0,\alpha}(\Gamma_0)$, respectively, $C^{2,\alpha}(\Gamma_0)$, functions having zero integral over Γ_0. It is well known that $\underline{\Delta}$ defines an isomorphism from $C_0^{2,\alpha}(\Gamma_0)$ into $C_0^{0,\alpha}(\Gamma_0)$ and its inverse $\underline{\Delta}^{-1}$ is compact from $C_0^{0,\alpha}(\Gamma_0)$ into itself. If $f_0 = f - \fint_{\Gamma_0} f$ and φ_0 is the solution in $C_0^{2,\alpha}(\Gamma_0)$ of

$$-\underline{\Delta}\varphi_0 - \frac{\mathcal{H}_0^2}{N-1}\varphi_0 + \nu_0 \cdot \nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}_0} \cdot \mathbf{t}(\varphi_0) = f_0, \tag{3.8}$$

then

$$\varphi = \varphi_0 + \frac{\mu}{P(\Omega_0)}, \quad \lambda = \mu \frac{\mathcal{H}_0^2}{(N-1)P(\Omega_0)} + \fint_{\Gamma_0} f$$

is the solution of (3.7). Thus, to prove that (3.7) has a solution is sufficient to prove that (3.8) has a solution. Multiplying (3.8) by $-\underline{\Delta}^{-1}$ we obtain

$$\varphi_0 + A\varphi_0 = -\underline{\Delta}^{-1} f_0,$$

where $A : C_0^{0,\alpha}(\Gamma_0) \mapsto C_0^{0,\alpha}(\Gamma_0)$ is given by

$$A\varphi_0 = \underline{\Delta}^{-1} \left(\frac{\mathcal{H}_0^2}{N-1} \varphi_0 - \nu_0 \cdot \nabla^2 e(B_x)|_{\mathbf{x}_0} \cdot \mathbf{t}(\varphi_0) \right).$$

But A is compact and A has no eigenvalue equal to -1 (from injectivity). Then $I + A$ is invertible, which proves the existence of a $C_0^{0,\alpha}(\Gamma_0)$ solution for (3.8). From the regularity results related to $\underline{\Delta}$ we have $\mathrm{Im}(A) \subset C_0^{2,\alpha}(\Gamma_0)$, which proves that $\varphi_0 \in C^{2,\alpha}(\Gamma_0)$ and that $\partial_{\varphi,\Lambda} F(0,0,0)$ defines an isomorphism from $C^{2,\alpha}(\Gamma_0) \times R$ into $C^{0,\alpha}(\Gamma_0) \times R$ and ends the proof. □

Proof of Theorem 1.6. The conditions of Theorem 1.4 are fulfilled and so for $\sigma \neq$ we have $(\Omega(\sigma, \varphi_\sigma), \Lambda_\sigma)$, a solution of (1.3). If σ is small enough, then $\mathbf{t}(\varphi_\sigma) + \sigma\varphi_\sigma\nu_0 \in \Theta_0$, where Θ_0 is given by Lemma 2.4. By virtue of this lemma, instead of θ perturbations of $\Omega_\sigma := \Omega(\sigma, \varphi_\sigma)$, one can consider only perturbations of the form $\mathbf{t}(\varphi) + \sigma\varphi\nu_0$. From Lemma 2.7 it is sufficient to consider $\varphi \in C^{2,\alpha}(\Gamma_0)$ with $|\mathbf{t}(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \leq \delta$ for any $\delta > 0$ small. In order to preserve the measure, one has to consider the perturbations of the form $I + \mathbf{t}(\varphi) + (\sigma\varphi + \beta(\sigma\varphi))\nu_0 =: I + \mathbf{u}(\varphi)$ with $\varphi \in K_0 := \{\partial_\theta m(\Omega_0)(\varphi\nu_0) = 0\}$; see Lemma 2.9.

It is easy to prove that $\varphi_\sigma^0 = \varphi_\sigma - \fint_{\Gamma_0} \varphi_\sigma \in K_0$ and $\Omega_\sigma = \Omega_{\mathbf{u}(\varphi_\sigma^0)}$. Then it is enough to show that

$$E(\Omega_\sigma) = \min\{E(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}), \quad \varphi \in C^{2,\alpha}(\Gamma_0) \cap K_0, \quad |t(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}} \text{ small enough}\}. \tag{3.9}$$

Let us first estimate $E(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}) - E(\Omega_{\mathbf{u}(\varphi_\sigma^0)})$. Let $G(\Omega)$ denote $e(\Omega)$, $P(\Omega)$, or $m(\Omega)$. Then, by virtue of (1.2), (1.5), and (1.10), we have

$$\begin{aligned}
&G(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}) - G(\Omega_{\mathbf{u}(\varphi_\sigma^0)}) \\
&= \partial_\theta G(\Omega_{\mathbf{u}(\varphi_\sigma^0)})(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&+ \partial_\theta^2 G(\Omega_{\mathbf{u}(\varphi_\sigma^0+s\varphi)})(\partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi)) \\
&+ \partial_\theta G(\Omega_{\mathbf{u}(\varphi_\sigma^0+s\varphi)})(\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi, \varphi)) \\
&= \partial_\theta G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&+ \partial_\theta^2 G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi)) + \partial_\theta G(\Omega_\sigma)(\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi, \varphi)) \\
&+ o(1)(\|\partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi)\|_{H^1(\Gamma_0)}^2 + \|\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi, \varphi)\|_{H^1(\Gamma_0)}),
\end{aligned}$$

where $\lim o(1) = 0$ when $|\mathbf{t}(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \to 0 = 0$, $s \in (0,1)$. From the continuity of $\partial_\varphi \beta$, $\partial_\varphi^2 \beta$ given by Lemma 2.9, it follows that

$$\begin{aligned}
\partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi) &= \partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi) + o_{\sigma\varphi}(1)\|\sigma\varphi\|_{H^1(\Gamma_0)}, \\
\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi) &= \mathbf{t}(\varphi) + \sigma\varphi\nu_0 + \partial_\varphi \beta(\sigma\varphi_\sigma^0)(\sigma\varphi) \\
&= \mathbf{t}(\varphi) + \sigma\varphi\nu_0 + o_\sigma(1)\|\sigma\varphi\|_{H^1(\Gamma_0)}, \\
\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi, \varphi) &= \partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0)(\varphi, \varphi) + o_{\sigma\varphi}(1)\|\sigma\varphi\|_{H^1(\Gamma_0)}^2,
\end{aligned}$$

where $\lim o_\sigma(1) = 0$ when $\sigma \to 0$ and $\lim o_{\sigma\varphi}(1) = 0$ when $\|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)} \to 0$. Then

$$\begin{aligned}
G(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}) - G(\Omega_{\mathbf{u}(\varphi_\sigma^0)}) &= \partial_\theta G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&+ \partial_\theta^2 G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) + \partial_\theta G(\Omega_\sigma)(\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0)(\varphi,\varphi)) \\
&+ o_{\sigma\varphi}(1)\|\sigma\varphi\|^2_{H^1(\Gamma_0)} \\
&+ o(1)(\|\partial_\varphi \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi)\|^2_{H^1(\Gamma_0)} + \|\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0 + s\varphi)(\varphi,\varphi)\|_{H^1(\Gamma_0)}) \\
&= \partial_\theta G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&+ \partial_\theta^2 G(\Omega_\sigma)(\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) + \partial_\theta G(\Omega_\sigma)(\partial_\varphi^2 \mathbf{u}(\varphi_\sigma^0)(\varphi,\varphi)) \\
&+ o(1)(|\mathbf{t}(\varphi)|^2 + \|\sigma\varphi\|^2_{H^1(\Gamma_0)}).
\end{aligned}$$

Consequently, taking into account (1.8) and the fact that $P(\Omega)$ and $m(\Omega)$ do not depend on $\mathbf{t}(\varphi)$, we may write

$$\begin{aligned}
&E(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}) - E(\Omega_{\mathbf{u}(\varphi_\sigma^0)}) \\
&\quad= \partial_\theta^2 \left[e(\Omega_\sigma) + \frac{1}{\sigma^2} P(\Omega_\sigma) + \left(\frac{\Lambda_\sigma}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2} \right) m(\Omega_\sigma) \right] (\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&\quad+ o(1)(|\mathbf{t}(\varphi)|^2 + \sigma^{-2}\|\sigma\varphi\|^2_{H^1(\Gamma_0)}) \\
&\quad= \partial_\theta^2 \left[e(\Omega_0) + \frac{1}{\sigma^2} P(\Omega_0) + \left(\frac{\Lambda_\sigma}{\sigma} - \frac{\mathcal{H}_0}{\sigma^2} \right) m(\Omega_0) \right] (\partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi), \partial_\varphi \mathbf{u}(\varphi_\sigma^0)(\varphi)) \\
&\quad+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \sigma^{-2}\|\sigma\varphi\|^2_{H^1(\Gamma_0)}) \\
&\quad= \partial_\theta^2 e(\Omega_0)(\mathbf{t}(\varphi) + \sigma\varphi\nu_0, \mathbf{t}(\varphi) + \sigma\varphi\nu_0) + \frac{1}{\sigma^2}\partial_\theta^2 [P(\Omega_0) - \mathcal{H}_0 m(\Omega_0)](\sigma\varphi\nu_0, \sigma\varphi\nu_0) \\
&\quad+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \sigma^{-2}\|\sigma\varphi\|^2_{H^1(\Gamma_0)}) \\
&\quad= \int_{\Gamma_0} |\overline{\nabla}\varphi|^2 - \frac{\mathcal{H}_0^2}{N-1}\varphi^2 d\Gamma_0 + \partial_\theta^2 e(\Omega_0)(\mathbf{t}(\varphi) + \sigma\varphi\nu_0, \mathbf{t}(\varphi) + \sigma\varphi\nu_0) \\
&\quad+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \sigma^{-2}\|\sigma\varphi\|^2_{H^1(\Gamma_0)}). \qquad (3.10)
\end{aligned}$$

Let us write $\varphi = \sum_{k,l} \varphi_{kl} u_{kl}$. As $\varphi \in K_0$, it follows that $\varphi_{00} = 0$. Moreover, from the estimations

$$\begin{aligned}
\partial_\theta^2 e(\Omega_0)(\mathbf{t}(\varphi), \sigma\varphi\nu_0) &= o_\sigma(1)(|\mathbf{t}(\varphi)|^2 + \|\varphi\|^2_{H^1(\Gamma_0)}), \\
\partial_\theta^2 e(\Omega_0)(\sigma\varphi\nu_0, \sigma\varphi\nu_0) &= o_\sigma(1)\|\varphi\|^2_{H^1(\Gamma_0)}, \\
\frac{k(N+k-2)}{(N-1)^2} - \frac{1}{N-1} &\geq \frac{1}{2}\frac{k(N+k-2)}{(N-1)^2}, \quad k \geq 2, \\
\left|\mathbf{t}(\varphi) \cdot \nabla^2 e(B_x)|_{\mathbf{x}_0} \cdot \mathbf{t}(\varphi)\right| &\geq \min\{\lambda_i, i = 1, \ldots, N\}|\mathbf{t}(\varphi)|^2 \\
&= \min\{\lambda_i, i = 1, \ldots, N\} \sum_{l=1,N} \left(\sum_{k=1,N} \varphi_{1k} \sqrt{\frac{N}{P(\Omega_0)}} \mathbf{t}_l(\nu_0^k) \right)^2 \\
&= \lambda_1 P(\Omega_0) \frac{N-1}{N}(N-1) \sum_l \varphi_{1l}^2,
\end{aligned}$$

where $0 < \lambda_1 < \lambda_2 < \cdots < \lambda_N$ are eigenvalues of $\nabla^2 e(B_x)|_{\mathbf{x}_0}$, one can obtain

$$\begin{aligned}
\int_{\Gamma_0} |\overline{\nabla}\varphi|^2 - \frac{\mathcal{H}_0^2}{N-1}\varphi^2 d\Gamma_0 + \mathbf{t}(\varphi)\cdot\nabla^2 e(B_x)|_{\mathbf{x}_0}\cdot\mathbf{t}(\varphi) \\
+ 2\partial_\theta^2 e(\Omega_0)(\mathbf{t}(\varphi), \sigma\varphi\nu_0) + \partial_\theta^2 e(\Omega_0)(\sigma\varphi, \sigma\varphi\nu_0) \\
= \sum_{k\geq 2,l} \varphi_{kl}^2 \mathcal{H}_0^2 \left(\frac{k(N+k-2)}{(N-1)^2} - \frac{1}{N-1}\right) + \mathbf{t}(\varphi)\cdot\nabla^2 e(B_x)|_{\mathbf{x}_0}\cdot\mathbf{t}(\varphi) \\
+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \|\varphi\|^2_{H^1(\Gamma_0)}), \\
\geq \frac{1}{2\mathcal{H}_0^2}\sum_{k\geq 2,l} \frac{k(N+k-2)}{(N-1)^2}\mathcal{H}_0^2\varphi_{kl}^2 + \lambda_1\frac{P(\Omega_0)}{\mathcal{H}_0^2}\frac{N-1}{N}\sum_l (N-1)\mathcal{H}_0^2\varphi_{1l}^2 \\
+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \|\varphi\|^2_{H^1(\Gamma_0)}), \\
= \frac{1}{2\mathcal{H}_0^2}\|\varphi_1^c\|^2_{H^1(\Gamma_0)} + \lambda_1\frac{P(\Omega_0)}{\mathcal{H}_0^2}\frac{N-1}{N}\|\varphi_1\|^2_{H^1(\Gamma_0)} \\
+ (o(1) + o_\sigma(1))(|\mathbf{t}(\varphi)|^2 + \|\varphi\|^2_{H^1(\Gamma_0)}), \\
\geq C_0\|\varphi\|^2_{H^1(\Gamma_0)} + (o(1) + o_\sigma(1))\|\varphi\|^2_{H^1(\Gamma_0)},
\end{aligned}$$

where $C_0 = \min\{\frac{1}{2\mathcal{H}_0^2}, \lambda_1\frac{P(\Omega_0)}{\mathcal{H}_0^2}\frac{N-1}{N}\}$. From (3.10) and (2.12) it follows that

$$E(\Omega_{\mathbf{u}(\varphi_\sigma^0+\varphi)}) - E(\Omega_{\mathbf{u}(\varphi_\sigma^0)}) \geq C_0\|\varphi\|^2_{H^1(\Gamma_0)} + (o_{\sigma\varphi}(1) + o_\sigma(1))\|\varphi\|^2_{H^1(\Gamma_0)},$$

which proves (3.9) for σ, $|\mathbf{t}(\varphi)| + \|\sigma\varphi\|_{C^{2,\alpha}(\Gamma_0)}$ small, and proves the theorem. □

4. Applications. We will consider an application which involves the Laplacian in R^N. We show that the hypotheses (1.2), (1.5), and (1.10) are satisfied. We give a sufficient condition on data for the hypothesis (1.6).

Let us consider $f \in C^{1,\alpha}(R^N)$, $N \geq 2$. For $\theta \in \Theta$ let's set $e(\Omega_\theta) = -\frac{1}{2}\int_{\Omega_\theta} |\nabla u(\theta)|^2$, where $u(\theta) \in C^{2,\alpha}(\overline{\Omega}_\theta)$ is the solution of

$$\left\{\begin{array}{rl} -\Delta u(\theta) = f & \text{in } \Omega_\theta, \\ u(\theta) = 0 & \text{on } \Gamma_\theta. \end{array}\right. \tag{4.1}$$

The main result we prove in this section follows.

THEOREM 4.1. *Let $f \in C^{1,\alpha}(R^N)$ be a radial function and $\mathbf{x}_0 = 0$.*

(i) *If $[\frac{N}{r_0^N}\int_0^{r_0} s^{N-1}f(s)ds - f(r_0)]\int_0^{r_0} s^{N-1}f(s)ds \neq 0$, then (1.3) has a unique $C^{2,\alpha}$ solution for σ small.*

(ii) *If $[\frac{N}{r_0^N}\int_0^{r_0} s^{N-1}f(s)ds - f(r_0)]\int_0^{r_0} s^{N-1}f(s)ds > 0$, then (1.1) has a unique $C^{2,\alpha}$ solution for σ small.*

To prove the theorem we need some preliminary results, most of them quite classical results in shape optimization theory. Let us point out that throughout this chapter, $\overset{*}{\cdot}$ denotes an extension operator from Θ to $C^{2,\alpha}(\overline{\Omega}_0)$, or (explicitly) from $H^{1/2}(\Gamma_0)$ to $H^1(\Omega_0)$.

PROPOSITION 4.2. *The shape functional $\theta \to u(\theta)\circ(I + \overset{*}{\theta})$ is differentiable from Θ into $C^{2,\alpha}(\overline{\Omega}_0)$. Moreover, $u(\theta)(\xi)$, the first shape derivative of $u(\theta)$, satisfies*

$u(\theta)(\xi) \in C^{1,\alpha}(\overline{\Omega}_0)$ *and*

$$u(\theta)(\xi) \circ (I + \overset{*}{\theta}) + \xi \cdot \nabla u(\theta) \circ (I + \overset{*}{\theta}) = \partial_\theta (u(\theta) \circ (I + \overset{*}{\theta}))(\xi), \tag{4.2}$$

$$\Delta u(\theta)(\xi) = 0 \qquad in \ \ \Omega_\theta, \tag{4.3}$$

$$u(\theta)(\xi) = -(\overset{\vee}{\xi} \cdot \nu_\theta) \frac{\partial u(\theta)}{\partial \nu_\theta} \quad on \ \ \Gamma_\theta, \tag{4.4}$$

$$\int_{\Omega_\theta} |\nabla u(\theta)(\xi)|^2 \leq C \|\xi\|^2_{H^{1/2}(\Gamma_0)}, \tag{4.5}$$

$$\int_{\Omega_\theta} |\nabla u(\theta + \zeta)(\xi) \circ (I + \overset{\vee}{\zeta}) - \nabla u(\theta)(\xi)|^2 = o_\zeta(1) \|\xi\|^2_{H^{1/2}(\Gamma_0)}, \tag{4.6}$$

where $\overset{\vee}{\zeta} = \overset{*}{\zeta} \circ (I + \overset{*}{\theta})^{-1}$ *and* $\lim_{\|\zeta\|_\Theta \to 0} o_\zeta(1) = 0$.

REMARK 4.3. *The estimation* (4.6) *is crucial in proving that* $e(\Omega)$ *satisfies* (1.10)*; see Lemma* 4.5.

Proof of Proposition 4.2. The differentiability of $u(\theta) \circ (I + \overset{*}{\theta})$ is a rather classical result. The proof is based on the implicit function theorem and the uniqueness of (4.1). A proof in a Sobolev spaces framework is shown in [12], [13].

Although the proof is quite standard, let us prove that the result is true even in Hölder spaces. Let $F(\theta, v)$ be defined by

$$\begin{array}{rccl} F: & \Theta \times C_0^{2,\alpha}(\overline{\Omega}_0) & \mapsto & C^\alpha(\overline{\Omega}_0), \\ & (\theta, v) & \mapsto & -\displaystyle\sum_{i,j,k=1,N} M_{i,j}(\theta) \frac{\partial}{\partial x_j} \left(M_{i,k}(\theta) \frac{\partial v}{\partial x_k} \right) + f \circ (I + \overset{*}{\theta}), \end{array}$$

where $C_0^{2,\alpha}(\overline{\Omega}_0) = C^{2,\alpha}(\overline{\Omega}_0) \cap \{u = 0 \text{ on } \Gamma_0\}$ and $[M_{i,j}(\theta)] = {}^t[\nabla(I + \overset{*}{\theta})]^{-1}$ (let us point out that the function $F(\theta, v)$ is obtained by transporting (4.1) in Ω_0 and replacing $u(\theta) \circ (I + \overset{*}{\theta})$ by v). The function F is linear in v and derivatives of v up to second order, while $\theta \mapsto M_{i,j}(\theta)$ is a C^1 function from Θ to $C^{1,\alpha}(\overline{\Omega}_0; R^N)$ in a small neighborhood of $0 \in \Theta$ (as a rational function in θ derivatives and with a denominator greater than, let's say, $1/2$), as well as $\theta \to f \circ (I + \overset{*}{\theta})$. Thus F is a C^1 function in a small neighborhood of $0 \in \Theta$. Moreover, $F(0, u(0)) = 0$, $\partial_v F(0, u(0))(v) = -\Delta v$, which defines an isomorphism from $C_0^{2,\alpha}(\overline{\Omega}_0)$ to $C^\alpha(\overline{\Omega}_0)$. From the implicit function theorem we have the existence of a C^1 map $\theta \mapsto v(\theta)$ from Θ to $C_0^{2,\alpha}(\overline{\Omega}_0)$ such that $F(\theta, v(\theta)) = 0$. It follows that $v(\theta) \circ (I + \overset{*}{\theta})^{-1}$ is the solution of (4.1) and from the uniqueness of its solutions we get $v(\theta) = u(\theta) \circ (I + \overset{*}{\theta})$ and thus the C^1 regularity for $\theta \mapsto u(\theta) \circ (I + \overset{*}{\theta})$.

From Sobolev space embeddings we have that $\theta \to u(\theta) \circ (I + \overset{*}{\theta})$ is a C^1 map from Θ to $H^2(\Omega_0)$. From [12, Lemma 2.1] it follows that $u(\theta)(\xi) \in H^1(\Omega_\theta)$, satisfying (4.2). The conditions of [12, Theorems 3.1 and 3.2] are satisfied, and (4.3) and (4.4) follow. The estimation (4.5) is proven, for example, in [4].

To prove (4.6), let us introduce $\tilde{u}(\theta)(\xi) = \frac{1}{\|\xi\|_{H^{1/2}(\Gamma_0)}} u(\theta)(\xi)$. The map $\theta \mapsto \tilde{u}(\theta)(\xi) \circ (I + \overset{*}{\theta})$ from Θ to $H^1(\Omega_0)$ is of class C^1. Indeed, as $\tilde{u}(\theta)(\xi)$ satisfies

$$\Delta \tilde{u}(\theta)(\xi) = 0 \quad \text{in} \ \ \Omega_\theta, \tag{4.7}$$

$$\tilde{u}(\theta)(\xi) = -\frac{\overset{\vee}{\xi} \cdot \nu_\theta}{\|\xi\|_{H^{1/2}(\Gamma_0)}} \frac{\partial u(\theta)}{\partial \nu_\theta} \quad \text{on} \ \ \Gamma_\theta, \tag{4.8}$$

let us introduce the function

$$\begin{aligned}\tilde{F}: \quad \Theta \times H_0^1(\Omega_0) &\mapsto H^{-1}(\Omega_0),\\ (\theta, v) &\mapsto \int_{\Omega_0} \nabla(v+g(\theta))\cdot[M_{ij}(\theta)]\cdot {}^t[M_{ij}(\theta)]\cdot\nabla\varphi \; Jac(I+\overset{*}{\theta}),\end{aligned}$$

where $\varphi \in H_0^1(\Omega_0)$, $g(\theta) = -\frac{\overset{*}{\xi}\cdot\overset{*}{\nu}_\theta}{\|\xi\|_{H^{1/2}(\Gamma_0)}}(\overset{*}{\nu}_\theta\cdot\nabla u(\theta))\circ(I+\overset{*}{\theta})$ and $\overset{*}{\cdot}$ is a $H^1(\Omega_0)$ extension of $\cdot$, thus, in particular, $\|\overset{*}{\xi}\|_{H^1(\Omega_0)} \le C\|\xi\|_{H^{1/2}(\Gamma_0)}$ (note that the function $\tilde{F}$ is obtained basically by transporting the weak form of (4.7) in Ω_0).

We have $\tilde{F}(0,\tilde{u}(0)(\xi)-g(0))=0$ and the function $\tilde{F}$ is of class C^1 near $(0,\tilde{u}(0)(\xi)-g(0))$. Indeed, it is linear in v. Moreover, from the first part of the proposition, $\theta\mapsto g(\theta)$ is a C^1 map from Θ to $H^1(\Omega_0)$ and $\partial_v\tilde{F}(0,\tilde{u}(0)(\xi)-g(0))(v)=\int_{\Omega_0}\nabla v\cdot\nabla\varphi$, which defines an isomorphism from $H^1(\Omega_0)$ into $H^{-1}(\Omega_0)$. The conditions of the implicit function theorem are satisfied. Then there exists a C^1 map $\theta\mapsto v(\theta)$ from a small open neighborhood of $0\in\Theta$ into $H^1(\Omega_0)$ such that $\tilde{F}(\theta,v(\theta))=0$. This neighborhood may be chosen independent of ξ because $\|g(\theta)\|_{H^1(\Omega_0)}\le C$, $\|\partial_\theta[g(\theta)](\eta)\|_{H^1(\Omega_0)} < C\|\eta\|_\Theta$ with C independent of ξ, and so $\tilde{F}(\theta,v)$ is a uniformly C^1 function (in ξ) from $\Theta\times H^1(\Omega_0)$ to $H^{-1}(\Omega_0)$. Writing $\tilde{F}(\theta,v(\theta))$ as an integral in Ω_θ, from the uniqueness result for (4.7), (4.8), it follows that $v(\theta)=\tilde{u}(\theta)(\xi)\circ(I+\overset{*}{\theta})-g(\theta)$, which proves that $\theta\mapsto\tilde{u}(\theta)(\xi)\circ(I+\overset{*}{\theta})$ is a C^1 function from Θ to $H^1(\Omega_0)$. It follows that for $\|\theta\|_\Theta$ small we have

$$\int_{\Omega_0}|\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\overset{*}{\theta}+\overset{*}{\zeta}))-\nabla(\tilde{u}(\theta)(\xi)\circ(I+\overset{*}{\theta}))|^2 = o_\zeta(1), \qquad \lim_{\|\zeta\|_\Theta\to 0} o_\zeta(1)=0.$$

On the other hand,

$$\begin{aligned}\nabla(\tilde{u}(\theta+\zeta)(\xi))\circ(I+\check{\zeta}) &= {}^t[\nabla(I+\check{\zeta})]^{-1}\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\check{\zeta}))\\ &= {}^t[\nabla(I+\check{\zeta})]^{-1}\cdot{}^t[\nabla(I+\overset{*}{\theta})]^{-1}\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\overset{*}{\theta}+\overset{*}{\zeta})),\\ [\nabla(I+\check{\zeta})]^{-1} &= I_N+o_\zeta(1), \quad I_N \text{ the identity matrix},\\ [\nabla(I+\overset{*}{\theta})]^{-1} &= I_N+o_\theta(1), \quad \lim_{\|\theta\|_\Theta\to 0} o_\theta(1)=0,\\ |[\nabla(I+\overset{*}{\theta})]^{-1}| &= 1+o_\theta(1).\end{aligned}$$

It follows that

$$\begin{aligned}&\int_{\Omega_\theta}|\nabla\tilde{u}(\theta+\zeta)(\xi)\circ(I+\check{\zeta})-\nabla\tilde{u}(\theta)(\xi)|^2\\ &=\int_{\Omega_\theta}|{}^t[\nabla(I+\check{\zeta})]^{-1}\nabla\tilde{u}(\theta+\zeta)(\xi)\circ(I+\check{\zeta})-\nabla\tilde{u}(\theta)(\xi)|^2\\ &=\int_{\Omega_\theta}|\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\check{\zeta}))-\nabla\tilde{u}(\theta)(\xi)|^2+o_\zeta(1)\\ &=\int_{\Omega_\theta}{}^t[\nabla(I+\overset{*}{\theta})]^{-1}|\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\overset{*}{\theta}+\overset{*}{\zeta}))-\nabla(\tilde{u}(\theta)(\xi)\circ(I+\overset{*}{\theta}))|^2+o_\zeta(1)\\ &\le C\int_{\Omega_0}|\nabla(\tilde{u}(\theta+\zeta)(\xi)\circ(I+\overset{*}{\theta}+\overset{*}{\zeta}))-\nabla(\tilde{u}(\theta)(\xi)\circ(I+\overset{*}{\theta}))|^2+o_\zeta(1)\\ &\le (C+1)o_\zeta(1).\end{aligned}$$

The estimation (4.6) is proved because $u(\theta)(\xi)=\|\xi\|_{H^{1/2}(\Gamma_0)}\tilde{u}(\theta)(\xi)$. □

PROPOSITION 4.4. *The functions $\theta \to e(\Omega_\theta)$, $\theta \to P(\Omega_\theta)$, and $\theta \to m(\Omega_\theta)$ are near $0 \in \Theta$ two times differentiable. Their derivatives are given by*

$$\partial_\theta e(\Omega_\theta)(\xi) = -\frac{1}{2}\int_{\Gamma_\theta} |\nabla u(\theta)|^2 (\check{\xi}\cdot\nu_\theta), \tag{4.9}$$

$$\begin{aligned}\partial^2_\theta e(\Omega_\theta)(\xi,\eta) = &-\frac{1}{2}\int_{\Gamma_\theta} (\check{\xi}\cdot\nu_\theta)(\check{\eta}\cdot\nu_\theta)\left[\mathcal{H}_\theta|\nabla u(\theta)|^2 + \partial_{\nu_\theta}|\nabla u(\theta)|^2\right]\\ &-\frac{1}{2}\int_{\Gamma_\theta}\left((\check{\xi}\cdot\nu_\theta)\partial_{\nu_\theta}u(\theta)(\eta) + (\check{\eta}\cdot\nu_\theta)\partial_{\nu_\theta}u(\theta)(\xi)\right)\partial_{\nu_\theta}u(\theta)\\ &+\frac{1}{2}\int_{\Gamma_\theta}\left(\nu_\theta\cdot\overline{\nabla}\check{\xi}\cdot\check{\eta} + \nu_\theta\cdot\overline{\nabla}\check{\eta}\cdot\check{\xi} + \check{\xi}\cdot\overline{\nabla}\nu_\theta\cdot\check{\eta}\right)|\nabla u(\theta)|^2,\end{aligned} \tag{4.10}$$

$$\partial_\theta P(\Omega_\theta)(\xi) = \int_{\Gamma_\theta} \mathcal{H}_\theta(\check{\xi}\cdot\nu_\theta), \tag{4.11}$$

$$\partial^2_\theta P(\Omega_\theta)(\xi,\eta) = \int_{\Gamma_\theta} (\overline{\nabla}\cdot\check{\xi})(\overline{\nabla}\cdot\check{\eta}) - tr[(\overline{\nabla}\check{\xi})\cdot(\overline{\nabla}\check{\eta})] + (\nu_\theta\cdot(\overline{\nabla}\check{\xi}))\cdot(\nu_\theta\cdot(\overline{\nabla}\check{\eta})), \tag{4.12}$$

$$\partial_\theta m(\Omega_\theta)(\xi) = \int_{\Gamma_\theta} (\check{\xi}\cdot\nu_\theta), \tag{4.13}$$

$$\partial^2_\theta m(\Omega_\theta)(\xi,\eta) = \int_{\Gamma_\theta} (\check{\xi}\cdot\nu_\theta)(\overline{\nabla}\cdot\check{\eta}) - \check{\xi}\cdot\overline{\nabla}\check{\eta}\cdot\nu_\theta, \tag{4.14}$$

where $\check{\xi} = \xi\circ(I+\theta)^{-1}$, $\check{\eta} = \eta\circ(I+\theta)^{-1}$.

Proof. The differentiability and the derivative (4.9) follow from [12, Theorem 3.3], taking $C(u(\theta)) = |\nabla u(\theta)|^2$. The derivative (4.10) follows from [12, Theorem 5.1], which says that (under some regularity assumptions)

$$\partial_\theta\left(\int_{\Gamma_\theta} G(u(\theta))\right)(\xi) = \int_{\Gamma_\theta} \partial_\theta G(u(\theta))(\xi) + (\check{\xi}\cdot\nu_\theta)\left[\mathcal{H}_\theta G(u(\theta)) + \partial_{\nu_\theta}G(u(\theta))\right].$$

The expression (4.10) then follows by taking in the previous formula $G(u(\theta)) = |\nabla u(\theta)|^2(\check{\xi}\cdot\nu_\theta)$ (a proof for three dimensions is given in [9]).

The derivatives (4.11) and (4.12) are proven in [5, Theorem 10.4]. Finally, the derivatives (4.13) and (4.14) follow by elementary calculus (a proof of them is presented in [9]). □

LEMMA 4.5. *The functionals $e(\Omega_\theta)$, $P(\Omega_\theta)$, and $m(\Omega_\theta)$ satisfy the hypotheses* (1.2), (1.5), *and* (1.10).

Proof. The proposition is true for $P(\Omega_\theta)$ and $m(\Omega_\theta)$. The proof follows immediately from Proposition 4.4 and (4.12), (4.14). Let us prove that $e(\Omega_\theta)$ satisfies Lemma 4.5. Proposition 4.4 proves the hypothesis (1.2) and gives $b(\theta) = -\frac{1}{2}|\nabla u(\theta)|^2$. The hypothesis (1.5) is satisfied by virtue of Proposition 4.2. For the hypothesis (1.10), from the form of $\partial^2_\theta e(\Omega_\theta)$, it is enough to show only that $\theta \mapsto \int_{\Gamma_\theta}(\check{\xi}\cdot\nu_\theta)\partial_{\nu_\theta}u(\theta)(\eta)$ is a continuous map from Θ to R. As $\int_{\Gamma_\theta}(\check{\xi}\cdot\nu_\theta)\partial_{\nu_\theta}u(\theta)(\eta) = -\int_{\Omega_\theta}\nabla u(\theta)(\xi)\cdot\nabla u(\theta)(\eta)$ it suffices to show that $\int_{\Omega_\theta}|\nabla u(\theta+\zeta)(\xi\circ(I+\check{\zeta}) - \nabla u(\theta)(\xi)|^2 = o_\zeta(1)\|\xi\|_{H^1(\Gamma_0)}$, which is proved in Proposition 4.2. □

PROPOSITION 4.6. *Let $N \geq 2$ and let us assume that f is a radial function. Then $\nabla e(B_{\mathbf{x}})|_{\mathbf{x}_0} = \mathbf{0}$ and the second derivative matrix of $e(B_{\mathbf{x}})$ at 0 is*

$$\nabla^2 e(B_{\mathbf{x}})|_{\mathbf{x}=\mathbf{0}} = \left(\frac{m(\Omega_0)}{r_0^N}\left[\frac{N}{r_0^N}\int_0^{r_0} s^{N-1}f(s)ds - f(r_0)\right]\int_0^{r_0} s^{N-1}f(s)ds\right)\mathrm{Id},$$

where Id *is the identity matrix.*

Proof. It is clear that the derivatives of $e(B_{\mathbf{x}})$ are intimately related to the shape derivatives of $e(\Omega_\theta)$. Indeed, we have

$$\partial_i e(B_{\mathbf{x}})|_{\mathbf{x}_0} = \partial_\theta e(\Omega_0)(\xi_i), \qquad i = 1, \dots, N, \tag{4.15}$$

$$\partial^2_{ij} e(B_{\mathbf{x}})|_{\mathbf{x}_0} = \partial^2_\theta e(\Omega_0)(\xi_i, \xi_j), \ i, j = 1, \dots, N, \tag{4.16}$$

where $\{\xi_1, \xi_2, \dots, \xi_N\}$ is the standard base of R^N. The solution $u(0)(\xi_i)$ of problems (4.3) and (4.4) is given by $u(0)(\xi_i) = -\frac{x_i}{r_0}\partial_{\nu_0} u(0)$. Also, for $\theta = 0$, the solution of (4.1) is a radial function, denoted by $u(0)$. We have

$$\begin{aligned}
u(0)(\cdot) &= -\int_0^{|\cdot|} t^{1-N} \int_0^t s^{N-1} f(t) ds dt + \text{constant},\\
\partial_r u(0)(\cdot) &= -|\cdot|^{1-N} \int_0^{|\cdot|} s^{N-1} f(s) ds,\\
\partial^2_r u(0)(\cdot) &= (N-1)|\cdot|^{-N} \int_0^{|\cdot|} s^{N-1} f(s) ds - f(|\cdot|).
\end{aligned}$$

From (4.15) and (4.9) it follows that

$$\partial_i e(B_{\mathbf{x}})|_{\mathbf{x}_0} = -\frac{1}{2}\int_{\Gamma_0} (\xi_i \cdot \nu_0)|\nabla u(0)|^2 = -\frac{1}{2}\int_{\Gamma_0} |\nabla u(0)|^2 \nu_0^i = 0.$$

From (4.16) and (4.10) it follows that

$$\begin{aligned}
\partial^2_{ij} e(B_{\mathbf{x}})|_{\mathbf{x}_0} &= -\frac{1}{2}\int_{\Gamma_0} (\xi_i \cdot \nu_0)(\xi_j \cdot \nu_0)\left[\mathcal{H}_0 |\nabla u(0)|^2 + \partial_{\nu_0}|\nabla u(0)|^2\right]\\
&\quad -\frac{1}{2}\int_{\Gamma_0} \left[(\xi_i \cdot \nu_0)\partial_{\nu_0} u(0)(\xi_j) + (\xi_j \cdot \nu_0)\partial_{\nu_0} u(0)(\xi_i)\right]\partial_{\nu_0} u(0)\\
&\quad +\frac{1}{2}\int_{\Gamma_0} \left[\nu_0 \cdot \overline{\nabla}\xi_i \cdot \xi_j + \nu_0 \cdot \overline{\nabla}\xi_j \cdot \xi_i + \xi_i \cdot \overline{\nabla}\nu_0 \cdot \xi_j\right]|\nabla u(0)|^2\\
&= -\frac{1}{2}\int_{\Gamma_0} \nu_0^i \nu_0^j \left[\mathcal{H}_0 |\partial_r u(0)|^2 + \partial_r |\partial_r u(0)|^2\right]\\
&\quad +\frac{1}{2}\int_{\Gamma_0} 2\nu_0^i \nu_0^j r_0^{-1} |\partial_r u(0)|^2 + \overline{\partial}_i \nu_0^j |\partial_r u(0)|^2.
\end{aligned}$$

But we have

$$\int_{\Gamma_0} \nu_0^i \nu_0^j = \delta_{ij}\frac{m(\Omega_0)}{r_0}, \qquad \int_{\Gamma_0} \overline{\partial}_i \nu_0^j = \int_{\Gamma_0} \mathcal{H}_0 \nu_0^i \nu_0^j = \delta_{ij}\mathcal{H}_0 \frac{m(\Omega_0)}{r_0}.$$

From the last equation of $\partial^2_{ij} e(B_{\mathbf{x}})$ we obtain

$$\begin{aligned}
\partial^2_{ij} e(B_{\mathbf{x}})|_{\mathbf{x}_0} &= -\frac{1}{2}\delta_{ij}\frac{m(\Omega_0)}{r_0}\left[\mathcal{H}_0 |\partial_r u(0)|^2 + \partial_r |\partial_r u(0)|^2 - 2r_0^{-1}|\partial_r u(0)|^2 - \mathcal{H}_0 |\partial_r u(0)|^2\right]\\
&= -\delta_{ij}\frac{m(\Omega_0)}{r_0}\left[\partial^2_r u(0) - r_0^{-1}\partial_r u(0)\right]\partial_r u(0)\\
&= \delta_{ij}\frac{m(\Omega_0)}{r_0}\left[N r_0^{-N}\int_0^{r_0} s^{N-1} f(s) ds - f(r_0)\right] r_0^{1-N}\int_0^{r_0} s^{N-1} f(s) ds,
\end{aligned}$$

which proves the proposition. ∎

Proof of Theorem 4.1. Item (i), respectively, item (ii), follows from Theorem 1.4, respectively, Theorem 1.6—the hypotheses are satisfied from Lemma 4.5 and Proposition 4.6. □

Acknowledgments. I am deeply grateful to professor Michel Pierre for several comments and suggestions, as well as to one of the anonymous referees for his constructive report.

SMALL BV SOLUTIONS OF HYPERBOLIC NONCOOPERATIVE DIFFERENTIAL GAMES*

ALBERTO BRESSAN† AND WEN SHEN†

Abstract. The paper is concerned with an n-person differential game in one space dimension. We state conditions for which the system of Hamilton–Jacobi equations for the value functions is strictly hyperbolic. In the positive case, we show that the weak solution of a corresponding system of conservation laws determines an n-tuple of feedback strategies. These yield a Nash equilibrium solution to the noncooperative differential game.

Key words. noncooperative differential games, Nash equilibrium, system of Hamilton–Jacobi equations, hyperbolic system of conservation laws, BV solutions, optimal control theory, discontinuous ODE

DOI. 10.1137/S0363012903425581

1. Introduction.

This paper is concerned with the global existence of a Nash equilibrium solution for a noncooperative n-person differential game. The evolution of the system is governed by a differential equation of the form

$$\dot{x}(t) = \sum_{i=1}^{n} f_i(x, u_i), \tag{1.1}$$

say, with initial data

$$x(\tau) = y. \tag{1.2}$$

Here the real valued map $t \mapsto u_i(t)$ is the control implemented by the ith player. Together with (1.1) we consider the cost functionals

$$J_i = J_i(\tau, y, u_1, \ldots, u_n) \doteq \int_{\tau}^{T} h_i(x(t), u_i(t))\, dt + g_i(x(T)), \tag{1.3}$$

consisting of a running cost h_i and a terminal cost g_i. The goal of the ith player is to minimize J_i. An n-tuple of feedback strategies

$$U_i^* = U_i^*(t, x), \quad i = 1, \ldots, n,$$

is called a Nash equilibrium solution if the following holds. For each i, if the ith player chooses an alternative strategy U_i while every other player sticks to his previous strategy U_j^*, $j \neq i$, then the cost for the ith player does not decrease:

$$J_i(\tau, y, U_1^*, \ldots, U_{i-1}^*, U_i, U_{i+1}^*, \ldots, U_n^*) \geq J_i(\tau, y, U_1^*, \ldots, U_{i-1}^*, U_i^*, U_{i+1}^*, \ldots, U_n^*). \tag{1.4}$$

Assume that a value function $V = (V_1, \dots, V_n)$ exists, so that $V_i(t,x)$ is the minimum cost for the ith player, when everyone plays optimally but no cooperation is allowed. Under suitable regularity conditions (see [F1, p. 292]), the function V provides a solution to the system of Hamiltonian equations

$$\frac{\partial}{\partial t} V_i + H_i(x, \nabla V_1, \dots, \nabla V_n) = 0, \tag{1.5}$$

with terminal data

$$V_i(T,x) = g_i(x). \tag{1.6}$$

The Hamiltonian functions H_i are defined as follows. Assume that, for any given gradient vectors $p_1, \dots, p_n$, there exist optimal control values $u_j^*(x,p_j)$, $j = 1, \dots, n$, such that

$$p_j \cdot f_j(x, u_j^*(x,p_j)) + h_j(x, u^*(x,p_j)) = \min_{\omega \in \mathbb{R}} \{p_j \cdot f_j(x,\omega) + h_j(x,\omega)\}. \tag{1.7}$$

Then

$$\begin{aligned} H_i(x,p_1,\dots,p_m) &= p_i \cdot \sum_{j=1}^{m} f_j(x, u_j^*(x,p_j)) + h_i(x, u_i^*(x,p_i)) \\ &= p_i \cdot \sum_{j \neq i} f_j(x, u_j^*(x,p_j)) + \min_{\omega \in \mathbb{R}} \{p_i \cdot f_i(x,\omega) + h_i(x,\omega)\}. \end{aligned} \tag{1.8}$$

In the case of a two-person, zero-sum differential game, the value function is obtained from the scalar Bellman–Isaacs equation [F1, I]. The analysis can thus rely on comparison principles and on the well-developed theory of viscosity solutions for Hamilton–Jacobi equations; see, for example, [BC]. On the other hand, in the case of noncooperative n-person games, one has to study a highly nonlinear system of Hamilton–Jacobi equations. Little is yet known in this direction, except for particular examples as in [CR, O]. Instead, local existence results are known within the class of open-loop strategies [F1, VZ]. They apply to the case where the players cannot use any additional information on the state $x(t)$ of the system, for $t > 0$.

In the one-dimensional case, differentiating (1.5) with respect to (w.r.t.) x, one obtains a system of conservation laws for the gradient functions $p_i \doteq V_{i,x}$, namely,

$$p_{i,t} + H_i(x,p)_x = 0. \tag{1.9}$$

In recent years, considerable progress has been achieved in the understanding of weak solutions to hyperbolic systems of conservation laws in one space dimension. In particular, entropy admissible solutions with small total variation are known to be unique and depend continuously on the initial data [B3, BLY]. Moreover, they can be obtained as the unique limits of vanishing viscosity approximations [BB].

The aim of the present paper is to investigate the relevance of these new results in the field of conservation laws toward the existence and stability of Nash equilibrium solutions, in the context of differential games. In particular, our main goals are

- to identify the situations where the hyperbolic theory is applicable, and
- in the favorable case, to derive the existence and properties of a Nash equilibrium solution.

The hyperbolicity of the system is clearly a crucial assumption, in order that the Cauchy problem for the value functions be well posed. In section 3 we show that hyperbolicity holds provided that the derivatives of the cost functions g_i all have the same sign. In practice, this means that all players wish to steer the system in the same direction.

Granted that the system is strictly hyperbolic, the known results on systems of conservation laws can be applied. The theorem of Glimm [G] or its more general versions [BB, ILF, L] provide then the existence of a global solution to the Hamilton–Jacobi equations for terminal data g_i whose gradients have sufficiently small total variation.

To obtain an existence result for solutions of differential games, one has to show that, for each single player, the feedback strategy corresponding to the solution of the Hamilton–Jacobi system is indeed an optimal one. We remark that, if the value functions V_i were smooth, the optimality would be an immediate consequence of the equations. The main technical difficulty stems from the nondifferentiability of these value functions.

In the literature on control theory, sufficient conditions for optimality have been obtained along two main directions. On one hand, there is the "regular synthesis" approach developed by Boltianskii [Bo], Brunovskii [Br], and Sussmann and Piccoli [PS]. In this case, one typically requires that the value function be piecewise $\mathcal{C}^1$ and satisfy the Hamilton–Jacobi equations outside a finite or countable number of smooth manifolds $\mathcal{M}_i$. On the other hand, one can use the Crandall–Lions theory of viscosity solutions, and show that the value function is the unique solution of the Hamilton–Jacobi equation in the viscosity sense [BC].

None of these approaches is applicable in the present situation because of lack of regularity. Indeed, each player now has to solve an optimal control problem for a system whose dynamics (determined by the feedbacks used by all other players) is discontinuous. Our proof of optimality will strongly rely on the special structure of BV solutions of hyperbolic systems of conservation laws. In particular, we show that the solution has bounded directional variation along a cone Γ bounded away from all characteristic directions. As a consequence, the value functions V_i always admit a directional derivative in the directions of the cone Γ. For trajectories whose speed remains inside Γ, the optimality can thus be tested directly from the equations. An additional argument, using Clarke's generalized gradients [C], will rule out the optimality of trajectories whose speed falls outside the above cone of directions.

It is interesting to observe that the entropy admissibility conditions play no role in our analysis. For example, a solution of the system of conservation laws consisting of a single, nonentropic shock still determines a Nash equilibrium solution, provided that the amplitude of the shock is small enough. There is, however, a way to distinguish entropy solutions from all others that is also in the context of differential games. Indeed, entropy solutions are precisely the ones obtained as vanishing viscosity limits [BB]. They can thus be derived from a stochastic differential game of the form

$$dx = \sum_{i=1}^{n} f_i(x, u_i)\, dt + \varepsilon\, dw,$$

letting the white noise parameter $\varepsilon \to 0$. Here dw formally denotes the differential of a Brownian motion. For a discussion of stochastic differential games we refer to [F2].

In general, a weak solution of the hyperbolic system of conservation laws uniquely determines a family of discontinuous feedback controls $U_i^* = U_i^*(t,x)$. Inserting these controls in (1.1) we obtain the ODE

$$\dot{x} = \sum_{i=1}^{n} f_i(x, U_i^*(t,x)). \tag{1.10}$$

In spite of the right-hand side being discontinuous, we show that the solution of the Cauchy problem is unique and depends continuously on the initial data. Indeed, every trajectory of (1.10) crosses transversally all lines of discontinuity in the functions f_i. Because of the bound on the total variation, the uniqueness result in [B1] can thus be applied.

Our analysis will be concerned with the spatially homogeneous case, where the functions f_i, h_i do not depend on x. In the last section we shall see what results remain valid in the nonhomogeneous case, and discuss other possible extensions.

2. The basic framework. Consider an n-person differential game on the real line, having the special form

$$\dot{x} = f_0 + \sum_i u_i, \qquad x(\tau) = y. \tag{2.1}$$

Here the controls u_i can be any measurable, real valued functions, while f_0 is a fixed real number. The cost functionals take the form

$$J_i = J_i(\tau, y, u_1, \dots, u_n) = \int_\tau^T h_i(u_i(t))\,dt + g_i(x(T)). \tag{2.2}$$

To simplify the problem, for the time being we thus assume that the system has the simple dynamics (2.1) and that the running costs h_i do not depend on the space variable x. In section 6 we shall discuss how to extend the results to more general situations.

A key assumption, used throughout the paper, is that the cost functions h_i are smooth and strictly convex, with a positive second derivative

$$\frac{\partial^2}{\partial \omega^2} h_i(\omega) > 0 \tag{2.3}$$

at every point ω. Each player seeks a feedback strategy $u_i = U_i^*(t,x)$, which minimizes his own cost. Call $V_i = V_i(\tau, y)$ the value function for the ith player, and consider the spatial derivative $p_i = V_{i,x}$. The Hamiltonian functions H_i are defined as

$$H_i(p_1, \dots, p_n) = p_i \cdot \left(f_0 + \sum_j u_j^*(p_j) \right) + h_i(u_i^*(p_i)), \tag{2.4}$$

where the controls $u_j^* = u_j^*(p_j)$ provide the solutions to the following minimization problems:

$$p_j u_j^* + h_j(u_j^*) = \min_\omega \{p_j \cdot \omega + h_j(\omega)\} \doteq \phi_j(p_j). \tag{2.5}$$

At a point of minimum the first derivative vanishes. For every p_j we thus have

$$p_j + \frac{\partial h_j}{\partial u_j}\big(u^*(p_j)\big) = 0. \tag{2.6}$$

The Hamiltonian functions in (2.4) can also be written as

$$H_i(p_1,\dots,p_n) = p_i\left(f_0 + \sum_{j\neq i} u_j^*(p_j)\right) + \phi_i(p_i). \tag{2.7}$$

The corresponding Hamilton–Jacobi equation for V_i takes the form

$$V_{i,t} + H_i(V_{1,x},\dots,V_{n,x}) = 0. \tag{2.8}$$

To determine the value functions V_i, the above system has to be solved backward in time, with data given at the terminal time $t = T$:

$$V_i(T,x) = g_i(x), \quad i = 1,\dots,n. \tag{2.9}$$

In turn, the gradients $p_i \doteq V_{i,x}$ of the value functions satisfy the system of conservation laws

$$\frac{\partial}{\partial t}p_i + \frac{\partial}{\partial x}H_i(p_1,\dots,p_n) = 0 \tag{2.10}$$

with the terminal data

$$p_i(T,x) = g_i'(x). \tag{2.11}$$

Computing the Jacobian matrix $A(p)$ of this system, with entries $A_{ij} = \partial H_i/\partial p_j$, we find

$$A_{ii} = f_0 + \sum_j u_j^*(p_j) = \dot{x}, \tag{2.12}$$

$$A_{ij} = p_i\frac{\partial u_j^*(p_j)}{\partial p_j} = p_i\frac{\partial^2\phi_j}{\partial p_j^2}, \quad i \neq j. \tag{2.13}$$

Indeed, by (2.6) the functions $\phi_j \doteq p_j u_j^*(p_j) + h_j(u_j^*(p_j))$ defined at (2.5) satisfy

$$\frac{\partial\phi_j}{\partial p_j} = u_j^* + p_j\frac{\partial u_j^*}{\partial p_j} + \frac{\partial h_j}{\partial u_j}\frac{\partial u_j^*}{\partial p_j} = u_j^*. \tag{2.14}$$

It will be convenient to write second derivatives as $h_j'' \doteq \partial^2 h_j/\partial u_j^2$, $\phi_j'' \doteq \partial^2\phi_j/\partial p_j^2$. Differentiating w.r.t. p_j the identity (2.6), we find

$$1 + h_j''(u_j^*(p_j))\cdot\frac{\partial u_j^*}{\partial p_j}(p_j) = 0. \tag{2.15}$$

Using (2.14) and (2.15) one obtains

$$\phi_j''(p_j) = \frac{\partial u_j^*}{\partial p_j}(p_j) = -\frac{1}{h_j''(u_j^*(p_j))}. \tag{2.16}$$

Of course, this relation is well known from the theory of Legendre transforms.

3. Hyperbolicity conditions. In order that the Cauchy problem (2.10)–(2.11) be well posed, the system of conservation laws should be hyperbolic. It is thus important to determine in which cases the Jacobian matrix $A(p)$ has n distinct real eigenvalues. According to (2.12)–(2.13), this matrix takes the form

$$A(p) = \begin{pmatrix} \dot{x} & p_1\phi_2'' & p_1\phi_3'' & \cdots & p_1\phi_n'' \\ p_2\phi_1'' & \dot{x} & p_2\phi_3'' & \cdots & p_2\phi_n'' \\ p_3\phi_1'' & p_3\phi_2'' & \dot{x} & \cdots & p_2\phi_n'' \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ p_n\phi_1'' & p_n\phi_2'' & p_n\phi_3'' & \cdots & \dot{x} \end{pmatrix}. \tag{3.1}$$

We recall that, by (2.16) and (2.3), all second derivatives ϕ_j'' are strictly negative. The next lemma provides sufficient conditions on $p_1, \dots, p_n$ by which the system of conservation laws (2.10) is hyperbolic.

LEMMA 3.1. *Assume that all p_j have the same sign, i.e., either $p_j > 0$ for all j, or $p_j < 0$ for all j. Moreover, assume that there are no distinct indices $i \neq j \neq k$ such that*

$$p_i\phi_i'' = p_j\phi_j'' = p_k\phi_k''. \tag{3.2}$$

Then the matrix $A(p)$ in (3.1) *has n real distinct eigenvalues, and the system in* (2.10) *is strictly hyperbolic. Furthermore, all of these eigenvalues are different from $\dot{x}$.*

Proof. To fix the ideas, consider the case where $p_i > 0$ for all $i = 1, \dots, n$. The case where $p_i < 0$ is entirely similar.

Let $B \doteq A - \dot{x}I$, where I is the $n \times n$ identity matrix, and call $\lambda(A)$ the eigenvalues of a matrix A. Since

$$\lambda(B) = \lambda(A) - \dot{x}, \tag{3.3}$$

it suffices to show that B has n distinct real eigenvalues, all different from zero.

First we show that B has no zero eigenvalue. This is clear because

$$\begin{aligned} \det(B) &= \begin{vmatrix} 0 & p_1\phi_2'' & \cdots & p_1\phi_n'' \\ p_2\phi_1'' & 0 & \cdots & p_2\phi_n'' \\ \vdots & \vdots & \ddots & \vdots \\ p_n\phi_1'' & p_n\phi_2'' & \cdots & 0 \end{vmatrix} = \prod_{i=1}^{n} p_i\phi_i'' \cdot \begin{vmatrix} 0 & 1 & \cdots & 1 \\ 1 & 0 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 0 \end{vmatrix} \\ &= (-1)^{n-1}(n-1)\prod_{i=1}^{n} p_i\phi_i'' \neq 0. \end{aligned}$$

As customary, the bars $|\cdot|$ around a matrix are used here to denote its determinant.

The eigenvalues of B are the zeros of the characteristic polynomial $\det(B - \lambda I)$. We observe that

$$\det(B - \lambda I) = \begin{vmatrix} -\dfrac{\lambda}{p_1\phi_1''} & 1 & \cdots & 1 \\ 1 & -\dfrac{\lambda}{p_2\phi_2''} & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & -\dfrac{\lambda}{p_n\phi_n''} \end{vmatrix} \cdot \prod_{i=1}^{n} p_i\phi_i''.$$

By assumption, the numbers $c_i \doteq -p_i \phi_i''$ are all strictly positive. Up to a permutation of indices, which does not affect the determinant, we can assume that $0 < c_1 \leq c_2 \leq \cdots \leq c_n$. The polynomial $\det(B - \lambda I)$ has the same zeros as $q(\lambda) \doteq \det \widetilde{B}(\lambda)$, where

$$\widetilde{B}(\lambda) \doteq \begin{pmatrix} \frac{\lambda}{c_1} & 1 & \cdots & 1 \\ 1 & \frac{\lambda}{c_2} & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & \frac{\lambda}{c_n} \end{pmatrix}. \tag{3.4}$$

The leading term of the polynomial $q(\lambda)$ is easily computed:

$$q(\lambda) = \prod_{i=1}^{n} \frac{\lambda}{c_i} + \mathcal{O}(1) \cdot \lambda^{n-1}.$$

For some constant $M > 0$ sufficiently large, we clearly have $\mathrm{sign}(q(\lambda)) = +1$ for $\lambda > M$ and $\mathrm{sign}(q(\lambda)) = (-1)^n$ for all $\lambda < -M$. Moreover, when $\lambda = 0$ we have $\mathrm{sign}(q(0)) = (-1)^{n-1}$.

Two cases need to be considered, depending on whether all c_i are distinct, or whether two of them coincide.

First case. Assume that all the c_i's are distinct, say $0 < c_1 < c_2 < \cdots < c_n$. Let us compute the determinant of $\widetilde{B}(\lambda)$ at the point $\lambda = c_i$. In this case, the ith row of $\widetilde{B}(\lambda)$ is identically 1, and we can subtract it from all the other rows, thus obtaining

$$\begin{aligned} q(\lambda) &= \begin{vmatrix} \frac{c_i}{c_1} & 1 & \cdots & 1 \\ 1 & \frac{c_i}{c_2} & \cdots & 1 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & \ddots & 1 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & \cdots & \frac{c_i}{c_n} \end{vmatrix} \quad \begin{matrix} \\ \\ \\ \leftarrow: i\text{th row} \\ \\ \\ \end{matrix} = \begin{vmatrix} \frac{c_i}{c_1} - 1 & 0 & \cdots & 0 \\ 0 & \frac{c_i}{c_2} - 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & \ddots & 1 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & \frac{c_i}{c_n} - 1 \end{vmatrix} \\ &= \prod_{j \neq i} \left(\frac{c_i}{c_j} - 1 \right). \end{aligned}$$

Since

$$\mathrm{sign} \left(\frac{c_i}{c_j} - 1 \right) = \begin{cases} 1 & \text{if } i > j, \\ -1 & \text{if } i < j, \end{cases}$$

we conclude that

$$\mathrm{sign}(q(\lambda)) = (-1)^{n-i} \quad \text{when } \lambda = c_i.$$

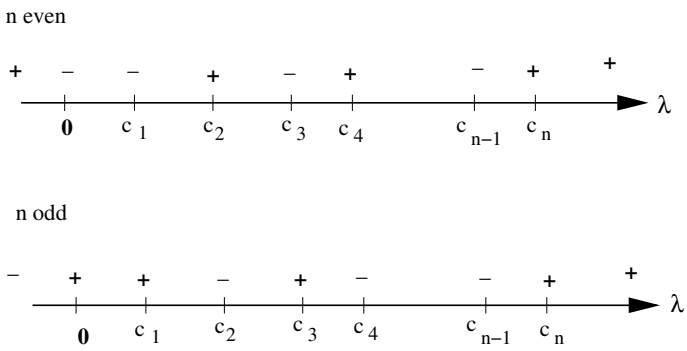

FIG. 3.1. *The sign of* $\det(\bar{B})(\lambda)$ *at various points. This shows the location of the real eigenvalues.*

As shown in Figure 3.1, the function $\lambda \mapsto q(\lambda)$ thus changes sign inside each of the intervals:

$$]-\infty, 0[\,,\ ]c_1, c_2[\,,\ \ldots\ ,\ ]c_{i-1}, c_i[\,,\ \ldots\ ,\ ]c_{n-1}, c_n[\,.$$

By continuity, there exist n distinct real zeros, with

$$\lambda_1 < 0 < c_1 < \lambda_2 < c_2 < \cdots < c_{i-1} < \lambda_i < c_i < \cdots < \lambda_n < c_n.$$

Notice that we must have $|\lambda_1| = \sum_{i=2}^{n} |\lambda_i|$ because the trace of $\widetilde{B}$ is zero.

Second case. Assume that two (but not three consecutive) numbers c_i coincide, say, $c_i = c_{i+1}$. We claim that the polynomial $q(\lambda)$ still has n distinct zeros, and the $(i+1)$th zero is $\lambda_{i+1} = c_i = c_{i+1}$.

When $\lambda = c_i = c_{i+1}$, the matrix $\widetilde{B}(\lambda)$ has both the ith and the $(i+1)$th rows identically equal to 1. Hence the determinant is zero. This shows that $\lambda_{i+1} = c_i = c_{i+1}$ is a zero of $q(\lambda)$.

To prove that it is a single root, we need to check that the derivative $q'(\lambda)$ does not vanish at $\lambda = c_i$. A direct computation yields

$$q'(\lambda) = \begin{vmatrix} \frac{1}{c_1} & 1 & \cdots & 1 \\ 0 & \frac{\lambda}{c_2} & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 1 & \cdots & \frac{\lambda}{c_n} \end{vmatrix} + \begin{vmatrix} \frac{\lambda}{c_1} & 0 & \cdots & 1 \\ 1 & \frac{1}{c_2} & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & \cdots & \frac{\lambda}{c_n} \end{vmatrix} + \cdots + \begin{vmatrix} \frac{\lambda}{c_1} & 1 & \cdots & 0 \\ 1 & \frac{\lambda}{c_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & \frac{1}{c_n} \end{vmatrix}$$

$$\doteq \det B_1(\lambda) + \det B_2(\lambda) + \cdots + \det B_n(\lambda).$$

When $\lambda = c_i = c_{i+1}$ we have $\det B_j(\lambda) = 0$ for all $j \neq i, i+1$, because the ith and $(i+1)$th rows of the matrix B_j are identical (all entries are 1 except the jth entry which is 0). Moreover, $\det B_i(\lambda) = \det B_{i+1}(\lambda)$ because $B_i(\lambda)$ can be obtained from $B_{i+1}(\lambda)$ by first exchanging ith and $(i+1)$th rows and then exchanging ith and $(i+1)$th columns. Now we compute $\det B_i(\lambda)$. The entries of the $(i+1)$th row are all 1 except the ith entry which is zero. We subtract this row from all the other rows

and obtain

$$\det B_i(\lambda) = \begin{vmatrix} \frac{c_i}{c_1} & \cdots & 0 & 1 & \cdots & 1 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 1 & \cdots & \frac{1}{c_i} & 1 & \cdots & 1 \\ 1 & \cdots & 0 & 1 & \cdots & 1 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \cdots & 0 & 1 & \cdots & \frac{c_i}{c_n} \end{vmatrix} \begin{matrix} \\ \\ \leftarrow: i\text{th row}, \\ \leftarrow: (i+1)\text{th row}, \\ \\ \\ \end{matrix}$$

$$= \begin{vmatrix} \frac{c_i}{c_1} - 1 & \cdots & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \frac{1}{c_i} & 0 & \cdots & 0 \\ 1 & \cdots & 0 & 1 & \cdots & 1 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & \cdots & \frac{c_i}{c_n} - 1 \end{vmatrix} \begin{matrix} \\ \\ \leftarrow: i\text{th row}, \\ \leftarrow: (i+1)\text{th row}, \\ \\ \\ \end{matrix}$$

$$= \frac{1}{c_i} \prod_{j \neq i, i-1} \left(\frac{c_i}{c_j} - 1 \right) \neq 0.$$

Observing that $q'(c_i) = 2 \cdot \det B_i(c_i) \neq 0$, we conclude that $\lambda = c_i$ is a single root.

It now remains to prove that we still have n distinct real zeros, i.e., that the coincidence of the two numbers c_i and c_{i+1} does not destroy any of the other sign changes in the polynomial $q(\lambda)$. In particular, there is still a zero inside each interval $]c_{i-1}, c_i[$ and $]c_{i+1}, c_{i+2}[$. From the previous computation we have that

$$\begin{aligned} \operatorname{sign}(q'(c_i)) &= (-1)^{n-i-1}, \\ \operatorname{sign}(q(c_{i-1})) &= (-1)^{n-i+1}, \\ \operatorname{sign}(q(c_{i+2})) &= (-1)^{n-i-2}. \end{aligned}$$

Therefore, $q'(c_i)$ and $q(c_{i-1})$ have the same sign, while $q'(c_i)$ and $q(c_{i+2})$ have opposite signs. Looking at Figure 3.2 it is clear that there is one root within the interval $]c_{i-1}, c_i[$, another inside the interval $]c_{i+1}, c_{i+2}[$, while $\lambda = c_i = c_{i+1}$ is still another root.

In the special case $i = 1$ (or $i = n - 1$), it can be checked in the same way that $c_1 = c_2$ (or $c_{n-1} = c_n$) is a single root, while another root lies in the interval $]c_2, c_3[$ (or in the interval $]c_{n-2}, c_{n-1}[$, respectively).

At last, we need to consider the case where more than one couple of numbers c_i, c_{i+1} coincide. We claim that, in all cases, the polynomial $q(\lambda)$ still has n distinct roots. Indeed, in the case where the two coinciding pairs $c_i = c_{i+1}$, $c_j = c_{j+1}$ are not adjacent (i.e., $j \neq i + 2$), the previous analysis applies. On the other hand, in the case where, say, $c_{i-2} = c_{i-1} < c_i = c_{i+1}$, the analysis of the signs of $q'(c_{i-1})$, $q'(c_i)$, $q(c_{i+2})$, and $q(c_{i-3})$ (see Figure 3.3) yields the desired results.

The proof of Lemma 3.1 is now completed. □

Remark 1. If three or more of the numbers c_j coincide, say, $c_{i-1} = c_i = c_{i+1}$, then c_i becomes a multiple zero of $\det(B - \lambda I)$. In this case, the system of conservation laws will still be hyperbolic, but no longer strictly hyperbolic.

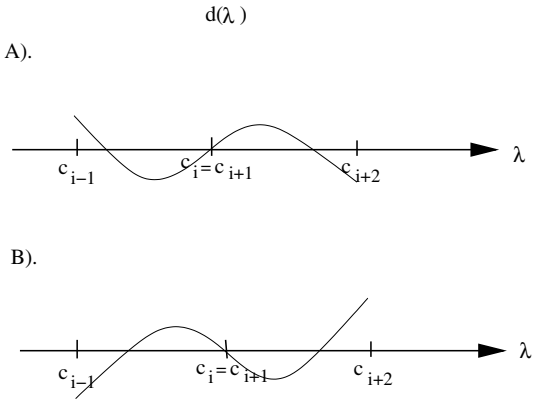

FIG. 3.2. *Checking that $\lambda = c_i = c_{i+1}$ is a single root.*

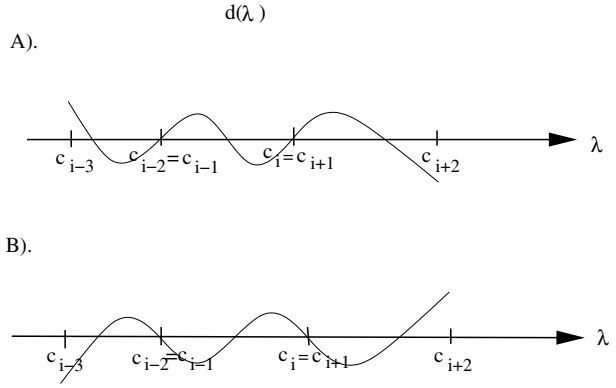

FIG. 3.3. *Two coinciding pairs next to each other.*

Remark 2. In the case of 2×2 systems, the condition $p_1 p_2 \geq 0$ is necessary for the hyperbolicity of the system. However, when $n \geq 3$, the system (2.10) can be strictly hyperbolic also at points where $p_1 < 0 < p_2 < p_3$. For example, let $n = 3$, $\phi_i'' = -1$ for all i, $p_1 = -1$, $p_2 = 5$, and $p_3 = 20$. Then the characteristic polynomial $q(\lambda) = \det \bar{B}(\lambda)$ is

$$q(\lambda) = \lambda^3 - 75\lambda + 200.$$

One can easily check that

$$q(-10) = -50, \quad q(0) = 200, \quad q(5) = -50, \quad q(10) = 450.$$

Therefore, there are three distinct real eigenvalues:

$$\lambda_1 \in]-10, 0[, \quad \lambda_2 \in]0, 5[, \quad \lambda_3 \in]5, 10[.$$

4. Review of hyperbolic systems and discontinuous ODE. In this section we collect some results on hyperbolic conservation laws and discontinuous ODEs, which will be used in what follows. Consider the Cauchy problem for a system of

conservation laws

$$v_t + F(v)_x = 0, \qquad v(0,x) = \bar v(x). \tag{4.1}$$

In the case where the system is strictly hyperbolic, the global existence of weak solutions with small BV initial data is well known.

PROPOSITION 4.1. *Assume that the flux function $F : \mathbb{R}^n \mapsto \mathbb{R}^n$ is smooth and that, at some point v^*, the Jacobian matrix $A(v^*) = DF(v^*)$ has n real distinct eigenvalues. Then there exists $\delta > 0$ for which the following holds. If*

$$\|\bar v(\cdot) - v^*\|_{\mathbf{L}^\infty} < \delta, \qquad \textit{Tot. Var.}\{\bar v\} < \delta, \tag{4.2}$$

then the Cauchy problem (4.1) *admits a unique entropy weak solution $v = v(t,x)$ defined for all $t \geq 0$, obtained as the limit of vanishing viscosity approximations.*

In the case where each characteristic field is either linearly degenerate or genuinely nonlinear, the existence of a global weak solution was proved by Glimm [G]. The more general case was later covered in [L, ILF] using the Glimm scheme and in [AM] using wave-front tracking. The convergence of vanishing viscosity approximations was recently proved in [BB], together with the uniqueness and Lipschitz continuous dependence of solutions on the initial data in the $\mathbf{L}^1$ distance. We remark that, for each time t, the function $v(t,\cdot)$ has small total variation. Its pointwise values can be uniquely assigned by the convention

$$v(t,x) = \lim_{y \to x+} v(t,y). \tag{4.3}$$

For applications to game theory, we shall need some additional properties of these weak solutions. By assumption, the matrix $A(v^*)$ has distinct eigenvalues $\lambda_1^* < \lambda_2^* < \cdots < \lambda_n^*$. By continuity, there exists $\varepsilon > 0$ such that, for all v in the ε-neighborhood

$$\Omega_\varepsilon^* \doteq \{v;\ |v - v^*| \leq \varepsilon\},$$

the characteristic speeds range inside disjoint intervals

$$\lambda_j(v) \in [\lambda_j^-, \lambda_j^+]. \tag{4.4}$$

Moreover, if $v^-, v^+ \in \Omega_\varepsilon^*$ are two states connected by a j-shock, the speed $\lambda_j(v^-, v^+)$ of the shock remains inside the interval $[\lambda_j^-, \lambda_j^+]$.

Now consider an open cone of the form

$$\Gamma \doteq \{(t,x);\ t > 0,\ a < x/t < b\}. \tag{4.5}$$

Following [B1] we define the *directional variation* of the function $(t,x) \mapsto v(t,x)$ along the cone Γ as

$$\sup \left\{ \sum_{i=1}^N |v(t_i,x_i) - v(t_{i-1},x_{i-1})| \right\}, \tag{4.6}$$

where the supremum is taken over all finite sequences $(t_0,x_0), (t_1,x_1), \ldots, (t_N,x_N)$ such that

$$(t_i - t_{i-1}, x_i - x_{i-1}) \in \Gamma \quad \text{for every } i = 1, \ldots, N. \tag{4.7}$$

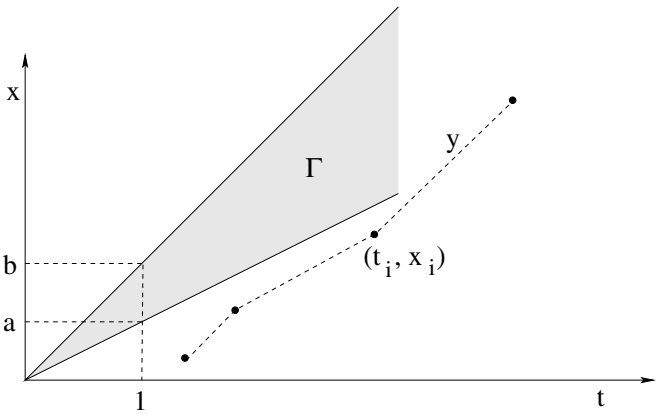

FIG. 4.1. *Directional variation along the cone* Γ.

(See Figure 4.1.) We now show that the weak solution $v = v(t,x)$ has bounded directional variation along a suitable cone Γ.

LEMMA 4.2. *Let $v = v(t,x)$ be an entropy weak solution of* (4.1) *taking values inside the domain Ω^*_ε. Assume that $\lambda^+_{k-1} < a < b < \lambda^-_k$ for some k. Then v has bounded directional variation along the cone Γ in* (4.5).

Proof. Fix any finite sequence of points (t_i, x_i), $i = 0, \dots, N$, satisfying (4.7). It is not restrictive to assume that $t_0 = 0$. Call $T \doteq t_N$ and define $y : [0,T] \mapsto \mathbb{R}$ as the polygonal line with nodes at the points (t_i, x_i) (Figure 4.1). Clearly y is almost everywhere differentiable, with $\dot y(t) \in]a,b[$. From the theory of conservation laws, it is well known that the entropy weak solution v can be obtained as the limit of a sequence of front tracking approximate solutions v_ν. For each $\nu \geq 1$, one can derive a uniform bound on the total variation of the map $t \mapsto v_\nu(t, y(t))$. Indeed, call $V^y(t)$ the total strength of all wave-fronts in $v_\nu(t,\cdot)$ approaching $y(t)$ at time t, i.e.,

$$V^y(t) \doteq \sum_{\alpha \in \mathcal{A}(y)} |\sigma_\alpha| \,. \tag{4.8}$$

Here σ_α denotes the strength of the wave-front in $v_\nu(t,\cdot)$ located at x_α. Observing that $\lambda^+_k < \dot y < \lambda^-_{k+1}$, the above summation will include the following fronts:

- the fronts of a family $k_\alpha \leq k$ located at a point $x_\alpha > y$, and
- the fronts of a family $k_\alpha > k$ located at a point $x_\alpha < y$.

We now call

$$Q(t) = \sum_{\alpha,\beta \in \mathcal{A}} |\sigma_\alpha||\sigma_\beta| \tag{4.9}$$

the *interaction potential* of $v_\nu(t,\cdot)$, i.e., the sum of products of all couples of approaching waves in $v_\nu(t,\cdot)$. Assuming that the total variation of the solution remains small, for some constant C_0 the positive functional

$$\Upsilon(t) \doteq V^y(t) + C_0 Q(t)$$

is nonincreasing in time. Moreover, at each time τ where a wave-front of strength σ_α crosses $y(\cdot)$, we have

$$\Upsilon(\tau+) - \Upsilon(\tau-) = -|\sigma_\alpha|.$$

Therefore, the total strength of all wave-fronts in v_ν which cross the polygonal line $y(\cdot)$ is bounded by

$$V^y(0) + C_0 Q(0) = \mathcal{O}(1) \cdot \text{Tot.Var.}\{\bar v\}.$$

This proves that the total variation of the maps $t \mapsto v_\nu\big(t, y(t)\big)$ is uniformly bounded for all $\nu \geq 1$. To get the desired estimate for the solution v, we now let $\nu \to \infty$. If we have the pointwise convergence $v_\nu(t_i, x_i) \to v(t_i, x_i)$ for every $i = 0, \ldots, N$, we can immediately conclude

$$\begin{aligned}\sum_{i=1}^N |v(t_i, x_i) - v(t_{i-1}, x_{i-1})| &\leq \limsup_{\nu\to\infty} |v_\nu(t_i, x_i) - v_\nu(t_{i-1}, x_{i-1})| \\ &= \mathcal{O}(1) \cdot \text{Tot.Var.}\{\bar v\},\end{aligned}$$

proving our claim. However, if v is discontinuous at some point (t_i, x_i), the pointwise convergence may not hold. To achieve the result also in the general case we observe that, for each time τ, we have the convergence $v_\nu(\tau, x) \to v(\tau, x)$ for a.e. $x \in \mathbb{R}$. Using the right continuity of the functions $v(t_i, \cdot)$, we can find points x_i' sufficiently close to x_i such that

$$|v(t_i, x_i') - v(t_i, x_i)| < 1/N, \qquad (t_i - t_{i-1}, x_i' - x_{i-1}') \in \Gamma,$$

and such that $v_\nu(t_i, x_i') \to v(t_i, x_i')$ for every i. This yields the estimate

$$\begin{aligned}&\sum_{i=1}^N |v(t_i, x_i) - v(t_{i-1}, x_{i-1})| \\ &\quad\leq \sum_{i=1}^N \{|v(t_i, x_i') - v(t_{i-1}, x_{i-1}')| + |v(t_i, x_i') - v(t_{i-1}, x_i)| \\ &\qquad\qquad + |v(t_i, x_{i-1}') - v(t_{i-1}, x_{i-1})|\} \\ &\quad\leq 2 + \limsup_{\nu\to\infty} \sum_{i=1}^N |v_\nu(t_i, x_i) - v_\nu(t_{i-1}, x_{i-1})| \\ &\quad= 2 + \mathcal{O}(1) \cdot \text{Tot.Var.}\{\bar v\},\end{aligned}$$

proving the lemma. □

Together with Γ we now consider a strictly smaller cone, say,

$$\Gamma' \doteq \{(t, x);\ t > 0,\ a' < x/t < b'\}, \tag{4.10}$$

with $a < a' < b' < b$. A standard theorem in real analysis states that a BV function of one real variable admits left and right limits at every point. We now prove an analogous result for functions with bounded directional variation.

LEMMA 4.3. *Let $v = v(t, x)$ be a function with bounded directional variation along the cone Γ in (4.5), and consider the smaller cone $\Gamma' \subset \Gamma$ in (4.10), with $a < a' < b' < b$. Then at every point $P = (t, x)$ there exist the directional limits*

$$v^+(P) \doteq \lim_{Q\to P,\ Q-P\in\Gamma'} v(Q), \qquad v^-(P) \doteq \lim_{Q\to P,\ P-Q\in\Gamma'} v(Q). \tag{4.11}$$

Proof. If the first limit does not exist, we can find two sequences $Q'_\nu \to P$, $Q''_\nu \to P$ with $Q'_\nu - P \in \Gamma'$, $Q''_\nu - P \in \Gamma'$ for every $\nu \geq 1$, along which the function v converges to distinct limits:

$$v(Q'_\nu) \to v', \qquad v(Q''_\nu) \to v'',$$

with $v' \neq v''$. Since Γ' is strictly smaller than Γ, by induction we can select two subsequences

$$Q'_{\nu(1)}, Q'_{\nu(2)}, \ldots, \qquad Q''_{\nu(1)}, Q''_{\nu(2)}, \ldots,$$

such that

$$Q'_{\nu(j)} - Q''_{\nu(j)} \in \Gamma, \qquad Q''_{\nu(j)} - Q'_{\nu(j+1)} \in \Gamma$$

for every j. In this case

$$\lim_{N\to\infty} \sum_{i=1}^{N} |v(Q'_{\nu(j)}) - v(Q''_{\nu(j)})| = \infty,$$

in contrast with the assumption of bounded directional variation. This proves the existence of the first limit in (4.11). The second one is entirely similar. □

Next, we recall some results on differential equations with discontinuous right-hand sides. Let $f = f(t,x)$ be a bounded function. By a *Carathéodory solution* of the ODE

$$\dot{x}(t) = f(t, x(t)), \tag{4.12}$$

we mean an absolutely continuous function $t \mapsto x(t)$ which satisfies the equation (4.12) at a.e. time t.

In the case where f is discontinuous, it is well known that the Cauchy problem may have no Carathéodory solutions. One can then relax the concept of solution, introducing multivalued regularizations of f. For example, consider the multifunction

$$F(t,x) \doteq \bigcap_{\varepsilon>0} \overline{co}\{f(s,y);\ |s-t| \leq \varepsilon,\ |y-x| \leq \varepsilon\}, \tag{4.13}$$

where $\overline{co}$ denotes the convex closure of a set. Following [H], by a *Krasovskii solution* of (4.12) we mean an absolutely continuous function $t \mapsto x(t)$ which satisfies the differential inclusion

$$\dot{x}(t) \in F(t, x(t)) \tag{4.14}$$

at a.e. time t. Another concept of solution, proposed by Filippov, relates to the multifunction

$$F^*(t,x) \doteq \bigcap_{\varepsilon>0} \bigcap_{\mathrm{meas}(\mathcal{N})=0} \overline{co}\{f(s,y);\ |s-t| \leq \varepsilon,\ |y-x| \leq \varepsilon,\ (s,y) \notin \mathcal{N}\}, \tag{4.15}$$

obtained as in (4.13), neglecting the behavior of f on sets of measure zero. An absolutely continuous function $t \mapsto x(t)$ which satisfies almost everywhere the differential inclusion

$$\dot{x}(t) \in F^*(t, x(t)) \tag{4.16}$$

is called a *Filippov solution* of (4.12). Notice that $F^* \subseteq F$. Moreover, the multifunction $F^*(t,x)$ is not affected if the function f is modified on sets of measure zero.

Under the only assumption that f is bounded, it is well known that the multifunctions F, F^* are both upper semicontinuous, with compact convex values [AC]. Hence the Cauchy problem

$$\dot{x}(t) = f(t, x(t)), \qquad x(s) = y \tag{4.17}$$

admits at least one solution, according to the definitions of Filippov and of Krasovskii. In the case where the function f has directionally bounded variation, a much stronger result can be proved.

LEMMA 4.4. *Assume that the function f has bounded directional variation along the cone Γ in* (4.5). *Moreover, assume that*

$$a < a' \leq f(t,x) \leq b' < b$$

for all t, x. Then the Cauchy problem (4.17) *has a unique Carathéodory solution, Lipschitz continuously depending on the initial data (s,y). Such a solution is also the unique Krasovskii and Filippov solution of the Cauchy problem.*

Proof. The existence, uniqueness, and continuous dependence of the Carathéodory solution was proved in [B1]. For directionally continuous vector fields, the equivalence between Carathéodory, Filippov, and Krasovskii solutions was shown in [B2, p. 26]. □

We conclude this section by proving a simple result from nonsmooth analysis.

LEMMA 4.5. *Consider a Lipschitz continuous function $V = V(t,x)$ and call $(\phi, \psi) \doteq (V_t, V_x)$ its partial derivatives, defined at a.e. point (t,x). Let Γ be the cone at* (4.5). *Assume that, at a given point $(\bar{t}, \bar{x})$, there exists the directional limit*

$$(\bar{\phi}, \bar{\psi}) = \lim_{\substack{(t,x)\to(\bar{t},\bar{x}) \\ (t-\bar{t},x-\bar{x})\in\Gamma}} (\phi(t,x), \psi(t,x))\,. \tag{4.18}$$

Moreover, consider a continuous function $t \mapsto x(t)$ which is differentiable at $t = \bar{t}$ and assume

$$x(\bar{t}) = \bar{x}, \qquad \dot{x}(\bar{t}) \in \,]a, b[.$$

Then the composite function admits the one-sided derivative

$$\lim_{h\to 0+} \frac{V(\bar{t}+h, x(\bar{t}+h)) - V(\bar{t},\bar{x})}{h} = \bar{\phi} + \bar{\psi}\cdot\dot{x}(\bar{t}). \tag{4.19}$$

Proof. From the theory of generalized gradients [C] it follows that, for $h > 0$ small,

$$\begin{aligned} V(\bar{t}+h, x(\bar{t}+h)) - V(\bar{t},\bar{x}) \in\; & h\cdot\overline{co}\{\phi(t,x);\ \bar{t} < t < t+h,\ (t-\bar{t}, x-\bar{x})\in\Gamma\} \\ & + h\cdot\overline{co}\{\psi(t,x);\ \bar{t} < t < t+h,\ (t-\bar{t}, x-\bar{x})\in\Gamma\}\cdot[x(t)-\bar{x}]. \end{aligned}$$

Letting $h \to 0+$ and using (4.18) one obtains (4.19). □

5. Optimal feedback strategies. The analysis in section 3 has identified conditions which ensure that the system of conservation laws (2.10) is strictly hyperbolic in a neighborhood of a point $p = (p_1, p_2, \ldots, p_n)$. In this case, assuming that the terminal condition (2.11) has small total variation, one can apply Glimm's theorem and obtain the global existence of a weak solution. We shall now prove that the components of this solution determine a family of feedback strategies $u_i = U_i^*(t, x)$, which provide a Nash equilibrium solution to the noncooperative differential game.

THEOREM 5.1. *Consider the differential game* (2.1)–(2.2)*, where the cost functions* h_i *are smooth and satisfy the convexity assumption* (2.3)*. In connection with the functions* ϕ_j *at* (2.5)*, let* $p^* \doteq (p_1^*, \ldots, p_n^*)$ *be a point where the assumptions of Lemma* 3.1 *are satisfied. Then there exists* $\delta > 0$ *such that the following holds. If*

$$\|g_i' - p_i^*\|_{\mathbf{L}^\infty} < \delta, \qquad \textit{Tot. Var.}\{g_i'(\cdot)\} < \delta, \tag{5.1}$$

then for any $T > 0$ *the terminal value problem* (2.10)–(2.11) *has a weak solution* $p : [0, T] \times \mathbb{R} \mapsto \mathbb{R}^n$*. The (possibly discontinuous) feedback controls* $U_j^*(t, x) \doteq u_j^*(p(t, x))$ *defined at* (2.5) *provide a Nash equilibrium solution to the differential game. The trajectories* $t \mapsto x(t)$ *are Lipschitz continuous functions of the initial data* (τ, y)*.*

Proof. The proof will be given in several steps.

Step 1. By the assumptions, the system of conservation laws

$$\frac{\partial}{\partial t} v_i - \frac{\partial}{\partial x} H_i(v_1, \ldots, v_n) = 0 \tag{5.2}$$

is strictly hyperbolic in a neighborhood of the point p^*. Given the initial data $v_i(0, x) = g_i'(x)$ with sufficiently small total variation, by Proposition 4.1 the Cauchy problem admits a weak solution $v = v(t, x)$, defined for all $t \geq 0$. Reversing time, we thus obtain a weak solution $p(t, x) \doteq v(T - t,\, x)$ of the terminal value problem (2.10)–(2.11). For each time t, the map $x \mapsto p(t, x)$ has small total variation. Its pointwise values can be uniquely assigned by the convention

$$p(t, x) = \lim_{y \to x+} p(t, y). \tag{5.3}$$

Step 2. By strict hyperbolicity and continuity, there exists $\varepsilon > 0$ such that, for all p in the ε-neighborhood

$$\Omega_\varepsilon^* \doteq \{p;\ |p - p^*| \leq \varepsilon\} \subset \mathbb{R}^n, \tag{5.4}$$

the following holds. The characteristic speeds for (2.10) range inside disjoint intervals

$$\lambda_j(p) \in [\lambda_j^-, \lambda_j^+]. \tag{5.5}$$

Moreover, the speed $\dot{x}$ at (2.1) remains bounded away from all characteristic speeds. Namely, there exists an index $k \in \{1, \ldots, n-1\}$ and numbers $\epsilon > 0$ and $a < b$ such that

$$\lambda_k^+ < a - \epsilon < b + \epsilon < \lambda_{k+1}^- \tag{5.6}$$

and

$$f_0 + \sum_j u_j^*(p_j) \in [a + \epsilon, b - \epsilon] \tag{5.7}$$

whenever $p \in \Omega^*_\varepsilon$.

Together with the cone Γ at (4.5) we now define

$$\Gamma^+_\epsilon \doteq \{(t,x);\ t>0,\ a-\epsilon \leq x/t \leq b+\epsilon\},$$
$$\Gamma^-_\epsilon \doteq \{(t,x);\ t>0,\ a+\epsilon \leq x/t \leq b-\epsilon\}.$$

Clearly, $\Gamma^-_\epsilon \subset \Gamma \subset \Gamma^+_\epsilon$. By Lemma 4.2, each $p_i = p_i(t,x)$ has bounded variation in the direction of the cone Γ. By the assumptions, the maps $p_j \mapsto u^*_j(p_j)$ in (2.5) are locally Lipschitz continuous. Hence, for $i = 1, \ldots, n$, all the composed maps $(t,x) \mapsto u^*_i(p_i(t,x))$ also have bounded directional variation along the cone Γ. By (5.7) we can thus apply Lemma 4.4, showing that the Cauchy problem for the ODE

$$\dot x(t) = f_0 + \sum_j u^*_j(p_j(t,x)) \tag{5.8}$$

has a unique Carathéodory (equivalently, Filippov or Krasovskii) solution, depending Lipschitz continuously on initial data (τ, y) in (1.2).

Step 3. We now construct the value functions V_i, corresponding to the feedback strategies $U^*_j(t,x) \doteq u^*_j(p_j(t,x))$. For $j = 1, \ldots, n$, define the cost functions

$$h^*_j(t,x) \doteq h_j(u^*_j(p_j(t,x))).$$

Given a point (τ, ξ), let $t \mapsto x(t;\tau,\xi)$ be the trajectory of (5.8) passing through (τ,ξ). For each $i = 1, \ldots, n$ we define

$$V_i(\tau,\xi) \doteq \int_\tau^T h^*_i(t, x(t;\tau,\xi))\, dt + g_i(x(T;\tau,\xi)). \tag{5.9}$$

By the same arguments as in [B1] one can show that the functions $V_i = V_i(t,x)$ are Lipschitz continuous, and hence almost everywhere differentiable. At every point where the differential exists, by construction one has

$$\frac{\partial V_i}{\partial t} + \dot x \cdot \frac{\partial V_i}{\partial x} = -h^*_i(t,x). \tag{5.10}$$

To derive further properties of the gradient of V_i, fix a time τ and any two points $\xi' < \xi''$. We claim that

$$V_i(\tau,\xi'') - V_i(\tau,\xi') = \int_{\xi'}^{\xi''} p_i(\tau,x)\, dx. \tag{5.11}$$

Indeed, let $x'(\cdot)$ and $x''(\cdot)$ be the two trajectories of (5.8) which start from the initial points $x'(\tau) = \xi'$ and $x''(\tau) = \xi''$, respectively. Consider the region $\Delta \subset \mathbb{R}^2$ defined as

$$\Delta \doteq \{(t,x);\ \tau \leq t \leq T,\ x'(t) \leq x \leq x''(t)\}.$$

Applying the divergence theorem to the vector field $\mathbf{v} \doteq (p_i, H_i)$ on the domain Δ and using the conservation equation (2.10), we obtain

$$\begin{aligned}\int_{x'(T)}^{x''(T)} p_i(T,x)\, dx = &\int_{\xi'}^{\xi''} p_i(\tau,x)\, dx + \int_\tau^T \{[p_i \cdot \dot x' + h^*_i(t,x'(t))] - p_i \cdot \dot x'\}\, dt \\ &- \int_\tau^T \{[p_i \cdot \dot x'' + h^*_i(t,x''(t))] - p_i \cdot \dot x''\}\, dt.\end{aligned}$$

Observing that $p_i(T,x) = g_{i,x}(x) = V_{i,x}(T,x)$, we conclude

$$g_i(x''(T)) - g_i(x'(T)) = \int_{\xi'}^{\xi''} p_i(\tau,x)\,dx + \int_\tau^T [h_i^*(t,x'(t)) - h_i^*(t,x''(t))]\,dt.$$

The above two equalities yield (5.11). Since ξ', ξ'' are arbitrary, this in turn implies

$$V_{i,x} = p_i \tag{5.12}$$

at a.e. point (t,x). Together with (5.10), this yields

$$V_{i,t} = -p_i \cdot \left(f_0 + \sum_j u_j^*(p_j) \right) - h_i^*. \tag{5.13}$$

Therefore, the value functions $(V_1, \ldots, V_n)$ satisfy almost everywhere the system of Hamilton–Jacobi equations

$$V_{i,t} + V_{i,x} \cdot \left(f_0 + \sum_j u_j^*(V_{j,x}) \right) + h_i(u_i^*(V_{i,x})) = 0. \tag{5.14}$$

We recall that $u_j^* = u_j^*(p_j)$ are the optimal control values defined at (2.5).

Step 4. We now conclude the proof, showing that the feedback strategies $U_j^*(t,x) \doteq u_j^*(p_j(t,x))$ represent a Nash equilibrium solution. Fix an index $i \in \{1, \ldots, n\}$ and consider the optimal control problem for the ith player:

$$\min_{z(\cdot)} \left\{ \int_\tau^T h_i(z(t))\,dt + g_i(T, x(T)) \right\}, \tag{5.15}$$

$$\dot{x}(t) = f_0 + \sum_{j \neq i} U_j^*(t,x) + z(t), \qquad x(\tau) = y. \tag{5.16}$$

We claim that the minimum cost is precisely $V_i(\tau,y)$. Consider any absolutely continuous trajectory $x : [\tau,T] \mapsto \mathbb{R}$ with $x(\tau) = y$. It suffices to show that, for a.e. $t \in [\tau,T]$,

$$\frac{d}{dt} V_i(t,x(t)) \geq -h_i(z(t)), \tag{5.17}$$

where the control function $z(\cdot)$ implemented by the ith player is

$$z(t) \doteq \dot{x}(t) - f_0 - \sum_{j \neq i} U_j^*(t,x).$$

Indeed, if (5.17) holds, then

$$\int_\tau^T h_i(z(t))\,dt + g_i(T,x(T)) \geq \int_\tau^T \left\{ -\frac{d}{dt} V_i(t,x(t)) \right\} dt + V_i(T,x(T)) = V_i(\tau,y),$$

as claimed.

We now give a proof of (5.17), assuming that the total variation of the functions $g_j'(\cdot)$ is sufficiently small. In connection with the vector $p^* = (p_1^*, \ldots, p_n^*)$ considered in (5.1), define the constant controls

$$\omega_j^* \doteq u_j^*(p_j^*).$$

Moreover, recalling (5.13), set

$$q_i^* \doteq -p_i^* \cdot \left(f_0 + \sum_j \omega_j^* \right) - h_i(\omega_i^*).$$

Choose $\varepsilon_1 > 0$ small enough so that, if $|u_j - \omega_j^*| \leq \varepsilon_1$ for all j, then

$$\dot{x} = f_0 + \sum_j u_j \in [a + \epsilon, b - \epsilon]. \tag{5.18}$$

Observe that our definitions imply

$$q_i^* + p_i^* \cdot \left(f_0 + \sum_{j \neq i} \omega_j^* \right) + \min_\omega \{ p_i^* \omega + h_i(\omega) \} = 0.$$

By the strict convexity of the cost function h_i at (2.5), there exists $\delta' > 0$ such that

$$q_i^* + p_i^* \cdot \left(f_0 + \sum_{j \neq i} \omega_j^* \right) + p_i^* \omega + h_i(\omega) > \delta'$$

whenever $|\omega - \omega_i^*| \geq \varepsilon_1$. By continuity, there exists $\varepsilon_2 > 0$ such that, if

$$|q_j - q_j^*| \leq \varepsilon_2, \quad |p_j - p_j^*| \leq \varepsilon_2, \quad j = 1, \ldots, n, \tag{5.19}$$

$$|\omega - \omega_i^*| \geq \varepsilon_1, \quad |u_j - \omega_j^*| \leq \varepsilon_2, \quad j \neq i, \tag{5.20}$$

then

$$q_i + p_i \cdot \left(f_0 + \sum_{j \neq i} u_j \right) + p_i \omega + h_i(\omega) > 0. \tag{5.21}$$

Choosing $\delta > 0$ in (5.1) sufficiently small, we can assume that the partial derivatives $p_j = V_{j,x}$, $q_j = V_{j,t}$ satisfy almost everywhere all the bounds in (5.19). Moreover, for $j \neq i$, the functions $u_j = u_j^*(p_j)$ satisfy the bounds in (5.20). Observe that a.e. time $\bar{t} \in [0, T]$ is in the Lebesgue set of all three measurable functions

$$z(t), \qquad \frac{d}{dt} x(t), \qquad \frac{d}{dt} V_i(t, x(t))$$

(see [Fo, p. 92]). Choose any such Lebesgue point $\bar{t}$ and call $\bar{x} = x(\bar{t})$. To prove (5.17) we consider two alternatives.

Case 1. $|z(\bar{t}) - \omega_i^*| \leq \varepsilon_1$. In this case (5.18) holds. Define the "one-sided" partial derivatives of V_i at $(\bar{t}, \bar{x})$:

$$(\bar{\phi}_i, \bar{\psi}_i) = \lim_{\substack{(t,x) \to (\bar{t}, \bar{x}) \\ (t - \bar{t}, x - \bar{x}) \in \Gamma}} (V_{i,t}(t,x), V_{i,x}(t,x)). \tag{5.22}$$

Notice that these directional limits exist because of (5.12)–(5.13) and the directional continuity of all functions p_j. Since (5.14) holds almost everywhere, we have

$$\bar{\phi}_i + \bar{\psi}_i \left(f_0 + \sum_{j \neq i} u_j^*(\bar{\psi}_j) \right) + \min_\omega \{ \bar{\psi}_i \omega + h_i(\omega) \} = 0. \tag{5.23}$$

By the assumptions, the function $t \mapsto V_i(t, x(t))$ is differentiable at $t = \bar{t}$. Its derivative can be computed by taking the one-sided limit in (4.19). Using Lemma 4.5 together with (5.23) we obtain

$$\begin{aligned}\frac{d}{dt} V_i(t, x(t))\bigg|_{t=\bar{t}} &= \bar{\phi}_i + \bar{\psi}_i \dot{x}(t) \\ &= -h_i(z(t)) + \{\bar{\psi}_i z(t) + h_i(z(t))\} - \min_{\omega}\{\bar{\psi}_i\, \omega + h_i(\omega)\} \\ &\geq -h_i(z(t)).\end{aligned}$$

Hence (5.17) holds.

Case 2. $|z(\bar{t}) - \omega_i^*| > \varepsilon_1$. In this case, by a nonsmooth version of the chain rule [C], there exist numbers

$$\begin{aligned}\phi_i &\in \overline{co}\{V_{i,t}(t,x);\ \ t \in [0,T],\ \ x \in \mathbb{R}\}, \\ \psi_i &\in \overline{co}\{V_{i,x}(t,x);\ \ t \in [0,T],\ \ x \in \mathbb{R}\}\end{aligned}$$

such that, at $t = \bar{t}$,

$$\frac{d}{dt} V_i(t, x(t))\bigg|_{t=\bar{t}} = \phi_i + \psi_i \dot{x}(\bar{t}). \tag{5.24}$$

The previous assumptions now imply

$$|\phi_i - q_j^*| \leq \varepsilon_2, \qquad |\psi_i - p_i^*| \leq \varepsilon_2.$$

Hence, by (5.21),

$$\frac{d}{dt} V_i(t, x(t))\bigg|_{t=\bar{t}} = \phi_i + \psi_i \left(f_0 + \sum_{j \neq i} u_j^*(p_j) \right) + \psi_i z(\bar{t}) > -h_i(z(\bar{t})), \tag{5.25}$$

showing that (5.17) holds also in this case. This completes the proof of Theorem 5.1. We remark that, if the other players adopt the feedback strategies $u_j = U_j^*(t,x)$, the choice $u_i = U_i^*(t,x)$ is the unique optimal strategy for the ith player. □

6. Concluding remarks. In this final section we point out some possible extensions of our previous results. Consider a differential game with the more general form

$$\dot{x} = f_0 + \sum_{i=1}^{n} f_i(\tilde{u}_i) \tag{6.1}$$

and cost functionals

$$J_i \doteq \int_{\tau}^{T} \tilde{h}_i(\tilde{u}_i(t))\, dt + g_i(x(T)). \tag{6.2}$$

Assume that each f_i is a homeomorphism from a (possibly unbounded) open interval $]a_i, b_i[$ into $\mathbb{R}$, with a smooth inverse $f_i^{-1} : \mathbb{R} \mapsto]a_i, b_i[$. Then the reparametrization of the control functions $u_i \doteq f_i(\tilde{u}_i)$ puts the system (6.1)–(6.2) in the standard form (2.1)–(2.2), with $h_i(\omega) \doteq \tilde{h}_i(f_i^{-1}(\omega))$. Of course, the key assumption (2.3) must now be carefully checked.

If the functions f_i in (6.1) and the running costs h_i in (6.2) also depend on x, then the corresponding system of conservation laws (1.9) will also depend on the space variable x. Assuming that the system is strictly hyperbolic, one can then use the results in [DH], and obtain the local existence of weak solutions, on a time interval $[0, T]$ suitably small. A similar analysis as in previous sections would now provide the existence of a Nash equilibrium solution in feedback form, but only locally in time.

Another possible extension of our results is to the case where the data $g_i'(\cdot)$ have large total variation. Using the local existence theorem of Schochet [Sc], one can still construct a weak solution to the system of conservation laws (2.10), at least on a short time interval $[0, T]$. For large BV solutions, however, checking that the feedbacks $U_i^*(t, x) \doteq u^*(p_i(t, x))$ at (2.5) yield a Nash equilibrium solution to the differential game will require a more accurate analysis. Furthermore, it is not clear whether, for large BV initial data, the solution to the system of conservation laws (5.2) can blow up in finite time. For general hyperbolic systems this can indeed happen [J]. The particular form of the flux functions H_i, however, may prevent such a blow up. To understand the matter, a more detailed analysis is again required.

The basic assumption in Theorem 5.1 was the hyperbolicity of the Hamiltonian system, in a neighborhood of the reference point p^*. When this condition is violated, searching for a Nash equilibrium in feedback form leads to an elliptic Cauchy problem. It is well known that this is ill posed [Lx]. Indeed, by elementary Fourier analysis one checks that even the constant solutions are linearly unstable. It thus appears that, in the elliptic regime, the model provided by noncooperative games must be revised. A concept of a "partially cooperative" solution should be considered, in order to recover the well posedness of the problem. This will be the content of a forthcoming paper [BS].

OPTIMALITY CONDITIONS FOR NONCONVEX MULTISTATE CONTROL PROBLEMS IN THE COEFFICIENTS*

JUAN CASADO-DÍAZ†, JULIO COUCE-CALVO†, AND JOSÉ D. MARTÍN-GÓMEZ†

Abstract. The purpose of this paper is to attain some optimality conditions for the identification of a diffusion matrix (material) under several restrictions. Assuming that the set of such diffusion matrices is closed for the H-convergence, we give a method to obtain admissible directions which applies to a not-necessarily convex control set. Our results permit obtaining the diffusion matrix from the state functions.

Key words. control in the coefficients, admissible directions, nonconvex control set

1. Introduction. The problem we consider in the present paper is related to the choice of an optimal material under several conditions, or the identification of a material from a finite number of observations. In a mathematical setting, we have the model problem

$$\min_{A\in M(\Omega)} J(y_1,\dots,y_k), \tag{1.1}$$

where $y_i = y_i(A)$, $1 \le i \le k$, are the solutions of the equations

$$\begin{cases} -\operatorname{div} A\nabla y_i = f_i & \text{in } \mathcal{D}'(\Omega), \\ y_i \in H_0^1(\Omega), & 1 \le i \le k. \end{cases} \tag{1.2}$$

Here Ω is a bounded open set of $\mathbf{R}^N$, J is a smooth objective functional in $H_0^1(\Omega)^k$, $f_1,\dots,f_k$ are k fixed elements of $H^{-1}(\Omega)$, and $M(\Omega)$ is a given set of measurable functions with values in the space of symmetric matrices of order N. The elements of $M(\Omega)$ are uniformly elliptic and bounded. Clearly, other generalizations can be considered: J depending on A, other boundary conditions, etc. A physical example is the identification of a material. For this purpose, we apply a finite number k of external conditions (in our case they are represented by f_i) and in each case we realize a measure of the corresponding state. For example, we give the value z_i of the state in a subset $\omega \subset \Omega$. Then the problem can be formulated as

$$\min \sum_{i=1}^{k} \int_{\omega} |y_i - z_i|^2 \, dx,$$

where y_i are the solutions of (1.2).

Assuming J is sequential lower semicontinuous for the weak topology of $H_0^1(\Omega)^k$ and $M(\Omega)$ is closed for the H-convergence or the G-convergence, because we are

†Depto. de Ecuaciones Diferenciales y Análisis Numérico, Fac. de Matemáticas, Universidad de Sevilla, C. Tarfia s/n, 41012 Sevilla, Spain (jcasadod@us.es, jcouce@us.es, jdmartin@us.es).

working with symmetric matrices and thus the two concepts are equivalent (see, e.g., [22], [19], [18], [4], [25]), it is well known that (1.1) has, at least, a solution (see, e.g., [25], [17]). If $M(\Omega)$ does not satisfy this last condition and J is sequential continuous for the weak topology of $H_0^1(\Omega)^k$, we can obtain a relaxed problem replacing $M(\Omega)$ by its H-closure. Thus, it is natural to assume $M(\Omega)$ is H-closed. The calculus of the H-closure of a set is a very difficult problem and there are a lot of works in this field (see, e.g., [23], [14], [13], [8], [25], [3], [16] and the references in them). In this paper we are interested in obtaining some necessary conditions which must satisfy the optimal solution of (1.1). For $k = 1$, the problem has been studied in [13], [20], [8], [25], [3]. For $k > 1$, there are few results to our knowledge (see [25], [6], [7], [3]).

The paper is organized as follows:

In section 3 we give a definition of admissible direction (see Definition 3.1). Then we prove that if A is a solution of (1.1), $y_1, \dots, y_k$ the corresponding state functions, $p_1, \dots, p_k$ the solutions of (3.2) (the adjoint states), and C the matrix defined by (3.3), we have

$$\int_\Omega H : C \, dx \leq 0 \tag{1.3}$$

for every admissible direction H. Related results can be found, for example, in [8], [13], [25], [3]. However, in these papers, the admissible directions are of the form $H = B - A$, with B in $M(\Omega)$, which needs some convexity assumptions. When $k \leq N - 1$ (in particular $k = 1$) and $M(\Omega)$ is obtained by homogenization, mixing a finite number of matrices with fixed proportions, a result of Tartar (see [25]) shows that although $M(\Omega)$ is not convex, for every $\xi_1, \dots, \xi_k \in \mathbf{R}^N$, the set

$$\{(B\xi_1, \dots, B\xi_k) \,/\, B \in M(\Omega)\} \subset L^\infty(\Omega)^k \tag{1.4}$$

is convex, and thus the directions $H = B - A$ can still be considered. However, this is not true for $k \geq N$ (or, in principle, for other choices of $M(\Omega)$ even if $k \leq N - 1$). This is the reason we have given a more general definition of admissible direction.

In section 4, assuming $M(\Omega)$ local (see Definition 4.1) and closed for the H-convergence, we give an original method to find admissible directions following our definition. As a consequence, we obtain the main result of the paper, Theorem 4.5, where we prove that for every $A, B \in M(\Omega)$, $l \in \{1, \dots, N\}$, $W \subset \mathbf{R}^N$ linear subspace of dimension l, and every bounded measurable set T of W, with l-dimensional positive measure, the matrix H defined by

$$H(x)e_i = (B(x) - A(x)) \left(e_i + \frac{1}{|T|_\ell} \int_T \nabla_z^W \hat{w}_i(x, z) \, d_\ell(z) \right) \tag{1.5}$$

is an admissible direction in A. Here $e_1, \dots, e_N$ is the standard basis of $\mathbf{R}^N$, ∇_z^W denotes the gradient with respect to W, and $\hat{w}_i$ is the solution of the partial differential problem given by (4.4). This direction has the difficulty that $\hat{w}_i$ (and then H) cannot be explicitly obtained. However, we think that it can be interesting, for example, to apply a descent method in order to solve numerically problem (1.1), where we can obtain $\hat{w}_i$ numerically. Related to this point, an interesting question, one that we want to study in the future, is the optimal choice of W and T to obtain the steepest descent direction. A criterion to determine this direction (see Remark 4.9) can be to calculate the maximum of $H : C$ on the set of matrices H obtained by (1.5).

Although, as we have said above, it is not possible in general to obtain $\hat{w}_i$ explicitly, we show in Theorem 4.12 that this can be carried out for a particular choice of

T (which probably is not optimal). This permits us to obtain a family of admissible direction, depending on the subspace W chosen. Essentially, they are of the form $B - A$ plus a term which has a growth of order two in $B - A$ for every $B \in M(\Omega)$. When the dimension of W is equal to 1, the corresponding admissible direction comes just from a lamination. In this case the expression of H is known and it can be found, for example, in [25] (it can also be obtained from the results in [10]), but to our knowledge its utility to obtain optimality conditions for problem (1.1) has not been exploited. Most of the consequences we obtain in the present paper using Theorem 4.12 use only, in fact, $l = 1$. However, we show that in some cases (see Remark 4.17) it is better to use a subspace of dimension greater than one. Using Theorem 4.12 we prove in Corollary 4.18 that for every $B \in M(\Omega)$, the condition

$$C : (A - B) \geq 0 \tag{1.6}$$

(which is the condition we find if the admissible directions are of the form $B-A$) is still true on the set where C has a nonpositive eigenvalue or where $\mathrm{Ker}(A - B) \neq \{0\}$. In particular (see Corollary 4.20) the condition (1.6) holds a.e. in Ω for every $B \in M(\Omega)$ when $k \leq N-1$. When $M(\Omega)$ comes from the mixture of a finite number of materials with fixed proportions, this result can also be obtained from the convexity of the set defined by (1.4), but we note that our set $M(\Omega)$ is more general.

In section 5 we study the case where $M(\Omega)$ is invariable by rotations, which is a natural assumption in the applications. Then we show that condition (1.3) implies that C and A are mutually diagonalizable a.e. in Ω. Moreover, assuming further hypotheses (in particular if $M(\Omega)$ is H-closed and $N \geq 3$), we prove in Proposition 5.4 that the eigenvalues of A and C are mutually ordered.

As application of the results stated above, it is possible to obtain, in some situations, the matrix A from C and then to reduce the set of optimality conditions to a nonlinear partial differential system with variables y_i, p_i, $1 \leq i \leq k$. The main problem to carrying out this point is that in general, the H-closure of a given set is unknown. In section 6, we apply our results to two examples: The first one is the mixture of two homogeneous isotropic materials, which has also been studied in [3] (see also [25] for $k = 1$). In this case $M(\Omega)$ is convex. In second problem we consider a polycrystal in dimension 2, where $M(\Omega)$ is not convex.

2. Notation. For a linear subspace $W \subset \mathbf{R}^N$, we define $\mathcal{L}(W, W)$ as the space of the linear applications from W into W and by $\mathcal{L}^s(W, W)$ the subspace of the symmetric applications. When $W = \mathbf{R}^N$ we write $\mathcal{M}_N = \mathcal{L}(\mathbf{R}^N, \mathbf{R}^N)$, $\mathcal{M}_N^s = \mathcal{L}^s(\mathbf{R}^N, \mathbf{R}^N)$.

The orthogonal projection of $\mathbf{R}^N$ into W is denoted by P^W.

For a matrix $A \in \mathcal{M}_N$, we define $A_W \in \mathcal{L}(W, W)$ by $A_W = P^W A_{|_W}$.

The orthogonal subspace of W is denoted by $W^\perp$.

For $u : W \to \mathbf{R}$, we denote $\nabla^W u : W \to W$ the gradient of u with respect to W, i.e., $\nabla^W u$ is defined by

$$\nabla^W u \, \xi = D_\xi u \quad \forall \xi \in W,$$

where $D_\xi u$ is the derivative of u in the direction ξ.

We denote by $\{e_1, \ldots, e_N\}$ the standard basis of $\mathbf{R}^N$.

The group of the orthogonal matrices in $\mathbf{R}^N$ of determinant 1 is denoted by $\mathcal{O}_N$.

The scalar product of two matrices $A, B \in \mathcal{M}_N$ is written $A : B$.

The tensorial product of two vectors $\xi, \eta \in \mathbf{R}^N$ is denoted as $\xi \otimes \eta$.

For a bounded open set $\Omega \subset \mathbf{R}^N$, we denote by $M(\Omega)$ a fixed subset of the space $L^\infty(\Omega, \mathcal{M}_N^s)$ such that there exist $\alpha, \beta > 0$ which satisfy

$$B(x)\xi\xi \geq \alpha|\xi|^2, \quad |B(x)\xi| \leq \beta|\xi| \quad \forall\, B \in M(\Omega) \text{ a.e. } x \in \Omega. \tag{2.1}$$

For a matrix $A \in M(\Omega)$, $K_A(M(\Omega))$ and $\bar{K}_A(M(\Omega))$ are the cones of admissible directions of $M(\Omega)$ in A; see Definition 3.1.

For $T \subset \mathbf{R}^N$ and $\ell \in (0, N]$, we denote by $|T|_\ell$ the ℓ-dimensional Hausdorff measure of T. The integral of a function $u : T \to \mathbf{R}$, with respect to the ℓ-dimensional Hausdorff measure, is written

$$\int_T u(z)\, d_\ell z.$$

When $\ell = N$, we simplify the notation by writing $|T|$ and

$$\int_T u(z)\, dz.$$

We use the subindex $\sharp$ to mean periodicity. For example, for a cube $Y \subset \mathbf{R}^N$, $H^1_\sharp(Y)$ is the space of functions of $H^1_{loc}(\mathbf{R}^N)$ which are Y-periodic.

3. Optimality conditions. In this section we introduce the definition of admissible direction. Using it, we obtain the first optimality result for the control problem (1.1).

DEFINITION 3.1. *For $A \in M(\Omega)$, let us define the cone of admissible directions $\bar{K}_A(M(\Omega))$ as the closure in the weak-$*$ topology of $L^\infty(\Omega, \mathcal{M}_N^s)$ of the set $K_A(M(\Omega))$, where $K_A(M(\Omega))$ is the set of $H \in L^\infty(\Omega, \mathcal{M}_N^s)$ such that there exist a constant $c > 0$ and $A_\varepsilon \in M(\Omega)$, $\varepsilon > 0$, such that*

$$\begin{cases} \|A_\varepsilon - A\|_{L^\infty(\Omega, \mathcal{M}_N^s)} \leq c\varepsilon, \\ \lim\limits_{\varepsilon \to 0} \dfrac{A_\varepsilon - A}{\varepsilon} = H \quad \text{a.e. in } \Omega. \end{cases} \tag{3.1}$$

THEOREM 3.2. *We consider $J : H_0^1(\Omega)^k \to \mathbf{R}$, Fréchet derivable, $f_1, \dots, f_k \in H^{-1}(\Omega)^k$. Let $A \in M(\Omega)$ be a solution of (1.1) and $y_1, \dots, y_k$ the solutions of (1.2). We define the adjoint states $p_1, \dots, p_k$ as the solutions of*

$$\begin{cases} -\operatorname{div}(A\nabla p_i) = \partial_i J(y_1, \dots, y_k) & \text{in } \mathcal{D}'(\Omega), \\ p_i \in H_0^1(\Omega), & 1 \leq i \leq k, \end{cases} \tag{3.2}$$

and the matrix $C \in L^1(\Omega, \mathcal{M}_N^s)$ by

$$C = \frac{1}{2} \sum_{i=1}^{k} (\nabla y_i \otimes \nabla p_i + \nabla p_i \otimes \nabla y_i). \tag{3.3}$$

Then we have

$$\int_\Omega H : C\, dx \leq 0 \quad \forall\, H \in \bar{K}_A(M(\Omega)). \tag{3.4}$$

Proof. Let us first prove the result for $H \in K_A(M(\Omega))$. For $\varepsilon > 0$ small enough, we define $y^*_{i,\varepsilon}$, $1 \le i \le k$, as the solution of

$$\begin{cases} -\operatorname{div}((A+\varepsilon H)\nabla y^*_{i,\varepsilon}) = f_i & \text{in } \mathcal{D}'(\Omega), \\ y^*_{i,\varepsilon} \in H^1_0(\Omega). \end{cases} \tag{3.5}$$

Then it is easy to check that for $1 \le i \le k$, we have

$$\lim_{\varepsilon\to 0} \frac{y^*_{i,\varepsilon} - y_i}{\varepsilon} = \dot{y}_i \quad \text{in } H^1_0(\Omega), \tag{3.6}$$

with $\dot{y}_i$ the solutions of

$$\begin{cases} -\operatorname{div}(A\nabla \dot{y}_i + H\nabla y_i) = 0 & \text{in } \mathcal{D}'(\Omega), \\ \dot{y}_i \in H^1_0(\Omega). \end{cases} \tag{3.7}$$

Now, for $\varepsilon > 0$, we consider $A_\varepsilon \in M(\Omega)$ in the conditions of (3.1). Then for $1 \le i \le k$, we define $y_{i,\varepsilon}$ as the solutions of

$$\begin{cases} -\operatorname{div}(A_\varepsilon \nabla y_{i,\varepsilon}) = f_i & \text{in } \mathcal{D}'(\Omega), \\ y_{i,\varepsilon} \in H^1_0(\Omega). \end{cases} \tag{3.8}$$

Taking $y^*_{i,\varepsilon} - y_{i,\varepsilon}$ as test function in the difference of (3.5) and (3.8), and dividing by ε, we get

$$\begin{aligned} &\frac{1}{\varepsilon}\int_\Omega (A+\varepsilon H)\nabla(y^*_{i,\varepsilon} - y_{i,\varepsilon})\nabla(y^*_{i,\varepsilon} - y_{i,\varepsilon})\,dx \\ &\quad = \int_\Omega \frac{A_\varepsilon - (A+\varepsilon H)}{\varepsilon}\nabla(y_{i,\varepsilon} - y^*_{i,\varepsilon})\nabla(y^*_{i,\varepsilon} - y_{i,\varepsilon})\,dx \\ &\qquad + \int_\Omega \frac{A_\varepsilon - (A+\varepsilon H)}{\varepsilon}\nabla y^*_{i,\varepsilon}\nabla(y^*_{i,\varepsilon} - y_{i,\varepsilon})\,dx. \end{aligned} \tag{3.9}$$

By the ellipticity of $A+\varepsilon H$ (for ε small enough) and (3.1), we deduce from (3.9) the existence of $c > 0$ such that

$$\frac{1}{\varepsilon}\|y^*_{i,\varepsilon} - y_{i,\varepsilon}\|^2_{H^1_0(\Omega)} \le c\|y^*_{i,\varepsilon} - y_{i,\varepsilon}\|_{H^1_0(\Omega)}\|\mu_\varepsilon\|_{L^2(\Omega)},$$

with

$$\mu_\varepsilon = \frac{A_\varepsilon - (A+\varepsilon H)}{\varepsilon}\nabla y^*_{i,\varepsilon}.$$

From (3.1), (3.6), and the Lebesgue-dominated convergence theorem, we deduce that μ_ε converges strongly to zero in $L^2(\Omega)^N$. Thus,

$$\lim_{\varepsilon\to 0} \frac{y^*_{i,\varepsilon} - y_{i,\varepsilon}}{\varepsilon} = 0 \quad \text{in } H^1_0(\Omega),$$

which, by (3.6), implies

$$\lim_{\varepsilon\to 0} \frac{y_{i,\varepsilon} - y_i}{\varepsilon} = \dot{y}_i \quad \text{in } H^1_0(\Omega). \tag{3.10}$$

On the other hand, since A is a solution of (1.1) and $A_\varepsilon \in M(\Omega)$, we have

$$\frac{J(y_\varepsilon) - J(y)}{\varepsilon} \geq 0 \quad \forall\, \varepsilon > 0,$$

with $y_\varepsilon = (y_{1,\varepsilon}, \dots, y_{k,\varepsilon})$ and $y = (y_1, \dots, y_k)$. From (3.10) and the Fréchet derivability of J, we get

$$\sum_{i=1}^{k} \langle \partial_i J(y), \dot{y}_i \rangle = \lim_{\varepsilon \to 0} \frac{J(y_\varepsilon) - J(y)}{\varepsilon} \geq 0. \tag{3.11}$$

But taking $\dot{y}_i$ as the test function in (3.2) and p_i as the test function in (3.7), we have

$$\sum_{i=1}^{k} \langle \partial_i J(y), \dot{y}_i \rangle = \sum_{i=1}^{k} \int_\Omega A \nabla p_i \nabla \dot{y}_i \, dx = -\sum_{i=1}^{k} \int_\Omega H \nabla y_i \nabla p_i \, dx.$$

This proves

$$\int_\Omega H : C \, dx = \sum_{i=1}^{k} \int_\Omega H \nabla y_i \nabla p_i \, dx \leq 0 \quad \forall\, H \in K_A(M(\Omega)). \tag{3.12}$$

Now let H be in $\bar{K}_A(M(\Omega))$. For $\delta > 0$ we define

$$G_\delta = \left\{ M \in L^\infty(\Omega, \mathcal{M}_N^s) / \ \left| \int_\Omega C : (M - H) \, dx \right| < \delta \right\}.$$

Since G_δ is a neighborhood of H in the weak-$*$ topology of $L^\infty(\Omega, \mathcal{M}_N^s)$, there exists H_δ in $G_\delta \cap K_A(M(\Omega))$ and then, from (3.12), we get

$$\int_\Omega C : H \, dx = \int_\Omega C : H_\delta \, dx + \int_\Omega C : (H - H_\delta) \, dx < \delta$$

for every $\delta > 0$. This proves (3.4). □

Remark 3.3. The above theorem is still true if the elements of $M(\Omega)$ are not necessarily symmetric by changing A to A^t in the definition (3.2) of the functions p_i and taking

$$C = \sum_{i=1}^{k} \nabla p_i \otimes \nabla y_i.$$

Remark 3.4. If $M(\Omega)$ is convex, the condition (3.4) implies

$$\int_\Omega A : C \, dx = \max \left\{ \int_\Omega B : C \, dx \, / \ B \in M(\Omega) \right\}. \tag{3.13}$$

Remark 3.5. Theorem 3.2 still holds if we take $K_A(M(\Omega))$ as the cone of matrices $H \in L^\infty(\Omega, \mathcal{M}_N^s(\Omega))$ such that for every sequence $\Phi_\varepsilon^1, \dots, \Phi_\varepsilon^k$, which respectively converges in $L^2(\Omega)^N$ to $\Phi^1, \dots, \Phi^k$, there exists $A_\varepsilon \in M(\Omega)$ such that

$$\frac{A_\varepsilon - A}{\varepsilon} \Phi_\varepsilon^i \to H \Phi^i \qquad \text{in } L^2(\Omega)^N, \qquad i = 1, \dots, k.$$

The advantage of this definition is the following: If $M(\Omega)$ is the set we obtain by mixing r materials with proportions fixed, then for every $\xi_1, \dots, \xi_{N-1} \in \mathbf{R}^N$, the set

$$\{(B\xi_1, \dots, B\xi_{N-1})/B \in M(\Omega)\} \subset L^\infty(\Omega)^{N-1}$$

is convex (see [24], [25]). So, with this definition of $K_A(M(\Omega))$, the matrices of the form $B - A$ belong to $K_A(M(\Omega))$ if $k \leq N-1$. Thus, (3.13) still holds in this case. Later we will deduce this result (see Corollary 4.20) for more general choices of $M(\Omega)$, using simply Definition 3.1 of admissible directions.

4. Calculus of admissible directions. In the following, let us calculate explicitely some admissible directions by imposing additional hypotheses about $M(\Omega)$.

DEFINITION 4.1. *We say that $M(\Omega)$ is local if there exists a multivaluated application $F : x \in \Omega \to F(x) \subset \mathcal{M}_N^s$ such that*

$$M(\Omega) = \{B \in L^\infty(\Omega, \mathcal{M}_N^s)/B(x) \in F(x) \text{ a.e. } x \in \Omega\},$$

where F is measurable in the sense that

$$\{x \in \Omega/F(x) \cap G \neq \emptyset\} \text{ is measurable} \quad \forall\, G \subset \mathcal{M}_N^s \text{ open.}$$

As it is proved in [21], the local property is satisfied in several typical examples of $M(\Omega)$. A first consequence of assuming $M(\Omega)$ is local follows.

PROPOSITION 4.2. *We assume $M(\Omega)$ is local. We consider $A \in M(\Omega)$, $H_1, \dots, H_m \in K_A(M(\Omega))$, $\omega_1, \dots, \omega_m \subset \Omega$ measurable such that $|\omega_i \cap \omega_j| = 0$ if $i \neq j$. Then the matrix $H = \sum_{i=1}^m H_i\, \chi_{\omega_i}$ belongs to $K_A(M(\Omega))$.*

Proof. By Definition 3.1, for every $i \in \{1, \dots, m\}$ there exists $A_\varepsilon^i \in M(\Omega)$ and $c > 0$ (which can be taken independent of i) such that

$$\|A_\varepsilon^i - A\|_{L^\infty(\Omega, \mathcal{M}_N^s)} \leq c\varepsilon, \qquad \lim_{\varepsilon \to 0} \frac{A_\varepsilon^i - A}{\varepsilon} = H_i \quad \text{a.e. in } \Omega.$$

Taking then

$$A_\varepsilon = \sum_{i=1}^m A_\varepsilon^i\, \chi_{\omega_i} + A\, \chi_{\Omega \setminus \cup_{i=1}^m \omega_i},$$

which belongs to $M(\Omega)$ because $M(\Omega)$ is local, we have

$$\|A_\varepsilon - A\|_{L^\infty(\Omega, \mathcal{M}_N^s)} \leq c\varepsilon, \qquad \lim_{\varepsilon \to 0} \frac{A_\varepsilon - A}{\varepsilon} = H \quad \text{a.e. in } \Omega,$$

and then H belongs to $K_A(M(\Omega))$. □

Remark 4.3. It is not difficult to show that the above result remains true if we replace $K_A(M(\Omega))$ by $\bar{K}_A(M(\Omega))$.

Using Proposition 4.2, we get the following.

PROPOSITION 4.4. *In the assumptions of Theorem 3.2, if $M(\Omega)$ is local, we have*

$$H : C \leq 0 \quad \text{a.e. in } \Omega\ \forall\, H \in \bar{K}_A(M(\Omega)). \tag{4.1}$$

Proof. By Proposition 4.2, for every $H \in K_A(M(\Omega))$ and every $\omega \subset \Omega$ measurable, the matrix $H\, \chi_\omega$ belongs to $K_A(M(\Omega))$. So, using (3.4), we get

$$\int_\omega H : C\, dx \leq 0. \tag{4.2}$$

Since $\bar{K}_A(M(\Omega))$ is the closure of $K_A(M(\Omega))$ in the weak-$*$ topology of $L^\infty(\Omega, \mathcal{M}_N^s)$, we deduce that (4.2) holds, in fact, for every $H \in \bar{K}_A(M(\Omega))$ and every $\omega \subset \Omega$ measurable, which implies (4.1). □

Let us now see how assuming $M(\Omega)$ is local permits us to obtain admissible directions.

THEOREM 4.5. *We suppose that $M(\Omega)$ is local and closed for the H-convergence. We consider a linear subspace $W \subset \mathbf{R}^N$ of dimension ℓ and a measurable bounded subset $T \subset W$ such that $|T|_\ell$ is positive. Then, for every $A, B \in M(\Omega)$, the matrix $H \in L^\infty(\Omega, \mathcal{M}_N^s)$ defined by*

$$H(x)e_i = (B(x) - A(x)) \left(e_i + \frac{1}{|T|_\ell} \int_T \nabla_z^W \hat{w}_i(x,z)\, d_\ell(z) \right) \tag{4.3}$$

for $1 \le i \le N$ and a.e. $x \in \Omega$ belongs to $K_A(M(\Omega))$. In (4.3), the function $\hat{w}_i$ is defined by

$$\begin{cases} \hat{w}_i(x,.) \in H^1_{loc}(W), \quad \nabla_z^W \hat{w}_i(x,.) \in L^2(W,W), \\ \displaystyle\int_W (A(x)\ \chi_{W\setminus T} + B(x)\ \chi_T) \nabla_z^W \hat{w}_i(x,.) \nabla_z^W \hat{v}\, d_\ell(z) \\ \qquad \displaystyle = \int_T (A(x) - B(x)) e_i \nabla_z^W \hat{v}\, d_\ell(z), \\ \forall\, \hat{v} \in H^1_{loc}(W), \quad \nabla_z^W \hat{v} \in L^2(W,W) \quad \text{a.e. } x \in \Omega. \end{cases} \tag{4.4}$$

Proof. We consider A, B, W, and T as in the statement of the theorem. For an orthonormal basis $\{e'_1, \dots, e'_\ell\}$ of W, we denote

$$Y = \left\{ \sum_{i=1}^{\ell} \lambda_i e'_i \,/\, -\frac{1}{2} < \lambda_i < \frac{1}{2},\ 1 \le i \le \ell \right\} \subset W.$$

For $\varepsilon > 0$ small enough, we denote $T_\varepsilon = \varepsilon^{\frac{1}{\ell}} T \subset Y$, $\tilde{T}_\varepsilon = \bigcup_{k \in \mathbf{Z}^\ell} (T_\varepsilon + \sum_{i=1}^{\ell} k_i e'_i)$, and we define $\tilde{A}_\varepsilon : \Omega \times W \to \mathcal{M}_N^s$ by

$$\tilde{A}_\varepsilon(x,y) = A(x)(1 - \chi_{\tilde{T}_\varepsilon}(y)) + B(x)\ \chi_{\tilde{T}_\varepsilon}(y).$$

Since $M(\Omega)$ is local and closed for the H-convergence, the matrix A_ε obtained by taking, for ε fixed, the H-limit when δ tends to zero of the matrices $x \to \tilde{A}_\varepsilon(x, \frac{1}{\delta} P^W(x))$ belongs to $M(\Omega)$. Since the matrices $\tilde{A}_\varepsilon$ are a tensorial product of functions which only depend on x and functions which only depend on y, it is well known (see, e.g., [5], [2]) that A_ε is given by

$$A_\varepsilon(x) e_i = \int_Y \tilde{A}_\varepsilon(x,y)(\nabla_y^W w_{i,\varepsilon} + e_i)\, d_\ell(y), \tag{4.5}$$

where $w_{i,\varepsilon}$ is the unique solution of

$$\begin{cases} w_{i,\varepsilon} \in L^2(\Omega, H^1_\sharp(Y)/\mathbf{R}), \\ \displaystyle\int_Y \tilde{A}_\varepsilon(x,y)(\nabla_y^W w_{i,\varepsilon}(x,y) + e_i) \nabla_y^W v(y)\, d_\ell(y) = 0 \\ \forall\, v \in H^1_\sharp(Y)/\mathbf{R} \quad \text{a.e. } x \in \Omega. \end{cases} \tag{4.6}$$

Let us study the asymptotic behavior of A_ε. First, we remark that for every $v \in H^1_\sharp(Y)/\mathbf{R}$ and a.e. $x \in \Omega$, we have

$$\int_Y \tilde{A}_\varepsilon(x,y)e_i\nabla_y^W v(y)\,d_\ell(y) = \int_Y A(x)e_i\nabla_y^W v(y)\,d_\ell(y) + \int_{T_\varepsilon}(B(x)-A(x))e_i\nabla_y^W v(y)\,d_\ell(y),$$

but for a.e. $x \in \Omega$, the first term on the right-hand side vanishes. So, $w_{i,\varepsilon}$ satisfies

$$\text{(4.7)} \qquad \begin{cases} \displaystyle\int_Y \tilde{A}_\varepsilon(x,y)\nabla_y^W w_{i,\varepsilon}(x,y)\nabla_y^W v(y)\,d_\ell(y) \\ \qquad \displaystyle = \int_{T_\varepsilon}(A(x)-B(x))e_i\nabla_y^W v(y)\,d_\ell(y) \\ \forall\, v \in H^1_\sharp(Y)/\mathbf{R} \quad \text{a.e. } x \in \Omega. \end{cases}$$

For $1 \le i \le N$, we take $w_{i,\varepsilon}$ as the test function in (4.7). Then we get

$$\int_Y \tilde{A}_\varepsilon(x,y)\nabla_y^W w_{i,\varepsilon}(x,y)\nabla_y^W w_{i,\varepsilon}(x,y)\,d_\ell(y) = \int_{T_\varepsilon}(A(x)-B(x))e_i\nabla_y^W w_{i,\varepsilon}(x,y)\,d_\ell(y)$$

for a.e. $x \in \Omega$. Using then (2.1) and the Cauchy–Schwarz inequality, we deduce there exists $c > 0$ such that

$$\text{(4.8)} \qquad \int_Y |\nabla_y^W w_{i,\varepsilon}(x,y)|^2\,d_\ell(y) \le c|T_\varepsilon|_\ell = c\varepsilon$$

for $\varepsilon > 0$ small enough and a.e. $x \in \Omega$.

We define $\hat{w}_{i,\varepsilon} : \Omega \times (\varepsilon^{-\frac{1}{\ell}}Y) \to \mathbf{R}$ by

$$\hat{w}_{i,\varepsilon}(x,z) = \varepsilon^{-\frac{1}{\ell}} w_{i,\varepsilon}(x, \varepsilon^{\frac{1}{\ell}} z).$$

From (4.8), we deduce that $\nabla_z^W \hat{w}_{i,\varepsilon}\ \chi_{\varepsilon^{-\frac{1}{\ell}}Y}$ is bounded in $L^\infty(\Omega, L^2(W,W))$. So there exists a subsequence of ε, which we still denote by ε, which converges weak-$*$ in $L^\infty(\Omega, L^2(W,W))$. Since the curl of the limit is zero, it is the gradient of a function $\hat{w}_i \in L^\infty(\Omega, H^1_{loc}(W))$. Once we prove that $\hat{w}_i$ is the solution of (4.4), we conclude that the whole of the sequence converges.

We consider $\hat{v} \in \mathcal{D}(W)$ and $\varepsilon > 0$ small enough, such that $\varepsilon^{\frac{1}{\ell}}\,\mathrm{supp}(\hat{v}) \subset Y$, then we define $v_\varepsilon \in H^1_\sharp(Y)$ by

$$v_\varepsilon(y) = \varepsilon^{\frac{1}{\ell}}\hat{v}(\varepsilon^{-\frac{1}{\ell}}y) \quad \text{a.e. } y \in Y.$$

Taking v_ε as the test function in (4.7), using the change of variables $z = \varepsilon^{-\frac{1}{\ell}}y$, and integrating with respect to x in a measurable set ω, we get

$$\int_\omega \int_{\varepsilon^{-\frac{1}{\ell}}Y} (A(x)\ \chi_{W\setminus T}(z) + B(x)\ \chi_T(z))\nabla_z^W \hat{w}_{i,\varepsilon}(x,z)\nabla_z^W \hat{v}(z)\,d_\ell(z)\,dx = \int_\omega \int_T (A(x)-B(x))e_i\nabla_z^W \hat{v}(z)\,d_\ell(z)\,dx.$$

Passing to the limit in this equality and taking into account the arbitrariness of $\hat{v}$ and ω, and the density of $\mathcal{D}(\mathbf{R}^N)/\mathbf{R}$ in the factor space of functions with gradient in $L^2(\mathbf{R}^N)$ over $\mathbf{R}$ (see, e.g., [9]), we show that $\hat{w}_i$ is the solution of (4.4) for $1 \le i \le N$.

Let us now prove

$$\nabla_z^W \hat{w}_{i,\varepsilon}\ \chi_{\varepsilon^{-\frac{1}{\ell}}Y} \to \nabla_z^W \hat{w}_i \quad \text{in } L^2(\Omega, L^2(W,W)) \tag{4.9}$$

for $1 \le i \le N$. For this purpose, it is enough to take $w_{i,\varepsilon}$ as the test function in (4.7), to use the change of variables $z = \varepsilon^{-\frac{1}{\ell}} y$, to take $\hat{w}_i$ as the test function in (4.4), and to use that $\nabla_z^W \hat{w}_{i,\varepsilon}\ \chi_{\varepsilon^{-\frac{1}{\ell}}Y}$ converges to $\nabla_z^W \hat{w}_i$, weak-$*$ in $L^\infty(\Omega, L^2(W,W))$. This gives

$$\begin{aligned}
&\int_\Omega \int_{\varepsilon^{-\frac{1}{\ell}}Y} (A\ \chi_{W\setminus T} + B\ \chi_T)\nabla_z^W \hat{w}_{i,\varepsilon} \nabla_z^W \hat{w}_{i,\varepsilon}\, d_\ell(z)\, dx \\
&\quad = \tfrac{1}{\varepsilon} \int_\Omega \int_Y \tilde{A}_\varepsilon \nabla_y^W w_{i,\varepsilon} \nabla_y^W w_{i,\varepsilon}\, d_\ell(y)\, dx = \frac{1}{\varepsilon} \int_\Omega \int_{T_\varepsilon} (A-B) e_i \nabla_y^W w_{i,\varepsilon}\, d_\ell(y)\, dx \\
&\quad = \int_\Omega \int_T (A-B) e_i \nabla_z^W \hat{w}_{i,\varepsilon}\, d_\ell(z)\, dx \to \int_\Omega \int_T (A-B) e_i \nabla_z^W \hat{w}_i\, d_\ell(z)\, dx \\
&\quad = \int_\Omega \int_W (A\ \chi_{W\setminus T} + B\ \chi_T)\nabla_z^W \hat{w}_i \nabla_z^W \hat{w}_i\, d_\ell(z)\, dx.
\end{aligned}$$

This implies (4.9).

Now, for $i, j \in \{1, \dots, N\}$ and a.e. $x \in \Omega$, we write

$$\begin{aligned}
A_\varepsilon(x) e_i e_j &= \int_Y \tilde{A}_\varepsilon(x,y)[\nabla_y^W w_{i,\varepsilon} + e_i] e_j\, d_\ell(y) \\
&= \int_Y \tilde{A}_\varepsilon(x,y) \nabla_y^W w_{i,\varepsilon} e_j\, d_\ell(y) + A(x) e_i e_j + \varepsilon |T|_l (B(x) - A(x)) e_i e_j.
\end{aligned} \tag{4.10}$$

Taking $w_{i,\varepsilon}$ as the test function in the problem satisfied by $w_{j,\varepsilon}$ and using the change of variables $z = \varepsilon^{-\frac{1}{\ell}} y$, we have

$$\begin{aligned}
&\int_Y \tilde{A}_\varepsilon(x,y) \nabla_y^W w_{i,\varepsilon} e_j\, d_\ell(y) = -\int_Y \tilde{A}_\varepsilon(x,y) \nabla_y^W w_{j,\varepsilon} \nabla_y^W w_{i,\varepsilon}\, d_\ell(y) \\
&\quad = -\varepsilon \int_{\varepsilon^{-\frac{1}{\ell}}Y} (A(x)\ \chi_{W\setminus T}(z) + B(x)\ \chi_T(z)) \nabla_z^W \hat{w}_{j,\varepsilon} \nabla_z^W \hat{w}_{i,\varepsilon}\, d_\ell(z).
\end{aligned}$$

So, from (4.10), we get

$$\begin{aligned}
\left(\frac{A_\varepsilon - A}{\varepsilon}\right) e_i e_j &= |T|_\ell (B(x) - A(x)) e_i e_j \\
&\quad - \int_{\varepsilon^{-\frac{1}{\ell}}Y} (A(x)\ \chi_{W\setminus T}(z) + B(x)\ \chi_T(z)) \nabla_z^W \hat{w}_{j,\varepsilon} \nabla_z^W \hat{w}_{i,\varepsilon}\, d_\ell(z).
\end{aligned}$$

Since $\nabla_z^W \hat{w}_{j,\varepsilon}$, $\nabla_z^W \hat{w}_{i,\varepsilon}$ are bounded in $L^\infty(\Omega, L^2(W,W))$, we deduce that $\frac{A_\varepsilon - A}{\varepsilon}$ is bounded in $L^\infty(\Omega, \mathcal{M}_N^s)$. On the other hand, using (4.9), we have

$$\begin{aligned}
&\lim_{\varepsilon \to 0} \int_{\varepsilon^{-\frac{1}{\ell}}Y} (A(x)\ \chi_{W\setminus T}(z) + B(x)\ \chi_T(z)) \nabla_z^W \hat{w}_{j,\varepsilon} \nabla_z^W \hat{w}_{i,\varepsilon}\, d_\ell(z) \\
&\quad = \int_W (A(x)\ \chi_{W\setminus T}(z) + B(x)\ \chi_T(z)) \nabla_z^W \hat{w}_j \nabla_z^W \hat{w}_i\, d_\ell(z) \\
&\quad = -\int_T (B(x) - A(x)) \nabla_z^W \hat{w}_i e_j\, d_\ell(z),
\end{aligned}$$

where we have used the problem satisfied by $\hat{w}_j$ and where the limit is taken in $L^1(\Omega)$. So we have proved that the matrix

$$e_i \to |T|_\ell (B(x) - A(x)) \left(e_i + \frac{1}{|T|_\ell} \int_T \nabla_z^W \hat{w}_i(x,z)\, d_\ell(z) \right)$$

is in $K_A(M(\Omega))$. Since $K_A(M(\Omega))$ is a cone, we conclude the proof of the theorem. □

Remark 4.6. Theorem 4.5 applies, for example, to the case where $M(\Omega)$ is the set of materials which can be obtained by homogenization, mixing m materials with the prescribed volume. These sets usually appear in problems of optimal design. Some applications are given in the last section of the paper; see also, e.g., [3], [8], [13], [25], and references therein.

Remark 4.7. The method used in the proof of Theorem 4.5 to obtain admissible directions, which consists of putting an inclusion of a tensor B in a background of tensor A, is a variation of the classical Weierstrass test. Related ideas have been used, for example, by K. A. Lurie (see [8] and references therein).

Remark 4.8. In Theorem 4.5 the expression of H when T is contained in a subspace W of dimension l can be obtained from the corresponding result to $W = \mathbf{R}^N$ (and then the case $W = \mathbf{R}^N$ can be consider as the most interesting one). It is enough to consider the matrix H_ε corresponding to $W = \mathbf{R}^N$ and $T_\varepsilon \subset \mathbf{R}^N$ defined by

$$T_\varepsilon = \{x + \varepsilon y :\ x \in B(0,1) \cap W^\perp,\ y \in T\}$$

and then pass to the limit in ε. The proof of Theorem 4.5 given above has the advantage that we do not need to realize this second limit.

Remark 4.9. The expression (4.3) of the admissible direction H has the difficulty that the function $\hat{w}_i$ is not explicit. However, as we said in the introduction, we think that it can be used, for example, to obtain a steepest descent direction. Then the function $\hat{w}_i$ can be calculated numerically. For this purpose we recall that by (3.11) in the proof of Theorem 3.2 we have

$$J(y_\varepsilon) \sim J(y) + \varepsilon \sum_{i=1}^{k} \langle \partial_i J(y), \dot{y}_i \rangle = J(y) - \varepsilon \int_\Omega H : C\, dx$$

and then, since $M(\Omega)$ is local, an idea to obtain the steepest direction is to maximize the product $H : C$ in the closure of the matrices H given by (4.3). By Remark 4.8, it is enough to consider $W = \mathbf{R}^N$. We remark that the set of such H is bounded and it is not difficult to show that its closure is convex and thus is essentially a ball (for some norm).

In Theorem 4.5, the set T does not depend on $x \in \Omega$. Thanks to Proposition 4.2 we can, in fact, take T depending on x. A result in this sense, which we use later in Theorem 4.12, is the following.

LEMMA 4.10. *Assume $M(\Omega)$ is local and closed for the H-convergence. We consider a linear subspace $W \subset \mathbf{R}^N$ of dimension ℓ, a measurable bounded subset $T_0 \subset W$, and a matrix $E \in L^\infty(\Omega, \mathcal{L}(W,W))$ which is invertible a.e. in Ω and such that E^{-1} also belongs to $L^\infty(\Omega, \mathcal{L}(W,W))$. Then, taking $T(x) = E(x)T_0$, for a.e. $x \in \Omega$, the matrix H defined by (4.3) with $T = T(x)$ is in $\bar{K}_A(M(\Omega))$ for every $A, B \in M(\Omega)$.*

Proof. For E in the conditions of the lemma, it is well known that there exists a sequence $E_n = \sum_{j=1}^{m(n)} E_{j,n}\, \chi_{\omega_{j,n}}$ with $E_{j,n} \in \mathcal{L}(W,W)$, $\omega_{j,n} \subset \Omega$ measurable,

$\cup_{j=1}^{m(n)}\omega_{j,n} = \Omega$, $\omega_{j,n} \cap \omega_{l,n} = \emptyset$ if $l \neq j$, and such that E_n converges strongly to E in $L^\infty(\Omega, \mathcal{L}(W,W))$. If $n \in \mathbf{N}$ is large enough (denoting by $\|\cdots\|$ the norm in $L^\infty(\Omega, \mathcal{L}(W,W))$), we have $\|E_n - E\| < \|E^{-1}\|^{-1}$, and then E_n is also invertible and satisfies

$$\|E_n^{-1} - E^{-1}\| \leq \frac{\|E^{-1}\|\|E - En\|}{\|E^{-1}\|^{-1} - \|E - E_n\|}.$$

So E_n^{-1} also converges to E^{-1} in $L^\infty(\Omega, \mathcal{L}(W,W))$.

We now take $T_n(x) = E_n(x)T_0$ and we denote by $H_n \in L^\infty(\Omega, \mathcal{M}_N^s)$ the matrix defined by

$$H_n(x)e_i = (B(x) - A(x))\left(e_i + \frac{1}{|T_n|_\ell}\int_{T_n} \nabla_z^W \hat{w}_{i,n}(x,z)\, d_\ell(z)\right),$$

where, for $i \in \{1, \ldots, n\}$, $\hat{w}_{i,n}$ is the solution of

$$\text{(4.11)} \qquad \begin{cases} \hat{w}_{i,n}(x,.) \in H^1_{loc}(W), \quad \nabla_z^W \hat{w}_{i,n}(x,.) \in L^2(W,W), \\ \displaystyle\int_W (A\ \chi_{W\setminus T_n} + B\ \chi_{T_n})\nabla_z^W \hat{w}_{i,n} \nabla_z^W \hat{v}\, d_\ell(z) \\ \qquad \displaystyle = \int_{T_n} (A-B)e_i \nabla_z^W \hat{v}\, d_\ell(z) \\ \forall\, \hat{v} \in H^1_{loc}(W), \quad \nabla_z^W \hat{v} \in L^2(W,W) \quad \text{a.e. } x \in \Omega. \end{cases}$$

From Theorem 4.5 and Proposition 4.2, this function belongs to $K_A(M(\Omega))$. Using the change of variables $\tilde{w}_{i,n}(\tilde{z}) = w_{i,n}(E_n\tilde{z})$, we deduce that $\tilde{w}_{i,n}$ is the solution of

$$\begin{cases} \tilde{w}_{i,n}(x,.) \in H^1_{loc}(W), \quad \nabla_{\tilde{z}}^W \tilde{w}_{i,n}(x,.) \in L^2(W,W), \\ \displaystyle\int_W (E_n^{-1})^t (A\ \chi_{W\setminus T_0} + B\ \chi_{T_0}) E_n^{-1} \nabla_{\tilde{z}}^W \tilde{w}_{i,n} \nabla_{\tilde{z}}^W \tilde{v}\, d_\ell(z) \\ \qquad \displaystyle = \int_{T_0} (E_n^{-1})^t (A-B) e_i \nabla_{\tilde{z}}^W \tilde{v}\, d_\ell(z) \\ \forall\, \tilde{v} \in H^1_{loc}(W), \quad \nabla_{\tilde{z}}^W \tilde{v} \in L^2(W,W) \quad \text{a.e. } x \in \Omega. \end{cases}$$

From the uniform convergence of E_n^{-1} to E^{-1}, we easily deduce that $\nabla_{\tilde{z}}^W \tilde{w}_{i,n}$ converges a $\nabla_{\tilde{z}}^W \tilde{w}_i$ in $L^\infty(\Omega, L^2(W,W))$, with $\tilde{w}_i$ the solution of

$$\begin{cases} \tilde{w}_i(x,.) \in H^1_{loc}(W), \quad \nabla_{\tilde{z}}^W \tilde{w}_i(x,.) \in L^2(W,W), \\ \displaystyle\int_W (E^{-1})^t (A\ \chi_{W\setminus T_0} + B\ \chi_{T_0}) E^{-1} \nabla_{\tilde{z}}^W \tilde{w}_i \nabla_{\tilde{z}}^W \tilde{v}\, d_\ell(z) \\ \qquad \displaystyle = \int_{T_0} (E^{-1})^t (A-B) e_i \nabla_{\tilde{z}}^W \tilde{v}\, d_\ell(z) \\ \forall\, \tilde{v} \in H^1_{loc}(W), \quad \nabla_{\tilde{z}}^W \tilde{v} \in L^2(W,W) \quad \text{a.e. } x \in \Omega. \end{cases}$$

Returning to the old variables, we then deduce that $\nabla_z^W \hat{w}_{i,n}$ converges to $\nabla_z^W \hat{w}_i$ in $L^\infty(\Omega, L^2(W,W))$, with $\hat{w}_i$ the solution of (4.4). Thus, H_n converges strongly to H in $L^\infty(\Omega, \mathcal{M}_N^s)$. So H belongs to $\bar{K}_A(M(\Omega))$. □

Let us now obtain the solutions $\hat{w}_i$ of (4.4) for some particular choices of T and then use Proposition 4.4 to obtain explicit optimality conditions.

LEMMA 4.11. *If $M(\Omega)$ is local and closed for the H-convergence, then, for every linear subspace $W \subset \mathbf{R}^N$ of dimension ℓ and every $A, B \in M(\Omega)$, the matrix*

$$(B-A) - (B-A)(B+(\ell-1)A)_W^{-1} P^W (B-A)$$

is in $\bar{K}_A(M(\Omega))$.

Proof. Let W be a linear subspace of $\mathbf{R}^N$ of dimension l. Since A and A^{-1} are in $L^\infty(\Omega, \mathcal{M}_N^s)$, there exists $R \in L^\infty(\Omega, \mathcal{L}(W,W))$, with $R^{-1} \in L^\infty(\Omega, \mathcal{L}(W,W))$, such that $RA_W R^t = I_W$ a.e. in Ω. We define T_0 the unitary ball in W and for a.e. $x \in \Omega$ we take $T(x) = R(x)^{-1} T_0$ and $H(x)$ the matrix given by (4.3) with $T = T(x)$. From Lemma 4.10, H belongs to $\bar{K}_A(M(\Omega))$.

The problem is to calculate the solution $\hat{w}_i$, $1 \le i \le N$, of (4.4). For this purpose, the idea is to use the change of variables $z' = Rz$, which transforms (4.4) in a similar problem, where A and T are respectively replaced by the identity and the unitary ball in W. This problem can be solved by using in a suitable way the fundamental solution of the laplacian. Doing this and returning to the old variables we deduce that (up to a function which only depends on x) $\hat{w}_i$ is given by

$$\hat{w}_i(x,z) = \begin{cases} \mu_i(x) z & \text{in T}, \\ \dfrac{\mu_i(x) z}{|Rz|^\ell} & \text{in } W \setminus T, \end{cases} \qquad 1 \le i \le N,$$

where $\mu_i(x) = (B(x) + (\ell-1)A(x))_W^{-1} P^W (A(x) - B(x)) e_i$. Then by (4.3) we deduce

$$H(x) e_i = (B(x) - A(x))(e_i + \mu_i(x)).$$

Taking into account the expression of μ_i, we finish the proof of the theorem. ∎

Using Lemma 4.11 and condition (3.4), we deduce the following theorem.

THEOREM 4.12. *In the assumptions of Theorem 3.2, if $M(\Omega)$ is local and closed for the H-convergence, then, for every linear subspace $W \subset \mathbf{R}^N$ of dimension ℓ, we have*

(4.12)
$$C : \{(A-B) + (A-B)(B+(\ell-1)A)_W^{-1} P^W (A-B)\} \ge 0 \quad \text{a.e. in } \Omega \ \forall\, B \in M(\Omega).$$

Remark 4.13. The condition (4.12) can also be written

(4.13)
$$C : (A-B) + \min_{1 \le \ell \le N} \min_{\dim(W) = l} C : (A-B)(B+(\ell-1)A)_W^{-1} P^W (A-B) \ge 0.$$

Thus, the better choice for W is to consider just the subspace which gives the minimum in this expression. This can also be related to the choice of the steepest descent direction, mentioned in Remark 4.9. If we restrict ourselves to the set of matrices H of the form

$$H = B - A - (A-B)(B+(\ell-1)A)_W^{-1} P^W (A-B),$$

then to choose the matrix giving the maximum of $H : C$ is equivalent to solving the minimization problem which appears in (4.13).

Remark 4.14. The condition (4.12) must be compared with the usual one when $M(\Omega)$ is convex, which is

$$C : (A-B) \ge 0 \quad \forall\, B \in M(\Omega), \text{ a.e. in } \Omega. \tag{4.14}$$

In general we get a perturbation of this condition with a term of second growth in $(B-A)$. We will see in Corollary 4.18 how condition (4.12) implies (4.14), at least in a subset of Ω.

COROLLARY 4.15. *In the assumptions of Theorem* 3.2*, if $M(\Omega)$ is local and closed for the H-convergence, then, for every $B \in M(\Omega)$, we have*

$$C : (A-B) + \frac{(A-B)C(A-B)\xi\xi}{B\xi\xi} \geq 0 \quad \forall\, \xi \in \mathbf{R}^N \setminus \{0\} \text{ a.e. in } \Omega. \tag{4.15}$$

Proof. It is enough, for $\xi \in \mathbf{R}^N \setminus 0$, to take $W = \{\lambda\xi \,/\, \lambda \in \mathbf{R}\}$ in Theorem 4.12 and to use that in this case:

$$(A-B)B_W^{-1}P^W(A-B) = \frac{(A-B)\xi \otimes (A-B)\xi}{B\xi\xi}. \qquad \square$$

Remark 4.16. The condition (4.15) is equivalent to

$$C : (A-B) + \min_{B\xi\xi=1} B[B^{-1}(A-B)C(A-B)]\xi\xi \geq 0$$

or, equivalently (observe that $B^{-1}(A-B)C(A-B)$ is symmetric with respect to the scalar product given by $(\xi|\eta) = B\xi\eta$ for every $\xi, \eta \in \mathbf{R}^N$),

$$C : (A-B) + \min\{\lambda :\ \lambda \text{ eigenvalue of } B^{-1}(A-B)C(A-B)\} \geq 0. \tag{4.16}$$

Remark 4.17. The inequality (4.15) has been obtained taking $\ell = 1$ in (4.12); then it comes just from a lamination in the direction ξ. So Corollary 4.15 holds if we assume only $M(\Omega)$ is local and stable under lamination (and not necessarily by H-convergence). The sets of matrices stable under lamination have been characterized by Francfort and Milton in [10] and [15]. In particular, it has been shown that, under a suitable change of variables, the set $M(\Omega)$, assumed stable under lamination, is convex. Corollary 4.15 can also be obtained from this result. In fact, deriving the usual formula for the lamination of two matrices A and B in the direction ξ, it has been proved in [25] that the matrix

$$B - A - \frac{(A-B)\xi \otimes (A-B)\xi}{B\xi\xi}$$

is an admissible direction. However, this has not been applied in our knowledge to the obtaining of optimality conditions for problem (1.1). Most of the results we obtain in the following can be deduced using (4.15), and then one can conjecture that the choice $\ell = 1$ is the best one in (4.12) (or even using all the matrices H given by Theorem 4.5) or, equivalently (see Remark 4.13), that the minimum in (4.13) is attained for $\ell = 1$. An easy counterexample shows that this is not true in general; it is enough to consider $C = B = I$ and $A = mI$ with $m > 1$. Then the minimum of the eigenvalues of $B^{-1}(A-B)C(A-B)$ is $(m-1)^2$ while taking, for example, $W = \mathbf{R}^N$ we have

$$\begin{aligned} C : (A-B)(B+(N-1)A)_W^{-1}P^W(A-B) \\ = C : (A-B)(B+(N-1)A)^{-1}(A-B) \\ = \frac{N(m-1)^2}{1+(N-1)m} < (m-1)^2. \end{aligned}$$

COROLLARY 4.18. *In the assumptions of Theorem* 3.2, *with* $M(\Omega)$ *local and closed for the* H*-convergence, we define*

$$\Omega^- = \{x \in \Omega : \ \exists\, \lambda \leq 0 \text{ eigenvalue of } C(x)\}$$

and

$$\Omega_B = \{x \in \Omega : \ \mathrm{Ker}(A(x) - B(x)) \neq \{0\}\} \quad \forall\, B \in M(\Omega).$$

Then we have

$$C : (A - B) \geq 0 \quad \text{a.e. in } \Omega^- \cup \Omega_B \quad \forall\, B \in M(\Omega). \tag{4.17}$$

Proof. Let B be in $M(\Omega)$. For a.e. $x \in \Omega_B$, we choose $\xi(x) \in \mathrm{Ker}(A(x) - B(x)) \setminus \{0\}$, and for a.e. $x \in \Omega^- \setminus \Omega_B$, we take $e(x)$ as an eigenvector associated with a nonpositive eigenvalue of $C(x)$ and $\xi(x) = (A(x) - B(x))^{-1} e(x)$. Then, taking $\xi = \xi(x)$ in (4.15), we obtain (4.17). □

By the above result, it is interesting to learn how many nonpositive eigenvalues have the matrix C. In this sense, we give the following theorem.

THEOREM 4.19. *For* $\xi_1, \ldots, \xi_k, \eta_1, \ldots, \eta_k \in \mathbf{R}^N \setminus \{0\}$, *we define*

$$\phi_i^+ = \frac{\xi_i}{|\xi_i|} + \frac{\eta_i}{|\eta_i|}, \qquad \phi_i^- = \frac{\xi_i}{|\xi_i|} - \frac{\eta_i}{|\eta_i|},$$

$$m = \dim(\mathrm{Span}\{\xi_i, \eta_i \,/\, 1 \leq i \leq k\}) = \dim(\mathrm{Span}\{\phi_i^+, \phi_i^- \,/\, 1 \leq i \leq k\}),$$

$$m^+ = \dim(\mathrm{Span}\{\phi_i^+ \,/\, 1 \leq i \leq k\}), \qquad m^- = \dim(\mathrm{Span}\{\phi_i^- \,/\, 1 \leq i \leq k\}),$$

$$\tilde{C}_i = \frac{1}{2}(\xi_i \otimes \eta_i + \eta_i \otimes \xi_i), \quad 1 \leq i \leq k, \quad \tilde{C} = \sum_{i=1}^{k} \tilde{C}_i.$$

Then we have the following:

(i) *For* $1 \leq i \leq k$, *the matrix* $\tilde{C}_i$ *has as eigenvalues* $\frac{1}{2}(\xi_i\eta_i + |\xi_i||\eta_i|) \geq 0$, $\frac{1}{2}(\xi_i\eta_i - |\xi_i||\eta_i|) \leq 0$, *with respective eigenvectors* ϕ_i^+, ϕ_i^-. *The other eigenvalues of* $\tilde{C}_i$ *are zero.*

(ii) *If* k^+ *and* k^- *are, respectively, the number of positive and negative eigenvalues of* $\tilde{C}$, *we have*

$$m - m^- \leq k^+ \leq m^+, \qquad m - m^+ \leq k^- \leq m^-. \tag{4.18}$$

Proof. The proof of (i) is easy to verify. In order to prove (ii), we use the Courant–Fischer characterization of the eigenvalues:

$$\lambda_{i+1} = \max_{\dim E \leq i} \min_{\substack{\phi \in E^\perp \\ |\phi| = 1}} \tilde{C}\phi\phi,$$

where $\lambda_1 \leq \cdots \leq \lambda_N$ are the eigenvalues of $\tilde{C}$.

Taking $i = m^-$ and $E = \mathrm{Span}\{\phi_j^- \,/\, 1 \leq j \leq k\}$, statement (i) gives

$$\lambda_{m^-+1} \geq \min_{\substack{\phi \in E^\perp \\ |\phi| = 1}} \tilde{C}\phi\phi \geq 0. \tag{4.19}$$

So $k^- \leq m^-$.

Now, if $m-m^- = 0$, then clearly $k^+ \geq m-m^-$. In another case, we consider $E = \mathrm{Span}(\{\phi_j^- \,/\, 1 \leq j \leq k\} \cup \{\phi_j^-, \phi_j^+ \,/\, 1 \leq j \leq k\}^\perp)$, which has dimension $m^- + N - m$. If $\phi \in E^\perp$, then, as above, statement (i) gives $\tilde{C}_j \phi\phi \geq 0$, $1 \leq j \leq k$, and then $\tilde{C}\phi\phi \geq 0$. Moreover, $\tilde{C}\phi\phi = 0$ iff $\tilde{C}_j \phi\phi = 0$, $1 \leq j \leq k$, which, by statement (i), implies that ϕ is orthogonal to ϕ_j^-, ϕ_j^+, $1 \leq j \leq k$; i.e., ϕ is in E and so $\phi = 0$. Thus, taking $i = m^- + N - m$ in (4.19) and using the compactness of the unitary ball in $\mathbf{R}^N$, we get

$$\lambda_{m^-+N-m+1} \geq \min_{\substack{\phi \in E^\perp \\ |\phi|=1}} \tilde{C}\phi\phi > 0,$$

and thus $k^+ \geq m - m^-$.

The other inequalities in (4.18) follow analogously. □

As a consequence we get the following.

COROLLARY 4.20. *In the assumptions of Theorem* 3.2, *if* $M(\Omega)$ *is local and closed for the* H*-convergence and* $k \leq N-1$, *then condition* (4.14) *holds.*

Proof. We apply Theorem 4.19 to $\xi_i = \nabla y_i(x)$, $\eta_i = \nabla p_i(x)$, $1 \leq i \leq k$, a.e. $x \in \Omega$. In this case $\tilde{C} = C(x)$. Since, clearly, the number m^+ which appears in this result is less than or equal to $k \leq N-1$, we deduce that the number of positive eigenvalues of C is less than or equal to $N-1$, and then there exists at least a nonpositive eigenvalue of C a.e. in Ω. Corollary 4.18 gives then (4.14). □

5. Invariability by rotations. In the applications, it is a natural hypothesis to assume that $M(\Omega)$ is invariable by rotations. We show in this section that this assumption implies that the eigenvectors of A and C agree.

DEFINITION 5.1. *We say that* $M(\Omega)$ *is invariable by rotations if for every* $B \in M(\Omega)$ *and every* $Q \in L^\infty(\Omega, \mathcal{M}_N)$, *with* $Q \in \mathcal{O}_N$ *a.e. in* Ω, *the matrix* QBQ^t *belongs to* $M(\Omega)$.

We have the following result.

PROPOSITION 5.2. *In the assumptions of Theorem* 3.2, *if* $M(\Omega)$ *is invariable by rotations, then* A *and* C *are mutually diagonalizable a.e. in* Ω.

Proof. Let us first prove that given a skew-symmetric matrix R and a measurable set $\omega \subset \Omega$, the function $(RA + AR^t)\, \chi_\omega$ belongs to $K_A(M(\Omega))$. To this purpose we define $G : \mathcal{M}_N \to \mathcal{M}_N \times \mathbf{R}$ by $G(M) = (MM^t, \det(M))$. Since $\mathrm{Ker}(G'(I))$ coincides with the space of skew-symmetric matrices, it is known (see, e.g., [1]) that for $\varepsilon \in \mathbf{R}$ with $|\varepsilon|$ small enough, there exists $P_\varepsilon \in \mathcal{M}_N$ such that $G(P_\varepsilon) = G(I)$ or, equivalently, $P_\varepsilon \in \mathcal{O}_N$, and $(P_\varepsilon - I)/\varepsilon$ converges to R. Defining then

$$A_\varepsilon = P_\varepsilon A P_\varepsilon^t\, \chi_\omega + A\, \chi_{\Omega \setminus \omega}$$

and using that $M(\Omega)$ is invariable by rotations, we deduce that A_ε belongs to $M(\Omega)$ and $(A_\varepsilon - A)/\varepsilon$ converges to $(RA + AR^t)\, \chi_\omega$ in $L^\infty(\Omega, \mathcal{M}_N^s)$. Thus $(RA + AR^t)\, \chi_\omega$ belongs to $K_A(M(\Omega))$.

Using now that the set of skew-symmetric matrices is a vectorial space, condition (3.4), and the arbitrariness of ω, we deduce

$$2(RA) : C = (RA + AR^t) : C = 0 \quad \text{a.e. in } \Omega.$$

For $i, j \in \{1, \ldots, N\}$, $i \neq j$, we take in the above equation R as the matrix

defined by

$$R_{lk} = \begin{cases} 1 & \text{if } l = i,\ k = j, \\ -1 & \text{if } l = j,\ k = i, \\ 0 & \text{in another case.} \end{cases}$$

Then we get

$$(AC)_{ij} - (CA)_{ij} = 0 \quad \text{a.e. in } \Omega,$$

i.e., A and C commute, and then they are mutually diagonalizable. □

Remark 5.3. From Proposition 5.2, assuming that the matrix C is known and that their eigenvalues are all different, we must look for the optimal solution A on the set of matrices of $M(\Omega)$ which have the same eigenvectors as C a.e. So it can be interesting to write condition (4.13) assuming that B is also mutually diagonalizable with C. If we restrict ourselves to the spaces W which are generated by eigenvectors of C, we get the following result: In the conditions of Proposition 5.2, if c_i, a_i, $i \in \{1, \dots, N\}$, are, respectively, the eigenvalues of C and A, then for every $B \in M(\Omega)$ mutually diagonalizable with A and C, with eigenvalues $b_1, \dots, b_N$, we have

$$\sum_{i=1}^{N} c_i(a_i - b_i) + \min_{1 \le \ell \le N} \min_{1 \le i_1 < \cdots < i_\ell \le N} \sum_{j=1}^{\ell} \frac{c_{i_j}(a_{i_j} - b_{i_j})^2}{b_{i_j} + (\ell - 1)a_{i_j}} \ge 0. \tag{5.1}$$

We also note that by Remark 4.16, for A, B, C as above, the condition (5.1) implies in particular (4.15).

Assuming stronger hypotheses, we can improve Proposition 5.2. Proposition 5.4 below is related to a theorem due to Lewis [11], which applies to the optimization of a function $h : \mathcal{M}_N^s \to \mathbf{R}$ convex and invariable by rotations (see also [12], where there is a review of results corresponding to optimization problems on symmetric matrices).

PROPOSITION 5.4. *In the assumptions of Theorem* 3.2*, we assume* $M(\Omega)$ *invariable by rotations and at least one of the following hypotheses:*

(i) $M(\Omega)$ *is convex.*
(ii) $M(\Omega)$ *is* H*-closed and* $N \ge 3$.
(iii) $M(\Omega)$ *is* H*-closed,* $N = 2$ *and* $k = 1$.

Then there exists $Q \in L^\infty(\Omega, \mathcal{M}_N)$*, with* $Q \in \mathcal{O}_N$ *a.e. in* Ω*, such that*

$$\begin{aligned} QAQ^t &= \operatorname{diag}(a_1, \dots, a_N), \\ QCQ^t &= \operatorname{diag}(c_1, \dots, c_N), \end{aligned} \tag{5.2}$$

and $a_1 \le \cdots \le a_N$, $c_1 \le \cdots \le c_N$.

Proof. From Proposition 5.2 there exists $Q \in L^\infty(\Omega, \mathcal{M}_N)$, with $Q \in \mathcal{O}_N$ a.e. in Ω, such that (5.2) holds. Clearly, we can also assume $c_1 \le \cdots \le c_N$ a.e. in Ω. We consider $i, j \in \{1, \dots, N\}$, $i \ne j$, and we take $L \in \mathcal{O}_N$, defined by

$$Le_i = e_j, \quad Le_j = -e_i, \quad Le_l = e_l \quad \forall\, l \ne i, j.$$

Since $M(\Omega)$ is invariable by rotations, the matrix $B = (LQ)^t \operatorname{diag}(a_1, \dots, a_N) LQ$ belongs to $M(\Omega)$. Let us now see that if one of the hypotheses (i), (ii) or (iii) hold, then

$$C : (A - B) \ge 0 \quad \text{a.e. in } \Omega. \tag{5.3}$$

For this purpose, we define $\tilde{M}(\Omega)$ as the convex hull of

$$\{SAS^t \,/\, S \in L^\infty(\Omega, \mathcal{M}_N),\ S \in \mathcal{O}_N \text{ a.e. in } \Omega\},$$

if (i) holds and as the H-closure of this set in cases (ii) and (iii). Then $\tilde{M}(\Omega)$ is contained in $M(\Omega)$ and A belongs to $\tilde{M}(\Omega)$, so A is also a solution of (1.1) with $M(\Omega)$ replaced by $\tilde{M}(\Omega)$.

In case (i), $\tilde{M}(\Omega)$ is convex and local, so from (4.1) and $B - A$ in $K_A(M(\Omega))$, we deduce (5.3).

In cases (ii) and (iii), $\tilde{M}(\Omega)$ is local and H-closed. Moreover, if (ii) holds, then $\mathrm{Ker}(B - A) \neq 0$ a.e. in Ω, while if we have (iii) then, from Theorem 4.19, C has at least a nonpositive eigenvalue. So, in both situations, we deduce (5.3) from (4.17).

From (5.3) we get

$$0 \leq C : (A - B) = c_i(a_i - a_j) + c_j(a_j - a_i) = (c_i - c_j)(a_i - a_j) \quad \text{a.e. in } \Omega.$$

This finishes the proof of Proposition 5.4. □

Remark 5.5. As we have seen in the proof of Proposition 5.4, the order relation between the eigenvalues of C and A is a consequence of (5.3) with B defined as above. So if $N = 2$ and $M(\Omega)$ is H-closed, by Corollary 4.18, the thesis of Proposition 5.4 still holds on the set where C has a least a nonnegative eigenvalue. Where the two eigenvalues are positive, assuming $c_1 < c_2$, the condition (4.15) implies

$$a_1 < a_2 \quad \text{or} \quad a_1 > a_2 \quad \text{and} \quad c_2 a_2 \leq c_1 a_1. \tag{5.4}$$

Related to this inequality, we also remark that if in the conditions of Proposition 5.4 (ii) there are two eigenvalues of C, c_i, c_j such that $c_i \leq c_j \leq 0$, then besides $a_i \leq a_j$, we have $|c_j| a_j \leq |c_i| a_i$.

6. Applications. In this section let us show how the condition (3.4) and the consequences we have obtained from it can be used, in some cases, to obtain $A\nabla y_i$, $A\nabla p_i$, $1 \leq i \leq k$, as explicit functions of ∇y_i, ∇p_i and then, from (1.2) and (3.2), to reduce the optimality conditions given in Theorem 3.2 to a nonlinear system in ∇y_i, ∇p_i. The main difficulty in carrying out this idea is that obtaining the H-closure of a subset of $L^\infty(\Omega, \mathcal{M}_N)$ is a very difficult problem, which has only been solved in some particular cases (see [23], [14], [13], [8], [16], [25]). To simplify the exposition, we have chosen two simple problems where the H-closure is well known. The first consists of the mixture of two homogeneous isotropic materials in dimension two (the problem can also be studied analogously for higher dimensions). This problem has also been studied in [3] and [7]. In this case the set $M(\Omega)$ is convex. In the second problem we consider a nonconvex situation corresponding to a polycrystal in dimension two.

First problem. We start by recalling the following result which has been proved in [23] and [14].

THEOREM 6.1. *We assume $N = 2$. For $0 < \alpha \leq \beta$ and $\theta \in L^\infty(\Omega)$ with $0 \leq \theta \leq 1$ a.e. in Ω, the set $\mathcal{M}_\theta(\Omega)$ of the H-limits of the sequences $\alpha I\ \chi_{\omega_n} + \beta(1 - \chi_{\omega_n})I$, such that $\omega_n \subset \Omega$ are measurable sets and satisfy χ_{ω_n} converges weakly-$*$ in $L^\infty(\Omega)$ to θ, is characterized as follows:*

$\mathcal{M}_\theta \subset L^\infty(\Omega, \mathcal{M}_2^s)$ is the set of matrices such that their eigenvalues λ_1, λ_2 satisfy

the following inequalities a.e. in Ω*:*

$$\begin{cases} \lambda^- \le \lambda_1, \lambda_2 \le \lambda^+, \\ \displaystyle\sum_{i=1}^{2} \frac{1}{\lambda_i - \alpha} \le \frac{1}{\lambda^- - \alpha} + \frac{1}{\lambda^+ - \alpha}, \\ \displaystyle\sum_{i=1}^{2} \frac{1}{\beta - \lambda_i} \le \frac{1}{\beta - \lambda^-} + \frac{1}{\beta - \lambda^+}, \end{cases} \tag{6.1}$$

where λ^-*,* λ^+ *are given by*

$$\lambda^+ = \alpha\theta + \beta(1-\theta), \qquad \lambda^- = \left(\frac{\theta}{\alpha} + \frac{1-\theta}{\beta}\right)^{-1}. \tag{6.2}$$

Let us see how the results obtained in the previous sections permit us to obtain A from C, and then from ∇y_i, ∇p_i, $1 \le i \le k$, for some choices of $M(\Omega)$ related to $\mathcal{M}_\theta(\Omega)$.

In the following, we define

$$\check{\Omega} = \{x \in \Omega \,/\, (c_1(x), c_2(x)) \neq (0,0)\}, \tag{6.3}$$

where c_1, c_2 are the eigenvalues of the matrix C.

PROPOSITION 6.2. *In the assumptions of Theorem* 3.2*, if* $M(\Omega)$ *is the set of matrices defined in Theorem* 6.1 *for a fixed function* θ *and* c_1*,* c_2*,* $c_1 \le c_2$*, are the eigenvalues of* C*, then there exists an associated basis* $\{\mu_1, \mu_2\}$ *of eigenvectors of* C *such that a.e. in* Ω*, we have*

$$A\mu_i = a_i \mu_i, \quad i = 1, 2, \tag{6.4}$$

where a.e. in $\check{\Omega}$*, the functions* a_1*,* a_2 *are given by the following:*

$$\textit{If } c_2 < 0 \textit{ and } \sqrt{\frac{c_2}{c_1}} \ge \frac{\alpha}{\alpha + (\beta-\alpha)\theta} \Rightarrow \begin{cases} a_1 = \alpha + \dfrac{\alpha(\beta-\alpha)(1-\theta)}{2\alpha + (\beta-\alpha)\theta}\left(1 + \sqrt{\dfrac{c_2}{c_1}}\right), \\ a_2 = \alpha + \dfrac{\alpha(\beta-\alpha)(1-\theta)}{2\alpha + (\beta-\alpha)\theta}\left(1 + \sqrt{\dfrac{c_1}{c_2}}\right). \end{cases}$$

$$\textit{If } c_1 > 0 \textit{ and } \sqrt{\frac{c_2}{c_1}} \le \frac{\beta}{\alpha + (\beta-\alpha)\theta} \Rightarrow \begin{cases} a_1 = \beta - \dfrac{\beta(\beta-\alpha)\theta}{\alpha + \beta + (\beta-\alpha)\theta}\left(1 + \sqrt{\dfrac{c_2}{c_1}}\right), \\ a_2 = \beta - \dfrac{\beta(\beta-\alpha)\theta}{\alpha + \beta + (\beta-\alpha)\theta}\left(1 + \sqrt{\dfrac{c_1}{c_2}}\right). \end{cases}$$

In another case $a_1 = \lambda^-$*,* $a_2 = \lambda^+$*, where* λ^-*,* λ^+ *are defined by* (6.2)*.*

Proof. In this case, the set $M(\Omega)$ is local, convex, and invariable by rotations. So we can apply Proposition 5.4 and (4.14), which imply that a.e. in Ω, A satisfies (6.4) for a basis of eigenvectors of C, and $a_1c_1 + a_2c_2$ is the maximum of $\lambda_1c_1 + \lambda_2c_2$, with λ_1, λ_2 in the set defined by (6.1). Solving this maximum problem we get the expressions a_1 and a_2 given in Proposition 6.2. ∎

The above result assumes that θ is known, but clearly this is not a realistic situation. Next, we consider two examples where θ also varies. In the first one we impose the condition

$$\frac{1}{|\Omega|}\int_\Omega \theta \, dx = s, \tag{6.5}$$

with $s \in (0,1)$. This means we know the proportion of the materials defined by α and β but not its local distribution. This usually holds when one material is better than the other but it is also more expensive. In the second situation we consider the case where we do not have any restriction on θ.

PROPOSITION 6.3. *In the assumptions of Theorem* 3.2*, if for* $s \in (0,1)$ *given,* $M(\Omega)$ *is the set of matrices defined in Theorem* 6.1*, with* $\theta \in L^\infty(\Omega)$, $0 \le \theta \le 1$ *a.e. in* Ω *and such that* (6.5) *holds, then the matrix* A *satisfies the thesis of Proposition* 6.2*, where the corresponding function* θ *is such that defining* $F \in L^\infty(\check{\Omega})$ *by*

$$F(x) = \begin{cases} \dfrac{\alpha(\beta^2-\alpha^2)(\sqrt{-c_1}-\sqrt{-c_2})^2}{(2\alpha+(\beta-\alpha)\theta)^2} & \text{if } c_2 < 0 \text{ and } \sqrt{\dfrac{c_2}{c_1}} \ge \dfrac{\alpha}{\alpha+(\beta-\alpha)\theta}, \\ -\dfrac{\beta(\beta^2-\alpha^2)(\sqrt{c_1}+\sqrt{c_2})^2}{(\alpha+\beta+(\beta-\alpha)\theta)^2} & \text{if } c_1 > 0 \text{ and } \sqrt{\dfrac{c_2}{c_1}} \le \dfrac{\beta}{\alpha+(\beta-\alpha)\theta}, \\ -(\beta-\alpha)\left(\dfrac{\alpha\beta}{(\alpha+(\beta-\alpha)\theta)^2}c_1 + c_2\right) & \text{in another case,} \end{cases}$$

there exists $r \in \mathbf{R}$ *which satisfies*

$$\begin{cases} F(x) \le r & \text{a.e. in } \{\theta = 0\} \cap \check{\Omega}, \\ F(x) = r & \text{a.e. in } \{0 < \theta < 1\} \cap \check{\Omega}, \\ F(x) \ge r & \text{a.e. in } \{\theta = 1\} \cap \check{\Omega}. \end{cases} \tag{6.6}$$

Proof. We remark that if θ is the corresponding function associated with A in the definition of the elements of $M(\Omega)$ and we define $M_\theta(\Omega)$ as in the statement of Theorem 6.1, then A is also the solution of (1.1) with $M(\Omega)$ replaced by $M_\theta(\Omega)$. So Proposition 6.2 applies.

Let us now vary θ. For every $\theta^* \in L^\infty(\Omega)$ such that $0 \le \theta^* \le 1$ a.e. in Ω,

$$\frac{1}{|\Omega|}\int_\Omega \theta^*\,dx = s,$$

and $\theta^* = \theta$ a.e. in $\Omega \setminus \check{\Omega}$, we define $A_{\theta^*} \in M(\Omega)$ as the function given by Proposition 6.2 applied to θ^* a.e. in $\check{\Omega}$ and $A_{\theta^*} = A$ a.e. in $\Omega \setminus \check{\Omega}$. Deriving A_{θ^*} with respect to θ^*, we obtain an admissible direction. Then, using condition (3.4), we get

$$\int_\Omega F\vartheta\,dx \le 0 \tag{6.7}$$

for every $\vartheta \in L^\infty(\Omega)$ such that $\vartheta = 0$ a.e. in $\Omega \setminus \check{\Omega}$, $\vartheta \ge 0$ a.e. in $\{\theta = 0\} \cap \check{\Omega}$, $\vartheta \le 0$ a.e. in $\{\theta = 1\} \cap \check{\Omega}$, and

$$\int_\Omega \vartheta\,dx = 0.$$

It is easy to check that this implies the existence of $r \in \mathbf{R}$, which satisfies the statement of the proposition. □

Remark 6.4. The expression of F is strictly decreasing with respect to θ. Then, from (6.6), it is possible to obtain θ as a function of c_1, c_2 and r.

Remark 6.5. In Proposition 6.3, if $r \ge 0$, then $\theta = 0$ a.e. in the set

$$\{c_1 > 0\} \bigcap \left\{\sqrt{\frac{c_2}{c_1}} \le \frac{\beta}{\alpha}\right\} \cap \check{\Omega}.$$

Analogously, if $r \leq 0$, then $\theta = 1$ a.e. in the set

$$\{c_2 < 0\} \bigcap \left\{ \sqrt{\frac{c_2}{c_1}} \geq \frac{\alpha}{\beta} \right\} \cap \check{\Omega}.$$

We finish with the following result.

PROPOSITION 6.6. *In the assumptions of Theorem* 3.2*, let* $M(\Omega)$ *be the set of matrices defined in Theorem* 6.1*, where* θ *is any function in* $L^\infty(\Omega)$ *such that* $0 \leq \theta \leq 1$ *a.e. in* Ω*, and denote by* c_1*,* c_2*,* $c_1 \leq c_2$*, the eigenvalues of* C*. Then there exists an associated basis* $\{\mu_1, \mu_2\}$ *of eigenvectors of* C *such that a.e. in* Ω *we have* (6.4)*. Moreover, a.e. in* $\check{\Omega}$*, the functions* a_1*,* a_2 *are given by the following:*

If $0 \leq c_1 \leq c_2$*, then* $a_1 = a_2 = \beta$*.*

If $c_1 \leq c_2 \leq 0$*, then* $a_1 = a_2 = \alpha$*.*

If $c_1 < 0 < c_2$*, then*

$$\begin{cases} \dfrac{\alpha}{\beta} \geq -\dfrac{c_1}{c_2} \Rightarrow a_1 = a_2 = \beta, \\ \dfrac{\beta}{\alpha} > -\dfrac{c_1}{c_2} > \dfrac{\alpha}{\beta} \Rightarrow a_1 = \sqrt{-\dfrac{\alpha\beta c_2}{c_1}}, \quad a_2 = \alpha + \beta - \sqrt{-\dfrac{\alpha\beta c_1}{c_2}}, \\ -\dfrac{c_1}{c_2} \geq \dfrac{\beta}{\alpha} \Rightarrow a_1 = a_2 = \alpha. \end{cases}$$

Proof. We proceed similarly to Proposition 6.3, but now, in the condition (6.7), the function ϑ does not necessarily satisfy

$$\int_\Omega \vartheta \, dx = 0.$$

This implies that the function F given in Proposition 6.3 satisfies (6.6) with $r = 0$, which easily gives the result. ∎

Second problem. Given a diagonal matrix $\Lambda = \operatorname{diag}(\alpha, \beta)$ with $0 < \alpha < \beta$, let us now consider the optimization problem (1.1) when $M(\Omega)$ is the H-closure of the matrices of the form $R(x)\Lambda R(x)^t$, where R is measurable, and $R(x)$ belongs to $\mathcal{O}_2$ for a.e. $x \in \Omega$ (observe that to assume Λ diagonal is not a restriction). This set $M(\Omega)$ is known (see, e.g., [25], [16]) and agrees with the set of functions $B \in L^\infty(\Omega, \mathcal{M}_2^s)$ such that for a.e. $x \in \Omega$, the eigenvalues $b_1(x)$ and $b_2(x)$ of $B(x)$ satisfy $\alpha \leq b_1(x)$, $b_2(x) \leq \beta$, $b_1(x)b_2(x) = \alpha\beta$. For this choice of $M(\Omega)$, we have the following result.

PROPOSITION 6.7. *In the assumptions of Theorem* 3.2*, if* c_1 *and* c_2*, with* $c_1 \leq c_2$*, are the eigenvalues of* C*, then there exists an associated basis* $\{\mu_1, \mu_2\}$ *of eigenvectors of* C *such that a.e. in* Ω*, we have*

$$A\mu_i = a_i \mu_i, \quad i = 1, 2, \tag{6.8}$$

where a.e. in the set $\check{\Omega}$ *defined by* (6.3)*, the functions* a_1*,* a_2 *are given by*

$$c_2 < 0 \quad \textit{and} \quad \frac{c_2}{c_1} > \frac{\alpha}{\beta} \Rightarrow \begin{cases} a_1 = \sqrt{\alpha\beta}\sqrt{\dfrac{c_2}{c_1}}, \\ a_2 = \sqrt{\alpha\beta}\sqrt{\dfrac{c_1}{c_2}}. \end{cases}$$

If $c_1 > 0$ *and* $\frac{c_2}{c_1} \le \frac{\beta}{\alpha}$, *then there exist three possibilites:*

$$\begin{cases} a_1 = \alpha, \\ a_2 = \beta, \end{cases} \quad or \quad \begin{cases} a_1 = \beta, \\ a_2 = \alpha, \end{cases} \quad or \quad \begin{cases} a_1 = \sqrt{\alpha\beta}\sqrt{\dfrac{c_2}{c_1}}, \\ a_2 = \sqrt{\alpha\beta}\sqrt{\dfrac{c_1}{c_2}}. \end{cases}$$

In another case $a_1 = \alpha$, $a_2 = \beta$.

Proof. Since the set $M(\Omega)$ is invariable by rotations, we can apply Proposition 5.2 to deduce that for a.e. $x \in \Omega$, there exists a basis $\{\mu_1(x), \mu_2(x)\}$ of $\mathbf{R}^2$ such that

$$C(x)\mu_i(x) = c_i(x)\mu_i(x), \quad A(x)\mu_i(x) = a_i(x)\mu_i(x), \quad i = 1, 2,$$

with $c_1(x) \le c_2(x)$, $a_1(x), a_2(x) \in \mathbf{R}$. From the definition of $M(\Omega)$, we also have that for a.e. $x \in \Omega$, there exists $t^*(x) \in [1, \frac{\beta}{\alpha}]$ such that

$$a_1(x) = \alpha t^*(x), \qquad a_2(x) = \frac{\beta}{t^*(x)}.$$

Moreover, from (5.1), we deduce that t^* satisfies

$$\begin{aligned} &(t^*(x) - t)\left(\alpha c_1(x) - \frac{\beta c_2(x)}{t^*(x)t}\right) \\ &\quad + (t^*(x) - t)^2 \min\left\{\frac{\alpha c_1(x)}{t}, \frac{\beta c_2(x)}{(t^*(x))^2 t}, \frac{1}{t^*(x) + t}\left(\alpha c_1(x) + \frac{\beta c_2(x)}{t^*(x)t}\right)\right\} \ge 0 \end{aligned} \tag{6.9}$$

for every $t \in [1, \frac{\beta}{\alpha}]$ and a.e. $x \in \Omega$. In the set where $t^*(x) = 1$, we have $t^*(x) - t < 0$ for every $t \in (1, \frac{\beta}{\alpha}]$. So, dividing by $1 - t$ and taking t converging to 1 on the right, we deduce

$$\alpha c_1 - \beta c_2 \le 0 \quad \text{a.e. in } \{x \in \Omega : \ t^*(x) = 1\}. \tag{6.10}$$

Analogously, we deduce

$$\beta c_1 - \alpha c_2 \ge 0 \quad \text{a.e. in } \left\{x \in \Omega : \ t^*(x) = \frac{\beta}{\alpha}\right\}, \tag{6.11}$$

$$\alpha c_1 - \frac{\beta c_2}{(t^*(x))^2} = 0 \quad \text{a.e. in } \left\{x \in \Omega : \ 1 < t^*(x) < \frac{\beta}{\alpha}\right\}, \tag{6.12}$$

where the statement (6.12) implies

$$c_1 c_2 > 0, \quad t^* = \sqrt{\frac{\beta c_2}{\alpha c_1}} \quad \text{a.e. in } \left\{x \in \check{\Omega} : \ 1 < t^*(x) < \frac{\beta}{\alpha}\right\}. \tag{6.13}$$

Analyzing the different cases which appear depending on the sign of c_1 or c_2, we easily conclude from (6.10), (6.11), and (6.13) the proof of Proposition 6.7. □

Remark 6.8. We have deduced (6.10), (6.11), and (6.13) from inequality (6.9). One could conjecture that this inequality gives, in fact, more information. However, a simple calculus shows that the statements (6.10), (6.11), and (6.13) also imply (6.9).

Remark 6.9. Proposition 6.7 does not give the expressions of a_1 and a_2 in the set where $c_1 > 0$ and $\frac{c_2}{c_1} \le \frac{\beta}{\alpha}$; it gives three possibilities. The possibility $a_1 = \alpha$, $a_2 = \beta$

seems to be the most natural in order to stick continuously with the values of a_1 and a_2 in the other zones. We also note that if $M(\Omega)$ was convex then, using that $B - A$ is an admissible direction for every $B \in M(\Omega)$, we should obtain in place of (6.9) that

$$\alpha t^* + \frac{\beta}{t^*} = \max\left\{\alpha t + \frac{\beta}{t} : \ t \in \left[1, \frac{\beta}{\alpha}\right]\right\},$$

which implies that $t^* = 1$ (and then $a_1 = \alpha$, $a_2 = \beta$) a.e. on the set where $c_1 > 0$ and $\frac{c_2}{c_1} \leq \frac{\beta}{\alpha}$ as well as the expressions of a_1 and a_2 given in Proposition 6.7 in the other cases. However, since $M(\Omega)$ is not convex, this reasoning is not good and thus the only conclusion we obtain is that stated in Proposition 6.7.

OPTIMAL CONTROL OF BILATERAL OBSTACLE PROBLEMS*

MAÏTINE BERGOUNIOUX† AND SUZANNE LENHART‡

Abstract. We consider an optimal control problem where the state satisfies a bilateral elliptic variational inequality and the control functions are the upper and lower obstacles. We seek a state that is close to a desired profile and the H^2 norms of the obstacles are not too large. Existence results are given and an optimality system is derived. A particular case is studied that needs no compactness assumption, via a monotonicity method.

Key words. optimal control, obstacle problem, variational inequalities, semilinear elliptic equations

1. Introduction.

We consider an optimal control problem where the state satisfies a bilateral elliptic variational inequality and the control functions are the upper and lower obstacles. We seek a state that is close to a desired profile and for which the H^2 norms of the obstacles are not too large.

This type of problem appears in shape optimization [11, 19]. It may concern, for example, the optimal shape for a dam. The obstacle gives the form to be designed such that the pressure of the fluid inside the dam is close to a desired value. This is equivalent in some sense to controlling the free boundary (see [14], for example).

There are few papers about the control of the obstacle in variational inequalities. In an early paper [10], Bucur, Buttazzo, and Trabeschi give an existence result for a problem of the following type:

$$\min\left\{F(g), g \in X_\psi(\Omega), \int_\Omega g(x)dx = c\right\},$$

where $X_\psi(\Omega) = \{g : \Omega \to \bar{\mathbb{R}},\ g \leq \psi\}$ and F is increasing γ lower semicontinuous. The monotonicity assumption on F allows the avoidance of the compactness assumption used in the present paper. In [3] the problem is studied with completely different methods (the γ-convergence is not used), using once again an implicit monotonicity assumption. Then [1, 2, 9, 17, 18] generalized that result to include source terms, semilinear and quasilinear elliptic operators, and parabolic operators, replacing the monotonicity hypothesis by a compactness one. One can refer also to the book by Chipot [13] and its references for background and estimates for bilateral variational inequalities. For recent work on control in lower order terms, see the works by Chen [12] on semilinear elliptic bilateral variational inequalities and by Bergounioux [8] on semilinear elliptic variational inequalities. The new feature in this paper is the control of the two obstacles in the bilateral case.

The motivation of our work is threefold. First, as mentioned above, many shape optimization problems can be modeled as the problem we describe here below. Sec-

ondly, as usual, in optimal control theory, we are looking for a first order necessary optimality system that allows us to compute the solution exactly (often not the case) or numerically. The numerical strategy can be the direct resolution of the optimality system by a shooting method or any other fixed point method, or the setting of adapted algorithms whose convergence may be proved using Lagrange multipliers; see [5, 6, 7]. Therefore, we claim that the establishment of optimality conditions is the first step before any numerical analysis.

Thirdly, from the theoretical point of view, the problem is involved in a wider class of (open) problems, which can be (formally) described as follows:

$$\min\{J(u,\chi),\ u=\mathcal{T}(\chi),\ \chi\in U_{ad}\subset\mathcal{U}\},$$

where $\mathcal{T}$ is an operator which associates u to χ, where u is a (or the only) solution to

$$\forall v\in K(u,\chi),\quad \langle\mathcal{A}(u,\chi),u-v\rangle\geq 0,$$

where K is a *multiapplication* from $\mathcal{X}\times\mathcal{U}$ to $2^{\mathcal{X}}$, where $\mathcal{X}$ is a Banach space and $\mathcal{U}$ a Hilbert space. Let us give an example: let $\mathcal{Y}$ be a Banach space and A a differential operator (linear or not), parabolic or elliptic from $\mathcal{Y}$ to the dual space $\mathcal{Y}'$, and h an application from $\mathbb{R}\times\mathbb{R}\times\mathbb{R}$ to $\mathbb{R}$. The differential equation that relates the control χ to the state function u (i.e., the state "equation") is

$$\langle Au,v-u,\rangle_{\mathcal{Y},\mathcal{Y}'}+h(u,\chi,v)-h(u,\chi,u)\geq(\chi,v-u)\qquad\forall v\in\mathcal{Y},$$

where

1. $h(u,\chi,v)=h(v)$ gives the classical variational inequalities;
2. $h(u,\chi,v)=h(\chi,v)$ gives (for example) obstacle problems (where the obstacle is the control): this is the problem we investigate here;
3. $h(u,\chi,v)=h(u,v)$ leads to quasi-variational inequalities whose study is very delicate.

Let us specify the problem under consideration as follows.

Let Ω be an open bounded subset of $\mathbb{R}^n$ with a smooth boundary $\partial\Omega$. We consider the bilinear form $a(.,.)$ defined on $H_o^1(\Omega)\times H_o^1(\Omega)$ by

$$a(u,v)=\sum_{i,j=1}^{n}\int_\Omega a_{ij}\frac{\partial u}{\partial x_i}\frac{\partial v}{\partial x_j}\,dx+\sum_{i=1}^{n}\int_\Omega b_i\frac{\partial u}{\partial x_i}v\,dx+\int_\Omega cu\,v\,dx,\tag{1.1}$$

where a_{ij},b_i,c belong to $L^\infty(\Omega)$. Moreover, we assume that a_{ij} belongs to $\mathcal{C}^{0,1}(\bar\Omega)$ (the space of Lipschitz continuous functions in Ω) and that c is nonnegative. The bilinear form $a(.,.)$ is continuous on $H_o^1(\Omega)\times H_o^1(\Omega)$,

$$\exists M>0,\ \forall(u,v)\in H_o^1(\Omega)\times H_o^1(\Omega),\qquad a(u,v)\leq M\,\|u\|_{H_o^1(\Omega)}\|v\|_{H_o^1(\Omega)},\tag{1.2}$$

and is coercive:

$$\exists\alpha>0,\ \forall u\in H_o^1(\Omega),\qquad a(u,u)\geq\alpha\|u\|^2_{H_o^1(\Omega)}.\tag{1.3}$$

We shall define $\|\cdot\|_V$, the norm in the Banach space V, and more precisely $\|\cdot\|_2$ the $L^2(\Omega)$-norm. In the same way, $\langle\cdot,\cdot\rangle$ denotes the duality product between $H^{-1}(\Omega)$ and $H_o^1(\Omega)$, and $(\cdot,\cdot)_2$ the $L^2(\Omega)$-inner product. We call $A\in\mathcal{L}(H_o^1(\Omega),H^{-1}(\Omega))$ the linear (elliptic) operator associated with a such that $\langle Au,v\rangle=a(u,v)$. Given $\varphi,\psi\in H_o^1(\Omega)$, we set

$$K(\varphi,\psi)=\{u\in H_o^1(\Omega)\mid\varphi\leq u\leq\psi\text{ a.e. in }\Omega\},\tag{1.4}$$

which is a nonempty, closed, convex subset of $H_o^1(\Omega)$. All inequalities as $u \leq \psi$ are understood in the almost everywhere sense. We choose $f \in L^2(\Omega)$ as a source term. For any $\varphi, \psi \in H_o^1(\Omega)$, it is well known (see [4], for example) that the variational inequality

$$\forall v \in K(\varphi,\psi), \qquad a(u, v-u) \geq (f, v-u),\ u \in K(\varphi,\psi), \tag{1.5}$$

has a unique solution u that belongs to $H_o^1(\Omega)$. In addition, if $\varphi, \psi \in H^2(\Omega)$, then u belongs to $H^2(\Omega) \cap H_o^1(\Omega)$ (see [4], for example). From now on, we consider H^2-obstacle functions so that we may define the operator $\mathcal{T}$ from $(H^2(\Omega) \cap H_o^1(\Omega)) \times (H^2(\Omega) \cap H_o^1(\Omega))$ to $H^2(\Omega) \cap H_o^1(\Omega)$ such that $\mathcal{T}(\varphi,\psi) = u$ is the unique solution to the variational inequality (1.5). It is known that this operator is not differentiable (and even not continuous if we define it on the whole space $H_o^1(\Omega)$).

Let U_{ad} be the set of admissible controls defined as follows:

$$U_{ad} = \{(\varphi,\psi) \in (H^2(\Omega) \cap H_o^1(\Omega)) \times (H^2(\Omega) \cap H_o^1(\Omega)) \ \mid \ \varphi \leq \psi \ \}.$$

Now, we consider the optimal control problem $(\mathcal{P})$ defined as follows:

$$\min\left\{ J(\varphi,\psi) \stackrel{def}{=} \frac{1}{2}\int_\Omega (\mathcal{T}(\varphi,\psi)-z)^2 dx + \frac{\nu}{2}\left(\int_\Omega \left((\Delta\varphi)^2 + (\Delta\psi)^2\right)\, dx\right), (\varphi,\psi) \in U_{ad} \right\},$$

where $z \in L^2(\Omega)$. In what follows we require continuity properties for $\mathcal{T}$; therefore we need H^2-a priori estimates. We could assume that U_{ad} is H^2-bounded, but this choice leads to technical difficulties in deriving an optimality system. An equivalent theoretical tool for getting such estimates is to involve the H^2-norm in the objective functional. That is why we have added the term $\int_\Omega \left((\Delta\varphi)^2 + (\Delta\psi)^2\right)\, dx$. The positive real number ν can be small but it is fixed: it ensures that the weight of the H^2-norm is not too large with respect to the least squared minimization to drive the state $u = \mathcal{T}(\varphi,\psi)$ as close as possible to a desired profile z. Of course, this is a regularizing term which gives compactness properties. It is not too unrealistic to look for smooth obstacles: the gradient is bounded, and thus we avoid oscillations, and the curvature is bounded as well.

Let us give an outline of the paper. The next section is devoted to the study of the state-inequality and some properties of the operator $\mathcal{T}$. Then we give an existence result for a solution of $(\mathcal{P})$. Section 3 is devoted to the optimality system. We consider an approximate optimality system and convergence results to pass to the limit in this system. In the last section, we present a particular case, where the H^2-boundedness assumption is weakened and replaced by an H^1-boundedness assumption. We use monotonicity tools to deal with the lack of compactness and obtain a "complete" optimality system.

2. Properties of the state operator $\mathcal{T}$. We consider the following technique (see [4, 3]) to approximate the variational inequality by a semilinear equation. More precisely, we define

$$\beta(r) = \begin{cases} 0 & \text{if } r \geq 0, \\ -r^2 & \text{if } r \in [-\frac{1}{2}, 0], \\ r + \frac{1}{4} & \text{if } r < -\frac{1}{2}. \end{cases} \tag{2.1}$$

Note that $\min\{0, r\} \le \beta(r) \le 0$ and $\beta \in \mathcal{C}^1(\mathbb{R})$ with

$$\beta'(r) = \begin{cases} 0 & \text{if } r \ge 0, \\ -2r & \text{if } r \in [-\frac{1}{2}, 0], \\ 1 & \text{if } r < -\frac{1}{2}. \end{cases} \tag{2.2}$$

We introduce the following semilinear elliptic equation:

$$Au + \frac{1}{\delta}\left(\beta(u-\varphi) - \beta(\psi - u)\right) = f \text{ in } \Omega,\ u = 0 \text{ on } \partial\Omega. \tag{2.3}$$

As $\beta(\cdot - \varphi) - \beta(\psi - \cdot)$ is nondecreasing, it is known that the above equation has a unique solution $u^\delta \in H^2(\Omega) \cap H_o^1(\Omega)$, and we set $u^\delta = \mathcal{T}^\delta(\varphi, \psi)$.

THEOREM 2.1. *Let $(\varphi^\delta, \psi^\delta) \in U_{ad}$ be a sequence strongly convergent in $H_o^1(\Omega)$ to some (φ, ψ) as δ tends to 0. Then the sequence $u^\delta = \mathcal{T}^\delta(\varphi^\delta, \psi^\delta)$ converges to $u = \mathcal{T}(\varphi, \psi)$ strongly in $H_o^1(\Omega)$.*

Proof. For every $(\varphi^\delta, \psi^\delta) \in U_{ad}$, we set $u^\delta = \mathcal{T}^\delta(\varphi^\delta, \psi^\delta)$. Equation (2.3) is equivalent to

$$\forall v \in H_o^1(\Omega), \qquad a(u^\delta, v) + \frac{1}{\delta}\left(\beta(u^\delta - \varphi^\delta) - \beta(\psi^\delta - u^\delta), v\right)_2 = (f, v)_2. \tag{2.4}$$

First, we choose $v = u^\delta - \varphi^\delta$. Equation (2.4) gives

$$a(u^\delta, u^\delta - \varphi^\delta) + \frac{1}{\delta}\int_\Omega \beta(u^\delta - \varphi^\delta)(u^\delta - \varphi^\delta)dx = \frac{1}{\delta}\int_\Omega \beta(\psi^\delta - u^\delta)(u^\delta - \varphi^\delta)dx + \int_\Omega f(u^\delta - \varphi^\delta)dx.$$

Note that if $u^\delta(x) - \varphi^\delta(x) \ge 0$, then $\beta(u^\delta(x) - \varphi^\delta(x)) = 0$; otherwise $\beta(u^\delta(x) - \varphi^\delta(x)) \le 0$. In any case we have

$$\beta(u^\delta - \varphi^\delta)(u^\delta - \varphi^\delta) \ge 0 \quad \text{a.e. in } \Omega.$$

Similarly, if $\psi^\delta(x) \le u^\delta(x)$, then with $\varphi^\delta(x) \le \psi^\delta(x)$ we get

$$\beta(\psi^\delta - u^\delta)(u^\delta - \varphi^\delta) \le 0 \quad \text{a.e. in } \Omega,$$

since $\beta(\psi^\delta(x) - u^\delta(x)) = 0$ if $\psi^\delta(x) > u^\delta(x)$. By the above, we obtain

$$a(u^\delta, u^\delta - \varphi^\delta) \le (f, u^\delta - \varphi^\delta)_2,$$

$$a(u^\delta, u^\delta) \le a(u^\delta, \varphi^\delta) + (f, u^\delta - \varphi^\delta)_2,$$

$$\alpha\|u^\delta\|^2_{H_o^1(\Omega)} \le M\|u^\delta\|_{H_o^1(\Omega)}\|\varphi^\delta\|_{H_o^1(\Omega)} + \|f\|_2\|u^\delta\|_2 + \|f\|_2\|\varphi^\delta\|_2,$$

$$\alpha\|u^\delta\|^2_{H_o^1(\Omega)} \le M\|u^\delta\|_{H_o^1(\Omega)}\|\varphi^\delta\|_{H_o^1(\Omega)} + \|f\|_2\|u^\delta\|_{H_o^1(\Omega)} + \|f\|_2\|\varphi^\delta\|_{H_o^1(\Omega)}.$$

This gives the existence of a constant C_1 depending only on f and a such that

$$\|u^\delta\|_{H_o^1(\Omega)} \le C_1\|\varphi^\delta\|_{H_o^1(\Omega)}. \tag{2.5}$$

Similarly, once again using $\varphi^\delta \le \psi^\delta$, we have the following estimate:

$$\|u^\delta\|_{H_o^1(\Omega)} \le C_2\|\psi^\delta\|_{H_o^1(\Omega)}, \tag{2.6}$$

where $C_2 \ge 0$ depends only on f and a.

• Next, we estimate $\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)$. As $0\le\beta'\le 1$, $\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\in H^1_o(\Omega)$. Using (2.4) with $v=\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)$ gives

$$\begin{aligned}
&\frac{1}{\delta}\|\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\|_2^2\\
&\quad= \ -a(u^\delta,\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta))+\big(f,\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\big)_2\\
&\quad\le M\|u^\delta\|_{H^1_o}\left(\|\beta(u^\delta-\varphi^\delta)\|_{H^1_o}+\|\beta(\psi^\delta-u^\delta)\|_{H^1_o}\right)\\
&\qquad+\|f\|_2\left(\|\beta(u^\delta-\varphi^\delta)\|_2+\|\beta(\psi^\delta-u^\delta)\|_2\right)\\
&\quad\le\left(M\|u^\delta\|_{H^1_o}+\|f\|_2\right)\left(\|\beta(u^\delta-\varphi^\delta)\|_{H^1_o}+\|\beta(\psi^\delta-u^\delta)\|_{H^1_o}\right).
\end{aligned}$$

As $\beta(0)=0$ and $0\le\beta'\le 1$, then $\|\beta(v)\|_2\le\|v\|_2$. In addition,

$$\frac{\partial\beta(v)}{\partial x_i}=\beta'(v)\frac{\partial v}{\partial x_i}$$

yields that $\|\nabla\beta(v)\|_2\le\|\nabla v\|_2$. Finally, $\|\beta(v)\|_{H^1_o(\Omega)}\le\|v\|_{H^1_o(\Omega)}$, and we get

$$\|\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\|_2^2\le\delta\left(M\|u^\delta\|_{H^1_o}+\|f\|_2\right)\left(\|u^\delta-\varphi^\delta\|_{H^1_o}+\|\ \psi^\delta-u^\delta\|_{H^1_o}\right).$$

With estimates (2.5) and (2.6) we obtain

$$\|\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\|_2^2\le\delta\left(C_3\|\varphi^\delta\|_{H^1_o}+\|f\|_2\right)\left(C_4\|\varphi^\delta\|_{H^1_o}+C_5\|\psi^\delta\|_{H^1_o}\right). \tag{2.7}$$

• Now, we consider a sequence $(\varphi^\delta,\psi^\delta)\in U_{ad}$ strongly convergent in $H^1_o(\Omega)$ to some (φ,ψ). As U_{ad} is H^1-closed, $(\varphi,\psi)\in U_{ad}$. In addition, $(\varphi^\delta,\psi^\delta)$ is bounded in $H^1_o(\Omega)$ uniformly with respect to δ. Therefore, estimates (2.5) and/or (2.6) imply the weak convergence of $u^\delta=\mathcal{T}(\varphi^\delta,\psi^\delta)$ to some $u\in H^1_o(\Omega)$.

Relation (2.7) proves that $\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)$ strongly converges to 0 in $L^2(\Omega)$. With the strong convergence of $(\varphi^\delta,\psi^\delta,u^\delta)$ to (φ,ψ,u) in $L^2(\Omega)$ and $0\le\beta'\le 1$, we get $\beta(u-\varphi)-\beta(\psi-u)=0$ and

$$\beta(u-\varphi)=\beta(\psi-u)\qquad\text{a.e. in }\Omega;$$

if $u(x)<\varphi(x)\le\psi(x)$, then $\beta(u-\varphi)(x)<0$ and $\beta(\psi-u)(x)=0$: this is not possible. Similarly, if $\varphi(x)\le\psi(x)<u(x)$, then $\beta(u-\varphi)(x)=0$ and $\beta(\psi-u)(x)>0$. The only remaining possibility is $\varphi\le u\le\psi$, that is, $u\in K(\varphi,\psi)$.

• Let us prove that $u=\mathcal{T}(\varphi,\psi)$. As we already know that $u\in K(\varphi,\psi)$, it is sufficient to prove that

$$\forall v\in K(\varphi,\psi),\qquad a(u,v-u)\ge(f,v-u)_2.$$

We choose $v\in K(\varphi,\psi)$ and set $v^\delta=\inf\left(\sup\left(v,\varphi^\delta\right),\psi^\delta\right)$. Then $v^\delta\in K(\varphi^\delta,\psi^\delta)$ and v^δ strongly converges to v in $H^1_o(\Omega)$. Equation (2.4) with $v=v^\delta-u^\delta$ gives

$$a(u^\delta,v^\delta-u^\delta)=\frac{1}{\delta}\int_\Omega\left(\beta(\psi^\delta-u^\delta)-\beta(u^\delta-\varphi^\delta)\right)(v^\delta-u^\delta)\,dx+\int_\Omega f(v^\delta-u^\delta)\,dx.$$

- ▷ If $\varphi^\delta\le u^\delta\le\psi^\delta$, then $\beta(\psi^\delta-u^\delta)=\beta(u^\delta-\varphi^\delta)=0$.
- ▷ If $u^\delta<\varphi^\delta\le\psi^\delta$, then $\beta(\psi^\delta-u^\delta)=0$ and $v^\delta-u^\delta>0$. As $\beta(u^\delta-\varphi^\delta)\le 0$, we get $(\beta(\psi^\delta-u^\delta)-\beta(u^\delta-\varphi^\delta))(v^\delta-u^\delta)\ge 0$.
- ▷ If $\varphi^\delta\le\psi^\delta<u^\delta$, then $\beta(u^\delta-\varphi^\delta)=0$ and $v^\delta-u^\delta<0$. As $\beta(\psi^\delta-u^\delta)\le 0$, so that $(\beta(\psi^\delta-u^\delta)-\beta(u^\delta-\varphi^\delta))(v^\delta-u^\delta)\ge 0$.

Finally,

$$a(u^\delta, v^\delta - u^\delta) \geq (f, v^\delta - u^\delta)_2,$$
$$a(u^\delta, u^\delta) \leq a(u^\delta, v^\delta) - (f, v^\delta - u^\delta)_2.$$

We may pass to the limit and use the lower semicontinuity of a:

$$a(u,u) \leq \liminf_{\delta\to 0} a(u^\delta, u^\delta) \leq \lim_{\delta\to 0} a(u^\delta, v^\delta) - (f, v^\delta - u^\delta)_2 = a(u,v) - (f, v-u)_2.$$

This gives $a(u, v-u) \geq (f, v-u)_2$ for every $v \in K(\varphi,\psi)$ and $u = \mathcal{T}(\varphi,\psi)$.

• It remains to prove the strong convergence of u^δ to u in $H^1_o(\Omega)$. We again use $w^\delta = \inf(\sup(u, \varphi^\delta), \psi^\delta)$ that strongly converges to u in $H^1_o(\Omega)$. It is sufficient to prove that $w^\delta - u^\delta$ strongly converges to 0 in $H^1_o(\Omega)$. We use (2.4) once again:

$$a(w^\delta - u^\delta, w^\delta - u^\delta) = a(w^\delta, w^\delta - u^\delta) - a(u^\delta, w^\delta - u^\delta)$$
$$= a(w^\delta, w^\delta - u^\delta) + \frac{1}{\delta}\int_\Omega \big(\beta(u^\delta - \varphi^\delta) - \beta(\psi^\delta - u^\delta)\big)(w^\delta - u^\delta)\,dx - \int_\Omega f(w^\delta - u^\delta)\,dx\,.$$

A similar analysis as above shows that $(\beta(u^\delta - \varphi^\delta) - \beta(\psi^\delta - u^\delta))(w^\delta - u^\delta) \leq 0$ a.e. in Ω. Thus

$$a(w^\delta - u^\delta, w^\delta - u^\delta) \leq a(w^\delta, w^\delta - u^\delta) - \big(f, w^\delta - u^\delta\big)_2\,,$$
$$\alpha\|w^\delta - u^\delta\|^2_{H^1_o(\Omega)} \leq a(w^\delta, w^\delta - u^\delta) - \big(f, w^\delta - u^\delta\big)_2\,.$$

The right-hand side is convergent to 0 (with the strong convergence of w^δ to u in $H^1_o(\Omega)$ and the weak convergence of $w^\delta - u^\delta$ to 0 in $H^1_o(\Omega)$). Therefore $w^\delta - u^\delta \to 0$ strongly in $H^1_o(\Omega)$. □

Remark 2.1. Note that the sequence $(\varphi^\delta, \psi^\delta)$ belongs to $H^2(\Omega)\times H^2(\Omega)$, and it is sufficient to assume that $(\varphi^\delta, \psi^\delta)$ weakly converges to some (φ,ψ) in $H^2(\Omega)\times H^2(\Omega)$ to get the conclusion of Theorem 2.1.

COROLLARY 2.1. *For any $(\varphi,\psi) \in U_{ad}$, the sequence $u^\delta = \mathcal{T}^\delta(\varphi,\psi)$ strongly converges to $u = \mathcal{T}(\varphi,\psi)$ in $H^1_o(\Omega)$.*

COROLLARY 2.2. *There exists a constant C depending only on f and a such that, for any $(\varphi,\psi) \in U_{ad}$,*

$$\|\mathcal{T}(\varphi,\psi)\|_{H^1_o(\Omega)} \leq C \min\big(\|\varphi\|_{H^1_o(\Omega)}, \|\psi\|_{H^1_o(\Omega)}\big)\,. \tag{2.8}$$

Proof. We choose $\varphi^\delta = \varphi$, $\psi^\delta = \psi$, and $u^\delta = \mathcal{T}^\delta(\varphi,\psi)$; as u^δ strongly converges to $\mathcal{T}(\varphi,\psi)$ in $H^1_o(\Omega)$, we pass to the limit in (2.5) and (2.6). □

Let us conclude this section with a continuity result for the operator $\mathcal{T}$.

THEOREM 2.2. *$\mathcal{T}$ is continuous from U_{ad} endowed with the $H^2(\Omega)\times H^2(\Omega)$ sequential weak topology to $H^1_o(\Omega)$ endowed with the sequential weak topology.*

Proof. Assume that $(\varphi_k, \psi_k) \in U_{ad}$ is a sequence that weakly converges to (φ,ψ) in $H^2(\Omega)\times H^2(\Omega)$. Then (φ,ψ) belongs to U_{ad}, and (φ_k,ψ_k) strongly converges to (φ,ψ) in $H^1_o(\Omega)\times H^1_o(\Omega)$ as well. We set $u_k = \mathcal{T}(\varphi_k,\psi_k)$.

Let $v \in K(\varphi,\psi)$ and set (as previously) $v_k = \inf(\sup(v,\varphi_k),\psi_k) \in K(\varphi_k,\psi_k)$ that strongly converges to v in $H^1_o(\Omega)$. As $u_k = \mathcal{T}(\varphi_k,\psi_k)$, we get $a(u_k, v_k - u_k) \geq (f, v_k - u_k)_2$, that is,

$$a(u_k,u_k) \geq a(u_k, v_k) - (f, v_k - u_k)_2.$$

Using Corollary 2.2, u_k is bounded in $H_o^1(\Omega)$ and weakly converges to some u (up to a subsequence). Using the lower semicontinuity of a in the previous relation gives

$$a(u,u) \geq a(u,v) - (f, v-u)_2.$$

In addition, $\varphi_k \leq u_k \leq \psi_k$ implies $\varphi \leq u \leq \psi$. Therefore $u = \mathcal{T}(\varphi,\psi)$, and the whole sequence converges. ∎

Now, we turn back to the optimal control problem $(\mathcal{P})$. We first give an existence result for the solution.

THEOREM 2.3. *Problem $(\mathcal{P})$ has (at least) an optimal solution (φ^*, ψ^*).*

Proof. Let (φ_k, ψ_k) be a minimizing sequence. As $J(\varphi_k, \psi_k)$ is bounded, φ_k and ψ_k are H^2-bounded and converge to some φ^* and ψ^*, respectively, weakly in $H^2(\Omega)$ (and strongly in $H_o^1(\Omega)$ (up to a subsequence)). The weak cluster point belongs to U_{ad} and with Theorem 2.2 we know that $u_k = \mathcal{T}(\varphi_k, \psi_k)$ weakly converges to $u^* = \mathcal{T}(\varphi^*, \psi^*)$ in $H_o^1(\Omega)$. Then,

$$\begin{aligned} J(\varphi^*, \psi^*) &= \frac{1}{2}\int_\Omega (\mathcal{T}(\varphi^*, \psi^*) - z)^2 dx + \frac{\nu}{2}\int_\Omega \left((\Delta\varphi^*)^2 + (\Delta\psi^*)^2\right) dx \\ &\leq \liminf_{k\to\infty} J(\varphi_k, \psi_k) = \inf(\mathcal{P}). \end{aligned}$$

Thus (φ^*, ψ^*) is an optimal solution to $(\mathcal{P})$. ∎

3. Optimality system.

3.1. An approximate problem. We first consider an approximate problem and establish an optimality system for this problem. Let (φ^*, ψ^*) be an optimal solution to $(\mathcal{P})$ and $u^* = \mathcal{T}(\varphi^*, \psi^*)$. For any $\delta > 0$, we define

$$J_\delta(\varphi,\psi) \stackrel{def}{=} \frac{1}{2}\left[\int_\Omega \left(\mathcal{T}^\delta(\varphi,\psi) - z\right)^2 dx + \nu\int_\Omega \left((\Delta\varphi)^2 + (\Delta\psi)^2\right) dx + \|\varphi-\varphi^*\|_2^2 + \|\psi-\psi^*\|_2^2\right].$$

The last term in J_δ is an adapted penalization term that focuses on a chosen solution (φ^*, ψ^*). Let us define an approximate optimal control problem as follows:

$$(\mathcal{P}_\delta) \qquad \min\{J_\delta(\varphi,\psi),\ (\varphi,\psi) \in U_{ad}\}.$$

THEOREM 3.1. *Problem $(\mathcal{P}_\delta)$ has (at least) an optimal solution $(\varphi^\delta, \psi^\delta)$. Moreover, the sequence $(\varphi^\delta, \psi^\delta)$ weakly converges to (φ^*, ψ^*) in $H^2(\Omega)$, while $u^\delta = \mathcal{T}^\delta(\varphi^\delta, \psi^\delta)$ strongly converges to $u^* = \mathcal{T}(\varphi^*, \psi^*)$ in $H_o^1(\Omega)$.*

Proof. The functional J_δ is obviously lower semicontinuous and coercive. Therefore, Problem $(\mathcal{P}_\delta)$ has (at least) an optimal solution $(\varphi^\delta, \psi^\delta)$. We call $u^\delta = \mathcal{T}^\delta(\varphi^\delta, \psi^\delta)$ and note that, for any $\delta > 0$,

$$J_\delta(\varphi^\delta, \psi^\delta) \leq J_\delta(\varphi^*, \psi^*) = \frac{1}{2}\left[\int_\Omega \left(\mathcal{T}^\delta(\varphi^*, \psi^*) - z\right)^2 dx + \nu\int_\Omega \left((\Delta\varphi^*)^2 + (\Delta\psi^*)^2\right) dx\right]; \tag{3.1}$$

using Corollary 2.1, $\mathcal{T}^\delta(\varphi^*, \psi^*) \to u^* = \mathcal{T}(\varphi^*, \psi^*)$ strongly in $H_o^1(\Omega)$, and $J_\delta(\varphi^*, \psi^*) \to J(\varphi^*, \psi^*)$. Therefore, there exist $\delta_o > 0$ and a constant j^* such that

$$\forall \delta \leq \delta_o, \qquad J_\delta(\varphi^\delta, \psi^\delta) \leq j^* < +\infty.$$

Therefore φ^δ and ψ^δ are H^2-bounded uniformly with respect to $\delta \leq \delta_o$. We apply Theorem 2.1: up to subsequences, we get

$$\varphi^\delta \to \tilde{\varphi} \text{ and } \psi^\delta \to \tilde{\psi} \text{ weakly in } H^2(\Omega) \text{ and strongly in } H_o^1(\Omega) \text{ and}$$
$$u^\delta \to \tilde{u} = \mathcal{T}(\tilde{\varphi}, \tilde{\psi}) \text{ strongly in } H_o^1(\Omega).$$

As U_{ad} is weakly closed, then $(\tilde{\varphi}, \tilde{\psi}) \in U_{ad}$. Using the lower semicontinuity of J_δ and (3.1), we obtain

$$\begin{aligned} J(\tilde{\varphi}, \tilde{\psi}) + \frac{1}{2}\|\tilde{\varphi} - \varphi^*\|_2^2 + \frac{1}{2}\|\tilde{\psi} - \psi^*\|_2^2 &\leq \liminf_{\delta \to 0} J_\delta(\varphi^\delta, \psi^\delta) \\ &\leq \limsup_{\delta \to 0} J_\delta(\varphi^\delta, \psi^\delta) \\ &\leq \lim_{\delta \to 0} J_\delta(\varphi^*, \psi^*) = J(\varphi^*, \psi^*) \\ &\leq J(\tilde{\varphi}, \tilde{\psi}). \end{aligned}$$

Here, we used that $(\tilde{\varphi}, \tilde{\psi})$ is an admissible pair for problem $(\mathcal{P})$. This yields that $\|\tilde{\varphi} - \varphi^*\|_2^2 + \|\tilde{\psi} - \psi^*\|_2^2 \leq 0$; thus $\tilde{\varphi} = \varphi^*$, $\tilde{\psi} = \psi^*$, and the whole sequence is convergent. In addition,

$$\lim_{\delta \to 0} J_\delta(\varphi^\delta, \psi^\delta) = J(\varphi^*, \psi^*). \qquad \square$$

3.2. An approximate optimality system. We first establish a (necessary) optimality system for $(\mathcal{P}_\delta)$, using the following result on the Gâteaux-derivative of the operator $\mathcal{T}^\delta$.

LEMMA 3.1. *The mapping $\mathcal{T}^\delta$ is Gâteaux-differentiable at any $(\varphi, \psi) \in U_{ad}$:*

$$\forall (\xi, \eta) \in H_o^1(\Omega) \times H_o^1(\Omega), \quad \frac{\mathcal{T}^\delta(\varphi + t\xi, \psi + t\,\eta) - \mathcal{T}^\delta(\varphi, \psi)}{t} \overset{w}{\rightharpoonup} v^\delta \text{ in } H_o^1(\Omega), \text{ as } t \to 0,$$

where v^δ is the solution of the sensitivity equation

$$\begin{aligned} &Av^\delta + \frac{1}{\delta}\left(\beta'(w^\delta - \varphi) + \beta'(\psi - w^\delta)\right) v^\delta = \frac{1}{\delta}\left(\beta'(w^\delta - \varphi)\,\xi + \beta'(\psi - w^\delta)\,\eta\right) \text{ in } \Omega, \\ &v^\delta = 0 \text{ on } \partial\Omega, \end{aligned}$$

where $w^\delta = \mathcal{T}^\delta(\varphi, \psi)$.

Proof. The proof is similar to [3, Lemma 5.1]. $\square$

In what follows, we keep the notation of subsection 3.1. As usual we define the (approximate) adjoint state of the problem as the solution $p^\delta \in H_o^1(\Omega)$ of

$$A^* p^\delta + \frac{1}{\delta}\left(\beta'(u^\delta - \varphi^\delta) + \beta'(\psi^\delta - u^\delta)\right) p^\delta = u^\delta - z \text{ in } \Omega, \ p^\delta = 0 \text{ on } \partial\Omega,$$

where A^* denotes the adjoint operator of A. As $(\varphi^\delta, \psi^\delta)$ is a solution to $(\mathcal{P}_\delta)$, we have

$$\forall (\varphi, \psi) \in U_{ad}, \qquad \frac{d}{dt} J_\delta\left(\varphi^\delta + t(\varphi - \varphi^\delta), \psi^\delta + t(\psi - \psi^\delta)\right)_{|t=0} \geq 0.$$

This gives

$$\begin{aligned} \int_\Omega \left(\chi^\delta(u^\delta - z) + \nu\Delta\varphi^\delta\Delta(\varphi - \varphi^\delta) + \nu\Delta\psi^\delta\Delta(\psi - \psi^\delta)\right) dx \\ + \int_\Omega \left((\varphi^\delta - \varphi^*)(\varphi - \varphi^\delta) + (\psi^\delta - \psi^*)(\psi - \psi^\delta)\right) dx \geq 0, \end{aligned}$$

where $\chi^\delta \in H_o^1(\Omega)$ satisfies

$$\begin{aligned} &A\chi^\delta + \frac{1}{\delta}\left(\beta'(u^\delta - \varphi^\delta) + \beta'(\psi^\delta - u^\delta)\right)\chi^\delta \\ &\quad = \frac{1}{\delta}\left(\beta'(u^\delta - \varphi^\delta)(\varphi - \varphi^\delta) + \beta'(\psi^\delta - u^\delta)(\psi - \psi^\delta)\right) \text{ in } \Omega. \end{aligned}$$

Using the definition of p^δ, we obtain

$$a^*(p^\delta,\chi^\delta)+\int_\Omega \frac{\beta'(u^\delta-\varphi^\delta)+\beta'(\psi^\delta-u^\delta)}{\delta}p^\delta\chi^\delta dx + \nu\int_\Omega \left(\Delta\varphi^\delta\Delta(\varphi-\varphi^\delta)+\Delta\psi^\delta\Delta(\psi-\psi^\delta)\right)dx + \int_\Omega \left((\varphi^\delta-\varphi^*)(\varphi-\varphi^\delta)+(\psi^\delta-\psi^*)(\psi-\psi^\delta)\right)\,dx\geq 0.$$

Here a^* denotes the adjoint form of a (associated with the adjoint operator A^*). Then,

$$a(\chi^\delta,p^\delta)+\int_\Omega \frac{\beta'(u^\delta-\varphi^\delta)+\beta'(\psi^\delta-u^\delta)}{\delta}\chi^\delta p^\delta dx + \nu\int_\Omega \left(\Delta\varphi^\delta\Delta(\varphi-\varphi^\delta)+\Delta\psi^\delta\Delta(\psi-\psi^\delta)\right)dx + \int_\Omega \left((\varphi^\delta-\varphi^*)(\varphi-\varphi^\delta)+(\psi^\delta-\psi^*)(\psi-\psi^\delta)\right)\,dx\geq 0;$$

we obtain

$$\int_\Omega \frac{\beta'(u^\delta-\varphi^\delta)}{\delta}p^\delta(\varphi-\varphi^\delta)+\frac{\beta'(\psi^\delta-u^\delta)}{\delta}p^\delta(\psi-\psi^\delta)\,dx + \nu\int_\Omega \left(\Delta\varphi^\delta\Delta(\varphi-\varphi^\delta)+\Delta\psi^\delta\Delta(\psi-\psi^\delta)\right)dx + \int_\Omega \left((\varphi^\delta-\varphi^*)(\varphi-\varphi^\delta)+(\psi^\delta-\psi^*)(\psi-\psi^\delta)\right)\,dx\geq 0.$$

In what follows we set

$$\mu_1^\delta=\frac{\beta'(u^\delta-\varphi^\delta)}{\delta}p^\delta,\quad \mu_2^\delta=\frac{\beta'(\psi^\delta-u^\delta)}{\delta}p^\delta,\quad \text{and } \mu^\delta=\mu_1^\delta+\mu_2^\delta\,(\in L^2(\Omega)). \tag{3.2}$$

Finally, we obtain the following result.

THEOREM 3.2. *Assume that $(\varphi^\delta,\psi^\delta)$ is an optimal solution to $(\mathcal{P}_\delta)$ and $u^\delta=\mathcal{T}^\delta(\varphi^\delta,\psi^\delta)$. Then there exist $p^\delta\in H_o^1(\Omega)\cap H^2(\Omega)$ and $\mu_1^\delta,\mu_2^\delta\in L^2(\Omega)$ such that the following optimality system is satisfied:*

$$Au^\delta+\frac{1}{\delta}\left(\beta(u^\delta-\varphi^\delta)-\beta(\psi^\delta-u^\delta)\right)=f \text{ in } \Omega,\ u^\delta=0 \text{ on } \partial\Omega, \tag{3.3a}$$

$$A^*p^\delta+\mu_1^\delta+\mu_2^\delta=u^\delta-z \text{ in } \Omega,\ p^\delta=0 \text{ on } \partial\Omega, \tag{3.3b}$$

$$\forall(\varphi,\psi)\in U_{ad},\quad \left(\mu_1^\delta+\varphi^\delta-\varphi^*,\varphi-\varphi^\delta\right)_2+\left(\mu_2^\delta+\psi^\delta-\psi^*,\psi-\psi^\delta\right)_2 + \nu\left(\Delta\varphi^\delta,\Delta(\varphi-\varphi^\delta)\right)_2+\nu\left(\Delta\psi^\delta,\Delta(\psi-\psi^\delta)\right)_2\geq 0. \tag{3.3c}$$

Let us give additional properties of μ_1^δ and μ_2^δ, as follows.

PROPOSITION 3.1. *The supports of μ_1^δ and μ_2^δ are disjoint so that*

$$\left(\mu_1^\delta,\mu_2^\delta\right)_2=0 \text{ and } \|\mu^\delta\|_2^2=\|\mu_1^\delta\|_2^2+\|\mu_2^\delta\|_2^2.$$

It follows that

$$\mu^\delta=\begin{cases}\mu_1^\delta & \text{on } \{\ x\in\Omega|\ u^\delta(x)<\varphi^\delta(x)\ \}\overset{def}{=}\omega_\delta^1,\\ \mu_2^\delta & \text{on } \{\ x\in\Omega|\ u^\delta(x)>\psi^\delta(x)\ \}\overset{def}{=}\omega_\delta^2,\\ 0 & \text{elsewhere.}\end{cases} \tag{3.4}$$

Moreover, $\mu_i^\delta\in H_o^1(\Omega)$ for $i=1,2$.

Proof. The first assertion is clear because of the definition of μ_i^δ. Note that ω_δ^i are open subsets of Ω since u^δ, ϕ^δ, and ψ^δ are continuous ($n \le 3$).

Let us compute the derivative of μ_1^δ in the distribution sense (the same proof holds for μ_2^δ); we recall that $\mu_1^\delta = \frac{\eta(u^\delta - \varphi^\delta)}{\delta}\, p^\delta$, where

$$\eta(r) = \begin{cases} 0 & \text{if } r \ge 0, \\ -2r & \text{if } r \in [-\frac{1}{2}, 0], \\ 1 & \text{if } r \le -\frac{1}{2}. \end{cases}$$

The function η is derivable as a distribution, and its derivative is

$$\eta'(r) = \begin{cases} 0 & \text{if } r \in \,]-\infty - \frac{1}{2}[\cup]0, +\infty[, \\ -2 & \text{if } r \in [-\frac{1}{2}, 0], \end{cases}$$

because η is continuous and piecewise $\mathcal{C}^1$. So μ_1^δ is differentiable in the distribution sense and

$$\frac{\partial \mu_1^\delta}{\partial x_i} = \frac{1}{\delta}\,\eta'(u^\delta - \varphi^\delta)\,\frac{\partial (u^\delta - \varphi^\delta)}{\partial x_i}\,p^\delta + \frac{1}{\delta}\,\eta(u^\delta - \varphi^\delta)\frac{\partial p^\delta}{\partial x_i}\ .$$

As $\eta(u^\delta - \varphi^\delta), \eta'(u^\delta - \varphi^\delta) \in L^\infty(\Omega)$, $p^\delta \in H^2(\Omega) \cap H_o^1(\Omega) \subset L^\infty(\Omega)$ (since $n \le 3$), and $\frac{\partial (u^\delta - \varphi^\delta)}{\partial x_i}, \frac{\partial p^\delta}{\partial x_i} \in L^2(\Omega)$, then $\frac{\partial \mu_1^\delta}{\partial x_i} \in L^2(\Omega)$. Therefore $\mu_1^\delta \in H^1(\Omega)$. As $\mu_1^\delta = 0$ on $\partial\Omega$ (since $p^\delta \in H_o^1(\Omega)$), then $\mu_1^\delta \in H_o^1(\Omega)$. ∎

3.3. Optimality system for ($\mathcal{P}$). We would like to pass to the limit in the previous system. We already know the weak convergence of $(\varphi^\delta, \psi^\delta)$ in H^2 and the strong convergence of u^δ in $H_o^1(\Omega)$. We have to estimate p^δ and μ_i^δ, $i = 1, 2$.

THEOREM 3.3. *When $\delta \to 0$, p^δ weakly converges in $H_o^1(\Omega)$ to some p^* (taking a subsequence). The sequence μ^δ is bounded in $H^{-1}(\Omega)$ and weakly converges to some $\mu^* \in H^{-1}(\Omega)$.*

Proof. We use (3.3b) to obtain

$$a^*(p^\delta, p^\delta) + \int_\Omega \frac{\beta'(u^\delta - \varphi^\delta) + \beta'(\psi^\delta - u^\delta)}{\delta}(p^\delta)^2\,dx = \left(u^\delta - z, p^\delta\right)_2. \tag{3.5}$$

As $\beta' \ge 0$, this implies

$$\alpha \|p^\delta\|^2_{H_o^1(\Omega)} \le \|u^\delta - z\|_2 \|p^\delta\|_2,$$

$$\|p^\delta\|_{H_o^1(\Omega)} \le \frac{1}{\alpha}\|u^\delta - z\|_2. \tag{3.6}$$

This implies that p^δ weakly converges to some p^* in $H_o^1(\Omega)$. Therefore $A^* p^\delta$ is bounded in $H^{-1}(\Omega)$ uniformly with respect to δ and $\mu^\delta = -A^* p^\delta + u^\delta - z$ as well. Thus, there exists $\mu^* \in H^{-1}(\Omega)$ such that μ^δ weakly converges to μ^* in $H^{-1}(\Omega)$. Therefore we may pass to the limit in (3.3b); this gives

$$A^* p^* + \mu^* = u^* - z \text{ in } \Omega,\ p^* = 0 \text{ on } \partial\Omega\ . \tag{3.7}$$ ∎

Let $\chi \in H^2(\Omega) \cap H_o^1(\Omega)$ and choose $\varphi = \varphi^\delta + \chi$, $\psi = \psi^\delta + \chi$. Obviously, $(\varphi, \psi) \in U_{ad}$, and we use relation (3.3c) to obtain

$$\left(\mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^*, \chi\right)_2 + \nu\left(\Delta\varphi^\delta + \Delta\psi^\delta, \Delta\chi\right)_2 \ge 0;$$

that is (since we have chosen any $\chi \in H^2(\Omega) \cap H_o^1(\Omega)$), $\forall \chi \in H^2(\Omega) \cap H_o^1(\Omega)$,

$$\left(\mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^*, \chi\right)_2 + \nu \left(\Delta\varphi^\delta + \Delta\psi^\delta, \Delta\chi\right)_2 = 0. \tag{3.8}$$

Let us set $h^\delta = (\Delta\varphi^\delta + \Delta\psi^\delta) \in L^2(\Omega)$ so that relation (3.8) reads

$$\forall \chi \in H^2(\Omega) \cap H_o^1(\Omega), \qquad \left(\mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^*, \chi\right)_2 + \nu \left(h^\delta, \Delta\chi\right)_2 = 0.$$

Using the previous relation with $\chi \in \mathcal{D}(\Omega)$ gives

$$-\nu\, \Delta h^\delta = \mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^* \tag{3.9}$$

in the sense of distributions, and relation (3.8) is equivalent to

$$\forall \chi \in H^2(\Omega) \cap H_o^1(\Omega), \qquad \left(-\Delta h^\delta, \chi\right)_2 + \left(h^\delta, \Delta\chi\right)_2 = 0. \tag{3.10}$$

As $\mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^* \in L^2(\Omega)$, we have

$$h^\delta \in \mathcal{V} \stackrel{def}{=} \{\ h \in L^2(\Omega)\ \mid\ \Delta h \in L^2(\Omega)\ \}.$$

Therefore, the traces $h^\delta_{|\partial\Omega}$ and $\frac{\partial h^\delta}{\partial n}{}_{|\partial\Omega}$ can be defined in $H^{-1/2}(\partial\Omega)$ and $H^{-3/2}(\partial\Omega)$, respectively (see Lions [15, p. 229], for example). Using a generalized Greens' formula gives

$$\left(h^\delta, \Delta\chi\right)_2 = \left(\Delta h^\delta, \chi\right)_2 + \int_{\partial\Omega} h^\delta \frac{\partial\chi}{\partial n}\, d\sigma$$

for any $\chi \in H^2(\Omega) \cap H_o^1(\Omega)$. Then with (3.10) we obtain

$$\forall \chi \in H^2(\Omega) \cap H_o^1(\Omega), \qquad \int_{\partial\Omega} h^\delta \frac{\partial\chi}{\partial n}\, d\sigma = 0,$$

that is, with the surjectivity of the trace application (see Lions and Magenes [16, p. 47]),

$$\forall \zeta \in H^{\frac{1}{2}}(\partial\Omega), \qquad \int_{\partial\Omega} h^\delta \zeta\, d\sigma = 0.$$

This implies $h^\delta_{|\partial\Omega} = 0$. Therefore, h^δ is the unique solution of

$$-\nu\Delta h^\delta = \mu^\delta + \varphi^\delta - \varphi^* + \psi^\delta - \psi^* \in L^2(\Omega), \qquad h^\delta = 0 \text{ on } \partial\Omega,$$

and belongs to $H^2(\Omega) \cap H_o^1(\Omega)$. Moreover, we know that μ^δ is weakly convergent to μ^* in $H^{-1}(\Omega)$ and that $(\varphi^\delta, \psi^\delta)$ is strongly convergent to (φ^*, ψ^*) in $H_o^1(\Omega)$. Therefore h^δ is weakly convergent to h^* weakly in $H_o^1(\Omega)$ and $-\nu\Delta h^* = \mu^*$. Uniqueness of the limit implies that $h^* = \Delta(\varphi^* + \psi^*)$.

As $0 \le \beta' \le 1$, we get with (3.5)

$$a^*(p^\delta, p^\delta) \le \left(u^\delta - z, p^\delta\right)_2.$$

Using the lower semicontinuity of a^* gives

$$a^*(p^*, p^*) \le \liminf_{\delta \to +\infty} \left(u^\delta - z, p^\delta\right)_2 = \left(u^* - z, p^*\right)_2.$$

Thus, with (3.7) we get

$$\langle A^*p^*, p^*\rangle = (u^* - z, p^*)_2 - \langle \mu^*, p^*\rangle \le (u^* - z, p^*)_2\,,$$

where $\langle\cdot,\cdot\rangle$ denotes the (H^{-1}, H^1_o) duality pairing. Thus $\langle \mu^*, p^*\rangle \ge 0$. Therefore, we obtain the following optimality system.

THEOREM 3.4. *Let (φ^*, ψ^*) be an optimal solution to $(\mathcal{P})$. Then $\Delta(\varphi^* + \psi^*) \in H^1_o(\Omega)$ and there exist $p^* \in H^1_o(\Omega)$ and $\lambda^* \ge 0$ in $H^{-1}(\Omega)$ such that the following optimality system is satisfied:*

$$u^* = \mathcal{T}(\varphi^*, \psi^*), \tag{3.11a}$$

$$A^*p^* = u^* - z^* - \mu^* \text{ in } \Omega,\ p^* = 0 \text{ on } \partial\Omega, \tag{3.11b}$$

$$\langle p^*, \mu^*\rangle \ge 0, \tag{3.11c}$$

$$\mu^* = \mu_1^* + \mu_2^*, \text{ with } \mu_1^* = -\lambda^* - \nu\Delta^2\varphi^* \text{ and } \mu_2^* = \lambda^* - \nu\Delta^2\psi^*, \tag{3.11d}$$

$$\langle \lambda^*, \varphi^* - u^*\rangle = 0 \text{ and } \langle \lambda^*, u^* - \psi^*\rangle = 0. \tag{3.11e}$$

Proof. We have already proved (3.11a)–(3.11c). It remains to show (3.11d) and (3.11e).

Setting $\varphi = \varphi^\delta - \chi$ and $\psi = \psi^\delta$ in relation (3.3c) with $\chi \in H^2(\Omega) \cap H^1_o(\Omega)$, $\chi \ge 0$, we get

$$\forall \chi \ge 0, \qquad \left(\mu_1^\delta + \varphi^\delta - \varphi^*, \chi\right)_2 + \nu\left(\Delta\varphi^\delta, \Delta\chi\right)_2 \le 0.$$

The application $\chi \mapsto (\mu_1^\delta + \varphi^\delta - \varphi^*, \chi)_2 + \nu(\Delta\varphi^\delta, \Delta\chi)_2$ from $H^2(\Omega) \cap H^1_o(\Omega)$ to $\mathbb{R}$ is clearly linear and continuous. Therefore, there exists a measure λ_1^δ (in the dual of $H^2(\Omega) \cap H^1_o(\Omega)$) such that

$$\left(\mu_1^\delta + \varphi^\delta - \varphi^*, \chi\right)_2 + \nu\left(\Delta\varphi^\delta, \Delta\chi\right)_2 = \left\langle \lambda_1^\delta, \chi\right\rangle.$$

As $\langle \lambda_1^\delta, \chi\rangle \le 0$, then λ_1^δ is a nonpositive measure. If we choose $\chi \in \mathcal{D}(\Omega)$, we get

$$\left(\mu_1^\delta + \varphi^\delta - \varphi^*, \chi\right)_2 + \nu\left(\Delta^2\varphi^\delta, \chi\right)_2 = \left\langle \lambda_1^\delta, \chi\right\rangle$$

in $\mathcal{D}'(\Omega)$, so that the measure is

$$\lambda_1^\delta = \mu_1^\delta + \varphi^\delta - \varphi^* + \nu\Delta^2\varphi^\delta.$$

Similarly, there exists a nonnegative measure: $\lambda_2^\delta = \mu_2^\delta + \psi^\delta - \psi^* + \nu\Delta^2\psi^\delta$.
In addition, we have seen that

$$\mu_1^\delta + \mu_2^\delta = \mu^\delta = -\nu\Delta h^\delta - (\varphi^\delta - \varphi^* + \psi^\delta - \psi^*),$$

where $h^\delta = (\Delta\varphi^\delta + \Delta\psi^\delta) \in H^2(\Omega) \cap H^1_o(\Omega)$. Thus

$$\lambda_1^\delta + \lambda_2^\delta = 0.$$

Finally we get the existence of a nonnegative measure λ^δ such that

$$\mu_1^\delta = -(\lambda^\delta + \varphi^\delta - \varphi^* + \nu\Delta^2\varphi^\delta) \text{ and } \mu_2^\delta = \lambda^\delta - (\psi^\delta - \psi^* + \nu\Delta^2\psi^\delta). \tag{3.12}$$

Now we claim that μ_i^δ, $i = 1, 2$, are bounded as measures by a constant independent of δ. Indeed, we use the following result: *let ω be an open subset of Ω and $\mu \in L^2(\Omega)$ $(\subset H^{-1}(\Omega))$. Then $\mu_{|\omega} \in H^{-1}(\omega)$ and $\|\mu_{|\omega}\|_{H^{-1}(\omega)} \le \|\mu\|_{H^{-1}(\Omega)}$.*

We have noticed with relation (3.4) that $\mu_{i|_{\omega_i^\delta}}^\delta = \mu_i^\delta$ for $i = 1, 2$. Moreover, the support of μ_i^δ is included in ω_i^δ and $\mu_i^\delta \in L^2(\Omega)$; thus

$$\|\mu_i^\delta\|_{H^{-1}(\Omega)} = \sup_{\substack{\varphi \in H_o^1(\Omega) \\ \|\varphi\|_{H_o^1} \leq 1}} \left\langle \mu_i^\delta, \varphi \right\rangle_{H^{-1}, H_o^1} = \sup_{\substack{\varphi \in H_o^1(\Omega) \\ \|\varphi\|_{H_o^1} \leq 1}} \left(\mu_i^\delta, \varphi\right)_{L^2(\omega_i^\delta)} = \sup_{\substack{\varphi \in H_o^1(\omega_i^\delta) \\ \|\varphi\|_{H_o^1} \leq 1}} \left\langle \mu_i^\delta, \varphi \right\rangle_{H^{-1}, H_o^1}$$

$$= \|\mu_i^\delta\|_{H^{-1}(\omega_i^\delta)} = \|\mu_{|_{\omega_i^\delta}}^\delta\|_{H^{-1}(\omega_i^\delta)} \leq \|\mu^\delta\|_{H^{-1}(\Omega)}.$$

As μ^δ is bounded in $H^{-1}(\Omega)$, then μ_i^δ is bounded in $H^{-1}(\Omega)$ as well by a constant independent of δ. Therefore μ_i^δ converges to μ_i^* (as a measure) and λ^δ converges to a nonnegative measure λ^*, as well, with

$$\mu_1^* = -\lambda^* - \nu\Delta^2\varphi^* \text{ and } \mu_2^* = \lambda^* - \nu\Delta^2\psi^* \ .$$

Let us show the complementarity relation (3.11e). Inserting (3.12) into relation (3.3c) with $\varphi = \psi = u^\delta$ gives

$$\forall \delta, \qquad \left(\lambda^\delta, \varphi^\delta - u^\delta\right) + \left(\lambda^\delta, u^\delta - \psi^\delta\right) \geq 0;$$

passing to the limit with respect to δ yields

$$\langle \lambda^*, \varphi^* - u^* \rangle + \langle \lambda^*, u^* - \psi^* \rangle \geq 0.$$

As $\lambda^* \geq 0$ (as a measure) and $\varphi^* - u^* \leq 0$, $u^* - \psi^* \leq 0$, we get

$$\langle \lambda^*, \varphi^* - u^* \rangle + \langle \lambda^*, u^* - \psi^* \rangle = 0.$$

Note that we have the sum of two terms that are separately nonpositive. Therefore

$$\langle \lambda^*, \varphi^* - u^* \rangle = \langle \lambda^*, u^* - \psi^* \rangle = 0.$$

This achieves the proof. □

4. A particular case. In some particular cases we may obtain a more complete optimality system using monotonicity methods instead of compactness methods. Let us consider the special case where the obstacle H^2-norm that occurs in the cost functional is replaced by the H^1-norm given by the way of the bilinear form a, with

$$a(u, v) = (\nabla u, \nabla v)_2 \text{ and } f \equiv 0.$$

More precisely, we define the following cost functional:

$$\hat{J}(\varphi, \psi) \stackrel{def}{=} \frac{1}{2} \int_\Omega (\mathcal{T}(\varphi, \psi) - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla\varphi\|_2^2 + \|\nabla\psi\|_2^2 \right).$$

In this case, obstacle functions are not necessarily H^2-regular, and the admissible control set is defined as follows:

$$\hat{U}_{ad} = \{ \ (\varphi, \psi) \in H_o^1(\Omega) \times H_o^1(\Omega) \ \mid \ \varphi \leq \psi \ \}.$$

We consider the corresponding optimal control problem:

$$(\hat{\mathcal{P}}) \qquad \min \{ \ \hat{J}(\varphi, \psi) \, , \, (\varphi, \psi) \in \hat{U}_{ad} \ \}.$$

THEOREM 4.1. *Problem* $(\hat{\mathcal{P}})$ *has (at least) an optimal control solution* $(\hat{\varphi}, \hat{\psi})$ *with* $\hat{\varphi} = \hat{\psi} = \hat{u} = \mathcal{T}(\hat{u}, \hat{u})$ *for some* $\hat{u} \in H_o^1(\Omega)$.

Proof. Let $(\varphi_k, \psi_k) \in \hat{U}_{ad}$ be a minimizing sequence:

$$\lim_{k \to +\infty} \hat{J}(\varphi_k, \psi_k) = \inf(\hat{\mathcal{P}}).$$

Therefore, (φ_k, ψ_k) is bounded in $H_o^1(\Omega)$ and weakly converges to some $(\hat{\varphi}, \hat{\psi})$ in $H_o^1(\Omega)$; moreover, $(\hat{\varphi}, \hat{\psi}) \in \hat{U}_{ad}$. Relation (2.8) of Corollary 2.2 yields that $u_k = \mathcal{T}(\varphi_k, \psi_k)$ is bounded in $H_o^1(\Omega)$ as well and weakly converges to some $\hat{u}$ in $H_o^1(\Omega)$. Note that $\hat{u} \in K(\hat{u}, \hat{u})$ and $\forall v \in K(\hat{u}, \hat{u})$, $a(\hat{u}, v - \hat{u}) = 0 = (f, v - \hat{u})_2$. Thus $\hat{u} = \mathcal{T}(\hat{u}, \hat{u})$. As $\hat{J}$ is lower semicontinuous, we have

$$\begin{aligned} \hat{J}(\hat{u}, \hat{u}) &= \frac{1}{2} \int_\Omega (\hat{u} - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla \hat{u}\|_2^2 + \|\nabla \hat{u}\|_2^2 \right) \\ &\leq \liminf_{k \to +\infty} \frac{1}{2} \int_\Omega (u_k - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla u_k\|_2^2 + \|\nabla u_k\|_2^2 \right). \end{aligned}$$

Note that if $u = \mathcal{T}(\varphi, \psi)$, we have

$$\forall v \in K(\varphi, \psi), \qquad (\nabla u, \nabla u)_2 \leq (\nabla u, \nabla v)_2 \ .$$

This gives

$$\forall v \in K(\varphi, \psi), \qquad \|\nabla u\|_2 \leq \|\nabla v\|_2,$$

and with $v = \varphi$ and $v = \psi$,

$$\|\nabla \mathcal{T}(\varphi, \psi)\|_2 \leq \|\nabla \varphi\|_2 \quad \text{and} \quad \|\nabla \mathcal{T}(\varphi, \psi)\|_2 \leq \|\nabla \psi\|_2. \tag{4.1}$$

These inequalities will replace the compactness assumption. Indeed,

$$\begin{aligned} \hat{J}(\hat{u}, \hat{u}) &\leq \liminf_{k \to +\infty} \frac{1}{2} \int_\Omega (u_k - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla \varphi_k\|_2^2 + \|\nabla \psi_k\|_2^2 \right) \\ &= \liminf_{k \to +\infty} \hat{J}(\varphi_k, \psi_k) \\ &= \inf(\hat{\mathcal{P}}). \end{aligned}$$

Thus $(\hat{u}, \hat{u})$ is a solution. □

In this very case, we may give the generic form for the optimal solution, as follows.

THEOREM 4.2. *Any solution* $(\tilde{\varphi}, \tilde{\psi})$ *to* $(\hat{\mathcal{P}})$ *satisfies*

$$\tilde{\varphi} = \tilde{\psi} = \mathcal{T}(\tilde{\varphi}, \tilde{\psi}).$$

Proof. We have just found a solution in this form. Let $(\tilde{\varphi}, \tilde{\psi})$ be another optimal solution, and set $\tilde{u} = \mathcal{T}(\tilde{\varphi}, \tilde{\psi})$. Then

$$\begin{aligned} \hat{J}(\tilde{u}, \tilde{u}) &= \frac{1}{2} \int_\Omega (\tilde{u} - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla \tilde{u}\|_2^2 + \|\nabla \tilde{u}\|_2^2 \right) \\ &\leq \frac{1}{2} \int_\Omega (\tilde{u} - z)^2 \, dx + \frac{\nu}{2} \left(\|\nabla \tilde{\varphi}\|_2^2 + \|\nabla \tilde{\psi}\|_2^2 \right) \text{ with (4.1)} \\ &= \hat{J}(\tilde{\varphi}, \tilde{\psi}) = \inf(\hat{\mathcal{P}}). \end{aligned}$$

Thus $\hat{J}(\tilde{u},\tilde{u}) = \hat{J}(\tilde{\varphi},\tilde{\psi})$ and

$$2\,\|\nabla\tilde{u}\|_2^2 = \|\nabla\tilde{\varphi}\|_2^2 + \|\nabla\tilde{\psi}\|_2^2\ .$$

With (4.1), we get

$$\|\nabla\tilde{\varphi}\|_2^2 + \|\nabla\tilde{\psi}\|_2^2 = \|\nabla\tilde{u}\|_2^2 + \|\nabla\tilde{u}\|_2^2 \le \|\nabla\tilde{u}\|_2^2 + \|\nabla\tilde{\psi}\|_2^2.$$

Therefore $\|\nabla\tilde{\varphi}\|_2^2 \le \|\nabla\tilde{u}\|_2^2$, and with (4.1) we obtain $\|\nabla\tilde{\varphi}\|_2 = \|\nabla\tilde{u}\|_2$ (and $\|\nabla\tilde{\psi}\|_2 = \|\nabla\tilde{u}\|_2$ in a similar way). Moreover, $(\nabla\tilde{u},\nabla\tilde{\varphi})_2 \le \|\nabla\tilde{u}\|_2\|\nabla\tilde{\varphi}\|_2 = \|\nabla\tilde{u}\|_2^2 = \|\nabla\tilde{\varphi}\|_2^2$; as $\tilde{u} = \mathcal{T}(\tilde{\varphi},\tilde{\psi})$, we already have $\|\nabla\tilde{u}\|_2^2 \le (\nabla\tilde{u},\nabla\tilde{\varphi})_2$, so that

$$(\nabla\tilde{u},\nabla\tilde{\varphi})_2 = \|\nabla\tilde{u}\|_2^2 = \|\nabla\tilde{\varphi}\|_2^2\ .$$

Similarly $(\nabla\tilde{u},\nabla\tilde{\psi})_2 = \|\nabla\tilde{u}\|_2^2$. Finally,

$$\|\nabla(\tilde{u}-\tilde{\varphi})\|_2^2 = \|\nabla\tilde{u}\|_2^2 + \|\nabla\tilde{\varphi}\|_2^2 - 2\,(\nabla\tilde{u},\nabla\tilde{\varphi})_2 = 0.$$

Thus $\nabla\tilde{u} = \nabla\tilde{\varphi}$ (and similarly $\nabla\tilde{u} = \nabla\tilde{\psi}$). As $\tilde{u}$, $\tilde{\varphi}$, and $\tilde{\psi}$ belong to $H_o^1(\Omega)$, this gives $\tilde{u} = \tilde{\varphi} = \tilde{\psi}$. □

Let us define $\hat{J}^*$ on $H_o^1(\Omega)$ as follows:

$$\hat{J}^*(w) = \hat{J}(w,w) = \frac{1}{2}\int_\Omega (w-z)^2\,dx + \nu\|\nabla w\|_2^2\ .$$

We have proved that any optimal pair (u,u) satisfies

$$\hat{J}^*(u) = \inf(\hat{\mathcal{P}}).$$

We consider the following optimal control problem:

$$(\hat{\mathcal{P}}^*) \qquad \min\{\ \hat{J}^*(v),\ v \in H_o^1(\Omega)\ \}.$$

It is clear that $(\hat{\mathcal{P}}^*)$ has a unique solution $\hat{u}^*$ since $\hat{J}^*$ is continuous, coercive, and strictly convex on $H_o^1(\Omega)$. Problems $(\hat{\mathcal{P}})$ and $(\hat{\mathcal{P}}^*)$ are equivalent in the following way.

THEOREM 4.3. *$(\hat{\mathcal{P}})$ has a unique optimal solution $(\hat{u},\hat{u})$, and $\hat{u}^* = \hat{u}$ is also the unique optimal solution to $(\hat{\mathcal{P}}^*)$. Conversely, if $\hat{u}^*$ is the solution to $(\hat{\mathcal{P}}^*)$, $(\hat{u}^*,\hat{u}^*)$ is the optimal solution to $(\hat{\mathcal{P}})$.*

Proof. Let us choose an optimal solution to $(\hat{\mathcal{P}})$: $(\bar{u},\bar{u})$. Then

$$\forall(\varphi,\psi) \in U_{ad}, \qquad \hat{J}^*(\bar{u}) = \hat{J}(\bar{u},\bar{u}) \le \hat{J}(\varphi,\psi);$$

in particular, we choose $\varphi = \psi$. Then,

$$\forall\varphi \in H_o^1(\Omega), \qquad \hat{J}^*(\bar{u}) \le \hat{J}(\varphi,\varphi) = \hat{J}^*(\varphi).$$

Therefore $\bar{u}$ is the optimal solution to $(\hat{\mathcal{P}}^*)$. As the solution to $(\hat{\mathcal{P}}^*)$ is unique, the solution to $(\hat{\mathcal{P}})$ is unique as well.

Conversely, let $\hat{u}^*$ be the solution to $(\hat{\mathcal{P}}^*)$, and $(\hat{u},\hat{u})$ the solution to $(\hat{\mathcal{P}})$. We get

$$\hat{J}(\hat{u}^*,\hat{u}^*) = \hat{J}^*(\hat{u}^*) \le \hat{J}^*(\hat{u}) = \hat{J}(\hat{u},\hat{u}) = \inf(\hat{\mathcal{P}}).$$

As the solution to $(\hat{\mathcal{P}})$ is unique, then $\hat{u}^* = \hat{u}$. □

It is easy now to derive optimality conditions, since $(\hat{\mathcal{P}}^*)$ is an unconstrained problem.

COROLLARY 4.1. *The optimal solution to $(\hat{\mathcal{P}})$ is characterized by*

$$u^* = \mathcal{T}(u^*,u^*) \text{ and } -2\nu\Delta u^* + u^* = z \text{ in } \Omega,\ u^* = 0 \text{ on } \partial\Omega.$$

SEPARATION PRINCIPLES FOR INPUT-OUTPUT AND INTEGRAL-INPUT-TO-STATE STABILITY*

D. ANGELI†, B. INGALLS‡, E. D. SONTAG§, AND Y. WANG¶

Abstract. We present new characterizations of input-output-to-state stability. This is a notion of detectability formulated in the ISS (input-to-state stability) framework. Equivalent properties are presented in terms of asymptotic estimates of the state trajectories based on the magnitudes of the external input and output signals. These results provide a set of *separation principles* for input-output-to-state stability—characterizations of the property as conjunctions of weaker stability notions. When applied to the notion of integral ISS, these characterizations yield analogous results.

Key words. nonlinear systems, input-to-output stability, detectability, Lyapunov method

1. Introduction.

Detectability is a central notion in control theory. It plays a major role both in static state-feedback design (LaSalle's invariance principle and Jurdjevic–Quinn control) as well as in stabilization by means of dynamic output feedback or observer design. Several possibilities are available when formulating such a notion in the context of nonlinear control. According to the specific problem under consideration, they capture some or most of the useful features of its linear counterpart. One approach that has proved to be especially powerful for systems subject to exogenous disturbances is to define zero-detectability in terms of estimates involving (possibly nonlinear) gains with respect to input and output norms. This leads to the so-called input-output-to-state stability (IOSS) property. Such a notion not only allows one to extend LaSalle-type stability results to the case of nonautonomous systems [2], but it also provides a machinery, fully compatible with the formalism of the input-to-state stability (ISS) property [8, 9, 13, 14, 15, 17, 18, 19, 23, 24, 25, 30, 31], that helps one understand relevant issues such as minimum-phase behavior or certainty equivalence [20, 11].

Although general nonlinear systems may often exhibit an overwhelming variety of behaviors, it turns out that many of the "reasonable" formulations of the detectability property (meaning at least compatible with the linear notion of detectability) are equivalent to each other. In this paper, we discuss characterizations of IOSS in terms of the asymptotic behavior of system solutions. This leads to several useful decompositions of the IOSS property in terms of weaker notions. These *separation principles* are in direct analogy to those previously provided for ISS [28] and input-to-output sta-

bility [12]. These results all generalize from differential equations the fact that global asymptotic stability can be characterized by the combination of (neutral) stability and attractivity.

As an application of our results, we will also discuss several ways of reformulating the notion of integral input-to-state stability (iISS) (cf. [5, 26]) in terms of asymptotic gains. This is accomplished by treating the iISS property as the IOSS property for suitable auxiliary systems. Similar results were also obtained for the so-called derivative-ISS property (DISS) in the recent work [7].

As mentioned, the main results are (far from obvious) generalizations to systems with outputs of the analogous separation principles which appeared in [28] dealing with the ISS notion. Actually, the ISS case is a special case of IOSS when the output map is identically zero. However, it takes much more effort to handle the general case of nonzero output maps. It can be seen from later sections that IOSS amounts to the requirement of convergence to 0 (or to balls whose radii are proportional to the norms of the input signals) *only* for those trajectories which evolve in a certain set constrained by the output signals. In the ISS case, by comparison, the output map is identically zero, so the constraints become trivial, and the restricted set becomes the whole state space.

2. Basic definitions. Consider systems in the following general form:

$$\dot{x}(t) = f(x(t), u(t)), \quad y(t) = h(x(t)), \tag{1}$$

where, for each $t \geq 0$, $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{U}$, a subset of $\mathbb{R}^m$. We assume that the maps $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ and $h : \mathbb{R}^n \to \mathbb{R}^p$ are locally Lipschitz continuous, with $f(0,0) = 0$ and $h(0) = 0$. The symbol $|\cdot|$ denotes the usual Euclidean norms. The open ball in $\mathbb{R}^l$ centered at the origin with radius r will be denoted by $\mathcal{B}_l(r)$.

By an *input* we mean a measurable and locally essentially bounded function $u : \mathcal{I} \to \mathbb{U}$, where $\mathcal{I}$ is a subinterval of $\mathbb{R}$ which contains the origin. Whenever the domain $\mathcal{I}$ of an input u is not specified, it will be understood that $\mathcal{I} = \mathbb{R}_{\geq 0}$. Given a system with input-value set $\mathbb{U}$, we will also often consider the same system with inputs restricted to some subset $\mathcal{O} \subseteq \mathbb{U}$. We use $\mathcal{M}_{\mathcal{O}}$ to denote the set of all such inputs.

Given any input u and any $\xi \in \mathbb{R}^n$, the unique maximal solution of the initial value problem $\dot{x} = f(x,u)$, $x(0) = \xi$ (defined on some maximal open subinterval of $\mathcal{I}$) is denoted by $x(\cdot, \xi, u)$. When $\mathcal{I} = \mathbb{R}_{\geq 0}$, this maximal subinterval has the form $[0, T_{\xi,u})$. The system is said to be *forward complete* if for every initial state ξ and for every input u defined on $\mathbb{R}_{\geq 0}$, $T_{\xi,u} = +\infty$. The corresponding output is denoted by $y(\cdot, \xi, u)$, that is, $y(t, \xi, u) = h(x(t, \xi, u))$ on the domain of definition of the solution.

The L_∞-norm (possibly infinite) of a function v defined on $\mathcal{I}$ is denoted by $\|v\|$, i.e.,

$$\|v\| = (\text{ess})\sup\{|v(t)|\,, t \in \mathcal{I}\}.$$

In particular, for a maximal trajectory $x(\cdot, \xi, u)$ and the corresponding output function $y(\cdot, \xi, u)$ of (1) defined on $[0, T_{\xi,u})$, $\|u\|$, $\|x\|$, and $\|y\|$ denote the L_∞-norm of $u(\cdot)$, $x(\cdot, \xi, u)$, and $y(\cdot, \xi, u)$, respectively, on $[0, T_{\xi,u})$. We will make a slight abuse of notation and use sup and lim sup to mean the essential supremum where appropriate. For a function v defined on an interval $\mathcal{I}$, if $\mathcal{I}_1 \subseteq \mathcal{I}$, we use $v_{\mathcal{I}_1}$ to denote the restriction of v to $\mathcal{I}_1$, i.e., $v_{\mathcal{I}_1}(t) = v(t)$ if $t \in \mathcal{I}_1$, and $v_{\mathcal{I}_1}(t) = 0$ otherwise. Notice the following fact: for a measurable function v defined on some interval $[0, T)$ for some $T \leq \infty$,

$$\limsup_{t \to T} |v(t)| = \lim_{t \to T} \|v_{[t,T)}\|. \tag{2}$$

We use standard terminology (cf. [10]): $\mathcal{N}$ is the class of continuous, increasing functions from $[0,\infty)$ to $[0,\infty)$; $\mathcal{K}$ is the set of $\mathcal{N}$ functions γ that are strictly increasing and satisfy $\gamma(0)=0$; $\mathcal{K}_\infty$ is the set of $\mathcal{K}$ functions that are unbounded; $\mathcal{L}$ is the set of functions $[0,+\infty)\to[0,+\infty)$ which are continuous, decreasing, and converge to 0 as their argument tends to $+\infty$; $\mathcal{KL}$ is the class of functions $[0,\infty)^2\to[0,\infty)$ which are class $\mathcal{K}$ on the first argument and class $\mathcal{L}$ on the second one. A positive definite function $\gamma:[0,\infty)\to[0,\infty)$ is one such that $\gamma(0)=0$ and $\gamma(s)>0$ for all $s>0$.

The following notions were introduced in [22] (see also [4]) and [16, 29], respectively.

DEFINITION 2.1. *The system* (1) *satisfies the* unboundedness observability *(UO) property if, for each state ξ and control u such that $T_{\xi,u}<\infty$, it holds that $\limsup_{t\to T_{\xi,u}}|y(t,\xi,u)|=+\infty$, that is, for each state ξ and control u,*

$$T_{\xi,u}<\infty \quad\Rightarrow\quad \|y\|=+\infty.$$

DEFINITION 2.2. *The system* (1) *is* input-output-to-state stable *(IOSS) if there exist some $\beta\in\mathcal{KL}$, $\gamma_u\in\mathcal{K}$, and $\gamma_y\in\mathcal{K}$ such that*

$$|x(t,\xi,u)|\le\beta(|\xi|,t)+\gamma_u(\|u\|)+\gamma_y\left(\|y_{[0,t]}\|\right) \tag{3}$$

for all $t\in[0,T_{\xi,u})$, all $\xi\in\mathbb{R}^n$, and all $u(\cdot)$. □

Clearly, the IOSS property implies the UO property. The following local version of it will also be used in the proof of our main result.

DEFINITION 2.3. *The system* (1) *is* locally IOSS *if there exist $\delta>0$ and functions $\beta\in\mathcal{KL}$, $\gamma_u,\gamma_y\in\mathcal{K}$ so that for any $\xi\in\mathbb{R}^n$, any $u(\cdot)$,*

$$\max\{|\xi|,\|u\|,\|y\|\}\le\delta\ \Rightarrow\ |x(t,\xi,u)|\le\beta(|\xi|,t)+\gamma_u(\|u\|)+\gamma_y(\|y_{[0,t]}\|) \tag{4}$$

for all $t\in[0,T_{\xi,u})$. □

Below we discuss several other properties for systems as in (1) regarding estimates of the state variables on the basis of external information provided by past input and output signals.

2.1. A catalog of properties.

DEFINITION 2.4. *Consider system* (1). *We say that*

- *the* input-output limit property *(IO-LIM) holds if for some $\gamma_u,\gamma_y\in\mathcal{K}$,*

$$\inf_{t\in[0,T_{\xi,u})}|x(t,\xi,u)|\le\max\{\gamma_u(\|u\|),\gamma_y(\|y\|)\}\quad\forall\,\xi\in\mathbb{R}^n,\ \forall\,u(\cdot); \tag{5}$$

- *the* input-output asymptotic gain property *(IO-AG) holds if solutions are ultimately bounded by some nonlinear gain function of $\|u\|$ and $\|y\|$, that is, for some $\gamma_u,\gamma_y\in\mathcal{K}$,*

$$\limsup_{t\to T_{\xi,u}}|x(t,\xi,u)|\le\max\{\gamma_u(\|u\|),\gamma_y(\|y\|)\}\quad\forall\,\xi\in\mathbb{R}^n,\ \forall\,u(\cdot); \tag{6}$$

- *the* input-output-to-state boundedness property *(IO-BND) holds if for some $\sigma_0,\sigma_u,\sigma_y\in\mathcal{N}$, it holds that*

$$|x(t,\xi,u)|\le\max\{\sigma_0(|\xi|),\sigma_u(\|u\|),\sigma_y(\|y_{[0,t]}\|)\} \tag{7}$$

for all $\xi\in\mathbb{R}^n$, all $u(\cdot)$, and all $t\in[0,T_{\xi,u})$;

- *the* input-output global stability property *(IO-GS) holds if the functions* $\sigma_0, \sigma_u, \sigma_y$ *in* (7) *can be taken to be of class* $\mathcal{K}$.

Thinking of these detectability properties as "stability modulo inputs and outputs," we can identify IOSS with asymptotic stability, IO-GS with (neutral) stability, and IO-AG with attractivity. In this context it seems perfectly natural that IOSS should be equivalent to the combination of IO-GS and IO-AG, and indeed that is one of the decompositions which appears in our main result. Related results follow by considering other "basic" stability-like notions, such as IO-LIM.

It is not hard to see that each of the IO-AG, the IO-GS, and the IO-BND properties implies the UO condition. This follows from the fact that, for any ξ, u, if $T_{\xi,u} < \infty$, then $|x(t,\xi,u)| \to \infty$ as $t \to T_{\xi,u}$. That the IO-LIM property also implies the UO condition follows from the next remark.

Remark 2.5. The IO-LIM property can be defined equivalently by replacing the "inf" in (5) by "lim inf", that is,

$$\liminf_{t \to T_{\xi,u}} |x(t,\xi,u)| \le \max\{\gamma_u(\|u\|), \gamma_y(\|y\|)\}. \tag{8}$$

It is straightforward that (8) implies (5). To see that (5) implies (8), take any $T \in [0, T_{\xi,u})$. Applying (5) to $x(t, \xi_T, u_T)$ with $\xi_T = x(T,\xi,u)$ and $u_T(t) = u(t+T)$, one gets

$$\inf_{t \in [T, T_{\xi,u})} |x(t,\xi,u)| \le \max\{\gamma_u(\|u_T\|), \gamma_y(\|y_T\|)\} \le \max\{\gamma_u(\|u\|), \gamma_y(\|y\|)\}, \tag{9}$$

where $y_T = h(x(\cdot, \xi_T, u_T))$. Since T can be arbitrary, one obtains (8). □

Another characterization of IO-LIM is as follows. This statement is proved (along with some related characterizations of the IO-LIM property) in Appendix A.

LEMMA 2.6. *System* (1) *satisfies the IO-LIM property if and only if there exist* γ_u, $\gamma_y \in \mathcal{K}$ *such that*

$$\inf_{t \in [0, T_{\xi,u})} \Big\{ |x(t,\xi,u)| - \max\{\gamma_u(\|u_{[0,t]}\|), \gamma_y(\|y_{[0,t]}\|)\} \Big\} \le 0 \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, u(\cdot). \tag{10}$$

The following implication will be needed.

LEMMA 2.7. *If* (1) *satisfies the IO-LIM property, then it satisfies the IO-BND property.*

Proof. Consider a system as in (1). For each subset $\mathcal{O}$ of the input space $\mathbb{U}$, each subset C of $\mathbb{R}^n$, and each $\mathcal{Y} \subset \mathbb{R}^p$ we denote

$$\mathcal{R}_{\mathcal{O}/\mathcal{Y}}(C) := \Big\{ x(t,\xi,u) :\ \xi \in C, u \in \mathcal{M}_{\mathcal{O}}, t \in [0, T_{\xi,u}) \\ \text{and } h(x(\lambda,\xi,u)) \in \mathcal{Y}\ \ \forall \lambda \in [0,t] \Big\}.$$

Then $\mathcal{R}_{\mathcal{O}/\mathcal{Y}}(C)$ is the reachable set with initial conditions in C, controls in $\mathcal{O}$, and subject to an output constraint.

Suppose a system as in (1) satisfies the IO-LIM property and, consequently, the UO property as well. By Lemma 2.6 one sees that (10) holds for some $\gamma_u, \gamma_y \in \mathcal{K}$. Pick an arbitrary $s > 0$. We let

$$\Omega = \mathcal{B}_n(2s),\ C = \mathrm{cl}(\Omega),\ K = \mathrm{cl}\left(\mathcal{B}_n\left(\frac{3s}{2}\right)\right),\ \mathcal{Y} = \mathrm{cl}\left(\mathcal{B}_p\left(\gamma_y^{-1}\frac{(s)}{2}\right)\right)$$

and

$$\mathcal{Y}_o = \mathcal{B}_p(\gamma_y^{-1}(s)),\ \mathcal{O} = \mathrm{cl}(\mathcal{B}_m(\gamma_u^{-1}(s))).$$

Finally we define $\sigma_0(s) := \sup\{|p| :\ p \in \mathcal{R}_{\mathcal{O}/\mathcal{Y}}(C)\}$.

Claim. $\sigma_0(s) < \infty$.

Proof. For any $\xi \in \mathbb{R}^n$ and any $u \in \mathcal{M}_{\mathcal{O}}$, by (10), there exists $\tau \in [0, T_{\xi,u})$ so that

$$|x(\tau, \xi, u)| \leq \frac{3}{2} \max\left\{s, \gamma_y(\|y_{[0,\tau]}\|)\right\}.$$

Considering separately the cases $\|y_{[0,\tau]}\| \leq \gamma_y^{-1}(s)$ and $\|y_{[0,\tau]}\| > \gamma_y^{-1}(s)$, we obtain that either

$$|x(\tau, \xi, u)| \leq \frac{3s}{2}$$

or there is some $t \in [0, \tau]$ so that

$$|h(x(t, \xi, u))| > \gamma_y^{-1}(s).$$

In other words, there exists $\tau \in [0, T_{\xi,u})$ such that either $x(\tau, \xi, u) \in K$ or for some $t \in [0, \tau]$, $h(x(t, \xi, u)) \notin \mathcal{Y}_o$. We then apply Lemma B.1 to conclude that $\mathcal{R}_{\mathcal{O}/\mathcal{Y}}(C)$ is bounded, and thus $\sigma_0(s) < \infty$.

Let $\sigma_u(r) = \sigma_0(\gamma_u(r))$ and $\sigma_y(r) = \sigma_0(\gamma_y(r))$. Now pick $\xi \in \mathbb{R}^n$, an input u, and $t \in [0, T_{\xi,u})$. Let $s = \max\{|\xi|, \gamma_u(\|u\|), \gamma_y(\|y_{[0,t]}\|)\}$. If $s = 0$, then $|x(t, 0, 0)| = 0$. If $s > 0$, by definition of σ_0 we have

$$|x(t, \xi, u)| \leq \sigma_0(s) \leq \max\{\sigma_0(|\xi|), \sigma_u(\|u\|), \sigma_y(\|y_{[0,t]}\|)\}. \tag{11}$$

This completes the proof of IO-LIM $\Rightarrow$ IO-BND. ∎

Remark 2.8. Note that in the above proof, if the function γ_u can be chosen to be the zero function, that is, if (10) can be strengthened to

$$\inf_{t \in [0, T_{\xi,u})} \left[|x(t, \xi, u)| - \gamma_y(\|y_{[0,t]}\|)\right] \leq 0,$$

then the function σ_u in (11) can be chosen to be the zero function. ∎

We next comment on some straightforward characterizations of the IO-AG property.

Remark 2.9. It is immediate from the definition that the IO-AG property (6) is equivalent to the UO property in combination with the following:

$$\limsup_{t \to \infty} |x(t, \xi, u)| \leq \max\left\{\gamma_u(\|u\|),\ \gamma_y\left(\|y\|\right)\right\} \tag{12}$$

for all ξ, u for which $T_{\xi,u} = \infty$. ∎

Combining this remark with (2), the following can be easily shown (using an argument as in Remark 2.5).

LEMMA 2.10. *A system as in* (1) *satisfies the IO-AG property if and only if it is UO and, for some* $\gamma_u, \gamma_y \in \mathcal{K}$, *the following holds for all* ξ *and* u *for which* $T_{\xi,u} = \infty$:

$$\limsup_{t \to \infty} |x(t, \xi, u)| \leq \max\left\{\gamma_u\left(\limsup_{t \to \infty} |u(t)|\right),\ \gamma_y\left(\limsup_{t \to \infty} |y(t)|\right)\right\}. \tag{13}$$

2.2. IOSS and OSS properties. Consider a system

$$\dot{x} = f(x),\ y = h(x) \tag{14}$$

without input. This can be considered as a system as in (1) with $\mathbb{U}$ consisting of a single point. We use $x(\cdot, \xi)$ to denote the solution of (14) with the initial state ξ defined on a maximal interval $[0, T_\xi)$, and we let $y(t, \xi) = h(x(t, \xi))$.

DEFINITION 2.11. *We say that the system* (14) *is*

- locally stable modulo outputs *(O-LS) if for any* $\varepsilon > 0$ *there exists* $\delta_\varepsilon > 0$ *such that for all* ξ *and all* $t \in [0, T_\xi)$ *it holds that*

$$\max\{|\xi|, \|y_{[0,t]}\|\} \le \delta_\varepsilon \ \Rightarrow\ |x(t, \xi)| \le \varepsilon; \tag{15}$$

- output-to-state stable *(OSS) (see* [29]*) if there exist some* $\beta \in \mathcal{KL}$ *and some* $\gamma \in \mathcal{K}$ *such that, for any trajectory* $x(\cdot)$ *of the system, it holds that*

$$|x(t, \xi)| \le \beta(|\xi|, t) + \gamma(\|y_{[0,t]}\|) \qquad \forall\, t \in [0, T_\xi). \tag{16}$$

For a system as in (1), we say that the system is *zero-input OSS* (zero-OSS) or *zero-input O-LS* (zero-O-LS) if the zero input system $\dot{x} = f(x, 0),\ y = h(x)$ is OSS or O-LS, respectively. The following technical lemma will be needed in the proof of our main result.

LEMMA 2.12. *The zero-OSS property implies the local IOSS property.*

Proof. Suppose the system (1) is zero-OSS. Then, by Theorem 3 in [29] there exists a smooth function $V : \mathbb{R}^n \to \mathbb{R}_{\ge 0}$ and class $\mathcal{K}_\infty$ functions α_1, α_2, α, and ρ such that $\alpha_1(|\xi|) \le V(\xi) \le \alpha_2(|\xi|)$ and

$$\frac{\partial V(\xi)}{\partial \xi} f(\xi, 0) \le -2\alpha(|\xi|) + \rho(|h(\xi)|) \qquad \forall\, \xi \in \mathbb{R}^n. \tag{17}$$

Let $\sigma : \mathbb{R}_{\ge 0} \times \mathbb{R}_{\ge 0} \to \mathbb{R}_{\ge 0}$ be defined as

$$\sigma(s, r) = sr + \max_{|\xi| \le s, |\mu| \le r} \left\{ \frac{\partial V(\xi)}{\partial \xi} [f(\xi, \mu) - f(\xi, 0)] \right\}. \tag{18}$$

Note that $\sigma(s, 0) = 0$ for all $s \ge 0$. Since V is smooth and $\frac{\partial V}{\partial \xi}(0) = 0$, we also have $\sigma(0, r) = 0$ for all $r \ge 0$. Furthermore, $\sigma(\cdot, r) \in \mathcal{K}$ for each $r \ge 0$ and $\sigma(s, \cdot) \in \mathcal{K}$ for each $s \ge 0$. By Corollary IV.5 in [5], there exist σ_1, $\sigma_2 \in \mathcal{K}_\infty$ so that $\sigma(s, r) \le \sigma_1(s)\sigma_2(r)$. Hence, combining (17) and (18), we get

$$\begin{aligned} \frac{\partial V(\xi)}{\partial \xi} f(\xi, \mu) &= \frac{\partial V(\xi)}{\partial \xi} f(\xi, 0) + \frac{\partial V(\xi)}{\partial \xi} [f(\xi, \mu) - f(\xi, 0)] \\ &\le -2\alpha(|\xi|) + \rho(|h(\xi)|) + \sigma(|\xi|, |\mu|) \\ &\le -2\alpha(|\xi|) + \rho(|h(\xi)|) + \sigma_1(|\xi|)\sigma_2(|\mu|). \end{aligned}$$

Therefore

$$\alpha^{-1}(\sigma_2(|\mu|) + \rho(|h(\xi)|)) \le |\xi| \le \sigma_1^{-1}(1) \quad \Rightarrow \quad \frac{\partial V(\xi)}{\partial \xi} f(\xi, \mu) \le -\alpha(|\xi|),$$

from which it follows that for some $\mathcal{K}_\infty$-functions χ_1, χ_2, and $\tilde{\alpha}$ and some $c > 0$, it holds that

$$\max\{\chi_1(|\mu|), \chi_2(|h(\xi)|)\} \le V(\xi) \le c \quad \Rightarrow \quad \frac{\partial V(\xi)}{\partial \xi} f(\xi, \mu) \le -\tilde{\alpha}(V(\xi)).$$

Pick any initial state ξ and input u. Denote the trajectory $x(t,\xi,u)$ by $x(t)$, and the output $y(t,\xi,u)$ by $y(t)$. Pick any $T \in [0, T_{\xi,\mu})$, and let

$$v^* = \max\{\chi_1(\|u\|), \chi_2(\|y_{[0,T]}\|)\}.$$

For almost all $t \in [0,T]$, we have

$$v^* \leq V(x(t)) \leq c \;\Rightarrow\; \frac{d}{dt}V(x(t)) \leq -\tilde{\alpha}(V(x(t))).$$

By Lemma 13 in [29], one sees that there exists some $\beta_0 \in \mathcal{KL}$ which depends only on $\tilde{\alpha}$ so that

$$\max_{t\in[0,T]} V(x(t)) \leq c \quad \Rightarrow\; V(x(t)) \leq \max\{\beta_0(V(x(0)),t), v^*\} \quad \forall\, t \in [0,T];$$

that is, if $V(x(t)) \leq c$ for all $t \in [0,T]$,

$$V(x(t)) \leq \max\{\beta_0(V(x(0)),t), \chi_1(\|u\|),\ \chi_2(\|y_{[0,T]}\|)\} \quad \forall\, t \in [0,T]. \tag{19}$$

Let $\hat{\beta}_0(r) = \beta_0(r,0)$. Without loss of generality, we assume that $\hat{\beta}_0(r) > r$, and thus, $\hat{\beta}_0 \in \mathcal{K}_\infty$. Let

$$\delta = \min\left\{\chi_1^{-1}\left(\frac{c}{2}\right),\ \chi_2^{-1}\left(\frac{c}{2}\right),\ \alpha_2^{-1}\left(\hat{\beta}_0^{-1}\left(\frac{c}{2}\right)\right)\right\}.$$

Claim. If $\max\{|x(0)|,\ \|u\|,\ \|y\|\} \leq \delta$, then $V(x(t)) \leq c$ for all $t \in [0, T_{\xi,u})$.

Suppose the claim fails. This means

$$\max\{\tilde{\beta}_0(\alpha_2(|x(0)|)),\ \chi_1(\|u\|),\ \chi_1(\|y\|)\} \leq \frac{c}{2},$$

but for some $t \in [0, T_{\xi,u})$, $V(x(t)) \geq c$. Let

$$t_0 = \inf\left\{t \geq 0 : V(x(t)) \geq \frac{c}{2}\right\}.$$

Then $t_0 < T_{\xi,u}$. By the continuity property of $x(\cdot)$, there is some $0 < \varepsilon < T_{\xi,u} - t_0$ such that on $[0, t_0+\varepsilon)$, $V(x(t)) < c$. By (19), we have

$$V(x(t)) \leq \max\{\hat{\beta}_0(V(x(0))),\ \chi_1(\|u\|),\ \chi_2(\|y\|)\} \leq \frac{c}{2}$$

for all $t \in [0, t_0+\varepsilon]$. This contradicts the definition of t_0.

Finally, applying (19) together with the proved claim, one sees that if

$$\max\{|x(0)|, \|u\|, \|y\|\} < \delta,$$

then

$$|x(t)| \leq \max\{\beta(|x(0)|,t),\ \gamma_1(\|u\|),\ \gamma_2(\|y_{[0,t]}\|)\}\ \forall\, t \in [0, T_{\xi,u}),$$

where $\beta(s,r) = \alpha_1^{-1}(\beta_0(\alpha_2(s),r)), \gamma_i(r) = \alpha_1^{-1}(\chi_i(r))$ for $i = 1,2$. □

3. Equivalent characterizations of IOSS. The following is our main result in the context of IOSS.

THEOREM 1. *Consider a system as in* (1) *with* $\mathbb{U} = \mathbb{R}^m$. *The following properties are equivalent:*

1. *(IOSS),*
2. *(IO-AG) & (IO-GS),*
3. *(IO-AG) & (zero-OSS),*
4. *(IO-AG) & (local IOSS),*
5. *(IO-AG) & (zero-O-LS),*
6. *(IO-LIM) & (IO-GS),*
7. *(IO-LIM) & (zero-OSS),*
8. *(IO-LIM) & (local IOSS),*
9. *(IO-LIM) & (zero-O-LS).*

Among the properties listed in Theorem 1, it is easy to see that the IOSS property implies every other one, and the zero-O-LS property is implied by any one of the local IOSS, the zero-OSS, and the IO-GS properties. Thus, to prove Theorem 1, it is enough to show the following implication:

$$\text{(IO-LIM) \& (zero-O-LS)} \Rightarrow \text{(IOSS)}.$$

We will proceed by the following technical lemmas.

LEMMA 3.1. *(IO-LIM) & (zero-O-LS)* $\Rightarrow$ *(zero-OSS).*

LEMMA 3.2. *(IO-LIM) & (local IOSS)* $\Rightarrow$ *(IO-LIM) & (IO-GS).*

LEMMA 3.3. *(IO-LIM) & (IO-GS)* $\Rightarrow$ *(IO-AG) & (IO-GS).*

Observe that Lemmas 3.1–3.3 together with Lemma 2.12 provide the following chain:

$$\begin{aligned}\text{(IO-LIM) \& (zero-O-LS)} &\Rightarrow \text{(IO-LIM) \& (zero-OSS)} \Rightarrow \text{(IO-LIM) \& (local IOSS)} \\ &\Rightarrow \text{(IO-LIM) \& (IO-GS)} \Rightarrow \text{(IO-AG) \& (IO-GS)}.\end{aligned}$$

To complete the proof of Theorem 1, we will need the following result.

PROPOSITION 3.4. *(IO-AG) & (IO-GS)* $\Rightarrow$ *(IOSS).*

The proofs of the lemmas and the proposition will be given in section 6.

Remark 3.5. Theorem 1 is a satisfying theoretical result in that it unifies a number of properties and provides a generalization of the separation principle for asymptotically stable differential equations. Moreover, the theorem is a useful tool for recognizing IOSS systems. The definition of IOSS rarely lends itself to direct verification. More often, this property is shown using the Lyapunov characterization provided in [16]. In cases where construction of an appropriate Lyapunov function proves difficult, Theorem 1 provides a number of alternative conditions which may be tested.

As an example, consider the following family of systems without inputs, with state $(x, z) \in \mathbb{R}^n \times \mathbb{R}$:

$$\begin{aligned}\dot{x} &= f(x), \\ \dot{z} &= |x|, \\ y &= z.\end{aligned} \tag{20}$$

Suppose that the system is forward complete. Provided that the function f is locally Lipschitz, this system satisfies the IO-LIM property, which can be shown as

follows. For each initial condition ξ, consider two cases. If $\int_0^\infty |x(s,\xi)|\, ds = \infty$, then $\lim_{t\to\infty} y(t,\xi) = \infty$, and so the IO-LIM bound (8) holds trivially for any $\gamma_y \in \mathcal{K}_\infty$. Otherwise, from the fact that $\int_0^\infty |x(s,\xi)|\, ds < \infty$, we have $\liminf_{t\to\infty} |x(t,\xi)| = 0 \leq \|y\|$. Thus, the IO-LIM estimate (8) holds in both cases.

Hence system (20) is known to satisfy the IOSS property (OSS in this case), provided that it satisfies one of the stability properties as in Theorem 1. For instance, if the system $\dot{x} = f(x)$ is locally stable, then the system (20) is (zero)-O-LS (since the z component of the state is trivially bounded by the output), and so the system enjoys the OSS property.

On the other hand, the Lyapunov approach would not be well suited to exploring the IOSS property in this situation, since little is assumed about the dynamics. ∎

4. On iISS. In this section, we indicate how the equivalences shown in Theorem 1 can be used to derive asymptotic characterizations of the iISS property.

DEFINITION 4.1 (see [26]). *A system as in* (1) *is* integral input-to-state stable *(iISS) if there exist functions $\beta \in \mathcal{KL}$, $\sigma \in \mathcal{K}$, and $\gamma \in \mathcal{K}$ such that, for all $\xi \in \mathbb{R}^n$ and all u, the solution $x(t,\xi,u)$ is defined for all $t \geq 0$, and*

$$|x(t,\xi,u)| \leq \beta(|\xi|, t) + \gamma\left(\int_0^t \sigma(|u(s)|)\, ds\right) \tag{21}$$

for all $t \geq 0$.

To make use of our main result, we reformulate the iISS property in terms of the IOSS property.

LEMMA 4.2. *System* (1) *is integral input-to-state stable with an estimate as in* (21) *if and only if the augmented system*

$$\dot{x} = f(x,u), \quad \dot{e} = \sigma(|u|), \quad y = e \tag{22}$$

is IOSS.

Proof. Let the augmented system be IOSS; then, for $e(0) = 0$ we have

$$\begin{aligned} |x(t,\xi,u)| &\leq |x(t,\xi,u)| + |e(t)| \leq \beta(|\xi|,t) + \gamma_1(\|u\|) + \gamma_2(\|y_{[0,t]}\|) \\ &= \beta(|\xi|,t) + \gamma_1(\|u\|) + \gamma_2\left(\int_0^t \sigma(|u(s)|)\, ds\right) \end{aligned} \tag{23}$$

for all $t \in [0, T_{\xi,u})$. By causality, (23) can be rewritten as

$$|x(t,\xi,u)| \leq \beta(|\xi|,t) + \gamma_1(\|u_{[0,t]}\|) + \gamma_2\left(\int_0^t \sigma(|u(s)|)\, ds\right). \tag{24}$$

Since on any finite interval, the integral term in (24) is finite, it follows that $T_{\xi,u} = \infty$. In turn, this implies that (24) holds on $[0,\infty)$. This estimate implies iISS for (1), by virtue of Theorem 1 in [6].

To see the converse, clearly, $|e(t)| = |y(t)| \leq \|y_{[0,t]}\|$. Also observe that the iISS property implies that the augmented system is forward complete. Thus, it is enough to show that a suitable estimate holds on $[0,\infty)$ for the x component of the state. By (21), we have

$$\begin{aligned} |x(t,\xi,u)| &\leq \beta(|\xi|,t) + \gamma\left(\int_0^t \sigma(|u(s)|)\, ds\right) \\ &= \beta(|\xi|,t) + \gamma(e(t) - e(0)) \\ &\leq \beta(|\xi|,t) + \gamma(|y(t)| + |y(0)|) \leq \beta(|\xi|,t) + \gamma(2\|y_{[0,t]}\|) \end{aligned} \tag{25}$$

for all $t \geq 0$. This completes the proof. ∎

4.1. Lyapunov characterizations of iISS. This IOSS formulation of the iISS property allows us to exploit known results on IOSS to develop new characterizations of iISS. For instance, the following new Lyapunov characterization for iISS follows directly from the Lyapunov characterization for IOSS presented in [16]. We prove the next two results under the assumption that the gain σ in (21) is locally Lipschitz. Remark 4.7 indicates how this can always be achieved through a simple modification.

THEOREM 2. *System* (1) *is iISS if and only if there exist functions* $\alpha_1, \alpha_2, \alpha$, γ_1, γ_2, σ *of class* $\mathcal{K}_\infty$ *and a smooth function* $V : \mathbb{R}^{n+1} \to \mathbb{R}_{\geq 0}$, *with*

$$\alpha_1(|\xi| + |\eta|) \leq V(\xi, \eta) \leq \alpha_2(|\xi| + |\eta|) \qquad \forall \xi \in \mathbb{R}^n, \eta \in \mathbb{R}, \tag{26}$$

such that the following dissipation inequality is satisfied:

$$\frac{\partial V(\xi,\eta)}{\partial \xi} f(\xi, \mu) + \frac{\partial V(\xi,\eta)}{\partial \eta} \sigma(|\mu|) \leq -\alpha(|\xi| + |\eta|) + \gamma_1(|\eta|) + \gamma_2(|\mu|) \tag{27}$$

for all $\xi \in \mathbb{R}^n,\ \eta \in \mathbb{R},\ \mu \in \mathbb{U}$. □

Remark 4.3. It is easy to see that estimates (26) and (27) imply

$$\alpha_1(|\xi|) \leq V(\xi, \eta) \leq \alpha_2(|\xi| + |\eta|) \qquad \forall \xi \in \mathbb{R}^n, \eta \in \mathbb{R}, \tag{28}$$

and for all $\xi \in \mathbb{R}^n,\ \eta \in \mathbb{R},\ \mu \in \mathbb{U}$,

$$\frac{\partial V(\xi,\eta)}{\partial \xi} f(\xi, \mu) + \frac{\partial V(\xi,\eta)}{\partial \eta} \sigma(|\mu|) \leq -\alpha(|\xi|) + \gamma_1(|\eta|) + \gamma_2(|\mu|). \tag{29}$$

On the other hand, suppose that for a given V, equations (28) and (29) hold for some $\alpha_1, \alpha_2, \alpha,\ \gamma_1,\ \gamma_2, \sigma$ of class $\mathcal{K}_\infty$; then one can again show that the following type of estimate holds for the x-component of (22):

$$|x(t, \xi, u)| \leq \beta(|\xi|, t) + \rho_1(\|e\|_{[0,t]}) + \rho_2(\|u\|) \qquad \forall\, t \geq 0,$$

where $\rho_1,\ \rho_2 \in \mathcal{K}$. Combining this with the fact that $|e(t)| \leq \|e\|_{[0,t]}$, one sees that the augmented system (22) is IOSS. Hence, the corresponding system as in (1) is iISS.

Thus, a system as in (1) is iISS if and only if there exists some smooth function $V : \mathbb{R}^{n+1} \to \mathbb{R}_{\geq 0}$ for which (28) and (29) hold for some $\mathcal{K}_\infty$-functions $\alpha_1, \alpha_2, \alpha, \gamma_1, \gamma_2$ and σ.

In [5], an equivalent Lyapunov characterization for iISS was formulated as in the following: for some $\alpha_1, \alpha_2, \gamma \in \mathcal{K}_\infty$ and some *continuous positive definite* function α

$$\alpha_1(|\xi|) \leq V(\xi) \leq \alpha_2(|\xi|) \qquad \forall \xi \in \mathbb{R}^n, \tag{30}$$

$$\frac{\partial V(\xi)}{\partial \xi} f(\xi, \mu) \leq -\alpha(|\xi|) + \gamma(|\mu|). \tag{31}$$

The significance of the new Lyapunov characterization by (28)–(29) (or (26)–(27)) is that in (27) or (29) one can require the function α be of class $\mathcal{K}_\infty$. This may lead to some interesting applications in feedback design. For instance, if V is an iISS-Lyapunov function defined by (30)–(31), then, given a $\mathcal{K}_\infty$-function, $\rho \circ V$ may fail to be an iISS-Lyapunov function. However, if V is an iISS-Lyapunov function satisfying (28)–(29), then, for any $\rho \in \mathcal{K}_\infty$, $\rho \circ V$ is again an iISS-Lyapunov function satisfying the same type of estimates as in (28)–(29) (cf. [27, 2] regarding changing "supply rates"). □

4.2. Asymptotic characterizations of iISS.

DEFINITION 4.4. *A system as in* (1) *satisfies the* bounded energy weakly converging state *(BEWCS) property if for some σ of class $\mathcal{K}_\infty$ the following holds:*

$$\int_0^{+\infty} \sigma(|u(s)|)\,ds < +\infty \Rightarrow \liminf_{t\to+\infty} |x(t,\xi,u)| = 0. \tag{32}$$

To be more precise, (32) means that for any ξ and any u for which

$$\int_0^{\infty} \sigma(|u(s)|)\,ds < \infty,$$

it holds that $T_{\xi,u} = \infty$, and $\liminf_{t\to+\infty} |x(t,\xi,u)| = 0$.

DEFINITION 4.5. *A system as in* (1) *satisfies the* bounded energy frequently bounded state *(BEFBS) property if for some σ of class $\mathcal{K}_\infty$ the following holds:*

$$\int_0^{+\infty} \sigma(|u(s)|)\,ds < +\infty \;\Rightarrow\; \liminf_{t\to+\infty} |x(t,\xi,u)| < +\infty. \tag{33}$$

To be more precise, (33) *means that for any ξ and any u for which $\int_0^{\infty} \sigma(|u(s)|)\,ds < \infty$, it holds that $T_{\xi,u} = \infty$ and $\liminf_{t\to+\infty} |x(t,\xi,u)| < \infty$.*

Remark 4.6. Note that, given any input function u, any $T < \infty$, and any $\mathcal{K}_\infty$-function σ, one has $\int_0^T \sigma(|u(s)|) < \infty$. Hence, together with the causality of the trajectories, the BEFBS property implies the forward completeness property. That is, if a system is BEFBS, then the system is forward complete. Since the BEWCS property implies the BEFBS property, the BEWCS property also implies the forward completeness property. □

We say that a system as in (1) is *zero-GAS* if the corresponding zero-input system $\dot{x} = f(x,0)$ is globally asymptotically stable, and is *zero-LS* if the zero-input system is locally (neutrally) stable.

THEOREM 3. *The following properties are equivalent for system* (1) *with* $\mathbb{U} = \mathbb{R}^m$:

1. *iISS,*
2. *BEWCS and zero-LS,*
3. *BEFBS and zero-GAS.*

Proof. Implication 1 $\Rightarrow$ 3 follows immediately from the definition of iISS. We show next 3 $\Rightarrow$ 2 and 2 $\Rightarrow$ 1.

[3 $\Rightarrow$ 2]. Assume that the system (1) is zero-GAS and satisfies (33) for some $\sigma \in \mathcal{K}_\infty$. By the Lyapunov characterization of zero-GAS in [5, Lemma IV.10], there exists a smooth Lyapunov function $U(\xi)$ such that for some $\tilde{\alpha}_1, \tilde{\alpha}_2 \in \mathcal{K}_\infty$,

$$\tilde{\alpha}_1(|\xi|) \le U(\xi) \le \tilde{\alpha}_2(|\xi|) \qquad \forall \xi \in \mathbb{R}^n,$$

and for some $\tilde{\alpha}, \gamma, \sigma_0 \in \mathcal{K}_\infty$, it holds that

$$\frac{\partial U(\xi)}{\partial \xi} f(\xi,\mu) \le -\tilde{\alpha}(|\xi|) + \gamma(|\xi|)\sigma_0(|\mu|) \qquad \forall \xi \in \mathbb{R}^n, \mu \in \mathbb{U}. \tag{34}$$

By Proposition II.5 in [5], there exists some smooth $\mathcal{K}$-function χ such that for the function V defined by $V = \chi \circ U$ it holds that

$$\frac{\partial V(\xi)}{\partial \xi} f(\xi,\mu) \le -\rho(|\xi|) + \sigma_1(|\mu|) \qquad \forall \xi \in \mathbb{R}^n, \mu \in \mathbb{U}, \tag{35}$$

for some $\mathcal{K}_\infty$ function σ_1 and some positive definite function ρ. Let $\tilde{\sigma} = \max\{\sigma_1, \sigma\}$, where σ is as in (33). Pick $\xi \in \mathbb{R}^n$ and u with $\int_0^\infty \tilde{\sigma}(|u(s)|)\, ds < +\infty$. By the BEFBS assumption,

$$m := \liminf_{t \to +\infty} |x(t, \xi, u)| < +\infty.$$

We want to show $m = 0$. For the sake of contradiction, assume $m > 0$. For any $r > 0$, let

$$w(r) := \max_{|\xi| \le r} V(\xi).$$

Claim. $w(3m) - w(2m) > 0$.

Proof. Suppose $w(3m) - w(2m) = 0$. Then there exists some ξ_0 with $|\xi_0| \le 2m$ at which V takes the maximum value $w(3m)$. Since ξ_0 is an interior point of the open ball centered at 0 with radius $3m$, it follows that $\frac{\partial}{\partial \xi} V(\xi_0) = 0$. This contradicts (35) applied with $\mu = 0$.

We let T be such that

$$\int_T^{+\infty} \tilde{\sigma}(|u(s)|)\, ds < w(3m) - w(2m).$$

By the definition of m, there exists $\tau \ge T$ such that $|x(\tau, \xi, u)| < 2m$. By virtue of (35), for all $t \ge \tau$

$$\begin{aligned} V(x(t, \xi, u)) - V(x(\tau, \xi, u)) &\le \int_\tau^t \sigma_1(|u(s)|)\, ds \\ &< \int_T^{+\infty} \tilde{\sigma}(|u(s)|)\, ds < w(3m) - w(2m). \end{aligned} \tag{36}$$

Hence $V(x(t, \xi, u)) < w(3m)$ for all $t \ge \tau$. This implies that

$$U(x(t, \xi, u)) \le \chi^{-1}(w(3m)) \quad \forall\, t \ge \tau$$

(note that $w(3m)$ is in the range of the $\mathcal{K}$-function χ). Hence, $x(t, \xi, u)$ stays bounded on $[\tau, \infty)$, and consequently, $x(t, \xi, u)$ is bounded on $[0, \infty)$. Let $M > 0$ be such that $|x(t, \xi, u)| < M$ for all t. By (34), one sees that

$$\frac{d}{dt} U(x(t)) \le -\tilde{\alpha}(|x(t)|) + \gamma(M)\sigma_1(|u(t)|),$$

where $x(t)$ denotes the considered trajectory $x(t, \xi, u)$. This is enough to conclude that for some $\beta \in \mathcal{KL}$ and some $\alpha \in \mathcal{K}_\infty$ it holds that

$$\alpha(|x(t, \xi, u)|) \le \beta(|\xi|, t) + \int_0^t \tilde{\sigma}(|u(s)|)\, ds,$$

and therefore, as shown in [26], $|x(t, \xi, u)| \to 0$. This implies $m = 0$, which is clearly a contradiction. □

[2 ⇒ 1]. Suppose that (1) satisfies the BEWCS property with an estimate as in (32). Consider the auxiliary system (22), where σ is the energy supply function as in (32). Note that this system is forward complete (cf. Remark 4.6). By (32), one sees that for any $\gamma_y \in \mathcal{K}_\infty$ it holds that

$$\liminf_{t \to \infty} |x(t, \xi, u)| \le \gamma_y(\|y\|).$$

Therefore, for any choice of γ_u and $\gamma_y \in \mathcal{K}_\infty$, the following asymptotic property is true:

$$\liminf_{t\to+\infty} |x(t,\xi,u)| \le \max\{\gamma_u(\|u\|), \gamma_y(\|y\|)\}. \tag{37}$$

Since $|e(t)| = |y(t)| \le \|y\|$ for all $t \ge 0$, system (22) satisfies the IO-LIM property. Also, it follows from the zero-LS and the BEWCS properties that the system (1) is zero-GAS. Hence, the corresponding augmented system (22) is zero-OSS. By applying the main result in section 3, we find that (22) is IOSS, and therefore, by virtue of Lemma 4.2, system (1) is iISS. ∎

Remark 4.7. Notice that, in the construction of the augmented system (22), the only requirement on the function σ is that it must be class $\mathcal{K}_\infty$. In order to apply the results for IOSS systems, though, the local Lipschitz condition of the dynamics is needed. This issue can be dealt with as follows. First of all, one may always choose a function $\hat\sigma \in \mathcal{K}_\infty$ that majorizes σ so that $\hat\sigma^{-1}$ is locally Lipschitz. Then the iISS, the BEWCS, or the BEFBS estimates as in (21), (32), or (33), respectively, are not violated by replacing σ by $\hat\sigma$. Consider the change of input variables by $u \doteq \frac{w}{|w|}\hat\sigma^{-1}(|w|)$. Clearly $\hat\sigma(|u|) = |w|$, and therefore, iISS, BEWCS, or BEFBS of (1) with $\hat\sigma$ as the input energy supply function is easily seen to be equivalent to iISS, BEWCS, or BEFBS, respectively, for

$$\dot x = f(x, w\sigma^{-1}(|w|)/|w|) \tag{38}$$

with the new supply function $(s) = |s|$. The augmented system corresponding to (38) will therefore be

$$\dot x = f(x, w\sigma^{-1}(|w|)/|w|), \quad \dot e = |w|, \quad y = e. \tag{39}$$

The proofs of the previously derived results, when applied to system (39) and (38), provide proofs of the results in Theorem 3 for the original system (1). Therefore the Lipschitz condition on σ can be dropped. ∎

5. Uniform detectability. In this section we develop some machinery which will be needed to prove Theorem 1. We will derive a separation principle for the property we call *uniform OSS*. Here we consider systems with inputs (unlike in the definition of OSS), but we think of those inputs not as additive disturbances but as multiplicative time-varying uncertainties. We restrict the possible values of these inputs by considering systems as in (1) with $u \in \mathcal{M}_\mathcal{O}$ for some $\mathcal{O} \subset \mathbb{U}$. Throughout this section, we assume that $\mathcal{O}$ is compact.

DEFINITION 5.1. *For a system as in* (1)*, the* global detectability property *holds if the following hold:*

- *there exist* $\bar\sigma_1$, $\bar\sigma_2 \in \mathcal{K}$ *so that*

$$|x(t,\xi,u)| \le \max\{\bar\sigma_1(|\xi|), \bar\sigma_2(\|y_{[0,t]}\|)\} \quad \forall\, \xi \in \mathbb{R}^n,\ \forall\, u,\ \forall\, t \in [0, T_{\xi,u}); \tag{40}$$

- *there exists* $\gamma \in \mathcal{K}_\infty$ *so that*

$$\limsup_{t\to T_{\xi,u}} |x(t,\xi,u)| \le \gamma(\|y\|) \tag{41}$$

for all $\xi \in \mathbb{R}^n$*, all* $u \in \mathcal{M}_\mathcal{O}$. ∎

Note that the last condition (41) is just the IO-AG condition as in (6) with $\gamma_u = 0$. It can be seen that if a system is globally detectable, then the system satisfies the UO property.

DEFINITION 5.2. *We say that the* uniform output-to-state stability property *holds for* (1) *with* $u \in \mathcal{M}_{\mathcal{O}}$ *if for some* $\tilde{\gamma} \in \mathcal{K}_\infty$ *and some* $\beta \in \mathcal{KL}$ *the system satisfies*

$$|x(t,\xi,u)| \leq \max\{\beta(|\xi|,t), \tilde{\gamma}(\|y_{[0,t]}\|)\} \tag{42}$$

for all $\xi \in \mathbb{R}^n$, *all* $u \in \mathcal{M}_{\mathcal{O}}$, *and all* $t \in [0, T_{\xi,u})$. □

Clearly, the uniform output-to-state stability property implies the global detectability property. The main result of this section says that the converse is true as well when $\mathcal{O}$ is compact.

THEOREM 4. *Consider a system as in* (1) *with* $\mathcal{O}$ *compact. The system is* globally detectable *if and only if it is* uniformly output-to-state stable.

To prove Theorem 4, we will need the following result.

LEMMA 5.3. *Consider system* (1) *with* $u \in \mathcal{M}_{\mathcal{O}}$ *for some compact set* $\mathcal{O}$. *Assume that the system* (1) *satisfies the global detectability property. Then there exists some* $\gamma_1 \in \mathcal{K}$ *such that for all* $\varepsilon > 0$ *and all* $r > 0$ *there exists* $T_{\varepsilon,r}$ *so that for any* $\xi \in \mathbb{R}^n$ *with* $|\xi| \leq r$ *and for any* $u \in \mathcal{M}_{\mathcal{O}}$, *if* $T_{\varepsilon,r} < T_{\xi,u}$, *then*

$$|x(t,\xi,u)| \leq \max\left\{\varepsilon,\ \gamma_1\left(\|y_{[0,t]}\|\right)\right\}$$

for all $t \in [T_{\varepsilon,r}\,,\ T_{\xi,u})$.

Proof. Suppose a system satisfies the global detectability property for $u \in \mathcal{M}_{\mathcal{O}}$ as in (40) and (41). Let $\rho(r) := \max\{\bar{\sigma}_2(r), \gamma(r)\}$. It can be seen that, with $z = x$, $w = y$, and $\hat{z}(t) = \max\{|z(t)| - \rho(|w(t)|),\ 0\}$, the system is globally error-detectable as defined in [3] (see also Appendix B of this paper). Hence, by Lemma B.6, the system is uniformly globally error-detectable. Combining this with Remark B.5, we have proved Lemma 5.3. □

Modifying $T_{\varepsilon,r}$ if necessary, we may restate Lemma 5.3 as in the following.

COROLLARY 5.4. *Consider system* (1) *with* $u \in \mathcal{M}_{\mathcal{O}}$ *for some compact set* $\mathcal{O}$. *Assume that the system* (1) *satisfies the global detectability property. Then there exists a continuous map* $T : \mathbb{R}_{>0} \times \mathbb{R}_{\geq 0}$ *with the properties that for each* $r > 0$, $T(\cdot, r)$ *is decreasing, and for each* $\varepsilon > 0$, $T(\varepsilon, \cdot)$ *is increasing, so that for any* $\varepsilon > 0$, $|\xi| \leq r$, *and any* $u \in \mathcal{M}_{\mathcal{O}}$, *the following holds:*

$$T(\varepsilon,r) < T_{\xi,u} \ \Rightarrow\ \Big\{|x(t,\xi,u)| \leq \max\left\{\varepsilon,\ \gamma_1\left(\|y_{[0,t]}\|\right)\right\} \quad \forall\, t \in [T(\varepsilon,r)\,,\ T_{\xi,u})\Big\}. \tag{43}$$

The following lemma on $\mathcal{KL}$ functions will also be needed. This fact is proved in [21] and is stated as Lemma 4.1 in [1]. (That reference requires φ to take nonnegative values, but this can always be assumed without loss of generality, simply replacing φ by $\max\{\varphi, 0\}$.)

PROPOSITION 5.5. *If a function* $\varphi : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}$ *satisfies*

- *for all* $r > 0$, $\varepsilon > 0$, *there exists some* $T = T(\varepsilon, r) > 0$ *so that* $\varphi(s,t) < \varepsilon$ *for all* $s \leq r$ *and* $t \geq T$;
- *for all* $\varepsilon > 0$, *there exists* $\delta > 0$ *so that* $\varphi(s,t) \leq \varepsilon$ *for all* $s \leq \delta$ *and all* $t \geq 0$,

then there exists some $\beta \in \mathcal{KL}$ *so that* $\varphi(s,t) \leq \beta(s,t)$ *for all* $s \geq 0$, $t \geq 0$. □

We are now ready to prove Theorem 4.

Proof of Theorem 4. Suppose that the system (1) with $u \in \mathcal{M}_{\mathcal{O}}$ is globally detectable. Then estimate (40) holds for some $\bar{\sigma}_1, \bar{\sigma}_2 \in \mathcal{K}$, and there exist some

$\gamma_1 \in \mathcal{K}$ and some $T(\cdot,\cdot)$ as in Corollary 5.4 such that (43) holds. Without loss of generality, we assume that $\gamma_1 = \bar{\sigma}_2$. For each $s \geq 0$, $t \geq 0$, set

$$\varphi(s,t) := \sup\left\{|x(t,\xi,u)| - \gamma_1(\|y_{[0,t]}\|) :\ |\xi| \leq s,\ u \in \mathcal{M}_{\mathcal{O}},\ t < T_{\xi,u}\right\}$$

(with the convention that $\sup \emptyset = -\infty$).

It follows from definitions of $T(\cdot,\cdot)$ and φ that for any $r > 0$ and any $\varepsilon > 0$, $\varphi(s,t) < \varepsilon$ for all $s \leq r$ and $t \geq T(\varepsilon, r)$. By (40), $\varphi(s,t) \leq \bar{\sigma}_1(|\xi|)$ for all $s \geq 0$ and $t \geq 0$. Hence, φ satisfies both conditions as in Proposition 5.5, and thus, there exists some $\beta \in \mathcal{KL}$ so that $\varphi(s,t) \leq \beta(s,t)$ for all $s \geq 0$, $t \geq 0$. Combining this with the definition of φ, we get

$$|x(t,\xi,u)| \leq \beta(|\xi|, t) + \gamma_1(\|y_{[0,t]}\|)$$

for all $\xi \in \mathbb{R}^n$, all $u \in \mathcal{M}_{\mathcal{O}}$, and all $t < T_{\xi,u}$. ∎

6. Proofs of the technical lemmas. To prove Lemmas 3.1–3.3, we need the following result.

DEFINITION 6.1. *A system as in* (1) *satisfies the* input-output local stability property *(IO-LS) if there exist $\delta > 0$ and $\mathcal{K}$ functions $\alpha_0, \alpha_u, \alpha_y \in \mathcal{K}$ so that for all ξ, all $u(\cdot)$, and all $t \in [0, T_{\xi,u})$ it holds that*

$$\max\{|\xi|, \|u\|, \|y_{[0,t]}\|\} \leq \delta \Rightarrow |x(t,\xi,u)| \leq \max\{\alpha_0(|\xi|), \alpha_u(\|u\|), \alpha_y(\|y_{[0,t]}\|)\}. \tag{44}$$

LEMMA 6.2. *(IO-LS) & (IO-BND) ⇔ (IO-GS).*

Proof. The implication (IO-GS) ⇒ (IO-LS) & (IO-BND) is obvious; therefore, we only show the converse. Let δ, α_0, α_u, α_y, σ_0, σ_u, σ_y be given as in (44) and (7). Pick a constant $c > 0$ and three class-$\mathcal{K}$ functions $\beta_\star$ such that for each $\star \in \{0, u, y\}$, $\sigma_\star(s) \leq \beta_\star(s) + c$ for all $s > 0$. Pick class-$\mathcal{K}$ functions $\gamma_\star$ so that for each $\star \in \{0, u, y\}$ it holds that

$$\gamma_\star(s) \geq \begin{cases} \max\{\alpha_\star(s), 3\beta_\star(s)\} & \forall\ 0 \leq s \leq \delta, \\ 3[\beta_\star(s) + 3c] & \forall s \geq \delta. \end{cases} \tag{45}$$

Consider any ξ and $u(\cdot)$. Then (IO-GS) holds with gains γ_0, γ_u, and γ_y. Indeed, if $|\xi| \leq \delta$, $\|u\| \leq \delta$, and $\|y_{[0,t]}\| \leq \delta$, this follows by (IO-LS). If instead $|\xi| > \delta$, the definition of (IO-BND) implies

$$\begin{aligned} |x(t,\xi,u)| &\leq \sigma_0(|\xi|) + \sigma_u(\|u\|) + \sigma_y(\|y_{[0,t]}\|) \\ &\leq \beta_0(|\xi|) + \beta_u(\|u\|) + \beta_y(\|y_{[0,t]}\|) + 3c \\ &\leq [\beta_0(|\xi|) + 3c] + [\gamma_u(\|u\|) + \gamma_y(\|y_{[0,t]}\|)]/3 \\ &\leq (1/3)[\gamma_0(|\xi|) + \gamma_u(\|u\|) + \gamma_y(\|y_{[0,t]}\|)] \\ &\leq \max\{\gamma_0(|\xi|), \gamma_u(\|u\|), \gamma_y(\|y_{[0,t]}\|)\}. \end{aligned} \tag{46}$$

The case $\|u\| > \delta$ can be treated in a similar way. Finally, we are left to deal with the case $\delta < \|y_{[0,t]}\| < +\infty$. (The case $\|y\| = +\infty$ is trivial.) By (UO), $x(t,\xi,u)$ is well defined, and therefore the argument as in (46) can be repeated. ∎

Remark 6.3. Observe that in the proof of Lemma 6.2, if the functions α_u and σ_u as in (44) and (7) can be chosen zero, and if the $\|u\|$ term is not presented in the $\max\{\cdots\} \leq \delta$ phrase in (44), then the function γ_u in (46) can also be chosen zero. That is, one has the following.

If for some $\alpha_0,\ \alpha_y \in \mathcal{K}$, $\sigma_0,\ \sigma_y \in \mathcal{N}$ it holds that

$$\max\{|\xi|\,, \|y_{[0,t]}\|\} \le \delta \Rightarrow |x(t,\xi,u)| \le \max\{\alpha_0(|\xi|),\ \alpha_y(\|y_{[0,t]}\|)\}, \tag{47}$$

and

$$|x(t,\xi,u)| \le \max\{\sigma_0(|\xi|),\ \sigma_y(\|y_{[0,t]}\|)\} \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, u,\ \forall\, t \in [0, T_{\xi,u}), \tag{48}$$

then for some $\tilde{\sigma}_0, \tilde{\sigma}_y \in \mathcal{K}$ it holds that

$$|x(t,\xi,u)| \le \max\{\tilde{\sigma}_0(|\xi|),\ \tilde{\sigma}_y(\|y_{[0,t]}\|)\} \qquad \forall\, \xi \in \mathbb{R}^n,\ \forall\, u,\ \forall\, t \in [0, T_{\xi,u}). \tag{49}$$

6.1. Proof of Lemma 3.3. Let $\gamma_u, \gamma_y, \sigma_0, \sigma_u, \sigma_y \in \mathcal{K}$ be as in (5) and (7). Pick any ξ, u and any $\varepsilon > 0$. By (5), there is some $T \in [0, T_{\xi,u})$ such that

$$|x(T,\xi,u)| \le \max\{\gamma_u(\|u\|),\ \gamma_y(\|y\|)\} + \varepsilon.$$

Applying (7) to the initial state $\xi_T := x(T,\xi,u)$ and the control $u_T(t) := u(t+T)$ (whose corresponding output function is $y_T(t,\xi_T,u_T) = y(t+T,\xi,u)$), we conclude that

$$\begin{aligned}\sup_{t\ge T} |x(t,\xi,u)| &= \sup_{0\le t< T_{\xi_T,u_T}} |x(t,\xi_T,u_T)| \le \max\{\sigma_0(|\xi_T|), \sigma_u(\|u_T\|), \sigma_y(\|y\|)\} \\ &\le \max\left\{\sigma_0(\gamma_u(\|u\|)+\varepsilon), \sigma_0(\gamma_y(\|y\|)+\varepsilon), \sigma_u(\|u\|), \sigma_y(\|y\|)\right\}.\end{aligned}$$

Letting $\varepsilon \to 0$, we get

$$\limsup_{t\to T_{\xi,u}} |x(t,\xi,u)| \le \max\{\hat{\gamma}_u(\|u\|),\ \hat{\gamma}_y(\|y\|)\}, \tag{50}$$

where $\hat{\gamma}_u(s) = \max\{\sigma_0(\gamma_u(s)), \sigma_u(s)\}$, $\hat{\gamma}_y(s) = \max\{\sigma_0(\gamma_y(s)), \sigma_y(s)\}$. □

Remark 6.4. We remark that if γ_u and σ_u as in (5) and (7) can be chosen to be the zero function, then the gain function $\hat{\gamma}_u$ in (50) can also be chosen to be the zero function. □

6.2. Proof of Lemma 3.1. Consider the zero-input system

$$\dot{x} = f(x,0), \quad y = h(x). \tag{51}$$

Denote the trajectory corresponding to an initial state ξ by $x(t,\xi)$. This trajectory is defined on a maximal interval $[0, T_\xi)$. Applying Lemma 2.7 and Remark 2.8 to the zero-input system, we know that there exists some $\sigma_0,\ \sigma_y \in \mathcal{N}$ such that for every trajectory of the system the following holds:

$$|x(t,\xi)| \le \max\{\sigma_0(|\xi|),\ \sigma_y(\|y_{[0,t]}\|)\} \qquad \forall\, t \in [0, T_\xi). \tag{52}$$

By Remark 6.3, one sees that, together with the zero-O-LS property (as defined in (15)), (52) implies that the system is locally detectable, that is, for some $\tilde{\sigma}_0, \tilde{\sigma}_y \in \mathcal{K}$, (49) holds.

Applying Remark 6.4 to (51) with the IO-LIM estimate (5) with $\gamma_u = 0$ and (49), one sees that the following holds for every trajectory $x(t,\xi)$ of (51):

$$\limsup_{t\to T_\xi} |x(t,\xi)| \le \gamma\left(\|y_{[0,T_\xi)}\|\right). \tag{53}$$

The combination of (52) and (53) means that the system (51) is globally detectable. By Theorem 4, the system (51) is OSS. □

6.3. Proof of Lemma 3.2. Clearly (local-IOSS) $\Rightarrow$ (IO-LS). Moreover, by Lemma 2.7, (IO-LIM) $\Rightarrow$ (IO-BND). Combining this with Lemma 6.2, we get

$$\text{(local IOSS) \& (IO-LIM)} \Rightarrow \text{(IO-LS) \& (IO-BND)} \Leftrightarrow \text{(IO-GS)}, \tag{54}$$

which completes the proof. □

6.4. Proof of Proposition 3.4. In order to complete the proof, the following result will be needed.

LEMMA 6.5. *Suppose that system* (1) *satisfies the IO-AG and IO-GS properties. Then there exists some locally Lipschitz* $\varphi \in \mathcal{K}_\infty$ *such that the system*

$$\dot{x}(t) = f(x(t), d(t)\varphi(|x(t)|)), \qquad y(t) = h(x(t)), \tag{55}$$

where d *denotes the disturbance functions taking values in the closed unit ball of* $\mathbb{R}^m$*, is globally detectable.*

Proof. Let σ_0, σ_u, $\sigma_y \in \mathcal{K}$ be such that the IO-GS estimate (7) holds, and let γ_u, $\gamma_y \in \mathcal{K}$ be such that the IO-AG estimate (6) holds for the system. Without loss of generality, we may assume that $\sigma_u = \gamma_u$ and $\sigma_y = \gamma_y$. Pick any locally Lipschitz $\mathcal{K}_\infty$-function φ such that $\sigma_u(\varphi(s)) \le s/2$ for all $s \ge 0$. Below we show that with the function φ, the corresponding system (55) is globally detectable. For any $\xi \in \mathbb{R}^n$ and any d, we let $x_\varphi(t, \xi, d)$ denote the corresponding solution for (55), $y_\varphi = h(x_\varphi)$, and let $[0, \tau_{\xi,d})$ denote the maximal interval of the solution. Observe that for any ξ, d it holds that

$$x_\varphi(t, \xi, d) = x(t, \xi, u_d) \qquad \forall\, 0 \le t < \tau_{\xi,d},$$

where $u_d(t) = d(t)\varphi(|x_\varphi(t, \xi, d)|)$. Consequently,

$$\begin{aligned} |x_\varphi(t, \xi, d)| &\le \max\left\{\sigma_0(|\xi|),\ \sigma_u\left(\varphi\left(\|x_\varphi(\cdot, \xi, d)_{[0,t)}\|\right)\right),\ \sigma_y(\|(y_\varphi)_{[0,t)}\|)\right\} \\ &\le \max\left\{\sigma_0(|\xi|),\ \frac{\|x_\varphi(\cdot, \xi, d)_{[0,t)}\|}{2},\ \sigma_y(\|(y_\varphi)_{[0,t)}\|)\right\} \qquad \forall\, 0 \le t < \tau_{\xi,d}\,. \end{aligned}$$

Thus, for any $0 \le t < \tau_{\xi,d}$,

$$\|x_\varphi(\cdot, \xi, d)_{[0,t)}\| \le \max\left\{\sigma_0(|\xi|),\ \frac{\|x_\varphi(\cdot, \xi, d)_{[0,t)}\|}{2},\ \sigma_y(\|(y_\varphi)_{[0,t)}\|)\right\}.$$

Consequently, for any $0 \le t < \tau_{\xi,d}$,

$$\|x_\varphi(\cdot, \xi, d)_{[0,t)}\| \le \max\left\{\sigma_0(|\xi|),\ \sigma_y(\|(y_\varphi)_{[0,t)}\|)\right\},$$

and in particular,

$$|x_\varphi(t, \xi, d)| \le \max\left\{\sigma_0(|\xi|),\ \sigma_y\left(\|(y_\varphi)_{[0,t)}\|\right)\right\} \tag{56}$$

for all $0 \le t < \tau_{\xi,d}$. This shows that property (40) holds. Below we show that the attractivity property as in (41) holds for the system (55). By (56), the system (55) satisfies the UO property. Pick any ξ, d. Suppose $\tau_{\xi,d} = \infty$ and $\|y\| < \infty$. Then, again, by (56),

$$\limsup_{t\to\infty} |x_\varphi(t, \xi, d)| < \infty. \tag{57}$$

By the IO-AG property (6), with Lemma 2.10,

$$\begin{aligned}\limsup_{t\to\infty}|x_\varphi(t,\xi,d)| &\le \max\left\{\gamma_u\left(\limsup_{t\to\infty}|u_d(t)|\right),\ \gamma_y\left(\limsup_{t\to\infty}|y_\varphi(t)|\right)\right\}\\ &\le \max\left\{\gamma_u\left(\varphi\left(\limsup_{t\to\infty}|x_\varphi(t,\xi,d)|\right)\right),\ \gamma_y\left(\limsup_{t\to\infty}|y_\varphi(t)|\right)\right\}\\ &\le \max\left\{\frac{1}{2}\limsup_{t\to\infty}|x_\varphi(t,\xi,d)|,\ \gamma_y\left(\limsup_{t\to\infty}|y_\varphi(t)|\right)\right\}.\end{aligned}$$

Combining this with (57), we get

$$\limsup_{t\to\infty}|x_\varphi(t,\xi,d)| \le \gamma_y\left(\limsup_{t\to\infty}|y_\varphi(t)|\right).$$

Again, with the UO property, we see that the attractivity property (41) holds for the system (55). Thus, the system is globally detectable. □

Proof of Proposition 3.4. Suppose that a system as in (1) satisfies the IO-AG and the IO-GS properties. By Lemma 6.5, there exists some locally Lipschitz $\varphi \in \mathcal{K}_\infty$ such that the corresponding system (55) is globally detectable. By Theorem 4, the system (55) is uniformly output-to-state stable. Applying Theorem 2.16 together with Corollary 3.6 of [16], one sees that the system (1) is IOSS. (Following the work in [16], if a system (1) admits a locally Lipschitz $\varphi \in \mathcal{K}_\infty$ such that the corresponding system (55) is uniformly OSS, then the system (1) is called robustly OSS.) □

Appendix A. Characterizations of IO-LIM. Consider the following variations of the IO-LIM property.

DEFINITION A.1. *For system* (1)*, we say that*

- *the asymptotic IO-LIM property holds if for some* $\gamma_u, \gamma_y \in \mathcal{K}$*,*

$$\liminf_{t\to T_{\xi,u}}|x(t,\xi,u)| \le \limsup_{t\to T_{\xi,u}}\max\{\gamma_u(|u(t)|),\gamma_y(|y(t)|)\} \tag{58}$$

  for all $\xi \in \mathbb{R}^n$*, all* $u(\cdot)$*;*
- *the causal IO-LIM property holds if for some* $\gamma_u, \gamma_y \in \mathcal{K}$*,*

$$\inf_{t\in[0,T_{\xi,u})}\Big\{|x(t,\xi,u)| - \max\{\gamma_u(\|u_{[0,t]}\|),\gamma_y(\|y_{[0,t]}\|)\}\Big\} \le 0 \tag{59}$$

  for all $\xi \in \mathbb{R}^n$*, all* $u(\cdot)$*;*
- *the asymptotic causal IO-LIM property holds if*

$$\liminf_{t\to T_{\xi,u}}\Big\{|x(t,\xi,u)| - \max\{\gamma_u(\|u_{[0,t]}\|),\gamma_y(\|y_{[0,t]}\|)\}\Big\} \le 0 \tag{60}$$

  for all $\xi \in \mathbb{R}^n$*, all* $u(\cdot)$*.* □

PROPOSITION A.2. *For a system as in* (1)*, the following properties are equivalent:*

1. *IO-LIM,*
2. *asymptotic IO-LIM,*
3. *causal IO-LIM,*
4. *asymptotic causal IO-LIM.* □

Proof. [1 ⇒ 2]: Suppose the IO-LIM property holds for system (1) with $\gamma_u, \gamma_y \in \mathcal{K}_\infty$ as in (5). Fix ξ, u. Pick any $T \in [0, T_{\xi,u})$. Let $\xi_T = x(T,\xi,u)$ and $u_T(t) = u(t+T)$. Applying (5) to ξ_T with u_T, we get

$$\inf_{t\ge T}|x(t,\xi,u)| = \inf_{t\ge 0}|x(t,\xi_T,u_T)| \le \max\left\{\gamma_u(\|u_{[T,T_{\xi,u})}\|),\ \gamma_y(\|y_{[T,T_{\xi,u})}\|)\right\}.$$

This implies that

$$\liminf_{t\to T_{\xi,u}} |x(t,\xi,u)| \le \lim_{T\to T_{\xi,u}} \left\{\max\left\{\gamma_u(\|u_{[T,T_{\xi,u})}\|),\ \gamma_y(\|y_{[T,T_{\xi,u})}\|)\right\}\right\}.$$

With (2), we get (58).

[$2 \Rightarrow 3$]: Assume that (58) holds for some $\gamma_u, \gamma_y \in \mathcal{K}$. Below we show that this will imply (59) with the same γ_u, γ_y functions. Suppose that this fails for some trajectory $x(t,\xi,u)$. It then follows that

$$|x(t,\xi,u)| \ge \max\{\gamma_u(\|u_{[0,t]}\|),\ \gamma_y(\|y_{[0,t]}\|)\} \quad \forall\, t \in [0, T_{\xi,u}).$$

Taking the lim inf on both sides of the inequality, one gets

$$\begin{aligned}\liminf_{t\to T_{\xi,u}} |x(t,\xi,u)| &\ge \liminf_{t\to T_{\xi,u}} \max\{\gamma_u(\|u_{[0,t]}\|),\ \gamma_y(\|y_{[0,t]}\|)\}\\ &= \max\{\gamma_u(\|u_{[0,T_{\xi,u})}\|),\ \gamma_y(\|y_{[0,T_{\xi,u})}\|)\},\end{aligned}$$

which contradicts (58).

[$3 \Rightarrow 4$]: The proof of this portion is trivial.

[$4 \Rightarrow 1$]: An estimate as in (60) in particular implies that

$$\liminf_{t\to T_{\xi,u}} \Big[|x(t,\xi,u)| - \max\{\gamma_u(\|u\|),\ \gamma_y(\|y\|)\}\Big] \le 0,$$

which is the same as (8). By Remark 2.5, IO-LIM holds. □

Appendix B. The error detectability properties. In some of the proofs in this paper, we have used some results from the recent work [3]. They are stated here, in the interest of making this paper self-contained. The first statement is a special case of Corollary 4.3 in [3].

LEMMA B.1. *For a given unboundedness observable system of the form* (1)*, assume*

- *a compact subset $\mathcal{O}$ of the input set $\mathbb{U}$;*
- *subsets K, C, and Ω of the state space $\mathbb{R}^n$ such that K and C are compact, Ω is open, and $K \subset \Omega \subset C$;*
- *subsets $\mathcal{Y}$ and $\mathcal{Y}_0$ of the output space $\mathbb{R}^p$ such that $\mathcal{Y}$ is compact, $\mathcal{Y}_0$ is open, and $\mathcal{Y} \subset \mathcal{Y}_0$*

such that, for all $\xi \in C$ and all inputs $u \in \mathcal{M}_{\mathcal{O}}$, there exists $t \in [0, T_{\xi,u})$ for which

$$x(t,\xi,u) \in K \quad \text{or} \quad h(x(t,\xi,u)) \notin \mathcal{Y}_0. \tag{61}$$

Then $\mathcal{R}_{\mathcal{O}/\mathcal{Y}}(C)$ is bounded. □

Considered a system as in the following:

$$\dot{x}(t) = f(x(t),u(t)),\ z(t) = \varphi(x(t)),\ w(t) = k(x(t)), \tag{62}$$

where $\varphi(\cdot), k(\cdot)$ are continuous maps from $\mathbb{R}^n$ to $\mathbb{R}^k$ and $\mathbb{R}^l$, respectively, for some k and l, and where f satisfies the same assumptions as were made for system (1). Following the work in [3], we call z the output signal and w the measurement signal. The inputs are functions in $\mathcal{M}_{\mathcal{O}}$ for some $\mathcal{O} \subset \mathbb{U}$.

DEFINITION B.2. *The system* (62) *is said to satisfy the* unboundedness observability property through w *(UO through w) if, for each ξ and u such that $T_{\xi,u} < \infty$, it holds that*

$$\limsup_{t\to T_{\xi,u}} |w(t)| = \infty.$$

The following definitions were proposed in [3].

DEFINITION B.3. *We say that system* (62) *is* globally error-detectable *if there exists some* $\gamma \in \mathcal{K}$ *such that for the map* $\hat{z}(\cdot)$ *defined by*

$$\hat{z}(t) = \max\{|z(t)| - \gamma(|w(t)|),\ 0\} \tag{63}$$

the following hold:

- *(Local uniform output-stability modulo measurements): for some* $\sigma_1, \sigma_2 \in \mathcal{K}$ *and some* $\delta > 0$*, it holds that*

$$|\hat{z}(0)| < \delta \Longrightarrow |\hat{z}(t)| \leq \sigma_1(|\hat{z}(0)|) + \sigma\left(\|w\|_{[0,t]}\right) \qquad \forall\, 0 \leq t < T_{\xi,u} \tag{64}$$

  for all ξ *and* $u \in \mathcal{M}_{\mathcal{O}}$.
- *(Asymptotic-detectablity):* $\inf_{0 \leq t < T_{\xi,u}} |\hat{z}(t)| = 0$ *for all* ξ *and* $u \in \mathcal{M}_{\mathcal{O}}$. ∎

DEFINITION B.4. *We say that system* (1) *is* uniformly globally error-detectable *if there exists some* $\gamma \in \mathcal{K}$ *such that for the map* $\hat{z}(\cdot)$ *defined by* (63) *the following hold:*

- *the local uniform output-stability modulo measurements property as in Definition* B.3 *holds, and*
- *(uniform asy-detectability): for any* $\varepsilon > 0$ *and any* $\kappa > 0$*, there exists* $T_{\varepsilon,\kappa}$ *so that for any* $\xi \in \mathbb{R}^n$ *with* $|\xi| \leq \kappa$ *and for any* u *there exists some* $\tau < \min\{T_{\varepsilon,\kappa},\ T_{\xi,u}\}$ *such that*

$$|\hat{z}(\tau)| \leq \varepsilon. \tag{65}$$

Remark B.5. The uniformly global error-detectability implies the following property: there exists some $\gamma_1 \in \mathcal{K}$ such that for all $\varepsilon > 0$ and all $\kappa > 0$ there exists $T_{\varepsilon,\kappa}$ so that for any $\xi \in \mathbb{R}^n$ with $|\xi| \leq \kappa$ and for any u, if $T_{\varepsilon,\kappa} < T_{\xi,u}$, then

$$|z(t)| \leq \varepsilon + \gamma_1\left(\|w\|_{[0,t)}\right)$$

for all $t \in [T_{\varepsilon,\kappa}\,,\ T_{\xi,u})$. ∎

A main result in [3] is the following.

LEMMA B.6. *Let* $\mathcal{O}$ *be compact. Assume that system* (62) *satisfies the UO property through the measurement* w*. Then the system is globally error-detectable in* $u \in \mathcal{M}_{\mathcal{O}}$ *if and only if it is uniformly globally error-detectable in* $u \in \mathcal{M}_{\mathcal{O}}$. ∎

REDUCTION OF CONTROLLED LAGRANGIAN AND HAMILTONIAN SYSTEMS WITH SYMMETRY*

DONG EUI CHANG† AND JERROLD E. MARSDEN‡

Abstract. We develop reduction theory for controlled Lagrangian and controlled Hamiltonian systems with symmetry. Reduction theory for these systems is needed in a variety of examples, such as a spacecraft with rotors, a heavy top with rotors, and underwater vehicle dynamics. One of our main results shows the equivalence of the method of reduced controlled Lagrangian systems and that of reduced controlled Hamiltonian systems in the case of simple mechanical systems with symmetry.

Key words. controlled Lagrangian systems, controlled Hamiltonian systems, reduction, equivalence

DOI. 10.1137/S0363012902412951

1. Introduction.

We develop the theory of symmetry reduction for the class of controlled Lagrangian (CL) and controlled Hamiltonian (CH) systems with symmetry and show the equivalence of the method of reduced CL systems and that of reduced CH systems for simple mechanical systems. The phrases "controlled Lagrangian" and "controlled Hamiltonian" systems were coined in [20], and their technical definition is recalled below. The concept of a CH system used here is the same as that of a "port-controlled Hamiltonian system" in [32]. We prefer to use the term "controlled Hamiltonian" in a way that is parallel to "controlled Lagrangian." The notion of an "implicit Hamiltonian system" is related to that of a CH system but is based on the more general notion of Dirac structures rather than symplectic and Poisson structures, and a type of reduction theory (different from what is given here) in that context was developed in [6]. The notion of an "implicit Lagrangian system" is developed, also using Dirac structures, in [35], and in future work we hope to explore the reduction theory of controlled implicit Hamiltonian and Lagrangian systems and the relation between them.

CL systems. We will begin by describing the Lagrangian side. To help design stabilizing controllers for mechanical systems whose equations are written in Euler–Lagrange form with control forces, the CL method was developed by a number of authors, including [3], [4], [7], [10], [11], [12], [13], [14], [15], [19], [20], [22], [23], [33]. In the study of CL systems, it is important to take into account external forces and control forces, including gyroscopic forces.

The main idea of the CL method is to proceed in the following steps:

1. Define a (feedback-transformation) equivalence relation among CL systems.
2. Given a CL system, find an equivalent CL system such that the energy of the second CL system has a minimum at the equilibrium of interest and the system is forced or controlled by a dissipative (plus gyroscopic) force.

‡Control and Dynamical Systems 107-81, California Institute of Technology, Pasadena, CA 91125 (marsden@cds.caltech.edu).

3. Using the energy as a Lyapunov function, obtain asymptotic stability of the equilibrium in the second CL system.
4. Since the two systems are equivalent, the equivalence relation gives an asymptotically stabilizing controller for the first system.

CH systems. A similar approach has been taken on the Hamiltonian side, too, where the main governing equations are in Hamiltonian form (see [5], [9], [32], [34] and references therein).

Equivalence. There have been some recent studies concerning the equivalence of both methods. First of all, [5] showed that the CH method is more general than the CL method for simple mechanical systems and used a limited definition of CL systems. Then [20] extended the theory of CL systems and showed the full equivalence of the method of CL systems with the method of CH systems for simple mechanical systems.

Symmetry. The main goal of the present paper is to include symmetry in the discussion. We do so in a systematic and general way. In previous works, symmetry was considered in certain cases (see, for instance, [15], [23], and [26]), but a comprehensive theory has been lacking.

In this paper, we define the notion of G-invariant CL and CH systems and develop a reduction theory for them. In addition, we trace through the equivalence of the CL and CH systems under the reduction process.

Reduction theory. Reduction theory for mechanical systems has been studied both on the Lagrangian side and on the Hamiltonian side. It has proven to be a powerful tool for studying the dynamics, stability, and control of many mechanical systems, such as rigid body and spacecraft systems, underwater vehicles, heavy tops, and fluid systems.

On the Lagrangian side, one reduces variational principles, an idea due to [29] and [30]. A comprehensive account of this theory is given in [17]. On the other hand, on the Hamiltonian side, one reduces symplectic and Poisson structures. See, for instance, [1], [27], and [28] and references therein. We shall merge these ideas with those of CL and CH systems to develop the notions and basic properties of reduced CL and CH systems.

Equivalence and reduction. Once we have developed the reduction theory, we will be in a position to define an equivalence relation among G-invariant CL (resp., CH) systems; in this context, we show that two reduced CL (resp., CH) systems are equivalent if and only if their unreduced G-invariant CL (resp., CH) systems are equivalent. This is given in Theorems 2.10 and 3.9.

We also show that this reduced equivalence relation is a feedback-transform equivalence relation (see Theorems 2.11 and 3.10). Based on these results and the equivalence of the methods of CL and CH systems for simple mechanical systems proven in [20], we prove that the method of reduced CL systems and that of reduced CH systems are equivalent for reduced simple mechanical systems (this is given in Theorem 4.3).

Example. In the final section, we review the example of a satellite controlled via a spinning rotor and show that the Euler–Poincaré matching conditions derived in [8] and [15] directly in the reduced context can be obtained in a natural way through the reduction process. We study the stabilization of the heavy top with rotors, using the reduced CL method as an illustration.

2. Reduction of CL systems with symmetry. We begin this section with some general notation, then we introduce the notion of a CL system with symmetry, and finally study the theory of reduction for such systems.

We first summarize some general notation that will be used. We refer to [2], [17], [25], and [28] for more details and background information.

Manifolds and bundles. Let Q be the configuration manifold, and let $\tau_Q : TQ \to Q$ and $\pi_Q : T^*Q \to Q$ be the tangent bundle projection and the cotangent bundle projection, respectively. The second order tangent bundle $\tau_Q^{(2)} : T^{(2)}Q \to Q$ is defined as follows. For $\bar{q} \in Q$, elements of $T_q^{(2)}Q$ are equivalence classes of curves in Q, the equivalence relation being defined as follows: two curves $q_i(t)$, $i = 1, 2$, with $q_1(\bar{t}) = q_2(\bar{t}) = \bar{q}$, are equivalent, by definition, if and only if in any local chart we have $q_1^{(l)}(\bar{t}) = q_2^{(l)}(\bar{t})$ for $l = 1, 2$, where $q^{(l)}(t)$ denotes the derivative of order l. The second order bundle has local coordinates given by $(q^i, \dot{q}^i, \ddot{q}^i)$ and may be thought of as a subbundle of the second tangent bundle TTQ via the embedding $(q^i, \dot{q}^i, \ddot{q}^i) \mapsto (q^i, \dot{q}^i, \dot{q}^i, \ddot{q}^i)$. As is explained in [28], the second order tangent bundle is the basic space on which the Euler–Lagrange operator of mechanics is defined; in fact, given a Lagrangian L, the associated Euler–Lagrange operator $\mathcal{EL}$ induces a bundle map $\mathcal{EL}(L) : T^{(2)}Q \to T^*Q$.

For a manifold M, $\mathcal{F}(M)$ denotes the set of smooth real-valued functions on M.

Symmetry groups. Let G be a Lie group acting (on the left) on Q freely and properly so that $\pi_G(Q) : Q \to Q/G$ becomes a principal bundle. The tangent (resp., cotangent) lift of the action of G on Q defines an action of G on TQ (resp., T^*Q), which is automatically free and proper as well, so that the maps $\tau_{/G} : TQ \to TQ/G$ (resp., $\pi_{/G} : T^*Q \to T^*Q/G$) also define principal bundles. When M is a manifold on which G acts, we let $[m]_G$ denote an equivalence class of $m \in M$ in the quotient space M/G. Even though we do not explicitly denote the manifold M in this notation, it will be clear which manifold is meant from the context. The space TQ/G becomes a vector bundle with base Q/G by inheriting the vector bundle structure of TQ as follows:

$$[u_q]_G + \lambda[v_q]_G = [u_q + \lambda v_q]_G,$$

where $\lambda \in \mathbb{R}$; $u_q, v_q \in T_qQ$; and $[u_q]_G, [v_q]_G$ are their equivalence classes in the quotient space TQ/G. The fiber $(TQ/G)_x$ is isomorphic, as a vector space, to T_qQ for each $x = [q]_G \in Q/G$, $q \in Q$ (see Lemma 2.4.1 in [17]). In the same manner, the space T^*Q/G becomes a vector bundle with base Q/G.

Vertical lifts. Let V be a vector bundle over a manifold Q. The vertical lift of a vector $w_q \in V_q$ along the vector $v_q \in V_q$ is the vector, $\mathrm{vlift}_{v_q}(w_q) \in T_{v_q}V$, defined by

$$\mathrm{vlift}_{v_q}(w_q) = \left.\frac{d}{dt}\right|_{t=0} (v_q + tw_q).$$

The vertical lift of a fiber-preserving map $F : V \to V$ is a section, $\mathrm{vlift}(F) : V \to TV$, defined by

$$\mathrm{vlift}(F)(v_q) = \mathrm{vlift}_{v_q}(F(v_q)). \tag{2.1}$$

The vertical lift of a subbundle W of V is the subbundle of TV defined by

$$\mathrm{vlift}(W) = \{\mathrm{vlift}_{v_q}(w_q) \mid v_q \in V_q, w_q \in W_q, q \in Q\}. \tag{2.2}$$

CL systems. We next recall the definition of a CL system from [20].

Definition 2.1. *A* controlled Lagrangian (CL) system *is a triple* (L, F, W), *where the function* $L : TQ \to \mathbb{R}$ *is the* Lagrangian, *the fiber-preserving map* F :

$TQ \to T^*Q$ is the (external) force map*, and the subbundle W of T^*Q is called the* control subbundle*. When one chooses a feedback control law $u : TQ \to W$, the triple (L, F, u) will denote the* closed-loop CL system*.*

Euler–Lagrange operator. The Euler–Lagrange operator $\mathcal{EL}$ assigns to a Lagrangian $L : TQ \to \mathbb{R}$ a bundle map $\mathcal{EL}(L) : T^{(2)}Q \to T^*Q$, which may be written in local coordinates (and using the index summation convention) as

$$\mathcal{EL}(L)(q, \dot{q}, \ddot{q}) = \left(\frac{d}{dt} \frac{\partial L}{\partial \dot{q}^i}(q, \dot{q}) - \frac{\partial L}{\partial q^i}(q, \dot{q}) \right) \mathbf{d}q^i,$$

in which it is understood that one regards the first term on the right-hand side as a function on the second order tangent bundle $T^{(2)}Q$ by formally applying the chain rule and replacing dq/dt by $\dot{q}$ everywhere. The equations of motion of a CL system (L, F, W) with a choice of feedback control $u : TQ \to W$ are written as

$$\mathcal{EL}(L)(q, \dot{q}, \ddot{q}) = F(q, \dot{q}) + u(q, \dot{q}), \tag{2.3}$$

which may be derived from the Lagrange–d'Alembert principle.

CL systems with symmetry. We next define the notion of a G-invariant CL system on TQ and the associated notion of a reduced CL system on TQ/G, where G is a Lie group acting on Q.

Definition 2.2. *Let G be a Lie group action on Q. A* G-invariant controlled Lagrangian (G-CL) system *is a CL system, (L, F, W), where L is a G-invariant Lagrangian, F is a G-equivariant force map, and W is a G-invariant subbundle of T^*Q.*

Reduction of CL systems with symmetry. Now we can define the notion of a reduced CL system.

Definition 2.3. *A* reduced controlled Lagrangian (RCL) system *is a triple (l, f, U), where the function $l : TQ/G \to \mathbb{R}$ is called the* reduced Lagrangian*, the fiber-preserving map $f : TQ/G \to T^*Q/G$ is called the* reduced force map*, and the subbundle U of T^*Q/G is called the* reduced control subbundle*. A* feedback control *for an RCL system is a fiber-preserving map of TQ/G into U.*

Suppose that we are given a G-CL system (L, F, W). The G-invariance of L induces the reduced Lagrangian l on TQ/G satisfying

$$l \circ \tau_{/G} = L. \tag{2.4}$$

The equivariance of F induces the reduced force map $[F]_G : TQ/G \to T^*Q/G$ satisfying

$$[F]_G \circ \tau_{/G} = \pi_{/G} \circ F. \tag{2.5}$$

Similarly, a G-invariant control subbundle W induces a reduced control subbundle W/G in a natural way; namely, we have $W = \pi_{/G}^{-1}(W/G)$.

These considerations lead to the following definition.

Definition 2.4. *The RCL system of a G-CL system (L, F, W) is the triple $(l, [F]_G, W/G)$, where l is the reduced Lagrangian satisfying* (2.4) *and $[F]_G$ is the reduced force satisfying* (2.5)*.*

One may ask whether there exists a G-CL system on TQ when one is given a RCL system on TQ/G. The following proposition proves its existence and uniqueness.

Proposition 2.5. *Given a RCL system (l, f, U), there is a unique G-CL system (L, F, W) whose RCL system is (l, f, U).*

Proof. Define L by (2.4). Define a force map F on TQ as follows: for $v_q, w_q \in T_qQ$,

$$\langle F(v_q),\, w_q\rangle = \langle f \circ \tau_{/G}(v_q),\, \tau_{/G}(w_q)\rangle. \tag{2.6}$$

One can check the G-equivariance of F. One can also check that relation (2.6) defines the unique *fiber-preserving* map F of TQ to T^*Q. Let $W := \pi_{/G}^{-1}(U)$. By construction, (L, F, W) is the unique G-CL system whose RCL system is (l, f, U). □

By Proposition 2.5, we can write an arbitrary RCL in the form of the RCL of a G-CL without loss of generality. Additionally, the proof of Proposition 2.5 establishes the following assertion: given a fiber-preserving map $f : TQ/G \to T^*Q/G$, there exists the unique fiber-preserving map $F : TQ \to T^*Q$ satisfying

$$f \circ \tau_{/G} = \pi_{/G} \circ F.$$

Reduced equations of motion. Given a G-CL system (L, F, W), the G-invariance of L implies the G-equivariance of the bundle map $\mathcal{EL}(L) : T^{(2)}Q \to T^*Q$, which induces a quotient map

$$\mathcal{REL}(l) := [\mathcal{EL}(L)]_G : T^{(2)}Q/G \to T^*Q/G,$$

which depends only on the reduced Lagrangian l on TQ/G induced from L. The operator $\mathcal{REL}$ is called the reduced Euler–Lagrange operator. The equations of motion of an RCL $(l, [F]_G, W/G)$ with a choice of control $[u]_G : TQ/G \to W/G$ are given by

$$\mathcal{REL}(l)([q, \dot q, \ddot q]_G) = [F]_G([q, \dot q]_G) + [u]_G([q, \dot q]_G).$$

To write computable equations of $\mathcal{REL}$, one normally chooses a principal connection on the principal bundle $Q \to Q/G$ to identify the quotient bundles,

$$TQ/G \text{ with } T(Q/G) \oplus \tilde{\mathfrak{g}},$$
$$T^{(2)}Q/G \text{ with } T^{(2)}(Q/G) \times_{Q/G} 2\tilde{\mathfrak{g}},$$

and

$$T^*Q/G \text{ with } T^*(Q/G) \oplus \tilde{\mathfrak{g}}^*,$$

where $\tilde{\mathfrak{g}} := Q \times_G \mathfrak{g}$ is the associated adjoint bundle, $\tilde{\mathfrak{g}}^* := Q \times_G \mathfrak{g}^*$ is the associated coadjoint bundle, $T^{(2)}(Q/G) \times_{Q/G} 2\tilde{\mathfrak{g}}$ is the product bundle over Q/G, $2\tilde{\mathfrak{g}} := \tilde{\mathfrak{g}} \oplus \tilde{\mathfrak{g}}$, and $\oplus$ is the Whitney sum (see Lemmas 2.4.2 and 3.2.2 in [17]). For example, a principal connection $A : TQ \to \mathfrak{g}$ on the principal bundle $\pi : Q \to Q/G$ induces the bundle isomorphism $\alpha_A : TQ/G \to T(Q/G) \oplus \tilde{\mathfrak{g}}$ as follows:

$$\alpha_A([q, \dot q]_G) = T\pi(q, \dot q) \oplus [q, A(q, \dot q)]_G. \tag{2.7}$$

With these identifications, $\mathcal{REL}$ induces the Lagrange–Poincaré operator $\mathcal{LP}$ as follows: for a reduced Lagrangian l,

$$\mathcal{LP}(l) : T^{(2)}(Q/G) \times_{Q/G} 2\tilde{\mathfrak{g}} \to T^*(Q/G) \oplus \tilde{\mathfrak{g}}^*. \tag{2.8}$$

Hence, the reduced Euler–Lagrange operator $\mathcal{REL}$ may be replaced by the Lagrange–Poincaré operator $\mathcal{LP}$ in this paper as far as one chooses a connection on $Q \to Q/G$. Further details may be found in [17].

Let us give the local coordinate expression of the Lagrange–Poincaré operator $\mathcal{LP}$ induced from a connection A on the principal bundle $Q \to Q/G$. This will be used in section 5. We choose a local trivialization of the bundle $Q \to Q/G$ to be $X \times G \to X$, where X is an open subset of $\mathbb{R}^r$ with $r = \dim(Q/G)$. Then, at any tangent vector $(x, g, \dot{x}, \dot{g}) \in T_{(x,g)}(X \times G)$, we have

$$A(x, g, \dot{x}, \dot{g}) = \mathrm{Ad}_g(A_e(x) \cdot \dot{x} + \xi),$$

where A_e is the $\mathfrak{g}$-valued 1-form on X defined by $A_e(x)\cdot\dot{x} = A(x, e, \dot{x}, 0)$ and $\xi = g^{-1}\dot{g}$. The bundle isomorphism α_A in this case becomes

$$\alpha_A([x, g, \dot{x}, \dot{g}]_G) = (x, \dot{x}) \oplus (x, \Omega),$$

where $\Omega = A_e(x) \cdot \dot{x} + \xi$ and we choose a local trivialization of the associated bundle $\tilde{\mathfrak{g}}$ to be $X \times \mathfrak{g} \to X$. The Lagrange–Poincaré operator $\mathcal{LP}$ for a reduced Lagrangian l on $TQ/G = T(Q/G) \oplus \tilde{\mathfrak{g}}$ gives

$$\mathcal{LP}(l) = \begin{pmatrix} \dfrac{d}{dt}\dfrac{\partial l}{\partial \dot{x}^\alpha} - \dfrac{\partial l}{\partial x^\alpha} + \dfrac{\partial l}{\partial \Omega^a}(B^a_{\beta\alpha}\dot{x}^\beta + C^a_{db}\Omega^d A^b_\alpha) \\ \dfrac{d}{dt}\dfrac{\partial l}{\partial \Omega^b} - \dfrac{\partial l}{\partial \Omega^a}(C^a_{db}\Omega^d - C^a_{db}A^d_\alpha \dot{x}^\alpha) \end{pmatrix}, \tag{2.9}$$

where $B^a_{\beta\alpha}$ is the curvature of the connection $A_e = (A^a_\alpha)$, C^a_{bd} are the structure constants of the Lie algebra $\mathfrak{g}$, and $\Omega = (\Omega^a)$ and $x = (x^\alpha)$ with $a = 1, \ldots, \dim \mathfrak{g}$ and $\alpha = 1, \ldots, \dim(Q/G)$. More details of the derivation of (2.9) may be found in sections 3.3 and 4.2 of [17]. In particular, if one chooses a local trivial connection, i.e., $A_e = 0$, then the Lagrange–Poincaré equation in (2.9) is given by

$$\mathcal{LP}(l) = \begin{pmatrix} \dfrac{d}{dt}\dfrac{\partial l}{\partial \dot{x}^\alpha} - \dfrac{\partial l}{\partial x^\alpha} \\ \dfrac{d}{dt}\dfrac{\partial l}{\partial \xi^b} - C^a_{db}\xi^d \dfrac{\partial l}{\partial \xi^a} \end{pmatrix}. \tag{2.10}$$

We briefly mention the relation between trajectories of G-CL systems and trajectories of RCL systems. Let (L, F, W) be a G-CL system and $(l, [F]_G, W/G)$ its RCL system. Choose an arbitrary *G-equivariant* feedback control law $u : TQ \to W$ for (L, F, W). The control u induces a reduced map $[u]_G : TQ/G \to W/G$. Then, if $(q(t), \dot{q}(t)) \in TQ$ is a trajectory of the closed-loop system (L, F, u), then $\tau_{/G}(q(t), \dot{q}(t)) \in TQ/G$ is the trajectory of the closed-loop system $(l, [F]_G, [u]_G)$.

Simple CL systems. We define simple CL systems, which include most mechanical systems in engineering applications.

Definition 2.6. *A CL system (L, F, W) on TQ is called* simple *if its Lagrangian $L : TQ \to \mathbb{R}$ is of the form kinetic minus potential energy as follows:*

$$L(q, \dot{q}) = \frac{1}{2} m_q(\dot{q}, \dot{q}) - V(q), \tag{2.11}$$

where m is a (generalized) mass tensor, i.e., a nondegenerate symmetric $(0, 2)$-tensor. A reduced CL system $(l, [F]_G, W/G)$ is called simple *if the reduced Lagrangian l is induced by a G-invariant simple Lagrangian L on TQ. The acronym (R)SCL will denote "(reduced) simple controlled Lagrangian."*

When a simple G-invariant Lagrangian L is given by (2.11), its RSCL $l : TQ/G \to \mathbb{R}$ is given by

$$l([q,\dot{q}]_G) = \frac{1}{2}[m]_G([q,\dot{q}]_G,[q,\dot{q}]_G) - [V]_G([q]_G),$$

where $[m]_G \in \Gamma(Q/G, T^*Q/G \otimes T^*Q/G)$ is the reduced mass tensor induced from the G-invariance of the mass tensor $m \in \Gamma(Q, T^*Q \otimes T^*Q)$ and $[V]_G : Q/G \to \mathbb{R}$ is the reduced potential energy.

SCL-equivalence. We now recall the fundamental definition of CL-equivalence from [20] as follows.

DEFINITION 2.7. *Two SCL systems* (L_1, F_1, W_1) *and* (L_2, F_2, W_2) *are said to be* CL-equivalent*, or simply,* $(L_1, F_1, W_1) \overset{L}{\sim} (L_2, F_2, W_2)$*, if the following* Euler–Lagrange matching conditions *hold:*

ELM-1: $W_1 = m_1 m_2^{-1}(W_2)$,

ELM-2: $\mathrm{Im}[\mathcal{EL}(L_1) - F_1 - m_1 m_2^{-1}(\mathcal{EL}(L_2) - F_2)] \subset W_1$,

where m_i *is the mass tensor of* L_i *and* Im *means the pointwise image of the map in brackets.*

The following proposition from [20] explains the significance of the CL-equivalence property. It shows that in a very natural sense the two control systems can be made to correspond by using an appropriate choice of control.

PROPOSITION 2.8. *Suppose that two SCL systems* (L_i, F_i, W_i)*,* $i = 1, 2$*, are CL-equivalent. Then, for an arbitrary control law for one system, there exists a control law for the other system such that the two closed-loop systems produce the same equations of motion. The explicit relation between the two control laws* u_i*,* $i = 1, 2$*, is given by*

$$u_1 = \mathcal{EL}(L_1) - F_1 - m_1 m_2^{-1}(\mathcal{EL}(L_2) - F_2) + m_1 m_2^{-1} u_2, \tag{2.12}$$

where m_i *is the mass tensor of* L_i*,* $i = 1, 2$*.*

Proof. Recall that the Euler–Lagrange operator is given by

$$\mathcal{EL}(L)(q,\dot{q},\ddot{q})_j = m_{ij}\ddot{q}^i + \frac{\partial m_{ij}}{\partial q^k}\dot{q}^i\dot{q}^k - \frac{1}{2}\frac{\partial m_{ik}}{\partial q^j}\dot{q}^i\dot{q}^k + \frac{\partial V}{\partial q^j},$$

where the Lagrangian L is given by

$$L = \frac{1}{2}m_{ij}\dot{q}^i\dot{q}^j - V(q).$$

One can solve (2.3) for $\ddot{q}$. Denote by $\ddot{q}_{L_i}$ the expression of the acceleration $\ddot{q}$ obtained from the closed-loop SCL system (L_i, F_i, u_i), $i = 1, 2$. Then,

$$m_1(\ddot{q}_{L_1} - \ddot{q}_{L_2}) = u_1 - m_1 m_2^{-1} u_2 - \left[(\mathcal{EL}(L_1) - F_1) - m_1 m_2^{-1}(\mathcal{EL}(L_2) - F_2)\right].$$

The conditions ELM-1 and ELM-2 imply that (2.12) holds if and only if $\ddot{q}_{L_1} = \ddot{q}_{L_2}$ if and only if they produce the same equations of motion. Notice that the term

$$\mathcal{EL}(L_1) - m_1 m_2^{-1}\mathcal{EL}(L_2)$$

in (2.12) can be regarded as a map defined on TQ because the acceleration $\ddot{q}$ cancels out. □

RSCL-equivalence. We now define an equivalence relation among RSCL systems on TQ/G.

DEFINITION 2.9. *Two RSCL systems* $(l_i, [F_i]_G, W_i/G)$, $i = 1, 2$, *are said to be* reduced-CL-equivalent (RCL-equivalent), *or simply*

$$(l_1, [F_1]_G, W_1/G) \overset{L}{\sim} (l_2, [F_2]_G, W_2/G),$$

if the following reduced Euler–Lagrange matching conditions *hold:*

RELM-1: $W_1/G = [m_1]_G [m_2]_G^{-1}(W_2/G)$,

RELM-2: $\operatorname{Im}[\mathcal{REL}(l_1) - [F_1]_G - [m_1]_G [m_2]_G^{-1}(\mathcal{REL}(l_2) - [F_2]_G)] \subset W_1/G$,

where $[m_i]_G$ *is the reduced mass tensor of* l_i, $i = 1, 2$, *and* Im *means the pointwise image of the map in brackets.*

Equivalence commutes with reduction. The following theorem explains the relationship between the CL-equivalence relation among G-SCL systems and the RCL-equivalence relation among RSCL systems.

THEOREM 2.10. *Two G-SCL systems are CL-equivalent if and only if their associated RSCL systems are RCL-equivalent.*

Proof. Let (L, F, W) be a G-SCL system, and $(l, [F]_G, W/G)$ its associated RSCL system. Then, the theorem follows from the G-invariance of W and the following relations:

$$\mathcal{REL}(l) \circ \tau_{/G}^{(2)} = \pi_{/G} \circ \mathcal{EL}(L), \qquad [F]_G \circ \tau_{/G} = \pi_{/G} \circ F,$$

where $\tau_{/G}^{(2)} : T^{(2)}Q \to T^{(2)}Q/G$ is the G-quotient map. □

Hence, one can check the RCL-equivalence of two RSCL systems in two ways; one is to directly check it, and the other is to check the CL-equivalence of their associated *unreduced* G-SCL systems. In practice, it is more convenient to check it directly at the reduced level; we shall see an example of this in section 5.

The following theorem explains the property of the RCL-equivalence relation.

THEOREM 2.11. *Suppose that two RSCL systems* $(l_i, [F_i]_G, W_i/G)$, $i = 1, 2$, *are RCL-equivalent. Then, for an arbitrary control law for one system, there exists a control law for the other system such that the two closed-loop systems produce the same equations of motion. The explicit relation between the two control laws* $[u_i]_G$, $i = 1, 2$, *is given by*

$$\begin{aligned}[u_1]_G = {} & \mathcal{REL}(l_1) - [F_1]_G - [m_1]_G [m_2]_G^{-1}(\mathcal{REL}(l_2) - [F_2]_G) \\ & + [m_1]_G [m_2]_G^{-1} [u_2]_G, \end{aligned} \tag{2.13}$$

where $[m_i]_G$ *is the reduced mass tensor of* l_i, $i = 1, 2$.

Proof. Let $[u_i]_G$ be a control for $(l_i, [F_i]_G, W_i/G)$, $i = 1, 2$. Let (L_i, F_i, W_i) be the unreduced G-CL system of $(l_i, [F_i]_G, W_i/G)$, $i = 1, 2$. By Theorem 2.10, the two G-SCL systems are CL-equivalent. By Proposition 2.8, the two closed-loop G-SCL systems (L_i, F_i, u_i), $i = 1, 2$, produce the same equations of motion when u_1 and u_2 satisfy (2.12). Hence, the two closed-loop RSCL systems $(l_i, [F_i]_G, [u_i]_G)$, $i = 1, 2$, produce the same equations of motion when $[u_1]_G$ and $[u_2]_G$ satisfy (2.13), because each term in (2.12) is G-equivariant. Also notice that, for any choice of $[u_i]_G$, one can choose the other $[u_j]_G$ such that (2.13) holds. □

One can prove Theorem 2.11 by comparing the expressions of "accelerations" of both equations using (2.9), as in the proof of Proposition 2.8. For this purpose, one needs to choose a connection on $Q \to Q/G$ because one has to split the variations

to write down the equations of motion in coordinates, because the Euler–Lagrange equations come from the variational principles (see (2.9) of this paper and Chapter 3 of [17] for more detail). In the current proof of Theorem 2.11, we were able to bypass this route by Theorem 2.10.

3. Reduction of CH systems with symmetry. There is a Hamiltonian counterpart to CL systems called *CH systems*. We study the reduction of CH systems with symmetry in this section.

CH systems. We first recall the definition of CH systems from [20].

DEFINITION 3.1. *A* CH system *is a quadruple (H, B, F, W), where the function $H : T^*Q \to \mathbb{R}$ is called the Hamiltonian, $B \in \Gamma(\wedge^2 TT^*Q)$ is called an* almost Poisson tensor *(the main point being that it need not satisfy the Jacobi identity) on T^*Q, the fiber-preserving map $F : T^*Q \to T^*Q$ is called the* (external) force map*, and the subbundle W of T^*Q is called the* control subbundle*. When a feedback control law $u : T^*Q \to W$ is chosen, the quadruple (H, B, F, u) denotes the closed-loop CH system.*

We remark that we choose to use almost Poisson tensors rather than almost symplectic forms, as it is more general and, moreover, is convenient in performing Poisson reduction. The vector field $X_{(H,B,F,u)}$ of a CH system (H, B, F, W) with a control law u is given by

$$X_{(H,B,F,u)} = B^\sharp \mathbf{d}H + \mathrm{vlift}(F) + \mathrm{vlift}(u),$$

where $\mathrm{vlift}(F)$ and $\mathrm{vlift}(u)$ are the vertical lifts defined in (2.1).

Reduction of G-invariant CH systems. We define G-invariant CH systems on T^*Q and reduced CH systems on T^*Q/Q as follows.

DEFINITION 3.2. *Let G be a Lie group action on Q. A* G-invariant CH (G-CH) system *is a CH system (H, B, F, W), where H, B, F, and W are all G-invariant.*

DEFINITION 3.3. *A* reduced CH (RCH) system *is a quadruple (h, b, f, U), where the function $h : T^*Q/G \to \mathbb{R}$ is called the* reduced Hamiltonian*, $b \in \Gamma(\wedge^2 T(T^*Q/G))$ is called the* reduced almost Poisson tensor*, the fiber-preserving map $f : T^*Q/G \to T^*Q/G$ is called the* reduced force map*, and the subbundle U of T^*Q/G is called the* reduced control subbundle.

Suppose that we are given a G-CH system (H, B, F, W) on T^*Q. The G-invariant Hamiltonian $H : T^*Q \to \mathbb{R}$ induces the reduced Hamiltonian $h : T^*Q/G \to \mathbb{R}$ as follows:

$$H = h \circ \pi_{/G}. \tag{3.1}$$

The G-invariance of the almost Poisson tensor $B \in \Gamma(\wedge^2 TT^*Q)$ induces a reduced almost Poisson tensor $[B]_G \in \Gamma(\wedge^2 T(T^*Q/G))$ as follows: for $f_1, f_2 \in \mathcal{F}(T^*Q/G)$,

$$[B]_{G\,[q,p]_G}(\mathbf{d}f_1, \mathbf{d}f_2) = B_{(q,p)}(\pi^*_{/G}\mathbf{d}f_1, \pi^*_{/G}\mathbf{d}f_2). \tag{3.2}$$

This is well defined since

$$\begin{aligned} B_{g(q,p)}(\mathbf{d}(f_1 \circ \pi_{/G}), \mathbf{d}(f_2 \circ \pi_{/G})) &= B_{(q,p)}(g^*\mathbf{d}(f_1 \circ \pi_{/G}), g^*\mathbf{d}(f_2 \circ \pi_{/G})) \\ &= B_{(q,p)}(\mathbf{d}(f_1 \circ \pi_{/G} \circ g), \mathbf{d}(f_2 \circ \pi_{/G} \circ g)) \\ &= B_{(q,p)}(\mathbf{d}(f_1 \circ \pi_{/G}), \mathbf{d}(f_2 \circ \pi_{/G})) \end{aligned}$$

for any $g \in G$, where we used the G-invariance of B in the first equality. One can easily check that $[B]_G$ is skew-symmetric. The G-invariance of F induces the reduced

force $[F]_G : T^*Q/G \to T^*Q/G$ satisfying

$$[F]_G \circ \pi_{/G} = \pi_{/G} \circ F. \tag{3.3}$$

This discussion motivates the following definition.

DEFINITION 3.4. *The* RCH system of a G-CH system (H, B, F, W) *is a quadruple* $(h, [B]_G, [F]_G, W/G)$, *where* h *is the reduced Hamiltonian defined in* (3.1), $[B]_G$ *is the reduced almost Poisson tensor defined in* (3.2), *and* $[F]_G$ *is the reduced force defined in* (3.3).

Similarly to Proposition 2.5, the following proposition explains the relations between G-CH systems and RCH systems.

PROPOSITION 3.5. *Given a RCH system* (h, b, f, U), *there is a (not necessarily unique)* G*-CH system* (H, B, F, W) *whose RCH system is* (h, b, f, U).

Proof. Define H by $H = h \circ \pi_{/G}$. Define a force map F on T^*Q as follows: for $\alpha_q \in T_q^*Q$, $v_q \in T_qQ$

$$\langle F(\alpha_q), v_q \rangle = \langle f \circ \pi_{/G}(\alpha_q), \tau_{/G}(v_q) \rangle.$$

Choose a connection on the principal bundle $T^*Q \to T^*Q/G$. (See Chapter 2, Theorem 2.1 in [25] for the proof of the existence.) Then we can split TT^*Q into the vertical space V and the horizontal space H as $TT^*Q = \mathrm{V} \oplus \mathrm{H}$. This induces the decomposition of T^*T^*Q as $T^*T^*Q = \mathrm{H}^\circ \oplus \mathrm{V}^\circ$, where H° and V° are the annihilators of H and V, respectively. Let $\mathrm{hor} : T(T^*Q/G) \to \mathrm{H}$ be the horizontal lift. Then its dual map $\mathrm{hor}^* : \mathrm{V}^\circ \to T^*(T^*Q/G)$ is an isomorphism. For simplicity, we use H° (resp., V°) as the projection of T^*T^*Q onto H° (resp., V°). Define an almost Poisson tensor B on T^*Q as follows: for $\alpha, \beta \in T_p^*T^*Q$

$$B(\alpha, \beta) := b(\mathrm{hor}^* \, \mathrm{V}^\circ \, \alpha, \, \mathrm{hor}^* \, \mathrm{V}^\circ \, \beta).$$

One can check that this almost Poisson tensor is G-invariant. We now show that $\pi_{/G} : T^*Q \to T^*Q/G$ is the Poisson map; i.e., $b = [B]_G$. Let h_1, h_2 be two functions on T^*Q/G. Then $\mathbf{d}(h_i \circ \pi_{/G}) \in V^\circ$, $i = 1, 2$. Thus, $\mathrm{hor}^* \, \mathbf{d}(h_i \circ \pi_{/G}) = \mathbf{d}h_i$, $i = 1, 2$. Hence,

$$\begin{aligned} [B]_G(\mathbf{d}h_1, \mathbf{d}h_2) &= B(\mathbf{d}(h_1 \circ \pi_{/G}), \mathbf{d}(h_2 \circ \pi_{/G})) \\ &= b(\mathbf{d}h_1, \mathbf{d}h_2). \end{aligned}$$

It follows that $[B]_G = b$. Let $W = \pi_{/G}^{-1}(U)$. Then one can see that (H, B, F, W) is a G-CH system and that its RCH system coincides with (h, b, f, U). This completes the proof. □

Notice in Proposition 3.5 that there can be more than one B satisfying $[B]_G = b$, which is the source of the nonuniqueness of the G-CH systems (H, B, F, W) in Proposition 3.5. By Proposition 3.5, we can write an arbitrary RCH system in the form of the RCH system of a G-CH system without loss of generality.

Reduced CH dynamics. Given a G-CH system (H, B, F, W), let $(h, [B]_G, [F]_G, W/G)$ be its RCH system. The (reduced) Hamiltonian vector field $X_{(h,[B]_G,[F]_G,[u]_G)}$ of $(h, [B]_G, [F]_G, W/G)$ with a control $[u]_G \in W/G$ is given by

$$X_{(h,[B]_G,[F]_G,[u]_G)} = [B]_G^\sharp \mathbf{d}h + \mathrm{vlift}([F]_G) + \mathrm{vlift}([u]_G), \tag{3.4}$$

where $\mathrm{vlift}([F]_G)$ and $\mathrm{vlift}([u]_G)$ are the vertical lifts defined in (2.1). Let $X_{(H,B,F,u)}$ be the vector field of (H, B, F, W) with control $u \in W$. Then we have

$$X_{(h,[B]_G,[F]_G,[u]_G)} \circ \pi_{/G} = T\pi_{/G} \cdot X_{(H,B,F,u)}. \tag{3.5}$$

The CH-equivalence relation. We shall first recall the CH-equivalence relation among CH systems on T^*Q from [20].

DEFINITION 3.6. *Two CH systems* (H_i, B_i, F_i, W_i), $i = 1, 2$, *are said to be* CH-equivalent*, or simply,* $(H_1, B_1, F_1, W_1) \overset{H}{\sim} (H_2, B_2, F_2, W_2)$, *if the following* Hamiltonian matching conditions *hold:*

HM-1: $W_1 = W_2$,

HM-2: $\mathrm{Im}[B_1^\sharp \mathbf{d}H_1 + \mathrm{vlift}(F_1) - B_2^\sharp \mathbf{d}H_2 - \mathrm{vlift}(F_2)] \subset \mathrm{vlift}(W_1)$,

where $\mathrm{vlift}(W_1)$ *is the vertical lift of* W_1 *defined in* (2.2).

The following proposition explains the significance of the CH-equivalence relation.

PROPOSITION 3.7. *Suppose that two CH systems* (H_i, B_i, F_i, W_i), $i = 1, 2$, *are CH-equivalent. Then, for an arbitrary control law for one system, there exists a control law for the other system such that the two closed-loop systems produce the same equations of motion. The explicit relation between the two control laws* u_i, $i = 1, 2$, *is given by*

$$\mathrm{vlift}(u_1) = -B_1^\sharp \mathbf{d}H_1 - \mathrm{vlift}(F_1) + B_2^\sharp \mathbf{d}H_2 + \mathrm{vlift}(F_2) + \mathrm{vlift}(u_2).$$

Proof. Just compare $X_{(H_1,B_1,F_1,u_1)}$ and $X_{(H_2,B_2,F_2,u_2)}$ with controls $u_1 : T^*Q \to W_1$ and $u_2 : T^*Q \to W_2$. □

RCH-equivalence. We now introduce an equivalence relation among RCH systems on T^*Q/G as follows.

DEFINITION 3.8. *Two RCH systems,* $(h_i, [B_i]_G, [F_i]_G, W_i/G)$, $i = 1, 2$, *are said to be* reduced-CH-equivalent (RCH-equivalent)*, or simply*

$$(h_1, [B_1]_G, [F_1]_G, W_1/G) \overset{H}{\sim} (h_2, [B_2]_G, [F_2]_G, W_2/G),$$

if the following reduced Hamiltonian matching conditions *hold:*

RHM-1: $W_1/G = W_2/G$,

RHM-2: $\mathrm{Im}[[B_1]_G^\sharp \mathbf{d}h_1 + \mathrm{vlift}([F_1]_G) - [B_2]_G^\sharp \mathbf{d}h_2 - \mathrm{vlift}([F_2]_G)] \subset \mathrm{vlift}(W_1/G)$,

where $\mathrm{vlift}(W_1/G)$ *is the vertical lift of the subbundle* W_1/G *defined in* (2.2).

Reduction commutes with equivalence. The following theorem explains the relation between the RCH-equivalence relation among RCH systems on T^*Q/G and the CH-equivalence relation among G-CH systems on T^*Q.

THEOREM 3.9. *Two G-CH systems are CH-equivalent if and only if their associated RCH systems are RCH-equivalent.*

Proof. Use Definitions 3.6 and 3.8 as well as the relation (3.5). □

THEOREM 3.10. *Suppose that two RCH systems* $(h_i, [B_i]_G, [F_i]_G, W_i/G)$, $i = 1, 2$, *are RCH-equivalent. Then, for an arbitrary control law for one system, there exists a control law for the other system such that the two closed-loop RCH systems produce the same equations of motion. The explicit relation between the two control laws* $[u_i]_G$, $i = 1, 2$, *is given by*

$$\mathrm{vlift}([u_1]_G) = -[B_1]_G^\sharp \mathbf{d}h_1 - \mathrm{vlift}([F_1]_G) + [B_2]_G^\sharp \mathbf{d}h_2 + \mathrm{vlift}([F_2]_G) + \mathrm{vlift}([u_2]_G).$$

Proof. The proof follows from a straightforward computation using (3.4). □

Simple CH systems. Let us review the definition of simple CH systems from [20].

DEFINITION 3.11. *A CH system* (H, B, F, W) *on* T^*Q *is called* simple *if the Hamiltonian* H *has the form kinetic plus potential energy,*

$$H(q, p) = \frac{1}{2}\langle p,\, m_q^{-1} p\rangle + V(q),$$

and its almost Poisson tensor B is nondegenerate and is of the form

$$B(q,p) = \begin{bmatrix} 0 & K(q)^T \\ -K(q) & J(q,p) \end{bmatrix} \tag{3.6}$$

in cotangent coordinates (q,p) on T^*Q, where $K(q), J(q,p)$ are $n \times n$ matrices with $n = \dim Q$. We call H the simple Hamiltonian and B the simple almost Poisson tensor. The acronym, SCH, denotes "simple controlled Hamiltonian."

One can check that the statement that B has the form (3.6) is independent of the choice of cotangent bundle coordinates on T^*Q.

Let B be a simple almost Poisson tensor. Then the relation

$$\text{vlift}(\psi_B) = B \circ \Theta \tag{3.7}$$

defines a unique $\psi_B \in \Gamma(\text{Aut}(T^*Q))$, where Θ is the canonical 1-form[1] on T^*Q and B is regarded as a bundle map $B : T^*T^*Q \to TT^*Q$. In other words, there exists a unique $\psi_B \in \Gamma(\text{Aut}(T^*Q))$ such that the following diagram commutes:

$$\begin{array}{ccc} T^*T^*Q & \xrightarrow{B} & TT^*Q \\ \uparrow{\scriptstyle \Theta} & & \uparrow{\scriptstyle \text{vlift}} \\ T^*Q & \xrightarrow{\psi_B} & T^*Q \end{array}$$

See [20] for the proof of the existence of ψ_B. When B is given in coordinates as in (3.6), the map ψ_B is given in coordinates by

$$\psi_B(q,p) = (q, K(q)p).$$

Now, we make the following definition of the reduced simple CH system.

DEFINITION 3.12. *An RCH system $(h, [B]_G, [F]_G, W/G)$ is called a reduced simple CH system (or* RSCH *system) if it is the reduced CH system of a G-invariant simple CH system.*

Simple almost Poisson tensors and their reductions. Recall that in Definition 3.11 we defined simple almost Poisson tensors on T^*Q using local coordinates. Here, we characterize the reduced simple almost Poisson tensors using local coordinates, so we may assume that $Q = G \times X$, where G is a Lie group acting on the manifold X trivially. Recall the following identifications by left translation of G:

$$T^*G = G \times \mathfrak{g}^*, \quad TT^*G = (G \times \mathfrak{g}^*) \times (\mathfrak{g} \times \mathfrak{g}^*), \quad T^*T^*G = (G \times \mathfrak{g}^*) \times (\mathfrak{g}^* \times \mathfrak{g}).$$

We use (g_a, μ_a, x_i, p_i) as local coordinates for $T^*Q = G \times \mathfrak{g}^* \times T^*X$, and (μ_a, x_i, p_i) for $T^*Q/G = \mathfrak{g}^* \times T^*X$, where $a = 1, \ldots, \dim G$ and $i = 1, \ldots, \dim X$. We will use $\{e_a\}$ as a basis for $\mathfrak{g}$, and $\{e_a^*\}$ as its dual basis. Let $B \in \Gamma(\wedge^2 TT^*Q)$ be a G-invariant simple almost Poisson tensor. Then it is of the following form:

$$\begin{aligned} B(g,\mu,x,p) = {} & A_{ab}(x)(e_a \otimes e_b^* - e_b^* \otimes e_a) + E_{ia}(x)(\partial_{x_i} \otimes e_b^* - e_b^* \otimes \partial_{x_i}) \\ & + C_{ai}(x)(e_a \otimes \partial_{p_i} - \partial_{p_i} \otimes e_a) + D_{ij}(x)(\partial_{x_i} \otimes \partial_{p_j} - \partial_{p_j} \otimes \partial_{x_i}) \\ & + R_{ab}(\mu,x,p) e_a^* \otimes e_b^* + S_{ai}(\mu,x,p)(e_a^* \otimes \partial_{p_i} - \partial_{p_i} \otimes e_a^*) \\ & + U_{ij}(\mu,x,p)\partial_{p_i} \otimes \partial_{p_j}. \end{aligned} \tag{3.8}$$

[1] The canonical 1-form Θ on T^*Q is given by $\Theta = p_i \mathbf{d}q^i$ in cotangent bundle coordinates $(q^i, p_j) \in T^*Q$.

In the matrix form, B is given by

$$B = \begin{bmatrix} O & O & A(x) & C(x) \\ O & O & E(x) & D(x) \\ -A(x)^T & -E(x)^T & R(\mu,x,p) & S(\mu,x,p) \\ -C(x)^T & -D(x)^T & -S(\mu,x,p)^T & U(\mu,x,p) \end{bmatrix},$$

where we used the basis for T_zT^*Q in the following order: $e_a,\ \partial_{x_i},\ e_a^*,\ \partial_{p_i}$. The nondegeneracy condition for B is given by

$$\operatorname{rank}\begin{bmatrix} A & C \\ E & D \end{bmatrix} = \dim Q.$$

The reduced simple Poisson tensor $[B]_G$ is given by

$$\begin{aligned}[B]_G(\mu,x,p) &= E_{ia}(x)(\partial_{x_i}\otimes e_b^* - e_b^*\otimes\partial_{x_i}) + D_{ij}(x)(\partial_{x_i}\otimes\partial_{p_j} - \partial_{p_j}\otimes\partial_{x_i}) \\ &\quad + R_{ab}(\mu,x,p)e_a^*\otimes e_b^* + S_{ai}(\mu,x,p)(e_a^*\otimes\partial_{p_i} - \partial_{p_i}\otimes e_a^*) \\ &\quad + U_{ij}(\mu,x,p)\partial_{p_i}\otimes\partial_{p_j}. \end{aligned} \tag{3.9}$$

In a matrix form,

$$[B]_G = \begin{bmatrix} R(\mu,x,p) & -E(x)^T & S(\mu,x,p) \\ E(x) & O & D(x) \\ -S(\mu,x,p)^T & -D(x)^T & U(\mu,x,p) \end{bmatrix},$$

where we used the basis for $T_{[z]}(T^*Q/G)$ in the following order: $e_a^*,\ \partial_{x_i},\ \partial_{p_i}$. The nondegeneracy condition for B induces the following rank condition for $[B]_G$:

$$\operatorname{rank}[E\ \ D] = \dim X. \tag{3.10}$$

Remark. One could argue that it might be better if we could characterize all the tensors $b \in \Gamma(\wedge^2 T(T^*Q/G))$ for which there exists a G-invariant simple almost Poisson tensor B such that $b = [B]_G$. Then we could define RSCH systems without reference to G-invariant SCH systems. This point has to be studied more, and we think that the use of connections is crucial; see [31] and [17].

4. Equivalence between reduced simple Lagrangian and Hamiltonian systems. In this section we show the equivalence between the method of RSCL systems on TQ/G and that of RSCH systems on T^*Q/G.

The CL-CH equivalence theorem. In [19] and [20], the equivalence between the method of SCL systems on TQ and that of SCH systems on T^*Q was shown. It is summarized in the following theorem.[2]

THEOREM 4.1. *The method of CL systems is equivalent to that of CH systems for simple mechanical systems in the following sense:*

1. *For any two simple CL systems (L_i, F_i^L, W_i^L), $i = 1, 2$, there exist two associated simple CH systems*[3] *(H_i, B_i, F_i^H, W_i^H), $i = 1, 2$, such that*

$$\begin{aligned}&(L_1, F_1^L, W_1^L) \overset{L}{\sim} (L_2, F_2^L, W_2^L) \\ &\quad\Longleftrightarrow\ (H_1, B_1, F_1^H, W_1^H) \overset{H}{\sim} (H_2, B_2, F_2^H, W_2^H).\end{aligned} \tag{4.1}$$

[2]The statement of Theorem 4.1 is slightly different from that of Corollary 4.1 in [20] in that there appears an additional term, $\psi_{B_2} \circ \psi_{B_1}^{-1} = m_{H_2}(m_{H_1})^{-1}$, in statement 2. However, one can still prove Theorem 4.1 of this paper using section 4 of [20]. For example, see [19] for the proof.

[3]Refer to section 4 of [20] to learn how to find the associated CH systems.

2. *For any two simple CH systems* (H_i, B_i, F_i^H, W_i^H), $i = 1, 2$, *there exist two associated simple CL systems* (L_i, F_i^L, W_i^L), $i = 1, 2$, *such that*

$$(H_1, B_1, F_1^H, W_1^H) \overset{H}{\sim} (H_2, B_2, F_2^H, W_2^H)$$
$$\iff (L_1, F_1^L, W_1^L) \overset{L}{\sim} (L_2, F_2^L, W_2^L) \quad \textit{and} \quad \psi_{B_2} \circ \psi_{B_1}^{-1} = m_{H_2}(m_{H_1})^{-1},$$

with m_{H_i} *the mass tensor of* H_i *and* ψ_{B_i} *defined in* (3.7) *for* $i = 1, 2$.

In statement 1, *one does not need the condition* $\psi_{B_2} \circ \psi_{B_1}^{-1} = m_{H_2}(m_{H_1})^{-1}$ *along with the CL equivalence condition for the two CL systems, because it automatically holds for the associated CH systems.*

This result implies the following: suppose that we want to find all SCL systems which are equivalent to a given SCL system. One can directly search for them on the Lagrangian side using the CL equivalence relation. Alternatively, one can first find an SCH system which is associated with the given SCL system, secondly search for all SCH systems which are CH-equivalent to this SCH system, and finally transform those SCH systems to SCL systems. Those SCL systems are all SCL systems CL-equivalent to the original SCL system. In the similar way, one can find all the SCH systems which are CH-equivalent to a given SCH system, directly or with a CL-equivalence relation. (Refer to [20] and [19] for more detail.) Hence, one can describe a given simple mechanical system as an SCL system or as an SCH system and then apply the CL method or the CH method, correspondingly. Both procedures are equivalent.

We now restrict Theorem 4.1 to G-invariant systems.

THEOREM 4.2. *The method of* G*-invariant SCL systems and that of* G*-invariant SCH systems are equivalent. In other words, Theorem* 4.1 *restricted to* G*-invariant simple CL and CH systems holds.*

Proof. For the proof, one just needs to keep track of the G-invariance in the proof of Theorem 4.1 in [20] and the proof of Theorem 3.2.1 in [19]. □

The following theorem explains the equivalence between the method of RSCL systems on TQ/G and that of RSCH systems on T^*Q/G.

THEOREM 4.3. *The method of RSCL systems is equivalent to that of RSCH systems in the following sense:*

1. *For two given RSCL systems* $(l_i, [F_i^L]_G, W_i^L/G)$, $i = 1, 2$, *there exist two associated RSCH systems* $(h_i, [B_i]_G, [F_i^H]_G, W_i^H/G)$, $i = 1, 2$, *such that*

$$(l_1, [F_1^L]_G, W_1^L/G) \overset{L}{\sim} (l_2, [F_2^L]_G, W_2^L/G)$$
$$\iff (h_1, [B_1]_G, [F_1^H]_G, W_1^H/G) \overset{H}{\sim} (h_2, [B_2]_G, [F_2^H]_G, W_2^H/G). \tag{4.2}$$

2. *For two given RSCH systems* $(h_i, [B_i]_G, [F_i^H]_G, W_i^H/G)$, $i = 1, 2$, *there exist two associated RSCL systems* $(l_i, [F_i^L]_G, W_i^L/G)$, $i = 1, 2$, *such that*

$$(h_1, [B_1]_G, [F_1^H]_G, W_1^H/G) \overset{H}{\sim} (h_2, [B_2]_G, [F_2^H]_G, W_2^H/G)$$
$$\iff (l_1, [F_1^L]_G, W_1^L/G) \overset{L}{\sim} (l_2, [F_2^L]_G, W_2^L/G) \ \textit{and} \ [\psi_{B_2} \circ \psi_{B_1}^{-1}]_G = [m_{H_2}]_G [m_{H_1}]_G^{-1},$$

where $[m_{H_i}]_G$ *is the reduced mass tensor of* h_i.

Proof. Let us prove statement 1. For given two RSCL systems $(l_i, [F_i^L]_G, W_i^L/G)$, $i = 1, 2$, consider their unreduced G-SCL systems (L_i, F_i^L, W_i^L), $i = 1, 2$, with $L_i = l_i \circ \tau_{/G}$ (see Proposition 2.5). Theorem 4.2 implies that there are two G-SCH systems

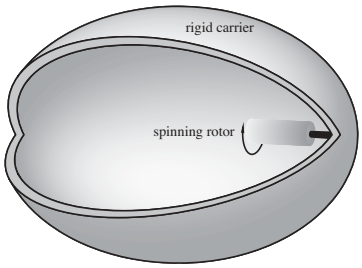

FIG. 5.1. *A satellite with a rotor along the third body axis.*

(H_i, B_i, F_i^H, W_i^H), $i = 1, 2$, such that (4.1) holds. Let $(h_i, [B_i]_G, [F_i^H]_G, W_i^H/G)$ be the RSCH system of (H_i, B_i, F_i^H, W_i^H) for $i = 1, 2$. Then (4.2) follows from Theorems 2.10 and 3.9 and (4.1). Now we prove statement 2. In this case, use Proposition 3.5 instead of Proposition 2.5, and then proceed in a similar manner. ∎

Hence, one can describe a given simple mechanical system as an SCL/SCH system, apply the CL/CH reduction, and then apply the reduced CL/CH method, correspondingly. Both procedures are equivalent.

Remark. Notice in (4.2) that $\psi_{B_2} \circ \psi_{B_1}^{-1}$ is G-equivariant even though each of ψ_{B_i} may not be. This equivariance is a consequence of the following commutative diagram:

$$\begin{array}{ccccc} TT^*Q & \xleftarrow{B_1} & T^*Q^*Q & \xrightarrow{B_2} & TT^*Q \\ \uparrow \text{vlift} & & \uparrow \Theta & & \uparrow \text{vlift} \\ T^*Q & \xleftarrow{\psi_{B_1}} & T^*Q & \xrightarrow{\psi_{B_2}} & T^*Q \end{array}$$

It follows that for $\alpha \in T^*Q$, $B_2 B_1^{-1}(\text{vlift}(\alpha)) = \text{vlift}(\psi_{B_2} \circ \psi_{B_1}^{-1}(\alpha))$. One can easily check that vlift is G-equivariant, i.e., $\text{vlift}(g\alpha) = g\,\text{vlift}(\alpha)$ for $g \in G$. Then the G-equivariance of $\psi_{B_2} \circ \psi_{B_1}^{-1}$ follows from the G-equivariance of B_1, B_2, and vlift and from the injectivity of vlift.

5. Examples. We review the example of a satellite with a rotor and the Euler–Poincaré matching conditions presented in [15] in the framework of the current paper. We then apply the RCL method to the stabilization of the heavy top with rotors. This will show the application of CL systems only. For an excellent application of CH systems to the problem of underwater vehicle stabilization by internal rotors, refer to [34] and [15].

5.1. Satellite with a rotor and Euler–Poincaré matching.

Satellite with a rotor (see [15]). We consider the example of a satellite with a rotor aligned along the third principal axis of the body (see Figure 5.1). The configuration space is $Q = G \times X = \text{SO}(3) \times S^1$, with the first factor being the satellite attitude and the second factor being the rotor angle. The Lie group $G = \text{SO}(3)$ acts on the first factor of Q only. We take a trivial (flat) connection on Q such that $TQ/G \simeq \mathfrak{g} \times TX$. Use $((\Omega_1, \Omega_2, \Omega_3), (\phi, \dot{\phi}))$ as coordinates for $\mathfrak{so}(3) \times TS^1 \simeq \mathbb{R}^3 \times TS^1$. This system is described by the RSCL system $(l_1, [F_1]_G = 0, W_1/G)$ given by

$$l_1(\Omega, \dot{\phi}) = \frac{1}{2}\big(\lambda_1 \Omega_1^2 + \lambda_2 \Omega_2^2 + (I_3 + J_3)\Omega_3^2 + 2J_3\Omega_3\dot{\phi} + J_3\dot{\phi}^2\big)$$

and $W_1/G = \text{span}\{\mathbf{d}\phi\}$, where $\lambda_1 > \lambda_2 > \lambda_3 := J_3 + I_3$. Notice that l_1 does not depend on ϕ. Recall that the reduced Euler–Lagrange operator $\mathcal{REL}$ induces the Lagrange–Poincaré operator $\mathcal{LP}$ in (2.8) with respect to the trivial connection on $Q \to X$. By (2.10), this Lagrange–Poincaré operator $\mathcal{LP}(l_1)$ is given by

$$\mathcal{LP}(l_1) = \begin{bmatrix} \dfrac{d}{dt}\dfrac{\partial l_1}{\partial \Omega} - \dfrac{\partial l_1}{\partial \Omega} \times \Omega \\ \dfrac{d}{dt}\dfrac{\partial l_1}{\partial \dot{\phi}} - \dfrac{\partial l_1}{\partial \phi} \end{bmatrix}, \tag{5.1}$$

where we switched the first and second components of (2.10).

Consider another RSCL system $(l_2, 0, W_2/G)$ with $W_2 = W_1$ and

$$l_2(\Omega, \dot{\phi}) = \frac{1}{2}\big(\lambda_1\Omega_1^2 + \lambda_2\Omega_2^2 + (I_3 + J_3)\Omega_3^3 + 2J_3\Omega_3\dot{\phi} + \rho J_3\dot{\phi}^2\big)$$

with $\rho \in \mathbb{R}$. Here we allow only one free parameter ρ as in [15], but one can consider a more general form of CL system. One can check that RELM-1 and RELM-2 in Definition 2.9 are satisfied. Since these two CL systems are equivalent, one has only to design a controller for the second system, which will give an asymptotically stabilizing controller for the first system by Theorem 2.11. See [8] for the discussion on asymptotic stabilization of the rotation about the middle axis in the body-fixed frame. There, it is shown how to choose ρ and the dissipative input for stability of the equivalent system $(l_2, 0, W_2/G)$. This leads to an asymptotically stabilizing controller for the original system $(l_1, 0, W_1/G)$.

Euler–Poincaré matching. Here we briefly sketch the proof that the set of Euler–Poincaré matching conditions in [12] and [15] is a special case of the reduced Euler–Lagrange matching conditions in this paper. This set of matching conditions can handle such examples as a satellite with a rotor and underwater vehicles with internal rotors. Let $Q = G \times X$ be the configuration space, where G is a Lie group acting trivially on the manifold X. We choose the trivial (flat) connection on $Q \to X$ to write down the Lagrange–Poincaré equation on $TQ/G \simeq \mathfrak{g} \times TX$ with the Lie algebra $\mathfrak{g}$ of the Lie group G. We use $\eta = (\eta^\alpha)$ as coordinates for $\mathfrak{g}$, and $(\theta, \dot{\theta}) = (\theta^a, \dot{\theta}^a)$ as coordinates for TX. By (2.10), the Lagrange–Poincaré operator $\mathcal{LP}$ with respect to the *trivial* connection is given by

$$\mathcal{LP}(l) = \begin{pmatrix} \dfrac{d}{dt}\dfrac{\partial l}{\partial \eta^\alpha} - C^\beta_{\gamma\alpha}\eta^\gamma \dfrac{\partial l}{\partial \eta^\beta} \\ \dfrac{d}{dt}\dfrac{\partial l}{\partial \dot{\theta}^a} - \dfrac{\partial l}{\partial \theta^a} \end{pmatrix} \tag{5.2}$$

for any reduced Lagrangian $l = l(\eta^\alpha, \dot{\theta}^a, \theta)$, where $C^\beta_{\gamma\alpha}$ are the structure constants of the Lie algebra $\mathfrak{g}$. In (5.2) we wrote the vertical part of $\mathcal{LP}(l)$ first, while in (2.10) the vertical part was written in the second component.

Let $(l, 0, T^*X)$ be the given RSCL system with the reduced Lagrangian

$$l(\eta^\alpha, \dot{\theta}^a) = \frac{1}{2}g_{\alpha\beta}\eta^\alpha\eta^\beta + g_{\alpha a}\eta^\alpha\dot{\theta}^a + \frac{1}{2}g_{ab}\dot{\theta}^a\dot{\theta}^b,$$

where $g_{\alpha\beta}, g_{\alpha a}, g_{ab}$ are constant functions on TQ/G. Notice that this Lagrangian is cyclic in the variables θ^a and that the controls act only on the cyclic variables. Let

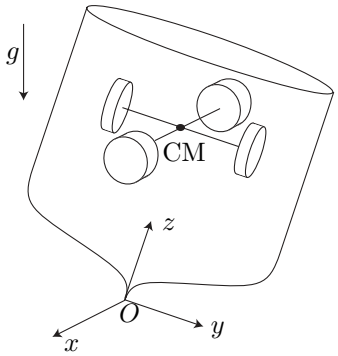

FIG. 5.2. *Heavy top with two rotors, each consisting of two rigidly coupled disks. The center of mass is at CM.*

$(l_{\tau,\sigma,\rho}, 0, T^*X)$ be another RSCL system with the reduced Lagrangian of the following form:

$$l_{\tau,\sigma,\rho} = l(\eta^\alpha, \dot\theta^a + \tau^a_\alpha \eta^\alpha) + \frac{1}{2}\sigma_{ab}\tau^a_\alpha \tau^b_\beta \eta^\alpha \eta^\beta + \frac{1}{2}(\rho_{ab} - g_{ab})(\dot\theta^a + g^{ac}g_{c\alpha}\eta^\alpha + \tau^a_\alpha \eta^\alpha)(\dot\theta^b + g^{bc}g_{c\beta}\eta^\beta + \tau^b_\beta \eta^\beta), \tag{5.3}$$

which is exactly the equation (11) in [15]. See also [14] for the motivation of this choice of the form in (5.3). [15] proposes the following so-called Euler–Poincaré matching conditions:

EP-1: $\tau^a_\alpha = -\sigma^{ab}g_{b\alpha}$,
EP-2: $\sigma^{ab} + \rho^{ab} = g^{ab}$.

Then one can show that the two assumptions of EP-1 and EP-2 imply the RCL-equivalence of the two RSCL systems $(l, 0, T^*X)$ and $(l_{\tau,\sigma,\rho}, 0, T^*X)$. Hence, one can equivalently work with the second system to design controllers. Refer to [15] for the method of constructing a Lyapunov function using the energy and Casimir functions.

5.2. Heavy top with rotors. It is well known that an upright spinning top is unstable if the angular velocity is small. The motion of a heavy top and the stability of the Lagrange top are well studied in [28] and [24]. We use the CL method to asymptotically stabilize the upright spinning motion of a heavy top with small vertical angular velocity, including zero velocity. See Figure 5.2 for the heavy top system. One can notice that the system dynamics are not SO(3)-invariant because the gravitational force breaks the SO(3) symmetry, and thus we cannot perform the usual reduction of the system by the SO(3) group. However, there is a way of doing the SO(3)-reduction of this system by considering this system as one depending on a parameter in $\mathbb{R}^3$.

In this section, we will first review the general theory of reduction of systems depending on a parameter and then apply this reduction theory to the design of a controller for the heavy top system. We will not develop the whole theory of *CL systems depending on a parameter* and the reduction theory for those systems with symmetry because it is a straightforward modification of the theory in section 2 of this paper. Moreover, the complete theory of reduction for (uncontrolled) systems depending on a parameter is in [17].

Systems depending on a parameter. We here review the reduction theory for systems depending on an advected parameter, as presented in [17]. Consider a Lagrangian

$$L : T(G \times X) \times V^* \to \mathbb{R},$$

where G is a Lie group, X is a manifold, and V^* is the dual space of the vector space V. The value of L at the point $(g, x, \dot{g}, \dot{x}, a_0) \in T(G \times X) \times V^*$ will be denoted by $L(g, x, \dot{g}, \dot{x}, a_0)$, as usual, and we will think of a_0 as a parameter that remains fixed along the evolution of the system. Assume that there is an action of G on V, so there is an induced action on V^* such that $\langle ga_0, gb_0 \rangle = \langle a_0, b_0 \rangle$ for all $a_0 \in V^*$, $b_0 \in V$, $g \in G$. Assume that G acts trivially on X and that L is G-invariant, i.e.,

$$L(hg, x, h\dot{g}, \dot{x}, ha_0) = L(g, x, \dot{g}, \dot{x}, a_0)$$

for $h \in G$, $(g, x, \dot{g}, \dot{x}, a_0) \in T(G \times X) \times V^*$. Define the reduced Lagrangian $l : \mathfrak{g} \times TX \times V^* \to \mathbb{R}$ by

$$l(\xi, x, \dot{x}, a) = L(e, x, \xi, \dot{x}, a) \tag{5.4}$$

for $\xi \in \mathfrak{g}$, $(x, \dot{x}) \in TX$, $a \in V^*$, where $\xi = g^{-1}\dot{g}$ and $a = g^{-1}a_0$.

Fix $a_0 \in V^*$. Let $L_{a_0} : T(G \times X) \to \mathbb{R}$ be the restriction of L to $T(G \times X) \times \{a_0\}$. Then, the Euler–Lagrange operator $\mathcal{EL}(L_{a_0})$ induces the reduced Euler–Lagrange operator

$$\mathcal{REL}(l) : 2\tilde{\mathfrak{g}} \oplus T^{(2)}X \times TV^* \to \mathfrak{g}^* \times T^*X$$

and the equation in (5.6) as follows:

$$\mathcal{REL}(l) = \begin{pmatrix} \dfrac{d}{dt}\dfrac{\partial l}{\partial \xi} - \mathrm{ad}^*_\xi \dfrac{\partial l}{\partial \xi} - \dfrac{\partial l}{\partial a} \diamond a \\ \dfrac{d}{dt}\dfrac{\partial l}{\partial \dot{x}} - \dfrac{\partial l}{\partial x} \end{pmatrix} \tag{5.5}$$

and

$$\dot{a} = -\xi a, \tag{5.6}$$

where the map $\diamond : V \times V^* \to \mathfrak{g}^*$ is defined by $\langle b \diamond a, \eta \rangle = -\langle \eta a, b \rangle$ for $\eta \in \mathfrak{g}$, $a \in V^*$, $b \in V$. One may find the derivation of (5.5) and (5.6) in section 7.4 of [17].

The equations of motion of the reduced Lagrangian l with a $(\mathfrak{g}^* \times T^*X)$-valued (reduced) force f, are given by

$$\mathcal{REL}(l) = f \quad \text{and} \quad \dot{a} = -\xi a, \tag{5.7}$$

where f includes external forces and control forces.

Heavy top with two pairs of rotors. We first describe a heavy top with two pairs of rotors. We mount two pairs of rotors within the top so that each pair's rotation axis is parallel to the first and the second principal axes of the top; see Figure 5.2. Let I_1, I_2, I_3 be the moments of inertia of the top in the body-fixed frame. Let J_1, J_2 be the moments of inertia of the rotors around their rotation axes. Let J_{i1}, J_{i2}, J_{i3} be the moments of inertia of the ith rotor with $i = 1, 2$ around the first, the second, and the third principal axis, respectively. Let $\bar{I}_1 = I_1 + J_{11} + J_{21}$, $\bar{I}_2 = I_2 + J_{12} + J_{22}$,

and $\bar{I}_3 = I_3 + J_{13} + J_{23}$. Let $\lambda_1 = \bar{I}_1 + J_1$ and $\lambda_2 = \bar{I}_2 + J_2$. Let M be the total mass of the system, g the magnitude of the gravitational acceleration, and h the distance from the origin O to the center of mass of the system.

Let $G = \mathrm{SO}(3)$, $X = S^1 \times S^1$, $V^* = \mathbb{R}^3$. We use the following notation for coordinates:

$$\mathbf{R} \in \mathrm{SO}(3), \quad \theta = (\theta_1, \theta_2) \in S^1 \times S^1, \quad a \in \mathbb{R}^3.$$

We will use $\Omega = (\Omega_1, \Omega_2, \Omega_3) \in \mathbb{R}^3$ as coordinates for the Lie algebra $\mathfrak{so}(3)$ under the Lie algebra isomorphism, $\vee : (\mathfrak{so}(3), [,]) \to (\mathbb{R}^3, \times)$,

$$\begin{pmatrix} 0 & -z & y \\ z & 0 & -x \\ -y & x & 0 \end{pmatrix}^{\vee} = (x, y, z).$$

Let $L : T(G \times X) \times V^* \to \mathbb{R}$ be the Lagrangian defined by

$$L(\mathbf{R}, \theta, \dot{\mathbf{R}}, \dot{\theta}, a) = \frac{1}{2} \begin{pmatrix} \Omega_1 \\ \Omega_2 \\ \Omega_3 \\ \dot{\theta}_1 \\ \theta_2 \end{pmatrix}^T \begin{pmatrix} \lambda_1 & 0 & 0 & J_1 & 0 \\ 0 & \lambda_2 & 0 & 0 & J_2 \\ 0 & 0 & \bar{I}_3 & 0 & 0 \\ J_1 & 0 & 0 & J_1 & 0 \\ 0 & J_2 & 0 & 0 & J_2 \end{pmatrix} \begin{pmatrix} \Omega_1 \\ \Omega_2 \\ \Omega_3 \\ \dot{\theta}_1 \\ \theta_2 \end{pmatrix} - Mgh\mathbf{R}^{-1}a \cdot \chi,$$

where $\Omega = (\Omega_1, \Omega_2, \Omega_3) = (\mathbf{R}^{-1}\dot{\mathbf{R}})^{\vee}$ is the body-fixed angular momentum and χ is the body-fixed unit vector on the line segment connecting the origin O with the body's center of mass, i.e., $\chi = (0, 0, 1)$ in the body-fixed frame.

Fix $\mathbf{k} := (0, 0, 1) \in \mathbb{R}^3$. Let $L_{\mathbf{k}}$ be the restriction of L to $T(G \times X) \times \{\mathbf{k}\}$ as follows:

$$L_{\mathbf{k}}(\mathbf{R}, \theta, \dot{\mathbf{R}}, \dot{\theta}) = L(\mathbf{R}, \theta, \dot{\mathbf{R}}, \dot{\theta}, \mathbf{k}).$$

Then one can check that $L_{\mathbf{k}}$ is the Lagrangian of the heavy top system in Figure 5.2. The actuation is exerted on each pair of rotors, so the control bundle U is given by $U = T^*X$.

By (5.4), the reduced Lagrangian $l : \mathfrak{so}(3) \times TX \times \mathbb{R}^3 \to \mathbb{R}$ is given by

$$\begin{aligned} l(\Omega, \theta, \dot{\theta}, \Gamma) = {} & \frac{1}{2}(\lambda_1\Omega_1^2 + \lambda_2\Omega_2^2 + \bar{I}_3\Omega_3^2 + 2J_1\Omega_1\dot{\theta}_1 + 2J_2\Omega_2\dot{\theta}_2) \\ & + \frac{1}{2}(J_1\dot{\theta}_1^2 + J_2\dot{\theta}_2^2) - Mgh\Gamma \cdot \chi, \end{aligned}$$

where $\Gamma = (\Gamma_1, \Gamma_2, \Gamma_3) = \mathbf{R}^{-1}\mathbf{k}$. Physically, the vector Γ represents the motion of the *unit vector* with the *opposite direction* of gravity as seen from the body. Recall that the reduced equations of motion are derived from (5.7) and (5.5).

Let us consider a new reduced Lagrangian $\tilde{l}$ defined by

$$\begin{aligned} \tilde{l}(\Omega, \theta, \dot{\theta}, \Gamma) = {} & \frac{1}{2}(\lambda_1\Omega_1^2 + \lambda_2\Omega_2^2 + \bar{I}_3\Omega_3^2 + 2J_1\Omega_1\dot{\theta}_1 + 2J_2\Omega_2\dot{\theta}_2) \\ & + \frac{1}{2}(\rho_1 J_1\dot{\theta}_1^2 + \rho_2 J_2\dot{\theta}_2^2) - Mgh\Gamma \cdot \chi, \end{aligned} \tag{5.8}$$

where $\rho_1, \rho_2 \in \mathbb{R}$ are free parameters to be chosen later. See [15] and [21] for the motivation of this choice of the form in (5.8).

Even though we have not developed the general theory of CL systems depending on a parameter and the associated reduction theory, one can check that Definition 2.9 and Theorem 2.11 hold for reduced CL systems depending on a parameter where one should use the reduced Euler–Lagrange operator in (5.5) instead of (2.9) or (2.10). Notice that the equation in (5.6) is common for all reduced CL systems depending on a parameter. With these modifications in mind, one can check that

$$(l, 0, T^*X) \overset{L}{\sim} (\tilde{l}, 0, T^*X).$$

By Theorem 2.11, we can work with the RCL system $(\tilde{l}, 0, T^*X)$ to design a controller.

Let us define the angular momentum, $\Pi = (\Pi_1, \Pi_2, \Pi_2)$, and the control momentum, $\tilde{J} = (\tilde{J}_1, \tilde{J}_2)$, as follows:

$$\Pi = \frac{\partial \tilde{l}}{\partial \Omega} = (\lambda_1\Omega_1 + J_1\dot{\theta}_1,\ \lambda_2\Omega_2 + J_2\dot{\theta}_2,\ \bar{I}_3\Omega_3), \tag{5.9}$$

$$\tilde{J} = \frac{\partial \tilde{l}}{\partial \dot{\theta}} = (J_1\Omega_1 + J_1\rho_1\dot{\theta}_1, J_2\Omega_2 + J_2\rho_2\dot{\theta}_2). \tag{5.10}$$

By (5.7) and (5.5), the equations of motion of the system $(\tilde{l}, 0, T^*X)$ with a choice of control $v = (v_1, v_2)$ are given as follows:

$$\dot{\Pi} = \Pi \times \Omega + Mgh\Gamma \times \chi, \tag{5.11}$$

$$\dot{\tilde{J}} = v, \tag{5.12}$$

$$\dot{\Gamma} = \Gamma \times \Omega. \tag{5.13}$$

These dynamics have two constants of motion,

$$\Pi \cdot \Gamma \quad \text{and} \quad \|\Gamma\| = 1,$$

where $\Pi \cdot \Gamma$ is the vertical component of the space-fixed angular momentum, and $\|\Gamma\| = \|\mathbf{R}^{-1}\mathbf{k}\| = \|\mathbf{k}\| = 1$.

Since the reduced Lagrangian $\tilde{l}$ (or l) does not depend on the rotor angle θ, and we are not interested in the angle of rotors but in the angular velocity of rotors, we will remove X from the *phase space* for the sake of simplicity. Hence, we will regard $\mathfrak{so}(3) \times \mathbb{R}^2 \times \mathbb{R}^3$ as a new phase space, where $\mathbb{R}^2$ is the velocity component of $TX = \mathbb{R}^2 \times \mathbb{R}^2$.

Let $\Omega(0)$, $\dot{\theta}(0)$, and $\Gamma(0)$ with $||\Gamma(0)||^2 = 1$ be an initial condition with

$$\Omega_3^\circ := \Pi(0) \cdot \frac{\Gamma(0)}{\bar{I}_3} < \sqrt{\frac{Mgh}{\bar{I}_3}}. \tag{5.14}$$

We are interested in the equilibrium $e = (\Omega_e, \dot{\theta}_e, \Gamma_e)$,

$$\Omega_e = (0, 0, \Omega_3^\circ),\ \ \dot{\theta_e} = (0, 0),\ \ \Gamma_e = (0, 0, 1) \tag{5.15}$$

or

$$\Omega_e = (0, 0, \Omega_3^\circ),\ \ \tilde{J}_e = (0, 0),\ \ \Gamma_e = (0, 0, 1),$$

which corresponds to the upright spinning top with the rotors at rest. Notice that this equilibrium lies in the same level set of $(\Pi \cdot \Gamma, ||\Gamma||^2)$ as the initial condition.

We construct a Lyapunov function using the energy-Casimir method (see [8] for more detail of this method). Set

$$E_{\tilde{\Phi}} = K + U + \Phi(\Pi \cdot \Gamma, ||\Gamma||^2) + \Psi(\tilde{J}_1, \tilde{J}_2), \tag{5.16}$$

where the potential energy U is given by $U(\Gamma) = Mgh\Gamma \cdot \chi = Mgh\Gamma_3$, and the kinetic energy K is given by

$$K = \frac{1}{2}\left(\lambda_1 - \frac{J_1}{\rho_1}\right)\Omega_1^2 + \frac{1}{2}\left(\lambda_2 - \frac{J_2}{\rho_2}\right)\Omega_2^2 + \frac{1}{2}\bar{I}_3\Omega_3^2 + \frac{\tilde{J}_1^2}{2J_1\rho_1} + \frac{\tilde{J}_2^2}{2J_2\rho_2},$$

in the new coordinates $(\Omega, \tilde{J}, \Gamma)$. Choose the function Ψ as follows:

$$\Psi(\tilde{J}_1, \tilde{J}_2) = \frac{\tilde{J}_1^2}{2\epsilon_1 J_1} + \frac{\tilde{J}_2^2}{2\epsilon_2 J_2}, \tag{5.17}$$

where coefficients ϵ_i will be determined later. Choose the function Φ of the form

$$\begin{aligned}\Phi(x, y) = &-\Omega_3^\circ(x - \bar{I}_3\Omega_3^\circ) + \frac{1}{2}\left(\bar{I}_3(\Omega_3^\circ)^2 - Mgh\right)(y-1)\\ &+ \frac{1}{2}a_1(x - \bar{I}_3\Omega_3^\circ)^2 + \frac{1}{2}a_2(y-1)^2,\end{aligned}$$

where the constants a_1 and a_2 are chosen such that

$$a_1 < \frac{-1}{\bar{I}_3}$$

and

$$4a_2 + a_1(\bar{I}_3\Omega_3^\circ)^2 + \bar{I}_3(\Omega_3^\circ)^2 - Mgh < \frac{\bar{I}_3(a_1\bar{I}_3\Omega_3^\circ - \Omega_3^\circ)^2}{1 + a_1\bar{I}_3}.$$

One can check that the equilibrium e is a critical point of $E_{\tilde{\Phi}}$. We now find conditions under which this critical point is a local *maximum*. First, choose ρ_i satisfying

$$\frac{\bar{I}_3(\Omega_3^\circ)^2 - Mgh}{(\Omega_3^\circ)^2} < \lambda_i - \frac{J_i}{\rho_i} < 0 \tag{5.18}$$

for $i = 1, 2$, and then we can choose ϵ_1 and ϵ_2 such that the second derivative of $E_{\tilde{\Phi}}$ becomes negative definite at e, which implies that $E_{\tilde{\Phi}}$ has a local maximum at e. For later use, we impose an additional condition on ρ_i and ϵ_i as follows:

$$J_i(\Omega_3^\circ)^2 + (\epsilon_i + \rho_i)\left((\Omega_3^\circ)^2(\bar{I}_3 - \lambda_i) - Mgh\right) \neq 0. \tag{5.19}$$

With (5.19), it is still possible to find ρ_i and ϵ_i to ensure negative definiteness of the second derivative of $E_{\tilde{\Phi}}$ at e.

The following choice of $v = (v_1, v_2)$,

$$v_i = c_i\left(\dot{\theta}_i + \frac{\tilde{J}_i}{\epsilon_i J_i}\right), \tag{5.20}$$

with $c_i > 0$ for $i = 1, 2$, implies

$$\frac{d}{dt}E_{\tilde{\Phi}} = \sum_{i=1}^{2} c_i\left(\dot{\theta}_i + \frac{\tilde{J}_i}{\epsilon_i J_i}\right)^2 \geq 0, \tag{5.21}$$

which proves the Lyapunov stability of the equilibrium e in the closed-loop system. The complete control law u for the original system $(l, 0, T^*X)$ can be obtained from Theorem 2.11.

Asymptotic stabilization will now be shown by using LaSalle's theorem. Since $E_{\tilde{\Phi}}$ has a local maximum at e, it is nondecreasing in time, and $\Pi \cdot \Gamma$ and $||\Gamma||^2$ are conserved, there is a number c such that the set

$$S = \{x \in \mathfrak{so}(3) \times \mathbb{R}^2 \times \mathbb{R}^3 \mid E_{\tilde{\Phi}} \geq c,\ \Pi \cdot \Gamma = \Pi_e \cdot \Gamma_e,\ ||\Gamma||^2 = 1\}$$

is nonempty, compact, and positively invariant. Define

$$\mathcal{E} = \{x \in S \mid \dot{E}_{\tilde{\Phi}} = 0\} = \{x \in S \mid v = 0\}.$$

Let $\mathcal{M}$ be the largest invariant subset of $\mathcal{E}$. One can show $\mathcal{M} = \{e\}$ by (5.19) after shrinking the set S if necessary. Thus, by LaSalle's theorem, e is asymptotically stable.

Here are the main points in the proof that $\mathcal{M} = \{e\}$. Let $(\Omega(t), \dot{\theta}(t), \Gamma(t))$ be a trajectory in $\mathcal{M}$. The condition $v = 0$ and (5.12) imply that $\tilde{J}(t)$ is constant. Hence, $\theta_i(t)$ and $\Omega_i(t)$ are constant for $i = 1, 2$. By (5.9), $\Pi_i(t)$, $i = 1, 2$ are constant. Then the third component of (5.11) becomes $\lambda_3 \dot{\Omega}_3(t) =$ constant. By the Lyapunov stability of the equilibrium, it follows $\dot{\Omega}_3(t) \equiv 0$. Hence, $\Omega_3(t)$ is constant. The first and second component of (5.11) imply that $\Gamma_1(t)$ and $\Gamma_2(t)$ are constant. Then the third component of (5.13) implies that $\Gamma_3(t)$ is constant. So far we have shown that the trajectory $(\Omega(t), \dot{\theta}(t), \Gamma(t))$, or $(\Pi(t), \dot{\theta}(t), \Gamma(t))$, is constant for all $t \geq 0$. Consider the map $f : \mathbb{R}^8 \to \mathbb{R}^{10}$ defined by

$$f(\Omega, \dot{\theta}, \Gamma) = \begin{pmatrix} \Pi \times \Omega + Mgh\Gamma \times \chi \\ \Gamma \times \Omega \\ J_1\Omega_1 + (\epsilon_1 + J_1\rho_1)\dot{\theta}_1 \\ J_2\Omega_2 + (\epsilon_2 + J_2\rho_2)\dot{\theta}_2 \\ \Pi \cdot \Gamma - \Pi_e \cdot \Gamma_e \\ \|\Gamma\|^2 - 1 \end{pmatrix} = \begin{pmatrix} \dot{\Pi} \\ \dot{\Gamma} \\ \epsilon_1 v_1 \\ \epsilon_2 v_2 \\ \Pi \cdot \Gamma - \Pi_e \cdot \Gamma_e \\ \|\Gamma\|^2 - 1 \end{pmatrix},$$

where Π is expressed in terms of $(\Omega, \dot{\theta})$ as in (5.9). Then one can see that all the trajectories lying in $\mathcal{M}$ are contained in the set $f^{-1}(O)$. In particular, the equilibrium $(\Omega_e, \dot{\theta}_e, \Gamma_e)$ in (5.15) is also contained in $f^{-1}(O)$. One can check that the rank of the Jacobian matrix Df at the equilibrium is the full rank 8 by (5.19). Thus, f is locally one-to-one around the equilibrium by Theorem 4.12 in [16]. Therefore, the only possible trajectory totally lying in $\mathcal{M}$ is the equilibrium point itself. It follows from LaSalle's theorem that the equilibrium is asymptotically stable.

Remarks. 1. The above procedure shows that the choice of control gains depends on the initial condition. This is unavoidable because we need to know the value of the constant of motion $\Pi \cdot \Gamma$, which the internal actuation cannot change; however, our suggested controller is robust to small errors in the measurement of the initial condition. Let $\tilde{e}$ be the equilibrium of the form (5.15), with $\tilde{\Omega}_3^\circ$ instead of Ω_3°. Suppose the Ω_3° used in constructing the control law is very close to the value $\tilde{\Omega}_3^\circ$. Let $\tilde{E}_{\tilde{\Phi}}$ be the function of the form (5.16), with Ω_3° replaced by $\tilde{\Omega}_3^\circ$. Then $\tilde{e}$ is a critical point of $\tilde{E}_{\tilde{\Phi}}$. By continuity, the second derivative of $\tilde{E}_{\tilde{\Phi}}$ at $\tilde{e}$ will remain negative definite, proving Lyapunov stability of $\tilde{e}$.

2. The same form of controller works for the asymptotic stabilization of the upright spinning top with $\Omega_3^\circ > \sqrt{Mgh/\bar{I}_3}$, which is the opposite of (5.14). All

that needs to be done is to choose ρ_i and ϵ_i to make $E_{\tilde{\Phi}}$ have a local minimum at the equilibrium and to choose negative c_i such that $E_{\tilde{\Phi}}$ decreases in time. LaSalle's theorem argument guarantees asymptotic stability.

6. Conclusions. In this paper we have studied the reduction of controlled Lagrangian (CL) and controlled Hamiltonian (CH) systems with symmetry. We have shown that the notion of equivalence of controlled systems is preserved by the reduction procedure. This leads to a natural derivation of the Bloch–Leonard–Marsden Euler–Poincaré matching conditions and shows in a precise sense how they are related to the unreduced Euler–Lagrange matching conditions. The theory also shows how to do the equivalent matching on the Hamiltonian side. We studied the examples of a rigid body with rotors (a spacecraft) as well as a heavy top with rotors to illustrate the theory.

In the future we will study more examples and also see to what extent this theory applies to controlled nonholonomic systems with or without symmetry, following [18] and [36], and to degenerate and implicit controlled Lagrangian and Hamiltonian systems, following [6] and [35].

Acknowledgments. The authors thank Hernán Cendra for helpful discussions and the anonymous referees for constructive comments.

HIGH-ORDER VARIATIONS FOR FAMILIES OF VECTOR FIELDS*

RONALD HIRSCHORN† AND ANDREW D. LEWIS†

Abstract. Sufficient conditions involving Lie brackets of arbitrarily high order are obtained for local controllability of families of vector fields. After providing a general framework for the generation of high-order control variations, we propose a specific method for generating such variations. The theory is applied to a number of nontrivial examples.

Key words. local controllability, nonlinear systems, higher-order conditions

1. Introduction. In this paper we present a technique for generating high-order variations of families of vector fields. Our approach is motivated by the early work of Sussmann on local controllability [10]. As in [10], we consider S a set of analytic vector fields on $\Omega \subset \mathbb{R}^n$ and an *S-trajectory* to be a continuous curve which is a finite concatenation of integral curves of vector fields in S. A point q is *S-reachable from p* if there exists an S-trajectory $t \mapsto \gamma(t)$ such that $\gamma(0) = p$, $q = \gamma(t)$ for some $t \geq 0$, and *S-reachable from p in time $\leq T$* if $t \leq T$. We say S is *locally controllable* (hereafter abbreviated *l.c.*) if, for every $T > 0$, the set of points S-reachable from p in time $\leq T$ contains p in its interior. In [10] Sussmann defines the set S^1_p of Lie brackets of order two of vector fields in S. His main result is that S is l.c. at p if $0 \in \operatorname{int}(\operatorname{co}(S(p) \cup S^1_p(p)))$, where co stands for convex hull. The main contribution in this paper is the construction of sets of vector fields $S^2_p, S^3_p, \ldots$ of higher-order Lie brackets of vector fields in S. In Theorem 4.5 we summarize our results concerning the generation of these high-order variations. This method of generating variations leads to a controllability result, Theorem 3.7, which states that S is l.c. at p if

$$0 \in \operatorname{int}(\operatorname{co}(S(p) \cup S^1_p(p) \cup \cdots \cup S^m_p(p)))$$

for some $m \geq 1$. Of course, the problem of local controllability, especially for control affine systems, has been studied in detail. We refer particularly to [1, 2, 3, 5, 6, 7, 11, 12].

The paper is organized as follows. In section 2 we review Sussmann's results on local controllability and consider an example. In section 3 we introduce our high-order condition for local controllability, Theorem 3.7. In section 4 we introduce a concrete class of higher-order variations which allow us to apply Theorem 3.7. In section 5 we give some examples illustrating our results.

2. First-order conditions. Suppose that S is a set of vector fields on an open set $\Omega \subset \mathbb{R}^n$ and $0 \in \operatorname{co}(S(p))$ for some $p \in \Omega$, where $\operatorname{co}(S(p))$ is the convex hull in $\mathbb{R}^n \simeq T_p\Omega$ of the set of vectors $S(p) = \{X(p) \mid X \in S\}$. Then, as in [10], we let $L^0(S,p) \subset \mathbb{R}^n$ denote the unique linear subspace of maximal dimension such that

$$0 \in \operatorname{int}_{L^0(S,p)}(\operatorname{co}(S(p)) \cap L^0(S,p))$$

and define

$$Z_p^0 = \{X \in S \mid X(p) \in L^0(S,p)\}.$$

Let $\tilde{S}_p^1$ denote the set of second-order Lie brackets $\tilde{S}_p^1 = \{[X,Y] \mid X, Y \in Z_p^0\}$, where $[X,Y](p) = dY_pX(p) - dX_pY(p)$. The following sufficient condition was established by Sussmann.

THEOREM 2.1 (see [10]). *Suppose that S is a finite set of vector fields such that $0 \in \operatorname{int}(\operatorname{co}(S(p) \cup \tilde{S}_p^1(p)))$. Then S is l.c. at p.*

Remark 2.2. A natural extension of this result would involve $\tilde{S}_p^2$, the set of all triple brackets of elements of Z_p^0. Sussmann points out that the corresponding second-order theorem, that S is l.c. at p if

$$0 \in \operatorname{int}(\operatorname{co}(S(p) \cup \tilde{S}_p^1(p) \cup \tilde{S}_p^2(p))), \tag{2.1}$$

is false. One consequence of our results is that this theorem does hold if $\tilde{S}_p^2$ is the restricted set of triple brackets of elements of Z_p^0 of the form $[X,[X,Y]]$. For example, if in $\mathbb{R}^3$ we take the vector fields

$$W = (1,z,0), \quad X = (-1,0,x^2), \quad Y = (0,1,0), \quad Z = (0,-1,0),$$

then (2.1) holds at $p = (0,0,0)$, but clearly the family is not l.c. at this point as one can never reach states with negative z coordinate.

3. Higher-order Lie brackets. In this section we develop our methodology for the generation of control variations involving arbitrarily high-order brackets of vector fields in S. Our method for doing so begins with some constructions involving what we call complementary sets of vector fields. After these considerations have been discussed in section 3.1, in section 3.2 we produce explicit S-trajectories, which give us control variations involving certain high-order Lie brackets of vector fields in S. In section 3.3 we apply these constructions to give a theorem on local controllability of S.

If X is a vector field, we denote its flow by $t \mapsto X_t(p)$. If X, Y are vector fields, we let $\operatorname{ad}_X Y$ denote the Lie bracket $[X,Y](p) = dY_pX(p) - dX_pY(p)$ (see [14]). We shall consider iterated brackets of vector fields from a family of vector fields, and so need the notion of degree of a bracket. For us, this will refer to the number of vector fields involved in the bracket. Thus a plain vector field has degree 1, and $[X,Y]$ is a bracket of degree 2. Of course, to be perfectly clear about this, one should use free Lie algebras [8]. However, the loss of rigor in what we do here does not merit the introduction of the additional terminology.

3.1. Complementary vector fields. A finite subset $\mathcal{X}_p \subset Z_p^0$ is said to be *complementary at p* if

$$0 \in \operatorname{int}_{\operatorname{aff}(\mathcal{X}_p(p))}(\operatorname{co}(\mathcal{X}_p(p))),$$

where aff denotes the affine hull. Equivalently, $\mathcal{X}_p$ is complementary if 0 can be written as a linear combination of the $X(p)$, $X \in \mathcal{X}_p$, with strictly positive coefficients. Clearly Z_p^0 is complementary at p. If Z_p^0 is convex, then there are many complementary sets. We note that Z_p^0 is convex if S is. Furthermore it is known that S is l.c. if and only if $\operatorname{co}(S)$ is l.c. While our results do not depend on S being convex, to simplify notation *we will assume that S is convex* for the rest of this paper. We will also assume that the family of vector fields has the property that $S(p) \subset T_p\Omega$ is compact.

PROPOSITION 3.1. *Suppose Z_p^0 is convex. Then for every $X \in Z_p^0$ there exists a vector field $Y \in Z_p^0$ such that $\{X, Y\}$ is complementary at p.*

Proof. Let $X \in Z_p^0$. From the definition of Z_p^0 there exist $\lambda_i > 0$ and $Y_i \in Z_p^0$ such that $\sum_{i=0}^k \lambda_i = 1$ and $\lambda_0 X(p) + \lambda_1 Y_1(p) + \cdots + \lambda_k Y_k(p) = 0$. Set $\lambda_* = \sum_{i=1}^k \lambda_i$ and $Y = \sum_{i=1}^k (\lambda_i/\lambda_*) Y_i$. Because Z_p^0 is convex, $Y \in Z_p^0$. This, together with the fact that $(\lambda_0 X + \lambda_* Y)(p) = 0$, completes the proof. □

Suppose that $\mathcal{X}_p = \{X^1, \ldots, X^k\} \subset Z_p^0$ is complementary at p. Then $\mathcal{X}_p$ gives rise to vector fields which vanish at p, namely those which can be expressed as $Z = \lambda_1 X^1 + \cdots + \lambda_k X^k$ for appropriate $\lambda_i > 0$. We define $\mathcal{Z}_p$ as the collection of all such vector fields Z. Since we assume that S is convex, we know that $Z \in S$ and thus

$$\mathcal{Z}_p = \{Z \mid \ Z \in S,\ Z(p) = 0\}.$$

Part of our approach will be to systematically consider rather general classes of S-trajectories. To this end, let π be a permutation of $\{1, \ldots, k\}$. We denote by $\mathcal{X}_t^\pi(p)$ the composition of integral curves of the vector fields in $\mathcal{X}_p$ with time rescaled, namely

$$\mathcal{X}_t^\pi(p) = X^{\pi(k)}_{\lambda_{\pi(k)} t} \circ \cdots \circ X^{\pi(1)}_{\lambda_{\pi(1)} t}(p),$$

where $\lambda_i > 0$ and $\sum_{i=0}^k \lambda_i X^i(p) = 0$. Note that $\mathcal{X}_t^\pi(p)$ is reachable in time $(\sum_i \lambda_i)t$. In spite of a rescaling of time, $\mathcal{X}_t^\pi(p)$ is an S-trajectory in the sense that all points of the form $\mathcal{X}_t^\pi(p)$ for t sufficiently small are the image of a proper S-trajectory. Let P_k denote the set of sequences of permutations of $\{1, 2, \ldots, k\}$. If $\eta \in P_k$, then $\eta = (\pi_\ell, \pi_{\ell-1}, \ldots, \pi_1)$ for some $\ell \in \mathbb{N}$, and we define a *$\mathcal{X}_p^1$-trajectory* $\mathcal{X}_t^\eta(p)$ to be the S-trajectory which is the composition of the curves $\mathcal{X}_t^{\pi_i}(p)$. Then the Campbell–Baker–Hausdorff formula [13] asserts that, for t sufficiently small, there exist vector fields $X^{\eta,i}$ and $X^{\pi,i}$ such that

$$\begin{aligned} \mathcal{X}_t^\pi(p) &= \left(\sum_{i=1}^k \lambda_{\pi(i)} X^{\pi(i)} + X^{\pi,1} t + X^{\pi,2} t^2 + o(t^2) \right)_t (p), \\ \mathcal{X}_t^\eta(p) &= \mathcal{X}_t^{\pi_s} \circ \cdots \circ \mathcal{X}_t^{\pi_1}(p) \\ &= (X^{\eta,1} + X^{\eta,2} t + o(t))_t(p), \end{aligned} \tag{3.1}$$

where $X^{\eta,1}$ is a multiple of $\sum_{i=1}^k \lambda_i X^i$ and hence vanishes at p. Note that the Campbell–Baker–Hausdorff formula also provides explicit expressions for these terms in the series. In any event, this leaves as dominant the second-order term $X^{\eta,2}(p)$. Sussmann [10] generates a richer class of S-trajectories, which allows him to prove his theorem on local controllability (stated as Theorem 2.1 here). However, the local controllability result can be proved using the smaller class of S-trajectories that we consider here. We also point out that, as with $\mathcal{X}_t^\pi(p)$ above, the point $\mathcal{X}_t^\eta(p)$ is reached by an S-trajectory after some time σt, $\sigma > 0$, has elapsed.

Remark 3.2. In (3.1) we have expressed $\mathcal{X}_t^\eta(p)$ as an integral curve for a "time-dependent" vector field $X(t) = X^{\eta,1} + X^{\eta,2} t + o(t)$. To make this more precise we fix $\tau > 0$ and let $\alpha_\tau(t)$ denote the integral curve of the vector field $X(\tau)$ through p, that is, $\alpha_\tau(t) = (X(\tau))_t(p)$, where $\frac{d}{dt}\alpha_\tau(t) = X(\tau)(\alpha_\tau(t))$ and $\alpha_\tau(0) = p$. Then $\mathcal{X}_t^\eta(p)$ denotes the point $\alpha_\tau(t)|_{\tau=t}$.

Remark 3.3. While our definition for S_p^1 differs slightly from Sussmann's $\tilde{S}_p^1$, we do have $\mathrm{co}(\tilde{S}_p^1) \subset \mathrm{co}(S_p^1)$. To show this we can utilize the limited set of permutations

used by Sussmann in his proof of his sufficiency condition for local controllability (Theorem 3 of [10]).

Before we define S^k_p, we motivate the notion of S-trajectories which approximate integral curves to orders higher than one. Let $X, Y \in S^1_p$. From the definition of S^1_p there exist S-trajectories $\mathcal{X}^\eta_t(p) = (X^1 + tX + o(t))_t(p)$ and $\mathcal{Y}^\eta_t(p) = (Y^1 + tY + o(t))_t(p)$ such that X^1 and Y^1 are linear combinations of vector fields in S that vanish at p. Now suppose that $(\lambda_1 X + \lambda_2 Y + \lambda_3 Z)(p) = 0$ for some $Z \in S$ and $\lambda_1, \lambda_2, \lambda_3 > 0$. Proceeding as above, while rescaling time to ensure compatibility between the vector fields in S and S^1_p, we construct the S-trajectory

$$\mathcal{X}_t(p) = \mathcal{X}^\eta_{\sqrt{\lambda_1}t} \circ \mathcal{Y}^\eta_{\sqrt{\lambda_2}t} \circ Z_{\lambda_3 t^2}(p).$$

From the Campbell–Baker–Hausdorff formula we obtain

$$\begin{aligned}
\mathcal{X}_t(p) &= \big(X^1 + X\sqrt{\lambda_1}t + o(t)\big)_{\sqrt{\lambda_1}t} \circ \big(Y^1 + Y\sqrt{\lambda_2}t + o(t)\big)_{\sqrt{\lambda_2}t} \circ Z_{\lambda_3 t^2}(p) \\
&= \Big(t(\sqrt{\lambda_1}X^1 + \sqrt{\lambda_2}Y^1) + t^2(\lambda_1 X + \lambda_2 Y + \lambda_3 Z + (1/2)\sqrt{\lambda_1\lambda_2}[Y^1, X^1]) \\
&\qquad + t^3 W + o(t^3)\Big)_1(p) \\
&= (tX^{\eta,1} + t^2 X^{\eta,2} + t^3 X^{\eta,3})_1(p)
\end{aligned}$$

for vector fields $X^{\eta,1}, X^{\eta,2}, X^{\eta,3}$ with the following properties:

1. $X^{\eta,1}$ is a linear combination of vector fields from S;
2. $X^{\eta,2}$ is a linear combination of degree 1 and 2 brackets of vector fields evaluated at p in S;
3. $X^{\eta,3}$ is a linear combination of degree 2 and 3 brackets of vector fields evaluated at p in S;
4. $X^{\eta,1}$ and $X^{\eta,2}$ vanish at p.

Since the coefficients of t and t^2 vanish at p, we have produced an S-trajectory which approximates, to the third order in t, the integral curve of $X^{\eta,3}$. We let $S^2_p(\mathcal{X}_p)$ denote the set of all such terms $X^{\eta,3}$, and S^2_p the union of the sets $S^2_p(\mathcal{X}_p)$ over all subsets $\mathcal{X}_p$ complementary at p.

3.2. Higher-order variations. We now define S^i_p for $i > 1$ inductively. Suppose that we have defined sets of vector fields $S^1_p, \dots, S^m_p$ with the following property: for any $X \in S^j_p$ there exists an S-trajectory of the form $\mathcal{X}^\eta_t(p) = (X^\eta(t))_t(p) = (tX^\eta(t))_1(p)$, with $X^\eta(t)$ a time-varying vector field so that for t sufficiently small $tX^\eta(t)$ can be represented by the convergent power series

$$tX^\eta(t) = tX^{\eta,1} + t^2 X^{\eta,2} + \cdots + t^{\sigma_j - 1} X^{\eta,\sigma_j - 1} + t^{\sigma_j} X^{\eta,\sigma_j} + o(t^{\sigma_j}),$$

where the vector fields $X^{\eta,1}, \dots, X^{\eta,\sigma_j - 1}$ vanish at p, $X = X^{\eta,\sigma_j}$, and σ_j is defined inductively by $\sigma_1 = 2$ and

$$\sigma_{k+1} = \frac{(\sigma_k + 1)\mathrm{lcm}\{\sigma_1, \dots, \sigma_k\}}{\sigma_k}, \tag{3.2}$$

where lcm denotes least common multiple. We note that one consequence of the above definition is that $\sigma_{m+1} > \sigma_m > \cdots > \sigma_1$. The reason for this definition becomes apparent in the proof of Lemma 3.4. Let $L^m(S, p)$ denote the unique linear subspace of maximal dimension such that

$$0 \in \mathrm{int}_{L^m(S,p)}\big(\mathrm{co}(S(p) \cup S^1_p(p) \cup \cdots \cup S^m_p(p)) \cap L^m(S, p)\big),$$

and set

$$Z_p^m = \{X \in S \cup S_p^1 \cup \cdots \cup S_p^m \mid X(p) \in L^m(S,p)\}.$$

A finite subset $\mathcal{X}_p \subset Z_p^m$ is said to be *complementary at* p if

$$0 \in \operatorname{int}_{\operatorname{aff}(\mathcal{X}_p(p))}\big(\operatorname{co}(\mathcal{X}_p(p))\big)$$

or, equivalently, if 0 can be written as a linear combination of the vectors $X(p), X \in \mathcal{X}_p$, with strictly positive coefficients. Suppose that $\mathcal{X}_p = \{X^1, \ldots, X^k\}$ is a subset of Z_p^m complementary at p, so that $\sum_{i=0}^k \lambda_i X^i(p) = 0$ for some $\lambda_i > 0$. Let π be a permutation of $\{1, 2, \ldots, k\}$. Then $X^i \in S$ or $X^i \in S_p^{m_i}$, where $m_i \in \{1, \ldots, m\}$. If $X^i \in S_p^{m_i}$, then, by our induction hypothesis, there exists an S-trajectory of the form $\mathcal{X}_t^{\eta_i}(p) = (X^{\eta_i}(t))_t(p)$, where the time-varying vector field $X^{\eta_i}(t)$ has the power series expansion

$$tX^{\eta_i}(t) = tX^{\eta_i,1} + \cdots + t^{\sigma_{m_i}-1}X^{\eta_i,\sigma_{m_i}-1} + t^{\sigma_{m_i}}X + o(t^{\sigma_{m_i}}) \tag{3.3}$$

and such that $X^{\eta_i,1}, \ldots, X^{\eta_i,\sigma_{m_i}-1}$ vanish at p. We rescale time by $t \mapsto \alpha_i t^{\gamma_i}$, where $\alpha_i = \lambda_i^{1/\sigma_{m_i}}$, and $\gamma_i = \operatorname{lcm}\{\sigma_1, \ldots, \sigma_m\}/\sigma_{m_i}$. If $X^i \in S$, we rescale time by $t \mapsto \alpha_i t^{\gamma_i}$, where $\gamma_i = \operatorname{lcm}\{\sigma_1, \ldots, \sigma_m\}$—in effect, we define $\sigma_0 = 1$. We denote by $\mathcal{X}_t^\pi(p)$ the S-trajectory

$$\mathcal{X}_t^\pi(p) = \mathcal{X}^{\eta_{\pi(k)}}_{\alpha_{\pi(k)}t^{\gamma_{\pi(k)}}} \circ \cdots \circ \mathcal{X}^{\eta_{\pi(1)}}_{\alpha_{\pi(1)}t^{\gamma_{\pi(1)}}}(p). \tag{3.4}$$

This rescaling is needed because, if $X \in S_p^k$, then, using a suitable control variation, we can generate an S-trajectory which achieves motion in the X direction to order σ_k in t. Finally, if $\eta \in P_k$, so that $\eta = (\pi_{s-1}, \pi_{k_{s-1}}, \ldots, \pi_1)$, we define $\mathcal{X}_t^\eta(p)$ to be the composition of the curves $\mathcal{X}_t^{\pi_i}(p)$ and say that $\mathcal{X}_t^\eta(p)$ is an $\mathcal{X}_p^{m+1}$*-trajectory*. Then

$$\mathcal{X}_t^\eta(p) = \mathcal{X}_t^{\pi_s} \circ \cdots \circ \mathcal{X}_t^{\pi_1}(p) = (X^\eta(t))_t(p).$$

For t sufficiently small the Campbell–Baker–Hausdorff formula yields

$$tX^\eta(t) = tX^{\eta,1} + \cdots + t^{\sigma_{m+1}-1}X^{\eta,\sigma_{m+1}-1} + t^{\sigma_{m+1}}X^{\eta,\sigma_{m+1}} + o(t^{\sigma_{m+1}}) \tag{3.5}$$

for vector fields $X^{\eta,i}$.

The following lemma makes clear why the inductive definitions of the σ_k's are as in (3.2). The idea essentially is that one needs to define time rescalings along vector fields in an S-trajectory to ensure that the desired term is the first nonzero term in the series expansion. This makes sense of our inductive definition of $S_p^m(p)$.

LEMMA 3.4. *The vector fields* $X^{\eta,1}, \ldots, X^{\eta,\sigma_{m+1}-1}$ *that appear in* (3.5) *vanish at* p.

Proof. Let $X \in S_p^i, Y \in S_p^j$, where $i, j \in \{0, \ldots, m\}$ and $S_p^0 = S$. By our induction hypotheses there exist time-varying vector fields $X^{\eta_i}(t), X^{\eta_j}(t)$, where

$$\begin{aligned} tX^{\eta_i}(t) &= (tX^{\eta_i,1} + \cdots + t^{\sigma_i-1}X^{\eta_i,\sigma_i-1} + t^{\sigma_i}X + o(t^{\sigma_i})), \\ tX^{\eta_j}(t) &= (tX^{\eta_j,1} + \cdots + t^{\sigma_j-1}X^{\eta_j,\sigma_j-1} + t^{\sigma_j}Y + o(t^{\sigma_j})), \end{aligned}$$

with $X^{\eta_j,k}, X^{\eta_i,\ell}$ vanishing at p as in (3.3) above. The corresponding S-trajectories are $\mathcal{X}_t^{\eta_j}(p) = (X^{\eta_j}(t))_t(p) = (tX^{\eta_j}(t))_1(p)$ and $\mathcal{X}_t^{\eta_i}(p) = (X^{\eta_i}(t))_t(p) = (tX^{\eta_i}(t))_1(p)$.

Rescaling time as above and concatenating these curves yields the S-trajectory

$$\begin{aligned}\beta(t) &= \mathcal{X}^{\eta_j}_{\alpha_j t^{\gamma_j}} \circ \mathcal{X}^{\eta_i}_{\alpha_i t^{\gamma_i}} \\ &= (X^{\eta_j}(\alpha_j t^{\gamma_j}))_{\alpha_j t^{\gamma_j}} \circ (X^{\eta_i}(\alpha_i t^{\gamma_i}))_{\alpha_i t^{\gamma_i}}(p) \\ &= (\alpha_j t^{\gamma_j} X^{\eta_j}(\alpha_j t^{\gamma_j}))_1 \circ (\alpha_i t^{\gamma_i} X^{\eta_i}(\alpha_i t^{\gamma_i}))_1(p) \\ &= \left(\sum_{k=1}^{\sigma_j+1} (\alpha_j t^{\gamma_j})^k X^{\eta_j,k} + o(t^{\gamma_j(\sigma_j+1)}) \right)_1 \circ \left(\sum_{\ell=1}^{\sigma_i+1} (\alpha_i t^{\gamma_i})^\ell X^{\eta_i,\ell} + o(t^{\gamma_i(\sigma_i+1)}) \right)_1 (p),\end{aligned}$$

where $X = X^{\eta_i,\sigma_i}$, $Y = X^{\eta_j,\sigma_j}$, and $X^{\eta_i,\ell}$ and $X^{\eta_j,k}$ vanish at p for $k < \sigma_j, \ell < \sigma_i$. For t sufficiently small, the Campbell–Baker–Hausdorff formula gives the coefficients of t in the power series expansion for $\beta(t)$. In particular, $\beta(t)$ can be written as a convergent power series whose terms are expressible as linear combinations of Lie brackets of the vector fields $X^{\eta_i,\ell}$ and $X^{\eta_j,k}$ and Lie brackets of these vector fields of all orders. Our induction hypothesis implies that $X^{\eta_i,\ell}$ and $X^{\eta_j,k}$ vanish at p if $k < \sigma_j$ and $\ell < \sigma_i$. Hence Lie brackets of these vector fields also vanish at p. Thus the lowest-order term with respect to t in the power series expansion for $\beta(t)$ which does not necessarily vanish at p will be

$$(\alpha_j t^{\gamma_j})^{\sigma_j} X^{\eta_j,\sigma_j} + (\alpha_i t^{\gamma_i})^{\sigma_i} X^{\eta_i,\sigma_i}.$$

From the above definitions

$$(\alpha_j t^{\gamma_j})^{\sigma_j} X^{\eta_j,\sigma_j} = ((\lambda_j^{1/\sigma_j})^{\sigma_j}) t^{\gamma_j \sigma_j} X^{\eta_j,\sigma_j}$$

and

$$(\alpha_i t^{\gamma_i})^{\sigma_i} X^{\eta_i,\sigma_i} = ((\lambda_i^{1/\sigma_i})^{\sigma_i}) t^{\gamma_i \sigma_i} X^{\eta_i,\sigma_i}.$$

Thus

$$(\alpha_j t^{\gamma_j})^{\sigma_j} X^{\eta_j,\sigma_j} + (\alpha_i t^{\gamma_i})^{\sigma_i} X^{\eta_i,\sigma_i} = t^{\operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\}} (\lambda_j X^{\eta_j,\sigma_j} + \lambda_i X^{\eta_i,\sigma_i}).$$

The next (higher) power of t which appears in the power series for $\beta(t)$ is t^r, which has as coefficient the linear combination of vector fields

$$\begin{aligned}(\alpha_j t^{\gamma_j})^{\sigma_j+1} X^{\eta_j,\sigma_j+1} + (\alpha_i t^{\gamma_i})^{\sigma_i+1} X^{\eta_i,\sigma_i+1} \\ = \alpha_j^{\sigma_j+1} t^{\gamma_j(\sigma_j+1)} X^{\eta_j,\sigma_j+1} + \alpha_i^{\sigma_i+1} t^{\gamma_i(\sigma_i+1)} X^{\eta_i,\sigma_i+1}.\end{aligned}$$

We now show that $r \geq \sigma_{m+1}$. Since $\gamma_j(\sigma_j+1) = (\frac{\sigma_j+1}{\sigma_j})\operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\}$; the sequence $\{\sigma_j\}$ is, by definition, monotone increasing; and $\sigma_{m+1} = (\frac{\sigma_m+1}{\sigma_m})\operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\}$, we see that $\gamma_j(\sigma_j+1) > \sigma_{m+1}$ for $j < m$ and $\gamma_j(\sigma_j+1) = \sigma_{m+1}$ if $j = m$. Among the Lie brackets of order 2 in the power series expansion of $\beta(t)$ which do not vanish at p, the terms with the lowest power of t will have the form

$$[\alpha_j t^{\gamma_j} X^{\eta_j,1}, (\alpha_i t^{\gamma_i})^{\sigma_i} X^{\eta_i,\sigma_i}] = \alpha_j {\alpha_i}^{\sigma_i} t^{\gamma_j+\gamma_i\sigma_i} [X^{\eta_j,1}, X^{\eta_i,\sigma_i}].$$

Here we have t to the power $\gamma_j + \gamma_i\sigma_i$ and

$$\begin{aligned}\gamma_j + \gamma_i\sigma_i &= \frac{\operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\}}{\sigma_j} + \operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\} \\ &= \Big(\frac{\sigma_j+1}{\sigma_j}\Big)\operatorname{lcm}\{\sigma_1,\ldots,\sigma_m\} \\ &\geq \sigma_{m+1},\end{aligned}$$

with equality holding if and only if $j = m$. Lie brackets of order greater than 2 which are coefficients of t^s with $s \le \sigma_{m+1}$ clearly must vanish at p. Thus if $\ell = \operatorname{lcm}\{\sigma_1, \dots, \sigma_m\}$, then the power series expansion for $\mathcal{X}_t^\pi(p)$ defined by (3.4) is of the form $(tZ^1 + \cdots + t^{\ell-1}Z^{\ell-1} + t^\ell Z^\ell + t^r Z^r + o(t^r))_1(p)$, where $Z^1, \dots, Z^{\ell-1}$ vanish at p, $Z^\ell = \sum_{i=1}^m \lambda_i X^i$; hence by our choice of the λ_i's we have $Z^\ell(p) = 0$, and $r \ge \sigma_{m+1}$ with $r = \sigma_{m+1}$ if and only if one of the vector fields $X^i \in S_p^m$. Extending this argument to $\mathcal{X}_t^\eta(p)$ completes the proof. □

This lemma implies that $\mathcal{X}_t^\eta(p)$ is an S-trajectory which approximates, to order $t^{\sigma_{m+1}}$, the integral curve of $X^{\eta,\sigma_{m+1}}$ with time rescaled to $t^{\sigma_{m+1}}$. We let $S_p^{m+1}(\mathcal{X}_p)$ denote the set of all such terms $X^{\eta,\sigma_{m+1}}$, indexed over all $\mathcal{X}_p^{m+1}$-trajectories $\mathcal{X}_t^\eta(p)$.

DEFINITION 3.5. *S_p^{m+1} is defined to be the union of the sets $S_p^{m+1}(\mathcal{X}_p)$ over all subsets $\mathcal{X}_p$ complementary at p.*

We note that vector fields in S_p^m will be linear combinations of brackets of degree at most $m+1$ of vector fields in S. The following is a consequence of the above discussion.

PROPOSITION 3.6. *Suppose that $X \in S_p^m$. Then*

1. *for t sufficiently small, there exists an S-trajectory $\mathcal{X}_t^\eta(p)$ of the form*

$$\mathcal{X}_t^\eta(p) = (X^{\eta,1} + \cdots + t^{\sigma_m - 1}X^{\eta,\sigma_m} + t^{\sigma_m}X^{\eta,\sigma_m+1} + o(t^{\sigma_m}))_t(p), \tag{3.6}$$

   where $X = X^{\eta,\sigma_m}$ and the vector fields $X^{\eta,k}$ vanish at p for $k = 1, \dots, \sigma_m - 1$;
2. *if $X(p) = 0$, then X^{η,σ_m+1} in (3.6) belongs to S_p^{m+1};*
3. *the S-trajectory (3.6) has the form*

$$\mathcal{X}_t^\eta(p) = p + t^{\sigma_m}X(p) + o(t^{\sigma_m}),$$

   where X is a linear combination of brackets of vector fields in S of degrees up to and including $m+1$.

Proof. Assertion 1 follows from our definition of S_p^m. In particular, the fact that, for t sufficiently small, there exists an S-trajectory $\mathcal{X}_t^\eta(p)$ of the form

$$\mathcal{X}_t^\eta(p) = (X^{\eta,1} + \cdots + t^{\sigma_m - 1}X^{\eta,\sigma_m} + t^{\sigma_m}X^{\eta,\sigma_m+1} + o(t^{\sigma_m}))_t(p),$$

where $X = X^{\eta,\sigma_m}$ and the vector fields $X^{\eta,k}$ vanish at p for $k = 1, \dots, \sigma_m - 1$, follows from the definition of S_p^m and Lemma 3.4. For point 2, suppose that X also vanishes at p. Then, by definition, $\mathcal{X}_p = \{X\} \subset Z_p^m$ is a set of vector fields complementary at p, and hence the $\mathcal{X}_p^m$-trajectory $\mathcal{X}_t^\eta(p)$ is also a $\mathcal{X}_p^{m+1}$-trajectory, and then $X^{\eta,\sigma_m+1} \in S_p^{m+1}$ by definition.

For assertion 3 we write (3.6) in exponential form:

$$\begin{aligned}\mathcal{X}_t^\eta(p) &= \exp(tX^{\eta,1} + \cdots + t^{\sigma_m-1}X^{\eta,\sigma_m-1} + t^{\sigma_m}X + o(t^{\sigma_m}))(p)\\ &= p + t^{\sigma_m}X(p) + o(t^{\sigma_m}),\end{aligned}$$

since $X^{\eta,1}(p) = \cdots = X^{\eta,\sigma_m-1}(p) = 0$. □

3.3. A theorem on local controllability. The main result in this section is the following high-order sufficient condition for local controllability.

THEOREM 3.7. *Suppose that S is a set of vector fields on $\Omega \subset \mathbb{R}^n$ such that*

$$0 \in \operatorname{int}\big(\operatorname{co}(S(p) \cup S_p^1(p) \cup \cdots \cup S_p^m(p))\big)$$

for some $m \ge 1$. Then S is l.c. at p.

Proof. By assumption there exist vector fields $X^i_1, \dots, X^i_{k_i} \in S^i_p$ for $0 \le i \le m$ such that 0 is contained in the absolute interior of the convex hull of $\{X^i_j(p) \mid 0 \le i \le m,\ 1 \le j \le k_i\}$. Here we set $S^0_p = S$. In light of Proposition 3.6(3) we can find corresponding S-trajectories

$$\mathcal{X}^{\eta_{i,j}}_t(p) = p + \frac{t^{\sigma_i}}{\sigma_i} X^i_j(p) + o(t^{\sigma_i}).$$

Rescaling time by $t^{\sigma_i} = \sigma_i s_{i,j}$ for $s_{i,j} > 0$, we have $\tilde{\mathcal{X}}^{\eta_{i,j}}_t(p) = p + s_{i,j} X^i_j(p) + o(s_{i,j})$. The composition of such S-trajectories yields

$$\alpha(s_{1,1}, s_{1,2}, \dots, s_{m,k_m}) = p + \sum_{i=0}^{m} \sum_{j=1}^{k_i} s_{i,j} X^i_j(p) + o(s_{1,1} + s_{1,2} + \cdots + s_{m,k_m}).$$

This is the form of the S-trajectories used in the proof of Theorem 3 in [10]. We can then apply Lemma 4 of [10] to conclude that S is l.c. at p. ∎

Remark 3.8. The result may also be proved using techniques of Frankowska [4].

Remark 3.9. Suppose that $X \in S^m_p$ and that $Z^1, \dots, Z^\ell \in \mathcal{Z}_p$. Then the directions spanned by $\pm \mathrm{ad}_{Z^1} \circ \mathrm{ad}_{Z^2} \circ \cdots \circ \mathrm{ad}_{Z^\ell} X(p)$ can be considered as available directions for the purposes of local controllability, provided that there exists $Y \in S^m_p$ so that $X(p) + Y(p) = 0$. This may be argued by slightly generalizing Theorem 2.4 in [2].

4. A concrete class of higher-order variations. While Theorem 3.7 is interesting, it is not so easy to apply, as we have not been very concrete about describing tangent vectors in $S^m_p(p)$. In this section we provide a description of some such tangent vectors. Our description arises from developing S-trajectories associated with sequences of permutations. One of the consequences of our development is the identification of terms in the series expansion for the S-trajectories that are independent of permutation. These are obstructions to local controllability in our setup. In the parlance of Sussmann [12], these are fixed points of a group action in a free Lie algebra.

4.1. Variations associated with sequences of permutations. Suppose that $X, Y \in S$. Then, for t sufficiently small,

$$Y_t \circ X_t(p) = \big(A^0(X,Y) + A^1(X,Y)t + A^2(X,Y)t^2 + A^3(X,Y)t^3 + \cdots\big)_t(p),$$

where, from the Campbell–Baker–Hausdorff formula,

$$\begin{aligned}
A^0(X,Y) &= X + Y,\\
A^1(X,Y) &= \frac{1}{2}\mathrm{ad}_X Y,\\
A^2(X,Y) &= \frac{1}{12}(\mathrm{ad}^2_Y X + \mathrm{ad}^2_X Y),\\
A^3(X,Y) &= -\frac{1}{24}\mathrm{ad}_Y \mathrm{ad}^2_X Y,\\
A^4(X,Y) &= -\frac{1}{180}\mathrm{ad}_Y \mathrm{ad}^3_X Y - \frac{1}{120}[\mathrm{ad}_X Y, \mathrm{ad}^2_X Y] + \frac{1}{180}\mathrm{ad}^2_Y \mathrm{ad}^2_X Y\\
&\quad + \frac{1}{360}[\mathrm{ad}_X Y, \mathrm{ad}^2_Y X] - \frac{1}{720}\mathrm{ad}^4_X Y - \frac{1}{720}\mathrm{ad}^4_Y X,
\end{aligned} \tag{4.1}$$

and $A^k(X,Y)$ can, in principal, be expressed explicitly as functions of X,Y for all $k>0$. Let $\mathbb{N}$ denote the positive integers. If $X^i,Y^i\in S$, $\boldsymbol{s}=(s_1,\dots,s_k)\in\mathbb{N}^k$, then for $\pi\in P_k^0$, the group of permutations of $\{1,2,\dots,k\}$, we form the S-trajectory

$$\begin{aligned}\mathcal{X}_t^\pi(p)&=Y^{\pi(1)}_{t^{s_{\pi(1)}}}\circ X^{\pi(1)}_{t^{s_{\pi(1)}}}\circ Y^{\pi(2)}_{t^{s_{\pi(2)}}}\circ X^{\pi(2)}_{t^{s_{\pi(2)}}}\circ\cdots\circ Y^{\pi(k)}_{t^{s_{\pi(k)}}}\circ X^{\pi(k)}_{t^{s_{\pi(k)}}}(p)\\&=(Q_\pi^0+Q_\pi^1t+Q_\pi^2t^2+\cdots)_t(p),\end{aligned}\tag{4.2}$$

where the vector fields $Q_\pi^\ell=Q_\pi^\ell(X^1,Y^1,\dots,X^k,Y^k,\boldsymbol{s})$ are linear combinations of the vector fields $A^j(X^i,Y^i)$ and their Lie brackets. For example, for $\boldsymbol{s}=(1,\dots,1)$ we have

$$\begin{aligned}Q_\pi^0&=A^0(X^1,Y^1)+\cdots+A^0(X^k,Y^k),\\Q_\pi^1&=\sum_{i=1}^k A^1(X^i,Y^i)+\frac{1}{2}\sum_{1\le i<j\le k}[A^0(X^{\pi(i)},Y^{\pi(i)}),A^0(X^{\pi(j)},Y^{\pi(j)})].\end{aligned}$$

The order of the group P_k^0 is $k!$, and we define P_k^1 to be the elements of the $k!$-fold direct product of P_k^0 with itself, $\Pi_{i=1}^{k!}P_k^0$, of the form $\pi=(\pi_1,\dots,\pi_{k!})$, where $\pi_i\in P_k^0$ are *distinct*. We note that P_k^1 is a set with $\Gamma=k!!$ elements. If $\pi=(\pi_1,\dots,\pi_{k!})\in P_k^1$, we define a corresponding S-trajectory

$$\mathcal{X}_t^\pi(p)=\mathcal{X}_t^{\pi_1}\circ\cdots\circ\mathcal{X}_t^{\pi_{k!}}(p)=(Q_\pi^0+Q_\pi^1t+Q_\pi^2t^2+\cdots)_t(p),$$

where, as above, $Q_\pi^\ell=Q_\pi^\ell(X^1,Y^1,\dots,X^k,Y^k,\boldsymbol{s})$ is a linear combination of the vector fields $A^j(X^i,Y^i)$ and their Lie brackets. Similarly $\pi\in P_k^2$ if $\pi=(\pi_1,\dots,\pi_\gamma)$, where $\pi_i\in P_k^1$ and

$$\mathcal{X}_t^\pi(p)=\mathcal{X}_t^{\pi_1}\circ\cdots\circ\mathcal{X}_t^{\pi_\Gamma}(p)=(Q_\pi^0+Q_\pi^1t+Q_\pi^2t^2+\cdots)_t(p).$$

In this way we can inductively define subsets of permutations P_k^ℓ. It will be convenient to use the notation $\Gamma(k,\ell)$ to denote the cardinality of P_k^ℓ. Thus $\Gamma(k,0)=k!$ and $\Gamma(k,\ell+1)=\Gamma(k,\ell)!$. Note that if $\pi=(\pi_1,\dots,\pi_{\Gamma(k,\ell)})\in P_k^{\ell+1}$, where $\pi_i\in P_k^\ell$, then $\mathcal{X}_t^\pi(p)$ denotes the S-trajectory

$$\begin{aligned}\mathcal{X}_t^\pi(p)&=\mathcal{X}_t^{\pi_1}\circ\cdots\circ\mathcal{X}_t^{\pi_{\Gamma(k,\ell)}}(p)\\&=(Q_\pi^0+Q_\pi^1t+\cdots)_t(p).\end{aligned}\tag{4.3}$$

For example, $P_2^0=\{\pi_1,\pi_2\}$ with

$$\pi_1=\begin{pmatrix}1&2\\1&2\end{pmatrix},\quad \pi_2=\begin{pmatrix}1&2\\2&1\end{pmatrix}.$$

Thus

$$\begin{aligned}P_2^1&=\{(\pi_1,\pi_2),\ \ (\pi_2,\pi_1)\},\\P_2^2&=\{((\pi_1,\pi_2),(\pi_2,\pi_1)),\ \ ((\pi_2,\pi_1),(\pi_1,\pi_2))\}.\end{aligned}$$

If $\pi=(\pi_1,\pi_2)\in P_2^1$, then

$$\mathcal{X}_t^\pi(p)=Y^1_{t^{s_1}}\circ X^1_{t^{s_1}}\circ Y^2_{t^{s_2}}\circ X^2_{t^{s_2}}\circ Y^2_{t^{s_2}}\circ X^2_{t^{s_2}}\circ Y^1_{t^{s_1}}\circ X^1_{t^{s_1}},$$

and if $\pi=(\pi_2,\pi_1)\in P_2^1$, then

$$\mathcal{X}_t^\pi(p)=Y^2_{t^{s_2}}\circ X^2_{t^{s_2}}\circ Y^1_{t^{s_1}}\circ X^1_{t^{s_1}}\circ Y^1_{t^{s_1}}\circ X^1_{t^{s_2}}\circ Y^2_{t^{s_2}}\circ X^2_{t^{s_2}}.$$

Similar expressions then hold for the elements of P_2^2. In essence these are analogous to the time reversal permutations considered by Sussmann [12].

4.2. Permutation-invariant elements. Next we turn to a more detailed investigation of the terms in the power series expansion for the S-trajectories of the preceding section. In particular, we show that such power series expansions possess terms that are independent of the sequence of permutations. In essence, these are terms in the series which cannot be modified by changing the sequence, and so may be thought of as obstructions to local controllability.

The first result exposes the pattern in which invariant terms arise in the series expansion (4.3) under sequences of permutations of a given length. If $\boldsymbol{s} = (s_1, \dots, s_k) \in \mathbb{N}^k$, we set

$$m(\boldsymbol{s}) = \min\{s_i \mid 1 \leq i \leq k\}$$

and define $m_i(\boldsymbol{s})$ inductively by

$$m_0(\boldsymbol{s}) + 2 = \min\{s_i + s_j \mid 1 \leq i, j \leq k,\ i \neq j\}$$

and

$$m_\ell(\boldsymbol{s}) = m_0(\boldsymbol{s}) + \ell m(\boldsymbol{s}).$$

LEMMA 4.1. *Let $\pi \in P_k^\ell$, and let $\mathcal{X}_t^\pi(p)$ be the S-trajectory*

$$\mathcal{X}_t^\pi(p) = (Q_\pi^0 + Q_\pi^1 t + \cdots)_t(p)$$

defined by (4.3). *Then $Q_\pi^0, \dots, Q_\pi^{m_\ell(\boldsymbol{s})}$ are independent of π, and $Q_\pi^0, \dots, Q_\pi^{m(\boldsymbol{s})-2}$ vanish identically.*

Proof. We begin by considering the case $\pi \in P_k^0$. To help with notation we set

$$X_j(t) = \sum_{i=0}^{\infty} A^i(X^{\pi(j)}, Y^{\pi(j)}) t^{(i+1)s_{\pi(j)}},$$

so that the S-trajectory $\mathcal{X}_t^\pi(p)$ defined by (4.2) is the composition of integral curves of the vector fields X_j followed for one unit of time. Thus $\mathcal{X}_t^\pi(p) = (X_1(t))_1 \circ \cdots \circ (X_k(t))_1(p)$, and, using the Campbell–Baker–Hausdorff formula, we have

$$\mathcal{X}_t^\pi(p) = \left(\sum_{j=1}^{k} X_j(t) + \sum_{1 \leq i < j \leq k} \frac{1}{2}[X_i(t), Y_i(t)] + \cdots \right)_1 (p), \tag{4.4}$$

where the additional terms are iterated brackets of the vector fields $X_i(t)$ of degree greater than 2. We note that $\sum_{j=1}^k X_j(t)$ is independent of our choice of $\pi \in P_k^0$. Writing the above vector field explicitly as a power series in t,

$$\mathcal{X}_t^\pi(p) = (Q_\pi^0 t + Q_\pi^1 t^2 + \cdots)_1(p),$$

we see that, from the definition of $X_j(t)$, the lowest power of t with a nonzero coefficient will be $t^{m(\boldsymbol{s})}$, where $m(\boldsymbol{s}) = \min\{s_i \mid 1 \leq i \leq k\}$ as above. In particular, $Q_\pi^0, \dots, Q_\pi^{m(\boldsymbol{s})-2}$ are identically zero. Similarly the lowest power of t with a nonzero coefficient in $\sum_{1 \leq i < j \leq k} \frac{1}{2}[X_i(t), Y_j(t)]$ will be $t^{m_0(\boldsymbol{s})+2}$, so that $Q_\pi^{m_0(\boldsymbol{s})+1}$ is the coefficient of the t which could vary with $\pi \in P_k^0$. From our definition of $m_0(\boldsymbol{s})$ we have

$$\mathcal{X}_t^\pi(p) = (Q_\pi^{m(\boldsymbol{s})-1} t^{m(\boldsymbol{s})-1} + \cdots + Q_\pi^{m_0(\boldsymbol{s})+1} t^{m_0(\boldsymbol{s})+1} + \cdots)_t(p),$$

where $Q_\pi^{m(\boldsymbol{s})-1}, \dots, Q_\pi^{m_0(\boldsymbol{s})}$ are invariant with respect to $\pi \in P_k^0$. This proves the lemma in the case $\ell = 0$. Now suppose that the lemma holds for $\pi \in P_k^\ell$. Let $\pi = (\pi_1, \dots, \pi_{\Gamma(k,\ell)}) \in P_k^{\ell+1}$, where $\pi_i \in P_k^\ell$, and set

$$\mathcal{X}_t^\pi(p) = \mathcal{X}_t^{\pi_1} \circ \cdots \circ \mathcal{X}_t^{\pi_{\Gamma(k,\ell)}}(p).$$

By assumption,

$$\mathcal{X}_t^{\pi_i}(p) = (Q_{\pi_i}^{m(\boldsymbol{s})-1} t^{m(\boldsymbol{s})-1} + Q_{\pi_i}^{m(\boldsymbol{s})} t^{m(\boldsymbol{s})} + \cdots)_t(p),$$

where $Q_{\pi_i}^{m(\boldsymbol{s})-1}, \dots, Q_{\pi_i}^{m_\ell(\boldsymbol{s})}$ are independent of π_i. Setting $Q^j = Q_{\pi_i}^j$ for $j = m(\boldsymbol{s}) - 1, \dots, m_\ell(\boldsymbol{s})$, it follows that $\mathcal{X}_t^{\pi_i}(p) = (\bar{X}_i(t))_t(p)$, where

$$\begin{aligned}\bar{X}_i(t) = {} & Q^{m(\boldsymbol{s})-1} t^{m(\boldsymbol{s})-1} + Q^{m(\boldsymbol{s})} t^{m(\boldsymbol{s})} + \cdots + Q^{m_\ell(\boldsymbol{s})} t^{m_\ell(\boldsymbol{s})} \\ & + Q_{\pi_i}^{m_\ell(\boldsymbol{s})+1} t^{m_\ell(\boldsymbol{s})+1} + \cdots.\end{aligned}$$

As in (4.4), the Campbell–Baker–Hausdorff formula yields an expression for $\mathcal{X}_t^\pi$ with $\bar{X}_i(t)$ replacing $X_i(t)$. Arguing as in the case $\ell = 0$ above, we can conclude that

$$\begin{aligned}\mathcal{X}_t^\pi(p) = \big(& \Gamma(k,\ell) Q^{m(\boldsymbol{s})-1} t^{m(\boldsymbol{s})-1} + \cdots + \Gamma(k,\ell) Q^{m_\ell(\boldsymbol{s})} t^{m_\ell(\boldsymbol{s})} \\ & + (Q_{\pi_1}^{m_\ell(\boldsymbol{s})+1} + \cdots + Q_{\pi_{\Gamma(k,\ell)}}^{m_\ell(\boldsymbol{s})+1}) t^{m_\ell(\boldsymbol{s})+1} + \cdots \\ & + (Q_{\pi_1}^{m_\ell(\boldsymbol{s})+m} + \cdots + Q_{\pi_{\Gamma(k,\ell)}}^{m_\ell(\boldsymbol{s})+m}) t^{m_\ell(\boldsymbol{s})+m} \\ & + Q_\pi^{m_\ell(\boldsymbol{s})+m+1} t^{m_\ell(\boldsymbol{s})+m+1} + \cdots \big)_t(p).\end{aligned}$$

Since $m_\ell(\boldsymbol{s}) + m = m_{\ell+1}(\boldsymbol{s})$ and in the above equation the coefficients of t^i with $i \le m_{\ell+1}(\boldsymbol{s})$ are π-invariant, the induction is complete. □

Let $\pi \in P_k^\ell$. In light of Lemma 4.1 we set

$$Q_{\text{inv}}^i = Q_\pi^i, \quad m_{\ell-1}(\boldsymbol{s}) < i \le m_\ell(\boldsymbol{s}),$$

where $Q_{\text{inv}}^i = Q_{\text{inv}}^i(X^1, Y^1, \dots, X^k, Y^k, \boldsymbol{s})$ depends on X^i, Y^i and $\boldsymbol{s}$ is independent of π. For $\ell = 0$ we set

$$Q_{\text{inv}}^i = Q_\pi^i, \quad i \in \{0, 1, \dots, m_0(\boldsymbol{s})\}.$$

In the case $\boldsymbol{s} = (1, \dots, 1)$ it is straightforward to show that $m_\ell(\boldsymbol{s}) = \ell$ and

$$\begin{aligned}Q_{\text{inv}}^0 &= A^0(X^1, Y^1) + \cdots + A^0(X^k, Y^k), \\ Q_{\text{inv}}^1 &= k!(A^1(X^1, Y^1) + \cdots + A^1(X^k, Y^k)), \\ Q_{\text{inv}}^2 &= (k!)^2(A^2(X^1, Y^1) + \cdots + A^2(X^k, Y^k)) + B,\end{aligned}$$

where B is a linear combination of degree 3 brackets of the vector fields $A^0(X^i, Y^i)$. For our application, the pairs $\{X^i, Y^i\}$ above will be complementary at p so that $A^0(X^i, Y^i)$ and hence B vanish at p.

The following proposition relates the definition of Q_{inv}^i to the S-trajectory corresponding to $\pi \in P_k^\ell$, where $i \le m_\ell(\boldsymbol{s})$.

PROPOSITION 4.2. *For each $\ell \ge 0$ and $\pi \in P_k^\ell$ there corresponds an S-trajectory of the form*

$$\mathcal{X}_t^\pi(p) = \big(\alpha_0 Q_{\text{inv}}^0 + \cdots + \alpha_{m_\ell(\boldsymbol{s})} Q_{\text{inv}}^{m_\ell(\boldsymbol{s})} t^{m_\ell(\boldsymbol{s})} + Q_\pi^{m_\ell(\boldsymbol{s})+1} t^{m_\ell(\boldsymbol{s})+1} + \cdots\big)_t(p),$$

where $\alpha_i > 0$, $i \in \{0, 1, \dots, m_\ell(\boldsymbol{s})\}$.

Proof. The proof of Lemma 4.1 contains this result with a slight change of notation using the subscript "inv" to keep track of the vector fields invariant with respect to the appropriate collection of permutations. □

Remark 4.3. In the case of a single-input affine system $\dot{x} = f(x)+ug(x)$, consider the sets $\{X^1 = f+g, Y^1 = f-g\}$ and $\{X^2 = f-g, Y^2 = f+g\}$, and take $s_1 = s_2 = 1$ to compute

$$
\begin{aligned}
Q^0_{\text{inv}} &= 4f,\\
Q^2_{\text{inv}} &= \frac{8}{3}\text{ad}_g^2 f,\\
Q^4_{\text{inv}} &= \frac{8}{15}\text{ad}_g^4 f + \frac{56}{45}\text{ad}_g\text{ad}_f^3 g - \frac{496}{45}[\text{ad}_f g, \text{ad}_f^2 g],\\
Q^6_{\text{inv}} &= \frac{1136}{315}[[f,g],\text{ad}_f^4 g] - \frac{119912}{945}[\text{ad}_f^2 g, \text{ad}_f^3 g] + \frac{32}{105}\text{ad}_g^3\text{ad}_f^3 g\\
&\quad - \frac{1024}{315}[\text{ad}_f g, \text{ad}_g^3\text{ad}_f^2 g] + \frac{3376}{315}[\text{ad}_f g, [\text{ad}_f g, \text{ad}_g^2 f]] - \frac{144}{35}[\text{ad}_f^2 g, \text{ad}_g^3 f]\\
&\quad + \frac{16}{315}\text{ad}_g^6 f + \frac{176}{945}[\text{ad}_g^2 f, [g, \text{ad}_f^2 g]] - \frac{176}{945}[g, \text{ad}_f^5 g].
\end{aligned}
$$

These are linear combinations of *bad* vector fields as per [12]. We show in Corollary 4.8 that, for two pairs of complementary vector fields, $Q^\ell_{\text{inv}} = 0$ for ℓ odd. We also remark that the eccentric character of the coefficients in the expressions for the permutation-invariant brackets is a consequence of our use of the Campbell–Baker–Hausdorff formula.

Remark 4.4. In a given example, one may have many more permutation-invariant vector fields than the Q^i_{inv}, which are invariant on essentially the free Lie algebra level.

4.3. Applications to local controllability. In this section we summarize the above developments as they apply to conditions for local controllability. The following result relates the permutation-dependent constructions to the more general constructions of section 3.2.

THEOREM 4.5. *Suppose that* $\{X^i, Y^i\} \subset S$ *for* $i = 1, \dots, k$, $\boldsymbol{s} \in \mathbb{N}^k$, *and* $Q^0_{\text{inv}}(p) = Q^1_{\text{inv}}(p) = \cdots = Q^{m_\ell(\boldsymbol{s})}_{\text{inv}}(p) = 0$. *Then*

1. $Q^{m_\ell(\boldsymbol{s})+1}_\pi \in S^{m_\ell(\boldsymbol{s})+1}_p$ *for all* $\pi \in P^\ell_k$ *and*
2. $Q^{m_\ell(\boldsymbol{s})+1}_{\text{inv}} \in S^{m_\ell(\boldsymbol{s})+1}_p$.

The next three corollaries specialize the theorem to interesting cases. The first deals with the case when all time rescalings are equal to 1. In practice, this will often be the case, but in Remark 4.10 we provide a situation where it is beneficial to allow the more general class of rescalings.

COROLLARY 4.6. *Suppose that* $\{X^i, Y^i\} \subset S$ *for* $i = 1, \dots, k$ *and* $\boldsymbol{s} = (1, \dots, 1)$. *Then*

1. *if* $Q^0_{\text{inv}}(p) = Q^1_{\text{inv}}(p) = \cdots = Q^\ell_{\text{inv}}(p) = 0$, *then* $Q^{\ell+1}_\pi \in S^{\ell+1}_p$ *for all* $\pi \in P^\ell_k$ *and*
2. *if* $\{X^i, Y^i\}$ *are complementary at* p *for* $i = 1, \dots, k$, *then*
   (a) $\pm\text{ad}_{X^i} Y^i \in S^1_p$,
   (b) $2\text{ad}^2_{X^i} Y^i - \text{ad}^2_{Y^i} X^i \in S^2_p$ *and* $\text{ad}^2_{X^i} Y^i \in S^2_p$, *and*
   (c) $\pm\text{ad}_{Y^i}\text{ad}^2_{X^i} Y^i \in S^3_p$ *if* $\sum_{i=1}^k (\text{ad}^2_{X^i} Y^i + \text{ad}^2_{Y^i} X^i)(p) = 0$.

Our next result specializes Theorem 4.5 to two pairs of vector fields.

COROLLARY 4.7. *Suppose that* $\{X^1, Y^1\}, \{X^2, Y^2\} \subset S$, $\boldsymbol{s} = (1,1)$, *and* $Q^0_{\text{inv}}(p) = Q^1_{\text{inv}}(p) = \cdots = Q^\ell_{\text{inv}}(p) = 0$. *Then*

1. $Q^{\ell+1}_{\text{inv}} \in S^{\ell+1}_p$ *and*
2. $-Q^{\ell+1}_{\text{inv}} \in S^{\ell+1}_p$ *and* $Q^{\ell+2}_{\text{inv}} \in S^{\ell+2}_p$ *if* ℓ *is even.*

Finally, we consider the case of a single pair of vector fields. In practice, this simple result is often the most useful, as we shall see in section 5.

COROLLARY 4.8. *Suppose* $\{X, Y\} \subset S$. *The following statements hold:*

1. *if* $\boldsymbol{s} = (1,1)$, *then for the pairs* $\{X^1, Y^1\} = \{X, Y\}$ *and* $\{X^2, Y^2\} = \{Y, X\}$ *we have* $Q^\ell_{\text{inv}} = 0$ *for* ℓ *odd;*
2. *if* $\boldsymbol{s} = (1)$, *then* $Q^\ell_{\text{inv}} = A^\ell(X, Y)$. *In particular,* $A^k(X, Y)(p) = 0$, $k \in \{0, 1, \ldots, \ell\}$, *implies* $A^{\ell+1}(X, Y) \in S^{\ell+1}_p$.

Remark 4.9. We can replace one or more of the pairs $\{X^i, Y^i\}$ in Theorem 4.5 with $\{Y^i, X^i\}$ to generate additional vector fields in $S^{\ell+1}_p$.

Remark 4.10. In Theorem 4.5 the vanishing of the vector fields Q^i_{inv} at p can be replaced by conditions for neutralization resembling those in the existing literature (e.g., [12, 2]). That is, we may ask not that $Q^0_{\text{inv}}(p) = \cdots = Q^\ell_{\text{inv}}(p) = 0$, but that $Q^0_{\text{inv}}(p) = \cdots = Q^{\ell-1}_{\text{inv}}(p) = 0$ and $0 \in \text{co}\{Q^0_{\text{inv}}(p), Q^1_{\text{inv}}(p), \ldots, Q^\ell_{\text{inv}}(p)\}$. More generally, suppose that for $i, j \in \mathbb{N}$ we denote

$$Q^i_{\text{inv}} = Q^i_{\text{inv}}(X^1, Y^1, \ldots, X^k, Y^k, \boldsymbol{s}), \quad \tilde{Q}^j_{\text{inv}} = \tilde{Q}^j_{\text{inv}}(\tilde{X}^1, \tilde{Y}^1, \ldots, \tilde{X}^{\tilde{k}}, \tilde{Y}^{\tilde{k}}, \tilde{\boldsymbol{s}}),$$

and that for a specific $\ell, m \in \mathbb{N}$ we have $Q^\ell_{\text{inv}}(p) + \tilde{Q}^m_{\text{inv}}(p) = 0$. Then we consider the augmented collection of pairs of vector fields

$$\{X^1, Y^1\}, \ldots, \{X^k, Y^k\}, \qquad \{\tilde{X}^1, \tilde{Y}^1\}, \ldots, \{\tilde{X}^{\tilde{k}}, \tilde{Y}^{\tilde{k}}\},$$

and choose $\hat{\boldsymbol{s}} = (ms_1, \ldots, ms_k, \ell\tilde{s}_1, \ldots, \ell\tilde{s}_{\tilde{k}})$. The resulting set of invariant vector fields $\hat{Q}^i_{\text{inv}}$ will have $\hat{Q}^{m\ell-1}_{\text{inv}}$, a positive multiple of $Q^\ell_{\text{inv}} + \tilde{Q}^m_{\text{inv}}$, and for $j < ml - 1$ the vector fields $\hat{Q}^j_{\text{inv}}$ will be linear combinations of $Q^0_{\text{inv}}, \ldots, Q^{\ell-1}_{\text{inv}}, \tilde{Q}^0_{\text{inv}}, \ldots, \tilde{Q}^{m-1}_{\text{inv}}$, and their Lie brackets. The notion of rescaling time to generate new higher-order S-trajectories is inherent in the definition of the sets S^k_p. In other words, if one generates "complementary" variations, they can be scaled to the same order, and then our methodology can be applied to the new variations. Examples 5.3 and 5.4 illustrate this point.

Remark 4.11. Stefani's example [9],

$$\begin{aligned} \dot{x} &= u, \\ \dot{y} &= x, \\ \dot{z} &= x^3 y \end{aligned}$$

in $\mathbb{R}^3$, fits the framework of Corollary 4.7. As noted in Sussmann's paper [12], the Lie brackets in $f = (0, x, x^3 y)$ and $g = (1, 0, 0)$ of degree 3, 4, and 5 vanish at $p = (0, 0, 0)$. Consider $\{X^1 = f+g, Y^1 = f-g\}, \{X^2 = f/2+2g, Y^2 = f/2-2g\} \subset S$ and $\boldsymbol{s} = (1,1)$. Corollary 4.6(2a) implies that $\pm[f, g] \in S^1_p$, while $f \pm g \in S = \text{co}\{f + g, f - g\}$. Thus we can find control variations in the directions $(\pm 1, 0, 0), (0, \pm 1, 0)$. To generate the control variations in the directions $(0, 0 \pm 1)$ we use Corollary 4.6(1). Note that $P^0_2 = \{\pi_1, \pi_2\}$, where $\pi_1(1) = 1, \pi_1(2) = 2$ and $\pi_2(1) = 2, \pi_2(2) = 1$, so that

$$\mathcal{X}^{\pi_1}_t(p) = X^1_t \circ Y^1_t \circ X^2_t \circ Y^2_t(p) = (Q^0_{\text{inv}} + Q^1_{\pi_1} t + Q^2_{\pi_1} t^2 + \cdots)_t(p).$$

However, $Q^0_{\rm inv} = 3f$, which vanishes at p, and Corollary 4.6(1) imply that $Q^1_{\pi_1} \in S^1_p$. However, $Q^1_{\pi_1} = 0$; hence $Q^2_{\pi_1} \in S^2_p$ as a consequence of Proposition 3.6(2). Similarly $Q^2_{\pi_1}, Q^3_{\pi_1}, Q^4_{\pi_1}$ vanish at p, as they consist of linear combinations of Lie brackets in f and g of degree 3, 4, and 5; hence $Q^5_{\pi_1} \in S^5_p$. Likewise $Q^5_{\pi_2} \in S^5_p$. Since $Q^5_{\pi_1}(p) = (0, 0, 21/18)$ and $Q^5_{\pi_2}(p) = (0, 0, -21/18)$, Theorem 3.7 implies local controllability.

Proof (proof of Theorem 4.5). Choose $\pi_j \in P^\ell_k$. Then Proposition 4.2 asserts that there exists an S-trajectory

$$\mathcal{X}^\pi_t(p) = \big(\alpha^j_0 Q^0_{\rm inv} + \cdots + \alpha^j_{m_\ell(\boldsymbol{s})} Q^{m_\ell(\boldsymbol{s})}_{\rm inv} t^{m_\ell(\boldsymbol{s})} + Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j} t^{m_\ell(\boldsymbol{s})+1} + \cdots\big)_t(p).$$

Since $Q^i_{\rm inv}(p)$ vanishes for $0 \le i \le m_\ell(\boldsymbol{s})$, it follows that $Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j} \in S^a_p$ for some $a \in \mathbb{N}$. Here $Q^{m_{\ell+1}(\boldsymbol{s})}_{\pi_j}$ is the coefficient Q_{π_j} of the lowest power of t with the property that Q_{π_j} could vary with $\pi_j \in P^\ell_k$. To determine a we note that, in light of Proposition 3.6(3), $X \in S^a_p$ implies X is a linear combination of brackets of vector fields in S of degrees up to and including $a+1$. To determine the bracket of highest degree in $Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j}$ we can, without loss of generality, assume that $\min\{s_1, \ldots, s_k\} = 1$ and take $s_1 = 1$. (If this is not the case, we can replace s_i with $s_i - (\min\{s_1, \ldots, s_k\} - 1)$ without changing the vector fields Q^j_π.) Then

$$\begin{aligned} Y^1_t \circ X^1_t(p) = \big(&A^0(X^1, Y^1) + A^1(X^1, Y^1)t + A^2(X^1, Y^1)t^2 \\ &+ A^3(X^1, Y^1)t^3 + \cdots\big)_t(p), \end{aligned}$$

which has the consequence that $Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j}$ is a linear combination of brackets of vector fields in S of degrees up to and including $m_\ell(\boldsymbol{s}) + 2$. Thus $a = m_\ell(\boldsymbol{s}) + 1$. Finally, if $P^{\ell+1}_k = \{\pi_1, \ldots, \pi_{\Gamma(k,\ell)}\}$, then we form the S-trajectory

$$\mathcal{X}^\pi_t(p) = \left(\alpha_0 Q^0_{\rm inv} + \cdots + \alpha_{m_\ell(\boldsymbol{s})} Q^{m_\ell(\boldsymbol{s})}_{\rm inv} t^{m_\ell(\boldsymbol{s})} + \sum_{j=1}^{\Gamma(k,\ell)} Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j} t^{m_\ell(\boldsymbol{s})+1} + \cdots\right)_t(p),$$

where $\alpha_i > 0$. Since

$$Q^{m_\ell(\boldsymbol{s})+1}_{\rm inv} = \sum_{j=1}^{\Gamma(k,\ell)} Q^{m_\ell(\boldsymbol{s})+1}_{\pi_j},$$

it follows that $Q^{m_\ell(\boldsymbol{s})+1}_{\rm inv} \in S^{\ell+1}_p$. □

Before proving the corollaries to Theorem 4.5, we establish some technical lemmas.

LEMMA 4.12. *Suppose that P, Q are vector fields on $\Omega \subset \mathbb{R}^n$. Then, for t sufficiently small, the integral curve $Q_t \circ P_t(p) = (\sum_{\ell=0}^\infty M^\ell(P, Q))_t(p)$ for vector fields $M^\ell(P, Q)$ with the following properties:*

1. *$M^\ell(P, Q) = (-1)^\ell M^\ell(Q, P)$;*
2. *if $P_t = \sum_{i=0}^\infty A^i_1 t^i$ and $Q_t = \sum_{i=0}^\infty A^i_2 t^i$, then $M^\ell(P, Q)$ has a power series expansion in t whose coefficients are Lie brackets of the vector fields A^i_j of degree $\ell + 1$.*

Proof. The existence of the vector fields $M^\ell(Q, P)$ follows from the Campbell–Baker–Hausdorff formula, and we have $M^0(P, Q) = P + Q = M^0(Q, P)$ and $M^1(P, Q) = \frac{1}{2}\mathrm{ad}_P Q = -\frac{1}{2}\mathrm{ad}_Q P = -M^1(Q, P)$. Thus $P + Q$ is a linear combination of the vector fields A^i_j, which we call Lie brackets of degree 1, while $M^1(P, Q)$ is a linear combination of the vector fields of the form $[A^i_1, A^j_2]$, which are Lie brackets of degree

2. Thus 1 and 2 hold for $\ell = 0, 1$. We now establish 4.12. Set $M^k = M^k(P,Q)$ and $\bar{M}^k = M^k(Q,P)$. Suppose that $M^j = (-1)^j \bar{M}^j$ for $j < \ell$. For $j = \ell$ the Campbell–Baker–Hausdorff formula [13] asserts that

$$(\ell+1)M^\ell = \frac{1}{2}[P-Q, M^{\ell-1}] + \sum_{\substack{p\geq 1\\ 2p\leq \ell}} K_{2p} V_p(P,Q)$$

with

$$V_p(P,Q) = \sum_{\substack{k_1,\dots,k_{2p}>0\\ k_1+\cdots+k_{2p}=\ell}} [M^{k_1-1}, [M^{k_2-1}, \dots, [M^{k_{2p}-1}, P+Q]\dots]].$$

Hence

$$(\ell+1)\bar{M}^\ell = \frac{1}{2}[Q-P, \bar{M}^{\ell-1}] + \sum_{\substack{p\geq 1\\ 2p\leq \ell}} K_{2p} \bar{V}_p(P,Q)$$

with

$$\bar{V}_p(P,Q) = \sum_{\substack{k_1,\dots,k_{2p}>0\\ k_1+\cdots+k_{2p}=\ell}} [\bar{M}^{k_1-1}, [\bar{M}^{k_2-1}, \dots, [\bar{M}^{k_{2p}-1}, P+Q]\cdots]].$$

By our induction hypothesis we know that $M^j = (-1)^j \bar{M}^j$ for $j < \ell$; thus $\frac{1}{2}[Q-P, \bar{M}^{\ell-1}] = (-1)^\ell \frac{1}{2}[P-Q, M^{\ell-1}]$ and

$$\begin{aligned}
\bar{V}_p(P,Q) &= \sum_{\substack{k_1,\dots,k_{2p}>0\\ k_1+\cdots+k_{2p}=\ell}} [(-1)^{k_1-1} M^{k_1-1}, [\cdots, [(-1)^{k_{2p}-1} M^{k_{2p}-1}, P+Q]\dots]] \\
&= \sum_{\substack{k_1,\dots,k_{2p}>0\\ k_1+\cdots+k_{2p}=\ell}} (-1)^{k_1+\cdots+k_{2p}-2p} [M^{k_1-1}, [\cdots, [M^{k_{2p}-1}, P+Q]\dots]] \\
&= (-1)^\ell V_p(P,Q)
\end{aligned}$$

since $(-1)^{k_1+\cdots+k_{2p}-2p} = (-1)^\ell (-1)^{2p} = (-1)^\ell$. This implies that $M^\ell(P,Q) = (-1)^\ell M^\ell(Q,P)$.

To establish point 2 we note that it holds for $\ell = 0, 1$. Suppose that assertion 2 holds for $j < \ell$. Thus $M^{\ell-1}(P,Q)$ has a power series expansion in t whose coefficients are Lie brackets of the vector fields A^i_j of degree ℓ. Now $P-Q$ has a power series expansion in t whose coefficients are Lie brackets of the vector fields A^i_j of degree 1; hence, in the above formula for $M^\ell(P,Q)$, the term $[P-Q, M^{\ell-1}]$ is a combination of Lie brackets of the vector fields A^i_j of degree $\ell+1$. The remaining terms in $M^\ell(P,Q)$ involve the vector fields $V_p(P,Q)$. By our induction hypothesis the vector fields M^{k_i-1} in $V_p(P,Q)$ involve Lie brackets of the vector fields A^i_j of degree k_i. Since $P+Q$ involve Lie brackets of the vector fields A^i_j of degree 1, it follows that $[M^{k_1-1}, [M^{k_2-1}, \dots, [M^{k_{2p}-1}, P+Q]\dots]]$ has a power series expansion in t whose coefficients are Lie brackets of the vector fields A^i_j of degree $k_1+\cdots+k_{2p}+1 = \ell+1$. This completes the induction. □

LEMMA 4.13. *Suppose that* $\{X^1, Y^1\}, \{X^2, Y^2\} \subset S$ *and* $\boldsymbol{s} = (1,1)$. *Then* Q^ℓ_{inv} *is a linear combination of Lie brackets of odd degree of the vector fields* $A^i_j = A^i(X^j, Y^j)$ *for all* $\ell \geq 0$.

In particular, $Q^\ell_{\text{inv}}(X^1,Y^1,X^2,Y^2,\boldsymbol{s}) = (-1)^\ell Q^\ell_{\text{inv}}(Y^1,X^1,Y^2,X^2,\boldsymbol{s})$.

Proof. We begin by examining the S-trajectories which correspond to permutation in P_2^0. By definition, $P_2^0 = \{\pi_1,\pi_2\}$, where $\pi_1(1) = 1, \pi_1(2) = 2$ and $\pi_2(1) = 2, \pi_2(2) = 1$. Then

$$\mathcal{X}_t^{\pi_1}(p) = X_t^1 \circ Y_t^1 \circ X_t^2 \circ Y_t^2(p) = \left(\sum_{i=0}^\infty A_1^i t^i\right)_t \circ \left(\sum_{i=0}^\infty A_2^i t^i\right)_t (p),$$

where $A_1^i = A^i(X^1,Y^1)$ and $A_2^i = A^i(X^2,Y^2)$. Set $P = \sum_{i=0}^\infty A_1^i t^i, Q = \sum_{i=0}^\infty A_2^i t^i$ so P and Q are power series in t whose coefficients are Lie brackets of the vector fields A_j^i of degree 1 (odd). Thus $\mathcal{X}_t^{\pi_1}(p) = P_t \circ Q_t(p)$ and, in light of Lemma 4.12, there exist vector fields $M^i(P,Q)$ such that $\mathcal{X}_t^{\pi_1}(p) = (\sum_{i=0}^\infty M^i(P,Q))_t(p)$. Since $\mathcal{X}_t^{\pi_2}(p) = Q_t \circ P_t(p)$, we have

$$\mathcal{X}_t^{\pi_2}(p) = \left(\sum_{i=0}^\infty M^i(Q,P)\right)_t (p) = \left(\sum_{i=0}^\infty (-1)^i M^i(P,Q)\right)_t (p),$$

where $M^\ell(P,Q)$ is a power series in t whose coefficients are Lie brackets of the vector fields A_j^i of degree $\ell+1$. We let $M^{\text{odd}}(P,Q) = \sum_{i=0}^\infty M^{2i}(P,Q)$ and $M^{\text{even}}(P,Q) = \sum_{i=0}^\infty M^{2i+1}(P,Q)$ so that $M^{\text{odd}}(P,Q)$ ($M^{\text{even}}(P,Q)$) is a power series in t whose coefficients are Lie brackets of the vector fields A_j^i of odd (even) degree. Furthermore $M^{\text{odd}}(P,Q) = M^{\text{odd}}(Q,P)$, while $M^{\text{even}}(P,Q) = -M^{\text{even}}(Q,P)$. We now explore the same issues for $P_2^1 = \{\hat\pi_1,\hat\pi_2\}$, where $\hat\pi_1 = (\pi_1,\pi_2)$ and $\hat\pi_2 = (\pi_2,\pi_1)$ for the permutations $\pi_1,\pi_2 \in P_2^0$ defined above. Setting $\hat P = \sum_{i=0}^\infty M^i(P,Q)$ and $\hat Q = \sum_{i=0}^\infty M^i(Q,P)$, we have, as above,

$$\mathcal{X}_t^{\hat\pi_1}(p) = \mathcal{X}_t^{\pi_1} \circ \mathcal{X}_t^{\pi_2}(p) = \hat P_t \circ \hat Q_t(p).$$

From Lemma 4.12 there now exist vector fields $\hat M^\ell(\hat P,\hat Q)$ such that $\hat M^\ell(\hat Q,\hat P) = (-1)^\ell \hat M^\ell(\hat P,\hat Q)$; hence

$$\mathcal{X}_t^{\hat\pi_1}(p) = \left(\sum_{\ell=0}^\infty \hat M^\ell(\hat P,\hat Q)\right)_t (p), \quad \mathcal{X}_t^{\hat\pi_2}(p) = \left(\sum_{\ell=0}^\infty (-1)^\ell \hat M^\ell(\hat P,\hat Q)\right)_t (p). \tag{4.5}$$

We now establish that the vector fields $\hat M^\ell(\hat P,\hat Q)$ are power series in t whose coefficients are Lie brackets of the vector fields A_j^i of odd degree. We showed above that we have $\hat P = \sum_{i=0}^\infty M^i(P,Q) = M^{\text{odd}}(P,Q) + M^{\text{even}}(P,Q)$, while $\hat Q = \sum_{i=0}^\infty M^i(Q,P) = M^{\text{odd}}(P,Q) - M^{\text{even}}(P,Q)$. From the Campbell–Baker–Hausdorff formula we know that $\hat M^0 = \hat P + \hat Q = 2M^{\text{odd}}(P,Q)$, a power series in t whose coefficients are Lie brackets of the vector fields A_j^i of odd degree. Also

$$\hat M^1 = \frac{1}{2}[\hat P,\hat Q] = [M^{\text{even}}(P,Q), M^{\text{odd}}(P,Q)].$$

Since $M^{\text{even}}(P,Q)$ is composed of Lie brackets of A_j^i of even degree and $M^{\text{odd}}(P,Q)$ is composed of Lie brackets of A_j^i of odd degree, it follows that $\hat M^1$ is composed of Lie brackets of A_j^i of odd degree. Now suppose that this holds for $\hat M^2, \hat M^3, \dots, \hat M^{\ell-1}$. From the Campbell–Baker–Hausdorff formula,

$$(\ell+1)\hat M^\ell = \frac{1}{2}[2M^{\text{even}}(P,Q), M^{\ell-1}] + \sum_{\substack{p\ge 1\\ 2p\le \ell}} K_{2p} V_p(P,Q)$$

with

$$V_p(P,Q) = \sum_{\substack{k_1,\dots,k_{2p}>0 \\ k_1+\cdots+k_{2p}=\ell}} [\hat{M}^{k_1-1},[\hat{M}^{k_2-1},\dots,[\hat{M}^{k_{2p}-1},2M^{\mathrm{odd}}(P,Q)]\cdots]].$$

By our induction hypothesis and the fact that $M^{\mathrm{even}}(P,Q)$ is composed of Lie brackets of A_j^i of even degree, we see that $[2M^{\mathrm{even}}(P,Q),M^{\ell-1}]$ is composed of Lie brackets of A_j^i of odd degree. Looking at the terms in $V_p(P,Q)$, we note that

$$[\hat{M}^{k_1-1},\dots,[\hat{M}^{k_{2p}-1},2M^{\mathrm{odd}}(P,Q)]\cdots]$$

has an even number of terms M^{k_i-1}, and $M^{\mathrm{odd}}(P,Q)$ is composed of Lie brackets of A_j^i of odd degree; it follows that $\hat{M}^\ell$ is composed of Lie brackets of A_j^i of odd degree. We can now repeat the initial argument to show that if $P_2^2=\{\pi_1,\pi_2\}$, then there exist vector fields $M^{\mathrm{even}}(P,Q)$ composed of Lie brackets of A_j^i of even degree and $M^{\mathrm{odd}}(P,Q)$ composed of Lie brackets of A_j^i of odd degree such that

$$\mathcal{X}_t^{\pi_1}(p) = \left(\sum_{i=0}^{\infty} M^i(P,Q)\right)_t(p) = (M^{\mathrm{odd}}(P,Q)+M^{\mathrm{even}}(P,Q))_t(p)$$

and

$$\begin{aligned}\mathcal{X}_t^{\pi_2}(p) &= \left(\sum_{i=0}^{\infty} M^i(Q,P)\right)_t(p) = \left(\sum_{i=0}^{\infty}(-1)^i M^i(P,Q)\right)_t(p)\\ &= (M^{\mathrm{odd}}(P,Q)-M^{\mathrm{even}}(P,Q))_t(p).\end{aligned}$$

We simply repeat the above steps for $P_2^3,P_2^4,\dots$ to conclude that the vector fields $\hat{M}^\ell(\hat{P},\hat{Q})$ are power series in t whose coefficients are Lie brackets of the vector fields A_j^i of odd degree.

We now are in a position to verify that Q_{inv}^ℓ is a linear combination of Lie brackets of the vector fields A_j^i of odd degree. We begin by choosing any $\pi\in P_2^k$. Then we know from above that the corresponding S-trajectory $\mathcal{X}_t^\pi(p) = (M^{\mathrm{odd}}(P,Q)+M^{\mathrm{even}}(P,Q))_t(p)$, where $M^{\mathrm{even}}(P,Q)$ is composed of Lie brackets of A_j^i of even degree and $M^{\mathrm{odd}}(P,Q)$ is composed of Lie brackets of A_j^i of odd degree. In the case where k is odd we showed that $M^{\mathrm{even}}(P,Q)=0$. Suppose $k=1$. Then $\mathcal{X}_t^\pi(p) = (M^{\mathrm{odd}}(P,Q))_t(p)$, where $M^{\mathrm{odd}}(P,Q)$ is a power series in t whose coefficients are Lie brackets of the vector fields A_j^i of odd degree. Thus there exist vector fields $Q_{0,1}^{\mathrm{odd}},Q_{1,1}^{\mathrm{odd}},\dots$, which are linear combinations of Lie brackets of the vector fields A_j^i of odd degree, such that

$$\mathcal{X}_t^\pi(p) = (Q_{0,1}^{\mathrm{odd}}+Q_{1,1}^{\mathrm{odd}}t+Q_{2,1}^{\mathrm{odd}}t^2+\cdots)_t(p).$$

However, from Proposition 4.2 we have

$$\mathcal{X}_t^\pi(p)F = (\alpha_0 Q_{\mathrm{inv}}^0+\alpha_1 Q_{\mathrm{inv}}^1 t+Q_\pi^2 t^2+\cdots)_t(p).$$

This means that $\alpha_0 Q_{\mathrm{inv}}^0 = Q_{0,1}^{\mathrm{odd}},\alpha_1$, $Q_{\mathrm{inv}}^1 = Q_{1,1}^{\mathrm{odd}}$, and Q_π^2 are linear combinations of Lie brackets of the vector fields A_j^i of odd degree. Next we consider the case where $\pi\in P_2^2=\{\pi_1,\pi_2\}$. Then

$$\mathcal{X}_t^{\pi_1}(p) = (M^{\mathrm{odd}}(P,Q)+M^{\mathrm{even}}(P,Q))_t(p),$$

where $M^{\text{odd}}(P,Q)$ (resp., $M^{\text{even}}(P,Q)$) is a power series in t whose coefficients are Lie brackets of the vector fields A^i_j of odd (resp., even) degree. Thus there exist vector fields $Q^{\text{odd}}_{0,1}, Q^{\text{odd}}_{1,1}, \dots$, and $Q^{\text{even}}_{0,1}, Q^{\text{even}}_{1,1}, \dots$, which are linear combinations of Lie brackets of the vector fields A^i_j of odd and even degrees, respectively, such that

$$\mathcal{X}^{\pi_1}_t(p) = ((Q^{\text{odd}}_{0,1} + Q^{\text{even}}_{0,1}) + (Q^{\text{odd}}_{1,1} + Q^{\text{even}}_{1,1})t + (Q^{\text{odd}}_{2,1} + Q^{\text{even}}_{2,1})t^2 + \cdots)_t(p).$$

However, from Proposition 4.2 we have

$$\mathcal{X}^{\pi_1}_t(p) = (\alpha_0 Q^0_{\text{inv}} + \alpha_1 Q^1_{\text{inv}} t + \alpha_2 Q^2_{\text{inv}} t^2 + Q^3_{\pi_1} t^3 + \cdots)_t(p).$$

Similarly, using the expansion for $\mathcal{X}^{\pi_2}_t(p)$ in (4.5),

$$\begin{aligned}\mathcal{X}^{\pi_2}_t(p) &= (\alpha_0 Q^0_{\text{inv}} + \alpha_1 Q^1_{\text{inv}} t + \alpha_2 Q^2_{\text{inv}} t^2 + Q^3_{\pi_2} t^3 + \cdots)_t(p)\\ &= ((Q^{\text{odd}}_{0,1} - Q^{\text{even}}_{0,1}) + (Q^{\text{odd}}_{1,1} - Q^{\text{even}}_{1,1})t + (Q^{\text{odd}}_{2,1} - Q^{\text{even}}_{2,1})t^2 + \cdots)_t(p).\end{aligned}$$

Since Q^ℓ_{inv} is invariant with respect to our choice of permutation in $P^{\ell+1}_2$, we can conclude that $Q^{\text{even}}_{0,1} = Q^{\text{even}}_{1,1} = Q^{\text{even}}_{2,1} = 0$. This in turn implies that Q^0_{inv}, Q^1_{inv}, and Q^2_{inv} are linear combinations of Lie brackets of the vector fields A^i_j of odd degree. It is straightforward to show by induction that this is the case for all Q^ℓ_{inv}.

Finally we show that

$$Q^\ell_{\text{inv}}(X^1, Y^1, X^2, Y^2) = (-1)^\ell Q^\ell_{\text{inv}}(Y^1, X^1, Y^2, X^2).$$

Using Lemma 4.12 with $P = X, Q = Y$, we conclude that $A^i(X,Y) = (-1)^i A^i(Y,X)$. The vector fields A^i_j enter into our S-trajectory in the power series $\sum_{i=0}^\infty A^i(X^j, Y^j)t^i$. Since Q^ℓ_{inv} is the coefficient of t^ℓ in a power series expansion of a similar S-trajectory, we can conclude that Q^ℓ_{inv} is a linear combination of iterated Lie brackets

$$B = [A^{i_1}_{j_1}, [A^{i_2}_{j_2}, \dots, [A^{i_{2k}}_{j_{2k}}, A^{i_{2k+1}}_{j_{2k+1}}] \dots]]$$

of an odd number of A^i_j's, where $j_m \in \{1,2\}$ and $i_1 + \cdots + i_{2k+1} = \ell - 2k$. In light of Lemma 4.12 with $Q = Y, P = X$, we know that if i_m is even, then $A^{i_m}_j(Y^j, X^j) = A^{i_m}_j(X^j, Y^j)$, and if i_m is odd, then $A^{i_m}_j(Y^j, X^j) = -A^{i_m}_j(X^j, Y^j)$ for $j \in \{1,2\}$. If ℓ is even, then there must be an even number of integers in $\{i_1, \dots, i_{2k+1}\}$ which are odd, and hence B does not change sign when X^i and Y^i are interchanged. This completes the proof. □

Proof of Corollary 4.6. Suppose that $\boldsymbol{s} = (1, \dots, 1)$. Then 4.6 follows from Theorem 4.5 and the observation that in the case $\boldsymbol{s} = (1, \dots, 1)$ we have $m_i(\boldsymbol{s}) = i$. Suppose that the subsets $\{X^i, Y^i\} \subset S$ are complementary at p for $i = 1, \dots, k$. From Remark 3.3 (or from the definition of $A^1(X^i, Y^i)$) we know that $\text{ad}_{X^i} Y^i \in S^1_p$. Also $\{X^i, Y^i\}$ complementary at p implies $\{Y^i, X^i\}$ complementary at p; hence $-\text{ad}_{X^i} Y^i \in S^1_p$. This gives part 2(a) of the corollary. To establish 2(b) we can use Lemma 4.13 with the choices $X^1 = X^i, Y^1 = Y^i, X^2 = Y^i, Y^2 = X^i$ to conclude $Q^1_{\text{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) = -Q^1_{\text{inv}}(X^2, Y^2, X^1, Y^1, \boldsymbol{s})$. Since Q^1_{inv} is invariant with respect to permutations of $\{1,2\}$, we conclude that $Q^1_{\text{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) = 0$. As a result of Theorem 4.5, we have $Q^2_\pi \in S^2_p$ for all $\pi \in P^1_2$. One can easily check from the definition that $Q^2_{\text{inv}} = (\text{ad}^2_{X^i} Y^i + \text{ad}^2_{Y^i} X^i)/6$, while $Q^2_\pi = 2\text{ad}^2_{X^i} Y^i - \text{ad}^2_{Y^i} X^i$ for all $\pi \in P^1_2$. Finally, if we reverse X^i and Y^i, we get $2\text{ad}^2_{Y^i} X^i - \text{ad}^2_{X^i} Y^i$, and $\text{co}\{2\text{ad}^2_{Y^i} X^i - \text{ad}^2_{X^i} Y^i, 2\text{ad}^2_{X^i} Y^i - \text{ad}^2_{Y^i} X^i\}$ contains a positive multiple of $\text{ad}^2_{X^i} Y^i$;

hence $\mathrm{ad}^2_{X^i}Y^i \in S^2_p$. To complete the proof we must show that 2(c) holds. Here we simply augment our set of complementary vector fields by adding in k additional pairs, namely those of the form (Y^i, X^i). Arguing as in the proof of 2(b) above, we find that $Q^1_{\mathrm{inv}} = 0$, $Q^2_{\mathrm{inv}} = \sum_{i=1}^k(\mathrm{ad}^2_{X^i}Y^i + \mathrm{ad}^2_{Y^i}X^i)$; hence $Q^2_{\mathrm{inv}}(p) = 0$ and $Q^3_{\mathrm{inv}} = \sum_{i=1}^k \mathrm{ad}_{Y^i}\mathrm{ad}^2_{X^i}Y^i$. Thus Theorem 4.5 implies $\sum_{i=1}^k \mathrm{ad}_{Y^i}\mathrm{ad}^2_{X^i}Y^i \in S^3_p$. Now we note that reversing X^i and Y^i in $\mathrm{ad}_{Y^i}\mathrm{ad}^2_{X^i}Y^i$ gives the negative of this vector field. In this way we can isolate each term in the above sum and conclude that $\pm\mathrm{ad}_{Y^i}\mathrm{ad}^2_{X^i}Y^i \in S^3_p$. □

Proof of Corollary 4.7. Suppose that $\{X^1, Y^1\}, \{X^2, Y^2\} \subset S$, $\boldsymbol{s} = (1, 1)$, and $Q^0_{\mathrm{inv}}(p) = Q^1_{\mathrm{inv}}(p) = \cdots = Q^\ell_{\mathrm{inv}}(p) = 0$. We begin by establishing assertion 4.7. We have $Q^{\ell+1}_\pi \in S^{\ell+1}_p$ by Corollary 4.6 for any $\pi \in P^\ell_2$. Since $Q^{\ell+1}_{\mathrm{inv}}$ is a linear combination of the vector fields $Q^{\ell+1}_\pi$ using positive coefficients, it follows that $Q^{\ell+1}_{\mathrm{inv}} \in S^{\ell+1}_p$. Alternatively, from Proposition 4.2, there is an S-trajectory of the form

$$\mathcal{X}_t(p) = \big(\alpha_0 Q^0_{\mathrm{inv}} + \cdots + \alpha_\ell Q^\ell_{\mathrm{inv}} t^\ell + \alpha_{\ell+1} Q^{\ell+1}_{\mathrm{inv}} t^{\ell+1} + Q^{\ell+2}_{\mathrm{inv}} t^{\ell+2} + \cdots\big)_t(p),$$

where $\alpha_i > 0$. Since $Q^0_{\mathrm{inv}}(p) = Q^1_{\mathrm{inv}}(p) = \cdots = Q^\ell_{\mathrm{inv}}(p) = 0$, we have $Q^{\ell+1}_{\mathrm{inv}} \in S^{\ell+1}_p$.

To establish 4.7 we note that

$$\begin{aligned} Q^{\ell+1}_{\mathrm{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) &= (-1)^{\ell+1} Q^{\ell+1}_{\mathrm{inv}}(Y^1, X^1, Y^2, X^2, \boldsymbol{s}) \\ &= -Q^{\ell+1}_{\mathrm{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) \end{aligned}$$

as a consequence of Lemma 4.13 and the assumption that $\ell + 1$ is odd. Similarly

$$Q^{\ell+2}_{\mathrm{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) = Q^{\ell+2}_{\mathrm{inv}}(Y^1, X^1, Y^2, X^2, \boldsymbol{s}).$$

Thus we can proceed as above using $\{Y^1, X^1\}, \{Y^2, X^2\} \subset S$, $\boldsymbol{s} = (1, 1)$ instead of $\{X^1, Y^1\}, \{X^2, Y^2\} \subset S$, to form an S-trajectory

$$\hat{\mathcal{X}}_t(p) = \big(\alpha_0 Q^0_{\mathrm{inv}} + \cdots + \alpha_\ell Q^\ell_{\mathrm{inv}} t^\ell - \alpha_{\ell+1} Q^{\ell+1}_{\mathrm{inv}} t^{\ell+1} + Q^{\ell+2}_{\mathrm{inv}} t^{\ell+2} + \cdots\big)_t(p),$$

and conclude that

$$-Q^{\ell+1}_{\mathrm{inv}} = -Q^{\ell+1}_{\mathrm{inv}}(X^1, Y^1, X^2, Y^2, \boldsymbol{s}) = Q^{\ell+1}_{\mathrm{inv}}(Y^1, X^1, Y^2, X^2, \boldsymbol{s}) \in S^{\ell+1}_p.$$

Finally, we form the S-trajectory

$$\hat{\mathcal{X}}_t \circ \mathcal{X}_{2t} \circ \hat{\mathcal{X}}_t(p) = \big(4\alpha_0 Q^0_{\mathrm{inv}} + \cdots + 4\alpha_\ell Q^\ell_{\mathrm{inv}} t^\ell + 4Q^{\ell+2}_{\mathrm{inv}} t^{\ell+2} + \cdots\big)_t(p)$$

and note that $Q^0_{\mathrm{inv}}(p) = Q^1_{\mathrm{inv}}(p) = \cdots = Q^\ell_{\mathrm{inv}}(p) = 0$ implies $Q^{\ell+2}_{\mathrm{inv}} \in S^{\ell+2}_p$. □

Proof of Corollary 4.8. The proof relies on Lemma 4.13 together with the fact that reversing the roles of $\{X^1, Y^1\}$ and $\{X^2, Y^2\}$ is, in this case, the same as interchanging X^i and Y^i. Thus permutation-invariance means that Q^ℓ_{inv} vanishes for ℓ odd, establishing 4.8. If $\boldsymbol{s} = (1)$, then P^ℓ_1 consists of the single permutation $1 \mapsto 1$, so $Q^\ell_{\mathrm{inv}} = A^\ell(X, Y)$. Then 4.8 follows from Corollary 4.6. □

5. Examples. In the examples, the sets S of vector fields are not convex. As noted in section 3.1, we can replace S by its convex hull without affecting local controllability. Certain of these examples may be treated using existing techniques in the literature. Therefore, such examples should be regarded as being illustrative of our theory, rather than as presenting new ideas. However, we might mention that we do not know of a theory that will cover Example 5.5.

Example 5.1. As in [10], we consider the system $S = \{X, Y, Z\}$ in the plane where, in local coordinates (x, y),

$$X = (1, 0), \quad Y = (-1, x^2), \quad Z = (0, -1).$$

Then

$$[X, Y] = (0, 2x), \quad [X, [X, Y]] = (0, 2),$$
$$[Y, [X, Y]] = (0, -2), \quad [Z, Y] = [Z, X] = (0, 0).$$

For $p = (0, 0)$ we have $L^0(S, p) = \mathbb{R} \times \{0\}$, and hence $Z_p^0 = \{X, Y\}$ and $S_p^1 = \{[X, Y], [Y, X]\}$. This implies that $S(p) = \{(1, 0), (-1, 0), (0, -1)\}$, $S_p^1(p) = \{(0, 0)\}$, and it follows that $L^1(S, p) = L^0(S, p)$ and $Z_p^1 = \{X, Y, [X, Y], [Y, X]\}$. Since $X(p) + Y(p) = (0, 0)$ the subset $\{X, Y\} \subset S$ is complementary at p. From Corollary 4.6(2b) we have $\mathrm{ad}_X^2 Y = (0, 2) \in S_p^2$. Thus

$$\mathrm{co}(\{(1, 0), (-1, 0), (0, -1), (0, 2)\}) \subset \mathrm{co}(S(p) \cup S_p^1(p) \cup S_p^2(p))$$

and $0 \in \mathrm{int}(\mathrm{co}(S(p) \cup S_p^1(p) \cup S_p^2(p)))$. Local controllability at p then follows from Theorem 3.7.

Example 5.2. Consider the affine system

$$\begin{aligned} \dot{x} &= u_1, \\ \dot{y} &= u_2, \\ \dot{z} &= x^2 - y^4, \end{aligned} \tag{5.1}$$

with $|u_a| \leq 1$ for $a = 1, 2$ and $p = (x(0), y(0), z(0)) = (0, 0, 0)$. Here the system model is of the form

$$\dot{x}(t) = f_0(x(t)) + u_1(t) f_1(x(t)) + u_2(t) f_2(x(t)),$$

where f_0, f_1, f_2 are smooth vector fields on $\mathbb{R}^3$ which, in local coordinates, are defined by $f_0 = (0, 0, x^2 - y^4)$, $f_1 = (1, 0, 0)$, and $f_2 = (0, 1, 0)$. The nonzero Lie brackets are

$$\begin{aligned} &\mathrm{ad}_{f_1} f_0 = (0, 0, 2x), && \mathrm{ad}_{f_1}^2 f_0 = (0, 0, 2), \\ &\mathrm{ad}_{f_2} f_0 = (0, 0, -4y^3), && \mathrm{ad}_{f_2}^2 f_0 = (0, 0, -12y^2), \\ &\mathrm{ad}_{f_2}^3 f_0 = (0, 0, -24y), && \mathrm{ad}_{f_2}^4 f_0 = (0, 0, -24), \end{aligned}$$

while $\mathrm{ad}_{f_1}^3 f_0 = \mathrm{ad}_{f_0}^k \mathrm{ad}_{f_1}^j f_0 = (0, 0, 0)$ for $j, k \geq 1$ and $\mathrm{ad}_{f_2}^5 f_0 = \mathrm{ad}_{f_0}^k \mathrm{ad}_{f_2}^j f_0 = (0, 0, 0)$ for $j, k \geq 1$. The tangent space to $\mathbb{R}^3$ at p is spanned by $f_1(p)$, $f_2(p)$, and $[f_1, [f_1, f_0]](p)$; hence the first-order sufficient condition Theorem 2.1 cannot be employed. The generalization of Hermes' condition, Theorem 7.3 of [12], does not apply because the "bad" bracket $\mathrm{ad}_{f_1}^2 f_0$ is not expressible in terms of "good" and "bad" brackets of the required orders. On the other hand, the drift vector field f_0 vanishes at p, so that $\{X^1, Y^1\} = \{f_0 + f_1, f_0 - f_1\}$ is complementary at p, as is $\{X^2, Y^2\} = \{f_0 + f_2, f_0 - f_2\}$. In light of (4.1), we have $A^0(X^1, Y^1)(p) = A^1(X^1, Y^1)(p) = (0, 0, 0)$, while $A^2(X^1, Y^1)(p)$ is a positive multiple of $(0, 0, 1)$. Corollary 4.8 lets us conclude that $(0, 0, 1) \in S_p^2(p)$. Similarly $A^i(X^2, Y^2)(p) = (0, 0, 0)$ for $i = 0, 1, 2, 3$, and $A^4(X^2, Y^2)(p)$ is a positive multiple of $(0, 0, -1)$, so that $(0, 0, -1) \in S_p^4(p)$, as a consequence of Corollary 4.8. Finally, we note that $f_0(p) \pm f_1(p) = (\pm 1, 0, 0) \in S(p)$ and

$f_0(p) \pm f_2(p) = (0, \pm 1, 0) \in S(p)$; hence $0 \in \operatorname{int}(\operatorname{co}(S(p) \cup S_p^1(p) \cup \cdots \cup S_p^4(p)))$. Thus system (5.1) is l.c. as a consequence of Theorem 3.7.

The next example illustrates the weakening of the hypotheses of Theorem 4.5 described in Remark 4.10.

Example 5.3. Consider the system $S = \{W, X, Y\}$ in $\mathbb{R}^3$ where, in local coordinates (x, y, z),

$$W = (0, 0, -1), \quad X = (1, z, 0), \quad Y = (-1, 0, x^2).$$

Then

$$[X, Y] = (0, -x^2, 2x), \quad [X, [X, Y]] = (0, -4x, 2),$$
$$[Y, [Y, X]] = (0, -2x, 2), \quad [Y, [X, [X, Y]]] = (0, 4, 4x).$$

We take $p = (0, 0, 0)$. Since $(X + Y)(p) = 0$, we have $\{X, Y\}$ complementary at p. In light of (4.1) and Corollary 4.8, Q^i_{inv} is a positive multiple of $A^i(X, Y)$, and we have the S-trajectory

$$\begin{aligned} X_t \circ Y_t(p) &= \left(A^0(X,Y) + A^1(X,Y)t + A^2(X,Y)t^2 + A^3(X,Y)t^3 + \cdots\right)_t(p) \\ &= \left((X+Y) + \frac{1}{2}\operatorname{ad}_X Y t + \frac{1}{12}(\operatorname{ad}_Y^2 X + \operatorname{ad}_X^2 Y)t^2 \right. \\ &\qquad \left. -\frac{1}{24}\operatorname{ad}_Y \operatorname{ad}_X^2 Y t^3 + \cdots\right)_t (p). \end{aligned}$$

Here $A^0(X, Y)(p) = (X + Y)(p) = 0$ and $A^1(X, Y)(p) = \frac{1}{2}\operatorname{ad}_X Y(p) = 0$. Thus $A^2(X, Y) = \frac{1}{12}(\operatorname{ad}_Y^2 X + \operatorname{ad}_X^2 Y) \in S_p^2$ by Corollary 4.8. We note that

$$W \in S, \quad A^2 = \frac{1}{12}(\operatorname{ad}_Y^2 X + \operatorname{ad}_X^2 Y) \in S_p^2, \quad \left(\frac{1}{3}W + A^2\right)(p) = (0, 0, 0),$$

where $A^i = A^i(X, Y)$. As in Remark 4.10, we consider the pairs $\{\frac{1}{6}W, \frac{1}{6}W\}, \{X, Y\} \subset \operatorname{co}(S)$ and take $\boldsymbol{s} = (3, 1)$. Here $k = 2$, and thus $P_2^0 = \{\pi_1, \pi_2\}$, where $\pi_1(1) = 1, \pi_1(2) = 2, \pi_2(1) = 2, \pi_2(2) = 1$. The S-trajectories (4.2) corresponding to π_1, π_2 are

$$\begin{aligned} \mathcal{X}_t^{\pi_1}(p) &= \left(\frac{1}{6}W\right)_{t^3} \circ \left(\frac{1}{6}W\right)_{t^3} \circ X_t \circ Y_t(p) \\ &= \left(\frac{1}{3}W\right)_{t^3} \circ (A^0 + A^1 t + A^2 t^2 + \cdots)_t(p) \\ &= \left(A^0 + A^1 t + \left(A^2 + \frac{1}{3}W\right)t^2 + \left(A^3 - \frac{1}{6}[A^0, W]\right)t^3 + \cdots\right)_t (p) \\ &= (Q^0_{\pi_1} + Q^1_{\pi_1} t + Q^2_{\pi_1} t^2 + \cdots)_t(p) \end{aligned}$$

and

$$\begin{aligned} \mathcal{X}_t^{\pi_2}(p) &= \left(A^0 + A^1 t + \left(A^2 + \frac{1}{3}W\right)t^2 + \left(A^3 + \frac{1}{6}[A^0, W]\right)t^3 + \cdots\right)_t (p) \\ &= (Q^0_{\pi_2} + Q^1_{\pi_2} t + Q^2_{\pi_2} t^2 + \cdots)_t(p). \end{aligned}$$

Here $m(\boldsymbol{s}) = 1, m_0(\boldsymbol{s}) = 2, m_1(\boldsymbol{s}) = 3, m_2(\boldsymbol{s}) = 4$ and Lemma 4.1 implies that $Q^0_\pi, Q^1_\pi, Q^2_\pi$ are constant functions of $\pi \in P_2^0$, which is shown explicitly above. From

our definition it follows that $Q^0_{\rm inv} = A^0$, $Q^1_{\rm inv} = A^1$, and $Q^2_{\rm inv} = A^2 + \frac{1}{3}W$. Similarly if $\pi = (\pi_1, \pi_2) \in P^1_2$, we have

$$\begin{aligned}\mathcal{X}^\pi_t(p) &= \mathcal{X}^{\pi_1}_t \circ \mathcal{X}^{\pi_2}_t(p)\\ &= \left(2A^0 + 2A^1 t + 2\left(A^2 + \frac{1}{3}W\right)t^2 + 2A^3t^3 + \cdots\right)_t(p);\end{aligned}$$

hence $Q^3_{\rm inv} = 2A^3 = -\frac{1}{12}{\rm ad}_Y{\rm ad}^2_X Y$. Since $Q^0_{\rm inv}$, $Q^1_{\rm inv}$, and $Q^2_{\rm inv}$ each vanish at p, Theorem 4.5 implies that

$$Q^3_{\rm inv} = -\frac{1}{12}{\rm ad}_Y{\rm ad}^2_X Y = \left(0, -\frac{1}{3}, -\frac{1}{3}x\right) \in S^3_p.$$

Interchanging X and Y and repeating the previous steps, we can conclude that $-\frac{1}{12}{\rm ad}_X{\rm ad}^2_Y X = (0, \frac{1}{3}, \frac{1}{3}x) \in S^3_p$. In summary, $S(p)$ contains the vectors

$$W(p) = (0, 0, -1), \quad X(p) = (1, 0, 0), \quad Y(p) = (-1, 0, 0);$$

$S^2_p(p)$ contains the vector $\frac{1}{12}({\rm ad}^2_Y X + {\rm ad}^2_X Y)(p) = (0, 0, \frac{1}{3})$; and $S^3_p(p)$ contains the vectors

$$-\frac{1}{12}{\rm ad}_Y{\rm ad}^2_X Y(p) = \left(0, -\frac{1}{3}, 0\right), \quad -\frac{1}{12}{\rm ad}_X{\rm ad}^2_Y X(p) = \left(0, \frac{1}{3}, 0\right).$$

Thus

$$\begin{aligned}{\rm co}\left(\left\{(\pm 1, 0, 0), \left(0, \pm\frac{1}{3}, 0\right), \left(0, 0, \frac{1}{3}\right), (0, 0, -1)\right\}\right) \subset {\rm co}(S(p) \cup S^1_p(p)\\ \cup S^2_p(p) \cup S^3_p(p))\end{aligned}$$

and $0 \in {\rm int}({\rm co}(S(p) \cup S^1_p(p) \cup S^2_p(p) \cup S^3_p(p)))$. Local controllability at p follows from Theorem 3.7. This example illustrates the use of time rescaling to generate new higher-order S-trajectories (see Remark 4.10).

Example 5.4. Here is a control affine system which has a "bad" bracket that can be neutralized as in [2]:

$$\begin{aligned}\dot{x} &= yz + u_1,\\ \dot{y} &= -xz + u_2,\\ \dot{z} &= -u_2,\end{aligned}$$

with $|u_i| \le 1$, $i = 1, 2$, and $p = (0, 0, 0)$. Here $f = (yz, -xz, 0)$, $g_1 = (1, 0, 0)$, $g_2 = (0, 1, -1)$, and the brackets are

$$\begin{gathered}[f, g_1] = (0, z, 0), \quad [f, g_2] = (y - z, -x, 0),\\ [g_1, [f, g_1]] = (0, 0, 0), \quad [g_2, [f, g_2]] = (2, 0, 0), \quad [g_1, [f, g_2]] = (0, -1, 0).\end{gathered}$$

Motivated by Remark 4.10, we will show that the *bad* bracket $[g_2, [f, g_2]]$ can be neutralized. To this end we set

$$\begin{aligned}S &= \{f + ag_1 + bg_2 \mid -1 \le a, b \le 1\},\\ W &= f + g_1, \quad X = f + g_2, \quad Y = f - g_2,\end{aligned}$$

and consider the pairs $\{\frac{1}{3}W, \frac{1}{3}W\}, \{X, Y\} \subset \mathrm{co}(S)$ and $\boldsymbol{s} = (3, 1)$. With $P_2^0 = \{\pi_1, \pi_2\}$ and $A^i = A^i(X, Y)$ as defined in Example 5.3, the S-trajectory (4.2) corresponding to π_1 is

$$\begin{aligned}
\mathcal{X}_t^{\pi_1}(p) &= \Big(\frac{1}{3}W\Big)_{t^3} \circ \Big(\frac{1}{3}W\Big)_{t^3} \circ X_t \circ Y_t(p) \\
&= \Big(\frac{2}{3}W\Big)_{t^3} \circ (A^0 + A^1 t + A^2 t^2 + \cdots)_t(p) \\
&= \Big(A^0 + A^1 t + \Big(A^2 + \frac{2}{3}W\Big)t^2 + \Big(A^3 - \frac{1}{3}[A^0, W]\Big)t^3 \\
&\quad + \Big(A^4 - \frac{1}{3}[A^1, W] + \frac{1}{18}[A^0, [A^0, W]]\Big)t^4 + \cdots\Big)_t(p) \\
&= (Q_{\pi_1}^0 + Q_{\pi_1}^1 t + Q_{\pi_1}^2 t^2 + \cdots)_t(p).
\end{aligned}$$

Here $A^2 = \frac{1}{3}\mathrm{ad}_{g_2}^2 f$ does not vanish at p but is neutralized in the above S-trajectory, as $A^2 + \frac{2}{3}W$ does vanish at p. It is straightforward to check that $Q_{\pi_1}^0, \ldots, Q_{\pi_1}^3$ vanish at p, while

$$Q_{\pi_1}^4(p) = -\frac{1}{3}[A^1, W](p) = -\frac{1}{3}[g_1, [f, g_2]](p) = \Big(0, \frac{1}{3}, 0\Big).$$

From our definition of S_p^m (or from Proposition 3.6(2) it follows that $(0, \frac{1}{3}, 0) \in S_p^4(p)$. Now we can repeat the above construction with X and Y interchanged to conclude that $(0, -\frac{1}{3}, 0) \in S_p^4(p)$. Since $f \pm g_1, f \pm g_2 \in S$, we have

$$\begin{aligned}
\mathrm{co}\left(\left\{\pm(1,0,0), \pm(0,1,-1), \pm\left(0, \frac{1}{3}, 0\right)\right\}\right) \subset \mathrm{co}(S(p) \cup S_p^1(p) \cup S_p^2(p) \\
\cup S_p^3(p) \cup S_p^4(p))
\end{aligned}$$

and $0 \in \mathrm{int}(\mathrm{co}(S(p) \cup \cdots \cup S_p^4(p)))$. Local controllability at p follows from Theorem 3.7.

Example 5.5. We consider the system on $\mathbb{R}^3$ defined by

$$\begin{aligned}
\dot{x} &= u_1, \\
\dot{y} &= u_2, \\
\dot{z} &= x^2(1 + \tfrac{1}{2}u_2),
\end{aligned}$$

and with $(u_1, u_2) \in U = [-\alpha, \alpha]^2$. We take as our reference point $p = (0, 0, 0)$. For $\alpha < 2$ the system is obviously not STLC (small-time locally controllable) from p ($\dot{z} > 0$ in this case). Let us show that this system *is* controllable if the controls are allowed to be sufficiently large. Some relevant Lie brackets for this system are

$$\begin{gathered}
[f, g_1] = (0, 0, -2x), \quad [f, g_2] = (0, 0, 0), \quad [g_1, g_2] = (0, 0, x), \\
[f, [f, g_1]] = [f, [f, g_2]] = (0, 0, 0), \quad [g_1, [f, g_1]] = (0, 0, -2), \\
[g_2, [f, g_2]] = [g_2, [f, g_1]] = [g_2, [g_1, g_2]] = (0, 0, 0), \quad [g_1, [g_1, g_2]] = (0, 0, 1).
\end{gathered}$$

We define two complementary sets $\{X^1, X^2\} = \{f + \alpha g_1, f - \alpha g_1\}$ and $\{Y^1, Y^2\} = \{f - \alpha g_2, f + \alpha g_2\}$. By Corollary 4.6(2b) we have $\mathrm{ad}_{X^1}^2 X^2(p) = -2\alpha^2[g_1, [f, g_1]](p) \in S_p^2$. Also consider $\pi = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 1 \end{smallmatrix}\right) \in P_2^0$. By Proposition 4.2 we have

$$\mathcal{X}_t^{\pi}(p) = (Q_{\mathrm{inv}}^0 + tQ_{\pi}^1 + t^2 Q_{\pi}^2 + \cdots)_t(p),$$

where a direct calculation using the Campbell–Baker–Hausdorff formula yields

$$\begin{aligned}
Q^0_{\text{inv}} &= 4f,\\
Q^1_\pi &= 2\alpha[f,g_2] - 2\alpha[f,g_1] - \alpha^2[g_1,g_2],\\
Q^2_\pi &= \alpha[f,[f,g_2]] + \alpha[f,[f,g_1]] + \frac{1}{2}\alpha^2[g_1,[f,g_2]] + \frac{1}{2}\alpha^2[g_2,[f,g_1]]\\
&\quad - \frac{5}{6}\alpha^2[g_2,[f,g_2]] + \frac{1}{2}\alpha^3[g_2,[g_1,g_2]] - \frac{5}{6}\alpha^2[g_1,[f,g_1]] - \frac{1}{2}\alpha^3[g_1,[g_1,g_2]].
\end{aligned}$$

Since $Q^0_{\text{inv}}(p) = 0$, by Corollary 4.6(1), we have $Q^1_\pi \in S^1_p$. Furthermore, since $Q^1_\pi(p) = 0$, by Proposition 3.6(2) we have $Q^2_\pi \in S^2_p$. One can then see that, provided that α is sufficiently large (to be exact, if $\alpha > \frac{10}{3}$), then we have $0 \in \text{int}(\text{co}(S(p) \cup S^2_p))$. Small-time local controllability of this example for the sufficiently large control set now follows from Theorem 3.7. The lower bound of $\frac{10}{3}$ on the size of the control set to ensure small-time local controllability is undoubtedly not sharp.

Acknowledgments. We would like to thank the anonymous reviewers whose comments significantly improved the paper. One reviewer, in particular, read the paper very carefully, and noticed a couple of significant errors which have now been corrected.

ON A REPRESENTATION OF THE LIMIT OCCUPATIONAL MEASURES SET OF A CONTROL SYSTEM WITH APPLICATIONS TO SINGULARLY PERTURBED CONTROL SYSTEMS*

VLADIMIR GAITSGORY†

Abstract. A representation of the limit occupational measures set of a control system in terms of the vector function defining the system's dynamics is established. Applications in averaging of singularly perturbed control systems are demonstrated.

Key words. singularly perturbed control systems, occupational measures, averaging method, limit occupational measures sets, approximation of slow motions

1. Introduction and preliminaries.

Under certain conditions, the set of occupational measures generated by admissible controls and corresponding solutions of a control system converges (as the length of the time interval tends to infinity) to a limit set. If this limit set is independent of the initial conditions within some subset of the state space, it is called a limit occupational measures set (LOMS) of the system.

Criteria for the existence of the LOMS were discussed in [24], [25], where it was used as a tool for analysis of singularly perturbed control systems (SPCS).

In this paper, we give a natural representation for the LOMS which enhances its applications in SPCS. Our main results are stated in Theorem 2.1. We establish that, under the assumptions made, the convex hull of a union of occupational measures sets converges to a convex and compact set of probability measures defined in (2.6) (Theorem 2.1(i)) and that the LOMS of the control system is equal to this set if it exists (Theorem 2.1(ii)). We also give necessary and sufficient conditions for the existence of the LOMS (Theorem 2.1(iii)).

The paper consists of six sections. Theorem 2.1 is stated in section 2 and proved in sections 4–6. Applications in SPCS are discussed in section 3.

Singularly perturbed problems of control and optimization have been studied intensively in both deterministic and stochastic settings (see [1], [2], [3], [4], [5], [6], [7], [8], [11], [12], [14], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [36], [37], [38], [39], [40], [41], [42], [45], [46], [48] and the references therein).

Originally, the most common approaches to SPCS, especially in the deterministic case, were related to an approximation of the SPCS by the systems obtained via equating the singular perturbations parameter to zero (with further application of the boundary layer method (see [37], [44]) for an asymptotical description of the fast dynamics). This type of approach was successfully applied to a number of important classes of problems (see [30], [31], [38] and also [17], [36], [39], [45] for some recent results obtained in this direction).

†School of Mathematics, University of South Australia, The Mawson Lakes Campus, Mawson Lakes SA 5095, Australia (v.gaitsgory@unisa.edu.au).

Various averaging type approaches allowing a consideration of more general classes of SPCS, in which the equating of the small parameter to zero may not lead to a right approximation, were developed in [2], [3], [4], [5], [6], [7], [11], [20], [21], [22], [23], [24], [25], [26], [27], [41], [46].

In [24] and [25], in particular (see also [3], [5], [46] for related results), the slow trajectories were approximated by the solutions of the averaged system in which the controls are measure-valued and take their values in the LOMS of the associated system (that is, the system that would describe the fast dynamics if the slow state variables were "frozen"). The paper continues this line of research by establishing that the LOMS allows a representation in terms of the vector function defining the right-hand side of the associated system.

Let us introduce some notation and definitions which are used throughout the paper. Given a compact metric space W, $\mathcal{B}(W)$ will stand for the σ-algebra of its Borel subsets and $\mathcal{P}(W)$ will denote the set of probability measures defined on $\mathcal{B}(W)$. The set $\mathcal{P}(W)$ will be treated as a compact metric space with a metric ρ, which is consistent with its weak convergence topology (see, e.g., [13]). A sequence $\gamma^k \in \mathcal{P}(W)$ converges to $\gamma \in \mathcal{P}(W)$ in this metric if and only if

$$\lim_{k\to\infty} \int_W q(w)\gamma^k(dw) \;=\; \int_W q(w)\gamma(dw) \tag{1.1}$$

for any continuous $q(w) : W \to \mathbb{R}^1$. There are many ways of defining such a metric ρ. In this paper, we will use the following definition: $\forall \gamma', \gamma'' \in \mathcal{P}(W)$,

$$\rho(\gamma', \gamma'') \stackrel{\text{def}}{=} \sum_{l=1}^{\infty} \frac{1}{2^l} \left| \int_W q_l(w)\gamma'(dw) - \int_W q_l(w)\gamma''(dw) \right|, \tag{1.2}$$

where $q_l(\cdot)$, $l = 1, 2, \ldots$, is a sequence of Lipschitz continuous functions which is dense in the unit ball of $C(W)$ (the space of continuous functions on W). Using the metric ρ, one can define the Hausdorff metric ρ_H on the set of subsets of $\mathcal{P}(W)$ as follows: $\forall\, \Gamma_i \subset \mathcal{P}(W)$, $i = 1, 2$,

$$\rho_H(\Gamma_1, \Gamma_2) \stackrel{\text{def}}{=} \max \left\{ \sup_{\gamma\in\Gamma_1} \rho(\gamma, \Gamma_2), \sup_{\gamma\in\Gamma_2} \rho(\gamma, \Gamma_1) \right\}, \tag{1.3}$$

where $\rho(\gamma, \Gamma_i) \stackrel{\text{def}}{=} \inf_{\gamma'\in\Gamma_i} \rho(\gamma, \gamma')$. It can be verified (see, e.g., Lemma П2.4, p. 205 in [22]) that, with the definition of the metric ρ as in (1.2),

$$\rho_H(co\Gamma_1, co\Gamma_2) \le \rho_H(\Gamma_1, \Gamma_2), \tag{1.4}$$

where *co* stands for the convex hull of the corresponding set.

In what follows, we will deal with the convergence in the Hausdorff metric of sets in $\mathcal{P}(W)$ defined as unions of occupational measures. Given a measurable function $w(t) : [0, S] \to W$, the occupational measure $p^{w(\cdot)} \in \mathcal{P}(W)$ generated by this function is defined by taking

$$p^{w(\cdot)}(Q) \stackrel{\text{def}}{=} \frac{1}{S}\text{meas}\left\{ t \;\middle|\; w(t) \in Q \right\} \qquad \forall Q \in \mathcal{B}(W),$$

where meas $\{\cdot\}$ stands for the Lebesgue measure on $[0, S]$.

2. Main theorem. Consider a control system

$$\dot{y}(\tau) \;=\; f(u(\tau), y(\tau)), \quad \tau \in [0, S], \tag{2.1}$$

where the function $f(u, y) : U \times \mathbb{R}^m \to \mathbb{R}^m$ is continuous in (u, y) and satisfies Lipschitz conditions in y, U is a compact metric space, and the controls are Lebesgue measurable functions $u(\tau) : [0, S] \to U$.

Let Y be a compact subset of $\mathbb{R}^m$ and $Y^\delta \stackrel{\text{def}}{=} Y + \delta B$, where δ is a positive number and B is the closed unit ball in $\mathbb{R}^m$, and let us introduce the following definition and assumptions.

DEFINITION. *A pair $(u(\tau), y(\tau))$ is called admissible (δ-admissible) for system (2.1) on the interval $[0, S]$ if $u(\tau)$ is a control, $y(\tau)$ is the corresponding solution of (2.1), and $y(\tau) \in Y$ ($y(\tau) \in Y^\delta$) $\forall \tau \in [0, S]$.*

Assumption I. For any initial condition $y(0) \in Y$, there exists a control $u(\tau)$ such that the corresponding solution of (2.1) does not leave Y on $[0, S]$ for any $S > 0$.

Assumption II. For any Lipschitz continuous function $g(u, y) : U \times \mathbb{R}^m \to \mathbb{R}^1$,

$$\left| \frac{1}{S} \sup_{(u(\cdot), y(\cdot))} \int_0^S g(u(\tau), y(\tau)) d\tau \;-\; \frac{1}{S} \sup_{(u^\delta(\cdot), y^\delta(\cdot))} \int_0^S g(u^\delta(\tau), y^\delta(\tau)) d\tau \right| \stackrel{\text{def}}{=} \mu_g(\delta, S) \;\to\; 0 \tag{2.2}$$

as $\delta \to 0$ and $S \to \infty$, where the *sup*s in the above expression are, respectively, over all admissible pairs and over all δ-admissible pairs which satisfy the condition $y^\delta(0) \in Y$.

Assumption I is equivalent to the assumption that the viability kernel of Y is equal to Y. It is satisfied, for example, if, for any $y \in Y$, there exists $u \in U$ such that $f(u, y) = 0$. More general sufficient (and necessary) conditions for this assumption to be satisfied can be found in [9], [10].

Note that if Assumption I is replaced by a stronger assumption that Y is a forward invariant set—that is, all solutions of (2.1) obtained with the measurable controls $u(\tau) : [0, S] \to U$ $\forall S > 0$ do not leave Y—then Assumption II is satisfied automatically. In this case, all δ-admissible pairs satisfying the condition $y^\delta(0) \in Y$ are admissible and (2.2) is valid with $\mu_g(\delta, S) \equiv 0$.

Let $(u(\tau), y(\tau)) : [0, S] \to U \times Y$ be an admissible pair and let $p^{(u(\cdot), y(\cdot))} \in \mathcal{P}(U \times Y)$ be the occupational measure generated by this pair. Denote by $\Gamma(S, y)$ and $\Gamma(S, Y)$ the sets of occupational measures defined by the equations

$$\Gamma(S, y) \stackrel{\text{def}}{=} \bigcup_{(u(\tau),\ y(\tau))} \left\{ p^{(u(\cdot), y(\cdot))} \right\}, \qquad \Gamma(S, Y) \stackrel{\text{def}}{=} \bigcup_{y \in Y} \left\{ \Gamma(S, y) \right\}, \tag{2.3}$$

where the first union is over all admissible pairs of (2.1) satisfying the initial conditions $y(0) = y$ and the second is over all initial conditions

$$y(0) \;=\; y \;\in\; Y. \tag{2.4}$$

DEFINITION. *A convex and compact set $\Gamma \subset \mathcal{P}(U \times Y)$ is called the LOMS of system (2.1) on Y if there exists a function $\nu(S)$, $\lim_{S \to \infty} \nu(S) = 0$, such that*

$$\rho_H(\Gamma(S, y), \Gamma) \;\le\; \nu(S) \quad \forall y \;\in\; Y. \tag{2.5}$$

In Theorem 2.1 below, we relate the LOMS of system (2.1) on Y to the set $W \subset \mathcal{P}(U \times Y)$ defined by the equation

$$W \stackrel{\text{def}}{=} \left\{ \gamma \mid \gamma \in \mathcal{P}(U \times Y);\ \int_{U \times Y} (\phi'(y))^T f(u, y) \gamma(du, dy) = 0 \ \forall \phi(\cdot) \in C^1 \right\}, \tag{2.6}$$

where C^1 is the space of continuously differentiable functions $\phi(y) : \mathbb{R}^m \to \mathbb{R}^1$ and $\phi'(y)$ is the vector column of partial derivatives (the gradient) of $\phi(y)$. Note that, as can be easily verified, the set W is convex and compact in the weak convergence topology of $\mathcal{P}(U \times Y)$.

THEOREM 2.1. *Let Assumptions* I *and* II *be satisfied. Then the following hold:*

(i) *The estimate*

$$\rho_H(co\Gamma(S,Y),W) \;\le\; \bar{\nu}(S) \tag{2.7}$$

is valid for some $\bar{\nu}(S)$, $\lim_{S\to\infty}\bar{\nu}(S)=0$.

(ii) *If the LOMS* Γ *of system* (2.1) *on* Y *exists, it is equal to the set* W*:*

$$\Gamma \;=\; W. \tag{2.8}$$

(iii) *The LOMS* Γ *of system* (2.1) *on* Y *exists if and only if*

$$\rho_H(\Gamma(S,y'),\Gamma(S,y'')) \;\le\; \hat{\nu}(S) \quad \forall y', y'' \in Y, \tag{2.9}$$

for some $\hat{\nu}(S)$, $\lim_{S\to\infty}\hat{\nu}(S)=0$.

Proof. Statements (i) and (ii) of the theorem are proved in sections 5–6. Statement (iii) is proved in section 4. □

3. On applications in SPCS. Let us consider an SPCS defined on the interval $[0,T]$ $(T>0)$ by the equations

$$\epsilon\dot{y}(t) = f(u(t),y(t),z(t)), \qquad y(0)=y_0, \tag{3.1}$$

$$\dot{z}(t) = g(u(t),y(t),z(t)), \qquad z(0)=z_0, \tag{3.2}$$

where $\epsilon>0$ is a small parameter; $f : U\times\mathbb{R}^m\times\mathbb{R}^n \to \mathbb{R}^m$, $g : U\times\mathbb{R}^m\times\mathbb{R}^n \to \mathbb{R}^n$ are continuous vector functions satisfying Lipschitz conditions in z and y; U is a compact metric space, and the controls are measurable functions satisfying the inclusion $u(t)\in U$.

Along with (3.1)–(3.2), let us consider the associated system

$$\dot{y}(\tau) = f(u(\tau),y(\tau),z), \quad \tau\in[0,S], \tag{3.3}$$

in which (in contrast to (3.1)) z is a vector of fixed parameters: $z=\text{const}$. The controls in (3.3) are measurable functions satisfying the inclusion $u(\tau)\in U$.

Assume that, $\forall z$ from a sufficiently large area $Z\subset\mathbb{R}^n$, the solutions of the associated system (3.3) with the initial conditions in a compact set $Y\subset\mathbb{R}^m$ do not leave this set $\forall\tau\ge 0$ (that is, Y is forward invariant with respect to the solutions of (3.3)). Assume also that the solutions of the SPCS (3.1)–(3.2) do not leave $Y\times Z'$ for $t\in[0,T]$, where Z' is a compact set belonging to the interior of Z.

Let $u(\tau)\in U$ be a control and $y(\tau)\in Y$ be the solution of the associated system (3.3), obtained with this control and the initial condition $y(0)=y$. Denote by $\gamma^{(u(\cdot),y(\cdot))}\in\mathcal{P}(U\times Y)$ the occupational measure generated by the pair $(u(\cdot),y(\cdot)) : [0,S]\to U\times Y$ and denote by $\Gamma(z,S,y)\subset\mathcal{P}(U\times Y)$ the union of all such occupational measures.

Assume that the LOMS $\Gamma(z)$ of the associated system exists, that is,

$$\lim_{S\to\infty}\rho_H(\Gamma(z,S,y),\Gamma(z))=0,$$

with the convergence being uniform with respect to $(y, z) \in Y \times Z$. Note that, by Theorem 2.1(ii), $\Gamma(z) = W(z)$ (the latter is defined in (2.6), with the dependence on z being due to the fact that the vector function $f(\cdot)$ includes the dependence on z).

Define $\tilde{g}(\gamma, z) : \mathcal{P}(U \times Y) \to \mathbb{R}^n$ by the equation

$$\tilde{g}(\gamma, z) \stackrel{\text{def}}{=} \int_{U \times Y} g(u, y, z)\gamma(du, dy)$$

and consider the *averaged* system

$$\dot{z}(t) = \tilde{g}(\gamma(t), z(t)), \qquad z(0) = z_0, \tag{3.4}$$

in which the controls are Lebesgue measurable functions $\gamma(\cdot) : [0, T] \to \mathcal{P}(U \times Y)$ satisfying the inclusion

$$\gamma(t) \in W(z(t)). \tag{3.5}$$

The following result is a corollary of Theorem 2.1(ii) and Theorem 4.2 in [24].

COROLLARY 3.1. *Let the assumptions made above be satisfied. Also let the multivalued map* $V_g(\cdot) : Z \to 2^{R^n}$,

$$V_g(z) \stackrel{\text{def}}{=} \bigcup_{\gamma \in W(z)} \{\tilde{g}(\gamma, z)\},$$

be Lipschitz continuous. Then the following hold:

(i) *Corresponding to any solution* $(z^{sp}(t), y^{sp}(t))$ *of* (3.1)–(3.2) *there exists a solution* $z^{av}(t)$ *of* (3.4) *such that*

$$\max_{t \in [0,T]} ||z^{sp}(t) - z^{av}(t)|| \le \mu(\epsilon), \qquad \lim_{\epsilon \to 0} \mu(\epsilon) = 0. \tag{3.6}$$

(ii) *Corresponding to any solution* $z^{av}(t)$ *of* (3.4) *there exists a solution* $(z^{sp}(t), y^{sp}(t))$ *of* (3.1)–(3.2) *which satisfies* (3.6).

Proof. The proof follows from Theorem 4.2 in [24] with the replacement of $\Gamma(z)$ by $W(z)$ (see also Theorem 2.6 in [25] and related results in [3]). □

Sufficient conditions for the assumptions used in Corollary 3.1 to be valid have been discussed in [24], [25], where it was noticed, in particular, that these assumptions (including the existence of the LOMS and the Lipschitz continuity of $V_g(z)$) are satisfied if there exist positive definite matrices C and D such that, for any $u \in U$, any $y^1, y^2 \in R^m$, and any $z \in Z$,

$$(f(u, y^1, z) - f(u, y^2, z))^T C(y^1 - y^2) \le -(y^1 - y^2)^T D(y^1 - y^2).$$

The existence of such C and D can be guaranteed, for example, if $f(u, y, z) = A(z)y + B(z)u$, where $A(z)$ and $B(z)$ are matrices functions of the corresponding dimensions and the eigenvalues of $A(z)$ have negative real parts $\forall z \in Z$.

Let $G(\cdot) : \mathbb{R}^n \to \mathbb{R}^1$ be a continuous function. From Corollary 3.1 it follows that the optimal value of the problem

$$\inf_{(z^{sp}(\cdot), y^{sp}(\cdot))} G(z^{sp}(T)) \stackrel{\text{def}}{=} G^\star_\epsilon, \tag{3.7}$$

where inf is over the solutions of (3.1)–(3.2), converges (as ϵ tends to zero) to the optimal value of the problem

$$\inf_{z^{av}(\cdot)} G(z^{av}(T)) \stackrel{\text{def}}{=} G^\star, \tag{3.8}$$

where inf is over the solutions of (3.4). That is,

$$\lim_{\epsilon\to 0} G^\star_\epsilon = G^\star. \tag{3.9}$$

Also, it can be shown that a near optimal solution of (3.7) can be constructed on the basis of the optimal (or near optimal) solution of (3.8) (see details in [23], [24], [25], [27]).

Note that statement (i) of Corollary 3.1 remains valid even in the event the assumption about the existence of the LOMS is not satisfied, with (3.9) being replaced in this case by a weaker statement that

$$\liminf_{\epsilon\to 0} G^\star_\epsilon \geq G^\star.$$

The validity of this can be established via a straightforward extension of the averaging techniques used in [23], [24], [25], [27] in combination with Theorem 2.1(i).

In conclusion, let us observe that a numerical analysis of the solutions of (3.4) satisfying the inclusion (3.5) can be based on the fact that the set $W(z)$ allows the representation in the form of a countable system of equations:

$$W(z) = \left\{ \gamma \mid \gamma \in \mathcal{P}(U\times Y); \int_{U\times Y} (\phi_i'(y))^T f(u,y,z)\gamma(du,dy) = 0\ ,\ i = 1,2,\dots \right\}\ . \tag{3.10}$$

Here, $\{\phi_i(\cdot)\}$ is a sequence of continuously differentiable functions such that any function $\phi(\cdot)\in C^1$ and its gradient $\phi'(\cdot)$ can be simultaneously approximated on Y by linear combinations of functions from $\{\phi_i\}$ and their corresponding gradients. (An example of such a sequence is the sequence of the monomials $y_1^{i_1}\dots y_m^{i_m}$, $i_1,\dots,i_m = 0,1,\dots$, where y_j $(j=1,\dots,m)$ stands for the jth component of y; see, e.g., [33].) To numerically approximate the solutions of the averaged system (3.4)–(3.5) one may need to truncate the system of equations in (3.10) and subsequently approximate the resulting set by the set of measures supported on a grid. The details of such a procedure will be studied in a different paper.

4. Sets of time averages and proof of Theorem 2.1(iii). Let $\delta_0 > 0$ be fixed and $q_l(u,y): U\times Y^{\delta_0}\to\mathbb{R}^1$, $l=1,2,\dots$, be a sequence of Lipschitz continuous functions which is dense in the space of continuous functions on $U\times Y^{\delta_0}$. Let

$$h(u,y) \ = \ (q_1(u,y),\dots,q_j(u,y)),\ j=1,2,\dots, \tag{4.1}$$

and let $V_h(S,y)$ be the set of time averages defined by the equation

$$V_h(S,y) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),\ y(\cdot))} \left\{ \frac{1}{S}\int_0^S h\big(u(\tau),y(\tau)\big)d\tau \right\}, \tag{4.2}$$

where the union is over all admissible pairs of (2.1) satisfying the initial conditions (2.4).

The proof of Theorem 2.1(iii) is based on the following proposition.

PROPOSITION 4.1. *Let Assumption* I *be satisfied. Then the following hold:*

(i) *The LOMS* Γ *of system* (2.1) *on* Y *exists if and only if, for every vector function* $h(u,y)$ *defined in* (4.1), *there exist a convex and compact set* V_h *and a function* $\nu_h(S)$, $\lim_{S\to\infty}\nu_h(S)=0$, *such that*

$$d_H(V_h(S,y),V_h) \ \leq\ \nu_h(S) \quad \forall y\ \in\ Y, \tag{4.3}$$

where $d_H(\cdot,\cdot)$ is the Hausdorff metric defined on the bounded subsets of the corresponding finite dimensional space by the Euclidean norm.

(ii) *For a given $h(u,y)$ as in* (4.1)*, a convex and compact set V_h satisfying* (4.3) *exists if and only if*

$$d_H(V_h(S,y'),V_h(S,y'')) \;\le\; \hat{\nu}_h(S) \quad \forall y', y'' \;\in\; Y \tag{4.4}$$

for some $\hat{\nu}_h(S)$ tending to zero as S tends to infinity.

Proof. The proof of Proposition 4.1(i) is similar to that of Theorem 3.1 in [24] (see also Corollary 3.7 in [25] and the more general result in [7]). The proof of the "if" statement in Proposition 4.1(ii) follows exactly the same steps as that of Proposition 3.2 in [26] (see also [21], [22], and [7]), where this statement was proved for the case when Y is forward invariant with respect to the system (2.1). The proof of the "only if" statement is obvious. □

Proof of Theorem 2.1(iii). If (2.9) is valid, then the estimate (4.4) is true for every $h(u,y)$ defined in (4.1). Hence, by Proposition 4.1(ii), for every such $h(u,y)$, there exists a convex and compact set V_h satisfying (4.3). This, by Proposition 4.1(i), implies the existence of the LOMS. Thus, the "if" statement in Theorem 2.1(iii) is proved. The proof of the "only if" statement is obvious. □

To conclude this section, let us show that Assumption II can be equivalently reformulated in terms of convergence to zero of the Hausdorff metric between the sets of time averages defined below. For $0 < \delta \le \delta_0$, let

$$V_h^\delta(S,y) \stackrel{\text{def}}{=} \bigcup_{(u^\delta(\cdot),\; y^\delta(\cdot))} \left\{ \frac{1}{S} \int_0^S h\big(u^\delta(\tau), y^\delta(\tau)\big) d\tau \right\}, \tag{4.5}$$

where, in contrast to (4.2), the union is over all δ-admissible pairs of (2.1) satisfying the initial conditions (2.4). Denote

$$V_h(S,Y) \stackrel{\text{def}}{=} \bigcup_{y\in Y} \{V_h(S,y)\}, \qquad V_h^\delta(S,Y) \stackrel{\text{def}}{=} \bigcup_{y\in Y} \left\{V_h^\delta(S,y)\right\}.$$

The following lemma is used in the proof of Theorem 2.1(i) (see section 5 below).

LEMMA 4.2. *Assumption* II *is equivalent to that, for any $h(\cdot)$ as in* (4.1)*,*

$$d_H(coV_h(S,Y), coV_h^\delta(S,Y)) \;\stackrel{\text{def}}{=}\; \bar{\nu}_h(\delta,S) \;\to\; 0 \tag{4.6}$$

as $\delta \to 0$ and $S \to \infty$.

Proof. Let $\Psi_V(\cdot)$ stand for the support function of a set $V \subset R^j$. That is, for any $\eta \in R^j$, $\Psi_V(\eta) \stackrel{\text{def}}{=} \sup_{v\in V} \eta^T v$. If Assumption II is satisfied, then, taking $g(u,y) = \eta^T h(u,y)$ in (2.2), one can obtain that the function $\mu_g(\delta,S)$ defined by the equation

$$|\Psi_{coV_h(S,Y)}(\eta) - \Psi_{coV_h^\delta(S,Y)}(\eta)| = |\Psi_{V_h(S,Y)}(\eta) - \Psi_{V_h^\delta(S,Y)}(\eta)| \;\stackrel{\text{def}}{=}\; \mu_g(\delta,S) \tag{4.7}$$

tends to zero as $\delta \to 0$ and $S \to \infty$. Using a standard argument based on the separability of convex sets, one can verify that (4.7) implies (4.6). Thus, the validity of (4.6) is implied by the validity of Assumption II.

Now let (4.6) be satisfied for any $h(\cdot)$ constructed as in (4.1). Then $\mu_g(\delta,S)$ in (4.7) tends to zero as δ tends to zero and S tends to infinity. By taking all but one component of η to be equal to zero in (4.7), one can verify that (2.2) is valid for any $g(u,y) = q_l(u,y)$, $l = 1,2,\ldots$. Since the sequence $q_l(u,y)$, $l = 1,2,\ldots$, is dense in $C(U \times Y^\delta)$, it implies that (2.2) is valid for any continuous (and, in particular, Lipschitz continuous) $g(\cdot)$. This completes the proof of the lemma. □

5. Proofs of Theorem 2.1(i) and Theorem 2.1(ii).

Proof of Theorem 2.1(i). To prove the required statement, one needs to establish the validity of the following two inequalities:

$$\sup_{\gamma\in W}\rho(\gamma, co\Gamma(S,Y)) \le \bar\nu(S), \tag{5.1}$$

$$\sup_{\gamma\in co\Gamma(S,Y)}\rho(\gamma, W) \le \bar\nu(S). \tag{5.2}$$

Let us first prove the validity of (5.2). It is straightforward to verify that from the convexity of W it follows that

$$\sup_{\gamma\in co\Gamma(S,Y)}\rho(\gamma, W) = \sup_{\gamma\in \Gamma(S,Y)}\rho(\gamma, W).$$

Hence, to prove (5.2) it is enough to show that the function $\bar\nu(S)$ defined by the equation

$$\bar\nu(S) \stackrel{\text{def}}{=} \sup_{\gamma\in\Gamma(S,Y)}\rho(\gamma, W) \tag{5.3}$$

tends to zero as S tends to infinity. Assume this is not the case. Then there exist a positive number δ, a sequence $S^k \to \infty$, and sequences $y^k \in Y$ and $\gamma^k \in \Gamma(S^k, y^k)$ such that $\rho(\gamma^k, W) \ge \delta$, $k = 1, 2, \dots$. Without loss of generality one may assume that there exists $\lim_{k\to\infty}\gamma^k \stackrel{\text{def}}{=} \gamma \in \mathcal{P}(U\times Y)$ (since $\mathcal{P}(U\times Y)$ is compact). From the continuity of the metric it follows that

$$\rho(\gamma, W) \ge \delta. \tag{5.4}$$

By the definition of the convergence in $\mathcal{P}(U\times Y)$ (see (1.1)),

$$\lim_{k\to\infty}\int_{U\times Y}(\phi\prime(y))^T f(u,y)\gamma^k(du,dy) \;=\; \int_{U\times Y}(\phi\prime(y))^T f(u,y)\gamma(du,dy) \tag{5.5}$$

for any $\phi \in C^1$. Also, from the fact that $\gamma^k \in \Gamma(S^k, y^k)$, it follows that there exists an admissible pair $(u^k(\tau), y^k(\tau))$ (for system (2.1) on the interval $[0, S^k]$) such that

$$\int_{U\times Y}(\phi\prime(y))^T f(u,y)\gamma^k(du,dy) \;=\; \frac{1}{S^k}\int_0^{S^k}(\phi\prime(y^k(\tau)))^T f(u^k(\tau), y^k(\tau))d\tau.$$

The second integral is apparently equal to

$$\frac{\phi(y^k(S^k)) - \phi(y^k(0))}{S^k}$$

and tends to zero as S^k tends to infinity (since $y^k(\tau) \in Y\ \forall\ \tau \in [0, S^k]$ and Y is a compact set). This and (5.5) imply that

$$\int_{U\times Y}(\phi\prime(y))^T f(u,y)\gamma(du,dy) \;=\; 0\ \ \forall\phi\in C^1 \quad\Rightarrow\quad \gamma\ \in\ W.$$

The latter contradicts (5.4) and, hence, $\bar\nu(s)$ defined in (5.3) tends to zero as S tends to infinity. This proves (5.2).

Let us now prove the validity of inequality (5.1). Let $\hat{r}$ be a positive number such that Y is contained in the interior of $\hat{r}B \stackrel{\text{def}}{=} \hat{B}$ (as above, B is the closed unit ball in $\mathbb{R}^m$) and let $\psi(y) : \mathbb{R}^m \to [0,1]$ be a continuously differentiable function such that

$$\psi(y) \;=\; 1 \quad \forall y \;\in Y, \qquad \psi(y) \;=\; 0 \quad \forall y \;\in \mathbb{R}^m/\hat{B}. \tag{5.6}$$

Define the function $F(u,y) : U \times \mathbb{R}^m \to \mathbb{R}^m$ by the equation

$$F(u,y) \;\stackrel{\text{def}}{=}\; \psi(y) f(u,y). \tag{5.7}$$

Note that, by (5.6),

$$F(u,y) \;=\; f(u,y) \quad \forall (u,y) \;\in U \times Y, \qquad F(u,y) = 0 \quad \forall (u,y) \;\in U \times \mathbb{R}^m/\hat{B}. \tag{5.8}$$

Let $\bar{C}(U \times \mathbb{R}^m)$ be the space of bounded continuous functions on $U \times \mathbb{R}^m$ taking values in $\mathbb{R}^1$, and let $\hat{C}^1$ be the space of continuously differentiable functions on $\mathbb{R}^m$ taking values in $\mathbb{R}^1$ and vanishing at infinity. Note that, since Y is a compact set, one can replace C^1 by $\hat{C}^1 \subset C^1$ in (2.6) without adding new elements to the set W. Define a linear operator $A : \hat{C}^1 \to \bar{C}(U \times \mathbb{R}^m)$ by the equation

$$(A\phi)(u,y) \;\stackrel{\text{def}}{=}\; (\phi'(y))^T F(u,y) \quad \forall \phi \;\in \hat{C}^1.$$

This operator satisfies the conditions of Theorem 4.1 in [43], namely, the following:

(i) $\hat{C}^1$, the domain of A, is an algebra and is dense in the space $\hat{C}$ of continuous functions on $\mathbb{R}^m$ which vanish at infinity (this is an immediate consequence of the Stone–Weierstrass theorem; see, e.g., Theorem IV.6.16 in [15]).

(ii) For each $\phi \in \hat{C}^1$ and $u \in U$, $(A\phi)(u,\cdot) \stackrel{\text{def}}{=} (\phi'(\cdot))^T F(u,\cdot) \in \hat{C}$.

(iii) For each $\phi \in \hat{C}^1$,

$$\lim_{||y|| \to \infty} \max_{u \in U} (A\phi)(u,y) \;=\; \lim_{||y|| \to \infty} \max_{u \in U} (\phi'(y))^T F(u,y) \;=\; 0.$$

(iv) For each $u \in U$, the operator $A_u \phi \stackrel{\text{def}}{=} (A\phi)(u,\cdot)$ satisfies the positive maximum principle, i.e., if $\phi(y^*) = \sup_y \phi(y) > 0$, then

$$(A_u\phi)(y^*) \;=\; (\phi'(y^*))^T F(u,y^*) \;\leq\; 0.$$

Note that (ii) and (iii) are satisfied because of (5.8) and that (iv) follows from the fact that $\phi'(y^*) = 0$.

Let us consider now an arbitrary $\gamma \in W$ and extend its definition to the Borel subsets of $U \times \mathbb{R}^m$ by taking $\gamma(Q) \stackrel{\text{def}}{=} \gamma(Q \cap (U \times Y))$ $\forall Q \in \mathcal{B}(U \times \mathbb{R}^m)$. By (5.8) and (2.6),

$$\int_{U \times \mathbb{R}^m} (A\phi)(u,y)\gamma(du,dy) \;=\; \int_{U \times \mathbb{R}^m} (\phi'(y))^T F(u,y)\gamma(du,dy)$$

$$= \int_{U \times Y} (\phi'(y))^T F(u,y)\gamma(du,dy) \;=\; \int_{U \times Y} (\phi'(y))^T f(u,y)\gamma(du,dy) \;=\; 0$$

$\forall \phi \in \hat{C}^1$. From Theorem 4.1 in [43] it follows that there exist a probability space $(\Omega, \mathcal{F}, P)$, a filtration $\{\mathcal{F}_\tau\}$ of σ-subalgebras of $\mathcal{F}$, and a $\mathcal{P}(U) \times \mathbb{R}^m$-valued random process $(\lambda(\tau), y(\tau)) \;=\; (\lambda(\tau,\omega), y(\tau,\omega))$ which satisfies the following conditions:

(a) $(\lambda(\cdot), y(\cdot))$ is $\{\mathcal{F}_\tau\}$-progressive and stationary with

$$E[\lambda(\tau)(D_1)\chi_{D_2}(y(\tau))] = \gamma(D_1 \times D_2) \quad \forall \tau \ \geq \ 0, \tag{5.9}$$

where D_1 and D_2 are arbitrary Borel subsets of U and $\mathbb{R}^m$, respectively, and $\chi_{D_2}(\cdot)$ is the indicator function of D_2.

(b) For every $\phi \in \hat{C}^1$, $\phi(y(\tau)) - \int_0^\tau \int_U (\phi'(y(s)))^T F(u, y(s))\lambda(s)(du)ds$ is an $\{\mathcal{F}_\tau\}$-martingale.

A further characterization of the pair $(\lambda(\tau,\omega), y(\tau,\omega))$ is given by the following lemma.

LEMMA 5.1. *There exists a subset Δ of Ω such that $P(\Delta) = 0$ and such that, $\forall \omega \in \Omega/\Delta$, the pair $(\lambda(\tau,\omega), y(\tau,\omega))$ satisfies the equation*

$$\dot{y}(\tau,\omega) \ = \ \bar{F}(\lambda(\tau,\omega), y(\tau,\omega)) \tag{5.10}$$

for almost all $\tau \in [0, S]$ $(\forall S > 0)$, where

$$\bar{F}(\lambda, y) \ \stackrel{\text{def}}{=} \int_U F(u, y)\lambda(du). \tag{5.11}$$

Proof. Proof of the lemma is given in section 6 below. □

Let τ_i, $i = 1, 2, \ldots$, stand for a sequence of all rational numbers belonging to the interval $[0, S]$. By (5.9),

$$P\{\omega \mid y(\tau_i, \omega) \ \in Y\} \ = \ E[\chi_Y(y(\tau_i))] \ = \ E[\lambda(\tau_i)(U)\chi_Y(y(\tau_i))] \ = \ \gamma(U \times Y) \ = \ 1.$$

That is, for every i there exists a subset Δ_i of Ω such that $P(\Delta_i) = 0$ and such that

$$y(\tau_i, \omega) \in Y \ \forall \omega \in \Omega/\Delta_i \quad \Rightarrow \quad y(\tau_i, \omega) \in Y, \ i = 1, 2, \ldots, \ \forall \omega \in \Omega/(\cup_i \Delta_i). \tag{5.12}$$

From the fact that $y(\tau,\omega)$ satisfies (5.10) it follows that $y(\cdot,\omega)$ is continuous (in fact, absolutely continuous) for $\omega \in \Omega/\Delta$. Thus, the inclusions (5.12) and the fact that Y is compact imply that

$$y(\tau,\omega) \ \in Y \ \ \forall \tau \in [0, S], \quad \forall \omega \in \Omega/\bar{\Delta}, \tag{5.13}$$

where $\bar{\Delta} \stackrel{\text{def}}{=} \Delta \cup (\cup_i \Delta_i)$, with

$$P(\bar{\Delta}) \ = \ 0. \tag{5.14}$$

Note that, by (5.8) and (5.11), equation (5.10) is equivalent to

$$\dot{y}(\tau,\omega) \ = \ \bar{f}(\lambda(\tau,\omega), y(\tau,\omega)) \tag{5.15}$$

for $\omega \in \Omega/\bar{\Delta}$, where

$$\bar{f}(\lambda, y) \ \stackrel{\text{def}}{=} \int_U f(u, y)\lambda(du). \tag{5.16}$$

Consider the control system

$$\dot{y}(\tau) \ = \ \bar{f}(\lambda(\tau), y(\tau)), \tag{5.17}$$

where $\lambda(\tau)$ is a relaxed control, that is, a Lebesgue measurable function $\lambda(\tau) : [0, S] \to \mathcal{P}(U)$ (see [47]). A pair $(\lambda(\tau), y(\tau))$ will be called admissible (for system (5.17) on

the interval $[0, S]$) if $\lambda(\tau)$ is a relaxed control, $y(\tau)$ is the corresponding solution of (5.17), and $y(\tau) \in Y \ \forall \tau \in [0, S]$. Let $h(u, y)$ be as in (4.1) and

$$\bar{h}(\lambda, y) \stackrel{\text{def}}{=} \int_U h(u, y)\lambda(du). \tag{5.18}$$

Consider the set of the time averages

$$\bar{V}_h(S, y) \stackrel{\text{def}}{=} \bigcup_{(\lambda(\cdot),\ y(\cdot))} \left\{ \frac{1}{S} \int_0^S \bar{h}\big(\lambda(\tau), y(\tau)\big) d\tau \right\}, \tag{5.19}$$

where the union is over all admissible pairs of (5.17) satisfying the initial conditions (2.4).

By the relaxation theorem (see, e.g., Theorem 10.4.4, p. 402 in [10]),

$$\bar{V}_h(S, y) \ \subset \ \mathrm{cl} V_h^{\delta}(S, y) \ \ \forall \delta \ > \ 0, \tag{5.20}$$

where cl stands for the closure of the set and $V_h^{\delta}(S, y)$ is defined in (4.5). Since $y(\tau, \omega)$ satisfies (5.13) and (5.15), from (5.20) and (4.6) it follows that, $\forall \omega \in \Omega / \bar{\Delta}$,

$$\begin{aligned} &\frac{1}{S} \int_0^S \bar{h}\big(\lambda(\tau, \omega), y(\tau, \omega)\big) d\tau \ \in \ \bar{V}_h(S, y(0, \omega)) \\ &\subset \ \mathrm{cl} V_h^{\delta}(S, Y) \ \subset \bar{co} V_h(S, Y) \ + \ \bar{\nu}_h(\delta, S) B_j, \end{aligned}$$

where $\bar{co}$ is the closed convex hull of the corresponding set and B_j is the closed unit ball in $\mathbb{R}^j$ (j is the dimension of the vector function $h(\cdot)$). Using now (5.14), one obtains from here that

$$\frac{1}{S} \int_0^S E[\bar{h}\big(\lambda(\tau, \omega), y(\tau, \omega)\big)] d\tau \ \in \ \bar{co} V_h(S, Y) \ + \ \bar{\nu}_h(\delta, S) B_j. \tag{5.21}$$

From (5.9), however, it follows that

$$E[\bar{h}\big(\lambda(\tau, \omega), y(\tau, \omega)\big)] \ = \ \int_{U \times Y} h(u, y) \gamma(du, dy). \tag{5.22}$$

Consequently, by (5.21),

$$\begin{aligned} &\int_{U \times Y} h(u, y) \gamma(du, dy) \ \in \ \bar{co} V_h(S, Y) \ + \ \bar{\nu}_h(\delta, S) B_j \\ \Rightarrow \quad &\int_{U \times Y} h(u, y) \gamma(du, dy) \ \in \ \bar{co} V_h(S, Y) \ + \ \bar{\nu}_h(S) B_j, \end{aligned}$$

where

$$\bar{\nu}_h(S) \stackrel{\text{def}}{=} \limsup_{\delta \to 0} \bar{\nu}_h(\delta, S).$$

Note that from the fact that $\bar{\nu}_h(\delta, S) \to 0$ as $\delta \to 0$ and $S \to \infty$ it follows that $\bar{\nu}_h(S) \to 0$ as $S \to \infty$. Since γ is an arbitrary element of W, one can conclude that

$$\bigcup_{\gamma \in W} \left\{ \int_{U \times Y} h(u, y) \gamma(du, dy) \right\} \ \subset \ \bar{co} V_h(S, Y) \ + \ \bar{\nu}_h(S) B_j. \tag{5.23}$$

The set $V_h(S,Y)$ allows the representation

$$V_h(S,Y) \;=\; \bigcup_{\gamma\in\Gamma(S,Y)}\Big\{\int_{U\times Y} h(u,y)\gamma(du,dy)\Big\}.$$

Hence,

$$\bar{co}V_h(S,Y) = \bar{co}\bigcup_{\gamma\in\Gamma(S,Y)}\Big\{\int_{U\times Y} h(u,y)\gamma(du,dy)\Big\}$$

$$= \bigcup_{\gamma\in\bar{co}\Gamma(S,Y)}\Big\{\int_{U\times Y} h(u,y)\gamma(du,dy)\Big\}.$$

That is, (5.23) can be rewritten in the form

$$\bigcup_{\gamma\in W}\Big\{\int_{U\times Y} h(u,y)\gamma(du,dy)\Big\} \;\subset\; \bigcup_{\gamma\in\bar{co}\Gamma(S,Y)}\Big\{\int_{U\times Y} h(u,y)\gamma(du,dy)\Big\} \;+\; \bar{\nu}_h(S)B_j.$$

Since it is true for any $h(u,y)$ as in (4.1), the validity of (5.1), with some $\bar{\nu}(S)$ tending to zero as S tends to infinity, follows from Lemma 3.5 in [25]. This completes the proof of Theorem 2.1(i). □

Proof of Theorem 2.1(ii). If the LOMS Γ exists, then, by (1.4),

$$\rho_H(co\Gamma(S,Y),\Gamma) \;=\; \rho_H(co\Gamma(S,Y),co\Gamma) \;\le\; \rho_H(\Gamma(S,Y),\Gamma) \;\le\; \nu(S),$$

where $\nu(S)$ is from (2.5). This and (2.7) imply equation (2.8) (because both Γ and W are compact). □

6. Proof of Lemma 5.1. The proof is divided into three steps. First, it is established that the random processes

$$J_i(\tau) \stackrel{\text{def}}{=} y_i(\tau) - \int_0^\tau \bar{F}_i(\lambda(s),y(s))ds\,, \qquad K_i(\tau) \stackrel{\text{def}}{=} y_i^2(\tau) - 2\int_0^\tau y_i(s)\bar{F}_i(\lambda(s),y(s))ds, \tag{6.1}$$

$i=1,\dots,m$, are $\{\mathcal{F}_\tau\}$-martingales, where $y_i(\cdot),\bar{F}_i(\cdot)$, are the ith components of $y(\cdot)$ and $\bar{F}(\cdot)$, respectively. That is, for $\tau>\sigma\ge 0$,

$$E[\,J_i(\tau)\mid\mathcal{F}_\sigma\,] = J_i(\sigma), \qquad E[\,K_i(\tau)|\mathcal{F}_\sigma\,] = K_i(\sigma). \tag{6.2}$$

Second, it is shown that the processes $J_i^2(\tau)$, $i=1,\dots,m$, are $\{\mathcal{F}_\tau\}$-martingales. That is, for $\tau>\sigma\ge 0$,

$$E[\,J_i^2(\tau)\mid\mathcal{F}_\sigma\,] = J_i^2(\sigma), \quad i=1,\dots,m. \tag{6.3}$$

Finally, the statement of the lemma is proved on the basis of (6.3).

Let us verify the validity of (6.2). Let $N>0$ and $\psi_N(\theta):[0,\infty)\to[0,\infty)$ be a continuously differentiable function such that

$$\psi_N(\theta)=1 \quad \forall\theta\in[0,N^2]\,, \qquad \psi_N(\theta)=0 \quad \forall\theta\in[N^2+1\,,\infty),$$

and $\psi_N(\theta)\in[0,1]$ $\forall\theta\in(N^2,N^2+1)$. Define $\phi_{i,N}(\cdot)\in\hat{C}^1$ by the equation $\phi_{i,N}(y)\stackrel{\text{def}}{=} y_i\psi_N(||y||^2)$, where $||y||$ is the Euclidean norm of y. Note that $|\phi_{i,N}(y)|\le|y_i|$ and that $\phi_{i,N}(y)=y_i$ for $||y||\le N$.

By condition (b), the process

$$J_{i,N}(\tau) \stackrel{\text{def}}{=} \phi_{i,N}(y(\tau)) - \int_0^\tau \phi'_{i,N}(y(s))^T \bar{F}_i(\lambda(s), y(s))ds$$

is an $\{\mathcal{F}_\tau\}$-martingale. Hence,

$$E[\, J_{i,N}(\tau) \mid \mathcal{F}_\sigma \,] = J_{i,N}(\sigma), \quad \tau > \sigma. \tag{6.4}$$

It can be seen, however, that for N large enough,

$$E[\,|J_{i,N}(\tau) - J_i(\tau)|\,] = E[\,|\phi_{i,N}(y(\tau)) - y_i(\tau)|\,] \le 2E[\,|y_i(\tau)|\chi_{Q_N}(y(\tau))\,]$$

$$\le 2\sqrt{E[\,|y_i(\tau)|^2]}\sqrt{E[\,\chi_{Q_N}(y(\tau))\,]} \le 2\sqrt{E[\,|y_i(\tau)|^2]}\sqrt{\gamma(U \times Q_N)} = 0,$$

where $\chi_{Q_N}(\cdot)$ is the indicator function of the set $Q_N \stackrel{\text{def}}{=} \{y \mid ||y|| > N\}$ and (5.8), (5.11) as well as (5.9) and the fact that $\gamma(U \times Y) = 1$ have been used. Thus, for sufficiently large N, $J_{i,N}(\tau) = J_i(\tau)$ a.s. and, hence, (6.4) implies the validity of the first equation in (6.2). The validity of the second equation in (6.2) is verified in a similar way (by using the test functions $\phi_{i,N}(y) \stackrel{\text{def}}{=} y_i^2\psi_N(||y||^2)$).

Let us now prove (6.3). Using the second equation in (6.2), one can write

$$E[J_i^2(\tau) \mid \mathcal{F}_\sigma] - J_i^2(\sigma) = E[J_i^2(\tau) - K_i(\tau) \mid \mathcal{F}_\sigma] - (J_i^2(\sigma) - K_i(\sigma))$$

$$= E\left[-2\int_0^\tau (y_i(\tau) - y_i(s))\bar{F}_i(\lambda(s), y(s))ds + \left(\int_0^\tau \bar{F}_i(\lambda(s), y(s))ds\right)^2 \mid \mathcal{F}_\sigma\right]$$

$$- \left(-2\int_0^\sigma (y_i(\sigma) - y_i(s))\bar{F}_i(\lambda(s), y(s))ds + \left(\int_0^\sigma \bar{F}_i(\lambda(s), y(s))ds\right)^2\right)$$

$$= E\left[-2(y_i(\tau) - y_i(\sigma))\int_0^\sigma \bar{F}_i(\lambda(s), y(s))ds - 2\int_\sigma^\tau (y_i(\tau) - y_i(s))\bar{F}_i(\lambda(s), y(s))ds \mid \mathcal{F}_\sigma\right]$$

$$+ E\left[2\int_\sigma^\tau \bar{F}_i(\lambda(s), y(s))ds \int_0^\sigma \bar{F}_i(\lambda(s), y(s))ds + \left(\int_\sigma^\tau \bar{F}_i(\lambda(s), y(s))ds\right)^2 \mid \mathcal{F}_\sigma\right].$$

Note that, by the first equation in (6.2),

$$E\left[(y_i(\tau) - y_i(\sigma))\int_0^\sigma \bar{F}_i(\lambda(s), y(s))ds \mid \mathcal{F}_\sigma\right]$$

$$- E\left[\int_\sigma^\tau \bar{F}_i(\lambda(s), y(s))ds \int_0^\sigma \bar{F}_i(\lambda(s), y(s))ds \mid \mathcal{F}_\sigma\right] = 0.$$

Hence, to complete the proof of (6.3), it is now sufficient to show that

$$E\left[\int_\sigma^\tau (y_i(\tau) - y_i(s))\bar{F}_i(\lambda(s), y(s))ds|\mathcal{F}_\sigma\right] = \frac{1}{2}E\left[\left(\int_\sigma^\tau \bar{F}_i(\lambda(s), y(s))ds\right)^2 |\mathcal{F}_\sigma\right]. \tag{6.5}$$

Using again the fact that $J_i(\cdot)$ is a martingale, one can obtain that

$$E\left[\int_\sigma^\tau (y_i(\tau)-y_i(s))\bar{F}_i(\lambda(s),y(s))ds \mid \mathcal{F}_\sigma\right]$$

$$=\int_\sigma^\tau E[\,(y_i(\tau)-y_i(s))\bar{F}_i(\lambda(s),y(s)) \mid \mathcal{F}_\sigma]ds$$

$$=\int_\sigma^\tau E[\,E[\,(y_i(\tau)-y_i(s)) \mid \mathcal{F}_s]\bar{F}_i(\lambda(s),y(s)) \mid \mathcal{F}_\sigma]ds$$

$$=\int_\sigma^\tau E\left[\left(\int_s^\tau \bar{F}_i(\lambda(s'),y(s'))ds'\right)\bar{F}_i(\lambda(s),y(s)) \mid \mathcal{F}_\sigma\right]ds$$

$$=E\left[\int_\sigma^\tau\left(\int_s^\tau \bar{F}_i(\lambda(s'),y(s'))ds'\right)\bar{F}_i(\lambda(s),y(s))ds \mid \mathcal{F}_\sigma\right].$$

Since

$$E\left[\int_\sigma^\tau\left(\int_s^\tau \bar{F}_i(\lambda(s'),y(s'))ds'\right)\bar{F}_i(\lambda(s),y(s))ds \mid \mathcal{F}_\sigma\right]$$

$$=E\left[\int_\sigma^\tau\left(\int_\sigma^s \bar{F}_i(\lambda(s'),y(s'))ds'\right)\bar{F}_i(\lambda(s),y(s))ds \mid \mathcal{F}_\sigma\right]$$

and the sum of the left- and the right-hand sides in the above equation is equal to $E[\,(\int_\sigma^\tau \bar{F}_i(\lambda(s),y(s))ds)^2 \mid \mathcal{F}_\sigma]$, it follows that (6.5) is valid and, thus, (6.3) is established.

From (6.3) and the first equation in (6.2), it follows that, for $\tau>\sigma\ge 0$,

$$E[\,(J_i(\tau)-J_i(\sigma))^2 \mid \mathcal{F}_\sigma]=0 \;\Rightarrow\; E[\,(J_i(\tau)-J_i(\sigma))^2]=0, \tag{6.6}$$

$i=1,\dots,m$. By Kolmogorov's continuity theorem (see, e.g., Theorem 1.10, p. 23 in [35]), there exists a continuous version of the $\mathbb{R}^m$-valued process $J(\cdot)\stackrel{\text{def}}{=}\{J_i(\cdot)\}$, $i=1,\dots,m$. For this version, (6.6) implies that

$$J(\tau)=J(0)\quad\forall\tau\in[0,S],\quad\forall S>0.$$

In accordance with our notation (see (6.1)), the latter is equivalent to

$$y(\tau)=y(0)+\int_0^\tau \bar{F}(\lambda(s),y(s))ds,$$

which, in turn, is equivalent to (5.10). This completes the proof of the lemma. □

Acknowledgment. The author wants to express his gratitude to J.-B. Lasserre for useful discussions enhancing the progress in writing this paper and also to V. Borkar for referring the author to the result of R. H. Stockbridge (see [43]) as well as to some other results in the theory of control martingale problems, which were used in the proof of the main theorem.

BOUNDARY FEEDBACK STABILIZATION OF THE UNDAMPED EULER–BERNOULLI BEAM WITH BOTH ENDS FREE*

FAMING GUO† AND FALUN HUANG‡

Abstract. In this paper, we are concerned with a boundary feedback system of a class of nonuniform undamped Euler–Bernoulli beam with both ends free. We give some sufficient conditions and some necessary conditions for the system to have exponential stability. Our method is based on the operator semigroup technique, the multiplier technique, and the contradiction argument of the frequency domain method.

Key words. C_0-semigroup, Euler–Bernoulli beam, exponential stability, multiplier technique, frequency domain method

1. Introduction. The exponential stability of the boundary feedback system of an Euler–Bernoulli beam with one or two ends fixed has been studied extensively during the past two decades, but little attention has been paid to the case of the beam with both ends free. However, a long and thin object flying in the sky can be considered as a elastic beam with both ends free, and the boundary feedback stabilization of this beam is of great interest, both in control theory and in engineering practice. In this paper we shall consider this kind of problem. More precisely, we consider a undamped nonuniform Euler–Bernoulli beam of length L with both ends free, and its transverse vibration can be described by the following boundary feedback system:

(1.1)
$$\begin{cases} \rho(x)\dfrac{\partial^2}{\partial t^2}\omega(x,t) + \dfrac{\partial^2}{\partial x^2}\left(EI(x)\dfrac{\partial^2}{\partial x^2}\omega(x,t)\right) = 0, & (x,t)\in(0,L)\times R^+, \\ EI(x)\dfrac{\partial^2}{\partial x^2}\omega(x,t)\Big|_{x=L} = -\dfrac{\partial}{\partial x}\left(EI(x)\dfrac{\partial^2}{\partial x^2}\omega(x,t)\right)\Big|_{x=L} = 0, & t\in R^+, \\ EI(x)\dfrac{\partial^2}{\partial x^2}\omega(x,t)\Big|_{x=0} = k_1\dfrac{\partial}{\partial x}\omega(0,t) + k_2\dfrac{\partial^2}{\partial t\partial x}\omega(0,t), & t\in R^+, \\ -\dfrac{\partial}{\partial x}\left(EI(x)\dfrac{\partial^2}{\partial x^2}\omega\right)\Big|_{x=0} = k_3\omega(0,t) + k_4\dfrac{\partial}{\partial t}\omega(0,t), & t\in R^+, \\ \omega(x,0) = \omega_0(x), \quad \dfrac{\partial}{\partial t}\omega(x,0) = \omega_1(x), & x\in(0,L), \end{cases}$$

where $\omega(x,t)$ denotes the transverse displacement of the beam at position x and time t, $\rho(x)$ its mass density at position x, $EI(x)$ its flexural rigidity, and $k_j \geq 0$ $(j = 1,2,3,4)$ the feedback coefficients. The bending moment at $x = 0$, $EI\frac{\partial^2}{\partial x^2}\omega|_{x=0}$, is controlled by the linear feedback of rotation angle and angular velocity, and the shear force at $x = 0$, $-\frac{\partial}{\partial x}\big(EI\frac{\partial^2}{\partial x^2}\omega\big)|_{x=0}$, is controlled by the linear feedback of displacement and velocity. We refer to [3], [5], [6], and [30] for the precise description of the problem and for more technical details.

In this paper we are interested in the following feedback stabilization problem: *Under what conditions on k_j $(j = 1,2,3,4)$, does the energy $E(t)$ (see* (2.2) *for its definition) of the system* (1.1) *exponentially decay?*

In 1980 a class of Euler–Bernoulli beams with structural damping was proposed for large flexible structures by Chen and Russell [6] and Russell [14], and the exponential stability of an Euler–Bernoulli beam with structural damping has been discussed at length, beginning with [6] by Chen and Russell and continuing with the more general results [13], [14] by Huang. We refer to Chen et al. [4] and Kim [15] for the beam with viscous damping, and to Chen, Liu, and Liu [7] and Liu and Liu [23], [24] for the beam with Kelvin–Voigt damping. For the boundary feedback stabilization of an undamped Euler–Bernoulli beam that is clamped at one end and free at the other end, Littman and Markus [22] proved the strong stabilization together with the lack of exponential stabilization under velocity feedback (also see Rao [27]); Conrad and Morgül [9] used the energy multiplier method to show the exponential stabilization under linear boundary feedback control $(-\alpha\omega_t(1,t)+\omega_{xxxt}(1,t))$. More recently, Guo [11] obtained the exponential stabilization of the nonuniform Euler–Bernoulli beam under linear boundary feedback control by the Riesz basis approach. See references therein for further articles.

In the literature, various techniques have been developed to address the stabilization/controllability problem for distributed parameter systems. The spectral method is a useful method for the one space dimensional problem (see Guo [11]). For the high dimensional system with constant coefficients, the Hilbert uniqueness method (HUM), introduced by Lions in [21], is a powerful tool. For the counterpart with variable coefficients, Yao [31] has introduced the Riemann geometry method. We refer to Bardos, Lebeau, and Rauch [2], Fursikov and Imanuvilov [10], and Zhang [32] for other related methods.

However, the known methods are not easily adapted to our stabilization problem. Indeed, in system (1.1), the beam equation uses variable coefficients, both ends of the beam are free, and the boundary conditions are more complex than those in the literature. These restrictions certainly introduce some technical difficulties. Therefore, we need to develop a new method to solve our problem. Our approach is based on the operator semigroup technique, the multiplier technique with the contradiction argument of a frequency domain method. Recall that multiplier techniques were developed in the work of Lions [21], Lagnese [18], Komornik [16], [17], Lasieka [19], Lasieka and Triggiani [20], and Zuazua [33], [34] for various PDEs and control problems. On the other hand, the frequency domain method is based on the boundedness on the imaginary axis of the resolvent of a C_0-semigroup generator to establish the exponential stability of the C_0-semigroup on a Hilbert space (see Huang [12] and Prüss [26]).

This paper is organized as follows. In section 2, we will state our main results. In section 3, we show the well-posedness of the system and derive some spectral properties of the underlying semigroup. Finally, in sections 4 and 5, we will prove our main results.

2. Statement of the main results. Throughout this paper, we need the following natural hypothesis:

$$\rho(\cdot) \in C^1[0,L], \quad EI(\cdot) \in C^2[0,L]; \quad \rho(x) > 0, \quad EI(x) > 0, \quad x \in [0,L]. \tag{2.1}$$

Denote the energy of system (1.1) by

$$E(t) = \frac{1}{2}\left[\int_0^L \left(EI\left|\frac{\partial^2}{\partial x^2}\omega\right|^2 + \rho\left|\frac{\partial}{\partial t}\omega\right|^2\right)dx + k_1\left|\frac{\partial}{\partial x}\omega(0,t)\right|^2 + k_3|\omega(0,t)|^2\right], \tag{2.2}$$

where $k_1|\frac{\partial}{\partial x}\omega(0,t)|^2 + k_3|\omega(0,t)|^2$ represents the energy of the rigid motion of the elastic system. Simple calculations yield that

$$\begin{aligned}\frac{d}{dt}E(t) = &\int_0^L \left[EI\frac{\partial^2}{\partial x^2}\omega\frac{\partial^3}{\partial t\partial x^2}\omega + \rho\frac{\partial}{\partial t}\omega\frac{\partial^2}{\partial t^2}\omega\right]dx \\ &+ k_1\frac{\partial}{\partial x}\omega(0,t)\frac{\partial^2}{\partial t\partial x}\omega(0,t) + k_3\omega(0,t)\frac{\partial}{\partial t}\omega(0,t)\end{aligned} \tag{2.3}$$

and

$$\begin{aligned}\int_0^L \rho\frac{\partial}{\partial t}\omega\frac{\partial^2}{\partial t^2}\omega dx &= -\int_0^L \frac{\partial}{\partial t}\omega\frac{\partial^2}{\partial x^2}\left(EI\frac{\partial^2}{\partial x^2}\omega\right)dx \\ &= -\frac{\partial}{\partial t}\omega(0,t)\left(k_3\omega(0,t) + k_4\frac{\partial}{\partial t}\omega(0,t)\right) \\ &\quad + \int_0^L \frac{\partial^2}{\partial t\partial x}\omega\frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\omega\right)dx \\ &= -\frac{\partial}{\partial t}\omega(0,t)\left(k_3\omega(0,t) + k_4\frac{\partial}{\partial t}\omega(0,t)\right) \\ &\quad - \frac{\partial^2}{\partial t\partial x}\omega(0,t)\left(k_1\frac{\partial}{\partial x}\omega(0,t) + k_2\frac{\partial^2}{\partial t\partial x}\omega(0,t)\right) \\ &\quad - \int_0^L \frac{\partial^3}{\partial t\partial x^2}\omega\left(EI\frac{\partial^2}{\partial x^2}\omega\right)dx.\end{aligned} \tag{2.4}$$

From (2.3) and (2.4) we obtain

$$\frac{d}{dt}E(t) = -k_4\left|\frac{\partial}{\partial t}\omega(0.t)\right|^2 - k_2\left|\frac{\partial^2}{\partial t\partial x}\omega(0,t)\right|^2, \tag{2.5}$$

which means that $k_2 \geq 0$ and $k_4 \geq 0$ are necessary for the energy $E(t)$ to be not increasing.

It is easy to see that $k_1 \neq 0$ and $k_3 \neq 0$ are necessary for the energy $E(t)$ to uniformly exponentially decay. In fact, if $k_1 = 0$, then the beam can be rotated rigidly, and $\omega(x,t) = x, x \in [0,L]$ is an eigenvector belonging to eigenvector $\lambda = 0$. Likewise, if $k_3 = 0$, then the beam can be translated rigidly, and $\omega(x,t) \equiv 1, x \in [0,L]$ is an eigenvector belonging to eigenvalue $\lambda = 0$.

For simplicity, we will denote $\frac{\partial}{\partial x}u$ and $\frac{\partial}{\partial t}u$ by u' and $\dot{u}$, respectively. Let $H = L^2_\rho(0,L)$ with the norm $\|u\| = (\int_0^L \rho(x)|u(x)|^2dx)^{\frac{1}{2}}$ and $H^k = H^k(0,L), k \geq 1$, where $H^k(0,L)$ is the Sobolev space of order k, and let $H_E = H^2(0,L)$ with the equivalent norm

$$\|u\|_{H_E} = \left(k_1|u'(0)|^2 + k_3|u(0)|^2 + \int_0^L EI|u''|^2dx\right)^{\frac{1}{2}} \quad (k_1, k_3 > 0).$$

Define $\mathcal{H} = H_E \oplus H$ with the norm

$$\|(u,v)\|_{\mathcal{H}} = (\|u\|^2_{H_E} + \|v\|^2_H)^{\frac{1}{2}}.$$

To formulate (1.1) as an abstract Cauchy problem on $\mathcal{H}$, we define a linear operator $\mathcal{A}$ as follows:

$$D(\mathcal{A}) = \Bigg\{(u,v) \in H^4 \oplus H^2| \quad EI\frac{d^2}{dx^2}u \in H^2,\, EI\frac{d^2}{dx^2}u\bigg|_{x=L} = -\frac{d}{dx}\left(EI\frac{d^2}{dx^2}u\right)\bigg|_{x=L} = 0,$$

$$EI\frac{d^2}{dx^2}u\bigg|_{x=0} = k_1u'(0) + k_2v'(0), -\frac{d}{dx}\left(EI\frac{d^2}{dx^2}u\right)\bigg|_{x=0} = k_3u(0) + k_4v(0)\Bigg\} \tag{2.6}$$

and

$$\mathcal{A}\begin{pmatrix}u\\v\end{pmatrix} = \begin{pmatrix}0 & I\\ -A & 0\end{pmatrix}\begin{pmatrix}u\\v\end{pmatrix}, \quad (u,v) \in D(\mathcal{A}), \tag{2.7}$$

where

$$A = \rho^{-1}\frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}\cdot\right)$$

and $D(A) = \{u \in H^2|$ there exists $v \in H^2$ such that $(u,v) \in D(\mathcal{A})\}$. Then the system (1.1) can be formulated as the following Cauchy problem on $\mathcal{H}$:

$$\begin{pmatrix}\dot{u}\\ \dot{v}\end{pmatrix} = \mathcal{A}\begin{pmatrix}u\\v\end{pmatrix}, \quad \begin{pmatrix}u(0)\\v(0)\end{pmatrix} = \begin{pmatrix}w_0\\w_1\end{pmatrix}.$$

Now we can state our main results as follows.

THEOREM 2.1. *Let* (2.1) *hold and* $k_j > 0, j = 1,2,3,4$. *Then the* C_0*-semigroup* $e^{t\mathcal{A}}$ *is uniformly exponentially stable; i.e., there exist constants* $M, \omega > 0$ *such that*

$$\|e^{t\mathcal{A}}\| \leq Me^{-\omega t}, \quad t \geq 0.$$

THEOREM 2.2. *Assume that* $k_1, k_3 > 0$ *and that the* C_0*-semigroup* $e^{t\mathcal{A}}$ *decays uniformly exponentially. Then* $k_2 > 0$ *and* $k_4 > 0$.

3. Preliminaries. In this section, we will prove that $(\mathcal{A}, D(\mathcal{A}))$ generates a C_0-contraction semigroup on $\mathcal{H}$, which shows the well-posedness of system (1.1), and give some spectral properties of the generator $\mathcal{A}$.

THEOREM 3.1. *Let $k_1, k_2, k_3, k_4 > 0$. Then $\mathcal{A}$ is the infinitesimal generator of a C_0-contraction semigroup $e^{t\mathcal{A}}$ on $\mathcal{H}$.*

Proof. It is easy to see that $\mathcal{A}$ is densely defined in $\mathcal{H}$. Furthermore, for any $(u, v) \in D(\mathcal{A})$, we have

$$\begin{aligned} \operatorname{Re}\left\langle \mathcal{A}\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle_{\mathcal{H}} &= \operatorname{Re}\left\langle \begin{pmatrix} v \\ -Au \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle_{\mathcal{H}} \\ &= \operatorname{Re}[\langle v, u\rangle_{H_E} - \langle Au, v\rangle_H], \end{aligned} \tag{3.1}$$

where

$$(v, u)_{H_E} = k_1 v'(0)\overline{u'(0)} + k_3 v(0)\overline{u(0)} + \int_0^L EIv''(x)\overline{u''(x)}dx \tag{3.2}$$

and

$$\begin{aligned} (Au, v)_H &= \int_0^L \frac{d^2}{dx^2}(EIu'')\overline{v}dx \\ &= k_3 u(0)\overline{v(0)} + k_4|v(0)|^2 + k_1 u'(0)\overline{v'(0)} + k_2|v'(0)|^2 + \int_0^L EIu''\overline{v''}dx. \end{aligned} \tag{3.3}$$

Substituting (3.2) and (3.3) into (3.1), we obtain

$$\operatorname{Re}\left\langle \mathcal{A}\begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle_{\mathcal{H}} = -k_4|v(0)|^2 - k_2|v'(0)|^2,$$

which implies that $\mathcal{A}$ is dissipative in $\mathcal{H}$.

Finally, we show that $\lambda = 0 \in \rho(\mathcal{A})$ (the resolvent set of $\mathcal{A}$). For any $(f, g) \in \mathcal{H}$, we are going to solve the following equation:

$$\mathcal{A}\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} f \\ g \end{pmatrix}, \quad (u, v) \in D(\mathcal{A}). \tag{3.4}$$

This implies

$$\begin{cases} v &= f, \\ Au &= -g, \end{cases} \tag{3.5}$$

and hence

$$\frac{d^2}{dx^2}(EIu'') = -\rho g. \tag{3.6}$$

Integrating from x to L and using the boundary conditions at $x = L$, we have

$$\frac{d}{dx}(EIu'') = \int_x^L \rho(z)g(z)dz, \tag{3.7}$$

and consequently,

$$EIu'' = -\int_x^L \int_y^L \rho(z)g(z)dzdy, \tag{3.8}$$

or equivalently,

$$u''(x) = -\frac{1}{EI(x)} \int_x^L \int_y^L \rho(z)g(z)dzdy, \quad x \in [0, L]. \tag{3.9}$$

Therefore, we have

$$u(x) = u(0) + xu'(0) - \int_0^x \int_0^y \frac{1}{EI(y_1)} \int_{y_1}^L \int_{y_2}^L \rho(z)g(z)dzdy_2dy_1dy, \quad x \in [0, L]. \tag{3.10}$$

Let $x = 0$ in (3.7); we can obtain

$$-(k_3u(0) + k_4v(0)) = \int_0^L \rho(z)g(z)dz,$$

which, using (3.5), yields

$$u(0) = -\frac{1}{k_3} \left(k_4 f(0) + \int_0^L \rho(z)g(z)dz \right). \tag{3.11}$$

Similarly, let $x = 0$ in (3.8); we have

$$u'(0) = -\frac{1}{k_1} \left(k_2 f'(0) + \int_0^L \int_y^L \rho(z)g(z)dzdy \right). \tag{3.12}$$

From (3.10), (3.11), and (3.12) we can assert that

$$u(x) = -\frac{1}{k_3} \left[k_4 f(0) + \int_0^L \rho(z)g(z)dz - \frac{x}{k_1} \left(k_2 f'(0) + \int_0^L \int_y^L \rho(z)g(z)dzdy \right) \right]$$

$$- \int_0^x \int_0^y \frac{1}{EI(y_2)} \int_{y_2}^L \int_{y_3}^L \rho(z)g(z)dzdy_3dy_2dy_1, \qquad x \in [0, L]. \tag{3.13}$$

Since hypothesis (2.1) is satisfied, we can easily deduce that $u \in H^2$ and that $(u, v) \in D(\mathcal{A})$ is the unique solution of (3.4) ($v = f$). Hence, $\lambda = 0 \in \rho(\mathcal{A})$. Finally, from the above discussion and the Lumer–Phillips theorem [25, Theorem 1.4.3], it follows that $\mathcal{A}$ generates a C_0-contraction semigroup. The proof has been completed. □

PROPOSITION 3.2. *Assume that $k_j > 0$, $j = 1, 2, 3, 4$. Then $iR \subset \rho(\mathcal{A})$.*

Proof. From the proof of Theorem 3.1 we have $\lambda = 0 \in \rho(\mathcal{A})$ and we can prove

$$\{\lambda \in \sigma(\mathcal{A}) : \mathrm{Im}\lambda \neq 0\} \subset \sigma_p(A)$$

in a similar way as in [7, Lemma 4.1]. Therefore it suffices to show $i\omega \notin \sigma_p(\mathcal{A})$. Indeed, if it is not true, then there exists $\omega \in R$, $\omega \neq 0$, such that $i\omega \in \sigma_p(\mathcal{A})$. Hence, there exists $(u, v) \in D(\mathcal{A})$, $(u, v) \neq 0$, such that

$$(i\omega - \mathcal{A}) \begin{pmatrix} u \\ v \end{pmatrix} = 0,$$

which implies

$$i\omega u = v \tag{3.14}$$

and

$$Au + i\omega v = 0. \tag{3.15}$$

From (3.14) and (3.15) it follows that

$$\frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}u\right) - \omega^2\rho u = 0, \tag{3.16}$$

and consequently,

$$\begin{aligned}
0 &= \int_0^L \frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}u\right)\overline{u}dx - \omega^2\int_0^L \rho|u|^2dx \\
&= k_3|u(0)|^2 + i\omega k_4|u(0)|^2 - \int_0^L \frac{d}{dx}\left(EI\frac{d^2}{dx^2}u\right)\frac{d}{dx}\overline{u}dx - \omega^2\int_0^L \rho|u|^2dx \\
&= k_3|u(0)|^2 + i\omega k_4|u(0)|^2 + k_1\left|\frac{d}{dx}u(0)\right|^2 + i\omega k_2\left|\frac{d}{dx}u(0)\right|^2 \\
&\quad + \int_0^L EI\left|\frac{d^2}{dx^2}u\right|^2 dx - \omega^2\int_0^L \rho|u|^2dx.
\end{aligned}$$

Using $\omega \neq 0$, we conclude that

$$\begin{cases}
k_3|u(0)|^2 + k_1\left|\dfrac{d}{dx}u(0)\right|^2 + \displaystyle\int_0^L EI\left|\frac{d^2}{dx^2}u\right|^2 dx - \omega^2\int_0^L \rho|u|^2dx = 0, \\
k_4|u(0)|^2 + k_2\left|\dfrac{d}{dx}u(0)\right|^2 = 0.
\end{cases} \tag{3.17}$$

Since hypothesis (2.1) is satisfied, we have $u \in H^4[0,L]$ and hence $u \in C^3[0,L]$. Moreover, it follows from (3.17) that

$$\begin{cases}
u(0) = u'(0) = 0, \\
\displaystyle\int_0^L EI|u''|^2dx = \omega^2\int_0^L \rho|u|^2dx,
\end{cases} \tag{3.18}$$

which implies that

$$v(0) = v'(0) = 0.$$

Therefore, using the boundary conditions at $x = 0$, we get

$$EI(0)u''(0) = k_1u(0) + k_2v(0) = 0$$

and

$$(EIu'')'|_{x=0} = EI'(0)u''(0) + EI(0)u'''(0) = k_3u'(0) + k_4v'(0) = 0,$$

which, together with $EI(0) > 0$, implies that

$$u''(0) = u'''(0) = 0. \tag{3.19}$$

From (3.18) and (3.19), it follows that u is a solution of the following equation:

$$\begin{cases} \dfrac{d^2}{dx^2}\left(EI\dfrac{d^2}{dx^2}u\right) - \omega^2\rho u = 0, \\ \\ u(0) = u'(0) = u''(0) = u'''(0) = 0. \end{cases} \tag{3.20}$$

The uniqueness theorem of ODEs shows that $u \equiv 0$ and $v = i\omega\rho u \equiv 0$. This is in contradiction with $(u, v) \neq 0$, and the proof is completed. □

4. Proof of Theorem 2.1. Clearly, if $w = w(x, t)$ is the solution of the system (1.1), then

$$\left(w, \frac{\partial}{\partial t}w\right) = e^{t\mathcal{A}}(w_0, w_1) \quad \text{and} \quad \left\|\left(w, \frac{\partial}{\partial t}w\right)\right\|_{\mathcal{H}}^2 = 2E(t), \qquad t > 0.$$

Hence, the uniformly exponential decay of the energy $E(t)$ is equivalent to the uniform exponential stability of C_0-semigroup $e^{t\mathcal{A}}$. It follows from Proposition 3.2 and the frequency domain results (see [12], [26]) that we need only to prove

$$\sup_{\lambda \in iR} \|(\lambda - \mathcal{A})^{-1}\| < +\infty. \tag{4.1}$$

If (4.1) is not true, using $iR \subset \rho(\mathcal{A})$, then we can deduce that there exist $\lambda_n = i\omega_n \in iR, (u_n, v_n) \in D(\mathcal{A})$ such that

$$\|(u_n, v_n)\|_{\mathcal{H}} = 1, \quad |\omega_n| \to \infty (n \to \infty) \tag{4.2}$$

and

$$(i\omega_n - \mathcal{A})(u_n, v_n) = (f_n, g_n) \to 0 \quad \text{in} \quad \mathcal{H}. \tag{4.3}$$

From (4.3), it follows that

$$i\omega_n u_n - v_n = f_n \to 0 \quad \text{in} \quad H_E, \tag{4.4}$$

$$\frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}u_n\right) + i\omega_n\rho v_n = \rho g_n \to 0 \quad \text{in} \quad H. \tag{4.5}$$

By (4.4), we have

$$\|f_n\|_{H_E}^2 = k_1|f_n'(0)|^2 + k_3|f_n(0)|^2 + \int_0^L EI|f_n''|^2 dx \to 0,$$

which yields that

$$f_n'(0) \to 0, \quad f_n(0) \to 0. \tag{4.6}$$

Again by (4.4), we have that $(f_n, u_n)_H = i\omega_n\|u_n\|_H^2 - (v_n, u_n)_H \to 0$, and consequently,

$$\|u_n\|_H^2 = \frac{1}{i\omega_n}[(f_n, u_n)_H + (v_n, u_n)_H] \to 0. \tag{4.7}$$

Moreover, we have

$$\begin{aligned}
(g_n, u_n)_H &= \int_0^L \frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}u_n\right)\overline{u_n}dx + i\omega_n\int_0^L \rho v_n\overline{u_n}dx \\
&= k_3|u_n(0)|^2 + k_4 v_n(0)\overline{u_n(0)} - \int_0^L \frac{d}{dx}\left(EI\frac{d^2}{dx^2}u_n\right)\overline{u_n'}dx + i\omega_n(v_n,u_n)_H \\
&= k_3|u_n(0)|^2 + k_4 v_n(0)\overline{u_n(0)} + k_1|u_n'(0)|^2 \\
&\qquad + k_2 v_n'(0)\overline{u_n'(0)} + \int_0^L EI|u_n''|^2dx + i\omega_n(v_n,u_n)_H \\
&= \|u_n\|_{H_E}^2 + k_4(i\omega_n u_n(0) - f_n(0))\overline{u_n(0)} \\
&\qquad + k_2(i\omega_n u_n'(0) - f_n'(0))\overline{u_n'(0)} + i\omega_n(v_n,u_n)_H \\
&= \|u_n\|_{H_E}^2 + k_4 i\omega_n|u_n(0)|^2 + k_2 i\omega_n|u_n'(0)|^2 \\
&\qquad - k_4 f_n(0)\overline{u_n(0)} - k_2 f_n'(0)\overline{u_n'(0)} + i\omega_n(v_n,u_n)_H \\
&\to 0. \qquad (4.8)
\end{aligned}$$

Therefore, from (4.6), (4.8), $\mathrm{Re}(v_n,u_n)_H \to 0$, and $|\omega_n| \to 0$, we can deduce that

$$u_n(0) \to 0, \quad u_n'(0) \to 0. \qquad (4.9)$$

From (4.4), it follows that

$$(f_n,u_n)_{H_E} = (i\omega_n u_n - v_n, u_n)_{H_E} = i\omega_n\|u_n\|_{H_E}^2 - \overline{(u_n,v_n)}_{H_E} \to 0,$$

and consequently,

$$\mathrm{Re}(u_n,v_n)_{H_E} \to 0, \quad \|u_n\|_{H_E}^2 + \mathrm{Im}\left(u_n, \frac{v_n}{\omega_n}\right)_{H_E} \to 0. \qquad (4.10)$$

Since

$$\begin{aligned}
&\left(\rho^{-1}\left[\frac{d^2}{dx^2}\left(EI\frac{d^2}{dx^2}u_n\right) + i\omega_n v_n\right], v_n\right)_H \qquad (4.11)\\
&\quad = (u_n,v_n)_{H_E} + k_4|v_n(0)|^2 + k_2|v_n'(0)|^2 + i\omega_n\|v_n\|_H^2 \to 0,
\end{aligned}$$

we can easily deduce that

$$\mathrm{Re}(u_n,v_n)_{H_E} + k_4|v_n(0)|^2 + k_2|v_n'(0)|^2 \to 0.$$

Combining this together with (4.10), we get

$$v_n(0) \to 0, \quad v_n'(0) \to 0. \qquad (4.12)$$

Without loss of generality, let $\|v_n\|^2 \to \gamma \in [0,1]$; we obtain that $\|u_n\|_{H_E}^2 \to 1-\gamma$. From (4.11) it follows that

$$\mathrm{Im}\left(u_n, \frac{v_n}{\omega_n}\right)_{H_E} + \|v_n\|_H^2 \to 0; \qquad (4.13)$$

combining this with (4.10) implies $\gamma = \frac{1}{2}$.

Furthermore, if

$$\begin{pmatrix}\xi_n(x,t)\\ \eta_n(x,t)\end{pmatrix} = e^{t\mathcal{A}}\begin{pmatrix}u_n(x)\\ v_n(x)\end{pmatrix},$$

then

$$\begin{aligned}\left\|\begin{pmatrix}\xi_n(.,t)\\ \eta_n(.,t)\end{pmatrix} - e^{t\omega_n i}\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}} &= \left\|e^{t(\mathcal{A}-i\omega_n)}\begin{pmatrix}u_n\\ v_n\end{pmatrix} - \begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}}\\ &= \left\|\int_0^t e^{\tau(\mathcal{A}-i\omega_n)}(\mathcal{A}-i\omega_n I)\begin{pmatrix}u_n\\ v_n\end{pmatrix} d\tau\right\|_{\mathcal{H}}\\ &\le \int_0^t \|e^{\tau(\mathcal{A}-i\omega_n)}\| \left\|(\mathcal{A}-i\omega_n I)\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}} d\tau\\ &\le t\left\|(\mathcal{A}-i\omega_n)\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}}.\end{aligned}$$

Therefore, we deduce that

$$\sup_{t\in[0,T]}\left\|\begin{pmatrix}\xi_n(.,t)\\ \eta_n(.,t)\end{pmatrix} - e^{i\omega_n t}\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}} \to 0 \tag{4.14}$$

for any $T>0$. Note that $|e^{i\omega_n t}u_n(0)| = |u_n(0)| \to 0$ and $|e^{i\omega_n t}u_n'(0)| = |u_n'(0)| \to 0$; together with the definition of $\|(.,.)\|_{\mathcal{H}}$ and (4.9), we can assert that

$$\xi_n(0,t)\to 0, \quad \frac{\partial}{\partial x}\xi_n(0,t)\to 0 \tag{4.15}$$

uniformly for t in compact intervals of R^+.

On the other hand, we have

$$\begin{aligned}\left\|\begin{pmatrix} i\omega_n\xi_n-\eta_n\\ \rho^{-1}\frac{\partial^2}{\partial x^2}(EI\frac{\partial^2}{\partial x^2}\xi_n)+i\omega_n\eta_n\end{pmatrix}\right\|_{\mathcal{H}} &= \left\|(i\omega_n-\mathcal{A})\begin{pmatrix}\xi_n\\ \eta_n\end{pmatrix}\right\|_{\mathcal{H}}\\ &= \left\|(i\omega_n-\mathcal{A})e^{t\mathcal{A}}\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}}\\ &= \left\|e^{t\mathcal{A}}(i\omega_n-\mathcal{A})\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}}\\ &\le \left\|(i\omega_n-\mathcal{A})\begin{pmatrix}u_n\\ v_n\end{pmatrix}\right\|_{\mathcal{H}} \to 0\end{aligned} \tag{4.16}$$

uniformly for $t\in[0,\infty)$. Therefore,

$$(i\omega_n\xi_n-\eta_n,\xi_n)_{H_E} = i\omega_n\|\xi_n\|_{H_E} - \overline{(\xi_n,\eta_n)} \to 0$$

uniformly for $t\in[0,\infty)$. This yields

$$\mathrm{Re}(\xi_n,\eta_n)_{H_E}\to 0 \quad \text{uniformly for} \quad t\in[0,\infty).$$

Similar to (4.11), we can get

$$\begin{aligned}&\left(\rho^{-1}\frac{\partial^2}{\partial x^2}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)+i\omega_n\eta_n,\eta_n\right)_H\\ &\quad= (\xi_n,\eta_n)_{H_E} + k_4|\eta_n(0,t)|^2 + k_2|\eta_n'(0,t)|^2 + i\omega_n\|\eta_n\|_H^2 \to 0\end{aligned}$$

uniformly for t in compact intervals of R^+, and consequently,

$$\eta_n(0,t) \to 0, \qquad \eta_n'(0,t) \to 0 \tag{4.17}$$

uniformly for t in compact intervals of R^+. Since $(\xi_n, \eta_n) \in D(\mathcal{A})$, using (4.15) and (4.16), we obtain

$$EI(0)\frac{\partial^2}{\partial x^2}\xi_n(0,t) = k_1\xi_n'(0,t) + k_2\eta_n'(0,t) \to 0$$

and

$$\begin{aligned} -\frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)\Big|_{x=0} &= \frac{d}{dx}EI(0)\frac{\partial^2}{\partial x^2}\xi_n(0,t) + EI(0)\frac{\partial^3}{\partial x^3}\xi_n(0,t) \\ &= k_3\xi_n(0,t) + k_4\eta_n(0,t) \to 0 \end{aligned}$$

uniformly for t in compact intervals of R^+. Hence

$$\frac{\partial^2}{\partial x^2}\xi_n(0,t) \to 0, \qquad \frac{\partial^3}{\partial x^3}\xi_n(0,t) \to 0 \tag{4.18}$$

uniformly for t in compact intervals of R^+. Moreover,

$$\begin{aligned} &EI(L)\frac{\partial^2}{\partial x^2}\xi_n(L,t) = 0, \\ &-\frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\xi_n(x,t)\right)\Big|_{x=L} = \left(\frac{\partial}{\partial x}EI\frac{\partial^2}{\partial x^2}\xi_n(x,t) + EI\frac{\partial^3}{\partial x^3}\xi_n(x,t)\right)\Big|_{x=L} = 0, \end{aligned}$$

which implies that

$$\frac{\partial^2}{\partial x^2}\xi_n(L,t) = 0, \qquad \frac{\partial^3}{\partial x^3}\xi_n(L,t) = 0, \quad t > 0. \tag{4.19}$$

Furthermore, it follows from (4.16) that

$$i\omega_n\xi_n - \eta_n = h_n \to 0$$

in H_E uniformly for t, and hence, it holds in H. Therefore,

$$\xi_n(.,t) = \frac{1}{i\omega_n}(h_n + \eta_n) \to 0 \tag{4.20}$$

in H uniformly for t.

Now let $M\xi = 2(x-L)e^{-\theta x}\frac{\partial}{\partial x}\xi$, where θ is such a positive constant that $\theta\rho - \rho' \geq 0$ and $3\theta EI + (EI)' \geq 0$. It is easy to see that hypothesis (2.1) guarantees the existence of θ. For $T > 0$, we have

$$\begin{aligned} 0 &= \operatorname{Re}\int_0^T\int_0^L \left[\rho\frac{\partial^2}{\partial t^2}\xi_n + \frac{\partial^2}{\partial x^2}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)\right] M\overline{\xi_n}dxdt \\ &= \operatorname{Re}\left\{\left[\int_0^L \rho\frac{\partial}{\partial t}\xi_n M\overline{\xi_n}dx\right]_0^L - \int_0^T\int_0^L \rho\frac{\partial}{\partial t}\xi_n M\frac{\partial}{\partial t}\overline{\xi_n}dxdt\right. \\ &\quad + \int_0^T\left[\frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)M\overline{\xi_n}\right]_0^L dt - \int_0^T\left[\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)\frac{\partial}{\partial x}M\overline{\xi_n}\right]_0^L dt \\ &\quad \left. + \int_0^T\int_0^L EI\frac{\partial^2}{\partial x^2}\xi_n\frac{\partial^2}{\partial x^2}M\overline{\xi_n}dxdt\right\}. \end{aligned} \tag{4.21}$$

Since

$$\frac{\partial}{\partial t}\xi_n = \eta_n$$

and

$$\mathrm{Re}\left(\rho\frac{\partial}{\partial t}\xi_n M\frac{\partial}{\partial t}\overline{\xi_n}\right) = \mathrm{Re}\left(\rho\frac{\partial}{\partial t}\xi_n 2(x-L)e^{-\theta x}\frac{\partial^2}{\partial x\partial t}\overline{\xi_n}\right) = e^{-\theta x}(x-L)\rho\frac{\partial}{\partial x}|\eta_n|^2,$$

we can deduce

$$\begin{aligned}
&\int_0^T\int_0^L \rho\frac{\partial}{\partial t}\xi_n M\frac{\partial}{\partial t}\overline{\xi_n}dxdt\\
&\quad= \int_0^T\int_0^L (x-L)\rho e^{\theta x}\frac{\partial}{\partial x}|\eta_n|^2 dxdt\\
&\quad= \int_0^T [(x-L)\rho e^{-\theta x}|\eta_n|^2]_0^L dt - \int_0^T\int_0^L e^{-\theta x}[\rho+(L-x)(\theta\rho-\rho')]|\eta_n|^2 dxdt\\
&\quad= \int_0^T L\rho(0)|\eta_n(0,t)|^2 dt - \int_0^T\int_0^L e^{-\theta x}[\rho+(L-x)(\theta\rho-\rho')]|\eta_n|^2 dxdt. \qquad (4.22)
\end{aligned}$$

From the definition of M, we have

$$\begin{aligned}
\frac{\partial^2}{\partial x^2}M\overline{\xi_n} &= \frac{\partial^2}{\partial x^2}\left[2(x-L)e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n}\right]\\
&= \frac{\partial}{\partial x}\left[2e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n} - 2\theta(x-L)e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n} + 2(x-L)e^{-\theta x}\frac{\partial^2}{\partial x^2}\overline{\xi_n}\right]\\
&= -2\theta e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n} + 2e^{-\theta x}\frac{\partial^2}{\partial x^2}\overline{\xi_n} - 2\theta e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n} + 2\theta^2(x-L)e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n}\\
&\quad - 2\theta(x-L)e^{-\theta x}\frac{\partial^2}{\partial x^2}\overline{\xi_n} + 2e^{-\theta x}\frac{\partial^2}{\partial x^2}\overline{\xi_n}\\
&\quad - 2\theta(x-L)e^{-\theta x}\frac{\partial^2}{\partial x^2}\overline{\xi_n} + 2(x-L)e^{-\theta x}\frac{\partial^3}{\partial x^3}\overline{\xi_n}\\
&= -[4\theta+2\theta^2(L-x)]e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n} + 4e^{-\theta x}[1+\theta(L-x)]\frac{\partial^2}{\partial x^2}\overline{\xi_n}\\
&\quad + 2(x-L)e^{-\theta x}\frac{\partial^3}{\partial x^3}\overline{\xi_n}.
\end{aligned}$$

Therefore,

$$\begin{aligned}
\int_0^T\int_0^L EI\frac{\partial^2}{\partial x^2}\xi_n\frac{\partial^2}{\partial x^2}M\overline{\xi_n}dxdt &= -\int_0^T\int_0^L EI\frac{\partial^2}{\partial x^2}\xi_n\ 2\theta[2+\theta(L-x)]e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n}dxdt\\
&\quad + \int_0^T\int_0^L 4e^{-\theta x}[1+\theta(L-x)]EI\left|\frac{\partial^2}{\partial x^2}\xi_n\right|^2 dxdt\\
&\quad + \int_0^T\int_0^L (x-L)e^{-\theta x}EI\frac{\partial}{\partial x}\left|\frac{\partial^2}{\partial x^2}\xi_n\right|^2 dxdt,
\end{aligned}$$

or equivalently,

(4.23)

$$\begin{aligned}
&\int_0^T \int_0^L (x-L)e^{-\theta x} EI \frac{\partial}{\partial x} \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 dxdt \\
&= \int_0^T \left[(x-L)e^{-\theta x} EI \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 \right]_0^L dt - \int_0^T \int_0^L \frac{d}{dx}[(x-L)e^{-\theta x} EI] \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 dxdt \\
&= EI(0)L \int_0^T \left| \frac{\partial^2}{\partial x^2}\xi_n(0,t) \right|^2 dt \\
&\quad - \int_0^T \int_0^L e^{-\theta x}[(1+\theta(L-x))EI - (L-x)(EI)'] \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 dxdt.
\end{aligned}$$

We also have

$$\begin{aligned}
&\int_0^T \int_0^L EI \frac{\partial^2}{\partial x^2}\xi_n \frac{\partial^2}{\partial x^2} M\overline{\xi_n} dxdt \\
&= EI(0)L \int_0^T \left| \frac{\partial^2}{\partial x^2}\xi_n(0,t) \right|^2 dt - \int_0^T \int_0^L \left(EI \frac{\partial^2}{\partial x^2}\xi_n \right) 2\theta(2+\theta(L-x))e^{-\theta x} \frac{\partial}{\partial x}\overline{\xi_n} dxdt \\
&\quad + \int_0^T \int_0^L e^{-\theta x}[3EI + 3\theta(L-x)EI + (L-x)(EI)'] \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 dxdt.
\end{aligned}$$

From (4.21), (4.22), and (4.23), it follows that

$$\begin{aligned}
&e^{-\theta L} \int_0^T \int_0^L \left(EI \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 + \rho|\eta_n|^2 \right) dxdt \\
&\quad \le \int_0^T \int_0^L e^{-\theta x}[3EI + 3\theta(L-x)EI + (L-x)(EI)'] \left| \frac{\partial^2}{\partial x^2}\xi_n \right|^2 dxdt \\
&\qquad + \int_0^T \int_0^L e^{-\theta x}[\rho + (L-x)(\theta\rho - \rho')]|\eta_n|^2 dxdt \\
&\quad = \mathrm{Re} \left\{ - \left[\int_0^L \rho \frac{\partial}{\partial t}\xi_n M\overline{\xi_n} dx \right]_0^T - \int_0^T \left[\frac{\partial}{\partial x} \left(EI \frac{\partial^2}{\partial x^2}\xi_n \right) M\overline{\xi_n} \right]_0^L dt \right. \\
&\qquad\quad + \int_0^T \left[EI \frac{\partial^2}{\partial x^2}\xi_n \frac{\partial}{\partial x} M\overline{\xi_n} \right]_0^L dt \\
&\qquad\quad + \int_0^T L\rho(0)|\eta_n(0,t)|^2 dt - EI(0)L \int_0^T \left| \frac{\partial^2}{\partial x^2}\xi_n(0,t) \right|^2 dt \\
&\qquad\quad \left. + \int_0^T \int_0^L EI \frac{\partial^2}{\partial x^2}\xi_n 2\theta(2+\theta(L-x))e^{-\theta x} \frac{\partial}{\partial x}\overline{\xi_n} dxdt \right\}. \qquad (4.24)
\end{aligned}$$

Finally, we are going to show that the right-hand side of (4.22) converges to zero as $n \to \infty$. Indeed, from (4.15), (4.17), and (4.18), we obtain

$$\int_0^T L\rho(0)|\eta_n(0,t)|^2 dt \to 0, \quad EI(0)L\int_0^T \left|\frac{\partial^2}{\partial x^2}\xi_n(0,t)\right|^2 dt \to 0 \tag{4.25}$$

and

$$\begin{aligned} &-\int_0^T \left[\frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)M\overline{\xi_n}\right]_0^L dt + \int_0^T \left[EI\frac{\partial^2}{\partial x^2}\xi_n\frac{\partial}{\partial x}M\overline{\xi_n}\right]_0^L dt \\ &\quad = \int_0^T \frac{\partial}{\partial x}\left(EI\frac{\partial^2}{\partial x^2}\xi_n\right)\Big|_{x=0}\left(-2L\frac{\partial}{\partial x}\overline{\xi_n(0,t)}\right)dt \\ &\qquad - \int_0^T EI(0)\frac{\partial^2}{\partial x^2}\xi_n(0,t)\left[2(1+L\theta)\frac{\partial}{\partial x}\overline{\xi_n(0,t)} - 2L\frac{\partial^2}{\partial x^2}\overline{\xi_n(0,t)}\right]dt \\ &\qquad \to 0. \end{aligned} \tag{4.26}$$

Since $\|\xi_n(.,t)\|_{H_E} < 1$ and $\|\xi_n(.,t)\|_H \to 0$ uniformly for $t \in [0,T]$, we can easily deduce that

$$\left\|\frac{\partial}{\partial x}\xi_n(0,t)\right\|_H \le C\left\|\frac{\partial^2}{\partial x^2}\xi_n(.,t)\right\|_H^{\frac{1}{2}}\|\xi_n\|_H^{\frac{1}{2}} \to 0 \ \text{ uniformly for } \ t \in [0,T]$$

by the Hardy–Littlewood inequality. Consequently,

$$2\theta\int_0^T\int_0^L EI\frac{\partial^2}{\partial x^2}\xi_n[2+\theta(L-x)]e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n}dxdt \to 0 \tag{4.27}$$

and

$$\int_0^L \rho\frac{\partial}{\partial t}\xi_n M\overline{\xi_n}dx|_0^T = \int_0^L \rho\eta_n 2(x-L)e^{-\theta x}\frac{\partial}{\partial x}\overline{\xi_n}dx|_0^T \to 0. \tag{4.28}$$

Using (4.25)–(4.28), we can assert that the right-hand side of (4.24) converges to zero as $n \to \infty$. Hence

$$\int_0^T\int_0^L \left(EI\left|\frac{\partial^2}{\partial x^2}\xi_n\right|^2 + \rho|\eta_n|^2\right)dxdt \to 0. \tag{4.29}$$

However, using $\|u_n\|_{H_E}^2 + \|v_n\|_H^2 = 1$, it follows from (4.14), (4.15), and (4.17) that

$$\begin{aligned} &\lim_{n\to\infty}\int_0^T\int_0^L \left(EI\left|\frac{\partial^2}{\partial x^2}\xi_n\right|^2 + \rho|\eta_n|^2\right)dxdt \\ &= \lim_{n\to\infty}\int_0^T\int_0^L \left(EI\left|\frac{\partial^2}{\partial x^2}e^{i\omega_n t}u_n\right|^2 + \rho|e^{i\omega_n t}v_n|^2\right)dxdt \\ &= \lim_{n\to\infty}\int_0^T\int_0^L \left(EI\left|\frac{\partial^2}{\partial x^2}u_n\right|^2 + \rho|v_n|^2\right)dxdt = T, \end{aligned}$$

which is in contradiction with (4.29), and the proof is completed. □

5. Proof of Theorem 2.2. First it is impossible that $k_2 = k_4 = 0$. Indeed, it follows from $k_2 = k_4 = 0$ and (2.5) that

$$\begin{aligned} E(t) &= \frac{1}{2}\left\| e^{t\mathcal{A}} \begin{pmatrix} \omega_0 \\ \omega_1 \end{pmatrix} \right\|_{\mathcal{H}}^2 \\ &\equiv E(0) \\ &= \frac{1}{2}\left[\int_0^L \left(EI \left| \frac{d^2}{dx^2}\omega_0 \right|^2 + \rho|\omega_1|^2 \right) dx + k_1|\omega_0'(0)|^2 + k_3|\omega_0(0)|^2 \right], \quad t \geq 0, \end{aligned}$$

for any $(\omega_0, \omega_1) \in D(\mathcal{A})$. Thus the energy $E(t)$ of the system (1.1) does not uniformly exponentially decay.

Next, let $k_2 = 0$ and $k_4 > 0$. We can define

$$H_E^0 = \{u \in H_E |\ u(0) = 0\}, \quad \mathcal{H}^0 = H_E^0 \oplus H, \quad \mathcal{A}^0 = \mathcal{A}|_{\mathcal{H}^0}.$$

That is,

$$D(\mathcal{A}^0) = \{(u, v) \in D(\mathcal{A}) \cap \mathcal{H}^0 |\ \mathcal{A}(u, v) \in \mathcal{H}^0\}$$

and

$$\mathcal{A}^0(u, v) = \mathcal{A}(u, v), \quad (u, v) \in D(\mathcal{A}^0).$$

By the same argument as in the proof of Theorem 3.1, we can conclude that $\mathcal{A}^0$ is dissipative and $0 \in \rho(\mathcal{A}^0)$. Hence, $\mathcal{A}^0$ is m-dissipative and generates a C_0-contraction semigroup $e^{t\mathcal{A}^0}$. Since $e^{t\mathcal{A}^0}(\omega_0, \omega_1) \in D(\mathcal{A}^0)$, the same proof of (2.5) yields

$$\frac{d}{dt}\left(\frac{1}{2}\left\| e^{t\mathcal{A}^0} \begin{pmatrix} \omega_0 \\ \omega_1 \end{pmatrix} \right\|_{\mathcal{H}^0}^2 \right) = \frac{d}{dt} E(t) = 0,$$

which implies that C_0-semigroup $e^{t\mathcal{A}^0}$ is an isometric semigroup. Therefore the energy of the system (1.1) does not exponentially decay. Finally, let $k_2 > 0$ and $k_4 = 0$; we only need to define $H_E^0 = \{u \in H_E |\ u'(0) = 0\}$ and the similar proof follows. This concludes the proof of the theorem. □

THE PRIMAL-DUAL ACTIVE SET METHOD FOR NONLINEAR OPTIMAL CONTROL PROBLEMS WITH BILATERAL CONSTRAINTS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. The primal-dual active set method has proved to be an efficient numerical tool in the context of diverse applications. So far it has been investigated mainly for linear problems. This paper is devoted to the study of global convergence of the primal-dual active set method for nonlinear problems with bilateral constraints. Utilizing the close relationship between the primal-dual active set method and semismooth Newton methods, local superlinear convergence of the method is investigated as well.

Key words. primal-dual active set method, semismooth Newton method, optimal control, bilateral constraints

1. Introduction.

This paper is devoted to the study of algorithms for solving problems of the type

$$\begin{aligned} &\min \tfrac{1}{2}\,|T(u)-z|^2 \;+\; \tfrac{\alpha}{2}\,|u|^2 \\ &\text{over } u \text{ subject to } \;\varphi \le u \le \psi, \end{aligned} \tag{1.1}$$

where T is a nonlinear operator between Hilbert spaces and α, z, φ, and ψ are given. A typical motivation for considering (1.1) is given by optimal control problems, where T is the control-to-output mapping. Depending on the type of dynamics and the way in which the control enters into the equation, T may be affine or nonlinear. The inequalities in (1.1) then describe bilateral constraints on the class of admissible controls. Without the presence of the constraints, (1.1) has received a considerable amount of attention over the last 20 years, and numerical methods for solving (1.1) have achieved a high level of sophistication. The presence of the infinite dimensional constraints, however, complicates the problem significantly, and analytical as well as numerical issues are not yet completely resolved.

It should be mentioned that discretizing (1.1) results in a finite dimensional problem, for which numerical algorithms are readily available. However, this approach cannot avoid the infinite dimensional problem, since grid refinement must be addressed. Moreover, in the process of discretization, important properties such as smoothing and compactness of T and existence of integrable Lagrange multiplier associated with inequality constraints are hidden. Such properties, however, have a significant effect on the behavior of any fine-tuned algorithm. We refer, e.g., to [IK2] for a discussion on the regularizing properties of T depending on whether control or state constraints or problems of obstacle or control-of-obstacle type are described by T. Smoothing

properties of T which hold for many optimal control problems will play an essential role in our analysis of (1.1).

We turn to a brief description of the primal-dual active set strategy and the contributions of this paper. The primal-dual active set strategy is an iterative algorithm that on the basis of the current primal variable u^k and the current Lagrange multiplier λ^k associated to the constraints in (1.1) predicts new active sets $A^+_{k+1} = A^+_{k+1}(u^k, \lambda^k)$ and $A^-_{k+1} = A^-_{k+1}(u^k, \lambda^k)$ and requires solving the equality constrained problems

$$\left\{ \begin{array}{l} \min \frac{1}{2} \, |T(u) - z|^2 \; + \; \frac{\alpha}{2} \, |u|^2 \\ \text{over } u \text{ with } \; u = \psi \;\; \text{on} \;\; A^+_{k+1}, \quad u = \varphi \;\; \text{on} \;\; A^-_{k+1}. \end{array} \right. \tag{1.2}$$

Here A^+ and A^- refer to the sets that are active at the upper, respectively, lower, bound. In case T is linear, the solution to (1.2) is characterized by a linear equation on the complement of $A^+_{k+1} \cup A^-_{k+1}$. In our work the strategy for choosing A^+_{k+1} and A^-_{k+1} is based on convex analysis techniques [IK1, BIK]. Due to the simple nature of the box constraints in (1.1), this strategy is related to strategies already used in [B, HI]. We shall further comment on this below.

To put the algorithm described above into a more general context, it will be convenient to recall that the first order optimality condition for (1.1) is given by

$$\left\{ \begin{array}{l} \alpha \, u + T'(u)^*(T(u) - z) + \lambda = 0, \\ \lambda = \max(0, \lambda + \alpha \, (u - \psi)) + \min(0, \lambda + \alpha \, (u - \varphi)). \end{array} \right. \tag{1.3}$$

We shall argue in section 6 that this is equivalent to

$$\begin{aligned} \alpha(u - \psi) + \max(0, \alpha \, \psi + T'(u)^*(T(u) - z)) \\ + \min(0, -T'(u)^*(T(u) - z) - \alpha \, \varphi) = 0. \end{aligned} \tag{1.4}$$

Note that (1.4) involves the term $p(u) := -T'(u)^*(T(u) - z)$, which is commonly referred to as the adjoint state in optimal control. Solving (1.1) by means of optimality conditions amounts to solving (1.4), which involves two types of nonlinearities of very different nature: the simple but nondifferentiable max and min operations and the nonlinear mapping T, which is typically smooth (the precise conditions will be formulated below) and possibly highly nonlinear. This difference between the nonlinearities max/min and $u \mapsto p(u)$ motivates us to separately consider their linearization in Newton-type iterative approaches. Linearizing $p(u)$ at the current iterate u^k and leaving the nondifferentiable functions unchanged results in

$$\begin{aligned} \alpha(u - \psi) + \max(0, \alpha \, \psi - p(u^k) - p'(u^k)(u - u^k)) \\ + \min(0, p(u^k) + p'(u^k)(u - u^k) - \alpha \, \varphi) = 0, \end{aligned} \tag{1.5}$$

where

$$p'(u^k)\delta \, u = -T'(u^k)^* T'(u^k)\delta \, u - (T(u^k) - z, T''(u^k)(\delta \, u, \cdot)). \tag{1.6}$$

This can be considered as a projected Newton iteration, as we shall show at the end of this section, and it is also closely related to the sequential quadratic programming (SQP) approach to (1.1), which has frequently been considered in the literature; see, e.g., [TV] and the references given there. In the SQP approach to (1.1) both u and $y = T(u)$ are considered as independent variables, and at each iteration level a quadratic approximation to the cost in (1.1) is minimized subject to the constraints $\varphi \le u \le \psi$.

Alternatively, one can take generalized derivatives of the nondifferentiable functions in (1.4), leaving the nonlinearity $p(u)$ unchanged. The resulting auxiliary problems are smooth and can be solved with an appropriate standard method. This partial (semismooth) Newton method is the focus of this paper. In fact, we shall start our analysis with the primal-dual active set strategy and only later argue its equivalence to the partial (semismooth) Newton method. Finally, of course, both nonlinearities max/min and $p(u)$ can be "linearized" simultaneously, resulting in a semismooth Newton method. The semismooth Newton method for general-purpose nonlinear finite dimensional optimization problems has been well studied; see, for instance, [LPR] and the references given there. Much less is known about such methods in infinite dimensions, specifically in the context of optimal control; see, however, [HIK, U]. We shall address the semismooth Newton approach to (1.4) in section 7.

We have studied the primal-dual active set strategy in several previous papers [IK1, BIK, HIK]. The significant difference in the present contribution compared with earlier work is the treatment of bilateral constraints and of nonlinear rather than only linear operators. As in earlier work the global convergence proofs are based on a properly chosen merit functional. The merit functional utilized in [BIK] is not appropriate for analyzing bilateral constraints. Therefore we were forced to find a new merit-functional that has the additional advantage over the one in [BIK] that the details of the convergence proof are more transparent.

Let us briefly describe the contents of this paper. In section 2 we give a precise problem statement and description of the primal-dual active set algorithm. Section 3 is devoted to a general framework for establishing convergence of the algorithm from arbitrary initial data. The applicability of the framework for linear and nonlinear problems is described in sections 4 and 5, respectively. In section 6 we give sufficient conditions for local superlinear convergence of the algorithm. In the context of local convergence we address in section 7 superlinear convergence of the semismooth Newton method, when both types of nonlinearities max/min and $p(u)$ in (1.4) are linearized. While the focus of this paper is an analytical one, we nevertheless present in section 8 a numerical example illustrating some effects of treating the nonlinearities in (1.4) separately rather than directly applying a generalized chain rule.

Let us comment on related contributions. In [H] the primal-dual active set algorithm is extended to bilateral constraints with convergence proofs based on the merit functional from [BIK]. This necessitates further assumptions and modifications of the algorithm, which can be avoided with the new merit functional. The primal-dual active set algorithm is closely related to the Bertsekas projected Newton method, which was developed for finite dimensional problems in [B] and extended to optimal control problems in [KS]. The main difference between the two algorithms is that Bertsekas' algorithm is a feasible algorithm, while ours is not. We comment further on this in Remark 7.4, where we also indicate how the local convergence proofs of this paper can be utilized for the Bertsekas method. The dual algorithm developed in [HI] for optimal control of ordinary differential equations is closely related to the primal-dual active set method. The concepts for the local convergence proofs based on generalized equations in [HI] and semismooth Newton methods in our work are significantly different. There are no global convergence results in [HI]. In [HH] the dual algorithm was modified by the introduction of backtracking steps, resulting in guaranteed convergence for finite dimensional problems. For a detailed comparison of the two methods, see [BK]. As mentioned, semismooth Newton methods were recently extended to nonlinear problems. One of the peculiarities in the application of such

methods to (1.1) is the lack of generalized differentiability (in a sense to be specified in section 7) of the max/min operations between L^p spaces. In [U] this difficulty is compensated by an additional smoothing step introduced to the semismooth Newton method. In our work the lack of generalized differentiability is incorporated in the form in which the optimality condition is expressed (see (1.3), (1.4)) as well as a regularity condition for the mapping $u \to T(u)$.

We close this introduction by establishing the announced relationship between the SQP method applied to (1.1) and (1.5). Let y represent an independent variable, denote by μ the Lagrange multiplier associated to the constraint $y - T(u) = 0$, and introduce the Lagrangian

$$L(y, u, \mu) = \tfrac{1}{2}\,|y - z|^2 + \tfrac{\alpha}{2}\,|u|^2 + (\mu, T(u) - y).$$

Given (y^k, u^k, μ^k) the new correction is obtained as the solution to

$$\text{(1.7)} \qquad \begin{cases} \min\ L'(y^k, u^k, \mu^k)(\delta y, \delta u) + \frac{1}{2}L''(y^k, u^k, \mu^k)((\delta y, \delta u), (\delta y, \delta u)) \\ \text{subject to} \\ T(u^k) + T'(u^k)\delta u\ =\ y^k + \delta y, \quad \varphi \le u_k + \delta u \le \psi, \end{cases}$$

over $(\delta y, \delta u)$, where primes denote differentiation with respect to (y, u). Denoting by $\delta\mu$ and $\bar\lambda$ the Lagrange multipliers to the two constraints in (1.7), and setting

$$(y^{k+1}, u^{k+1}, \mu^{k+1}) = (y^k, u^k, \mu^k) + (\delta y, \delta u, \delta \mu)$$

the optimality condition for (1.7) is given by

$$y^{k+1} = T(u^k) + T'(u^k)\delta u,$$

$$\mu^{k+1} = y^{k+1} - z,$$

$$\alpha\, u^{k+1} + T'(u^k)^*\mu^{k+1} + (\mu^k, T''(u^k)(\delta u, \cdot)) + \bar\lambda = 0,$$

$$\bar\lambda = \max(0, \bar\lambda + (u^{k+1} - \psi)) + \min(0, \bar\lambda + (u^{k+1} - \varphi)).$$

From the first three equations we get

$$\alpha\, u^{k+1} + T'(u^k)^*(T(u^k) + T'(u^k)\delta u - z) + (y^k - z, T''(u^k)(\delta u, \cdot)) + \bar\lambda = 0.$$

This, together with the last equation in the optimality condition, implies that

$$\text{(1.8)} \qquad \alpha(u^{k+1} - \psi) + \max(0, \alpha\,\psi - \omega^k) + \min(0, \omega^k - \alpha\,\varphi),$$

where

$$\text{(1.9)} \qquad \omega^k = -T'(u^k)^*(T(u^k) + T'(u^k)\delta u - z) - (y^k - z, T''(u^k)(\delta u, \cdot)).$$

Comparing to (1.5)–(1.6), we observe that the only difference between the SQP method and the Newton method applied to the smooth operator T in (1.4) occurs in the second summand of the second derivative. In the SQP method y^k is computed from the linearized equation $y^k = T(u^{k-1}) + T'(u^{k-1})\delta u)$, whereas $T(u^k)$ in (1.6) requires the computation of the nonlinear operator T at u^k. Concerning the term $(T(u^k) - z, T''(u^k)(\delta u, \cdot))$ in (1.6) it is worthwhile to observe that

$$\begin{aligned} &(T(u^k) - z, T''(u^k)(\delta u, v)) \\ &\quad = -(T'(u^k)^*(T(u^k) - z), T^{-1}(T(u^k))''(T'(u^k)\delta u, T'(u^k)v)) \\ &\quad = (p(u^k), T^{-1}(T(u^k))''(T'(u^k)\delta u, T'(u^k)v)). \end{aligned}$$

In applications to optimal control of differential equations $T(u)$, respectively, $T'(u)v$, require the solution of a nonlinear, respectively linearized, differential equation.

2. Problem statement and algorithm. Let Y and U be Hilbert spaces with $U = L^2(\Sigma)$, where Σ a bounded measurable set in $\mathbb{R}^n$, and let $T\colon U \to Y$ be a, possibly nonlinear, continuously differentiable, injective, mapping with Fréchet derivative denoted by T'. Further let $\varphi, \psi \in U$ with $\varphi < \psi$ a.e. in Σ. For $\alpha > 0$ and $z \in Y$ consider

$$\min_{\varphi \le u \le \psi} J(u) = \tfrac{1}{2}\,|T(u) - z|_Y^2 + \tfrac{\alpha}{2}\,|u|_U^2. \tag{2.1}$$

We refer to (2.1) as the bilaterally constrained problem. When the constraint $\varphi \le u$ is not present, formally obtained by setting $\varphi = -\infty$, we have the unilaterally constrained problem. The necessary optimality condition for (2.1) is given by

$$(\alpha u + T'(u)^*(T(u) - z), \tilde{u} - u)_U \ge 0 \quad \text{for all } \varphi \le \tilde{u} \le \psi.$$

A direct computation shows that this is equivalent to the existence of $\lambda \in U$ such that

$$\begin{cases} \alpha u + T'(u)^*(T(u) - z) + \lambda = 0, \\ \lambda = 0 \text{ on } I, \quad \lambda \ge 0 \text{ on } A^+, \quad \lambda \le 0 \text{ on } A^-, \end{cases}$$

where $I = \{x : \varphi(x) < u(x) < \psi(x)\}$, $A^+ = \{x : u(x) = \psi(x)\}$, and $A^- = \{x : u(x) = \varphi(x)\}$, in the a.e. sense. The second condition can be equivalently expressed as

$$\lambda = \max(0, \lambda + \alpha(u - \psi)) + \min(0, \lambda + \alpha(u - \varphi)),$$

where $c > 0$ is arbitrarily fixed. For our work the choice $c = \alpha$ is convenient and results in the first order optimality system,

$$\begin{cases} \alpha u + T'(u)^*(T(u) - z) + \lambda = 0, \\ \lambda = \max(0, \lambda + \alpha(u - \psi)) + \min(0, \lambda + \alpha(u - \varphi)), \end{cases} \tag{2.2}$$

where $(u, \lambda) \in U \times U$, and max as well as min are interpreted as pointwise a.e. operations.

We next specify the primal-dual active set algorithm. The iteration index is denoted by k and an initial choice (u^0, λ^0) is assumed to be available.

Primal-dual active set algorithm.

(i) Given (u^k, λ^k), determine

$$A_{k+1}^+ = \{x\colon (\lambda^k + \alpha(u^k - \psi))(x) > 0\},$$

$$\begin{aligned} I_{k+1} &= \{x\colon (\lambda^k + \alpha(u^k - \psi))(x) \le 0 \le \lambda^k + \alpha(u^k - \varphi)(x)\}, \\ A_{k+1}^- &= \{x\colon (\lambda^k + \alpha(u^k - \varphi))(x) < 0\}. \end{aligned}$$

(ii) Determine (u^{k+1}, λ^{k+1}) from

$$u^{k+1} = \psi \ \text{ on } \ A_{k+1}^+, \quad u^{k+1} = \varphi \ \text{ on } \ A_{k+1}^-, \quad \lambda^{k+1} = 0 \ \text{ on } \ I_{k+1},$$

and

$$\alpha\, u^{k+1} + T'(u^{k+1})^*(T(u^{k+1}) - z) + \lambda^{k+1} = 0. \tag{2.3}$$

Note that the equations for (u^{k+1}, λ^{k+1}) in step (ii) of the algorithm constitute the necessary optimality condition for the auxiliary problem

$$\left\{ \begin{array}{l} \min \frac{1}{2} \, |T(u) - z|_Y^2 + \frac{\alpha}{2} \, |u|_U^2 \ \text{ over } \ u \in U \\ \text{subject to } \quad u = \psi \ \text{ on } \ A_{k+1}^+, \quad u = \varphi \ \text{ on } \ A_{k+1}^-. \end{array} \right. \tag{2.4}$$

For the global convergence analysis which will be given in the following sections we require the primal-adjoint structure of the optimality system that arises if the action of T is given as the solution of an equation. This situation typically arises in optimal control and parameter estimation problems. Thus we consider the case where $y = T(u)$ is given as the solution of an equation of the form

$$H(y) = u.$$

Assume that for every $u \in U$ this equation has a unique solution $y = T(u) \in X$, where X is dense subset of Y, and that $u \to T(u)$ is continuous from u to X. Assume further that $H : X \to U$ is C^1 and that $H'(y)$ has a bounded inverse $H'(y)^{-1} \in \mathcal{L}(U, Y)$. Then,

$$T'(u) = (H'(y))^{-1} \text{ and } T'(u)^* = (H'(y)^*)^{-1} \in \mathcal{L}(Y, U) \qquad \text{for } u \in U,$$

where $y = T(u)$ and the adjoint of $H'(y)$ is taken as an operator with domain in Y to U. Consequently (2.2) can equivalently be expressed as

$$\left\{ \begin{array}{l} H(y) = u, \\ \\ H'(y)^* p = -(y - z), \\ \\ \alpha \, u - p + \lambda = 0, \\ \\ \lambda = \max(0, \lambda + (u - \psi)) + \min(0, \lambda + (u - \varphi)), \end{array} \right. \tag{2.5}$$

where $p = -T'(u)^*(T(u) - z)$ is the adjoint state. Analogously, for $u^{k+1} \in U$, setting $y^{k+1} = T(u^{k+1})$, $p^{k+1} = -T'(u^{k+1})^*(T(u^{k+1}) - z)$, (2.3) can equivalently be expressed as

$$\left\{ \begin{array}{l} H(y^{k+1}) = \left\{ \begin{array}{lll} \psi & \text{on} & A_{k+1}^+, \\ \frac{1}{\alpha} \, p^{k+1} & \text{on} & I_{k+1}, \\ \varphi & \text{on} & A_{k+1}^-, \end{array} \right. \\ \\ H'(y^{k+1})^* p^{k+1} = -(y^{k+1} - z), \\ \\ \alpha \, u^{k+1} - p^{k+1} + \lambda^{k+1} = 0. \end{array} \right. \tag{2.6}$$

Example 2.1. Let $\Omega \subset \mathbb{R}^n$ be a bounded domain in $\mathbb{R}^n$ with Lipschitz continuous boundary Γ and $\widetilde{\Omega} \subset \Omega$, $\widetilde{\Gamma} \subset \Gamma$ measurable subsets. Let $E_{\widetilde{\Gamma}} \colon L^2(\widetilde{\Gamma}) \to L^2(\Gamma)$ be the extension-by-zero operator and $R_{\widetilde{\Omega}} \colon L^2(\Omega) \to L^2(\widetilde{\Omega})$ the canonical restriction operator. Define $L \colon L^2(\Gamma) \to L^2(\Omega)$ as the solution operator to the inhomogeneous Neumann boundary value $L \, u = y$, i.e., y is the solution to

$$(\nabla y, \nabla v)_\Omega + (y, v)_\Omega = (u, v)_\Gamma \quad \text{for all } \ v \in H^1(\Omega), \tag{2.7}$$

and then $T = R_{\widetilde{\Omega}} L\, E_{\widetilde{\Gamma}} \colon L^2(\widetilde{\Gamma}) \to L^2(\widetilde{\Omega})$. Then $T^* \colon L^2(\widetilde{\Omega}) \to L^2(\widetilde{\Gamma})$ is given by

$$T^* = R_{\widetilde{\Gamma}} L^*\, E_{\widetilde{\Omega}}$$

with $R_{\widetilde{\Gamma}}$ the restriction operator to $\widetilde{\Gamma}$ and $E_{\widetilde{\Omega}}$ the extension operator from $\widetilde{\Omega}$ to Ω by zero. Further, the adjoint $L^* \colon L^2(\Omega) \to L^2(\Gamma)$ of L is given by $L^* z = \tau_\Gamma p$, where τ_Γ is the Dirichlet trace operator from $H^1(\Omega)$ to $L^2(\Gamma)$ and p is the solution to

$$(\nabla p, \nabla w)_\Omega + (p, w)_\Omega = (z, w)_\Omega \quad \text{for all} \quad w \in H^1(\Omega). \tag{2.8}$$

3. Global convergence. In this section we give conditions that guarantee convergence of the primal-dual active set strategy for linear and certain nonlinear operators T from arbitrary initial data. The convergence proof is based on an appropriately defined functional that decays when evaluated along the iterates of the algorithm. An a priori estimate for the adjoint variable p in (2.6) will play an essential role. In this section we shall assume this estimate to hold. In the following sections the estimate will be investigated separately for the linear and nonlinear cases.

To specify the condition alluded to above let us consider two consecutive iterates of the algorithm. For every $k = 1, 2, \ldots$, the sets A_k^+, A_k^-, and I_k give a mutually disjoint decomposition of Σ. According to (i) and (ii) in the form (2.6) we find

$$H(y^{k+1}) - H(y^k) = u^{k+1} - u^k = \begin{cases} R^k_{A^+} & \text{on} \quad A^+_{k+1}, \\ \frac{1}{\alpha}(p^{k+1} - p^k) + R^k_I & \text{on} \quad I_{k+1}, \\ R^k_{A^-} & \text{on} \quad A^-_{k+1} \end{cases} \tag{3.1}$$

and

$$H'(y^{k+1})^* p^{k+1} - H'(y^k)^* p^k + y^{k+1} - y^k = 0, \tag{3.2}$$

where the residual R^k is given by

$$R^k_{A^+} = \begin{cases} 0 & \text{on} \quad A^+_k \cap A^+_{k+1}, \\ \psi - \frac{1}{\alpha} p^k = \psi - u^k < 0 & \text{on} \quad I_k \cap A^+_{k+1}, \\ \psi - \varphi < \frac{1}{\alpha} \lambda_k & \text{on} \quad A^-_k \cap A^+_{k+1}, \end{cases} \tag{3.3}$$

$$R^k_I = \begin{cases} \frac{1}{\alpha} \lambda^k = \frac{1}{\alpha} p^k - \psi \le 0 & \text{on} \quad A^+_k \cap I_{k+1}, \\ 0 & \text{on} \quad I_k \cap I_{k+1}, \\ \frac{1}{\alpha} \lambda^k = \frac{1}{\alpha} p^k - \varphi \ge 0 & \text{on} \quad A^-_k \cap I_{k+1}, \end{cases} \tag{3.4}$$

$$R^k_{A^-} = \begin{cases} \varphi - \psi > \frac{1}{\alpha} \lambda_k & \text{on} \quad A^+_k \cap A^-_{k+1}, \\ \varphi - \frac{1}{\alpha} p^k = \varphi - u^k > 0 & \text{on} \quad I_k \cap A^-_{k+1}, \\ 0 & \text{on} \quad A^-_k \cap A^-_{k+1}. \end{cases} \tag{3.5}$$

Let R^k denote the function defined on Ω whose restrictions to A^+_{k+1}, I_{k+1}, A^-_{k+1} coincide with $R^k_{A^+}$, R^k_I, and $R^k_{A^-}$.

We shall utilize the following a priori estimate:

$$\begin{cases} \text{There exists} \ \ \rho < \alpha \ \ \text{such that} \\ \\ |p^{k+1} - p^k|_U < \rho\, |R^k|_U \ \ \text{for every} \ \ k = 1, 2, \ldots. \end{cases} \tag{3.6}$$

The convergence proof will be based on the following merit functional $M: U \times U \to R$ given by

$$M(u,\lambda) = \alpha^2 \int_\Sigma (|(u-\psi)^+|_U^2 + |(\varphi - u)^+|_U^2)\, dx + \int_{\mathcal{A}^+(u)} |\lambda^-|_U^2\, dx + \int_{\mathcal{A}^-(u)} |\lambda^+|_U^2\, dx,$$

where $\mathcal{A}^+(u) = \{x\colon u \geq \psi\}$ and $\mathcal{A}^-(u) = \{x\colon u \leq \varphi\}$. For pairs $(u,\lambda) \in U \times U$ satisfying

$$\lambda(u-\psi)(\varphi - u)(x) = 0 \quad \text{for a.a. } x \in \Sigma, \tag{3.7}$$

at most one of the integrands of M can be strictly positive at $x \in \Sigma$.

THEOREM 3.1. *Assume that* (3.6) *holds for the iterates of the primal-dual active set strategy. Then* $M(u^{k+1},\lambda^{k+1}) \leq \alpha^{-2}\rho^2 M(u^k,\lambda^k)$ *for every* $k = 1,\dots$. *Moreover there exist* $(u^*,y^*,p^*,\lambda^*) \in U \times Y \times U \times U$ *with* $(y^*,p^*) \in$ *range* $(T(u^*))\times$ *range* $(T'(u^*)^*)$ *such that* $\lim_{k\to\infty}(u^k,p^k,\lambda^k) = (u^*,p^*,\lambda^*)$ *and* (u^*,y^*,p^*,λ^*) *satisfies* (2.5).

Proof. From (2.6) we have

$$\begin{aligned} \lambda^{k+1} &= p^{k+1} - \alpha\psi \quad \text{on} \quad A_{k+1}^+, \\ u^{k+1} &= \tfrac{1}{\alpha}\, p^{k+1} \quad \text{on} \quad I_{k+1}, \\ \lambda^{k+1} &= p^{k+1} - \alpha\varphi \quad \text{on} \quad A_{k+1}^-. \end{aligned}$$

Using step (ii) of the algorithm in the form of (2.6) implies that

$$\lambda^{k+1} = p^{k+1} - p^k + p^k - \alpha\psi = p^{k+1} - p^k + \begin{cases} \lambda^k > 0 & \text{on} \quad A_k^+ \cap A_{k+1}^+, \\ \alpha(u^k - \psi) > 0 & \text{on} \quad I_k \cap A_{k+1}^+, \\ \alpha u^k + \lambda^k - \alpha\psi \geq 0 & \text{on} \quad A_k^- \cap A_{k+1}^+, \end{cases}$$

and therefore

$$|\lambda^{k+1,-}(x)| \leq |p^{k+1}(x) - p^k(x)| \quad \text{for } x \in A_{k+1}^+. \tag{3.8}$$

Analogously one derives

$$|\lambda^{k+1,+}(x)| \leq |p^{k+1}(x) - p^k(x)| \quad \text{for } x \in A_{k+1}^-. \tag{3.9}$$

Moreover

$$\begin{aligned} u^{k+1} - \psi &= \frac{1}{\alpha}(p^{k+1} - p^k + p^k) - \psi \\ &= \frac{1}{\alpha}(p^{k+1} - p^k) + \begin{cases} \frac{1}{\alpha}\lambda^k \leq 0 & \text{on} \quad A_k^+ \cap I_{k+1}, \\ u^k - \psi \leq 0 & \text{on} \quad I_k \cap I_{k+1}, \\ \frac{1}{\alpha}\lambda^k + u - \psi \leq 0 & \text{on} \quad A_k^- \cap I_{k+1}, \end{cases} \end{aligned}$$

which implies that

$$|(u^{k+1} - \psi)^+(x)| \;\leq\; \tfrac{1}{\alpha}\, |p^{k+1}(x) - p^k(x)| \quad \text{for } x \in I_{k+1}. \tag{3.10}$$

Analogously one derives that

$$|(\varphi - u^{k+1})^+(x)| \;\leq\; \tfrac{1}{\alpha}\, |p^{k+1}(x) - p^k(x)| \quad \text{for } x \in I_{k+1}. \tag{3.11}$$

Due to (ii) of the algorithm we have that

$$(u^{k+1}-\psi)^+ = (\varphi - u^{k+1})^+ = 0 \quad \text{on} \quad A_{k+1}^+ \cup A_{k+1}^-,$$

which together with (3.10)–(3.11) implies that

$$|(u^{k+1}-\psi)^+(x)| + |(\varphi - u^{k+1})^+(x)| \le \tfrac{1}{\alpha}|p^{k+1}(x) - p^k(x)| \quad \text{for } x \in \Sigma. \tag{3.12}$$

From (3.8), (3.9) and since $\varphi < \psi$ a.e. on Σ we find

$$|\lambda^{k+1,-}(x)| \;\le\; |p^{k+1}(x) - p^k(x)| \quad \text{for} \quad x \in \mathcal{A}^+(u^{k+1}) \tag{3.13}$$

and

$$|\lambda^{k+1,+}(x)| \;\le\; |p^{k+1}(x) - p^k(x)| \quad \text{for} \quad x \in \mathcal{A}^-(u^{k+1}). \tag{3.14}$$

Combining (3.11)–(3.14) implies that

$$M(u^{k+1}, \lambda^{k+1}) \;\le\; \int_\Sigma |p^{k+1}(x) - p^k(x)|^2 dx. \tag{3.15}$$

Since (3.6) is supposed to hold we have

$$M(u^{k+1}, \lambda^{k+1}) \;\le\; \rho^2 |R^k|_U^2.$$

Moreover, from (3.3)–(3.5) we deduce that

$$|R^k|_U^2 \;\le\; \alpha^{-2} M(u^k, \lambda^k), \tag{3.16}$$

and consequently

$$M(u^{k+1}, \lambda^{k+1}) \;\le\; \alpha^{-2}\rho^2 M(u^k, \lambda^k) \quad \text{for} \quad k = 1, 2, \ldots. \tag{3.17}$$

From (3.6), (3.16), and (3.17) it follows that $|p^{k+1} - p^k|_U \le (\frac{\rho}{\alpha})^k \rho |R^0|_U$. Thus there exists $p^* \in U$ such that $\lim_{k\to\infty} p^k = p^*$.

Note that for $k \ge 1$

$$A_{k+1}^+ = \{x\colon p^k(x) > \alpha\,\psi(x)\}, \quad I_{k+1} = \{x\colon \alpha\,\varphi(x) \le p^k(x) \le \alpha\,\psi(x)\},$$

$$A_{k+1}^- = \{x\colon p^k(x) < \alpha\,\varphi(x)\},$$

and hence

$$\lambda^{k+1} = \max(0, p^k - \alpha\,\psi) + \min(0, p^k - \alpha\,\varphi) + (p^{k+1} - p^k)_{\chi_{A_{k+1}^+ \cup A_{k+1}^-}}.$$

Since $\lim_{k\to\infty}(p^{k+1} - p^k) = 0$ and $\lim_{k\to\infty} p^k$ exists, it follows that there exists $\lambda^* \in U$ such that $\lim_{k\to\infty} \lambda^k = \lambda^*$, and

$$\lambda^* = \max(0, p^* - \alpha\,\psi) + \min(0, p^* - \alpha\,\varphi). \tag{3.18}$$

From the last equation in (2.6) it follows that there exists u^* such that $\lim_{k\to\infty} u^k = u^*$ and $\alpha\,u^* - p^* + \lambda^* = 0$. Combined with (3.18) the triple (u^*, p^*, λ^*) satisfies the complementarity condition given by the second equation in (2.2). Passing to the limit with respect to k in (2.3) we obtain that the first equation in (2.1) is satisfied by (u^*, λ^*). Setting $y^* = T(u^*)$ we find that $(u^*, y^*, p^*, \lambda^*)$ satisfies (2.5). □

4. The linear case. In this section we give sufficient conditions for (3.6) to hold if $T \in \mathcal{L}(U, Y)$ is an injective operator with dense range in Y. If we define $H = T^{-1}$, then H is closed and (3.1)–(3.2) can be expressed as

$$\left\{ \begin{array}{l} H(y^{k+1} - y^k) = R^k + \frac{1}{\alpha}(p^{k+1} - p^k)\chi_{I_{k+1}}, \\ H^*(p^{k+1} - p^k) + y^{k+1} - y^k = 0. \end{array} \right. \tag{4.1}$$

THEOREM 4.1. *If T is linear and $\|T\|^2_{\mathcal{L}(U,Y)} < \alpha$, then* (3.6) *holds.*

Proof. Since $y^{k+1} - y^k \in \text{range } (H)$ we can apply H to the second equation in (4.1) and obtain

$$H\,H^*(p^{k+1} - p^k) + \frac{1}{\alpha}(p^{k+1} - p^k)\chi_{I_{k+1}} = -R^k. \tag{4.2}$$

Taking the inner product with respect to $p^{k+1} - p^k$ implies

$$|H^*(p^{k+1} - p^k)|^2_Y \;\le\; |R^k|\,|p^{k+1} - p^k|_U.$$

Since $|p^{k+1} - p^k|_U \le |T^*H^*(p^{k+1} - p^k)|_U \le \|T\|_{\mathcal{L}(U,Y)}|H^*(p^{k+1} - p^k)|_Y$, the claim follows. □

Remark 4.1. In [BIK] the condition $\|T\|^2_{\mathcal{L}(U,Y)} \le \frac{\alpha}{2}$ was obtained for global convergence by a different technique for the unilateral case. Note that in applications to optimal control problems, T represents the solution operator to a differential equation. For elliptic or parabolic equations T is smoothing and it is reasonable to assume that $\|T\|$ is relatively small. (For $T = (-\Delta)^{-1}$ with Dirichlet boundary conditions on the unit square in R^2, we have $\|T\|^2 = \frac{1}{4\pi^4}$.)

The smallness condition of Theorem 4.1 is not required if appropriate structural properties can be utilized. For example, in finite dimensions, if T is an M matrix, then global convergence was obtained in [HIK]. Sufficient conditions for global convergence if T is a P-matrix are also given in [HIK]. Global convergence of infinite dimensional obstacle problems was analyzed in [IK2] exploiting the maximum principle.

5. A class of nonlinear problems. This section is devoted to an analysis of specific nonlinear problems for which (3.6) can be satisfied. Let $\Sigma = \Omega \subset \mathbb{R}^n$, $n = 2$ or 3, with smooth boundary $\partial\,\Omega$. Further let $\phi\colon \mathbb{R} \to \mathbb{R}$ be a monotone mapping with locally Lipschitzian derivative, satisfying $\phi(0) = 0$, and such that the substitution operator determined by ϕ maps $H^1(\Omega)$ into $L^2(\Omega)$. In the notation of section 2 we choose $U = Y = L^2(\Omega)$ and define T as the solution operator to

$$\left\{ \begin{array}{lll} H(y) = -\Delta y + \phi(y) = u & \text{in} & \Omega, \\ y = 0 & \text{on} & \partial\Omega, \end{array} \right. \tag{5.1}$$

where Δ denotes the Laplacian. The adjoint equation is given by

$$\left\{ \begin{array}{lll} H'(y)^*p = -\Delta p + \phi'(y)p = -(y - z) & \text{in} & \Omega, \\ p = 0 & \text{on} & \partial\Omega. \end{array} \right. \tag{5.2}$$

Let (u^0, λ^0) be an arbitrary initialization and let $\widetilde{U} = \{u^k\colon k = 1, \dots\}$ denote the set of iterates generated by the algorithm. Since these iterates are solutions to the auxiliary problem (2.4) it follows that for every $\bar{\alpha} > 0$ the set $\widetilde{U}$ is bounded in $L^2(\Omega)$ uniformly with respect to $\alpha \ge \bar{\alpha}$.

By monotone operator theory and regularity theory of elliptic partial differential equations it follows that the set of primal states $\{y^k = y(u^k)\colon k = 1, \dots\}$ and adjoint

states $\{p^k = p(y(u^k))\colon k = 1, \dots\}$ are bounded subsets of $L^\infty(\Omega)$. Let C denote this bound and let L_C denote the Lipschitz constant of ϕ on the ball $B_C(0)$ with center 0 and radius C in $\mathbb{R}$. Let $H_0^1(\Omega) = \{u \in H^1(\Omega) : u = 0 \text{ on } \partial\Omega\}$ be the Hilbert space endowed with norm $|\nabla u|_{L^2}$ and let κ stand for the embedding constant from $H_0^1(\Omega)$ into $L^2(\Omega)$.

PROPOSITION 5.1. *Assume that* $0 < \frac{(1+C\,L_C)\,\kappa^4}{\alpha-(1+C\,L_C)\,\kappa^4} < 1$. *Then* (3.6) *holds for the mapping* T *determined by the solution operator to* (5.1).

Proof. For the case under consideration, (3.1) and (3.2) can be expressed as

$$-\Delta(y^{k+1} - y^k) + \phi(y^{k+1}) - \phi(y^k) = \frac{1}{\alpha}\,(p^{k+1} - p^k)\chi_{I^{k+1}} + R^k, \tag{5.3}$$

$$-\Delta(p^{k+1} - p^k) + \phi'(y^{k+1})(p^{k+1} - p^k) + (\phi'(y^{k+1}) - \phi'(y^k))p^k + y^{k+1} - y^k = 0. \tag{5.4}$$

Taking the inner product of (5.3) with $y^{k+1} - y^k$ we have, using monotonicity of ϕ,

$$|y^{k+1} - y^k|_1 \le \frac{\kappa^2}{\alpha}\,|(p^{k+1} - p^k)|_1 + |R^k|_{-1}, \tag{5.5}$$

where $|\cdot|_1$ and $|\cdot|_{-1}$ denote the norms in $H_0^1(\Omega)$ and $H^{-1}(\Omega)$, respectively. Note that $\phi'(y^{k+1}) \ge 0$. Hence from (5.4) we find

$$\begin{aligned} |p^{k+1} - p^k|_1^2 &\le C\,L_C|y^{k+1} - y^k|_{L^2}|p^{k+1} - p^k|_{L^2} + |(y^{k+1} - y^k, p^{k+1} - p^k)| \\ &\le (1 + C\,L_C)\,\kappa^2|y^{k+1} - y^k|_1|p^{k+1} - p^k|_1. \end{aligned}$$

Thus,

$$|p^{k+1} - p^k|_1 \;\le\; (1 + C\,L_C)\,\kappa^2\,|y^{k+1} - y^k|_1$$

and hence from (5.5)

$$|y^{k+1} - y^k|_1 \;\le\; \frac{\alpha}{\alpha - (1 + C\,L_C)\,\kappa^4}|R^k|_{-1}.$$

It thus follows that

$$|p^{k+1} - p^k|_{L^2} \;\le\; \frac{\alpha\,(1 + C\,L_C)\,\kappa^4}{\alpha - (1 + C\,L_C)\,\kappa^4}\;|R^k|_{L^2}.$$

This implies (3.6) with

$$\rho \;= \frac{(1 + C\,L_C)\,\kappa^4}{\alpha - (1 + C\,L_C)\,\kappa^4}. \qquad \square$$

6. Local superlinear convergence. In this section we derive sufficient conditions for superlinear convergence. Our analysis is based on expressing the primal-dual algorithm as a partial semismooth Newton algorithm for solving the optimality system (2.2). We refer to the procedure as partial semismooth Newton approach, since only the nonlinearity due to the max operation is linearized whereas the mapping $u \to T(u)$ is not. Observe that the second equation in (2.2) can equivalently be expressed as

$$\lambda = \max(0, \lambda + c(u - \psi)) + \min(0, \lambda + c(u - \varphi)) \quad \text{for every } c > 0. \tag{6.1}$$

Choosing $\alpha = c$, the necessary optimality condition can equivalently be formulated as

$$\mathcal{F}(u) = \alpha(u-\psi) + \max(0, \alpha\,\psi - p(u)) + \min(0, p(u) - \alpha\,\varphi) = 0, \tag{6.2}$$

where

$$p(u) = -T'(u)^*(T(u) - z).$$

Aside from the initialization, the iterative step of the algorithm can be equivalently expressed as

$$\begin{aligned}\alpha(u^{k+1}-\psi) - G^k_{\max}(p(u^{k+1}) - p(u^k)) + G^k_{\min}(p(u^{k+1}) - p(u^k))\\ + \max(0, \alpha\,\psi - p(u^k)) + \min(0, p(u^k) - \alpha\,\varphi) = 0,\end{aligned} \tag{6.3}$$

where

$$G^k_{\max}\phi = \begin{cases} 0 & \text{on} \quad A^+_{k+1} = \{x\colon p^k - \alpha\,\psi > 0\},\\ \phi & \text{on} \quad I^\psi_{k+1} = \{x\colon p^k - \alpha\,\psi \le 0\},\end{cases}$$

$$G^k_{\min}\phi = \begin{cases} \phi & \text{on} \quad A^-_{k+1} = \{x\colon p^k - \alpha\,\varphi < 0\},\\ 0 & \text{on} \quad I^\varphi_{k+1} = \{x\colon p^k - \alpha\,\varphi \ge 0\},\end{cases}$$

and $p^k = p(u^k)$.

Henceforth let u^* denote a solution to (2.1), set $y^* = T(u^*)$, and let λ^* be such that (u^*, λ^*) satisfy (2.1). Further, let $\{u^k\}_{k=1}^\infty$ denote the sequence of iterates which, together with u^* are assumed to be contained in $\mathcal{N}$, introduced in section 2. Note that (u^*, λ^*) satisfy

$$\begin{aligned}&\alpha\,u^* - p(u^*) + \lambda^* = 0,\\ &\alpha(u^* - \psi) + \max(0, \alpha\,\psi - p(u^*)) + \min(0, p(u^*) - \alpha\,\varphi) = 0.\end{aligned} \tag{6.4}$$

Combined with (6.3) we obtain

$$\begin{aligned}&\alpha(u^{k+1} - u^*) - G^k_{\max}(p(u^{k+1}) - p(u^*)) + G^k_{\min}(p(u^{k+1}) - p(u^*))\\ &= \max(0, \alpha\,\psi - p(u^*)) - \max(0, \alpha\,\psi - p(u^k)) + G^k_{\max}(p(u^*) - p(u^k))\\ &+ \min(0, p(u^*) - \alpha\,\varphi) - \min(0, p(u^k) - \alpha\,\varphi) - G^k_{\min}(p(u^*) - p(u^k)) =: R(u^k).\end{aligned} \tag{6.5}$$

Thus, given u^k, the new iterate u^{k+1} satisfies

$$\alpha(u - u^*) - G^I(p(u) - p(u^*)) = R, \tag{6.6}$$

where $R = R(u^k)$, and G^I is the characteristic function of the set $\{x\colon \alpha\,\varphi(x) \le p(u^k)(x) \le \alpha\,\psi(x)\}$. Equivalently, (6.6) can be expressed as

$$\begin{cases} H(y) - H(y^*) = \frac{1}{\alpha}\,G^I(p - p(u^*)) + \frac{1}{\alpha}\,R,\\ H'(y)^*p - H'(y^*)^*p(u^*) + y - y^* = 0,\end{cases} \tag{6.7}$$

with $R = R(u^k)$, $I = I(p(u^k))$, where y and u are related by $y = T(u)$.

In the statement of the following conditions, which will be used to establish local superlinear convergence, $N(u^*)$ denotes a neighborhood of u^* in $L^2(\Sigma)$.

$$\begin{cases} \text{There exists } q > 2, \text{ a neighborhood } N(u^*) \text{ and } L > 0 \text{ such that}\\ |p(u) - p(u^*)|_{L^q(\Sigma)} \le L|u - u^*|_{L^2(\Sigma)} \quad \text{for all } u \in N(u^*),\end{cases} \tag{6.8}$$

where $p(u) = -T'(u)^*(T(u) - z)$.

$$\text{(6.9)} \qquad \begin{cases} \text{There exists a constant } C \text{ independent of } I \text{ and } R \text{ such that} \\ \text{for every solution } u \text{ to (6.6) with } u \in N(u^*) \\ |u - u^*|_{L^2(\Sigma)} \le C|R|_{L^2(\Sigma)}. \end{cases}$$

Condition (6.9) will be applied with $u = u^k$ and $R = R(u^k)$, so that existence of u satisfying (6.6), respectively (y, p) satisfying (6.7), is a priori established. Throughout the remainder of the paper we require that $\varphi, \psi \in L^q(\Sigma)$.

LEMMA 6.1. *Assume that* (6.8) *is satisfied. Then*

$$|\max(0, \alpha\,\psi - p(u^* + h)) - \max(0, \alpha\,\psi - p(u^*)) + G_{\max}^{\psi(p(u^*+h))}(p(u^* + h) - p(u^*))|_{L^2(\Sigma)} = o(|h|_{L^2(\Sigma)}).$$

Proof. The mapping $u \to \max(0, u)$ is Newton differentiable for every $q > 2$, i.e.,

$$\text{(6.10)} \qquad |\max(0, u + v) - \max(0, u) - G(u + v)v|_{L^2(\Sigma)} = o(|v|_{L^q(\Sigma)}),$$

where

$$G(u + v)(x) = \begin{cases} 1 & \text{if } (u + v)(x) \ge 0, \\ 0 & \text{if } (u + v)(x) < 0; \end{cases}$$

see [HIK, U]. Applying (6.10) with $u = \alpha\,\psi - p(u^*)$ and $u + v = \alpha\,\psi - p(u^* + h)$ implies

$$|\max(0, \alpha\,\psi - p(u^* + h)) - \max(0, \alpha\,\psi - p(u^*)) + G_{\max}^{\psi(p(u^*+h))}(p(u^* + h) - p(u^*))|_{L^2(\Sigma)} = o(|p(u^* + h) - p(u^*)|_{L^q(\Sigma)}).$$

The claim follows with (6.8). □

THEOREM 6.2. *Assume that the iterates u^k converge to a solution u^* of* (2.1) *and that* (6.8) *is satisfied. If in addition* (6.9) *holds, then u^k converges superlinearly.*

Proof. In case (6.9) is satisfied, we have for all sufficiently large k

$$|u^{k+1} - u^*|_U \;\le\; C|R(u^k)|_U.$$

Using Lemma 6.1 with $h = u^k - u^*$, and an analogous estimate for the min operation, it follows from 6.5 that

$$|u^{k+1} - u^*|_U \;\le\; o(|u^k - u^*|_U). \qquad \square$$

PROPOSITION 6.3. *If T is linear, then* (6.9) *is satisfied.*

Proof. Let I be an arbitrary subset of Σ and let $R \in L^2(\Sigma)$. Denote by A the complement of I in Σ. For $\phi \in L^2(\Sigma)$ let $\phi_I = \phi\,\chi_I$ and $\phi_A = \phi\,\chi_A$. From (6.6) we have

$$\text{(6.11)} \qquad |(u - u^*)_A|_U \;\le\; \tfrac{1}{\alpha}|R_A|_U,$$

where u is any solution to (6.6). Moreover,

$$\alpha(u - u^*)_I - (p(u) - p(u^*))_I \;=\; R_I$$

and hence

$$\alpha(u - u^*)_I + (T^*T(u - u^*))\chi_I \;=\; R_I.$$

Taking the inner product with $(u-u^*)_I$ we find

$$\alpha|(u-u^*)_I|_U^2 + |T(u-u^*)_I|_Y^2 \;\le\; \tfrac{1}{2}|T(u-u^*)_I|_Y^2 \;+\; \tfrac{1}{2}|T(u-u^*)_A|_Y + \tfrac{\alpha}{2}|(u-u^*)_I|_U^2 \;+\; \tfrac{1}{\alpha}|R_I|_U^2,$$

and therefore

$$|(u-u^*)_I|_U^2 + |T(u-u^*)_I|_Y^2 \;\le\; \tfrac{1}{\alpha^2}\|T\|^2|R_A|_U^2 + \tfrac{1}{\alpha}|R_I|_U^2.$$

Combined with (6.11) this gives the desired result. □

In the following propositions we turn to providing conditions that imply (6.9) in case T is nonlinear. The abbreviations $y^* = y(u^*)$ and $p^* = p(u^*)$ will be used.

PROPOSITION 6.4. *Assume that $p : U \to U$ is Lipschitz continuous with Lipschitz constant γ. If $\alpha > \gamma$, then* (6.9) *is satisfied.*

Proof. From (6.6),

$$(\alpha - \gamma)\,|u-u^*|_U \le |R|_U,$$

and (6.9) follows. □

PROPOSITION 6.5. *Assume that there exists a neighborhood $\mathcal{N}(u^*)$ and constants $c > 0$ and $\delta > 0$ such that*

$$((H'(y) - H'(y^*))^* p^*, y - y^*)_U + |y-y^*|_Y^2 \ge \delta\,|y-y^*|_Y^2 \tag{6.12}$$

and

$$|p-p^*|_U \le c\,|y-y^*|_Y \tag{6.13}$$

for $u \in \mathcal{N}(u^*)$, where $y = T(u)$ and $p = -T'(u)^*(T(u)-z)$. If further

$$(H(y) - H(y^*) - H'(y)(y-y^*), p-p^*)_U \le \epsilon\,|y-y^*|_Y^2, \tag{6.14}$$

where $\epsilon \to 0$ as $|u-u^*| \to 0$, then (6.9) *is satisfied.*

Proof. From (6.7),

$$H'(y)(y-y^*) + H(y) - H(y^*) - H'(y)(y-y^*) = \tfrac{1}{\alpha}G^I(p-p^*) + \tfrac{1}{\alpha}R,$$

$$H'(y)^*(p-p^*) + (H'(y) - H'(y^*))^* p^* + y - y^* = 0.$$

Multiplying the first equation by $-(p-p^*)$ and the second equation by $y-y^*$ and then summing them, we have

$$((H'(y) - H'(y^*))^* p^*, y-y^*)_U + |y-y^*|_Y^2 + \tfrac{1}{\alpha}|(p-p^*)_I|_U^2$$

$$\le (H(y) - H(y^*) - H'(y)(y-y^*), p-p^*)_U - \tfrac{1}{\alpha}(R, p-p^*).$$

The assumptions of the proposition imply the existence of a constant C and a neighborhood $N(u^*)$ such that

$$|p-p^*|_U \le C\,|R|_U$$

for all $u \in N(u^*)$. The conclusion now follows from (6.2) and (6.4). □

If H is twice continuously Fréchet differentiable in a neighborhood of y^* and $H''(y^*)p^*$ is small, then (6.12) in Proposition 6.4 is satisfied. This smallness condition

can be implied by smallness of $y^* - z$, for example. The solution u^* itself and hence y^* depend on α, and the question arises whether by appropriate choice of α it can be guaranteed that $y^* - z$ is sufficiently small. This problem is addressed by assuming that there exists a feasible control $\bar{u}$ such that $T(\bar{u}) - z$ is sufficiently small. Then, it can be shown that under appropriate conditions, the smallness condition for $y^* - z$ holds for all sufficiently small α.

Remark 6.1. We demonstrate the applicability of Proposition 6.5. For this purpose we return to the class of problems described at the beginning of section 5 and assume in addition that $\phi \in C^2$. Let B denote a bounded subset of $L^2(\Omega)$. Then $y = y(u)$ and $p = p(u)$ with $u \in B$ are bounded sets in $H^2(\Omega) \cap H_0^1(\Omega) \cap L^\infty(\Omega)$. We have

$$-\Delta(y - y^*) + \phi(y) - \phi(y^*) = u - u^*,$$

$$-\Delta(p - p^*) + \phi'(y)(p - p^*) + (\phi'(y) - \phi'(y^*))p^* + y - y^* = 0.$$

Since ϕ is monotone, it follows from the first equation with the arguments of Proposition 5.1 that

$$|y - y^*|_1 \leq \kappa^2 \, |u - u^*|_{L^2},$$

and from the second equation we deduce that

$$|p - p^*|_1 \leq (\kappa + M|p^*|_{L^\infty}) \, |y - y^*|_{L^2}$$

for a constant M independent of $u \in B$. Thus, (6.13) holds. Moreover, since $|(\phi'(y) - \phi'(y^*))p^* + y - y^*|_{L^2} \to 0$ as $|u - u^*|_{L^2} \to 0$, it follows that $|p - p^*|_{H^2} \to 0$ for $|u - u^*| \to 0$ as well. To argue (6.14) observe that

$$(H(y) - H(y^*) - H'(y)(y - y^*), p - p^*)$$

$$= \int_0^1 (\phi''(y + t(y - y^*))(y - y^*)^2, p - p^*) \, dt \leq \bar{M} \, |p - p^*|_{L^\infty} ||y - y^*|_{L^2}^2,$$

for a constant $\bar{M}$ independent of $u \in B$. Moreover $|p - p^*|_{L^\infty} \to 0$ as $|u - u^*|_{L^2} \to 0$ and hence (6.14) holds. Finally note that

$$|(\phi'(y) - \phi'(y^*))p^*|_{L^2} \leq \hat{M} \, |y^* - z|_{L^2} |y - y^*|_{L^2},$$

where $\hat{M}$ is independent of $\alpha > 0$ and thus (6.12) follows.

7. Semismooth Newton method. So far we have analyzed global convergence as well as local superlinear convergence of the partial semismooth Newton method for solving (2.1). In this section we consider the semismooth Newton method for (2.1). The starting point is the optimality condition in the form (6.2). Given u^0, the semismooth Newton iteration is determined by

$$\begin{aligned} &\alpha(u^{k+1} - \psi) - G_{\max}^k \, p'(u^k)(u^{k+1} - u^k) + G_{\min}^k \, p'(u^k)(u^{k+1} - u^k) \\ &\qquad + \max(0, \alpha\,\psi - p(u^k)) + \min(0, p(u^k) - \alpha\,\varphi) = 0, \end{aligned} \tag{7.1}$$

where $G_{\max}^k$ and $G_{\min}^k$ are as given for (6.3). Combined with (6.4) the error equation is found to be

$$\begin{cases} \alpha(u^{k+1} - u^*) - G_{\max}^k p'(u_k)(u^{k+1} - u^*) + G_{\min}^k p'(u_k)(u^{k+1} - u^*) \\ = -\max(0, \alpha\,\psi - p(u^k)) + \max(0, \alpha\,\psi - p(u^*)) - G'_{\max} p'(u_k)(u^k - u^*) \\ -\min(0, p(u^k) - \alpha\,\varphi) + \min(0, p(u^*) - \alpha\,\varphi) + G'_{\min} p'(u^k - u^*) = \widetilde{R}. \end{cases} \tag{7.2}$$

Thus, given u^k the next iterate u^{k+1} is the solution to

$$\alpha(u-u^*) - G^{I_k} p'(u_k)(u-u^*) = \widetilde{R}, \tag{7.3}$$

where $\widetilde{R} = \widetilde{R}(u^k)$ and G^{I_k} is the characteristic function of the set $I_k = \{x\colon \alpha\,\varphi(x) \le p(u^k)(x) \le \alpha\,\psi(x)\}$. Equation (7.3) is the analogue to (6.6), which characterized the error equation for the partial semismooth Newton method. From (7.3) it follows that the convergence rate of u^k to u^* is determined by $\widetilde{R}$ and invertibility of the family of operators

$$M(u, I) = \alpha\, I - G^I p'(u)$$

as elements of $\mathcal{L}(L^2(\Sigma))$, where $u \in L^2(\Sigma)$ and I is a measurable subset of Ω. With respect to the latter we shall utilize the following assumption:

$$\begin{cases} \text{There exists a neighborhood } \bar{N}(u^*) \text{ of } u^* \text{ and a constant } C > 0 \\ \text{such that} \\ \|M^{-1}(u, I)\|_{\mathcal{L}(L^2(\Sigma))} \le C \quad \text{for all } u \in U(u^*) \ \text{ and } \ I \subset \Omega. \end{cases} \tag{7.4}$$

If we assume p to be C^1 and the conditions of either Proposition 6.4 or 6.5 are satisfied, then (7.4) holds. This follows from minor modifications of the proofs of these results. Turning to the estimate of $\widetilde{R}$ we observe that it involves the generalized derivatives of the composite mappings $u \to \max(0, \alpha\,\psi - p(u))$ and $u \to \min(0, p(u) - \alpha\,\varphi)$. We recall the notion of Newton differentiability from [HIK] and prove a chain rule.

Let X, Z be Banach spaces, $D \subset X$ an open subset, and $\omega \subset \mathbb{R}^n$ bounded.

Definition 7.1. *$F\colon D \subset X \to Z$ is called Newton differentiable at x^* if there exists a neighborhood $N(x^*) \subset D$ and a family of mappings $G\colon N(x^*) \to \mathcal{L}(X, Z)$ such that $\{\|G(x)\|\colon x \in N(x^*)\}$ is bounded and*

$$\lim_{|h|_X \to 0} \frac{1}{|h|_X} |F(x^* + h) - F(x^*) - G(x^* + h)h|_Z = 0. \tag{A}$$

Lemma 7.2 (chain rule). *Let $g\colon D \subset L^p(\omega) \to L^q(\omega)$, $1 \le p < q < \infty$, be continuously Fréchet differentiable at $y^* \in D$ and let $\phi\colon L^q(\omega) \to L^p(\omega)$ be Newton differentiable at $g(y^*)$ with a generalized gradient G. Then $F = \phi(g)$ is Newton differentiable at y^* with a generalized gradient given by $G(g)g' \in \mathcal{L}(L^p(\omega), L^p(\omega))$.*

Proof. Let U be a convex neighborhood of y^* in $L^p(\Omega)$ such that g' is continuous in U and $g(U)$ is contained in the neighborhood $N(g(y^*))$ according to the definition of Newton differentiability of ϕ at $g(y^*)$. Further let U and $C > 0$ be such that

$$\|G(g(y))\|_{\mathcal{L}(L^q, L^p)} \le C \quad \text{for all } y \in U$$

and

$$\|g'(y)\|_{\mathcal{L}(L^p, L^q)} \le C \quad \text{for all } y \in U.$$

Let $h \in L^p(\Omega)$ be such that $y^* + h \in U$. We shall utilize that

$$g(y^* + h) = g(y^*) + \int_0^1 g'(y^* + sh)h\, ds \tag{7.5}$$

and $g(y^* + h) \in N(g(y^*))$. Newton differentiability of ϕ at $g(y^*)$ implies that

(7.6)
$$\lim_{|h|_{L^p}\to 0} \frac{1}{|h|_{L^p}} \left|\phi(g(y^* + h)) - \phi(g(y^*)) - G(g(y^* + h)) \int_0^1 g'(y + sh)h \, ds\right|_{L^p} = 0.$$

Here we use (7.5) and the fact that

$$\left|\int_0^1 g'(y + sh)h \, ds\right|_{L^q} \le \int_0^1 \|g'(y + sh)\|_{\mathcal{L}(L^p,L^q)} ds |h|_{L^p} \le C|h|_{L^p}.$$

Let $\epsilon > 0$ be arbitrary. Due to continuity of g' at y^*, there exists a convex neighborhood $U_\epsilon \subset U$ of y^* such that $\|g'(y) - g'(y^*)\|_{\mathcal{L}(L^p,L^q)} < \epsilon$ for all $y \in U_\epsilon$. Consequently

$$\begin{aligned}
&\tfrac{1}{|h|_{L^p}} \left|G(g(y^* + h))\Big(\int_0^1 g'(y^* + sh)h \, ds - g'(y^* + h)h\Big)\right|_{L^p} \\
&\quad \le \tfrac{C}{|h|_{L^p}} \int_0^1 \|g'(y^* + sh) - g'(y^* + h)\|_{\mathcal{L}(L^p,L^q)} ds |h|_{L^p} \\
&\quad \le C\,\epsilon \quad \text{for all } y \in U_\epsilon.
\end{aligned}$$

Combining this estimate with (7.6) we find

$$\lim_{|h|_{L^p}\to 0} \frac{1}{|h|_{L^p}} |\phi(g(y^* + h)) - \phi(g(y^*)) - G(g(y^* + h))g'(y^* + h)|_{L^p} \le C\,\epsilon. \qquad \square$$

THEOREM 7.3. *If* (7.4) *holds and* $u \to p(u) = -(T(u)')^*(T(u) - z)$ *is continuously Fréchet differentiable from neighborhood* $N(u^*) \subset L^2(\Sigma)$ *of* u^* *to* $L^q(\Sigma)$ *for some* $q > 2$, *then the semismooth Newton iteration* (7.1) *converges superlinearly provided* $|u^0 - u^*|_U$ *is sufficiently small.*

Proof. The mappings $u \to \max(0, u)$ and $u \to \min(0, u)$ are Newton differentiable at every u from $L^q(\Sigma)$ to $L^2(\Sigma)$ for each $q > 2$. The claim follows from (7.3), (7.4), and Lemma 7.2 with $p = 2$ applied to $\widetilde{R}$. $\square$

Remark 7.1. For the results of sections 6 and 7, the requirement $\varphi < \psi$ can be relaxed to $\varphi \le \psi$ a.e. in Σ. However, we require $\varphi, \psi \in L^q(\Sigma)$.

Remark 7.2. While the analysis of semismoothness in function space is rather recent, it has a long tradition in finite dimensional spaces. We refer to the pioneering work [M] for semismooth functionals and its extensions, e.g., in [QS, SQ] to R^n-valued functions and nonsmooth versions of Newton's method.

Remark 7.3. The results of sections 6 and 7 depend in an essential manner on the regularity properties of the composite functions $u \to \max(0, \alpha\,\psi - p(u))$ and $u \to \min(0, p(u) - \alpha\,\varphi)$. Recall that $u \to \max(0, u)$ is not Newton differentiable with the indicator function of $\{x\colon u(x) > 0\}$ as generalized derivative from $L^2(\Sigma)$ to itself [HIK], and therefore the smoothing properties that were assumed to hold for $u \to p(u)$ as mapping from $L^2(\Sigma)$ to $L^q(\Sigma)$, for some $q > 2$, are essential. They are satisfied by many optimal control problems related to elliptic and parabolic partial differential equations. The results of section 7 are closely related to the general theory on semismooth Newton methods developed in [U]. In [U] composite functions $\Psi = \psi(F)$ are considered, where F is a differentiable mapping between vector-valued functions

spaces and ψ is a semismooth mapping from R^n to R^k. The generalized derivative of Ψ is given as the composition of the generalized derivative of ψ and F'. The mapping $u \to \max(0, u)$ is not generalized differentiable in the sense of [U] from $L^2(\Sigma)$ to itself. Expressed in the present context, the results in [U] are based on generalized differentiability of $u \to \max(0, \alpha\,\psi - p(u)) + \min(0, p(u) - \alpha\varphi)$ from $L^q(\Sigma)$ to $L^2(\Sigma)$, with $2 < q$, solvability (under appropriate conditions) of the Newton equation in $L^2(\Sigma)$, and an additional smoothing step in the Newton iteration resulting in an update that is again in $L^q(\Sigma)$. Convergence rates are subsequently obtained in $L^q(\Sigma)$. In our work, on the contrary, we utilize smoothing properties of p, which guarantee that the composite mapping $u \to \max(0, \alpha\,\psi - p(u)) + \min(0, p(u) - \alpha\varphi)$ is Newton differentiable.

Remark 7.4. There is a close relationship between the algorithms analyzed in this paper and Bertsekas' projected Newton method for simple constraints; see [B, p. 76 ff]. In the Bertsekas algorithm the new iterate is projected onto the admissible set $U_{\text{ad}} = \{u\colon \varphi \le u \le \psi\}$, before the new system matrix and right-hand side are computed. A more complete comparison is given in [BK]. Since to our knowledge the Bertsekas algorithm was not analyzed in a general context in the infinite dimensional setting, the following observation is of interest. Let P denote the projection in $L^2(\Sigma)$ onto U_{ad}, and assume that for the iterates of the partial (or full) semismooth Newton method we have $|u^{k+1} - u^*| \le \delta_k |u^k - u^*|$ with $\lim_{k\to\infty} \delta_k = 0$. Then the feasible iterates $\tilde{u}^k = P(u^*)$ which are obtained from modifying the algorithm by including a projection step after the Newton update converge superlinearly as well. In fact we have

$$|\tilde{u}^{k+1} - u^*|_{L^2(\Sigma)} = |P(u^{k+1}) - P(u^*)|_{L^2(\Sigma)} \le |u^{k+1} - u^*|_{L^2(\Sigma)} \le \delta_k |\tilde{u}^k - u^*|_{L^2(\Sigma)},$$

as desired.

8. Numerical tests. We give a brief account of some numerical tests that we carried out to solve optimal control problems with unilateral constraints for nonlinear problems of the form

$$\text{(8.1)} \qquad \begin{cases} \min \frac{1}{2}\,|y(u) - z|^2_{L^2(\Omega)} + \frac{\alpha}{2}\,|u|^2_{L^2(\Omega)} \\ -\mu\,\Delta\, y + g(y) = u \ \text{ in } \Omega, \\ y = 0 \ \text{ on } \partial\Omega, \\ u \le \psi \ \text{ in } \Omega. \end{cases}$$

The domain Ω was chosen as the unit square, and the discretization of (8.1) was obtained on the basis of finite differences with a five-point star approximation of the Laplacian and a uniform grid with mesh size $h = \frac{1}{n}$. When applying the primal-dual active set strategy specified at the beginning of section 2, then (2.3) can be expressed as in (2.6) with $H(y) = -\mu\,\Delta\, y + g(y)$. The auxiliary equality constrained problems (2.4) were solved by an SQP method with stopping criterion 10^{-12} for the discrete L^2-norm of the increments. The primal-dual algorithm was initialized by solving (8.1) without the constrained $u \le \psi$ by the SQP method with stopping criterion 10^{-3}.

In the numerical examples that we tested we observed that the primal-dual active set algorithm terminated after finitely many iterations by producing identical active sets in two consecutive iterations. We refer to the corresponding iterate as the solution u_h^* of the discretized problem. This is justified by the fact that such a solution satisfies the discretized form of the optimality system (2.6).

TABLE 1

k	1	2	3	4
q^k	0.3776	0.4082	0.1587	0.0334
$q\text{lam}^{\,k}$	0.1656	0.2462	0.0954	0.0207

The first question that we addressed is whether superlinear convergence can be observed in numerical practice. The problem data are specified by

$$z = e^{x_1} \sin x_2 - 1, \quad \psi = x_1 x_2 - 1, \quad \mu = 0.1, \quad \alpha = 10^{-3},$$
$$g(y) = \sin 3y, \quad \text{and} \quad n = 40.$$

In Table 1 we give the results for

$$q^k = \frac{|u^{k+1} - u_h^*|_{L^2}}{|u^k - u_h^*|_{L^2}}, \quad q\text{lam}^k = \frac{|\lambda^{k+1} - \lambda_h^*|_{L^2}}{|\lambda^k - \lambda_h^*|_{L^2}},$$

where u^0 is the solution from the initialization phase, $u^k, k \geq 1$, the solution of the kth iteration of the primal-dual active set strategy, and u_h^* the solution of the discretized problem as introduced above. Further, λ^k and λ_h^* denote the corresponding Lagrange multipliers and $|\cdot|$ stands for the discrete L^2-norm.

We tested with several other nonlinearities, including $g(y) = y^3$, $g(y) = y^5$, $g(y) = e^y$ and different mesh sizes, and again observed that the algorithm self-terminates due to the coincidence of two consecutive active sets.

In the second class of tests we compared three algorithms. For the sake of the following discussion let us refer to the algorithm that we described at the beginning of this section as the PD-SQP algorithm. This refers to the fact that in an outer loop we utilize the primal-dual active set strategy, and the resulting nonlinear equality constrained problem, see (2.4), is solved by an SQP method. For the second algorithm, referred to as SQP-PD, the order of the two loops is reversed. This is to say, an SQP approach is applied to (8.1) and the resulting inequality constrained linear-quadratic subproblems are solved by the primal-dual active set strategy. This strategy is described in [TV], for example. Here the primal-dual active set strategy allows us to solve the subproblems exactly since again for sufficiently large values of μ and α the algorithm terminates when the active sets coincide in two consecutive iterations. The outer loop is terminated with a stopping criterion measuring the increment in the SQP iteration and is set to 10^{-12} in the examples. The third algorithm arises by applying a semismooth Newton algorithm to the optimality system (2.5) with $H(y) = -\mu\,\Delta\, y + g(y)$. This algorithm, the SSN algorithm, coincides with SQP-PD as well as PD-SQP if in the latter two only one iteration in the inner loops is carried out. The SSN algorithm treats both nonlinearities $g(y)$ as well as $\lambda = \max(0, \lambda + (u - \psi))$ simultaneously. Differently from SQP-PD and PD-SQP, it is not inherent to this algorithm that the nonlinearity $\lambda = \max(0, \lambda + (u - \psi))$ is realized exactly, although depending on the stopping criterion in numerical practice this can occur.

For our comparison the stopping criterion was set to 10^{-12} as for the other algorithms. The comparison itself was made on the basis of the overall number of required solves of linear optimality systems. For test examples with moderate values of μ and α, PD-SQP requires more solves than SQP-PD or SSN. This situation changes for problems with smaller values of α and μ. In view of Theorem 4.1 and Proposition 5.1 it is then less likely that sufficient conditions for global convergence of the primal-dual active set strategy (in SQP-PD as well as in PD-SQP) are satisfied. For such problems

PD-SQP proved to be superior to SQP-PD, with the latter possibly nonterminating in the inner (PD) loop by the criterion of equality of two consecutive active sets. We therefore added the criterion of a maximum of 10 inner iterations to the SQP-PD algorithm. For the problem data given by

$$z = e^{x_1} \sin x_2 - 1,\ \psi = x_1 \cdot x_2 - 1,\ \mu = 10^{-4},\ \alpha = 10^{-4},\ g(y) = y^5,\ n = 40, \tag{8.2}$$

the number of problem solves required by the PD-SQP/SSN/SQP-PD methods is 34/36/66, and with μ, α changed to $\mu = 10^{-3}$, $\alpha = 10^{-5}$ the number of solves is given by 39/51/99. A similar comparison with z, ψ as in (8.1) and $\mu = 10^{-3}$, $\alpha = 10^{-4}$, $g(y) = y^3$ resulted in 27/18/81 required problem solves.

ERRATUM: NONLINEAR OBSERVER DESIGN IN THE SIEGEL DOMAIN*

ARTHUR J. KRENER† AND MINGQING XIAO‡

Abstract. There is an error in the proof of the main result of our paper [*SIAM J. Control Optim.*, 41 (2002), pp. 932–953]. An additional assumption is needed for the main result to hold. In this erratum, we supply a corrected version of the main result.

DOI. 10.1137/S0363012903435114

In our paper [1], we considered the problem of transforming the real analytic system

$$\dot{x} = f(x) = Fx + \cdots, \tag{0.1}$$

$$y = h(x) = Hx + \cdots \tag{0.2}$$

by a local, analytic change of coordinates

$$z = \theta(x)$$

and an analytic output injection

$$\beta(y)$$

into the system

$$\dot{z} = Az + \beta(y).$$

As shown by Kazantzis and Kravaris [2], this question is of interest because the latter system admits an observer

$$\dot{\hat{z}} = A\hat{z} + \beta(y)$$

with linear error dynamics

$$\dot{\tilde{z}} = A\tilde{z},$$

where $\tilde{z} = z - \hat{z}$. Such a $\theta(x)$ and $\beta(y)$ must satisfy the PDE

$$\frac{\partial \theta}{\partial x}(x) f(x) = A\theta(x) + \beta(h(x)). \tag{0.3}$$

Using the Lyapunov auxiliary theorem, Kazantzis and Kravaris showed, given an analytic β, that this PDE admits a unique solution if all the eigenvalues of F lie in the same half plane, either the left or the right, and the eigenvalues of A are not resonant with those of F.

‡Department of Mathematics, Southern Illinois University, Carbondale, IL 62901-4408 (mxiao@math.siu.edu).

In our paper, we claimed (Theorem 2) the existence of solutions to this PDE under considerably weaker hypothesis on the spectrum of F, but there is an error in our proof. An additional assumption is required: that the eigenvalues of the linear part of the system are of type (C, ν) with respect to (w.r.t.) themselves. The correct statement of the main result is as follows.

MAIN THEOREM. *Assume that* $f : \mathbf{R}^n \to \mathbf{R}^n, h : \mathbf{R}^n \to \mathbf{R}^p$, *and* $\beta : \mathbf{R}^p \to \mathbf{R}^n$ *are analytic vector fields with* $f(0) = 0,\ h(0) = 0,\ \beta(0) = 0$, *and* $F = \frac{\partial f}{\partial x}(0),\ H = \frac{\partial h}{\partial x}(0),\ B = \frac{\partial \beta}{\partial y}(0)$. *Suppose*

1. *there exists an invertible* $n \times n$ *matrix* T *so that* $TF = AT - BH$,
2. *there exists a* $C > 0, \nu > 0$ *such that all the eigenvalues of* A *are of type* (C, ν) *w.r.t.* $\sigma(F)$,
3. *there exists a* $C > 0, \nu > 0$ *such that all the eigenvalues of* F *are of type* (C, ν) *w.r.t.* $\sigma(F)$.

Then there exists a unique analytic solution $z = \theta(x)$ *to the PDE* (0.3) *locally around* $x = 0$. *Moreover* $\frac{\partial \theta}{\partial x}(0) = T$, *so* θ *is a local diffeomorphism.*

Proof. Because the eigenvalues of F are of type (C, ν) w.r.t. themselves, it follows from Siegel's theorem [3] that there exists an analytic local change of coordinates which linearizes the dynamics of the system (0.1). Therefore without loss of generality we may assume that the system is of the form

$$\dot{x} = Fx, \tag{0.4}$$

$$y = h(x). \tag{0.5}$$

Then the PDE (0.3) becomes

$$\frac{\partial \theta}{\partial x}(x)Fx = A\theta(x) + \beta(h(x)), \tag{0.6}$$

which has a unique local solution by Theorem 1 of [1]. □

Remarks. With the additional assumption, our result is no longer a generalization of that of Kazantzis and Kravaris [2]. The set of complex vectors $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n$ which are not of type (C, ν) w.r.t. themselves for any C is a set of measure zero if ν is large enough [3]. Therefore the additional assumption is satisfied by almost all systems.

MAX-PLUS EIGENVECTOR METHODS FOR NONLINEAR H_∞ PROBLEMS: ERROR ANALYSIS*

WILLIAM M. MCENEANEY†

Abstract. The H_∞ problem for a nonlinear system is considered. The corresponding dynamic programming equation is a fully nonlinear, first-order, steady-state partial differential equation (PDE), possessing a term which is quadratic in the gradient. The solutions are typically nonsmooth, and further, there is nonuniqueness among the class of viscosity solutions. In the case where one tests a feedback control to see if it yields an H_∞ controller, or where either the controller or disturbance sufficiently dominates, the PDE is a Hamilton–Jacobi–Bellman equation. The computation of the solution of a nonlinear, steady-state, first-order PDE is typically quite difficult. In a companion paper, we developed an entirely new class of methods for obtaining the "correct" solution of such PDEs. These methods are based on the linearity of the associated semigroup over the max-plus (or, in some cases, min-plus) algebra. In particular, solution of the PDE is reduced to solution of a max-plus (or min-plus) eigenvector problem for known unique eigenvalue 0 (the max-plus multiplicative identity). It was demonstrated that the eigenvector is unique and that the power method converges to it. In the companion paper, the basic method was laid out without discussion of errors and convergence. In this paper, we both approach the error analysis for such an algorithm, and demonstrate convergence. The errors are due to both the truncation of the basis expansion and computation of the matrix whose eigenvector one computes.

Key words. nonlinear H_∞ control, dynamic programming, numerical methods, partial differential equations, max-plus algebra

1. Introduction.

We consider the H_∞ problem for a nonlinear system. The corresponding dynamic programming equation (DPE) is a fully nonlinear, first-order, steady-state partial differential equation (PDE), possessing a term which is quadratic in the gradient (for background, see [1], [2], [18], [19], [37] among many notable others). The solutions are typically nonsmooth, and further, there are multiple viscosity solutions—that is, one does not even have uniqueness among the class of viscosity solutions (cf. [32], [33]). The computation of the solution of a nonlinear, steady-state, first-order PDE is typically quite difficult, and possibly even more so in the presence of the nonuniqueness mentioned above. Some previous works in the general area of numerical methods for these problems are [3], [7], [8], [15], [17], [22], and the references therein. In the companion paper [25] to this article, the mathematical background and basic algorithm for a class of numerical methods for such PDEs was discussed. This class of methods employs the max-plus linearity of the associated semigroup. It is a completely new class of methods. The approach is appropriate for two classes of PDEs associated with nonlinear (infinite time-horizon) H_∞ problems. The first is the (design) case where one tests a feedback control to see if it yields an H_∞ controller; the corresponding PDE is a Hamilton–Jacobi–Bellman (HJB) equation. In the case where the "optimal" feedback control is being determined as well, the problem takes

*Received by the editors September 17, 2002; accepted for publication (in revised form) October 12, 2003; published electronically July 2, 2004. Research for this work was partially supported by NSF grants DMS-9971546 and DMS-0307229.

the form of a differential game, and the PDE is, in general, an Isaacs equation. However, if the controller sufficiently dominates the disturbance, the PDE is still an HJB equation, and this is the second case. There is a slight difference in that the second case makes use of the min-plus algebra rather than the max-plus algebra. In this paper, we will consider only the first case, so as to simplify the discussion. However, one can certainly generalize the discussion to the second case.

The recent history of this new class of methods stems from a study of the robust/H_∞ filter ([31], [13], [11], [14], [28]; see also [5], [21], [6]), which has an associated time-dependent, fully nonlinear, first-order PDE. In [12], the linearity of the associated semigroup *over the max-plus algebra* was noted and provided a key ingredient in the development of a numerical algorithm for this filter. This linearity had previously been noted in [24]. A second key ingredient (first noted to our knowledge in [12]) was the development of an appropriate basis for the solution space over the max-plus algebra, i.e., with the max-plus algebra replacing the standard underlying field. (See also [20], [23] for related work.) This reduced the problem of propagation of the solution of the PDE forward in time to max-plus matrix-vector multiplication—with dimension being that of the number of basis functions being used. A key point here is that only a finite number of basis functions are used, and so one needs to determine a bound on the induced errors.

Returning to the (design case) H_∞ problem, the associated steady-state PDE is solved to determine whether this is indeed an H_∞ controller with that disturbance attenuation level. (If there is a nonnegative, locally bounded solution which is zero at the origin, then it is such an H_∞ controller; see, for instance, [1], [36].) The Hamiltonian is concave in the gradient variable. An example of such a PDE is

$$0 = H(x, \nabla W) = -\left[\frac{1}{2\gamma^2}(\nabla W)^T a(x) \nabla W + (f(x))^T \nabla W + l(x)\right],$$

where the notation will be described further below. There are typically multiple solutions of such PDEs—even when one normalizes by requiring $W(0) = 0$. In the linear-quadratic case, two of these solutions correspond to the stable and antistable manifolds associated with the Hamiltonian. The "correct" solution (i.e., the one corresponding to the available storage or value) was characterized in [36] as the smallest, nonnegative viscosity solution which is zero at the origin. In [33], [32], for the class of problems considered here, a specific quadratic growth bound was given which isolated this correct solution as the unique, nonnegative solution satisfying $0 \le W(x) \le C|x|^2$ for a specific C depending on the problem data.

The max-plus–based methods make use of the fact that the solutions are actually fixed points of the associated semigroup, that is,

$$W = S_\tau[W], \tag{1.1}$$

where S_τ is the semigroup with time-step $\tau > 0$. (See (2.7) for a definition of the semigroup.) In this case, one does not actually use the infinitesimal version of the semigroup (the PDE).

The max-plus algebra is a commutative semifield over $\mathbf{R} \cup \{-\infty\}$ with the addition and multiplication operations given by

$$\begin{aligned} a \oplus b &= \max\{a, b\}, \\ a \otimes b &= a + b, \end{aligned} \tag{1.2}$$

where the operations are defined for $-\infty$ in the obvious way. Note that $-\infty$ is the additive identity, and 0 is the multiplicative identity. Note that it is not a field since the additive inverses are missing. Roughly speaking, it can be extended to mimic the inclusion of additive inverses [4], but we do not need that here. Note that since 0 is the multiplicative identity, we can rewrite (1.1) as

$$0 \otimes W = S_\tau[W]. \tag{1.3}$$

In the companion paper [25] (see also the references therein), we showed that S_τ is linear over the max-plus algebra. With this in mind, one then thinks of W as an infinite-dimensional eigenvector (or eigenfunction) for S_τ corresponding to eigenvalue 0. If one approximates W by some finite-dimensional vector of coefficients in a max-plus basis expansion, then (1.3) can be recast as a finite-dimensional max-plus eigenvector equation (approximating the true solution). Thus, the nonlinear PDE problem is reduced to the solution of a (max-plus) linear eigenvector problem. In [25], an algorithm was generated under the assumption that the actual solution was spanned by a finite number of the basis functions. It also assumed exact computation of the finite-dimensional matrix which had the solution as the eigenvector. (Uniqueness of the eigenvalue and eigenvector were proven there.) In order to keep the paper at a reasonable size, further results regarding details of the numerical methods, convergence proofs, and error bounds were delayed to the current paper (although one may note that [26], [27] contain some of the main points).

Since, in reality, the value function would not have a *finite* max-plus expansion in any but the most unusual cases, we must consider the errors introduced by truncation of the expansion. In [16], the question was addressed in a broad sense. In [27], it was shown that as the number of basis functions increased, the approximation obtained by the algorithm converged to the true value function (assuming perfect computation of the matrix whose eigenvector one wants). We will now obtain some error estimates for the size of the errors introduced by this basis truncation. We also consider errors introduced by the approximation of the elements of the matrix corresponding to the H_∞ problem. Finally, these lead us to consider the relative rates at which the spacing between the basis functions and the improvement in the time-propagation errors in the matrix element computations must converge.

First, we need to review some results from [25] and other earlier papers which will be needed here. This is done in section 2. In section 3, we obtain a bound on the size of the errors in the computation of the finite-dimensional matrix, beyond which one cannot guarantee that the method will produce an approximate solution. Then, in section 4, we consider the errors in the solution introduced by truncation of the basis functions. In section 5, we consider the errors in the solution introduced by approximation of the elements of the finite-dimensional matrix. In section 6, we combine these to determine the relative rates at which the spacing between the basis functions and the matrix element errors must go to zero together.

Portions of this paper have appeared previously in [29], [30], [27], and [26], and the last two specifically discuss aspects of the convergence and error analysis.

2. Review of the max-plus based algorithm. In this section, the H_∞ problem class under consideration and accompanying assumptions are given. This is followed by a review of previous results regarding the max-plus–based algorithm which are necessary for the error analysis to follow.

We will consider the infinite time-horizon H_∞ problem in the fixed-feedback case where the control is built into the choice of dynamics. Recall that the case of active

control computation (i.e., the game case) is discussed briefly in [25], [29], and [30]. Consider the system

$$\dot{X} = f(X) + \sigma(X)w, \qquad X(0) = x, \tag{2.1}$$

where X is the state taking values in $\mathbf{R}^m$, f represents the nominal dynamics, the disturbance w lies in $\mathcal{W} \doteq \{w : [0,\infty) \to \mathbf{R}^\kappa : w \in L_2[0,T] \text{ for all } T < \infty\}$, and σ is an $m \times \kappa$ matrix-valued multiplier on the disturbance.

We will make the following assumptions. These assumptions are not necessary but are sufficient for the results to follow. No attempt has been made at this point to formulate tight assumptions. In particular, in order to provide some clear sketches of proofs, we will assume that all the functions f, σ, and l (given below) are smooth, although that is not required for the results. We will assume that there exist $K_f, c \in (0,\infty)$ such that

$$\begin{aligned} &(x-y)^T(f(x)-f(y)) \le -c|x-y|^2 \quad \forall\, x,y \in \mathbf{R}^m, \\ &f(0) = 0, \\ &|f_x(x)| \le K_f \quad \forall\, x \in \mathbf{R}^m. \end{aligned} \tag{A1}$$

Note that this automatically implies the closed-loop stability criterion of H_∞ control. We assume that there exist $M, K_\sigma < \infty$ such that

$$\begin{aligned} &|\sigma(x)| \le M \quad \forall\, x \in \mathbf{R}^m, \\ &|\sigma^{-1}(x)| \le M \quad \forall\, x \in \mathbf{R}^m, \\ &|\sigma_x(x)| \le K_\sigma \quad \forall\, x \in \mathbf{R}^m. \end{aligned} \tag{A2}$$

Here, we, of course, use σ^{-1} to indicate the Moore–Penrose pseudoinverse, and it is implicit in the bound on $\sigma^{-1}(x)$ that σ is uniformly nondegenerate. Let $l(x)$ be the running cost (to which the L_2-norm disturbance penalty will be added). We assume that there exist $\beta, \alpha < \infty$ such that

$$\begin{aligned} &l_{xx}(x) \le \beta \quad \forall\, x \in \mathbf{R}^m, \\ &0 \le l(x) \le \alpha|x|^2 \quad \forall\, x \in \mathbf{R}^m, \end{aligned} \tag{A3}$$

where notation such as $l_{xx} \le \beta$ will be used as a shorthand to indicate that the matrix $l_{xx} - \beta I$ is negative semidefinite. (There is a reason for allowing β to be greater than 2α, which one might notice; see [32].)

The system is said to satisfy an H_∞ attenuation bound (of γ) if there exists $\gamma \in (0,\infty)$ and a locally bounded available storage function (again, also referred to as the value function in what follows), $W(x)$, such that

$$W(x) = \sup_{w \in \mathcal{W}} \sup_{T < \infty} \int_0^T l(X(t)) - \frac{\gamma^2}{2}|w(t)|^2\, dt. \tag{2.2}$$

The corresponding DPE is

$$\begin{aligned} 0 &= -\sup\nolimits_{w \in \mathbf{R}^\kappa} \left\{ [f(x) + \sigma(x)w]^T \nabla W + l(x) - \tfrac{\gamma^2}{2}|w|^2 \right\} \\ &= -\left[\tfrac{1}{2\gamma^2} (\nabla W)^T \sigma(x) \sigma^T(x) \nabla W + f^T(x) \nabla W + l(x) \right]. \end{aligned} \tag{2.3}$$

Since W itself does not appear in (2.3), one can always scale by an additive constant. It will be assumed throughout that we are looking for a solution satisfying $W(0) = 0$.

We will also suppose that the above constants satisfy

$$\frac{\gamma^2}{2M^2} > \frac{\alpha}{c^2}. \tag{A4}$$

We note that there are examples where (A4) fails and the available storage is ∞. Then one has the following result. (See [32, Thms. 2.5 and 2.6] and [33, Thm. 2.5], where the proofs also appear.)

THEOREM 2.1. *There exists a unique continuous viscosity solution of* (2.3) *in the class*

$$0 \le W(x) \le c\frac{(\gamma-\delta)^2}{2M^2}|x|^2 \tag{2.4}$$

for sufficiently small $\delta > 0$. *Further, this unique continuous viscosity solution is given by*

$$W(x) = \lim_{T\to\infty} V(T,x) = \sup_{T<\infty} V(T,x), \tag{2.5}$$

where V *is the value of the finite time horizon problem with dynamics* (2.1) *and payoff and value*

$$\begin{aligned} J(T,x,w) &= \int_0^T l(X(t)) - \frac{\gamma^2}{2}|w(t)|^2\,dt, \\ V(T,x) &= \sup_{w\in\mathcal{W}} J(T,x,w). \end{aligned} \tag{2.6}$$

Define the semigroup

$$S_\tau[W(\cdot)](x) = \sup_{w\in\mathcal{W}}\Big\{\int_0^\tau l(X(t)) - \frac{\gamma^2}{2}|w(t)|^2\,dt + W(X(\tau))\Big\}, \tag{2.7}$$

where X satisfies (2.1). The next result demonstrates that we may solve the problem by obtaining the fixed point of the semigroup. See [25, Thm. 3.2] and the accompanying proof (or alternatively [30, Thm. 3.2 and proof]).

THEOREM 2.2. *For any* $\tau \in [0,\infty)$, W *given by* (2.5) *satisfies* $S_\tau[W] = W$, *and further, it is the unique solution in the class* (2.4).

The following key result is proved in [25, p. 1153] as well as in earlier references such as [30, Thm. 3.3] and [12, pp. 689–690]. However, to the best of the author's knowledge, the first statement of the result is due to Maslov [24].

THEOREM 2.3. *The solution operator,* S_τ, *is linear in the max-plus algebra.*

As noted in the introduction, the above linearity is a key to the development of the algorithms. A second key is the use of the space of semiconvex functions and a max-plus basis for the space. A function ϕ is *semiconvex* if for every $R < \infty$, there exists C_R such that $\widehat{\phi}(x) \doteq \phi(x) + (C_R/2)|x|^2$ is convex on the ball $B_R \doteq \{x \in \mathbf{R}^m : |x| < R\}$. The infimum over such C_R will be known as the semiconvexity constant for ϕ over B_R. We denote the space of semiconvex functions by $\mathcal{S}$. (The scalar C_R may sometimes be replaced by a symmetric, positive definite matrix where the condition becomes $\phi(x) + (1/2)x^T C_R x$ being convex; the case will be clear from the context.) Let $0 < R < \widehat{R}$, and suppose that ϕ is semiconvex over $B_{\widehat{R}}(0)$ with constant $C_{\widehat{R}}$. Then ϕ is Lipschitz over $B_R(0)$, with some constant L_R. See, for instance, [10] for a proof. Therefore any $\phi \in \mathcal{S}$ must be semiconvex and Lipschitz with some constants

C_R and L_R over any ball $B_R(0)$. Consequently, we define the notation $\mathcal{S}^R_{C,L}$ to be the set of $\phi : \overline{B_R}(0) \to \mathbf{R}$ such that ϕ is semiconvex and Lipschitz over $\overline{B_R}(0)$ with constants C and L, respectively. For simplicity of notation, we will henceforth use the notation $\overline{B}_\rho$ for the closed ball $\overline{B_\rho}(0)$ for any $\rho \in (0,\infty)$. It is essential that the value, W, be semiconvex, and that is given by the next result. The proof appears on pages 1154–1155 in [25].

THEOREM 2.4. *W lies in $\mathcal{S}$; for any $R < \infty$, there exist $C_R, L_R < \infty$ such that $W \in \mathcal{S}^R_{C_R,L_R}$.*

We now turn to the max-plus basis over $\mathcal{S}^R_{C_R,L_R}$. The following theorem is a minor variant of the semiconvex duality result given in [12]. It is derived from convex duality [34], [35] in a straightforward manner. There is a change from [12] in that a scalar constant there is replaced by a symmetric matrix C such that $C - C_R I > 0$, where I is the (usual algebra) identity matrix. This replacement allows more freedom in the actual numerical implementation.

THEOREM 2.5. *Let $\phi \in \mathcal{S}$. In particular, let $C_R, L_R \in (0,\infty)$ be the semiconvexity and Lipschitz constants, respectively, for ϕ over $\overline{B}_R$. Let C be a symmetric, positive definite matrix such that $C - C_R I > 0$. Let $D_R \geq R + |C^{-1}|L_R$, where $|C^{-1}|$ indicates the matrix norm of C^{-1}. (In particular, one may take $D_R = R + L_R/C_R$.) Then for all $x \in \overline{B}_R$,*

(2.8)
$$\phi(x) = \max_{\widetilde{x} \in \overline{B}_{D_R}} \Big[-\frac{1}{2}(x - \widetilde{x})^T C (x - \widetilde{x}) + a_{\widetilde{x}} \Big] = \max_{\widetilde{x} \in \mathbf{R}^m} \Big[-\frac{1}{2}(x - \widetilde{x})^T C (x - \widetilde{x}) + a_{\widetilde{x}} \Big],$$

where

$$a_{\widetilde{x}} = - \max_{x \in \overline{B}_R} \Big[-\frac{1}{2}(x - \widetilde{x})^T C (x - \widetilde{x}) - \phi(x) \Big]. \tag{2.9}$$

COROLLARY 2.6. *Let C_R, L_R, D_R be as in Theorem 2.5. Let $\phi \in \mathcal{S}^R_{C',L'}$, where in this case, C' may be a symmetric, positive definite matrix such that $C - C' > 0$, and $R + |C^{-1}|L' \leq D_R$. Then, (2.8), (2.9) hold.*

Remark 2.7. $R + |C^{-1}|L_R$ may be replaced by $|C^{-1}|\overline{L}_R$, where $\overline{L}_R$ is a Lipschitz constant for $\tilde{\phi}(x) \doteq \phi(x) + \frac{1}{2}x^T C x$ over $\overline{B}_R$. Note that $\overline{L}_R \leq L_R + |C|R$.

Let $\phi \in \mathcal{S}^R_{C_R,L_R}$. Let $\{x_i\}$ be a countable, dense set over $\overline{B}_{D_R}$, and let symmetric $C - C_R I > 0$, where (again) $C_R > 0$ is a semiconvexity constant for ϕ over $\overline{B}_R$. Define

$$\psi_i(x) \doteq -\frac{1}{2}(x - x_i)^T C (x - x_i) \quad \forall\, x \in \overline{B}_R$$

for each i. It may occasionally be handy to extend the domain beyond $\overline{B}_R$ by letting $\psi_i(x) = -\infty$ for $x \notin \overline{B}_R$. Then, using Theorem 2.5, one finds (see [12, pp. 695–698])

$$\phi(x) = \bigoplus_{i=1}^{\infty} [a_i \otimes \psi_i(x)] \quad \forall x \in \overline{B}_R, \qquad \text{where} \qquad a_i \doteq - \max_{x \in \mathbf{R}^m} [\psi_i(x) - \phi(x)]. \tag{2.10}$$

This is a countable max-plus basis expansion for ϕ. More generally, the set $\{\psi_i\}$ forms a max-plus basis for the space $\mathcal{S}^R_{C_R,L_R}$. We now have the following.

THEOREM 2.8. *Given $R < \infty$, there exist semiconvexity and Lipschitz constants constant $C_R, L_R < \infty$ such that $W \in \mathcal{S}^R_{C_R,L_R}$. Let $C - C_R I > 0$ and $\{x_i\}$ be dense*

over $\overline{B}_{D_R}$*, and define the basis* $\{\psi_i\}$ *as above. Then*

$$W(x) = \bigoplus_{i=1}^{\infty} [a_i \otimes \psi_i(x)] \quad \forall\, x \in \overline{B}_R, \tag{2.11}$$

where

$$a_i \doteq -\max_{x \in \overline{B}_R} [\psi_i(x) - W(x)]. \tag{2.12}$$

For the remainder of the section, fix any $\tau \in (0, \infty)$. We also assume throughout this section that one may choose C such that $C - C_R I > 0$ and such that

$$S_\tau[\psi_i] \in \mathcal{S}^R_{C',L'} \ \forall i, \tag{A5}$$

where $C - C' > 0$ and $R + |C^{-1}|L' \leq D_R$. This assures that each $S_\tau[\psi_i]$ has a max-plus basis expansion in terms of the basis $\{\psi_j\}$. We will not discuss this assumption in detail here but simply note that we have verified that this assumption holds for the problems where we have used this max-plus method. We also note that this assumption will need to be replaced by a slightly stricter assumption (A5′) in section 4 for the results there and beyond.

We now proceed to review the basics of the algorithm. In [25], the above theory was developed, and then, rather than proving convergence results for the algorithms, drastic assumptions were made so that the basic concept could be presented, while still keeping the paper to a reasonable length. In [25], [29], [30], it was simply assumed that there was a finite set of basis functions, $\{\psi_i\}_{i=1}^n$, such that W had a finite max-plus basis expansion over $\overline{B}_R$ in those functions, that is,

$$W(x) = \bigoplus_{i=1}^{n} a_i \otimes \psi_i(x), \tag{2.13}$$

and we let $a^T \doteq (a_1\ a_2 \cdots a_n)$, and $B_{j,i} = -\max_{x \in B_R}[\psi_j(x) - S_\tau(\psi_i(x))]$. Let B be the $n \times n$ matrix of elements $B_{j,i}$. Note that B actually depends on τ, but we suppress the dependence in the notation. We made the further drastic assumption that for each $j \in \{1, 2, \ldots, n\}$, $S_\tau[\psi_j]$ also had a finite basis expansion in the same set of basis functions, $\{\psi_i\}_{i=1}^n$, so that

$$S_\tau[\psi_j(x)] = \bigoplus_{i=1}^{n} B_{j,i} \otimes \psi_i(x) \tag{2.14}$$

for all $x \in \overline{B}_R$. Specifically, under (2.13), (2.14) one has the following theorem (see, for instance, [25, Thm. 5.1] or [30, Thm. 5.1]).

THEOREM 2.9. *Suppose expansion* (2.13) *requires* $a_i > -\infty$ *for all* i. $S_\tau[W] = W$ *if and only if* $a = B \otimes a$*, where* $B \otimes a$ *represents max-plus matrix multiplication.*

Continuing with the review, suppose that one has computed B exactly. One must then compute the max-plus eigenvector. We should note that B has a unique max-plus eigenvalue, although possibly many eigenvectors corresponding to that eigenvalue [4]. By the above results, this eigenvalue must be zero. As discussed in [25], [29], [27], one can compute the max-plus eigenvector via the power method; this has the added benefit that the convergence analysis to follow is performed in an analogous way. In the power method, one computes an eigenvector a by

$$a = \lim_{N \to \infty} B^N \otimes \vec{0},$$

where the power is to be understood in the max-plus sense and $\vec{0}$ is the zero vector. Throughout the paper, we let the $\{x_j\}$ be such that $x_1 = 0$, that is, $\psi_1(x) = -\frac{1}{2}x^T Cx$. Since this is simply an approach to arrangement of the basis functions, we do not annotate it as an assumption. The fact that the power method works is encapsulated in the following series of three results which hold under (2.13), (2.14) and are proved in [25, pp. 1158–1160].

LEMMA 2.10. *$B_{1,1} = 0$. Also, there exists $\delta > 0$ such that for all $j \neq 1$, $B_{j,j} \leq -\delta$.*

THEOREM 2.11. *Let $N \in \{1, 2, \ldots, n\}$, $\{k_i\}_{i=1}^{i=N+1}$ such that $1 \leq k_i \leq n$ for all i and $k_{N+1} = k_1$. Suppose we are not in the case $k_i = 1$ for all i. Then*

$$\sum_{i=1}^{N} B_{k_i,k_{i+1}} \leq -\delta.$$

Recall that B has a unique max-plus eigenvalue, although possibly many max-plus eigenvectors corresponding to that eigenvalue [4], and that by the above results, this eigenvalue must be zero (ignoring errors due to approximation).

THEOREM 2.12. *$\lim_{N\to\infty} B^N \otimes 0$ exists, converges in a finite number of steps and satisfies $e = B \otimes e$. Further, this is the unique max-plus eigenvector up to a max-plus multiplicative constant.*

Thus, under the drastic assumptions above, one finds that the power method converges to the unique solution of the eigenvector problem (in a finite number of steps), and that this eigenvector is the finite set of coefficients in the max-plus basis expansion of the value function, W. The next sections will deal with the facts that we actually need to truncate infinite basis expansions, and that the computations of the elements of B are only approximate. Convergence results and error analysis will be performed. This not only will indicate that one can achieve arbitrarily good approximations to W via the above max-plus approach, but also will indicate the rate at which the distance between basis function centers should drop as the time-propagation errors in B drop so as to guarantee convergence. This is somewhat analogous to results for finite difference schemes which indicate the required relative rates at which the time and space step must go to zero for such problems.

For purposes of readability, we briefly *outline* the steps in the max-plus algorithm for (approximate) computation of W over a ball, $\overline{B}_R$.

1. Choose a set of max-plus basis functions of the form $\psi_i(x) = -\frac{1}{2}(x-x_i)^T C(x-x_i)$ where the x_i lie in $\overline{B}_{D_R}$. (In practice however, a rectangular grid has been used.) Choose a "time-step," τ.
2. Compute (approximately) elements of the matrix B given by

$$B_{j,i} = -\max_{x\in\overline{B}_R}[\psi_j(x) - S_\tau(\psi_i(x))].$$

   A reasonably efficient means of computing B is important, and a Runge–Kutta–based approach is indicated in section 5.1.
3. Compute the max-plus eigenvector of B corresponding to max-plus eigenvalue $\lambda = 0$ (i.e., the solution of $e = B \otimes e$). This is obtained from the max-plus power method $a_{k+1} = B \otimes a_k$. This converges exactly in a finite number of steps.
4. Construct the solution approximation from $\widehat{W}(x) \doteq \bigoplus_{i=1}^{n} a_i \otimes \psi_i(x)$ on $B_R(0)$.

3. Allowable errors in computation of B. In this section, we obtain a bound on the maximum allowable errors in the computation of B. If the errors are below this bound, then we can guarantee convergence of the power method to the unique eigenvector. In particular, the guaranteed convergence of the power method relies on Lemma 2.10 and Theorem 2.11 since these imply a certain structure to a directed graph associated with B (see [25], [29]). If there was a sequence $\{k_i\}_{i=1}^{i=N+1}$ such that $1 \le k_i \le n$ for all i and $k_{N+1} = k_1$ such that one does not have $k_i = 1$ for all i and such that

$$\sum_{i=1}^{N} B_{k_i,k_{i+1}} \ge 0$$

then there would be no guarantee of convergence of the power method (nor the ensuing uniqueness result for that matter). In order to determine more exactly, the allowable errors in the computation of the elements of B, we first need to obtain a more exact expression for the δ that appears in Lemma 2.10 and Theorem 2.11, and this will appear in Theorems 3.4 and 3.6. That will be followed by results indicating the allowable error bounds. To begin, one needs the following lemma.

LEMMA 3.1. *Let X satisfy* (2.1) *with initial state $X(0) = x \in \mathbf{R}^m$. Let $K, \tau \in (0, \infty)$, and let $w \in L_2[0, \tau]$. Suppose $\delta > 0$ sufficiently small so that*

$$\delta \le KM^2/[c(1 - e^{-c\tau})], \tag{3.1}$$

where c, M are given in assumptions (A1), (A2). *Then*

$$K|X(\tau) - x|^2 + \delta\|w\|^2_{L_2[0,\tau]} \ge \frac{\delta c}{8M^2}|x|^2\big(1 - e^{-c\tau}\big)^4.$$

Remark 3.2. It may be of interest to note that the assumption on the size of δ does not seem necessary. At one point in the proof to follow, this assumption is used in order to eliminate a case which would lead to a more complex expression on the right-hand side in the result in the lemma statement. If some later technique benefited from not having such an assumption, the lemma proof could be revisited in order to eliminate it. However, at this point, that would seem to be a needless technicality.

Remark 3.3. It is perhaps also worth indicating the intuition behind the inequality obtained in Lemma 3.1. Essentially, it states that, due to the nature of the dynamics of the system, the only way that $|X(\tau) - x|^2$ can be kept small is through input disturbance energy $\|w\|^2$, and so their weighted sum is bounded from below. The dependence on $|x|$ on the right-hand side is indicative of the fact that $|f(x)|$ goes to zero at the origin.

Proof. Note that by (2.1) and assumptions (A1) and (A2),

$$\frac{d}{dt}|X|^2 \le -2c|X|^2 + 2M|X||w| \tag{3.2}$$

$$\le -c|X|^2 + \tfrac{M^2}{c}|w|^2. \tag{3.3}$$

Consequently, for any $t \in [0, \tau]$,

$$|X(t)|^2 \le e^{-ct}|x|^2 + \tfrac{M^2}{c}\int_0^t |w(r)|^2\, dr$$

and so

$$\|w\|^2_{L_2(0,t)} \geq \tfrac{c}{M^2}\Big[|X(t)|^2 - |x|^2\Big] \quad \forall\, t \in [0,\tau]. \tag{3.4}$$

We may suppose

$$|X(t)| \leq \sqrt{1 + (1-e^{-c\tau})^4/2}\,|x| \quad \forall\, t \in [0,\tau]. \tag{3.5}$$

Otherwise by (3.4) and the reverse of (3.5), there exists $t \in [0,\tau]$ such that

$$K|X(\tau)-x|^2 + \delta\|w\|^2_{L_2[0,\tau]} \geq \delta\|w\|^2_{L_2[0,t]} \geq \tfrac{\delta c}{2M^2}(1-e^{-c\tau})^4|x|^2, \tag{3.6}$$

in which case one already has the desired result. Define $\overline{K} \doteq \sqrt{1 + (1-e^{-c\tau})^4/2}$.

Recalling (3.2), and applying (3.5), one has

$$\frac{d}{dt}|X(t)|^2 \leq -2c|X(t)|^2 + 2M\overline{K}|x||w(t)|.$$

Solving this ODI for $|X(t)|^2$, and using the Hölder inequality, yields the bound

$$|X(\tau)|^2 \leq |x|^2 e^{-2c\tau} + \frac{M\overline{K}|x|\|w\|}{\sqrt{c}}\big(1-e^{-4c\tau}\big)^{1/2}. \tag{3.7}$$

This implies

$$|X(\tau)| \leq |x|e^{-c\tau} + \frac{1}{c^{1/4}}\sqrt{M\overline{K}|x|\|w\|}\big(1-e^{-4c\tau}\big)^{1/4}. \tag{3.8}$$

We consider two cases separately. First, we consider the case where $|X(\tau)| \leq |x|$. Then, by (3.8)

$$|X(\tau)-x| \geq |x| - |X(\tau)| \geq |x|(1-e^{-c\tau}) - \frac{1}{c^{1/4}}\sqrt{M\overline{K}|x|\|w\|}\big(1-e^{-4c\tau}\big)^{1/4}. \tag{3.9}$$

Now note that for general $a,b,c \in [0,\infty)$, $a+c \geq b$ implies

$$a^2 \geq \frac{b^2}{2} - c^2. \tag{3.10}$$

By (3.9) and (3.10) (and noting the nonnegativity of the norm),

$$|X(\tau)-x|^2 \geq \max\left\{\frac{1}{2}|x|^2(1-e^{-c\tau})^2 - \frac{M\overline{K}}{\sqrt{c}}|x|\|w\|\big(1-e^{-4c\tau}\big)^{1/2},\, 0\right\},$$

which implies

$$\begin{aligned} K|X(\tau)-x|^2 + \delta\|w\|^2 \geq \max\Big\{ &\frac{K}{2}|x|^2(1-e^{-c\tau})^2 - \frac{KM\overline{K}}{\sqrt{c}}|x|\|w\|\big(1-e^{-4c\tau}\big)^{1/2} \\ &+ \delta\|w\|^2, \delta\|w\|^2\Big\}. \end{aligned} \tag{3.11}$$

The right-hand side of (3.11) is a maximum of two convex quadratic functions of $\|w\|$. The second is monotonically increasing, while the first is positive at $\|w\| = 0$ and initially decreasing. This implies that there are two possibilities for the location of the

minimum of the maximum of the two functions. If the minimum of the first function is to the left of the point where the two functions intersect, then the minimum occurs at the minimum of the first function; alternatively it occurs where the two functions intersect. The minimum of the first function occurs at $\|w\|_{min}$ (where we are abusing notation here, using the *min* subscript on the norm to indicate the value of $\|w\|$ at which the minimum occurs), and this is given by

$$\|w\|_{min} = \frac{KM\overline{K}|x|(1-e^{-4c\tau})^{1/2}}{2\sqrt{c}\delta}. \tag{3.12}$$

The point of intersection of the two functions occurs at

$$\|w\|_{int} = \frac{\sqrt{c}|x|(1-e^{-c\tau})^2}{2M\overline{K}(1-e^{-4c\tau})^{1/2}}. \tag{3.13}$$

The two points coincide when

$$\delta = \frac{KM^2\overline{K}^2(1-e^{-4c\tau})}{c(1-e^{-c\tau})^2} = \frac{KM^2[1+(1-e^{-c\tau})^4/2](1-e^{-4c\tau})}{c(1-e^{-c\tau})^2},$$

and $\|w\|_{int}$ occurs to the left of $\|w\|_{min}$ for δ less than this. It is easy to see that assumption (3.1) implies that δ is less than the value at which the points coincide, and consequently, the minimum of the right-hand side of (3.11) occurs at $\|w\|_{int}$.

Using the value of the right-hand side of (3.11) corresponding to $\|w\|_{int}$, we find that for any disturbance, w,

$$K|X(\tau)-x|^2 + \delta\|w\|^2 \geq \frac{\delta c|x|^2}{4M^2\overline{K}^2}\frac{(1-e^{-c\tau})^4}{(1-e^{-4c\tau})}$$

which, using definition of $\overline{K}$, equals

$$\frac{\delta c|x|^2}{4M^2}\frac{(1-e^{-c\tau})^4}{(1-e^{-4c\tau})[1+(1-e^{-c\tau})^4/2]} \geq \frac{\delta c|x|^2}{8M^2}(1-e^{-c\tau})^4. \tag{3.14}$$

Now we turn to the second case,

$$|X(\tau)| > |x|. \tag{3.15}$$

In this case, (3.15) and (3.8) yield

$$|x|e^{-c\tau} + \frac{1}{c^{1/4}}\sqrt{M\overline{K}|x|\|w\|}\left(1-e^{-4c\tau}\right)^{1/4} > |x|. \tag{3.16}$$

Upon rearrangement, (3.16) yields

$$\|w\| > \frac{\sqrt{c}|x|}{M\overline{K}}\frac{(1-e^{-c\tau})^2}{(1-e^{-4c\tau})^{1/2}}.$$

Consequently, using the definition of $\overline{K}$ and some simple manipulations,

$$\begin{aligned} K|X(\tau)-x|^2 + \delta\|w\|^2 &\geq \frac{\delta c|x|^2(1-e^{-c\tau})^4}{M^2(1-e^{-4c\tau})[1+(1-e^{-c\tau})^4/2]} \\ &\geq \frac{\delta c|x|^2}{2M^2}(1-e^{-c\tau})^4. \end{aligned} \tag{3.17}$$

Combining (3.14) and (3.17) completes the proof. □

Now we turn to how Lemma 3.1 can be used to obtain a more detailed replacement for the δ that appears in Theorems 2.10 and 2.11. Fix $\tau > 0$. Let

$$\hat{\gamma}_0^2 \in \left(\frac{2M^2\alpha}{c^2}, \gamma^2\right), \tag{3.18}$$

and in particular, let $\hat{\gamma}_0^2/2 = \gamma^2/2 - \delta$, where δ is sufficiently small so that

$$2\delta < \gamma^2 - \frac{2M^2\alpha}{c^2}. \tag{3.19}$$

Then all results of section 2 for W hold with γ^2 replaced by $\hat{\gamma}_0^2$, and we denote the corresponding value by $W^{\hat{\gamma}_0}$. In particular, by Theorem 2.8, for any $R < \infty$ there exists semiconvexity constant $C_R^0 < \infty$ for $W^{\hat{\gamma}_0}$ over $\overline{B}_R$, and a Lipschitz constant, L_R^0. Note that the required constants satisfy $C_R^0 < C_R$ (see the proof of Theorem 2.8 as given in [25]). If $L_R^0 > L_R$ sufficiently so that $R + |C^{-1}|L_R^0 > D_R$, we modify our basis to be dense over $\overline{B}_{D_R^0}$, where $D_R^0 \geq R + |C^{-1}|L_R^0$ (and redefine $D_R \doteq D_R^0$ in that case). Then, as before, the set $\{\psi_i\}$ forms a max-plus basis for the space of semiconvex functions over $\overline{B}_R$ with semiconvexity constant, C_R^0, i.e., $\mathcal{S}^R_{C_R^0, L_R^0}$.

For any j, let

$$\overline{x}_j \in \operatorname*{argmax}_{|x| \leq R} \{\psi_j(x) - W^{\hat{\gamma}_0}(x)\}. \tag{3.20}$$

Then for any $x \in \overline{B}_R$,

$$\psi_j(x) - \psi_j(\overline{x}_j) \leq W^{\hat{\gamma}_0}(x) - W^{\hat{\gamma}_0}(\overline{x}_j) - K_0|x - \overline{x}_j|^2, \tag{3.21}$$

where $K_0 > 0$ is the minimum eigenvalue of $C - C_R^0 I > 0$. Note that K_0 depends on $\hat{\gamma}_0$.

THEOREM 3.4. *Let $\hat{\gamma}_0$ satisfy* (3.18). *Let $K = K_0$ satisfy* (3.21) *(where we may take $K_0 > 0$ to be the minimum eigenvalue of $C - C_R^0 I > 0$ if desired). Let $\delta > 0$ satisfy $\delta \leq \frac{\gamma^2}{2} - \frac{\hat{\gamma}_0^2}{2}$ and* (3.1). *Then, for any $j \neq 1$,*

$$B_{j,j} \leq \frac{-\delta c|\overline{x}_j|^2}{8M^2}\left(1 - e^{-c\tau}\right)^4.$$

(Recall that by the choice of ψ_1 as the basis function centered at the origin, $B_{1,1} = 0$; see Lemma 2.10.)

Proof. Let K_0, τ, δ satisfy the assumptions. Then

$$S_\tau[\psi_j](\overline{x}_j) - \psi_j(\overline{x}_j) = \sup_{w \in L_2}\left\{\int_0^\tau l(X(t)) - \frac{\gamma^2}{2}|w(t)|^2\,dt + \psi_j(X(\tau)) - \psi_j(\overline{x}_j)\right\}, \tag{3.22}$$

where X satisfies (2.1) with $X(0) = \overline{x}_j$. Let $\varepsilon > 0$, and w^ε be ε-optimal. Then this implies

$$S_\tau[\psi_j](\overline{x}_j) - \psi_j(\overline{x}_j) \leq \int_0^\tau l(X^\varepsilon(t)) - \frac{\gamma^2}{2}|w^\varepsilon(t)|^2\,dt + \psi_j(X^\varepsilon(\tau)) - \psi_j(\overline{x}_j) + \varepsilon,$$

and by (3.21) and the definition of $\hat{\gamma}_0$

$$\leq \int_0^\tau l(X^\varepsilon(t)) - \frac{\hat{\gamma}_0^2}{2}|w^\varepsilon(t)|^2 - \delta|w^\varepsilon(t)|^2\,dt + W^{\hat{\gamma}_0}(X^\varepsilon(\tau)) - W^{\hat{\gamma}_0}(\overline{x}_j) - K_0|X^\varepsilon(\tau) - \overline{x}_j|^2 + \varepsilon$$

and by Theorem 2.2 (for $W^{\hat{\gamma}_0}$),

$$\leq -\delta\|w^\varepsilon\|^2 - K_0|X^\varepsilon(\tau) - \overline{x}_j|^2 + \varepsilon.$$

Combining this with Lemma 3.1 yields

$$S_\tau[\psi_j](\overline{x}_j) - \psi_j(\overline{x}_j) \leq \frac{-\delta c|\overline{x}_j|^2}{8M^2}\left(1 - e^{-c\tau}\right)^4 + \varepsilon.$$

Since this is true for all $\varepsilon > 0$, one has

$$S_\tau[\psi_j](\overline{x}_j) - \psi_j(\overline{x}_j) \leq \frac{-\delta c|\overline{x}_j|^2}{8M^2}\left(1 - e^{-c\tau}\right)^4. \tag{3.23}$$

But

$$B_{j,j} = \min_{|x|\leq R}\left\{S_\tau[\psi_j](x) - \psi_j(x)\right\}, \tag{3.24}$$

which by (3.23)

$$\leq \frac{-\delta c|\overline{x}_j|^2}{8M^2}\left(1 - e^{-c\tau}\right)^4. \qquad \square$$

Remark 3.5. It is interesting to note that one may modify (3.24) as $B_{j,j} = \min_{x\in\mathbf{R}^m}\{S_\tau[\psi_j](x) - \psi_j(x)\}$ since one has $\psi_j(x) = -\infty$ for $x \notin \overline{B}_R$. One might also note that by the nondegeneracy of σ (assumption (A2)), if any function $\phi > -\infty$ on $\overline{B}_R$, then $S_\tau[\phi] > -\infty$ on $\overline{B}_R$.

THEOREM 3.6. *Let $\hat{\gamma}_0$ satisfy* (3.18). *Let K_0 be as in* (3.21), *and let $\delta > 0$ be given by*

$$\delta = \min\left\{\frac{K_0M^2}{c},\ \frac{\gamma^2}{2} - \frac{\hat{\gamma}_0^2}{2}\right\} \tag{3.25}$$

(which is somewhat tighter than the requirement in the previous theorem). Let $N \in \mathcal{N}$, $\{k_i\}_{i=1}^{i=N+1}$ such that $1 \leq k_i \leq n$ for all i and $k_{N+1} = k_1$. Suppose we are not in the case $k_i = 1$ for all i. Then

$$\sum_{i=1}^N B_{k_i,k_{i+1}} \leq -\max_{k_i}|\overline{x}_{k_i}|^2\frac{\delta c}{8M^2}\left(1 - e^{-cN\tau}\right)^4.$$

Proof. By Theorem 3.4, this is true for $N = 1$. We prove the case $N = 2$. The proof of the general case will then be obvious. First, note the monotonicity of the semigroup in the sense that if $g_1(x) \leq g_2(x)$ for all x, then

$$S_\tau[g_1](x) \leq S_\tau[g_2](x) \quad \forall\, x \in \mathbf{R}^m. \tag{3.26}$$

Suppose either $i \neq 1$ or $j \neq 1$. By definition, $\psi_j(x) + B_{j,i} \leq S_\tau[\psi_i](x)$ for all $x \in \mathbf{R}^m$. Using (3.26) and the max-plus linearity of the semigroup yields

$$S_\tau[\psi_j](x) + B_{j,i} \leq S_{2\tau}[\psi_i](x) \quad \forall\, x,$$

which implies in particular that

$$S_\tau[\psi_j](\overline{x}_i) + B_{j,i} \leq S_{2\tau}[\psi_i](\overline{x}_i). \tag{3.27}$$

Now, employing the same proof as that of Theorem 3.4, but with τ replaced by 2τ (noting that condition (3.1) is satisfied with 2τ replacing τ by our assumption (3.25)), one has as in (3.23)

$$S_{2\tau}[\psi_i](\overline{x}_i) - \psi_i(\overline{x}_i) \leq \frac{-\delta c|\overline{x}_i|^2}{8M^2}\big(1 - e^{-2c\tau}\big)^4. \tag{3.28}$$

Combining (3.27) and (3.28) yields

$$\Big[S_\tau[\psi_j](\overline{x}_i) - \psi_i(\overline{x}_i)\Big] + B_{j,i} \leq \frac{-\delta c|\overline{x}_i|^2}{8M^2}\big(1 - e^{-2c\tau}\big)^4.$$

Using the definition of $B_{i,j}$, this implies

$$B_{i,j} + B_{j,i} \leq \frac{-\delta c|\overline{x}_i|^2}{8M^2}\big(1 - e^{-2c\tau}\big)^4. \tag{3.29}$$

By symmetry, one also has

$$B_{i,j} + B_{j,i} \leq \frac{-\delta c|\overline{x}_j|^2}{8M^2}\big(1 - e^{-2c\tau}\big)^4. \tag{3.30}$$

Combining (3.29) and (3.30) yields

$$B_{i,j} + B_{j,i} \leq -\max\Big\{|\overline{x}_i|^2, |\overline{x}_j|^2\Big\}\frac{\delta c}{8M^2}\big(1 - e^{-2c\tau}\big)^4. \qquad \square$$

The convergence of the power method (described in the previous section) relied on a certain structure of B ($B_{1,1} = 0$ and strictly negative loop sums as described in the assumptions of Theorem 2.11). Combining this with the above result on the size of loop sums, one can obtain a condition which guarantees convergence of the power method to a unique eigenvector corresponding to eigenvalue zero. This is given in the next theorem.

THEOREM 3.7. *Let B be given by $B_{j,i} = -\max_{x \in \overline{B}_R}\big(\psi_j(x) - S_\tau[\psi_i](x)\big)$ for all $i, j \leq n$, and let $\widetilde{B}$ be an approximation of B with $\widetilde{B}_{1,1} = 0$ and such that there exists $\varepsilon > 0$ such that*

$$|\widetilde{B}_{i,j} - B_{i,j}| \leq \max\big\{|\overline{x}_i|^2, |\overline{x}_j|^2\big\}\left(\frac{\delta c}{8M^2}\right)\frac{\big(1 - e^{-c\tau}\big)^4}{n^2} - \varepsilon \quad \forall\, i, j \text{ such that } (i,j) \neq (1,1), \tag{3.31}$$

where

$$\delta = \min\left\{\frac{K_0 M^2}{c},\ \frac{\gamma^2}{2} - \frac{\hat{\gamma}_0^2}{2}\right\}. \tag{3.32}$$

Then the power method applied to $\widetilde{B}$ converges in a finite number of steps to the unique eigenvector $\widetilde{e}$ corresponding to eigenvalue zero, that is,

$$\widetilde{e} = \widetilde{B} \otimes \widetilde{e}.$$

Proof. Let $N \in \mathcal{N}$, and consider a sequence of nodes $\{k_i\}_{i=1}^{N+1}$ with $k_1 = k_{N+1}$. We must show that if we are not in the case $k_i = 1$ for all i, then

$$\sum_{i=1}^{N} \widetilde{B}_{k_i,k_{i+1}} < 0.$$

Suppose $N > n^2$. Then any sequence $\{k_i\}_{i=1}^{N+1}$ with $k_1 = k_{N+1}$ must be composed of subloops of length no greater than n^2. Therefore, it is sufficient to prove the result for $N \le n^2$. Note that by the assumptions and Theorem 3.6,

$$\begin{aligned}\sum_{i=1}^{N} \widetilde{B}_{k_i,k_{i+1}} &\le \sum_{i=1}^{N} B_{k_i,k_{i+1}} + \sum_{i=1}^{N} |\widetilde{B}_{k_i,k_{i+1}} - B_{k_i,k_{i+1}}| \\ &\le -\max_{k_i} |\overline{x}_{k_i}|^2 \frac{\delta c}{8M^2} \left(1 - e^{-cN\tau}\right)^4 + \max_{k_i} |\overline{x}_{k_i}|^2 \frac{\delta c}{8M^2} \left(1 - e^{-cN\tau}\right)^4 (N/n^2) - \varepsilon \\ &\le -\varepsilon.\end{aligned}$$

Then by the same proofs as for Theorem 2.12, the result follows. ∎

Theorem 3.7 will be useful later when we analyze the size of errors introduced by our computational approximation to the elements of B.

If the conditions of Theorem 3.7 are met, then one can ask what the size of the errors in the corresponding eigenvector are. Specifically, if eigenvector $\tilde{e}$ is computed using approximation $\widetilde{B}$, what is a bound on the size of the difference between e (the eigenvector of B) and $\tilde{e}$? The following theorem gives a rough, but easily obtained, bound.

THEOREM 3.8. *Let B be given by $B_{i,j} = -\max_{x \in \overline{B}_R} \big(\psi_j(x) - S_\tau[\psi_i](x)\big)$ for all $i, j \le n$, and let $\widetilde{B}$ be an approximation of B with $\widetilde{B}_{1,1} = 0$ and such that there exists $\varepsilon > 0$ such that*

$$|\widetilde{B}_{i,j} - B_{i,j}| \le \max\big\{|\overline{x}_i|^2, |\overline{x}_j|^2\big\} \left(\frac{\delta c}{8M^2}\right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^\mu} - \varepsilon \quad \forall\, i, j, \tag{3.33}$$

where $\mu \in \{2, 3, 4, \dots\}$ and δ is given by (3.32)*. Then the power method will yield the unique eigenvectors e and $\tilde{e}$ of B and $\widetilde{B}$, respectively, in finite numbers of steps, and*

$$\|e - \tilde{e}\| \doteq \max_i |e_i - \tilde{e}_i| \le \big(D_R\big)^2 \left(\frac{\delta c}{8M^2}\right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^{\mu-2}} - \varepsilon.$$

Proof. By Theorem 3.7, one may use the power method to compute $\tilde{e}$, and so one has that for any $j \le n^2$,

$$\tilde{e}_j = \big[\widetilde{B}^{n^2} \otimes 0\big]_j = \max_{m \le n^2} \big[\widetilde{B}^m \otimes 0\big]_j = \max_{m \le n^2} \max_{\{k_l\}_{l=1}^m,\, k_1 = j} \sum_{l=1}^{m} \widetilde{B}_{k_l,k_{l+1}},$$

where the exponents on $\widetilde{B}$ represent max-plus exponentiation and the bound $m \le n^2$ follows from the fact that under the assumption, the sums around any loop other than

that of the trivial loop, $\widetilde{B}_{1,1} = 0$, are strictly negative. Therefore,

$$\tilde{e}_j \leq \max_{m \leq n^2} \max_{\{k_l\}_{l=1}^m,\, k_1 = j} \left[\sum_{l=1}^{m} \left| \widetilde{B}_{k_l,k_{l+1}} - B_{k_l,k_{l+1}} \right| + \sum_{l=1}^{m} B_{k_l,k_{l+1}} \right],$$

which by the assumption (3.33) and the fact that e is the eigenvector of B,

$$\leq \left(D_R\right)^2 \left(\frac{\delta c}{8M^2} \right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^{\mu-2}} - \varepsilon + e_j.$$

By a symmetrical argument, one obtains

$$|\tilde{e}_j - e_j| \leq \left(D_R\right)^2 \left(\frac{\delta c}{8M^2} \right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^{\mu-2}} - \varepsilon. \qquad \square$$

We remark that by taking ε sufficiently small, and noting that $1 - e^{-c\tau} \leq c\tau$ for nonnegative τ, Theorem 3.8 implies (under its assumptions)

$$\|e - \tilde{e}\| = \max_i |e_i - \tilde{e}_i| \leq \left(D_R\right)^2 \left(\frac{\delta c^5}{8M^2} \right) \frac{\tau^4}{n^{\mu-2}}. \tag{3.34}$$

Also note that aside from the case $i = j = 1$ (recall $B_{1,1} = 0$), one has

$$\min_{i \neq 1} \left\{ |\overline{x}_i|^2 \right\} \leq \max \left\{ |\overline{x}_i|^2, |\overline{x}_j|^2 \right\} \quad \forall\, i, j.$$

Using this, and choosing $\varepsilon > 0$ appropriately, one has the following theorem (where we note the condition on the errors in B is uniform but potentially significantly stricter). The proof is nearly identical to that for Theorem 3.8

THEOREM 3.9. *Let B be as in Theorem* 3.8*, and let $\widetilde{B}$ be an approximation of B with $\widetilde{B}_{1,1} = 0$ and such that*

$$|\widetilde{B}_{i,j} - B_{i,j}| \leq \min_{i \neq 1} \left\{ |\overline{x}_i|^2 \right\} \left(\frac{\delta c}{9M^2} \right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^{\mu}} \quad \forall\, i, j, \tag{3.35}$$

where $\mu \in \{2, 3, 4, \dots\}$ and δ is given by (3.32)*. Then the power method will yield the unique eigenvectors e and $\tilde{e}$ of B and $\widetilde{B}$, respectively, in finite numbers of steps, and*

$$\|e - \tilde{e}\| \leq \min_{i \neq 1} \left\{ |\overline{x}_i|^2 \right\} \left(\frac{\delta c}{9M^2} \right) \frac{\left(1 - e^{-c\tau}\right)^4}{n^{\mu-2}}.$$

A simpler variant on this result may be worth using. Note that for $\tau \in [0, 1/c]$, one has $1 - e^{-c\tau} \geq (c/2)\tau$. Then by a proof again nearly identical to that of Theorem 3.8, one has the following.

THEOREM 3.10. *Suppose $\tau \leq 1/c$. Let B be as in Theorem* 3.8*, and let $\widetilde{B}$ be an approximation of B with $\widetilde{B}_{1,1} = 0$ and such that*

$$|\widetilde{B}_{i,j} - B_{i,j}| \leq \min_{i \neq 1} \left\{ |\overline{x}_i|^2 \right\} \left(\frac{\delta c^5}{9(16)M^2} \right) \frac{\tau^4}{n^{\mu}} \quad \forall\, i, j, \tag{3.36}$$

where $\mu \in \{2, 3, 4, \dots\}$ and δ is given by (3.32)*. Then the power method will yield the unique eigenvectors e and $\tilde{e}$ of B and $\widetilde{B}$, respectively, in finite numbers of steps, and*

$$\|e - \tilde{e}\| \leq \min_{i \neq 1} \left\{ |\overline{x}_i|^2 \right\} \left(\frac{\delta c^5}{9(16)M^2} \right) \frac{\tau^4}{n^{\mu-2}}.$$

This variant is included since the simpler right-hand sides might simplify analysis.

4. Convergence and truncation errors. In this section we consider the approximation due to using only a finite number of functions in the max-plus basis expansion. It will be shown that as the number of functions increases (in a reasonable way), the approximate solution obtained by the eigenvector computation of section 2 converges from below to the value function, W. Error bounds will also be obtained.

4.1. Convergence. This subsection contains a quick proof that the errors due to truncation of the basis go to zero as the number of basis functions increases (in a reasonable way). No specific error bounds are obtained; those require the more tedious analysis of the next subsection.

Note that in this subsection a slightly different notation for the indexing and numbers of basis functions in the sets of basis functions is used. This will make the proof simpler. *This alternate notation appears only in this subsection.* Specifically, let us have the sets of basis functions indexed by n; that is, the *sets* are indexed by n. Let the cardinality of the nth set be $\mathcal{I}^{(n)}$. For each n, let $\mathcal{X}^{(n)} \doteq \{x_i^{(n)}\}_{i=1}^{\mathcal{I}^{(n)}}$ and $\mathcal{X}^{(n)} \subset \mathcal{X}^{(n+1)}$. For instance, in the one-dimensional case, one might have $\mathcal{X}^{(1)} = \{0\}$, $\mathcal{X}^{(2)} = \{-1/2, 0, 1/2\}$, $\mathcal{X}^{(3)} = \{-3/4, -1/2, -1/4, 0, 1/4, 1/2, 3/4\}$, and so on. Further, we will let the basis functions be given by $\psi_i^{(n)} \doteq -\frac{1}{2}(x - x_i^{(n)})^T C(x - x_i^{(n)})$, and consider the sets of basis functions $\Psi^{(n)} \doteq \{\psi_i^{(n)} : i \in \mathcal{I}^{(n)}\}$. Then define the approximations to the semigroup operator S_τ by

$$S_\tau^{(n)}[\phi](x) \doteq \bigoplus_{i=1}^{\mathcal{I}^n} a_i^{(n)} \otimes \psi_i^{(n)}(x), \tag{4.1}$$

where

$$a_i^{(n)} \doteq -\max_x \left[\psi_i^{(n)}(x) - S_\tau[\phi](x)\right]. \tag{4.2}$$

In other words, $S_\tau^{(n)}$ is the result of the application of the S_τ followed by the truncation due to a finite number of basis functions. More specifically, if one defines $\mathcal{T}^{(n)}[\phi](x) = \bigoplus_{i=1}^{\mathcal{I}^n} a_i^{(n)} \otimes \psi_i^{(n)}(x)$ with the $a_i^{(n)}$ given by (4.2), then $S_\tau^{(n)}[\phi] = \mathcal{T}^{(n)} \circ S_\tau[\phi]$. Also, let $\mathcal{Y}^{(n)} = \{\phi : \overline{B}_R(0) \to \mathbf{R} \mid \exists\{a_i^{(n)}\}$ such that $\phi(x) = \bigoplus_{i=1}^{\mathcal{I}^n} a_i^{(n)} \otimes \psi_i^{(n)}(x)$ for all $x \in \overline{B}_R(0)\}$. Then note that for $\phi \in \mathcal{Y}^{(n)}$, one has

$$S_\tau^{(n)}[\phi](x) = \bigoplus_{i=1}^{\mathcal{I}^n} \left[\bigoplus_{j=1}^{\mathcal{I}^n} B_{i,j}^{(n)} \otimes a_j^{(n)}\right] \otimes \psi_i^{(n)}(x), \tag{4.3}$$

where $B_{i,j}^{(n)}$ corresponds to $S_\tau^{(n)}[\phi]$.

Lastly, we use the notation ${S_\tau}^N$ to indicate repeated application of S_τ N times. (Of course, by the semigroup property, ${S_\tau}^N = S_{N\tau}$.) Correspondingly, we use the notation ${S_\tau^{(n)}}^N$ to indicate the application of $S_\tau^{(n)}$ N times.

Define $\phi_0(x) \equiv 0$ and

$$\phi_0^{(n)}(x) \doteq \bigoplus_{i=1}^{\mathcal{I}^n} {a^0}_i^{(n)} \otimes \psi_i^{(n)}(x), \qquad {a^0}_i^{(n)} \doteq -\max_x \left[\psi_i^{(n)}(x) - \phi_0(x)\right]. \tag{4.4}$$

It is well known (see [29], [32] among many others) that

$$\lim_{N\to\infty} {S_\tau}^N[\phi_0] = W. \tag{4.5}$$

Also, note that since $\mathcal{X}^{(n)} \subset \mathcal{X}^{(n+1)}$, one has

$$S_\tau^{(n)^N}[\phi_0^{(n)}](x) \leq S_\tau{}^{(n+1)^N}[\phi_0^{(n+1)}](x) \leq S_\tau{}^N[\phi_0](x) \tag{4.6}$$

for all $x \in B_R$.

Note that by (4.4), and the definition of ϕ_0, the corresponding coefficients, $a_i^{0^{(n)}}$, satisfy $a_i^{0^{(n)}} = 0$ for all i. Combining this with Theorem 2.12 and (4.3), one finds that for each n, there exists $\overline{N}(n)$ such that

$$S_\tau^{(n)^N}[\phi_0^{(n)}] = S_\tau^{(n)^{\overline{N}(n)}}[\phi_0^{(n)}] \quad \forall\, N \geq \overline{N}(n). \tag{4.7}$$

Defining

$$W^{(n)^\infty} \doteq S_\tau^{(n)^{\overline{N}(n)}}[\phi_0^{(n)}], \tag{4.8}$$

we further find that the limit is the fixed point. That is,

$$S_\tau^{(n)}[W^{(n)^\infty}] = W^{(n)^\infty}. \tag{4.9}$$

Then, by (4.5), (4.6), and (4.8), we find that

$$W^{(n)^\infty} \text{ is monotonically increasing in } n \tag{4.10}$$

and

$$W^{(n)^\infty} \leq W. \tag{4.11}$$

Therefore, there exists $W^{\infty^\infty} \leq W$ such that

$$W^{(n)^\infty} \uparrow W^{\infty^\infty}, \tag{4.12}$$

and in fact, one can demonstrate equicontinuity of the $W^{(n)^\infty}$ on $\overline{B}_R$ given the assumptions (and consequently uniform convergence).

Under assumption (A5), one can show (see, for instance, Lemma 4.3, although this is more specific than what is needed, or Theorem 3.3 in [27]) that given $\varepsilon > 0$, there exists $n_\varepsilon < \infty$ such that

$$W^{(n)^\infty}(x) = S_\tau^{(n)}[W^{(n)^\infty}](x) \geq S_\tau[W^{(n)^\infty}](x) - \varepsilon$$

for all $x \in B_R$ for any $n \geq n_\varepsilon$. On the other hand, one always has

$$S_\tau^{(n)}[\phi] \leq S_\tau[\phi].$$

Combining these last two inequalities, one obtains

$$W^{(n)^\infty} = S_\tau^{(n)}[W^{(n)^\infty}] \leq S_\tau[W^{(n)^\infty}] \leq S_\tau^{(n)}[W^{(n)^\infty}] + \varepsilon = W^{(n)^\infty} + \varepsilon. \tag{4.13}$$

Combining this with (4.12), one finds the following theorem.

THEOREM 4.1.

$$W^{\infty^\infty} = S_\tau[W^{\infty^\infty}], \tag{4.14}$$

or in other words, W^{∞^∞} is a fixed point of S_τ.

Then, with some more work (see [27], Theorem 3.2), one obtains a convergence theorem.

THEOREM 4.2.

$$W^{\infty^\infty}(x) = W(x) \quad \forall\, x \in \overline{B}_R.$$

4.2. Truncation error estimate. Theorem 4.2 demonstrates convergence of the algorithm to the value function as the basis function density increases. Here we outline one approach to obtaining specific error estimates. The estimates may be rather conservative due to the form of the truncation error bound used; this issue will become more clear below. The main results are in Theorem 4.5 and Remark 4.6. Note that these are only the errors due to truncation to a finite number of basis functions; as noted above, analysis of the errors due to approximation of the entries in the B matrix is discussed further below.

Recall that we choose the basis functions throughout such that $x_1^{(n)} = 0$, or in other words, $\psi_1^{(n)}(x) = \frac{-1}{2}x^T Cx$ for all n. (Note that we return here to the notation where the (n) superscript corresponds to the number of basis functions—as opposed to the more complex notation with cardinality $\mathcal{I}^{(n)}$ which was used in the previous subsection only.) Also, we will use the notation

$$W_{N,\tau}^{(n)}(x) \doteq {S_\tau}^{(n)^N}[\phi_0^{(n)}](x)$$

and we reiterate that the N superscript indicates repeated application of the operator N times. Also, $\phi_0^{(n)}$ is the finite basis expansion of ϕ_0 (with n basis functions).

To specifically set C, we will replace assumption (A5) of section 2 with the following. We assume throughout the remainder of the paper that one may choose matrix $C > 0$ and $\delta' \in (0,1)$ such that with $C' \doteq (1-\delta')C$

$$S_\tau[\psi_i] \in \mathcal{S}^R_{C',L'} \ \forall i, \tag{A5$'$}$$

where $R + |C^{-1}|L' \le D_R$. Again, we do not discuss this assumption in detail, but simply note that we have verified that this assumption holds for the problems we have run. Also note that one could be more general, allowing C' to be a more general positive definite symmetric matrix such that $C - C' > 0$, but we will not include that here. Finally, it should be noted that δ' would depend on τ; as $\tau \downarrow 0$, one would need to take $\delta' \downarrow 0$. Since δ' will appear in the denominator of the error bound of the next lemma (as well as implicitly in the denominator of the fraction on the right-hand side of the error bound in Theorem 4.5), this implies that one does not want to take $\tau \downarrow 0$ as the means for reducing the errors. This will be discussed further in the next section.

The following lemma is a general result about the errors due to truncation when using the above max-plus basis expansion.

LEMMA 4.3. *Let δ', C', L' be as in assumption* (A5$'$)*, and let $\phi \in \mathcal{S}_{R,C'}$ with $\phi(0) = 0$, ϕ differentiable at zero with $\nabla_x \phi(0) = 0$, and $-\frac{1}{2}x^T C'x \le \phi(x) \le \frac{1}{2}\widehat{\mathcal{M}}|x|^2$ for all x for some $\widehat{\mathcal{M}} < \infty$. Let $\{\psi_i\}_{i=1}^n$ consist of basis functions with matrix C, centers $\{x_i\} \subseteq \overline{B}_{D_R}$ such that $C - C'I > 0$, and let $\Delta \doteq \max_{x \in \overline{B}_{D_R}(0)} \min_i |x - x_i|$. Let*

$$\phi^\Delta(x) = \max_i [a_i + \psi_i(x)] \quad \forall\, x \in \overline{B}_R,$$

where

$$a_i = -\max_{x \in \overline{B}_R} [\psi_i(x) - \phi(x)] \quad \forall\, i.$$

Then

$$0 \le \phi(x) - \phi^\Delta(x) \le \begin{cases} |C|\Big[2\widehat{\beta} + 1 + |C|/(\delta' C_R)\Big]|x|\Delta & \text{if } |x| \ge \Delta, \\ \frac{1}{2}\big[\widehat{\mathcal{M}} + |C|\big]|x|\Delta & \text{otherwise,} \end{cases}$$

where $\widehat{\beta}$ is specified in the proof.

Proof. Note that (see [12])

$$\phi(x) = \max_{\widetilde{x}\in\overline{B}_{D_R}} [a(\widetilde{x}) + \psi_{\widetilde{x}}(x)] \quad \forall\, x \in \overline{B}_R(0),$$

where

$$a(\widetilde{x}) = -\max_{x\in\overline{B}_R} [\psi_{\widetilde{x}}(x) - \phi(x)] \quad \forall\, \widetilde{x} \in \overline{B}_{D_R}$$

and

$$\psi_{\widetilde{x}}(x) \doteq -\tfrac{1}{2}(x-\widetilde{x})^T C(x-\widetilde{x}) \quad \forall\, x \in \overline{B}_R(0),\ \widetilde{x} \in \overline{B}_{D_R}.$$

It is obvious that $0 \le \phi(x) - \phi^{\Delta}(x)$, and so we prove the other bound.

Consider any $\overline{x} \in \overline{B}_R$. Then

$$\phi(\overline{x}) = a(\widetilde{x}) + \psi_{\widetilde{x}}(\overline{x}) \tag{4.15}$$

if and only if

$$C(\overline{x} - \widetilde{x}) \in -D_x^- \phi(\overline{x}),$$

where

$$D_x^- \phi(x) = \left\{ p \in \mathbf{R}^m : \ \liminf_{|y-x|\to 0} \frac{\phi(y) - \phi(x) - (y-x)\cdot p}{|y-x|} \ge 0 \right\}.$$

We denote such an $\widetilde{x}$ corresponding to $\overline{x}$ (in (4.15)) as $\overline{\widetilde{x}}$. By the Lipschitz nature of ϕ, one can easily establish that

$$|\overline{\widetilde{x}} - \overline{x}| \le |C^{-1}| L'. \tag{4.16}$$

However, it will be desirable to have a bound where the right-hand side depends linearly on $|\overline{x}|$. (Actually, this may only be necessary for small $\overline{x}$, while (4.16) may be a smaller bound for large $\overline{x}$, but we will obtain it for general $\overline{x}$.) Noting that $\phi \ge -\frac{1}{2}x^T C' x \ge -\frac{1}{2}x^T C x$, one has

$$\tfrac{1}{2}(\overline{x} - \overline{\widetilde{x}})^T C(\overline{x} - \overline{\widetilde{x}}) \le a(\overline{\widetilde{x}}) + \tfrac{1}{2}\overline{x}^T C \overline{x}.$$

Also, since $a(\overline{\widetilde{x}}) + \psi_{\overline{\widetilde{x}}}(\cdot)$ touches ϕ from below at $\overline{x}$, one must have

$$\begin{aligned} \tfrac{1}{2}(\overline{x} - \overline{\widetilde{x}})^T C(\overline{x} - \overline{\widetilde{x}}) - \tfrac{1}{2}(x - \overline{\widetilde{x}})^T C(x - \overline{\widetilde{x}}) &\le a(\overline{\widetilde{x}}) + \tfrac{1}{2}\overline{x}^T C \overline{x} - \tfrac{1}{2}(x - \overline{\widetilde{x}})^T C(x - \overline{\widetilde{x}}) \\ &\le \phi(x) + \tfrac{1}{2}\overline{x}^T C \overline{x} \le \tfrac{1}{2}\widehat{\mathcal{M}}|x|^2 + \tfrac{1}{2}\overline{x}^T C \overline{x} \end{aligned}$$

for all $x \in \overline{B}_R$, where the last inequality is by assumption. Define

$$F(x) \doteq \tfrac{1}{2}(\overline{x} - \overline{\widetilde{x}})^T C(\overline{x} - \overline{\widetilde{x}}) - \tfrac{1}{2}(x - \overline{\widetilde{x}})^T C(x - \overline{\widetilde{x}}) - \tfrac{1}{2}\widehat{\mathcal{M}}|x|^2,$$

and we see that we require $F(x) \le \frac{1}{2}\overline{x}^T C \overline{x}$ for all $x \in \overline{B}_R$. Taking the derivative, we find the maximum of F at $\widehat{x}$ given by

$$\widehat{x} = (C + \widehat{\mathcal{M}} I)^{-1} C \overline{\widetilde{x}} \tag{4.17}$$

and so

$$\widehat{x} - \overline{\widehat{x}} = -\widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}\overline{\widehat{x}}. \tag{4.18}$$

(In the interests of readability, we ignore the detail of the case where $\widehat{x} \notin B_R(0)$ here.) Therefore, $F(\widehat{x}) \le \frac{1}{2}\overline{x}^T C\overline{x}$ implies

$$\begin{aligned}
(\overline{x} - \overline{\widehat{x}})^T C(\overline{x} - \overline{\widehat{x}}) &\le \overline{\widehat{x}}^T \widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}C(C + \widehat{\mathcal{M}}I)^{-1}\widehat{\mathcal{M}}\overline{\widehat{x}} \\
&\quad + \overline{\widehat{x}}^T C(C + \widehat{\mathcal{M}}I)^{-1}\widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}C\overline{\widehat{x}} + \overline{x}^T C\overline{x} \\
&= \widehat{\mathcal{M}}\overline{\widehat{x}}^T \Big[\widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}C(C + \widehat{\mathcal{M}}I)^{-1} \\
&\qquad + \widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}\widehat{\mathcal{M}}I(C + \widehat{\mathcal{M}}I)^{-1} \\
&\qquad - \widehat{\mathcal{M}}^2(C + \widehat{\mathcal{M}}I)^{-2} + C(C + \widehat{\mathcal{M}}I)^{-2}C\Big]\overline{\widehat{x}} + \overline{x}^T C\overline{x} \\
&= \widehat{\mathcal{M}}\overline{\widehat{x}}^T \Big[\widehat{\mathcal{M}}C(C + \widehat{\mathcal{M}}I)^{-2} + C(C + \widehat{\mathcal{M}}I)^{-2}C\Big]\overline{\widehat{x}} + \overline{x}^T C\overline{x} \\
&= \overline{\widehat{x}}^T \widehat{\mathcal{M}}C(C + \widehat{\mathcal{M}}I)^{-1}\overline{\widehat{x}} + \overline{x}^T C\overline{x}. \qquad (4.19)
\end{aligned}$$

Noting that C is positive definite symmetric, and writing it as $C = \sqrt{C}\sqrt{C}^T$ where $\sqrt{C} = S\sqrt{\Lambda}$ with S unitary and Λ the matrix of eigenvalues, one may rewrite the first term in the right-hand side of (4.19) as

$$\overline{\widehat{x}}^T \widehat{\mathcal{M}}C(C + \widehat{\mathcal{M}}I)^{-1}\overline{\widehat{x}} = \overline{\widehat{x}}^T \widehat{\mathcal{M}}\tfrac{1}{2}\Big[C(C + \widehat{\mathcal{M}}I)^{-1} + (C + \widehat{\mathcal{M}}I)^{-1}C\Big]\overline{\widehat{x}} = \overline{\widehat{x}}^T \sqrt{C}Q\sqrt{C}^T\overline{\widehat{x}},$$

where

$$Q \doteq \tfrac{1}{2}\widehat{\mathcal{M}}\Big[\sqrt{C}^T(C + \widehat{\mathcal{M}}I)^{-1}\sqrt{C}^{-T} + \sqrt{C}^{-1}(C + \widehat{\mathcal{M}}I)^{-1}\sqrt{C}\Big].$$

Making the change of variables $y = \sqrt{C}^T x$, (4.19) becomes

$$|\overline{y} - \overline{\widehat{y}}|^2 \le \overline{\widehat{y}}^T Q\overline{\widehat{y}} + |\overline{y}|^2.$$

Noting that $\sqrt{C}^T(C + \widehat{\mathcal{M}}I)^{-1}\sqrt{C}^{-T}$ is a similarity transform of $(C + \widehat{\mathcal{M}}I)^{-1}$, one sees that the eigenvalues of Q are the eigenvalues of $\widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1}$. Now, since $(C + \widehat{\mathcal{M}}I)$ is positive definite,

$$(C + \widehat{\mathcal{M}}I) = \overline{S}\,\overline{\Lambda}\,\overline{S}^{-1}$$

with $\overline{\Lambda}$ the diagonal matrix of eigenvalues and $\overline{S}$ the unitary matrix of eigenvectors. Therefore, $\widehat{\mathcal{M}}(C + \widehat{\mathcal{M}}I)^{-1} = \overline{S}(\widehat{\mathcal{M}}\overline{\Lambda}^{-1})\overline{S}^{-1}$, and note that $\beta \doteq \max_i\{\widehat{\mathcal{M}}\overline{\lambda}_i^{-1}\} < 1$ where the $\overline{\lambda}_i$ are the diagonal elements of $\overline{\Lambda}$. Consequently,

$$|\overline{y} - \overline{\widehat{y}}|^2 \le \beta|\overline{\widehat{y}}|^2 + |\overline{y}|^2, \tag{4.20}$$

where $\beta \in (0, 1)$. This implies

$$\begin{aligned}
|\overline{\widehat{y}} - \overline{y}|^2 &\le \beta|\overline{\widehat{y}} - \overline{y} + \overline{y}|^2 + |\overline{y}|^2 \\
&= \beta\Big[|\overline{\widehat{y}} - \overline{y}|^2 + |\overline{y}|^2 + 2(\overline{\widehat{y}} - \overline{y}) \cdot \overline{y}\Big] + |\overline{y}|^2 \\
&\le \beta|\overline{\widehat{y}} - \overline{y}|^2 + (\beta + 1)|\overline{y}|^2 + \beta\Big[\frac{(1 - \beta)/2}{\beta}|\overline{\widehat{y}} - \overline{y}|^2 + \frac{\beta}{(1 - \beta)/2}|\overline{y}|^2\Big],
\end{aligned}$$

which after some rearrangement, yields

$$|\overline{\overline{y}} - \overline{y}|^2 \leq \frac{2(1+\beta^2)}{(1-\beta)^2}|\overline{y}|^2 \tag{4.21}$$

which implies

$$(\overline{x} - \overline{\overline{x}})^T C(\overline{x} - \overline{\overline{x}}) \leq \left[\frac{2(1+\beta^2)}{(1-\beta)^2}\right]\overline{x}^T C\overline{x}.$$

Consequently, there exists $\widehat{\beta} < \infty$ (i.e., $\widehat{\beta} = [|\sqrt{C}|/C_R^0][\sqrt{2(1+\beta^2)}/(1-\beta)]$) such that

$$|\overline{x} - \overline{\overline{x}}| \leq \widehat{\beta}|\overline{x}|. \tag{4.22}$$

Given $\overline{\overline{x}}$, let $\bar{i} \in \operatorname{argmin}_i |x_i - \overline{\overline{x}}|$, and note that

$$|x_{\bar{i}} - \overline{\overline{x}}| \leq \Delta. \tag{4.23}$$

It is easy to see that

$$\begin{aligned}
|\psi_{\overline{\overline{x}}}(x) - \psi_{\bar{i}}(x)| &\leq \tfrac{1}{2}|(x-\overline{\overline{x}})^T C(x-\overline{\overline{x}}) - (x-\overline{\overline{x}})^T C(x-x_{\bar{i}})| \\
&\quad + \tfrac{1}{2}|(x-\overline{\overline{x}})^T C(x-x_{\bar{i}}) - (x-x_{\bar{i}})^T C(x-x_{\bar{i}})| \\
&\leq \tfrac{1}{2}|C|\Big[|\overline{\overline{x}} - x_{\bar{i}}||x-\overline{\overline{x}}| + |\overline{\overline{x}} - x_{\bar{i}}||x-x_{\bar{i}}|\Big] \\
&\leq \tfrac{1}{2}|C|\Big[|\overline{\overline{x}} - x_{\bar{i}}||x-\overline{\overline{x}}| + |\overline{\overline{x}} - x_{\bar{i}}|(|x-\overline{\overline{x}}| + |\overline{\overline{x}} - x_{\bar{i}}|)\Big],
\end{aligned}$$

which by (4.23)

$$\leq |C|\Big[|x-\overline{\overline{x}}|\Delta + \tfrac{1}{2}\Delta^2\Big]. \tag{4.24}$$

Combining (4.22) and (4.24), one finds

$$|\psi_{\overline{\overline{x}}}(\overline{x}) - \psi_{\bar{i}}(\overline{x})| \leq |C|\Big[\widehat{\beta}|\overline{x}|\Delta + \tfrac{1}{2}\Delta^2\Big]. \tag{4.25}$$

Now note that

$$\phi(\overline{x}) - \phi^{\Delta}(\overline{x}) \leq a(\overline{\overline{x}}) + \psi_{\overline{\overline{x}}}(\overline{x}) - [a_{\bar{i}} + \psi_{\bar{i}}(\overline{x})],$$

which by (4.25)

$$\leq |C|\Big[\widehat{\beta}|\overline{x}|\Delta + \tfrac{1}{2}\Delta^2\Big] + a(\overline{\overline{x}}) - a_{\bar{i}}. \tag{4.26}$$

We now deal with the last two terms in this bound. Let

$$\overline{x}_{\bar{i}} \doteq \operatorname*{argmax}_{x \in \overline{B}_R}[\psi_{\bar{i}}(x) - \phi(x)].$$

(Note that we will also skip the technical details of the additional case where $\overline{x}_{\bar{i}}$ lies on the boundary of $\overline{B}_R$.) Then,

$$-C(\overline{x}_{\bar{i}} - x_{\bar{i}}) \in D^- \phi(\overline{x}_{\bar{i}})$$

and

$$-C(\overline{x} - \overline{\overline{x}}) \in D^- \phi(\overline{x}).$$

By the semiconvexity, one has the general result that $p \in D^- \phi(x)$, $q \in D^- \phi(y)$ implies

$$(p - q) \cdot (x - y) \geq -(x - y)^T C'(x - y).$$

Consequently,

$$-(\overline{x}_{\overline{i}} - x_{\overline{i}} + \overline{\overline{x}} - \overline{x})^T C(\overline{x}_{\overline{i}} - \overline{x}) \geq -(\overline{x}_{\overline{i}} - \overline{x})^T C'(\overline{x}_{\overline{i}} - \overline{x}).$$

Recalling that $C' = (1 - \delta')C$, we see that this implies

$$\begin{aligned} -(\overline{x}_{\overline{i}} - \overline{x})^T C(\overline{x}_{\overline{i}} - \overline{x}) + (1 - \delta')(\overline{x}_{\overline{i}} - \overline{x})^T C(\overline{x}_{\overline{i}} - \overline{x}) &\geq -|C|\,|\overline{x}_{\overline{i}} - \overline{x}|\,|x_{\overline{i}} - \overline{\overline{x}}| \\ &\geq -|C|\,|\overline{x}_{\overline{i}} - \overline{x}|\Delta, \end{aligned}$$

or

$$\delta'(\overline{x}_{\overline{i}} - \overline{x})^T C(\overline{x}_{\overline{i}} - \overline{x}) \leq |C|\,|\overline{x}_{\overline{i}} - \overline{x}|\Delta.$$

Noting that $C - C_R I > 0$, this implies

$$|\overline{x}_{\overline{i}} - \overline{x}| \leq \frac{|C|}{\delta' C_R}\Delta. \tag{4.27}$$

Now,

$$\begin{aligned} \overline{\overline{a}} - a_{\overline{i}} &\leq \psi_{\overline{i}}(\overline{x}_{\overline{i}}) - \psi_{\overline{\overline{x}}}(\overline{x}_{\overline{i}}) \\ &= \psi_{\overline{i}}(\overline{x}) - \psi_{\overline{\overline{x}}}(\overline{x}) + [\psi_{\overline{i}}(\overline{x}_{\overline{i}}) - \psi_{\overline{\overline{x}}}(\overline{x}_{\overline{i}})] - [\psi_{\overline{i}}(\overline{x}) - \psi_{\overline{\overline{x}}}(\overline{x})], \end{aligned}$$

which, after cancellation,

$$\begin{aligned} &= \psi_{\overline{i}}(\overline{x}) - \psi_{\overline{\overline{x}}}(\overline{x}) - (\overline{x} - \overline{x}_{\overline{i}})C(x_{\overline{i}} - \overline{\overline{x}}) \\ &\leq |\psi_{\overline{i}}(\overline{x}) - \psi_{\overline{\overline{x}}}(\overline{x})| + |C|\Delta|\overline{x} - \overline{x}_{\overline{i}}|, \end{aligned}$$

which by (4.25) and (4.27)

$$\leq |C|\Big[\widehat{\beta}|\overline{x}| + \big(\tfrac{1}{2} + |C|/(\delta' C_R)\big)\Delta\Big]\Delta. \tag{4.28}$$

Combining (4.26) and (4.28) yields

$$\phi(\overline{x}) - \phi^{\Delta}(\overline{x}) \leq |C|\Big[2\widehat{\beta}|\overline{x}| + \big(1 + |C|/(\delta' C_R)\big)\Delta\Big]\Delta. \tag{4.29}$$

Suppose $|\overline{x}| \geq \Delta$. Then, (4.29) implies

$$\phi(\overline{x}) - \phi^{\Delta}(\overline{x}) \leq |C|\Big[2\widehat{\beta} + 1 + |C|/(\delta' C_R)\Big]|\overline{x}|\Delta, \tag{4.30}$$

which is the first case in right-hand side of the assertion.

Last, suppose $|\overline{x}| < \Delta$. By assumption, there exists $\widehat{\mathcal{M}} < \infty$ such that $\phi(x) \leq \frac{1}{2}\widehat{\mathcal{M}}|x|^2$. Therefore,

$$\phi(\overline{x}) - \phi^{\Delta}(\overline{x}) \leq \tfrac{1}{2}(\widehat{\mathcal{M}} + |C|)|\overline{x}|^2 \leq \tfrac{1}{2}(\widehat{\mathcal{M}} + |C|)|\overline{x}|\Delta,$$

which completes the proof. ∎

The above lemma is a general result about the errors due to truncation with the above max-plus basis expansion. In order to apply this to the problem at hand, one must consider the effect of repeated application of the truncated operator $S_\tau^{(n)}$. Note that $S_\tau^{(n)}$ may be written as the composition of S_τ and a truncation operator, $\mathcal{T}^{(n)}$, where we have

$$\mathcal{T}^{(n)}[\phi] = \phi^\Delta$$

in the notation of the previous lemma, where, in particular, ϕ^Δ was given by

$$\phi^\Delta(x) = \max_i [a_i + \psi_i(x)] \quad \forall\, x \in \overline{B}_R,$$

where

$$a_i = - \max_{x \in \overline{B}_R(0)} [\psi_i(x) - \phi(x)] \quad \forall\, i.$$

In other words, one has the equivalence of notation

$$S_\tau^{(n)}[\phi] = \{\mathcal{T}^{(n)} \circ S_\tau\}[\phi] = \{S_\tau[\phi]\}^\Delta, \tag{4.31}$$

which we shall use freely throughout.

We now proceed to consider how truncation errors accumulate. In order to simplify the analysis, we simply let

$$\mathcal{M}_{C'} \doteq \max\Big\{ |C| \big[2\widehat{\beta} + 1 + |C|/(\delta' C_R)\big],\ \tfrac{1}{2}\big[\widehat{\mathcal{M}} + |C|\big] \Big\}.$$

Fix Δ. We suppose that we have n sufficiently large (with properly distributed basis function centers) so that

$$\max_{x \in \overline{B}_{D_R}} \min_i |x - x_i| \le \Delta.$$

Let ϕ_0 satisfy the conditions on ϕ in Lemma 4.3. (One can simply take $\phi_0 \equiv 0$.) Then, by Lemma 4.3,

$$\phi_0(x) - \mathcal{M}_{C'} |x| \Delta \le \phi_0^{(n)}(x) \le \phi_0(x) \quad \forall\, x \in \overline{B}_R(0). \tag{4.32}$$

Now, for any $x \in \overline{B}_R(0)$, let $w_x^{1,\overline{\varepsilon}}$ be $\overline{\varepsilon}/2$-optimal for $S_\tau[\phi_0](x)$, and let $X_x^{1,\overline{\varepsilon}}$ be the corresponding trajectory. Then,

$$\begin{aligned} 0 &\le S_\tau[\phi_0](x) - S_\tau[\phi_0^{(n)}](x) \\ &\le \phi_0(X_x^{1,\overline{\varepsilon}}(\tau)) - \phi_0^{(n)}(X_x^{1,\overline{\varepsilon}}(\tau)) + \frac{\overline{\varepsilon}}{2}, \end{aligned}$$

which by (4.32)

$$\le \mathcal{M}_{C'} |X_x^{1,\overline{\varepsilon}}(\tau)| \Delta + \frac{\overline{\varepsilon}}{2}. \tag{4.33}$$

Proceeding along, one then finds

$$\begin{aligned} 0 &\le S_\tau[\phi_0](x) - S_\tau^{(n)}[\phi_0^{(n)}](x) \\ &= S_\tau[\phi_0](x) - S_\tau[\phi_0^{(n)}](x) + S_\tau[\phi_0^{(n)}](x) - S_\tau^{(n)}[\phi_0^{(n)}](x), \end{aligned}$$

which by Lemma 4.3, the fact that $S_\tau[\phi_0^{(n)}] \in \mathcal{S}^R_{C',L}$ (by assumption (A5′)), and (4.33)

$$\leq \mathcal{M}_{C'}|X_x^{1,\overline{\varepsilon}}(\tau)|\Delta + \mathcal{M}_{C'}|x|\Delta + \frac{\overline{\varepsilon}}{2}. \tag{4.34}$$

Let us proceed one more step with this approach. For any $x \in \overline{B}_R(0)$, let $w_x^{2,\overline{\varepsilon}}$ be $\overline{\varepsilon}/4$-optimal for $S_\tau[S_\tau[\phi_0]](x)$ (that is $\overline{\varepsilon}/4$-optimal for problem S_τ with terminal cost $S_\tau[\phi_0]$), and let $X_x^{2,\overline{\varepsilon}}$ be the corresponding trajectory. Then, as before,

$$\begin{aligned} 0 &\leq S_{2\tau}[\phi_0](x) - S_\tau[S_\tau^{(n)}\phi_0^{(n)}](x) \\ &= S_\tau[S_\tau[\phi_0]](x) - S_\tau[S_\tau^{(n)}[\phi_0^{(n)}]](x) \\ &\leq S_\tau[\phi_0](X_x^{2,\overline{\varepsilon}}(\tau)) - S_\tau^{(n)}[\phi_0^{(n)}](X_x^{2,\overline{\varepsilon}}(\tau)) + \frac{\overline{\varepsilon}}{4}. \end{aligned} \tag{4.35}$$

Now let

$$w_2^{\overline{\varepsilon}}(t) \doteq \begin{cases} w_x^{2,\overline{\varepsilon}}(t) & \text{if } t \in [0,\tau], \\ w^{1,\overline{\varepsilon}}_{X_x^{2,\overline{\varepsilon}}(\tau)}(t-\tau) & \text{if } t \in (\tau, 2\tau], \end{cases}$$

and let $\overline{X}_x^{2,\overline{\varepsilon}}$ be the corresponding trajectory. Then combining (4.34) and (4.35), one has

$$\begin{aligned} 0 &\leq S_{2\tau}[\phi_0](x) - S_\tau[S_\tau^{(n)}\phi_0^{(n)}](x) \\ &\leq \mathcal{M}_{C'}|\overline{X}_x^{2,\overline{\varepsilon}}(2\tau)|\Delta + \mathcal{M}_{C'}|\overline{X}_x^{2,\overline{\varepsilon}}(\tau)|\Delta + \frac{\overline{\varepsilon}}{2} + \frac{\overline{\varepsilon}}{4}. \end{aligned} \tag{4.36}$$

Applying Lemma 4.3 again, but now using (4.36), one has

$$\begin{aligned} 0 &\leq S_{2\tau}[\phi_0](x) - S_\tau^{(n)}[S_\tau^{(n)}[\phi_0^{(n)}]](x) \\ &= S_\tau[S_\tau[\phi_0]](x) - S_\tau[S_\tau^{(n)}[\phi_0^{(n)}]](x) + S_\tau[S_\tau^{(n)}[\phi_0^{(n)}]](x) - S_\tau^{(n)}[S_\tau^{(n)}[\phi_0^{(n)}]](x) \\ &\leq \mathcal{M}_{C'}|\overline{X}_x^{2,\overline{\varepsilon}}(2\tau)|\Delta + \mathcal{M}_{C'}|\overline{X}_x^{2,\overline{\varepsilon}}(\tau)|\Delta + \mathcal{M}_{C'}|x|\Delta + \frac{\overline{\varepsilon}}{2} + \frac{\overline{\varepsilon}}{4} \\ &= \mathcal{M}_{C'}\Delta \sum_{i=0}^{2} |\overline{X}_x^{2,\overline{\varepsilon}}(i\tau)| + \sum_{i=1}^{2} \frac{\overline{\varepsilon}}{2^i}. \end{aligned} \tag{4.37}$$

It is then clear that, by induction, one obtains the following lemma.

LEMMA 4.4.

$$0 \leq S_{N\tau}[\phi_0](x) - S_\tau^{(n)^N}[\phi_0](x) \leq \mathcal{M}_{C'}\Delta \sum_{i=0}^{N} |\overline{X}_x^{N,\overline{\varepsilon}}(i\tau)| + \sum_{i=1}^{N} \frac{\overline{\varepsilon}}{2^i}, \tag{4.38}$$

where the construction of $\overline{\varepsilon}$-optimal $\overline{X}_x^{N,\overline{\varepsilon}}(\cdot)$ by induction follows in the obvious way as above.

THEOREM 4.5. *Let $\{\psi_i\}_{i=1}^n$, C', and Δ be as in Lemma 4.3. Then, there exists $\overline{m}, \overline{\lambda} \in (0,\infty)$ such that*

$$0 \leq W(x) - W^{(n)^\infty}(x) \leq \mathcal{M}_{C'}\left(\frac{e^{\overline{m}}}{1 - e^{-\overline{\lambda}\tau}}\right)|x|\Delta \quad \forall\, x \in \overline{B}_R(0).$$

Remark 4.6. By Theorem 2.12, there exists $N = N(n) < \infty$ such that

$$W^{(n)^\infty}(x) = W^{(n)^N}(x) \quad \forall\, x \in \overline{B}_R(0),$$

and so Theorem 4.5 also implies

$$0 \le W(x) - W^{(n)^N}(x) \le \mathcal{M}_{C'}\left(\frac{e^{\overline{m}}}{1 - e^{-\overline{\lambda}\tau}}\right)|x|\Delta \quad \forall\, x \in \overline{B}_R(0)$$

for $N \ge N(n)$.

Proof. Let $\overline{\varepsilon} \in (0,1)$. Fix ϕ_0 and x. For each $N < \infty$, construct $w_N^{\overline{\varepsilon}}(\cdot)$ as above along with the corresponding $\overline{X}_x^{N,\overline{\varepsilon}}$. Let $w_\infty^{\overline{\varepsilon}}(t) = w_N^{\overline{\varepsilon}}(t)$ if $t \in [0, N\tau]$, and similarly, $\overline{X}_x^{\infty,\overline{\varepsilon}}(t) = \overline{X}_x^{N,\overline{\varepsilon}}(t)$ if $t \in [0, N\tau]$. Then, by [32] (see also [33]), there exists $\widetilde{K} < \infty$ (independent of $\overline{\varepsilon} \in (0,1)$) such that

$$\|w_\infty^{\overline{\varepsilon}}\|_{L_2(0,N\tau)} \le \widetilde{K}(1 + |x|^2)$$

for all $N < \infty$. Consequently, using assumptions (A1) and (A2), there exist $\overline{m}, \overline{\lambda} \in (0, \infty)$ such that

$$|\overline{X}_x^{\infty,\overline{\varepsilon}}(t)| \le |x| e^{\overline{m} - \overline{\lambda} t} \quad \forall\, t \in [0, \infty). \tag{4.39}$$

Then, by Lemma 4.4 and (4.39),

$$\begin{aligned} 0 \le S_{N\tau}[\phi_0](x) - S_\tau^{(n)^N}[\phi_0](x) &\le \mathcal{M}_{C'}\Delta|x| e^{\overline{m}} \sum_{i=0}^{N} e^{-\overline{\lambda} i\tau} + \sum_{i=1}^{N} \frac{\overline{\varepsilon}}{2^i} \\ &\le \mathcal{M}_{C'}\Delta|x| \frac{e^{\overline{m}}}{1 - e^{-\overline{\lambda}\tau}} + \overline{\varepsilon}. \end{aligned}$$

Since this is true for all $N \in \mathcal{N}$, and $S_\tau^{(n)^N}[\phi_0](x) = S_\tau^{(n)^{N+1}}[\phi_0](x) = W^{(n)^\infty}(x)$ for all $N \ge N(n)$, one obtains the result by taking the limit as $N \to \infty$ and then as $\overline{\varepsilon} \downarrow 0$. □

Last, we note that for τ sufficiently small, where

$$\tau \le 1/\overline{\lambda} \tag{4.40}$$

is sufficient (so that $\overline{\lambda}\tau/2 \le (1 - e^{-\overline{\lambda}\tau})$), one has

$$0 \le W(x) - W^{(n)^\infty}(x) \le \mathcal{M}_{C'}\Delta\Big(\frac{e^{\overline{m}}}{1 - e^{-\overline{\lambda}\tau}}\Big)|x| \le K_1|x|(\Delta/\tau) \tag{4.41}$$

with

$$K_1 \doteq 2\mathcal{M}_{C'} e^{\overline{m}}/\overline{\lambda}. \tag{4.42}$$

5. Errors in the approximation of B. In the previous section, we considered the errors due to truncation while assuming that B and, consequently, the eigenvector e were computed exactly. Of course, as discussed in section 3, there is an allowable upper limit for errors in the elements of B, below which one can guarantee the convergence of the power method. The errors in B also translate into errors in the eigenvector and consequently the approximate solution as discussed in sections 3

and 6. In this section, we consider a power series (in t) for $V(t,x) \doteq S_t[\psi_i](x)$, where we recall $B_{j,i} = -\max_{x\in\overline{B}_R(0)}[-\psi_j(x) - S_\tau[\psi_i](x)]$. With the power series for $V(t,x) = S_t[\psi_i](x)$ truncated at some level, $t^{n'-1}$ (for each i), we obtain a relationship between n', τ, and basis function density which guarantees that the errors in B do not exceed the allowable bounds obtained in section 3. In addition to the errors incurred by truncation of the power series, there may be errors in the computation of the terms in the series themselves. In subsection 5.1, one particular method for computing the power series terms to sufficient accuracy is given.

As noted above, one approach to the computation of B is a Taylor series (in t) approximation to $S_t[\psi_i](x)$. More specifically, letting $V(t,x) = S_t[\psi_i](x)$, so that V satisfies

$$\begin{aligned} V_t &= f\cdot\nabla V + l + \frac{1}{2\gamma^2}\nabla V^T\sigma\sigma^T\nabla V, \\ V(0,x) &= \psi_i(x), \end{aligned} \tag{5.1}$$

one may approximate V as

$$V(t,x) = V_0(x) + V_1(x)t + \frac{1}{2}V_2(x)t^2 + \cdots. \tag{5.2}$$

Here $V_0(x) = \psi_i(x)$ and V_1 is the right-hand side of (5.1) with ψ_i replacing V. Specifically,

$$V_1(x) = f\psi_{ix} + l + \frac{1}{2\gamma^2}\psi_{ix}a\psi_{ix},$$

where $a = \sigma\sigma^T$ and we drop the gradient/vector notation for simplification here and below. The higher order terms are computed by differentiating (5.1) at $t = 0$. Of course this process requires some smoothness for V. The following is well known, and so we only sketch a proof.

THEOREM 5.1. *Given $R' < \infty$ and $n' \in \mathcal{N}$, there exists $\tau' > 0$ such that $V \in C^{n'}((0,\tau')\times B_{R'}(0))$.*

Proof. The result for C^2 can be found, for instance, in [9] as well as many earlier works (see the references in [9] as well as [15]). In order to obtain continuity of higher derivatives, one simply differentiates (5.2) and applies the same technique. For example, the partial $V_{x_l}(t,x)$ satisfies

$$\begin{aligned} U_t &= \Big[f_{x_l}V_x + l_{x_l} + V_x a_{x_l}V_x\Big] + \Big[f + 2V_x a\Big]U_x, \\ U(0,x) &= \psi_{ix_l}(x). \end{aligned}$$

Note that τ' may depend on n'. ∎

Fix some $R', n' < \infty$. Let τ' be given by Theorem 5.1. We assume $\tau < \min\{\tau', 1, 1/c\}$ (where the motivation for the bounds of 1 and $1/c$ appear in (5.8) and (5.11) below) and $\widetilde{R} < R'$. Then we may approximate V over $(0,\tau)\times\overline{B}_{\widetilde{R}}(0)$ by

$$\widetilde{V}(t,x) = V_0(x) + V_1(x)t + V_2(x)\frac{t^2}{2} + \cdots + V_{n'-1}(x)\frac{t^{n'-1}}{(n'-1)!}. \tag{5.3}$$

Letting

$$M_{R',n'} \doteq \max_{(t,x)\in[0,\tau]\times\overline{B}_{\widetilde{R}}(0)} |V_{t^{(n')}}(t,x)|,$$

one has

$$|V(t,x) - \widetilde{V}(t,x)| \leq M_{R',n'} \frac{\tau^{n'}}{(n')!} \quad \forall\, (t,x) \in [0,\tau] \times \overline{B}_{\widetilde{R}}(0). \tag{5.4}$$

Now define the corresponding approximation to B by

$$\widetilde{B}_{j,i} = - \max_{x \in \overline{B}_{\widetilde{R}}(0)} \left\{ \psi_j(x) - \widetilde{V}(\tau, x) \right\}. \tag{5.5}$$

By (5.4) and (5.5), one has

$$|B_{j,i} - \widetilde{B}_{j,i}| \leq M_{R',n'} \frac{\tau^{n'}}{(n')!}. \tag{5.6}$$

Comparing (5.6) with Theorem 3.10, one finds that a sufficient condition for the convergence of the power method (using $\widetilde{B}$ computed from approximation $\widetilde{V}$) is that $\tau \leq 1/c$ and that for some $\mu \in \{2, 3, 4, \dots\}$ ($\mu = 2$ is the weakest condition)

$$M_{R',n'} \frac{\tau^{n'}}{(n')!} \leq \left[\min_{i \neq 1} |\overline{x}_i|^2 \right] \left(\frac{\delta c^5}{9(16) M^2} \right) \frac{\tau^4}{n^\mu}.$$

Note that the $\tau \leq 1/c$ condition can be removed by using Theorems 3.8 and 3.9 instead of Theorem 3.10.

Since computation of $\widetilde{B}_{j,i}$ requires the maximization operation, below we will introduce an approximation for $\widetilde{B}_{j,i}$, to be denoted by $\widehat{B}_{j,i}$ (where the maximum may only be computed approximately rather than exactly). Suppose further that

$$|\widetilde{B}_{j,i} - \widehat{B}_{j,i}| \leq M_{R',n'} \frac{\tau^{n'}}{(n')!}. \tag{5.7}$$

Then, by (5.7), (5.6) with Theorem 3.10, one finds that a sufficient condition for the convergence of the power method (using $\widehat{B}$) is that $\tau \leq 1/c$ and that for some $\mu \in \{2, 3, 4, \dots\}$ ($\mu = 2$ is the weakest condition)

$$2 M_{R',n'} \frac{\tau^{n'}}{(n')!} \leq \left[\min_{i \neq 1} |\overline{x}_i|^2 \right] \left(\frac{\delta c^5}{9(16) M^2} \right) \frac{\tau^4}{n^\mu}, \tag{5.8}$$

and so a sufficient condition is

$$\tau^{n'-4} \leq \left[\min_{i \neq 1} |\overline{x}_i|^2 \right] \left(\frac{\delta c^5 (n')!}{9(32) M^2 M_{R',n'}} \right) \frac{1}{n^\mu}. \tag{5.9}$$

Suppose a rectangular grid of evenly spaced basis function centers with N_D center-points per dimension, and recall that ψ_1 is centered at the origin which implies N_D is odd. (Perhaps it should be noted that this is conservative in that we are considering a rectangular grid encompassing $\overline{B}_{D_R}$ rather than just those basis functions centered in the sphere itself.) This implies $\min_{i \neq 1} |\overline{x}_i|^2 = 4 D_R^2 / (N_D - 1)^2$, and (5.9) becomes

$$\tau^{n'-4} \leq \left(\frac{D_R^2 \delta c^5 (n')!}{9(8) M^2 M_{R',n'}} \right) \left(\frac{1}{N_D} \right)^{m\mu} \left(\frac{1}{N_D - 1} \right)^2,$$

which implies a sufficient condition is

$$\tau^{n'-4} \le \left(\frac{D_R^2 \delta c^5 (n')!}{9(8) M^2 M_{R',n'}}\right)\left(\frac{1}{N_D}\right)^{m\mu+2} \doteq \widetilde{\mathcal{M}}_{R',n'}\left(\frac{1}{N_D}\right)^{m\mu+2}, \tag{5.10}$$

where we recall that m is the dimension of the state space.

Therefore, if one fixes $\tau < \min\{1, 1/c\}$, then it is sufficient that

$$n' \ge 4 + \frac{\log \widetilde{\mathcal{M}}_{R',n'} + (m\mu+2)\log(1/N_D)}{\log \tau}. \tag{5.11}$$

Alternatively, one may, without loss of generality, require $\widetilde{\mathcal{M}}_{R',n'} \ge 1$ in which case (noting that $\log \tau < 0$ since $\tau < 1$) (5.11) yields the sufficient condition

$$n' \ge 4 + \frac{(m\mu+2)\log(1/N_D)}{\log \tau}, \tag{5.12}$$

in which case the lower bound on n' scales like $\log(1/N_D)$. We remark that this sufficient condition may be quite conservative.

5.1. A method for computing B. As noted above, one would not typically have a closed-form expression for the $B_{j,i}$ or even the $\widetilde{B}_{j,i}$ terms, and we denote the approximation of $\widetilde{B}$ by $\widehat{B}$. In this subsection, we indicate some specifics of a numerical method for the approximation. This is not essential to the paper, but we felt that it was useful to sketch an approximation technique so as to concretely indicate one approach to this subproblem.

The approach taken was to define

$$\widetilde{X}_{j,i}(t) \doteq \operatorname{argmax}\{\psi_j(x) - \widetilde{V}(t,x)\},$$

where $\widetilde{V}$ is given by (5.3) (i.e., the truncated power series expansion of $S_t[\psi_i](x)$), and then to propagate $\widetilde{X}_{j,i}$ as the solution of an ODE forward from $t = 0$ to τ via a Runge–Kutta method. One difficulty is that $\widetilde{X}_{j,i}(t)$ diverges as $t \downarrow 0$. In order to remedy this, and also remedy unbounded derivatives as $t \downarrow 0$, we replace $\psi_j(x)$ by $\psi^\tau_{j,i}(t,x)$, where

$$\psi^\tau_{j,i}(t,x) \doteq -\frac{1}{2}(x - \xi(t))^T[(C + \overline{\delta}(1 - t/\tau))I](x - \xi(t)), \tag{5.13}$$

where

$$\xi(t) \doteq x_i + (t/\tau)(x_j - x_i), \tag{5.14}$$

and $\overline{\delta} > 0$. Then one may define

$$\widetilde{X}^\tau_{j,i}(t) \doteq \operatorname*{argmax}_x\{\psi^\tau_{j,i}(t,x) - \widetilde{V}(t,x)\}, \tag{5.15}$$

and note that

$$\widetilde{X}^\tau_{j,i}(\tau) = \widetilde{X}_{j,i}(\tau) = \operatorname{argmax}\{\psi_j(x) - \widetilde{V}(t,x)\}.$$

Since $\widetilde{X}^\tau_{j,i}(t)$ is the argmax at each time $t \in [0,\tau]$, this implies

$$[\psi^\tau_{j,i}]_x(t, \widetilde{X}^\tau_{j,i}(t)) - \widetilde{V}_x(t, \widetilde{X}^\tau_{j,i}(t)) = 0$$

for all $t \in [0,\tau]$. Differentiating with respect to time, implies

$$\Big[[\psi^\tau_{j,i}]_{xx}(t,\widetilde{X}^\tau_{j,i}(t)) - \widetilde{V}_{xx}(t,\widetilde{X}^\tau_{j,i}(t))\Big]\dot{\widetilde{X}}^\tau_{j,i}(t) + \Big[[\psi^\tau_{j,i}]_{tx}(t,\widetilde{X}^\tau_{j,i}(t)) - \widetilde{V}_{tx}(t,\widetilde{X}^\tau_{j,i}(t))\Big] = 0,$$

or,

$$\dot{\widetilde{X}}^\tau_{j,i}(t) = \Big[[\psi^\tau_{j,i}]_{xx}(t,\widetilde{X}^\tau_{j,i}(t)) - \widetilde{V}_{xx}(t,\widetilde{X}^\tau_{j,i}(t))\Big]^{-1}\Big[[\psi^\tau_{j,i}]_{tx}(t,\widetilde{X}^\tau_{j,i}(t)) - \widetilde{V}_{tx}(t,\widetilde{X}^\tau_{j,i}(t))\Big]. \tag{5.16}$$

The initial state for (5.16) is

$$\begin{aligned}\widetilde{X}^\tau_{j,i}(0) &= \operatorname*{argmax}_x\{\psi^\tau_{j,i}(0,x) - \widetilde{V}(0,x)\}\\ &= \operatorname*{argmax}_x\{-\tfrac{1}{2}(x-x_i)^T(C+\overline{\delta}I)(x-x_i) - \psi_i(x)\} = x_i.\end{aligned}$$

Note that

$$\Big[[\psi^\tau_{j,i}]_{xx}(0,x) - \widetilde{V}_{xx}(0,x)\Big] = -[C+\overline{\delta}I] + C = -\overline{\delta}I, \tag{5.17}$$

which is negative definite, and

$$\Big[[\psi^\tau_{j,i}]_{xx}(\tau,x) - \widetilde{V}_{xx}(\tau,x)\Big] = -C - \widetilde{V}_{xx}(\tau,x) \tag{5.18}$$

would be negative definite on $\overline{B}_R$ by assumption (A5′) if approximation $\widetilde{V}(\tau,\cdot)$ were replaced by $S_\tau[\psi_i]$. Also,

$$\widetilde{X}^\tau_{j,i}(0) = x_i \in \overline{B}_{D_R}, \quad \text{and} \quad \widetilde{X}^\tau_{j,i}(\tau) \in \overline{B}_R \tag{5.19}$$

if approximation $\widetilde{V}(\tau,\cdot)$ is replaced by $S_\tau[\psi_i]$. This suggests the following assumption (which is only used for this approach to computing B). Suppose there exists $\hat{\delta} > 0$ such that

$$\begin{aligned}&\Big[[\psi^\tau_{j,i}]_{xx}(t,x) - \widetilde{V}_{xx}(t,x)\Big] + \hat{\delta}I < 0 \quad \forall\, |x| \le \hat{g}(t),\, \forall t \in [0,\tau],\\ &|\widetilde{X}^\tau_{j,i}(t)| \le \hat{g}(t) \quad \forall\, t \in [0,\tau],\end{aligned} \tag{5.20}$$

where $g : [0,\tau] \to \mathbf{R}$ is any function such that $\hat{g}(0) = D_R$, $\hat{g}(\tau) = R$ and $\hat{g}$ is monotonically decreasing. Note that, by (5.17)–(5.19), the conditions are satisfied at both endpoints ($t = 0$ and $t = \tau$) when $\widetilde{V}(\tau,\cdot)$ is replaced by $S_\tau[\psi_i]$. Consequently, this may not be significantly more restrictive than the general assumptions, and for the purposes of sketching this particular approach to computing B, let us assume (5.20). Note that this guarantees the existence of the inverse in (5.16) and further that $\widetilde{X}^\tau_{j,i}(\tau)$ is the unique maximizer in $\overline{B}_R$.

Analytical expressions for the right-hand side of (5.16) can be obtained from (5.3) and (5.13). (These can be used to generate sufficient conditions that guarantee (5.20), but these are likely much too conservative.) Thus, one merely needs to propagate the n-dimensional ODE (5.16) forward to time τ. A Runge–Kutta method may be used for this and the resulting approximate solution is denoted by $\widehat{X}^\tau_{j,i}$. The approximation of the elements of $\widehat{B}$ are then given by

$$\begin{aligned}\widehat{B}_{j,i} &= -\Big\{\psi^\tau_{j,i}(\widehat{X}^\tau(\tau)) - \widetilde{V}(\tau,\widehat{X}^\tau(\tau))\Big\}\\ &= -\Big\{\psi_j(\widehat{X}^\tau(\tau)) - \widetilde{V}(\tau,\widehat{X}^\tau(\tau))\Big\}.\end{aligned} \tag{5.21}$$

Note that

(5.22) the number of steps in the Runge–Kutta algorithm must be controlled so that (5.7) is satisfied.

6. Error summary. The error analyses of the previous three sections will now be combined. In particular, the errors due to truncation and the errors in computation of B will be combined to produce overall error bounds (6.8), (6.9). A condition required for the algorithm to work (assuming one uses the power series of section 5 for computation of B) is also obtained.

Theorems 3.7 to 3.10 provided sufficient conditions for the power method step to converge to the max-plus eigenvector. Employing the simplest condition (but also the strictest), that of Theorem 3.10, convergence of the power method with approximation $\widehat{B}$ to B is guaranteed if

$$|\widehat{B}_{i,j} - B_{i,j}| \le \min_{i\neq 1}\{|\overline{x}_i|^2\}\left(\frac{\delta c^5}{9(16)M^2}\right)\frac{\tau^4}{n^\mu} \quad \forall\, i,j, \tag{6.1}$$

where $\mu \in \{2,3,4,\dots\}$ and δ is given by (3.32). Note that we are assuming $\tau \le \min\{1, 1/c, \tau'\}$ as in section 5 (as well as all assumptions including (A5′) and technical conditions (3.1), (3.19) which appear in section 3). Then, Theorem 3.10 implies a resulting error bound for the max-plus eigenvector given by

$$\|e - \hat{e}\| \doteq \max_i |e_i - \hat{e}_i| \le \min_{i\neq 1}\{|\overline{x}_i|^2\}\left(\frac{\delta c^5}{9(16)M^2}\right)\frac{\tau^4}{n^{\mu-2}}, \tag{6.2}$$

where $\hat{e}$ corresponds to $\widehat{B}$. We remark that slightly different error estimates (under slightly different conditions) are also given in Theorems 3.8 and 3.9.

Suppose we adopt the notation $\widehat{W}(x) \doteq \bigoplus_{i=1}^n \hat{e}_i \otimes \psi_i(x)$ and $W^f(x) \doteq \bigoplus_{i=1}^n e_i \otimes \psi_i(x)$ so that W^f corresponds to the finite expansion with zero error in the computation/approximation of B. Then, by (6.2),

$$\begin{aligned}\|\widehat{W} - W^f\| \doteq \max_{|x|\le R} |\widehat{W}(x) - W^f(x)| &\le \min_{i\neq 1}\{|\overline{x}_i|^2\}\left(\frac{\delta c^5}{9(16)M^2}\right)\frac{\tau^4}{n^{\mu-2}} \\ &= \min_{i\neq 1}\{|\overline{x}_i|^2\}\left(\frac{\delta c^5\tau^4}{9(16)M^2}\right)\left(\frac{1}{N_D}\right)^{m(\mu-2)},\end{aligned} \tag{6.3}$$

where again, N_D is the number of centers of basis functions per dimension of the state space with a rectangular, evenly spaced grid of centers. It should be recalled that the basis functions are such that ψ_1 is centered at the origin ($\overline{x}_1 = 0$), and so N_D is odd. (Perhaps one should note that we are being sloppy here by using the number of basis functions corresponding to covering the entire rectangle which encloses the sphere $\overline{B}_{D_R}$, although only those with centers covering the sphere itself are required for the bound. Consequently, the above bound is conservative.) Also, with the evenly spaced basis function centers, (6.3) can be written as

$$\|\widehat{W} - W^f\| \le \left(\frac{D_R^2\delta c^5\tau^4}{9(4)M^2}\right)\left(\frac{1}{N_D}\right)^{m(\mu-2)}\left(\frac{1}{N_D - 1}\right)^2. \tag{6.4}$$

Using the approach of section 5, (6.1) is satisfied if

$$\tau^{n'-4} \le \widetilde{\mathcal{M}}_{R',n'}\left(\frac{1}{N_D}\right)^{m\mu+2}, \tag{6.5}$$

where $\widetilde{\mathcal{M}}_{R',n'}$ is given by (5.10) and n' is the number of terms (including zeroth order) in the Taylor series, *and* if (5.22) is satisfied.

This does not account for the truncation errors induced by using only a finite number of basis functions. Let W be the true value function (see section 2). Then, by (4.41),

$$|W(x) - W^f(x)| \leq K_1 \frac{|x|}{\tau}\left(\frac{2D_R}{N_D - 1}\right) \quad \forall\, x \in \overline{B}_R, \tag{6.6}$$

where K_1 is given by (4.42), $2D_R/(N_D - 1) = \Delta$, and τ satisfies (4.40); τ now must satisfy

$$\tau \leq \min\{1, 1/c, 1/\overline{\lambda}, \tau'\}. \tag{6.7}$$

The error bound (6.6) is not without drawbacks. In particular, τ appears in the denominator. However, it does not seem possible with the techniques of this paper to remove that term. This is the reason for concentrating in section 5 on fixed τ with increasing n' as the means for reducing errors.

Combining (6.4) and (6.6), the total error bound (assuming convergence of the power method—for which (6.5) and (5.22) form a sufficient condition—and $\tau \leq \min\{1, 1/c, 1/\overline{\lambda}, \tau'\}$) is given by

$$|W(x) - \widehat{W}(x)| \leq \left(\frac{D_R^2 \delta c^5 \tau^4}{9(4) M^2}\right)\left(\frac{1}{N_D}\right)^{m(\mu-2)}\left(\frac{1}{N_D - 1}\right)^2 + K_1 \frac{|x|}{\tau}\left(\frac{2D_R}{N_D - 1}\right),$$

which for $N_D \geq 3$

$$\leq \left(\frac{D_R^2 \delta c^5 \tau^4}{18 M^2}\right)\left(\frac{1}{N_D}\right)^{m(\mu-2)+2} + K_1 \frac{|x|}{\tau}\left(\frac{2D_R}{N_D}\right). \tag{6.8}$$

Since the best error rate in the last term in $1/N_D$, we take $\mu = 2$, and find in that case

$$|W(x) - \widehat{W}(x)| \leq \left[\frac{D_R^2 \delta c^5 \tau^4}{18 M^2} + 2K_1 D_R \frac{|x|}{\tau}\right]\left(\frac{1}{N_D}\right). \tag{6.9}$$

That is, the total error goes down linearly in $(1/N_D)$. Note that this rate is constrained by the fact that the solutions are only viscosity solutions—which may have discontinuous first derivatives. It is conjectured that with smooth solutions, the rate would instead be $(1/N_D)^2$.

This assumes that conditions (6.5) and (5.22) are met as well as (6.7). Also, as in section 5, one may prefer to write (6.5) as

$$n' \geq 4 + \frac{\log \widetilde{\mathcal{M}}_{R',n'} + (m\mu + 2)\log(1/N_D)}{\log \tau},$$

or assuming without loss of generality that $\widetilde{\mathcal{M}}_{R',n'} \geq 1$, one has the less tight but clearer bound of

$$n' \geq 4 + \frac{(m\mu + 2)\log(1/N_D)}{\log \tau},$$

in which case the lower bound on n' scales like $\log(1/N_D)$. From this, one sees for instance that doubling N_D would typically imply the addition of

$$\lceil\Big(\frac{(2m+2)\log(1/2)}{\log\tau}\Big) = \lceil\Big(\frac{(2m+2)\log 2}{\log(1/\tau)}\Big)$$

to n', where $\lceil(z)$ indicates the smallest integer greater than or equal to z. Again, this assumes the use of the Taylor series/Runge–Kutta approach of section 5 toward the approximation of B. Alternate approaches may yield different conditions.

Remark 6.1. All error bounds are actually conceived as the errors which may be achieved with given computer effort. A key underlying assumption of this paper is that all the elements of B are computed. This requires substantial effort since the number of terms in B is the square of the number of basis functions. In practice, it has been observed that elements of B, $B_{i,j}$, corresponding to basis function pairs where $|x_i - x_j|$ is large generally, do not contribute at all to the resulting eigenvector (recall that this is the max-plus algebra). By not computing these terms, one could greatly reduce the computations. This is a question for further study which lies beyond the bounds of the current paper.

Acknowledgments. The author would like to thank Professors Wendell H. Fleming and Matthew R. James for helpful discussions, both during the author's visit to Australian National University and subsequently. The author also thanks the referees for helpful comments.

STABILIZABILITY OF STOCHASTIC LINEAR SYSTEMS WITH FINITE FEEDBACK DATA RATES*

GIRISH N. NAIR† AND ROBIN J. EVANS†

Abstract. Feedback control with limited data rates is an emerging area which incorporates ideas from both control and information theory. A fundamental question it poses is how low the closed-loop data rate can be made before a given dynamical system is impossible to stabilize by *any* coding and control law. Analogously to source coding, this defines the smallest error-free data rate sufficient to achieve "reliable" control, and explicit expressions for it have been derived for linear time-invariant systems without disturbances. In this paper, the more general case of finite-dimensional linear systems with process and observation noise is considered, the object being mean square state stability. By inductive arguments employing the *entropy power inequality* of information theory, and a new quantizer error bound, an explicit expression for the infimum stabilizing data rate is derived, under very mild conditions on the initial state and noise probability distributions.

Key words. stochastic control, communication theory, source coding, entropy

1. Introduction.

Communications and control have traditionally been areas with little common ground. For the most part communications theory is concerned with the reliable transmission of information from one point to another, and is relatively indifferent to its specific purpose or whether it is eventually fed back to the source. Control theory, in contrast, is concerned mainly with using information in a feedback loop to achieve some performance objective, and usually assumes that limitations in the communications links are not significant enough to affect performance drastically.

The reasons usually given for this mutual indifference are, first, that a communications system is generally used for a broad range of purposes and can rarely be designed to match a particular objective and, secondly, that to explicitly model communication limitations would complicate controller synthesis. However, in recent years emerging applications such as microelectromechanical systems, mobile telephone power control, and networked industrial control systems have begun to cross the boundary between these disciplines. In these applications, the aim is to control a dynamical system consisting of many separate components connected by a digital communication network. Although the total available capacity in bits per second may be large, each component is effectively allocated only a small portion. This can introduce significant quantization errors and delays, due to the low resolution and finite transmission time of each discrete-valued, digital *symbol*. Quantization resolution can be improved at the expense of delay and vice-versa, but nonetheless there remains an upper bound on the amount of *information*, in some sense, that may be exchanged per unit time. Clearly, by designing coders and decoders that are matched to the dynamical system

and controllers, a more economical use of communication resources ought to be possible. Conversely, closed-loop performance should improve by matching the feedback laws to the specific coding and decoding schemes used.

The first step towards gaining a comprehensive understanding of these issues is to analyze the simplest possible network topology, consisting of one controller and dynamical system connected by a feedback loop with a given data rate in bits per unit time. In view of the limited communication resource, a natural question is: what is the smallest data rate above which there exists a coding and control law that stabilizes the system? This is analogous to Shannon's *source coding* theory, which seeks to determine the smallest data rate above which a given random process can be reliably communicated, i.e., with arbitrarily small error, by some coder and decoder [25, 7]. However, despite this analogy, Shannon's theory has generally not been fruitful in real-time control systems since its reliance on arbitrarily long *block* coders entails arbitrarily long delays. While this can be overcome by recursive coders such as *delta* and *differential pulse code* modulators, stationarity or ergodicity are still assumed [17]. Although this may be justified in communications, it does not always suit the unstable dynamics encountered in control.

In recent years, somewhat more progress on this topic has been made in the control literature. Beginning with the seminal paper [8] and continuing with [29, 2, 6, 10, 3, 23, 11, 16, 18], various schemes have been proposed and proven to asymptotically or *practically* stabilize linear time-invariant (LTI) systems at sufficiently high data rates. The first rigorous results on minimum data rates were in [29, 2], where it was shown that a discretized scalar plant with parameter a was stabilizable iff the data rate was not less than $\log_2 |a|$ bits per sampling interval. Similar tight bounds were subsequently obtained for noiseless autoregressive moving average [20] and linear state-space systems [27, 22, 14], using different formulations and techniques. With regard to stochastic plants, separation principles, causal *rate-distortion* theorems [28, 5], and the notion of feedback capacity [24] have been introduced.

This paper focuses on finite-dimensional, stochastic linear plants, under very mild assumptions on the noise and initial state probability distributions. In particular, the objective is to construct a coding and control scheme which achieves mean square state stability *while consuming as little data rate as possible*. The problem is formulated precisely in the next section, and the main result, which specifies the infimum stabilizing data rate, is stated. Somewhat counter-intuitively, the infimum rate depends only on the unstable dynamics of the plant and not on the noise statistics.

The remainder of the paper essentially constitutes the proof. As the presence of noise makes it difficult to extend the asymptotic quantization approach of [20, 22], a completely different method is developed here. In section 4, the well-known *entropy power inequality* of information theory [7, 9] is used to derive a strict lower bound on the data rate of any stabilizing, causal coding and control scheme, regardless of structure. It is shown that as the feedback data rate approaches this bound from above, the mean square state norms become arbitrarily large. In section 5, a specific, finite-dimensional scheme is then proposed. By applying a new, finite-level quantizer error inequality, it is proven to achieve mean square stability at any data rate exceeding the critical bound.

2. Formulation. First, certain conventions are defined. Vectors are written in bold-face type, matrices in bold-face upper-case, random variables in upper-case, and their realizations in corresponding lower-case letters. All random variables are assumed to exist on a common probability space with measure P. The probability

density of random vector $\mathbf{X}$ in Euclidean space with respect to (w.r.t.) Lebesgue measure λ on the space is denoted by $p_{\mathbf{X}}$, the probability density conditioned on the σ-field generated by an event $A = a$ by $p_{\mathbf{X}|a}$, expectation by E, and expectation conditioned on $A = a$ by E_a. The *(differential) entropy* of $\mathbf{X}$ is written $\mathrm{H}\{\mathbf{X}\} \triangleq -\mathrm{E}\{\ln p_{\mathbf{X}}(\mathbf{X})\}$; the *conditional entropy* of $\mathbf{X}$, given $A = a$, as $\mathrm{H}_a\{\mathbf{X}\} \triangleq -\mathrm{E}_a\{\ln p_{\mathbf{X}|A}(\mathbf{X})\}$; and the *average conditional entropy* of $\mathbf{X}$, given $A = a$, $B = b$, and averaged over B, as $\mathrm{H}_a\{\mathbf{X}|B\} \triangleq -\mathrm{E}_a\{\mathrm{H}_{A,B}\{\mathbf{X}\}\}$. Sequences $\{a_j\}_{j=0}^{k}$ are denoted $\tilde{a}_k$ (defined as the empty sequence when $k < 0$), and $\|\cdot\|$ represents either the Euclidean norm on a real vector space or the matrix norm induced by it. The $d \times d$ identity matrix is written $\mathbf{I}_d$, the $m \times n$ null matrix $\mathbf{0}_{m\times n}$, real numbers $\mathbb{R}$, positive reals $\mathbb{R}_+$, complex numbers $\mathbb{C}$, integers $\mathbb{Z}$, positive integers $\mathbb{Z}_+$, and nonnegative integers $\mathbb{W}$.

Consider the partially observed, discrete-time, stochastic linear system

$$\mathbf{x}_{k+1} = \mathbf{A}\mathbf{x}_k + \mathbf{B}\mathbf{u}_k + \mathbf{v}_k, \quad \mathbf{y}_k = \mathbf{C}\mathbf{x}_k + \mathbf{w}_k \qquad \forall k \in \mathbb{W}, \tag{2.1}$$

with state $\mathbf{x}_k$ and process noise $\mathbf{v}_k \in \mathbb{R}^n$, control signal $\mathbf{u}_k \in \mathbb{R}^m$, and measurement $\mathbf{y}_k$ and measurement noise $\mathbf{w}_k \in \mathbb{R}^p$. It is assumed that the following hold:

- A1. $(\mathbf{A}, \mathbf{B})$ is reachable and $(\mathbf{C}, \mathbf{A})$, observable;
- A2. $\mathbf{x}_0$, $\mathbf{v}_k$, and $\mathbf{w}_k$ are realizations of random variables $\mathbf{X}_0$, $\mathbf{V}_k$, and $\mathbf{W}_k$, respectively, where $\mathbf{X}_0, \mathbf{V}_k, \mathbf{W}_j$ are mutually independent $\forall k, j \in \mathbb{W}$;
- A3. $\exists \varepsilon > 0$ s.t. $\mathbf{X}_0, \mathbf{V}_k, \mathbf{W}_k$ have uniformly bounded $(2+\varepsilon)$th absolute moments over $k \in \mathbb{W}$;
- A4. the probability distribution of each random variable $\mathbf{V}_k$ is absolutely continuous with respect to Lebesgue measure λ on $\mathbb{R}^n$;
- A5. $\inf_{k\in\mathbb{W}} \mathrm{H}\{\mathbf{V}_k^{\mathrm{u}}\} > -\infty$, where $\mathbf{V}_k^{\mathrm{u}} \in \mathbb{R}^{f\times n}$ is the process noise seen by the $f \geq 1$ unstable eigenvectors of $\mathbf{A}$; i.e., the process noise injects a minimum amount of uncertainty into the unstable dynamics.

Suppose that the sensor producing the measurements is connected to the controller via a digital channel, onto which one symbol s_k from a finite alphabet $\mathcal{S}_k$, of possibly time-varying size $\mu_k \geq 1$, is transmitted during the $(k+1)$th sampling interval. It is assumed that each transmitted symbol is received without error, as in Shannon source coding, after a delay of d intervals. The *(asymptotic average) data rate* of the channel may then be defined as

$$R \triangleq \liminf_{t\to\infty} \frac{1}{t} \sum_{k=0}^{t-1} \log_2 \mu_k. \tag{2.2}$$

This is a more general definition than in [21, 22], in which the alphabet size μ_k is constant. In particular, it permits the alphabet $\mathcal{S}_k$ to vary periodically. For technical reasons, it is also assumed that $\mu_k/k \to 0$ as $k \to \infty$.

As the symbols in the channel are discrete-valued but the plant measurements are continuous-valued, analog-to-digital conversion, or coding, is required. In practice, constraints such as complexity and finite memory may be important but, in the spirit of source coding, such limitations will be largely ignored here in order to concentrate on the communication aspect of the problem. Each transmitted symbol may thus depend on all past and present measurements and past symbols,

$$s_k = \gamma_k(\tilde{\mathbf{y}}_k, \tilde{s}_{k-1}) \qquad \forall k \in \mathbb{W}, \tag{2.3}$$

where $\gamma_k : \mathbb{R}^{p\times(k+1)} \times \tilde{\mathcal{S}}_{k-1} \to \mathcal{S}_k$ is the coder mapping at time k. Note in particular that s_k does not necessarily correspond to a quantized version of the latest

measurement alone. At time k the controller has the symbols $s_0, \ldots, s_{k-d}$ available to it and can then generate a control signal of the general form

$$\mathbf{u}_k = \delta_k(\tilde{s}_{k-d}) \quad \forall k \in \mathbb{W}, \tag{2.4}$$

where $\delta_k : \tilde{\mathcal{S}}_{k-d} \to \mathbb{R}^m$ is the controller mapping at time k. As $\tilde{s}_k$ is the empty sequence $\{\}$ when $k < 0$, the first d control signals $\mathbf{u}_0, \ldots, \mathbf{u}_{d-1}$ are just preset inputs. Similarly, in the coder equation (2.3) at time $k = 0$, s_0 is a function only of $\mathbf{y}_0$.

Now, define the *coder-controller* as the triple of alphabet, coder, and controller mapping sequences $(\tilde{\mathcal{S}}_\infty, \tilde{\gamma}_\infty, \tilde{\delta}_\infty)$. The objective here is to construct a coder-controller which stabilizes the plant in the mean square sense,

$$\sup_{k \in \mathbb{W}} \mathrm{E}\|\mathbf{X}_k\|^2 < \infty, \tag{2.5}$$

while using as small a data rate as possible. The main result of this paper is now stated as follows.

THEOREM 2.1. *Given assumptions* A1–A5*, any coder-controller which stabilizes the plant* (2.1) *in the mean square sense* (2.5) *must have a data rate* R *(see* (2.2)*) strictly satisfying*

$$R > \sum_{|\eta_j| \geq 1} \log_2 |\eta_j| =: H, \tag{2.6}$$

where $\eta_1, \ldots, \eta_n$ *are the open-loop eigenvalues. As* R *approaches this bound from above, the supremum mean square state norm* (2.5) *approaches* ∞*.*

This inequality is also tight. In other words, for any number $R' > H$*, a mean-square-stabilizing coder-controller at data rate* $R \leq R'$ *can be constructed, which furthermore is finite-dimensional with periodic alphabet.*

This result assumes nothing about the coding and control laws except causality, and imposes only mild requirements on the noise distributions. It thus draws a fundamental line of demarcation between what is and is not achievable with stochastic linear systems when communication rates are limited. In this sense, H plays a role similar to source entropy in errorless Shannon source coding, and can be taken as a measure of the rate at which information is generated by an unstable, stochastic linear plant. Hence (2.6) states that, to achieve stability, the channel must transport data as fast as it is produced.

A more physical insight can be gained by rewriting the inequality above as $2^R > \prod_{|\eta_j| \geq 1} |\eta_j|$. The right-hand side (RHS) is simply the factor by which a volume in the unstable subspace increases at each time step due to the plant dynamics, while the left-hand side (LHS) is the asymptotic average number of disjoint regions into which the coder can partition the volume. In other words, the system is stabilizable iff the dynamical increase in "uncertainty volume" due to unstable dynamics is outweighed by the partitioning induced by the coder.

Note also that the data rate bound above is completely independent of the noise distributions and link delay, a consequence of the weak notion of stability used here. Increasing the noise variances (or delay) would obviously increase the mean square state norms, but as long as (2.6) is satisfied it remains possible to keep the state uniformly bounded in a mean square sense. The reason for this is that the noise increases state uncertainty volumes in an additive rather than multiplicative fashion but is averaged out exponentially, in effect, by the coder. However, as the data rate

approaches the critical limit, this exponential averaging becomes increasingly weak, leading to an unbounded increase in uncertainty volumes and hence mean square states.

Finally, it is remarked that in the problem formulation above there is no explicit communication constraint between the controller and actuator. This is reasonable if they are colocated, but even otherwise the formulation above is applicable, since from a plant output-to-input perspective the location of the controller is purely nominal. The symbols that would be transmitted by it over an additional digital link to the actuator would have to be converted once again into inputs, making intermediate calculations redundant. In other words the "bottle-neck" link determines the effective data rate, as expected, and Theorem 2.1 still applies. This is stated below more precisely.

PROPOSITION 2.2. *Suppose that two cascaded digital links connect the sensor to the actuator, with associated mappings*

$$s_k^1 = \gamma_k^1(\tilde{\mathbf{y}}_k, \tilde{s}_{k-1}^1) \in \mathcal{S}_k^1, \qquad \textit{(link-1 coder)} \tag{2.7}$$

$$s_k^2 = \gamma_k^2(\tilde{s}_{k-d_1}^1) \in \mathcal{S}_k^2, \qquad \textit{(link-2 coder)} \tag{2.8}$$

$$\mathbf{u}_k = \delta_k^2(\tilde{s}_{k-d_2}^2) \in \mathbb{R}^m. \qquad \textit{(actuator)} \tag{2.9}$$

Let R_1 be the data rate (2.2) *of the first link and R_2 that of the second. Then this coding and control scheme can be expressed as a single-link coder-controller of the form* (2.3)–(2.4)*, with delay $d = d_1 + d_2$ and data rate $R = \min\{R_1, R_2\}$.*

Conversely, any single-link coder-controller with periodic alphabet, data rate R, and delay d can always be expressed as a two-link coding and control scheme of the form above, with periodic alphabet sizes, link data rates both equal to R, and arbitrary delays $d_1, d_2 \in \mathbb{W}$ s.t. $d_1 + d_2 = d$.

Proof. See Appendix A for the proof.

The remainder of this paper is devoted to proving Theorem 2.1, in three stages. In the next section, the system dynamics are transformed into a simpler form. In section 4, the strict necessity of (2.6) is established via an inductive argument using the *entropy power inequality* of information theory [9]. Finally, the sufficiency of (2.6) is demonstrated in section 5 by constructing a coder-controller and using a new quantizer error result to recursively bound the mean square state norms.

3. Real Jordan form. Before proceeding, it is convenient to transform the system so as to decouple its dynamical modes. The obvious approach of putting the matrix $\mathbf{A}$ into *Jordan canonical form* generally requires a transformation matrix with complex elements. As this would complicate the analysis somewhat, the *real Jordan canonical form* [15] is used here.

Let $\lambda_1, \ldots, \lambda_b$ be the *distinct* eigenvalues of $\mathbf{A} \in \mathbb{R}^{n\times n}$, ordered by nonincreasing magnitude with conjugates excluded, and let the algebraic multiplicity of each λ_i be m_i. The real Jordan canonical form $\mathbf{J}$ then has the block diagonal structure

$$\mathbf{J} \equiv \operatorname{diag}(\mathbf{J}_1, \ldots, \mathbf{J}_b) \in \mathbb{R}^{n\times n}, \tag{3.1}$$

where the block $\mathbf{J}_i \in \mathbb{R}^{n_i \times n_i}$ with

$$n_i \triangleq \begin{cases} m_i & \text{if } \lambda_i \in \mathbb{R}, \\ 2m_i & \text{otherwise.} \end{cases} \tag{3.2}$$

More detail regarding the structure of each block can be found in, e.g., [15, pp. 150–153] or [26]. For the purposes of this paper, the most important fact is that

each block $\mathbf{J}_i$ is *similar* to the block diagonal matrix of all *standard* Jordan blocks corresponding to λ_i, λ_i^*. Hence $\mathbf{J}_i$ has either exactly one distinct eigenvalue λ_i or a pair of complex conjugate eigenvalues λ_i, λ_i^*, each with multiplicity m_i.

The real Jordan canonical form is related to the matrix $\mathbf{A}$ via a real similarity matrix $\mathbf{T} \in \mathbb{R}^{n\times n}$ s.t. $\mathbf{T}^{-1}\mathbf{J}\mathbf{T} = \mathbf{A}$. Defining the transformed state

$$\acute{\mathbf{x}}_k \triangleq \mathbf{T}\mathbf{x}_k \quad \forall k \in \mathbb{W}, \tag{3.3}$$

the system equations (2.1) can then be written

$$\acute{\mathbf{x}}_{k+1} = \mathbf{J}\acute{\mathbf{x}}_k + \mathbf{T}\mathbf{B}\mathbf{u}_k + \mathbf{T}\mathbf{v}_k \in \mathbb{R}^n, \quad \mathbf{y}_k \triangleq \mathbf{C}\mathbf{T}^{-1}\acute{\mathbf{x}}_k + \mathbf{w}_k \in \mathbb{R}^p \qquad \forall k \in \mathbb{W}. \tag{3.4}$$

By partitioning the transformed state vector into the vectors $\acute{\mathbf{x}}_k^{(1)}, \ldots, \acute{\mathbf{x}}_k^{(b)}$ corresponding to each subsystem, the dynamical equation above can be rewritten more explicitly as

$$\acute{\mathbf{x}}_{k+1}^{(i)} = \mathbf{J}_i\acute{\mathbf{x}}_k^{(i)} + (\mathbf{T}\mathbf{B}\mathbf{u}_k)^{(i)} + (\mathbf{T}\mathbf{v}_k)^{(i)} \in \mathbb{R}^{d_i} \quad \forall k \in \mathbb{W},\ i \in [1, \ldots, b], \tag{3.5}$$

where $(\cdot)^{(i)}$ denotes that portion of the vector argument that feeds into the ith subsystem.

The original system has thus been decomposed into b real subsystems, with dynamics characterized by either a single eigenvalue or a pair of complex conjugate eigenvalues, possibly repeated. As $\mathbf{T}$ is invertible, it follows that the problems of stabilizing (3.4) and (2.1) are equivalent.

4. Proof of necessity. The first step towards proving Theorem 2.1 is to establish the necessity of (2.6) for mean square stability. In order to do so, a recursive lower bound for $\mathrm{E}\|\acute{\mathbf{X}}_k\|^2$ shall be sought, which is independent of the coder-controller and easier to analyze in terms of dynamics and data rate. More precisely, this bound will be sought for the state vector corresponding to subsystems with eigenvalue $|\lambda_i| \geq 1$.

If a strict inequality in (2.6) was not desired, a lower bound could quickly be obtained by observing that since the noise terms are independent, the mean square state norm cannot increase if they are all suppressed. In other words, the mean square state norm is bounded below by the mean square state norm of the plant with a random initial state but no noise. This is precisely the situation explored in [22] and, by a slight modification of the quantization argument used there, the nonstrict version of (2.6) is easily seen to be necessary for mean square stability.

However, this reduction to a noiseless system does not reveal that stability is in fact impossible at a data rate equal to the critical bound H. More importantly, it states nothing about behavior *near* H, in particular the fact that, as the data rate approaches H, the supremum mean square state norm (2.5) becomes arbitrarily large, drastically degrading performance, regardless of the coder-controllers used. This is made apparent by the entropy-based analysis below.

Denote the index set of unstable subsystems and their total dimension, respectively, by

$$\mathcal{U} \triangleq \{i : |\lambda_i| \geq 1\}, \quad f \triangleq \sum_{i\in\mathcal{U}} n_i, \tag{4.1}$$

and stack the unstable subsystem states $\acute{\mathbf{x}}_k^{(i)}$, $i \in \mathcal{U}$, to construct

$$\mathbf{x}_k^{\mathrm{u}} := \left[\acute{\mathbf{x}}_k^{(1)\mathrm{T}} \cdots \acute{\mathbf{x}}_k^{(|\mathcal{U}|)\mathrm{T}}\right]^{\mathrm{T}} \equiv \mathbf{R}\acute{\mathbf{x}}_k \in \mathbb{R}^f \qquad \forall k \in \mathbb{W},$$

$$\text{where } \mathbf{R} \triangleq \begin{bmatrix}\mathbf{I}_f & \mathbf{0}_{f\times(n-f)}\end{bmatrix} \in \mathbb{R}^{f\times n}. \tag{4.2}$$

Now, suppose that the coder-controller $(\tilde{\mathcal{S}}_\infty, \tilde{\gamma}_\infty, \tilde{\delta}_\infty)$ stabilizes (2.1), and hence (3.4), in mean square state norm. As $\|\mathbf{x}_k^{\mathrm{u}}\| \leq \|\hat{\mathbf{x}}_k\|$, it follows that $\{\mathbf{X}_k^{\mathrm{u}}\}_{k\in\mathbb{W}}$ is also bounded in mean square norm. Following the usual definition of *entropy power* (see, e.g., [9]), let the *conditional entropy power* of a random variable $\mathbf{X} \in \mathbb{R}^f$, given an event $A = a$, be

$$\mathrm{N}_a\{\mathbf{X}\} \triangleq (2\pi\mathrm{e})^{-1}\mathrm{e}^{2\mathrm{H}_a\{\mathbf{X}\}/f}. \tag{4.3}$$

In connection with the uncertainty volume interpretation of Theorem 2.1, $(\mathrm{N}_a\{\mathbf{X}\})^{f/2}$ can be regarded as the volume of the effective support set of $p_{\mathbf{X}|a}$. Furthermore,

$$\mathrm{N}_a\{\mathbf{X}\} \leq \mathrm{e}^{1/f-1}\mathrm{E}_a\|\mathbf{X}\|^2, \tag{4.4}$$

with equality iff $\mathbf{X}$ is symmetric Gaussian with zero mean when conditioned on $A = a$ (see Appendix B). This is essentially a statement of the well-known entropy-maximizing property of Gaussian distributions.

By analogy with the notation for average conditional entropy, denote the *average conditional entropy power* of $\mathbf{X}$, given $A = a$, averaged over A, by

$$\mathrm{N}\{\mathbf{X}|A\} \triangleq \mathrm{E}\left\{\mathrm{N}_A\{\mathbf{X}\}\right\}. \tag{4.5}$$

Setting $\mathbf{X} = \mathbf{X}_k^{\mathrm{u}}$ and $A = \tilde{S}_{k-d-1}$, the random variable associated with the sequence $\tilde{s}_{k-d-1}$, it then follows that

$$\begin{aligned} n_k &:= \mathrm{N}\{\mathbf{X}_k^{\mathrm{u}}|\tilde{S}_{k-d-1}\} = \mathrm{E}\big\{\mathrm{N}_{\tilde{S}_{k-d-1}}\{\mathbf{X}_k^{\mathrm{u}}\}\big\}, \\ &\leq \mathrm{e}^{1/f-1}\mathrm{E}\big\{\mathrm{E}_{\tilde{S}_{k-d-1}}\|\mathbf{X}_k^{\mathrm{u}}\|^2\big\} = \mathrm{e}^{1/f-1}\mathrm{E}\|\mathbf{X}_k^{\mathrm{u}}\|^2 \quad \forall k \in \mathbb{W}, \end{aligned} \tag{4.6}$$

so that $\{n_k\}_{k\in\mathbb{W}}$ must also be bounded. Note here that n_k can be interpreted as the average unstable subspace uncertainty volume, given the symbol sequence $\tilde{s}_{k-d-1}$.

Another important property of conditional entropy power is its superadditivity for summed independent random variables, i.e.,

$$\mathrm{N}_a\{\mathbf{X}+\mathbf{Y}\} \geq \mathrm{N}_a\{\mathbf{X}\} + \mathrm{N}_a\{\mathbf{Y}\}, \tag{4.7}$$

where $\mathbf{X}, \mathbf{Y} \in \mathbb{R}^f$ are mutually independent when conditioned on an event $A = a$ (see, e.g., [7, 9]). By means of a recursive argument that employs this so-called *entropy power inequality*, it shall be shown that any stabilizing data rate must satisfy (2.6) strictly. First, observe from (4.2) that

$$\mathbf{RJ} = \mathbf{J}^{\mathrm{u}}\mathbf{R}, \quad \text{where } \mathbf{J}^{\mathrm{u}} \triangleq \mathrm{diag}(\mathbf{J}_1, \ldots, \mathbf{J}_{|\mathcal{U}|}) \in \mathbb{R}^{f\times f}. \tag{4.8}$$

Left-multiplying (3.4) by $\mathbf{R}$ and using (2.4), the dynamical equation for $\mathbf{x}_k^{\mathrm{u}}$ is then

$$\mathbf{x}_{k+1}^{\mathrm{u}} = \mathbf{J}^{\mathrm{u}}\mathbf{x}_k^{\mathrm{u}} + \mathbf{RTv}_k + \mathbf{RTB}\delta_k(\tilde{s}_{k-d}), \tag{4.9}$$

$$\begin{aligned} \Rightarrow \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{X}_{k+1}^{\mathrm{u}}\} &= \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{J}^{\mathrm{u}}\mathbf{X}_k^{\mathrm{u}} + \mathbf{RTV}_k + \mathbf{RTB}\delta_k(\tilde{S}_{k-d})\} \\ &= \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{J}^{\mathrm{u}}\mathbf{X}_k^{\mathrm{u}} + \mathbf{RTV}_k\} \qquad (4.10) \\ &\geq \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{J}^{\mathrm{u}}\mathbf{X}_k^{\mathrm{u}}\} + \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{RTV}_k\} = \mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{J}^{\mathrm{u}}\mathbf{X}_k^{\mathrm{u}}\} + \mathrm{N}\{\mathbf{RTV}_k\} \qquad (4.11) \\ &= |\det\mathbf{J}^{\mathrm{u}}|^{2/f}\mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{X}_k^{\mathrm{u}}\} + \mathrm{N}\{\mathbf{RTV}_k\} \quad \forall k \in \mathbb{W}. \qquad (4.12) \end{aligned}$$

The equality in (4.10) is due to the property that $\mathrm{H}_a\{\mathbf{X}+g(A)\} = \mathrm{H}_a\{\mathbf{X}\}$ for any function g (translation invariance). The inequality (4.11) uses the mutual independence of $\mathbf{V}_k$ and $\mathbf{X}_k, \tilde{S}_{k-d}$, the latter both being determined by $\mathbf{X}_0, \mathbf{V}_j, \mathbf{W}_j$, $j \le k-1$, to apply the entropy power inequality (4.7), and finally (4.12) expresses the effect of an invertible linear transformation on differential entropy; see Corollary 9.6.4 in [7].

Now, denote the conditional entropy power of $\mathbf{X}$, given $A = a$, $S = s$ and averaged only over S, by $\mathrm{N}_a\{\mathbf{X}|S\} \triangleq \mathrm{E}_a\{\mathrm{N}_{A,S}\{\mathbf{X}\}\}$. The next step utilizes the result below.

LEMMA 4.1. *Let $\mathbf{X} \in \mathbb{R}^f$ and $S \in \mathcal{S}$, a finite alphabet, be random variables conditioned on an event $A = a$. Then*

$$\mathrm{N}_a\{\mathbf{X}|S\} \ge |\mathcal{S}|^{-2/f}\mathrm{N}_a\{\mathbf{X}\}. \tag{4.13}$$

Proof. See Appendix C for the proof.

As $(\mathrm{N}_a\{\mathbf{X}|S\})^{f/2}$ can be viewed as the average uncertainty volume of $\mathbf{X}$, given S conditioned on $A = a$, this inequality states that knowledge of a correlated random variable $S \in \mathcal{S}$ with $|\mathcal{S}|$ distinct values reduces the average uncertainty volume of $\mathbf{X}$ by at most a factor of $|\mathcal{S}|$. In a sense, this is an extension of deterministic volume partitioning to a stochastic setting.

Setting $\mathbf{X} = \mathbf{X}^{\mathrm{u}}_k$, $A = \tilde{S}_{k-d-1}$, $S = S_{k-d}$, and averaging (4.12),

$$\begin{aligned}
n_{k+1} &\equiv \mathrm{E}\left\{\mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{X}^{\mathrm{u}}_{k+1}\}\right\} \\
&\ge |\det\mathbf{J}^{\mathrm{u}}|^{2/f}\mathrm{E}\left\{\mathrm{E}_{\tilde{S}_{k-d-1}}\left\{\mathrm{N}_{\tilde{S}_{k-d}}\{\mathbf{X}^{\mathrm{u}}_k\}\right\}\right\} + \mathrm{E}\left\{\mathrm{N}\{\mathbf{RTV}_k\}\right\} \\
&= |\det\mathbf{J}^{\mathrm{u}}|^{2/f}\mathrm{E}\left\{\mathrm{N}_{\tilde{S}_{k-d-1}}\{\mathbf{X}^{\mathrm{u}}_k|S_{k-d}\}\right\} + \mathrm{N}\{\mathbf{RTV}_k\} \\
&\ge \left|\frac{\det\mathbf{J}^{\mathrm{u}}}{|\mathcal{S}_{k-d}|}\right|^{2/f}\mathrm{E}\left\{\mathrm{N}_{\tilde{S}_{k-d-1}}\{\mathbf{X}^{\mathrm{u}}_k\}\right\} + \mathrm{N}\{\mathbf{RTV}_k\} \\
&\equiv \left|\frac{\det\mathbf{J}^{\mathrm{u}}}{\mu_{k-d}}\right|^{2/f} n_k + \mathrm{N}\{\mathbf{RTV}_k\} \quad \forall k \in \mathbb{W}.
\end{aligned} \tag{4.14}$$

By assumption A5 in section 2, $\exists\theta \in \mathbb{R}$ s.t. $\mathrm{H}\{\mathbf{RTV}_j\} \ge \theta\ \forall j \in \mathbb{W}$. Hence

$$\mathrm{N}\{\mathbf{RTV}_j\} \ge (2\pi)^{-1}\mathrm{e}^{2\theta/f-1} =: \beta > 0 \quad \forall j \in \mathbb{W}, \tag{4.15}$$

by definition (4.3). Substituting this into (4.14) and for convenience setting $\mu_i = 1$ when $i < 0$,

$$\begin{aligned}
n_{k+1} &\ge \left|\frac{\det\mathbf{J}^{\mathrm{u}}}{\mu_{k-d}}\right|^{2/f} n_k + \beta \ge \beta\sum_{j=0}^{k}\prod_{i=j+1}^{k}\left|\frac{\det\mathbf{J}^{\mathrm{u}}}{\mu_{i-d}}\right|^{2/f} \\
&\equiv \beta\sum_{j=0}^{k}\frac{h_k}{h_j}, \qquad \text{where } h_k := \prod_{i=0}^{k}\left|\frac{\det\mathbf{J}^{\mathrm{u}}}{\mu_{i-d}}\right|^{2/f} \\
\Rightarrow\ \infty > \alpha &\triangleq \frac{1}{\beta}\sup_{k\in\mathbb{Z}_+} n_k \ge \sum_{j=0}^{k}\frac{h_k}{h_j} \ \Leftrightarrow\ \frac{\alpha-1}{h_k} \ge \sum_{j=0}^{k-1}\frac{1}{h_j} \quad \forall k \in \mathbb{Z}_+.
\end{aligned} \tag{4.16}$$

As $h_k > 0$, $\alpha > 1$. By upward induction on k it can be verified that

$$
\begin{aligned}
& h_k \le \alpha(1-1/\alpha)^k h_0 \quad \forall k \in \mathbb{Z}_+ \\
\Rightarrow\ & 0 > \log_2(1-1/\alpha) \ge \frac{1}{k}\log_2\left(\frac{h_k}{\alpha}\right) \\
\Rightarrow \log_2\left(1-\frac{1}{\alpha}\right) &= \frac{2(k+1)}{fk}\log_2|\det \mathbf{J}^{\mathrm{u}}| - \frac{2}{fk}\sum_{i=0}^{k}\log_2\mu_{i-d} - \frac{\log_2\alpha}{k} \quad \forall k \in \mathbb{Z}_+ \\
& \ge \frac{2}{f}\log_2|\det \mathbf{J}^{\mathrm{u}}| - \liminf_{k\to\infty}\left[\frac{2}{fk}\sum_{i=0}^{k}\log_2\mu_{i-d} - \frac{2\log_2|\det \mathbf{J}^{\mathrm{u}}|}{fk} + \frac{\log_2\alpha}{k}\right] \\
& \equiv (2/f)\left(\log_2|\det \mathbf{J}^{\mathrm{u}}| - R\right) \equiv (2/f)(H-R). \qquad (4.17)
\end{aligned}
$$

This proves the strict necessity of (2.6). Furthermore, after rearranging the inequalities above and using (4.6),

$$
\sup_{k\in\mathbb{Z}_+} \mathrm{E}\|\mathbf{X}_k^{\mathrm{u}}\|^2 \ge \mathrm{e}^{1-1/f}\sup_{k\in\mathbb{Z}_+} n_k = \mathrm{e}^{1-1/f}\beta\alpha \ge \frac{\mathrm{e}^{1-1/f}\beta}{1-2^{-2(R-H)/f}}. \qquad (4.18)
$$

As β in (4.15) depends only on process noise statistics, this is a universal lower bound on the supremum mean square state of *all* coder-controllers with data rate R. Hence as $R \searrow H$, the supremum mean square state becomes arbitrarily large. □

Note that the argument above can be adapted to deal with stability in the sense of uniform boundedness with bounded disturbances. The idea is to replace the average conditional entropy power n_k with the maximum state uncertainty volume, given past symbols, and then use the deterministic analogue of the entropy power inequality, the *Brunn–Minkowski inequality* (see, e.g., [7]). This states that, given two λ-measurable regions $X, Y \subset \mathbb{R}^f$, the volume of the set sum $X+Y \triangleq \{x+y | x \in X, y \in Y\}$ satisfies $\lambda(X+Y)^{1/f} \ge \lambda(X)^{1/f} + \lambda(Y)^{1/f}$. It then follows that (2.6) is also strictly necessary for uniformly bounded stabilizability.

5. Achievability of data rate bound. The final step in proving Theorem 2.1 is to establish that (2.6) is attainable, i.e., that the system (2.1) can in principle be stabilized at any data rate arbitrarily close to but greater than the critical bound H. The general, entropy-based argument of the preceding section does not offer many clues as to how to prove this, so in this section a completely different approach is taken. Based on a semiheuristic line of reasoning, a finite-dimensional coder-controller with periodically varying coding alphabet is constructed in section 5.2. By means of a new quantizer bound, it is then demonstrated in section 5.3 that it achieves means square stability at data rates arbitrarily close to H.

The chief complications in the design and analysis of this scheme arise from the unbounded support of the noise terms. With uniformly bounded noise, any coding and control law which achieves asymptotic contraction *without* disturbances, in the sense that $\exists \gamma \in (0,1)$ s.t. $\forall$ sufficiently large k, $\|\mathbf{x}_k\| < \gamma r$, $\forall r > 0$, $\|\mathbf{x}_0\| \le r$, can easily be modified to achieve uniformly bounded stability. The idea is to recast such a law as an equivalent open-loop scheme which generates symbols according to the initial state alone. Assuming no noise, $\exists$ a sufficiently large $\tau \in \mathbb{Z}_+$ s.t. any state with norm $\le r$ will after τ steps have norm $\le \gamma r$. The effect of bounded disturbances then boosts the radius of this worst-case region by an additive constant $c \cdot \tau$, so the open-loop scheme can then be reapplied with $r^{\mathrm{new}} = \gamma r + c\tau$. As the recursion $r \mapsto \gamma r + c\tau$ is stable, a uniform bound on the state at times $0, \tau, 2\tau, \ldots$ is guaranteed and trivially leads to a bound over all integer times.

The situation is quite different when dealing with unbounded stochastic disturbances, because of the impossibility of a coder-controller which uniformly contracts mean square norms in an analogous sense. Briefly, the reason for this is that even though a distribution may have finite second absolute moment, the tail integral $\int_{\|\mathbf{x}\|\geq t} \|\mathbf{x}\|^2 \mathrm{d}P_{\mathbf{X}}(\mathbf{x})$ can approach 0 arbitrarily slowly with large t. In section 5.3 this difficulty is overcome by dealing with a functional M_ε (see (5.9)) instead of the mean square state norm. Before proceeding to the construction and analysis of the stabilizing coder-controller, several structural issues are first discussed below.

5.1. Structural issues. In order to make the analysis tractable, a certain amount of structure will need to be imposed on the general coder-controller equations (2.3)–(2.4). It is known (see, e.g., [28]) that for a linear Gauss–Markov system under a mean quadratic cost there exist optimal coding and control schemes with the following form:

1. Prior to coding, a Kalman filter is applied to recursively calculate the linear minimum variance prediction $\bar{\mathbf{x}}_{k+d|k}$ of $\acute{\mathbf{x}}_{k+d}$, given the measurement and control sequences $\tilde{\mathbf{y}}_k, \tilde{\mathbf{u}}_{k+d-1}$. Note that the control signals are not observed directly by the coder, but inferred from knowledge of the symbol sequence $\tilde{s}_{k-1}$ and the controller mappings.
2. Based on the past symbol sequence $\tilde{s}_{k-1}$, the latest prediction $\bar{\mathbf{x}}_{k+d}$ is recursively (and possibly nonuniformly) quantized to yield a coded estimate

$$\hat{\mathbf{x}}_{k+d} \equiv Q_k(\bar{\mathbf{x}}_{k+d|k}, \tilde{s}_{k-1}) \equiv \varpi_k(s_k)$$

   with μ_k possible values. The index s_k of the selected quantizer point $\varpi_k(s_k)$ is transmitted.
3. Upon receiving s_k at time $k+d$, the controller uses it and the previous symbols to regenerate $\hat{\mathbf{x}}_{k+d}$ and applies a certainty-equivalent linear control law $\mathbf{u}_{k+d} \equiv \mathbf{L}\hat{\mathbf{x}}_{k+d}$.

Although no Gaussian assumptions are made in this paper, it is convenient to use a modified version of this tristage structure as a basis for constructing a stabilizing scheme.

Considering the first stage, recall that the linear minimum variance predictions satisfy the separation principle

$$\mathrm{E}\|\acute{\mathbf{X}}_k\|^2 = \mathrm{E}\|\acute{\mathbf{X}}_k - \bar{\mathbf{X}}_{k|k-d}\|^2 + \mathrm{E}\|\bar{\mathbf{X}}_{k|k-d}\|^2 \quad \forall k \in \mathbb{W},$$

even with non-Gaussian noise. The first term on the RHS is uniformly bounded, by the observability and $(2+\varepsilon)$th moment assumptions A1 and A3 in section 2, and independent of the control law (see, e.g., [1]). Hence the mean square stability of the partially observed system (3.4) is equivalent to that of the fully observed filter process. Furthermore, this process satisfies a recursive equation of the same form as (3.4), i.e.,

$$\bar{\mathbf{x}}_{k+1+d|k+1} = \mathbf{J}\bar{\mathbf{x}}_{k+d|k} + \mathbf{TBu}_k + \mathbf{z}_{k+1} \quad \forall k \in \mathbb{W}, \tag{5.1}$$

where, by assumption A3, the $(2+\varepsilon)$th absolute moments of the *innovation* $\mathbf{Z}_{k+1}$ can be shown to be uniformly bounded over $k \in \mathbb{W}$.

The second stage above is not quite so straightforward, since the optimal quantizer $Q_k(\cdot,\cdot)$ is generally time-varying and stores all past symbols. As the objective here

is not optimality but stability, it is natural to investigate whether simpler quantizer structures will suffice. One possibility is a static, memoryless coder,

$$\hat{\mathbf{x}}_{k+d} \equiv Q(\bar{\mathbf{x}}_{k+d|k}) \equiv \varpi(s_k) \in \mathbb{R}^n, \tag{5.2}$$

where Q is a fixed quantizer with points $\varpi(0), \varpi(1), \ldots, \varpi(\mu-1)$. Another option is a *finite-state, predictive quantizer* (see, e.g., [12]), in which the latest coded state estimate is stored and the *prediction error* is recursively coded according to a finite-valued internal variable $\iota_k \in \mathcal{I}$,

$$Q\left(\bar{\mathbf{x}}_{k+d|k} - (\mathbf{J}+\mathbf{TBL})\hat{\mathbf{x}}_{k-1+d|k-1}, \iota_k\right) \equiv \varpi(s_k), \tag{5.3}$$

$$\begin{aligned} \hat{\mathbf{x}}_{k+d} &\equiv (\mathbf{J}+\mathbf{TBL})\hat{\mathbf{x}}_{k-1+d} + \varpi(s_k), \\ \iota_{k+1} &\equiv g(\iota_k, s_k), \end{aligned} \tag{5.4}$$

where $\mathbf{L}$ is a certainty-equivalent control gain such that $\mathbf{J}+\mathbf{TBL}$ is stable. The symbol s_k, corresponding to the index of the selected quantizer point, is then used to update the finite state, $(\iota_k, s_k) \mapsto \iota_{k+1}$. Examples are *differential pulse code* and *delta modulation* in speech processing.

For noise distributions with compact support, it can be shown that either type of coder can achieve stability. It may seem as if this should also hold in the case of infinite support, since if stability has been achieved, then the states and prediction errors remain with high probability in some bounded region, which could then be quantized without memory. However, this somewhat circular argument fails drastically if the plant is strictly unstable and either the initial state or a process noise term has infinite support in all directions.

PROPOSITION 5.1. *Suppose that the plant* (2.1) *has at least one open-loop eigenvalue with magnitude strictly greater than* 1*, and that, for any nonzero* $\mathbf{h} \in \mathbb{R}^n$*, either*

$$\mathrm{P}\{\mathbf{h}^{\mathrm{T}}\mathbf{X}_0 > \theta\} > 0 \quad \forall \theta \in \mathbb{R} \quad \textit{or} \quad \exists t \in \mathbb{W} \textit{ s.t. } \mathrm{P}\{\mathbf{h}^{\mathrm{T}}\mathbf{V}_t > \theta\} > 0 \quad \forall \theta \in \mathbb{R}. \tag{5.5}$$

Then for any static memoryless coder (5.2) *or finite-state predictive quantizer* (5.3)–(5.4)*, the* r*th absolute state moments are unbounded with time,* $\forall r > 0$*, regardless of the number of quantization points.*

Proof. See Appendix D for the proof.

This distinguishes the stochastic, communication-limited stabilization problem from the deterministic, bounded disturbance version, for which either memoryless or finite-state quantization suffices. The reason for the difference is basically that the finite range of the quantizer causes controller saturation. If the initial state or process noise has infinite support, there is consequently a finite chance that at some time k, the propagated state $\mathbf{A}\mathbf{x}_k$ is beyond reach of the control signal. The unstable plant dynamics then amplify this shortfall, causing the same phenomenon to occur with increasing probability at subsequent times, and inevitably leading to instability.

An obvious solution is to use an adaptive quantizer with possibly unbounded range, thereby allowing the control signal to "catch up" with the state. One simple approach is to use a predictive scheme with a scaling factor $l_k > 0$ which is recursively adjusted according to the symbols transmitted:

$$\begin{aligned} Q\left(\frac{\bar{\mathbf{x}}_{k+d|k} - (\mathbf{J}+\mathbf{TBL})\hat{\mathbf{x}}_{k-1+d|k-1}}{l_k}\right) &\equiv \varpi(s_k), \\ \hat{\mathbf{x}}_{k+d} &\equiv (\mathbf{J}+\mathbf{TBL})\hat{\mathbf{x}}_{k-1+d} + l_k\varpi(s_k), \\ l_{k+1} &\equiv g(l_k, s_k) \in \mathbb{R}_+. \end{aligned}$$

This approach, similar to [6, 19], is adopted in section 5.2.

Another characteristic of the coder-controller constructed here is that its symbol alphabet varies periodically with time, a point of departure from the time-invariant, constant data rate schemes in [3] and elsewhere. If the symbol alphabet were fixed, then the data rate in bits/interval could only take the discrete values $\log_2 \mu$, $\mu = 1, 2, \ldots$, making it impossible in general to attain data rates arbitrarily close to H. In [3] this is not an issue, since the underlying plant is in continuous time and the corresponding data rate bound, in bits/*second*, can be approached by increasing the sampling period. In the scenario considered in this paper, it is assumed that the sampling interval is not adjustable. However, by using a symbol alphabet which varies periodically, *average* data rates as close as desired to H can be achieved with sufficiently large cycle lengths, similar to the way that irrationals are approximated by rationals.

A periodic alphabet is also suggested by a consideration of the plant dynamics. By the block structure of the real Jordan form $\mathbf{J}$, the filter process (5.1) consists of b subsystems with decoupled dynamical matrices $\mathbf{J}_i \in \mathbb{R}^{n_i \times n_i}$, $i = 1, \ldots, b$. The speed at which the ith subsystem grows in any direction is determined by the eigenvalue λ_i and, intuitively, a larger $|\lambda_i|$ necessitates using a higher data rate. A natural approach is to cycle through the subsystems and encode each at a rate determined by the corresponding level of instability.

Notwithstanding the discussion above, the implementation of time-varying alphabets can be difficult. In the coder-controller presented below, the alphabet size is in fact kept constant for the initial part of each cycle, and no data is transmitted for the remainder. The subsystems are then allocated different effective data rates by means of a time-sharing protocol. More explicitly, time is divided into cycles of sufficiently large duration $\tau \in \mathbb{Z}_+$ and, within each cycle, the components of the unstable subsystem states $\bar{\mathbf{x}}_k^{(i)} \in \mathbb{R}^{n_i}$ are allocated transmission slots of fixed length τ_i, roughly proportional to $\log_2 |\lambda_i|$. During each slot a fixed alphabet of size $\mu_k \equiv \mu \geq 2$ is used to quantize the corresponding subsystem state component with a total of μ^{τ_i} levels. Towards the end of each cycle, there is then a quiet slot during which no information is transmitted, i.e., $\mu_k = 1$.

5.2. Stabilizing coder-controller. The coder-controller to be applied is defined below and analyzed in subsection 5.3. First, however, the static quantizer which is its basis is constructed, and a key lemma which stochastically bounds the quantizer errors is presented.

5.2.1. Quantizer. Recall that the floating point representation of a number $x \geq 1$ can be generated recursively by means of the following algorithm:

1. At iteration i, let $x \in J_i$, where $J_0 = [1, \infty)$.
2. At iteration $i+1$, if J_i was the semi-infinite interval $[10^i, \infty)$, then partition it into nine contiguous, disjoint subintervals of length 10^i and one semi-infinite interval $[10^{i+1}, \infty)$. If J_i was bounded, however, then partition it into ten equally long subintervals. In both cases set J_{i+1} to the subinterval containing x.
3. Repeat step 2 until $i =$ some predefined $\nu \geq 1$.
4. Approximate x by the lower limit of J_ν.

At termination, each interval $[10^{i-1}, 10^i)$, $i = 1, \ldots, \nu$, has been partitioned into $9 \times 10^{\nu - i}$ subintervals of equal length, and each x in it approximated as a floating point number with $\nu - i$ significant figures. Including the semi-infinite "overload" subinterval $[10^\nu, \infty)$, there are 10^ν subintervals in total, and so this algorithm can be

viewed as a nonuniform quantization of $x \geq 1$ with 10^ν points.

The scalar quantizer which underpins the coder-controller constructed here is basically an extension of this floating point scheme to $x \in \mathbb{R}$, with a base which may be nondecimal. First, select $\varrho > 1$ and let

$$r_i \stackrel{\Delta}{=} \varrho^{i-1}, \quad i \in \mathbb{Z}_+. \tag{5.6}$$

Then select a base $\mu \geq 2$ and for any integer $\nu \geq 2$ generate μ^ν disjoint, exhaustive intervals symmetrically about the origin by

(i) partitioning $[-r_1, r_1] = [-1, 1]$ into $(\mu^2 - 2)\mu^{\nu-2}$ intervals of length $2/[(\mu^2 - 2)\mu^{\nu-2}]$,

(ii) partitioning $(r_{i-1}, r_i]$ and $[-r_i, -r_{i-1})$ each into $(\mu - 1)\mu^{\nu-i}$ intervals of length $(\varrho^{i-1} - \varrho^{i-2})/[(\mu - 1)\mu^{\nu-i}]$ $\forall i \in [2, 3, \ldots, \nu]$,

(iii) leaving (r_ν, ∞) and $(-\infty, -r_\nu)$ as the right- and left-most intervals.

In general, there are precisely $(\mu^2 - 2)\mu^{\nu-2} + 2 + \sum_{2 \leq i \leq \nu} 2(\mu - 1)\mu^{\nu-i} = \mu^\nu$ intervals. Label them $I(0), I(1), \ldots, I(\mu^\nu - 1)$, from left- to right-most, and $\forall x \in \mathbb{R}$ let

$$\kappa_\nu(\omega) \stackrel{\Delta}{=} \begin{cases} \text{half-length of } I(\omega) & \text{if } 1 \leq \omega \leq \mu^\nu - 2, \\ 0.5(1 - 1/\mu)^{-1}(r_{\nu+1} - r_\nu) & \text{if } \omega = \mu^\nu - 1, \\ -0.5(1 - 1/\mu)^{-1}(r_{\nu+1} - r_\nu) & \text{if } \omega = 0, \end{cases} \tag{5.7}$$

$$q_\nu(x) := \varpi_\nu(\omega) := \left\{ \begin{array}{ll} \text{midpoint of } I(\omega) & \text{if } 1 \leq \omega \leq \mu^\nu - 2, \\ r_\nu + \kappa_\nu(\omega) & \text{if } \omega = \mu^\nu - 1, \\ -r_\nu - \kappa_\nu(\omega) & \text{if } \omega = 0, \end{array} \right\} \text{ if } x \in I(\omega). \tag{5.8}$$

The precise form of the equations above is immaterial, some of the constants being selected solely to simplify subsequent analysis. Observe that, like the floating point quantizer, the intervals of $q_{\nu+1}$ can be generated recursively by partitioning each interval of q_ν into μ subintervals. Furthermore, as $\nu \to \infty$, the range $[-r_\nu, r_\nu]$ covered by finite I's becomes unbounded, and at the same time any number x is eventually captured in an interval with length $\to 0$. Both these competing properties are necessary for the quantization error of a random variable with infinite support to approach zero pointwise as ν increases.

However, to show the attainability of (2.6), convergence in a stronger sense will be required; in particular, the mean square quantization error should diminish like the inverse square of the number of levels, $\mu^{-2\nu}$. Guaranteeing this for fat-tailed distributions is the real motivation for the exponential form of (5.6). If the distribution being quantized had exponentially decaying tails, then it can be shown that (5.6) leads to a waste of quantizer levels on regions of very low probability and, consequently, a shortage of levels in high-probability regions. However, as the tails may decay according to a power law, a sufficiently large ϱ ensures that both the low- and high-probability mean square error contributions die off like $\mu^{-2\nu}$.

In fact, a slightly stronger result can be proven. Before stating it formally, for any random variable $L \in \mathbb{R}_+$ and random vector $\mathbf{X}$ define the functional

$$\mathrm{M}_\varepsilon\{\mathbf{X}|L\} := \mathrm{E}\{L^2\} + \mathrm{E}\{\|\mathbf{X}\|^{2+\varepsilon} L^{-\varepsilon}\}. \tag{5.9}$$

This cannot be smaller than the mean square norm of $\mathbf{X}$, since

$$\begin{aligned} \mathrm{E}\|\mathbf{X}\|^2 &= \mathrm{E}\left\{\|\mathbf{X}\|^2 \left[\chi(\|\mathbf{X}\| \leq L) + \chi(\|\mathbf{X}\| > L)\right]\right\} \\ &\leq \mathrm{E}\{L^2\} + \mathrm{E}\left\{\|\mathbf{X}\|^2 (\|\mathbf{X}\|/L)^\varepsilon \chi(\|\mathbf{X}\| > L)\right\} \\ &\leq \mathrm{E}\{L^2\} + \mathrm{E}\left\{\|\mathbf{X}\|^{2+\varepsilon} L^{-\varepsilon}\right\} \equiv \mathrm{M}_\varepsilon\{\mathbf{X}|L\}, \end{aligned} \tag{5.10}$$

where χ is the usual indicator function. The mean square quantizer errors generated by q_ν can then be bounded as follows.

LEMMA 5.2. *Let $X \in \mathbb{R}$, $L > 0$ be random variables with $\mathrm{E}|X|^{2+\varepsilon} < \infty$ for some $\varepsilon > 0$. If the quantizer parameter ϱ of (5.6) and the base $\mu \in [2, 3, \ldots)$ are selected so that $\varrho > \mu^{2/\varepsilon}$, then the quantizer errors $X - Lq_\nu(X/L)$ satisfy*

$$\mathrm{M}_\varepsilon \left\{ X - Lq_\nu\left(\frac{X}{L}\right) \middle| L\kappa_\nu(\Omega) \right\} \leq \frac{\zeta}{\mu^{2\nu}} \mathrm{M}_\varepsilon\{X|L\} \quad \forall \nu \in [2, 3, \ldots), \tag{5.11}$$

where q_ν, κ_ν are defined in (5.8)–(5.7), $\Omega \in [0, 1, \ldots \mu^\nu - 1]$ is the index of the quantizer level $q_\nu(X/L)$, and $\zeta > 0$ is determined only by ε, μ, and ϱ.

Proof. See Appendix E for the proof.

By (5.10), the LHS exceeds the mean square quantizer error $\mathrm{E}|X - Lq_\nu(X/L)|^2$, so this result upper-bounds the latter and guarantees that it decreases as fast as the square of the number of quantizer levels. The condition $\varrho > \mu^{2/\varepsilon}$ is crucial here, as it relates the speed at which the quantizer range increases with ν to the fatness of the distribution tails, and thereby ensures that the contribution of the overload regions decays faster than $\mu^{-2\nu}$ for any fixed integer $\mu \geq 2$.

However, the real utility of this lemma lies in the appearance of M_ε on both sides, together with the independence of the constant ζ of the distribution of X. These two facts permit (5.11) to be used recursively when proving coder-controller stability in subsection 5.3. In contrast, a similar inequality relating the mean square norms of the error and X, via a density-independent factor decaying like the number of levels squared, is impossible.[1] What can be done instead is to upper-bound the mean square error by some higher moment of X as in Lemma 6.6 of [13], an approach which does not permit recursive application.

5.2.2. Time-sharing protocol and coder. The quantizer above will now be used to construct a coder-controller. The measurements are first passed through a Kalman filter to generate a fully observed process of the form (5.1). In order to simplify the analysis, and reduce subscript clutter, a nonpredictive filter with output $\bar{\mathbf{x}}_k := \bar{\mathbf{x}}_{k|k}$ is used. As discussed in section 5.1, its mean square stability is equivalent to that of the original system (2.1), and its innovations $\mathbf{z}_k$, $k \in \mathbb{Z}_+$, are uniformly bounded in the $(2+\varepsilon)$th absolute moment.

Divide times $k \in \mathbb{W}$ into *cycles* $[j\tau, \ldots, (j+1)\tau - 1]$, $j \in \mathbb{W}$, of uniform integer duration $\tau \in \mathbb{Z}_+$. Let R' be any given number greater than H from (2.6), and select any integer $\mu \geq 2^{R'}$. With $\mathcal{U}$ denoting the index set of unstable subsystems (4.1), subdivide each cycle into f *transmission slots* of duration τ_i, for each scalar component of $\bar{\mathbf{x}}_{j\tau}^{(i)} \in \mathbb{R}^{n_i}$, followed by a *quiet slot* of duration $\tau - \sum_{i\in\mathcal{U}} n_i\tau_i$, where

$$\tau_i \triangleq \lfloor \tau \log_\mu(\xi|\lambda_i|) \rfloor + 1 \quad \forall i \in \mathcal{U}, \tag{5.12}$$

with $\lfloor\cdot\rfloor$ denoting rounding down. If the parameter ξ is chosen to satisfy

$$0 < f \log_2 \xi < R' - \sum_{i\in\mathcal{U}} n_i \log_2 |\lambda_i| \equiv R' - \sum_{|\eta_l|\geq 1} \log_2 |\eta_l|, \tag{5.13}$$

[1] The reason for this is essentially that even if p_X has a finite second moment, $|x|^2 p_X(x)$ may decay so slowly with large x that the overload regions dominate the mean square error, making it decrease more slowly than the inverse square number of levels.

then the choice of transmission slot durations (5.12) is feasible, since

$$\sum_{i\in\mathcal{U}} n_i\tau_i \le \sum_{i\in\mathcal{U}} n_i\left(\tau\frac{\log_2(\xi|\lambda_i|)}{\log_2\mu}+1\right) \le \tau\frac{\sum_{i\in\mathcal{U}} n_i\log_2|\lambda_i| + f\log_2\xi}{R'} + f. \tag{5.14}$$

As the coefficient of τ is less than unity by (5.13), the sum of transmission slot durations is less than any sufficiently large cycle length τ.

Let the symbol alphabet $\mathcal{S}_k = \mathbb{Z}_\mu$ during transmission slots, and $= \{0\}$ during the quiet slot. Then by reasoning similar to the above, the asymptotic average data rate R of this periodic alphabet, equal to the average data rate over one cycle, satisfies

$$\begin{aligned} R &= \frac{1}{\tau}\sum_{i\in\mathcal{U}} n_i\tau_i\log_2\mu \le \frac{\log_2\mu}{\tau}\sum_{i\in\mathcal{U}} n_i\left(\tau\frac{\log_2(\xi|\lambda_i|)}{\log_2\mu}+1\right)\\ &= \sum_{i\in\mathcal{U}} n_i\log_2|\lambda_i| + f\log_2\xi + \frac{f\log_2\mu}{\tau} < R' \end{aligned}$$

for all sufficiently large τ. As R' is any number exceeding H, this confirms that the data rate of this protocol can be made arbitrarily close to H, leaving aside for now the question of stability.

Just before the start of a cycle at time $k = j\tau$, let $l_j \in \mathbb{R}_+$ be the adaptive quantizer scaling factor discussed in section 5.1, and $\hat{\mathbf{x}}_{j\tau} \in \mathbb{R}^n$ be an estimate of $\bar{\mathbf{x}}_{j\tau}$ internal to the coder. The *coder state* is then defined as $\psi_j \triangleq (\hat{\mathbf{x}}_{j\tau}, l_j)$. Indexing the scalar components of vectors $\in \mathbb{R}^{n_i}$ by an additional superscript $h \in [1,\dots,n_i]$, at the start of the transmission slot for $\bar{x}_{j\tau}^{(i,h)}$ let it be scaled and quantized via

$$\varpi_{\tau_i}(\omega_j^{(i,h)}) \equiv q_{\tau_i}([\bar{x}_{j\tau}^{(i,h)} - \hat{x}_{j\tau}^{(i,h)}]/l_j) \quad \forall h \in [1,\dots,n_i], \tag{5.15}$$

where ϖ_ν and q_ν are defined in (5.8). The index $\omega_j^{(i,h)} \in [0,\dots,\mu^\tau - 1]$ of the selected quantizer level is then expanded as τ_i base-μ digits and transmitted. After this has been done for all unstable state components, the coder state is updated via

$$\hat{\mathbf{x}}_{(j+1)\tau} = \mathbf{J}^\tau\left[\hat{\mathbf{x}}_{j\tau} + l_j\varpi(\omega_j)\right] + \sum_{k=j\tau}^{(j+1)\tau-1} \mathbf{J}^{(j+1)\tau-1-k}\mathbf{TBL}\hat{\mathbf{x}}_k, \tag{5.16}$$

$$\text{where } \hat{\mathbf{x}}_{k+1} = (\mathbf{J}+\mathbf{TBL})\hat{\mathbf{x}}_k \ \ \forall k \in [j\tau,\dots,j\tau+\tau-2], \ \ \hat{\mathbf{x}}_0 = \mathbf{0}, \tag{5.17}$$

$$l_{j+1} = \max_{i\in\mathcal{U}, h\in[1,\dots,n_i]}\left\{\sigma,\, l_j|\lambda_i|^\tau\kappa_{\tau_i}\left(\omega_j^{(i,h)}\right)\right\} \quad \forall j \in \mathbb{W}, \ \ l_0 = \sigma. \tag{5.18}$$

In the above, $\varpi(\omega_j) \in \mathbb{R}^n$ is the vector with (i,h)th component $\varpi_{\tau_i}(\omega_j^{(i,h)})$ for $i \in \mathcal{U}$ and 0 for $i \notin \mathcal{U}$, $\mathbf{L} \in \mathbb{R}^{p\times n}$ is the certainty-equivalent controller gain matrix, and $\sigma^{2+\varepsilon}$ is a uniform upper bound on the $(2+\varepsilon)$th absolute moment of

$$\mathbf{G}_j := \sum_{i=1}^{\tau} \mathbf{J}^{\tau-i}\mathbf{Z}_{j\tau+i} \ \ \forall j \in \mathbb{W}. \tag{5.19}$$

5.2.3. Controller. Similar to the coder, define a controller internal state $\psi_j^{\text{con}} \triangleq (\hat{\mathbf{x}}_{j\tau}^{\text{con}}, l_j^{\text{con}}) \in \mathbb{R}^n \times \mathbb{R}_+$, initialized when $j = 0$ to $(\mathbf{0}, \sigma)$. At any time $k \in [j\tau,\dots, j\tau+\tau-1]$ in the cycle, a certainty-equivalent control signal

$$\mathbf{u}_k = \mathbf{L}\hat{\mathbf{x}}_k^{\text{con}} \tag{5.20}$$

is applied, where $\hat{\mathbf{x}}_k^{\rm con}$ is given by (5.17) (with superscripts "con"), and $\mathbf{L}$ is the given gain matrix s.t. $\mathbf{J}+\mathbf{TBL}$ is strictly stable.

By the time-sharing protocol, the last transmission slot during this cycle ends at time $j\tau + c(\tau) - 1$, where $c(\tau) \triangleq \sum_{i\in\mathcal{U}} n_i\tau_i$. Recalling that the channel has a delay d, at time $k = j\tau + c(\tau) - 1 + d$ the controller then has available all the symbols $s_{j\tau}, \ldots, s_{j\tau+c-1}$, comprising the base-$\mu$ expansions of the quantizer level indices $\omega_j^{(i,h)}$, $h \in [1, \ldots, n_i]$, $i \in \mathcal{U}$. By reasoning similar to (5.14), $c(\tau) + d \leq \tau$ sufficiently large, so that these indices are guaranteed to be received before the beginning of the next cycle at time $(j+1)\tau$. The controller then updates its internal state via the same recursive equations (5.16)–(5.18) as the coder.

5.3. Analysis. A uniform bound on the mean square norms of the filter process (5.1) using the coder-controller above will now be derived, for a data rate arbitrarily close to the lower bound (2.6). First, it is shown that the coder error $\mathbf{F}_k \triangleq \bar{\mathbf{X}}_k - \hat{\mathbf{X}}_k$ is uniformly bounded in mean square norm over times $k = j\tau$, $j \in \mathbb{W}$, by using the functional M_ε defined in (5.9) and Lemma 5.2. The mean square stability of $\mathbf{F}_k$ over all integer times is then deduced, which in turn will be shown to imply that of $\bar{\mathbf{X}}_k$, $k \in \mathbb{W}$.

Observe that since the initial controller and coder internal states $\psi_0^{\rm con}, \psi_0$ are equal and, furthermore, the same update equations (5.16)–(5.18) are used for each, it follows that $\hat{\mathbf{x}}_k^{\rm con} = \hat{\mathbf{x}}_k$ and $l_j^{\rm con} = l_j$ $\forall j, k \in \mathbb{W}$. The superscript "con" is thus dropped in the analysis. Substituting (5.20) into the filter recursion (5.1) and iterating over a cycle,

$$\begin{aligned}\bar{\mathbf{x}}_{(j+1)\tau} &= \mathbf{J}^\tau \bar{\mathbf{x}}_{j\tau} + \sum_{k=j\tau}^{(j+1)\tau-1} \mathbf{J}^{(j+1)\tau-1-k}\left(\mathbf{TBL}\hat{\mathbf{x}}_k + \mathbf{z}_{k+1}\right)\\ &= \mathbf{J}^\tau \bar{\mathbf{x}}_{j\tau} + \mathbf{g}_j + \sum_{k=j\tau}^{(j+1)\tau-1} \mathbf{J}^{(j+1)\tau-1-k}\mathbf{TBL}\hat{\mathbf{x}}_k,\end{aligned}$$

where $\mathbf{g}_j \triangleq \sum_{k=1}^{\tau} \mathbf{J}^{\tau-k}\mathbf{z}_{j\tau+k}$ (see (5.19)). Subtracting this from (5.16), and then exploiting the block diagonal structure $\mathbf{J} \equiv \mathrm{diag}(\mathbf{J}_1, \ldots \mathbf{J}_b)$ of the real Jordan form, where $\mathbf{J}_i \in \mathbb{R}^{n_i\times n_i}$,

$$\begin{aligned}&\mathbf{f}_{(j+1)\tau} = \mathbf{J}^\tau[\mathbf{f}_{j\tau} - l_j\varpi(\omega_j)] + \mathbf{g}_j,\\ \Leftrightarrow\ &\mathbf{f}^{(i)}_{(j+1)\tau} = \mathbf{J}_i^\tau\left[\mathbf{f}^{(i)}_{j\tau} - l_j\varpi(\omega_j)^{(i)}\right] + \mathbf{g}_j^{(i)} \in \mathbb{R}^{n_i} \quad \forall i \in [1, \ldots, b], j \in \mathbb{W}.\end{aligned} \tag{5.21}$$

By (5.15) and the definition of $\varpi(\omega_j)$, $\varpi(\omega_j)^{(i)} \triangleq \mathbf{0}$ $\forall i \notin \mathcal{U}$, in which case the RHS above simply becomes the recursion $\mathbf{f}^{(i)}_{(j+1)\tau} = \mathbf{J}_i^\tau \mathbf{f}^{(i)}_{j\tau} + \mathbf{g}_j^{(i)}$. Recall that each block $\mathbf{J}_i$ has exactly either one real eigenvalue λ_i or two complex conjugate eigenvalues λ_i, λ_i^*. As $|\lambda_i| < 1$ $\forall i \notin \mathcal{U}$, and furthermore the noise term has a uniform moment bound $\mathrm{E}\|\mathbf{G}_j^{(i)}\|^2 \leq \sigma^2$, it immediately follows that $\mathrm{E}\|\mathbf{F}^{(i)}_{j\tau}\|^2$ must be uniformly bounded for all strictly stable subsystems.

Hence, only the unstable subsystems $i \in \mathcal{U}$ need be considered. For each such i, $\varpi(\omega_j)^{(i)} \in \mathbb{R}^{n_i}$ is defined to be the quantizer point vector with hth component $q_{\tau_i}(f^{(i,h)}_{j\tau}/l_j)$. Applying square norms and the triangle inequality to (5.21), $\forall i \in \mathcal{U}$, $j \in \mathbb{W}$,

$$\begin{aligned}\|\mathbf{f}^{(i)}_{(j+1)\tau}\|^2 &\le 2^2\left[\|\mathbf{J}_i^\tau\|^2\|\mathbf{f}^{(i)}_{j\tau} - l_j\varpi(\omega_j)^{(i)}\|^2 + \|\mathbf{g}_j^{(i)}\|^2\right]\\ &= 4\left[\|\mathbf{g}_j^{(i)}\|^2 + \|\mathbf{J}_i^\tau\|^2\sum_{h=1}^{n_i}\left|f^{(i,h)}_{j\tau} - l_j q_{\tau_i}\left(f^{(i,h)}_{j\tau}/l_j\right)\right|^2\right],\end{aligned} \tag{5.22}$$

using (5.15) and the definition of $\varpi(\omega_j)$. As each $\mathbf{J}_i$ is *similar* to the block diagonal matrix of all Jordan blocks associated with λ_i, a trivial adaptation of a result in [15, p. 138] states that $\exists\zeta_0 > 0$ s.t.

$$\|\mathbf{J}_i^\tau\| \le \zeta_0\tau^{n_i-1}|\lambda_i|^\tau \quad \forall i \in [1,\dots,b], \tau \in \mathbb{Z}_+. \tag{5.23}$$

Let the stacked vector of unstable subsystem errors be $\mathbf{f}^{\mathrm{u}}_k \triangleq [\mathbf{f}^{(1)\mathrm{T}}_k, \dots, \mathbf{f}^{(|\mathcal{U}|)\mathrm{T}}_k]^{\mathrm{T}}$, and define $\mathbf{g}^{\mathrm{u}}_j$ in a similar way. By summing (5.22) over $i \in \mathcal{U}$, applying the growth rate bound above, and twice using the trivial inequality $(\sum_{1\le l\le r}|y_l|)^\alpha \le r^\alpha\sum_{1\le l\le r}|y_l|^\alpha$ $\forall r \in \mathbb{Z}_+$, $\alpha > 0$, it then follows that $\exists\phi \ge 1$ s.t.

$$\begin{aligned}\|\mathbf{f}^{\mathrm{u}}_{(j+1)\tau}\|^{2+\varepsilon} &= \left(\sum_{i\in\mathcal{U}}\|\mathbf{f}^{(i)}_{(j+1)\tau}\|^2\right)^{1+\varepsilon/2}\\ &\le \phi\left(\|\mathbf{g}^{\mathrm{u}}_j\|^{2+\varepsilon} + \sum_{i\in\mathcal{U}}|\tau^{n_i-1}\lambda_i^\tau|^{2+\varepsilon}\sum_{h=1}^{n_i}\left|f^{(i,h)}_{j\tau} - l_j q_{\tau_i}\left(f^{(i,h)}_{j\tau}/l_j\right)\right|^{2+\varepsilon}\right).\end{aligned}$$

Dividing by l^ε_{j+1} and taking expectations,

$$\begin{aligned}&\mathrm{E}\left\{\|\mathbf{F}^{\mathrm{u}}_{(j+1)\tau}\|^{2+\varepsilon}L^{-\varepsilon}_{j+1}\right\}\\ &\le \phi\left(\mathrm{E}\left\{\frac{\|\mathbf{G}^{\mathrm{u}}_j\|^{2+\varepsilon}}{L^\varepsilon_{j+1}}\right\} + \sum_{i\in\mathcal{U}}\left|\tau^{n_i-1}\lambda_i^\tau\right|^{2+\varepsilon}\sum_{h=1}^{n_i}\mathrm{E}\left\{\frac{|F^{(i,h)}_{j\tau} - L_j q_{\tau_i}(F^{(i,h)}_{j\tau}/L_j)|^{2+\varepsilon}}{L^\varepsilon_{j+1}}\right\}\right)\\ &\le \phi\left(\mathrm{E}\left\{\frac{\|\mathbf{G}^{\mathrm{u}}_j\|^{2+\varepsilon}}{\sigma^\varepsilon}\right\} + \sum_{i\in\mathcal{U}}\left|\tau^{n_i-1}\lambda_i^\tau\right|^{2+\varepsilon}\sum_{h=1}^{n_i}\mathrm{E}\left\{\frac{|F^{(i,h)}_{j\tau} - L_j q_{\tau_i}(F^{(i,h)}_{j\tau}/L_j)|^{2+\varepsilon}}{[L_j|\lambda_i|^\tau\kappa_{\tau_i}(\Omega^{(i,h)}_j)]^\varepsilon}\right\}\right)\\ &= \phi\left(\mathrm{E}\left\{\frac{\|\mathbf{G}^{\mathrm{u}}_j\|^{2+\varepsilon}}{\sigma^\varepsilon}\right\} + \sum_{i\in\mathcal{U}}\tau^{(n_i-1)(2+\varepsilon)}|\lambda_i|^{2\tau}\sum_{h=1}^{n_i}\mathrm{E}\left\{\frac{|F^{(i,h)}_{j\tau} - L_j q_{\tau_i}(F^{(i,h)}_{j\tau}/L_j)|^{2+\varepsilon}}{[L_j\kappa_{\tau_i}(\Omega^{(i,h)}_j)]^\varepsilon}\right\}\right),\end{aligned} \tag{5.24}$$

where the second inequality is a consequence of the definition of l_{j+1} (see (5.18)).

Now, let

$$\vartheta_j := \mathrm{M}_\varepsilon\{\mathbf{F}^{\mathrm{u}}_{(j+1)\tau}|L_j\} \equiv \mathrm{E}\{L_j^2\} + \mathrm{E}\{\|\mathbf{F}^{\mathrm{u}}_{(j+1)\tau}\|^{2+\varepsilon}L_j^{-\varepsilon}\} \quad \forall j \in \mathbb{W}. \tag{5.25}$$

By (5.10), the RHS is never less than $\mathrm{E}\|\mathbf{F}^{\mathrm{u}}_{(j+1)\tau}\|^2$, so to establish the mean square boundedness of the errors it is sufficient to show that $\sup_{j\in\mathbb{W}}\vartheta_j < \infty$. Observe that

$$\begin{aligned}\mathrm{E}\{L^2_{j+1}\} &\equiv \mathrm{E}\left\{\max_{i\in\mathcal{U},h\in[1,\dots,n_i]}\left\{\sigma^2,\, L_j^2|\lambda_i|^{2\tau}\kappa_{\tau_i}\left(\Omega^{(i,h)}_j\right)^2\right\}\right\}\\ &\le \sigma^2 + \sum_{i\in\mathcal{U}}|\lambda_i|^{2\tau}\sum_{h=1}^{n_i}\mathrm{E}\left|L_j\kappa_{\tau_i}\left(\Omega^{(i,h)}_j\right)\right|^2.\end{aligned}$$

Adding this to (5.24), noting that $\mathrm{E}\|\mathbf{G}_j^{\mathrm{u}}\|^{2+\varepsilon} \leq \sigma^{2+\varepsilon}$, $\tau \geq 1$, and using definition (5.25),

$$\vartheta_{j+1} \leq \phi\left(\sigma^2 + \sum_{i\in\mathcal{U}} \tau^{(n_i-1)(2+\varepsilon)}|\lambda_i|^{2\tau} \sum_{h=1}^{n_i} \mathrm{M}_\varepsilon\left\{F_{j\tau}^{(i,h)} - L_j q_{\tau_i}\left(\frac{F_{j\tau}^{(i,h)}}{L_j}\right)\middle| L_j\kappa_{\tau_i}\left(\Omega_j^{(i,h)}\right)\right\}\right). \tag{5.26}$$

Applying Lemma 5.2 to each term in the inner sum, with $X = F_{j\tau}^{(i,h)}$, $L = L_j$, $\nu = \tau_i$, and $\Omega = \Omega_j^{(i,h)}$ $\forall j \in \mathbb{W}$,

$$\begin{aligned}\vartheta_{j+1} &\leq \phi\left(\sigma^2 + \sum_{i\in\mathcal{U}} \tau^{(n_i-1)(2+\varepsilon)}|\lambda_i|^{2\tau} \sum_{h=1}^{n_i} \frac{\zeta}{\mu^{2\tau_i}}\mathrm{M}_\varepsilon\left\{F_{j\tau}^{(i,h)}|L_j\right\}\right)\\ &\leq \phi\left(\sigma^2 + \sum_{i\in\mathcal{U}} \tau^{(n_i-1)(2+\varepsilon)}|\lambda_i|^{2\tau} \sum_{h=1}^{n_i} \frac{\zeta}{\mu^{2\tau_i}}\mathrm{M}_\varepsilon\left\{\mathbf{F}_{j\tau}^{\mathrm{u}}|L_j\right\}\right)\\ &\equiv \phi\sigma^2 + \phi\zeta\left(\sum_{i\in\mathcal{U}} n_i\tau^{(n_i-1)(2+\varepsilon)}\frac{|\lambda_i|^{2\tau}}{\mu^{2\tau_i}}\right)\vartheta_j, \end{aligned} \tag{5.27}$$

where the second inequality is obtained from the definition of M_ε in (5.9) and the trivial fact that the magnitude of a vector is never less than the magnitude of any of its components.

The inequality above is a first order, sublinear recursion for ϑ_j with a forcing term. By (5.12) and the fact that $x - \lfloor x\rfloor < 1$ $\forall x \in \mathbb{R}$, it follows that $\tau_i > \tau\log_\mu(\xi|\lambda_i|)$ $\forall i \in \mathcal{U}$, $\tau \in \mathbb{Z}_+$. This is equivalent to $\xi^\tau|\lambda_i|^\tau < \mu^{\tau_i}$, which when substituted into the above yields

$$\vartheta_{j+1} \leq \phi\sigma^2 + \phi\zeta\left(\sum_{i\in\mathcal{U}} n_i\tau^{(n_i-1)(2+\varepsilon)}\frac{1}{\xi^{2\tau}}\right)\vartheta_j \qquad \forall j \in \mathbb{W}.$$

As $\xi > 1$ by the left inequality of (5.13), $\tau^{(n_i-1)(2+\varepsilon)}\xi^{-2\tau} \to 0$ as $\tau \to \infty$ $\forall i$. Hence, by choosing a sufficiently large, finite cycle length τ, the coefficient of ϑ_j above can be made strictly less than 1. As the τ-dependent noise term σ^2 is finite for any fixed τ, the recursion above is then stable and yields uniformly bounded ϑ_j. By definition (5.25) and the inequality (5.10), $\mathrm{E}\|\mathbf{F}_{j\tau}^{\mathrm{u}}\|^2$ is then also uniformly bounded over $j \in \mathbb{W}$. Recalling the discussion after (5.21), the overall error vector $\mathbf{F}_{j\tau}$ must be as well.

The rest of the proof is straightforward. Subtracting (5.17) from (5.1), iterating forward r steps from time $j\tau$, and taking norms, at any time $k \equiv j\tau + r$ with $r \in [0, \ldots, \tau-1]$,

$$\|\mathbf{f}_k\| \leq \|\mathbf{J}^r\|\|\mathbf{f}_{j\tau}\| + \sum_{l=0}^{r-1}\|\mathbf{J}^{r-l}\mathbf{TBL}\|\|\mathbf{Z}_{j\tau+l+1}\|.$$

As $\mathbf{F}_{j\tau}$ and $\mathbf{Z}_{j\tau+l+1}$ are uniformly bounded in mean square norm and r can only take a finite number of values, the RHS and hence LHS are also uniformly mean square bounded over $k \in \mathbb{W}$. Rewriting (5.1) as

$$\bar{\mathbf{x}}_{k+1} = (\mathbf{J}+\mathbf{TBL})\bar{\mathbf{x}}_k + \mathbf{TBL}(\hat{\mathbf{x}}_k - \mathbf{x}_k) + \mathbf{z}_{k+1} = (\mathbf{J}+\mathbf{TBL})\bar{\mathbf{x}}_k - \mathbf{TBLf}_k + \mathbf{z}_{k+1} \ \ \forall k \in \mathbb{W},$$

the strict stability of $\mathbf{J} + \mathbf{TBL}$ then ensures the uniform boundedness of the mean square filter outputs $\mathrm{E}\|\bar{\mathbf{X}}_{k+1}\|^2$ over $k \in \mathbb{W}$. This completes the proof that the coder-controller constructed in subsection 5.2 stabilizes the system (2.1) at data rates arbitrarily close to, but exceeding, the critical bound (2.6). □

In the foregoing analysis, the assumption that the coder and controller internal states have the same initial value is crucial. Even if true, real digital channels invariably introduce data errors, causing the coder and controller states to eventually differ. It is thus important to emphasize that the scheme presented here is not intended in the present form to be a practical solution to communication-limited stabilization problems, but is primarily a theoretical construct for demonstrating stabilizability in the limited sense of (2.5). Nonetheless it does possess some attributes, such as finite dimensionality, which make implementation easy and may serve as a foundation for a more practical scheme. In this respect, an important and as yet open extension of this research is the *internal* stability of finite-dimensional, data-rate-limited control loops, i.e., ensuring that the plant and coder-controller internal states remain mean square stable with a random *overall* initial condition, channel errors, and process and measurement noise. It is easy to see that redundancy must be incorporated in the transmitted symbols to counteract channel noise, but it is not evident if an analogue of the well-known *source-channel separation theorem* of information theory [25] applies.

6. Conclusion. In this paper, the problem of stabilizing a general stochastic linear system in mean square state norm under a feedback data rate constraint was investigated. By employing information-theoretic techniques and a new quantizer error bound, an expression was derived for the smallest data rate above which such a system is stabilizable by a coding and control law, without imposing any structural or computational constraints and with very mild conditions on the system noise. This infimum rate is determined only by the unstable eigenvalues of the dynamical matrix, and it was demonstrated that, as the data rate approaches it from above, the mean square states become unbounded for any coder-controller. To establish the attainability of this bound, a finite-dimensional scheme was constructed and shown to achieve stability at data rates arbitrarily close to the bound. Extensions of these results to nonlinear systems, linear systems with Markov parameters, and decentralized control are being investigated.

Appendix A. Proof of Proposition 2.2. Suppose that $R_1 \leq R_2$. By direct substitution of (2.8) into (2.9), each input $\mathbf{u}_k$ depends (in a time-varying way) on the link-1 symbol sequence $\tilde{s}^1_{k-d_1-d_2}$,

$$\mathbf{u}_k \equiv \phi_k(\tilde{s}^1_{k-d_1-d_2}) \quad \forall k \in \mathbb{W}.$$

This mapping, (2.7), and the alphabet sequence $\tilde{\mathcal{S}}^1_\infty$ then constitute a coder-controller with data rate R_1 (see (2.2)) and link delay $d = d_1 + d_2$.

Now suppose that $R_2 < R_1$. By (2.7), the link-1 symbol sequence $\tilde{s}^1_{k-d_1}$ is also a time-varying function of the measurement sequence $\tilde{\mathbf{y}}_{k-d_1}$. Hence (2.8) can be rewritten in the form

$$s^2_k \equiv \theta_k(\tilde{\mathbf{y}}_{k-d_1}).$$

Defining the d_1-step-ahead link-2 symbol $c_k \triangleq s^2_{k+d_1}$, $\forall k \in \mathbb{W}$, the expression above and the actuator mapping (2.9) become

$$c_k = \theta_k(\tilde{\mathbf{y}}_k) \in \mathcal{S}^2_{k+d_1}, \quad \mathbf{u}_k = \delta^2_k(\tilde{c}_{k-d_1-d_2}).$$

This is a single-link coder-controller with delay $d = d_1 + d_2$. As the asymptotic average data rate is independent of constant time shifts of the alphabet, its value remains R_2.

The proof of the second part is straightforward. Let the coder (2.7) for link-1, with delay d_1, be given by (2.3), and set the coder and actuator for link-2, with delay $d_2 = d - d_1$, to be

$$s_k^2 = s_{k-d_1}^1 \equiv s_{k-d_1}, \quad \mathbf{u}_k = \delta_k(\tilde{s}_{k-d_2}^2) \equiv \delta_k(\tilde{s}_{k-d_1-d_2}).$$

Evidently, with regard to the plant this is equivalent to the single-link coder-controller (2.3)–(2.4). Furthermore, the link-2 alphabet is obviously periodic if that of link-1 is, with the same average data rate. □

Appendix B. Proof of inequality (4.4). The argument is essentially that of Lemma 5 in [9]. Denote the mean square norm of $\mathbf{X}$, given $A = a$, by σ^2, and let ϕ be the symmetric, f-dimensional Gaussian distribution with zero mean and variance σ^2. By the nonnegativity of the *Kullback–Leibler information distance* D,

$$\begin{aligned} 0 \le D(p_{\mathbf{X}|a} \| \phi) &\triangleq \int_{\mathbb{R}^f} p_{\mathbf{X}|a}(\mathbf{x}) \ln \frac{p_{\mathbf{X}|a}(\mathbf{x})}{\phi(\mathbf{x})} \mathrm{d}\lambda(\mathbf{x}) \\ &= \int_{\mathbb{R}^f} p_{\mathbf{X}|a}(\mathbf{x}) \ln p_{\mathbf{X}|a}(\mathbf{x}) \mathrm{d}\lambda(\mathbf{x}) - \int_{\mathbb{R}^f} p_{\mathbf{X}|a}(\mathbf{x}) \ln \phi(\mathbf{x}) \mathrm{d}\lambda(\mathbf{x}) \\ &= -\mathrm{H}_a\{\mathbf{X}\} - \int_{\mathbb{R}^f} p_{\mathbf{X}|a}(\mathbf{x}) \left(-\frac{f}{2} \ln(2\pi\sigma^2) - \frac{\|\mathbf{x}\|^2}{2\sigma^2} \right) \mathrm{d}\lambda(\mathbf{x}) \\ &= -\mathrm{H}_a\{\mathbf{X}\} + 0.5 f \ln(2\pi\sigma^2) + 0.5 \\ \Rightarrow \mathrm{N}_a\{\mathbf{X}\} &\equiv (2\pi\mathrm{e})^{-1} \mathrm{e}^{2\mathrm{H}_a\{\mathbf{X}\}/f} \le \mathrm{e}^{1/f-1} \sigma^2. \end{aligned}$$ □

Appendix C. Proof of Lemma 4.1. By standard properties of joint and average differential entropy [7, 9],

$$\mathrm{H}_a\{\mathbf{X}|S\} = \mathrm{H}_a\{\mathbf{X}, S\} - \mathrm{H}_a S \ge \mathrm{H}_a\{\mathbf{X}\} - \mathrm{H}_a S \ge \mathrm{H}_a\{\mathbf{X}\} - \ln|\mathcal{S}|.$$

Differential entropy is undefined for discrete-valued random variables, but the joint entropy above may be taken to denote $-\mathrm{E}_a \ln\big(p_{\mathbf{X}|S,A}(\mathbf{X})\mathrm{P}\{S|A\}\big)$, while $\mathrm{H}_a\{S\}$ represents the base-e discrete entropy of S, given $A = a$. The first inequality arises from the fact that the entropy of joint random variables can never be smaller than the individual entropies, while the second inequality is a consequence of the fact that the base-e entropy of a random variable in a finite alphabet $\mathcal{S}$ is at most $\ln|\mathcal{S}|$. Using Jensen's inequality for convex functions [7] and the lower bound above,

$$\begin{aligned} 2\pi\mathrm{e}\mathrm{N}_a\{\mathbf{X}|S\} &= \mathrm{E}_a\{\mathrm{e}^{2\mathrm{H}_{S,A}\{\mathbf{X}\}/f}\} \ge \mathrm{e}^{\mathrm{E}_a\{2\mathrm{H}_{S,A}\{\mathbf{X}\}/f\}} \\ &\equiv \mathrm{e}^{2\mathrm{H}_a\{\mathbf{X}|S\}/f} \ge \mathrm{e}^{2(\mathrm{H}_a\{\mathbf{X}\} - \ln|\mathcal{S}|)/f} = |\mathcal{S}|^{-2/f} 2\pi\mathrm{e}\mathrm{N}_a\mathbf{X}. \end{aligned}$$ □

Appendix D. Proof of Proposition 5.1. Consider the finite-state predictive quantizer (5.4). As there are a finite number $|\mathcal{I}|$ of possible internal variables ι_k, $Q(\cdot)$ is bounded. By the strict stability of $\mathbf{J} + \mathbf{TBL}$, it then follows from (5.4) that $\hat{\mathbf{x}}_k$ is bounded over k, and hence $\exists \rho > 0$ s.t. $\|\mathbf{u}_k\| = \|\mathbf{L}\hat{\mathbf{x}}_k\| \le \rho$.

Now, convert (2.1) into *standard* Jordan form via a complex similarity matrix $\mathbf{S}$. There is then at least one scalar component $x_k \in \mathbb{C}$ of the transformed state vector that satisfies the scalar, decoupled recursion

$$x_{k+1} = \eta x_k + v_k + u_k = \sum_{j=-1}^{k} \eta^{k-j}(v_j + u_j) \in \mathbb{C},$$

where $|\eta| > 1$ and v_k, u_k are the corresponding scalar components of $\mathbf{S}\mathbf{v}_k, \mathbf{S}\mathbf{u}_k$, respectively. For convenience, $u_{-1} \triangleq 0$ and $\mathbf{v}_{-1} \triangleq \mathbf{S}\mathbf{x}_0$. Evidently $V_{-1}, V_0, \ldots$ are still independent, and $|u_k| \le \rho$. Defining

$$\beta_k := \rho \sum_{j=0}^{k} |\eta|^{k-j} \ge \left| \sum_{j=0}^{k} \eta^{k-j} u_j \right|,$$

$$g_k := \sum_{j=-1}^{k} \eta^{k-j} v_j, \quad \bar{v}_k \triangleq \sum_{-1 \le j \le k, j \ne t} \eta^{-j} v_j \quad \forall k \in \mathbb{W},$$

where the time $t \ge -1$ is specified in (5.5), it follows that

$$\begin{aligned}
&\mathrm{P}\{\|\mathbf{S}\mathbf{X}_{k+1}\| \ge \beta_k\} \ge \mathrm{P}\{|X_{k+1}| \ge \beta_k\} = \mathrm{P}\left\{ \left| G_k - \sum_{j=0}^{k} \eta^{k-j} U_j \right| \ge \beta_k \right\} \\
&\ge \mathrm{P}\{|G_k| - \beta_k \ge \beta_k\} = \mathrm{P}\{|G_k| \ge 2\beta_k\} \\
&= \mathrm{P}\left\{ \left| \sum_{j=-1}^{k} \eta^{k-j} V_j \right| \ge 2\rho \sum_{j=0}^{k} |\eta|^{k-j} \right\} = \mathrm{P}\left\{ \left| \sum_{j=-1}^{k} \eta^{-j} V_j \right| \ge 2\rho \sum_{j=0}^{k} |\eta|^{-j} \right\} \\
&\ge \mathrm{P}\left\{ \left| \sum_{j=-1}^{k} \eta^{-j} V_j \right| \ge \theta \right\} \equiv \mathrm{P}\{|\eta^{-t} V_t + \bar{V}_k| \ge \theta\} \ge \mathrm{P}\left\{ \Re(\eta^{-t} V_t) + \Re(\bar{V}_k) \ge \theta \right\} \\
&\ge \mathrm{P}\left\{ \Re(\eta^{-t} V_t) \ge \alpha\theta,\ \Re(\bar{V}_k) \ge (1-\alpha)\theta \right\} \\
&= \mathrm{P}\left\{ \Re(\eta^{-t} V_t) \ge \alpha\theta \right\} \mathrm{P}\left\{ \Re(\bar{V}_k) \ge (1-\alpha)\theta \right\} \quad \forall \alpha \in \mathbb{R}, k \ge t,
\end{aligned} \tag{D.1}$$

where $\theta \triangleq 2\rho \sum_{j \in \mathbb{W}} |\eta|^{-j} = 2\rho/(1 - |\eta|^{-1})$ and the last step follows from the mutual independence of V_j, $j \ge -1$.

Furthermore, as $\mathrm{E}|V_j|^2$ is uniformly bounded, it follows from Holder's inequality that

$$\mathrm{E}|\Re(\bar{V}_k)|^2 \le \mathrm{E}\left| \sum_{j \ge -1, j \ne t} \eta^{-j} V_j \right|^2 \le \sum_{j \ge -1} |\eta|^{-j} \mathrm{E}\left\{ \sum_{j \ge -1} |\eta|^{-j} |V_j|^2 \right\} < \infty \quad \forall k \in \mathbb{W}.$$

By Theorem 22.6 in [4], $\Re(\bar{V}_k)$ then converges with probability 1, and thus in distribution, to a random variable $\bar{V}$. Hence $\exists \alpha_* \in \mathbb{R}$, $\epsilon > 0$, $k_* \in \mathbb{W}$ s.t. $\forall k \ge k_*$,

$$\mathrm{P}\left\{ \Re(\bar{V}_k) \ge (1-\alpha_*)\theta \right\} \ge \mathrm{P}\left\{ \bar{V} \ge (1-\alpha_*)\theta \right\} - \epsilon > 0.$$

In addition, since $\Re(\eta^{-t} V_t)$ is just a scalar linear function of $\mathbf{V}_t$, (5.5) implies that $\mathrm{P}\{\Re(\eta^{-t} V_t) > \vartheta\} > 0$ $\forall \vartheta \in \mathbb{R}$. Applying this and the inequality above to (D.1),

$$\mathrm{P}\{\|\mathbf{X}_{k+1}\| \ge \beta_k\} \ge \mathrm{P}\left\{ \Re(\eta^{-t} V_t) \ge \alpha_* \theta \right\} \left[\mathrm{P}\left\{ \bar{V} \ge (1-\alpha_*)\theta \right\} - \epsilon \right] \equiv \nu > 0 \quad \forall k \ge k_*.$$

It then follows that, $\forall r > 0$,

$$\mathrm{E}\|\mathbf{X}_{k+1}\|^r \ge \mathrm{E}\left\{ \|\mathbf{X}_{k+1}\|^r \chi(\|\mathbf{X}_{k+1}\| \ge \beta_k) \right\} \ge \beta_k^r \mathrm{P}\{\|\mathbf{X}_{k+1}\| \ge \beta_k\} \ge \beta_k^r \nu \to \infty,$$

since $\beta_k \to \infty$. The same reasoning applies to static memoryless coding (5.2). □

Appendix E. Proof of Lemma 5.2. Let $\phi = l\kappa_\nu(\omega)$, where $\omega \in \mathbb{Z}_{\mu^\nu}$ is the index of the selected quantizer point $q_\nu(x/l) \equiv \varpi_\nu(\omega)$ and κ_ν, ϖ_ν are defined by (5.8), (5.7), respectively. If $1 \le \omega \le \mu^\nu - 2$, then the interval $I(\omega)$ which contains x/l is bounded with length $2\kappa_\nu(\omega) \equiv 2\phi/l$ and midpoint $q_\nu(x/l) \triangleq \varpi_\nu(\omega)$. In this case, $|x - lq_\nu(x/l)| < \phi$, and $\forall \omega \in [1, \dots \mu^\nu - 2]$,

$$\mathrm{E}_{\omega,l}\left\{|X - Lq_\nu(X/L)|^{2+\varepsilon}\Phi^{-\varepsilon}\right\} \le \mathrm{E}_{\omega,l}\{\Phi^{2+\varepsilon}\Phi^{-\varepsilon}\} = \phi^2. \tag{E.1}$$

If $\omega = \mu^\nu - 1$, then x/l lies inside the semi-infinite interval $I(\mu^\nu - 1)$, defined as $(\varpi_\nu(\omega) - \phi/l, \infty)$. Hence

$$\begin{aligned}
&\mathrm{E}_{\omega,l}\left\{|X - Lq_\nu(X/L)|^{2+\varepsilon}\Phi^{-\varepsilon}\right\} \\
&= \mathrm{E}_{\omega,l}\left\{|X - L\varpi_\nu(\Omega)|^{2+\varepsilon}\Phi^{-\varepsilon}\chi(|X - L\varpi_\nu(\Omega)| \le \Phi)\right\} \\
&\quad + \mathrm{E}_{\omega,l}\left\{[X - L\varpi_\nu(\Omega)]^{2+\varepsilon}\,\Phi^{-\varepsilon}\chi(X - L\varpi_\nu(\Omega) > \Phi)\right\} \\
&\le \mathrm{E}_{\omega,l}\{\Phi^{2+\varepsilon}\Phi^{-\varepsilon}\} + \mathrm{E}_{\omega,l}\left\{X^{2+\varepsilon}\Phi^{-\varepsilon}\chi(X - L\varpi_\nu(\Omega) > \Phi)\right\} \\
&= \phi^2 + \mathrm{E}_{\omega,l}\left\{|X|^{2+\varepsilon}\,[L\kappa_\nu(\omega)]^{-\varepsilon}\,\chi\left(X - L\varpi_\nu(\omega) > L\kappa_\nu(\omega)\right)\right\} \\
&\le \phi^2 + \kappa_\nu(\omega)^{-\varepsilon}\mathrm{E}_{\omega,l}\{|X|^{2+\varepsilon}L^{-\varepsilon}\} \\
&= \phi^2 + \left[0.5(1 - 1/\mu)^{-1}(1 - \varrho^{-1})\varrho^\nu\right]^{-\varepsilon}\mathrm{E}_{\omega,l}\{|X|^{2+\varepsilon}L^{-\varepsilon}\} \\
&\le \phi^2 + \left[0.5(1 - 4^{-1/\varepsilon})\varrho^\nu\right]^{-\varepsilon}\mathrm{E}_{\omega,l}\{|X|^{2+\varepsilon}L^{-\varepsilon}\},
\end{aligned} \tag{E.2}$$

since $1 - \varrho^{-1} > 1 - \mu^{-2/\varepsilon} > 1 - 4^{-1/\varepsilon}$ for $\mu \ge 2$. By the symmetry of the quantizer about the origin, the same bound applies if $\omega = 0$, corresponding to the other semi-infinite interval $I(0)$. Averaging this, (E.1) and (E.2) over Ω, L,

$$\begin{aligned}
&\mathrm{E}\left\{\frac{|X - Lq_\nu(X/L)|^{2+\varepsilon}}{\Phi^\varepsilon}\right\} \\
&\le \mathrm{E}\{\Phi^2\} + \left[0.5(1 - 4^{-1/\varepsilon})\right]^{-\varepsilon}\varrho^{-\varepsilon\nu}\mathrm{E}\left\{\frac{|X|^{2+\varepsilon}}{L^\varepsilon}\right\} =: \beta_\nu.
\end{aligned} \tag{E.3}$$

By the definitions of $\phi \equiv l\kappa_\nu(\omega)$ from (5.7), and q_ν from (5.8),

$$\begin{aligned}
&\mathrm{E}_l\{\Phi^2\} \\
&= \left[\frac{l}{(\mu^2 - 2)\mu^{\nu-2}}\right]^2 \mathrm{P}_l\left\{\frac{|X|}{L} \le r_1\right\} + \sum_{i=2}^{\nu}\left[\frac{(r_i - r_{i-1})l}{2(\mu - 1)\mu^{\nu-i}}\right]^2 \mathrm{P}_l\left\{r_{i-1} < \frac{|X|}{L} \le r_i\right\} \\
&\quad + \left[\frac{(r_{\nu+1} - r_\nu)l}{2(1 - 2/\mu)}\right]^2 \mathrm{P}_l\left\{\frac{|X|}{L} > r_\nu\right\} \\
&= \left[\frac{l}{(\mu^2 - 2)\mu^{\nu-2}}\right]^2 \mathrm{P}_l\left\{\frac{|X|}{L} \le r_1\right\} \\
&\quad + \left[\frac{\varrho^{-1} - \varrho^{-2}}{2(\mu - 1)\mu^\nu}\right]^2 \left[\sum_{i=2}^{\nu}(\varrho\mu)^{2i}l^2\mathrm{P}_l\left\{r_{i-1} < \frac{|X|}{L} \le r_i\right\} + (\varrho\mu)^{2(\nu+1)}l^2\mathrm{P}_l\left\{\frac{|X|}{L} > r_\nu\right\}\right] \\
&\le \left[\frac{\mu^2 l}{(\mu^2 - 2)\mu^\nu}\right]^2 + \left[\frac{\varrho^{-1} - \varrho^{-2}}{2(\mu - 1)\mu^\nu}\right]^2 \sum_{i=2}^{\nu+1}(\varrho\mu)^{2i}l^2\mathrm{P}_l\left\{\frac{|X|}{L} \ge r_{i-1}\right\} \\
&\le \left[\frac{2l}{\mu^\nu}\right]^2 + \left[\frac{1}{2(\mu - 1)\varrho\mu^\nu}\right]^2 \sum_{i=2}^{\nu+1}(\varrho\mu)^{2i}l^2\mathrm{P}_l\left\{\frac{|X|}{L} \ge r_{i-1}\right\},
\end{aligned} \tag{E.4}$$

since $\mu^2/(\mu^2-2) \le 2$ for $\mu \ge 2$ and $\varrho > 1$. By a Chebyshev inequality type of argument,

$$\begin{aligned} l^2 \mathrm{P}_l\{|X| > r_{i-1}L\} &\le l^2 \mathrm{E}_l \left\{ [|X|/(r_{i-1}L)]^{2+\varepsilon}\, \chi(|X| > r_{i-1}L) \right\} \\ &= r_{i-1}^{-2-\varepsilon} \mathrm{E}_l \left\{ |X|^{2+\varepsilon} L^{-\varepsilon} \chi(|X| > r_{i-1}L) \right\} \\ &\le r_{i-1}^{-2-\varepsilon} \mathrm{E}_l \{ |X|^{2+\varepsilon} L^{-\varepsilon} \} = \varrho^{-(i-2)(2+\varepsilon)} \mathrm{E}_l \{ |X|^{2+\varepsilon} L^{-\varepsilon} \} \quad \forall i \ge 2. \end{aligned}$$

Substituting this into (E.4), averaging over L, and letting $b \triangleq \mathrm{E}\{|X|^{2+\varepsilon} L^{-\varepsilon}\}$,

$$\mathrm{E}\Phi^2 \le \frac{4\mathrm{E}L^2}{\mu^{2\nu}} + \left[\frac{1}{2(\mu-1)\varrho\mu^\nu} \right]^2 \sum_{i=2}^{\nu+1} \frac{(\varrho\mu)^{2i} b}{\varrho^{(i-2)(2+\varepsilon)}} = \frac{4\mathrm{E}L^2}{\mu^{2\nu}} + \left[\frac{\varrho^{1+\varepsilon}}{2(\mu-1)\mu^\nu} \right]^2 \sum_{i=2}^{\nu+1} \left(\frac{\mu^2}{\varrho^\varepsilon} \right)^i b.$$

As $\varrho > \mu^{2/\varepsilon}$, the geometric sum on the RHS is bounded with limit $\mu^4 \varrho^{-2\varepsilon}/(1-\mu^2\varrho^{-\varepsilon})$. Hence

$$\mathrm{E}\Phi^2 \le \frac{4\mathrm{E}L^2}{\mu^{2\nu}} + \left[\frac{\varrho^{1+\varepsilon}}{2(\mu-1)\mu^\nu} \right]^2 \frac{\mu^4 \varrho^{-2\varepsilon}}{1-\mu^2\varrho^{-\varepsilon}} b \equiv \frac{4\mathrm{E}L^m + \zeta_0 b}{\mu^{2\nu}}.$$

Adding this to (E.3),

$$\begin{aligned} \mathrm{M}_\varepsilon\{X - Lq_\nu(X/L)|\Phi\} &\le \mathrm{E}\Phi^2 + \beta_\nu \le 2\frac{4\mathrm{E}L^2 + \zeta_0 b}{\mu^{2\nu}} + \frac{[0.5(1-4^{-1/\varepsilon})]^{-\varepsilon} b}{\varrho^{\varepsilon\nu}} \\ &\le 2\frac{4\mathrm{E}L^2 + \zeta_0 b}{\mu^{2\nu}} + \frac{[0.5(1-4^{-1/\varepsilon})]^{-\varepsilon} b}{\mu^{2\nu}} \\ &\le \max\left\{ 8,\, 2\zeta_0 + [0.5(1-4^{-1/\varepsilon})]^{-\varepsilon} \right\} \frac{\mathrm{E}L^2 + b}{\mu^{2\nu}}. \qquad \square \end{aligned}$$

Note that virtually the same argument holds for the mean mth power quantization error, $m > 0$, by defining $\mathrm{M}_{\varepsilon,m}\{X|L\} \triangleq \mathrm{E}L^m + \mathrm{E}\{|X|^{m+\varepsilon} L^{-\varepsilon}\}$ and setting $\varrho > \mu^{m/\varepsilon}$.

FINITE ELEMENT METHODS IN LOCAL ACTIVE CONTROL OF SOUND*

ALFREDO BERMÚDEZ†, PABLO GAMALLO†, AND RODOLFO RODRÍGUEZ‡

Abstract. The active control of sound is analyzed in the framework of the mathematical theory of optimal control. After setting the problem in the frequency domain, we deal with the state equation, which is a Helmholtz partial differential equation. We show the existence of a unique solution and analyze a finite element approximation when the source term is a Dirac delta measure. Two optimization problems are successively considered. The first one concerns the choice of phases and amplitudes of the actuators to minimize the noise at the sensors' location. The second one consists of determining the optimal actuators' placement. Both problems are then numerically solved. Error estimates are settled and numerical results for some tests are reported.

Key words. dissipative acoustics, noise reduction, active control, optimal control problem, finite element approximation

1. Introduction.

Noise reduction is an important problem in acoustical and environmental engineering. While passive methods are good for middle and high frequencies, they are not efficient for low ones. However, the latter can be significantly reduced by active control techniques. This is an old concept that has generated increasing interest in recent years due to the development of fast digital signal processors (DSP). It is based on the principle of destructive interference of waves: an opposite pressure is generated by a secondary source to cancel an undesired noise. In order to achieve a significant reduction, this source must produce, with great precision, an equal amplitude but inverted replica of the noise to be canceled. Applications of these techniques can be used, for instance, to reduce noise in aircrafts or cars.

Reference books on this subject are [3] and [11]. The general principles of active control of noise were described in an early patent by Leug in 1936. A microphone detects the undesired noise and provides an input signal to an electronic control system. The transfer from the microphone to the loudspeaker is adjusted so that the sound wave generated will destructively interfere with the noise to be canceled.

In this paper we state the problem of active control of noise in the framework of the optimal control theory of distributed systems and present its mathematical and numerical analysis. For the sake of simplicity we consider that the noise to be canceled has one single frequency, although it is also possible to control broad-band or even nonperiodic noises. Two problems are successively considered. In a first step, complex amplitudes are taken as control variables with the objective of minimizing the pressure at some particular points in the domain. In a second step, the loudspeakers' location is optimized with respect to the same objective function. A third step that is

not included here would consist of determining the microphones' location in view of minimizing the global noise, i.e., the norm of the pressure in the whole domain under consideration rather than at some finite number of points.

The outline of the paper is as follows. In section 2 we introduce the physical problem and pose it in the framework of the optimal control theory. In section 3 we analyze the state equation. Although our main concern is when the inner source terms are Dirac delta measures, to tackle this problem we analyze first the same equation with data in L^2. We prove the existence and uniqueness of the solution and analyze its regularity, including some local $W^{2,\infty}$ a priori estimates which are used in the following section. In section 4 we introduce a finite element method to approximate the state equation. Once more we study first the case with L^2 data and then with Dirac delta measures. In both cases we prove L^2 and pointwise error estimates. In section 5 we state an optimal control problem to determine the optimal amplitudes of the actuators and show that it is well-posed. Then we approximate it by using the finite element approximation of the state equation introduced in the previous section. Next, we prove an error estimate for the approximate optimal control. In section 6 we report some numerical results which confirm our theoretical assertions. In section 7 we study how to determine the optimal location of the actuators, again in the framework of the optimal control theory. We prove the existence of an optimal control in this case and settle the optimality conditions. Finally, we report the results of some numerical experiments.

2. Mathematical model. The optimal control problem. Let $\Omega \subset \mathbb{R}^n$ ($n = 2$ or 3) be a bounded, convex, two-dimensional polygonal or three-dimensional polyhedral domain enclosing a nondissipative acoustic fluid (i.e., inviscid, compressible, and barotropic). The propagation of acoustic waves in this domain is modeled by the well-known equation

$$\frac{1}{c^2}\frac{\partial^2 P(x,t)}{\partial t^2} - \Delta P(x,t) = F(x,t) \quad \text{in } \Omega,$$

where P is the pressure fluctuation, c the sound speed, and F an inner source term. In our case, F will correspond to the secondary source of noise produced by loudspeakers, which will be the control variable. Moreover, there is a primary noise source acting on a part Γ_{N} of the boundary of the domain, $\partial\Omega$, which is modeled by

$$\frac{\partial P(x,t)}{\partial \boldsymbol{n}} = G(x,t) \quad \text{on } \Gamma_{\text{N}},$$

where $\boldsymbol{n}$ is an outward unit normal vector to $\partial\Omega$. This means that normal displacements are imposed on $\Gamma_{\text{N}} = \bigcup_{j=1}^{J} \Gamma_{\text{N}}^j$, where $\Gamma_{\text{N}}^1, \ldots, \Gamma_{\text{N}}^J$ denote the plane faces of Γ_{N}. In practice, it corresponds to the effect of an external vibration source transmitted to the enclosure Ω by the vibrations of some of the walls. Finally, we assume that the rest of the boundary $\Gamma_{\text{Z}} := \partial\Omega \setminus \bar{\Gamma}_{\text{N}} = \bigcup_{k=1}^{K} \Gamma_{\text{Z}}^k$ is formed by damping plane walls $\Gamma_{\text{Z}}^1, \ldots, \Gamma_{\text{Z}}^K$ characterized by a frequency-dependent *wall impedance* $Z(\omega)$. We assume that $|\Gamma_{\text{Z}}| > 0$ and $|\Gamma_{\text{N}}| > 0$, too.

In this paper we consider that G is a harmonic source with angular frequency $\omega \in \mathbb{R}$, $\omega \neq 0$. Hence, the secondary source F must be chosen also harmonic with the same frequency, i.e.,

$$G(x,t) = \text{Re}[g(x)\,\text{e}^{-i\omega t}], \qquad F(x,t) = \text{Re}[f(x)\,\text{e}^{-i\omega t}],$$

where $g(x)$ and $f(x)$ are complex functions which correspond to the respective complex amplitudes. Actually, their modulus are the physical amplitudes while their arguments are the phase angles. Since the model is linear, the stationary solution of the wave equation is also harmonic with the same frequency:

$$P(x,t) = \mathrm{Re}[p(x)\,\mathrm{e}^{-i\omega t}].$$

In such a case, we are led to the following Helmholtz problem, whose solution is the complex pressure amplitude:

$$\left\{\begin{array}{ll} -\Delta p - \left(\dfrac{\omega}{c}\right)^2 p = f & \text{in } \Omega, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = \dfrac{i\omega\rho}{Z(\omega)}\, p & \text{on } \Gamma_{\mathrm{Z}}, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = g & \text{on } \Gamma_{\mathrm{N}}, \end{array}\right. \tag{2.1}$$

where ρ is the density of the fluid and $Z(\omega) \in \mathbb{C}$ is the wall impedance given by

$$Z(\omega) := \beta(\omega) + \frac{\alpha(\omega)}{\omega}\, i.$$

The boundary condition on Γ_{Z} allows modeling the behavior of absorbing viscoelastic materials covering the enclosure walls which are typically used as passive systems to reduce low-frequency noise. The frequency-dependent coefficients $\alpha(\omega)$ and $\beta(\omega)$ are related to the viscous and elastic responses of the isolating material, respectively. Both are strictly positive functions of the angular frequency ω. However, in what follows, we will assume only that $\beta(\omega) \neq 0$.

In our case, the secondary source f will be a linear combination of N Dirac delta measures supported at some given points, $y_1, \ldots, y_N \in \Omega$ with complex amplitudes $u_1, \ldots, u_N$ to be determined:

$$f = \sum_{i=1}^{N} u_i \delta_{y_i} \quad \text{with } u_i \in \mathbb{C},\ i = 1, \ldots, N. \tag{2.2}$$

This amounts to considering loudspeakers as acoustic monopoles (see, for instance, [11]).

In order to state the noise active control as an optimal control problem, we make the following choices:

- the *state of the system* is given by the pressure $p(x)$ in the domain Ω;
- the *control variable* $\boldsymbol{u}$ is the vector of complex amplitudes of the loudspeakers (actuators),

$$\boldsymbol{u} := (u_1, \ldots, u_N) \in \mathbb{C}^N,$$

which define the source term f in (2.1) by means of (2.2);

- the *set of admissible controls* is a convex closed set $U_{\mathrm{ad}} \subseteq \mathbb{C}^N$;
- the *model of the system* relating the control variable to the state is the Helmholtz problem (2.1);
- the *observation* $\boldsymbol{z}$ is the set of pressure values at M microphones (sensors) located at given points $w_1, \ldots, w_M \in \Omega$,

$$\boldsymbol{z}(\boldsymbol{u}) := (p(w_1), \ldots, p(w_M)) \in \mathbb{C}^M,$$

where, for $\boldsymbol{u} \in \mathbb{C}^N$, p denotes the solution of problem (2.1) with f given by (2.2); in the next section it will be shown that evaluating pressure at points $w_i \in \Omega$ makes sense as long as they do not coincide with the locations of the actuators;

- the *cost function* to be minimized depends on the observation and eventually on the cost of the control itself, namely,

$$J(\boldsymbol{u}) := \frac{1}{2}\|\boldsymbol{z}(\boldsymbol{u})\|^2 + \frac{\nu}{2}\|\boldsymbol{u}\|^2, \tag{2.3}$$

where $\nu \geq 0$ is a weighting factor, and $\|\cdot\|$ denotes the Euclidean norm in $\mathbb{C}^N$ or $\mathbb{C}^M$. Thus we are led to the following *optimal control problem*:

Find $\boldsymbol{u}^{\rm op} \in U_{\rm ad}$ *such that*

$$J(\boldsymbol{u}^{\rm op}) = \inf_{\boldsymbol{u}\in U_{\rm ad}} J(\boldsymbol{u}). \tag{2.4}$$

Any solution $\boldsymbol{u}^{\rm op}$ of this minimization problem will be called an *optimal control*.

3. State equation. In this section we prove the existence and uniqueness of solution of the state equation and analyze its regularity, which will be used to study the optimal control problem. Our goal is the Helmholtz equation with singular data because, in our case, f is a linear combination of Dirac delta measures. However, we tackle this problem by first analyzing the same equation with data in $L^2(\Omega)$.

3.1. Data in $L^2(\Omega)$. We consider the Helmholtz problem (2.1) with $f \in L^2(\Omega)$ and $g \in L^2(\Gamma_{\rm N})$. Multiplying the first equation by a test function $q \in H^1(\Omega)$, taking into account the boundary conditions, and using a Green's formula, we obtain the following weak formulation of (2.1):

Find $p \in H^1(\Omega)$ *such that*

$$\begin{aligned} &\int_\Omega \nabla p \cdot \nabla \bar{q}\, dx - \frac{i\omega\rho}{Z(\omega)} \int_{\Gamma_{\rm Z}} p\bar{q}\, d\Gamma - \Big(\frac{\omega}{c}\Big)^2 \int_\Omega p\bar{q}\, dx \\ &\qquad = \int_\Omega f\bar{q}\, dx + \int_{\Gamma_{\rm N}} g\bar{q}\, d\Gamma \quad \forall q \in H^1(\Omega). \end{aligned} \tag{3.1}$$

We denote by a_ω the sesquilinear continuous form in $H^1(\Omega)$ appearing in the left-hand side of this problem:

$$a_\omega(p,q) := \int_\Omega \nabla p \cdot \nabla \bar{q}\, dx - \frac{i\omega\rho}{Z(\omega)} \int_{\Gamma_{\rm Z}} p\bar{q}\, d\Gamma - \Big(\frac{\omega}{c}\Big)^2 \int_\Omega p\bar{q}\, dx, \quad p, q \in H^1(\Omega).$$

It is clear that a_ω is not positive definite and therefore the *Lax–Milgram lemma* can not be applied to show the existence and uniqueness of the solution. Instead, we show below that a_ω satisfies a Gårding's inequality. Then, according to Fredholm's alternative, uniqueness implies the existence of solution.

To prove uniqueness we consider the homogeneous problem

$$\widetilde{p} \in H^1(\Omega): \quad a_\omega(\widetilde{p}, q) = 0 \quad \forall q \in H^1(\Omega). \tag{3.2}$$

Due to the damping viscous term $\beta \neq 0$ of the wall impedance Z, from the viewpoint of physics, no solution $\widetilde{p} \neq 0$ of problem (3.2) should be expected when $\omega \in \mathbb{R}$, $\omega \neq 0$. Indeed, we have the following result.

LEMMA 3.1. *If* $|\Gamma_{\rm Z}| > 0$, $\omega \in \mathbb{R}$, $\omega \neq 0$, *and* $\beta \neq 0$, *then* $\widetilde{p} = 0$ *is the unique solution of problem* (3.2).

Proof. Let $\widetilde{p}$ be a solution of (3.2). By choosing $q = \widetilde{p}$ in (3.2) we obtain

$$A - \frac{i\omega\rho}{\beta + \frac{\alpha}{\omega}i}B - \left(\frac{\omega}{c}\right)^2 C = A - \frac{\alpha\rho}{\beta^2 + \frac{\alpha^2}{\omega^2}}B - \left(\frac{\omega}{c}\right)^2 C - i\frac{\omega\rho\beta}{\beta^2 + \frac{\alpha^2}{\omega^2}}B = 0,$$

where $A := \int_\Omega |\nabla\widetilde{p}|^2\, dx$, $B := \int_{\Gamma_z} |\widetilde{p}|^2\, d\Gamma$, and $C = \int_\Omega |\widetilde{p}|^2\, dx$ are real numbers. Then the imaginary part must vanish too. Hence, for $\beta \neq 0$ and $\omega \neq 0$, we have $B = 0$ and, consequently, $\widetilde{p} = 0$ on Γ_z. Then, by taking test functions $q \in \mathcal{C}^\infty(\bar{\Omega})$ in (3.2), we obtain that $\widetilde{p}$ satisfies

$$\begin{cases} -\Delta\widetilde{p} = \left(\dfrac{\omega}{c}\right)^2 \widetilde{p} & \text{in } \Omega, \\ \dfrac{\partial\widetilde{p}}{\partial \boldsymbol{n}} = 0 & \text{on } \partial\Omega, \\ \widetilde{p} = 0 & \text{on } \Gamma_z. \end{cases}$$

According to these equations, if $\widetilde{p} \neq 0$, then it would be an eigenfunction of the Laplace operator satisfying simultaneously Neumann and Dirichlet homogeneous conditions on Γ_z, which is not possible because of the *unique prolongation theorem*. Thus $\widetilde{p} = 0$, and we conclude the proof. ∎

On the other hand, the following lemma shows that the sesquilinear form a_ω satisfies a Gårding's inequality.

LEMMA 3.2. *There exist strictly positive constants γ and C_ω, the latter depending on $\omega \in \mathbb{R}$, such that*

$$|a_\omega(q,q) + C_\omega \|q\|^2_{L^2(\Omega)}| \geq \gamma \|q\|^2_{H^1(\Omega)} \quad \forall q \in H^1(\Omega). \tag{3.3}$$

Proof. For all $q \in H^1(\Omega)$ and $\omega \in \mathbb{R}$, we have

$$\mathrm{Re}[a_\omega(q,q)] = \|q\|^2_{H^1(\Omega)} - \frac{\alpha\rho}{\beta^2 + \frac{\alpha^2}{\omega^2}}\|q\|^2_{L^2(\Gamma_z)} - \left(1 + \frac{\omega^2}{c^2}\right)\|q\|^2_{L^2(\Omega)}.$$

Thus, if $\alpha \leq 0$, then (3.3) holds with $\gamma = 1$ and $C_\omega = 1 + \omega^2/c^2$. Otherwise, from the trace theorem (see, for instance, [2]), $\exists C > 0$ such that

$$\|q\|_{L^2(\Gamma_z)} \leq C\|q\|^{1/2}_{L^2(\Omega)}\|q\|^{1/2}_{H^1(\Omega)} \quad \forall q \in H^1(\Omega).$$

Hence, $\forall \varepsilon > 0$ we have that

$$\|q\|^2_{L^2(\Gamma_z)} \leq \varepsilon\|q\|^2_{H^1(\Omega)} + \frac{C^2}{4\varepsilon}\|q\|^2_{L^2(\Omega)} \quad \forall q \in H^1(\Omega).$$

Then, the choice $\varepsilon = (\beta^2 + \alpha^2/\omega^2)/(2\alpha\rho) > 0$ leads to

$$\mathrm{Re}[a_\omega(q,q) + C_\omega\|q\|^2_{L^2(\Omega)}] \geq \gamma\|q\|^2_{H^1(\Omega)}$$

with $\gamma := 1/2$ and $C_\omega := 1 + \omega^2/c^2 + C^2/(8\varepsilon^2)$. Therefore, since $|\cdot| \geq \mathrm{Re}(\cdot)$, we end the proof. ∎

Now we are able to conclude the following existence, uniqueness, and regularity of solution results for the Helmholtz problem given above. From now on C denotes a strictly positive constant not necessarily the same at each occurrence.

THEOREM 3.3. *Let $\omega \in \mathbb{R}$, $\omega \neq 0$, $\beta \neq 0$, $f \in L^2(\Omega)$, and $g \in L^2(\Gamma_{\rm N})$. Then problem* (3.1) *has a unique solution $p \in H^1(\Omega)$. Moreover, if $g|_{\Gamma_{\rm N}^j} \in H^{1/2}(\Gamma_{\rm N}^j)$, $j = 1, \ldots, J$, then $p \in H^2(\Omega)$ and the following estimate holds*:

$$\|p\|_{H^2(\Omega)} \leq C \left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\rm N}^j)} \right]. \tag{3.4}$$

Proof. Uniqueness has been proved in Lemma 3.1. Because of Lemma 3.2 we know that the problem satisfies Fredholm's alternative (see, for instance, Theorem 6.5.15 of [10]). Then existence is a consequence of uniqueness. Moreover, because of the *open mapping theorem*,

$$\|p\|_{H^1(\Omega)} \leq C[\|f\|_{L^2(\Omega)} + \|g\|_{L^2(\Gamma_{\rm N})}]. \tag{3.5}$$

Next, by testing (3.1) with functions $q \in \mathcal{C}^\infty(\bar{\Omega})$ we obtain that p satisfies

$$\begin{cases} -\Delta p + p = \left(1 + \dfrac{\omega^2}{c^2}\right) p + f & \text{in } \Omega, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = \dfrac{i\omega\rho}{Z(\omega)} p & \text{on } \Gamma_{\rm Z}, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = g & \text{on } \Gamma_{\rm N}. \end{cases}$$

Since the domain Ω is a convex two-dimensional polygon or three-dimensional polyhedron, the standard a priori estimate for this Neumann problem (see [5] and [9]) yields

$$\|p\|_{H^2(\Omega)} \leq C \left[\|p\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega)} + \sum_{k=1}^{K} \|p\|_{H^{1/2}(\Gamma_{\rm Z}^k)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\rm N}^j)} \right],$$

where C is a constant independent of f, g, and p. Then (3.4) is a direct consequence of this inequality and (3.5). ∎

Remark 3.4. The convexity assumption on Ω is used only to obtain the estimate (3.4) and the analogous one for the Green's function (3.11) below. Similar results are valid for smooth nonconvex domains, too.

3.2. Dirac delta measures. Let us now consider the Helmholtz problem (2.1) with homogeneous Neumann boundary data and inner source $f = \delta_y$ being the Dirac delta measure supported at an inner point $y \in \Omega$. Its solution is the Green's function $G^y \in L^2(\Omega)$ of problem (2.1):

$$\begin{cases} -\Delta G^y - \left(\dfrac{\omega}{c}\right)^2 G^y = \delta_y & \text{in } \Omega, \\ \dfrac{\partial G^y}{\partial \boldsymbol{n}} = \dfrac{i\omega\rho}{Z(\omega)} G^y & \text{on } \Gamma_{\rm Z}, \\ \dfrac{\partial G^y}{\partial \boldsymbol{n}} = 0 & \text{on } \Gamma_{\rm N}, \end{cases} \tag{3.6}$$

where the first equation must be understood in the sense of distributions.

It is simple to show that this problem has a unique solution. Indeed, let Φ^y be the fundamental solution of the Helmholtz equation in the whole space, namely, the solution of

$$-\Delta\Phi^y - \left(\frac{\omega}{c}\right)^2 \Phi^y = \delta_y \quad \text{in } \mathbb{R}^n.$$

This fundamental solution is explicitly known (see, for instance, [6]):

$$\Phi^y(x) := \begin{cases} \dfrac{1}{4} Y_0\left(\dfrac{\omega}{c}|x-y|\right) & \text{if } n = 2, \\ \dfrac{\cos\left(\dfrac{\omega}{c}|x-y|\right)}{4\pi|x-y|} & \text{if } n = 3, \end{cases} \tag{3.7}$$

where Y_0 denotes the zero-order second-kind Bessel function. It clearly satisfies $\Phi^y \in \mathcal{C}^\infty(\mathbb{R}\setminus\{y\})$ and $\Phi^y|_\Omega \in L^2(\Omega)$. Then G^y is a solution of (3.6) if and only if $G^y = \Phi^y|_\Omega + p^y$, with p^y satisfying

$$\begin{cases} -\Delta p^y - \left(\dfrac{\omega}{c}\right)^2 p^y = 0 & \text{in } \Omega, \\ \dfrac{\partial p^y}{\partial \boldsymbol{n}} = \dfrac{i\omega\rho}{Z(\omega)} p^y + \dfrac{i\omega\rho}{Z(\omega)} \Phi^y - \dfrac{\partial \Phi^y}{\partial \boldsymbol{n}} & \text{on } \Gamma_{\mathrm{Z}}, \\ \dfrac{\partial p^y}{\partial \boldsymbol{n}} = -\dfrac{\partial \Phi^y}{\partial \boldsymbol{n}} & \text{on } \Gamma_{\mathrm{N}}. \end{cases} \tag{3.8}$$

The variational formulation of this problem consists of finding $p^y \in H^1(\Omega)$ such that

$$a_\omega(p^y, q) = \int_{\Gamma_{\mathrm{Z}}} \left[\frac{i\omega\rho}{Z(\omega)}\Phi^y - \frac{\partial \Phi^y}{\partial \boldsymbol{n}}\right] \bar{q}\, d\Gamma - \int_{\Gamma_{\mathrm{N}}} \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \bar{q}\, d\Gamma \quad \forall q \in H^1(\Omega), \tag{3.9}$$

with a_ω as defined above. Then the arguments in the proof of Theorem 3.3 allow us to conclude that this problem has a unique solution and, hence, problem (3.6) does too. Moreover, these arguments also show that $p^y \in H^2(\Omega)$ and, furthermore,

$$\|p^y\|_{H^2(\Omega)} \le C \left[\sum_{k=1}^{K} \left\| \frac{i\omega\rho}{Z(\omega)}\Phi^y - \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \right\|_{H^{1/2}(\Gamma_{\mathrm{Z}}^k)} + \sum_{j=1}^{J} \left\| \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \right\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)}\right]. \tag{3.10}$$

Consequently p^y is a continuous function and, hence, $G^y = \Phi^y + p^y$ is continuous in $\Omega\setminus\{y\}$. This shows that evaluating the pressure at a point $w \in \Omega$ where a microphone is located makes sense as long as $w \neq y$. Therefore, the control problem (2.4) is well-posed whenever the sets of sensors' and actuators' locations do not intersect.

Furthermore, if $d > 0$ is such that $\mathcal{B}_d(y) := \{x \in \mathbb{R}^n : |x-y| < d\} \subset\subset \Omega$, then $\|\Phi^y\|_{H^2(\Omega\setminus\bar{\mathcal{B}}_d(y))}$ is bounded by a constant which depends on d. Thus, from the estimate (3.10) we have that

$$\|G^y\|_{H^2(\Omega\setminus\bar{\mathcal{B}}_d(y))} \le \|\Phi^y\|_{H^2(\Omega\setminus\bar{\mathcal{B}}_d(y))} + \|p^y\|_{H^2(\Omega)} \le C, \tag{3.11}$$

with C depending on d, too.

To end this subsection we present an alternative characterization of the solution of problem (3.6) obtained by *transposition techniques*. This will be used to prove convergence in $L^2(\Omega)$ of the numerical scheme introduced in the following section.

To this goal, note that given $q \in L^2(\Omega)$, the adjoint problem to (3.6) reads

$$\left\{\begin{array}{ll} -\Delta r - \left(\dfrac{\omega}{c}\right)^2 r = q & \text{in } \Omega, \\ \dfrac{\partial r}{\partial \boldsymbol{n}} = -\dfrac{i\omega\rho}{\bar{Z}(\omega)} r & \text{on } \Gamma_{\mathrm{Z}}, \\ \dfrac{\partial r}{\partial \boldsymbol{n}} = 0 & \text{on } \Gamma_{\mathrm{N}}. \end{array}\right. \tag{3.12}$$

In spite of the conjugate in the coefficient of the middle equation, Theorem 3.3 applies to this problem since it has been proved with the only assumptions that $\omega \neq 0$ and $\beta \neq 0$. Hence (3.12) has a unique solution which satisfies $r \in H^2(\Omega)$ and

$$\|r\|_{H^2(\Omega)} \leq C \|q\|_{L^2(\Omega)}. \tag{3.13}$$

In what follows we prove that the solution G^y of (3.6) is the unique function in $L^2(\Omega)$ which satisfies

$$\int_\Omega G^y \bar{q}\, dx = \langle \delta_y, r \rangle \quad \forall q \in L^2(\Omega). \tag{3.14}$$

Indeed, standard computations (see, for instance, Chapter 2.2.4 of [7]) show that

$$\langle \delta_y, r \rangle = \int_\Omega \Phi^y \left(-\Delta \bar{r} - \frac{\omega^2}{c^2} \bar{r} \right) dx + \int_{\partial\Omega} \left(\Phi^y \frac{\partial \bar{r}}{\partial \boldsymbol{n}} - \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \bar{r} \right) d\Gamma.$$

On the other hand, integration by parts in (3.9) with r as a test function yields

$$\int_\Omega p^y \left(-\Delta \bar{r} - \frac{\omega^2}{c^2} \bar{r} \right) dx - \frac{i\omega\rho}{Z(\omega)} \int_{\Gamma_{\mathrm{Z}}} (p^y + \Phi^y) \bar{r}\, d\Gamma + \int_{\partial\Omega} \left(p^y \frac{\partial \bar{r}}{\partial \boldsymbol{n}} + \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \bar{r} \right) d\Gamma = 0.$$

Then, by adding these two equations, we obtain

$$\langle \delta_y, r \rangle = \int_\Omega G^y \left(-\Delta \bar{r} - \frac{\omega^2}{c^2} \bar{r} \right) dx - \frac{i\omega\rho}{Z(\omega)} \int_{\Gamma_{\mathrm{Z}}} G^y \bar{r}\, d\Gamma + \int_{\partial\Omega} G^y \frac{\partial \bar{r}}{\partial \boldsymbol{n}} = \int_\Omega G^y \bar{q}\, dx,$$

where we have used the three equations of (3.12) for the last equality. Thus we conclude (3.14).

3.3. Local $W^{2,\infty}$ a priori estimates. The following lemma yields L^∞ local a priori estimates for the second derivatives of the solutions of problems (3.1) and (3.6). These bounds will be used in the following section to obtain pointwise error estimates for the finite element method proposed therein to solve these problems.

LEMMA 3.5. *Let D_0 and D_1 be disjoint open subsets of Ω satisfying $D_i \subset\subset \Omega$, $i = 0, 1$. Let $d > 0$ be such that* $\operatorname{dist}(D_i, \partial\Omega) \geq d$, *$i = 0, 1$, and* $\operatorname{dist}(D_0, D_1) \geq d$. *Then the following hold*:

1. *For each $y \in D_0$, the solution of problem* (3.6) *satisfies $G^y|_{D_1} \in W^{2,\infty}(D_1)$ and there exists a constant $C > 0$ depending on d such that*

$$\|G^y\|_{W^{2,\infty}(D_1)} \leq C \quad \forall y \in D_0.$$

2. *Let $f \in L^2(\Omega)$ be such that* $\operatorname{supp}(f) \subset D_0$. *Let $g \in L^2(\Gamma_{\mathrm{N}})$ be such that $g|_{\Gamma_{\mathrm{N}}^j} \in H^{1/2}(\Gamma_{\mathrm{N}}^j)$, $j = 1, \ldots, J$. Let p be the solution of problem* (3.1). *Then there exists a constant $C > 0$ depending on d such that*

$$\|p\|_{W^{2,\infty}(D_1)} \leq C \left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right].$$

Proof. Consider the following subsets of Ω: $D_2 := \{x \in \mathbb{R}^n : \operatorname{dist}(x, D_1) < \frac{d}{4}\}$ and $D_3 := \{x \in \mathbb{R}^n : \operatorname{dist}(x, D_1) < \frac{d}{2}\}$. Then $\operatorname{dist}(D_3, \partial\Omega) \geq \frac{d}{2}$ and $\operatorname{dist}(D_0, D_3) \geq \frac{d}{2}$. Let χ be a $\mathcal{C}^\infty$ cut-off real function supported in D_3 such that $\chi|_{D_2} = 1$ and $\|\chi\|_{W^{2,\infty}(\mathbb{R}^n)}$ is bounded by a constant depending on d.

Given $y \in D_0$, we write the solution of problem (3.6) in the form $G^y = \Phi^y|_\Omega + p^y$, with Φ^y given by (3.7) and p^y being the solution of (3.8). Explicit differentiation of (3.7) shows that, for all $y \in D_0$, since $\operatorname{dist}(y, D_3) \geq \frac{d}{2}$, $\|\Phi^y\|_{W^{2,\infty}(D_3)}$ is bounded by a constant depending on d but not on y. So, to prove the first part of the theorem we only need to estimate $\|p^y\|_{W^{2,\infty}(D_1)}$.

Given $z \in D_1$, let G^z be the solution of problem (3.6) with y substituted by z. Then we have

$$p^y(z) = \langle \delta_z, \chi p^y \rangle = \left\langle -\Delta G^z - \frac{\omega^2}{c^2} G^z, \chi p^y \right\rangle = \left\langle G^z, -\Delta(\chi p^y) - \frac{\omega^2}{c^2} \chi p^y \right\rangle,$$

and

$$\begin{aligned} -\Delta(\chi p^y) - \frac{\omega^2}{c^2} \chi p^y &= \chi \left(-\Delta p^y - \frac{\omega^2}{c^2} p^y \right) - 2\nabla\chi \cdot \nabla p^y - (\Delta\chi) p^y \\ &= -[2\nabla\chi \cdot \nabla p^y + (\Delta\chi) p^y]. \end{aligned}$$

Hence, $\operatorname{supp}(-\Delta(\chi p^y) - \frac{\omega^2}{c^2} \chi p^y) \subset \operatorname{supp}(\nabla\chi) \subset D_3 \setminus \bar{D}_2$, and thus

$$p^y(z) = -\int_{D_3 \setminus \bar{D}_2} G^z(x) [2\nabla\chi(x) \cdot \nabla \bar{p}^y(x) + \Delta\chi(x)\, \bar{p}^y(x)]\, dx.$$

Because of the symmetry of the operator involved, the Green's function is symmetric, i.e., $G^z(x) = G^x(z)\ \forall x, z \in \Omega :\ x \neq z$. Then by differentiating the expression above we obtain $\forall \alpha \in \mathbb{N}^n$

$$D_z^\alpha p^y(z) = -\int_{D_3 \setminus \bar{D}_2} D_x^\alpha G^z(x) [2\nabla\chi(x) \cdot \nabla \bar{p}^y(x) + \Delta\chi(x)\, \bar{p}^y(x)]\, dx.$$

Consequently, by (3.11) and (3.10), we have $\forall \alpha \in \mathbb{N}^n$ such that $|\alpha| := \sum_{l=1}^n \alpha_l \leq 2$

$$\begin{aligned} |D_z^\alpha p^y(z)| &\leq \|G^z\|_{H^2(D_3 \setminus \bar{D}_2)} \|\chi\|_{W^{2,\infty}(D_3 \setminus \bar{D}_2)} \|p^y\|_{H^1(D_3 \setminus \bar{D}_2)} \\ &\leq C \left[\sum_{k=1}^{K} \left\| \frac{i\omega\rho}{Z(\omega)} \Phi^y - \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \right\|_{H^{1/2}(\Gamma_{\mathrm{Z}}^k)} + \sum_{j=1}^{J} \left\| \frac{\partial \Phi^y}{\partial \boldsymbol{n}} \right\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right] \leq C, \end{aligned}$$

with C depending on d but not on the particular point $z \in D_1$. Thus we conclude the proof of the first part of the lemma.

For the second part, let $f \in L^2(\Omega)$ with $\mathrm{supp}(f) \subset D_0$. We proceed exactly as above and use that

$$-\Delta(\chi p) - \frac{\omega^2}{c^2}(\chi p) = \chi\left(-\Delta p - \frac{\omega^2}{c^2} p\right) - 2\nabla\chi\cdot\nabla p - \Delta\chi\, p = -(2\nabla\chi\cdot\nabla p + \Delta\chi\, p),$$

because of $-\Delta p - \frac{\omega^2}{c^2} p = f$ and $\mathrm{supp}(f) \cap \mathrm{supp}\,\chi = \emptyset$. Then we obtain from (3.11) and Theorem 3.3

$$\begin{aligned} |D_z^\alpha p(z)| &\le \left| \int_{D_3\setminus\bar{D}_2} D_x^\alpha G^z(x)[2\nabla\chi(x)\cdot\nabla\bar{p}^y(x) + \Delta\chi(x)\,\bar{p}^y(x)]\,dx \right| \\ &\le \|G^z\|_{H^2(D_3\setminus\bar{D}_2)} \|\chi\|_{W^{2,\infty}(D_3\setminus\bar{D}_2)} \|p\|_{H^1(D_3\setminus\bar{D}_2)} \\ &\le C\left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right] \quad \forall \alpha \in \mathbb{N}^n :\ |\alpha| \le 2, \end{aligned}$$

with C again depending on d but not on the particular point $z \in D_1$. Thus we conclude the proof. ∎

4. Numerical approximation of the state equation. For the construction of the finite element spaces we consider a quasi-uniform family of shape-regular triangulations $\{\mathcal{T}_h\}_{h>0}$ of Ω. More precisely, for each element $T \in \mathcal{T}_h$ (T being a two-dimensional triangle or a three-dimensional tetrahedron) we associate two parameters: h_T and ρ_T. The first one denotes the diameter of T and the second one the diameter of the largest ball contained in T. We denote $h := \max_{T\in\mathcal{T}_h} h_T$ and make the following hypothesis of regularity of the triangulation: there exist positive constants σ_1 and σ_2 such that

$$\frac{h_T}{\rho_T} \le \sigma_1, \quad \frac{h}{h_T} \le \sigma_2 \quad \forall\, T \in \mathcal{T}_h,\ \forall h > 0.$$

We associate with each triangulation $\mathcal{T}_h$ a finite element space $\mathcal{V}_h$ which consists of functions globally continuous in Ω and linear on each element $T \in \mathcal{T}_h$. Then, the discrete problem associated with problem (3.1) is the following:

Find $p_h \in \mathcal{V}_h$ such that

$$a_\omega(p_h, q_h) = \langle f, q_h\rangle + \int_{\Gamma_{\mathrm{N}}} g\bar{q}_h\, d\Gamma \quad \forall q_h \in \mathcal{V}_h. \tag{4.1}$$

Notice that this problem is well defined for $f \in L^2(\Omega)$ as well as for f given by (2.2), because the functions in $\mathcal{V}_h$ are continuous.

4.1. Data in $L^2(\Omega)$. Again, to tackle the numerical approximation when the source term is a Dirac delta measure, we consider first the problem with data in $L^2(\Omega)$.

Since a_ω is continuous and satisfies the Gårding's inequality (3.3), and since the continuous problem (3.1) has a unique solution, the following existence and approximation result is readily obtained from [12].

THEOREM 4.1. *Given $f \in L^2(\Omega)$ and $g \in L^2(\Gamma_{\mathrm{N}})$, let p be the solution of problem (3.1). Then there exists $h_0 > 0$ such that, $\forall\, h \in (0, h_0]$, problem (4.1) has a unique solution p_h. Moreover, if $g|_{\Gamma_{\mathrm{N}}^j} \in H^{1/2}(\Gamma_{\mathrm{N}}^j)$, $j = 1, \dots, J$, then the following estimate holds*:

$$\|p - p_h\|_{L^2(\Omega)} \le Ch^2 \left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right].$$

Since the observation $\boldsymbol{z}(\boldsymbol{u})$ consists of point values of the solution of problem (3.1), a pointwise error estimate will be used in the following section to obtain an error bound for the approximate control. To this aim, we have the following result, which is a consequence of the interior maximum norm estimates proved in [13].

THEOREM 4.2. *Given $f \in L^2(\Omega)$ such that $\mathrm{supp}(f) \subset\subset \Omega$ and $g \in L^2(\Gamma_{\mathrm{N}})$ such that $g|_{\Gamma_{\mathrm{N}}^j} \in H^{1/2}(\Gamma_{\mathrm{N}}^j)$, $j = 1, \ldots, J$, let p be the solution of problem (3.1). Given $w \in \Omega \setminus \mathrm{supp}(f)$, let $d > 0$ be such that $\mathrm{dist}(w, \partial\Omega) \geq d$, $\mathrm{dist}(w, \mathrm{supp}(f)) \geq d$, and $\mathrm{dist}(\mathrm{supp}(f), \partial\Omega) \geq d$. Let $h_0 > 0$ be such that, $\forall\, h \in (0, h_0]$, problem (4.1) has a unique solution p_h. Then, there exist strictly positive constants $h_1 < h_0$ and C, both depending on d, such that the following pointwise error estimate holds $\forall h \in (0, h_1]$:*

$$|p(w) - p_h(w)| \leq Ch^2 \ln\left(\frac{1}{h}\right) \left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right].$$

Proof. Let $D := \mathcal{B}_{d/8}(w)$, $D_1 := \mathcal{B}_{d/4}(w)$, and $D_2 := \mathcal{B}_{d/2}(w)$. Then $D_2 \subset\subset \Omega$ and $D_2 \cap \mathrm{supp}(f) = \emptyset$, with $\mathrm{dist}(D_2, \partial\Omega) \geq \frac{d}{2}$ and $\mathrm{dist}(D_2, \mathrm{supp}(f)) \geq \frac{d}{2}$.

Now, for $h < h_0$, since p and p_h are solutions of (3.1) and (4.1), respectively, $\forall q_h \in \mathcal{V}_h$ with $\mathrm{supp}(q_h) \subset D_1$ there holds

$$\int_\Omega \nabla(p - p_h) \cdot \nabla \bar{q}_h \, dx - \left(\frac{\omega}{c}\right)^2 \int_\Omega (p - p_h)\bar{q}_h \, dx = 0.$$

Then, according to Theorem 5.1 in [13], there exist $C > 0$ and $h_1 > 0$ such that, $\forall h \in (0, h_1]$ and $\forall q_h \in \mathcal{V}_h$, the following inequality holds:

$$\|p - p_h\|_{L^\infty(D)} \leq C \ln\left(\frac{1}{h}\right) [\|p - q_h\|_{L^\infty(D_1)} + \|p - p_h\|_{L^2(D_1)}].$$

Because of Lemma 3.5 (part 2) and the standard error estimate for the Lagrange interpolation (see, for instance, [2]), if $h < d/4$, then

$$\inf_{q_h \in \mathcal{V}_h} \|p - q_h\|_{L^\infty(D_1)} \leq Ch^2 \|p\|_{W^{2,\infty}(D_2)} \leq C \left[\|f\|_{L^2(\Omega)} + \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \right].$$

Thus, the theorem follows from the last two inequalities and Theorem 4.1. ∎

4.2. Dirac delta measures. We consider now problem (4.1) with $g = 0$ and f being a Dirac delta measure:

$$G_h^y \in \mathcal{V}_h : \quad a_\omega(G_h^y, q_h) = \langle \delta_y, q_h \rangle \quad \forall q_h \in \mathcal{V}_h. \tag{4.2}$$

This is a discretization of problem (3.6). Let us recall that it is well defined because the functions in $\mathcal{V}_h$ are continuous. Then, by proceeding as in the previous subsection, it can be shown that $\exists h_0$ such that $\forall h \in (0, h_0]$, this problem has a unique solution. Here and thereafter, h_0 denotes a maximum mesh size that is not necessarily the same at each occurrence.

To show convergence in $L^2(\Omega)$, we are going to use the scheme proposed for elliptic problems in [14] (see also [4]). This scheme allows splitting the approximation error into two parts: the first one due to the error in the approximation of the Dirac delta measure by $L^2(\Omega)$ functions and the second one due to the approximation error of the Helmholtz equation with data in $L^2(\Omega)$.

Consider the following auxiliary variational problem:

$$\widetilde{G} \in H^1(\Omega): \quad a_\omega(\widetilde{G}, q) = \langle \delta_h, q \rangle \quad \forall q \in H^1(\Omega),$$

where $\delta_h \in L^2(\Omega)$ is an approximation of δ_y satisfying the following properties:

1. $\langle \delta_h, q_h \rangle = \int_\Omega \delta_h \bar{q}_h \, dx = \bar{q}_h(y) \quad \forall q_h \in \mathcal{V}_h$;
2. $\|\delta_h\|_{L^2(\Omega)} \leq Ch^{-n/2}$;
3. $\|\delta_y - \delta_h\|_{H^{-2}(\Omega)} \leq Ch^{2-n/2}$;
4. $\delta_h = 0$ outside the elements in which y lies.

A construction of such δ_h is given in [14].

We use the triangular inequality to separate the error in two terms:

$$\|G^y - G_h^y\|_{L^2(\Omega)} \leq \|G^y - \widetilde{G}\|_{L^2(\Omega)} + \|\widetilde{G} - G_h^y\|_{L^2(\Omega)}.$$

From property 1 above we conclude that δ_y and δ_h are identical functionals on $\mathcal{V}_h$. Consequently G_h^y can be seen as a finite element approximation of $\widetilde{G}$, too. Therefore, from Theorem 4.1 and property 2 of δ_h, we obtain the following approximation result for h sufficiently small:

$$\|\widetilde{G} - G_h^y\|_{L^2(\Omega)} \leq Ch^2 \|\delta_h\|_{L^2(\Omega)} \leq Ch^{2-n/2}.$$

To estimate the remaining term, note that by property 4 above δ_h has its support included in a certain set $D \subset\subset \Omega$, for h sufficiently small. Then we can apply to $\widetilde{G}$ the arguments of the transposition technique that allow us to prove (3.14). By so doing, we obtain that $\forall q \in L^2(\Omega)$, if $r \in H^2(\Omega)$ is the solution of (3.12), then

$$\int_\Omega (G^y - \widetilde{G}) \bar{q} = \langle \delta_y - \delta_h, r \rangle.$$

Hence, by taking $q = G^y - \widetilde{G}$ and using the a priori estimate (3.13), we have

$$\|G^y - \widetilde{G}\|^2_{L^2(\Omega)} \leq \|\delta_y - \delta_h\|_{H^{-2}(\Omega)} \|r\|_{H^2(\Omega)} \leq C \|\delta_y - \delta_h\|_{H^{-2}(\Omega)} \|G^y - \widetilde{G}\|_{L^2(\Omega)}.$$

Consequently, from property 3 of δ_h we have

$$\|G^y - \widetilde{G}\|_{L^2(\Omega)} \leq C \|\delta_y - \delta_h\|_{H^{-2}(\Omega)} \leq Ch^{2-n/2}.$$

Thus we have proved the following result.

THEOREM 4.3. *For $y \in \Omega$, let $G^y \in L^2(\Omega)$ be the solution of problem* (3.6). *There exists $h_0 > 0$ such that, $\forall\, h \in (0, h_0]$, problem* (4.2) *has a unique solution G_h^y. Moreover, there exists a strictly positive constant C such that the following error bound holds*:

$$\|G^y - G_h^y\|_{L^2(\Omega)} \leq Ch^{2-n/2}.$$

Next, we prove an error estimate for $|G^y(w) - G_h^y(w)|$, for $w \neq y$. This will be used in the following section to obtain an error bound for the approximate control. A similar result with the explicit dependence of the constant of the estimate on $|w - y|$ has been proved in Theorem 6.1(i) of [13], but for a coercive second-order linear operator with homogeneous Neumann boundary conditions on a smooth domain. The additional hypotheses of this theorem were used only to obtain an explicit estimate for the corresponding Green's function (see (4.9) of [13]). However, to the best of

the authors' knowledge, such an estimate is not available for our Helmholtz problem with mixed Neumann–Robin boundary conditions on a convex polyhedron. Instead, we will use the local maximum norm a priori estimate proved in Lemma 3.5 (part 1) to obtain a similar result, although without making explicit the dependence of the constant of the estimate on $|w-y|$.

THEOREM 4.4. *Let $y \in \Omega$ and $G^y \in L^2(\Omega)$ be the solution of problem (3.6). Let $h_0 > 0$ be such that, $\forall h \in (0, h_0]$, problem (4.2) has a unique solution G_h^y. Given $w \in \Omega$, $w \neq y$, let $d > 0$ be such that $|w-y| \geq d$, $\operatorname{dist}(w, \partial\Omega) \geq d$, and $\operatorname{dist}(y, \partial\Omega) \geq d$. Then there exist strictly positive constants $h_1 < h_0$ and C, both depending on d, such that, $\forall h \in (0, h_1]$,*

$$|G^y(w) - G_h^y(w)| \leq Ch^2 \ln\left(\frac{1}{h}\right).$$

Proof. The proof is essentially identical to that of Theorem 6.1(i) of [13]. Thus, we include here only its main steps and emphasize those which differ in our case.

Let $D_1 := \mathcal{B}_{d/4}(w)$, $D_2 := \mathcal{B}_{d/2}(w)$, and $D' := \mathcal{B}_{d/4}(y)$. Then $\operatorname{dist}(D_1, D') \geq \frac{d}{2}$. Applying Theorem 5.1 in [13] we know that there exist constants $C > 0$ and $h_1 > 0$, both depending on d, such that, $\forall h \in (0, h_1]$ and $\forall q_h \in \mathcal{V}_h$,

$$|G^y(w) - G_h^y(w)| \leq C \ln\left(\frac{1}{h}\right) [\|G^y - q_h\|_{L^\infty(D_1)} + \|G^y - G_h^y\|_{L^1(D_1)}].$$

The first term in the right-hand side can be bounded by using Lemma 3.5 (part 1) and the standard error estimate for the Lagrange interpolation (see, for instance, [2]); namely, if $h < d/4$, then

$$\inf_{q_h \in \mathcal{V}_h} \|G^y - q_h\|_{L^\infty(D_1)} \leq Ch^2 \|G^y\|_{W^{2,\infty}(D_2)} \leq Ch^2.$$

For the second term, we apply the same duality argument as in the proof of Theorem 6.1(i) of [13]. By doing so, we can repeat all the steps of this proof with the exception of the following one: Given $q \in \mathcal{C}_0^\infty(D_1)$, let

$$r \in W^{1,\infty}(\Omega): \quad a_\omega(s, r) = \int_\Omega s\bar{q}\, dx \quad \forall s \in W^{1,1}(\Omega);$$

it has to be proved that $\|r\|_{W^{2,\infty}(D')} \leq C\|q\|_{L^\infty(D_1)}$. In our case, we do it by repeating the arguments in the proof of Lemma 3.5 (part 2).

The rest of the proof runs essentially as that of Theorem 6.1(i) of [13]. ∎

5. Optimal amplitudes of actuators. Numerical methods. From now on we assume that the primary source g is such that $g|_{\Gamma_N^j} \in H^{1/2}(\Gamma_N^j)$, $j = 1, \ldots, J$, and the secondary source is given by (2.2) in terms of the control variable $\boldsymbol{u} = (u_1, \ldots, u_N) \in \mathbb{C}^N$: $f := \sum_{i=1}^N u_i \delta_{y_i}$, with $y_i \in \Omega$, $i = 1, \ldots, N$.

Let p be the solution of problem (2.1) with such f. Due to the linearity of the Helmholtz equation, p can be written in terms of the control variable as follows:

$$p = p_0 + \sum_{i=1}^N u_i G^{y_i}, \tag{5.1}$$

where p_0 is the pressure field arising from the primary source g without any control; more precisely, p_0 is the solution of problem (2.1) for $\boldsymbol{u} = \boldsymbol{0}$ (i.e., $f = 0$). In its

turn, G^{y_i} is the solution of problem (3.6) with $y = y_i$, $i = 1, \dots, N$. This corresponds to the pressure field when the system is only excited by the ith loudspeaker with unit amplitude, excluding the effect of the primary source. Note that according to Theorem 3.3 and (3.11), it makes sense to evaluate p at points $w \in \Omega$, $w \neq y_i$, $i = 1, \dots, N$.

Let $w_1, \dots, w_M \in \Omega$ be such that $\{y_1, \dots, y_N\}$ and $\{w_1, \dots, w_M\}$ are disjoint. Proving the existence of an optimal control is an easy task because the control space is finite-dimensional. It relies upon the fact that the mapping giving the observation from the control, namely,

$$\begin{aligned} \mathbb{C}^N &\longrightarrow \mathbb{C}^M, \\ \boldsymbol{u} &\longmapsto \boldsymbol{z}(\boldsymbol{u}) = (p(w_i), \dots, p(w_M)), \end{aligned}$$

is affine (and thus continuous). The mapping $\boldsymbol{z}(\boldsymbol{u})$ is the so-called *transfer function*, which establishes the relation between controls and observations.

Therefore, the cost function (2.3) is quadratic. The first term of the cost function is convex since the observation $\boldsymbol{z}(\boldsymbol{u})$ is affine and the second one is strictly convex when $\nu > 0$. Therefore, it is clear that the function J is strictly convex under either of the two following assumptions:

- $\nu > 0$,
- $\nu \geq 0$ and $\boldsymbol{z}(\boldsymbol{u})$ is one-to-one,

in which case there exists a unique optimal control.

We notice that $\boldsymbol{z}(\boldsymbol{u})$ is one-to-one if and only if the observations corresponding to each single actuator are linearly independent. Obviously this can happen only if the number of microphones is greater than or equal to the number of loudspeakers: $M \geq N$.

To write the control problem in matrix form, we introduce the vectors

$$\begin{aligned} \boldsymbol{z}_0 &:= (p_0(w_1), \dots, p_0(w_M)) \in \mathbb{C}^M, \\ \boldsymbol{z}_i &:= (G^{y_i}(w_1), \dots, G^{y_i}(w_M)) \in \mathbb{C}^M, \quad i = 1, \dots, N. \end{aligned}$$

Note that according to Theorem 3.3 and (3.11), respectively, there hold

$$\|\boldsymbol{z}_0\| \leq C \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)} \quad \text{and} \quad \|\boldsymbol{z}_i\| \leq C, \quad i = 1, \dots, N. \tag{5.2}$$

The observation $\boldsymbol{z}$ can be written in terms of the control variable $\boldsymbol{u} \in \mathbb{C}^N$ and the observations $\boldsymbol{z}_0, \boldsymbol{z}_1, \dots, \boldsymbol{z}_N$ in the following way:

$$\boldsymbol{z}(\boldsymbol{u}) = \boldsymbol{z}_0 + \sum_{i=1}^{N} u_i \boldsymbol{z}_i.$$

Then the cost function becomes

$$\begin{aligned} J(\boldsymbol{u}) &= \frac{1}{2} \left\| \boldsymbol{z}_0 + \sum_{i=1}^{N} u_i \boldsymbol{z}_i \right\|^2 + \frac{\nu}{2} \|\boldsymbol{u}\|^2 \\ &= \frac{1}{2} \left[\bar{\boldsymbol{z}}_0^{\mathrm{t}} \boldsymbol{z}_0 + 2 \operatorname{Re} \left(\sum_{i=1}^{N} \bar{u}_i \bar{\boldsymbol{z}}_i^{\mathrm{t}} \boldsymbol{z}_0 \right) + \sum_{i,j=1}^{N} u_j \bar{u}_i (\bar{\boldsymbol{z}}_i^{\mathrm{t}} \boldsymbol{z}_j + \nu \delta_{ij}) \right]. \end{aligned}$$

Let us define the matrix $\boldsymbol{Z} \in \mathbb{C}^{N\times N}$ and the vector $\boldsymbol{d} \in \mathbb{C}^N$ by

$$(\boldsymbol{Z})_{ij} := \bar{\boldsymbol{z}}_i^{\mathrm{t}} \boldsymbol{z}_j, \quad i,j = 1,\dots,N,$$
$$(\boldsymbol{d})_i := \bar{\boldsymbol{z}}_i^{\mathrm{t}} \boldsymbol{z}_0, \quad i = 1,\dots,N.$$

Then the optimal control problem (2.4) is equivalent to the following quadratic programming problem:

Find $\boldsymbol{u}^{\mathrm{op}} \in U_{\mathrm{ad}}$ *such that*

$$J(\boldsymbol{u}^{\mathrm{op}}) = \inf_{\boldsymbol{u}\in U_{\mathrm{ad}}} \frac{1}{2}[\bar{\boldsymbol{u}}^{\mathrm{t}}(\boldsymbol{Z} + \nu \boldsymbol{I})\boldsymbol{u} + 2\,\mathrm{Re}(\bar{\boldsymbol{u}}^{\mathrm{t}}\boldsymbol{d}) + \|\boldsymbol{z}_0\|^2].$$

Although the cost function is defined in a finite-dimensional space, it involves the solution of a partial differential equation which has to be approximated by means of some discretization process as, for instance, the finite element method described in section 4. This leads to approximate observations and thereby to an approximate cost function.

Similar definitions hold for the approximate observations. Given $\boldsymbol{u} \in \mathbb{C}^N$, let

$$\boldsymbol{z}_h(\boldsymbol{u}) := (p_h(w_i),\dots,p_h(w_M)) \in \mathbb{C}^M,$$

where p_h is the solution of the discrete problem (4.1) with f defined by (2.2) as above. Let $\boldsymbol{z}_{ih} \in \mathbb{C}^M$ be defined by

$$\boldsymbol{z}_{0h} := (p_{0h}(w_1),\dots,p_{0h}(w_M)) \in \mathbb{C}^M,$$
$$\boldsymbol{z}_{ih} := (G_h^{y_i}(w_1),\dots,G_h^{y_i}(w_M)) \in \mathbb{C}^M, \quad i = 1,\dots,N,$$

where p_{0h} is the solution of problem (4.1) for $\boldsymbol{u} = \boldsymbol{0}$ (i.e., $f = 0$), and $G_h^{y_i}$ is the solution of the discrete problem (4.2) for $y = y_i$, $i = 1,\dots,N$. Then $\boldsymbol{z}_h(\boldsymbol{u}) \in \mathbb{C}^M$ is given by

$$\boldsymbol{z}_h(\boldsymbol{u}) := \boldsymbol{z}_{0h} + \sum_{i=1}^{N} u_i \boldsymbol{z}_{ih}.$$

Let $\boldsymbol{Z}_h \in \mathbb{C}^{N\times N}$ and $\boldsymbol{d}_h \in \mathbb{C}^N$ be defined by

$$(\boldsymbol{Z}_h)_{ij} := \bar{\boldsymbol{z}}_{ih}^{\mathrm{t}} \boldsymbol{z}_{jh}, \quad i,j = 1,\dots,N,$$
$$(\boldsymbol{d}_h)_i := \bar{\boldsymbol{z}}_{ih}^{\mathrm{t}} \boldsymbol{z}_{0h}, \quad i = 1,\dots,N.$$

Then the approximate cost function can be written as

$$J_h(\boldsymbol{u}) := \frac{1}{2}\|\boldsymbol{z}_h(\boldsymbol{u})\|^2 + \frac{\nu}{2}\|\boldsymbol{u}\|^2 = \frac{1}{2}[\bar{\boldsymbol{u}}^{\mathrm{t}}(\boldsymbol{Z}_h + \nu \boldsymbol{I})\boldsymbol{u} + 2\,\mathrm{Re}(\bar{\boldsymbol{u}}^{\mathrm{t}}\boldsymbol{d}_h) + \|\boldsymbol{z}_{0h}\|^2].$$

These definitions lead us to the following discrete optimal control problem:

Find $\boldsymbol{u}_h^{\mathrm{op}} \in U_{\mathrm{ad}}$ *such that*

$$J_h(\boldsymbol{u}_h^{\mathrm{op}}) = \inf_{\boldsymbol{u}\in U_{\mathrm{ad}}} \frac{1}{2}[\bar{\boldsymbol{u}}^{\mathrm{t}}(\boldsymbol{Z}_h + \nu \boldsymbol{I})\boldsymbol{u} + 2\,\mathrm{Re}(\bar{\boldsymbol{u}}^{\mathrm{t}}\boldsymbol{d}_h) + \|\boldsymbol{z}_{0h}\|^2]. \tag{5.3}$$

The argument $\boldsymbol{u}_h^{\mathrm{op}}$, where the minimum is attained, is expected to be an approximation of the optimal control $\boldsymbol{u}^{\mathrm{op}}$. Our next goal is to obtain an estimate for this approximation. To this aim, we denote

$$\delta \boldsymbol{d} := \boldsymbol{d} - \boldsymbol{d}_h \quad \text{and} \quad \delta \boldsymbol{Z} := \boldsymbol{Z} - \boldsymbol{Z}_h.$$

LEMMA 5.1. *There exist strictly positive constants C and h_0 such that, $\forall\, h \in (0, h_0]$, the following inequalities hold:*

$$\|\delta \boldsymbol{d}\| \le Ch^2 \ln\left(\frac{1}{h}\right) \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)}, \qquad \|\delta \boldsymbol{Z}\| \le Ch^2 \ln\left(\frac{1}{h}\right).$$

Moreover, if $\boldsymbol{Z}$ is positive definite, then so is $\boldsymbol{Z}_h$ for h small enough.

Proof. First we settle an error estimate for the observations $\boldsymbol{z}_0, \boldsymbol{z}_1, \ldots, \boldsymbol{z}_N$. We denote the corresponding errors by

$$\delta \boldsymbol{z}_i := \boldsymbol{z}_{ih} - \boldsymbol{z}_i, \quad i = 0, \ldots, N.$$

From Theorem 4.2, for h small enough we have

$$\|\delta \boldsymbol{z}_0\| = \left[\sum_{k=1}^{M} |p_0(w_k) - p_{0h}(w_k)|^2\right]^{1/2} \le Ch^2 \ln\left(\frac{1}{h}\right) \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)},$$

whereas from Theorem 4.4,

$$\|\delta \boldsymbol{z}_i\| = \left[\sum_{k=1}^{M} |G^{y_i}(w_k) - G_h^{y_i}(w_k)|^2\right]^{1/2} \le Ch^2 \ln\left(\frac{1}{h}\right).$$

Therefore, if h is small enough,

$$\begin{aligned}
\|\delta \boldsymbol{d}\| &= \left[\sum_{i=1}^{N} |\bar{\boldsymbol{z}}_0^{\mathrm{t}} \boldsymbol{z}_i - (\bar{\boldsymbol{z}}_0 + \delta \bar{\boldsymbol{z}}_0)^{\mathrm{t}} (\boldsymbol{z}_i + \delta \boldsymbol{z}_i)|^2\right]^{1/2} \\
&\le \left[\sum_{i=1}^{N} (\|\boldsymbol{z}_0\| \|\delta \boldsymbol{z}_i\| + \|\delta \boldsymbol{z}_0\| \|\boldsymbol{z}_i\| + \|\delta \boldsymbol{z}_0\| \|\delta \boldsymbol{z}_i\|)^2\right]^{1/2} \\
&\le Ch^2 \ln\left(\frac{1}{h}\right) \sum_{j=1}^{J} \|g\|_{H^{1/2}(\Gamma_{\mathrm{N}}^j)},
\end{aligned}$$

the last inequality because of (5.2).

The error bound for $\|\delta \boldsymbol{Z}\|$ is proved essentially in the same way. Furthermore, since $\boldsymbol{Z}_h$ converges to $\boldsymbol{Z}$, if $\boldsymbol{Z}$ is positive definite, then for h small enough $\boldsymbol{Z}_h$ is positive definite too. ∎

As an immediate consequence of the above lemma we have the existence and uniqueness of solution of the discrete optimal control problem, for h sufficiently small.

COROLLARY 5.2. *Let us assume that $\nu > 0$ or $\nu \ge 0$ and $\boldsymbol{z}(\boldsymbol{u})$ is one-to-one. Then, there exists $h_0 > 0$ such that, $\forall\, h \in (0, h_0]$, problem (5.3) has a unique solution.*

To obtain a bound for $\|\boldsymbol{u}^{\mathrm{op}} - \boldsymbol{u}_h^{\mathrm{op}}\|$, we prove first the following a priori error estimate for the solution of a variational inequality subject to data perturbations.

LEMMA 5.3. *Let U_{ad} be a convex subset of $\mathbb{C}^N$, $\boldsymbol{b} \in \mathbb{C}^N$, and $\boldsymbol{A} \in \mathbb{C}^{N \times N}$ a positive definite Hermitian matrix. Let $\alpha > 0$ be such that*

$$\bar{\boldsymbol{v}}^{\mathrm{t}} \boldsymbol{A} \boldsymbol{v} \ge \alpha \|\boldsymbol{v}\|^2 \quad \forall \boldsymbol{v} \in \mathbb{C}^N.$$

Let $\delta\boldsymbol{b} \in \mathbb{C}^N$ and $\delta\boldsymbol{A} \in \mathbb{C}^{N\times N}$ be such that $\|\delta\boldsymbol{A}\| < \alpha$. Let $\boldsymbol{u} \in U_{\rm ad}$ and $(\boldsymbol{u}+\delta\boldsymbol{u}) \in U_{\rm ad}$ be the solutions of the following variational inequalities:

$$\mathrm{Re}[(\bar{\boldsymbol{v}} - \bar{\boldsymbol{u}})^{\rm t}(\boldsymbol{A}\boldsymbol{u} + \boldsymbol{b})] \geq 0 \quad \forall \boldsymbol{v} \in U_{\rm ad}, \tag{5.4}$$

$$\mathrm{Re}\{[\bar{\boldsymbol{v}} - (\bar{\boldsymbol{u}} + \bar{\delta\boldsymbol{u}})]^{\rm t}[(\boldsymbol{A} + \delta\boldsymbol{A})(\boldsymbol{u} + \delta\boldsymbol{u}) + (\boldsymbol{b} + \delta\boldsymbol{b})]\} \geq 0 \quad \forall \boldsymbol{v} \in U_{\rm ad}. \tag{5.5}$$

Then

$$\|\delta\boldsymbol{u}\| \leq \frac{1}{\alpha - \|\delta\boldsymbol{A}\|}(\|\delta\boldsymbol{A}\|\|\boldsymbol{u}\| + \|\delta\boldsymbol{b}\|). \tag{5.6}$$

Furthermore, if $U_{\rm ad} \ni \boldsymbol{0}$ and $\|\delta\boldsymbol{A}\| < \theta\alpha$ with $0 < \theta < 1$, then

$$\|\delta\boldsymbol{u}\| \leq \frac{1}{(1-\theta)\alpha}\left(\frac{\|\boldsymbol{b}\|}{\alpha}\|\delta\boldsymbol{A}\| + \|\delta\boldsymbol{b}\|\right). \tag{5.7}$$

Proof. By taking $\boldsymbol{v} = \boldsymbol{u} + \delta\boldsymbol{u}$ in (5.4) and $\boldsymbol{v} = \boldsymbol{u}$ in (5.5) we obtain

$$\mathrm{Re}[\bar{\delta\boldsymbol{u}}^{\rm t}(\boldsymbol{A}\boldsymbol{u} + \boldsymbol{b})] \geq 0,$$
$$\mathrm{Re}\{-\bar{\delta\boldsymbol{u}}^{\rm t}[(\boldsymbol{A} + \delta\boldsymbol{A})(\boldsymbol{u} + \delta\boldsymbol{u}) + (\boldsymbol{b} + \delta\boldsymbol{b})]\} \geq 0.$$

By adding these inequalities we obtain

$$\mathrm{Re}(\bar{\delta\boldsymbol{u}}^{\rm t}\boldsymbol{A}\delta\boldsymbol{u}) \leq \mathrm{Re}\{-\bar{\delta\boldsymbol{u}}^{\rm t}[\delta\boldsymbol{A}(\boldsymbol{u} + \delta\boldsymbol{u}) + \delta\boldsymbol{b}]\}.$$

Then, since $\boldsymbol{A}$ is Hermitian and positive definite, we have

$$\alpha\|\delta\boldsymbol{u}\|^2 \leq \bar{\delta\boldsymbol{u}}^{\rm t}\boldsymbol{A}\delta\boldsymbol{u} = \mathrm{Re}(\bar{\delta\boldsymbol{u}}^{\rm t}\boldsymbol{A}\delta\boldsymbol{u}) \leq \|\delta\boldsymbol{u}\|(\|\delta\boldsymbol{A}\|\|\delta\boldsymbol{u}\| + \|\delta\boldsymbol{A}\|\|\boldsymbol{u}\| + \|\delta\boldsymbol{b}\|),$$

and, therefore,

$$(\alpha - \|\delta\boldsymbol{A}\|)\|\delta\boldsymbol{u}\| \leq \|\delta\boldsymbol{A}\|\|\boldsymbol{u}\| + \|\delta\boldsymbol{b}\|.$$

Hence, for $\|\delta\boldsymbol{A}\| < \alpha$, we obtain (5.6). Moreover, if $\|\delta\boldsymbol{A}\| < \theta\alpha$ with $0 < \theta < 1$, then

$$\|\delta\boldsymbol{u}\| \leq \frac{1}{(1-\theta)\alpha}(\|\delta\boldsymbol{A}\|\|\boldsymbol{u}\| + \|\delta\boldsymbol{b}\|). \tag{5.8}$$

On the other hand, if $U_{\rm ad} \ni \boldsymbol{0}$, then we can take $\boldsymbol{v} = \boldsymbol{0}$ in (5.4) and we obtain $\mathrm{Re}[-\bar{\boldsymbol{u}}^{\rm t}(\boldsymbol{A}\boldsymbol{u} + \boldsymbol{b})] \geq 0$. Then

$$\alpha\|\delta\boldsymbol{u}\|^2 \leq \bar{\boldsymbol{u}}^{\rm t}\boldsymbol{A}\boldsymbol{u} = \mathrm{Re}(\bar{\boldsymbol{u}}^{\rm t}\boldsymbol{A}\boldsymbol{u}) \leq \mathrm{Re}(-\bar{\boldsymbol{u}}^{\rm t}\boldsymbol{b}) \leq \|\delta\boldsymbol{u}\|\|\delta\boldsymbol{b}\|.$$

Hence, $\|\delta\boldsymbol{u}\| \leq \|\delta\boldsymbol{b}\|/\alpha$, and (5.7) follows from this inequality and (5.8). Thus we conclude the proof. □

From the above lemma and the error estimates of Lemma 5.1 it is easy to prove the following result.

THEOREM 5.4. *Let us assume that $\nu > 0$ or $\nu \geq 0$ and $\boldsymbol{z}(\boldsymbol{u})$ is one-to-one. If $U_{\rm ad} \ni \boldsymbol{0}$, then there exist $C > 0$ and $h_0 > 0$ such that, $\forall\, h \in (0, h_0]$,*

$$\|\boldsymbol{u}^{\rm op} - \boldsymbol{u}_h^{\rm op}\| \leq Ch^2 \ln\left(\frac{1}{h}\right)\sum_{j=1}^{J}\|g\|_{H^{1/2}(\Gamma_{\rm N}^j)}.$$

Proof. Let $\delta\boldsymbol{u} := \boldsymbol{u}_h^{\rm op} - \boldsymbol{u}^{\rm op}$. The exact and the approximate optimal controls satisfy the variational inequalities

$$\begin{aligned}
&\mathrm{Re}\{(\bar{\boldsymbol{v}} - \bar{\boldsymbol{u}}^{\rm op})^{\rm t}[(\boldsymbol{Z} + \nu\boldsymbol{I})\boldsymbol{u}^{\rm op} + \boldsymbol{d}]\} \geq 0 \quad \forall \boldsymbol{v} \in U_{\rm ad},\\
&\mathrm{Re}\{(\boldsymbol{v} - \boldsymbol{u}_h^{\rm op})^{\rm t}[(\boldsymbol{Z} + \nu\boldsymbol{I} + \delta\boldsymbol{Z})(\boldsymbol{u}^{\rm op} + \delta\boldsymbol{u}) + (\boldsymbol{d} + \delta\boldsymbol{d})]\} \geq 0 \quad \forall \boldsymbol{v} \in U_{\rm ad}.
\end{aligned}$$

Since $\boldsymbol{Z} + \nu\boldsymbol{I}$ is a Hermitian positive definite matrix, let $\alpha > 0$ be such that

$$\bar{\boldsymbol{v}}^{\rm t}(\boldsymbol{Z} + \nu\boldsymbol{I})\boldsymbol{v} \geq \alpha\|\boldsymbol{v}\|^2 \quad \forall \boldsymbol{v} \in U_{\rm ad}.$$

According to Lemma 5.1, for h sufficiently small $\|\delta\boldsymbol{Z}\| < \alpha/2$. Then we can apply Lemma 5.3 to the variational inequalities above and obtain

$$\|\boldsymbol{u}^{\rm op} - \boldsymbol{u}_h^{\rm op}\| \leq \frac{2}{\alpha}\left(\frac{\|\boldsymbol{d}\|}{\alpha}\|\delta\boldsymbol{Z}\| + \|\delta\boldsymbol{d}\|\right).$$

Thus, we conclude the proof from this inequality, (5.2), and Lemma 5.1. ∎

Remark 5.5. The assumption made on the admissible set, $U_{\rm ad} \ni \boldsymbol{0}$, to prove the error estimate of this theorem is not restrictive at all in practice. It just means that a vanishing control is also admissible.

6. Numerical results. In this section we present some numerical results for a three-dimensional test. In order to assess the effect of the control we use the following measure of attenuation:

$$\text{Attenuation (dB)} = -10\log_{10}\left[\frac{J(\boldsymbol{u}^{\rm op})}{J(\boldsymbol{0})}\right].$$

The data of the test are the following:

- the domain is $\Omega = [0,1]\,\mathrm{m} \times [0,1]\,\mathrm{m} \times [0,1]\,\mathrm{m}$;
- the physical parameters are $\omega = 680\,\mathrm{s}^{-1}$, $c = 340\,\mathrm{m\,s}^{-1}$, and $\rho = 1\,\mathrm{kg\,m}^{-3}$;
- the amplitude of the primary source of noise is $g(x,y,0) = \mathrm{e}^{iy}\,\mathrm{kg\,m}^{-2}\,\mathrm{s}^{-2}$ on the wall $z = 0$;
- there is one loudspeaker located at $y_1 = (\frac{4}{6}, \frac{4}{6}, \frac{4}{6})\,\mathrm{m}$;
- there are two microphones at $w_1 = (\frac{1}{6}, \frac{2}{6}, \frac{1}{6})\,\mathrm{m}$ and $w_2 = (\frac{5}{6}, \frac{1}{6}, \frac{3}{6})\,\mathrm{m}$;
- on the wall $z = 1$, the acoustic impedance is $Z = (102 + 340\,i) \times 10^3\,\mathrm{kg\,m}^{-2}\,\mathrm{s}^{-1}$;
- the rest of the walls are perfectly rigid;
- the admissible set of controls is $U_{\rm ad} = \mathbb{C}$ and the weighting factor is $\nu = 0$.

The optimal control has been computed for several meshes which have been obtained by uniformly refining the coarse mesh shown in Figure 6.1.

Then a more accurate value of the optimal control has been determined by extrapolating the controls computed on these meshes. This more accurate value has been used to compute the relative errors of the real and imaginary parts of the computed controls. These errors are shown in Figure 6.2, where it can be clearly observed that the order of convergence is essentially $\mathcal{O}(h^2)$ as predicted by the theoretical results.

For $h = 1/24$, the computed attenuation is 0.75 dB. The modulus of the complex pressure field on the plane containing the actuator and the two sensors is shown in Figures 6.3 and 6.4. The first one corresponds to the system without control, whereas the second one shows the pressure with the optimal control.

Finally Figure 6.5 shows the local attenuation field computed on the same plane: $\mathrm{Att}(w) = -10\log_{10}[|p_h(w)|^2/|p_{0h}(w)|^2]$.

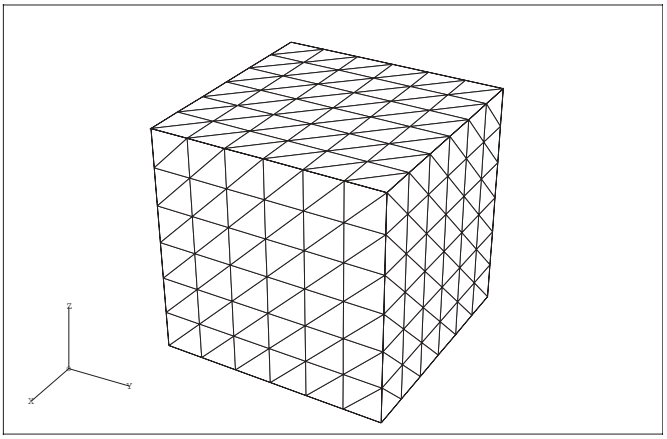

FIG. 6.1. *Coarsest mesh* ($h = 1/6\,\mathrm{m}$).

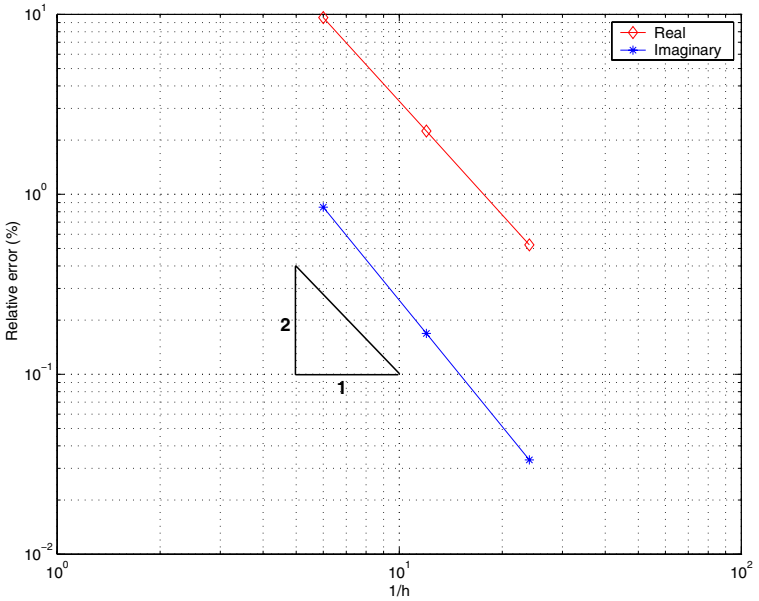

FIG. 6.2. *Relative error (%) as a function of* $1/h$ *in log-log scale.*

In this case, it can be observed that there exist zones where the noise is reinforced, that is, where primary and secondary sources interfere in a constructive way. This happens, for instance, in the location of the first sensor. Indeed, the noise level without control is low around this sensor and too high around the other one (see Figure 6.3). Thus, to obtain a minimum of the cost functional, the optimal amplitude of the actuator is such that it produces a noise reinforcement in the first sensor. Anyway, the comparison of Figures 6.3 and 6.4 shows that the global attenuation has been significant in the whole domain, except for the vicinity of the actuator.

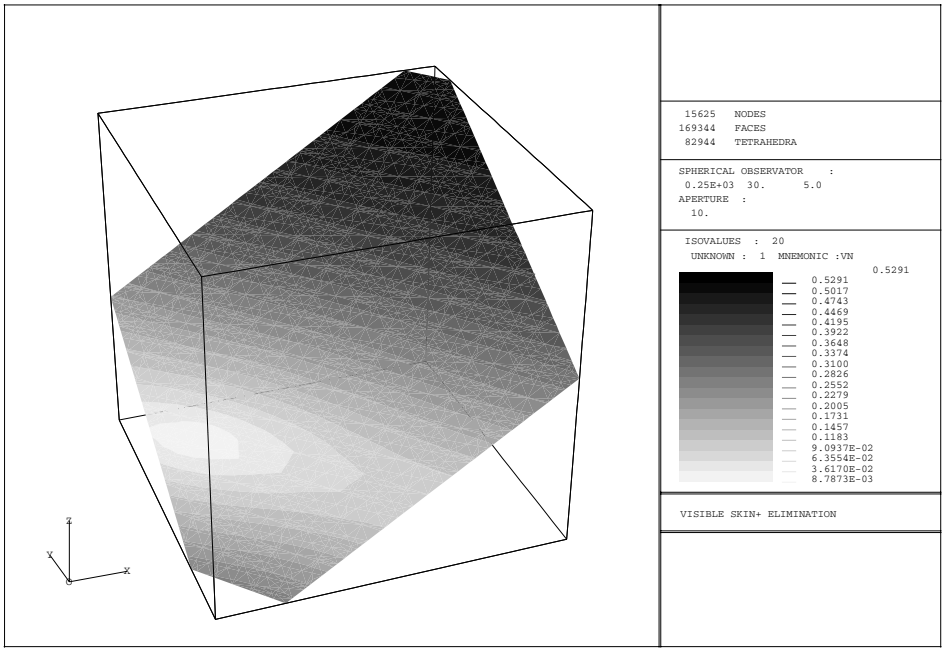

FIG. 6.3. *Modulus of the pressure field without control* ($h = 1/24\,\mathrm{m}$).

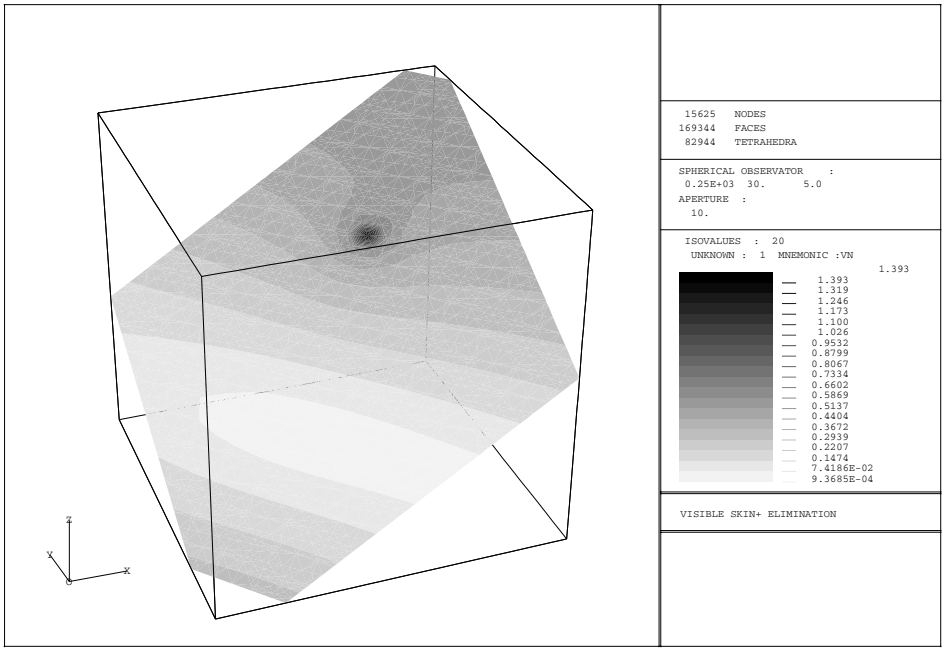

FIG. 6.4. *Modulus of the pressure field with control* ($h = 1/24\,\mathrm{m}$).

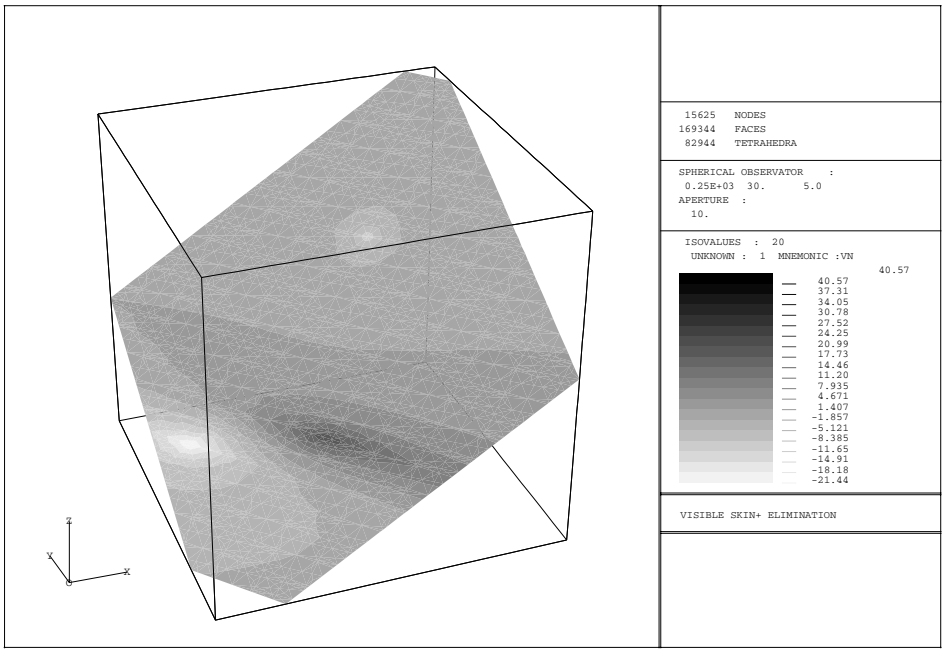

FIG. 6.5. *Attenuation field* ($h = 1/24\,\mathrm{m}$).

7. Optimal location of actuators. In the previous sections, the positions of the sensors (microphones) were given and the positions of the actuators (loudspeakers) were given, too. Then we have used the complex amplitudes of the actuators as the unique control variable and have determined their optimal values with the objective of minimizing the pressure level at those points where the sensors were located. Now we assume that the positions of the actuators can also be chosen in certain subsets of the domain and we will try to determine those that minimize the same objective function as above, when the complex amplitudes are optimal with respect to these positions. This is the most important problem when a system of active control of sound has to be implemented to reduce noise in an enclosure. It can also be formulated as an optimal control problem.

In this case the *control variables* are the complex amplitudes (modulus and phases) and the positions of the actuators,

$$\boldsymbol{u} = (u_1, \ldots, u_N) \in \mathbb{C}^N \quad \text{and} \quad \boldsymbol{y} = (y_1, \ldots, y_N) \in \Omega^N,$$

respectively, which define the secondary source by means of (2.2).

We consider the *set of admissible controls* $U_{\mathrm{ad}} \times Y_{\mathrm{ad}} \subset \mathbb{C}^N \times \Omega^N$, where $U_{\mathrm{ad}} \subset \mathbb{C}^N$ and $Y_{\mathrm{ad}} \subset\subset (\Omega \setminus \{w_1, \ldots, w_M\})^N$ are closed convex subsets.

The *observation* $\boldsymbol{z}(\boldsymbol{u}, \boldsymbol{y})$ is again the set of pressure values at the microphones' locations $w_1, \ldots, w_M \in \Omega$. The *transfer function* is now

$$\begin{aligned} U_{\mathrm{ad}} \times Y_{\mathrm{ad}} &\longrightarrow \mathbb{C}^M, \\ (\boldsymbol{u}, \boldsymbol{y}) &\longmapsto \boldsymbol{z}(\boldsymbol{u}, \boldsymbol{y}) = (p(w_i), \ldots, p(w_M)), \end{aligned}$$

where, for each admissible set of values of the control variables, $\boldsymbol{u} \in U_{\mathrm{ad}}$ and $\boldsymbol{y} \in Y_{\mathrm{ad}}$, p denotes again the solution of the *state equation* (2.1) with f given by (2.2). Notice

that the sensors' locations are excluded from the domain of admissible locations for the actuators, to ensure the continuity of the transfer function.

The *cost function* is given again by

$$J(\boldsymbol{u},\boldsymbol{y}) := \frac{1}{2}\|\boldsymbol{z}(\boldsymbol{u},\boldsymbol{y})\|^2 + \frac{\nu}{2}\|\boldsymbol{u}\|^2,$$

and then the *optimal control problem* is as follows:

Find $(\boldsymbol{u}^{\rm op},\boldsymbol{y}^{\rm op}) \in U_{\rm ad}\times Y_{\rm ad}$ *such that*

$$J(\boldsymbol{u}^{\rm op},\boldsymbol{y}^{\rm op}) = \inf_{(\boldsymbol{u},\boldsymbol{y})\in U_{\rm ad}\times Y_{\rm ad}} J(\boldsymbol{u},\boldsymbol{y}). \tag{7.1}$$

The difficulty now is that the dependency of the state with respect to the additional control variables (the positions of actuators) is no longer affine. Thus the cost function may have many local minima, and therefore gradient-like methods are not suitable to solve the problem. In practice, the number of feasible locations is typically finite, and hence the optimization problem becomes an integer programming problem. In these cases one can use, for instance, genetic or simulated annealing algorithms. Once the optimal locations have been determined, it will be possible to improve them in some given neighborhoods by performing a local minimization using the gradient of the cost function with respect to the location of the actuators. As we will see below, the first order optimality conditions allow computing the gradient of the cost function through an adjoint state.

7.1. Existence of an optimal control. Optimality conditions. We recall that the pressure field defining the observations can be written in terms of the control variables by means of (5.1): $p = p_0 + \sum_{i=1}^N u_i G^{y_i}$. Then the transfer function is affine with respect to $\boldsymbol{u}$, although it is nonlinear with respect to $\boldsymbol{y}$.

Therefore, the optimal control problem (7.1) has a solution as a direct consequence of the following facts:

- the function $J(\boldsymbol{u},\boldsymbol{y})$ is continuous in $U_{\rm ad}\times Y_{\rm ad}$;
- the set $Y_{\rm ad}$ is compact;
- $U_{\rm ad}$ is a closed set; and
- $J(\boldsymbol{u},\boldsymbol{y}) \to \infty$ when $\|\boldsymbol{u}\| \to \infty$ $\forall \boldsymbol{y} \in Y_{\rm ad}$.

In what follows we deduce the optimality condition for a local minimum of the cost function $J(\boldsymbol{u},\boldsymbol{y})$ given by (7.1). We notice that in the present case J is convex with respect to the amplitudes $\boldsymbol{u}$ but not with respect to the actuators' positions $\boldsymbol{y}$. Therefore, this optimality condition will be necessary but not sufficient.

The cost function can be written explicitly in terms of the control variables as follows:

$$J(\boldsymbol{u},\boldsymbol{y}) = \frac{1}{2}\sum_{k=1}^M |p(w_k)|^2 + \frac{\nu}{2}\|\boldsymbol{u}\|^2 = \frac{1}{2}\sum_{k=1}^M \left| p_0(w_k) + \sum_{i=1}^N u_i G^{y_i}(w_k)\right|^2 + \frac{\nu}{2}\sum_{i=1}^N |u_i|^2.$$

This function is differentiable in $\mathbb{C}^N \times (\Omega\setminus\{w_1,\ldots,w_M\})^N$. Hence, it is well known that if it attains a local minimum in the convex subset $U_{\rm ad}\times Y_{\rm ad}$ at $(\boldsymbol{u}^{\rm op},\boldsymbol{y}^{\rm op})$, then the following inequality holds:

$$DJ(\boldsymbol{u}^{\rm op},\boldsymbol{y}^{\rm op})(\boldsymbol{u}-\boldsymbol{u}^{\rm op},\boldsymbol{y}-\boldsymbol{y}^{\rm op}) \geq 0 \quad \forall (\boldsymbol{u},\boldsymbol{y}) \in U_{\rm ad}\times Y_{\rm ad}.$$

Since J depends on the complex variables $u_1, \ldots, u_N$, some care must be taken to compute its differential. Indeed, by using that

$$D\left(\frac{1}{2}\|\boldsymbol{v}\|^2\right)(\delta\boldsymbol{v}) = \mathrm{Re}(\bar{\boldsymbol{v}}^{\mathrm{t}}\delta\boldsymbol{v}) = \mathrm{Re}(\bar{\delta\boldsymbol{v}}^{\mathrm{t}}\boldsymbol{v}) \quad \forall \boldsymbol{v}, \delta\boldsymbol{v} \in \mathbb{C}^M \text{ or } \mathbb{C}^N,$$

straightforward computations lead to

$$D_{\boldsymbol{u}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{u}) = \mathrm{Re}\left\{\sum_{i=1}^{N}\sum_{k=1}^{M}\left[p(w_k)\frac{\partial\bar{p}(w_k)}{\partial u_i}\,\bar{\delta u_i}\right] + \nu\sum_{i=1}^{N}u_i\bar{\delta u_i}\right\} \tag{7.2}$$

and

$$D_{\boldsymbol{y}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{y}) = \mathrm{Re}\left[\sum_{i=1}^{N}\sum_{k=1}^{M}p(w_k)\nabla_{y_i}\bar{p}(w_k)\cdot\delta y_i\right] \tag{7.3}$$

$\forall(\boldsymbol{u},\boldsymbol{y}) \in U_{\mathrm{ad}} \times Y_{\mathrm{ad}}$, $\forall\delta\boldsymbol{u} \in \mathbb{C}^N$, and $\forall\delta\boldsymbol{y} \in (\mathbb{R}^n)^N$. As a consequence of all this we obtain the optimality condition of the following theorem.

THEOREM 7.1. *If* $(\boldsymbol{u}^{\mathrm{op}}, \boldsymbol{y}^{\mathrm{op}}) \in U_{\mathrm{ad}} \times Y_{\mathrm{ad}}$ *is a solution of the control problem* (7.1)*, then it satisfies*

$$\mathrm{Re}\left\{\sum_{i=1}^{N}\sum_{k=1}^{M}\left[p(w_k)\frac{\partial\bar{p}(w_k)}{\partial u_i}\,(\bar{u}_i - \bar{u}_i^{\mathrm{op}}) + p(w_k)\nabla_{y_i}\bar{p}(w_k)\cdot(y_i - y_i^{\mathrm{op}})\right] + \nu\sum_{i=1}^{N}u_i^{\mathrm{op}}\,(\bar{u}_i - \bar{u}_i^{\mathrm{op}})\right\} \geq 0 \quad \forall(\boldsymbol{u},\boldsymbol{y}) \in U_{\mathrm{ad}} \times Y_{\mathrm{ad}}.$$

Standard duality arguments can be used to compute the gradient of the cost function. To this aim, given $(\boldsymbol{u},\boldsymbol{y}) \in U_{\mathrm{ad}} \times Y_{\mathrm{ad}}$, we recall the *state equation*,

$$\begin{cases} -\Delta p - \left(\dfrac{\omega}{c}\right)^2 p = \displaystyle\sum_{i=1}^{N} u_i\delta_{y_i} & \text{in } \Omega, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = \dfrac{i\omega\rho}{Z(\omega)}\,p & \text{on } \Gamma_{\mathrm{Z}}, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = g & \text{on } \Gamma_{\mathrm{N}}, \end{cases} \tag{7.4}$$

and introduce the *adjoint state equation*,

$$\begin{cases} -\Delta r - \left(\dfrac{\omega}{c}\right)^2 r = \displaystyle\sum_{k=1}^{M} p(w_k)\delta_{w_k} & \text{in } \Omega, \\ \dfrac{\partial r}{\partial \boldsymbol{n}} = -\dfrac{i\omega\rho}{\bar{Z}(\omega)}\,r & \text{on } \Gamma_{\mathrm{Z}}, \\ \dfrac{\partial r}{\partial \boldsymbol{n}} = 0 & \text{on } \Gamma_{\mathrm{N}}, \end{cases} \tag{7.5}$$

with p being the solution of the state equation (7.4). Then we have the following result.

THEOREM 7.2. *Let* $(\boldsymbol{u},\boldsymbol{y}) \in U_{\rm ad} \times Y_{\rm ad}$ *and* $(\delta\boldsymbol{u},\delta\boldsymbol{y}) \in \mathbb{C}^N \times (\mathbb{R}^n)^N$. *Let* p *be the solution of the state equation* (7.4) *and let* r *be the solution of the adjoint state equation* (7.5). *Then*

$$D_{\boldsymbol{u}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{u}) = \mathrm{Re}\left\{\sum_{i=1}^{N}[r(y_i)+\nu u_i]\bar{\delta u}_i\right\}$$

and

$$D_{\boldsymbol{y}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{u}) = \mathrm{Re}\left[\sum_{i=1}^{N}\bar{u}_i\nabla r(y_i)\cdot\delta y_i\right].$$

Proof. Let G^{w_k} be the solution of problem (3.6) with $y = w_k$, $k = 1,\dots,M$. Then

$$r = \sum_{k=1}^{M} p(w_k)\bar{G}^{w_k}.$$

On the other hand, from (5.1), for $w_k \neq y_i$, $i = 1,\dots,N$, $k = 1,\dots,M$,

$$\frac{\partial\bar{p}(w_k)}{\partial u_i} = \frac{\partial}{\partial u_i}\left[\bar{p}_0(w_k) + \sum_{i=1}^{N} u_i\bar{G}^{y_i}(w_k)\right] = \bar{G}^{y_i}(w_k) = \bar{G}^{w_k}(y_i)$$

and

$$\nabla_{y_i}\bar{p}(w_k) = \bar{u}_i\nabla_{y_i}\bar{G}^{y_i}(w_k) = \bar{u}_i\nabla\bar{G}^{w_k}(y_i),$$

where we have used the symmetry of $G^y(w)$ with respect to y and w in Ω.

Consequently, from (7.2) and (7.3) we have

$$\begin{aligned} D_{\boldsymbol{u}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{u}) &= \mathrm{Re}\left\{\sum_{i=1}^{N}\sum_{k=1}^{M}[p(w_k)\bar{G}^{w_k}(y_i)\,\bar{\delta u}_i] + \nu\sum_{i=1}^{N}u_i\bar{\delta u}_i\right\} \\ &= \mathrm{Re}\left\{\sum_{i=1}^{N}[r(y_i)+\nu u_i]\bar{\delta u}_i\right\} \end{aligned}$$

and

$$D_{\boldsymbol{y}}J(\boldsymbol{u},\boldsymbol{y})(\delta\boldsymbol{y}) = \mathrm{Re}\left[\sum_{i=1}^{N}\sum_{k=1}^{M}p(w_k)\bar{u}_i\nabla\bar{G}^{w_k}(y_i)\cdot\delta y_i\right] = \mathrm{Re}\left[\sum_{i=1}^{N}\bar{u}_i\nabla r(y_i)\cdot\delta y_i\right].$$

Thus we conclude the proof. ∎

As a consequence of this theorem, we can write the optimality condition of problem (7.1) in terms of the solution p of the state equation and the solution r of the adjoint state equation. Thus we obtain the following *Euler inequality*:

$$\mathrm{Re}\left(\sum_{i=1}^{N}\{[r(y_i^{\rm op})+\nu u_i^{\rm op}](\bar{u}_i-\bar{u}_i^{\rm op}) + \bar{u}_i^{\rm op}\,\nabla r(y_i^{\rm op})\cdot(y_i-y_i^{\rm op})\}\right) \geq 0$$
$$\forall(\boldsymbol{u},\boldsymbol{y}) \in U_{\rm ad}\times Y_{\rm ad}.$$

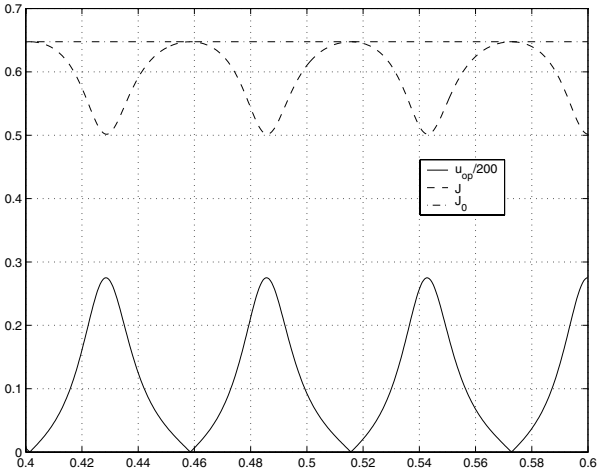

FIG. 7.1. *J and $u_{\rm op}$ as functions of the loudspeaker position* ($\omega = 18700\,\mathrm{s}^{-1}$).

7.2. Numerical experiments. In this section we present two numerical tests. The goal of the first one is to show that many local minima can actually arise. It is a one-dimensional problem, and then the Helmholtz equation becomes

$$\begin{cases} -\dfrac{d^2p}{dx^2} - \left(\dfrac{\omega}{c}\right)^2 p = f, & x \in (a,b), \\ \dfrac{dp}{dx} = \dfrac{i\omega\rho}{Z(\omega)}\, p & \text{at } x = a, \\ \dfrac{dp}{dx} = g & \text{at } x = b. \end{cases}$$

This one-dimensional equation can be easily solved when the secondary source is a linear combination of Dirac delta measures:

$$f = \sum_{i=1}^{N} u_i \delta_{y_i}, \quad u_i \in \mathbb{C},\ y_i \in (a,b),\ i = 1, \ldots, N.$$

Thus, we can determine the corresponding optimal amplitudes and then the optimal value of the cost function.

First, we consider the following data:

- the domain is the segment $[0,1]\,\mathrm{m}$;
- the physical parameters are $\rho = 1\,\mathrm{kg\,m^{-3}}$, $c = 340\,\mathrm{m\,s^{-1}}$, and $\omega = 18700\,\mathrm{s^{-1}}$;
- the amplitude of the primary source is $g = 1\,\mathrm{kg\,m^{-2}\,s^{-2}}$ at $x = 1\,\mathrm{m}$;
- the wall impedance at $x = 0$ is $Z = 34 \times 10^7 + 34 \times 10^3\, i\,\mathrm{kg\,m^{-2}\,s^{-1}}$;
- there is one actuator located at any point in the segment $Y_{\rm ad} = [0.4, 0.6]\,\mathrm{m}$;
- there are 4 sensors at the points $w_1 = 0.15\,\mathrm{m}$, $w_2 = 0.25\,\mathrm{m}$, $w_3 = 0.65\,\mathrm{m}$, and $w_4 = 0.85\,\mathrm{m}$;
- the admissible set of amplitudes is $U_{\rm ad} = \mathbb{C}$ and the weighting factor is $\nu = 0$.

For each position of the actuator in $Y_{\rm ad}$, we compute the optimal amplitude and represent the corresponding value of the cost function. Figure 7.1 shows this function. We observe several local minima. Furthermore, in this case, the values of J at all these minima are the same and correspond to maximum values of the optimal amplitude.

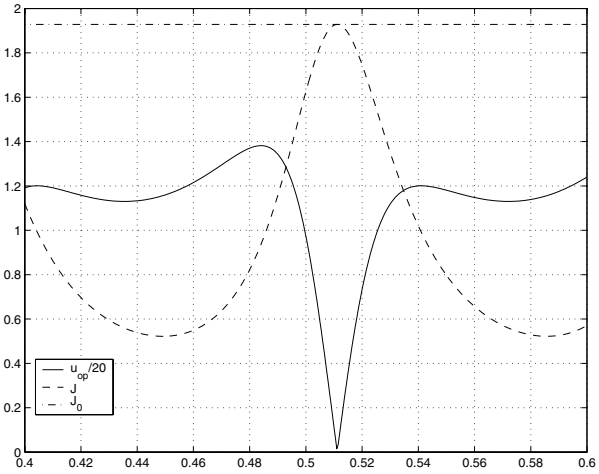

FIG. 7.2. *J and $u_{\rm op}$ as functions of the loudspeaker position* ($\omega = 7820\,\mathrm{s}^{-1}$).

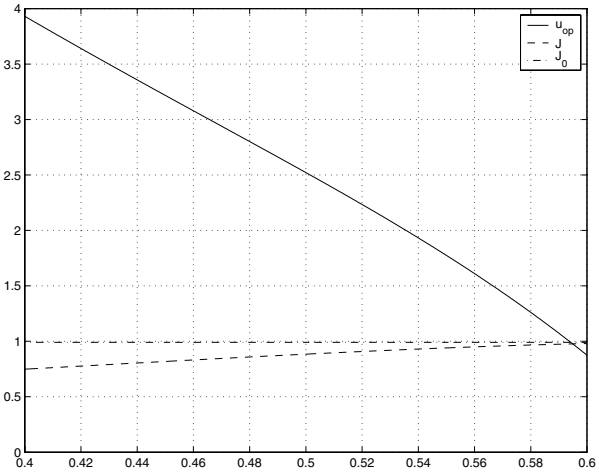

FIG. 7.3. *J and $u_{\rm op}$ as functions of the loudspeaker position* ($\omega = 1700\,\mathrm{s}^{-1}$).

Second, we analyze the system as the angular frequency decreases. Figures 7.2 and 7.3 show similar graphs for $\omega = 7820\,\mathrm{s}^{-1}$ and $\omega = 1700\,\mathrm{s}^{-1}$, respectively.

We observe in Figure 7.2 that the local minima of the cost functional do not necessarily coincide with local maxima of the optimal amplitude.

We also notice that the number of local minima diminishes with the angular frequency. For instance, in the case of Figure 7.3, J has only one minimum in the interval $Y_{\rm ad} = [0.4, 0.6]\,\mathrm{m}$.

Figure 7.4 shows the corresponding graph for the same frequency $\omega = 1700\,\mathrm{s}^{-1}$, when the admissible set of locations for the actuator is the whole domain of the problem: $Y_{\rm ad} = [0, 1]\,\mathrm{m}$. In this case it can be seen that, as expected, complete attenuation is attained as the actuator gets close to the primary source at $x = 1$.

The second test corresponds to a three-dimensional enclosure. We use the simu-

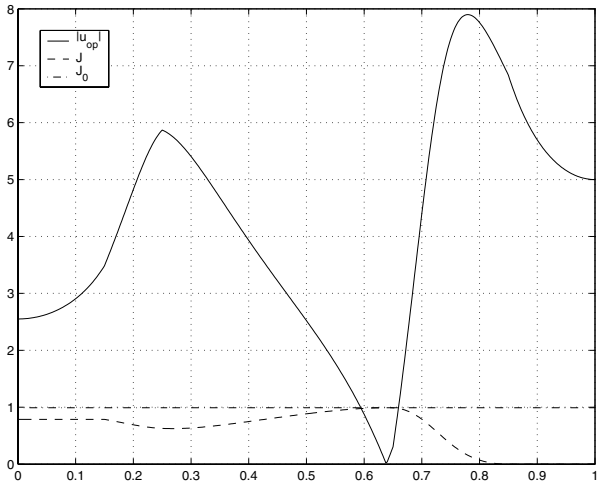

FIG. 7.4. *J and $u_{\rm op}$ as functions of the loudspeaker position* ($\omega = 1700\,\mathrm{s}^{-1}$, $Y_{\rm ad} = [0,1]\,\mathrm{m}$).

lated annealing algorithm (see, for instance, [1]) to determine the optimal location of loudspeakers among a given finite number of feasible ones.

The data of the test are the following:

- domain $\Omega = [0,1]\,\mathrm{m} \times [0,1]\,\mathrm{m} \times [0,1]\,\mathrm{m}$;
- physical parameters $\rho = 1\,\mathrm{kg\,m^{-3}}$, $c = 340\,\mathrm{m\,s^{-1}}$, and $\omega = 1360\,\mathrm{s^{-1}}$;
- wall impedance at $z = 1\,\mathrm{m}$, $Z = (102 + 340\,i) \times 10^3\,\mathrm{kg\,m^{-2}\,s^{-1}}$;
- primary source at wall $z = 0$ with amplitude $g(x,y,0) = \mathrm{e}^{iy}\,\mathrm{kg\,m^{-2}\,s^{-2}}$;
- the rest of the walls are perfectly rigid;
- we have to locate 8 actuators and consider 16 possible locations which are shown in Table 7.1;
- there are 10 sensors and their positions are shown in Table 7.2;
- admissible set of amplitudes $U_{\rm ad} = \mathbb{C}^8$ and weighting factor $\nu = 0$.

We have used a mesh like that of Figure 6.1 for $h = 1/24\,\mathrm{m}$.

The attenuation is computed again by

$$\text{Attenuation (dB)} = -10\log_{10}\left(\frac{J(\boldsymbol{u}^{\rm op},\boldsymbol{y}^{\rm op})}{J(\boldsymbol{0},\boldsymbol{y})}\right).$$

Notice that $J(\boldsymbol{0},\boldsymbol{y})$ is the value of the cost function with no control, and hence it does not depend on $\boldsymbol{y}$. In Table 7.3 we show the attenuation obtained for different executions of the simulated annealing algorithm. We also include the value obtained with the exhaustive search, i.e., by computing the cost function for all of the possible $\binom{16}{8} = 12870$ configurations.

Remark 7.3. Some experiments show that the use of a basis consisting of rigid cavity vibration modes can be more efficient in terms of computer effort (CPU time and memory) than the purely finite element technique introduced in this paper. This is due to the fact that the number of vibration modes needed to obtain accurate results for low frequencies (which is the typical case in active control of sound) is not large. Then the time to calculate these first modes by solving the corresponding eigenvalue problem by finite element methods, together with that to solve the Helmholtz problems in this small vibration modes basis, can be significantly less than the time needed to solve the same number of Helmholtz problem in the large finite element basis. This approach will be reported elsewhere.

Acknowledgments. The authors wish to thank Dr. Pedro Cobo from IAC/CSIC, Madrid, Spain, for very useful discussions.

This work was partially done while R. Rodríguez participated in the program *Computational Challenges in PDEs* at the Newton Institute of the University of Cambridge in June 2003. He is grateful for the support and stimulating atmosphere at the institute.

Last but not least, the authors wish to thank Ricardo Durán and Ricardo Nochetto for very helpful discussions.

A BOGOLYUBOV-TYPE THEOREM WITH A NONCONVEX CONSTRAINT IN BANACH SPACES*

F. S. DE BLASI†, G. PIANIGIANI‡, AND A. A. TOLSTONOGOV§

Abstract. We prove an analogue of the classical Bogolyubov theorem, with a nonconvex constraint. In the case we consider, the constraint is the solution set of a Cauchy problem for a differential inclusion with a nonconvex right-hand side satisfying a Lipschitz condition. Our approach is based on a relaxation argument, as in the Filippov–Wazewski theorem.

Key words. differential inclusion, Banach space, minimization, relaxation

1. Introduction and main result.

In relaxation theory for variational problems, the classical Bogolyubov theorem [3] has been extended in several directions by many authors including Young [16], MacShane [10], Warga [15], Ioffe [7], Ioffe and Tikhomirov [8, 9], and Ekeland and Temam [5]. More recently an analogue of Bogolyubov's theorem with a convex constraint has been obtained by Suslov [12]. The aim of the present paper is to present a Bogolyubov-type theorem in a case in which the constraint is not necessarily convex. In our approach we use a relaxation argument in the spirit of the classical Filippov–Wazewski theorem (see [1, Chap. 2]).

Throughout the paper, I is the unit interval $[0,1]$ with Lebesgue measure μ and σ-algebra Σ of the μ-measurable subsets of I, $\mathbb{E}$ is a separable Banach space with norm $||\cdot||$, and $\mathcal{K}(\mathbb{E})$ is the space of all nonempty compact subsets of $\mathbb{E}$ endowed with the Hausdorff metric h. Further, $\Sigma \otimes \mathcal{B}(\mathbb{E})$ is the σ-algebra of $I \times \mathbb{E}$ generated by the sets $A \times B$, with $A \in \Sigma$ and $B \in \mathcal{B}(\mathbb{E})$, where $\mathcal{B}(\mathbb{E})$ is the σ-algebra of the Borel subsets of $\mathbb{E}$. We set $B(a,r) = \{x \in \mathbb{E} \mid \|x - a\| \le r\}$ and denote by $\overline{\mathbb{R}}$ the set of the extended real numbers.

Let M be a metric space. A multifunction $F : M \to K(\mathbb{E})$ is said to be *upper semicontinuous* (resp., *lower semicontinuous*) if for each closed $C \subset \mathbb{E}$ the set $\{x \in M \mid F(x) \cap C \neq \emptyset\}$ (resp., $\{x \in M \mid F(x) \subset C\}$) is closed in $\mathbb{E}$. F is said to be *continuous* when it is both lower and upper semicontinuous. In our setting, the above definitions are equivalent to the corresponding definitions of upper semicontinuity, lower semicontinuity, and continuity in the sense of Hausdorff. A multifunction $F : C \to K(\mathbb{E})$ with closed values is said to be *measurable* if for each closed set $C \subset \mathbb{E}$ the set $\{t \in I \mid F(t) \cap C \neq \emptyset\} \in \Sigma$.

Given $F : I \times \mathbb{E} \to \mathcal{K}(\mathbb{E})$, consider the Cauchy problem

$$(\mathrm{C}_F) \qquad \dot{x} \in F(t,x), \quad x(0) = x_0,$$

and the convexified Cauchy problem

$$(\mathrm{C}_{\overline{\mathrm{co}}\,F}) \qquad \dot{x} \in \overline{\mathrm{co}}\,F(t,x), \quad x(0) = x_0,$$

where $x_0 \in \mathbb{E}$ and $\overline{\mathrm{co}}\,F(t,x)$ denotes the closed convex hull of $F(t,x)$.

By a *solution* of the Cauchy problem (C_F) (resp., $(\mathrm{C}_{\overline{\mathrm{co}}\,F})$) we mean an absolutely continuous function $x : I \to \mathbb{E}$ given by $x(t) = x_0 + \int_0^t u(s)ds$, where $u : I \to \mathbb{E}$ is Bochner integrable, satisfying the differential inclusion (C_F) (resp., $(\mathrm{C}_{\overline{\mathrm{co}}\,F})$) almost everywhere (a.e.) in I. We denote by $\mathcal{M}_F$ (resp., $\mathcal{M}_{\overline{\mathrm{co}}\,F}$) the solution set of the Cauchy problem (C_F) (resp., $(\mathrm{C}_{\overline{\mathrm{co}}\,F})$). $\mathcal{M}_F$ and $\mathcal{M}_{\overline{\mathrm{co}}\,F}$ are equipped with the induced metric of $C(I,\mathbb{E})$, the Banach space of the continuous functions from I to $\mathbb{E}$.

Let $F : I \times \mathbb{E} \to \mathcal{K}(\mathbb{E})$ and $g : I \times \mathbb{E} \times \mathbb{E} \to \mathbb{R}$ be given. We say that F satisfies condition (H_F) if

$$(\mathrm{H}_F) \qquad \begin{cases} \text{(i) } t \to F(t,x) \text{ is measurable for every } x \in \mathbb{E}, \\ \text{(ii) } h(F(t,x),F(t,y)) \le k(t)\|x-y\| \quad \text{for every } x,y \in \mathbb{E},\ t \in I \text{ a.e.}, \\ \text{(iii) } h(F(t,0),0) \le m(t) \quad \text{for } t \in I \text{ a.e.}, \end{cases}$$

where $m, k \in L^1(I,\mathbb{R})$ and $m(t), k(t) > 0$.

We say that g satisfies condition (H_g) if

$$(\mathrm{H}_g) \qquad \begin{cases} \text{(i) } t \to g(t,x,u) \text{ is measurable for every } x,u \in \mathbb{E}, \\ \text{(ii) } (x,u) \to g(t,x,u) \text{ is continuous for } t \in I \text{ a.e.}, \\ \text{(iii) } |g(t,x,u)| \le a(t) + b(t)||x|| + c||u|| \quad \text{for every } x,y \in \mathbb{E},\ t \in I \text{ a.e.}, \end{cases}$$

where $a, b \in L^1(I,\mathbb{R})$, and $a(t), b(t), c > 0$.

In what follows we will use the following Banach space version, proved in [13], of the classical relaxation theorem of Filippov and Wazewski.

Relaxation theorem. Let F satisfy (H_F). Then $\mathcal{M}_F$ is nonempty, $\mathcal{M}_{\overline{\mathrm{co}}\,F}$ is compact, and

$$\overline{\mathcal{M}}_F = \mathcal{M}_{\overline{\mathrm{co}}\,F}, \tag{1.1}$$

where $\overline{\mathcal{M}}_F$ denotes the closure of $\mathcal{M}_F$ in $C(I,\mathbb{E})$.

For any $f : \mathbb{E} \to \overline{\mathbb{R}}$, we denote by $f^{**} : \mathbb{E} \to \overline{\mathbb{R}}$ the bipolar of f (see [5, Chap. 1]). It is known that if f has an affine continuous minorant, then f^{**} coincides with the upper envelope of all affine continuous minorants of f. Hence f^{**} is lower semicontinuous and convex.

Given $F : I \times \mathbb{E} \to \mathcal{K}(\mathbb{E})$ and $g : I \times \mathbb{E} \times \mathbb{E} \to \mathbb{R}$, we define $g_F : I \times \mathbb{E} \times \mathbb{E} \to \overline{\mathbb{R}}$ by

$$g_F(t,x,u) = \begin{cases} g(t,x,u) & \text{if} \quad u \in F(t,x), \\ +\infty & \text{if} \quad u \notin F(t,x). \end{cases} \tag{1.2}$$

Further, we denote by $u \to g_F^{**}(t,x,u)$ the bipolar of the function $u \to g_F(t,x,u)$.

The following theorem is an analogue of Bogolyubov's theorem [3] with a nonconvex constraint.

THEOREM 1.1. *Let F, g satisfy (H_F) and (H_g). Then, for every $x \in \mathcal{M}_{\overline{\mathrm{co}}F}$, there exists a sequence $\{x_n\} \subset \mathcal{M}_F$ such that*

(i) *x_n converges to x in $C(I,\mathbb{E})$,*

(ii) $\lim_{n\to\infty} \sup_{t\in I} |\int_0^t (g_F^{**}(s,x(s),\dot{x}(s)) - g(s,x_n(s),\dot{x}_n(s)))ds| = 0$.

Observe that when F is merely continuous, both statements of Theorem 1.1 can fail, as is shown by the following example, which is patterned after Plis [11].

Example 1.2. Let $F : \mathbb{R}^2 \to \mathcal{K}(\mathbb{R}^2)$ and $g : \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}$ be given by

$$F(x) = \{(-1, |x_1| + 2\sqrt{|x_2|}), (1, |x_1| + 2\sqrt{|x_2|})\}\ , \qquad g(x,u) = \|x\| + \|u\|,$$

where $x = (x_1, x_2)$, $u = (u_1, u_2)$, and $\|.\|$ is the Euclidean norm. Clearly F satisfies $(\mathrm{H}_F)_{\mathrm{i}}$ and $(\mathrm{H}_F)_{\mathrm{iii}}$ but not $(\mathrm{H}_F)_{\mathrm{ii}}$, while g satisfies (H_g).

As $F(0) = \{p^+, p^-\}$, where $p^+ = (1,0)$, $p^- = (-1,0)$, one has $g_F(0,u) = 1$ if $u \in \{p^+, p^-\}$, while $g_F(0,u) = +\infty$ if $u \notin \{p^+, p^-\}$. Further, $g_F^{**}(0,0) = 1$. In fact, $g_F^{**}(0,0) \geq 1$, for 1 is a minorant of $u \to g_F(0,u)$. On the other hand, $u \to g_F^{**}(0,u)$ is convex, and hence

$$g_F^{**}(0,0) = g_F^{**}\left(0, \frac{p^+ + p^-}{2}\right) \leq \frac{g_F^{**}(0,p^+) + g_F^{**}(0,p^-)}{2} \leq \frac{g_F(0,p^+) + g_F(0,p^-)}{2} = 1,$$

whence $g_F^{**}(0,0) = 1$.

Observe now that the function $x_0 = (0,0)$ is a solution of the convexified Cauchy problem $\dot{x} \in \overline{\mathrm{co}}\ F(x), x(0) = 0$, i.e., $x_0 \in \mathcal{M}_{\overline{\mathrm{co}}F}$. For an arbitrary $x \in \mathcal{M}_F$, $x(t) = (x_1(t), x_2(t))$, $t \in I$, one has $|\dot{x}_1(t)| = 1$ and $\dot{x}_2(t) = |x_1(t)| + 2\sqrt{|x_2(t)|}$ for $t \in I$ a.e., $x_1(0) = x_2(0) = 0$. Since $|x_1(t)| \neq 0$, $t \in I$ a.e., it follows that $x_2(t) \geq t^2$, and thus $||x(t)|| \geq t^2$. Moreover, $\|\dot{x}(t)\| \geq 1$, $t \in I$ a.e., and hence

$$\left|\int_0^t (g(x(s),\dot{x}(s)) - g_F^{**}(0,0))ds\right| = \int_0^t (\|x(s)\| + \|\dot{x}(s)\| - 1)ds \geq \int_0^t \|x(s)\|ds \geq \frac{t^3}{3}\ , \ t \in I.$$

Therefore, for the solution $x_0 \in \mathcal{M}_{\overline{\mathrm{co}}F}$ neither statement of Theorem 1.1 is satisfied.

It is known [14] that the equality (1.1) remains valid if $(\mathrm{H}_F)_{\mathrm{ii}}$ is replaced by

$$h(\overline{\mathrm{co}}\, F(t,x), \overline{\mathrm{co}}\, F(t,y)) \leq k(t)||x - y|| \ \text{ for every } x, y \in \mathbb{E},\ t \in I \text{ a.e.}, \tag{1.3}$$

where $k \in L^1(I, \mathbb{R})$, $k(t) > 0$.

The following example shows that property (ii) in Theorem 1.1 can fail if $H(F)_{\mathrm{ii}}$ is replaced by (1.3).

Example 1.3. Let $F : \mathbb{R} \to \mathcal{K}(\mathbb{R})$ and $g : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be given by

$$F(x) = \begin{cases} \{-1, 1\} & \text{if} \quad x \neq 0, \\ \{-1, -1/2, 1/2, 1\} & \text{if} \quad x = 0, \end{cases} \qquad g(x,u) = |x| + |u|.$$

Here F satisfies $(\mathrm{H}_F)_{\mathrm{i}}$, $(\mathrm{H}_F)_{\mathrm{iii}}$, and (1.3), while g satisfies (H_g), yet (ii) does not hold.

In fact, $x_0 = 0$ is a solution of the convexified Cauchy problem $\dot{x} \in \overline{\mathrm{co}}\ F(x)$, $x(0) = 0$, i.e., $x_0 \in \mathcal{M}_{\overline{\mathrm{co}}F}$. Moreover for every $x \in \mathcal{M}_F$ one has $|\dot{x}(t)| = 1$, $t \in I$ a.e., which implies $g(x(t), \dot{x}(t)) \geq 1$, $t \in I$ a.e. Since in addition $g_F^{**}(0,0) = 1/2$, it follows that

$$\left|\int_0^t (g(x(s),\dot{x}(s)) - g_F^{**}(0,0))ds\right| \geq \frac{t}{2}, \quad t \in I,$$

showing that (ii) cannot be satisfied.

Remark 1.4. Observe that the above Bogolyubov-type Theorem 1.1 is also an extension of the theorem of Filippov and Wazewski.

2. Lemmas. For $f : I \times \mathbb{E} \times \mathbb{E} \to \overline{\mathbb{R}}$ we denote by $\operatorname{epi} f(t,x)$ the *epigraph* of the function $u \to f(t,x,u)$, i.e.,

$$\operatorname{epi} f(t,x) = \{(u,\lambda) \in \mathbb{E} \times \mathbb{R} \mid f(t,x,u) \le \lambda\}.$$

In what follows we consider the Banach space $\mathbb{Y} = \mathbb{E} \times \mathbb{R}$ equipped with the norm $||(x,\lambda)|| = \max(||x||, |\lambda|)$ and denote by $h_{\mathbb{Y}}$ the Hausdorff metric of $\mathcal{K}(\mathbb{Y})$.

For F, g satisfying (H_F), (H_g) define $G : I \times \mathbb{E} \to \mathcal{K}(\mathbb{Y})$ by

$$G(t,x) = \{(u, g(t,x,u)) \in \mathbb{E} \times \mathbb{R} \mid u \in F(t,x)\}. \tag{2.1}$$

LEMMA 2.1. *Let F, g satisfy (H_F), (H_g). Then, for each $x \in \mathbb{E}$ and $t \in I$ a.e. we have*

(i) $(u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)$ *implies* $u \in \overline{\operatorname{co}}\, F(t,x)$,

(ii) $u \in \overline{\operatorname{co}}\, F(t,x)$ *implies* $(u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)$ *for some* $\lambda \in \mathbb{R}$.

Proof. (i) Let $(u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)$, and let $\{\sum_{i=1}^{p_n} \alpha_n^i (u_n^i, \lambda_n^i)\}$, where $\sum_{i=1}^{p_n} \alpha_n^i = 1$, $\alpha_n^i > 0$, be a sequence of convex combinations of points $(u_n^i, \lambda_n^i) \in G(t,x)$, converging to (u,λ). As $u_n^i \in F(t,x)$, one has $\sum_{i=1}^{p_n} \alpha_n^i u_n^i \in \operatorname{co} F(t,x)$, and thus $u \in \overline{\operatorname{co}}\, F(t,x)$.

(ii) Let $u \in \overline{\operatorname{co}}\, F(t,x)$, and let $\{\sum_{i=1}^{p_n} \alpha_n^i u_n^i\}$ be a sequence of convex combinations of points $u_n^i \in F(t,x)$, converging to u. Clearly, $\sum_{i=1}^{p_n} \alpha_n^i (u_n^i, g(t,x,u_n^i)) \in \operatorname{co} G(t,x)$. In view of $(\mathrm{H}_g)_{\mathrm{iii}}$, the sequence $\{\sum_{i=1}^{p_n} \alpha_n^i g(t,x,u_n^i)\}$ is bounded, and thus, passing to a subsequence, one can assume that it converges to some $\lambda \in \mathbb{R}$. Hence $(u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)$, completing the proof.

Property (ii) of the next lemma could be derived from known results on normal integrands (see Castaing and Valadier [4, Chap. 7]), yet a direct proof is provided to make the exposition self-contained.

LEMMA 2.2. *Let F, g satisfy (H_F), (H_g). Then, for each $x \in \mathbb{E}$ and $t \in I$ a.e. we have*

(i) $$g_F^{**}(t,x,u) = \begin{cases} \min\{\lambda \in \mathbb{R} \mid (u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)\} & \text{if} \quad u \in \overline{\operatorname{co}}\, F(t,x), \\ +\infty \quad \text{if} \quad u \notin \overline{\operatorname{co}}\, F(t,x). \end{cases}$$

In particular, $(u, g_F^{**}(t,x,u)) \in \overline{\operatorname{co}}\, G(t,x)$ for every $u \in \overline{\operatorname{co}}\, F(t,x)$. Moreover,

(ii) *for every $\varepsilon > 0$ there is a closed set $I_\varepsilon \subset I$, with $\mu(I \setminus I_\varepsilon) < \varepsilon$, such that $g_F^{**}(t,x,u)$ restricted to $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ is lower semicontinuous.*

Proof. (i) Let $x \in \mathbb{E}$ and $t \in I$ a.e. be arbitrary. By $(\mathrm{H}_g)_{\mathrm{iii}}$ the function $u \to g_F(t,x,u)$ has an affine continuous minorant and hence by [5, Chap. 1],

$$\operatorname{epi} g_F^{**}(t,x) = \overline{\operatorname{co}}\, \operatorname{epi} g_F(t,x). \tag{2.2}$$

Let $u \in \mathbb{E}$ and suppose $g_F^{**}(t,x,u) < +\infty$. As $(u, g_F^{**}(t,x,u)) \in \operatorname{epi} g_F^{**}(t,x)$, then, by (2.2), there exists a sequence of convex combinations $\sum_{i=1}^{p_n} \alpha_n^i (u_n^i, \lambda_n^i)$ of points $(u_n^i, \lambda_n^i) \in \operatorname{epi} g_F(t,x)$, converging to $(u, g_F^{**}(t,x,u))$. Clearly $u_n^i \in F(t,x)$, for $g_F(t,x,u_n^i) \le \lambda_n^i < +\infty$, and thus $u \in \overline{\operatorname{co}}\, F(t,x)$. Consequently, $g_F^{**}(t,x,u) = +\infty$ for every $u \notin \overline{\operatorname{co}}\, F(t,x)$.

Let $u \in \overline{\operatorname{co}}\, F(t,x)$, and set

$$\mu = \min\{\lambda \in \mathbb{R} \mid (u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)\}. \tag{2.3}$$

By virtue of Lemma 2.1(ii) and the compactness of $\overline{\operatorname{co}}\, G(t,x)$, the definition of μ is meaningful. We have $g_F^{**}(t,x,u) = \mu$. To show this, take any $\lambda \in \mathbb{R}$ so that $(u,\lambda) \in \overline{\operatorname{co}}\, G(t,x)$, and consider a sequence of convex combinations $\sum_{i=1}^{p_n} \alpha_n^i (u_n^i, \lambda_n^i)$ of points $(u_n^i, \lambda_n^i) \in G(t,x)$, where $\lambda_n^i = g(t,x,u_n^i)$, converging to (u,λ). As $u_n^i \in F(t,x)$,

one has $\lambda_n^i = g_F(t,x,u_n^i) \geq g_F^{**}(t,x,u_n^i)$. Thus, $\sum_{i=1}^{p_n} \alpha_n^i \lambda_n^i \geq \sum_{i=1}^{p_n} \alpha_n^i g_F^{**}(t,x,u_n^i)$, which implies $\lambda \geq g_F^{**}(t,x,u)$, by the convexity of $g_F^{**}(t,x,u)$ with respect to u. As $(u,\lambda) \in \overline{\mathrm{co}}\, G(t,x)$ and λ is arbitrary, it follows that $\mu \geq g_F^{**}(t,x,u)$.

On the other hand, $(u, g_F^{**}(t,x,u)) \in \operatorname{epi} g_F^{**}(t,x)$ and hence, by (2.2), there exists a sequence of convex combinations $\sum_{i=1}^{p_n} \alpha_n^i (u_n^i, \lambda_n^i)$ of points $(u_n^i, \lambda_n^i) \in \operatorname{epi} g_F(t,x)$, converging to $(u, g_F^{**}(t,x,u))$. Clearly, $+\infty > \lambda_n^i \geq g_F(t,x,u_n^i) = g(t,x,u_n^i)$ and $u_n^i \in F(t,x)$, whence $\sum_{i=1}^{p_n} \alpha_n^i \lambda_n^i \geq \sum_{i=1}^{p_n} \alpha_n^i g(t,x,u_n^i)$. Thus, setting $\gamma = \liminf_{n\to\infty} \sum_{i=1}^{p_n} \alpha_n^i g(t,x,u_n^i)$, one obtains $g_F^{**}(t,x,u) \geq \gamma$. Furthermore, $(u_n^i, g(t,x,u_n^i)) \in G(t,x)$, which implies that $(\sum_{i=1}^{p_n} \alpha_n^i u_n^i, \sum_{i=1}^{p_n} \alpha_n^i g(t,x,u_n^i)) \in \mathrm{co} G(t,x)$, and hence $(u,\gamma) \in \overline{\mathrm{co}}\, G(t,x)$. Then, by (2.3), $\gamma \geq \mu$ and, a fortiori, $g_F^{**}(t,x,u) \geq \mu$. Therefore $g_F^{**}(t,x,u) = \mu$, and (i) is proved.

(ii). Let $\varepsilon > 0$. F, g satisfy (H_F) and (H_g), and thus, by [6], there is a closed set $I_\varepsilon \subset I$, with $\mu(I \setminus I_\varepsilon) < \varepsilon$, such that the restrictions of $F(t,x)$ and $g(t,x,u)$ to $I_\varepsilon \times \mathbb{E}$ and $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ are both continuous. Without loss of generality, the restrictions to I_ε of the functions $k(t), m(t), a(t), b(t)$ can also be supposed to be continuous. For every closed $V \subset I \times \mathbb{R}$ the set $Z = \{(t,x) \in I_\epsilon \times \mathbb{E} \mid G(t,x) \cap V \neq \emptyset\}$ is closed. To show this, consider any sequence of points $(t_n, x_n) \in Z$ converging to $(t,x) \in I_\epsilon \times \mathbb{E}$, and take, for each $n \in \mathbb{N}$, a point $(u_n, g(t_n,x_n,u_n)) \in G(t_n,x_n) \cap V$. As $u_n \in F(t_n,x_n)$ and $F(t_n,x_n)$ converges to $F(t,x)$, a compact set, there exists a subsequence, say $\{u_n\}$, which converges to some $u \in F(t,x)$. Thus $(u, g(t,x,u)) \in G(t,x) \cap V$, and thus the set Z is closed, which proves that $G(t,x)$, and so also $\overline{\mathrm{co}}\, G(t,x)$, restricted to $I_\epsilon \times \mathbb{E}$, are upper semicontinuous.

The function $g_F^{**}(t,x,u)$ restricted to $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ is lower semicontinuous. It suffices to show that, for every $(t,x,u) \in I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ and any sequence $\{(t_n,x_n,u_n)\} \subset I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ converging to (t,x,u), one has

$$g_F^{**}(t,x,u) \leq \lambda, \quad \text{where} \quad \lambda = \liminf_{n\to\infty} g_F^{**}(t_n,x_n,u_n). \tag{2.4}$$

Suppose $\lambda < +\infty$ (the case $\lambda = +\infty$ is trivial). By virtue of $(\mathrm{H}_g)_{\mathrm{iii}}$, there exists $M \in \mathbb{R}$ such that for all $n \in \mathbb{N}$ large enough one has $g(t_n,x_n,u_n) \geq M$, which implies $g_F^{**}(t_n,x_n,u_n) \geq M$, and so $\lambda > -\infty$. As λ is finite, passing to a subsequence (without changing notation) one can assume that each $g_F^{**}(t_n,x_n,u_n)$ is finite, whence by (i), $u_n \in \overline{\mathrm{co}}\, F(t_n,x_n)$, and thus $(u_n, g_F^{**}(t,x_n,u_n)) \in \overline{\mathrm{co}}\, G(t_n,x_n)$ for all $n \in \mathbb{N}$. Since the map $\overline{\mathrm{co}}\, G(t,x)$ restricted to $I_\varepsilon \times \mathbb{E}$ is upper semicontinuous, it follows that $(u,\lambda) \in \overline{\mathrm{co}}\, G(t,x)$. Then, by the definition of $g_F^{**}(t,x,u)$, (2.4) holds; that is, the function $g_F^{**}(t,x,u)$ restricted to $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ is lower semicontinuous, proving (ii). This completes the proof.

Remark 2.3. By Lemma 2.2(ii) it follows that, for each $x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}$ and any measurable selector $u(t) \in \overline{\mathrm{co}}\, F(t,x(t))$, the function $t \to g_F^{**}(t,x(t),u(t))$ is measurable on I.

LEMMA 2.4. *Let F satisfy (H_F), and let g satisfy $(\mathrm{H}_g)_{\mathrm{i}}$, $(\mathrm{H}_g)_{\mathrm{iii}}$, and*

$$|g(t,x,u) - g(t,y,v)| \leq l(||x-y|| + ||u-v||) \quad \textit{for every } x,y,u,v \in \mathbb{E},\ \ t \in I \textit{ a.e.}, \tag{2.5}$$

where $l > 0$. Then the multifunction $G : I \times \mathbb{E} \to \mathcal{K}(\mathbb{Y})$ given by (2.1) *has the following properties:*

(i) *the map $t \to G(t,x)$ is measurable for every $x \in \mathbb{E}$,*
(ii) *$h_{\mathbb{Y}}(G(t,x),G(t,y)) \leq L(t)||x-y||$ for every $x,y, \in \mathbb{E},\ t \in I$ a.e.,*
(iii) *$h_{\mathbb{Y}}(G(t,0),0) \leq M(t),\ t \in I$ a.e.,*

where $L, M \in L^1(I, \mathbb{R})$ *and* $L(t), M(t) > 0$.

Proof. As in the proof of Lemma 2.2, for each $\varepsilon > 0$ there is a closed set $I_\varepsilon \subset I$, with $\mu(I \setminus I_\varepsilon) < \varepsilon$, such that the map $G(t,x)$ restricted to $I_\varepsilon \times \mathbb{E}$ is continuous. Hence the map $t \to G(t,x)$ is measurable for every $x \in \mathbb{E}$, proving (i). To show (ii), take $x, y \in \mathbb{E}$, $t \in I$ a.e. By virtue of $(\mathrm{H}_F)_{\mathrm{ii}}$, for each $u \in F(t,x)$ there exists $v \in F(t,y)$ such that $||u-v|| \le k(t)||x-y||$. Moreover, by (2.1), $(u, g(t,x,u)) \in G(t,x)$ and $(v, g(t,y,v)) \in G(t,y)$, and thus, in view of (2.5), $|g(t,x,u) - g(t,y,v)| \le l(1 + k(t))||x-y||$. Consequently,

$$G(t,x) \subset G(t,y) + L(t)||x-y||B,$$

where B is the closed unit ball in $\mathbb{Y}$ and $L(t) = \max\{k(t), l(1+k(t))\}$. By changing the role of x and y, (ii) follows. In view of $(\mathrm{H}_F)_{\mathrm{iii}}$, $||u|| \le m(t)$ for every $u \in F(t,0)$. Further, $(\mathrm{H}_g)_{\mathrm{iii}}$ implies $|g(t,0,u)| \le a(t) + cm(t)$. Hence, setting $M(t) = \max\{m(t), a(t) + cm(t)\}$, (iii) is also satisfied, completing the proof.

3. Proof of Theorem 1.1. We will first construct a convenient Lipschitzean ε-approximation φ of g. For $t \in I$ set $U(t) = \{x(t) \mid x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}\}$. Since $\mathcal{M}_{\overline{\mathrm{co}}\, F}$ is compact in $C(I, \mathbb{E})$, using the Ascoli–Arzelà theorem, one can show that the function $t \to U(t)$ is continuous from I to $\mathcal{K}(\mathbb{E})$, and the set $A = \cup_{t \in I} U(t)$ is compact in $\mathbb{E}$. By virtue of [6], for every $\varepsilon > 0$ there exists a closed set $I_\varepsilon \subset I$, with $\mu(I \setminus I_\varepsilon) < \varepsilon$, such that the restriction of $F(t,x)$ to $I_\varepsilon \times \mathbb{E}$ is continuous. A is compact, and thus the maps $F(t, \overline{\mathrm{co}}\, A)$ and $\overline{\mathrm{co}}\, F(t, \overline{\mathrm{co}}\, A)$, restricted to I_ε, are both compact valued and continuous; moreover, $\overline{\mathrm{co}}\, F(t, \overline{\mathrm{co}}\, A)$ is measurable on I.

Let $x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}$ be arbitrary. Take $R > 0$ so that $A \subset B(0,R)$. In view of $(\mathrm{H}_F)_{\mathrm{ii}}$ and $(\mathrm{H}_F)_{\mathrm{iii}}$, for $u \in \overline{\mathrm{co}}\, F(t, x(t))$ and $t \in I$ a.e. one has $F(t, x(t)) \subset B(0, m(t) + Rk(t))$. From the latter and $(\mathrm{H}_g)_{\mathrm{iii}}$ it follows that

$$|g(t, x(t), u)| \le M(t) \quad \text{for every } u \in \overline{\mathrm{co}}\, F(t, x(t)),\ t \in I \text{ a.e.}, \tag{3.1}$$

where the function $M(t) = a(t) + Rb(t) + c(m(t) + Rk(t))$ is in $L^1(I, \mathbb{R})$.

Moreover, $-M(t) \le g_F^{**}(t, x(t), u)$ for all $u \in \mathbb{E}$, $t \in I$ a.e., since $-M(t)$ is a minorant of $u \to g_F(t, x(t), u)$. On the other hand, as $u \to g_F^{**}(t, x(t), u)$ is convex, lower semicontinuous, and $g_F^{**}(t, x(t), u) \le g_F(t, x(t), u) = g(t, x(t), u) \le M(t)$ for all $u \in F(t, x(t))$, $t \in I$ a.e., it follows that $g_F^{**}(t, x(t), u) \le M(t)$ for all $u \in \overline{\mathrm{co}}\, F(t, x(t))$, $t \in I$ a.e. Therefore

$$|g_F^{**}(t, x(t), u)| \le M(t) \ \text{ for all } u \in \overline{\mathrm{co}}\, F(t, x(t)),\ t \in I \ \text{ a.e.} \tag{3.2}$$

Let $\epsilon > 0$. By virtue of [6], (3.1), and (3.2), there exists a closed set $I_\varepsilon \subset I$ such that the map $t \to \overline{\mathrm{co}}\, F(t, \overline{\mathrm{co}}\, A)$ restricted to I_ε is continuous, g restricted to $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ is continuous, and furthermore

$$\int_{I \setminus I_\varepsilon} |g(t, x(t), \dot{x}(t))| dt \le \frac{\varepsilon}{5}, \quad \int_{I \setminus I_\varepsilon} |g_F^{**}(t, x(t), \dot{x}(t))| dt \le \frac{\varepsilon}{5} \quad \text{for all } x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}. \tag{3.3}$$

By Tietze's extension theorem the function g restricted to $I_\varepsilon \times \mathbb{E} \times \mathbb{E}$ admits a continuous extension, say $\overline{g}$, to all of $I \times \mathbb{E} \times \mathbb{E}$. Set $B = \cup_{t \in I_\varepsilon} \overline{\mathrm{co}}\, F(t, \overline{\mathrm{co}}\, A)$ and observe that B is compact. Let $\overline{g}_\varepsilon : I \times \overline{\mathrm{co}}\, A \times \overline{\mathrm{co}}\, B \to \mathbb{R}$ be a locally Lipschitzean function satisfying

$$|\overline{g}_\varepsilon(t,x,u) - \overline{g}(t,x,u)| \le \frac{\varepsilon}{5} \quad \text{for all } (t,x,u) \in I \times \overline{\mathrm{co}}\, A \times \overline{\mathrm{co}}\, B.$$

Since $\overline{g}_\varepsilon$ is defined on a compact convex set, $\overline{g}_\varepsilon$ is actually Lipschitzean. Hence, by the MacShane lemma [5, p. 276], $\overline{g}_\varepsilon$ admits a bounded Lipschitzean extension g_ε (with the same Lipschitz constant) to the whole space $I \times \mathbb{E} \times \mathbb{E}$.

Define $\varphi : I \times \mathbb{E} \times \mathbb{E} \to \mathbb{R}$ by

$$\varphi(t,x,u) = \begin{cases} g_\varepsilon(t,x,u) & \text{if } t \in I_\epsilon, \\ 0 & \text{if } t \in I \backslash I_\varepsilon. \end{cases} \tag{3.4}$$

It is easily seen that φ satisfies $(\mathrm{H}_g)_{\mathrm{i}}$, $(\mathrm{H}_g)_{\mathrm{iii}}$ and (2.5) (with different $a(t), b(t), c, l$); moreover,

$$|\varphi(t,x,u) - g(t,x,u)| \le \frac{\varepsilon}{5} \qquad \text{for all} \quad (t,x,u) \in I_\varepsilon \times \overline{\mathrm{co}}\, A \times \overline{\mathrm{co}}\, B. \tag{3.5}$$

Consider now the function φ_F given by (1.2), with φ in place of g. Then,

$$\varphi_F(t,x,u) - \frac{\varepsilon}{5} \le g_F(t,x,u) \le \varphi_F(t,x,u) + \frac{\varepsilon}{5} \qquad \text{for all } (t,x,u) \in I_\varepsilon \times \overline{\mathrm{co}}\, A \times \overline{\mathrm{co}}\, B. \tag{3.6}$$

In fact, let $(t,x) \in I_\epsilon \times \overline{\mathrm{co}}\, A$. If $u \in F(t,x)$, then $u \in \overline{\mathrm{co}}\, B$, and thus (3.6) follows from (3.5) as $g_F(t,x,u) = g(t,x,u)$ and $\varphi_F(t,x,u) = \varphi(t,x,u)$. If $u \notin F(t,x)$, then $\varphi_F(t,x,u) = g_F(t,x,u) = +\infty$, and hence (3.6) holds trivially. From (3.6) one has

$$\varphi_F^{**}(t,x,u) - \frac{\varepsilon}{5} \le g_F^{**}(t,x,u) \le \varphi_F^{**}(t,x,u) + \frac{\varepsilon}{5} \qquad \text{for all } (t,x,u) \in I_\varepsilon \times \overline{\mathrm{co}}\, A \times \mathbb{E}.$$

Observe that if $u \in \overline{\mathrm{co}}\, F(t,x)$, then $\varphi_F^{**}(t,x,u)$ and $g_F^{**}(t,x,u)$ are both finite by Lemma 2.2(i), and hence

$$|\varphi_F^{**}(t,x,u) - g_F^{**}(t,x,u)| \le \frac{\varepsilon}{5} \qquad \text{for all } t \in I_\varepsilon,\ x \in \overline{\mathrm{co}}\, A,\ u \in \overline{\mathrm{co}}\, F(t,x). \tag{3.7}$$

Furthermore,

$$\varphi_F^{**}(t,x,u) = 0 \quad \text{for } t \in I \setminus I_\varepsilon,\ x \in E,\ u \in \overline{\mathrm{co}}\, F(t,x). \tag{3.8}$$

In fact, $\varphi_F^{**}(t,x,u) \ge 0$ for all $u \in E$, as 0 is a minorant of $u \to \varphi_F(t,x,u)$. On the other hand, since $u \to \varphi_F^{**}(t,x,u)$ is convex, lower semicontinuous, and $\varphi_F^{**}(t,x,u) \le \varphi_F(t,x,u) = \varphi(t,x,u) = 0$ for all $u \in F(t,x)$, it follows that $\varphi_F^{**}(t,x,u) \le 0$, and thus (3.8) holds.

In view of (3.5), (3.4), (3.3) and (3.7), (3.8), (3.3), for each $x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}$ one has

$$\int_I |\varphi(t,x(t),\dot{x}(t)) - g(t,x(t),\dot{x}(t))|dt \tag{3.9}$$

$$\le \int_{I_\epsilon} |\varphi(t,x(t),\dot{x}(t)) - g(t,x(t),\dot{x}(t))|dt + \int_{I \setminus I_\epsilon} |g(t,x(t),\dot{x}(t))|dt \le \frac{2\varepsilon}{5}$$

and

$$\int_I |\varphi_F^{**}(t,x(t),\dot{x}(t)) - g_F^{**}(t,x(t),\dot{x}(t))|dt \tag{3.10}$$

$$\le \int_{I_\epsilon} |\varphi_F^{**}(t,x(t),\dot{x}(t)) - g_F^{**}(t,x(t),\dot{x}(t))|dt + \int_{I \setminus I_\epsilon} |g_F^{**}(t,x(t),\dot{x}(t))|dt \le \frac{2\varepsilon}{5}.$$

Consider now the Cauchy problem

$$\begin{cases} \dot{x}(t) \in F(t, x(t)), \ \ x(0) = x_0, \\ \dot{\lambda}(t) = \varphi(t, x(t), \dot{x}(t)), \ \ \lambda(0) = 0. \end{cases}$$

Let $G : I \times \mathbb{E} \to \mathcal{K}(\mathbb{Y})$ be the multifunction given by (2.1), with φ in place of g, and set $z = (x, \lambda) \in \mathbb{Y}$. Then the previous Cauchy problem and the corresponding convexified problem can be written in the form

$$\begin{aligned} \dot{z}(t) &\in G(t, x(t)), \ \ z(0) = (x_0, 0), \\ \dot{z}(t) &\in \overline{\text{co}}\, G(t, x(t)), \ \ z(0) = (x_0, 0). \end{aligned}$$

Denote by $\mathcal{M}_G$, $\mathcal{M}_{\overline{\text{co}}\, G}$ the solution sets of the above Cauchy problems. In view of Lemma 2.4, the map $G(t, x)$ satisfies (i)–(iii) and thus, by the relaxation theorem, $\mathcal{M}_{\overline{\text{co}}\, G}$ is nonempty and compact and

$$\overline{\mathcal{M}}_G = \mathcal{M}_{\overline{\text{co}}\, G}. \tag{3.11}$$

Let $x \in \mathcal{M}_{\overline{\text{co}}\, F}$ be arbitrary, and set $v(t) = \int_0^t \varphi_F^{**}(s, x(s), \dot{x}(s))ds, \ t \in I$. Since $\dot{x}(t) \in \overline{\text{co}}\, F(t, x(t)), \ t \in I$ a.e., Lemma 2.2(i) implies that $(\dot{x}(t), \dot{v}(t)) \in \overline{\text{co}}\, G(t, x(t)), \ t \in I$ a.e., and hence $(x, v) \in \mathcal{M}_{\overline{\text{co}}\, G}$. By (3.11) there exists $(y, w) \in \mathcal{M}_G$ such that $\|(x, v) - (y, w)\| < \varepsilon/5$. Thus $y \in \mathcal{M}_F$, by Lemma 2.1(i); moreover, $w(t) = \int_0^t \varphi(s, y(s), \dot{y}(s))ds$ and

$$\sup_{t \in I} ||x(t) - y(t)|| \le \frac{\varepsilon}{5}, \qquad \sup_{t \in I} \left| \int_0^t (\varphi_F^{**}(s, x(s), \dot{x}(s)) - \varphi(s, y(s), \dot{y}(s)))ds \right| \le \frac{\varepsilon}{5}. \tag{3.12}$$

Since, for each $t \in I$,

$$\left| \int_0^t (g_F^{**}(s, x(s), \dot{x}(s)) - g(s, y(s), \dot{y}(s)))ds \right| \le \int_I |g_F^{**}(s, x(s), \dot{x}(s)) - \varphi_F^{**}(s, x(s), \dot{x}(s))|ds$$

$$+ \sup_{t \in I} \left| \int_0^t (\varphi_F^{**}(s, x(s), \dot{x}(s)) - \varphi(s, y(s), \dot{y}(s)))ds \right| + \int_I |\varphi(s, y(s), \dot{y}(s)) - g(s, y(s), \dot{y}(s))|ds,$$

then, by virtue of (3.10), (3.12), and (3.9), as $t \in I$ is arbitrary, it follows that

$$\sup_{t \in I} \left| \int_0^t (g_F^{**}(s, x(s), \dot{x}(s)) - g(s, y(s), \dot{y}(s)))ds \right| \le \varepsilon.$$

Thus, setting $\epsilon = 1/n$, $\varphi_n = \varphi$, and $y = x_n$, one obtains a sequence $\{x_n\} \subset \mathcal{M}_F$ for which (i) and (ii) are satisfied. This completes the proof.

4. An application. We present an application of the previous result. In what follows, $\mathbb{E}$ is a separable reflexive Banach space. Consider the minimization problem

$$\text{(P)} \qquad \text{minimize} \int_I g(t, x(t), \dot{x}(t))dt \quad \text{for } x \in \mathcal{M}_F,$$

and associate with (P) the relaxed minimization problem

$$\text{(P}^{**}\text{)} \qquad \text{minimize} \int_I g_F^{**}(t, x(t), \dot{x}(t))dt \quad \text{for } \ x \in \mathcal{M}_{\overline{\text{co}}\, F}.$$

THEOREM 4.1. *Let F, g satisfy* (H_F), (H_g). *Then,*

$$\min(\mathrm{P}^{**}) = \inf(\mathrm{P}). \tag{4.1}$$

Furthermore, for each solution x of problem (P^{**}), *there exists a minimizing sequence* $\{x_n\}$ *of problem* (P) *such that*

(i) x_n *converges to x in* $C(I,E)$,

(ii) $\lim_{n\to\infty} \sup_{t\in I} | \int_0^t (g_F^{**}(s,x(s),\dot{x}(s)) - g(s,x_n(s),\dot{x}_n(s)))ds| = 0$.

Conversely, if $\{x_n\}$ *is a minimizing sequence of problem* (P), *then there exists a subsequence* $\{x_{n_k}\}$ *and a solution x of problem* (P^{**}) *so that* (i) *and* (ii) *are satisfied.*

Proof. Set $A = \{x(t) \mid t \in I, x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}\}$. As was shown in the proof of Theorem 1.1, the set A is compact in $\mathbb{E}$. Define $\varphi : I \times \mathbb{E} \times \mathbb{E} \to \overline{\mathbb{R}}$ by

$$\varphi(t,x,u) = \begin{cases} g_F^{**}(t,x,u), & t \in I,\ x \in A,\ u \in \mathbb{E}, \\ +\infty & \text{elsewhere.} \end{cases} \tag{4.2}$$

By Lemma 2.2(ii), there exists a sequence of closed sets $I_n \subset I_{n+1} \subset I$ with $\mu(I \setminus I_n) < 1/n$, $n \in \mathbb{N}$, such that the function $g_F^{**}(t,x,u)$ restricted to $I_n \times \mathbb{E} \times \mathbb{E}$ is lower semicontinuous. As $\varphi(t,x,u)$ equals $g_F^{**}(t,x,u)$ on the closed set $I_n \times A \times \mathbb{E}$, while $\varphi(t,x,u) = +\infty$ on $I_n \times (\mathbb{E} \setminus A) \times \mathbb{E}$, the function $\varphi(t,x,u)$ restricted to $I_n \times \mathbb{E} \times \mathbb{E}$ is lower semicontinuous. Moreover, $J = I \setminus \cup_{n=1}^{\infty} I_n$ is a Borel set, whence the function $\tilde{\varphi} : I \times \mathbb{E} \times \mathbb{E} \to \overline{\mathbb{R}}$ given by

$$\tilde{\varphi}(t,x,u) = \begin{cases} \varphi(t,x,u), & t \in J,\ x \in \mathbb{E},\ u \in \mathbb{E}, \\ 0 & \text{elsewhere} \end{cases}$$

is Borel and thus $\Sigma \otimes \mathcal{B}(\mathbb{E} \times \mathbb{E})$ measurable. Therefore, $\varphi(t,x,u) = \tilde{\varphi}(t,x,u)$ for all $x, u \in \mathbb{E}$ and $t \in I$ a.e., for $\mu(I \setminus J) = 0$. Thus, without loss of generality, we can assume that $\varphi(t,x,u)$ is $\Sigma \otimes \mathcal{B}(\mathbb{E} \times \mathbb{E})$ measurable. Moreover, the function $u \to \varphi(t,x,u)$ is convex. Thanks to $(\mathrm{H}_F)_{\mathrm{ii}}$, $(\mathrm{H}_F)_{\mathrm{iii}}$, $(\mathrm{H}_g)_{\mathrm{iii}}$, the inequality (2.3) in [2] is satisfied, and so $\varphi(t,x,u)$ meets all assumptions of Theorem 2.1 in [2].

Consider now the integral functional $J_\varphi : C(I,\mathbb{E}) \times L^1(I,\mathbb{E}) \to \overline{\mathbb{R}}$ defined by

$$J_\varphi(x,u) = \int_I \varphi(t,x(t),u(t))dt,$$

where the space $L^1(I,\mathbb{E})$ is endowed with the weak topology $\sigma(L^1, L^\infty)$. By Theorem 2.1 in [2], the functional $(x,u) \to J_\varphi(x,u)$ is sequentially lower semicontinuous on $C(I,\mathbb{E}) \times L^1(I,\mathbb{E})$. As $\mathcal{R}_{\overline{\mathrm{co}}\, F} = \{(x,\dot{x}) \mid x \in \mathcal{M}_{\overline{\mathrm{co}}\, F}\}$ is a metrizable compact subset of $C(I,\mathbb{E}) \times L^1(I,\mathbb{E})$, the functional $J_\varphi(x,u)$ has a minimum on $\mathcal{R}_{\overline{\mathrm{co}}\, F}$; i.e., there exists $(x,\dot{x}) \in \mathcal{R}_{\overline{\mathrm{co}}\, F}$ such that

$$\int_I \varphi(t,x(t),\dot{x}(t))dt = \min\{J_\varphi(y,\dot{y}) \mid (y,\dot{y}) \in \mathcal{R}_{\overline{\mathrm{co}}\, F}\}.$$

Then, by (4.2),

$$\int_I g_F^{**}(t,x(t),\dot{x}(t))dt = \min(\mathrm{P}^{**}),$$

and hence problem (P^{**}) has a solution.

As $x \in \mathcal{M}_{\overline{\text{co}}\, F}$, then, by Theorem 1.1, there exists a sequence $\{x_n\} \subset \mathcal{M}_F$ satisfying (i), (ii). By (ii),

$$\lim_{n\to\infty} \int_I g(t, x_n(t), \dot{x}_n(t))dt = \int_I g_F^{**}(t, x(t), \dot{x}(t))dt,$$

and thus $\inf(\mathrm{P}) \leq \min(\mathrm{P}^{**})$. Furthermore, for each $x \in \mathcal{M}_F$, one has $g(t, x(t), \dot{x}(t)) = g_F(t, x(t), \dot{x}(t)) \geq g_F^{**}(t, x(t), \dot{x}(t))$ for $t \in I$ a.e., which implies $\inf(\mathrm{P}) \geq \min(\mathrm{P}^{**})$. Therefore (4.1) holds, and $\{x_n\}$ is actually a minimizing sequence of problem (P).

Let $\{x_n\} \subset \mathcal{M}_F$ be a minimizing sequence of problem (P). Then $(x_n, v_n) \in \mathcal{M}_G$, $n \in \mathbb{N}$, where $v_n(t) = \int_0^t g(s, x_n(s), \dot{x}_n(s))ds$ and G is given by (2.1). As $\mathcal{M}_{\overline{\text{co}}\, G}$ is compact in $C(I, \mathbb{Y})$, there exists a subsequence $\{(x_{n_k}, v_{n_k})\}$ which converges to some $(x, v) \in \mathcal{M}_{\overline{\text{co}}\, G}$, where $x \in \mathcal{M}_{\overline{\text{co}}\, F}$ by Lemma 2.1(i). Since $\{x_{n_k}\}$ is a minimizing sequence of problem (P), $\min(\mathrm{P}^{**}) = \inf(\mathrm{P})$ and, by Lemma 2.2(i), $g_F^{**}(t, x(t), \dot{x}(t)) \leq \dot{v}(t),\ t \in I$ a.e., then one has

$$\lim_{k\to\infty} \int_I g(t, x_{n_k}(t), \dot{x}_{n_k}(t))dt = \min(\mathrm{P}^{**}) \leq \int_I g_F^{**}(t, x(t), \dot{x}(t))dt \leq \int_I \dot{v}(t)dt.$$

However, v_{n_k} converges to v in $C(I, \mathbb{R})$, and thus the first and the last terms in the above expression are equal. Consequently,

$$\min(\mathrm{P}^{**}) = \int_I g_F^{**}(t, x(t), \dot{x}(t))dt.$$

Moreover, $g_F^{**}(t, x(t), \dot{x}(t)) = \dot{v}(t),\ t \in I$ a.e., and thus $\int_0^t g(s, x_{n_k}(s), \dot{x}_{n_k}(s))ds$ converges to $\int_0^t g_F^{**}(s, x(s), \dot{x}(s))ds$ in $C(I, \mathbb{R})$. Therefore x is a solution of problem (P^{**}) and (ii) is satisfied (with x_{n_k} in place of x_n). As (i) also holds, the proof is complete.

Remark 4.2. A similar result was obtained in [14, Appendix] under the assumption that the function $(x, u) \to g(t, x, u)$ is Lipschitzean.

HESSIAN RIEMANNIAN GRADIENT FLOWS IN CONVEX PROGRAMMING*

FELIPE ALVAREZ†, JÉRÔME BOLTE‡, AND OLIVIER BRAHIC§

Abstract. In view of solving theoretically constrained minimization problems, we investigate the properties of the gradient flows with respect to Hessian Riemannian metrics induced by Legendre functions. The first result characterizes Hessian Riemannian structures on convex sets as metrics that have a specific integration property with respect to variational inequalities, giving a new motivation for the introduction of Bregman-type distances. Then, the general evolution problem is introduced, and global convergence is established under quasi-convexity conditions, with interesting refinements in the case of convex minimization. Some explicit examples of these gradient flows are discussed. Dual trajectories are identified, and sufficient conditions for dual convergence are examined for a convex program with positivity and equality constraints. Some convergence rate results are established. In the case of a linear objective function, several optimality characterizations of the orbits are given: optimal path of viscosity methods, continuous-time model of Bregman-type proximal algorithms, geodesics for some adequate metrics, and projections of $\dot{q}$-trajectories of some Lagrange equations and completely integrable Hamiltonian systems.

Key words. gradient flow, Hessian Riemannian metric, Legendre-type convex function, existence, global convergence, Bregman distance, Lyapunov functional, quasi-convex minimization, convex and linear programming, Legendre transform coordinates, Lagrange and Hamilton equations

1. Introduction.

The aim of this paper is to study the existence, global convergence, and geometric properties of gradient flows with respect to a specific class of Hessian Riemannian metrics on convex sets. Our work is indeed deeply related to the constrained minimization problem

$$\text{(P)} \qquad \min\{f(x) \mid x \in \overline{C},\ Ax = b\},$$

where $\overline{C}$ is the closure of a nonempty, *open*, and convex subset C of $\mathbb{R}^n$; A is an $m \times n$ real matrix with $m \leq n$; $b \in \mathbb{R}^m$ and $f \in C^1(\mathbb{R}^n)$. A strategy for solving (P) consists of endowing C with a Riemannian metric g, restricting it to the relative interior of the feasible set $\mathcal{F} := C \cap \{x \mid Ax = b\}$, and then considering the trajectories generated by the steepest descent vector field. We focus on those metrics that are induced by the Hessian $H = \nabla^2 h$ of a *Legendre-type* convex function h defined on C (cf. Definition 3.3), that is, $g_{ij} = \frac{\partial^2 h}{\partial x_i \partial x_j}$. This leads to the initial value problem

$$\text{(H-SD)} \qquad \dot{x}(t) + \nabla_H f_{|\mathcal{F}}(x(t)) = 0, \qquad x(0) \in \mathcal{F},$$

where (H-SD) stands for H-steepest descent.

The use of Riemannian methods in optimization has increased recently. For interior point methods in linear programming, see Karmarkar [31], Bayer and Lagarias [7], and Nesterov and Todd [37]; for continuous-time models of proximal-type algorithms and related topics, see Iusem, Svaiter, and Da Cruz Neto [29], Bolte and Teboulle [8], and Attouch and Teboulle [3]. For a systematic dynamical system approach to constrained optimization based on double bracket flows, see Brockett [10, 11], Helmke and Moore [24], and the references therein. See Smith [41] and Udriste [43] for general optimization techniques on Riemannian manifolds. On the other hand, the structure of (H-SD) is also at the heart of some important problems in applied mathematics. For connections with population dynamics and game theory, see Akin [1] and Hofbauer and Sygmund [27]. We will see that (H-SD) can be reformulated as the differential inclusion $\frac{d}{dt}\nabla h(x(t)) + \nabla f(x(t)) \in \operatorname{Im} A^T$, $x(t) \in \mathcal{F}$, which is formally similar to some evolution problems in infinite dimensional spaces arising in thermodynamical systems; see Kenmochi and Pawlow [32] and references therein.

A classical approach in the asymptotic analysis of dynamical systems consists of exhibiting attractors of the orbits by using Lyapunov functionals. Our choice of Hessian Riemannian metrics is based on this idea. In fact, we consider first the important case where f is convex, a condition that permits us to reformulate (P) as a variational inequality problem: find $a \in \overline{\mathcal{F}}$ such that $(\nabla_{H} f_{|\mathcal{F}}(x), x-a)_x^H \geq 0$ for all x in $\mathcal{F}$. In order to identify a suitable Lyapunov functional, this variational problem is met through the following integration problem: *find the metrics $(\cdot,\cdot)^H$ for which the vector fields $V^a : \mathcal{F} \to \mathbb{R}^n$, $a \in \mathcal{F}$, defined by $V^a(x) = x - a$, are $(\cdot,\cdot)^H$-gradient vector fields.* Our first result (cf. Theorem 3.1) establishes that such metrics are given by the Hessian of strictly convex functions, and in that case the vector fields V^a appear as gradients with respect to the second variable of some distance-like functions that are called D-functions. Indeed, if $(\cdot,\cdot)^H$ is induced by the Hessian $H = \nabla^2 h$ of $h : \mathcal{F} \mapsto \mathbb{R}$, we have for all a, x in $\mathcal{F}$, $\nabla_{H} D_h(a,.)(x) = x - a$, where $D_h(a,x) = h(a) - h(x) - dh(x)(a-x)$. See Duistermaat [19] for a related characterization of Hessian metrics.

Motivated by the previous result and with the aim of solving (P), we are then naturally led to consider Hessian Riemannian metrics that cannot be smoothly extended out of $\mathcal{F}$. Such a requirement is fulfilled by the Hessian of a *Legendre (convex) function* h, whose definition is recalled in section 3. We give then a differential inclusion reformulation of (H-SD), which permits us to show that in the case of a linear objective function f, the flow of $-\nabla_{H} f_{|\mathcal{F}}$ stands at the crossroad of many optimization methods. In fact, following [29], we prove that viscosity methods and Bregman proximal algorithms produce their paths or iterates in the orbit of (H-SD). The D-function of h plays an essential role for this. In section 4.4 we give a systematic method for constructing Legendre functions based on barrier functions for convex inequality problems, which is illustrated with some examples; relations to other works are discussed.

Section 4 deals with global existence and convergence properties. After having given a nontrivial well-posedness result (cf. Theorem 4.1), we prove in section 4.2 that $f(x(t)) \to \inf_{\overline{\mathcal{F}}} f$ as $t \to +\infty$ whenever f is convex. A natural problem that arises is the trajectory convergence to a critical point. Since one expects the limit to be a (local) solution to (P), which may belong to the boundary of C, the notion of critical point must be understood in the sense of the optimality condition for a local minimizer a of f over $\overline{\mathcal{F}}$:

$$(\mathcal{O}) \qquad \nabla f(a) + N_{\overline{\mathcal{F}}}(a) \ni 0, \qquad a \in \overline{\mathcal{F}},$$

where $N_{\overline{\mathcal{F}}}(a)$ is the normal cone to $\overline{\mathcal{F}}$ at a, and ∇f is the Euclidean gradient of f. This involves an asymptotic singular behavior that is rather unusual in the classical theory of dynamical systems, where the critical points are typically supposed to be in the manifold. In section 4.3 we assume that the Legendre-type function h is a *Bregman function with zone C* (see [5] and [34] for comprehensive surveys) and prove that, under a quasi convexity assumption on f, the trajectory converges to some point a satisfying $(\mathcal{O})$. When f is convex, the preceding result amounts to the convergence of $x(t)$ toward a global minimizer of f over $\overline{\mathcal{F}}$. We also give a variational characterization of the limit and establish an abstract result on the rate of convergence under uniqueness of the solution. We consider in section 4.5 the case of linear programming, for which asymptotic convergence as well as a variational characterization are proved without the Bregman-type condition. Within this framework, we also give some estimates on the convergence rate that are valid for the specific Legendre functions commonly used in practice. In section 4.6, we consider the interesting case of positivity and equality constraints, introducing a *dual* trajectory $\lambda(t)$ that, under some appropriate conditions, converges to a solution to the dual problem of (P) whenever f is convex, even if primal convergence is not ensured.

Finally, for a linear objective function, and inspired by the seminal work [7], we define in section 5 a change of coordinates called *Legendre transform coordinates*, which permits us to show that the orbits of (H-SD) may be seen as straight lines in a positive cone. This leads to additional geometric interpretations of the flow of $-\nabla_{H} f_{|\mathcal{F}}$. On the one hand, the orbits are geodesics with respect to an appropriate metric and, on the other hand, they may be seen as $\dot{q}$-trajectories of some Lagrangian, with consequences in terms of completely integrable Hamiltonians.

Notation. $\operatorname{Ker} A = \{x \in \mathbb{R}^n \mid Ax = 0\}$. The orthogonal complement of $\mathcal{A}_0$ is denoted by $\mathcal{A}_0^{\perp}$, and $\langle \cdot, \cdot \rangle$ is the standard Euclidean scalar product of $\mathbb{R}^n$. Let us denote by $\mathbb{S}^n_{++}$ the cone of real symmetric definite positive matrices. Let $\Omega \subset \mathbb{R}^n$ be an open set. If $f : \Omega \to \mathbb{R}$ is differentiable, then ∇f stands for the Euclidean gradient of f. If $h : \Omega \mapsto \mathbb{R}$ is twice differentiable, then its Euclidean Hessian at $x \in \Omega$ is denoted by $\nabla^2 h(x)$ and is defined as the endomorphism of $\mathbb{R}^n$ whose matrix in canonical coordinates is given by $\left[\frac{\partial^2 h(x)}{\partial x_i \partial x_j}\right]_{i,j \in \{1,\dots,n\}}$. Thus, for all $x \in \Omega$, $d^2 h(x) = \langle \nabla^2 h(x) \cdot, \cdot \rangle$.

2. Preliminaries.

2.1. The minimization problem and optimality conditions.

Given a positive integer $m < n$, a full rank matrix $A \in \mathbb{R}^{m \times n}$, and $b \in \operatorname{Im} A$, let us define

$$\mathcal{A} = \{x \in \mathbb{R}^n \mid Ax = b\}. \tag{2.1}$$

Set $\mathcal{A}_0 = \mathcal{A} - \mathcal{A} = \operatorname{Ker} A$. Of course, $\mathcal{A}_0^{\perp} = \operatorname{Im} A^T$, where A^T is the transpose of A. Let C be a nonempty, open, and convex subset of $\mathbb{R}^n$, and $f : \mathbb{R}^n \to \mathbb{R}$ a $\mathcal{C}^1$ function. Consider the constrained minimization problem

$$\inf\{f(x) \mid x \in \overline{C},\ Ax = b\}. \tag{P}$$

The set of optimal solutions of (P') is denoted by $S(P')$. We call f the *objective function* of (P'). The *feasible set* of (P') is given by $\overline{\mathcal{F}} = \{x \in \mathbb{R}^n \mid x \in \overline{C},\ Ax = b\} = \overline{C} \cap \mathcal{A}$, and $\mathcal{F}$ stands for the *relative interior* of $\overline{\mathcal{F}}$, that is,

$$\mathcal{F} = \operatorname{ri} \overline{\mathcal{F}} = \{x \in \mathbb{R}^n \mid x \in C,\ Ax = b\} = C \cap \mathcal{A}. \tag{2.2}$$

Throughout this article, we assume that

$$\mathcal{F} \neq \emptyset. \tag{2.3}$$

It is well known that a necessary condition for a to be locally minimal for f over $\overline{\mathcal{F}}$ is $(\mathcal{O})$: $-\nabla f(a) \in N_{\overline{\mathcal{F}}}(a)$, where $N_{\overline{\mathcal{F}}}(x) = \{\nu \in \mathbb{R}^n \mid \forall y \in \overline{\mathcal{F}},\ \langle y - x, \nu\rangle \leq 0\}$ is the *normal cone* to $\overline{\mathcal{F}}$ at $x \in \overline{\mathcal{F}}$ ($N_{\overline{\mathcal{F}}}(x) = \emptyset$ when $x \notin \overline{\mathcal{F}}$); see, for instance, [40, Theorem 6.12]. By [39, Corollary 23.8.1], $N_{\overline{\mathcal{F}}}(x) = N_{\overline{C}\cap\mathcal{A}}(x) = N_{\overline{C}}(x) + N_{\mathcal{A}}(x) = N_{\overline{C}}(x) + \mathcal{A}_0^{\perp}$ for all $x \in \overline{\mathcal{F}}$. Therefore, the necessary optimality condition for $a \in \overline{\mathcal{F}}$ is

$$-\nabla f(a) \in N_{\overline{C}}(a) + \mathcal{A}_0^{\perp}. \tag{2.4}$$

If f is convex, then this condition is also sufficient for $a \in \overline{\mathcal{F}}$ to be in $S(\mathrm{P})$.

2.2. Riemannian gradient flows on the relative interior of the feasible set. Let M be a smooth manifold. The tangent space to M at $x \in M$ is denoted by T_xM. If $f : M \mapsto \mathbb{R}$ is a $\mathcal{C}^1$ function, then $df(x)$ denotes its differential or tangent map $df(x) : T_xM \to \mathbb{R}$ at $x \in M$. A $\mathcal{C}^k$ metric on M, $k \geq 0$, is a family of scalar products $(\cdot,\cdot)_x$ on each T_xM, $x \in M$, such that $(\cdot,\cdot)_x$ depends in a $\mathcal{C}^k$ way on x. The couple $M, (\cdot,\cdot)_x$ is called a $\mathcal{C}^k$ Riemannian manifold. This structure permits us to identify T_xM with its dual, i.e., the cotangent space T_xM^*, and thus to define a notion of gradient vector. Indeed, given f in M, the gradient of f is denoted by $\nabla_{(\cdot,\cdot)} f$ and is uniquely determined by the following conditions:

(g_1) tangency condition: for all $x \in M$, $\nabla_{(\cdot,\cdot)} f(x) \in T_xM^* \simeq T_xM$;

(g_2) duality condition: for all $x \in M$, $v \in T_xM$, $df(x)(v) = (\nabla_{(\cdot,\cdot)} f(x), v)_x$.

We refer the reader to [18, 35] for further details.

Let us return to the minimization problem (P). Since C is open, we can take $M = C$ with the usual identification $T_xC \simeq \mathbb{R}^n$ for every $x \in C$. Given a continuous mapping $H : C \to \mathbb{S}^n_{++}$, the metric defined by

$$\forall x \in C,\ \forall u, v \in \mathbb{R}^n, \qquad (u,v)_x^H = \langle H(x)u, v\rangle \tag{2.5}$$

endows C with a $\mathcal{C}^0$ Riemannian structure. The corresponding Riemannian gradient vector field of the objective function f restricted to C, which we denote by $\nabla_{H} f_{|C}$, is given by

$$\nabla_{H} f_{|C}(x) = H(x)^{-1}\nabla f(x). \tag{2.6}$$

Next, take $N = \mathcal{F} = C \cap \mathcal{A}$, which is a smooth submanifold of C with $T_x\mathcal{F} \simeq \mathcal{A}_0$ for each $x \in \mathcal{F}$. Definition (2.5) induces a metric on $\mathcal{F}$ for which the gradient of the restriction $f_{|\mathcal{F}}$ is denoted by $\nabla_{H} f_{|\mathcal{F}}$. Conditions ($\mathrm{g}_1$) and ($\mathrm{g}_2$) imply that for all $x \in \mathcal{F}$

$$\nabla_{H} f_{|\mathcal{F}}(x) = P_x H(x)^{-1}\nabla f(x), \tag{2.7}$$

where, given $x \in C$, $P_x : \mathbb{R}^n \to \mathcal{A}_0$ is the $(\cdot,\cdot)_x^H$-orthogonal projection onto the linear subspace $\mathcal{A}_0$. Since A has full rank, it is easy to see that

$$P_x = I - H(x)^{-1}A^T(AH(x)^{-1}A^T)^{-1}A, \tag{2.8}$$

and we conclude that for all $x \in \mathcal{F}$

$$\nabla_{H} f_{|\mathcal{F}}(x) = H(x)^{-1}[I - A^T(AH(x)^{-1}A^T)^{-1}AH(x)^{-1}]\nabla f(x). \tag{2.9}$$

Given $x \in \mathcal{F}$, the vector $-\nabla_{H} f_{|\mathcal{F}}(x)$ can be interpreted as that direction in $\mathcal{A}_0$ such that f decreases the most steeply at x with respect to the metric $(\cdot,\cdot)_x^H$. The *steepest descent method* for the (local) minimization of f on the Riemannian manifold

$\mathcal{F}, (\cdot,\cdot)_x^H$ consists of finding the solution trajectory $x(t)$ of the vector field $-\nabla_H f_{|\mathcal{F}}$ with initial condition $x^0 \in \mathcal{F}$:

$$\left\{ \begin{array}{l} \dot{x} + \nabla_H f_{|\mathcal{F}}(x) = 0, \\ x(0) = x^0 \in \mathcal{F}. \end{array} \right. \tag{2.10}$$

3. Legendre gradient flows in constrained optimization.

3.1. Lyapunov functionals, variational inequalities, and Hessian metrics. This section is intended to motivate the particular class of Riemannian metrics that is studied in this paper in view of the asymptotic convergence of the solution to (2.10).

Let us consider the minimization problem (P) and assume that C is endowed with some Riemannian metric $(\cdot,\cdot)_x^H$ as defined in (2.5). Recall that $V : \mathcal{F} \mapsto \mathbb{R}$ is a *Lyapunov functional* for the vector field $-\nabla_H f_{|\mathcal{F}}$ if, for all $x \in \mathcal{F}$, $(-\nabla_H f_{|\mathcal{F}}(x), \nabla_H V(x))_x^H \leq 0$. If $x(t)$ is a solution to (2.10), this implies that $t \mapsto V(x(t))$ is nonincreasing. Although $f_{|\mathcal{F}}$ is indeed a Lyapunov functional for $-\nabla_H f_{|\mathcal{F}}$, this does not ensure the convergence of $x(t)$. (See, for instance, the counterexample of Palis and De Melo [38] in the Euclidean case.)

Suppose that the objective function f is convex. For simplicity, we also assume that $A = 0$ so that $\mathcal{F} = C$. In the framework of convex minimization, the set of minimizers of f over $\overline{C}$, denoted by $\operatorname{Argmin}_{\overline{C}} f$, is characterized in variational terms as follows:

$$a \in \operatorname{Argmin}_{\overline{C}} f \quad \Leftrightarrow \quad \forall x \in \overline{C}, \qquad \langle \nabla f(x), x - a \rangle \geq 0. \tag{3.1}$$

Setting $q_a(x) = \frac{1}{2}|x-a|^2$ for all $a \in \operatorname{Argmin}_{\overline{C}}$, one observes that $\nabla q_a(x) = x - a$ and thus, by (3.1), q_a is a Lyapunov functional for $-\nabla f$. This key property allows one to establish the asymptotic convergence as $t \to +\infty$ of the corresponding steepest descent trajectories; see [12] for more details in a very general nonsmooth setting. To use the same kind of arguments in a non-Euclidean context, observe that, by (2.6) together with the continuity of ∇f, the following variational Riemannian characterization holds:

$$a \in \operatorname{Argmin}_{\overline{C}} f \quad \Leftrightarrow \quad \forall x \in C, \qquad (\nabla_H f(x), x - a)_x^H \geq 0. \tag{3.2}$$

We are thus naturally led to the problem of *finding the Riemannian metrics on C for which the mappings $C \ni x \mapsto x - y \in \mathbb{R}^n$, $y \in C$, are gradient vector fields.* The next result gives a characterization of such metrics: they are induced by the Hessian of strictly convex functions.

THEOREM 3.1. *Assume that $H \in \mathcal{C}^1(C; \mathbb{S}^n_{++})$ or, in other words, that $(\cdot,\cdot)_x^H$ is a $\mathcal{C}^1$ metric. The family of vector fields $\{V^y : C \ni x \mapsto x - y \in \mathbb{R}^n\}$, $y \in C$ is a family of $(\cdot,\cdot)^H$-gradient vector fields iff there exists a strictly convex function $h \in \mathcal{C}^3(C)$ such that for all $x \in C$, $H(x) = \nabla^2 h(x)$. Additionally, defining $D_h : C \times C \mapsto \mathbb{R}$ by*

$$D_h(y,x) = h(y) - h(x) - \langle \nabla h(x), y - x \rangle, \tag{3.3}$$

we obtain $\nabla_H D_h(y,\cdot)(x) = x - y$.

Proof. The set of metrics complying with the "gradient" requirement is denoted by $\mathcal{M}$, that is, $(\cdot,\cdot)_x^H \in \mathcal{M} \Leftrightarrow H \in \mathcal{C}^1(C; \mathbb{S}^n_{++})$ and for all $y \in C$ there exists $\varphi_y \in \mathcal{C}^1(C; \mathbb{R})$, $\nabla_H \varphi_y(x) = x - y$. Let $(x_1, \ldots, x_n)$ denote the canonical coordinates

of $\mathbb{R}^n$, and write $\sum_{i,j} H_{ij}(x)dx_i dx_j$ for $(\cdot,\cdot)_x^H$. By (2.6), the mappings $x \mapsto x-y$, $y \in C$, define a family of $(\cdot,\cdot)_x^H$ gradients iff $k_y : x \mapsto H(x)(x-y)$, $y \in C$, is a family of Euclidean gradients. Setting $\alpha^y(x) = \langle k_y(x), \cdot\rangle$, $x, y \in C$, the problem amounts to finding necessary (and sufficient) conditions under which the 1-forms α^y are all exact. Let $y \in C$. Since C is convex, the Poincaré lemma [35, Theorem V.4.1] states that α^y is exact iff it is closed. In canonical coordinates we have $\alpha^y(x) = \sum_i \left(\sum_k H_{ik}(x)(x_k - y_k)\right) dx_i$, $x \in C$, and therefore α^y is exact iff for all $i, j \in \{1,\dots,n\}$ we have $\frac{\partial}{\partial x_j}\sum_k H_{ik}(x)(x_k-y_k) = \frac{\partial}{\partial x_i}\sum_k H_{jk}(x)(x_k-y_k)$, which is equivalent to $\sum_k \frac{\partial}{\partial x_j} H_{ik}(x)(x_k-y_k) + H_{ij}(x) = \sum_k \frac{\partial}{\partial x_i} H_{jk}(x)(x_k-y_k) + H_{ji}(x)$. Since $H_{ij}(x) = H_{ji}(x)$, this gives the following condition: $\sum_k \frac{\partial}{\partial x_j} H_{ik}(x)(x_k-y_k) = \sum_k \frac{\partial}{\partial x_i} H_{jk}(x)(x_k-y_k)$, for all $i, j \in \{1,\dots,n\}$. If we set $V_x = (\frac{\partial}{\partial x_j} H_{i1}(x), \dots, \frac{\partial}{\partial x_j} H_{in}(x))^T$ and $W_x = (\frac{\partial}{\partial x_i} H_{j1}(x), \dots, \frac{\partial}{\partial x_i} H_{jn}(x))^T$, the latter can be rewritten $\langle V_x - W_x, x-y\rangle = 0$, which must hold for all $(x,y) \in C \times C$. Fix $x \in C$. Let $\epsilon_x > 0$ be such that the open ball of center x with radius ϵ_x is contained in C. For every ν such that $|\nu| = 1$, take $y = x + \epsilon_x/2\nu$ to obtain that $\langle V_x - W_x, \nu\rangle = 0$. Consequently, $V_x = W_x$ for all $x \in C$. Therefore, $(\cdot,\cdot)_x^H \in \mathcal{M}$ iff

$$\forall x \in C,\ \forall i,j,k \in \{1,\dots,n\}, \qquad \frac{\partial}{\partial x_i} H_{jk}(x) = \frac{\partial}{\partial x_j} H_{ik}(x). \tag{3.4}$$

LEMMA 3.2. *If $H : C \mapsto \mathbb{S}^n_{++}$ is a differentiable mapping satisfying* (3.4)*, then there exists $h \in \mathcal{C}^3(C)$ such that, for all $x \in C$, $H(x) = \nabla^2 h(x)$. In particular, h is strictly convex.*

Proof of Lemma 3.2. For all $i \in \{1,\dots,n\}$, set $\beta^i = \sum_k H_{ik}dx_k$. By (3.4), β^i is closed and therefore exact. Let $\phi_i : C \mapsto \mathbb{R}$ be such that $d\phi_i = \beta^i$ on C, and set $\omega = \sum_k \phi_k dx_k$. We have that $\frac{\partial}{\partial x_j}\phi_i(x) = H_{ij}(x) = H_{ji}(x) = \frac{\partial}{\partial x_i}\phi_j(x)$ for all $x \in C$. This proves that ω is closed, and therefore there exists $h \in \mathcal{C}^2(C,\mathbb{R})$ such that $dh = \omega$. To conclude, we just have to notice that $\frac{\partial}{\partial x_i} h(x) = \phi_i$, and thus $\frac{\partial^2 h}{\partial x_j \partial x_i}(x) = H_{ji}(x)$ for all $x \in C$. ∎

To finish the proof of Theorem 3.1, we note that taking $\varphi_y = D_h(y,\cdot)$ with D_h being defined by (3.3), we obtain $\nabla\varphi_y(x) = \nabla^2 h(x)(x-y)$, and therefore $\nabla_H \varphi_y(x) = x - y$ in virtue of (2.6). ∎

Remark 3.1. (a) In the theory of Bregman proximal methods for convex optimization, the distance-like function D_h defined by (3.3) is called the *D-function* of h. Theorem 3.1 is a new and surprising motivation for the introduction of D_h in relation with variational inequality problems. (b) For a geometrical approach to Hessian Riemannian structures, the reader is referred to the recent work of Duistermaat [19].

Theorem 3.1 suggests that we endow C with a Riemannian structure associated with the Hessian $H = \nabla^2 h$ of a strictly convex function $h : C \mapsto \mathbb{R}$. As we will see under some additional conditions, the D-function of h is essential to establishing the asymptotic convergence of the trajectory. On the other hand, if it is possible to replace h by a sufficiently smooth strictly convex function $h' : C' \mapsto \mathbb{R}$ with $C' \supset\supset C$ and $h'_{|_C} = h$, then the gradient flows for h and h' are the same on C, but the steepest descent trajectories associated with the latter may leave the feasible set of (P) and in general they will not converge to a solution of (P). We shall see that to avoid this drawback it is sufficient to require that $|\nabla h(x^j)| \to +\infty$ for all sequences (x^j) in C converging to a boundary point of C. This may be interpreted as a sort of *barrier technique*, a classical strategy for enforcing feasibility in optimization theory.

3.2. Legendre-type functions and the (H-SD) dynamical system. In what follows, we adopt the standard notation of convex analysis theory; see [39]. Given a closed convex subset S of $\mathbb{R}^n$, we say that an extended-real-valued function $g : S \mapsto \mathbb{R} \cup \{+\infty\}$ belongs to the class $\Gamma_0(S)$ when g is lower semicontinuous, proper ($g \not\equiv +\infty$), and convex. For such a function $g \in \Gamma_0(S)$, its *effective domain* is defined by $\operatorname{dom} g = \{x \in S \mid g(x) < +\infty\}$. When $g \in \Gamma_0(\mathbb{R}^n)$, its *Legendre–Fenchel conjugate* is given by $g^*(y) = \sup\{\langle x, y\rangle - g(x) \mid x \in \mathbb{R}^n\}$, and its *subdifferential* is the set-valued mapping $\partial g : \mathbb{R}^n \to \mathcal{P}(\mathbb{R}^n)$ given by $\partial g(x) = \{y \in \mathbb{R}^n \mid \forall z \in \mathbb{R}^n,\ f(x) + \langle y, z - x\rangle \leq f(z)\}$. We set $\operatorname{dom} \partial g = \{x \in \mathbb{R}^n \mid \partial g(x) \neq \emptyset\}$.

DEFINITION 3.3 (see [39, Chapter 26]). *A function $h \in \Gamma_0(\mathbb{R}^n)$ is called:*

(i) essentially smooth *if h is differentiable on* $\operatorname{int}\operatorname{dom} h$*, with, moreover, $|\nabla h(x^j)| \to +\infty$ for every sequence $(x^j) \subset \operatorname{int} \operatorname{dom} h$ converging to a boundary point of $\operatorname{dom} h$ as $j \to +\infty$;*

(ii) of Legendre type *if h is essentially smooth and strictly convex on* $\operatorname{int} \operatorname{dom} h$.

We remark that by [39, Theorem 26.1], $h \in \Gamma_0(\mathbb{R}^n)$ is essentially smooth iff $\partial h(x) = \{\nabla h(x)\}$ if $x \in \operatorname{int} \operatorname{dom} h$, and $\partial h(x) = \emptyset$ otherwise; in particular, $\operatorname{dom} \partial h = \operatorname{int} \operatorname{dom} h$.

Motivated by the results of section 3.1, we define a Riemannian structure on C by introducing a function $h \in \Gamma_0(\mathbb{R}^n)$ such that

$$(\mathrm{H}_0) \qquad \begin{cases} \text{(i)} & h \text{ is of Legendre type with } \operatorname{int} \operatorname{dom} h = C. \\ \text{(ii)} & h_{|C} \in \mathcal{C}^2(C;\mathbb{R}) \text{ and } \forall x \in C, \nabla^2 h(x) \in \mathbb{S}^n_{++}. \\ \text{(iii)} & \text{The mapping } C \ni x \mapsto \nabla^2 h(x) \text{ is locally Lipschitz continuous.} \end{cases}$$

Here and subsequently, we take $H = \nabla^2 h$ with h satisfying (H_0). The Hessian mapping $C \ni x \mapsto H(x)$ endows C with the (locally Lipschitz continuous) Riemannian metric

$$\forall x \in C,\ \forall u, v \in \mathbb{R}^n, \qquad (u, v)^H_x = \langle H(x)u, v\rangle = \langle \nabla^2 h(x)u, v\rangle, \tag{3.5}$$

and we say that $(\cdot,\cdot)^H_x$ is the *Legendre metric* on C induced by the Legendre-type function h, which also defines a metric on $\mathcal{F} = C \cap \mathcal{A}$ by restriction. In addition to $f \in \mathcal{C}^1(\mathbb{R}^n)$, we suppose that the objective function satisfies

$$\nabla f \text{ is locally Lipschitz continuous on } \mathbb{R}^n. \tag{3.6}$$

The corresponding steepest descent method in the manifold $\mathcal{F}, (\cdot,\cdot)^H_x$, which we refer to as (H-SD) for short, is then the following continuous dynamical system:

$$\text{(H-SD)} \qquad \begin{cases} \dot{x}(t) + \nabla_{H} f_{|\mathcal{F}}(x(t)) = 0, & t \in (T_m, T_M), \\ x(0) = x^0 \in \mathcal{F}, \end{cases}$$

with $H = \nabla^2 h$ and where $-\infty \leq T_m < 0 < T_M \leq +\infty$ defines the interval corresponding to the unique maximal solution of (H-SD). Given an initial condition $x^0 \in \mathcal{F}$, we shall say that (H-SD) is *well posed* when its maximal solution satisfies $T_M = +\infty$. In section 4.1 we will give some sufficient conditions ensuring the well-posedness of (H-SD).

3.3. Differential inclusion formulation of (H-SD) and some consequences. It is easily seen that the solution $x(t)$ of (H-SD) satisfies

$$\begin{cases} \dfrac{d}{dt}\nabla h(x(t)) + \nabla f(x(t)) \ \in\ \mathcal{A}_0^{\perp} \text{ on } (T_m, T_M), \\ x(t) \ \in\ \mathcal{F} \ \text{ on } (T_m, T_M), \\ x(0) \ =\ x^0 \in \mathcal{F}. \end{cases} \tag{3.7}$$

This differential inclusion problem makes sense even when $x \in W^{1,1}_{loc}(T_m, T_M; \mathbb{R}^n)$, the inclusions being satisfied almost everywhere on (T_m, T_M). Actually, the following result establishes that (H-SD) and (3.7) describe the same trajectory.

PROPOSITION 3.4. *Let $x \in W^{1,1}_{loc}(T_m, T_M; \mathbb{R}^n)$. Then, x is a solution of* (3.7) *iff x is the solution of* (H-SD). *In particular,* (3.7) *admits a unique solution of class $\mathcal{C}^1$.*

Proof. Assume that x is a solution of (3.7), and let I' be the subset of (T_m, T_M) on which $t \mapsto (x(t), \nabla h(x(t))$ is derivable. We may assume that $x(t) \in \mathcal{F}$ and $\frac{d}{dt}\nabla h(x(t)) + \nabla f(x(t)) \in \mathcal{A}_0^\perp$ for all $t \in I'$. Since x is absolutely continuous, $\dot{x}(t) + H(x(t))^{-1}\nabla f((x(t)) \in H(x(t))^{-1}\mathcal{A}_0^\perp$ and $\dot{x}(t) \in \mathcal{A}_0$ for all $t \in I'$. However, the orthogonal complement of $\mathcal{A}_0$ with respect to the inner product $\langle H(x)\cdot, \cdot\rangle$ is exactly $H(x)^{-1}\mathcal{A}_0^\perp$ when $x \in \mathcal{F}$. It follows that $\dot{x} + P_x H(x)^{-1}\nabla f(x) = 0$ on I'. This implies that x is the $\mathcal{C}^1$ solution of (H-SD). ∎

Suppose that f is convex. On account of Proposition 3.4, (H-SD) can be interpreted as a continuous-time model for a well-known class of iterative minimization algorithms. In fact, an implicit discretization of (3.7) yields the following iterative scheme: $\nabla h(x^{k+1}) - \nabla h(x^k) + \mu_k \nabla f(x^{k+1}) \in \operatorname{Im} A^T,\ Ax^{k+1} = b$, where $\mu_k > 0$ is a step-size parameter and $x^0 \in \mathcal{F}$. This is the optimality condition for

$$x^{k+1} \in \operatorname{Argmin}\left\{ f(x) + 1/\mu_k D_h(x, x^k) \mid Ax = b \right\}, \tag{3.8}$$

where D_h is given by

$$D_h(x, y) = h(x) - h(y) - \langle \nabla h(y), x - y\rangle, \qquad x \in \operatorname{dom} h,\ y \in \operatorname{dom} \partial h = C. \tag{3.9}$$

The above algorithm is accordingly called the *Bregman proximal minimization* method; for an insight into its importance in optimization see, for instance, [5, 14, 15, 28, 34].

Next, assume that $f(x) = \langle c, x\rangle$ for some $c \in \mathbb{R}^n$. As already noticed in [6, 23, 36] for the log-metric and in [29] for a fairly general h, in this case the (H-SD) gradient trajectory can be viewed as a *central optimal path*. Indeed, integrating (3.7) over $[0, t]$, we obtain $\nabla h(x(t)) - \nabla h(x^0) + tc \in \mathcal{A}_0^\perp$. Since $x(t) \in \mathcal{A}$, it follows that

$$x(t) \in \operatorname{Argmin}\left\{ \langle c, x\rangle + 1/t D_h(x, x^0) \mid Ax = b \right\}, \tag{3.10}$$

which corresponds to the so-called *viscosity method* relative to $g(x) = D_h(x, x^0)$; see [2, 4, 29] and Corollary 4.8. We note now that, for a linear objective function, (3.8) and (3.10) are essentially the same: the sequence generated by the former belongs to the optimal path defined by the latter. Indeed, setting $t_0 = 0$ and $t_{k+1} = t_k + \mu_k$ for all $k \geq 0$ ($\mu_0 = 0$) and integrating (3.7) over $[t_k, t_{k+1}]$, we obtain that $x(t_{k+1})$ satisfies the optimality condition for (3.8). The following result summarizes the previous discussion.

PROPOSITION 3.5. *Assume that f is linear and that the corresponding* (H-SD) *dynamical system is well posed. Then, the viscosity optimal path $\widetilde{x}(\varepsilon)$ relative to $g(x) = D_h(x, x^0)$ and the sequence (x^k) generated by* (3.8) *exist and are unique, with in addition $\widetilde{x}(\varepsilon) = x(1/\varepsilon)$ for all $\varepsilon > 0$, and $x^k = x(\sum_{l=0}^{k-1} \mu_l)$ for all $k \geq 1$, where $x(t)$ is the solution of* (H-SD).

Remark 3.2. In order to ensure asymptotic convergence for proximal-type algorithms, it is usually required that the step-size parameters satisfy $\sum \mu_k = +\infty$. By Proposition 3.5, this is necessary for the convergence of (3.8) in the sense that when (H-SD) is well posed, if x^k converges to some $x^* \in S(P)$, then either $x^0 = x^*$ or $\sum \mu_k = +\infty$.

4. Global existence, asymptotic analysis, and examples.

4.1. Well-posedness of (H-SD). In this section we establish the well-posedness of (H-SD) (i.e., $T_M = +\infty$) under three different conditions. In order to avoid any confusion, we say that a set $E \subset \mathbb{R}^n$ is *bounded* when it is so for the usual Euclidean norm $|y| = \sqrt{\langle y, y\rangle}$. First, we propose the following condition:

(WP_1) The lower level set $\{y \in \overline{\mathcal{F}} \mid f(y) \leq f(x^0)\}$ is bounded.

Notice that (WP_1) is weaker than the classical assumption requiring f to have bounded lower level sets in the H metric sense. Next, let D_h be the D-function of h that is defined by (3.9) and consider the following condition:

(WP_2)
$$\begin{cases} \text{(i) } \operatorname{dom} h = \overline{C} \text{ and } \forall a \in \overline{C},\ \forall \gamma \in \mathbb{R},\ \{y \in \mathcal{F} \,|D_h(a, y) \leq \gamma\} \text{ is bounded.} \\ \text{(ii) } S(P) \neq \emptyset \text{ and } f \text{ is quasi-convex (i.e., the lower level sets of } f \text{ are convex).} \end{cases}$$

When $\overline{\mathcal{F}}$ is unbounded (WP_1) and (WP_2) involve some a priori properties on f. This is actually not necessary for the well-posedness of (H-SD). Consider

(WP_3) $\exists\ K \geq 0,\ L \in \mathbb{R}$ such that $\forall x \in C,\ ||H(x)^{-1}|| \leq K|x| + L.$

This property is satisfied by relevant Legendre-type functions; take, for instance, (4.13).

THEOREM 4.1. *Assume that* (3.6) *and* (H_0) *hold and additionally that either* (WP_1)*,* (WP_2)*, or* (WP_3) *is satisfied. If* $\inf_{\mathcal{F}} f > -\infty$*, then the dynamical system* (H-SD) *is well posed. Consequently, the mapping* $t \mapsto f(x(t))$ *is nonincreasing and convergent as* $t \to +\infty$*.*

Proof. When no confusion may occur, we drop the dependence on the time variable t. By definition,

$$T_M = \sup\{T > 0 \,|\exists!\text{ solution } x \text{ of } (H\text{-}SD) \text{ on } [0, T) \text{ s.t. } x([0, T)) \subset \mathcal{F}\}.$$

We have that $T_M > 0$. The definition (2.8) of P_x implies that, for all $y \in \mathcal{A}_0$, $(H(x)^{-1}\nabla f(x) + \dot{x}, y + \dot{x})_x^H = 0$ on $[0, T_M)$ and therefore

$$\langle \nabla f(x) + H(x)\dot{x}, y + \dot{x}\rangle = 0 \text{ on } [0, T_M). \tag{4.1}$$

Letting $y = 0$ in (4.1) yields

$$\frac{d}{dt} f(x) + \langle H(x)\dot{x}, \dot{x}\rangle = 0. \tag{4.2}$$

By (H_0)(ii), $f(x(t))$ is convergent as $t \to T_M$. Moreover,

$$\langle H(x(\cdot))\dot{x}(\cdot), \dot{x}(\cdot)\rangle \in L^1(0, T_M; \mathbb{R}). \tag{4.3}$$

Suppose that $T_M < +\infty$. To obtain a contradiction, we begin by proving that x is bounded. If (WP_1) holds, then x is bounded because $f(x(t))$ is nonincreasing so that $x(t) \in \{y \in \overline{\mathcal{F}} \,|f(y) \leq f(x^0)\}$ for all $t \in [0, T_M)$. Assume now that f and h comply with (WP_2), and let $a \in \overline{\mathcal{F}}$. For each $t \in [0, T_M)$ take $y = x(t) - a$ in (4.1) to obtain $\langle \nabla f(x) + \frac{d}{dt}\nabla h(x), x - a + \dot{x}\rangle = 0$. By (4.2), this gives $\langle \frac{d}{dt}\nabla h(x), x - a\rangle + \langle \nabla f(x), x - a\rangle = 0$, which we rewrite as

$$\frac{d}{dt} D_h(a, x(t)) + \langle \nabla f(x(t)), x(t) - a\rangle = 0 \qquad \forall\ t \in [0, T_M). \tag{4.4}$$

Now let $a \in \overline{\mathcal{F}}$ be a minimizer of f on $\overline{\mathcal{F}}$. From the quasi-convexity property of f, it follows that, for all $t \in [0, T_M)$, $\langle \nabla f(x(t)), x(t) - a\rangle \geq 0$. Therefore, $D_h(a, x(t))$ is nonincreasing, and (WP_2)(ii) implies that x is bounded. Suppose that (WP_3) holds and fix $t \in [0, T_M)$; we have $|x(t)-x^0| \leq \int_0^t |\dot{x}(s)|ds \leq \int_0^t ||\sqrt{H(x(s))^{-1}}||\sqrt{H(x(s))}\dot{x}(s)|ds \leq (\int_0^t ||H(x(s))^{-1}||ds)^{1/2}(\int_0^t \langle H(x(s))\dot{x}(s), \dot{x}(s)\rangle ds)^{1/2}$. The latter follows from the Cauchy–Schwarz inequality, together with the fact that $\|H(x)\|^2$ is the biggest eigenvalue of $H(x)$. Thus $|x(t) - x^0| \leq 1/2[\int_0^t ||H(x(s))^{-1}||ds + \int_0^t \langle H(x(s))\dot{x}(s), \dot{x}(r)\rangle ds]$. Combining (WP_3) and (4.3), Gronwall's lemma yields the boundedness of x.

Let $\omega(x^0)$ be the set of limit points of x, and set $K = x([0, T_M)) \cup \omega(x^0)$. Since x is bounded, $\omega(x^0) \neq \emptyset$ and K is compact. If $K \subset C$, then the compactness of K implies that x can be extended beyond T_M, which contradicts the maximality of T_M. Let us prove $K \subset C$. We argue again by contradiction. Assume that $x(t_j) \to x^*$, with $t_j < T_M$, $t_j \to T_M$ as $j \to +\infty$, and $x^* \in \mathrm{bd} C = \overline{C} \backslash C$. Since h is of Legendre type, we have $|\nabla h(x(t_j))| \to +\infty$, and we may assume that $\nabla h(x(t_j))/|\nabla h(x(t_j))| \to \nu \in \mathbb{R}^n$ with $|\nu| = 1$.

LEMMA 4.2. *If $(x^j) \subset C$ is such that $x^j \to x^* \in \mathrm{bd}\, C$ and $\nabla h(x^j)/|\nabla h(x^j))| \to \nu \in \mathbb{R}^n$, h being a function of Legendre type with $C = \mathrm{int\,dom}\, h$, then $\nu \in N_{\overline{C}}(x^*)$.*

Proof of Lemma 4.2. By convexity of h, $\langle \nabla h(x^j) - \nabla h(y), x^j - y\rangle \geq 0$ for all $y \in C$. Dividing by $|\nabla h(x^j)|$ and letting $j \to +\infty$, we get $\langle \nu, y - x^*\rangle \leq 0$ for all $y \in C$, which holds also for $y \in \overline{C}$. Hence, $\nu \in N_{\overline{C}}(x^*)$. ∎

Therefore, $\nu \in N_{\overline{C}}(x^*)$. Let $\nu_0 = \Pi_{\mathcal{A}_0}\nu$ be the Euclidean orthogonal projection of ν onto $\mathcal{A}_0$, and take $y = \nu_0$ in (4.1). Using (4.2), integration gives

$$\langle \nabla h(x(t_j)), \nu_0\rangle = \left\langle \nabla h(x^0) - \int_0^{t_j} \nabla f(x(s))ds, \nu_0 \right\rangle. \tag{4.5}$$

By (H_0) and the boundedness property of x, the right-hand side of (4.5) is bounded under the assumption $T_M < +\infty$. Hence, to draw a contradiction from (4.5) it suffices to prove $\langle \nabla h(x(t_j)), \nu_0\rangle \to +\infty$. Since $\langle \nabla h(x(t_j))/|\nabla h(x(t_j))|, \nu_0\rangle \to |\nu_0|^2$, the proof of the result is complete if we check that $\nu_0 \neq 0$. This is a direct consequence of the following claim.

LEMMA 4.3. *Let C be a nonempty open convex subset of $\mathbb{R}^n$, and $\mathcal{A}$ an affine subspace of $\mathbb{R}^n$ such that $C \cap \mathcal{A} \neq \emptyset$. If $x^* \in (\mathrm{bd}\, C) \cap \mathcal{A}$, then $N_{\overline{C}}(x^*) \cap \mathcal{A}_0^{\perp} = \{0\}$ with $\mathcal{A}_0 = \mathcal{A} - \mathcal{A}$.*

Proof of Lemma 4.3. Let us argue by contradiction and suppose that we can pick some $v \neq 0$ in $\mathcal{A}_0^{\perp} \cap N_{\overline{C}}(x^*)$. For $y_0 \in C \cap \mathcal{A}$ we have $\langle v, x^* - y_0\rangle = 0$. For $r \geq 0$, $z \in \mathbb{R}^n$, let $B(z, r)$ denote the ball with center z and radius r. There exists $\epsilon > 0$ such that $B(y_0, \epsilon) \subset C$. Take w in $B(0, \epsilon)$ such that $\langle v, w\rangle < 0$; then $y_0 + w \in C$, and yet $\langle v, x^* - (y_0 + w)\rangle = \langle v, w\rangle < 0$. This contradicts the fact that v is in $N_{\overline{C}}(x^*)$. ∎

This completes the proof of the theorem. ∎

4.2. Value convergence for a convex objective function. As a first result concerning the asymptotic behavior of (H-SD), we have the following.

PROPOSITION 4.4. *If* (H-SD) *is well-posed and f is convex, then for all $a \in \mathcal{F}$, for all $t > 0$, $f(x(t)) \leq f(a) + \frac{1}{t} D_h(a, x^0)$, where D_h is defined by* (3.9)*; hence* $\lim_{t\to+\infty} f(x(t)) = \inf_{\overline{\mathcal{F}}} f$.

Proof. We begin by noticing that $f(x(t))$ converges as $t \to +\infty$ (see Theorem 4.1). Fix $a \in \mathcal{F}$. By (4.4), we have that the solution $x(t)$ of $(H\text{-}SD)$ satisfies $\frac{d}{dt} D_h(a, x(t)) + \langle \nabla f(x(t)), x(t) - a\rangle = 0$, $\forall t \geq 0$. The convex inequality$f(x) + \langle \nabla f(x), x - a\rangle \leq f(a)$ yields $D_h(a, x(t)) + \int_0^t [f(x(s)) - f(a)]ds \leq D_h(a, x^0)$. Using that

$D_h \geq 0$ and since $f(x(t))$ is non-increasing, we get the estimate. Letting $t \to +\infty$, it follows that $\lim_{t\to+\infty} f(x(t)) \leq f(a)$. Since $a \in \mathcal{F}$ was arbitrary chosen, the proof is complete. ∎

4.3. Bregman metrics and trajectory convergence. In this section we establish the convergence of $x(t)$ under some additional properties on the D-function of h. Let us begin with a definition.

DEFINITION 4.5. *A function $h \in \Gamma_0(\mathbb{R}^n)$ is called a* Bregman function with zone C *when the following conditions are satisfied:*

(i) $\operatorname{dom} h = \overline{C}$, *$h$ is continuous and strictly convex on $\overline{C}$ and $h_{|C} \in \mathcal{C}^1(C;\mathbb{R})$.*

(ii) *for all $a \in \overline{C}$, for all $\gamma \in \mathbb{R}$, $\{y \in C | D_h(a,y) \leq \gamma\}$ is bounded, where D_h is defined by* (3.9).

(iii) *for all $y \in \overline{C}$, for all $y^j \to y$ with $y^j \in C$, $D_h(y, y^j) \to 0$.*

Observe that this notion slightly weakens the usual definition of Bregman function that was proposed by Censor and Lent in [13]; see also [9]. Actually, a Bregman function in the sense of Definition 4.5 belongs to the class of B-functions introduced by Kiwiel (see [33, Definition 2.4]). Recall the following important asymptotic separation property.

LEMMA 4.6 (see [33, Lemma 2.16]). *If h is a Bregman function with zone C, then for all $y \in \overline{C}$, for all $(y^j) \subset C$ such that $D_h(y, y^j) \to 0$, we have $y^j \to y$.*

THEOREM 4.7. *Suppose that* (H_0) *holds, with h being a Bregman function with zone C. If f is quasi-convex satisfying* (3.6) *and $S(P) \neq \emptyset$, then* (H-SD) *is well-posed, and its solution $x(t)$ converges as $t \to +\infty$ to some $x^* \in \overline{\mathcal{F}}$ with $-\nabla f(x^*) \in N_{\overline{C}}(x^*) + \mathcal{A}_0^{\perp}$. If in addition f is convex then $x(t)$ converges to a solution of* (P).

Proof. Notice first that (WP_2) is satisfied. By Theorem 4.1, (H-SD) is well-posed, $x(t)$ is bounded, and for each $a \in S(P)$, $D_h(a, x(t))$ is nonincreasing and hence convergent. Set $f_\infty = \lim_{t\to+\infty} f(x(t))$ and define $L = \{y \in \overline{\mathcal{F}} \mid f(y) \leq f_\infty\}$. The set L is nonempty and closed. Since f is supposed to be quasi-convex, L is convex, and similar arguments as in the proof of Theorem 4.1 under (WP_2) show that $D_h(a, x(t))$ is convergent for all $a \in L$. Let $x^* \in L$ denote a cluster point of $x(t)$, and take $t_j \to +\infty$ such that $x(t_j) \to x^*$. Then, by Definition 4.5(iii), $\lim_t D_h(x^*, x(t)) = \lim_j D_h(x^*, x(t_j)) = 0$. Therefore, $x(t) \to x^*$, thanks to Lemma 4.6. Let us prove that x^* satisfies the optimality condition $-\nabla f(x^*) \in N_{\overline{C}}(x^*) + \mathcal{A}_0^{\perp}$. Fix $z \in \mathcal{A}_0$, and for each $t \geq 0$ take $y = -\dot{x}(t) + z$ in (4.1) to obtain $\langle \frac{d}{dt}\nabla h(x(t)) + \nabla f(x(t)), z\rangle = 0$. This gives

$$\frac{1}{t}\int_0^t \langle \nabla f(x(s)), z\rangle ds = \langle s(t), z\rangle, \tag{4.6}$$

where $s(t) = [\nabla h(x^0) - \nabla h(x(t))]/t$. If $x^* \in \mathcal{F}$, then $\nabla h(x(t)) \to \nabla h(x^*)$, and hence $\langle \nabla f(x^*), z\rangle = \lim_{t\to+\infty} \frac{1}{t}\int_0^t \langle \nabla f(x(s)), z\rangle ds = \lim_{t\to+\infty} \langle s(t), z\rangle = 0$. Thus $\Pi_{\mathcal{A}_0}\nabla f(x^*) = 0$. However, $N_{\overline{\mathcal{F}}}(x^*) = \mathcal{A}_0^{\perp}$ when $x^* \in \mathcal{F}$, which proves our claim in this case. Assume now that $x^* \notin \mathcal{F}$, which implies that $x^* \in \partial C \cap \mathcal{A}$. By (4.6), we have that $\langle s(t), z\rangle$ converges to $\langle \nabla f(x^*), z\rangle$ as $t \to +\infty$ for all $z \in \mathcal{A}_0$, and therefore $\Pi_{\mathcal{A}_0} s(t) \to \Pi_{\mathcal{A}_0}\nabla f(x^*)$ as $t \to +\infty$. On the other hand, by Lemma 4.2, we have that there exists $\nu \in -N_{\overline{C}}(x^*)$ with $|\nu| = 1$ such that $\nabla h(x(t_j))/|\nabla h(x(t_j))| \to \nu$ for some $t_j \to +\infty$. Since $N_{\overline{C}}(x^*)$ is positively homogeneous, we deduce that there exists a $\bar{\nu} \in -N_{\overline{C}}(x^*)$ such that $\Pi_{\mathcal{A}_0}\nabla f(x^*) = \Pi_{\mathcal{A}_0}\bar{\nu}$. Thus, $-\nabla f(x^*) \in -\Pi_{\mathcal{A}_0}\bar{\nu} + \mathcal{A}_0^{\perp} \subseteq N_{\overline{C}}(x^*) + \mathcal{A}_0^{\perp}$, which proves the theorem. ∎

Following [29], we remark that when f is linear, the limit point can be characterized as a sort of "D_h-projection" of the initial condition onto the optimal set $S(P)$.

In fact, we have the following result.

COROLLARY 4.8. *Under the assumptions of Theorem* 4.7*, if f is linear, then the solution $x(t)$ of* (H-SD) *converges as $t \to +\infty$ to the unique optimal solution x^* of*

$$\min_{x \in S(P)} D_h(x, x^0). \tag{4.7}$$

Proof. Let $x^* \in S(P)$ be such that $x(t) \to x^*$ as $t \to +\infty$. Let $\bar{x} \in S(P)$. Since $x(t) \in \mathcal{F}$, the optimality of $\bar{x}$ yields $f(x(t)) \geq f(\bar{x})$, and it follows from (3.10) that $D_h(x(t), x^0) \leq D_h(\bar{x}, x^0)$. Letting $t \to +\infty$ in the last inequality, we deduce that x^* solves (4.7). Noticing that $D_h(\cdot, x^0)$ is strictly convex due to Definition 4.5(i), we conclude the result. ∎

We finish this section with an abstract result concerning the rate of convergence under uniqueness of the optimal solution. We will apply this result in the next section. Suppose that f is convex and satisfies (2.3) and (3.6), with in addition $S(P) = \{a\}$. Given a Bregman function h complying with (H_0), consider the following growth condition:

$$f(x) - f(a) \geq \alpha D_h(a, x)^\beta \qquad \forall x \in U_a \cap \overline{C}, \tag{GC}$$

where U_a is a neighborhood of a and with $\alpha > 0$, $\beta \geq 1$. The next abstract result gives an estimation of the convergence rate with respect to the D-function of h.

PROPOSITION 4.9. *Assume that f and h satisfy the above conditions, and let $x : [0, +\infty) \to \mathcal{F}$ be the solution of* (H-SD)*. Then we have the following estimations:*

- *if $\beta = 1$, then there exists $K > 0$ such that $D_h(a, x(t)) \leq Ke^{-\alpha t}$ for all $t > 0$;*
- *if $\beta > 1$, then there exists $K' > 0$ such that $D_h(a, x(t)) \leq K'/t^{\frac{1}{\beta - 1}}$ for all $t > 0$.*

Proof. The assumptions of Theorem 4.7 are satisfied; this yields the well-posedness of (H-SD) and the convergence of $x(t)$ to a as $t \to +\infty$. Additionally, from (4.4) it follows that for all $t \geq 0$, $\frac{d}{dt} D_h(a, x(t)) + \langle \nabla f(x(t)), x(t) - a \rangle = 0$. By the convexity of f, we have $\frac{d}{dt} D_h(a, x(t)) + f(x(t)) - f(a) \leq 0$. Since $x(t) \to a$, there exists t_0 such that for all $t \geq t_0$, $x(t) \in U_a \cap \mathcal{F}$. Therefore by combining (GC) and the last inequality, it follows that

$$\frac{d}{dt} D_h(a, x(t)) + \alpha D_h(a, x(t))^\beta \leq 0 \qquad \forall t \geq t_0. \tag{4.8}$$

In order to integrate this differential inequality, let us first observe that we have the following equivalence: $D_h(a, x(t)) > 0$ for all $t \geq 0$ iff $x^0 \neq a$. Indeed, if $a \in \overline{\mathcal{F}} \setminus \mathcal{F}$, then the equivalence follows from $x(t) \in \mathcal{F}$ together with Lemma 4.6; if $a \in \mathcal{F}$, then the optimality condition that is satisfied by a is $\Pi_{\mathcal{A}_0} \nabla f(a) = 0$, and the equivalence is a consequence of the uniqueness of the solution $x(t)$ of (H-SD). Hence, we can assume that $x^0 \neq a$ and divide (4.8) by $D_h(a, x(t))^\beta$ for all $t \geq t_0$. A simple integration procedure then yields the result. ∎

4.4. Examples: Interior point flows in convex programming. This section gives a systematic method for constructing explicit Legendre metrics on a quite general class of convex sets. By so doing, we will also show that many systems studied earlier by various authors [6, 31, 20, 23, 36] appear as particular cases of (H-SD) systems.

Let $p \geq 1$ be an integer, and set $I = \{1, \ldots, p\}$. Let us assume that to each $i \in I$ there corresponds a $\mathcal{C}^3$ concave function $g_i : \mathbb{R}^n \to \mathbb{R}$ such that

$$\exists x^0 \in \mathbb{R}^n, \quad \text{s.t. } \forall i \in I,\ g_i(x^0) > 0. \tag{4.9}$$

Suppose that the open convex set C is given by

$$C = \{x \in \mathbb{R}^n \mid g_i(x) > 0, i \in I\}. \tag{4.10}$$

By (4.9) we have that $C \neq \emptyset$ and $\overline{C} = \{x \in \mathbb{R}^n \mid g_i(x) \geq 0, i \in I\}$. Let us introduce a class of convex functions of Legendre type $\theta \in \Gamma_0(\mathbb{R})$ satisfying

$$(\mathrm{H}_1) \quad \begin{cases} \text{(i) } (0,\infty) \subset \operatorname{dom}\theta \subset [0,\infty); \\ \text{(ii) } \theta \in \mathcal{C}^3(0,\infty) \text{ and } \lim_{s\to 0^+} \theta'(s) = -\infty; \\ \text{(iii) for all } s > 0,\ \theta''(s) > 0; \\ \text{(iv) either } \theta \text{ is nonincreasing or for all } i \in I, g_i \text{ is an affine function.} \end{cases}$$

Proposition 4.10. *Under* (4.9) *and* (H_1)*, the function* $h \in \Gamma_0(\mathbb{R}^n)$ *defined by*

$$h(x) = \sum_{i\in I} \theta(g_i(x)) \tag{4.11}$$

is essentially smooth, with $\operatorname{int}\operatorname{dom} h = C$ *and* $h \in \mathcal{C}^3(C)$*, where* C *is given by* (4.10)*. If we assume in addition the nondegeneracy condition*

$$\forall x \in C, \qquad \operatorname{span}\{\nabla g_i(x) \mid i \in I\} = \mathbb{R}^n, \tag{4.12}$$

then $H = \nabla^2 h$ *is positive definite on* C*, and consequently* h *satisfies* (H_0)*.*

Proof. Define $h_i \in \Gamma_0(\mathbb{R}^n)$ by $h_i(x) = \theta(g_i(x))$. We have that for all $i \in I$, $C \subset \operatorname{dom} h_i$. Hence $\operatorname{int}\operatorname{dom} h = \bigcap_{i\in I} \operatorname{int}\operatorname{dom} h_i \supseteq C \neq \emptyset$, and by [39, Theorem 23.8] we conclude that $\partial h(x) = \sum_{i\in I} \partial h_i(x)$ for all $x \in \mathbb{R}^n$. But $\partial h_i(x) = \theta'(g_i(x))\nabla g_i(x)$ if $g_i(x) > 0$, and $\partial h_i(x) = \emptyset$ if $g_i(x) \leq 0$; see [26, Theorem IX.3.6.1]. Therefore $\partial h(x) = \sum_{i\in I} \theta'(g_i(x))\nabla g_i(x)$ if $x \in C$, and $\partial h(x) = \emptyset$ otherwise. Since ∂h is a single-valued mapping, it follows from [39, Theorem 26.1] that h is essentially smooth and $\operatorname{int}\operatorname{dom} h = \operatorname{dom}\partial h = C$. Clearly, h is of class $\mathcal{C}^3$ on C. Assume now that (4.12) holds. For $x \in C$, we have $\nabla^2 h(x) = \sum_{i\in I} \theta''(g_i(x))\nabla g_i(x)\nabla g_i(x)^T + \sum_{i\in I} \theta'(g_i(x))\nabla^2 g_i(x)$. By (H_1)(iv), it follows that for any $v \in \mathbb{R}^n$, $\sum_{i\in I} \theta'(g_i(x))\langle \nabla^2 g_i(x)v, v\rangle \geq 0$. Let $v \in \mathbb{R}^n$ be such that $\langle \nabla^2 h(x)v, v\rangle = 0$, which yields $\sum_{i\in I} \theta''(g_i(x))\langle v, \nabla g_i(x)\rangle^2 = 0$. According to (H_1)(iii), the latter implies that $v \in \operatorname{span}\{\nabla g_i(x) | i \in I\}^\perp = \{0\}$. Hence $\nabla^2 h(x) \in \mathbb{S}^n_{++}$, and the proof is complete. ∎

If h is defined by (4.11) with $\theta \in \Gamma_0(\mathbb{R})$ satisfying (H_1), we say that θ is the *Legendre kernel* of h. Such kernels can be divided into two classes. The first class corresponds to those kernels θ for which $\operatorname{dom}\theta = (0,\infty)$ so that $\theta(0) = +\infty$, and these kernels are associated with *interior barrier* methods in optimization such as, for instance, the log-barrier $\theta_1(s) = -\ln(s)$, $s > 0$, and the inverse barrier $\theta_2(s) = 1/s$, $s > 0$. The kernels θ belonging to the second class satisfy $\theta(0) < +\infty$ and are connected with the notion of a *Bregman function* in proximal algorithm theory. Here are some examples: the Boltzmann–Shannon entropy $\theta_3(s) = s\ln(s) - s$, $s \geq 0$ (with $0\ln 0 = 0$); $\theta_4(s) = -\frac{1}{\gamma}s^\gamma$ with $\gamma \in (0,1)$, $s \geq 0$ (Kiwiel [33]); $\theta_5(s) = (\gamma s - s^\gamma)/(1-\gamma)$ with $\gamma \in (0,1)$, $s \geq 0$ (Teboulle [42]); the "$x\log x$" entropy $\theta_6(s) = s\ln s$, $s \geq 0$. In relation with Theorem 4.7 given in the previous section, note that the Legendre kernels θ_i, $i = 3,\ldots,6$, are all Bregman functions with zone $\mathbb{R}_+$. Moreover, it is easily seen that each corresponding Legendre function h defined by (4.11) is indeed a Bregman function with zone C.

In order to illustrate the type of dynamical systems given by (H-SD), consider the case of positivity constraints where $p = n$ and $g_i(x) = x_i$, $i \in I$. Thus $C = \mathbb{R}^n_{++}$

and $\overline{C} = \mathbb{R}^n_+$. Let us assume that there exists $x^0 \in \mathbb{R}^n_{++}$ such that $Ax^0 = b$. Recall that the corresponding minimization problem is (P), $\min\{f(x) \mid x \geq 0,\ Ax = b\}$, and take first the kernel θ_3 from above. The associated Legendre function (4.11) is given by

$$h(x) = \sum_{i=1}^{n} x_i \ln x_i - x_i, \quad x \in \mathbb{R}^n_+, \tag{4.13}$$

and the differential equation in (H-SD) is given by

$$\dot{x} + [I - XA^T(AXA^T)^{-1}A]X\nabla f(x) = 0, \tag{4.14}$$

where $X = \operatorname{diag}(x_1, \ldots, x_n)$. If $f(x) = \langle c, x\rangle$, for some $c \in \mathbb{R}^n$ and in absence of linear equality constraints, then (4.14) is $\dot{x} + Xc = 0$. The change of coordinates $y = \nabla h(x) = (\ln x_1, \ldots, \ln x_n)$ gives $\dot{y} + c = 0$. Hence, $x(t) = (x_1^0 e^{-c_1 t}, \ldots, x_n^0 e^{-c_n t})$, $t \in \mathbb{R}$, where $x^0 = (x_1^0, \ldots, x_n^0) \in \mathbb{R}^n_{++}$. If $c \in \mathbb{R}^n_+$, then $\inf_{x\in\mathbb{R}^n_+}\langle c, x\rangle = 0$ and $x(t)$ converges to a minimizer of $f = \langle c, \cdot\rangle$ on $\mathbb{R}^n_+$; if $c_{i_0} < 0$ for some i_0, then $\inf_{x\in\mathbb{R}^n_+}\langle c, x\rangle = -\infty$ and $x_{i_0}(t) \to +\infty$ as $t \to +\infty$. Next, take $A = (1, \ldots, 1) \in \mathbb{R}^{1\times n}$ and $b = 1$ so that the feasible set of (P) is given by $\overline{\mathcal{F}} = \Delta_{n-1} = \{x \in \mathbb{R}^n \mid x \geq 0,\ \sum_{i=1}^n x_i = 1\}$, that is, the $(n-1)$-dimensional simplex. In this case, (4.14) corresponds to $\dot{x} + [X - xx^T]\nabla f(x) = 0$, or componentwise

$$\dot{x}_i + x_i\left(\frac{\partial f}{\partial x_i} - \sum_{j=1}^{n} x_j \frac{\partial f}{\partial x_j}\right) = 0, \quad i = 1, \ldots, n. \tag{4.15}$$

For suitable choices of f, this is a *Lotka–Volterra*-type equation that naturally arises in population dynamics theory and, in that context, the structure $(\cdot,\cdot)^H$ with h as in (4.13) is usually referred to as the *Shahshahani* metric; see [1, 27] and the references therein.

Karmarkar studied (4.15) in [31] for a quadratic objective function as a continuous model of the interior point algorithm introduced by him in [30]. Equation (4.14) is studied by Faybusovich in [20, 21, 22] when (P) is a linear program, establishing connections with completely integrable Hamiltonian systems and exponential convergence rate, and by Herzel, Recchini, and Zirilli in [25], who prove quadratic convergence for an explicit discretization.

Take now the log barrier kernel θ_1 and $h(x) = -\sum_{i=1}^n \ln x_i$. Since $\nabla^2 h(x) = X^{-2}$ with X defined as above, the associated differential equation is

$$\dot{x} + [I - X^2A^T(AX^2A^T)^{-1}A]X^2\nabla f(x) = 0. \tag{4.16}$$

This equation was considered by Bayer and Lagarias in [6] for a linear program. In the particular case $f(x) = \langle c, x\rangle$ and without linear equality constraints, (4.16) amounts to $\dot{x} + X^2c = 0$, or $\dot{y} + c = 0$ for $y = \nabla h(x) = -X^{-1}e$, with $e = (1, \ldots, 1) \in \mathbb{R}^n$, which gives $x(t) = \big(1/(1/x_1^0 + c_1 t), \ldots, 1/(1/x_n^0 + c_n t)\big)$, $T_m \leq t \leq T_M$, with $T_m = \max\{-1/x_i^0 c_i \mid c_i > 0\}$ and $T_M = \min\{-1/x_i^0 c_i \mid c_i < 0\}$ (see [6, p. 515]). A similar system was considered in [23, 36] as a continuous log-barrier method for nonlinear inequality constraints and with $\mathcal{A}_0 = \mathbb{R}^n$.

New systems may be derived by choosing other kernels. For instance, taking $h(x) = -1/\gamma \sum_{i=1}^n x_i^\gamma$ with $\gamma \in (0, 1)$, $A = (1, \ldots, 1) \in \mathbb{R}^{1\times n}$, and $b = 1$, we obtain

$$\dot{x}_i + \frac{x_i^{2-\gamma}}{1-\gamma}\left(\frac{\partial f}{\partial x_i} - \sum_{j=1}^{n} \frac{x_j^{2-\gamma}}{\sum_{k=1}^n x_k^{2-\gamma}} \frac{\partial f}{\partial x_j}\right) = 0, \quad i = 1, \ldots, n. \tag{4.17}$$

4.5. Convergence results for linear programming. Let us consider the specific case of a linear program

$$\min_{x\in\mathbb{R}^n}\{\langle c,x\rangle \mid Bx\geq d,\ Ax=b\}, \tag{LP}$$

where A and b are as in section 2.1, $c\in\mathbb{R}^n$, B is a $p\times n$ full rank real matrix with $p\geq n$, and $d\in\mathbb{R}^p$. We assume that the optimal set satisfies

$$S(LP) \text{ is nonempty and bounded} \tag{4.18}$$

and that there exists a Slater point $x^0\in\mathbb{R}^n$, $Bx^0>d$, and $Ax^0=b$. Take the Legendre function

$$h(x)=\sum_{i=1}^{n}\theta(g_i(x)),\quad g_i(x)=\langle B_i,x\rangle-d_i, \tag{4.19}$$

where $B_i\in\mathbb{R}^n$ is the ith row of B and the Legendre kernel θ satisfies (H_1). By (4.18), (WP_1) holds, and therefore (H-SD) is well posed due to Theorem 4.1. Moreover, $x(t)$ is bounded and all its cluster points belong to $S(LP)$ by Proposition 4.4. The variational property (3.10) ensures the convergence of $x(t)$ and gives a variational characterization of the limit as well. Indeed, we have the following result.

PROPOSITION 4.11. *Let h be given by* (4.19) *with θ satisfying* (H_1). *Under* (4.18), *(H-SD) is well posed and $x(t)$ converges as $t\to+\infty$ to the unique solution x^* of*

$$\min_{x\in S(LP)}\sum_{i\notin I_0}D_\theta(g_i(x),g_i(x^0)), \tag{4.20}$$

where $I_0=\{i\in I \mid g_i(x)=0$ for all $x\in S(LP)\}$.

Proof. Assume that $S(LP)$ is not a singleton; otherwise there is nothing to prove. The relative interior ri $S(LP)$ is nonempty, and moreover ri $S(LP)=\{x\in\mathbb{R}^n \mid g_i(x)=0$ for $i\in I_0$, $g_i(x)>0$ for $i\notin I_0$, $Ax=b\}$. By compactness of $S(LP)$ and strict convexity of $\theta\circ g_i$, there exists a unique solution x^* of (4.20). Indeed, it is easy to see that $x^*\in$ ri (LP). Let $\bar{x}\in S(LP)$ and $t_j\to+\infty$ be such that $x(t_j)\to\bar{x}$. It suffices to prove that $\bar{x}=x^*$. When $\theta(0)<+\infty$, the latter follows by the same arguments as in Corollary 4.8. When $\theta(0)=+\infty$, the proof of [4, Theorem 3.1] can be adapted to our setting (see also [29, Theorem 2]). Set $x^*(t)=x(t)-\bar{x}+x^*$. Since $Ax^*(t)=b$ and $D_h(x,x^0)=\sum_{i=1}^m D_\theta(g_i(x),g_i(x^0))$, equation (3.10) gives

$$\langle c,x(t)\rangle+\frac{1}{t}\sum_{i=1}^{m}D_\theta(g_i(x(t)),g_i(x^0))\leq\langle c,x^*(t)\rangle+\frac{1}{t}\sum_{i=1}^{m}D_\theta(g_i(x^*(t)),g_i(x^0)). \tag{4.21}$$

However, $\langle c,x(t)\rangle=\langle c,x^*(t)\rangle$ and for all $i\in I_0$, $g_i(x^*(t))=g_i(x(t))>0$. Since $x^*\in$ ri $S(LP)$, for all $i\notin I_0$ and j large enough, $g_i(x^*(t_j))>0$. Thus, the right-hand side of (4.21) is finite at t_j, and it follows that $\sum_{i\notin I_0}D_\theta(g_i(\bar{x}),g_i(x^0))\leq\sum_{i\notin I_0}D_\theta(g_i(x^*),g_i(x^0))$. Hence, $\bar{x}=x^*$. ∎

Rate of convergence. We turn now to the case where there is no equality constraint so that the linear program is

$$\min_{x\in\mathbb{R}^n}\{\langle c,x\rangle \mid Bx\geq d\}. \tag{4.22}$$

We assume that (4.22) admits a unique solution a, and we study the rate of convergence when θ is a Bregman function with zone $\mathbb{R}_+$. To apply Proposition 4.9, we need the following result.

LEMMA 4.12. *Set* $C = \{x \in \mathbb{R}^n | Bx > d\}$. *If* (4.22) *admits a unique solution* $a \in \mathbb{R}^n$, *then there exists* $k_0 > 0$, *s.t. for all* $y \in \overline{C}$, $\langle c, y - a\rangle \geq k_0 \mathcal{N}(y - a)$, *where* $\mathcal{N}(x) = \sum_{i\in I} |\langle B_i, x\rangle|$ *is a norm on* $\mathbb{R}^n$.

Proof. Set $I_0 = \{i \in I \mid \langle B_i, a\rangle = d_i\}$. The optimality conditions for a imply the existence of a *multiplier* vector $\lambda \in \mathbb{R}^p_+$ such that $\lambda_i[d_i - \langle B_i, a\rangle] = 0$, for all $i \in I$, and $c = \sum_{i\in I} \lambda_i B_i$. Let $y \in \overline{C}$. We deduce that $\langle c, y - a\rangle = N(y - a)$, where $N(x) = \sum_{i\in I_0} \lambda_i |\langle B_i, x\rangle|$. By uniqueness of the optimal solution, it is easy to see that $\operatorname{span}\{B_i \mid i \in I_0\} = \mathbb{R}^n$; hence N is a norm on $\mathbb{R}^n$. Since $\mathcal{N}(x) = \sum_{i\in I} |\langle B_i, x\rangle|$ is also a norm on $\mathbb{R}^n$ (recall that B is a full rank matrix), we deduce that there exists k_0 such that $N(x) \geq k_0 \mathcal{N}(x)$. ∎

The following lemma is a sharper version of Proposition 4.9 in the linear context.

LEMMA 4.13. *Under the assumptions of Proposition* 4.11, *assume in addition that* θ *is a Bregman function with zone* $\mathbb{R}_-$ *and that there exist* $\alpha > 0$, $\beta \geq 1$, *and* $\varepsilon > 0$ *such that*

$$\forall s \in (0, \varepsilon), \qquad \alpha D_\theta(0, s)^\beta \leq s. \tag{4.23}$$

Then there exist positive constants K, L, M *such that for all* $t > 0$ *the trajectory of* (H-SD) *satisfies* $D_h(a, x(t)) \leq Ke^{-Lt}$ *if* $\beta = 1$, *and* $D_h(a, x(t)) \leq M/t^{\frac{1}{\beta-1}}$ *if* $\beta > 1$.

Proof. By Lemma 4.12, there exists k_0 such that for all $t > 0$,

$$\langle c, x(t) - a\rangle \geq \sum_{i\in I} k_0 |\langle B_i, x(t)\rangle - \langle B_i, a\rangle|. \tag{4.24}$$

Now, if we prove that there exists $\lambda > 0$ such that

$$|\langle B_i, x(t)\rangle - \langle B_i, a\rangle| \geq \lambda D_\theta(\langle B_i, a\rangle - d_i, \langle B_i, x(t)\rangle - d_i) \tag{4.25}$$

for all $i \in I$ and for t large enough, then from (4.24) it follows that $f(\cdot) = \langle c, \cdot\rangle$ satisfies the assumptions of Proposition 4.9, and the conclusion follows easily. Since $x(t) \to a$, to prove (4.25) it suffices to show that for all $r_0 \geq 0$ there exist $\eta, \mu > 0$ such that for all s, $|s - r_0| < \eta$, $\mu D_\theta(r_0, s)^\beta \leq |r_0 - s|$. The case where $r_0 = 0$ is a direct consequence of (4.23). Let $r_0 > 0$. An easy computation yields $\frac{d^2}{ds^2} D_\theta(r_0, s)_{|s=r_0} = \theta''(r_0)$, and by Taylor's expansion formula,

$$D_\theta(r_0, s) = \frac{\theta''(r_0)}{2}(s - r_0)^2 + o(s - r_0)^2 \tag{4.26}$$

with $\theta''(r_0) > 0$ due to (H_1)(iii). Let η be such that for all s, $|s - r_0| < \eta$, $s > 0$, $D_\theta(r_0, s) \leq \theta''(r_0)(s - r_0)^2$, and $D_\theta(r_0, s) \leq 1$; since $\beta \geq 1$, $D_\theta(r_0, s)^\beta \leq D_\theta(r_0, s) \leq \theta''(r_0)|s - r_0|$. ∎

To obtain Euclidean estimates, the functions $s \mapsto D_\theta(r_0, s)$, $r_0 \in \mathbb{R}_+$, have to be locally compared to $s \mapsto |r_0 - s|$. By (4.26) and the fact that $\theta'' > 0$, for each $r_0 > 0$ there exist $K, \eta > 0$ such that $|r_0 - s| \leq K\sqrt{D_\theta(r_0, s)}$, for all s, $|r_0 - s| < \eta$. This shows that, in practice, the Euclidean estimate depends only on a property of the type (4.23). Examples:

- The Boltzmann–Shannon entropies $\theta_3(s) = s\ln(s) - s$ and $\theta_6(s) = s\ln s$ satisfy $D_{\theta_i}(0, s) = s$, $s > 0$; hence for some $K, L > 0$, $|x(t) - a| \leq Ke^{-Lt}$, for all $t \geq 0$.
- With either $\theta_4(s) = -s^\gamma/\gamma$ or $\theta_5(s) = (\gamma s - s^\gamma)/(1 - \gamma)$, $\gamma \in (0, 1)$, we have $D_{\theta_i}(0, s) = (1 + 1/\gamma)s^\gamma$, $s > 0$; hence $|x(t) - a| \leq K/t^{\frac{\gamma}{2-2\gamma}}$, for all $t > 0$.

4.6. Dual convergence. In this section we focus on the case $C = \mathbb{R}^n_{++}$, so that the minimization problem is

$$\min\{f(x) \mid x \geq 0,\ Ax = b\}. \tag{P}$$

We assume

$$f \text{ is convex and } S(P) \neq \emptyset, \tag{4.27}$$

together with the Slater condition

$$\exists x^0 \in \mathbb{R}^n,\ x^0 > 0,\ Ax^0 = b. \tag{4.28}$$

In convex optimization theory, it is usual to associate with (P) the *dual* problem given by

$$\min\{p(\lambda) \mid \lambda \geq 0\}, \tag{D}$$

where $p(\lambda) = \sup\{\langle \lambda, x\rangle - f(x) \mid Ax = b\}$. For many applications, dual solutions are as important as primal ones. In the particular case of a linear program where $f(x) = \langle c, x\rangle$ for some $c \in \mathbb{R}^n$, writing $\lambda = c + A^T y$ with $y \in \mathbb{R}^m$, the linear dual problem may equivalently be expressed as $\min\{\langle b, y\rangle \mid A^T y + c \geq 0\}$. Thus, λ is interpreted as a vector of *slack* variables for the dual inequality constraints. In the general case, $S(\mathrm{D})$ is nonempty and bounded under (4.27) and (4.28), and moreover $S(\mathrm{D}) = \{\lambda \in \mathbb{R}^n \mid \lambda \geq 0,\ \lambda \in \nabla f(x^*) + \operatorname{Im} A^T,\ \langle \lambda, x^*\rangle = 0\}$, where x^* is any solution of (P); see, for instance, [26, Theorems VII.2.3.2 and VII.4.5.1].

Let us introduce a Legendre kernel θ satisfying (H_1) and define

$$h(x) = \sum_{i=1}^{n} \theta(x_i). \tag{4.29}$$

Suppose that (H-SD) is well posed. Integrating the differential inclusion (3.7), we obtain

$$\lambda(t) \in c(t) + \operatorname{Im} A^T, \tag{4.30}$$

where $c(t) = \frac{1}{t}\int_0^t \nabla f(x(\tau))d\tau$ and $\lambda(t)$ is the *dual trajectory* defined by

$$\lambda(t) = \frac{1}{t}[\nabla h(x^0) - \nabla h(x(t))]. \tag{4.31}$$

Assume that $x(t)$ is bounded. From (4.27), it follows that ∇f is constant on $S(\mathrm{P})$, and then it is easy to see that $\nabla f(x(t)) \to \nabla f(x^*)$ as $t \to +\infty$ for any $x^* \in S(\mathrm{P})$. Consequently, $c(t) \to \nabla f(x^*)$. By (4.31) together with [39, Theorem 26.5], we have $x(t) = \nabla h^*(\nabla h(x^0) - t\lambda(t))$, where the Fenchel conjugate h^* is given by $h^*(\lambda) = \sum_{i=1}^n \theta^*(\lambda_i)$. Take any solution $\widetilde{x}$ of $A\widetilde{x} = b$. Since $Ax(t) = b$, we have $\widetilde{x} - \nabla h^*(\nabla h(x^0) - t\lambda(t)) \in \operatorname{Ker} A$. On account of (4.30), $\lambda(t)$ is the unique optimal solution of

$$\lambda(t) \in \operatorname{Argmin}\left\{\langle \widetilde{x}, \lambda\rangle + \frac{1}{t}\sum_{i=1}^{n} \theta^*(\theta'(x_i^0) - t\lambda_i) \mid \lambda \in c(t) + \operatorname{Im} A^T\right\}. \tag{4.32}$$

By (H_1)(iii), θ' is increasing in $\mathbb{R}_{++}$. Set $\eta = \lim_{s\to+\infty} \theta'(s) \in (-\infty, +\infty]$. Since θ^* is a Legendre-type function, $\operatorname{int dom}\, \theta^* = \operatorname{dom} \partial\theta^* = \operatorname{Im} \partial\theta = (-\infty, \eta)$. From

$(\theta^*)' = (\theta')^{-1}$, it follows that $\lim_{u\to-\infty}(\theta^*)'(u) = 0$ and $\lim_{u\to\eta^-}(\theta^*)'(u) = +\infty$. Consequently, (4.32) can be interpreted as a *penalty approximation scheme* of the dual problem (D), where the dual positivity constraints are penalized by a separable strictly convex function. Similar schemes have been treated in [4, 16, 17, 28]. Consider the additional condition

(4.33) Either $\theta(0) < \infty$, or $S(P)$ is bounded, or f is linear.

As a direct consequence of [28, Propositions 10 and 11], we obtain that under (4.27), (4.28), (4.33) and (H_1), $\{\lambda(t) \mid t \to +\infty\}$ is bounded and its cluster points belong to $S(D)$. The convergence of $\lambda(t)$ is more difficult to establish. In fact, under some additional conditions on θ^* (see [16, Conditions (H_0)–(H_1)] or [28, Conditions (A7) and (A8)]) it is possible to show that $\lambda(t)$ converges to a particular element of the dual optimal set (the "θ^*-center" in the sense of [16, Definition 5.1] or the $D_h(\cdot, x^0)$-center as defined in [28, p. 616]), which is characterized as the unique solution of a *nested hierarchy* of optimization problems on the dual optimal set. We will not develop this point here. Let us only mention that for all the examples of section 4.4, θ_i^* satisfies such additional conditions and consequently we have the following result.

PROPOSITION 4.14. *Under* (4.27), (4.28), *and* (4.33), *for each of the explicit Legendre kernels given in section* 4.4, $\lambda(t)$ *given by* (4.31) *converges to a particular dual solution.*

5. Legendre transform coordinates.

5.1. Legendre functions on affine subspaces. The first objective of this section is to slightly generalize the notion of a Legendre-type function to the case of functions whose domains are contained in an affine subspace of $\mathbb{R}^n$. We begin by noticing that the Legendre-type property does not depend on canonical coordinates.

LEMMA 5.1. *Let $g \in \Gamma_0(\mathbb{R}^r)$, $r \geq 1$, and $T : \mathbb{R}^r \to \mathbb{R}^r$ an affine invertible mapping. Then g is of a Legendre type iff $g \circ T$ is of Legendre type.*

Proof. The proof is elementary and is left to the reader. □

From now on, $\mathcal{A}$ is the affine subspace defined by (2.1), whose dimension is $r = n - m$.

DEFINITION 5.2. *A function $g \in \Gamma_0(\mathcal{A})$ is said to be of* Legendre type *if there exists an affine invertible mapping $T : \mathcal{A} \to \mathbb{R}^r$ such that $g \circ T^{-1}$ is a Legendre-type function in $\Gamma_0(\mathbb{R}^r)$.*

By Lemma 5.1, the previous definition is consistent.

PROPOSITION 5.3. *Let $h \in \Gamma_0(\mathbb{R}^n)$ be a function of Legendre type with $C = \operatorname{int}\operatorname{dom} h$. If $\mathcal{F} = C \cap \mathcal{A} \neq \emptyset$, then the restriction $h_{|\mathcal{A}}$ of h to $\mathcal{A}$ is of Legendre type, and moreover $\operatorname{int}_{\mathcal{A}}\operatorname{dom} h_{|\mathcal{A}} = \mathcal{F}$ (where $\operatorname{int}_{\mathcal{A}} B$ stands for the interior of B in $\mathcal{A}$ as a topological subspace of $\mathbb{R}^n$).*

Proof. From the inclusions $\mathcal{F} \subset \operatorname{dom} h_{|\mathcal{A}} \subset \overline{\mathcal{F}} = \overline{C} \cap \mathcal{A}$ and since $\operatorname{ri}\overline{\mathcal{F}} = \mathcal{F}$, we conclude that $\operatorname{int}_{\mathcal{A}}\operatorname{dom} h_{|\mathcal{A}} = \mathcal{F} \neq \emptyset$. Let $T : \mathbb{R}^r \to \mathcal{A}$ be an invertible transformation with $Tz = Lz + x^0$ for all $z \in \mathbb{R}^r$, where $x^0 \in \mathcal{A}$ and $L : \mathbb{R}^r \to \mathcal{A}_0$ is a nonsingular linear mapping. Define $k = h_{|\mathcal{A}} \circ T$. Clearly, $k \in \Gamma_0(\mathbb{R}^r)$. Let us prove that k is essentially smooth. We have $\operatorname{dom} k = T^{-1}\operatorname{dom} h_{|\mathcal{A}}$ and therefore $\operatorname{int}\operatorname{dom} k = T^{-1}\mathcal{F}$. Since h is differentiable on C, we conclude that k is differentiable on $\operatorname{int}\operatorname{dom} k$. Now, let $(z^j) \in \operatorname{int}\operatorname{dom} k$ be a sequence that converges to a boundary point $z \in \operatorname{bd}\operatorname{dom} k$. Then, $Tz^j \in \operatorname{int}_{\mathcal{A}}\operatorname{dom} h_{|\mathcal{A}}$ and $Tz^j \to Tz \in \operatorname{bd}_{\mathcal{A}}\operatorname{dom} h_{|\mathcal{A}} \subset \operatorname{bd}\operatorname{dom} h$. Since h is essentially smooth, $|\nabla h(Tz^j)| \to +\infty$. Thus, to prove that $|\nabla k(z^j)| \to +\infty$, it suffices to show that there exists $\lambda > 0$ such that $|\nabla k(z^j)| \geq \lambda |\nabla h(Tz^j)|$ for all j

large enough. Note that $\nabla k(z^j) = \nabla[h_{|\mathcal{A}} \circ T](z^j) = L^* \nabla h_{|\mathcal{A}}(Tz^j) = L^* \Pi_{\mathcal{A}_0} \nabla h(Tz^j)$, where $L^* : \mathcal{A}_0 \to \mathbb{R}^r$ is defined by $\langle z, L^* x \rangle = \langle Lz, x \rangle$ for all $(z, x) \in \mathbb{R}^r \times \mathcal{A}_0$. Of course, L^* is linear with $\operatorname{Ker} L^* = \{0\}$. Therefore $\frac{\nabla k(z^j)}{|\nabla h(Tz^j)|} = L^* \Pi_{\mathcal{A}_0} \frac{\nabla h(Tz^j)}{|\nabla h(Tz^j)|}$. Let ω denote the nonempty and compact set of cluster points of the normalized sequence $\nabla h(Tz^j)/|\nabla h(Tz^j)|$, $j \in \mathbb{N}$. By Lemma 4.2, we have that $\omega \subset \{\nu \in N_{\overline{C}}(Tz) \,|\, |\nu| = 1\}$, and consequently Lemma 4.3 yields $\Pi_{\mathcal{A}_0} \omega \cap \{0\} = \emptyset$. By the compactness of ω, we obtain $\liminf_{j \to +\infty} |\Pi_{\mathcal{A}_0} \nabla h(Tz^j)|/|\nabla h(Tz^j)| > 0$, which proves our claim. Finally, the strict convexity of k on $\operatorname{dom} \partial k = \operatorname{int} \operatorname{dom} k = T^{-1}\mathcal{F}$ is a direct consequence of the strict convexity of h in $\mathcal{F}$. □

5.2. Legendre transform coordinates. The prominent fact of Legendre functions theory is that $h \in \Gamma_0(\mathbb{R}^n)$ is of Legendre type iff its Fenchel conjugate h^* is of Legendre type [39, Theorem 26.5], and $\nabla h : \operatorname{int} \operatorname{dom} h \to \operatorname{int} \operatorname{dom} h^*$ is onto with $(\nabla h)^{-1} = \nabla h^*$. In the case of Legendre functions on affine subspaces, we have the following generalization.

PROPOSITION 5.4. *If $g \in \Gamma_0(\mathcal{A})$ is of Legendre type in the sense of Definition 5.2, then $\nabla g(\operatorname{int}_{\mathcal{A}} \operatorname{dom} g)$ is a nonempty, open, and convex subset of $\mathcal{A}_0$. In addition, ∇g is a one-to-one continuous mapping from $\operatorname{int}_{\mathcal{A}} \operatorname{dom} g$ onto its image.*

Proof. Let $Tx = Lx + z_0$, with $L : \mathcal{A}_0 \to \mathbb{R}^r$ being a linear invertible mapping and $z_0 \in \mathbb{R}^p$. Set $k = g \circ T^{-1} \in \Gamma_0(\mathbb{R}^r)$, which is of Legendre type. We have $\operatorname{dom} k = T \operatorname{dom} g$. Define $L^* : \mathbb{R}^r \to \mathcal{A}_0$ by $\langle L^* z, x \rangle = \langle z, Lx \rangle$ for all $(z, x) \in \mathbb{R}^r \times \mathcal{A}_0$. We have that $\nabla g(x) = \nabla[k \circ T](x) = L^* \nabla k(Tx)$ for all $x \in \operatorname{int}_{\mathcal{A}} \operatorname{dom} g$. Therefore $\nabla g(\operatorname{int}_{\mathcal{A}} \operatorname{dom} g) = L^* \nabla k(T \operatorname{int}_{\mathcal{A}} \operatorname{dom} g) = L^* \nabla k(\operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k) = L^* \operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k^*$. Since $\operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k^*$ is a nonempty, open, and convex subset of $\mathbb{R}^r$ and L^* is an invertible linear mapping, then $L^* \operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k^*$ is an open and nonempty subset of $\mathcal{A}_0$. Moreover, by [39, Theorem 6.6], we have $L^* \operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k^* = \operatorname{ri} L^* \operatorname{dom} k^*$. Consequently, $\nabla g(\operatorname{int}_{\mathcal{A}} \operatorname{dom} g) = \operatorname{ri} L^* \operatorname{dom} k^* = \operatorname{int}_{\mathcal{A}_0} L^* \operatorname{dom} k^* \neq \emptyset$. Finally, since $\nabla k : \operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k \to \operatorname{int}_{\mathbb{R}^r} \operatorname{dom} k^*$ is one-to-one and continuous, the same result holds for $\nabla g = L^* \circ \nabla k \circ T$ on $\operatorname{int}_{\mathcal{A}} \operatorname{dom} g$. □

In what follows, we assume that h satisfies the basic condition (H_0) and $\mathcal{F} = C \cap \mathcal{A} \neq \emptyset$. The *Legendre transform coordinates mapping* on $\mathcal{F}$ associated with h is defined by

$$\begin{array}{rccl} \phi_h : & \mathcal{F} & \to & \mathcal{F}^* = \phi_h(\mathcal{F}), \\ & x & \mapsto & \phi_h(x) = \nabla(h_{|\mathcal{A}}) = \Pi_{\mathcal{A}_0} \nabla h(x). \end{array} \tag{5.1}$$

This definition retrieves the Legendre transform coordinates introduced by Bayer and Lagarias in [6] for the particular case of the log-barrier on a polyhedral set.

THEOREM 5.5. *Under the above definitions and assumptions, $\mathcal{F}^*$ is a convex, (relatively) open, and nonempty subset of $\mathcal{A}_0$; ϕ_h is a $\mathcal{C}^1$ diffeomorphism from $\mathcal{F}$ to $\mathcal{F}^*$; and for all $x \in \mathcal{F}$, $d\phi_h(x) = \Pi_{\mathcal{A}_0} H(x)$ and $d\phi_h(x)^{-1} = \sqrt{H(x)^{-1}} \Pi_{\sqrt{H(x)}\mathcal{A}_0} \sqrt{H(x)^{-1}}$, where $H(x) = \nabla^2 h(x)$.*

Proof. By Propositions 5.3 and 5.4, $\mathcal{F}^*$ is a convex, open, and nonempty subset of $\mathcal{A}_0$ and ϕ_h is a continuous bijection. By (H_0)(ii), ϕ_h is of class $\mathcal{C}^1$ on $\mathcal{F}$, and we have, for all $x \in \mathcal{F}$, $d\phi_h(x) = \Pi_{\mathcal{A}_0} \nabla^2 h(x) = \Pi_{\mathcal{A}_0} H(x)$. Let $v \in \mathcal{A}_0$ be such that $d\phi_h(x)v = 0$. It follows that $H(x)v \in \mathcal{A}_0^\perp$ and, in particular, $\langle H(x)v, v \rangle = 0$. Hence, $v = 0$, thanks to (H_0)(iii). The implicit function theorem implies then that ϕ_h is a $\mathcal{C}^1$ diffeomorphism. Finally, the formula concerning $d\phi_h(x)^{-1}$ is a direct consequence of the next lemma, which is analogous to [7, p. 545], and whose proof is omitted.

LEMMA 5.6. *Define the linear operators $L_i : \mathbb{R}^n \to \mathbb{R}^n$ by $L_1 = \Pi_{\mathcal{A}_0} H(x)$ and*

$L_2 = \sqrt{H(x)^{-1}}\Pi_{\sqrt{H(x)}\mathcal{A}_0}\sqrt{H(x)^{-1}}$. *Then* $L_2L_1v = v$ *for all* $v \in \mathcal{A}_0$. □

Similarly to the classical Legendre-type functions theory, the inverse of ϕ_h can be expressed in terms of Fenchel conjugates. For that purpose, we notice that inverting ϕ_h is a minimization problem. Indeed, given $y \in \mathcal{A}_0$, the problem of finding $x \in \mathcal{F}$ such that $y = \Pi_{\mathcal{A}_0}\nabla h(x)$ is equivalent to $x = \operatorname{Argmin}\{h(z) - \langle y, z\rangle | z \in \mathcal{A}\}$, or equivalently

$$x = \operatorname{Argmin}\{(h + \delta_{\mathcal{A}})(z) - \langle y, z\rangle\}, \tag{5.2}$$

where $\delta_{\mathcal{A}}$ is the *indicator* of $\mathcal{A}$, i.e., $\delta_{\mathcal{A}}(z) = 0$ if $z \in \mathcal{A}$ and $+\infty$ otherwise. Let us recall the definition of *epigraphical sum* of two functions $g_1, g_2 \in \Gamma_0(\mathbb{R}^n)$, which is given by $(g_1 \square g_2)(y) = \inf\{g_1(u) + g_2(v) | u + v = y\}$ for all $y \in \mathbb{R}^n$. We have $g_1 \square g_2 \in \Gamma_0(\mathbb{R}^n)$, and if g_1 and g_2 satisfy $\operatorname{ri}\operatorname{dom} g_1 \cap \operatorname{ri}\operatorname{dom} g_2 \neq \emptyset$, then $(g_1 + g_2)^* = g_1^* \square g_2^*$ (see [39]).

PROPOSITION 5.7. *We have that* $\phi_h^{-1} : \mathcal{F}^* \to \mathcal{F}$ *is given by* $\phi_h^{-1}(y) = \nabla[h^* \square (\delta_{\mathcal{A}_0^\perp} + \langle \cdot, \widetilde{x}\rangle)](y)$ *for any* $\widetilde{x} \in \mathcal{A}$, *and moreover* $\mathcal{F}^* = \Pi_{\mathcal{A}_0}\operatorname{int}\operatorname{dom} h^*$.

Proof. The optimality condition for (5.2) yields $y \in \partial(h + \delta_{\mathcal{A}})(x)$. Thus, $x \in \partial(h + \delta_{\mathcal{A}})^*(y)$. From $\mathcal{F} \neq \emptyset$, we conclude that the function $g \in \Gamma_0(\mathbb{R}^n)$ defined by $g = (h + \delta_{\mathcal{A}})^*$ satisfies $g = h^* \square \delta_{\mathcal{A}}^* = h^* \square (\delta_{\mathcal{A}_0^\perp} + \langle \cdot, \widetilde{x}\rangle)$ with $\widetilde{x} \in \mathcal{A}$. Moreover, by [39, Corollary 26.3.2], g is essentially smooth and we deduce that indeed $x = \nabla g(y)$. Since g is essentially smooth, $\operatorname{dom}\partial g = \operatorname{int}\operatorname{dom} g$. By the definition of an epigraphical sum, $g(y) = \inf\{h^*(u) + \delta_{\mathcal{A}_0^\perp}(v) + \langle v, \widetilde{x}\rangle | u + v = y\}$, and consequently we have that $y \in \operatorname{dom} g$ iff $y \in \operatorname{dom} h^* + \mathcal{A}_0^\perp$. Hence, $\operatorname{int}\operatorname{dom} g = \operatorname{int}\operatorname{dom} h^* + \mathcal{A}_0^\perp$ (see, for instance, [39, Corollary 6.6.2]). Recalling that $\mathcal{F}^*$ is a relatively open subset of $\mathcal{A}_0$, we deduce that $\mathcal{F}^* = \Pi_{\mathcal{A}_0}\operatorname{dom}\partial g = \Pi_{\mathcal{A}_0}\operatorname{int}\operatorname{dom} h^*$. □

5.3. Linear problems in Legendre transform coordinates.

5.3.1. Polyhedral sets in Legendre transform coordinates. One of the first applications of Legendre transform coordinates is to transform linear constraints into positive cones.

PROPOSITION 5.8. *Assume that* $C = \{x \in \mathbb{R}^n | Bx > d\}$, *where* B *is a* $p \times n$ *full rank matrix, with* $p \geq n$. *Suppose also that* h *is of the form* (4.19) *with* θ *satisfying* (H_1), *and let* $\eta = \lim_{s \to +\infty}\theta'(s) \in (-\infty, +\infty]$. *If* $\eta < +\infty$, *then* $\overline{\operatorname{dom} h^*} = \{y \in \mathbb{R}^n \mid y + B^T\lambda = 0,\ \lambda_i \geq -\eta\}$, *and* $\operatorname{dom} h^* = \mathbb{R}^n$ *when* $\eta = +\infty$.

Proof. By [40, Theorem 11.5], $\overline{\operatorname{dom} h^*} = \{y \in \mathbb{R}^n \mid \langle y, d\rangle \leq h^\infty(d)\, \forall d \in \mathbb{R}^n\}$, where h^∞ is the *recession* function, also known as *horizon* function, of h. The recession function is defined by $h^\infty(d) = \lim_{t \to +\infty}\frac{1}{t}[h(\bar{x} + td) - h(\bar{x})]$, $d \in \mathbb{R}^n$, where $\bar{x} \in \operatorname{dom} h$; this limit does not depend of $\bar{x}$ and eventually $h^\infty(d) = +\infty$ (see also [39]). In this case, it is easy to verify that $h^\infty(d) = \sum_{i=1}^p \theta^\infty(\langle B_i, d\rangle)$. Clearly, $\theta^\infty(-1) = +\infty$ and $\theta^\infty(1) = \lim_{s \to +\infty}\theta'(s) = \eta$. In particular, if $\eta = +\infty$, then $\operatorname{dom} h^* = \mathbb{R}^n$. If $\eta < +\infty$, then $y \in \overline{\operatorname{dom} h^*}$ iff for all $d \in \mathbb{R}^n$ such that $Bd \geq 0$, $\langle y, d\rangle \leq h^\infty(d) = \sum_{i=1}^p \eta\langle B_i, d\rangle$, that is $\langle y - \eta B^T e, d\rangle \leq 0$ with $e = (1, \ldots, 1)$. Thus, by the Farkas lemma, $y \in \overline{\operatorname{dom} h^*}$ iff there exists $\mu \geq 0$, $y - \eta B^T e + B^T\mu = 0$. □

As a direct consequence of Propositions 5.7 and 5.8, we have the following.

COROLLARY 5.9. *Under the assumptions of Proposition* 5.8, *if* $\eta = 0$, *then* $\mathcal{F}^*$ *is a positive convex cone, and if* $\eta = +\infty$, *then* $\mathcal{F}^* = \mathcal{A}_0$.

5.3.2. (H-SD)-trajectories as geodesic curves. In what follows, we assume that $f(x) = \langle c, x\rangle$ for some $c \in \mathbb{R}^n$. As another striking application of Legendre transform coordinates, we prove that the trajectories of (H-SD) may be seen as straight lines in $\mathcal{F}^* = \phi_h(\mathcal{F})$ and also as geodesic curves in $\mathcal{F}$ with respect to some appropriate metric, extending to the general case a result of [7] for the log-metric.

PROPOSITION 5.10. *For every $y \in \mathcal{F}^*$ we have $[(\phi_h)_* \nabla_{H} f_{|\mathcal{F}}]\,(y) = \Pi_{\mathcal{A}_0} c$, where $(\phi_h)_* \nabla_{H} f_{|\mathcal{F}}$ is the* push forward *vector field of $\nabla_{H} f_{|\mathcal{F}}$ by ϕ_h.*

Proof. Let $y \in \mathcal{F}^*$. By definition, $[(\phi_h)_* \nabla_{H} f_{|\mathcal{F}}](y) = d\phi_h(\phi_h^{-1}(y)) \nabla_{H} f_{|\mathcal{F}}(\phi_h^{-1}(y))$. Setting $x = \phi_h^{-1}(y)$, by Theorem 5.5 we get $[(\phi_h)_* \nabla_{H} f_{|\mathcal{F}}]\,(y) = d\phi_h(x) \nabla_{H} f_{|\mathcal{F}}(x) = \Pi_{\mathcal{A}_0} H(x) H(x)^{-1} [I - A^T (AH(x)^{-1} A^T)^{-1} AH(x)^{-1}] c = \Pi_{\mathcal{A}_0} c - \Pi_{\mathcal{A}_0} A^T z$, where $z = [(AH(x)^{-1} A^T)^{-1} AH(x)^{-1}] c$. Since $\operatorname{Im} A^T = \mathcal{A}_0^{\perp}$, the conclusion follows. ∎

It follows directly from Proposition 5.10 that $\Phi_h(x(t)) = \Phi_h(x^0) + t \Pi_{\mathcal{A}_0} c$ with $x(t)$ being a solution to (H-SD). Endow $\mathcal{F}^*$ with the Euclidean metric, which allows us to define on $\mathcal{F}$ the metric

$$(\cdot, \cdot)^{H^2} = (\phi_h)^* \langle \cdot, \cdot \rangle, \tag{5.3}$$

that is, $(u, v)_x^{H^2} = \langle d\phi_h(x) u, d\phi_h(x) v \rangle = \langle \Pi_{\mathcal{A}_0} H(x) u, \Pi_{\mathcal{A}_0} H(x) v \rangle$ for all $(x, u, v) \in \mathcal{F} \times \mathbb{R}^n \times \mathbb{R}^n$. For each initial condition $x^0 \in \mathcal{F}$, and for every $c \in \mathbb{R}^n$, we set

$$v = d\phi_h(x^0)^{-1} \Pi_{\mathcal{A}_0} c = \sqrt{H(x^0)^{-1}} \Pi_{\sqrt{H(x^0)}\mathcal{A}_0} \sqrt{H(x^0)^{-1}} \Pi_{\mathcal{A}_0} c. \tag{5.4}$$

THEOREM 5.11. *Let $(x^0, c) \in \mathcal{F} \times \mathbb{R}^n$, set $f(x) = \langle c, x \rangle$, for all $x \in C$, and define v as in* (5.4)*. If $\mathcal{F}$ is endowed with the metric $(\cdot, \cdot)^{H^2}$ given by* (5.3)*, then the solution $x(t)$ of* (H-SD) *is the unique geodesic passing through x^0 with velocity v.*

Proof. Since $\mathcal{F}$, $(\cdot, \cdot)^{H^2}$ is isometric to the Euclidean manifold $\mathcal{F}^*$, $\langle \cdot, \cdot \rangle$, the geodesic joining two points of $\mathcal{F}$ exists and is unique. Let us denote by $\gamma : J \subset \mathbb{R} \mapsto \mathcal{F}$ the geodesic passing through x^0 with velocity v. By definition of $(\cdot, \cdot)^{H^2}$, $\phi_h(\gamma)$ is a geodesic in $\mathcal{F}^*$, whence $\phi_h(\gamma(t)) = \phi_h(x^0) + t d\phi_h(x^0) v$, $t \in J$. In view of (5.4), this can be rewritten as $\phi_h(\gamma(t)) = \phi_h(x^0) + t \Pi_{\mathcal{A}_0} c$. By Proposition 5.10, $\gamma = \phi_h^{-1}(\phi_h(\gamma))$ solves (H-SD). ∎

5.3.3. Lagrange equations. Following the ideas of [7], we describe the orbits of (H-SD) as orthogonal projections on $\mathcal{A}$ of $\dot{q}$-trajectories of a specific *Lagrangian system*. Recall that, given a real-valued mapping $\mathcal{L}(q, \dot{q})$, called the Lagrangian, where $q = (q_1, \ldots, q_n)$ and $\dot{q} = (\dot{q}_1, \ldots, \dot{q}_n)$, the associated Lagrange equations of motion are the following:

$$\frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{q}_i} = \frac{\partial \mathcal{L}}{\partial q_i}, \quad \frac{d}{dt} q_i = \dot{q}_i, \quad \forall i = 1, \ldots, n. \tag{5.5}$$

Their solutions are C^1-piecewise paths $\gamma : t \longmapsto (q(t), \dot{q}(t))$, defined for $t \in J \subset \mathbb{R}$, that satisfy (5.5) and appear as extremals of the functional $\widehat{\mathcal{L}}(\gamma) = \int_J \mathcal{L}(q(t), \dot{q}(t)) dt$. Notice that, in general, the solutions are not unique, in the sense that they do not only depend on the initial condition $\gamma(0)$. Let us introduce the Lagrangian $\mathcal{L} : \mathbb{R}^n \times C \to \mathbb{R}$ defined by

$$\mathcal{L}(q, \dot{q}) = \langle \Pi_{\mathcal{A}_0} c, q \rangle - h(\Pi_{\mathcal{A}} \dot{q}), \tag{5.6}$$

where $\Pi_{\mathcal{A}}$ is the orthogonal projection onto $\mathcal{A}$, i.e., $\Pi_{\mathcal{A}} x = \widetilde{x} + \Pi_{\mathcal{A}_0}(x - \widetilde{x})$ for any $\widetilde{x} \in \mathcal{A}$.

THEOREM 5.12. *For any solution $\gamma(t) = (q(t), \dot{q}(t))$ of the Lagrangian dynamical system* (5.5) *with Lagrangian given by* (5.6)*, the projection $x(t) = \Pi_{\mathcal{A}} \dot{q}(t)$ is the solution of* (H-SD) *with initial condition $x^0 = \Pi_{\mathcal{A}} \dot{q}(0)$.*

Proof. It is easy to verify that $\nabla(h \circ \Pi_{\mathcal{A}})(x) = \Pi_{\mathcal{A}_0} \nabla h(\Pi_{\mathcal{A}} x)$ for any $x \in \mathbb{R}^n$. Given a solution $\gamma(t) = (q(t), \dot{q}(t))$ of (5.6) defined on J, we set $p(t) = (p_1(t), \ldots, p_n(t)) =$

$\big(\frac{\partial \mathcal{L}}{\partial \dot{q}_1}(\gamma(t)), \dots, \frac{\partial \mathcal{L}}{\partial \dot{q}_n}(\gamma(t))\big)$. We have $p(t) = \nabla(h \circ \Pi_{\mathcal{A}})(\dot{q}(t)) = \Pi_{\mathcal{A}_0} \nabla h(\Pi_{\mathcal{A}} \dot{q}(t)) = \phi_h(\Pi_{\mathcal{A}} \dot{q}(t))$. Equations of motion become $\frac{d}{dt} p(t) = \Pi_{\mathcal{A}_0} c$, that is, $\frac{d}{dt} \phi_h(\Pi_{\mathcal{A}} \dot{q}(t)) = \Pi_{\mathcal{A}_0} c$. Since $\phi_h : \mathcal{F} \to \mathcal{F}^*$ is a diffeomorphism, the latter means, according to Proposition 5.10, that $\Pi_{\mathcal{A}} \dot{q}(t)$ is a trajectory for the vector field $\nabla_H f_{|_{\mathcal{F}}}$. Notice that, C being convex, as soon as $\dot{q}(0) \in C$, $\Pi_{\mathcal{A}} \dot{q}(0) \in C \cap \mathcal{A} = \mathcal{F}$, and what precedes forces $\Pi_{\mathcal{A}} \dot{q}(t)$ to stay in $\mathcal{F}$ for any $t \in J$. □

5.3.4. Completely integrable Hamiltonian systems. In the following, all mappings are supposed to be at least of class $\mathcal{C}^2$. Let us first recall the notion of a Hamiltonian system. Given an integer $r \geq 1$ and a real-valued mapping $\mathcal{H}(q,p)$ on $\mathbb{R}^{2r}$ with coordinates $(q,p) = (q_1, \dots, q_r, p_1, \dots, p_r)$, the *Hamiltonian vector field* $X_{\mathcal{H}}$ *associated with* $\mathcal{H}$ is defined by $X_{\mathcal{H}} = \sum_{i=1}^{r} \frac{\partial \mathcal{H}}{\partial p_i} \frac{\partial}{\partial q_i} - \frac{\partial \mathcal{H}}{\partial q_i} \frac{\partial}{\partial p_i}$. The trajectories of the dynamical system induced by $X_{\mathcal{H}}$ are the solutions to

$$\left\{ \begin{array}{ll} \dot{p}_i(t) = -\frac{\partial}{\partial q_i} \mathcal{H}(q(t), p(t)), & i = 1, \dots, r, \\ \dot{q}_i(t) = \frac{\partial}{\partial p_i} \mathcal{H}(q(t), p(t)), & i = 1, \dots, r. \end{array} \right. \tag{5.7}$$

Following a standard procedure, Lagrangian functions $\mathcal{L}(q, \dot{q})$ are associated with Hamiltonian systems by means of the so-called Legendre transform

$$\Phi : \left\{ \begin{array}{ccc} \mathbb{R}^{2r} & \longrightarrow & \mathbb{R}^{2r}, \\ (q, \dot{q}) & \longmapsto & (q, \frac{\partial \mathcal{L}}{\partial \dot{q}}(q, \dot{q})). \end{array} \right.$$

In fact, when Φ is a diffeomorphism, the Hamiltonian function $\mathcal{H}$ associated with the Lagrangian $\mathcal{L}$ is defined on $\Phi(\mathbb{R}^{2r})$ by $\mathcal{H}(p,q) = \sum_{i=1}^{r} p_i \dot{q}_i - \mathcal{L}(q, \dot{q}) = \langle p, \psi^{-1}(q,p) \rangle - \mathcal{L}(q, \psi^{-1}(q,p))$, where $(q, \psi^{-1}(q,p)) := \Phi^{-1}(q,p)$. With these definitions, Φ sends the trajectories of the corresponding Lagrangian system on the trajectories of the Hamiltonian system (5.7).

In general, the Lagrangian (5.6) does not lead to an invertible Φ on $\mathbb{R}^{2n}$. However, we are interested only in the projections $\Pi_{\mathcal{A}} \dot{q}$ of the trajectories, which, according to Theorem 5.12, take their values in $\mathcal{F}$. Moreover, notice that for any differentiable path $t \mapsto q^{\perp}(t)$ lying in $\mathcal{A}_0^{\perp}$, $t \mapsto (q(t), \dot{q}(t))$ is a solution of (5.5) iff $t \mapsto (q(t) + q^{\perp}(t), \dot{q}(t) + \dot{q}^{\perp}(t))$ is. This legitimates the idea of restricting $\mathcal{L}$ to $\mathcal{A}_0 \times \Pi_{\mathcal{A}_0} \mathcal{F}$. Hence and from now on, $\mathcal{L}$ denotes the function

$$\mathcal{L} : \left\{ \begin{array}{ccc} \mathcal{A}_0 \times \Pi_{\mathcal{A}_0} \mathcal{F} & \longrightarrow & \mathbb{R}, \\ (q, \dot{q}) & \longmapsto & \mathcal{L}(q, \dot{q}). \end{array} \right. \tag{5.8}$$

Taking $(q_1, \dots, q_r)$, with $r = n - m$, a linear system of coordinates induced by an Euclidean orthonormal basis for $\mathcal{A}_0$, we easily see that this "new" Lagrangian has trajectories $(q(t), \dot{q}(t))$ lying in $\mathcal{A}_0 \times \Pi_{\mathcal{A}_0} \mathcal{F}$, whose projections $\Pi_{\mathcal{A}} \dot{q}(t)$ are exactly the (H-SD) trajectories. Moreover, an easy computation yields $\frac{\partial \mathcal{L}}{\partial \dot{q}}(q, \dot{q}) = \Pi_{\mathcal{A}_0} \nabla h(\Pi_{\mathcal{A}_0} \dot{q}) = [\phi_h \circ \Pi_{\mathcal{A}}](\dot{q})$, which is a diffeomorphism by Proposition 5.5. The Legendre transform is then given by

$$\Phi : \left\{ \begin{array}{ccc} \mathcal{A}_0 \times \Pi_{\mathcal{A}_0} \mathcal{F} & \longrightarrow & \mathcal{A}_0 \times \mathcal{F}^*, \\ (q, \dot{q}) & \longmapsto & (q, [\phi_h \circ \Pi_{\mathcal{A}}](\dot{q})), \end{array} \right.$$

and therefore, $\mathcal{L}$ is converted into the Hamiltonian system associated with

$$\mathcal{H} : \left\{ \begin{array}{ccc} \mathcal{A}_0 \times \mathcal{F}^* & \longrightarrow & \mathbb{R}, \\ (q,p) & \longmapsto & \langle p, [\phi_h \circ \Pi_{\mathcal{A}}]^{-1}(p) \rangle - \mathcal{L}(q, [\phi_h \circ \Pi_{\mathcal{A}}]^{-1}(p)). \end{array} \right. \tag{5.9}$$

Let us now introduce the concept of a completely integrable Hamiltonian system. The Poisson bracket of two real-valued functions f_1, f_2 on $\mathbb{R}^{2r}$ is given by $\{f_1, f_2\} = \sum_{i=1}^{r} \frac{\partial f_1}{\partial p_i}\frac{\partial f_2}{\partial q_i} - \frac{\partial f_1}{\partial q_i}\frac{\partial f_2}{\partial p_i}$. Notice that, from the definitions, we have $\{f_1, f_2\} = X_{f_1}(f_2)$ and $X_{\{f_1,f_2\}} = [X_{f_1}, X_{f_2}]$, where $[\cdot,\cdot]$ is the standard *bracket product* of vector fields [35]. Now, the system (5.7) is called *completely integrable* if there exist r functions $f_1, \dots, f_r$ with $f_1 = \mathcal{H}$, satisfying

$$\begin{cases} \{f_i, f_j\} = 0 \quad \forall i, j = 1, \dots, r, \\ df_1(x), \dots, df_r(x) \text{ are linearly independent at any } x \in \mathbb{R}^{2r}. \end{cases}$$

As a motivation for completely integrable systems, we will just point out the following: the functions f_i are called *integrals of motions* because $X_{\mathcal{H}}(f_i) = \{h, f_i\} = 0$, which means that any trajectory of $X_{\mathcal{H}}$ lies on the level sets of each f_i (the same holds for all X_{f_j}). Also, the trajectory passing through (q_0, p_0) lies in the set $\bigcap_{i=1,\dots,r} f_i^{-1}(\{f_i(q_o, p_0)\})$. Additionally, $[X_{f_i}, X_{f_j}] = 0$ implies that we can find, at least locally, coordinates $(x_1, \dots, x_r)$ on this set such that $X_{\mathcal{H}} = \frac{\partial}{\partial x_1}, X_{f_2} = \frac{\partial}{\partial x_2}, \dots, X_{f_r} = \frac{\partial}{\partial x_r}$; that is, in these coordinates, the trajectories of X_{f_i} are straight lines.

THEOREM 5.13. *Suppose* $\Pi_{\mathcal{A}_0} c \neq 0$. *The Lagrangian system on* $\mathcal{A}_0 \times \Pi_{\mathcal{A}_0}\mathcal{F}$ *associated with* (5.6), (5.8) *gives rise, by the Legendre transform, to a completely integrable Hamiltonian system on* $\mathcal{A}_0 \times \mathcal{F}^*$ *with Hamiltonian given by* (5.9).

Proof. There remains only to prove the complete integrability of the system. To this end, we adapt the proof of [6, Theorem II.12.2] to our abstract framework. Take the integrals of motion to be $f_1 = \mathcal{H}$, $f_i(q,p) = \langle v_i, p\rangle$, $i = 2, \dots, r$, where $r = n - m$ and $\{\Pi_{\mathcal{A}_0} c, v_2, \dots, v_r\}$ is chosen to be an orthonormal basis of $\mathcal{A}_0$. For any $i, j \in \{2, \dots, r\}$, $\{f_i, f_j\}$ is zero since f_i and f_j depend only on p. Let $\phi_{h,l}^{-1}(q,p)$ (resp., $(\Pi_{\mathcal{A}_0} c)_l$) stand for the lth component of $\phi_h^{-1}(q,p)$ (resp., the lth component of $\Pi_{\mathcal{A}_0} c$), and take some $k \in \{1, \dots, r\}$. Since

$$\begin{aligned} \frac{\partial \mathcal{H}}{\partial q_k}(q,p) &= \frac{\partial(\sum_{l=1}^{r} p_l \phi_{h,l}^{-1})}{\partial q_k}(q,p) - \frac{\partial(\mathcal{L}\circ\Phi^{-1})}{\partial q_k}(q,p) \\ &= \sum_{l=1}^{r} p_l \frac{\partial \phi_{h,l}^{-1}}{\partial q_k}(p,q) - \frac{\partial \mathcal{L}}{\partial q_k}(q, \phi_h^{-1}(q,p)) - \sum_{l=1}^{r} \frac{\partial \mathcal{L}}{\partial \dot{q}_l}(q, \phi_h^{-1}(q,p)) \frac{\partial \phi_{h,l}}{\partial q_k}(q,p) \\ &= -(\Pi_{\mathcal{A}_0} c)_k, \end{aligned}$$

we deduce that for all $i \in \{2, \dots, r\}$, $\{\mathcal{H}, f_i\} = \sum_{k=1}^{r} -\frac{\partial f_i}{\partial p_k}\frac{\partial \mathcal{H}}{\partial q_k} = \langle \Pi_{\mathcal{A}_0} c, v_i\rangle = 0$. The second condition for complete integrability is satisfied too, as the $r \times 2r$ matrix

$$\left(\left[\frac{\partial f_i}{\partial q_1}, \dots, \frac{\partial f_i}{\partial q_r}, \frac{\partial f_i}{\partial p_1}, \dots, \frac{\partial f_i}{\partial p_r}\right]\right)_{i=1,\dots,r} = \begin{pmatrix} \Pi_{\mathcal{A}_0} c^T & \star \\ & v_2^T \\ 0 & \dots \\ & v_r^T \end{pmatrix}$$

is full rank. ∎

AN APPLICATION OF STOCHASTIC CONTROL THEORY TO FINANCIAL ECONOMICS*

WENDELL H. FLEMING† AND TAO PANG‡

Abstract. We consider a portfolio optimization problem which is formulated as a stochastic control problem. Risky asset prices obey a logarithmic Brownian motion, and interest rates vary according to an ergodic Markov diffusion process. The goal is to choose optimal investment and consumption policies to maximize the infinite horizon expected discounted hyperbolic absolute risk aversion (HARA) utility of consumption. A dynamic programming principle is used to derive the dynamic programming equation (DPE). The subsolution–supersolution method is used to obtain existence of solutions of the DPE. The solutions are then used to derive the optimal investment and consumption policies.

Key words. portfolio optimization, dynamic programming equations, subsolutions, supersolutions

1. Introduction. In the classical Merton portfolio optimization problem, an investor dynamically allocates wealth between a risky and a riskless asset and chooses a consumption rate, with the goal of maximizing total expected discounted utility of consumption. For a hyperbolic absolute risk aversion (HARA) utility function the Merton problem has a simple explicit solution. See, for example, Fleming and Soner [16, Example 5.2]. In the Merton model, the interest rate r of the riskless asset is a constant and the risky asset price fluctuates randomly according to a logarithmic Brownian motion. However, in our real world, even for money in the bank, the interest rate may fluctuate from time to time. Therefore, in the present paper we assume that the "riskless" interest rate r_t is an ergodic Markov diffusion process on the real line $-\infty < r < \infty$. A typical example is the Vasicek model, in which r_t is of Ornstein–Uhlenbeck type. In addition, the change of interest rate could be correlated with price fluctuation of the risky asset. A recent example is that the U.S. Federal Reserve has lowered the interest rate several times since 2000, due to the poor performance of the U.S. stock market. We also take this into account in this paper; see section 2. For the case where the change of interest rate is independent of the price change of the risky asset, similar problems were considered in [27, 28].

Another motivation for our work comes from models for optimal investment, production, and consumption, of a kind considered by Fleming and Stein [18]. This interpretation of our model will be explained at the end of section 2. See also Fleming and Pang [12].

We use the dynamic programming method. The stochastic control problem we consider has state variables x_t, r_t, where x_t is wealth. The controls are the fraction u_t of wealth in the risky asset and $c_t = \frac{C_t}{x_t}$, where C_t is the consumption rate. The state

dynamics are the SDEs (2.1)–(2.4). For a HARA utility, the value function $V(x,r)$ is a homogeneous function of x: $V(x,r) = \frac{1}{\gamma}x^\gamma W(r)$, where γ is the HARA parameter. For $\gamma > 0$, a source of technical difficulty is that $W(r)$ increases rapidly to infinity as $|r| \to \infty$. In fact, $Z(r) = \log W(r)$ should grow quadratically as $|r| \to \infty$. The dynamic programming equation (DPE) (2.14) for $V(x,r)$ is equivalent to a nonlinear ODE (2.22) for $Z(r)$. We call (2.22) the reduced DPE.

We use a method of subsolution and supersolution to show that the reduced DPE (2.22) has a solution $\tilde{Z}(r)$ with appropriate behavior as $|r| \to \infty$. The subsolution–supersolution method is developed in section 3. It is applied in section 4 with $\gamma > 0$ to find a classical solution $\tilde{Z}(r)$ to (2.22) which is bounded below and which grows at most quadratically as $|r| \to \infty$. A verification result (Theorem 4.13) then shows that $\tilde{Z}(r) = Z(r)$ and that the corresponding control policies $u^*(r), c^*(r)$ in formulas (4.60) are optimal. These results require that $0 < \gamma < \bar{\gamma}$ for suitable $\bar{\gamma} \leq 1$. In section 5 we consider $\gamma < 0$. In this case $\tilde{W}(r) = \exp(\tilde{Z}(r))$ decays to 0 as $|r| \to \infty$ like $|r|^{2(\gamma-1)}$. The verification result is Theorem 5.7 in this case.

The results in this paper are adapted from the second author's Ph.D. thesis [27]. In Chapter 2 of [27], a related optimal investment problem on a finite time horizon $0 \leq t \leq T$ was also considered. The goal is then to choose an investment control u_t to maximize the expected HARA utility of final wealth $E[\gamma^{-1}x_T^\gamma]$. This model is of a type previously considered by Bielecki and Pliska [2], Zariphopoulou [32], and Fleming and Sheu [14]. The analysis for that finite horizon stochastic control problem is considerably simpler than for the optimal investment-consumption model considered in the present paper.

Fleming and Hernandez-Hernandez [10] considered an investment-consumption model in which the interest rate is constant but the volatility of the risky asset price is stochastic. The approach in [10] has some features in common with the present paper. However, the methods and technical issues to be resolved in the two papers are different.

Our methods should apply to a wider class of stochastic control problems in which the DPE reduces to an ODE of the form $-LZ = h(r,Z)$ as in (4.3). The function $h(r,Z)$ in (4.2) is the sum of a term $\gamma Q(r) - \beta$ and a decreasing function of Z. The function $Q(r)$ grows quadratically as $|r| \to \infty$. This feature significantly complicated the analyses in sections 4 and 5, in the cases $\gamma > 0$ and $\gamma < 0$.

2. The DPE. We use a logarithmic Brownian motion to describe the price P_t of the risky asset:

$$\frac{dP_t}{P_t} = bdt + \sigma_1 dw_{1,t},$$

where b, σ_1 are positive constants and $w_{1,t}$ is a standard one-dimensional Brownian motion. Let x_t be the wealth at time t. The investment control u_t at time t is the fraction of wealth invested in the risky asset. So $(1-u_t)$ is the fraction of the wealth invested in the riskless asset. Denote by C_t the consumption rate at time t. For technical reasons, we take $c_t \equiv \frac{C_t}{x_t}$ as a control instead of C_t. Suppose the initial wealth is $x > 0$. Then the SDE for the process x_t is

$$dx_t = x_t[r_t + (b - r_t)u_t - c_t]dt + \sigma_1 u_t x_t dw_{1,t}, \tag{2.1}$$

$$x_0 = x, \tag{2.2}$$

where r_t is the interest rate of the riskless asset at time t. Instead of a constant interest rate in the classical Merton's model, we consider a randomly fluctuating interest rate

model,

$$dr_t = f(r_t)dt + \sigma_2 d\tilde{w}_t, \tag{2.3}$$

$$r_0 = r, \tag{2.4}$$

where σ_2 is a constant and $\tilde{w}_t$ is a standard one-dimensional Brownian motion. In some cases, the fluctuation of the interest rate is correlated with the price change of the risky asset. To describe this, we let $w_t = (w_{1,t}, w_{2,t})'$ be a standard two-dimensional Brownian motion. Define $\tilde{w}_t$ such that

$$d\tilde{w}_t = \rho dw_{1,t} + \sqrt{1-\rho^2} dw_{2,t}, \tag{2.5}$$

where $\rho \in [-1, 1]$ is a constant. Since $w_{1,t}$ and $w_{2,t}$ are independent, we have

$$E[dw_{1,t} \cdot d\tilde{w}_t] = \rho dt. \tag{2.6}$$

So ρ is the correlation coefficient.

In this paper, we will consider the generalized Vasicek model,

$$f(r) \in \mathbf{C}^2(\mathbf{R}), \tag{2.7}$$

$$|f_{rr}(r)| \le K(1 + |r|^\alpha), \tag{2.8}$$

$$-c_2 \le f_r(r) \le -c_1, \tag{2.9}$$

where K, α, c_1, and c_2 are positive constants.

We consider a HARA utility function $U(\cdot)$:

$$U(C) = \frac{1}{\gamma} C^\gamma, \quad -\infty < \gamma < 1, \quad \gamma \neq 0. \tag{2.10}$$

Our goal is then to maximize the objective function

$$J(x, r, u_\cdot, c_\cdot) \equiv E_{x,r} \int_0^\infty e^{-\beta t} U(c_t x_t) dt, \tag{2.11}$$

where $(u_\cdot, c_\cdot)$ belong to a class Π of admissible controls. Then our value function is

$$V(x, r) = \sup_{u_\cdot, c_\cdot} E_{x,r} \int_0^\infty e^{-\beta t} U(c_t x_t) dt. \tag{2.12}$$

We require that the control $(u_t, c_t; t \ge 0)$ is an $\mathbf{R}^2$-valued process. In addition, we require that it is $\mathcal{F}_t$-progressively measurable for some $(w_{1,t}, \tilde{w}_t)$-adapted increasing family of σ-algebras $(\mathcal{F}_t, t \ge 0)$. See Fleming and Soner [16, Chapter 4] for details. In certain cases, (u_t, c_t) may be obtained from locally Lipschitz continuous control policies $(\hat{u}, \hat{c})$,

$$u_t = \hat{u}(t, x_t, r_t), \quad c_t = \hat{c}(t, x_t, r_t),$$

where x_t is obtained by substituting these policies in (2.1).

We also assume that $c_t \ge 0$, and there is no constraint for the value of u_t. In other words, we take the u-value space $\mathbf{U} = (-\infty, \infty)$ in this paper. The negative value of u_t corresponds to disinvestment such as short selling.

In addition, we require that

$$P\left(\int_0^T u_t^2 dt < \infty\right) = 1 \quad \forall T > 0. \tag{2.13}$$

Given this, we can use Ito's differential rule to verify that

$$x_t = x \exp\left\{\int_0^t \left[r_s + (b - r_s)u_s - c_s - \frac{1}{2}\sigma_1^2 u_s^2\right] ds + \int_0^t \sigma_1 u_s dw_{1,s}\right\}$$

is a solution of (2.1)–(2.2). We can see that $x_t > 0$ as long as $x > 0$.

Remark 2.1. The admissible control space Π will be specified later in Definition 4.11 ($\gamma > 0$ case) and Definition 5.6 ($\gamma < 0$ case). For fixed $\beta > 0$, there exists a constant $\bar{\gamma} \leq 1$ such that $0 < \gamma < \bar{\gamma}$ will ensure that $V(x, r) < \infty$. For a constant interest r, a condition about β and γ is given in [16, p. 176].

Remark 2.2. The log utility case, which corresponds to a HARA utility with $\gamma = 0$, is studied in Pang [27, section 1.4]. It is much easier to deal with.

By the definition of $V(x, r)$, using the dynamic programming principle, we can obtain that the corresponding DPE is

$$\begin{aligned}\beta V = &\sup_u \left[(b - r)uxV_x + \frac{1}{2}\sigma_1^2 u^2 x^2 V_{xx} + \rho\sigma_1\sigma_2 uxV_{xr}\right] + rxV_x \\ &+ f(r)V_r + \frac{1}{2}\sigma_2^2 V_{rr} + \sup_{c \geq 0}\left[-cxV_x + \frac{1}{\gamma}(cx)^\gamma\right].\end{aligned} \tag{2.14}$$

For details, refer to [16, section 4.5].

Since we consider a HARA utility function that is homogeneous in x with an order of γ, it is not hard to get the following lemma.

LEMMA 2.3. *$V(x, r)$ is homogeneous in x with an order of γ.*

Proof. According to (2.1)–(2.2), for any $k > 0$, we have

$$\begin{aligned} dkx_t &= kx_t[r_t + (b - r_t)u_t - c_t]dt + \sigma_1 u_t kx_t dw_{1,t}, \\ kx_0 &= kx. \end{aligned}$$

Therefore,

$$J(kx, r, u_\cdot, c_\cdot) = E_{x,r}\int_0^\infty e^{-\beta t}\frac{1}{\gamma}(c_t kx_t)^\gamma dt = k^\gamma J(x, r, u_\cdot, c_\cdot).$$

Thus we have

$$V(x, r) = \sup_{u_\cdot, c_\cdot} J(x, r, u_\cdot, c_\cdot) = \sup_{u_\cdot, c_\cdot} x^\gamma J(1, r, u_\cdot, c_\cdot) = x^\gamma V(1, r).$$

That is, $V(x, r)$ is homogeneous in x. ∎

From Lemma 2.3, we can assume that

$$V(x, r) = \frac{1}{\gamma}x^\gamma W(r). \tag{2.15}$$

Then, the differential equation for $W(r)$ can be written as

$$\begin{aligned}\frac{\beta}{\gamma}W = &\sup_u \left[(b - r)uW + \frac{1}{2}(\gamma - 1)\sigma_1^2 u^2 W + \rho\sigma_1\sigma_2 uW_r\right] + rW \\ &+ \frac{1}{\gamma}f(r)W_r + \frac{1}{2\gamma}\sigma_2^2 W_{rr} + \sup_{c \geq 0}\left[-cW + \frac{1}{\gamma}c^\gamma\right].\end{aligned}$$

By the definition of $V(x,r)$, it is not hard to see that the suitable $W(r)$ should be positive.

Actually, if $W(r) > 0$ and smooth enough, we can define

$$u^*(r) \equiv \frac{(b-r)W(r) + \rho\sigma_1\sigma_2 W_r(r)}{(1-\gamma)\sigma_1^2 W(r)}, \tag{2.16}$$

$$c^*(r) \equiv W(r)^{\frac{1}{\gamma-1}}. \tag{2.17}$$

Then we have

$$u^*(r) \in \arg\max_u \left[(b-r)uW + \frac{1}{2}(\gamma-1)\sigma_1^2 u^2 W + \rho\sigma_1\sigma_2 u W_r\right],$$
$$c^*(r) \in \arg\max_c \left[-cW + \frac{1}{\gamma}c^\gamma\right].$$

Actually, (u^*, c^*) will be verified to be the optimal control policy later in section 4 and section 5 for $\gamma > 0$ and $\gamma < 0$, respectively.

Now we can rewrite the differential equation of $W(r)$ as

$$\begin{aligned}\frac{1}{2}\sigma_2^2 W_{rr} + \left[\frac{\gamma\rho\sigma_2(b-r)}{\sigma_1(1-\gamma)} + f(r)\right]W_r + \frac{\gamma\rho^2\sigma_2^2 W_r^2}{2(1-\gamma)W} \\ + [\gamma Q(r) - \beta]W + (1-\gamma)W^{\frac{\gamma}{\gamma-1}} = 0,\end{aligned} \tag{2.18}$$

where

$$Q(r) = \frac{(b-r)^2}{2(1-\gamma)\sigma_1^2} + r. \tag{2.19}$$

We can see that $Q(r)$ is quadratic with respect to r. Let

$$Z(r) \equiv \log W(r). \tag{2.20}$$

Then the ODE for $Z(r)$ is

$$\begin{aligned}\frac{\sigma_2^2}{2}Z_{rr} + \frac{\sigma_2^2}{2}\left[1 + \frac{\gamma\rho^2}{1-\gamma}\right]Z_r^2 + \left[\frac{\gamma\rho\sigma_2(b-r)}{\sigma_1(1-\gamma)} + f(r)\right]Z_r \\ + \gamma Q(r) - \beta + (1-\gamma)e^{\frac{Z}{\gamma-1}} = 0.\end{aligned}$$

Define

$$\begin{aligned}H(r,z,p) \equiv -\frac{\sigma_2^2}{2}\left[1 + \frac{\gamma\rho^2}{1-\gamma}\right]p^2 - \left[\frac{\gamma\rho\sigma_2(b-r)}{\sigma_1(1-\gamma)} + f(r)\right]p \\ - \gamma Q(r) + \beta - (1-\gamma)e^{\frac{z}{\gamma-1}};\end{aligned} \tag{2.21}$$

then the equation for $Z(r)$ can be rewritten as

$$\frac{\sigma_2^2}{2}Z_{rr} = H(r, Z, Z_r). \tag{2.22}$$

We call (2.22) the reduced DPE. Our goal is to find a suitable solution $\tilde{V}(x,r)$ of the DPE (2.14) and verify that $\tilde{V}(x,r)$ is equal to the value function defined by (2.12). To obtain $\tilde{V}(x,r)$, it is sufficient to find a suitable solution $Z(r)$ of (2.22).

Then, $\tilde{V}(x,r) = \frac{1}{\gamma}x^\gamma e^{Z(r)}$ will be the desired solution of (2.14). Although (2.22) is a nonlinear equation, we can get some existence results by using a subsolution–supersolution method.

Investment, production, and consumption model. In addition to Merton-type, small-investor portfolio optimization problems with randomly fluctuating interest rates, another motivation for our work comes from considering models of the following kind. An economic unit has productive capital and also liabilities in the form of debt. Let K_t denote the worth of capital at time t and L_t the debt. K_t changes through investment, at rate I_t. Debt changes through interest payments, investment, consumption C_t, and income from production Y_t:

$$dK_t = I_t dt, \tag{2.23}$$

$$dL_t = (r_t L_t + I_t + C_t - Y_t)dt. \tag{2.24}$$

It is assumed that productivity of capital fluctuates randomly about a mean rate b. This is expressed by writing (formally)

$$Y_t dt = K_t(bdt + \sigma_1 dw_{1,t}), \tag{2.25}$$

where $w_{1,t}$ is a Brownian motion as above. The constraints imposed are $K_t \geq 0, C_t \geq 0, x_t > 0$, where $x_t = K_t - L_t$ is the net worth of the economic unit. By subtracting (2.24) from (2.23) we find that x_t satisfies the SDE (2.1) with

$$u_t = x_t^{-1}K_t, \quad c_t = x_t^{-1}C_t. \tag{2.26}$$

If no bounds are imposed on the investment rate I_t, then u_t can be taken as the investment control and c_t the consumption control. The constraint $K_t \geq 0$ is equivalent to the "no short selling" constraint $u_t \geq 0$. We will ignore this constraint in the sections to follow. To include this constraint, it requires rather easy modifications. For example, in (2.14), the first sup would be taken over $u \geq 0$ rather than over all u.

In [18], a similar international finance and debt model was considered. In that interpretation the economic unit is a nation. Y_t represents the national gross domestic product and L_t is the foreign debt. However, instead of a "mean reverting" model (2.3) for the interest rate r_t, it is assumed in [18] that (formally)

$$r_t dt = rdt + \sigma_2 dw_{2,t},$$

where $w_{2,t}$ is a Brownian motion. As in the Merton problem, there is an explicit solution in the model considered in [18]. However, if the interest rate r_t satisfies the SDE (2.3), then the optimal investment and consumption policies $u^*(r), c^*(r)$ depend on the solution $W(r)$ to a reduced DPE as in (2.16) and (2.17). This differential equation, or the equivalent differential equation for $Z(r) = \log W(r)$, can be solved numerically.

3. Method of subsolution and supersolution. In this section, we will give an existence result for some type of ODEs, which includes (2.22). The method of subsolution and supersolution will be used. This idea is partially from [29], [3], and [31].

Consider a second order differential equation

$$Z_{rr} = \bar{H}(r, Z, Z_r). \tag{3.1}$$

First let us define subsolutions and supersolutions of (3.1).

DEFINITION 3.1. *A function $\hat{Z}$ is said to be a subsolution of* (3.1) *on the whole real line if*

$$\hat{Z}_{rr} \geq \bar{H}(r, \hat{Z}, \hat{Z}_r).$$

$\bar{Z}$ is a supersolution if

$$\bar{Z}_{rr} \leq \bar{H}(r, \bar{Z}, \bar{Z}_r).$$

In addition, $(\hat{Z}, \bar{Z})$ is said to be an ordered pair of subsolution/supersolution of (3.1) *if they also satisfy*

$$\hat{Z}(r) \leq \bar{Z}(r) \quad \forall r \in \mathbf{R}.$$

We also want to define supersolutions and subsolutions of the corresponding boundary value problem on a finite interval $[r_1, r_2]$,

$$\begin{cases} Z_{rr} = \bar{H}(r, Z, Z_r), \\ Z(r_1) = Z_1, \quad Z(r_2) = Z_2. \end{cases} \tag{3.2}$$

DEFINITION 3.2. *A function $\hat{Z}$ is said to be a subsolution of* (3.2) *if*

$$\hat{Z}_{rr} \geq \bar{H}(r, \hat{Z}, \hat{Z}_r), \quad \hat{Z}(r_1) \leq Z_1, \quad \hat{Z}(r_2) \leq Z_2.$$

$\bar{Z}$ is a supersolution of (3.2) *if*

$$\bar{Z}_{rr} \leq \bar{H}(r, \bar{Z}, \bar{Z}_r), \quad \bar{Z}(r_1) \geq Z_1, \quad \bar{Z}(r_2) \geq Z_2.$$

In addition, $\hat{Z}$ and $\bar{Z}$ are said to be an ordered pair of subsolution/supersolution if they also satisfy

$$\hat{Z}(r) \leq \bar{Z}(r) \quad \forall r \in [r_1, r_2].$$

First we will show that a similar existence result holds for (3.2). Then we will extend the result to the whole real line and get an existence result of (3.1). Equation (2.22) will be a special case. The following lemma is needed.

LEMMA 3.3. *Let $F(r, z, p)$ be continuous and bounded on $J \times \mathbf{R}^2$, where $J = [r_1, r_2]$. Then the boundary value problem*

$$\begin{cases} Z_{rr} = F(r, Z, Z_r), \\ Z(r_1) = Z_1, \quad Z(r_2) = Z_2 \end{cases}$$

has at least one solution.

Proof. This is a direct result of Walter [31, p. 262, Existence Theorem XX]. □

Some a priori estimates are needed to get the existence results for the boundary value problem (3.2).

LEMMA 3.4. *Suppose $Z(r)$ is a classical $\mathbf{C}^2$ solution of* (3.2) *on $J = [r_1, r_2]$, and it satisfies*

$$\hat{Z}(r) \leq Z(r) \leq \bar{Z}(r) \quad \text{on } J,$$

where $\hat{Z}(r)$ and $\bar{Z}(r)$ are subsolution and supersolution of (3.2)*, respectively. Define*

$$M \equiv \max\left\{ \sup_J |\bar{Z}(r)|, \sup_J |\hat{Z}(r)| \right\}. \tag{3.3}$$

Suppose that

$$|\bar{H}(r,z,p)| \le C_1(p^2 + C_2) \tag{3.4}$$

for $r \in J$ *and* $|z| \le 3M$, *where* M *is given by* (3.3) *and* $C_1 > 0, C_2 \ge 0$ *are two constants. Then there exists a constant* Λ, *which depends only on* M, C_1, *and* C_2, *such that*

$$|Z_r| \le \Lambda \quad \text{on } J.$$

Proof. Take $\bar{\mu} \equiv \max\left\{2C_1, \sqrt{C_2}\right\}$. Then, by the above definition, we can get that if $|p| \ge \bar{\mu}$, we have

$$|\bar{H}(r,z,p)| \le C_1(p^2 + C_2) \le C_1(p^2 + p^2) \le \bar{\mu}p^2. \tag{3.5}$$

Take constants k, δ such that

$$k \ge \bar{\mu}^2 e^{2\bar{\mu}M}, \quad k\delta = e^{2\bar{\mu}M} - 1.$$

Fix an $r_0 \in [r_1, r_2]$. For $r \in [r_0, r_0 + \delta]$, define

$$w(r) \equiv \frac{1}{\bar{\mu}} \log[1 + k(r - r_0)] + Z(r_0).$$

Then we can verify that

$$\begin{aligned} w(r_0) = Z(r_0), \quad & w(r_0 + \delta) = 2M + Z(r_0) \ge M \ge Z(r_0 + \delta), \\ & |w(r)| \le 2M + |Z(r_0)| \le 3M, \quad |w_r(r)| \ge \bar{\mu}. \end{aligned}$$

Given this, noting (3.4), we can show that

$$w_{rr} - \bar{H}(r, w, w_r) \le -\bar{\mu}w_r^2 + |\bar{H}(r, w, w_r)| \le -\bar{\mu}w_r^2 + \bar{\mu}w_r^2 = 0.$$

Now, by virtue of Gilbarg and Trudinger [20, Theorem 10.1, p. 263], we can get

$$w(r) \ge Z(r) \quad \forall r \in [r_0, r_0 + \delta].$$

Similarly, for $\breve{w}(r) \equiv -w(r)$, using the same method, we can get

$$-w(r) = \breve{w}(r) \le Z(r) \quad \forall r \in [r_0, r_0 + \delta].$$

Therefore, for any $r \in (r_0, r_0 + \delta)$, we have

$$\frac{|Z(r) - Z(r_0)|}{|r - r_0|} \le \frac{|w(r) - w(r_0)|}{|r - r_0|}.$$

Let $r \to r_0^+$; we can get

$$|Z_r(r_0)| \le \left|\frac{k}{\bar{\mu}}\right| \equiv \Lambda.$$

Since $r_0 \in J$ is arbitrary, we are done. □

LEMMA 3.5. *Suppose* $\bar{H}(r,z,p)$ *is strictly increasing with respect to* z, *and it satisfies* (3.4). *If* $\hat{Z}$ *and* $\bar{Z}$ *are an ordered pair of subsolution/supersolution of* (3.2)

on $J = [r_1, r_2]$, then the boundary value problem (3.2) *has at least one solution on J such that*

$$\hat{Z}(r) \le Z(r) \le \bar{Z}(r) \quad \forall r \in J.$$

Proof. Define

$$\Omega \equiv \{(r, z, p) : r \in J,\ z \in [\hat{Z}, \bar{Z}],\ |p| < \Lambda_0\}, \tag{3.6}$$

where $\Lambda_0 \equiv \max\{\Lambda, \max_J \hat{Z}_r, \max_J \bar{Z}_r\}$ and Λ is a constant as in Lemma 3.4.

Since $\bar{H}(r, z, p)$ is strictly increasing with respect to z, and it satisfies (3.4), it is not hard to extend $\bar{H}$ to the domain $J \times \mathbf{R}^2$, such that it is a continuous, bounded function and it is strictly increasing with respect to z. Denote the extension to be $\tilde{H}$. In addition, we can suppose that $\tilde{H}$ satisfies (3.4). For example, we can take

$$\tilde{H}_1(r, z, p) = \begin{cases} \bar{H}(r, z, p) & \text{if } r \in J,\ \hat{Z} \le z \le \bar{Z}, \\ \bar{H}(r, \hat{Z}, p) + e^z - e^{\hat{Z}} & \text{if } r \in J,\ z < \hat{Z}, \\ \bar{H}(r, \bar{Z}, p) + e^{-\bar{Z}} - e^{-z} & \text{if } r \in J,\ z \ge \bar{Z}, \end{cases}$$

and

$$\tilde{H}(r, z, p) = \begin{cases} \tilde{H}_1(r, z, p) & \text{if } |p| \le \Lambda_0, \\ \tilde{H}_1(r, z, -\Lambda_0) & \text{if } p < -\Lambda_0, \\ \tilde{H}_1(r, z, \Lambda_0) & \text{if } p > \Lambda_0. \end{cases}$$

It is not hard to verify that $\tilde{H}(r, z, p)$ is a bounded continuous function on $J \times \mathbf{R}^2$. In addition, $\tilde{H}(r, z, p)$ is strictly increasing with respect to z, and it satisfies (3.4).

Take constants Z_1, Z_2 such that

$$\hat{Z}(r_i) \le Z_i \le \bar{Z}(r_i), \quad i = 1, 2.$$

Now according to Lemma 3.3, we know that the boundary value problem

$$\begin{cases} Z_{rr} = \tilde{H}(r, Z, Z_r), \\ Z(r_1) = Z_1, \quad Z(r_2) = Z_2 \end{cases}$$

has a solution, say, $Z(r)$. Now we need to show that $\hat{Z} \le Z \le \bar{Z}$ and $|Z_r| \le \Lambda_0$. Assume that $Z \le \bar{Z}$ does not always hold on J. Then $\bar{Z} - Z$ is negative in an open set I_0 and is nonnegative at its endpoints. Suppose $\bar{Z} - Z$ reaches its minimum at $r_0 \in I_0$; then we have

$$\bar{Z}_r(r_0) = Z_r(r_0), \quad \bar{Z}(r_0) < Z(r_0).$$

Noting that $\tilde{H}$ is strictly increasing with respect to z, we can get

$$(\bar{Z}_{rr} - Z_{rr})(r_0) \le \tilde{H}(r_0, \bar{Z}(r_0), \bar{Z}_r(r_0)) - \tilde{H}(r_0, Z(r_0), Z_r(r_0)) < 0.$$

So $(\bar{Z} - Z)$ cannot reach its minimum in I_0. This is a contradiction. Therefore, we must have $Z \le \bar{Z}$ on J. A similar argument gives $\hat{Z} \le Z$. Further, since $\tilde{H}$ satisfies (3.4), following the same procedure in the proof of Lemma 3.4, we can show that $|Z_r| \le \Lambda \le \Lambda_0$ on J. Therefore, we can get that $\tilde{H}(r, Z, Z_r) = \bar{H}(r, Z, Z_r)$. Therefore, Z is a solution of (3.2). ∎

The following uniqueness result is needed later.

LEMMA 3.6 (uniqueness). *Suppose $\bar{H}(r,z,p)$ is strictly increasing with respect to z, and it satisfies* (3.4). *If two $\mathbf{C}^2$ functions $Z(r)$ and $\tilde{Z}(r)$ are solutions of* (3.1) *on $J=[r_1,r_2]$, such that*

$$\hat{Z}(r) \le Z(r), \quad \tilde{Z}(r) \le \bar{Z}(r), \tag{3.7}$$

then

$$Z(r) \equiv \tilde{Z}(r) \quad \text{on } J. \tag{3.8}$$

Proof. Let $\psi(r) \equiv Z(r) - \tilde{Z}(r)$. Then we have that $\psi(r_1) = \psi(r_2) = 0$. Assume that ψ reaches it minimum at $r_0 \in (r_1, r_2)$, such that $\psi(r_0) < 0$, that is, $Z(r_0) < \tilde{Z}(r_0)$, and $Z_r(r_0) = \tilde{Z}_r(r_0)$. Then, by virtue of (3.1) and the definition of ψ, noting that $\bar{H}(r,z,p)$ is strictly increasing with z, we can get

$$\psi_{rr}(r_0) < 0.$$

This contradicts the assumption that ψ reaches its minimum at $r_0 \in (r_1, r_2)$. Therefore, we must have $Z(r) \ge \tilde{Z}(r)$ on J. The same argument for $\psi = \tilde{Z} - Z$ will lead to $Z(r) \le \tilde{Z}(r)$ on J. □

Let $(\hat{Z}(r), \bar{Z}(r))$ be an ordered pair of subsolution/supersolution of (3.1) on the whole real line, that is, $\forall r \in \mathbf{R}$,

$$\hat{Z}_{rr} \ge \bar{H}(r, \hat{Z}, \hat{Z}_r), \tag{3.9}$$

$$\bar{Z}_{rr} \le \bar{H}(r, \bar{Z}, \bar{Z}_r), \tag{3.10}$$

$$\hat{Z}(r) \le \bar{Z}(r). \tag{3.11}$$

According to the definitions, it is immediate that $\hat{Z}$ and $\bar{Z}$ are an ordered pair of subsolution/supersolution of the following problem on any $I_m \equiv [-m, m]$:

$$\begin{cases} Z_{rr} = \bar{H}(r, Z, Z_r), \\ Z(-m) = \bar{Z}(-m), \quad Z(m) = \bar{Z}(m). \end{cases} \tag{3.12}$$

Now by virtue of Lemma 3.5, the above problem has at least one solution $\tilde{Z}_m^0(r)$, such that

$$\hat{Z}(r) \le \tilde{Z}_m^0(r) \le \bar{Z}(r) \quad \text{on } I_m.$$

Define its extension on $\mathbf{R}$ by

$$\tilde{Z}_m(r) = \begin{cases} \tilde{Z}_m^0(r) & \text{if } r \in I_m, \\ \bar{Z}(r) & \text{otherwise.} \end{cases}$$

Then $\tilde{Z}_m$ is continuous. Further, we have the following lemma.

LEMMA 3.7. *For any m, we have*

$$\hat{Z}(r) \le \tilde{Z}_{m+1}(r) \le \tilde{Z}_m(r) \le \bar{Z}(r). \tag{3.13}$$

Proof. By definition, for any m, we must have

$$\hat{Z} \le \tilde{Z}_m \le \bar{Z}.$$

So we only need to show that

$$\tilde{Z}_{m+1}(r) \le \tilde{Z}_m(r) \quad \forall r. \tag{3.14}$$

By the definitions of $\{Z_m, m = 1, 2, 3, \ldots\}$, it is sufficient to show that the above inequality holds on I_m. Actually, it is not hard to verify that $\tilde{Z}_{m+1}$ is a subsolution of (3.12)–(3.13) on I_m. Then by virtue of Lemma 3.5, there exists a solution $\tilde{Z}^*(r)$ of (3.12)–(3.13), such that

$$\tilde{Z}_{m+1}(r) \le \tilde{Z}^*(r) \le \bar{Z}(r) \quad \forall r \in I_m.$$

Noting the result of Lemma 3.6, we must have

$$\tilde{Z}^*(r) \equiv \tilde{Z}_m(r) \quad \forall r \in I_m,$$

which implies that (3.14) holds on I_m. This completes our proof. □

Finally, we have the following existence result.

THEOREM 3.8. *Suppose $\bar{H}(r, z, p)$ is strictly increasing with respect to z, and it satisfies* (3.4). *Let $(\hat{Z}, \bar{Z})$ be an ordered pair of subsolution/supersolution of* (3.1) *on* **R**. *Then* (3.1) *has a solution $Z(r)$ such that*

$$\hat{Z}(r) \le Z(r) \le \bar{Z}(r). \tag{3.15}$$

Proof. Consider the sequence $\{\tilde{Z}_m\}$ as in Lemma 3.7. It is easy to show that $\tilde{Z}_m$ converges in pointwise sense to a function Z as $m \to \infty$.

Since any bounded interval J is contained in I_m for some m, a $\mathbf{C}^2$ function Z is a solution of (3.1) if it satisfies (3.1) in I_m for any m. Let m be fixed, and let $k > m$ be arbitrary. Then for $r \in I_m$, $\tilde{Z}_k(r)$ satisfies

$$\frac{\partial^2 \tilde{Z}_k}{\partial r^2} = \bar{H}\left(r, \tilde{Z}_k, \frac{\partial \tilde{Z}_k}{\partial r}\right), \quad \tilde{Z}_k(-m) \le \bar{Z}(-m), \quad \tilde{Z}_k(m) \le \bar{Z}(m).$$

Since $\hat{Z} \le \tilde{Z}_k \le \bar{Z}$ $\forall r \in I_m$, we know that $\{\tilde{Z}_k\}$ is uniformly bounded on I_m. In addition, noting Lemma 3.4, we can get that $\{\frac{\partial \tilde{Z}_k}{\partial r}\}$ is uniformly bounded on I_m. Finally, by virtue of (3.1), (3.4), and (3.15), it is not hard to show that $\{\frac{\partial^2 \tilde{Z}_k}{\partial r^2}\}$ and $\{[\frac{\partial^2 \tilde{Z}_k}{\partial r^2}]_{\alpha; I_m}\}$ are uniformly bounded on I_m.

Given the above results, using the Arzela–Ascoli theorem, we can show that $\{\tilde{Z}_m\}$ contains a subsequence that converges in $\mathbf{C}^2(I_m)$ to a function $\tilde{Z} \in \mathbf{C}^{2,\alpha}(I_m)$. Since $\{\tilde{Z}_k\}$ converges to Z in pointwise sense, $\tilde{Z}$ must coincide with Z. Moreover, the whole sequence $\{\tilde{Z}_k\}$ converges in $\mathbf{C}^2(I_m)$ to Z as $k \to \infty$. Let $k \to \infty$, and we can get that Z is a solution of (3.1) on I_m. By the arbitrariness of I_m, Z is a solution of (3.1) on **R**. □

Now we need only find an ordered pair of subsolution/supersolution to get the existence of the classical solution $\tilde{Z}(r) = Z(r)$. Then we can obtain the classical solution $\tilde{V}(x, r) = \frac{1}{\gamma} x^\gamma e^{\tilde{Z}(r)}$. This will be done for the $\gamma > 0$ case in section 4 and for the $\gamma < 0$ case in section 5. The solution will be verified to be the value function in both cases. These verification results imply that the solution $Z(r)$ to (3.1) satisfying the bounds (3.16) is unique.

It is not hard to show that the function $H(r, z, p)$ defined by (2.21) is strictly increasing with respect to z, and it satisfies (3.4). Therefore, we have the following lemma.

LEMMA 3.9. *Let* $(\hat{Z}, \bar{Z})$ *be an ordered pair of subsolution/supersolution of* (2.22) *on* $\mathbf{R}$. *Then* (2.22) *has a solution* $Z(r)$ *such that*

$$\hat{Z}(r) \leq Z(r) \leq \bar{Z}(r). \tag{3.16}$$

4. $\gamma > 0$ case. In this section, we will find an ordered pair of subsolution/supersolution when $\gamma > 0$ under some conditions, which will be specified in Lemma 4.1 and Lemma 4.2. Then we can get the existence of the solution of the reduced DPE (2.22) by using Lemma 3.9. Further, we need to verify that this solution is actually our value function. This result is given in Theorem 4.4. The admissible control space is defined by Definition 4.11.

Define

$$LZ = \frac{\sigma_2^2}{2} Z_{rr} + \frac{\sigma_2^2}{2}\left[1 + \frac{\gamma\rho^2}{1-\gamma}\right] Z_r^2 + \left[\frac{\gamma\rho\sigma_2(b-r)}{\sigma_1(1-\gamma)} + f(r)\right] Z_r, \tag{4.1}$$

$$h(r, Z) = [\gamma Q(r) - \beta] + (1-\gamma) e^{\frac{Z}{\gamma-1}}. \tag{4.2}$$

Then (2.22) for Z can be written as

$$-LZ = h(r, Z). \tag{4.3}$$

It is easy to verify that Z is a subsolution (supersolution) of (2.22) if and only if

$$-LZ \leq (\geq) h(r, Z).$$

LEMMA 4.1. *Suppose*

$$\beta > \gamma b - \frac{\sigma_1^2}{2}\gamma(1-\gamma). \tag{4.4}$$

Define K_1 *as*

$$K_1 \equiv \log \tilde{K}_1, \tag{4.5}$$

where $\tilde{K}_1$ *is a positive constant defined by*

$$\tilde{K}_1^{\frac{1}{\gamma-1}} = \frac{1}{1-\gamma}\left[\beta - b\gamma + \frac{\sigma_1^2}{2}\gamma(1-\gamma)\right]. \tag{4.6}$$

Then, any constant $K_2 \leq K_1$ *is a subsolution of* (2.22).

Proof. Since K_2 is a constant, we have

$$-LK_2 = 0.$$

On the other hand, since $Q(r)$ is quadratic, by the definition of K_1, it is not hard to verify that

$$h(r, K_2) > 0$$

for any constant $K_2 \leq K_1$. Thus, we have

$$-LK_2 < h(r, K_2).$$

Therefore, K_2 is a subsolution of (2.22). □

The constant K_1 has the following interpretation. The constant investment control $u_t = 1\ \forall t$ (no wealth in the riskless asset) is suboptimal. The solution to the optimal consumption problem with this special choice for u_t has value function $\gamma^{-1}K_1 x^\gamma$. Condition (4.4) is equivalent to $K_1 > 0$.

A formal asymptotic analysis suggests (but does not prove) that $Z(r)$ in (2.20) grows quadratically as $|r| \to \infty$. With this in mind, we next seek a quadratic supersolution $\bar{Z}(r)$ of the form (4.13), where the constants a_1 and a_2 are to be suitably chosen. The bounds (4.8) on the risk sensitivity parameter γ and the lower bound (4.14) on the discount factor β give sufficient conditions that such a supersolution $\bar{Z}(r)$ exists. Later in the section, further restrictions on a_1, a_2, and β will be imposed to ensure that the solution $\tilde{V}(x,r)$ to the DPE obtained by the subsolution–supersolution method is indeed the value function $V(x,r)$. See Theorem 4.13.

LEMMA 4.2. *Define*

$$\gamma_1 \equiv \frac{\sigma_1^2 c_1^2}{\sigma_1^2 c_1^2 + \sigma_2^2 - 2c_1\rho\sigma_1\sigma_2}. \tag{4.7}$$

Assume that

$$0 < \gamma < \min\{1, \gamma_1\}. \tag{4.8}$$

In addition, define

$$\mu_1 \equiv -2\sigma_2^2 \left[1 + \frac{\gamma\rho^2}{1-\gamma}\right], \tag{4.9}$$

$$\mu_2 \equiv 2c_1 + \frac{2\gamma\rho\sigma_2}{\sigma_1(1-\gamma)}, \tag{4.10}$$

$$\mu_3 \equiv -\frac{\gamma}{2\sigma_1^2(1-\gamma)}. \tag{4.11}$$

Let a^+, a^- be the real roots of $\mu_1 a^2 + \mu_2 a + \mu_3 = 0$. Then we have

$$0 < a^- < a^+. \tag{4.12}$$

Moreover, for any $a_1 \in I_1 \equiv (a^-, a^+)$, there exist constants $a_2 > K_1$ and $C_1(a_1)$, where K_1 is given by (4.5) *and $C_1(\cdot)$ are given by* (4.20)*, such that*

$$\bar{Z}(r) \equiv a_1 r^2 + a_2 \tag{4.13}$$

is a supersolution of (2.22)*, provided that*

$$\beta > -C_1(a_1). \tag{4.14}$$

Proof. Since $|\rho| \le 1$, by (4.7) we can get $\gamma_1 > 0$. Moreover, under condition (4.8), it is not hard to verify that (4.12) holds.

On the other hand, for $\bar{Z}(r)$ defined by (4.13), it is easy to verify that

$$\bar{Z}_r = 2a_1 r, \quad \bar{Z}_{rr} = 2a_1.$$

Then we have

$$-L\bar{Z} = -2a_1^2\sigma_2^2\left[1+\frac{\gamma\rho^2}{1-\gamma}\right]r^2 - 2a_1 f(r)r - \frac{2a_1\gamma\rho\sigma_2}{\sigma_1(1-\gamma)}(b-r)r - a_1\sigma_2^2.$$

By virtue of (2.9), there exists a $\xi \in [0,r]$ such that

$$\begin{aligned} -2a_1 r f(r) &= -2a_1 r[f(0) + f_r(\xi)r] \\ &= -2a_1 f_r(\xi)r^2 - 2a_1 f(0)r \\ &\geq 2c_1 a_1 r^2 - 2a_1 f(0)r. \end{aligned}$$

Therefore, we have

$$\begin{aligned} -L\bar{Z} \geq &\left[2a_1\left(c_1 + \frac{\gamma\rho\sigma_2}{\sigma_1(1-\gamma)}\right) - 2a_1^2\sigma_2^2\left(1+\frac{\gamma\rho^2}{1-\gamma}\right)\right]r^2 \\ &-2a_1\left[f(0) + \frac{\gamma\rho\sigma_2 b}{\sigma_1(1-\gamma)}\right]r - a_1\sigma_2^2. \end{aligned} \tag{4.15}$$

To ensure that $\bar{Z}(r)$ is a supersolution of (2.22), we need only show that

$$-L\bar{Z} \geq h(r,\bar{Z}). \tag{4.16}$$

Define

$$\lambda_1(a_1) \equiv \mu_1 a_1^2 + \mu_2 a_1 + \mu_3, \tag{4.17}$$

$$\lambda_2(a_1) \equiv -\left[2f(0) + \frac{2\gamma\rho\sigma_2}{\sigma_1(1-\gamma)}\right]a_1 + \frac{b\gamma}{\sigma_1^2(1-\gamma)} - \gamma, \tag{4.18}$$

$$\lambda_3(a_1) \equiv -a_1\sigma_2^2 - \frac{\gamma b^2}{2\sigma_1^2(1-\gamma)}, \tag{4.19}$$

$$C_1(a_1) \equiv \frac{4\lambda_1(a_1)\lambda_3(a_1) - \lambda_2^2(a_1)}{4\lambda_1(a_1)}, \tag{4.20}$$

where μ_1, μ_2, μ_3 are given by (4.9)–(4.11). Then, by virtue of (4.15), to show (4.16), it is sufficient to show that

$$\lambda_1(a_1)r^2 + \lambda_2(a_1)r + \lambda_3(a_1) \geq -\beta + (1-\gamma)e^{\frac{a_1 r^2 + a_2}{\gamma-1}}. \tag{4.21}$$

A basic calculation implies that $\lambda_1(a_1) > 0$, provided that $a_1 \in I_1$. Then it is not hard to verify that the left-hand side of (4.21) is bounded below by $C_1(a_1)$. From the definition, we know that $C_1(a_1)$ depends only on $a_1, c_1, b, \rho, \sigma_1, \sigma_2, \gamma$, and $f(0)$. Since $0 < \gamma < \min\{\gamma_1, 1\}$ and $a_1 > 0$, we have

$$e^{\frac{a_1 r^2}{\gamma-1}} \leq 1.$$

Thus, if (4.14) holds, we can take $a_2 > K_1$ large enough such that

$$(1-\gamma)e^{\frac{a_2}{\gamma-1}}e^{\frac{a_1 r^2}{\gamma-1}} \leq (1-\gamma)e^{\frac{a_2}{\gamma-1}} \leq \beta - C_1(a_1),$$

which implies (4.21). □

Remark 4.3. From (4.7), we can get that $\gamma_1 \leq 1$ if and only if $\sigma_2 \geq 2c_1\rho\sigma_1$.

We have the following existence results for (2.22).

THEOREM 4.4. *Suppose* (4.4), (4.8), *and* (4.14) *hold. Then* (2.22) *possesses a classical solution* $\tilde{Z}(r)$ *such that*

$$K_1 \le \tilde{Z}(r) \le \bar{Z}(r), \tag{4.22}$$

where K_1 *and* $\bar{Z}$ *are given by* (4.5) *and* (4.13), *respectively. Define*

$$\tilde{V}(x,r) \equiv \frac{1}{\gamma} x^\gamma e^{\tilde{Z}(r)}. \tag{4.23}$$

Then $\tilde{V}(x,r)$ *is a classical solution of* (2.14).

Proof. It is not hard to verify that $\big(K_1, \bar{Z}(r)\big)$ is an ordered pair of subsolution/supersolution. Then by Lemma 3.9, there exists a classical solution $\tilde{Z}(r)$ of (2.22) such that (4.22) holds. By virtue of (4.23), it is not hard to verify that $\tilde{V}(x,r)$ is a classical solution of (2.14). □

Now we need to verify that $\tilde{V}(x,r)$ is equal to our value function. This will be done in Theorem 4.13. We will also specify the admissible control space in Definition 4.11. Before we go to the verification theorem, we need some lemmas. In those lemmas, we always suppose that $(r_t, t \ge 0)$ is a solution of (2.3)–(2.4).

LEMMA 4.5. *Suppose* $v(r) \in \mathbf{C}^2(\mathbf{R})$ *is bounded. In addition, suppose* v_r *and* v_{rr} *are all bounded. Then* $\phi(r,T) \equiv E_r e^{\int_0^T v(r_t)dt}$ *is in* $\mathbf{C}^{2,1}(\mathbf{R}, [0,\infty))$ *and it is a classical solution of*

$$\begin{cases} \phi_T = \frac{1}{2}\sigma_2^2 \phi_{rr} + f(r)\phi_r + v(r)\phi, \\ \phi(r,0) = 1. \end{cases} \tag{4.24}$$

The proof is rather standard; see Pang [27, Lemma 1.12] for details.

LEMMA 4.6. *Suppose* $\check{v}(r) \in \mathbf{C}^2(\mathbf{R})$. *In addition, suppose* $\check{v}, \check{v}_r, \check{v}_{rr}$ *are all bounded. Then* $\eta(r,T) \equiv E_r e^{\check{v}(r_T)}$ *is in* $\mathbf{C}^{2,1}(\mathbf{R}, [0,\infty))$ *and it is a classical solution of*

$$\begin{cases} \eta_T = \frac{1}{2}\sigma_2^2 \eta_{rr} + f(r)\eta_r, \\ \eta(r,0) = e^{\check{v}(r)}. \end{cases} \tag{4.25}$$

This is a direct corollary of Theorem 5.6.1 of Friedman [19].

LEMMA 4.7. *Let*

$$\check{Q}(r) \equiv \nu_1 r^2 + \nu_2 r + \nu_3, \tag{4.26}$$

where ν_1, ν_2, *and* ν_3 *are constants and* ν_1 *satisfies*

$$\nu_1 < \frac{c_1^2}{2\sigma_2^2}. \tag{4.27}$$

Define $\check{a}^-, \check{a}^+$ *as the real roots of the equation* $2\sigma_2^2 \check{a}^2 - 2c_1 \check{a} + \nu_1 = 0$. *Then we have*

$$0 < \check{a}^- < \check{a}^+. \tag{4.28}$$

Moreover, suppose $(r_t, t \ge 0)$ *is a solution of* (2.3)–(2.4) *and suppose that*

$$\check{a}^- \le \check{a}_1 \le \check{a}^+. \tag{4.29}$$

Then we have

$$e^{-\beta t}Ee^{\int_0^t \check{Q}(r_s)ds} \le \Lambda \quad \forall t \in [0,T], \tag{4.30}$$

where Λ *is a constant, provided that*

$$\beta > -C_2(\check{a}_1), \tag{4.31}$$

where $C_2(\check{a}_1)$ *is given by* (4.36).

Proof. Define a sequence of functions $\{\check{Q}_M(r), M = 1,2,3,\ldots\}$ such that

$$\check{Q}_M \in \mathbf{C}^\infty; \quad 0 \le \check{Q}_M \le M; \quad \left|\frac{\partial \check{Q}_M(r)}{\partial r}\right| \le \check{M}; \quad \left|\frac{\partial^2 \check{Q}_M(r)}{\partial r^2}\right| \le \check{M};$$
$$\check{Q}_{M_1}(r) \le \check{Q}_{M_2}(r) \le \check{Q}(r), \ M_1 < M_2; \quad \lim_{M\to\infty} \check{Q}_M(r) = \check{Q}(r),$$

where $\check{M}, M_1, M_2$ are constants. Define

$$\psi(r,t) \equiv e^{-\beta t}Ee^{\int_0^t \check{Q}_M(r_s)ds}.$$

Then according to Lemma 4.5, $\psi \in \mathbf{C}^{2,1}(\mathbf{R},[0,\infty))$ and it is a solution of the problem

$$\begin{cases} \frac{\partial \psi}{\partial t} = \frac{\sigma_2^2}{2}\frac{\partial^2 \psi}{\partial r^2} + f(r)\frac{\partial \psi}{\partial r} + [\check{Q}_M(r) - \beta]\psi, \\ \psi(r,0) = 1. \end{cases} \tag{4.32}$$

It is easy to verify that, under condition (4.27), $\check{a}^-$ and $\check{a}^+$ are real, positive numbers. So we can take an $\check{a}_1$ such that (4.29) holds.

Define

$$\check{\lambda}_1(\check{a}_1) = -2\sigma_2^2\check{a}_1^2 + 2c_1\check{a}_1 - \nu_1, \tag{4.33}$$
$$\check{\lambda}_2(\check{a}_1) = -2\check{a}_1 - \nu_2, \tag{4.34}$$
$$\check{\lambda}_3(\check{a}_1) = -\sigma_2^2\check{a}_1 - \nu_3, \tag{4.35}$$
$$C_2(\check{a}_1) = \frac{4\check{\lambda}_1(\check{a}_1)\check{\lambda}_3(\check{a}_1) - \check{\lambda}_2(\check{a}_1)}{4\check{\lambda}_1(\check{a}_1)}. \tag{4.36}$$

Following the same procedure in the proof of Lemma 4.2, it is not hard to verify that, under conditions (4.29) and (4.31), $\bar{\psi}(r) \equiv e^{\check{a}_1 r^2}$ satisfies

$$\begin{cases} \frac{\partial \bar{\psi}}{\partial T} \ge \frac{\sigma_2^2}{2}\frac{\partial^2 \bar{\psi}}{\partial r^2} + f(r)\frac{\partial \bar{\psi}}{\partial r} + [\check{Q}_M(r) - \beta]\bar{\psi}, \\ \bar{\psi}(r,0) \ge 1. \end{cases}$$

Define $\xi(r,T) \equiv \psi(r,T) - \bar{\psi}(r)$. Then it satisfies

$$\begin{cases} \frac{\partial \xi}{\partial T} \le \frac{\sigma_2^2}{2}\frac{\partial^2 \xi}{\partial r^2} + f(r)\frac{\partial \xi}{\partial r} + [\check{Q}_M(r) - \beta]\xi, \\ \xi(r,0) \le 0. \end{cases}$$

Since $\check{Q}_M$ is bounded, there exists a constant $B > 0$ such that $\check{Q}_M(r) - \beta < B$. Define

$$\tilde{\xi}(r,T) \equiv e^{-BT}\xi(r,T), \quad \tilde{Q}_M(r) \equiv \check{Q}_M(r) - \beta - B.$$

Then $\tilde{Q}_M(r) < 0$ and $\tilde{\xi}$ satisfies

$$\begin{cases} \frac{\partial \tilde{\xi}}{\partial T} \le \frac{\sigma_2^2}{2}\frac{\partial^2 \tilde{\xi}}{\partial r^2} + f(r)\frac{\partial \tilde{\xi}}{\partial r} + \tilde{Q}_M(r)\tilde{\xi}, \\ \tilde{\xi}(r,0) \le 0. \end{cases}$$

Since $\check{Q}_M(r)$ is bounded, by definitions of $\psi, \bar{\psi}, \xi$, and $\tilde{\xi}$, we can get

$$\lim_{|r|\to\infty} \tilde{\xi}(r,T) = -\infty.$$

If $\tilde{\xi}(r,T)$ reaches its maximum on $\mathbf{R}\times[0,T_1]$ at a point (r_0,T_0), such that $\tilde{\xi}(r_0,T_0) > 0$, then we must have $T_0 > 0$ and

$$\tilde{\xi}_r(r_0,T_0) = 0, \quad \tilde{\xi}_{rr}(r_0,T_0) \le 0, \quad \tilde{\xi}_T(r_0,T_0) \ge 0.$$

This contradicts

$$\frac{\partial \tilde{\xi}}{\partial T} \le \frac{\sigma_2^2}{2}\frac{\partial^2 \tilde{\xi}}{\partial r^2} + f(r)\frac{\partial \tilde{\xi}}{\partial r} + \tilde{Q}_M(r)\tilde{\xi}.$$

Therefore, we must have

$$\tilde{\xi}(r,T) \le 0 \quad \forall r, T.$$

By definitions of $\tilde{\xi}$ and ξ, we can get

$$\psi(r,T) \le \bar{\psi}(r) \quad \forall r, T.$$

Define $\Lambda \equiv \bar{\psi}(r)$. Then Λ is a constant that does not depend on $M, \check{M}$, or T. Thus, by the monotone convergence theorem, we can get (4.30). □

LEMMA 4.8. *Define*

$$\gamma_2 \equiv \frac{\sigma_1^2 c_1^2}{2\sigma_1^2 c_1^2 + 4\sigma_2^2}, \tag{4.37}$$

and suppose that

$$0 < \gamma < \gamma_2. \tag{4.38}$$

Define

$$I_2 \equiv \left(\frac{c_1}{2\sigma_2^2} - \frac{1}{2\sigma_2^2}\sqrt{c_1^2 - \frac{4\sigma_2^2\gamma}{\sigma_1^2(1-2\gamma)}},\ \frac{c_1}{2\sigma_2^2} + \frac{1}{2\sigma_2^2}\sqrt{c_1^2 - \frac{4\sigma_2^2\gamma}{\sigma_1^2(1-2\gamma)}} \right), \tag{4.39}$$

and assume that

$$\check{a}_2 \in I_2. \tag{4.40}$$

Define

$$\nu_1 = \frac{2\gamma}{\sigma_1^2(1-2\gamma)}, \quad \nu_2 = -\frac{4b\gamma}{\sigma_1^2(1-2\gamma)} + 4\gamma, \quad \nu_3 = \frac{2b^2\gamma}{\sigma_1^2(1-2\gamma)}. \tag{4.41}$$

Then for any

$$\beta > -\frac{1}{2}C_2(\check{a}_2), \tag{4.42}$$

where $C_2(\check{a}_2)$ *is given by* (4.36) *with* ν_1, ν_2, ν_3 *defined above, there is a constant* Λ*, which is independent of* T*, such that*

$$e^{-2\beta T} E_r e^{\int_0^T 4\gamma Q_1(r_t)dt} \leq \Lambda, \tag{4.43}$$

where

$$Q_1(r) \equiv \frac{(b-r)^2}{2\sigma_1^2(1-2\gamma)} + r. \tag{4.44}$$

Proof. This is a direct corollary of Lemma 4.7. □

LEMMA 4.9. *Define*

$$I_3 \equiv \left(0, \frac{c_1}{K\sigma_2^2}\right), \tag{4.45}$$

where $K > 8$ *is a constant. Assume that*

$$a_3 \in I_3. \tag{4.46}$$

Define

$$C_3(a_3) \equiv \frac{Kf(0)^2 a_3}{2K\sigma_2^2 a_3 - 2c_1} - K\sigma_2^2 a_3. \tag{4.47}$$

Then for any

$$\beta > -\frac{1}{2}C_3(a_3), \tag{4.48}$$

there is a constant Λ*, which is independent of* T*, such that*

$$e^{-2\beta T} E_r e^{Ka_3 r_T^2} \leq \Lambda.$$

The proof is almost the same as the proof of Lemma 4.7, and so we omit it here. Refer to Pang [27, Lemma 1.15] for details.

LEMMA 4.10. *Suppose* (4.8) *holds. Define*

$$k_1 \equiv \frac{K\rho\sigma_2}{\sigma_1} - 2c_1\rho^2, \quad k_2 \equiv \frac{K^2(2c_1\rho\sigma_1\sigma_2 - \sigma_2^2)}{\sigma_1^2}, \quad \bar{\nu}_1 \equiv \frac{(2-K)c_1}{k_1},$$

$$\gamma_3 \equiv \frac{\bar{\nu}_1}{1+\bar{\nu}_1}, \tag{4.49}$$

$$\bar{\nu}_2 \equiv \frac{-2(K-2)c_1k_1 + k_2}{2k_1} + \frac{\sqrt{(2(K-2)c_1k_1 - k_2)^2 + 4(4K-4)c_1^2k_1^2}}{2k_1^2},$$

$$\gamma_4 \equiv \frac{\bar{\nu}_2}{1+\bar{\nu}_2}, \tag{4.50}$$

where K *is the constant in Lemma* 4.9*. Then if*

$$k_1 < 0, \quad 0 < \gamma < \gamma_3, \tag{4.51}$$

or

$$k_1 > 0, \quad 0 < \gamma < \gamma_4, \tag{4.52}$$

we have

$$I_1 \cap I_3 \neq \emptyset. \tag{4.53}$$

Proof. It can be verified by virtue of some basic calculations. For details, see the proof of Lemma 1.16 in Pang [27]. □

DEFINITION 4.11. *The admissible control space* Π *is*

$$\Pi \equiv \left\{ (u_t, c_t) : P\left(\int_0^T u_t^2 dt < \infty \right) = 1 \quad \forall T > 0,\ c_t \geq 0 \right\}. \tag{4.54}$$

We have the following lemma.

LEMMA 4.12. *For* $(u_t, c_t) \in \Pi$, *define*

$$Y_t \equiv e^{2\gamma\sigma_1 \int_0^t u_s dw_{1,s} - 2\gamma^2\sigma_1^2 \int_0^t u_s^2 ds}, \tag{4.55}$$

and define τ_R *to be the exit time of* (x_t, r_t) *from the ball* $\{x^2 + r^2 \leq R^2\}$. *Then we have*

$$EY_{T\wedge\tau_R} \leq 1 \quad \forall T > 0. \tag{4.56}$$

Proof. Since $(u_t, c_t) \in \Pi$, we can get that $P(Y_t < \infty) = 1$. Then, by virtue of Ito's rule, we can get

$$Y_{T\wedge\tau_R} = 1 + 2\gamma\sigma_1 \int_0^{T\wedge\tau_R} u_s Y_s dw_{1,s}.$$

Denote $\tau_n \equiv \inf\{t \leq T : \int_0^t u_s^2 Y_s^2 ds \geq n^2\}$. Then it is easy to verify that $Y_{T\wedge\tau_R\wedge\tau_n}$ is a martingale for any $n > 0$, and it satisfies $EY_{T\wedge\tau_R\wedge\tau_n} = 1$. Since Y_t is nonnegative, by virtue of Fatou's lemma, we can get (4.56). □

THEOREM 4.13. *Suppose that* (4.4), (4.8), (4.38) *hold and either* (4.51) *or* (4.52) *holds. In addition, assume*

$$a_1 \in I_1 \cap I_3, \quad a_2 \in I_2, \tag{4.57}$$

and

$$\beta > \max\left\{ -C_1(a_1), -\frac{1}{2}C_2(a_2), -\frac{1}{2}C_3(a_1) \right\}, \tag{4.58}$$

where $C_1(\cdot), C_2(\cdot)$, *and* $C_3(\cdot)$ *are given by* (4.20), (4.36), *and* (4.47), *respectively.*

Define $V(x, r)$ *as in* (2.12) *and define* $\tilde{V}(x, r), \tilde{Z}(r)$ *as in Theorem* 4.4. *Then we have*

$$\tilde{V}(x, r) \equiv V(x, r). \tag{4.59}$$

In addition, $J(x, r, u_\cdot, c_\cdot)$ *reaches its maximum at*

$$u^*(r) = \frac{(b - r)}{\sigma_1^2(1 - \gamma)} + \frac{\rho\sigma_2 \tilde{Z}_r(r)}{\sigma_1(1 - \gamma)}, \quad c^*(r) = e^{\frac{\tilde{Z}(r)}{\gamma - 1}}. \tag{4.60}$$

Proof. For any admissible control $(u_t, c_t) \in \Pi$, denote $\mathcal{G}^{u_t,c_t}$ as the generator of the process (x_t, r_t) under control (u_t, c_t). Then, by virtue of Ito's rule, we can get

$$\begin{aligned} d\left[e^{-\beta t}\tilde{V}(x_t, r_t)\right] &= e^{-\beta t}\left[d\tilde{V}(x_t, r_t) - \beta\tilde{V}(x_t, r_t)dt\right] \\ &= e^{-\beta t}\left[\mathcal{G}^{u_t,c_t}\tilde{V}(x_t, r_t) - \beta\tilde{V}(x_t, r_t)\right]dt + dm_{1,t} + dm_{2,t}, \end{aligned}$$

where $m_{1,t}$ and $m_{2,t}$ are local martingales under P.

Integrate it on $[0, T]$. Since $\tilde{V}$ is a classical solution of (2.14), we have

$$e^{-\beta T}\tilde{V}(x_T, r_T) - \tilde{V}(x, r) \leq -\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt + m_{1,T} + m_{2,T}.$$

Let τ_R define the exit time of (x_t, r_t) from the ball $\{x^2 + r^2 < R^2\}$. Then, for every finite T, we have

$$\tilde{V}(x, r) \geq E\int_0^{T\wedge\tau_R} e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt + E\left[e^{-\beta T\wedge\tau_R}\tilde{V}(x_{T\wedge\tau_R}, r_{T\wedge\tau_R})\right]. \tag{4.61}$$

Noting $\tilde{V} > 0$, by virtue of Fatou's lemma as $R \to \infty$, we can take $\liminf$ to get

$$\tilde{V}(x, r) \geq E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt.$$

Now, let $T \to \infty$; then we have

$$\tilde{V}(x, r) \geq E\int_0^\infty e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt,$$

which holds for any admissible control $(u_t, c_t) \in \Pi$. By the definition of $V(x, r)$, we must have, for any r,

$$\tilde{V}(x, r) \geq V(x, r). \tag{4.62}$$

On the other hand, for control (u^*, c^*) defined by (4.60), it is not hard to verify that $(u_t^*, c_t^*) \in \Pi$. Then, instead of (4.61), we can get

$$\tilde{V}(x, r) = E\int_0^{T\wedge\tau_R} e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt + E\left[e^{-\beta T\wedge\tau_R}\tilde{V}(x_{T\wedge\tau_R}, r_{T\wedge\tau_R})\right]. \tag{4.63}$$

Using the monotone convergence theorem, for any fixed $T > 0$, we can show that

$$\lim_{R\to\infty} E\int_0^{T\wedge\tau_R} e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt = E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt. \tag{4.64}$$

Define $\tilde{W}(r) \equiv e^{\tilde{Z}(r)}$. Then by virtue of (4.23), we can rewrite $\tilde{V}(x, r)$ as

$$\tilde{V}(x, r) \equiv \frac{1}{\gamma}x^\gamma\tilde{W}(r). \tag{4.65}$$

Define

$$\tilde{l}(r, u) = r + (b - r)u - \frac{1}{2}\sigma_1^2 u^2.$$

Then for any admissible control $(u_t, c_t) \in \Pi$, using Ito's formula, we can get

$$x_t = x \exp\left\{ \int_0^t [\tilde{l}(r_s, u_s) - c_s]ds + \int_0^t \sigma_1 u_s dw_{1,s} \right\}.$$

Given the above equality, by virtue of the Cauchy–Schwarz inequality, we can get

$$\begin{aligned}
&E\left[e^{-\beta T\wedge\tau_R}\tilde{V}(x_{T\wedge\tau_R}, r_{T\wedge\tau_R})\right] \\
&\quad = \frac{1}{\gamma}E\left[e^{-\beta T\wedge\tau_R}x^{\gamma}_{T\wedge\tau_R}\tilde{W}(r_{T\wedge\tau_R})\right] \\
&\quad \le \frac{1}{\gamma}x^{\gamma}\left(Ee^{\int_0^{T\wedge\tau_R} 2[\gamma l(r_s,u_s)-\gamma c_s-\beta]ds}\tilde{W}^2(r_{T\wedge\tau_R})\right)^{\frac{1}{2}} \\
&\qquad \cdot\left(Ee^{\int_0^{T\wedge\tau_R}[2\gamma\sigma_1 u_t dw_{1,t}-2\gamma^2\sigma_1^2 u_t^2 dt]}\right)^{\frac{1}{2}},
\end{aligned}$$

where

$$l(r,u) \equiv r + (b-r)u + \left(\gamma - \frac{1}{2}\right)\sigma_1^2 u^2. \tag{4.66}$$

Using the result of Lemma 4.12, we have

$$Ee^{\int_0^{T\wedge\tau_R}[2\gamma\sigma_1 u_t dw_{1,t}-2\gamma^2\sigma_1^2 u_t^2 dt]} \le 1. \tag{4.67}$$

Thus, we can get

$$\begin{aligned}
\tilde{V}(x,r) &= E\int_0^{T\wedge\tau_R} e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^{\gamma}dt \\
&\quad + \frac{1}{\gamma}x^{\gamma}\left(Ee^{\int_0^{T\wedge\tau_R} 2[\gamma l(r_s,u_s)-\gamma c_s-\beta]ds}\tilde{W}^2(r_{T\wedge\tau_R})\right)^{\frac{1}{2}}.
\end{aligned} \tag{4.68}$$

From (4.37), we can get that $\gamma_2 < \frac{1}{2}$. Since $0 < \gamma < \gamma_2 < \frac{1}{2}$, by virtue of (4.44) and (4.66), we can get

$$l(r,u) \le Q_1(r).$$

Therefore, for $0 < \gamma < \gamma_2$, $\gamma Q_1(r) - \beta$ is lower bounded. Choose B such that $\gamma Q_1(r) - \beta - B \ge 0$. Noting that $c^* > 0, \tilde{W}(r) \le e^{a_1 r^2 + a_2}$ and using the Cauchy–Schwarz inequality, we have

$$\begin{aligned}
&\left[e^{\int_0^{T\wedge\tau_R} 2[\gamma l(r_s,u_s^*)-\gamma c_s^*-\beta]ds}\tilde{W}^2(r_{T\wedge\tau_R})\right] \\
&\le \left[e^{\int_0^{T\wedge\tau_R} 2[\gamma Q_1(r_s)-\beta]ds}\tilde{W}^2(r_{T\wedge\tau_R})\right] \\
&= e^{2B(T\wedge\tau_R)}\left[e^{\int_0^{T\wedge\tau_R} 2[\gamma Q_1(r_s)-\beta-B]ds}\sup_{0\le t\le T}\tilde{W}^2(r_t)\right] \\
&\le e^{2B(T\wedge\tau_R)}\left[e^{\int_0^{T} 2[\gamma Q_1(r_s)-\beta-B]ds}\sup_{0\le t\le T}\tilde{W}^2(r_t)\right]
\end{aligned}$$

$$
\begin{aligned}
&= e^{2B(T\wedge\tau_R - T)}\left[e^{\int_0^T 2[\gamma Q_1(r_s)-\beta]ds}\sup_{0\le t\le T}\tilde{W}^2(r_t)\right]\\
&\le e^{2|B|T}\left[e^{\int_0^T 2[\gamma Q_1(r_s)-\beta]ds}\sup_{0\le t\le T}\tilde{W}^2(r_t)\right]\\
&\le \frac{1}{2}e^{2(|B|-\beta)T}\left[e^{\int_0^T 4\gamma Q_1(r_s)ds} + \sup_{0\le t\le T}\tilde{W}^4(r_t)\right]\\
&\le \frac{1}{2}e^{2(|B|-\beta)T}\left[e^{\int_0^T 4\gamma Q_1(r_s)ds} + A^2\sup_{0\le t\le T}e^{4a_1 r_t^2}\right]\\
&\equiv \eta_T,
\end{aligned}
$$

where $A \equiv e^{2a_2}$. Next, we are going to show that

$$E_r\eta_T < \infty, \tag{4.69}$$

which ensures that we can use Fatou's lemma in (4.68) to get rid of the stopping time.

First, by virtue of Lemma 4.8, we have

$$E_r e^{\int_0^T 4\gamma Q_1(r_s)ds} < \infty \tag{4.70}$$

provided that $0 < \gamma < \gamma_2$. Define $\psi(r_t) \equiv e^{4a_1 r_t^2}$. Then we also need to show that

$$E_r\left[\sup_{0\le t\le T}\psi(r_t)\right] < \infty. \tag{4.71}$$

By virtue of Ito's lemma, we have

$$
\begin{aligned}
d\psi(r_t) &= 8a_1 r_t\psi(r_t)[f(r_t)dt + \sigma_2 dw_{2,t}] + \frac{\sigma_2^2}{2}[8a_1\psi(r_t) + 64a_1^2 r_t^2\psi(r_t)]dt\\
&\le [8a_1(4a_1\sigma_2^2 - c_1)r_t^2 + 8a_1 f(0)r_t + 4a_1\sigma_2^2]\psi(r_t)dt + dm_t,
\end{aligned}
$$

where

$$m_t \equiv 8a_1\sigma_2\int_0^t r_s\psi(r_s)dw_{2,s}. \tag{4.72}$$

By the definition of a_1, we know that $4a_1\sigma_2^2 - c_1 < 0$. Therefore, $8a_1(4a_1\sigma_2^2 - c_1)r_t^2 + 8a_1 f(0)r_t + 4a_1\sigma_2^2$ is upper bounded. Suppose $N > 0$ is an upper bound; then we have

$$\psi(r_t) \le \psi(r) + \int_0^t N\psi(r_s)ds + m_t. \tag{4.73}$$

By the definition of m_t, we have

$$E_r m_t^2 = 64a_1^2\sigma_2^2 E\int_0^t r_s^2\psi^2(r_s)ds.$$

For any $s \in [0,t]$, by virtue of Lemma 4.9, we have

$$E_r\left[r_s^2\psi^2(r_s)\right] = E_r\left[r_s^2 e^{8a_1 r_s^2}\right] \le \Lambda_1[E_r e^{(8+\epsilon)a_1 r_s^2}] < \infty, \tag{4.74}$$

where $\Lambda_1 > 0$ is a constant and ϵ can be any positive number. Therefore, we must have $E_r m_t^2 < \infty$. So m_t is a martingale. Using fundamental martingale inequalities, we can show that

$$E_r\left[\sup_{0\le t\le T} m_t^2\right] \le 4E_r m_T^2 \le \Lambda_2 < \infty, \tag{4.75}$$

where Λ_1 is a positive constant. Given this and (4.73), using the Chebyshev inequality, we can show that

$$E_r\left[\sup_{0\le t\le T}\psi(r_t)\right] \le \psi(r) + \Lambda_2 + \int_0^T NE_r\left[\sup_{0\le s\le t}\psi(r_s)\right]dt. \tag{4.76}$$

Then, by virtue of Gronwall's inequality, it is easy to get (4.71). Combined with (4.70), this implies (4.69). Now, when we let $R\to\infty$ and take lim sup in (4.68), we can use the monotone convergence theorem and Fatou's lemma to get

$$\begin{aligned}\tilde V(x,r) \le{}& E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt \\ &+ \frac{1}{\gamma}x^\gamma\left(E\left[e^{\int_0^T 2[\gamma Q_1(r_s)-\gamma c_s^*-\beta]ds}\tilde W^2(r_T)\right]\right)^{\frac12}.\end{aligned} \tag{4.77}$$

Denote $\delta = \beta - \max\{-C_1(a_1), C_2(\tilde a), C_3(a_1)\}$. Then, from (4.58), we can get that $\delta > 0$. Take $\check\beta = \beta - \frac{\delta}{2}$. Then, by virtue of $c^* \ge 0$, using the Cauchy–Schwarz inequality, we can get

$$\begin{aligned}&E_r\left[e^{\int_0^T 2[\gamma Q_1(r_s)-\gamma c_s^*-\beta]ds}\tilde W^2(r_T)\right]\\ &< e^{-2\beta T}\left[E_r e^{\int_0^T 4\gamma Q_1(r_s)ds}\right]^{\frac12}\cdot\left[E_r\tilde W^4(r_T)\right]^{\frac12}\\ &\le e^{-\delta T}e^{4a_2}\left[e^{-2\check\beta T}E_r e^{\int_0^T 4\gamma Q_1(r_s)ds}\right]^{\frac12}\left[e^{-2\check\beta T}E_r e^{4a_1 r_T^2}\right]^{\frac12}.\end{aligned}$$

Given the above inequality, by virtue of Lemmas 4.8 and 4.9, we can show that, for any fixed $T > 0$,

$$\lim_{T\to\infty} E_r\left[e^{\int_0^T 2[\gamma Q(r_s)-\gamma c_s^*-\beta]ds}\tilde W^2(r_T)\right] = 0.$$

Now in (4.77), let $T\to\infty$; then we have

$$\tilde V(x,r) \le E\int_0^\infty e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt \le V(x,r). \tag{4.78}$$

Combined with (4.62), this implies

$$\tilde V(x,r) = E\int_0^\infty e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt = V(x,r).$$

Thus, (u^*, c^*) is optimal and $\tilde V(x,r)\equiv V(x,r)$. □

5. $\gamma < 0$ case. In this section, we will investigate the $\gamma < 0$ case. The existence results will be given in Theorem 5.4 and the verification results will be given in Theorem 5.7. The admissible control space will be specified in Definition 5.6.

Using the same notations as in the last section, we can write the equation of $Z(r)$ as

$$-LZ = h(r, Z). \tag{5.1}$$

For the $\gamma < 0$ case, we have the following results. A formal asymptotic analysis suggests that, for $\gamma < 0$, $Z(r)$ in (2.20) behaves like $2(\gamma - 1)\log r$ as $|r| \to \infty$. This leads to the choice of $\hat{Z}(r)$ in (5.3) and the choice of $\bar{Z}(r)$ in (5.7). Condition (5.6) is sufficient for the existence of a supersolution of the form (5.7).

LEMMA 5.1. *Suppose $\gamma < 0$. Define*

$$a_1 \equiv \frac{-2\gamma}{3\sigma_1^2(1-\gamma)^2}, \qquad a_2 \equiv b - \sigma_1^2(1-\gamma). \tag{5.2}$$

Then there exists a constant $\bar{a}_3 > 0$ such that for any $a_3 \geq \bar{a}_3$

$$\hat{Z}(r) \equiv \log\left[(a_1(r-a_2)^2 + a_3)^{\gamma-1}\right] \tag{5.3}$$

is a subsolution of (5.1).

It can be verified by virtue of direct calculations. See Pang [27, Lemma 1.18] for details.

LEMMA 5.2. *Suppose $\gamma < 0$. Define*

$$b_1 \equiv \frac{-\gamma}{2\sigma_1^2(1-\gamma)^2}, \qquad b_2 \equiv b - \sigma_1^2(1-\gamma), \tag{5.4}$$

$$b_3 \equiv b_1 \frac{2\sigma_2^2[\frac{3}{2} - \gamma + \gamma\rho^2] - 2\rho\sigma_1^3\sigma_2\gamma(1-\gamma) + |f(b_2)|}{2c_2 + |f(b_2)|}. \tag{5.5}$$

If

$$\begin{aligned}\beta \geq b\gamma + (1-\gamma)\left[2c_2|f(b_2)| - \frac{\sigma_1^2\gamma}{2}\right] \\ - \frac{2\gamma\sigma_2^2[\frac{3}{2} - \gamma + \gamma\rho^2] - 2\rho\sigma_1^3\sigma_2\gamma^2(1-\gamma) + \gamma|f(b_2)|}{2\sigma_1^2(1-\gamma)[2c_2 + |f(b_2)|]},\end{aligned} \tag{5.6}$$

then

$$\bar{Z}(r) \equiv \log\left[(b_1(r-b_2)^2 + b_2)^{\gamma-1}\right] \tag{5.7}$$

is a supersolution of (5.1).

The proof involves a lot of calculations. The techniques used in the proof are very similar to those used in the proof of Lemma 4.2. See Pang [27, Lemma 1.19] for details.

Remark 5.3. From (5.2), (5.3), (5.6), and (5.7) we can see that

$$a_1 > b_1, \quad a_2 = b_2. \tag{5.8}$$

In addition, we can take a_3 large enough such that

$$a_3 > b_3. \tag{5.9}$$

Then

$$\bar{Z}(r) > \hat{Z}(r) \quad \forall r. \tag{5.10}$$

Given the above results, we can get the following theorem.

THEOREM 5.4. *Suppose* $\gamma < 0$ *and* (5.6) *holds. Then* (5.1) *possesses a classical solution* $\tilde{Z}(r)$ *such that*

$$\hat{Z}(r) \le \tilde{Z}(r) \le \bar{Z}(r), \tag{5.11}$$

where $\hat{Z}(r)$ *and* $\bar{Z}(r)$ *are given by* (5.3) *and* (5.7)*, respectively. Define*

$$\tilde{V}(x,r) \equiv \frac{1}{\gamma} x^\gamma e^{\tilde{Z}(r)}. \tag{5.12}$$

Then $\tilde{V}(x,r)$ *is a classical solution of* (2.14)*, and it satisfies*

$$\frac{1}{\gamma} x^\gamma e^{\hat{Z}(r)} \le \tilde{V}(x,r) \le \frac{1}{\gamma} x^\gamma e^{\bar{Z}(r)}. \tag{5.13}$$

The proof is almost the same as the proof of Theorem 4.4, and we omit it here.

LEMMA 5.5. *Suppose* $\gamma < 0$*. Let* $\tilde{Z}(r)$ *be a solution of* (5.1) *which satisfies* (5.11)*. Then we have*

$$\lim_{|r|\to\infty} \tilde{Z}_r(r) = 0. \tag{5.14}$$

Proof. By the definitions of $\bar{Z}$ and $\hat{Z}$, we can get

$$(\gamma-1)\log(a_1(r-a_2)^2 + a_3) \le \tilde{Z}(r) \le (\gamma-1)\log(b_1(r-b_2)^2 + b_3). \tag{5.15}$$

The above inequality implies

$$\liminf_{|r|\to\infty} |\tilde{Z}_r(r)| = 0. \tag{5.16}$$

Otherwise, $\tilde{Z}(r)$ will have at least a linear growth as $|r| \to \infty$, which contradicts (5.15).

If (5.14) does not hold, $\tilde{Z}_r(r)$ must have a sequence of either positive local maxima or negative local minima at points $\{r_m, m = 1, 2, 3, \ldots\}$, which tend to either $+\infty$ or $-\infty$ with the following property: there exists $\delta > 0$, such that

$$|\tilde{Z}_r(r_m)| \ge \delta. \tag{5.17}$$

Suppose that $\tilde{Z}_r(r)$ has a positive local maximum at r_m. Since $\tilde{Z}(r) \in \mathbf{C}^2(\mathbf{R})$, by virtue of (5.1), we have that $\tilde{Z}(r) \in \mathbf{C}^3(\mathbf{R})$. Therefore, $\tilde{Z}_{rr}(r_m) = 0$, $\tilde{Z}_{rrr}(r_m) \le 0$. Define

$$\check{\sigma}_2^2 \equiv \sigma_2^2 \left(1 + \frac{\gamma\rho}{1-\gamma}\right), \quad \check{f}(r) \equiv f(r) + \frac{\gamma\rho\sigma_2(b-r)}{\sigma_1(1-\gamma)}, \quad \check{c}_1 \equiv c_1 + \frac{\gamma\rho\sigma_2}{\sigma_1(1-\gamma)}.$$

Noting (2.9), we can get that

$$\check{f}_r(r) \le -\check{c}_1. \tag{5.18}$$

By virtue of (5.1), we can get

$$0 = \frac{\sigma_2^2}{2}\tilde{Z}_{rrr} + \check{\sigma}_2^2\tilde{Z}_r\tilde{Z}_{rr} + \check{f}\tilde{Z}_{rr} + \check{f}_r\tilde{Z}_r + \gamma Q_r - e^{-\frac{\tilde{Z}}{1-\gamma}}\tilde{Z}_r,$$

where $Q(r)$ is defined by (2.19) and Q_r stands for its derivative. Since $\tilde{Z}_{rr}(r_m) = 0$, $\tilde{Z}_{rrr}(r_m) \le 0$, noting that $\tilde{Z} \le \bar{Z}$, we have

$$0 \le (\check{f}_r(r_m) - b_1(r_m - b_2)^2 - b_3)\tilde{Z}_r(r_m) + \gamma\left(1 + \frac{r_m - b}{\sigma_2^2(1-\gamma)}\right). \tag{5.19}$$

If $|r_m|$ is big enough, by virtue of (5.18), we will have

$$-\check{f}_r(r_m) + b_1(r_m - b_2)^2 + b_3 \ge \check{c}_1 + b_1(r_m - b_2)^2 + b_3 > 0.$$

Therefore, by virtue of (5.19), we can get

$$\tilde{Z}_r(r_m) \le \frac{\left|\gamma\left(1 + \frac{r_m - b}{\sigma_2^2(1-\gamma)}\right)\right|}{\check{c}_1 + b_1(r_m - b_2)^2 + b_3}.$$

But the right-hand side of the above inequality goes to 0 as $|r_m|$ goes to $+\infty$, so we must have

$$\lim_{|r_m|\to\infty} \tilde{Z}_r(r_m) = 0. \tag{5.20}$$

This contradicts our assumption (5.17). Similarly, if $\tilde{Z}_r$ has a negative local minimum at $\{r_m, m = 1, 2, 3, \ldots\}$, and we can also get (5.20). Therefore, (5.17) holds. □

Define the admissible control space Π as follows.

DEFINITION 5.6 (admissible control space). *A control* $(u_t, c_t) \in \mathbf{R}^2$ *is in the admissible control space* Π*, if the following hold:*

$$0 \le c_t \le A_1(r_t - A_2)^2 + A_3 \quad \forall t \ge 0, \tag{5.21}$$

$$E\int_0^T u_t^2 dt < \infty \quad \forall T \ge 0, \tag{5.22}$$

$$E\int_0^T e^{-2\beta t}u_t^2 x_t^{2\gamma} dt < \infty \quad \forall T \ge 0, \tag{5.23}$$

where $A_1 > 0, A_3 > 0$*, and* A_2 *are some constants.*

We have the following verification theorem.

THEOREM 5.7. *Suppose* $\gamma < 0$ *and* (5.6) *holds. In addition, assume that*

$$\frac{4\gamma(1+3\gamma)}{\sigma_1^2(1-\gamma)^2} \le \frac{c_1^2}{2\sigma_2^2}. \tag{5.24}$$

Define $V(x, r)$ *as in* (2.12) *and define* $\tilde{V}(x, r)$ *and* $\tilde{Z}(r)$ *as in Theorem* 5.4. *Then we have*

$$\tilde{V}(x, r) \equiv V(x, r). \tag{5.25}$$

In addition, $J(x, r, u_\cdot, c_\cdot)$ *reaches its maximum at*

$$u^*(r) = \frac{(b-r)}{\sigma_1^2(1-\gamma)} + \frac{\rho\sigma_2\tilde{Z}_r(r)}{\sigma_1(1-\gamma)}, \quad c^*(r) = e^{\frac{\tilde{Z}(r)}{\gamma-1}}. \tag{5.26}$$

Proof. For any admissible control $(u_t, c_t) \in \Pi$, denote $\mathcal{G}^{u_t,c_t}$ as the generator of the process (x_t, r_t) under control (u_t, c_t). Then, by Ito's rule, we can get

$$d\left[e^{-\beta t}\tilde{V}(x_t, r_t)\right] = e^{-\beta t}\left[\mathcal{G}^{u_t,c_t}\tilde{V}(x_t, r_t) - \beta\tilde{V}(x_t, r_t)\right]dt + dm_{1,t} + dm_{2,t}, \tag{5.27}$$

where

$$m_{1,t} \equiv \int_0^t e^{-\beta s}\sigma_1 u_s x_s^\gamma \tilde{W}(r_s)dw_{1,s}, \quad m_{2,t} \equiv \frac{1}{\gamma}\int_0^t e^{-\beta s}\sigma_2 x_s \gamma \tilde{W}_r(r_s)d\tilde{w}_s,$$

and $\tilde{W}(r)$ is defined by $\tilde{W}(r) \equiv e^{\tilde{Z}(r)}$. It is not hard to verify that $\tilde{W}(r)$ is a classical solution of (2.18).

From the definition of $\tilde{W}(r)$, we know that $e^{\hat{Z}(r)} \le \tilde{W}(r) \le e^{\bar{Z}(r)}$. Thus, by virtue of the definitions of $\hat{Z}(r)$ and $\bar{Z}(r)$, we can get that $\tilde{W}(r)$ is bounded. In addition, from Lemma 5.5, we know that $\tilde{Z}_r(r)$ is bounded. Since $\tilde{W}_r(r) = \tilde{W}(r)Z_r(r)$, $\tilde{W}_r(r)$ is also bounded. Therefore, it is not hard to show that $m_{1,t}, m_{2,t}$ are both martingales.

Now integrate (5.27) on $[0, T]$. Since $\tilde{W}(r)$ is a classical solution of (2.18), it is not hard to verify that $\tilde{V}(x, r)$ is a classical solution of (2.14). Then we have

$$e^{-\beta T}\tilde{V}(x_T, r_T) - \tilde{V}(x, r) \le -\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt + m_{1,T} + m_{2,T}.$$

Take expectation for both sides, and we can get

$$\begin{aligned}\tilde{V}(x, r) &\ge E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt + E\left[e^{-\beta T}\tilde{V}(x_T, r_T)\right] \\ &= E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t x_t)^\gamma dt + \frac{1}{\gamma}E\left[e^{-\beta T}x_T^\gamma \tilde{W}(r_T)\right].\end{aligned} \tag{5.28}$$

If $J(x, r, u_\cdot, c_\cdot) = -\infty$, then we must have

$$\tilde{V}(x, r) \ge J(x, r, u_\cdot, c_\cdot). \tag{5.29}$$

Otherwise, if $J(x, r, u_\cdot, c_\cdot) > -\infty$, i.e.,

$$\int_0^\infty E\left[e^{-\beta t}c_t^\gamma x_t^\gamma\right]dt < \infty, \tag{5.30}$$

we must have

$$\liminf_{T\to\infty} E\left[e^{-\beta T}c_T^\gamma x_T^\gamma\right] = 0. \tag{5.31}$$

In addition, it not hard to find a constant Λ such that

$$\Lambda[b_1(r - b_2)^2 + b_3] \ge \left[A_1(r - A_2)^2 + A_3\right].$$

Therefore, since $\gamma < 0$, by virtue of (5.21), we can get

$$\begin{aligned}c_t^\gamma &\ge \left[A_1(r_t - A_2)^2 + A_3\right]^\gamma \\ &\ge \Lambda^\gamma\left[b_1(r_t - b_2)^2 + b_3\right]^\gamma \\ &\ge b_3\Lambda^\gamma b_3^{-1}\left[b_1(r_t - b_2)^2 + b_3\right]^\gamma \\ &\ge b_3\Lambda^\gamma\left[b_1(r_t - b_2)^2 + b_3\right]^{\gamma-1} \\ &\ge b_3\Lambda^\gamma\tilde{W}(r_t).\end{aligned}$$

Combined with (5.31), this implies

$$\liminf_{T\to\infty} E\left[e^{-\beta T}x_T^{\gamma}\tilde{W}(r_T)\right]=0. \tag{5.32}$$

Then, let $T\to\infty$ in (5.28) and take lim inf, and we can get

$$\tilde{V}(x,r)\geq J(x,r,u_\cdot,c_\cdot). \tag{5.33}$$

On the other hand, for u_t^*, c_t^* defined by (5.26), since $\tilde{Z}_r(r)$ is bounded, it is not hard to verify that

$$0\leq c_t^*\leq a_1(r_t-a_2)^2+a_3 \quad \forall t\geq 0, \tag{5.34}$$

$$E\int_0^T (u_t^*)^2 dt<\infty \quad \forall T\geq 0. \tag{5.35}$$

So (5.21), (5.22) hold if we take $A_1\geq a_1, A_2=a_2$, and $A_3\geq a_3$. Thus, to ensure that $(u^*,c^*)\in\Pi$, we need to show that (5.23) holds for u_t^*, c_t^*. By Ito's rule, define $\tilde{l}(r,u)\equiv r+(b-r)u-\frac{1}{2}\sigma_1^2u^2$. Then using Ito's rule, we can get

$$x_t=x\exp\left\{\int_0^t[\tilde{l}(r_s,u_s^*)-c_s^*]ds+\int_0^t\sigma_1u_s^*dw_{1,s}\right\}.$$

It is not hard to verify that $e^{\int_0^t[4\gamma\sigma_1u_s^*dw_{1,s}-8\gamma^2\sigma_1^2(u_s^*)^2ds]}$ is a positive supermartingale which satisfies

$$Ee^{\int_0^t[4\gamma\sigma_1u_s^*dw_{1,s}-8\gamma^2\sigma_1^2(u_s^*)^2ds]}\leq 1.$$

Given the above equality and by virtue of the Cauchy–Schwarz inequality, we can get

$$\begin{aligned}
&E\left[e^{-2\beta t}(u_t^*)^2x_t^{2\gamma}\right]\\
&\leq x^{2\gamma}e^{-2\beta t}\left(E\left[(u_t^*)^4e^{\int_0^t 4\gamma[l(r_s,u_s^*)-c_s^*]ds}\right]\right)^{\frac{1}{2}}\cdot\left(Ee^{\int_0^t[4\gamma\sigma_1u_s^*dw_{1,s}-8\gamma^2\sigma_1^2(u_s^*)^2ds]}\right)^{\frac{1}{2}}\\
&\leq x^{2\gamma}e^{-2\beta t}\left(E\left[(u_t^*)^4e^{\int_0^t 4\gamma[l(r_s,u_s^*)-c_s^*]ds}\right]\right)^{\frac{1}{2}}\\
&\leq x^{2\gamma}e^{-2\beta t}\left(E[(u_t^*)^8]\right)^{\frac{1}{4}}\cdot\left(Ee^{\int_0^t 8\gamma[l(r_s,u_s^*)-c_s^*]ds}\right)^{\frac{1}{4}},
\end{aligned}$$

where

$$l(r,u)\equiv r+(b-r)u+\left(2\gamma-\frac{1}{2}\right)\sigma_1^2u^2. \tag{5.36}$$

Since $\tilde{Z}_r$ is bounded, using the Cauchy–Schwarz inequality, we can get

$$l(r_s,u_s^*)\geq\Lambda_1+r_s+\frac{(b-r_s)^2}{2\sigma_1^2(1-\gamma)^2}\left(1+\frac{5}{2}\gamma\right). \tag{5.37}$$

In addition, by virtue of (5.34), (5.2), we can get

$$8\gamma[l(r_s,u_s^*)-c_s^*]\leq 8\gamma\left[\Lambda_1+\Lambda_2r_s+\frac{(1+3\gamma)r_s^2}{2\sigma_1^2(1-\gamma)^2}\right]. \tag{5.38}$$

By Lemma 4.7, we can get that if (5.24) holds, then

$$Ee^{\int_0^t 8\gamma[l(r_s,u_s^*)-c_s^*]ds} \le \Lambda(T) < \infty \quad \forall t \in [0,T]. \tag{5.39}$$

In addition, since $\tilde{Z}_r(r)$ is bounded, we can get

$$E\left[(u_t^*)^8\right] \le \Lambda(T) < \infty \quad \forall t \in [0,T]. \tag{5.40}$$

Therefore, we now have

$$E\left[e^{-2\beta t}(u_t^*)^2 x_t^{2\gamma}\right] \le \Lambda(T) \quad \forall t \in [0,T], \tag{5.41}$$

which implies (5.23). Thus, we have shown that $(u_t^*, c_t^*) \in \Pi$. Given this, instead of (5.28), we can now get

$$\tilde{V}(x,r) = E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt + E\left[e^{-\beta T}\tilde{V}(x_T, r_T)\right]. \tag{5.42}$$

Since $\tilde{V}(x_T, r_T) \le 0$, we can get

$$\tilde{V}(x,r) \le E\int_0^T e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt.$$

Let T go to $+\infty$; then we have

$$\tilde{V}(x,r) \le E\int_0^\infty e^{-\beta t}\frac{1}{\gamma}(c_t^* x_t)^\gamma dt,$$

i.e.,

$$\tilde{V}(x,r) \le J(x,r,u_\cdot^*, c_\cdot^*). \tag{5.43}$$

This completes the proof. □

ON THE BELLMAN EQUATION FOR THE MINIMUM TIME PROBLEM IN INFINITE DIMENSIONS*

PIERMARCO CANNARSA† AND OVIDIU CÂRJĂ‡

Abstract. We consider the time optimal control problem for a semilinear parabolic control system, where the target is the closed ball with center 0 and radius $R \geq 0$ in a Hilbert space X. In particular, we allow the origin of X to be the target. Using an appropriate Kružkov-type transformation, we give an existence and uniqueness result for the associated Hamilton–Jacobi–Bellman equation, even when the reachable set is not the whole space.

Key words. Hamilton–Jacobi–Bellman equation, viscosity solutions, optimality principle, time optimal control

AMS subject classifications. 49L20, 49K20, 93C10

DOI. 10.1137/S0363012902419011

1. Introduction.

This paper is concerned with the time optimal control problem for the system

$$y'(t) = Ay(t) + f(y(t)) + u(t), \quad t > 0, \quad y(0) = x, \tag{1}$$

where the operator A generates a C_0-semigroup on a Hilbert space X, f is a Lipschitz continuous function, and $u(\cdot)$ is a control taking values in B_r, the closed ball of center 0 and radius $r > 0$ in X. Here, the problem we consider is to reach a given *target set*, starting from the initial point x in minimum time $T(x)$, by trajectories of the state equation (1). We restrict our attention to the case where the target set is B_R, the closed ball of center 0 and radius $R \geq 0$ in X. Since the literature on this problem is huge, we refer the reader to some of the most recent monographs on this subject, such as [2], [15], and [13].

The goal of this paper is to study the Hamilton–Jacobi–Bellman equation associated with our time optimal control problem. Such equations have been analyzed by many authors using various approaches and—at times—different frameworks within the same approach, as in [8], [9], [10], [11], [12], [14], [16], [17] and [5], where variants of the viscosity solution method are proposed. The aforementioned results, however, cannot be applied to the problem we are interested in due to the presence of boundary conditions.

The viscosity solution technique was adapted to the specific case of Hamilton–Jacobi–Bellman equations related to the minimum time problem in [3], for a nonlinear case, as well as in [4], for a linear problem, obtaining existence and uniqueness results. We point out that, in both [3] and [4], the reachable set $\mathcal{R} = \{x \in X : T(x) < \infty\}$ is the whole space X, and the authors apply the Kružkov transformation $W(x) = 1 - e^{-T(x)}$ in order to arrive at a new Hamiltonian, more suitable for getting uniqueness under appropriate boundary conditions.

The main purpose of this paper is to characterize W as the unique solution of the associated Hamilton–Jacobi–Bellman equation, in case the reachable set is not necessarily the whole space. A major difficulty to overcome is related to the behavior of W at the boundary of the reachable set. More precisely, our technique for uniqueness requires W to be uniformly continuous, as well as sequentially weakly continuous, on $\partial\mathcal{R}$.

The key idea of our approach is to modify the Kružkov transformation as follows:

$$W(x) = \begin{cases} 1 - e^{-kT(x)} & \text{for } x \in \mathcal{R}, \\ 1 & \text{for } x \notin \mathcal{R}, \end{cases}$$

where $k > 0$ is a constant to be chosen so that W be differentiable on $X \setminus \mathcal{R}$. This is indeed possible since, as we will show, $T(x)$ has a logarithmic behavior near $\partial\mathcal{R}$; see Proposition 3.3.

Some technical tools of our method are built on the results of [1], where regularity properties of the minimum time function are obtained for system (1) with a target of the form B_R, $R > 0$. In order to recover the smoothness of W on $\partial\mathcal{R}$ that is needed to handle the Hamilton–Jacobi–Bellman equation, we had to produce a finer version of the Lipschitz regularity result of [1]. It is worth noting that such a regularity result holds for a point target ($R = 0$) as well.

The outline of this paper is the following. In section 2 we recall known results on semiconcave functions and generalized gradients. Section 3 is focussed on the regularity properties of the minimum time function, while section 4 contains our existence and uniqueness result for the Hamilton–Jacobi–Bellman equation.

2. Preliminaries. Throughout this paper we denote by X a Hilbert space with scalar product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$. We denote by $\|\cdot\|$ the standard norm of a linear operator between Banach spaces. For any $R \geq 0$ and $x \in X$, $B_R(x)$ stands for the *closed* ball of radius R centered at x, that is,

$$B_R(x) = \{y \in X \,:\, |y - x| \leq R\}.$$

We abbreviate $B_R = B_R(0)$.

Let us recall the definition of semiconcave functions, a basic notion for our approach. Indeed, if the target is a closed ball B_R with $R > 0$, then both the minimum time function and its Kružkov transformation are semiconcave on the reachable set.

DEFINITION 2.1. *Given $\alpha \in (0, 1]$ and Ω an open subset of X, a function $g : \Omega \to \mathbb{R}$ is said to be* semiconcave *with exponent α (or with modulus Cr^α) if, for any point $x_0 \in \Omega$, there exist $\rho > 0$ and $C \geq 0$ such that*

$$g(x) + g(y) - 2g\left(\frac{x+y}{2}\right) \leq C|x - y|^{1+\alpha}$$

for all $x, y \in B_\rho(x_0)$.

Semiconcave functions share many properties with concave functions; see, e.g., [1]. We now recall two such properties that will be used later on in the paper.

Recall first the notion of *superdifferential* of g in $x \in \Omega$, $D^+g(x)$. Namely,

$$D^+g(x) = \left\{ p \in X \;:\; \limsup_{y \to x} \frac{g(y) - g(x) - \langle p, y - x \rangle}{|y - x|} \leq 0 \right\}.$$

Similarly, the *subdifferential* of g in $x \in \Omega$ is defined as

$$D^-g(x) = \left\{ p \in X \;:\; \liminf_{y \to x} \frac{g(y) - g(x) - \langle p, y - x \rangle}{|y - x|} \geq 0 \right\}.$$

PROPOSITION 2.2. *For a semiconcave function g with exponent α, the superdifferential $D^+g(x)$ is nonempty for any $x \in \Omega$. Moreover, for any $x_0 \in \Omega$ there exist $\gamma > 0$ and $C > 0$ such that*

$$g(y) - g(x) - \langle p, y - x\rangle \le C|y - x|^{1+\alpha} \quad \forall x, y \in B_\gamma(x_0),\ p \in D^+g(x). \tag{2}$$

Another property of the minimum time function that plays a prominent role in our approach is a stronger variant of the local Lipschitz continuity. It is a Lipschitz property, labelled below as (P_θ), with respect to a weaker norm on X, $x \mapsto |(-A)^{-\theta}x|$, where $\theta \in (0, 1]$, $(-A)^{-\theta}$ is the inverse of the fractional power of $-A$ and A is the generator of an analytic semigroup of type $-\omega$ with $\omega > 0$. Recall that the semigroup $S(t)$ is of type $-\omega$ if it satisfies the property

$$\|S(t)\| \le e^{-\omega t} \quad \forall t \ge 0. \tag{3}$$

PROPOSITION 2.3. *Let $\theta \in (0, 1]$ and let $g : \Omega \to \mathbb{R}$. Suppose that*

(P_θ) *for any $x_0 \in \Omega$ there exist $\delta, K > 0$ such that*

$$|g(x) - g(z)| \le K|(-A)^{-\theta}(x - z)| \qquad \forall x, z \in B_\delta(x_0).$$

Then

$$D^+g(x),\ D^-g(x) \subset D((-A)^\theta) \qquad \forall x \in \Omega$$

and

$$|(-A)^\theta p| \le K \qquad \forall x \in B_\delta(x_0),\ \forall p \in D^+g(x),\ \forall p \in D^-g(x).$$

Proof. A proof for the case of $\theta = 1$ is given in [4]. To assist the reader, we outline here the proof of the general case. Given $y \in B_1$ and $\lambda > 0$ small enough, we have

$$-\langle p, y\rangle \le \frac{g(x + \lambda y) - g(x) - \langle p, \lambda y\rangle}{\lambda} + \frac{|g(x + \lambda y) - g(x)|}{\lambda}$$

for all x in a neighborhood of x_0. By letting $\lambda \to 0$, we obtain

$$-\langle p, y\rangle \le K|(-A)^{-\theta}y| \qquad \forall p \in D^+g(x).$$

Since this holds for any $y \in B_1$, we get that $p \in D((-A)^\theta)$ and $|(-A)^\theta p| \le K$. For $p \in D^-g(x)$ we start with the inequality

$$-\langle p, y\rangle \ge \frac{g(x + \lambda y) - g(x) - \langle p, \lambda y\rangle}{\lambda} - \frac{|g(x + \lambda y) - g(x)|}{\lambda}$$

and proceed as above. □

Property (P_θ) and the semiconcavity of g yield a useful result for the graph of D^+g.

PROPOSITION 2.4. *Suppose that a function $g : \Omega \to \mathbb{R}$ is semiconcave with some exponent $\alpha > 0$ and satisfies property (P_θ) for some $\theta \in (0, 1]$. Let $\{x_n\}$, $\{p_n\}$ be given sequences in X such that $p_n \in D^+g(x_n)$ and $x_n \to x$ strongly. Then, at least on a subsequence, $(-A)^\theta p_n \to q$ weakly for some $q \in X$, $p_n \to (-A)^{-\theta}q$ weakly, and $(-A)^{-\theta}q \in D^+g(x)$.*

Proof. By Proposition 2.3 we get that $\{(-A)^\theta p_n\}$ is a bounded sequence in X. Hence, it admits a subsequence (still labelled $\{(-A)^\theta p_n\}$) that weakly converges to some $q \in X$. Since operator $(-A)^{-\theta}$ is bounded, we have $p_n \to (-A)^{-\theta} q$ weakly. Next, by (2) we obtain

$$g(y) - g(x_n) - \langle p_n, y - x_n \rangle \le C|y - x_n|^{1+\alpha}$$

for any y in a neighborhood of x and for any n sufficiently large. Letting $n \to \infty$ and then $y \to x$, we conclude that $(-A)^{-\theta} q \in D^+ g(x)$, as claimed. □

We end this section recalling some facts about *proximal gradients*, a notion that plays a basic role in the study of the Bellman equation in case the target is the origin of X. We refer the reader to [7, p. 27] for details. For our purposes here, it is suitable to take the characterization given in [7, Theorem 2.5] as the definition of the *proximal subdifferential* of g at x, namely,

$$\partial_P g(x) = \{\zeta \in H : \exists \sigma, \rho > 0;\ g(y) - g(x) + \sigma|y - x|^2 \ge \langle \zeta, y - x \rangle \ \ \forall y \in B_\rho(x)\}.$$

Clearly $\partial_P g(x) \subseteq D^- g(x)$. Further, the following proposition, proved in [7, pp. 37–38], will be useful in what follows.

PROPOSITION 2.5. *Assume that $g : X \to \mathbb{R}$ is lower semicontinuous.*

(a) *If g has a local minimum at x, then $0 \in \partial_P g(x)$.*

(b) *If $h : X \to \mathbb{R}$ is of class C^2 in a neighborhood of x, then*

$$\zeta \in \partial_P(g + h)(x) \ \Rightarrow\ \zeta - Dh(x) \in \partial_P g(x),$$

where $Dh(x)$ is the Fréchet derivative of h in x.

The *proximal superdifferential* of g at x is defined as

$$\partial^P g(x) = \{\zeta \in H : \exists \sigma, \rho > 0;\ g(y) - g(x) - \sigma|y - x|^2 \le \langle \zeta, y - x \rangle \ \ \forall y \in B_\rho(x)\}.$$

Since $\partial^P g(x) = -\partial_P(-g)(x)$, a similar result as in Proposition 2.5 holds with upper instead of lower and maximum instead of minimum.

3. The minimum time function. First, let us list the basic assumptions we shall refer to in what follows.

(H1) X is a Hilbert space with scalar product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$, and $A : D(A) \subset X \to X$ is the infinitesimal generator of an analytic semigroup $S(t)$, $t \ge 0$, on X. Further, A is self-adjoint and satisfies

$$\langle Ax, x \rangle \le -\omega |x|^2 \quad \forall x \in D(A),$$

for some constant $\omega > 0$.

(H2) $f : X \to X$ is a Lipschitz continuous function satisfying, for some constant $L > 0$,

$$|f(x) - f(y)| \le L|x - y| \quad \forall x, y \in X,$$

$$f(0) = 0.$$

(H3) Two constants $r > 0$ and $R \ge 0$ are given such that $(L - \omega)R < r$.

(H4) The function f above is Gâteaux differentiable on X and there exist $\theta_1 \in (0, 1/2)$, $\alpha \in (0, 1]$, and C' such that

$$|f(x + y) - f(x) - \delta f(x) y| \le C' |(-A)^{\theta_1} y|^{1+\alpha}$$

for all $x, y \in D((-A)^{\theta_1})$. Moreover, the map $x \mapsto \delta f(x)$ is strongly continuous on X; that is, for any sequence $\{x_n\}$ in X,

$$\lim_{n\to\infty} x_n = x_\infty \quad \Rightarrow \quad \lim_{n\to\infty} \delta f(x_n)x = \delta f(x_\infty)x \qquad \forall x \in X.$$

(H5) $S(\cdot)$ is a compact semigroup; i.e., for any $t > 0$, $S(t)$ is a compact operator.

Let $\mathcal{U}$ be the set of all *control strategies* (or, briefly, *controls*), i.e., measurable functions $u : [0, \infty) \to B_r$. For $x \in X$ and $u \in \mathcal{U}$, consider the mild solution of (1) which satisfies the initial condition $y(0) = x$, i.e., a function $y \in C([0, \infty); X)$ satisfying

$$y(t) = S(t)x + \int_0^t S(t-s)[f(y(s)) + u(s)]ds. \tag{4}$$

We call such a solution the *trajectory* of system (1) starting from x with control u and denote it by $y(\cdot, x, u)$. For any $x \in X$, and any control u we define

$$\tau(x, u) = \min\{t \geq 0 : \ y(t, x, u) \in B_R\} \in [0, \infty],$$

called the transition time from x to B_R. Define now the *reachable set* $\mathcal{R}$ as the set of all points x such that $\tau(x, u) < \infty$ for some u. A control u at which $\tau(x, \cdot)$ attains its minimum is called *optimal* for x, and the corresponding solution $y(\cdot, x, u)$ of (1) is called the *optimal trajectory*. Finally, define the *minimum time function* as

$$T : \mathcal{R} \to [0, \infty), \quad T(x) = \inf_{u\in\mathcal{U}} \tau(x, u).$$

It is well known that assumption (H1) implies that semigroup $S(\cdot)$ satisfies (3). Moreover, the fractional powers of $-A$, denoted by $(-A)^\theta$, are well defined for any $\theta \in [0, 1]$ and satisfy

$$|(-A)^\theta S(t)x| \leq \frac{M_\theta}{t^\theta}|x| \qquad \forall x \in X, \ t > 0,$$

$$|x| \leq M'_\theta |(-A)^\theta x| \qquad \forall x \in D((-A)^\theta)$$

for some constants $M_\theta, M'_\theta > 0$. These facts are used to prove that the minimum time function satisfies property (P_θ).

Assumption (H4) is used to prove that, in case the target is B_R with $R > 0$, the minimum time function is *semiconcave* with exponent α; see [1, Theorem 4.3].

In the next propositions we gather some basic properties of the trajectories of (1), the reachable set, and the associated minimum time function.

PROPOSITION 3.1. *Assume* (H1), (H2), *and* (H3). *Then the following properties hold:*

(i) *In case $L - \omega > 0$, for every $x \in X$ satisfying $R < |x| < r/(L - \omega)$ a control strategy u^* exists such that the corresponding trajectory of* (1) *reaches the target B_R with $R \geq 0$ and satisfies*

$$|y(t, x, u^*)| \leq e^{(L-\omega)t}\left(|x| - \frac{r}{L-\omega}\right) + \frac{r}{L-\omega} \tag{5}$$

for any

$$0 \leq t \leq \tau(x, u^*) \leq \frac{1}{L-\omega} \log \frac{\frac{r}{L-\omega} - R}{\frac{r}{L-\omega} - |x|}.$$

(ii) *In case* $L - \omega \le 0$, *for any* $x \in X$ *a control strategy* u^* *exists such that the corresponding trajectory of* (1) *reaches* B_R *with* $R \ge 0$ *and satisfies*

$$|y(t, x, u^*)| \le |x| - rt \tag{6}$$

for any $0 \le t \le \tau(x, u^*) \le (|x| - R)r^{-1}$.

Remark 3.1. The above proposition is a considerable extension of [1, Lemma 3.6 (i)], where the authors proved (5) for $t \le \omega^{-1} \log(1 + r^{-1}\omega|x|)$. Indeed, under the last restriction one does not get controllability to the target B_R with $R > 0$ for all points satisfying $|x| < r/(L - \omega)$. Nor does one get null controllability at all. Finally, the results provided by Proposition 3.1 hold in any Banach space and for any C_0-semigroup satisfying $\|S(t)\| \le e^{-\omega t}$ for some $\omega \in \mathbb{R}$.

Proof of Proposition 3.1. (i) First, let us consider the case $R > 0$. Observe that the function

$$F_R(y) = \begin{cases} -\frac{r}{R} y & \text{if } |y| \le R, \\ -r\frac{y}{|y|} & \text{if } |y| \ge R \end{cases}$$

is Lipschitz continuous in X. Then, for every $x \in D(A)$, the equation

$$y'(t) = Ay(t) + f(y(t)) + F_R(y(t)), \quad t > 0, \tag{7}$$

has a unique classical solution on each interval $[0, T]$ satisfying $y(0) = x$ (see, e.g., [6, p. 60]). Multiplying (7) by $y(t)$ and taking into account that

$$\langle y'(t), y(t) \rangle = \frac{1}{2} \frac{d}{dt} |y(t)|^2 \quad \forall t > 0,$$

we easily get

$$|y(t)| \frac{d}{dt} |y(t)| \le (L - \omega)|y(t)|^2 - r\,|y(t)|$$

for $t \in [0, \tilde{t}]$, where $\tilde{t}$ is the minimum of t for which $y(t) \in B_R$. Then,

$$|y(t)| \le |x| - rt + (L - \omega) \int_0^t |y(t)|\, ds \quad \forall t \in [0, \tilde{t}],$$

which, if $L - \omega \le 0$, immediately gives (6). In case $L - \omega > 0$, (5) follows from the above inequality and Gronwall's lemma. Notice that the existence of time $\tilde{t}$ is a consequence of (5) and (6).

Therefore, (5) and (6) have been proven for every $x \in D(A)$. By a density argument, they also hold for any $x \in X$. Thus, the desired control is

$$u^*(t) = \frac{-ry(t)}{|y(t)|}. \tag{8}$$

In the case of $R = 0$, we observe that, if $R_1 < R_2$, then the corresponding times $\tilde{t}_1$ and $\tilde{t}_2$ satisfy $\tilde{t}_1 > \tilde{t}_2$, while the corresponding solutions of (7), $y_1(\cdot)$ and $y_2(\cdot)$, satisfy

$$y_1(t) = y_2(t) \quad \forall t \in [0, \tilde{t}_2].$$

In other words, the trajectory of (7) does not depend on $R > 0$ until it reaches B_R. Taking a sequence R_n decreasing to 0, we get a sequence $\tilde{t}_n$ increasing to some $\bar{t}$ that

satisfies the inequalities requested in (i) or (ii). The proof ends by considering the control given by (8) on $[0, \bar{t}]$. □

Remark 3.2. The above proof shows that for any $x \in B_R$ there exists a control strategy u^* keeping the corresponding trajectory $y(t, x, u^*)$ inside B_R for every $t \geq 0$. Indeed, for $R = 0$ it suffices to take $u^* \equiv 0$, while, for $R > 0$, one can take the feedback control u^* given in (8) until y reaches the origin, and then 0.

In the next proposition $d(x)$ denotes the distance of x from the target, that is,

$$d(x) = \max\{|x| - R, 0\}, \qquad x \in X\,.$$

PROPOSITION 3.2. *Assume* (H1), (H2), *and* (H3).
(i) *In case* $L - \omega > 0$, *for any* $\rho \in (0, r/(L-\omega) - R)$ *we have*

$$T(x) \leq \frac{d(x)}{r - (R+\rho)(L-\omega)}$$

for all points x *satisfying* $d(x) \leq \rho$.
(ii) *In case* $L - \omega \leq 0$ *we have*

$$T(x) \leq \frac{d(x)}{r}$$

for every $x \in X$.

The proof goes as in [1, Proposition 3.8] and is based on Proposition 3.1 above.

Remark 3.3. The Lipschitz continuity of T around the target, which plays a basic role in our analysis, is essentially a consequence of the fact that we have full control for the state equation (1). The same property can be obtained, using the same idea, in case the state equation is

$$y'(t) = Ay(t) + f(y(t)) + Du(t), \tag{9}$$

where D is a bounded linear operator from a Banach space U *onto* X. In fact, assuming that controls take values in B_r, the closed ball of center 0 and radius r in U, let us note that, by the open mapping theorem, there exists a ball B_p in X, contained in the image of B_r under D. Then, reasoning as above and using Filippov's selection theorem, we obtain the Lipschitz property around the target for the minimum time function for (9) with target B_R, $R \geq 0$.

Let us now show that the surjectivity of D is a necessary condition in order for T to be Lipschitz around the point target 0. Indeed, assume that there exist $\rho > 0$ and $\gamma > 0$ such that $T(x) \leq \gamma|x|$ for every $x \in B_\rho$. This implies that, if $|x| \leq t/\gamma$, then x can be transferred to 0 in time t by some control strategy $\bar{u}$. Hence,

$$S(t)x = -\int_0^t S(t-s)[f(y(s, x, \bar{u})) + D\bar{u}(s)]ds.$$

Taking the scalar product of the both sides with a fixed element x^* in X (or in the dual of X, should X be a reflexive Banach space), we get

$$\langle x, S^*(t)x^*\rangle \leq L\int_0^t |S^*(t-s)x^*||y(s, x, u)|ds + r\int_0^t |D^*S^*(s)x^*|ds. \tag{10}$$

Notice that, arguing by Gronwall's inequality as in [1, Lemma 3.6], we have

$$|y(t, x, \bar{u})| \leq e^{(L-\omega)t}\left(|x| + \frac{r\|D\|}{L-\omega}\right) - \frac{r\|D\|}{L-\omega} \qquad \forall t \geq 0.$$

Using this inequality in (10), we obtain

$$\langle x, S^*(t)x^*\rangle \le \frac{Lt}{\gamma}|x^*|\int_0^t e^{\omega(s-t)+(L-\omega)t}ds + L|x^*|\frac{r\|D\|}{L-\omega}\int_0^t e^{\omega(s-t)}[e^{(L-\omega)t}-1]ds + r\int_0^t |D^*S^*(s)x^*|ds.$$

Finally, take the supremum for $x \in B_{t/\gamma}$, divide by t, and let $t \downarrow 0$ to obtain

$$C|x^*| \le |D^*x^*| \quad \forall x^* \in X$$

for some constant $C > 0$. This implies the surjectivity of D, as claimed.

It is well known that, in finite dimensional control theory, the Lipschitz continuity of T around the target is equivalent to the so-called Petrov condition. It is easy to see that, when $\dim X < \infty$, the Petrov condition for (9) reduces to the surjectivity of D.

The next result shows that the Lipschitz property around the target yields the local Lipschitz continuity of T on the whole reachable set, as well as a precise estimate of the behavior of T near the boundary, $\partial\mathcal{R}$, of the reachable set. To this end, the following well-known dynamic programming principle is a main tool: for any $x \in \mathcal{R}$ and for any control u,

$$T(x) \le t + T(y(t,x,u)) \quad \forall t \in [0, \tau(x,u)]. \tag{11}$$

Furthermore, equality holds in (11) if and only if u is optimal for x.

PROPOSITION 3.3. *Assume* (H1), (H2), *and* (H3).

(i) *Suppose* $L-\omega > 0$, *let* $\rho \in (0, r/(L-\omega) - R)$, *and define*

$$\gamma = \frac{1}{r-(R+\rho)(L-\omega)}.$$

If $x \in \mathcal{R}$ *and* z *is such that*

$$|z-x| \le \rho\, e^{-(L-\omega)T(x)},$$

then $z \in \mathcal{R}$ *and*

$$T(z) \le T(x) + \gamma\, e^{(L-\omega)T(x)}|x-z|.$$

Moreover, the reachable set $\mathcal{R}$ *is open, and the minimum time function is locally Lipschitz continuous on* $\mathcal{R}$.

(ii) *If* $L-\omega \le 0$, *then the minimum time function is globally Lipschitz continuous on* X. *More precisely, for any* $x, z \in X$ *we have*

$$|T(z) - T(x)| \le \frac{1}{r}|x-z|.$$

(iii) *For every* $x \in \mathcal{R}$ *and* $z \notin \mathcal{R}$ *we have*

$$T(x) \ge -\frac{1}{L-\omega}\log\frac{|x-z|}{\rho}.$$

Consequently,

$$\lim_{x\to z} T(x) = \infty \quad \forall z \in \partial\mathcal{R}.$$

Proof. (i) Recall first that, for any $x, z \in X$ and any control strategy u, we have

$$|y(t,x,u) - y(t,z,u)| \le e^{(L-\omega)t}|x-z| \quad \forall t \ge 0. \tag{12}$$

This follows easily by the Gronwall inequality. Without loss of generality, we can assume the existence of an optimal control u for x. In the general case, the conclusion follows by an approximation argument. Since $y(T(x),x,u) \in B_R$, by using (12) we get

$$d(y(T(x),z,u)) \le e^{(L-\omega)T(x)}|x-z| \le \rho,$$

so $y(T(x),z,u) \in \mathcal{R}$, which, in turn, implies that $z \in \mathcal{R}$ and

$$T(y(T(x),z,u)) \le \gamma e^{(L-\omega)T(x)}|x-z|.$$

Here, we have used Proposition 3.2. Now, apply the dynamic programming principle to obtain the first part of the claim in (i). To conclude the proof of (i), for each $x_0 \in \mathcal{R}$, take

$$\delta = \frac{\rho}{2} e^{-(L-\omega)(T(x_0)+\gamma\rho)}$$

and observe that, from the first part, we have

$$|T(x_1) - T(x_2)| \le \gamma e^{(L-\omega)(T(x_0)+\gamma\rho)}|x_1 - x_2|$$

for every $x_1, x_2 \in B_\delta(x_0)$.

Similar arguments can be used to prove (ii). For the proof of (iii), let us recall, first, that we are assuming $L - \omega > 0$. Suppose $(L-\omega)T(x) < -\log|x-z|/\rho$. Then we would have $|x-z| < \rho\, e^{-(L-\omega)T(x)}$. This, along with (i), implies the contradiction $z \in \mathcal{R}$. □

In the next proposition we show that, if $S(\cdot)$ is compact, then the minimum time function is sequentially weakly continuous. For this, we will use a well-known compactness result.

LEMMA 3.4. *Let $0 < a < t$, let $\{x_n\}$ be a sequence, weakly convergent to x, and $\{u_n\}$ be a sequence weakly convergent to u in $L^2(0,t;X)$. Then, $y(\cdot,x_n,u_n) \to y(\cdot,x,u)$ in $C([a,t];X)$.*

Proof. The proof is standard and relies on the compactness of the operator $\varphi \mapsto P(\varphi)$ from $L^p(0,t;X)$, $p > 1$, to $C([0,t];X)$, where

$$P(\varphi)(s) = \int_0^s S(s-\tau)\varphi(\tau)\, d\tau$$

(see [15, p. 104]). □

PROPOSITION 3.5. *Assume* (H1), (H2), (H3), *and* (H5).

(i) *If $x \in \mathcal{R}$ and $x_n \to x$ weakly, then, for n large enough, we have $x_n \in \mathcal{R}$ and $T(x_n) \to T(x)$.*

(ii) *For any $x \notin \mathcal{R}$ and any sequence $\{x_n\}$, contained in $\mathcal{R}$ and weakly convergent to x,*

$$\lim_{n\to\infty} T(x_n) = \infty.$$

Proof. In this proof we shall assume $L-\omega>0$, the reasoning being simpler for $L-\omega\le 0$.

In order to prove the first statement of (i), let $\bar t>0$ be such that $y(\bar t,x,0)\in\mathcal{R}$ (this is possible because $\mathcal{R}$ is open). Then, by Lemma 3.4, $y(\bar t,x_n,0)\in\mathcal{R}$ for n sufficiently large. This clearly implies that $x_n\in\mathcal{R}$.

Now, take a subsequence $\{x_{n_k}\}$ such that

$$T(x_{n_k})\to T^*=\limsup_{n\to\infty}T(x_n),$$

and fix $\varepsilon>0$. Again by Lemma 3.4, we have that $y(\varepsilon,x_{n_k},0)\to y(\varepsilon,x,0)$. Thus, $T(y(\varepsilon,x_{n_k},0))$ converges to $T(y(\varepsilon,x,0))$ as $k\to\infty$. By the dynamic programming principle (11), we get

$$T(x_{n_k})\le\varepsilon+T(y(\varepsilon,x_{n_k},0))\,.$$

Therefore, $T^*\le\varepsilon+T(y(\varepsilon,x,0))$. Let $\varepsilon\to 0$ to obtain $\limsup_{n\to\infty}T(x_n)\le T(x)$. We have thus proven that $T(\cdot)$ is sequentially weakly upper semicontinuous at x.

Next, let us show that $T(\cdot)$ is sequentially weakly lower semicontinuous at x. To this end, take a subsequence $\{x_{n_k}\}$ such that

$$T(x_{n_k})\to T^\#=\liminf_{n\to\infty}T(x_n).$$

First, suppose $T^\#>0$ and, having fixed $0<\varepsilon<T^\#$, let u_{n_k} be the time optimal control for x_{n_k}. By Lemma 3.4, we may assume with no loss of generality (by extracting a subsequence if necessary) that there exists some control strategy u such that $y(\varepsilon,x_{n_k},u_{n_k})\to y(\varepsilon,x,u)$ strongly. Taking into account the dynamic programming principle, we have

$$T(x_{n_k})=\varepsilon+T(y(\varepsilon,x_{n_k},u_{n_k})),$$

which implies that $T(y(\varepsilon,x_{n_k},u_{n_k}))\le M$ for some $M>0$. Let $\rho\in(0,r/(L-\omega)-R)$, and let k_0 be such that

$$|y(\varepsilon,x,u)-y(\varepsilon,x_{n_k},u_{n_k})|\le\rho\,e^{-(L-\omega)M}$$

for every $k>k_0$. By Proposition 3.3 we obtain that $y(\varepsilon,x,u)\in\mathcal{R}$ and

$$T(y(\varepsilon,x,u))\le T(y(\varepsilon,x_{n_k},u_{n_k}))+\gamma\,e^{(L-\omega)M}|y(\varepsilon,x_{n_k},u_{n_k})-y(\varepsilon,x,u)|$$

for every $k>k_0$. Therefore,

$$T(x_{n_k})=\varepsilon+T(y(\varepsilon,x_{n_k},u_{n_k}))\ge\varepsilon+T(y(\varepsilon,x,u))-\gamma\,e^{(L-\omega)M}|y(\varepsilon,x_{n_k},u_{n_k})-y(\varepsilon,x,u)|.$$

Let $k\to\infty$ and then $\varepsilon\to 0$ to obtain $\liminf_{n\to\infty}T(x_n)\ge T(x)$. Now, let us suppose $T^\#=0$ and prove that $T(x)=0$. To this end, fix $\varepsilon>0$ and note that $T(x_{n_k})<\varepsilon$ for k sufficiently large. Then, for x_{n_k} define a control strategy, v_k, on $[0,\varepsilon]$ as follows: on $[0,T(x_{n_k})]$, v_k equals the time optimal control steering x_{n_k} to B_R, and on $[T(x_{n_k}),\varepsilon]$, v_k is any control strategy that forces the trajectory to remain in B_R. This is possible in view of Remark 3.2. Taking into account that (at least on a subsequence) $y(\varepsilon,x_{n_k},v_k)\to y(\varepsilon,x,u)$ for some control strategy u, we deduce that $y(\varepsilon,x,u)\in B_R$, and hence $T(x)\le\varepsilon$. Since this fact holds for any $\varepsilon>0$, we get $T(x)=0$, as claimed.

To prove (ii), consider $x \notin \mathcal{R}$, take a sequence $\{x_n\}$ in $\mathcal{R}$ weakly convergent to x, and assume, by contradiction, that

$$\liminf_{n\to\infty} T(x_n) < \infty.$$

Arguing as in the above proof of the lower semicontinuity of T, we get that $y(\varepsilon, x, u) \in \mathcal{R}$. This clearly implies that $x \in \mathcal{R}$, a contradiction. Thus, $\liminf_{n\to\infty} T(x_n) = \infty$. □

We end this section by recalling some results of [1] concerning the semiconcavity of the minimum time function and property (P_θ).

PROPOSITION 3.6. *Assume* (H1), (H2), *and* (H3). *Then the minimum time function satisfies property* (P_θ) *for any* $\theta \in [0, 1)$. *If, in addition,* (H4) *holds and the target is* B_R *with* $R > 0$, *then the minimum time function is semiconcave with exponent* α.

We note that, in [1], only the case of $R > 0$ is considered. However, taking into account Proposition 3.3, one can use the same arguments to recover property (P_θ) in the case of $R = 0$.

4. The Bellman equation. Let us introduce a variant of the Kružkov transformation that we shall use in this section, namely the function $W : X \to \mathbb{R}$ defined by

$$W(x) = \begin{cases} 1 - e^{-2(L-\omega)T(x)} & \text{if } x \in \mathcal{R}, \\ 1 & \text{if } x \notin \mathcal{R}. \end{cases} \tag{13}$$

Since the value function is known to be semiconcave only in the case of $R > 0$, we shall give two results for the Hamilton–Jacobi–Bellman equation. The former assumes semiconcavity and therefore applies only if $R > 0$; the latter applies to the general case $R \geq 0$.

THEOREM 4.1. *Assume* (H1)–(H5), *and consider the target* B_R *with* $R > 0$. *Then the Kružkov transformation* W *defined by* (13) *is the unique function from* X *to* $\mathbb{R}$ *which satisfies the following properties:*

(a) W *is sequentially weakly continuous.*

(b) $\emptyset \neq D^+W(x) \subset D((-A)^\theta))$ *for any* $x \in X \setminus B_R$ *and for any* $\theta \in (0, 1)$.

(c) *There exist* $\rho > 0$ *and* $M > 0$ *such that if* $|z - x| \leq \rho\sqrt{1 - W(x)}$, *then*

$$W(z) - W(x) \leq M\sqrt{1 - W(x)}|z - x|.$$

(d) $W(x) = 0$ *for any* $x \in B_R$, *and* $W(x) \in [0, 1]$ *for any* $x \in X$.

(e) W *satisfies the Hamilton–Jacobi–Bellman equation in the following sense: for any* $x \in X \setminus B_R$ *with* $x \in \cap_{\theta\in(0,1)} D((-A)^\theta)$ *and for any* $\gamma \in (0, 1)$,

(i) *there exists* $p \in D^+W(x)$ *such that*

$$r\,|p| + \langle(-A)^{1-\gamma}p, (-A)^\gamma x\rangle - \langle p, f(x)\rangle + 2(L - \omega)W(x) \geq 2(L - \omega);$$

(ii) *for any* $p \in D^+W(x)$ *we have*

$$r\,|p| + \langle(-A)^{1-\gamma}p, (-A)^\gamma x\rangle - \langle p, f(x)\rangle + 2(L - \omega)W(x) \leq 2(L - \omega).$$

Proof. Let us show, first, that the function W defined by (13) satisfies properties (a)–(e). To begin with, we note that property (a) follows from Proposition 3.5, while

(d) is obvious. In order to prove (c), we use the elementary inequality $1 - e^t \le -t$ to obtain

$$W(z) - W(x) \le 2(L-\omega)e^{-2(L-\omega)T(x)}(T(z) - T(x)) .$$

This, in view of Proposition 3.3, gives

$$W(z) - W(x) \le 2(L-\omega)\gamma\, e^{-(L-\omega)T(x)}|z-x|,$$

and hence the conclusion. Let us now prove (b). For any $x \in \mathcal{R}$, we have $\emptyset \neq D^+W(x)$ because, when restricted to $\mathcal{R}$, W is semiconcave together with T on $\mathcal{R}$ (see Proposition 3.6). Furthermore, $D^+W(x) \subset D((-A)^\theta)$ for any $\theta \in (0,1)$ because of Proposition 2.3. To complete the proof of (b), we observe that

$$0 \le W(x) - W(z) \le \frac{1}{\rho^2}|z-x|^2 \qquad \forall x \notin \mathcal{R},\ z \in \mathcal{R}. \tag{14}$$

This follows by Proposition 3.3(iii) and easily implies that

$$D^+W(x) = \{0\} \qquad \forall x \notin \mathcal{R}. \tag{15}$$

Next, let us prove (e). Let $x \in X \setminus B_R$ be such that $x \in \cap_{\theta\in(0,1)} D((-A)^\theta)$, and take $\gamma \in (0,1)$. Let us observe first that, owing to (15), both (i) and (ii) are verified in case $x \notin \mathcal{R}$. Now, take $x \in \mathcal{R}$. To prove (i), let $u(\cdot)$ be an optimal control strategy for x and apply the Lebourg's mean value theorem to deduce that, for any t small enough, there exists a point x_t in the segment joining $y(t) = y(t,x,u)$ to x, and an element $p_t \in D^+W(x_t)$ such that

$$W(x) - W(y(t)) = \langle p_t, x - y(t)\rangle.$$

By the dynamic programming principle and the definition of W we obtain

$$\frac{e^{kt}-1}{t}(1 - W(x)) = \left\langle p_t, \frac{x-y(t)}{t}\right\rangle .$$

Hereafter, we set $k = 2(L-\omega)$ for simplicity. By Propositions 2.4 and 3.6, there exists a sequence $\{t_n\}$ such that $t_n \to 0$ and $(-A)^{1-\gamma}p_n \to (-A)^{1-\gamma}p$ weakly, for some $p \in D^+W(x)$. In particular, $p_n \to p$ weakly. (We have written, for simplicity, p_n instead of p_{t_n}.) Reasoning as in [1, p. 943], we first get

$$\begin{aligned}\lim_{n\to\infty}\left\langle p_n, \frac{S(t)x - x}{t}\right\rangle &= -\lim_{n\to\infty}\frac{1}{t_n}\int_0^{t_n}\langle (-A)^{1-\gamma}p_n, (-A)^\gamma S(s)x\rangle\, ds \\ &= -\langle (-A)^{1-\gamma}p, (-A)^\gamma x\rangle\end{aligned}$$

and then

$$\liminf_{n\to\infty}\left\langle p_n, \frac{x - y(t_n)}{t_n}\right\rangle \le \langle (-A)^{1-\gamma}p, (-A)^\gamma x\rangle - \langle p, f(x)\rangle + r|p|.$$

This ends the proof of (i).

To prove (ii), take $p \in D^+W(x)$, $v \in B_r$ and denote by $y(\cdot)$ the trajectory of (1) associated with the constant control $u(t) = v$. We have

$$W(y(t)) - W(x) = (1 - W(x))(1 - e^{-k(T(y(t))-T(x))}) \ge (1 - W(x))(1 - e^{kt});$$

thus

$$\frac{W(y(t))-W(x)}{t} \geq (1-W(x))\frac{1-e^{kt}}{t}.$$

In order to evaluate the left-hand side of the above inequality we use (2), taking into account that W is semiconcave on $\mathcal{R}$. We have

$$\frac{W(y(t))-W(x)}{t} \leq \left\langle p, \frac{y(t)-x}{t} \right\rangle + C\frac{1}{t}|y(t)-x|^{1+\alpha} \tag{16}$$

for t sufficiently small. Reasoning as above, we get

$$\lim_{t\downarrow 0} \left\langle p, \frac{y(t)-x}{t} \right\rangle \leq -\langle (-A)^{1-\gamma}p, (-A)^{\gamma}x\rangle + \langle p, f(x)\rangle + \langle p, u\rangle.$$

Now,

$$\lim_{t\downarrow 0} \frac{1}{t}|y(t)-x|^{1+\alpha} = 0$$

since $x \in D((-A)^{\theta})$ with $\theta > 1/(1+\alpha)$. Thus, the last three inequalities imply

$$kW(x) + \langle (-A)^{1-\gamma}p, (-A)^{\gamma}x\rangle - \langle p, f(x)\rangle + \langle -p, u\rangle \leq k$$

for each $u \in B_r$, yielding the conclusion. We have thus proven that the Kružkov transformation (13) satisfies all the properties (a)–(e).

To prove uniqueness, we will use the viscosity approach and borrow an idea from [4]. Let us show that two functions W_1 and W_2 satisfying (a)–(e) must coincide. Since we can exchange the role of W_1 and W_2, it is enough to prove that $W_1 \leq W_2$. For any $0 < \varepsilon < 1$, consider the function

$$\Phi_{\varepsilon}(x,y) = W_1(x) - W_2(y) - \frac{1}{2\varepsilon}|x-y|^2 - \frac{\varepsilon}{2}(|x|^2+|y|^2) \qquad \forall x, y \in X.$$

The function Φ_{ε} is weakly upper semicontinuous and tends to $-\infty$ as $|(x,y)| \to \infty$. Therefore, it attains its maximum at some point $(x_{\varepsilon}, y_{\varepsilon})$. With no loss of generality, we can restrict the analysis to the case when $\max \Phi_{\varepsilon}$ is positive and ε is small enough, since otherwise we get the conclusion immediately. We proceed by a sequence of steps, beginning with an estimate on $|x_{\varepsilon} - y_{\varepsilon}|$.

Step 1. Let us prove that

$$\frac{1}{\varepsilon}|x_{\varepsilon}-y_{\varepsilon}|^2 \leq C\sqrt{\varepsilon}. \tag{17}$$

(Hereafter, we denote by C any positive constant independent of ε.) An easy computation, based on the inequality $2\Phi_{\varepsilon}(x_{\varepsilon}, y_{\varepsilon}) \geq \Phi_{\varepsilon}(x_{\varepsilon}, x_{\varepsilon}) + \Phi_{\varepsilon}(y_{\varepsilon}, y_{\varepsilon})$, shows that

$$\frac{1}{\varepsilon}|x_{\varepsilon}-y_{\varepsilon}|^2 \leq W_1(x_{\varepsilon}) - W_1(y_{\varepsilon}) + W_2(x_{\varepsilon}) - W_2(y_{\varepsilon}), \tag{18}$$

whence

$$\frac{1}{\varepsilon}|x_{\varepsilon}-y_{\varepsilon}|^2 \leq 2.$$

In order to prove (17), suppose $W_1(x_{\varepsilon}) - W_1(y_{\varepsilon}) \leq W_2(x_{\varepsilon}) - W_2(y_{\varepsilon})$. In case $W_2(x_{\varepsilon}) - W_2(y_{\varepsilon}) \leq W_1(x_{\varepsilon}) - W_1(y_{\varepsilon})$, we work with W_1 instead of W_2 as follows. We distinguish two cases, as follows:

Case 1: $\sqrt{2\varepsilon} \le \rho\sqrt{1 - W_2(y_\varepsilon)}$. In this case we have $|x_\varepsilon - y_\varepsilon| \le \rho\sqrt{1 - W_2(y_\varepsilon)}$, which, by (c), gives

$$W_2(x_\varepsilon) - W_2(y_\varepsilon) \le M\,|x_\varepsilon - y_\varepsilon| \le M\sqrt{2\varepsilon}.$$

Hence, by (18), we obtain

$$\frac{1}{\varepsilon}|x_\varepsilon - y_\varepsilon|^2 \le 2M\sqrt{2\varepsilon}.$$

Case 2: $\sqrt{2\varepsilon} \ge \rho\sqrt{1 - W_2(y_\varepsilon)}$. Since $W_2(x_\varepsilon) - W_2(y_\varepsilon) \le 1 - W_2(y_\varepsilon)$, we easily obtain

$$\frac{1}{\varepsilon}|x_\varepsilon - y_\varepsilon|^2 \le \frac{4\varepsilon}{\rho^2},$$

and (17) follows.

Step 2. Suppose $y_\varepsilon \in B_R$. Then, for any $x \in X$,

$$W_1(x) - W_2(x) \le \Phi_\varepsilon(x_\varepsilon, y_\varepsilon) + \varepsilon\,|x|^2 \le W_1(x_\varepsilon) + \varepsilon\,|x|^2\,.$$

By Step 1, we have that $|x_\varepsilon - y_\varepsilon| \le \rho$ for ε small, so, by (c), we get

$$W_1(x_\varepsilon) - W_1(y_\varepsilon) \le M|x_\varepsilon - y_\varepsilon| \le\ M\,\sqrt{2\varepsilon}.$$

Since $W_1(y_\varepsilon) = 0$, we finally obtain

$$W_1(x) - W_2(x) \le\ M\,\sqrt{2\varepsilon} + \varepsilon|x|^2.$$

Step 3. Suppose now that $y_\varepsilon \notin B_R$, and observe that $x_\varepsilon \notin B_R$ since $\max \Phi_\varepsilon > 0$. Define

$$\phi(x) = W_2(y_\varepsilon) + \frac{1}{2\varepsilon}|x - y_\varepsilon|^2 + \frac{\varepsilon}{2}(|x|^2 + |y_\varepsilon|^2).$$

Then $W_1 - \phi$ attains its maximum at x_ε. This implies that

$$D\phi(x_\varepsilon) \in D^+W_1(x_\varepsilon). \tag{19}$$

Analogously, for

$$\psi(y) = W_2(x_\varepsilon) - \frac{1}{2\varepsilon}|x_\varepsilon - y|^2 - \frac{\varepsilon}{2}(|x_\varepsilon|^2 + |y|^2)$$

we get

$$D\psi(y_\varepsilon) \in D^-W_2(y_\varepsilon). \tag{20}$$

Since, by (b), $D^+W_2(y_\varepsilon) \ne \emptyset$, we deduce that

$$D^+W_2(y_\varepsilon) = D^-W_2(y_\varepsilon) = D\psi(y_\varepsilon).$$

Furthermore, since $D\phi(x_\varepsilon) = \varepsilon^{-1}(x_\varepsilon - y_\varepsilon) + \varepsilon\,x_\varepsilon$ and $D\psi(y_\varepsilon) = \varepsilon^{-1}(x_\varepsilon - y_\varepsilon) - \varepsilon\,y_\varepsilon$, and since, again by (b), $D\phi(x_\varepsilon)$, $D\psi(y_\varepsilon) \subset D((-A)^\theta)$ for any $\theta \in (0,1)$, we obtain x_ε, $y_\varepsilon \in D((-A)^\theta)$ for any $\theta \in (0,1)$. Now, apply (e) with some $\gamma \in (0,1)$ to obtain

$$r\,|D\psi(y_\varepsilon)| + \langle(-A)^{1-\gamma}D\psi(y_\varepsilon), (-A)^\gamma y_\varepsilon\rangle - \langle D\psi(y_\varepsilon), f(y_\varepsilon)\rangle + kW_2(y_\varepsilon) \ge k$$

and

$$r\,|D\phi(x_\varepsilon)| + \langle (-A)^{1-\gamma} D\phi(x_\varepsilon), (-A)^{\gamma} x_\varepsilon\rangle - \langle D\phi(x_\varepsilon), f(x_\varepsilon)\rangle + kW_1(x_\varepsilon) \le k.$$

Taking the difference of the last two estimates and recalling assumption (H2), we conclude that

$$W_1(x_\varepsilon) - W_2(y_\varepsilon) \le \frac{r}{k}|D\phi(x_\varepsilon) - D\psi(y_\varepsilon)| + C\varepsilon(|x_\varepsilon|^2 + |y_\varepsilon|^2) + \frac{L}{k\varepsilon}|x_\varepsilon - y_\varepsilon|^2$$

$$\le \varepsilon C(|x_\varepsilon| + |y_\varepsilon| + |x_\varepsilon|^2 + |y_\varepsilon|^2) + C\sqrt{\varepsilon}.$$

Step 4. We make estimates on $|x_\varepsilon|, |y_\varepsilon|$. Given $\delta > 0$, let $x_\delta \in X$ be such that

$$W_1(x_\delta) - W_2(x_\delta) > \sup_{x\in X}(W_1(x) - W_2(x)) - \delta.$$

Then

$$W_1(x_\varepsilon) - W_2(y_\varepsilon) - \frac{1}{2\varepsilon}|x_\varepsilon - y_\varepsilon|^2 \le W_1(x_\varepsilon) - W_2(x_\varepsilon) + W_2(x_\varepsilon) - W_2(y_\varepsilon)$$

$$\le W_1(x_\delta) - W_2(x_\delta) + \delta + W_2(x_\varepsilon) - W_2(y_\varepsilon).$$

Therefore,

$$\begin{aligned}\frac{\varepsilon}{2}(|x_\varepsilon|^2 + |y_\varepsilon|^2) &\le -\Phi_\varepsilon(x_\varepsilon, y_\varepsilon) + W_1(x_\delta) - W_2(x_\delta) + \delta + W_2(x_\varepsilon) - W_2(y_\varepsilon)\\ &\le -\Phi_\varepsilon(x_\delta, x_\delta) + W_1(x_\delta) - W_2(x_\delta) + \delta + W_2(x_\varepsilon) - W_2(y_\varepsilon)\\ &= \varepsilon|x_\delta|^2 + \delta + W_2(x_\varepsilon) - W_2(y_\varepsilon).\end{aligned}$$

If $W_2(y_\varepsilon) = 1$, then $W_2(x_\varepsilon) - W_2(y_\varepsilon) \le 0$, so that

$$\frac{\varepsilon}{2}(|x_\varepsilon|^2 + |y_\varepsilon|^2) \le \varepsilon|x_\delta|^2 + \delta.$$

If, on the contrary, $W_2(y_\varepsilon) < 1$, then we proceed as in Step 1 by considering two cases. In case $\sqrt{2\varepsilon} \le \rho\sqrt{1 - W_2(y_\varepsilon)}$, we get

$$\frac{\varepsilon}{2}(|x_\varepsilon|^2 + |y_\varepsilon|^2) \le \varepsilon|x_\delta|^2 + \delta + M\sqrt{2\varepsilon},$$

whereas, in case $\sqrt{2\varepsilon} \ge \rho\sqrt{1 - W_2(y_\varepsilon)}$, we obtain

$$\frac{\varepsilon}{2}(|x_\varepsilon|^2 + |y_\varepsilon|^2) \le \varepsilon|x_\delta|^2 + C\varepsilon.$$

Since $\delta > 0$ is arbitrary, in both cases we have

$$\lim_{\varepsilon\to 0} \varepsilon(|x_\varepsilon|^2 + |y_\varepsilon|^2) = 0.$$

Step 5. Conclusion: for any $x \in X$ we have

$$W_1(x) - W_2(x) \le \Phi_\varepsilon(x_\varepsilon, y_\varepsilon) + \varepsilon\,|x|^2 \le W_1(x_\varepsilon) - W_2(y_\varepsilon) + \varepsilon|x|^2$$

$$\le C\varepsilon(|x_\varepsilon| + |y_\varepsilon| + |x_\varepsilon|^2 + |y_\varepsilon|^2) + C\sqrt{\varepsilon} + \varepsilon|x|^2.$$

Letting $\varepsilon \to 0$, we obtain $W_1(x) - W_2(x) \le 0$ for any $x \in X$, which proves the theorem. □

Remark 4.1. Theorem 4.1 remains true if (e) is weakened requiring that (i) and (ii) hold for $\gamma \in (1/(1+\alpha), 1)$, and also if (i) is replaced by

(i′) for any $p \in D^- W(x)$ we have

$$r\,|p| + \langle (-A)^{1-\gamma} p, (-A)^{\gamma} x\rangle - \langle p, f(x)\rangle + 2(L-\omega)W(x) \geq 2(L-\omega).$$

This remark prepares our second result on the Hamilton–Jacobi–Bellman equation, which can be applied even when the target is the origin of X.

THEOREM 4.2. *Assume* (H1), (H2), (H3), *and* (H5). *Suppose that the target is* B_R *with* $R \geq 0$. *Then* W *defined by* (13) *is the unique function from* X *to* $\mathbb{R}$ *which satisfies the following properties:*

(a) W *is sequentially weakly continuous.*

(b) $\partial_P W(x), \partial^P W(x) \subset D((-A)^{\theta}))$ *for any* $x \in X \setminus B_R$ *and for any* $\theta \in [0,1)$.

(c) *There exist* $\rho > 0$ *and* $M > 0$ *such that if* $|z-x| \leq \rho\sqrt{1-W(x)}$, *then*

$$W(z) - W(x) \leq M\sqrt{1-W(x)}|z-x|.$$

(d) $W(x) = 0$ *for any* $x \in B_R$, *and* $W(x) \in [0,1]$ *for any* $x \in X$.

(e) W *satisfies the Hamilton–Jacobi–Bellman equation in the following sense: for any* $x \in X \setminus B_R$ *with* $x \in \cap_{\theta\in(0,1)} D((-A)^{\theta})$ *and for any* $\gamma \in (0,1)$,

(i) *for any* $p \in \partial_P W(x)$ *we have*

$$r\,|p| + \langle (-A)^{1-\gamma} p, (-A)^{\gamma} x\rangle - \langle p, f(x)\rangle + 2(L-\omega)W(x) \geq 2(L-\omega);$$

(ii) *for any* $p \in \partial^P W(x)$ *we have*

$$r\,|p| + \langle (-A)^{1-\gamma} p, (-A)^{\gamma} x\rangle - \langle p, f(x)\rangle + 2(L-\omega)W(x) \leq 2(L-\omega).$$

Proof. To prove that W satisfies properties (a), (c), and (d), we argue as in Theorem 4.1. For $x \in \mathcal{R}$, (b) is satisfied because of Proposition 2.3, since $\partial_P g(x) \subseteq D^- g(x)$ and $\partial^P g(x) \subseteq D^+ g(x)$. In case $x \notin \mathcal{R}$, it follows by (14) that

$$\partial_P W(x) = \partial^P W(x) = \{0\}, \tag{21}$$

and hence (b) is satisfied. Let us prove (e). In virtue of (21), W satisfies both (i) and (ii) in case $x \notin \mathcal{R}$. To prove (ii) in case $x \in \mathcal{R}$, we argue as in Theorem 4.1. The only difference is in the use of inequality (16): in Theorem 4.1 it is a consequence of semiconcavity, while here we have the inequality (16) with $\alpha = 1$ as a consequence of the definition of $\partial^P W(x)$. A similar argument goes for the proof of (i). For the uniqueness part, the only modification in the proof of Theorem 4.1 is to set

$$D\phi(x_\varepsilon) \in \partial^P W_1(x_\varepsilon)$$

instead of (19), and

$$D\psi(y_\varepsilon) \in \partial_P W_2(y_\varepsilon)$$

instead of (20). This is possible because of Proposition 2.5. □

Remark 4.2. Theorem 4.2 holds true if in (e) we set that (i) and (ii) hold for any $\gamma \in (1/2, 1)$ and for any $x \in D((-A)^{\gamma})$.

GLOBAL STEADY-STATE CONTROLLABILITY OF ONE-DIMENSIONAL SEMILINEAR HEAT EQUATIONS*

JEAN-MICHEL CORON† AND EMMANUEL TRÉLAT†

Abstract. We investigate the problem of exact boundary controllability of semilinear one-dimensional heat equations. We prove that it is possible to move from any steady-state to any other by means of a boundary control, provided that both are in the same connected component of the set of steady-states. The proof is based on an effective feedback stabilization procedure, which is implemented.

Key words. heat equation, controllability, pole shifting, Lyapunov functional

1. Introduction.

1.1. Statement of the main result. Let $L > 0$ be fixed and $f : \mathbb{R} \to \mathbb{R}$ be a function of class C^2. Let us consider the boundary control system

$$\begin{cases} \dfrac{\partial y}{\partial t} = \dfrac{\partial^2 y}{\partial x^2} + f(y), \\ y(t,0) = 0,\ y(t,L) = u(t), \end{cases} \tag{1.1}$$

where the state is $y(t,.) : [0,L] \to \mathbb{R}$ and the control is $u(t) \in \mathbb{R}$.

Concerning the global controllability problem, one of the main results [5] asserts that if f is globally Lipschitzian, then this control system is approximately globally controllable (see also [11] for exact controllability). When f is superlinear, the situation is still widely open, in particular because of possible blowing up. Indeed, it is well known that if $yf(y) > 0$ as $y \neq 0$, then blow-up phenomena may occur for the Cauchy problem

$$\begin{cases} \dfrac{\partial y}{\partial t} = \dfrac{\partial^2 y}{\partial x^2} + f(y), \\ y(t,0) = 0,\ y(t,L) = 0, \\ y(0,x) = y_0(x). \end{cases} \tag{1.2}$$

For example, if $f(y) = y^3$, then for numerous initial data there exists $T > 0$ such that the unique solution to the previous Cauchy problem is well defined on $[0,T) \times [0,L]$ and satisfies

$$\lim_{t \to T} \|y(t,.)\|_{L^\infty(0,L)} = +\infty$$

(see, for instance, [1, 8, 2, 12, 14, 15, 18] and references therein).

One may ask if, acting on the boundary of $[0, L]$, one could avoid the blow-up phenomenon. Actually the answer to this question is negative in general (see [7]; see also [6] for a weaker nonlinearity): for some nonlinear functions f satisfying

$$|f(y)| \sim |y| \log^p(1 + |y|) \quad \text{as } |y| \to +\infty,$$

with $p > 2$, and for any time $T > 0$, there exist initial data which lead to blow-up before time T, whatever the control function u is. Notice, however, that if

$$|f(y)| = \mathrm{o}\left(|y| \log^{3/2}(1 + |y|)\right) \quad \text{as } |y| \to +\infty,$$

then the blow-up (which could occur in the absence of control) can be avoided by means of boundary control (see [7]).

Nevertheless, in the first case where the blow-up phenomenon cannot be compensated by means of boundary control, the situation is not completely desperate. In fact, as we shall see in this paper, we can move from any given steady-state to any other belonging to the same connected component of the set of steady-states. More precisely, let us define the notion of steady-state.

DEFINITION 1.1. *A function $y \in C^2([0, L])$ is a steady-state of the control system* (1.1) *if*

$$\frac{d^2y}{dx^2} + f(y) = 0, \ y(0) = 0.$$

We denote by $\mathcal{S}$ the set of steady-states endowed with the C^2 topology.

Let us also introduce the Banach space

$$Y_T = \left\{ y(t,x), (t,x) \in (0,T) \times (0,L) \ / \ y \in L^2(0,T, W^{2,2}(0,L)) \right. \\ \left. \text{and } \frac{\partial y}{\partial t} \in L^2((0,T) \times (0,L)) \right\} \tag{1.3}$$

endowed with the norm

$$\|y\|_{Y_T} = \|y\|_{L^2(0,T,W^{2,2}(0,L))} + \left\| \frac{\partial y}{\partial t} \right\|_{L^2((0,T)\times(0,L))}.$$

Notice that Y_T is continuously imbedded in $L^\infty((0,T) \times (0,L))$.

The main result of the paper is the following.

THEOREM 1.2. *Let y_0 and y_1 be two steady-states belonging to a same connected component of $\mathcal{S}$. There exist a time $T > 0$ and a control function $u \in L^2(0,T)$ such that the solution $y(t,x)$ in Y_T of*

$$\begin{cases} \dfrac{\partial y}{\partial t} = \dfrac{\partial^2 y}{\partial x^2} + f(y), \\ y(t,0) = 0, \ y(t,L) = u(t), \\ y(0,x) = y_0(x) \end{cases} \tag{1.4}$$

satisfies $y(T,.) = y_1(.)$.

Remark 1.3. In fact, we prove the following result: for all neighborhood V of y_1 in H^1-topology, there exists a positive real number ε_0 such that for all $\varepsilon \in (0, \varepsilon_0)$

there exists a control function $u \in H^1(0, 1/\varepsilon)$ such that the solution $y(t, x)$ in Y_T of the Cauchy–Dirichlet problem (1.4) satisfies $y(1/\varepsilon, .) \in V$.

In the proof of this result, which represents the main part of the paper, we give an explicit construction of the control u in a *feedback-type form* and also of a *Lyapunov functional*. We stress that the procedure is effective and consists actually of solving a stabilization problem in finite dimension. Indeed, in order to construct u we need to compute only a finite number of quantities related to a Hilbertian expansion of the solution. The procedure has been implemented numerically, and simulations are presented in the last section of the paper.

Remark 1.4. For any $T > 0$ and $u \in L^2(0, T)$, there is at most one solution of (1.4) in the Banach space Y_T.

Remark 1.5. This is a (partial) global exact controllability result. The time needed in our proof is large, but on the other hand there are indeed cases where the time T of controllability cannot be taken arbitrarily small. For instance, in the case where $f(y) = -y^3$, any solution of (1.4) starting from 0 satisfies the inequality

$$\int_0^L (L - x)^4 y(T, x)^2 dx \leq 8LT,$$

and hence, if $y_0 = 0$, a minimal time is needed to reach a given $y_1 \neq 0$. This result is due to Bamberger [10] (see also [9, Lemma 2.1]).

Remark 1.6. In section 3 we prove that if y_0 and y_1 belong to distinct connected components of $\mathcal{S}$, then it is actually impossible to move either from y_0 to y_1 or from y_1 to y_0, whatever the time and the control are. In the same section we also investigate the connectedness of the set $\mathcal{S}$ of steady-states.

Remark 1.7. The result of Theorem 1.2 may be achieved directly by using repeatedly a local exact controllability theorem (see [9, Theorem 4.4] or [11, Theorem 3.3]). Here we present a new controllability strategy based on a feedback stabilization procedure, which is more effective. It is clear also that this approach may be applied to other problems without requiring controllability of the linearized system around an equilibrium (see [3]).

1.2. The idea of the proof. The method we shall use to prove Theorem 1.2 stems from classical Lyapunov stability theory together with quasi-static deformation theory. For the sake of simplicity we explain it in finite dimension. Let us consider in $\mathbb{R}^n$ a general control system of the form

$$\dot{y}(t) = g(y(t), u(t)), \tag{1.5}$$

where $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ is of class C^1, $u(t) \in \mathcal{U}$, and $\mathcal{U}$ denotes the set of measurable essentially bounded admissible controls. Let $y_0, y_1 \in \mathbb{R}^n$ be two equilibrium points of system (1.5); that is,

$$g(y_i, u_i) = 0, \ i = 0, 1,$$

for some $u_0, u_1 \in \mathbb{R}^m$. We assume that (y_0, u_0) and (y_1, u_1) belong to the same connected component of the zero set of g in $\mathbb{R}^n \times \mathbb{R}^m$. Our aim is to steer the system from y_0 to y_1 in some (large) time $T > 0$. The method splits into four steps.

First step. Construct a C^1-path $(\bar{y}(\tau), \bar{u}(\tau))$, with $\tau \in [0, 1]$, connecting (y_0, u_0) to (y_1, u_1) and such that

$$\forall \tau \in [0, 1], \quad g(\bar{y}(\tau), \bar{u}(\tau)) = 0.$$

Of course, this path is not in general a solution of system (1.5), but if $\varepsilon > 0$ is small enough, then the C^1-path $(y^\varepsilon, u^\varepsilon)$

$$\begin{array}{rcl} [0, 1/\varepsilon] & \to & \mathbb{R}^n \times \mathbb{R}^m, \\ t & \mapsto & (y^\varepsilon(t), u^\varepsilon(t)) = (\bar{y}(\varepsilon t), \bar{u}(\varepsilon t)) \end{array}$$

is "almost" a solution of system (1.5). Indeed,

$$\|\dot{y}^\varepsilon - g(y^\varepsilon, u^\varepsilon)\| = \mathrm{O}(\varepsilon).$$

Second step. This quasi-static trajectory is not in general stable, and thus has to be stabilized. To this aim, introduce the following change of variable:

$$\begin{aligned} z(t) &= y(t) - y^\varepsilon(t), \\ v(t) &= u(t) - u^\varepsilon(t), \end{aligned}$$

where $t \in [0, 1/\varepsilon]$. In the new variables z, v, the control system writes, at least if $\|z(t)\| + \|v(t)\|$ is small enough,

$$\dot{z}(t) = A(\varepsilon t)z(t) + B(\varepsilon t)v(t) + \mathrm{O}(\|z(t)\|^2 + \|v(t)\|^2 + \varepsilon),$$

where $t \in [0, 1/\varepsilon]$, and where

$$A(\tau) = \frac{\partial g}{\partial y}(\bar{y}(\tau), \bar{u}(\tau)) \quad \text{and} \quad B(\tau) = \frac{\partial g}{\partial u}(\bar{y}(\tau), \bar{u}(\tau)),$$

with $\tau = \varepsilon t \in [0, 1]$. Therefore we have to stabilize near the origin a *slowly-varying in time* linear control system; we refer to [13] for this classical theory.

Third step. Under mild controllability assumptions, namely,

$$\forall \tau \in [0, 1], \quad \operatorname{rank}\big(B(\tau), A(\tau)B(\tau), \dots, A(\tau)^{n-1}B(\tau)\big) = n$$

(Kalman condition), it is actually possible to stabilize the system by *pole shifting* and to construct a quadratic Lyapunov function. Notice that this does not work in general if the system is not slowly-varying. So if ε is small enough, then using this Lyapunov function we infer that $y(1/\varepsilon)$ belongs to some prescribed neighborhood of the target y_1. At this stage, a stabilization result is achieved.

Fourth step. If the system (1.5) is *locally controllable* near the point y_1, we conclude that it is possible to steer the system in finite time from the point $y(1/\varepsilon)$ to the desired target y_1. Usually such a local controllability result is achieved by using an implicit function argument, after proving that the linearized system is controllable.

Remark 1.8. The use of quasi-static deformation for the controllability of a nonlinear partial differential control system has already been used in [3]. But note that in [3] the quasi-static trajectory $(y^\varepsilon, u^\varepsilon)$ was stable, so it was not necessary to perform steps 2 and 3.

2. Proof of the main results. In order to prove Theorem 1.2 we shall follow exactly the steps described previously.

2.1. Construction of a path of steady-states. The following lemma is obvious.

LEMMA 2.1. *Let $\phi_0, \phi_1 \in \mathcal{S}$. Then ϕ_0 and ϕ_1 belong to the same connected component of $\mathcal{S}$ if and only if, for any real number α between $\phi_0'(0)$ and $\phi_1'(0)$, the maximal solution of*

$$\frac{d^2y}{dx^2} + f(y) = 0, \ y(0) = 0, y'(0) = \alpha,$$

denoted by $y^\alpha(.)$, is defined on $[0, L]$.

Now let y_0 and y_1 be in the same connected component of $\mathcal{S}$. Let us construct in $\mathcal{S}$ a C^1-path $(\bar{y}(\tau, .), \bar{u}(\tau))$, $0 \le \tau \le 1$, joining y_0 to y_1. For each $i = 0, 1$, set

$$\alpha_i = y_i'(0).$$

Then with our previous notation, $y_i(.) = y^{\alpha_i}(.), i = 0, 1$. Now set

$$\bar{y}(\tau, x) = y^{(1-\tau)\alpha_0 + \tau\alpha_1}(x) \text{ and } \bar{u}(\tau) = \bar{y}(\tau, L),$$

where $\tau \in [0, 1]$ and $x \in [0, L]$. By construction we have

$$\bar{y}(0, .) = y_0(.),\ \bar{y}(1, .) = y_1(.) \text{ and } \bar{u}(0) = \bar{u}(1) = 0,$$

and thus $(\bar{y}(\tau, .), \bar{u}(\tau))$ is a C^1-path in $\mathcal{S}$ connecting y_0 to y_1.

2.2. Reduction of the problem. Let $\varepsilon > 0$. We set, for any $t \in [0, 1/\varepsilon]$ and any $x \in [0, L]$,

$$\begin{aligned} z(t, x) &= y(t, x) - \bar{y}(\varepsilon t, x), \\ v(t) &= u(t) - \bar{u}(\varepsilon t). \end{aligned} \tag{2.1}$$

Then from the definition of $(\bar{y}, \bar{u})$ we infer that z satisfies the initial boundary problem

$$\begin{cases} z_t = z_{xx} + f'(\bar{y})z + z^2 \displaystyle\int_0^1 (1-s) f''(\bar{y} + sz) ds - \varepsilon \bar{y}_\tau, \\ z(t, 0) = 0,\ z(t, L) = v(t), \\ z(0, x) = 0. \end{cases} \tag{2.2}$$

Now, in order to deal with a Dirichlet-type problem instead, we set

$$w(t, x) = z(t, x) - \frac{x}{L} v(t), \tag{2.3}$$

and we suppose that the control v is derivable. This leads to the equation

$$\begin{cases} w_t = w_{xx} + f'(\bar{y})w + \dfrac{x}{L} f'(\bar{y})v - \dfrac{x}{L} v' + r(\varepsilon, t, x), \\ w(t, 0) = w(t, L) = 0, \\ w(0, x) = -\dfrac{x}{L} v(0), \end{cases} \tag{2.4}$$

where

$$r(\varepsilon, t, x) = -\varepsilon \bar{y}_\tau + \left(w + \frac{x}{L} v\right)^2 \int_0^1 (1-s) f'' \left(\bar{y} + s\left(w + \frac{x}{L} v\right)\right) ds, \tag{2.5}$$

and the next step is to prove that there exist ε small enough and a pair (v, w) solution of (2.4) such that $w(1/\varepsilon, .)$ belongs to some arbitrary neighborhood of 0 in H_0^1-topology. To achieve this we shall construct an appropriate control function and a Lyapunov functional which stabilizes system (2.4) to 0.

In fact, as we shall see, the control will be chosen in $H^1(0, 1/\varepsilon)$ and such that $v(0) = 0$.

2.3. Construction of a Lyapunov functional. This is the most technical part of the work. In order to motivate what follows, let us first notice that if the residual term r and the control v were equal to zero, then (2.4) would reduce to

$$w_t = w_{xx} + f'(\bar{y})w,$$
$$w(t,0) = w(t,L) = 0.$$

This suggests that we introduce the *one-parameter family of linear operators*

$$A(\tau) = \Delta + f'(\bar{y}(\tau,.))Id,\ \tau \in [0,1], \tag{2.6}$$

defined on $H^2(0,L) \cap H_0^1(0,L)$. Let $(e_j(\tau,.))_{j\geq 1}$ be a Hilbertian basis of $L^2(0,L)$ of eigenfunctions of $A(\tau)$, such that for each $j \geq 1$ and each $\tau \in [0,1]$,

$$e_j(\tau,.) \in H_0^1(0,L) \cap C^2([0,L]),$$

and let $(\lambda_j(\tau))_{j\geq 1}$ denote the corresponding eigenvalues. A standard application of the minimax principle (see, for instance, [16]) shows that these eigenfunctions and eigenvalues are C^1 functions of τ. Moreover, for each $\tau \in [0,1]$,

$$-\infty < \cdots < \lambda_n(\tau) < \cdots < \lambda_1(\tau) \quad \text{and} \quad \lambda_n(\tau) \underset{n\to+\infty}{\longrightarrow} -\infty.$$

From the continuity of the eigenvalues on $[0,1]$, we can define n as the maximal number of eigenvalues taking at least a nonnegative value as $\tau \in [0,1]$; i.e., there exists $\eta > 0$ such that

$$\forall t \in [0,1/\varepsilon], \quad \forall k > n, \quad \lambda_k(\varepsilon t) < -\eta < 0. \tag{2.7}$$

Remark 2.2. Note that the integer n can be arbitrarily large. For example, if $f(y) = y^3$ and if $y_1'(0) \to +\infty$, then $n \to +\infty$.

We also set, for any $\tau \in [0,1]$ and $x \in [0,L]$,

$$a(\tau,x) = \frac{x}{L} f'(\bar{y}(\tau,x)) \ \text{ and } \ b(x) = -\frac{x}{L}.$$

In this notation, system (2.4) leads to

$$w_t(t,.) = A(\varepsilon t)w(t,.) + a(\varepsilon t,.)v(t) + b(.)v'(t) + r(\varepsilon,t,.). \tag{2.8}$$

Any solution $w(t,.) \in H^2(0,L) \cap H_0^1(0,L)$ of (2.8) can be expanded as a series in the eigenfunctions $e_j(\varepsilon t,.)$, convergent in $H_0^1(0,L)$:

$$w(t,.) = \sum_{j=1}^{\infty} w_j(t) e_j(\varepsilon t,.).$$

In fact, the w_j's depend on ε and should be called, for example, w_j^ε. For simplicity we omit the index ε, and we shall also omit the index ε for other functions.

In what follows we are going to move, by means of an appropriate *feedback control*, the n first eigenvalues of the operator A, without moving the others, in order to make all eigenvalues negative. This pole shifting process is the first part of the stabilization procedure (see [17, p. 711]).

For any $\tau \in [0,1]$, let $\pi_1(\tau)$ denote the orthogonal projection onto the subspace of $L^2(0,L)$ spanned by $e_1(\tau,.),\dots,e_n(\tau,.)$, and let

$$w^1(t) = \pi_1(\varepsilon t)w(t,.) = \sum_{j=1}^{n} w_j(t)e_j(\varepsilon t,.). \tag{2.9}$$

It is clear that for any τ, the operators $\pi_1(\tau)$ and $A(\tau)$ commute, and moreover, for any $y \in L^2(0,L)$, we have

$$\pi_1'(\tau)y = \sum_{j=1}^{n} \langle y, e_j(\tau,.)\rangle_{L^2(0,L)} \frac{\partial e_j}{\partial \tau}(\tau,.) + \sum_{j=1}^{n} \left\langle y, \frac{\partial e_j}{\partial \tau}(\tau,.)\right\rangle_{L^2(0,L)} e_j(\tau,.).$$

Hence, derivating (2.9) with respect to t, we get

$$\sum_{j=1}^{n} w_j'(t)e_j(\varepsilon t,.) = \pi_1(\varepsilon t)w_t(t,.) + \varepsilon \sum_{j=1}^{n} \left\langle w(t,.), \frac{\partial e_j}{\partial \tau}(\varepsilon t,.)\right\rangle_{L^2(0,L)} e_j(\varepsilon t,.).$$

On the other hand

$$A(\varepsilon t)w^1(t) = \sum_{j=1}^{n} \lambda_j(\varepsilon t)w_j(t)e_j(\varepsilon t,.),$$

and thus (2.8) yields

$$\begin{aligned}\sum_{j=1}^{n} w_j'(t)e_j(\varepsilon t,.) = &\sum_{j=1}^{n} \lambda_j(\varepsilon t)w_j(t)e_j(\varepsilon t,.) + \pi_1(\varepsilon t)a(\varepsilon t,.)v(t)\\ &+ \pi_1(\varepsilon t)b(.)v'(t) + r^1(\varepsilon,t,.),\end{aligned} \tag{2.10}$$

where

$$r^1(\varepsilon,t,.) = \pi_1(\varepsilon t)r(\varepsilon,t,.) + \varepsilon \sum_{j=1}^{n} \left\langle w, \frac{\partial e_j}{\partial \tau}(\varepsilon t,.)\right\rangle_{L^2(0,L)} e_j(\varepsilon t,.). \tag{2.11}$$

Let us set an upper bound to the residual term r^1. First, it is not difficult to check that there exists a constant C such that, if $|v(t)|$ and $\|w(t,.)\|_{L^\infty(0,L)}$ are less than 1, then the inequality

$$\|r(\varepsilon,t,.)\|_{L^\infty(0,L)} \le C(\varepsilon + v(t)^2 + \|w(t,.)\|^2_{L^\infty(0,L)})$$

holds, where r is defined by (2.5). Therefore we get easily

$$\|r^1(\varepsilon,t,.)\|_{L^\infty(0,L)} \le C_1(\varepsilon + v(t)^2 + \|w(t,.)\|^2_{L^\infty(0,L)}).$$

Moreover, since $H^1(0,L)$ is continuously imbedded in $C^0([0,L])$, we can assert that there exists a constant C_2 such that, if $|v(t)|$ and $\|w(t,.)\|_{L^\infty(0,L)}$ are less than 1, then

$$\|r^1(\varepsilon,t,.)\|_{L^\infty(0,L)} \le C_2(\varepsilon + v(t)^2 + \|w(t,.)\|^2_{H_0^1(0,L)}). \tag{2.12}$$

Now projecting (2.10) on each $e_i, i = 1,\dots,n$, one comes to

$$w_i'(t) = \lambda_i(\varepsilon t)w_i(t) + a_i(\varepsilon t)v(t) + b_i(\varepsilon t)v'(t) + r_i^1(\varepsilon,t), \quad i = 1,\dots,n, \tag{2.13}$$

where

$$
\begin{aligned}
r_i^1(\varepsilon,t) &= \langle r^1(\varepsilon,t,.), e_i(\varepsilon t,.)\rangle_{L^2(0,L)},\\
a_i(\varepsilon t) &= \langle a(\varepsilon t,.), e_i(\varepsilon t,.)\rangle_{L^2(0,L)} = \frac{1}{L}\int_0^L x f'(\bar y(\varepsilon t,x)) e_i(\varepsilon t,x)dx,\\
b_i(\varepsilon t) &= \langle b(.), e_i(\varepsilon t,.)\rangle_{L^2(0,L)} = -\frac{1}{L}\int_0^L x e_i(\varepsilon t,x)dx.
\end{aligned}
\tag{2.14}
$$

The n equations (2.13) form a differential system controlled by v, v'. Set

$$
\alpha(t) = v'(t), \tag{2.15}
$$

and consider now $v(t)$ as a state and $\alpha(t)$ as a control. Then the former finite dimensional system may be rewritten as

$$
\begin{cases}
v' = \alpha,\\
w_1' = \lambda_1 w_1 + a_1 v + b_1\alpha + r_1^1,\\
\quad\vdots\\
w_n' = \lambda_n w_n + a_n v + b_n\alpha + r_n^1.
\end{cases}
\tag{2.16}
$$

If we introduce the matrix notation

$$
X_1(t) = \begin{pmatrix} v(t)\\ w_1(t)\\ \vdots\\ w_n(t)\end{pmatrix},\ R_1(\varepsilon,t) = \begin{pmatrix} 0\\ r_1^1(\varepsilon,t)\\ \vdots\\ r_n^1(\varepsilon,t)\end{pmatrix},
$$

$$
A_1(\tau) = \begin{pmatrix} 0 & 0 & \cdots & 0\\ a_1(\tau) & \lambda_1(\tau) & \cdots & 0\\ \vdots & \vdots & \ddots & \vdots\\ a_n(\tau) & 0 & \cdots & \lambda_n(\tau)\end{pmatrix},\ B_1(\tau) = \begin{pmatrix} 1\\ b_1(\tau)\\ \vdots\\ b_n(\tau)\end{pmatrix},
$$

then equations (2.16) yield the *finite dimensional linear control system*

$$
X_1'(t) = A_1(\varepsilon t)X_1(t) + B_1(\varepsilon t)\alpha(t) + R_1(\varepsilon,t). \tag{2.17}
$$

Let us now prove the following lemma.

LEMMA 2.3. *For each $\tau \in [0,1]$, the pair $(A_1(\tau), B_1(\tau))$ satisfies the Kalman condition, i.e.,*

$$
\operatorname{rank}\big(B_1(\tau), A_1(\tau)B_1(\tau), \dots, A_1(\tau)^{n-1}B_1(\tau)\big) = n. \tag{2.18}
$$

Proof. Let $\tau \in [0,1]$ be fixed. We compute directly

$$
\det\big(B_1, A_1B_1, \dots, A_1^{n-1}B_1\big) = \prod_{j=1}^n (a_j + \lambda_j b_j)\ \mathrm{VdM}(\lambda_1,\dots,\lambda_n), \tag{2.19}
$$

where $\mathrm{VdM}(\lambda_1, \ldots, \lambda_n)$ is a Van der Monde determinant and thus is never equal to zero, since the $\lambda_i(\tau), i = 1, \ldots, n$, are distinct for any $\tau \in [0,1]$. On the other hand, using the fact that each $e_j(\tau, .)$ is an eigenfunction of $A(\tau)$ and belongs to $H_0^1(0,L)$, we compute

$$\begin{aligned} a_j(\tau) + \lambda_j(\tau) b_j(\tau) &= \frac{1}{L} \int_0^L x \left(f'(\bar{y}(\tau,x)) e_j(\tau,x) - \lambda_j(\tau) e_j(\tau,x) \right) dx \\ &= -\frac{1}{L} \int_0^L x \frac{\partial^2 e_j}{\partial x^2}(\tau,x) dx \\ &= -\frac{\partial e_j}{\partial x}(\tau, L). \end{aligned}$$

But this quantity is never equal to zero since $e_j(\tau, L) = 0$ and $e_j(\tau, .)$ is a nontrivial solution of a linear second-order scalar differential equation. Therefore the determinant (2.19) is never equal to zero and we are done. □

It is a standard fact that the Kalman condition (2.18) implies a *pole shifting* result, and we get the following corollary (see [13]).

COROLLARY 2.4. *For each $\tau \in [0,1]$, there exist scalars $k_0(\tau), \ldots, k_n(\tau)$ such that, if we denote*

$$K_1(\tau) = (k_0(\tau), \ldots, k_n(\tau)),$$

then the matrix $A_1(\tau) + B_1(\tau) K_1(\tau)$ admits -1 as an eigenvalue with order $n+1$.

Moreover, there exists a C^1 application $\tau \mapsto P(\tau)$ on $[0,1]$, where $P(\tau)$ is an $(n+1) \times (n+1)$ symmetric positive definite matrix, such that the identity

$$P(\tau) \left(A_1(\tau) + B_1(\tau) K_1(\tau) \right) + {}^t\left(A_1(\tau) + B_1(\tau) K_1(\tau) \right) P(\tau) = -I \tag{2.20}$$

holds for any $\tau \in [0,1]$.

We are now able to construct a control Lyapunov functional in order to stabilize system (2.8). Leave $c > 0$ to be chosen later. For any $t \in [0, 1/\varepsilon]$, $v \in \mathbb{R}$, and $w \in H^2(0,L) \cap H_0^1(0,L)$, we set

$$V(t,v,w) = c\, {}^t X_1(t) P(\varepsilon t) X_1(t) - \frac{1}{2} \langle w, A(\varepsilon t) w \rangle_{L^2(0,L)}, \tag{2.21}$$

where $X_1(t)$ denotes the matrix vector in $\mathbb{R}^{n+1}$,

$$X_1(t) = \begin{pmatrix} v \\ w_1(t) \\ \vdots \\ w_n(t) \end{pmatrix},$$

and

$$w_i(t) = \langle w, e_i(\varepsilon t, .) \rangle_{L^2(0,L)}.$$

In particular, we have

$$V(t,v,w) = c\, {}^t X_1(t) P(\varepsilon t) X_1(t) - \frac{1}{2} \sum_{j=1}^{\infty} \lambda_j(\varepsilon t) w_j(t)^2. \tag{2.22}$$

In what follows we will repeatedly use the equivalence of norms in finite dimension. The following notation will thus be useful.

NOTATION. *Let Λ be a set and let $\Delta = \{(\varepsilon, t) \ / \ 0 < \varepsilon \leq 1,\ 0 \leq t \leq 1/\varepsilon\}$. Let F_1, F_2 be two real functions defined on $\Delta \times \Lambda$. The notation $F_1 \lesssim F_2$ means that $F_2 \geq 0$ and that there exists a positive constant C such that*

$$F_1(\varepsilon, t, \lambda) \leq C F_2(\varepsilon, t, \lambda) \quad \forall (\varepsilon, t) \in \Delta, \quad \forall \lambda \in \Lambda.$$

We say that $F_1 \sim F_2$ if both $F_1 \lesssim F_2$ and $F_2 \lesssim F_1$. Moreover, if F_3 is a real function defined on $\Delta \times \Lambda$ and if $\theta \in [0, +\infty)$, the notation $F_1 \lesssim F_2$ for $F_3 \leq \theta$ means that $F_2 \geq 0$ and that there exists a positive constant C such that

$$\forall (\varepsilon, t) \in \Delta, \quad \forall \lambda \in \Lambda, \quad (F_3(\varepsilon, t, \lambda) \leq \theta) \Rightarrow (F_1(\varepsilon, t, \lambda) \leq C F_2(\varepsilon, t, \lambda)) \,.$$

For simplicity, when the set Λ is clear from the context it will not be given explicitly.

Let $\| \ \|_2$ denote the euclidean norm in $\mathbb{R}^{n+1}$. Since $P(\tau)$ is symmetric positive definite, we can write (with $\Lambda = \mathbb{R} \times (H^2(0, L) \cap H_0^1(0, L))$)

$$^t X_1(t) P(\varepsilon t) X_1(t) \sim \|X_1(t)\|_2^2 = v^2 + \sum_{j=1}^{n} w_j(t)^2.$$

From (2.7) we know that, except the n first ones, the eigenvalues of A are all negative, less than $-\eta < 0$. By continuity the n first eigenvalues are bounded as $\tau \in [0, 1]$ and thus we can assert that, if c is large enough in the definition of V, then

$$V(t, v, w) \sim \|X_1(t)\|_2^2 - \sum_{j=n+1}^{\infty} \lambda_j(\varepsilon t) w_j(t)^2, \tag{2.23}$$

where $t \in [0, 1/\varepsilon]$. In particular, $V(t, ., .)$ is positive definite. Let us further prove the following lemma.

LEMMA 2.5. *The equivalence*

$$V(t, v, w) \sim v^2 + \|w\|_{H_0^1(0,L)}^2 \tag{2.24}$$

holds with $\Lambda = \{(v, w) \ / \ v \in \mathbb{R}, w \in H^2(0, L) \cap H_0^1(0, L)\}$, where $\|w\|_{H_0^1(0,L)} = \|w_x\|_{L^2(0,L)}$. Moreover,

$$V(t, v, w) \lesssim \|X_1(t)\|_2^2 + \|Aw\|_{L^2(0,L)}^2. \tag{2.25}$$

Proof. Any $w \in H^2(0, L) \cap H_0^1(0, L)$ can be expanded as a series in the eigenfunctions of $A(\varepsilon t)$, convergent in $H_0^1(0, L)$,

$$w(.) = \sum_i w_i(t) e_i(\varepsilon t, .).$$

Hence

$$\|w\|_{H_0^1(0,L)}^2 = \sum_{i,j} w_i(t) w_j(t) \int_0^L e_{ix}(\varepsilon t, x) e_{jx}(\varepsilon t, x) dx.$$

Integrating by parts and using the definition of e_j, we compute

$$\int_0^L e_{ix}(\varepsilon t,x)e_{jx}(\varepsilon t,x)dx=\int_0^L f'(\bar y(\varepsilon t,x))e_i(\varepsilon t,x)e_j(\varepsilon t,x)dx-\lambda_j\delta_{ij},$$

and thus

$$\|w\|^2_{H_0^1(0,L)}=\int_0^L f'(\bar y(\varepsilon t,x))w(x)^2dx-\sum_{j=1}^{\infty}\lambda_j(\varepsilon t)w_j(t)^2.$$

Therefore, since $f'(\bar y)$ is bounded on $[0,1/\varepsilon]\times[0,L]$ uniformly in $\varepsilon\in(0,1]$,

$$\|w\|^2_{H_0^1(0,L)}\ \lesssim\ \|w\|^2_{L^2(0,L)}-\sum_{j=n+1}^{\infty}\lambda_j(\varepsilon t)w_j(t)^2\ \lesssim\ V(t,v,w).$$

Conversely, we have

$$\begin{aligned}-\sum_{j=n+1}^{\infty}\lambda_j(\varepsilon t)w_j(t)^2&=\|w\|^2_{H_0^1(0,L)}-\int_0^L f'(\bar y(\varepsilon t,x))w(x)^2dx+\sum_{j=1}^{n}\lambda_j(\varepsilon t)w_j(t)^2\\&\lesssim\|w\|^2_{H_0^1(0,L)}+\|w\|^2_{L^2(0,L)}\\&\lesssim\|w\|^2_{H_0^1(0,L)},\end{aligned}$$

and using (2.23) we conclude easily that (2.24) holds.

On the other hand, notice that

$$\|w\|^2_{H_0^1(0,L)}\lesssim\sum_{j=n+1}^{\infty}|\lambda_j|w_j^2+\sum_{j=1}^{n}w_j^2.$$

Therefore, using (2.7),

$$\|w\|^2_{H_0^1(0,L)}\lesssim\sum_{j=1}^{n}w_j^2+\sum_{j=1}^{\infty}\lambda_j^2w_j^2=\sum_{j=1}^{n}w_j^2+\|Aw\|^2_{L^2(0,L)},$$

and hence the estimate (2.25) follows. □

Let now $(v(t),w(t,.))$ denote a solution of (2.8) in which we choose the control in the feedback form suggested from Corollary 2.4, namely,

$$\alpha(t)=K_1(\varepsilon t)X_1(t),$$

such that $v(0)=0$ and $w(0,.)=0$, i.e., $(v(t),w(t,.))$ satisfies

$$w_t=Aw+av+bK_1(\varepsilon t)X_1(t)+r,\quad v'(t)=K_1(\varepsilon t)X_1(t), \tag{2.26}$$

$$v(0)=0,\quad w(0,x)=0. \tag{2.27}$$

We set

$$V_1(t)=V(t,v(t),w(t,.))=c\,{}^tX_1(t)P(\varepsilon t)X_1(t)-\frac{1}{2}\langle w(t,.),A(\varepsilon t)w(t,.)\rangle_{L^2(0,L)}.$$

Let us compute $V_1'(t)$ and state a differential inequality satisfied by V_1. We have

$$\begin{aligned} V_1'(t) &= c\left({}^tX_1'(t)P(\varepsilon t)X_1(t) + {}^tX_1(t)P(\varepsilon t)X_1'(t)\right) + \varepsilon c\,{}^tX_1(t)P'(\varepsilon t)X_1(t) \\ &\quad -\frac{1}{2}\langle w_t(t,.), A(\varepsilon t)w(t,.)\rangle_{L^2(0,L)} - \frac{1}{2}\langle w(t,.), A(\varepsilon t)w_t(t,.)\rangle_{L^2(0,L)} \\ &\quad -\frac{1}{2}\varepsilon\langle w(t,.), A'(\varepsilon t)w(t,.)\rangle_{L^2(0,L)}. \end{aligned} \tag{2.28}$$

Note the following facts:

- From (2.17) and (2.20), we infer

$$ {}^tX_1'PX_1 + {}^tX_1PX_1' = -\|X_1\|_2^2 + {}^tR_1PX_1 + {}^tX_1PR_1. $$

- The operator A is self-adjoint in L^2, hence

$$ \langle w, Aw_t\rangle_{L^2(0,L)} = \langle Aw, w_t\rangle_{L^2(0,L)}. $$

- Equation (2.26) leads to

$$\begin{aligned} \langle Aw, w_t\rangle_{L^2(0,L)} &= \langle Aw, Aw + av + bK_1X_1 + r\rangle_{L^2(0,L)} \\ &= \|Aw\|_{L^2(0,L)} + \langle Aw, a\rangle_{L^2(0,L)}v \\ &\quad + \langle Aw, b\rangle_{L^2(0,L)}K_1X_1 + \langle Aw, r\rangle_{L^2(0,L)}. \end{aligned}$$

- From the definition of $A(\tau)$, we have

$$ A'(\tau) = f''(\bar y(\tau,.))\bar y_\tau(\tau,.)Id, $$

and thus

$$ \langle w(t,.), A'(\varepsilon t)w(t,.)\rangle_{L^2(0,L)} = \langle w(t,.), f''(\bar y(\varepsilon t,.))\bar y_\tau(\varepsilon t,.)w(t,.)\rangle_{L^2(0,L)}. $$

Therefore, turning back to (2.28),

$$\begin{aligned} V_1' =& -c\,\|X_1\|_2^2 - \|Aw\|_{L^2(0,L)}^2 - \langle Aw, a\rangle_{L^2(0,L)}v - \langle Aw, b\rangle_{L^2(0,L)}K_1X_1 \\ &- \langle Aw, r\rangle_{L^2(0,L)} + \varepsilon c\,{}^tX_1P'X_1 + c\left({}^tR_1PX_1 + {}^tX_1PR_1\right) \\ &- \frac{1}{2}\varepsilon\langle w, f''(\bar y)\bar y_\tau w\rangle_{L^2(0,L)}. \end{aligned} \tag{2.29}$$

Let us set an upper bound for the terms of the second line of (2.29), as follows:

- From Corollary 2.4, the application $\tau \mapsto P'(\tau)$ is bounded on $[0,1]$, hence

$$ \left|\varepsilon c{}^tX_1P'X_1\right| \lesssim \varepsilon\|X_1\|_2^2 \lesssim \varepsilon V_1. $$

- Inequality (2.12) yields, for $|v(t)| + \|w(t,.)\|_{L^\infty(0,L)} \le 1$,

$$ \|R_1(\varepsilon,t)\|_{L^\infty(0,L)} \lesssim \varepsilon + v(t)^2 + \|w(t,.)\|_{H_0^1(0,L)}^2, $$

and thus, still for $|v(t)| + \|w(t,.)\|_{L^\infty(0,L)} \le 1$,

$$\begin{aligned} {}^tR_1PX_1 + {}^tX_1PR_1 &\lesssim \|X_1\|_2\left(\varepsilon + v^2 + \|w\|_{H_0^1(0,L)}^2\right) \\ &\lesssim \sqrt{V_1}\,(\varepsilon + V_1) = \varepsilon\sqrt{V_1} + V_1^{3/2}. \end{aligned}$$

- Since f is of class C^2, we can assert

$$\varepsilon\left|\frac{1}{2}\langle w, f''(\bar{y})\bar{y}_\tau w\rangle_{L^2(0,L)}\right| \lesssim \varepsilon\|w\|^2_{L^2(0,L)} \lesssim \varepsilon\|w\|^2_{H_0^1(0,L)} \lesssim \varepsilon V_1.$$

- The term $\langle Aw, r\rangle_{L^2(0,L)}$ is the most difficult to handle. Using (2.5), write

$$\begin{aligned}\langle Aw, r\rangle_{L^2(0,L)} &= \left\langle Aw, -\varepsilon\bar{y}_\tau + \Big(w+\frac{x}{L}v\Big)^2\int_0^1(1-s)f''\Big(\bar{y}+s(w+\frac{x}{L}v)\Big)ds\right\rangle_{L^2(0,L)}\\ &= \left\langle Aw, \Big(w+\frac{x}{L}v\Big)^2\int_0^1(1-s)f''\Big(\bar{y}+s(w+\frac{x}{L}v)\Big)ds\right\rangle_{L^2(0,L)}\\ &\quad -\varepsilon\langle Aw, \bar{y}_\tau\rangle_{L^2(0,L)}.\end{aligned}$$

We clearly have

$$|\varepsilon\langle Aw, \bar{y}_\tau\rangle_{L^2(0,L)}| \lesssim \varepsilon\|Aw\|_{L^2(0,L)}.$$

Let us now deal with the integral term. First of all, using the continuous imbedding of H_0^1 in C^0, we estimate

$$\begin{aligned}\left\|\Big(w(t,x)+\frac{x}{L}v(t)\Big)^2\right\|_{L^\infty(0,L)} &\lesssim \|w(t,.)\|^2_{L^\infty(0,L)} + v(t)^2\\ &\lesssim \|w(t,.)\|^2_{H_0^1(0,L)} + \|X_1(t)\|_2^2\\ &\lesssim V_1(t)\end{aligned}$$

since $V_1 \sim \|w\|^2_{H_0^1(0,L)} + \|X_1\|_2^2$. For $|v(t)| + \|w(t,.)\|_{L^\infty(0,L)} \le 1$, one has

$$\left\langle Aw, \Big(w+\frac{x}{L}v\Big)^2\int_0^1(1-s)f''\left(\bar{y}+s\left(w+\frac{x}{L}v\right)\right)ds\right\rangle_{L^2(0,L)} \lesssim \|Aw\|_{L^2(0,L)}V_1,$$

and we arrive at the estimate

$$\big|\langle Aw, r\rangle_{L^2(0,L)}\big| \lesssim \varepsilon\|Aw\|_{L^2(0,L)} + \|Aw\|_{L^2(0,L)}V_1$$

for $|v(t)| + \|w(t,.)\|_{L^\infty(0,L)} \le 1$.

Let us also estimate the terms of the principal part of (2.29). We clearly have

$$\big|\langle Aw, a\rangle_{L^2(0,L)}v\big| \le \frac{1}{4}\|Aw\|^2_{L^2(0,L)} + \|a\|^2_{L^2(0,L)}\|X_1\|_2^2$$

and

$$\big|\langle Aw, b\rangle_{L^2(0,L)}K_1X_1\big| \le \frac{1}{4}\|Aw\|^2_{L^2(0,L)} + M\|X_1\|_2^2,$$

where

$$M = \|b\|_{L^2(0,L)}\max\left\{\sum_{i=0}^n k_i(\tau)^2/\tau \in [0,1]\right\}.$$

Hence, concerning the principal part of (2.29), we first get

$$\begin{aligned} &- c\|X_1\|_2^2 - \|Aw\|^2_{L^2(0,L)} - \langle Aw, a\rangle_{L^2(0,L)} v - \langle Aw, b\rangle_{L^2(0,L)} K_1 X_1 \\ &\quad \leq \ -c_1\|X_1\|_2^2 - \frac{1}{2}\|Aw\|^2_{L^2(0,L)}, \end{aligned}$$

where $c_1 = c - \|a\|^2_{L^2(0,L)} - M$. We choose c so that $c_1 > 0$.

The previous estimates and (2.29) now yield, for $|v(t)| + \|w(t,.)\|_{L^\infty(0,L)} \leq 1$,

(2.30)
$$V_1' + \|X_1\|_2^2 + \|Aw\|^2_{L^2(0,L)} \ \lesssim \ \varepsilon\sqrt{V_1} + V_1^{3/2} + \varepsilon\|Aw\|_{L^2(0,L)} + V_1\|Aw\|_{L^2(0,L)}.$$

Note that, for every $\theta \in (0, +\infty)$,

$$\begin{aligned} \varepsilon\sqrt{V_1} &\leq \frac{\theta}{2}V_1 + \frac{1}{2\theta}\epsilon^2, \\ \varepsilon\|Aw\|_{L^2(0,L)} &\leq \frac{\theta}{2}\|Aw\|^2_{L^2(0,L)} + \frac{1}{2\theta}\varepsilon^2, \\ V_1\|Aw\|_{L^2(0,L)} &\leq \frac{\theta}{2}\|Aw\|^2_{L^2(0,L)} + \frac{1}{2\theta}V_1^2. \end{aligned}$$

Hence, taking $\theta > 0$ small enough, we get, using (2.25) and (2.30), the existence of $\sigma > 0$ and $\rho \in (0, \sigma]$ such that, for every $\varepsilon \in (0, 1]$ and for every $t \in [0, 1/\varepsilon]$ such that $V_1(t) \leq \rho$,

$$V_1'(t) \leq \sigma\varepsilon^2.$$

Hence, since $V_1(0) = 0$, we get, if $\varepsilon \in (0, \rho/\sigma]$, that

$$V_1(t) \leq \sigma\varepsilon \quad \forall t \in [0, 1/\varepsilon]$$

and, in particular,

$$V_1\left(\frac{1}{\varepsilon}\right) \leq \sigma\varepsilon.$$

Coming back to definitions (2.1) and (2.3), we have proved

$$\left\| y\left(\frac{1}{\varepsilon}, .\right) - y_1(.)\right\|_{H^1(0,L)} \leq \gamma\varepsilon, \tag{2.31}$$

where $y_1(.) = \bar{y}(1, .)$ is the final target and γ is a positive constant which does not depend on $\varepsilon \in (0, \rho/\sigma]$. This concludes the third step, and thus the proof of the stabilization part of Theorem 1.2 (see Remark 1.3).

2.4. End of the proof. The last step consists of solving a local exact controllability result: from the previous section, $y(\frac{1}{\varepsilon}, .)$ belongs to an arbitrarily small neighborhood of $y_1(.)$ in H^1-topology if ε is small enough, and our aim is now to construct a trajectory $q(t, x)$ solution of the control system steering $y(\frac{1}{\varepsilon}, .)$ to $y_1(.)$ in some time $T > 0$ (for instance, $T = 1$), i.e.,

$$\begin{cases} q_t = q_{xx} + f(q), \\ q(t, 0) = 0, \ q(t, L) = u(t), \\ q(0, x) = y\left(\frac{1}{\varepsilon}, x\right), \ q(T, x) = y_1(x). \end{cases}$$

Existence of such a solution q is given by [11, Theorem 3.3]. Actually, in [11] the function f is assumed to be globally Lipschitzian, but the local result we need here follows readily from the proofs and the estimates contained in this paper. Indeed, let $T > 0$ and let $\tilde{f}$ be a globally Lipschitzian mapping such that

$$\tilde{f}(s) = f(s) \quad \forall s \in [-\|y_1\|_{L^\infty} - 1, \|y_1\|_{L^\infty} + 1]. \tag{2.32}$$

From the proof of [11, Theorem 3.3], we get the existence of $\mu > 0$ such that there exists $z \in Y_T$ satisfying

$$\begin{cases} z_t = z_{xx} + \tilde{f}(z + y_1) - \tilde{f}(y_1), \\ z(t,0) = 0, \\ z(0,x) = y\left(\dfrac{1}{\varepsilon}, x\right) - y_1(x), \ z(T,x) = 0 \end{cases}$$

and the estimate

$$\|z\|_{Y_T} \leq \mu \left\| y\left(\frac{1}{\varepsilon}, \cdot\right) - y_1(\cdot) \right\|_{H^1(0,L)}, \tag{2.33}$$

which leads, with $q = z + \tilde{y}_1$, to

$$\begin{cases} q_t = q_{xx} + \tilde{f}(q), \\ q(t,0) = 0, \\ q(0,x) = y\left(\dfrac{1}{\varepsilon}, x\right), \ q(T,x) = y_1(x) \end{cases}$$

and

$$\|q - \tilde{y}_1\|_{Y_T} \leq \mu \left\| y\left(\frac{1}{\varepsilon}, \cdot\right) - y_1(\cdot) \right\|_{H^1(0,L)}, \tag{2.34}$$

where $\tilde{y}_1(t,x) := y_1(x)$. From (2.33) and (2.34), we get

$$\|q - \tilde{y}_1\|_{L^\infty((0,T)\times(0,L))} \leq 1 \tag{2.35}$$

for $\|y(1/\varepsilon, \cdot) - y_1(\cdot)\|_{H^1(0,L)}$ small enough. From (2.32) and (2.35), we infer that $\tilde{f}(q) = f(q)$, which ends the proof.

3. Controllability versus connectedness. Let us first give some sufficient conditions ensuring the connectedness of $\mathcal{S}$.

PROPOSITION 3.1. *In each of the following cases, the set of steady-states $\mathcal{S}$ is connected:*

- *The function F, defined as*

$$F(y) = \int_0^y f(s)ds,$$

satisfies the asymptotic condition

$$F(y) \underset{|y|\to+\infty}{\longrightarrow} +\infty.$$

- *For any $\alpha > 0$, the indefinite integral*

$$\int \frac{dy}{\sqrt{\alpha - F(y)}}$$

diverges in $-\infty$ and in $+\infty$ (if it makes sense).
- *The function f is odd, i.e., for any $y \in \mathbb{R}$,*

$$f(-y) = -f(y).$$

Remark 3.2. Notice that, contrary to the two first cases of the proposition, in the third case blow-up phenomena may occur. Nevertheless, the set of steady-states is connected.

On the other hand, we have the following result.

PROPOSITION 3.3. *If y_0 and y_1 belong to distinct connected components of $\mathcal{S}$, then it is not possible to move either from y_0 to y_1, or from y_1 to y_0, whatever the control $u \in L^2(0,T)$ and the time T are.*

Remark 3.4. If y_0 and y_1 are both periodic, then they are in the same connected component.

In order to prove these two propositions, let us first note some general facts about the maximal solutions of the scalar differential equation

$$y''(x) + f(y(x)) = 0,\ y(0) = 0. \tag{3.1}$$

LEMMA 3.5.

- *Any solution of* (3.1) *satisfies on its maximal interval of definition the conservation law*

$$y'(x)^2 + 2F(y(x)) = y'(0)^2. \tag{3.2}$$

- *Any solution of* (3.1) *such that y' vanishes at least at two distinct points is actually periodic.*
- *The phase portrait in the plane (y, y') of the associated differential system*

$$y' = z,\ z' = -f(y),$$

is symmetric with respect to the y axis, and moreover, all singular points of the system are located on this axis.

The proof of these facts is obvious. Now the key lemma for proving Propositions 3.1 and 3.3 is the following.

LEMMA 3.6. *Let y_0 and y_1 be two steady-states, extended on their maximal interval of definition as solutions of* (3.1)*, belonging to distinct connected components of $\mathcal{S}$, such that $y_0'(0) < y_1'(0)$. Then there exists an $l \in (0, L]$ and $\bar{y} \in C^2([0,l))$ solution of* (3.1) *such that either*

$$\bar{y}(x) \underset{x \to l}{\longrightarrow} +\infty \tag{3.3}$$

or

$$\bar{y}(x) \underset{x \to l}{\longrightarrow} -\infty. \tag{3.4}$$

In the first case we have, moreover (see Figure 3.1*), the following:*

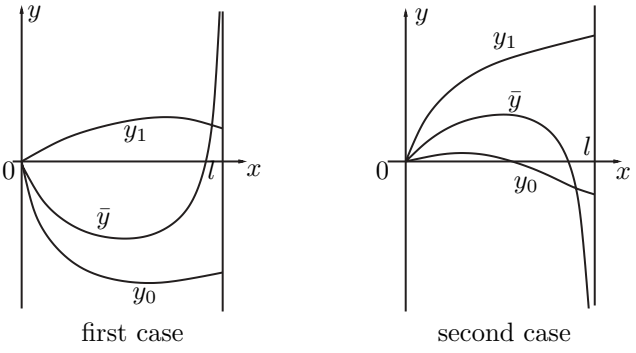

FIG. 3.1. *Existence of an explosive solution.*

1. $y_0(x) < \bar{y}(x)$ *for any* $x \in [0, l)$.
2. $y_0'(0) < \bar{y}'(0) < y_1'(0)$, $|y_1'(0)| < |\bar{y}'(0)|$, *and* $\bar{y}'(0) < 0$.
3. $\#\{x \in [0, l) \ / \ \bar{y}(x) = y_1(x)\} = 1$.
4. y_0 *is not periodic, and* $y_1(x)$ *does not tend to* $-\infty$ *as* x *tends to* b, *where* (a, b) *denotes the maximal interval of definition of* y_1.

In the second case we have the symmetric situation (see Figure 3.1*), as follows:*

1. $y_1(x) > \bar{y}(x)$ *for any* $x \in [0, l)$.
2. $y_0'(0) < \bar{y}'(0) < y_1'(0)$, $|y_0'(0)| < |\bar{y}'(0)|$, *and* $\bar{y}'(0) > 0$.
3. $\#\{x \in [0, l) \ / \ \bar{y}(x) = y_0(x)\} = 1$.
4. y_1 *is not periodic, and* $y_0(x)$ *does not tend to* $+\infty$ *as* x *tends to* b, *where* (a, b) *denotes the maximal interval of the definition of* y_0.

Proof of Lemma 3.6. Clearly one of the two cases (3.3) and (3.4) occurs, with, moreover, $y_0'(0) < \bar{y}'(0) < y_1'(0)$. Assume we are in the first case, and let us first prove the second of the four properties claimed in that case. To proceed, we have to distinguish between the following three possibilities:

- y_1 is monotonic on $[0, l]$. In this case the conservation law (3.2) immediately implies that $|y_1'(0)| < |\bar{y}'(0)|$.
- y_1 is not monotonic on $[0, l]$ and is not periodic on its maximal interval (a, b). That is, y_1' vanishes exactly once on (a, b). The only nonobvious case occurs when $y_1'(0) > 0$. But then, since the phase portrait is symmetric with respect to the y axis, either $y_1(x)$ tends to $-\infty$ as x tends to a and b or $y_1(x)$ tends to a finite limit which corresponds to a singular point on the phase portrait (see Figure 3.2). In both cases it is clear on the phase portrait that $\bar{y}(x)$ may tend to $+\infty$ as x tends to l only if $|y_1'(0)| < |\bar{y}'(0)|$.
- y_1 is periodic (i.e., y_1' vanishes at least two times). Again in this case the phase portrait immediately implies the desired inequality.

Before proving that $\bar{y}'(0) < 0$, let us prove the third point. The only nonobvious case occurs when y_1 is periodic and $\bar{y}$ is not monotonic on $[0, l)$. Notice that $\bar{y}'$ vanishes only once (if not, $\bar{y}$ would be periodic), and thus it decreases on an interval $[0, x_0]$ and increases on $[x_0, l)$. Now, on the one hand, the function y_1 cannot intersect $\bar{y}$ on the interval $[0, x_0]$, for this would contradict the conservation law (3.2). On the other hand, if y_1 would intersect $\bar{y}$ more than once on the interval $[x_0, l)$, then there would be at least three intersections, and again this leads to a contradiction with (3.2). This proves the third point.

Now the inequality $\bar{y}(0) < 0$ is an obvious consequence of (3.2).

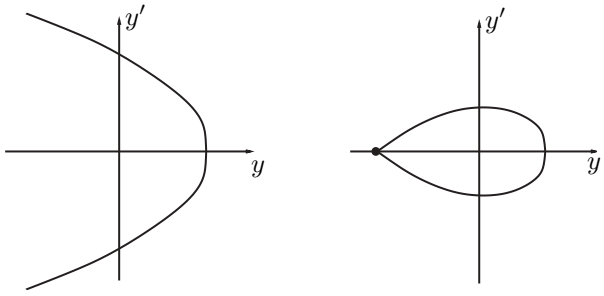

FIG. 3.2. *Behavior of* $(y_1(x), y_1'(x))$ *in the phase plane.*

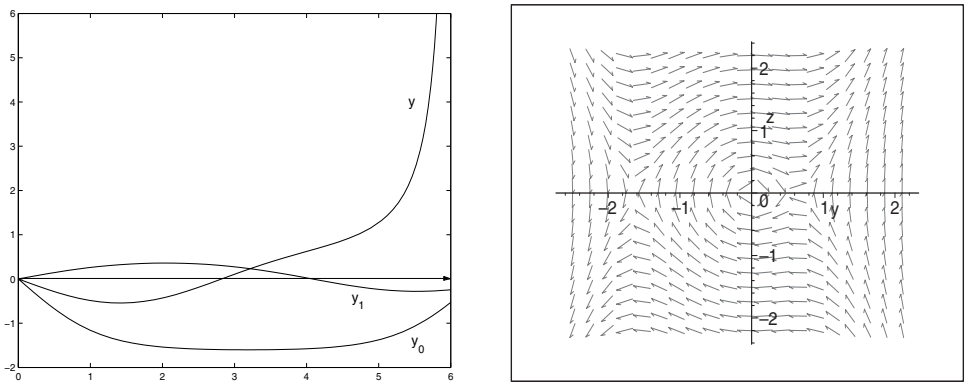

FIG. 3.3. *An example where* y_0 *and* y_1 *are not in the same connected component of* $\mathcal{S}$.

Let us now prove that $y_0 < \bar{y}$ on $[0, l)$. The same reasoning as above shows that $\bar{y}$ intersects y_0 at most once (notice that y_0' cannot vanish more than once). But such an intersection would contradict the fact that $\bar{y}(x)$ tends to $+\infty$ as x tends to l.

Finally, the last point of the lemma is proved by observing the phase portrait. □

Proof of Proposition 3.3. Proposition 3.3 follows from Lemma 3.6. Indeed, let us assume, for example, that we are in the first case of the lemma. Then for any $T > 0$ and $u \in L^2([0, T])$, the solution y of the control system (1.4) satisfies, as long as defined, the inequality

$$y(t, x) \leq \bar{y}(x)$$

(see [4] for this application of the classical maximum principle to similar control problems). In particular, $y(T, .) \neq y_1(.)$. □

Finally let us prove Proposition 3.1. The only difficult case is to prove that if f is odd, then the set $\mathcal{S}$ is connected. In this case the conservation law (3.2) implies that the phase portrait is symmetric with respect to the y axis and the y' axis. As a consequence, any solution of (3.1) such that y' vanishes at least once is necessarily periodic.

Now from Lemma 3.6 we know that if y_0 and y_1 are not in the same connected component, then there exists an explosive solution $\bar{y}$ of (3.1) such that $\bar{y}'$ vanishes at least once. Hence, $\bar{y}$ must be periodic, and we get a contradiction.

Example 3.7. An example where the situation of Proposition 3.3 and Lemma 3.6 occurs is given by

$$f(y) = y - y^2 - y^3.$$

The graph of y_0, y_1, an explosive y, and the phase portrait are drawn on Figure 3.3.

4. Numerical simulations. In this section we present numerical simulations using Matlab for the nonlinear function $f(y) = y^3$. Let $L = 1$; the set $\mathcal{S}$ of steady-states consists of all solutions of class C^2 on $[0,1]$ such that

$$y''(x) + y(x)^3 = 0,\ y(0) = 0. \tag{4.1}$$

It follows from Proposition 3.1 that this set is connected. Let y_0 be identically zero, and let y_1 denote the solution of (4.1) vanishing at 0, 1/2, and 1, and having no other zero on $[0,1]$ (see Figure 4.1).

For all $\tau \in [0,1]$, we define the function $\bar{y}(\tau, .)$ on $[0,1]$ as the solution of (4.1) such that

$$\frac{\partial \bar{y}}{\partial x}(\tau, 0) = \tau y_1'(0)$$

and we set $\bar{u}(\tau) = \bar{y}(\tau, 1)$. We then introduce on $H^2(0,1) \cap H_0^1(0,1)$ the one-parameter family of linear operators

$$A(\tau) = \Delta + 3\bar{y}(\tau, .)^2 Id,\ \tau \in [0,1].$$

For $\tau = 0$, we have $A(0) = \Delta$, and the eigenvalues and eigenvectors write

$$\lambda_i(0) = -i^2\pi^2,\ e_i(0,x) = \sqrt{2}\sin k\pi x.$$

Then, solving by homotopy as $\tau \in [0,1]$ boundary value problems, we compute numerically, using a standard finite difference code implemented in Matlab, the first eigenvalues and associated eigenvectors. In the present example, numerical experiments show that only the two first eigenvalues may take positive values as $\tau \in [0,1]$. In other words, with the notations of section 2.3, one has $n = 2$. Then we achieve a

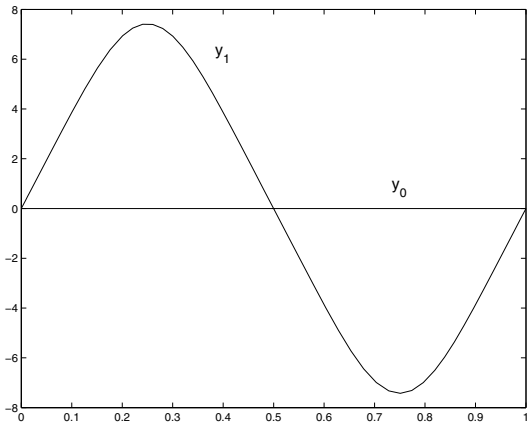

FIG. 4.1. *Definition of the steady-states* y_0 *and* y_1.

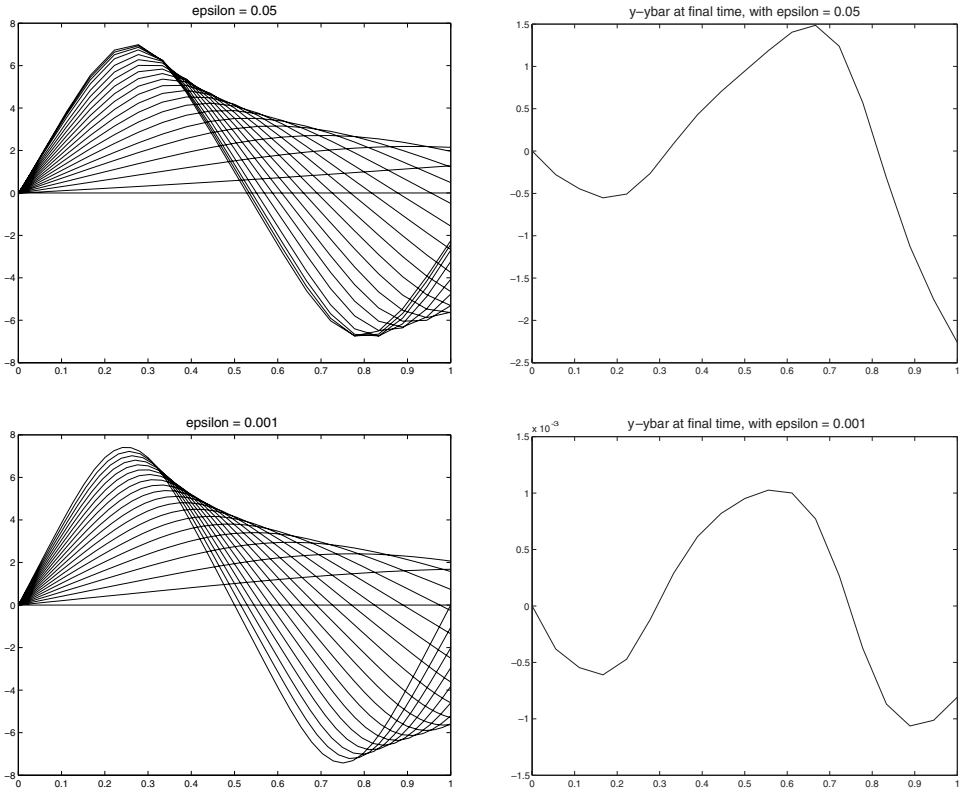

FIG. 4.2. *Simulations results for $y(t,.)$, where $t \in [0, 1/\varepsilon]$.*

pole placement on the finite dimensional system (2.16) by applying an LQR algorithm (see [13]). Notice that the finite dimensional system corresponding to these two first modes is very unstable: numerically, one has $\lambda_1(1) \simeq 89.743$ and $\lambda_2(1) \simeq 82.518$.

Results are drawn on Figure 4.2 for $\varepsilon = 0.05$ and $\varepsilon = 0.001$. Notice that if ε is too large, then the solution blows up.

QUASI-VARIATIONAL INEQUALITIES WITH DIRICHLET BOUNDARY CONDITION RELATED TO EXIT TIME PROBLEMS FOR IMPULSE CONTROL*

A. L. AMADORI†

Abstract. We study degenerate-elliptic quasi-variational inequalities with Dirichlet boundary condition, which are related to the value function of the exit time problem for stochastic impulse control by means of the dynamic programming principle. The boundary condition in the viscosity solutions sense does not identify a unique solution, because in this nonlocal problem the boundary layer gives rise to a loss of information also at the interior points. The eventual discontinuities of solutions at the boundary of the domain play an essential role and cannot be removed. Therefore we superimpose a selection criterion which, enforcing the information coming from the boundary datum, picks up the value function among all possible viscosity solutions. As a result, we attain the continuity of the value function up to the boundary. In addition, we produce a monotone iterative scheme approximating the value function.

Key words. impulse stochastic control, quasi-variational inequality, boundary condition

1. Introduction.

This paper concerns a stochastic impulse control problem in an open bounded domain $\Omega \subset \mathbb{R}^{\mathrm{N}}$. The state of the controlled system is given by the solution $(X_t^x)_t$ of the following equation:

$$\begin{cases} dX_t^x = b(X_t^x, \alpha_t)\, dt + \sigma(X_t^x, \alpha_t)\, dW_t, & t \in]\theta_i, \theta_{i+1}[, \\ X_{\theta_i}^x = X_{\theta_i^-}^x + \xi_i, \\ X_0^x = x \in \Omega, \end{cases} \tag{1.1}$$

where $(W_t)_t$ is a D-dimensional Brownian motion (with, possibly, $\mathrm{D} \le \mathrm{N}$), $(\alpha_t)_t$ is any adapted process with values in a compact set $\mathcal{A} \subset \mathbb{R}^{\mathrm{P}}$, $(\theta_i)_i$ is an increasing sequence of stopping times (both with respect to the filtration generated by the Brownian motion W_t), $(\xi_i)_i$ is a sequence in $\mathbb{R}^{\mathrm{N}}_+$, and b, σ are continuous functions on $\overline{\Omega} \times \mathcal{A}$ taking values respectively in $\mathbb{R}^{\mathrm{N}}$ and in the space of $\mathrm{N} \times \mathrm{D}$ real matrices.

The control is the triplet $A = ((\alpha_t)_t, (\theta_i, \xi_i)_i)$, where the item $\theta_i = \infty$ for some $i \in \mathbb{N}$ is allowed. For any fixed x and A, the cost function is

$$\mathcal{J}(x, A) := \mathbb{E}\left[\int_0^{\tau_x} f(X_t^x, \alpha_t) e^{-\lambda t} dt + \sum_{i \le \tau_x} (c(\xi_i) + k) e^{-\lambda \theta_i} + 1_{\{\tau_x < \infty\}} \varphi(X_{\tau_x}^x) e^{-\lambda \tau_x} \right],$$

where f and c are real continuous functions, λ and k are positive numbers, and τ_x stands for the first exit time from $\overline{\Omega}$ of the trajectory $(X_t^x)_t$. We are interested in value function $\mathbf{U}$ of type

$$\mathbf{U}(x) := \inf_A \mathcal{J}(x, A).$$

It is easily seen that the minimization problem is equivalent to

$$\mathbf{U}(x) = \inf_{A} \mathbb{E}\left[\int_0^{\tau_x} f(X_t^x, \alpha_t) e^{-\lambda t} dt + \sum_{i\in\mathbb{N}} (c(\xi_i) + k) e^{-\lambda\theta_i} + 1_{\{\tau_x<\infty\}} \varphi(X_{\tau_x}^x) e^{-\lambda\tau_x}\right]. \tag{1.2}$$

Stochastic impulse control problems arise, for instance, in the modeling of portfolio management with transaction costs and have been studied, among others, by [17]: it is assumed that $\operatorname{rank}\sigma = \mathrm{N}$ so that the market is complete. The investigation of incomplete markets has to be addressed to control problems with $\operatorname{rank}\sigma < \mathrm{N}$, which is the topic of this present work.

The dynamic programming principle relates the optimization problem (1.1)–(1.2) to a Hamilton–Jacobi–Bellman equation, which now stands in the quasi-variational inequality

$$\max\{H(x, u, Du, D^2u), u - Mu\} = 0 \qquad \text{on } \Omega, \tag{1.3}$$

coupled with the Dirichlet boundary condition

$$u = \varphi \qquad \text{on } \partial\Omega. \tag{1.4}$$

Here, H is the (possibly degenerate) elliptic operator

$$H(x, u, p, X) := \sup_{\alpha\in\mathcal{A}} \left\{ -\frac{1}{2}\operatorname{tr}\left[a(x,\alpha)X\right] - b(x,\alpha)\cdot p + \lambda u - f(x,\alpha) \right\}$$

for any $x \in \overline{\Omega}$, $u \in \mathbb{R}$, $p \in \mathbb{R}^{\mathrm{N}}$, and $X \in \mathcal{S}^{\mathrm{N}}$ (the space of $\mathrm{N}\times\mathrm{N}$ symmetric matrices), where we have used the abbreviated notation $a(x,\alpha) = \sigma(x,\alpha)\sigma^T(x,\alpha)$ for any $x \in \overline{\Omega}$ and $\alpha \in \mathcal{A}$. Besides, M is a nonlocal operator of the form

$$Mu(x) := \inf\left\{u(x+\xi) + c(\xi) + k \,:\, \xi \in \mathbb{R}^{\mathrm{N}}_+, x+\xi \in \overline{\Omega}\right\}.$$

We refer to [6] for a detailed analysis of the relations between impulse control problems (1.1)–(1.2) and quasi-variational inequalities (1.3)–(1.4). If the matrix a is positively defined, the value function has been characterized as the unique strong solution to the quasi-variational inequality with Dirichlet boundary condition in [18]. In the general case when a may degenerate, it is necessary to turn to the theory of viscosity solutions. If one manages to establish that the value function is continuous on Ω and continuously extendable to $\overline{\Omega}$, one can characterize it as the unique continuous (viscosity) solution by combining the dynamic programming principle and uniqueness arguments. Such a program has been successfully performed in [1], dealing with deterministic impulse control in all $\mathbb{R}^{\mathrm{N}}$. However, in the case of exit time problems, it is well known that the value function is not continuous, in general. Concerning deterministic control, this topic has been discussed in [4, 7, 19, 20]. With respect to standard stochastic control, this problem has been solved quite generally by achieving a strong comparison result, i.e., a comparison among discontinuous sub/supersolutions satisfying the boundary condition in the relaxed sense, in [5, 15]. Both these results may handle cases when $\mathbf{U}$ is not equal to φ on the boundary points where σ degenerates along the normal direction, and they bring as a by-product that the value function is continuous; moreover, they rely heavily on the fact that the continuous extension of $\mathbf{U}$ to $\overline{\Omega}$ still solves the Dirichlet problem with relaxed boundary condition. Concerning stochastic impulse control, comparison results can be found in

[13, 14], both postulating the behavior of sub/supersolutions at the boundary. In [13] it is assumed that the sub/supersolutions are "strong," namely that they verify the boundary condition in the following sense:

$$\max\{u-Mu, u-\varphi\} \le 0 \quad \text{on } \partial\Omega, \tag{1.5}$$

$$\max\{u-Mu, u-\varphi\} \ge 0 \quad \text{on } \partial\Omega, \tag{1.6}$$

respectively. Next, by following the line of [15], [14] improves the previous comparison result, after assuming the nontangential semicontinuity of viscosity sub/supersolutions. These two comparison results allow characterization of the value function $\mathbf{U}$ as the "unique" viscosity solution to (1.3), in a restricted class of solutions which are known a priori to satisfy some technical regularity assumption at the boundary. Furthermore they apply only to the case when the value function is continuous in $\overline{\Omega}$.

Here, following the line of [5], we prefer to impose some "nondegeneracy"-type conditions on the boundary $\partial\Omega$, which can be read as "partial controllability" assumptions. As a first result we obtain comparison among any viscosity sub/supersolutions in the cases studied before in [13, 14]. Moreover we may deal with the general case, in which the value function is not continuous and its extension to $\overline{\Omega}$ does not solve (1.3). To be clear, we denote by $\Gamma_{in} \subset \partial\Omega$ the region of the boundary which can be reached only through a jump and not by using a standard continuous controlled trajectory (a precise definition is given later). Example 3.4 shows that, if the optimal trajectory jumps to Γ_{in}, the continuous extension of $\mathbf{U}$ to $\overline{\Omega}$ does not solve (1.3)–(1.4); nor is this the case if the boundary condition is understood in the relaxed sense

$$\min\left\{\max\left\{H\left(x,u,Du,D^2u\right), u-Mu\right\}, u-\varphi\right\} \le 0 \quad \text{on } \partial\Omega, \tag{1.7}$$

$$\max\left\{H\left(x,u,Du,D^2u\right), u-Mu, u-\varphi\right\} \ge 0 \qquad \text{on } \partial\Omega. \tag{1.8}$$

This matter breaks the analogy with previously mentioned control problems: the main difference is that not only are discontinuities at the boundary a by-product of the degeneracy of a, but they can be generated by the impulse control. In the case of standard stochastic control, the points of Γ_{in} behave as interior points, and imposing that the equation is satisfied at those points is sufficient to balance the loss of boundary data. On the contrary, in the case of impulse control, the points of Γ_{in} can be reached by jumping: as a result, the value function exactly takes the boundary value φ, but it is discontinuous. Such discontinuity is an integral part of the control problem and cannot be removed. The boundary condition (1.7)–(1.8) does not capture the information coming from the region Γ_{in}, so that the viscosity solution may even be discontinuous inside Ω and, in general, is not unique. These difficulties are overcome by giving a suitable notion of a boundary condition, which takes into account the jumps of the value function due to impulse control. The information about the boundary cost has to be strengthened by imposing that

$$\begin{aligned} u(x) &\le \tilde{M}\varphi(x) && \text{on } \Omega, \\ \limsup_{\Omega \ni y \to x} u(y) &\le \tilde{M}\varphi(x) && \text{on } \partial\Omega, \end{aligned} \tag{1.9}$$

where

$$\tilde{M}\varphi(x) := \inf\left\{\varphi(x+\xi) + c(\xi) + k \,:\, \xi \in \mathbb{R}^{\mathrm{N}}_{+}, x+\xi \in \Gamma_{in}\right\}. \tag{1.10}$$

This selection criterion picks up the value function among all the viscosity solutions and appears to be the natural way to read the boundary condition as more than a technical assumption. It is worth mentioning that the value function is neither the more regular solution nor the limit of an iterative procedure: indeed the standard iterative scheme possibly converges to the "wrong" solution.

This paper is organized as follows. In section 2, we introduce the assumptions that shall be in force in what follows and present some preliminary results concerning the behavior of any sub/supersolutions near the boundary. Section 3 concerns the case when $\Gamma_{in} = \emptyset$. We establish a comparison result which yields the continuity of the value function on $\overline{\Omega}$ and we show by means of a counterexample that it is not true anymore if $\Gamma_{in} \neq \emptyset$. Section 4 concerns the case when $\Gamma_{in} \neq \emptyset$: as shown in Example 4.1, comparison does not hold in general. Thus, we introduce a selection criterion and we obtain a comparison result between selected subsolutions and any supersolutions. As a by-product, we establish the continuity of the value function in $\overline{\Omega} \setminus \Gamma_{in}$ and we describe the eventual discontinuity in Γ_{in}. Finally, in section 5 we produce a monotone iterative scheme which approximates the value function.

2. Assumptions and preliminary results. We make the following standard assumptions:

H.1. The functions σ, b, and f are continuous on $\overline{\Omega} \times \mathcal{A}$. For any $\alpha \in \mathcal{A}$, $\sigma(\cdot, \alpha)$ and $b(\cdot, \alpha)$ are Lipschitz continuous on $\overline{\Omega}$; in addition,

$$\sup_{\alpha \in \mathcal{A}} \|\sigma_{ij}(\cdot, \alpha)\|_{\mathcal{C}^{0,1}(\overline{\Omega})}, \qquad \sup_{\alpha \in \mathcal{A}} \|b_i(\cdot, \alpha)\|_{\mathcal{C}^{0,1}(\overline{\Omega})} < \infty$$

as $1 \leq i \leq \mathrm{N}$, $1 \leq j \leq \mathrm{D}$.

H.2. $\lambda > 0$.

H.3. The function c is continuous, nonnegative, and subadditive, namely, $c(\xi_1 + \xi_2) \leq c(\xi_1) + c(\xi_2)$. In addition $c(0) = 0$ and $k > 0$.

H.4. $\varphi \in \mathcal{C}\big(\partial\Omega\big)$.

H.5. Ω is a bounded domain of $\mathbb{R}^{\mathrm{N}}$ with a $W^{3,\infty}$-boundary $\partial\Omega$.

Remark 2.1. The assumption H.2 can be easily relaxed by assuming that λ is a continuous function of x, α on $\overline{\Omega} \times \mathcal{A}$, with $\lambda > 0$.

The regularity assumption H.5 is not enough to handle the nonlocal term Mu. In order to avoid pathological shapes for Ω, we use the same hypothesis as in [13, 14], namely, the following:

H.6. There exists a mapping $P : \overline{\Omega} \times \mathbb{R}^{\mathrm{N}}_+ \to \mathbb{R}^{\mathrm{N}}_+$ satisfying

$$\begin{aligned} x + P(x, \xi) &\in \overline{\Omega} && \text{for all } (x, \xi) \in \overline{\Omega} \times \mathbb{R}^{\mathrm{N}}_+, \\ P(x, \xi) &= \xi && \text{if } x + \xi \in \overline{\Omega}, \\ P(\cdot, \xi) &\in \mathcal{C}\big(\overline{\Omega}\big) && \text{for any } \xi \in \mathbb{R}^{\mathrm{N}}_+. \end{aligned}$$

Assumption H.6 is not trivial. As shown in [14, Proposition 3.2], it guarantees that M preserves semicontinuity, and so it justifies the following definition in the framework of viscosity solutions to discontinuous equations started by [12].

Definition 2.1. *A function u which is locally bounded and upper semicontinuous on $\overline{\Omega}$ is a* viscosity subsolution *to* (1.3)–(1.4) *if it satisfies in the viscosity sense the inequalities*

$$\max\big\{H\big(x, u, Du, D^2u\big), u - Mu\big\} \leq 0 \qquad \text{on } \Omega \tag{2.1}$$

and (1.7) *on* $\partial\Omega$.

A function u which is locally bounded and lower semicontinuous on $\overline{\Omega}$ is a viscosity supersolution *to* (1.3)–(1.4) *if it satisfies in the viscosity sense the inequalities*

$$\max\{H(x,u,Du,D^2u),u-Mu\}\geq 0 \qquad \text{on } \Omega \tag{2.2}$$

and (1.8) *on* $\partial\Omega$.

Any locally bounded function u is a viscosity solution *to* (1.3)–(1.4) *if its upper and lower semicontinuous envelopes are, respectively, a subsolution and a supersolution.*

Remark 2.2. It is easily seen that any subsolution to (1.3)–(1.4) is a subsolution to the differential equation

$$H\left(x,u,Du,D^2u\right)=0 \qquad \text{on } \Omega, \tag{1.3.o}$$

which takes the boundary value (1.4) in the relaxed sense

$$\min\{H\left(x,u,Du,D^2u\right),u-\varphi\}\leq 0 \qquad \text{on } \partial\Omega.$$

Afterward, we use the same nondegeneracy-type assumptions as in [5]. To this end, we denote by d the distance to the boundary, which is a $W^{3,\infty}$ function in a neighborhood of $\partial\Omega$, by assumption H.5. For all $x\in\partial\Omega$, we set

$$\mathcal{A}_{\rm in}(x)=\left\{\alpha\in\mathcal{A}\,:\,\sigma^T(x,\alpha)Dd(x)=0,\frac{1}{2}\mathrm{tr}\left[a(x,\alpha)D^2d(x)\right]+b(x,\alpha)\cdot Dd(x)\geq 0\right\},$$

and we denote by $\Gamma_{\rm in}$ the set of all $x\in\partial\Omega$ such that $\mathcal{A}_{\rm in}(x)=\mathcal{A}$, by $\Gamma_{\rm out}$ the set of all $x\in\partial\Omega$ such that $\mathcal{A}_{\rm in}(x)=\emptyset$, and by $\Gamma=\partial\Omega\setminus(\Gamma_{\rm in}\cup\Gamma_{\rm out})$. We assume the following:

H.7. $\Gamma_{\rm in}$ and $\Gamma_{\rm out}$ are the union of connected components of $\partial\Omega$.

H.8. For every $x\in\Gamma$, one of the following assumptions holds:

H.8.i. There exist $\eta=\eta(x)>0$ and $\mathcal{V}=\mathcal{V}(x)$ an $\overline{\Omega}$-neighborhood of x and three subsets $\mathcal{A}_1(x),\mathcal{A}_2(x),\mathcal{A}_3(x)$ of $\mathcal{A}$ such that $\mathcal{A}=\mathcal{A}_1(x)\cup\mathcal{A}_2(x)\cup\mathcal{A}_3(x)$ and

(a) for any $\alpha\in\mathcal{A}_1(x)$, $\left|\sigma^T(x,\alpha)Dd(x)\right|\geq\eta$;

(b) for any $\alpha\in\mathcal{A}_2(x)\cup\mathcal{A}_3(x)$, the function $\phi_\alpha(y)=\sigma^T(y,\alpha)Dd(y)$ is of class $W^{2,\infty}$ on $\mathcal{V}$ and identically zero on $\mathcal{V}\cup\Gamma$; moreover, $\sup\{\|\phi_\alpha\|_{W^{2,\infty}(\mathcal{V})}:\alpha\in\mathcal{A}_2(x)\cup\mathcal{A}_3(x)\}<\infty$;

(c) for any $\alpha\in\mathcal{A}_2(x)$, $\frac{1}{2}\mathrm{tr}\left[a(x,\alpha)D^2d(x)\right]+b(x,\alpha)\cdot Dd(x)\leq-\eta$;

(d) for any $\alpha\in\mathcal{A}_3(x)$ and $y\in\mathcal{V}$, there exists $\alpha'=\alpha'(y)\in\mathcal{A}_3(x)$ such that $a(y,\alpha')=a(y,\alpha)$ and $\frac{1}{2}\mathrm{tr}\left[a(y,\alpha')D^2d(x)\right]+b(y,\alpha')\cdot Dd(x)\geq\eta$.

H.8.ii. There exists $\mathcal{V}=\mathcal{V}(x)$ an $\overline{\Omega}$-neighborhood of x and, for any $y\in\mathcal{V}$, $\alpha(y)\in\mathcal{A}$ depending continuously on y such that the function $\phi(y)=\sigma^T(y,\alpha'(y))$ is of class $W^{1,\infty}$ on $\mathcal{V}$ and identically zero on $\mathcal{V}\cup\Gamma$; moreover, $\sigma^T(x,\alpha(x))=0$ and $b(x,\alpha(x))\cdot Dd(x)>0$.

When dealing with impulse control problems, $\Gamma_{\rm in}$ plays a particular role, being the set of the points that can be reached only after a jump. In order to prevent tangential trajectories from causing some disturbing effects, we shall assume the following:

H.9. For every $x\in\Gamma_{\rm in}$, there exist $\eta=\eta(x)>0$ and $\mathcal{V}=\mathcal{V}(x)$ a $\partial\Omega$-neighborhood of x such that for all $y\in\mathcal{V}$ and $\alpha\in\mathcal{A}$

$$\frac{1}{2}\mathrm{tr}\left[a(y,\alpha)D^2d(y)\right]+b(y,\alpha)\cdot Dd(y)\geq\eta.$$

We now investigate the behavior of discontinuous sub/supersolutions near at the boundary, with the object of "cleaning" them by replacing their actual values on $\partial\Omega$ by their limits from inside Ω. Such a cleaning procedure avoids artificial discontinuities coming from the underdetermination of the boundary values due to the relaxation of the boundary condition. Furthermore, the solutions to quasi-variational inequalities may also present some discontinuities at the boundary which are not artificial, and these cannot be removed, unless some balancing condition is added. In view of this fact, subsolutions and supersolutions have to be treated in a completely different way.

2.1. Boundary behavior of subsolutions. With respect to subsolutions, the cleaning at the boundary does not change the nonlocal operator M.

LEMMA 2.3. *Let u be an upper semicontinuous function on $\overline{\Omega}$ and set*

$$\tilde{u}(x) = \begin{cases} \limsup_{\Omega \ni y \to x} u(y) & \text{if } x \in \partial\Omega, \\ \\ u(x) & \text{if } x \in \Omega. \end{cases} \tag{2.3}$$

Under assumptions H.3 *and* H.6*, then $M\tilde{u} = Mu$ on Ω.*

Proof. Since $\tilde{u} \le u$ on $\overline{\Omega}$ by construction, $M\tilde{u} \le Mu$; hence, it suffices to show that

$$\inf\{\tilde{u}(x+\xi)+c(\xi) : \xi \in \mathbb{R}^{\mathrm{N}}_+, x+\xi \in \partial\Omega\} \ge \inf\{u(x+\xi)+c(\xi) : \xi \in \mathbb{R}^{\mathrm{N}}_+, x+\xi \in \Omega\}$$

for all $x \in \Omega$. We now claim that the desired inequality follows by the following geometrical property of $\partial\Omega$: for any $x \in \Omega$ and $\xi \in \mathbb{R}^{\mathrm{N}}_+$ with $x + \xi \in \partial\Omega$, there is a sequence $r_n \to 0$ such that

$$\Omega \cap B(x+\xi, r_n) \cap \left(x + \mathbb{R}^{\mathrm{N}}_+\right) \ne \emptyset, \tag{2.4}$$

where $B(z, r)$ stands for the open ball in $\mathbb{R}^{\mathrm{N}}$ centered at z with radius r.

Indeed, let ξ_j be a sequence in $\mathbb{R}^{\mathrm{N}}_+$ such that $x + \xi_j \in \partial\Omega$ and $\tilde{u}(x+\xi_j)+c(\xi_j) \to \inf\{\tilde{u}(x+\xi)+c(\xi) : \xi \in \mathbb{R}^{\mathrm{N}}_+, x + \xi \in \partial\Omega\}$ as $j \to \infty$. If property (2.4) holds true, for any j there is a sequence $\xi_{j,n} \in \mathbb{R}^{\mathrm{N}}_+$ such that $x + \xi_{j,n} \in \Omega$ and $\xi_{j,n} \to \xi_j$ as $n \to \infty$; in particular for all j, n it holds that

$$u(x+\xi_{j,n})+c(\xi_{j,n}) \ge \inf\{u(x+\xi)+c(\xi) : \xi \in \mathbb{R}^{\mathrm{N}}_+, x + \xi \in \Omega\}.$$

Eventually the thesis follows by extracting the limit with respect to both n and j. Thus we need to check (2.4). The proof is trivial if $\xi \in \mathcal{I}nt(\mathbb{R}^{\mathrm{N}}_+)$. Otherwise, we assume for simplicity that the first component of ξ is zero. Since Ω is open, there is a sequence $x_n \in \Omega$ that converges to x and such that the first component of $x_n - x$ is strictly positive for all n. We set $\xi_n = x_n - x + P(x_n, \xi)$ and $r_n = 2|\xi_n - \xi|$. Notice also that the first component of ξ_n is strictly positive, so that $r_n > 0$. Besides, by force of assumption H.6, $r_n \to 0$ and $x+\xi_n \in \overline{\Omega} \cap B(x+\xi, r_n) \cap (x+\mathcal{I}nt(\mathbb{R}^{\mathrm{N}}_+))$. Finally, because $B(x+\xi, r_n) \cap (x + \mathcal{I}nt(\mathbb{R}^{\mathrm{N}}_+))$ is open, we get that (2.4) holds true. □

A relevant consequence of Lemma 2.3 is the following result, which will play a central role in the proofs of Theorems 3.1 and 4.6.

PROPOSITION 2.4. *Let assumptions* H.1–H.7 *hold and u be a subsolution to* (1.3)–(1.4)*. Then the function $\tilde{u}$ defined by* (2.3) *is a subsolution to* (1.3)–(1.4)*.*

Proof. By construction, $\tilde{u}$ is upper semicontinuous on $\overline{\Omega}$. At all $x \in \Omega$, the inequality $H(x, \tilde{u}, D\tilde{u}, D^2\tilde{u}) \le 0$ holds in the viscosity sense because $\tilde{u} \equiv u$ near x. Besides, since $\tilde{u}(x) = u(x) \le Mu(x)$, Lemma 2.3 implies that $\tilde{u}(x) \le M\tilde{u}(x)$.

If $x \in \partial\Omega$, two cases may happen: the first one is $u(x) \le \varphi(x)$. In that case, $\tilde{u}(x) \le u(x) \le \varphi(x)$, and then the proof is completed.

The second one is $u(x) > \varphi(x)$. Now, remembering Remark 2.2, [5, Proposition 4.1] yields that $x \in \Gamma_{\rm in}$. Next, by assumption H.7 there exists $r > 0$ such that $\partial\Omega \cap B_r(x) \subset \Gamma_{in}$. It suffices to check that $\max\{H\big(x, \tilde{u}, D\psi, D^2\psi\big),\ \tilde{u} - M\tilde{u}\} \le 0$ for all smooth test functions ψ such that x is a strict global maximum of $\tilde{u} - \psi$ on $\overline{\Omega} \cap B_r(x)$. To this aim, we introduce the function $y \mapsto \tilde{u}(y) - \psi(y) - \varepsilon/d(y)$. By classical arguments, for all $\varepsilon > 0$ this function achieves its maximum at $x_\varepsilon \in \Omega \cap \overline{B_r}(x)$, and one can prove that $x_\varepsilon \to x$, $u(x_\varepsilon) \to \tilde{u}(x)$, $\varepsilon/d(x_\varepsilon) \to 0$. In particular, x_ε is a local maximum point for $u - \psi - \varepsilon/d$ on $\Omega \cap B_r(x)$; therefore $\max\{H(x_\varepsilon, u, D\psi, D^2\psi), u - Mu\} \le 0$. So the same arguments of [5, Lemma 4.1] yield $H(x, \tilde{u}, D\psi, D^2\psi) \le 0$. Moreover, recalling Lemma 2.3, we get $\tilde{u}(x) = \lim_{\varepsilon\to 0} u(x_\varepsilon) \le \lim_{\varepsilon\to 0} M\tilde{u}(x_\varepsilon) \le M\tilde{u}(x)$ by the upper semicontinuity of $M\tilde{u}$ (see [14, Proposition 3.2]). □

Remark 2.5. It is easily seen that $\tilde{u}(x) \le M\tilde{u}(x)$ at all $x \in \overline{\Omega}$.

It is clear that the property stated by Lemma 2.3 does not hold for supersolutions.

EXAMPLE 2.6. *Take* $\Omega = (0,1)$, $\sigma \equiv 0$, $b \equiv -1$, c *any increasing function of class* $\mathcal{C}^1$, $f(x) > -c'(1-x) + \lambda\,[c(1-x) + k]$, *and*

$$\varphi(x) = \begin{cases} \mathrm{C}_o & \text{if } x = 0, \\ 0 & \text{if } x = 1, \end{cases}$$

where C_o *is any constant greater than or equal to* $c(1) + k$. *Then the function*

$$u(x) = \begin{cases} c(1-x) + k & \text{if } x \in [0,1), \\ 0 & \text{if } x = 1 \end{cases}$$

is a viscosity solution, which is discontinuous at the point $x = 1$. *Since* $Mu(x) = u(1) + c(1-x) + k$ *at all* $x \in \Omega$, *the discontinuity at the boundary point* $x = 1$ *plays an essential role and cannot be removed. Actually* $\tilde{u}(x) = c(1-x) + k$ *on* $[0,1]$ *is not a supersolution because it does not satisfy* (2.2) *at any* $x \in (0,1)$.

2.2. Boundary behavior of supersolutions. We begin by noticing that, under assumption H.9, a discontinuity at $\Gamma_{\rm in}$ may occur only if the optimal trajectory stands in jumping.

LEMMA 2.7. *We suppose that* H.1–H.7 *and* H.9 *hold. If* v *is a supersolution and* $x_o \in \Gamma_{\rm in}$ *is such that* $v(x_o) < \liminf_{\Omega \ni y \to x_o} v(y)$, *then* $v(x_o) \ge \min\{Mv(x_o), \varphi(x_o)\}$.

Proof. We assume by contradiction that $v(x_o) < \min\{Mv(x_o), \varphi(x_o)\}$. By semicontinuity arguments, we may suppose that $v(x_\varepsilon) < \min\{Mv(x_\varepsilon), \varphi(x_\varepsilon)\}$ for all sequences x_ε such that $x_\varepsilon \to x_o$ and $v(x_\varepsilon) \to v(x_o)$. Notice that we may assume without loss of generality that $x_\varepsilon \in \Gamma_{\rm in}$ for any ε small enough. Next, we take x_ε as a minimum point for the function

$$x \mapsto v(x) + \frac{|x - x_o|^2}{\varepsilon^2} - \frac{1}{\varepsilon^3} d(x).$$

Because v satisfies (1.8), then

$$H\left(x_\varepsilon, v(x_\varepsilon), -\frac{2}{\varepsilon^2}(x_\varepsilon - x_o) + \frac{1}{\varepsilon^3} Dd(x_\varepsilon), -\frac{2}{\varepsilon^2} I + \frac{1}{\varepsilon^3} D^2 d(x_\varepsilon)\right) \ge 0.$$

After computations we get

$$\sup_{\alpha\in\mathcal{A}}\left\{\operatorname{tr} a(x_\varepsilon,\alpha)+2b(x_\varepsilon,\alpha)\cdot(x_\varepsilon-x_o)+\varepsilon^2\left[\lambda v(x_\varepsilon)-f(x_\varepsilon,\alpha)\right]\right\}$$

$$\geq\frac{1}{\varepsilon}\inf_{\alpha\in\mathcal{A}}\left\{\frac{1}{2}\operatorname{tr}\left[a(x_\varepsilon,\alpha)D^2d(x_\varepsilon)\right]+b(x_\varepsilon,\alpha)\cdot Dd(x_\varepsilon)\right\}.$$

Passing to the limit as ε goes to zero gives a contradiction, because the left-hand side is bounded by virtue of H.1, while the right-hand side blows up because of H.9. □

In order to state a property of supersolutions that corresponds to Lemma 2.3 for subsolutions, we need to introduce the obstacle $\tilde{M}\varphi(x)$ defined by (1.10).

LEMMA 2.8. *Let v be a supersolution to* (1.3)–(1.4) *and set*

$$\tilde{v}(x)=\begin{cases}\liminf\limits_{\Omega\ni y\to x}v(y) & \text{if } x\in\Gamma_{\text{in}},\\ \\ v(x) & \text{if } x\in\overline{\Omega}\setminus\Gamma_{\text{in}}.\end{cases}\tag{2.5}$$

Under assumptions H.1–H.7, H.9*, then* $\min\{M\tilde{v},\tilde{M}\varphi\}\leq Mv$ *on* $\overline{\Omega}$.

Proof. We assume by contradiction that, at a certain $x\in\overline{\Omega}$, the desired inequality does not hold; equivalently, there exists $\xi_o\in\mathbb{R}^{\mathrm{N}}_+$, with $x+\xi_o\in\Gamma_{\text{in}}$, such that

$$Mv(x)=v(x+\xi_o)+c(\xi_o)+k,\tag{2.6}$$

$$v(x+\xi_o)<\liminf_{\Omega\ni y\to x+\xi_o}v(y),\tag{2.7}$$

$$v(x+\xi_o)+c(\xi_o)+k<\tilde{M}\varphi(x).\tag{2.8}$$

Since v is a supersolution, (2.7) and (2.8) imply that $v(x+\xi_o)\geq Mv(x+\xi_o)$, via Lemma 2.7. However, this is impossible because, in force of the subadditivity of c and of (2.6), we have that $Mv(x+\xi_o)\geq Mv(x)-c(\xi_o)>v(x+\xi_o)$. □

Eventually, we can remove the discontinuities at Γ_{in} of any supersolution to (1.3)–(1.4) and obtain a supersolution to the modified quasi-variational inequality

$$\max\left\{H\left(x,u,Du,D^2u\right),u-Mu,u-\tilde{M}\varphi\right\}=0\qquad\text{on }\Omega,\tag{2.9}$$

which satisfies the boundary condition (1.4) in the relaxed sense.

PROPOSITION 2.9. *Let assumptions* H.1–H.7, H.9 *hold and let v be a supersolution to* (1.3)–(1.4)*. Then the function $\tilde{v}$ defined by* (2.5) *is a supersolution to* (2.9)–(1.4).

Proof. By construction $\tilde{v}$ is lower semicontinuous on $\overline{\Omega}$ and $\tilde{v}\geq v$. Let $x\in\overline{\Omega}$ with $\tilde{v}(x)<\varphi(x)$ if $x\in\partial\Omega$ (otherwise there is nothing to prove): if $v(x)\geq Mv(x)$, then $\max\{\tilde{v}(x)-M\tilde{v}(x),\tilde{v}(x)-\tilde{M}\varphi(x)\}\geq 0$ by Lemma 2.8 and we are done. Otherwise, $H\left(x,v,Dv,D^2v\right)\geq 0$, and we need to check that $H(x,\tilde{v},D\tilde{v},D^2\tilde{v})\geq 0$ in the viscosity sense. $H(x,\tilde{v},D\tilde{v},D^2\tilde{v})\geq 0$ in the viscosity sense follows by the same argument of [5, Lemma 4.1] by force of the semicontinuity of Mv established by [14, Proposition 3.2]. □

We emphasize that, if u is any subsolution to (1.3)–(1.4), it is not true that $\tilde{u}$ is a subsolution to (2.9).

EXAMPLE 2.10. *Take Ω, σ, b, and c as in Example* 2.6*, $f(x)=-c'(1-x)+\lambda\left[c(1-x)+2k\right]$, and*

$$\varphi(x)=\begin{cases}c(1)+2k & \text{if } x=0,\\ 0 & \text{if } x=1.\end{cases}$$

In this case $u(x) = c(1-x) + 2k$ *is a viscosity solution, continuous on* $[0,1]$*, but it is not a subsolution to* (2.9) *because* $u(x) > \tilde{M}\varphi(x)$ *at all* $x \in [0,1]$*.*

3. The case when $\Gamma_{\rm in}$ is empty. This section concerns the case when, anytime that the diffusion degenerates along the normal direction to the boundary, there exists at least one continuous trajectory of (1.1) exiting from Ω with probability 1. So, any point of $\partial\Omega$ can be reached by means of a standard control, and the behavior at the boundary of the value function of the impulse control problem is similar to the standard one.

In view of attaining the continuity of the value function up to the boundary, we establish a strong comparison result for the related quasi-variational inequality.

THEOREM 3.1 (comparison principle). *Assume that* H.1–H.8 *hold and that* $\Gamma_{\rm in} = \emptyset$*. If* u *and* v *are a bounded upper semicontinuous subsolution and lower semicontinuous supersolution to* (1.3)–(1.4)*, then* $u \le v$ *in* Ω*. Moreover* $\tilde{u} \le v$ *in* $\overline{\Omega}$*, where* $\tilde{u}$ *is the subsolution defined in* (2.3)*.*

A relevant consequence of this comparison result is the characterization of the value function of the impulse control problem.

THEOREM 3.2. *Assume that* H.1–H.8 *hold and that* $\Gamma_{\rm in} = \emptyset$*. Then the value function* $\mathbf{U}$ *of the impulse control problem* (1.1)–(1.2) *is characterized in* Ω *as the unique viscosity solution to* (1.3)–(1.4)*. Moreover, it is continuous on* Ω *and can be continuously extended into* $\overline{\Omega}$*, by setting* $\mathbf{U}(x) = \limsup_{\Omega \ni y \to x} \mathbf{U}(y)$ *on* $\partial\Omega$*.*

Before entering into the details of the proofs, we want to emphasize that the assumption $\Gamma_{\rm in} = \emptyset$ cannot be dropped. To this end we sum up some properties of viscosity solutions that come out immediately by Theorem 3.1.

COROLLARY 3.3. *Assume that* H.1–H.8 *hold, that* $\Gamma_{\rm in} = \emptyset$*, and that* u *is a viscosity solution in the sense of Definition* 2.1*. Then* u *is continuous on* Ω *and*

$$u(x) \ge \limsup_{\Omega \ni y \to x} u(y) \qquad \text{on } \partial\Omega.$$

Moreover the function $\tilde{u}$ *defined as in* (2.3) *is the unique viscosity solution of* (1.3)–(1.4) *continuous on* $\overline{\Omega}$*.*

Next we show that the conclusions of Corollary 3.3 (and so the ones of Theorems 3.1 and 3.2) do not hold if there is some point of the boundary that can be reached only by jumping.

EXAMPLE 3.4. *Take* Ω*,* σ*,* b*,* c*,* f*, and* φ *as in Example* 2.6*. Now* $\Gamma_{\rm out} = \{0\}$*,* $\Gamma_{\rm in} = \{1\}$*, and for all* $\mathrm{C} \in [c(1) + k, \mathrm{C}_o]$*, the function*

$$u_{\mathrm{C}}(x) = \begin{cases} \mathrm{C} & \text{if } x = 0, \\ c(1-x) + k & \text{if } x \in (0,1), \\ 0 & \text{if } x = 1 \end{cases}$$

is a viscosity solution whose continuous extension to $\overline{\Omega}$ *is not a solution anymore.*

The phenomenon appearing on $\Gamma_{\rm out}$ *is the well-known boundary layer which characterizes viscosity solutions to the Dirichlet problem. In particular, choosing* $\mathrm{C} = c(1) + k$ *gives a solution which is continuous to* $\Gamma_{\rm out}$*. In contrast, the discontinuity coming up on* $\Gamma_{\rm in}$ *is intrinsic in the problem and cannot be removed, as observed in Example* 2.6*. When replacing the exact value of* u_{C} *with the limit from inside at* $\Gamma_{\rm in}$*, a bit of crucial information about the boundary datum is lost because* $M\tilde{u}_{\mathrm{C}}(x) > \tilde{M}\varphi(x)$ *near* $\Gamma_{\rm in}$*. Therefore, even though* $\tilde{u}_{\mathrm{C}}$ *satisfies* (1.8) *on* $\Gamma_{\rm in}$*, it fails to be a solution because* (2.2) *is no longer satisfied near* $\Gamma_{\rm in}$*.*

It is worth mentioning that the value function of the related impulse control problem is

$$\mathbf{U}(x) = \begin{cases} c(1-x)+k & \text{if } x \in [0,1), \\ 0 & \text{if } x = 1. \end{cases}$$

Thus, it is continuous in $\overline{\Omega} \setminus \Gamma_{\text{in}}$*, but its continuous extension to* $\overline{\Omega}$ *does not solve* (1.3).

Let us come to the proof of the strong comparison principle.

Proof of Theorem 3.1. The proof relies on establishing a comparison between the subsolution $\tilde{u}$ and the supersolution v. In order to deal with the nonlocal term M, we do not directly compare $\tilde{u}$ with v. Following an idea by [2], we define for any parameter $\mu \in (0,1)$

$$\hat{u} = (1-\mu)\,(\tilde{u} - \mathrm{B}), \qquad \hat{v} = v - \mathrm{B}, \qquad \hat{\varphi} = \varphi - \mathrm{B},$$

where $\mathrm{B} = \min\{0, \min\varphi, \min f/\lambda\}$. The functions $\hat{u}$ and $\hat{v}$ satisfy, respectively,

$$\max\{H(x,\hat{u},D\hat{u},D^2\hat{u}) + \lambda\mathrm{B}, \hat{u} - M\hat{u} + \mu k\} \le 0, \qquad x \in \Omega, \tag{3.1}$$

$$\min\{\max\{H(x,\hat{u},D\hat{u},D^2\hat{u}) + \lambda\mathrm{B}, \hat{u} - M\hat{u} + \mu k\}, \hat{u} - \hat{\varphi}\} \le 0, \quad x \in \partial\Omega, \tag{3.2}$$

$$\max\{H(x,\hat{v},D\hat{v},D^2\hat{v}) + \lambda\mathrm{B}, \hat{v} - M\hat{v}\} \ge 0, \qquad x \in \Omega, \tag{3.3}$$

$$\max\{H(x,\hat{v},D\hat{v},D^2\hat{v}) + \lambda\mathrm{B}, \hat{v} - M\hat{v}, \hat{v} - \hat{\varphi}\} \ge 0, \qquad x \in \partial\Omega. \tag{3.4}$$

The proof consists of showing that

$$\beta = \max_{\overline{\Omega}} (\hat{u} - \hat{v}) \le 0,$$

and it is achieved by making use of the standard technique of doubling variables and approaching the maximum point by means of two sequences x_n, y_n. The motivation for replacing $\tilde{u}$, v by $\hat{u}$, $\hat{v}$ is made clear by the following lemma.

LEMMA 3.5. *Let* x_n, y_n *be two sequences in* $\overline{\Omega}$ *such that* $x_n, y_n \to x_o \in \overline{\Omega}$ *and* $\hat{u}(x_n) - \hat{v}(y_n) \to \beta$*. Then* $\hat{v}(y_n) < M\hat{v}(y_n)$ *for all large* n*.*

Proof. We suppose by contradiction that there is a subsequence (that we still denote by n) such that $\hat{v}(y_n) \ge M\hat{v}(y_n)$, and we take $\xi_n \in \mathbb{R}^{\mathrm{N}}_+$ such that $y_n + \xi_n \in \overline{\Omega}$, $M\hat{v}(y_n) = \hat{v}(y_n + \xi_n) + c(\xi_n) + k$. Recalling Remark 2.5, we have

$$\hat{u}(x_n) - \hat{v}(y_n) \le \hat{u}(x_n + \eta_n) + c(\eta_n) + (1-\mu)k - \hat{v}(y_n + \xi_n) - c(\xi_n) - k$$

for all $\eta_n \in \mathbb{R}^{\mathrm{N}}_+$ such that $x_n + \eta_n \in \overline{\Omega}$. Besides, by classical compactness arguments we may assume without loss of generality that ξ_n converges to $\xi_o \in \mathbb{R}^{\mathrm{N}}_+$, with $x_o + \xi_o \in \overline{\Omega}$. Thus, choosing $\eta_n = P(x_n, \xi_o)$ and extracting the limit as $n \to 0$ gives the contradiction $\beta \le \hat{u}(x_o + \xi_o) - \hat{v}(x_o + \xi_o) - \mu k \le \beta - \mu k$. □

The inequality stated by Lemma 3.5 suggests that, when approaching a maximum point, $\hat{u}$ and $\hat{v}$ are close to being sub/supersolutions to the plain Dirichlet problem. Next, we suppose by contradiction that $\beta > 0$ and take a point $x_o \in \overline{\Omega}$ such that $\hat{u}(x_o) - \hat{v}(x_o) = \beta$. We reach a contradiction arguing separately from case to case.

Case $x_o \in \Omega$. We proceed as in the standard proof (see, for instance, [9]) by taking $(x_\varepsilon, y_\varepsilon)$ as a global maximum point for

$$\overline{\Omega}^2 \ni (x,y) \mapsto \hat{u}(x) - \hat{v}(y) - \frac{|x-y|^4}{\varepsilon^4} - |x - x_o|^4.$$

For all $\varepsilon > 0$, $H(x_\varepsilon, \hat{u}, D\hat{u}, D^2\hat{u}) + \lambda_B \leq 0$ by Remark 2.2, while $H(y_\varepsilon, \hat{v}, D\hat{v}, D^2\hat{v}) + \lambda_B \geq 0$ by Lemma 3.5. Eventually the thesis follows by classical arguments.

Case $x_o \in \Gamma_{\text{out}}$. Recalling Remark 2.2, [5, Proposition 4.1] yields that $\hat{u} \leq \hat{\varphi}$ on $\Gamma_{\text{out}} \cup \Gamma = \partial\Omega$. Hence, the assumption $\beta > 0$ implies that $\hat{v}(x_o) < \hat{\varphi}(x_o)$. Let us set

$$\psi_\varepsilon(y) = \frac{|y - x_o|^4}{\varepsilon^4} + \frac{1}{\varepsilon^2} d(y) - \frac{1}{2\varepsilon^3} d(y)^2.$$

It is easily seen that there exists a sequence y_ε of local minimum points for $\hat{v} + \psi_\varepsilon$ such that $y_\varepsilon \to x_o$ and $\hat{v}(y_\varepsilon) \to \hat{v}(x_o)$ as $\varepsilon \to 0$. In particular, we may suppose without loss of generality that $\hat{v}(y_\varepsilon) < \hat{\varphi}(y_\varepsilon)$ whenever $y_\varepsilon \in \partial\Omega$; in addition, Lemma 3.5 gives that $\hat{v}(y_\varepsilon) < M\hat{v}(y_\varepsilon)$ for small ε. Eventually (3.3)–(3.4) give that $H(x, \hat{v}, -D\psi_\varepsilon, -D^2\psi_\varepsilon) + \lambda_B \geq 0$ and, arguing as in the proof of [3, Proposition 1.1], one gets the contradiction $\mathcal{A}_{\text{in}}(x_o) \neq \emptyset$.

Case $x_o \in \Gamma$. As noticed while looking into the case $x_o \in \Gamma_{\text{out}}$, we already know that $\hat{u}(x_o) \leq \hat{\varphi}(x_o)$, and we have to check that the item $\hat{v}(x_o) < \hat{\varphi}(x_o)$ gives a contradiction. To begin, by replacing $\hat{v}$ with $\hat{v} + |\cdot - x_o|^4$, we may suppose that x_o is a strict maximum point. Next, we perturb $\hat{u}$ and $\hat{v}$ by means of a change of variable,

$$\hat{u}_\delta(x) = \omega_\delta^{-1}(\hat{u}(x)), \qquad \hat{v}_\delta(x) = \omega_\delta^{-1}\big(\hat{v}(x) + |x - x_o|^4\big),$$

where ω_δ is chosen close to identity, namely, $\omega_\delta'(s) = 1 - \delta e^{\omega_\delta(s)}$ and $\omega_\delta(0) = 0$. Moreover we set $\beta_\delta = \max\big\{\hat{u}_\delta(x) - \hat{v}_\delta(x) : x \in \overline{\Omega}\big\}$ and x_δ a maximum point. An easy computation gives that $x_\delta \to x_o$, $\beta_\delta \to \beta$, and $\hat{u}(x_\delta) - \hat{v}(x_\delta) \to \hat{u}(x_o) - \hat{v}(x_o)$, up to an extracted sequence. From now on, the proof proceeds as in [5, section 5.2], by force of Lemma 3.5. □

Remark 3.6. If $\partial\Omega = \Gamma_{\text{out}}$, Theorem 3.1 can be compared with [13, Theorem 3.1]: the main difference is that our proof does not need the sub/supersolutions to be "strong" in the sense of (1.5)–(1.6). Indeed, the comparison principle stated by Theorem 3.1 allows to enlarge the uniqueness class of [13, Theorem 4.1], including any viscosity solutions.

Next, if $\partial\Omega = \Gamma$, Theorem 3.1 can be compared with the result in [14]. Since we do not need to know a priori the behavior of the sub/supersolutions near the boundary, our nondegeneracy assumption H.8 is different from assumptions C.3 and C.4 of [14, Theorem 4.2]. On the other hand, following the proof of [14, Theorem 4.2], namely combining the iterative approximation scheme by Hanouzet and Joly [11] with the comparison principle stated by Theorem 3.1, gives the existence of a (unique) continuous viscosity solution.

Eventually we attain the characterization of the value function as the unique continuous viscosity solution to the quasi-variational inequality, as an easy consequence of Theorem 3.1.

Proof of Theorem 3.2. By virtue of the dynamic programming principle (see, for instance, [8, section III.1]), the value function satisfies

$$\mathbf{U}(x) = \inf_A \mathbb{E}\Bigg[\int_0^{T\wedge\tau_x} f(X_t^x, \alpha_t)\, e^{-\lambda t} dt + \sum_{\theta_i \leq T\wedge\tau_x} (c(\xi_i) + k)\, e^{-\lambda\theta_i} + 1_{\{T<\tau_x\}} \mathbf{U}\left(X_T^x\right) e^{-\lambda T} + 1_{\{T\geq\tau_x\}} \varphi\left(X_{\tau_x}^x\right) e^{-\lambda\tau_x} \Bigg]$$

for all $x \in \Omega$ and all stopping times T. Hence, standard arguments (see, for instance, [10, section V.3] and [4, section I]) give that $\mathbf{U}$ solves (1.3)–(1.4) in the viscosity

sense. Besides, Corollary 3.3 guarantees that any solution is continuous and that its extension, obtained by setting $\mathbf{U}(x) = \limsup_{\Omega \ni y \to x} \mathbf{U}(y)$ on $\partial\Omega$, is continuous in $\overline{\Omega}$ and still solves (1.3)–(1.4). Eventually, via Theorem 3.1, $\mathbf{U}$ is the unique continuous solution on Ω. □

4. The case when Γ_{in} is nonempty. Example 3.4 shows that, in general, if Γ_{in} is nonempty, we do not expect to have continuous solutions up to the boundary; in addition, we have to face the new difficulty that the continuous extension of the value function to $\overline{\Omega}$ does not satisfy (1.3). On the other hand, such situations are relevant for the applications to control theory, because a discontinuous value function at a boundary point reveals that the optimal trajectory stands in jumping to the boundary.

In this section, we first show that, in this case, it is possible to construct a number of viscosity solutions, which, in addition, are discontinuous inside Ω. This is due to the fact that the notion of relaxed boundary condition (1.7)–(1.8) does not capture all the information coming from (1.4) when the value function is discontinuous at Γ_{in}. Therefore, we enforce it by imposing the extra condition (1.9). Next, we characterize the value function as the unique viscosity solution fulfilling the strengthened notion of boundary condition, by means of a comparison result.

4.1. A suitable notion of boundary condition. With respect to the plain Dirichlet problem, the prescription of a boundary value is only a constraint at the boundary, which can be relaxed in the viscosity sense by substituting (1.4) with (1.7)–(1.8). When dealing with quasi-variational inequalities, the prescription of a boundary value is also a constraint inside Ω, because it is implicitly required that

$$u(x) \le \inf\left\{\varphi(x+\xi) + c(\xi) + k \,:\, \xi \in \mathbb{R}^{\mathrm{N}}_{+}, x+\xi \in \partial\Omega\right\} \qquad \text{in } \Omega. \tag{4.1}$$

If the diffusion is nondegenerate, the boundary condition (1.4) is fulfilled; therefore (4.1) is implied by requiring that $u \le Mu$ on Ω. However, if the diffusion degenerates at the boundary, a boundary layer arises and the constraint (4.1) can be violated. It is the case, for instance, if the optimal trajectory stands in jumping at a point $x \in \partial\Omega$: now $\mathbf{U}(x) = \varphi(x)$ and $\mathbf{U}(y) = M\mathbf{U}(y) = \mathbf{U}(x) + c(x-y) + k$ around x. The "standard" viscosity boundary condition only requires that the upper semicontinuous envelope of $\mathbf{U}$ satisfy the quasi-variational inequality at x and neglects that, when replacing $\mathbf{U}$ by its upper semicontinuous envelope, the obstacle $M\mathbf{U}$ is artificially increased all over Ω. Therefore this notion of boundary condition does not capture the constraint (4.1). As a consequence, it is not sufficient to pick up a unique solution, as shown by the following example.

EXAMPLE 4.1. *Take* $\Omega = (0,3)$, $\sigma \equiv 0$,

$$b(x) = \begin{cases} -(x-1)^2 & \text{if } x \in [0,1], \\ 0 & \text{if } x \in [1,2], \\ -(x-2)^2 & \text{if } x \in [2,3], \end{cases}$$

c *a strictly increasing function,* $f(x) \ge \lambda[c(3-x) + 2k]$, *and*

$$\varphi(x) = \begin{cases} c(3) + 2k & \text{if } x = 0, \\ 0 & \text{if } x = 3. \end{cases}$$

In that case $\Gamma_{\mathrm{out}} = \{0\}$, $\Gamma_{\mathrm{in}} = \{3\}$, *and jumping immediately to* Γ_{in} *is a better strategy than following any continuous trajectory. The value function is given by*

$$\mathbf{U}(x) = \begin{cases} c(3-x) + k & \text{if } x \in [0,3), \\ 0 & \text{if } x = 3. \end{cases}$$

Notice that the $\mathbf{U}$ *is continuous on* $\overline{\Omega} \setminus \Gamma_{\text{in}}$ *and lower semicontinuous on* $\overline{\Omega}$*, and that it fulfills the condition* $\mathbf{U} \leq \tilde{M}\varphi$ *on* $\overline{\Omega}$*. Moreover, its continuous extension on* $\overline{\Omega}$ *is not a solution anymore, by the same arguments of Example* 4.1.

On the other hand, for all $z \in (1,2)$ *the function*

$$u_z(x) = \begin{cases} c(3-x) + 2k & \text{if } x \in [0,z), \\ c(3-x) + k & \text{if } x \in [z,3), \\ 0 & \text{if } x = 3 \end{cases}$$

is a viscosity solution, which is discontinuous at the interior point z*. When taking the upper semicontinuous envelope of* u_z*, the information about the boundary datum on* Γ_{in} *is lost: removing the discontinuity at* Γ_{in} *artificially increases the nonlocal term* Mu_z^**, so that* $Mu_z^*(x) > \tilde{M}\varphi(x)$*.*

This example reveals that some selection criterion is needed for uniqueness. Replacing a subsolution with its upper semicontinuous envelope makes the term Mu increase and possibly exceed $M\phi$, so that some relevant information about the boundary datum is lost. Hence we need to give a more appropriate notion of the relaxed boundary condition.

Definition 4.1. *A function* u *which is locally bounded and upper semicontinuous on* $\overline{\Omega}$ *is a* selected viscosity subsolution *to* (1.3)–(1.4) *if it is a viscosity subsolution in the sense of Definition* 2.1 (*i.e., it fulfills* (2.2), (1.8)) *and, in addition, satisfies* (1.9)*.*

A locally bounded function u *is a* selected viscosity solution *to* (1.3)–(1.4) *if it is a viscosity solution in the sense of Definition* 2.1 *and, in addition, its upper semicontinuous envelope satisfies* (1.9)*.*

Remark 4.2. Let u be an upper semicontinuous function. Because in general $\limsup_{\Omega \ni y \to x} u(y) \leq u(x)$, the condition (1.9) is weaker than $u \leq \tilde{M}\varphi$ on $\overline{\Omega}$. On the other hand, since we do not ask a priori that the function $\overline{\Omega} \ni x \mapsto \tilde{M}\varphi(x)$ be upper semicontinuous, condition (1.9) is not implied by asking that $u(x) \leq \tilde{M}\varphi$ on Ω. Actually, the condition (1.9) is equivalent to asking that $\tilde{u} \leq \tilde{M}\varphi$ on $\overline{\Omega}$, where $\tilde{u}$ has been defined in (2.3).

We explicitly notice that any function is a selected viscosity solution if and only if its upper semicontinuous envelope is a selected viscosity subsolution and its lower semicontinuous envelope is a supersolution according to Definition 2.1. In view of Proposition 2.9, a selection criterion for supersolutions is not needed.

Up to modifying the values in the Γ_{in} part of the boundary, there is a one-to-one correspondence between the selected solutions to (1.3) and the solutions to (2.9) which do not jump downward at Γ_{in}.

Lemma 4.3. *If* u *is a selected solution to* (1.3)–(1.4)*, then*

$$w(x) = \begin{cases} u(x) & \text{if } x \in \overline{\Omega} \setminus \Gamma_{\text{in}}, \\ \liminf\limits_{\Omega \ni y \to x} u(y) & \text{if } x \in \Gamma_{\text{in}} \end{cases}$$

solves (2.9)–(1.4)*. Conversely, let* w *be a solution to* (2.9)–(1.4) *with the regularity property*

$$w_*(x) = \liminf_{\Omega \ni y \to x} w(y) \quad \text{for all } x \in \Gamma_{\text{in}}$$

(where w_* stands for the lower semicontinuous envelope of w) and set

$$u(x) = \begin{cases} w(x) & \text{if } x \in \overline{\Omega} \setminus \Gamma_{\text{in}}, \\ \min\left\{ \liminf_{\Omega \ni y \to x} w(y), \varphi(x) \right\} & \text{if } x \in \Gamma_{\text{in}}. \end{cases}$$

Then u is a selected solution to (1.3)–(1.4).

Proof. The first part of the statement is an immediate consequence of Proposition 2.9. With respect to the second part, we begin by noticing that w^* is a subsolution to (1.3)–(1.4). Moreover the same arguments of Proposition 2.4 yield that $u^*(x)$ is a subsolution to (1.3)–(1.4). Therefore, since u^* satisfies (1.9) by construction, it is a selected subsolution.

In order to check that the lower semicontinuous envelope of u is a supersolution to (1.3)–(1.4) in the sense of Definition 2.1, take $x \in \overline{\Omega}$ with $u_*(x) < \varphi(x)$ if $x \in \partial\Omega$ (otherwise there is nothing to prove). By construction, $u_*(x) = w_*(x)$ and $Mu_*(x) = \min\{Mw_*(x), \tilde{M}\varphi(x)\}$. If $w_*(x) \geq \min\{Mw_*(x), \tilde{M}\varphi(x)\}$, then $u_*(x) = w_*(x) \geq \min\{Mw_*(x), \tilde{M}\varphi(x)\} = Mu_*(x)$. Otherwise, $H(x, w_,* Dw_*, D^2 w_*) \geq 0$ and the same arguments of the proof of Proposition 2.9 yield that $H(x, u_*, Du_*, D^2 u_*) \geq 0$. □

As our goal relies on eliminating solutions which are not related to the impulse control problem, we have to verify that the value function is a selected viscosity solution.

PROPOSITION 4.4. *The value function of the impulse control problem* (1.1)–(1.2) *is a selected viscosity solution to* (1.3)–(1.4).

Proof. Proceeding as in the proof of Theorem 3.2, one gets that the value function $\mathbf{U}$ solves (1.3)–(1.4) according to Definition 2.1. On the other hand, at all $x \in \overline{\Omega}$ and for all $\xi \in \mathbb{R}^{\mathrm{N}}_+$ such that $x + \xi \in \overline{\Omega}$, one may chose the control $\theta_o = 0, \theta_1 = \infty, \xi_o = \xi$. Therefore (1.2) gives that $\mathbf{U}(x) \leq \varphi(x + \xi) + c(\xi) + k$, and taking the infimum over all ξ gives $\mathbf{U}(x) \leq \tilde{M}\varphi(x)$ at all $x \in \overline{\Omega}$. □

4.2. Comparison principle. We are now ready to characterize the value function as the unique selected viscosity solution.

THEOREM 4.5. *Under assumptions* H.1–H.9*, the value function* $\mathbf{U}$ *of the impulse control problem* (1.1)–(1.2) *is characterized in* Ω *as the unique selected viscosity solution to* (1.3)–(1.4)*. Moreover, it is continuous on* Ω *and can be continuously extended into* $\overline{\Omega} \setminus \Gamma_{\text{in}}$ *by setting*

$$\mathbf{U}(x) = \begin{cases} \limsup_{\Omega \ni y \to x} \mathbf{U}(y) & \text{if } x \in \Gamma_{\text{out}} \cup \Gamma, \\ \min\left\{ \liminf_{\Omega \ni y \to x} \mathbf{U}(y), \varphi(x) \right\} & \text{if } x \in \Gamma_{\text{in}}. \end{cases} \tag{4.2}$$

This characterization is achieved by means of the following comparison result.

THEOREM 4.6 (comparison principle). *Under assumptions* H.1–H.9*, if u is a bounded upper semicontinuous selected subsolution and v is a bounded lower semicontinuous supersolution to* (1.3)–(1.4)*, then $u \leq v$ in Ω. Moreover, $\tilde{u} \leq \tilde{v}$ in $\overline{\Omega}$, where $\tilde{u}$ and $\tilde{v}$ have been defined in* (2.3) and (2.5)*, respectively.*

Before entering into the details of the proof of the comparison principle, we show how it brings us to Theorem 4.5. To this end, we first list the properties of viscosity solutions that arise from Theorem 4.6.

COROLLARY 4.7. *Assume that* H.1–H.9 *hold and let* u *be a selected viscosity solution to* (1.3)–(1.4). *Then* u *is continuous on* Ω *and*

$$\begin{aligned} u(x) &\geq \limsup_{\Omega \ni y \to x} u(y) \qquad \text{on } \Gamma_{\text{out}} \cup \Gamma, \\ u(x) &\leq \liminf_{\Omega \ni y \to x} u(y) \qquad \text{on } \Gamma_{\text{in}}. \end{aligned}$$

Moreover, the function

$$\underline{u}(x) = \begin{cases} u(x) & \text{if } x \in \Omega, \\ \limsup_{\Omega \ni y \to x} u(y) & \text{if } x \in \Gamma_{\text{out}} \cup \Gamma, \\ \min\left\{ \liminf_{\Omega \ni y \to x} u(y), \varphi(x) \right\} & \text{if } x \in \Gamma_{\text{in}} \end{cases}$$

is continuous on $\overline{\Omega} \setminus \Gamma_{\text{in}}$, *still is a selected viscosity solution, and is the minimal bounded solution to* (1.3)–(1.4) *(according to Definition* 2.1*).*

Notice that, in view of Example 4.1, the continuous extension of a solution to $\overline{\Omega}$ generally is not a solution.

Proof. The first part of the statement is a trivial consequence of Theorem 4.6, and we prove only that $\underline{u}$ is the minimal solution. By taking advantage of Lemma 4.3, one may easily obtain that $\underline{u}$ is a selected solution by checking that

$$w(x) = \begin{cases} u(x) & \text{if } x \in \Omega, \\ \limsup_{\Omega \ni y \to x} u(y) & \text{if } x \in \Gamma_{\text{out}} \cup \Gamma, \\ \liminf_{\Omega \ni y \to x} u(y) & \text{if } x \in \Gamma_{\text{in}} \end{cases}$$

solves (2.9)–(1.4).

Next we prove that $\underline{u}$ is the minimal solution. First of all, we observe that any viscosity solution which lacks property (1.9) is bigger (at least at some point) than any selected viscosity solution. Therefore, it suffices to show that $\underline{u} \leq v$ on $\overline{\Omega}$ for any bounded selected viscosity solution v. However, the comparison principle stated by Theorem 4.6 implies that $\underline{u} = u = v$ on Ω and $v(x) \geq \underline{u}(x)$ for all $x \in \Gamma_{\text{out}} \cup \Gamma$. Hence, it remains to show that $\underline{u} \leq v$ on Γ_{in}.

To this end we suppose by contradiction that $v(x) < \underline{u}(x)$ at some $x \in \Gamma_{\text{in}}$; then Lemma 2.7 yields that $v(x) \geq \min\{Mv(x), \varphi(x)\}$ and, because $v(x) < \varphi(x)$, $v(x) \geq Mv(x)$, indeed. Set $\xi_o \in \mathbb{R}^{\text{N}}_+$ such that $Mv(x) = v(x+\xi_o) + c(\xi_o) + k$: in particular, $\xi_o \neq 0$ and $M\underline{u}(x) \geq \underline{u}(x) > v(x) \geq v(x+\xi_o) + c(\xi_o) + k$. Therefore $v(x+\xi_o) < \underline{u}(x+\xi_o)$ and $x+\xi_o \in \Gamma_{\text{in}}$. Iterating these arguments brings the existence of two sequences $\xi_n \in \mathbb{R}^{\text{N}}_+$, $\xi_n \neq 0$, and $y_n = x + \sum_{j=0}^{n+1} \xi_j \in \overline{\Omega}$ for which

$$v(x) \geq v(y_n) + \sum_{j=0}^{n+1} c(\xi_j) + (n+1)k.$$

However, this is absurd because it implies that

$$\inf_{\overline{\Omega}} v \le \lim_{n\to\infty} v(y_n) \le v(x) - \lim_{n\to\infty} \left[\sum_{j=0}^{n+1} c(\xi_j) + (n+1)k\right] = -\infty. \qquad \square$$

Corollary 4.7 immediately implies the result stated by Theorem 4.5. We conclude this section by proving the comparison result.

Proof of Theorem 4.6. We follow the same scheme of the proof of Theorem 3.1, by replacing $\tilde{u}$ and $\tilde{v}$ with

$$\hat{u} = (1-\mu)\,(\tilde{u} - \mathrm{B})\,, \qquad\qquad \hat{v} = \tilde{v} - \mathrm{B}.$$

We recall that $\hat{u}$ satisfies (3.1)–(3.2) and, in addition,

$$\hat{u} \le \tilde{M}\hat{\varphi} - \mu k \qquad \text{on } \overline{\Omega}. \tag{4.3}$$

Besides, $\hat{v}$ satisfies

$$\max\Big\{H(x,\hat{v},D\hat{v},D^2\hat{v}) + \lambda\mathrm{B}, \hat{v} - M\hat{v}, \hat{v} - \tilde{M}\hat{\varphi}\Big\} \ge 0, \qquad x \in \Omega, \tag{4.4}$$

$$\max\Big\{H(x,\hat{v},D\hat{v},D^2\hat{v}) + \lambda\mathrm{B}, \hat{v} - M\hat{v}, \hat{v} - \tilde{M}\hat{\varphi}, \hat{v} - \hat{\varphi}\Big\} \ge 0, \ x \in \partial\Omega. \tag{4.5}$$

The proof consists of checking that

$$\beta = \max_{\overline{\Omega}} (\hat{u} - \hat{v}) \le 0,$$

and it is achieved arguing by contradiction. The role of Lemma 3.5 is now played by the following result.

LEMMA 4.8. *Let x_n, y_n be two sequences in $\overline{\Omega}$ such that*

$$x_n, y_n \to x_o \in \overline{\Omega},$$

$$\hat{u}(x_n) - \hat{v}(y_n) \to \beta > 0.$$

Then $\hat{v}(y_n) < \min\{M\hat{v}(y_n), \tilde{M}\hat{\varphi}(y_n)\}$ for all large n.

Proof. We suppose by contradiction that there is a subsequence (that we still denote by n) such that $\hat{v}(y_n) \ge \min\{M\hat{v}(y_n), \tilde{M}\hat{\varphi}(y_n)\}$. Without loss of generality, we may assume that one of the following items is fulfilled:

(a) for all n, there exists $\xi_n \in \mathbb{R}^{\mathrm{N}}_+$ such that $y_n + \xi_n \in \overline{\Omega} \setminus \Gamma_{\mathrm{in}}$ and

$$\min\Big\{M\hat{v}(y_n), \tilde{M}\hat{\varphi}(y_n)\Big\} = \hat{v}(y_n + \xi_n) + c(\xi_n) + k;$$

(b) for all n, there exists $\xi_n \in \mathbb{R}^{\mathrm{N}}_+$ such that $y_n + \xi_n \in \Gamma_{\mathrm{in}}$ and

$$\min\Big\{M\hat{v}(y_n), \tilde{M}\hat{\varphi}(y_n)\Big\} = \hat{\varphi}(y_n + \xi_n) + c(\xi_n) + k.$$

In the first case, the thesis is obtained as in Lemma 3.5. Otherwise, because Γ_{in} is closed by hypothesis H.7, we may assume without loss of generality that ξ_n converges

to $\xi_o \in \mathbb{R}^N_+$ with $x_o+\xi_o \in \Gamma_{\rm in}$. Therefore, by making use of the property (4.3) at the point x_o, we obtain

$$\hat u(x_n) - \hat v(y_n) \le \hat u(x_n) - \hat u(x_o) + \hat\varphi(x_o+\xi_o) + c(\xi_o) + (1-\mu)k - \hat\varphi(y_n+\xi_n) - c(\xi_n) - k.$$

Eventually, by taking advantage of the semicontinuity of $\hat u$ and of the continuity of $\hat\varphi$, c, passing to the limit as $n \to \infty$ gives the contradiction $\beta \le -\mu k < 0$. □

Next, we take a point $x_o \in \overline\Omega$ such that $\hat u(x_o) - \hat v(x_o) = \beta > 0$, and we reach a contradiction arguing separately from case to case. In view of Lemma 4.8, the cases $x_o \in \Omega \cup \Gamma_{\rm out} \cup \Gamma$ may be dealt with as in the proof of Theorem 3.1. Therefore, it remains to study the case $x_o \in \Gamma_{\rm in}$.

Case $x_o \in \Gamma_{\rm in}$. Take $(x_\varepsilon, y_\varepsilon)$ as a global maximum point for

$$\overline\Omega^2 \ni (x,y) \mapsto \hat u(x) - \hat v(y) - \frac{|x-y|^4}{\varepsilon^4} - |y-x_o|^4 - \frac{\varepsilon}{d(y)},$$

and notice that $x_\varepsilon, y_\varepsilon \to x_o$ and $\hat u(x_\varepsilon) - \hat v(y_\varepsilon) \to \beta$ as ε goes to zero; in particular, $x_\varepsilon \in \Omega \cup \Gamma_{\rm in}$ and $y_\varepsilon \in \Omega$. Next, via Remark 2.2, [5, Proposition 4.2] yields that $H(x_\varepsilon, \hat u, D\hat u, D^2\hat u) + \lambda_{\rm B} \le 0$. In addition (4.4) and Lemma 4.8 imply that $H(y_\varepsilon, \hat v, D\hat v, D^2\hat v) + \lambda_{\rm B} \ge 0$. Therefore the thesis follows by standard arguments. □

5. Existence of solution: A constructive procedure. We conclude this paper by producing a selected viscosity solution by making use of the iterative approximation scheme introduced by Hanouzet and Joly in [11]. This procedure has been used before in [14, Theorem 4.2], where a solution to (1.3)–(1.4), continuous on $\overline\Omega$, has been produced as the uniform limit of the sequence:

- u_o is the solution to the plain Dirichlet problem (1.3.o)–(1.4),
- for all $n \ge 1$, u_n is the solution to the variational inequality

$$(1.3.n) \qquad \max\left\{H\left(x, u_n, Du_n, D^2u_n\right), u_n - Mu_{n-1}\right\} = 0 \qquad \text{on } \Omega,$$

satisfying the boundary condition (1.4).

If $\Gamma_{\rm in} \neq \emptyset$, in general the sequence u_n does not converge to the value function of the control problem.

EXAMPLE 5.1. *Take Ω, σ, b, φ as in Example* 4.1, *c of class $\mathcal{C}^1$ with $c' > 0$, and $f(x) = b(x)c'(3-x) + \lambda\,[c(3-x) + 2k]$. It is easy to check that $u_o(x) = c(3-x) + 2k$ is the unique solution in $\mathcal{C}(\overline\Omega)$ to the Dirichlet problem* (1.3.o)–(1.4). *In addition, $Mu_o = u_o + k$ on $\overline\Omega$, so that u_o also solves* (1.3.1)–(1.4) *and, by iteration, $u_n = u_o$ for all $n \in \mathbb{N}$. Actually u_o is a solution to* (1.3)–(1.4) *continuous on $\overline\Omega$, but $\tilde M\varphi = u_o(x) - k$. Hence u_o does not satisfy* (1.9) *and differs from the value function of the related control problem (whose explicit form has been given in Example* 4.1*).*

Notice that, if we do not superimpose the condition (1.9), *any information about the boundary cost on $\Gamma_{\rm in} = \{3\}$ is forgotten just in the zeroth step of the iterative scheme: indeed, u_o solves the Dirichlet problem with any boundary cost $\hat\varphi$ such that $\hat\varphi(3) \le 2k$.*

Therefore, in order to achieve convergence to the value function, it is necessary to add the information coming from the $\Gamma_{\rm in}$-part of the boundary into the iterative scheme. This allows us to exploit the stability of a modified version of the monotone iterative scheme by Hanouzet and Joly.

THEOREM 5.2. *Assume that* H.1–H.9 *hold and that $\tilde M\varphi \in \mathcal{C}(\overline\Omega)$. Then there exists a selected viscosity solution $u \in \mathcal{C}\left(\overline\Omega \setminus \Gamma_{\rm in}\right)$ to* (1.3)–(1.4). *Such a solution has*

the form

$$u(x) = \begin{cases} w(x), & x \in \overline{\Omega} \setminus \Gamma_{\text{in}}, \\ \min\{w(x), \varphi(x)\}, & x \in \Gamma_{\text{in}}, \end{cases}$$

where $w \in \mathcal{C}(\overline{\Omega})$ *is the uniform limit of the sequence:*

- u_o *is the solution to the plain Dirichlet problem* (1.3.o)–(1.4)*,*
- *for all* $n \geq 1$*,* u_n *is the solution to the variational inequality*

$$\max\Big\{H\big(x, u_n, Du_n, D^2u_n\big), u_n - Mu_{n-1}, u_n - \tilde{M}\varphi\Big\} = 0 \quad \text{on } \Omega, \tag{2.9.n}$$

satisfying the boundary condition (1.4)*.*

The proof of Theorem 5.2 requires the study of variational inequalities of type

$$\max\big\{H\big(x, v, Dv, D^2v\big), v - \psi_1, v - \psi_2\big\} = 0 \qquad \text{on } \Omega. \tag{5.1}$$

We begin by noticing that (5.1)–(1.4) may be interpreted as a Hamilton–Jacobi–Bellman equation after redefining the set of the controls as $\hat{\mathcal{A}} = \mathcal{A} \times \{0, 1, 2\}$ and the coefficients of the dynamics and the running cost as

$$\hat{\sigma}(x, \alpha, i) = \begin{cases} \sigma(x, \alpha) & \text{if } i = 0, \\ 0 & \text{if } i = 1, 2, \end{cases}$$

$$\hat{b}(x, \alpha, i) = \begin{cases} b(x, \alpha) & \text{if } i = 0, \\ 0 & \text{if } i = 1, 2, \end{cases}$$

$$\hat{f}(x, \alpha, i) = \begin{cases} f(x, \alpha) & \text{if } i = 0, \\ \psi_i(x) & \text{if } i = 1, 2. \end{cases}$$

In particular, the strong comparison principle [5, Theorem 2.1] applies, under assumptions H.1–H.5, H.7, H.8, whenever $\psi_i \in \mathcal{C}(\overline{\Omega})$, as $i = 1, 2$. Therefore, the proof of the next well-posedness result follows from a standard application of the technique of half-relaxed limits by Barles and Perthame [4].

PROPOSITION 5.3. *Let* $\psi_1, \psi_2 \in \mathcal{C}(\overline{\Omega})$*. Under assumptions* H.1–H.5*,* H.7*,* H.8*, there exists a unique continuous viscosity solution to the variational inequality* (5.1)–(1.4)*.*

Finally we establish the convergence of the modified Hanouzet and Joly scheme $(2.9.n)_n$.

Proof of Theorem 5.2. Because of Lemma 4.3, it suffices to show that w solves (2.9)–(1.4). We begin by noticing that, by virtue of the Perron method [9, Theorem 4.1] and of the strong comparison principle [5, Theorem 2.1], the Dirichlet problem (1.3.o)–(1.4) has a unique solution u_o in $\mathcal{C}(\overline{\Omega})$.

Next, [14, Proposition 3.2] yields that $Mu_o \in \mathcal{C}(\overline{\Omega})$, while $\tilde{M}\varphi \in \mathcal{C}(\overline{\Omega})$ by hypothesis. Hence, Proposition 5.3 guarantees the existence of a solution $u_1 \in \mathcal{C}(\overline{\Omega})$ to (2.9.1)–(1.4). In addition, u_1 is a subsolution to (1.3.o)–(1.4), so that [5, Theorem 2.1] gives that $u_1 \leq u_o$.

Again, [14, Proposition 3.2] yields that $Mu_1 \in \mathcal{C}(\overline{\Omega})$, and Proposition 5.3 guarantees the existence of a solution $u_2 \in \mathcal{C}(\overline{\Omega})$ to (1.3.2)–(1.4). Since $u_1 \leq u_o$, $Mu_1 \leq Mu_o$,

$$\max\Big\{H\big(x, u_2, Du_2, D^2u_2\big), u_2 - Mu_o, u_2 - \tilde{M}\varphi\Big\}$$

$$\leq \max\Big\{H\big(x, u_2, Du_2, D^2u_2\big), u_2 - Mu_1, u_2 - \tilde{M}\varphi\Big\} \leq 0.$$

Thus u_2 is a subsolution to (2.9.1)–(1.4), and [5, Theorem 2.1] gives that $u_2 \le u_1$. By iterating these arguments, we obtain a decreasing sequence $u_n \in \mathcal{C}(\overline{\Omega})$.

On the other hand, up to replacing φ by $\varphi - \mathrm{B}$ and f by $f + \lambda \mathrm{B}$, with $\mathrm{B} = \min\{0, \min \varphi, \min f/\lambda\}$, we may suppose without loss of generality that $\varphi, f \ge 0$, so that 0 is a subsolution to all problems (2.9.n)–(1.4), and [5, Theorem 2.1] guarantees that $u_n \ge 0$ on $\overline{\Omega}$ for all n.

Afterward, the same arguments of the proof of [14, Theorem 4.2] give that

$$u_{n+1} - u_{n+2} \le (1-\mu)^n \|u_o\|_{\mathcal{C}(\overline{\Omega})} \qquad \text{on } \overline{\Omega},$$

where $\mu < 1$ such that $\mu \|u_o\|_{\mathcal{C}(\overline{\Omega})} \le k$. Therefore the sequence u_n converges to a function $w \in \mathcal{C}(\overline{\Omega})$, uniformly on $\overline{\Omega}$. Eventually, the stability result [16, Proposition I.3] implies that w is a solution to (2.9)–(1.4). □

6. Conclusions. The counterexamples 4.1 and 5.1 show that reading the boundary condition (1.4) in the "standard" viscosity sense (1.7)–(1.8) is underdetermining when dealing with nonlocal problems such as (1.3).

In these cases, the loss of information caused by the boundary layer propagates into the interior of Ω. Thus the additional request $H(x, u, Du, D^2u) = 0$ at the boundary points where loss of boundary data may occur is not sufficient to offset such loss of information. Actually, it is needed to introduce the selection criterion (1.9) in order to spread the information coming from the boundary condition into all Ω.

Eventually, the triplet of conditions (1.7)–(1.8)–(1.9) seems to be the suitable way to relax the boundary condition, with respect to a nonlocal problem such as (1.3).

Acknowledgment. The author wishes to thank Prof. Guy Barles for having proposed to her the study of this problem and for his useful advice.

OBSERVATION AND CONTROL OF VIBRATIONS IN TREE-SHAPED NETWORKS OF STRINGS*

RENÉ DÁGER†

Abstract. In this paper we study the controllability problem for a system that models the vibrations of a controlled tree-shaped network of vibrating elastic strings. The control acts through one of the exterior nodes of the network. With the help of the d'Alembert representation formula for the solutions of the one-dimensional wave equation, we find certain linear relations between the traces of the solutions at the nodes of the network. These relations allow us to prove a weighted observability inequality with weights that may be explicitly computed in terms of the eigenvalues of the associated elliptic problem. We characterize the class of trees for which all those weights are different from zero, which leads to the spectral controllability of the system. Additionally, we consider the same one-node control problem for several networks that are controlled simultaneously.

Introduction. In this paper we study the one-node controllability property of the vibrations of a planar network (i.e., several strings connected at their ends) of elastic homogeneous strings. That is, we analyze the possibility of driving to rest the motion of the network produced by an initial deformation of its strings, by means of a control applied through one of the nodes.

The network considered in this paper coincides at rest with a planar, finite, connected graph without closed paths, whose edges are straight segments. The deformations of the strings of the network are assumed to be transverse to the plane determined by the at-rest graph. The deformation of every string is expressed by means of a scalar function, defined on the edge of the graph that corresponds to the string and satisfying the one-dimensional (1-d) wave equation. At the interior nodes of the network, i.e., those where the strings are coupled, it is assumed that the displacements of all the strings coincide and that the sum of their tensions is equal to zero. These conditions express the continuity of the network and the balance of forces at the junction points. A control acts on one of the exterior nodes that regulates its displacement. The remaining exterior nodes are supposed to be clamped; that is, their displacements are equal to zero.

By now, there is an extensive literature devoted to the nodal controllability and stabilizability of networks (see, e.g., [7, 8] and the references therein). The main tool used to solve these problem has been the Hilbert uniqueness method, introduced by Lions [10], combined with multiplier and characteristic methods.

The question of the nodal controllability of networks of strings was first raised by Rolewicz in [12], where a network controlled at all its nodes was studied. Later on, Schmidt introduced in [13] the model of a network controlled at exterior (simple)

nodes as considered in this paper, and proved the exact controllability of networks supported by tree-shaped graphs if all but one of the exterior nodes are controlled.

More general hyperbolic systems on graphs, including Timoshenko-beam models, have been considered by Lagnese, Leugering, and Schmidt in a series of papers which are collected in [8], where again exact controllability and stabilizability from exterior nodes were studied. These authors also noticed that the controllability property, even in an approximate sense, may fail for systems with rationally dependent physical characteristics supported on graphs containing cycles, or when two or more exterior nodes are left uncontrolled. This fact led to the question of characterizing those networks which are controllable under the action of a small number of controls. This problem was then studied by Leugering and Zuazua in [9] for a three-string star-shaped network controlled from a single exterior node. They found that the network is controllable if and only if the ratio of the lengths of the uncontrolled strings is an irrational number.

This paper extends the results in [9] for general tree-shaped networks controlled from the root. Our main results are related to the possibility of proving weighted observability inequalities for the solutions of the system modelling the network. Under certain conditions imposed over the lengths of the strings of the networks, which are verified in a generic sense, those observability results allow one to obtain information on the controllability properties of the tree-shaped networks from one exterior node. Thus, we provide a complete answer to the one-node controllability problem for tree-shaped networks.

1. Notation and statement of the problem.

1.1. Notation for the elements of the graph. In this section, we introduce precise notation for the elements of the rest configuration graph. This is needed to write the equations of the motion of the network in a way that takes into account the topological structure of the graph.

Let $\mathcal{A}$ be a planar, connected graph without closed paths. According to the usual terminology in graph theory, those graphs will be called *trees*. By the multiplicity of a vertex of $\mathcal{A}$ we mean the number of edges that branch out from that vertex. If the multiplicity is equal to one, the vertex is called exterior; otherwise, it is said to be interior. We assume that the graph $\mathcal{A}$ does not contain vertices of multiplicity two, since they are irrelevant for our model.

In what follows, we describe a procedure for indexing the edges and vertices of the graph. In Figure 1.1 an example is given of a tree with indices defined according to this rule. First, we choose an exterior vertex and denote it by $\mathcal{R}$. It is called the root of $\mathcal{A}$. The remaining edges and vertices will be denoted by $\mathbf{e}_{\bar\alpha}$ and $\mathcal{O}_{\bar\alpha}$, respectively, where $\bar\alpha = (\alpha_1, \dots, \alpha_k)$ is a multi-index (possibly empty) of variable length k defined by recurrence for every edge in the following way.

For the edge containing the root $\mathcal{R}$ we choose the empty index. Thus, that edge is denoted by $\mathbf{e}$ and its vertex different from $\mathcal{R}$ is denoted by $\mathcal{O}$.

Assume now that the interior vertex $\mathcal{O}_{\bar\alpha}$, contained in the edge $\mathbf{e}_{\bar\alpha}$, has multiplicity equal to $m_{\bar\alpha}+1$. This means that there are $m_{\bar\alpha}$ edges, different from $\mathbf{e}_{\bar\alpha}$, that branch out from $\mathcal{O}_{\bar\alpha}$. We denote these edges by $\mathbf{e}_{\bar\alpha\circ\beta}$, $\beta = 1, \dots, m_{\bar\alpha}$, and the other vertex of the edge $\mathbf{e}_{\bar\alpha\circ\beta}$ by $\mathcal{O}_{\bar\alpha\circ\beta}$. Here, $\bar\alpha\circ\beta$ represents the index $(\alpha_1, \dots, \alpha_k, \beta)$, obtained by adding a new component β to the index $\bar\alpha = (\alpha_1, \dots, \alpha_k)$. In general, if $\bar\alpha = (\alpha_1, \dots, \alpha_k)$ and $\bar\beta = (\beta_1, \dots, \beta_m)$, then $\bar\alpha\circ\bar\beta$ will denote the multi-index of length $k+m$ defined by $\bar\alpha\circ\bar\beta = (\alpha_1, \dots, \alpha_k, \beta_1, \dots, \beta_m)$.

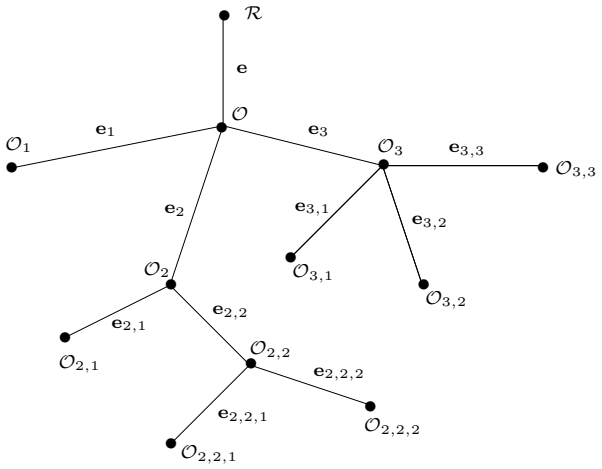

FIG. 1.1. *A tree with indices for its vertices and edges.*

Now let $\mathcal{M}$ be the set of the interior vertices of $\mathcal{A}$, and $\mathcal{S}$ the set of exterior vertices, except $\mathcal{R}$, and define

$$\mathcal{I}_{\mathcal{M}} = \{\bar{\alpha}; \quad \mathcal{O}_{\bar{\alpha}} \in \mathcal{M}\}, \qquad \mathcal{I}_{\mathcal{S}} = \{\bar{\alpha}; \quad \mathcal{O}_{\bar{\alpha}} \in \mathcal{S}\},$$

which are the sets of the indices of the interior and exterior vertices (except $\mathcal{R}$), respectively. Note that with these notations, we admit the empty multi-index, which corresponds to the vertex $\mathcal{O}$ and belongs to one of the sets $\mathcal{I}_{\mathcal{M}}$ or $\mathcal{I}_{\mathcal{S}}$. Finally, $\mathcal{I} = \mathcal{I}_{\mathcal{S}} \bigcup \mathcal{I}_{\mathcal{M}}$ is the set of the indices of all the vertices, except that of the root $\mathcal{R}$.

Further, for $\bar{\alpha} \in \mathcal{I}_{\mathcal{M}}$, the sets

$$\mathcal{A}_{\bar{\alpha}} = \left\{\mathbf{e}_{\bar{\alpha}\circ\bar{\beta}}; \quad \bar{\alpha}\circ\bar{\beta} \in \mathcal{I}\right\}$$

are called subtrees of $\mathcal{A}$. Note that $\mathcal{A}_{\bar{\alpha}}$ is formed by the edges having indices with a common initial part $\bar{\alpha}$. This means that $\mathcal{A}_{\bar{\alpha}}$ is also a tree branching out from the vertex of $\mathbf{e}_{\bar{\alpha}}$ different from $\mathcal{O}_{\bar{\alpha}}$. Then, if one chooses that vertex as the root $\mathcal{R}_{\bar{\alpha}}$ of $\mathcal{A}_{\bar{\alpha}}$ and denotes by $\mathbf{e}^{\bar{\alpha}}_{\bar{\beta}}$ the edge with index $\bar{\beta}$ in $\mathcal{A}_{\bar{\alpha}}$ according to the numbering rule defined above for trees, it holds that

$$\mathbf{e}_{\bar{\alpha}\circ\bar{\beta}} = \mathbf{e}^{\bar{\alpha}}_{\bar{\beta}}, \qquad \mathcal{O}_{\bar{\alpha}\circ\bar{\beta}} = \mathcal{O}^{\bar{\alpha}}_{\bar{\beta}}.$$

In order to prove properties of trees, we shall often proceed by induction with respect to the largest length of the indices $\bar{\alpha}$ used to number the edges according to the procedure described above. To do this we should prove that (1) the property is true for the simplest case of a one-edged tree (i.e., the corresponding network is formed by a single string) and also that (2) if the property is true for all the subtrees $\mathcal{A}_1, \ldots, \mathcal{A}_m$ branching out from $\mathcal{O}$, then it is also true for the whole tree $\mathcal{A}$. In what follows, such a process will be called simply induction.

Furthermore, the length of the edge $\mathbf{e}_{\bar{\alpha}}$ will be denoted by $\ell_{\bar{\alpha}}$. Then, $\mathbf{e}_{\bar{\alpha}}$ may be parameterized by its arc length by means of the functions $\pi_{\bar{\alpha}}$, defined in $[0, \ell_{\bar{\alpha}}]$ such that $\pi_{\bar{\alpha}}(\ell_{\bar{\alpha}}) = \mathcal{O}_{\bar{\alpha}}$ and $\pi_{\bar{\alpha}}(0)$ is the other vertex of this edge.

Finally, we denote by $L_{\mathcal{A}}$ and $L_{\bar{\alpha}}$, $\bar{\alpha} \in \mathcal{I}$, the sum of the lengths of all the edges of the tree $\mathcal{A}$ (i.e., the total length of $\mathcal{A}$) and of its subtrees $\mathcal{A}_{\bar{\alpha}}$, respectively.

1.2. The equations of the motion of the network. With the notation introduced above we can write the equations that describe the motion of the network.

Let $u^{\bar\alpha}(t,x):\ \mathbb{R}\times[0,\ell_{\bar\alpha}]\to\mathbb{R}$ be the transverse displacement of the string with index $\bar\alpha$ with respect to the rest position. These functions allow us to identify the network with its rest graph. In this sense, the vertices of $\mathcal{A}$ are called *nodes* and the edges, *strings*.

For every $\bar\alpha\in\mathcal{I}$, the function $u^{\bar\alpha}(t,x)$ is assumed to satisfy the 1-d wave equation

$$u^{\bar\alpha}_{tt}(t,x)=u^{\bar\alpha}_{xx}(t,x)\qquad\text{in }\mathbb{R}\times[0,\ell_{\bar\alpha}], \tag{1.1}$$

where the subscripts t, x denote the derivatives with respect to those variables.

The coupling conditions between the strings are given by

$$u^{\bar\alpha\circ\beta}(t,0)=u^{\bar\alpha}(t,\ell_{\bar\alpha})\qquad\text{in }\mathbb{R},\quad\beta=1,\dots,m_{\bar\alpha}, \tag{1.2}$$

$$\sum_{\beta=1}^{m_{\bar\alpha}}u^{\bar\alpha\circ\beta}_x(t,0)=u^{\bar\alpha}_x(t,\ell_{\bar\alpha})\qquad\text{in }\mathbb{R}, \tag{1.3}$$

for $\bar\alpha\in\mathcal{I}_{\mathcal{M}}$. The conditions (1.2), (1.3) express the network continuity and the balance of forces at the interior nodes, respectively. At the root $\mathcal{R}$ the deformation of the string $\mathbf{e}$ is determined by a "control" v:

$$u(t,0)=v(t)\quad\text{in }\mathbb{R}, \tag{1.4}$$

while the remaining exterior nodes are fixed:

$$u^{\bar\alpha}(t,\ell_{\bar\alpha})=0\quad\text{in }\mathbb{R}\quad\text{if }\bar\alpha\in\mathcal{I}_{\mathcal{S}}. \tag{1.5}$$

Besides, the initial displacement and velocity of the strings (i.e., the initial state of the system) are given:

$$u^{\bar\alpha}(0,x)=u^{\bar\alpha}_0(x),\quad u^{\bar\alpha}_t(0,x)=u^{\bar\alpha}_1(x)\quad\text{in }[0,\ell_{\bar\alpha}],\ \bar\alpha\in\mathcal{I}. \tag{1.6}$$

Now we provide a functional setting for problem (1.1)–(1.6). Assume the set of indices $\mathcal{I}$ has been ordered in some way. Then denote by $\bar u$ the vector function with components $u^{\bar\alpha},\ \bar\alpha\in\mathcal{I}$, and define the Hilbert spaces

$$V=\Bigg\{\bar u\in\prod_{\bar\alpha\in\mathcal{I}}H^1(0,\ell_{\bar\alpha}):u^{\bar\alpha\circ\beta}(0)=u^{\bar\alpha}(\ell_{\bar\alpha})\ \text{ for }\bar\alpha\in\mathcal{I}_{\mathcal{M}},\ \ \beta=1,\dots,m_{\bar\alpha};$$
$$u^{\bar\alpha}(\ell_{\bar\alpha})=0\ \text{ for }\bar\alpha\in\mathcal{I}_{\mathcal{S}}\text{ and }u(0)=0\Bigg\},$$

$$H=\prod_{\bar\alpha\in\mathcal{I}}L^2(0,\ell_{\bar\alpha}),$$

endowed with the natural product structures of those of H^1 and L^2, respectively.

When $v\in L^2(0,T)$ and $\bar u_0=(u^{\bar\alpha}_0)_{\bar\alpha\in\mathcal{I}}\in H,\ \bar u_1=(u^{\bar\alpha}_1)_{\bar\alpha\in\mathcal{I}}\in V'$ (the dual space of V), (1.1)–(1.6) has a unique weak solution, defined by transposition, that verifies

$$\bar u\in C([0,T]:H)\cap C^1([0,T]:V').$$

If the function v is equal to zero in the interval $[0,T]$ and $\bar{u}_0 = (u_0^{\bar{\alpha}})_{\bar{\alpha}\in\mathcal{I}} \in V$, $\bar{u}_1 = (u_1^{\bar{\alpha}})_{\bar{\alpha}\in\mathcal{I}} \in H$, then the system (1.1)–(1.6) has a unique solution that satisfies

$$\bar{u} \in C([0,T]:V) \cap C^1([0,T]:H)$$

(see [8, Chapter III] for details).

In this latter case, the solution $\bar{u}$ of (1.1)–(1.6) is expressed in terms of the initial data $\bar{u}_0$, $\bar{u}_1$ by the formula

$$\bar{u}(t) = \sum_{k\in\mathbf{Z}_+} \left(u_{0,k} \cos \lambda_k t + \frac{u_{1,k}}{\lambda_k} \sin \lambda_k t \right) \bar{\theta}_k. \tag{1.7}$$

In (1.7), $\lambda_k := \sqrt{\mu_k}$, where $\{\mu_k\}_{k\in\mathbf{Z}_+}$ is the increasing (and positive) sequence of the eigenvalues of the elliptic operator defined by the system (1.1)–(1.5) and $\{\bar{\theta}_k\}_{k\in\mathbf{Z}_+}$ is the corresponding sequence of eigenfunctions, chosen to be an orthonormal basis of H, while $\{u_{0,k}\}_{k\in\mathbf{Z}_+}$, $\{u_{1,k}\}_{k\in\mathbf{Z}_+}$ are the sequences of Fourier coefficients of $\bar{u}_0$ and $\bar{u}_1$ with respect to that basis.

1.3. Statement of the problem. Our main goal is to study the controllability problem for the system (1.1)–(1.6). That is, given $T > 0$ and $\bar{u}_0 \in H$, $\bar{u}_1 \in V'$, to choose the control function $v \in L^2(0,T)$ such that the solution of (1.1)–(1.6) with initial data $\bar{u}_0$, $\bar{u}_1$ verifies

$$\bar{u}(T,x) = \bar{u}_t(T,x) = \bar{0},$$

i.e., it reaches rest at time T. When this is possible, we say that the initial state $(\bar{u}_0, \bar{u}_1)$ is controllable in time T.

Let $W_T \subset H\times V'$ be the set of controllable initial states in time T. If $W_T = H\times V'$, the system is said to be *exactly controllable* in time T, and if W_T is dense in $H \times V'$, it is said to be *approximately controllable*.

A simple application of the Hilbert uniqueness method (HUM) of Lions (see [10]) allows us to show that if there exist positive numbers c_n, $n \in \mathbb{Z}_+$, such that

$$\int_0^T |u(t,x)|^2 dt \geq \sum_{n\in\mathbb{Z}_+} c_n^2 \left(\mu_n |u_n^0|^2 + |u_n^1|^2 \right) \tag{1.8}$$

for every solution $\bar{u}$ of (1.1)–(1.6) with $v = 0$ and initial data $\bar{u}_0 = \sum_{n\in\mathbb{Z}_+} u_n^0 \bar{\theta}_n \in V$, $\bar{u}_1 = \sum_{n\in\mathbb{Z}_+} u_n^1 \bar{\theta}_n \in H$, then the space

$$\mathcal{W} = \left\{ (\bar{u}_0, \bar{u}_1) \in V \times H' : \ \|(\bar{u}_0, \bar{u}_1)\|^2 = \sum_{n\in\mathbb{Z}_+} \frac{1}{c_n^2} \left(|u_n^0|^2 + \frac{1}{\mu_n} |u_n^1|^2 \right) < \infty \right\} \tag{1.9}$$

verifies $\mathcal{W} \subset W_T$; i.e., all the initial states from $\mathcal{W}$ are controllable in time T.

In particular, if (1.8) holds, W_T contains, for every $T' \geq T$, the space $Z\times Z$, where Z is the set of all finite linear combinations of the eigenfunctions $\{\bar{\theta}_k\}_{k\in\mathbf{Z}_+}$. In that case it is said that the system is *spectrally controllable in time* T. The space $Z \times Z$ being dense in $H \times V'$, the spectral controllability obviously implies the approximate controllability and is apparently stronger. We shall show, however, that these two properties coincide for the networks considered here. This will imply that a network is approximately controllable in some time T if and only if all the initial states (ϕ, ψ), where ϕ and ψ are eigenfunctions, are controllable in time T.

The main result of this paper is contained in Theorem 5.1 of section 5, where we prove an inequality like (1.8) for any $T \geq 2L_{\mathcal{A}}$ (i.e., when the control time is at least twice the sum of all the lengths of the strings of the network) and with coefficients c_n, which may be explicitly computed in terms of the eigenvalues μ_n. In general, a tree is said to be *nondegenerate* if an inequality like (1.8) is true with coefficients which are all different from zero. In the subsection 5.2 we give a characterization, in terms of the eigenfunctions of the associated elliptic problem, of nondegenerate trees.

Moreover, it turns out that, if some of the coefficients vanish (i.e., if the tree degenerates), then there exist eigenfunctions vanishing identically at the controlled string. It is very well known that this fact implies that the space of controllable initial data is not dense in $H \times V'$. Therefore, if some inequality (1.8) takes place in this case, then necessarily some of the coefficients vanish (otherwise the system would be approximately controllable). Thus, Theorem 5.1 will provide an inequality (1.8) with nonzero coefficients whenever such an inequality exists.

If we were able to establish uniform lower estimates of the form

$$|c_n| \geq C\lambda_n^{-\alpha},$$

it would imply that $\mathcal{W} \supset W^{\alpha} \times W^{\alpha-\frac{1}{2}}$, where W^{α} is the domain of the α-power of the elliptic problem defined by (1.1)–(1.5), and we would obtain an explicitly characterized space of controllable initial states. This has been done in [4] for star-shaped networks under suitable assumptions on the lengths of the strings. However, even in that simple case, the results are based on deep facts from number theory concerning the uniform approximation by rational numbers, and thus it is unlikely that one could obtain similar results in the case of general trees.

The results of this paper were essentially announced in [6]. We should also remark that the similar problem of simultaneous controllability of networks (see section 7 below) has been considered by several authors for the case of one-string networks in, e.g., [1], [2], and [3]. The proofs given in those papers are based on generalizations of the Ingham inequality for sums of complex exponentials. In [5] we used the method presented here, which considerably simplified the solution of the problem.

1.4. Additional notation. For technical purposes, we consider also solutions $\bar{u}$ of (1.1) such that $\bar{u}_{\bar{\alpha}} \in C^2(\mathbb{R} \times [0, \ell_{\bar{\alpha}}])$, which verify (1.2), (1.3), and (1.5), but not necessarily (1.4). That is, $\bar{u}$ is a smooth solution that satisfies the boundary conditions at all the nodes, except possibly at the root $\mathcal{R}$. We shall briefly refer to such solutions as *solutions of* (N).

To simplify the notation we introduce for a solution $\bar{u}$ of (N) the functions

$$G_{\bar{\alpha}}(t) := u_t^{\bar{\alpha}}(t,0), \qquad F_{\bar{\alpha}}(t) := u_x^{\bar{\alpha}}(t,0), \tag{1.10}$$

$$\widehat{G}_{\bar{\alpha}}(t) := u_t^{\bar{\alpha}}(t,\ell_{\bar{\alpha}}), \qquad \widehat{F}_{\bar{\alpha}}(t) := u_x^{\bar{\alpha}}(t,\ell_{\bar{\alpha}}), \tag{1.11}$$

for $\bar{\alpha} \in \mathcal{I}$. These functions are the velocity and the tension at the extremes of the edge $\mathbf{e}_{\bar{\alpha}}$.

According to the coupling conditions (1.2)–(1.3), it holds that

$$G_{\bar{\alpha}\circ\beta}(t) = \widehat{G}_{\bar{\alpha}}(t), \qquad \sum_{\beta=1}^{m_{\bar{\alpha}}} F_{\bar{\alpha}\circ\beta}(t) = \widehat{F}_{\bar{\alpha}}(t), \tag{1.12}$$

for all $t \in \mathbb{R}$, $\bar{\alpha} \in \mathcal{I}_{\mathcal{M}}$, and $\beta = 1, \ldots, m_{\bar{\alpha}}$.

If $\bar{w}(t)$ is a function on the tree $\mathcal{A}$, we define the energy of $\bar{w}$ in the edge $\mathbf{e}_{\bar{\alpha}}$ by

$$E^{\bar{\alpha}}_{\bar{w}}(t) := \int_0^{\ell_{\bar{\alpha}}} \left(|w^{\bar{\alpha}}_t(t,x)|^2 + |w^{\bar{\alpha}}_x(t,x)|^2\right) dx,$$

and by

$$\mathbf{E}_{\bar{w}}(t) := \sum_{\bar{\alpha}\in\mathcal{I}} E^{\bar{\alpha}}_{\bar{w}}(t)$$

the energy of $\bar{w}$ in the whole tree. We will also use the notation $\mathbf{E}^{\bar{\alpha}}_{\bar{\omega}}$ for the total energy of $\bar{\omega}$ in the subtree $\mathcal{A}_{\bar{\alpha}}$.

For the solutions of (N) a simple expression for the energy is obtained. It takes the following form.

PROPOSITION 1.1. *If $\bar{u}$ is a solution of* (N)*, then for any $t \in \mathbb{R}$*

$$\frac{d}{dt}\mathbf{E}_{\bar{u}}(t) = -G(t)F(t). \tag{1.13}$$

Proof. If we multiply (1.1) by $u^{\bar{\alpha}}_t$, it follows, after integration by parts in $[0, \ell_{\bar{\alpha}}]$, that

$$\frac{d}{dt}E^{\bar{\alpha}}(t) = \widehat{G}_{\bar{\alpha}}(t)\widehat{F}_{\bar{\alpha}}(t) - G_{\bar{\alpha}}(t)F_{\bar{\alpha}}(t), \qquad \bar{\alpha}\in\mathcal{I}_{\mathcal{M}},$$
$$\frac{d}{dt}E^{\bar{\alpha}}(t) = -G_{\bar{\alpha}}(t)F_{\bar{\alpha}}(t), \qquad \bar{\alpha}\in\mathcal{I}_{\mathcal{S}}.$$

Formula (1.13) is then obtained from the definition of $\mathbf{E}_{\bar{u}}$, taking into account the coupling conditions at the interior vertices. □

Remark 1. From the previous proposition it follows that, for the solutions of (1.1)–(1.6) with $v = 0$, the energy is conserved. In this case, as a consequence of the expansion (1.7), the energy of the solution $\bar{u}$ with initial data $\bar{u}_0 = \sum_{n\in\mathbb{Z}_+} u^0_n \bar{\theta}_n$, $\bar{u}_1 = \sum_{n\in\mathbb{Z}_+} u^1_n \bar{\theta}_n$ may be expressed by the formula

$$\mathbf{E}_{\bar{u}} = \frac{1}{2}\sum_{k\in\mathbf{Z}_+} \left(\lambda^2_k u^2_{0,k} + u^2_{1,k}\right). \tag{1.14}$$

2. The operators $\mathcal{P}$ and $\mathcal{Q}$. In this section we define two linear operators $\mathcal{P}$ and $\mathcal{Q}$ that allow us to express the relation

$$\mathcal{P}G + \mathcal{Q}F = 0 \tag{2.1}$$

between the traces of the velocity and the tension of the solutions of (N) at the root of the tree. These operators will play an essential role in the proof of the main results, and so we study them in detail. In particular, we need information on how they act on the traces $F_{\bar{\alpha}}$ and $G_{\bar{\alpha}}$ of the other components of the solution at the interior nodes.

First, $\mathcal{P}$ and $\mathcal{Q}$ are constructed for a string. Then, using a recursive argument, they are obtained for general trees.

2.1. The case of a single string. Assume that $u(t,x)$ satisfies the wave equation in $\mathbb{R}\times[0,\ell]$. Then $u(t,x)$ can be expressed by the d'Alembert formula

$$u(t,x) = \frac{1}{2}\left(u(t+x,0) + u(t-x,0)\right) + \frac{1}{2}\int_{t-x}^{t+x} u_x(\tau,0)d\tau, \tag{2.2}$$

from which, after differentiation, we get the equalities

$$\begin{aligned} u_x(t,x) &= \tfrac{1}{2}\left(u_t(t+x,0) - u_t(t-x,0)\right) + \tfrac{1}{2}\left(u_x(t+x,0) + u_x(t-x,0)\right), \\ u_t(t,x) &= \tfrac{1}{2}\left(u_t(t+x,0) + u_t(t-x,0)\right) + \tfrac{1}{2}\left(u_x(t+x,0) - u_x(t-x,0)\right). \end{aligned} \tag{2.3}$$

Now let the functions F, G, $\widehat{F}$, $\widehat{G}$ be defined as in (1.10), (1.11), that is,

$$G(t) = u_t(t,0), \quad F(t) = u_x(t,0), \qquad \widehat{G}(t) = u_t(t,\ell), \quad \widehat{F} = u_x(t,\ell).$$

With this notation, formulas (2.3) for $x = \ell$ can be written as

$$\widehat{F} = \ell^+ F + \ell^- G, \tag{2.4}$$

$$\widehat{G} = \ell^- F + \ell^+ G, \tag{2.5}$$

where ℓ^+, ℓ^- are the linear operators acting on a time-dependent function f according to

$$\ell^\pm f(t) = \frac{f(t+\ell) \pm f(t-\ell)}{2}. \tag{2.6}$$

If u is a solution of (N) for a one-string network, then u satisfies for $x = \ell$ the homogeneous Dirichlet boundary condition $\widehat{G} = 0$, and the equality (2.5) becomes

$$\ell^- F + \ell^+ G = 0,$$

which provides a relation of type (2.1) with $\mathcal{P} = \ell^+$, $\mathcal{Q} = \ell^-$.

The following proposition is a classical result on the observability of 1-d waves from the boundary. It is easily proved using the d'Alembert representation formula.

PROPOSITION 2.1. *If $u(t,x)$ satisfies the wave equation $u_{tt} = u_{xx}$ in $\mathbb{R} \times [0,\ell]$, then*

$$\mathbf{E}_u(t) \le \frac{1}{4}\int_{t-\ell}^{t+\ell} \left(|u_x(\tau,0)|^2 + |u_t(\tau,0)|^2\right) d\tau.$$

Proof. In view of (2.3), it holds that

$$\begin{aligned} \mathbf{E}_u(t) &= \frac{1}{8}\int_0^\ell \big\{|u_t(t+x,0) - u_t(t-x,0) + u_x(t+x,0) + u_x(t-x,0)|^2 \\ &\qquad + |u_t(t+x,0) + u_t(t-x,0) + u_x(t+x,0) - u_x(t-x,0)|^2\big\}\, dx \\ &\le \frac{1}{4}\int_0^\ell \left\{|u_t(t+x,0)|^2 + |u_t(t-x,0)|^2 + |u_x(t+x,0)|^2 + |u_x(t-x,0)|^2\right\} dx \\ &= \frac{1}{4}\int_{t-\ell}^{t} \left\{|u_t(\tau,0)|^2 + |u_x(\tau,0)|^2\right\} dx + \frac{1}{4}\int_{t}^{t+\ell} \left\{|u_t(\tau,0)|^2 + |u_x(\tau,0)|^2\right\} dx \\ &= \frac{1}{4}\int_{t-\ell}^{t+\ell} \left(|u_x(\tau,0)|^2 + |u_t(\tau,0)|^2\right) dt. \qquad \square \end{aligned}$$

We remark in the next proposition a simple fact that is widely used in what follows.

PROPOSITION 2.2. *Let $w(t,x)$ be a function defined in $\mathbb{R}\times[0,\ell]$. Then*

$$\mathbf{E}_{\ell^\pm w}(t)\le \ell^+\mathbf{E}_w(t).$$

(Here, the operators $\ell^\pm$ act on the variable t; i.e., $\ell^\pm w(t,x)=\frac{1}{2}(w(t+\ell,x)\pm w(t-\ell,x))$.)

Proof. For every $t\in\mathbb{R}$

$$\begin{aligned}\mathbf{E}_{\ell^\pm w}&=\frac{1}{8}\int_0^\ell \left\{|w_x(t+\ell,x)\pm w_x(t-\ell,x)|^2+|w_t(t+\ell,x)\pm w_t(t-\ell,x)|^2\right\}dx\\ &\le\ \frac{1}{4}\int_0^\ell \left\{|w_x(t+\ell,x)|^2+|w_x(t-\ell,x)|^2+|w_t(t+\ell,x)|^2+|w_t(t-\ell,x)|^2\right\}dx\\ &=\frac{1}{2}(\mathbf{E}_w(t+\ell)+\mathbf{E}_w(t-\ell))=\ell^+\mathbf{E}_w(t).\qquad\square\end{aligned}$$

2.2. Operators of type S. As stated above, we are interested not only in the existence of the operators $\mathcal{P}$ and $\mathcal{Q}$ satisfying (2.1), but also in their structure. That is why we consider a class of linear operators that are linear combinations of certain shift operators. This allows us to describe some properties of the operators $\mathcal{P}$ and $\mathcal{Q}$ that we shall use later.

For the real number h we denote by τ_h the shift operator defined by $\tau_h f(t):=f(t+h)$. As we shall be concerned only with algebraic properties of those operators, we may assume τ_h to act on the vector spaces of mappings $f=f(t):\mathbb{R}\to\mathbf{W}$, where $\mathbf{W}$ is a vector space.

Let $\Lambda=\{\ell_1,\dots,\ell_n\}$ be a set of positive numbers, not necessarily different. In what follows, whenever a set is denoted by Λ we tacitly assume that it may contain repeated elements. If $\tilde\Lambda=\{\tilde\ell_1,\dots,\tilde\ell_{n'}\}$ is another such set, we use the notation $\Lambda\sqcup\tilde\Lambda$ for the set $\{\ell_1,\dots,\ell_n,\tilde\ell_1,\dots,\tilde\ell_{n'}\}$, which once again may contain repeated elements. We set

$$S(\Lambda):=\operatorname{span}\{\tau_h : h\in\mathcal{H}_\Lambda\}$$

(the set of all linear combinations of shift operators τ_h with $h\in\mathcal{H}_\Lambda$), where

$$\mathcal{H}_\Lambda=\left\{h=\sum_{i=1}^n \varepsilon_i\ell_i,\ \varepsilon_i=\pm1\right\}.$$

Observe that the set $\mathcal{H}_\Lambda$ contains at most 2^n elements, so $S(\Lambda)$ is of finite dimension.

For an operator $\mathcal{B}\in S(\Lambda)$ we shall write $s(\mathcal{B}):=s(\Lambda):=\sum_{i=1}^n\ell_i$. We say that $\mathcal{B}$ *is of type* S if $\mathcal{B}\in S(\Lambda)$ for some set Λ.

The operators ℓ^+ and ℓ^-, defined in the previous section by (2.6), can be expressed as

$$\ell^\pm=\frac{\tau_\ell\pm\tau_{-\ell}}{2},$$

and thus they belong to $S(\{\ell\})$.

We gather in the following two propositions some elementary properties of the operators of type S, which will be used in the proof of our main results.

PROPOSITION 2.3. (i) $\mathcal{B} \in S(\Lambda)$ *if and only if it may be written as a linear combination of operators of the form* $\ell_1^{\pm}\ell_2^{\pm}\cdots\ell_n^{\pm}$, *where* $\pm$ *means that we choose one of the operators* ℓ_i^+ *or* ℓ_i^-.

(ii) *If* $\mathcal{B}_1 \in S(\Lambda_1)$ *and* $\mathcal{B}_2 \in S(\Lambda_2)$, *then* $\mathcal{B}_1\mathcal{B}_2 = \mathcal{B}_2\mathcal{B}_1 \in S(\Lambda_1 \sqcup \Lambda_2)$ *and* $s(\mathcal{B}_1\mathcal{B}_2) = s(\mathcal{B}_1) + s(\mathcal{B}_2)$.

PROPOSITION 2.4. *If* $\mathcal{B}$ *is an operator of type* S *with* $s(\mathcal{B}) = s$, *then there exist positive constants* C_1, C_2, *depending only on the coefficients of* $\mathcal{B}$, *such that*

$$\text{(i)} \qquad \int_a^b |\mathcal{B}f(t)|^2 dt \le C_1 \int_{a-s}^{b+s} |f(t)|^2 dt$$

for all the functions f *for which the integrals are defined.*[1]

(ii) *If the function* $w(t,x)$ *is defined in* $\mathbb{R} \times [0,\ell]$ *and there exists a constant* M *such that* $\mathbf{E}_w(t) \le M$ *for* $t \in [a,b]$, *then* $\mathbf{E}_{\mathcal{B}w}(t) \le C_2 M$ *for* $t \in [a+s, b-s]$.

Proof. (i) For $n = 1$, $\Lambda = \{\ell\}$ we have that $\mathcal{B} = c_1\ell^+ + c_2\ell^-$ and $s(\mathcal{B}) = \ell$. Then

$$\begin{aligned}
\int_a^b |\mathcal{B}f(t)|^2 dt &= \int_a^b \left|c_1\ell^+ f(t) + c_2\ell^- f(t)\right|^2 dt \\
&= \int_a^b \left|\frac{c_1+c_2}{2} f(t+\ell) + \frac{c_1-c_2}{2} f(t-\ell)\right|^2 dt \\
&\le \left(\frac{c_1+c_2}{2}\right)^2 \int_a^b |f(t+\ell)|^2 dt + \left(\frac{c_1-c_2}{2}\right)^2 \int_a^b |f(t-\ell)|^2 dt \\
&\le \left(\frac{c_1+c_2}{2}\right)^2 \int_{a+\ell}^{b+\ell} |f(t)|^2 dt + \left(\frac{c_1-c_2}{2}\right)^2 \int_{a-\ell}^{b-\ell} |f(t)|^2 dt \\
&\le (c_1^2 + c_2^2) \int_{a-\ell}^{b+\ell} |f(t)|^2 dt.
\end{aligned}$$

When $n \ge 2$, it suffices to iterate this inequality, taking into account Proposition 2.3(i). Note that C_1 may be chosen as the maximum of the squares of the coefficients of $\mathcal{B}$ in the representation of $\mathcal{B}$ given by Proposition 2.3(i), and thus C_1 depends only on $\mathcal{B}$.

(ii) This point is an immediate consequence of Proposition 2.2. □

The next proposition plays a crucial role in this paper.

PROPOSITION 2.5. *Let* $\Lambda = \{\ell_1, \dots, \ell_m\}$ *with* $\ell_1 \le \cdots \le \ell_m$, *and denote* $T_\Lambda = 2s(\Lambda) = 2\sum_{i=1}^m \ell_i$. *Assume that* $\mathcal{B} = \sum_{h\in\mathcal{H}_\Lambda} c_h\tau_h \in S(\Lambda)$ *and that the coefficient* $c_{\ell_1+\cdots+\ell_m}$ *is different from zero. Then, for any* $T > 0$ *there exists a constant* $C_T > 0$ *such that*

$$\int_0^T |u(t)|^2 dt \le C_T \int_0^{T_\Lambda} |u(t)|^2 dt$$

for any continuous function u *satisfying* $\mathcal{B}u \equiv 0$.

Proof. We shall prove that, for any natural number n and any function u satisfying $\mathcal{B}u \equiv 0$, it holds that

$$\int_0^{T_\Lambda + 2n\ell_1} |u(t)|^2 dt \le \gamma^n \int_0^{T_\Lambda} |u(t)|^2 dt, \tag{2.7}$$

[1] In other words, the operator $\mathcal{B}$ is bounded from $L^2[a-s, b+s]$ to $L^2[a,b]$.

where γ is a positive constant depending only on $\mathcal{B}$. Clearly, the assertion of the proposition immediately follows from inequality (2.7).

If $\mathcal{B}u \equiv 0$, i.e., $0 = \sum_{h\in\mathcal{H}_\Lambda} c_h\tau_h u(t) = \sum_{h\in\mathcal{H}_\Lambda} c_h u(t+h)$, then, replacing the variable t by $t-(\ell_1+\cdots+\ell_m)$ and taking into account that $c_{\ell_1+\cdots+\ell_m}\neq 0$, we get

$$u(t) = \sum_{h'\in\mathcal{H}^*_\Lambda} \delta_{h'} u(t-h'), \tag{2.8}$$

where $\mathcal{H}^*_\Lambda = \{h' = h-(\ell_1+\cdots+\ell_m) : h\in\mathcal{H}_\Lambda,\ h\neq(\ell_1+\cdots+\ell_m)\}$ and $\delta_{h'} = -\frac{c_{h'+(\ell_1+\cdots+\ell_m)}}{c_{\ell_1+\cdots+\ell_m}}$.

From (2.8) and the Cauchy–Schwarz inequality it follows that

$$|u(t)|^2 \le \delta \sum_{h'\in\mathcal{H}^*_\Lambda} |u(t-h')|^2, \tag{2.9}$$

where $\delta = \sum_{h'\in\mathcal{H}^*_\Lambda} \delta^2_{h'}$.

Note that for every $h'\in\mathcal{H}^*_\Lambda$ we have $2\ell_1 \le h' \le 2(\ell_2+\cdots+\ell_m)$, and therefore,

$$T_\Lambda + 2(n+1)\ell_1 - h' \le T_\Lambda + 2n\ell_1 \quad\text{and}\quad T_\Lambda + 2n\ell_1 - h' \ge 2(n+1)\ell_1 \ge 0.$$

This fact implies that

$$\int_{T_\Lambda+2n\ell_1-h'}^{T_\Lambda+2(n+1)\ell_1-h'} |u(t)|^2dt \le \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt. \tag{2.10}$$

On the other hand, from (2.9) it follows that

$$\begin{aligned}\int_{T_\Lambda+2n\ell_1}^{T_\Lambda+2(n+1)\ell_1} |u(t)|^2dt &\le \delta \sum_{h'\in\mathcal{H}^*_\Lambda} \int_{T_\Lambda+2n\ell_1}^{T_\Lambda+2(n+1)\ell_1} |u(t-h')|^2dt\\ &= \delta \sum_{h'\in\mathcal{H}^*_\Lambda} \int_{T_\Lambda+2n\ell_1-h'}^{T_\Lambda+2(n+1)\ell_1-h'} |u(t)|^2dt.\end{aligned}$$

Now, taking into account (2.10), the previous inequality becomes

$$\int_{T_\Lambda+2n\ell_1}^{T_\Lambda+2(n+1)\ell_1} |u(t)|^2dt \le (2^m-1)\delta \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt.$$

From this latter inequality we obtain

$$\begin{aligned}\int_0^{T_\Lambda+2(n+1)\ell_1} |u(t)|^2dt &= \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt + \int_{T_\Lambda+2n\ell_1}^{T_\Lambda+2(n+1)\ell_1} |u(t)|^2dt\\ &\le \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt + (2^m-1)\delta \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt\\ &\le (1+(2^m-1)\delta) \int_0^{T_\Lambda+2n\ell_1} |u(t)|^2dt,\end{aligned}$$

which proves inequality (2.7) with $\gamma = 1+(2^m-1)\delta$. □

Remark 2. If $\mathcal{B}$ is an operator of type S, there exists a unique function $b(\lambda)$ such that $\mathcal{B}e^{i\lambda t} = b(\lambda)e^{i\lambda t}$. The function $b(\lambda)$ is obtained by replacing in the expression of $\mathcal{B}$ given by Proposition 2.3(i) the operators ℓ_i^+ and ℓ_i^- by the functions $\cos\lambda t$ and $i\sin\lambda t$, respectively.

2.3. Construction of $\mathcal{P}$ and $\mathcal{Q}$ in the general case. The construction of $\mathcal{P}$ and $\mathcal{Q}$ will be done by induction. We note that such operators have already been constructed for a network consisting of a single string.

We shall denote by Λ_i the set of all the lengths of the strings of the subtree $\mathcal{A}_i$, and by $\Lambda_{\mathcal{A}}$ that of all the lengths of the tree $\mathcal{A}$. Suppose that for the subtrees $\mathcal{A}_i$, $i = 1, \dots, m$, we have already constructed the operators $\mathcal{P}_i, \mathcal{Q}_i$ that belong to $S(\Lambda_i)$ and verify

$$\mathcal{P}_i G_i + \mathcal{Q}_i F_i = 0, \tag{2.11}$$

where G_i and F_i are the velocity and the tension at the root of the subtree $\mathcal{A}_i$, i.e., at the vertex $\mathcal{O}$ of $\mathcal{A}$.

We define the operators

$$\mathcal{P} = \ell^+ \sum_{i=1}^{m} \mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j + \ell^- \prod_{j=1}^{m} \mathcal{Q}_j, \tag{2.12}$$

$$\mathcal{Q} = \ell^- \sum_{i=1}^{m} \mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j + \ell^+ \prod_{j=1}^{m} \mathcal{Q}_j \tag{2.13}$$

(here the products denote the composition of operators).

PROPOSITION 2.6. *The operators $\mathcal{P}$ and $\mathcal{Q}$ defined by* (2.12)–(2.13) *belong to $S(\Lambda_{\mathcal{A}})$. If $\bar{u}$ is a solution of* (N), *then $\mathcal{P}G + \mathcal{Q}F = 0$.*

Proof. To prove that $\mathcal{P}, \mathcal{Q} \in S(\Lambda_{\mathcal{A}})$, it suffices to observe that, according to Proposition 2.3, all the terms of the sums in (2.12) and (2.13) belong to $S(\{\ell\} \sqcup \Lambda_1 \sqcup \cdots \sqcup \Lambda_m) = S(\Lambda_{\mathcal{A}})$. Using (2.4)–(2.5), the coupling conditions (1.12) between the strings may be expressed as

$$\sum_{i=1}^{m} F_i = \ell^- G + \ell^+ F, \qquad G_i = \ell^+ G + \ell^- F, \quad i = 1, \dots, m. \tag{2.14}$$

From (2.12)–(2.13) we have

$$\begin{aligned}\mathcal{P}G + \mathcal{Q}F &= \sum_{i=1}^{m} \left(\mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j \right) \ell^+ G + \prod_{j=1}^{m} \mathcal{Q}_j \ell^- G + \sum_{i=1}^{m} \left(\mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j \right) \ell^- F + \prod_{j=1}^{m} \mathcal{Q}_j \ell^+ F \\ &= \sum_{i=1}^{m} \left(\mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j \right) (\ell^+ G + \ell^- F) + \prod_{j=1}^{m} \mathcal{Q}_j (\ell^- G + \ell^+ F).\end{aligned}$$

Then, using formulas (2.14),

$$\mathcal{P}G + \mathcal{Q}F = \sum_{i=1}^{m} \left(\mathcal{P}_i \prod_{j\neq i} \mathcal{Q}_j \right) G_i + \sum_{i=1}^{m} \left(\prod_{j=1}^{m} \mathcal{Q}_j \right) F_i = \sum_{i=1}^{m} \left(\prod_{j\neq i} \mathcal{Q}_j \right) (\mathcal{P}_i G_i + \mathcal{Q}_i F_i) = 0,$$

where the last equality follows from the hypotheses (2.11). Thus, $\mathcal{P}$ and $\mathcal{Q}$, defined by (2.12)–(2.13), satisfy (2.1). ∎

Remark 3. From the definition, an $S(\Lambda)$-operator $\mathcal{B}$ may be written in the form

$$\mathcal{B} = \sum_{h \in \mathcal{H}_\Lambda} c_h \tau_h. \tag{2.15}$$

In general, this representation is not unique, since some elements of $\mathcal{H}_\Lambda$ may coincide. However, the coefficient $c_{s(\mathcal{B})} = c_{\ell_1 + \cdots + \ell_m}$, corresponding to the largest value of h, is determined in a unique way, as $\ell_1 + \cdots + \ell_m$ cannot be equal to another element of $\mathcal{H}_\Lambda$. Besides, it is easy to see that $c_{s(\mathcal{B})}$ is a multiplicative function; i.e., if $\mathcal{B}_1$ and $\mathcal{B}_2$ are S-operators with $s(\mathcal{B}_1) = s_1$ and $s(\mathcal{B}_2) = s_2$, then $c_{s_1+s_2}(\mathcal{B}_1\mathcal{B}_2) = c_{s_1}(\mathcal{B}_1)c_{s_2}(\mathcal{B}_2)$. In the next proposition we study this coefficient for the operators $\mathcal{P}$ and $\mathcal{Q}$.

PROPOSITION 2.7. *Let $c_{L_\mathcal{A}}(\mathcal{B})$ denote the coefficient corresponding to $h = s(\Lambda_\mathcal{A}) = L_\mathcal{A} \in \mathcal{H}_{\Lambda_\mathcal{A}}$ in the expansion* (2.15) *of an $S(\Lambda_\mathcal{A})$-operator $\mathcal{B}$. Then $c_{L_\mathcal{A}}(\mathcal{P}) = c_{L_\mathcal{A}}(\mathcal{Q}) > 0$.*

Proof. We proceed by induction. For a string, $\mathcal{P} = \ell^+ = \frac{\tau_h + \tau_{-h}}{2}$ and $\mathcal{Q} = \ell^+ = \frac{\tau_h - \tau_{-h}}{2}$. This implies $c_\ell(\mathcal{P}) = c_\ell(\mathcal{Q}) = \frac{1}{2}$.

Now assume the assertion is true for the subtrees $\mathcal{A}_1, \ldots, \mathcal{A}_m$. This means that

$$c_{L_i}(\mathcal{P}) = c_{L_i}(\mathcal{Q}) > 0, \quad i = 1, \ldots, m, \tag{2.16}$$

where, as above, L_i is the sum of the lengths of all the strings of the subtree $\mathcal{A}_i$.

Then, from formula (2.12) and the assumption (2.16),

$$\begin{aligned}
c_{L_\mathcal{A}}(\mathcal{P}) &= c_{L_\mathcal{A}} \left(\ell^+ \sum_{i=1}^m \mathcal{P}_i \prod_{j \neq i} \mathcal{Q}_j + \ell^- \prod_{j=1}^m \mathcal{Q}_j \right) \\
&= c_{L_\mathcal{A}} \left(\ell^+ \sum_{i=1}^m \mathcal{P}_i \prod_{j \neq i} \mathcal{Q}_j \right) + c_{L_\mathcal{A}} \left(\ell^- \prod_{j=1}^m \mathcal{Q}_j \right) \\
&= c_\ell(\ell^+) \sum_{i=1}^m c_{L_i}(\mathcal{P}_i) \prod_{j \neq i} c_{L_j}(\mathcal{Q}_j) + c_\ell(\ell^-) \prod_{j=1}^m c_{L_j}(\mathcal{Q}_j) \\
&= \frac{1}{2}(m+1) \prod_{j=1}^m c_{L_j}(\mathcal{Q}_j) > 0.
\end{aligned}$$

In the same way it may be proved that

$$c_{L_\mathcal{A}}(\mathcal{Q}) = \frac{1}{2}(m+1) \prod_{j=1}^m c_{L_j}(\mathcal{Q}_j),$$

which completes the proof. □

2.4. The action of $\mathcal{P}$ and $\mathcal{Q}$ on the tensions and velocities at the interior nodes. For the index $\bar{\alpha} = (\alpha_1, \ldots, \alpha_k) \in \mathcal{I}$ we denote

$$\tilde{\Lambda}_{\bar{\alpha}} := \{\ell, \ell_{\alpha_1}, \ell_{\alpha_1,\alpha_2}, \ldots, \ell_{\alpha_1,\alpha_2,\ldots,\alpha_{k-1}}\}.$$

Observe that $\tilde{\Lambda}_{\bar{\alpha}}$ is the set of the lengths of the strings forming the unique simple path that connects the root $\mathcal{R}$ with the subtree $\mathcal{A}_{\bar{\alpha}}$. For completeness we take for the empty index $\tilde{\Lambda} = \emptyset$. The following proposition gives information on how the operators

$\mathcal{P}$ and $\mathcal{Q}$ act on traces of the components of a solution at the interior nodes of the network.

PROPOSITION 2.8. *For any $\bar{\alpha} \in \mathcal{I}$ there exist operators $\mathcal{L}_{\bar{\alpha}} \in S(\Lambda_{\mathcal{A}} \sqcup \tilde{\Lambda}_{\bar{\alpha}})$ such that, for any solution of* (N),

$$\mathcal{Q}F_{\bar{\alpha}} = \mathcal{L}_{\bar{\alpha}}G, \qquad \mathcal{P}F_{\bar{\alpha}} = -\mathcal{L}_{\bar{\alpha}}F.$$

Proof. We proceed by induction. Note that from the relation $\mathcal{P}G + \mathcal{Q}F = 0$ it follows that when $\bar{\alpha}$ is the empty multi-index, the property is true with $\mathcal{L} = -\mathcal{P} \in S(\Lambda_{\mathcal{A}}) = S(\Lambda_{\mathcal{A}} \sqcup \tilde{\Lambda})$. In particular, for a single string the assertion of the proposition holds.

Suppose now that the operators $\mathcal{L}_{\bar{\alpha}}$ have already been constructed for the subtrees $\mathcal{A}_i$, $i = 1, \dots, m$, of $\mathcal{A}$. This means that we have for $i = 1, \dots, m$ the operators $\mathcal{L}^i_{\bar{\alpha}} \in S(\Lambda_i \sqcup \tilde{\Lambda}^i_{\bar{\alpha}})$ such that

$$\mathcal{P}_i F_{i\circ\bar{\alpha}} = -\mathcal{L}^i_{\bar{\alpha}} F_i, \qquad \mathcal{Q}_i F_{i\circ\bar{\alpha}} = \mathcal{L}^i_{\bar{\alpha}} G_i,$$

where $\tilde{\Lambda}^i_{\bar{\alpha}}$ is the set defined as $\tilde{\Lambda}_{\bar{\alpha}}$ for the subtree $\mathcal{A}_i$ and $\mathcal{P}_i$, $\mathcal{Q}_i$ are the operators $\mathcal{P}$, $\mathcal{Q}$ corresponding to that subtree.

Then, using relation (2.13),

$$\begin{aligned}
\mathcal{Q}F_{i\circ\bar{\alpha}} &= \ell^- \left(\sum_{j=1}^{m} \mathcal{P}_j \prod_{k\neq j} \mathcal{Q}_k \right) F_{i\circ\bar{\alpha}} + \ell^+ \left(\prod_{k=1}^{m} \mathcal{Q}_k \right) F_{i\circ\bar{\alpha}} \\
&= \ell^- \left(\sum_{\substack{j=1 \\ j\neq i}}^{m} \mathcal{P}_j \prod_{\substack{k\neq j \\ k\neq i}} \mathcal{Q}_k \right) \mathcal{Q}_i F_{i\circ\bar{\alpha}} + \ell^- \left(\mathcal{P}_i \prod_{k\neq i} \mathcal{Q}_k \right) F_{i\circ\bar{\alpha}} + \ell^+ \left(\prod_{k=1}^{m} \mathcal{Q}_k \right) F_{i\circ\bar{\alpha}} \\
&= \mathcal{L}^i_{\bar{\alpha}} \left(\ell^- \left(\sum_{\substack{i=1 \\ j\neq i}}^{m} \mathcal{P}_j \prod_{\substack{k\neq j \\ k\neq i}} \mathcal{Q}_k \right) G_i - \ell^- \left(\prod_{k\neq i} \mathcal{Q}_k \right) F_i + \ell^+ \left(\prod_{k=1}^{m} \mathcal{Q}_k \right) G_i \right) \\
&= \mathcal{L}^i_{\bar{\alpha}} \left(\ell^- \sum_{j\neq i} \left(\prod_{\substack{k\neq j \\ k\neq i}} \mathcal{Q}_k \right) (\mathcal{P}_j G_i + \mathcal{Q}_j \widehat{F}) - \ell^- \left(\prod_{k\neq i} \mathcal{Q}_k \right) \widehat{F} + \ell^+ \left(\prod_{k\neq i} \mathcal{Q}_k \right) G_i \right) \\
&= \mathcal{L}^i_{\bar{\alpha}} \left(\prod_{k\neq i} \mathcal{Q}_k \right) (\ell^+ \widehat{G} - \ell^- \widehat{F}) = \mathcal{L}^i_{\bar{\alpha}} \left(\prod_{k\neq i} \mathcal{Q}_k \right) \left(\ell^+ (\ell^- F + \ell^+ G) - \ell^- (\ell^+ F + \ell^- G) \right) \\
&= \mathcal{L}^i_{\bar{\alpha}} \left(\prod_{k\neq i} \mathcal{Q}_k \right) \left((\ell^+)^2 - (\ell^-)^2 \right) G.
\end{aligned}$$

In a similar way, it may be obtained that

$$\mathcal{P}F_{i\circ\bar{\alpha}} = -\mathcal{L}^i_{\bar{\alpha}} \prod_{k\neq i} \mathcal{Q}_k \left((\ell^+)^2 - (\ell^-)^2 \right) F.$$

Thus, we arrive at the recursive formula

$$\mathcal{L}_{i\circ\bar{\alpha}} = \mathcal{L}^i_{\bar{\alpha}} \prod_{k\neq i} \mathcal{Q}_k \left((\ell^+)^2 - (\ell^-)^2 \right),$$

from which, in particular, according to Proposition 2.3, it holds that the operators $\mathcal{L}_{i\circ\bar\alpha}$ belong to $S(\Lambda_i \sqcup \tilde\Lambda^i_{\bar\alpha} \sqcup \{\ell,\ell\}) = S(\Lambda_i \sqcup \{\ell\} \sqcup \tilde\Lambda^i_{\bar\alpha} \sqcup \{\ell\}) = S(\Lambda_{\mathcal{A}} \sqcup \tilde\Lambda_{i\circ\bar\alpha})$. This proves the proposition. □

The action of $\mathcal{P}$ and $\mathcal{Q}$ on the velocities $G_{\bar\alpha}$ may be described in a similar way, as follows.

PROPOSITION 2.9. *For any $\bar\alpha \in \mathcal{I}$ there exist operators $\mathcal{K}_{\bar\alpha}$, $\widehat{\mathcal{K}}_{\bar\alpha} \in S(\Lambda_{\mathcal{A}} \sqcup \tilde\Lambda_{\bar\alpha})$ such that, for any solution of* (N),

$$\mathcal{Q}G_{\bar\alpha} = \mathcal{K}_{\bar\alpha}G, \qquad \mathcal{P}G_{\bar\alpha} = \widehat{\mathcal{K}}_{\bar\alpha}F.$$

Proof. From the relation $\mathcal{P}G + \mathcal{Q}F = 0$, it follows that, for the empty multi-index, $\mathcal{K} = \mathcal{Q}$ and $\widehat{\mathcal{K}} = -\mathcal{Q}$. For the remaining indices the operators $\mathcal{K}_{\bar\alpha}$ and $\widehat{\mathcal{K}}_{\bar\alpha}$ are constructed by recurrence. Assume that for the index $\bar\alpha$ the operators $\mathcal{K}_{\bar\alpha}$ and $\widehat{\mathcal{K}}_{\bar\alpha}$, verifying the conditions of the proposition, have been already constructed.

Then, for the indices $\bar\alpha \circ i$ with $i = 1, \dots, m_{\bar\alpha}$ we have that

$$\mathcal{Q}G_{\bar\alpha\circ i} = \mathcal{Q}\widehat{G}_{\bar\alpha} = \ell^+_{\bar\alpha}\mathcal{Q}G_{\bar\alpha} + \ell^-_{\bar\alpha}\mathcal{Q}F_{\bar\alpha} = \left(\ell^+_{\bar\alpha}\mathcal{K}_{\bar\alpha} + \ell^-_{\bar\alpha}\mathcal{L}_{\bar\alpha}\right)G,$$

where $\mathcal{L}_{\bar\alpha}$ is the operator constructed in the previous proposition.

In an analogous way it may be obtained that

$$\mathcal{P}G_{\bar\alpha\circ i} = (\ell^+_{\bar\alpha}\widehat{\mathcal{K}}_{\bar\alpha} - \ell^-_{\bar\alpha}\mathcal{L}_{\bar\alpha})F.$$

Then the needed operators may be constructed by the rules

$$\mathcal{K}_{\bar\alpha\circ i} = \ell^+_{\bar\alpha}\mathcal{K}_{\bar\alpha} + \ell^-_{\bar\alpha}\mathcal{L}_{\bar\alpha}, \tag{2.17}$$

$$\widehat{\mathcal{K}}_{\bar\alpha\circ i} = \ell^+_{\bar\alpha}\widehat{\mathcal{K}}_{\bar\alpha} - \ell^-_{\bar\alpha}\mathcal{L}_{\bar\alpha}. \tag{2.18}$$

As in the proof of the Proposition 2.8, from the relations (2.17)–(2.18) it holds, in particular, that the operators $\mathcal{K}_{\bar\alpha\circ i}$ and $\widehat{\mathcal{K}}_{\bar\alpha\circ i}$ belong to $S(\Lambda_{\mathcal{A}} \sqcup \tilde\Lambda_{\bar\alpha\circ i})$. □

2.5. Action of $\mathcal{P}$ and $\mathcal{Q}$ on the solution. If $\bar u$ is a solution of (N) and $\mathcal{B}$ is an operator of type S, then, due to the linearity of $\mathcal{B}$ and (N), $\mathcal{B}\bar u$ is also a solution of (N). Moreover, if $G^{\mathcal{B}\bar u}_{\bar\alpha}$ and $F^{\mathcal{B}\bar u}_{\bar\alpha}$, $\bar\alpha \in \mathcal{I}$, denote the velocity and strength traces of the strings at the vertices of the network for the solution $\mathcal{B}\bar u$, then

$$G^{\mathcal{B}\bar u}_{\bar\alpha} = \mathcal{B}G_{\bar\alpha}, \qquad F^{\mathcal{B}\bar u}_{\bar\alpha} = \mathcal{B}F_{\bar\alpha}.$$

That is true, in particular, when $\mathcal{B}$ is one of the operators $\mathcal{P}$ or $\mathcal{Q}$. The following lemma contains a fundamental technical step in our construction.

LEMMA 2.10. *There exists a constant C, independent of $\bar u$, such that*

$$\mathbf{E}_{\mathcal{P}\bar u}(t) \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |F(t)|^2 dt, \qquad \mathbf{E}_{\mathcal{Q}\bar u}(t) \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |G(t)|^2 dt \tag{2.19}$$

for every $T^* \in \mathbb{R}$ and $t \in [T^* - L_{\mathcal{A}}, T^* + L_{\mathcal{A}}]$.

Proof. (i) Fix $T^* \in \mathbb{R}$. We shall prove first that

$$\mathbf{E}_{\mathcal{P}\bar u}(T^*) \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |F(t)|^2 dt, \qquad \mathbf{E}_{\mathcal{Q}\bar u}(T^*) \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |G(t)|^2 dt. \tag{2.20}$$

As a consequence of Propositions 2.8 and 2.9 we have

$$\mathcal{Q}F_{\bar\alpha} = \mathcal{L}_{\bar\alpha}G, \qquad \mathcal{Q}G_{\bar\alpha} = \mathcal{K}_{\bar\alpha}G,$$
$$\mathcal{P}F_{\bar\alpha} = -\mathcal{L}_{\bar\alpha}F, \qquad \mathcal{P}G_{\bar\alpha} = \widehat{\mathcal{K}}_{\bar\alpha}F$$

for $\bar\alpha \in \mathcal{I}$. Then, from Propositions 2.1 and 2.4(i) it follows that

$$E^{\bar\alpha}_{\mathcal{Q}\bar u}(T^*) \le C\int_{T^*-\ell_{\bar\alpha}}^{T^*+\ell_{\bar\alpha}} \left(|\mathcal{L}_{\bar\alpha}G(t)|^2 + |\mathcal{K}_{\bar\alpha}G(t)|^2\right) dt \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |G(t)|^2 dt,$$

$$E^{\bar\alpha}_{\mathcal{P}\bar u}(T^*) \le C\int_{T^*-\ell_{\bar\alpha}}^{T^*+\ell_{\bar\alpha}} \left(|\mathcal{L}_{\bar\alpha}F(t)|^2 + |\widehat{\mathcal{K}}_{\bar\alpha}F(t)|^2\right) dt \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |F(t)|^2 dt,$$

where, as above, $E^{\bar\alpha}$ is the energy of the solution in the string $\mathbf{e}_{\bar\alpha}$. It suffices to note that $\mathbf{E} = \sum_{\bar\alpha\in\mathcal{I}} E^{\bar\alpha}$ to obtain the inequalities (2.20).

(ii) Now we prove that these inequalities remain true for all $t \in [T^* - L_{\mathcal{A}}, L^* + T_{\mathcal{A}}]$. Indeed, if $t \in [T^* - L_{\mathcal{A}}, T^* + L_{\mathcal{A}}]$, from Proposition 1.1 we have

$$\begin{aligned}
\mathbf{E}_{\mathcal{P}\bar u}(t) &= \mathbf{E}_{\mathcal{P}\bar u}(T^*) - \int_{T^*}^{t} F^{\mathcal{P}\bar u}(\tau)G^{\mathcal{P}\bar u}(\tau)dt \\
&\le \mathbf{E}_{\mathcal{P}\bar u}(T^*) + \left|\int_{T^*}^{t} (|F^{\mathcal{P}\bar u}(\tau)|^2 + |G^{\mathcal{P}\bar u}(\tau)|^2)dt\right| \\
&\le \mathbf{E}_{\mathcal{P}\bar u}(T^*) + \int_{T^*-L_{\mathcal{A}}}^{T^*+L_{\mathcal{A}}} (|\mathcal{P}F(\tau)|^2 + |\mathcal{P}G(\tau)|^2)dt \\
&\le \mathbf{E}_{\mathcal{P}\bar u}(T^*) + \int_{T^*-L_{\mathcal{A}}}^{T^*+L_{\mathcal{A}}} (|\mathcal{P}F(\tau)|^2 + |\mathcal{Q}F(\tau)|^2)dt \le C\int_{T^*-2L_{\mathcal{A}}}^{T^*+2L_{\mathcal{A}}} |F(\tau)|^2 dt.
\end{aligned}$$

(In the last step we have used Proposition 2.4(i) and the result of (i).) For the operator $\mathcal{Q}$ the proof is similar. □

Remark 4. When $\bar u$ is a solution of (1.1)–(1.5) (i.e., $G \equiv 0$), Lemma 2.10 gives $\mathbf{E}_{\mathcal{Q}\bar u}(t) = 0$. This implies that $\mathcal{Q}\bar u(t) = 0$. This relation may be viewed as a generalization of the time periodicity property of the solutions of the 1-d wave equation with homogeneous Dirichlet boundary conditions, which with our notation may be written as $\ell^- u(t) = 0$. As we have shown in Proposition 2.5, this generalized periodicity implies that all the essential L^2 information on $\bar u$ is contained in an interval of length $2L_{\mathcal{A}}$.

3. The main observability theorem. In this section we prove our main observability result for the solutions of the homogeneous system (1.1)–(1.5).

For every nonempty multi-index $\bar\alpha = (\alpha_1, \dots, \alpha_k) \in \mathcal{I}$ we define the operator $\mathcal{D}_{\bar\alpha}$ by

$$\mathcal{D}_{\bar\alpha} := \left(\prod_{i=1,\ i\ne\alpha_1}^{m} \mathcal{Q}_i\right)\left(\prod_{i=1,\ i\ne\alpha_2}^{m_{\alpha_1}} \mathcal{Q}_{\alpha_1,i}\right)\cdots\left(\prod_{i=1,\ i\ne\alpha_{k-1}}^{m_{\alpha_1,\dots,\alpha_{k-1}}} \mathcal{Q}_{\alpha_1,\dots,\alpha_{k-1},i}\right), \tag{3.1}$$

and for the empty index $\mathcal{D}$ is the identity operator. We recall that $\mathcal{Q}_{\bar\beta}$ is the operator constructed in the previous section for the subtree $\mathcal{A}_{\bar\beta}$ and that the products in (3.1) denote the composition of operators.

Note that for every $\bar\alpha \in \mathcal{I}$ the operator $\mathcal{D}_{\bar\alpha}$ is of type S with $s(\mathcal{D}_{\bar\alpha}) < L_{\mathcal{A}}$.

Now the following result holds.

LEMMA 3.1. *There exists a positive constant C such that for every $\bar\alpha \in \mathcal{I}_{\mathcal{S}}$ and every solution $\bar u$ of* (N)

$$\mathbf{E}_{\mathcal{D}_{\bar\alpha}\bar u}(t) \le C \int_{t-2L_{\mathcal{A}}}^{t+2L_{\mathcal{A}}} \left(|F(\tau)|^2 + |G(\tau)|^2\right) d\tau$$

for any $t \in \mathbb{R}$.

Proof. We proceed by induction. For the case of a single string the assertion is an immediate consequence of Proposition 2.1.

Now let $\bar\alpha = (\alpha_1, \dots, \alpha_k) \in \mathcal{I}_{\mathcal{S}}$ and assume that the assertion of the theorem is true for the subtree $\mathcal{A}_{\alpha_1}$. That implies that

$$\mathbf{E}^{\alpha_1}_{\mathcal{D}^{\alpha_1}_{\bar\alpha}\bar u}(t) \le C \int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} \left(|F_{\alpha_1}(\tau)|^2 + |G_{\alpha_1}(\tau)|^2\right) d\tau \tag{3.2}$$

for any solution $\bar u$ of (N), where

$$\mathcal{D}^{\alpha_1}_{\bar\alpha} := \left(\prod_{i=1,\ i\neq\alpha_2}^{m_{\alpha_1}} \mathcal{Q}_{\alpha_1,i}\right) \cdots \left(\prod_{i=1,\ i\neq\alpha_{k-1}}^{m_{\alpha_1,\dots,\alpha_{k-1}}} \mathcal{Q}_{\alpha_1,\dots,\alpha_{k-1},i}\right) \tag{3.3}$$

is the operator $\mathcal{D}_{\bar\alpha}$ for the subtree $\mathcal{A}_{\alpha_1}$ with $\bar\alpha = (\alpha_2, \dots, \alpha_k)$.

First, we estimate the energy $\mathbf{E}^{\alpha_1}_{\mathcal{D}_{\bar\alpha}\bar u}$ of $\mathcal{D}_{\bar\alpha}\bar u$ on the subtree $\mathcal{A}_{\alpha_1}$. To do this, we set

$$\bar\omega := \left(\prod_{j=1,\ j\neq\alpha_1}^{m} \mathcal{Q}_j\right) \bar u, \qquad \bar\omega_i := \left(\prod_{\substack{j=1,\ j\neq\alpha_1\\ j\neq i}}^{m} \mathcal{Q}_j\right) \bar u, \quad i = 1, \dots, m. \tag{3.4}$$

Note that these functions are also solutions of (N). They verify $\bar\omega = \mathcal{Q}_i\bar\omega_i$ and

$$\mathcal{D}_{\bar\alpha}\bar u = \mathcal{D}^{\alpha_1}_{\bar\alpha}\bar\omega. \tag{3.5}$$

Additionally, from (3.2),

$$\mathbf{E}^{\alpha_1}_{\mathcal{D}^{\alpha_1}_{\bar\alpha}\bar\omega}(t) \le C \int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} \left(|F^{\bar\omega}_{\alpha_1}(\tau)|^2 + |G^{\bar\omega}_{\alpha_1}(\tau)|^2\right) d\tau. \tag{3.6}$$

However, from the coupling formulas (1.12) we obtain that

$$\sum_{i=1}^{m} F^{\bar\omega}_i = \widehat{F}^{\bar\omega}, \qquad G^{\bar\omega}_i = \widehat{G}^{\bar\omega}, \tag{3.7}$$

so that

$$F^{\bar\omega}_{\alpha_1} = \widehat{F}^{\bar\omega} - \sum_{i=1,\ i\neq\alpha_1}^{m} \mathcal{Q}_i F^{\bar\omega_i}_i = \widehat{F}^{\bar\omega} + \sum_{i=1,\ i\neq\alpha_1}^{m} \mathcal{P}_i \widehat{G}^{\bar\omega_i}, \qquad G^{\bar\omega}_{\alpha_1} = \hat{G}^{\bar\omega}, \tag{3.8}$$

holds. Then, using the equalities (3.8), (3.6) gives

$$\mathbf{E}^{\alpha_1}_{\mathcal{D}^{\alpha_1}_{\bar\alpha}\bar\omega}(t) \le C\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} \left(\left| \widehat{F}^{\bar\omega}(\tau) + \sum_{i=1,\, i\neq\alpha_1}^{m} \mathcal{P}_i \widehat{G}^{\bar\omega_i}(\tau) \right|^2 + |\hat{G}^{\bar\omega}(\tau)|^2 \right) d\tau,$$

and this implies

$$\mathbf{E}^{\alpha_1}_{\mathcal{D}^{\alpha_1}_{\bar\alpha}\bar\omega}(t) \le C\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} \left(|\widehat{F}^{\bar\omega}(\tau)|^2 + \sum_{i=1,\, i\neq\alpha_1}^{m} |\mathcal{P}_i \widehat{G}^{\bar\omega_i}(\tau)|^2 + |\hat{G}^{\bar\omega}(\tau)|^2 \right) d\tau. \tag{3.9}$$

Now, from the definition of $\bar\omega$ and the formulas (2.4), (2.5) we have

$$\widehat{F}^{\bar\omega} = \left(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j \right) \widehat{F} = \left(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j \right) \ell^+ F + \left(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j \right) \ell^- G$$

and consequently

$$\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} |\widehat{F}^{\bar\omega}|^2 d\tau \le 2\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} \left(\left| \left(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j \right) \ell^+ F \right|^2 + \left| \left(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j \right) \ell^- G \right|^2 \right) d\tau.$$

Observe that the operators $(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j)\ell^+$ and $(\prod_{j=1,\, j\neq\alpha_1}^{m} \mathcal{Q}_j)\ell^-$ are of type S with $s < L_{\mathcal{A}} - L_{\alpha_1}$, so that the latter inequality combined with Proposition 2.4 provides

$$\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} |\widehat{F}^{\bar\omega}(\tau)|^2 d\tau \le C\int_{t-2L_{\mathbb{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau.$$

In a similar way it may be proved that

$$\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} |\mathcal{P}_i \widehat{G}^{\bar\omega_i}(\tau)|^2 d\tau \le C\int_{t-2L_{\mathbb{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau$$

and

$$\int_{t-2L_{\alpha_1}}^{t+2L_{\alpha_1}} |\hat{G}^{\bar\omega}(\tau)|^2 d\tau \le C\int_{t-2L_{\mathbb{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau.$$

Therefore, these three inequalities together with (3.5) and (3.9) give

$$\mathbf{E}^{\alpha_1}_{\mathcal{D}_{\bar\alpha}\bar u}(t) \le C\int_{t-2L_{\mathbb{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau. \tag{3.10}$$

Now we proceed to estimate the energies $\mathbf{E}^{i}_{\mathcal{D}_{\bar\alpha}\bar u}$ of $\mathcal{D}_{\bar\alpha}\bar u$ on the remaining subtrees $\mathcal{A}_i$ (i.e., for $i \neq \alpha_1$). According to Lemma 2.10, applied to $\bar\omega_i$ in the subtree $\mathcal{A}_i$, it holds that for every t' in $[t - L_i, t + L_i]$

$$\mathbf{E}^{i}_{\bar\omega}(t') = \mathbf{E}^{i}_{\mathcal{Q}_i\bar\omega_i}(t') \le C\int_{t-2L_i}^{t+2L_i} |G_i^{\bar\omega_i}(\tau)|^2 d\tau \tag{3.11}$$

for $i = 1, \dots, m$. Taking into account that

$$G_i^{\bar\omega_i} = \left(\prod_{\substack{j=1,\ j\neq\alpha_1\\ j\neq i}}^{m} \mathcal{Q}_j \right) \widehat{G} = \left(\prod_{\substack{j=1,\ j\neq\alpha_1\\ j\neq i}}^{m} \mathcal{Q}_j \right) \ell^+ F + \left(\prod_{\substack{j=1,\ j\neq\alpha_1\\ j\neq i}}^{m} \mathcal{Q}_j \right) \ell^- G, \tag{3.12}$$

we get from (3.11) and Proposition 2.4(i)

$$\mathbf{E}^i_{\bar\omega}(t') \leq C \int_{t-L_{\mathcal{A}}-L_i+L_{\alpha_1}}^{t+L_{\mathcal{A}}+L_i-L_{\alpha_1}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau \leq C \int_{t-2L_{\mathcal{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau. \tag{3.13}$$

(Here we have used the fact that the operators applied to F and G in the right-hand term of (3.12) are of type S with $s = L_{\mathcal{A}} - L_{\alpha_1} - L_i$.)

Now, if we apply Proposition 2.4(ii) with $\mathcal{B} = \mathcal{D}_{\bar\alpha}^{\alpha_1}$ to (3.13) (recall that $s(\mathcal{D}_{\bar\alpha}^{\alpha_1}) < L_{\alpha_1}$), we obtain, after choosing $t' = t$,

$$\mathbf{E}^i_{\mathcal{D}_{\bar\alpha}} \bar u(t) = \mathbf{E}^i_{\mathcal{D}_{\bar\alpha}^{\alpha_1}\bar\omega}(t') \leq \ C \int_{t-2L_{\mathcal{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau. \tag{3.14}$$

Finally, from Proposition 2.1 we obtain that the component u of $\bar u$ verifies, for every $t' \in [t - L_{\mathcal{A}}, t + L_{\mathcal{A}}]$,

$$E_u(t') \leq \ C \int_{t-\ell-L_{\mathcal{A}}}^{t+\ell+L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau.$$

Thus, using Proposition 2.4(ii), it holds that

$$E_{\mathcal{D}_{\bar\alpha}\bar u}(t') \leq \ C \int_{t-\ell-L_{\mathcal{A}}}^{t+\ell+L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau$$

for every $t' \in [t - L_{\mathcal{A}} + s(\mathcal{D}_{\bar\alpha}), t + L_{\mathcal{A}} - s(\mathcal{D}_{\bar\alpha})]$, and, since $s(\mathcal{D}_{\bar\alpha}) < L_{\mathcal{A}}$, this is true in particular for $t' = t$. Therefore,

$$E_{\mathcal{D}_{\bar\alpha}\bar u}(t) \leq \ C \int_{t-2L_{\mathcal{A}}}^{t+2L_{\mathcal{A}}} (|F(\tau)|^2 + |G(\tau)|^2) d\tau. \tag{3.15}$$

Now it suffices to combine (3.10), (3.14), (3.15) and the fact that $\mathbf{E}_{\mathcal{D}_{\bar\alpha}\bar u} = E_{\mathcal{D}_{\bar\alpha}\bar u} + \sum_{i=1}^m \mathbf{E}^i_{\mathcal{D}_{\bar\alpha}\bar u}$ to conclude the proof. □

With the help of Lemma 3.1 we obtain the following important property of the solutions of the system (1.1)–(1.6).

THEOREM 3.2. *There exists a constant C such that*

$$E_{\mathcal{D}_{\bar\alpha}\bar u}(0) = E_{\mathcal{D}_{\bar\alpha}\bar u}(t) \leq \ C \int_0^{2L_{\mathcal{A}}} |F(\tau)|^2 d\tau$$

for every solution $\bar u$ of (1.1)–(1.5) *and any $\bar\alpha \in \mathcal{I}_{\mathcal{S}}$.*

Proof. If $\bar u$ is a solution of (1.1)–(1.6), so is $\mathcal{D}_{\bar\alpha}\bar u$. In particular, the energy of $\mathcal{D}_{\bar\alpha}\bar u$ is conserved. Then, taking into account that $G \equiv 0$ for the solutions of (1.1)–(1.5), from Lemma 3.1 it holds that

$$\mathbf{E}_{\mathcal{D}_{\bar\alpha}\bar u}(0) = \mathbf{E}_{\mathcal{D}_{\bar\alpha}\bar u}(2T_{\mathcal{A}}) \leq \ C \int_0^{4L_{\mathcal{A}}} |F(\tau)|^2 d\tau. \tag{3.16}$$

On the other hand, in this case $\mathcal{Q}F \equiv 0$, and then, using Proposition 2.5 (which may be applied to $\mathcal{Q}$ on the basis of Proposition 2.7), we have

$$\int_0^{4L_{\mathcal{A}}} |F(\tau)|^2 d\tau \le C \int_0^{2L_{\mathcal{A}}} |F(\tau)|^2 d\tau.$$

With this, the assertion of the theorem follows from (3.16). ∎

4. Relation between $\mathcal{P}$ and $\mathcal{Q}$ and the eigenvalues.

4.1. The eigenvalue problem. We consider the eigenvalue problem for the Laplace operator on the network associated with the hyperbolic problem (1.1)–(1.5):

$$-\theta^{\bar\alpha}_{xx}(x) = \mu\ \theta^{\bar\alpha}(x) \qquad \text{in } [0,\ell_{\bar\alpha}], \quad \bar\alpha \in \mathcal{I}, \tag{4.1}$$

$$\theta^{\bar\alpha\circ\beta}(0) = \theta^{\bar\alpha}(\ell_{\bar\alpha}), \qquad \bar\alpha \in \mathcal{I}_{\mathcal{M}}, \quad \beta = 1,\dots,m_{\bar\alpha}, \tag{4.2}$$

$$\sum_{\beta=1}^{m_{\bar\alpha}} \theta^{\bar\alpha\circ\beta}_x(0) = \theta^{\bar\alpha}_x(\ell_{\bar\alpha}), \qquad \bar\alpha \in \mathcal{I}_{\mathcal{M}}, \tag{4.3}$$

$$\theta^{\bar\alpha}(\ell_{\bar\alpha}) = 0, \qquad \bar\alpha \in \mathcal{I}_{\mathcal{S}}, \tag{4.4}$$

$$\theta(0) = 0 \qquad \text{at the root } \mathcal{R}. \tag{4.5}$$

It is well known (see, e.g., [8]) that the spectrum of this problem is formed by a positive, increasing sequence $\{\mu_k\}_{k\in\mathbb{Z}_+}$ of eigenvalues. We call it *spectrum of* $\mathcal{A}$ and denote it by $\sigma_{\mathcal{A}}$.

Clearly, we may consider the problem (4.1)–(4.5) for each subtree $\mathcal{A}_{\bar\alpha}$ of $\mathcal{A}$. The corresponding spectrum is called the *spectrum of* $\mathcal{A}_{\bar\alpha}$ and is denoted by $\sigma_{\bar\alpha}$.

For technical reasons, as we did for the system (1.1)–(1.5), we will also consider smooth solutions of (4.1), which verify the boundary conditions (4.2)–(4.4) but not necessarily (4.5). For brevity, they are simply called *solutions of* (N_E) *corresponding to* μ.

PROPOSITION 4.1. *If μ is a common eigenvalue of two subtrees $\mathcal{A}_{\bar\alpha\circ i}$, $\mathcal{A}_{\bar\alpha\circ j}$ $(i \ne j)$ with the same root $\mathcal{O}_{\bar\alpha}$, then μ is also an eigenvalue of $\mathcal{A}$. Moreover, there exists a nonzero eigenfunction $\bar\theta$ associated with μ such that $\theta(0) = \theta_x(0) = 0$.*

Proof. Let $\bar\theta^{\bar\alpha\circ i}$, $\bar\theta^{\bar\alpha\circ j}$ be nonzero eigenfunctions corresponding to the eigenvalue μ for the subtrees $\mathcal{A}_{\bar\alpha\circ i}$ and $\mathcal{A}_{\bar\alpha\circ j}$, respectively. These functions are defined in the corresponding subtrees, but it will be sufficient to paste them conveniently to build up an eigenfunction of $\mathcal{A}$.

We may assume that the numbers $\theta^{\bar\alpha\circ i}_x(0)$, $\theta^{\bar\alpha\circ j}_x(0)$ are both different from zero. Indeed, if one of them, say $\theta^{\bar\alpha\circ i}_x(0)$, vanishes, then the relations $\theta^{\bar\alpha\circ i}(0) = \theta^{\bar\alpha\circ i}_x(0) = 0$ ensure that the function $\bar\theta$, obtained by extending by zero the function $\bar\theta^{\bar\alpha\circ i}$ to the whole tree $\mathcal{A}$, is an eigenfunction of $\mathcal{A}$.

Now define the function $\bar\theta$ by

$$\theta_{\bar\alpha'} = \begin{cases} \theta^{\bar\alpha\circ j}_x(0)\ \theta^{\bar\alpha\circ i}_{\bar\beta,x} & \text{if } \bar\alpha' = \bar\alpha\circ i\circ\bar\beta, \\ -\theta^{\bar\alpha\circ i}_x(0)\ \theta^{\bar\alpha\circ j}_{\bar\beta,x} & \text{if } \bar\alpha' = \bar\alpha\circ j\circ\bar\beta, \\ 0 & \text{otherwise;} \end{cases}$$

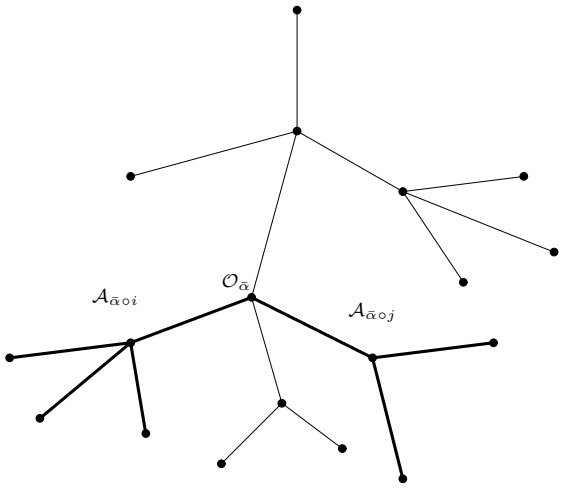

FIG. 4.1. *The subtree* $\mathcal{A}_{\bar\alpha\circ i} \vee \mathcal{A}_{\bar\alpha\circ j}$.

i.e., $\bar\theta$ coincides in the subtree $\mathcal{A}_{\bar\alpha\circ i}$ with $\theta_x^{\bar\alpha\circ j}(0)\bar\theta^{\bar\alpha\circ i}$, in $\mathcal{A}_{\bar\alpha\circ j}$ with $-\theta_x^{\bar\alpha\circ i}(0)\bar\theta^{\bar\alpha\circ j}$, and vanishes outside those subtrees. It is easy to see that $\bar\theta$ satisfies the boundary conditions (4.2)–(4.3) at $\mathcal{O}_{\bar\alpha}$:

$$\sum_{k=1}^{m_{\bar\alpha}} \theta_x^{\bar\alpha\circ k}(0) = \theta_x^{\bar\alpha\circ j}(0)\theta_x^{\bar\alpha\circ i}(0) - \theta_x^{\bar\alpha\circ i}(0)\theta_x^{\bar\alpha\circ j}(0) = 0 = \theta_x^{\bar\alpha}(\ell_{\bar\alpha}).$$

At the other nodes the coupling conditions are obviously satisfied, and therefore $\bar\theta$ is an eigenfunction of $\mathcal{A}$.

Finally, observe that in both cases the eigenfunction $\bar\theta$ constructed here is such that $\theta(0) = \theta_x(0) = 0$ (and thus, $\theta \equiv 0$; i.e., $\bar\theta$ vanishes at the whole string containing the root). □

Remark 5. Note that the eigenfunction obtained in the proof of the previous proposition vanishes everywhere outside the subtrees $\mathcal{A}_{\bar\alpha\circ i}$, $\mathcal{A}_{\bar\alpha\circ j}$. If we denote by $\mathcal{A}_{\bar\alpha\circ i} \vee \mathcal{A}_{\bar\alpha\circ j}$ the tree formed by $\mathcal{A}_{\bar\alpha\circ i}$ and $\mathcal{A}_{\bar\alpha\circ j}$ in which the node $\mathcal{O}_{\bar\alpha}$ is considered as an interior point of a string of length $\ell_{\bar\alpha\circ i} + \ell_{\bar\alpha\circ j}$ (see Figure 4.1), we obtain that these subtrees have a common eigenvalue if and only if there exists an eigenfunction of $\mathcal{A}_{\bar\alpha\circ i} \vee \mathcal{A}_{\bar\alpha\circ j}$ that vanishes at the point $\mathcal{O}_{\bar\alpha}$.

As has been shown above, the operators $\mathcal{P}$ and $\mathcal{Q}$ are of type S with $s(\mathcal{P}) = s(\mathcal{Q}) = L_{\mathcal{A}}$. According to Remark 2, there exist functions p and q such that

$$\mathcal{P}e^{i\lambda t} = p(\lambda)e^{i\lambda t}, \qquad \mathcal{Q}e^{i\lambda t} = q(\lambda)e^{i\lambda t}. \tag{4.6}$$

PROPOSITION 4.2. *Let* $\lambda \in \mathbb{R} \setminus \{0\}$ *and* $f, g \in \mathbb{C}$ *such that*

$$q(\lambda)f + i\lambda p(\lambda)g = 0. \tag{4.7}$$

If the tree $\mathcal{A}$ *satisfies the property*

$$|q_{\bar\alpha\circ i}(\lambda)| + |q_{\bar\alpha\circ j}(\lambda)| \neq 0 \quad \text{for any } \bar\alpha \in \mathcal{I}_{\mathcal{M}},\ i, j = 1, \dots, m_{\bar\alpha},\ i \neq j, \tag{4.8}$$

then there exists a unique solution $\bar{\theta}$ *of* (N_E) *corresponding to the value* $\mu = \lambda^2$ *such that*

$$\theta(0) = g \quad \textit{and} \quad \theta_x(0) = f. \tag{4.9}$$

Proof. First we construct the component θ of $\bar{\theta}$ (the one corresponding to the string $\mathbf{e}$). We set

$$\theta(x) = g\cos\lambda x + \frac{f}{\lambda}\sin\lambda x, \tag{4.10}$$

which clearly satisfies (4.9).

If the network consists of a single string of length ℓ, then $p(\lambda) = \cos\lambda\ell$, $q(\lambda) = i\sin\lambda\ell$, and condition (4.7) becomes $if\sin\lambda\ell + ig\lambda\cos\lambda\ell = 0$. This implies that $\theta(\ell) = g\cos\lambda\ell + \frac{f}{\lambda}\sin\lambda\ell = 0$, which means that θ is a solution of (N_E), and so the assertion is true in this case.

In the general case the remaining components of $\bar{\theta}$ are constructed by induction. Assume that the proposition is true for the subtrees $\mathcal{A}_1, \dots, \mathcal{A}_m$.

If we were able to choose numbers $f_1, \dots, f_m$ verifying

$$\sum_{k=1}^{m} f_k = \theta_x(\ell) \ \text{ and } \ q_k(\lambda)f_k + i\lambda p_k(\lambda)\theta(\ell) = 0 \quad \text{for } k = 1, \dots, m, \tag{4.11}$$

then, according to the induction assumption, we could find solutions $\bar{\theta}^1, \dots, \bar{\theta}^m$, defined on the subtrees $\mathcal{A}_1, \dots, \mathcal{A}_m$, respectively, such that

$$\theta^k(0) = \theta(\ell), \quad \theta^k_x(0) = f_k \text{ for } k = 1, \dots, m.$$

This would imply that

$$\sum_{k=1}^{m} \theta^k_x(0) = \theta(\ell) \ \text{ and } \quad \theta^k(0) = \theta(\ell) \ \text{ for } k = 1, \dots, m.$$

Therefore, the function $\bar{\theta}$ defined on the tree by $\theta_{k\circ\bar{\alpha}} = \theta^k_{\bar{\alpha}}$ would be the solution of (N_E), whose existence is asserted in the proposition. Consequently, it remains to prove the possibility of the decomposition (4.11).

We remark that from the definition of p and q and formulas (2.12), (2.13) it follows that

$$p = \cos\lambda\ell \sum_{k=1}^{m} p_k \prod_{j\neq k} q_j + i\sin\lambda\ell \prod_{j=1}^{m} q_j, \tag{4.12}$$

$$q = i\sin\lambda\ell \sum_{k=1}^{m} p_k \prod_{j\neq k} q_j + \cos\lambda\ell \prod_{j=1}^{m} q_j. \tag{4.13}$$

Note that condition (4.8) implies that among the numbers $q_k(\lambda)$, $k = 1, \dots, m$, at most one may be equal to zero. Thus, we consider two cases: (a) all the numbers $q_k(\lambda)$, $k = 1, \dots, m$, are different from zero and (b) exactly one of those numbers, say, $q_1(\lambda)$, is equal to zero.

Case (a). If we take

$$f_k = \frac{-i\lambda p_k(\lambda)\theta(\ell)}{q_k(\lambda)},$$

then

$$\sum_{k=1}^{m} f_k = -i\lambda\theta(\ell)\sum_{k=1}^{m}\frac{p_k}{q_k} = -i\lambda\left(g\cos\lambda\ell + \frac{f}{\lambda}\sin\lambda\ell\right)\frac{\sum_{k=1}^{m} p_k\prod_{j\neq k} q_j}{\prod_{j=1}^{m} q_j}.$$

This equality, taking into account (4.12) and (4.13), gives

$$\begin{aligned}\sum_{k=1}^{m} f_k &= -i\lambda g\left(\frac{p}{\prod_{j=1}^{m} q_j} - i\sin\lambda\ell\right) - f\left(\frac{q}{\prod_{j=1}^{m} q_j} - \cos\lambda\ell\right)\\ &= -\lambda g\sin\lambda\ell + f\cos\lambda\ell - \frac{i\lambda pg + qf}{\prod_{j=1}^{m} q_j} = -\lambda g\sin\lambda\ell + f\cos\lambda\ell = \theta_x(\ell).\end{aligned}$$

Thus, the numbers $f_1,\dots,f_m$ satisfy (4.11).

Case (b). The relations (4.12), (4.13) together with $q_1(\lambda) = 0$ give

$$p(\lambda) = \cos\lambda\ell p_1(\lambda)\prod_{j\neq 1} q_j(\lambda), \qquad q(\lambda) = i\sin\lambda\ell p_1(\lambda)\prod_{j\neq 1} q_j(\lambda),$$

and from (4.7) we obtain

$$0 = q(\lambda)f + i\lambda p(\lambda)g = i\lambda\left(g\cos\lambda\ell + \frac{g}{\lambda}\sin\lambda\ell\right)p_1(\lambda)\prod_{j\neq 1} q_j(\lambda) = i\lambda\theta(\ell)p_1(\lambda)\prod_{j\neq 1} q_j(\lambda).$$

However, $\prod_{j\neq 1} q_j(\lambda) \neq 0$ and then, necessarily, $\theta(\ell)p_1(\lambda) = 0$. This means that if we choose $f_1 = \theta_x(\ell)$ and $f_2,\dots,f_m$ verifying

$$\sum_{k=2}^{m} f_k = 0 \ \text{ and } \ q_k(\lambda)f_k + i\lambda p_k(\lambda)\theta(\ell) = 0 \quad \text{for } k = 2,\dots,m,$$

as in the previous case, then the condition (4.11) is satisfied.

So far, we have proved the existence of a solution. It turns out that for the solutions satisfying (4.2) we can give an explicit formula. Indeed, if we apply Propositions 2.8 and 2.9 to the solution $\bar\theta(t,x) = e^{i\lambda t}\bar\theta(x)$ of (N), we obtain

$$i\lambda p(\lambda)\theta^{\bar\alpha}(0) = \hat k(\lambda)\theta_x(0) = \hat k(\lambda)f, \qquad p(\lambda)\theta_x^{\bar\alpha}(0) = -l(\lambda)\theta_x(0) = -l(\lambda)f, \tag{4.14}$$

$$q(\lambda)\theta^{\bar\alpha}(0) = k(\lambda)\theta(0) = k(\lambda)g, \qquad q(\lambda)\theta_x^{\bar\alpha}(0) = i\lambda l(\lambda)\theta(0) = i\lambda l(\lambda)g, \tag{4.15}$$

where k, $\hat k$, l, and r are the functions associated with the operators $\mathcal{K}$, $\hat{\mathcal{K}}$, $\mathcal{L}$, and $\mathcal{R}$, respectively, according to Remark 2.

On the other hand, the condition (4.8) implies that at least one of the numbers $p(\lambda)$ or $q(\lambda)$ is different from zero (see Proposition 4.4 below). Therefore, one of the equalities (4.14), (4.15) provides us with an explicit formula for the values of $\theta^{\bar\alpha}(0)$ and $\theta_x^{\bar\alpha}(0)$ for any $\bar\alpha \in \mathcal{I}_{\mathcal{M}}$ and thus for the solution $\bar\theta$. In particular, if $f = g = 0$, the corresponding solution vanishes identically on $\mathcal{A}$, which clearly implies the uniqueness of the solution for arbitrary values of f and g. □

Remark 6. The converse assertion is also true, even if the condition (4.8) is not fulfilled. Indeed, if $\bar\theta$ is a solution of ($\mathrm{N_E}$), then $\bar\theta(t,x) = e^{i\lambda t}\bar\theta(x)$ is a solution of (N) and $\theta_t(t,0) = i\lambda e^{i\lambda t}\theta(0)$, $\theta_x(t,0) = e^{i\lambda t}\theta_x(0)$. Then, from the relations (2.1) and (4.6) it follows that

$$0 = \mathcal{P}\theta_t(t,0) + \mathcal{Q}\theta_x(t,0) = (ip\lambda\theta(0) + q\theta_x(0))e^{i\lambda t}$$

for every $t \in \mathbb{R}$. Thus, (4.7) holds.

Now we are ready to prove the following basic property.

PROPOSITION 4.3. *Let $0 \neq \lambda \in \mathbb{R}$. Then λ^2 is an eigenvalue of $\mathcal{A}$ if and only if $q(\lambda) = 0$.*

Proof. First we prove that $q(\lambda) = 0$ implies that λ^2 is an eigenvalue, i.e., that there exists a nonzero solution of (4.1)–(4.5) for that value of λ. If the tree verifies (4.8), then this fact follows immediately from Proposition 4.2, choosing $g = 0$, $f \neq 0$. Note that the condition $0 \neq f = \theta_x(0)$ guarantees that $\bar\theta$ is not identically equal to zero. In particular, the assertion is true for a string, as it always verifies (4.8).

In the general case when the condition (4.8) may fail, we follow an induction argument: we suppose that the assertion has been proved for all the subtrees $\mathcal{A}_{\bar\alpha}$ with nonempty $\bar\alpha$.

If $q_{\bar\alpha\circ i}(\lambda) = q_{\bar\alpha\circ j}(\lambda) = 0$ for some $\bar\alpha \in \mathcal{I}_{\mathcal{M}}$, $i \neq j$, then, according to the induction hypothesis, λ^2 is an eigenvalue of both $\mathcal{A}_{\bar\alpha\circ i}$ and $\mathcal{A}_{\bar\alpha\circ j}$. Then from Proposition 4.1 it follows that λ^2 is also an eigenvalue of $\mathcal{A}$.

Let us see now the converse assertion. Let $\bar\theta$ be a nonzero eigenfunction corresponding to the eigenvalue λ^2. Then the function $\bar u(t,x) = e^{i\lambda t}\bar\theta(x)$ is a solution of (N). Choose $\bar\alpha \in \mathcal{I}$ such that one of the numbers $\theta^{\bar\alpha}(0)$ or $\theta^{\bar\alpha}_x(0)$ is different from zero (that is possible since, otherwise, it would be $\bar\theta \equiv 0$). For this solution of (N) we have for every $\bar\alpha \in \mathcal{I}$

$$F_{\bar\alpha}(t) = e^{i\lambda t}\theta^{\bar\alpha}_x(0), \qquad G_{\bar\alpha}(t) = i\lambda e^{i\lambda t}\theta^{\bar\alpha}(0),$$

and in particular, $G \equiv 0$. Then, from the Propositions 2.8 and 2.9 it follows that

$$0 = \mathcal{L}_{\bar\alpha}G = \mathcal{Q}F_{\bar\alpha} = \mathcal{Q}e^{i\lambda t}\theta^{\bar\alpha}_x(0) = q(\lambda)\theta^{\bar\alpha}_x(0),$$

$$0 = \mathcal{K}_{\bar\alpha}G = \mathcal{Q}G_{\bar\alpha} = \mathcal{Q}e^{i\lambda t}\theta^{\bar\alpha}(0) = i\lambda q(\lambda)\theta^{\bar\alpha}(0),$$

and therefore, necessarily, $q(\lambda) = 0$. ∎

4.2. Further properties of p and q. Now we give some additional properties of the functions p and q, which are used in the next section.

PROPOSITION 4.4. *For every tree $\mathcal{A}$ the following properties hold:*

(i) *one of the functions p, q is even and the other is odd;*

(ii) *there exists $\lambda_0 \in \mathbb{R}$ such that $p(\lambda_0) = q(\lambda_0) = 0$ if and only if there exist two subtrees $\mathcal{A}_{\bar\alpha\circ i}$, $\mathcal{A}_{\bar\alpha\circ j}$, $i \neq j$, with common root $\mathcal{O}_{\bar\alpha}$ such that $q_{\bar\alpha\circ i}(\lambda_0) = q_{\bar\alpha\circ j}(\lambda_0) = 0$.*

Proof. We proceed by induction. For a single string

$$p(\lambda) = \cos\lambda\ell, \quad q(\lambda) = i\sin\lambda\ell.$$

In this case (i) is trivial. Assertion (ii) follows from the fact that $|p|^2 + |q|^2 = 1$.

Suppose now that (i), (ii) are true for the subtrees $\mathcal{A}_1, \dots, \mathcal{A}_m$. Let h be a function, which is either even or odd. Denote

$$\rho(h) = \begin{cases} 1 & \text{if } h \text{ is even,} \\ -1 & \text{if } h \text{ is odd.} \end{cases}$$

The function ρ is multiplicative: $\rho(h_1h_2) = \rho(h_1)\rho(h_2)$.

According to the definitions of p and q and the formulas (2.12), (2.13) we have that

$$q(\lambda) = i \sin \lambda\ell \sum_{i=1}^{m} p_i(\lambda) \prod_{j \neq i} q_j(\lambda) + \cos \lambda\ell \prod_{i=1}^{m} q_i(\lambda), \tag{4.16}$$

$$p(\lambda) = \cos \lambda\ell \sum_{i=1}^{m} p_i(\lambda) \prod_{j \neq i} q_j(\lambda) + i \sin \lambda\ell \prod_{i=1}^{m} q_i(\lambda). \tag{4.17}$$

The hypotheses with respect to the subtrees imply that $\rho(p_i) = -\rho(q_i)$, $i = 1, \ldots, m$. Then,

$$\rho\left(i \sin \lambda\ell \; p_i(\lambda) \prod_{j \neq i} q_j\right) = \prod_{i=1}^{m} \rho(q_i), \qquad \rho\left(\cos \lambda\ell \prod_{i=1}^{m} q_i\right) = \prod_{i=1}^{m} \rho(q_i),$$

and consequently, $\rho(q) = \prod_{i=1}^{m} \rho(q_i)$. In an analogous way it is proved that $\rho(p) = -\prod_{i=1}^{m} \rho(q_i)$, and then $\rho(p) = -\rho(q)$. This proves the property (i).

We now prove (ii). If $p(\lambda_0) = q(\lambda_0) = 0$, then from (4.16), (4.17) it follows that

$$0 = q(\lambda_0) = i \sin \lambda_0\ell \sum_{i=1}^{m} p_i(\lambda_0) \prod_{j \neq i} q_j(\lambda_0) + \cos \lambda_0\ell \prod_{i=1}^{m} q_i(\lambda_0),$$

$$0 = p(\lambda_0) = \cos \lambda_0\ell \sum_{i=1}^{m} p_i(\lambda_0) \prod_{j \neq i} q_j(\lambda_0) + i \sin \lambda_0\ell \prod_{i=1}^{m} q_i(\lambda_0).$$

This implies that

$$\sum_{i=1}^{m} p_i(\lambda_0) \prod_{j \neq i} q_j(\lambda_0) = 0, \tag{4.18}$$

$$\prod_{i=1}^{m} q_i(\lambda_0) = 0. \tag{4.19}$$

These equalities are verified if and only if for some i_0

$$q_{i_0}(\lambda_0) = 0, \qquad p_{i_0}(\lambda_0) \prod_{j \neq i_0} q_j(\lambda_0) = 0,$$

and this is equivalent to the fact that one of the following assertions is true:

(a) there exists $i_1 \neq i_0$ such that $q_{i_1}(\lambda_0) = 0$;

(b) $p_{i_0}(\lambda_0) = 0$.

In the first case assertion (ii) follows immediately. In (b), according to the induction assumption, there exist subtrees of $\mathcal{A}_{i_0}$, and consequently also of $\mathcal{A}$, that verify condition (ii). □

With the aid of the previous proposition it is possible to calculate how the operator $\mathcal{Q}$ acts on the functions $\sin \lambda t$ and $\cos \lambda t$.

COROLLARY 4.5. *The following equalities are verified:*

$$\mathcal{Q}\sin\lambda t = \begin{cases} q(\lambda)\sin\lambda t & \text{if } q \text{ is even,} \\ -iq(\lambda)\cos\lambda t & \text{if } q \text{ is odd,} \end{cases}$$

$$\mathcal{Q}\cos\lambda t = \begin{cases} q(\lambda)\cos\lambda t & \text{if } q \text{ is even,} \\ iq(\lambda)\sin\lambda t & \text{if } q \text{ is odd.} \end{cases}$$

Remark 7. As a consequence of the previous formulas, when q is an even function, then it is real valued, while when it is odd, then iq is real valued.

5. Observability results. In this section we express the inequalities from Theorem 3.2 in terms of the initial data of the solution $\bar{u}$. This allows us to obtain weighted observability inequalities, with explicit weights on the Fourier coefficient of the initial data of the solution. Further, we study under what conditions those weights are different from zero.

5.1. Weighted observability inequalities. As stated above, a solution $\bar{u}$ of (1.1)–(1.5) is expressed in terms of the initial data $\bar{u}_0$, $\bar{u}_1$ by the formula

$$\bar{u}(t) = \sum_{k\in\mathbf{Z}_+} \left(u_{0,k}\cos\lambda_k t + \frac{u_{1,k}}{\lambda_k}\sin\lambda_k t \right)\bar{\theta}_k, \tag{5.1}$$

where $\{u_{0,k}\}$, $\{u_{1,k}\}$ are the sequences of Fourier coefficients of $\bar{u}_0$, $\bar{u}_1$ with respect to the orthonormal basis of eigenfunctions $\{\bar{\theta}_k\}_{k\in\mathbb{Z}_+}$ and $\lambda_k = \sqrt{\mu_k}$.

Furthermore, the energy of the solution $\bar{u}$ is given by

$$\mathbf{E}_{\bar{u}} = \frac{1}{2}\sum_{k\in\mathbf{Z}_+} \left(\lambda_k^2 u_{0,k}^2 + u_{1,k}^2\right). \tag{5.2}$$

The operators $\mathcal{D}_{\bar{\alpha}}$ defined in section 3 are of type S. Then, according to Remark 2, there exist functions $d_{\bar{\alpha}}$ such that

$$\mathcal{D}_{\bar{\alpha}} e^{i\lambda t} = d_{\bar{\alpha}}(\lambda) e^{i\lambda t}.$$

In particular, when $\bar{\alpha}$ is the empty index, we have $d(\lambda) \equiv 1$.

These functions, in view of (3.1), are expressed as

$$d_{\bar{\alpha}} := \left(\prod_{i=1,\, i\neq\alpha_1}^{m} q_i\right)\left(\prod_{i=1,\, i\neq\alpha_2}^{m_{\alpha_1}} q_{\alpha_1,i}\right)\cdots\left(\prod_{i=1,\, i\neq\alpha_{k-1}}^{m_{\alpha_1,\ldots,\alpha_{k-1}}} q_{\alpha_1,\ldots,\alpha_{k-1},i}\right), \tag{5.3}$$

and then Proposition 4.4 ensures that, for every $\bar{\alpha}\in\mathcal{I}$, $d_{\bar{\alpha}}$ is an even or odd function. Moreover, from Corollary 4.5 we have the equalities

$$\begin{aligned} \mathcal{D}_{\bar{\alpha}}\sin\lambda t &= \begin{cases} d_{\bar{\alpha}}(\lambda)\sin\lambda t & \text{for } d_{\bar{\alpha}} \text{ even,} \\ -id_{\bar{\alpha}}(\lambda)\cos\lambda t & \text{for } d_{\bar{\alpha}} \text{ odd,} \end{cases} \\ \mathcal{D}_{\bar{\alpha}}\cos\lambda t &= \begin{cases} d_{\bar{\alpha}}(\lambda)\cos\lambda t & \text{for } d_{\bar{\alpha}} \text{ even,} \\ id_{\bar{\alpha}}(\lambda)\sin\lambda t & \text{for } d_{\bar{\alpha}} \text{ odd.} \end{cases} \end{aligned} \tag{5.4}$$

Now fix $\bar{\alpha} \in \mathcal{I}_M$ and denote $\bar{\omega} = \mathcal{D}_{\bar{\alpha}}\bar{u}$. The function $\bar{\omega}$ is also a solution of (1.1)–(1.5) and, from (5.1),

$$\bar{\omega}(t) = \mathcal{D}_{\bar{\alpha}}\bar{u}(t) = \sum_{k\in\mathbf{Z}_+} \left(u_{0,k}\, \mathcal{D}_{\bar{\alpha}} \cos\lambda_k t + \frac{u_{1,k}}{\lambda_k}\, \mathcal{D}_{\bar{\alpha}} \sin\lambda_k t \right) \bar{\theta}_k.$$

Then, from (5.4) it follows that

$$\bar{\omega}(t) = \sum_{k\in\mathbf{Z}_+} d_{\bar{\alpha}}(\lambda_k) \left(u_{0,k} \cos\lambda_k t + \frac{u_{1,k}}{\lambda_k} \sin\lambda_k t \right) \bar{\theta}_k \qquad \text{if } d_{\bar{\alpha}} \text{ is even,}$$

$$\bar{\omega}(t) = \sum_{k\in\mathbf{Z}_+} i d_{\bar{\alpha}}(\lambda_k) \left(u_{0,k} \sin\lambda_k t - \frac{u_{1,k}}{\lambda_k} \cos\lambda_k t \right) \bar{\theta}_k \qquad \text{if } d_{\bar{\alpha}} \text{ is odd.}$$

Thus, in both cases, the energy of $\bar{\omega}$ computed by the formula (5.2) is given by

$$\mathbf{E}_{\bar{\omega}} = \frac{1}{2} \sum_{k\in\mathbf{Z}_+} |d_{\bar{\alpha}}(\lambda_k)|^2 \left(\lambda_k^2 u_{0,k}^2 + u_{1,k}^2 \right). \tag{5.5}$$

With this, the inequality of Theorem 3.2 may be written in terms of the initial data of the solution $\bar{u}$ as

$$\sum_{k\in\mathbf{Z}_+} |d_{\bar{\alpha}}(\lambda_k)|^2 \left(\lambda_k^2 u_{0,k}^2 + u_{1,k}^2 \right) \le C \int_0^{2T_{\mathcal{A}}} |F(t)|^2 dt = C \int_0^{2T_{\mathcal{A}}} |u_x(t,0)|^2 dt. \tag{5.6}$$

Consequently, if we define

$$c_k = \max_{\bar{\alpha}\in\mathcal{I}_{\mathcal{S}}} |d_{\bar{\alpha}}(\lambda_k)|, \tag{5.7}$$

we obtain the following result.

THEOREM 5.1. *There exists a positive constant C such that*

$$\sum_{k\in\mathbf{Z}_+} c_k^2 \left(\lambda_k^2 u_{0,k}^2 + u_{1,k}^2 \right) \le C \int_0^{2T_{\mathcal{A}}} |u_x(t,0)|^2 dt, \tag{5.8}$$

for every solution $\bar{u}$ with initial data $(\bar{u}_0,\ \bar{u}_1) \in V \times H$.

Remark 8. It is easy to prove, using, e.g., formula (5.1) for the solutions, that if inequality (5.8) holds, then for every $\alpha, T \in \mathbb{R}$,

$$\sum_{k\in\mathbf{Z}_+} c_k^2 \left(\lambda_k^2 u_{0,k}^2(T) + u_{1,k}^2(T) \right) \le C \int_\alpha^{\alpha+2T_{\mathcal{A}}} |u_x(t,0)|^2 dt, \tag{5.9}$$

where $u_{0,k}(T)$ and $u_{1,k}(T)$ are the Fourier coefficients of $\bar{u}|_{t=T}$ and $\bar{u}_t|_{t=T}$, respectively, in the basis $\{\bar{\theta}_k\}_{k\in\mathbb{Z}_+}$.

5.2. Nondegenerate trees. In general, some of the coefficients c_k in the inequality (5.8) may vanish. That is why we consider a special class of trees for which all those numbers are different from zero.

DEFINITION 5.2. *A tree $\mathcal{A}$ is said to be nondegenerate if the numbers c_k, defined for that tree by* (5.7)*, are different from zero for every $k \in \mathbb{Z}_+$. Otherwise, the tree is said to be degenerate.*

The following proposition provides us with a more transparent characterization of nondegenerate trees.

PROPOSITION 5.3. *The tree $\mathcal{A}$ is nondegenerate if and only if the spectra $\sigma_{\bar{\alpha}\circ i}$, $\sigma_{\bar{\alpha}\circ j}$ of any two subtrees $\mathcal{A}_{\bar{\alpha}\circ i}$, $\mathcal{A}_{\bar{\alpha}\circ j}$ of $\mathcal{A}$ with common $\mathcal{O}_{\bar{\alpha}}$ root are disjoint.*

Proof. Note that the following general fact is true: an inequality like (5.8) with different-from-zero coefficients c_k (not necessarily given by (5.7)) is impossible for a tree having two subtrees with common root that share an eigenvalue μ. Indeed, in such a case, with the help of Proposition 4.1 we can construct a nonzero solution $\bar{u}$ of (1.1)–(1.5) such that $u_x(t,0) \equiv 0$. With this, a (5.8)-like inequality would give

$$\sum_{k\in\mathbf{Z}_+} c_k^2 \left(\lambda_k^2 u_{0,k}^2 + u_{1,k}^2\right) \le 0,$$

which is false, since $\bar{u}$ is not identically equal to zero.

For the converse assertion we argue by contradiction. We will prove that if $c_k = 0$ for some $k \in \mathbb{Z}_+$ and any two subtrees of $\mathcal{A}$ with common root have disjoint spectra, then $d_{\bar{\alpha}}(\lambda_k) = 0$ for any $\bar{\alpha} \in \mathcal{I}$. In particular, $d(\lambda_k) = 0$, which would contradict the fact that $d(\lambda_k) = 1$.

Note first that the property is immediate for exterior nodes, since $c_k \ge |d_{\bar{\alpha}}(\lambda_k)|$ for $\bar{\alpha} \in \mathcal{I}_{\mathcal{S}}$.

For the interior nodes we follow a recursive argument: if $\bar{\alpha} \in \mathcal{I}_{\mathcal{M}}$ and $d_{\bar{\alpha}\circ\beta}(\lambda_k) = 0$ for all $\beta = 1, \dots, m_{\bar{\alpha}}$, then $d_{\bar{\alpha}}(\lambda_k) = 0$.

Indeed, we have that, for every $\beta = 1, \dots, m_{\bar{\alpha}}$,

$$d_{\bar{\alpha}\circ\beta} = d_{\bar{\alpha}} \prod_{i\neq\beta} q_{\bar{\alpha}\circ i}. \tag{5.10}$$

Assume that $d_{\bar{\alpha}} \neq 0$. Then (5.10) implies that $\prod_{i\neq 1} q_{\bar{\alpha}\circ i} = 0$, and thus there exists $i^* \neq 1$ such that

$$q_{\bar{\alpha}\circ i^*} = 0. \tag{5.11}$$

But then, from the equalities $d_{\bar{\alpha}\circ i^*} = 0$ and (5.10) it follows that there exists $j^* \neq i^*$ satisfying

$$q_{\bar{\alpha}\circ j^*} = 0. \tag{5.12}$$

However, the equalities (5.11) and (5.12) ensure, according to Proposition 4.3, that $\mu_k = \lambda_k^2$ is a common eigenvalue of the subtrees $\mathcal{A}_{\bar{\alpha}\circ i^*}$ and $\mathcal{A}_{\bar{\alpha}\circ j^*}$. But that is impossible for the tree $\mathcal{A}$. Thus, $d_{\bar{\alpha}}(\mu_k) = 0$. This completes the proof of the proposition. □

Remark 9. According to the previous proposition, if the spectra of some two subtrees of $\mathcal{A}$ have a nonvoid intersection, inequality (5.8) degenerates. However, as indicated in the proof, this fact is not due to the technique used to obtain the inequality, since for degenerate trees no (5.8)-like inequality holds with all the coefficients c_k being different from zero. Thus, Theorem 5.1 is sharp in the following sense: *it provides inequality* (5.8) *whenever such an inequality exists.*

COROLLARY 5.4 (unique continuation property). *If the tree $\mathcal{A}$ is nondegenerate and $\bar{u}$ is a solution of (1.1)–(1.5) such that $u_x(t,0) = 0$ for $t \in [0, 2L_{\mathcal{A}}]$, then $\bar{u} \equiv 0$.*

Remark 10. Combining Propositions 4.4(ii) and 5.3, we obtain an alternative characterization of the nondegenerate trees: $\mathcal{A}$ is nondegenerate if and only if $|p(\lambda)|^2 + |q(\lambda)|^2 \neq 0$ for every $\lambda \in \mathbb{R}$.

PROPOSITION 5.5. *If the tree $\mathcal{A}$ is nondegenerate, then all its eigenvalues are simple.*

Proof. If λ_k^2 is an eigenvalue of a nondegenerate tree, then, according to Proposition 4.3 and Remark 10, $q(\lambda_k) = 0$ and $p(\lambda_k) \neq 0$. Consequently, if $\bar{\theta_k}$ is an eigenfunction of $\mathcal{A}$ corresponding to λ_k^2, formula (4.14) gives

$$\theta^{\bar{\alpha}}(0) = \frac{\hat{k}(\lambda_k)}{i\lambda_k p(\lambda_k)}\theta_x(0), \qquad \theta_x^{\bar{\alpha}}(0) = \frac{-l(\lambda_k)}{p(\lambda_k)}\theta_x(0),$$

Thus, $\bar{\theta_k}$ is determined, up to the constant factor $\theta_x(0)$, in a unique way. □

Remark 11. Let $\{\tilde{\mu}_k\}_{n\in\mathbb{Z}_+}$ be the strictly increasing sequence of the eigenvalues μ_k of a tree without taking into account their multiplicity. It may be shown that $\tilde{\mu}_k$ verifies $\mu_k^N \leq \tilde{\mu}_k \leq \mu_k^D$, for $k \in \mathbb{Z}_+$, where $\{\mu_k^D\}_{k\in\mathbb{Z}_+}$ and $\{\mu_k^N\}_{k\in\mathbb{Z}_+}$ are the ordered sequences formed by the distinct eigenvalues of the strings with Dirichlet or Neumann homogeneous boundary conditions, respectively (see [11]). This fact allows us to prove that the complete radius of the sequence $\lambda_k = \sqrt{\mu_k}$ is equal to $L_{\mathcal{A}}$ and therefore that a (5.8)-like inequality is impossible for $T < 2L_{\mathcal{A}}$.

Besides, it may be also proved that, if the network contains more than one string and (5.8) holds, then necessarily $\liminf c_k = 0$. This fact implies that the whole space $H \times V'$ is not controllable; i.e., there exist initial states in $H \times V'$, which cannot be driven to rest under the action of L^2-controls.

5.3. On the size of the set of nondegenerate trees. Now we give some information on the size of the set of degenerate trees.

We shall say that two trees are topologically equivalent if their edges can be numbered with the same set of multi-indices. This means that they may differ only in the lengths of their edges. In particular, two equivalent trees have the same number of edges and vertices. The classes of topologically equivalent trees are called topological configurations.

Fix a topological configuration Σ with d edges. We assume that in the set of indices $\mathcal{I}$ for the elements of the trees belonging to Σ a criterion of ordering has been defined, and we use the notation $\langle\mathcal{A}\rangle$ for the corresponding ordered set of the lengths of the edges of $\mathcal{A} \in \Sigma$.

Then Σ may be identified with $(\mathbb{R}_+)^d$ by means of the mapping $\pi : \Sigma \to \mathbb{R}^d$ defined by

$$\pi(\mathcal{A}) = \langle\mathcal{A}\rangle \in \mathbb{R}^d.$$

Let μ_Σ be the measure induced in Σ by the Lebesgue measure of $\mathbb{R}^d$ through the mapping π. That is, if $B \subset \Sigma$, then $\mu_\Sigma(B) = m_d(\pi(B))$, where m_d is the usual Lebesgue measure in $\mathbb{R}^d$.

We now have the following result.

PROPOSITION 5.6. *Given a topological configuration Σ, almost every tree (in the sense of the measure μ_Σ) with that topological configuration is nondegenerate.*

Proof. Let $D_{\bar{\alpha}}^{i,j} \subset \Sigma$ denote the set of those trees $\mathcal{A}$ such that the subtrees $\mathcal{A}_{\bar{\alpha}\circ i}$ and $\mathcal{A}_{\bar{\alpha}\circ j}$ are nondegenerate and have a common eigenvalue. Then the set $\Sigma_{deg} \subset \Sigma$

of degenerate trees may be decomposed as

$$\Sigma_{deg} = \bigcup_{\bar\alpha\in\mathcal{I}_{\mathcal{M}}} \bigcup_{i,j=1\ i\neq j}^{m_{\bar\alpha}} D_{\bar\alpha}^{i,j}. \tag{5.13}$$

We will prove that $\mu_\Sigma(D_{\bar\alpha}^{i,j}) = 0$ for every $\bar\alpha \in \mathcal{I}_{\mathcal{M}}$, $i, j = 1, \dots, m_{\bar\alpha}$, $i \neq j$. This fact, in view of (5.13), will imply $\mu_\Sigma(\Sigma_{deg}) = 0$. In what follows we consider that $\bar\alpha$, i, and j are fixed.

The idea of the proof is simple. We fix a tree $\mathcal{B}$ having the structure of $\mathcal{A}_{\bar\alpha\circ i} \vee \mathcal{A}_{\bar\alpha\circ j}$ (defined as in Remark 5) and extend it to a tree $\mathcal{A} \in D_{\bar\alpha}^{i,j}$. According to Remark 5, that is equivalent to choosing the node $\mathcal{O}_{\bar\alpha}$ of $\mathcal{A} \in \Sigma$ in a point of a string of $\mathcal{B}$ (precisely, of that string where it should be located to agree with the structure of Σ) where some eigenfunction of $\mathcal{B}$ vanishes. Once $\mathcal{O}_{\bar\alpha}$ has been chosen, the lengths of the remaining strings of $\mathcal{A}$ may be taken arbitrarily.

Observe that we may assume that no (nonidentically zero) eigenfunction of $\mathcal{B}$ vanishes identically on the string that contains $\mathcal{O}_{\bar\alpha}$, since, otherwise, one of the subtrees of $\mathcal{A}_{\bar\alpha\circ i}$ or $\mathcal{A}_{\bar\alpha\circ j}$ of the tree $\mathcal{A}$ obtained with this procedure would be degenerate and thus $\mathcal{A} \notin D_{\bar\alpha}^{i,j}$. This assumption implies that all the eigenfunctions of $\mathcal{B}$ are simple, and then the node $\mathcal{O}_{\bar\alpha}$ should be chosen in a set of points, which is at most denumerable.

Thus, we have obtained, after some reordering if needed, that the set $\pi(D_{\bar\alpha}^{i,j})$ is contained in a set of the form

$$\left\{(h_1, h_2, \dots, h_d) \in (\mathbb{R}_+)^d :\ h_1 + h_2 = h,\ h_1 \in \mathbf{N}(h, h_3, \dots, h_d)\right\}, \tag{5.14}$$

where $\mathbf{N}(h, h_3, \dots, h_d)$ is a denumerable set depending on h and $h_3, \dots, h_d$.

It is easy to see, using, e.g., Fubini's theorem, that a set defined by (5.14) has d-dimensional Lebesgue measure equal to zero. Thus, the same is true of $\pi(D_{\bar\alpha}^{i,j})$, and then $\mu_\Sigma(D_{\bar\alpha}^{i,j}) = 0$. This completes the proof. □

COROLLARY 5.7. *The set $\Sigma \setminus \Sigma_{deg}$ of nondegenerate trees is dense in Σ provided with the metrics induced in Σ by the usual metrics of $\mathbb{R}^d$ through π.*

Remark 12. The set Σ_{deg}, even though is small in the sense of μ_Σ, is dense in Σ. Indeed, it suffices to see that, if two edges of a tree with rationally dependent lengths have a common vertex and their other vertices are exterior, then the tree is degenerate.

6. Consequences concerning controllability. Gathering the facts of the previous sections, we obtain the following characterization of the controllability properties of trees.

THEOREM 6.1. *Let $\mathcal{A}$ be a tree and $T > 0$; then*

(a) *If $T \geq 2L_{\mathcal{A}}$, the properties*

– *$\mathcal{A}$ is spectrally controllable in time T,*

– *$\mathcal{A}$ is approximately controllable in time T,*

– *$\mathcal{A}$ is nondegenerate,*

– *any two subtrees of $\mathcal{A}$ with common root have disjoint spectra*

are equivalent, and when they are true, all the initial data in the space $\mathcal{W}$, defined by (1.9)*, are controllable. Moreover, these properties hold for almost every tree topologically equivalent to $\mathcal{A}$.*

(b) *If $T < 2L_{\mathcal{A}}$, the properties of spectral and approximate controllability are false, regardless of whether $\mathcal{A}$ is degenerate or not.*

7. Simultaneous observability and controllability of networks. The results of the previous sections allow us to consider the one-node control problem for several (a finite number of) tree-shaped networks when the same control function is used to control all of them, i.e., when they are controlled simultaneously.

Let $\mathcal{A}^1, \dots, \mathcal{A}^R$ be the trees associated with the controlled networks. For the elements of the network whose graph is $\mathcal{A}^r$, we will use the same notation as in the preceeding sections but adding the superscript r to them. Thus, the solution of (1.1)–(1.6) for the tree $\mathcal{A}^r$ (in what follows we shall briefly refer to this problem as $(1.1)_r$–$(1.6)_r$) is denoted by $\bar{u}^r$, and the spaces V and H constructed for that tree are denoted by V^r and H^r.

We define the space

$$\mathbf{W} = \prod_{r=1}^{R} V^r \times H^r,$$

endowed with the product Hilbert structure. The elements of $\mathbf{W}$ are called *simultaneous states*.

We shall say that the simultaneous state $\bar{w} \in \mathbf{W}$ is *controllable in time* T if it is possible to find a control function $v \in L^2(0,T)$ such that the solutions $\bar{u}^r$ of $(1.1)_r$–$(1.6)_r$ with initial states $(\bar{u}_0^r, \bar{u}_1^r)$ (the components of $\bar{w}$) and $v^r = v$ verify

$$\bar{u}^r(T,x) = \bar{u}_t^r(T,x) = \bar{0}$$

for every $i = 1, \dots, R$.

Once again using HUM, the problem of characterizing the controllable simultaneous states is reduced to the study of observability inequalities for the corresponding homogeneous systems. Indeed, assume that there exist nonzero numbers c_n^k, $n \in \mathbb{Z}_+$, $k = 1, \dots, R$, such that for every k the inequality

$$\int_0^T \left| \sum_{r=1}^{R} u_x^r(0,t) \right|^2 dt \geq \sum_{n \in \mathbf{Z}_+} (c_n^k)^2 \left(\mu_n^k |u_{0,n}^k|^2 + |u_{1,n}^k|^2 \right) \tag{7.1}$$

holds for all the initial simultaneous states $\bar{w} \in \mathbf{W}$, where $\{u_{0,n}^r\}$ and $\{u_{1,n}^r\}$ are the sequences of Fourier coefficients of the components $\bar{u}_0^r$ and $\bar{u}_1^r$, respectively, of the initial state in the bases $\{\bar{\theta}_n^r\}$ of H^r, and $\bar{u}^r$ is the solution of $(1.1)_r$–$(1.6)_r$ with $v^r = 0$. Define the sets

(7.2)

$$\mathcal{W}^r = \left\{ (\bar{u}_0^r, \bar{u}_1^r) \in V^r \times (H^r)' : \ \|(\bar{u}_0^r, \bar{u}_1^r)\|_r^2 = \sum_{n \in \mathbb{Z}_+} \frac{1}{(c_n^r)^2} \left(|u_{0,n}^r|^2 + \frac{1}{\mu_n^r} |u_{1,n}^r|^2 \right) < \infty \right\}.$$

Then all the initial simultaneous states $\bar{w} \in \mathcal{W} = \prod_{i=1}^{r} \mathcal{W}^r$ are controllable in time T.

In particular, if the inequalities (7.1) hold, then the initial simultaneous states $\bar{w} \in \prod_{1=1}^{r} Z^r \times Z^r$ are controllable. (Recall that Z^r is the set of all finite linear combinations of the eigenfunctions $\bar{\theta}_n^r$.) In this case, the networks are said to be *simultaneously spectrally controllable*.

Moreover, the set of controllable simultaneous states in time T is dense in $\mathbf{W}$ (when that holds, the networks are said to be *simultaneously approximately control-*

lable in time T) if and only if the following unique continuation property holds:

$$\sum_{r=1}^{R} u_x^r(0,t) = 0 \ \text{ in } \ L^2(0,T) \ \text{ implies } \ (\bar{u}_0^r, \bar{u}_1^r) = \bar{0} \ \text{ for every } \ r = 1, \dots, R. \tag{7.3}$$

It is clear that if a simultaneous state is controllable, then each of its components is also controllable for the corresponding network. This implies that if we expect at least the approximate controllability to hold, then we need to assume that all the trees supporting the networks are nondegenerate.

On the other hand, if two of the trees, say $\mathcal{A}^1$ and $\mathcal{A}^2$, have a common eigenvalue, then, using the pasting procedure described in the proof of Proposition 4.1, we can construct nonzero solutions of $(1.1)_r$–$(1.6)_r$, $r = 1, 2$, such that

$$u_x^1(t,0) + u_x^2(t,0) = 0, \qquad t \in \mathbb{R}.$$

Therefore, choosing zero initial states for all the remaining trees $\mathcal{A}^r$, $r = 3, \dots, R$, we obtain a simultaneous initial state in $\mathbf{W}$ for which inequalities (7.1) are impossible and, moreover, for which the unique continuation property (7.3) fails.

Thus, the conditions that the trees $\mathcal{A}^r$, $r = 1, \dots, R$, be nondegenerate and their spectra be pairwise disjoint are necessary for simultaneous approximate controllability, and then for spectral controllability. As we shall see, these conditions are also sufficient.

Set $T^* = \sum_{i=1}^{r} L^i$. For every $k = 1, \dots, R$ we define the operator

$$\widehat{\mathcal{Q}}_k := \prod_{r=1,\ r\neq k}^{R} \mathcal{Q}^r,$$

where $\mathcal{Q}^r$ is the operator $\mathcal{Q}$ for the tree $\mathcal{A}^r$. Note that $\widehat{\mathcal{Q}}_k$ is an S-operator with $s(\widehat{\mathcal{Q}}_k) = T^* - L^k$.

Let $\widehat{q}_k$ be the function associated with $\widehat{\mathcal{Q}}_k$ according to Remark 2. Then

$$\widehat{q}_k = \prod_{r=1,\ r\neq k}^{R} q^r, \tag{7.4}$$

where q^r is the function corresponding to $\mathcal{Q}^r$.

PROPOSITION 7.1. *If for a given k there exist numbers c_n, $n \in \mathbb{Z}_+$, such that every solution of $(1.1)_k$–$(1.6)_k$ with $v_k = 0$ and initial state*

$$(\bar{u}_0^k, \bar{u}_1^k) = \left(\sum_{n\in\mathbb{Z}_+} u_{0,n}^k \bar{\theta}_n^k, \sum_{n\in\mathbb{Z}_+} u_{1,n}^k \bar{\theta}_n^k \right) \in V^k \times H^k$$

satisfies

$$\int_0^{2L_k} |u_x^k(0,t)|^2 dt \geq \sum_{n\in\mathbf{Z}_+} c_n^2 \left(\mu_n^k |u_{0,n}^k|^2 + |u_{1,n}^k|^2 \right), \tag{7.5}$$

then

$$\int_0^{2T^*} \left| \sum_{r=1}^{R} u_x^r(0,t) \right|^2 dt \geq \sum_{n\in\mathbf{Z}_+} c_n^2 |\widehat{q}_k(\lambda_n^k)|^2 \left(\mu_n^k |u_{0,n}^k|^2 + |u_{1,n}^k|^2 \right) \tag{7.6}$$

for every $(\bar{u}_0^r, \bar{u}_1^r) \in V^r \times H^r$, $r = 1, \dots, R$.

Proof. As $\widehat{\mathcal{Q}}_k$ is an S-operator with $s(\widehat{\mathcal{Q}}_k) = T^* - L^k$, using Proposition 2.4(i), we get

$$\int_0^{2T^*} \left| \sum_{r=1}^{R} u_x^i(0,t) \right|^2 dt \geq \int_{T^*-L^k}^{T^*+L^k} \left| \widehat{\mathcal{Q}}_k \sum_{r=1}^{R} u_x^i(0,t) \right|^2 dt. \tag{7.7}$$

However, as $\mathcal{Q}^r u_x^r(0,t) = 0$, then $\widehat{\mathcal{Q}}_k \bar{u}^k$ if $r \neq k$. Thus, inequality (7.7) becomes

$$\int_0^{2T^*} \left| \sum_{r=1}^{R} u_x^i(0,t) \right|^2 dt \geq \int_{T^*-L^k}^{T^*+L^k} |\widehat{\mathcal{Q}}_k u_x^k(0,t)|^2 dt. \tag{7.8}$$

Now we consider the function $\bar{\omega} = \widehat{\mathcal{Q}}_k \bar{u}$. As $\bar{\omega}$ is clearly a solution of $(1.1)_k$–$(1.5)_k$, then, according to (7.5) and Remark 5.9 we have

$$\int_{T^*-L^k}^{T^*+L^k} |\omega_x(0,t)|^2 dt \geq \sum_{n\in\mathbb{Z}_+} c_n^2 \left(\mu_n^k \omega_{0,n}^2 + \omega_{1,n}^2\right). \tag{7.9}$$

On the other hand, it is simple to prove that the Fourier coefficients of the initial data of $\bar{u}$ and $\bar{\omega}$ are related by

$$\mu_n^k \omega_{0,n}^2 + \omega_{1,n}^2 = q_k^2(\lambda_n^k) \left(\mu_n^k u_{0,n}^2 + u_{1,n}^2\right). \tag{7.10}$$

Finally, combining (7.8)–(7.10) and the fact that $\omega_x(0,t) = \widehat{\mathcal{Q}}_k u_x^k(0,t)$, the inequality (7.6) is obtained. □

Now, if the trees $\mathcal{A}^1, \ldots, \mathcal{A}^R$ are nondegenerate, then we have for every $r = 1, \ldots, R$ inequalities (7.5) with nonzero coefficients c_n (depending on r), which are explicitly computed by formulas (5.7). Therefore, according to the previous proposition, we shall also have inequalities (7.1) with explicitly computed coefficients $c_n^r = |\widehat{q}_r(\lambda_n^r)| c_n$, which are all different from zero whenever the spectra of any two of the trees $\mathcal{A}^r$ are disjoint, since $\widehat{q}_r(\lambda_n^r) \neq 0$ for all $r = 1, \ldots, R$ and $n \in \mathbb{Z}_+$. Indeed, if $\widehat{q}_r(\lambda_n^r) = 0$ for some r and n, then equality (7.4) would imply that $q^i(\lambda_n^r) = 0$ for some $i \neq r$, and thus, from Proposition (4.3), μ_n^r would be a common eigenvalue of the trees $\mathcal{A}^r$ and $\mathcal{A}^i$.

Consequently, we are able to construct, under those assumptions, a space $\mathcal{W} = \prod_{r=1}^{R} \mathcal{W}^r$, where $\mathcal{W}^r$ are defined by (7.2), of controllable simultaneous states in time $2T^*$. In particular, we obtain the following.

COROLLARY 7.2. *The trees $\mathcal{A}^1, \ldots, \mathcal{A}^R$ are simultaneously spectrally controllable in some time T (and then in time $2T^*$) if and only if they are spectrally controllable and their spectra are pairwise disjoint.*

Acknowledgment. The author would like to thank E. Zuazua for suggesting that we study this problem, as well as for his valuable help.

NASH EQUILIBRIUM PAYOFFS FOR NONZERO-SUM STOCHASTIC DIFFERENTIAL GAMES*

RAINER BUCKDAHN†, PIERRE CARDALIAGUET†, AND CATHERINE RAINER†

Abstract. Existence and characterization of Nash equilibrium payoffs are proved for stochastic nonzero-sum differential games.

Key words. nonzero-sum differential game, stochastic differential game, Nash equilibrium

AMS subject classifications. 91A23, 91A15

DOI. 10.1137/S0363012902411556

1. Introduction. In this paper, we investigate the notion of Nash equilibrium payoff for nonzero-sum stochastic two-players differential games. Our main result is an existence theorem for such equilibrium payoffs. We also give a characterization of these payoffs.

Let us denote by $X_s^{t,x,u,v}$ the solution of the following equation:

$$dX_s = f(s, X_s, u_s, v_s)ds + \sigma(s, X_s, u_s, v_s)dB_s, \qquad t \le s,$$

with initial condition

$$X_t = x.$$

Here $B_\cdot$ is a d-dimensional standard Brownian motion, and $u_\cdot$ and $v_\cdot$ are stochastic processes taking values in some compact subsets U and V of some finite dimensional spaces. Precise assumptions on $f : [0,T] \times \mathbb{R}^n \times U \times V \to \mathbb{R}^n$ and on $\sigma : [0,T] \times \mathbb{R}^n \times U \times V \to \mathbb{R}^{n\times d}$ are given in the next section.

The payoff of the players is a terminal payoff, given by $J_1(t,x,u,v) = E[g_1(X_T^{t,x,u,v})]$ for Player I and by $J_2(t,x,u,v) = E[g_2(X_T^{t,x,u,v})]$ for Player II. Loosely speaking, Player I aims to maximize $J_1(t,x,u,v)$ while the goal of Player II is to maximize $J_2(t,x,u,v)$. As usual in differential game theory, the players play not time-measurable controls but *strategies*. In order to avoid for the moment the technical details, we postpone the definition of the strategies to the next section. Here we only need to assume that for any strategy α of Player I and any strategy β of Player II one can define a payoff $J_1(t,x,\alpha,\beta)$ for Player I and a payoff $J_2(t,x,\alpha,\beta)$ for Player II.

A particularly important notion for investigating nonzero-sum games is given by Nash equilibria. In our framework, a Nash equilibrium is a pair $(\bar\alpha, \bar\beta)$ of strategies such that, for any other pair (α,β) of strategies, we have

$$J_1(t,x,\bar\alpha,\bar\beta) \ge J_1(t,x,\alpha,\bar\beta) \quad \text{and} \quad J_2(t,x,\bar\alpha,\bar\beta) \ge J_2(t,x,\bar\alpha,\beta). \tag{1.1}$$

The couple $(J_1(t,x,\bar\alpha,\bar\beta), J_2(t,x,\bar\alpha,\bar\beta))$ is called a Nash equilibrium payoff. In general, we do not expect Nash equilibria to exist but only Nash equilibrium payoffs

†Département de Mathématiques, Université de Bretagne Occidentale, 6, avenue Victor-le-Gorgeu, B.P. 809, 29285 Brest cedex, France (Rainer.Buckdahn@univ-brest.fr, Pierre.Cardaliaguet@univ-brest.fr, Catherine.Rainer@univ-brest.fr).

(e_1, e_2) which can be approximated by the payoffs of strategies $(\bar{\alpha}_\epsilon, \bar{\beta}_\epsilon)$ for which the inequalities (1.1) hold true only up to some $\epsilon > 0$ for any (α, β). (Note also that, in general, Nash equilibrium payoffs are not unique.)

The main result of this paper (Theorem 2.9) states that Nash equilibrium payoffs exist for any initial position. Moreover, we characterize these Nash equilibrium payoffs. To explain this characterization, we have to introduce the zero-sum games associated with the payoffs J_1 and J_2. Under the Isaacs condition (see (2.2)), Fleming and Souganidis [2] (see also [7]) have proved that the zero-sum game, where Player I wants to maximize J_1 and Player II wants to minimize J_1, has a value, which will be denoted here by W_1:

$$W_1(t,x) = \inf_\beta \sup_\alpha J_1(t,x,\alpha,\beta) = \sup_\alpha \inf_\beta J_1(t,x,\alpha,\beta).$$

In the same way, the zero-sum game, in which Player I aims at minimizing the payoff J_2 and Player II aims at maximizing it, has also a value, denoted W_2:

$$W_2(t,x) = \sup_\beta \inf_\alpha J_2(t,x,\alpha,\beta) = \inf_\alpha \sup_\beta J_2(t,x,\alpha,\beta).$$

Our characterization result Theorem 2.10 loosely states (up to technical details) that a pair $(e_1, e_2) \in \mathbb{R}^2$ is a Nash equilibrium payoff for the initial position (t,x) if and only if there is some pair $(u_\cdot, v_\cdot) : [t,T] \to U \times V$ of adapted controls such that

(i) for $j = 1, 2$, $E[g_j(X_T^{t,x,u,v})|\mathcal{F}_{t,s}] \geq W_j(s, X_s^{t,x,u,v})$ a.s. for any $s \in [t,T]$, where $\mathcal{F}_{t,s}$ is the σ-algebra generated by $\{B_u - B_t,\ u \in [t,s]\}$;

(ii) for $j = 1, 2$, $e_j = J_j(t,x,u,v)$.

(In practice, the existence of such $(u_\cdot, v_\cdot)$ is out of reach, and we prove only the existence, for any $\epsilon > 0$, of some adapted controls $(u_\cdot^\epsilon, v_\cdot^\epsilon)$ for which (i) holds true up to ϵ with a probability larger than $1 - \epsilon$ and (ii) holds true up to ϵ. However, this is enough for characterizing the Nash equilibrium payoffs.)

The controls $u_\cdot$ and $v_\cdot$ can be interpreted as follows. The players agree at the beginning of the game to play, respectively, $u_\cdot$ and $v_\cdot$. Condition (ii) then guarantees that their payoff is (e_1, e_2) if they indeed play $u_\cdot$ and $v_\cdot$ up to the terminal time T. If on the contrary one of the players (say, Player II) deviates at some time $t' \in (t,T)$, i.e., does not play $v_\cdot$ on $[t',T]$, then Player I punishes Player II by playing some strategy that minimizes the expected payoff of Player II. Condition (i) guarantees that such a strategy exists and that the resulting payoff of Player II is not larger than e_2. So Player II gains nothing by deviating.

In the deterministic case, the results presented in this paper have already been established by Kononenko in [6] and by Kleimenov in [5] in the framework of positional strategies, and by Tolwinski, Haurie, and Leitmann in [9] in the framework of Friedman strategies. Let us point out that the generalization to the stochastic case is far from being straightforward for at least two reasons: first, because of measurability issues, already encountered by Fleming and Souganidis when generalizing the existence of a value (and the dynamic programming) from deterministic zero-sum differential games to zero-sum stochastic differential games, and second, because the method used by Kononenko and Kleimenov—which makes an extensive use of the extremal aiming and of the existence of quasi-optimal positional strategies for some associated zero-sum differential games—does not apply to stochastic differential games.

Let us finally recall another approach for the existence problem of Nash equilibrium payoffs—the dynamic programming approach. The idea is to find the Nash equilibrium payoff (e_1, e_2) as a function of the initial position (t,x): $(e_1, e_2) =$

$(e_1(t,x), e_2(t,x))$. This function can be constructed as a solution of some system of parabolic PDE (as in [1], for instance) or by using backward or backward-forward stochastic differential equations (as in [3], [4]). Both methods rely heavily on a nondegeneracy assumption on σ. In fact, it can be proved (see [8]) that a payoff $(e_1(t,x), e_2(t,x))$ given by such a method is a Nash equilibrium payoff in our sense.

The paper is organized as follows. We first state the assumptions, notation, and main results of the paper. Then we prove the characterization theorem, from which we derive the existence result. We complete the paper with some remarks on the notions of strategies.

2. Statements of the main results. Let $T > 0$ be a fixed finite time horizon. For $t \in [0,T]$, we consider the following doubly controlled stochastic system:

$$\begin{aligned} &dX_s = f(s, X_s, u_s, v_s)ds + \sigma(s, X_s, u_s, v_s)dB_s, \qquad s \in [t,T], \\ &X_t = x, \end{aligned} \tag{2.1}$$

where B is a d-dimensional standard Brownian motion on the canonical Wiener space $(\Omega, \mathcal{F}, P)$, i.e., Ω is the set of continuous functions from $[0,T]$ to $\mathbb{R}^d$ issued from 0, $\mathcal{F}$ is the completed Borell σ-algebra over Ω, P is the Wiener measure, and B is the canonical process: $B_s(\omega) = \omega(s), s \in [0,T]$. The processes u and v are assumed to take their values in some compact metric spaces U and V, respectively. We suppose that the functions $f : [0,T] \times \mathbb{R}^n \times U \times V \to \mathbb{R}^n$ and $\sigma : [0,T] \times \mathbb{R}^n \times U \times V \to \mathbb{R}^{n \times d}$ are measurable and satisfy the assumption (H):

(H) f and σ are bounded and Lipschitz continuous with respect to (t,x), uniformly in $(u,v) \in U \times V$.

We should also assume that the Isaacs condition, i.e., that for all $(t,x) \in [0,T] \times \mathbb{R}^n$, $p \in \mathbb{R}^n$, and all $A \in \mathcal{S}_n$ (where $\mathcal{S}_n$ is the set of symmetric $n \times n$ matrices), holds:

$$\begin{aligned} &\inf_u \sup_v \{\langle f(t,x,u,v), p\rangle + \tfrac{1}{2} Tr(A\sigma(t,x,u,v)\sigma^*(t,x,u,v))\} \\ &\qquad = \sup_v \inf_u \{\langle f(t,x,u,v), p\rangle + \tfrac{1}{2} Tr(A\sigma(t,x,u,v)\sigma^*(t,x,u,v))\}. \end{aligned} \tag{2.2}$$

We define the sets of admissible controls as follows.

DEFINITION 2.1. *An admissible control process u for Player* I *(resp.,* II*) on $[t,T]$ is a process taking values in U (resp., V), progressively measurable with respect to the filtration $(\mathcal{F}_{t,s}, s \geq t)$, where*

$$\mathcal{F}_{t,s} = \sigma\{B_r - B_t, r \in [t,s]\}, \qquad s \in [t,T],$$

augmented by all null-sets of P.

The set of admissible controls for Player I *(resp.,* II*) on $[t,T]$ is denoted by $\mathcal{U}(t)$ (resp., $\mathcal{V}(t)$).*

We identify two processes u and $\bar{u}$ in $\mathcal{U}(t)$ and write $u \equiv \bar{u}$, if $P\{u = \bar{u}$ a.e. in $[t,s]\} = 1$.

Under assumption (H), for all $(t,x) \in [0,T] \times \mathbb{R}^n$ and $(u,v) \in \mathcal{U}(t) \times \mathcal{V}(t)$, there exists a unique solution to (2.1) that we denote by $X_\cdot^{t,x,u,v}$.

Now we have to define strategies. Let us first recall the definition of nonanticipative strategies.

DEFINITION 2.2. *A nonanticipative strategy for Player* I *on $[t,T]$ is a mapping $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ such that, for any $s \in [t,T]$ and for any $v_1, v_2 \in \mathcal{V}(t)$, if $v_1 \equiv v_2$ on $[t,s]$, then $\alpha(v_1) \equiv \alpha(v_2)$ on $[t,s]$.*

Nonanticipative strategies for Player II are defined symmetrically.

For several reasons explained below, nonanticipative strategies are not the proper ones for nonzero-sum differential games. We merely use the notion of admissible strategies, whose definition needs some preliminary remarks, as follows.

For all $\bar{t}, t \in [0,T]$ with $\bar{t} \le t$, let $\Omega_{\bar{t},t}$ be the set of continuous functions from $[\bar{t},t]$ to $\mathbb{R}^d$, issued from 0 and $P_{\bar{t},t}$ the Wiener measure on $\Omega_{\bar{t},t}$ (in particular $\Omega_{0,T} = \Omega$ and $P_{0,T} = P$). If, for fixed $0 \le \bar{t} \le t \le T$, and $\omega \in \Omega_{\bar{t},T}$, we define $\pi(\omega) = (\omega_1, \omega_2)$ by

$$\begin{aligned} \omega_1 &= \omega|_{[\bar{t},t]}, \\ \omega_2 &= (\omega - \omega(t))|_{[t,T]}, \end{aligned}$$

we can identify $\Omega_{\bar{t},T}$ with $\Omega_{\bar{t},t} \times \Omega_{t,T}$, and we have $P_{\bar{t},T} = P_{\bar{t},t} \otimes P_{t,T}$.

Furthermore, to every random variable Y on $\Omega_{\bar{t},T}$ and all $\omega_1 \in \Omega_{\bar{t},t}$, we can associate a random variable $(Y(\omega_1))(\cdot)$ on $\Omega_{t,T}$, by setting $(Y(\omega_1))(\omega_2) = Y(\omega)$.

We also remark that, for all $(\mathcal{F}_{\bar{t},s}, s \ge \bar{t})$-progressively measurable processes $(Y_s, s \ge \bar{t})$ and almost every $\omega_1 \in \Omega_{\bar{t},t}$, the process $(Y(\omega_1)_s, s \ge t)$ is $(\mathcal{F}_{t,s}, s \ge t)$-progressively measurable. This allows us to apply a nonanticipative strategy α defined on $[t,T]$ to controls living on the larger time interval $[\bar{t},T]$: for $v \in \mathcal{V}(\bar{t})$, we define $\alpha(v|_{[t,T]})$ by

$$\alpha(v|_{[t,T]})(\omega)_s = (\alpha(v(\omega_1)))(\omega_2)_s, \qquad s \in [t,T] \tag{2.3}$$

(with a symmetric notation for strategies β for Player II).

DEFINITION 2.3. *An admissible strategy for Player* I *on* $[t,T]$ *is a mapping* $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ *such that the following hold:*

(i) α *is a strongly nonanticipative strategy. Namely, for any* $(\mathcal{F}_{t,s})_{s\in[t,T]}$*-stopping time* S *and any* $v, \tilde{v} \in \mathcal{V}(t)$*, if* $v \equiv \tilde{v}$ *on* $[\![t,S]\!]$*, then* $\alpha(v) \equiv \alpha(\tilde{v})$ *on* $[\![t,S]\!]$ *(with the notation* $[\![t,S]\!] = \{(s,\omega) \in [0,T] \times \Omega, t \le s \le S(\omega)\}$*).*

(ii) α *is a nonanticipative strategy with delay. Namely, there is some partition* $t = t_0 < t_1 < \cdots < t_m = T$ *such that for all* $v, \tilde{v} \in \mathcal{V}(t)$*, we have* $\alpha(v) = \alpha(\tilde{v})$ *on* $[t,t_1]$ *and for any* $i < n$*, if* $v \equiv \tilde{v}$ *on* $[t,t_i]$*, then* $\alpha(v) \equiv \alpha(\tilde{v})$ *on* $[t,t_{i+1}]$*.*

(iii) α *is an r-strategy. Namely, for every* $0 \le \bar{t} < t$ *and* $v \in \mathcal{V}(\bar{t})$ *the process* $\alpha(v|_{[t,T]})$ *is* $(\mathcal{F}_{\bar{t},s}, s \ge t)$*-progressively measurable.*

The set of all admissible strategies for Player I *on* $[t,T]$ *is denoted by* $\mathcal{A}(t)$*. The set of admissible strategies* $\beta : \mathcal{U}(t) \to \mathcal{V}(t)$ *for Player* II*, which are defined symmetrically, is denoted by* $\mathcal{B}(t)$*.*

The r-strategies were introduced in [2], motivated by technical problems related to measurability issues. Not surprisingly, we have encountered the same kind of difficulties, hence the requirement for the admissible strategies to be r-strategies.

To the best of our knowledge, the notion of *strongly* nonanticipative strategies has never been introduced before. However, it is, in our opinion, much more natural for stochastic differential games than that of standard nonanticipative strategies. Indeed strongly nonanticipative strategies formalize the fact that a player is allowed to take into account only the control of his opponent he observes in the present state of the world. In other words, if we want to make rigorous the requirement "If for some ω, there exists a time $s \ge 0$ such that $v_1(\omega) = v_2(\omega)$ before s, then $\alpha(v_1(\omega)) = \alpha(v_2(\omega))$ before s," it becomes clear that s depends on ω and thus that the nonanticipativity has to involve random times.

The main reason for introducing nonanticipative strategies *with delay* is the following lemma.

LEMMA 2.4. *Let $\alpha \in \mathcal{A}(t)$ be an admissible strategy and $\beta : \mathcal{U}(t) \to \mathcal{V}(t)$ be nonanticipative. There is a unique control-pair $(u, v) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that*

$$\alpha(v) = u \quad \text{and} \quad \beta(u) = v. \tag{2.4}$$

Of course, a symmetric result holds if α is nonanticipative and β is admissible, or if both α and β are admissible. Let us point out that one cannot omit one of the strategies to be with delay.

Proof of Lemma 2.4. Let $t = t_0 < t_1 < \cdots < t_m = T$ be a partition associated with the admissible strategy α. We construct the controls $(u_\cdot, v_\cdot)$ by induction on the interval $[t_k, t_{k+1})$.

For $k = 0$, we know that, for any $v' \in \mathcal{V}(t)$, the restriction of $u = \alpha(v')$ to the interval $[t, t_1)$ is independent of v' since α admissible. Let us set $v = \beta(u)$ on $[t, t_1)$, which depends only on the values of u on $[t, t_1)$ since β is nonanticipative. Let us point out that this procedure uniquely defines (u, v) on $[t, t_1)$.

Let us now assume that u and v are uniquely defined on $[t, t_k)$. Then the restriction of $u = \alpha(v')$ to the interval $[t_k, t_{k+1}]$ does not depend on the values of v' on $[t_k, t_{k+1})$ provided that $v' = v$ on $[t, t_k)$, because α is admissible. This defines u on $[t, t_{k+1})$. Then v is uniquely defined on $[t, t_{k+1})$ by $v = \beta(u)$ since β is nonanticipative.

This completes the proof by induction. □

We give several remarks and comments on strategies later, in the appendix. Here is an example of admissible strategy. This example is borrowed from [2].

Example 2.5. Let $t_0 = t < t_1 < \cdots < t_m = T$ be a fixed partition of $[t, T]$, and, for $1 \le j \le m$, let $(O_{ij})_{i \in \mathbb{N}}$ be a Borel partition of $\mathbb{R}^n$ and $u_{ij} \in U$, for $i \in \mathbb{N}$, be fixed. For any control $v \in \mathcal{V}(t)$, we define $\alpha(v)$ by induction on $[t, t_j)$ by setting

$$\alpha(v)(s) = u_{10} \text{ on } [t, t_1),$$

and, if $\alpha(v)$ is built on $[t, t_j)$, we set

$$\alpha(v)(s) = \sum_i u_{ij} 1_{\{X_{t_j}^{t,x,\alpha(v),v} \in O_{ij}\}} \text{ on } [t_j, t_{j+1}).$$

Then α is an admissible strategy.

The main result of [2] is that zero-sum stochastic games have a value when the players play nonanticipative strategies. A careful examination of the proof of [2] shows the following result.

THEOREM 2.6. *Let $g : \mathbb{R}^n \to \mathbb{R}$ be bounded and Lipschitz continuous and set*

$$\forall (u, v) \in \mathcal{U}(t) \times \mathcal{V}(t), \quad J(t, x, u, v) = E[g(X_T^{t,x,u,v})].$$

Let f and σ satisfy the assumption (H) *and the Isaacs condition* (2.2). *Then*

$$\inf_{\beta \in \mathcal{B}(t)} \sup_{u \in \mathcal{U}(t)} J(t, x, u, \beta(u)) = \sup_{\alpha \in \mathcal{A}(t)} \inf_{v \in \mathcal{V}(t)} J(t, x, \alpha(v), v).$$

We briefly explain this result, which is a straightforward consequence of several results of [2], in the following proof.

Proof of Theorem 2.6. Let us set

$$W^\sharp = \sup_{\alpha \in \mathcal{A}(t)} \inf_{v \in \mathcal{V}(t)} J(t, x, \alpha(v), v) \quad \text{and} \quad W^\flat = \inf_{\beta \in \mathcal{B}(t)} \sup_{u \in \mathcal{U}(t)} J(t, x, u, \beta(u)).$$

For any $\epsilon > 0$, let us choose some admissible strategies α and β such that

$$W^\sharp \le \inf_{v\in\mathcal{V}(t)} J(t,x,\alpha(v),v) + \epsilon \quad \text{and} \quad W^\flat \ge \sup_{u\in\mathcal{U}(t)} J(t,x,u,\beta(u)) - \epsilon.$$

Using Lemma 2.4, there is some control-pair $(u,v) \in \mathcal{U}(t)\times\mathcal{V}(t)$ such that $\alpha(v) = u$ and $\beta(u) = v$. Hence

$$W^\sharp \le J(t,x,\alpha(v),v) + \epsilon = J(t,x,u,v) + \epsilon = J(t,x,u,\beta(u)) + \epsilon \le W^\flat + 2\epsilon.$$

Therefore we have proved that $W^\sharp \le W^\flat$.

For proving the reverse inequality, let us set

$$V^\flat = \inf_{\substack{\beta\,:\,\mathcal{U}(t)\to\mathcal{V}(t)\\ \text{nonanticipative}}} \sup_{u\in\mathcal{U}(t)} J(t,x,u,\beta(u)).$$

Combining formula (2.4), Proposition 2.5, and Theorem 2.6 of [2] yields the existence of some nonanticipative strategy α such that

$$V^\flat \le \inf_{v\in\mathcal{V}(t)} J(t,x,\alpha(v),v) + \epsilon.$$

A careful examination of the proof of (2.4) also shows that the strategy α can be chosen from $\mathcal{A}(t)$. Indeed it is actually of the form of Example 2.5. This proves that $V^\flat \le W^\sharp$. Using symmetric argument, one can prove that $V^\sharp \ge W^\flat$, where

$$V^\sharp = \sup_{\substack{\alpha\,:\,\mathcal{V}(t)\to\mathcal{U}(t)\\ \text{nonanticipative}}} \inf_{v\in\mathcal{V}(t)} J(t,x,\alpha(v),v).$$

Hence we have already proved that

$$V^\flat \le W^\sharp \le W^\flat \le V^\sharp.$$

Since, under the Isaacs condition (2.2), the game has a value, i.e., $V^\sharp = V^\flat$ (Theorem 2.6 of [2]), equality $W^\sharp = W^\flat$ holds. □

Now let $g_1 : \mathbb{R}^n \to \mathbb{R}$ and $g_2 : \mathbb{R}^n \to \mathbb{R}$ be two Lipschitz continuous functions bounded by some $C > 0$. For $(t,x) \in [0,T]\times\mathbb{R}^n, (u,v) \in \mathcal{U}(t)\times\mathcal{V}(t)$, set

$$J_1(t,x,u,v) = E[g_1(X_T^{t,x,u,v})] \quad \text{and} \quad J_2(t,x,u,v) = E[g_2(X_T^{t,x,u,v})].$$

In what follows, for all couples of a nonanticipative and an admissible strategy (α,β), we will also use the following notation:

$$J_j(t,x,\alpha,\beta) = J_j(t,x,u,v) \qquad (\text{for } j=1 \text{ or } j=2),$$

where (u,v) are associated to (α,β) by (2.4).

Recall that Player I wants to maximize $J_1(t,x,\alpha,\beta)$, while Player II wants to maximize $J_2(t,x,\alpha,\beta)$.

DEFINITION 2.7. *We say that a couple $(e_1,e_2) \in \mathbb{R}^2$ is a Nash equilibrium payoff at the point (t,x) if, for any $\epsilon > 0$, there exist $(\alpha_\epsilon,\beta_\epsilon) \in \mathcal{A}(t)\times\mathcal{B}(t)$ such that*

(2.5) $\forall \quad (\alpha,\beta) \in \mathcal{A}(t)\times\mathcal{B}(t)$ *it holds that*

$$J_1(t,x,\alpha_\epsilon,\beta_\epsilon) \ge J_1(t,x,\alpha,\beta_\epsilon) - \epsilon \quad \text{and} \quad J_2(t,x,\alpha_\epsilon,\beta_\epsilon) \ge J_2(t,x,\alpha_\epsilon,\beta) - \epsilon$$

and

(2.6) $$\text{for } j=1,2, \quad |J_j(t,x,\alpha_\epsilon,\beta_\epsilon) - e_j| \le \epsilon.$$

Remarks.

1. Condition (2.5) means that if one of the players deviates from his strategy (α_ϵ or β_ϵ), then he cannot expect to get much more (less than ϵ) than what he would have had by keeping his strategy.
2. The definition still makes sense if one uses the notion of nonanticipative strategies with delay instead of admissible strategies.

In what follows, we shall often use an equivalent formulation of Condition (2.5) given by the following lemma.

LEMMA 2.8. *Let $\epsilon > 0$ and $(\alpha_\epsilon, \beta_\epsilon) \in \mathcal{A}(t) \times \mathcal{B}(t)$. Condition* (2.5) *holds if and only if*

$$\begin{aligned} &\text{for any } (u,v) \in \mathcal{U}(t) \times \mathcal{V}(t), \\ &J_1(t,x,\alpha_\epsilon,\beta_\epsilon) \geq J_1(t,x,u,\beta_\epsilon(u)) - \epsilon \quad \text{and} \quad J_2(t,x,\alpha_\epsilon,\beta_\epsilon) \geq J_2(t,x,\alpha_\epsilon(v),v) - \epsilon. \end{aligned} \tag{2.7}$$

Proof of Lemma 2.8. Suppose that (2.7) holds and let $\alpha \in \mathcal{A}(t)$. By Lemma 2.4, there exists $(u,v) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that $\alpha(v) = u$ and $\beta_\epsilon(u) = v$. By (2.7) applied to this couple (u,v), we get

$$J_1(t,x,\alpha_\epsilon,\beta_\epsilon) \geq J_1(t,x,u,\beta_\epsilon(u)) - \epsilon = J_1(t,x,\alpha,\beta_\epsilon) - \epsilon.$$

Repeating the same argument for some $\beta \in \mathcal{B}(t)$, we get Condition (2.5).

Conversely, for any fixed $u \in \mathcal{U}(t)$, we can define a strategy $\alpha \in \mathcal{A}(t)$ by setting $\alpha(v) = u$ for all $v \in \mathcal{V}(t)$. In particular, for $v = \beta_\epsilon(u)$, we have again $u = \alpha(v)$ and $v = \beta_\epsilon(u)$. It is then easy to deduce (2.7) from (2.5). □

From now on, we denote by W_1 and W_2 the value functions of the zero-sum games where Player I (resp., Player II) aims at maximizing g_1 (resp., g_2). According to Theorem 2.6, this means that

$$W_1(t,x) = \inf_{\beta \in \mathcal{B}(t)} \sup_{u \in \mathcal{U}(t)} J_1(t,x,u,\beta(u)) = \sup_{\alpha \in \mathcal{A}(t)} \inf_{v \in \mathcal{V}(t)} J_1(t,x,\alpha(v),v)$$

and

$$W_2(t,x) = \sup_{\beta \in \mathcal{B}(t)} \inf_{u \in \mathcal{U}(t)} J_2(t,x,u,\beta(u)) = \inf_{\alpha \in \mathcal{A}(t)} \sup_{v \in \mathcal{V}(t)} J_2(t,x,\alpha(v),v).$$

Now, once all notation and assumptions are stated, we are able to announce the two results of this paper, as follows.

THEOREM 2.9 (existence). *Under the Isaacs condition* (2.2)*, for any initial position $(t,x) \in [0,T] \times \mathbb{R}^n$, there is some Nash equilibrium payoff at (t,x).*

THEOREM 2.10 (characterization). *Assume the Isaacs condition holds. Then a couple $(e_1,e_2) \in \mathbb{R}^2$ is a Nash equilibrium payoff at a point (t,x) if and only if for any $\epsilon > 0$ there exists $(u^\epsilon, v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that*

(i) *for any $s \in [t,T]$ and $j = 1,2$,*

$$P\left\{E[g_j(X_T^\epsilon)|\mathcal{F}_{t,s}] \geq W_j(s,X_s^\epsilon) - \epsilon\right\} \;\geq\; 1 - \epsilon,$$

where $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$,

(ii) *and*

$$\text{for } \; j = 1,2, \quad |E[g_j(X_T^\epsilon)] - e_j| \leq \epsilon.$$

Remarks.

1. For proving that the conditions in Theorem 2.10 are necessary, we do not need the notion of admissible strategies; in fact, we need only that the strategies defining the Nash equilibrium payoff are nonanticipative with delay and satisfy some condition (**C**) introduced in the appendix. The fact that the strategy is a strongly nonanticipative r-strategy is not needed. However, although the notion of Nash equilibrium payoff still could be defined by using the bigger class of nonanticipative strategies with delay, we do not know whether the characterization result remains true if one removes the requirement that the strategies satisfy condition (**C**). In other words, we do not know if this characterization holds if one allows the players to use the knowledge of the full control of his or her opponent (in any state of the world).
2. The generalization to the case of more than two players is not difficult. (The idea is that each player can act as if he would be confronted by only one opponent which activates the set of all the other controls.) But to write it down properly, it needs to reintroduce the whole definition and notation and several preliminary results. We will not do it here.

The sketch of the proof of the two previous results is the following: We first show the equivalence in Theorem 2.10, and, using this equivalence, we finally prove Theorem 2.9.

3. Proof of the characterization: Sufficient condition. The object of this section is the proof of the sufficient condition of Theorem 2.10.

We first point out a technical lemma, which will also be used in the proof of the other results.

LEMMA 3.1. *Fix* $(t,x) \in [0,T] \times \mathbb{R}^n$ *and* $u \in \mathcal{U}(t)$.

(a) *For all* $\theta \in [t,T]$ *and* $\epsilon > 0$, *there exists a strongly nonanticipative r-strategy* $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ *such that, for any* $v \in \mathcal{V}(t)$,

$$\begin{aligned} &\alpha(v) \equiv u \quad \text{on } [t,\theta], \\ &E[g_2(X_T^{t,x,\alpha(v),v})|\mathcal{F}_{t,\theta}] \le W_2(\theta, X_\theta^{t,x,\alpha(v),v}) + \epsilon, \qquad P \text{ a.s.} \end{aligned} \tag{3.1}$$

(b) *Let* B *be a compact subset of* $\mathbb{R}^n$. *For all* $\theta \in [t,T]$ *and* $\epsilon > 0$, *there exists an admissible strategy* $\alpha \in \mathcal{A}(t)$ *such that, for any* $v \in \mathcal{V}(t)$,

$$\begin{aligned} &\alpha(v) \equiv u \quad \text{on } [t,\theta], \\ &E[g_2(X_T^{t,x,\alpha(v),v})|\mathcal{F}_{t,\theta}] \le W_2(\theta, X_\theta^{t,x,\alpha(v),v}) + \epsilon, \qquad P \text{ a.s. on } \{X_\theta^{t,x,\alpha(v),v} \in B\}. \end{aligned} \tag{3.2}$$

Remark. It can be proved similarly that, for all $\theta \in [t,T]$ and $\epsilon > 0$, there exists a strongly nonanticipative r-strategy $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ such that, for any $v \in \mathcal{V}(t)$,

$$\begin{aligned} &\alpha(v) \equiv u \quad \text{on } [t,\theta], \\ &E[g_1(X_T^{t,x,\alpha(v),v})|\mathcal{F}_{t,\theta}] \ge W_1(\theta, X_\theta^{t,x,\alpha(v),v}) - \epsilon, \qquad P \text{ a.s.} \end{aligned}$$

Proof of Lemma 3.1.

(a) From the definition of the value function W_2, for any $y \in \mathbb{R}^n$, there is some admissible strategy $\alpha_y \in \mathcal{A}(\theta)$ such that

$$\sup_{v\in\mathcal{V}(\theta)} E[g_2(X_T^{\theta,y,\alpha_y(v),v})] \le W_2(\theta,y) + \epsilon/2.$$

Since $z \to W_2(\theta,z)$ and $z \to \sup_{v\in\mathcal{V}(\theta)} E[g_2(X_T^{\theta,z,\alpha_y(v),v})]$ are continuous, one can find a Borelian partition $(O_i,\ i=1,2,\ldots)$ of $\mathbb{R}^n$ such that, for any i, there is some $y_i \in O_i$ with

$$\forall z \in O_i,\ \sup_{v\in\mathcal{V}(\theta)} E[g_2(X_T^{\theta,z,\alpha_{y_i}(v),v})] \le W_2(\theta,z) + \epsilon. \tag{3.3}$$

Now we define the following strategy α:

$$\forall v \in \mathcal{V}(t), \alpha(v)_s = \begin{cases} u_s & \text{for } s \in [t,\theta], \\ \alpha_{y_i}(v|_{[\theta,T]})_s & \text{for } s \in (\theta,T] \qquad \text{on } \{X_\theta^{t,x,u,v} \in O_i\}, \end{cases} \tag{3.4}$$

where the notation $\alpha_{y_i}(v|_{[\theta,T]})_s$ is defined by (2.3). By a tiresome but straightforward proof, we get that α is a nonanticipative r-strategy. The fact that it is strongly nonanticipative is proved in Lemma 6.1. It is clear that $\alpha(v) \equiv u$ on $[t,\theta]$.

Further, we obviously have (see also Lemma 1.11 in [2]), if we set $X = X^{t,x,\alpha(v),v}$,

$$\begin{aligned} E[g_2(X_T)|\mathcal{F}_{t,\theta}](\omega_1,\cdot) &= E_{\theta,T}[g_2(X_T^{\theta,X_\theta(\omega_1),\alpha(v(\omega_1)),v(\omega_1)})] \\ &= \textstyle\sum_{i\in\mathbb{N}} 1_{\{X_\theta(\omega_1)\in O_i\}} E_{\theta,T}[g_2(X_T^{\theta,X_\theta(\omega_1),\alpha_{y_i}(v(\omega_1)),v(\omega_1)})], \\ &\qquad\qquad P_{t,\theta}(d\omega_1) \text{ a.s.} \end{aligned} \tag{3.5}$$

Now (3.1) follows from (3.3).

(b) Let $(O_i)_{i\in\{0,\ldots,m\}}$ be a finite Borelian partition of $\mathbb{R}^n$ and $y_i \in O_i, i \in \{0,\ldots,k\}$, be such that $O_0 = B^c$ and, for $i \in \{1,\ldots,m\}$, (3.3) holds. (Indeed, since B is compact, a finite partition of B is sufficient to get (3.3).) Note that there is no condition on $y_0 \in B^c$.

Now let α be built like in (3.4). We already know that $\alpha(v) \equiv u$ on $[t,\theta]$ and that α is a strongly nonanticipative r-strategy. Let us prove that α is nonanticipative with delay. It is easy to see that α has delays corresponding to a partition that, from θ on, is a partition for all strategies $\alpha_{y_i}, i \in \{0,\ldots,m\}$. Since the number of strategies α_{y_i} involved in the construction of α is finite, this partition is also finite. It follows from the construction and from Proposition 6.3 that $\alpha \in \mathcal{A}(t)$.

Using again (3.3) and (3.5) and the choice of $O_1,\ldots,O_m$, one has that

$$1_{\{X_\theta\in B\}} E[g_2(X_T)|\mathcal{F}_{t,\theta}] \le 1_{\{X_\theta\in B\}}(W_2(\theta,X_\theta)+\epsilon)$$

for any $v \in \mathcal{V}(t)$, and relation (3.2) follows evidently. □

Now let us assume that (e_1,e_2) satisfies conditions (i) and (ii) of Theorem 2.10. For any $\epsilon > 0$, there is some control pair $(u^\epsilon, v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that

(i) for any $s \in [t,T]$ and $j = 1,2$,

$$P\left\{E[g_j(X_T^\epsilon)|\mathcal{F}_{t,s}] \ge W_j(s,X_s^\epsilon) - \epsilon\right\} \ \ge\ 1-\epsilon, \tag{3.6}$$

where $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$, and

(ii)

$$\text{for } j=1,2, \qquad |E[g_j(X_T^{\epsilon})]-e_j|\le\epsilon. \tag{3.7}$$

We have to prove that (e_1,e_2) is a Nash equilibrium payoff for the initial position (t,x).

To do this, we are going to define, for any $\epsilon>0$, some strategies $(\alpha_\epsilon,\beta_\epsilon)\in\mathcal{A}(t)\times\mathcal{B}(t)$ satisfying (2.5) and (2.6). We explain only the construction of α_ϵ, the construction of β_ϵ being symmetric.

To simplify the notation, we assume throughout the proof that $g_j\ge 0$ for $j=1,2$. Let us point out that we can make this assumption without loss of generality since this just adds some constant to the functions g_j. In particular, this assumption entails that $W_j\ge 0$. Recall that there exists also some $C>0$ such that $|g_j|\le C$.

Since the dynamic is bounded, it is easy to prove that, for all $(u,v),(u',v')\in\mathcal{U}(t)\times\mathcal{V}(t)$, for all $(\mathcal{F}_{t,s},s\ge t)$-stopping times S with $P[S\le T]=1$ and such that $X_S^{t,x,u,v}=X_S^{t,x,u',v'}$, P a.s., and for all $\tau\ge 0$,

$$E\left[\sup_{0\le s\le\tau}|X^{t,x,u,v}_{(S+s)\wedge T}-X^{t,x,u',v'}_{(S+s)\wedge T}|^2\right]\le C_0\tau,$$

where the constant $C_0>0$ depends only on the dynamic. Thus, since $W_2(s,\cdot)$ is Lipschitz, uniformly in s, we can choose $\tau>0$ such that, for all $(u,v),(u',v')\in\mathcal{U}(t)\times\mathcal{V}(t)$, for all $(\mathcal{F}_{t,s},s\ge t)$-stopping times S with $P[S\le T]=1$, and such that $X_S^{t,x,u,v}=X_S^{t,x,u',v'}$, P a.s.,

$$E\left[\sup_{0\le s\le\tau}|W_2((S+s)\wedge T,X^{t,x,u,v}_{(S+s)\wedge T})-W_2((S+s)\wedge T,X^{t,x,u',v'}_{(S+s)\wedge T})|^2\right]\le(\epsilon/4)^2. \tag{3.8}$$

Let us fix some partition $t_0=t<t_1<\cdots<t_m=T$ which satisfies $\sup_i|t_{i+1}-t_i|\le\tau$.

We also fix some M large enough such that

$$\sup_{u\in\mathcal{U}(t)}\sup_{v\in\mathcal{V}(t)}P\left(\sup_{t\le s\le T}|X_s^{t,x,u,v}|>M\right)\le\epsilon/(4C). \tag{3.9}$$

Let us set

$$\epsilon_0=\frac{\epsilon}{4(2+mC)} \tag{3.10}$$

and let $(\bar u,\bar v)=(u^{\epsilon_0},v^{\epsilon_0})$ satisfy (3.6) and (3.7) for $\epsilon=\epsilon_0$.

By Lemma 3.1(b) applied to the closed ball B in $\mathbb{R}^n$ with center 0 and radius M, to the control $\bar u$ and to $\theta=t_1,\dots,t_m$, we get m admissible strategies $\alpha_1\in\mathcal{A}(t),\dots,\alpha_m\in\mathcal{A}(t)$ such that, for any $v\in\mathcal{V}(t)$, for any $l\in\{1,\dots,m\}$, $\alpha_j(v)\equiv\bar u$ on $[t,t_j]$ and

$$1_{\{X^{\alpha_j}_{t_j}\in B\}}E[g_2(X_T^{\alpha_j})|\mathcal{F}_{t,t_j}]\le 1_{\{X^{\alpha_j}_{t_j}\in B\}}W_2(t_j,X^{\alpha_j}_{t_j})+\epsilon/4, \tag{3.11}$$

where we have set $X_\cdot^{\alpha_j}=X_\cdot^{t,x,\alpha_j(v),v}$.

For all $v\in\mathcal{V}(t)$, we introduce the stopping times

$$S^v=\inf\{s\ge t,v_s\ne\bar v_s\}\qquad\text{and}\qquad t^v=\inf\{t_i>S^v,\ i\ge 1\},$$

with the convention $t^v = T$ if $v_s = \bar{v}_s$ on $[t, T]$.

We are now ready to define the admissible strategy α_ϵ by setting

$$\forall v \in \mathcal{V}(t), \alpha_\epsilon(v) = \begin{cases} \bar{u} & \text{on } [\![t, t^v]\!], \\ \alpha_j(v) & \text{on } (t_j, T] \times \{t^v = t_j\}. \end{cases} \tag{3.12}$$

It is easy to check that α_ϵ is an admissible strategy.

Let $v \in \mathcal{V}(t)$ be fixed and let us set $X_\cdot = X_\cdot^{t,x,\alpha_\epsilon(v),v}$. Let us notice that $\alpha_\epsilon(v) \equiv \bar{u}$ on $[\![t, t^v]\!]$ and that

$$X = \begin{cases} X^{t,x,\bar{u},v} & \text{on } [\![t, t^v]\!] \ P \text{ a.s.}, \\ \sum_j X^{t,x,\alpha_j(v),v} 1_{t^v = t_j} & \text{on } [\![t^v, T]\!] \ P \text{ a.s.} \end{cases}$$

Then using (3.11) we get

$$1_{\{X_{t^v} \in B\}} E[g_2(X_T) | \mathcal{F}_{t,t^v}] \le 1_{\{X_{t^v} \in B\}} W_2(t^v, X_{t^v}) + \epsilon/4. \tag{3.13}$$

We now claim that

$$\forall v \in \mathcal{V}(t), \ J_2(t, x, \alpha_\epsilon(v), v) \le e_2 + \epsilon \qquad \text{and} \qquad \alpha_\epsilon(\bar{v}) = \bar{u}. \tag{3.14}$$

Indeed, it follows from (3.13) that for any $v \in \mathcal{V}(t)$, if we set $X_\cdot = X_\cdot^{t,x,\alpha_\epsilon(v),v}$, we have

$$\begin{aligned} J_2(t, x, \alpha_\epsilon(v), v) &\le E[g_2(X_T) 1_{\{|X_{t^v}| > M\}}] + E[W_2(t^v, X_{t^v}) 1_{\{|X_{t^v}| \le M\}}] + \epsilon/4 \\ &\le E[W_2(t^v, X_{t^v})] + \epsilon/2, \end{aligned} \tag{3.15}$$

where the last inequality comes from the choice of M in (3.9).

Now set $\overline{X} = X^{t,x,\bar{u},\bar{v}}$. Recall that, by the definition of S^v and the fact that $\alpha_\epsilon(v) = \bar{u}$ on $[\![t, t^v]\!]$, we have $\overline{X}_s = X_s$ on $\{s \le S^v\}$.

Further, we have $S^v \le t^v \le S^v + \tau$; thus, by (3.8), we get

$$\|W_2(t^v, X_{t^v}) - W_2(t^v, \overline{X}_{t^v})\|_2 \le \epsilon/4.$$

Accordingly,

$$E[W_2(t^v, X_{t^v})] \le E[W_2(t^v, \overline{X}_{t^v})] + \epsilon/4. \tag{3.16}$$

Let us now denote by Ω_s (for $s \in [t, T]$) the set

$$\Omega_s = \left\{ E[g_2(\overline{X}_T) | \mathcal{F}_{t,s}] \ge W_2(s, \overline{X}_s) - \epsilon_0 \right\}.$$

We recall that $P(\Omega_s) \ge 1 - \epsilon_0$ thanks to (3.6). Thus

$$\begin{aligned} E[W_2(t^v, \overline{X}_{t^v})] &= \textstyle\sum_{i=1}^m E[W_2(t_i, \overline{X}_{t_i}) 1_{t^v = t_i} 1_{\Omega_{t_i}}] + \sum_{i=1}^m E[W_2(t_i, \overline{X}_{t_i}) 1_{t^v = t_i} 1_{\Omega_{t_i}^c}] \\ &\le \textstyle\sum_{i=1}^m E[(E[g_2(\overline{X}_T) | \mathcal{F}_{t,t_i}] + \epsilon_0) 1_{t^v = t_i} 1_{\Omega_{t_i}}] \\ &+ \textstyle\sum_{i=1}^m CP(\Omega_{t_i}^c \cap \{t^v = t^i\}) \\ &\le E[g_2(\overline{X}_T)] + \epsilon_0 + \textstyle\sum_{i=1}^m CP(\Omega_{t_i}^c) \\ &\le (e_2 + 2\epsilon_0) + mC\epsilon_0, \end{aligned} \tag{3.17}$$

where we have used in the last inequality on the one hand the fact that $g_2 \ge 0$ and (3.7) and, on the other hand, the fact that $P(\Omega_{t_i}^c) \le \epsilon_0$ for any i.

Putting (3.15), (3.16), and (3.17) together yields

$$J_2(t,x,\alpha_\epsilon(v),v) \le (e_2+2\epsilon_0) + mC\epsilon_0 + \epsilon/4 + \epsilon/2 \le e_2+\epsilon$$

from the choice of ϵ_0. The last assertion of (3.14) being obvious, (3.14) is proved.

In the same way one can build an admissible strategy $\beta_\epsilon \in \mathcal{B}(t)$ such that

$$\forall u \in \mathcal{U}(t),\ J_1(t,x,u,\beta_\epsilon(u)) \le e_1+\epsilon \qquad \text{and} \qquad \beta_\epsilon(\bar{u}) = \bar{v}.$$

Combining (3.14), the previous assertion, and Lemma 2.8 implies that $(\alpha_\epsilon,\beta_\epsilon)$ satisfies the two inequalities of the definition of a Nash equilibrium payoff. □

4. Proof of the characterization: Necessary condition. Suppose that there is a Nash equilibrium payoff $(e_1,e_2) \in \mathbb{R}^2$ at a point (t,x). For some fixed $\epsilon > 0$, let $(\alpha_\epsilon,\beta_\epsilon) \in \mathcal{A}(t) \times \mathcal{B}(t)$ be such that for any $(\alpha,\beta) \in \mathcal{A}(t) \times \mathcal{B}(t)$, the following inequalities hold:

$$J_1(t,x,\alpha_\epsilon,\beta_\epsilon) \ge J_1(t,x,\alpha,\beta_\epsilon) - \epsilon^2/2 \ \text{ and } \ J_2(t,x,\alpha_\epsilon,\beta_\epsilon) \ge J_2(t,x,\alpha_\epsilon,\beta) - \epsilon^2/2 \tag{4.1}$$

and

$$\text{for } j=1,2,\ |J_j(t,x,\alpha_\epsilon,\beta_\epsilon) - e_j| \le \epsilon^2/2.$$

Thanks to Lemma 2.4, there exists a unique couple of controls $(u^\epsilon,v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that

$$\alpha_\epsilon(v^\epsilon) = u^\epsilon \text{ and } \beta_\epsilon(u^\epsilon) = v^\epsilon.$$

Let us set $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$.

We argue by contradiction and assume that there is some time $\theta \in [t,T)$ and some $j=1,2$ (say, $j=1$ to fix the idea) such that

$$P\left\{E[g_1(X_T^\epsilon)|\mathcal{F}_{t,\theta}] < W_1(\theta,X_\theta^\epsilon) - \epsilon\right\} > \epsilon.$$

We set

$$A = \left\{E[g_1(X_T^\epsilon)|\mathcal{F}_{t,\theta}] < W_1(\theta,X_\theta^\epsilon) - \epsilon\right\}. \tag{4.2}$$

By Lemma 3.1 (and the remark following the lemma) applied to θ and to the control u^ϵ, there exists a nonanticipative strategy $\tilde{\alpha} : \mathcal{V}(t) \to \mathcal{U}(t)$ such that, for any $v \in \mathcal{V}(t)$, $\tilde{\alpha}(v) = u^\epsilon$ on $[t,\theta]$ and P a.s.,

$$E[g_1(X_T^{t,x,\tilde{\alpha}(v),v})|\mathcal{F}_{t,\theta}] \ge W_1(\theta,X_\theta^{t,x,\tilde{\alpha}(v),v}) - \epsilon/2. \tag{4.3}$$

Let (u,v) be the unique couple associated with $(\tilde{\alpha},\beta_\epsilon)$. Let us notice that $u \equiv u^\epsilon$ on $[t,\theta]$. We define a control $\bar{u}$ in the following way:

$$\bar{u} = u^\epsilon \text{ on } ([t,\theta)\times\Omega) \cup ([\theta,T]\times A^c), \qquad \bar{u} = u \text{ on } [\theta,T]\times A.$$

Since β_ϵ is *strongly* nonanticipative, Corollary 6.4 states that

$$\beta_\epsilon(\bar{u}) \equiv v^\epsilon \text{ on } [t,\theta) \text{ and } \beta_\epsilon(\bar{u})_s = \begin{cases} v_s & \text{on } A \\ v_s^\epsilon & \text{on } A^c \end{cases} \quad \text{for } s \in [\theta,T].$$

Hence, we have

$$X^{t,x,\bar{u},\beta_\epsilon(\bar{u})} \equiv X^\epsilon \text{ on } [t,\theta] \qquad \text{and } X_s^{t,x,\bar{u},\beta_\epsilon(\bar{u})} = \begin{cases} X_s^{t,x,\tilde{\alpha}(v),v} & \text{on } A \\ X_s^\epsilon & \text{on } A^c \end{cases} \text{ for } s \in [\theta,T].$$

Accordingly, by (4.3), we have

$$\begin{aligned} J_1(t,x,\bar{u},\beta_\epsilon(\bar{u})) &= E\left[g_1(X_T^\epsilon)1_{A^c}\right] + E\left[E[g_1(X_T^{t,x,\tilde{\alpha}(v),v})|\mathcal{F}_{t,\theta}]1_A\right] \\ &\geq E\left[g_1(X_T^\epsilon)1_{A^c}\right] + E\left[W_1(\theta,X_\theta^\epsilon)1_A\right] - \tfrac{\epsilon}{2}P[A]. \end{aligned} \tag{4.4}$$

It follows from the definition (4.2) of A that

$$J_1(t,x,\bar{u},\beta_\epsilon(\bar{u})) > E\left[g_1(X_T^\epsilon)\right] + \frac{\epsilon}{2}P(A) \geq J_1(t,x,\alpha_\epsilon,\beta_\epsilon) + \epsilon^2/2.$$

This is in contradiction with (4.1) and the proof is complete. □

5. Proof of the existence. For proving Theorem 2.9, it is enough to show that, for any $\epsilon > 0$, there are some controls u^ϵ and v^ϵ satisfying the conditions (i) and (ii) of Theorem 2.10. In fact, we give a slightly stronger result, as follows.

PROPOSITION 5.1. *Suppose the assumptions of Theorem* 2.9 *hold. Then, for any* $\epsilon > 0$*, there is a control-pair* $(u^\epsilon, v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ *such that, for any* $t \leq s_1 \leq s_2 \leq T$ *and* $j = 1, 2$*,*

$$P\left\{E[W_j(s_2, X_{s_2}^\epsilon)|\mathcal{F}_{t,s_1}] \geq W_j(s_1, X_{s_1}^\epsilon) - \epsilon\right\} \geq 1 - \epsilon,$$

where $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$.

Proof of Theorem 2.9. Combining the above proposition applied to $s_1 = s$ and $s_2 = T$ with Theorem 2.10 gives the result for any (e_1, e_2) which is an accumulation point of the payoff $(J_1(t,x,u^\epsilon,v^\epsilon), J_2(t,x,u^\epsilon,v^\epsilon))$ as $\epsilon \to 0^+$. □

The proof of Proposition 5.1 is split into several lemmas.

LEMMA 5.2. *For any* $\epsilon > 0$*, there is a couple* $(u^\epsilon, v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ *such that, for any* $t \leq s \leq T$ *and* $j = 1, 2$*,*

$$E[W_j(s, X_s^\epsilon)] \geq W_j(t,x) - \epsilon,$$

where $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$.

Proof. Let us choose $\alpha_\epsilon \in \mathcal{A}(t)$ and $\beta_\epsilon \in \mathcal{B}(t)$ such that α_ϵ is $\epsilon/2$-optimal for $W_1(t,x)$ while β_ϵ is $\epsilon/2$-optimal for $W_2(t,x)$. Namely,

$$W_1(t,x) \leq \inf_{v\in\mathcal{V}(t)} J_1(t,x,\alpha_\epsilon(v),v) + \epsilon/2 \quad \text{and} \quad W_2(t,x) \leq \inf_{u\in\mathcal{U}(t)} J_2(t,x,u,\beta_\epsilon(u)) + \epsilon/2. \tag{5.1}$$

Let (u^ϵ, v^ϵ) be the unique pair of controls such that

$$\alpha_\epsilon(v^\epsilon) = u^\epsilon \text{ and } \beta_\epsilon(u^\epsilon) = v^\epsilon.$$

We intend to prove that the couple (u^ϵ, v^ϵ) satisfies the conclusion of the lemma. For this, we argue by contradiction and assume that there is some $\theta \in (t,T]$ and some $j = 1, 2$ (to fix the ideas, we suppose $j = 2$) such that

$$E[W_2(\theta, X_\theta^\epsilon)] < W_2(t,x) - \epsilon. \tag{5.2}$$

By Lemma 3.1 applied to θ and to the control u^ϵ, there exists a nonanticipative strategy $\alpha : \mathcal{U}(t) \to \mathcal{V}(t)$ such that, for any $v \in \mathcal{V}(t)$, $\alpha(v) \equiv u^\epsilon$ on $[t, \theta]$ and

$$E[g_2(X_T^{t,x,\alpha(v),v})|\mathcal{F}_{t,\theta}] \le W_2(\theta, X_\theta^{t,x,\alpha(v),v}) + \epsilon/2, \qquad P \text{ a.s.} \tag{5.3}$$
