SMOOTHNESS OF MULTIPLE REFINABLE FUNCTIONS AND MULTIPLE WAVELETS*

RONG-QING JIA†, SHERMAN D. RIEMENSCHNEIDER†, AND DING-XUAN ZHOU‡

Abstract. We consider the smoothness of solutions of a system of refinement equations written in the form

$$\phi = \sum\nolimits_{\alpha\in\mathbb{Z}} a(\alpha)\phi(2\cdot-\alpha),$$

where the vector of functions $\phi = (\phi_1, \dots, \phi_r)^T$ is in $(L_p(\mathbb{R}))^r$ and a is a finitely supported sequence of $r \times r$ matrices called the refinement mask. We use the generalized Lipschitz space $\mathrm{Lip}^*(\nu, L_p(\mathbb{R}))$, $\nu > 0$, to measure smoothness of a given function.

Our method is to relate the optimal smoothness, $\nu_p(\phi)$, to the p-norm joint spectral radius of the block matrices A_ε, $\varepsilon = 0, 1$, given by $A_\varepsilon = (a(\varepsilon + 2\alpha - \beta))_{\alpha,\beta}$, when restricted to a certain finite dimensional common invariant subspace V. Denoting the p-norm joint spectral radius by $\rho_p(A_0|_V, A_1|_V)$, we show that $\nu_p(\phi) \ge 1/p - \log_2 \rho_p(A_0|_V, A_1|_V)$ with equality when the shifts of $\phi_1, \dots, \phi_r$ are stable and the invariant subspace is generated by certain vectors induced by difference operators of sufficiently high order. This allows an effective use of matrix theory. Also the computational implementation of our method is simple.

When $p = 2$, the optimal smoothness is also given in terms of the spectral radius of the transition matrix associated with the refinement mask.

To illustrate the theory, we give a detailed analysis of two examples where the optimal smoothness can be given explicitly. We also apply our methods to the smoothness analysis of multiple wavelets. These examples clearly demonstrate the applicability and practical power of our approach.

1. Introduction.

The purpose of this paper is to investigate the smoothness properties of multiple refinable functions and multiple wavelets.

Suppose $\phi_1, \dots, \phi_r$ are compactly supported distributions on $\mathbb{R}$. Denote by ϕ the vector $(\phi_1, \dots, \phi_r)^T$, the transpose of $(\phi_1, \dots, \phi_r)$. We say that ϕ is *refinable* if it satisfies the following *refinement equation*:

$$\phi = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(2\cdot-\alpha), \tag{1.1}$$

where each $a(\alpha)$ is an $r \times r$ matrix of complex numbers and $a(\alpha) = 0$ except for finitely many α. We view a as a sequence from $\mathbb{Z}$ to $\mathbb{C}^{r\times r}$ and call it the *refinement mask*.

In our previous paper [20], we gave a characterization for the accuracy of a vector of multiple refinable functions in terms of the corresponding mask. In another paper [21], we characterized the L_p-convergence ($1 \le p \le \infty$) of a subdivision scheme in

terms of the p-norm joint spectral radius of two matrices derived from the mask. (See [17] for the definition of the p-norm joint spectral radius of a finite collection of matrices.) In this paper, we will take the same approach as we did in [21] to a study of the smoothness properties of the solutions of the refinement equation (1.1).

Taking the Fourier transform of both sides of (1.1), we obtain

$$\hat{\phi}(\xi) = H(\xi/2)\hat{\phi}(\xi/2), \qquad \xi \in \mathbb{R}, \tag{1.2}$$

where

$$H(\xi) := \sum_{\alpha\in\mathbb{Z}} a(\alpha)e^{-i\alpha\xi}/2, \qquad \xi \in \mathbb{R}.$$

Evidently, H is 2π-periodic. Let

$$M := H(0) = \sum_{\alpha\in\mathbb{Z}} a(\alpha)/2.$$

If ϕ is a solution of (1.1), then it follows from (1.2) that $\hat{\phi}(0) = M\hat{\phi}(0)$. In other words, either $\hat{\phi}(0) = 0$, or $\hat{\phi}(0)$ is an eigenvector of M corresponding to the eigenvalue 1.

Before proceeding, we introduce some notation. For $1 \le p \le \infty$, let $(L_p(\mathbb{R}))^r$ denote the linear space of all vectors $f = (f_1, \ldots, f_r)^T$ such that $f_1, \ldots, f_r \in L_p(\mathbb{R})$. The norm on $(L_p(\mathbb{R}))^r$ is defined by

$$\|f\|_p := \left(\sum_{j=1}^r \|f_j\|_p^p\right)^{1/p}, \qquad f = (f_1, \ldots, f_r)^T \in (L_p(\mathbb{R}))^r.$$

By $(C(\mathbb{R}))^r$ we denote the linear space of all $r \times 1$ vectors of continuous functions.

The shifts of functions $\phi_1, \ldots, \phi_r \in L_p(\mathbb{R})$ are said to be *stable* if there exist two positive constants C_1 and C_2 such that, for arbitrary $b_1, \ldots, b_r \in \ell_p(\mathbb{Z})$,

$$C_1 \sum_{j=1}^r \|b_j\|_p \le \left\| \sum_{j=1}^r \sum_{\alpha\in\mathbb{Z}} b_j(\alpha)\phi_j(\cdot - \alpha) \right\|_p \le C_2 \sum_{j=1}^r \|b_j\|_p.$$

It was proved by Jia and Micchelli [19] that the shifts of the functions $\phi_1, \ldots, \phi_r$ are stable if and only if, for any $\xi \in \mathbb{R}$, the sequences $(\hat{\phi}_j(\xi + 2\pi\beta))_{\beta\in\mathbb{Z}}$ $(j = 1, \ldots, r)$ are linearly independent.

Let $\ell_0(\mathbb{Z})$ denote the linear space of all finitely supported sequences on $\mathbb{Z}$. Similarly, we denote by $\ell_0(\mathbb{Z} \to \mathbb{C}^r)$ (resp., $\ell_0(\mathbb{Z} \to \mathbb{C}^{r\times r})$) the linear space of all finitely supported sequences of $r \times 1$ vectors (resp., $r \times r$ matrices). We identify $\ell_0(\mathbb{Z} \to \mathbb{C}^r)$ with $(\ell_0(\mathbb{Z}))^r$ and identify $\ell_0(\mathbb{Z} \to \mathbb{C}^{r\times r})$ with $(\ell_0(\mathbb{Z}))^{r\times r}$.

For $\beta \in \mathbb{Z}$, we use δ_β to denote the sequence given by

$$\delta_\beta(\alpha) = \begin{cases} 1 & \text{for } \alpha = \beta, \\ 0 & \text{for } \alpha \in \mathbb{Z} \setminus \{\beta\}. \end{cases}$$

In particular, we write δ for δ_0.

We denote by ∇ the difference operator on $\ell_0(\mathbb{Z})$:

$$\nabla v := v - v(\cdot - 1), \qquad v \in \ell_0(\mathbb{Z}).$$

The domain of the difference operator ∇ can be naturally extended to include $(\ell_0(\mathbb{Z}))^r$ and $(\ell_0(\mathbb{Z}))^{r\times r}$.

Let a be an element of $(\ell_0(\mathbb{Z}))^{r\times r}$. For $\varepsilon = 0, 1$, let A_ε be the linear operator on $(\ell_0(\mathbb{Z}))^r$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}} a(\varepsilon + 2\alpha - \beta)v(\beta), \quad \alpha \in \mathbb{Z}, \quad v \in (\ell_0(\mathbb{Z}))^r. \tag{1.3}$$

Our first concern is the existence and uniqueness of the refinement equation (1.1) with the mask a. Under the condition that $\lim_{n\to\infty} M^n$ exists, Heil and Colella [13] established existence and uniqueness of distributional solutions of (1.1). In this case, convergence of the subdivision scheme was studied by Cohen, Dyn, and Levin in [4]. Without assuming the condition that $\lim_{n\to\infty} M^n$ exists, the existence and uniqueness of distributional solutions of (1.1) were studied by several authors, including Cohen, Daubechies, and Plonka [3], Jiang and Shen [23], and Zhou [34].

In section 2, we will investigate the existence of L_p-solutions of the refinement equation (1.1) with the mask a. For $j = 1, \dots, r$, we use e_j to denote the jth column of the $r \times r$ identity matrix. Let A_0 and A_1 be the linear operators given by (1.3) and V the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla\delta)$, $j = 1, \dots, r$, in $(\ell_0(\mathbb{Z}))^r$. We will prove that, for an eigenvector y of the matrix $M := \sum_{\alpha\in\mathbb{Z}} a(\alpha)/2$ corresponding to the eigenvalue 1, there exists a compactly supported solution $\phi \in (L_p(\mathbb{R}))^r$ ($\phi \in (C(\mathbb{R}))^r$ in the case $p = \infty$) of the refinement equation (1.1) subject to $\hat{\phi}(0) = y$, provided

$$\rho_p(A_0|_V, A_1|_V) < 2^{1/p},$$

where $\rho_p(A_0|_V, A_1|_V)$ denotes the p-norm joint spectral radius of $A_0|_V$ and $A_1|_V$. This condition is necessary if, in addition, the shifts of $\phi_1, \dots, \phi_r$ are stable.

We use the generalized Lipschitz space to measure smoothness of a given function. Let us recall from [8] the definition of the generalized Lipschitz space. For $y \in \mathbb{R}$, the difference operator ∇_y is defined by

$$\nabla_y f = f - f(\cdot - y),$$

where f is a function from $\mathbb{R}$ to $\mathbb{C}$. The *modulus of continuity* of a function f in $L_p(\mathbb{R})$ ($1 \le p \le \infty$) is defined by

$$\omega(f, h)_p := \sup_{|y|\le h} \left\|\nabla_y f\right\|_p, \qquad h \ge 0.$$

Let k be a positive integer. The kth *modulus of smoothness* of $f \in L_p(\mathbb{R})$ is defined by

$$\omega_k(f, h)_p := \sup_{|y|\le h} \left\|\nabla_y^k f\right\|_p, \qquad h \ge 0.$$

For $\nu > 0$, let k be an integer greater than ν. The *generalized Lipschitz space* $\mathrm{Lip}^*(\nu, L_p(\mathbb{R}))$ consists of those functions $f \in L_p(\mathbb{R})$ for which

$$\omega_k(f, h)_p \le Ch^\nu \qquad \forall\, h > 0,$$

where C is a positive constant independent of h.

By $(\mathrm{Lip}^*(\nu, L_p(\mathbb{R})))^r$ we denote the linear space of all vectors $f = (f_1, \ldots, f_r)^T$ such that $f_1, \ldots, f_r \in \mathrm{Lip}^*(\nu, L_p(\mathbb{R}))$. The optimal smoothness of a vector $f \in (L_p(\mathbb{R}))^r$ in the L_p-norm is described by its *critical exponent* $\nu_p(f)$ defined by

$$\nu_p(f) := \sup\Big\{ \nu : f \in \big(\mathrm{Lip}^*(\nu, L_p(\mathbb{R}))\big)^r \Big\}.$$

In section 3, we will establish our main result on characterization of the smoothness of multiple refinable functions. Suppose $\phi = (\phi_1, \ldots, \phi_r)^T$ is a compactly supported solution of the refinement equation (1.1) with the mask a. Let k be a positive integer and V the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla^k \delta)$, $j = 1, \ldots, r$. If ϕ lies in $(L_p(\mathbb{R}))^r$ for $1 \le p < \infty$ (ϕ lies in $(C(\mathbb{R}))^r$ for $p = \infty$), then

$$\nu_p(\phi) \ge 1/p - \log_2 \rho_p(A_0|_V, A_1|_V). \tag{1.4}$$

If, in addition, the shifts of $\phi_1, \ldots, \phi_r$ are stable, and if $k > 1/p - \log_2 \rho_p(A_0|_V, A_1|_V)$, then equality holds in (1.4). When $p = 2$, the critical exponent is also given in terms of the spectral radius of the transition operator associated with the refinement mask a.

Regularity of multiple refinable functions was studied by Cohen, Daubechies, and Plonka in [3] and by Micchelli and Sauer in [25]. Both approaches are based on the factorization technique introduced by Plonka [26]. Our approach is different from theirs and does not rely on factorization. Thus, our methods can be applied to multiple refinable functions and multiple wavelets of several variables. For smoothness analysis of a single multivariate refinable function, the reader is referred to [18] and [27]. Even in the univariate case our methods have advantages over the factorization technique. Indeed, our methods use the joint spectral radius of finite matrices. This allows a more effective use of matrix theory to reduce the size of the matrices by a restriction to a certain common invariant subspace. Thus, the computational implementation of our method becomes much simpler. In fact, in the multiple case, the factorization would usually enlarge the support of the mask making the order of the matrices larger, hence computationally more complex. For a discussion of the size of the support of vector scaling functions, see So and Wang [30].

To illustrate the general theory, we shall give detailed analysis of smoothness for two examples in section 4. One example is taken from [10], the other from [21]. In particular, for the example of Donovan et al. [10], our method gives explicitly the exact smoothness in all p-norms. In comparison, Cohen, Daubechies, and Plonka [3] partially recovered the result of [10] for the regularity in the L_∞-norm, while Micchelli and Sauer [25] gave a crude estimate for the regularity in the L_1-norm for a special case.

In section 5, applying our study to multiple wavelets, we construct a family of orthogonal double wavelets which includes the one of Chui and Lian [2]. We give a complete smoothness analysis in L_2 for this family, and in all L_p for the example of Chui and Lian (who did not discuss smoothness).

The examples in sections 4 and 5 clearly demonstrate the applicability and practical power of our approach.

2. Existence of L_p-solutions. In order to solve the refinement equation (1.1), we introduce the linear operator Q_a on $(L_p(\mathbb{R}))^r$ $(1 \le p \le \infty)$ as follows:

$$Q_a f := \sum_{\alpha \in \mathbb{Z}} a(\alpha) f(2 \cdot - \alpha), \qquad f \in (L_p(\mathbb{R}))^r. \tag{2.1}$$

If ϕ is a fixed point of Q_a, i.e., $Q_a\phi = \phi$, then ϕ is a solution of the refinement equation (1.1).

Let Q_a be the linear operator given in (2.1). For an initial vector $f \in (L_p(\mathbb{R}))^r$, we have

$$Q_a^n f = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha) f(2^n \cdot -\alpha), \qquad n = 1, 2, \ldots,$$

where each a_n is independent of the choice of f. In particular, $a_1 = a$. Consequently, for $n > 1$ we have

$$\begin{aligned} Q_a^n f = Q_a^{n-1}(Q_a f) &= \sum_{\beta\in\mathbb{Z}} a_{n-1}(\beta)(Q_a f)(2^{n-1}\cdot -\beta) \\ &= \sum_{\beta\in\mathbb{Z}}\sum_{\alpha\in\mathbb{Z}} a_{n-1}(\beta)a(\alpha) f(2^n\cdot -2\beta-\alpha) \\ &= \sum_{\alpha\in\mathbb{Z}} \left[\sum_{\beta\in\mathbb{Z}} a_{n-1}(\beta)a(\alpha-2\beta)\right] f(2^n\cdot-\alpha). \end{aligned}$$

This establishes the following iteration relation for a_n $(n = 1, 2, \ldots)$:

$$a_1 = a \quad \text{and} \quad a_n(\alpha) = \sum_{\beta\in\mathbb{Z}} a_{n-1}(\beta)a(\alpha-2\beta), \quad \alpha\in\mathbb{Z}. \tag{2.2}$$

For $\varepsilon \in \mathbb{Z}$, we denote by $A_\varepsilon = (A_\varepsilon(\alpha,\beta))_{\alpha,\beta\in\mathbb{Z}}$ the bi-infinite block matrix given by

$$A_\varepsilon(\alpha,\beta) := a(\varepsilon + 2\alpha - \beta), \qquad \alpha,\beta\in\mathbb{Z}. \tag{2.3}$$

For $a \in (\ell_0(\mathbb{Z}))^{r\times r}$ and $n = 1, 2, \ldots$, let $a_n \in (\ell_0(\mathbb{Z}))^{r\times r}$ be given by the iteration relation (2.2). If $\alpha = \varepsilon_1 + 2\varepsilon_2 + \cdots + 2^{n-1}\varepsilon_n + 2^n\gamma$, where $\varepsilon_1, \ldots, \varepsilon_n, \gamma \in \mathbb{Z}$, then

$$a_n(\alpha-\beta) = A_{\varepsilon_n}\cdots A_{\varepsilon_1}(\gamma,\beta) \qquad \forall\,\beta\in\mathbb{Z}. \tag{2.4}$$

This can be proved easily by induction on n. For $n = 1$ and $\alpha = \varepsilon_1 + 2\gamma$, where $\varepsilon_1, \gamma \in \mathbb{Z}$, we have

$$a_1(\alpha-\beta) = a(\varepsilon_1 + 2\gamma - \beta) = A_{\varepsilon_1}(\gamma,\beta).$$

Suppose $n > 1$ and (2.4) has been verified for $n-1$. For $\alpha = \varepsilon_1 + 2\alpha_1$, where $\alpha_1, \varepsilon_1 \in \mathbb{Z}$, by the iteration relation (2.2) we have

$$a_n(\alpha-\beta) = \sum_{\eta\in\mathbb{Z}} a_{n-1}(\eta)a(\alpha-\beta-2\eta) = \sum_{\eta\in\mathbb{Z}} a_{n-1}(\alpha_1-\eta)a(\varepsilon_1+2\eta-\beta). \tag{2.5}$$

Suppose $\alpha_1 = \varepsilon_2 + \cdots + 2^{n-2}\varepsilon_n + 2^{n-1}\gamma$, where $\varepsilon_2, \ldots, \varepsilon_n, \gamma \in \mathbb{Z}$. Then by the induction hypothesis we have

$$a_{n-1}(\alpha_1-\eta) = A_{\varepsilon_n}\cdots A_{\varepsilon_2}(\gamma,\eta).$$

This in connection with (2.5) gives

$$a_n(\alpha-\beta) = \sum_{\eta\in\mathbb{Z}} A_{\varepsilon_n}\cdots A_{\varepsilon_2}(\gamma,\eta)A_{\varepsilon_1}(\eta,\beta) = A_{\varepsilon_n}\cdots A_{\varepsilon_2}A_{\varepsilon_1}(\gamma,\beta),$$

thereby completing the induction procedure.

The relation (2.4) motivates us to consider the joint spectral radius of a finite multiset of linear operators. The uniform joint spectral radius was introduced by Rota and Strang [28]. The use of the joint spectral radius to obtain regularity results was initiated by Daubechies and Lagarias [6, 7] for the scalar case. Colella and Heil [5] used the joint spectral radius to characterize continuous solutions of scalar refinement equations.

The p-norm joint spectral radius was introduced by Jia in [17]. Let us recall from [17] the definition of the p-norm joint spectral radius. Let V be a *finite-dimensional* vector space equipped with a vector norm $\|\cdot\|$. For a linear operator A on V, define

$$\|A\| := \max_{\|v\|=1} \big\{\|Av\|\big\}.$$

Let $\mathcal{A}$ be a finite multiset of linear operators on V. For a positive integer n we denote by $\mathcal{A}^n$ the nth Cartesian power of $\mathcal{A}$:

$$\mathcal{A}^n = \big\{(A_1, \ldots, A_n) : A_1, \ldots, A_n \in \mathcal{A}\big\}.$$

For $1 \le p < \infty$, let

$$\|\mathcal{A}^n\|_p := \left(\sum_{(A_1,\ldots,A_n)\in\mathcal{A}^n} \|A_1 \cdots A_n\|^p\right)^{1/p},$$

and, for $p = \infty$, define

$$\|\mathcal{A}^n\|_\infty := \max\big\{\|A_1 \cdots A_n\| : (A_1, \ldots, A_n) \in \mathcal{A}^n\big\}.$$

For $1 \le p \le \infty$, the *p-norm joint spectral radius* of $\mathcal{A}$ is defined to be

$$\rho_p(\mathcal{A}) := \lim_{n\to\infty} \|\mathcal{A}^n\|_p^{1/n}.$$

It is easily seen that this limit indeed exists, and

$$\lim_{n\to\infty} \|\mathcal{A}^n\|_p^{1/n} = \inf_{n\ge 1} \|\mathcal{A}^n\|_p^{1/n}.$$

Clearly, $\rho_p(\mathcal{A})$ is independent of the choice of the vector norm on V.

If $\mathcal{A}$ consists of a single linear operator A, then $\rho_p(\mathcal{A}) = \rho(A)$, where $\rho(A)$ denotes the spectral radius of A, which is independent of p. It is easily seen that $\rho(A) \le \rho_\infty(\mathcal{A})$ for any element A in $\mathcal{A}$.

Now let $\mathcal{A}$ be a finite multiset of linear operators on a normed vector space V, which is not necessarily finite dimensional. A subspace W of V is said to be invariant under $\mathcal{A}$, or *$\mathcal{A}$-invariant*, if it is invariant under every operator A in $\mathcal{A}$. For a vector $w \in V$, we define

$$\|\mathcal{A}^n w\|_p := \begin{cases} \left(\sum_{(A_1,\ldots,A_n)\in\mathcal{A}^n} \|A_1 \cdots A_n w\|^p\right)^{1/p} & \text{for } 1 \le p < \infty, \\ \max\big\{\|A_1 \cdots A_n w\| : (A_1, \ldots, A_n) \in \mathcal{A}^n\big\} & \text{for } p = \infty. \end{cases} \tag{2.6}$$

If the minimal $\mathcal{A}$-invariant subspace W generated by w is finite dimensional, then we have

$$\lim_{n\to\infty} \big\|\mathcal{A}^n w\big\|_p^{1/n} = \rho_p(\mathcal{A}|_W), \qquad 1 \le p \le \infty.$$

See [12, Lemma 2.4] for a proof of this result.

If $V = (\ell_0(\mathbb{Z}))^r$, it is often convenient to choose the ℓ_p-norm as the underlying vector norm in (2.6). We denote by $\ell_p(\mathbb{Z} \to \mathbb{C}^r)$ the linear space of all sequences $u : \mathbb{Z} \to \mathbb{C}^r$ such that $u(\alpha) = (u_1(\alpha), \dots, u_r(\alpha))^T$ for some $u_1, \dots, u_r \in \ell_p(\mathbb{Z})$ and all $\alpha \in \mathbb{Z}$. Obviously, $u \mapsto (u_1, \dots, u_r)^T$ is a canonical isomorphism between $\ell_p(\mathbb{Z} \to \mathbb{C}^r)$ and $(\ell_p(\mathbb{Z}))^r$. Thus, we may identify $\ell_p(\mathbb{Z} \to \mathbb{C}^r)$ with $(\ell_p(\mathbb{Z}))^r$. The norm of $u = (u_1, \dots, u_r)^T$ is given by

$$\|u\|_p := \Big(\sum\nolimits_{j=1}^r \|u_j\|_p^p\Big)^{1/p}.$$

Equipped with this norm, $(\ell_p(\mathbb{Z}))^r$ becomes a Banach space.

We denote by $\ell_p(\mathbb{Z} \to \mathbb{C}^{r\times r})$ the linear space of all sequences $b : \mathbb{Z} \to \mathbb{C}^{r\times r}$ such that $b(\alpha) = (b_{jk}(\alpha))_{1\le j,k\le r}$ for some $b_{jk} \in \ell_p(\mathbb{Z})$ $(j, k = 1, \dots, r)$ and all $\alpha \in \mathbb{Z}$. We also identify $\ell_p(\mathbb{Z} \to \mathbb{C}^{r\times r})$ with $(\ell_p(\mathbb{Z}))^{r\times r}$. The norm of $b = (b_{jk})_{1\le j,k\le r}$ is defined by

$$\|b\|_p := \left(\sum_{j=1}^r \sum_{k=1}^r \|b_{jk}\|_p^p\right)^{1/p}.$$

Let a be an element of $(\ell_0(\mathbb{Z}))^{r\times r}$. The bi-infinite block matrices A_ε $(\varepsilon \in \mathbb{Z})$ defined in (2.3) may be viewed as the linear operators on $(\ell_0(\mathbb{Z}))^r$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}} a(\varepsilon + 2\alpha - \beta)v(\beta), \quad \alpha \in \mathbb{Z}, \quad v \in (\ell_0(\mathbb{Z}))^r. \tag{2.7}$$

Suppose $y \in \mathbb{C}^r$ and $\alpha = \varepsilon_1 + 2\varepsilon_2 + \cdots + 2^{n-1}\varepsilon_n + 2^n\gamma$, where $\varepsilon_1, \dots, \varepsilon_n, \gamma \in \mathbb{Z}$. Then it follows from (2.4) that

$$a_n(\alpha - \beta)y = A_{\varepsilon_n} \cdots A_{\varepsilon_1}(y\delta_\beta)(\gamma) \qquad \forall\, \beta \in \mathbb{Z}. \tag{2.8}$$

For a bounded subset K of $\mathbb{R}$, we use $\ell(K)$ to denote the linear space of all sequences on $\mathbb{Z}$ supported in $K \cap \mathbb{Z}$. Suppose a is supported on $[0, N]$, where N is a positive integer. Then, for $j \le 0$ and $k \ge N - 1$, $(\ell([j, k]))^r$ is invariant under both A_0 and A_1. Consequently, the minimal common invariant subspace of A_0 and A_1 generated by a finite subset of $(\ell_0(\mathbb{Z}))^r$ is finite dimensional.

THEOREM 2.1. *For an element $a \in (\ell_0(\mathbb{Z}))^{r\times r}$, let y be an eigenvector of the matrix $M := \sum_{\alpha\in\mathbb{Z}} a(\alpha)/2$ corresponding to the eigenvalue 1, and let V be the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla\delta)$, $j = 1, \dots, r$, in $(\ell_0(\mathbb{Z}))^r$. If*

$$\rho_p(A_0|_V, A_1|_V) < 2^{1/p}, \tag{2.9}$$

then there exists a compactly supported solution $\phi \in (L_p(\mathbb{R}))^r$ ($\phi \in (C(\mathbb{R}))^r$ in the case $p = \infty$) of the refinement equation (1.1) with the mask a subject to $\hat\phi(0) = y$. Conversely, if $\phi = (\phi_1, \dots, \phi_r)^T \in (L_p(\mathbb{R}))^r$ ($\phi \in (C(\mathbb{R}))^r$ in the case $p = \infty$) is a compactly supported solution of (1.1) such that the shifts of $\phi_1, \dots, \phi_r$ are stable, then (2.9) holds true.

Proof. The proof follows the lines of [21, Theorem 5.3]. Let $f := yg$, where g is the hat function supported on $[0, 2]$ satisfying $g(x) = x$ for $0 \le x \le 1$ and $g(x) = 2 - x$ for $1 < x \le 2$. Since $\hat g(0) = 1$, we have $\hat f(0) = y$.

Consider $f_n := Q_a^n f$, $n = 1, 2, \ldots$. We have

$$f_n = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha) f(2^n \cdot -\alpha),$$

where the sequences a_n $(n = 1, 2, \ldots)$ are given by the iteration relation (2.2). Since $g = g(2\cdot)/2 + g(2\cdot -1) + g(2\cdot -2)/2$, we have

$$f_n = \sum_{\alpha\in\mathbb{Z}} \frac{1}{2}\big[a_n(\alpha)y + a_n(\alpha-1)y\big] g(2^{n+1}\cdot -2\alpha) + \sum_{\alpha\in\mathbb{Z}} \big[a_n(\alpha)y\big] g(2^{n+1}\cdot -2\alpha -1).$$

Moreover,

$$f_{n+1} = \sum_{\alpha\in\mathbb{Z}} \big[a_{n+1}(2\alpha)y\big] g(2^{n+1}\cdot -2\alpha) + \sum_{\alpha\in\mathbb{Z}} \big[a_{n+1}(2\alpha+1)y\big] g(2^{n+1}\cdot -2\alpha -1).$$

Subtracting the first equation from the second, we obtain

$$f_{n+1} - f_n = \sum_{\alpha\in\mathbb{Z}} \big[b_n(\alpha)y\big] g(2^{n+1}\cdot -2\alpha) + \sum_{\alpha\in\mathbb{Z}} \big[c_n(\alpha)y\big] g(2^{n+1}\cdot -2\alpha -1),$$

where

$$b_n(\alpha) := a_{n+1}(2\alpha) - \frac{1}{2}a_n(\alpha) - \frac{1}{2}a_n(\alpha-1) \quad \text{and} \quad c_n(\alpha) := a_{n+1}(2\alpha+1) - a_n(\alpha), \quad \alpha\in\mathbb{Z}.$$

It follows that

$$\|f_{n+1} - f_n\|_p \le 2^{1-(n+1)/p}\big(\|b_n y\|_p + \|c_n y\|_p\big). \tag{2.10}$$

Let us estimate $\|b_n y\|_p$ and $\|c_n y\|_p$. Suppose $\alpha = \varepsilon_1 + 2\varepsilon_2 + \cdots + 2^{n-1}\varepsilon_n + 2^n\gamma$, where $\gamma\in\mathbb{Z}$ and $\varepsilon_1, \ldots, \varepsilon_n \in \{0, 1\}$. Then $2\alpha = 0 + 2\varepsilon_1 + 2^2\varepsilon_2 + \cdots + 2^n\varepsilon_n + 2^{n+1}\gamma$, and an application of (2.8) gives

$$\begin{aligned} b_n(\alpha)y &= a_{n+1}(2\alpha)y - \frac{1}{2}a_n(\alpha)y - \frac{1}{2}a_n(\alpha-1)y \\ &= A_{\varepsilon_n}\cdots A_{\varepsilon_1}A_0(y\delta)(\gamma) - \frac{1}{2}A_{\varepsilon_n}\cdots A_{\varepsilon_1}(y\delta + y\delta_1)(\gamma) \\ &= A_{\varepsilon_n}\cdots A_{\varepsilon_1}u(\gamma), \end{aligned}$$

where $u := A_0(y\delta) - (y\delta + y\delta_1)/2$. Similarly, we have

$$c_n(\alpha)y = A_{\varepsilon_n}\cdots A_{\varepsilon_1}v(\gamma),$$

where $v := A_1(y\delta) - y\delta$.

Let $\mathcal{A} := \{A_0, A_1\}$. The norm in (2.6) is chosen to be the ℓ_p-norm. The discussion above tells us that

$$\|b_n y\|_p = \|\mathcal{A}^n u\|_p \quad \text{and} \quad \|c_n y\|_p = \|\mathcal{A}^n v\|_p. \tag{2.11}$$

Write ρ for $\rho_p(A_0|_V, A_1|_V)$. In order to prove that the sequence $(f_n)_{n=1,2,\ldots}$ converges in the L_p-norm, it suffices to show that

$$\lim_{n\to\infty} \|\mathcal{A}^n u\|_p^{1/n} \le \rho \quad \text{and} \quad \lim_{n\to\infty} \|\mathcal{A}^n v\|_p^{1/n} \le \rho. \tag{2.12}$$

Indeed, since $\rho < 2^{1/p}$, we may pick a number σ such that $2^{-1/p}\rho < \sigma < 1$. Hence, there exists a constant C independent of n such that

$$2^{-n/p}\|\mathcal{A}^n u\|_p \le C\sigma^n \quad \text{and} \quad 2^{-n/p}\|\mathcal{A}^n v\|_p \le C\sigma^n.$$

This together with (2.10) and (2.11) yields

$$\|f_{n+1} - f_n\|_p \le 2^{1-(n+1)/p}\big(\|b_n y\|_p + \|c_n y\|_p\big) \le 4C\sigma^n \qquad \forall\, n \in \mathbb{N}.$$

Since $\sigma < 1$, this shows that $(f_n)_{n=1,2,\dots}$ converges to some $\phi \in (L_p(\mathbb{R}))^r$ in the L_p-norm. In the case $p = \infty$, since each f_n is continuous, the limit ϕ is also continuous. Furthermore, since y is an eigenvector of the matrix M corresponding to the eigenvalue 1, we have

$$\hat{f}_n(0) = M^n \hat{f}(0) = M^n y = y.$$

Taking the limit as $n \to \infty$ in the above equation, we obtain $\hat{\phi}(0) = y$.

Let us verify (2.12). For this purpose, we set $v_j := A_j(y\delta) - y\delta$ for $j = 0, 1$. Then $v = v_1$ and $u = v_0 + (y\nabla\delta)/2$. But

$$\lim_{n\to\infty} \|\mathcal{A}^n(y\nabla\delta)\|_p^{1/n} \le \rho.$$

Thus, it suffices to show that

$$\lim_{n\to\infty} \|\mathcal{A}^n(v_0 + v_1)\|_p^{1/n} \le \rho \quad \text{and} \quad \lim_{n\to\infty} \|\mathcal{A}^n(v_0 - v_1)\|_p^{1/n} \le \rho. \tag{2.13}$$

To verify the first inequality in (2.13), we observe that

$$v_0 + v_1 = A_0(y\delta) - y\delta + A_1(y\delta) - y\delta = \sum_{\alpha\in\mathbb{Z}} \big[a(2\alpha) + a(2\alpha+1)\big] y\delta_\alpha - 2y\delta.$$

But $\sum_{\alpha\in\mathbb{Z}}[a(2\alpha) + a(2\alpha+1)]\, y = 2My = 2y$. Hence it follows that

$$v_0 + v_1 = \sum\nolimits_{\alpha\in\mathbb{Z}} \big[a(2\alpha) + a(2\alpha+1)\big] y(\delta_\alpha - \delta).$$

Note that only finitely many terms in the above sum do not vanish, while $\delta_\alpha - \delta$ can be written as $-\sum_{\beta=0}^{\alpha-1} \nabla\delta_\beta$. Therefore, $v_0 + v_1$ can be written as a finite linear combination of $e_j(\nabla\delta_\beta)$, $j = 1, \dots, r$, $\beta \in \mathbb{Z}$. We claim that

$$\|\mathcal{A}^n(e_j\nabla\delta_\beta)\|_p = \|\mathcal{A}^n(e_j\nabla\delta)\|_p \qquad \forall\, \beta \in \mathbb{Z}.$$

Indeed, for $w \in \mathbb{C}^r$ and $\alpha = \varepsilon_1 + 2\varepsilon_2 + \cdots + 2^{n-1}\varepsilon_n + 2^n\gamma$, where $\varepsilon_1, \dots, \varepsilon_n \in \{0, 1\}$ and $\gamma \in \mathbb{Z}$, by (2.8) we have

$$A_{\varepsilon_n} \cdots A_{\varepsilon_1}\big[w(\delta_\beta - \delta_{\beta+1})\big](\gamma) = a_n(\alpha - \beta)w - a_n(\alpha - \beta - 1)w.$$

Note that $\|a_n(\cdot - \beta)w - a_n(\cdot - \beta - 1)w\|_p = \|a_n w - a_n(\cdot - 1)w\|_p$. Consequently,

$$\|\mathcal{A}^n(w\nabla\delta_\beta)\|_p = \|\nabla a_n w\|_p = \|\mathcal{A}^n(w\nabla\delta)\|_p \qquad \forall\, \beta \in \mathbb{Z}. \tag{2.14}$$

This verifies our claim, and thereby establishes the first inequality in (2.13).

As to the second inequality in (2.13), we observe that

$$A_0(y\delta) = \sum_{\alpha\in\mathbb{Z}} a(2\alpha) y\delta_\alpha = A_1(y\delta_1).$$

It follows that

$$v_0 - v_1 = A_0(y\delta) - A_1(y\delta) = A_1(y\delta_1) - A_1(y\delta) = -A_1(y\nabla\delta).$$

Hence, for $n = 1, 2, \ldots$, we have

$$\|\mathcal{A}^n(v_0 - v_1)\|_p \le \|\mathcal{A}^{n+1}(y\nabla\delta)\|_p.$$

This verifies the second inequality in (2.13). The proof for the sufficiency part of the theorem is complete.

It remains to prove the necessity part of the theorem. Suppose $\phi = (\phi_1, \ldots, \phi_r)^T$ is a solution of (1.1), where $\phi_1, \ldots, \phi_r$ are compactly supported functions in $L_p(\mathbb{R})$ ($\phi_1, \ldots, \phi_r$ are continuous in the case $p = \infty$). Iterating the refinement equation (1.1) n times, we obtain

$$\phi = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha)\phi(2^n \cdot -\alpha),$$

where the sequences a_n ($n = 1, 2, \ldots$) are given by (2.2). It follows that

$$\phi - \phi(\cdot - 1/2^n) = \sum_{\alpha\in\mathbb{Z}} \nabla a_n(\alpha)\phi(2^n \cdot -\alpha).$$

If the shifts of $\phi_1, \ldots, \phi_r$ are stable, then there exists a constant $C_1 > 0$ such that

$$2^{-n/p}\|\nabla a_n\|_p \le C_1\|\phi - \phi(\cdot - 1/2^n)\|_p \qquad \forall\, n \in \mathbb{N}.$$

Consequently, there exists a constant $C > 0$ such that

$$2^{-n/p}\|\nabla a_n e_j\|_p \le C\|\phi - \phi(\cdot - 1/2^n)\|_p \qquad \forall\, j = 1, \ldots, r;\ n \in \mathbb{N}. \tag{2.15}$$

But (2.14) tells us that

$$\lim_{n\to\infty} \|\nabla a_n e_j\|_p^{1/n} = \lim_{n\to\infty} \|\mathcal{A}^n(e_j\nabla\delta)\|_p^{1/n}.$$

Note that $\rho = \max_{1\le j\le r}\{\lim_{n\to\infty} \|\mathcal{A}^n(e_j\nabla\delta)\|_p^{1/n}\}$. Since $\lim_{n\to\infty} \|\phi - \phi(\cdot - 1/2^n)\|_p = 0$, (2.15) holds true only if $2^{-1/p}\rho < 1$. This shows $\rho < 2^{1/p}$, as desired. □

3. Characterization of smoothness. In this section, we give a characterization for the smoothness of solutions of the refinement equation (1.1) in terms of the corresponding refinement mask. Our work is based on the following results from approximation theory: For a function f in $L_p(\mathbb{R})$ (f is continuous in the case $p = \infty$), f lies in $\mathrm{Lip}^*(\nu, L_p(\mathbb{R}))$ ($\nu > 0$) if and only if, for some integer $k > \nu$, there exists a constant $C > 0$ such that

$$\|\nabla_{2^{-n}}^k f\|_p \le C2^{-n\nu} \qquad \forall\, n \in \mathbb{N}.$$

For these results we refer the reader to the work of Boman [1] and Ditzian [9].

Suppose $\phi = (\phi_1, \dots, \phi_r)^T$ is a solution of the refinement equation (1.1). Iterating (1.1) n times, we obtain

$$\phi = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha)\phi(2^n\cdot - \alpha), \tag{3.1}$$

where a_n $(n = 1, 2, \dots)$ are given by (2.2). Applying the difference operator $\nabla_{2^{-n}}$ to both sides of (3.1), we obtain

$$\nabla_{2^{-n}}\phi = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha)\big[\phi(2^n\cdot - \alpha) - \phi(2^n\cdot - \alpha - 1)\big] = \sum_{\alpha\in\mathbb{Z}} \nabla a_n(\alpha)\phi(2^n\cdot - \alpha).$$

For $k = 1, 2, \dots$, an induction argument tells us that

$$\nabla^k_{2^{-n}}\phi = \sum_{\alpha\in\mathbb{Z}} \nabla^k a_n(\alpha)\phi(2^n\cdot - \alpha). \tag{3.2}$$

Suppose $\phi_1, \dots, \phi_r$ are compactly supported functions in $L_p(\mathbb{R})$. It follows from (3.2) that

$$2^{n/p}\big\|\nabla^k_{2^{-n}}\phi\big\|_p \le C_1\big\|\nabla^k a_n\big\|_p \qquad \forall\, n \in \mathbb{N}, \tag{3.3}$$

where C_1 is a constant independent of n. If, in addition, the shifts of $\phi_1, \dots, \phi_r$ are stable, then there exists a constant $C_2 > 0$ such that

$$2^{n/p}\big\|\nabla^k_{2^{-n}}\phi\big\|_p \ge C_2\big\|\nabla^k a_n\big\|_p \qquad \forall\, n \in \mathbb{N}, \tag{3.4}$$

but, for $0 < \nu < k$, ϕ lies in $(\mathrm{Lip}^*(\nu, L_p(\mathbb{R})))^r$ if and only if there exists a constant $C > 0$ such that

$$\|\nabla^k_{2^{-n}}\phi\|_p \le C2^{-n\nu} \qquad \forall\, n \in \mathbb{N}.$$

Thus, we have established the following result.

LEMMA 3.1. *Suppose $\phi = (\phi_1, \dots, \phi_r)^T \in (L_p(\mathbb{R}))^r$ ($\phi \in (C(\mathbb{R}))^r$ in the case $p = \infty$) is a compactly supported solution of the refinement equation* (1.1) *with mask a. For $n = 1, 2, \dots$, let a_n be given by the iteration relation* (2.2). *Let $k > \nu > 0$, where k is an integer. If there exists a constant $C > 0$ such that*

$$\|\nabla^k a_n\|_p \le C2^{-n(\nu-1/p)} \qquad \forall\, n \in \mathbb{N}, \tag{3.5}$$

then ϕ belongs to $(Lip^*(\nu, L_p(\mathbb{R})))^r$. Conversely, if ϕ lies in $(Lip^*(\nu, L_p(\mathbb{R})))^r$, then (3.5) *holds true, provided the shifts of $\phi_1, \dots, \phi_r$ are stable.*

For two elements b and c in $\ell_0(\mathbb{Z})$, the *discrete convolution* of b and c, denoted by $b*c$, is defined by

$$b*c(\alpha) = \sum_{\beta\in\mathbb{Z}} b(\alpha - \beta)c(\beta), \qquad \alpha \in \mathbb{Z}.$$

Evidently, $b*\delta = b$ for any $b \in \ell_0(\mathbb{Z})$. If $b \in (\ell_0(\mathbb{Z}))^{r\times r}$ and $c \in (\ell_0(\mathbb{Z}))^r$, then $b*c$ is defined in a similar way.

LEMMA 3.2. *Let a be an element of $(\ell_0(\mathbb{Z}))^{r\times r}$, and let a_n $(n = 1, 2, \dots)$ be given by the iteration relation* (2.2). *For $\varepsilon = 0, 1$, let A_ε be the linear operator on $(\ell_0(\mathbb{Z}))^r$ given by* (2.7). *Then, for each integer $k \ge 0$,*

$$\lim_{n\to\infty}\big\|\nabla^k a_n\big\|_p^{1/n} = \rho_p(A_0|_V, A_1|_V),$$

where V is the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla^k\delta)$, $j = 1, \ldots, r$.

Proof. Write $\mathcal{A}$ for $\{A_0, A_1\}$. For an element $w \in (\ell_0(\mathbb{Z}))^r$, the quantity $\|\mathcal{A}^n w\|_p$ is defined as in (2.6) with the ℓ_p-norm being the underlying vector norm on $(\ell_0(\mathbb{Z}))^r$.

Let v be an element in $(\ell_0(\mathbb{Z}))^r$. We observe that

$$(\nabla^k a_n) * v = a_n * (\nabla^k v).$$

Suppose $\alpha = \varepsilon_1 + 2\varepsilon_2 + \cdots + 2^{n-1}\varepsilon_n + 2^n\gamma$, where $\varepsilon_1, \ldots, \varepsilon_n \in \{0, 1\}$ and $\gamma \in \mathbb{Z}$. Then by (2.4) we have

$$\begin{aligned}\big(\nabla^k a_n * v\big)(\alpha) &= \sum_{\beta\in\mathbb{Z}} a_n(\alpha - \beta)\nabla^k v(\beta) \\ &= \sum_{\beta\in\mathbb{Z}} A_{\varepsilon_n}\cdots A_{\varepsilon_1}(\gamma, \beta)\nabla^k v(\beta) = A_{\varepsilon_n}\cdots A_{\varepsilon_1}(\nabla^k v)(\gamma).\end{aligned}$$

It follows that

$$\|\nabla^k a_n * v\|_p = \|\mathcal{A}^n(\nabla^k v)\|_p. \tag{3.6}$$

Choosing $v = e_j\delta$ in (3.6), we obtain

$$\|(\nabla^k a_n)e_j\|_p = \|(\nabla^k a_n) * (e_j\delta)\|_p = \|\mathcal{A}^n(e_j\nabla^k\delta)\|_p.$$

This shows that

$$\lim_{n\to\infty} \|(\nabla^k a_n)e_j\|_p^{1/n} = \lim_{n\to\infty} \|\mathcal{A}^n(e_j\nabla^k\delta)\|_p^{1/n} = \rho_p(A_0|_{V_j}, A_1|_{V_j}),$$

where V_j is the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla^k\delta)$. But

$$\|\nabla^k a_n\|_p = \left(\sum_{j=1}^r \|(\nabla^k a_n)e_j\|_p^p\right)^{1/p}.$$

Therefore, we arrive at the conclusion that

$$\lim_{n\to\infty} \big\|\nabla^k a_n\big\|_p^{1/n} = \max\big\{\rho_p(A_0|_{V_j}, A_1|_{V_j}) : j = 1, \ldots, r\big\} = \rho_p(A_0|_V, A_1|_V),$$

where V is the sum of $V_1, \ldots, V_r$. ∎

We are in a position to prove the main result of this paper.

THEOREM 3.3. *Let a be an element of $(\ell_0(\mathbb{Z}))^{r\times r}$. For $\varepsilon = 0, 1$, let A_ε be the linear operator on $(\ell_0(\mathbb{Z}))^r$ given by (2.7). Let k be a positive integer and V the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla^k\delta)$, $j = 1, \ldots, r$. Suppose $\phi = (\phi_1, \ldots, \phi_r)^T$ is compactly supported and lies in $(L_p(\mathbb{R}))^r$ for $1 \le p < \infty$ (f lies in $(C(\mathbb{R}))^r$ for $p = \infty$). If ϕ is a solution of the refinement equation (1.1) with the mask a, then*

$$\nu_p(\phi) \ge 1/p - \log_2 \rho_p(A_0|_V, A_1|_V). \tag{3.7}$$

In addition, if the shifts of $\phi_1, \ldots, \phi_r$ are stable and if $k > 1/p - \log_2 \rho_p(A_0|_V, A_1|_V)$, then equality holds in (3.7).

Proof. Write ρ for $\rho_p(A_0|_V, A_1|_V)$. By Lemma 3.2, we have $\lim_{n\to\infty} \|\nabla^k a_n\|_p^{1/n} = \rho$. Thus, for $\varepsilon > 0$, there exists a constant $C > 0$ such that, $\forall n \in \mathbb{N}$,

$$\|\nabla^k a_n\|_p \le C(\rho+\varepsilon)^n = C2^{n\log_2(\rho+\varepsilon)} = C2^{-n(\nu-1/p)},$$

where $\nu := 1/p - \log_2(\rho+\varepsilon)$. By Lemma 3.1, ϕ belongs to $(\mathrm{Lip}^*(\nu, L_p(\mathbb{R})))^r$. This shows that

$$\nu_p(\phi) \ge 1/p - \log_2(\rho+\varepsilon),$$

but $\varepsilon > 0$ can be arbitrarily small; hence, we obtain

$$\nu_p(\phi) \ge 1/p - \log_2 \rho.$$

Now suppose $k > 1/p - \log_2\rho$ and the shifts of $\phi_1, \dots, \phi_r$ are stable. We wish to show $\nu_p(\phi) \le 1/p - \log_2\rho$. If this is not true, then there exists μ such that $1/p - \log_2\rho < \mu < k$ and $\phi \in (\mathrm{Lip}^*(\mu, L_p(\mathbb{R})))^r$. By Lemma 3.1, there exists a constant $C > 0$ such that

$$\|\nabla^k a_n\|_p \le C2^{-n(\mu-1/p)} \qquad \forall\, n \in \mathbb{N}.$$

By Lemma 3.2 we get

$$\rho = \lim_{n\to\infty} \|\nabla^k a_n\|_p^{1/n} \le 2^{-\mu+1/p}.$$

It follows that

$$\mu \le 1/p - \log_2\rho,$$

which contradicts the assumption $\mu > 1/p - \log_2\rho$. Therefore, we obtain the desired result $\nu_p(\phi) \le 1/p - \log_2\rho$. □

The case $p = 2$ is of particular interest. In this case, the smoothness is usually measured by using Sobolev spaces. For $\nu \ge 0$ we denote by $W_2^\nu(\mathbb{R})$ the Sobolev space of all functions $f \in L_2(\mathbb{R})$ such that

$$\int_{\mathbb{R}} \big|\hat f(\xi)\big|^2 \big(1+|\xi|^\nu\big)^2\, d\xi < \infty.$$

It is well known that, for $\nu > \varepsilon > 0$, the inclusion relations

$$W_2^\nu(\mathbb{R}) \subseteq \mathrm{Lip}^*(\nu, L_2(\mathbb{R})) \subseteq W_2^{\nu-\varepsilon}(\mathbb{R})$$

hold true. Therefore, for a vector $f = (f_1, \dots, f_r)^T \in (L_2(\mathbb{R}))^r$, we have

$$\nu_2(f) = \sup\big\{\nu : f \in (W_2^\nu(\mathbb{R}))^r\big\}.$$

In [29] Shen obtained lower bounds for the L_2-smoothness of refinable vectors.

When $p = 2$, the joint spectral radius in (3.7) can be computed by finding the spectral radius of a certain finite matrix associated to the mask a (see [11] and [21]).

Let us review some related results from [21]. For an element $a \in (\ell_0(\mathbb{Z}))^{r\times r}$, define the *transition operator* F_a to be the linear mapping from $(\ell_0(\mathbb{Z}))^{r\times r}$ to $(\ell_0(\mathbb{Z}))^{r\times r}$ given by

$$F_a w(\alpha) := \sum_{\beta,\gamma\in\mathbb{Z}} a(2\alpha-\beta)w(\beta+\gamma)a(\gamma)^*/2, \qquad \alpha \in \mathbb{Z},\ w \in (\ell_0(\mathbb{Z}))^{r\times r}, \tag{3.8}$$

where $a(\gamma)^*$ denotes the complex conjugate transpose of $a(\gamma)$. For $n = 1, 2, \ldots$, let a_n be the sequences given by the iteration relation (2.2). It was proved [21, Lemma 7.3] that, for any $v \in (\ell_0(\mathbb{Z}))^r$,

$$\lim_{n\to\infty} \|a_n * v\|_2^{1/n} = \sqrt{2\rho(F_a|_W)}, \tag{3.9}$$

where W is the minimal invariant subspace of F_a generated by the element $w \in (\ell_0(\mathbb{Z}))^{r\times r}$ given by

$$w(\beta) := \sum_{\gamma\in\mathbb{Z}} v(\beta+\gamma)v(\gamma)^*, \qquad \beta \in \mathbb{Z}.$$

Let Δ denote the difference operator on $\ell_0(\mathbb{Z})$ given by

$$\Delta v := -v(\cdot - 1) + 2v - v(\cdot + 1), \qquad v \in \ell_0(\mathbb{Z}).$$

In particular, $\Delta\delta := -\delta_{-1} + 2\delta - \delta_1$. Suppose V is the minimal common invariant subspace of A_0 and A_1 generated by $e_j(\nabla^k\delta)$, $j = 1, \ldots, r$. Then Lemma 3.2 and (3.9) tell us that

$$\rho_2(A_0|_V, A_1|_V) = \sqrt{2\rho(F_a|_W)},$$

where W is the minimal invariant subspace of F_a generated by $e_j e_j^T(\Delta^k\delta)$, $j = 1, \ldots, r$.

Thus, for the case $p = 2$, Theorem 3.3 can be strengthened as follows.

THEOREM 3.4. *Suppose $\phi = (\phi_1, \ldots, \phi_r)^T \in (L_2(\mathbb{R}))^r$ is a compactly supported solution of the refinement equation* (1.1) *with mask a. Let F_a be the transition operator given in* (3.8)*. Then, for any positive integer k,*

$$\nu_2(\phi) \ge -\log_2 \sqrt{\rho(F_a|_W)},$$

where W is the minimal invariant subspace of F_a generated by $e_j e_j^T(\Delta^k\delta)$, $j = 1, \ldots, r$. Moreover, $\nu_2(\phi) = -\log_2 \sqrt{\rho(F_a|_W)}$, provided $k > -\log_2 \sqrt{\rho(F_a|_W)}$ and the shifts of $\phi_1, \ldots, \phi_r$ are stable.

In order to apply Theorems 3.3 and 3.4 to smoothness analysis, one must check the stability of refinable functions in terms of the refinement mask. For the scalar case ($r = 1$), Jia and Wang [22] gave a characterization for the stability and linear independence of the shifts of a refinable function in terms of the refinement mask. Their results were extended by Zhou [33] to the case where the scaling factor is an arbitrary integer greater than 1. For the vector case ($r > 1$), stability of the shifts of multiple refinable functions was discussed by Hervé [15], Hogan [16], and Wang [32]. Assuming the vector of refinable functions lies in $(L_2(\mathbb{R}))^r$, Shen [29] gave a characterization for L_2-stability.

4. Examples. In this section, we give two examples to illustrate the general theory.

Let A be a linear operator on a linear space V with $\{v_1, \ldots, v_s\}$ as its basis. Suppose $Av_j = \sum_{k=1}^s a_{jk}v_k$ for $1 \le j \le s$. Then the matrix $(a_{jk})_{1\le j,k\le s}$ is said to be the matrix representation of A.

The definition of joint spectral radius given in section 2 also applies to a finite multiset of square matrices of the same size. Indeed, an $s \times s$ matrix can be viewed as a linear operator on $\mathbb{C}^s$. Obviously, the p-norm joint spectral radius of a finite multiset

of linear operators is the same as that of the multiset of the matrices representing those linear operators.

Now suppose $\mathcal{A} = \{A_0, A_1\}$, where $A_0 = (\lambda)$ and $A_1 = (\mu)$ are two 1×1 matrices. For $\varepsilon_1, \ldots, \varepsilon_n \in \{0, 1\}$, we have

$$A_{\varepsilon_1} \cdots A_{\varepsilon_n} = \prod_{j=1}^{n} (\lambda^{1-\varepsilon_j} \mu^{\varepsilon_j}).$$

Hence for $1 \le p < \infty$,

$$\|\mathcal{A}^n\|_p = \big(|\lambda|^p + |\mu|^p\big)^{n/p},$$

while

$$\|\mathcal{A}^n\|_\infty = \big(\max\{|\lambda|, |\mu|\}\big)^n.$$

Therefore we obtain

$$\rho_p(A_0, A_1) = \big(|\lambda|^p + |\mu|^p\big)^{1/p}, \qquad 1 \le p \le \infty, \tag{4.1}$$

where the right-hand side of (4.1) is interpreted as $\max\{|\lambda|, |\mu|\}$ for the case $p = \infty$.

Suppose $\mathcal{A} = \{A_1, \ldots, A_m\}$ and each A_j is a block triangular matrix:

$$A_j = \begin{pmatrix} E_j & 0 \\ G_j & F_j \end{pmatrix}, \qquad j = 1, \ldots, m,$$

where $E_1, \ldots, E_m$ are square matrices of the same size, and so are $F_1, \ldots, F_m$. It was proved [21, Lemma 4.2] that

$$\rho_p(A_1, \ldots, A_m) = \max\{\rho_p(E_1, \ldots, E_m), \rho_p(F_1, \ldots, F_m)\}, \qquad 1 \le p \le \infty. \tag{4.2}$$

Let A_0 and A_1 be two triangular matrices of the same type:

$$A_0 = \begin{bmatrix} \lambda_{11} & & & \\ \lambda_{12} & \lambda_{22} & & \\ \vdots & \vdots & \ddots & \\ \lambda_{s1} & \lambda_{s2} & \cdots & \lambda_{ss} \end{bmatrix} \quad \text{and} \quad A_1 = \begin{bmatrix} \mu_{11} & & & \\ \mu_{12} & \mu_{22} & & \\ \vdots & \vdots & \ddots & \\ \mu_{s1} & \mu_{s2} & \cdots & \mu_{ss} \end{bmatrix}.$$

Then (4.1) and (4.2) tell us that

$$\rho_p(A_0, A_1) = \max_{1 \le j \le s} \big(|\lambda_{jj}|^p + |\mu_{jj}|^p\big)^{1/p}, \qquad 1 \le p \le \infty. \tag{4.3}$$

Let us analyze the following example considered by Donovann et al. [10]. Suppose a is a sequence on $\mathbb{Z}$ supported on $[0, 3]$ and

$$a(0) = \begin{bmatrix} h_1 & 1 \\ h_2 & h_3 \end{bmatrix}, \qquad a(1) = \begin{bmatrix} h_1 & 0 \\ h_4 & 1 \end{bmatrix},$$

$$a(2) = \begin{bmatrix} 0 & 0 \\ h_4 & h_3 \end{bmatrix}, \qquad a(3) = \begin{bmatrix} 0 & 0 \\ h_2 & 0 \end{bmatrix},$$

where

$$h_1 = -\frac{s^2-4s-3}{2(s+2)}, \qquad h_2 = -\frac{3(s^2-1)(s^2-3s-1)}{4(s+2)^2},$$

$$h_3 = \frac{3s^2+s-1}{2(s+2)}, \qquad h_4 = -\frac{3(s^2-1)(s^2-s+3)}{4(s+2)^2}.$$

The matrix $M := \sum_{\alpha=0}^{3} a(\alpha)/2$ has two eigenvalues, 1 and s. We assume that $|s| < 1$. The eigenvectors of M corresponding to the eigenvalue 1 are cy, where $c \neq 0$ and

$$y = \begin{bmatrix} 1 \\ (s-1)^2/(s+2) \end{bmatrix}.$$

EXAMPLE 4.1. *Let $\phi = (\phi_1, \phi_2)^T$ be the solution of the refinement equation with the mask a such that $\hat{\phi}(0) = y$. Then*

$$\nu_p(\phi) = \begin{cases} 1 + 1/p & \text{if } |s| < 2^{-1-1/p}, \\ -\log_2 |s| & \text{if } 2^{-1-1/p} \le |s| < 1. \end{cases}$$

Proof. First, we prove that the solution ϕ is continuous, provided $|s| < 1$. For this purpose, let A_ε ($\varepsilon = 0, 1$) be the linear operators on $(\ell_0(\mathbb{Z}))^2$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta \in \mathbb{Z}} a(\varepsilon + 2\alpha - \beta) v(\beta), \qquad \alpha \in \mathbb{Z},\ v \in (\ell_0(\mathbb{Z}))^2.$$

Since a is supported on $[0, 3]$, the linear space $(\ell([0,3]))^2$ is invariant under both A_0 and A_1. Choose

$$\{e_1\delta_0, e_2\delta_0, e_1\delta_1, e_2\delta_1, e_1\delta_2, e_2\delta_2, e_1\delta_3, e_2\delta_3\}$$

as a basis for $(\ell([0,3]))^2$. With respect to this basis, the matrix representations of A_0 and A_1 are $(a(2\beta-\alpha)^T)_{0\le\alpha,\beta\le3}$ and $(a(1+2\beta-\alpha)^T)_{0\le\alpha,\beta\le3}$, respectively. We have

$$(a(2\beta-\alpha)^T)_{0\le\alpha,\beta\le3} = \begin{bmatrix} h_1 & h_2 & 0 & h_4 & & & & \\ 1 & h_3 & 0 & h_3 & & & & \\ & & h_1 & h_4 & 0 & h_2 & & \\ & & 0 & 1 & 0 & 0 & & \\ & & h_1 & h_2 & 0 & h_4 & & \\ & & 1 & h_3 & 0 & h_3 & & \\ & & & & h_1 & h_4 & 0 & h_2 \\ & & & & 0 & 1 & 0 & 0 \end{bmatrix}$$

and

$$(a(1+2\beta-\alpha))^T_{0\le\alpha,\beta\le3} = \begin{bmatrix} h_1 & h_4 & 0 & h_2 & & & & \\ 0 & 1 & 0 & 0 & & & & \\ h_1 & h_2 & 0 & h_4 & & & & \\ 1 & h_3 & 0 & h_3 & & & & \\ & & h_1 & h_4 & 0 & h_2 & & \\ & & 0 & 1 & 0 & 0 & & \\ & & h_1 & h_2 & 0 & h_4 & 0 & 0 \\ & & 1 & h_3 & 0 & h_3 & 0 & 0 \end{bmatrix}.$$

We observe that s is a common eigenvalue of both A_0 and A_1. Corresponding to this eigenvalue, A_0 and A_1 have a common eigenvector v_1 given by

$$v_1 := \begin{bmatrix} 1 \\ -\mu \end{bmatrix} \delta + \begin{bmatrix} 0 \\ -\mu \end{bmatrix} \delta_1,$$

where

$$\mu := \frac{3(1-s^2)}{2(s+2)}.$$

This motivates us to choose

$$v_2 := \begin{bmatrix} 1 \\ -\mu \end{bmatrix} \delta_1 + \begin{bmatrix} 0 \\ -\mu \end{bmatrix} \delta_2.$$

It is easily verified that $A_0 v_2 = s v_2$ and $A_1 v_2 = s v_1$. From Theorem 2.1, we need to add the generators $e_j \nabla\delta$, $j = 1, 2$, which motivates us to set $v_3 := e_2 \nabla\delta$ and $v_4 := e_2 \nabla\delta_1$, i.e.,

$$v_3 := \begin{bmatrix} 0 \\ 1 \end{bmatrix} \delta - \begin{bmatrix} 0 \\ 1 \end{bmatrix} \delta_1 \qquad \text{and} \qquad v_4 := \begin{bmatrix} 0 \\ 1 \end{bmatrix} \delta_1 - \begin{bmatrix} 0 \\ 1 \end{bmatrix} \delta_2.$$

Denote by V the linear span of v_1, v_2, v_3, and v_4. Then $e_1 \nabla\delta = v_1 - v_2 + \mu(v_3 + v_4) \in V$ and $e_2 \nabla\delta = v_3 \in V$. Using the matrix representations of A_0 and A_1 we find that

$$A_0 \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} s & & & \\ 0 & s & & \\ 1 & 0 & 0.5 & \\ 0 & -1 & 0 & 0.5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}$$

and

$$A_1 \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} s & & & \\ s & 0 & & \\ -1 & 0 & 0.5 & \\ 1 & 0 & 0.5 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}.$$

Thus, V is invariant under both A_0 and A_1. Applying (4.3) to the two 4×4 matrices above, we obtain

$$\rho_\infty(A_0|_V, A_1|_V) = \max\{1/2, |s|\}.$$

Thus, $\rho_\infty(A_0|_V, A_1|_V) < 1$ for $|s| < 1$. Therefore, by Theorem 2.1, the solution ϕ is continuous, provided $|s| < 1$.

We claim that the shifts of ϕ_1 and ϕ_2 are stable. For this purpose it suffices to show that the shifts of ϕ_1 and ϕ_2 are linearly independent (see [19]), that is,

$$\sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi_1(\cdot - \alpha) + \sum_{\alpha\in\mathbb{Z}} c(\alpha)\phi_2(\cdot - \alpha) = 0 \quad \Longrightarrow \quad b(\alpha) = c(\alpha) = 0 \quad \forall\, \alpha \in \mathbb{Z}. \tag{4.4}$$

In order to verify (4.4), we first compute $\phi(\alpha)$ for $\alpha \in \mathbb{Z}$. Since ϕ is supported on $[0, 3]$, we have $\phi(\alpha) = 0$ for $\alpha \in \mathbb{Z} \setminus \{1, 2\}$. The vector $\phi = (\phi_1, \phi_2)^T$ satisfies the refinement equation

$$\phi(x) = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(2x - \alpha) \qquad \forall\, x \in \mathbb{R}. \tag{4.5}$$

In particular,

$$\phi(\beta) = \sum_{\alpha=1}^{2} a(2\beta - \alpha)\phi(\alpha) \qquad \text{for } \beta = 1, 2.$$

Solving the above system of linear equations, we get

$$\phi(1) = (0, t)^T \quad \text{and} \quad \phi(2) = 0,$$

where t is a nonzero constant. Moreover, it follows from (4.5) that

$$\phi(\beta + 1/2) = \sum_{\alpha=1}^{2} a(2\beta + 1 - \alpha)\phi(\alpha) \qquad \forall\, \beta \in \mathbb{Z}.$$

Consequently, $\phi(1/2) = t(1, h_3)^T$, $\phi(3/2) = t(0, h_3)^T$, and $\phi(\beta + 1/2) = 0$ for $\beta \in \mathbb{Z} \setminus \{0, 1\}$. Suppose

$$\sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi_1(x - \alpha) + \sum_{\alpha\in\mathbb{Z}} c(\alpha)\phi_2(x - \alpha) = 0 \qquad \forall x \in \mathbb{R}. \tag{4.6}$$

Choosing $x = \beta$ for $\beta \in \mathbb{Z}$ in (4.6), we obtain $c(\beta - 1) = 0$. This is true for all $\beta \in \mathbb{Z}$. Hence (4.6) implies

$$\sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi_1(x - \alpha) = 0 \qquad \forall x \in \mathbb{R}.$$

For $\beta \in \mathbb{Z}$, setting $x = \beta + 1/2$ in the above equation gives $b(\beta) = 0$. Thus, (4.4) has been verified.

We are in a position to determine the smoothness of ϕ. For the subspace W, we retain the first two generators, v_1, v_2, but replace the others by $e_j(\nabla^2\delta)$, $j = 1, 2$, as required by Theorem 3.3:

$$w_1 := \begin{bmatrix} 1 \\ -\mu \end{bmatrix} \delta + \begin{bmatrix} 0 \\ -\mu \end{bmatrix} \delta_1, \qquad w_2 := \begin{bmatrix} 1 \\ -\mu \end{bmatrix} \delta_1 + \begin{bmatrix} 0 \\ -\mu \end{bmatrix} \delta_2,$$
$$w_3 := e_2(\nabla^2\delta), \qquad \text{and} \qquad w_4 := e_1(\nabla^2\delta).$$

Using the matrix representations of A_0 and A_1, we find

$$A_0 \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix} = \begin{bmatrix} s & & & \\ 0 & s & & \\ 1 & 1 & 0.5 & \\ h_1 & -h_1 & \mu/2 & 0 \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix}$$

and

$$A_1 \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix} = \begin{bmatrix} s & & & \\ s & 0 & & \\ -2 & 0 & 0 & \\ -h_1 & h_1 & \mu/2 & 0 \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix}.$$

Let W be the linear span of w_1, w_2, w_3, and w_4. Then W is the minimal common invariant subspace of A_0 and A_1 generated by $e_1(\nabla^2\delta)$ and $e_2(\nabla^2\delta)$. Applying (4.3) to the two 4×4 matrices above, we obtain

$$\rho_p(A_0|_W, A_1|_W) = \max\{2^{1/p}|s|, 1/2\}.$$

If $|s| < 2^{-1-1/p}$, then $\rho_p(A_0|_W, A_1|_W) = 1/2$; hence $\nu_p(\phi) = 1 + 1/p$ for $1 < p \le \infty$, by Theorem 3.3. When $p = 1$, we have $\nu_1(\phi) \ge 2$. But $\nu_1(\phi) > 2$ is impossible. Indeed, $\nu_1(\phi) > 2$ would imply $\nu_p(\phi) > 2$ for some $p > 1$, by the embedding theorem. But we know that $\nu_p(\phi) < 2$ for $1 < p \le \infty$. Therefore, $\nu_1(\phi) = 2$ for $|s| < 1/4$. If $2^{-1-1/p} \le |s| < 1$, then $\rho_p(A_0|_W, A_1|_W) = 2^{1/p}|s|$. Theorem 3.3 tells us that $\nu_p(\phi) = -\log_2 |s|$ for $1 \le p \le \infty$. Thus, for $1 \le p \le \infty$, we have found the optimal L_p-smoothness of ϕ explicitly. □

Using fractal interpolation, Donovan et al. [10] showed that $\phi \in \operatorname{Lip} 1$ for $|s| < 1/2$ and $\phi \in \operatorname{Lip} \nu$ for $1/2 < |s| < 1$, where $\nu = -\log_2 |s|$. In [3], Cohen, Daubechies, and Plonka established the continuity of ϕ for $|s| < 1/2$. The case $p = 1$ was considered by Micchelli and Sauer [25], who obtained $\nu_1(\phi) > 1.1087$ for $s = -0.2$. In comparison with their result, our method gives $\nu_1(\phi) = 2$ for $|s| < 1/4$.

Our second example is taken from [20, 21]. Let a be the element in $(\ell_0(\mathbb{Z}))^{2\times 2}$ supported in $[0, 2]$ given by

$$a(0) = \begin{bmatrix} \frac{1}{2} & \frac{s}{2} \\ t & \lambda \end{bmatrix}, \qquad a(1) = \begin{bmatrix} 1 & 0 \\ 0 & \mu \end{bmatrix}, \quad \text{and} \quad a(2) = \begin{bmatrix} \frac{1}{2} & -\frac{s}{2} \\ -t & \lambda \end{bmatrix}. \tag{4.7}$$

The matrix $M := \sum_{\alpha=0}^{2} a(\alpha)/2$ has two eigenvalues: 1 and $\lambda + \mu/2$. We assume that $|2\lambda + \mu| < 2$. Then there exists a unique distributional solution $\phi = (\phi_1, \phi_2)^T$ of the refinement equation with the mask a subject to $\hat{\phi}(0) = (1, 0)^T$. The distribution ϕ_1 is symmetric about 1, and ϕ_2 is antisymmetric about 1. It was proved [20, Example 4.3] that the shifts of ϕ_1 and ϕ_2 reproduce all quadratic polynomials if and only if

$$t \ne 0, \quad \mu = 1/2, \quad \text{and} \quad \lambda = 1/4 + 2st. \tag{4.8}$$

In this case, the condition $|2\lambda + \mu| < 2$ reduces to $-3/4 < st < 1/4$.

EXAMPLE 4.2. *Let a be the mask given in* (4.7) *with $-3/4 < st < 1/4$. Let $\phi = (\phi_1, \phi_2)^T$ be the solution of the refinement equation with the mask a such that $\hat{\phi}(0) = (1, 0)^T$. Suppose the conditions in* (4.8) *are satisfied. Then, for $s \ne 0$ we have*

$$\nu_p(\phi) = \begin{cases} 2 + \frac{1}{p} & \text{if } |st + 1/4| \le 2^{-3-1/p}, \\ -\log_2 |\frac{1}{2} + 2st| & \text{if } 2^{-3-1/p} < |st + 1/4| < 1/2. \end{cases}$$

In the case $s = 0$, $\mu = 1/2$, and $\lambda = 1/4$, we have $\nu_p(\phi) = 1 + 1/p$.

Proof. First, we investigate the case $s = 0$. Under the conditions in (4.8), the refinement equation

$$\phi(x) = \sum_{\alpha \in \mathbb{Z}} a(\alpha)\phi(2x - \alpha) \qquad \forall\, x \in \mathbb{R} \tag{4.9}$$

can be solved explicitly (see [20, Example 4.3]). The solution $\phi = (\phi_1, \phi_2)^T$ of (4.9) subject to $\hat{\phi}(0) = (1, 0)^T$ is given by

$$\phi_1(x) = \begin{cases} x & \text{for } 0 \le x < 1, \\ 2 - x & \text{for } 1 \le x \le 2, \\ 0 & \text{otherwise,} \end{cases}$$

and

$$\phi_2(x) = \begin{cases} 4tx(1 - x) & \text{for } 0 \le x < 1, \\ -4t(2 - x)(x - 1) & \text{for } 1 \le x \le 2, \\ 0 & \text{otherwise.} \end{cases}$$

Consequently, $\nu_p(\phi) = 1+1/p$ for $1 \le p \le \infty$. In this case, the shifts of ϕ_2 are linearly *dependent*.

Second, we consider the case $s \neq 0$. Under the conditions in (4.8), the solution $\phi = (\phi_1, \phi_2)^T$ is continuous, provided $-3/4 < st < 1/4$ (see [21, Example 6.3]). In this case, we claim that the shifts of ϕ_1 and ϕ_2 are linearly independent. To justify our claim, we find $\phi(\alpha)$ for $\alpha \in \mathbb{Z}$. Since ϕ is supported on $[0, 2]$, we have $\phi(\alpha) = 0$ for $\alpha \in \mathbb{Z} \setminus \{1\}$. From [20, Example 3.2] we see that $\sum_{\alpha\in\mathbb{Z}} \phi_1(\alpha) = 1$. Hence $\phi_1(1) = 1$. Moreover, it follows from (4.9) that $\phi(1) = a(1)\phi(1)$, which implies $\phi_2(1) = 0$. Next, we find $\phi(\beta + 1/2)$ for $\beta \in \mathbb{Z}$. Using the refinement equation (4.9), we obtain

$$\phi(\beta + 1/2) = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(2\beta + 1 - \alpha) = a(2\beta)[1, 0]^T.$$

Therefore, $\phi(1/2) = [1/2, t]^T$, $\phi(3/2) = [1/2, -t]^T$, and $\phi(\beta+1/2) = 0\ \forall\beta \in \mathbb{Z}\setminus\{0, 1\}$. Furthermore, we can use (4.9) to find $\phi(\gamma + 1/4)\ \forall\gamma \in \mathbb{Z}$. As a result, we obtain $\phi(\gamma + 1/4) = 0\ \forall\gamma \in \mathbb{Z} \setminus \{0, 1\}$,

$$\phi(1/4) = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(1/2 - \alpha) = a(0)\phi(1/2),$$

and

$$\phi(5/4) = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(5/2 - \alpha) = a(1)\phi(3/2) + a(2)\phi(1/2).$$

Suppose

$$\sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi_1(x - \alpha) + \sum_{\alpha\in\mathbb{Z}} c(\alpha)\phi_2(x - \alpha) = 0 \qquad \forall x \in \mathbb{R}. \tag{4.10}$$

Choosing $x = \beta$ for $\beta \in \mathbb{Z}$ in the above equation, we obtain $b(\beta - 1) = 0$. This is true for all $\beta \in \mathbb{Z}$. Hence (4.10) implies

$$\sum_{\alpha\in\mathbb{Z}} c(\alpha)\phi_2(x - \alpha) = 0 \qquad \forall x \in \mathbb{R}. \tag{4.11}$$

For $\beta \in \mathbb{Z}$, setting $x = \beta + 1/2$ in the above equation gives

$$t\,[c(\beta) - c(\beta - 1)] = 0.$$

Since $t \neq 0$, we have $c(\beta) = c(\beta - 1)\ \forall\beta \in \mathbb{Z}$. Setting $x = 5/4$ in (4.11), we get

$$c(0)[\phi_2(1/4) + \phi_2(5/4)] = 0, \quad \text{i.e.}, \quad c(0)(2\lambda - \mu)t = 0.$$

But $(2\lambda - \mu)t = 4st^2 \neq 0$; hence $c(0) = 0$. So $c(\beta) = c(0) = 0$ for all $\beta \in \mathbb{Z}$. This justifies our claim that the shifts of ϕ_1 and ϕ_2 are linearly independent.

We are in a position to determine the smoothness of ϕ. Let A_ε ($\varepsilon = 0, 1$) be the linear operators on $(\ell_0(\mathbb{Z}))^2$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}} a(\varepsilon + 2\alpha - \beta)v(\beta), \qquad \alpha \in \mathbb{Z},\ v \in (\ell_0(\mathbb{Z}))^2.$$

We observe that $1/2 + 2st$ is a common eigenvalue of both A_0 and A_1. Corresponding to this eigenvalue, A_0 and A_1 have a common eigenvector v_1 given by

$$v_1 := \begin{bmatrix} 1 \\ 4t \end{bmatrix} \delta + \begin{bmatrix} -1 \\ 4t \end{bmatrix} \delta_1.$$

This motivates us to choose

$$v_2 := \begin{bmatrix} 1 \\ 4t \end{bmatrix} \delta_1 + \begin{bmatrix} -1 \\ 4t \end{bmatrix} \delta_2.$$

Then we have $A_0 v_2 = (1/2 + 2st)v_2$ and $A_1 v_2 = (1/2 + 2st)v_1$. We also must add $e_j(\nabla^3\delta)$, $j = 1, 2$, by Theorem 3.3 and from the action of A_0, A_1 on those vectors, we are led to our choice of v_3, v_4, v_5:

$$v_3 := e_2(\nabla^2\delta), \qquad v_4 := e_1(\nabla^3\delta), \qquad \text{and} \qquad v_5 := e_2(\nabla^3\delta).$$

By computation we find that

$$A_0 \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{bmatrix} = \begin{bmatrix} 1/2 + 2st & & & & \\ 0 & 1/2 + 2st & & & \\ s/2 & s/2 & 1/4 & & \\ 1/2 & -1/2 & -t & 0 & \\ s/2 & 3s/2 & 1/4 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{bmatrix}$$

and

$$A_1 \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{bmatrix} = \begin{bmatrix} 1/2 + 2st & & & & \\ 1/2 + 2st & 0 & & & \\ -s & 0 & 0 & & \\ -1/2 & 1/2 & -t & 0 & \\ -3s/2 & -s/2 & -1/4 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{bmatrix}.$$

Let V be the linear span of v_j, $j = 1, \ldots, 5$. Then V is the minimal common invariant subspace of A_0 and A_1 generated by $e_1(\nabla^3\delta)$ and $e_2(\nabla^3\delta)$. Applying (4.3) to the two 5×5 matrices above, we obtain

$$\rho_p(A_0|_V, A_1|_V) = \max\{2^{1/p}|1/2 + 2st|, 1/4\}.$$

If $|1/2 + 2st| < 2^{-2-1/p}$, then $\rho_p(A_0|_V, A_1|_V) = 1/4$; hence $\nu_p(\phi) = 2 + 1/p$ for $1 < p \le \infty$, by Theorem 3.3. When $p = 1$, we have $\nu_1(\phi) \ge 3$. But $\nu_1(\phi) > 3$ is impossible. Indeed, $\nu_1(\phi) > 3$ would imply $\nu_p(\phi) > 3$ for some $p > 1$, by the embedding theorem. But we know that $\nu_p(\phi) < 3$ for $1 < p \le \infty$. Therefore, $\nu_1(\phi) = 3$ for $|1/2 + 2st| < 2^{-2-1/p}$. If $2^{-2-1/p} \le |1/2 + 2st| < 1$, then $\rho_p(A_0|_V, A_1|_V) = 2^{1/p}|1/2 + 2st|$. Theorem 3.3 tells us that $\nu_p(\phi) = -\log_2 |1/2 + 2st|$ for $1 \le p \le \infty$. Thus, for $1 \le p \le \infty$, we have found the optimal L_p-smoothness of ϕ explicitly. □

The special case $s = 3/2$, $t = -1/8$, $\lambda = -1/8$, and $\mu = 1/2$ was discussed by Heil, Strang, and Strela [14]. In this case, ϕ can be solved explicitly as follows:

$$\phi_1(x) = \begin{cases} x^2(-2x + 3) & \text{for } 0 \le x \le 1, \\ (2 - x)^2(2x - 1) & \text{for } 1 < x \le 2, \\ 0 & \text{for } x \in \mathbb{R} \setminus [0, 2] \end{cases}$$

and

$$\phi_2(x) = \begin{cases} x^2(x - 1) & \text{for } 0 \le x \le 1, \\ (2 - x)^2(x - 1) & \text{for } 1 < x \le 2, \\ 0 & \text{for } x \in \mathbb{R} \setminus [0, 2]. \end{cases}$$

It is evident that $\nu_p(\phi) = 2 + 1/p$.

5. Multiple wavelets. In this section we apply the general theory to smoothness analysis of orthogonal multiple wavelets.

In Example 4.1, if $\phi = (\phi_1, \phi_2)^T$ is the solution of the refinement equation corresponding to the parameter $s = -0.2$, then the shifts of ϕ_1 and ϕ_2 are orthogonal. It was shown in the last section that the optimal smoothness of ϕ is $\nu_p(\phi) = 1 + 1/p$. This example of continuous symmetric orthogonal double refinable functions was first constructed by Donovan et al. [10] by means of fractal interpolation. On the basis of their work, Strang and Strela constructed symmetric orthogonal double wavelets in [31].

In this section we shall use refinement equations to study multiple wavelets. Let a be an element in $(\ell_0(\mathbb{Z}))^{r\times r}$ such that the matrix $M = \sum_{\alpha\in\mathbb{Z}} a(\alpha)/2$ has the following form:

$$M = \begin{bmatrix} 1 & 0 \\ 0 & \Lambda \end{bmatrix} \qquad \text{and} \qquad \lim_{n\to\infty} \Lambda^n = 0.$$

There exists a unique solution ϕ of the refinement equation

$$\phi = \sum_{\alpha\in\mathbb{Z}} a(\alpha)\phi(2\cdot - \alpha)$$

such that $\hat{\phi}(0) = (1, 0, \ldots, 0)^T$. This solution is called the *normalized solution*.

The following theorem summarizes the general theory on orthogonal multiple wavelets (see, e.g., [21]). Some different forms of this result were obtained by Long, Chen, and Yuan [24] and Shen [29].

THEOREM 5.1. *Let $\phi = (\phi_1, \ldots, \phi_r)^T$ be the normalized solution of the refinement equation with mask a. Then $\{\phi_j(\cdot - \alpha) : j = 1, \ldots, r;\ \alpha \in \mathbb{Z}\}$ forms an orthonormal system in $L_2(\mathbb{R})$ if and only if*

a. *$\sum_{\alpha\in\mathbb{Z}} a(\alpha)a(\alpha + 2\gamma)^* = 2\delta_{\gamma,0} I_r$ $\forall\gamma \in \mathbb{Z}$, where I_r denotes the $r \times r$ identity matrix, and*

b. *$\rho(F_a|_W) < 1$ where F_a is the linear operator on $(\ell_0(\mathbb{Z}))^{r\times r}$ given by (3.8) and W is the minimal invariant subspace of F_a generated by $e_1 e_1^T(\Delta\delta)$, $e_2 e_2^T\delta, \ldots, e_r e_r^T\delta$.*

Furthermore, if ψ is given by $\psi = (\psi_1, \ldots, \psi_r)^T = \sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi(2\cdot - \alpha)$, where b is a sequence in $(\ell_0(\mathbb{Z}))^{s\times s}$ satisfying

$$\sum_{\alpha\in\mathbb{Z}} a(\alpha)b(\alpha + 2\gamma)^* = 0 \qquad \forall\gamma \in \mathbb{Z}$$

and

$$\sum_{\alpha\in\mathbb{Z}} b(\alpha)b(\alpha + 2\gamma)^* = 2\delta_{\gamma,0} I_r \qquad \forall\gamma \in \mathbb{Z},$$

then $\{\sqrt{2}^k \psi_j(2^k\cdot - \alpha) : j = 1, \ldots, r;\ k, \alpha \in \mathbb{Z}\}$ forms an orthonormal basis for $L_2(\mathbb{R})$. In other words, $\psi_1, \ldots, \psi_r$ are orthogonal multiple wavelets.

In [21] we constructed a class of continuous orthogonal double wavelets with symmetry. In our construction the mask a is supported on $[0, 2]$ and

$$a(0) = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ t & t \end{bmatrix}, \quad a(1) = \begin{bmatrix} 1 & 0 \\ 0 & \sqrt{2 - 4t^2} \end{bmatrix}, \quad \text{and} \quad a(2) = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} \\ -t & t \end{bmatrix},$$

where the parameter t is in the range $-1/\sqrt{2} \le t < -1/2$. Let $\phi = (\phi_1, \phi_2)^T$ be the normalized solution of the refinement equation with mask a. Then ϕ_1 is symmetric

about 1, ϕ_2 is antisymmetric about 1, and $\{\phi_j(\cdot-\alpha) : j = 1, 2,\ \alpha \in \mathbb{Z}\}$ forms an orthonormal system in $L_2(\mathbb{R})$. Moreover, for the coefficients

$$b(0) := \begin{bmatrix} -\frac{1}{2} & -\frac{1}{2} \\ \frac{\mu}{2} & \frac{\mu}{2} \end{bmatrix}, \quad b(1) := \begin{bmatrix} 1 & 0 \\ 0 & -2t \end{bmatrix}, \quad \text{and} \quad b(2) := \begin{bmatrix} -\frac{1}{2} & \frac{1}{2} \\ -\frac{\mu}{2} & \frac{\mu}{2} \end{bmatrix},$$

where $\mu = \sqrt{2-4t^2}$, the vector

$$\psi = (\psi_1, \psi_2)^T := \sum_{\alpha\in\mathbb{Z}} b(\alpha)\phi(2\cdot-\alpha)$$

gives orthogonal double wavelets ψ_1 and ψ_2 which are continuous. Furthermore, ψ_1 is symmetric about 1, and ψ_2 is antisymmetric about 1.

The special case $t = -\sqrt{7}/4$ was studied by Chui and Lian [2]. The following example gives a detailed analysis for the smoothness of the corresponding double-refinable functions.

EXAMPLE 5.2. *Let $\phi = (\phi_1, \phi_2)^T$ be the normalized solution of the refinement equation with mask a, where a is supported on $[0, 2]$ and*

$$a(0) = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ t & t \end{bmatrix}, \quad a(1) = \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{2} \end{bmatrix}, \quad a(2) = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} \\ -t & t \end{bmatrix}$$

with $t = -\sqrt{7}/4$. Then

$$\nu_p(\phi) = \frac{1}{p} - \frac{1}{p}\log_2\left[\Big(\frac{\sqrt{7}}{4}\Big)^p + \Big(\frac{\sqrt{7}-2}{4}\Big)^p\right], \qquad 1 \le p \le \infty. \tag{5.1}$$

Proof. Denote by A_ε $(\varepsilon = 0, 1)$ the linear operators on $(\ell_0(\mathbb{Z}))^2$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}} a(\varepsilon + 2\alpha - \beta)v(\beta), \qquad \alpha \in \mathbb{Z},\ v \in (\ell_0(\mathbb{Z}))^2.$$

Set

$$v_1 := \begin{bmatrix} 1 \\ 2t \end{bmatrix}\delta + \begin{bmatrix} -1 \\ 2t-1 \end{bmatrix}\delta_1, \qquad v_2 := \begin{bmatrix} 1 \\ 2t-1 \end{bmatrix}\delta + \begin{bmatrix} -1 \\ 2t \end{bmatrix}\delta_1,$$
$$v_3 := \begin{bmatrix} 1 \\ 2t \end{bmatrix}\delta_1 + \begin{bmatrix} -1 \\ 2t-1 \end{bmatrix}\delta_2, \qquad \text{and} \qquad v_4 := \begin{bmatrix} 1 \\ 2t-1 \end{bmatrix}\delta_1 + \begin{bmatrix} -1 \\ 2t \end{bmatrix}\delta_2.$$

By computation we obtain

$$A_0\begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} t+\frac{1}{2} & 0 & & \\ t & 0 & & \\ & & 0 & t \\ & & 0 & t+\frac{1}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}$$

and

$$A_1\begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} 0 & t & & \\ 0 & t+\frac{1}{2} & & \\ t+\frac{1}{2} & 0 & 0 & 0 \\ t & 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}.$$

Let V be the linear span of v_1 and v_2, and let W be the linear span of v_j, $j = 1, \ldots, 4$. Then V and W are invariant under both A_0 and A_1. It is easily seen that W is the minimal common invariant subspace of A_0 and A_1 generated by $e_1(\nabla^2\delta)$ and $e_2(\nabla^2\delta)$. By the remark made at the beginning of section 4 we see that

$$\rho_p(A_0|_W, A_1|_W) = \max\big\{\rho_p(A_0|_V, A_1|_V), |t + 1/2|\big\}.$$

It remains to compute $\rho_p(A_0|_V, A_1|_V)$. For this purpose, we choose the norm on V as follows:

$$\|\xi_1 v_1 + \xi_2 v_2\| := \max\{|\xi_1|, |\xi_2|\} \qquad \text{for } \xi_1, \xi_2 \in \mathbb{C}.$$

In particular, $\|v_1\| = \|v_2\| = 1$. Suppose $1 \le p < \infty$. Then

$$\|\mathcal{A}^n v_1\|_p^p = \sum_{\varepsilon_1, \ldots, \varepsilon_n \in \{0,1\}} \|A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p.$$

Write s for $t + 1/2$. We claim that

$$\sum_{\varepsilon_1, \ldots, \varepsilon_n \in \{0,1\}} \|A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p = (|s|^p + |t|^p)^n. \tag{5.2}$$

This will be proved by induction on n. For $n = 1$, we have $A_0 v_1 = s v_1$ and $A_1 v_1 = t v_2$. Hence

$$\|A_0 v_1\|^p + \|A_1 v_1\|^p = |s|^p + |t|^p.$$

This verifies (5.2) for $n = 1$. Suppose (5.2) is valid for n. We wish to establish it for $n + 1$. Recall that $A_0 v_2 = t v_1$ and $A_1 v_2 = s v_2$. Thus, either $A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = \xi v_1$ for some $\xi \in \mathbb{C}$, or $A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = \eta v_2$ for some $\eta \in \mathbb{C}$. In the former case, we have

$$A_0 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = s\xi v_1 \qquad \text{and} \qquad A_1 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = t\xi v_2.$$

It follows that

$$\|A_0 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p + \|A_1 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p = (|s|^p + |t|^p)|\xi|^p.$$

But $|\xi| = \|A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|$. Therefore, by the induction hypothesis, we obtain

$$\sum_{\varepsilon_1, \ldots, \varepsilon_n \in \{0,1\}} \big[\|A_0 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p + \|A_1 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1\|^p\big] = (|s|^p + |t|^p)^{n+1}. \tag{5.3}$$

In the latter case, we have

$$A_0 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = t\eta v_1 \qquad \text{and} \qquad A_1 A_{\varepsilon_n} \cdots A_{\varepsilon_1} v_1 = s\eta v_2.$$

Hence (5.3) is also valid. This completes the induction procedure.

Finally, we derive from (5.2) that

$$\rho_p(A_0|_V, A_1|_V) = \lim_{n\to\infty} \|\mathcal{A}^n v_1\|_p^{1/n} = \big(|s|^p + |t|^p\big)^{1/p}, \qquad 1 \le p < \infty.$$

For the case $p = \infty$, a similar argument gives

$$\rho_\infty(A_0|_V, A_1|_V) = \max\{|s|, |t|\}.$$

Note that $t = -\sqrt{7}/4$ and $s = t + 1/2 = (2 - \sqrt{7})/4$. By Theorem 3.3, we obtain the desired result (5.1). In particular,

$$\nu_\infty(\phi) = -\log_2 \frac{\sqrt{7}}{4} \approx 0.59632,$$

$$\nu_2(\phi) = \frac{1}{2} - \frac{1}{2}\log_2 \frac{9 - 2\sqrt{7}}{8} \approx 1.05458,$$

and

$$\nu_1(\phi) = 1 - \log_2 \frac{\sqrt{7} - 1}{2} \approx 1.28125. \qquad \square$$

We now return to the general mask and discuss the L_2-smoothness of the normalized solution ϕ.

EXAMPLE 5.3. *Let a be the mask*

$$a(0) = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ t & t \end{bmatrix}, \quad a(1) = \begin{bmatrix} 1 & 0 \\ 0 & \mu \end{bmatrix}, \quad \textit{and} \quad a(2) = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} \\ -t & t \end{bmatrix},$$

where $\mu := \sqrt{2 - 4t^2}$ and the parameter t is in the range $-1/\sqrt{2} \le t < -1/2$. Then

$$\nu_2(\phi) = -\log_2 \sqrt{\rho(B(t))}, \qquad t \ne -\sqrt{7}/4,$$

where $B(t)$ is the matrix

$$B(t) := \begin{bmatrix} 1/4 & t^2 & 0 & 0 \\ 1/4 & t\mu - t^2 & 1 & 0 \\ \frac{2t+2-\mu-4t\mu}{8} & -\frac{2t^2\mu - t\mu^2 + 4t^2 - 8t^3\mu}{4} & 1 & \frac{4t^2-1-8t^2\mu+2\mu}{8} \\ 1/2 & -\mu t & 0 & \frac{\mu+2t}{4} \end{bmatrix}.$$

Proof. To apply Theorem 3.4 with $k = 1$, we need to determine the minimal invariant subspace W of F_a generated by $e_1 e_1^T(\Delta\delta) =: w_1$ and $e_2 e_2^T(\Delta\delta) =: w_2$. From a computation, we find that W can be described as $W := \operatorname{span}\{w_1, w_2, w_3, w_4\}$ using the additional matrices

$$w_3 := \begin{bmatrix} 0 & (t/2 - \mu/4)(\delta_{-1} - \delta_1) \\ -(t/2 - \mu/4)(\delta_{-1} - \delta_1) & (2 - 4t\mu)\Delta\delta \end{bmatrix}$$

and

$$w_4 := \begin{bmatrix} 0 & \delta_{-1} - \delta_1 \\ \delta_1 - \delta_{-1} & 0 \end{bmatrix}.$$

Furthermore, $F_a|_W$ has the matrix representation given by

$$F_a \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix} = B(t) \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix}.$$

One of the eigenvalues of $B(t)$ is zero. The absolute value of the dominant eigenvalue has minimum $1/4$ precisely at $t = -\sqrt{7}/4$. Hence when $t \ne -\sqrt{7}/4$, $-\log_2 \sqrt{\rho(F_a|_W)} < 1$ and $\nu_2(\phi) = -\log_2 \sqrt{\rho(B(t))}$ by Theorem 3.4. $\square$

When $t = -\sqrt{7}/4$, the matrix B takes the form

$$B\left(-\frac{\sqrt{7}}{4}\right) = \begin{bmatrix} 1/4 & 7/16 & 0 & 0 \\ 1/4 & -\frac{2\sqrt{7}+7}{16} & 1 & 0 \\ 3/16 & -\frac{35+8\sqrt{7}}{64} & 1 & 0 \\ 1/2 & \frac{\sqrt{7}}{8} & 0 & \frac{1-\sqrt{7}}{8} \end{bmatrix}.$$

It is evident that in this case, the minimal invariant subspace W of F_a generated by $e_1 e_1^T(\Delta\delta) = w_1$ and $e_2 e_2^T(\Delta\delta) = w_2$ is span $\{w_1, w_2, w_3\}$. Moreover, the eigenvalues of the matrix representation of F_a on W are 0, $(9-2\sqrt{7})/16$, and $1/4$. From Example 5.2, we know that $\nu_2(\phi) = -\log_2 \sqrt{(9-2\sqrt{7})/16}$ for $t = -\sqrt{7}/4$; hence, this case provides an example to show that the condition $k > -\log_2 \sqrt{\rho(F_a|_W)}$ is necessary for the equality in Theorem 3.4.

We have seen above that the choice $t = -\sqrt{7}/4$ of the parameter t yields the best smoothness in $L_2(\mathbb{R})$ among all the orthonormal wavelets generated by the masks in Example 5.3. That same choice of the parameter also is the only one for which the resulting vector of functions $\phi = (\phi_1, \phi_2)^T$ achieves accuracy 2. However, if we measure the smoothness in L_∞, then the choice $t = -\sqrt{7}/4$ no longer provides optimal smoothness. Recall from [21] that the operators A_0 and A_1, when restricted to the subspace V generated by

$$\big\{2e_2\delta, \quad 2e_2\delta_1, \quad -e_1\nabla\delta + e_2\delta + e_2\delta_1\big\},$$

have the matrix representation

$$A_0|_V := \begin{bmatrix} \frac{1}{2}+t & \frac{1}{2}+t & -1 \\ 0 & \sqrt{2-4t^2} & 0 \\ 0 & \frac{2t+\sqrt{2-4t^2}}{2} & 0 \end{bmatrix} \quad \text{and} \quad A_1|_V := \begin{bmatrix} \sqrt{2-4t^2} & 0 & 0 \\ \frac{1}{2}+t & \frac{1}{2}+t & -1 \\ \frac{2t+\sqrt{2-4t^2}}{2} & 0 & 0 \end{bmatrix}.$$

Clearly, V contains the subspace generated by $e_1\nabla\delta$, $e_2\nabla\delta$.

A lower bound for the joint spectral radius $\rho_\infty(A_0|_V, A_1|_V)$ is given by the maximal spectral radius of the square root of the $\rho_\infty(A_{\varepsilon_1}|_V A_{\varepsilon_2}|_V)$, $\varepsilon_1, \varepsilon_2 \in \{0, 1\}$. Now

$$f_1(t)^2 := \rho_\infty(A_0|_V^2) = \rho_\infty(A_1|_V^2) = \max\big(|t+1/2|, \mu\big)^2,$$

and

$$\begin{aligned} f_2(t)^2 &:= \rho_\infty(A_0|_V A_1|_V) = \rho_\infty(A_1|_V A_0|_V) \\ &= \max\big(0, |\eta \pm \sqrt{\eta^2 - 64t^2(\mu-1)^2}|/8\big), \end{aligned}$$

where $\eta = 8\mu t + 1 + 4t^2 - 4t$. In the interval $-1/\sqrt{2} \le t < -1/2$, the function f_1 is increasing, the function f_2 is decreasing, and they are equal in the point $t \approx -0.64268764$ at which the minimum value, $.5897545\ldots$, of $g := \max(f_1, f_2)$ is achieved. Perhaps surprisingly, the lower bound g for the joint spectral radius is exact for the point $t = -\sqrt{7}/4$. This suggests that the value $t \approx -0.64268764$ should give rise to ϕ which is smoother when measured in the L_∞ norm. This is indeed the case as a numerical computation shows that

$$\|\mathcal{A}^n\|^{\frac{1}{n}} < .6064 < \sqrt{7}/4 \quad \text{for} \quad t = -0.64268764 \quad \text{and} \quad n = 28.$$

Thus,

$$\nu_\infty(\phi) \ge -\log_2(.6064) = 0.721658\ldots \quad \text{for} \quad t = -0.64268764.$$

Acknowledgment. We thank Bin Han for the numerical computation for the above joint spectral radius.

REDUCED SYSTEMS FOR THREE-DIMENSIONAL ELLIPTIC EQUATIONS WITH VARIABLE COEFFICIENTS*

CHEN GREIF†

Abstract. We consider large sparse nonsymmetric linear systems arising from finite difference discretization of three-dimensional (3D) convection-diffusion equations with variable coefficients. We show that performing one step of cyclic reduction yields a system of equations which is well conditioned and for which fast convergence can be obtained. A certain block ordering strategy is applied, and analytical results concerning symmetrizability conditions and bounds on convergence rates are given. The analysis is accompanied by numerical examples.

Key words. cyclic reduction, 3D elliptic problems, variable coefficients

1. Introduction.

Consider the following three-dimensional (3D) convection-diffusion equation

$$-[(pu_x)_x + (qu_y)_y + (ru_z)_z] + su_x + tu_y + vu_z = w \ , \tag{1.1}$$

on a domain $\Omega \subset \mathbb{R}^3$, subject to Dirichlet, Neumann, or mixed boundary conditions, where all the functions in (1.1) are trivariate, and $p,\ q,\ r > 0$ on Ω. Several discretization schemes are possible. See Morton [11] for a comprehensive survey on numerical solution of the convection-diffusion problem. In this work we use a seven-point discretization technique as a starting point and extend the analysis of Elman and Golub [4], done for the two-dimensional (2D) variable coefficient case, and the analysis of Greif and Varah [8], [9] for the 3D problem with constant coefficients to the 3D problem with variable coefficients.

Let h denote the width of a uniform mesh. In the description that follows we use the notation $G_{i,j,k} \equiv G(ih, jh, kh)$, where G is a trivariate function. The seven-point discretization is done as follows (see, e.g., [4] for the analogous 2D case). For the first term in (1.1) we have

$$(pu_x)_x \approx \frac{p_{i+\frac{1}{2},j,k}u_{i+1,j,k} - (p_{i+\frac{1}{2},j,k} + p_{i-\frac{1}{2},j,k})u_{i,j,k} + p_{i-\frac{1}{2},j,k}u_{i-1,j,k}}{h^2} \ ,$$

and an analogous discretization is performed for $(qu_y)_y$ and $(ru_z)_z$. For the convective terms $su_x,\ tu_y$, and vu_z we use either upwind or centered difference schemes.

Let F denote the corresponding difference operator, scaled by h^2, and denote the values of the associated computational molecule by $a_{i,j,k},\ b_{i,j,k},\ c_{i,j,k},\ d_{i,j,k},\ e_{i,j,k},\ f_{i,j,k}$, and $g_{i,j,k}$, in the following manner: if (i,j,k) is a gridpoint not next to the boundary, then

$$\begin{aligned} F\,u_{i,j,k} = {} & a_{i,j,k}\,u_{i,j,k} + b_{i,j,k}\,u_{i,j-1,k} + c_{i,j,k}\,u_{i-1,j,k} + d_{i,j,k}\,u_{i+1,j,k} \\ & + e_{i,j,k}\,u_{i,j+1,k} + f_{i,j,k}\,u_{i,j,k-1} + g_{i,j,k}\,u_{i,j,k+1} \ . \end{aligned} \tag{1.2}$$

(**a**) seven-point operator (**b**) reduced operator

FIG. 1.1. *Computational molecules of the unreduced and the reduced operators.*

The computational molecule is graphically illustrated in Figure 1.1(a) (in the figure the subscripts are dropped).

If centered differences are used to discretize the convective terms, the values of the computational molecule are given by

$$
\begin{aligned}
(1.3)\qquad a_{i,j,k} &= p_{i+\frac{1}{2},j,k} + p_{i-\frac{1}{2},j,k} + q_{i,j+\frac{1}{2},k} + q_{i,j-\frac{1}{2},k} + r_{i,j,k+\frac{1}{2}} + r_{i,j,k-\frac{1}{2}};\\
b_{i,j,k} &= -q_{i,j-\frac{1}{2},k} - \frac{t_{i,j,k}h}{2}; \quad e_{i,j,k} = -q_{i,j+\frac{1}{2},k} + \frac{t_{i,j,k}h}{2};\\
c_{i,j,k} &= -p_{i-\frac{1}{2},j,k} - \frac{s_{i,j,k}h}{2}; \quad d_{i,j,k} = -p_{i+\frac{1}{2},j,k} + \frac{s_{i,j,k}h}{2};\\
f_{i,j,k} &= -r_{i,j,k-\frac{1}{2}} - \frac{v_{i,j,k}h}{2}; \quad g_{i,j,k} = -r_{i,j,k+\frac{1}{2}} + \frac{v_{i,j,k}h}{2}.
\end{aligned}
$$

If one uses upwind schemes, then the type of scheme depends on the sign of the convective terms. Assuming that s, t, and v do not change sign in the domain, if they are positive one can use the backward scheme, and if they are negative one can use the forward scheme. Discretizing using backward differences yields

$$
\begin{aligned}
(1.4)\qquad a_{i,j,k} &= p_{i+\frac{1}{2},j,k} + p_{i-\frac{1}{2},j,k} + q_{i,j+\frac{1}{2},k} + q_{i,j-\frac{1}{2},k} + r_{i,j,k+\frac{1}{2}} + r_{i,j,k-\frac{1}{2}} + s_{i,j,k}h\\
&\quad + t_{i,j,k}h + v_{i,j,k}h;\\
b_{i,j,k} &= -q_{i,j-\frac{1}{2},k} - t_{i,j,k}h; \quad e_{i,j,k} = -q_{i,j+\frac{1}{2},k};\\
c_{i,j,k} &= -p_{i-\frac{1}{2},j,k} - s_{i,j,k}h; \quad d_{i,j,k} = -p_{i+\frac{1}{2},j,k};\\
f_{i,j,k} &= -r_{i,j,k-\frac{1}{2}} - w_{i,j,k}h; \quad g_{i,j,k} = -r_{i,j,k+\frac{1}{2}},
\end{aligned}
$$

and for forward differences (1.4) needs to be modified in an obvious manner.

The sparsity structure of the matrix representing the system of equations depends on the ordering of the unknowns. A common strategy is the red/black ordering, which is depicted in Figure 1.2: the gridpoints are colored using two colors in a checkerboard fashion, and the points that correspond to one of the colors (say, red) are numbered first. In this case the corresponding matrix can be written as

$$
(1.5)\qquad \begin{pmatrix} B & C \\ D & E \end{pmatrix} \begin{pmatrix} u^{(r)} \\ u^{(b)} \end{pmatrix} = \begin{pmatrix} w^{(r)} \\ w^{(b)} \end{pmatrix},
$$

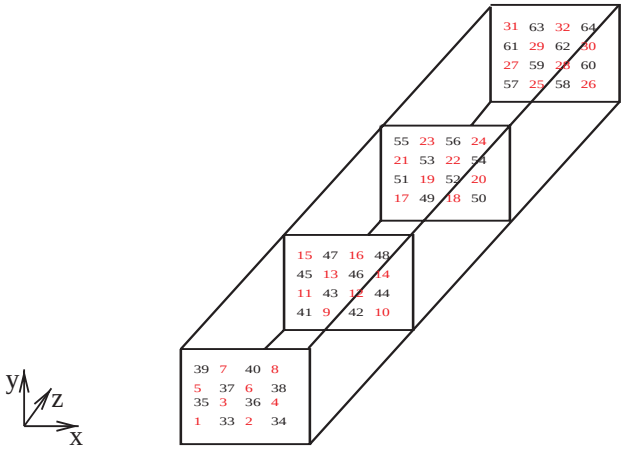

FIG. 1.2. *Red/black ordering of the 3D grid.*

where both B and E are diagonal. In (1.5) superscripts (r) and (b) are attached to denote the associated colors. A simple process of block Gaussian elimination leads to a smaller system, for the black points only, which is called a *reduced system* [2]:

$$[E - DB^{-1}C]u^{(b)} = w^{(b)} - DB^{-1}w^{(r)} \ . \tag{1.6}$$

Since B is diagonal, the matrix of (1.6) is sparse. In the 3D case the corresponding difference operator has a computational molecule which consists of 19 points, as illustrated in Figure 1.1(b). Once the solution for the black points is computed, the solution for the red points corresponds to solving a diagonal system and thus is readily obtained. Moving from system (1.5) to system (1.6) amounts to performing *one step of cyclic reduction* [2]. This procedure can be repeated until a small system of equations is obtained, which can be solved directly. An overview of the idea of cyclic reduction and several references are given in [5, pp. 177–180].

The elimination of half of the unknowns is accompanied by permutation of the matrix (equivalently, reordering of the unknowns). Once the permuted reduced system is formed, an iterative method can be used to find the solution. The procedure of performing one step of cyclic reduction for a non-self-adjoint problem and solving the resulting system using an iterative solver was extensively investigated by Elman and Golub for 2D problems [2], [3], [4]. They showed that one step of cyclic reduction leads to systems with valuable properties, such as symmetrizability by a real diagonal nonsingular matrix for a large set of the underlying PDE coefficients (which is effectively used to derive bounds on the convergence rates of iterative solvers), and fast convergence. In [2] the univariate case, which is naturally more transparent, is used to illustrate the advantages of this technique. Many of the highly effective techniques presented and used by Elman and Golub can be generalized to the 3D case and will be mentioned throughout this paper.

An outline of the rest of this paper follows. In section 2 we introduce the cyclically reduced operator. In section 3 we discuss block orderings and present a family of orderings for the reduced grid. In section 4 we present symmetrization results. In section 5 we use the results of section 4 to derive bounds on convergence rates for block stationary methods. In section 6 we present numerical examples, which include solving the systems using Krylov subspace solvers. Finally, in section 7 we draw some conclusions.

2. The reduced operator. One step of cyclic reduction for a 3D model problem with constant coefficients has been described in [9], where full details on the construction of the matrix are given. Convergence analysis and techniques for solving the resulting system of equations using block stationary methods are described in [8], [9]. In the case of constant coefficients, the values of the computational molecule associated with a given gridpoint do not depend on the point's coordinates, as opposed to the variable coefficient case. Nevertheless, the sparsity structure of the reduced matrix is identical in both cases.

The explicit difference equation associated with the reduced operator for the 3D variable coefficient case can be found in [7] and should be used for constructing the reduced matrix. The alternative of performing the matrix products in (1.6) might be significantly more costly, especially in the 3D case, and in particular, in programming environments where vectorization is crucial (e.g., Matlab).

Consider the following constant coefficient model problem: $p(x,y,z) = q(x,y,z) = r(x,y,z) \equiv 1,\ s(x,y,z) = \sigma,\ t(x,y,z) = \tau,\ v(x,y,z) = \mu$. After scaling by ah^2, the difference equation has the form

$$\begin{aligned}(2.1)\qquad \tilde{R}\,u_{i,j,k} = {} & (a^2 - 2be - 2cd - 2fg)\,u_{i,j,k} - f^2\,u_{i,j,k-2} - 2ef\,u_{i,j+1,k-1} \\ & -2cf\,u_{i-1,j,k-1} - 2df\,u_{i+1,j,k-1} - 2bf\,u_{i,j-1,k-1} - e^2\,u_{i,j+2,k} \\ & -2de\,u_{i+1,j+1,k} - c^2\,u_{i-2,j,k} - d^2\,u_{i+2,j,k} - 2bc\,u_{i-1,j-1,k} \\ & -b^2\,u_{i,j-2,k} - 2eg\,u_{i,j+1,k+1} - 2cg\,u_{i-1,j,k+1} - 2ce\,u_{i-1,j+1,k} \\ & -2bd\,u_{i+1,j-1,k} - 2dg\,u_{i+1,j,k+1} - 2bg\,u_{i,j-1,k+1} - g^2\,u_{i,j,k+2}\ .\end{aligned}$$

Denote the continuous operator corresponding to this model problem

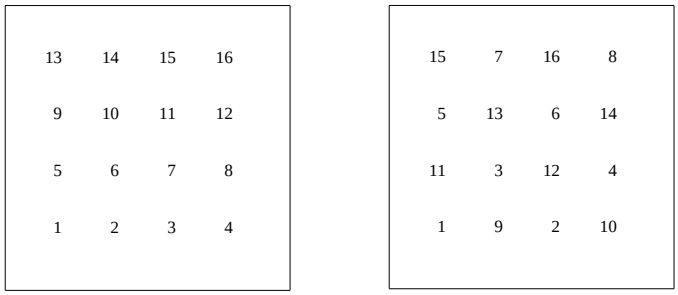
$$(2.2)\qquad L = -\Delta + (\sigma,\tau,\mu)^T\nabla\ .$$

The reduced operator can be derived directly as a discretization scheme of the original PDE, with $O(h^2)$ correction terms in the case of centered difference discretization and $O(h)$ correction terms if upwind discretization is used. This can be done by means analogous to the techniques used for the 2D case (see Elman and Golub [3] and Golub and Tuminaro [6]). Consider the centered difference discretization. Expanding (2.2) in a multivariate Taylor expansion about the gridpoint (ih, jh, kh) yields, after scaling by $2ah^2$,

$$\begin{aligned}(2.3)\qquad 2\tilde{R}\,u = {} & L\,u - \frac{1}{6}\,h^2\,u_{yyyy} - \frac{1}{6}\,h^2\,u_{yyzz} - \frac{1}{6}\,h^2\,\tau\,\mu\,u_{yz} + \frac{1}{6}\,h^2\,\mu\,u_{yyz} + \frac{1}{6}\,h^2\,\sigma u_{xzz} \\ & + \frac{1}{6}\,h^2\,\tau\,u_{xxy} + \frac{1}{6}\,h^2\,\sigma\,u_{xyy} + \frac{1}{3}\,h^2\,\sigma\,u_{xxx} - \frac{1}{6}\,h^2\,\sigma\,\mu\,u_{xz} - \frac{1}{6}\,h^2\,\sigma\,\tau\,u_{xy} + \frac{1}{3}\,h^2\,\mu\,u_{zzz} \\ & - \frac{1}{12}\,h^2\,\mu^2\,u_{zz} + \frac{1}{3}\,h^2\,\tau\,u_{yyy} - \frac{1}{12}\,h^2\,\tau^2\,u_{yy} + \frac{1}{6}\,h^2\,\tau\,u_{yzz} - \frac{1}{6}\,h^2\,u_{xxyy} - \frac{1}{6}\,h^2\,u_{xxzz} \\ & + \frac{1}{6}\,h^2\,\mu\,u_{xxz} - \frac{1}{12}\,h^2\,\sigma^2\,u_{xx} - \frac{1}{6}\,h^2\,u_{xxxx} - \frac{1}{6}\,h^2\,u_{zzzz} + O(h^3)\ .\end{aligned}$$

The above computation was carried out using Maple V. The $O(h^2)$ terms contain, among other terms, the expression $-\frac{h^2}{12}(\sigma^2 u_{xx} + \tau^2 u_{yy} + \mu^2 u_{zz})$, which can be thought of as addition of artificial viscosity to the original equation. The reduced right-hand side is equal to $w_{i,j,k}$ with an $O(h^2)$ error. Gaussian elimination yields the following right-hand side,

$$w_{i,j,k} - \frac{b}{a}\,w_{i,j-1,k} - \frac{c}{a}\,w_{i-1,j,k} - \frac{d}{a}\,w_{i+1,j,k} - \frac{e}{a}\,w_{i,j+1,k} - \frac{f}{a}\,w_{i,j,k-1} - \frac{g}{a}\,w_{i,j,k+1}\ ,$$



(**a**) Natural (**b**) Red/black

FIG. 3.1. *Two possible orderings of the block grid. Each point in these grids corresponds to a one-dimensional (1D) block of gridpoints in the underlying 3D grid.*

whose Taylor expansion about the gridpoint (ih, jh, kh), after scaling by $2ah^2$, is $w - \frac{h^2}{12}[\,-\Delta w + (\sigma w_x + \tau w_y + \mu w_z)\,]$, evaluated at the point (ih, jh, kh). This is another similarity with the 2D case [3].

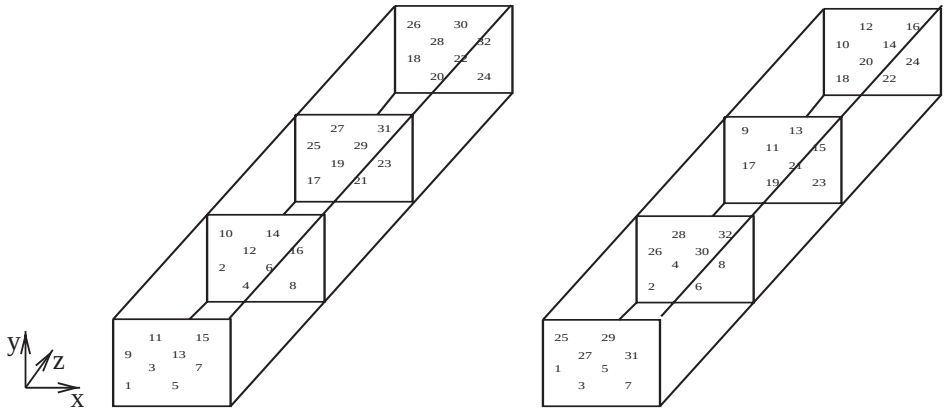
3. Block ordering strategies for the reduced grid. The question of ordering is of major importance, as a good ordering strategy can lead to fast convergence. An excellent overview of the literature that deals with ordering strategies is found in a recent report by Benzi, Szyld, and van Duin [1]. For 3D problems it seems useful to consider the ordering of *blocks* of unknowns, rather than "pointwise" ordering. Such a strategy could be particularly useful for the cyclically reduced problem, as the reduced grid is somewhat irregular. Instead of ordering the unknowns directly in the 3D reduced grid, the problem of ordering is divided into two parts. First, define blocks of gridpoints and order them in a tensor-product 2D "block grid." Once the ordering of the blocks is determined, the task of the "inner" ordering in each of the blocks is relatively simple.

We can define an x-oriented "1D block of gridpoints" by referring to a set of gridpoints whose collection of all x-coordinate values include all the possible values $\{jh\}$ on the grid. A simple example is a single horizontal line of gridpoints in a tensor-product 3D grid. Similarly, y-oriented and z-oriented 1D blocks can be defined. Once the 1D blocks of gridpoints are defined, a *block computational molecule* can be defined as follows.

DEFINITION 3.1. *For a certain given 3D grid and a 1D block of gridpoints in it, the associated* block computational molecule *is defined as the computational molecule in the corresponding block grid. That is, its components are the 1D blocks in the block grid, each of which contains at least one gridpoint which belongs to the (point) computational molecule associated with the 3D problem.*

Using the above, we can now easily define different families and types of orderings. For example, a certain ordering strategy is a *natural* block ordering strategy relative to the 1D blocks of gridpoints if these blocks are ordered in the block grid using natural lexicographic ordering. Similarly, one can define a red/black block ordering strategy, and so on (see Figure 3.1).

Below we focus on a particular family of orderings for the reduced grid, which we call the *two-plane* ordering. This ordering corresponds to defining each of the 1D blocks of gridpoints as a collection of $2n$ gridpoints from two horizontal lines and two adjacent planes (here n is the number of gridpoints in a single line in the original



(**a**) 2PNxy (**b**) 2PRBxy

FIG. 3.2. *Two types of two-plane ordering.*

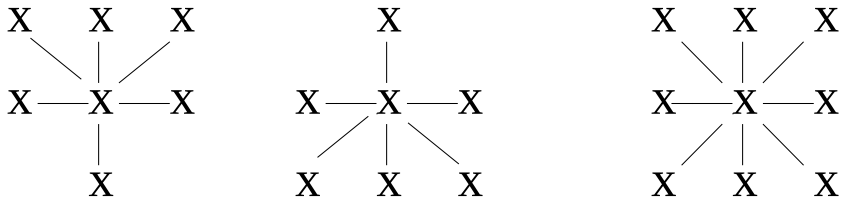
FIG. 3.3. *Possible orientations of the* 1*D blocks of gridpoints in the set of natural two-plane orderings.*

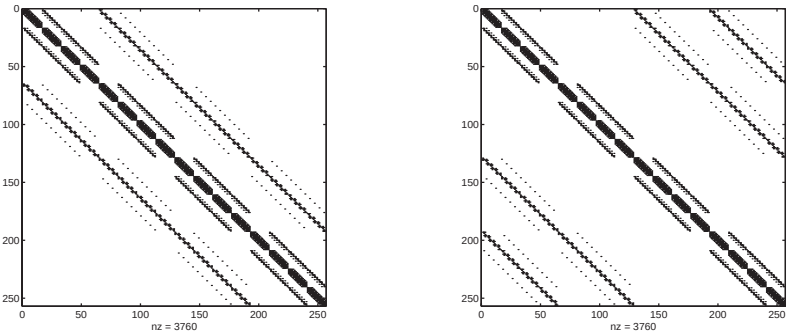
unreduced grid). A single member of this family was introduced in [9]. In Figure 3.2 two members of the family are depicted: natural two-plane ordering and red/black two-plane ordering. For notational convenience, we label them "2PN" and "2PRB," respectively. Two additional letters are added in order to distinguish between different orientations of the $2n$-item 1D blocks of gridpoints. Let us illustrate this for the specific case depicted in Figure 3.2(a). Here $n = 4$. Indices 1–8, 9–16, 17–24, and 25–32 are each an x-oriented 1D block. The block grid is of size 2×2 and its components are ordered in natural lexicographic fashion. Each of the sets of indices 1–16 and 17–32 forms an x-y–oriented pair of planes. Hence the name 2PNxy. In Figure 3.3 other orientations of the blocks in the natural two-plane ordering are depicted.

Figures 3.4(a) and (b) illustrate what blocks are associated with a single gridpoint. In these figures, each "X" corresponds to a 1D block which contains at least one gridpoint in the "point" computational molecule associated with the selected gridpoint (the one that is at the center of the computational molecule). As is evident, the



(**a**) even $k = \frac{z}{h}$ (**b**) odd $k = \frac{z}{h}$ (**c**) computational molecule

FIG. 3.4. *Block computational molecule associated with the two-plane ordering.*



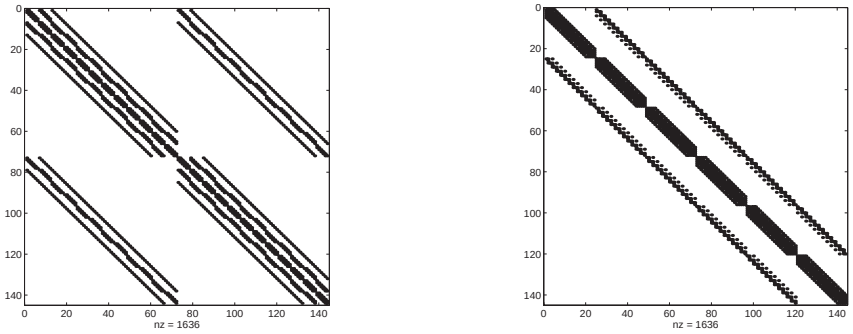
(**a**) natural (**b**) red/black based on 2D blocks

FIG. 3.5. *Sparsity structures of two matrices which belong to the family of two-plane orderings.*

structure depends on the parity of this gridpoint's index. The block computational molecule (Figure 3.4(c)) is obtained by taking the union of all the 1D blocks associated with each of the gridpoints in the block, and thus it is identical to the computational molecule of the classical nine-point operator. This allows one to conclude, e.g., that the reduced matrix does not have block property A [14] relative to partitioning into $2n \times 2n$ blocks. On the other hand, applying a 4-color scheme to the blocks of gridpoints can be effective for parallelization.

The same ideas as above can be applied to $2D$ *blocks* of gridpoints. The block grid in this case is univariate. The reduced matrix is consistently ordered relative to partitioning associated with 2D blocks. In Figure 3.5 the sparsity structures of 256×256 matrices corresponding to natural two-plane ordering and red/black block ordering relative to 2D blocks are depicted.

In order to illustrate the effectiveness of the two-plane ordering, we present in Figure 3.6 a single 2D block of a natural two-plane matrix vs. one that corresponds to ("point") natural lexicographic ordering. The matrices in the figure are associated with a $12 \times 12 \times 12$ grid. As is evident, the main diagonal block of the two-plane matrix is more dense. Compared to the natural lexicographic ordering, there are significantly more nonzero entries in the block diagonal submatrix whose bandwidth does not depend on n. As a result, direct preconditioner solves will be more efficient due to less fill-in. If a stationary scheme such as block Jacobi is used, by [13, Thm. 3.15] it is guaranteed that if the reduced matrix is an M-matrix, then the convergence of a scheme associated with the two-plane matrix is faster than that of a scheme with



(**a**) lexicographic (**b**) natural two-plane

FIG. 3.6. *A zoom on 2D blocks of the matrices corresponding to two ordering strategies of the reduced grid.*

the lexicographic ordering. (The circumstances in which the reduced matrix is an M-matrix in the constant coefficient case are discussed in [9].)

4. Symmetrization of the reduced matrix. In order to obtain bounds on convergence rates for block stationary methods, we consider the following technique, suggested and used in [2], [3], [4] and also effectively applied in [8], [9]: if there exists a real diagonal matrix Q, such that $\hat{S} = Q^{-1}SQ$ is symmetric, then for a splitting $S = D - C$ and an analogous splitting of $\hat{S}$, namely $\hat{S} = Q^{-1}DQ - Q^{-1}CQ \equiv \hat{D} - \hat{C}$, we have

$$\rho(D^{-1}C) = \rho(\hat{D}^{-1}\hat{C}) \leq ||\hat{D}^{-1}||_2||\hat{C}||_2 = \frac{\rho(\hat{C})}{\lambda_{min}(\hat{D})} \ . \tag{4.1}$$

A bound for the spectral radius of the iteration matrix can thus be obtained by evaluating the expression on the right-hand side of (4.1). Denote the entries of S by $\{s_{i,j}\}_{i,j=1}^{n^3/2}$. Since S is sparse and has a block structure, a small amount of work is needed in order to find Q—by requiring for the entries of $\hat{S}$, which we denote by $\{\hat{s}_{i,j}\}_{i,j=1}^{n^3/2}$, that $\hat{s}_{i,j} = \hat{s}_{j,i}$. Since matrices that correspond to different orderings are merely symmetric permutations of one another, we can pick a matrix that corresponds to a specific ordering strategy and do all the work for it. This will result in obtaining general symmetrization conditions for the reduced matrices (regardless of the ordering used). Thus we pick the specific ordering strategy 2PNxz.

Let q_ℓ denote the ℓth diagonal entry in Q. Then

$$\hat{s}_{j,\ell} = \frac{s_{j,\ell}q_\ell}{q_j} \ , \qquad 1 \leq j, \ell \leq \frac{n^3}{2} \ , \tag{4.2}$$

and the symmetry conditions can be expressed as

$$\frac{q_\ell}{q_j} = \sqrt{\frac{s_{\ell,j}}{s_{j,\ell}}} \ , \qquad 1 \leq \ell \leq \frac{n^3}{2}, \quad 1 \leq j \leq \ell \ . \tag{4.3}$$

It is sufficient to look at $2n \times 2n$ blocks. We start with the main diagonal blocks. We have to examine all the entries of the main block that appear in the ℓth row of

the matrix, namely $s_{\ell,\ell-4}, s_{\ell,\ell-3}, \ldots, s_{\ell,\ell}, \ldots, s_{\ell,\ell+4}$. For $s_{\ell,\ell-4}$, if $\ell \bmod 2n \geq 5$ or is equal to 0, then $\ell - 4$ corresponds to the $(i-2, j, k)$ mesh point. Thus

$$s_{\ell-4,\ell} = - \left. \frac{d_{\tilde{\alpha}+1,\tilde{\beta},\tilde{\gamma}} d_{\tilde{\alpha},\tilde{\beta},\tilde{\gamma}}}{a_{\tilde{\alpha}+1,\tilde{\beta},\tilde{\gamma}}} \right|_{\tilde{\alpha}=i-2,\tilde{\beta}=j,\tilde{\gamma}=k}, \tag{4.4}$$

and from this it follows that

$$\left(\frac{q_\ell}{q_{\ell-4}}\right)^2 = \frac{-\left(\frac{c_{i-1,j,k}c_{i,j,k}}{a_{i-1,j,k}}\right)}{-\left(\frac{d_{i-2,j,k}d_{i-1,j,k}}{a_{i-1,j,k}}\right)} = \frac{c_{i-1,j,k}c_{i,j,k}}{d_{i-2,j,k}d_{i-1,j,k}} \,. \tag{4.5}$$

In this case the values associated with the center of the computational molecule (namely, $a_{i,j,k}$) are canceled, but this happens only for rows that involve the $(i \pm 2, j, k)$, $(i, j \pm 2, k)$, and $(i, j, k \pm 2)$ gridpoints. Applying the same procedure to the rest of the entries of the main diagonal block, we obtain the following:

$$\left(\frac{q_\ell}{q_{\ell-3}}\right)^2 = \frac{\frac{c_{i,j,k-1}f_{i,j,k}}{a_{i,j,k-1}} + \frac{c_{i,j,k}f_{i-1,j,k}}{a_{i-1,j,k}}}{\frac{g_{i,j,k-1}d_{i-1,j,k-1}}{a_{i,j,k-1}} + \frac{g_{i-1,j,k-1}d_{i-1,j,k}}{a_{i-1,j,k}}} \quad \ell \bmod 2n = 0, 4, 6, \ldots, 2n-2; \tag{4.6}$$

$$\left(\frac{q_\ell}{q_{\ell-2}}\right)^2 = \frac{\frac{c_{i,j+1,k}e_{i,j,k}}{a_{i,j+1,k}} + \frac{c_{i,j,k}e_{i-1,j,k}}{a_{i-1,j,k}}}{\frac{b_{i,j+1,k}d_{i-1,j+1,k}}{a_{i,j+1,k}} + \frac{d_{i-1,j,k}b_{i-1,j+1,k}}{a_{i-1,j,k}}} \qquad \ell \bmod 4 = 2 \text{ or } 3; \tag{4.7}$$

$$\left(\frac{q_\ell}{q_{\ell-2}}\right)^2 = \frac{\frac{b_{i-1,j,k}c_{i,j,k}}{a_{i-1,j,k}} + \frac{c_{i,j-1,k}b_{i,j,k}}{a_{i,j-1,k}}}{\frac{d_{i-1,j,k}e_{i-1,j-1,k}}{a_{i-1,j,k}} + \frac{e_{i,j-1,k}d_{i-1,j-1,k}}{a_{i,j-1,k}}} \qquad \ell \bmod 4 = 0 \text{ or } 1; \tag{4.8}$$

$$\left(\frac{q_\ell}{q_{\ell-1}}\right)^2 = \frac{\frac{g_{i-1,j,k}c_{i,j,k}}{a_{i-1,j,k}} + \frac{c_{i,j,k+1}g_{i,j,k}}{a_{i,j,k+1}}}{\frac{d_{i-1,j,k}f_{i-1,j,k+1}}{a_{i-1,j,k}} + \frac{d_{i-1,j,k+1}f_{i,j,k+1}}{a_{i,j,k+1}}} \qquad \ell \bmod 2n = 3, \ldots, 2n-1; \tag{4.9}$$

$$\left(\frac{q_\ell}{q_{\ell-1}}\right)^2 = \frac{\frac{e_{i,j,k-1}f_{i,j,k}}{a_{i,j,k-1}} + \frac{f_{i,j+1,k}e_{i,j,k}}{a_{i,j+1,k}}}{\frac{g_{i,j,k-1}b_{i,j+1,k-1}}{a_{i,j,k-1}} + \frac{b_{i,j+1,k}f_{i,j+1,k-1}}{a_{i,j+1,k}}} \qquad \ell \bmod 4 = 2; \tag{4.10}$$

$$\left(\frac{q_\ell}{q_{\ell-1}}\right)^2 = \frac{\frac{b_{i,j,k-1}f_{i,j,k}}{a_{i,j,k-1}} + \frac{f_{i,j-1,k}b_{i,j,k}}{a_{i,j-1,k}}}{\frac{g_{i,j,k-1}e_{i,j-1,k-1}}{a_{i,j,k-1}} + \frac{e_{i,j-1,k}g_{i,j-1,k-1}}{a_{i,j-1,k}}} \qquad \ell \bmod 4 = 0. \tag{4.11}$$

As is evident, (4.5)–(4.11) overdetermine the nonzero values of the matrix Q. Indeed, (4.9)–(4.11) are sufficient to determine all the diagonal entries, except the first entry in each $2n \times 2n$ block, which at this stage can be arbitrarily chosen. We have to make sure, therefore, that (4.5)–(4.8) are consistent with these three equations, and this requirement imposes some additional conditions. In the constant coefficient case there is unconditional consistency. The problematic nature of the variable coefficient case can be demonstrated simply by looking at one of the consistency conditions.

Consider a gridpoint (i,j,k) whose associated index, ℓ, satisfies $\ell \bmod 4 = 0$. Applying (4.9) to $\ell - 1$ means looking at the row corresponding to the $(i, j-1, k-1)$ gridpoint, and multiplying (4.9), applied to $\ell - 1$, by (4.11) results in an equation for $\frac{q_\ell}{q_{\ell-2}}$, which should be consistent with (4.8). There are three additional consistency conditions for the main block and then eight additional conditions for the rest of the blocks of the reduced matrix. In the consistency condition, if we equate variables that belong to the same location in the computational molecule, we find that sufficient conditions for the above-mentioned consistency conditions to hold are $b_{i-1,j,k} = b_{i,j,k-1}$, $c_{i,j-1,k-1} = c_{i,j,k}$, $d_{i-1,j-1,k-1} = d_{i-1,j,k}$, $e_{i,j-1,k-1} = e_{i-1,j-1,k}$, $f_{i,j,k} = f_{i-1,j-1,k}$, $g_{i,j,k-1} = g_{i-1,j-1,k-1}$. If $b_{i,j,k} = b_j$ for all i, k, and similarly $c_{i,j,k} = c_i$, $d_{i,j,k} = d_i$, $e_{i,j,k} = e_j$, $f_{i,j,k} = f_k$, $g_{i,j,k} = g_k$, the consistency condition becomes

$$\frac{c_i g_{k-1}}{f_k d_{i-1}} \cdot \frac{b_j f_k}{e_{j-1} g_{k-1}} = \frac{b_j c_i}{d_{i-1} e_{j-1}} \ , \tag{4.12}$$

which is obviously satisfied. The actual meaning of these conditions is that the continuous problem is separable.

The analysis for off-diagonal blocks is identical, and the following additional conditions are obtained:

$$\left(\frac{q_\ell}{q_{\ell-2n}}\right)^2 = \frac{f_{i,j,k} f_{i,j,k-1}}{g_{i,j,k-1} g_{i,j,k-2}} \ , \qquad 2n \le \ell \le \frac{n^3}{2} \ ; \tag{4.13}$$

$$\left(\frac{q_\ell}{q_{\ell-n^2}}\right)^2 = \frac{b_{i,j-1,k} b_{i,j,k}}{e_{i,j-1,k} e_{i,j-2,k}} \ , \qquad n^2 \le \ell \le \frac{n^3}{2} \ . \tag{4.14}$$

The two equations above determine the rest of the entries of the matrix, and only the first entry in the symmetrizer can be determined arbitrarily.

Last, in order for the symmetrizer to be real, we must require that the products $c_i d_{i-1}$, $b_j e_{j-1}$, and $f_k g_{k-1}$ have the same sign.

All that has been said can be summarized in the following theorem, which demonstrates another point of similarity between the 2D [4] and the 3D problems with variable coefficients.

THEOREM 4.1. *Suppose the operator of* (1.1) *is separable. If* $c_i d_{i-1}$, $b_j e_{j-1}$, *and* $f_k g_{k-1}$ *are all nonzero and have the same sign for all* i, j, *and* k, *then there exists a real nonsingular diagonal matrix* Q *such that* $Q^{-1} S Q$ *is symmetric.*

The symmetrized computational molecule can be derived *without* actually performing the similarity transformation. For example, the symmetrized value corresponding to $-\frac{c_{i,j,k} c_{i-1,j,k}}{a_{i-1,j,k}}$ is $-\sqrt{\frac{c_{i-1,j,k} c_{i,j,k} d_{i-2,j,k} d_{i-1,j,k}}{a_{i-1,j,k}}}$, and so on. The symmetrization operation should not actually be performed in order to solve the linear system, as the symmetrizing matrix has entries that are unbounded as h goes to zero. The symmetrization should be done for the mere purpose of convergence analysis.

5. Bounds on convergence rates for block stationary methods. The reduced matrix which corresponds to the family of natural two-plane orderings is of size $(n^3/2) \times (n^3/2)$ and can be thought of as a block tridiagonal matrix, relative to $n^2 \times n^2$ blocks:

$$S = tri[S_{j,j-1}, S_{j,j}, S_{j,j+1}] \ . \tag{5.1}$$

$S_{i,j}$ are block tridiagonal matrices with respect to $2n \times 2n$ blocks.

In [8] two partitionings are considered: a partitioning into 1D blocks ($2n \times 2n$ blocks) and a partitioning into 2D blocks (of size $n^2 \times n^2$). In order to find a bound, if symmetrization is possible, then the strategy in [4] can be applied. In Theorem 5.1, we refer to the ordering strategy 2PNxz. Since other orderings are symmetric permutations of 2PNxz, finding the bounds for other ordering strategies discussed in this paper is straightforward.

THEOREM 5.1. *Suppose the continuous problem is separable and $c_{i+1}d_i, b_{j+1}e_j$, and $f_{k+1}g_k$ are all positive and bounded by β_x, β_y, and β_z, respectively. Suppose also that $a_{i,j,k} \geq \alpha$ for all i, j, and k. Denote $\tilde{h} = \frac{1}{\frac{n}{2}+1}$. Then the spectral radii of the iteration matrices associated with the block Jacobi scheme which correspond to 1D splitting and 2D splitting are bounded by $\frac{\phi+\xi}{\eta}$ and $\frac{\phi}{\eta-\xi}$, respectively, where η, ξ, and ϕ are defined as follows:*

$$\eta = \alpha^2 - 2\beta_y - 2\beta_z - 2\sqrt{\beta_y\beta_z} - 4(\sqrt{\beta_x\beta_y} + \sqrt{\beta_x\beta_z})\cos(\pi h) - 4\beta_x \cos^2(\pi h); \tag{5.2a}$$

$$\xi = 2\beta_z \cos(\pi\tilde{h}) + \sqrt{4\beta_y\beta_z + 16\beta_x\beta_z\cos^2(\pi h) + 16\beta_z\sqrt{\beta_x\beta_y}\cos(\pi h)}\,; \tag{5.2b}$$

$$\phi = 4\sqrt{\beta_y\beta_z} + 4\sqrt{\beta_x\beta_y}\cdot\cos(\pi h) + 2\beta_y\cos(\pi\tilde{h})\,. \tag{5.2c}$$

Proof. The proof follows by using the technique of [4, pp. 346–347]. The conditions stated in the theorem guarantee that the matrix is symmetrizable. Denote the reduced matrix by S and the symmetrized matrix by $\hat{S}$. Suppose S^* is obtained by modifying $\hat{S}$ in the following manner: replace each occurrence of c_i and d_i by $\sqrt{\beta_x}$, replace each occurrence of b_j and e_j by $\sqrt{\beta_y}$, replace each occurrence of f_k and g_k by $\sqrt{\beta_z}$, and replace each occurrence of $a_{i,j,k}$ by α. Denote by $S^* = D^* - C^*$ the splitting, which is analogous, as far as sparsity structure is concerned, to the splitting $S = D - C$. For the 1D splitting, the matrix D^* is block diagonal with semibandwidth 4, its sparsity structure is identical to that of $\hat{D}$, and moreover, it is componentwise smaller than or equal to the entries of $\hat{D}$. By [9, Lem. 3.3], D^* is an irreducible diagonally dominant M-matrix.

The matrix C^* is nonnegative and satisfies $C^* \geq \hat{C}$. Thus the Perron–Frobenius theorem [13, p. 30] can be used to obtain an upper bound on the convergence rate for this splitting. Since the matrix S^* can now be referred to as a symmetrized version of a matrix that is associated with a constant coefficient case, the bound on the convergence rate is readily obtained from [9, Thm. 3.15]. For the 2D splitting the procedure is completely analogous and the bound is obtained from [8, Thm. 3.6]. ∎

We remark that estimates for the convergence rates of block Gauss–Seidel and block SOR schemes can be obtained by using the "near property A" analysis presented in [7], [8].

6. Numerical experiments. In the examples that follow, we begin with some results which validate the convergence analysis of section 5 for stationary methods. We then compare the performance of Krylov subspace solvers for the reduced and the unreduced systems. The experiments were performed on an SGI Origin 2000 machine. The program is written in Matlab 5.

6.1. Test problem 1. Consider the separable problem

$$-\Delta u + p_1\, x\, u_x + p_2\, y\, u_y + p_3\, z\, u_z = w(x, y, z) \tag{6.1}$$

TABLE 6.1
Comparison between the computed spectral radii of the block Jacobi iteration matrices and the bounds, using centered differences for the two splittings, with $p_1 = p_2 = p_3 = 1$.

Splitting		1D			2D		
n	n^3	ρ	Bound	Ratio	ρ	Bound	Ratio
8	512	0.793	0.894	1.13	0.682	0.826	1.21
12	1728	0.895	0.946	1.06	0.825	0.908	1.10
16	4096	0.937	0.968	1.03	0.892	0.944	1.06
20	8000	0.958	0.979	1.02	0.927	0.962	1.04
24	13824	0.970	0.985	1.02	0.948	0.973	1.03

on $\Omega = (0,1) \times (0,1) \times (0,1)$, with Dirichlet boundary conditions, where $w(x,y,z)$ is constructed so that the solution is

$$u(x,y,z) = x\ y\ z\ (1-x)\ (1-y)\ (1-z)\ \exp(x+y+z)\ . \tag{6.2}$$

For notational convenience, let $\gamma = \frac{p_1 h}{2}$, $\delta = \frac{p_2 h}{2}$, and $\mu = \frac{p_3 h}{2}$. Suppose h is sufficiently small and centered difference discretization is performed. Then

$$c_{i+1} d_i = (1+\gamma x_{i+1})(1-\gamma x_i) = 1 + \gamma h - \gamma^2 h^2 (i^2 + i)\ , \tag{6.3}$$

hence

$$1 + \gamma h - \gamma^2 (1-h) \le c_{i+1} d_i \le 1 + \gamma h - 2\gamma^2 h^2\ . \tag{6.4}$$

If $-1 < \gamma < \frac{1}{1-h}$, then $c_{i+1} d_i > 0$. For $b_{j+1} e_j$ and $f_{k+1} g_k$ the bounds are obtained in an identical manner. The center of the computational molecule is $a = 6$. In terms of the PDE coefficients, the condition on γ means that the convergence analysis of section 5 is applicable if the PDE coefficients are $O(n)$.

If the above conditions hold, the matrix is symmetrizable. Using the notation of the previous sections, let $\hat{S}$ be the symmetrized matrix, let $\beta_x = 1 + \gamma h - 2\gamma^2 h^2, \beta_y = 1 + \delta h - 2\delta^2 h^2,\ \beta_z = 1 + \mu h - 2\mu^2 h^2$, and let S^* be a modified version of $\hat{S}$, such that each occurrence of $c_{i+1} d_i,\ b_{j+1} e_j$, and $f_{k+1} g_k$ in $\hat{S}$ is replaced by the upper bounds, namely $\beta_x,\ \beta_y$, and β_z, respectively. Since $S^* \ge \hat{S}$, S^* is a symmetrized version of a matrix corresponding to the constant coefficient case, and by [9, Lem. 3.3], it is a diagonally dominant M-matrix. Using Theorem 5.1, the bounds on the convergence rate of the block Jacobi method are given in Table 6.1. As is evident, the bounds are tight even for small n. It should be noted, however, that as the PDE coefficients grow larger, the bounds are not expected to be as tight, as the inequalities in (6.4) become less effective.

Next, the spectral radii of the block Jacobi and block Gauss–Seidel iteration matrices and an approximation to the optimal SOR parameter have been computed for both the upwind scheme and the centered scheme. The relaxation parameter was computed according to the formula $\frac{2}{1+\sqrt{1-\rho_J^2}}$. It is only an approximation to the optimal SOR parameter since the matrix is only "close" to being consistently ordered [8]. The experiments were done on an $8 \times 8 \times 8$ grid (512 gridpoints). In Tables 6.2 and 6.3 the superscripts c and u stand for centered or upwind, respectively, R and U stand for reduced system and unreduced system, respectively, and the subscripts J and GS stand for Jacobi and Gauss–Seidel, respectively. We present the results for

two different cases, one of which has convection of moderate size, and the other with large convection, for which the upwind scheme is more effective than the centered scheme.

Note that for the unreduced system, in most cases the matrix satisfies all the conditions required for Young's SOR analysis [14]; thus, the spectral radius of the Gauss–Seidel matrix and the optimal relaxation parameter can be computed from the spectral radius of the block Jacobi matrix. By comparing Tables 6.2 and 6.3 it is evident that stationary solvers for the reduced system converge faster than for the unreduced system. In one case there is convergence for the reduced system and divergence for the unreduced system.

Moving to consider Krylov subspace solvers, in Table 6.4 we make a comparison between the performance of solvers for the two systems. The stopping criterion was relative residual smaller than 10^{-10}. The method that is used is nonpreconditioned Bi-CGSTAB. The table presents information on the complete process, namely, construction of the systems and the iterative solves. The increase in iteration counts as the grid is refined agrees with theory, at least if one assumes that for this well conditioned and mildly nonsymmetric system, the condition number is of magnitude $O(h^{-2})$ and the convergence rate is similar to that of the conjugate gradient method for symmetric positive definite systems. When one step of cyclic reduction is applied, the savings become more dramatic as the systems grow larger. An explanation for this is that the construction of the reduced system, which requires significantly more floating point operations compared with the construction of the unreduced system, becomes a less significant factor in the overall computation as the grid becomes finer. In general, since the iterative solve is the costly component of the computation, it is significant that the number of iterations until convergence of the unreduced solver is larger by a factor of approximately 2 compared with the reduced solver. Figure 6.1 illustrates the saving and the convergence behavior for this problem.

In Table 6.5 we provide some numerical evidence which suggests that the good performance of reduced solvers is due to effective preconditioning of the original matrix. In the table, estimates of the condition numbers for $p_1 = 500$, $p_2 = 200$, $p_3 = 100$ with upwind difference discretization are presented. The estimates were obtained using Matlab's command "condest." The factor of approximately 2 has been obtained for several additional cases that have been tested. More observations on the condition

number of the reduced matrix can be found in [7].

6.2. Test problem 2. Consider the nonseparable problem

$$-\Delta u + p_1 x\ \exp(x+y+z)u_x + p_2 y\ \exp(x+y+z)u_y + p_3\ z\ \exp(x+y+z)u_z = w(x,y,z)$$

on $\Omega = (0,1) \times (0,1) \times (0,1)$, with Dirichlet boundary conditions, where $w(x,y,z)$ is constructed so that the solution is (6.2). For this problem the convergence analysis of section 5 does not apply. Results are given in Table 6.6. The experiments were done for $n = 24$, so that the tensor-product grid has $13,824$ gridpoints. GMRES(5) [12] was used, preconditioned by ILU with drop tolerance of 10^{-3}. The stopping criterion was $||r_i||/||r_0|| < 10^{-7}$. In all cases that have been tested, setting up and solving the reduced system is faster compared with setting up and solving the unreduced system. It should be noted that the CPU times are affected by a long preconditioner setup time. When convection dominates, the centered scheme performs poorly. (In general, this scheme suffers numerical instability when the Reynolds numbers are large [10].) Additional numerical experiments indicate that both solvers have the property that for centered difference discretization the solver of mildly nonsymmetric systems converges faster than the solver of a close-to-symmetric system. This phenomenon was proved analytically for stationary methods for the constant coefficient case in [2] (2D) and in [9] (3D).

TABLE 6.5

100	148.2	37.3	62.1	23.8

6.3. Test problem 3. Consider the nonseparable problem

$$-0.1\Delta u + yzu_x + xzu_y + xyu_z = w,$$

with Neumann boundary conditions $u_z = 0$ on $z = 0$ and zero Dirichlet conditions for $x = 0$ and $y = 0$ on the unit cube. w was constructed so that the exact solution is $u(x, y, z) = \sin(\pi x)\sin(\pi y)\cos(\pi z)$. Here we compare the performance of a few Krylov subspace solvers; thus, the focus is on the actual iterative solve time, once the systems and the preconditioners were set up.

The results in Table 6.7 are for a $20 \times 20 \times 20$ grid. ILU(0) was used as a preconditioner. The stopping criterion was $||r_i||/||r_0|| < 10^{-7}$. In all cases the reduced solver converges faster than the unreduced solver. The factor of approximately 2 can be a good indication for the gain in performing one step of cyclic reduction in much finer grids. Bi-CGSTAB is slightly faster than CGS. These two schemes are faster than BiCG. The differences in performance between the solvers are qualitatively similar for the reduced and the unreduced systems.

TABLE 6.7
Iteration counts and solving times for three Krylov solvers.

Method	Iterations		Time (sec.)	
—-	Unreduced	Reduced	Unreduced	Reduced
BiCG	32	19	13.9	6.9
CGS	23	14	8.7	4.1
Bi-CGSTAB	19	11	8.2	3.8

7. Concluding remarks. A cyclically reduced operator for a 3D convection-diffusion equation with variable coefficients has been derived. Block orderings have been discussed, some solving techniques for the reduced system have been examined,

and numerical experiments illustrate the fact that the reduced system is easier to solve than the unreduced system.

The results presented in this work show that one step of cyclic reduction can be effectively used as a preconditioning technique for solving the convection-diffusion equation with variable coefficients. The questions of parallelism and applications are topics for further investigation.

Acknowledgments. I am very grateful to Jim Varah for carefully reading this manuscript and for his valuable advice. I would also like to thank Gene Golub, who has held helpful discussions with me and has pointed out some useful references. Many thanks to the two referees for their helpful comments and suggestions.

A SMOOTHING NEWTON METHOD FOR EXTENDED VERTICAL LINEAR COMPLEMENTARITY PROBLEMS*

HOU-DUO QI† AND LI-ZHI LIAO‡

Abstract. In this paper, we reformulate the extended vertical linear complementarity problem (EVLCP(m,q)) as a nonsmooth equation $H(t,x)=0$, where $H:\mathbb{R}^{n+1}\to\mathbb{R}^{n+1}$, $t\in\mathbb{R}$ is a parameter variable, and $x\in\mathbb{R}$ is the original variable. H is continuously differentiable except at such points (t,x) with $t=0$. Furthermore H is strongly semismooth. The reformulation of EVLCP(m,q) as a nonsmooth equation is based on the so-called aggregation (smoothing) function. As a result, a Newton-type method is proposed which generates a sequence $\{w^k=(t^k,x^k)\}$ with all $t^k>0$. We prove that every accumulation point of this sequence is a solution of EVLCP(M,q) under the assumption of row $\mathcal{W}_0$-property. If row $\mathcal{W}$-property holds at the solution point, then the convergence rate is quadratic. Promising numerical results are also presented.

1. Introduction.

Let $M_0,M_1,\dots,M_k$ be $k+1$ linear transformations from $\mathbb{R}^n$ to itself, and let $q_0,q_1,\dots,q_k$ be $k+1$ vectors in $\mathbb{R}^n$. Denote

$$M:=(M_0,M_1,\dots,M_k),\qquad q:=(q_0,q_1,\dots,q_k). \tag{1.1}$$

The extended vertical linear complementarity problem (EVLCP) associated with (M,q) is to find $x\in\mathbb{R}^n$ such that

$$G(x):=\min\{M_0x+q_0,M_1x+q_1,\dots,M_kx+q_k\}=0, \tag{1.2}$$

where min is the component minimum operator. We denote the above problem as EVLCP(M,q), which is considered by Gowda and Sznajder [15]. When M_0 equals I and q_0 is the zero vector, the resulting EVLCP(M,q), as observed by Gowda and Sznajder [15], is equivalent to the generalized complementarity problem considered by Cottle and Dantzig [7], which is now known as the vertical linear complementarity problem (VLCP). It is easy to see that when $k=1$, $M_0=I$, and $q_0=0$ EVLCP reduces to the standard linear complementarity problem (LCP) (see the book by Cottle, Pang, and Stone [8]). The VLCP has many applications such as control theory [28], the generalized bimatrix game problem [16], the generalized Leontief input-output model [11], and the nonlinear network [12]. For applications of EVLCP(M,q), see Gowda [14] and the references therein.

Several papers address both VLCP and EVLCP; see [15, 14, 29, 21, 16, 19] and the references therein. Most of these papers pay attention primarily to the theoretical

aspects including the existence and uniqueness of a solution, the boundedness of the solution set, the stability analysis of the problem involved, and extending the basic properties of LCP to their counterparts in VLCP and EVLCP. For example Mohan, Neogy, and Sridhar [21] reformulate VLCP as an LCP and extend many well-known results in LCP to VLCP. The analysis presented in [14] depends, in a somewhat crucial way, on the properties of bilinear programs and on the fact that there are only two variables in the complementarity condition (i.e., $k = 1$). In [28], Sun applied Mangasarian's iterative algorithm to EVLCP(M, q) with $k = 1$. De Schutter and De Moor [9] studied a more general version of EVLCP and developed an algorithm to find all solutions of their problem. The feasible/infeasible interior point method for EVLCP(M, q) by Sznajder and Gowda [29] considers $(k+1)n$ equations with $(k+1)n$ variables, where they extend P_0- and P-properties for square matrix to the block matrix M defined in (1.1). The new extended properties in [29] play important roles in our smoothing Newton method for EVLCP. These properties include $\mathcal{W}_0$-property and $\mathcal{W}$-property of M. Our method is based on the reformulation of EVLCP(M, q) as $(n + 1)$ equations with $(n + 1)$ variables. This reformulation, in turn, is based on the so-called aggregation function for a max-type function.

The definition of the aggregation function for a max-type function is given as follows. Let $g_i : \mathbb{R}^n \to \mathbb{R}, i = 1, \ldots, m$, be continuously differentiable functions. Define

$$g(x) := \max\{g_1(x), g_2(x), \ldots, g_m(x)\}. \tag{1.3}$$

Then $g(x)$ is continuous in $\mathbb{R}^n$ but not differentiable everywhere. Furthermore, if each g_i is an affine function, then g is a piecewise linear function. For any $t > 0$, the aggregation function $g(t, x) : \mathbb{R}^{n+1} \to \mathbb{R}^n$ is defined by

$$g(t, x) := t \ln \sum_{i=1}^{m} \exp(g_i(x)/t). \tag{1.4}$$

The function, viewed as an exponential penalty function, is intensively studied in an excellent paper [13] by Goldstein, who attributed the basic approximation formula (3.4) to his former student Chang [2]. When a multiplier method with an exponential penalty function was applied to $g(x)$, Bertsekas obtained a slight variant of $g(t, x)$ [1]. Independently, the function was studied and named as the aggregation function by Li [18]. The exponential penalty has been employed by others. For example, see Tseng and Bertsekas [30] and Kachiyan [17]. An interesting feature of $g(t, x)$ (see (3.4) below) is

$$\lim_{t \downarrow 0} g(t, x) = g(x). \tag{1.5}$$

Therefore, it is natural to define $g(0, x) = g(x)$. It can be seen that $g(t, x)$ is continuously differentiable on $\mathbb{R}_{++} \times \mathbb{R}^n$, where $\mathbb{R}_{++}$ denotes the set of all positive real numbers. Notice that

$$G(x) = -\max\{-(M_0x + q_0), -(M_1x + q_1), \ldots, -(M_kx + q_k)\}.$$

By using the aggregation technique, we can approximate nonsmooth (1.2) by the following equation:

$$G(t, x) := 0,$$

where $G(t,x):\mathbb{R}\times\mathbb{R}^n\to\mathbb{R}^n$, its ith component is defined by

$$(G(t,x))_i := \begin{cases} -|t|\ln(\sum_{j=1}^k \exp(-(M_jx+q_j)_i/|t|)) & \text{if } t\neq 0,\\ G(x) & \text{if } t=0, \end{cases} \tag{1.6}$$

and $(M_jx+q_j)_i$ denotes the ith component of vector M_jx+q_j. Furthermore, it follows from (1.5) that

$$\lim_{t\downarrow 0} G(t,x) = G(x),$$

and $G(t,x)$ is continuously differentiable whenever $t\neq 0$. Similarly, it is natural to define $G(0,x)=G(x)$. The above smoothing procedure suggests the possibility to extend the smoothing Newton methods, which were proposed recently in [26, 27, 23] for nonlinear complementarity problems and box constrained variational inequality problems, to EVLCP. The first globally and superlinearly (quadratically) convergent smoothing Newton method was proposed by Chen, Qi, and Sun in [5], where the authors exploited a Jacobian consistence property and applied this property to an infinite sequence of smoothing approximation functions to develop high-order convergent methods. We note that Chen, Qi, and Sun's smoothing Newton method is applicable to the general order complementarity problem, but their smoothing approach, as indicated in the last part of their paper, is very complicated. In this paper, we use only one smoothing approximation function $G(t,x)$ instead of an infinite sequence of functions as in [5]. In this way, our smoothing Newton method becomes much simpler.

Based on the approximation function $G(t,x)$ on $\mathbb{R}^{n+1}$, the sequence generated from our algorithm, $w^k=(t^k,x^k)$, satisfies $t^k>0$ for all k. This attractive feature stems from the fact that the smoothing parameter t is defined as the first component of the following function:

$$H(t,x) := \begin{pmatrix} t \\ G(t,x) \end{pmatrix}. \tag{1.7}$$

The equation $H(t,x)=0$ can be solved by invoking the Newton method and enforcing the parameter t positively converging to zero. Such consideration is not new (see [26, 27, 23] for details). In a recent report, Peng and Lin [22] used the aggregation function to VLCP. They proposed a continuation method via neighborhood strategy. Hence their method is quite different from ours.

The paper is organized as follows. In section 2 we introduce some generalized properties with respect to M defined in (1.1) and some preliminary properties on a semismooth function. In section 3 we study the continuity properties of the aggregation function and show that function $G(t,x)$ is a strongly semismooth function. In section 4 we present our smoothing Newton method for EVLCP(M,q). Section 5 is devoted to the global and quadratic convergence analysis of our method. In section 6 we report some preliminary numerical results on several EVLCP problems. Some concluding remarks are made in section 7.

To help the later discussion, we introduce some notation here. Let $\mathbb{R}_+$ be the set of nonnegative real numbers, $\mathbb{R}_{++}$ be the set of all positive real numbers, and e denote the vector of all ones in $\mathbb{R}^n$. For $u\in\mathbb{R}^n$, diag(u) is the diagonal matrix whose ith diagonal element is u_i. For $X\in\mathbb{R}^{n\times n}$, diag$(X)$ is the vector in $\mathbb{R}^n$ consisting of the diagonal elements of X. For a continuously differentiable function $\Phi:\mathbb{R}^n\to\mathbb{R}^m$,

we denote the Jacobian of Φ at $x \in \mathbb{R}^n$ by $\Phi'(x)$, whereas the transposed Jacobian as $\nabla\Phi(x)$. $\|\cdot\|$ denotes the Euclidean norm. If $f : \mathbb{R}^n \to \mathbb{R}$ is directionally differentiable in the classic sense, we denote $f'(x;h)$ as the derivative of f at x along direction $h \in \mathbb{R}^n$. If $L(t,x) : \mathbb{R}^{n+1} \to \mathbb{R}$ is continuously differentiable, we denote the partial gradient with respect to t and x by $\nabla_t L(t,x)$ and $\nabla_x L(t,x)$, respectively. For $R \in \mathbb{R}^{n\times n}$, R_j denotes the jth row of R. For some index set $I(x)$, $|I(x)|$ denotes the cardinality of $I(x)$. Finally let e_i denote the ith column of the identity matrix I.

2. Preliminaries. For M defined in (1.1), a matrix $R \in \mathbb{R}^{n\times n}$ is called a row representative of M if for each $j = 1, 2, \ldots, n$ the jth row of R is the jth row of some M_i, i.e.,

$$R_{j\cdot} \in \{(M_0)_{j\cdot}, (M_1)_{j\cdot}, \ldots, (M_k)_{j\cdot}\} \quad \text{for } j = 1, 2, \ldots, n.$$

Now we state a generalization of P_0- and P-properties for matrix M in (1.1).

DEFINITION 2.1 (see [29]). *Consider M given by* (1.1). *We say that M has the*

(a) *row $\mathcal{W}_0$-property if one of the following holds:*
   (i) *Determinants of all row representative matrices of M are nonnegative and there is at least one such determinant which is positive.*
   (ii) *Determinants of all row representative matrices of M are nonpositive and there is at least one such determinant which is negative.*

(b) *row $\mathcal{W}$-property if one of the following holds:*
   (i) *Determinants of all row representative matrices of M are positive.*
   (ii) *Determinants of all row representative matrices of M are negative.*

(c) *R_0-property if*

$$\min\{M_0x, M_1x, \ldots, M_kx\} = 0 \quad \Longrightarrow \quad x = 0.$$

In fact R_0-property is introduced by Gowda and Sznajder in [15]. A direct consequence of [15, Theorem 17] is that any M satisfying $\mathcal{W}$-property also satisfies R_0-property. The following two propositions reveal some results for row $\mathcal{W}$- and $\mathcal{W}_0$-properties which will be used later.

PROPOSITION 2.2 (see [29, Theorem 3]). *For M given in* (1.1), *the following are equivalent:*

(a) *M has row $\mathcal{W}$-property.*
(b) *For arbitrary nonnegative diagonal matrices $X_0, X_1, \ldots, X_k \in \mathbb{R}^{n\times n}$ with $\operatorname{diag}(X_0 + X_1 + \cdots + X_k) > 0$,*

$$\det(X_0M_0 + X_1M_1 + \cdots + X_kM_k) \neq 0.$$

PROPOSITION 2.3 (see [29, Theorem 3]). *For M given in* (1.1), *the following are equivalent:*

(1) *M has row $\mathcal{W}_0$-property.*
(2) *For arbitrary positive diagonal matrices $X_0, \ldots, X_k \in \mathbb{R}^{n\times n}$,*

$$\det(X_0M_0 + X_1M_1 + \cdots + X_kM_k) \neq 0.$$

The concept of semismoothness was originally introduced by Mifflin [20] for functionals and later was extended by Qi and Sun [25] to vector valued functions. Suppose $\Phi : \mathbb{R}^{m_1} \to \mathbb{R}^{m_2}$ is a locally Lipschitzian function. According to Rademacher's theorem, Φ is differentiable almost everywhere. Let us denote the set of points at which

Φ is differentiable by D_F. Then we define

$$\partial_B\Phi(x) := \left\{ V \in \mathbb{R}^{m_2\times m_1} |\ V = \lim_{\substack{x'\to x\\ x'\in D_F}} \Phi'(x') \right\}.$$

Let $\partial\Phi(x)$ be the generalized Jacobian defined by Clarke [6]. Then $\partial\Phi(x) = \mathrm{co}\partial_B\Phi(x)$. Suppose that Φ is directionally differentiable at x; then Φ is said to be *semismooth* at x if

$$Vh - \Phi'(x;h) = o(\|h\|), \qquad d \to 0,$$

and Φ is said to be *strongly semismooth* if

$$Vh - \Phi'(x;h) = o(\|h\|^2), \qquad d \to 0,$$

where $V \in \partial\Phi(x+h)$. If Φ is strongly semismooth at x, then for any $h \to 0$ [25]

$$\Phi(x+h) - \Phi(x) - \Phi'(x;h) = O(\|h\|^2). \tag{2.1}$$

A function Φ is said to be a (strongly) semismooth function if it is (strongly) semismooth everywhere.

3. Aggregation function and its properties. Throughout this section, we assume that each $g_i : \mathbb{R}^n \to \mathbb{R},\ i = 1, \cdots, m$, is continuously differentiable. Let $g(t,x)$ be defined in (1.4). The first result in the following proposition can be calculated directly and the other is by Chang [2].

PROPOSITION 3.1. *Let $g(t,x)$ be defined in* (1.4). *Then*

(i) *$g(t,x)$ is continuously differentiable at any point $(t,x) \in \mathbb{R}_{++}\times\mathbb{R}^n$ and its partial gradients with respect to t and x are given by*

$$\nabla_t g(t,x) = \ln\sum_{i=1}^m \exp(g_i(x)/t) - \frac{1}{t}\sum_{i=1}^m \lambda_i(t,x) g_i(x) \tag{3.1}$$

and

$$\nabla_x g(t,x) = \sum_{i=1}^m \lambda_i(t,x)\nabla g_i(x), \tag{3.2}$$

where

$$\lambda_i(t,x) = \frac{\exp(g_i(x)/t)}{\sum_{i=1}^m \exp(g_i(x)/t)} \in (0,1),\ i = 1,\ldots,m \quad \textit{and} \quad \sum_{i=1}^m \lambda_i(t,x) = 1. \tag{3.3}$$

(ii) *For any $(t,x) \in \mathbb{R}_+\times\mathbb{R}^n$,*

$$0 \le g(t,x) - g(x) \le t\ln m. \tag{3.4}$$

Let $I(x)$ denote the set of the active indices of g at x, i.e.,

$$I(x) := \{i \mid g_i(x) = g(x),\ i = 1,\ldots,m\}.$$

We note that

$$\lambda_i(t,x) = \frac{\exp((g_i(x) - g(x))/t)}{\sum_{i=1}^{m} \exp((g_i(x) - g(x))/t)}$$

and

$$\exp((g_i(x) - g(x))/t) = 1 \quad \text{if } i \in I(x), \tag{3.5}$$

$$\lim_{t\downarrow 0} \exp((g_i(x) - g(x))/t) = 0 \quad \text{if } i \notin I(x), \tag{3.6}$$

$$\lambda_i(t,x) = O(t^2), \qquad t \downarrow 0 \text{ and } i \notin I(x). \tag{3.7}$$

Therefore from (3.2) we have

$$\lim_{t\downarrow 0} \nabla_x g(t,x) = \frac{1}{|I(x)|} \sum_{i\in I(x)} \nabla g_i(x). \tag{3.8}$$

In order to show the semismoothness property of $G(t,x)$, we need to define the following. Let $\Gamma : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ be defined by

$$\Gamma(w) := \begin{cases} g(|t|,x) & \text{if } t \neq 0, \\ g(0,x) & \text{if } t = 0, \end{cases} \tag{3.9}$$

where $w = (t,x) \in \mathbb{R} \times \mathbb{R}^n$. Then it is easy to see that Γ is continuously differentiable at any point w with $t \neq 0$ and for $t < 0$

$$\nabla\Gamma(t,x) = \begin{pmatrix} -1 & 0_{1\times n} \\ 0_{n\times 1} & I_n \end{pmatrix} \nabla\Gamma(-t,x). \tag{3.10}$$

Note that $g(x)$ is a locally Lipschitz continuous function since $g(x)$ is a piecewise smooth function.

PROPOSITION 3.2. *The function $\Gamma(t,x)$ is a locally Lipschitz continuous function.*

Proof. Let $w_1 = (t_1, x_1) \in \mathbb{R} \times \mathbb{R}^n$ be given. If $t_1 \neq 0$, then Γ is continuously differentiable near w_1. Hence it is Lipschitz continuous near w_1. Now we assume $t_1 = 0$. Consider another point $w_2 = (t_2, x_2)$ near w_1. If $t_2 = 0$, then

$$\Gamma(w_2) - \Gamma(w_1) = g(x_2) - g(x_1) \leq L\|x_2 - x_1\| \leq L\|w_2 - w_1\|,$$

where L is the Lipschitz constant of g near x_1. If $t_2 \neq 0$, without loss of generality, we assume $t_2 > 0$. Then from (3.4)

$$\begin{aligned} &\Gamma(w_2) - \Gamma(w_1) = \Gamma(t_2, x_2) - \Gamma(t_2, x_1) + \Gamma(t_2, x_1) - \Gamma(0, x_1) \\ &\leq L\|x_2 - x_1\| + t_2 \ln m \leq \sqrt{2}(L + \ln m)\|w_2 - w_1\|, \end{aligned}$$

where L is the uniform Lipschitz constant of $\Gamma(t_2, \cdot)$ near w_1. Hence Γ is locally Lipschitz continuous. □

Since we will apply the above results to EVLCP(M,q), we are interested in the case where functions $g_i,\ i=1,\ldots,m$, are affine functions. Let $a_i\in\mathbb{R}^n,\ b_i\in\mathbb{R},\ i=1,\ldots,m$. We assume that

$$g_i(x)=a_i^Tx+b_i,\quad i=1,\ldots,m.$$

Then $g(x)$ defined by (1.3) is a continuously piecewise linear function and hence it is strongly semismooth. It is easy to verify that the directional derivative of g at x along any direction $d\in\mathbb{R}^n$ is given by

$$g'(x;d)=\max_{i\in I(x)}a_i^Td. \tag{3.11}$$

In the rest of the paper, we assume that each g_i is an affine function. In order to establish the strong semismoothness of functions $G(t,x)$ and $H(t,x)$, we need the following two results.

LEMMA 3.3. *Let $x\in\mathbb{R}^n, d\in\mathbb{R}^n$ be given. Then*

(i) *$I(x+h)\subseteq I(x)$ holds for all $\|h\|$ sufficiently small.*

(ii) *$g_i'(x+h;d)=g'(x;d)$ for all $i\in I(x+h)$ holds for all $\|h\|$ sufficiently small.*

Proof. (i) If the statement is not true, there exists a sequence $\{h^k\}\subset\mathbb{R}^n$ with $\|h^k\|\to 0$ and an index $i(k)\in I(x+h^k)$ but $i(k)\notin I(x)$. By subsequencing, we assume, without loss of generality, that $i(k)=i$ for all k. From the definition of $I(x+h^k)$, we have

$$g_i(x+h^k)=g(x+h^k).$$

From the continuity of g and g_i, we obtain $g_i(x)=g(x)$, which indicates that $i\in I(x)$. This contradiction establishes (i).

(ii) Let h be sufficiently small such that $I(x+h)\subseteq I(x)$. Let $i\in I(x+h)$ and $j\in I(x)$. We have

$$a_i^T(x+h)+b_i\geq a_j^T(x+h)+b_j. \tag{3.12}$$

Since $i\in I(x)$, we have

$$a_i^Tx+b_i=a_j^Tx+b_j. \tag{3.13}$$

Equations (3.12) and (3.13) imply that

$$a_i^Th\geq a_j^Th.$$

Hence

$$a_i^Th=\max_{j\in I(x)}\{a_j^Th\}.$$

This equality establishes (ii). ∎

PROPOSITION 3.4. *Assume that $g_i,\ i=1,\ldots,m$, are affine functions. Then $\Gamma:\mathbb{R}\times\mathbb{R}^n$ defined by (3.9) is a strongly semismooth function.*

Proof. Let $w=(t,x),\ h=(h_1,h_2)\in\mathbb{R}\times\mathbb{R}^n$. To show Γ is strongly semismooth at w, it suffices to verify

$$Vh-\Gamma'(w;h)=O(\|h\|^2)\quad\text{for any } V\in\partial\Gamma(w+h), h\to 0. \tag{3.14}$$

From (3.9) and (3.10), it is easy to see that Γ is at least twice continuously differentiable at any $w = (t, x) \in \mathbb{R} \times \mathbb{R}^n$ with $t \neq 0$. Thus we need only to verify (3.14) at any $w = (0, x)$. There are two cases.

Case 1. $h_1 = 0$. Then

$$\Gamma'(w;h) = \lim_{\tau \downarrow 0} \frac{\Gamma(w+\tau h) - \Gamma(w)}{\tau} = \lim_{\tau \downarrow 0} \frac{g(x+\tau h_2) - g(x)}{\tau} = g'(x;h_2). \tag{3.15}$$

Let $V = \begin{pmatrix} V_1 \\ V_2 \end{pmatrix} \in \partial\Gamma(w+h)$, it follows from $h_1 = 0$ that

$$Vh = V_2 h_2. \tag{3.16}$$

From (3.8) and (3.10) it can be seen that

$$V_2 \in \operatorname{co}\left\{ \frac{1}{|I(x+h_2)|} \sum_{i \in I(x+h_2)} \nabla g_i(x+h_2), \partial_B g(x+h_2) \right\}.$$

Since $\partial_B g(x+h_2)$ is finite, (3.15) and (3.16) indicate that (3.14) is equivalent to

$$V_2 h_2 - g'(x;h_2) = O(\|h\|^2) \tag{3.17}$$

for $h \to 0$ and

$$V_2 = \frac{1}{|I(x+h_2)|} \sum_{i \in I(x+h_2)} \nabla g_i(x+h_2) \quad \text{or} \quad V_2 \in \partial_B g(x+h_2). \tag{3.18}$$

Since $g(x)$ is strongly semismooth (continuously piecewise linear), (3.17) holds for $V_2 \in \partial_B g(x+h_2)$. If V_2 takes the first value in (3.18), we have

$$V_2 h_2 = \frac{1}{|I(x+h_2)|} \sum_{i \in I(x+h_2)} g_i'(x+h_2;h_2).$$

By Lemma 3.3, we have

$$V_2 h_2 - g'(x;h) = 0 = O(\|h\|^2) \quad \text{for all} \quad h \to 0.$$

Hence (3.17) is true for Case 1.

Case 2. $h_1 \neq 0$. We assume $h_1 > 0$; the case $h_1 < 0$ can be proved similarly. We note that

$$\begin{aligned}
\Gamma'(w;h) &= \lim_{\tau \downarrow 0} (\Gamma(w+\tau h) - \Gamma(w))/\tau \\
&= \lim_{\tau \downarrow 0} (\Gamma(\tau h_1, x+\tau h_2) - \Gamma(0,x))/\tau \\
&= \lim_{\tau \downarrow 0} \frac{\tau h_1 \ln\left(\sum_{i=1}^m \exp(g_i(x+\tau h_2)/(\tau h_1))\right) - g(x)}{\tau} \\
&= \lim_{\tau \downarrow 0} h_1 \ln\left(\sum_{i=1}^m \exp[(g_i(x+\tau h_2) - g(x))/(\tau h_1)]\right) \\
&= h_1 \ln \sum_{i \in I(x)} \exp(g_i'(x;h_2)/h_1) \\
&= h_1 \ln \sum_{i \in I(x)} \exp(a_i^T h_2/h_1).
\end{aligned}$$

The fifth equality involves (3.6). In addition, we have

$$\begin{aligned}\Delta_1 :&= h_1 \ln \sum_{i=1}^{m} \exp(g_i(x+h_2)/h_1) - g(x)\\ &= h_1 \ln \sum_{i=1}^{m} \exp((g_i(x+h_2) - g(x))/h_1)\\ &= h_1 \ln \left[\sum_{i\in I(x)} \exp((g_i(x+h_2) - g(x))/h_1) + \sum_{i\notin I(x)} \exp((g_i(x+h_2) - g(x))/h_1) \right]\\ &= h_1 \ln \left[\sum_{i\in I(x)} \exp(a_i^T h_2/h_1) + \sum_{i\notin I(x)} \exp((g_i(x+h_2) - g(x))/h_1) \right]\end{aligned}$$

and

$$\begin{aligned}\Delta_2 :&= \sum_{i=1}^{m} \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 + g(x) - \sum_{i=1}^{m} \lambda_i(h_1, x+h_2) g_i(x+h_2)\\ &= \sum_{i=1}^{m} \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 - \sum_{i=1}^{m} \lambda_i(h_1, x+h_2)[g_i(x+h_2) - g(x)]\\ &= \sum_{i\in I(x)} \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 - \sum_{i\in I(x)} \lambda_i(h_1, x+h_2)[g_i(x+h_2) - g(x)]\\ &\quad + \sum_{i\notin I(x)} \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 - \sum_{i\notin I(x)} \lambda_i(h_1, x+h_2)[g_i(x+h_2) - g(x)]\\ &= \sum_{i\notin I(x)} \lambda_i(h_1, x+h_2)(a_i^T h_2) - \sum_{i\notin I(x)} \lambda_i(h_1, x+h_2)[g_i(x+h_2) - g(x)].\end{aligned}$$

The second equality in Δ_2 observes the fact $\sum_{i=1}^{m} \lambda_i(h_1, x+h_2) = 1$. From (3.7), we have for each $i \notin I(x)$

$$\lambda_i(h_1, x+h_2) = O(h_1^2) \quad \text{for } \ h \to 0.$$

Hence

$$\Delta_2 = O(\|h\|^2). \tag{3.19}$$

Let $j \notin I(x),\ i \in I(x),\ \epsilon > 0$; then there exists a $\delta > 0$ such that

$$g_j(x+h_2) - g_i(x+h_2) \le \epsilon \tag{3.20}$$

for all $\|h\| \le \delta$. Then from (3.20)

$$\begin{aligned}&\exp[(g_j(x+h_2) - g(x))/h_1] / \exp(a_i^T h_2/h_1)\\ &= \exp[(g_j(x+h_2) - g(x) - a_i^T h_2)/h_1]\\ &= \exp[(g_j(x+h_2) - g_i(x+h_2))/h_1]\\ &\le \exp(-\epsilon/h_1)\end{aligned}$$

for all $\|h\| \le \delta$. Thus we have for all h with $\|h\|$ sufficiently small

$$\begin{aligned}
&\Delta_1 - \Gamma'(w;h)\\
&= h_1 \ln\left[\sum_{i\in I(x)} \exp(a_i^T h_2/h_1) + \sum_{i\notin I(x)} \exp((g_i(x+h_2)-g(x))/h_1)\right]\\
&\quad -h_1 \ln \sum_{i\in I(x)} \exp(a_i^T h_2/h_1)\\
&= h_1 \ln\left(1 + \frac{\displaystyle\sum_{i\notin I(x)} \exp((g_i(x+h_2)-g(x))/h_1)}{\displaystyle\sum_{i\in I(x)} \exp(a_i^T h_2/h_1)}\right)\\
&\le h_1 \ln\left(1 + \sum_{i\notin I(x)} \exp(-\epsilon/h_1)\right)\\
&= O(\|h_1\|^2) = O(\|h\|^2). \qquad (3.21)
\end{aligned}$$

It follows from (3.19) and (3.21) that

$$\begin{aligned}
&Vh - \Gamma'(w;h)\\
&= h_1 \ln \sum_{i=1}^m \exp(g_i(x+h_2)/h_1) - \sum_{i=1}^m \lambda_i(h_1, x+h_2) g_i(x+h_2)\\
&\quad + \sum_{i=1}^m \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 - \Gamma'(w;h)\\
&= h_1 \ln \sum_{i=1}^m \exp(g_i(x+h_2)/h_1) - g(x) - \Gamma'(w;h)\\
&\quad + \sum_{i=1}^m \lambda_i(h_1, x+h_2)(\nabla g_i(x+h_2))^T h_2 - \sum_{i=1}^m \lambda_i(h_1, x+h_2) g_i(x+h_2) + g(x)\\
&= \Delta_1 - \Gamma'(w;h) + \Delta_2 = O(\|h\|^2).
\end{aligned}$$

Hence (3.17) is true for Case 2. □

Now we can state the main result of this section.

THEOREM 3.5. *Function $G(t,x)$ defined in* (1.6) *is a strongly semismooth function. Consequently function $H(t,x)$ is also a strongly semismooth function.*

Proof. We note that the ith component of $G(t,x)$ is defined by $-\Gamma(t,x)$ with $m = k$ and $g_j(x) = -[(M_j)_{i\cdot}x + (q_j)_i]$, $j = 1,\dots,k$. Hence each g_j is an affine function. By Proposition 3.4, $(G(t,x))_i$ is strongly semismooth. Then $G(t,x)$ is strongly semismooth since a function is strongly semismooth if and only if its component functions are [25, Corollary 2.4]. Linear function t is strongly semismooth; hence the strong semismoothness of $G(t,x)$ implies the strong semismoothness of $H(t,x)$. □

4. A smoothing Newton method for EVLCP. Theorem 3.5 indicates that we can approximate the nonsmooth function $G(x)$ by a strongly semismooth function $H(t,x)$ given in (1.7) through the aggregation technique. It is easy to see that a solution of EVLCP(M,q) must be a zero point of $H(t,x)$. This observation plays a key role in the development of our smoothing Newton method. The idea behind

our smoothing Newton method is to solve equation $H(t,x) = 0$ approximately for every smoothing parameter $t > 0$ and gradually reduce t to zero. Hopefully, as t approaches zero, the iterate approaches to a solution of EVLCP(M,q). Note that our reformulation function (1.7) includes the parameter t as a function component; our method will adjust t to zero in the limit. Since the parameter t always remains positive in our method, we assume $t > 0$ in the rest of the paper. To develop our new method, we define $g^j : \mathbb{R}^n \to \mathbb{R}^n$ as

$$g^j(x) = M_j x + q_j, \quad j = 0, 1, \ldots, k,$$

where M_j and q_j are given in (1.1). Hence each component of $G(t,x)$ has the form

$$(G(t,x))_i = -t \ln \sum_{j=0}^{k} \exp(-(g^j(x))_i/t).$$

Since the Jacobian matrix $H'(t,x)$ will play an important role in the later convergence analysis, it would be beneficial to exploit its structure. By Proposition 3.1(i), we have for each $i = 1, \ldots, n$

$$\frac{\partial (G(t,x))_i}{\partial t} = -\ln \left(\sum_{j=0}^{k} \exp(-(g^j(x))_i/t) \right) - \frac{1}{t} \sum_{j=0}^{k} \lambda_j^i(t,x)(g^j(x))_i$$

and

$$\frac{\partial (G(t,x))_i}{\partial x} = \sum_{j=0}^{k} \lambda_j^i(t,x)(g^j(x))_i',$$

where

$$\lambda_j^i(t,x) = \frac{\exp(-(g^j(x))_i/t)}{\sum_{j=0}^{k} \exp(-(g^j(x))_i/t)} \in (0,1) \quad \text{and} \quad \sum_{j=0}^{k} \lambda_j^i(t,x) = 1.$$

Note that for each $j = 0, 1, \ldots, k$

$$(\nabla g^j(x))^T = M_j,$$

then

$$(\nabla_x G(t,x))^T = \sum_{j=0}^{k} \Lambda_j M_j,$$

where

$$\Lambda_j = \operatorname{diag}(\lambda_j^1(t,x), \lambda_j^2(t,x), \ldots, \lambda_j^n(t,x)), \ j = 0, 1, \ldots, k. \tag{4.1}$$

Let

$$r = \left(\frac{\partial (G(t,x))_1}{\partial t}, \ldots, \frac{\partial (G(t,x))_n}{\partial t} \right)^T \in R^n.$$

Then the Jacobian matrix of H has the form

$$H'(t,x) = \begin{pmatrix} 1 & 0_{1\times n} \\ r & \sum_{j=0}^{k} \Lambda_j M_j \end{pmatrix}. \tag{4.2}$$

PROPOSITION 4.1. *Let $H(t,x)$ be defined in* (1.7). *Then $H(t,x)$ is continuously differentiable at any point $(t,x) \in \mathbb{R}_{++} \times \mathbb{R}^n$. If M satisfies row $\mathcal{W}_0$-property, then the Jacobian matrix $H'(t,x)$ is nonsingular at any point $(t,x) \in \mathbb{R}_{++} \times \mathbb{R}^n$.*

Proof. For any point $(t,x) \in \mathbb{R}_{++} \times \mathbb{R}^n$, it has been observed that $H(t,x)$ is continuously differentiable at such point. If M satisfies row $\mathcal{W}_0$-property, it follows from Proposition 2.3 and (4.2) that

$$\det H'(t,x) = \det(\Lambda_0 M_0 + \Lambda_1 M_1 + \cdots + \Lambda_k M_k) \neq 0$$

since $\sum_{j=0}^{k} \Lambda_j = I$. Therefore, $H'(t,x)$ is nonsingular at any point $(t,x) \in \mathbb{R}_{++} \times \mathbb{R}^n$. □

Now select $\bar{t} \in \mathbb{R}_{++}$, $\gamma \in (0,1)$ such that $\gamma\bar{t} < 1$, and let $\bar{w} := (\bar{t}, 0) \in \mathbb{R}_{++} \times \mathbb{R}^n$. Then we define the merit function $\psi : \mathbb{R}^{n+1} \to \mathbb{R}_+$ by

$$\psi(w) := \|H(w)\|^2 = t^2 + \|G(t,x)\|^2,$$

where $w = (t,x) \in \mathbb{R}^{n+1}$, and we define $\beta : \mathbb{R}^{n+1} \to \mathbb{R}_+$ by

$$\beta(w) := \gamma \min\{1, \psi(w)\}.$$

It is easy to see that

$$\beta(w) \leq \gamma\psi(w)^{1/2}. \tag{4.3}$$

Let

$$\Omega := \{w = (t,x) \in \mathbb{R} \times \mathbb{R}^n \mid t \geq \beta(w)\bar{t}\}.$$

Then, because for any $w \in \mathbb{R}^{n+1}, \beta(w) \leq \gamma < 1$, it follows that for any $x \in \mathbb{R}^n$,

$$(\bar{t}, x) \in \Omega.$$

The above discussion leads to our new algorithm, which is a modification of the algorithm used in [26, 23, 27] for nonlinear complementarity problems and box constrained variational inequality problems. The modification allows the original algorithm to be applicable for EVLCP. Our new algorithm will generate a sequence in Ω. In section 5 we will show that, even if Ω is unbounded, the generated sequence remains bounded under mild conditions.

ALGORITHM 4.2 (smoothing Newton method for EVLCP).

(S.0) (Initialization)

Choose constants δ, $\gamma \in (0,1)$, $\bar{t} > 0$ with $\gamma\bar{t} < 1$ and $\sigma \in (0, 1/2)$. Let $t^0 = \bar{t}$, $x^0 \in \mathbb{R}^n$ be arbitrary point, $\bar{w} = (\bar{t}, 0)$, $w^0 = (t^0, x^0)$, and $k = 0$.

(S.1) (Termination criterion)

If $H(w^k) = 0$ then stop. Otherwise, let $\beta_k := \beta(w^k)$.

(S.2) (Modified Newton direction)

Compute $\Delta w^k := (\Delta t^k, \Delta x^k) \in \mathbb{R} \times \mathbb{R}^n$ by

$$H(w^k) + H'(w^k)\Delta w^k = \beta_k \bar{w}. \tag{4.4}$$

(S.3) (Line search strategy)
Let ℓ_k be the smallest nonnegative integer ℓ satisfying

$$\psi(w^k + \delta^\ell \Delta w^k) \le [1 - 2\sigma(1 - \gamma\bar{t})\delta^\ell]\psi(w^k). \tag{4.5}$$

Define $w^{k+1} := w^k + \delta^{\ell_k}\Delta w^k$, $k := k + 1$, go to (S.1).

Remarks. The direction Δw^k computed in (4.4) is a little bit different from the conventional Newton direction because $\beta_k \bar{w}$ is introduced in the right-hand side of (4.4). However, as $H(w^k)$ approaches zero, β_k goes to zero as well. Therefore, direction Δw^k would converge to Newton direction in the limit. The special structure of the Jacobian matrix as shown in (4.4) and the extra term $\beta_k \bar{w}$ in (4.4) benefit Algorithm 4.2 in at least the following two aspects: (a) they guarantee that all t^k are positive, and (b) they ensure that the whole iteration sequence $\{w^k\}$ always stays in Ω (see Propositions 4.3–4.5 for proofs). Before any proofs, the following two questions must be answered:

(i) Is Algorithm 4.2 well defined?

(ii) What are the convergence (global and local) results of Algorithm 4.2?

Qi, Sun, and Zhou [26] have established a standard procedure in addressing (i) and (ii) for their methods. The following discussion on Algorithm 4.2 follows the similar argument as in [26]. To avoid the interruption of our presentation, the proofs of Propositions 4.3 and 4.4 are moved to the appendix.

PROPOSITION 4.3. *Suppose that M satisfies row $\mathcal{W}_0$-property. For any $k \ge 0$, if $w^k = (t^k, x^k) \in \mathbb{R}_{++} \times \mathbb{R}^n$, then Algorithm 4.2 is well defined at the kth iteration and $w^{k+1} = (t^k, x^k) \in \mathbb{R}_{++} \times \mathbb{R}^n$.*

PROPOSITION 4.4. *Suppose that M satisfies row $\mathcal{W}_0$-property. For each fixed $k \ge 0$, if $t^k > 0$, $w^k \in \Omega$, then for any $\alpha \in [0, 1]$ such that*

$$\psi(w^k + \alpha\Delta w^k) \le [1 - 2\sigma(1 - \gamma\bar{t})\alpha]\psi(w^k), \tag{4.6}$$

we have $w^k + \alpha\Delta w^k \in \Omega$.

PROPOSITION 4.5. *Suppose that M satisfies row $\mathcal{W}_0$-property. Then any sequence $\{w^k = (t^k, x^k)\}$ (properly initialized) generated by Algorithm 4.2 satisfies $t^k \in \mathbb{R}_{++}$ and $w^k \in \Omega$ for all $k \ge 0$.*

Proof. First, because $w^0 = (\bar{t}, x^0) \in \Omega$, we have from Propositions 4.3 and 4.4 that w^1 is well defined, $t^1 > 0$, and $w^1 \in \Omega$. Then, by repeatedly resorting to Propositions 4.3 and 4.4, we can prove that an infinite sequence $\{w^k\}$ can be generated with $t^k > 0$ and $w^k \in \Omega$ for the whole sequence. ∎

5. Global and quadratic convergence. Thus far, we have answered the first question raised in section 4 for Algorithm 4.2. In this section, we will address the second one. First, let us focus on the global convergence. The proof of the following global convergence result is relatively long, so we have put it in the appendix.

THEOREM 5.1. *Suppose that M satisfies row $\mathcal{W}_0$-property and an infinite sequence $\{w^k = (t^k, x^k)\}$ is generated by Algorithm 4.2. Then each accumulation point $\tilde{w}$ of $\{w^k\}$ is a solution of $H(w) = 0$.*

Theorem 5.1 states that any accumulation point of $\{w^k\}$ generated by Algorithm 4.2, if it exists, is a solution of $H(w) = 0$; hence the x-part of any accumulation point is a solution of EVLCP(M, q). It is necessary and essential to know when such an accumulation point exists. In the following, we will show that R_0-property of M provides a sufficient condition. First, we define the level set of $\psi(w)$ as

$$\mathcal{L}(w^0) := \{w \in \mathbb{R}^{n+1} \,|\, \psi(w) \le \psi(w^0)\}.$$

THEOREM 5.2. *Suppose that M satisfies R_0-property; then $\mathcal{L}(w^0)$ is bounded.*

Proof. Since $\psi(w) = t^2 + \|G(t,x)\|^2$, for all $w = (t,x) \in \mathcal{L}(w^0)$, we have

$$|t| \le \psi(w^0)^{1/2} \quad \text{and} \quad \|G(t,x)\| \le \psi(w^0)^{1/2}. \tag{5.1}$$

From Proposition 3.1(ii), for each component of $G(t,x)$ we have

$$-(G(0,x))_i \le -(G(t,x))_i \le -(G(0,x))_i + |t| \ln k, \ i = 1, \ldots, n.$$

For all $w = (t,x) \in \mathcal{L}(w^0)$, from (5.1), we have

$$-\psi(w)^{1/2} \le (G(0,x))_i \le (1 + \ln k)\psi(w)^{1/2}, \ i = 1, \ldots, n. \tag{5.2}$$

Then, for all $w = (t,x) \in \mathcal{L}(w^0)$, (5.2) is equivalent to the system

$$-\psi(w)^{1/2} e \le \min\{M_0 x + q_0, M_1 x + q_1, \ldots, M_k x + q_k\} \le (1 + \ln k)\psi(w)^{1/2} e. \tag{5.3}$$

If this theorem is not true, there must exist a sequence $w^k = (t^k, x^k) \in \mathcal{L}(w^0)$ such that $\|w^k\| \to \infty$. Since t^k is bounded by $\psi(w^0)^{1/2}$, it must hold that $\|x^k\| \to \infty$. Without loss of generality, we assume that $x^k/\|x^k\| \to \bar{x}$. Then $\|\bar{x}\| = 1$. Replacing x by x^k and dividing inequality (5.3) by $\|x^k\|$ on both sides and taking the limit, we obtain

$$\min\{M_0 \bar{x}, M_1 \bar{x}, \ldots, M_k \bar{x}\} = 0.$$

However, R_0-property of M implies $\bar{x} = 0$, and the contradiction establishes the result. □

An M satisfying row $\mathcal{W}_0$-property does not necessarily satisfy R_0-property, as the following example shows.

EXAMPLE 5.3. Let $M = (M_1, M_2)$, where

$$M_1 = \begin{bmatrix} 2 & 1 \\ 0 & 0 \end{bmatrix}, \qquad M_2 = \begin{bmatrix} 0 & 0 \\ 1 & 2 \end{bmatrix}.$$

By simple computation, the determinants of all row representative matrices of M are nonnegative and the determinant of the row representative matrix R is positive; here

$$R = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}.$$

Hence M satisfies $\mathcal{W}_0$-property. The solution set of the system $\min\{M_1 x, M_2 x\} = 0$ is the nonnegative orthant R^2_+; hence M does not satisfy R_0-property.

Now we state the quadratic convergence result of Algorithm 4.2. The proof is provided in the appendix.

THEOREM 5.4. *Suppose that M satisfies row $\mathcal{W}_0$-property and w^* is an accumulation point of the infinite sequence $\{w^k\}$ generated by Algorithm 4.2. If all elements $V \in \partial H(w^*)$ are nonsingular, then the sequence $\{w^k\}$ converges to w^* quadratically, i.e.,*

$$\|w^{k+1} - w^*\| = O(\|w^k - w^*\|^2), \quad t^{k+1} = O((t^k)^2). \tag{5.4}$$

In addition, $l_k = 0$, i.e., the full step will be accepted, for sufficiently large k.

Now we show that row $\mathcal{W}$-property ensures the nonsingularity of all elements in $\partial H(w^*)$.

PROPOSITION 5.5. *Suppose that $w^* = (t^*, x^*) \in \mathbb{R}\times\mathbb{R}^n$ is a solution of $H(w) = 0$. If M satisfies row $\mathcal{W}$-property, then all elements $V \in \partial H(w^*)$ are nonsingular.*

Proof. Let $\mathcal{S}$ be the set of all $n \times n$ matrices V with the form

$$V = \sum_{j=0}^{k} X_j R_j,$$

where $X_j,\ j = 0, 1, \ldots, k$, are nonnegative diagonal matrices; $\sum_{j=0}^{k} \operatorname{diag}(X_j) > 0$; and $R_j,\ j = 0, 1, \ldots, k$, are row representative matrices of M. Since M satisfies $\mathcal{W}$-property, from Proposition 2.2, such matrix V is nonsingular. Then it is easy to see from (3.10) that

$$\partial_x H(w^*) \subset \mathcal{S}.$$

Hence all elements in $\partial H(w^*)$ are nonsingular. □

Besides row $\mathcal{W}$-property, other sufficient conditions for the nonsingularity of the elements in $\partial H(w^*)$ do exist—for example, the strict complementarity condition. Roughly speaking, sufficient conditions studied in nonlinear complementarity problems can be extended to their EVLCP counterparts. These extensions should be straightforward. To conclude the section, we stress that the results obtained for EVLCP can be obtained similarly for VLCP since the latter is a special case of the former.

6. Preliminary numerical results. In this section, some numerical experiments will be reported for Algorithm 4.2. First we would like to replace the classical monotone Armijo condition (4.5) in Algorithm 4.2 by a nonmonotone line search. The new (S.3) for Algorithm 4.2 is given as follows.

(S.3′) Let ℓ_k be the smallest nonnegative integer ℓ satisfying

$$w^k + \delta^\ell \Delta w^k \in \Omega \tag{6.1}$$

and

$$\psi(w^k + \delta^\ell \Delta w^k) \le \mathcal{W} - 2\sigma(1 - \gamma\bar{t})\delta^\ell \psi(w^k), \tag{6.2}$$

where $\mathcal{W}$ is any value satisfying

$$\psi(w^k) \le \mathcal{W} \le \max_{j=0,1,\ldots,M^k} \psi(w^{k-j})$$

and M^k are nonnegative integers bounded above for all k such that the occurrence of nonnegative indices does not happen. Define $w^{k+1} := w^k + \delta^{\ell_k}\Delta w^k$, $k := k + 1$, go to (S.1).

The reason we choose a nonmonotone line search here is that in most cases it increases the stability of algorithms. The requirement (6.1), which automatically holds for Algorithm 4.2, is to guarantee the global convergence of the algorithm. In our implementation, $\mathcal{W}$ is chosen as follows:

(1) Set $\mathcal{W} = \psi(w^0)$ at the beginning of the algorithm.

(2) Keep the value of $\mathcal{W}$ fixed as long as

$$\psi(w^k) \le \min_{j=0,1,\ldots,5} \psi(w^{k-j}). \tag{6.3}$$

(3) If (6.3) is not satisfied at the kth iteration, set $\mathcal{W} = \psi(w^k)$.

Algorithm 4.2 with above adjustments was implemented in MATLAB on an SGI INDIGO workstation. In all computation, the termination criterion is $\psi(w^k) \le 10^{-12}$ and the setting for all parameters is $\sigma = 0.5 \times 10^{-4}$, $\delta = 0.5$, $\bar{t} = 1$, $\gamma = 0.2$. Our numerical results are summarized in Table 6.1 where the following data are reported: Example—number of test example, Dim—dimension of the test problem, SP—starting point, Iter—number of iterations needed until termination, NF—number of function evaluation needed until termination, FF—value of $\psi(\cdot)$ at the final iterate.

The following is a brief description of the test problems.

EXAMPLE 6.1. This is a problem from [10] with $n = 2,\ k = 2,\ M_0 = I,\ q_0 = 0$, and

$$M_1 = \begin{pmatrix} 3 & -2 \\ -4 & 5 \end{pmatrix},\ M_2 = \begin{pmatrix} 4 & -4 \\ -1 & 2 \end{pmatrix},\ q_1 = q_2 = (-1,-1)^T.$$

M satisfies $\mathcal{W}$-property; hence EVLCP(M,q) has a unique solution $x = (2.25, 2)^T$.

EXAMPLE 6.2. This is a VLCP with $k = 4,\ M_0 = I,\ q_0 = 0,\ q_2 = q_3 = (-1,\ldots,-1)^T$,

$$M_1 = \begin{bmatrix} 4 & -2 & 0 & \cdots & 0 \\ -2 & 4 & -2 & \cdots & 0 \\ 0 & -2 & 4 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & -2 \\ 0 & 0 & 0 & \cdots & 4 \end{bmatrix}, \quad M_2 = \begin{bmatrix} 1 & 1 & 0 & \cdots & 0 \\ 1 & 2 & 1 & \cdots & 0 \\ 0 & 1 & 2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 2 \end{bmatrix},$$

and M_3 is same as M_1 except $M_3(1,1) = 2,\ M_3(2,1) = 2,\ M_3(2,3) = 2$, and $M_3(n,n) = 2$. M satisfies $\mathcal{W}$-property.

EXAMPLE 6.3. This is an example satisfying $\mathcal{W}_0$-property. $M_0 = I, q_0 = 0$, and

$$M_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 1 \end{bmatrix}, \quad M_2 = \begin{bmatrix} 0 & -1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad q_1 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad q_2 = \begin{bmatrix} 3/4 \\ -1/2 \\ 0 \end{bmatrix}.$$

The solution set is $\{(0, x_2, 0) |\, 1/2 \le x_2 \le 3/4\} \cup \{(x_1, 3/4, 0) |\, x_1 \ge 0\}$.

We note that the matrices M_2, M_3 in Example 6.3 are singular; however, our method can still satisfactorily solve this problem from various starting points. Based on the limited numerical results presented above, it can be seen that the proposed algorithm works very well for all test problems with various dimensions.

7. Concluding remarks. In this paper, we reformulate EVLCP(M,q) as a nonsmooth equation via the aggregation function. Strong semismoothness of the aggregation function is proved for the linear case. As a result, we are able to propose a smoothing Newton method for the nonsmooth equation. Both the global and the local convergence of the proposed method under mild conditions are proved. The numerical results confirm our theoretical analysis.

The aggregation function plays an important role in this paper. A very interesting feature of the function can be seen as follows. Notice that

$$\min\{x, f(x)\} = -\max\{-x, -f(x)\} = x - (x - f(x))_+;$$

TABLE 6.1
Numerical results of Examples 6.1–6.3.

Example	Dim	SP	Iter	NF	FF
6.1	2	(1, 1)	6	7	2.3e-21
		(0, 0)	8	9	2.5e-18
6.2	6	(3,$\cdots$,3)	8	17	3.1e-20

	48	(1,$\cdots$,1)	12	19	4.4e-13
	100	(1,$\cdots$,1)	14	23	3.2e-13
6.3	3	(0, 0, 0)	7	8	2.2e-15
		(1, 1, 1)	5	6	3.0e-16
		(1, 2, 3)	6	9	4.1e-14
		(-1,-1,-1)	7	8	8.6e-24

if the aggregation function is applied directly to the above function, we obtain

$$\begin{aligned} g(t,x) &= -t\ln(\exp(-x/t)+\exp(-f(x)/t)) \\ &= x - t\ln(1+\exp((x-f(x))/t)). \end{aligned}$$

This function is exactly the smoothing function obtained by using the neural network smoothing function to the function $x-(x-f(x))_+$ in [4]. In fact, the aggregation function and the smoothing function in [4] share many similar properties [22]. It would be very useful and practical to explain why they have so many similarities.

Appendix.

Proof of Proposition 4.3. If $t^k \in \mathbb{R}_{++}$, it is easy to see $\beta_k = \beta(w^k) > 0$. Since M satisfies $\mathcal{W}_0$-property, it follows from Proposition 4.1 that $H'(w^k)$ is nonsingular. Hence Δw^k can be computed by (4.4). From the structure of $H'(w^k)$, we have

$$\Delta t^k = -t^k + \beta_k \bar{t}. \tag{A.1}$$

Hence for any $\alpha \in [0,1]$, we have

$$t^k + \alpha \Delta t^k = (1-\alpha)t^k + \alpha\beta_k\bar{t}. \tag{A.2}$$

Then, from (4.3) and (A.2), for any $\alpha \in [0,1]$, we have

$$\begin{aligned} &(t^k+\alpha\Delta t^k)^2 \\ &= (1-\alpha)^2(t^k)^2 + 2\alpha(1-\alpha)\beta_k t^k\bar{t} + \alpha^2\beta_k^2\bar{t}^2 \\ &\le (1-\alpha)^2(t^k)^2 + 2\alpha\beta_k t^k\bar{t} + O(\alpha^2) \\ &\le (1-\alpha)^2(t^k)^2 + 2\alpha\gamma\bar{t}\psi(w^k)^{1/2}\|H(w^k)\| + O(\alpha^2) \\ &= (1-\alpha)^2(t^k)^2 + 2\alpha\gamma\bar{t}\psi(w^k) + O(\alpha^2). \end{aligned} \tag{A.3}$$

Define

$$f(\alpha) := G(w^k+\alpha\Delta w^k) - G(w^k) - \alpha G'(w^k)\Delta w^k.$$

Since $G(\cdot)$ is continuously differentiable at $w^k \in \mathbb{R}_{++}\times\mathbb{R}^n$, then

$$f(\alpha) = o(\alpha).$$

From the second part of (4.4), we have

$$G'(w^k)\Delta w^k = -G(w^k).$$

Hence

$$\begin{aligned}
&\|G(w^k + \alpha\Delta w^k)\|^2 \\
&= \|G(w^k) + \alpha G'(w^k)\Delta w^k + f(\alpha)\|^2 \\
&= \|(1-\alpha)G(w^k) + f(\alpha)\|^2 \\
&= (1-\alpha)^2\|G(w^k)\|^2 + 2(1-\alpha)G(w^k)^T f(\alpha) + \|f(\alpha)\|^2 \\
&= (1-\alpha)^2\|G(w^k)\|^2 + o(\alpha). \qquad \text{(A.4)}
\end{aligned}$$

It then follows from (A.4) and (A.3) that for all $\alpha \in [0,1]$, we have

$$\begin{aligned}
&\psi(w^k + \alpha w^k) \\
&= (t^k + \alpha\Delta t^k)^2 + \|G(w^k + \alpha\Delta w^k)\|^2 \\
&\le (1-\alpha)^2(t^k)^2 + 2\alpha\gamma\bar{t}\psi(w^k) + (1-\alpha)^2\|G(w^k)\|^2 + o(\alpha) + O(\alpha^2) \\
&= (1-\alpha)^2\psi(w^k) + 2\alpha\gamma\bar{t}\psi(w^k) + o(\alpha) \\
&= (1-2\alpha)\psi(w^k) + 2\alpha\gamma\bar{t}\psi(w^k) + o(\alpha) \\
&= [1 - 2(1-\gamma\bar{t})\alpha]\psi(w^k) + o(\alpha). \qquad \text{(A.5)}
\end{aligned}$$

Inequality (A.5) indicates that there exists a positive number $\bar{\alpha} \in (0, \alpha]$ such that for all $\alpha \in [0, \bar{\alpha}]$,

$$\psi(w^k + \alpha\Delta w^k) \le [1 - 2\sigma(1-\gamma\bar{t})\alpha]\psi(w^k),$$

which means that ℓ_k in (S.3) of Algorithm 4.2 can be always found after a finite number of tries. Thus w^{k+1} can be computed if $t^k \in \mathbb{R}_{++}$. □

Proof of Proposition 4.4. We prove this proposition by considering the following two cases:

(i) $\psi(w^k) > 1$. Then $\beta_k = \gamma$. It follows from $w^k \in \Omega$ and $\beta(w) \le \gamma$ for any $w \in \mathbb{R}^{n+1}$ that for all $\alpha \in [0,1]$, we have

$$\begin{aligned}
&t^k + \alpha\Delta t^k - \beta(w^k + \alpha\Delta w^k)\bar{t} \ge (1-\alpha)t^k + \alpha\beta_k\bar{t} - \gamma\bar{t} \\
&\ge (1-\alpha)\beta_k\bar{t} + \alpha\beta_k\bar{t} - \beta_k\bar{t} = 0. \qquad \text{(A.6)}
\end{aligned}$$

(ii) $\psi(w^k) \le 1$. Then for any $\alpha \in [0,1]$ satisfying (4.6), we have

$$\psi(w^k + \alpha\Delta w^k) \le 1. \qquad \text{(A.7)}$$

Thus for any $\alpha \in [0,1]$ satisfying (4.6),

$$\beta(w^k + \alpha\Delta w^k) = \gamma\psi(w^k + \alpha\Delta w^k).$$

Hence, again because $w^k \in \Omega$, for any $\alpha \in [0,1]$ satisfying (4.6), we have

$$\begin{aligned}
&t^k + \alpha\Delta t^k - \beta(w^k + \alpha w^k)\bar{t} \\
&= (1-\alpha)t^k + \alpha\beta_k\bar{t} - \gamma\psi(w^k + \alpha\Delta w^k)\bar{t} \\
&\ge (1-\alpha)\beta_k\bar{t} + \alpha\beta_k\bar{t} - \gamma[1 - 2\sigma(1-\gamma\bar{t})\alpha]\psi(w^k)\bar{t} \\
&= \beta_k\bar{t} - \gamma[1 - 2\sigma(1-\gamma\bar{t})\alpha]\psi(w^k)\bar{t} \\
&= \gamma\psi(w^k)\bar{t} - \gamma[1 - 2\sigma(1-\gamma\bar{t})\alpha]\psi(w^k)\bar{t} \\
&= 2\gamma\sigma(1-\gamma\bar{t})\alpha\psi(w^k)\bar{t} \ge 0. \qquad \text{(A.8)}
\end{aligned}$$

Thus, by combining (A.6) and (A.8), we finish the proof. □

Proof of Theorem 5.1. Since M satisfies $\mathcal{W}_0$-property, it follows from Proposition 4.5 that an infinite sequence $\{w^k\}$ can be generated by Algorithm 4.2. From (4.5), $\psi(w^{k+1}) < \psi(w^k)$ for all $k \geq 0$. Hence the two sequences $\{\psi(w^k)\}$ and $\{\beta(w^k)\}$ are monotonically decreasing. Since $\psi(w^k),\ \beta(w^k) \geq 0$ $(k \geq 0)$, there exist $\tilde{\psi},\ \tilde{\beta} \geq 0$ such that $\psi(w^k) \to \tilde{\psi}$ and $\beta(w^k) \to \tilde{\beta}$ as $k \to \infty$. Let $\tilde{w}$ be any accumulation point of $\{w^k\}$. If $\tilde{\psi} = 0$, then from the continuity of ψ we must have $\psi(\tilde{w}) = 0$; therefore $\tilde{w}$ is a solution of $H(w) = 0$. Now we assume $\tilde{\psi} > 0$. It is easy to see

$$\tilde{\beta} = \gamma \min\{1, \tilde{\psi}\} > 0.$$

By taking a subsequence if necessary, we may assume that $\{w^k\}$ converges to $\tilde{w}$. It is easy to see that

$$\tilde{\psi} = \psi(\tilde{w}),\ \beta(\tilde{w}) = \tilde{\beta} \quad \text{and} \quad \tilde{w} \in \Omega,\ \tilde{t} \geq \tilde{\beta}\bar{t} > 0.$$

Then from Proposition 4.1, $H'(\tilde{w})$ exists and is nonsingular. Therefore there exists a small closed neighborhood $\mathcal{N}(\tilde{w})$ of $\tilde{w}$ such that for any $w = (t, x) \in \mathcal{N}(\tilde{w})$ we have $t \in \mathbb{R}_{++}$ and that $H'(w)$ is nonsingular. For any $w \in \mathcal{N}(\tilde{w})$, let $\Delta w = (\Delta t, \Delta x) \in \mathbb{R} \times \mathbb{R}^n$ be the unique solution of the equation

$$H(w) + H'(w)\Delta w = \beta(w)\bar{w}, \tag{A.9}$$

and for any $\alpha \in [0, 1]$ define

$$g_w(\alpha) = G(w + \alpha\Delta w) - G(w) - \alpha G'(w)\Delta w.$$

It is easy to see that $\Delta w \to \Delta\tilde{w}$ as $w \to \tilde{w}$ for all $w \in \mathcal{N}(\tilde{w})$. From (A.9), for any $w \in \mathcal{N}(\tilde{w})$,

$$\Delta t = -t + \beta(w)\bar{t}.$$

Then for all $\alpha \in [0, 1]$ and all $w \in \mathcal{N}(\tilde{w})$,

$$t + \alpha\Delta t = (1 - \alpha)t + \alpha\beta(w)\bar{t} \in \mathbb{R}_{++}. \tag{A.10}$$

It follows from the mean value theorem that

$$g_w(\alpha) = \alpha \int_0^1 [G'(w + \theta\alpha\Delta w) - G'(w)]\Delta w d\theta.$$

Since $G'(\cdot)$ is uniformly continuous on $\mathcal{N}(\tilde{w})$ for all $w \in \mathcal{N}(\tilde{w})$ we have

$$\lim_{\alpha \downarrow 0} \|g_w(\alpha)\|/\alpha = 0.$$

Then, from (A.9), (A.10), and the fact that $\beta(w) \leq \gamma\psi(w)^{1/2}$ for all $\alpha \in [0, 1]$ and all $w \in \mathcal{N}(\tilde{w})$, we have by repeating the arguments in (A.3)–(A.5) that

$$(t + \alpha\Delta t)^2 \leq (1 - \alpha)^2 t^2 + 2\alpha\gamma\psi(w)\bar{t} + O(\alpha^2), \tag{A.11}$$

$$\|G(w + \alpha\Delta w)\|^2 = (1 - \alpha)^2\|G(w)\|^2 + o(\alpha), \tag{A.12}$$

$$\psi(w + \alpha\Delta w) \leq [1 - 2(1 - \gamma\bar{t})\alpha]\psi(w) + o(\alpha). \tag{A.13}$$

Then from inequality (A.13) we can find a positive number $\bar{\alpha} \in [0,1]$ such that for all $\alpha \in [0, \bar{\alpha}]$ and all $w \in \mathcal{N}(\tilde{w})$,

$$\psi(w + \alpha \Delta w) \leq [1 - 2\sigma(1 - \gamma \bar{t})\alpha]\psi(w).$$

Therefore, for a nonnegative integer ℓ such that $\delta^\ell \in (0, \bar{\alpha}]$, we have

$$\psi(w^k + \delta^\ell \Delta w^k) \leq [1 - 2\sigma(1 - \gamma \bar{t})\delta^\ell]\psi(w^k)$$

for all sufficiently large k. Then for every sufficiently large k, we see that $\ell_k \leq \ell$ and hence $\delta^{\ell_k} \geq \delta^\ell$. Therefore

$$\psi(w^{k+1}) \leq [1 - 2\sigma(1 - \gamma \bar{t})\delta^{\ell_k}]\psi(w^k) \leq [1 - 2\sigma(1 - \gamma \bar{t})\delta^\ell]\psi(w^k)$$

for all sufficiently large k. This contradicts the fact that sequence $\{\psi(w^k)\}$ converges to $\tilde{\psi} > 0$. Thus we have proved that $\tilde{\psi} = 0$, which means that $\tilde{w}$ is a solution of $H(w) = 0$. □

Proof of Theorem 5.4. First, from Theorem 5.1, w^* is a solution of $H(w) = 0$. Then, from Proposition 3.1 in [25], for all w^k sufficiently close to w^*,

$$\|(H'(w^k))^{-1}\| = O(1).$$

Theorem 3.5 implies H is strongly semismooth at w^*. From (2.1), for w^k sufficiently close to w^*, we have

$$\begin{aligned} &\|w^k + \Delta w^k - w^*\| \\ &= \|w^k + H'(w^k)^{-1}[-H(w^k) + \beta_k \bar{w}] - w^*\| \\ &= O(\|H(w^k) - H(w^*) - H'(w^k)(w^k - w^*)\| + \beta_k \bar{t} \\ &= O(\|w^k - w^*\|^2) + O(\psi(w^k))). \end{aligned} \tag{A.14}$$

Since H is strongly semismooth at w^*, H is locally Lipschitz continuous near w^*. Then for all w^k sufficiently close to w^*, we have

$$\psi(w^k) = \|H(w^k)\|^2 = O(\|w^k - w^*\|^2).$$

Thus, from (A.14), we have for all w^k sufficiently close to w^*,

$$\|w^k + \Delta w^k - w^*\| = O(\|w^k - w^*\|^2).$$

Since each $V \in \partial H(w^*)$ is nonsingular, following the proof of Theorem 3.1 of [24], we have for all w^k sufficiently close to w^*,

$$\|w^k - w^*\| = O(\|H(w^k) - H(w^*)\|).$$

Hence, for all w^k sufficiently close to w^*, we have

$$\begin{aligned} &\psi(w^k + \Delta w^k) = \|H(w^k + \Delta w^k)\|^2 \\ &= O(\|w^k + \Delta w^k - w^*\|^2) = O(\|w^k - w^*\|^4) \\ &= O(\|H(w^k) - H(w^*)\|^4) = O(\psi(w^k)^2). \end{aligned} \tag{A.15}$$

Therefore, for all w^k sufficiently close to w^*, we have

$$w^{k+1} = w^k + \Delta w^k, \tag{A.16}$$

which means that $\ell_k = 0$ for all sufficiently large k. Equations (A.16) and (A.14) prove the first result in (5.4).

Next, from the definition of β_k and the fact $H(w^k) \to 0$ as $k \to \infty$ for all k sufficiently large, $\beta_k = \gamma\|H(w^k)\|^2$. In addition for k sufficiently large, $w^{k+1} = w^k + \Delta w^k$, then

$$t^{k+1} = t^k + \Delta t^k = \beta_k \bar{t} = \gamma\|H(w^k)\|^2\bar{t},$$

which, together with (A.15), leads to the second result in (5.4). □

Acknowledgments. We are much indebted to Paul Tseng, who drew our attention to [13, 17]. We are grateful to Al Goldstein for providing us with his excellent paper [13] and for his up-to-date comments on exponential penalty method. We are also very thankful to M. Seetharama Gowda for his valuable comments on the solution structure of the EVLCP. We would like to thank Defeng Sun for his detailed comments on an earlier version of this paper. Finally we would like to thank both referees; their opinions and comments improved the presentation of the paper greatly.

ON THE CONVERGENCE OF THE MULTISPLITTING METHODS FOR THE LINEAR COMPLEMENTARITY PROBLEM*

ZHONG-ZHI BAI†

Abstract. The convergence properties of a variant of the multisplitting methods for solving the large sparse linear complementarity problems presented by Machida, Fukushima, and Ibaraki [*J. Comput. Appl. Math.*, 62 (1995), pp. 217–227] are further discussed when the system matrices are nonsymmetric and the weighting matrices are nonnegative and diagonal. This directly results in several novel sufficient conditions for guaranteeing the convergence of these multisplitting methods. Moreover, some applicable parallel multisplitting relaxation methods and their corresponding convergence properties are discussed in detail.

Key words. linear complementarity problem, matrix multisplitting, relaxed method, convergence

1. Introduction.

The linear complementarity problem LCP(M,q) consists of finding a vector $z \in \mathbb{R}^n$ such that

$$Mz + q \geq 0, \qquad z \geq 0, \qquad z^T(Mz + q) = 0, \tag{1.1}$$

where $M \in \mathbb{R}^{n\times n}$ and $q \in \mathbb{R}^n$ are a given real matrix and a vector, respectively. This problem usually arises in (linear and) convex quadratic programming, in the problem of finding a Nash equilibrium point of a bimatrix game (e.g., Cottle and Dantzig [3] and Lemke [12]), and also in a number of free boundary problems of fluid mechanics (e.g., Cryer [7]). Therefore, it has various practical applications. To get a numerical solution to this linear complementarity problem, we often utilize the splitting methods, in particular when the system matrix $M \in \mathbb{R}^{n\times n}$ is large and sparse. This class of splitting methods originates from the matrix splitting methods such as the Jacobi, Gauss–Seidel, and SOR iterations for solving systems of linear equations. It was first introduced into the linear complementarity problem by Cottle and Sacher [6] and Cottle, Golub, and Sacher [4] and was further developed by many authors, e.g., Mangasarian [15], Pang [19], Luo and Tseng [13], and Iusem [10, 11]. Now, it has become one of the most practical and efficient iterative solvers for the large sparse linear complementarity problems, possessing systematic and deepened mathematical theories. For details, one can refer to Cottle, Pang, and Stone [5], Berman and Plemmons [2], and references therein.

To suit the requirements of high-speed parallel multiprocessor systems, Machida, Fukushima, and Ibaraki [14] recently presented a class of parallel multisplitting iterative methods for solving the symmetric linear complementarity problems in the synchronous parallel computing environments. These methods are based on several splittings of the system matrix $M \in \mathbb{R}^{n\times n}$ and are constructed with a suitable weighting combination of the solutions of the linear complementarity problems resulting

from the splittings. Therefore, they are technical extensions of the matrix multisplitting methods for the system of linear equations in O'Leary and White [17] to large sparse symmetric linear complementarity problems, and they can attain high parallel efficiency in practical computations. Under suitable restrictions on the weighting matrices and the multiple splittings, Machida, Fukushima, and Ibaraki [14] proved the convergence of these methods for the case where the system matrices are symmetric.

In fact, the convergence of the multisplitting methods in [14] is guaranteed for many symmetric linear complementarity problems with multiple solutions, including cases in which the system matrix $M \in \mathbb{R}^{n\times n}$ is just positive semidefinite, and for many matrix multisplittings with standard restrictions on the splitting matrices and certain necessary requirements on the weighting matrices. However, the convergence of these multisplitting methods for nonsymmetric linear complementarity problems and for general nonnegative diagonal weighting matrices still requires study. In this paper, we will discuss further the convergence of a variant of these multisplitting methods, which includes the multisplitting methods in [14] as special cases, and develop the convergence theory of Machida, Fukushima, and Ibaraki [14] to the nonsymmetric linear complementarity problems. For some nonsymmetric matrix class and arbitrary nonnegative diagonal weights, we establish the convergence theory of this new method under suitable constraints of the multiple splittings of the system matrix $M \in \mathbb{R}^{n\times n}$. This directly results in several novel sufficient conditions for guaranteeing the convergence of the new multisplitting method. Since the nonsymmetric problem is considerably harder than the symmetric one, a price is also paid for this development, which imposes more demanding conditions on the multiple splittings in order to ensure the convergence of the new multisplitting method as well as the existence of such splitting matrices. Moreover, as applications, we present some applicable parallel multisplitting relaxation methods which are naturally induced by the above multisplitting method, and we discuss the convergence of these relaxed methods in detail.

2. Preliminaries. In this section, we briefly review the multisplitting method discussed by Machida, Fukushima, and Ibaraki in [14] for solving the LCP(M,q).

First, we introduce some necessary notations and concepts. A matrix $A = (a_{ij}) \in \mathbb{R}^{n\times n}$ is called a monotone matrix if it is nonsingular and satisfies $A^{-1} \geq 0$; an M-matrix if it is a monotone matrix and satisfies $a_{ij} \leq 0$ for $i \neq j$, $i, j = 1, 2, \ldots, n$; an H-matrix if its comparison matrix $\langle A\rangle$ is an M-matrix, where $\langle A\rangle = (\langle a_{ij}\rangle) \in \mathbb{R}^{n\times n}$ is defined by $\langle a_{ii}\rangle = |a_{ii}|$ for $i = 1, 2, \ldots, n$, and $\langle a_{ij}\rangle = -|a_{ij}|$ for $i \neq j$, $i, j = 1, 2, \ldots, n$; an H_+-matrix if it is an H-matrix having positive diagonal elements; and a Q-matrix if the LCP(A,b) has a solution for any $b \in \mathbb{R}^n$. A sufficient condition for $A \in \mathbb{R}^{n\times n}$ to be a Q-matrix is that either A is an H_+-matrix [1] or A is a strictly copositive matrix [5].

For a given matrix $A \in \mathbb{R}^{n\times n}$, let $F, G \in \mathbb{R}^{n\times n}$ be such that $A = F + G$. Then (F, G) is called a splitting of the matrix A. The splitting (F, G) is called a convergent splitting if the spectral radius of the matrix $(F^{-1}G)$ is less than one, i.e., $\rho(F^{-1}G) < 1$. It is called a weak regular splitting if $F^{-1} \geq 0$ and $F^{-1}G \leq 0$; a regular splitting if $F^{-1} \geq 0$ and $G \leq 0$; an M-splitting if F is an M-matrix and $G \leq 0$; an H-splitting if $\langle F\rangle - |G|$ is an M-matrix; an H-compatible splitting if $\langle A\rangle = \langle F\rangle - |G|$; and a Q-splitting if F is a Q-matrix. In particular, the splitting (F, G) is called an H_+-splitting and H_+-compatible splitting if it is an H-splitting and H-compatible splitting, respectively, with F an H_+-matrix. Let (B, C) be a splitting of the matrix A such that $\langle B\rangle$ is nonsingular, and let (F, G) be a matrix pair. Then we call the

matrix pair (F, G) a majorizing pair of the splitting (B, C) if F is an H-matrix and it holds that $\langle B\rangle^{-1} \leq \langle F\rangle^{-1}$ and $|C| \leq |G|$. In such a case, we say that (B, C) is majorized by (F, G). Note that here (F, G) is not necessarily a splitting of the matrix A. Evidently, if $A = B + C$ is an H-splitting, then A and B are H-matrices and $\rho(B^{-1}C) \leq \rho(\langle B\rangle^{-1}|C|) < 1$; if it is an H-compatible splitting and A is an H-matrix, then it is an H-splitting and thus convergent; and if (F, G) is a majorizing pair of the splitting (B, C) such that $\langle F\rangle - |G|$ is an M-matrix, then (B, C) is a convergent splitting.

A matrix $A \in \mathbb{R}^{n\times n}$ is symmetric if $A^T = A$, where A^T denotes the transposed matrix of A. It is positive semidefinite if $z^T Az \geq 0$ for all $z \in \mathbb{R}^n$ and positive definite if $z^T Az > 0$ for all $z \in \mathbb{R}^n \setminus \{0\}$. Let $N_0 = \{0, 1, 2, \dots\}$ and $\{A_p\}_{p\in N_0}$ be a sequence of matrices in $\mathbb{R}^{n\times n}$. Then we call $A_p (p \in N_0)$ positive definite uniformly in p if there exists a positive constant c, independent of p, such that $z^T A_p z \geq cz^T z$ holds for all $z \in \mathbb{R}^n$.

We now cite some lemmas which were proved in [8, 9, 18], respectively, and which will frequently be used in what follows.

LEMMA 2.1 (see [8, 18]). *Let $A \in \mathbb{R}^{n\times n}$ have nonpositive off-diagonal entries. Then A is an M-matrix if and only if there exists a positive vector $u \in \mathbb{R}^n$ such that $Au \geq 0$.*

LEMMA 2.2 (see [9, 18]). *Let $A \in \mathbb{R}^{n\times n}$ be an H-matrix, $D = \mathrm{diag}(A)$, and $A = D - B$. Then*

(a) *A is nonsingular,*

(b) *$|A^{-1}| \leq \langle A\rangle^{-1}$, and*

(c) *$|D|$ is nonsingular and $\rho(|D|^{-1}|B|) < 1$.*

The following result deals with the existence and uniqueness of the solution of the LCP(M,q).

LEMMA 2.3 (see [1]). *Let $M \in \mathbb{R}^{n\times n}$ be an H_+-matrix. Then the LCP(M,q) has a unique solution for any $q \in \mathbb{R}^n$.*

A multisplitting of a matrix $M \in \mathbb{R}^{n\times n}$ is a collection of triples $(B_k, C_k, E_k)(k = 1, 2, \dots, K)$, which satisfies

(1) $M = B_k + C_k (k = 1, 2, \dots, K)$ are Q-splittings; and

(2) $E_k (k = 1, 2, \dots, K)$ are nonnegative diagonal matrices with $\sum_{k=1}^{K} E_k = I$ (the $n \times n$ identity matrix).

Let $(B_{k,p}, C_{k,p}, E_{k,p})(k = 1, 2, \dots, K)$, $p \in N_0$, be a sequence of multisplittings of the matrix M. Then we consider the following multisplitting method for solving the LCP(M,q).

METHOD 2.1 (multisplitting method for the LCP(M,q)).

Step 1. *Choose an arbitrary starting vector $z^0 \in \mathbb{R}^n$. Set $p := 0$.*

Step 2. *For each $k \in \{1, 2, \dots, K\}$, let $z^{k,p}$ be an arbitrary solution of LCP$(B_{k,p}, q_{k,p})$:*

$$z \geq 0, \qquad B_{k,p}z + q_{k,p} \geq 0, \qquad z^T(B_{k,p}z + q_{k,p}) = 0,$$

where $q_{k,p} = C_{k,p}z^p + q$.

Step 3. $z^{p+1} = \sum_{k=1}^{K} E_{k,p} z^{k,p}$.

Step 4. *If $z^{p+1} = z^p$, then stop. Otherwise, set $p := p + 1$ and return to Step* 2.

This multisplitting method has quite good parallel computational properties. At every iterate step p, each subproblem LCP$(B_{k,p}, C_{k,p})(k = 1, 2, \dots, K)$ can be solved independently on one processor of the multiprocessor system, and hence Method 2.1 can be implemented in parallel. The K splitting matrices $B_{k,p}(k = 1, 2, \dots, K)$ and

the K weighting matrices $E_{k,p}(k = 1, 2, \ldots, K)$ can be chosen in such a way that the tasks distributed on the K processors of the multiprocessor system are well balanced so that Method 2.1 achieves high parallel efficiency. Moreover, considerable saving on the computational workload is available because the entries of $z^{k,p}$ corresponding to the zero elements of the weighting matrix $E_{k,p}$ need not be computed.

We remark that Method 2.1 is somewhat more general than Algorithm 3.2 in [14]. Here, the multiple splittings $M = B_{k,p} + C_{k,p}(k = 1, 2, \ldots, K, p \in N_0)$ of the system matrix $M \in \mathbb{R}^{n\times n}$ are permitted to vary with p, the iteration index, and the weighting matrices $E_{k,p}(k = 1, 2, \ldots, K, p \in N_0)$ are allowed to be arbitrary nonnegative diagonal matrices. Moreover, the stopping instruction of Method 2.1 is issued by the host processor, and the other processors can get this instruction directly to terminate their computations. This greatly decreases the unnecessary data exchanges among the processors and hence improves the parallel efficiency of Method 2.1.

When the system matrix $M \in \mathbb{R}^{n\times n}$ is symmetric, an analogous demonstration to Machida, Fukushima, and Ibaraki [14] immediately gives the following convergence theorem of Method 2.1.

THEOREM 2.1. *Let $M \in \mathbb{R}^{n\times n}$ be a symmetric matrix, and for every $p \in N_0$, let $(B_{k,p}, C_{k,p}, E_{k,p})(k = 1, 2, \ldots, K)$ be a multisplitting of the matrix M such that*

(a) *$B_{k,p} - C_{k,p}(k = 1, 2, \ldots, K)$ are positive definite uniformly in p; and*

(b) *$f(\sum_{k=1}^{K} E_{k,p} z^{k,p}) \le \max_{1\le k\le K} f(z^{k,p})$, where $f(z) = \frac{1}{2} z^T M z + z^T q$.*

Assume that $f(z)$ is bounded below on $z \ge 0$ and that $0 \ne z \ge 0$, $Mz \ge 0$, and $z^T M z = 0$ imply $q^T z > 0$. Then the sequence $\{z^p\}_{p\in N_0}$ generated by Method 2.1 is bounded and any accumulation point of it solves LCP(M,q).

We remark again that when $B_{k,p} = B_k(k = 1, 2, \ldots, K)$ and $C_{k,p} = C_k(k = 1, 2, \ldots, K)$ for all $p \in N_0$, Method 2.1 reduces to Algorithm 3.2 in [14] and Theorem 2.1 recovers Theorem 3.6 in [14], respectively. Various choices of the weighting matrices $E_{k,p}(k = 1, 2, \ldots, K, p \in N_0)$ satisfy condition (b) in Theorem 2.1. As shown in [14], one of the possibilities is given by the choices of $E_{k,p} = \alpha_{k,p} I$ $(k = 1, 2, \ldots, K, p \in N_0)$, where $\alpha_{k,p}(k = 1, 2, \ldots, K, p \in N_0)$ are nonnegative real numbers satisfying $\sum_{k=1}^{K} \alpha_{k,p} = 1$ $(p \in N_0)$. In this case, condition (b) is automatically satisfied if any of the following three classes of restrictions is further imposed:

(1) For a positive integer sequence $\{k_p\} \in \{1, 2, \ldots, K\}$,

$$\alpha_{k,p} = \begin{cases} 1 & \text{for } k = k_p, \\ 0 & \text{for } k \ne k_p, \end{cases} \qquad k = 1, 2, \ldots, K, \quad p \in N_0,$$

where the indices $k_p(p \in N_0)$ are chosen either randomly at every iteration or in a certain predetermined order such as the cyclic rule, or they are based on the function values $f(z^{k,p})(k = 1, 2, \ldots, K)$ such that, for $p \in N_0$, $f(z^{k_p,p}) = \min_{1\le k\le K} f(z^{k,p})$.

(2) $\alpha_{k,p}(k = 1, 2, \ldots, K, p \in N_0)$ are the minimizers of the functions $g(\alpha_{1,p}, \alpha_{2,p}, \ldots, \alpha_{K,p}) = f(\sum_{k=1}^{K} \alpha_{k,p} z^{k,p})$, $p \in N_0$.

(3) $M \in \mathbb{R}^{n\times n}$ is a positive semidefinite matrix.

For detailed discussions about the choices of the splitting and the weighting matrices, one can refer to [1, 9, 14, 16, 17, 21] and references therein.

3. New convergence theories. In this section, we will discuss the convergence of Method 2.1 for the case where the system matrix $M \in \mathbb{R}^{n\times n}$ belongs to the H_+-matrix class. We first establish a general convergence result.

THEOREM 3.1. *Let $M \in \mathbb{R}^{n\times n}$ be an H_+-matrix, and for every $p \in N_0$ let $(B_{k,p}, C_{k,p}, E_{k,p})(k = 1, 2, \dots, K)$ be a multisplitting of the matrix M such that*

(a) *$B_{k,p}(k = 1, 2, \dots, K)$ are H_+-matrices;*

(b) *for each k, there exists a majorizing pair $(\widehat{B}_{k,p}, \widehat{C}_{k,p})$ of the splitting $(B_{k,p}, C_{k,p})$ satisfying*

$$\widehat{H}_p u \le \theta u, \qquad \widehat{H}_p = \sum_{k=1}^{K} E_{k,p}\langle \widehat{B}_{k,p}\rangle^{-1}|\widehat{C}_{k,p}| \qquad \forall p \in N_0 \tag{3.1}$$

for some nonnegative constant $\theta \in [0, 1)$ and some positive vector $u \in \mathbb{R}^n$.

Then the sequence $\{z^p\}_{p\in N_0}$ generated by Method 2.1 converges to the unique solution of the LCP(M,q).

Proof. Because $M \in \mathbb{R}^{n\times n}$ is an H_+-matrix, the LCP(M,q) has a unique solution $z^* \in \mathbb{R}^n$. That is to say, it holds that

$$z^* \ge 0, \qquad Mz^* + q \ge 0, \qquad (z^*)^T(Mz^* + q) = 0. \tag{3.2}$$

On the other hand, since for each $k \in \{1, 2, \dots, K\}$ and each $p \in N_0$, $B_{k,p}$ is an H_+-matrix, by Lemma 2.3 the LCP$(B_{k,p}, q_{k,p})$ has a unique solution $z^{k,p}$, where $q_{k,p} = C_{k,p}z^p + q$. That is to say, it holds that

$$z^{k,p} \ge 0, \qquad B_{k,p}z^{k,p} + q_{k,p} \ge 0, \qquad (z^{k,p})^T(B_{k,p}z^{k,p} + q_{k,p}) = 0. \tag{3.3}$$

Now, we claim that the following estimates hold:

$$|z^{p+1} - z^*| \le \sum_{k=1}^{K} E_{k,p}\langle B_{k,p}\rangle^{-1}|C_{k,p}||z^p - z^*| \qquad \forall p \in N_0. \tag{3.4}$$

In fact, denoting $D_{k,p} = \mathrm{diag}(B_{k,p})$ and $\widetilde{B}_{k,p} = B_{k,p} - D_{k,p}$, we will verify (3.4) in all cases.

First, when the ith element of z^*, $[z^*]_i$, is positive and $[B_{k,p}z^{k,p} + q_{k,p}]_i = 0$, it clearly holds that

$$[B_{k,p}(z^{k,p} - z^*) + C_{k,p}(z^p - z^*)]_i = 0$$

or equivalently

$$[D_{k,p}(z^{k,p} - z^*)]_i = [-\tilde{B}_{k,p}(z^{k,p} - z^*) - C_{k,p}(z^p - z^*)]_i.$$

Therefore,

$$[D_{k,p}|z^{k,p} - z^*|]_i \le [|\tilde{B}_{k,p}||z^{k,p} - z^*| + |C_{k,p}||z^p - z^*|]_i,$$

and hence

$$[\langle B_{k,p}\rangle|z^{k,p} - z^*|]_i \le [|C_{k,p}||z^p - z^*|]_i. \tag{3.5}$$

Second, when $[z^*]_i > 0$ and $[B_{k,p}z^{k,p} + q_{k,p}]_i > 0$, it holds that $[z^{k,p}]_i = 0$ and

$$\begin{cases} [\widetilde{B}_{k,p}z^{k,p} + C_{k,p}z^p + q]_i > 0, \\ [\widetilde{B}_{k,p}z^* + C_{k,p}z^* + q]_i = -[D_{k,p}z^*]_i. \end{cases}$$

By subtracting these two inequalities we obtain

$$[\widetilde{B}_{k,p}(z^{k,p}-z^*)+C_{k,p}(z^p-z^*)]_i > [D_{k,p}z^*]_i.$$

Therefore,

$$\begin{aligned}[D_{k,p}|z^{k,p}-z^*|]_i = [D_{k,p}z^*]_i &< |[\widetilde{B}_{k,p}(z^{k,p}-z^*)+C_{k,p}(z^p-z^*)]_i| \\ &\le [|\widetilde{B}_{k,p}||z^{k,p}-z^*|+|C_{k,p}||z^p-z^*|]_i,\end{aligned}$$

and hence (3.5) also holds.

Finally, noticing that when $[z^*]_i = 0$ and $[z^{k,p}]_i = 0$ (3.5) holds automatically, and that when $[z^*]_i = 0$ and $[z^{k,p}]_i > 0$, (3.5) can be demonstrated analogously to the second case, we conclude that (3.5) holds for all $i \in \{1, 2, \dots, n\}$, all $k \in \{1, 2, \dots, K\}$, and all $p \in N_0$.

Since $B_{k,p}(k = 1, 2, \dots, K, p = 0, 1, 2, \dots)$ are H-matrices, it holds that

$$|z^{k,p}-z^*| \le \langle B_{k,p}\rangle^{-1}|C_{k,p}||z^p-z^*|, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots .$$

Because for each $k \in \{1, 2, \dots, K\}$ and $p \in N_0$, $B_{k,p}$ is an H_+-matrix and $(\widehat{B}_{k,p}, \widehat{C}_{k,p})$ is a majorizing sequence of $(B_{k,p}, C_{k,p})$, we have

$$\langle B_{k,p}\rangle^{-1}|C_{k,p}| \le \langle \widehat{B}_{k,p}\rangle^{-1}|\widehat{C}_{k,p}|, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots ,$$

and hence

$$\begin{aligned}|z^{p+1}-z^*| = \left|\sum_{k=1}^{K} E_{k,p}(z^{k,p}-z^*)\right| &\le \sum_{k=1}^{K} E_{k,p}|z^{k,p}-z^*| \\ &\le \sum_{k=1}^{K} E_{k,p}\langle \widehat{B}_{k,p}\rangle^{-1}|\widehat{C}_{k,p}||z^p-z^*| := \widehat{H}_p|z^p-z^*|.\end{aligned}$$

Let $\delta > 0$ be such that $|z^0 - z^*| \le \delta u$. Then we have

$$|z^{p+1}-z^*| \le \widehat{H}_p\widehat{H}_{p-1}\cdots\widehat{H}_0\delta u \le \theta^{p+1}\delta u \longrightarrow 0 \qquad (p \to \infty).$$

That is to say, $\lim_{p\to\infty} z^p = z^*$. □

In Theorem 3.1 no restriction is imposed on the weighting matrices $E_{k,p}(k = 1, 2, \dots, K, p \in N_0)$. Hence, we can choose them suitably such that Method 2.1 achieves high parallel computational efficiency. On the other hand, the restriction on the matrix splittings $M = B_{k,p} - C_{k,p}(k = 1, 2, \dots, K, p \in N_0)$ in Theorem 3.1 is quite different from that in Theorem 2.1. Conditions imposed to ensure the existence of the multiple splittings satisfying (3.1) may be more restrictive than those in Theorem 2.1 and in [14] in some sense. However, because the nonsymmetric problem is considerably harder than the symmetric one, these conditions are necessary for guaranteeing the convergence of Method 2.1. As a matter of fact, they naturally originate from the standard conditions for the parallel matrix multisplitting iterative methods of the systems of linear equations [9, 16, 17]. Two concrete choices of the multiple splittings satisfying condition (3.1) are given in the following examples.

EXAMPLE 3.1. *Let $M = (m_{ij}) \in \mathbb{R}^{n\times n}$ be an H_+-matrix, $\overline{D} = \mathrm{diag}(M)$, and $\overline{B} = M - \overline{D}$. For a given positive constant $\beta \ge 1$, let $D_{k,p}(k = 1, 2, \dots, K, p \in N_0)$ be positive diagonal matrices satisfying $\overline{D} \le D_{k,p} \le \beta\overline{D}$ $(k = 1, 2, \dots, K, p \in N_0)$. Take*

$$B_{k,p} = D_{k,p}, \quad C_{k,p} = M - D_{k,p}, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots .$$

Then condition (3.1) *is satisfied because*

$$\widehat{B}_{k,p} = D_{k,p}, \quad \widehat{C}_{k,p} = D_{k,p} - \overline{D} + |\overline{B}|, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots,$$

$u = \langle M \rangle^{-1} e$ *with* $e = (1, 1, \dots, 1)^T \in \mathbb{R}^n$, *and* $\theta = \max\{0, 1 - \frac{1}{\max\{\beta m_{ii} u_i\}}\}$.

EXAMPLE 3.2. *Let* $M = (m_{ij}) \in \mathbb{R}^{n \times n}$ *be an* H_+*-matrix,* $\overline{D} = \operatorname{diag}(M)$, *and* $\overline{B} = M - \overline{D}$. *For each* $p \in N_0$ *and* $k \in \{1, 2, \dots, K\}$, *take* $B_{k,p} = (b_{ij}^{(k,p)}) \in \mathbb{R}^{n \times n}$ *and* $C_{k,p} = (c_{ij}^{(k,p)}) \in \mathbb{R}^{n \times n}$ *in accordance with the following rule:*

$$b_{ij}^{(k,p)} = \begin{cases} m_{ij} & \text{for } i = j, \\ b_{ij}^{(k,p)} \in [0, m_{ij}] & \text{for } i \neq j \text{ and } m_{ij} \geq 0, \\ b_{ij}^{(k,p)} \in [m_{ij}, 0] & \text{for } i \neq j \text{ and } m_{ij} < 0, \end{cases} \qquad i, j = 1, 2, \dots, n,$$

$$c_{ij}^{(k,p)} = \begin{cases} 0 & \text{for } i = j, \\ m_{ij} - b_{ij}^{(k,p)} & \text{for } i \neq j, \end{cases} \qquad i, j = 1, 2, \dots, n.$$

Then condition (3.1) *is satisfied because*

$$\widehat{B}_{k,p} = \langle B_{k,p} \rangle, \quad \widehat{C}_{k,p} = |C_{k,p}|, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots,$$

$u = \langle M \rangle^{-1} e$ *with* $e = (1, 1, \dots, 1)^T \in \mathbb{R}^n$, *and* $\theta = \max\{0, 1 - \frac{1}{\max\{m_{ii} u_i\}}\}$.

Theorem 3.1 immediately implies the following convergence conclusion about Method 2.1.

THEOREM 3.2. *Let* $M \in \mathbb{R}^{n \times n}$ *be an* H_+*-matrix, and for every* $p \in N_0$ *let* $(B_{k,p}, C_{k,p}, E_{k,p})(k = 1, 2, \dots, K)$ *be a multisplitting of the matrix* M *such that*

(a) $B_{k,p}(k = 1, 2, \dots, K)$ *are* H_+*-matrices;*

(b) *for each* k, *there exists a majorizing pair* $(\widehat{B}_{k,p}, \widehat{C}_{k,p})$ *of the splitting* $(B_{k,p}, C_{k,p})$ *satisfying*

$$\begin{cases} \langle \widehat{B}_{k,p} \rangle - |\widehat{C}_{k,p}| \geq \widehat{M}_k, \\ u > 0, \quad \widehat{M}_k u > 0 \Longrightarrow \langle \widehat{B}_{k,p} \rangle u \leq \dfrac{1}{1 - \theta} \widehat{M}_k u \quad \text{for some} \quad \theta \in [0, 1), \end{cases} \tag{3.6}$$

for some matrices $\widehat{M}_k \in \mathbb{R}^{n \times n}(k = 1, 2, \dots, K)$, *for which there exists a positive vector* $u \in \mathbb{R}^n$ *satisfying* $\widehat{M}_k u > 0$.

Then the sequence $\{z^p\}_{p \in N_0}$ *generated by Method* 2.1 *converges to the unique solution of the LCP(M,q).*

Proof. Obviously, we need only to verify that (3.6) implies the validity of (3.1). As a matter of fact, because there exists a positive vector $u \in \mathbb{R}^n$ such that $\widehat{M}_k u > 0(k = 1, 2, \dots, K)$, in accordance with Lemma 2.1 we know that $\widehat{M}_k \in \mathbb{R}^{n \times n}$ are M-matrices. From (3.6) we have

$$\langle \widehat{B}_{k,p} \rangle u - |\widehat{C}_{k,p}| u \geq \widehat{M}_k u$$

or equivalently

$$\langle \widehat{B}_{k,p} \rangle^{-1} |\widehat{C}_{k,p}| u \leq u - \langle \widehat{B}_{k,p} \rangle^{-1} \widehat{M}_k u \leq u - (1 - \theta) u = \theta u.$$

Therefore,

$$\widehat{H}_p u = \sum_{k=1}^{K} E_{k,p}\langle \widehat{B}_{k,p}\rangle^{-1}|\widehat{C}_{k,p}|u \le \sum_{k=1}^{K} E_{k,p}\theta u = \theta u.$$

That is to say, (3.1) holds. □

Theorems 3.1 and 3.2 and Lemmas 2.1 and 2.2 directly give the following results.

THEOREM 3.3. *Let $M \in \mathbb{R}^{n\times n}$ be an H_+-matrix. Assume that for each $p \in N_0$ and $k \in \{1, 2, \dots, K\}$, $M = B_{k,p} + C_{k,p}$ is a splitting with $B_{k,p}$ having positive diagonal elements, and there exist matrices $M_k \in \mathbb{R}^{n\times n}(k = 1, 2, \dots, K)$, a constant $\theta \in [0, 1)$, and a positive vector $u \in \mathbb{R}^n$ such that $M_k u > 0$ and*

$$\begin{cases} \langle B_{k,p}\rangle - |C_{k,p}| \ge M_k, \\ \langle B_{k,p}\rangle u \le \dfrac{1}{1-\theta} M_k u. \end{cases}$$

Then the sequence $\{z^p\}_{p\in N_0}$ generated by Method 2.1 converges to the unique solution of the LCP(M,q).

Proof. Noticing that

$$\langle M\rangle \ge \langle B_{k,p}\rangle - |C_{k,p}| \ge M_k, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots,$$

we see that $\langle B_{k,p}\rangle - |C_{k,p}|$ and $\langle B_{k,p}\rangle$ are M-matrices and hence $B_{k,p}$ are H_+-matrices. Now, taking

$$\widehat{B}_{k,p} = B_{k,p}, \qquad \widehat{C}_{k,p} = C_{k,p}, \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots,$$

we know that all the conditions of Theorem 3.2 are satisfied, and thus the conclusion of this theorem holds. □

THEOREM 3.4. *Let $M \in \mathbb{R}^{n\times n}$ be an H_+-matrix. Assume that for each $p \in N_0$ and $k \in \{1, 2, \dots, K\}$, $M = B_{k,p} + C_{k,p}$ is an H_+-compatible splitting. Then the sequence $\{z^p\}_{p\in N_0}$ generated by Method 2.1 converges to the unique solution of the LCP(M,q).*

4. Applications to multisplitting relaxation methods. Method 2.1 is an implicit one, and at every iterate each processor needs to solve a linear complementarity problem of much smaller size. This makes it less convenient in concrete applications. In this section, we will discuss several special explicit forms of Method 2.1, which are convenient for practical implementations.

For $M = (m_{ij}) \in \mathbb{R}^{n\times n}$, denote $D = \mathrm{diag}(M) = \mathrm{diag}(m_{11}, m_{22}, \dots, m_{nn})$. For $k = 1, 2, \dots, K$ and $p \in N_0$, let $L_{k,p} = (l_{ij}^{(k,p)}) \in \mathbb{R}^{n\times n}$ be strictly lower triangular matrices, let $W_{k,p} = (w_{ij}^{(k,p)}) \in \mathbb{R}^{n\times n}$ be zero-diagonal matrices, and let $E_{k,p} = \mathrm{diag}(e_i^{(k,p)}) \in \mathbb{R}^{n\times n}$ be nonnegative diagonal matrices, such that

(1) $M = D + L_{k,p} + W_{k,p}$, $k = 1, 2, \dots, K$, $p = 0, 1, 2, \dots$;
(2) $\det(D) \ne 0$;
(3) $\sum_{k=1}^{K} E_{k,p} = I$, $p = 0, 1, 2, \dots$.

Given real constants γ_k and $\omega_k (\ne 0)$, $k = 1, 2, \dots, K$. Take

$$\begin{cases} B_{k,p} = \dfrac{1}{\omega_k}(D + \gamma_k L_{k,p}), \\ C_{k,p} = \dfrac{1}{\omega_k}((1-\omega_k)D - (\omega_k - \gamma_k)L_{k,p} - \omega_k W_{k,p}), \end{cases} \qquad k = 1, 2, \dots, K, \quad p = 0, 1, 2, \dots$$

in Method 2.1. Then we obtain the following dynamic multisplitting AOR method for solving the LCP(M,q).

METHOD 4.1 (multisplitting AOR method for the LCP(M,q)).

Step 1. *Choose an arbitrary starting vector* $z^0 \in \mathbb{R}^n$. *Set* $p := 0$.

Step 2. *For each* $k \in \{1, 2, \ldots, K\}$ *and for* $i = 1, 2, \ldots, n$, *let* $z^{k,p}$ *be calculated according to*

$$[z^{k,p}]_i = \begin{cases} 0 & \text{if} \quad \gamma_k \sum_{j=1}^{i-1} l_{ij}^{(k,p)}([z^{k,p}]_j - [z^p]_j) + \omega_k[Mz^p + q]_i > m_{ii}[z^p]_i, \\ [z^p]_i + \frac{\gamma_k}{m_{ii}} \sum_{j=1}^{i-1} l_{ij}^{(k,p)}([z^p]_j - [z^{k,p}]_j) - \frac{\omega_k}{m_{ii}}[Mz^p + q]_i & \text{otherwise.} \end{cases}$$

Step 3. $z^{p+1} = \sum_{k=1}^{K} E_{k,p} z^{k,p}$.

Step 4. *If* $z^{p+1} = z^p$, *then stop. Otherwise, set* $p := p + 1$ *and return to Step* 2.

Evidently, Method 4.1 includes Algorithm 4.1 in Machida, Fukushima, and Ibaraki [14] as a special case. On the other hand, when we choose the parameter pairs (γ_k, ω_k), $k = 1, 2, \ldots, K$, to be (ω_k, ω_k), $k = 1, 2, \ldots, K$, $(1, 1)$ and $(0, 1)$, respectively, Method 4.1 gives the dynamic multisplitting SOR, Gauss–Seidel, and Jacobi methods, correspondingly, for the LCP(M,q). Hence, an extensive sequence of parallel multisplitting relaxation methods can be obtained, which is quite practical and efficient for solving the large sparse linear complementarity problems on the high-speed multiprocessor systems. Moreover, the parameters (γ_k, ω_k), $k = 1, 2, \ldots, K$, can be adjusted suitably so that the convergence property of the multisplitting AOR method can be substantially improved. We remark that Method 4.1 is stationary if the matrices $L_{k,p}$, $W_{k,p}$, and $E_{k,p}$ are chosen independently of p, the iterate index.

We have the following convergence theorem for Method 4.1.

THEOREM 4.1. *Let* $M \in \mathbb{R}^{n \times n}$ *be an* H_+*-matrix and* $D = \operatorname{diag}(M)$. *Assume that there exists a matrix* $B \in \mathbb{R}^{n \times n}$ *such that, for every* $p \in N_0$,

$$|L_{k,p}| + |W_{k,p}| \le |B|, \qquad k = 1, 2, \ldots, K. \tag{4.1}$$

If $\rho(D^{-1}|B|) < 1$, *then the sequence* $\{z^p\}_{p \in N_0}$ *generated by Method* 4.1 *converges to the unique solution of the LCP(M,q), provided the relaxation parameters* γ_k *and* ω_k, $k = 1, 2, \ldots, K$, *satisfy*

$$0 \le \gamma_k \le \omega_k, \qquad 0 < \omega_k < \frac{2}{1 + \rho(D^{-1}|B|)}, \qquad k = 1, 2, \ldots, K. \tag{4.2}$$

Proof. Because for each $k \in \{1, 2, \ldots, K\}$ and each $p \in N_0$

$$\begin{cases} \langle B_{k,p} \rangle = \dfrac{1}{\omega_k}(D - \gamma_k |L_{k,p}|) := \widehat{\mathcal{B}}_{k,p}, \\ |C_{k,p}| \le \dfrac{1}{\omega_k}[|1 - \omega_k| D + (\omega_k - \gamma_k)|L_{k,p}| + \omega_k |W_{k,p}|] := \widehat{\mathcal{C}}_{k,p}, \end{cases}$$

$\widehat{\mathcal{B}}_{k,p}$ is an M-matrix, and $\widehat{\mathcal{C}}_{k,p}$ is a nonnegative matrix, by Lemma 2.2 we see that $(\widehat{\mathcal{B}}_{k,p}, \widehat{\mathcal{C}}_{k,p})$ is a majorizing pair of the splitting $(B_{k,p}, C_{k,p})$. Moreover, it holds that

$$\begin{aligned}\widehat{\mathcal{B}}_{k,p} - \widehat{\mathcal{C}}_{k,p} &= \frac{1}{\omega_k}[(1-|1-\omega_k|)D - \omega_k(|L_{k,p}| + |W_{k,p}|)] \\ &\geq \frac{1}{\omega_k}[(1-|1-\omega_k|)D - \omega_k|B|] \\ &> \frac{1}{\omega_k}[(1-|1-\omega_k|)D - \omega_k(|B| + \varepsilon ee^T)] := \widehat{M}_k,\end{aligned}$$

where $\varepsilon > 0$ is an arbitrary number and $e = (1, 1, \ldots, 1)^T \in \mathbb{R}^n$.

Considering that $\rho(D^{-1}|B|) < 1$, by the continuity of the spectral radius we know that it has $\rho(D^{-1}(|B| + \varepsilon ee^T)) < 1$ for a sufficiently small ε. Hence, in accordance with the Perron–Frobenius theorem (see [20]), there exists a positive vector $u \in \mathbb{R}^n$ such that

$$D^{-1}(|B| + \varepsilon ee^T)u = \rho u, \qquad \rho := \rho(D^{-1}(|B| + \varepsilon ee^T)).$$

On the other hand, since (4.2) implies that the relaxation parameters ω_k, $k = 1, 2, \ldots, K$, satisfy

$$|1-\omega_k| + \omega_k\rho(D^{-1}|B|) < 1, \qquad k = 1, 2, \ldots, K,$$

in accordance with the continuity of the spectral radius we can again let ε be small enough such that

$$|1-\omega_k| + \omega_k\rho < 1, \qquad k = 1, 2, \ldots, K.$$

Now, by direct calculations we have

$$\widehat{M}_k u = \left(\frac{1-|1-\omega_k|}{\omega_k} - \rho\right) Du > 0, \qquad k = 1, 2, \ldots, K,$$

provided the relaxation parameters γ_k and $\omega_k (k = 1, 2, \ldots, K)$ are within the regions defined by (4.2). Moreover, since

$$\begin{aligned}\langle B_{k,p}\rangle u &= \frac{1}{\omega_k}(D - \gamma_k|L_{k,p}|)u \leq \frac{1}{\omega_k}Du \\ &= \frac{1}{1-(|1-\omega_k| + \omega_k\rho)}\widehat{M}_k u,\end{aligned}$$

by letting $\theta = \max_{1\leq k\leq K}\{|1-\omega_k| + \omega_k\rho\}$, we see that $\theta \in [0, 1)$ and

$$\langle B_{k,p}\rangle u \leq \frac{1}{1-\theta}\widehat{M}_k u.$$

By making use of Theorem 3.2, we immediately reach the conclusion of this theorem. □

The condition $\rho(D^{-1}|B|) < 1$ in Theorem 4.1 is a natural alternative to condition (3.1) for the multisplitting AOR Method 4.1. One concrete choice of the multiple splittings that can ensure the existence of the splitting matrices satisfying (4.1) and $\rho(D^{-1}|B|) < 1$ is given in the following example.

EXAMPLE 4.1. *Let $M = (m_{ij}) \in \mathbb{R}^{n\times n}$ be an H_+-matrix and $D = \mathrm{diag}(M)$, $B = M - D$. For each $p \in N_0$ and $k \in \{1, 2, \ldots, K\}$, take $L_{k,p} = (l_{ij}^{(k,p)}) \in \mathbb{R}^{n\times n}$ and*

$W_{k,p} = (w_{ij}^{(k,p)}) \in \mathbb{R}^{n\times n}$ *in accordance with the following rule:*

$$l_{ij}^{(k,p)} = \begin{cases} l_{ij}^{(k,p)} \in [0, m_{ij}] & \text{for } i > j \text{ and } m_{ij} \geq 0, \\ l_{ij}^{(k,p)} \in [m_{ij}, 0] & \text{for } i > j \text{ and } m_{ij} < 0, \\ 0 & \text{otherwise,} \end{cases} \qquad i, j = 1, 2, \ldots, n,$$

$$w_{ij}^{(k,p)} = \begin{cases} 0 & \text{for } i = j, \\ m_{ij} - l_{ij}^{(k,p)} & \text{for } i \neq j, \end{cases} \qquad i, j = 1, 2, \ldots, n.$$

Then (4.1) *and* $\rho(D^{-1}|B|) < 1$ *are satisfied.*

Theorem 4.1 directly results in the following convergence results for the multisplitting SOR, Gauss–Seidel, and Jacobi methods.

THEOREM 4.2. *Let the conditions of Theorem* 4.1 *be satisfied. Then*

(a) *the sequence* $\{z^p\}_{p\in N_0}$ *generated by the multisplitting SOR method converges to the unique solution of the LCP(M,q), provided the relaxation parameters* $\omega_k (k = 1, 2, \ldots, K)$ *satisfy*

$$0 < \omega_k < \frac{2}{1 + \rho(D^{-1}|B|)}, \qquad k = 1, 2, \ldots, K;$$

(b) *the sequence* $\{z^p\}_{p\in N_0}$ *generated by the multisplitting Gauss–Seidel method converges to the unique solution of the LCP(M,q);*

(c) *the sequence* $\{z^p\}_{p\in N_0}$ *generated by the multisplitting Jacobi method converges to the unique solution of the LCP(M,q).*

5. Conclusions. A new variant of the multisplitting methods in Machida, Fukushima, and Ibaraki [14] is presented for the linear complementarity problems. This new method inherits the good parallel computational properties of its predecessor and, in particular, includes a class of practical multisplitting relaxation methods. The convergence of these new methods is generally and systematically studied for the nonsymmetric linear complementarity problems. In addition, sufficient conditions and concrete examples about the multiple splittings that satisfy the general convergence criteria are investigated. Hence, the convergence theorems of the multisplitting methods in [14] for the symmetric linear complementarity problems are developed for the nonsymmetric linear complementarity problems, which completes the convergence theory of this class of parallel multisplitting iterative methods.

Acknowledgments. The author is very much indebted to Professor R. W. Cottle for his warm encouragement and valuable suggestions. He also wants to thank the referees for their comprehensive comments and suggestions, which greatly improved the original manuscript. Part of this work was fulfilled during the author's visit to Oxford University Computing Laboratory and Atlas Centre, Rutherford Appleton Laboratory in England. Therefore, he sincerely thanks his advisors, Dr. Andrew J. Wathen and Professor Iain S. Duff, for their constant direction and warm encouragement.

SPECTRAL RADII OF FIXED FROBENIUS NORM PERTURBATIONS OF NONNEGATIVE MATRICES*

LIXING HAN†, MICHAEL NEUMANN†, AND MICHAEL TSATSOMEROS‡

Abstract. Let A be an $n \times n$ nonnegative matrix. In this paper we consider the problems of maximizing the spectral radii of (i) $A + X$ and (ii) $A + D$, where X is a real $n \times n$ matrix whose Frobenius norm is restricted to be 1 and where D is as X but is further constrained to be a diagonal matrix. For both problems the maximums occur at nonnegative X and D, and we use tools of nonnegative matrices, most notably due to Levinger and Fiedler, as well as the Kuhn–Tucker criterion for constrained optimization, to find upper and lower bounds on the maximums, and, when A is additionally assumed to be irreducible, to characterize cases of equalities in these bounds. In the case of the first problem, when A is irreducible, we characterize a matrix which gives the global maximum. A matrix which yields a global maximum to the second problem is more complicated to characterize as, depending on A, the problem admits local maximums within the nonnegative diagonal matrices of Frobenius norm 1.

Key words. nonnegative matrices, Perron eigenvalue, perturbation, maximization

1. Introduction.

Let A be an $n \times n$ nonnegative matrix. In this paper we consider optimization questions about the spectral radius of $A + X$, where X is a matrix whose *Frobenius norm* is constrained to be 1. After examining the case when X is any such matrix, we turn to the more restricted case of when X is diagonal. To be specific, we shall be concerned here with the following problems.

Maximization Problem I. Let A be an $n \times n$ nonnegative matrix. Then determine

$$\max_{\substack{X \in \mathbb{R}^{n \times n} \\ \|X\|_F = 1}} \rho(A + X). \tag{1.1}$$

Maximization Problem II. Let A be an $n \times n$ nonnegative matrix. Then determine

$$\max_{\substack{D \in \mathbb{R}^{n \times n}, \|D\|_F = 1 \\ D \text{ diagonal}}} \rho(A + D). \tag{1.2}$$

As the sets over which the maximizations are desired in both problems are compact and the spectral radius is a continuous function in the matrix entries, we are guaranteed that both problems have a solution within the restricted sets. Moreover, since $\|X\|_F = \||X|\|_F$ for any $X \in \mathbb{R}^{n,n}$, where $|X|$ is the nonnegative matrix whose entries are the absolute values of the corresponding entries in X, we have from the Perron–Frobenius theory that

$$\rho(A + X) \leq \rho(A + |X|).$$

Thus the solutions to the above maximization problems must occur at a nonnegative element whose Frobenius norm is 1.

In section 3 we analyze Maximization Problem I and prove a string of results that can be summarized as follows.

THEOREM 1.1. *Let A be an $n \times n$ nonnegative matrix and let*

$$\mu := \max_{\substack{X \in \mathbb{R}^{n\times n} \\ \|X\|_F = 1}} \rho(A + X). \tag{1.3}$$

Then

$$\rho(A) + 1 \leq \mu \leq \rho\left(\frac{A + A^T}{2}\right) + 1 \tag{1.4}$$

and μ is the unique value in the interval $(\rho(A), \infty)$ for which

$$\left\|(\mu I - A)^{-1}\right\|_2 = 1. \tag{1.5}$$

Moreover, if A is also irreducible, then μ is attained at a matrix W, $\|W\|_F = 1$, of rank 1. Furthermore, for the case when A is irreducible, equality holds in either of the inequalities in (1.4) *if and only if A has a common right and left Perron vector.*

In section 4 we examine the Maximization Problem II. We can summarize our observations there as follows.

THEOREM 1.2. *Let A be an $n \times n$ nonnegative matrix. Set*

$$\nu := \max_{\substack{D \in \mathbb{R}^{n\times n}, \|D\|_F = 1 \\ D \text{ diagonal}}} \rho(A + D). \tag{1.6}$$

Then

$$\rho(A) + \frac{1}{\sqrt{n}} \leq \nu \leq \rho(A) + 1. \tag{1.7}$$

Furthermore, suppose in addition that $n \geq 2$ and that A is irreducible and let $x = (x_1 \dots x_n)^T$ and $y = (y_1 \dots y_n)^T$ be, respectively, right and left Perron vectors of A normalized so that $y^T x = 1$. Then

$$\rho(A) + \frac{1}{\sqrt{n}} \leq \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2} \leq \nu < \rho(A) + 1. \tag{1.8}$$

Moreover, equality holds in the inequality

$$\rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2} \leq \nu$$

if and only if

$$\rho(A) + \frac{1}{\sqrt{n}} = \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2} = \nu$$

and, under either equivalent conditions, we have that

$$x_i y_i = \frac{1}{n}, \quad i = 1, \dots, n. \tag{1.9}$$

Last, equality holds in the leftmost inequality in (1.8) *if and only if condition* (1.9) *holds.*

Our results in this paper are made possible with the help of three useful tools in analysis and in the theory of nonnegative matrices: the Kuhn–Tucker criterion for constrained optimization, an inequality for the spectral radius of an $n \times n$ nonnegative matrix due to Levinger, and a characterization for the spectral radius of an $n \times n$ nonnegative and irreducible matrix due to Fiedler. For convenience we quote these required results in section 2, where we also present other essential preliminaries.

We may view Theorems 1.1 and 1.2 as nonlocal in the sense that they tell us about the maxima of the spectral radii "far away" from A. In section 2 we also make the simple observation that the steepest ascent of the spectral radius at A occurs in the direction of the transpose of the eigenprojection onto the Perron eigenspace of A.

We comment that in section 3 it will be argued, using (1.5), that when A is irreducible, the Maximization Problem I has no local maxima in the nonnegative orthant other than, of course, the global maximum.[1] However, Maximization Problem II can have local maxima. We further mention that the results of Theorems 1.1 and 1.2 can be easily modified to solve the respective maximization problems subject to the perturbation matrices X or D having Frobenius norm $t > 0$ rather than 1. All that needs to be done is to replace that matrix A in (1.1) and (1.2) by the matrix A/t.

It should finally be remarked that in two recent papers, Johnson, Stanford, Olesky, and van den Driessche [7] and Johnson, Loewy, Olesky, and van den Driessche [8] consider optimization problems for the spectral radius of $A + D$, where A is an $n \times n$ nonnegative and irreducible matrix, but now D is a diagonal matrix whose *trace* is constrained in some fashion rather than its Frobenius norm.

2. Preliminaries. In this section we shall present some preliminary notation, some known results from the literature, as well as some observations which should aid in the understanding of the paper.

The following basic tenets of the Perron–Frobenius theory are taken from the book of Berman and Plemmons [1]. Let B be an $n \times n$ nonnegative irreducible matrix. The latter condition is equivalent to the existence of *no* permutation matrix P for which

$$PBP^T = \begin{pmatrix} \tilde{B}_{1,1} & \tilde{B}_{1,2} \\ 0 & \tilde{B}_{2,2} \end{pmatrix},$$

where both diagonal blocks are square and nonvacuous. The spectral radius of B, denoted by $\rho(B)$, is a simple eigenvalue, frequently called the *Perron root of* B, and it possesses right and left Perron eigenvectors having only positive entries. We shall use "$\gg 0$" to denote an array, square, or rectangular, whose entries are all positive and we shall use "$\circ$" to denote the entrywise product of two arrays whose dimensions coincide.

As a *function* of any of the matrix entries, the Perron root is strictly increasing at B. Moreover, as it is a *simple* eigenvalue we know, for instance from Wilkinson [11], that $\rho(\cdot)$ is an analytic function in each of the entries in an $\mathbb{R}^{n,n}$-neighborhood of B and hence the partial derivative of $\rho(\cdot)$ with respect to each of the entries exists at B.

Let x and y be positive right and left Perron vectors of B, respectively. Then

[1] Note the different sense in which the notion of "local" is used now compared with the sense in which it was used in the previous paragraph.

according to, e.g., Stewart [10, Ex. 1, p. 305], we have that

$$\frac{\partial \rho(B)}{\partial_{i,j}} = \frac{y_i x_j}{x^T y}, \quad i,j = 1, \ldots, n. \tag{2.1}$$

Thus, since the eigenprojection onto the Perron eigenspace is given by

$$E := \frac{xy^T}{y^T x},$$

it follows at once, relying on the said differentiability of the Perron root at B, that

$$\rho'(B) = \nabla \rho(B) = E^T = \frac{yx^T}{y^T x}. \tag{2.2}$$

With an expression for the gradient of the Perron root at our disposal, we can compute its directional derivatives at B. For that purpose let us recall that the inner product on $\mathbb{R}^{n,n}$ is given by

$$P \cdot Q = \operatorname{trace}(P^T Q)$$

which induces the matrix norm

$$\|P\|_F = \sqrt{\operatorname{trace}(P^T P)}.$$

Now let $X \in \mathbb{R}^{n,n}$ with $\|X\|_F = 1$. Then the directional derivative in the direction of X at B is given by

$$\rho'_X(B) = \lim_{t \to 0} \frac{\rho(B + tX) - \rho(B)}{t} = \nabla \rho(B) \cdot X = E^T \cdot X = \operatorname{trace}(EX). \tag{2.3}$$

Multivariate calculus tells us now that the steepest rate of increase at B is in the direction of the gradient and hence it is given by

$$\rho'_{E^T/\|E\|_F}(B) = \lim_{t \to 0} \frac{\rho\left(B + t\dfrac{E^T}{\|E\|_F}\right) - \rho(B)}{t} = E^T \cdot \frac{E^T}{\|E\|_F} = \|E\|_F. \tag{2.4}$$

By the Cauchy–Schwarz inequality we know that

$$\rho'_X(B) < \rho'_{E^T/\|E\|_F}(B) \tag{2.5}$$

unless for $X \in R^{n,n}$ with $\|X\|_F = 1$, $X = kE^T$ for some constant k. Thus we can conclude the following about the local behavior of the Perron root in the vicinity of B.

THEOREM 2.1. *Let B be an $n \times n$ nonnegative irreducible matrix and let E be the eigenprojection onto the eigenspace of $\rho(B)$. Then for any $X \in \mathbb{R}^{n \times n}$ with $\|X\|_F = 1$ and $X \neq kE^T$, k a constant, there exists $t_X > 0$ such that for all $0 < t \leq t_X$,*

$$\rho\left(B + t\frac{E^T}{\|E\|_F}\right) > \rho(B + tX). \tag{2.6}$$

Proof. Let X be as prescribed. The conclusion follows at once from (2.3), (2.5), and (2.4). ∎

If we regard for a moment the Perron root as a function of the diagonal entries only, then from (2.1) we see that

$$\rho'(B) = \nabla\rho(B) = \frac{1}{y^T x}\begin{pmatrix} x_1 y_1 \\ \vdots \\ x_n y_n \end{pmatrix} := E_D. \tag{2.7}$$

Moreover, we see that the rate of steepest ascent of the spectral radius as a function of the diagonal entries at B is given by

$$\rho'_{\mathrm{diag}(E_D)/\|\mathrm{diag}(E_D)\|_F}(B) = \frac{\|x \circ y\|_2}{y^T x}.$$

Now using similar argumentation which led us to Theorem 2.1, we have the following local behavior of the Perron root with regard to diagonal perturbations.

THEOREM 2.2. *Let B be an $n \times n$ nonnegative irreducible matrix. Then for any diagonal matrix $\Delta \in \mathbb{R}^{n\times n}$ with $\|\Delta\|_F = 1$ and $\Delta \neq kE_D^T = kE_D$, k a constant, there exists $t_\Delta > 0$ such that for all $0 < t \leq t_\Delta$,*

$$\rho\left(B + t\frac{\mathrm{diag}\,(E_D)}{\|\mathrm{diag}\,(E_D)\,\|_F}\right) \;>\; \rho(B + t\Delta). \tag{2.8}$$

To obtain our goal of proving Theorems 1.1 and 1.2, we shall rely on the following results on the spectral radius of $n \times n$ nonnegative matrices.

THEOREM LEVINGER (see [9]). *Let B be an $n \times n$ nonnegative matrix. Then*

$$\rho(B) \leq \rho\left(\frac{B + B^T}{2}\right) \tag{2.9}$$

with equality holding in the inequality if and only if B has common right and left Perron vectors.

THEOREM FIEDLER (see [4, Theorem]). *Let B be an irreducible $n \times n$ nonnegative matrix with x and y positive right and left Perron vectors, respectively, viz., $Bx = \rho(B)x$ and $B^T y = \rho(B)y$. Then*

(a)

$$\rho(B) = \max_{z\gg 0}\ \min_{\substack{u,v\gg 0\\ u\circ v = z}} \frac{v^T B u}{v^T u}. \tag{2.10}$$

(b) *$v^T Bu \geq y^T Bx = \rho(B)y^T x$ whenever $u, v \gg 0$ and $u \circ v = x \circ y$, and equality holds if and only if $u = kx$ for some positive scalar k.*

(c) *In particular, $x^T By \geq y^T Bx = \rho(B)y^T x$, with equality if and only if B has the same right and left Perron vectors.*

We mention that while no proof of Theorem Levinger is given in [9], a variety of proofs of his result can be found in the literature. Actually, Theorem Fiedler, whose statement and proof are given in [4, Theorem] comes from Fiedler [2]. For a more recent treatment of both the Levinger and Fiedler theorems see [3].

Finally, as both Maximization Problems I and II are of *constrained optimization problems*, we shall make use of the Kuhn–Tucker constrained optimization criterion subject to one equality constraint as in the following theorem.

THEOREM KUHN–TUCKER (see [6, p. 81]). *Consider the equality constrained maximization problem*

$$\begin{cases} \max_{t\in\mathbb{R}^k} F(t), \\ \\ \textit{subject to } c(t) = 0. \end{cases} \tag{2.11}$$

Suppose the functions F and c are differentiable in some $\mathbb{R}^k$-neighborhood of the optimal solution t_*. Then

$$\nabla F(t_*) = \lambda \nabla c(t_*) \tag{2.12}$$

for some real scalar λ.

3. Maximation Problem I. The goal of this section is to provide all claims and proofs that are necessary to establish Theorem 1.1.

To get an initial lower estimate on the value of μ in (1.3) is trivial. All we need to do is make the following observation.

Observation 3.1. *Let A be an $n \times n$ nonnegative matrix and let x be a right Perron vector of A with $\|x\|_2 = 1$. Then*

$$\rho(A + xx^T) = \rho(A) + 1. \tag{3.1}$$

Proof. Observe that $\|xx^T\|_F = 1$ and that

$$(A + xx^T)x = [\rho(A) + 1]x. \qquad \square$$

The above observation implies at once that

$$\max_{\substack{X \in \mathbb{R}^{n \times n} \\ \|X\|_F = 1}} \rho(A + X) \geq \rho(A) + 1. \tag{3.2}$$

For the symmetric case we can obtain with the aid of (3.2) that the following corollary holds.

COROLLARY 3.2. *Let A be an $n \times n$ symmetric nonnegative matrix. Then*

$$\max_{\substack{X \in \mathbb{R}^{n \times n} \\ \|X\|_F = 1}} \rho(A + X) = \rho(A) + 1. \tag{3.3}$$

Proof. On the one hand, we know by (3.2) that

$$\max_{\substack{X \in \mathbb{R}^{n \times n} \\ \|X\|_F = 1}} \rho(A + X) \geq \rho(A) + 1.$$

On the other hand, we can write that for any nonnegative $X \in \mathbb{R}^{n,n}$ with Frobenius norm 1,

$$\begin{aligned} \rho(A + X) &\leq \|A + X\|_2 \leq \|A\|_2 + \|X\|_2 \\ &\leq \rho\left(\frac{A + A^T}{2}\right) + \|X\|_F = \rho\left(\frac{A + A^T}{2}\right) + 1 \\ &= \rho(A) + 1. \end{aligned} \tag{3.4}$$

This completes the proof. $\square$

Now if A is *not necessarily symmetric*, then we can use Theorem Levinger (see section 2) to obtain the following upper estimate:

$$\rho(A + X) \leq \rho\left(\frac{A + A^T}{2} + \frac{X + X^T}{2}\right).$$

However,

$$\left\| \frac{X + X^T}{2} \right\|_2 \leq 1$$

so that we can certainly increase elements of $(X + X^T)/2$ if necessary to arrive at a matrix $\tilde{X}$ with $\|\tilde{X}\|_F = 1$, in which case we see from (3.4) that

$$\begin{aligned}\rho(A+X) &\leq \rho\left(\frac{A+A^T}{2}+\frac{X+X^T}{2}\right)\\ &\leq \rho\left(\frac{A+A^T}{2}+\tilde{X}\right) \leq \rho\left(\frac{A+A^T}{2}\right)+1.\end{aligned}$$

We have thus shown that Proposition 3.3 holds.

PROPOSITION 3.3. *Let A be an $n \times n$ nonnegative matrix. Then*

$$\max_{X\in\mathbb{R}^{n\times n},\|X\|_F=1} \rho(A+X) \leq \rho\left(\frac{A+A^T}{2}\right)+1. \tag{3.5}$$

We turn now to the problem of showing that the value of μ given in (1.3) is given by the unique value of μ which satisfies (1.5). To this end, we begin by assuming that A is also irreducible and we characterize a nonnegative matrix W with $\|W\|_F = 1$ which solves (1.1). We can use the remarks preceding Theorem 1.1 to reason as follows: As there exists a matrix W that furnishes a global solution and that is nonnegative and as A is irreducible and nonnegative, at such a W, $A + W$ is nonnegative and irreducible, thus securing the differentiability of the Perron root at $A + W$ in each of the matrix entries. This means that we can use the Kuhn–Tucker necessary conditions for the solution of the constrained optimization problem (see Theorem Kuhn–Tucker in section 2) to make an observation essential to this section.

LEMMA 3.4. *Let A be an $n \times n$ nonnegative and irreducible matrix and let W be a nonnegative global maximizer for* (1.1). *Then $W \gg 0$ and* $\operatorname{rank}(W) = 1$.

Proof. On the one hand, we know by (2.2) that the gradient of $\rho(\cdot)$ at $A + W$ is the eigenprojection onto the Perron eigenspace of $(A + W)^T$ and hence is a positive matrix of rank 1. On the other hand, the gradient of $c(X) = \|X\|_F^2 - 1$ at W is $2W$ from which our conclusion simply follows. ∎

Lemma 3.4 leads us to the following characterization for the maximal value attained in (1.1).

THEOREM 3.5. *Let A be an $n \times n$ nonnegative matrix. If*

$$\mu = \max_{\substack{X\in\mathbb{R}^{n,n}\\ \|X\|_F=1}} \rho(A+X), \tag{3.6}$$

then

$$\left\|(\mu I - A)^{-1}\right\|_2 = 1. \tag{3.7}$$

Proof. Let us begin by assuming that A is (also) irreducible and suppose that W is a maximizing nonnegative solution to (1.1). Then, by Lemma 3.4, W is positive, of rank 1, and of Frobenius norm 1 and therefore can be taken without loss of generality to be $W = qp^T$, where $\|q\|_2 = \|p\|_2 = 1$. Moreover, it follows from the arguments in the proof of Lemma 3.4 that W is a multiple of the eigenprojection of $(A+W)^T$ onto its Perron eigenspace and so

$$(A+W)^T W = \mu W \tag{3.8}$$

so that

$$(A^T + pq^T)q = \mu q. \tag{3.9}$$

It is easily realized that W^T is the global optimal solution to (1.1) when $A \to A^T$. Thus we also have that

$$(A + qp^T)p = \mu p. \tag{3.10}$$

However, (3.9) and (3.10) together give that

$$\left(\mu I - A^T\right)^{-1} (\mu I - A)^{-1} q = q.$$

As both matrices in the product above are positive, 1 is the spectral radius of this product and hence $\|(\mu I - A)^{-1}\|_2 = 1$.

Suppose now that A is reducible and let J be the $n \times n$ matrix of all 1's. For $\epsilon > 0$, set $A_\epsilon = A + \epsilon J$, and let

$$\mu_\epsilon := \max_{X \in \mathbb{R}^{n\times n} \|X\|_F = 1} \rho(A_\epsilon + X) = \rho\left(A_\epsilon + X_\epsilon\right). \tag{3.11}$$

Then by the initial part of the proof,

$$\left\|(\mu_\epsilon I - A)^{-1}\right\|_2 = 1. \tag{3.12}$$

Since the set

$$\{X \in \mathbb{R}^{n,n} \mid X \geq 0,\ \|X\|_F = 1\} \tag{3.13}$$

is compact, there exists a monotonically decreasing sequence $\{\epsilon_i\}_{i=1}^{\infty}$ such that $X_{\epsilon_i} \to \tilde{X}$ with $\|\tilde{X}\|_F = 1$ as $\epsilon_i \to 0$. Note that $A_{\epsilon_i} \to A$ and so, by the continuity of the spectral radius,

$$\mu_{\epsilon_i} = \rho\left(A_{\epsilon_i} + X_{\epsilon_i}\right) \ \to \rho\left(A + \tilde{X}\right) = \tilde{\mu} \tag{3.14}$$

with

$$\left\|(\tilde{\mu} I - A)^{-1}\right\|_2 = 1. \tag{3.15}$$

Next, clearly for some $\hat{X} \in \mathbb{R}^{n,n}$ with $\hat{X} \geq 0$ and with $\|\hat{X}\|_F = 1$,

$$\tilde{\mu} \leq \max_{\substack{X \in \mathbb{R}^{n\times n} \\ \|X\|_F = 1}} \rho(A + X) = \rho\left(A + \hat{X}\right) = \mu.$$

On the other hand,

$$\mu_\epsilon \geq \rho(A_\epsilon + \hat{X})$$

and so

$$\tilde{\mu} \geq \lim_{i \to \infty} \rho\left(A_{\epsilon_i} + \hat{X}\right) = \mu.$$

Thus $\mu = \tilde{\mu}$ and $\left\|(\mu I - A)^{-1}\right\|_2 = 1$ and our proof is complete. ∎

COROLLARY 3.6. *Let A be an $n \times n$ nonnegative matrix. Then*

$$\mu := \max_{\substack{X \in \mathbb{R}^{n\times n} \\ \|X\|_F = 1}} \rho(A + X)$$

if and only if

$$\left\|(\mu I - A)^{-1}\right\|_2 = 1.$$

Since for $\nu > \rho(A)$,

$$\left\|(\nu I - A)^{-1}\right\|_2^2 = \rho\left\{(\nu I - A)^{-1}\left(\nu I - A^T\right)^{-1}\right\},$$

and due to Neumann's expansion, as a function of ν in the interval $(\rho(A), \infty)$, $\left\|\left(\nu I - A\right)^{-1}\right)\right\|_2$ is strictly decreasing and hence for only one value of ν, namely, $\nu = \mu$, the function assumes the value 1.

Remark 3.7. If A is an $n \times n$ irreducible matrix, then on the set of nonnegative X's in $\mathbb{R}^{n,n}$ with Frobenius norm 1, $\rho(A + X)$ has no local maxima in addition to its global maximum. This is because, once again, the use of the Kuhn–Tucker conditions as in Lemma 3.4 would give that a local maximum has to occur at a rank 1 element. An analysis such as in the proof of Theorem 3.5 would then imply that the value of the local maximum has to be equal to the only value of μ that can render $\|(\mu I - A)^{-1}\|_2 = 1$.

As an example for the results of Lemma 3.4 and Theorem 3.5, consider that matrix

$$A = \begin{bmatrix} 12 & 1 \\ 99 & 2 \end{bmatrix}.$$

Our computations yield that the maximizing matrix is given by the rank 1 matrix

$$W \approx \begin{bmatrix} 0.1963 & 0.9756 \\ 0.01946 & 0.09675 \end{bmatrix}$$

and

$$\rho(A + W) - \rho(A) \approx 22.0166 - 18.1355 = 3.8811.$$

We remark that the upper bound $\rho((A + A)^T/2) + 1$ on $\mu = \rho(A + W)$ given on the right-hand side of (1.4) comes to approximately 53.2494. Finally, if we attempt to verify (3.8) for this example, then we get that

$$(A + W)^T W - \rho(A + W)W \approx 10^{-3} \begin{bmatrix} -0.09520 & -0.4730 \\ 0.01910 & 0.09520 \end{bmatrix}.$$

We computed W above using a function routine in conjunction with the MATLAB Optimization Toolbox. In our function, the search was done only over the rank 1 nonnegative matrices of Frobenius norm 1. However, to confirm the results, as well as the results for other examples, we used a version of the SQP method, (see Fletcher [5]) devised by M. J. D. Powell, FRS. We implemented the algorithm on an IBM mainframe with single precision arithmetic. This usually gave nonsingular solutions W to our various examples. A quick check showed that the computed W's had a high condition number.

In our next results we shall characterize precisely when equalities hold in (3.2) and (3.5) for the case when A is irreducible.

THEOREM 3.8. *Let A be an $n \times n$ nonnegative and irreducible matrix. Then equality holds in* (3.2) *if and only if A has a common left and right eigenvector.*

Proof. Since A is irreducible, there exist unique n-vectors $x \gg 0$ and $y \gg 0$ with $\|x\|_2 = \|y\|_2 = 1$ such that $Ax = \rho(A)x$ and $A^T y = \rho(A)y$. Suppose that $\mu = \rho(A)+1$. Then

$$(\mu I - A)^{-1} x = x \tag{3.16}$$

and

$$\left(\mu I - A^T\right)^{-1} y = y. \tag{3.17}$$

Now from the proof of Theorem 3.5, there exists a unique n-vector $z \gg 0$ with $\|z\|_2 = 1$ such that

$$\left(\mu I - A^T\right)^{-1} (\mu I - A)^{-1} z = z. \tag{3.18}$$

However, from (3.17), (3.18), and the irreducibility of $\left(\mu I - A^T\right)^{-1}$ and $\left(\mu I - A^T\right)^{-1}$ $(\mu I - A)^{-1}$ we get that $y = z$ and $y = (\mu I - A)^{-1} z$, whence $y = (\mu I - A)^{-1} y$ so that, by (3.16), $x = y$ from which we conclude that A has a common left and right Perron vector.

Conversely, if $x = y$, then

$$\left((1 + \rho(A))I - A^T\right)^{-1} ((1 + \rho(A))I - A)^{-1} x = x.$$

Hence

$$\|(1 + \rho(A)I - A)^{-1}\|_2 = 1$$

which implies that $\mu = \rho(A) + 1$. □

THEOREM 3.9. *Let A be an $n \times n$ nonnegative and irreducible matrix. Then equality holds in* (3.5) *if and only if A has a common right and left Perron eigenvector.*

Proof. Let W be a nonnegative global maximizer for the maximization problem (1.1). Then by the Theorem Levinger inequality, inequality (3.5) as applied to the matrix $(A + A^T)/2$, and because $\|(W + W^T)/2\|_F \leq 1$, we can write that

$$\rho(A + W) \leq \rho\left(\frac{A + A^T}{2} + \frac{W + W^T}{2}\right) \leq \rho\left(\frac{A + A^T}{2}\right) + 1. \tag{3.19}$$

However, by the hypothesis of the theorem,

$$\rho(A + W) = \rho\left(\frac{A + A^T}{2} + \frac{W + W^T}{2}\right). \tag{3.20}$$

It now follows by the equality case in Levinger's inequality that $A + W$ has a common right and left Perron vector. Now according to our characterization of the maximizing element using the Kuhn–Tucker condition, $W = qp^T$, with $(A + W)p = \rho(A + W)p$ and $(A^T + W^T)q = \rho(A + W)q$, so that we must have that $p = q$. However, again using the fact that $W = qp^T$, it easily follows that p (or $q = p$) has to be concurrently a right and left Perron vector of A.

Conversely, if A has a common right and left Perron vector, then by Levinger's inequality, $\rho(A) = \rho((A + A^T)/2)$. That equality holds in (3.5) now follows from Theorem 3.8 and (3.5). □

4. Diagonal perturbations. In this section we consider the solution to Maximization Problem II. We begin by establishing the results which give the lower bounds in (1.8) in the irreducible case.

LEMMA 4.1. *Let A be an $n \times n$ nonnegative and irreducible matrix and suppose that $x = (x_1 \dots x_n)^T$ and $y = (y_1 \dots y_n)^T$ are, respectively, right and left Perron vectors of A normalized so that $y^T x = 1$. Then*

$$\rho(A) + \frac{1}{\sqrt{n}} \leq \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2} \leq \nu. \tag{4.1}$$

Moreover, for equality to hold in the rightmost inequality it is necessary and sufficient that equalities hold throughout (4.1)*, that is,* $\nu = \rho(A) + 1/\sqrt{n}$*, and, under either equivalent conditions,*

$$x_i y_i = \frac{1}{n}, \quad i = 1, \dots, n. \tag{4.2}$$

Last, equality holds in the leftmost inequality in (4.1) *if and only if* (4.2) *holds.*

Proof. We begin by showing the validity of the rightmost inequality in (4.1). For that purpose let $z = x \circ y$ and let $D = \operatorname{diag}\left(\sqrt{z_1}, \dots, \sqrt{z_n}\right)$ so that D is a diagonal matrix whose Frobenius norm is 1. Then for any two positive vectors $\xi = (\xi_1 \dots \xi_n)^T$ and $\eta = (\eta_1 \dots \eta_n)^T$ with $\xi_i \eta_i = z_i$, $i = 1, \dots, n$, we have, by Theorem Fiedler part (b) of section 2 as applied to the matrix A, that

$$\xi^T (A + D)\eta \geq \rho(A) + \sum_{i=1}^{n} \xi_i \left(\sqrt{z_i}\right) \eta_i = \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2}. \tag{4.3}$$

Next, the proof of Theorem Fiedler given in [4], as applied now to the matrix $A + D$, assures us that for the vector $z \gg 0$, there exist positive vectors $\tilde{\xi}$ and $\tilde{\eta}$ such that $\tilde{\xi} \circ \tilde{\eta} = z$ and such that

$$\tilde{\xi}^T (A + D)\tilde{\eta} = \min_{\substack{\xi \circ \eta = z \\ \xi \gg 0, \eta \gg 0}} \xi^T (A + D)\eta. \tag{4.4}$$

Thus, from the maximization that occurs in Theorem Fiedler part (a) when applied to the matrix $A + D$ and by (4.3) we can write that

$$\nu \geq \rho(A + D) \geq \tilde{\xi}^T (A + D)\tilde{\eta} \geq \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2}. \tag{4.5}$$

We have thus proved that the rightmost inequality in (4.1) holds.

Suppose now that equality holds in the rightmost inequality in (4.1) so that

$$\nu = \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2}.$$

Then, by (4.4) and (4.5), we have that

$$\nu = \tilde{\xi}^T (A + D)\tilde{\eta} = \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2}. \tag{4.6}$$

As $\tilde{\xi}^T A \tilde{\eta} \geq \rho(A)$, we must actually have that $\tilde{\xi}^T A \tilde{\eta} = \rho(A)$. However, by part (b) of Theorem Fiedler, now as applied to the matrix A, it follows that $\tilde{\eta} = kx$ for some positive scalar k and therefore also that $\tilde{\xi} = (1/k)y$. Without loss of generality we can assume that $k = 1$. Hence, by (4.6) and part (b) of Theorem Fiedler as applied again to the matrix $A + D$, it follows that

$$(A + D)\tilde{\eta} = \nu \tilde{\eta} \quad \text{and} \quad (A^T + D)\tilde{\xi} = \nu \tilde{\xi}.$$

This means that x and y are also right and left Perron eigenvectors of $A + D$, respectively, and so it holds that

$$Dx = (\nu - \rho(A))x \quad \text{and} \quad Dy = (\nu - \rho(A))y.$$

As the diagonal entries of D are $\sqrt{x_i y_i}$, $i = 1, \ldots, n$, the above relations easily yield that

$$x_i y_i = (\nu - \rho(A))^2, \quad i = 1, \ldots, n, \tag{4.7}$$

whence

$$\sum_{i=1}^{n} (x_i y_i)^{3/2} = n(\nu - \rho(A))^3 \tag{4.8}$$

which easily yields, using (4.6), that $\nu - \rho(A) = 1/\sqrt{n}$. This shows that equality must hold also in the leftmost inequality in (4.1). Observe too that (4.7) validates (4.2) under the present assumptions.

Let us now show the leftmost inequality in (4.1). Consider the problem of minimizing the function $\sum_{i=1}^{n} u_i^{3/2}$ subject to the conditions that $u_i > 0$, $i = 1, \ldots, n$, and $\sum_{i=1}^{n} u_i = 1$. The method of the Lagrange multipliers easily gives that we must have the vector equality $(u_1^{1/2} \ldots u_n^{1/2})^T = \lambda(1 \ldots 1)^T$ for some nonzero scalar λ so that $u_1 = \cdots = u_n$. As $\sum_{i=1}^{n} u_i = 1$, it is necessary that $u_i = 1/n$, $i = 1, \ldots, n$, and so the leftmost inequality in (4.1) holds.

That (4.2) is a necessary and sufficient condition for equality to hold in the leftmost equality of (4.1) is an immediate consequence of the arguments in the preceding paragraph.

Finally, if $\nu = \rho(A) + 1/\sqrt{n}$, then by (4.3) and the last paragraph but one, we have that

$$\nu = \rho(A) + \sum_{i=1}^{n} (x_i y_i)^{3/2}$$

which implies, again by using the preceding paragraphs, that $x_i y_i = 1/n$, $i = 1, \ldots, n$. □

We remark that the lower bound

$$\nu \geq \rho(A) + \frac{1}{\sqrt{n}}$$

holds also when A is reducible by obvious continuity arguments.

We next provide two examples to illustrate the behavior of some matrices in the presence of equalities in some or all of the inequalities of (4.1). We begin with the case when $\nu = \rho(A) + (1/\sqrt{n})$; i.e., equalities hold throughout (4.1). This can occur without A being either symmetric or doubly stochastic. To see this let

$$A_1 = \begin{bmatrix} 2.0 & 1.0 \\ 2.0 & 2.0 \end{bmatrix}.$$

On computing right and left eigenvectors of A_1, say $x = (0.6124\ 0.8660)^T$ and $y = (0.8165\ 0.5774)^T$, we see $x \circ y = (1/2\ 1/2)^T$. In our second example we show that equality in the leftmost inequality of (4.1) *does not* imply equality also in the rightmost

inequality of (4.1). Take

$$A_2 = \begin{bmatrix} 0 & 0 & 0 & 0.6124 & 0.2494 & 0.1381 \\ 0 & 0 & 0 & 0.2494 & 0.3685 & 0.3821 \\ 0 & 0 & 0 & 0.1381 & 0.3821 & 0.4797 \\ 0.6124 & 0.2494 & 0.1381 & 0 & 0 & 0 \\ 0.2494 & 0.3685 & 0.3821 & 0 & 0 & 0 \\ 0.1381 & 0.3821 & 0.4797 & 0 & 0 & 0 \end{bmatrix}. \tag{4.9}$$

Then A_2 is symmetric, doubly stochastic, and even has a constant diagonal, but $\nu > \rho(A_2) + 1/\sqrt{6}$ as can be seen by selecting

$$D = \operatorname{diag}(0.07869, 0.1312, 0.8979, 0.08612, 0.2206, 0.3382)$$

for which $\|D\|_F = 1$ and $\rho(A + D) - \rho(A) = 0.4245 > 1/\sqrt{6}$.

Obtaining the upper bound in Theorem 1.2 is simple.

LEMMA 4.2. *Let A be an $n \times n$, $n \geq 2$, nonnegative matrix. Then, in the notation of Theorem* 1.2, *$\nu \leq \rho(A) + 1$. If, in addition, A is irreducible, then strict inequality holds.*

Proof. Recall that

$$\nu := \max_{\substack{D \in \mathbb{R}^{n \times n}, \|D\|_F = 1 \\ D \text{ diagonal}}} \rho(A + D). \tag{4.10}$$

Without loss of generality, we can assume that $D \geq 0$. As $D \leq I$, we have from the Perron–Frobenius theory that

$$\rho(A + D) \leq \rho(A + I) = 1 + \rho(A).$$

As $n \geq 2$, we must have that $D \neq I$ and hence strict inequality when A is irreducible. ∎

Two comments are in order as follows concerning our findings in this section:

(i) Consider for a moment the doubly stochastic and symmetric matrix A in (4.9) for which we showed that $\nu \geq 1.4245$. By Theorem Kuhn–Tucker of section 2 and by the preceding lemma, we know that there exists a positive diagonal matrix W, $\|W\|_F = 1$, for which

$$(A + W)\, p = \nu p \quad \text{and} \quad \left(A^T + W\right) q = \nu q$$

for some positive vectors n-vectors p and q. On the other hand, we know that the vector $e = (1, \ldots, 1)^T$ is both a right and left Perron eigenvector of A. Moreover, e is, in fact, both a left and right Perron vector of the matrix $A + \operatorname{diag}(e \circ e) := A + E$. Thus, for the Perron root viewed as a function of the diagonal entries, we observe via (2.7) that

$$\rho'(A + E) = \nabla \rho(A + E) = k_1 (e \circ e) = k_1 e$$

for some positive constant k. Now as $2e$ is the gradient of the function $\|x\|_2^2 - 1$ at $x = e$, we see not only that W satisfies the necessary condition (2.11) of Theorem Kuhn–Tucker but also the matrix E. This suggests that unlike Maximization Problem I for which we showed that in the nonnegative orthant it has no local maxima other than the global maximum, Maximization Problem II can have local maxima.

(ii) In Lemma 4.2 we show that for $n \geq 2$, the solution to Maximization Problem II always satisfies that $\nu < \rho(A)+1$ when A is irreducible, but that when A is reducible, equality can hold. As can be expected, we can show that there are irreducible A's for which ν is arbitrarily close to $\rho(A)+1$. This is borne out by analyzing nonnegative diagonal perturbations of Frobenius norm 1 in the example

$$A(\epsilon) = \begin{pmatrix} 1 & \epsilon \\ \epsilon & \epsilon \end{pmatrix}, \quad \epsilon > 0,$$

and by letting $\epsilon \to 0+$.

Acknowledgments. The authors wish to thank the referee for many helpful suggestions that in some places have led to improvements, simplifications, and economizations in our proofs. The authors also wish to acknowledge interesting conversations and exchange of ideas with Professor Paul van Dooren and Mr. Vincent Vermaut of the Université Catholique de Louvain.

POINTWISE AND UNIFORMLY CONVERGENT SETS OF MATRICES*

ADAM L. COHEN†, LEIBA RODMAN‡, AND DAVID P. STANFORD‡

Abstract. Pointwise and uniform convergence properties of sets of real matrices are investigated. In particular, topological properties of uniformly and pointwise convergent sets are studied, as well as uniformly and pointwise convergent sets of matrices with special features: entrywise nonnegative or triangular. A detailed description of pointwise and uniformly convergent sets of two 2×2 matrices is presented.

Key words. pointwise convergent, uniformly convergent, matrix sets

1. Introduction.

Let $\mathcal{A} = \{A_j\}_{j \in J}$ be an indexed set of matrices, where each A_j is an $n \times n$ real matrix. The set $\mathcal{A}$ is said to be *pointwise convergent* if, for each $x \in \mathbb{R}^n$, there is an index sequence $\{p(x)_i\}_{i=1}^{\infty}$ such that $\lim_{k\to\infty}((\prod_{i=k}^{1} A_{p(x)_i})x) = 0$. $\mathcal{A}$ is said to be *uniformly convergent* if the index sequence can be taken independent of x; that is, there is an index sequence $\{p_i\}_{i=1}^{\infty}$ such that, for each $x \in \mathbb{R}^n$, $\lim_{k\to\infty}((\prod_{i=k}^{1} A_{p_i})x) = 0$.

The notions of pointwise and uniform convergence of sets of matrices arise naturally in multimodal control problems; see [BCS], [S]. To describe such control problems, it is convenient to assume that the set $\mathcal{A} = \{A_1, \ldots, A_m\}$ is finite. Consider m discrete linear time invariant systems $x_{k+1} = A_j x_k$, $k = 1, 2, \ldots$. A *control function* is a map $\sigma : \{1, 2, \ldots\} \to \{1, 2, \ldots, m\}$. Given a control function σ, we define the control system by $x_{k+1} = A_{\sigma(k)} x_k$, $k = 1, 2, \ldots$. Now, the set $\mathcal{A}$ is pointwise convergent if and only if for any initial state x_1 the state can be steered to zero using a suitable control function. The set $\mathcal{A}$ is uniformly convergent if and only if there exists a control function that will steer the state to zero from any initial position.

Recently, pointwise and uniform convergence have been studied in [GR], where it was proved that both types of convergence are equivalent for polynomially bounded semigroups, and in [SU], where criteria for pointwise and uniform convergence of sets $\mathcal{A}$ have been presented. In the next section, we summarize some results from [SU].

In the present paper we investigate further pointwise and uniform convergence properties of matrix sets, with emphasis on topological properties (description of the closure) and special classes of matrices: entrywise nonnegative or triangular. In section 5, we present a detailed description of pointwise and uniformly convergent sets of two 2×2 matrices; the description is partial in the case of pointwise convergence.

It should be noted that, in the absence of special properties such as the matrices being triangular or having nonnegative entries, the pointwise convergence property is

often much harder to assess than the uniform convergence. Our results bear this out; compare Theorems 4.3 and 4.6 and compare Theorems 5.1 and 5.2.

We remark that other types of convergence of matrix sets have been studied in the literature as well; see for example [BY], [DL1], [DL2], motivated by the problem of constructing wavelets with compact support and other applications, and [G1],[G2], motivated by the problem of stability of linear inclusions. In contrast with the definitions given above, the other types of convergence require convergence (or convergence to zero) of *every* infinite product.

Preliminary versions of many results of the present paper have been reported in [CRS].

2. Previous results. The results presented in this section are found in [SU].

Given a norm $\|\ \|$ on $\mathbb{R}^n$ the set $\mathcal{A} = \{A_j\}_{j\in J}$ is *contractive relative to* $\|\ \|$ provided that if $x \in \mathbb{R}^n$, $x \neq 0$, then there is an index j such that $\|A_j x\| < \|x\|$. $\mathcal{A}$ is *precontractive relative to* $\|\ \|$ provided that if $x \in \mathbb{R}^n$, $x \neq 0$, then there is an index sequence $\{p(x)_i\}_{i=1}^r$ such that $\| \left(\prod_{i=1}^r A_{p(x)_i}\right) x\| < \|x\|$. It follows from the compactness of the unit sphere in $\mathbb{R}^n$ that $\mathcal{A}$ is precontractive relative to $\|\ \|$ if and only if some finite set of finite products of the members of $\mathcal{A}$ is contractive relative to $\|\ \|$.

THEOREM 2.1. *The set $\mathcal{A}$ is pointwise convergent if and only if $\mathcal{A}$ is precontractive relative to some norm on $\mathbb{R}^n$.*

THEOREM 2.2. *The set $\mathcal{A}$ is uniformly convergent if and only if there is a finite product $P = \prod_{i=1}^k A_{p_i}$ of members of $\mathcal{A}$ with $\rho(P) < 1$, where ρ denotes spectral radius.*

Theorem 2.1 implies that precontractiveness is norm independent, and so we may omit reference to a particular norm in using that term. Clearly, in applying the definition of pointwise convergence or that of precontractiveness, it is sufficient to consider only vectors x of norm 1 (any norm).

While it is obvious that every uniformly convergent set is pointwise convergent, there are sets $\mathcal{A}$ that are pointwise convergent and not uniformly convergent. In fact, we will see examples in section 4 of sets of two 2×2 matrices that are pointwise, but not uniformly, convergent.

LEMMA 2.3. *Pointwise convergence and uniform convergence are invariant under simultaneous similarity of the matrices in $\mathcal{A}$ and under the replacement of any of the matrices in $\mathcal{A}$ with its negative.*

LEMMA 2.4. *Pointwise and uniform convergence are equivalent for sets $\mathcal{A}$ of diagonal matrices.*

Thus, we may omit the modifier "pointwise" or "uniform" for convergence of sets of diagonal matrices.

A real $m \times n$ matrix A is said to be *semipositive* provided there is an $x \in \mathbb{R}^n$, $x \geq 0$, such that $Ax > 0$. Here, and throughout the paper, inequalities involving vectors or matrices are to be interpreted as entrywise inequalities. See [JKS] for a discussion of semipositivity.

Given a finite set $\mathcal{D} = \{D_1, D_2, \ldots, D_m\}$ of $n \times n$ diagonal matrices $D_j = \operatorname{diag}(d_{1j}, d_{2j}, \ldots, d_{nj})$, the $n \times m$ matrix $C(\mathcal{D}) = [c_{ij}]$ is defined by

$$c_{ij} = \begin{cases} 1 & \text{if } d_{ik} = 0 \text{ for some } k, \\ -\ln(|d_{ij}|) & \textit{otherwise.} \end{cases}$$

THEOREM 2.5. *The finite set $\mathcal{D}$ of diagonal matrices is convergent if and only if the matrix $C(\mathcal{D})$ is semipositive.*

If $\mathcal{A}$ is a set of square matrices, we denote by $\mathcal{D}(\mathcal{A})$ the set of diagonal matrices obtained by setting all off-diagonal entries of the matrices in $\mathcal{A}$ equal to 0. The following is then a corollary to Theorem 2.2.

COROLLARY 2.6. *A set $\mathcal{A}$ of upper triangular matrices (or of lower triangular matrices) is uniformly convergent if and only if the set $\mathcal{D}(\mathcal{A})$ is convergent.*

It follows from the results presented in this section that a set $\mathcal{A}$ is pointwise (resp., uniformly) convergent if and only if some finite subset of $\mathcal{A}$ is pointwise (resp., uniformly) convergent. Therefore, in what follows we often will focus attention on finite sets $\mathcal{A}$.

3. Sets of nonnegative matrices. In this section we focus on *nonnegative* matrices, i.e., matrices with nonnegative elements.

THEOREM 3.1. *Let $\mathcal{A}$ be a set of nonnegative $n \times n$ matrices. Then $\mathcal{A}$ is pointwise convergent if and only if it is uniformly convergent. Moreover, if $\mathcal{A}$ is uniformly convergent, then $\mathcal{D}(\mathcal{A})$ is convergent as well.*

Proof. Let $\mathcal{A}$ be a pointwise convergent set of nonnegative matrices. Then $\mathcal{A}$ is precontractive relative to any norm on $\mathbb{R}^n$ and in particular is relative to $\|x\|_\infty = \max\{|x_i| : 1 \le i \le n\}$. Hence there is a product P of matrices in $\mathcal{A}$ satisfying $\|Pu\|_\infty < 1$, where u denotes the vector of 1's in $\mathbb{R}^n$. Since P is nonnegative, the entries in the vector Pu are the sums of absolute values of entries along the rows of P, so $\|P\|_\infty < 1$, where for any $n \times n$ matrix A, $\|A\|_\infty$ denotes the matrix row sum norm, $\|A\|_\infty = \max\{\sum_{j=1}^n |a_{ij}| : 1 \le i \le n\}$. Since every matrix norm dominates the spectral radius, we have $\rho(P) < 1$; thus $\mathcal{A}$ is uniformly convergent by Theorem 2.2.

Now suppose that $\mathcal{A}$ is uniformly convergent but $\mathcal{D}(\mathcal{A}) = \{D_i\}_{i\in J}$ is not convergent. Then there is a vector $x \in \mathbb{R}^n$, $x \neq 0$, such that, for each index sequence $\{p_i\}_{i=1}^r$, we have $\|(\prod_{i=1}^r D_{p_i})\, x\|_\infty \ge \|x\|_\infty$. We let $|x|$ denote the entrywise absolute value of x. Since the A_i's are nonnegative and $\prod_{i=1}^r D_{p_i}$ is diagonal, we may write

$$\left\| \left(\prod_{i=1}^r A_{p_i} \right) |x| \right\|_\infty \ge \left\| \left(\prod_{i=1}^r D_{p_i} \right) |x| \right\|_\infty = \left\| \left| \left(\prod_{i=1}^r D_{p_i} \right) x \right| \right\|_\infty$$
$$= \left\| \left(\prod_{i=1}^r D_{p_i} \right) x \right\|_\infty \ge \|x\|_\infty = \| \, |x| \, \|_\infty.$$

This contradicts the pointwise convergence of $\mathcal{A}$, and therefore the theorem is proved. ∎

We note that in the absence of triangularity, the pointwise convergence of $\mathcal{D}(\mathcal{A})$ does not imply that of $\mathcal{A}$. The set $\mathcal{A} = \{\left[\begin{smallmatrix} .5 & 10 \\ 10 & .5 \end{smallmatrix}\right]\}$ is not uniformly convergent but $\mathcal{D}(\mathcal{A})$ is.

For any matrix $A = [a_{ij}]$, we denote $[|a_{ij}|]$ by $|A|$, and for $\mathcal{A} = \{A_j\}_{j\in J}$, the set $\{|A_1|\}_{j\in J}$ is denoted by $|\mathcal{A}|$.

COROLLARY 3.2. *If $\mathcal{A}$ is a set of $n \times n$ matrices and $|\mathcal{A}|$ is pointwise convergent, then $\mathcal{A}$ is uniformly convergent.*

Proof. By Theorem 3.1, $|\mathcal{A}|$ is uniformly convergent, so $\rho\,(\prod_{i=1}^r |A_{p_i}|) < 1$ for some index sequence $\{p_i\}_{i=1}^r$. Now $|\prod_{i=1}^r A_{p_i}| \le \prod_{i=1}^r |A_{p_i}|$ and therefore, using monotonicity properties of the spectral radius of real matrices (see [HJ, Thm. 8.1.18]), we have $\rho\,(\prod_{i=1}^r A_{p_i}) \le \rho\,(|\prod_{i=1}^r A_{p_i}|) \le \rho\,(\prod_{i=1}^r |A_{p_i}|) < 1$. Hence $\mathcal{A}$ is uniformly convergent. ∎

The converse fails because if $\mathcal{A} = \{A\}$ with $A = \left[\begin{smallmatrix} -2/3 & 2/3 \\ 2/3 & 2/3 \end{smallmatrix}\right]$, then $\rho(A) = \frac{2\sqrt{2}}{3}$. Thus $\mathcal{A}$ is uniformly convergent but $\rho(|A|) = \frac{4}{3}$, so $|\mathcal{A}|$ is not uniformly convergent

and hence is not pointwise convergent.

The property of uniform convergence for sets of nonnegative matrices is inherited by sets of principal submatrices in the following sense. If A is an $n \times n$ matrix and $\alpha \subset \{1, 2, \ldots, n\}$, then $A[\alpha]$ denotes the principal submatrix of A lying in the rows and columns indexed by α. If $\mathcal{A} = \{A_j\}_{j \in J}$ is a set of $n \times n$ matrices, then $\mathcal{A}[\alpha]$ denotes $\{A_j[\alpha]\}_{j \in J}$.

THEOREM 3.3. *Let $\mathcal{A}$ be a uniformly convergent set of nonnegative $n \times n$ matrices and let $\alpha \subset \{1, 2, \ldots, n\}$. Then $\mathcal{A}[\alpha]$ is uniformly convergent.*

Proof. By simultaneous permutation similarity, it suffices to prove the theorem for the case $\alpha = \{1, 2, \ldots, t\}$ for $1 \leq t \leq n$. Suppose first that $n = 2$ so that we need consider only $\alpha = \{1\}$. By Theorem 3.1, $\mathcal{D}(\mathcal{A})$ is uniformly convergent. Hence there is a matrix in $\mathcal{D}(\mathcal{A})$ with a $1,1$ entry less than 1. The 1×1 matrix with only this entry is a member of $\mathcal{A}[\{1\}]$, and so $\mathcal{A}[\{1\}]$ is uniformly convergent and the theorem holds when $n = 2$. Now let $n > 2$ and suppose the theorem holds for sets of nonnegative $(n-1) \times (n-1)$ matrices. Let $\mathcal{A}$ be a uniformly convergent set of $n \times n$ nonnegative matrices and let $\alpha = \{1, 2, \ldots, t\}$ with $t \leq n$. If $t = n$, there is nothing to prove. If $t < n - 1$, the uniform convergence of $\mathcal{A}[\alpha]$ will follow from that of $\mathcal{A}[\{1, 2, \ldots, n-1\}]$ by the inductive assumption. Hence we may assume $t = n - 1$ so that $\alpha = \{1, 2, \ldots, n-1\}$.

If $i, j \in J$, we have

$$A_i A_j = \begin{bmatrix} A_i[\alpha] & X \\ Y^t & a \end{bmatrix} \begin{bmatrix} A_j[\alpha] & Z \\ W^t & b \end{bmatrix} = \begin{bmatrix} A_i[\alpha]A_j[\alpha] + XW^t & * \\ * & * \end{bmatrix}$$

and so, since $XW^t \geq 0$, $(A_i A_j)[\alpha] \geq A_i[\alpha]A_j[\alpha]$. By induction on the number of factors, it follows that if $P = \prod_{i=1}^{r} A_{p_i}$ is any product of matrices in $\mathcal{A}$, then $P[\alpha] \geq \prod_{i=1}^{r} A_{p_i}[\alpha]$. Since $\mathcal{A}$ is uniformly convergent, we may take P to satisfy $\rho(P) < 1$. Again using [HJ, Thm. 8.1.18], we have $\rho\left(\prod_{i=1}^{r} A_{p_i}[\alpha]\right) \leq \rho(P[\alpha]) \leq \rho(P) < 1$ and so $\mathcal{A}[\alpha]$ is uniformly convergent. ∎

We note that if $\mathcal{A}$ is as given after the proof of Theorem 3.1, then $\mathcal{A}[\alpha]$ is uniformly convergent for all proper α but $\mathcal{A}$ is not uniformly convergent.

4. Topological properties of the class of convergent matrix sets. In this section we identify points in $\mathbb{R}^{mn^2}$ with the set of ordered m-tuples of $n \times n$ real matrices $\mathcal{A} = \{A_1, A_2, \ldots, A_m\}$ and discuss topological properties of the collections of pointwise and uniformly convergent sets as subsets of $\mathbb{R}^{mn^2}$. While the convergence properties of $\mathcal{A}$ are invariant under reordering of the matrices in the set, it is convenient to think of the matrix sets as ordered sets. We denote by $\mathcal{U}_{m,n}$ (resp., $\mathcal{P}_{m,n}$) the collection of all uniformly convergent (resp., pointwise convergent) sets in $\mathbb{R}^{mn^2}$.

Suppose that for each positive integer k and for each p with $1 \leq p \leq m$, $A_p^{(k)} = [a_{p,ij}^{(k)}]$ is a real $n \times n$ matrix and $A_p = [a_{p,ij}]$ is a real $n \times n$ matrix. Let $\mathcal{A}^{(k)} = \{A_1^{(k)}, A_2^{(k)}, \ldots, A_m^{(k)}\}$ and $\mathcal{A} = \{A_1, A_2, \ldots, A_m\}$. Then the sequence $\{\mathcal{A}^{(k)}\}_{k=1}^{\infty}$ converges to the set $\mathcal{A}$ provided that, for each i and j with $1 \leq i, j \leq n$ and each p with $1 \leq p \leq m$, we have $\lim_{k \to \infty} a_{p,ij}^{(k)} = a_{p,ij}$.

If $\mathcal{A} = \{A_1, A_2, \ldots, A_m\} \in \mathbb{R}^{mn^2}$ and if $c \in \mathbb{R}^m$, then $\mathcal{A}_c$ will denote the set $\{c_1 A_1, c_2 A_2, \ldots, c_m A_m\}$. In case $c_i = \epsilon$ for $1 \leq i \leq m$, $\mathcal{A}_c$ may be denoted by $\epsilon\mathcal{A}$.

LEMMA 4.1. *Let $\mathcal{A} = \{A_1, A_2, \ldots, A_m\} \in \mathbb{R}^{mn^2}$ and let $|c_p| \leq 1$ for $1 \leq p \leq m$. If $\mathcal{A} \in \mathcal{U}_{m,n}$, then $\mathcal{A}_c \in \mathcal{U}_{m,n}$. If $\mathcal{A} \in \mathcal{P}_{m,n}$, then $\mathcal{A}_c \in \mathcal{P}_{m,n}$.*

The proof of Lemma 4.1 is immediate.

THEOREM 4.2. *The sets $\mathcal{U}_{mn}$ and $\mathcal{P}_{mn}$ are open and star shaped about zero (in particular, connected) in $\mathbb{R}^{mn^2}$.*

Proof. Let $\lim_{k\to\infty} \mathcal{A}^{(k)} = \mathcal{A}$.

First suppose that no $\mathcal{A}^{(k)}$ is uniformly convergent. Any product P of matrices in $\mathcal{A}$ is the limit of corresponding products $P^{(k)}$ of matrices in $\mathcal{A}^{(k)}$, and $\rho(P^{(k)}) \geq 1$. Then $\rho(P) = \lim_{k\to\infty} \rho(P^{(k)}) \geq 1$; thus, $\mathcal{A}$ is not uniformly convergent. Hence the complement of $\mathcal{U}_{m,n}$ is closed and thus $\mathcal{U}_{m,n}$ is open.

Now suppose that no $\mathcal{A}^{(k)}$ is pointwise convergent. For each k, we may choose a vector $x_k \in \mathbb{R}^n$ with $\|x_k\|_\infty = 1$ such that no product of the matrices in $\mathcal{A}^{(k)}$ contracts x_k relative to $\| \ \|_\infty$. By compactness, we may assume that $\lim_{k\to\infty} x_k = x$, where $\|x\|_\infty = 1$. Any product P of matrices in $\mathcal{A}$ is the limit of corresponding products $P^{(k)}$ of matrices in $\mathcal{A}^{(k)}$, and $\|P^{(k)}x\|_\infty \geq 1$. Then $\|Px\|_\infty = \lim_{k\to\infty} \|P^{(k)}x_k\|_\infty \geq 1$, so P does not contract x relative to $\| \ \|_\infty$, and $\mathcal{A}$ is not precontractive. Thus $\mathcal{A}$ is not pointwise convergent, so the complement of $\mathcal{P}_{m,n}$ is closed and $\mathcal{P}_{m,n}$ is open.

The star-shapedness property follows from Lemma 4.1. ∎

We now present results concerning the closures of $\mathcal{U}_{m,n}$ and $\mathcal{P}_{m,n}$. For $\mathcal{A} \in \mathbb{R}^{mn^2}$, we denote by $\Pi_\mathcal{A}$ the set of all finite products of members of $\mathcal{A}$. The quantity $\inf\{\rho(P) : P \in \Pi_\mathcal{A}\}$ will be denoted by $\rho_\mathcal{A}$. Note that if $\rho_\mathcal{A} < 1$, then a consideration of P^k, where $P \in \Pi_\mathcal{A}$ and $\rho(P) < 1$, shows that $\rho_\mathcal{A} = 0$.

THEOREM 4.3. *Let $\mathcal{A} \in \mathbb{R}^{mn^2}$ and suppose that either* (1) *or* (2) *holds:*

(1) $\rho_\mathcal{A} \in \{0, 1\}$*;*

(2) $\rho(P) > \rho_\mathcal{A}$ *for all* $P \in \Pi_\mathcal{A}$.

Then $\mathcal{A}$ is in the closure of $\mathcal{U}_{m,n}$.

Proof. Suppose (1) holds. The result is clear if $\rho_\mathcal{A} = 0$, so let $\rho_\mathcal{A} = 1$. Assume first that there is a $P = \prod_{i=1}^r A_{q(i)} \in \Pi_\mathcal{A}$ such that $\rho(P) = 1$. For $0 < \epsilon < 1$, consider $\epsilon\mathcal{A}$. Then $\rho\left(\prod_{i=1}^r \epsilon A_{q(i)}\right) = \epsilon^r \rho(P) < 1$, so $\epsilon\mathcal{A} \in \mathcal{U}_{m,n}$. Clearly, $\lim_{\epsilon\to 1} \epsilon\mathcal{A} = \mathcal{A}$ and so $\mathcal{A}$ is in the closure of $\mathcal{U}_{m,n}$.

Now suppose $\rho_\mathcal{A} \geq 1$ and $\rho(P) > \rho_\mathcal{A}$ for all $P \in \Pi_\mathcal{A}$. For each positive integer t, let $\Pi_\mathcal{A}^t = \{\prod_{i=1}^r A_{q(i)} : 1 \leq r \leq t, \ 1 \leq q(i) \leq m\}$. $\Pi_\mathcal{A}^t$ is finite, so there is an index sequence $\{s_t(i)\}_{i=1}^{r_t}$, where $r_t \leq t$, such that $P_t = \prod_{i=1}^{r_t} A_{s_t(i)}$ satisfies $\rho_\mathcal{A} < \rho(P_t) \leq \rho(P)$ for all $P \in \Pi_\mathcal{A}^t$. Let $\delta_t = (2\rho(P_t))^{-\frac{1}{r_t}}$. Now $\rho\left(\prod_{i=1}^{r_t} \delta_t A_{s_t(i)}\right) = \delta_t^{r_t}\rho(P_t) = \frac{1}{2} < 1$, so $\delta_t\mathcal{A} \in \mathcal{U}_{m,n}$. If $\{r_t\}_{t=1}^\infty$ were bounded, then $\rho_\mathcal{A} = \inf\{\rho(P) : P \in \Pi_\mathcal{A}\}$ would be attained by some some P_t. Hence $\lim_{t\to\infty} r_t = \infty$. Since $A_1 \in \Pi_\mathcal{A}^1 \subset \Pi_\mathcal{A}^t$, we have $1 \leq \rho_\mathcal{A} < \rho(P_t) \leq \rho(A_1)$ for all t, and it follows that $\lim_{t\to\infty} \delta_t = 1$. Hence $\lim_{t\to\infty} \delta_t\mathcal{A} = \mathcal{A}$, and $\mathcal{A}$ is in the closure of $\mathcal{U}_{m,n}$. ∎

The following example shows a situation in which $\rho_\mathcal{A} = 1$ but $\rho(P) > 1$ for every $P \in \Pi_\mathcal{A}$. Let

$$\mathcal{A} = \{A_1, A_2\}, \quad A_1 = \begin{bmatrix} a & 0 \\ 0 & a^{-1} \end{bmatrix}, \quad A_2 = \begin{bmatrix} b & 0 \\ 0 & b^{-1} \end{bmatrix},$$

where $a > 1$ and $b > 1$ are real numbers such that their logarithms $\ln(a)$, $\ln(b)$ are not commensurable. Then there exists a sequence (m_q, n_q), $q = 1, 2, \ldots$, of pairs of integers such that $\lim_{q\to\infty}(m_q\ln(a) + n_q\ln(b)) = 0$. We can assume that all integers m_q are of the same sign and all integers n_q are of the same sign, say, $m_q > 0$ and $n_q < 0$ for all q. Then, replacing A_2 by A_2^{-1}, we obtain a set $\mathcal{A}$ with the desired properties.

While we have not obtained the converse of Theorem 4.3 in general, we can show that if $\mathcal{A}$ is a set of upper triangular matrices (or of lower triangular ones) and if $\mathcal{A}$ is in the closure of $\mathcal{U}_{m,n}$, then (1) must hold.

THEOREM 4.4. *Suppose $\mathcal{A} = \{A_1, A_2, \ldots, A_m\}$ is a set of upper triangular matrices, and suppose $\mathcal{A}$ is in the closure of $\mathcal{U}_{m,n}$. Then $\rho_{\mathcal{A}} \leq 1$.*

We need a lemma for the proof of Theorem 4.4.

LEMMA 4.5. *Let A be a $p \times q$ real matrix such that $Ax \geq 0$ (componentwise) for some nonzero vector $x \in \mathbb{R}^q$ with nonnegative components. Then for every positive ϵ there exists a nonzero vector y with nonnegative integer components such that no component of Ay is less than $-\epsilon$.*

Proof. We use induction on q. When $p = q = 1$, then either $A = 0$ (in which case every positive integer y will do), or $A > 0$, $x > 0$. In the latter case, approximate x by a rational number $\frac{u}{v}$, where u and v are positive integers, so that

$$\left| x - \frac{u}{v} \right| < \frac{1}{v^2}.$$

Now

$$Au = A(u - vx) + Avx \geq A(u - vx) \geq \frac{-A}{v},$$

which can be made not smaller than $-\epsilon$ for v large enough; thus, one can take $y = u$. If $q = 1$ but $p > 1$, then apply the foregoing argument with A replaced by the minimal positive element of A.

Consider now the general case. If a component of x is equal to zero, then we can omit the corresponding column of A, thereby reducing q by one, and use the induction hypothesis. Thus we can assume that all components of x are positive. Write $x = [x_1, \ldots, x_q]^T > 0$. By a result in geometric number theory (Sect. V.10 of [C]), for every sufficiently large positive integer Q there exist positive integers $u_0, u_1, \ldots, u_q$ such that

$$|u_0 x_j - u_j| < \frac{1}{\sqrt[q]{Q}} \qquad \text{for} \quad j = 1, \ldots, q.$$

We claim that $y = [u_1, \ldots, u_q]^T$ will do (for sufficiently large Q). Indeed, letting a_{ij} be the (i, j) element of the matrix A, we obtain

$$\sum_{j=1}^{q} a_{ij} u_j = \sum_{j=1}^{q} a_{ij}(u_j - u_0 x_j) + u_0 \sum_{j=1}^{q} a_{ij} x_j \geq \sum_{j=1}^{q} a_{ij}(u_j - u_0 x_j)$$

$$\geq -q \max_{1 \leq i \leq p; 1 \leq j \leq q} |a_{ij}| \frac{1}{\sqrt[q]{Q}},$$

and this expression tends to zero as $Q \to \infty$. ∎

Proof of Theorem 4.4. Let $\{\mathcal{A}^{(k)}\}_{k=1}^{\infty}$ be a sequence of matrix sets in $\mathcal{U}_{m,n}$ such that $\lim_{k \to \infty} \mathcal{A}^{(k)} = \mathcal{A}$. By Corollary 2.6, $\mathcal{D}^{(k)} = \mathcal{D}(\mathcal{A}^{(k)}) \in \mathcal{U}_{m,n}$ for each k and clearly $\lim_{k \to \infty} \mathcal{D}^{(k)} = \mathcal{D}(\mathcal{A})$. Let $\mathcal{D} = \mathcal{D}(\mathcal{A}) = \{D_1, D_2, \ldots, D_m\}$ with $D_j = diag(d_{1j}, d_{2j}, \ldots, d_{nj})$ for $1 \leq j \leq m$. By Theorem 2.5, the $n \times m$ matrix $C(\mathcal{D}^{(k)})$ is semipositive, so there is a nonnegative vector $x_k \in \mathbb{R}^m$ such that $C(\mathcal{D}^{(k)})x_k > 0$. We may assume that $\|x_k\|_2 = 1$, where $\| \ \|_2$ denotes the Euclidean norm on $\mathbb{R}^m$, and by compactness we may further assume that $\lim_{k \to \infty} x_k = x \geq 0$. It follows that $\lim_{k \to \infty} C(\mathcal{D}^{(k)})x_k = C(\mathcal{D})x \geq 0$.

We now choose $\epsilon > 0$ and construct $P_\epsilon \in \Pi_{\mathcal{A}}$ such that $\rho_{\mathcal{A}} \leq \rho(P_\epsilon) < e^\epsilon$. It will follow that $\rho_{\mathcal{A}} \leq \lim_{\epsilon \to 0} e^\epsilon = 1$.

Since $C(\mathcal{D})x \geq 0$, by Lemma 4.4 there is a nonzero nonnegative vector $p^{(\epsilon)} \in \mathbb{R}^m$ with integer entries such that $C(\mathcal{D})p^{(\epsilon)} > -\epsilon u$, where u denotes the vector of 1's in $\mathbb{R}^m$. Thus $\sum_{j=1}^m (-\ln|d_{ij}|)p_j^{(\epsilon)} > -\epsilon$ for $1 \leq i \leq m$. Hence, for $1 \leq i \leq m$, we have $\ln(\prod_{j=1}^m |d_{ij}|^{p_j^{(\epsilon)}}) < \epsilon$, and taking exponentials we have $\prod_{j=1}^m |d_{ij}|^{p_j^{(\epsilon)}} < e^\epsilon$. Let $P_\epsilon = \prod_{j=1}^m A_j^{p_j^{(\epsilon)}}$. Then $P_\epsilon \in \Pi_{\mathcal{A}}$ and, because of triangularity, we have

$$\rho(P_\epsilon) = \rho\left(\prod_{j=1}^m D_j^{p_j^{(\epsilon)}}\right) = \max\left\{\prod_{j=1}^m |d_{ij}|^{p_j^{(\epsilon)}} : 1 \leq i \leq n\right\} < e^\epsilon. \qquad \square$$

It is instructive to compare $\rho_{\mathcal{A}}$ with another measure of joint spectral radii, namely, the lower joint spectral radius. Given an ordered m-tuple $\mathcal{A}$ of $n \times n$ real matrices, denote by $\pi_{\mathcal{A}}^k$ the set of all products of exactly k matrices from $\mathcal{A}$, $k = 1, 2, \ldots$. The *lower joint spectral radius* of $\mathcal{A}$ is defined by

$$\underline{\rho}_{\mathcal{A}} = \liminf_{k\to\infty}\Big(\min\{\rho(P)^{1/k} \ : \ P \in \pi_{\mathcal{A}}^k\}\Big).$$

This definition was introduced in [G1]; a discussion of this notion in the context of Lyapunov exponents, as well as an extensive bibliography, is found in [TB]. It was proved in [G1] that for any (submultiplicative) matrix norm we have

$$\underline{\rho}_{\mathcal{A}} = \liminf_{k\to\infty}\Big(\min\{\|P\|^{1/k} \ : \ P \in \pi_{\mathcal{A}}^k\}\Big).$$

(The finiteness of the set $\mathcal{A}$ is essential for the proof of this equality to hold.) It turns out that if $\underline{\rho}_{\mathcal{A}} \leq 1$, then $\mathcal{A}$ belongs to the closure of $\mathcal{U}_{mn}$. Indeed,

$$\underline{\rho}_{c\mathcal{A}} = c\underline{\rho}_{\mathcal{A}} \leq c$$

for any positive constant c; if $c < 1$, then some finite product of matrices from $c\mathcal{A}$ has spectral radius less than one, and therefore $c\mathcal{A} \in \mathcal{U}_{mn}$.

We also observe that condition (2) of Theorem 4.3 implies $\underline{\rho}_{\mathcal{A}} \leq 1$. To verify that, note that if this condition holds, then there is an infinite sequence of positive integers $k_1 < k_2 < \cdots$ such that $\rho(P_j) < \rho_{\mathcal{A}} + 1$ for some $P_j \in \pi_{\mathcal{A}}^{k_j}$, $j = 1, 2, \ldots$. Therefore,

$$\underline{\rho}_{\mathcal{A}} \leq \liminf_{j\to\infty}\Big(\rho(P_j)^{\frac{1}{k_j}}\Big) \leq \lim_{j\to\infty} \ (\rho_{\mathcal{A}} + 1)^{\frac{1}{k_j}} = 1.$$

A pointwise analogy to Theorem 4.3 seems difficult to obtain. The following theorem is a partial result with rather restrictive hypotheses. Its formulation requires the following definitions. Let $\|\ \|$ be any norm on $\mathbb{R}^n$ and let S^{n-1} denote the unit sphere $\{x \in \mathbb{R}^n : \|x\| = 1\}$. For $\mathcal{A} \in \mathbb{R}^{mn^2}$ and $t \in \mathbb{N}$, the set of all positive integers, define $\pi_{\mathcal{A}}^t$ and $\Pi_{\mathcal{A}}^t$ as before, and define $\mu_{\mathcal{A}}^t$ on S^{n-1} by $\mu_{\mathcal{A}}^t(x) = \min\{\|Px\| : P \in \Pi_{\mathcal{A}}^t\}$. Let

$$\mu_{\mathcal{A}}(x) = \inf\{\mu_{\mathcal{A}}^t(x) : t \in \mathbb{N}\} = \inf\{\|Px\| : P \in \Pi_{\mathcal{A}}\}.$$

THEOREM 4.6. *Let $\mathcal{A} \in \mathbb{R}^{mn^2}$ and let $B = \{x \in S^{n-1} : \mu_{\mathcal{A}}(x) \geq 1\}$. Suppose that either*

(1) *for each $x \in S^{n-1}$, there is a $P_x \in \Pi_{\mathcal{A}}$ such that $\|P_x x\| \leq 1$, or*

(2) *there is a sequence $\{r_t\}_{t=1}^\infty$ of positive integers such that $\lim_{t\to\infty} r_t = \infty$ and, for each sufficiently large positive integer t and each $x \in B$, there is a $P_{t,x} \in \pi_{\mathcal{A}}^{r_{t,x}}$*

such that $r_t \le r_{t,x} \le t$ *and* $\mu_{\mathcal{A}}^t(x) = \|P_{t,x}x\|$.
Then $\mathcal{A}$ *is in the closure of* $\mathcal{P}_{m,n}$.

Proof. Suppose (1). For $x \in S^{n-1}$, let $P_x = \prod_{i=1}^{w_x} A_{s_x(i)}$. Then, for $0 < \epsilon < 1$ and for each $x \in S^{n-1}$,

$$\left\| \left(\prod_{i=1}^{w_x} \epsilon A_{s_x(i)} \right) x \right\| = \epsilon^{w_x} \|P_x x\| < 1.$$

Hence by Theorem 2.1 $\epsilon\mathcal{A} \in \mathcal{P}_{m,n}$ and $\mathcal{A}$ is in the closure of $\mathcal{P}_{m,n}$.

Now suppose (2). For each $t \in \mathbb{N}$, $\mu_{\mathcal{A}}^t$ is the minimum of finitely many continuous functions of the form $f_P : x \to \|Px\|$. Therefore on the compact set B, $\mu_{\mathcal{A}}^t$ is continuous and assumes a maximum value M_t. Let $\delta_t = (2M_t)^{-\frac{1}{r_t}}$. We claim that $\delta_t\mathcal{A} \in \mathcal{P}_{m,n}$. Clearly, $M_t \ge 1$, so $\delta_t < 1$ and so for each $x \in B$, $\delta_t^{r_{t,x}} \le \delta_t^{r_t}$. Let $P_{t,x} = \prod_{i=1}^{r_{t,x}} A_{s_{t,x}(i)}$. Then, for $x \in B$ we have

$$\left\| \left(\prod_{i=1}^{r_{t,x}} \delta_t A_{s_{t,x}(i)} \right) x \right\| = \|\delta_t^{r_{t,x}} P_{t,x}x\| \le \delta_t^{r_t} \|P_{t,x}x\| = \frac{1}{2M_t}\mu_{\mathcal{A}}^t(x) \le \frac{1}{2} < 1.$$

For $x \notin B$, any product of matrices in $\mathcal{A}$ that reduces the norm of x will provide a product of matrices in $\delta_t\mathcal{A}$ that does so. Hence $\delta_t\mathcal{A} \in \mathcal{P}_{m,n}$ by Theorem 2.1 again.

For each $t \in \mathbb{N}$ and each $x \in B$, $P_{1,x} \in \Pi_{\mathcal{A}}^t$, and so $\mu_{\mathcal{A}}^t(x) \le \mu_{\mathcal{A}}^1(x)$. It follows that $1 \le M_t \le M_1$ and since $\lim_{t\to\infty} r_t = \infty$, $\lim_{t\to\infty} \delta_t = 1$. Hence $\mathcal{A}$ is in the closure of $\mathcal{P}_{m,n}$. ∎

5. Upper triangular matrices of size two. Throughout this section, we consider sets of two real upper triangular 2×2 matrices:

$$\mathcal{A} = \left\{ A_1 = \begin{bmatrix} a_1 & b_1 \\ 0 & c_1 \end{bmatrix}, \quad A_2 = \begin{bmatrix} a_2 & b_2 \\ 0 & c_2 \end{bmatrix} \right\}.$$

The uniform convergence of such $\mathcal{A}$ is easily decided using Theorem 2.5 and Corollary 2.6, as follows.

THEOREM 5.1. *Assume that* $a_1c_1a_2c_2 \neq 0$ *and* $|a_1| \le |a_2|$. *Then* $\mathcal{A}$ *is uniformly convergent if and only if either the spectral radius of at least one of the matrices* A_1 *and* A_2 *is less than one or the following conditions hold:* $\rho(A_j) \ge 1$ $(j = 1, 2)$, $\max\{|a_1|, |c_2|\} < 1$, *and* $\ln(|a_1|) \cdot \ln(|c_2|) > \ln(|a_2|) \cdot \ln(|c_1|)$.

Under the hypotheses of Theorem 5.1, the matrix $\mathcal{C}(\mathcal{D}(\mathcal{A}))$ (see the definitions immediately before and after Theorem 2.5) is given by

$$\mathcal{C}(\mathcal{D}(\mathcal{A})) = \begin{bmatrix} -\ln|a_1| & -\ln|a_2| \\ -\ln|c_1| & -\ln|c_2| \end{bmatrix}.$$

The uniform convergence of $\mathcal{A}$ in the case $a_1a_2c_1c_2 = 0$ is easily sorted out. We omit the proof of Theorem 5.1.

For the pointwise convergence the situation is much more subtle. We consider first the case when $|\det(A_1)| = |\det(A_2)| = 1$. Obviously, in this case the set $\mathcal{A}$ cannot be uniformly convergent. However, often it is pointwise convergent, as follows.

THEOREM 5.2. *Assume* $|a_1c_1| = |a_2c_2| = 1$. *Then* $\mathcal{A}$ *is pointwise convergent unless at least one of the three following conditions occur:* (1) $\min\{|a_1|, |a_2|\} \ge 1$ *or* $\min\{|c_1|, |c_2|\} \ge 1$; (2) $\det A_1 = \det A_2 = 1$; (3) A_1 *and* A_2 *are diagonalizable by simultaneous similarity, i.e.,* $S^{-1}A_1S$ *and* $S^{-1}A_2S$ *are diagonal for some invertible*

(real) matrix S. If one of the conditions (1)–(3) *occurs, then the set $\mathcal{A}$ is not pointwise convergent.*

Proof. We dispose of the conditions (1)–(3) first. If (1) holds and, say, min $\{|c_1|, |c_2|\} \geq 1$, then the vector $[0\ 1]^T \in \mathbb{R}^2$ is not contracted (relative to the Euclidean norm) by any finite product of the matrices A_1 and A_2. Hence by Theorem 2.1, $\mathcal{A}$ is not pointwise convergent.

For the rest of the proof we assume that (1) does not hold. In particular, the numbers a_j and c_j $(j = 1, 2)$ are different from ± 1. If (3) holds, then in view of Lemma 2.4 $\mathcal{A}$ is not pointwise convergent (because it is not uniformly convergent). If (2) holds, then (multiplying if necessary one or both matrices A_j by -1, which does not affect pointwise convergence) we can assume that a_1, c_1, a_2, c_2 are positive. Since $a_1 \neq c_1$, we also can assume (using a simultaneous similarity with an upper triangular similarity matrix S) that $b_1 = 0$. If $b_2 \geq 0$, then by Theorem 3.1 $\mathcal{A}$ cannot be pointwise convergent. If $b_2 < 0$, then the simultaneous similarity with $S = \left[\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right]$ replaces b_2 by $-b_2$, thereby reducing to the previous case.

We assume from now on in the proof that none of the conditions (1), (2), or (3) hold, and we will prove that $\mathcal{A}$ is pointwise convergent. Throughout the proof we will repeatedly use the following easily verified fact: if a subset of the multiplicative semigroup generated by $\mathcal{A}$ is pointwise convergent, then the set $\mathcal{A}$ itself is pointwise convergent.

Without loss of generality, we assume that $\det A_2 = -1$. Further, by reducing A_1 to a diagonal form using simultaneous similarity with a suitable upper triangular matrix S, we assume that

$$\mathcal{A} = \left\{ A_1 = \begin{bmatrix} \delta a & 0 \\ 0 & a^{-1} \end{bmatrix},\ A_2 = \begin{bmatrix} -b^{-1} & 1 \\ 0 & b \end{bmatrix} \right\}.$$

Here a and b are nonzero real numbers such that $|a|$ and $|b|$ are both greater than, or both less than, 1 and $\delta = \pm 1$.

First, consider the case when $a = b$:

$$A_1 = \begin{bmatrix} \delta a & 0 \\ 0 & a^{-1} \end{bmatrix}, \qquad A_2 = \begin{bmatrix} -a^{-1} & 1 \\ 0 & a \end{bmatrix},$$

where $a \neq \pm 1, 0$. Assume $a > 1$. If $\delta = 1$, a calculation reveals that, relative to the Euclidean norm, A_2 contracts $\left[\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right]$; A_1 contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $|x| < 1/a$; A_2A_1 contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $x > 1/(2a)$; and $A_2^2A_1^2$ contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $x < -1/(2a)$. By Theorem 2.1, the set $\{A_1, A_2\}$ is pointwise convergent.

If $\delta = -1$ and $a > 1$, a calculation reveals that A_2 contracts $\left[\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right]$; A_1 contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $|x| \leq 1/a$; and A_2A_1 contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $x < -1/(2a)$. Let k be a positive integer such that $k < a^2 \leq k + 1$, and consider

$$B_k = A_1A_2(A_2A_1)^k = \begin{bmatrix} 1 & \frac{k}{a} - a \\ 0 & 1 \end{bmatrix}.$$

Then B_k contracts $\left[\begin{smallmatrix} x \\ 1 \end{smallmatrix}\right]$ if $x > 1/(2a)$. Again, by Theorem 2.1, $\{A_1, A_2\}$ is pointwise convergent.

If $0 < a < 1$ and $\delta = -1$, then by simultaneuos similarity we reduce A_2 to the form $\left[\begin{smallmatrix} -a^{-1} & 0 \\ 0 & a \end{smallmatrix}\right]$ and A_1 to the form $\left[\begin{smallmatrix} -a & 1 \\ 0 & a^{-1} \end{smallmatrix}\right]$. Now apply the already proved part to the new pair of matrices, with the roles of A_1 and A_2 interchanged and a^{-1} playing

the role of a. The pointwise convergence of $\{A_1, A_2\}$ follows. If $0 < a < 1$ and $\delta = 1$, then consider

$$B_1 = A_1^2 A_2 = \begin{bmatrix} -a & a^2 \\ 0 & a^{-1} \end{bmatrix}.$$

A simultaneous similarity reduces the matrices B_1 and A_2 to the forms $\left[\begin{smallmatrix} -a & 0 \\ 0 & a^{-1} \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} -a^{-1} & 1 \\ 0 & a \end{smallmatrix}\right]$. But the pair of matrices in this form is already proved to be pointwise convergent (the case $0 < a < 1$, $\delta = -1$, considered above), therefore the pair B_1, A_2 is also pointwise convergent. Since B_1 belongs to the semigroup generated by A_1 and A_2, the same property holds for A_1 and A_2.

Finally, if $a < 0$, then by multiplying the matrices A_1 and A_2 by -1 and applying a simultaneous similarity with an upper triangular similarity matrix S, we reduce the proof of pointwise convergence to the previously considered case $a > 0$. This concludes the consideration of the case when $a = b$.

We now assume $a \neq b$ and consider first the case when $a, b > 1$. We already know that the two sets

$$\mathcal{A}_1 = \left\{ \begin{bmatrix} \pm a & 0 \\ 0 & a^{-1} \end{bmatrix}, \begin{bmatrix} -a^{-1} & 1 \\ 0 & a \end{bmatrix} \right\}, \qquad \mathcal{A}_2 = \left\{ \begin{bmatrix} \pm a/b & 0 \\ 0 & b/a \end{bmatrix}, \begin{bmatrix} -b/a & 1 \\ 0 & a/b \end{bmatrix} \right\}$$

are pointwise convergent. By Theorem 4.2, there exist $\epsilon_1, \epsilon_2 > 0$ such that

$$|c - a| < \epsilon_1 \Rightarrow \left\{ \begin{bmatrix} \pm a & 0 \\ 0 & a^{-1} \end{bmatrix}, \begin{bmatrix} -c^{-1} & 1 \\ 0 & c \end{bmatrix} \right\} \text{ is pointwise convergent} \tag{5.1}$$

and

$$|c - a/b| < \epsilon_2 \Rightarrow \left\{ \begin{bmatrix} \pm a/b & 0 \\ 0 & b/a \end{bmatrix}, \begin{bmatrix} -c^{-1} & 1 \\ 0 & c \end{bmatrix} \right\} \text{ is pointwise convergent.} \tag{5.2}$$

The 1 in the $(1,2)$ position of the second matrices in (5.1) and (5.2) can be changed to any nonzero real number without affecting either implication by using simultaneous similarity.

Let $\epsilon = \min\{\epsilon_1, \epsilon_2\}$. By Theorem 6.8 in [NZ] there exist positive integers x and $y + 1$ such that

$$\left| \frac{x}{y+1} - \log(a) \right| < \frac{\ln(\epsilon/a + 1)}{(y+1)\ln(b)},$$

where $\log(a) = \frac{\ln(a)}{\ln(b)}$ is the base b logarithm. Multiplying by $(y+1)\ln(b)$ and then taking the exponential on both sides, we get

$$1 \leq b^{|x - (\log(a))(y+1)|} < \epsilon/a + 1. \tag{5.3}$$

If the expression inside the absolute value sign in (5.3) is positive, then

$$1 \leq \frac{b^x}{b^{(\log(a))(y+1)}} < 1 + \epsilon/a,$$

and therefore

$$a \leq \frac{b^x}{a^y} < a + \epsilon. \tag{5.4}$$

Similarly, if the expression inside the absolute value sign in (5.3) is negative, we obtain

$$1 \leq \frac{b^{(\log(a))(y+1)}}{b^x} < \epsilon/a + 1;$$

therefore

$$\frac{b^x}{a^y} \leq a < \frac{b^x}{a^y}(\epsilon/a + 1) = \frac{b^x}{a^y}\left(\frac{\epsilon}{a}\right) + \frac{b^x}{a^y} \leq a\left(\frac{1}{a}\right)\epsilon + \frac{b^x}{a^y} = \frac{b^x}{a^y} + \epsilon. \tag{5.5}$$

Inequalities (5.4) and (5.5) imply that $\left|\frac{b^x}{a^y} - a\right| < \epsilon$. If $\delta^y(-1)^x = -1$, then the set $\{A_1, A_1^y A_2^x\}$ is pointwise convergent by the implication (5.1). Hence the set $\mathcal{A}$ itself is pointwise convergent. If $\delta^y(-1)^x = 1$, then

$$\left|\frac{b^{x-1}}{a^y} - \frac{a}{b}\right| < \epsilon/b < \epsilon.$$

Now,

$$A_1A_2 = \begin{bmatrix} \delta a/(-b) & \delta a \\ 0 & b/a \end{bmatrix}, \qquad A_2A_1 = \begin{bmatrix} \delta a/(-b) & 1/a \\ 0 & b/a \end{bmatrix},$$
$$A_1^y A_2^{x-1} = \begin{bmatrix} -a^y/b^{x-1} & q \\ 0 & b^{x-1}/a^y \end{bmatrix}$$

for some real number q. Since $\delta a \neq 1/a$, reducing by simultaneous similarity (with an upper triangular similarity matrix) at least one of the two pairs $\{A_1A_2, A_1^y A_2^{x-1}\}$ and $\{A_2A_1, A_1^y A_2^{x-1}\}$ to the form

$$\left\{\begin{bmatrix} \delta a/(-b) & 0 \\ 0 & b/a \end{bmatrix}, \begin{bmatrix} -a^y/b^{x-1} & q' \\ 0 & b^{x-1}/a^y \end{bmatrix}\right\}$$

will result in a nonzero number q', which can be made to equal 1 by a subsequent simultaneous similarity. By the implication (5.2) it follows that at least one of the two pairs $\{A_1A_2, A_1^y A_2^{x-1}\}$ and $\{A_2A_1, A_1^y A_2^{x-1}\}$ is pointwise convergent, and then the pointwise convergence holds for the pair $\mathcal{A}$ as well.

Now assume $0 < a < 1$ and $0 < b < 1$. There are a positive even integer k such that $a/(-b)^k > 1$ and a positive integer j such that $0 > a^j/(-b) > -1$. The set

$$\left\{\begin{bmatrix} \frac{a}{b^k} & 0 \\ 0 & \frac{b^k}{a} \end{bmatrix}, \quad \begin{bmatrix} -\frac{a^j}{b} & 1 \\ 0 & \frac{b}{a^j} \end{bmatrix}\right\} \tag{5.6}$$

is pointwise convergent by the already proved part of the theorem. If $\delta = 1$, then at least one of the two pairs $(A_1A_2^k, A_1^jA_2)$ and $(A_1A_2^k, A_2A_1^j)$ can be reduced to (5.6) by simultaneous similarity (an analogous argument was used in the preceding paragraph) and therefore itself is pointwise convergent. However, the pointwise convergence of $\mathcal{A}$ then follows. If $0 < a < 1$ and $0 < b < 1$, but $\delta = -1$, then (A_1^2, A_2) is already proved to be pointwise convergent, and therefore $\mathcal{A}$ also has this property.

Finally, if a and/or b are negative, then negating one or both matrices in $\mathcal{A}$ and performing (if necessary) a simultaneous diagonal similarity to make the $(1,2)$ entry of A_2 equal to 1 will produce a set of a form already proved to be pointwise convergent. Therefore, $\mathcal{A}$ is itself pointwise convergent. □

It follows from Theorem 4.2 that given $N > 0$, there exists positive ϵ such that the set

$$\left\{ A_1 = \begin{bmatrix} a_1 & b_1 \\ 0 & c_1 \end{bmatrix}, \quad A_2 = \begin{bmatrix} a_2 & b_2 \\ 0 & c_2 \end{bmatrix} \right\}$$

is pointwise convergent, provided

$$|a_1c_1 - 1| < \epsilon, \ |a_2c_2 - 1| < \epsilon, \ \max\{|a_1|, |b_1|, |c_1|, |a_2|, |b_2|, |c_2|\} \leq N, \tag{5.7}$$

and none of the conditions (1), (2), (3) of Theorem 5.2 occurs when $|a_1c_1| = |a_2c_2| = 1$. However, the thickness of this "fringe" ϵ is unknown.

The following example illustrates Theorems 5.1 and 5.2.

EXAMPLE 5.3. *Fix $a > 1$ and consider the pair*

$$\left\{ A_1 = \begin{bmatrix} a & 0 \\ 0 & 1/a \end{bmatrix}, \quad A_2 = \begin{bmatrix} c & 1 \\ 0 & d \end{bmatrix} \right\}, \tag{5.8}$$

where c and d are real numbers. The set (5.8) *is uniformly convergent if and only if $|c| < 1$ and $|cd| < 1$. If $|c| \geq 1$ or if $|c| < 1$ and $cd \geq 1$, then the set* (5.8) *is not pointwise convergent. If $|c| < 1$ and $cd = -1$, then the set* (5.8) *is pointwise convergent. By Theorem* 4.2, (5.8) *is also pointwise convergent in a sufficiently small neighborhood of each of the two hyperbolic arcs $cd = -1, -1 < c < 0$ and $cd = -1, 0 < c < 1$. It is not known whether the set* (5.8) *is pointwise convergent for every pair (c, d) in the region $0 < |c| < 1, cd < -1$.*

ON SINGULARITIES OF A BOUNDARY OF THE STABILITY DOMAIN*

ALEXEI A. MAILYBAEV† AND ALEXANDER P. SEYRANIAN†

This paper is dedicated to V. I. Arnold on the occasion of his 60th birthday.

Abstract. This paper deals with the study of generic singularities of a boundary of the stability domain in a parameter space for systems governed by autonomous linear differential equations $\dot{y} = Ay$ or $x^{(m)} + a_1 x^{(m-1)} + \cdots + a_m x = 0$. It is assumed that elements of the matrix A and coefficients of the differential equation of mth order smoothly depend on one, two, or three real parameters. A constructive approach allowing the geometry of singularities (orientation in space, magnitudes of angles, etc.) to be determined with the use of tangent cones to the stability domain is suggested. The approach allows the geometry of singularities to be described using only first derivatives of the coefficients a_i of the differential equation or first derivatives of the elements of the matrix A with respect to problem parameters with its eigenvectors and associated vectors calculated at the singular points of the boundary. Two methods of study of singularities are suggested. It is shown that they are constructive and can be applied to investigate more complicated singularities for multiparameter families of matrices or polynomials. Two physical examples are presented and discussed in detail.

Key words. stability boundary, generic singularity, tangent cone, collapse of the Jordan block, versal deformation

Introduction. We consider a system of autonomous linear differential equations $\dot{y} = Ay$ assuming that the real matrix operator A of dimension $m \times m$ smoothly depends on n real parameters. Stability of the trivial solution $y \equiv 0$ of the system is considered. It is well known that the trivial solution is asymptotically stable, if all eigenvalues of A have negative real part, and unstable if at least one of the eigenvalues of A has positive real part. According to this definition the parameter space $\mathbf{R}^n$ is divided into the stability and instability domains. Boundary between these domains corresponds to the cases when some of the eigenvalues have zero real part while other eigenvalues have negative real part.

Arnold [3, 4, 5] listed all the generic singularities arising at the stability boundary in two- and three-dimensional space of parameters and gave their description up to a smooth change of problem parameters (diffeomorphism). In this paper we suggest a constructive approach allowing one to determine the geometry of singularities (orientation in space, magnitudes of angles, etc.) using only first derivatives of the matrix A with respect to parameters and left and right eigenvectors and associated vectors of A, corresponding to the Jordan structure of the matrix A at the singular points of the boundary. Our study is essentially based on the perturbation theory of eigenvalues and eigenvectors, developed by Vishik and Lyusternik [16] and Lidskii [11] and applied by Seyranian [12, 13] to the case of multiple parameters, and the theory of

normal forms of families of matrices by Arnold [2] and Galin [7]. Investigation of the boundary of the stability domain is closely related to construction of tangent cones to the stability domain at the boundary point, introduced by Levantovskii [9], and the problem of finding stable perturbations of nonsymmetric matrices considered by Burke and Overton [6].

We investigate generic singularities of a boundary of the stability domain for linear autonomous differential equation of mth order $x^{(m)} + a_1 x^{(m-1)} + \cdots + a_m x = 0$, assuming that the coefficients a_i smoothly depend on one, two, or three real parameters. Explicit formulae to describe the geometry of singularities in the parameter space are derived.

As examples, two physical problems are considered: stability of equilibrium of a voltaic arc in an electric circuit and stability of Ziegler's double pendulum with two different damping parameters. In the first problem at the singular point "double zero" we find the angle of the corner of the stability boundary and its orientation in parameter plane. In the second problem it is shown that the singularity, arising at the critical load of the system without damping, represents, according to Arnold's terminology [3, 4], the "deadlock of an edge." This leads to the effects of destabilization due to small damping and absence of a limit of the critical load when damping parameters tend to zero. Similar effects could be expected for systems with singularities like "break of an edge."

The main result of the paper is that the Jordan structure of the matrix A and its first derivatives with respect to problem parameters at any point of the stability boundary define a linear approximation of the stability domain in the vicinity of the considered point. Similar results are valid for stability problems governed by a linear differential equation of mth order: to determine the geometry of the stability domain in the vicinity of a singular point of the boundary we need only to know the multiplicity of the root of the characteristic polynomial and the first derivatives of the coefficients of the differential equation with respect to problem parameters at this point.

1. Collapse of Jordan blocks. Let us consider an eigenvalue problem

$$A\,u = \lambda\,u. \tag{1.1}$$

Here A is a real nonsymmetric square $m \times m$ matrix, the elements of which, $a_{ij}(p)$, $i, j = 1, 2, \ldots, m$, are smooth functions of a real vector of parameters $p = (p_1, p_2, \ldots, p_n)^T$; λ is an eigenvalue; and u is a corresponding eigenvector of dimension m.

It is assumed that at fixed $p = p_0$, λ_0 is an eigenvalue of $A(p_0)$, and a change of the eigenvalue λ_0 is sought that depends on a change of the vector of parameters p. For this purpose let us consider a perturbation of the vector p_0 in the form $p = p(\varepsilon)$, $p(0) = p_0$, where ε is a small positive number and $p(\varepsilon)$ is a smooth function of ε. Determine a real vector of direction $e = (e_1, e_2, \ldots, e_n) = dp/d\varepsilon \neq 0$, where the derivative is calculated at $\varepsilon = 0$. As a result the matrix A takes the increment

$$A(p(\varepsilon)) = A_0 + \varepsilon A_1 + \varepsilon^2 A_2 + \cdots, \tag{1.2}$$

where the matrices A_0 and A_1 are given by the relations

$$A_0 = A(p_0), \quad A_1 = \sum_{s=1}^{n} \frac{\partial A}{\partial p_s}\, e_s. \tag{1.3}$$

The derivatives in (1.3) are taken at $p = p_0$.

Due to the perturbation of the vector p_0, the eigenvalue λ_0 and the eigenvector u_0 take increments. According to the perturbation theory of non-self-adjoint operators, developed in [16, 11], these increments can be expressed as series in integer or fractional powers of ε, depending on the Jordan structure corresponding to the eigenvalue λ_0. A multiple eigenvalue λ_0 generally splits into l simple eigenvalues under the perturbation of parameters $p = p(\varepsilon)$. Expansions for eigenvalues and eigenvectors contain terms with fractional powers $\varepsilon^{j/l}$, $j = 0, 1, 2 \ldots$, where l is the length of the Jordan chain [16, 11].

1.1. Simple eigenvalue. Assume that λ_0 is a simple eigenvalue of the matrix A_0 and u_0 is the corresponding eigenvector. In this case expansions of λ and u take the form [16, 11]

$$\begin{aligned} \lambda &= \lambda_0 + \varepsilon\,\lambda_1 + \varepsilon^2\lambda_2 + \cdots, \\ u &= u_0 + \varepsilon\,w_1 + \varepsilon^2 w_2 + \cdots. \end{aligned} \tag{1.4}$$

For the following presentation we also need the left eigenvector v_0, corresponding to λ_0,

$$v_0^T A_0 = \lambda_0\, v_0^T. \tag{1.5}$$

The eigenvectors u_0 and v_0 in the case of simple eigenvalue λ_0 are related by the condition $v_0^T u_0 \neq 0$. Substituting (1.2), (1.4) into (1.1) and using (1.5) we find [16, 11]

$$\lambda_1 = \frac{v_0^T A_1 u_0}{v_0^T u_0}. \tag{1.6}$$

This expression with the use of (1.3) can be given in the form

$$\lambda_1 = (r,\, e) + i\,(k,\, e), \tag{1.7}$$

where brackets denote the scalar product in $\mathbf{R}^n$, i.e., $(a,\, b) = \sum_{s=1}^n a_s b_s$. Vectors $r = (r^1,\, r^2,\, \ldots,\, r^n)^T$ and $k = (k^1,\, k^2,\, \ldots,\, k^n)^T$ are the gradient vectors of real and imaginary parts of λ at $p = p_0$, given by

$$r^s + i\,k^s = \frac{v_0^T \dfrac{\partial A}{\partial p_s}\, u_0}{v_0^T u_0}\,, \quad s = 1,\, 2,\, \ldots\,,\, n. \tag{1.8}$$

There are two complex-conjugate quantities λ_1, $\overline{\lambda}_1 = (r,\, e) \pm i\,(k,\, e)$ corresponding to a complex-conjugate pair of simple eigenvalues λ_0, $\overline{\lambda}_0 = \alpha_0 \pm i\,\omega_0$. The increments of these eigenvalues are given in the form

$$\lambda,\, \overline{\lambda} = \alpha_0 + (r,\, e)\,\varepsilon \pm i\,[\,\omega_0 + (k,\, e)\,\varepsilon\,] + o(\varepsilon). \tag{1.9}$$

In the case of a real eigenvalue $\lambda_0 = \alpha_0$, the vector $k = 0$.

1.2. Double eigenvalue. Let us consider the case of a double eigenvalue λ_0 with the length of the Jordan chain equal to 2. This means that at $p = p_0$ the eigenvalue λ_0 corresponds to an eigenvector u_0 and an associated vector u_1 governed by the equations

$$\begin{aligned} A_0\, u_0 &= \lambda_0\, u_0, \\ A_0\, u_1 &= \lambda_0\, u_1 + u_0. \end{aligned} \tag{1.10}$$

For a left eigenvector v_0 and an associated vector v_1 we have

$$\begin{aligned} v_0^T A_0 &= \lambda_0 v_0^T, \\ v_1^T A_0 &= \lambda_0 v_1^T + v_0^T. \end{aligned} \tag{1.11}$$

From (1.10) and (1.11) it directly follows that the vectors u_0, u_1, v_0, and v_1 are related by the conditions [16]

$$v_0^T u_0 = 0, \quad v_1^T u_0 = v_0^T u_1 \neq 0. \tag{1.12}$$

In the case of a double eigenvalue we have expansions [16, 11]

$$\begin{aligned} \lambda &= \lambda_0 + \varepsilon^{1/2}\lambda_1 + \varepsilon\,\lambda_2 + \varepsilon^{3/2}\lambda_3 + \cdots, \\ u &= u_0 + \varepsilon^{1/2} w_1 + \varepsilon\, w_2 + \varepsilon^{3/2} w_3 + \cdots. \end{aligned} \tag{1.13}$$

Substituting (1.13) and (1.2) into (1.1) and using (1.10)–(1.12) we obtain expressions for determining λ_1 and λ_2:

$$\begin{aligned} \lambda_1 &= \pm\sqrt{\frac{v_0^T A_1 u_0}{v_0^T u_1}}, \\ \lambda_2 &= \frac{v_0^T A_1 u_1 + v_1^T A_1 u_0 - \lambda_1^2\, v_1^T u_1}{2\, v_0^T u_1}. \end{aligned} \tag{1.14}$$

Expressions (1.13), (1.14) are correct if $v_0^T A_1 u_0 \neq 0$ (the condition Γ in [16]).

Note that the vectors u_0 and v_0 are defined up to arbitrary nonzero multipliers; the vectors u_1 and v_1 are defined up to additive terms αu_0 and βv_0, respectively, where α and β are arbitrary constants. However, the values of λ_1 and λ_2 in (1.14) don't depend on the way that the vectors u_0, u_1, v_0, and v_1 are chosen.

Assuming that the vectors u_0, u_1 are fixed we use the following normalization conditions for v_0 and v_1:

$$v_0^T u_1 = 1, \quad v_1^T u_1 = 0. \tag{1.15}$$

Combining the expressions (1.14) with (1.3), (1.13) and the normalization conditions (1.15) gives

$$\lambda = \lambda_0 \pm \sqrt{[\,(f_1,\, e) + i\,(q_1,\, e)\,]\,\varepsilon} + \frac{1}{2}\,[\,(f_2,\, e) + i\,(q_2,\, e)\,]\,\varepsilon + o(\varepsilon), \tag{1.16}$$

where components of the vectors $f_j = (f_j^1,\, f_j^2,\, \ldots,\, f_j^n)$, $q_j = (q_j^1,\, q_j^2,\, \ldots,\, q_j^n)$, $j = 1,\, 2$, are real and imaginary parts of quantities defined by

$$\begin{aligned} f_1^s + i\, q_1^s &= v_0^T \frac{\partial A}{\partial p_s}\, u_0, \\ f_2^s + i\, q_2^s &= v_0^T \frac{\partial A}{\partial p_s}\, u_1 + v_1^T \frac{\partial A}{\partial p_s}\, u_0, \quad s = 1,\, 2,\, \ldots,\, n. \end{aligned} \tag{1.17}$$

If λ_0 is a real number, then the vectors $q_1 = q_2 = 0$.

1.3. Triple eigenvalue. Consider the case of a triple eigenvalue that is characterized by a Jordan chain of the length 3. This means that there are an eigenvector u_0 and associated vectors u_1, u_2 satisfying the equations

$$\begin{aligned} A_0\,u_0 &= \lambda_0\,u_0,\\ A_0\,u_1 &= \lambda_0\,u_1 + u_0,\\ A_0\,u_2 &= \lambda_0\,u_2 + u_1. \end{aligned} \tag{1.18}$$

For a left eigenvector v_0 and associated vectors v_1 and v_2 we have

$$\begin{aligned} v_0^T A_0 &= \lambda_0\,v_0^T,\\ v_1^T A_0 &= \lambda_0\,v_1^T + v_0^T,\\ v_2^T A_0 &= \lambda_0\,v_2^T + v_1^T. \end{aligned} \tag{1.19}$$

The vectors u_j, v_j, $j = 1, 2, 3$, are related by the conditions

$$\begin{gathered} v_0^T u_0 = v_0^T u_1 = v_1^T u_0 = 0,\\ v_0^T u_2 = v_1^T u_1 = v_2^T u_0 \neq 0,\\ v_1^T u_2 = v_2^T u_1. \end{gathered} \tag{1.20}$$

These conditions can be proved by means of (1.18), (1.19). Assuming that the vectors u_j, $j = 1, 2, 3$, are fixed we use the following normalization conditions for the vectors v_j, $j = 1, 2, 3$:

$$v_0^T u_2 = 1, \quad v_1^T u_2 = v_2^T u_2 = 0. \tag{1.21}$$

These conditions define the vectors v_j, $j = 1, 2, 3$, uniquely.

The eigenvalue λ_0 generally splits to three simple eigenvalues due to perturbation of parameters. Then eigenvalues and eigenvectors can be given in the form [16, 11]

$$\begin{aligned} \lambda &= \lambda_0 + \varepsilon^{1/3}\lambda_1 + \varepsilon^{2/3}\lambda_2 + \varepsilon\,\lambda_3 + +\varepsilon^{4/3}\lambda_4 + \cdots,\\ u &= u_0 + \varepsilon^{1/3}w_1 + \varepsilon^{2/3}w_2 + \varepsilon\,w_3 + \varepsilon^{4/3}w_4 + \cdots. \end{aligned} \tag{1.22}$$

Substituting expansions (1.22) and (1.2) into (1.1) and using (1.18)–(1.21) we obtain expressions for the first three coefficients λ_j, $j = 1, 2, 3$:

$$\begin{aligned} \lambda_1 &= \sqrt[3]{v_0^T A_1 u_0},\\ \lambda_2 &= \frac{v_0^T A_1 u_1 + v_1^T A_1 u_0}{3\,\lambda_1},\\ \lambda_3 &= \frac{1}{3}\left(v_0^T A_1 u_2 + v_1^T A_1 u_1 + v_2^T A_1 u_0\right). \end{aligned} \tag{1.23}$$

These expressions are correct if $v_0^T A_1 u_0 \neq 0$ (the condition Γ in [16]). In this case the first expression of (1.23) defines three different complex roots λ_1. Then values of λ_2 and λ_3 are determined for each root λ_1 from the second and third expressions of (1.23).

Combining expressions (1.23) with (1.22) and (1.3) gives

$$\begin{aligned} \lambda = \lambda_0 &+ \sqrt[3]{[\,(h_1,\,e) + i\,(t_1,\,e)\,]\,\varepsilon}\\ &+ \frac{(h_2,\,e) + i\,(t_2,\,e)}{3\sqrt[3]{(h_1,\,e) + i\,(t_1,\,e)}}\,\varepsilon^{2/3} + \frac{1}{3}\,[\,(h_3,\,e) + i\,(t_3,\,e)\,]\,\varepsilon + o(\varepsilon), \end{aligned} \tag{1.24}$$

where components of the vectors $h_j = (h_j^1, h_j^2, \ldots, h_j^n)$, $t_j = (t_j^1, t_j^2, \ldots, t_j^n)$, $j = 1, 2, 3$, are real and imaginary parts of the quantities

$$
\begin{aligned}
h_1^s + i\,t_1^s &= v_0^T \frac{\partial A}{\partial p_s}\, u_0, \\
h_2^s + i\,t_2^s &= v_0^T \frac{\partial A}{\partial p_s}\, u_1 + v_1^T \frac{\partial A}{\partial p_s}\, u_0, \\
h_3^s + i\,t_3^s &= v_0^T \frac{\partial A}{\partial p_s}\, u_2 + v_1^T \frac{\partial A}{\partial p_s}\, u_1 + v_2^T \frac{\partial A}{\partial p_s}\, u_0, \\
s &= 1, 2, \ldots, n.
\end{aligned} \tag{1.25}
$$

The cubic roots in the second and third terms of the right-hand side of (1.24) are the same and take three different complex values.

If λ_0 is a real number, then the vectors $t_j = 0$, $j = 1, 2, 3$.

2. One- and two-parameter families of matrices. Let us consider a linear evolutionary system of the form

$$\dot{y} = A\,y, \tag{2.1}$$

where A is a real autonomous $m \times m$ matrix and y is a real vector of dimension m. The system is stable (asymptotically stable) if all eigenvalues λ of the matrix A have negative real parts, $\operatorname{Re}\lambda < 0$. If there exists at least one eigenvalue such that $\operatorname{Re}\lambda > 0$, the system is unstable. If there are some eigenvalues with $\operatorname{Re}\lambda = 0$ while for all others $\operatorname{Re}\lambda < 0$, we have a boundary point.

A *family* of matrices is a mapping $A : \Lambda \longrightarrow \mathbf{R}^{m^2}$ of the parameter space into the space of matrices. The set of values $p \in \Lambda$, such that $A(p)$ is a stable matrix, is called the stability domain. First, let us consider a one-parameter family $A(p)$, $p \in \mathbf{R}$. The stability domain boundary of a *generic* one-parameter family is characterized by one simple eigenvalue $\lambda = 0$ or by one pair of complex-conjugate simple eigenvalues $\lambda = \pm i\,\omega$ of the matrix A [3, 4]. In the technical literature these cases are called divergence and flutter boundaries, respectively.

Using (1.9) we have

$$\operatorname{Re}\lambda = r\,(p - p_0) + o(p - p_0) \tag{2.2}$$

for a simple eigenvalue λ in the neighborhood of the stability boundary point p_0, $\operatorname{Re}\lambda_0 = 0$. Hence, location of the stability and instability domains is determined by the sign of the quantity

$$r = \operatorname{Re}\left[\left(v_0^T\, dA/dp\, u_0\right)/\left(v_0^T u_0\right)\right].$$

For example, if $r > 0$, then the system is stable ($\operatorname{Re}\lambda < 0$) at $p < p_0$ and unstable ($\operatorname{Re}\lambda > 0$) at $p > p_0$ for p sufficiently close to p_0. Note that $r \neq 0$ in the generic case, i.e., the case $r = 0$ can be removed by an arbitrarily small shift of the family.

In the case of a two-parameter generic family $A(p)$, $p \in \mathbf{R}^2$, the stability boundary is a smooth curve whose only singularities are corners. The curve in nonsingular points is characterized by a simple eigenvalue $\lambda = 0$ or a simple pair $\lambda = \pm i\,\omega$ and has a normal vector r defined in (1.8). From (1.9) it follows that the normal r lies in the instability domain. The corners correspond to matrices $A(p)$ of the three following types (strata) [3, 4, 5]: $F_1(0^2)$—double eigenvalue $\lambda = 0$ with the

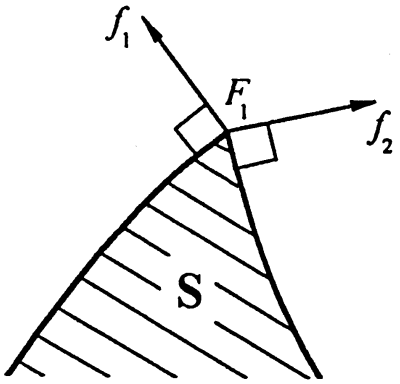

FIG. 2.1. *A corner of the stability domain.*

corresponding Jordan block of the order 2; $F_2(0,\, \pm i\,\omega)$— simple eigenvalues 0, $\pm i\,\omega$; $F_3(\pm i\,\omega_1,\, \pm i\,\omega_2)$—two pairs of simple different eigenvalues $\pm i\,\omega_1$, $\pm i\,\omega_2$. Other types of singularities can be destroyed by an arbitrarily small shift of the family.

Using expansions (1.16) for a double eigenvalue $\lambda_0 = 0$ we have

$$\lambda = \pm\sqrt{(f_1,\, e)\,\varepsilon} + \frac{1}{2}\,(f_2,\, e)\,\varepsilon + o(\varepsilon), \tag{2.3}$$

where vectors f_1 and f_2 are defined by means of (1.17) and e is a vector of variation (direction). In the generic case the vectors f_1 and f_2 are linearly independent. For an arbitrary fixed vector e, such that $(f_1,\, e) < 0$ and $(f_2,\, e) < 0$, we have $\operatorname{Re}\lambda < 0$ (stability) for sufficiently small ε. If at least one of these inequalities has the opposite sign, we have $\operatorname{Re}\lambda > 0$ (instability).

For the following presentation we need a concept of *tangent cone*. A tangent cone to the stability domain at the boundary point is a set of direction vectors of the curves starting at this point and lying in the stability domain [9]. A tangent cone is nondegenerate if it cuts out on a sphere a set of nonzero measure. Otherwise, the cone is called degenerate. A tangent cone can be considered as a linear approximation of the stability domain.

In accordance with (2.3) a tangent cone at the boundary point corresponding to the stratum $F_1(0^2)$ takes the form

$$K_{F_1} = \big\{\, e : (f_1,\, e) \le 0,\ \ (f_2,\, e) \le 0 \,\big\}. \tag{2.4}$$

Using expression (2.2) for a simple eigenvalue we similarly obtain tangent cones at boundary points corresponding to the strata $F_2(0,\, \pm i\,\omega)$ and $F_3(\pm i\,\omega_1,\, \pm i\,\omega_2)$:

$$K_{F_2} = \big\{\, e : (r_0,\, e) \le 0,\ \ (r,\, e) \le 0 \,\big\}, \tag{2.5}$$

$$K_{F_3} = \big\{\, e : (r_1,\, e) \le 0,\ \ (r_2,\, e) \le 0 \,\big\}. \tag{2.6}$$

Here the vectors r_0, r, r_1, r_2 correspond to the simple eigenvalues 0, $\pm i\,\omega$, $\pm i\,\omega_1$, $\pm i\,\omega_2$, respectively, and are calculated using (1.8). In the generic case the vectors r, r_0 and also r_1, r_2 are linearly independent.

Using the relations (2.4)–(2.6) for tangent cones we can find tangent vectors to the stability boundary. For example, in the case of a singular point of the type F_1

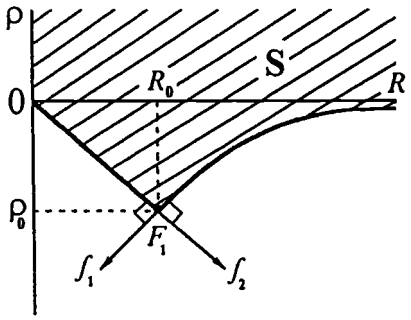

FIG. 3.1. *The stability domain of equilibrium of the voltaic arc in electric circuit.*

tangent vectors g_1 and g_2 can be found from the following system of linear equations (see Figure 2.1):

$$(f_i,\, g_j) = -\delta_{ij}, \quad i,\, j = 1,\, 2, \tag{2.7}$$

where δ_{ij} is Kronecker's delta and f_1, f_2 are the vectors from (2.4).

The inequalities in (2.4)–(2.6) define an intersection of two halfplanes. Hence, the stability domain wedges into the instability domain with the angle of wedge less than π; see Figure 2.1. This is a quantitative justification of the Arnold's principle of "fragility of all good things" [3, 4, 5] and quasi convexity of the stability domain [9].

3. Example: Stability of equilibrium of a voltaic arc in electric circuit. As an example let us consider a stability problem of equilibrium of a circuit consisting of a voltaic arc, resister R, inductance L, and shunting capacitor C connected in series. Linearized differential equations near the equilibrium of the system have the form [1]

$$\begin{aligned} \frac{d\xi}{dt} &= -\frac{\rho\xi}{L} + \frac{\eta}{L}, \\ \frac{d\eta}{dt} &= -\frac{\xi}{C} - \frac{\eta}{RC}, \end{aligned} \tag{3.1}$$

where $\xi(t)$, $\eta(t)$ are, respectively, an electric current and a voltage in the voltaic arc, and ρ is a resistance of the arc.

The system (3.1) depends on four parameters: three positive quantities L, C, R and parameter ρ, which can take both positive and negative values. Assuming that the parameters L and C are fixed, we consider the stability problem on the plane of two parameters: $p_1 = R$ and $p_2 = \rho$. The matrix A corresponding to the system (3.1) is

$$A = \begin{pmatrix} -\dfrac{\rho}{L} & \dfrac{1}{L} \\ -\dfrac{1}{C} & -\dfrac{1}{CR} \end{pmatrix}. \tag{3.2}$$

The characteristic equation of the system takes the form

$$\lambda^2 + \left(\frac{1}{RC} + \frac{\rho}{L}\right)\lambda + \frac{1}{LC}\left(\frac{\rho}{R} + 1\right) = 0. \tag{3.3}$$

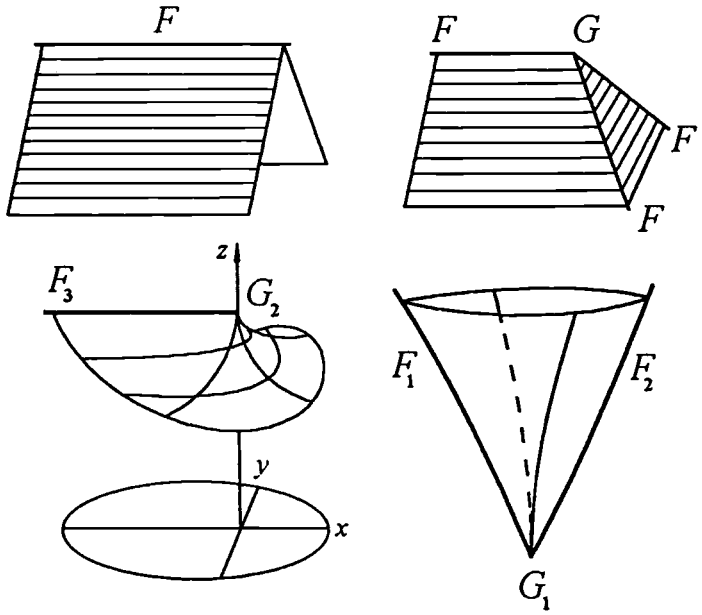

FIG. 4.1. *Singularities of the stability boundary of a three-parameter generic family.*

At the point $R_0 = \sqrt{L/C}$, $\rho_0 = -\sqrt{L/C}$ the characteristic equation (3.3) has a double root $\lambda_0 = 0$ with the length of the Jordan chain equal to 2. The equations for Jordan chains (1.10), (1.11) yield at this point

$$u_0 = \begin{pmatrix} 1 \\ -\sqrt{L/C} \end{pmatrix}, \quad u_1 = \begin{pmatrix} 0 \\ L \end{pmatrix}, \quad v_0 = \begin{pmatrix} 1/\sqrt{LC} \\ 1/L \end{pmatrix}, \quad v_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Using these vectors and the matrix A from (3.2) we calculate the vectors f_1 and f_2 according to (1.17):

$$f_1 = -\frac{1}{L\sqrt{LC}} \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad f_2 = \frac{1}{L} \begin{pmatrix} 1 \\ -1 \end{pmatrix}. \tag{3.4}$$

Thus, we have found the tangent cone (2.4) to the stability domain at the point $R = R_0$, $\rho = \rho_0$; see Figure 3.1. The tangent vectors to the stability boundary (2.7) up to a positive factor are $g_1 = (1, 1)^T$, $g_2 = (-1, 1)^T$. Hence, the angle of the wedge of the stability domain is equal to $\pi/2$. This result is in accordance with [1], where it has been shown that the stability boundary consists of the line $\rho = -R$, $0 \le R \le \sqrt{L/C}$ and the hyperbola $\rho = -L/(CR)$, $\sqrt{L/C} \le R$; see Figure 3.1.

4. Three-parameter family of matrices. Consider a generic three-parameter family of matrices $A(p)$, $p \in \mathbf{R}^3$. The stability domain boundary of the family is a smooth surface characterized by one simple eigenvalue $\lambda = 0$ or a pair of simple eigenvalues $\lambda = \pm i\,\omega$ [3, 4]. The normal vector r to this surface is defined by the relation (1.8) in the same way as in the two-parameter case. The vector r lies in the instability domain. According to [3, 4] the only singularities of the stability boundary of a generic three-parameter family are of four types: dihedral angle, trihedral angle, deadlock of an edge, and break of an edge; see Figure 4.1.

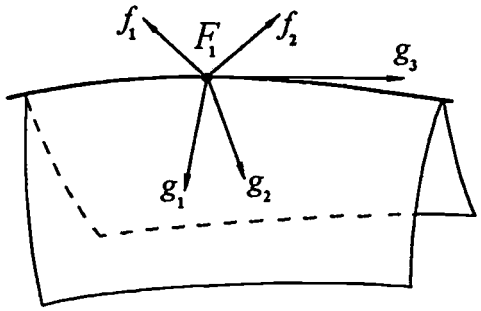

FIG. 4.2. *An edge of the stability domain.*

The dihedral angle singularity is connected with the strata $F_1(0^2)$, $F_2(0, \pm i\,\omega)$, $F_3(\pm i\,\omega_1, \pm i\,\omega_2)$ examined in section 2. Therefore tangent cones to the stability domain at these singular points are determined by the relations (2.4)–(2.6), respectively.

The tangent cone K_{F_1} can be written in a more suitable form introducing vectors g_1, g_2, g_3 by the equations

$$(f_i, g_j) = -\delta_{ij}, \quad i = 1, 2, \quad j = 1, 2, 3, \tag{4.1}$$

where f_1, f_2 are the vectors from (2.4). The equations (4.1) are solvable because the vectors f_1 and f_2 are linearly independent for a generic family. The vector g_3 is directed along the edge and the vectors g_1, g_2 are tangent to the sides of the dihedral angle; see Figure 4.2. Using these vectors the set (2.4) can be written in the form

$$K_{F_1} = \{\, e :\ e = \alpha\, g_1 + \beta\, g_2 + \gamma\, g_3;\ \ \alpha, \beta, \gamma \in \mathbf{R},\ \alpha \geq 0,\ \beta \geq 0 \,\}. \tag{4.2}$$

Substituting the expression $e = \alpha\, g_1 + \beta\, g_2 + \gamma\, g_3$ into (2.4) and using (4.1) we find $(f_1, e) = -\alpha \leq 0$, $(f_2, e) = -\beta \leq 0$. It proves the representation (4.2). Similar representations can be obtained for the tangent cones K_{F_2} and K_{F_3} using in (4.1) the vectors r_0, r and r_1, r_2 instead of f_1, f_2, respectively.

The trihedral angle singularity is characterized by the following strata [3, 4]: $G_3(0^2, \pm i\,\omega)$—a double eigenvalue $\lambda = 0$ with the length of the Jordan chain equal to 2 and a pair of simple pure imaginary eigenvalues; $G_4(0, \pm i\,\omega_1, \pm i\,\omega_2)$—simple $\lambda = 0$ and two different pairs of simple pure imaginary eigenvalues; $G_5(\pm i\,\omega_1, \pm i\,\omega_2, \pm i\,\omega_3)$—three different pairs of simple pure imaginary eigenvalues.

Note that these strata differ from the strata F_1, F_2, F_3 by the presence of an additional pair of simple eigenvalues of the type $\lambda = \pm i\,\omega$. Therefore tangent cones at the boundary points of these types, similarly to (2.4)–(2.6), can be written in the form

$$K_{G_3} = \{\, e : (f_1, e) \leq 0,\ \ (f_2, e) \leq 0,\ \ (r, e) \leq 0 \,\}, \tag{4.3}$$

$$K_{G_4} = \{\, e : (r_0, e) \leq 0,\ \ (r_1, e) \leq 0,\ \ (r_2, e) \leq 0 \,\}, \tag{4.4}$$

$$K_{G_5} = \{\, e : (r_1, e) \leq 0,\ \ (r_2, e) \leq 0,\ \ (r_3, e) \leq 0 \,\}, \tag{4.5}$$

where the vectors r_0, r, r_j, $j = 1, 2, 3$ correspond to the eigenvalues 0, $\pm i\,\omega$, $\pm i\,\omega_j$, $j = 1, 2, 3$, respectively, and are defined in (1.8). The vectors f_1 and f_2 correspond

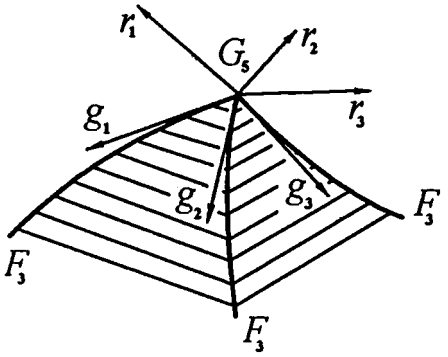

FIG. 4.3. *The singularity trihedral angle.*

to the double eigenvalue $\lambda = 0$ and are defined in (1.17). The sets (4.3)–(4.5) describe a trihedral angle, which is located entirely in a closed half-space; see Figure 4.3.

As in (4.1), using the vectors determining the cones, we can find vectors g_1, g_2, g_3 tangential to the edges of the trihedral angle; see Figure 4.3. For example, for the singular point of the type G_5 we have

$$(r_i,\, g_j) = -\delta_{ij}, \quad i,\, j = 1,\, 2,\, 3, \tag{4.6}$$

where r_j, $j = 1, 2, 3$ are the vectors from (4.5). With the use of these vectors the tangent cone K_{G_5} can be described in the following way:

$$K_{G_5} = \big\{\, e :\ e = \alpha\, g_1 + \beta\, g_2 + \gamma\, g_3;\ \ \alpha,\, \beta,\, \gamma \geq 0 \,\big\}. \tag{4.7}$$

Similar representations can be deduced for the cones K_{G_3} and K_{G_4}.

Note that the vectors determining dihedral and trihedral angles are linearly independent for a generic family.

Singularity deadlock of an edge is characterized by the stratum $G_2\big((\pm i\,\omega)^2\big)$—a pair of double pure imaginary eigenvalues $\lambda = \pm i\,\omega$ with the length of the Jordan chain equal to 2. It is well known that the stability domain in the neighborhood of this singularity up to a smooth change of parameters (diffeomorphism) is given by [3, 4]

$$z + \left|\, \mathrm{Re}\sqrt{x + i\,y}\,\right| < 0. \tag{4.8}$$

The stability boundary of (4.8) is a half of the so-called Witney–Cayley umbrella surface [4, 5]. The tangent cone to the domain (4.8) at the singular point G_2, i.e., at $x = y = z = 0$, is degenerate and represents a plane angle

$$K^0_{G_2} = \big\{\, e = (e_1,\, e_2,\, e_3) :\ e_1 \leq 0,\ \ e_2 = 0,\ \ e_3 \leq 0 \,\big\}.$$

Note that the singularity G_2 is formed by a collision of two different simple pure imaginary eigenvalues $i\,\omega_1$ and $i\,\omega_2$ at the singular point when they move along the edge of the type F_3.

Let us calculate the tangent cone for G_2 in the generic case. Using the expansions (1.16) for a double eigenvalue $\lambda = i\,\omega$ we have

$$\lambda = i\,\omega \pm \sqrt{[\,(f_1,\, e) + i\,(q_1,\, e)\,]\,\varepsilon} + \frac{1}{2}\,[\,(f_2,\, e) + i\,(q_2,\, e)\,]\,\varepsilon + o(\varepsilon), \tag{4.9}$$

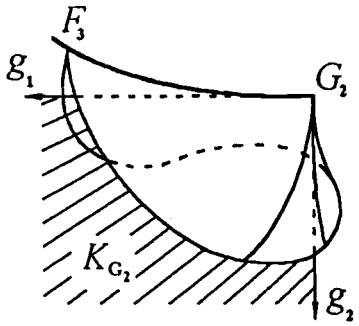

FIG. 4.4. *The singularity deadlock of an edge.*

where the vectors f_1, q_1, f_2, q_2 correspond to $\lambda = i\,\omega$ and are defined in (1.17). The expansions for a complex-conjugate double eigenvalue $\overline{\lambda} = -i\,\omega$ can be found by taking complex conjugation of (4.9).

If either $(f_1,\, e) > 0$ or $(q_1,\, e) \neq 0$ under the radical in (4.9), then one of the eigenvalues has positive real part for sufficiently small ε (instability). In the case when $(f_1,\, e) < 0,\ (q_1,\, e) = 0$, the second (with the radical) term is a pure imaginary number. Hence, for $(f_2,\, e) < 0$ and small ε we have $\operatorname{Re}\lambda < 0$ (stability) and for $(f_2,\, e) > 0$ we have $\operatorname{Re}\lambda > 0$ (instability). Therefore, the tangent cone to the stability domain at a singular point G_2 is the plane angle of the form

$$K_{G_2} = \big\{\, e : (f_1,\, e) \le 0,\ (f_2,\, e) \le 0,\ (q_1,\, e) = 0 \,\big\}. \tag{4.10}$$

From (4.9) it directly follows that all smooth curves, emitted from the singular point along the direction e, satisfying the conditions $(f_1,\, e) < 0,\ (f_2,\, e) < 0,\ (q_1,\, e) = 0$, lie in the stability domain for rather small ε.

Determining the vectors g_1, g_2 by

$$(f_i,\, g_j) = -\delta_{ij}, \quad (q_1,\, g_j) = 0, \quad i,\, j = 1,\, 2,$$

we can write (4.10) in the form

$$K_{G_2} = \big\{\, e :\ e = \alpha\, g_1 + \beta\, g_2;\ \ \alpha,\, \beta \ge 0 \,\big\}. \tag{4.11}$$

The vectors g_1 and g_2 are directed along the sides of the plane angle K_{G_2}. The vector g_1 is tangent to the edge F_3 of the stability domain characterized by two different pairs of simple eigenvalues $\pm i\,\omega_1$, $\pm i\,\omega_2$; see Figure 4.4.

Note, that the vectors f_1, f_2, q_1 are linearly independent for a generic family of matrices.

5. Singularity break of an edge. The singularity break of an edge is characterized by the stratum $G_1(0^3)$—by one triple zero eigenvalue of the matrix $A(p_0)$ with the Jordan chain of the length equal to 3. The expansion of a triple eigenvalue is described by (1.24). The cubic root in (1.24) takes three different complex values. This means that if $(h_1, e) \neq 0$ (note that $t_1 = 0$ since $\lambda_0 = 0$), then at least one eigenvalue has positive real part (instability). Hence, the tangent cone to the stability domain lies in the plane $(h_1, e) = 0$, where the expansion (1.24) is not valid due to violation of the Γ condition $v_0^T A_1 u_0 = (h_1, e) \neq 0$. Therefore the tangent cone in this case cannot be found with the method used for the investigation of the previous singularities. For this reason we take another approach to study this singularity.

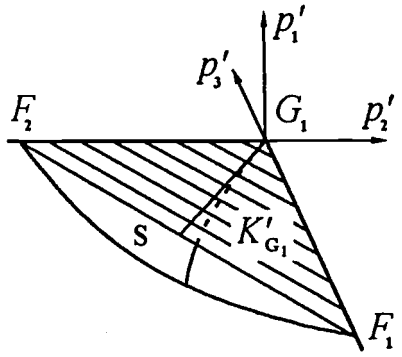

FIG. 5.1. *The singularity break of an edge.*

Let us construct a versal deformation of the matrix $A_0 = A(p_0)$ that is a smooth matrix family $A'(p')$, $p' \in \mathbf{R}^d$, such that any smooth family $A(p)$, $A(p_0) = A_0$, can be represented in a neighborhood of $p = p_0$ in the form

$$A(p) = C(p)A'(\varphi(p))C^{-1}(p), \tag{5.1}$$

where C(p) is a smooth family of nonsingular matrices, $p' = \varphi(p)$ is a smooth mapping from a neighborhood of the point p_0 in $\mathbf{R}^3$ into a neighborhood of the origin of coordinate system in $\mathbf{R}^d$, and $\varphi_1(p_0) = \varphi_2(p_0) = \cdots = \varphi_d(p_0) = 0$. A versal deformation with the minimum possible number of parameters d is called miniversal one. The miniversal deformation of the matrix A_0 can be chosen in the block diagonal form [2, 7]

$$A'(p') = A'(0) + B(p'). \tag{5.2}$$

Here $A'(0)$ is the Jordan form of A_0 and $B(p')$ is a family of block diagonal matrices whose blocks are determined in accordance with the structure of $A'(0)$. The first block of $A'(p')$ corresponding to the triple zero eigenvalue (0^3) can be taken in the form

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ p_1' & p_2' & p_3' \end{pmatrix}. \tag{5.3}$$

The other blocks correspond to eigenvalues with negative real parts. Due to (5.1) the characteristic equations for the matrices $A(p)$ and $A'(p')$, $p' = \varphi(p)$, coincide identically. Stability of the matrix $A'(p')$ in a neighborhood of the point $p' = 0$ is determined by the first block (5.3) due to its block diagonal structure. The characteristic equation of (5.3) takes the form $\lambda^3 - p_3'\lambda^2 - p_2'\lambda - p_1' = 0$. The stability domain of this equation is found using the Routh–Hurwitz conditions

$$\begin{gathered} p_1' + p_2'p_3' > 0, \\ p_1' < 0, \quad p_2' < 0, \quad p_3' < 0. \end{gathered} \tag{5.4}$$

This domain in 3-parameter space p_1', p_2', p_3' is shown in Figure 5.1. Directly from (5.4) we find that the tangent cone to the stability domain at $p' = 0$ is degenerate. It is defined by the relations

$$e_1' = 0, \quad e_2' \le 0, \quad e_3' \le 0. \tag{5.5}$$

Let us calculate the vectors h'_j, $j = 1, 2, 3$, defining collapse of a triple zero eigenvalue of the matrix $A'(0)$. Finding eigenvectors and associated vectors u'_j, v'_j, $j = 1, 2, 3$, satisfying the normalization conditions (1.21), and using (1.25) we obtain

$$h'_1 = (1, 0, 0, 0, \dots, 0)^T,$$
$$h'_2 = (0, 1, 0, 0, \dots, 0)^T,$$
$$h'_3 = (0, 0, 1, 0, \dots, 0)^T.$$

By means of these vectors the tangent cone (5.5) can be given in the form

$$K'_{G_1} = \left\{ e' \in \mathbf{R}^d : (h'_1, e') = 0,\ (h'_2, e') \le 0,\ (h'_3, e') \le 0 \right\}. \tag{5.6}$$

Let us determine a tangent cone for the family $A(p)$. For this purpose we have to find a relation between the vectors h'_j and h_j, $j = 1, 2, 3$. Let u'_j, v'_j, $j = 0, 1, 2$, be left and right eigenvectors and associated vectors of the matrix $A'(0)$, corresponding to the triple eigenvalue $\lambda_0 = 0$ and satisfying the normalization conditions (1.21). Then, using (5.1) we get relations between u'_j, v'_j, $j = 1, 2, 3$, and eigenvectors and associated vectors u_j, v_j, $j = 1, 2, 3$, of the matrix A_0

$$\begin{aligned} u_j &= C(p_0)u'_j, \\ v_j^T &= v_j'^T C^{-1}(p_0)\ , \quad j = 0, 1, 2. \end{aligned} \tag{5.7}$$

We differentiate the expression (5.1) with respect to p_j and find the value of the derivative at $p = p_0$, $p' = \varphi(p_0) = 0$,

$$\frac{\partial A}{\partial p_j} = \frac{\partial C}{\partial p_j} A' C^{-1} + C A' \frac{\partial C^{-1}}{\partial p_j} + \sum_{s=1}^{d} \left(C \frac{\partial A'}{\partial p'_s} C^{-1} \right) \frac{\partial \varphi_s}{\partial p_j}\ , \quad j = 1, 2, 3. \tag{5.8}$$

Multiplying (5.8) by v_0^T and u_0 from left and right, respectively, we have

$$\begin{aligned} h_1^j = v_0^T \frac{\partial A}{\partial p_j} u_0 &= v_0^T \frac{\partial C}{\partial p_j} A' C^{-1} u_0 \\ + v_0^T C A' \frac{\partial C^{-1}}{\partial p_j} u_0 &+ \sum_{s=1}^{d} v_0^T C \frac{\partial A'}{\partial p'_s} \frac{\partial \varphi_s}{\partial p_j} C^{-1} u_0 \\ &= \sum_{s=1}^{d} \frac{\partial \varphi_s}{\partial p_j} \left[v_0'^T \frac{\partial A'}{\partial p'_s} u'_0 \right], \quad j = 1, 2, 3. \end{aligned} \tag{5.9}$$

Here we have used the relations (5.7) and $A'(0)u'_0 = 0$, $v_0'^T A'(0) = 0$. Thus, from (5.9) we get the relation between the vectors h_1 and h'_1:

$$h_1^T = h_1'^T D_\varphi, \quad D_\varphi = \left[\frac{\partial \varphi_i}{\partial p_j} \right], \quad i = 1, 2, \dots, d, \quad j = 1, 2, 3.$$

Analogously, we can prove this relation for the vectors h_2, h'_2 and h_3, h'_3. In this proof expressions (5.7), (5.8), and the equalities

$$v_s^T \frac{\partial C}{\partial p_i} C^{-1} u_j + v_s^T C \frac{\partial C^{-1}}{\partial p_i} u_j = v_s^T \frac{\partial C C^{-1}}{\partial p_i} u_j = 0,$$
$$i = 1, 2, \dots, n, \quad s, j = 0, 1,$$

are used. Thus, the vectors h_s and h'_s are related by

$$h_s^T = h_s'^T D_\varphi, \quad s = 1, 2, 3. \tag{5.10}$$

Now we find a relation between direction vectors e and e' from the tangent cones in $\mathbf{R}^3$ and $\mathbf{R}^d$, respectively:

$$e'_i = \frac{\partial p'_i}{d\varepsilon} = \sum_{j=1}^{d} \frac{\partial \varphi_i}{\partial p_j} \frac{dp_j}{d\varepsilon} = \sum_{j=1}^{d} \frac{\partial \varphi_i}{\partial p_j} e_j, \quad i = 1, 2, \ldots, d\,, \quad j = 1, 2, 3.$$

Consequently,

$$e' = D_\varphi e. \tag{5.11}$$

Any curve $p(\varepsilon)$, $p(0) = p_0$, with the direction $e = dp/d\varepsilon$, lying in the stability domain, corresponds to a curve $p'(\varepsilon) = \varphi(p(\varepsilon))$ with the direction $e' = D_\varphi e$ lying in the stability domain in $\mathbf{R}^d$. Similarly, for any curve $p'(\varepsilon)$, $p'(0) = 0$, $dp'/d\varepsilon = e'$, lying in the stability domain in $\mathbf{R}^d$, in the case of linearly independent vectors h_s, $s = 1, 2, 3$, there exist curves $p(\varepsilon)$, $p(0) = p_0$, with directions e, related to e' by (5.11), and lying in the stability domain. In the case of the generic family of matrices $A(p)$ the vectors h_s, $s = 1, 2, 3$, are linearly independent.

Multiplying (5.10) by e and using (5.11) we obtain

$$h_s^T e = h_s'^T e', \quad s = 1, 2, 3. \tag{5.12}$$

Using (5.6) and (5.12) we find the tangent cone to the stability domain at the singular point $G_1(0^3)$ in the form

$$K_{G_1} = \big\{\, e : (h_1, e) = 0,\ (h_2, e) \le 0,\ (h_3, e) \le 0 \,\big\}. \tag{5.13}$$

The tangent cone K_{G_1} is degenerate and represents a plane angle. Recall that the vectors h_s, $s = 1, 2, 3$, determining the cone, are defined by (1.25) and need only eigenvectors and associated vectors corresponding to the triple zero eigenvalue and the derivatives of A with respect to p_j, $j = 1, 2, 3$, at the point under consideration.

Introducing the vectors g_1, g_2 by formulae

$$(g_j, h_{4-s}) = -\delta_{js}, \quad j = 1, 2, \quad s = 1, 2, 3,$$

the tangent cone K_{G_1} can be written in the form

$$K_{G_1} = \big\{\, e : e = \alpha g_1 + \beta g_2, \quad \alpha, \beta \ge 0 \,\big\},$$

where the vectors g_1, g_2 are tangent to the edges of the singularity.

6. A simple model of a damped follower force column. A simple, two-degrees-of-freedom pendulum loaded by a follower force P has been studied by Ziegler [17] and in the present extended version with two different damping parameters by Herrmann and Jong [8]. Boundary surface of the stability domain of this system was plotted and studied by Seyranian and Pedersen [15]. We consider this example from the point of view of singularities of the stability boundary and show that the effects known as destabilization due to damping [8] and uncertainty of the critical load when damping parameters tend to zero [14, 15] are closely related to the deadlock of an

edge singularity, which takes place at the point of the critical load of the system with no damping, and the dihedral angle singularity at lower values of the load.

The linearized equations of free motion of the pendulum in nondimensional variables are [8]

$$\begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} \ddot{\varphi}_1 \\ \ddot{\varphi}_2 \end{pmatrix} + \begin{pmatrix} \gamma_1+\gamma_2 & -\gamma_2 \\ -\gamma_2 & \gamma_2 \end{pmatrix} \begin{pmatrix} \dot{\varphi}_1 \\ \dot{\varphi}_2 \end{pmatrix} + \begin{pmatrix} 2-p & -1+p \\ -1 & 1 \end{pmatrix} \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{6.1}$$

where γ_1 and γ_2 are independent nonnegative damping parameters and p is a magnitude of the follower force.

Introducing variables $\varphi_3 = \dot{\varphi}_1$ and $\varphi_4 = \dot{\varphi}_2$, (6.1) takes the form

$$\dot{\varphi} = A\varphi, \qquad \varphi = (\varphi_1, \varphi_2, \varphi_3, \varphi_4)^T, \tag{6.2}$$

$$A = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ p/2-3/2 & 1-p/2 & -\gamma_1/2-\gamma_2 & \gamma_2 \\ 5/2-p/2 & p/2-2 & \gamma_1/2+2\gamma_2 & -2\gamma_2 \end{pmatrix}. \tag{6.3}$$

We investigate the stability domain of the system in the space of three parameters (γ_1, γ_2, p). The characteristic equation of the system (6.2), (6.3) is

$$2\lambda^4 + (\gamma_1 + 6\gamma_2)\lambda^3 + (7 - 2p + \gamma_1\gamma_2)\lambda^2 + (\gamma_1+\gamma_2)\lambda + 1 = 0. \tag{6.4}$$

At $\gamma_1 = \gamma_2 = 0$ (the system without damping) we find

$$\lambda^2 = \frac{1}{2}\left(p - 7/2 \pm \sqrt{(p-7/2)^2 - 2}\right). \tag{6.5}$$

Hence at $p \in [0,\, 7/2 - \sqrt{2})$ we have two different pairs of simple complex conjugate imaginary eigenvalues corresponding to the dihedral angle singularity (F_3). At $p_0 = 7/2 - \sqrt{2}$ there exists a pair of double complex conjugate imaginary eigenvalues with the Jordan chain (1.10), corresponding to the singularity deadlock of an edge (G_2). Thus, the segment $\gamma_1 = \gamma_2 = 0,\ p \in [0,\, p_0]$ is an edge of the stability boundary with the deadlock at the point $p = p_0$; see Figure 6.1.

At the point $\gamma_1 = \gamma_2 = 0,\ p \in [0,\, p_0)$ the tangent cone $K_{F_3}(p)$ has been determined in (2.6). The vectors r_1 and r_2, given by (1.8), for the matrix A from (6.3) take the form

$$r_{1,2}(p) = \frac{1}{8}\begin{pmatrix} \pm\dfrac{3/2-p}{\sqrt{(p-7/2)^2-2}} - 1 \\ \pm\dfrac{19-6p}{\sqrt{(p-7/2)^2-2}} - 6 \\ 0 \end{pmatrix}, \tag{6.6}$$

where plus corresponds to r_1 and minus to r_2. The angle between r_1 and r_2 (equal to the difference of π and the angle of the dihedron) increases with the increase of p from zero and reaches π at $p = p_0$. But at $p = p_0$ the vectors r_1 and r_2 become infinite because the radicand in (6.6) is equal to zero. Therefore the tangent cone K_{F_3}

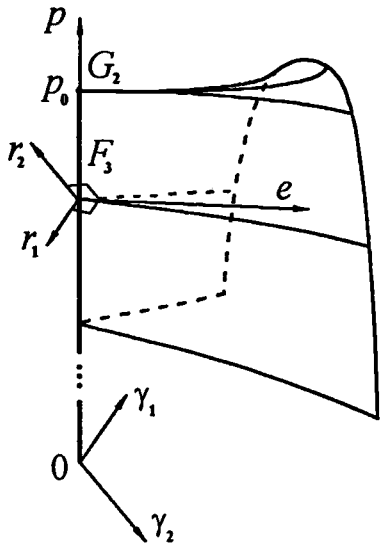

FIG. 6.1. *The stability domain of Ziegler's double pendulum.*

degenerates into the cone K_{G_2} of the deadlock of an edge singularity at $p = p_0$; see Figure 6.1.

The cone K_{G_2} has been found in (4.10), where the vectors f_1, q_1, f_2 are given by (1.17). For the matrix (6.3) they are, up to a positive factor, equal to

$$\begin{aligned} f_1 &= (0, 0, 1), \\ q_1 &= (1, -4 - 5\sqrt{2}, 0), \\ f_2 &= (-1, -6, 0). \end{aligned} \tag{6.7}$$

This cone also can be written in the form

$$K_{G_2} = \left\{ (e_1, e_2, e_3) : \ e_1 = (4 + 5\sqrt{2})e_2, \ \ e_2 \geq 0, \ \ e_3 \leq 0 \right\}. \tag{6.8}$$

In the parameter space (γ_1, γ_2, p) it represents a plane angle.

At fixed values of damping parameters γ_1, γ_2 a critical load p_{cr} is defined as the smallest value of p at which the system becomes unstable. Consider damping in the form $\gamma_1 = e_1\varepsilon$, $\gamma_2 = e_2\varepsilon$, where ε is a small positive number. Since the segment $\gamma_1 = \gamma_2 = 0$, $p \in [0, p_0]$ is the edge of the stability boundary, the limit of the critical load, when damping tends to zero, $p_0^e = \lim_{\varepsilon \to 0} p_{cr}(\gamma_1, \gamma_2)$ for a fixed direction (e_1, e_2) is equal to the value of p at which the vector $e = (e_1, e_2, 0)$ leaves the tangent cone $K_{F_3}(p)$ with the increase of p from zero. In this case either the condition $(r_1(p_0^e), e) = 0$ or $(r_2(p_0^e), e) = 0$ is fulfilled. For example, at $\gamma_1 = \varepsilon$, $\gamma_2 = 0$ we have $e = (1, 0, 0)$, $p_0^e = 2$, $r_2(2) = (0, -5/2, 0)$, $(r_2(2), e) = 0$. From this it is seen that the limit of the critical load p_0^e is different for various directions (e_1, e_2). For all $(e_1, e_2) \neq c(4+5\sqrt{2}, 1)$, $c > 0$, this limit is less then p_0. At $(e_1, e_2) = c(4+5\sqrt{2}, 1)$, $c > 0$, we have $p_0^e = p_0$. It is connected with the fact that the directions $c(4 + 5\sqrt{2}, 1, \alpha)$, $\alpha \leq 0$, $c > 0$, belong to the tangent cone K_{G_2} from (6.8).

Degeneration of the dihedral angle at the deadlock of an edge singular point geometrically illustrates the effects of destabilization of a nonconservative system by small dissipative forces [8] and uncertainty of the critical load when damping

parameters tend to zero [14]. Similar effects should be expected for other systems with deadlock of an edge and break of an edge singularities of the stability boundary.

7. Family of polynomials. Consider a linear homogeneous differential equation of the order m

$$x^{(m)} + a_1 x^{(m-1)} + \cdots + a_m x = 0 \tag{7.1}$$

whose coefficients $a_j \in \mathbf{R},\ j = 1, 2, \ldots, m$ smoothly depend on a vector of parameters $p \in \mathbf{R}^n$. The characteristic equation for (7.1) is

$$\lambda^m + a_1 \lambda^{m-1} + \cdots + a_m = 0. \tag{7.2}$$

The trivial solution of (7.1) is asymptotically stable if and only if every root of (7.2) has a negative real part $\mathrm{Re}\lambda < 0$.

The stability domain boundary of a generic one-parameter family of polynomials ($n = 1$) is characterized by a simple root $\lambda = 0$ or a pair of simple imaginary roots $\lambda = \pm i\,\omega$. The stability boundary of a generic two-parameter (three-parameter) family consists of smooth curves (surfaces), corresponding to simple roots $\lambda = 0$ or $\lambda = \pm i\,\omega$, whose only singularities are characterized by the following strata [10]:

$$\begin{aligned} n = 2: &\quad \widehat{F}_1(0^2),\ \widehat{F}_2(0, \pm i\,\omega),\ \widehat{F}_3(\pm i\,\omega_1, \pm i\,\omega_2), \\ n = 3: &\quad \widehat{F}_1(0^2),\ \widehat{F}_2(0, \pm i\,\omega),\ \widehat{F}_3(\pm i\,\omega_1, \pm i\,\omega_2),\ \widehat{G}_1(0^3), \\ &\quad \widehat{G}_2\big((\pm i\,\omega)^2\big), \widehat{G}_3(0^2, \pm i\,\omega),\ \widehat{G}_4(0, \pm i\,\omega_1, \pm i\,\omega_2), \\ &\quad \widehat{G}_5(\pm i\,\omega_1, \pm i\,\omega_2, \pm i\,\omega_3), \end{aligned} \tag{7.3}$$

where all imaginary roots at the singular point are taken in brackets with a power denoting the multiplicity of a root. Other singularities disappear under an arbitrary small deformation of the family.

Introducing the vector $y \in \mathbf{R}^m$, with the components $y_i = x^{(i-1)},\ i = 1, 2, \ldots, m$, (7.1) takes the form

$$\dot{y} = Ay, \tag{7.4}$$

$$A = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ -a_m & -a_{m-1} & -a_{m-2} & \cdots & -a_1 \end{pmatrix}. \tag{7.5}$$

The characteristic equation for the matrix (7.5) is identically equal to (7.2); hence the stability domains for (7.1) and (7.4) coincide. For every root λ_0 of (7.2) there exists precisely one corresponding eigenvector u_0,

$$u_0 = c(1, \lambda_0, \lambda_0^2, \ldots, \lambda_0^{m-1}), \quad c = \mathrm{const}.$$

For every multiple root λ_0 there exists one corresponding Jordan chain with the length equal to the multiplicity of λ_0. It is easy to see that in the case of generic one-, two-, and three-parameter families the singularities of the stability boundary $\widehat{F}_j$,

$\widehat{G}_s$, $j = 1, 2, 3$, $s = 1, 2, \ldots, 5$, for polynomials coincide with the singularities F_j, G_s, $j = 1, 2, 3$, $s = 1, 2, \ldots, 5$, for matrices, studied above. All the results for tangent cones and other geometric characteristics of singularities, obtained for families of matrices, are directly transferred to families of polynomials. The tangent cones to the stability domain of (7.1) at singular points (7.3) are determined in (2.4)–(2.6), (4.3)–(4.5), (4.10), (5.13), where the vectors r_j, f_j, q_j, h_j are calculated by the formulae (1.8), (1.17), (1.25) for the matrix (7.5).

Let us find the expressions for these vectors by means of the coefficients a_j, $j = 1, 2, \ldots, m$, of the equation (7.1). Denoting $Q(\lambda, p) = \lambda^m + a_1\lambda^{m-1} + \cdots + a_m$ and differentiating the equation $Q(\lambda, p) = 0$ for a simple root λ ($Q = 0$, $\partial Q/\partial\lambda \neq 0$) we have

$$\frac{\partial Q}{\partial \lambda} d\lambda + (\nabla Q, dp) = 0,$$

$$\nabla\lambda = -\nabla Q \Big/ \frac{\partial Q}{\partial \lambda},$$

where ∇ is the gradient operator

$$\nabla = \left(\frac{\partial}{\partial p_1}, \frac{\partial}{\partial p_2}, \ldots, \frac{\partial}{\partial p_n}\right)^T.$$

Recall that the vector r, determined in (1.8), is the gradient of the real part of a simple eigenvalue with respect to p. Hence,

$$r = -\mathrm{Re}\left(\nabla Q \Big/ \frac{\partial Q}{\partial \lambda}\right). \tag{7.6}$$

Substituting the expression for $Q(\lambda, p)$ into (7.6) we obtain

$$r = -\mathrm{Re}\,\frac{\displaystyle\sum_{j=1}^{m} \nabla a_j \lambda^{m-j}}{m\lambda^{m-1} + \displaystyle\sum_{j=1}^{m-1} (m-j) a_j \lambda^{m-j-1}}. \tag{7.7}$$

For the simple root $\lambda = 0$ ($a_m = 0$, $a_{m-1} \neq 0$) it gives

$$r = -\frac{\nabla a_m}{a_{m-1}}. \tag{7.8}$$

Consider a double root λ_0. The vectors f_j, q_j, $j = 1, 2$, determined by (1.17), describe collapse of a double eigenvalue with the Jordan chain (1.10). Expanding $Q(\lambda, p)$ in Taylor series in the neighborhood of $\lambda = \lambda_0$, $p = p_0$ we have

$$\begin{aligned} Q(\lambda, p) = (\nabla Q, \Delta p) + \frac{1}{2}\frac{\partial^2 Q}{\partial \lambda^2}\Delta\lambda^2 + \left(\nabla \frac{\partial Q}{\partial \lambda}, \Delta p\right)\Delta\lambda \\ + \frac{1}{2}\Delta p^T \nabla\nabla^T Q \Delta p + \frac{1}{6}\frac{\partial^3 Q}{\partial \lambda^3}\Delta\lambda^3 + \cdots, \end{aligned} \tag{7.9}$$

$$\Delta\lambda = \lambda - \lambda_0, \quad \Delta p = p - p_0.$$

Here the equalities $Q = 0,\ \partial Q/\partial\lambda = 0$ at $\lambda = \lambda_0,\ p = p_0$, determining a double root, were used. We substitute the perturbation of p in the form $\Delta p = \varepsilon e + O(\varepsilon^2)$ and the expansion for λ (1.13) into (7.9) and then equate the coefficients at ε and $\varepsilon^{3/2}$ zero. As the result, for the coefficient at ε we get

$$(\nabla Q, e) + \frac{1}{2}\frac{\partial^2 Q}{\partial\lambda^2}\lambda_1^2 = 0,$$

$$\lambda_1^2 = -\frac{2(\nabla Q, e)}{\dfrac{\partial^2 Q}{\partial\lambda^2}}.$$

If $\lambda_1^2 \neq 0$, then equating the coefficient at $\varepsilon^{3/2}$ zero we obtain

$$\lambda_2 = -\frac{\left(\nabla\dfrac{\partial Q}{\partial\lambda}, e\right) + \dfrac{1}{6}\dfrac{\partial^3 Q}{\partial\lambda^3}\lambda_1^2}{\dfrac{\partial^2 Q}{\partial\lambda^2}}$$

$$= \frac{\dfrac{1}{3}\dfrac{\partial^3 Q}{\partial\lambda^3}(\nabla Q, e) - \dfrac{\partial^2 Q}{\partial\lambda^2}\left(\nabla\dfrac{\partial Q}{\partial\lambda}, e\right)}{\left(\dfrac{\partial^2 Q}{\partial\lambda^2}\right)^2}.$$

Note that $\partial^2 Q/\partial\lambda^2 \neq 0$ for a double root. Thus, for the vectors $f_j,\ q_j,\ \ j = 1, 2$, we get the following expressions:

$$f_1 + i\,q_1 = -\frac{2\nabla Q}{\dfrac{\partial^2 Q}{\partial\lambda^2}},$$

$$f_2 + i\,q_2 = \frac{\dfrac{2}{3}\dfrac{\partial^3 Q}{\partial\lambda^3}\nabla Q - 2\dfrac{\partial^2 Q}{\partial\lambda^2}\nabla\dfrac{\partial Q}{\partial\lambda}}{\left(\dfrac{\partial^2 Q}{\partial\lambda^2}\right)^2}. \tag{7.10}$$

Substituting the explicit form of $Q(\lambda, p)$ into (7.10), by analogy with (7.7), the expression (7.10) can be written by means of the coefficients $a_j(p),\ \ j = 1, 2, \ldots, m$, and λ_0. In the case of the double root $\lambda_0 = 0$ we get

$$f_1 = -\frac{\nabla a_m}{a_{m-2}},$$

$$f_2 = \frac{a_{m-3}\nabla a_m - a_{m-2}\nabla a_{m-1}}{a_{m-2}^2}. \tag{7.11}$$

The vectors $h_j,\ \ j = 1, 2, 3$, used for determining the tangent cone K_{G_1}, are needed only for $\lambda_0 = 0$. In this case $a_m = a_{m-1} = a_{m-2} = 0,\ \ a_{m-3} \neq 0$. The left and right eigenvectors and the associated vectors of the matrix (7.5), corresponding to the triple zero root and satisfying the normalization conditions (1.21), are

$$u_0 = (1, 0, 0, 0, \ldots, 0)^T,$$

$$u_1 = (0, 1, 0, 0, \dots, 0)^T,$$

$$u_2 = (0, 0, 1, 0, \dots, 0)^T,$$

$$v_0 = \left(0, 0, 1, *, \dots, *, \frac{1}{a_{m-3}}\right)^T,$$

$$v_1 = \left(0, 1, 0, *, \dots, *, -\frac{a_{m-4}}{a_{m-3}^2}\right)^T,$$

$$v_2 = \left(1, 0, 0, *, \dots, *, \frac{a_{m-4}^2 - a_{m-3}a_{m-5}}{a_{m-3}^3}\right)^T,$$

where asterisks denote the components, which don't affect the resultant expressions. Substitution of these vectors into (1.25) gives

$$h_1 = -\frac{\nabla a_m}{a_{m-3}},$$

$$h_2 = \frac{a_{m-4}\nabla a_m - a_{m-3}\nabla a_{m-1}}{a_{m-3}^2}, \tag{7.12}$$

$$h_3 = \frac{(a_{m-3}a_{m-5} - a_{m-4}^2)\nabla a_m + a_{m-3}a_{m-4}\nabla a_{m-1} - a_{m-3}^2\nabla a_{m-2}}{a_{m-3}^3}.$$

Note that in the case of the generic family of polynomials, vectors determining tangent cones to the stability domain at a singular point are linearly independent.

Example. As an example let us consider the stability problem from section 3. The characteristic equation has the form (3.3). The system is considered as dependent on two parameters R and ρ. At the point $R_0 = \sqrt{L/C}$, $\rho_0 = -\sqrt{L/C}$ the characteristic equation (3.3) has the double zero root corresponding to the singularity $\widehat{F}_1(0^2)$. The vectors f_1 and f_2, calculated with the use of (7.11), are

$$f_1 = \frac{1}{L\sqrt{LC}}\begin{pmatrix}-1\\-1\end{pmatrix}, \quad f_2 = \frac{1}{L}\begin{pmatrix}1\\-1\end{pmatrix}.$$

These expressions coincide with (3.4), where these vectors were calculated using (1.17). The tangent cone to the stability domain $K_{\widehat{F}_1}$ at the point under consideration has the form (2.4); see Figure 3.1.

Also, the results (6.6)–(6.8) on singularities of the stability boundary for Ziegler's pendulum can be derived using polynomial formulation (6.4).

8. Concluding remarks. Two methods of investigation of singularities are developed in this paper. They are constructive and convenient for numerical implementation. These methods can be applied for studying other types of singularities (also nongeneric) of the stability domain of systems depending on an arbitrary number of parameters. The first method connected with expansions of eigenvalues can be applied

if the tangent cone of the singularity does not belong to the set of directions violating the condition Γ [16] (for nonderogatory eigenvalue of the matrix A this condition is ${v_0}^T A_1 u_0 \neq 0$):

$$K \not\subset \{e : \Gamma \text{ is not satisfied}\}.$$

In this set of directions the expansions of eigenvalues in powers of $\varepsilon^{1/l}$ (l is a multiplicity) are not valid. For example, this method can be applied to the singularities, where there are only simple and double eigenvalues with zero real part. Singularities investigated in sections 2 and 4 are just of this type.

The second method connected with versal deformations can be useful for investigation of singularities determined by pure imaginary eigenvalues with higher multiplicities. The main point here is to find appropriate vectors, like h_1, h_2, h_3 in section 5, which connect parameter space of the problem with parameter space of the versal deformation.

As an example of application of the second method let us consider the singular point of the stability domain determined by zero eigenvalue with one Jordan block of the order k. Let $u_0, u_1, \ldots, u_{k-1}$ and $v_0, v_1, \ldots, v_{k-1}$ be corresponding Jordan chains of right and left eigenvectors and associated vectors satisfying normalization conditions $v_0^T u_{k-1} = 1$, $v_i^T u_{k-1} = 0$, $i = 1, \ldots, k-1$. Then introducing the vectors h_i, $i = 1, 2, \ldots, k$, with components defined by the formulae

$$h_i^j = \sum_{s=0}^{i-1} v_s^T \frac{\partial A}{\partial p_j} u_{i-s-1}, \quad i = 1, 2, ..., k, \;\; j = 1, 2, ..., n,$$

and making the same steps as in the section 5, in the case of linearly independent vectors h_i, $i = 1, 2, \ldots, k$, we get the expression for the tangent cone K_0 to the stability domain at this singular point:

$$K_0 = \{\, e : (h_1, e) = \cdots = (h_{k-2}, e) = 0,\ (h_{k-1}, e) \leq 0,\ (h_k, e) \leq 0 \,\}.$$

Note that for $k = 3$ these expressions are the same as the expressions which have been found in section 5 for the singularity G_1. Evidently, to fulfill the linear independence condition we need $n \geq k$, i.e., the dimension of the parameter space must be greater than or equal to the multiplicity of zero eigenvalue. If $n \geq k$, then the vectors h_i, $i = 1, 2, \ldots, k$, are linearly independent for the generic family of matrices.

To investigate singularities of a boundary of the stability domain of a family of polynomials, first we have to consider the singularity of the corresponding family of matrices (7.5) and then express the result in terms of the coefficients of the polynomial and their derivatives with respect to parameters.

IMMANANT INEQUALITIES FOR LAPLACIANS OF TREES*

ONN CHAN† AND T. K. LAM†

Abstract. Let $\mathcal{T}_n$ be the collection of trees on n vertices. Let $\mathcal{T}_n(b;p,q)$, $\mathcal{T}_n(m;k)$, and $\mathcal{T}_n(d;k)$ be subsets of $\mathcal{T}_n$ comprising trees, each whose vertex set has bipartition (p,q), trees whose maximum matching has size k, and trees of diameter k, respectively. Brualdi and Goldwasser [*Discrete Math.*, 48 (1984), pp. 1–21] obtained lower bounds on the permanent of the Laplacian matrix of a tree from each of these subsets. They characterized the tree in each of these subsets whose Laplacian matrix has the smallest permanent as the "double star" in $\mathcal{T}_n(b;p,q)$, the "spur" in $\mathcal{T}_n(m;k)$, and the "broom" in $\mathcal{T}_n(d;k)$. In this work, the concept of vertex orientations and a new interpretation of the matching numbers in a tree allow us to formulate a unified approach to extending these results to all other immanant functions besides the permanent. It turns out that the "double star" and the "spur" remain the tree in $\mathcal{T}_n(b;p,q)$ and the tree in $\mathcal{T}_n(m;k)$, respectively, whose Laplacian matrix has the smallest immanant value for all immanants. For $\mathcal{T}_n(d;k)$ the tree that has the smallest immanant value varies with the immanant function, but it belongs to a small family of "caterpillars" whose legs are all concentrated on a single vertex.

Key words. immanants, Laplacians of trees, matchings

1. Introduction.

Let S_n be the permutation group on n symbols and χ_λ be an irreducible character of the symmetric group S_n, indexed by a partition λ of n. The *immanant function*, d_λ associated with the character χ_λ acting on an $n \times n$ matrix $A = [a_{ij}]$, is defined as

$$d_\lambda(A) = \sum_{\sigma \in S_n} \chi_\lambda(\sigma) \prod_{i=1}^{n} a_{i\sigma(i)}.$$

Both the determinant and permanent functions are special cases of the immanant function corresponding to the alternating and trivial characters, respectively.

Here we consider immanant functions over the family of Laplacian matrices of graphs. Much is known about the permanent of the Laplacian of a graph, and its polynomial analogues have been studied by several researchers (see, for example, [2, 9, 10, 17, 22]). Some results pertaining to the study of other immanants may be found in [1, 6, 18, 19, 26]. For example, in [19], it is shown that if $L(G)$ is the Laplacian matrix of a graph G, then

$$d_{(2,1^{n-2})}(L(G)) = 2e(G)\tau(G),$$

where $e(G)$ is the number of edges in G and $\tau(G)$ is the number of spanning trees in G. Another result of a similar flavor links a hook immanant to the sum of all distances in a tree. If T is a tree on n vertices with vertex set $V(T)$, then

$$d_{(3,1^{n-3})}(L(T)) = 4 \sum_{\substack{u,v \in V(T) \\ u \neq v}} (d(u,v) - 1),$$

where $d(u, v)$ denotes the distance between u and v, measured by the number of edges on the unique path joining u and v (see [6, Theorem 4.3]). The interested reader may consult [8, 13, 12, 14, 15, 16, 20, 21, 23, 24] for other works in this area.

Let $\mathcal{T}_n$ denote the collection of trees on n vertices. Let $\mathcal{T}_n(b; p, q)$ denote the subset of $\mathcal{T}_n$ that contains all the trees whose vertex set admits a bipartition of sizes p and q where $p + q = n$. Let $\mathcal{T}_n(m; k)$ and $\mathcal{T}_n(d; k)$ be subsets of $\mathcal{T}_n$ comprising trees whose maximum matching has size k and trees of diameter k, respectively. Brualdi and Goldwasser [2] studied the permanent of the Laplacian matrix $L(G)$ of a graph G. They obtained bounds for the permanent per $L(G)$ when G is connected and bipartite and lower bounds for per $L(T)$ in each of the three cases where $T \in \mathcal{T}_n(b; p, q)$, $T \in \mathcal{T}_n(m; k)$, and $T \in \mathcal{T}_n(d; k)$. In each of these families, there is a unique tree whose Laplacian matrix attains the smallest permanent, and in [2] they are called the "double star," the "spur," and the "broom," respectively. As the permanent is an immanant function, it is natural to seek lower bounds for all the other immanant functions for each of these three families of trees and to characterize the trees that attain the lower bounds whenever possible.

To this end, we first give a combinatorial description to the term $\prod_{i=1}^{n} a_{i\sigma(i)}$ in the expansion of the immanant of the Laplacian matrix of a graph. This is done by introducing the notion of vertex orientation, which is based on the idea of a functional digraph defined by Goulden and Jackson in [11, 12]. It turns out that the "double star" and the "spur" are still the "smallest" in $\mathcal{T}_n(b; p, q)$ and $\mathcal{T}_n(m; k)$, respectively. In the case of $\mathcal{T}_n(d; k)$, this is no longer true. The tree that attains the smallest immanant value depends on the immanant function. However we manage to show that it must come from a small collection of "caterpillars" whose legs are all concentrated on a single vertex.

It is well known that $d_{(1^n)}(L(T)) = \det L(T) = 0$. From [19, Theorem 2], we also know that $d_{(2,1^{n-2})}(L(T)) = 2(n-1)$ for all trees T with n vertices. These two immanants are constants on all trees of the same size. In this paper, we will consider only immanants which are different from these two unless otherwise stated.

2. Weighted matching and vertex orientation. Let T be a tree with vertex set $V(T) = \{v_1, v_2, \ldots, v_n\}$ and edge set $E(T)$. Its *Laplacian matrix* $L(T) = [l_{ij}]$ is defined by

$$l_{ij} := \begin{cases} \deg_T(v_i) & \text{if } i = j, \\ -1 & \text{if } \{v_i, v_j\} \in E(T), \\ 0 & \text{otherwise,} \end{cases}$$

where $\deg_T(v_i)$ is the degree of the vertex v_i in T. We shall write $\deg(v)$ in place of $\deg_T(v)$ when the tree T being discussed is obvious from the context.

As observed in [1], in the expansion of $d_\lambda(L(T)) = \sum_{\sigma \in S_n} \chi_\lambda(\sigma) \prod_{i=1}^{n} l_{i\sigma(i)}$, many of the terms are zero. The only instances when the term $\prod_{i=1}^{n} l_{i\sigma(i)} \neq 0$ are when $\{v_i, v_{\sigma(i)}\} \in E(T)$ for every i such that $i \neq \sigma(i)$. This induces us to define the weighted j-matching numbers.

A *j-matching* $M \subseteq E(T)$ is a subset of j independent edges in T. Two edges are said to be independent if they are not incident with a common vertex. In Figure 2.1 below, $\{\{v_1, v_6\}, \{v_3, v_4\}\}$ is a 2-matching, while $\{\{v_0, v_1\}, \{v_2, v_3\}, \{v_4, v_5\}\}$ is a 3-matching.

We use the notation $v \in M$ to mean that the vertex v is incident with some edge in M and $v \notin M$ to mean otherwise. For $j = 0, 1, \ldots, \lfloor \frac{n}{2} \rfloor$, the *weighted j-matching*

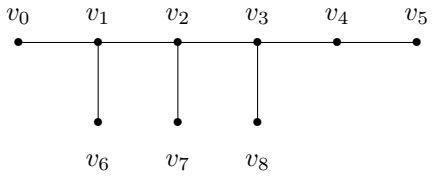

FIG. 2.1.

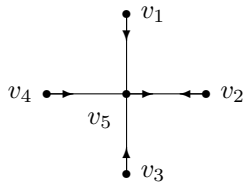

FIG. 2.2.

number of T is defined to be

$$m_T(j) = \sum_M \prod_{v \notin M} \deg(v),$$

where the sum is taken over all possible j-matchings M of the tree T. Note that $m_T(0) = \prod_{v \in V(T)} \deg(v)$ and, if M is a total matching, $m_T(j)$ is taken to be 1. Set $\chi_\lambda(j) := \chi_\lambda(\sigma)$ where σ has cycle type $(2^j, 1^{n-2j})$. It is straightforward to check that

$$d_\lambda(L(T)) = \sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} \chi_\lambda(j) m_T(j).$$

This derivation in terms of matchings was used for immanantal polynomials [1, equation (4)].

We now describe another graph-theoretic invariant that is closely related to the j-matching numbers. Let T be a tree. For each vertex v, we assign an arrow pointing away from the vertex along one of its adjacent edges. There are $\deg(v)$ ways to do this. This is essentially the same as a functional digraph defined in [12, section 4] and [11, Proposition 3.3.11]. However, in our context, the resulting graph is not a digraph, as not all the edges will have arrows on them, and there are some edges with two arrows on them. We call such an arrangement with exactly j edges having two arrows on them a *j-vertex orientation*. These edges can be viewed as directed cycles of length 2. For $j = 1, 2, \ldots, \lfloor \frac{n}{2} \rfloor$, define $a_T(j)$ as the number j-vertex orientations. We also define $a_T(0) = 0$.

Example. Consider the star $S(5)$ on five vertices as shown in Figure 2.2.

There are four possible arrangements of arrows for $S(5)$, but they all resemble the 1-vertex orientation shown above. So, $a_{S(5)}(1) = 4$ and $a_{S(5)}(j) = 0$ for all $j \neq 1$.

In general, the star $S(n)$ is the tree on n vertices with one central vertex of degree $n-1$ and the remaining vertices of degree 1 joined to the central vertex. A simple calculation gives

$$m_{S(n)}(0) = m_{S(n)}(1) = n - 1 \quad \text{and} \quad m_{S(n)}(j) = 0 \text{ for } j > 1$$

and

$$a_{S(n)}(1) = n-1 \quad \text{and} \quad a_{S(n)}(j) = 0 \text{ for } j \neq 1. \tag{2.1}$$

Observe that there are $\deg(v)$ ways to assign an arrow for the vertex v. Thus the product of the degrees of the vertices in a tree gives the total number of all the vertex orientations of the tree. For a tree T with n vertices, we have

$$\sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} a_T(j) = \prod_{v \in V(T)} \deg(v) = m_T(0).$$

The relation between $m_T(j)$ and $a_T(j)$ is made more explicit below.

THEOREM 2.1. *Let T be a tree with n vertices. Then*

$$m_T(j) = \sum_{k=j}^{\lfloor \frac{n}{2} \rfloor} \binom{k}{j} a_T(k), \tag{2.2}$$

$$a_T(j) = \sum_{k=j}^{\lfloor \frac{n}{2} \rfloor} (-1)^{k-j} \binom{k}{j} m_T(k) \tag{2.3}$$

for $j = 0, 1, \ldots, \lfloor \frac{n}{2} \rfloor$.

Proof. We will prove only (2.2) since (2.3) follows easily from it. This is done by counting the set

$$Q_j = \{(M, O) : M \text{ is a } j\text{-matching}, O \text{ is a } k\text{-vertex orientation with } k \geq j \text{ such that the edges in } M \text{ all have two arrows in } O\}.$$

Given a j-matching M, we can form a k-vertex orientation O by directing the vertices $v \in M$ along the edges $e \in M$. The other vertices are allowed to point in any direction. Clearly, $(M, O) \in Q_j$. Therefore,

$$|Q_j| = \sum_M \prod_{v \notin M} \deg(v) = m_T(j),$$

where the sum is over all j-matchings.

Given a k-vertex orientation O where $j \leq k \leq \lfloor \frac{n}{2} \rfloor$, we note that the k edges which have two arrows on them are independent. We can form an ordered pair (M, O) by choosing j edges from them. This gives

$$m_T(j) = |Q_j| = \sum_{k=j}^{\lfloor \frac{n}{2} \rfloor} \binom{k}{j} a_T(k),$$

proving (2.2). ∎

This relation allows us to express $d_\lambda(L(T))$ in terms of $a_T(j)$. So,

$$\begin{aligned} d_\lambda(L(T)) &= \sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} \chi_\lambda(j) m_T(j) \\ &= \sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} \chi_\lambda(j) \sum_{k=j}^{\lfloor \frac{n}{2} \rfloor} \binom{k}{j} a_T(k) \\ &= \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} a_T(k) \sum_{j=0}^{k} \chi_\lambda(j) \binom{k}{j}. \end{aligned} \tag{2.4}$$

It is natural to examine the properties of the sum $\sum_{j=0}^{k} \chi_\lambda(j)\binom{k}{j}$ since $d_\lambda(L(T))$ depends on them. We do this in the next section.

3. Binomial sums of characters. It is well known that $\sum_{j=0}^{n}\binom{n}{j} = 2^n$ and $\sum_{j=0}^{n}(-1)^j\binom{n}{j} = 0$. These two sums are special cases of the more general sum

$$\sum_{j=0}^{n} \chi_\lambda(j)\binom{n}{j}.$$

It turns out that these sums are always nonnegative.

LEMMA 3.1 (see [4, Theorem 2.2]). *Let χ_λ be an irreducible character of S_m where $m \geq 2n$. The sum*

$$\sum_{j=0}^{n} \chi_\lambda(j)\binom{n}{j} \geq 0.$$

Define $l(\lambda)$ to be the number of parts in the partition λ. The sum is exactly 0 if and only if $m - l(\lambda) < n$.

Proof. We induct on n. When $n = 1$, the sum on the left is $\chi_\lambda(0) + \chi_\lambda(1)$. An application of the Murnaghan–Nakayama rule (see, for example, page 177 in [25]) shows that this sum is nonnegative since

$$\chi_\lambda(0) + \chi_\lambda(1) \;=\; 2\sum_{\mu\in I(\lambda)} \chi_\mu(0) \;+\; 2\sum_{\mu\in K(\lambda)} \chi_\mu(0) \;\geq\; 0,$$

where $I(\lambda)$ and $K(\lambda)$ are the sets of partitions of $m-2$ that are obtained from λ by removing a rim hook of the form $\square\square$ and two nonadjacent rim hooks of size 1, respectively, from the Young tableau associated with λ. Furthermore, the sum is zero if and only if $\lambda = (1^m)$ where $m \geq 2$. Note that $\lambda = (1^m)$ is the only partition with $l(\lambda) = m$, thus satisfying the stated condition.

For bigger values of n, we use the Murnaghan–Nakayama rule again to get

$$\begin{aligned}
&\sum_{j=0}^{n} \chi_\lambda(j)\binom{n}{j} \\
=\;& \sum_{j=0}^{n} \chi_\lambda(j)\left(\binom{n-1}{j-1} + \binom{n-1}{j}\right) \\
=\;& \sum_{j=0}^{n-1} (\chi_\lambda(j) + \chi_\lambda(j+1))\binom{n-1}{j} \\
=\;& \sum_{j=0}^{n-1} \left(\sum_{\mu\in I(\lambda)} \chi_\mu(j) + \sum_{\mu\in J(\lambda)} \chi_\mu(j) + 2\sum_{\mu\in K(\lambda)} \chi_\mu(j) + \sum_{\mu\in I(\lambda)} \chi_\mu(j) - \sum_{\mu\in J(\lambda)} \chi_\mu(j)\right) \\
\times\;& \binom{n-1}{j} \\
=\;& 2\sum_{\mu\in I(\lambda)} \sum_{j=0}^{n-1} \chi_\mu(j)\binom{n-1}{j} + 2\sum_{\mu\in K(\lambda)} \sum_{j=0}^{n-1} \chi_\mu(j)\binom{n-1}{j},
\end{aligned}$$

where $I(\lambda), J(\lambda), K(\lambda)$ are the sets of partitions of size $m-2$ that are obtained from λ by removing a rim hook of the form $\square\square$, a rim hook of the form $\begin{smallmatrix}\square\\\square\end{smallmatrix}$, and two nonadjacent rim hooks of size 1, respectively. In the penultimate line above, the first

three terms come from the term $\chi_\lambda(j)$ of the previous line, while the last two terms come from the term $\chi_\lambda(j+1)$ of the previous line. Since all the irreducible characters χ_μ that appear in the final expression are characters of S_{m-2} and $m-2 \geq 2(n-1)$, we can apply the induction hypothesis to the sums in the expression above and obtain

$$\sum_{j=0}^{n} \chi_\lambda(j) \binom{n}{j} \geq 0.$$

For the second half of the lemma, note that for all $\mu \in I(\lambda)$ and $K(\lambda)$, $l(\mu) = l(\lambda) - 1$ or $l(\lambda)$. If λ is such that $m - l(\lambda) < n$, then $m - 2 - l(\mu) < n - 1$. By the induction hypothesis, $\sum \chi_\mu(j)\binom{n-1}{j} = 0$ for all such $\mu \in I(\lambda) \cup K(\lambda)$. Therefore, $\sum \chi_\lambda(j)\binom{n}{j} = 0$ for those λ where $m - l(\lambda) < n$.

In the case when λ satisfies the condition $m - l(\lambda) \geq n$, we claim that we can always find some $\mu \in I(\lambda) \cup K(\lambda)$ such that $l(\mu) \leq m - n - 1$. Clearly, this is true for all $\mu \in I(\lambda) \cup K(\lambda)$ if $l(\lambda) \leq m - n - 1$. If $l(\lambda) = m - n$, then $l(\lambda) \geq \frac{m}{2}$. This forces λ to have at least $\lceil \frac{m}{2} \rceil$ parts and smallest part of size 1 or 2. However, this would mean that $I(\lambda)$ or $K(\lambda)$ contains a partition μ such that $l(\mu) = l(\lambda) - 1$, hence using the recurrence relation

$$\sum_{j=0}^{n} \chi_\lambda(j) \binom{n}{j} \geq 2 \sum_{j=0}^{n} \chi_\mu(j) \binom{n-1}{j} > 0$$

by the induction hypothesis. This proves the lemma. □

We state the special case of the theorem for $n = 2$ below, as we will need it later.

COROLLARY 3.2. *For irreducible characters of $m \geq 4$, the sum $\chi_\lambda(0) + 2\chi_\lambda(1) + \chi_\lambda(2)$ is zero if and only if $\lambda = (1^m), (2, 1^{m-2})$.*

Improved lower bounds on the quantity $\sum_{j=0}^{n} \chi_\lambda(j)\binom{n}{j}$ including a combinatorial formula for the exact value of $\chi_\lambda(0) + 2\chi_\lambda(1) + \chi_\lambda(2)$ may be found on page 48 in [26]; see also [5].

4. The family of trees $\mathcal{T}_n$. In this section, we show that the lower bound on the immanant of the Laplacian matrix of a tree is attained by the star. In [8], the proof of this result is based on a reduction argument on the diameter of the tree. Here we present a simpler proof using vertex orientations.

LEMMA 4.1. *Let T be a tree with n vertices. Then*

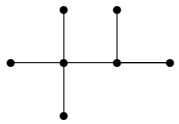
$$a_T(1) = n - 1.$$

Proof. Given an edge e of T, we point all arrows toward e. This gives an arrangement of arrows with exactly one edge, namely, e, with two arrows. Clearly, any arrangement that has this property must be of this form. Since there are $n-1$ edges, $a_T(1) = n - 1$. □

THEOREM 4.2 (see [8, Theorem 5]). *Let $S(n)$ denote the star on n vertices and let T be any tree on n vertices which is not the star. Then*

$$d_\lambda(L(T)) > d_\lambda(L(S(n))).$$

Proof. From Lemma 4.1, $a_T(1) = n - 1$ and since T is not the star, T admits a 2-vertex orientation. From Corollary 3.2, we also know that $\sum_{j=0}^{2} \chi_\lambda(j)\binom{2}{j} > 0$ when



$D(4,3)$

FIG. 5.1.

$\lambda \neq (1^n), (2,1^{n-2})$. Hence

$$\begin{aligned} d_\lambda(L(T)) &= \sum_{k=1}^{\lfloor \frac{n}{2} \rfloor} a_T(k) \sum_{j=0}^{k} \chi_\lambda(j) \binom{k}{j} \\ &> (n-1)(\chi_\lambda(0) + \chi_\lambda(1)) \\ &= d_\lambda(L(S(n))) \end{aligned}$$

using the values of $a_{S(n)}(j)$ given by (2.1). This completes the proof. □

When $\lambda = (n)$, both $\chi_\lambda(0)$ and $\chi_\lambda(1)$ are equal to 1. We obtain as a corollary the lower bound on the permanent of all trees given in [17].

COROLLARY 4.3 (see [17]). *Let T be a tree with n vertices. Then*

$$\operatorname{per} L(T) \geq 2(n-1)$$

with equality if and only if T is the star $S(n)$.

5. Trees with given bipartition $\mathcal{T}_n(b; p, q)$. Since a tree is also a bipartite graph, we can divide the vertices into two sets V_1 and V_2 so that every edge has one end in V_1 and the other in V_2. If we let $p = |V_1|$ and $q = |V_2|$, we then say that the tree T has a (p,q)-*bipartition*.

Take the star $S(p+1)$ and append $q-1$ vertices to one of the leaves. Call this new tree the *double star* and denote it by $D(p,q)$. For example, the double star $D(4,3)$ is shown in Figure 5.1.

It can be shown that $a_{D(p,q)}(1) = n-1$, $a_{D(p,q)}(2) = (p-1)(q-1)$, and $a_{D(p,q)}(j) = 0$ for all $j > 2$.

LEMMA 5.1. *Let T be a tree on n vertices which has a (p,q)-bipartition. Then*

$$a_T(2) \geq (p-1)(q-1).$$

Furthermore, equality holds if and only if $T = D(p,q)$.

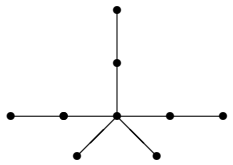
Proof. Let V_1, V_2 be the partition of the vertices of the tree T corresponding to the (p,q) bipartition. It is obvious that $\sum_{v \in V_1} \deg(v) = \sum_{v \in V_2} \deg(v) = n-1$.

For any tree T, the number of 2-matchings is given by the formula

$$\binom{n-1}{2} - \sum_{v \in V_1} \binom{\deg(v)}{2} - \sum_{v \in V_2} \binom{\deg(v)}{2}.$$

The number of 2-vertex orientations is greater than or equal to the number of 2-matchings. A simple exercise shows that

$$a_T(2) \geq \binom{n-1}{2} - \sum_{v \in V_1} \binom{\deg(v)}{2} - \sum_{v \in V_2} \binom{\deg(v)}{2}$$



$S(9,4)$

FIG. 6.1.

$$\geq \binom{n-1}{2} - \binom{n-1-p+1}{2} - \binom{n-1-q+1}{2}$$
$$= (p-1)(q-1)$$

with equality if and only if the degrees of the vertices in V_1 are $q, 1, 1, \ldots, 1$ and the degrees of the vertices in V_2 are $p, 1, 1, \ldots, 1$. This means equality holds if and only if T is the double star $D(p,q)$. □

We are now ready to determine the lower bound of $d_\lambda(L(T))$ when $T \in \mathcal{T}_n(b; p, q)$.

THEOREM 5.2. *Let T be a tree with n vertices which has a (p,q)-bipartition, $n = p+q$, and T is not the double star $D(p,q)$. Then*

$$d_\lambda(L(T)) > d_\lambda(L(D(p,q))).$$

Proof. The proof is similar to Theorem 4.2. We use Corollary 3.2 and Lemma 5.1:

$$d_\lambda(L(T)) = \sum_{k=1}^{\lfloor \frac{n}{2} \rfloor} a_T(k) \sum_{j=0}^{k} \chi_\lambda(j) \binom{k}{j}$$
$$> (n-1)(\chi_\lambda(0) + \chi_\lambda(1)) + (p-1)(q-1)(\chi_\lambda(0) + 2\chi_\lambda(1) + \chi_\lambda(2))$$
$$= d_\lambda(L(D(p,q))). \quad \square$$

In the special case of the permanent, a simple calculation gives

$$\begin{aligned} \operatorname{per} L(D(p,q)) &= (n-1)2 + (p-1)(q-1)4 \\ &= (2p-1)(2q-1) + 1. \end{aligned}$$

This gives a lower bound on the permanent of the Laplacian matrix of a tree with a (p,q)-bipartition.

COROLLARY 5.3 (see [2, Theorem 2.16]). *Let T be a tree with a (p,q)-bipartition. Then*

$$\operatorname{per} L(T) \geq (2p-1)(2q-1) + 1$$

with equality if and only if T is a double star $D(p,q)$.

6. Trees with maximum matching of size k, $\mathcal{T}_n(m; k)$. Take the star $S(n-k+1)$ and add a leaf to each $k-1$ of its leaves. The resulting tree is called a *spur* and we denote it by $S(n,k)$. The spur $S(9,4)$ is shown in Figure 6.1.

Let $\alpha'(T)$ denote the size of a maximum matching in T. Note that $S(n,1)$ is just the star $S(n)$ and $\alpha'(S(n,k)) = k$.

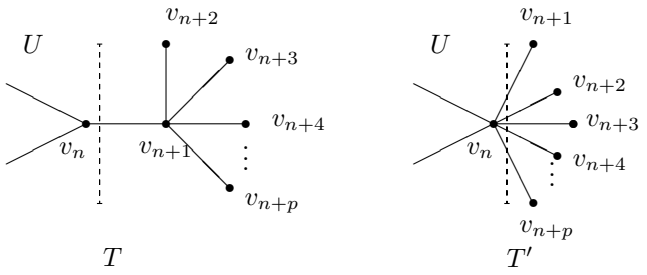


FIG. 6.2.

It can be shown that for $j = 1, 2, \ldots, k$,

$$a_{S(n,k)}(j) = (n + 1 - 2j)\binom{k-1}{j-1}$$

and $a_{S(n,k)}(j) = 0$ for $j > k$. The set of j-orientations of $S(n, k)$ can be partitioned into two types: those in which the central vertex is not incident with an edge having two arrows and those in which the central vertex is incident with an edge having two arrows. The number of j-orientations of the former type is $j\binom{k-1}{j}$ and the number of the latter type is $((n-k)-(j-1))\binom{k-1}{j-1}$. The sum of these two numbers equals $a_{S(n,k)}(j)$.

Again, we will use the same idea of showing that these are lower bounds for $a_T(j)$ for trees T such that $\alpha'(T) = k$. We will first prove a recursive relation on the $a_T(j)$'s. The analogue of this result for weighted j-matching numbers may be found in [8, Lemma 4] and [6, Lemma 5.4].

LEMMA 6.1. *Let U be a tree with n vertices. Let T and T' be trees with $n + p$ vertices where $p \geq 2$ and both trees contain U as a common subtree as shown in Figure* 6.2.

Then for $j = 1, 2, \ldots, \lfloor \frac{n}{2} \rfloor + 1$,

$$a_T(j) = a_{T'}(j) + (p-1)a_U(j-1).$$

Proof. We give a combinatorial proof of this result. Consider the j-vertex orientations of T.

Case 1. The arrow from v_n points toward v_{n+1} and for some $i = 2, 3, \ldots, p$, the edge $\{v_{n+1}, v_{n+i}\}$ has two arrows. We associate the j-vertex orientation with a j-vertex orientation of T' where $\{v_n, v_{n+i}\}$ has two arrows and all the arrows in the common subtree U remain the same.

Case 2. The edge $\{v_n, v_{n+1}\}$ has two arrows. We associate this j-vertex orientation of T with a j-vertex orientation of T' where $\{v_n, v_{n+1}\}$ has two arrows and the rest remains the same.

Case 3. The arrow from v_n points away from v_{n+1} and none of the edges $\{v_{n+1}, v_{n+i}\}$ has two arrows for some $i = 2, \ldots, p$. Here, the arrow from v_{n+1} points toward v_n. We associate this j-vertex orientation with a j-vertex orientation of T' where the arrows point from v_{n+i} to v_n for all $i = 1, 2, \ldots, p$, and the arrows in the common subtree U remain the same.

Case 4. The arrow from v_n points away from v_{n+1} and for some $i = 2, 3, \ldots, p$, the edge $\{v_{n+1}, v_{n+i}\}$ has two arrows. We associate this j-vertex orientation with a $(j-1)$-vertex orientation of U and take note of the number i.

The number of j-vertex orientations in Cases 1, 2, and 3 combined is exactly $a_{T'}(j)$, and the number in Case 4 is $(p-1)a_U(j-1)$. Therefore,

$$a_T(j) = a_{T'}(j) + (p-1)a_U(j-1). \qquad \square$$

Remarks.

1. If the subtree U has one or more edges, that is, if T is not the star, then $a_T(j) > a_{T'}(j)$ for all $j = 2, 3, \ldots, \alpha'(T)$. By Lemma 3.1 and formula (2.4), it follows that $d_\lambda(L(T)) > d_\lambda(L(T'))$ whenever T is not the star.
2. The construction of T' from T is a useful one and we shall give it a name to facilitate discussion later on. A vertex v in T attached to $\deg(v) - 1$ leaves is called a *penultimate vertex*. In the construction we shall say that T' is the contraction of T via the penultimate vertex v_{n+1} and write $T' = \mathrm{co}(T, v_{n+1})$.

LEMMA 6.2. *Let T be a tree with a matching of maximum size $\alpha'(T) = k$. Then*

$$a_T(j) \geq (n+1-2j)\binom{k-1}{j-1} = a_{S(n,k)}(j)$$

for $j = 1, 2, \ldots, k$.

Furthermore for $j = 2, \ldots, k$, equality holds if and only if T is the spur $S(n, k)$.

Proof. We prove this by induction on $i(T)$ where $i(T)$ is the number of vertices in T of degree greater than 1. The "i" in $i(T)$ stands for "interior vertices" of T. The base case is when $i(T) = 1$, that is, when T is the star $S(n)$. In this case $k = 1$ and the inequality is true since $a_{S(n)} = n-1$. Recall that the star $S(n)$ is the spur $S(n, 1)$.

If $i(T) > 1$, then T is not the star $S(n)$. We can find a penultimate vertex v in T. That is to say, T has the form given in Lemma 6.1. Let $T' = \mathrm{co}(T, v)$ as in Lemma 6.1. By Lemma 6.1

$$a_T(j) = a_{T'}(j) + (p-1)a_U(j-1),$$

where U is the common subtree obtained from T by deleting v and all its leaves. Note that T' has the same number of vertices as T but $i(T') = i(T) - 1$. We split the induction step into two cases.

Case 1. $\alpha'(T') = k = \alpha'(T)$. Then by the remarks following Lemma 6.1 and the induction hypothesis,

$$a_T(j) > a_{T'}(j) \geq (n+1-2j)\binom{k-1}{j-1} = a_{S(n,k)}(j).$$

Note that the inequality is strict for $j = 2, 3, \ldots, k$. This shows that T is not the spur $S(n, k)$.

Case 2. $\alpha'(T') = k - 1$. It follows that $\alpha'(U) = k - 1$ as well. Also $i(U) \leq i(T')$. So,

$$\begin{aligned}
a_T(j) &= a_{T'}(j) + (p-1)a_U(j-1) \\
&\geq (n+1-2j)\binom{k-2}{j-1} + (p-1)(n-p+1-2(j-1))\binom{k-2}{j-2} \\
&= (n+1-2j)\binom{k-2}{j-1} + (n+1-2j)\binom{k-2}{j-2} + (p-2)(n-p-2(j-1))\binom{k-2}{j-2} \\
&\geq (n+1-2j)\binom{k-2}{j-1} + (n+1-2j)\binom{k-2}{j-2} \\
&= (n+1-2j)\binom{k-1}{j-1}.
\end{aligned}$$

In this case, equality holds if and only if $p = 2$ and both T' and U are the spurs $S(n, k-1)$ and $S(n-2, k-1)$, respectively. This means that T has to be the spur $S(n, k)$. □

Basically, Lemma 6.2 says that among all trees in $\mathcal{T}_n(m; k)$, $a_T(j)$ is smallest when T is $S(n, k)$.

THEOREM 6.3. *Let T be a tree on n vertices with a maximum matching of size k and where T is different from the spur $S(n, k)$. Then*

$$d_\lambda(L(T)) > d_\lambda(L(S(n,k))).$$

Proof. Using Lemma 6.2 and Corollary 3.2, we see that if T is not the spur $S(n, k)$,

$$\begin{aligned} d_\lambda(L(T)) &= \sum_{h=1}^{\lfloor \frac{n}{2} \rfloor} a_T(h) \sum_{j=0}^{h} \chi_\lambda(j) \binom{h}{j} \\ &> \sum_{h=1}^{\lfloor \frac{n}{2} \rfloor} a_{S(n,k)}(h) \sum_{j=0}^{h} \chi_\lambda(j) \binom{h}{j} \\ &= d_\lambda(L(S(n,k))). \end{aligned}$$ □

The permanent for the spur $S(n, k)$ can be easily computed using the values for $a_{S(n,k)}(j)$:

$$\begin{aligned} \text{per } L(S(n,k)) &= \sum_{j=1}^{k} (n+1-2j) \binom{k-1}{j-1} 2^j \\ &= 3^{k-2}(6n-8k+2). \end{aligned}$$

The lower bound for the permanent in this case is thus attained by the spur $S(n, k)$.

COROLLARY 6.4 (see [2, Theorem 2.9]). *Let T be a tree with n vertices and a k-matching where $k \geq 1$. Then*

$$\text{per } L(T) \geq 3^{k-2}(6n-8k+2),$$

with equality if and only if T is the spur $S(n, k)$.

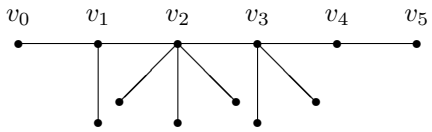
7. Trees with diameter k, $\mathcal{T}_n(d; k)$. From the previous sections, we see that in $\mathcal{T}_n$, $\mathcal{T}_n(b; p, q)$, and $\mathcal{T}_n(m, k)$ the minimum immanant value is attained by the same tree independent of the character chosen. However, this property no longer holds for $\mathcal{T}_n(d; k)$. This makes the characterization of the tree having the minimum immanant value more challenging.

Let P be a path of length k. We label the vertices of P by $v_0, v_1, v_2, \ldots, v_k$. Then a *caterpillar* of diameter k can be described as the path P with leaves (or legs) attached to the vertices $v_1, v_2, \ldots, v_{k-1}$.

Note that in the caterpillar, $\deg(v_0) = \deg(v_k) = 1$ and $\deg(v_i) \geq 2$ for $i = 1, 2, \ldots, k-1$. Since it depends only on $\deg(v_i)$ where $i = 1, 2, \ldots, k-1$, we denote it by

$$C(k; l_1, l_2, \ldots, l_{k-1}),$$

where $l_i = \deg(v_i) - 2$ is the number of legs at vertex v_i. In Figure 7.1, we show the caterpillar $C(5; 1, 3, 2, 0)$.



$C(5; 1, 3, 2, 0)$

FIG. 7.1.

Let $T \in \mathcal{T}_n(d; k)$ and P be a path $v_0, v_1, \ldots, v_k$ in T of length k. Suppose T is not a caterpillar. Then it has a penultimate vertex, say, v, that is neither v_1 nor v_{k-1}. Let $T' = \mathrm{co}(T, v)$ be the contraction of T via v as in Lemma 6.1. Then $d_\lambda(L(T')) < d_\lambda(L(T))$ and T' still has diameter k. By using the contraction process repeatedly, we see that the tree in $\mathcal{T}_n(d; k)$ that has the smallest immanant value must be a caterpillar. We summarize this in a lemma.

LEMMA 7.1. *Let $T \in \mathcal{T}_n(d; k)$. If T is not a caterpillar, then there exists a caterpillar C such that*

$$d_\lambda(L(T)) > d_\lambda(L(C)).$$

In fact, as we shall see later, the caterpillar that is minimum must have all its legs concentrated at a vertex.

For a caterpillar $C = C(k; l_1, l_2, \ldots, l_{k-1})$, the numbers $a_C(j)$'s can be expressed as polynomials in l_i's. For example, a direct calculation gives

$$\begin{aligned} a_C(1) &= \sum_{i=1}^{k-1} l_i + k, \\ a_C(2) &= \sum_{j=2}^{k-2} (l_1+1) l_j (j-1) + \sum_{1<i<j<k-1} l_i l_j (j-i) + \sum_{i=2}^{k-2} l_i (l_{k-1}+1)(k-1-i) \\ &\quad + (l_1+1)(l_{k-1}+1)(k-2) + (l_1+1)\binom{k-1}{2} + \sum_{i=2}^{k-2} l_i \left(\binom{i}{2} + \binom{k-1-i}{2} \right) \\ &\quad + (l_{k-1}+1)\binom{k-1}{2} + \binom{k-2}{3}. \end{aligned} \tag{7.1}$$

We say that a polynomial is *square-free* if the highest power of any of its variables is not greater than 1. So both $a_C(1)$ and $a_C(2)$ are square-free polynomials in the variables l_i. This is also true of other $a_C(j)$.

LEMMA 7.2. *Let C be the caterpillar $C(k; l_1, l_2, \ldots, l_{k-1})$. Then we have that for $j = 1, 2, \ldots, k-1$, $a_C(j)$ is a square-free polynomial in the variables $l_1, l_2, \ldots, l_{k-1}$ with nonnegative integer coefficients.*

Proof. We will prove a stronger statement that $a_C(j)$ is a square-free polynomial in the variables $l_1+1, l_2, \ldots, l_{k-2}, l_{k-1}+1$. We prove this by induction on the diameter k. When $k = 2$, $C(2; l_1)$ is just the star with $l_1 + 3$ vertices and $a_C(1) = l_1 + 2$.

For larger values of k, let C' denote the caterpillar $C(k-1; l_1, \ldots, l_{k-3}, l_{k-2} + (l_{k-1}+1))$ and C'' denote the caterpillar $C(k-1; l_1, \ldots, l_{k-3}, l_{k-2}-1)$. In the case $l_{k-2} = 0$, we let C'' be the caterpillar $C(k-2; l_1, \ldots, l_{k-3})$. Then we can apply Lemma 6.1 to C and C' to obtain

$$a_C(j) = a_{C'}(j) + (l_{k-1}+1) a_{C''}(j-1).$$

Since C' and C'' have shorter diameters, by the induction hypothesis, $a_{C'}(j)$ and $a_{C''}(j)$ can be expressed in terms of $l_1+1, l_2, \ldots, l_{k-2}, l_{k-1}+1$ and $l_1+1, l_2, \ldots, l_{k-2}$, respectively, with nonnegative integer coefficients. Both these expressions are square-free. Hence, $a_C(j)$ is a square-free polynomial in the variables $l_1+1, l_2, \ldots, l_{k-2}, l_{k-1}+1$ with nonnegative integer coefficients. □

We will make use of this to prove Theorem 7.3.

THEOREM 7.3. *Let* $C[n;k;i]$ *denote the caterpillar* $C(k;\underbrace{0,\ldots,0}_{i-1},n-k-1,\underbrace{0,\ldots,0}_{k-1-i})$. *For any tree* T *with order* n *and diameter* k,

$$d_\lambda(L(T)) \geq d_\lambda(L(C[n;k;i]))$$

for some $i = 1, 2, \ldots, \lfloor \frac{k}{2} \rfloor$ *where* i *depends on* λ. *Furthermore, the inequality is strict if* T *is not* $C[n;k;j]$ *for* $j = 1, 2, \ldots, k-1$.

Proof. Let $C[n;k;i]$ denote the caterpillar $C(k;\underbrace{0,\ldots,0}_{i-1},n-k-1,\underbrace{0,\ldots,0}_{k-1-i})$. From Lemma 7.1, it suffices to consider the smaller set of caterpillars C with diameter k and $C \neq C[n;k;i]$ for all i. Using Lemma 7.2 and (2.4), we can express $d_\lambda(L(C))$ as a square-free polynomial in the variables l_i with nonnegative coefficients. Let $t_{j;i_1,i_2,\ldots,i_h}$ denote the coefficient of $l_{i_1}l_{i_2}\cdots l_{i_h}$ in $a_C(j)$ where $1 \leq i_1 < i_2 < \cdots < i_h \leq k-1$. The constant will be denoted by t_j. Note that $t_{j;i_1,i_2,\ldots,i_h}$ is independent of the values of l_i. Also from (7.1), $t_{2;i_1,i_2} > 0$ for all i_1, i_2. Then

$$\begin{aligned}
d_\lambda(L(C)) &= \sum_g a_C(g) \sum_{j=0}^{g} \chi_\lambda(j) \binom{g}{j} \\
&= \sum_g \left(t_g + \sum_{1 \leq i_1 < \cdots < i_h \leq k-1} l_{i_1} l_{i_2} \cdots l_{i_h} t_{g;i_1,i_2,\ldots,i_h} \right) \sum_{j=0}^{g} \chi_\lambda(j) \binom{g}{j} \\
&= \sum_g t_g \sum_j \chi_\lambda(j) \binom{g}{j} \\
&\quad + \sum_{1 \leq i_1 < \cdots < i_h \leq k-1} l_{i_1} l_{i_2} \cdots l_{i_h} \left(\sum_g t_{g;i_1,i_2,\ldots,i_h} \sum_j \chi_\lambda(j) \binom{g}{j} \right) \\
&> \sum_g t_g \sum_j \chi_\lambda(j) \binom{g}{j} + \sum_{i=1}^{k-1} l_i \sum_g t_{g;i} \sum_j \chi_\lambda(j) \binom{g}{j}
\end{aligned}$$

since for C, $l_i l_j > 0$ for some i, j and by Corollary 3.2, $\sum_j \chi_\lambda(j)\binom{2}{j} > 0$. Now, recall that the total number of legs is $\sum_{i=1}^{k-1} l_i = n-k-1$. So, we can pick i such that the sum $\sum_g t_{g;i} \sum_j \chi_\lambda(j)\binom{g}{j}$ is minimum. Then the inequality becomes

$$\begin{aligned}
d_\lambda(L(C)) &> \sum_g t_g \sum_j \chi_\lambda(j) \binom{g}{j} + (n-k-1) \sum_g t_{g;i} \sum_j \chi_\lambda(j) \binom{g}{j} \\
&= d_\lambda(L(C[n;k;i])). \qquad \square
\end{aligned}$$

From this theorem, we see that to find the tree in $\mathcal{T}(d;k)$ that attains the minimum for some particular immanant it suffices to compare the values $d_\lambda(L(C[n;k;i]))$ where $i = 1, 2, \ldots, \lfloor \frac{k}{2} \rfloor$. As an example, we illustrate this for the permanent.

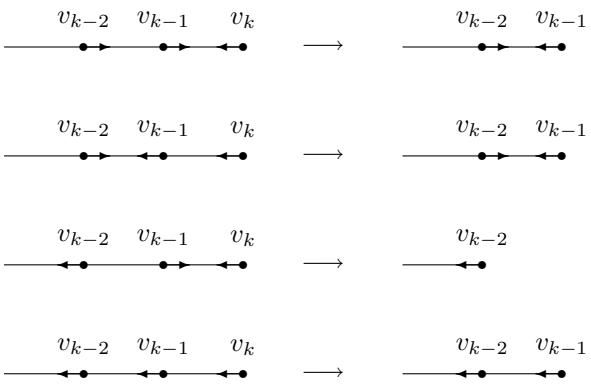
LEMMA 7.4. *Let $C[n;k;i]$ denote the caterpillar with n vertices, diameter k, and all its legs concentrated at the vertex v_i. If $i < k-2$, then for $j = 1, 2, \ldots, \alpha'(C[n;k;i])$,*

$$a_{C[n;k;i]}(j) = 2a_{C[n-1;k-1;i]}(j) + a_{C[n-2;k-2;i]}(j-1) - a_{C[n-2;k-2;i]}(j). \tag{7.2}$$

Proof. We give a combinatorial proof of the equivalent statement

$$a_{C[n;k;i]}(j) + a_{C[n-2;k-2;i]}(j) = 2a_{C[n-1;k-1;i]}(j) + a_{C[n-2;k-2;i]}(j-1).$$

We divide the j-vertex orientations of $C[n;k;i]$ into four cases as shown below. We map these to the vertex orientations of $C[n-1;k-1;i]$ and $C[n-2;k-2;i]$, changing only the arrows shown.



For j-vertex orientations of $C[n-2;k-2;i]$, we map them to j-vertex orientations of $C[n-1;k-1;i]$.

Clearly, this gives a bijection. Therefore, the formula holds. □

THEOREM 7.5 (see [2, Theorem 2.14]). *Let T be a tree from the set $\mathcal{T}(d;k)$. Then*

$$\text{per } L(T) \geq \text{per } L(C[n;k;1])$$

with equality if and only if $T = C[n;k;1]$.

Proof. It suffices to show that per $L(C[n;k;i]) >$ per $L(C[n;k;1])$ for $i = 2, \ldots, \lfloor \frac{k}{2} \rfloor$. We prove this by induction on k. The base case is when $k = 4$. There are only two caterpillars to compare. A computation gives

$$\text{per } L(C[n;4;1]) = 14n - 46 \text{ and per } L(C[n;4;2]) = 18n - 66$$

, and since $n > 5$, $C[n;4;1]$ attains the unique permanent value.

Assume $k \geq 5$. In this case, $1 < i \leq \lfloor \frac{k}{2} \rfloor < k-2$. So, we can use (7.2) to obtain

$$\begin{aligned}
& \text{per } L(C[n;k;i]) \\
= \;& 2 \text{ per } L(C[n-1;k-1;i]) + 2 \text{ per } L(C[n-2;k-2;i]) - \text{per } L(C[n-2;k-2;i]) \\
> \;& 2 \text{ per } L(C[n-1;k-1;1]) + \text{per } L(C[n-2;k-2;1]) \\
= \;& \text{per } L(C[n;k;1]).
\end{aligned}$$

Thus per $L(T) >$ per $L(C[n;k;1])$ if $T \neq C[n;k;1]$. □

TABLE 7.1

λ	(1^8)	$(2,1^6)$	$(3,1^5)$	$(4,1^4)$	$(5,1^3)$	$(6,1^2)$	$(7,1)$	(8)
$C[8;6;1]$	0	14	52	270	600	660	372	82
$C[8;6;2]$	0	14	40	226	560	680	424	102
$C[8;6;3]$	0	14	26	222	568	684	420	98

The caterpillar $C[n;k;1]$ is called the *broom* in [2] and is denoted by $B(n,k,n-k)$. Just for the record,

$$\text{per } L(C[n;k;1]) = \left(n-k+\frac{1}{\sqrt{2}}\right)(1+\sqrt{2})^{k-1} + \left(n-k-\frac{1}{\sqrt{2}}\right)(1-\sqrt{2})^{k-1}.$$

Lest it be thought that $C[n;k;1]$ attains the smallest immanant value for all immanants, we quote a result to dispel this notion.

THEOREM 7.6 (see [6, Theorem 4.3]). *When* $\lambda = (3,1^{n-3})$,

$$d_\lambda(L(T)) = 4 \sum_{v_i,v_j \in V(T)} \left(d(v_i,v_j)-1\right),$$

where $d(v_i,v_j)$ *is the distance between the vertices* v_i *and* v_j.

Using this, it is easy to see that $d_\lambda(L(T))$ attains a minimum when $T = C[n;k;\lfloor \frac{k}{2} \rfloor]$.

8. Open problems. To conclude, we list some interesting problems. It is natural to propose the following problems.

PROBLEM 1. *For each partition* λ *of* n *determine the tree or trees in* $\mathcal{T}_n(d;k)$ *such that* $d_\lambda(\cdot)$ *is minimized.*

Example. Consider the set of trees of order 8 and diameter 6. By symmetry, we only need to calculate the immanant values for the three caterpillars, $C[8;6;1]$, $C[8;6;2]$, and $C[8;6;3]$, where the explicit values corresponding to the hook characters are listed below.

From Table 7.1, we can see that there is a gradual movement of the minimum from $C[8;6;3]$ to $C[8;6;1]$ when the partition changes.

PROBLEM 2. *For every* $C[n;k;i]$, *does there exist a partition* λ *such that* $C[n;k;i]$ *is the tree in* $\mathcal{T}(d;k)$ *that attains the minimum immanant value corresponding to* λ*?*

The methods in this article can be used to show that among all the trees in $\mathcal{T}_n$, the path attains the maximum for all immanant values. However, if we restrict the discussion to the subsets of trees $\mathcal{T}_n(b;p,q)$, $\mathcal{T}_n(m;k)$, and $\mathcal{T}_n(d;k)$ our approach fails to provide a satisfactory answer.

PROBLEM 3. *Characterize the tree that attains the maximum immanantal value in each of* $\mathcal{T}_n(b;p,q), \mathcal{T}_n(m;k)$, *and* $\mathcal{T}_n(d;k)$.

Finally, we note that these problems can also be extended to bipartite graphs and graphs in general.

THE KREISS MATRIX THEOREM ON A GENERAL COMPLEX DOMAIN*

KIM-CHUAN TOH† AND LLOYD N. TREFETHEN‡

Abstract. Let A be a bounded linear operator in a Hilbert space $\mathcal{H}$ with spectrum $\Lambda(A)$. The Kreiss matrix theorem gives bounds based on the resolvent norm $\|(zI-A)^{-1}\|$ for $\|A^n\|$ if $\Lambda(A)$ is in the unit disk or for $\|e^{tA}\|$ if $\Lambda(A)$ is in the left half-plane. We generalize these results to a complex domain Ω, giving bounds for $\|F_n(A)\|$ if $\Lambda(A) \subset \Omega$, where F_n denotes the nth Faber polynomial associated with Ω. One of our bounds takes the form

$$\tilde{\mathcal{K}}(\Omega) \;\le\; 2 \sup_n \|F_n(A)\|, \qquad \|F_n(A)\| \;\le\; 2\,e\,(n+1)\,\tilde{\mathcal{K}}(\Omega),$$

where $\tilde{\mathcal{K}}(\Omega)$ is the "Kreiss constant" defined by

$$\tilde{\mathcal{K}}(\Omega) = \inf\left\{ C \,:\, \|(zI-A)^{-1}\| \;\le\; C/\mathrm{dist}(z,\Omega)\ \forall\ z \notin \Omega \right\}.$$

By means of an inequality due originally to Bernstein, the second inequality can be extended to general polynomials p_n. In the case where $\mathcal{H}$ is finite-dimensional, say, $\dim(\mathcal{H}) = N$, analogous results are also established in which $\|F_n(A)\|$ is bounded in terms of N instead of n when the boundary of Ω is twice continuously differentiable.

Key words. Kreiss matrix theorem, conformal mapping, Faber polynomials, polynomials of a matrix, Krylov subspaces

1. Introduction.

Let A be a bounded linear operator in a Hilbert space $\mathcal{H}$ with spectrum $\Lambda(A)$, and let $\|\cdot\|$ denote the operator 2-norm. The Kreiss matrix theorem, originally published in 1962 [9], concerns the problem of characterizing families of bounded linear operators that are uniformly power-bounded, with spectra contained in the closed unit disk D. Let us define

$$\mathcal{K}(D) = \inf\left\{ C \,:\, \|(zI-A)^{-1}\| \;\le\; \frac{C}{\mathrm{dist}(z,D)}\ \ \forall\ z \notin D \right\},$$

the *Kreiss constant* of A with respect to D. If $\mathcal{H}$ is finite-dimensional, say, $\dim(\mathcal{H}) = N$, the current, sharp form of the theorem reads as follows [17], [20]:

$$\mathcal{K}(D) \;\le\; \sup_n \|A^n\| \;\le\; e\,N\,\mathcal{K}(D). \tag{1}$$

Since its original appearance, the Kreiss matrix theorem has been one of the fundamental results for establishing numerical stability of discrete evolution process $\{\|A^n\|\}$.

When $\mathcal{H}$ is infinite-dimensional, unfortunately, the upper bound of (1) becomes vacuous. But there is another upper bound in the following (more elementary) variant of the Kreiss matrix theorem:

$$\|A^n\| \le e\,(n+1)\,\mathcal{K}(D). \tag{2}$$

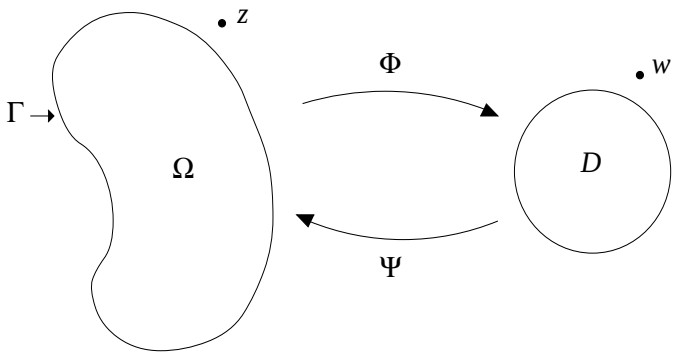

FIG. 1. *Conformal maps between the exterior of* Ω *and the exterior of the closed unit disk* D. Γ *is the boundary of* Ω.

In this paper, we generalize both (1) and (2) to a general complex domain Ω, giving bounds for $\|F_n(A)\|$ if $\Lambda(A) \subset \Omega$, where F_n is the nth Faber polynomial associated with Ω. On the unit disk D, the Faber polynomials are just the monomials z^n, and on the interval $[-1, 1]$, or on any ellipse with foci ± 1, they are twice the Chebyshev polynomials $T_n(z)$.

Let Ω be a compact set (possibly having empty interior) with boundary Γ in the complex plane $\mathbb{C}$ that contains $\Lambda(A)$, and assume that its complement Ω^c is simply connected in the extended complex plane. (This will be our assumption throughout this paper, except section 2.) By the Riemann mapping theorem [6], there exists a unique conformal map normalized by $\Phi(\infty) = \infty$ and $\Phi'(\infty) > 0$,

$$w \;=\; \Phi(z) \;=\; dz + d_0 + \sum_{k=1}^{\infty} \frac{d_k}{z^k} \quad (d > 0), \quad z \in \Omega^c,$$

from Ω^c to the exterior of the closed unit disk D (Figure 1). If $\Psi : D^c \longrightarrow \Omega^c$ is the inverse map of Φ, then Ψ has a similar expansion

$$z \;=\; \Psi(w) \;=\; cw + c_0 + \sum_{k=1}^{\infty} \frac{c_k}{w^k}, \qquad w \in D^c,$$

where $c = 1/d$. The positive constant c is known as the *logarithmic capacity* of Ω. For each nonnegative integer n, the polynomial part of $[\Phi(z)]^n$ is a polynomial of degree n. This polynomial is known as the nth Faber polynomial associated with Ω and is generally denoted by $F_n(z)$. For more details on Faber polynomials, see [2], [6], [16].

We define the Kreiss constant of A with respect to the region Ω by the following formula:

$$\mathcal{K}(\Omega) = \inf \left\{ C \,:\, \|(zI - A)^{-1}\| \;\le\; \frac{C\,|\,\Phi'(z)\,|}{|\,\Phi(z)\,| - 1} \;\forall\, z \in \Omega^c \right\}. \tag{3}$$

Our generalizations of the Kreiss matrix theorem read as follows.

THEOREM 1.1 (Kreiss matrix theorem I). *Suppose* A *is a bounded linear operator in a Hilbert space with spectrum* $\Lambda(A) \subset \Omega$ *and* $\mathcal{K}(\Omega) < \infty$. *Then* $\forall n \ge 0$,

$$\|F_n(A)\| \le e\,(n+1)\,\mathcal{K}(\Omega). \tag{4}$$

Conversely, if $\sup_{n\geq 0}\|F_n(A)\| < \infty$, *then* $\Lambda(A) \subset \Omega$, $\mathcal{K}(\Omega)$ *is finite, and*

$$\mathcal{K}(\Omega) \leq \sup_{n\geq 0}\|F_n(A)\|. \tag{5}$$

THEOREM 1.2 (Kreiss matrix theorem II). *Suppose* A *is bounded linear operator in a Hilbert space* $\mathcal{H}$ *with* $\Lambda(A) \subset \Omega$ *and* $\mathcal{K}(\Omega) < \infty$. *If* $\mathcal{H}$ *is finite-dimensional, say,* $\dim(\mathcal{H}) = N$, *and the boundary of* Ω *is twice continuously differentiable, then* $\forall n \geq 0$,

$$\|F_n(A)\| \leq C_\Omega\, e\, N\, \mathcal{K}(\Omega), \tag{6}$$

where the constant C_Ω *depends only on* Ω.

Remark. If the boundary of Ω is not smooth, then (6) holds with the constant C_Ω replaced by a constant of the form $C_\Omega\,(1 + \log n/N)$. We do not know if this latter bound is sharp.

Note that if Ω is the unit disk, with $F_n(A)$ equal to A^n, then we get back the standard results (1) and (2) from Theorems 1.1 and 1.2, aside from the introduction of an unspecified constant in Theorem 1.2.

In applications such as Krylov subspace iterations [4], we may not know the Faber polynomials for any particular region Ω of interest. Fortunately, this is not an essential restriction. By means of an inequality due to Bernstein in 1912, Theorem 1.1 can be extended to general polynomials p_n. We have the following theorem.

THEOREM 1.3 (Kreiss matrix theorem for p_n). *Suppose* A *is a bounded linear operator in a Hilbert space with spectrum* $\Lambda(A) \subset \Omega$ *and* $\mathcal{K}(\Omega) < \infty$. *Then for any polynomial* p_n *of any degree* n,

$$\|p_n(A)\| \leq e\,(n+1)\,\mathcal{K}(\Omega)\,\|p_n\|_\Omega. \tag{7}$$

Given the simplicity of the definition of the Kreiss constant with respect to the unit disk, one may wonder why we did not define the Kreiss constant for A with respect to Ω simply by

$$\tilde{\mathcal{K}}(\Omega) = \inf\left\{C \,:\, \|(zI-A)^{-1}\| \,\leq\, \frac{C}{\operatorname{dist}(z,\Omega)}\ \forall\, z \in \Omega^c\right\}. \tag{8}$$

The answer is that, as we shall see in sections 4 and 5, it is the constant $\mathcal{K}(\Omega)$ that is mathematically the most natural generalization of $\mathcal{K}(D)$. On the other hand, the constant $\tilde{\mathcal{K}}(\Omega)$ has undeniable appeal because of its geometric simplicity. In particular, $\tilde{\mathcal{K}}(\Omega)$ does not involve the conformal map Φ. We shall see that although we have two different versions of the Kreiss constant, they are equivalent in the sense that they differ by at most a factor of 2 (in either direction; see Theorem 3.2). If Ω is the unit disk itself, or any other disk, then $\tilde{\mathcal{K}}(\Omega) = \mathcal{K}(\Omega)$ for any A.

Besides being more memorable and intuitive, for most practical purposes, it is the constant $\tilde{\mathcal{K}}(\Omega)$ that is easier to use. Thus it is worthwhile for the reader to bear in mind that the Kreiss matrix theorems 1.1, 1.2, and 1.3 have a more memorable version where the constant $\mathcal{K}(\Omega)$ can be replaced by $2\tilde{\mathcal{K}}(\Omega)$ or $\frac{1}{2}\tilde{\mathcal{K}}(\Omega)$, depending on whether it appears as part of an upper bound or lower bound.

The paper is organized as follows. In section 2, we discuss some properties of $\tilde{\mathcal{K}}(\Omega)$. In section 3, we show the equivalence of the Kreiss constants $\mathcal{K}(\Omega)$ and $\tilde{\mathcal{K}}(\Omega)$. In section 4, we prove Theorems 1.1 and 1.3. In section 5, we prove Theorem 1.2. In section 6, we consider the special case $\Omega = [-1, 1]$, obtaining a Kreiss matrix theorem for the Chebyshev polynomials T_n. An example is also given to show that the linear dependence on N in the upper bound of this Kreiss matrix theorem is sharp.

Throughout, we write $\mathcal{K}(\Omega)$ simply as $\mathcal{K}$ when there is no danger of confusion.

2. Some properties of the Kreiss constant $\tilde{\mathcal{K}}(\Omega)$. In this section, Ω will denote any compact subset of the complex plane. Note that $\tilde{\mathcal{K}}(\Omega)$ remains well defined without the assumption that Ω^c is simply connected in the extended complex plane. In particular, it is well defined for $\Omega = \Lambda(A)$.

The Kreiss constant $\tilde{\mathcal{K}}(\Omega)$, being defined geometrically, can be computed without the knowledge of the conformal map Φ. This is a great advantage over $\mathcal{K}(\Omega)$ since, except for special domains such as ellipses or polygons, Φ cannot be computed easily. In practice, one might want to choose Ω to be an ϵ-pseudospectrum [19] of A for some ϵ, in which case Ω is rarely one of these special domains.

Besides this computational advantage, we shall see in this section that $\tilde{\mathcal{K}}(\Omega)$ has some appealing geometrical properties. The most important of these is that it has a geometrical interpretation: It measures the largest amount by which some ϵ-pseudospectrum of A protrudes outside the region Ω, relative to ϵ. We discuss this in Proposition 2.1. Also, $\tilde{\mathcal{K}}(\Omega) \geq 1$ for all Ω and A, since in the limit $z \to \infty$, $\|(zI - A)^{-1}\|$ and $\mathrm{dist}(z, \Omega)$ tend to $|z|^{-1}$ and $|z|$, respectively.

PROPOSITION 2.1. *For each $\epsilon \geq 0$, let $\Lambda_\epsilon(A)$ be the ϵ-pseudospectrum of A defined by*

$$\Lambda_\epsilon(A) \;=\; \{z \in \mathbb{C} \,:\, \|(zI - A)^{-1}\| \geq 1/\epsilon\}.$$

Then the following statements are equivalent:

1. $\|(zI - A)^{-1}\| \;\leq\; C/\mathrm{dist}(z, \Omega)\ \forall\ z$ *such that* $\mathrm{dist}(z, \Omega) > 0$;
2. $\mathrm{dist}(z, \Omega) \;\leq\; C\,\epsilon\ \forall\ z \in \Lambda_\epsilon(A),\ \epsilon \geq 0$;
3. $\Lambda_\epsilon(A) \;\subset\; \Omega + C\,D_\epsilon\ \forall\ \epsilon \geq 0$, *where D_ϵ is the closed disk with radius ϵ.*

Therefore, an equivalent definition for $\tilde{\mathcal{K}}(\Omega)$ is

$$\tilde{\mathcal{K}}(\Omega) = \sup_{\epsilon > 0} \frac{\mathrm{dist}(\Lambda_\epsilon(A), \Omega)}{\epsilon}, \tag{9}$$

where

$$\mathrm{dist}(\Lambda_\epsilon(A), \Omega) \;=\; \max_{z \in \Lambda_\epsilon(A)} \mathrm{dist}(z, \Omega).$$

Proof. This is an easy consequence of the definitions of $\tilde{\mathcal{K}}(\Omega)$ and $\Lambda_\epsilon(A)$. ∎

Other appealing properties of $\tilde{\mathcal{K}}(\Omega)$ include monotonicity and the fact that in the special case when A is normal and $\Omega = \Lambda(A)$ or Ω is the field of values $\mathcal{F}(A)$, $\tilde{\mathcal{K}}(\Omega)$ is equal to 1. (The field of values $\mathcal{F}(A)$ is the set $\{x^*Ax/x^*x : x \in \mathbb{C}^N, x \neq 0\}$.)

PROPOSITION 2.2. *Suppose Ω_1 and Ω_2 are subsets of $\mathbb{C}$ such that $\Lambda(A) \subset \Omega_1 \subset \Omega_2$. Then*

$$\tilde{\mathcal{K}}(\Omega_2) \leq \tilde{\mathcal{K}}(\Omega_1).$$

Proof. This result follows from the definitions of $\tilde{\mathcal{K}}(\Omega_1)$ and $\tilde{\mathcal{K}}(\Omega_2)$:

$$\begin{aligned}
\tilde{\mathcal{K}}(\Omega_2) &= \sup_{z \notin \Omega_2} \mathrm{dist}(z, \Omega_2)\, \|(zI - A)^{-1}\| \\
&\leq \sup_{z \notin \Omega_2} \mathrm{dist}(z, \Omega_1)\, \|(zI - A)^{-1}\| \\
&\leq \sup_{z \notin \Omega_1} \mathrm{dist}(z, \Omega_1)\, \|(zI - A)^{-1}\| \\
&= \tilde{\mathcal{K}}(\Omega_1). \qquad \blacksquare
\end{aligned}$$

PROPOSITION 2.3. *If A is a diagonalizable matrix with an eigenvalue decomposition $A = VDV^{-1}$, then*

$$\tilde{\mathcal{K}}(\Lambda(A)) \leq \kappa(V),$$

where $\kappa(V)$ is the condition number of V.

Proof. It is readily shown that

$$(zI - A)^{-1} = V\,(zI - D)^{-1}\,V^{-1}.$$

Taking norms on both sides gives

$$\|(zI - A)^{-1}\| \leq \frac{\kappa(V)}{\operatorname{dist}(z, \Lambda(A))}.$$

This implies that $\Lambda_\epsilon(A) \subset \Lambda(A) + \kappa(V)\,D_\epsilon$ for all $\epsilon \geq 0$, where D_ϵ is the closed disk of radius ϵ. Thus by Proposition 2.1, $\tilde{\mathcal{K}}(\Lambda(A)) \leq \kappa(V)$. ∎

PROPOSITION 2.4. *If A is a normal matrix and $\Lambda(A) \subset \Omega$, then*

$$\tilde{\mathcal{K}}(\Omega) = 1.$$

Proof. Since $\tilde{\mathcal{K}}(\Omega) \geq 1$ for any Ω and A, we need only show $\tilde{\mathcal{K}}(\Omega) \leq 1$. This follows from Propositions 2.2 and 2.3. ∎

PROPOSITION 2.5. *If $\mathcal{F}(A)$ is the field of values of A, then*

$$\tilde{\mathcal{K}}(\mathcal{F}(A)) = 1.$$

Proof. This is a restatement in a nonstandard language of mathematically standard material that is, for example, essentially the Hille–Yosida theorem of functional analysis [13]. ∎

3. Equivalence of the Kreiss constants $\tilde{\mathcal{K}}(\Omega)$ and $\mathcal{K}(\Omega)$. We have defined two different Kreiss constants: $\tilde{\mathcal{K}}(\Omega)$, which is defined geometrically, and $\mathcal{K}(\Omega)$, whose definition depends on the conformal maps Φ and Ψ. Thanks to results in geometric function theory stemming from the Koebe one-quarter theorem, these two constants are equivalent in the sense that they differ by at most a factor of 2.

THEOREM 3.1 (R. Kühnau [11]). *Suppose that Ψ is a conformal map of the exterior of the closed unit disk D to the exterior of a compact set Ω with boundary Γ and Ω^c is simply connected, with $\Psi(\infty) = \infty$. Then for any $|\,w_0\,| > 1$,*

$$\frac{1}{2}\,(|\,w_0\,| - 1) \;\leq\; \frac{\operatorname{dist}(z_0, \Gamma)}{|\,\Psi'(w_0)\,|} \;\leq\; 2\,(|\,w_0\,| - 1), \tag{10}$$

where $z_0 = \Psi(w_0)$. If Ψ is an "interval map" (defined below), then the factor $1/2$ on the left is attained in the limit $|\,w_0\,| \to 1$, and if Ψ is a "circular arc map" (likewise), then the factor 2 on the right is attained in the limit $|\,w_0\,| \to 1$.

Proof. We establish the right-hand inequality first. Let w_0 be fixed, and consider the "circular arc map"

$$g(w) = w\frac{w - w_0}{1 - \bar{w}_0 w}, \quad w \in D^c.$$

This function maps the exterior of D onto the exterior of an arc S of the unit circle, and w_0 to 0, as shown in Figure 2. The angle subtended by S at the origin is $4 \arctan 1/(|\,w_0\,|^2 - 1)^{1/2}$.

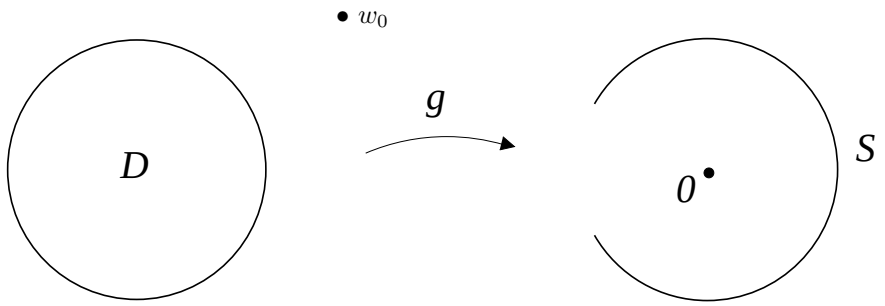

FIG. 2. *"Circular arc map," mapping the exterior of D onto the exterior of an arc S of the unit circle.*

On the contour $|w|=1$, we have $|\Psi(w)-\Psi(w_0)| = |\Psi(w)-z_0| \geq \operatorname{dist}(z_0,\Gamma)$. Thus

$$\frac{|\Psi(w)-\Psi(w_0)|}{|g(w)|} \geq \operatorname{dist}(z_0,\Gamma) \quad \forall \ |w|=1. \tag{11}$$

By the minimum principle applied to the analytic function $(\Psi(\cdot)-\Psi(w_0))/g(\cdot)$ defined on D^c, (11) holds $\forall\, |w| \geq 1$. In particular,

$$\lim_{w\to w_0} \left| \frac{\Psi(w)-\Psi(w_0)}{g(w)} \right| \ = \ \frac{|\Psi'(w_0)|}{|g'(w_0)|} \ \geq \ \operatorname{dist}(z_0,\Gamma). \tag{12}$$

Substituting $g'(w_0) = w_0/(1-|w_0|^2)$ into (12) gives

$$\frac{\operatorname{dist}(z_0,\Gamma)}{|\Psi'(w_0)|} \ \leq \ \frac{|w_0|^2-1}{|w_0|} \ \leq \ 2\operatorname{dist}(w_0,D). \tag{13}$$

If Ψ is a circular arc map, the left-hand inequality of (13) is actually an equality for all $|w_0|>1$. In this case, the factor 2 is attained in the limit as $|w_0|\to 1$.

To be precise in the above proof, we actually have to consider contours which are inside D^c, say, $|w|=r$ for $1<r<|w_0|$, and then take the limit as r tends to 1. We omit the details.

Next we show the left-hand inequality in (10). Again let w_0 be fixed, and this time, consider the "interval map"

$$h(w) = \frac{(w-w_0)(1-\bar{w}_0 w)}{4w\,(|w_0|-1)^2}, \quad w \in D^c.$$

This function maps the exterior of D onto the exterior of an interval I on the real line, and w_0 to 0, as shown in Figure 3. It is easily shown that

$$I = \left[\frac{1}{4}, \frac{(|w_0|+1)^2}{4(|w_0|-1)^2}\right] \ = \ \partial I, \tag{14}$$

$$h'(w_0) = \frac{1+|w_0|}{4w_0\,(1-|w_0|)}. \tag{15}$$

Now consider the conformal map $f = \Psi \circ h^{-1} \circ \kappa$, where $\kappa(\xi) = -\xi/(1-\xi)^2$ is the Koebe function defined on the open unit disk $\overset{\circ}{D}$ (a conformal map of $\overset{\circ}{D}$ onto

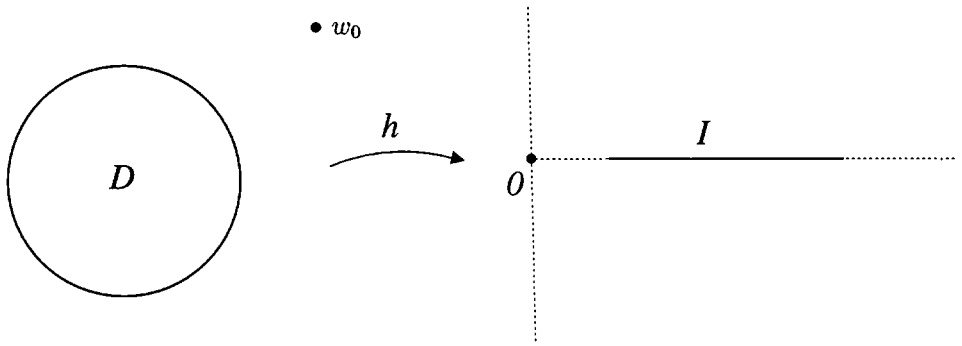

FIG. 3. *"Interval map," mapping the exterior of D onto the exterior of the interval* $I = \left[1/4,\ (|\,w_0\,|+1)^2/4(|\,w_0\,|-1)^2\right]$.

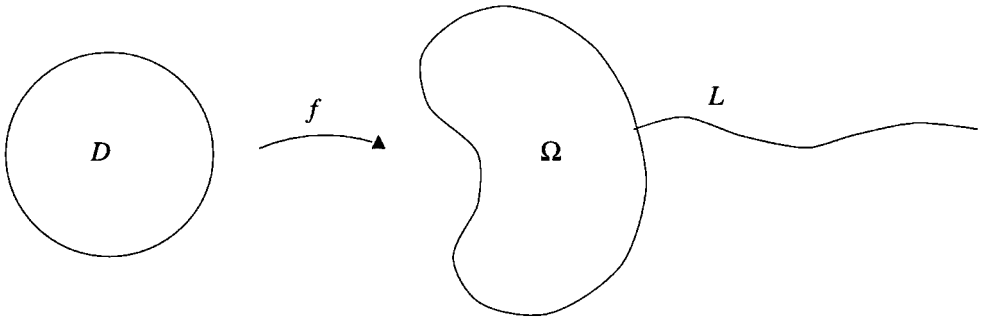

FIG. 4. *The function f maps the open unit disk $\overset{\circ}{D}$ onto the exterior of the set $\Omega \cup L$.*

$\mathbb{C} \setminus [1/4,\ \infty))$. The function f maps the open unit disk onto the exterior of $\Omega \cup L$, where L is a curve extending from the boundary of Ω to ∞, as shown in Figure 4.

By the Koebe one-quarter theorem [1, p. 29] applied to the function f, we have

$$\operatorname{dist}(f(0), \partial f(\overset{\circ}{D})) \geq \frac{1}{4}\,|\,f'(0)\,|\,. \tag{16}$$

Now

$$f(0) \;=\; \Psi(w_0), \quad f'(0) \;=\; \frac{\Psi'(w_0)}{h'(w_0)}, \quad \partial f(\overset{\circ}{D}) \;=\; \Gamma \cup L, \tag{17}$$

where

$$L = \Psi \circ h^{-1}\left(\frac{(|\,w_0\,|+1)^2}{4(|\,w_0\,|-1)^2}, \infty\right).$$

Substituting (17) into (16) gives

$$\operatorname{dist}(\Psi(w_0), \Gamma) \;\geq\; \operatorname{dist}(\Psi(w_0), \Gamma \cup L) \;\geq\; \frac{1}{4}\,\frac{|\,\Psi'(w_0)\,|}{|\,h'(w_0)\,|}. \tag{18}$$

Next, substituting (15) into (18) gives

$$\operatorname{dist}(\Psi(w_0), \Gamma) \geq \frac{|\,\Psi'(w_0)\,|}{1 + 1/\,|\,w_0\,|}\operatorname{dist}(w_0, D) \tag{19}$$

$$\geq \frac{1}{2}\ |\,\Psi'(w_0)\,|\ \mathrm{dist}(w_0, D).$$

If Ψ is an interval map, the inequality of (19) is actually an equality. In this case, the factor $1/2$ is attained in the limit as $|\,w_0\,| \to 1$. ∎

With the above theorem, it is now easy to show the equivalence of $\tilde{\mathcal{K}}(\Omega)$ and $\mathcal{K}(\Omega)$.

THEOREM 3.2. *Suppose A is a bounded linear operator in a Hilbert space with spectrum $\Lambda(A) \subset \Omega$. Then the Kreiss constants* (3) *and* (8) *are related by*

$$\frac{1}{2} \ \leq\ \frac{\tilde{\mathcal{K}}(\Omega)}{\mathcal{K}(\Omega)}\ \leq\ 2. \tag{20}$$

If Ω is an interval, then the factor $1/2$ on the left is attained in the limit as Ω becomes an infinitely long interval in the complex plane. If Ω is an arc of a circle, then the factor 2 on the right is attained in the limit as Ω approaches the full circle.

Proof. The result follows readily from Theorem 3.1 and the definitions of $\mathcal{K}(\Omega)$ and $\tilde{\mathcal{K}}(\Omega)$. ∎

4. The Kreiss matrix theorem (I). In this section, our goal is to establish Theorems 1.1 and 1.3 for a bounded linear operator A in a Hilbert space. The tools that we need are Faber series, the matrix analogue of the Cauchy integral formula, and Bernstein's lemma.

We shall begin with some basic results on Faber series. The following notation will be used in this and later sections:

- C_r: For each $r \geq 1$, C_r is the circle of radius r centered at the origin. The unit circle C_1 is also denoted by C.
- Γ_r: For each $r \geq 1$, Γ_r denotes the curve $\Psi(C_r)$. In the special case $r = 1$, Γ_1 is the boundary of Ω, and we denote this boundary also by Γ.
- Ω_r: For each $r \geq 1$, Ω_r denotes the closed region in the z-plane enclosed by $\Psi(C_r)$.
- $\|f\|_E$: For any continuous complex-valued function f defined on a compact subset E of the complex plane, $\|f\|_E$ denotes the maximum absolute value of f over E, i.e., $\|f\|_E = \max_{z\in E}\ |\,f(z)\,|$.
- P_n: The symbol P_n denotes the set of polynomials of degree at most n.

Suppose f is a function that is analytic in the interior of Ω and continuous on Ω. The *Faber series* associated with f is the formal series [2], [6, p. 44], [16]

$$f(\xi) \sim \sum_{n=0}^{\infty} a_n F_n(\xi), \quad \xi \in \Omega,$$

where

$$a_n = \frac{1}{2\pi i} \oint_C \frac{f(\Psi(w))}{w^{n+1}} dw.$$

Under suitable conditions, the Faber series actually converges to f in Ω. One sufficient condition for this is that the series converges uniformly in Ω [6, pp. 51–52]. For example, the function $(z-\xi)^{-1}$, where $z \in \Omega^c$ is fixed and $\xi \in \Omega$, can be expressed in terms of its Faber series because this series converges uniformly in Ω.

LEMMA 4.1. *For a fixed $z \in \Omega^c$, we have*

$$(z-\xi)^{-1} = \sum_{n=0}^{\infty} F_n(\xi) \frac{\Phi'(z)}{\Phi^{n+1}(z)} \quad \textit{for}\ \ \xi \in \Omega. \tag{21}$$

Proof. We omit the proof. ∎

We shall establish Theorem 1.3 first and then (4) of Theorem 1.1. Before doing so, let us state the Bernstein lemma.

LEMMA 4.2 (Bernstein). *Let $p_n \in P_n$ be arbitrary. Then*

$$\|p_n\|_{\Omega_r} \leq r^n \, \|p_n\|_{\Omega} \quad \forall \quad r \geq 1.$$

Proof. See [6, p. 27]. ∎

Now we can prove Theorem 1.3.

Proof of Theorem 1.3. Under the assumption that $\Lambda(A) \subset \Omega$, the matrix $p_n(A)$ can be represented in terms of the resolvent of A via a Cauchy integral (see [5, pp. 555–577])

$$p_n(A) = \frac{1}{2\pi i} \oint_{\Gamma_r} (zI - A)^{-1} \, p_n(z) dz \tag{22}$$

for any $r > 1$. Taking norms on both sides, we obtain the inequalities

$$\begin{aligned} \|p_n(A)\| &\leq \frac{1}{2\pi} \oint_{\Gamma_r} \|(zI - A)^{-1}\| \, |p_n(z)| \, |dz| \\ &\leq \frac{\|p_n\|_{\Omega_r}}{2\pi} \oint_{\Gamma_r} \|(zI - A)^{-1}\| \, |dz| \, . \end{aligned} \tag{23}$$

On the contour Γ_r, the resolvent norm $\|(zI - A)^{-1}\|$ is bounded above by $\mathcal{K} \, |\Phi'(z)| \, /(r-1)$, and $\|p_n\|_{\Omega_r}$ is bounded above by $r^n \|p_n\|_{\Omega}$ (by the Bernstein lemma). The inequality (23) thus reduces to

$$\|p_n(A)\| \;\leq\; \mathcal{K} \, \frac{\|p_n\|_{\Omega}}{2\pi} \, \frac{r^n}{r-1} \oint_{\Gamma_r} |\Phi'(z)| \, |dz| \;\leq\; \mathcal{K} \, \|p_n\|_{\Omega} \, \frac{r^{n+1}}{r-1}. \tag{24}$$

In deriving (24), we have used the equality

$$\oint_{\Gamma_r} |\Phi'(z)| \, |dz| \;=\; \oint_{C_r} |dw| \;=\; 2\pi r.$$

Taking $r = 1 + 1/(n+1)$ in (24) and noting that $r^{n+1} \leq e$ completes the proof. ∎

The proof of Theorem 1.3 is essentially based on ideas taken from [12], with the additional application of the Bernstein lemma. The Cauchy integral formula (22) is the standard tool that provides a link between the matrix or operator $p_n(A)$ and the resolvent $(zI - A)^{-1}$ of A, and this is the main tool that we use in this paper.

Proof of (4) *of Theorem* 1.1. The result follows immediately by applying the proof of Theorem 1.3 to the formula

$$F_n(A) = \frac{1}{2\pi i} \oint_{C_r} w^n \, \Psi'(w) \, (\Psi(w) I - A)^{-1} \, dw, \quad r > 1. \qquad ∎$$

Next we complete the proof of Theorem 1.1 by establishing the inequality (5), which states that the Kreiss constant $\mathcal{K}(\Omega)$ is bounded by the supremum of the norms $\{\|F_n(A)\|\}$. In the case of the standard Kreiss matrix theorem, a proof of such a result depends on the power series expansion of $(zI - A)^{-1}$. Here, the Faber series expansion of $(zI - A)^{-1}$ is required.

LEMMA 4.3. *Suppose* $\Lambda(A) \subset \Omega$. *Then*

$$(zI - A)^{-1} = \sum_{n=0}^{\infty} \frac{\Phi'(z)}{\Phi^{n+1}(z)} F_n(A) \quad \forall\ z \in \Omega^c. \tag{25}$$

Proof. By Theorem 16 in [5, p. 571], (25) is an easy consequence of Lemma 4.1. □

Proof of (5) *of Theorem* 1.1. Suppose $\sup_{n\geq 0} \|F_n(A)\| < \infty$. First we prove that $\Lambda(A) \subset \Omega$. Suppose there exists $\lambda \in \Lambda(A) \cap \Omega^c$. Then

$$\sup_n |F_n(\lambda)| \leq \sup_n \|F_n(A)\| < \infty.$$

But we also have (see [16])

$$\lim_{n\to\infty} |F_n(\lambda)|^{1/n} = |\Phi(\lambda)|,$$

which implies that $\sup_n |F_n(\lambda)| = \infty$ since $|\Phi(\lambda)| > 1$. Thus we have a contradiction. Hence $\Lambda(A) \subset \Omega$.

Now we prove the inequality (5). Let $z \in \Omega^c$ be fixed. Taking norms on both sides of (25) gives

$$\begin{aligned} \|(zI - A)^{-1}\| &\leq \sup_{n\geq 0} \|F_n(A)\| \sum_{k=0}^{\infty} \left| \frac{\Phi'(z)}{\Phi^{n+1}(z)} \right| \\ &= \sup_{n\geq 0} \|F_n(A)\| \frac{|\Phi'(z)|}{|\Phi(z)| - 1}, \end{aligned} \tag{26}$$

and (5) follows from (26). □

An analogue of (5) for a sequence of polynomials $\{p_n : p_n \in P_n\}$ can be derived from (5), but it is much less elegant. We give the result in the next corollary, for the sake of completeness.

COROLLARY 4.1. *Suppose* $\{p_n : p_n \in P_n,\ n \geq 0\}$ *is a sequence of polynomials,* $\Lambda(A) \subset \Omega$, *and* $\sup_{n\geq 0} \|p_n(A)\| < \infty$. *Let* $\mathbf{a}$ *denote the upper triangular array of Faber coefficients associated with* $\{p_n\}$, *i.e., for* $0 \leq k \leq n,\ n = 0, 1, 2, \ldots,$

$$a_{kn} = \frac{1}{2\pi i} \oint_C \frac{p_n(\Psi(w))}{w^{k+1}} dw.$$

If the inverse $\mathbf{b}$ *of* $\mathbf{a}$ *exists and* $\|\mathbf{b}\|_1 := \sup_{n\geq 0} \sum_{k=0}^{n} |b_{kn}| < \infty$, *then*

$$\mathcal{K}(\Omega) \leq \|\mathbf{b}\|_1 \sup_{n\geq 0} \|p_n(A)\|. \tag{27}$$

Proof. Let $\mathcal{P} = \sup\{\|p_n(A)\| : n \geq 0\}$. From the Faber series representation of p_n, we have

$$p_n(A) = \sum_{k=0}^{n} a_{kn} F_k(A), \quad n = 0, 1, 2, \ldots.$$

Thus

$$F_n(A) = \sum_{k=0}^{n} b_{kn}\, p_k(A), \quad n = 0, 1, 2, \ldots,$$
$$\|F_n(A)\| \le \sum_{k=0}^{n} |\, b_{kn}\,|\ \|p_k(A)\| \ \le\ \mathcal{P} \sum_{k=0}^{n} |\, b_{kn}\,|\,.$$

This implies that

$$\sup_{n\ge 0} \|F_n(A)\| \le \mathcal{P}\ \sup_{n\ge 0} \sum_{k=0}^{n} |\, b_{kn}\,|\ =\ \mathcal{P}\ \|\mathbf{b}\|_1.$$

By Theorem 1.1, we have established (27). □

The Kreiss matrix theorem as formulated so far is scaled to the domain Ω. However, it is an easy matter to extend this to the domain Ω_r for any fixed $r \ge 1$ by scaling the conformal map Φ of Ω by r. We conclude this section with a theorem summarizing this extension.

THEOREM 4.1. *Suppose $\Lambda(A) \subset \Omega$ and $\mathcal{K}(\Omega) < \infty$. For each fixed $r \ge 1$, let $\mathcal{K}_r$ be the Kreiss constant with respect to the domain Ω_r. If p_n is a polynomial of degree n and F_n is the nth Faber polynomial associated with Ω, then the following bounds hold for any $n \ge 0$:*

$$\|p_n(A)\| \le e\,(n+1)\, r^n\, \mathcal{K}_r\, \|p_n\|_\Omega; \tag{28}$$

$$\|F_n(A)\| \le e\,(n+1)\, r^n\, \mathcal{K}_r; \tag{29}$$

$$\mathcal{K}_r \le \sup_{n\ge 0}\ \|F_n(A)\|/r^n. \tag{30}$$

In addition,

$$\mathcal{K}_r = \inf\left\{ C\ :\ \|(zI - A)^{-1}\| \ \le\ \frac{C\,|\,\Phi'(z)\,|}{|\,\Phi(z)\,| - r} \quad \forall\ z \notin \Omega_r \right\}, \tag{31}$$

where Φ is the conformal map associated with Ω.

Proof. First, we note that (28) follows from Theorem 1.3 with an application of the Bernstein lemma.

Next we note that the conformal map associated with the domain Ω_r is simply $\Phi(\cdot)/r$. Hence the nth Faber polynomial associated with Ω_r is $F_n(\cdot)/r^n$. With this observation, (29) and (30) follow from Theorem 1.1.

Finally, (31) follows from the definition of $\mathcal{K}_r$. □

5. The Kreiss matrix theorem (II). Let $N = \dim(\mathcal{H})$. In this section, we shall assume that N is finite and that the boundary Γ of Ω is a rectifiable Jordan curve or a slit in the complex plane. We assume further that Γ is of bounded total rotation. The total rotation of Γ, denoted by V, is the total variation in the argument of the tangent to the curve Γ as the curve is described once; see [6, p. 45] for details. If Ω is a convex domain, then V is 2π; if it is a polygon, then V is the total exterior turning angle. A region Ω for which Γ is of bounded total rotation need not have an interior; it might be, for example, the interval $[-1, 1]$ or a circular arc.

The Kreiss matrix theorem of the last section gives an upper bound for $\|F_n(A)\|$ that depends linearly on n. Here we establish another upper bound for $\|F_n(A)\|$ that

depends linearly on N and at most logarithmically on n; if Γ is smooth, it depends only on N. The proof of these results depend on a sequence of lemmas established in Appendix A.

THEOREM 5.1. *Suppose A is a bounded linear operator in a finite-dimensional Hilbert space $\mathcal{H}$ with $\dim(\mathcal{H}) = N$, $\Lambda(A) \subset \Omega$, and $\mathcal{K}(\Omega) < \infty$. Let V be the total rotation of Γ. Then $\forall n \geq 0$,*

$$\|F_n(A)\| \leq \mathcal{K}\, e\, \frac{V}{2\pi}\,(4N\, +\, 1\, +\, \alpha_n), \tag{32}$$

where

$$\alpha_n\ :=\ \frac{2}{V}\int_{|w|=1+1/n} \frac{|\,\Psi''\,|}{|\,\Psi'\,|}|dw|\ \leq\ \frac{4}{\pi}\ [1\, +\, \operatorname{arcsinh}(2n+1)]\,. \tag{33}$$

Proof. As in the proof of Theorem 1.1, we can express $F_n(A)$ in terms of the resolvent of A via the Cauchy integral formula,

$$F_n(A) = \frac{1}{2\pi i}\int_{C_r} w^n\ (\Psi(w)I - A)^{-1}\,\Psi'(w)\,dw \quad \forall\ r > 1.$$

Let u, v be N-vectors such that $\|u\| = \|v\| = 1$. Then

$$v^* F_n(A) u = \frac{1}{2\pi i}\int_{C_r} w^n R(\Psi(w))\,\Psi'(w)\,dw \quad \forall\ \ r > 1, \tag{34}$$

where $R(z) = v^*(zI - A)^{-1}u$. It can be shown that $R(z)$ is a rational function of order $(N-1, N)$ with the characteristic polynomial $\det(zI - A)$ as its denominator (hence $R(z)$ has poles only inside Ω).

Performing integration by parts in (34) gives

$$2\pi i\,(v^*\,F_n(A)\,u) = \frac{-1}{n+1}\int_{C_r} w^{n+1}\frac{d}{dw}\,[R(\Psi(w))\Psi']\ dw,$$

implying that

$$\begin{aligned}|\,2\pi\, v^* F_n(A) u\,| &\leq \frac{r^{n+1}}{n+1}\int_{C_r}\left|\frac{d}{dw}[R(\Psi(w))\Psi']\right|\ |dw| \\ &\leq \frac{r^{n+1}}{n+1}\left[\int_{C_r}|\,\Psi'^2 R'(\Psi)\,|\ |dw|\ +\ \int_{C_r}|\,\Psi'' R(\Psi)\,|\ |dw|\right].\end{aligned} \tag{35}$$

Using the inequality of (58) in Lemma A.1, we get

$$\begin{aligned}|\,2\pi\, v^* F_n(A) u\,| &\leq \frac{r^{n+1}}{n+1}\left[\int_{C_r}|\,h'\,|\,|\,\Psi' R(\Psi)\,|\ |dw|\ +\ 2\int_{C_r}|\,\Psi'' R(\Psi)\,|\ |dw|\right] \\ &\leq \frac{r^{n+1}}{n+1}\,\|R(\Psi)\Psi'\|_{C_r}\left[\int_{C_r}|\,h'\,|\ |dw|\ +\ 2\int_{C_r}\frac{|\,\Psi''\,|}{|\,\Psi'\,|}\,|dw|\right],\end{aligned}$$

where $h(w) = \arg(w\,\Psi'(w)^2\,R'(\Psi(w)))$.

On the contour C_r, $|\,R(\Psi(w))\Psi'(w)\,| \leq \mathcal{K}/(r-1)$. Thus we have

$$|\,2\pi\, v^* F_n(A) u\,| \leq \frac{\mathcal{K}\, r^{n+1}}{(n+1)(r-1)}\left[\int_{C_r}|\,h'\,|\ |dw|\ +\ 2\int_{C_r}\frac{|\,\Psi''\,|}{|\,\Psi'\,|}\,|dw|\right].$$

Taking $r = 1 + 1/n$ and using the inequality of (59) in Lemma A.2, we get

$$|\, v^* F_n(A) u \,| \le \mathcal{K}\, e \left[\frac{V}{2\pi} (4N+1) \;+\; \frac{1}{\pi} \int_{|w|=1+1/n} \frac{|\,\Psi''\,|}{|\,\Psi'\,|} |dw| \right]$$

$$\le \mathcal{K}\, e\, \frac{V}{2\pi} (4N \;+\; 1 \;+\; \alpha_n). \tag{36}$$

Since $\|F_n(A)\|$ is the supremum of $|\, v^* F_n(A) u \,|$ over all unit vectors u and v, (32) follows from (36), and by Lemma A.3, it is easy to show that α_n satisfies the inequality of (33). This completes the proof. □

Ideally, one would like to have a bound that depends only on N in Theorem 5.1, as is the case with the standard Kreiss matrix theorem. However we have been unable to prove such a bound without making a stronger assumption on Γ. If we assume that Γ is *twice continuously differentiable*, then indeed we have a bound that depends only on N. This is the content of Theorem 1.2, whose proof follows easily from Theorem 5.1.

Proof of Theorem 1.2. From Theorem 5.1, we have

$$\|F_n(A)\| \le \mathcal{K}\, e\, \frac{V}{2\pi} (4N + 1 + \alpha), \tag{37}$$

where α is a constant independent of n, defined by

$$\alpha \;:=\; \sup_{n \ge 0} \alpha_n \;=\; \frac{2}{V} \int_C \frac{|\,\Psi''(w)\,|}{|\,\Psi'(w)\,|} \;|\, dw \,|\,. \tag{38}$$

(Note that α_n increases with n.) Under the assumption that Γ is twice continuously differentiable, α is finite, and therefore Theorem 1.2 is proved with

$$C_\Omega = \frac{V}{2\pi} \left(4 \;+\; \frac{1+\alpha}{N} \right). \qquad \square$$

Again, some of the ideas in the proof of Theorem 5.1 are taken from [12].

Like the first version of the Kreiss matrix theorem in the last section, analogous results of Theorem 4.1 scaled to the domain Ω_r can also be established for Theorem 5.1. This goes exactly as before, so we omit stating the results.

6. The Kreiss matrix theorem for the unit interval $[-1, 1]$. We have shown in section 5 that if the boundary of Ω is smooth, then $\|F_n(A)\|$ can be bounded in terms of N, independently of n. For a domain Ω such that the associated conformal map Ψ has the form

$$\Psi(w) = c\, w \;+\; \sum_{k=0}^{p} \frac{c_k}{w^k}, \tag{39}$$

where p is some nonnegative integer, it is also possible to bound $\|F_n(A)\|$ in terms of N, independently of n, even if $\partial\Omega$ is not smooth. In this section, we illustrate how this can be done for the special case $\Omega = [-1, 1]$. With this special case, it should be clear to the reader how an analogous result can be established for the general case.

For the unit interval $\Omega = [-1, 1]$, $\Psi(w)$ and $\Psi'(w)$ are given by

$$\Psi(w) = \frac{1}{2} \left(w + \frac{1}{w} \right), \qquad |w| > 1,$$

$$\Psi'(w) = \frac{1}{2} \left(1 - \frac{1}{w^2} \right).$$

It is well known that for $n \geq 1$, the nth Faber polynomial $F_n(z)$ associated with $[-1,1]$ is given by $F_n(z) = 2T_n(z)$, where $T_n(z) := \cos(n \arccos(z))$ is the nth Chebyshev polynomial. By means of Spijker's lemma, we shall establish a Kreiss matrix theorem for $[-1,1]$, giving a bound for $\|T_n(A)\|$ in terms of N. We state Spijker's lemma first and then prove the Kreiss matrix theorem.

LEMMA 6.1 (Spijker's lemma). *Suppose R is a rational function of order N. For any $r > 0$ such that R has no poles on C_r, there holds*

$$\int_{C_r} |R'(w)|\,|dw| \leq 2\pi N \,\|R\|_{C_r}.$$

Proof. See [17] or [20]. □

THEOREM 6.1. *Suppose A is a bounded linear operator in a finite-dimensional Hilbert space H with $\dim(\mathcal{H}) = N$, $\Lambda(A) \subset [-1,1]$, and $\mathcal{K}(\Omega) < \infty$. Then*

$$\|T_n(A)\| \leq e\,(N+1)\,\mathcal{K}(\Omega), \tag{40}$$

where $T_n(z) = \cos(n \arccos(z))$, for $n = 1, 2, \ldots$. Consequently,

$$\sup_{n \geq 0} \|T_n(A)\| \leq e\,(N+1)\,\mathcal{K}(\Omega). \tag{41}$$

Proof. For any unit N-vectors u and v, we have, as in (35),

$$\begin{aligned} |\,2\pi v^*(2T_n(A))u\,| &\leq \frac{r^{n+1}}{n+1} \int_{C_r} \left| \frac{d}{dw}[R(\Psi(w))\Psi'(w)] \right| |dw| \\ &= \frac{r^{n+1}}{n+1} \int_{C_r} |q'(w)|\,|dw|, \end{aligned}$$

where R is a rational function of order $(N-1, N)$ and $q(w) = R(\Psi(w))\Psi'(w)$. Since Ψ and Ψ' are rational functions of order $(2,1)$ and $(2,2)$, respectively, it is readily shown that q is a rational function of order $(2N+1, 2N+2)$. Applying Spijker's lemma to the rational function q and noting that $\|q\|_{C_r} \leq \mathcal{K}/(r-1)$ on the contour $C_r = \{w : |w| = r\}$, we obtain

$$|\,v^* T_n(A) u\,| \leq \frac{r^{n+1}}{(n+1)(r-1)}\,(N+1)\,\mathcal{K}. \tag{42}$$

Now (40) follows by taking $r = 1 + 1/(n+1)$ in (42). □

Next we give an example, analogous to a similar example in [12] for the standard Kreiss matrix theorem, to show that the linear dependence N in (41) is sharp.

Consider the $N \times N$ matrix

$$A = \begin{bmatrix} x_1 & \gamma & & & \\ & \ddots & \ddots & & \\ & & & x_{N-1} & \gamma \\ & & & & x_N \end{bmatrix}, \tag{43}$$

where γ is a positive real number greater than 3 and

$$x_i = \cos\left(\frac{i-1}{N-1}\pi\right), \quad i = 1, \ldots, N. \tag{44}$$

For this particular matrix, we have

$$(45)\quad (zI-A)^{-1} = \begin{bmatrix} \dfrac{1}{z-x_1} & \dfrac{\gamma}{\prod_{i=1}^{2}(z-x_i)} & \cdots & \dfrac{\gamma^{N-1}}{\prod_{i=1}^{N}(z-x_i)} \\ & \ddots & & \vdots \\ & & \dfrac{1}{z-x_{N-1}} & \dfrac{\gamma}{\prod_{i=N-1}^{N}(z-x_i)} \\ & & & \dfrac{1}{z-x_N} \end{bmatrix}$$

and

$$T_n(A) = \frac{1}{2\pi i}\int T_n(z)(zI-A)^{-1}dz$$

$$= \frac{1}{2\pi i}\begin{bmatrix} \displaystyle\int \frac{T_n(z)}{(z-x_1)}dz & \cdots & \displaystyle\int \frac{\gamma^{N-1}\,T_n(z)}{\prod_{i=1}^{N}(z-x_i)}dz \\ & \ddots & \vdots \\ & & \displaystyle\int \frac{T_n(z)}{(z-x_N)}dz \end{bmatrix}$$

$$(46)\qquad = \begin{bmatrix} T_n[x_1] & \gamma T_n[x_1,x_2] & \cdots & \gamma^{N-1}\,T_n[x_1,\cdots,x_N] \\ & \ddots & & \vdots \\ & & T_n[x_{N-1}] & \gamma\,T_n[x_{N-1},x_N] \\ & & & T_n[x_N] \end{bmatrix},$$

where $T_n[x_i,\ldots,x_j]$ denotes the divided difference of the polynomial T_n with respect to the points $x_i,\ldots,x_j$.

To show that the linear dependence on N in (41) is sharp, we need to establish a result of the form $\sup_{n\geq 0}\|T_n(A)\| \geq c\,N\,\mathcal{K}$ for some constant c independent of N.

THEOREM 6.2. *For the matrix A of* (43)*, we have*

$$(47)\qquad \frac{\gamma-3}{2\pi\gamma}\,(N-1)\,\mathcal{K} \leq \sup_{n\geq 0}\,\|T_n(A)\|,$$

where $T_n(z)=\cos(n\cos^{-1}(z))$, $z\in[-1,1]^c$.

Proof. For readability, we divide the proof into three parts.

(a) It is clear that

$$\sup_{n\geq 0}\,\|T_n(A)\| \geq \|T_{N-1}(A)\|$$

$$(48)\qquad \geq \gamma^{N-1}\,T_{N-1}[x_1,\ldots,x_N] \;=\; \gamma^{N-1}\,2^{N-2}.$$

(b) We need an upper bound for $\mathcal{K}$. But first we must obtain an upper bound for $\|(zI-A)^{-1}\|_2$, where $z\in[-1,1]^c$. For this purpose, we shall use the inequality

$$\|(zI-A)^{-1}\|_2^2 \leq \|(zI-A)^{-1}\|_1\,\|(zI-A)^{-1}\|_\infty.$$

It is easily shown that

$$\|(zI-A)^{-1}\|_1 = \frac{1}{\gamma}\sum_{k=1}^{N}\prod_{i=N-k+1}^{N}\frac{\gamma}{|z-x_i|}, \tag{49}$$

$$\|(zI-A)^{-1}\|_\infty = \frac{1}{\gamma}\sum_{k=1}^{N}\prod_{i=1}^{k}\frac{\gamma}{|z-x_i|}. \tag{50}$$

Now consider the region E defined by

$$E = \{z \in \mathbb{C} : |z-x_i| \le 3 \quad \forall\, i = 1,\ldots,N\}.$$

Noting that if $z \in E^c$, then $|z-x_i| \ge 1$ for all $i = 1,\ldots,N$, and with some algebraic manipulations in (49) and (50), we obtain

$$\|(zI-A)^{-1}\|_1\,,\ \|(zI-A)^{-1}\|_\infty \ \le\ \begin{cases} \dfrac{\gamma^N}{(\gamma-1)\,\mathrm{dist}(z,\Omega)} & \text{if } z \in E^c, \\ \dfrac{1}{(\gamma-3)}\ \dfrac{\gamma^N}{\prod_{i=1}^{N}|z-x_i|} & \text{if } z \in E\cap[-1,1]^c. \end{cases}$$

Therefore

$$\|(zI-A)^{-1}\|_2 \ \le\ \begin{cases} \dfrac{\gamma^N}{(\gamma-1)\,\mathrm{dist}(z,\Omega)} & \text{if } z \in E^c, \\ \dfrac{1}{(\gamma-3)}\ \dfrac{\gamma^N}{\prod_{i=1}^{N}|z-x_i|} & \text{if } z \in E\cap[-1,1]^c. \end{cases} \tag{51}$$

(c) Finally, recall that $\tilde{\mathcal{K}}$ is the supremum of the function $\mathrm{dist}(z,\Omega)\,\|(zI-A)^{-1}\|_2$ over the region $[-1,1]^c$. From (51), we get

$$\tilde{\mathcal{K}} \ \le\ \frac{\gamma^N}{\gamma-3}\ \max\left\{\sup_{z\in[-1,1]^c}\ \frac{\mathrm{dist}(z,\Omega)}{\prod_{i=1}^{N}|z-x_i|},\ 1\right\} \ =\ \pi\,\frac{\gamma^N}{\gamma-3}\,\frac{2^{N-2}}{N-1}, \tag{52}$$

where (52) follows from Lemma 6.2. Comparing (48) and (52), we get

$$\tilde{\mathcal{K}}\,(N-1)\,\frac{\gamma-3}{\pi\gamma} \le \sup_{n\ge 0}\|T_n(A)\|. \tag{53}$$

By Theorem 3.2, $\mathcal{K} \le 2\,\tilde{\mathcal{K}}$, and thus (47) follows from (53). ∎

The next lemma is a technical result used in the proof of Theorem 6.2. The reader is encouraged to skip the proof.

LEMMA 6.2. *Suppose* $\Omega = [-1,1]$ *and* x_i, $i = 1,\ldots,N$, *are given as in* (44). *If* $N \ge 3$, *then* $\forall z \in \Omega^c$,

$$\frac{\mathrm{dist}(z,\Omega)}{\prod_{i=1}^{N}|z-x_i|} \le \pi\,\frac{2^{N-2}}{N-1}. \tag{54}$$

Proof. First we note that the zeros of $T'_{N-1}(z)$ are the extrema $x_2,\ldots,x_{N-1}$ of $T_{N-1}(z)$ in the open interval $(-1,1)$. Thus

$$T'_{N-1}(z) = (N-1)\,2^{N-2}\prod_{i=2}^{N-1}(z-x_i).$$

We shall make use of this equation without explicitly referring to it in this proof. Note also that $|T'_{N-1}(1)| = (N-1)^2$.

We shall prove (54) for z in two separate regions, E and F, to be defined below. Note that by symmetry, it is sufficient to consider these two regions.

(a) Let E be the region defined by

$$E = \{z = x + iy \,:\, x \geq 1, y \in \mathbb{R}\}.$$

For $z \in E$, $\operatorname{dist}(z, \Omega) = |z - 1|$, and thus

$$\frac{\operatorname{dist}(z,\Omega)}{\prod_{k=1}^{N} |z - x_k|} = \frac{1}{\prod_{k=2}^{N} |z - x_k|}. \tag{55}$$

Since $1/\prod_{k=2}^{N}(z - x_k)$ is an analytic function in the interior of E and continuous in E, it is sufficient to show that for $z \in \partial E = \{1 + iy \,:\, y \in \mathbb{R}\}$, the function of (55) satisfies the bound of (54). Let $f(y)$ be the function defined by

$$f(y) = \frac{1}{\prod_{k=2}^{N} |(1 - x_k) + iy|}, \qquad y \in \mathbb{R}.$$

Elementary calculus shows that $y = 0$ is the maximizer of f and

$$f(0) \;=\; \frac{(N-1)\,2^{N-3}}{|T'_{N-1}(1)|} \;=\; \frac{2^{N-3}}{(N-1)}. \tag{56}$$

This establishes (54) for $z \in E$.

(b) Let $\theta = \pi/(N-1)$ and $I_j = [\xi_j,\ \xi_{j-1}]$, $j = 1, \ldots, N$, where $\xi_0 = 1$, $\xi_N = -1$, $\xi_j = \cos(j - \frac{1}{2})\theta$ for $j = 1, \ldots, N-1$.

Now consider the region $F = \{x + iy \,:\, -1 \leq x \leq 1,\ y > 0\}$. It is clear that $F = \cup_{j=1}^{N} F_j$, where

$$F_j \;=\; \{x + iy \,:\, x \in I_j,\ y > 0\}.$$

For $z = x + iy \in F_j$, we have

$$\frac{\operatorname{dist}(z,\Omega)}{\prod_{k=1}^{N} |z - x_k|} \;\leq\; \frac{1}{g_j(x)} \;\leq\; \frac{1}{\min_{x \in I_j} g_j(x)},$$

where $g_j(x)$, $x \in (x_{j+1},\ x_{j-1})$, is the function defined by

$$\begin{aligned} g_j(x) &:= \prod_{k=1,\, k \neq j}^{N} |x - x_k| \\ &= \frac{T'_{N-1}(x)}{(N-1)\,2^{N-1}} \, \frac{|1 - x^2|}{|x - x_j|}. \end{aligned}$$

It is easy to see that $g_j(x)$ has the form shown in Figure 5 in the interval (x_{j+1}, x_{j-1}) and the minimizer of g_j in the interval I_j is located at the end points of I_j. With some tedious algebra, it can be shown that

$$\min_{x \in I_j} g_j(x) = \min(g_j(\xi_{j-1}),\ g_j(\xi_j)) \;=\; g_j(\xi_{j-1})$$

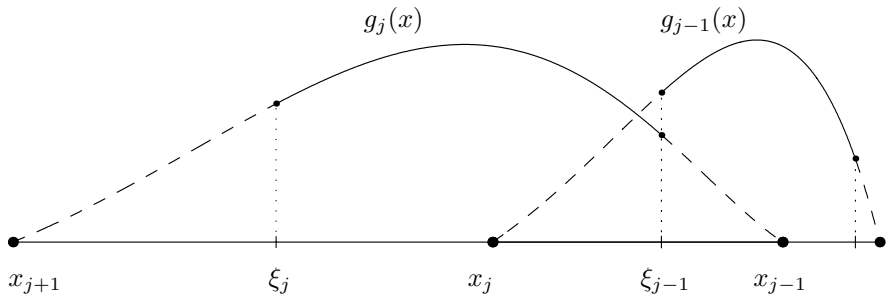

FIG. 5. *Proof of Lemma* 6.2.

$$
\begin{aligned}
&= \frac{1}{2^{N-1}} \, \frac{\sin(j-\frac{3}{2})\theta}{\sin\theta/4 \, \sin(j-\frac{5}{4})\theta} \\
&\geq \frac{1}{2^{N-1}} \, \frac{\sin\theta/2}{\sin\theta/4 \, \sin 3\theta/4} \\
&\geq \frac{1}{2^{N-1}} \, \frac{8}{3\theta} \;\geq\; \frac{(N-1)}{2^{N-2}} \, \frac{1}{\pi}. \qquad (57)
\end{aligned}
$$

By (57), we have established (54) for $z \in F_j$, $j = 1, \ldots, N$. This completes the proof. ∎

7. Discussion. We have generalized the Kreiss matrix theorem from the unit disk to a general complex domain, giving bounds for the associated Faber polynomials as well as for arbitrary polynomials. There are other generalizations of the Kreiss matrix theorem in the literature, in particular for the purpose of linear stability analysis of semidiscrete methods for time-dependent PDEs. In these problems, one is concerned with the boundedness of $\{\|\phi(\delta t\, A)^n\|\}$, where ϕ is a fixed rational function determined by the time-discretization scheme, A is determined by the space discretization scheme, and δt is the time step. The Kreiss matrix theorem has been generalized to the stability region S associated with the time-discretization scheme by a transplantation of the Kreiss matrix theorem from the unit disk to S [14]. Such a result is prototypical of the kind of generalizations of the Kreiss matrix theorem to regions in the complex plane for the purpose of linear stability analysis. For more details in this subject, see the survey article by van Dorsselaer, Kraaijevanger, and Spijker [3]. In the special case when ϕ is a fixed polynomial, our generalized Kreiss matrix theorems give the same results as those obtained from the transplantation technique, except for some technical differences.

We end with a note on the case when Ω consists of several connected components each bounded by a Jordan curve. We believe that analogues of our Kreiss matrix theorems can be established for this case. The main reason is that results such as the Bernstein lemma and the Cauchy integral formula that we have used in establishing our Kreiss matrix theorems continue to hold for this more general Ω; see [5], [21], [22].

Appendix A.

In this appendix, we present a sequence of lemmas whose results are applied in the proof of Theorem 5.1. The reader may skip these lemmas without any loss of understanding.

LEMMA A.1. *Suppose f is a analytic function defined in Ω^c. Then for each*

$r > 1$,

$$\int_{C_r} \left|\Psi'^2 f'(\Psi)\right| |dw| \le \int_{C_r} |h'|\,|\Psi' f(\Psi)|\ |dw| \ + \ \int_{C_r} |\Psi'' f(\Psi)|\ |dw|, \tag{58}$$

where $h(w) = \arg\left[w\Psi'^2(w) f'(\Psi(w))\right]$.

Proof. It is readily shown that

$$\begin{aligned}\int_{C_r} \left|\Psi'^2 f'(\Psi)\right| |dw| &= -i \int_{C_r} \Psi'(w) \frac{df(\Psi(w))}{dw} e^{-ih(w)} dw \\ &= -i \int_{C_r} \Psi'(w) e^{-ih(w)}\, df(\Psi(w)).\end{aligned}$$

Integration by parts gives

$$\int_{C_r} \left|\Psi'^2 f'(\Psi)\right| |dw| = \int_{|w|=r} h'\Psi' f(\Psi) e^{-ih} dw \ + \ i \int_{|w|=r} \Psi'' f(\Psi) e^{-ih} dw.$$

From this equation, (58) follows readily. □

LEMMA A.2. *Suppose R is a rational function of order $(N-1, N)$ with no poles inside Ω^c. Then*

$$\int_{C_r} |h'(w)|\,|dw| \le (4N+1)V \quad \forall\ r > 1, \tag{59}$$

where $h(w) = \arg\left[w\Psi'^2(w) R'(\Psi(w))\right]$.

Proof. Since R is a rational function of order $(N-1, N)$, this implies that R' is a rational function of order $(2N-2, 2N)$. Hence $R'(\Psi)$ can be written as a product

$$R'(\Psi(w)) = \prod_{k=1}^{2N-2} (a_k \Psi(w) + b_k) \prod_{k=2N-1}^{4N-2} \frac{1}{(a_k \Psi(w) + b_k)}.$$

This implies that

$$h(w) \ = \ 2\arg(w\Psi'(w)) \ - \ \arg w \ + \ \sum_{k=1}^{2N-2} \arg\left(a_k \Psi(w) + b_k\right) \ - \ \sum_{k=2N-1}^{4N-2} \arg\left(a_k \Psi(w) + b_k\right).$$

Therefore the total variation $\mathrm{TV}[h]$ of h around the circle C_r satisfies

$$\begin{aligned}\mathrm{TV}[h] &\le 2\,\mathrm{TV}[\arg(w\Psi'(w))] \ + \ \mathrm{TV}[\arg w] \ + \ \sum_{k=1}^{2N-2} \mathrm{TV}\left[\arg\left(a_k \Psi(w) + b_k\right)\right] \\ &\quad + \sum_{k=2N-1}^{4N-2} \mathrm{TV}\left[\arg\left(a_k \Psi(w) + b_k\right)\right] \\ &= 2\,\mathrm{TV}[\arg(w\Psi'(w))] \ + \ 2\pi \ + \ \sum_{k=1}^{4N-2} \mathrm{TV}\left[\arg\left(\Psi(w) + \gamma_k\right)\right],\end{aligned}$$

where $\gamma_k = b_k/a_k$.

Now by Lemma 1 of [8],

$$\mathrm{TV}[\arg(\Psi(w) + \gamma)] \le \mathrm{TV}[\arg(w\Psi'(w))] \quad \forall\ \ \gamma \in \mathbb{C}.$$

Thus

$$\mathrm{TV}[h] \le 4N\ \mathrm{TV}[\arg(w\Psi'(w))]\ +\ 2\pi. \tag{60}$$

Noting that $\mathrm{TV}[\arg(w\Psi'(w))]$ is the total variation in the argument of the tangent to the curve Γ_r as the curve is described counterclockwise once, and by definition, this is the total rotation $V(\Gamma_r)$ of Γ_r. It follows from (60) that

$$\mathrm{TV}[h]\ \le\ 4N\,V(\Gamma_r)\ +\ 2\pi\ \le\ (4N\ +\ 1)\,V(\Gamma_r).$$

It is known that $V(\Gamma_r) \le V\ \forall\ r > 1$ (see [10]). Thus we have established (59). ∎

LEMMA A.3. *For each $r > 1$,*

$$\int_{C_r} \frac{|\,\Psi''(w)\,|}{|\,\Psi'(w)\,|}|dw| \le \frac{2V}{\pi}\left[1 + \operatorname{arcsinh}\left(\frac{r+1}{r-1}\right)\right]. \tag{61}$$

Proof. From Lemma 5 of [10, p. 202], we have

$$\log\Psi'(w) = \frac{1}{\pi}\int_0^{2\pi} \log\left(1 - \frac{e^{i\theta}}{w}\right) du(\theta) \quad \forall\ \ |\,w\,| > 1, \tag{62}$$

where $u(\theta)$ is a function of bounded variation such that $\int_0^{2\pi}\ |\,du(\theta)\,| = V$. Differentiating (62) with respect to w gives

$$\frac{\Psi''(w)}{\Psi'(w)} = \frac{1}{\pi w}\int_0^{2\pi} \frac{e^{i\theta}}{w - e^{i\theta}}\, du(\theta).$$

Thus

$$\begin{aligned}\int_{C_r} \frac{|\,\Psi''(w)\,|}{|\,\Psi'(w)\,|}|dw| &\le \frac{1}{\pi r}\int_0^{2\pi}\int_{|w|=r} \frac{|dw|}{|\,w - e^{i\theta}\,|}\ |\,du(\theta)\,| \\ &\le \frac{4V}{\pi(r+1)}\left[1 + \operatorname{arcsinh}\left(\frac{r+1}{r-1}\right)\right], \end{aligned} \tag{63}$$

because

$$\int_{C_r} \frac{|dw|}{|\,w - e^{i\theta}\,|} = \frac{4r}{r+1}\left[1 + \operatorname{arcsinh}\left(\frac{r+1}{r-1}\right)\right].$$

Since $r > 1$, (61) follows from (63). ∎

Acknowledgments. We are grateful to Professor R. Kühnau for providing us the proof of Theorem 3.1 and to D. Gaier for helpful comments on a draft of this paper.

SOLVING GENERALIZED LEAST-SQUARES PROBLEMS WITH LSQR*

STEVEN J. BENBOW†

Abstract. An iterative method for solving augmented linear systems in a generalized least-squares sense is given. The method, LSQR(A^{-1}), is shown to be a natural extension of the LSQR algorithm of Paige and Saunders [*ACM Trans. Math. Software*, 8 (1982), pp. 43–71], with generalized orthogonality properties so that the Cholesky factor of A is not required. Instead it is only assumed that some method of calculating the effect of A^{-1} on a vector is available. Numerical experiments comparing LSQR(A^{-1}) with similar preconditioned Krylov methods are described which demonstrate that the new method exhibits superior numerical properties when the Schur complement $B^TA^{-1}B$ is ill conditioned.

1. Introduction.

Linear systems of the form

$$\begin{bmatrix} A & B \\ B^T & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} b \\ 0 \end{bmatrix}, \tag{1.1}$$

where the matrices $A \in \mathbb{R}^{n\times n}$ and $B \in \mathbb{R}^{n\times m}$ $(n \geq m)$ are large and sparse, A is symmetric positive definite, and B is of full column rank, arise frequently in the numerical solution of problems in applied mathematics. Two classic examples from computational fluid dynamics which give rise to such systems are Darcy's law for incompressible flow in a saturated medium,

$$\frac{\mu}{k}u + \nabla p = 0, \qquad \nabla \cdot u = 0,$$

and the steady Stokes' equations for incompressible flow,

$$-\mu\triangle u + \nabla p = f, \qquad \nabla \cdot u = 0,$$

both in 2- or 3D together with some appropriate boundary conditions. Here the variable x of (1.1) represents the discretized velocity u, and y represents the discretized pressure p. The constant μ is the fluid viscosity and k is a discontinuous permeability function that is assumed to be piecewise constant. The equations are typically discretized using finite difference or finite element methods.

It can be seen (section 2) that the y component of the solution of (1.1) is the solution of the *generalized least-squares* problem

$$\textit{minimize}_{\ p\in\mathbb{R}^m} \|Bp - b\|_{A^{-1}}. \tag{1.2}$$

†Quintessa Ltd., Bix Manor, Broadplat Lane, Bix, Henley-on-Thames, Oxfordshire, RG9 4RS, UK (stevenbenbow@quintessa.ltd.uk).

The LSQR algorithm [9] introduced in section 3 is a method for solving (linear) least-squares problems of the form *minimize* $_{p\in\mathbb{R}^m}\|Cp-c\|$, where $\|\cdot\|$ is used to denote the Euclidean norm. LSQR could be used naïvely to solve the generalized least-squares problem above, if the Cholesky factorization $A = LL^T$ were known, upon setting $C = L^{-1}B$ and $c = L^{-1}b$. This approach would require one operation with each of L^{-1} and L^{-T} per iteration step since C and C^T are both involved in LSQR. In section 4, it is shown that a variation of the LSQR algorithm exists that can be applied to the generalized least-squares problem in which the solves with L and L^T are replaced with a single solve with A. In cases where the level of fill-in in L is high, operations involving L can be expensive whereas an iterative method which calculates the effect of A^{-1} using only operations involving A can be relatively inexpensive. It is essential that L be computed accurately if it is to be used to form a linear least-squares problem as described above. This can be impractical if A is large. However, if a good preconditioner for A is known it may still be reasonable to expect to be able to operate with A^{-1}.

For example, consider the case when $A := A_M$ is the mass matrix associated with a piecewise linear finite element basis on an arbitrary triangular grid. Wathen [11] has shown that if $D = \mathrm{diag}(A)$, then $\kappa := \kappa(D^{-1}A) = 4$, so that the diagonally preconditioned conjugate gradient method applied to systems with coefficient matrix A will converge quickly at a rate independent of the mesh parameter. The matrix A representing the discretization of the μ/k operator is often badly scaled because the discontinuous permeability function can vary over several orders of magnitude. However, it is easy to show that $\kappa(D^{-1}A)$ (where $D = \mathrm{diag}(A)$) satisfies the same bound as the equivalent diagonally preconditioned mass matrix given in [11]. Hence the matrix A appearing in discretizations of Darcy's law can be preconditioned to be independent of k (and independent of the mesh parameter for suitable choices of finite elements). For a Stokes problem it may be the case that A^{-1} can be performed cheaply using FFT methods.

If it is assumed that it is possible to calculate the effect of A^{-1}, an obvious method of solving (1.1) is to solve the Schur complement system

$$B^TA^{-1}By = B^TA^{-1}b \tag{1.3}$$

and then recover x. In section 5, this approach is compared with the generalized least-squares approach outlined above.

2. The generalized least-squares connection. Notice that x can be eliminated from (1.1) to form (1.3), an equation in y only. From (1.3),

$$q^TB^TA^{-1}By = q^TB^TA^{-1}b \quad \forall q \in \mathbb{R}^m,$$

so that, on defining the inner-product $\langle\cdot\ ,\ \cdot\rangle$ on $\mathbb{R}^n$ by $\langle u\ ,\ v\rangle = u^TA^{-1}v$, (1.3) can be reformulated as

$$\textit{find } y \in \mathbb{R}^m \textit{ such that} \quad \langle Bq\ ,\ By\rangle = \langle Bq\ ,\ b\rangle \quad \forall q \in \mathbb{R}^m. \tag{2.1}$$

Setting $r = b - By$ implies that if y solves (2.1), $\langle Bq\ ,\ r\rangle = 0 \quad \forall q \in \mathbb{R}^m$, so that the residual r is orthogonal to the span of the columns of B, denoted span(B), with respect to $\langle\cdot\ ,\ \cdot\rangle$. This condition implies that By is the closest representation of b in span(B) with respect to the norm induced by $\langle\cdot\ ,\ \cdot\rangle$, i.e., that y is determined by the generalized least-squares problem

$$\textit{find } y \in \mathbb{R}^m \textit{ such that } \min_{q\in\mathbb{R}^m}\|b-Bq\|_{A^{-1}} = \|b-By\|_{A^{-1}}, \tag{2.2}$$

where $\|u\|_{A^{-1}} = \langle u\ ,\ u\rangle^{\frac{1}{2}} = (u^T A^{-1} u)^{\frac{1}{2}}$. The reverse argument, that (2.2) is equivalent to (1.3), can be seen by minimizing the functional $F(q) = \frac{1}{2}\|b - Bq\|^2_{A^{-1}}$.

3. Golub–Kahan bidiagonalization and LSQR. Before considering solving generalized least-squares problems, an introduction to the LSQR algorithm [9] is given. The LSQR algorithm can be seen to have its roots buried in the Lanczos process [6]. In section 3.1 the Lanczos process is reintroduced, and in section 3.2 it is explained how Golub and Kahan used the Lanczos process to reduce a given matrix to bidiagonal form [3] and how Paige and Saunders extended this bidiagonalization process to form an iterative solution method for least-squares problems [9].

3.1. The Lanczos Process. Given a symmetric matrix M and a starting vector b, the Lanczos process [6] reduces M to tridiagonal form as follows.

The Lanczos Process.
Set $\hat{\beta}_1 \hat{v}_1 = b$,
For $i = 1, 2, \ldots,$

$$\begin{aligned} w_i &= M\hat{v}_i - \hat{\beta}_i \hat{v}_{i-1}, \\ \hat{\alpha}_i &= \hat{v}_i^T w_i, \\ \hat{\beta}_{i+1}\hat{v}_{i+1} &= w_i - \hat{\alpha}_i \hat{v}_i, \qquad \text{where } \hat{\beta}_{j+1} > 0 \text{ and } \|\hat{v}_{j+1}\| = 1. \end{aligned}$$

Here $\hat{v}_0 := 0$. These recurrences can be written more succinctly as

$$M\hat{V}_k = \hat{V}_k T_k + \hat{\beta}_{k+1}\hat{v}_{k+1} e_k^T = \hat{V}_{k+1} H_k, \tag{3.1}$$

where $\hat{V}_k = [\hat{v}_1, \ldots, \hat{v}_k]$,

$$T_k = \begin{bmatrix} \hat{\alpha}_1 & \hat{\beta}_2 & & & \\ \hat{\beta}_2 & \hat{\alpha}_2 & \hat{\beta}_3 & & \\ & \cdot & \cdot & \cdot & \\ & & \cdot & \cdot & \hat{\beta}_k \\ & & & \hat{\beta}_k & \hat{\alpha}_k \end{bmatrix}, \text{ and } H_k = \begin{bmatrix} T_k \\ \hat{\beta}_{k+1} e_k^T \end{bmatrix}.$$

The set $\{\hat{v}_i\}_{i=1}^k$ can be seen to be constructed so that $\hat{v}_i^T \hat{v}_j = \delta_{ij}$ (in the absence of rounding error) so that $\hat{V}_k^T \hat{V}_k = I_k$.

Many iterative solution methods for the system $Mz = f$ can be derived from the Lanczos process. For example, if $\hat{p}_k$ is the solution of the system

$$T_k \hat{p}_k = \hat{\beta}_1 e_1 \tag{3.2}$$

and if $z_k := \hat{V}_k \hat{p}_k$, then (3.1) gives $Mz_k = f + \hat{\beta}_{k+1}\hat{\eta}_k \hat{v}_{k+1}$, where η_k is the last entry in $\hat{p}_k$. Hence, z_k will solve $Mz = f$ whenever $\hat{\beta}_{k+1}\hat{\eta}_k$ is negligible. When M (and therefore T_k) is positive definite, using Cholesky decompositions to solve (3.2) is equivalent to the conjugate gradient method [5]. Solving subproblems with H_k as coefficient matrix are the basis of the SYMMLQ and MINRES algorithms (see [8, 10]).

3.2. Golub–Kahan bidiagonalization and LSQR. In [3], the Lanczos process is applied to the coefficient matrix, denoted $\mathcal{A}_{LS}$, in the problem

$$\begin{bmatrix} I & B \\ B^T & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} b \\ 0 \end{bmatrix} \tag{3.3}$$

to generate a bidiagonal matrix, E, having the same singular values as B. Applying the Lanczos process to $\mathcal{A}_{LS}$ with starting vector $[b^T \;\; 0^T]^T$, it can be seen that the orthonormal vectors $\hat{v}_i$ are of the form

$$\hat{v}_i =: \begin{cases} \begin{bmatrix} u_j \\ 0 \end{bmatrix} & i = 2j-1, \quad j \in \mathbb{N}, \\ \\ \begin{bmatrix} 0 \\ v_j \end{bmatrix} & i = 2j, \quad j \in \mathbb{N}, \end{cases} \tag{3.4a}$$

and that

$$\hat{\alpha}_i = \begin{cases} 1 & i = 2j-1, \quad j \in \mathbb{N}, \\ 0 & i = 2j, \quad j \in \mathbb{N}. \end{cases} \tag{3.4b}$$

Notice that since $\{\hat{v}_i\}_{i=1}^{k}$ is an orthonormal set, both $\{u_j\}_{j=1}^{[\frac{k+1}{2}]}$ and $\{v_j\}_{j=1}^{[\frac{k}{2}]}$ are orthonormal sets. Renaming the $\hat{\beta}_i$'s as

$$\hat{\beta}_i =: \begin{cases} \beta_j & i = 2j-1, \quad j \in \mathbb{N}, \\ \alpha_j & i = 2j, \quad j \in \mathbb{N} \end{cases} \tag{3.4c}$$

allows the Lanczos process on $\mathcal{A}_{LS}$ to be expressed in the following form, to be referred to as the Golub–Kahan lower-bidiagonalization procedure (GKLB).

The Golub–Kahan Lower-Bidiagonalization Procedure (GKLB).
Set $\beta_1 u_1 = b, \quad \alpha_1 v_1 = B^T u_1$,
For $j = 1, 2, \ldots,$

$$\begin{aligned} \beta_{j+1} u_{j+1} &= B v_j - \alpha_j u_j, && \text{where } \beta_{j+1} > 0 \text{ and } \|u_{j+1}\| = 1, \\ \alpha_{j+1} v_{j+1} &= B^T u_{j+1} - \beta_{j+1} v_j, && \text{where } \alpha_{j+1} > 0 \text{ and } \|v_{j+1}\| = 1. \end{aligned}$$

One step of GKLB is equivalent to performing two Lanczos steps on $\mathcal{A}_{LS}$ but requires only two multiplications with B, as opposed to four, because of relations (3.4a–3.4c). Defining $U_l = [u_1, \ldots, u_l]$ and $V_l = [v_1, \ldots, v_l]$ allows the recurrence relations of GKLB to be expressed as

$$\begin{aligned} U_{l+1}(\beta_1 e_1) &= b, \\ B V_l &= U_{l+1} E_l, \\ B^T U_{l+1} &= V_l E_l^T + \alpha_{l+1} v_{l+1} e_{l+1}^T, \end{aligned} \qquad \text{where} \quad E_l = \begin{bmatrix} \alpha_1 & & & \\ \beta_2 & \alpha_2 & & \\ & \cdot & \cdot & \\ & & \cdot & \alpha_l \\ & & & \beta_{l+1} \end{bmatrix}.$$

The lower-bidiagonal matrix E_l represents the restriction of B to the space spanned by the columns of V_l with respect to the basis formed by the columns of U_{l+1}.

The solution of the system (3.3) is now considered. Permuting rows and columns of the tridiagonal matrix T_k, it can be seen that the Lanczos subproblem (3.2) with $k = 2l + 1$ corresponds to

$$\begin{bmatrix} I & E_l \\ E_l^T & 0 \end{bmatrix} \begin{bmatrix} s_{l+1} \\ t_l \end{bmatrix} = \beta_1 \begin{bmatrix} e_1 \\ 0 \end{bmatrix},$$

where $\begin{bmatrix} s_{l+1}^T & t_l^T \end{bmatrix}^T$ is the permutation of $\hat{p}_{2l+1}$. Hence t_l is the solution of the least-squares problem

$$\textit{minimize}_{\; t \in \mathbb{R}^l} \|E_l t - \beta_1 e_1\|, \tag{3.5}$$

and $y_l = V_l t_l$, $x_l = U_{l+1} s_{l+1}$ are approximations to y and x from the spans of V_l and U_{l+1}, respectively. Paige and Saunders [9] showed that (3.5) can be easily solved at negligible cost using (updateable) QR decompositions of the matrices E_l. (See section 4.2 for a listing of the algorithm.)

4. Solution of generalized least-squares problems. In section 4.1, the bidiagonalization procedure GKLB is used to obtain a bidiagonalization procedure for B with new orthogonality properties. In the same way that LSQR was constructed from GKLB, an iterative solution method for the generalized least-squares problem (2.2) will then be derived from the new bidiagonalization procedure in section 4.2.

4.1. A bidiagonalization procedure with a different inner product. Typically, to solve (2.2) it is first assumed that the Cholesky factorization $A = LL^T$, where L is lower-triangular, is available. Then the problem (2.2) can be recast as the linear least-squares problem

$$\text{find } y \in \mathbb{R}^m \text{ such that } \min_{p \in \mathbb{R}^m} \|L^{-1}(b - Bp)\| = \|L^{-1}(b - By)\|, \tag{4.1}$$

which is then solved using any favorite method for linear least-squares. An example of solving (2.2) in this way is given in [7]. From section 2, it is obvious that (4.1) is equivalent to the linear system (3.3) with B and b replaced by $L^{-1}B$ and $L^{-1}b$, respectively, so clearly LSQR could be the method used to solve (4.1). However there is another way in which an LSQR-type method can be applied to solve (2.2) without using the Cholesky factor of A, which sacrifices some of the Euclidean orthonormality properties of the LSQR vectors for a similar orthonormality condition.

The GKLB procedure can be applied with the operator $L^{-1}B$ and with the transformed vector $w_i = Mu_i$ (where the choice of the nonsingular matrix M will be discussed shortly). Since the vectors $\{u_i\}$ form an orthonormal set,

$$w_i^T \left(MM^T\right)^{-1} w_j = \delta_{ij}. \tag{4.2}$$

Judicious choices for M are $M \in \{L, L^{-T}\}$. Choosing $M = L$ will cancel all applications of L^{-1}, and all occurrences of $L^{-T}M^{-1}$ become applications of A^{-1}. Similarly choosing $M = L^{-T}$ cancels all L^{-T} operations, and ML^{-1} becomes A^{-1}. In both cases, the Cholesky factor L is completely removed from the picture. The lower-bidiagonalization procedure resulting from the choice $M = L$ will be referred to as GKLB(A^{-1}) (since the vectors w_j are A^{-1}-orthonormal by (4.2)), and the procedure resulting from the choice $M = L^{-T}$ will be referred to as GKLB(A) for an analogous reason. The GKLB(A^{-1}) algorithm is presented below.

GKLB(A^{-1})
Set $\beta_1 w_1 = b$, $\alpha_1 v_1 = B^T A^{-1} w_1$,
For $j = 1, 2, \ldots$,

$$\begin{aligned} \beta_{j+1} w_{j+1} &= Bv_j - \alpha_j w_j, && \text{where } \beta_{j+1} > 0 \text{ and } \|w_{j+1}\|_{A^{-1}} = 1, \\ \alpha_{j+1} v_{j+1} &= B^T A^{-1} w_{j+1} - \beta_{j+1} v_j, && \text{where } \alpha_{j+1} > 0 \text{ and } \|v_{j+1}\| = 1. \end{aligned}$$

The GKLB(A) algorithm is similar, with A^{-1} acting on b and B, B^T appearing in place of $B^T A^{-1}$, and with $\beta_j \geq 0$ chosen so that $\|w_j\|_A = 1$. The recurrences of GKLB(A^{-1}) are more nicely expressed as

$$\begin{aligned} W_{k+1}(\beta_1 e_1) &= b, \\ BV_k &= W_{k+1} E_k, \\ B^T A^{-1} W_{k+1} &= V_k E_k^T + \alpha_{k+1} v_{k+1} e_{k+1}^T. \end{aligned}$$

The procedure for carrying out the calculation of $\beta_{j+1}w_{j+1}$ in GKLB(A^{-1}) is

$$\begin{aligned} \hat{w}_{j+1} &= Bv_j - \alpha_j w_j, \\ t &= A^{-1}\hat{w_{j+1}}, \\ \beta_{j+1} &= (\hat{w_{j+1}}^T t)^{\frac{1}{2}}, \\ w_{j+1} &= \hat{w_{j+1}}/\beta_{j+1}, \\ A^{-1}w_{j+1} &= t/\beta_{j+1}, \end{aligned}$$

so that $A^{-1}w_{j+1}$ is already known before it is required in the calculation of v_{j+1}; this does not require an operation with A^{-1}. The calculation for GKLB(A) is similar.

Since both bidiagonalization procedures GKLB(A^{-1}) and GKLB(A) are computationally equivalent, only GKLB(A^{-1}) will be considered further, although all the results given are equally true of both methods. The last note on GKLB(A) is the following: At each iteration step, one solve of the form $Af = g$ is required. If $f_k = W_k h_k$ is an approximation to f from span(W_k), then it may be hoped that $AW_k h_k \approx g$ (in some sense). If the matrix W_k is that obtained from GKLB(A), $h_k = W_k^T g$ and so $f_k = (W_k W_k^T)g$. This observation has not proved useful so far.

4.2. Extension of the bidiagonalization procedure to an iterative solution method. In exactly the same way that LSQR was derived from GKLB, GKLB(A^{-1}) forms the basis for an iterative solution method for generalized least-squares problems.

Let $y_k = V_k z_k$ be an approximation to the solution of (2.2). The optimal z_k is then the solution of $\min_{z\in\mathbb{R}^k} \|b - BV_k z\|_{A^{-1}}$, and, using the recurrences of GKLB(A^{-1}), it can be shown that the optimal z_k also solves $\min_{z\in\mathbb{R}^k} \|E_k z - \beta_1 e_1\|$, which is exactly the same subproblem which is solved by LSQR (cf. (3.5)), so that only the bidiagonalization step of LSQR needs to be swapped for GKLB(A^{-1}) in order to apply an LSQR-type algorithm to the generalized least-squares problem (2.2). The algorithm described above will be referred to as LSQR(A^{-1}) and is given below for completeness.

THE LSQR(A^{-1}) ALGORITHM.

Set $y_0 = 0$, $\beta_1 w_1 = b$, $\alpha_1 v_1 = B^T A^{-1} w_1$, $d_1 = v_1$, $\overline{\varphi}_1 = \beta_1$, $\overline{\rho}_1 = \alpha_1$,

For $j = 1, 2, \ldots$,

(Bidiagonalization step)

$$\begin{aligned} \beta_{j+1}w_{j+1} &= Bv_j - \alpha_j w_j, && \text{where } \beta_{j+1} > 0 \text{ and } \|w_{j+1}\|_{A^{-1}} = 1, \\ \alpha_{j+1}v_{j+1} &= B^T A^{-1} w_{j+1} - \beta_{j+1} v_j, && \text{where } \alpha_{j+1} > 0 \text{ and } \|v_{j+1}\| = 1; \end{aligned}$$

(Orthogonal transformation step)

$$\begin{aligned} \rho_j &= \left(\overline{\rho}_j^2 + \beta_{j+1}^2\right)^{\frac{1}{2}}, \\ c_j &= \overline{\rho}_j/\rho j, \\ s_j &= \beta_{j+1}/\rho_j, \\ \theta_{j+1} &= s_j \alpha_{j+1}, \\ \overline{\rho}_{j+1} &= -c_j \alpha_{j+1}, \\ \varphi_j &= c_j \overline{\varphi}_j, \\ \overline{\varphi}_{j+1} &= s_j \overline{\varphi}_j; \end{aligned}$$

(Solution update)

$$\begin{aligned} y_j &= y_{j-1} + (\varphi_j/\rho_j) d_j, \\ d_{j+1} &= v_{j+1} - (\theta_{j+1}/\rho_j) d_j. \end{aligned}$$

A computationally equivalent algorithm to that above, LSQR(A), can be derived from the GKLB(A) bidiagonalization process.

The LSQR(A^{-1}) and LSQR(A) algorithms can also provide estimates to the x component of the solution of (1.1) for a little more computational expense. If x_j is defined by $Ax_j = b - By_j$, then it can be seen that x_j can be updated with the rules

$$\begin{aligned} A^{-1}Bd_j &= A^{-1}Bv_j - (\theta_j/\rho_{j-1})A^{-1}Bd_{j-1}, \\ x_j &= x_{j-1} - (\varphi_j/\rho_j)A^{-1}Bd_j. \end{aligned}$$

Since $A^{-1}Bv_j$ is available in both algorithms from the first stage of the bidiagonalization step (provided one extra VAXPY operation (see [4]) is performed in the calculation of β_{j+1}), it is possible to update the quantity $A^{-1}Bd_j$ and hence the quantity x_j without performing any extra A^{-1} operations, the total extra cost being three VAXPY operations and storage of three n-vectors. Alternatively, once y_l is deemed sufficiently accurate, x_l can be recovered at a cost of less than one LSQR(A^{-1}) step using the rule $x_l = A^{-1}(b - By_l)$, which may be more numerically stable.

4.3. Preconditioning. When solving systems of the form

$$Mz = f,$$

where $M \in \mathbb{R}^{n\times n}$, it is usual to introduce a nonsingular preconditioning matrix N, or if N is positive definite, its Cholesky factor L, and instead solve one of the systems

$$\begin{aligned} N^{-1}Mz_L &= N^{-1}f \quad \text{(left preconditioning)}, \\ MN^{-1}z_R &= f \quad \text{(right preconditioning)}, \\ L^{-1}ML^{-T}z_C &= L^{-1}f \quad \text{(central preconditioning)}, \end{aligned}$$

where $z_L = z$, $z_R = Nz$, and $z_C = L^T z$; the idea in all cases being that the matrix $N^{-1}M$ should have better condition than M.

It is clear that of these preconditioning strategies, only right preconditioning is applicable to (generalized) least-squares problems since any other form of preconditioning affects the norm in which the minimization is taking place. Hence, preconditioned generalized least-squares problems,

$$\min \|BN^{-T}p - b\|_{A^{-1}}, \tag{4.3}$$

can be considered when solving (1.1), where $p = N^T y$. Analogous to the extension from least-squares to generalized least-squares, an iterative method for (4.3) can be devised from the Golub–Kahan bidiagonalization procedures by altering the inner product in which the m-vectors, $\{v_i\}$, are orthonormal. GKLB(A^{-1}) can be applied with the operator BN^{-T} with $z_i := Sv_i$. If $S = N$ is chosen and $H = NN^T$, the resulting algorithm, to be referred to as GKLB(A^{-1}, H^{-1}), is

GKLB(A^{-1}, H^{-1})
Set $\beta_1 w_1 = b$, $\quad \alpha_1 z_1 = B^T A^{-1} w_1$,
For $j = 1, 2, \ldots$,

$$\begin{aligned} \beta_{j+1}w_{j+1} &= BH^{-1}z_j - \alpha_j w_j, && \text{where } \beta_{j+1} > 0 \text{ and } \|w_{j+1}\|_{A^{-1}} = 1, \\ \alpha_{j+1}z_{j+1} &= B^T A^{-1} w_{j+1} - \beta_{j+1} z_j, && \text{where } \alpha_{j+1} > 0 \text{ and } \|z_{j+1}\|_{H^{-1}} = 1. \end{aligned}$$

The procedure for carrying out the calculation of $\alpha_{j+1}z_{j+1}$ is similar to that given for calculating $\beta_{j+1}w_{j+1}$ in GKLB(A^{-1}).

A similar algorithm, GKLB(A^{-1}, H), can be obtained on taking $S = N^{-T}$ above. Algorithms GKLB(A, H^{-1}) and GKLB(A, H) are also defined. Any of these bidiagonalization procedures can be plugged into the bidiagonalization step of LSQR to form an algorithm for the preconditioned system (4.3), the one corresponding to GKLB(A^{-1}, H^{-1}) being denoted LSQR(A^{-1}, H^{-1}), etc.

5. Comparing LSQR(A^{-1}) with preconditioned Krylov methods. The main factor influencing whether the LSQR(A^{-1}) method is applicable to a particular system of form (1.1) is that the action of A^{-1} must be easy to perform. Hence, it would be fair to compare the LSQR(A^{-1}) method with preconditioned Krylov methods, where the preconditioner contains the matrix A. In [2], preconditioners of the form

$$\begin{bmatrix} A & 0 \\ 0 & \pm H \end{bmatrix} \tag{5.1}$$

are considered for (1.1), where H is symmetric positive definite and is typically an approximation to the Schur complement $B^T A^{-1} B$. The coefficient matrix $\hat{\mathcal{A}}_{\pm}$ in the preconditioned system is symmetric if $+H$ is chosen, and positive semidefinite if $-H$ is chosen. Some elegant results depending on the choice of $\pm H$ are presented in [2], the most relevant being that if MINRES is used to solve the symmetrically preconditioned version of (1.1) with $\hat{\mathcal{A}}_{+}$ as coefficient matrix, then MINRES makes no progress every second step, in the sense that $\|r_{2k+1}^{\text{MINRES}}\| = \|r_{2k}^{\text{MINRES}}\|$, where r_j^{MINRES} denotes the residual in the preconditioned system.

The preconditioned system is the same as that solved by LSQR(A^{-1}, H^{-1}). The matrix H will certainly affect the convergence of both the least-squares and the MINRES methods of solution, but since only a comparison of these two approaches is required, the matrix H plays no part. Therefore it will be assumed that $H = I$. The MINRES approach then corresponds to solving the system

$$\begin{bmatrix} I & L^{-1}B \\ B^T L^{-T} & 0 \end{bmatrix} \begin{bmatrix} L^T x \\ y \end{bmatrix} = \begin{bmatrix} L^{-1} b \\ 0 \end{bmatrix}. \tag{5.2}$$

In the following table, the operation counts for one step of MINRES on (5.2) (taken from [1]) and LSQR(A^{-1}) are given. Here $(\cdot)$ indicates the dimension of the operation.

	MINRES	LSQR(A^{-1})	
Matrix-vector products	$2(n \times m)$	$2(n \times m)$	
A^{-1} operations	1	1	
Vector products	$2(n)$, $2(m)$	$1(n)$, $1(m)$	
Additional flops	$12n + 12m$	$4n + 8m$	($+6n$ with x update)
Stored vectors	$7(n)$, $7(m)$	$1(n)$, $4(m)$	($+3n$ with x update)

After $2l + 1$ steps of MINRES on (5.2), the approximation y_{2l+1}^{MINRES} is made from span (V_l) (see section 3.1), whereas LSQR(A^{-1}) provides an approximation from span(V_l) after only l steps, i.e., LSQR(A^{-1}) takes half the number of iterations (and hence half the number of matrix operations) of MINRES on (5.2) to produce an approximation to y from a subspace of the same size. Obviously the two approximations $y_l^{\text{LSQR}(A^{-1})}$ and y_{2l+1}^{MINRES} will not necessarily be the same since each method uses a different minimization subproblem. Hence the LSQR(A^{-1}) method provides a way of stepping over the redundant MINRES iterations found in [2] by using the GKLB process to step over the redundancies in the Lanczos process on the coefficient matrix in (5.2).

In [2], the authors concluded that the most efficient way to solve (1.1) (if the preconditioning (5.1) is viable) is to apply MINRES (or CG if B is of full column rank) to the Schur complement equations. Then an approximation y_l^{SCHUR} to y, from the same Krylov subspace as $y_l^{\text{LSQR}(A^{-1})}$, is obtained after l iterations. However, since the Schur complement equations are the normal equations of (1.1), the MINRES–

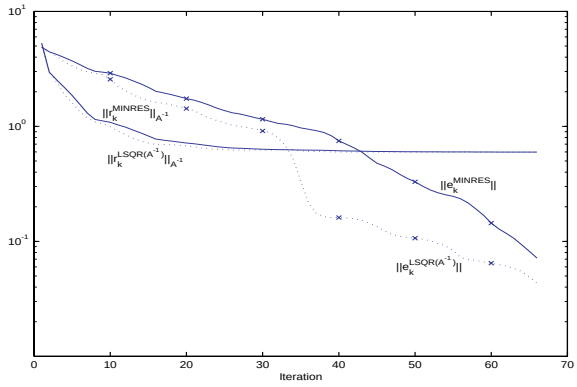

FIG. 1. *Graphs comparing the performance of MINRES on the Schur complement equations and LSQR(A^{-1}) for Example* 1. *LSQR(A^{-1}) is faster to reduce the error and slightly faster at reducing the residual norms.*

Schur complement approach is likely to be numerically inferior to LSQR(A^{-1}). This is investigated in the following section.

6. Numerical experiments and implementation. Following from the final comments of section 5, little difference between applying MINRES to (1.3) and LSQR(A^{-1}) to (1.2) is to be expected when the Schur complement is well conditioned. Experiments have shown this to be the case, with LSQR(A^{-1}) proving only slightly better at minimizing the error $\|y - y_k\|$ and the residual $\|By_k - b\|_{A^{-1}}$. The advantage of LSQR(A^{-1}) over the MINRES approach is more obvious when considering more ill-conditioned problems. The computations were performed on machines with precision $\epsilon \approx 10^{-16}$ using MATLAB 4.2*c*.

Example 1. Figure 1 illustrates the performance of LSQR(A^{-1}) and MINRES at minimizing the error $\|e_k\| = \|y - y_k\|$ and residual $\|r_k\|_{A^{-1}} = \|By_k - b\|_{A^{-1}}$ for a finite element discretization of pressure-driven Darcy flow in a porous region containing nonporous "fingers." Then (1.2) is incompatible ($By \neq b$), since $x = 0$ would correspond to a flow with zero velocity. After a similar initial performance, LSQR(A^{-1}) reduces the error faster than MINRES. Both methods perform similarly in reducing the residual, with LSQR(A^{-1}) being only slightly faster. The fact that (1.2) is incompatible makes a more precise comparison of each method's residual reducing properties difficult.

For the purpose of these experiments, $\|r_k\|_{A^{-1}}$ has been calculated exactly using an A^{-1} solve at each step of the iteration. In practice, however, the estimate

$$\|r_k\|_{A^{-1}} = \overline{\varphi}_{k+1} = \beta_1 s_k s_{k-1} \dots s_1$$

should be used since it is virtually free and has been observed to agree closely with the calculated value of $\|r_k\|_{A^{-1}}$. This estimate is analogous to that given in [9] for $\|r_k\|$ in LSQR and its derivation is the same.

Example 2. The system described in Example 1 was used to construct a compatible problem by setting $b = Bq$, where q is a vector all of whose entries equal 1. Since the system is compatible, comparison of the abilities of LSQR(A^{-1}) and MINRES at reducing the residual is easier. Figure 2 shows the performance of both methods on

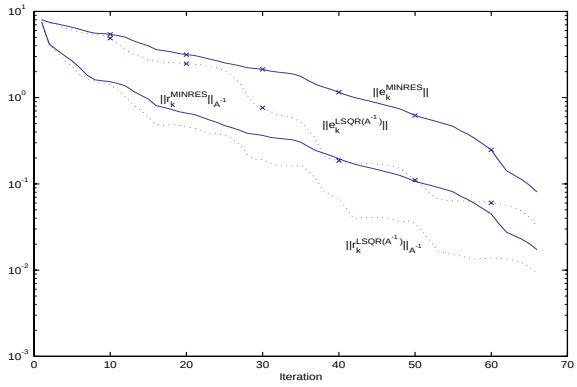

FIG. 2. *Graphs comparing the performance of MINRES on the Schur complement system and LSQR*(A^{-1}) *for Example* 2. *LSQR*(A^{-1}) *is faster at reducing the error and residual norms.*

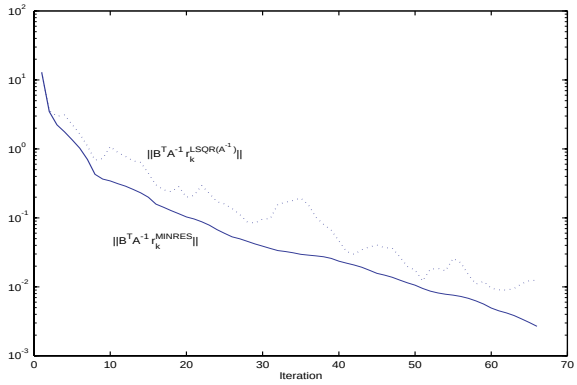

FIG. 3. *Graphs comparing* $\|B^T A^{-1} r_k\|$ *for Example* 3. *MINRES performs better at minimizing* $\|B^T A^{-1} r_k\|$ *as expected from its minimization property.*

this system. Again the advantage of LSQR(A^{-1}) is clear after only a small number of iterations.

Example 3. A similar estimate to that above for $\|r_k\|_{A^{-1}}$ is available for the residual of the Schur complement equations,

$$\|B^T A^{-1} r_k\| = \overline{\varphi}_{k+1} \alpha_{k+1} |c_k|.$$

This estimate is a useful stopping criterion since $\|B^T A^{-1} r_k\|$ tends to zero as y_k tends to y. MINRES on (1.3) is expected to be the superior of the two methods at minimizing $\|B^T A^{-1} r_k\|$ since this is precisely the quantity that is minimized at each step. This can be observed in Figure 3, which shows $\|B^T A^{-1} r_k\|$ for the groundwater flow problem in Example 1. Hence, care should be taken when using the residual of the Schur complement equations as a stopping criterion, since in Figure 1 MINRES was seen to be inferior when minimizing the error.

Example 4. As a final example, it is shown that LSQR(A^{-1}) can succeed in solving a moderately ill-conditioned problem upon which MINRES fails. Figure 4 depicts

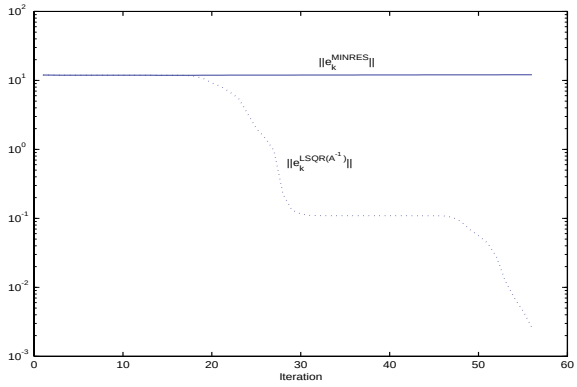

FIG. 4. *Graphs showing* $\|y - y_k\|$ *for Example* 4. *MINRES fails to reduce the norm of the error,* $LSQR(A^{-1})$ *succeeds eventually.*

what happens when both methods are applied to a system with $B \in \mathbb{R}^{32\times 16}$ and with $\kappa(B^T A^{-1} B) = 5.3 \times 10^4$. Although LSQR($A^{-1}$) requires a greater number of iterates than expected, it successfully minimizes $\|y - y_k\|$, whereas the MINRES approach fails to noticeably reduce the norm of the error.

7. Summary. Considering augmented systems as generalized least-squares problems can be advantageous when constructing iterative solution methods. LSQR can be extended to the algorithm LSQR(A^{-1}) for generalized least-squares problems without assuming availability of the Cholesky decomposition of the matrix A. LSQR(A^{-1}) is essentially twice as fast as the corresponding preconditioned MINRES method and is numerically superior to MINRES applied to the Schur complement system.

In conclusion, if it is reasonable to operate with A^{-1}, the LSQR(A^{-1}) algorithm should be used to solve (1.2) in favor of MINRES on the Schur complement equations.

Acknowledgments. The author would like to thank Professor Michael Saunders and Dr. Andrew Wathen for useful discussions and pointers to the literature, and Professor Alastair Spence, Andrew Cliffe, and two anonymous referees for suggesting improvements to the manuscript.

A REALIZATION ALGORITHM FOR $\mathrm{SL}_2(R[x_1,\ldots,x_m])$ OVER THE EUCLIDEAN DOMAIN*

HYUNGJU PARK†

Abstract. Let R be an arbitrary Euclidean domain and $\mathbf{A}$ be an $n\times n$ matrix of determinant 1 whose entries are elements of R. Gaussian elimination process based on Euclidean division algorithm (on R) allows one to write $\mathbf{A}$ as a product of elementary matrices over R. Suslin's stability theorem states that any $n\times n$ multivariate polynomial matrix of determinant 1 with $n\geq 3$ can be written as a product of elementary matrices. This result fails when $n=2$, and a counter-example was constructed by P. M. Cohn [*Inst. Hautes Études Sci. Publ. Math.* 30 (1996), pp. 365–413]. In this paper, an algorithm is developed that determines precisely when a given matrix in $\mathrm{SL}_2(R[x_1,\ldots,x_m])$ allows a factorization into elementary matrices and, if it does, expresses it as a product of elementary matrices. This algorithm has potential applications to signal processing, in which case the coefficient ring R is usually taken as a field or a ring $\mathbb{Z}$ of integers. Extending the idea used in this algorithm, we disprove a conjecture of Tolhuizen–Hollmann–Kalker regarding the realizability of a certain FIR filter.

1. Introduction.

Throughout this paper, the symbol k will denote a field and the symbol R will denote a Euclidean domain which is an integral domain equipped with an analogue of Euclidean division algorithm. Examples of such R are a field k, a univariate polynomial ring $k[x]$, or a ring $\mathbb{Z}$ of integers. Although many results used in this paper are valid over more general rings, we will exclusively work on Euclidean domains.

DEFINITION 1.1.

1. $\mathrm{SL}_n(R)$ *is the group of all the* $n\times n$ *matrices of determinant* 1 *whose entries are elements of* R.
2. *An* $n\times n$ *elementary matrix* $\mathbf{E}_{ij}(a)$ *over* R *is* $\mathbf{I}+a\cdot\mathbf{e}_{ij}$, *where* $i\neq j, a\in R$, *and* $\mathbf{e}_{ij}$ *is the* $n\times n$ *matrix whose* (i,j) *component is* 1 *and all other components are zero.*
3. *If a square matrix* $\mathbf{A}$ *can be written as a product of elementary matrices, then* $\mathbf{A}$ *is called* realizable.

Suslin's stability theorem asserts that any matrix in $\mathrm{SL}_n(R[x_1,\ldots,x_m])$ with $n\geq 3$ can be written as a product of elementary matrices, i.e.,

$$\mathrm{SL}_n(R[x_1,\ldots,x_m])=\mathrm{E}_n(R[x_1,\ldots,x_m]) \quad \text{for} \quad n\geq 3,$$

where $\mathrm{E}_n(R)$ is defined as the subgroup of $\mathrm{SL}_n(R)$ generated by the elementary matrices.

The above theorem was first proved by A. A. Suslin in [7], and an algorithmic proof for the case $R=k$ was found recently by C. Woodburn and H. Park in [6].

†Department of Mathematics and Statistics, Oakland University, Rochester, MI 48309 (park@oakland.edu).

Suslin's stability theorem, however, fails when $n = 2$, and a counterexample was constructed by P. M. Cohn in [1], i.e., the *Cohn matrix*,

$$\begin{pmatrix} 1+xy & x^2 \\ -y^2 & 1-xy \end{pmatrix} \in \mathrm{SL}_2(k[x,y]),$$

was shown to be nonrealizable.

Recently, it was noted by L. Tolhuizen, H. Hollmann, and A. Kalker in [8] that the problem of decomposing a causal biorthogonal multidimensional 2-band filter bank into elementary ladder steps is essentially equivalent to developing an algorithm that determines if a given matrix in $\mathrm{SL}_2(k[x_1,\dots,x_m])$ is realizable, and if it is, expresses it as a product of elementary matrices. A reader interested in this application to signal processing should see [8] or [5].

In this paper, we develop a new algorithm for this task based on a monomial order on the polynomial ring $R[x_1,\dots,x_m]$, and we show that our algorithm terminates in a finite number of steps.

In [8, p. 647], the importance and the difficulty of extending a realization algorithm to matrices over a Laurent polynomial ring $k[x_1^{\pm},\dots,x_m^{\pm}]$ were mentioned, and a particular matrix in $\mathrm{SL}_2(k[x^{\pm},y^{\pm}])$ was conjectured to be nonrealizable. We prove that this conjecture is false and provide an explicit factorization of that matrix into elementary matrices.

2. Main theorem.

2.1. Preliminaries. For any monomial $x_1^{i_1}x_2^{i_2}\cdots x_m^{i_m}$ in $R[x_1,\dots,x_m]$, we use the shorthand notation

$$\boldsymbol{x}^{\mathbf{i}} := x_1^{i_1}x_2^{i_2}\cdots x_m^{i_m},$$

where $\mathbf{i} = (i_1,\dots,i_m) \in \mathbb{Z}_{\geq 0}^m$. Also, the polynomial ring $R[x_1,\dots,x_m]$ will be abbreviated as $R[\boldsymbol{x}]$.

DEFINITION 2.1. *A* monomial order *on $R[x_1,\dots,x_m]$ is any relation $>$ on $\mathbb{Z}_{\geq 0}^m$, or equivalently, any relation on the set of monomials $\boldsymbol{x}^{\mathbf{i}}$, $\mathbf{i} \in \mathbb{Z}_{\geq 0}^m$, satisfying the following:*

1. *$>$ is a total (or linear) order on $\mathbb{Z}_{\geq 0}^m$.*
2. *If $\mathbf{i} > \mathbf{j}$ and $\mathbf{h} \in \mathbb{Z}_{\geq 0}^m$, then $\mathbf{i}+\mathbf{h} > \mathbf{j}+\mathbf{h}$.*
3. *$>$ is a well-ordering on $\mathbb{Z}_{\geq 0}^m$. This means that every nonempty subset of $\mathbb{Z}_{\geq 0}^m$ has a smallest element under $>$.*

The following lemma plays a crucial role in proving the finite termination of our algorithm.

LEMMA 2.2 (see [2, Lemma 2, p. 53]). *An order relation $>$ on $\mathbb{Z}_{\geq 0}^m$ is a well-ordering if and only if every strictly decreasing sequence in $\mathbb{Z}_{\geq 0}^m$*

$$\mathbf{i}(1) > \mathbf{i}(2) > \mathbf{i}(3) > \cdots$$

eventually terminates.

A simple example of a monomial order is the usual numerical order

$$\cdots > m+1 > m > \cdots 3 > 2 > 1 > 0$$

on the elements of $\mathbb{Z}_{\geq 0}$. We list two popular monomial orders below.

DEFINITION 2.3 (lexicographic order). *For* $\mathbf{i}, \mathbf{j} \in \mathbb{Z}_{\geq 0}^m$, *we say* $\mathbf{i} >_{lex} \mathbf{j}$ *if the leftmost nonzero entry of the vector difference* $\mathbf{i} - \mathbf{j}$ *is positive. We write* $\boldsymbol{x}^{\mathbf{i}} >_{lex} \boldsymbol{x}^{\mathbf{j}}$ *if* $\mathbf{i} >_{lex} \mathbf{j}$.

Lexicographic order is usually abbreviated as lex order. As an example, consider the two monomials $xy^2, y^3z^4 \in k[x, y, z]$. Then we have $xy^2 >_{lex} y^3z^4$ since $(1, 2, 0) - (0, 3, 4) = (1, -1, -4)$.

DEFINITION 2.4 (degree lexicographic order). *For* $\mathbf{i}, \mathbf{j} \in \mathbb{Z}_{\geq 0}^m$, *we say* $\mathbf{i} >_{dlex} \mathbf{j}$ *if*

$$|\mathbf{i}| := \sum_{k=1}^{m} i_k > |\mathbf{j}| := \sum_{k=1}^{m} j_k, \qquad \text{or} \quad |\mathbf{i}| = |\mathbf{j}| \quad \text{and} \quad \mathbf{i} >_{lex} \mathbf{j}. \tag{2.1}$$

Note that degree lex order compares total degrees first, and then breaks ties using lex order.

Suppose that a fixed monomial order $>$ on $R[\boldsymbol{x}]$ is given. For any polynomial $f \in R[\boldsymbol{x}]$, its *leading term* or *highest degree term* with respect to $>$ is denoted as $\mathrm{lt}(f)$. Also, for a matrix $\mathbf{A} \in \mathrm{M}_n(R[\boldsymbol{x}])$, we define the matrix of its leading terms as $\mathrm{lt}(\mathbf{A}) := (\mathrm{lt}(a_{ij}))$.

2.2. A necessary condition for realizability. If a realizable matrix $\mathbf{A} \in \mathrm{SL}_2(R[\boldsymbol{x}])$ is a constant matrix, then the standard Gaussian elimination (based on Euclidean division algorithm on R) produces an explicit factorization of $\mathbf{A}$ into elementary matrices over R. Now the following theorem gives an important property for the *nonconstant* realizable 2×2 matrices.

THEOREM 2.1. *Suppose that* $\mathbf{A} = \left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) \in \mathrm{SL}_2(R[\boldsymbol{x}])$ *is a nonconstant realizable matrix. Then with respect to an arbitrary fixed monomial order* $>$, *either* $\mathbf{A}$ *has a zero entry or one of the row vectors of* $\mathrm{lt}(\mathbf{A})$ *is a monomial multiple of the other row.*

Remark 2.1. In the case of the Cohn matrix

$$\mathbf{A} = \begin{pmatrix} 1 + xy & x^2 \\ -y^2 & 1 - xy \end{pmatrix},$$

note that, with respect to the degree lex order, $\mathrm{lt}(\mathbf{A}) = \left(\begin{smallmatrix} xy & x^2 \\ -y^2 & -xy \end{smallmatrix}\right)$ is of rank 1, but neither of the two row vectors $(xy, x^2) = x \cdot (y, x)$ or $(-y^2, -xy) = -y \cdot (y, x)$ is a monomial multiple of the other. Therefore, the above theorem shows that the Cohn matrix is not realizable.

Remark 2.2. Note that the above theorem is valid with respect to an *arbitrary* monomial order. Since $\mathrm{lt}(\mathbf{A})$ usually changes as monomial order changes, we may get several relationships among different monomial vectors.

Remark 2.3. Theorem 2.1 is not valid for *constant* realizable matrices. For example, consider $\mathbf{A} := \left(\begin{smallmatrix} 5 & 2 \\ 2 & 1 \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z}[x, y])$.

Proof. Since $\mathbf{A}$ is realizable, we can write $\mathbf{A}$ as a product of elementary matrices. Let $\mathbf{A} = \mathbf{E}_1 \cdots \mathbf{E}_l$ be such a representation without a trivial factor, i.e., for each $i = 1, \ldots, l$, $\mathbf{E}_i$ is either $\mathbf{E}_{12}(f)$ or $\mathbf{E}_{21}(f)$ for some $f \neq 0 \in R[\boldsymbol{x}]$. Now we will do an induction on l.

If $l = 1$, the statement of the theorem is trivial since we have either $\mathbf{A} = \left(\begin{smallmatrix} 1 & q \\ 0 & 1 \end{smallmatrix}\right)$ or $\mathbf{A} = \left(\begin{smallmatrix} 1 & 0 \\ r & 1 \end{smallmatrix}\right)$ for some $q, r \in R[\boldsymbol{x}]$, and in both cases, $\mathbf{A}$ has a zero entry.

Now let

$$\begin{aligned} \mathbf{A}' &= \mathbf{E}_1 \cdots \mathbf{E}_{l-1} \\ &= \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(R[\boldsymbol{x}]). \end{aligned}$$

Suppose that $\mathbf{A}'$ does not have a zero entry. Then by the induction hypothesis, we may assume without loss of generality that

$$(\mathrm{lt}(a), \mathrm{lt}(b)) = h \cdot (\mathrm{lt}(c), \mathrm{lt}(d))$$

for some nonzero monomial $h \in R[\boldsymbol{x}]$.

We have two cases:

$$\mathbf{A} = \begin{pmatrix} p & q \\ r & s \end{pmatrix} = \mathbf{A}'\mathbf{E}_{12}(f) = \begin{pmatrix} a & b + fa \\ c & d + fc \end{pmatrix}$$

or

$$\mathbf{A} = \begin{pmatrix} p & q \\ r & s \end{pmatrix} = \mathbf{A}'\mathbf{E}_{21}(f) = \begin{pmatrix} a + fb & b \\ c + fd & d \end{pmatrix}.$$

In the first case, since $\mathbf{A}$ is a nonconstant matrix with $\det(\mathbf{A}) = 1$, we have $\det(\mathrm{lt}(\mathbf{A})) = 0$. Hence,

$$\mathrm{lt}(c) \cdot \mathrm{lt}(b + fa) = \mathrm{lt}(a) \cdot \mathrm{lt}(d + fc) = h \cdot \mathrm{lt}(c) \cdot \mathrm{lt}(d + fc).$$

Therefore, $\mathrm{lt}(b + fa) = h \cdot \mathrm{lt}(d + fc)$.

Now

$$(\mathrm{lt}(r), \mathrm{lt}(s)) = (\mathrm{lt}(c), \mathrm{lt}(d + fc))$$

and

$$\begin{aligned} (\mathrm{lt}(p), \mathrm{lt}(q)) &= (\mathrm{lt}(a), \mathrm{lt}(b + fa)) \\ &= (h \cdot \mathrm{lt}(c), h \cdot \mathrm{lt}(d + fc)) \\ &= h \cdot (\mathrm{lt}(c), \mathrm{lt}(d + fc)) \\ &= h \cdot (\mathrm{lt}(r), \mathrm{lt}(s)) \end{aligned}$$

as desired.

The same method gives the same conclusion in the second case.

To complete the proof, we have to consider the case when $\mathbf{A}'$ has a zero entry. Let us assume $c = 0$. The case when another entry of $\mathbf{A}$ is zero can be treated in the same way.

Again there are two cases:

$$\mathbf{A}'\mathbf{E}_{12}(f) = \begin{pmatrix} a & b + fa \\ 0 & d \end{pmatrix}$$

and

$$\mathbf{A}'\mathbf{E}_{21}(f) = \begin{pmatrix} a + fb & b \\ fd & d \end{pmatrix}.$$

In the first case, $\mathbf{A} = \mathbf{A}'\mathbf{E}_{12}(f)$ has a zero entry; therefore, we are done.

In the second case, $\det(\mathbf{A}') = ad = 1$ implies that a and d are invertible elements of $R[\boldsymbol{x}]$, i.e., a and d are invertible elements of R. Since

$$\mathbf{A} = \begin{pmatrix} a + fb & b \\ fd & d \end{pmatrix}$$

is not a constant matrix, fb is not a constant. Hence we have $a < fb$ with respect to an arbitrary fixed term order $<$, and

$$\mathrm{lt}(\mathbf{A}) = \begin{pmatrix} \mathrm{lt}(f)\mathrm{lt}(b) & \mathrm{lt}(b) \\ \mathrm{lt}(f)d & d \end{pmatrix}.$$

Since d is an invertible element of R, we have

$$\begin{aligned} \text{1st row of } \mathrm{lt}(\mathbf{A}) &= (\mathrm{lt}(f)\mathrm{lt}(b), \mathrm{lt}(b)) \\ &= d^{-1}\mathrm{lt}(b) \cdot (\mathrm{lt}(f)d, d) \\ &= \text{a monomial multiple of the 2nd row of } \mathrm{lt}(\mathbf{A}). \end{aligned}$$ □

3. Realization algorithm for $\mathbf{SL_2(k[x_1, \ldots, x_m])}$. Let us now see how to obtain a realization algorithm for $\mathrm{E}_2(R[\boldsymbol{x}])$ from Theorem 2.1.

If $\mathbf{A} = \mathrm{SL}_2(R[\boldsymbol{x}])$ is a constant matrix, then the standard Gaussian elimination (based on Euclidean division algorithm on R) produces an explicit factorization of $\mathbf{A}$ into elementary matrices over R. Hence we have a trivial realization algorithm in this case.

Suppose that one of the entries of

$$\mathbf{A} := \begin{pmatrix} p & q \\ r & s \end{pmatrix} \in \mathrm{SL}_2(k[\boldsymbol{x}]),$$

say, r, is zero. Then $\det(\mathbf{A}) = ps = 1$ implies that p and s are invertible elements of R, and thus

$$\mathbf{E}_{12}(-s^{-1}q)\mathbf{A} = \begin{pmatrix} p & 0 \\ 0 & s \end{pmatrix}$$

is a constant matrix for which we already have a realization algorithm, say, $\mathbf{E}_{12}(-s^{-1}q)\mathbf{A} = \mathbf{E}_1 \cdots \mathbf{E}_l$. Then

$$\mathbf{A} = \mathbf{E}_{12}(s^{-1}q)\mathbf{E}_1 \cdots \mathbf{E}_l$$

is a desired realization for $\mathbf{A}$.

Definition 3.1.

1. *For a polynomial $f \in R[x_1, \ldots, x_m]$ with $\mathrm{lt}(f) = \boldsymbol{x}^{\mathbf{i}}$, we define its* multidegree, $\mathrm{multideg}(f)$, *to be $\mathbf{i} \in (\mathbb{Z}_{\geq 0})^m$.*
2. *Suppose $\mathbf{B} = (b_{ij}) \in \mathrm{SL}_n(R[\boldsymbol{x}])$. Then we define* $\mathrm{multideg}(\mathbf{B})$ *by*

$$\mathrm{multideg}(\mathbf{B}) = \max_{1 \leq i,j \leq n} \{\mathrm{multideg}(b_{ij})\} \in (\mathbb{Z}_{\geq 0})^m.$$

Remark 3.1. If $\mathrm{multideg}(\mathbf{B}) = (0, \ldots, 0) \in (\mathbb{Z}_{\geq 0})^m$, then clearly all the entries of $\mathbf{B}$ are constants.

Now out of a given $\mathbf{A} \in \mathrm{SL}_2(R[\boldsymbol{x}])$, we try to make a constant matrix or matrix with a zero entry by applying elementary operations. If $\mathbf{A} = \left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) \in \mathrm{SL}_2(R[\boldsymbol{x}])$ doesn't have a zero entry, then compare the two vectors $(\mathrm{lt}(p), \mathrm{lt}(q))$ and $(\mathrm{lt}(r), \mathrm{lt}(s))$.

- Step 1. If neither of them is a monomial multiple of the other, then by Theorem 2.1, $\mathbf{A}$ is not realizable. Otherwise, go to step 2.
- Step 2. Assume without loss of generality that

$$(\mathrm{lt}(p), \mathrm{lt}(q)) = h \cdot (\mathrm{lt}(r), \mathrm{lt}(s))$$

for some monomial $h \in R[\boldsymbol{x}]$. There are two cases to consider. If h is a constant, replace $\mathbf{A}$ by $\mathbf{E}_{12}(-h)\mathbf{A}$ and go to step 1. Otherwise, go to step 3.

- Step 3. Note that the matrix

$$\mathbf{E}_{12}(-h)\mathbf{A} = \begin{pmatrix} p - hr & q - hs \\ r & s \end{pmatrix}$$

has a strictly smaller multidegree than $\mathbf{A}$. Now replace $\mathbf{A}$ by $\mathbf{E}_{12}(-h)\mathbf{A}$. If $\mathbf{A}$ is a constant matrix or has a zero entry, then terminate the process. Otherwise go to step 1 with the new $\mathbf{A}$.

If any intermediate matrix in the above process is not realizable by step 1, then $\mathbf{A}$ itself is not realizable. Otherwise, since the above procedure strictly reduces the multidegree of $\mathbf{A}$ each time, by Lemma 2.2, we get either a constant matrix or a matrix with a zero entry in $\mathrm{SL}_2(k[\boldsymbol{x}])$ after a **finite** number of steps. By keeping track of all the intermediate matrices, we find elementary matrices $\mathbf{E}_1, \ldots, \mathbf{E}_l$ over $k[\boldsymbol{x}]$ such that $\mathbf{A} = \mathbf{E}_1 \cdots \mathbf{E}_l$.

4. A conjecture of Tolhuizen–Hollmann–Kalker. In [8, p. 647], the difficulty of extending a realization algorithm to matrices of FIR filters was mentioned. Mathematically, this is about realization of matrices over a Laurent polynomial ring $R[x_1^{\pm}, \ldots, x_m^{\pm}]$. While discussing this problem, the authors of [8] conjectured that the following particular matrix in $\mathrm{SL}_2(k[x^{\pm}, y^{\pm}])$ would be nonrealizable:

$$\mathbf{A} := \begin{pmatrix} 1 + (x+y)(x-y) & (x+y)^2 \\ -(x-y)^2 & 1 - (x+y)(x-y) \end{pmatrix}. \tag{4.1}$$

We prove that this conjecture is false by providing an explicit factorization of the matrix $\mathbf{A}$ into elementary matrices over $k[x^{\pm}, y^{\pm}]$.

The definitions of lex order or degree lex order for the polynomial ring $R[x_1, \ldots, x_m]$ can be extended to the Laurent polynomial ring $R[x_1^{\pm}, \ldots, x_m^{\pm}]$. For example, in Definition 2.3 or Definition 2.4, one can replace $\mathbb{Z}_{\geq 0}$ by $\mathbb{Z}$. However, it has to be noted that the resulting ordering is not a well-ordering anymore. This may cause the realization algorithm of the previous section, when applied to matrices in $\mathrm{SL}_2(R[x_1^{\pm}, \ldots, x_m^{\pm}])$, not to terminate in a finite number of steps. Although we do not have a complete solution to this problem, the realization algorithm with respect to degree lex order terminates in a finite number of steps for the above matrix.

Let "$\longrightarrow$" indicate that we are applying elementary operations, and apply the realization algorithm of the previous section with respect to degree lex order with $x < y$:

$$\begin{aligned}
\mathbf{A} &= \begin{pmatrix} 1+x^2-y^2 & x^2+2xy+y^2 \\ -x^2+2xy-y^2 & 1-x^2+y^2 \end{pmatrix} \xrightarrow{\uparrow -1} \begin{pmatrix} 1+2x^2-2xy & -1+2x^2+2xy \\ -x^2+2xy-y^2 & 1-x^2+y^2 \end{pmatrix} \\
&\xrightarrow{\downarrow -\frac{y}{2x}} \begin{pmatrix} 1+2x^2-2xy & -1+2x^2+2xy \\ -\frac{y}{2x}-x^2+xy & 1+\frac{y}{2x}-xy-x^2 \end{pmatrix} \xrightarrow{\uparrow 2} \begin{pmatrix} 1-\frac{y}{x} & 1+\frac{y}{x} \\ -\frac{y}{2x}-x^2+xy & 1+\frac{y}{2x}-xy-x^2 \end{pmatrix} \\
&\xrightarrow{\downarrow x^2} \begin{pmatrix} 1-\frac{y}{x} & 1+\frac{y}{x} \\ -\frac{y}{2x} & 1+\frac{y}{2x} \end{pmatrix} \xrightarrow{\uparrow -2} \begin{pmatrix} 1 & -1 \\ -\frac{y}{2x} & 1+\frac{y}{2x} \end{pmatrix} \xrightarrow{\downarrow \frac{y}{2x}} \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} \xrightarrow{\uparrow 1} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.
\end{aligned}$$

In terms of elementary matrices, this reduction process can be written as:

$$\mathbf{E}_{12}(1)\mathbf{E}_{21}(\tfrac{y}{2x})\mathbf{E}_{12}(-2)\mathbf{E}_{21}(x^2)\mathbf{E}_{12}(2)\mathbf{E}_{21}(\tfrac{-y}{2x})\mathbf{E}_{12}(-1) \cdot \mathbf{A} = \mathbf{I},$$

from which, one gets a desired factorization of $\mathbf{A}$ over $k[x^{\pm}, y^{\pm}]$:

$$\mathbf{A} = \mathbf{E}_{12}(1)\mathbf{E}_{21}(\tfrac{y}{2x})\mathbf{E}_{12}(-2)\mathbf{E}_{21}(-x^2)\mathbf{E}_{12}(2)\mathbf{E}_{21}(-\tfrac{y}{2x})\mathbf{E}_{12}(-1). \tag{4.2}$$

Acknowledgment. The author wishes to thank Ton Kalker for showing him the interaction between polynomial ring theory and signal processing.

TIKHONOV REGULARIZATION AND TOTAL LEAST SQUARES*

GENE H. GOLUB†, PER CHRISTIAN HANSEN‡, AND DIANNE P. O'LEARY§

Abstract. Discretizations of inverse problems lead to systems of linear equations with a highly ill-conditioned coefficient matrix, and in order to compute stable solutions to these systems it is necessary to apply regularization methods. We show how Tikhonov's regularization method, which in its original formulation involves a least squares problem, can be recast in a total least squares formulation suited for problems in which both the coefficient matrix and the right-hand side are known only approximately. We analyze the regularizing properties of this method and demonstrate by a numerical example that, in certain cases with large perturbations, the new method is superior to standard regularization methods.

Key words. total least squares, discrete ill-posed problems, regularization, bidiagonalization

1. Introduction.

In this paper we study a class of methods for producing an approximate solution to a linear system of equations $A\,x \approx b$, where A is $m \times n$ with $m \geq n$. We assume that the elements of A and those of b are contaminated by some noise. An appropriate statement of the problem in the case of noisy data is the *total least squares* (TLS) formulation [5], [6, section 12.3], [17]:

$$\min_{\tilde{A},\tilde{b},x} \|(A\,,\,b) - (\tilde{A}\,,\,\tilde{b})\|_F \qquad \text{subject to} \qquad \tilde{b} = \tilde{A}\,x. \tag{1}$$

In contrast, if the elements of A are exact and only b contains noise, then the corresponding formulation is the *least squares* (LS) problem

$$\min_{x} \|Ax - b\|_2. \tag{2}$$

Our focus in this work is on very ill-conditioned problems where the singular values of A decay gradually to zero. Such problems arise, for example, from the discretization of ill-posed problems such as integral equations of the first kind. See, e.g., [2], [3], [7], [8], and [10] for examples and details.

In these problems, the solutions to the two formulations in (1) and (2) can be hopelessly contaminated by the noise in directions corresponding to small singular values of A or $(A\,,\,b)$. Because of this, it is necessary to compute a *regularized solution* in which the effect of such noise is filtered out. For LS problems, the filtering is often done by Tikhonov's regularization method, where a damping is added to each *singular value decomposition* (SVD) component of the solution, thus effectively filtering out

the components corresponding to the small singular values. Alternatively, one can truncate the SVD expansion of the solution, leaving out all the SVD components corresponding to the small singular values.

For the TLS problem, the truncation approach has already been studied by Fierro et al. [4]. In the present work we focus on the Tikhonov regularization approach for TLS. We thus arrive at a new regularization method in which stabilization enters the formulation in a natural way and which is able to produce regularized solutions with superior properties for certain problems in which the perturbations are large.

Our paper is organized as follows. In section 2 we introduce the regularized TLS method and we study its regularizing properties. Computational aspects are described in section 3, and we conclude the paper with a numerical example in section 4. A preliminary report on this work appeared as [12].

2. The regularized TLS method. Our regularization of the TLS problem is based on Tikhonov regularization. For the linear LS problem (2), a general version of Tikhonov's method [16] takes the form

$$\min \left\{ \|A\,x - b\|_2^2 + \lambda\,\|L\,x\|_2^2 \right\}, \tag{3}$$

where λ is a positive constant chosen to control the size of the solution vector and L is a matrix that defines a (semi)norm on the solution through which the "size" is measured [11]. Often, L represents the first or second derivative operator. If L is the identity matrix, then the Tikhonov problem is said to be in standard form. The solution x_λ to (3) solves the problem

$$(A^T A + \lambda\,L^T L)x = A^T b. \tag{4}$$

As λ increases, the (semi)norm $\|L\,x\|_2$ of the solution vector decreases monotonically while the residual $\|A\,x - b\|_2$ increases monotonically.

Tikhonov regularization has an important equivalent formulation as

$$\min \|A\,x - b\|_2 \qquad \text{subject to} \qquad \|L\,x\|_2 \le \delta, \tag{5}$$

where δ is a positive constant. Problem (5) is an LS problem with a quadratic constraint and, using the Lagrange multiplier formulation,

$$\mathcal{L}(x,\lambda) = \|A\,x - b\|_2^2 + \lambda\,\left(\|L\,x\|_2^2 - \delta^2\right), \tag{6}$$

it can be shown that if $\delta \le \|x_{\mathrm{LS}}\|_2$, where x_{LS} is the LS solution to (2), then the solution x_δ to (5) is identical to the solution x_λ to (3) for an appropriately chosen λ, and there is a monotonic relation between the parameters δ and λ.

To carry this idea over to the TLS setting, we add an upper bound on the (semi)norm $\|L\,x\|_2$ of the solution vector x in the TLS problem (1). The formulation of the regularized TLS (R-TLS) problem thus becomes

$$\min \|(A\,,\,b) - (\tilde{A}\,,\,\tilde{b})\|_F \qquad \text{subject to} \qquad \tilde{b} = \tilde{A}\,x, \quad \|L\,x\|_2 \le \delta, \tag{7}$$

and the corresponding Lagrange multiplier formulation is

$$\hat{\mathcal{L}}(\tilde{A},x,\mu) = \|(A\,,\,b) - (\tilde{A}\,,\,\tilde{A}\,x)\|_F^2 + \mu\,(\|L\,x\|_2^2 - \delta^2), \tag{8}$$

where μ is the Lagrange multiplier, zero if the inequality constraint is inactive. The solution $\bar{x}_\delta$ to this problem is different from the solution x_{TLS} to (1) whenever δ is

less than $\|L\,x_{\mathrm{TLS}}\|_2$. The two solutions $\bar{x}_\delta$ and x_δ to the two regularized problems in (5) and (7) have a surprising relationship, explained by the following theorem.

THEOREM 2.1. *The R-TLS solution $\bar{x}_\delta$ to* (7), *with the inequality constraint replaced by equality, is a solution to the problem*

$$(A^TA + \lambda_I I_n + \lambda_L L^TL)\,x = A^Tb, \tag{9}$$

where the parameters λ_I and λ_L are given by

$$\lambda_I = -\,\frac{\|b - A\,x\|_2^2}{1 + \|x\|_2^2}, \tag{10}$$

$$\lambda_L = \mu\,(1 + \|x\|_2^2) \tag{11}$$

and where μ is the Lagrange multiplier in (8). *The two parameters are related by*

$$\lambda_L\,\delta^2 = b^T(b - A\,x) + \lambda_I. \tag{12}$$

Moreover, the TLS residual satisfies

$$\|(A\,,\,b) - (\tilde{A}\,,\,\tilde{b})\|_F^2 = -\lambda_I. \tag{13}$$

Proof. Define $\tilde{r} \equiv b - \tilde{b} = b - \tilde{A}\,x$. We characterize the solution to (7) by setting the partial derivatives of the Lagrangian $\hat{\mathcal{L}}$ (8) to zero. Differentiation with respect to the entries in $\tilde{A}$ yields

$$\tilde{A} - A - \tilde{r}x^T = 0,$$

and differentiation with respect to the entries in x yields

$$-\tilde{A}^T\tilde{r} + \mu\,L^TL\,x = 0 \tag{14}$$

or

$$(\tilde{A}^T\tilde{A} + \mu\,L^TL)\,x = \tilde{A}^Tb.$$

Since $A = \tilde{A} - \tilde{r}x^T$ and $\tilde{A}^T\tilde{r} = \mu\,L^TL\,x$, we see that

$$\begin{aligned} A^TA &= (\tilde{A}^T - x\tilde{r}^T)(\tilde{A} - \tilde{r}x^T) \\ &= \tilde{A}^T\tilde{A} - \mu\,xx^TL^TL + x\tilde{r}^T\tilde{r}x^T - \mu\,L^TL\,xx^T \end{aligned}$$

and

$$\tilde{A}^Tb = A^Tb + x\tilde{r}^Tb.$$

Gathering terms, we arrive at (9), with

$$\begin{aligned} \lambda_I &= \mu\,\delta^2 - \|\tilde{r}\|_2^2\,\|x\|_2^2 - \tilde{r}^Tb, \\ \lambda_L &= \mu\,(1 + \|x\|_2^2). \end{aligned}$$

To simplify the expression for λ_I, we first rewrite $\tilde{r}$ as

$$\tilde{r} = b - \tilde{A}\,x = b - (A + \tilde{r}\,x^T)\,x = b - A\,x - \tilde{r}\,x^Tx,$$

from which we obtain the relation

$$\tilde{r}\,(1+\|x\|_2^2) = b - A\,x \tag{15}$$

and, therefore, $(1+\|x\|_2^2)\|\tilde{r}\|_2^2 = (1+\|x\|_2^2)^{-1}\|b - A\,x\|_2^2$. In (14), multiplication from the left by x^T leads to

$$\mu = \frac{x^T\tilde{A}^T\tilde{r}}{x^T L^T L x} = \frac{b^T\tilde{r} - \|\tilde{r}\|_2^2}{\delta^2}\ . \tag{16}$$

Inserting (15) and (16) into the above expression for λ_I, we obtain (10). Equation (12) is proved by multiplying λ_L by δ^2 and inserting (15) and (16). Finally, to prove the expression for the TLS residual, we use the relation

$$(A\,,\,b) - (\tilde{A}\,,\,\tilde{b}) = (A-\tilde{A}\,,\,b-\tilde{b}) = (-\tilde{r}\,x^T\,,\,\tilde{r}) = -\tilde{r}\begin{pmatrix} x \\ -1 \end{pmatrix}^T .$$

Taking the Frobenius norm and using (15), we obtain (13). □

This theorem characterizes the solution to the problem in (7) whenever δ is small enough that the constraint on Lx is binding. When the solution $\bar{x}_\delta$ to (7) satisfies $\|L\bar{x}_\delta\|_2 < \delta$(with $L = 0$ as a special case), then (7) is just the standard TLS problem.

Below, we discuss the implications of this theorem for both the standard-form case $L = I_n$ (the identity matrix) and the general-form case $L \neq I_n$, both of which are important in applications.

2.1. The standard-form case. In the standard-form case, the problems simplify considerably. The Tikhonov problem (5) becomes

$$\min \|A\,x - b\|_2 \qquad \text{subject to} \qquad \|x\|_2 \leq \delta, \tag{17}$$

with solution x_δ satisfying

$$(A^T A + \lambda\, I_n)x_\delta = A^T b \tag{18}$$

for some value of $\lambda \geq 0$. Similarly, the R-TLS problem takes the form

$$\min \|(A\,,\,b) - (\tilde{A}\,,\,\tilde{b})\|_F \qquad \text{subject to} \qquad \tilde{b} = \tilde{A}\,x, \quad \|x\|_2 \leq \delta, \tag{19}$$

and (9) says that the solution $\bar{x}_\delta$ satisfies

$$(A^T A + \lambda_{IL} I_n)\,x = A^T b \tag{20}$$

whenever $\|\bar{x}_\delta\|_2 > \delta$, with $\lambda_{IL} = \lambda_I + \lambda_L$. Clearly, these two solutions are closely related.

THEOREM 2.2. *Let $L = I_n$ and let $\bar{\sigma}_{n+1}$ denote the smallest singular value of $(A\,,\,b)$. Then, for each value of δ, the resulting solutions $\bar{x}_\delta$ and x_δ are related as in the following chart.*

δ	Solutions	λ_{IL}
$\delta < \|x_{\rm LS}\|_2$	$\bar{x}_\delta = x_\delta$	$\lambda_{IL} > 0$
$\delta = \|x_{\rm LS}\|_2$	$\bar{x}_\delta = x_\delta = x_{\rm LS}$	$\lambda_{IL} = 0$
$\|x_{\rm LS}\|_2 < \delta < \|x_{\rm TLS}\|_2$	$\bar{x}_\delta \neq x_\delta = x_{\rm LS}$	$0 > \lambda_{IL} > -\bar{\sigma}_{n+1}^2$
$\delta \geq \|x_{\rm TLS}\|_2$	$\bar{x}_\delta = x_{\rm TLS},\ x_\delta = x_{\rm LS}$	$\lambda_{IL} = -\bar{\sigma}_{n+1}^2$

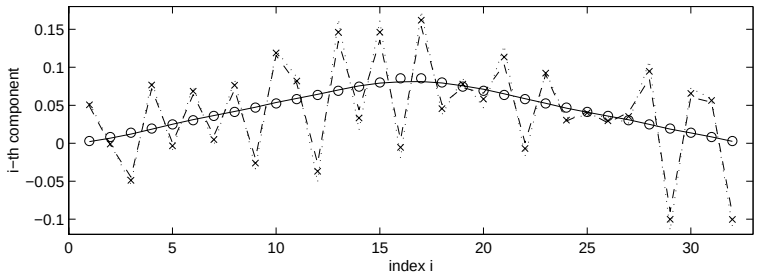

FIG. 1. *Regularized solutions to* (3) *for various values of the regularization parameter* λ; *see Table* 1 *for details.*

TABLE 1
The solutions shown in Figure 1.

Solution	λ	Solution norm	Symbol
x_λ	10^{-5}	0.289	solid line
x_{LS}	0	0.385	dashed line
x_λ	$-\frac{1}{2}\bar{\sigma}_{n+1}^2$	0.408	crosses
x_{TLS}	$-\bar{\sigma}_{n+1}^2$	0.443	dotted line
x^{exact}	–	0.288	circles

Proof. Consider the LS problem (17) first. If $\delta \geq \|x_{\mathrm{LS}}\|$, then the constraint is not binding and the solution to the problem is x_{LS}, with $\lambda = 0$. As δ is reduced below $\|x_{\mathrm{LS}}\|$, the value of λ increases monotonically, as can be seen by using the SVD $A = \Sigma_{i=1}^n u_i \sigma_i v_i^T$ in (18) to obtain

$$x_\delta = \sum_{i=1}^{n} \frac{\sigma_i u_i^T b}{\sigma_i^2 + \lambda} v_i \tag{21}$$

and then taking norms.

Similarly, as long as $\delta \geq \|x_{\mathrm{TLS}}\|$, the constraint in (19) is not binding, and in this case we have the standard TLS problem with $\lambda_{IL} = -\bar{\sigma}_{n+1}^2$ [17, Theorem 2.7]. As δ is reduced below $\|x_{\mathrm{TLS}}\|$, (21) again shows that the λ_{IL} value must increase monotonically in order to reduce the solution norm.

Noting that $\|x_{\mathrm{LS}}\| \leq \|x_{\mathrm{TLS}}\|$ [17, Corollary 6.2], the theorem's conclusion follows. □

In regularization problems, the norm $\|x_{\mathrm{LS}}\|_2$ of the LS solution is normally very large due to the errors; thus, one will choose $\delta \leq \|x_{\mathrm{LS}}\|_2$. When this is the case, we conclude from Theorem 2.2 that R-TLS produces solutions that are identical to the Tikhonov solutions. In other words, replacing the LS residual with the TLS residual in the Tikhonov formulation has no effect when $L = I_n$ and $\delta \leq \|x_{\mathrm{LS}}\|_2$.

We remark that since $\|x_{\mathrm{TLS}}\|_2 \geq \|x_{\mathrm{LS}}\|_2$, there is usually a nontrivial set of "large" values of δ for which the multiplier λ_{IL} is negative. The corresponding R-TLS solutions $\bar{x}_\delta$ are distinctly different from the Tikhonov solutions and can be expected to be even more dominated by errors than the LS solution x_{LS}.

We illustrate Theorem 2.2 with an example: discretization of a Fredholm integral equation with the second derivative operator as kernel. The implementation is deriv2 from [9], the size of the matrix A is 64×32, and both A and b are perturbed by

Gaussian noise with zero mean and standard deviation 10^{-5}. We have $\bar{\sigma}_{n+1}^2 \approx 2.38 \cdot 10^{-9}$. Figure 1 shows the solutions listed in Table 1. We see that both x_{LS} and x_{TLS} have large oscillations (the oscillations of x_{TLS} being larger than those of x_{LS}), while the regularized LS solution x_λ corresponding to $\lambda = 10^{-5}$ is much smoother. The R-TLS solution, corresponding to $\lambda = -\frac{1}{2}\bar{\sigma}_{n+1}^2 = -1.19 \cdot 10^{-9}$, has large oscillations whose amplitude is between that of x_{TLS} and x_{LS}.

We conclude that if we use Tikhonov regularization with $L = I$ in order to reduce the norm of the solution below $\|x_{\mathrm{LS}}\|_2$, then the R-TLS formulation produces the same solution as the regularized LS formulation. This is in contrast to the truncating approach, since we have shown in [4] that truncated TLS can be superior to truncated LS.

2.2. The general-form case. In many applications, it is necessary to choose a matrix L different from the identity matrix; these issues are discussed, e.g., in [10, section 4.3]. In this case, the R-TLS solution $\bar{x}_\delta$ is different from the Tikhonov solution whenever the residual $b - Ax$ is different from zero, since both λ_I and λ_L are nonzero.

From Theorem 2.1 we notice that λ_L is always positive when $\delta < \|x_{\mathrm{TLS}}\|_2$, because the Lagrange parameter μ is positive for these values of λ. On the other hand, λ_I is always negative and thus adds some *deregularization* to the solution. Statistical aspects of a negative regularization parameter in Tikhonov's method are discussed in [13].

For a given δ, there are usually several pairs of parameters λ_I and λ_L (and thus several solutions x) that satisfy relations (9)–(11), but only one of these solves the optimization problem (7). According to (13), this is the solution that corresponds to the smallest value of $|\lambda_I|$. The following relations hold.

THEOREM 2.3. *For a given value of δ, the solution $\bar{x}_\delta$ to the R-TLS problem is related to the solution to the TLS problem x_{TLS} as in the following chart.*

δ	Solution	λ_I	λ_L
$\delta < \|L\,x_{\mathrm{TLS}}\|_2$	$\bar{x}_\delta \neq x_{\mathrm{TLS}}$	$\lambda_I < 0 \quad \partial\lambda_I/\partial\delta > 0$	$\lambda_L > 0$
$\delta \geq \|L\,x_{\mathrm{TLS}}\|_2$	$\bar{x}_\delta = x_{\mathrm{TLS}}$	$\lambda_I = -\bar{\sigma}_{n+1}^2$	$\lambda_L = 0$

Proof. For $\delta < \|L\,x_{\mathrm{TLS}}\|_2$, the inequality constraint is binding and the Lagrange multiplier μ is positive, since this is a necessary condition for optimality; see, for example, [14]. Thus λ_L is positive. The residual (13) is monotonically decreasing as δ increases, since optimal solutions for smaller values of δ are candidate solutions for larger δs, so λ_I is monotonically increasing.

For $\delta = \|L\,x_{\mathrm{TLS}}\|_2$, the Lagrange multiplier is zero, and the solution becomes the unconstrained minimizer x_{TLS}. The value $-\bar{\sigma}_{n+1}^2$ follows from [5, Theorem 4.1]. The constraint is never again binding for larger δ, so the solution to the problem remains unchanged. ∎

We note that if the matrix $\lambda_I I_n + \lambda_L L^T L$ is positive definite, then the R-TLS solution corresponds to a Tikhonov solution for which the expression $\lambda\,\|L\,x\|_2$ in (3) is replaced with the norm $(\lambda_I\|x\|_2^2 + \lambda_L\|L\,x\|_2^2)^{1/2}$. If $\lambda_I I_n + \lambda_L L^T L$ is indefinite or negative definite then there is no equivalent interpretation.

3. Computational aspects. To compute the R-TLS solutions for $L \neq I_n$, we have found it most convenient to avoid explicit use of δ; instead we use λ_L as the free parameter, fixing its value and then computing the value of λ_I that satisfies (10) and is smallest in absolute value. The corresponding value of δ can then easily be computed from relation (12).

We now discuss how to solve (9) efficiently for many values of λ_I and λ_L. First, we note that the equation is equivalent to the augmented system

$$\begin{pmatrix} I_m & 0 & A \\ 0 & I_p & \lambda_L^{1/2} L \\ A^T & \lambda_L^{1/2} L^T & -\lambda_I I_n \end{pmatrix} \begin{pmatrix} r \\ s \\ x \end{pmatrix} = \begin{pmatrix} b \\ 0 \\ 0 \end{pmatrix}. \tag{22}$$

Our algorithm is based on this formulation.

We assume that the matrix L is a banded matrix, often the case when L represents a derivative operator. The key to efficiency, then, is to reduce A to $n \times n$ bidiagonal form B by means of orthogonal transformations: $H^T A K = B$. The orthogonal right transformations also should be applied to L, and simultaneously we should apply orthogonal transformations to L from the left in order to maintain its banded form. It is convenient to use sequences of Givens transformations to form J, H, and K, since this gives us the most freedom to retain the banded form of $C = J^T L K$.

Once B and C have been computed, we can recast the augmented system in (22) in the following form:

$$\begin{pmatrix} I_n & 0 & B \\ 0 & I_p & \lambda_L^{1/2} C \\ B^T & \lambda_L^{1/2} C^T & -\lambda_I I_n \end{pmatrix} \begin{pmatrix} H^T r \\ J^T s \\ K^T x \end{pmatrix} = \begin{pmatrix} H^T b \\ 0 \\ 0 \end{pmatrix}. \tag{23}$$

Since λ_I changes more frequently than λ_L in our approach, we will now use Givens rotations to annihilate $\lambda_L^{1/2} C$ using B by means of Elden's algorithm [1, section 5.3.4], which can be represented as

$$\begin{pmatrix} B \\ \lambda_L^{1/2} C \end{pmatrix} = G \begin{pmatrix} \hat{B} \\ 0 \end{pmatrix} = \begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix} \begin{pmatrix} \hat{B} \\ 0 \end{pmatrix}.$$

When we insert this G into the augmented system (23), it becomes

$$\begin{pmatrix} I_n & 0 & \hat{B} \\ 0 & I_p & 0 \\ \hat{B}^T & 0 & -\lambda_I I_n \end{pmatrix} \begin{pmatrix} \hat{r} \\ \hat{s} \\ K^T x \end{pmatrix} = \begin{pmatrix} G_{11}^T H^T b \\ G_{12}^T H^T b \\ 0 \end{pmatrix}.$$

The middle block row is now decoupled, and we obtain

$$\begin{pmatrix} I_n & \hat{B} \\ \hat{B}^T & -\lambda_I I_n \end{pmatrix} \begin{pmatrix} \hat{r} \\ K^T x \end{pmatrix} = \begin{pmatrix} G_{11}^T H^T b \\ 0 \end{pmatrix}.$$

Finally, we apply a symmetric perfect shuffle reordering

$$n+1, 1, n+2, 2, n+3, 3, \ldots, n, 2n$$

to the rows and columns of the above matrix, to obtain a symmetric, tridiagonal, indefinite matrix of size $2n \times 2n$:

$$\begin{pmatrix} -\lambda_I & \hat{b}_{11} & & & \\ \hat{b}_{11} & 1 & \hat{b}_{12} & & \\ & \hat{b}_{12} & -\lambda_I & \hat{b}_{22} & \\ & & \hat{b}_{22} & 1 & \ddots \\ & & & \ddots & \ddots \end{pmatrix}.$$

Up until now, we have used only orthogonal transformations in order to preserve numerical stability. We can solve this permuted system in a stable way using a general tridiagonal solver (e.g., Gauss elimination with partial pivoting).

4. Numerical results. In this section we present a numerical example that demonstrates the usefulness of the R-TLS method. Our computations are carried out in MATLAB using the *Regularization Tools* package [9].

It is a generally accepted fact that, for small noise levels, we should not expect the ordinary TLS solution to differ much from the ordinary LS solution; see [15]. The same observation is made in [4] for the T-TLS solution, and the numerical results presented below also support this observation for the R-TLS method. We emphasize that the precise meaning of "small" depends on the particular problem.

In several test problems from [9], the R-TLS algorithm was able to compute better results than Tikhonov's method. The test problem we have chosen to illustrate the R-TLS algorithm is the one for which the improvement is most dramatic. This test problem is a discretization by means of Gauss–Laguerre quadrature of the inverse Laplace transform

$$\int_0^\infty \exp(-s\,t)\,f(t)\,dt = \frac{1}{2} - \frac{1}{s+4/25}, \quad 0 \le s,$$

$$f(t) = 1 - \exp(-t\,4/25),$$

originating from [18] and implemented in the function ilaplace(n,2) in [9], except that the constant $4/25$ was chosen instead of $1/2$. The matrix L approximates the first-derivative operator. The dimensions are $m = n = 16$, the matrix A and the exact solution x^* are scaled such that $\|A\|_F = \|A\,x^*\|_2 = 1$, and the perturbed right-hand side is generated as

$$b = (A + \sigma\|E\|_F^{-1}E)x^* + \sigma\|e\|_2^{-1}e,$$

where the elements of the perturbations E and e are from a normal distribution with zero mean and unit standard deviation.

Figure 2 shows the relative errors $\|x^* - x_\delta\|_2/\|x^*\|_2$ and $\|x^* - \bar{x}_\delta\|_2/\|x^*\|_2$ in the Tikhonov and R-TLS solutions, respectively, for four values of the noise level:

$$\sigma = 0.001,\ 0.01,\ 0.1,\ 1.$$

We see that, for small values of σ, the two methods lead to almost the same minimum relative error, for almost the same value of λ_L. However, for larger values of σ, the minimum relative error for the R-TLS method is clearly smaller than that for Tikhonov's method, and it occurs for a larger value of λ_L. This shows the potential advantage of the R-TLS method, provided, of course, that a good estimate of the optimal regularization parameter can be found. This topic is outside the scope of the current paper.

In Figure 3 we have plotted the "optimal" Tikhonov and R-TLS solutions, defined as the solutions that correspond to the minima of the curves in Figure 2. In addition, we have plotted the exact solution x^*. Clearly, the addition of the term $\lambda_I I_n$ in (9) introduces a nonconstant component in the right part of the plot of the regularized solution; it is precisely this component that improves the R-TLS error compared to the Tikhonov error.

Conclusion. We have proved that the R-TLS solution to the regularized form (7) of the TLS problem is closely related to the Tikhonov solution to (3). In the standard-form case, $L = I_n$, the two solutions are identical, showing that Tikhonov

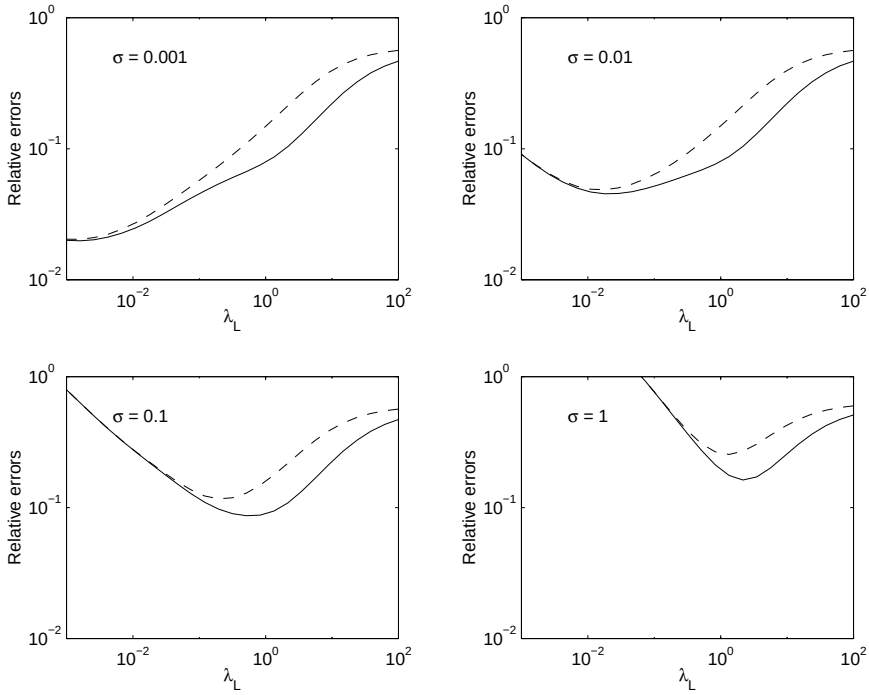

FIG. 2. *Plots of the relative errors in the Tikhonov solutions (dashed lines) and R-TLS solutions (solid lines) versus λ_L for four values of the noise level.*

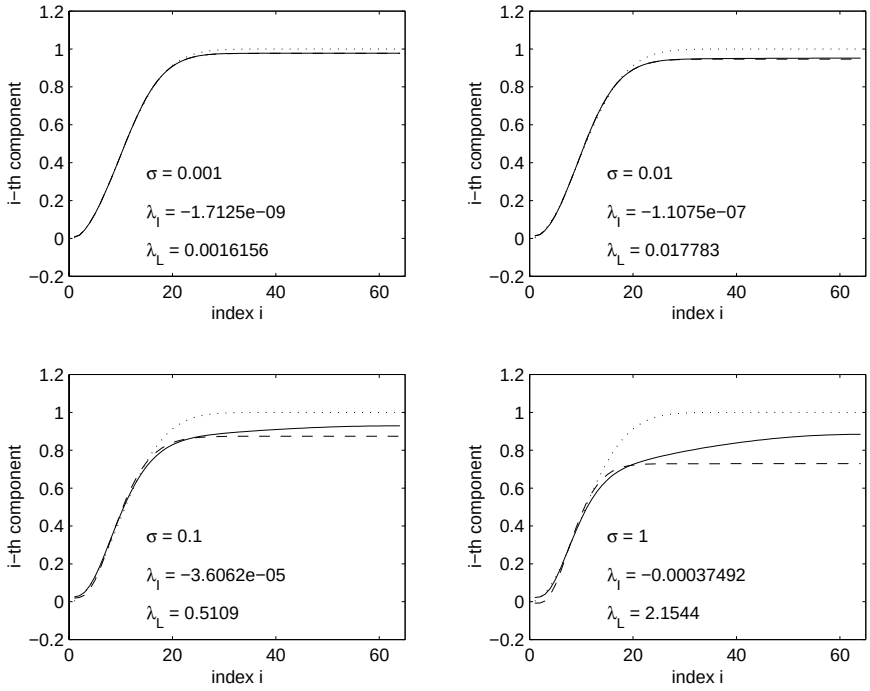

FIG. 3. *Plots of the "optimal" Tikhonov solutions (dashed lines) and R-TLS solutions (solid lines) for four values of the noise level. Also shown is the exact solution (dotted lines).*

regularization in this case is also suited for problems with a perturbed coefficient matrix. For general problems with $L \neq I_n$, the R-TLS solution is different from the corresponding Tikhonov solution in that a deregularizing term $\lambda_I I_n$ with a negative parameter λ_I is added to the formulation in (4).

ON THE OPTIMAL VALUE OF THE SPECTRAL ABSCISSA FOR A SYSTEM OF LINEAR OSCILLATORS*

PEDRO FREITAS† AND PETER LANCASTER‡

Abstract. We consider the linear system of differential equations $Au''(t) + Bu'(t) + Cu(t) = 0$, where A, B, and C are $n \times n$ real symmetric matrices, and study the problem of, given A and C, finding B which optimizes the asymptotic rate of decay of solutions of this equation. The optimal value for this rate of decay is found and we show that it is attained within this class of matrices. We then study some of the properties of optimal matrices. In particular, we show that the solution is not unique in general and that optimal matrices do not have to be positive definite. A sufficient condition for all optimal matrices to be positive definite is given and some examples are discussed.

1. Introduction.

By a system of linear oscillators we mean here a linear time-invariant differential system

$$\begin{cases} Au''(t) + Bu'(t) + Cu(t) = 0, \\ u(0) = u_0, \quad u'(0) = u_1, \end{cases} \tag{1.1}$$

where A, B, and C are $n \times n$ real symmetric matrices. We assume A and C to be positive definite, and write $A, C > 0$. In the engineering literature, these coefficients are called the mass and stiffness of the system, and are associated with kinetic and potential energies, respectively. The energy of a solution of (1.1) at time t is then defined to be

$$E(t) = \frac{1}{2}\langle u'(t), Au'(t)\rangle + \frac{1}{2}\langle u(t), Cu(t)\rangle, \tag{1.2}$$

where $\langle \cdot\, , \cdot \rangle$ denotes the usual inner product on $\mathbb{R}^n$.

Our objective here is the solution of the following optimization problem: given A and C as above, determine a real symmetric $n \times n$ matrix B which will, in a suitable sense (see section 2), maximize the rate of decay of $E(t)$ as t goes to infinity (more precisely, maximize the minimal asymptotic rate of decay of $E(t)$ with respect to solutions $u(t)$). In physical terms, this corresponds to the determination of the damping that causes solutions to converge to zero in the (asymptotically) fastest possible way.

This question and similar questions have received some attention in the mathematics literature but, so far, the problem has been solved only under restrictive

conditions. See [3], for instance. For the general problem, Cox showed that the optimal rate of decay is bounded by the square root of the largest eigenvalue of the matrix $A^{-1}C$.

From the simple case where n is 1 it is known that the function that gives the spectral abscissa in terms of the entries of B is not differentiable at all points. This turns out to be quite a general situation, in the sense that this type of optimization problem tends to cause the coalescence of points of the spectrum, giving rise to eigenvalues which have different geometric and algebraic multiplicities (see [1]).

In [4], for instance, the authors considered the problem of optimizing the spectral abscissa for the wave equation and studied the perturbation along straight lines of a double eigenvalue occurring in the case of constant damping. At the end of that paper they point out that a similar approach can be used for the case of equation (1.1). However, this method cannot, without any further calculations, distinguish between a saddle point and an optimum. In particular, the optimum produced in [3] under one of the restrictions mentioned above also gives rise to a double eigenvalue and a similar perturbation analysis will show that this is optimal for matrices $B + \epsilon\Gamma$.

In relation to this it should be pointed out that the problem of optimizing the spectral abscissa is global, in the sense that it requires full knowledge of the spectrum. Because of this, in the present work we shall use a different strategy which will allow us to improve Cox's bounds and show that in fact the best possible decay rate for the energy is given by

$$\left[\frac{\det(C)}{\det(A)}\right]^{1/n}.$$

We then prove that this value is indeed attained for some real symmetric matrix B.

In this case we shall solve the optimization problem by showing that the above bound can only be attained if the associated eigenvalue problem has a single eigenvalue of multiplicity $2n$. This allows us to reformulate the problem as an inverse spectral problem: given A and C, find B such that

$$-\left[\frac{\det(C)}{\det(A)}\right]^{1/2n}$$

is an eigenvalue of the quadratic matrix polynomial $L(\lambda) = \lambda^2 A + \lambda B + C$ with multiplicity $2n$.

Another issue that is important when considering problems of this type is that of positive definiteness of the matrices involved. For example, if $A > 0$ and C is indefinite, then there will exist unbounded solutions irrespectively of B. Regarding the damping term B it is well known that for positive definite A and C the decay rate is necessarily positive if B is a positive definite matrix. Here we will show that optimal rates of decay can be achieved (for the same pair (A, C)) with more than one matrix B, and, under some conditions, even with matrices B which are not positive definite. This is, at least at first, quite a surprising result, as the physical interpretation is that in some sense we have to supply energy to the system for the solutions to decay faster. We give a sufficient condition for all optimal matrices to be positive definite and then, through examples, show that in some cases there is coexistence of indefinite and positive definite optimal matrices and that it may also happen that all optimal matrices are indefinite.

In systems theory language the situation can be described in a different way. Given $A > 0$, $C > 0$, and $B_0 = B_0^T$, consider the system

$$Au''(t) + B_0u'(t) + Cu(t) = B_1v(t)$$

with a symmetric feedback matrix B_1. We show that with *velocity feedback*, $v(t) = u'(t)$ there are matrices B_1 which yield the optimal decay rate described and we examine the cases for which $B := B_0 - B_1 > 0$. As indicated above, it turns out that we solve a *spectral assignment problem*, and the solution by standard system theory methods is far from clear, as we assume C to be fixed [2].

The organization of the paper is as follows. In section 2 we formulate the problem and state our main results in a precise way. In section 3 we establish the optimal value for the rate of decay and show that it can be attained. Section 4 contains a complete analysis of the case where n is two. Properties of optimal matrices are presented in section 5 and a discussion of the elementary divisor structure of optimal $L(\lambda)$ is made in section 6. Section 7 contains a sufficient condition for all optimal matrices to be positive definite and we conclude in section 8 with a discussion of the results presented and another example.

2. Statement of the problem and main results. As the matrix A is assumed to be positive definite, it is possible to make the change of variables $u = A^{-1/2}v$ in (1.1) to obtain

$$v''(t) + A^{-1/2}BA^{-1/2}v'(t) + A^{-1/2}CA^{-1/2}v(t) = 0.$$

From this we see that we can assume, without loss of generality, that A is the identity matrix and then study the system

$$u''(t) + Bu'(t) + Cu(t) = 0, \tag{2.1}$$

where B and C belong to S_n, the space of $n \times n$ real symmetric matrices. We shall assume that C is positive definite with eigenvalues $0 < c_1 \leq \cdots \leq c_n$. In order to study the decay of solutions of this equation, we are then led to the quadratic pencil

$$L(\lambda) = I\lambda^2 + B\lambda + C. \tag{2.2}$$

Denote by Σ_L the spectrum of $L(\lambda)$, that is, the set of complex numbers λ for which there exists a nontrivial vector v such that $L(\lambda)v = 0$, and for each fixed matrix C of the form above, define the function $\Omega : S_n \to \mathbb{R}$ by

$$\Omega(B) = \min_{\lambda \in \Sigma_L} \left[-\mathrm{Re}(\lambda)\right].$$

For each pair of matrices (B, C), this function gives the corresponding spectral abscissa, that is, minus the largest of the real parts of the eigenvalues of $L(\lambda)$. Thus there exists a constant κ such that the energy of solutions of system (2.1) as defined by (1.2) satisfies

$$E(t) \leq \kappa E(0) e^{(-2\omega+\delta)t}$$

with $\omega = \Omega(B)$ and for all positive δ and t. It is clear that each pair (B, C) at which ω is equal to $\Omega(B)$ gives the best possible value that can be considered in this energy inequality.

If we want to maximize the asymptotic rate at which the total energy of the system decays to zero, we must thus maximize the function Ω over the space S_n and determine if this value is attained. Note that, because Ω depends continuously on the entries of B, Ω will attain its maximum on compact subsets of S_n. Thus, since it is known that the spectral abscissa is bounded, it would in principle be possible to find a suitable compact subset of S_n where the maximum over all symmetric matrices would be attained. However, this argument cannot ensure that a larger value could not be obtained over the set of all $n \times n$ matrices. Moreover, it is not even clear at the start that the value of ω_o given below in Theorem 1 can be attained within the set of all $n \times n$ matrices.

Thus our problem reduces to determining the supremum of Ω over the space S_n, that is,

$$\omega_o = \sup_{B \in S_n} \left[\Omega(B)\right]. \tag{2.3}$$

This number will be called the optimal spectral abscissa of (2.2).

In [3] it was shown that the function Ω is bounded from above over the set of all positive definite matrices. More precisely, and in our notation, it was shown that ω_o is smaller than or equal to $c_n^{1/2}$, the square root of the largest eigenvalue of C. However, this bound will not be sharp in general—only in the trivial case when C is scalar—and in Theorem 3.1 we give an improvement of this estimate. We then go on to show that this new bound is actually the best possible, and we prove in Theorem 3.2 that it is attainable. The main results of our paper (in the context of the system (1.1)) can be summarized in the following two theorems, the first concerning existence and nonuniqueness, the second regarding positivity of optimal matrices:

THEOREM 1 (existence). *The function*

$$\Omega(B) = \min_{\lambda \in \Sigma_L} \left[-\mathrm{Re}(\lambda)\right]$$

attains its maximum

$$\omega_o = \left[\frac{\det(C)}{\det(A)}\right]^{1/2n}$$

within the set S_n. The optimal matrix is unique if and only if there exists a positive constant c such that $C = cA$, in which case $B_o = 2c^{1/2}A$.

THEOREM 2 (positivity). *Let $\gamma_1, \ldots, \gamma_n$ denote the eigenvalues of the problem*

$$Cv = \gamma Av$$

in increasing order. If

$$\gamma_1 > \frac{\left(\gamma_2^{1/2} + \cdots + \gamma_n^{1/2}\right)^{2n}}{n^{2n}\gamma_2, \ldots, \gamma_n},$$

then all optimal matrices are positive definite.

Although not optimal (see section 7), this result is important as it says when the optimum can be achieved by means of a positive definite matrix. This may be of interest in applications where there are restrictions that force the damping term to be positive. We also remark that in fact we prove a stronger result which gives a bound on the number of positive eigenvalues of an optimal matrix in terms of the separation of the spectrum (see Theorem 7.1).

3. The optimal rate of decay and attainability.

THEOREM 3.1. *The function Ω is bounded from above and the optimal spectral abscissa satisfies*

$$\omega_o \leq [\det(C)]^{1/(2n)}.$$

Furthermore, equality holds if and only if $L(\lambda)$ has one single (real) eigenvalue with algebraic multiplicity $2n$ and, in this case, $L(\lambda) \geq 0$ for all real λ.

Proof. Define the companion matrix M by

$$M = \begin{bmatrix} 0 & I \\ -C & -B \end{bmatrix}.$$

Then the eigenvalues of M and of the pencil $L(\lambda)$ coincide. Let $\{\lambda_j\}_{j=1}^{2n}$ denote these eigenvalues written in increasing order of their real parts so that $\Omega(B) = -\mathrm{Re}(\lambda_{2n})$ (note that it can thus be assumed that all eigenvalues have negative real parts, for otherwise the zero matrix would give zero as an upper bound for Ω). Now let $p(\lambda)$ denote the characteristic polynomial of M (and thus also of $L(\lambda)$), that is, $p(\lambda) = \det(\lambda I - M) = \det(L(\lambda))$. Then

$$p(0) = \det(M) = \det(C) = \prod_{j=1}^{2n} \lambda_j,$$

and thus this product is independent of the matrix B. This in turn implies that the function Ω is bounded from above.

On the other hand,

$$\det(M) = \prod_{j=1}^{2n} \lambda_j \geq \prod_{j=1}^{2n} \mathrm{Re}(\lambda_j) \geq [\mathrm{Re}(\lambda_{2n})]^{2n} = [\Omega(B)]^{2n}, \tag{3.1}$$

and thus

$$\omega_o \leq [\det(C)]^{1/(2n)}.$$

To prove the second part of the theorem, note first that if $L(\lambda)$ has a single eigenvalue with multiplicity $2n$, then clearly equality will hold. On the other hand, if there are two distinct eigenvalues, then the second inequality used in (3.1) will be strict and ω_o will be strictly smaller than $[\det(C)]^{1/(2n)}$.

To see that $L(\lambda) \geq 0$ for all λ in $\mathbb{R}$, observe that $L(\lambda) > 0$ for all λ sufficiently large, and then use the continuity of the (λ-dependent) eigenvalues of $L(\lambda)$. ∎

REMARK 3.1. This bound actually extends to the space of all real $n \times n$ matrices, as it is determined by C independently of B.

We shall now prove that this bound is actually attained, meaning that there will exist a matrix B in S_n for which $\Omega(B) = [\det(C)]^{1/(2n)}$, and thus the quadratic pencil $L(\lambda)$ will have a multiple eigenvalue with multiplicity $2n$. In this way, the original optimization problem has been transformed into an inverse spectral problem.

THEOREM 3.2. *There exists a matrix B_o in S_n such that*

$$\Omega(B_o) = [\det(C)]^{1/(2n)},$$

that is, the upper bound for ω_o given in Theorem 3.1 *is attained.*

The idea behind the proof of this theorem is as follows. Let W be a real $n \times n$ matrix (not generally symmetric) with one single eigenvalue, say $-\alpha$, with algebraic multiplicity n. Then the quadratic pencil

$$(\lambda I - W^t)(\lambda I - W) = \lambda^2 I - \lambda(W^t + W) + W^t W$$

is symmetric and will have an eigenvalue at $\lambda = -\alpha$ with algebraic multiplicity $2n$. If it is possible to find a matrix W which also satisfies $W^t W = C$, it follows that $[\det(W)]^2 = \det(C)$ and so α must satisfy

$$\alpha = [\det(C)]^{1/(2n)}.$$

If such a matrix W exists, then the matrix $B = -(W^t + W)$ is a solution to the inverse problem and thus also to the optimization problem. We remark that this construction originates in the theory of matrix polynomials which are nonnegative whenever λ is real (see [6]).

We begin our construction of the matrix W by building an upper triangular matrix with the desired properties.

PROPOSITION 3.3. *Let $\omega_o = [\det(C)]^{1/(2n)}$. Then there exists a real upper triangular $n \times n$ matrix J having one single eigenvalue equal to $-\omega_o$ with multiplicity n, and such that $J^t J$ is similar to C.*

As C is symmetric, this result is equivalent to saying that there exists a real upper triangular $n \times n$ matrix J with an eigenvalue at $-\alpha$ with multiplicity n and whose singular values are the square roots of the eigenvalues of C. In order to show that such a matrix exists, we shall make use of the following result of A. Horn [7]. See also the discussion of these inequalities in [8].

THEOREM 3.4 (Horn's theorem). *Let $(\sigma_1, \ldots, \sigma_n) \in \mathbb{R}^n$ and $(\alpha_1, \ldots, \alpha_n) \in \mathbb{C}^n$ be a pair of n-tuples satisfying*

$$|\alpha_1| \geq \cdots \geq |\alpha_n|, \quad \sigma_1 \geq \cdots \geq \sigma_n \geq 0$$

and

$$|\alpha_1| \cdots |\alpha_k| \leq \sigma_1 \cdots \sigma_k, \tag{3.2}$$

for $k = 1, \ldots, n$, with equality for $k = n$.

Then there exists an upper triangular matrix Δ which has the n-tuples $(\alpha_1, \ldots, \alpha_n)$ and $(\sigma_1, \ldots, \sigma_n)$ as its eigenvalues and singular values respectively. Furthermore, if $\alpha_1, \ldots, \alpha_n$ are real, then the matrix Δ can be taken to be real.

The upper triangular property of Δ is not essential in the proof of Proposition 3.3, but is retained here for historical reasons. Relations (3.2) are known as Weyl inequalities, and they establish a relation between the eigenvalues and the singular values of a matrix. Basically, Horn's result is the converse of Weyl's Theorem, showing that these inequalities are also sufficient.

In our case, we have $\alpha_i = -\omega_o$ for $i = 1, \ldots, n$, and we want to build a matrix which will have the square roots of the eigenvalues of C as its singular eigenvalues. We first prove that the corresponding n-tuples built in this way satisfy Weyl's inequalities.

LEMMA 3.5. *If $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$ and $\alpha = (\sigma_1 \cdots \sigma_n)^{1/n}$, then*

$$\alpha^k \leq \sigma_1 \cdots \sigma_k, \quad k = 1, \ldots, n,$$

with equality for $k = n$.

Proof. Equality when k equals n is immediate from the definition of α. For $k < n$ notice first that $\sigma_1 \geq \cdots \geq \sigma_k$ implies

$$(\sigma_1 \cdots \sigma_k)^{n-k} \geq \sigma_k^{k(n-k)}.$$

Similarly, $\sigma_{k+1} \geq \cdots \geq \sigma_n$ gives

$$\sigma_{k+1}^{k(n-k)} \geq (\sigma_{k+1} \cdots \sigma_n)^k$$

and thus $\sigma_k \geq \sigma_{k+1}$ yields

$$(\sigma_1 \cdots \sigma_k)^{n-k} \geq (\sigma_{k+1} \cdots \sigma_n)^k.$$

Hence

$$\begin{aligned} \alpha^k &= (\sigma_1 \cdots \sigma_k)^{k/n} (\sigma_{k+1} \cdots \sigma_n)^{k/n} \\ &\leq (\sigma_1 \cdots \sigma_k)^{k/n} (\sigma_1 \cdots \sigma_k)^{(n-k)/n} \\ &= \sigma_1 \cdots \sigma_k. \qquad \square \end{aligned}$$

REMARK 3.2. This inequality can also be obtained from a well-known property of the arithmetic mean by putting $a_j = \log(\sigma_j)$.

Proof of Theorem 3.2. By Horn's theorem and Lemma 3.5 there will exist a real $n \times n$ matrix J, such that J has $-\alpha = -[\det(C)]^{1/(2n)}$ as its single eigenvalue (with multiplicity n) and the numbers $c_1^{1/2}, \ldots, c_n^{1/2}$ as its singular values. The last statement is equivalent to saying that the matrix $P = J^t J$ has eigenvalues $c_1, \ldots, c_n$, and thus there exists a real orthogonal matrix R such that $C = R^t P R$.

We now claim that the matrix $W = R^t J R$ satisfies the properties mentioned previously, that is, W has one single eigenvalue $-\alpha$ with multiplicity n, and $W^t W = C$. The first property is immediate from the definition of W. For the second, just notice that $W^t W = R^t J^t R R^t J R = R^t J^t J R = R^t P R = C$. From this it follows that the matrix $B_o = -(W^t + W)$ satisfies the conditions of the theorem.

4. The case $n = 2$. At this stage, the only situation for which it is feasible to compute explicitly all possible solutions of the optimization problem (2.3) by hand is when n equals 2. As this case already displays some of the features of the general problem, we shall present a full description of the solution.

We consider the quadratic polynomial (2.2) when n equals 2,

$$B = \begin{bmatrix} b_{11} & b_{12} \\ b_{12} & b_{22} \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix}.$$

In this case, the characteristic polynomial associated with $L(\lambda)$ is given by

$$p(\lambda) = \lambda^4 + \operatorname{trace}(B)\lambda^3 + [\det(B) + \operatorname{trace}(C)]\,\lambda^2 + (b_{11}c_2 + b_{22}c_1)\lambda + \det(C),$$

and in order for it to have $\lambda = -\alpha$ as a root with multiplicity 4 it has to be of the form $\lambda^4 + 4\alpha\lambda^3 + 6\alpha^2\lambda^2 + 4\alpha^3\lambda + \alpha^4$. Comparing the two polynomials gives a set of three equations in the entries of the matrix B, namely

$$\text{(4.1)} \qquad \begin{cases} \operatorname{trace}(B) = 4\alpha, \\ \det(B) + \operatorname{trace}(C) = 6\alpha^2, \\ b_{11}c_2 + b_{22}c_1 = 4\alpha^3, \end{cases}$$

and a fourth equation which is just the statement that $\alpha = [\det(C)]^{1/4}$. Solving these equations with respect to the entries of B gives

$$\begin{cases} b_{11} = \dfrac{4c_1^{3/4}c_2^{1/4}}{c_1^{1/2}+c_2^{1/2}}, \\ b_{22} = \dfrac{4c_1^{1/4}c_2^{3/4}}{c_1^{1/2}+c_2^{1/2}}, \\ b_{12}^2 = \dfrac{16\det(C)}{\left(c_1^{1/2}+c_2^{1/2}\right)^2} + \operatorname{trace}(C) - 6\left[\det(C)\right]^{1/2}. \end{cases}$$

The expression for b_{12}^2 gives

$$b_{12} = \pm\frac{\left(c_1^{1/2}-c_2^{1/2}\right)^2}{c_1^{1/2}+c_2^{1/2}},$$

and we thus have the following

PROPOSITION 4.1. *In the case where n equals 2, there always exist two and only two optimal matrices B, except in the case where C is scalar when the solution is unique. These solutions are given by*

$$B = \frac{1}{c_1^{1/2}+c_2^{1/2}}\begin{bmatrix} 4c_1^{3/4}c_2^{1/4} & \pm\left(c_1^{1/2}-c_2^{1/2}\right)^2 \\ \pm\left(c_1^{1/2}-c_2^{1/2}\right)^2 & 4c_1^{1/4}c_2^{3/4} \end{bmatrix}.$$

Furthermore, these optimal matrices are positive definite if and only if

$$c_2 < (17+12\sqrt{2})c_1.$$

Proof. It only remains to prove the positivity result. As B must have at least one positive eigenvalue, it will be positive definite if and only if its determinant is positive. From (4.1),

$$\det(B) = 6\alpha^2 - \operatorname{trace}(C) = 6\left[\det(C)\right]^{1/2} - \operatorname{trace}(C)$$

and the result follows (note that it is assumed that $c_1 \le c_2$). ∎

5. Properties of optimal matrices. We begin by giving two simple properties of optimal matrices. The first is the fact that all optimal matrices have the same trace. This will be useful in obtaining a sufficient condition for positivity of optimal matrices.

PROPOSITION 5.1. *Let B be an optimal matrix. Then* $\operatorname{trace}(B) = 2n\omega_o$.

Proof. Consider the companion matrix M defined in the proof of Theorem 3.1. If B is optimal, then M has an eigenvalue at $-\omega_o$ with multiplicity $2n$. This means that $\operatorname{trace}(M) = -2n\omega_o$. On the other hand, $\operatorname{trace}(M) = -\operatorname{trace}(B)$ and the result follows. ∎

A second property has to do with bounds for the eigenvalues of an optimal matrix.

PROPOSITION 5.2. *Let B be an optimal matrix with eigenvalues $b_1 \le \cdots \le b_n$. Then $-2c_{n-j}^{1/2} \le b_j \le 2c_j^{1/2}$.*

Proof. If B is optimal, then, by Theorem 3.1, $L(\lambda)$ is nonnegative for all real λ. We thus have that $\lambda^2 I + B\lambda + C \geq 0$ and, for negative λ,

$$B \leq -\lambda I - \frac{1}{\lambda} C.$$

This inequality in turn implies that the (ordered) eigenvalues of B and C satisfy

$$b_j \leq -\lambda - \frac{1}{\lambda} c_j.$$

The expression on the right-hand side takes its (local) minimum value $2c_j^{1/2}$ when λ equals $-c_j^{1/2}$, and thus $b_j \leq 2c_j^{1/2}$. A similar argument for positive λ gives $b_j \geq -2c_{n-j}^{1/2}$. ∎

In the 2×2 case we saw that there existed two different optimal matrices, except in the case where C was a scalar matrix. We shall now show that a similar nonuniqueness result holds for any n.

PROPOSITION 5.3. *The solution of the optimization problem is unique if and only if the matrix C is scalar.*

Proof. If C is a scalar matrix, say $C = cI$, then it is easily seen that the optimal matrix B_o is unique and is given by $2c^{1/2}I$.

Assume now that C is not scalar but that, without loss of generality, it is in diagonal form. Let B_o be a corresponding optimal matrix. Then B_o cannot be diagonal, for this would not yield a single multiple eigenvalue. Let b_{ij} $(i \neq j)$ be an entry of B_o which is nonzero, and let δ be an n-dimensional vector whose components δ_k are either $+1$ or -1, such that $\delta_i \neq \delta_j$. Then, if $D = \operatorname{diag}\{\delta\}$, the polynomials $L(\lambda) = I\lambda^2 + B_o\lambda + C$ and $\tilde{L}(\lambda) = \lambda^2 I + DB_oD\lambda + C$ have the same (optimal) spectrum. Because of the way in which the vector δ was constructed, the entries ij of the matrices B_o and DB_oD have opposite signs, and thus DB_oD is an optimal matrix different from B_o. ∎

By using the same argument used to prove nonuniqueness it is possible to obtain the following.

PROPOSITION 5.4. *Let B_o be an optimal matrix and let m_r and m_c denote, respectively, the number of rows and the number of columns of B_o which have at least one nonzero entry above the main diagonal. If $m = \max\{m_r, m_c\}$, then there will exist at least 2^m distinct optimal matrices (including B_0). These optimal matrices have the same spectrum.*

Proof. Assume $m = m_r$: a similar argument holds if $m = m_c$ instead. Let $b_{i_k j_k}$ be m entries above the main diagonal with $i_k \neq i_l$ for $k \neq l$, and build a vector $\delta = (\delta_1, \ldots, \delta_n)$ with $\delta_{i_k} = +1$ or -1 and $\delta_j = 1$ if $j \neq i_k$ for all k. This gives 2^m possible vectors δ and if $T_p = \operatorname{diag}\{\delta^p\}$, $p = 1, \ldots, 2^m$, then $T_pCT_p = C$ and $T_pB_oT_p \neq T_qB_oT_q$ for $p \neq q$. ∎

REMARK 5.1. Note that if any of the entries δ_j which are fixed to be $+1$ are changed to -1 this will not affect the corresponding matrix $T_pB_oT_p$, so that in fact this gives all the matrices that can be obtained in this way from a single matrix.

From Example 7.1 below, we know that for n greater than 2 not all optimal matrices can be obtained in this way from a single optimal matrix.

6. The elementary divisor structure of an optimal $L(\lambda)$. As the optimal decay occurs at an eigenvalue of maximum possible multiplicity, it is natural to inquire

about the elementary divisors of $L(\lambda)$ associated with the eigenvalue $\lambda_o = \omega_o$. Recall that $L(\lambda)$ is equivalent to a diagonal matrix of monic invariant polynomials,

$$\mathrm{diag}[a_1(\lambda), \ldots, a_n(\lambda)]$$

of nonincreasing degree (the Smith normal form). Here $a_j(\lambda)$ divides $a_{j-1}(\lambda)$, $j = 2, \ldots, n$ and satisfies

$$a_j = (\lambda + \omega_o)^{k_j} q_j(\lambda),\ j = 1, \ldots, n$$

where the q_j are polynomials for which $q_j(-\omega_o) \neq 0$, and $k_1 \geq \cdots \geq k_n \geq 0$. Since $-\omega_o$ is the *only* eigenvalue of $L(\lambda)$, we have

$$\sum_{j=1}^{n} k_j = 2n$$

and $q_j(\lambda) \equiv 1$ for all j. Since $L(\lambda) \geq 0$ for all real λ (Theorem 3.1) it also follows that all the degrees k_j are *even* (see [6, section 12.5], for example). From the Smith form we see that the geometric multiplicity of the eigenvalue $-\omega_o$ (the nullity of $L(-\omega_o)$) is just the number of nonzero integers k_j and, a priori, can range from 1 (when $k_1 = 2n$) to n (when $k_1 = k_2 = \cdots = k_n = 2$). We first show that the latter case can arise only when $L(\lambda)$ has a degenerate form.

PROPOSITION 6.1. *The matrix $L(-\omega_o)$ has a zero eigenvalue with geometric multiplicity n if and only if C is a scalar matrix.*

Proof. We can consider, without loss of generality, that C is in diagonal form.

Clearly if C is a scalar matrix, say $C = cI$, then the optimal matrix B_o would also be scalar and be given, uniquely, by $B_o = 2c^{1/2}I$.

Assume now that C is not a scalar matrix. Then B_o cannot be diagonal, for this would not yield a single multiple eigenvalue. On the other hand, if the real symmetric matrix $L(-\omega_o)$ has a zero eigenvalue with multiplicity n, it must be the zero matrix. But this implies that

$$B_o = -\frac{1}{\omega_o} C - \omega_o I,$$

which is diagonal, a contradiction. ∎

Expressed in terms of the elementary divisor structure of $L(\lambda)$, this means that all n elementary divisors $(\lambda + \omega_o)^k$ of $L(\lambda)$ have $k = 2$.

When $n = 3$, for instance, the *interesting* elementary divisor cases are now $(k_1, k_2, k_3) = (6, 0, 0)$ and $(k_1, k_2, k_3) = (4, 2, 0)$. The following examples show that both can occur.

EXAMPLE 6.1. Let $C = \mathrm{diag}\{2, 4, 8\}$. Then $\omega_o = [\det(C)]^{1/6} = 2$ and the matrix

$$B_o = \frac{1}{3} \begin{bmatrix} 8 & 0 & \sqrt{2} \\ 0 & 12 & 0 \\ \sqrt{2} & 0 & 16 \end{bmatrix}$$

is an optimal matrix for this problem. In this instance,

$$L(-2) = \frac{2}{3} \begin{bmatrix} 1 & 0 & -\sqrt{2} \\ 0 & 0 & 0 \\ -\sqrt{2} & 0 & 2 \end{bmatrix},$$

which has a double zero eigenvalue. The polynomial $L(\lambda)$ has elementary divisors $(\lambda+2)^4, (\lambda+2)^2$, and $(\lambda+2)^0$.

On the other hand, the matrix

$$B_o' = \begin{bmatrix} \sqrt{33}-3 & \dfrac{\sqrt{2}(7-\sqrt{33})\sqrt{3\sqrt{33}-17}}{1+\sqrt{33}} & \dfrac{3\sqrt{33}-17}{\sqrt{2}} \\ \dfrac{\sqrt{2}(7-\sqrt{33})\sqrt{3\sqrt{33}-17}}{1+\sqrt{33}} & \dfrac{(\sqrt{33}-3)(15-\sqrt{33})}{1+\sqrt{33}} & \dfrac{(\sqrt{33}-5)\sqrt{3\sqrt{33}-17}}{2} \\ \dfrac{3\sqrt{33}-17}{\sqrt{2}} & \dfrac{(\sqrt{33}-5)\sqrt{3\sqrt{33}-17}}{2} & \dfrac{4(15-\sqrt{33})}{1+\sqrt{33}} \end{bmatrix}$$

is also an optimal matrix and now

$$L(-2) = \begin{bmatrix} 12-2\sqrt{33} & \dfrac{2\sqrt{2}(\sqrt{33}-7)\sqrt{3\sqrt{33}-17}}{1+\sqrt{33}} & \sqrt{2}(17-3\sqrt{33}) \\ \dfrac{2\sqrt{2}(\sqrt{33}-7)\sqrt{3\sqrt{33}-17}}{1+\sqrt{33}} & \dfrac{4(41-7\sqrt{33})}{1+\sqrt{33}} & (5-\sqrt{33})\sqrt{3\sqrt{33}-17} \\ \sqrt{2}(17-3\sqrt{33}) & (5-\sqrt{33})\sqrt{3\sqrt{33}-17} & \dfrac{4(5\sqrt{33}-27)}{1+\sqrt{33}} \end{bmatrix}$$

has zero as a simple eigenvalue and $L(\lambda)$ has elementary divisors $(\lambda+2)^6, (\lambda+2)^0$ and $(\lambda+2)^0$.

7. Positivity of optimal matrices. As can be seen from the 2×2 case, optimal matrices might not be positive definite when the eigenvalues of C are too far apart. For n larger than 2 the situation becomes more complex and, as will be seen from the examples below, it is possible to have situations where there are optimal matrices which are positive definite and others which are indefinite for the same matrix C. This of course poses some problems from a practical point of view in systems where structural restrictions imply that the damping has to be positive. Our main result in this section is a sufficient condition for all optimal matrices to be positive definite.

THEOREM 7.1. *If*

$$\omega_o > \frac{c_{k+1}^{1/2} + \cdots + c_n^{1/2}}{n}$$

for some integer k in $\{1, \ldots, n-1\}$, then an optimal matrix will have at most $k-1$ nonpositive eigenvalues. In particular, if

$$c_1 > \frac{\left(c_2^{1/2} + \cdots + c_n^{1/2}\right)^{2n}}{n^{2n} c_2 \cdots c_n},$$

then all optimal matrices will be positive definite.

Proof. Assume that B has k (and only k) nonpositive eigenvalues; that is,

$$b_1 \le \cdots \le b_k \le 0 < b_{k+1} \le \cdots \le b_n.$$

Then

$$\text{trace}(B) = b_1 + \cdots + b_n \leq b_{k+1} + \cdots + b_n \leq 2(c_{k+1}^{1/2} + \cdots + c_n^{1/2}), \tag{7.1}$$

where the second inequality follows from Proposition 5.2. On the other hand, we have from Proposition 5.1 that $\text{trace}(B) = 2\omega_o n$, where $\omega_o = [det(C)]^{1/(2n)}$, and thus

$$2\omega_o n \leq 2(c_{k+1}^{1/2} + \cdots + c_n^{1/2}).$$

In order that B has k nonpositive eigenvalues it is then necessary that

$$\omega_o \leq \frac{c_{k+1}^{1/2} + \cdots + c_n^{1/2}}{n}$$

and the result follows. □

Clearly this result is not optimal—just consider the case where n equals 2, and compare with the necessary and sufficient condition given in Proposition 4.1. However, the following example shows that for n larger than 2 it is no longer possible to obtain a simple necessary and sufficient condition for positive definiteness of the optimal matrices.

EXAMPLE 7.1. Let $n = 3$ and consider the matrix $C = \text{diag}\{1/4, 4, 16\}$ for which $\omega_o = 2^{2/3}$. The condition in Theorem 7.1 does not apply when k is one; in fact, it is possible to obtain an optimal matrix which is not positive definite,

$$B_o \approx \begin{bmatrix} 0.6603 & -1.0226 & -1.4899 \\ -1.0226 & 3.1176 & -1.7190 \\ -1.4899 & -1.7190 & 5.7465 \end{bmatrix},$$

with eigenvalues $-0.3876, 3.1748$ and 6.7372.

On the other hand, it is also possible to obtain a positive definite optimal matrix

$$B_o' \approx \begin{bmatrix} 0.6998 & 0.8102 & 1.6470 \\ 0.8102 & 2.2874 & 0.4608 \\ 1.6470 & 0.4608 & 6.5371 \end{bmatrix},$$

with eigenvalues $0.0619, 2.4026$, and 7.0599.

In this case Theorem 7.1 can be used to show that optimal matrices may have at most one nonpositive eigenvalue.

REMARK 7.1. The value of ω_o obtained for these matrices is not precisely $2^{2/3}$. Apart from the obvious fact that we are dealing with approximations, it is also important to note that the optimal is attained at a point where Ω is not smooth. In particular, some of the directional derivatives may become unbounded and, as a consequence, small changes in the entries of B_o may cause large deviations in the value of the spectral abscissa. This aspect of the problem will be discussed in more detail in section 8. We also note that the eigenvalues of the matrices B_o and B_o' are not as sensitive to small changes.

8. Discussion. By reformulating the problem of optimizing the decay of solutions of system (1.1) as an inverse problem, we have been able to show attainment and, in general, nonuniqueness, within the space of real symmetric matrices. However, and as we have seen in the 2×2 case and in Example 7.1, it turns out that it might be possible to obtain this optimal by means of an indefinite matrix or, in some cases, that

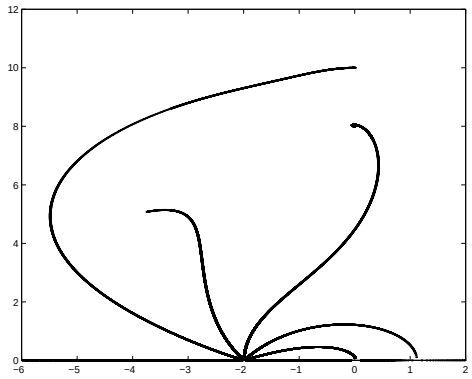

FIG. 8.1. *Eigenvalue loci for Example* 8.1.

all optimal matrices are indefinite. If in the formulation of the optimization problem we further impose the restriction that it should be possible to attain the optimal with a positive definite matrix, then clearly in this last situation the best possible value for the spectral abscissa is no longer $[\det(C)/\det(A)]^{1/2n}$.

A related aspect that should be taken into account at this point is that, due to the unbounded directional derivatives referred to in the remark following Example 7.1, it might be difficult to obtain good numerical approximations of optimal matrices. To see how this might affect the problem, we consider a parametrized version of the quadratic pencil $L(\lambda)$ given by

$$L_\epsilon(\lambda) = I\lambda^2 + \epsilon B\lambda + C,$$

where A, B, and C are as before and ϵ is a nonnegative parameter. One way of measuring the effect of small changes in the optimal matrix is to vary ϵ and see the effect that that will have on the spectral abscissa.

For indefinite damping terms, it is known from [5] that if ϵ is made large enough, then there will exist eigenvalues with positive real parts, and the system becomes unstable. Another phenomenon associated with this is that of stability switching, where the stability of the trivial solution changes as the parameter ϵ is increased. In [5] an example was given with $n = 5$ where solutions became unstable, then stable, and finally unstable again. Here we build an example of an optimal matrix for which a sequence s–u–s–u is achieved and for which two of the stability switching points are obtained for ϵ close to one.

EXAMPLE 8.1. Let $C = \mathrm{diag}\{1/100, 64, 100\}$. Then $\omega_o = 2$ and

$$B_o = \begin{bmatrix} \dfrac{4(a-493)}{17775} & \dfrac{(851201-32a)b}{35550(9887+16a)} & \dfrac{4bc}{395\ 3^{3/2}} \\ \dfrac{(851201-32a)b}{35550(9887+16a)} & \dfrac{64(493-a)(a-53818)}{17775(9887+16a)} & \dfrac{16(a-1204)c}{395\ 3^{3/2}} \\ \dfrac{4bc}{395\ 3^{3/2}} & \dfrac{64(493-a)(a-53818)}{17775(9887+16a)} & \dfrac{4(53818-a)}{9887+16a} \end{bmatrix},$$

where

$$a = \sqrt{385249}, \quad b = \sqrt{2585257 + 15776a} \quad \text{and } c = \sqrt{103a - 63929}$$

is an optimal matrix with eigenvalues $-8.6804, 4.7353$ and 15.9451. In this case, the stability switching points are $\epsilon_1 \approx 0.228$, $\epsilon_2 \approx 0.9279$, and $\epsilon_3 \approx 1.0092$. We thus see that a very small variation in the parameter ϵ might take it past the point ϵ_3 and that this will make the system unstable. In Figure 8.1 we have plotted the changes of the eigenvalues with ϵ as this parameter is increased from 0 to 1.5. Apart from the stability switching, we also see that the eigenvalues come together to give a single eigenvalue of multiplicity 6 at $\epsilon = 1$, and that when they split for ϵ larger than 1, one pair will remain real, while the other two pairs become complex again.

In the notation of section 6, the elementary divisors of $L(\lambda)$ have degrees $(6, 0, 0)$. This also accounts for the form of the splitting of the eigenvalues at $\epsilon = 1$, determining the angles that the eigencurves make with the $x-$axis: as the geometric multiplicity is 1, the tangents to the incoming and outcoming eigencurves will divide the plane in 12 equal angles.

ITERATIVE SOLUTION OF THE HELMHOLTZ EQUATION BY A SECOND-ORDER METHOD*

KURT OTTO† AND ELISABETH LARSSON†

Abstract. The numerical solution of the Helmholtz equation subject to nonlocal radiation boundary conditions is studied. The specific problem is the propagation of hydroacoustic waves in a two-dimensional curvilinear duct. The problem is discretized with a second-order accurate finite difference method, resulting in a linear system of equations. To solve the system of equations, a preconditioned Krylov subspace method is employed. We construct a preconditioner that is based on fast transforms and yields a direct fast Helmholtz solver for rectangular domains. Numerical experiments for curved ducts demonstrate that the rate of convergence is high. The fast transform preconditioner is compared with a symmetric successive over-relaxation (SSOR) preconditioner, and also with band Gaussian elimination. For the preconditioned iterative methods, the gains in storage requirement are large compared with band Gaussian elimination. Regarding the arithmetic complexity, the fast transform preconditioner yields a significant gain, whereas the SSOR preconditioner performs worse than band Gaussian elimination.

Key words. Helmholtz equation, waveguide problems, finite difference discretization, preconditioners, fast trigonometric transforms

1. Introduction.

The Helmholtz equation arises in many physical applications, e.g., scattering problems in electromagnetics and acoustics [Ernst96], [AbKr94]. In realistic applications, a wide range of wavenumbers is often of interest. For a finite element (or finite difference) discretization of the two-dimensional Helmholtz equation, it is necessary that the number of grid points grows faster than quadratically in the wavenumber in order to maintain a given accuracy [BaGoTu85a], [IhlBa97]. Thus, for high wavenumbers, the discretized Helmholtz equation "leads to a huge linear system of equations" [AbKr94, p. 2]. Due to the large bandwidth, the storage requirement renders Gaussian elimination prohibitive. To handle high wavenumbers and large domains for the Helmholtz equation in duct acoustics, Abrahamsson and Kreiss [AbKr94] devised a special iteration technique related to separation of variables. However, the effectiveness of the method relies on the degree of separability of the problem. Another way to address the computational difficulties for the discretized Helmholtz equation is to design iterative methods. Bayliss, Goldstein, and Turkel [BaGoTu83] used a preconditioned conjugate gradient method applied to the normal equations for a finite element discretization [BaGuTu82]. Due to the ill-conditioning of the normal equations, the unpreconditioned algorithm suffered from extremely slow convergence. The convergence rate was substantially improved through preconditioners based on SSOR [BaGoTu83] or a multigrid V-cycle [BaGoTu85b], [Gold82] only for

the Laplacian part of the Helmholtz operator. Recently, a block version of the quasi-minimal residual algorithm has been exploited for problems with multiple right-hand sides in structural acoustics. The method was tested in conjunction with different preconditioners, and an SSOR preconditioner gave the best performance [MaFrPi97]. The quasi-minimal residual algorithm has been applied also to capacitance matrix methods for exterior Helmholtz problems [Ernst96]. A somewhat different approach is to employ Schwarz-type domain decomposition methods. If the subdomains are reasonably small, direct solvers can be used locally. These methods are appealing because they are easy to parallelize, but in their unembellished form they converge very slowly. Kim [Kim98] introduces an automatic procedure for choosing Robin interface conditions that improve convergence significantly. However, the iteration count still depends on the number of subdomains. This may lead to poor performance for problems with many or large subdomains, in the latter case due to the excessive memory requirements and the high arithmetic costs for the direct solvers. In [CCEW98], it is demonstrated that an overlapping Schwarz method with GMRES acceleration and coarse grid corrections converges rather rapidly.

The objective of this paper is to develop a technique for solving the Helmholtz equation with an iterative method. In order to be a viable method, it should exploit the sparsity of the discretization matrix in an efficient way, converge rapidly, and be competitive with Gaussian elimination in regard to the total arithmetic complexity. Our approach is to apply a preconditioned Krylov subspace method [FrGoNa92] directly to the discretized equations. Typically, for high wavenumbers the discretization matrix is large, complex, indefinite, and ill-conditioned. As a result, standard preconditioning techniques like diagonal scaling and incomplete LU decomposition are likely to do poorly. Instead we construct preconditioners based on fast transforms; see [Otto96] and the survey in [ChanNg96]. In order to get a highly structured matrix, facilitating the design of the preconditioner, a finite difference method is used for the discretization. For the same reason, special attention is given to the choice of radiation boundary conditions. A finite element method would be more flexible for complicated geometries, but also less amenable to fast transform-based preconditioners. This is particularly noticeable for higher orders of approximation, where some of the degrees of freedom typically are *not* node values.

The paper is organized as follows. In section 2 the governing equations, the boundary conditions, and the finite difference discretization of a Helmholtz problem are derived. The specific problem is the propagation of hydroacoustic waves in a curvilinear duct. Issues concerning the preconditioner are treated in section 3. Section 4 is devoted to computational aspects with an emphasis on resolution criteria, i.e., relations between the wavenumber, the grid size, and the desired accuracy. Finally, numerical experiments are presented in section 5 followed by conclusions.

2. The model problem. In this section the theory needed to determine the system of equations for the model problem is discussed.

2.1. Notation. The quantity I_m denotes the identity matrix of order m. The square matrices $\mathrm{diag}_{j,m}(\beta_j)$ and $\mathrm{trid}_{j,m}(\alpha_j, \beta_j, \gamma_j)$ are defined in the following way:

$$\mathrm{diag}_{j,m}(\beta_j) = \begin{pmatrix} \beta_1 & & \\ & \ddots & \\ & & \beta_m \end{pmatrix},$$

$$\mathrm{trid}_{j,m}(\alpha_j,\beta_j,\gamma_j) = \begin{pmatrix} \beta_1 & \gamma_1 & & & \\ \alpha_2 & \beta_2 & \gamma_2 & & \\ & \ddots & \ddots & \ddots & \\ & & \alpha_{m-1} & \beta_{m-1} & \gamma_{m-1} \\ & & & \alpha_m & \beta_m \end{pmatrix}.$$

2.2. Governing equations. We study the propagation of time-harmonic sound waves under water. Neglecting sound absorption and assuming that the fluid is homogeneous, the waves are governed by the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x_1^2} - \frac{\partial^2 u}{\partial x_2^2} - \kappa^2 u = 0, \tag{1}$$

where $u(x_1, x_2)$ is the phasor of the acoustic pressure $\mathbb{R}\mathrm{e}(u(x_1,x_2)e^{-i2\pi ft})$ [JKPS94, p. 73]. The wavenumber is given by $\kappa = 2\pi f/c$, where f is the frequency and $c = 1500$ m/s is the sound speed. For heterogeneous media, the sound speed and consequently the wavenumber would depend on the space coordinates.

We consider a physical domain

$$\begin{cases} x_1 = x_1(\xi_1,\xi_2) \\ x_2 = x_2(\xi_1,\xi_2) \end{cases}$$

that can be mapped onto the unit square

$$\begin{cases} 0 \le \xi_1 \le 1 \\ 0 \le \xi_2 \le 1 \end{cases}$$

via an orthogonal transformation [KnSt93, p. 82]. Equation (1) is then transformed into

$$-\frac{\partial}{\partial \xi_1}\left(a\frac{\partial u}{\partial \xi_1}\right) - \frac{\partial}{\partial \xi_2}\left(a^{-1}\frac{\partial u}{\partial \xi_2}\right) - eu = 0, \tag{2}$$

where the metric coefficients a and e are given by

$$a = \sqrt{\frac{\left(\frac{\partial x_1}{\partial \xi_2}\right)^2 + \left(\frac{\partial x_2}{\partial \xi_2}\right)^2}{\left(\frac{\partial x_1}{\partial \xi_1}\right)^2 + \left(\frac{\partial x_2}{\partial \xi_1}\right)^2}},$$

$$e = \kappa^2 \sqrt{\left(\left(\frac{\partial x_1}{\partial \xi_1}\right)^2 + \left(\frac{\partial x_2}{\partial \xi_1}\right)^2\right)\left(\left(\frac{\partial x_1}{\partial \xi_2}\right)^2 + \left(\frac{\partial x_2}{\partial \xi_2}\right)^2\right)}.$$

Because of the orthogonality of the transformation, no mixed terms appear in (2).

2.3. Boundary conditions. We now choose the physical domain to be a two-dimensional duct; see the shaded area in Figure 1.

For the problem to be well posed, conditions are needed on all four boundaries. Our model problem is partly fixed by letting the physical boundary Γ_1 be a soft wall (air), whereas Γ_2 is a rigid wall (rock). The sound field is generated by a source along

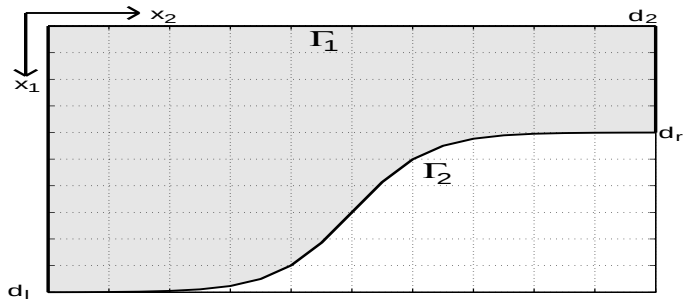

FIG. 1. *The physical domain.*

$x_2 = 0$, specified by a source term $g(\xi_1) \equiv g(x_1(\xi_1, 0))$. At $x_2 = d_2$ an artificial far-zone boundary has been introduced. Originally, the domain is semi-infinite ($d_2 \to \infty$), but for computational reasons it is truncated by assigning d_2 some finite value. For the soft wall Γ_1, the boundary condition is $u = 0$ (pressure release). This leads to

$$u(0, \xi_2) = 0, \quad 0 \le \xi_2 \le 1, \tag{3}$$

in the computational domain. Since the bottom Γ_2 is rigid, a condition on the normal derivative is imposed:

$$\frac{\partial u}{\partial n} = 0, \quad (x_1, x_2) \in \Gamma_2.$$

Due to the orthogonal transformation this becomes

$$\frac{\partial u}{\partial \xi_1}(1, \xi_2) = 0, \quad 0 \le \xi_2 \le 1. \tag{4}$$

For the radiation conditions (11) and (14) at the near- and far-zone boundaries, Dirichlet–to–Neumann (DtN) maps [KeGi89] are employed. The main reason for choosing nonlocal DtN maps, instead of the local radiation conditions described in [BaGuTu82], is that discretized DtN maps are more apt to preconditioning by fast transforms. Another desirable feature of DtN maps is that they easily achieve highly accurate radiation conditions. Our design of radiation conditions follows the principles outlined in [FixMa78], where a variational formulation of DtN conditions was derived for an axially symmetric duct parametrized by cylindrical coordinates. Boundary conditions based on DtN maps require the boundary in question to be a separable coordinate surface. Moreover, for the radiation condition in [FixMa78], it is implicitly assumed that the duct could be extended beyond the artificial boundary by parallel straight walls. This is a so-called anechoic termination [AbKr94]. Since the wave-number κ is independent of ξ_2, the above prerequisites are fulfilled by requiring the duct to be flat *only* in an infinitesimal neighborhood of $x_2 = d_2$ and $x_2 = 0$. In the present application, the wavenumber is actually a constant. Thus, without any significant loss of accuracy we can use the slightly more restrictive assumption that, in the vicinity of $x_2 = 0$, there is a local transformation

$$\begin{cases} x_1 = \xi_1 d_\ell, & 0 \le \xi_1 \le 1, \\ x_2 = \xi_2 d_2. \end{cases}$$

Substituting this into (2), together with (3) and (4), yields

$$\left\{\begin{array}{l} -\frac{d_2}{d_\ell}\frac{\partial^2 u}{\partial \xi_1^2} - \frac{d_\ell}{d_2}\frac{\partial^2 u}{\partial \xi_2^2} - \kappa^2 d_\ell d_2 u = 0, \\ u(0,\xi_2) = 0, \\ \frac{\partial u}{\partial \xi_1}(1,\xi_2) = 0. \end{array}\right. \tag{5}$$

The condition at the near-zone boundary is based on the fact that the solution for

$$0 \le \xi_1 \le 1, \quad \xi_2 \le 0,$$

can be obtained through separation of variables [MorFe53, p. 498], i.e., $u(\xi_1,\xi_2) = \psi(\xi_1)\chi(\xi_2)$. Solving (5) with this ansatz gives

$$\begin{aligned} \psi_m(\xi_1) &= \sqrt{2}\sin((m-\tfrac{1}{2})\pi\xi_1), \\ \chi_m(\xi_2) &= A_m \exp(i\sqrt{-\lambda_m}\xi_2) + B_m \exp(-i\sqrt{-\lambda_m}\xi_2), \quad m = 1,2,\ldots, \end{aligned}$$

where

$$\lambda_m = \big((m-\tfrac{1}{2})\pi d_2/d_\ell\big)^2 - (\kappa d_2)^2.$$

The eigenfunctions $\{\psi_m(\xi_1)\}_{m=1}^{\infty}$ are orthonormal with respect to the scalar product

$$\langle f, g\rangle \equiv \int_0^1 \bar{f}(\xi_1) g(\xi_1) d\xi_1.$$

The general solution to the eigenproblem (5) becomes

$$u(\xi_1,\xi_2) = \sum_{m=1}^{\infty} \psi_m(\xi_1)\big(A_m \exp(i\sqrt{-\lambda_m}\xi_2) + B_m \exp(-i\sqrt{-\lambda_m}\xi_2)\big). \tag{6}$$

For mode indices below the cutoff limit, i.e.,

$$m \le \mu_\ell = \left\lfloor \frac{\kappa d_\ell}{\pi} + \frac{1}{2} \right\rfloor, \tag{7}$$

the eigenvalues λ_m become negative, yielding propagating modes [JKPS94, p. 279]. If λ_m were positive, we would get evanescent modes [JKPS94, p. 279]. Analogously to the motivation in [FixMa78], the influence of the evanescent modes is negligible, especially on the far field. Thus, an appropriate way to truncate the series in (6) is to retain only the terms with mode indices $m \le \mu_\ell$. The situation is somewhat different for a purely exterior Helmholtz problem, where an appropriate truncation of DtN maps is a more delicate matter [GroKe95].

The A_m-terms in (6) correspond to right-going waves, and the B_m-terms correspond to left-going waves. In our model we have a source at the left boundary. We will treat the right-going waves as originating from a "truncated" point source positioned at depth $\xi_1 = \delta_s$. This is done by specifying the Fourier coefficients of the source term g:

$$A_m = \langle \psi_m, g\rangle = \psi_m(\delta_s), \quad m = 1,\ldots,\mu_\ell. \tag{8}$$

Note that left-going waves are feasible in order to handle possible reflections from the curved bottom. Inserting (7) and (8) into (6) yields

$$u(\xi_1,\xi_2) = \sum_{m=1}^{\mu_\ell} \psi_m(\xi_1)\big(\psi_m(\delta_s)\exp(i\sqrt{-\lambda_m}\xi_2) + B_m \exp(-i\sqrt{-\lambda_m}\xi_2)\big). \tag{9}$$

The coefficients B_m are determined from the solution by exploiting the orthonormality of the functions $\psi_m(\xi_1)$. From (9) we get

$$B_m = \langle \psi_m, u(\cdot, 0) \rangle - \psi_m(\delta_s). \tag{10}$$

The nonlocal boundary condition at $\xi_2 = 0$ is obtained by differentiating (9) with respect to ξ_2 and using (10). Thus,

$$-\frac{\partial u}{\partial \xi_2}(\xi_1, 0) - i \sum_{m=1}^{\mu_\ell} \sqrt{-\lambda_m} \langle \psi_m, u(\cdot, 0) \rangle \psi_m(\xi_1) = -i \sum_{m=1}^{\mu_\ell} 2\sqrt{-\lambda_m} \psi_m(\delta_s) \psi_m(\xi_1). \tag{11}$$

The boundary condition at $\xi_2 = 1$ is derived in a similar way. Due to the anechoic termination of the duct, there are no reflections, i.e., there are only right-going waves:

$$u(\xi_1, \xi_2) = \sum_{m=1}^{\mu_r} A_m \psi_m(\xi_1) \exp\bigl(i\sqrt{-\lambda_m}(\xi_2 - 1)\bigr), \tag{12}$$

where

$$\lambda_m = \bigl((m - \tfrac{1}{2})\pi d_2/d_r\bigr)^2 - (\kappa d_2)^2,$$
$$\mu_r = \left\lfloor \frac{\kappa d_r}{\pi} + \frac{1}{2} \right\rfloor.$$

The coefficients A_m are determined by

$$A_m = \langle \psi_m, u(\cdot, 1) \rangle. \tag{13}$$

Differentiation of (12) and insertion of (13) give the condition for the far-zone boundary:

$$\frac{\partial u}{\partial \xi_2}(\xi_1, 1) - i \sum_{m=1}^{\mu_r} \sqrt{-\lambda_m} \langle \psi_m, u(\cdot, 1) \rangle \psi_m(\xi_1) = 0. \tag{14}$$

2.4. Discretization. Now when the analytical problem is defined, we design the numerical method. Introduce a uniform grid as

$$\begin{cases} \xi_{1,j} = jh_1, & j = 0, \ldots, m_1 + 1, \\ \xi_{2,k} = \bigl(k - \frac{3}{2}\bigr) h_2, & k = 1, \ldots, m_2, \end{cases}$$

where

$$h_1 = \frac{1}{m_1 + \frac{1}{2}}, \qquad h_2 = \frac{1}{m_2 - 2}.$$

The grid is centered around those boundaries where the boundary conditions (4), (11), (14) involve derivatives. The main reason for centering the grid [RiMor67, p. 134] is to facilitate the construction of discretized boundary conditions that have the same order of accuracy as the rest of the scheme. Let $u_{j,k}$ denote the approximate solution at the point $(\xi_{1,j}, \xi_{2,k})$. We use centered difference operators to obtain second-order accuracy. Equation (2) is approximated with

$$\begin{aligned} &- h_1^{-2}\bigl(a_{j+\frac{1}{2},k}(u_{j+1,k} - u_{j,k}) - a_{j-\frac{1}{2},k}(u_{j,k} - u_{j-1,k})\bigr) \\ &- h_2^{-2}\bigl(a^{-1}_{j,k+\frac{1}{2}}(u_{j,k+1} - u_{j,k}) - a^{-1}_{j,k-\frac{1}{2}}(u_{j,k} - u_{j,k-1})\bigr) - e_{j,k}u_{j,k} = 0 \end{aligned} \tag{15}$$

for inner points $k = 2, \ldots, m_2 - 1$ and $j = 1, \ldots, m_1$. The boundary conditions (3) and (4) become

$$u_{0,k} = 0, \quad k = 1, \ldots, m_2, \tag{16}$$

$$u_{m_1+1,k} = u_{m_1,k}, \quad k = 1, \ldots, m_2. \tag{17}$$

For the other two boundaries matters are more complicated. We discretize the modal expansions involving the eigenfunctions $\psi_m(\xi_1)$ by evaluating them on the ξ_1-grid, i.e.,

$$\psi_m \equiv \{\psi_m(\xi_{1,j})\}_{j=1}^{m_1} = \left\{\sqrt{2}\sin\left((m - \tfrac{1}{2})\pi j h_1\right)\right\}_{j=1}^{m_1}, \quad m = 1, \ldots, m_1, \tag{18}$$

and by approximating the integrals with a second-order accurate combination of the composite trapezoid rule and the rectangle rule. Our specific choice of ξ_1-grid and quadrature rule makes the column vectors (18) orthonormal with respect to the discrete scalar product

$$\langle \psi_m, \psi_n \rangle \equiv \psi_m^* h_1 \psi_n \approx \int_0^1 \bar{\psi}_m(\xi_1)\psi_n(\xi_1)d\xi_1.$$

Moreover, a second-order accurate finite difference discretization of the eigenproblem yields *exactly* the same eigenvectors as (18). The resulting discretization of conditions (11) and (14) is

$$h_2^{-1}(u_1 - u_2) - i\sum_{m=1}^{\mu_\ell} \sqrt{-\lambda_m}\psi_m\psi_m^* h_1 \tfrac{1}{2}(u_1 + u_2) = -i\sum_{m=1}^{\mu_\ell} 2\sqrt{-\lambda_m}\psi_m(\delta_s)\psi_m, \tag{19}$$

$$h_2^{-1}(u_{m_2} - u_{m_2-1}) - i\sum_{m=1}^{\mu_r} \sqrt{-\lambda_m}\psi_m\psi_m^* h_1 \tfrac{1}{2}(u_{m_2-1} + u_{m_2}) = 0, \tag{20}$$

where

$$u_k \equiv (u_{1,k} \cdots u_{m_1,k})^T.$$

This can be written

$$\begin{aligned}(I_{m_1} - C_\ell)u_1 + (-I_{m_1} - C_\ell)u_2 &= g_1,\\ (-I_{m_1} - C_r)u_{m_2-1} + (I_{m_1} - C_r)u_{m_2} &= 0,\end{aligned}$$

where

$$C_\ell = ih_2\sum_{m=1}^{\mu_\ell} \sqrt{-\lambda_m}\psi_m\psi_m^*\frac{h_1}{2}, \qquad C_r = ih_2\sum_{m=1}^{\mu_r} \sqrt{-\lambda_m}\psi_m\psi_m^*\frac{h_1}{2}, \tag{21}$$

$$g_1 = -ih_2\sum_{m=1}^{\mu_\ell} 2\sqrt{-\lambda_m}\psi_m(\delta_s)\psi_m.$$

Notice that λ_m depends on the depth and is different for the left and right boundaries.

Applying (15) to inner grid points, using (19) and (20), and eliminating the boundary values defined by (16) and (17) gives the complete system of equations

$$Bu = g,$$

$$u \equiv \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_{m_2} \end{pmatrix}, \qquad g = \begin{pmatrix} g_1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \qquad B = \mathrm{trid}_{k,m_2}(B_{k,-1}, B_{k,0}, B_{k,1}),$$

where

$$\begin{aligned} B_{1,0} &= I_{m_1} - C_\ell, \quad B_{1,1} = -I_{m_1} - C_\ell, \\ B_{m_2,-1} &= -I_{m_1} - C_r, \quad B_{m_2,0} = I_{m_1} - C_r, \end{aligned} \tag{22}$$

and for $k = 2, \ldots, m_2 - 1$,

$$\begin{aligned} B_{k,-1} &= \mathrm{diag}_{j,m_1}(-\gamma a^{-1}_{j,k-\frac{1}{2}}), \\ B_{k,0} &= \mathrm{trid}_{j,m_1}(-a_{j-\frac{1}{2},k}, \alpha_{j,k}, -a_{j+\frac{1}{2},k}), \\ B_{k,1} &= \mathrm{diag}_{j,m_1}(-\gamma a^{-1}_{j,k+\frac{1}{2}}), \end{aligned}$$

where

$$\begin{aligned} \alpha_{1,k} &= a_{\frac{1}{2},k} + a_{\frac{3}{2},k} + \gamma(a^{-1}_{1,k-\frac{1}{2}} + a^{-1}_{1,k+\frac{1}{2}}) - h_1^2 e_{1,k}, \\ \alpha_{j,k} &= a_{j-\frac{1}{2},k} + a_{j+\frac{1}{2},k} + \gamma(a^{-1}_{j,k-\frac{1}{2}} + a^{-1}_{j,k+\frac{1}{2}}) - h_1^2 e_{j,k}, \quad j = 2, \ldots, m_1 - 1, \\ \alpha_{m_1,k} &= a_{m_1-\frac{1}{2},k} + \gamma(a^{-1}_{m_1,k-\frac{1}{2}} + a^{-1}_{m_1,k+\frac{1}{2}}) - h_1^2 e_{m_1,k}, \\ \gamma &= \frac{h_1^2}{h_2^2}. \end{aligned}$$

By some minor modifications, the discretization could accommodate other combinations of boundary conditions on the boundaries Γ_1 and Γ_2. For Neumann conditions at Γ_1 and Γ_2, a suitable grid for ξ_1 would be

$$\xi_{1,j} = (j - \tfrac{1}{2})h_1, \quad j = 0, \ldots, m_1 + 1, \quad h_1 = \frac{1}{m_1}.$$

The resulting alteration of the matrix B would mainly be

$$\alpha_{1,k} = a_{\frac{3}{2},k} + \gamma(a^{-1}_{1,k-\frac{1}{2}} + a^{-1}_{1,k+\frac{1}{2}}) - h_1^2 e_{1,k}.$$

For Dirichlet conditions at Γ_1 and Γ_2, a convenient choice of ξ_1-grid would be

$$\xi_{1,j} = jh_1, \quad j = 0, \ldots, m_1 + 1, \quad h_1 = \frac{1}{m_1 + 1}.$$

This would cause $\alpha_{m_1,k}$ to change into

$$\alpha_{m_1,k} = a_{m_1-\frac{1}{2},k} + a_{m_1+\frac{1}{2},k} + \gamma(a^{-1}_{m_1,k-\frac{1}{2}} + a^{-1}_{m_1,k+\frac{1}{2}}) - h_1^2 e_{m_1,k},$$

but leave the rest of B essentially intact. Nota bene that the mth eigenvector ψ_m appearing in (21) and (18) changes with the boundary conditions. For the Neumann–Neumann case, it becomes $\psi_m \propto \{\cos((m-1)\pi\xi_{1,j})\}_{j=1}^{m_1}$, whereas the Dirichlet–Dirichlet case leads to $\psi_m \propto \{\sin(m\pi\xi_{1,j})\}_{j=1}^{m_1}$.

3. Preconditioning. We employ a Krylov subspace method to solve the system of equations. For simplicity and robustness, we choose the restarted generalized minimal residual (GMRES(ℓ)) algorithm [SaadSch86], where ℓ is the restarting length. For the iterative method to be competitive, an effective preconditioner is needed. Otherwise the cost of computing the solution would be too high. After left preconditioning, the original system $Bu = g$ is transformed into $M^{-1}Bu = M^{-1}g$.

3.1. Normal block preconditioners. We construct a preconditioner that preserves the block structure of B, thus exploiting sparsity. Moreover, it should be possible to form and apply the preconditioner at low arithmetic costs. To meet these demands, we use a normal block preconditioner [Otto96] based on fast trigonometric transforms [VLoan92, section 4.4], [BaiSw91]. The main idea in the design is to approximate the matrix B with a preconditioner having the same block structure, and where all the blocks have the same prescribed eigenvectors. These eigenvectors depend on the boundary conditions, but are chosen so that the corresponding similarity transformation is associated with a fast transform.

For the discretization matrix B in section 2.4, a Dirichlet condition was imposed on Γ_1 and a Neumann condition on Γ_2. Hence, a suitable choice for the unitary eigenvector matrix is

$$Q \equiv [q_1, \ldots, q_{m_1}], \qquad q_m = \sqrt{h_1}\psi_m,$$

which is connected to a slightly modified sine transform-II [VLoan92, p. 229]. Form a preconditioner

$$M = \mathrm{trid}_{k,m_2}(M_{k,-1}, M_{k,0}, M_{k,1}),$$

the blocks of which are diagonalized by Q, i.e.,

$$M_{k,r} \equiv Q\Lambda_{k,r}Q^*, \tag{23}$$

where $\Lambda_{k,r}$, $r = -1, 0, 1$, are diagonal matrices. There are several possible choices for $\Lambda_{k,r}$. The specific choice

$$\Lambda_{k,r} = \mathrm{diag}(Q^* B_{k,r} Q)$$

minimizes $\|B_{k,r} - M_{k,r}\|_F$ for matrices of type (23), and it also minimizes $\|B - M\|_F$. Observe that the blocks defined by (21) can be rewritten as linear combinations of outer products $q_m q_m^*$. This means that the matrix blocks (22) corresponding to the left and right boundaries will be diagonalized by Q. In fact, for a duct with a flat bottom, all the blocks in B would be diagonalized by Q, yielding $M = B$ [Otto96]. Hence, the operator M^{-1} is a direct fast Helmholtz solver for rectangular domains. For a duct with a curved bottom, blocks corresponding to inner grid lines will not be completely diagonalized. However, when the domain is moderately curved, the preconditioner presumably acts like a viable convergence accelerator.

For the Neumann–Neumann and Dirichlet–Dirichlet boundary conditions discussed in section 2.4, the eigenvector matrices Q should be chosen to match the boundary conditions, i.e., as those associated with the cosine and sine transforms, respectively. The preconditioners thus arising also yield direct fast solvers for rectangular domains, and indeed perform well [Otto96] when the domains are moderately curved.

For each iteration, the computation $x = M^{-1}y$ has to be performed. Due to the structure of the blocks of M, it holds that

$$\Lambda \equiv (I_{m_2} \otimes Q^*)M(I_{m_2} \otimes Q) = \mathrm{trid}_{k,m_2}(\Lambda_{k,-1}, \Lambda_{k,0}, \Lambda_{k,1}),$$

leading to

$$M^{-1} = (I_{m_2} \otimes Q)\Lambda^{-1}(I_{m_2} \otimes Q^*).$$

The computation $x = M^{-1}y$ can now be done in three steps:

1. $v = (I_{m_2} \otimes Q^*)y$,
2. solve $\Lambda z = v$,
3. $x = (I_{m_2} \otimes Q)z$.

Step 2 consists of solving a block tridiagonal system, where each block is diagonal. By permuting the unknowns, we get m_1 independent tridiagonal systems of order m_2. Steps 1 and 3 consist of m_2 sine transforms-II and inverse sine transforms-II of length m_1. We can utilize fast Fourier transform methods [BaiSw91] for computing these transforms.

3.2. Generalizations. The key principle for the normal block preconditioner is that a discretized two-dimensional problem is reduced to a set of one-dimensional problems by applying fast transforms in one coordinate direction. The same technique is applicable to three-dimensional waveguide problems and scattering problems. As an example, we consider a three-dimensional waveguide parametrized by cylindrical coordinates (r, ϕ, z). The waveguide is enclosed by two physical boundaries

$$\begin{aligned} \Gamma_1 : &\quad z = z_1(r,\phi), \quad d_0 \le r \le d_\infty, \quad 0 \le \phi \le 2\pi, \\ \Gamma_2 : &\quad z = z_2(r,\phi), \quad d_0 \le r \le d_\infty, \quad 0 \le \phi \le 2\pi, \end{aligned}$$

a near-zone boundary, and an artificial far-zone boundary,

$$\begin{aligned} \Gamma_0 : &\quad z_1(d_0,\phi) \le z \le z_2(d_0,\phi), \quad 0 \le \phi \le 2\pi, \\ \Gamma_\infty : &\quad z_1(d_\infty,\phi) \le z \le z_2(d_\infty,\phi), \quad 0 \le \phi \le 2\pi. \end{aligned}$$

The parameters d_0 and $d_\infty \gg d_0$ are the distances to the near-zone and far-zone boundaries, whereas $z_1(r,\phi)$ and $z_2(r,\phi)$ are smooth functions. The special case $z_1 \equiv 0$ could be viewed as the natural three-dimensional generalization of the domain depicted in Figure 1 or the geometry considered in [FixMa78]. For the near-zone boundary Γ_0, a Dirichlet condition $u(d_0, \phi, z) = g(\phi, z)$ is given, where the boundary data g acts like a source term. Depending on the physical nature of the walls of the waveguide, the appropriate combinations of boundary conditions for Γ_1 and Γ_2 involve Dirichlet–Neumann, Neumann–Neumann, or Dirichlet–Dirichlet. The computational domain

$$\begin{cases} 0 \le \rho(x,y,z) \le 1, \\ 0 \le \varphi(x,y,z) \le 2\pi, \\ 0 \le \zeta(x,y,z) \le 1, \end{cases}$$

is mapped onto the hollow, deformed cylinder in the physical domain via a boundary conforming transformation [KnSt93, p. 5]. At the far-zone boundary, an outgoing radiation condition is imposed by employing a DtN map. By making the separability assumption that the surfaces z_1 and z_2 are horizontal *only* in an infinitesimal

neighborhood of Γ_∞, the outgoing modes are built up by Hankel functions H_n of the first kind [MorFe53, p. 623], complex exponentials, and the eigenfunctions ψ_m and eigenvalues λ_m of a Sturm–Liouville problem. Thus, in the vicinity of Γ_∞, a solution containing only propagating modes has an approximate representation

$$u(\rho,\varphi,\zeta) \approx \sum_{n=0}^{\nu} \sum_{m=1}^{\mu} H_n(\sqrt{-\lambda_m}\rho) A_{\pm n,m} \exp(\pm in\varphi)\psi_m(\zeta),$$

where μ is the number of axial modes that propagate (cf. (12)), and $2\nu+1$ is the number of azimuthal modes that are selected. An adequate choice of ν depends mainly on the energy contents of the azimuthal modes for the source term, i.e., the magnitude of the Fourier coefficients of g with respect to the functions $\{\exp(\pm in\varphi)\}_{n=0}^{\infty}$. By differentiating u with respect to ρ, and determining the coefficients $A_{\pm n,m}$ by exploiting the orthogonality of the functions $\exp(\pm in\varphi)\psi_m(\zeta)$, a DtN condition like (14) is obtained. If we define a uniform grid for the coordinates (ρ,φ,ζ) of the computational domain, and construct a finite difference discretization of the same type as in section 2.4 for the transformed Helmholtz problem, then a linear system of equations $Bu = g$ arises. By ordering the components of u properly, the matrix B will get a two-level block structure, where the block sizes are given by the numbers of grid points m_φ and m_ζ for the φ- and ζ-directions.

As a convergence accelerator that matches the block structure of B, we employ a normal block preconditioner [Otto96] with two block levels. For such a preconditioner, it is optional to apply transforms either for only one of the block levels or for both. In the current application, we obtain at least two possible types of preconditioners, which will be referred to as being monotransform and ditransform. For the monotransform preconditioner, the Fourier transform is applied for the block level corresponding to the φ-direction, thus matching the condition of azimuthal periodicity. In the ditransform case, the Fourier transform is used for the φ-coordinate, whereas the sine transform-II, cosine transform, or sine transform is applied in the ζ-direction when the matching boundary conditions are Dirichlet–Neumann, Neumann–Neumann, or Dirichlet–Dirichlet, respectively. The effect of applying the transforms in the ditransform preconditioner is to decouple the three-dimensional problem with $m_\varphi m_\zeta m_\rho$ degrees of freedom into $m_\varphi m_\zeta$ independent one-dimensional problems of size m_ρ. The discretization matrices for those one-dimensional problems will be narrow banded. Analogously, the monotransform preconditioner reduces the three-dimensional problem into m_φ two-dimensional problems with $m_\zeta m_\rho$ degrees of freedom. The two-dimensional discretization matrices will not be narrow banded. This will cause fill-in, but to a lesser degree than for the original three-dimensional problem. Moreover, the rate of convergence for the monotransform preconditioner is presumably better than for its ditransform counterpart, since the former retains more information from the original discretization matrix B. If z_1, z_2, and the wavenumber κ are axially symmetric, i.e., independent of φ, the boundary conforming transformation can be simplified in such a way[1] that the monotransform preconditioner becomes a direct solver. Note that this holds even for source terms without axial symmetry and wavenumbers depending on ζ and ρ, which is of importance for applications in ocean acoustics where the sound speed might vary with depth and range [JKPS94, p. 3]. If z_1 and z_2 also are radially independent, and $\kappa = \kappa(\rho)$, both the monotransform and ditransform preconditioners become direct solvers. Based on these observations, we expect the

[1] The φ-coordinate enters the transformation simply as a rotation around the $z(\rho,\zeta)$-axis.

monotransform or the ditransform preconditioner to be an effective convergence accelerator when z_1, z_2, and κ vary moderately with φ or in the latter case with ρ, φ, and ζ.

Fast transform-based preconditioners could also be applied to discretizations of the Helmholtz equation arising in scattering problems. Grote and Keller [GroKe95] have designed DtN conditions for Helmholtz problems where the scatterer aligns with the coordinate surfaces of, e.g., spherical coordinates or prolate spheroidal coordinates [MorFe53, p. 661]. The latter coordinate system accommodates elongated scattering obstacles such as hulls of submarines. For both the spherical and prolate spheroidal cases described in [GroKe95], a monotransform preconditioner using the Fourier transform for the azimuthal coordinate would yield a direct solution method, provided that the wavenumber is azimuthally independent. For the more general case where the obstacle does not align with a coordinate surface, Ernst [Ernst96] has constructed and analyzed iterative capacitance matrix methods. A key observation is that the irregular shape of the obstacle gives rise to a low rank perturbation of a regular discretization matrix, which is invertible by means of fast transform methods. The inverse of the original matrix is then updated by employing the Sherman–Morrison–Woodbury formula.

The techniques described in this section would easily carry over to, e.g., electromagnetic waveguides and scatterers. Even though the phase velocity and the range of frequencies would be different from those in hydroacoustics, the relevant parameters determining the size of the discretized problem would still be the size of the domain in terms of wavelengths and the resolution requirement.

4. Computational issues.

4.1. Resolution. Since the solutions to the Helmholtz equation are waves, it is evident that the grid size h must follow the wavenumber κ in order to achieve a given accuracy. A naïve approach would be to use a fixed number of grid points per wavelength, i.e., keeping κh constant. Bayliss, Goldstein, and Turkel [BaGoTu85a] established that such a resolution criterion is insufficient. Instead they presented estimates predicting that the L_2 norm of the error behaves like $\mathcal{O}(\kappa^{p+1}h^p)$ for a pth-order finite element discretization. Similar estimates have been rigorously proved [IhlBa97] for a one-dimensional model problem with Dirichlet–Robin boundary conditions. The estimates are in accordance with results conjected from numerical experiments [ThoPin94]. The objective of this section is to specify convenient resolution criteria for the finite difference discretization in section 2.4, resembling those in [BaGoTu85a].

The analysis is based on a one-dimensional counterpart of (2), i.e.,

$$-\frac{d^2v}{d\xi_2^2} - (\kappa d_2)^2 v = 0, \quad 0 < \xi_2 < 1, \tag{24}$$

with Robin boundary conditions

$$\begin{aligned} -\frac{dv}{d\xi_2}(0) - i\kappa d_2 v(0) &= -2i\kappa d_2 A, \\ \frac{dv}{d\xi_2}(1) - i\kappa d_2 v(1) &= 0, \end{aligned} \tag{25}$$

replacing (11) and (14). Note that for a one-dimensional problem, the Sommerfeld condition (25) is exact inasmuch as it allows only right-going waves. Applying the

same discretization as in section 2.4 to (24) results in

$$-(v_{k+1} - 2v_k + v_{k-1}) - (\kappa d_2)^2 h_2^2 v_k = 0, \qquad k = 2, \ldots, m_2 - 1, \tag{26}$$

$$-(v_2 - v_1) - i\kappa d_2 \frac{h_2}{2}(v_1 + v_2) = -2i\kappa d_2 h_2 A, \tag{27}$$

$$(v_{m_2} - v_{m_2-1}) - i\kappa d_2 \frac{h_2}{2}(v_{m_2-1} + v_{m_2}) = 0 \tag{28}$$

for the finite difference approximation $v_k \approx v(\xi_{2,k})$. The difference equation (26) has the following characteristic equation

$$r^2 - (2 - (\kappa d_2)^2 h_2^2) r + 1 = 0$$

with roots denoted by r_1 and r_2. The root

$$r_1 = 1 - \frac{(\kappa d_2)^2 h_2^2}{2} + \sqrt{-(\kappa d_2)^2 h_2^2 + \frac{(\kappa d_2)^4 h_2^4}{4}}$$

corresponds to the right-going mode; whereas the remaining root

$$r_2 = 1 - \frac{(\kappa d_2)^2 h_2^2}{2} - \sqrt{-(\kappa d_2)^2 h_2^2 + \frac{(\kappa d_2)^4 h_2^4}{4}}$$

is associated with the left-going mode. Thus, the solution to (26) is

$$v_k = C_1 r_1^{k-\frac{3}{2}} + C_2 r_2^{k-\frac{3}{2}},$$

where the coefficients C_1 and C_2 are determined from (27) and (28), yielding

$$C_1 = \left(1 + \mathcal{O}((\kappa d_2)^2 h_2^2)\right) A, \qquad C_2 = \mathcal{O}\left((\kappa d_2)^2 h_2^2 A\right).$$

Combining this with a Taylor expansion of $r_1^{k-\frac{3}{2}}$ leads to

$$v_k = A \exp\left(i\kappa d_2 \xi_{2,k} + \frac{i(\kappa d_2)^3 h_2^2}{24} \xi_{2,k} + \mathcal{O}((\kappa d_2)^4 h_2^3) \right) + \mathcal{O}((\kappa d_2)^2 h_2^2 A).$$

Comparing this with the true solution to (24), i.e.,

$$v(\xi_{2,k}) = A \exp(i\kappa d_2 \xi_{2,k}),$$

we conclude that the leading phase error of magnitude $\frac{(\kappa d_2)^3 h_2^2}{24} \xi_{2,k}$ grows linearly in ξ_2. Furthermore, a reasonable resolution criterion is

$$\frac{(\kappa d_2)^3 h_2^2}{24} = \tau,$$

where τ is a given tolerance. Notice that for this resolution we obtain

$$v_k = A \exp\left(i\kappa d_2 \xi_{2,k} + i\tau \xi_{2,k} + \mathcal{O}(\tau^{\frac{3}{2}} (\kappa d_2)^{-\frac{1}{2}})\right) + \mathcal{O}(\tau (\kappa d_2)^{-1} A).$$

When κd_2 is sufficiently large and τ is less than one, the terms $\mathcal{O}(\tau(\kappa d_2)^{-1} A)$ and $\mathcal{O}(\tau^{\frac{3}{2}} (\kappa d_2)^{-\frac{1}{2}})$, representing artificial reflections and amplitude errors, are negligible compared with the phase error $\tau \xi_{2,k}$. Under these circumstances, the phase error is a

measure of the pointwise relative error. Extensive numerical experiments, comparing the numerical solution v_k with the true solution $v(\xi_{2,k})$, corroborate that the phase error prediction above is sharp.

Thus, for the two-dimensional problem in section 2.4, we are led to the following resolution in the ξ_2-direction:

$$h_2 \leftarrow \frac{(24\tau)^{\frac{1}{2}}}{(\kappa d_2)^{\frac{3}{2}}}, \qquad m_2 \leftarrow \left\lceil \frac{1}{h_2} + 2 \right\rceil . \tag{29}$$

For the ξ_1-direction, the choice of resolution is more subtle. Lacking a more sophisticated analysis, a rescaling of condition (29) is advocated:

$$\begin{aligned} d_1 &\leftarrow \max(d_\ell, d_r), \\ h_1 &\leftarrow \frac{(24\tau d_1/d_2)^{\frac{1}{2}}}{(\kappa d_1)^{\frac{3}{2}}}, \qquad m_1 \leftarrow \left\lceil \frac{1}{h_1} - \frac{1}{2} \right\rceil . \end{aligned} \tag{30}$$

4.2. Complexity. In this section we discuss the efficiency of the normal block preconditioned iterative method regarding memory requirement and arithmetic complexity. Note that only the highest order terms will be considered and that the number of arithmetic operations will be normalized by the number of unknowns $m_1 m_2$. A complex addition will be counted as two arithmetic operations, a complex multiplication as six arithmetic operations, and a complex division as nine arithmetic operations.

In order to determine the arithmetic complexity, we must specify how the initial approximation and the stopping criterion are computed. As an initial approximation we use the preconditioned right-hand side $M^{-1}g$, which is advantageous if $M^{-1}B$ is close to the identity matrix. We have imposed the following stopping criterion

$$\frac{\|M^{-1}(g - Bu^{(i)})\|_2}{\|M^{-1}g\|_2} < \epsilon$$

with tolerance $\epsilon = 10^{-4}$.

The arithmetic work can be divided into initialization and iteration. The initial part consists of forming [Otto96] the preconditioner and factorizing the tridiagonal systems at a cost of $a_{pf} = 20\frac{\hat{m}}{m_1}\log_2 \hat{m} + 125$, where $\hat{m} = 2^{\lceil \log_2(2m_1+1)\rceil+1}$. The computation of the initial approximation is done with a preconditioner solve that requires $a_{ps} = 20\frac{\hat{m}}{m_1}\log_2 \hat{m} + 115$ arithmetic operations per unknown. The iterative method also goes through some initial steps. The cost for these is $a_{in} = 2a_{ps} + a_m + 10$, where $a_m = 40$ is the work required for a matrix–vector product $y = Bx$. Accordingly, the total arithmetic cost for the initialization becomes $a_{init} = a_{pf} + a_{ps} + a_{in}$.

The work for one iteration of GMRES(ℓ) is taken as the average over a complete cycle of ℓ iterations and is given by $a_{it} = a_m + a_{ps} + 8\ell + 38$.

If we let n_{it} be the number of iterations required for convergence, then the total work for solving $M^{-1}Bu = M^{-1}g$ with the GMRES(ℓ) method is $a_{init} + n_{it}a_{it}$.

The memory requirement for our method is $m_m + m_p + m_{it}$; where $m_m = 7m_1m_2$ is the number of memory positions needed for the coefficient matrix, the right-hand side, and the solution; $m_p = 8m_1m_2 + 4\hat{m}m_2$ is the number of memory positions used by the preconditioner; and $m_{it} = 2(\ell+1)m_1m_2$ denotes the storage requirement for the iterative method. Note that a complex value is considered to take up two memory positions.

TABLE 1
Comparison of preconditioned GMRES(ℓ) *and band Gaussian elimination.*

	Arithmetic complexity	Memory requirement
Band GE	$8m_1^2 + 25m_1$	$4m_1 + 4$
GMRES(ℓ,`ssor`)	$203 + n_{it}(8\ell + 128)$	$2\ell + 12$
GMRES(ℓ,`nb`)	$80\frac{\hat{m}}{m_1}\log_2 \hat{m} + 520$ $+ n_{it}(20\frac{\hat{m}}{m_1}\log_2 \hat{m} + 8\ell + 193)$	$2\ell + 17 + 4\frac{\hat{m}}{m_1}$

In Table 1, our method, denoted by GMRES(ℓ,`nb`), is compared with band Gaussian elimination, which is the standard direct method. We also consider SSOR preconditioning, which is a technique commonly used for Helmholtz problems [BaGoTu83], [MaFrPi97]. For the implementation of GMRES(ℓ) combined with the SSOR preconditioner, the so-called Eisenstat trick [MaFrPi97, and the references therein] was used. The storage requirements have been normalized by the number of unknowns.

5. Numerical experiments. In this section the results from some numerical experiments are presented. In all experiments, the systems of equations have been solved using the GMRES(ℓ) method combined with the preconditioner defined in section 3.1 and in some cases also combined with the SSOR preconditioner. The orthogonal grid is generated by a code based on the method described in [Abra91]. The implementations are made in Fortran 90, utilizing 64-bit precision for the grid generation, and 32-bit precision for the iterative method and the preconditioner. The numerical experiments were performed on a DEC AlphaServer 8200 EV5/300.[2] The geometry of the duct, i.e., the bottom profile, is defined by the following functions:

$$\begin{cases} x_1(\theta) = d_\ell + (d_r - d_\ell)\frac{\tanh(s(\theta-\delta_c))-\tanh(-s\delta_c)}{\tanh(s(1-\delta_c))-\tanh(-s\delta_c)}, \\ x_2(\theta) = \theta d_2, \end{cases} \qquad 0 \le \theta \le 1,$$

where

$$\delta_c = 0.5, \qquad s = \frac{4}{\min(\delta_c, 1-\delta_c)}.$$

By this choice the depth varies smoothly from d_ℓ at the left boundary to d_r at the right boundary. The parameter δ_c determines the center of the slope, whereas s controls the steepness. By increasing s, the slope steepens and the bottom flattens out at the ends. The relative source depth δ_s is set to 0.5 in all experiments. We use resolution criteria (29) and (30) with a phase error tolerance $\tau = 8\%$.

It would be interesting to investigate the arithmetic speedup for GMRES(ℓ,`nb`) compared with restarted GMRES using a very simple preconditioner such as symmetric diagonal scaling, but the latter method with restarting length $\ell \le 17$ does not converge in 8361 iterations for any of the problem sizes considered. However, the effectiveness of the normal block preconditioner M is indicated when comparing the corresponding preconditioned spectrum with the one arising after symmetric diagonal scaling. The spectra for a small (2730 unknowns) problem are shown in Figures 2 and 3. The preconditioned spectrum exhibits a high degree of clustering around one, which is favorable for Krylov subspace methods [Green97, p. 55], [Axel88].

[2]The actual computer is part of the Yggdrasil computing facilities at the Department of Scientific Computing, Uppsala University.

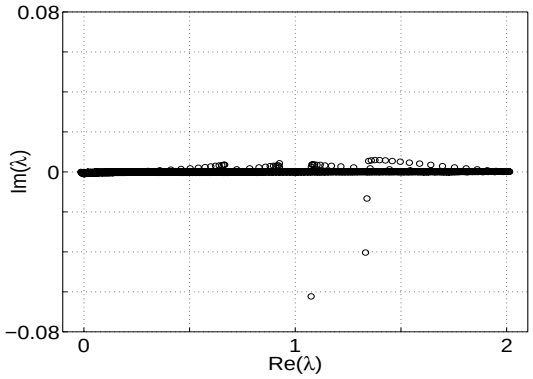

FIG. 2. *The spectrum of B (after symmetric diagonal scaling) for $d_2 = 300$, $d_\ell = 50$, $d_r = 20$, and $f = 25$.*

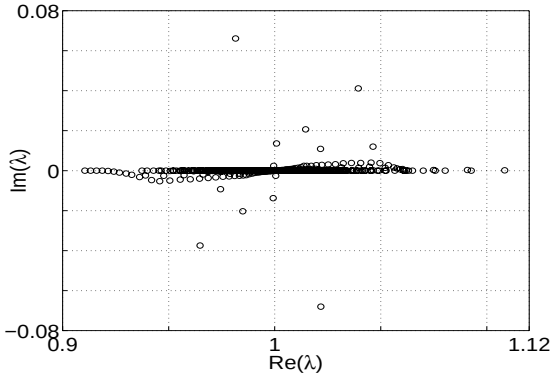

FIG. 3. *The spectrum of $M^{-1}B$ for $d_2 = 300$, $d_\ell = 50$, $d_r = 20$, and $f = 25$.*

Since the preconditioner coincides with the discretization matrix for the model problem in a duct with a flat bottom, it is to be expected that the rate of convergence will be affected by the geometry. When the bottom of the duct gets more curved, the preconditioner is not as good an approximation of B. Figure 4 shows how the geometry influences the number of iterations for GMRES(6,nb). Notice that here the number of iterations decreases when the problem size increases (and the duct gets less curved).

Another interesting issue is how the frequency affects the number of iterations. This is demonstrated in Figure 5 for a duct of medium steepness and frequencies in the low–to–intermediate range. For the same duct and frequencies, we investigated the effect of mismatching the transform and the Dirichlet–Neumann boundary conditions. To this end, preconditioners based on the cosine and the sine transforms were used. The result was that preconditioned GMRES(6) did not converge in 695 iterations. For Helmholtz problems with Neumann–Neumann or Dirichlet–Dirichlet boundary conditions, a similar severe degradation of the convergence rate is triggered by choosing inapt transforms [Otto96].

In Figures 6 and 7, the results from comparative experiments are shown. The number of unknowns depends cubicly on the frequency and ranges from 7452 to 2563902. We define the arithmetic gain for one method over another as the total

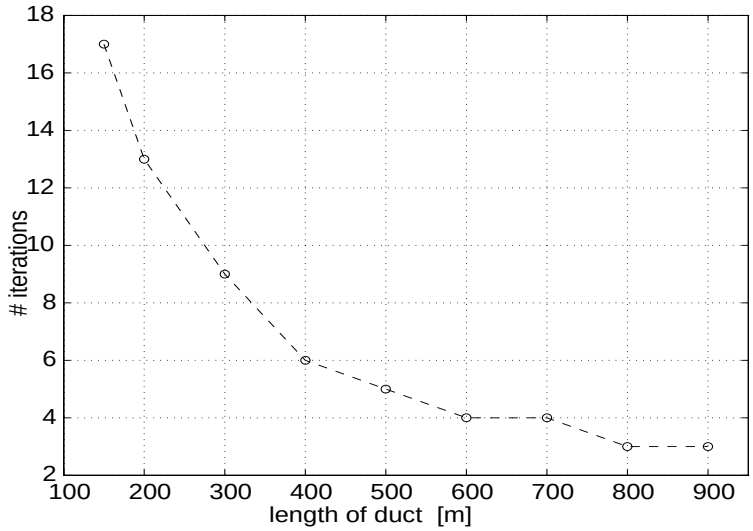

FIG. 4. *Number of iterations for ducts where the length d_2 is varied. All the other parameters are held constant, $d_\ell = 50$, $d_r = 20$, and $f = 100$.*

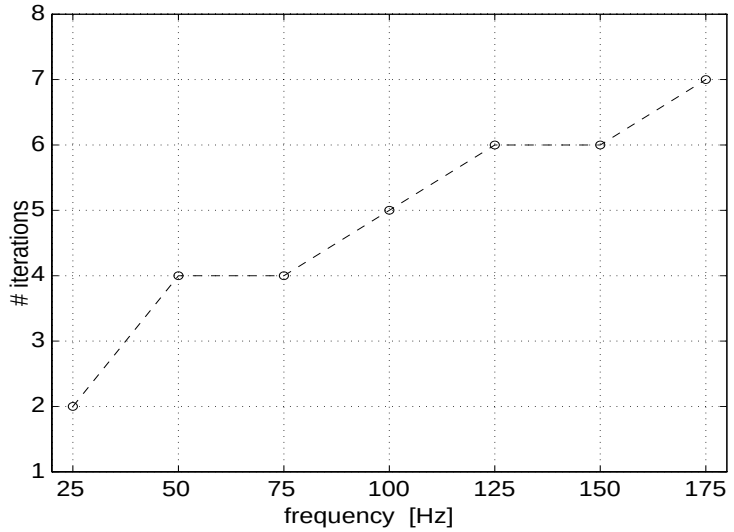

FIG. 5. *Number of iterations for different frequencies, $d_2 = 500$, $d_\ell = 50$ and $d_r = 20$.*

number of arithmetic operations for the latter divided by the total arithmetic complexity of the former. Analogously, the memory gain is defined in terms of memory requirements. To make a fair comparison between the two preconditioned methods, the restarting length ℓ_s for the GMRES(ℓ_s,`ssor`) method is chosen such that the memory requirement equals that of GMRES(ℓ,`nb`). In addition, the relaxation parameter for SSOR is set to its optimal value, which is determined within three decimal digits by a bisecting procedure in each test case. It is clear that GMRES(6,`nb`) is more efficient than band Gaussian elimination both regarding arithmetic complexity and memory requirement for all problem sizes considered. Furthermore, the gains increase as the

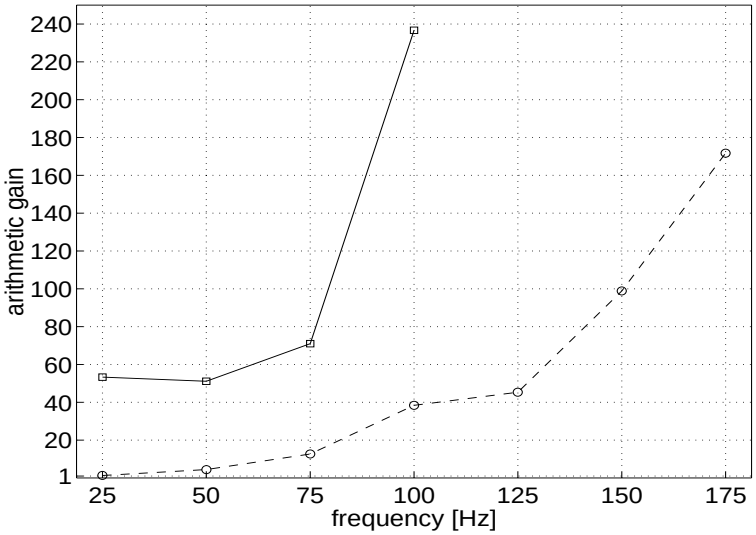

FIG. 6. *Arithmetic gain for* GMRES(6,`nb`) *compared with* GMRES(17,`ssor`) *(solid line) and band Gaussian elimination (dashed line).*

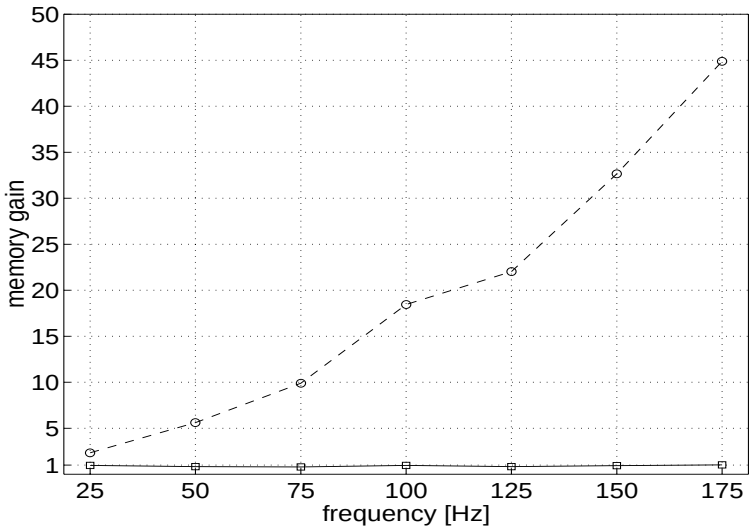

FIG. 7. *Memory gain for* GMRES(6,`nb`) *compared with* GMRES(17,`ssor`) *(solid line) and band Gaussian elimination (dashed line).*

frequency increases. Notice that, with respect to arithmetic complexity, the SSOR preconditioned method is even more outperformed than band Gaussian elimination. The actual iteration counts for GMRES(17,`ssor`) are 1006, 2141, 3504, and 9092 for the smaller problems, whereas the method fails to converge in 10000 iterations for the three largest problems.

Finally, Figures 8 and 9 display the solutions for two different frequencies. We have chosen rather low frequencies because those solutions are easier to visualize. Note that, for the lower frequency, only one wave mode is transmitted in the narrow part

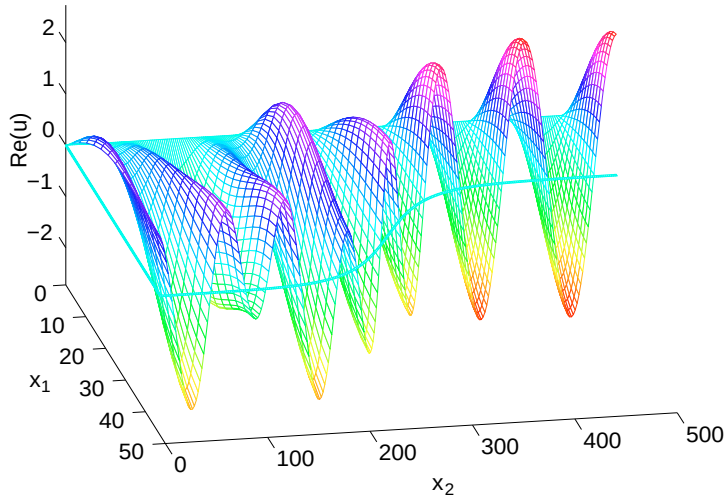

FIG. 8. *The solution for* $f = 25$, $d_2 = 500$, $d_\ell = 50$ *and* $d_r = 20$. *The contour of the duct is also depicted.*

of the duct. For the higher frequency, several modes are transmitted and interfere.

6. Conclusions. We have applied a preconditioned GMRES(ℓ) algorithm to a second-order finite difference discretization of the Helmholtz equation subject to Dirichlet, Neumann, and DtN boundary conditions for a two-dimensional waveguide problem. We utilize a normal block preconditioner, which results in a direct fast Helmholtz solver for rectangular domains, provided that the transform matches the boundary conditions. The memory requirement for this preconditioned method is linear in the number of unknowns. Thus, the sparsity of the original discretization

matrix is efficiently exploited. Numerical experiments for a hydroacoustic wave propagation problem show that the iterative method accelerated by the normal block preconditioner yields a significant gain both in storage requirement and arithmetic complexity when it is compared with band Gaussian elimination. In comparison with an SSOR preconditioned method having the same memory requirement, the gain in arithmetic complexity is even larger. For the normal block method versus band Gaussian elimination, the gain increases when the wavenumber is raised. Moreover, the number of iterations required for convergence grows moderately (or even decreases) as the number of unknowns increases.

In order to suppress the phase error, the number of unknowns has to grow cubicly in the wavenumber due to the second-order accurate discretization. Thus, for high wavenumbers, the *discretization* is less tractable from a computational point of view. The memory requirement might be a bottle-neck. To mitigate this adverse effect, high-order discretizations will be investigated in a forthcoming paper. Another pertinent concern is to perform a more rigorous phase error analysis. Further directions of research will also entail applications to heterogeneous media, e.g., cases where the sound speed depends on the depth due to temperature gradients, changes in hydrostatic pressure, and variable salinity.

Acknowledgments. The authors would like to thank Dr. Leif Abrahamsson for supplying the grid generation code. The first author also expresses his gratitude to Prof. Howard Elman, who invited the author to a postdoctoral visit at the Department of Computer Science, University of Maryland, where this research was completed.

COMPRESSIONS AND DILATIONS OF NUMERICAL RANGES*

J. MAROULAS† AND M. ADAM†

Abstract. Inner and outer approximation of numerical ranges of $n \times n$ complex matrices and matrix polynomials is investigated in this paper, which is based on the numerical ranges of matrices of smaller or double dimensions.

Key words. numerical range, matrix polynomials

AMS subject classifications. 15A60

PII. S0895479898340524

1. Introduction. Let M_n be the algebra of all $n \times n$ complex matrices. For a matrix $A \in M_n$, the *numerical range* $NR[A]$, also known as the *field of values*, is the set of complex numbers

$$NR[A] = \{\langle Ax, x\rangle : \quad x \in C^n, \ \ \|x\| = 1\}. \tag{1.1}$$

The radius

$$r(A) = \ \max \{|z| : \quad z \in NR[A]\}$$

of the smallest circle $|z| = r(A)$ that encloses $NR[A]$ is called the *numerical radius*. The usefulness of the numerical range and numerical radii is well known. As an extensive background for this active research topic we refer to [HJ] and [AL]. Replacing in (1.1) the Euclidean inner product with the *indefinite scalar product* on $\mathbf{C}^n$, it is known [GLR] that there exists an invertible indefinite hermitian matrix S such that $\langle x, y\rangle_S = \langle Sx, y\rangle$. Hence, we obtain the *S-numerical range* of A:

$$W_S(A) = \left\{ \frac{\langle Ax, x\rangle_S}{\langle x, x\rangle_S} : \ \ x \in \mathbf{C}^n, \quad \langle x, x\rangle_S \neq 0 \right\} = W_S^+(A) \bigcup W_{-S}^+(A), \tag{1.2}$$

where

$$W_S^+ = \{\langle Ax, x\rangle_S : \ \ x \in \mathbf{C}^n, \ \ \langle x, x\rangle_S = 1\}. \tag{1.3}$$

In particular, the set $W_S^+(A)$ is called the *positive S-numerical range*. The S-numerical ranges generalize the classical numerical range, and some properties of the $NR[A]$ can be extended to $W_S(A)$. In [B] it is proved that $W_S^+(A)$ is a convex set and also that the closure of set $W_S(A)$ contains all eigenvalues of A if A is positive definite. Moreover, we can readily verify the following:

(i) $W_S^+(A + kI) = W_S^+(A) + k, \quad k \in \mathbf{C}$.
(ii) $W_S^+(kA) = kW_S^+(A), \quad k \in \mathbf{C}$.
(iii) $W_S^+(A + B) \subseteq W_S^+(A) + W_S^+(B)$.
(iv) $W_S^+(A_1) \subseteq W_S^+(A), A_1,$ a submatrix of A.

(v) $z \in W_S^+(A)$, S real symmetric $\Rightarrow \overline{z} \in W_S^+(\bar{A})$.

A further study of both $W_S(A)$ and $W_S^+(A)$ has been presented by [LTU], where it is shown that $W_S(A)$ is always p-convex, i.e., for any distinct pair of points $z_1, z_2 \in W_S(A)$ either the closed line segment $\overline{z_1 z_2} \subset W_S(A)$ or the line $\{az_1 + (1-a)z_2 : a \leq 0 \text{ or } 1 \leq a\} \subset W_S(A)$. Clearly, if S is positive definite, then

$$W_S(A) = W_S^+(A) = NR[S^{1/2}AS^{-1/2}].$$

The idea of the numerical range has also been extended to matrix polynomials [LR], [M]:

$$L(\lambda) = I\lambda^q + A_1\lambda^{q-1} + \cdots + A_q; \quad A_i \in M_n,$$

where

$$NR[L(\lambda)] = \{\lambda : \ \langle L(\lambda)x, x\rangle = 0 \ \text{ for some } \ x \in \mathbf{C}^n\}. \tag{1.4}$$

$NR[L(\lambda)]$ has peculiar geometric properties with respect to the boundedness and connectedness of this set, which are important to the factorization of matrix polynomials [M], [MP1, MP2, MP3], [MMP], and [LMZ].

In this paper we continue our effort for further development of the subject and the study of related problems. In section 2 we express $NR[A]$ as the union of the numerical ranges of matrices of dimensions $k \times k$ for $2 \leq k < n$. In this way, each set in the union can be considered as an *inner approximation* or *dilation* of $NR[A]$. This result generalizes the approach of Markus and Pesce [MP], where $NR[A]$ is the union of the numerical ranges of 2×2 matrices, i.e., of ellipsoid regions using only real orthogonal vectors. Taking advantage of the fact that $NR[A]$ and $NR[e^{2i\theta}\bar{A}]$ are symmetric with respect to the straight line $y = (\tan\theta)x$, we have set the convex hull of $NR[A] \bigcup NR[e^{2i\theta}\bar{A}]$ equal to the numerical range of a suitable matrix. This result for $\theta = 0$ leads to the convenient equality

$$\text{Conv.hull}\left(NR[A] \cup NR[\bar{A}]\right) = NR\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right),$$

where M, N are real matrices defined by $A = M + iN$. Therefore, $NR[A]$ is presented as the intersection of numerical ranges as the line $y = (\tan\theta)x$ rotates around the origin for $0 \leq \theta \leq \pi$. The last equality is generalized further for the matrix

$$C = \begin{bmatrix} A & B \\ -\bar{B} & \bar{A} \end{bmatrix},$$

which, as is known, corresponds to a quartenionic matrix. Clearly, the outer set Conv.hull$(NR[A] \cup NR[\bar{A}])$ can be considered as a *compression* of $NR[A]$. Some additional comments on projections on the axes, on the joint numerical range [HJ], and on the numerical radius have been presented. The MATLAB procedure is exposed and examples are given.

In the third section we refer to $W_S^+(A)$. We show that for any indefinite hermitian matrix S,

$$NR[A] \cap W_S^+(A) \neq \emptyset,$$

and also that

$$W^+_{I_2\otimes S}(A\oplus B) = \text{Conv.hull}(W^+_S(A)\cup W^+_S(B)).$$

This equality clarifies Conv.hull$(W^+_S(A)\cup W^+_S(e^{2i\theta}\bar{A}))$ as the $(I_2\otimes S)$-numerical range of a matrix depending on A.

Finally, in the fourth section, we present two properties of $NR[L(\lambda)]$. In particular, the first one refers to the reduction of this set to $NR[M(\lambda)]$, where the $k\times k$ $(k\geq 2)$ matrix polynomial $M(\lambda)$ depends on $L(\lambda)$.

2. The numerical range of a matrix. An approximation or a *dilation* of $NR[A]$ in (1.1) is presented as a first statement.

THEOREM 2.1. *For a prefix number $k<n$,*

$$NR[A] = \bigcup_{\xi_1,\ldots,\xi_k} NR\left(\begin{bmatrix} \xi_1^*A\xi_1 & \ldots & \xi_1^*A\xi_k \\ \vdots & & \vdots \\ \xi_k^*A\xi_1 & \ldots & \xi_k^*A\xi_k \end{bmatrix}\right), \tag{2.1}$$

where $\xi_1,\ \ldots,\xi_k$ run over all sets by k orthonormal vectors of $\mathbf{C}^n$.

Proof. Any vector $x\in\mathbf{C}^n$ belongs to a k-dimensional subspace $\mathbf{E}\subset\mathbf{C}^n$. Let $\xi_1,\ \ldots,\xi_k$ be an orthonormal basis of $\mathbf{E}$ such that $\xi_i\in\mathbf{C}^n$. Then

$$x = [\xi_1\ \ldots\ \xi_k]\,\omega,$$

where $\omega\in\mathbf{C}^k$. Clearly, ω is a unit vector if and only if x is a unit, and due to

$$x^*Ax = \omega^*\begin{bmatrix}\xi_1^*\\ \vdots\\ \xi_k^*\end{bmatrix} A\,[\xi_1\ldots\xi_k]\,\omega = \omega^*\begin{bmatrix} \xi_1^*A\xi_1 & \ldots & \xi_1^*A\xi_k \\ \vdots & & \vdots \\ \xi_k^*A\xi_1 & \ldots & \xi_k^*A\xi_k \end{bmatrix}\omega,$$

we verify the relationship (2.1). □

For $k=2$, the interior of $NR[A]$ is covered by the ellipses

$$NR\left(\begin{bmatrix} \xi_1^*A\xi_1 & \xi_1^*A\xi_2 \\ \xi_2^*A\xi_1 & \xi_2^*A\xi_2 \end{bmatrix}\right),$$

where $\{\xi_1,\ \xi_2\}$ is any pair of orthonormal vectors. The estimation of $NR[A]$ clearly is realized easily if $k>2$, since the fields of values in the left part of (2.1) are convex sets and even they occupy a more extensive area of $NR[A]$ as k increases. This is illustrated in example 1. In particular, for $k=2$ and for $\xi_1,\ \xi_2$ real orthogonal vectors, (2.1) has been presented in [MP] using a different approach.

A similar approximation for the q-numerical range of A:

$$NR_q[A] = \{\ y^*Ax\quad :\quad \|x\| = \|y\| = 1,\ \ y^*x = q\},\qquad q\in[0,1],$$

is given by the formula:

$$NR_q[A] = \bigcup_{\xi_1,\xi_2} NR_q\left(\begin{bmatrix} \xi_1^*A\xi_1 & \xi_1^*A\xi_2 \\ \xi_2^*A\xi_1 & \xi_2^*A\xi_2 \end{bmatrix}\right),$$

since for $x \in \mathbf{\Delta} = \mathrm{span}\{\xi_1, \xi_2\}$, there exists $y \in \mathbf{\Delta}$ such that $y^*x = q$.

For the *compression* of $NR[A]$ we state the following theorem.

THEOREM 2.2. *For any matrix* A,

$$\text{(2.2)}\quad \text{Conv.hull}(NR[A] \cup NR[e^{2i\theta}\bar{A}]) = NR\left(\frac{1}{2}\begin{bmatrix} A + e^{2i\theta}\bar{A} & -i(A - e^{2i\theta}\bar{A}) \\ i(A - e^{2i\theta}\bar{A}) & A + e^{2i\theta}\bar{A} \end{bmatrix})\right),$$

where $0 \le \theta \le \pi$.

Proof. Since

$$\text{Conv.hull}(NR[A] \cup NR[e^{2i\theta}\bar{A}]) = NR\left(\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}\right),$$

we have to show that

$$NR\left(\frac{1}{2}\begin{bmatrix} A + e^{2i\theta}\bar{A} & -i(A - e^{2i\theta}\bar{A}) \\ i(A - e^{2i\theta}\bar{A}) & A + e^{2i\theta}\bar{A} \end{bmatrix}\right) = NR\left(\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}\right).$$

In fact, for a unit vector $x \in \mathbf{C}^{2n}$ and for $A = M + iN$, where $M, N \in \mathbf{R}_{n\times n}$, we have

$$\begin{aligned} x^*\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}x &= \frac{1}{2}x^*\begin{bmatrix} I & O \\ O & e^{2i\theta}I \end{bmatrix}\begin{bmatrix} I & -iI \\ -iI & I \end{bmatrix}\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\begin{bmatrix} I & iI \\ iI & I \end{bmatrix}x \\ &= \frac{1}{4}x^*\begin{bmatrix} I & -iI \\ -iI & I \end{bmatrix}\begin{bmatrix} (1+e^{2i\theta})I & -i(1-e^{2i\theta})I \\ i(1-e^{2i\theta})I & (1+e^{2i\theta})I \end{bmatrix} \\ &\quad \times \begin{bmatrix} M & N \\ -N & M \end{bmatrix}\begin{bmatrix} I & iI \\ iI & I \end{bmatrix}x \\ &= \frac{1}{2}x^*\left(\begin{bmatrix} 1 & -i \\ -i & 1 \end{bmatrix} \otimes I\right)\begin{bmatrix} \frac{A+e^{2i\theta}\bar{A}}{2} & \frac{-i(A-e^{2i\theta}\bar{A})}{2} \\ \frac{i(A-e^{2i\theta}\bar{A})}{2} & \frac{A+e^{2i\theta}\bar{A}}{2} \end{bmatrix} \\ &\quad \times \left(\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix} \otimes I\right)x \\ &= y^*\begin{bmatrix} \frac{A+e^{2i\theta}\bar{A}}{2} & \frac{-i(A-e^{2i\theta}\bar{A})}{2} \\ \frac{i(A-e^{2i\theta}\bar{A})}{2} & \frac{A+e^{2i\theta}\bar{A}}{2} \end{bmatrix}y, \end{aligned}$$

where $y = \frac{1}{\sqrt{2}}x^*\left(\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix} \otimes I\right)x$. Since

$$y^*y = \frac{1}{2}x^*\left(\begin{bmatrix} 1 & -i \\ -i & 1 \end{bmatrix} \otimes I\right)\left(\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix} \otimes I\right)x = x^*x = 1,$$

the relationship (2.2) is verified readily. ∎

COROLLARY 2.3. *For any matrix* $A = M + iN$, *where* $M, N \in \mathbf{R}_{n\times n}$,

$$\text{(2.3)}\qquad \text{Conv.hull } (NR[A] \cup NR[\bar{A}]) = NR\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right).$$

Proof. Equation (2.3) comes from (2.2) with $\theta = 0$. □

From Corollary 2.3, we have the following comments.

(I) For any matrix $A = M + iN$, the numerical range of a $2n \times 2n$ matrix $\begin{bmatrix} M & N \\ -N & M \end{bmatrix}$ is symmetric to the real axis.

(II)

$$NR\left(\begin{bmatrix} M & -N \\ N & M \end{bmatrix}\right) = NR\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right). \tag{2.4}$$

This is evident, due to

$$\begin{bmatrix} M & -N \\ N & M \end{bmatrix} = \begin{bmatrix} O & I \\ I & O \end{bmatrix}\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\begin{bmatrix} O & I \\ I & O \end{bmatrix}.$$

(III)

$$\mathrm{proj}_{ox} NR[A] = \mathrm{proj}_{ox} NR\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right). \tag{2.5}$$

In fact, by the symmetry of $NR[A]$ and $NR[\bar{A}]$ to the real axis, it is implied that the field Conv.hull$(NR[A] \cup NR[\bar{A}])$ is also symmetric to the same axis. Hence, by (2.3) we obtain (2.5).

(IV)

$$\mathrm{proj}_{oy} NR[A] = \mathrm{proj}_{ox} NR\left(\begin{bmatrix} N & M \\ -M & N \end{bmatrix}\right). \tag{2.6}$$

By the equalities (2.4) and $\mathrm{Im}(x^*Ax) = \mathrm{Re}(x^*(-iA)x)$, (2.6) is obvious.

(V) The real field of values [HJ, p. 85]

$$JNR\left(\begin{bmatrix} M & -N \\ N & M \end{bmatrix}, \begin{bmatrix} N & M \\ -M & N \end{bmatrix}\right) \equiv NR[A]. \tag{2.7}$$

In fact, if we denote the unit vector $x = u + iv$, then by the relationship

$$x^*Ax = w^T \begin{bmatrix} M & -N \\ N & M \end{bmatrix} w + i\left(w^T \begin{bmatrix} N & M \\ -M & N \end{bmatrix} w\right),$$

where $w = \begin{bmatrix} u \\ v \end{bmatrix} \in \mathbf{R}^{2n}$, we confirm the truth of the contention.

THEOREM 2.4. *For any matrix* $A \in \mathbf{C}_{n\times n}$,

$$NR[A] = \bigcap_{0\le\theta\le\pi} NR\left(\frac{1}{2}\begin{bmatrix} A + e^{2i\theta}\bar{A} & -i(A - e^{2i\theta}\bar{A}) \\ i(A - e^{2i\theta}\bar{A}) & A + e^{2i\theta}\bar{A} \end{bmatrix}\right). \tag{2.8}$$

Proof. Let $z \in NR[A]$. Then the complex number

$$w = e^{2i\theta}\overline{z} = \frac{1 + i\lambda}{1 - i\lambda}\overline{z},$$

where $\lambda = \tan\theta$, is symmetric in z with respect to the straight line $y = \lambda x$. Since $w \in NR[e^{2i\theta}\bar{A}]$, the fields $NR[A]$ and $NR[e^{2i\theta}\bar{A}]$ are symmetric with respect to the line $y = \lambda x$, and hence by (2.2),

$$\bigcap_{0\le\theta\le\pi} NR\left(\frac{1}{2}\begin{bmatrix} A+e^{2i\theta}\bar{A} & -i(A-e^{2i\theta}\bar{A}) \\ i(A-e^{2i\theta}\bar{A}) & A+e^{2i\theta}\bar{A} \end{bmatrix}\right)$$
$$= \bigcap_{0\le\theta\le\pi} \text{Conv.hull}\left(NR[A]\cup NR\left[\frac{1+i\lambda}{1-i\lambda}\bar{A}\right]\right) = NR[A]. \qquad \square$$

Setting $e^{-i\theta}A = S_\theta + iT_\theta$, where S_θ, T_θ are real matrices, by (2.8) we have directly the following corollary.

COROLLARY 2.5.

$$NR[A] = \bigcap_{0\le\theta\le\pi} NR\left(e^{i\theta}\begin{bmatrix} S_\theta & T_\theta \\ -T_\theta & S_\theta \end{bmatrix}\right). \tag{2.9}$$

Hence, by the theory of the numerical range of matrices [HJ], we can say that Theorems 2.1 and 2.4 give a better approximation of $NR[A]$ than the polygonal approximation. This happens because the boundary of the numerical ranges of matrices in (2.1) and also of those in (2.8) contain parts of $\partial NR[A]$ and not points, i.e., the vertices of polygons. Hence, the verification of $NR[A]$ by the intersection in (2.8), due to the convexity of $NR[A]$, needs a small number for θ.

A further generalization of (2.3) is the investigation of a relationship between the numerical ranges of matrices:

$$C = \begin{bmatrix} A & B \\ -\bar{B} & \bar{A} \end{bmatrix} \quad K = \begin{bmatrix} M & N & \vdots & U & V \\ -N & M & \vdots & -V & U \\ \dots & \dots & \dots & \dots & \dots \\ -U & V & \vdots & M & -N \\ -V & -U & \vdots & N & M \end{bmatrix}, \tag{2.10}$$

where $A = M + iN$ and $B = U + iV$.

THEOREM 2.6. *For the matrices C and K in* (2.10) *it is true that* $NR[C] = NR[K]$.

Proof. Denote by R the unitary matrix

$$R = \frac{1}{2}\begin{bmatrix} 1 & i & 1 & -i \\ i & 1 & -i & 1 \\ -i & 1 & i & 1 \\ -1 & i & -1 & -i \end{bmatrix} \otimes I.$$

Then

$$R^* K R = \text{diag}(C, \bar{C}),$$

and thus we obtain

$$NR[K] = NR[\text{diag}(C,\bar{C})] = \text{Conv.hull}\left(NR[C]\cup NR[\bar{C}]\right).$$

Moreover, by the equation

$$\begin{bmatrix} O & -I \\ I & O \end{bmatrix} C \begin{bmatrix} O & I \\ -I & O \end{bmatrix} = \bar{C},$$

we have $NR[C] = NR[\bar{C}]$ and consequently the equality of $NR[C]$ and $NR[K]$ is evident. □

In the special case where

$$C = \begin{bmatrix} p+iq & u+iv \\ -u+iv & p-iq \end{bmatrix}, \qquad p,q,u,v \in \mathbf{R},$$

we can check that $NR[C]$ is the interval $[p - i\sqrt{q^2+u^2+v^2},\ p + i\sqrt{q^2+u^2+v^2}]$.

For the *numerical radius* $r(A)$, defined by $r(A) = \max\{|z| : z \in NR[A]\}$, we verify the following theorem.

THEOREM 2.7.

$$r\left(\begin{bmatrix} \xi_1^* A\xi_1 & \dots & \xi_1^* A\xi_k \\ \vdots & & \vdots \\ \xi_k^* A\xi_1 & \dots & \xi_k^* A\xi_k \end{bmatrix}\right) \le r(A) = r\left(\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}\right). \tag{2.11}$$

Proof. By the relationship (2.1), clearly the NR of the matrix on the right is a subset of $NR[A]$, which implies the inequality in (2.11). For the equality, note that

$$r\left(\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}\right) = \max\left(r(A),\ r(e^{2i\theta}\bar{A})\right) = r(A),$$

since $r(e^{2i\theta}\bar{A}) = |e^{2i\theta}| r(\bar{A}) = r(A)$. □

MATLAB procedure. The inner approximation of $NR[A]$, as it is expressed in Theorem 2.1, can be illustrated as follows:

Step 1. Introduce the matrix.

Step 2. For a prefix number $k < n$ introduce k arbitrary linearly independent vectors of $\mathbf{C}^n$.

Step 3. Orthonormalize this set to $\xi_1, \dots, \xi_k$.

Step 4. Calculate the matrix $B = [\xi_i^* A \xi_j], \quad i,j = 1,2,\dots,k$.

Step 5. Determine the numerical range of B.

Step 6. Illustrate $NR[B]$.

Step 7. Repeat this procedure for some other set of vectors.

Example 1. Let

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 2 & 0 \\ 1 & 0 & -1 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix}.$$

In Figure 2.1, the $NR[A]$ are defined as the union of the numerical ranges of 2×2 and 3×3 matrices, an application of (2.1) for $k = 2$ and $k = 3$.

As an implication of Theorem 2.4 we give the next example.

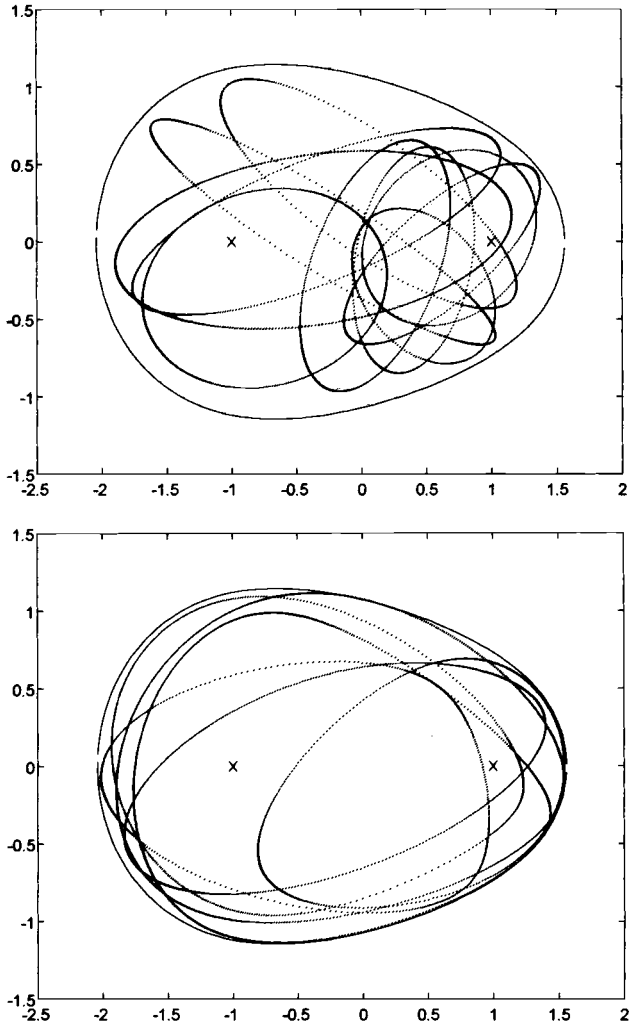

FIG. 2.1

Example 2. Let

$$A = \begin{bmatrix} 2-i & 1 \\ 0 & 1-i \end{bmatrix}.$$

Then for $\theta = 0,\ \frac{\pi}{6},\ \frac{\pi}{3},\ \frac{\pi}{2},\ \frac{2\pi}{3}$ we illustrate the NR of the matrix

$$\frac{1}{2}\begin{bmatrix} A + e^{2i\theta}\bar{A} & -i(A - e^{2i\theta}\bar{A}) \\ i(A - e^{2i\theta}\bar{A}) & A + e^{2i\theta}\bar{A} \end{bmatrix}$$

(see Figure 2.2).

From this, (2.8) is evident.

3. Numerical range on an indefinite inner product. Properties of the numerical range of a matrix on an indefinite inner product space have been presented

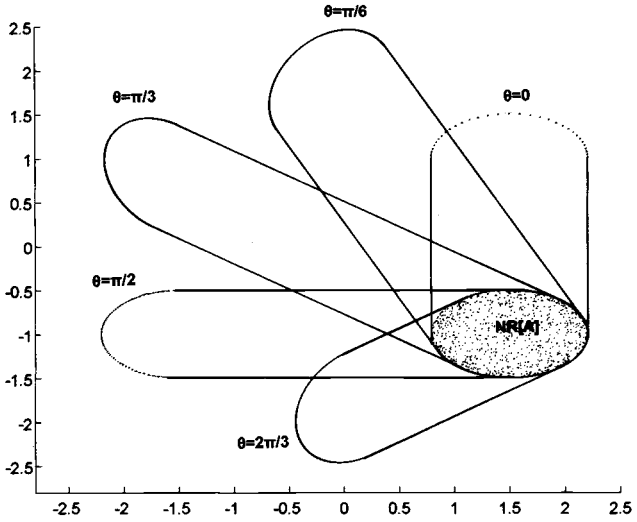

FIG. 2.2

in a recent publication [LTU]. The authors have extended some properties of the classical numerical range and have given a detailed description of $W_S^+(A)$ and

$$V_S^+(A) = \{\langle Ax, x\rangle : \quad x \in \mathbf{C}^n, \quad \langle x, x\rangle_S = 1\}.$$

Obviously, by (1.3), $W_S^+(A) = V_S^+(SA)$ and it is proved that $W_S^+(A)$ and $V_S^+(A)$ are always convex in a different approach from that in [B]. We next state a connection of $NR[A]$ and $W_S^+(A)$.

THEOREM 3.1. *For any hermitian matrix S, the set $NR[A] \cap W_S^+(A)$ is nonempty.*

Proof. For the hermitian S, let P be an orthonormal matrix such that $S = P^*DP$, where D is a real diagonal matrix. Then for any S-unit vector $x \in \mathbf{C}^n$ (i.e., $x^*Sx = 1$), we have

$$\langle Ax, x\rangle_S = x^*SAx = x^*P^*DPAx = y^*DBy = \langle By, y\rangle_D,$$

where $y = Px \in \mathbf{C}^n$ and $B = PAP^*$. Since y is a D-unit vector, $W_S^+(A) = W_D^+(B)$. Moreover, for any unit vector $w \in \mathbf{C}^n$, the equations

$$w^*Aw = w^*P^*BPw = z^*Bz, \qquad z = Pw, \ \|z\| = 1$$

imply $NR[A] = NR[B]$.

Therefore, it is enough to prove that $NR[B] \cap W_D^+(B) \neq \emptyset$, where D is a real diagonal matrix. Next we denote $D = \operatorname{diag}(D_1, -D_2)$, where $D_1 > 0$ and $D_2 \geq 0$ are the subdiagonal matrices. Let $\mathbf{E}$ be a subspace of $\mathbf{C}^n$ and $\xi_1, \ldots, \xi_k$ be a D-orthonormal basis of $\mathbf{E}$, i.e., $\langle \xi_j, \xi_i\rangle_D = \xi_i^* D\xi_j = \pm\delta_{ij}$, where δ_{ij} is Kronecker's symbol. In particular, we can consider that

$$1 = \langle \xi_i, \xi_i\rangle_D = \langle \xi_{io}, \xi_{io}\rangle_{D_1} \qquad \text{for } \xi_i = \begin{bmatrix} \xi_{io} \\ 0 \end{bmatrix}, \qquad i = 1, 2, \ldots, p$$

and

$$-1 = \langle \xi_j, \xi_j\rangle_D = \langle \xi_{jo}, \xi_{jo}\rangle_{D_2} \quad \text{for } \xi_j = \begin{bmatrix} 0 \\ \xi_{jo} \end{bmatrix}, \quad j = p+1, \ldots, k.$$

Then, for $\lambda \in W_D^+(B)$, there exists a vector $x_0 = [\xi_1, \ldots, \xi_k]\,\eta$ of $\mathbf{E}$ such that

$$\lambda = \langle Bx_0, x_0\rangle_D = x_0^* DBx_0 = \eta^* \begin{bmatrix} \langle B\xi_1, \xi_1\rangle_D & \ldots & \langle B\xi_k, \xi_1\rangle_D \\ \vdots & & \vdots \\ \langle B\xi_1, \xi_k\rangle_D & \ldots & \langle B\xi_k, \xi_k\rangle_D \end{bmatrix} \eta$$

and

$$1 = \langle x_0, x_0\rangle_D = \eta^* \begin{bmatrix} \xi_1^* \\ \vdots \\ \xi_k^* \end{bmatrix} D\,[\xi_1 \ldots \xi_k]\,\eta = \eta^* \mathrm{diag}\,(I_p, -I_{k-p})\,\eta.$$

For $\eta = \begin{bmatrix} \eta_1 \\ 0 \end{bmatrix}$, with $\eta_1 \in \mathbf{C}^p$, clearly $\|\eta_1\| = 1$ and

$$\lambda = \eta_1^* \begin{bmatrix} \langle B\xi_1, \xi_1\rangle_D & \ldots & \langle B\xi_p, \xi_1\rangle_D \\ \vdots & & \vdots \\ \langle B\xi_1, \xi_p\rangle_D & \ldots & \langle B\xi_p, \xi_p\rangle_D \end{bmatrix} \eta_1$$

$$= \eta_1^* \begin{bmatrix} \langle B_1\xi_{10}, \xi_{10}\rangle_{D_1} & \ldots & \langle B_1\xi_{p0}, \xi_{10}\rangle_{D_1} \\ \vdots & & \vdots \\ \langle B_1\xi_{10}, \xi_{p0}\rangle_{D_1} & \ldots & \langle B_1\xi_{p0}, \xi_{p0}\rangle_{D_1} \end{bmatrix} \eta_1,$$

where B_1 is the $p \times p$ principal submatrix of B. Since $\xi_{10}, \ldots, \xi_{p0}$ are D_1-orthonormal vectors and $D_1 > 0$, the vectors $D_1^{1/2}\xi_{10}, \ldots, D_1^{1/2}\xi_{p0}$ are orthonormal, and by Theorem 2.1,

$$\lambda \in NR\left[D_1^{1/2} B_1 D_1^{-1/2}\right] = NR\,[B_1] \subset NR\,[B]\,. \qquad \square$$

Due to the fact that $W_{-S}^+(A) = W_{-D}^+(B)$ and $W_S(A) = W_S^+(A) \cup W_{-S}^+(A) = W_D^+(B) \cup W_{-D}^+(B)$, clearly we have the following.

COROLLARY 3.2. *For any hermitian matrix S, the sets $NR[A] \cap W_{-S}^+(A)$ and $NR[A] \cap W_S(A)$ are nonempty.*

COROLLARY 3.3. *For any hermitian matrix S, $NR[A] \cap V_S^+(A) \neq \emptyset$.*

Proof. Let $S = P^*DP$, where $D = \mathrm{diag}(D_1, -D_2)$ is a real diagonal matrix with $D_1 > 0$ and $D_2 \geq 0$. If x is an S-unit vector, then the vector $y = Px$ is D-unit and $V_S^+(A) = V_D^+(B)$, where $A = P^*BP$. For $y = \begin{bmatrix} \theta \\ 0 \end{bmatrix}$, we have

$$1 = \langle Dy, y\rangle = \theta^* D_1 \theta = (\theta^* D_1^{1/2})(D_1^{1/2}\theta)$$

and

$$\langle By, y\rangle = \langle B_1\theta, \theta\rangle = \langle \tilde{B}_1\theta_1, \theta_1\rangle,$$

where B_1 is a submatrix of B and $\theta_1 = D_1^{1/2}\theta$, $B_1 = D^{1/2}\tilde{B}_1 D^{1/2}$.
Therefore,

$$NR[\tilde{B}_1] = NR[B_1] \subset NR[B] = NR[A]$$

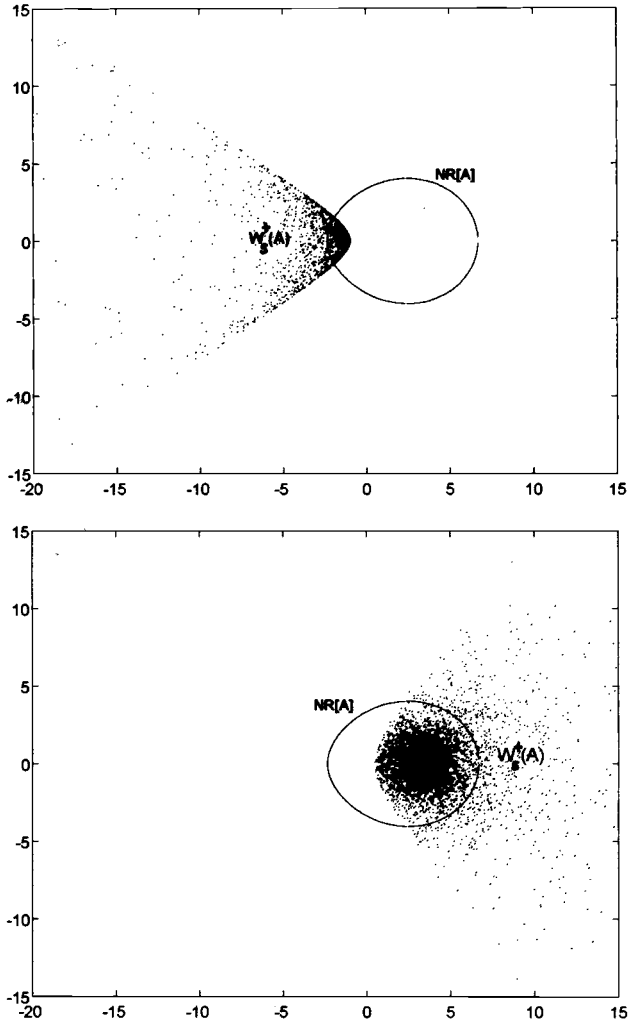

FIG. 3.1

and

$$NR[\tilde{B}_1] \,=\, V_{D_1}^+(B_1) \subset V_D^+(B) = V_S^+(A). \qquad \square$$

Example 3. The statement of Theorem 3.1 is illustrated in Figure 3.1 for

$$A = \begin{bmatrix} -1 & 0 & 2 \\ 0 & 2 & 8 \\ 1 & 0 & 3 \end{bmatrix},$$

first for $S = \mathrm{diag}(2, 0, -4)$, and then for $S = \mathrm{diag}(-2, 1, 4)$.

Another property of the numerical range of a matrix on an indefinite inner product, an analogue of Theorem 2.2, is as follows.

THEOREM 3.4. *For any matrix A,*

$$W^+_{I_2\otimes S}\left(\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}\right) = W^+_{I_2\otimes S}\left(\frac{1}{2}\begin{bmatrix} A+e^{2i\theta}\bar{A} & -i(A-e^{2i\theta}\bar{A}) \\ i(A-e^{2i\theta}\bar{A}) & A+e^{2i\theta}\bar{A} \end{bmatrix}\right), \tag{3.1}$$

where $0 \le \theta \le \pi$.

Proof. Let a vector $x \in \mathbf{C}^{2n}$ such that $x^*(I_2 \otimes S)x = 1$. Then

$$x^*(I_2\otimes S)\begin{bmatrix} A & O \\ O & e^{2i\theta}\bar{A} \end{bmatrix}x = \frac{1}{2}y^*(I_2\otimes S)\begin{bmatrix} A+e^{2iy}\bar{A} & -i(A-e^{2i\theta}\bar{A}) \\ i(A-e^{2i\theta}\bar{A}) & A+e^{2i\theta}\bar{A} \end{bmatrix}y,$$

where $y = \frac{1}{\sqrt{2}}\left(\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix}\otimes I\right)x$. Since

$$y^*\,(I_2\otimes S)\,y \;=\; x^*\,(I_2\otimes S)\,x \;=\; 1,$$

(3.1) is obtained. □

On the other hand we have the following theorem.

THEOREM 3.5. *Let the hermitian matrix S have at least one positive eigenvalue. Then*

$$W^+_{I_2\otimes S}\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right) = \text{Conv.hull}(W^+_S(A)\cup W^+_S(B)). \tag{3.2}$$

Proof. Let

$$\lambda \in W^+_{I_2\otimes S}\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right)$$

correspond to the $I_2 \otimes S$-unit vector $\upsilon = \begin{bmatrix} x \\ y \end{bmatrix}$ (i.e., $x^*Sx + y^*Sy = 1$). According to Lemma 2.2 in [LTU], we can consider that $x^*Sx > 0$ and $y^*Sy > 0$ and then

$$\lambda = \upsilon^*(I_2\otimes S)\begin{bmatrix} A & O \\ O & B \end{bmatrix}\upsilon = x^*SAx + y^*SBy = x^*Sx\frac{x^*SAx}{x^*Sx} + y^*Sy\frac{y^*SBy}{y^*Sy}.$$

Hence, λ is a convex combination of

$$\frac{x^*SAx}{x^*Sx} \in W^+_S(A) \qquad \text{and} \qquad \frac{y^*SBy}{y^*Sy} \in W^+_S(B)$$

and consequently

$$W^+_{I_2\otimes S}\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right) \subset \text{Conv.hull}(W^+_S(A)\cup W^+_S(B)).$$

For the reverse relationship let $x^*Sx = 1$. Then the vector $z = \begin{bmatrix} x \\ 0 \end{bmatrix}$ is $I_2 \otimes S$-unit and due to

$$z^*(I_2\otimes S)\begin{bmatrix} A & O \\ O & B \end{bmatrix}z = x^*SAx,$$

it is implied that

$$W_S^+(A) \subset W_{I_2\otimes S}^+\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right).$$

Similarly, for $y^*Sy = 1$,

$$W_S^+(B) \subset W_{I_2\otimes S}^+\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right).$$

Therefore,

$$W_S^+(A) \cup W_S^+(B) \subset W_{I_2\otimes S}^+\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right),$$

and due to the convexity of

$$W_{I_2\otimes S}^+\left(\begin{bmatrix} A & O \\ O & B \end{bmatrix}\right)$$

(3.2) follows. □

These two statements lead to an analogue of (2.2) in Theorem 2.2:

$$\begin{aligned}&\text{Conv.hull}(W_S^+(A) \cup W_S^+(e^{2i\theta}\bar{A}))\\ &\quad = W_{I_2\otimes S}^+\left(\frac{1}{2}\begin{bmatrix} A+e^{2i\theta}\bar{A} & -i(A-e^{2i\theta}\bar{A}) \\ i(A-e^{2i\theta}\bar{A}) & A+e^{2i\theta}\bar{A} \end{bmatrix}\right).\end{aligned} \tag{3.3}$$

Denoting $A = M + iN$ for $\theta = 0$, by (3.3) we obtain

$$\text{Conv.hull}(W_S^+(A) \cup W_S^+(\bar{A})) = W_{I_2\otimes S}^+\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right), \tag{3.4}$$

and by (3.1)

$$W_{I_2\otimes S}^+\left(\begin{bmatrix} A & O \\ O & \bar{A} \end{bmatrix}\right) = W_{I_2\otimes S}^+\left(\begin{bmatrix} M & N \\ -N & M \end{bmatrix}\right).$$

Similar results of (3.3) and (3.4) are obtained for $V_S^+(A)$.

4. Reduction of NR of matrix polynomials. Transferring the idea of Theorem 2.1 for the numerical range of matrix polynomials $L(\lambda)$ we state the next proposition.

THEOREM 4.1. *For $k \le n$,*

$$NR[L(\lambda)] = \bigcup_{\xi_1,\ldots,\xi_k} NR[M_\xi(\lambda)], \tag{4.1}$$

where the $k \times k$ matrix polynomial

$$M_\xi(\lambda) = G^*(E \otimes L(\lambda))G,$$

with

$$E = \begin{bmatrix} 1 & \dots & 1 \\ \vdots & & \vdots \\ 1 & \dots & 1 \end{bmatrix}_{k\times k}, \qquad G = \operatorname{diag}(\xi_1, \dots, \xi_k)_{nk\times k},$$

and $\xi_1, \dots, \xi_k$ *are orthonormal vectors of* $\mathbf{C}^n$. *In* (4.1) *the union runs over all sets by* k *orthonormal vectors of* $\mathbf{C}^n$.

Proof. Let the vectors $\xi_1, \dots, \xi_k \in \mathbf{C}^n$ be an orthonormal basis of a subspace $\mathbf{E} \subset \mathbf{C}^n$ and let $x \in \mathbf{E}$. Then

$$x = [\xi_1 \dots \xi_k]y, \quad y \in \mathbf{C}^k$$

and

$$\begin{aligned} x^*L(\lambda)x &= y^*[\xi_1 \dots \xi_k]^*L(\lambda)[\xi_1 \dots \xi_k]y \\ &= y^* \begin{bmatrix} \xi_1^*L(\lambda)\xi_1 & \dots & \xi_1^*L(\lambda)\xi_k \\ \vdots & & \vdots \\ \xi_k^*L(\lambda)\xi_1 & \dots & \xi_k^*L(\lambda)\xi_k \end{bmatrix} y = y^*M_\xi(\lambda)y. \end{aligned}$$

Hence, running over all sets by k orthonormal vectors, (4.1) results. ∎

Obviously (4.1) for $k = 2$ is simple. Denoting $L(\lambda)$ as

$$\overline{L}(\lambda) = I\lambda^q + \bar{A}_1\lambda^{q-1} + \dots + \bar{A}_q,$$

a nearly similar relation to (2.2) arises.

THEOREM 4.2.

$$\begin{aligned} &NR\left(\begin{bmatrix} L(\lambda) & O \\ O & e^{2i\theta}\overline{L}(\lambda) \end{bmatrix}\right) \\ &= NR\left(\frac{1}{2}\begin{bmatrix} L(\lambda) + e^{2i\theta}\overline{L}(\lambda) & -i(L(\lambda) - e^{2i\theta}\overline{L}(\lambda)) \\ i(L(\lambda) - e^{2i\theta}\overline{L}(\lambda)) & L(\lambda) + e^{2i\theta}\overline{L}(\lambda) \end{bmatrix}\right). \end{aligned} \tag{4.2}$$

Proof. Let the vector $z \in \mathbf{C}^{2n}$. Then, as in Theorem 2.2,

$$z^*\begin{bmatrix} L(\lambda) & O \\ O & e^{2i\theta}\overline{L}(\lambda) \end{bmatrix} z = \frac{1}{2}w^*\begin{bmatrix} L(\lambda) + e^{2i\theta}\overline{L}(\lambda) & -i(L(\lambda) - e^{2i\theta}\overline{L}(\lambda)) \\ i(L(\lambda) - e^{2i\theta}\overline{L}(\lambda)) & L(\lambda) + e^{2i\theta}\overline{L}(\lambda) \end{bmatrix} w,$$

where

$$w = \frac{1}{\sqrt{2}}\begin{bmatrix} I & iI \\ iI & I \end{bmatrix} z.$$

Note that $\|w\| = \|z\|$. ∎

Writing $L(\lambda) = L_1(\lambda) + iL_2(\lambda)$, where the coefficients of $L_1(\lambda)$ and $L_2(\lambda)$ are real matrices, by (4.2) and for $\theta = 0$, we have the following corollary.

COROLLARY 4.3.

$$NR\left(\begin{bmatrix} L(\lambda) & O \\ O & \overline{L}(\lambda) \end{bmatrix}\right) = NR\left(\begin{bmatrix} L_1(\lambda) & L_2(\lambda) \\ -L_2(\lambda) & L_1(\lambda) \end{bmatrix}\right).$$

MINIMAL DEGREE COPRIME FACTORIZATION OF RATIONAL MATRICES*

CRISTIAN OARĂ† AND ANDRAS VARGA‡

Abstract. Given a rational matrix G with complex coefficients and a domain Γ in the closed complex plane, both arbitrary, we develop a complete theory of coprime factorizations of G over Γ, with denominators of McMillan degree as small as possible. The main tool is a general pole displacement theorem which gives conditions for an invertible rational matrix to dislocate by multiplication a part of the poles of G. We apply this result to obtain the parametrized class of all coprime factorizations over Γ with denominators of minimal McMillan degree n_b—the number of poles of G outside Γ. Specific choices of the parameters and of Γ allow us to determine coprime factorizations, as for instance, with polynomial, proper, or stable factors. Further, we consider the case in which the denominator has a certain symmetry, namely it is J all-pass with respect either to the imaginary axis or to the unit circle. We give necessary and sufficient solvability conditions for the problem of coprime factorization with J all-pass denominator of McMillan degree n_b and, when a solution exists, we give a construction of the class of coprime factors. When no such solution exists, we discuss the existence of, and give solutions to, coprime factorizations with J all-pass denominators of minimal McMillan degree ($> n_b$). All the developments are carried out in terms of descriptor realizations associated with rational matrices, leading to explicit and computationally efficient formulas.

Key words. rational matrices, coprime factorizations, J all-pass, descriptor realizations, numerical algorithms

1. Introduction.

Let G be an arbitrary rational matrix (possible improper) and Γ be a given domain of the closed complex plane. A *left coprime factorization* (LCF) over Γ of G is a fractional representation of the form $G = M^{-1}N$, with N and M rational matrices having poles only in Γ and satisfying $MU + NV = I$ for certain rational matrices U and V with all poles in Γ. Analogously, a factorization in the form $G = NM^{-1}$, with N and M having poles only in Γ and satisfying $UM + VN = I$ for certain rational matrices U and V with poles in Γ, is called a *right coprime factorization* over Γ.

In this paper we develop a complete theory of LCFs over Γ with denominators M of smallest possible McMillan degree (see the precise definition below). For brevity, we call such factorizations of *minimal degree*, and define the degree of the factorization to be the McMillan degree of the denominator M. We address only LCFs since all results for right coprime factorizations follow by duality.

Apparently, the theory of minimal degree coprime factorizations has not been previously considered as such in the literature, although it is crucial to solving various problems encountered in the theory of linear systems and networks [29, 32], to canonical and noncanonical spectral factorizations of unstable rational matrices [6, 11, 4, 5], to several conjugation-based approaches to nonstandard H_∞ control problems [30, 31],

and it brings important numerical advantages as for instance in computing coprime factorizations with denominators which are polynomial, proper, stable, all-pass, or J lossless. The only noticeable exception is [2], where coprime factorizations are addressed with another requirement of minimality, namely, the sum of the McMillan degrees of the denominator and nominator to be as small as possible. However, even in the case treated in [2] in which the matrix to be factored is square and of full rank over rationals this sum minimality leads to combinatorial problems over an infinite set which have little interest from an algorithmic viewpoint as well as for the type of applications that we have mentioned above.

Our main tool in the derivations, which is also of independent interest, is a general pole displacement theorem which gives a characterization in terms of realizations for an invertible rational matrix M to cancel in the product MG all poles of G in Γ. An important feature of our result is the possibility of coping with domains containing infinity, without using conformal mapping techniques. In particular, we show that the minimal degree of an LCF over Γ is n_b, where n_b is the number of poles of G outside Γ, and give a description in terms of realizations of all factors solving the minimal degree LCF over Γ. It turns out that the basic ingredient in computing LCFs of minimal degree lies in the solution of a generalized eigenvalue assignment problem of order n_b.

We develop also a theory of minimal degree LCFs with the additional requirement that the denominator has a certain symmetry. We consider here two cases, in which the denominator is J all-pass, either with respect to the imaginary axis or to the unit circle, and the domain Γ is adequately chosen to reflect the respective symmetry. We study first LCFs with J all-pass denominator of degree n_b, which we call the *canonical case*, and give necessary and sufficient solvability conditions. When solutions exist we give a parameterized description of the factors in terms of associated realizations. When such canonical solutions do not exist, we discuss the solution of *noncanonical* LCFs with J all-pass denominators of McMillan degree as small as possible ($> n_b$). The computation of factors in the canonical case relies on solving a generalized Lyapunov equation of order n_b. In the noncanonical case, the rank r of the solution of the same Lyapunov equation allows us to determine the minimal degree of the factorization as $2n_b - r$. The noncanonical factors can then be constructed by embedding the solution of this Lyapunov equation of order n_b into a $(2n_b - r)$-order Lyapunov equation with nonsingular solution. The noncanonical case treated here has important connections with the noncanonical Wiener–Hopf and J spectral factorizations as discussed in [6] for proper and invertible rational matrices. Another connected work is [31], which in contrast to our results is restricted to the canonical case with J lossless denominator with respect to the imaginary axis, and involves the solution of a Riccati equation of order equal to the McMillan degree of G.

For an extensive treatment of related topics in factorization theory of rational matrices we refer to the excellent collections of papers [4, 6, 11] for the regular case, and to [19, 20, 3] for the nonregular and nonsquare cases.

The paper is organized as follows. The main definitions and notation used throughout the paper are presented in a preliminary section together with a brief discussion on various descriptor realizations of rational matrices. In section 3 we obtain formulas for an invertible factor that dislocates by left multiplication certain prescribed poles of a given rational matrix. In section 4 we give a parameterization of the class of factors that solve the minimal degree LCF over Γ. Section 5 is devoted to the theory of minimal degree LCFs with J all-pass denominators with respect to the

imaginary axis. In section 6 we develop the analogous results in the case in which the denominator is J all-pass with respect to the unit circle. Several numerical examples are presented in section 7 together with a discussion of appropriate computational methods. Some conclusions summarize the main aspects of the proposed theory and provide hints to possible applications and extensions. We defer to an appendix the characterization in terms of realizations of an arbitrary J all-pass rational matrix.

2. Preliminaries.

2.1. Basic notation. We start with some notation and definitions. For a matrix A we denote by A^T and A^* its transpose and its conjugate transpose, respectively, and, if A is invertible, by A^{-T} and A^{-*} its transposed inverse and its conjugated transposed inverse, respectively.

By $\mathbb{C}$, $\mathbb{C}^-$, $\mathbb{C}^+$, $\mathbb{C}^0$, and $\mathbb{R}$ we denote the complex plane, the open left half plane, the open right half plane, the imaginary axis, and the real axis, respectively, and let $\overline{\mathbb{C}} := \mathbb{C} \cup \{\infty\}$ be the closed complex plane, and $\overline{\mathbb{C}}^- := \mathbb{C}^- \cup \mathbb{C}^0 \cup \{\infty\}$, $\overline{\mathbb{C}}^+ := \mathbb{C}^+ \cup \mathbb{C}^0 \cup \{\infty\}$, $\overline{\mathbb{C}}^0 := \mathbb{C}^0 \cup \{\infty\}$. Here the overbar denotes closure. By $\mathbb{D}$ we denote the open unit disk, and $\mathbb{D}^c = \overline{\mathbb{C}} \setminus \overline{\mathbb{D}}$ stands for the exterior of the closed unit disk containing the infinity.

Consider the disjoint partition of the closed complex plane into a "good" region Γ_g and a "bad" region Γ_b as

$$\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b. \tag{2.1}$$

A frequent interpretation of Γ_g in system theory is related to the standard stability concept, that is, for linear continuous-time systems $\Gamma_g = \mathbb{C}^-$, while for linear discrete-time systems $\Gamma_g = \mathbb{D}$ (or, sometimes, their closures). However, we use also other interpretations, as for instance $\Gamma_g = \{\infty\}$ to obtain coprime factorizations with polynomial factors. When dealing with LCFs of rational matrices with real coefficients, we assume that Γ_g is symmetric with respect to the imaginary axis, that is, if $\lambda \in \Gamma_g$ then $\overline{\lambda} \in \Gamma_g$. This is in particular true for all the aforementioned examples of Γ_g and guarantees that the resulting factors of the LCF have real coefficients as well.

2.2. Rational matrices. Throughout the paper we consider matrices with coefficients in the field $\mathbb{F}$, where $\mathbb{F}$ denotes either $\mathbb{R}$ or $\mathbb{C}$. We view a $p \times m$ rational matrix $G(\lambda)$ as a matrix whose entries are rational functions with coefficients in $\mathbb{F}$ and of the complex variable λ. Alternatively, we shall assimilate the rational matrix $G(\lambda)$ with the *transfer-function matrix* (TFM) of a linear time-invariant continuous-time or discrete-time descriptor system, and λ is either s or z, the complex variables appearing in the Laplace- or Z-transform, respectively, according to the type of system. We denote by $G^\sim$ the *adjoint* of G, where $G^\sim(s) = G^*(-\overline{s})$ in continuous time and $G^\sim(z) = G^*(1/\overline{z})$ in discrete time. In particular, if G has real coefficients we have $G^\sim(s) = G^T(-s)$ and $G^\sim(z) = G^T(1/z)$, respectively. Let J be a *signature* matrix, i.e., a matrix satisfying $J = J^* = J^{-1}$. We say that the rational matrix G is J *all-pass with respect to the imaginary axis* if $G^\sim JG = J$, where $G^\sim$ denotes the adjoint in continuous time. Accordingly, we say that G is J *all-pass with respect to the unit circle* if $G^\sim JG = J$, where $G^\sim$ denotes now the adjoint in discrete time.

2.3. Structural elements of rational matrices. For an arbitrary rational matrix we recall now several structural elements that play an important role in the sequel: normal rank, finite and infinite poles and zeros, and their orders. It is easy to realize that $G(\lambda)$ has constant rank for all but a finite number of points $\lambda \in \mathbb{C}$ for

which it has smaller rank. The *normal rank* of G is by definition the rank of $G(\lambda)$ for almost all $\lambda \in \mathbb{C}$. A rational matrix which is square (say $p \times p$) and has full normal rank p is called nonsingular; otherwise it is called singular. Clearly, a nonsingular rational matrix has an inverse which is a rational matrix as well.

In this paper, a particular focus is on the *poles* and *zeros* of a rational matrix, defined now. For an arbitrary $p \times m$ rational matrix G of normal rank r there always exists a $p \times p$ polynomial matrix $U(\lambda)$ with $\det U(\lambda) = 1$ and an $m \times m$ polynomial matrix $V(\lambda)$ with $\det V(\lambda) = 1$ that bring G to the so-called Smith–McMillan form

$$D(\lambda) = U(\lambda)G(\lambda)V(\lambda),$$

where

$$D(\lambda) = \operatorname{diag}\left\{\frac{\epsilon_1(\lambda)}{\eta_1(\lambda)}, \frac{\epsilon_2(\lambda)}{\eta_2(\lambda)}, \ldots, \frac{\epsilon_r(\lambda)}{\eta_r(\lambda)}, 0, \ldots, 0\right\},$$

and the polynomials $\epsilon_i(\lambda)$, $\eta_i(\lambda)$ are pairwise coprime for $i = 1, \ldots, r$ and satisfy the divisibility properties

$$\epsilon_i(\lambda) | \epsilon_{i+1}(\lambda), \qquad \eta_{i+1}(\lambda) | \eta_i(\lambda), \qquad i = 1, \ldots, r-1.$$

The polynomials $\epsilon_i(\lambda)$ and $\eta_i(\lambda)$ are uniquely defined by $G(\lambda)$ and are called *elementary divisors* of G. Define

$$z(\lambda) = \epsilon_1(\lambda) \cdots \epsilon_r(\lambda), \qquad p(\lambda) = \eta_1(\lambda) \cdots \eta_r(\lambda).$$

Then the n_z (n_p) roots of $z(\lambda)$ ($p(\lambda)$) are by definition *the finite zeros (poles)* of G and their *multiplicities* are by definition the multiplicities of the roots of $z(\lambda)$ ($p(\lambda)$). The *orders* of the zero (pole) λ_0 of G are by definition the nonzero multiplicities of λ_0 as a root of $\epsilon_i(\lambda)$ ($\eta_i(\lambda)$) for $i = 1, \ldots, r$. We say that ∞ is a zero (pole) of G if 0 is a zero (pole) of the rational matrix $\widehat{G}(\lambda) = G(\frac{1}{\lambda})$, and we define the orders of the (zero) pole $\lambda = \infty$ of $G(\lambda)$ as the orders of the pole $\lambda = 0$ of $\widehat{G}(\lambda)$.

By definition, the *McMillan degree* of G—denoted $\delta(G)$—is the sum of the orders of all its poles (finite and infinite). Once a partition (2.1) is fixed, we have $\delta(G) = n_b + n_g$, where n_g denotes the number of "good" poles in Γ_g and n_b denotes the number of "bad" poles in Γ_b (counting multiplicities).

A rational matrix G which is J all-pass with respect to the imaginary axis features a pole-zero symmetry with respect to the imaginary axis. Precisely, if $\{\lambda_1, \lambda_2, \ldots, \lambda_n\}$ is the union of poles of G, then $\{-\overline{\lambda}_1, -\overline{\lambda}_2, \ldots, -\overline{\lambda}_n\}$ is the union of zeros of G. A similar property holds for a rational matrix G which is J all-pass with respect to the unit circle where now the pole–zero symmetry is with respect to the unit circle.

2.4. Descriptor realizations of rational matrices.

Standard descriptor realizations of rational matrices. It is well known (see, for example, [28, 27]) that any $p \times m$ rational matrix $G(\lambda)$ with coefficients in $\mathbb{F}$ (even improper or polynomial) has a descriptor realization of the form

$$G(\lambda) = D + C(\lambda E - A)^{-1}B =: \left[\begin{array}{c|c} A - \lambda E & B \\ \hline C & D \end{array}\right], \tag{2.2}$$

where $A, E \in \mathbb{F}^{n \times n}$, $B \in \mathbb{F}^{n \times m}$, $C \in \mathbb{F}^{p \times n}$, $D \in \mathbb{F}^{p \times m}$, and the so-called pole pencil $A - \lambda E$ is *regular*, i.e., it is square and $\det(A - \lambda E) \not\equiv 0$. The dimension n of the

square matrices A and E is called the *order of the realization* (2.2). We use $\Lambda(A-\lambda E)$ to denote the union of generalized eigenvalues of the regular pencil $A-\lambda E$ (finite and infinite, multiplicities counting). Occasionally, we shall also use the more compact notation $G=(A-\lambda E,B,C,D)$ to denote (2.2). The descriptor realization (2.2) of G is called *minimal* if its order is as small as possible among all realizations of this kind. Well-known criteria for minimality of a descriptor realization (2.2) are (see [27])

$$\operatorname{rank}\begin{bmatrix} A-\lambda E & B \end{bmatrix} = n \quad \forall \lambda \in \mathbb{C}, \tag{2.3a}$$

$$\operatorname{rank}\begin{bmatrix} E & B \end{bmatrix} = n, \tag{2.3b}$$

$$\operatorname{rank}\begin{bmatrix} A-\lambda E \\ C \end{bmatrix} = n \quad \forall \lambda \in \mathbb{C}, \tag{2.3c}$$

$$\operatorname{rank}\begin{bmatrix} E \\ C \end{bmatrix} = n, \tag{2.3d}$$

$$A\ker(E) \subseteq \operatorname{Im}(E). \tag{2.3e}$$

The conditions of minimality (2.3) are usually known as finite and infinite controllability, finite and infinite observability, and absence of nondynamic modes, respectively. For a minimal descriptor realization (2.2) of order n we have $\delta(G)=\operatorname{rank} E \le n$.

The principal inconvenience of realizations of the form (2.2) is that their minimal possible order is greater than the McMillan degree of G unless G is proper, and this brings important technical difficulties in factorization problems in which the McMillan degree plays a paramount role. A remedy to this is to use a generalization of (2.2) in which either the B or the C matrix is replaced by a matrix pencil, as explained in the next section.

Alternative descriptor realizations. Any rational $p\times m$ matrix G has a realization

$$G(\lambda) = D + C(\lambda E - A)^{-1}(B-\lambda F) =: \left[\begin{array}{c|c} A-\lambda E & B-\lambda F \\ \hline C & D \end{array}\right], \tag{2.4}$$

and for any fixed $\alpha,\beta\in\mathbb{F}$, not both zero, there exists a realization

$$G(\lambda) = D + C(\lambda E - A)^{-1}B(\alpha-\lambda\beta) =: \left[\begin{array}{c|c} A-\lambda E & B(\alpha-\lambda\beta) \\ \hline C & D \end{array}\right], \tag{2.5}$$

where $A,E\in\mathbb{F}^{n\times n}$, $B,F\in\mathbb{F}^{n\times m}$, $C\in\mathbb{F}^{p\times n}$, $D\in\mathbb{F}^{p\times m}$, and the pole pencil $A-\lambda E$ is regular. A realization (2.5) will be called centered at $\frac{\alpha}{\beta}$. (If $\beta=0$ we interpret $\frac{\alpha}{\beta}$ as ∞.) Occasionally, we shall use also the more compact notation $G=(A-\lambda E,B-\lambda F,C,D)$ and $G=(A-\lambda E,B(\alpha-\lambda\beta),C,D)$ to denote (2.4) and (2.5), respectively. Realizations of type (2.5) have been used for example in [12, 13, 14] for various problems related to factorizations of rational matrix functions.

All realizations (2.2), (2.4), and (2.5) are formally contained in the following general realization of a rational matrix due to Rosenbrock [21]:

$$G(\lambda) = W(\lambda) - V(\lambda)T^{-1}(\lambda)U(\lambda) =: \left[\begin{array}{c|c} T(\lambda) & U(\lambda) \\ \hline V(\lambda) & W(\lambda) \end{array}\right],$$

where $T(\lambda)$, $U(\lambda)$, $V(\lambda)$, and $W(\lambda)$ are matrix polynomials, with $T(\lambda)$ square and invertible. It is easy to see that

$$\begin{bmatrix} \widetilde{T}(\lambda) & \widetilde{U}(\lambda) \\ \widetilde{V}(\lambda) & \widetilde{W}(\lambda) \end{bmatrix} = \begin{bmatrix} Q & O \\ X & I \end{bmatrix} \begin{bmatrix} T(\lambda) & U(\lambda) \\ V(\lambda) & W(\lambda) \end{bmatrix} \begin{bmatrix} Z & Y \\ O & I \end{bmatrix}, \tag{2.6}$$

where Q and Z are constant invertible matrices and X and Y are arbitrary constant matrices, defines an *equivalent realization* in the form

$$G(\lambda) = \left[\begin{array}{c|c} \widetilde{T}(\lambda) & \widetilde{U}(\lambda) \\ \hline \widetilde{V}(\lambda) & \widetilde{W}(\lambda) \end{array}\right].$$

(See also [21] for a more general case.) This type of transformation performed on a realization is called *equivalence*, and if in addition $X = 0$ and $Y = 0$ it is called *state-space equivalence*.

We call realizations of the type (2.4) or (2.5) *minimal* if the dimension of the square matrices A and E (also called the order of the realization) is as small as possible among all realizations of the respective kind. It can be easily shown that any rational matrix $G(\lambda)$ has a minimal realization of type (2.4) of order equal to $\delta(G)$. For any fixed α and β, not both zero, and such that $\frac{\alpha}{\beta}$ is not a pole of G there also exists a minimal realization of type (2.5) of order equal to $\delta(G)$. The condition imposed on $\frac{\alpha}{\beta}$ is needed only for writing down minimal realizations (2.5) which have order equal to $\delta(G)$. More precisely, even if $\frac{\alpha}{\beta}$ is a pole of G we can still write a realization (2.5) but the minimal order will necessarily be greater than $\delta(G)$. This is exactly what is happening for realizations (2.2) which are obtained from (2.5) for $\alpha = 1$ and $\beta = 0$ and for which the minimal order is necessarily greater than $\delta(G)$, provided $\frac{\alpha}{\beta} = \infty$ is a pole of G. Notice that for (2.5) we can always freely choose α and β such as to ensure that $\frac{\alpha}{\beta}$ is not a pole of G. For the rest of the paper, if not otherwise stated, we assume this choice implicitly. The nice feature of (2.4) and (2.5) that their minimal order equals the McMillan degree of G recommends them for the kind of problems treated in this paper.

It is relatively straightforward to show that the criteria of minimality for a descriptor realization of type (2.4) are

$$\text{rank}\left[\begin{array}{cc} A-\lambda E & B-\lambda F \end{array}\right] = n \quad \forall \lambda \in \mathbb{C}, \tag{2.7a}$$

$$\text{rank}\left[\begin{array}{cc} E & F \end{array}\right] = n, \tag{2.7b}$$

$$\text{rank}\left[\begin{array}{c} A-\lambda E \\ C \end{array}\right] = n \quad \forall \lambda \in \mathbb{C}, \tag{2.7c}$$

$$\text{rank}\left[\begin{array}{c} E \\ C \end{array}\right] = n, \tag{2.7d}$$

while for realizations of type (2.5) similar conditions result by simply replacing (a) and (b) in (2.7) with

$$\text{rank}\left[\begin{array}{cc} A-\lambda E & B(\alpha-\lambda\beta) \end{array}\right] = n, \quad \forall \lambda \in \mathbb{C}, \tag{2.8a}$$

$$\text{rank}\left[\begin{array}{cc} E & B \end{array}\right] = n. \tag{2.8b}$$

Of particular importance in the case of (2.5) is that any two minimal realizations $G = (A-\lambda E, B(\alpha-\lambda\beta), C, D)$ and $G = (\widetilde{A}-\lambda\widetilde{E}, \widetilde{B}(\alpha-\lambda\beta), \widetilde{C}, \widetilde{D})$ are always related by an equivalence transformation as

$$\widetilde{E} = QEZ, \quad \widetilde{A} = QAZ, \quad \widetilde{B} = QB, \quad \widetilde{C} = CZ, \quad \widetilde{D} = D,$$

where Q and Z are unique invertible matrices. Moreover, for an invertible rational matrix $G(\lambda)$, it is possible to choose a realization (2.5) with D invertible, provided α

and β are such that $\frac{\alpha}{\beta}$ is neither a pole nor a zero of $G(\lambda)$. In this case we can use explicit formulas for the inverse G^{-1} in the form

$$G^{-1}(\lambda) = \left[\begin{array}{c|c} A - \lambda E - BD^{-1}C(\alpha - \lambda\beta) & BD^{-1}(\alpha - \lambda\beta) \\ \hline -D^{-1}C & D^{-1} \end{array}\right]. \tag{2.9}$$

An additional nice feature of realizations (2.5) is revealed in the appendix, where we show that an appropriate choice of α and β leads to nice formulas in case of rational matrices featuring certain symmetries.

Conversions between the representations (2.2), (2.4), and (2.5) are straightforward. Here we only show how to obtain from an nth-order realization (2.2) a realization of the form (2.4) of order equal to $\operatorname{rank} E$. We can always determine two invertible (even unitary) matrices Q and Z such that

$$G(\lambda) = \left[\begin{array}{c|c} Q(A - \lambda E)Z & QB \\ \hline CZ & D \end{array}\right] = \left[\begin{array}{cc|c} A_d - \lambda E_d & A_{dn} - \lambda E_{dn} & B_d \\ O & A_n & B_n \\ \hline C_d & C_n & D \end{array}\right], \tag{2.10}$$

where the invertible matrix $A_n \in \mathbb{R}^{\kappa\times\kappa}$ contains the so-called infinite *nondynamic* modes, and $\operatorname{rank}\left[\begin{array}{cc} E_d & E_{dn} \end{array}\right] = \operatorname{rank} E$. By using a general transformation as in (2.6) we get an equivalent realization of the type (2.4) in the form

$$G(\lambda) = \left[\begin{array}{c|c} A_d - \lambda E_d & B_d - A_{dn}A_n^{-1}B_n + \lambda E_{dn}A_n^{-1}B_n \\ \hline C_d & D - C_nA_n^{-1}B_n \end{array}\right], \tag{2.11}$$

which has order equal to $\operatorname{rank} E$. Provided (2.2) is minimal, the realization (2.11) is minimal as well.

All the above stated features of realizations (2.4) and (2.5), although not well known, follow by standard arguments from the realization theory [21, 27], and therefore we do not give detailed proofs here.

Structural elements in terms of realizations. The following result adapted from [21] and [28] will be instrumental in subsequent discussion.

THEOREM 2.1. *Let $G(\lambda)$ be an arbitrary rational matrix with a realization* (2.4) (*or* (2.5)).

Poles. *The poles of $G(\lambda)$ are among the generalized eigenvalues of the pole pencil $A - \lambda E$. If the realization* (2.4) *is minimal (or if $\frac{\alpha}{\beta}$ is not a pole of $G(\lambda)$, and* (2.5) *is minimal), then the poles of $G(\lambda)$ are exactly the generalized eigenvalues of $A - \lambda E$, and the orders of the poles are pairwise equal to the multiplicities of the generalized eigenvalues of $A - \lambda E$.*

Zeros. *The zeros of $G(\lambda)$ are among the zeros of the* system pencil *associated with* (2.4),

$$\left[\begin{array}{cc} A - \lambda E & B - \lambda F \\ C & D \end{array}\right], \tag{2.12}$$

or of the system pencil associated with (2.5),

$$\left[\begin{array}{cc} A - \lambda E & B(\alpha - \lambda\beta) \\ C & D \end{array}\right]. \tag{2.13}$$

For a careful discussion of the delicate notions of pole and zero at infinity of a rational matrix and connection with the realization theory we refer to [28].

Separated realizations. As a methodological question, throughout the paper we assume that the rational matrix G is given by a minimal descriptor realization (2.2), as this type of realization is most frequently used in the literature to represent arbitrary (possibly improper) rational matrices. The solutions M and N to the LCF $G = M^{-1}N$ will be given directly by minimal realizations of the type (2.4) or (2.5) of order equal to their respective McMillan degree. Furthermore, once a partition (2.1) is fixed, we assume that G is given by a *separated realization* with respect to (2.1), namely,

$$G(\lambda) = \left[\begin{array}{cc|c} A_b - \lambda E_b & A_{bg} - \lambda E_{bg} & B_b \\ O & A_g - \lambda E_g & B_g \\ \hline C_b & C_g & D \end{array}\right], \tag{2.14}$$

where the $n_b \times n_b$ pencil $A_b - \lambda E_b$ contains the n_b poles of $G(\lambda)$ in Γ_b and

$$\operatorname{rank} \left[\begin{array}{cc} E_b & E_{bg} \end{array}\right] = n_b; \tag{2.15}$$

that is, all infinite nondynamic modes are included in $A_g - \lambda E_g$. Starting with an arbitrary minimal realization (2.2) it is always possible to arrive to a separated realization by first determining a realization as in (2.10) and further making a spectral decomposition of the pencil $A_d - \lambda E_d$ with respect to the partition (2.1). Furthermore, if the realization to start with has real coefficients, and Γ_g is symmetric, we can always determine a separated realization with real coefficients as well.

3. Basic pole displacement result. In this section we solve the general *pole displacement problem* (PDP) formulated below.

PDP: Given a $p \times m$ rational matrix G and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$, both arbitrary, determine an invertible $p \times p$ rational matrix M with all poles in Γ_g which cancels by left multiplication all poles of G located in Γ_b, i.e., such that $N(\lambda) := M(\lambda)G(\lambda)$ has all poles in Γ_g.

The following theorem gives an answer to the PDP in terms of descriptor realizations of G and M. It is a rich extension of Theorem 3.1 and Lemma 4.1 in [24] and can be viewed also as an extension to the nonsquare case of the results in [10].

THEOREM 3.1. *Given a rational matrix $G(\lambda)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$, both arbitrary, let n_b be the number of poles of G in Γ_b. Assume that* (2.14) *is a minimal descriptor realization of G separated with respect to the given partition and satisfying the condition* (2.15). *Then the class of solutions to the PDP is given by*

$$M(\lambda) = \left[\begin{array}{c|c} A_x - \lambda E_x & B_x p(\lambda) \\ \hline C_x & D_x \end{array}\right], \tag{3.1}$$

where the realization (3.1) *is minimal and satisfies the following: $A_x - \lambda E_x$ has all eigenvalues in Γ_g; D_x is invertible; $p(\lambda) := \alpha - \lambda\beta$, where $\frac{\alpha}{\beta} \notin \Lambda(A_b - \lambda E_b)$; and*

$$\left[\begin{array}{cc} A_x - \lambda E_x & B_x p(\lambda) \\ C_x & D_x \end{array}\right] \left[\begin{array}{c} X \\ C_b \end{array}\right] = \left[\begin{array}{c} Y \\ O \end{array}\right] (A_b - \lambda E_b) \tag{3.2}$$

holds for certain injective matrices X and Y.

The minimal McMillan degree of a solution to the PDP is n_b.

Before proceeding with the proof, we make the following remark.

REMARK 3.2. *Using Theorem* 3.1, *it is easy to see that by an appropriate equivalence transformation, each solution* $M(\lambda)$ *of the PDP has a minimal realization* (3.1) *such that*

$$\left[\begin{array}{cc|c} A_{x,11}-\lambda E_{x,11} & A_{x,12}-\lambda E_{x,12} & B_{x,1}(\alpha-\beta\lambda) \\ A_{x,21}-\lambda E_{x,21} & A_{x,22}-\lambda E_{x,22} & B_{x,2}(\alpha-\beta\lambda) \\ \hline C_{x,1} & C_{x,2} & D_x \end{array}\right]\left[\begin{array}{c} I \\ O \\ C_b \end{array}\right]=\left[\begin{array}{c} I \\ O \\ O \end{array}\right](A_b-\lambda E_b), \tag{3.3}$$

where (3.3) *follows directly from* (3.2). *Then it can be rapidly checked that* $M^{-1}(\lambda)$ *has a realization of the form*

$$M^{-1}(\lambda)=\left[\begin{array}{cc|c} A_b-\lambda E_b & * & * \\ O & * & * \\ \hline C_b & * & * \end{array}\right]; \tag{3.4}$$

that is, $M^{-1}(\lambda)$ *and* $G(\lambda)$ *have a "common" pair* $(C_b, A_b-\lambda E_b)$. *This fact shows the connections of our result with the "spectral triples" discussed in* [10] *for an invertible and proper* $G(\lambda)$ *and will be instrumental in obtaining solutions to the noncanonical problems in sections* 5 *and* 6.

Proof. Before proceeding with the proof we make several preparations. Using conversion formulas as for getting from (2.10) to (2.11), we can put (2.14) in the form

$$G(\lambda)=\left[\begin{array}{cc|c} A_b-\lambda E_b & \widetilde{A}_{bg}-\lambda\widetilde{E}_{bg} & \widetilde{B}_b-\lambda\widetilde{F}_b \\ O & \widetilde{A}_g-\lambda\widetilde{E}_g & \widetilde{B}_g-\lambda\widetilde{F}_g \\ \hline C_b & \widetilde{C}_g & \widetilde{D} \end{array}\right], \tag{3.5}$$

where

$$\operatorname{rank}\left[\begin{array}{ccc} E_b & \widetilde{E}_{bg} & \widetilde{F}_b \end{array}\right]=n_b, \tag{3.6}$$

$$\Lambda(A_b-\lambda E_b)\cap\Lambda(\widetilde{A}_g-\lambda\widetilde{E}_g)=\emptyset. \tag{3.7}$$

This conversion is necessary so as to enforce (3.7) and can be skipped if $\infty\in\Gamma_g$. Using (3.5) and (3.1) we can write a realization of $N(\lambda)=M(\lambda)G(\lambda)$ as

$$N(\lambda)=\left[\begin{array}{ccc|c} A_x-\lambda E_x & B_xC_bp(\lambda) & B_x\widetilde{C}_gp(\lambda) & B_x\widetilde{D}p(\lambda) \\ O & A_b-\lambda Ethat_b & \widetilde{A}_{bg}-\lambda\widetilde{E}_{bg} & \widetilde{B}_b-\lambda\widetilde{F}_b \\ O & O & \widetilde{A}_g-\lambda\widetilde{E}_g & \widetilde{B}_g-\lambda\widetilde{F}_g \\ \hline C_x & D_xC_b & D_x\widetilde{C}_g & D_x\widetilde{D} \end{array}\right]. \tag{3.8}$$

Assume that X and Y are two matrices that satisfy the generalized Sylvester equation

$$(A_x-\lambda E_x)X-Y(A_b-\lambda E_b)+B_xC_b(\alpha-\beta\lambda)=0, \tag{3.9}$$

and let $\widetilde{X}$ and $\widetilde{Y}$ be the unique solutions that satisfy the generalized Sylvester equation

$$(A_b-\lambda E_b)\widetilde{X}-\widetilde{Y}(\widetilde{A}_g-\lambda\widetilde{E}_g)+\widetilde{A}_{bg}-\lambda\widetilde{E}_{bg}=0. \tag{3.10}$$

Note that $\widetilde{X}$ and $\widetilde{Y}$ always exist due to (3.7). Define

$$Q:=\left[\begin{array}{ccc} I & -Y & O \\ O & I & -\widetilde{Y} \\ O & O & I \end{array}\right],\quad Z:=\left[\begin{array}{ccc} I & X & O \\ O & I & \widetilde{X} \\ O & O & I \end{array}\right]. \tag{3.11}$$

By using the transformation matrices (3.11) we obtain an equivalent realization in the form

$$N(\lambda) = \left[\begin{array}{ccc|c} A_x - \lambda E_x & O & * & * \\ O & A_b - \lambda E_b & O & \widehat{B}_b - \lambda \widehat{F}_b \\ O & O & \widetilde{A}_g - \lambda \widetilde{E}_g & \widetilde{B}_g - \lambda \widetilde{F}_g \\ \hline C_x & D_x C_b + C_x X & * & D_x \widetilde{D} \end{array}\right], \tag{3.12}$$

where from the minimality of $G(\lambda)$ and from (3.6) we have

$$\begin{aligned} \operatorname{rank} \left[\begin{array}{cc} A_b - \lambda E_b & \widehat{B}_b - \lambda \widehat{F}_b \end{array}\right] &= n_b \quad \forall \lambda \in \mathbb{C}, \\ \operatorname{rank} \left[\begin{array}{cc} E_b & \widehat{F}_b \end{array}\right] &= n_b. \end{aligned} \tag{3.13}$$

We show first that if $M(\lambda)$ is given by the minimal realization (3.1) satisfying the respective conditions in the statement, then it is a solution to the PDP. Notice first that $M(\lambda)$ is invertible. Since $\Lambda(A_x - \lambda E_x) \subset \Gamma_g$ we get that all poles of $M(\lambda)$ are in Γ_g. From (3.2) it will follow that $N(\lambda) = M(\lambda)G(\lambda)$ has all its poles in Γ_g. Indeed, (3.2) shows that (3.9) is satisfied and let $\widetilde{X}$ and $\widetilde{Y}$ be the unique solutions to (3.10). We perform an equivalence transformation with Q and Z defined by (3.11) to get to (3.12). From (3.2) we also get that the entry $D_x C_b + C_x X$ in (3.12) is zero. Thus, after removing the unobservable part we get

$$N(\lambda) := \left[\begin{array}{cc|c} A_x - \lambda E_x & * & * \\ O & \widetilde{A}_g - \lambda \widetilde{E}_g & \widetilde{B}_g - \lambda \widetilde{F}_g \\ \hline C_x & * & D_x \widetilde{D} \end{array}\right], \tag{3.14}$$

which clearly has *all* its poles in Γ_g. Thus $M(\lambda)$ has canceled by left multiplication all poles of $G(\lambda)$ located in Γ_b and thus it is a solution to the PDP.

Conversely, now let $M(\lambda)$ be a solution to the PDP and let (3.1) be a minimal realization of it, with D_x invertible. From minimality it follows that $\Lambda(A_x - \lambda E_x) \subset \Gamma_g$. Hence $\Lambda(A_x - \lambda E_x) \cap \Lambda(A_b - \lambda E_b) = \emptyset$ and thus there exist unique matrices X and Y to satisfy the generalized Sylvester equation (3.9). For similar reasons, the equation (3.10) has unique solutions $\widetilde{X}$ and $\widetilde{Y}$. Define Q and Z as in (3.11) and perform an equivalence transformation to get (3.12). Since $M(\lambda)$ is a solution to the PDP it follows that $N(\lambda)$ has no poles in Γ_b. However, (3.12) shows that this is possible only if

$$(D_x C_b + C_x X)(A_b - \lambda E_b)^{-1}(\widehat{B}_b - \lambda \widehat{F}_b) \tag{3.15}$$

has no poles in Γ_b. Since (3.13) holds, it follows by standard minimality arguments that (3.15) has no poles in Γ_b only if $D_x C_b + C_x X = 0$. Combining this with (3.9) we obtain

$$\left[\begin{array}{cc} A_x - \lambda E_x & B_x(\alpha - \beta\lambda) \\ C_x & D_x \end{array}\right] \left[\begin{array}{c} X \\ C_b \end{array}\right] = \left[\begin{array}{c} Y \\ O \end{array}\right] (A_b - \lambda E_b). \tag{3.16}$$

It only remains to show that X and Y are injective. Since $M(\lambda)$ is invertible, the leftmost pencil in (3.16) is regular. Thus, there exists $\lambda = \lambda_0$ for which the rightmost and leftmost pencils in (3.16) are invertible, from which it follows that

$$\operatorname{rank} \left[\begin{array}{c} X \\ C_b \end{array}\right] = \operatorname{rank} \left[\begin{array}{c} Y \\ O \end{array}\right]. \tag{3.17}$$

We show that X is injective and the injectiveness of Y follows then from (3.17). Let $\mathcal{V} = \mathrm{Ker}X$. Since D_x is invertible, we get from (3.16) that

$$C_b\mathcal{V} = 0. \tag{3.18}$$

From (3.16) we further get

$$\begin{bmatrix} Y \\ O \end{bmatrix} (A_b - \lambda E_b)\mathcal{V} = 0,$$

from which

$$A_b\mathcal{V} + E_b\mathcal{V} \subset \mathrm{Ker}Y. \tag{3.19}$$

But (3.17) and (3.18) show that $\dim \mathcal{V} = \dim \mathrm{Ker}\left[\begin{smallmatrix} X \\ C_b \end{smallmatrix}\right] = \dim \mathrm{Ker}\left[\begin{smallmatrix} Y \\ O \end{smallmatrix}\right] = \dim \mathrm{Ker}Y$. Thus

$$\dim(A_b\mathcal{V} + E_b\mathcal{V}) \leq \dim \mathrm{Ker}Y = \dim \mathcal{V}, \tag{3.20}$$

where only equality can take place, since, in general, for a regular pencil $A_b - \lambda E_b$ and an arbitrary space $\mathcal{V}$ we have $\dim(A_b\mathcal{V} + E_b\mathcal{V}) \geq \dim \mathcal{V}$. It follows that

$$\dim(A_b\mathcal{V} + E_b\mathcal{V}) = \dim \mathcal{V} \tag{3.21}$$

and thus $\mathcal{V}$ is a deflating subspace (see [23]) of the pencil $A_b - \lambda E_b$ contained in $\mathrm{Ker}\, C_b$. However, this is possible only if $\mathcal{V} = 0$ [22] because (3.5) is a minimal realization of $G(\lambda)$ and thus

$$\mathrm{rank}\begin{bmatrix} A_b - \lambda E_b \\ C_b \end{bmatrix} = n_b \quad \forall \lambda \in \mathbb{C}, \quad \mathrm{rank}\begin{bmatrix} E_b \\ C_b \end{bmatrix} = n_b.$$

It follows that X and Y are both injective, and thus any solution to the PDP satisfies the requirements in the statement.

Finally, from the injectiveness of X it follows that $\delta(M) \geq n_b$. ∎

4. Minimal degree coprime factorization. For a given rational matrix $G(\lambda)$ and a domain Γ_g, both arbitrary, we characterize now the class of LCFs over Γ_g having minimal degree which we show to be n_b. Recall that n_b is the number of poles of $G(\lambda)$ in Γ_b. For our proofs, we need the following result on the solution in a particular form to the generalized eigenvalue assignment problem.

LEMMA 4.1. *Let $A - \lambda E$ be a regular pencil, with A, $E \in \mathbb{F}^{n\times n}$, $B \in \mathbb{F}^{n\times m}$; let $\Gamma \subset \overline{\mathbb{C}}$ be a set of n elements (not necessarily distinct and assumed to be symmetric if $\mathbb{F} = \mathbb{R}$); and let $\alpha, \beta \in \mathbb{F}$, not both zero, such that $\frac{\alpha}{\beta} \notin \Lambda(A - \lambda E)$ and $\frac{\alpha}{\beta} \notin \Gamma$. Assume that*

$$\mathrm{rank}\begin{bmatrix} A - \lambda E & B \end{bmatrix} = n \quad \forall \lambda \in \mathbb{C}, \tag{4.1a}$$

$$\mathrm{rank}\begin{bmatrix} E & B \end{bmatrix} = n. \tag{4.1b}$$

Then there exists a matrix $F \in \mathbb{F}^{m\times n}$ such that

$$\Lambda(A - \lambda E + BF(\alpha - \beta\lambda)) = \Gamma. \tag{4.2}$$

Proof. To reduce (4.2) to a standard eigenvalue assignment problem we use the conformal mapping $\lambda = (\alpha z + \beta)/(\beta z - \alpha)$. Under this mapping Γ changes to Γ_z,

which will contain only finite points. Define $A_z - zE_z := \alpha A + \beta E - z(\beta A - \alpha E)$ and $B_z := (\alpha^2 + \beta^2)B$. With the transformed data we have reduced (4.2) to

$$\Lambda(A_z + B_z F - zE_z) = \Gamma_z, \tag{4.3}$$

with E_z invertible. From assumption (4.1a), for $z \neq \frac{\alpha}{\beta}$, and (4.1b), for $z = \frac{\alpha}{\beta}$, we get

$$\operatorname{rank}[\, A_z - zE_z \;\; B_z \,] = n, \quad \forall z \in \mathbb{C}.$$

Thus (4.3) is a standard eigenvalue assignment problem for the controllable pair $(E_z^{-1}A_z, E_z^{-1}B_z)$ and the set Γ_z, and has always a solution F which is the solution of the original problem (4.2) as well. If $\mathbb{F} = \mathbb{R}$, and Γ is symmetric, then Γ_z will be symmetric as well, and F can be chosen with elements in $\mathbb{R}$. ∎

THEOREM 4.2. *Given a rational matrix $G(\lambda)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$, both arbitrary, let n_b be the number of poles of G in Γ_b. Assume that* (2.14) *is a minimal descriptor realization of G separated with respect to the given partition and satisfying condition* (2.15). *Then we have the following:*

1. *The minimal degree of a LCF of G over Γ_g is n_b.*

2. *The class of solutions to the minimal degree LCF problem $G(\lambda) = M^{-1}(\lambda)N(\lambda)$ is given by*

$$\begin{aligned} &N(\lambda) \\ &= \left[\begin{array}{cc|c} A_b - \lambda E_b + KC_b p(\lambda) & A_{bg} - \lambda E_{bg} + KC_g p(\lambda) & B_b + KDp(\lambda) \\ O & A_g - \lambda E_g & B_g \\ \hline WC_b & WC_g & WD \end{array}\right], \end{aligned} \tag{4.4}$$

$$M(\lambda) = \left[\begin{array}{c|c} A_b - \lambda E_b + KC_b p(\lambda) & Kp(\lambda) \\ \hline WC_b & W \end{array}\right], \tag{4.5}$$

where W is an arbitrary invertible matrix, K is any matrix that solves the generalized eigenvalue assignment problem $\Lambda(A_b - \lambda E_b + KC_b p(\lambda)) \subset \Gamma_g$, $p(\lambda) := \alpha - \lambda\beta$, and α and β are chosen to satisfy the requirements of Lemma 4.1.

If G has real coefficients and Γ_g is a symmetric set then the class of solutions with real coefficients to the minimal degree LCF problem is also given by (4.4) *and* (4.5), *where now all the intervening elements can be chosen real.*

Proof. We show first that $N(\lambda)$ and $M(\lambda)$ of the form (4.4)–(4.5) solve the minimal LCF problem with degree n_b. To show that $G(\lambda) = M^{-1}(\lambda)N(\lambda)$ is a matter of straightforward computations involving realizations and equivalence transformations. Further, we see from (4.5) that $\delta(M(\lambda)) \leq n_b$. But we have also from Theorem 3.1 that $\delta(M(\lambda)) \geq n_b$ since $M(\lambda)$ solves in particular the corresponding PDP formulated for $G(\lambda)$. Thus $\delta(M(\lambda)) = n_b$ which proves part 1 of the theorem. We show further that $M(\lambda)$ and $N(\lambda)$ are left coprime. As both $N(\lambda)$ and $M(\lambda)$ have poles only in Γ_g, it is enough to show that the compound rational matrix $[\, N(\lambda) \;\; M(\lambda) \,]$ has no zeros outside Γ_g. (See [21] and [29] for equivalent characterizations of left coprimeness.) Indeed, using the descriptor realization of $G = (A - \lambda E, B, C, D)$ separated as in (2.14), a realization of $[\, N(\lambda) \;\; M(\lambda) \,]$ is

$$[\, N(\lambda) \;\; M(\lambda) \,] = \left[\begin{array}{c|cc} A - \lambda E + \overline{K}Cp(\lambda) & B + \overline{K}Dp(\lambda) & \overline{K}p(\lambda) \\ \hline WC & WD & W \end{array}\right], \tag{4.6}$$

where $\overline{K} = \left[\begin{smallmatrix} K \\ O \end{smallmatrix}\right]$. Incidentally, it is easy to see that (4.6) is a minimal realization. From Theorem 2.1 we have that the zeros of $[\, N(\lambda)\ M(\lambda)\,]$ are among the zeros (including infinity) of the system pencil associated with the above realization and given by

$$\left[\begin{array}{ccc} A - \lambda E + \overline{K}Cp(\lambda) & B + \overline{K}Dp(\lambda) & \overline{K}p(\lambda) \\ WC & WD & W \end{array}\right], \tag{4.7}$$

which is strictly equivalent to (see [8] for the definition of strict equivalence for matrix pencils)

$$\left[\begin{array}{ccc} A - \lambda E & B & \overline{K}p(\lambda) \\ O & O & W \end{array}\right].$$

Thus the zeros of $[\, N(\lambda)\ M(\lambda)\,]$ are among those of $[\, A - \lambda E\ B\,]$. However, this last pencil has no zeros since the representation of $G(\lambda)$ is minimal, and thus $\operatorname{rank}[\, A - \lambda E\ B\,] = n\ \forall \lambda \in \mathbb{C}$, λ finite, and $\operatorname{rank}[\, E\ B\,] = n$. We conclude that $[\, N(\lambda)\ M(\lambda)\,]$ has no zeros as well and therefore $M(\lambda)$ and $N(\lambda)$ result in left coprime over Γ_g. Actually, $M(\lambda)$ and $N(\lambda)$ result in left coprime (over the whole $\overline{\mathbb{C}}$).

Conversely, we show now that if $M(\lambda)$ and $N(\lambda)$ solve the LCF over Γ_g with minimal degree n_b then they are of the form (4.4)–(4.5). Since $M(\lambda)$ and $N(\lambda)$ have all poles in Γ_g, it follows from Theorem 3.1 that there exists a minimal realization (3.1) of $M(\lambda)$ which satisfies (3.2). Since the McMillan degree of $M(\lambda)$ is precisely n_b, the injective matrices X and Y in (3.2) are actually square and thus nonsingular. Therefore, using Remark 3.2, we can simply take $X = Y = -I_{n_b}$. Then, the expression for $M(\lambda)$ follows immediately from (3.2), where $B_x := K$ solves the eigenvalue assignment problem $\Lambda(A_b - \lambda E_b + KC_b(\alpha - \lambda\beta)) \subset \Gamma_g$. Lemma 4.1 shows that this last problem always has a solution since from the minimality of the realization (2.14) we get that the pair $(A_b^* - \lambda E_b^*, C_b^*)$ satisfies (4.1a) written for actual data, and α and β can always be chosen a priori to satisfy the respective requirements. The expression (4.4) results immediately after a simple equivalence transformation and removing the unobservable part from the descriptor representation of the product $N(\lambda) = M(\lambda)G(\lambda)$.

For the case of real coefficients, we can start with a separated realization for G having real elements. Then we choose α and β real, and since Γ_g is symmetric it follows from Lemma 4.1 that the feedback matrix K can be chosen with real elements as well. □

Notice from the above theorem that the class of all solutions depends essentially only on the pair $(C_b, A_b - \lambda E_b)$ that is unique (up to an equivalence transformation) for a given $G(\lambda)$.

5. LCF with J all-pass denominator with respect to the imaginary axis. In this section we solve the minimal degree LCF with the additional requirement on the denominator to have a certain symmetry, namely we consider here the case in which the denominator is J all-pass with respect to the imaginary axis. To reflect this symmetry accordingly, we take throughout this section the disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by

$$\Gamma_b := \mathbb{C}^+ \text{ (or } \Gamma_b := \mathbb{C}^-) \qquad \Gamma_g := \overline{\mathbb{C}} \setminus \Gamma_b. \tag{5.1}$$

However, due to the additional requirement on the denominator to be J all-pass it is not always possible to solve the LCF over Γ_g with minimal degree n_b. When this is

possible, we call the factorization *canonical*; otherwise we call it *noncanonical*. Notice that for both of the choices in (5.1), Γ_b is an open set while Γ_g is a closed one. This will be instrumental for the solution in the noncanonical case.

The following result that will prove useful later gives a characterization of *proper* J all-pass rational matrices in terms of minimal realizations. It is a particular case (with $\alpha = 1, \beta = 0$) of the general theorem Theorem A.1 given in the appendix.

COROLLARY 5.1. *Let $M(s)$ be a proper square invertible rational matrix, having a minimal realization*

$$M(s) := \left[\begin{array}{c|c} A - sE & B \\ \hline C & D \end{array}\right].$$

Then M is J all-pass with respect to the imaginary axis if and only if $D^*JD = J$ and there exists an invertible Hermitian matrix X such that

$$\begin{aligned} A^*XE + E^*XA - C^*JC &= 0, \\ C - DJB^*XE &= 0. \end{aligned}$$

5.1. The canonical case. The following theorem gives a complete solution to the LCF problem with J all-pass denominator of McMillan degree n_b.

THEOREM 5.2. *Given an arbitrary rational matrix $G(s)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by* (5.1)*, let n_b be the number of poles of G in Γ_b. Assume* (2.14) *is a minimal descriptor realization of G separated with respect to the given partition and satisfying condition* (2.15)*. Then the LCF with J all-pass denominator with respect to the imaginary axis has a solution $G(s) = M^{-1}(s)N(s)$ of minimal degree n_b if and only if the equation*

$$A_b^*XE_b + E_b^*XA_b - C_b^*JC_b = 0 \tag{5.2}$$

has an invertible Hermitian solution X. In this case, the class of all solutions is given by

$$N(s) = \left[\begin{array}{cc|c} A_b + KC_b - sE_b & A_{bg} + KC_g - sE_{bg} & B_b + KD \\ O & A_g - sE_g & B_g \\ \hline WC_b & WC_g & WD \end{array}\right], \tag{5.3}$$

$$M(s) = \left[\begin{array}{c|c} A_b + KC_b - sE_b & K \\ \hline WC_b & W \end{array}\right], \tag{5.4}$$

where

$$K = -X^{-1}E_b^{-*}C_b^*J, \tag{5.5}$$

and W is any J unitary matrix satisfying

$$W^*JW = J. \tag{5.6}$$

If G has real coefficients then the class of solutions with real coefficients is also given by (5.3) *and* (5.4)*, where now all the intervening coefficients can be chosen real.*

Proof. Notice first that E_b in a minimal realization (2.14) is invertible due to the choice of Γ_b in (5.1).

We show first that any solution $G = M^{-1}N$ to the LCF with J all-pass denominator of McMillan degree n_b is given by (5.3) and (5.4). In particular, M and N solve the minimal degree LCF problem (without any requirement on M) and must have minimal realizations of the form (4.4) and (4.5), respectively, where we can take $\alpha = 1$ and $\beta = 0$. Thus N and M are of the form (5.3) and (5.4), respectively. Since the realization (5.4) is minimal, and $M(s)$ is J all-pass, it follows from Corollary 5.1 that (5.2) has an invertible Hermitian solution and (5.5) and (5.6) are satisfied. Moreover, it follows that K given by (5.5) is such that $\Lambda(A_b + KC_b - sE_b) \subset \Gamma_g$.

Conversely, we have to show that N and M given by (5.3) and (5.4) are a solution to the LCF with J all-pass denominator of McMillan degree n_b. But this follows immediately from Theorem 4.2 and Corollary 5.1.

For the case of real coefficients, we can start with a separated realization for G having real elements, and it will follow from (5.2) that X is real and symmetric. □

If in the statement of the above theorem we add the condition $X > 0$ or $X < 0$ we obtain the solution to the LCF with J lossless or J expansive denominator, respectively (see [16]). Notice that for the chosen partition (5.1) equation (5.2) always has a unique solution, and thus the above theorem is an effective tool for checking the existence of, and computing the solutions to, the LCF with J all-pass denominator or, as a particular case, with J lossless denominator. We do not elaborate further in this direction.

For $J = I$, the above theorem provides the solution of an important particular case: LCF with all-pass denominator $M(s)$, (i.e., $M^*(-\overline{s})M(s) = I$). In this case, (5.2) has always a sign definite (positive or negative) solution. If we take $\Gamma_b = \mathbb{C}^+$, then we obtain the well known results for the LCF with inner denominator.

5.2. The noncanonical case. We study now LCFs with J all-pass denominator in the noncanonical case, i.e., when there is no solution with a J all-pass denominator of minimal McMillan degree n_b. This case is considerably more intricate than the canonical case. The idea is to introduce additional poles and zeros in $M(s)$ such that it could simultaneously be J all-pass and solve the LCF problem for $G(s)$. At the same time, we want to keep the McMillan degree of M as small as possible. It turns out that the additional poles/zeros can be taken only on the imaginary axis (including infinity) since the pole-zero symmetry featured by a J all-pass factor implies with necessity that all additional poles will be reflected into symmetric additional zeros that will be also zeros of the compound matrix $[N(s)\ M(s)]$.

Before stating our main result we construct a particular separated realization of G which facilitates the subsequent developments. Let $G(s)$ be an arbitrary rational matrix given by a minimal realization (2.14) separated with respect to $\Gamma_g \cup \Gamma_b$ and satisfying (2.15), and let n_b be the number of poles of G in Γ_b. Then the generalized Lyapunov equation

$$A_b^* X E_b + E_b^* X A_b - C_b^* J C_b = 0 \tag{5.7}$$

has a unique Hermitian solution X, and let $r := \operatorname{rank}(X)$. Let

$$U^* X U = \begin{bmatrix} \Sigma_r & O \\ O & O \end{bmatrix} \tag{5.8}$$

be a spectral decomposition of X where Σ_r is diagonal and nonsingular and U is unitary. Further, let

$$U^* E_b Q^* = \begin{bmatrix} E_{11} & O \\ E_{21} & E_{22} \end{bmatrix} \tag{5.9}$$

be an RQ decomposition of U^*E_b, where Q is unitary; E_{11} and E_{22} are lower triangular, square, and invertible; and the partition in (5.9) corresponds to the partition in (5.8). With (5.8) and (5.9) it is easy to see that

$$G(s) = \left[\begin{array}{cc|c} U^*(A_b-\lambda E_b)Q^* & U^*(A_{bg}-\lambda E_{bg}) & U^*B_b \\ O & A_g-\lambda E_g & B_g \\ \hline C_bQ^* & C_g & D \end{array}\right] \tag{5.10}$$

is another realization of G separated with respect to $\Gamma_g \cup \Gamma_b$ which we call *balanced with respect to the Lyapunov equation* (5.7). Thus we may assume from the beginning that for the separated realization (2.14) we have E_b lower triangular and the corresponding Lyapunov equation (5.7) has a diagonal solution. We are now ready for our main result.

THEOREM 5.3. *Given an arbitrary rational matrix $G(s)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by* (5.1)*, let n_b be the number of poles of G in Γ_b. Assume that* (2.14) *is a minimal descriptor realization of G, separated with respect to the given partition and satisfying condition* (2.15)*. Let $r := \mathrm{rank}(X)$, where X is the unique Hermitian solution to the Lyapunov equation*

$$A_b^*XE_b + E_b^*XA_b - C_b^*JC_b = 0. \tag{5.11}$$

Then the minimal degree of the LCF with J all-pass denominator is $2n_b - r$.

Proof. Without restricting the generality, we may assume from the beginning that the realization (2.14) is balanced with respect to the Lyapunov equation (5.11). Further, as E_b is invertible we could, as a first simplifying step in the whole proof, reduce (5.11) to a standard Lyapunov equation with $E_b = I$. However, we prefer not to invert E_b as far as possible as this will bring benefits in terms of the reliability of the associated numerical algorithms.

The proof is quite lengthy and we divide it in several steps: we show first that any solution $G = M^{-1}N$ to the LCF with J all-pass denominator satisfies

$$\delta(M) \geq 2n_b - r \tag{5.12}$$

and further prove that M^{-1} has exactly n_b poles in Γ_b (which are the poles of G in Γ_b) and the rest (additional) $\delta(M) - n_b$ poles are with necessity on $\overline{\mathbb{C}}^0$. Finally, we construct a solution of minimal degree $2n_b - r$ with the additional $n_b - r$ poles placed arbitrary on $\overline{\mathbb{C}}^0$.

Proof of $\delta(M) \geq 2n_b - r$. Let $G(s) = M^{-1}(s)N(s)$ be a solution to the LCF with J all-pass denominator. As M cancels in the product $N = MG$ all poles of G in Γ_b and M^{-1} is J all-pass, we get with Remark 3.2 and Theorem A.1 in the appendix that there exists a minimal realization of M^{-1} of the form

$$M^{-1}(s) = \left[\begin{array}{c|c} A_M - sE_M & B_Mp(s) \\ \hline C_M & D_M \end{array}\right] = \left[\begin{array}{cc|c} A_b - sE_b & A_{bx} - sE_{bx} & B_{x1}p(s) \\ O & A_x - sE_x & B_{x2}p(s) \\ \hline C_b & C_x & D_M \end{array}\right], \tag{5.13}$$

where $p(s) := \alpha - s\beta$, and there exists a Hermitian invertible matrix X_M such that

$$A_M^*X_ME_M + E_M^*X_MA_M - C_M^*JC_M = 0. \tag{5.14}$$

According to the partition of the right–hand side of (5.13), X can be written in the partitioned form

$$X_M = \left[\begin{array}{cc} X & X_{12} \\ X_{12}^* & X_{22} \end{array}\right], \tag{5.15}$$

where it follows that X is the unique solution to (5.11). Since X_M is invertible and the rank of X is r, it follows from (5.15) that $\operatorname{rank}(X_M) \geq 2n_b - r$ and thus (5.12) holds.

Location of the poles of M^{-1}. Let $G = M^{-1}N$ be a solution to the LCF with J all-pass denominator. From (5.13) we see that the union of poles of $M^{-1}(s)$ contains $\Lambda(A_b - sE_b) \subset \mathbb{C}^+$ which are also the poles of G in Γ_b. From the pole-zero symmetry of a J all-pass rational matrix it follows that the poles of $M(s)$ are the conjugated of the poles of $M^{-1}(s)$. Since M has all poles in Γ_g we infer that the poles of M^{-1} are in $\overline{\Gamma}_b := \Gamma_b \cup \overline{\mathbb{C}}^0$, from which we have

$$\Lambda(A_x - sE_x) \subset \overline{\Gamma}_b. \tag{5.16}$$

We show now that

$$\Lambda(A_x - sE_x) \subset \Gamma_g, \tag{5.17}$$

from where we shall conclude with (5.16) that $\Lambda(A_x - sE_x) \subset \overline{\mathbb{C}}^0$ and thus M^{-1} has exactly n_b poles in Γ_b and the additional $\delta(M) - n_b$ poles are on $\overline{\mathbb{C}}^0$. We prove in fact that the coprimeness of N and M over Γ_g implies (5.17). To this end we compute realizations for M and N. Using (5.13) we write a realization of M in the form

$$\begin{aligned} M(s) &= \left[\begin{array}{c|c} A_M - sE_M - B_M W C_M(\alpha - s\beta) & -B_M W(\alpha - s\beta) \\ \hline WC_M & W \end{array}\right] \\ &= \left[\begin{array}{cc|c} A_b - sE_b - B_{x1}WC_b p(s) & A_{bx} - sE_{bx} - B_{x1}WC_x p(s) & -B_{x1}Wp(s) \\ -B_{x2}WC_b p(s) & A_x - sE_x - B_{x2}WC_x p(s) & -B_{x2}Wp(s) \\ \hline WC_b & WC_x & W \end{array}\right], \end{aligned} \tag{5.18}$$

where $W := D_M^{-1}$. With (5.18) and (2.14) we get successively a realization of

$$\begin{aligned} N(s) &= M(s)G(s) \\ &= \left[\begin{array}{ccc|c} A_b - sE_b - B_{x1}WC_b p(s) & A_{bx} - sE_{bx} - B_{x1}WC_x p(s) & -B_{x1}WC_b p(s) & -B_{x1}WC_g p(s) & -B_{x1}WDp(s) \\ -B_{x2}WC_b p(s) & A_x - sE_x - B_{x2}WC_x p(s) & -B_{x2}WC_b p(s) & -B_{x2}WC_g p(s) & -B_{x2}WDp(s) \\ O & O & A_b - sE_b & A_{bg} - sE_{bg} & B_b \\ O & O & O & A_g - sE_g & B_g \\ \hline WC_b & WC_x & WC_b & WC_g & WD \end{array}\right] \\ &= \left[\begin{array}{cc|ccc} A_b - sE_b - B_{x1}WC_b p(s) & A_{bx} - sE_{bx} - B_{x1}WC_x p(s) & A_{bg} - B_{x1}WC_g p(s) - sE_{bg} & B_b - B_{x1}WDp(s) \\ -B_{x2}WC_b p(s) & A_x - sE_x - B_{x2}C_x p(s) & -B_{x2}WC_g p(s) & -B_{x2}WDp(s) \\ O & O & A_g - sE_g & B_g \\ \hline WC_b & WC_x & WC_g & WD \end{array}\right], \end{aligned} \tag{5.19}$$

where we have removed the unobservable part with the help of a state-space equivalence transformation. From (5.19) we see that the poles of $N(s)$ are among $\Lambda(A_M - sE_M - B_M W C_M(\alpha - s\beta)) \cup \Lambda(A_g - sE_g)$ and thus they are indeed included in Γ_g. We use now (5.18) and (5.19) to write the system pencil associated with the compound matrix $[N(s)\ M(s)]$ and we get after some strict equivalence operations that the zeros of $[N(s)\ M(s)]$ are among the zeros of the pencil

$$\left[\begin{array}{ccccc} A_b - sE_b & A_{bg} - sE_{bg} & B_b & A_{bx} - sE_{bx} & -B_{x1}Wp(s) \\ O & A_g - sE_g & B_g & O & O \\ O & O & O & A_x - sE_x & -B_{x2}Wp(s) \\ O & O & O & O & W \end{array}\right]. \tag{5.20}$$

The realization (2.14) of G is minimal and thus controllable, from which it follows that the only zeros of $[N(s)\ M(s)]$ are given by $\Lambda(A_x - sE_x)$ which should be included in Γ_g since N and M are coprime over Γ_g. Thus we proved that the coprimeness of N and M over Γ_g implies that (5.17) holds.

Construction of a minimal solution. We show now that the LCF with J all-pass denominator has a solution $G = M^{-1}N$ such that $\delta(M) \leq 2n_b - r$, from which it will follow with (5.12) that the minimal degree $2n_b - r$ can be achieved. To this end, we shall construct $M(s)$, define $N(s) = M(s)G(s)$, and prove that they both satisfy the required properties. Of course, M should simultaneously be J all-pass, and M^{-1} should have the form (5.13), with the additional poles given by $\Lambda(A_x - sE_x) \subset \overline{\mathbb{C}}^0$.

For the sake of clarity we assume first that the additional poles/zeros $\Lambda(A_x - sE_x)$ are placed in finite locations on $\mathbb{C}^0$. The case with poles at infinity follows analogously, although the formulas become more intricate.

Placing additional poles/zeros in finite locations on $\mathbb{C}^0$. In this case we can take for M^{-1} a realization (5.13) with $\alpha = 1$, $\beta = 0$, i.e.,

$$M^{-1}(s) = \left[\begin{array}{c|c} A_M - sE_M & B_M \\ \hline C_M & D_M \end{array}\right] = \left[\begin{array}{cc|c} A_b - sE_b & A_{bx} - sE_{bx} & B_{x1} \\ O & A_x - sE_x & B_{x2} \\ \hline C_b & C_x & D_M \end{array}\right]. \tag{5.21}$$

The key idea of the construction is to embed the Lyapunov equation (5.11) into a larger Lyapunov equation (5.14) with an invertible solution X_M as in (5.15) and where the matrices A_x, E_x, A_{bx}, E_{bx}, B_{x1}, B_{x2}, C_x have to be determined. We can simply take $E_{bx} = 0$, $\quad E_x = I_{n_b - r}$ in case of placing additional poles/zeros at finite locations. We choose further $X_{12} = \left[\begin{smallmatrix} O \\ I_{n_b - r} \end{smallmatrix}\right]$, $X_{22} = O$ and get

$$\begin{aligned} X_M &= \left[\begin{array}{ccc} \Sigma_r & O & O \\ O & O & I_{n_b - r} \\ O & I_{n_b - r} & O \end{array}\right], \quad E_M = \left[\begin{array}{ccc} E_{11} & O & O \\ E_{21} & E_{22} & O \\ O & O & I_{n_b - r} \end{array}\right], \\ A_M &= \left[\begin{array}{ccc} A_{11} & A_{12} & A_{x1} \\ A_{21} & A_{22} & A_{x2} \\ O & O & A_x \end{array}\right], \quad C_M = \left[\begin{array}{ccc} C_1 & C_2 & C_x \end{array}\right], \end{aligned} \tag{5.22}$$

where we have taken into account that the realization (2.14) is balanced with respect to (5.11) and we have partitioned

$$A_b = \left[\begin{array}{cc} A_{11} & A_{12} \\ A_{21} & A_{22} \end{array}\right], \quad A_{bx} = \left[\begin{array}{c} A_{x1} \\ A_{x2} \end{array}\right], \quad C_b = \left[\begin{array}{cc} C_1 & C_2 \end{array}\right]$$

conformably with (5.8). The matrices A_{x1}, A_{x2}, A_x, C_x remain to be determined as to satisfy (5.14). We use (5.22) to write (5.14) componentwise as

$$A_{11}^*\Sigma_r E_{11} + E_{11}^*\Sigma_r A_{11} - C_1^* J C_1 = 0, \tag{5.23a}$$

$$E_{11}^*\Sigma_r A_{12} - C_1^* J C_2 = 0, \tag{5.23b}$$

$$C_2^* J C_2 = 0, \tag{5.23c}$$

$$A_{21}^* + E_{11}^*\Sigma_r A_{x1} + E_{21}^* A_x - C_1^* J C_x = 0, \tag{5.23d}$$

$$A_{22}^* + E_{22}^* A_x - C_2^* J C_x = 0, \tag{5.23e}$$

$$A_{x2}^* + A_{x2} - C_x^* J C_x = 0, \tag{5.23f}$$

where the rest of equations are transpose conjugated versions of the ones above. Equations (5.23a), (5.23b) and (5.23c) are automatically fulfilled due to (5.11). Before showing how the remaining equations can be satisfied, we prove that the pair $(C_2, A_{22} - sE_{22})$ is observable. Indeed, since the pair $(C_b, A_b - sE_b)$ is observable, the standard PHB observability tests shows that

$$\operatorname{rank}\begin{bmatrix} A_b - sE_b \\ C_b \end{bmatrix} = \operatorname{rank}\begin{bmatrix} A_{11} - sE_{11} & \Sigma_r^{-1}E_{11}^{-*}C_1^* J C_2 \\ A_{21} - sE_{22} & A_{22} - sE_{22} \\ C_1 & C_2 \end{bmatrix} = n_b \ \forall s \in \mathbb{C} \tag{5.24}$$

where we have replaced $A_{12} = \Sigma_r^{-1}E_{11}^{-*}C_1^* J C_2$ from (5.23b). From (5.24) we get

$$\operatorname{rank}\begin{bmatrix} A_{22} - sE_{22} \\ C_2 \end{bmatrix} = n_b - r, \qquad \forall s \in \mathbb{C}.$$

Thus $(C_2, A_{22} - sE_{22})$ is observable. It follows from (5.23e) that we can take the matrix C_x such that the poles of $A_x = E_{22}^{-*}(-A_{22}^* + C_2^* J C_x)$ are on the imaginary axis by simply solving an eigenvalue assignment problem for the controllable pair

$$(-E_{22}^{-*}A_{22}^*, E_{22}^{-*}C_2^* J). \tag{5.25}$$

Alternatively, we may compute C_x as to solve a generalized eigenvalue assignment problem for the controllable pair $(-A_{22}^* + sE_{22}^*, -C_2^* J)$ with the benefit of not inverting E_{22}^*. Finally, we choose A_{x1} as the unique solution of (5.23d) and A_{x2} as any solution to (5.23f). With all these choices it results that (5.14) is satisfied.

We take D_M to be any J unitary matrix and define

$$B_M = \begin{bmatrix} B_{x1} \\ B_{x2} \end{bmatrix} := E_M^{-*} X_M^{-1} C_M^* D_M^* J. \tag{5.26}$$

We get from Corollary 5.1 that M^{-1} given in (5.21) is J all-pass. It follows that M has all its poles in Γ_g, is J all-pass, and has McMillan degree less than or equal to $2n_b - r$, and a realization is given by

$$\begin{aligned} M(s) &= \left[\begin{array}{c|c} A_M - sE_M - B_M W C_M & -B_M W \\ \hline W C_M & W \end{array}\right] \\ &= \left[\begin{array}{cc|c} A_b - sE_b - B_{x1} W C_b p(s) & A_{bx} - B_{x1} W C_x p & -B_{x1} W \\ -B_{x2} W C_b & A_x - sI - B_{x2} W C_x & -B_{x2} W \\ \hline W C_b & W C_x & W \end{array}\right], \end{aligned} \tag{5.27}$$

where $W = D_M^{-1}$. We define $N(s) := M(s)G(s)$ and get

$$N(s) = \left[\begin{array}{ccc|c} A_b - sE_b - B_{x1}WC_b & A_{bx} - B_{x1}WC_x & A_{bg} - B_{x1}WC_g - sE_{bg} & B_b - B_{x1}WD \\ -B_{x2}WC_b & A_x - sI - B_{x2}C_x & -B_{x2}WC_g & -B_{x2}WD \\ O & O & A_g - sE_g & B_g \\ \hline WC_b & WC_x & WC_g & WD \end{array}\right]. \tag{5.28}$$

We can check successively that N has all poles in Γ_g, and that N and M are coprime over Γ_g. The details are skipped since the argument is identical as in the first part of the proof for showing that the additional poles of M^{-1} should be placed on $\overline{\mathbb{C}}^0$. Thus N and M define a solution to the LCF with J all-pass denominator, having degree less than or equal to $2n_b - r$. This together with (5.12) shows that the minimal degree $2n_b - r$ is attained and concludes the proof.

Placing additional poles/zeros arbitrary on $\overline{\mathbb{C}^0}$. We show that this case can be reduced to the case of finite poles/zeros. Indeed, we chose a realization for $M(s)$ of the form (5.13), where we take $\alpha \in \mathbb{R}$ and $\beta \in \mathbb{C}^0$ such that $\frac{\alpha}{\beta}$ is neither an eigenvalue of $A_b - sE_b$ nor a desired location of additional poles/zeros. A characterization of J all-pass rational matrices with a realization centered at $\frac{\alpha}{\beta}$ is given in Theorem A.1 in the appendix. Thus we have again to embed a Lyapunov equation (5.11) into a larger Lyapunov equation (5.14) but where now E_M will be singular if we would like to place additional poles/zeros at infinity. To this end we transform the Lyapunov equation (5.14) into the equivalent Lyapunov equation

$$\widehat{A}_M^* X_M \widehat{E}_M + \widehat{E}_M^* X_M \widehat{A}_M - \widehat{C}_M^* J \widehat{C}_M = 0, \tag{5.29}$$

where the coefficients to be determined are

$$\widehat{A}_M := \alpha A_M + \beta E_M, \quad \widehat{E}_M := \alpha E_M - \beta A_M, \quad \widehat{C}_M = \sqrt{\alpha^2 + \beta^2} C_M, \tag{5.30}$$

with $\widehat{E}_M$ invertible. Thus we apply exactly the same procedure as for finite poles/zeros but now we determine the coefficients of the equation (5.29) instead of (5.14). Finally, the coefficients of (5.14) follow immediately from (5.30). The only precaution is with respect to the locations in which the additional poles/zeros have to be placed which are mapped by a bilinear transformations moving ∞ into the finite point $\frac{\alpha}{\beta} \in \mathbb{C}^0$. The rest of the argument is identical and is therefore not repeated. ∎

The proof of Theorem 5.3 also gives a procedure to compute solutions of minimal McMillan degree. Moreover, the result below shows that from (5.21) one can get the class of all solutions.

THEOREM 5.4. *Assume the same notation and hypotheses as for Theorem* 5.3. *The class of all solutions to the minimal degree LCF with J all-pass denominator $G = M^{-1}N$, with M proper, is given by* (5.27) *and* (5.28), *where C_x and A_x follow by solving the eigenvalue assignment problem for the pair* (5.25) *with $A_x = E_{22}^{-*}(-A_{22}^* + C_2^* J C_x) \subset \mathbb{C}^0$, A_{x2} is any solution to* (5.23f), *A_{x1} is the unique solution to* (5.23d), *W is any J unitary matrix, and B_{x1} and B_{x2} are given by* (5.26).

Proof. Most of the proof is already contained in the proof of Theorem 5.3. We have only to prove that any solution may be obtained by the procedure given in the statement. Let $G = M^{-1}N$ be a solution to the LCF with J all-pass denominator M of minimal degree $2n_b - r$, and proper. Let G be given by a separated realization

(2.14) balanced with respect to the Lyapunov equation (5.11). Then M^{-1} is given by a realization (5.21), and (5.14) is satisfied for an invertible Hermitian matrix X_M as in (5.15), where X has the form in the right-hand side of (5.8). We show that by equivalence state-space transformations on (5.21) we obtain a realization for which the corresponding Lyapunov equation (5.14) has all the intervening matrices of the form depicted in (5.22), and this will end the proof.

Writing X_M in partitioned form we get

$$X_M = \begin{bmatrix} \Sigma_r & O & X_1 \\ O & O & X_2 \\ X_1^* & X_2^* & X_{22} \end{bmatrix}$$

where we have denoted $X_{12} = \left[\begin{smallmatrix} X_1 \\ X_2 \end{smallmatrix}\right]$. Since the matrix X_M is square and invertible, and has dimension $2n_b - r$ we get that X_2 is invertible, and thus we can write

$$U_M^* X_M U_M = \begin{bmatrix} \Sigma_r & O & O \\ O & O & I_{n_b-r} \\ O & I_{n_b-r} & O \end{bmatrix}, U_M := \begin{bmatrix} I & O & -\Sigma_r X_1 X_2^{-1} \\ O & I & -\frac{1}{2} X_2^{-*}(X_{22} - X_1^* \Sigma_r^{-1} X_1) X_2^{-1} \\ O & O & X_2^{-1} \end{bmatrix}. \tag{5.31}$$

Further, let

$$\widetilde{E}_M := U_M^{-1} E_M = \begin{bmatrix} \widetilde{E}_b & \widetilde{E}_{bx} \\ O & \widetilde{E}_x \end{bmatrix},$$

where the block upper triangular structure in the right-hand side follows from the block upper triangular structure of both E_M and U_M^{-1}. With $\widehat{E}_M := I$, $\widehat{A}_M := U_M^{-1} A_M \widetilde{E}_M^{-1}$, $\widehat{C}_M := C_M \widetilde{E}_M^{-1}$ and $\widehat{X}_M := U_M^* X_M U_M$ we get that (5.14) can be written equivalently as

$$\widehat{A}_M^* \widehat{X}_M \widehat{E}_M + \widehat{E}_M^* \widehat{X}_M \widehat{A}_M - \widehat{C}_M^* J \widehat{C}_M = 0,$$

where the intervening matrices with "hat" have the same block structure as their counterparts in (5.22). It follows that the corresponding equations (5.23a)–(5.23f) are satisfied from where the conclusion is immediate. ∎

The class of all solutions, including the case of improper M, is obtained from (5.18) and (5.19), where the unknown coefficients are obtained by first using the transformation (5.30) to reduce the problem to the case of a proper M. We do not elaborate further in this direction.

REMARK 5.5. *From the proof of Theorem* 5.3 *we can give an answer to the general problem of existence of a LCF with J lossless denominator as follows. If the solution X to* (5.11) *is positive definite, then the problem is solvable; otherwise there is no solution of any degree. Indeed, assume by contrary that X is not positive definite and there is a solution to the LCF with J lossless denominator of a certain degree. Then* (5.14) *should be satisfied with* $X_M > 0$ *given in* (5.15)*, from which* $X > 0$ *which contradicts our assumption.*

6. LCF with *J* all-pass denominators with respect to the unit circle. In this section we give the discrete-time version of the results presented in section 6. More precisely, we solve the minimal degree LCF problem with the additional requirement that the denominator have another type of symmetry, namely, that it be

J all-pass with respect to the unit circle. Throughout this section we take the disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by

$$\Gamma_b := \mathbb{D}^c \text{ (or } \Gamma_b := \mathbb{D}), \qquad \Gamma_g := \overline{\mathbb{C}} \setminus \Gamma_b. \tag{6.1}$$

Similarly as for the symmetry discussed in the previous section, it is not always possible to solve the LCF over Γ_g with minimal degree n_b. Again, when this is possible, we call the factorization *canonical*, otherwise we call it *noncanonical*.

Since our theory encompasses the cases in which $M(z)$ has to cancel a pole of G at ∞ or at 0, it follows that $M(z)$ or $M^{-1}(z)$ could, in general, be improper. Therefore, to achieve the full generality we have to use for $M(z)$ a descriptor representation of type (2.5), with singular E. The following result gives a characterization of J all-pass rational matrices (possible improper) without poles at 1 in terms of associated realizations. It is a particular case for $\alpha = \beta = 1$ of the general theorem Theorem A.2 given in the appendix.

COROLLARY 6.1. *Let $M(z)$ be a square invertible rational matrix, without poles at 1, having a minimal realization*

$$M(z) := \left[\begin{array}{c|c} A - zE & (1-z)B \\ \hline C & D \end{array}\right].$$

Then M is J all-pass with respect to the unit circle if and only if $D^*JD = J$ and there exists an invertible Hermitian matrix X such that

$$\begin{aligned} E^*XE - A^*XA - C^*JC &= 0, \\ C - DJB^*X(E-A) &= 0. \end{aligned}$$

6.1. The canonical case. The following theorem gives a complete solution to the LCF with J all-pass denominator of McMillan degree n_b.

THEOREM 6.2. *Given an arbitrary rational matrix $G(z)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by* (6.1)*, let n_b be the number of poles of G in Γ_b. Assume* (2.14) *is a minimal descriptor realization of G separated with respect to the given partition and satisfying the condition* (2.15)*. Then the LCF with J all-pass denominator with respect to the unit circle has a solution $G(z) = M^{-1}(z)N(z)$ of minimal degree n_b if and only if the Stein equation*

$$E_b^*XE_b - A_b^*XA_b - C_b^*JC_b = 0 \tag{6.2}$$

has an invertible Hermitian solution X. In this case the class of all solutions is given by

$$N(z) = \left[\begin{array}{cc|c} A_b - zE_b + KC_b(1-z) & A_{bg} - zE_{bg} + KC_g(1-z) & B_b + KD(1-z) \\ O & A_g - zE_g & B_g \\ \hline WC_b & WC_g & WD \end{array}\right], \tag{6.3}$$

$$M(z) = \left[\begin{array}{c|c} A_b - zE_b + KC_b(1-z) & K(1-z) \\ \hline WC_b & W \end{array}\right] \tag{6.4}$$

where $K = -X^{-1}(E_b - A_b)^{-*}C_b^*J$ and W is a J unitary matrix, $W^*JW = J$.

If G has real coefficients, then the class of solutions with real coefficients is also given by (6.3) *and* (6.4)*, where now all the intervening coefficients can be chosen real.*

Proof. The proof is identical as for Theorem 5.2, where we replace Corollary 5.1 with Corollary 6.1. □

If in the statement of the above theorem we add the condition $X > 0$ or $X < 0$, we obtain the solution to the LCF with J lossless or J expansive denominator, respectively. Notice that for the chosen partition (6.1) equation (6.2) has always a unique solution, and thus the above theorem is an effective tool for checking the existence of, and for computing solutions to, the LCF with J all-pass denominator or, as a particular case, with J lossless denominator.

For $J = I$, the above theorem provides the solution of an important particular case: LCF with all-pass denominator $M(z)$, (i.e., $M^*(1/\overline{z})M(z) = I$). In this case, (6.2) has always a sign definite (positive or negative) solution. If we take $\Gamma_b = \mathbb{D}^c$, then we obtain the LCF with inner denominator.

6.2. The noncanonical case. We give now solvability conditions in the noncanonical case.

THEOREM 6.3. *Given an arbitrary rational matrix $G(z)$ and a disjoint partition $\overline{\mathbb{C}} = \Gamma_g \cup \Gamma_b$ defined by* (6.1)*, let n_b be the number of poles of G in Γ_b. Assume that* (2.14) *is a minimal descriptor realization of G, separated with respect to the given partition, and satisfying condition* (2.15)*. Let $r := \mathrm{rank}(X)$ where X is the unique Hermitian solution to the Stein equation* (6.2)*. Then the minimal degree of the LCF with J all-pass denominator is $2n_b - r$.*

Proof. The proof is almost identical to the proof of Theorem 5.3. The key is to first transform (6.2) into the equivalent equation

$$\widehat{A}_b^* X \widehat{E}_b + \widehat{E}_b^* X \widehat{A}_b - \widehat{C}_b^* J \widehat{C}_b = 0, \tag{6.5}$$

where $\widehat{A}_b := E_b + A_b$, $\widehat{E}_b := E_b - A_b$, $\widehat{C}_b := \sqrt{2}C_b$. Since $\widehat{E}_b$ is invertible and (6.5) is of the form (5.11) we may use further a technique similar to that in the proof of Theorem 5.3. We note that the role of ∞ in placing additional poles/zeros in the proof of Theorem 5.3 is played in this case by 1. □

A remark similar to Remark 5.5 holds in this case as well.

7. Numerical aspects and examples. In this section we comment briefly on the numerical algorithms that are recommended for the methods proposed so far, and give several numerical examples.

7.1. Numerical aspects. Separated realizations as used in this paper can always be obtained by starting with an arbitrary realization (2.2) and performing unitary state-space equivalence transformations. If $\infty \in \Gamma_b$ then the preliminary transformation depicted in (2.10) is needed as to enforce further condition (2.15). The unitary matrices Q and Z in (2.10) can be obtained by a row compression of E followed by a column compression of A. The row/column compressions can be achieved by using any rank revealing procedure [7] based on unitary transformations. Further, we can arrive at (2.14) satisfying (2.15) by performing a spectral decomposition of the regular pencil $A_d - \lambda E_d$ (or $A - \lambda E$ if the preliminary step is skipped). The spectral decomposition of a regular pencil can be achieved by unitary transformations using the QZ algorithm [17] followed by a reordering of the generalized eigenvalues [23].

For solving the generalized eigenvalue assignment problem in Lemma 4.1 we can adapt almost all existing algorithms for pole assignment. (See [18] for a collection of such algorithms.)

For solving generalized Lyapunov equations (5.11) or Stein equations (6.2) one can use the algorithms proposed in [9]. Once the solution is computed, the balanced

form can be obtained by solving a symmetric eigenvalue problem for X [15]. Again, we can rely solely on unitary transformations.

7.2. Numerical examples.

Example 1. Minimal degree factorization with proper factors. Consider the improper rational matrix

$$G(\lambda) = \begin{bmatrix} \lambda^2 & \dfrac{\lambda}{\lambda - 1} \\ 0 & \dfrac{1}{\lambda} \end{bmatrix}$$

having finite poles at $\lambda_1 = 1$ and $\lambda_2 = 0$ and two poles at infinity, and let $\Gamma_g = \mathbb{C}^-$. A minimal order descriptor realization for G in the form (2.14) is given by

$$\left[\begin{array}{c|c} A_b - \lambda E_b & A_{bg} - \lambda E_{bg} \\ \hline O & A_g - \lambda E_g \end{array}\right] = \left[\begin{array}{cccc|c} -\lambda & 1 & 0 & 0 & 0 \\ 0 & 1-\lambda & 0 & 0 & 0 \\ 0 & 0 & 1 & -\lambda & 0 \\ 0 & 0 & 0 & 1 & -\lambda \\ \hline 0 & 0 & 0 & 0 & 1 \end{array}\right], \left[\begin{array}{c} B_b \\ \hline B_g \end{array}\right] = \left[\begin{array}{cc} 0 & 0 \\ 0 & -1 \\ 0 & 0 \\ 0 & 0 \\ \hline 1 & 0 \end{array}\right],$$

$$\left[\begin{array}{c|c} C_b & C_g \end{array}\right] = \left[\begin{array}{cccc|c} 0 & -1 & -1 & 0 & 0 \\ 1 & -1 & 0 & 0 & 0 \end{array}\right], \quad D = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}.$$

To compute a minimal degree LCF over Γ_g we use Theorem 4.2 and first determine a matrix K such that

$$\Lambda(A_b - \lambda E_b + K C_b(\alpha - \beta\lambda)) = \{-1, -1, -1, -1\}, \tag{7.1}$$

where we chose for convenience $\alpha = -2$ and $\beta = 1$. By using Lemma 4.1 for the dual pair $(A_b^T - \lambda E_b^T, C_b^T)$ we can assign the eigenvalues for the modified pair

$$(A_z - \lambda E_z, C_z) := (\alpha A_b^T - \beta E_b^T - \lambda(\beta A_b^T - \alpha E_b^T), (\alpha^2 + \beta^2) C_b^T)$$

to $\Gamma_z := \{3, 3, 3, 3\}$, where E_z is nonsingular. By using a pole assignment algorithm for generalized eigenvalues, we determine

$$K = \begin{bmatrix} -8 & 1 \\ -8 & 0 \\ 6 & 0 \\ 3 & 0 \end{bmatrix},$$

which fulfills (7.1). Using (4.4) and (4.5), we get the following solution to the minimal degree LCF over Γ_g:

$$N(\lambda) = \begin{bmatrix} \dfrac{(\lambda-1)\lambda^2}{3(\lambda+1)^3} & \dfrac{\lambda}{3(\lambda+1)^3} \\ 0 & \dfrac{1}{2(\lambda+1)} \end{bmatrix}, \quad M(\lambda) = \begin{bmatrix} \dfrac{\lambda-1}{3(\lambda+1)^3} & 0 \\ 0 & \dfrac{\lambda}{2(\lambda+1)} \end{bmatrix}$$

where the minimal degree of the LCF is clearly 4.

Example 2. Minimal degree coprime factorization with J all-pass denominator with respect to the imaginary axis. Consider the TFM of a continuous-time system

$$G(s) = \begin{bmatrix} \dfrac{1}{s-2} & \dfrac{1}{s-1} \\ \dfrac{\gamma_1}{s-2} & \dfrac{\gamma_2}{s-1} \end{bmatrix},$$

where $\gamma_1, \gamma_2 \in \mathbb{R}$ are two parameters, and let $\Gamma_b = \mathbb{C}^+$. It is easy to check that G has two unstable finite poles at $s_1 = 1$ and $s_2 = 2$. A minimal order realization for G in the form (2.14) is given by

$$A_b - sE_b = \begin{bmatrix} 1-s & 0 \\ 0 & 2-s \end{bmatrix}, B_b = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, C_b = \begin{bmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{bmatrix}, D = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

With $J = \left[\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right]$, the solution to the Lyapunov equation (5.2) in Theorem 5.2 is

$$X = \begin{bmatrix} \dfrac{1-\gamma_1^2}{2} & \dfrac{1-\gamma_1\gamma_2}{3} \\ \dfrac{1-\gamma_1\gamma_2}{3} & \dfrac{1-\gamma_2^2}{4} \end{bmatrix},$$

which for $\gamma_1(\gamma_2+3) - 1 - 3\gamma_2 \neq 0$ is nonsingular, for $\gamma_1(\gamma_2+3) - 1 - 3\gamma_2 = 0$ and $\gamma_2 \neq 1$ has rank equal to 1 and for $\gamma_1 = \gamma_2 = 1$ has rank equal to 0.

The canonical case. Consider $\gamma_1 = 2$ and $\gamma_2 = 1$ for which the solution of (5.2) is

$$X = \begin{bmatrix} -\dfrac{3}{2} & -\dfrac{1}{3} \\ -\dfrac{1}{3} & 0 \end{bmatrix}$$

and the corresponding K in Theorem 5.2 is

$$K = -X^{-1}C_b^T J = \begin{bmatrix} 3 & -3 \\ -\dfrac{21}{2} & \dfrac{15}{2} \end{bmatrix}.$$

The resulting factors $N(s)$ and $M(s)$ are

$$N(s) = \frac{1}{2}\begin{bmatrix} \dfrac{2\,s+11}{(s+1)\,(s+2)} & \dfrac{2}{(s+1)} \\ \dfrac{4\,s+13}{(s+1)\,(s+2)} & \dfrac{2}{(s+1)} \end{bmatrix},$$

$$M(s) = \frac{1}{2}\begin{bmatrix} \dfrac{2\,s^2-9\,s-5}{(s+1)\,(s+2)} & \dfrac{9\,s-3}{(s+1)\,(s+2)} \\ \dfrac{-9\,s+3}{(s+1)\,(s+2)} & \dfrac{2\,s^2+9\,s-5}{(s+1)\,(s+2)} \end{bmatrix}.$$

The noncanonical case: rank$(X) = 1$. Consider $\gamma_1 = 2$ and $\gamma_2 = 5$ for which the solution of (5.2) is

$$X = \begin{bmatrix} -\frac{3}{2} & -3 \\ -3 & -6 \end{bmatrix}$$

and has only a nonzero eigenvalue at $-\frac{15}{2}$. With

$$U = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & -2 \\ 2 & 1 \end{bmatrix}$$

we obtain

$$U^T X U = \begin{bmatrix} -\frac{15}{2} & 0 \\ 0 & 0 \end{bmatrix},$$

and the known matrices in (5.22) result with $Q = U^T$ as

$$U^T A U := \left[\begin{array}{c|c} A_{11} & A_{12} \\ \hline A_{21} & A_{22} \end{array}\right] = \frac{1}{5} \begin{bmatrix} 9 & 2 \\ 2 & 6 \end{bmatrix}, \quad CU := \left[\begin{array}{c|c} C_1 & C_2 \end{array}\right] = \frac{1}{\sqrt{5}} \begin{bmatrix} 3 & -1 \\ 12 & 1 \end{bmatrix},$$
$$U^T E U = \begin{bmatrix} E_{11} & O \\ E_{21} & E_{22} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

The matrix

$$X_M = \begin{bmatrix} -\frac{15}{2} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

fulfills (5.14) for

$$A_{x1} = \frac{8}{15}, \quad A_{x2} = \frac{18}{5}, \quad A_x = 0, \quad C_x = \begin{bmatrix} -\frac{6}{\sqrt{5}} \\ 0 \end{bmatrix},$$

where we have chosen C_x such that A_x has a zero eigenvalue. The corresponding B_M is

$$B_M = X_M^{-1} C_M^T J = \frac{1}{\sqrt{5}} \begin{bmatrix} -\frac{2}{5} & \frac{8}{5} \\ -6 & 0 \\ -1 & -1 \end{bmatrix}.$$

With M^{-1} defined by (5.21) we finally obtain

$$M(s) = \frac{1}{75} \begin{bmatrix} \dfrac{75\,s^3 + 63\,s^2 - 336\,s - 50}{s\,(s+2)\,(s+1)} & -\dfrac{2(81\,s^2 - 168\,s + 25)}{s\,(s+2)\,(s+1)} \\ \dfrac{2(81\,s^2 + 168\,s + 25)}{s\,(s+2)\,(s+1)} & \dfrac{75\,s^3 - 63\,s^2 - 336\,s + 50}{s\,(s+2)\,(s+1)} \end{bmatrix},$$

$$N(s) := M(s)G(s) = \frac{1}{25} \begin{bmatrix} \dfrac{25\,s^2 - 62\,s + 50}{s\,(s+2)\,(s+1)} & \dfrac{25\,s^2 - 199\,s + 50}{s\,(s+2)\,(s+1)} \\ \dfrac{2(25\,s^2 + 31\,s - 25)}{s\,(s+2)\,(s+1)} & \dfrac{125\,s^2 + 199\,s - 50}{s\,(s+2)\,(s+1)} \end{bmatrix}.$$

The noncanonical case: rank(X) = 0. Consider $\gamma_1 = \gamma_2 = 1$ for which the solution of (5.2) is $X = 0$. With $U = I$, we further have $A_{22} = A$ and $C_2 = C$. The matrix X_M has the form

$$X_M = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

and fulfills (5.14) for

$$A_{x2} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad A_x = \begin{bmatrix} -3 & 5 \\ -2 & 3 \end{bmatrix}, \quad C_x = \begin{bmatrix} -1 & \frac{5}{2} \\ 1 & -\frac{5}{2} \end{bmatrix},$$

where this time we have chosen C_x such that A_x has two eigenvalues on the imaginary axis at $\pm j$. The corresponding B_M results as

$$B_M = X_M^{-1} C_M^T J = \begin{bmatrix} -1 & -1 \\ \frac{5}{2} & \frac{5}{2} \\ 1 & -1 \\ 1 & -1 \end{bmatrix}.$$

With M^{-1} defined by (5.21) we eventually obtain

$$M(s) = \frac{1}{2} \begin{bmatrix} \dfrac{2\,s^4 - 3\,s^2 + 5}{(s^2+1)\,(s+2)\,(s+1)} & \dfrac{-7\,s^2 + 3}{(s^2+1)\,(s+2)\,(s+1)} \\ \dfrac{-7\,s^2 + 3}{(s^2+1)\,(s+2)\,(s+1)} & \dfrac{2\,s^4 - 3\,s^2 + 5}{(s^2+1)\,(s+2)\,(s+1)} \end{bmatrix},$$

$$N(s) := M(s)G(s) = \begin{bmatrix} \dfrac{s-2}{s^2+1} & \dfrac{s-1}{s^2+1} \\ \dfrac{s-2}{s^2+1} & \dfrac{s-1}{s^2+1} \end{bmatrix}.$$

Example 3. Minimal degree coprime factorization with J all-pass denominator with respect to the unit circle. Consider the TFM of a discrete-time system

$$G(z) = \begin{bmatrix} z^2 & \dfrac{1}{z-2} \\ 0 & z \end{bmatrix}$$

having an unstable finite pole at $z_1 = 2$ and three poles at infinity, and let $\Gamma_b := \mathbb{D}^c$. A minimal order descriptor realization for G in the form (2.14) is given by

$$\left[\begin{array}{c|c} A_b - zE_b & A_{bg} - zE_{bg} \\ \hline O & A_g - zE_g \end{array}\right] = \left[\begin{array}{cccc|cc} 2-z & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -z & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & -z & 0 \\ 0 & 0 & 0 & 1 & 0 & -z \\ \hline 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array}\right],$$

$$\left[\begin{array}{c} B_b \\ \hline B_g \end{array}\right] = \left[\begin{array}{cc} 0 & 1 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ \hline 1 & 0 \\ 0 & 1 \end{array}\right],$$

$$\left[\begin{array}{c|c} C_b & C_g \end{array}\right] = \left[\begin{array}{cccc|cc} 1 & -1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 & 0 & 0 \end{array}\right], \quad D = \left[\begin{array}{cc} 0 & 1 \\ 0 & 0 \end{array}\right].$$

The solution of (6.2) is

$$X = \left[\begin{array}{cccc} -1/3 & 1/2 & 1/4 & 0 \\ 1/2 & -1 & 0 & 0 \\ 1/4 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right],$$

and the corresponding K in Theorem 6.2 is

$$K = -X^{-1}(E_b - A_b)^{-T} C_b^T J = \left[\begin{array}{cc} -12 & 0 \\ -5 & 0 \\ -2 & 0 \\ 0 & 1 \end{array}\right].$$

The factors $N(z)$ and $M(z)$ resulting from Theorem 6.2 are

$$N(z) = \left[\begin{array}{cc} -\dfrac{z-2}{2\,z-1} & -\dfrac{1}{z^2\,(2\,z-1)} \\ 0 & 1 \end{array}\right], \quad M(z) = \left[\begin{array}{cc} -\dfrac{z-2}{z^2\,(2\,z-1)} & 0 \\ 0 & \dfrac{1}{z} \end{array}\right].$$

8. Conclusions. We have presented a comprehensive theory of minimal degree coprime factorization of rational matrices over a given domain of the closed complex plane. The given formulas allow us to compute the coprime factors by a one-shot approach and, in many case, also recursively by dislocating one pole (or a pair of poles) at a time (see for example the pole dislocation technique in [24]). In general, the one-shot approach brings advantages in terms of numerical reliability, efficiency, and versatility as any algorithm for pole assignment may be used, while the recursive method is more advantageous if a certain form of the coprime factors is needed at further computational steps. Nevertheless, the recursive techniques are applicable only when the involved Lyapunov equations have sign definite solutions (positive or negative), and then these equations are solved only implicitly. The recursive techniques cannot be employed in the more general cases discussed in this paper, not even in the canonical J all-pass case. Essentially, the recursive techniques fail since a J all-pass rational matrix cannot be written in general as a product of elementary J all-pass factors. In this respect, the paper provides a systematic theoretical framework for the recursive algorithms proposed in [25, 26] and elucidates in which cases they are applicable and provide the right answer.

A particular feature of the results developed in this paper is that the methods are exactly tailored to the dimension of the problem to be solved avoiding unnecessary

redundancy. As an example, the solution of a full-order Riccati equation (order equal to the McMillan degree of the rational matrix to be factored) that is usually employed in such factorizations (see for example [16], [31]) is completely avoided. Instead, we solve a Lyapunov equation of lower dimension with the benefits of increased numerical accuracy and computational efficiency.

The approach taken in this paper also gives ground for extensions to LCFs with denominators satisfying other symmetries, as for example with respect to the real line, or with respect to a certain contour in the complex plane. The theory presented here has been already applied as a preliminary step to the computation of the most general inner-outer, spectral, and J lossless factorizations and it is a promising step toward computing the more general J spectral factorizations, either canonical or noncanonical.

Appendix. In this appendix we give a characterization in terms of associated realizations for an arbitrary J all-pass rational matrix, with respect to either the imaginary axis or the unit circle. In this context we see the importance of centered realizations of the type (2.5) for which a suitable choice of α and β provides very handy formulas. A suitable choice means that α and β are such that $\frac{\alpha}{\beta}$ is on the contour with respect to which the symmetry is defined (either the imaginary axis or the unit circle). This choice guarantees, for a given rational matrix M with a minimal realization centered at $\frac{\alpha}{\beta}$, that its adjoint $M^{\sim}$ has a minimal realization centered at $\frac{\alpha}{\beta}$ which can be simply expressed in terms of the realization of M. This is especially important when working with TFMs of discrete-time systems as it avoids the intricacies related to the feature that ∞ is the symmetrized value of 0.

We start with the case in which the symmetry occurs with respect to the imaginary axis.

THEOREM A.1. *Let $M(s)$ be a square and invertible rational matrix. Let $\alpha \in \mathbb{R}$ and $\beta \in \mathbb{C}^0$ such that $\frac{\alpha}{\beta}$ is not a pole of M, let $p(s) := \alpha - s\beta$, and assume*

$$M(s) := \left[\begin{array}{c|c} A - sE & Bp(s) \\ \hline C & D \end{array}\right] \tag{A.1}$$

is a minimal realization. Then M is J all-pass with respect to the imaginary axis if and only if

$$D^*JD = J \tag{A.2a}$$

and there exists an invertible Hermitian matrix X such that

$$A^*XE + E^*XA - C^*JC = 0, \tag{A.2b}$$

$$C - DJB^*X(\alpha E - \beta A) = 0. \tag{A.2c}$$

Proof. Notice first that $M(s)$ having no poles at $\frac{\alpha}{\beta}$ implies that in a minimal realization (A.1) $\alpha E - \beta A$ is invertible.

Only if. Since $M(s)$ is J all-pass, we have

$$M^*(-\overline{s})JM(s) = J \tag{A.3}$$

$\forall\, s = j\omega$ which are not poles of $M(s)$. In particular, for $s = \frac{\alpha}{\beta}$ we get (A.2a). Hence D is invertible. Further, (A.3) may be rewritten as $M^*(-\overline{s})J = JM^{-1}(s)$ or,

equivalently, in terms of realizations

$$\left[\begin{array}{c|c} -A^*-sE^* & C^*Jp(s) \\ \hline -B^* & D^*J \end{array}\right] = \left[\begin{array}{c|c} A-\alpha BD^{-1}C-s(E-\beta BD^{-1}C) & BD^{-1}p(s) \\ \hline -JD^{-1}C & JD^{-1} \end{array}\right]. \tag{A.4}$$

Since both realizations in (A.4) are minimal and they realize the same rational matrix, there exist unique invertible matrices Q and Z such that

$$Q(A-\alpha BD^{-1}C)Z = -A^*, \tag{A.5a}$$

$$Q(E-\beta BD^{-1}C)Z = E^*, \tag{A.5b}$$

$$QBD^{-1} = C^*J, \tag{A.5c}$$

$$JD^{-1}CZ = B^*. \tag{A.5d}$$

It is easy to see that equations (A.5a)–(A.5d) also hold with Q and Z replaced by Z^{-*} and Q^{-*}, respectively. Due to the uniqueness of Q and Z we get that $Q = Z^{-*}$. Substituting this in (A.5a) and (A.5b) we get

$$(A-\alpha BD^{-1}C)Z = -Z^*A^*, \tag{A.6a}$$

$$(E-\beta BD^{-1}C)Z = Z^*E^*. \tag{A.6b}$$

Rewriting (A.5d) we get

$$C - DJB^*Z^{-1} = 0. \tag{A.7}$$

Comparing (A.7) with (A.2c) we define

$$X := Z^{-1}(\alpha E-\beta A)^{-1} \tag{A.8}$$

that is clearly invertible. To show that X is Hermitian, we subtract (A.6a) multiplied by β from (A.6b) multiplied by α and get

$$X^{-1} = (\alpha E-\beta A)Z = Z^*(\alpha E^*+\beta A^*) = X^{-*}. \tag{A.9}$$

It remains only to show (A.2b). We rewrite the left-hand side of (A.2b) successively as

$$\begin{aligned} &\frac{1}{\alpha^2+\beta^2}[(-\beta E^*+\alpha A^*)X(\alpha E-\beta A)+(\alpha E^*+\beta A^*)X(\alpha A+\beta E)] - C^*JC \\ &\quad \overset{(A.8)}{=} \frac{1}{\alpha^2+\beta^2}[(-\beta E^*+\alpha A^*)Z^{-1}+Z^{-*}(\alpha A+\beta E)] - C^*JC \\ &\quad \overset{(A.6a)-(A.6b)}{=} Z^{-*}BD^{-1}C - C^*JC \overset{(A.7)}{=} 0, \end{aligned}$$

which ends the first part of the proof.

If. We show that if (A.2a)–(A.2c) hold for an invertible Hermitian matrix X, then $M(s)$ is J all-pass. Starting with (A.1) we get a realization of

$$M^{\sim}(s)JM(s) = \left[\begin{array}{cc|c} -A^*-sE^* & C^*JC & C^*JDp(s) \\ O & A-sE & Bp(s) \\ \hline -B^* & D^*JC & D^*JD \end{array}\right].$$

Let

$$Q := \left[\begin{array}{cc} I & -(\beta A^*+\alpha E^*)X \\ O & I \end{array}\right], \qquad Z := \left[\begin{array}{cc} I & X(\alpha E-\beta A) \\ O & I \end{array}\right],$$

and performing an equivalence state-space transformation with Q to the left and Z to the right we get

$$M^*(-\overline{s})JM(s) = \left[\begin{array}{cc|c} -A^*-sE^* & C^*JC-E^*XA-A^*XE & [C^*JD-(\beta A^*+\alpha E^*)XB]p(s) \\ O & A-sE & Bp(s) \\ \hline -B^* & -B^*X(\alpha E-\beta A)+D^*JC & D^*JD \end{array}\right]. \tag{A.10}$$

Now using (A.2a)–(A.2c) we get that the $(1,2)$, $(1,3)$ and $(3,2)$ entries of (A.10) are identically zero. Thus removing the uncontrollable and unobservable part of (A.10) we finally get

$$M^{\sim}(s)JM(s) = D^*JD$$

from which the conclusion follows that $M(s)$ is J all-pass. □

Here follows the case of a J all-pass rational matrix with respect to the unit circle.

THEOREM A.2. *Let $M(z)$ be a square and invertible rational matrix. Let $\alpha \in \mathbb{C}$, with $\|\alpha\| = 1$ and such that α^2 is not a pole of M, let $p(z) := (\alpha - \overline{\alpha}z)$, and assume that*

$$M(z) := \left[\begin{array}{c|c} A-zE & Bp(z) \\ \hline C & D \end{array}\right] \tag{A.11}$$

is a minimal realization. Then M is J all-pass with respect to the unit circle if and only if

$$D^*JD = J \tag{A.12a}$$

and there exists an invertible Hermitian matrix X such that

$$E^*XE - A^*XA - C^*JC = 0, \tag{A.12b}$$

$$C - DJB^*X(\alpha E - \overline{\alpha}A) = 0. \tag{A.12c}$$

Proof. Notice first that since $M(z)$ has no pole at α^2 and (A.11) is a minimal realization it follows that $\overline{\alpha}A - \alpha E$ is invertible.

Only if. Since $M(z)$ is J all-pass, we have

$$M^{\sim}(z)JM(z) = J \tag{A.13}$$

for all $z = e^{j\theta}$ which are not poles of $M(z)$. In particular, for $z = \alpha$ we get (A.12a) and it follows that D is invertible. Further, (A.13) may be rewritten as

$$M^*\left(\frac{1}{\overline{z}}\right)J = JM^{-1}(z)$$

or, equivalently, in terms of realizations

$$\left[\begin{array}{c|c} E^*-zA^* & C^*Jp(z) \\ \hline B^* & D^*J \end{array}\right] = \left[\begin{array}{c|c} (A-\alpha BD^{-1}C)-z(E-\overline{\alpha}BD^{-1}C) & BD^{-1}p(z) \\ \hline -JD^{-1}C & JD^{-1} \end{array}\right]. \tag{A.14}$$

Since both realizations in (A.14) are minimal and they realize the same rational matrix, there exist two unique invertible matrices Q and Z such that

$$Q(A-\alpha BD^{-1}C)Z = E^*, \tag{A.15a}$$
$$Q(E-\overline{\alpha}BD^{-1}C)Z = A^*, \tag{A.15b}$$
$$QBD^{-1} = C^*J, \tag{A.15c}$$
$$-JD^{-1}CZ = B^*. \tag{A.15d}$$

It is easy to see that equations (A.15a)–(A.15d) hold if we replace Q and Z with $-Z^{-*}$ and $-Q^{-*}$, respectively. Due to the uniqueness of Q and Z we get

$$Q = -Z^{-*}. \tag{A.16}$$

Thus substituting (A.16) in (A.15a)–(A.15d) results in

$$(A-\alpha BD^{-1}C)Z = -Z^*E^*, \tag{A.17a}$$
$$(E-\overline{\alpha}BD^{-1}C)Z = -Z^*A^*. \tag{A.17b}$$

Rewriting (A.15d) we get

$$C + DJB^*Z^{-1} = 0. \tag{A.18}$$

Comparing (A.12c) with (A.18) we define

$$X := -Z^{-1}(\alpha E - \overline{\alpha}A)^{-1}, \tag{A.19}$$

which is clearly invertible. To show that X is Hermitian we subtract (A.17b) multiplied by α from (A.17a) multiplied by $\overline{\alpha}$ and get

$$X^{-1} = (\overline{\alpha}A - \alpha E)Z = Z^*(\alpha A^* - \overline{\alpha}E^*) = X^*.$$

It remains only to show (A.12b). We rewrite the left-hand side of (A.12b) successively as

$$\begin{aligned}
&\frac{1}{2}[(\alpha A^* + \overline{\alpha}E^*)X(\alpha E - \overline{\alpha}A) + (\overline{\alpha}E^* - \alpha A^*)X(\alpha E + \overline{\alpha}A)] - C^*JC \\
&\overset{(A.19)}{=} -\frac{1}{2}[(\alpha A^* + \overline{\alpha}E^*)Z^{-1} + Z^{-*}(\alpha E + \overline{\alpha}A)] - C^*JC \\
&\overset{(A.17a)-(A.17b)}{=} -Z^{-*}BD^{-1}C - C^*JC \overset{(A.18)}{=} 0
\end{aligned}$$

which ends this part of the proof.

If. We show that if (A.12a)–(A.12c) hold for an invertible Hermitian matrix X, then $M(z)$ is J all-pass. Starting with (A.11) we get a realization of

$$M^*\left(\frac{1}{\overline{z}}\right)JM(z) = \left[\begin{array}{cc|c} E^* - zA^* & C^*JCp(z) & C^*JDp(z) \\ O & A - zE & Bp(z) \\ \hline B^* & D^*JC & D^*JD \end{array}\right].$$

Let

$$Q := \begin{bmatrix} I & (\alpha A^* - \overline{\alpha}E^*)X \\ O & I \end{bmatrix}, \qquad Z := \begin{bmatrix} I & X(\overline{\alpha}A - \alpha E) \\ O & I \end{bmatrix}.$$

Performing an equivalence state-space transformation with Q to the left and Z to the right we obtain

$$M^*\left(\frac{1}{\overline{z}}\right)JM(z) = \left[\begin{array}{ccc|c} E^* - zA^* & O & & O \\ O & A - zE & & Bp(z) \\ \hline B^* & O & & D^*JD \end{array}\right], \tag{A.20}$$

where we have used (A.12b) and (A.12c) to get that the $(1,2)$, $(1,3)$ and $(3,2)$ entries are zero. Thus, removing the uncontrollable and unobservable part of (A.20) we finally get $M^{\sim}(z)JM(z) = D^*JD$, from which with (A.12a) we conclude that $M(z)$ is J all-pass. □

BILUTM: A DOMAIN-BASED MULTILEVEL BLOCK ILUT PRECONDITIONER FOR GENERAL SPARSE MATRICES*

YOUSEF SAAD† AND JUN ZHANG‡

Abstract. This paper describes a domain-based multilevel block ILU preconditioner (BILUTM) for solving general sparse linear systems. This preconditioner combines a high accuracy incomplete LU factorization with an algebraic multilevel recursive reduction. Thus, in the first level the matrix is permuted into a block form using (block) independent set ordering and an ILUT factorization for the reordered matrix is performed. The reduced system is the approximate Schur complement associated with the partitioning, and it is obtained implicitly as a by-product of the partial ILUT factorization with respect to the complement of the independent set. The incomplete factorization process is repeated with the reduced systems recursively. The last reduced system is factored approximately using ILUT again. The successive reduced systems are not stored. This implementation is efficient in controlling the fill-in elements during the multilevel block ILU factorization, especially when large size blocks are used in domain decomposition-type implementations. Numerical experiments are used to show the robustness and efficiency of the proposed technique for solving some difficult problems.

Key words. incomplete LU factorization, ILUT, multilevel ILU preconditioner, Krylov subspace methods, multielimination ILU factorization

1. Introduction.

The preconditioning technique proposed in this paper is based on a multilevel block incomplete LU factorization. It is intended for solving general sparse linear systems of the form

$$Ax = b, \tag{1.1}$$

where A is an unstructured matrix of order n. Such linear systems are often solved by Krylov subspace methods coupled with a suitable preconditioner [52]. The research and design of preconditioners with inherent parallelism have received much attention recently, spurred by the popularity of distributed memory architectures. The main considerations when comparing preconditioners are their intrinsic efficiency, generality, parallelism, and robustness. An experimental study on robustness of a few general purpose preconditioners has been conducted in [22] and a number of ILU-type preconditioners have been tested for solving some difficult problems from computational fluid dynamics in [19, 20].

The incomplete LU factorization without fill-in (ILU(0)) is probably the best known general purpose preconditioner [40]. However, this preconditioner is not robust and is inefficient and fails for many real-life problems. Many extensions of ILU(0), which increase its accuracy and robustness, have been designed, and we refer to [52]

for a partial account of the literature and to [25, 26, 33, 44, 60, 64] for just a few ideas described.

The moderate parallelism which can be extracted from the triangular solves in standard ILU factorization [1, 52] is limited, and becomes inadequate for the more accurate ILU factorizations. Alternatives have been considered in the past to develop preconditioners with inherently more parallelism than standard ILU; see, e.g., [48, 52, 58] for references. A standard technique used for this purpose is to exploit "multicolor orderings" or "independent sets" [49]. A well-known drawback of using a multicolor ordering prior to building an ILU factorization is that the quality of the preconditioning on the reordered system is generally worse than that on the original system [29, 30, 32]. However, numerical results in [50] show that some high accuracy ILU-type preconditioners with red-black ordering may eventually outperform their counterparts with natural ordering, if enough fill-in is allowed. Conversely, the higher amount of fill-in usually reduces the parallelism that is available in ILU(0). Therefore, a desirable goal is to achieve high accuracy while retaining parallelism achieved by using multicoloring or independent sets. Other alternatives for developing parallel preconditioners have been proposed that are based on sparse approximate inverse techniques; see, e.g., [9, 16, 21, 23, 35, 37, 62]. These preconditioners afford potential maximum parallelism both in their construction stage (except [9, 62]) and in the application stage which requires only matrix-vector operations. However, these methods tend to become inefficient for handling very large matrices because of their local nature.

The multielimination ILU preconditioner (ILUM), introduced in [51], is based on exploiting the idea of successive independent set orderings. It has a multilevel structure and offers a good degree of parallelism without sacrificing overall effectiveness. Similar preconditioners developed in [12, 55] show near grid-independent convergence for certain types of problems. In a recent report, some of these multilevel preconditioners were tested and compared favorably with other preconditioned iterative methods and direct methods, at least for the Laplace equation [10].

The idea of combining multilevel techniques with ILU is not new. Alternative multilevel approaches that require grid information have been developed. Examples of such approaches include the nested recursive two-level factorization, repeated red-black orderings, and generalized cyclic reduction [2, 4, 11, 31, 43] (see also the survey paper by Axelsson and Vassilevski [3]). Some recently developed methods require only the adjacency graph of the coefficient matrices [12, 46, 51, 55]. For the repeated red-black ordering approach, a near-optimal bound for the condition number of the preconditioned matrix was reported [42]. Other methods which bear some similarity with ILUM-type techniques are the algebraic multigrid methods [13, 18, 46, 47, 59] and certain types of multigrid methods which consider matrix entries [28, 27, 45]. Equally interesting are the multilevel preconditioning techniques based on hierarchical basis, multigraph, or ILU decomposition associated with the finite difference or finite element analysis [6, 8, 7, 15, 36].

A block version of ILUM (BILUM) was recently defined by using small dense matrices as pivots instead of scalars [55, 57]. For some hard-to-solve problems, BILUM may perform much better than ILUM. Tests with large blocks indicate that the larger the block, the more robust the resulting preconditioner. The solution with the independent blocks in BILUM uses the exact inverse or a regularized inverse based on the singular value decomposition (SVD) [55, 57]. These strategies are efficient for blocks of small size, but the cost of such inversion strategies grows cubically as the size of the blocks increases.

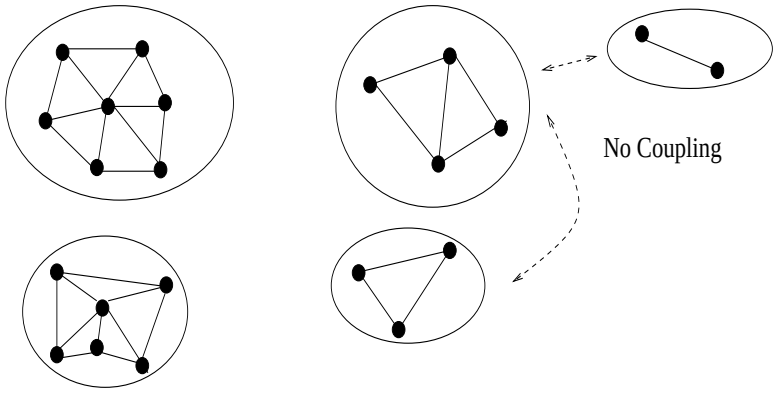

FIG. 2.1. *Independent groups or blocks.*

In this paper we focus on *domain decomposition-based* block ILUM. In this case the blocks can be very large and are associated with a subdomain, as in domain decomposition methods. For these large size blocks, the computational and memory costs of computing exact or regularized inverses used for BILUM become prohibitive. The dropping strategies that have been proposed [57] are not able to deal with both problems (computation and memory costs) simultaneously. It is therefore vital to exploit sparsity for domain decomposition-based block ILUM. This paper introduces an efficient approach to constructing BILUM based on this principle. The construction of such a preconditioner is based on a restricted ILU factorization with a dual dropping strategy (ILUT); see [50]. This multilevel block ILUT preconditioner (BILUTM) retains the efficiency and flexibility of ILUT and offers inherent parallelism that can be exploited on parallel or distributed architectures.

This paper is organized as following. Section 2 gives an overview and background on multigrid and multilevel preconditioning techniques. Section 3 provides some details on the construction of the reduced system by partial Gaussian elimination. Section 4 discusses the proposed BILUTM. Section 5 describes some numerical experiments, and section 6 gives a few concluding remarks.

2. Multilevel preconditioning techniques. Multilevel preconditioners take advantage of the fact that different parts of the error spectrum can be treated independently on different levels. In construction, multilevel preconditioners also exploit, explicitly or implicitly, the property that a set of unknowns that are not coupled to each other can be eliminated simultaneously in a Gaussian elimination–type process. Such a set is usually called an *independent set* [34]. This concept of independent set can easily be generalized to blocks. Thus a block independent set is a set of groups (blocks) of unknowns such that there is no coupling between unknowns of any two different groups (blocks) [55]. Unknowns within the same group (block) may be coupled. This is illustrated in Figure 2.1.

Thus, point (scalar) independent sets are a particular case which use blocks of uniform size of 1. Various heuristic strategies may be used to find a block independent set with different properties [51, 55]. A simple and usually efficient strategy is a greedy algorithm, which groups the nearest nodes together. Since the focus of this paper is not on finding block independent sets, we assume that this greedy algorithm is used throughout to find block independent sets.

A maximal independent set is an independent set that cannot be augmented by other nodes and still remain independent. Independent sets are often constructed with some other conditions such as guaranteeing certain diagonal dominance for the nodes of the independent set or the vertex cover, which is defined as the complement of the independent set. Thus, in practice, the maximality of an independent set is rarely guaranteed, especially when some dropping strategies are applied [57].

Algebraic and "black box" multigrid methods try to mimic geometric multigrid methods by defining a prolongation operator $\mathbf{I}_{\alpha+1}^{\alpha}$ based on some heuristic arguments; here $0 \leq \alpha < \mathcal{L}$ is an integer used to label the level. For convenience and for satisfying certain conservation laws, the restriction operator, $\mathbf{I}_{\alpha}^{\alpha+1}$, is traditionally defined as the adjoint of the prolongation operator (possibly scaled by a constant), i.e., $\mathbf{I}_{\alpha}^{\alpha+1} = {\mathbf{I}_{\alpha+1}^{\alpha}}^T$ [47]. With $A_0 = A$, the recursive coarse grid operators are then generated by using the Galerkin technique as

$$A_{\alpha+1} = \mathbf{I}_{\alpha}^{\alpha+1} A_{\alpha} \mathbf{I}_{\alpha+1}^{\alpha}. \tag{2.1}$$

Note that, in order for the grid transfer operators to be defined efficiently, a logically rectangular grid is explicitly or implicitly assumed for the black box or matrix-dependent approaches [28]. Most such multigrid methods are designed for two-dimensional problems, and their extensions to higher dimensions are not straightforward [5]. For algebraic multigrid methods, improvements have recently been reported by defining more accurate grid transfer operators [17, 18].

In independent set orderings, the unknowns may be permuted such that those associated with the independent set are listed first, followed by the other unknowns. The permutation matrix P_{α}, associated with such an ordering, transforms the original matrix into a matrix which has the following block structure:

$$A_{\alpha} \sim P_{\alpha} A_{\alpha} P_{\alpha}^T = \begin{pmatrix} D_{\alpha} & F_{\alpha} \\ E_{\alpha} & C_{\alpha} \end{pmatrix}, \tag{2.2}$$

where D_{α} is a block diagonal matrix of dimension m_{α}, and C_{α} is a square matrix of dimension $n_{\alpha} - m_{\alpha}$. In what follows, the notation is slightly abused by not distinguishing the original system from the permuted system, so both permuted and unpermuted matrices will be denoted by A_{α}.

To improve load balancing on parallel computers, it is desirable to have uniformly sized independent blocks. However, this is not a necessary requirement for the techniques described in this paper.

In algebraic multilevel preconditioning techniques, the reduced systems are recursively constructed as the Schur complement with respect to either D_{α} or C_{α}. In the case of BILUM [51, 55], such a construction amounts to performing a block LU factorization of the form

$$\begin{pmatrix} D_{\alpha} & F_{\alpha} \\ E_{\alpha} & C_{\alpha} \end{pmatrix} = \begin{pmatrix} I_{\alpha} & 0 \\ E_{\alpha} D_{\alpha}^{-1} & I_{\alpha} \end{pmatrix} \times \begin{pmatrix} D_{\alpha} & F_{\alpha} \\ 0 & A_{\alpha+1} \end{pmatrix}, \tag{2.3}$$

where $A_{\alpha+1}$ is the Schur complement with respect to C_{α} and I_{α} is the generic identity matrix on level α. Note that $n_{\alpha+1} = m_{\alpha}$. The solution process with the above factorization consists of level-by-level forward elimination, followed by an exact solution on the last reduced system $A_{\mathcal{L}}$. The solution of the original system is obtained by level-by-level backward substitution (with suitable permutation).

The procedure described above is a direct solution method and the reduced systems become denser and denser as the level number increases, a consequence of the

fill-in caused by the elimination process. In BILUM, some dropping strategies are used to control the amount of fill-in by discarding certain elements of small magnitude or by limiting the number of elements allowed in each row of the L and U factors [51, 54, 55]. The resulting incomplete multilevel block LU factorization is then used as a preconditioner in a Krylov subspace method based iterative solver.

In the implementation of BILUM in [55], the block diagonals D_α consist of small size blocks. These small blocks are usually dense and an exact inverse technique is used to compute D_α^{-1} by inverting each small block independently (in parallel). In [57], some regularized-inverse technique based on SVD is used to invert the (potentially near-singular) blocks approximately. As we noted in the introduction, such direct inversion strategies usually produce dense inverse matrices even if the original blocks are highly sparse with large sizes. Thus some heuristic approaches have been proposed to drop small elements from the exactly or approximately inverted blocks to recover sparsity. Obviously this approach cannot reduce the cost of inverting these blocks.

The link between the algebraic multigrid methods and BILUM was discussed briefly in [57]. If we define the grid transfer operators naturally based on the matrix, the reduced system based on the Schur complement technique as in (2.3) also satisfies the Galerkin condition (2.1). In other words, BILUM can be viewed as a naturally defined algebraic multigrid or multilevel technique.

3. Gaussian elimination and ILUT. ILUT is a high-order (high accuracy) preconditioner based on incomplete LU factorization. It uses a dual dropping strategy to control the storage cost (the amount of fill-in) [50]. Its implementation is based on the IKJ variant of Gaussian elimination, which we recall next.

ALGORITHM 3.1. GAUSSIAN ELIMINATION–IKJ VARIANT.

1. *For* $i = 2, n$, *Do*
2. *For* $k = 1, i-1$, *Do*
3. $a_{i,k} := a_{i,k}/a_{k,k}$
4. *For* $j = k+1, n$, *Do*
5. $a_{i,j} := a_{i,j} - a_{i,k} * a_{k,j}$
6. *End Do*
7. *End Do*
8. *End Do*

The ILUT(τ, p) preconditioner attempts to control fill-in elements by applying a dual dropping strategy in Algorithm 3.1. The accuracy of ILUT(τ, p) is controlled by two dropping parameters, τ and p. In Algorithm 3.2, w is a work array, $a_{i,\beta}$ and $u_{k,\beta}$ denote the ith and kth rows of A and U, respectively.

ALGORITHM 3.2. STANDARD ILUT(τ, p) FACTORIZATION [50, 52].

1. *For* $i = 2, n$, *Do*
2. $w := a_{i,\beta}$
3. *For* $k = 1, i-1$ *and when* $w_k \neq 0$, *Do*
4. $w_k := w_k/a_{k,k}$
5. *If* $|w_k| < \tau * \text{nzavg}(a_{i,\beta})$, *set* $w_k := 0$
6. *If* $w_k \neq 0$, *then*
7. $w := w - w_k * u_{k,\beta}$
8. *End If*
9. *End Do*
10. *Apply a dropping strategy to row* w
11. *Set* $l_{i,j} := w_j$ *for* $j = 1, \ldots, i-1$ *whenever* $w_j \neq 0$
12. *Set* $u_{i,j} := w_j$ *for* $j = i, \ldots, n$ *whenever* $w_j \neq 0$

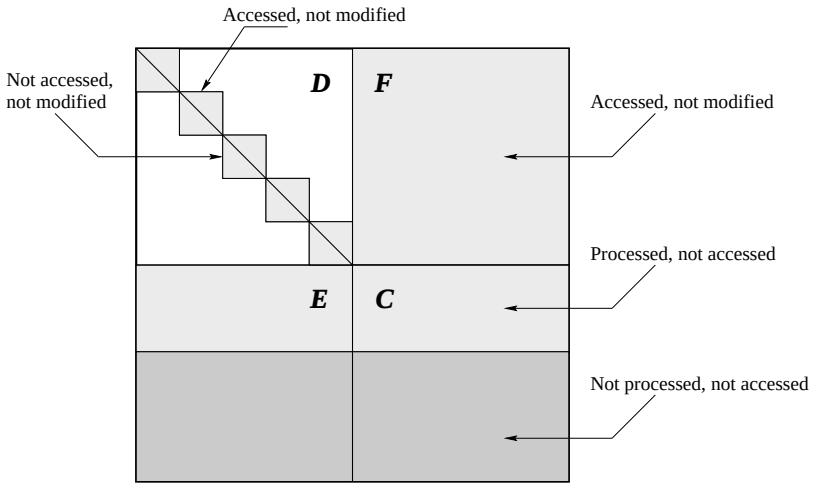

FIG. 3.1. *Illustration of restricted IKJ version of Gaussian elimination.*

13. *Set* $w := 0$
14. *End Do*

In Line 5, the function nzavg($a_{i,\beta}$) returns the average magnitude of the nonzero elements of a given sparse row. Elements with relatively small magnitude are dropped. In Line 10, a different dropping strategy is applied. First, small elements are dropped according to the relative magnitude similar to the criterion used in Line 5. Then a sorting operation is performed and only the largest p elements in absolute value of the L and U factors are kept. After the dual dropping strategy, there are at most p elements kept in each row of the L and U factors.

We now consider a slightly different elimination procedure. Assume that the first m equations are associated with the independent set as in the left-hand side of (3.2). If we perform the LU factorization (Gaussian elimination) to the upper part (the first m rows) of the matrix, i.e., to the submatrix $(D\ F)$, we have

$$(D\ \ F) = (LU\ \ L^{-1}F). \tag{3.1}$$

We then continue the Gaussian elimination to the lower part, but the elimination is only performed with respect to the submatrix E; i.e., we only eliminate those elements $a_{i,k}$ for which $m < i \le n, 1 \le k \le m$. Appropriate linear combinations are also performed with respect to the C submatrix, in connection with the eliminations in the E submatrix, as in the usual Gaussian elimination. Note that when doing these operations on the lower part, the upper part of the matrix is only accessed but not modified; see Figure 3.1. The processed rows of the lower part are never accessed again. This gives the following "restricted" version of Algorithm 3.1.

ALGORITHM 3.3. RESTRICTED IKJ VERSION OF GAUSSIAN ELIMINATION.

1. *For* $i = 2, n$, *Do*
2. *For* $k = 1, \min(i-1, m)$, *Do*
3. $a_{i,k} := a_{i,k}/a_{k,k}$
4. *For* $j = k+1, n$, *Do*
5. $a_{i,j} := a_{i,j} - a_{i,k} * a_{k,j}$
6. *End Do*
7. *End Do*
8. *End Do*

Here m is a parameter which defines the size of the matrix D. Algorithm 3.3 performs a block factorization of the form

$$\begin{pmatrix} D & F \\ E & C \end{pmatrix} = \begin{pmatrix} L & 0 \\ EU^{-1} & I \end{pmatrix} \times \begin{pmatrix} U & L^{-1}F \\ 0 & A_1 \end{pmatrix} = \mathbf{LU}. \tag{3.2}$$

In other words, the $a_{i,k}$'s (of the lower part) for $k \leq m$ are the elements in EU^{-1} and the other elements are those in A_1.

PROPOSITION 3.4. *The matrix A_1 computed by Algorithm* 3.3 *is the Schur complement of A with respect to C.*

Proof The part of the matrix after the upper part Gaussian elimination (with respect to the independent set, see (3.1)) that is accessed is $(U\ L^{-1}F)$; the L part is never accessed again. So we may write the active part of the (partially processed) matrix A as

$$\begin{pmatrix} U & \tilde{F} \\ E & C \end{pmatrix} = \begin{pmatrix} U & L^{-1}F \\ E & C \end{pmatrix}.$$

In order to eliminate an element in E, say, $e_{i,j}(= a_{i,j})$ with $m < i \leq n, 1 \leq j \leq m$, we perform a linear combination of the ith row of A and jth row of the U-part $(U\ L^{-1}F)$. Hence, the elements in C are modified according to the operations

$$\tilde{c}_{i,k} = c_{i,k} - \frac{e_{i,j}}{u_{j,j}} \tilde{f}_{j,k}.$$

After eliminating all $e_{i,j}$'s in E, the elements of the C matrix are changed to

$$\tilde{c}_{i,k} = c_{i,k} - \sum_{j=1}^{m} \frac{e_{i,j}}{u_{j,j}} \tilde{f}_{j,k}.$$

It follows that

$$A_1 = \tilde{C} = C - EU^{-1}\tilde{F} = C - EU^{-1}L^{-1}F = C - ED^{-1}F. \qquad \square$$

Note that $D = LU$ is factored. However, even in exact factorization, LU is usually sparser than D^{-1}. The submatrices DU^{-1} and $L^{-1}F$ are formed automatically, and the Schur complement is formed implicitly, during the partial Gaussian elimination with respect to the lower part of A.

Dropping strategies similar to those used in Algorithm 3.2 can be applied to Algorithm 3.3, resulting in an incomplete LU factorization with an approximate Schur complement A_1. We formally describe the restricted ILUT factorization as in Algorithm 3.5.

ALGORITHM 3.5. RESTRICTED ILUT(τ, p) FACTORIZATION.

1. *For* $i = 2, n$, *Do*
2. $\quad w := a_{i,\beta}$
3. $\quad$ *For* $k = 1, \min(i-1, m)$ *and when* $w_k \neq 0$, *Do*
4. $\quad\quad w_k := w_k / a_{k,k}$
5. $\quad\quad$ *Set* $w_k := 0$ *if* $|w_k| < \tau * \text{nzavg}(a_{i,\beta})$
6. $\quad\quad$ *If* $w_k \neq 0$, *then*
7. $\quad\quad\quad w := w - w_k * u_{k,\beta}$
8. $\quad\quad$ *End If*
9. $\quad$ *End Do*

10. *Apply a dropping strategy to row w*
11. *Set* $l_{i,j} := w_j$ *for* $j = 1, \ldots, \min(i-1, m)$ *whenever* $w_j \neq 0$
12. *Set* $u_{i,j} := w_j$ *for* $j = \min(i, m), \ldots, n$ *whenever* $w_j \neq 0$
13. *Set* $w := 0$
14. *End Do*

Algorithm 3.5 yields an ILU factorization of the form

$$A = \mathbf{LU} + R, \tag{3.3}$$

where R is the residual matrix representing the difference between A and $\mathbf{LU}$. The ILUT implementation gives an easy representation of the residual matrix.

PROPOSITION 3.6. *The elements of the residual matrix* R *as in* (3.3) *are those elements dropped in Algorithm* 3.5.

Proof. The proof can be formulated from the arguments in [52, p. 274] and [56]. □

Clearly, Algorithm 3.5 will fail when any individual ILUT fails on at least one of the blocks due to zero pivots. There are at least three strategies that can be used to deal with this situation. First, one can use pivoting as in ILUTP [52], a variant of ILUT which incorporates column pivoting. Second, we may use a diagonal threshold strategy as was done in ILUM [56]. In this technique, nodes with small absolute diagonal values are put in the vertex cover. This strategy may reduce the size of the independent set. Third, we may replace a small (absolute) diagonal value by a larger one and proceed with the normal ILUT. The third strategy is suitable and is almost free of cost since ILUT is not an exact factorization anyway. In our implementation we chose the third strategy and replaced a zero diagonal value by a value that is determined by the dropping tolerance and the absolute average nonzero elements of the current row.

We mention that in Algorithm 3.5 the diagonals of the approximate Schur complement (A_1) are not dropped regardless of their values. From Figure 3.1 the accuracy of the EU^{-1} part is related to that of the LU part; the accuracy of the A_1 part is related to that of the $L^{-1}F$ part. It may be profitable to use different dropping parameters (τ, p) for the upper and lower parts of the ILU factorizations in Algorithm 3.5. We did some numerical experiments and did not find overwhelming evidence for supporting the use of different dropping parameter set for most test problems. However, even if other problems may be tested to show certain advantages, the increased difficulty of determining more parameters for a general purpose preconditioner may offset the gain in convergence. Thus, the numerical results reported in this paper all use uniform dropping parameters during the construction phase. We even kept the parameters the same between different levels.

We point out that the inherent parallelism in the construction phase is excellent. The construction of the upper part factorization is parallelizable with respect to individual blocks. The construction of the lower part factorization is fully parallelizable relative to individual rows, as processing each row needs only information from (access to) the upper part. In addition, parallel algorithms for finding independent sets are available [38, 39].

4. Multilevel block ILUT. The BILUTM is based on the restricted ILUT Algorithm 3.5. On each level α, an incomplete LU factorization is performed and an approximate reduced system $A_{\alpha+1}$ is formed as in Algorithm 3.5. Formally, we have

$$\begin{pmatrix} D_\alpha & F_\alpha \\ E_\alpha & C_\alpha \end{pmatrix} = \begin{pmatrix} L_\alpha & 0 \\ E_\alpha U_\alpha^{-1} & I_\alpha \end{pmatrix} \times \begin{pmatrix} U_\alpha & L_\alpha^{-1} F_\alpha \\ 0 & A_{\alpha+1} \end{pmatrix} = \mathbf{L}_\alpha \mathbf{U}_\alpha. \tag{4.1}$$

The whole process of finding block independent sets, permuting the matrix, and performing the restricted ILUT factorization is recursively repeated on the matrix $A_{\alpha+1}$. The recursion is stopped when the last reduced system $A_{\mathcal{L}}$ is small enough. Then a standard ILUT factorization $\mathbf{L}_{\mathcal{L}}\mathbf{U}_{\mathcal{L}}$ is performed on $A_{\mathcal{L}}$ (Algorithm 3.2). However, we do not store any reduced systems on any level, including the last one. Instead, we store two sparse matrices on each level

$$\mathbf{L}_\alpha = \begin{pmatrix} L_\alpha & 0 \\ E_\alpha U_\alpha^{-1} & I_\alpha \end{pmatrix} \qquad \text{and} \qquad \mathbf{U}_\alpha = \begin{pmatrix} U_\alpha & L_\alpha^{-1}F_\alpha \\ 0 & 0 \end{pmatrix}, \quad \text{for} \quad 0 \le \alpha < \mathcal{L}-1,$$

along with the factors $\mathbf{L}_{\mathcal{L}}$ and $\mathbf{U}_{\mathcal{L}}$.

The approximate solution on the last level is obtained by applying one sweep of ILUT of the last reduced system using the factors $\mathbf{L}_{\mathcal{L}}\mathbf{U}_{\mathcal{L}}$. This is different from the implementation of BILUM [55], where the last reduced system is solved to certain accuracy by a Krylov subspace method preconditioned by ILUT. The advantage of BILUTM includes the added flexibility in controlling the amount of fill-in (and the computation costs during the construction), especially when large-sized blocks are used.

Suppose the right-hand side b and the solution vector x are partitioned according to the independent set ordering as in (2.2); then we would have, on each level,

$$x_\alpha = \begin{pmatrix} x_{\alpha,1} \\ x_{\alpha,2} \end{pmatrix} \qquad \text{and} \qquad b_\alpha = \begin{pmatrix} b_{\alpha,1} \\ b_{\alpha,2} \end{pmatrix}.$$

The forward elimination is performed by solving for a temporary vector y_α, i.e., for $\alpha = 0, 1, \ldots, \mathcal{L}-1$, by solving

$$\begin{pmatrix} L_\alpha & 0 \\ E_\alpha U_\alpha^{-1} & I_\alpha \end{pmatrix} \begin{pmatrix} y_{\alpha,1} \\ y_{\alpha,2} \end{pmatrix} = \begin{pmatrix} b_{\alpha,1} \\ b_{\alpha,2} \end{pmatrix}, \text{ with } \begin{array}{lrcl} \text{(F1)}: & y_{\alpha,1} & = & L_\alpha^{-1} b_{\alpha,1}, \\ \text{(F2)}: & y_{\alpha,2} & = & b_{\alpha,2} - E_\alpha U_\alpha^{-1} y_{\alpha,1}. \end{array}$$

We then solve the last reduced system as

$$\mathbf{L}_{\mathcal{L}}\mathbf{U}_{\mathcal{L}} x_{\mathcal{L}} = b_{\mathcal{L}}.$$

A backward substitution is performed to obtain the solution by solving, for $\alpha = \mathcal{L}-1, \ldots, 1, 0$,

$$\begin{pmatrix} U_\alpha & L_\alpha^{-1}F_\alpha \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x_{\alpha,1} \\ x_{\alpha,2} \end{pmatrix} = \begin{pmatrix} y_{\alpha,1} \\ y_{\alpha,2} \end{pmatrix}, \text{ with } \begin{array}{lrcl} \text{(B1)}: & x_{\alpha,1} & = & y_{\alpha,1} - L_\alpha^{-1}F_\alpha x_{\alpha,2}, \\ \text{(B2)}: & x_{\alpha,1} & = & U_\alpha^{-1} x_{\alpha,1}. \end{array}$$

The backward substitution will work since $x_{\alpha,2} = x_{\alpha+1,1}$ and $x_{\mathcal{L}-1,2} = x_{\mathcal{L}}$. The preconditioned iteration process is reminiscent of a multigrid V-cycle algorithm [14], see Figure 4.1. A Krylov subspace iteration is performed on the finest level acting as a smoother; the residual is then transferred level-by-level to the coarsest level, where one sweep of ILUT is used to yield an approximate solution. In the current situation, the coarsest-level ILUT is actually a direct solver with limited accuracy comparable to the accuracy of the whole preconditioning process.

Let us rewrite (4.1) as

$$\begin{pmatrix} I_\alpha & 0 \\ E_\alpha U_\alpha^{-1} L_\alpha^{-1} & I_\alpha \end{pmatrix} \times \begin{pmatrix} L_\alpha U_\alpha & 0 \\ 0 & A_{\alpha+1} \end{pmatrix} \times \begin{pmatrix} I_\alpha & U_\alpha^{-1} L_\alpha^{-1} F_\alpha \\ 0 & I_\alpha \end{pmatrix} \tag{4.2}$$

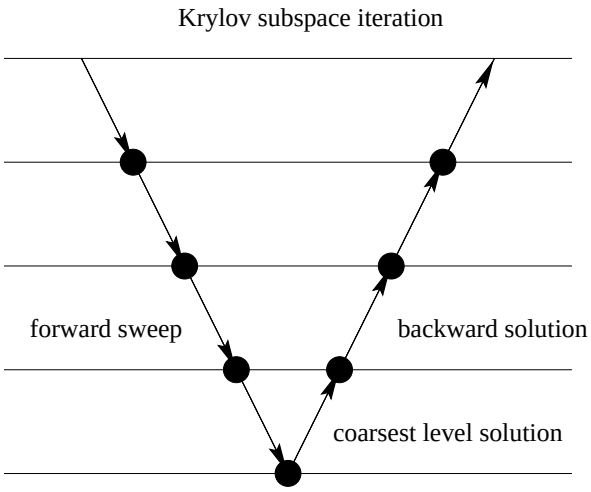

FIG. 4.1. *The multilevel structure of the BILUTM preconditioned Krylov subspace solver.*

and examine a few interesting properties. It is clear that the central part of (4.2) is an operator acting on the full vector, say, x_α ($L_\alpha U_\alpha$ on $x_{\alpha,1}$ and $A_{\alpha+1}$ on $x_{\alpha,2}$). In a two-level analysis, we may define

$$\mathbf{I}_\alpha^{\alpha+1} = \begin{pmatrix} -E_\alpha U_\alpha^{-1} L_\alpha^{-1} & I_\alpha \end{pmatrix} \qquad \text{and} \qquad \mathbf{I}_{\alpha+1}^{\alpha} = \begin{pmatrix} -U_\alpha^{-1} L_\alpha^{-1} F_\alpha \\ I_\alpha \end{pmatrix}$$

as the restriction and interpolation operators, respectively. Then the following results linking BILUTM with the algebraic multigrid methods can be verified directly; see [57].

PROPOSITION 4.1. *Suppose the factorization* (4.2) *exists and is exact. Then*

1. *the reduced system $A_{\alpha+1}$ satisfies the Galerkin condition* (2.1);
2. *if, in addition, A_α is symmetric, then $\mathbf{I}_\alpha^{\alpha+1} = \mathbf{I}_{\alpha+1}^{\alpha}{}^T$.*

The above discussion of the solution procedure omitted the permutation and inverse permutation that must be performed before and after each operation on each level. This is also the approach that we used in our current implementation (and that of BILUM [55]). On the other hand, we may permute the matrices on each level in the construction phase. In this case, only the global permutation is needed before and after the application of the preconditioner [51].

All of the steps of the procedure, including the construction of the preconditioner, are fully parallelizable, except potentially the solution of the last reduced system.[1] For example, the step (F1) of the forward solve with L_α^{-1} can be performed in parallel because only the unknowns within each block are coupled. The same is true for the backward solve with U_α^{-1} in step (B2). All other parts are just matrix-vector operations and vector updates.

Finally, the sparsity of BILUTM depends primarily on the parameter p used to control the amount of fill-in allowed and the size of the block independent sets.

PROPOSITION 4.2. *Let m_α be the size of the block independent set on level α. The number of nonzeros of BILUTM with $\mathcal{L}$ levels of reductions is bounded by $p(2n + \sum_{\alpha=1}^{\mathcal{L}} \alpha m_\alpha)$.*

[1] For this, we may employ a sparse approximate inverse technique [21] or a multicoloring strategy [52] to solve the last reduced system; see [61].

Proof. On each level $0 \le \alpha < \mathcal{L} - 1$, the L and U factors of the upper part have at most p elements in each row. The left-hand side of the lower part also has at most p elements in each row; the right-hand side (the reduced system) is not stored. Suppose the sizes of the block independent set and the vertex cover are m_α and r_α, respectively. On level α, the total number of nonzeros is bounded by $2pm_\alpha + pr_\alpha$. Since the last reduced system is factored by ILUT(τ, p), the amount of nonzeros is bounded by $2pn_{\mathcal{L}} = 2pm_{\mathcal{L}}$ and $r_{\mathcal{L}} = 0$. Summing all levels yields the bound

$$\sum_{\alpha=0}^{\mathcal{L}-1}(2pm_\alpha + pr_\alpha) + 2pm_{\mathcal{L}} = p\left(2\sum_{\alpha=0}^{\mathcal{L}} m_\alpha + \sum_{\alpha=0}^{\mathcal{L}-1} r_\alpha\right). \tag{4.3}$$

Since the nodes of all independent sets and the last reduced system constitute the order of the matrix, we have

$$\sum_{\alpha=0}^{\mathcal{L}} m_\alpha = n. \tag{4.4}$$

Note that $r_\alpha = m_{\alpha+1} + r_{\alpha+1}$ for $0 \le \alpha < \mathcal{L} - 1$, and $r_{\mathcal{L}} = 0$. It is easy to verify

$$\sum_{\alpha=0}^{\mathcal{L}-1} r_\alpha = \sum_{\alpha=1}^{\mathcal{L}} \alpha m_\alpha. \tag{4.5}$$

Substituting (4.4) and (4.5) into (4.3) gives the bound for the number of nonzeros of BILUTM as

$$2pn + p\sum_{\alpha=1}^{\mathcal{L}} \alpha m_\alpha = p\left(2n + \sum_{\alpha=1}^{\mathcal{L}} \alpha m_\alpha\right). \tag{4.6}$$

□

We remark that in (4.6), the term $2pn$ is the bound for the number of nonzeros of the standard ILUT. Due to the block structure of BILUTM, the first few rows of each block of the upper L factors have less than p elements and the overall nonzero number of BILUTM is actually smaller. The term $p\sum_{\alpha=1}^{\mathcal{L}} \alpha m_\alpha$ represents the extra nonzeros for the multilevel implementation. Note that m_0 is not in the second term and the factor α grows as the level increases. It is therefore advantageous to have large block independent sets in the first few levels.

5. Numerical experiments. Implementations of ILUM and BILUM have been described in detail in [51, 55]. One significant difference between BILUTM and BILUM and ILUM is that we do not use an inner iteration to solve the last reduced system. Instead, backward and forward solution steps are performed with the incomplete LU factors $\mathbf{L}_{\mathcal{L}}\mathbf{U}_{\mathcal{L}}$ of the last reduced system. Unless otherwise explicitly indicated, we used the following default parameters for our preconditioned iterative solver: GMRES with a restart value of 50 was used as the accelerator; the maximum number of reductions (levels) allowed was 10, i.e., $\mathcal{L} = 10$; the threshold dropping tolerance was set to be $\tau = 10^{-4}$, and the block sizes were chosen to be equal to the parameter p used to control the number of fill-in elements.

All matrices were considered general sparse matrices and any available structures were not exploited. The right-hand side was generated by assuming that the solution is a vector of all ones and the initial guess was a vector of some random numbers. The computations were terminated when the 2-norm of the residual was reduced by a factor

100000	100	43	43.8	22.5	15.2	180	25	192.5	44.7	71.5

of 10^7. We also set an upper bound of 100 for the GMRES iteration. The numerical experiments were conducted on a Power-Challenge XL Silicon Graphics workstation equipped with 512 MB of main memory, two 190 MHZ R10000 processors, and 1 MB secondary cache.

In all tables with numerical results, "bsize" is the size of the uniform blocks (used only when bsize $\neq p$), "iter" shows the number of GMRES iterations, "total" shows the CPU time in seconds for the preprocessing and solution phases, "solu" shows the CPU time for the solution phase only, and "spar" shows the sparsity ratio which is the ratio between the number of nonzeros of the preconditioner to that of the original matrix. The symbol "–" indicates lack of convergence. We mainly compare BILUTM with (single-level) ILUT and sometimes BILUTM with different parameters.

Convection-diffusion problem. We first consider a convection-diffusion problem

$$u_{xx} + u_{yy} + \mathrm{Re}(\exp(xy-1)u_x - \exp(-xy)u_y) = 0, \tag{5.1}$$

defined on the unit square. Here Re is the so-called Reynolds number. A Dirichlet boundary condition was assumed, but the linear systems used the artificially generated right-hand side as stated above. We used the standard 5-point central difference discretization scheme with a uniform mesh $h = 1/201$. The resulting matrices with different values of Re have 40,000 unknowns and 199,200 nonzeros. The percentage of the rows with diagonal dominance becomes smaller as Re increases [63].

Table 5.1 gives some performance data of BILUTM and ILUT for solving (5.1) with different Re. Here p was varied so that BILUTM and ILUT used approximately the same storage space. There was an exception for $\mathrm{Re} = 10^5$ when ILUT did not converge for $p < 180$ while BILUTM converged for $p = 100$. It can be seen that for simple problems (small Re), ILUT was more efficient than BILUTM. They performed similarly for $\mathrm{Re} = 10^4$. For $\mathrm{Re} \geq 10^5$, ILUT failed to converge unless it used very large storage space. Conversely, BILUTM did very well for this difficult problem.

Note that BILUTM took more steps to converge for small Re problems. However, note also that the inherent parallelism in BILUTM is far superior to that in ILUT. Table 5.2 gives another set of tests with larger values for p. We see that BILUTM performed better than ILUT (solution time) with high accuracy. This improvement comes without sacrificing potential for parallelism but the cost of preprocessing increased somewhat.

The next test is to show how the performance of BILUTM is affected by the block sizes. Here we chose $p = 10$ and $\mathrm{Re} = 10^3$. The size of the uniform blocks varied from 1 to 400. Note that for the large block sizes, we actually had only three levels of reductions. The results are given in Table 5.3.

We note that for most values of the block size, the performance of BILUTM has no significant difference. This property is desirable since it implies that, for this test

problem and with current test conditions, the convergence rate of BILUTM would not be very sensitive to the number of processors had our test been implemented on a parallel computer.

TOKAMAK matrices. The TOKAMAK matrices are real unsymmetric matrices which arise from nuclear fusion plasma simulations in a tokamak reactor.[2] These are part of the SPARSKIT collections and have been provided by P. Brown of Lawrence Livermore National Laboratory. Table 5.4 shows some data on these matrices.

The solution details for the first four TOKAMAK matrices are listed in Table 5.5, and those for UTM5940 are listed in Table 5.6. We note that for the first three matrices of small sizes, ILUT seemed to outperform BILUTM, given a similar memory consumption. They were almost tied for UTM3060. For the largest TOKAMAK matrix, BILUTM performed much better than ILUT by virtually all measures (Table 5.6). In fact, ILUT could not converge for $p \leq 70$, while BILUTM still converged

[2]The TOKAMAK matrices are available online from the matrix market of the National Institute of Standards Technology at http://math.nist.gov/MatrixMarket.

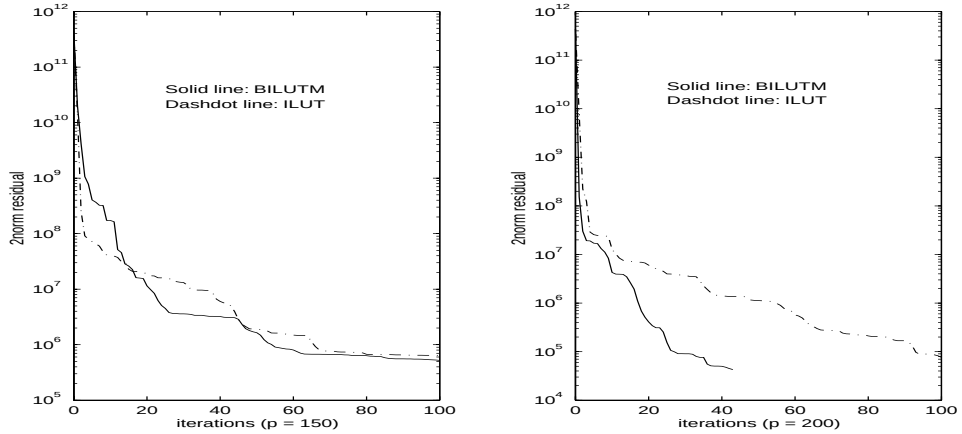

FIG. 5.1. *Convergence history of BILUTM and ILUT for solving the RAEFSKY4 matrix.*

with $p = 20$. It can be seen that BILUTM needed less than half the storage required for ILUT to converge. With more storage space made available for ILUT, BILUTM still outperformed ILUT with a faster convergence rate (and less memory consumption.)

RAEFSKY4 matrix. The RAEFSKY4 matrix[3] has 19,779 unknowns and 1,328,611 nonzeros. It is from the buckling problem for the container model and was supplied by H. Simon from Lawrence Berkeley National Laboratory (originally created by A. Raefsky from Centric Engineering). This is probably the hardest one in the total of six RAEFSKY matrices. (BILUM with diagonal threshold techniques was able to solve all but the RAEFSKY4 matrix [56].) In order for BILUTM to converge fast, we found it necessary to use a larger restart value (100) for GMRES. Figure 5.1 shows the convergence history of BILUTM and ILUT with $p = 150$ and 200, respectively. In both tests, the block size was 200 for BILUTM. We note that with $p = 150$, both preconditioners had similar lack of full convergence. However, with $p = 200$, BILUTM converged in 43 iterations while ILUT was still not fully converged in 100 iterations.

Figure 5.2 depicts performance comparisons when BILUTM was used with differ-

ent parameters. The left part of Figure 5.2 shows that BILUTM with block size 100 gave the best results. Larger and smaller block sizes resulted in deterioration of convergence. The right part of Figure 5.2 shows that $\tau = 10^{-4}$ was the best among the three values tested for this parameter. It is interesting to note that higher accuracy ($\tau = 10^{-5}$) did not yield faster convergence.

WIGTO966 matrix. The WIGTO966 matrix[4] has 3,864 unknowns and 238,252 nonzeros. It comes from an Euler equation model and was supplied by L. Wigton from Boeing. It is solvable by ILUT with large values of p [19]. This matrix was also used to compare BILUM with ILUT in [54] and to test point and block preconditioning techniques in [20, 22]. BILUM (with GMRES(10)) was shown to be six times faster than ILUT with only one-third of the memory required by ILUT [54]. In our current tests, we chose several values for τ and p for BILUTM and ILUT, and the size of the blocks in case of BILUTM. We tabulate the results in Table 5.7. Amazingly BILUTM converged for this problem with a sparsity ratio of 1.60. The smallest sparsity ratio that yields convergence for ILUT is 7.90. In addition, BILUTM converged almost five

[4]The WIGTO966 matrix is available from the authors.

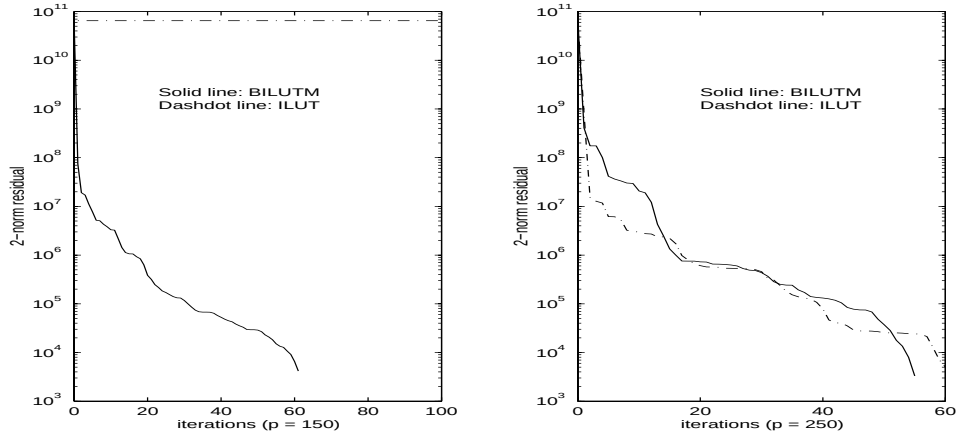

FIG. 5.3. *Convergence history of BILUTM and ILUT with different amount of fill-in (p) for solving the OLAFU matrix.*

times faster (total CPU time) than ILUT and used just about one-fifth of the memory that was required by ILUT.

OLAFU matrix. The OLAFU matrix[5] has 16,146 unknowns and 1,015,156 nonzeros. It is a structural modeling problem from NASA Langley. The tests with OLAFU also used GMRES(100) as the accelerator. Figure 5.3 shows the comparison between BILUM and ILUT with two different values of p. We point out that with $p = 150$, ILUT did not show any signs of convergence (see the left part of Figure 5.3), while BILUTM converged within 61 iterations. The right part of Figure 5.3 shows that ILUT did converge with more fill-in ($p = 200$), but BILUTM was still faster. These results indicate that the OLAFU matrix cannot be solved by ILUT without sufficient accuracy. We remark that for the comparison shown in Figure 5.3, both BILUTM

[5]The OLAFU matrix is available online from the University of Florida sparse matrix collection [24] at http://www.cise.ufl.edu/~davis/sparse.

TABLE 5.8
Description of the BARTH matrices.

BARTHS2A	15 735	1 510 325	Small airfoil 2D Navier–Stokes, distance 2

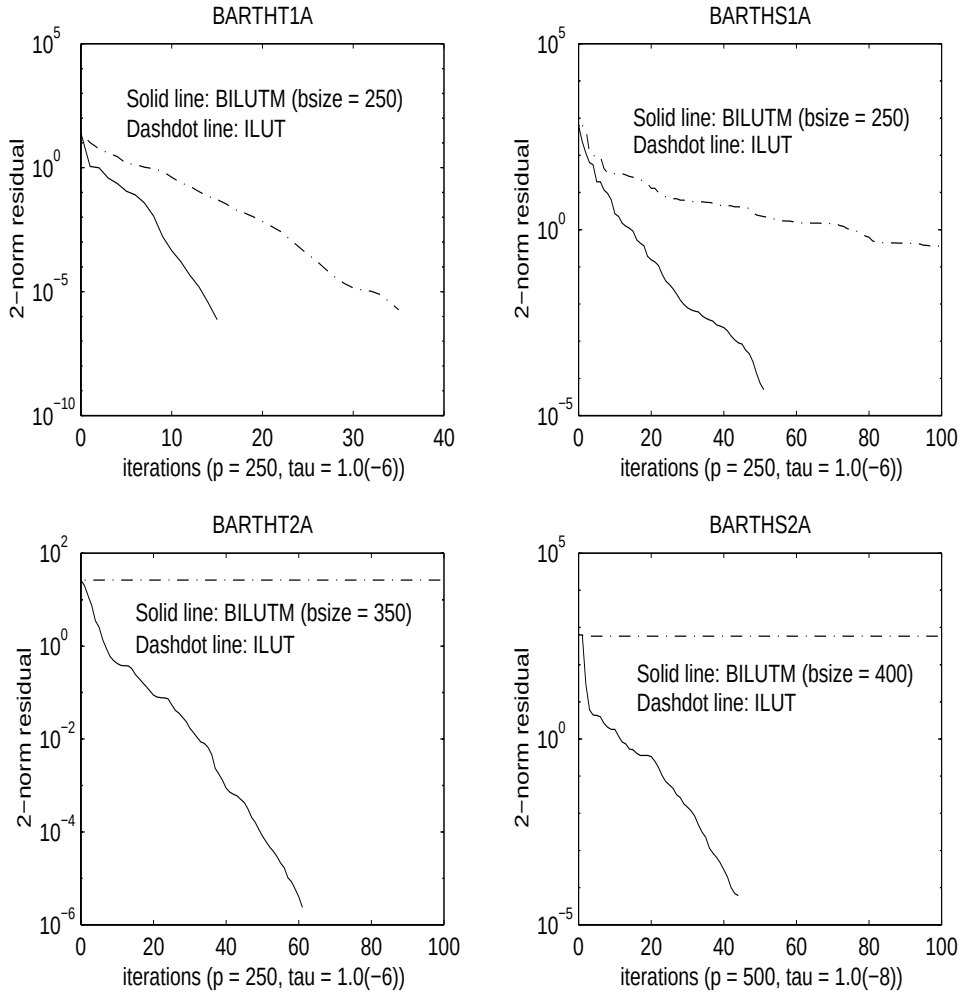

FIG. 5.5. *Convergence history of BILUTM and ILUT for solving the BARTH matrices.*

and ILUT used approximately the same memory space for the same value of p.

In Figure 5.4, we show test results of using BILUTM with different parameters to solve OLAFU. The parameter $p = 150$ was fixed. The left part of Figure 5.4 shows that the size of the blocks did affect the convergence of BILUTM for this large problem. It seems that taking the block size to be equal to the fill-in parameter p yielded the best results. The right part of Figure 5.4 indicates that the number of levels (reductions) did not have significant effect on the convergence of BILUTM. This is probably because the largest independent set had been factored out in the

first level and the use of ILUT on the coarsest level gave comparable accuracy. Recall that there is a big difference between one level of reduction and no reduction at all, since Figure 5.3 shows that BILUTM without reduction (actually equivalent to ILUT) failed to converge.

BARTH matrices. The BARTH matrices[6] were supplied by T. Barth of NASA Ames. They are for a two-dimensional high Reynolds number airfoil problem, with one equation turbulence model. The S and T matrices are results of using different grids. The grid of the T matrices has a concentration of elements unrealistically close to the airfoil. The four BARTH matrices are described in Table 5.8. Note that in order for ILUT and BILUTM to work properly, zero diagonals are added. The BARTH matrices have been used as test matrices for other ILU-type techniques in [19], but none of them has been solved by enhanced BILUM techniques [57], partly because of the prohibitive computation and memory costs associated with the use of very large-sized blocks (on the given computer).

We present in Figure 5.5 only one set of comparisons of BILUTM and ILUT by solving the BARTH matrices using large size blocks and GMRES(100). We remark that for this set of test parameters, ILUT took about three times more CPU time (BARTHT1A) and used about 20% more memory than BILUTM did. We found that BILUTM converged much faster than ILUT for these indefinite matrices with small and zero diagonals. For the two largest BARTH matrices, ILUT almost completely failed to reduce the residual norm within 100 iterations, while BILUTM converged satisfactorily.

6. Concluding remarks. We have presented a mulitlevel block ILU preconditioner with a dual dropping strategy for solving general sparse matrices. The method offers flexibility in controlling the amount of fill-in during the ILU factorization when large size blocks are used for domain decomposition based implementation of multilevel ILU preconditioning method. A particular merit of BILUTM is that both the construction and application phases of the preconditioner have a high level of inherent parallelism.

We gave an upper bound for the number of nonzeros of the preconditioner. We showed that the extra storage costs of multilevel implementation are not substantial if large block independent sets can be found in the first few reductions. It may also be beneficial not to have too many levels, especially when the size of the block independent sets becomes small.

Our numerical experiments with several matrices show that the proposed technique indeed demonstrates the anticipated flexibility and effectiveness. As a parallelizable high accuracy preconditioner, BILUTM is comparable with sequential ILUT for solving easy problems. For some difficult problems, where high accuracy preconditioning is a must, BILUTM is more robust and is more efficient than ILUT and usually requires less memory. In other words, this preconditioner does not sacrifice convergence in order to improve parallelism. This is in sharp contrast with lower order preconditioner such as ILU(0) or the high-order single-level preconditioner such as ILUT.

Although we did not directly compare BILUTM with other multilevel preconditioning techniques, we did remark that BILUTM solved several difficult matrices that might not be solved by BILUM efficiently on the given computer because of the computation and memory costs associated with the use of very large size blocks.

[6]The BARTH matrices are available from the authors.

Implementations of grid-based multilevel methods on parallel and vector computers can be found in [41] (for structured matrices) and those of domain-based (two-level) methods can be found in [53, 54]. Those and other implementations on shared-memory machines [11] demonstrate the advantage of the inherent parallelism of the multilevel preconditioning methods. Conversely, implementing multilevel preconditioning methods on distributed-memory machines requires the consideration of cost trade-off between communications and computations. It is obviously not advantageous to have too small blocks and too many levels. The parallel solution of the last reduced system may also be desirable in certain applications.

THE CHANGE-OF-VARIABLES FORMULA USING MATRIX VOLUME*

ADI BEN-ISRAEL†

Abstract. The matrix volume is a generalization, to rectangular matrices, of the absolute value of the determinant. In particular, the matrix volume can be used in change-of-variables formulae, instead of the determinant (if the Jacobi matrix of the underlying transformation is rectangular). This result is applicable to integration on surfaces, illustrated here by several examples.

Key words. determinants, Jacobians, matrix volume, change-of-variables in integration, surface integrals, Radon transform, Fourier transform, generalized Pythagorean theorem

1. Introduction.

The change-of-variables formula is

$$\int_{\mathcal{V}} f(\mathbf{v})\, d\mathbf{v} = \int_{\mathcal{U}} (f \circ \phi)(\mathbf{u})\ |\det J_\phi(\mathbf{u})|\ d\mathbf{u}, \tag{1}$$

where $\mathcal{U}, \mathcal{V}$ are sets in $\mathbb{R}^n$, ϕ is a sufficiently well-behaved function: $\mathcal{U} \to \mathcal{V}$, and f is integrable on $\mathcal{V}$. Here $d\mathbf{x}$ denotes the volume element $|dx_1 \wedge dx_2 \wedge \cdots \wedge dx_n|$, and J_ϕ is the Jacobi matrix (or Jacobian)

$$J_\phi := \left(\frac{\partial \phi_i}{\partial u_j}\right), \quad \text{also denoted} \quad \frac{\partial(v_1, v_2, \ldots, v_n)}{\partial(u_1, u_2, \ldots, u_n)},$$

representing the derivative of ϕ. An advantage of (1) is that integration on $\mathcal{V}$ is translated to (perhaps simpler) integration on $\mathcal{U}$.

This formula was given in 1841 by Jacobi [8], following Euler (the case $n = 2$) and Lagrange ($n = 3$). It gave prominence to functional (or symbolic) determinants, i.e., (nonnumerical) determinants of matrices including functions or operators as elements.

If $\mathcal{U}$ and $\mathcal{V}$ are in spaces of different dimensions, say, $\mathcal{U} \subset \mathbb{R}^n$ and $\mathcal{V} \subset \mathbb{R}^m$ with $n > m$, then the Jacobian J_ϕ is a rectangular matrix and (1) cannot be used in its present form. However, if J_ϕ is of full column rank throughout $\mathcal{U}$, we can replace $|\det J_\phi|$ in (1) by the volume $\operatorname{vol} J_\phi$ of the Jacobian to get

$$\int_{\mathcal{V}} f(\mathbf{v})\, d\mathbf{v} = \int_{\mathcal{U}} (f \circ \phi)(\mathbf{u}) \operatorname{vol} J_\phi(\mathbf{u})\, d\mathbf{u}. \tag{2}$$

Recall that the volume of an $m \times n$ matrix of rank r is

$$\operatorname{vol} A := \sqrt{\sum_{(I,J)\in\mathcal{N}} \det^2 A_{IJ}}, \tag{3}$$

†Rutgers Center for Operations Research, Rutgers University, 640 Bartholomew Road, Piscataway, NJ 08854-8003 (bisrael@rutcor.rutgers.edu).

where A_{IJ} is the submatrix of A with rows I and columns J, and $\mathcal{N}$ is the index set of $r \times r$ nonsingular submatrices of A; see, e.g., [1]. Alternatively, $\operatorname{vol} A$ is the product of the singular values of A. If A is of full column rank, its volume is simply

$$\operatorname{vol} A = \sqrt{\det A^T A}. \tag{4}$$

If $m = n$, then $\operatorname{vol} J_\phi = |\det J_\phi|$ and (2) reduces to the classical result (1).

The formula (2) is well known in differential geometry; see, e.g., [2, Proposition 6.6.1] and [6, section 3.2.3]. Although there are elementary accounts of this formula (see, e.g., [3, Volume II, Chapter IV, section 4], [7, section 8.1], and [13, section 3.4]), it is infrequently used in applications.

The objectives of this note are (i) to establish the usefulness of (2) for various surface integrals, (ii) to simplify the computation of the Radon and Fourier transforms and general integrals in $\mathbb{R}^n$ (see Examples 7–9 and Appendix A below), and (iii) to introduce the *functional matrix volume*, in analogy with the functional determinant.

We illustrate (2) for an elementary calculus example. Let $\mathcal{S}$ be a subset of a surface in $\mathbb{R}^3$ represented by

$$z = g(x, y) \tag{5}$$

and let $f(x, y, z)$ be a function integrable on $\mathcal{S}$. Let $\mathcal{A}$ be the projection of $\mathcal{S}$ on the xy-plane. Then $\mathcal{S}$ is the image of $\mathcal{A}$ under a mapping ϕ

$$\mathcal{S} = \phi(\mathcal{A}) \quad \text{or} \quad \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x \\ y \\ g(x,y) \end{pmatrix} = \phi \begin{pmatrix} x \\ y \end{pmatrix}, \quad \begin{pmatrix} x \\ y \end{pmatrix} \in \mathcal{A}. \tag{6}$$

The Jacobi matrix of ϕ is the 3×2 matrix

$$J_\phi(x, y) = \frac{\partial(x, y, z)}{\partial(x, y)} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ g_x & g_y \end{pmatrix}, \tag{7}$$

where $g_x = \frac{\partial g}{\partial x}$, $g_y = \frac{\partial g}{\partial y}$. The volume of (7) is, by (4),

$$\operatorname{vol} J_\phi(x, y) = \sqrt{1 + g_x^2 + g_y^2}. \tag{8}$$

Substituting (8) into (2) we get the well-known formula

$$\int_{\mathcal{S}} f(x, y, z)\, ds = \int_{\mathcal{A}} f(x, y, g(x, y)) \sqrt{1 + g_x^2 + g_y^2}\, dx\, dy, \tag{9}$$

giving an integral over $\mathcal{S}$ as an integral over its projection in the xy-plane.

The simplicity of this approach is not lost in higher dimensions or with different coordinate systems, as demonstrated below by 11 elementary examples from calculus and analysis.

- Example 1 concerns line integrals, in particular the *arc length* of a curve in $\mathbb{R}^n$.
- Example 2 is an application to surface integration in $\mathbb{R}^3$ using cylindrical coordinates.
- Examples 3 and 4 concern integration on an *axially symmetric surface* (or *surface of revolution*) in $\mathbb{R}^3$. In these integrals, the volume of J_ϕ contains the necessary information on the surface symmetry.

- Example 5 shows integration on an $(n-1)$-dimensional surface in $\mathbb{R}^n$.
- The area of the unit sphere in $\mathbb{R}^n$, a classical exercise, is computed in Example 6.
- Example 7 uses (2) to compute the Radon transform of a function $f : \mathbb{R}^n \to \mathbb{R}$.
- Example 8 computes an integral over $\mathbb{R}^n$ as an integral on $\mathbb{R}^{n-1}$ followed by an integral on $\mathbb{R}$.
- Example 9 applies this to the computation of the Fourier transforms of a function $f : \mathbb{R}^n \to \mathbb{R}$.
- The last two examples concern simplex faces in $\mathbb{R}^n$. Example 10 is the generalized Pythagorean theorem. Example 11 computes the largest face of the n-dimensional regular simplex.

These examples show that the full rank assumption for J_ϕ is quite natural and presents no real restriction in applications.

The solutions given here should be compared with the "classical" solutions, as taught in calculus. We see that (2) offers a unified method for a variety of curve and surface integrals and coordinate systems, without having to construct (and understand) the differential geometry in each application. The computational tractability of (2) is illustrated in Appendix A.

By a blanket assumption, throughout this paper all functions are continuously differentiable as needed, all surfaces are smooth, and all curves are rectifiable.

2. Examples and applications. If the mapping $\phi : \mathcal{U} \to \mathcal{V}$ is given by

$$y_i = \phi_i(x_1, x_2, \ldots, x_n), \quad i \in \overline{1, m},$$

we denote its Jacobi matrix J_ϕ by

$$\frac{\partial(y_1, y_2, \ldots, y_m)}{\partial(x_1, x_2, \ldots, x_n)} = \left(\frac{\partial \phi_i}{\partial x_j}\right), \quad i \in \overline{1, m}\,,\ j \in \overline{1, n}, \tag{10}$$

the customary notation for Jacobi matrices (in the square case).

Example 1. Let $\mathcal{C}$ be an arc on a curve in $\mathbb{R}^n$, represented in parametric form as

$$\mathcal{C} := \phi([0,1]) = \{(x_1, x_2, \ldots, x_n) \,:\, x_i := \phi_i(t),\ 0 \le t \le 1\}. \tag{11}$$

The Jacobi matrix $J_\phi(t) = \frac{\partial(x_1, x_2, \ldots, x_n)}{\partial t}$ is the column matrix $(\phi_i'(t))$ and its volume is

$$\operatorname{vol} J_\phi = \sqrt{\sum_{i=1}^{n} \left(\phi_i'(t)\right)^2}.$$

The *line integral* (assuming it exists) of a function f along $\mathcal{C}$, $\int_{\mathcal{C}} f$, is given in terms of the volume of J_ϕ as follows:

$$\int_{\mathcal{C}} f = \int_0^1 f(\phi_1(t), \ldots, \phi_n(t)) \sqrt{\sum_{i=1}^{n} \left(\phi_i'(t)\right)^2}\, dt. \tag{12}$$

In particular, $f \equiv 1$ gives

$$\text{arc length } \mathcal{C} = \int_0^1 \sqrt{\sum_{i=1}^{n} \left(\phi_i'(t)\right)^2}\, dt. \tag{13}$$

If one of the variables, say, $a \le x_1 \le b$, is used as parameter, (13) gives the familiar result

$$\text{arc length } \mathcal{C} = \int_a^b \sqrt{1 + \sum_{i=2}^{n} \left(\frac{dx_i}{dx_1}\right)^2}\, dx_1.$$

Example 2. Let $\mathcal{S}$ be a surface in $\mathbb{R}^3$ represented by

$$z = z(r, \theta), \tag{14}$$

where $\{r, \theta, z\}$ are *cylindrical coordinates*

$$x = r\,\cos\theta, \tag{15a}$$
$$y = r\,\sin\theta, \tag{15b}$$
$$z = z. \tag{15c}$$

The Jacobi matrix of the mapping (15a), (15b), and (14) is

$$\frac{\partial(x, y, z)}{\partial(r, \theta)} = \begin{pmatrix} \cos\theta & -r\,\sin\theta \\ \sin\theta & r\,\cos\theta \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial \theta} \end{pmatrix}; \tag{16}$$

see also (A.4), Appendix A. The volume of (16) is

$$\text{vol } J_\phi = \sqrt{r^2 + r^2 \left(\frac{\partial z}{\partial r}\right)^2 + \left(\frac{\partial z}{\partial \theta}\right)^2} = r\sqrt{1 + \left(\frac{\partial z}{\partial r}\right)^2 + \frac{1}{r^2}\left(\frac{\partial z}{\partial \theta}\right)^2}; \tag{17}$$

see also (A.7), Appendix A. An integral over a domain $\mathcal{V} \subset \mathcal{S}$ is therefore

$$\int_{\mathcal{V}} f(x, y, z)\, dV = \int_{\mathcal{U}} f(r\,\cos\theta,\, r\,\sin\theta, z(r, \theta))\, r \sqrt{1 + \left(\frac{\partial z}{\partial r}\right)^2 + \frac{1}{r^2}\left(\frac{\partial z}{\partial \theta}\right)^2}\, dr\, d\theta. \tag{18}$$

Example 3. Let $\mathcal{S}$ be a surface in $\mathbb{R}^3$, symmetric about the z-axis. This axial symmetry is expressed in cylindrical coordinates by

$$z = z(r) \quad \text{or} \quad \frac{\partial z}{\partial \theta} = 0 \quad \text{in} \quad (16)\text{–}(18).$$

The volume (17) thus becomes

$$\text{vol } J_\phi = r\sqrt{1 + z'(r)^2} \tag{19}$$

with the axial symmetry "built in." An integral over a domain $\mathcal{V}$ in a z-symmetric surface $\mathcal{S}$ is therefore

$$\int_{\mathcal{V}} f(x, y, z)\, dV = \int_{\mathcal{U}} f(r\,\cos\theta, r\,\sin\theta, z(r))\, r\sqrt{1 + z'(r)^2}\, dr\, d\theta.$$

Example 4. Again let $\mathcal{S}$ be a z-symmetric surface in $\mathbb{R}^3$. We use *spherical coordinates*

$$x = \rho \sin\phi \cos\theta, \tag{20a}$$

$$y = \rho \sin\phi \sin\theta, \tag{20b}$$

$$z = \rho \cos\phi. \tag{20c}$$

The axial symmetry is expressed by

$$\rho \;:=\; \rho(\phi),$$

showing that $\mathcal{S}$ is given in terms of the two variables ϕ and θ. The volume of the Jacobi matrix is easily computed,

$$\operatorname{vol} \frac{\partial(x,y,z)}{\partial(\phi,\theta)} = \rho \sqrt{\rho^2 + (\rho'(\phi))^2}\, \sin\phi,$$

and the change-of-variables formula gives

$$\int_{\mathcal{V}} f(x,y,z)\, dV = \int_{\mathcal{U}} f(\rho(\phi)\, \sin\phi\, \cos\theta, \rho(\phi)\, \sin\phi\, \sin\theta, \rho(\phi)\, \cos\phi)\, \rho(\phi) \sqrt{\rho(\phi)^2 + (\rho'(\phi))^2}\, \sin\phi\, d\phi\, d\theta. \tag{21}$$

Example 5. Let a surface $\mathcal{S}$ in $\mathbb{R}^n$ be given by

$$x_n \;:=\; g(x_1, x_2, \ldots, x_{n-1}), \tag{22}$$

let $\mathcal{V}$ be a subset on $\mathcal{S}$, and let $\mathcal{U}$ be the projection of $\mathcal{V}$ on $\mathbb{R}^{n-1}$, the space of variables $(x_1, \ldots, x_{n-1})$. The surface $\mathcal{S}$ is the graph of the mapping $\phi : \mathcal{U} \to \mathcal{V}$, given by its components $\phi \;:=\; (\phi_1, \phi_2, \ldots, \phi_n)$,

$$\begin{aligned} &\phi_i(x_1, \ldots, x_{n-1}) := x_i, \quad i = 1, \ldots, n-1, \\ &\phi_n(x_1, \ldots, x_{n-1}) := g(x_1, \ldots, x_{n-1}). \end{aligned}$$

The Jacobi matrix of ϕ is

$$J_\phi = \begin{pmatrix} 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 \\ 0 & 0 & \ddots & 0 & 0 \\ 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & \cdots & 0 & 1 \\ \dfrac{\partial g}{\partial x_1} & \dfrac{\partial g}{\partial x_2} & \cdots & \dfrac{\partial g}{\partial x_{n-2}} & \dfrac{\partial g}{\partial x_{n-1}} \end{pmatrix}$$

and its volume is

$$\operatorname{vol} J_\phi = \sqrt{1 + \sum_{i=1}^{n-1} \left(\frac{\partial g}{\partial x_i}\right)^2}. \tag{23}$$

For any function f integrable on $\mathcal{V}$ we therefore have

(24)
$$\int_{\mathcal{V}} f(x_1, x_2, \ldots, x_{n-1}, x_n)\, dV$$
$$= \int_{\mathcal{U}} f(x_1, x_2, \ldots, x_{n-1}, g(x_1, x_2, \ldots, x_{n-1})) \sqrt{1 + \sum_{i=1}^{n-1} \left(\frac{\partial g}{\partial x_i}\right)^2}\, dx_1 dx_2 \cdots dx_{n-1}.$$

In particular, $f \equiv 1$ gives the area of $\mathcal{V}$

$$\int_{\mathcal{V}} 1\, dV = \int_{\mathcal{U}} \sqrt{1 + \sum_{i=1}^{n-1} \left(\frac{\partial g}{\partial x_i}\right)^2}\, dx_1 dx_2 \cdots dx_{n-1}. \tag{25}$$

Example 6. Let $\mathcal{B}_n$ be the unit ball in $\mathbb{R}^n$, $\mathcal{S}_n$ the unit sphere, and a_n the area of $\mathcal{S}_n$. Integrals on $\mathcal{S}_n$, in particular the area a_n, can be computed using spherical coordinates, e.g., [12, section VII.2], or the surface element of $\mathcal{S}_n$, e.g., [11]. An alternative, simpler, approach is to use the results of Example 5, representing the "upper hemisphere" as $\phi(\mathcal{B}_{n-1})$, where $\phi = (\phi_1, \phi_2, \ldots, \phi_n)$ is

$$\phi_i(x_1, x_2, \ldots, x_{n-1}) = x_i \ , \ i \in \overline{1, n-1},$$
$$\phi_n(x_1, x_2, \ldots, x_{n-1}) = \sqrt{1 - \sum_{i=1}^{n-1} x_i^2}.$$

The Jacobi matrix is

$$J_\phi = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -\dfrac{x_1}{x_n} & -\dfrac{x_2}{x_n} & \cdots & -\dfrac{x_{n-1}}{x_n} \end{pmatrix}$$

and its volume is easily computed:

$$\operatorname{vol} J_\phi = \sqrt{1 + \sum_{i=1}^{n-1} \left(\frac{x_i}{x_n}\right)^2} = \frac{1}{|x_n|} = \frac{1}{\sqrt{1 - \sum_{i=1}^{n-1} x_i^2}}. \tag{26}$$

The area a_n is twice the area of the "upper hemisphere." Therefore, by (26),

$$a_n = 2 \int_{\mathcal{B}_{n-1}} \frac{dx_1 dx_2 \cdots dx_{n-1}}{\sqrt{1 - \sum_{i=1}^{n-1} x_i^2}}, \tag{27}$$

which is easily integrated to give

$$a_n = \frac{2\, \pi^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}\right)} \tag{28}$$

using well-known properties of the *beta function*

$$B(p,q) := \int_0^1 (1-x)^{p-1}\ x^{q-1}\ dx,$$

and the *gamma function* $\quad \Gamma(p) := \displaystyle\int_0^\infty x^{p-1}\ e^{-x}\ dx.$

Example 7 (Radon transform). Let $\mathcal{H}_{\boldsymbol{\xi},p}$ be a hyperplane in $\mathbb{R}^n$ represented by

$$\mathcal{H}_{\boldsymbol{\xi},p} := \left\{ \mathbf{x} \in \mathbb{R}^n : \sum_{i=1}^n \xi_i\, x_i = p \right\} = \{\mathbf{x} : \langle \boldsymbol{\xi}, \mathbf{x} \rangle = p\}, \tag{29}$$

where $\xi_n \neq 0$ in the normal vector $\boldsymbol{\xi} = (\xi_1, \ldots, \xi_n)$ of $\mathcal{H}_{\boldsymbol{\xi},p}$. (Such hyperplanes are called *nonvertical*.) Then $\mathcal{H}_{\boldsymbol{\xi},p}$ is given by

$$x_n \ := \ \frac{p}{\xi_n} - \sum_{i=1}^{n-1} \frac{\xi_i}{\xi_n}\, x_i, \tag{30}$$

which is of the form (22). The volume (23) is here

$$\operatorname{vol} J_\phi = \sqrt{1 + \sum_{i=1}^{n-1} \left(\frac{\xi_i}{\xi_n} \right)^2} = \frac{\|\boldsymbol{\xi}\|}{|\xi_n|}. \tag{31}$$

The Radon transform $(\mathbf{R}f)(\boldsymbol{\xi}, p)$ of a function $f : \mathbb{R}^n \to \mathbb{R}$ is its integral over the hyperplane $\mathcal{H}_{\boldsymbol{\xi},p}$ (see [4])

$$(\mathbf{R}f)(\boldsymbol{\xi}, p) \ := \int_{\{\mathbf{x}:\langle \boldsymbol{\xi}, \mathbf{x} \rangle = p\}} f(\mathbf{x})\, d\mathbf{x}. \tag{32}$$

Using (30) and (31), the Radon transform can be computed as an integral in $\mathbb{R}^{n-1}$:

$$(\mathbf{R}f)(\boldsymbol{\xi}, p) = \frac{\|\boldsymbol{\xi}\|}{|\xi_n|} \int_{\mathbb{R}^{n-1}} f\left(x_1, \ldots, x_{n-1}, \frac{p}{\xi_n} - \sum_{i=1}^{n-1} \frac{\xi_i}{\xi_n}\, x_i \right) dx_1 dx_2 \cdots dx_{n-1}. \tag{33}$$

See (A.15) and (A.17), Appendix A, for Radon transform in $\mathbb{R}^2$ and (A.20) for $\mathbb{R}^3$.

In tomography applications the Radon transforms $(\mathbf{R}f)(\boldsymbol{\xi}, p)$ are computed by the scanning equipment, so (33) is not relevant. The issue is the *inverse problem* of reconstructing f from its Radon transforms $(\mathbf{R}f)(\boldsymbol{\xi}, p)$ for all $\boldsymbol{\xi}, p$. The inverse Radon transform is also an integral (see, e.g., [4], [12]) and can be expressed analogously to (33), using the method of the next example.

Example 8. Consider an integral over $\mathbb{R}^n$:

$$\int_{\mathbb{R}^n} f(\mathbf{x})\, d\mathbf{x} = \int_{\mathbb{R}^n} f(x_1, x_2, \ldots, x_n)\, dx_1 dx_2 \cdots dx_n. \tag{34}$$

Since $\mathbb{R}^n$ is a union of (parallel) hyperplanes,

$$\mathbb{R}^n = \bigcup_{p=-\infty}^{\infty} \{\mathbf{x} : \langle \boldsymbol{\xi}, \mathbf{x} \rangle = p\}, \quad \text{where } \boldsymbol{\xi} \neq \mathbf{0}, \tag{35}$$

we can compute (34) iteratively: an integral over $\mathbb{R}^{n-1}$ (Radon transform), followed by an integral on $\mathbb{R}$,

$$\int_{\mathbb{R}^n} f(\mathbf{x})\, d\mathbf{x} = \int_{-\infty}^{\infty} \frac{dp}{\|\boldsymbol{\xi}\|}\, (\mathbf{R}f)(\boldsymbol{\xi}, p), \tag{36}$$

where $dp/\|\boldsymbol{\xi}\|$ is the differential of the distance along $\boldsymbol{\xi}$ (i.e., dp times the distance between the parallel hyperplanes $\mathcal{H}_{\boldsymbol{\xi},p}$ and $\mathcal{H}_{\boldsymbol{\xi},p+1}$). Combining (33) and (36) we get the integral of f on $\mathbb{R}^n$:

$$\begin{aligned}\int_{\mathbb{R}^n} & f(\mathbf{x})\, d\mathbf{x} \\ &= \frac{1}{|\xi_n|} \int_{-\infty}^{\infty} \left\{ \int_{\mathbb{R}^{n-1}} f\left(x_1, \ldots, x_{n-1}, \frac{p}{\xi_n} - \sum_{i=1}^{n-1} \frac{\xi_i}{\xi_n}\, x_i \right) dx_1 dx_2 \cdots dx_{n-1} \right\} dp;\end{aligned} \tag{37}$$

see (A.21), Appendix A, for integration over $\mathbb{R}^3$.

It is possible to derive (37) directly from the classical change-of-variables formula (1) by changing variables from $\{x_1, \ldots, x_{n-1}, x_n\}$ to $\{x_1, \ldots, x_{n-1}, p := \sum_{i=1}^n \xi_i x_i\}$ and using

$$\det\left(\frac{\partial(x_1, \ldots, x_{n-1}, x_n)}{\partial(x_1, \ldots, x_{n-1}, p)} \right) = \frac{1}{\xi_n}.$$

An advantage of our development is that it can be used recursively, i.e., the inner integral in (37) can again be expressed as an integral in $\mathbb{R}^{n-2}$ followed by an integral in $\mathbb{R}$, etc.

Example 9 (Fourier transform). In particular, the Fourier transform $(\mathbf{F}f)(\boldsymbol{\xi})$ of f is the integral

$$\begin{aligned}(\mathbf{F}f)(\boldsymbol{\xi}) &:= (2\,\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-i\langle \boldsymbol{\xi}, \mathbf{x} \rangle}\, f(\mathbf{x})\, d\mathbf{x} \\ &= (2\,\pi)^{-n/2} \int_{\mathbb{R}^n} f\,(x_1, \ldots, x_n)\ \exp\left\{ -i \sum_{k=1}^{n} \xi_k\, x_k \right\} dx_1 dx_2 \cdots dx_n.\end{aligned} \tag{38}$$

For $\xi_n \neq 0$ we can compute (38) analogously to (37) as

$$(\mathbf{F}f)(\boldsymbol{\xi}) = \frac{(2\pi)^{-n/2}}{|\xi_n|} \int_{-\infty}^{\infty} e^{-ip} \left\{ \int_{\mathbb{R}^{n-1}} f\left(x_1, \ldots, x_{n-1}, \frac{p}{\xi_n} - \sum_{i=1}^{n-1} \frac{\xi_i}{\xi_n} x_i \right) \prod_{k=1}^{n-1} dx_k \right\} dp. \tag{39}$$

The Fourier transform of a function of n variables is thus computed as an integral over $\mathbb{R}^{n-1}$ followed by an integral on $\mathbb{R}$. The inverse Fourier transform of a function $g(\boldsymbol{\xi})$ is of the same form as (38),

$$(\mathbf{F}^{-1}g)(\mathbf{x}) := (2\,\pi)^{-n/2} \int_{\mathbb{R}^n} e^{i\langle \mathbf{x}, \boldsymbol{\xi} \rangle}\, g(\boldsymbol{\xi})\, d\boldsymbol{\xi}, \tag{40}$$

and can be computed as in (39).

Example 10 (the generalized Pythagorean theorem [10]). Consider an n-dimensional simplex

$$\boldsymbol{\Delta}_n \ := \ \left\{ (x_1, x_2, \ldots, x_n) \ : \ \sum_{i=1}^{n} a_i\, x_i \leq a_0,\ x_i \geq 0,\ i \in \overline{1, n} \right\}, \tag{41}$$

with all $a_j > 0\,,\ j \in \overline{0,n}$. We denote the $n+1$ faces of $\mathbf{\Delta}_n$ by

$$\mathcal{F}_0 := \left\{ (x_1, x_2, \ldots, x_n) \in \mathbf{\Delta}_n \,:\, \sum_{i=1}^n a_i\, x_i = a_0 \right\} \tag{42a}$$

$$\mathcal{F}_j := \{ (x_1, x_2, \ldots, x_n) \in \mathbf{\Delta}_n \,:\, x_j = 0 \}\,,\ j \in \overline{1,n}, \tag{42b}$$

and denote their areas by A_0, A_j, respectively. The generalized Pythagorean theorem (see [10]) states that

$$A_0^2 = \sum_{j=1}^n A_j^2. \tag{43}$$

We prove it here using the change-of-variables formula (2). For any $j \in \overline{1,n}$ we can represent the (largest) face $\mathcal{F}_0$ as $\mathcal{F}_0 = \phi^{\{j\}}(\mathcal{F}_j)$, where $\phi^{\{j\}} = (\phi_1^{\{j\}}, \ldots, \phi_n^{\{j\}})$ is

$$\begin{aligned} \phi_i^{\{j\}}(x_1, x_2, \ldots, x_n) &= x_i,\ i \neq j, \\ \phi_j^{\{j\}}(x_1, x_2, \ldots, x_n) &= \frac{a_0}{a_j} - \sum_{i \neq j} \frac{a_i}{a_j}\, x_i. \end{aligned}$$

The Jacobi matrix of $\phi^{\{j\}}$ is an $n \times (n-1)$ matrix with the ith unit vector in row $i \neq j$ and

$$\left(-\frac{a_1}{a_j}, -\frac{a_2}{a_j}, \ldots, -\frac{a_{j-1}}{a_j}, -\frac{a_{j+1}}{a_j}, \ldots, -\frac{a_{n-1}}{a_j}, -\frac{a_n}{a_j} \right)$$

in row j. The volume of the Jacobi matrix of $\phi^{\{j\}}$ is computed as

$$\operatorname{vol} J_{\phi^{\{j\}}} = \sqrt{1 + \sum_{i \neq j} \left(\frac{a_i}{a_j} \right)^2} = \sqrt{\frac{\sum_{i=1}^n a_i^2}{a_j^2}} = \frac{\|\mathbf{a}\|}{|a_j|},$$

where $\mathbf{a}$ is the vector $(a_1, \ldots, a_n)$. Therefore, the area of $\mathcal{F}_0$ is

$$A_0 = \int_{\mathcal{F}_j} \left(\frac{\|\mathbf{a}\|}{|a_j|} \right) \prod_{i \neq j} dx_i = \left(\frac{\|\mathbf{a}\|}{|a_j|} \right) A_j, \quad j \in \overline{1,n}, \tag{44}$$

$$\therefore \quad \frac{\sum_{j=1}^n A_j^2}{A_0^2} = \frac{\sum_{j=1}^n |a_j|^2}{\|\mathbf{a}\|^2}$$

and the generalized Pythagorean theorem (43) reduces to the ordinary Pythagorean theorem

$$\|\mathbf{a}\|^2 = \sum_{j=1}^n |a_j|^2.$$

Example 11. The simplex (41) with $a_j = 1$ for all $j \in \overline{0,n}$ is the n-dimensional *regular simplex*

$$\mathbf{\Delta}_n \ := \ \left\{ (x_1, x_2, \ldots, x_n) \,:\, \sum_{i=1}^n x_i \leq 1,\ x_i \geq 0,\ i \in \overline{1,n} \right\}. \tag{45}$$

The area A_0 of its largest face

$$\mathcal{F}_0 = \left\{ (x_1, \ldots, x_n) \,:\, \sum_{i=1}^{n} x_i = 1,\ x_i \geq 0, i \in \overline{1,n} \right\} \tag{46}$$

is given by (44) as

$$A_0 = \sqrt{n}\, V_{n-1},$$

where V_{n-1}, the volume of the $(n-1)$-dimensional regular simplex, is

$$V_{n-1} = \frac{1}{(n-1)!}.$$

See, e.g., [9, section 47]. Therefore,

$$A_0 = \frac{\sqrt{n}}{(n-1)!}. \tag{47}$$

Note that $A_0 \to 0$ as $n \to \infty$, although the side faces of the unit cube (of which the face $\mathcal{F}_0$ is a diagonal section) have areas 1.

Appendix A. Illustrations with Derive. The integrations of this paper can be done symbolically. We illustrate this for the symbolic package Derive [5], omitting details such as the commands (e.g., `Simplify`, `Approximate`) and settings (e.g., `Trigonometry:=Expand`) that are used to obtain these results.

The Jacobi matrix is computed by the function

$$\texttt{JACOBIAN}(u, \alpha) := \texttt{VECTOR(GRAD}(u_{m_}, \alpha), m_, \texttt{DIMENSION}(u)) \tag{A.1}$$

found in the Derive utility file `VECTOR.mth`.

For example, to compute the surface integral of Example 2 we define the surface as a function of r and θ:

$$Z(r, \theta) := \tag{A.2}$$

(see (14)). Then

$$\texttt{JACOBIAN}([r * \texttt{COS}(\theta), r * \texttt{SIN}(\theta), Z(r, \theta)], [r, \theta]) \tag{A.3}$$

gives (16),

$$\begin{bmatrix} \texttt{COS}(\theta) & -r * \texttt{SIN}(\theta) \\ \texttt{SIN}(\theta) & r * \texttt{COS}(\theta) \\ \dfrac{\partial Z(r,\theta)}{\partial r} & \dfrac{\partial Z(r,\theta)}{\partial \theta} \end{bmatrix}. \tag{A.4}$$

The volume of an $(n+1) \times n$ matrix of full rank is computed by

$$\texttt{VOL}(a) := \texttt{SQRT}(\texttt{SUM}(\texttt{DET}(\texttt{DELETE_ELEMENT}(a, k_))^2, k_, 1, \texttt{DIMENSION}(a))). \tag{A.5}$$

For example,

$$\texttt{VOL}(\texttt{JACOBIAN}([r * \texttt{COS}(\theta), r * \texttt{SIN}(\theta), Z(r, \theta)], [r, \theta])) \tag{A.6}$$

gives (17),

$$\sqrt{r^2 * \left(\frac{\partial Z(r,\theta)}{\partial r}\right)^2 + \left(\frac{\partial Z(r,\theta)}{\partial \theta}\right)^2 + r^2}. \tag{A.7}$$

In Example 3 the surface is symmetric about the z-axis and we use $Z(r)$ instead of $Z(r,\theta)$ in (A.6),

$$\texttt{VOL}(\texttt{JACOBIAN}([r * \texttt{COS}(\theta), r * \texttt{SIN}(\theta), Z(r)], [r, \theta])), \tag{A.8}$$

to get (19),

$$|r| * \sqrt{Z'(r)^2 + 1}. \tag{A.9}$$

For example, the volume associated with the surface $z = 1/r$

$$\texttt{VOL}(\texttt{JACOBIAN}([r * \texttt{COS}(\theta), r * \texttt{SIN}(\theta), 1/r], [r, \theta])) \quad \text{gives} \quad \frac{\sqrt{r^4+1}}{|r|}. \tag{A.10}$$

The surface area of $z = 1/r$ is 2π times the integral of (A.10). In particular, the surface area from $r = 1$ to $r = 100$

$$2 * \pi * \texttt{INT}\left[\frac{\texttt{SQRT}(r^4+1)}{|r|}, r, 1, 100\right] \quad \text{gives} \quad 3.14142524131 \times 10^4.$$

Consider now the Radon transform in $\mathbb{R}^2$. A line

$$a\,x + b\,y = p \tag{A.11}$$

can be solved for y

$$y = \frac{p}{b} - \frac{a}{b}\,x$$

if $b \neq 0$. Then

$$\texttt{VOL}\left(\texttt{JACOBIAN}\left(\left[x, \frac{p}{b} - \frac{a}{b}\,x\right], [x]\right)\right) \quad \text{gives} \quad \frac{\sqrt{a^2+b^2}}{|b|} \tag{A.12}$$

in agreement with (31). The Radon transform (33) is then computed by

$$\begin{aligned} &\texttt{RADON_AUX}(f, x, y, a, b, p) \\ &\quad := \texttt{INT}(\texttt{LIM}(f, y, p/b - a/b * x), x, -\infty, \infty) * \texttt{SQRT}(a^2+b^2)/|b|. \end{aligned} \tag{A.13}$$

For example, the Radon transform of $e^{-x^2-y^2}$,

$$\texttt{RADON_AUX}(\texttt{EXP}(-x^2-y^2), x, y, a, b, p) \quad \text{is} \quad \sqrt{\pi}\,\texttt{EXP}\left[-\frac{p^2}{a^2+b^2}\right]. \tag{A.14}$$

The function (A.13) requires $b \neq 0$. We modify it for lines with $b = 0$ (i.e., vertical lines) as follows:

$$\begin{aligned} &\texttt{RADON}(f, x, y, a, b, p) \\ &:= \texttt{IF}(b = 0, \texttt{INT}(\texttt{LIM}(f, x, p/a), y, -\infty, \infty), \texttt{RADON_AUX}(f, x, y, a, b, p)). \end{aligned} \tag{A.15}$$

For example, the Radon transform of $e^{-x^2-y^2}$ with respect to a vertical line

$$\texttt{RADON}(\texttt{EXP}(-x^2-y^2),x,y,a,0,p) \quad \text{gives} \quad \sqrt{\pi}\,\texttt{EXP}\left[-\frac{p^2}{a^2}\right],$$

which is (A.14) with $b=0$.

An alternative way is to normalize the coefficients of the lines (A.11), say, $a=\cos\alpha$ and $b=\sin\alpha$. The Radon transform is then

(A.16)
$$\begin{aligned}&\texttt{RADON_NORMAL_AUX}(f,x,y,\alpha,p)\\ &\qquad := \texttt{INT}(\texttt{LIM}(f,y,p/\texttt{SIN}(\alpha)-\texttt{COT}(\alpha)*x),x,-\infty,\infty)/\texttt{ABS}(\texttt{SIN}(\alpha)).\end{aligned}$$

provided $\alpha\neq 0$. The following function treats $\alpha=0$ separately:

(A.17)
$$\begin{aligned}&\texttt{RADON_NORMAL}(f,x,y,\alpha,p)\\ &:= \texttt{IF}(\alpha=0,\texttt{INT}(\texttt{LIM}(f,x,p),y,-\infty,\infty),\texttt{RADON_NORMAL_AUX}(f,x,y,\alpha,p))\end{aligned}$$

For example, the Radon transform of

$$f(x,y) := \begin{cases} 1 & \text{if } 0\le x,y\le 1,\\ 0 & \text{otherwise}\end{cases}$$

is computed by

(A.18)
$$\texttt{RADON_NORMAL}(\texttt{CHI}(0,x,1)*\texttt{CHI}(0,y,1),x,y,\alpha,p),$$

giving

(A.19)
$$\texttt{SIGN}(\texttt{COS}(\alpha)-p)*\left[\frac{p}{\texttt{SIN}(2\alpha)}-\frac{0.5}{\texttt{SIN}(\alpha)}\right]+\frac{|p|}{\texttt{SIN}(2\alpha)}.$$

The Radon transform in $\mathbb{R}^3$ is computed with respect to a plane

$$a\,x+b\,y+c\,z=p$$

as follows (ignoring the case $c=0$):

(A.20)
$$\begin{aligned}&\texttt{RADON_3}(f,x,y,z,a,b,c,p)\\ &\quad := \texttt{INT}(\texttt{INT}(\texttt{LIM}(f,z,p/c-a/c*x-b/c*y),x,-\infty,\infty),y,-\infty,\infty)\\ &\qquad *\texttt{SQRT}(a^2+b^2+c^2)/|c|.\end{aligned}$$

Finally, an integral over $\mathbb{R}^3$ is computed, using (37) as follows:

(A.21)
$$\begin{aligned}&\texttt{INT_3}(f,x,y,z,a,b,c)\\ &\quad := \texttt{INT}(\texttt{RADON_3}(f,x,y,z,a,b,c,p),p,-\infty,\infty)/\texttt{SQRT}(a^2+b^2+c^2).\end{aligned}$$

For example, the integral over $\mathbb{R}^3$ of $f(x,y,z)=e^{x+y+z-x^2-y^2-z^2}$,

$$\texttt{INT_3}(\texttt{EXP}(x+y+z-x^2-y^2-z^2),x,y,z,a,b,c) \quad \text{gives} \quad \pi^{3/2}\,e^{3/4}.$$

ROW-WISE BACKWARD STABLE ELIMINATION METHODS FOR THE EQUALITY CONSTRAINED LEAST SQUARES PROBLEM*

ANTHONY J. COX† AND NICHOLAS J. HIGHAM‡

Abstract. It is well known that the solution of the equality constrained least squares (LSE) problem $\min_{Bx=d} \|b - Ax\|_2$ is the limit of the solution of the unconstrained weighted least squares problem

$$\min_x \left\| \begin{bmatrix} \mu d \\ b \end{bmatrix} - \begin{bmatrix} \mu B \\ A \end{bmatrix} x \right\|_2$$

as the weight μ tends to infinity, assuming that $[\,B^T \quad A^T\,]^T$ has full rank. We derive a method for the LSE problem by applying Householder QR factorization with column pivoting to this weighted problem and taking the limit analytically, with an appropriate rescaling of rows. The method obtained is a type of direct elimination method. We adapt existing error analysis for the unconstrained problem to obtain a row-wise backward error bound for the method. The bound shows that, provided row pivoting or row sorting is used, the method is well-suited to problems in which the rows of A and B vary widely in norm. As a by-product of our analysis, we derive a row-wise backward error bound of precisely the same form for the standard elimination method for solving the LSE problem. We illustrate our results with numerical tests.

1. Introduction.

Consider the equality constrained least squares (LSE) problem

$$\min_{Bx=d} \|b - Ax\|_2, \qquad A \in \mathbb{R}^{m\times n}, \quad B \in \mathbb{R}^{p\times n}, \quad m + p \geq n \geq p. \tag{1.1}$$

We assume throughout this work that $\operatorname{rank}(B) = p$, which ensures that the constraint system is consistent, and also that $\operatorname{rank}\begin{bmatrix} B \\ A \end{bmatrix} = n$, which ensures that the LSE problem has a unique solution. Two commonly used methods for solving the LSE problem are based on QR factorization. The null space method (of which there are several variations [6]) begins by factorizing $B^T = QR$ to obtain a basis for the null space of B. The elimination method, on the other hand, uses QR factorization with column pivoting to factorize

$$B\Pi = Q\,[\,R_1 \quad R_2\,], \qquad R_1 \in \mathbb{R}^{p\times p} \text{ upper triangular, nonsingular.} \tag{1.2}$$

Partitioning $\Pi^T x = [\widetilde{x}_1^T,\ \widetilde{x}_2^T]^T$, $\widetilde{x}_1 \in \mathbb{R}^p$ and substituting the factorization (1.2) into the constraints yields

$$R_1\widetilde{x}_1 = Q^T d - R_2\widetilde{x}_2.$$

By solving for $\widetilde{x}_1$ and partitioning $A\Pi = [\widetilde{A}_1,\ \widetilde{A}_2]$, $\widetilde{A}_1 \in \mathbb{R}^{m\times p}$ we reduce the LSE problem to the unconstrained problem

$$\min_{\widetilde{x}_2} \left\| (\widetilde{A}_2 - \widetilde{A}_1 R_1^{-1} R_2)\widetilde{x}_2 - (b - \widetilde{A}_1 R_1^{-1} Q^T d) \right\|_2 .$$

Solving this unconstrained problem by QR factorization completes the elimination method as originally presented by Björck and Golub [5] (see also [13, Chapter 21]). It is instructive to think of the method in terms of transformations on the matrix "B-over-A":

$$\begin{bmatrix} B \\ A \end{bmatrix} \begin{matrix} \\ {\scriptstyle m} \end{matrix} \begin{matrix} \overset{p}{} \\ \end{matrix} \!\!\begin{matrix} {\scriptstyle p} \\ \end{matrix}\!\! \begin{bmatrix} B_1 & B_2 \\ A_1 & A_2 \end{bmatrix} \to \begin{bmatrix} R_1 & R_2 \\ \widetilde{A}_1 & \widetilde{A}_2 \end{bmatrix} \to \begin{bmatrix} R_1 & R_2 \\ 0 & \widetilde{A}_2 - \widetilde{A}_1 R_1^{-1} R_2 \end{bmatrix} \to \begin{bmatrix} R_1 & R_2 \\ 0 & R_3 \\ 0 & 0 \end{bmatrix},$$

where $R_3 \in \mathbb{R}^{(n-p)\times(n-p)}$ is upper triangular. Note that the penultimate transformation is simply the annihilation of $\widetilde{A}_1$ by Gaussian elimination. We will refer to this method as the *EG method*.

The B-over-A matrix also arises in the method of weighting for solving the LSE problem, which is based on the observation that the LSE solution is the limit of the solution of the unconstrained problem

$$\min_x \left\| \begin{bmatrix} \mu d \\ b \end{bmatrix} - \begin{bmatrix} \mu B \\ A \end{bmatrix} x \right\|_2 \tag{1.3}$$

as the weight μ tends to infinity. Van Loan [18] describes an algorithm that solves (1.3) for a single weight and uses a refinement procedure to approximate the required limit. The algorithm is analyzed further by Barlow and Vemulapati [1], [3].

In this work we derive a method for the LSE problem by taking the limit $\mu \to \infty$ analytically rather than numerically. To be precise, we apply Householder QR factorization with column pivoting to (1.3), rescale the first p rows, and then take the limit $\mu \to \infty$ to obtain a matrix that we view as an update of B-over-A. The new method is an elimination method very similar, but not identical, to the EG method. We show that it satisfies a pleasing row-wise backward error bound when row pivoting or row sorting is used—a result that makes the method attractive when the rows of A and B vary widely in norm. We also show that a row-wise backward error bound of exactly the same form holds for the EG method. We give some numerical experiments to confirm the stability properties of the methods.

After this paper was submitted for publication, we learned that Reid [15] has obtained the method derived here by a different argument involving infinite weights. He shows that the algorithm of Powell and Reid [14], including its error analysis, may be applied to the weighted problem with implicit scaling, that is, with the weights stored separately. By holding inverse weights, the constrained case can be accommodated. He obtains a backward error bound similar to our Theorem 4.3 and also shows that iterative refinement may be applied. Reid points out that the method is equivalent to a method of Gulliksson and Wedin [9], [10], which is expressed in the language of "M-invariant reflections."

2. A single stage of the method. Define

$$C = \begin{bmatrix} B \\ A \end{bmatrix}, \quad f = \begin{bmatrix} d \\ b \end{bmatrix}, \quad C_\mu = \begin{bmatrix} \mu B \\ A \end{bmatrix}, \quad f_\mu = \begin{bmatrix} \mu d \\ b \end{bmatrix}, \tag{2.1}$$

where $\mu > 0$. We consider the first stage of Householder QR factorization applied to C_μ, examining what happens as $\mu \to \infty$. In outline, we write the transformed matrix as

$$C'_\mu = \begin{bmatrix} \mu B'_\mu \\ A'_\mu \end{bmatrix},$$

divide the first p rows of C'_μ by μ and take the limit as $\mu \to \infty$, obtaining a matrix

$$C' = \begin{bmatrix} B' \\ A' \end{bmatrix}$$

that is independent of μ. Then we view C' as the result of an update of C. We will show that all the elements of C' remain finite as $\mu \to \infty$. In this way, we set up a one-to-one correspondence between performing the first step of Householder QR factorization on C_μ,

$$\begin{bmatrix} \mu B \\ A \end{bmatrix} \to \begin{bmatrix} \mu B'_\mu \\ A'_\mu \end{bmatrix}, \tag{2.2}$$

and carrying out the update

$$\begin{bmatrix} B \\ A \end{bmatrix} \to \begin{bmatrix} B' \\ A' \end{bmatrix} \tag{2.3}$$

on the unscaled matrix C. Our aim is to determine the nature of this update.

We mention that Stewart [17] compares the equations for Householder QR factorization on C_μ with those for the EG method. While his analysis is related to ours, his aim (to understand the method of weighting) is different and he does not take limits.

We will denote by a_j, b_j, and c_j the jth columns of A, B, and C_μ, respectively (we will have no need to refer to the columns of C, so this slightly inconsistent notation should not cause any confusion); similarly, we write $C_\mu = (c_{ij})$. The first stage of Householder QR factorization applied to C_μ is

$$C'_\mu = C_\mu - 2v_\mu \frac{v_\mu^T C_\mu}{v_\mu^T v_\mu},$$

where

$$v_\mu = c_1 + \tau \|c_1\|_2 e_1, \qquad \tau = \operatorname{sign}(c_{11}), \tag{2.4}$$

which we can rewrite as

$$c'_{ij} = c_{ij} - 2v_\mu(i) \frac{v_\mu^T c_j}{v_\mu^T v_\mu}, \qquad i = 1\colon p+m, \quad j = 1\colon n. \tag{2.5}$$

We assume the use of column pivoting, so that columns are interchanged, if necessary, to ensure that

$$\|c_1\|_2 = \max_j \|c_j\|_2.$$

For notational simplicity, we assume that no interchanges are required by column pivoting. Our first concern is with the behavior of the multipliers

$$2\frac{v_\mu^T c_j}{v_\mu^T v_\mu}, \qquad j = 1\colon n,$$

which we will refer to as *Householder multipliers*, as $\mu \to \infty$. As a preliminary, we define ζ by

$$\|c_1\|_2 = \sqrt{\mu^2\|b_1\|_2^2 + \|a_1\|_2^2} = \mu\sqrt{\|b_1\|_2^2 + \frac{1}{\mu^2}\|a_1\|_2^2} = \mu\zeta,$$

and note that

$$\lim_{\mu\to\infty} \zeta = \|b_1\|_2.$$

We have

$$v_\mu^T c_j = c_1^T c_j + \tau\|c_1\|_2 c_{1j} = \mu^2 b_1^T b_j + a_1^T a_j + \mu^2\tau\zeta b_{1j}$$

and

$$v_\mu^T v_\mu = 2\|c_1\|_2(\|c_1\|_2 + |c_{11}|) = 2\mu^2\zeta(\zeta + |b_{11}|).$$

Hence

$$2\frac{v_\mu^T c_j}{v_\mu^T v_\mu} = \frac{b_1^T b_j + a_1^T a_j/\mu^2 + \tau\zeta b_{1j}}{\zeta(\zeta + |b_{11}|)},$$

which yields

$$\lim_{\mu\to\infty} 2\frac{v_\mu^T c_j}{v_\mu^T v_\mu} = \frac{b_1^T b_j + \tau\|b_1\|_2 b_{1j}}{\|b_1\|_2(\|b_1\|_2 + |b_{11}|)} = 2\frac{v_B^T b_j}{v_B^T v_B}, \tag{2.6}$$

where

$$v_B = b_1 + \tau\|b_1\|_2 e_1.$$

We see that, in the limit, A's contribution to the Householder multiplier $2v_\mu^T c_j/v_\mu^T v_\mu$ is lost.

Using (2.5) and (2.4) we have, for $i = 1\colon p$,

$$\begin{aligned} b'_{ij} := \lim_{\mu\to\infty} b_{ij}(\mu)' &= \lim_{\mu\to\infty} \frac{c'_{ij}}{\mu} \\ &= \lim_{\mu\to\infty} \left(b_{ij} - \frac{2v_\mu(i)}{\mu}\frac{v_\mu^T c_j}{v_\mu^T v_\mu} \right) \\ &= b_{ij} - 2v_B(i)\frac{v_B^T b_j}{v_B^T v_B}. \end{aligned}$$

This is just the first stage of Householder QR factorization applied to B, which corresponds to the application of the Householder update

$$C' = C - 2v_C\frac{v_C^T C}{v_C^T v_C}, \quad v_C = \begin{bmatrix} v_B \\ 0 \end{bmatrix} \tag{2.7}$$

to the unscaled matrix C. Moreover, $\|c_i\|_2/\|c_j\|_2 \to \|b_i\|_2/\|b_j\|_2$ so, in the limit, column pivoting based on the columns of C is equivalent to column pivoting based on the columns of B.

Now we turn to the rows of A. In the limit as $\mu \to \infty$, we have, from (2.4)–(2.6),

$$a'_{ij} = a_{ij} - 2a_{i1}\frac{v_B^T b_j}{v_B^T v_B},$$

which corresponds to the update

$$C' = C - 2v_A\frac{v_C^T C}{v_C^T v_C}, \quad v_A = \begin{bmatrix} 0 \\ a_1 \end{bmatrix}. \tag{2.8}$$

Combining (2.7) and (2.8) we see that, in the limit as $\mu \to \infty$, carrying out one step of Householder QR factorization on C_μ is equivalent to carrying out the outer product update

$$C' = PC = C - 2v\frac{v_C^T C}{v_C^T v_C}, \quad \text{where} \quad v = \begin{bmatrix} v_B \\ a_1 \end{bmatrix}, \tag{2.9}$$

on the unscaled matrix C. Note that the transformation matrix P is not a Householder matrix, because $v \neq v_C$.

It is natural to ask whether the equations we have derived are equivalent to those for the EG method described in section 1. Recall that the EG method QR factorizes B as in (1.2) and then eliminates the first p columns of $\widetilde{A} = A\Pi$ by Gaussian elimination. It is easily shown that the first row of $[\, R_1 \quad R_2 \,]$ is proportional to

$$[\, b_1^T b_1 \quad b_1^T b_2 \quad \dots \quad b_1^T b_n \,]. \tag{2.10}$$

The first column of $\widetilde{A}$ is therefore zeroed by performing one step of Gaussian elimination with this row as the pivot row. Using the fact that $v_B^T v_B = 2v_B^T b_1$, it is easy to show that for the new method we are effectively performing Gaussian elimination with the "virtual pivot row"

$$[\, v_B^T b_1 \quad v_B^T b_2 \quad \dots \quad v_B^T b_n \,], \tag{2.11}$$

which is not actually present in the matrix C. The vectors (2.10) and (2.11) are proportional only if B is upper trapezoidal, which shows that the new method and the EG method are mathematically different in general.

3. The complete method. By carrying out p eliminations of the type described in the previous section, we reduce C to the form

$$\begin{bmatrix} R_1 & R_2 \\ 0 & A'_2 \end{bmatrix},$$

where $R_1 \in \mathbb{R}^{p\times p}$ is upper triangular and nonsingular. We mention that in place of column pivoting some other pivoting strategy that keeps $R_1^{-1}R_2$ small could be used instead; cf. [2].

The remaining $\min(n-p, m-1)$ steps of the method consist of applying standard Householder QR factorization with column pivoting to the matrix A'_2, after which the whole of C has been reduced to upper trapezoidal form. By applying the same sequence of updates to f and solving the resulting triangular system, we obtain the solution to the LSE problem (1.1). We summarize our method as follows.

ALGORITHM EH *This algorithm solves the LSE problem* (1.1).

1. Let
$$C^{(1)} = \begin{bmatrix} B \\ A \end{bmatrix}, \qquad f^{(1)} = \begin{bmatrix} d \\ b \end{bmatrix}, \qquad q = p + m.$$
2. Stage I
for $k = 1\colon p$
Interchange the columns of $C^{(k)}$ so that $\|c_k^{(k)}(k\colon p)\|_2 = \max_{j \geq k} \|c_j^{(k)}(k\colon p)\|_2$.
Update
$$C^{(k+1)}(k\colon q, k\colon n) = C^{(k)}(k\colon q, k\colon n) - 2v_k(k\colon q)\frac{v_k(k\colon p)^T C^{(k)}(k\colon p, k\colon n)}{v_k(k\colon p)^T v_k(k\colon p)},$$
$$f^{(k+1)}(k\colon q) = f^{(k)}(k\colon q) - 2v_k(k\colon q)\frac{v_k(k\colon p)^T f^{(k)}(k\colon p)}{v_k(k\colon p)^T v_k(k\colon p)},$$
where
$$v_k(i) = \begin{cases} 0, & i = 1\colon k-1, \\ c_{kk}^{(k)} + \operatorname{sign}\left(c_{kk}^{(k)}\right)\left\|c_k^{(k)}(k\colon p)\right\|_2, & i = k, \\ c_{ik}^{(k)}, & i = k+1\colon q. \end{cases}$$
end
3. Stage II (standard Householder QR factorization with column pivoting)
for $k = p+1\colon \min(n, m+p-1)$
Interchange the columns of $C^{(k)}$ so that $\left\|c_k^{(k)}(k\colon q)\right\|_2 = \max_{j \geq k} \left\|c_j^{(k)}(k\colon q)\right\|_2$.
Update
$$C^{(k+1)}(k\colon q, k\colon n) = C^{(k)}(k\colon q, k\colon n) - 2v_k(k\colon q)\frac{v_k(k\colon q)^T C^{(k)}(k\colon q, k\colon n)}{v_k(k\colon q)^T v_k(k\colon q)},$$
$$f^{(k+1)}(k\colon q) = f^{(k)}(k\colon q) - 2v_k(k\colon q)\frac{v_k(k\colon q)^T f^{(k)}(k\colon q)}{v_k(k\colon q)^T v_k(k\colon q)},$$
where
$$v_k(i) = \begin{cases} 0, & i = 1\colon k-1, \\ c_{kk}^{(k)} + \operatorname{sign}\left(c_{kk}^{(k)}\right)\left\|c_k^{(k)}(k\colon q)\right\|_2, & i = k, \\ c_{ik}^{(k)}, & i = k+1\colon q. \end{cases}$$
end
4. Solve the triangular system $C^{(k+1)}(1\colon n, 1\colon n)y = f^{(k+1)}(1\colon n)$.
5. Obtain x by permuting y to take account of the column interchanges.

Algorithm EH implicitly computes a matrix factorization: ignoring column interchanges, we have
$$\underbrace{\begin{bmatrix} I & 0 \\ 0 & \widetilde{Q}_3 \end{bmatrix}}_{\text{Stage II}} \underbrace{\begin{bmatrix} \widetilde{Q}_1 & 0 \\ \widetilde{Q}_2 & I \end{bmatrix}}_{\text{Stage I}} \begin{bmatrix} B_1 & B_2 \\ A_1 & A_2 \end{bmatrix} = \begin{bmatrix} R_1 & R_2 \\ 0 & R_3 \\ 0 & 0 \end{bmatrix},$$
where $\widetilde{Q}_1$ and $\widetilde{Q}_3$ are orthogonal and $R_1 \in \mathbb{R}^{p\times p}$ and $R_3 \in \mathbb{R}^{(n-p)\times(n-p)}$ are upper triangular. Rewriting, we have
$$\begin{bmatrix} \widetilde{Q}_1 & 0 \\ \widetilde{Q}_3\widetilde{Q}_2 & \widetilde{Q}_3 \end{bmatrix} \begin{bmatrix} B_1 & B_2 \\ A_1 & A_2 \end{bmatrix} = \begin{bmatrix} R \\ 0 \end{bmatrix},$$

or, with $Q_1 = \widetilde{Q}_1^T$, $Q_2 = -\widetilde{Q}_2\widetilde{Q}_1^T$ and $Q_3 = \widetilde{Q}_3^T$,

$$\begin{array}{c} \\ p \\ m \end{array}\!\!\begin{array}{c} \begin{array}{cc} p & n-p \end{array} \\ \begin{bmatrix} B_1 & B_2 \\ A_1 & A_2 \end{bmatrix} \end{array} = \begin{array}{c} \\ p \\ m \end{array}\!\!\begin{array}{c} \begin{array}{cc} p & m \end{array} \\ \begin{bmatrix} Q_1 & 0 \\ Q_2 & Q_3 \end{bmatrix} \end{array} \begin{array}{c} \begin{array}{c} n \end{array} \\ \begin{bmatrix} R \\ 0 \end{bmatrix} \end{array} \begin{array}{l} \\ n \\ m-n+p \end{array}. \tag{3.1}$$

The EG method produces exactly the same factorization; the difference in the methods lies in the intermediate quantities computed. Note that another way to derive both the EG method and Algorithm EH is to substitute the factorization into the associated augmented system; this is done in [4] and [5] for the EG method.

4. Numerical stability. Now we consider the stability of Algorithm EH. First, we recall what is known about the stability of Householder QR factorization for solving the LS problem $\min_x \|b - Ax\|_2$. The method is normwise backward stable. Moreover, when column pivoting is used the following row-wise backward error result holds, which is of interest in situations in which the rows of A vary widely in norm. We employ the standard model of floating point arithmetic with unit roundoff u [12, Section 2.2], and define the constant

$$\widetilde{\gamma}_k = \frac{cku}{1 - cku},$$

where k is a positive integer and c is a small integer constant whose exact value is unimportant. We assume that the signs in the Householder vectors are chosen as in (2.4), which is the standard choice. For the other choice of sign, the following theorem is invalid (see [8] for more details).

THEOREM 4.1. *Let the LS problem* $\min_x \|b - Ax\|_2$*, where* $A \in \mathbb{R}^{m\times n}$ *is of full rank* n*, be solved using Householder QR factorization with column pivoting. Then the computed solution* $\widehat{x}$ *is the exact solution to*

$$\min_x \|(b + \Delta b) - (A + \Delta A)x\|_2,$$

where the perturbations satisfy

$$|\Delta a_{ij}| \le j^2\widetilde{\gamma}_m\alpha_i \max_s |a_{is}|, \qquad |\Delta b_i| \le n^2\widetilde{\gamma}_m\beta_i \max(\phi \max_j |a_{ij}|, |b_i|),$$

where

$$\alpha_i = \frac{\max_{j,k} |\widehat{a}_{ij}^{(k)}|}{\max_j |a_{ij}|}, \quad \beta_i = \frac{\max\bigl(\phi \max_{j,k} |\widehat{a}_{ij}^{(k)}|, |\widehat{b}_i^{(k)}|\bigr)}{\max(\phi \max_j |a_{ij}|, |b_i|)}, \quad \phi = \max_k \frac{\|\widehat{b}^{(k)}(k\colon m)\|_2}{\|\widehat{a}_k^{(k)}(k\colon m)\|_2}.$$

Proof. A similar result was originally proved under some additional assumptions by Powell and Reid [14]. The analysis was reworked by Cox and Higham [8]. The result as stated is a slightly improved version of the result in [8], with a minor error in the Δb bound corrected. □

Theorem 4.1 shows that, when column pivoting is used, the backward errors ΔA and Δb are bounded row-wise in terms of the element growth within each row, as measured by the α_i and β_i. Ideally, we would like the overall row-wise growth factor

$$\rho_{m,n} = \max_i\{\, \alpha_i, \beta_i \,\}$$

to be of order 1. In general, $\rho_{m,n}$ is unbounded. However, two techniques lead to a bounded $\rho_{m,n}$. Prior to carrying out the factorization, we can sort the rows so that

$$\|A(i,:)\|_\infty = \max_{j\geq i} \|A(j,:)\|_\infty, \qquad i = 1\colon m.$$

Alternatively, we can use row pivoting: at the kth stage of the factorization, after the column interchange has taken place, we interchange rows to ensure that

$$|a_{kk}^{(k)}| = \max_{i\geq k} |a_{ik}^{(k)}|.$$

The following result was obtained by Powell and Reid [14] for row pivoting and by Cox and Higham [8] for row sorting. As usual for growth factor bounds, this one assumes exact arithmetic; however, the growth of exact and computed quantities differs by only $O(u)$.

THEOREM 4.2. *With row pivoting or row sorting in Householder QR factorization with column pivoting applied to* $A \in \mathbb{R}^{m\times n}$,

$$\rho_{m,n} \leq \sqrt{m}(1+\sqrt{2})^{n-1}.$$

The bound of the theorem can be nearly attained, but $\rho_{m,n}$ is almost always small in practice.

The scalar ϕ in Theorem 4.1 is easily seen to be independent of the row ordering and so is beyond our control.

The limit technique used in the derivation of Algorithm EH can be used to obtain a row-wise backward error result. We apply Theorem 4.1 to $\min_x \|f_\mu - C_\mu x\|_2$ (see (2.1)) and then use a straightforward limit argument to deduce the following theorem. As a check on the plausibility of the theorem, we note that a key result used in the proof of Theorem 4.1 is that the Householder multipliers are all bounded by $\sqrt{2}$ (without column pivoting these multipliers are unbounded). For Stage I of Algorithm EH, the Householder multipliers

$$\eta_{k,j} = 2\frac{v_k(k\colon p)^T c_j^{(k)}(k\colon p)}{v_k^T(k\colon p)v_k(k\colon p)}$$

are precisely those determined by QR factorization with column pivoting applied to B, as we have already noted. Therefore $|\eta_{k,j}| \leq \sqrt{2}$. Stage II of Algorithm EH is standard QR factorization with column pivoting, so again the multipliers are bounded by $\sqrt{2}$.

THEOREM 4.3. *Let the LSE problem* (1.1) *be solved by Algorithm EH. Then the computed solution* $\widehat{x}$ *is the exact solution to*

$$\min_{(B+\Delta B)x=d+\Delta d} \|(b+\Delta b) - (A+\Delta A)x\|_2,$$

where, defining

$$\Delta C = \begin{bmatrix} \Delta B \\ \Delta A \end{bmatrix}, \qquad \Delta f = \begin{bmatrix} \Delta d \\ \Delta b \end{bmatrix},$$

we have

$$|\Delta c_{ij}| \leq j^2 \widetilde{\gamma}_{p+m}\alpha_i \max_s |c_{is}|, \qquad |\Delta f_i| \leq n^2\widetilde{\gamma}_{p+m}\beta_i \max(\phi \max_j |c_{ij}|, |f_i|),$$

with

$$\alpha_i = \frac{\max_{j,k} |\widehat{c}_{ij}^{(k)}|}{\max_j |c_{ij}|}, \quad \beta_i = \frac{\max\bigl(\phi \max_{j,k} |\widehat{c}_{ij}^{(k)}|, |\widehat{f}_i^{(k)}|\bigr)}{\max(\phi \max_j |c_{ij}|, |f_i|)},$$

$$\phi = \max\left\{ \max_{1\le k\le p} \frac{\|\widehat{f}^{(k)}(k\colon p)\|_2}{\|\widehat{c}_k^{(k)}(k\colon p)\|_2}, \max_{p+1\le k\le p+m} \frac{\|\widehat{f}^{(k)}(k\colon p+m)\|_2}{\|\widehat{c}_k^{(k)}(k\colon p+m)\|_2} \right\}.$$

Theorem 4.3 shows that Algorithm EH is row-wise backward stable provided that the row-wise growth factor $\rho_{m,n} = \max_i\{\,\alpha_i, \beta_i\,\}$ and the scalar ϕ are both of order 1. As for the LS problem, we can use row sorting or row pivoting in order to bound $\rho_{m,n}$, and we obtain a bound analogous to that in Theorem 4.2. For row sorting we sort the rows of A and B separately (that is, we do not sort the rows of C, which would change the LSE problem). For row pivoting, we interchange the rows of B in Stage I and the rows of A in Stage II.

The two stages of Algorithm EH can be implemented as a single loop with the help of a parameter that specifies the extent of the Householder vector, yielding the succinct pseudocode shown in Figure 4.1. The EG method and a variant of it based on modified Gram-Schmidt orthogonalization can be expressed in similarly concise fashions, as shown in [4], [5].

How does the stability of Algorithm EH compare with that of the EG method? The only published result for the EG method is one of Barlow and Handy [2], which bounds $\|C - \widehat{Q}\widehat{R}\|_2$ for the factorization (3.1) in terms of $\|C\|_2$; this result does not reveal the stability of the overall solution process or provide any information about row-wise stability.

From the remarks at the end of section 2 we know that if B is upper triangular, then Algorithm EH is identical to the EG method. We can therefore interpret the EG method as the two-stage process: (1) QR factorize B, using column pivoting, (2) apply Algorithm EH to the LSE problem with a triangular constraint matrix. Theorem 4.3 applies to stage (2), and an analogue of Theorem 4.1 for the QR factorization itself applies to Stage 1 [8] (essentially, we obtain $(B + \Delta B)\Pi = \widehat{Q}\widehat{R}$, with ΔB bounded in the same way as ΔA in Theorem 4.1). These two results can be combined, using the same techniques as in the proof of Theorem 4.1, to obtain a new result for the EG method.

THEOREM 4.4. *Theorem* 4.3 *holds also for the EG method.*

5. Numerical experiments. Backward errors of an approximate solution y to the LSE problem (1.1) can be defined by minimizing suitable measures of the quadruple $(\Delta A, \Delta b, \Delta B, \Delta d)$ over all perturbations ΔA, Δb, ΔB, and Δd for which y solves $\min_{(B+\Delta B)y=d+\Delta d} \|b + \Delta b - (A + \Delta A)y\|_2$. Ideally, we would verify the row-wise backward stability results in Theorems 4.3 and 4.4 by comparing the actual row-wise backward errors with the bounds for a range of problems. Unfortunately, no computable expression is known for any backward error (even just the normwise backward error) of an arbitrary approximate LSE solution. We therefore compute upper bounds for the backward errors using a technique developed in [7].

Given an approximate LSE solution y, suppose we have determined perturbations ΔB and Δd such that $(B + \Delta B)y = d + \Delta d$. Let ΔA_* and Δb_* be solutions of the problem

$$\min\{\, \|\,[\,\Delta A \quad \theta \Delta b\,]\,\|_F : y \text{ solves } \min_{(B+\Delta B)x=d+\Delta d} \|b + \Delta b - (A + \Delta A)x\|_2 \,\}, \tag{5.1}$$

This algorithm solves the LSE problem $\min_{Bx=d} \|b - Ax\|_2$*, where* $A \in \mathbb{R}^{m\times n}$*,* $B \in \mathbb{R}^{p\times n}$ *and* $m + p \geq n \geq p$*. A flag rp determines whether row pivoting is carried out.*

$C^{(1)} = \begin{bmatrix} B \\ A \end{bmatrix}$, $f^{(1)} = \begin{bmatrix} d \\ b \end{bmatrix}$, $top = p$, $q = p + m$.

for $k = 1\colon \min(n, m + p - 1)$

Permute columns so that $\|C^{(k)}(k\colon top, k)\|_2 = \max_{j\geq k} \|C^{(k)}(k\colon top, j)\|_2$.

If rp
Permute rows so that $|c_{kk}^{(k)}| = \max_{i=k\colon top} |c_{ik}^{(k)}|$.
Apply same row interchanges to $f^{(k)}$.
end

% Implicitly construct Householder-like matrix $I - \beta vv'^T$.
$v = C^{(k)}(k\colon q, k)$
$s = \operatorname{sign}(v_1)\|C^{(k)}(k\colon top, k)\|_2$
$v_1 = v_1 + s$
$\beta = 1/(s\, v_1)$

$C^{(k+1)}(k\colon q, k\colon n) = C^{(k)}(k\colon q, k\colon n)$
$\qquad - \beta\, v(v(1\colon top - k + 1)^T C^{(k)}(k\colon top, k\colon n))$
$f^{(k+1)}(k\colon q) = f^{(k)}(k\colon q) - \beta\, v(v(1\colon top - k + 1)^T f^{(k)}(k\colon top))$

% Once $k > p$ we do standard Householder QR factorization.
If $k = p$, $top = q$, end

end

Solve $C^{(k+1)}(1\colon n, 1\colon n)x = f^{(k+1)}(1\colon n)$ by substitution.
Permute x to undo the effect of column pivoting.

FIG. 4.1. *Concise pseudocode for Algorithm EH.*

where θ is a parameter. How to compute ΔA_* and Δb_* is explained in [7]. Here we are minimizing over ΔA and Δb for fixed ΔB and Δd instead of minimizing over all ΔA, Δb, ΔB and Δd. Therefore by taking an appropriate measure of the quadruple $(\Delta A_*, \Delta b_*, \Delta B, \Delta d)$ we obtain an upper bound for the corresponding backward error. We choose the perturbations

$$\Delta B_* = \frac{\|B\|_2\|y\|_2}{(\|B\|_2\|y\|_2 + \|d\|_2)} \frac{ry^T}{y^T y}, \quad \Delta d_* = \frac{-\|d\|_2}{\|B\|_2\|y\|_2 + \|d\|_2} r,$$

where $r = d - By$. These are the perturbations corresponding to the relative 2-norm backward error for the constraint system [16]; in other words, they minimize $\max(\|\Delta B\|_2/\|B\|_2, \|\Delta d\|_2/\|d\|_2)$. We define two backward error bounds in terms of

the perturbations ΔA_*, Δb_*, ΔB_* and Δd_*: the normwise backward error bound

$$\eta_N = \max\left\{ \frac{\|\Delta A_*\|_2}{\|A\|_2}, \frac{\|\Delta b_*\|_2}{\|b\|_2}, \frac{\|\Delta B_*\|_2}{\|B\|_2}, \frac{\|\Delta d_*\|_2}{\|d\|_2} \right\}$$

and the row-wise backward error bound

$$\eta_R = \max_i \frac{\|\Delta G(i,:)\|_2}{\|G(i,:)\|_2},$$

where

$$G = \begin{bmatrix} B & d \\ A & b \end{bmatrix}, \qquad \Delta G = \begin{bmatrix} \Delta B_* & \Delta d_* \\ \Delta A_* & \Delta b_* \end{bmatrix}.$$

In our experiments we took $\theta = 1$ in (5.1) since our chosen A, B, d, and f all have norms of order 1.

The experiments were performed in MATLAB, using simulated single precision arithmetic ($u = 2^{-24} \approx 5.96 \times 10^{-8}$). The backward error bounds were computed in double precision arithmetic.

We give results for four problems with $m = 16$, $n = 10$, $p = 6$. We denote by randn a matrix or vector from the normal(0,1) distribution and by randsvd(κ) a random matrix with 2-norm condition number κ and geometrically distributed singular values, generated by the routine `randsvd` in the Test Matrix Toolbox [11].

PROBLEM 1 $A =$ randn, $b =$ randn, $B =$ randn, $d =$ randn.

PROBLEM 2 $A =$ randsvd(10), $b =$ randn, $B =$ randsvd(10^4), $d =$ randn.

PROBLEM 3 $A =$ randsvd(10^6), $b =$ randn, $B =$ randsvd(10), $d =$ randn.

PROBLEM 4 $A =$ randsvd(10^4), $b =$ randn, $B =$ randsvd(10^4), $d =$ randn.

For each problem, a parameter tol $\in (0, 1]$ determines a row scaling applied to the original data:

$$[\,A \quad b\,] \leftarrow D_{m,\mathrm{tol}}\,[\,A \quad b\,], \quad [\,B \quad d\,] \leftarrow D_{p,\mathrm{tol}}\,[\,B \quad d\,],$$

where

$$D_{k,\mathrm{tol}} = \mathrm{diag}(\theta^k, \theta^{k-1}, \ldots, \theta, 1), \quad \theta^k = \mathrm{tol}.$$

The backward error results are given in Tables 5.1–5.3. We give results for Algorithm EH with no row interchanges and with row sorting; the results for row pivoting were very similar and so are omitted. We do not report results for the EG method because they were very similar to those for Algorithm EH. For comparison, we also give results for the null space method (implemented using generalized QR factorization, as in LAPACK). Results for tol = 1 are given only for Problem 1; for Problems 2 and 3 with tol = 1 the backward error bounds were again all of order u.

The main observations from the results are as follows.

1. The importance of row pivoting or row sorting in Algorithm EH for badly row scaled problems is shown by Tables 5.1–5.3, in which when tol is small η_R is much smaller when row sorting is used than when it is not. Row sorting produces a growth factor $\rho_{m,n}$ of order 1 in each case.
2. Tables 5.2 and 5.3 show that a large value of ϕ does not necessarily lead to a large row-wise backward error. Although ϕ is theoretically independent of the row ordering, it varies between Algorithm EH with and without row sorting in some of the tests as a result of roundoff: in these cases ϕ is determined by ratios of quantities that are of order u and have large relative error.

TABLE 5.1
Results for Problem 1 *(random normal A and B).*

tol = 1

	η_N	η_R	$\rho_{m,n}$	ϕ
Alg. EH (no row interchanges)	6.3e-8	6.4e-8	4.5e0	1.5e0

Null space method	5.1e-8	2.7e-7		

TABLE 5.2
Results for Problem 2 *($\kappa_2(A) = 10$, $\kappa_2(B) = 10^4$), $\mathrm{tol} = 10^{-7}$.*

	η_N	η_R	$\rho_{m,n}$	ϕ
Alg. EH (no row interchanges)	4.3e-4	1.1e-2	6.6e6	4.6e3
Alg. EH (row sorting)	2.4e-8	1.6e-7	2.7e0	1.4e4
Null space method	7.2e-8	2.2e-7		

3. The normwise backward error bound η_N is small in every case except for Algorithm EH without row interchanges in two instances. However, using numerical optimization by direct search we found alternative choices of ΔB_* and Δd_* for which $\eta_N \approx u$ in these two examples, confirming normwise backward stability. In the cases where Algorithm EH without row interchanges produced a large value of η_R, we were unable to reduce this value significantly using direct search.
4. The null space method gives very similar values of η_N and η_R to Algorithm EH with row sorting. It is surprising that η_R is small for the null space method when $\mathrm{tol} = 10^{-7}$ because our implementation does not incorporate any form of row interchanges. The reason for this excellent performance is not clear (it is not explained by the normwise backward error results in [6], for example).

Finally, although our concern in this work is with backward errors rather than forward errors, we carried out an experiment to show the effect of row interchanges on the forward error, $\|x - \widehat{x}\|_2/\|x\|_2$. For Problems 1 and 4 we computed forward errors by taking as the exact solution the one computed in double precision by Algorithm EH with row sorting. Table 5.4 shows that row sorting can greatly decrease the forward error when A and B have badly scaled rows.

6. Concluding remarks. We have used a limit argument to derive a method, Algorithm EH, for solving the LSE problem and have derived a row-wise backward error bound for the method by exploiting existing error analysis. The row-wise backward error is guaranteed to be small when the growth factor $\rho_{m,n}$ is small (which is usually the case with row pivoting or sorting) and when the scalar ϕ is small (ϕ can be arbitrarily large, and is independent of the row interchanges).

The method is closely related to the EG method, which dates back to the 1960s, and this relation enabled us to obtain a row-wise backward error bound for that

TABLE 5.3

method, too. Which method should be preferred? There is no difference between the two methods in terms of the backward error results or the numerical backward error bounds that we have evaluated. The methods also have similar operation counts. Algorithm EH can be coded slightly more concisely, since it carries out transformations on B-over-A as a whole while the EG method applies Householder transformations to B and separate elimination operations to A, and this difference should make Algorithm EH more efficient on high-performance computers.

NOTE ON PERTURBATION THEORY FOR ALGEBRAIC RICCATI EQUATIONS*

M. KONSTANTINOV† AND P. PETKOV‡

Abstract. The expressions for the induced norms of two complex matrix operators, given in [J.-G. Sun, *SIAM J. Matrix Anal. Appl.*, 19 (1998), pp. 39–65], must be corrected. In this note we give the true values of these induced norms, which are involved in the perturbation analysis of matrix algebraic Riccati equations in the complex domain.

PII. S0895479898338111

In a recent paper [1] improvements of existing perturbation bounds for continuous- and discrete-time algebraic Riccati equations (CARE and DARE, respectively) are proposed. An important quantity here is the value of the induced norm of the operator $\mathbf{P}_c : \mathcal{C}^{n\times n} \to \mathcal{C}^{n\times n}$, defined from $\mathbf{P}_c N = \mathbf{L}_c^{-1}(XN + N^H X)$ for CARE and a similar operator $\mathbf{P}_d$ for DARE, where $\mathbf{L}_c$ is an invertible Lyapunov operator. (Note that the operators $\mathbf{P}$ are additive but not homogeneous and hence they are not linear over $\mathcal{C}$.)

The expressions (3.33) for the norm of $\mathbf{P}_c$ and (4.53) for the norm of $\mathbf{P}_d$ should be corrected as follows. (There are several ways to derive the proper expressions; the most instructive is to consider the realification of the corresponding operator.)

Let X_c be the positive definite solution of CARE (see (1.3)), and let T_c be the matrix (3.31) of $\mathbf{L}_c$. Let X_d and T_d be the corresponding matrices for DARE, defined from (1.5) and (4.51). Finally, let $K = X_d F(I + GX_d)^{-1}A$ be defined from (4.3). Denote

$$T_c^{-1}(I_n \otimes X_c) = \Psi_{c,0} + \jmath\Psi_{c,1}, T_c^{-1}(X_c^\top \otimes I_n)\Pi = \Theta_{c,0} + \jmath\Theta_{c,1},$$
$$T_d^{-1}(I_n \otimes K^H) = \Psi_{d,0} + \jmath\Psi_{d,1}, T_d^{-1}(K^\top \otimes I_n)\Pi = \Theta_{d,0} + \jmath\Theta_{d,1}.$$

Then the correct values for (3.33) and (4.53) are

$$p_e = \left\| \begin{bmatrix} \Psi_{e,0} + \Theta_{e,0} & \Theta_{e,1} - \Psi_{e,1} \\ \Psi_{e,1} + \Theta_{e,1} & \Psi_{e,0} - \Theta_{e,0} \end{bmatrix} \right\|_2; \quad e = c, d.$$

It may be observed that the operators $\mathbf{P}_e$ are somehow misfortunate in the complex case. In the report of Konstantinov et al. [2] there was a mistake in the vec representation of $\mathbf{P}_c$, which is corrected in the published version.

ON THE SEQUENCE OF CONSECUTIVE POWERS OF A MATRIX IN A BOOLEAN ALGEBRA*

BART DE SCHUTTER† AND BART DE MOOR‡

Abstract. In this paper we consider the sequence of consecutive powers of a matrix in a Boolean algebra. We characterize the ultimate behavior of this sequence, we study the transient part of the sequence, and we derive upper bounds for the length of this transient part. We also indicate how these results can be used in the analysis of Markov chains and in max-plus algebraic system theory for discrete event systems.

Key words. Boolean algebra, Boolean matrices, transient behavior, Markov chains, max-plus algebra

PII. S0895479897326079

1. Introduction.

In this paper we consider the sequence of consecutive powers of a matrix in a Boolean algebra. This sequence reaches a "cyclic" behavior after a finite number of terms. Even for more complex algebraic structures, such as the max-plus algebra (which has maximization and addition as its basic operations) this ultimate behavior has already been studied extensively by several authors (see, e.g., [1, 9, 13, 26] and the references therein). In this paper we completely characterize the ultimate behavior of the sequence of the consecutive powers of a matrix in a Boolean algebra. Furthermore, we also study the *transient* part of this sequence. More specifically, we give upper bounds for the length of the transient part of the sequence as a function of structural parameters of the matrix.

Our main motivation for studying this problem lies in the max-plus algebraic system theory for discrete event systems. Furthermore, our results can also be used in the analysis of the transient behavior of Markov chains.

This paper is organized as follows. In section 2 we introduce some of the notations and concepts from number theory, Boolean algebra, matrix algebra, and graph theory that will be used in the paper. In section 3 we characterize the ultimate behavior of the sequence of consecutive powers of a given matrix in a Boolean algebra, and we derive upper bounds for the length of the transient part of this sequence. In section 4 we briefly sketch how our results can be used in the analysis of Markov chains and in the max-plus algebraic system theory for discrete event systems. In this section we also explain why we have restricted ourselves to Boolean algebras in this paper and we indicate some of the phenomena that should be taken into account when extending our results to more general algebraic structures. Finally we present some conclusions in section 5.

TABLE 2.1
The operations $\oplus$ and $\otimes$ for the Boolean algebra $(\{\mathtt{0},\mathtt{1}\},\oplus,\otimes)$.

$\oplus$	$\mathtt{0}$	$\mathtt{1}$
$\mathtt{0}$	$\mathtt{0}$	$\mathtt{1}$
$\mathtt{1}$	$\mathtt{1}$	$\mathtt{1}$

$\otimes$	$\mathtt{0}$	$\mathtt{1}$
$\mathtt{0}$	$\mathtt{0}$	$\mathtt{0}$
$\mathtt{1}$	$\mathtt{0}$	$\mathtt{1}$

2. Preliminaries.

2.1. Notation, definitions, and some lemmas from number theory. In this paper we use "vector" as a synonym for "column matrix." If a is a vector, then a_i is the ith component of a. If A is a matrix, then a_{ij} or $(A)_{ij}$ is the entry on the ith row and the jth column and $A_{\alpha\beta}$ is the submatrix of A obtained by removing all rows that are not indexed by the set α and all columns that are not indexed by the set β.

The set of the real numbers is denoted by $\mathbb{R}$, the set of the nonnegative integers by $\mathbb{N}$, and the set of the positive integers by $\mathbb{N}_0$.

If S is a set, then the number of elements of S is denoted by $\#S$. If γ is a set of positive integers, then the least common multiple of the elements of γ is denoted by $\operatorname{lcm}\gamma$ and the greatest common divisor of the elements of γ is denoted by $\gcd\gamma$.

If $x \in \mathbb{R}$, then $\lceil x \rceil$ is the smallest integer that is larger than or equal to x, and $\lfloor x \rfloor$ is the largest integer that is less than or equal to x.

LEMMA 2.1. *Let $p, q \in \mathbb{N}_0$ be coprime. The smallest integer n such that for any integer $m \geq n$ there exist two nonnegative integers α and β such that $m = \alpha p + \beta q$ is given by $n = (p-1)(q-1)$.*

Proof. See, e.g., the proof of Lemma 3.5.5 of [5]. □

Let $a_1, a_2, \ldots, a_n \in \mathbb{N}_0$ with $\gcd(a_1, a_2, \ldots, a_n) = 1$. We define $g(a_1, a_2, \ldots, a_n)$ to be the largest positive integer N for which the equation $a_1x_1 + a_2x_2 + \cdots + a_nx_n = N$ subject to $x_1, x_2, \ldots, x_n \in \mathbb{N}$ has *no* solution. From Lemma 2.1 it follows that $g(a,b) = (a-1)(b-1) - 1 = ab - a - b$. Although a formula exists for the case where $n = 3$, no general formulas are known for $n \geq 4$. However, some upper bounds have been proved [4, 11].

LEMMA 2.2. *If $a_1, a_2, \ldots, a_n \in \mathbb{N}_0$ with $a_1 < a_2 < \cdots < a_n$ and $\gcd(a_1, \ldots, a_n) = 1$, then $g(a_1, \ldots, a_n) \leq (a_1 - 1)(a_n - 1) - 1$.*

LEMMA 2.3. *If $a_1, a_2, \ldots, a_n \in \mathbb{N}_0$ with $a_1 < a_2 < \cdots < a_n$ and $\gcd(a_1, \ldots, a_n) = 1$, then we have $g(a_1, \ldots, a_n) \leq 2a_{n-1}\left\lfloor \frac{a_n}{n} \right\rfloor - a_n$.*

2.2. Boolean algebra. A Boolean algebra is an algebraic structure of the form $(\mathbb{B}, \oplus, \otimes)$ with $\mathbb{B} = \{\mathtt{0}, \mathtt{1}\}$ such that the operations $\oplus$ and $\otimes$ applied on $\mathtt{0}$ and $\mathtt{1}$ yield the results of Table 2.1, where $\oplus$ and $\otimes$ are associative and where $\otimes$ is distributive with respect to $\oplus$. The element $\mathtt{0}$ is called the Boolean zero element, $\mathtt{1}$ is called the Boolean identity element, $\oplus$ is called the Boolean addition, and $\otimes$ is called the Boolean multiplication.

Some examples of Boolean algebras are $(\{\text{false}, \text{true}\}, \text{or}, \text{and})$, $(\{0, \infty\}, \min, +)$, $(\{0,1\}, \max, \cdot)$, $(\{\emptyset, \mathbb{N}\}, \cup, \cap)$, $(\{0,1\}, \max, \min)$, $(\{-\infty, \infty\}, \max, \min)$, and so on (see [1, 15]). In this paper we shall use the following examples of Boolean algebra to transform known results from max-plus algebra and from nonnegative matrix algebra to Boolean algebra:

1. The Boolean algebra $(\{-\infty, 0\}, \max, +)$ is a subalgebra of the max-plus algebra $(\mathbb{R} \cup \{-\infty\}, \max, +)$.

2. The Boolean algebra $(\{0, \mathfrak{p}\}, +, \cdot)$, where $\mathfrak{p}$ stands for an arbitrary positive number,[1] can be considered as a Boolean restriction of nonnegative algebra.

A matrix with entries in $\mathbb{B}$ is called a Boolean matrix. The operations $\oplus$ and $\otimes$ are extended to matrices as follows. If $A, B \in \mathbb{B}^{m\times n}$, then we have

$$(A \oplus B)_{ij} \;=\; a_{ij} \oplus b_{ij}$$

for all i, j. If $A \in \mathbb{B}^{m\times p}$ and $B \in \mathbb{B}^{p\times n}$, then

$$(A \otimes B)_{ij} \;=\; \bigoplus_{k=1}^{p} a_{ik} \otimes b_{kj}$$

for all i, j. Note that these definitions resemble the definitions of the sum and the product of matrices in linear algebra but with $\oplus$ instead of $+$ and $\otimes$ instead of $\cdot$.

The $n \times n$ Boolean identity matrix is denoted by $\mathcal{I}_n$, the $m \times n$ Boolean zero matrix is denoted by $\mathcal{O}_{m\times n}$, and the $m \times n$ matrix all the entries of which are equal to $\mathbb{1}$ is denoted by $\mathcal{E}_{m\times n}$. If the dimensions of these matrices are not indicated, they should be clear from the context.

The Boolean matrix power of the matrix $A \in \mathbb{B}^{n\times n}$ is defined as follows:

$$A^{\otimes 0} = \mathcal{I}_n \qquad \text{and} \qquad A^{\otimes k} = A \otimes A^{\otimes k-1} \qquad \text{for } k = 1, 2, \ldots.$$

If we permute the rows or the columns of the Boolean identity matrix, we obtain a Boolean permutation matrix. If $P \in \mathbb{B}^{n\times n}$ is a Boolean permutation matrix, then we have $P \otimes P^T = P^T \otimes P = \mathcal{I}_n$. A matrix $R \in \mathbb{B}^{m\times n}$ is a Boolean upper triangular matrix if $r_{ij} = \mathbb{0}$ for all i, j with $i > j$.

2.3. Boolean algebra and graph theory. We assume that the reader is familiar with basic concepts of graph theory such as directed graph, path, (elementary) circuit, and so on (see, e.g., [1, 18, 27]). In this paper we shall use the definitions of [1] since they are well suited for our proofs. Sometimes these definitions differ slightly from the definitions adopted by other schools in the literature. The most important differences are as follows:

- In this paper we also consider *empty* paths, i.e., paths that consist of only one vertex and have length 0. However, unless it is explicitly specified, we always assume that paths have a nonzero length.
- The precedence graph of the matrix $A \in \mathbb{B}^{n\times n}$, denoted by $\mathcal{G}(A)$, is a directed graph with vertices 1, 2, ..., n and an arc $j \to i$ for each $a_{ij} \neq \mathbb{0}$. Note that vertex i is the *end point* of this arc.
- A directed graph is called strongly connected if for any two *different* vertices v_i, v_j there exists a path from v_i to v_j. Note that this implies that a graph consisting of one vertex (with or without a loop) is always strongly connected.
- A matrix is irreducible if its precedence graph is strongly connected. Since, according to the definition we use, a graph with only one vertex is always strongly connected, the 1×1 Boolean zero matrix $[\mathbb{0}]$ is irreducible. However, the 1×1 Boolean zero matrix $[\mathbb{0}]$ is the only Boolean zero matrix that is irreducible.

Let us now give a graph-theoretic interpretation of the Boolean matrix power. Let $A \in \mathbb{B}^{n\times n}$ and let $k \in \mathbb{N}_0$. Recall that there is an arc $j \to i$ in $\mathcal{G}(A)$ if and only if

[1] So $\mathfrak{p} + \mathfrak{p} = \mathfrak{p}$ and $\mathfrak{p} \cdot \mathfrak{p} = \mathfrak{p}$.

$a_{ij} = \mathbb{1}$. Since

$$\left(A^{\otimes^k}\right)_{ij} = \bigoplus_{i_1,i_2,\ldots,i_{k-1}} a_{ii_1} \otimes a_{i_1 i_2} \otimes \cdots \otimes a_{i_{k-1}j}$$

for all i, j and since $\mathbb{0}$ is absorbing for $\otimes$, $(A^{\otimes^k})_{ij}$ is equal to $\mathbb{1}$ if and only if there exists a path of length k from vertex j to vertex i in $\mathcal{G}(A)$.

A maximal strongly connected subgraph (m.s.c.s.) $\mathcal{G}_{\text{sub}}$, of a directed graph $\mathcal{G}$ is a strongly connected subgraph that is maximal, i.e., if we add an extra vertex (and some extra arcs) of $\mathcal{G}$ to $\mathcal{G}_{\text{sub}}$, then $\mathcal{G}_{\text{sub}}$ is no longer strongly connected.

A well-known result from matrix algebra states that any square matrix can be transformed into a block upper diagonal matrix with irreducible blocks by simultaneously reordering the rows and columns of the matrix (see, e.g., [1, 2, 5, 12, 17, 22] for the proof of this theorem and for its interpretation in terms of graph theory and Markov chains).

THEOREM 2.4. *If $A \in \mathbb{B}^{n\times n}$, then there exists a permutation matrix $P \in \mathbb{B}^{n\times n}$ such that the matrix $\hat{A} = P \otimes A \otimes P^T$ is a block upper triangular matrix of the form*

$$\hat{A} = \begin{bmatrix} \hat{A}_{11} & \hat{A}_{12} & \ldots & \hat{A}_{1l} \\ \mathcal{O} & \hat{A}_{22} & \ldots & \hat{A}_{2l} \\ \vdots & \vdots & \ddots & \vdots \\ \mathcal{O} & \mathcal{O} & \ldots & \hat{A}_{ll} \end{bmatrix} \tag{1}$$

with $l \geq 1$ and where the matrices $\hat{A}_{11}$, $\hat{A}_{22}$, ..., $\hat{A}_{ll}$ are square and irreducible. The matrices $\hat{A}_{11}$, $\hat{A}_{22}$, ..., $\hat{A}_{ll}$ are uniquely determined to within simultaneous permutation of their rows and columns, but their ordering in (1) *is not necessarily unique.*

The form in (1) is called the Frobenius normal form of the matrix A. If A is irreducible, then there is only one block in (1) and then A is a Frobenius normal form of itself. Each diagonal block of $\hat{A}$ corresponds to an m.s.c.s. of the precedence graph of $\hat{A}$.

THEOREM 2.5. *If $A \in \mathbb{B}^{n\times n}$ is irreducible, then*

$$\exists k_0 \in \mathbb{N}, \exists c \in \mathbb{N}_0, \text{ such that for all } k \geq k_0 : A^{\otimes^{k+c}} = \lambda^{\otimes^c} \otimes A^{\otimes^k}, \tag{2}$$

where λ is equal to $\mathbb{1}$ if there exists a circuit in $\mathcal{G}(A)$, and equal to $\mathbb{0}$ otherwise.

Proof. See, e.g., [1, 7, 13]. □

The smallest c for which (2) holds is called the cyclicity [1], index of cyclicity [2], or index of *im*primitivity[2] [5, 12] of the matrix A. The cyclicity $c(A)$ of a matrix A is equal to the cyclicity of the precedence graph $\mathcal{G}(A)$ of A and can be computed as follows. The cyclicity of a strongly connected graph or of an m.s.c.s. is the greatest common divisor of the lengths of all the circuits of the given graph or m.s.c.s. If an m.s.c.s. or a graph contains no circuits then its cyclicity is equal to 0 by definition. The cyclicity of general graph is the least common multiple of the nonzero cyclicities of the m.s.c.s.'s of the given graph.

LEMMA 2.6. *If $A \in \mathbb{B}^{n\times n}$ is irreducible, then $c(A) \leq n$.*

Proof. Let $c = c(A)$. Since A is irreducible, $\mathcal{G}(A)$ contains only one m.s.c.s.

[2]We prefer to use the terms "cyclicity" and "index of cyclicity" in this paper to avoid confusion with the concept "index of primitivity" [2, 25] of a nonnegative matrix A, which is defined to be the least positive integer $\gamma(A)$ such that all the entries of $A^{\gamma(A)}$ are positive.

If $A = [\,\mathtt{0}\,]$, then we have $c = 0 \leq 1 = n$.

From now on we assume that $A \neq \mathcal{O}$. Since c is the greatest common divisor of the lengths of the (elementary) circuits in $\mathcal{G}(A)$, c is maximal if there is only one circuit and if this circuit has length n. In that case we have $c = n$. In the other cases, c will be less than n. Thus $c(A) \leq n$. □

LEMMA 2.7. *Let $A \in \mathbb{B}^{n\times n}$ be irreducible and let c be the cyclicity of A. Consider $i, j \in \{1, 2, \ldots, n\}$. If $c > 0$ and if there exists a (nonempty) path of length l_1 from j to i and a (nonempty) path of length l_2 from j to i, then there exists a (possibly negative) integer z such that $l_2 = l_1 + zc$.*

Proof. This lemma is a reformulation of Lemma 3.4.1 of [5] that states that if $\mathcal{G}$ is a strongly connected directed graph with cyclicity c, then for each pair of vertices j and i of $\mathcal{G}$, the lengths of the paths from j to i are congruent modulo c. □

Remark 2.8. Consider $A \in \mathbb{B}^{n\times n}$ and $i, j \in \{1, 2, \ldots, n\}$. Let l_{ij} be the length of the shortest path from vertex j to vertex i in $\mathcal{G}(A)$. Note that Lemma 2.7 does *not* imply that there exists a path of length $l_{ij} + kc$ from j to i for *every* $k \in \mathbb{N}$.

In the next section we discuss upper bounds for the integer k_0 that appears in Theorem 2.5. We also extend this theorem to Boolean matrices that are not irreducible.

3. Consecutive powers of a Boolean matrix. In this section we consider the sequence $\{A^{\otimes^k}\}_{k=1}^{\infty}$ where A is a Boolean matrix. First we consider matrices with a cyclicity that is equal to 0. Next we consider matrices with a cyclicity that is larger than or equal to 1. Here we shall make a distinction among four different cases depending on whether the given matrix is irreducible and whether its cyclicity is equal to 1 or larger than or equal to 1. Of course the last case that will be considered is the most general one, but for the other cases we can provide tighter upper bounds on the length of the transient part of the sequence $\{A^{\otimes^k}\}_{k=1}^{\infty}$ and that is why we consider four different cases.

If possible we also give examples of matrices for which the sequence of the consecutive matrix powers exhibits the longest possible transient behavior.

3.1. Boolean matrices with a cyclicity that is equal to 0.

LEMMA 3.1. *Let $A \in \mathbb{B}^{n\times n}$. If $c(A) = 0$, then we have $A^{\otimes^k} = \mathcal{O}_{n\times n}$ for all $k \geq n$.*

Proof. If the cyclicity of A is equal to 0, then there are no circuits in $\mathcal{G}(A)$, which means that there do not exist paths in $\mathcal{G}(A)$ with a length that is larger than or equal to n since in such paths at least one vertex would appear twice, which implies that such paths contain a circuit. Therefore, we have $A^{\otimes^k} = \mathcal{O}$ for all $k \geq n$. □

Example 3.2. If there exists a permutation matrix P such that $A \in \mathbb{B}^{n\times n}$ can be written as

$$\hat{A} = P \otimes A \otimes P^T = \begin{bmatrix} \mathtt{0} & \mathtt{1} & \mathtt{0} & \ldots & \mathtt{0} \\ \mathtt{0} & \mathtt{0} & \mathtt{1} & \ldots & \mathtt{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathtt{0} & \mathtt{0} & \mathtt{0} & \ldots & \mathtt{1} \\ \mathtt{0} & \mathtt{0} & \mathtt{0} & \ldots & \mathtt{0} \end{bmatrix},$$

then the upper bound of Lemma 3.1 is tight, that is, we have $A^{\otimes^k} \neq \mathcal{O}$ for $k = 1, 2, \ldots, n-1$ and $A^{\otimes^k} = \mathcal{O}$ for all $k \geq n$. The graph of the matrix $\hat{A}$ is represented

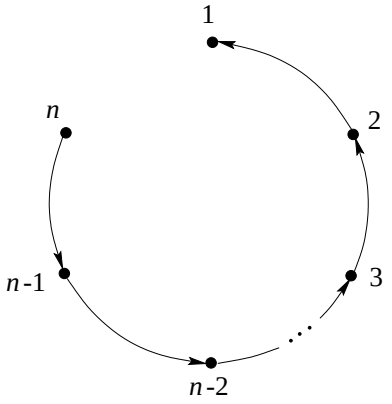

FIG. 3.1. *The precedence graph of the matrix $\hat{A}$ of Example* 3.2.

in Figure 3.1. Note that $c(A) = c(\hat{A}) = 0$ since $\mathcal{G}(\hat{A})$ contains no circuits and since the transformation from A to $\hat{A}$ corresponds to a simultaneous reordering of the rows and the columns of A (or of the vertices of $\mathcal{G}(A)$).

From now on we consider only matrices with a cyclicity that is larger than or equal to 1.

3.2. Boolean matrices with cyclicity 1.

THEOREM 3.3. *Let $A \in \mathbb{B}^{n\times n}$. If the cyclicity of A is equal to* 1 *and if A is irreducible, then we have $A^{\otimes^{k+1}} = A^{\otimes^k} = \mathcal{E}_{n\times n}$ for all $k \geq (n-1)^2 + 1$.*

Proof. This theorem can be considered as the Boolean equivalent of Theorem 4.14 of [2] or of Theorem 3.5.6 of [5]. Note that A cannot be equal to $[\mathtt{0}]$ because $c(A) = 1$. □

If more information about the structure of A is known (such as the number of diagonal entries that are equal to $\mathtt{1}$, the length of the shortest elementary circuit of $\mathcal{G}(A)$, or whether A is symmetrically nonnegative), other upper bounds for the length of the transient part of the sequence $\left\{A^{\otimes^k}\right\}_{k=1}^{\infty}$ where A is a Boolean matrix with cyclicity 1 can be found in section 2.4 of [2].

Example 3.4. If there exists a permutation matrix P such $A \in \mathbb{B}^{n\times n}$ can be written as

$$\hat{A} = P \otimes A \otimes P^T = \begin{bmatrix} \mathtt{0} & \mathtt{1} & \mathtt{0} & \dots & \mathtt{0} \\ \mathtt{0} & \mathtt{0} & \mathtt{1} & \dots & \mathtt{0} \\ \vdots & \vdots & \mathtt{0} & \ddots & \vdots \\ \mathtt{1} & \mathtt{0} & \mathtt{0} & \dots & \mathtt{1} \\ \mathtt{1} & \mathtt{0} & \mathtt{0} & \dots & \mathtt{0} \end{bmatrix}, \tag{3}$$

then the bound in Theorem 3.3 is tight: we have $A^{\otimes^k} = \mathcal{E}$ for all $k \geq (n-1)^2 + 1$ but $A^{\otimes^{(n-1)^2}} \neq \mathtt{1}$. Let us now show that the latter part of this statement indeed holds.

Since the transformation from A to $\hat{A} = P \otimes A \otimes P^T$ corresponds to a simultaneous reordering of the rows and columns of A, we may assume without loss of generality that P is the identity matrix. Thus $A = \hat{A}$. If $n = 2$, then we have $(n-1)^2 + 1 = 2$. Since

$$A = \begin{bmatrix} \mathtt{1} & \mathtt{1} \\ \mathtt{1} & \mathtt{0} \end{bmatrix} \quad \text{and} \quad A^{\otimes^2} = A^{\otimes^3} = \cdots = \mathcal{E},$$

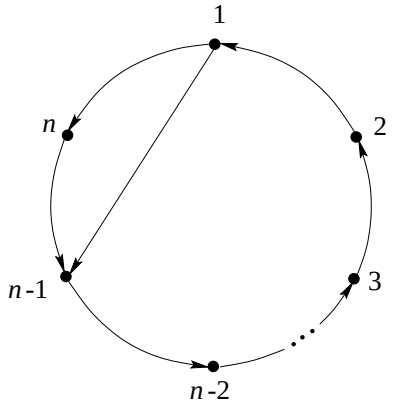

FIG. 3.2. *The precedence graph of the matrix $\hat{A}$ of Example* 3.4.

we indeed have $A^{\otimes^{(n-1)^2}} \neq \mathcal{E}$ if $n = 2$.

From now on we assume that $n > 2$. In Figure 3.2 we have drawn $\mathcal{G}(A)$. There are two elementary circuits in $\mathcal{G}(A)$: circuit $C_1 : n \to n-1 \to \cdots \to 1 \to n$ of length n and circuit $C_2 : n-1 \to n-2 \to 1 \to n-1$ of length $n-1$. Note that only the longest circuit passes through vertex n. Furthermore, if $n > 2$, then $\gcd(n-1, n) = 1$. Any circuit that passes through vertex n can be considered as a concatenation of α times C_1, a path from vertex n to a vertex t in C_2, β times C_2, and a path from t to n for some nonnegative integers α and β. The length of this circuit is equal to $n + \alpha n + \beta(n-1)$. By Lemma 2.1 the smallest integer N such that for any integer $p \geq N$ there exist nonnegative integers α and β such that $p = \alpha n + \beta(n-1)$ is given by $N = (n-1)(n-2)$. This implies that $(n-1)(n-2) - 1$ cannot be written as $\gamma n + \delta(n-1)$ with $\gamma, \delta \in \mathbb{N}$. This implies that there does not exist a circuit of length $n + (n-1)(n-2) - 1 = (n-1)^2$ that passes through vertex n. Hence,

$$\left(A^{\otimes^{(n-1)^2}}\right)_{nn} = \mathtt{o}$$

and thus $A^{\otimes^{(n-1)^2}} \neq \mathcal{E}$.

Let $A \in \mathbb{B}^{n\times n}$. If $\hat{A} = P \otimes A \otimes P^T$ is the Frobenius normal form of A, then we have $A = P^T \otimes \hat{A} \otimes P$. Hence,

$$A^{\otimes^k} = \left(P^T \otimes \hat{A} \otimes P\right)^{\otimes^k} = P^T \otimes \hat{A}^{\otimes^k} \otimes P$$

for all $k \in \mathbb{N}$. Therefore, we may consider without loss of generality the sequence $\left\{\hat{A}^{\otimes^k}\right\}_{k=1}^{\infty}$ instead of the sequence $\left\{A^{\otimes^k}\right\}_{k=1}^{\infty}$. Furthermore, since the transformation from A to $\hat{A}$ corresponds to a simultaneous reordering of the rows and columns of A (or to a reordering of the vertices of $\mathcal{G}(A)$), we have $c(A) = c(\hat{A})$.

THEOREM 3.5. *Let $\hat{A} \in \mathbb{B}^{n\times n}$ be a matrix of the form* (1)*, where the matrices $\hat{A}_{11}$, $\hat{A}_{22}$, …, $\hat{A}_{ll}$ are irreducible and such that $c(\hat{A}) = 1$. Define sets α_1, α_2, …, α_l such that $\hat{A}_{\alpha_i\alpha_j} = \hat{A}_{ij}$ for all i, j with $i \leq j$. Let $n_i = \#\alpha_i$ for all i. Define*

$$\lambda_i = \begin{cases} \mathtt{o} & \text{if } \hat{A}_{ii} = [\mathtt{o}], \\ \mathtt{1} & \text{otherwise} \end{cases}$$

for $i = 1, 2, \ldots, l$. *Define*

$$S_{ij} = \Big\{ \{i_0, i_1, \ldots, i_s\} \subseteq \{1, 2, \ldots, l\} \;\Big|\; i = i_0 < i_1 < \cdots < i_s = j \text{ and } \hat{A}_{i_r i_{r+1}} \neq \mathcal{O} \text{ for } r = 0, 1, \ldots, s-1 \Big\}$$

for all i, j *with* $i < j$.

Let $\lambda_{ii} = \lambda_i$ *and* $k_{ii} = (n_i - 1)^2 + 1$ *for* $i = 1, 2, \ldots, n$. *Define*

$$\Gamma_{ij} = \big\{ t \,\big|\, \exists \gamma \in S_{ij} \text{ such that } t \in \gamma \big\},$$

$$\lambda_{ij} = \begin{cases} \bigoplus\limits_{t \in \Gamma_{ij}} \lambda_t & \text{if } \Gamma_{ij} \neq \emptyset, \\ \mathfrak{o} & \text{otherwise}, \end{cases}$$

$$t_{ij} = \begin{cases} \arg\min \{n_t \,|\, t \in \Gamma_{ij} \text{ and } \lambda_{tt} \neq \mathfrak{o}\} & \text{if } \lambda_{ij} \neq \mathfrak{o}, \\ 0 & \text{otherwise}, \end{cases}$$

$$k_{ij} = \begin{cases} \sum\limits_{\substack{t \in \Gamma_{ij} \\ t \neq t_{ij}}} n_t + k_{t_{ij} t_{ij}} & \text{if } \lambda_{ij} \neq \mathfrak{o}, \\ \#\Gamma_{ij} & \text{if } \Gamma_{ij} \neq \emptyset \text{ and } \lambda_{ij} = \mathfrak{o}, \\ 1 & \text{if } \Gamma_{ij} = \emptyset \end{cases}$$

for all i, j *with* $i < j$. *Then we have for all* i, j *with* $i \leq j$*:*

$$\left(\hat{A}^{\otimes^k}\right)_{\alpha_i \alpha_j} = \begin{cases} \mathcal{E}_{n_i \times n_j} & \text{if } \lambda_{ij} \neq \mathfrak{o}, \\ \mathcal{O}_{n_i \times n_j} & \text{if } \lambda_{ij} = \mathfrak{o} \end{cases} \qquad \text{for all } k \geq k_{ij}. \tag{4}$$

For all i, j *with* $i > j$ *we have*

$$\left(\hat{A}^{\otimes^k}\right)_{\alpha_i \alpha_j} = \mathcal{O}_{n_i \times n_j} \qquad \text{for all } k \in \mathbb{N}. \tag{5}$$

Remark 3.6. Note that $\hat{A}_{ij}$ is an $n_i \times n_j$ matrix for all i, j.

Let us now give a graphical interpretation of the sets S_{ij} and Γ_{ij}.

Let C_i be the m.s.c.s. of $\mathcal{G}(\hat{A})$ that corresponds to $\hat{A}_{ii}$ for $i = 1, 2 \ldots, l$. Thus α_i is the set of vertices of C_i.

If $\{i_0 = i, i_1, \ldots, i_{s-1}, i_s = j\} \in S_{ij}$, then there exists a path from a vertex in C_{i_r} to a vertex in $C_{i_{r-1}}$ for each $r = 1, 2, \ldots, s$. Since each m.s.c.s. C_i of $\mathcal{G}(\hat{A})$ either is strongly connected or consists of only one vertex, this implies that there exists a path from a vertex in C_j to a vertex in C_i that passes through $C_{i_{s-1}}$, $C_{i_{s-2}}$, ..., C_{i_1}.

If $S_{ij} = \emptyset$, then there does not exist any path from a vertex in C_j to a vertex in C_i.

The set Γ_{ij} is the set of indices of the m.s.c.s.'s of $\mathcal{G}(\hat{A})$ through which some path from a vertex of C_j to a vertex of C_i passes.

If $S_{ij} \neq \emptyset$, then $C_{t_{ij}}$ is the smallest m.s.c.s. of $\mathcal{G}(A)$ that contains a circuit and through which some path from a vertex of C_j to a vertex of C_i passes.[3]

[3]Or more precisely: if $S_{ij} \neq \emptyset$, then $C_{t_{ij}}$ belongs to the set of the smallest m.s.c.s.'s of $\mathcal{G}(A)$ that contain a circuit and through which some path from a vertex of C_j to a vertex of C_i passes.

Proof of Theorem 3.5. Let C_i be the m.s.c.s. of $\mathcal{G}(\hat{A})$ that corresponds to $\hat{A}_{ii}$ for $i = 1, 2 \ldots, l$. Since $\hat{A}_{\alpha_i \alpha_j} = \mathcal{O}$ if $i > j$, there are no arcs from any vertex of C_j to a vertex in C_i. As a consequence, (5) holds if $i > j$.

Note that $c(\hat{A}_{ii}) = 1$ for all $i \in \{1, 2, \ldots, l\}$ with $\hat{A}_{ii} \neq [\mathfrak{o}]$ since $c(\hat{A}) = 1$ and since each $\hat{A}_{ii}$ corresponds to an m.s.c.s. of $\mathcal{G}(\hat{A})$.

If $l = 1$, then $\hat{A}$ is irreducible and then (4) holds by Theorem 3.3. It is easy to verify that (4) holds if $i = j$.

From now on we assume that $l > 1$ and $i < j$.

If $\Gamma_{ij} = \emptyset$, then there does not exist a path from a vertex in C_j to a vertex in C_i. Hence, $\left(\hat{A}^{\otimes^k}\right)_{\alpha_i \alpha_j} = \mathcal{O}$ for all $k \in \mathbb{N}$.

If $\Gamma_{ij} \neq \emptyset$ and $\lambda_{ij} = \mathfrak{o}$, then we have $\hat{A}_{tt} = [\mathfrak{o}]$ for all $t \in \Gamma_{ij}$. Thus there exist paths from a vertex in C_j to a vertex in C_i, but each path passes only through m.s.c.s.'s that consist of one vertex and contain no loop. Such a path passes through at most $\#\Gamma_{ij}$ of such m.s.c.s.'s (C_j and C_i included). This implies that there does not exist a path with a length that is larger than or equal to $\#\Gamma_{ij}$ from a vertex in C_j to a vertex in C_i. Hence, we have $\left(A^{\otimes^k}\right)_{\alpha_i \alpha_j} = \mathcal{O}$ for all $k \geq \#\Gamma_{ij}$.

From now on we assume that $l > 1$, $i < j$, $\Gamma_{ij} \neq \emptyset$, and $\lambda_{ij} \neq \mathfrak{o}$. Then there exists a set $\{i_0, i_1, \ldots, i_s\} \subseteq \{1, 2, \ldots, l\}$ with $t_{ij} \in \{i_0, i_1, \ldots, i_s\}$ and there exist indices $u_r \in \alpha_{i_r}$, $v_{r+1} \in \alpha_{i_{r+1}}$ for $r = 0, 1, \ldots, s-1$ such that $i = i_0 < i_1 < \cdots < i_s = j$ and $\hat{A}_{u_r v_{r+1}} \neq \mathfrak{o}$ for each r. Thus there exists an arc from vertex v_{r+1} of $C_{i_{r+1}}$ to vertex u_r of C_{i_r} for each $r \in \{0, 1, \ldots, s-1\}$. Select an arbitrary vertex u_s of $C_{i_s} = C_j$ and an arbitrary vertex v_0 of $C_{i_0} = C_i$. Note that $s \in \{1, 2, \ldots, j-i\}$. Let $r \in \{0, 1, \ldots, s\}$. Recall that the only Boolean zero matrix that is irreducible is the 1×1 Boolean zero matrix $[\mathfrak{o}]$. Now we distinguish between two cases:

- If $\hat{A}_{i_r i_r} = [\mathfrak{o}]$, then we have $n_{i_r} = 1$ and $u_r = v_r$. Thus in this case we could say that there exists an empty path of length $l_r = 0$ from vertex u_r to vertex v_r of C_{i_r}.
- On the other hand, if $\hat{A}_{i_r i_r} \neq [\mathfrak{o}]$, then there exists a (possibly empty) path of length $l_r \leq n_{i_r} - 1$ from vertex u_r to vertex v_r of C_{i_r} since $\mathcal{G}(\hat{A}_{i_r i_r})$ is strongly connected. If $u_r = v_r$, then this path is empty and has length 0.

Therefore for each $r \in \{0, 1, \ldots, s\}$ there exists a (possible empty) path of length $l_r \leq n_{i_r} - 1$ from vertex u_r to vertex v_r of C_{i_r}.

Let $\tilde{t} = i_{\tilde{r}} = t_{ij}$. Clearly, we have $\hat{A}_{i_{\tilde{r}} i_{\tilde{r}}} \neq [\mathfrak{o}]$. Since $\hat{A}_{i_{\tilde{r}} i_{\tilde{r}}}$ is irreducible and since $c(\hat{A}_{i_{\tilde{r}} i_{\tilde{r}}}) = 1$, it follows from Theorem 3.3 that there exists a path of length k from vertex $u_{\tilde{r}}$ to vertex $v_{\tilde{r}}$ of $C_{i_{\tilde{r}}}$ for any $k \geq k_{i_{\tilde{r}} i_{\tilde{r}}} = k_{\tilde{t}\tilde{t}}$. Note that $\#\Gamma_{ij} \geq s + 1$. Hence,

$$k_{ij} = \sum_{\substack{t \in \Gamma_{ij} \\ t \neq \tilde{t}}} n_t + k_{\tilde{t}\tilde{t}} = \sum_{\substack{t \in \Gamma_{ij} \\ t \neq \tilde{t}}} (n_t - 1) + (\#\Gamma_{ij} - 1) + k_{\tilde{t}\tilde{t}} \geq \sum_{\substack{r=0 \\ r \neq \tilde{r}}}^{s} l_r + s + k_{\tilde{t}\tilde{t}} \ .$$

Thus if we have an integer $k \geq k_{ij}$, we can decompose it as

$$k = l_0 + l_1 + \cdots + l_{\tilde{r}-1} + l_{\tilde{r}+1} + \cdots + l_s + s + k_{\tilde{t}\tilde{t}} + \tilde{k}$$

with $\tilde{k} \in \mathbb{N}$. By Theorem 3.3 there exists a path of length $k_{\tilde{t}\tilde{t}} + \tilde{k}$ from $u_{\tilde{r}}$ to $v_{\tilde{r}}$ in $C_{i_{\tilde{r}}}$ for each $\tilde{k} \in \mathbb{N}$. This implies that there exists a path from vertex u_s to vertex v_0 of length k in $\mathcal{G}(\hat{A})$. This path consists of the concatenation of paths of length l_r from vertex u_r to vertex v_r of C_{i_r} for $r = 0, 1, \ldots, \tilde{r}-1, \tilde{r}+1, \ldots, s$; paths of length 1 from vertex v_{r+1} of $C_{i_{r+1}}$ to vertex u_r of C_{i_r} for $r = 0, 1, \ldots, s-1$; and a path of

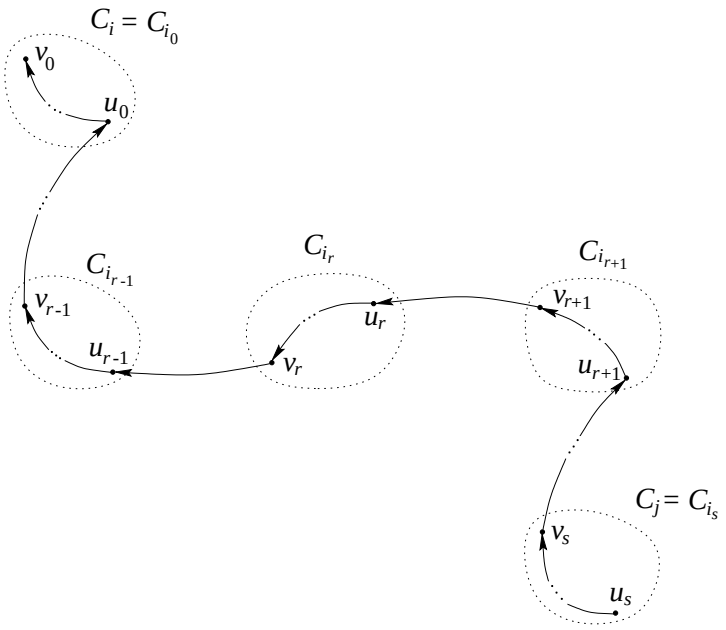

FIG. 3.3. *Illustration of the proof of Theorem* 3.5. *There exists a path from vertex u_s of m.s.c.s. C_j to vertex v_0 of m.s.c.s. C_i that passes through the m.s.c.s.'s $C_{i_{s-1}}$, $C_{i_{s-2}}$, ..., C_{i_1}.*

length $k_{\tilde{t}\tilde{t}} + \tilde{k}$ from vertex $u_{\tilde{r}}$ to vertex $v_{\tilde{r}}$ of $C_{i_{\tilde{r}}}$ (see Figure 3.3). This implies that $\left(\hat{A}^{\otimes^k}\right)_{v_0 u_s} = \mathbb{1}$ for all $k \geq k_{ij}$. Since u_s is an arbitrary vertex of C_j and since v_0 is an arbitrary vertex of C_i, this implies that $\left(\hat{A}^{\otimes^k}\right)_{\alpha_i \alpha_j} = \mathcal{E}$ for all $k \geq k_{ij}$. Thus (4) also holds if $\lambda_{ij} \neq \mathbb{0}$. □

Example 3.7. Consider the following matrix:

$$\hat{A} = \left[\begin{array}{ccc|c} \mathbb{0} & \mathbb{1} & \mathbb{0} & \mathbb{0} \\ \mathbb{1} & \mathbb{0} & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{0} & \mathbb{0} & \mathbb{1} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right].$$

This matrix is in Frobenius normal form and its block structure is indicated by the vertical and horizontal lines. The precedence graph of $\hat{A}$ is represented in Figure 3.4. Using the notations and definitions of Theorem 3.5, we have $l = 2$,

$$\hat{A}_{11} = \left[\begin{array}{ccc} \mathbb{0} & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{0} & \mathbb{1} \\ \mathbb{1} & \mathbb{0} & \mathbb{0} \end{array}\right], \quad \hat{A}_{12} = \left[\begin{array}{c} \mathbb{0} \\ \mathbb{0} \\ \mathbb{1} \end{array}\right], \text{ and } \quad \hat{A}_{22} = [\mathbb{0}].$$

Furthermore, $\alpha_1 = \{1, 2, 3\}$, $\alpha_2 = \{4\}$, $n_1 = 3$, $n_2 = 1$, $\lambda_1 = \lambda_{11} = \mathbb{1}$, $\lambda_2 = \lambda_{22} = \mathbb{0}$, $S_{12} = \big\{ \{1, 2\} \big\}$, $\Gamma_{12} = \{1, 2\}$, $\lambda_{12} = \mathbb{1}$, $t_{12} = 1$, $k_{11} = 5$, $k_{22} = 1$, and $k_{12} = 1 + 5 = 6$. We have

$$\hat{A}^{\otimes^2} = \left[\begin{array}{ccc|c} \mathbb{1} & \mathbb{0} & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{1} & \mathbb{0} & \mathbb{1} \\ \mathbb{0} & \mathbb{1} & \mathbb{0} & \mathbb{0} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right], \quad \hat{A}^{\otimes^3} = \left[\begin{array}{ccc|c} \mathbb{1} & \mathbb{1} & \mathbb{0} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{0} & \mathbb{1} & \mathbb{0} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right], \quad \hat{A}^{\otimes^4} = \left[\begin{array}{ccc|c} \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{0} & \mathbb{1} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right],$$

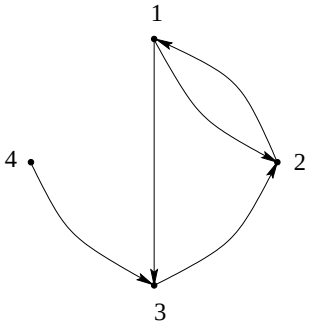

FIG. 3.4. *The precedence graph of the matrix $\hat{A}$ of Example* 3.7.

$$\hat{A}^{\otimes 5} = \left[\begin{array}{ccc|c} \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{0} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right], \quad \hat{A}^{\otimes 6} = \left[\begin{array}{ccc|c} \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \mathbb{1} & \mathbb{1} & \mathbb{1} & \mathbb{1} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \mathbb{0} \end{array}\right] = A^{\otimes 7} = \cdots.$$

Note that $\hat{A}_{11}$ is a matrix of the form (3). Therefore the smallest K_{11} for which $\hat{A}_{11}^{\otimes k} = \mathcal{E}$ for all $k \geq K_{11}$ is equal to $k_{11} = 5$. Furthermore, the smallest K_{12} such that $\left(\hat{A}^{\otimes k}\right)_{\alpha_1\alpha_2} = \mathcal{E}$ for all $k \geq K_{12}$ is equal to $k_{12} = 6$. Thus for the matrix $\hat{A}$ of this example all the bounds k_{ij} that appear in Theorem 3.5 are tight.

It is easy to verify that for a matrix of the form

$$\left[\begin{array}{ccccc|c} \mathbb{0} & \mathbb{1} & \mathbb{0} & \dots & \mathbb{0} & \mathbb{0} \\ \mathbb{0} & \mathbb{0} & \mathbb{1} & \dots & \mathbb{0} & \mathbb{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \mathbb{1} & \mathbb{0} & \mathbb{0} & \dots & \mathbb{1} & \mathbb{0} \\ \mathbb{1} & \mathbb{0} & \mathbb{0} & \dots & \mathbb{0} & \mathbb{1} \\ \hline \mathbb{0} & \mathbb{0} & \mathbb{0} & \dots & \mathbb{0} & \mathbb{0} \end{array}\right]$$

all the bounds k_{ij} that appear in Theorem 3.5 are tight.

LEMMA 3.8. *Let $A \in \mathbb{B}^{n\times n}$ with $c(A) = 1$. Then we have $A^{\otimes k+1} = A^{\otimes k}$ for all $k \geq (n-1)^2 + 1$.*

Proof. If A is irreducible, then we have $A^{\otimes k+1} = A^{\otimes k}$ for all $k \geq (n-1)^2 + 1$ by Theorem 3.3.

So from now on we assume that A is not irreducible. Let $\hat{A} = P \otimes A \otimes P^T$ be the Frobenius normal form of A. Assume that $\hat{A}$ is of the form (1) where the $\hat{A}_{ii}$'s are square and irreducible. Let the numbers λ_{ij}, n_i, t_{ij}, k_{ij} and the sets α_i and Γ_{ij} be defined as in Theorem 3.5.

We have $k_{ii} = (n_i - 1)^2 + 1 \leq (n-1)^2 + 1$ for all i.

Let us now prove that $k_{ij} \leq (n-1)^2 + 1$ for all i, j with $i < j$. Consider indices $i, j \in \{1, 2, \dots, l\}$ with $i < j$.

- If $\Gamma_{ij} = \emptyset$, then we have $k_{ij} = 1 \leq (n-1)^2 + 1$ for all $n \in \mathbb{N}_0$.
- We have $n \leq (n-1)^2 + 1$ for all $n \in \mathbb{N}_0$. Thus if $\Gamma_{ij} \neq \emptyset$ and $\lambda_{ij} = \mathbb{0}$, then we have

$$k_{ij} \;=\; \#\Gamma_{ij} \;\leq\; j - i + 1 \;\leq\; n \;\leq\; (n-1)^2 + 1.$$

- Since $n_t \geq 1$ for each $t \in \{1, 2, \ldots, l\}$ and since $l \geq 1$, we have

$$\sum_{\substack{t,s=1 \\ t \neq s}}^{l} n_t n_s \geq \sum_{\substack{t,s=1 \\ t \neq s}}^{l} 1 \geq l^2 - l \geq l - 1.$$

Hence,

$$l \leq \sum_{\substack{t,s=1 \\ t \neq s}}^{l} n_t n_s + 1. \tag{6}$$

Therefore if $\lambda_{ij} \neq \mathfrak{o}$, then we have

$$\begin{aligned}
k_{ij} &= \sum_{\substack{t \in \Gamma_{ij} \\ t \neq t_{ij}}} n_t + k_{t_{ij} t_{ij}} \\
&\leq \sum_{t=1}^{l} k_{tt} \qquad \text{(since } k_{ii} = (n_i - 1)^2 + 1 \geq n_i \text{ for each } i\text{)} \\
&\leq \sum_{t=1}^{l} \left((n_t - 1)^2 + 1 \right) \\
&\leq \sum_{t=1}^{l} (n_t^2 - 2n_t + 2) \\
&\leq \sum_{t=1}^{l} n_t^2 - 2 \sum_{t=1}^{l} n_t + 2l \\
&\leq \sum_{t=1}^{l} n_t^2 - 2n + 2l \\
&\leq \sum_{t=1}^{l} n_t^2 - 2n + 2 \left(\sum_{\substack{t,s=1 \\ t \neq s}}^{l} n_t n_s + 1 \right) \qquad \text{(by (6))} \\
&\leq \left(\sum_{t=1}^{l} n_t^2 + 2 \sum_{\substack{t,s=1 \\ t \neq s}}^{l} n_t n_s \right) - 2n + 2 \\
&\leq \left(\sum_{t=1}^{l} n_t \right)^2 - 2n + 1 + 1 \\
&\leq n^2 - 2n + 1 + 1 \\
&\leq (n-1)^2 + 1.
\end{aligned}$$

Hence, $k_{ij} \leq (n-1)^2 + 1$ for all i, j with $i \leq j$. As a consequence, it follows from Theorem 3.5 that $\left(\hat{A}^{\otimes^{k+1}}\right)_{\alpha_i \alpha_j} = \left(\hat{A}^{\otimes^k}\right)_{\alpha_i \alpha_j}$ for all $k \geq (n-1)^2 + 1$ and for all $i, j \in \{1, 2, \ldots, l\}$. Hence, $\hat{A}^{\otimes^{k+1}} = \hat{A}^{\otimes^k}$ for all $k \geq (n-1)^2 + 1$. Since $A^{\otimes^k} = P^T \otimes \hat{A}^{\otimes^k} \otimes P$, this implies that $A^{\otimes^{k+1}} = A^{\otimes^k}$ for all $k \geq (n-1)^2 + 1$. □

3.3. Boolean matrices with a cyclicity that is larger than or equal to 1.

LEMMA 3.9. *Let $A \in \mathbb{B}^{n\times n}$ be an irreducible matrix with $c(A) \geq 2$ and let $i, j \in \{1, 2, \ldots, n\}$. Then there exists a (possibly empty) path P_{ij} from j to i in $\mathcal{G}(A)$ that passes through at least one vertex of each (elementary) circuit of $\mathcal{G}(A)$ and that has a length that is less than or equal to $\frac{n^2-1}{2}$.*

Proof. Since the cyclicity of A is larger than or equal to 2, there are no loops in $\mathcal{G}(A)$. Hence, A contains at least one circuit. Since A is irreducible, this implies that j has to belong to an elementary circuit of $\mathcal{G}(A)$. Since the length of any elementary circuit of $\mathcal{G}(A)$ is larger than or equal to 2, there exists a set $S = \{i_1 = j, i_2, \ldots, i_m\} \subseteq \{1, 2, \ldots, n\}$ with $m \leq \lceil \frac{n}{2} \rceil$ such that any (elementary) circuit of $\mathcal{G}(A)$ contains at least one vertex that belongs to S. Define $i_{m+1} = i$. Since $\mathcal{G}(A)$ is strongly connected there exists a (possibly empty) path P_k with length $l_k \leq n-1$ from vertex i_k to vertex i_{k+1} for each $k \in \{1, 2, \ldots, m\}$. Let l_k be the length of P_k. There exists a path P_{ij} from j to i that contains at least one vertex of each (elementary) circuit of $\mathcal{G}(A)$: this path consists of the concatenation of P_1, P_2, ..., P_m. If l_{ij} is the length of P_{ij}, then we have

$$l_{ij} = l_1 + \cdots + l_m \leq m(n-1) \leq \left(\frac{n+1}{2}\right)(n-1) \leq \frac{n^2-1}{2}. \qquad \square$$

Remark 3.10. Note that we could have derived an upper bound that is more tight in Lemma 3.9. The upper bound of Lemma 3.9 will be used in the proof of Theorem 3.11. However, in that proof we shall also use Lemmas 2.2 and 2.3, which also yield upper bounds, and therefore we do not refine the upper bound of Lemma 3.9.

THEOREM 3.11. *Let $A \in \mathbb{B}^{n\times n}$ be irreducible and let $c = c(A) > 0$. If we define*

$$k_{n,c} = \begin{cases} (n-1)^2 + 1 & \text{if } c = 1, \\ \max\left(n-1,\ \dfrac{n^2-1}{2} + \dfrac{n^2}{c} - 3n + 2c\right) & \text{if } c > 1, \end{cases} \tag{7}$$

then we have

$$A^{\otimes^{k+c}} = A^{\otimes^k} \text{ and } A^{\otimes^k} \oplus A^{\otimes^{k+1}} \oplus \cdots \oplus A^{\otimes^{k+c-1}} = \mathcal{E}_{n\times n} \quad \text{for all } k \geq k_{n,c}. \tag{8}$$

Proof. From Theorem 3.3 it follows that (8) holds if c is equal to 1. Furthermore, if the first part of (8) holds, then the second part also holds since A is irreducible.

From now on we assume that $c > 1$. Let $i, j \in \{1, 2, \ldots, n\}$.

Let C_1, C_2, ..., C_m be the elementary circuits of $\mathcal{G}(A)$. Let l_i be the length of C_i for $i = 1, 2, \ldots, m$. Since A is irreducible, we have $c = \gcd(l_1, l_2, \ldots, l_m)$. Hence, there exist positive integers w_1, w_2, ..., w_m such that $w_i\, c = l_i$ for each i and such that $\gcd(w_1, w_2, \ldots, w_m) = 1$.

First we consider the case where there is only one elementary circuit or where all the elementary circuits have the same length. Hence, $c = l_1$. Since A is irreducible, both i and j have to belong to some elementary circuit. We may assume without loss of generality that j belongs to C_1. Since A is irreducible there exist paths from vertex j to vertex i of $\mathcal{G}(A)$. Let P_{ij} be the shortest (possibly empty) path from j to i and let l_{ij} be the length of this path. We have $l_{ij} \leq n-1$. (Note that $l_{ij} = 0$ if i is equal to j.) For any integer $k \in \mathbb{N}$ there exists a path of length $l_{ij} + kc$ from j

to i: this path consists of k times C_1 followed by P_{ij}. Hence $\left(A^{\otimes^{l_{ij}+kc}}\right)_{ij} = \mathbb{1}$ for all $k \geq 0$. Let $l \in \mathbb{N}$ with $l \geq n-1$. Now there are two possibilities. If l can be written as $l = l_{ij} + kc$ for some $k \in \mathbb{N}$, then we have $\left(A^{\otimes^l}\right)_{ij} = \mathbb{1}$. If l cannot be written as $l = l_{ij} + kc$ for any $k \in \mathbb{N}$, then it follows from Lemma 2.7 that there does not exist a path from j to i and then we have $\left(A^{\otimes^l}\right)_{ij} = \mathbb{0}$.

This implies that (8) holds if all the elementary circuits of $\mathcal{G}(A)$ have the same length.

From now on we assume that there exist at least two elementary circuits in $\mathcal{G}(A)$ that have different lengths.

Since A is irreducible it follows from Lemma 3.9 that there exists a (possibly empty) path P_{ij} from vertex j to vertex i of $\mathcal{G}(A)$ with length $l_{ij} \leq \frac{n^2-1}{2}$ that passes through at least one vertex of each elementary circuit of $\mathcal{G}(A)$. For each circuit C_k we select one vertex v_k that belongs to the path P_{ij}. Let l be an integer that can be written as $l = l_{ij} + pc$ with $p \geq g(w_1, w_2, \ldots, w_m) + 1$. Since $\gcd(w_1, w_2, \ldots, w_m) = 1$, there exist nonnegative integers α_1, α_2, …, α_m such that $p = \alpha_1 w_1 + \alpha_2 w_2 + \cdots + \alpha_m w_m$. As a consequence, we have

$$l = l_{ij} + \alpha_1 w_1 c + \alpha_2 w_2 c + \cdots + \alpha_m w_m c = l_{ij} + \alpha_1 l_1 + \alpha_2 l_2 + \cdots + \alpha_m l_m.$$

Thus there exists a path of length l from j to i: this path consists of the concatenation of P_{ij} and α_k times the circuit C_k $(v_k \to \cdots \to v_k)$ for $k = 1, 2, \ldots, m$. Hence, $\left(A^{\otimes^{l_{ij}+pc}}\right)_{ij} = \mathbb{1}$ for all $p \geq g(w_1, w_2, \ldots, w_m) + 1$.

Let us now determine an upper bound for $g(w_1, w_2, \ldots, w_m)$. If $w_s = w_t$ for some $s, t \in \{1, 2, \ldots, m\}$ with $s \neq t$, then $g(w_1, w_2, \ldots, w_m) = g(w_1, w_2, \ldots, w_{s-1}, w_{s+1}, \ldots, w_m)$. Therefore, we may assume without loss of generality that all the w_i's are different and thus also that $w_1 < w_2 < \cdots < w_m$.

Since there are at least two elementary circuits in $\mathcal{G}(A)$ that have different lengths, we have $m \geq 2$. We have $w_k = \frac{l_k}{c} \leq \frac{n}{c}$ for all k. Hence, $w_m \leq \frac{n}{c}$ and $w_1 \leq \frac{n}{c} - (m-1) \leq \frac{n}{c} - 1$ since $w_1 < w_2 < \cdots < w_m$ and $m \geq 2$. As a consequence, we have

$$\begin{aligned} g(w_1, w_2, \ldots, w_m) &\leq (w_1 - 1)(w_m - 1) - 1 \qquad \text{(by Lemma 2.2)} \\ &\leq \left(\frac{n}{c} - 2\right)\left(\frac{n}{c} - 1\right) - 1 \\ &\leq \left(\frac{n}{c}\right)^2 - 3\frac{n}{c} + 1. \end{aligned} \tag{9}$$

If we define

$$K = \frac{n^2 - 1}{2} + \left(\left(\frac{n}{c}\right)^2 - 3\frac{n}{c} + 2\right) c,$$

then we have $l_{ij} + \big(g(w_1, w_2, \ldots, w_m) + 1\big)\, c \leq K$. Thus if we have an integer l that is larger than K, then either it can be written as $l = l_{ij} + pc$ with $p \geq g(w_1, w_2, \ldots, w_m) + 1$ and then $\left(A^{\otimes^l}\right)_{ij} = \mathbb{1}$ or it cannot be written as $l = l_{ij} + pc$ for any $p \in \mathbb{N}$ and then it follows from Lemma 2.7 that there does not exist a path of length l from j to i, i.e., $\left(A^{\otimes^l}\right)_{ij} = \mathbb{0}$. Note that $K \leq k_{n,c}$.

Hence, (8) also holds in this case. □

Remark 3.12. In the proof of Theorem 3.11 we also could have used Lemma 2.3 to determine an upper bound for $g(w_1, w_2, \ldots, w_m)$. We have $m \geq 2$ and thus also $w_m \geq 2$. Furthermore, $w_{m-1} \leq \frac{n}{c} - 1$. Hence,

$$\begin{aligned} g(w_1, w_2, \ldots, w_m) &\leq 2w_{m-1} \left\lfloor \frac{w_m}{m} \right\rfloor - w_m \\ &\leq 2\left(\frac{n}{c} - 1\right)\frac{n}{2c} - 2 \\ &\leq \left(\frac{n}{c}\right)^2 - \frac{n}{c} - 2. \end{aligned} \tag{10}$$

In the second part of the proof of Theorem 3.11 we have $c \geq 2$. Since A is irreducible, it follows from Lemma 2.6 that $c \leq n$. Hence, $1 \leq \frac{n}{c} \leq \frac{n}{2}$. It is easy to verify that the upper bound of (10) is less than the upper bound of (9) if $\frac{n}{c} < \frac{3}{2}$. However, if $\frac{n}{c} < \frac{3}{2}$, then we would have $w_{m-1} \leq \frac{1}{2}$, which is not possible. This implies that for combinations of n and c for which there are at least two elementary circuits in $\mathcal{G}(A)$ with different lengths, the upper bound of (9) is less than or equal to the upper bound of (10).

The Boolean sum of sequences is defined as follows. Consider sequences $g_i = \{(g_i)_k\}_{k=1}^{\infty}$ for $i = 1, 2, \ldots, m$ with $(g_i)_k \in \mathbb{B}$ for all i, k. The sequence $g = g_1 \oplus g_2 \oplus \cdots \oplus g_m$ is defined by $g_k = (g_1)_k \oplus (g_2)_k \oplus \cdots \oplus (g_m)_k$ for all $k \in \mathbb{N}_0$.

LEMMA 3.13. *Consider sequences $g_i = \{(g_i)_k\}_{k=1}^{\infty}$ for $i = 1, 2, \ldots, m$ with $(g_i)_k \in \mathbb{B}$ for all i, k. Suppose that for each $i \in \{1, 2, \ldots, m\}$ there exist integers $K_i, c_i \in \mathbb{N}_0$ such that*

$$(g_i)_{k+c_i} = (g_i)_k \qquad \text{for all } k \geq K_i. \tag{11}$$

If $K = \max_i K_i$ and

$$c = \begin{cases} 1 & \text{if } c_i = 1 \text{ and } (g_i)_{K_i} = \mathbb{1} \text{ for some } i \in \{1, 2, \ldots, m\}, \\ \operatorname{lcm}(c_1, c_2, \ldots, c_m) & \text{otherwise,} \end{cases}$$

then the sequence $g = g_1 \oplus g_2 \oplus \cdots \oplus g_m$ satisfies $g_{k+c} = g_k$ for all $k \geq K$.

Proof. Note that (11) implies that

$$(g_i)_{k+pc_i} = (g_i)_k \qquad \text{for all } k \geq K \geq K_i \text{ and for all } p \in \mathbb{N}. \tag{12}$$

First we assume that there exists an index $i \in \{1, 2, \ldots, m\}$ such that $c_i = 1$ and $(g_i)_{K_i} = \mathbb{1}$. Then we have $(g_i)_k = \mathbb{1}$ for all $k \geq K_i$ and thus also $g_k = \mathbb{1}$ for all $k \geq K \geq K_i$.

From now on we assume that there does not exist any index $i \in \{1, 2, \ldots, m\}$ such that $c_i = 1$ and $(g_i)_{K_i} = \mathbb{1}$.

Since $c = \operatorname{lcm}(c_1, c_2, \ldots, c_m)$ there exist positive integers $w_1, w_2, \ldots, w_m$ such that $c = w_i c_i$ for $i = 1, 2, \ldots, m$. Consider an integer $k \geq K$. We have

$$\begin{aligned} g_{k+c} &= \bigoplus_{i=1}^{m} (g_i)_{k+c} \\ &= \bigoplus_{i=1}^{m} (g_i)_{k+w_i c_i} \\ &= \bigoplus_{i=1}^{m} (g_i)_k \qquad \text{(by (12))} \\ &= g_k \ . \end{aligned}$$

□

Example 3.14. Consider the sequences

$$g_1 = \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \ldots,$$
$$g_2 = \mathtt{1}, \mathtt{0}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{0}, \mathtt{1}, \ldots.$$

If we use the notation of Lemma 3.13, then we have $c_1 = 2$, $c_2 = 3$, and $K_1 = K_2 = 1$. Hence, $c = \operatorname{lcm}(2,3) = 6$ and $K = \max(K_1, K_2) = 1$. We have

$$g = g_1 \oplus g_2 = \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{1}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{1}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{0}, \mathtt{1}, \mathtt{1}, \ldots.$$

It is easy to verify that $g_{k+6} = g_k$ for all $k \geq 1$.

THEOREM 3.15. *Let $\hat{A} \in \mathbb{B}^{n\times n}$ be a matrix of the form* (1) *where the matrices $\hat{A}_{11}$, $\hat{A}_{22}$, …, $\hat{A}_{ll}$ are irreducible. Define sets α_1, α_2, …, α_l such that $\hat{A}_{\alpha_i\alpha_j} = \hat{A}_{ij}$ for all i, j with $i \leq j$. Let $n_i = \#\alpha_i$ and $c_{ii} = c_i = c(\hat{A}_{ii})$ for all i. Define*

$$\lambda_i = \begin{cases} \mathtt{0} & \text{if } \hat{A}_{ii} = [\mathtt{0}], \\ \mathtt{1} & \text{otherwise} \end{cases}$$

for $i = 1, 2, \ldots, l$. Define

$$S_{ij} = \big\{\, \{i_0, i_1, \ldots, i_s\} \subseteq \{1, 2, \ldots, l\} \;\big|\; i = i_0 < i_1 < \ldots < i_s = j \text{ and } \hat{A}_{i_r i_{r+1}} \neq \mathcal{O} \text{ for } r = 0, 1, \ldots, s-1 \,\big\}$$

for all i, j with $i < j$.

Let $\lambda_{ii} = \lambda_i$ and $k_{ii} = k_i = k_{n_i,c_i}$ for $i = 1, 2, \ldots, n$, where k_{n_i,c_i} is defined as in (7) *with $k_{n_i,0} = 0$ by definition.*

For each i, j with $i < j$ we define for each $\gamma \in S_{ij}$:

$$\delta_\gamma = \{t \in \gamma \,|\, \lambda_t \neq \mathtt{0}\}$$
$$c_\gamma = \begin{cases} \gcd\{c_t \,|\, t \in \delta_\gamma\} & \text{if } \delta_\gamma \neq \emptyset, \\ 1 & \text{otherwise.} \end{cases}$$

Define

$$\Gamma_{ij} = \big\{\, t \,\big|\, \exists \gamma \in S_{ij} \text{ such that } t \in \gamma \,\big\},$$
$$\Delta_{ij} = \big\{\, t \,\big|\, t \in \Gamma_{ij} \text{ and } \lambda_t \neq \mathtt{0} \,\big\},$$
$$\lambda_{ij} = \begin{cases} \mathtt{1} & \text{if } \Delta_{ij} \neq \emptyset, \\ \mathtt{0} & \text{otherwise,} \end{cases}$$
$$c_{ij} = \begin{cases} \operatorname{lcm}\{c_\gamma | \gamma \in S_{ij}\} & \text{if } \lambda_{ij} \neq \mathtt{0} \text{ and } c_\gamma \neq 1 \text{ for each } \gamma \in S_{ij} \text{ with } \delta_\gamma \neq \emptyset, \\ 1 & \text{otherwise,} \end{cases}$$
$$r_{ij} = \begin{cases} \arg\max\{n_t \,|\, t \in \Delta_{ij}\} & \text{if } \lambda_{ij} \neq \mathtt{0}, \\ 1 & \text{otherwise,} \end{cases}$$
$$k_{ij} = \begin{cases} \displaystyle\sum_{t\in\Delta_{ij}} k_{n_t,c_t} + \#\Gamma_{ij} - 1 + \max\left(0, \max_{\substack{\gamma\in S_{ij}\\ \delta_\gamma\neq\emptyset}} \left\{ \frac{n_{r_{ij}}^2}{c_\gamma} - 3n_{r_{ij}} + 2c_\gamma \right\}\right) & \text{if } \lambda_{ij} \neq \mathtt{0}, \\ \#\Gamma_{ij} & \text{if } \Gamma_{ij} \neq \emptyset \text{ and } \lambda_{ij} = \mathtt{0}, \\ 1 & \text{if } \Gamma_{ij} = \emptyset \end{cases}$$

for all i, j with $i < j$.

Then we have for all i, j with $i \leq j$:

$$\left(\hat{A}^{\otimes^{k+c_{ij}}}\right)_{\alpha_i\alpha_j} = \left(\hat{A}^{\otimes^{k}}\right)_{\alpha_i\alpha_j} \qquad \text{for all } k \geq k_{ij} \tag{13}$$

and

$$\left(\hat{A}^{\otimes^{k}} \oplus \hat{A}^{\otimes^{k+1}} \oplus \ldots \oplus \hat{A}^{\otimes^{k+c_{ij}-1}}\right)_{\alpha_i\alpha_j} = \begin{cases} \mathcal{E}_{n_i\times n_j} & \text{if } \lambda_{ij} \neq \mathfrak{o}, \\ \mathcal{O}_{n_i\times n_j} & \text{if } \lambda_{ij} = \mathfrak{o} \end{cases} \tag{14}$$

for all $k \geq k_{ij}$.

For all i, j with $i > j$ we have

$$\left(\hat{A}^{\otimes^{k}}\right)_{\alpha_i\alpha_j} = \mathcal{O}_{n_i\times n_j} \qquad \text{for all } k \in \mathbb{N}. \tag{15}$$

Proof. Let C_i be the m.s.c.s. of $\mathcal{G}(\hat{A})$ that corresponds to $\hat{A}_{ii}$ for $i = 1, 2, \ldots, l$.

Let $i, j \in \{1, 2, \ldots, l\}$. In the proof of Theorem 3.15 it has already been proved that (15) holds if $i > j$ and that (13) and (14) hold if $i \leq j$ and $\Gamma_{ij} = \emptyset$, or if $i \leq j$, $\Gamma_{ij} \neq \emptyset$ and $\lambda_{ij} = \mathfrak{o}$. Furthermore, (13) and (14) hold by Theorem 3.11 if $i = j$.

From now on we assume that $i < j$, $\Gamma_{ij} \neq \emptyset$, and $\lambda_{ij} \neq \mathfrak{o}$. Note that $i < j$ implies that $l > 1$.

Select an arbitrary vertex u of C_i and an arbitrary vertex v of C_j.

Since $\lambda_{ij} \neq \mathfrak{o}$ there exists at least one set $\gamma \in S_{ij}$ for which $\delta_\gamma \neq \emptyset$. Thus $\Delta_{ij} \neq \emptyset$ and k_{ij} is well defined. Note that $k_{ij} \geq \#\Gamma_{ij}$. If $\gamma_\delta = \emptyset$ for some set $\gamma \in S_{ij}$, then there do not exist paths from v to u of length $n \geq \#\Gamma_{ij}$ that correspond to γ. Therefore from now on we consider only sets $\gamma \in S_{ij}$ for which $\delta_\gamma \neq \emptyset$.

Let $\gamma = \{i_0, i_1, \ldots, i_s\} \in S_{ij}$ with $i = i_0 < i_1 < \cdots < i_s = j$. Since we assume that $\delta_\gamma \neq \emptyset$, we have $\hat{A}_{i_r i_r} \neq [\mathfrak{o}]$ for at least one index $i_r \in \gamma$. Assume that δ_γ is given by $\{j_0, j_1, \ldots, j_{\hat{s}}\}$. Define

$$\begin{aligned} \mathcal{S} = \big\{(U, V) \,\big|\, & U = \{u_0, u_1, \ldots, u_s\},\ V = \{v_0, v_1, \ldots, v_s\},\ u_s = v,\ v_0 = u, \text{ and} \\ & u_r \in \alpha_{i_r},\ v_{r+1} \in \alpha_{i_{r+1}} \text{ and } (\hat{A})_{u_r v_{r+1}} \neq \mathfrak{o} \text{ for } r = 0, 1, \ldots, s\big\}. \end{aligned}$$

Let $(U, V) \in \mathcal{S}$ with $U = \{u_0, u_1, \ldots, u_s\}$ and $V = \{v_0, v_1, \ldots, v_s\}$. Let $\mathcal{P}(\gamma, U, V)$ be the set of paths from v to u that pass through m.s.c.s. C_{i_r} for $r = 0, 1, \ldots, s$ and that enter C_{i_r} at vertex u_r for $r = 0, 1, \ldots, s-1$ and exit from C_{i_r} through vertex v_r for $r = 1, 2, \ldots, s$ (see also Figure 3.3). Let the sequences $\{(g_{\gamma,U,V})_k\}_{k=1}^\infty$ and $\{(g_\gamma)_k\}_{k=1}^\infty$ be defined by

$$(g_{\gamma,U,V})_k = \begin{cases} \mathfrak{1} & \text{if there exists a path of length } k \text{ that belongs to } \mathcal{P}(\gamma, U, V), \\ \mathfrak{o} & \text{otherwise,} \end{cases}$$

$$(g_\gamma)_k = \begin{cases} \mathfrak{1} & \text{if there exists a path of length } k \text{ that belongs to } \mathcal{P}(\gamma, U, V) \\ & \text{for some pair } (U, V) \in \mathcal{S}, \\ \mathfrak{o} & \text{otherwise.} \end{cases}$$

Define $c_\gamma = \gcd\{c_t | t \in \delta_\gamma\}$. Let us now show that the sequences $\{(g_{\gamma,U,V})_k\}_{k=1}^\infty$ and $\{(g_\gamma)_k\}_{k=1}^\infty$ satisfy

$$(g_{\gamma,U,V})_{k+c_\gamma} = (g_{\gamma,U,V})_k \quad \text{for all } k \geq k_{ij}, \tag{16}$$

$$(g_{\gamma,U,V})_k \oplus (g_{\gamma,U,V})_{k+1} \oplus \cdots \oplus (g_{\gamma,U,V})_{k+c_\gamma-1} = \mathbf{1} \quad \text{for all } k \geq k_{ij}, \tag{17}$$

$$(g_\gamma)_{k+c_\gamma} = (g_\gamma)_k \quad \text{for all } k \geq k_{ij}, \tag{18}$$

$$(g_\gamma)_k \oplus (g_\gamma)_{k+1} \oplus \cdots \oplus (g_\gamma)_{k+c_\gamma-1} = \mathbf{1} \quad \text{for all } k \geq k_{ij}. \tag{19}$$

Note that if (16) and (17) hold for each pair $(U,V) \in \mathcal{S}$, then (18) and (19) also hold. Therefore, we now show that (16) and (17) hold. Define $\tilde{u}_r = u_s$ and $\tilde{v}_r = v_s$ if $j_r = i_s$ for $r = 0, 1, \ldots, \hat{s}$. We consider three cases:

Case A. $c_{j_{\tilde{r}}} = 1$ for some $\tilde{r} \in \{0, 1, \ldots, \hat{s}\}$.

In this case we have $c_\gamma = 1$.

Let l_r be the length of the shortest (possibly empty) path from vertex $\tilde{u}_r$ to vertex $\tilde{v}_r$ of C_{j_r} for each $r \in \{0, 1, \ldots, \hat{s}\}$. We have $l_r \leq n_{j_r} - 1$ for each r. Since $\hat{A}_{j_{\tilde{r}} j_{\tilde{r}}}$ is irreducible and since $c_{j_{\tilde{r}}} = 1$, it follows from Theorem 3.3 that for any integer $p \geq (n_{j_{\tilde{r}}} - 1)^2 + 1$ there exists a path of length p from vertex $\tilde{u}_{\tilde{r}}$ to vertex $\tilde{v}_{\tilde{r}}$ of $C_{j_{\tilde{r}}}$. If we also take into account that there are s arcs of the form $v_{r+1} \to u_r$ for $r = 0, 1, \ldots, s-1$, then it follows that for any

$$k \geq \sum_{\substack{r=0 \\ r \neq \tilde{r}}}^{\hat{s}} (n_{j_r} - 1) + s + (n_{j_{\tilde{r}}} - 1)^2 + 1 \stackrel{\text{def}}{=} K_{\mathrm{A}}$$

there exists a path of length k that belongs to $\mathcal{P}(\gamma, U, V)$. Let us now show that $K_{\mathrm{A}} \leq k_{ij}$. Let $r \in \{0, 1, \ldots, \hat{s}\}$. If $c_{j_r} > 1$, then it follows from the definition of $k_{n_{j_r}, c_{j_r}}$ that $n_{j_r} - 1 \leq k_{n_{j_r}, c_{j_r}}$. Furthermore, if $c_{j_r} = 1$, then we have $n_{j_r} - 1 \leq (n_{j_r} - 1)^2 + 1 = k_{n_{j_r}, c_{j_r}}$. Since $c_{j_{\tilde{r}}} = 1$, we have $(n_{j_{\tilde{r}}} - 1)^2 + 1 = k_{n_{j_{\tilde{r}}}, c_{j_{\tilde{r}}}}$. Furthermore, $\delta_\gamma \subseteq \Delta_{ij}$ and $s \leq \#\Gamma_{ij} - 1$. Hence, $K_{\mathrm{A}} \leq k_{ij}$, which implies that (16) and (17) hold in this case.

Case B. $c_t = c_\gamma$ and $c_t \neq 1$ for all $t \in \delta_\gamma$.

Assume that $c_{j_{\tilde{r}}} = c_\gamma$ with $\tilde{r} \in \{0, 1, \ldots, \hat{s}\}$.

Let l_r be the length of the shortest (possibly empty) path from vertex $\tilde{u}_r$ to vertex $\tilde{v}_r$ of C_{j_r} for each $r \in \{0, 1, \ldots, \tilde{r}-1, \tilde{r}+1, \ldots, \hat{s}\}$. Thus $l_r \leq n_{j_r} - 1$ for each $r \neq \tilde{r}$. From Lemma 2.7 and from the proof of Theorem 3.11 it follows that there exists an integer $K_{\tilde{r}}$ with $k_{n_{j_{\tilde{r}}}, c_{j_{\tilde{r}}}} \leq K_{\tilde{r}} \leq k_{n_{j_{\tilde{r}}}, c_{j_{\tilde{r}}}} + c_{j_{\tilde{r}}} - 1$ such that there exist paths of length $K_{\tilde{r}} + p\, c_{j_{\tilde{r}}}$ from vertex $\tilde{u}_{\tilde{r}}$ to vertex $\tilde{v}_{\tilde{r}}$ of $C_{j_{\tilde{r}}}$ for any $p \in \mathbb{N}$, while there do not exist paths of length $K_{\tilde{r}} + p c_{j_{\tilde{r}}} + q$ from $\tilde{u}_{\tilde{r}}$ to $\tilde{v}_{\tilde{r}}$ for any $p \in \mathbb{N}$ and any $q \in \{1, 2, \ldots, c_{j_{\tilde{r}}} - 1\}$. Therefore if we define

$$K_{\mathrm{B}} = \sum_{\substack{r=0 \\ r \neq \tilde{r}}}^{\hat{s}} l_r + s + k_{n_{j_{\tilde{r}}}, c_{j_{\tilde{r}}}},$$

then it follows from Lemma 2.7 that for any $k \geq K_{\mathrm{B}}$ either there exists a path of length $k + p\, c_\gamma$ that belongs to $\mathcal{P}(\gamma, U, V)$ for each $p \in \mathbb{N}$, or there do not exist paths of length $k + p\, c_\gamma$ that belong to $\mathcal{P}(\gamma, U, V)$ for any $p \in \mathbb{N}$. It is easy to verify that $K_{\mathrm{B}} \leq k_{ij}$. Hence, (16) and (17) also hold in this case.

Case C. $c_{j_r} \neq 1$ for all $r \in \{0, 1, \ldots, \hat{s}\}$ and $c_{j_a} \neq c_{j_b}$ for some $a, b \in \{0, 1, \ldots, \hat{s}\}$.

From Lemma 2.7 and from the proof of Theorem 3.11 it follows that for each $r \in \{0, 1, \ldots, \hat{s}\}$ there exists an integer K_r with $k_{n_{j_r}, c_{j_r}} \leq K_r \leq k_{n_{j_r}, c_{j_r}} + c_{j_r} - 1$ such that there exist paths of length $K_r + p\, c_{j_r}$ from $\tilde{u}_r$ to $\tilde{v}_r$ for each $p \in \mathbb{N}$, while there do not exist paths of length $K_r + p\, c_{j_r} + q$ from $\tilde{u}_r$ to $\tilde{v}_r$ for any $p \in \mathbb{N}$ and for any $q \in \{1, 2, \ldots, c_{j_r} - 1\}$. This implies that there exist paths of length $K_0 +$

$K_1 + \cdots + K_{\hat{s}} + s + p_0 c_{j_0} + p_1 c_{j_1} + \cdots + p_{\hat{s}} c_{j_{\hat{s}}}$ that belong to $\mathcal{P}(\gamma, U, V)$ for each choice of $p_0, p_1, \ldots, p_{\hat{s}}$ such that $p_r \geq 0$ for each r. Define $K_\gamma = \sum_{r=0}^{\hat{s}} K_r + s$. Since $c_\gamma = \gcd\{c_t \,|\, t \in \delta_\gamma\}$ there exist positive integers $w_0, w_1, \ldots, w_{\hat{s}}$ such that $c_{j_r} = w_r\, c_\gamma$ for each $r \in \{0, 1, \ldots, \hat{s}\}$ and such that $\gcd(w_0, w_1, \ldots, w_{\hat{s}}) = 1$. Thus for any integer $q \geq g(w_0, w_1, \ldots, w_{\hat{s}}) + 1$ there exist nonnegative integers $\alpha_0, \alpha_1, \ldots, \alpha_{\hat{s}}$ such that $q = \alpha_0 w_0 + \alpha_1 w_1 + \cdots + \alpha_{\hat{s}} w_{\hat{s}}$.

Since $c_{j_a} \neq c_{j_b}$ we have $w_a \neq w_b$. Therefore, we may assume without loss of generality that $w_0 < w_1 < \cdots < w_{\hat{s}}$ with $\hat{s} \geq 2$. We have $w_{\hat{s}} = \frac{c_{j_{\hat{s}}}}{c_\gamma} \leq \frac{n_{j_{\hat{s}}}}{c_\gamma} \leq \frac{n_{r_{ij}}}{c_\gamma}$. Hence, $w_0 \leq \frac{n_{r_{ij}}}{c_\gamma} - 1$ since $w_0 < w_{\hat{s}}$. Furthermore, $w_0 \geq 1$ and thus $w_{\hat{s}} \geq 2$. Using a reasoning that is similar to the one used in the proof of Theorem 3.11 and Remark 3.12 we can show that

$$g(w_0, w_1, \ldots, w_{\hat{s}}) + 1 \leq \left(\frac{n_{r_{ij}}}{c_\gamma}\right)^2 - 3\,\frac{n_{r_{ij}}}{c_\gamma} + 2.$$

Thus if we define

$$K_{\mathrm{C}} = K_\gamma + c_\gamma \left(\left(\frac{n_{r_{ij}}}{c_\gamma}\right)^2 - 3\,\frac{n_{r_{ij}}}{c_\gamma} + 2\right),$$

then we have $K_{\mathrm{C}} \geq K_\gamma + c_\gamma\big(g(w_0, w_1, \ldots, w_{\hat{s}}) + 1\big)$. Let $k \in \mathbb{N}$ with $k \geq K_{\mathrm{C}}$. Now there are two possibilities:

- If k can be written as $K_\gamma + q\, c_\gamma$ with $q \geq g(w_0, w_1, \ldots, w_{\hat{s}}) + 1$ then we have

$$k = K_\gamma + (\alpha_0 w_0 + \alpha_1 w_1 + \cdots + \alpha_{\hat{s}} w_{\hat{s}}) c_\gamma = K_\gamma + \alpha_0\, c_{j_0} + \alpha_1\, c_{j_1} + \cdots + \alpha_{\hat{s}}\, c_{j_{\hat{s}}},$$

which implies that there exists a path of length k that belongs to $\mathcal{P}(\gamma, U, V)$.

- On the other hand, if k cannot be written as $K_\gamma + q\, c_\gamma$ for any $q \in \mathbb{N}$, then it follows from Lemma 2.7 that there does not exist a path of length k that belongs to $\mathcal{P}(\gamma, U, V)$.

Since $k_{ij} \geq K_{\mathrm{C}}$ this implies that (16) and (17) also hold in this case.

If we consider all possible paths from vertex v to vertex u of length $k \in \mathbb{N}$ with $k \geq \#\Gamma_{ij}$, then each of these paths corresponds to some set $\gamma \in S_{ij}$ with $\delta_\gamma \neq \emptyset$. Since $(\hat{A}^{\otimes^k})_{uv}$ is equal to $\mathbb{1}$ if and only if there exists a path of length k from v to u, we have

$$\left(\hat{A}^{\otimes^k}\right)_{uv} = \bigoplus_{\substack{\gamma \in S_{ij} \\ \delta_\gamma \neq \emptyset}} (g_\gamma)_k$$

if $k \geq \#\Gamma_{ij}$. Note that if $c_\gamma = 1$ and $\delta_\gamma \neq \emptyset$ then we have $(g_\gamma)_{k_{ij}} = \mathbb{1}$. Since each sequence $\{(g_\gamma)_k\}_{k=1}^{\infty}$ satisfies (18), it follows from Lemma 3.13 that

$$\left(\hat{A}^{\otimes^{k+c_{ij}}}\right)_{uv} = \left(\hat{A}^{\otimes^k}\right)_{uv} \qquad \text{for all } k \geq k_{ij}.$$

Furthermore, since each sequence $\{(g_\gamma)_k\}_{k=1}^{\infty}$ satisfies (19), we have

$$\left(\hat{A}^{\otimes^k} \,\oplus\, \hat{A}^{\otimes^{k+1}} \,\oplus\, \cdots \,\oplus\, \hat{A}^{\otimes^{k+c_{ij}-1}}\right)_{uv} = \mathbb{1} \qquad \text{for all } k \geq k_{ij}.$$

Thus (13) and (14) also hold if $\lambda_{ij} \neq \mathbb{0}$. □

Remark 3.16. Note that if $\gamma_1, \gamma_2 \in S_{ij}$ and $\gamma_1 \subseteq \gamma_2$, then we do not have to consider γ_1 when we are determining S_{ij}. Hence, we could have defined S_{ij} as the set of *maximal* subsets $\{i_0, i_1, \ldots, i_s\}$ of $\{1, 2, \ldots, l\}$ with $i = i_0 < i_1 < \cdots < i_s = j$ and $\hat{A}_{i_r i_{r+1}} \neq \mathcal{O}$ for $r = 0, 1, \ldots, s-1$.

Let us now give an example in which the various sets and indices that appear in the formulation of Theorem 3.15 are illustrated.

Example 3.17. Consider the matrix

$$A = \left[\begin{array}{c|cc|ccc|c} 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right].$$

This matrix is in Frobenius normal form and its block structure is indicated by the horizontal and vertical lines. The precedence graph of A is represented in Figure 3.5. We have

$$A^{\otimes 2} = \left[\begin{array}{ccc|ccc|c} 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right], \quad A^{\otimes 3} = \left[\begin{array}{ccc|ccc|c} 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right],$$

$$A^{\otimes 4} = \left[\begin{array}{ccc|ccc|c} 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right], \quad A^{\otimes 5} = \left[\begin{array}{ccc|ccc|c} 0 & 1 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right],$$

$$A^{\otimes 6} = \left[\begin{array}{ccc|ccc|c} 0 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right], \quad A^{\otimes 7} = \left[\begin{array}{ccc|ccc|c} 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right],$$

$$A^{\otimes 8} = \left[\begin{array}{ccc|ccc|c} 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right], \quad A^{\otimes 9} = \left[\begin{array}{ccc|ccc|c} 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right],$$

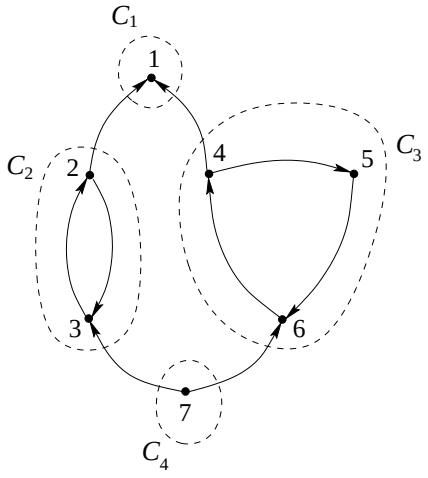

FIG. 3.5. *The precedence graph $\mathcal{G}(A)$ of the matrix A of Example* 3.17. *The subgraphs C_1, C_2, C_3, and C_4 are the m.s.c.s.'s of $\mathcal{G}(A)$.*

$$A^{\otimes^{10}} = \left[\begin{array}{c|cc|ccc|c} \mathtt{0} & \mathtt{0} & \mathtt{1} & \mathtt{1} & \mathtt{0} & \mathtt{0} & \mathtt{0} \\ \hline \mathtt{0} & \mathtt{1} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{1} \\ \mathtt{0} & \mathtt{0} & \mathtt{1} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} \\ \hline \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{1} & \mathtt{0} \\ \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{1} & \mathtt{0} & \mathtt{0} & \mathtt{0} \\ \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{1} & \mathtt{0} & \mathtt{1} \\ \hline \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} & \mathtt{0} \end{array}\right], \ldots.$$

Thus $A^{\otimes^{k+6}} = A^{\otimes^k}$ for all $k \geq 2$.

We have $\alpha_1 = \{1\}$, $\alpha_2 = \{2,3\}$, $\alpha_3 = \{4,5,6\}$, and $\alpha_4 = \{7\}$. Furthermore, $\lambda_1 = \lambda_4 = \mathtt{0}$ and $\lambda_2 = \lambda_3 = \mathtt{1}$. Let us now look at the sequence $\left\{\left(A^{\otimes^k}\right)_{\alpha_1\alpha_4}\right\}_{k=1}^{\infty}$. We have $S_{14} = \{\gamma_1, \gamma_2\}$ with $\gamma_1 = \{1,2,4\}$ and $\gamma_2 = \{1,3,4\}$. So $\delta_{\gamma_1} = \{2\}$, $c_{\gamma_1} = 2$, $\delta_{\gamma_2} = \{3\}$, and $c_{\gamma_2} = 3$. We have $\Gamma_{14} = \{1,2,3,4\}$, $\Delta_{14} = \{2,3\}$, $\lambda_{14} = \mathtt{1}$, $c_{14} = \mathrm{lcm}(2,3) = 6$, and $r_{14} = 3$. Hence,

$$\begin{aligned} k_{14} &= k_{2,2} + k_{3,3} + \#\Gamma_{14} - 1 + \max\left(0,\, \frac{n_3^2}{c_{\gamma_1}} - 3n_3 + 2\,c_{\gamma_1},\, \frac{n_3^2}{c_{\gamma_2}} - 3n_3 + 2\,c_{\gamma_2}\right) \\ &= \frac{3}{2} + 4 + 4 - 1 + \max\left(0,\, \frac{9}{2} - 9 + 4,\, \frac{9}{3} - 9 + 6\right) = \frac{17}{2}\,. \end{aligned}$$

Note that we indeed have $\left(A^{\otimes^{k+6}}\right)_{\alpha_1\alpha_4} = \left(A^{\otimes^k}\right)_{\alpha_1\alpha_4}$ for all $k \geq 9$.

LEMMA 3.18. *Consider m positive integers c_1, c_2, ..., c_m. Let $c = \mathrm{lcm}(c_1, c_2, \ldots, c_m)$. Consider r nonempty subsets α_1, α_2, ..., α_r of $\{1,2,\ldots,m\}$. Define $d_i = \gcd\{c_k \,|\, k \in \alpha_i\}$ for each i. If $d = \mathrm{lcm}(d_1, d_2, \ldots, d_r)$, then d is a divisor of c.*

Proof. We may assume without loss of generality that $c_i \neq c_j$ for all i, j with $i \neq j$. If d is a divisor of $\mathrm{lcm}(c_1, c_2, \ldots, c_{m-1})$, then it also is a divisor of $\mathrm{lcm}(c_1, c_2, \ldots, c_m)$. Therefore, we may assume without loss of generality that $\alpha_1 \cup \alpha_2 \cup \cdots \cup \alpha_r = \{1,2,\ldots,m\}$. If $\alpha_i \subseteq \alpha_j$, then d_j is a divisor of d_i and then $\mathrm{lcm}(d_1, d_2, \ldots, d_r) = \mathrm{lcm}(d_1, d_2, \ldots, d_{j-1}, d_{j+1}, \ldots, d_r)$, which implies that α_j is redundant and may be removed. If $d_i = d_j$, then α_j is also redundant and may be removed. It is easy

to verify that if we remove all redundant sets, then the resulting number of sets α_i is less than or equal to m (the worst cases being when $\alpha_i = \{1, 2, \ldots, m\} \setminus \{i\}$ for $i = 1, 2, \ldots, m$ or when $\alpha_i = \{i\}$ for $i = 1, 2, \ldots, m$). Hence, we may assume without loss of generality that $r \leq m$ and that $d_i \neq d_j$ for all i, j with $i \neq j$.

Since $r \leq m$, $\alpha_1 \cup \alpha_2 \cup \cdots \cup \alpha_r = \{1, 2, \ldots, m\}$ and $\alpha_i \not\subseteq \alpha_j$ for all i, j with $i \neq j$, we can select indices l_1, l_2, ..., l_r such that $l_i \in \alpha_i$ for $i = 1, 2, \ldots, r$ and $l_i \neq l_j$ for all i, j with $i \neq j$.

Since $d_i = \gcd\{c_k \,|\, k \in \alpha_i\}$, d_i is a divisor of c_{l_i} for each i.

Since all c_i's are different we have

$$c = \operatorname{lcm}(c_1, c_2, \ldots, c_m) = \frac{c_1\, c_2\, \ldots\, c_m}{\gcd(c_1, c_2, \ldots, c_m)}\,.$$

We also have

$$d = \frac{d_1\, d_2\, \ldots\, d_r}{\gcd(d_1, d_2, \ldots, d_r)}\,.$$

Since $\alpha_1 \cup \alpha_2 \cup \ldots \cup \alpha_r = \{1, 2, \ldots, m\}$ we have $\gcd(c_1, c_2, \ldots, c_m) = \gcd(d_1, d_2, \ldots, d_r)$. Therefore

$$c = \frac{c_1\, c_2\, \ldots\, c_m}{d_1\, d_2\, \ldots\, d_r}\, d.$$

Since d_i is a divisor of c_{l_i} for $i = 1, 2, \ldots, r$ there exist integers $w_i \in \mathbb{N}$ such that $c_{l_i} = w_i\, d_i$ for $i = 1, 2, \ldots, r$. If we define $\beta = \{1, 2, \ldots, m\} \setminus \{l_1, l_2, \ldots, l_r\}$, then we have

$$c = w_1\, w_2\, \ldots\, w_r \left(\prod_{i \in \beta} c_i \right) d,$$

where $\prod_{i \in \emptyset} c_i$ is equal to 1 by definition. Thus $c = wd$ for some integer $w \in \mathbb{N}$, which implies that d is a divisor of c. □

LEMMA 3.19. *Let $n \in \mathbb{N}$ and let $c \in \{0, 1, \ldots, n\}$. If $k_{n,c}$ is defined by* (7) *if $c > 0$ and if $k_{n,c} = 0$ if $c = 0$, then we have $k_{n,c} \leq (n-1)^2 + 1$.*

Proof. It is obvious that the lemma holds if $c = 0$ or if $c = 1$, so from now on we assume that $c > 1$.

Define $f(c) = \frac{n^2-1}{2} + \frac{n^2}{c} - 3n + 2c$. Let us now show that $f(c) \leq (n-1)^2 + 1$.

We have $\frac{df}{dc} = -\frac{n^2}{c^2} + 2$. Thus f reaches a local minimum in $c = \frac{n}{\sqrt{2}}$ and is decreasing if $1 < c < \frac{n}{\sqrt{2}}$ and increasing if $c > \frac{n}{\sqrt{2}}$.

Let us first consider the cases where n is equal to 2 or 3. If $n = 2$, then we have $c = 2$ and $f(c) = \frac{4-1}{2} + 2 - 6 + 4 = \frac{3}{2} \leq 2 = (2-1)^2 + 1$. If $n = 3$, then $\frac{n}{\sqrt{2}}$ does not belong to the interval $[2, 3]$ and then the maximal value of f in $[2, 3]$ is equal to $f(3) = \frac{9-1}{2} + \frac{9}{3} - 9 + 6 = \frac{9}{2} \leq 5 = (3-1)^2 + 1$.

From now on we assume that n is larger than or equal to 4. If $n \geq 4$, then $\frac{n}{\sqrt{2}}$ belongs to the interval $[2, n]$ and then the maximal value of f in $[2, n]$ is equal to

$$\begin{aligned}
\max(f(2), f(n)) &= \max\left(\frac{n^2-1}{2} + \frac{n^2}{2} - 3n + 4,\ \frac{n^2-1}{2} + n - 3n + 2n \right) \\
&= \max\left(n^2 - 3n + \frac{7}{2}\,,\ \frac{n^2}{2} - \frac{1}{2} \right) \\
&= n^2 - 3n + \frac{7}{2} \qquad (\text{since } n \geq 4) \\
&\leq (n-1)^2 + 1 \qquad (\text{since } n \geq 2).
\end{aligned}$$

Hence, $k_{n,c} \leq (n-1)^2 + 1$. □

THEOREM 3.20. *Let $A \in \mathbb{B}^{n\times n}$ and let c be the cyclicity of A. We have $A^{\otimes^{k+c}} = A^{\otimes^k}$ for all $k \geq 2n^2 - 3n + 2$.*

Proof. Let $\hat{A} = P \otimes A \otimes P^T$ be the Frobenius normal from of A where P is a permutation matrix. Assume that $\hat{A}$ is a matrix of the form (1) with $\hat{A}_{ii}$ irreducible for $i = 1, 2, \ldots, l$. Consider $i, j \in \{1, 2, \ldots, l\}$ with $i \leq j$. Let S_{ij}, Γ_{ij}, Δ_{ij}, λ_{ij}, c_{ij}, r_{ij}, and k_{ij} be defined as in Theorem 3.15. Let us now show that $k_{ij} \leq 2(n-1)^2 + n$. It is easy to verify that this holds if $i = j$, or if $i < j$ and $\lambda_{ij} = \mathfrak{o}$. Thus from now on we assume that $\lambda_{ij} \neq \mathfrak{o}$. Hence,

$$k_{ij} = \sum_{t\in\Delta_{ij}} k_{n_t,c_t} + \#\Gamma_{ij} - 1 + \max\left(0, \max_{\substack{\gamma\in S_{ij}\\ \delta_\gamma\neq\emptyset}} \left\{ \frac{n_{r_{ij}}^2}{c_\gamma} - 3n_{r_{ij}} + 2c_\gamma \right\}\right).$$

Since we have $k_{n_i,c_i} \leq (n_i - 1)^2 + 1$ for each $i \in \{1, 2, \ldots, l\}$ by Lemma 3.19, it follows from the proof of Lemma 3.8 that

$$\sum_{t\in\Delta_{ij}} k_{n_t,c_t} \leq (n-1)^2 + 1.$$

Furthermore, $\#\Gamma_{ij} \leq j - i + 1 \leq n$.

Let us now show that

$$\frac{n_{r_{ij}}^2}{c_\gamma} - 3n_{r_{ij}} + 2c_\gamma \leq (n-1)^2$$

for each $\gamma \in S_{ij}$ with $\delta_\gamma \neq \emptyset$. Let $\gamma \in S_{ij}$ with $\delta_\gamma \neq \emptyset$. From Lemma 2.6 it follows that $c_t \leq n_t$ for each $t \in \delta_\gamma$. Hence, $1 \leq c_\gamma = \gcd\{n_t \,|\, t \in \delta_\gamma\} \leq \max\{n_t \,|\, t \in \delta_\gamma\} \leq n_{r_{ij}}$.

Define $f(c) = \frac{n_{r_{ij}}^2}{c} - 3n_{r_{ij}} + 2c$. From the proof of Lemma 3.19 it follows that f is decreasing if $c < \frac{n_{r_{ij}}}{\sqrt{2}}$ and increasing if $c > \frac{n_{r_{ij}}}{\sqrt{2}}$.

If $n_{r_{ij}} = 1$, then we have $c_\gamma = 1$ and $f(c_\gamma) = 1 - 3 + 2 = 0 \leq 0 = (1-1)^2$.

If $n_{r_{ij}} > 1$, then the maximum value of f in the interval $[1, n_{r_{ij}}]$ is equal to

$$\begin{aligned}
\max(f(1), f(n_{r_{ij}})) &= \max\big(n_{r_{ij}}^2 - 3n_{r_{ij}} + 2,\, n_{r_{ij}} - 3n_{r_{ij}} + 2n_{r_{ij}}\big)\\
&= \max\big((n_{r_{ij}} - 1)^2 + 1 - n_{r_{ij}},\, 0\big)\\
&\leq (n_{r_{ij}} - 1)^2 \qquad\qquad (\text{since } n_{r_{ij}} \geq 1)\\
&\leq (n-1)^2.
\end{aligned}$$

Hence, $k_{ij} \leq 2(n-1)^2 + n = 2n^2 - 3n + 2$. Furthermore, c_{ij} is a divisor of c by Lemma 3.18. Hence, $\hat{A}^{\otimes^{k+c}} = \hat{A}^{\otimes^k}$ for all $k \geq 2n^2 - 3n + 2$. Since $A^{\otimes^k} = P^T \otimes \hat{A}^{\otimes^k} \otimes P$ for all $k \in \mathbb{N}$, this implies that $A^{\otimes^{k+c}} = A^{\otimes^k}$ for all $k \geq 2n^2 - 3n + 2$. □

4. Applications and extensions.

4.1. Markov chains. It is often possible to represent the behavior of a physical system by describing all the different states the system can occupy and by specifying how the system moves from one state to another at each time step. If the state space of the system is discrete and if the future evolution of the system depends only on the

current state of the system and not on past history, the system may be represented by a Markov chain. Markov chains can be used to describe a wide variety of systems and phenomena in domains such as diffusion processes, genetics, learning theory, sociology, and economics, [22].

A finite homogeneous Markov chain is a stochastic process with a finite number of states s_1, s_2, ..., s_n, where the transition probability to go from one state to another state depends only on the current state and is independent of the time step. We define an $n \times n$ matrix P such that p_{ij} is equal to the probability that the next state is s_i given that the current state is s_j. Note that $p_{ij} \geq 0$ for all i, j. We define a sequence of vectors $\{\theta(k)\}_{k=0}^{\infty}$ with $\theta(k) \in [0,1]^n$, where $\big(\theta(k)\big)_i$ is the probability that the system is in state s_i at time step k. If the initial probability vector $\theta(0)$ is given, the evolution of the system is described by

$$\theta(k+1) = P\theta(k) \qquad \text{for } k \in \mathbb{N}.$$

Hence,

$$\theta(k) = P^k\theta(0) \qquad \text{for } k \in \mathbb{N}.$$

Thus if we consider the Boolean algebra $(\{0, \mathfrak{p}\}, +, \cdot)$, where $\mathfrak{p}$ stands for an arbitrary positive number, and if we define a matrix $\tilde{P} \in \{0, \mathfrak{p}\}^{n\times n}$ such that $\tilde{p}_{ij} = 0$ if $p_{ij} = 0$ and $\tilde{p}_{ij} = \mathfrak{p}$ if $p_{ij} > 0$, then we can give the following interpretation to the Boolean matrix power $\tilde{P}^{\otimes^k}$. We can go from state s_j to state s_i in k steps if and only if $\big(P^k\big)_{ij} > 0$ or equivalently if $\big(\tilde{P}^{\otimes^k}\big)_{ij} = \mathfrak{p}$. As a consequence, the results of this paper can also be used to obtain upper bounds for the length of the transient behavior of a finite homogeneous Markov chain.

For more information on Markov chains and their applications the interested reader is referred to [2, 12, 20, 22] and the references therein.

4.2. Max-plus algebra. Our main motivation for studying sequences of consecutive powers of a matrix in a Boolean algebra lies in the max-plus algebraic system theory for discrete event systems. Typical examples of discrete event systems are flexible manufacturing systems, telecommunication networks, parallel processing systems, traffic control systems, and logistic systems. The class of the discrete event systems essentially consists of man-made systems that contain a finite number of resources (e.g., machines, communications channels, or processors) that are shared by several users (e.g., product types, information packets, or jobs), all of which contribute to the achievement of some common goal (e.g., the assembly of products, the end-to-end transmission of a set of information packets, or a parallel computation).

There are many modeling and analysis techniques for discrete event systems, such as queuing theory, (extended) state machines, max-plus algebra, formal languages, automata, temporal logic, generalized semi-Markov processes, Petri nets, perturbation analysis, and computer simulation (see [1, 6, 19, 23, 24] and the references cited therein). In general models that describe the behavior of a discrete event system are nonlinear in conventional algebra. However, there is a class of discrete event systems — the max-linear discrete event systems — that can be described by a model that is "linear" in the max-plus algebra [1, 7, 8]. The model of a max-linear discrete event system can be characterized by a triple of matrices (A, B, C), which are called the system matrices of the model.

One of the open problems in the max-plus algebraic system theory is the minimal realization problem, which consists of determining the system matrices of the model

of a max-linear discrete event system starting from its "impulse response"[4] such that the dimensions of the system matrices are as small as possible (see [1] for more information). In order to tackle the general minimal realization problem it is useful first to study a simplified version: the Boolean minimal realization problem, in which only models with Boolean system matrices are considered. The results of this paper on the length of the transient part of the sequence of consecutive powers of a matrix in a Boolean algebra can be used to obtain some results for the Boolean minimal realization problem in the max-plus algebraic system theory for discrete event systems [10]: they can be used to obtain a lower bound for the minimal system order (i.e., the smallest possible size of the system matrix A) and to prove that the Boolean minimal realization problem in the max-plus algebra is decidable (and can be solved in a time that is bounded from above by a function that is exponential in the minimal system order).

Both Boolean algebras and the max-plus algebra are special cases of a dioid (i.e., an idempotent semiring) [1, 16]. For applications of dioids in graph theory, generating languages, and automata theory the interested reader is referred to [14, 15, 16].

4.3. Extensions. In this paper we have restricted ourselves to Boolean algebras. In this section we give some examples that illustrate some of the phenomena that could occur when we want to extend our results to more general algebraic structures. In our examples we shall use the max-plus algebra $(\mathbb{R} \cup \{-\infty\}, \max, +)$, but for other extensions of Boolean algebras similar examples can be constructed.

In contrast to Boolean algebra (cf. Theorem 3.20) the sequence of consecutive powers of a matrix in a more general algebraic structure does not always reach a stationary or cyclic regime after a finite number of terms, as is shown by the following example.

Example 4.1. Consider the matrix

$$A = \begin{bmatrix} 0 & -\infty \\ -\infty & -1 \end{bmatrix}.$$

Since the kth max-plus algebraic power of A is given by

$$A^{\otimes^k} = \begin{bmatrix} 0 & -\infty \\ -\infty & -k \end{bmatrix}$$

for $k \in \mathbb{N}_0$, the sequence $\left\{A^{\otimes^k}\right\}_{k=1}^{\infty}$ does not reach a stationary or cyclic regime in a finite number of steps.

Note that the matrix A of Example 4.1 is not irreducible. However, if a matrix is irreducible, then it can be shown [1, 7, 13] that the sequence of consecutive max-plus algebraic powers of the given matrix always reaches a cyclic regime of the form (2) after a finite number of terms. However, even if the sequence of consecutive powers reaches a stationary regime, then in general the length of the transient part will not depend only on the size and the cyclicity of the matrix but also on the range and the resolution (i.e., on the size of the representation) of the finite elements of the matrix, as is shown by the following examples.

Example 4.2. Let $N \in \mathbb{N}$ and consider

$$A(N) = \begin{bmatrix} -1 & -N \\ 0 & 0 \end{bmatrix}.$$

[4]This is the output of the system when a certain standardized input sequence is applied to the system.

The matrix $A(N)$ is irreducible and has cyclicity 1 and its λ-value[5] is equal to 0. The kth max-plus algebraic power of $A(N)$ is given by

$$\big(A(N)\big)^{\otimes^k} = \begin{bmatrix} \max(-k,-N) & -N \\ 0 & 0 \end{bmatrix}$$

for each $k \in \mathbb{N}_0$. This implies that the smallest integer k_0 for which (2) holds is given by $k_0 = N$, i.e., k_0 depends on the range of the finite entries of $A(N)$.

Example 4.3. Let $\varepsilon > 0$ and consider the matrix

$$A(\varepsilon) = \begin{bmatrix} 0 & 0 \\ -1 & -\varepsilon \end{bmatrix}.$$

This matrix is irreducible and has cyclicity 1 and its λ-value is equal to 0. Since the kth max-plus algebraic power of $A(\varepsilon)$ is given by

$$\big(A(\varepsilon)\big)^{\otimes^k} = \begin{bmatrix} 0 & 0 \\ -1 & \max(-1,-k\varepsilon) \end{bmatrix},$$

the smallest integer k_0 for which (2) holds is $k_0 = \lceil \frac{1}{\varepsilon} \rceil$. This example—which has been inspired by the example on p. 152 of [1]—shows that in general the length of the transient part of the sequence $\{A^{\otimes^k}\}_{k=1}^{\infty}$ depends on the resolution of the finite entries of A.

5. Conclusions. In this paper we have studied the ultimate behavior of the sequence of consecutive powers of a matrix in a Boolean algebra, and we have derived some upper bounds for the length of the transient part of this sequence. The results that have been derived in this paper can be used in the analysis of the transient behavior of Markov chains and in the max-plus algebraic system theory for discrete event systems.

Topics for future research are the derivation of tighter upper bounds for the length of the transient part of the sequence of consecutive power of a matrix in a Boolean algebra, and extension of our results to more general algebraic structures such as the max-plus algebra.

Acknowledgments. The authors want to thank the anonymous reviewers for their useful comments and remarks and for pointing out the connection with Markov chains.

A NOTE ON RELATIVE PERTURBATION BOUNDS*

TRISTAN LONDRÉ† AND NOAH H. RHEE†

Abstract. In this paper we provide an actual bound for the distance between the original and the perturbed right singular vector subspaces of a general matrix with full column rank. We also provide actual relative componentwise bounds for perturbed eigenvectors of a positive definite matrix.

Key words. perturbation theory, positive definite eigenproblem, singular value decomposition, right singular vector subspace

AMS subject classifications. 65F15, 15A18

1. Introduction. Some relative perturbation bounds for eigenvectors and singular vectors have been studied in [2], [3], [4], [5], [6], [7], and [8]. In this note we provide an improved actual (nonasymptotic) bound for the perturbed right singular vector subspace of a matrix which is of full column rank. If the perturbation is reasonably small, this bound is always comparable to the result of [4], and it can be arbitrarily sharper. Mathias [5] has already provided actual componentwise bounds for relative accuracy of perturbed right singular vectors. We provide actual relative componentwise bounds for eigenvectors of a positive definite matrix.

Let $H = V\Lambda V^*$ and $\tilde{H} = H + \Delta H = \widetilde{V}\widetilde{\Lambda}\widetilde{V}^*$ be positive definite, where $V, \tilde{V}$ are unitary and $\Lambda, \tilde{\Lambda}$ are diagonal. We partition $V = \begin{pmatrix} V_1 & V_2 \end{pmatrix}$ and $\tilde{V} = \begin{pmatrix} \tilde{V}_1 & \tilde{V}_2 \end{pmatrix}$ so that $V_1, \tilde{V}_1 \in C^{n\times k}$. If $\sin\Theta(V_1, \tilde{V}_1)$ denotes the diagonal matrix whose entries are the sines of the canonical angles between the column spaces of V_1 and $\tilde{V}_1$, then it is well known ([4], for example) that

$$\left\|\sin\Theta\left(V_1, \tilde{V}_1\right)\right\| = \left\|V_1^*\tilde{V}_2\right\|$$

for any unitarily invariant norm. Using this notation, the next theorem, which we will use in sections 2 and 3, follows easily from the proof given by Mathias and Veselić in [6].

THEOREM 1.1. *Let $H = V\Lambda V^*$ and $\tilde{H} = H + \Delta H = \widetilde{V}\widetilde{\Lambda}\widetilde{V}^*$ be positive definite where $V, \tilde{V}$ are unitary and $\Lambda, \tilde{\Lambda}$ are diagonal with diagonal entries λ_i and $\widetilde{\lambda}_i$, respectively. (Here we don't assume any ordering of the eigenvalues.) Assume*

$$\eta \equiv \left\|H^{-1/2}\left(\Delta H\right)H^{-1/2}\right\|_2 < 1,$$

and write

$$\eta_F \equiv \left\|H^{-1/2}\left(\Delta H\right)H^{-1/2}\right\|_F.$$

For any i, j satisfying

$$\chi\left(\lambda_i, \widetilde{\lambda}_j\right) > 0,$$

†Department of Mathematics and Statistics, University of Missouri at Kansas City, Kansas City, MO 64110 (tlondre@cctr.umkc.edu, rhee@cctr.umkc.edu).

where $\chi(a,b) \equiv |a-b|/\sqrt{ab}$, *we have*

$$|s_{ij}| \leq \frac{|y_{ij}|}{\chi\left(\lambda_i, \widetilde{\lambda}_j\right)}, \tag{1.1}$$

where $S \equiv V^*\tilde{V}$ *and* $Y \equiv \Lambda^{-1/2}\left[V^*(\Delta H)\tilde{V}\right]\tilde{\Lambda}^{-1/2}$ *satisfies*

$$\|Y\|_2 \leq \frac{\eta}{\sqrt{1-\eta}} \qquad \textit{and} \qquad \|Y\|_F \leq \frac{\eta_F}{\sqrt{1-\eta}}. \tag{1.2}$$

Also, if

$$\xi_\chi \equiv \min_{1\leq i\leq k, k+1\leq j\leq n} \chi\left(\lambda_i, \tilde{\lambda}_j\right) > 0,$$

then

$$\left\|\sin\Theta\left(V_1, \tilde{V}_1\right)\right\|_F = \left\|V_1^*\tilde{V}_2\right\|_F \leq \frac{1}{\sqrt{1-\eta}} \cdot \frac{\eta_F}{\xi_\chi}. \tag{1.3}$$

Remark. The bound given by (1.3) is identical to the result of [4, Theorem 4.3], but the method of proof used by Mathias and Veselić is different.

2. Right singular vector subspace bound. We will now apply Theorem 1.1 to the estimation of a bound for the distance between the perturbed and the original right singular vector subspaces. Mathias gives a first-order version of this bound for the case of a single perturbed right singular vector in [5, Theorem 2.8].

THEOREM 2.1. *Let* $G \in C^{m\times n}$ *be of full column rank and partition it as follows:*

$$G = (U_1, U_2)\begin{pmatrix} \Sigma_1 & 0 \\ 0 & \Sigma_2 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} V_1^* \\ V_2^* \end{pmatrix},$$

where $U_1 \in C^{m\times k}, V_1 \in C^{n\times k}, \Sigma_1 = \operatorname{diag}(\sigma_1, \ldots, \sigma_k)$ *and* $\Sigma_2 = \operatorname{diag}(\sigma_{k+1}, \ldots, \sigma_n)$. *Let* $\tilde{G} = G + \Delta G$ *be partitioned and* $\widetilde{\sigma}_i$ *be defined in a similar way. Assume*

$$\delta \equiv \left\|(\Delta G)G^\dagger\right\|_2 < \frac{1}{3} \quad \textit{and} \quad \xi_{\hat{\chi}} \equiv \min_{1\leq i\leq k, k+1\leq j\leq n} \chi\left(\sigma_i^2, \widetilde{\sigma}_j^2\right) > 0.$$

Then

$$\left\|\sin\Theta\left(V_1, \tilde{V}_1\right)\right\|_F \leq \frac{1}{\sqrt{1-3\delta}} \cdot \frac{2\delta_F + \delta_F^2}{\xi_{\hat{\chi}}},$$

where $\delta_F \equiv \left\|(\Delta G)G^\dagger\right\|_F$.

Proof. Let $\Sigma = \Sigma_1 \oplus \Sigma_2, H \equiv G^*G = V\Sigma^2V^*$, and $\tilde{H} \equiv (G+\Delta G)^*(G+\Delta G)$. If we write $\tilde{H} \equiv H + \Delta H$, then $\Delta H \equiv G^*\Delta G + \Delta G^*G + \Delta G^*\Delta G$. Note that $\delta \equiv \left\|\Delta G G^\dagger\right\|_2 = \left\|\Delta G V\Sigma^{-1}\right\|_2$. Since $H^{-1/2} = V\Sigma^{-1}V^*$ one can easily show that

$$\eta_F \equiv \left\|H^{-1/2}(\Delta H)H^{-1/2}\right\|_F \leq 2\delta_F + \delta_F^2,$$

and (using the assumption on δ) that

$$\eta \equiv \left\|H^{-1/2}(\Delta H)H^{-1/2}\right\|_2 \leq 2\delta + \delta^2 < 3\delta < 1.$$

Since the right singular vectors of G are also the eigenvectors of H and the squares of the singular values of G are also the eigenvalues of H, applying Theorem 1.1 gives the result. ∎

In [4, Theorem 4.9] Li gives the bound

$$\left\|\sin\Theta\left(V_1,\tilde{V}_1\right)\right\|_F \leq \frac{2-\delta}{2-2\delta}\cdot\frac{\delta_F}{\xi_\chi}$$

for the square case, under the assumptions that

$$\delta \equiv \left\|\Delta G G^{-1}\right\|_2 < 1 \qquad \text{and} \qquad \xi_\chi \equiv \min_{1\leq i\leq k, k+1\leq j\leq n} \chi\left(\sigma_i,\widetilde{\sigma}_j\right) > 0.$$

The most useful comparison will be the case where $\delta \ll 1$. For ease of analysis we compare first-order bounds. Notice that our bound and Li's bound can be written as

$$\left\|\sin\Theta\left(V_1,\tilde{V}_1\right)\right\|_F \leq \frac{2\delta_F}{\xi_{\hat{\chi}}} + O(\delta_F^2) \quad \text{and} \quad \left\|\sin\Theta\left(V_1,\tilde{V}_1\right)\right\|_F \leq \frac{\delta_F}{\xi_\chi} + O(\delta_F^2),$$

respectively. Note that

$$\frac{2\delta_F}{\xi_{\hat{\chi}}} \leq \frac{\delta_F}{\xi_\chi},$$

because $2\chi(a,b) \leq \chi\left(a^2,b^2\right)$ for any positive a, b. So if δ is reasonably small, our bound is always comparable with Li's. In fact, since it is possible for $\xi_{\hat{\chi}}$ to be arbitrarily bigger than ξ_χ, our bound can be arbitrarily sharper. The following example demonstrates this.

Example. Consider the 4×4 matrix $G = \operatorname{diag}\left(1, 2, 10^{-6}, 2\cdot 10^6\right)$ and the perturbed matrix

$$G + \Delta G = \begin{pmatrix} 1 & 10^{-4} & 10^{-10} & 100 \\ 0 & 2 & 10^{-10} & 100 \\ 0 & 0 & 10^{-6} & 100 \\ 0 & 0 & 0 & 2\cdot 10^6 \end{pmatrix}.$$

Here $\delta = 1.6378\cdot 10^{-4}$ and $\delta_F = 1.7320\cdot 10^{-4}$. We will let $V_1\left(\tilde{V}_1\right)$ be the matrix of the right singular vectors corresponding to the second and third biggest singular values of G $(G+\Delta G)$. The actual value of $\left\|\sin\Theta\left(V_1,\tilde{V}_1\right)\right\|_F$ is $1.2499\cdot 10^{-10}$. Our bound is $3.4652\cdot 10^{-10}$ and Li's bound is $1.7321\cdot 10^{-7}$ up to the accuracy shown.

3. Componentwise relative bounds. In this section we will find relative componentwise bounds for a perturbed eigenvector of a positive definite matrix. To our knowledge these results are the only actual componentwise bounds available.

THEOREM 3.1. *Let $H = V\Lambda V^*$ and $\tilde{H} = H + \Delta H = \tilde{V}\tilde{\Lambda}\tilde{V}^*$ be positive definite, where $V, \tilde{V}$ are unitary, $\Lambda = \operatorname{diag}(\lambda_1,\ldots,\lambda_n)$ with $\lambda_1 \geq \cdots \geq \lambda_n$, and $\tilde{\Lambda} = \operatorname{diag}\left(\widetilde{\lambda}_1,\ldots,\widetilde{\lambda}_n\right)$ with $\widetilde{\lambda}_1 \geq \cdots \geq \widetilde{\lambda}_n$. Assume*

$$\eta \equiv \left\|H^{-1/2}(\Delta H)H^{-1/2}\right\|_2 < 1$$

and

$$\eta\left(1 + \frac{1}{2\sqrt{1-\eta}}\right) < \min_{k\neq j}\rho\left(\lambda_k,\lambda_j\right), \tag{3.1}$$

where $\rho(a,b) \equiv |a-b|/(a+b)$. *Then for all* i

$$|v_{ij} - \widetilde{v}_{ij}| \leq \left(\sqrt{n-1} + .5\right) \frac{\eta}{(1-\eta)\left[\min_{k\neq j} \rho(\lambda_k, \lambda_j) - \eta\right]} \overline{v}_{ij},$$

where

$$\overline{v}_{ij} \equiv \min\left\{ \frac{1}{\sqrt{\lambda_n(A)}} \sqrt{\frac{\lambda_j}{h_{ii}}}, \sqrt{\lambda_1(A)} \sqrt{\frac{h_{ii}}{\lambda_j}} \right\},$$

$H = DAD$, *and* D *is a diagonal matrix chosen so that* A *has a unit diagonal.*

Proof. In this proof S and Y are defined as in Theorem 1.1. Also, for any matrix A, the symbol a_j will denote the jth column of A. Mathias has shown in [5, Corollary 3.3] that $|V| \leq \overline{V} \equiv (\overline{v}_{ij})$. For convenience, let $R \equiv I - S$. We can see that

$$|v_j - \widetilde{v}_j| = |V(e_j - s_j)| \leq \overline{V}\,|e_j - s_j| = \overline{V}\,|r_j|, \tag{3.2}$$

where e_j is the jth unit vector. One can verify that the condition (3.1) implies that

$$\frac{\eta}{\sqrt{1-\eta}} \cdot \frac{1}{\min_{k\neq j} \chi\left(\lambda_k, \widetilde{\lambda}_j\right)} < 1, \tag{3.3}$$

using $2\rho(a,b) \leq \chi(a,b)$ and Theorem 2.3 and the inequality (1.1) in [5]. This also implies that $\chi\left(\lambda_k, \widetilde{\lambda}_j\right) > 0$ when $k \neq j$. So for $k \neq j$, (1.1) from Theorem 1.1 tells us that

$$|r_{kj}| = |s_{kj}| \leq \frac{|y_{kj}|}{\chi\left(\lambda_k, \widetilde{\lambda}_j\right)}.$$

When $k = j$, since we may assume that s_{jj} is positive, we can use (1.1), (1.2), the fact that $1 - \sqrt{1-x} \leq x$ if $0 \leq x \leq 1$, and (3.3) to get

$$|r_{jj}| = 1 - s_{jj} = 1 - \sqrt{1 - \sum_{k\neq j} |s_{kj}|^2} \leq \frac{\eta^2}{1-\eta} \cdot \frac{1}{\min_{k\neq j}\left[\chi\left(\lambda_k, \widetilde{\lambda}_j\right)\right]^2}.$$

Thus taking the ith component from (3.2) gives

$$\begin{aligned} |v_{ij} - \widetilde{v}_{ij}| &\leq \sum_{k=1}^{n} \overline{v}_{ik}\,|r_{kj}| \\ &\leq \frac{\eta^2}{1-\eta} \cdot \frac{\overline{v}_{ij}}{\min_{k\neq j}\left[\chi\left(\lambda_k, \widetilde{\lambda}_j\right)\right]^2} + \sum_{k\neq j} \overline{v}_{ik} \frac{|y_{kj}|}{\chi\left(\lambda_k, \widetilde{\lambda}_j\right)}. \end{aligned} \tag{3.4}$$

Using (3.3) above and Theorem 2.3 and the inequality (1.1) in [5], the first term can be bounded as

$$\begin{aligned} \frac{\eta^2}{1-\eta} \cdot \frac{\overline{v}_{ij}}{\min_{k\neq j}\left[\chi\left(\lambda_k, \widetilde{\lambda}_j\right)\right]^2} &\leq \frac{\eta}{\sqrt{1-\eta}} \cdot \frac{\overline{v}_{ij}}{\min_{k\neq j} \chi\left(\lambda_k, \widetilde{\lambda}_j\right)} \\ &\leq \frac{\eta}{\sqrt{1-\eta}} \cdot \frac{\overline{v}_{ij}}{2 \cdot \min_{k\neq j} \rho\left(\lambda_k, \widetilde{\lambda}_j\right)} \\ &\leq \frac{1}{2} \cdot \frac{\eta}{(1-\eta)\left[\min_{k\neq j} \rho(\lambda_k, \lambda_j) - \eta\right]} \overline{v}_{ij}. \end{aligned} \tag{3.5}$$

We begin to bound the second term by following Mathias [5, Lemma 3.4]:

$$\begin{aligned}\sum_{k\neq j}\overline{v}_{ik}\frac{|y_{kj}|}{\chi\left(\lambda_k,\widetilde{\lambda}_j\right)} &= \sum_{k\neq j}\min\left\{\frac{1}{\sqrt{\lambda_n(A)}}\sqrt{\frac{\lambda_k}{h_{ii}}},\sqrt{\lambda_1(A)}\sqrt{\frac{h_{ii}}{\lambda_k}}\right\}\frac{|y_{kj}|}{\chi\left(\lambda_k,\widetilde{\lambda}_j\right)}\\ &\leq \max_{k\neq j}\frac{\lambda_k+\tilde{\lambda}_j}{\left|\lambda_k-\tilde{\lambda}_j\right|}\min\left\{\frac{1}{\sqrt{\lambda_n(A)}}\sqrt{\frac{\tilde{\lambda}_j}{h_{ii}}},\sqrt{\lambda_1(A)}\sqrt{\frac{h_{ii}}{\tilde{\lambda}_j}}\right\}\sum_{k\neq j}|y_{kj}|\\ &\leq \frac{\sqrt{n-1}}{\min\limits_{k\neq j}\rho\left(\lambda_k,\widetilde{\lambda}_j\right)}\cdot\min\left\{\frac{1}{\sqrt{\lambda_n(A)}}\sqrt{\frac{\tilde{\lambda}_j}{h_{ii}}},\sqrt{\lambda_1(A)}\sqrt{\frac{h_{ii}}{\tilde{\lambda}_j}}\right\}\sqrt{\sum_{k\neq j}|y_{kj}|^2}.\end{aligned}$$

Using (1.2) above, Theorem 2.3 and the inequality (1.1) in [5], the fact that $\sqrt{1+\eta}\leq 1/\sqrt{1-\eta}$, and the definition of $\overline{v}_{ij}$, the second term can be bounded by

$$\sqrt{n-1}\cdot\frac{\eta}{(1-\eta)\left[\min\limits_{k\neq j}\rho\left(\lambda_k,\lambda_j\right)-\eta\right]}\overline{v}_{ij}. \tag{3.6}$$

So it follows from (3.4), (3.5), and (3.6) that

$$|\tilde{v}_{ij}-v_{ij}|\leq\left(\sqrt{n-1}+.5\right)\frac{\eta}{(1-\eta)\left[\min\limits_{k\neq j}\rho\left(\lambda_k,\lambda_j\right)-\eta\right]}\overline{v}_{ij}$$

for all i, which proves the theorem. □

Relative componentwise bounds for right singular vectors can easily be obtained from this theorem in a manner similar to the derivation of Theorem 2.1 from Theorem 1.1; however, Mathias [5] has already provided essentially the same result.

Acknowledgments. We thank the anonymous referees whose suggestions helped improve this note.

BOUNDS ON THE EXTREME EIGENVALUES OF REAL SYMMETRIC TOEPLITZ MATRICES*

A. MELMAN†

Abstract. We derive upper and lower bounds on the smallest and largest eigenvalues, respectively, of real symmetric Toeplitz matrices. The bounds are first obtained for positive-definite matrices and then extended to the general real symmetric case. They are computed as the roots of rational and polynomial approximations to spectral, or secular, equations for the symmetric and antisymmetric parts of the spectrum; this leads to separate bounds on the even and odd eigenvalues. We also present numerical results.

Key words. Toeplitz matrix, eigenvalues, bounds, spectral equation, secular equation, rational approximation

1. Introduction.

The study of eigenvalues of Toeplitz matrices continues to be of interest, due to the occurrence of these matrices in a host of applications (see [4] for a good overview) including linear prediction, a well-known problem in digital signal processing.

In this work we present improved bounds on the extreme eigenvalues of real symmetric positive-definite Toeplitz matrices and describe their extension to matrices that are not positive definite. The computation of the smallest eigenvalue of such matrices was considered in, e.g., [8, 18, 21, 22, 25, and 27], whereas bounds were studied in [11, 16, and 26]. Among the latter, the best currently available bounds seem to have been obtained in [11]. In our approach, which is similar to the one used in aforementioned papers, the eigenvalues of the matrix are computed as the roots of a one-dimensional rational function. The extreme eigenvalues can then be bounded by computing bounds on the roots of the aforementioned equation, often called a *spectral equation*, or *secular equation* (see [14]).

In [11] the bounds are obtained by using a Taylor series expansion for the secular equation. We propose to improve this in two ways: first by considering "better" secular equations (of a similar rational nature) and second by considering rational approximations to the secular function, rather than a Taylor series, which is an inappropriate approximation for a rational function. As an added advantage of our different equations, we obtain separate bounds on the even and odd eigenvalues.

To put matters in perspective, we note that these "better" equations are hinted at in [11] without being explicitly stated; they also appear in [9] in an equivalent form that is less suitable for computation. No applications of these equations were considered in either paper. More recently, in [24] and [27], these same equations were derived in a form suitable for applications. In [24], they were applied to the study of spectral evolution as a function of one parameter, whereas in [25] and [27], they were used to compute the smallest eigenvalue. In [18], an equation such as one of

ours is derived in a different way, without taking into account the spectral structure of the submatrices, thereby obscuring key properties of the equation. It is used there to compute the smallest even eigenvalue.

The idea of a rational approximation for secular equations is not new. In a different context, it was already used in, e.g., [5] and many other references, the most relevant to this work being [21, 25, and 27]. However, such rational approximations seem to be rarely considered beyond the first order. We use techniques from [23] to analyze higher-order rational approximations, which we prove to be better than polynomial ones of the same order. The combination of the equations for the even and odd spectra with higher-order rational approximations to compute bounds on the extreme eigenvalues results in a significant improvement over existing bounds.

The paper is organized as follows: Section 1 contains definitions, a brief overview of the properties of Toeplitz matrices, and basic results for a class of rational functions. In section 2 we develop spectral equations, and in section 3 we consider the approximations which lead, in section 4, to the bounds on the extreme eigenvalues. Finally, we present numerical results in section 5. In sections 2 and 3, we have included a summary of parts of [24] to improve readability and to make the paper as self-contained as possible.

2. Preliminaries. A symmetric matrix $T \in \mathbb{R}^{(n,n)}$ is said to be *Toeplitz* if its elements T_{ij} satisfy $T_{ij} = \mathbf{t}_{|j-i|}$ for some vector $\mathbf{t} = (t_0, \ldots, t_{n-1})^T \in \mathbb{R}^n$. Many early results about such matrices can be found in, e.g., [3, 6, and 9].

Toeplitz matrices are *persymmetric*; i.e., they are symmetric about their southwest-northeast diagonal. For such a matrix T, this is the same as requiring that $JT^TJ = T$, where J is a matrix with ones on its southwest-northeast diagonal and zeros everywhere else (the exchange matrix). It is easy to see that the inverse of a persymmetric matrix is also persymmetric. A matrix that is both symmetric and persymmetric is called *doubly symmetric*.

The identity matrix is denoted by I throughout this paper. As with J, we will not specifically indicate its dimension, which is assumed to be clear from the context.

A *symmetric vector* v is defined as a vector satisfying $Jv = v$ and an *antisymmetric vector* w as one that satisfies $Jw = -w$. If these vectors are eigenvectors, then their associated eigenvalues are called *even* and *odd*, respectively. Drawing on results in [3], it was shown in [6] that, given a real symmetric Toeplitz matrix T of order n, there exists an orthonormal basis for $\mathbb{R}^n$, composed of $n - \lfloor n/2 \rfloor$ symmetric and $\lfloor n/2 \rfloor$ antisymmetric eigenvectors of T, where $\lfloor \alpha \rfloor$ denotes the integral part of α. In the case of simple eigenvalues, this is easy to see from the fact that if $Tu = \lambda u$, then $T(Ju) = \lambda(Ju)$, because $JTJ = T$ and $J^2 = I$. Therefore u and Ju must be proportional, and therefore u must be an eigenvector of J, which means that either $Ju = u$ or $Ju = -u$. Finally, we note that for $\alpha \in \mathbb{R}$, the matrix $(T - \alpha I)$ is symmetric and Toeplitz, whenever T is.

We now state two lemmas, the proofs of which can be found in [23]. They concern the relation between a class of rational functions, which will be considered later, and their approximations.

LEMMA 2.1. *Let $g(\lambda)$ be a strictly positive and twice continuously differentiable real function, defined on some interval $K \subset \mathbb{R}$. With γ a nonzero integer, consider the real function of $\lambda : a(b-\lambda)^\gamma$, where the parameters a and b are such that it interpolates g up to first order at a point $\bar{\lambda} \in K$ with $g'(\bar{\lambda}) \neq 0$. If*

$$\frac{1-\gamma}{\gamma} g'^2(\lambda) + g(\lambda) g''(\lambda)$$

is positive (negative) for all $\lambda \in K$, then for all λ such that $a(b-\lambda)^\gamma \geq 0$, the interpolant $a(b-\lambda)^\gamma$ lies below (above) the function $g(\lambda)$. ∎

LEMMA 2.2. *The function*

$$g(\lambda) = \sum_{j=1}^{m} \alpha_j \, (\beta_j - \lambda)^\gamma,$$

with m a positive and γ a nonzero integer and the α_j's nonnegative, satisfies

$$\frac{1-\gamma}{\gamma} g'^2(\lambda) + g(\lambda) g''(\lambda) \geq 0$$

for all λ such that for all $j : \beta_j - \lambda > 0$. ∎

The following lemma is closely related to Lemma 2.2 for $\lambda = 0$.

LEMMA 2.3. *Define*

$$R_p \triangleq \sum_{j=1}^{m} \frac{\alpha_j}{\beta_j^p},$$

where $\alpha_j, \beta_j > 0$ $(j = 1, \ldots, m)$, and p a positive integer with $p \geq 2$. Then the following inequality holds:

$$R_p^2 \leq R_{p-1} R_{p+1}.$$

The inequality holds as an equality if and only if $\beta_1 = \beta_2 = \cdots = \beta_m$.

Proof. Define the m-dimensional vectors a and b by $a_j = \sqrt{\alpha_j}/\beta_j^{\frac{p-1}{2}}$ and $b_j = \sqrt{\alpha_j}/\beta_j^{\frac{p+1}{2}}$, so that $\|a\|^2 = R_{p-1}$, $\|b\|^2 = R_{p+1}$, and $|a^T b|^2 = R_p^2$. The proof then follows from the Cauchy–Schwarz inequality, which states that $|a^T b|^2 \leq \|a\|^2 \|b\|^2$ with equality if and only if $\frac{a_1}{b_1} = \frac{a_2}{b_2} = \cdots = \frac{a_m}{b_m}$. ∎

3. Spectral equations. In this section we derive various spectral, or secular, equations for the eigenvalues of a real symmetric Toeplitz matrix. Several of these results are not new, even though some were not explicitly stated elsewhere or appear in a form less suitable for computation.

Let us consider the following partition of a symmetric Toeplitz matrix T :

$$T = \begin{pmatrix} t_0 & t^T \\ t & Q \end{pmatrix},$$

where $t = (t_1, \ldots, t_{n-1})^T$ and Q is an $(n-1) \times (n-1)$ symmetric Toeplitz matrix, generated by the vector $(t_0, \ldots, t_{n-2})^T$. Then the following well-known theorem (see, e.g., [8]) holds.

THEOREM 3.1. *The eigenvalues of T that are not shared with those eigenvalues of Q, whose associated eigenspaces are not entirely contained in $\{t\}^\perp$, are given by the solutions of the equation*

$$-t_0 + \lambda + t^T (Q - \lambda I)^{-1} t = 0. \qquad \blacksquare \tag{3.1}$$

We define the function $\phi(\lambda)$ by

$$\phi(\lambda) \triangleq -t_0 + \lambda + t^T (Q - \lambda I)^{-1} t. \tag{3.2}$$

Equation (3.1) is equivalent to

$$-t_0 + \lambda + \sum_{i=1}^{p} \frac{c_i^2}{\omega_i - \lambda} = 0, \tag{3.3}$$

where $\{\omega_i\}_{i=1}^p$ are the p eigenvalues of Q for which the associated eigenspace U_{ω_i} is not entirely contained in the subspace $\{t\}^\perp$, i.e., for which $U_{\omega_i} \not\subset \{t\}^\perp$(see, e.g., [11] for more details). Denote the orthonormal vectors which form a basis for U_{ω_i} by $\{u_j^{(i)}\}_{j=1}^{d_i}$, where d_i is the dimension of U_{ω_i}. Then the scalars c_i^2 are given by $c_i^2 = \sum_{j=1}^{d_i} (t^T u_j^{(i)})^2$. The rational function in (3.1) or (3.3) has p simple poles, dividing the real axis into $p+1$ intervals on each of which it is monotonically increasing from $-\infty$ to $+\infty$. The $p+1$ solutions $\{\lambda_j\}_{j=1}^{p+1}$ of (3.3) therefore satisfy

$$\lambda_1 < \omega_1 < \lambda_2 < \omega_2 < \cdots < \omega_p < \lambda_{p+1};$$

i.e., the eigenvalues ω_i strictly interlace the eigenvalues λ_j, which is known as Cauchy's interlacing theorem. These results are well known and we refer to, e.g., [8] and [11].

A positive-definite matrix T will therefore certainly have an eigenvalue in the interval $(0, \omega_1)$. An upper bound can then be found by approximating the function in (3.1) at $\lambda = 0$ in such a way that the approximation always lies below that function and by subsequently computing the root of this approximation. This is the approach used in [11], where the approximations are the Taylor polynomials. However, such polynomials are inadequate for rational functions, and we shall return to this matter after deriving additional spectral equations.

It would appear that our previous partition of T is inappropriate, given the persymmetry of Toeplitz matrices. We therefore consider the following, more natural, partition for a matrix that is both symmetric and persymmetric:

$$T = \begin{pmatrix} t_0 & \tilde{t}^T & t_{n-1} \\ \tilde{t} & G & J\tilde{t} \\ t_{n-1} & (J\tilde{t})^T & t_0 \end{pmatrix},$$

where $\tilde{t} = (t_1, \ldots, t_{n-2})^T$ and G is an $(n-2) \times (n-2)$ symmetric Toeplitz matrix, generated by the vector $(t_0, \ldots, t_{n-3})^T$. This is the partition used in [24] and [27]. It is also used in [11, Theorem 4], but without exploiting it to compute or bound eigenvalues. In what follows, we denote the even and odd eigenvalues of T by λ_i^e and λ_i^o and the even and odd eigenvalues of G by μ_i and ν_i, respectively. We then have the following theorem, which yields two equations: one for even and one for odd eigenvalues of T. It can be found in [24] and, in a slightly different form, in [27].

THEOREM 3.2. *The even eigenvalues of T that are not shared with those even eigenvalues of G, whose associated eigenspaces are not entirely contained in $\{\tilde{t}\}^\perp$, are the solutions of*

$$-t_0 - t_{n-1} + \lambda + \tilde{t}^T (G - \lambda I)^{-1} (\tilde{t} + J\tilde{t}) = 0, \tag{3.4}$$

whereas the odd eigenvalues of T that are not shared with those odd eigenvalues of G, whose associated eigenspaces are not entirely contained in $\{\tilde{t}\}^\perp$, are the solutions of

$$-t_0 + t_{n-1} + \lambda + \tilde{t}^T (G - \lambda I)^{-1} (\tilde{t} - J\tilde{t}) = 0. \tag{3.5}$$

Proof. The proof is based on finding the conditions under which $(T - \lambda I)x = 0$ has a nontrivial solution for x. These conditions take the form of a factorable equation, which then leads directly to (3.4) and (3.5). For more details, we refer to [24]. ∎

To gain a better understanding of (3.4) and (3.5), let us assume for a moment that all eigenvalues of G are simple (the general case does not differ substantially) and denote an orthonormal basis of $\mathbb{R}^{n-2}$, composed of orthonormal eigenvalues of G, by $\{v_i\}_{i=1}^{r} \bigcup \{w_j\}_{j=1}^{s}$, where $r = n-2-\lfloor (n-2)/2 \rfloor$, $s = \lfloor (n-2)/2 \rfloor$, (v_i, μ_i) are (symmetric eigenvector, even eigenvalue) pairs, and (w_j, ν_j) are (antisymmetric eigenvector, odd eigenvalue) pairs. With $\tilde{t} = \sum_{i=1}^{r} a_i v_i + \sum_{j=1}^{s} b_j w_j$, this means that

$$J\tilde{t} = \sum_{i=1}^{r} a_i (Jv_i) + \sum_{j=1}^{s} b_j (Jw_j) = \sum_{i=1}^{r} a_i v_i - \sum_{j=1}^{s} b_j w_j.$$

Once more, exploiting the orthonormality of the eigenvectors yields

$$\tilde{t}^T (G - \lambda I)^{-1} (\tilde{t} + J\tilde{t}) = 2 \sum_{i=1}^{r} \frac{a_i^2}{\mu_i - \lambda}.$$

Analogously, we obtain

$$\tilde{t}^T (G - \lambda I)^{-1} (\tilde{t} - J\tilde{t}) = 2 \sum_{j=1}^{s} \frac{b_j^2}{\nu_j - \lambda}.$$

Equations (3.4) and (3.5) now become

$$-t_0 - t_{n-1} + \lambda + 2 \sum_{i=1}^{r} \frac{a_i^2}{\mu_i - \lambda} = 0, \tag{3.6}$$

$$-t_0 + t_{n-1} + \lambda + 2 \sum_{j=1}^{s} \frac{b_j^2}{\nu_j - \lambda} = 0, \tag{3.7}$$

which shows that the rational functions in each of (3.4) and (3.5) are of the same form as the function in (3.1). It is also clear that T will certainly have an even eigenvalue on $(0, \mu_1)$ and an odd one on $(0, \nu_1)$. These equations were also hinted at in [11] without, however, being derived or stated in an explicit way. The meaning of Theorem 3.2 is therefore that those even and odd eigenvalues of G, whose associated eigenspaces are not completely contained in $\{\tilde{t}\}^{\perp}$, interlace, respectively, the even and odd eigenvalues of T that are not shared with those eigenvalues of G. This result was obtained in [9] in a different way, along with equivalent forms of (3.6) and (3.7). However, the use of determinants there makes them less suitable for applications.

Finally, because of the orthonormality of the eigenvectors, (3.4) and (3.5) can be written in a more symmetric way, as shown in the following two equations, which at the same time define the functions $\phi^e(\lambda)$ and $\phi^o(\lambda)$:

$$\phi^e(\lambda) \triangleq -t_0 - t_{n-1} + \lambda + \frac{1}{2} (\tilde{t} + J\tilde{t})^T (G - \lambda I)^{-1} (\tilde{t} + J\tilde{t}) = 0, \tag{3.8}$$

$$\phi^o(\lambda) \triangleq -t_0 + t_{n-1} + \lambda + \frac{1}{2} (\tilde{t} - J\tilde{t})^T (G - \lambda I)^{-1} (\tilde{t} - J\tilde{t}) = 0. \tag{3.9}$$

We note that (3.8) was also obtained in [18], where it was used to compute the smallest eigenvalue which was known in advance to be even. However, the derivation of the equation is quite different, concentrating exclusively on the smallest eigenvalue and

disregarding the spectral structure of the submatrices of T, which obscures important properties of that equation.

To evaluate the functions $\phi(\lambda)$, $\phi^e(\lambda)$, and $\phi^o(\lambda)$, and their derivatives, as we will need to do later on, we need to compute expressions of the form $s^T S^{-k} s$ for a positive integer k, where S is the real symmetric Toeplitz matrix defined by $(s_0, s_1, \ldots, s_{n-1})$ and where $s = (s_1, \ldots, s_n)$. In this work, we will use the *Levinson–Durbin algorithm* (LDA). The original references for this algorithm are [13] and [20], but an excellent overview of this and other Toeplitz-related algorithms can be found in [15]. Let us start with $k = 1$. In this case we have to solve $Sw = -s$, where the minus sign in the right-hand side is by convention. This system of linear equations is called the Yule–Walker (YW) system, and the LDA solves this problem recursively in $2n^2 + \mathcal{O}(n)$ flops, where we define one flop as in [15], namely, a multiplication/division or an addition/subtraction. Because of the persymmetry of S, once the YW equations are solved, the solution to $Sy = -Js$ is given by $y = Jw$.

After solving the YW system, we have obtained $w = -S^{-1}s$. The expression $s^T S^{-2} s$ can then be evaluated as $\|S^{-1}s\|_2^2$ in $\mathcal{O}(n)$ flops. To compute higher-order derivatives, we use a decomposition of S, supplied by the LDA itself in the process of solving the YW system. Denoting by $w^{(\ell)}$ the solution to the ℓth-dimensional YW subsystem, obtained in the course of the LDA algorithm, this decomposition is given by $U^T S U = D$, where D is a diagonal matrix and U is the upper triangular $n \times n$ matrix, whose ℓth column is given by $(Jw^{(\ell-1)}, 1)^T$; i.e., all its diagonal elements are equal to one. This result is due to [7]. We calculate $s^T S^{-3} s$ as follows:

$$s^T S^{-3} s = (S^{-1}s)^T S^{-1}(S^{-1}s) = w^T U D^{-1} U^T w = (U^T w)^T D^{-1}(U^T w).$$

This computation costs $n^2 + \mathcal{O}(n)$ flops. To evaluate $s^T S^{-4} s$, we compute first $S^{-2}s$ as $UD^{-1}U^T w$, which requires, once again, $n^2 + \mathcal{O}(n)$ flops, and then compute $\|S^{-2}s\|_2^2$ with an additional $\mathcal{O}(n)$ flops. Roughly speaking, we can say that, for each increase of k by one, we need to execute an additional n^2 flops. We mention here that $4n^2 + \mathcal{O}(n)$ flops are required to compute the second derivative of both the even and odd spectral functions. This doubling of the number of flops does not take place for the second and third derivatives.

Of course, other, potentially faster, algorithms could be substituted for the classical LDA, such as the superfast Toeplitz solvers (see, e.g., [1] and [2]) or a version of the LDA which exploits the symmetry of the solution (see, e.g., [10, 12]). However, this influences only the complexity of computing our bounds and not the bounds themselves, which are the focus of this work.

4. Approximations. As we mentioned before, our bounds will be obtained by the roots of approximations to the secular equations. In the case of the smallest eigenvalue, those approximations will be shown to be dominated by the spectral function, so that their root will provide an upper bound on the smallest eigenvalue. Bounds for the largest eigenvalue will be based on the bounds for the smallest eigenvalue of a different matrix. In the derivation of the bounds, we will assume that the matrices are positive definite, even though a slight modification suffices to extend our results to general symmetric matrices. All this will be explained in section 5.

We shall now construct approximations to our spectral equations. These will be of two types: rational and polynomial, each of which will be of three kinds: first, second, and third order.

Throughout this section we will consider approximations, obtained by interpola-

tion at $\lambda = 0$, for a function g of the form

$$g(\lambda) = \sum_{j=1}^{m} \frac{\alpha_j}{\beta_j - \lambda}, \tag{4.1}$$

where $\alpha_j > 0$, $0 < \beta_1 < \beta_2 < \cdots < \beta_m$, and $m \geq 2$. Functions of this form occur in all the equations considered in this paper. We note that g has simple poles at the β_j's and is a positive, monotonically increasing convex function (or $g, g', g'' > 0$) on the interval $(-\infty, \beta_1)$. Our results are applicable for interpolation at a point $\bar{\lambda} \in (-\infty, \beta_1)$, different from zero, simply by translating the origin to that point.

We will denote the approximations of first, second, and third order by ρ_1, ρ_2, ρ_3 for the rational ones and by τ_1, τ_2, τ_3 for the polynomial ones, respectively. The polynomial approximations are nothing but the Taylor polynomials of degree 1, 2, and 3. We now define these approximations but warn that some of the parameters are defined "locally"; i.e., the same letter may have different meanings in different contexts, when no confusion is possible.

(1) *First-order rational.* A function $\rho_1(\lambda) \stackrel{\triangle}{=} a/(b-\lambda)$ such that $\rho_1(0) = g(0)$ and $\rho_1'(0) = g'(0)$. The coefficients a and b are easily computed to be $a = g^2(0)/g'(0)$ and $b = g(0)/g'(0)$. Since

$$b = \frac{g(0)}{g'(0)} = \frac{\sum_{j=1}^{m}(\alpha_j/\beta_j)}{\sum_{j=1}^{m}(\alpha_j/\beta_j^2)} = \sum_{j=1}^{m} \left(\frac{\alpha_j/\beta_j^2}{\sum_{j=1}^{m}(\alpha_j/\beta_j^2)} \right) \beta_j, \tag{4.2}$$

which is a strictly convex combination of the β_j's, this means that $\beta_1 < b < \beta_m$. We also have $a > 0$, so that ρ_1 is a positive, monotonically increasing convex function on $(-\infty, \beta_1)$.

(2) *Second-order rational.* A function $\rho_2(\lambda) \stackrel{\triangle}{=} a + b/(c - \lambda)$ such that $\rho_2(0) = g(0)$, $\rho_2'(0) = g'(0)$, and $\rho_2''(0) = g''(0)$. The coefficients a, b, and c are then given by $a = g(0) - 2g'^2(0)/g''(0)$, $b = 4g'^3(0)/g''^2(0)$, and $c = 2g'(0)/g''(0)$. It is clear immediately that $b > 0$. From Lemma 2.2 with $\gamma = -1$, we have that $a > 0$ as well. Since

$$c = \frac{2g'(0)}{g''(0)} = \frac{\sum_{j=1}^{m}(\alpha_j/\beta_j^2)}{\sum_{j=1}^{m}(\alpha_j/\beta_j^3)} = \sum_{j=1}^{m} \left(\frac{\alpha_j/\beta_j^3}{\sum_{j=1}^{m}(\alpha_j/\beta_j^3)} \right) \beta_j, \tag{4.3}$$

we have once again obtained a strictly convex combination of the β_j's, so that $\beta_1 < c < \beta_m$. The approximation ρ_2 is therefore positive, monotonically increasing, and convex on $(-\infty, \beta_1)$. Since $\beta_1 < \beta_2 < \cdots < \beta_m$, we also have (in the notation of Lemma 2.3) that $R_2^2 < R_1 R_3$, or $R_2/R_3 < R_1/R_2$, which is the same as saying that $2g'(0)/g''(0) < g(0)/g'(0)$. This means that the pole of ρ_2 lies closer to β_1 than the pole of ρ_1.

(3) *Third-order rational.* A function $\rho_3(\lambda) \stackrel{\triangle}{=} a/(b - \lambda) + c/(d - \lambda)$ such that $\rho_3(0) = g(0)$, $\rho_3'(0) = g'(0)$, $\rho_3''(0) = g''(0)$, and $\rho_3'''(0) = g'''(0)$. For convenience, we temporarily leave out the argument of g and its derivatives, i.e., $g \equiv g(0)$, and we denote $v = 1/b$ and $w = 1/d$. To compute the coefficients of ρ_3, we then have to find a solution for the following system of equations in a, c, v, and w:

$$av + cw = g, \tag{4.4}$$

$$av^2 + cw^2 = g', \tag{4.5}$$

$$2av^3 + 2cw^3 = g'', \tag{4.6}$$

$$6av^4 + 6cw^4 = g''', \tag{4.7}$$

establish that $v, w \neq 0$, and set $b = 1/v$, $d = 1/w$.

We first show that $acvw \neq 0$. To see this, assume that $av = 0$. Since $g > 0$, this would mean that $cw \neq 0$, so that (4.4)–(4.6) imply $g'/g = g''/2g'$ or $R_2^2 = R_1 R_3$, in the notation of Lemma 2.3. This same lemma then shows that this is possible only if all β_j's are equal, which contradicts our assumption that $\beta_1 < \beta_2 < \cdots < \beta_m$. Therefore, $av \neq 0$. Similarly, we find that $cw \neq 0$, so that a, c, v, and w are all nonzero.

Furthermore, neither $a/(b-\lambda)$ nor $c/(d-\lambda)$ can be equal to any of the terms $\alpha_j/(\beta_j - \lambda)$ appearing in $g(\lambda)$. If this were the case, e.g., for $a/(b-\lambda)$, then the effect on (4.4)–(4.7) would be to set $a = 0$ and to leave out one term in the expressions for g, g', g'', g'''. An argument analogous to the one in the previous paragraph then leads, once again, to a contradiction.

We also claim that $v \neq w$. To show this, assume that $v = w$. Equation (4.4) then yields $a + c \neq 0$ and (4.4)–(4.6) once again produce $R_2^2 = R_1 R_3$, which, as we already saw, is impossible.

From Cramer's rule, applied to (4.4)–(4.7), we have

$$a = \frac{\begin{vmatrix} g & w \\ g' & w^2 \end{vmatrix}}{\begin{vmatrix} v & w \\ v^2 & w^2 \end{vmatrix}} = \frac{\begin{vmatrix} g' & w^2 \\ g'' & 2w^3 \end{vmatrix}}{\begin{vmatrix} v^2 & w^2 \\ 2v^3 & 2w^3 \end{vmatrix}} = \frac{\begin{vmatrix} g'' & 2w^3 \\ g''' & 6w^4 \end{vmatrix}}{\begin{vmatrix} 2v^3 & 2w^3 \\ 6v^4 & 6w^4 \end{vmatrix}}.$$

Since $v, w \neq 0$ and $v \neq w$, these expressions are well defined and are equivalent to

$$a = \frac{gw - g'}{(w-v)v} = \frac{2g'w - g''}{2(w-v)v^2} = \frac{3g''w - g'''}{6(w-v)v^3}. \tag{4.8}$$

Expression (4.8) then leads to

$$v = \frac{1}{2}\left(\frac{2g'w - g''}{gw - g'}\right), \tag{4.9}$$

$$v = \frac{1}{3}\left(\frac{3g''w - g'''}{2g'w - g''}\right). \tag{4.10}$$

Analogously, by considering c instead of a, we obtain

$$c = \frac{g' - gv}{(w-v)w} = \frac{g'' - 2g'v}{2(w-v)w^2} = \frac{g''' - 3g''v}{6(w-v)w^3}, \tag{4.11}$$

and

$$w = \frac{1}{2}\left(\frac{2g'v - g''}{gv - g'}\right), \tag{4.12}$$

$$w = \frac{1}{3}\left(\frac{3g''v - g'''}{2g'v - g''}\right). \tag{4.13}$$

Because $a, c \neq 0$, (4.8) and (4.11) imply that neither v nor w can be equal to g'/g, $g''/2g'$, or $g'''/3g''$, so that the above identities are well defined.

Equations (4.9) and (4.10) then yield, after some algebra,

$$v + w \stackrel{\triangle}{=} \eta = \frac{gg''' - 3g'g''}{3gg'' - 6g'^2}, \tag{4.14}$$

$$vw \stackrel{\triangle}{=} \zeta = \frac{g'g''' - \frac{3}{2}g''^2}{3gg'' - 6g'^2}. \tag{4.15}$$

From Lemma 2.3, we have

$$3gg'' - 6g'^2 = 6\left(\frac{1}{2}gg'' - g'^2\right) = 6\left(R_1R_3 - R_2^2\right) > 0,$$

so that the denominators in (4.14) and (4.15) are well defined. This means that v and w are the solutions for x of the quadratic equation $x^2 - \eta x + \zeta = 0$. Since $v, w \neq 0$, b and d are then determined by $b = 1/v$ and $d = 1/w$. Our equations are symmetric in v and w, so let us choose v as the larger of the two. This makes b the smaller of the two poles of ρ_3.

Since no two β_j's are the same, Lemma 2.3 with $p = 2, 3$ yields $g'''/3g'' > g''/2g' > g'/g$, so that $v + w > 0$ and $vw > 0$, which in turn means that $v, w > 0$. As a direct consequence of (4.9), (4.10), (4.12), and (4.13), we then have that $v > g'''/3g''$ and $w < g'/g$ or $b < 3g''/g'''$ and $d > g/g'$, since we designated b as the smaller of the two poles of ρ_3. Using these inequalities in (4.8) and (4.11) then shows that $a, c > 0$.

Finally, we claim that $b > \beta_1$ and $d < \beta_m$, so that both poles of ρ_3 lie in the interval (β_1, β_m). We first note that, because of (4.2) and (4.3), we also have that $b < 3g''/g''' < 2g'/g'' < \beta_m$ and $d > g'/g > \beta_1$. Let us prove that $b > \beta_1$. From (4.12) and (4.13), we have

$$\frac{1}{2}\left(\frac{\sum_{j=1}^m \frac{2\alpha_j}{\beta_j^2}v - \sum_{j=1}^m \frac{2\alpha_j}{\beta_j^3}}{\sum_{j=1}^m \frac{\alpha_j}{\beta_j}v - \sum_{j=1}^m \frac{\alpha_j}{\beta_j^2}}\right) = \frac{1}{3}\left(\frac{\sum_{j=1}^m \frac{6\alpha_j}{\beta_j^3}v - \sum_{j=1}^m \frac{6\alpha_j}{\beta_j^4}}{\sum_{j=1}^m \frac{2\alpha_j}{\beta_j^2}v - \sum_{j=1}^m \frac{2\alpha_j}{\beta_j^3}}\right).$$

This can be rewritten as follows:

$$\frac{\sum_{j=1}^m \frac{\alpha_j(v-\beta_j^{-1})}{\beta_j^2}}{\sum_{j=1}^m \frac{\alpha_j(v-\beta_j^{-1})}{\beta_j}} = \frac{\sum_{j=1}^m \frac{\alpha_j(v-\beta_j^{-1})}{\beta_j^3}}{\sum_{j=1}^m \frac{\alpha_j(v-\beta_j^{-1})}{\beta_j^2}}. \tag{4.16}$$

Assume now that $v \geq \beta_1^{-1}$ and therefore also $v \geq \beta_j^{-1}$ for $j = 1, 2, \ldots, m$. We can then define two m-dimensional vectors ζ and η by

$$\zeta_j = \frac{\left(\alpha_j\left(v - \beta_j^{-1}\right)\right)^{\frac{1}{2}}}{\beta_j^{\frac{1}{2}}} \quad \text{and} \quad \eta_j = \frac{\left(\alpha_j\left(v - \beta_j^{-1}\right)\right)^{\frac{1}{2}}}{\beta_j^{\frac{3}{2}}},$$

so that (4.16) becomes $|\zeta^T\eta|^2 = \|\zeta\|^2\|\eta\|^2$, which by the Cauchy–Schwarz inequality cannot hold when $\beta_1 < \beta_2 < \cdots < \beta_m$. The conclusion therefore is that $v < \beta_1^{-1}$, or $b > \beta_1$. Using (4.9) and (4.10), we find entirely analogously that $d < \beta_m$.

Putting all of the above together, one obtains that ρ_3 is a positive, monotonically increasing convex function on the interval $(-\infty, \beta_1)$, with its poles on the interval (β_1, β_m). Since $b < 3g''/g''' < 2g'/g''$, its smallest pole lies between β_1 and the pole of ρ_2.

(4) *First-order polynomial.* A function $\tau_1(\lambda) \triangleq a + b\lambda$ such that $\tau_1(0) = g(0)$ and $\tau_1'(0) = g'(0)$. The coefficients a and b are easily computed to be $a = g(0)$ and $b = g'(0)$, which are both positive. The function τ_1 is therefore a linear and increasing function everywhere.

(5) *Second-order polynomial.* A function $\tau_2(\lambda) \triangleq a + b\lambda + c\lambda^2$ such that $\tau_2(0) = g(0)$, $\tau_2'(0) = g'(0)$, and $\tau_2''(0) = g''(0)$. The coefficients a, b, and c are given by $a = g(0)$, $b = g'(0)$, and $c = g''(0)/2$, and they are all positive. The function τ_2 is therefore an increasing and convex function for $\lambda \geq 0$.

(6) *Third-order polynomial.* A function $\tau_3(\lambda) \triangleq a + b\lambda + c\lambda^2 + d\lambda^3$ such that $\tau_2(0) = g(0)$, $\tau_2'(0) = g'(0)$, $\tau_2''(0) = g''(0)$, and $\tau_2'''(0) = g'''(0)$. The coefficients a, b, c, and d are $a = g(0)$, $b = g'(0)$, $c = g''(0)/2$, and $d = g'''(0)/6$, and they are all positive. The function τ_3 is therefore an increasing and convex function for $\lambda \geq 0$.

THEOREM 4.1. *The following inequalities hold on the interval* $[0, \beta_1)$:

$$\tau_i(\lambda) \leq \rho_i(\lambda) \leq g(\lambda) \qquad (i = 1, 2, 3), \tag{4.17}$$

$$\rho_1(\lambda) \leq \rho_2(\lambda) \leq \rho_3(\lambda) \leq g(\lambda), \tag{4.18}$$

$$\tau_1(\lambda) \leq \tau_2(\lambda) \leq \tau_3(\lambda) \leq g(\lambda). \tag{4.19}$$

Proof. We start with the remark that some inequalities will be proved on the larger interval $(-\infty, \beta_1)$. Let us begin with inequalities (4.17). The function $\rho_1(\lambda)$ is a first-order rational approximation to $g(\lambda)$ at $\lambda = 0$. It is then immediate from Lemmas 2.1 and 2.2 with $\gamma = -1$ that $\rho_1(\lambda) \leq g(\lambda)$ on $(-\infty, \beta_1)$. The linear approximation $\tau_1(\lambda)$ to $g(\lambda)$ at $\lambda = 0$ is also the linear approximation to $\rho_1(\lambda)$ at that same point. Since $\rho_1(\lambda)$ is a convex function on $(-\infty, \beta_1)$, $\tau_1(\lambda)$ must lie below it on the same interval. This concludes the proof for $i = 1$.

For $i = 2$, we have that $\rho_2(\lambda) \equiv a + b/(c - \lambda)$ approximates $g(\lambda)$ up to second order. This is the same as saying that $b/(c-\lambda)^2$ approximates $g'(\lambda)$ up to first order. Lemmas 2.1 and 2.2 with $\gamma = -2$ then yield that $b/(c - \lambda)^2 \leq g'(\lambda)$, from which it follows, with $\lambda \in [0, \beta_1)$, that

$$\int_0^\lambda \frac{b}{(c-\sigma)^2} \mathrm{d}\sigma \leq \int_0^\lambda g'(\sigma) \mathrm{d}\sigma.$$

Integrating, we obtain $b/(c - \lambda) - b/c \leq g(\lambda) - g(0)$. Adding and subtracting a in the left-hand side and using the function value interpolation condition then yields $\rho_2(\lambda) \leq g(\lambda)$ on $[0, \beta_1)$. Furthermore, $\tau_2(\lambda)$ interpolates both $g(\lambda)$ and $\rho_2(\lambda)$ at $\lambda = 0$ up to second order. This means that $2c\lambda + b$ interpolates $\rho_2'(\lambda)$ up to first order at $\lambda = 0$. Because $\rho_2''' > 0$ on $(-\infty, \beta_1)$, ρ_2' is convex on that interval. We then have that $2c\lambda + b \leq \rho_2'(\lambda)$ on that same interval and we integrate back, as we did before, to obtain the desired inequality for $\lambda \in [0, \beta_1)$. This concludes the proof for $i = 2$.

For $i = 3$, we consider the function

$$h(\lambda) \triangleq g(\lambda) - \rho_3(\lambda) = g(\lambda) - \frac{a}{b - \lambda} - \frac{c}{d - \lambda}.$$

We recall that $b, d \in (\beta_1, \beta_m)$, that $b < d$, and that neither $a/(b-\lambda)$ nor $c/(d-\lambda)$ can be equal to any of the terms $\alpha_j/(\beta_j - \lambda)$ of $g(\lambda)$. We then have the following cases.

Case 1. Neither b nor d are equal to any of the poles β_j of $g(\lambda)$. This means that the function $h(\lambda)$ must have a total of $m+1$ roots. There are four roots at $\lambda = 0$ and

an additional $m-3$ roots on the $m-3$ intervals of the form (β_k, β_{k+1}) that do not contain either b or d. This argument also shows that it would be impossible for both b and d to lie together in any such interval, as this would add at least $m-2$ roots, bringing the total number of roots to at least $m+2$.

Case 2. Either b or d (but not both) is equal to one of the poles of $g(\lambda)$. This means that the function $h(\lambda)$ must have a total of m roots. There are four roots at $\lambda = 0$ and an additional $m-4$ roots on the $m-4$ intervals of the form (β_k, β_{k+1}) that do not contain either b or d in their closure. This argument also shows that it would be impossible for both b and d to lie together in the closure of any such interval, as this would add at least $m-3$ roots, bringing the total number of roots to at least $m+1$.

Case 3. Both b and d are equal to (different) poles of $g(\lambda)$. This means that the function $h(\lambda)$ must have a total of $m-1$ roots. There are four roots at $\lambda = 0$ and an additional $m-5$ roots on the $m-5$ intervals of the form (β_k, β_{k+1}) that do not have either b or d as one of their endpoints. This argument also shows that it would be impossible for any such interval to have both b and d as their endpoints, as this would add at least $m-4$ roots, bringing the total number of roots to at least m.

In each of the above three cases, $h(\lambda)$ cannot have roots on the interval $[0, \beta_1)$ other than at $\lambda = 0$ and must therefore have the same sign throughout that interval. Since $h(\lambda) \to +\infty$ as $\lambda \to \beta_1^-$, $h(\lambda)$ must be positive on that interval, which means that $\rho_3(\lambda) \leq g(\lambda)$ on $[0, \beta_1)$.

Turning now to $\tau_3(\lambda)$, we have, similar to the case $i = 2$, that $\tau_3(\lambda)$ also interpolates $\rho_3(\lambda)$ up to third order at $\lambda = 0$, which is equivalent to $2c + 6d\lambda$ interpolating ρ_3'' up to first order at $\lambda = 0$. Because $\rho_3^{(iv)} > 0$ on $(-\infty, \beta_1)$, $\rho_3''(\lambda)$ is convex on that same interval, which means that on that interval $2c + 6d\lambda \leq \rho_3''(\lambda)$. Integrating back twice, we obtain once again our inequality for $\lambda \in [0, \beta_1)$. This concludes the proof for the inequalities in (4.17).

Let us now consider inequalities (4.18), starting with the inequality between ρ_1 and ρ_2. We first note that ρ_1 approximates ρ_2 up to first order. We also have

$$-2\rho_2'^2(\lambda) + \rho_2(\lambda)\rho_2''(\lambda) = -2\left(\frac{b}{c-\lambda}\right)'^2 + \left(\frac{b}{c-\lambda}\right)\left(\frac{b}{c-\lambda}\right)'' + a\left(\frac{b}{c-\lambda}\right)''. \tag{4.20}$$

Taking into account that a and b are positive and that $c > \beta_1 > 0$, we easily see that the last term in the right-hand side of (4.20) is positive on $(-\infty, \beta_1)$, whereas the sum of the first two terms is positive on that same interval because of Lemma 2.2 with $\gamma = -1$. Lemma 2.1, with $\gamma = -1$, then shows that $\rho_1(\lambda) \leq \rho_2(\lambda)$ on $(-\infty, \beta_1)$.

For the inequality between ρ_2 and ρ_3, it suffices to note that ρ_2 approximates ρ_3 up to second order and that ρ_3 is a function of the same form and with the same general properties as g. An argument analogous to the one used to prove that $\rho_2(\lambda) \leq g(\lambda)$ then also yields that $\rho_2(\lambda) \leq \rho_3(\lambda)$ for $\lambda \in [0, \beta_1)$, and this concludes the proof for inequality (4.18).

Inequalities (4.19) all follow by an analogous argument to the one used to prove the inequalities between $\tau_i(\lambda)$ $(i = 1, 2, 3)$ and $g(\lambda)$, after observing that τ_1 is the first-order approximation to τ_2, which itself is the second-order approximation to τ_3. This concludes the proof of the theorem. □

5. Bounds. We now finally derive our bounds on the extreme eigenvalues and we start with the smallest eigenvalue. We first consider matrices that are positive definite. Upper bounds are then obtained by computing the roots of the various

approximations at $\lambda = 0$ to the secular equations $\phi(\lambda)$, $\phi^e(\lambda)$, and $\phi^o(\lambda)$, which were defined in (3.2), (3.8), and (3.9). As we have shown before, all these equations are of the form

$$-\alpha + \lambda + g(\lambda) = 0, \tag{5.1}$$

where $g(\lambda)$ is of the form defined in (4.1) and $\alpha \in \mathbb{R}$. Their approximations are obtained by replacing $g(\lambda)$ with the various approximations that were described in the previous section.

We define the following:

$$f(\lambda) \triangleq t^T(Q - \lambda I)^{-1}t,$$

$$f^e(\lambda) \triangleq \frac{1}{2}(\tilde{t} + J\tilde{t})^T(G - \lambda I)^{-1}(\tilde{t} + J\tilde{t}),$$

$$f^o(\lambda) \triangleq \frac{1}{2}(\tilde{t} - J\tilde{t})^T(G - \lambda I)^{-1}(\tilde{t} - J\tilde{t}),$$

where all quantities are as previously defined. Once again, all these functions are of the same form as the function g, defined in (4.1).

The bounds obtained by replacing $f(\lambda)$ in $\phi(\lambda)$ with ρ_1, ρ_2, and ρ_3 will be denoted r_1, r_2, and r_3, respectively. Those bounds obtained by replacing $f(\lambda)$ with τ_1, τ_2, and τ_3 will be denoted p_1, p_2, and p_3, respectively. As an example, this means that r_1 is the root of the equation

$$-t_0 + \lambda + \frac{g^2(0)/g'(0)}{g(0)/g'(0) - \lambda} = 0,$$

which is obtained by solving a quadratic equation. To compute r_3 and p_3, a cubic equation needs to be solved, which can either be accomplished in closed form or by an iterative method such as Newton's method (at negligible cost, compared with the computation of $g(0)$).

This notation is now applied to $\phi^e(\lambda)$ and $\phi^o(\lambda)$ as well; i.e., the bounds on the smallest even eigenvalue, obtained by approximating $f^e(\lambda)$ in $\phi^e(\lambda)$, will be denoted by r_1^e, r_2^e, and r_3^e for the rational approximations and p_1^e, p_2^e, and p_3^e for the polynomial approximations. For the odd eigenvalues, approximating $f^o(\lambda)$ in $\phi^o(\lambda)$ yields the bounds r_1^o, r_2^o, r_3^o and p_1^o, p_2^o, p_3^o for the rational and polynomial approximations, respectively.

If one uses the LDA for the computation of the spectral equations and their derivatives as was discussed in section 3, then the computational cost for first-, second-, and third-order bounds is $2n^2 + \mathcal{O}(n)$, $3n^2 + \mathcal{O}(n)$, and $4n^2 + \mathcal{O}(n)$ flops, respectively, and is $\mathcal{O}(n^2)$ in storage space for the higher-order bounds (higher than one). As was mentioned before, the computational cost for the second-order bounds, when using the even and odd spectral functions, is doubled. To avoid this, one could start by computing the first-order bounds and then compute the second-order bound only for that equation which yielded the lower first-order bound. Of course, there is no guarantee that this would indeed yield the best second-order bound. However, even though we did not include it in the section on numerical experiments, we did verify that such a procedure would not significantly alter our results. A lower computational cost might be achieved by using methods other than the LDA, as was mentioned at the end of section 3.

One of the advantages of the rational approximations is that, contrary to polynomial approximations, they always generate bounds that are guaranteed not to exceed the largest pole of f, f^e, or f^o, whichever applies, as is obvious from their properties, regardless of how badly behaved the matrix is. In addition to providing separate bounds on the even and odd eigenvalues, the approximations to the functions $\phi^e(\lambda)$ and $\phi^o(\lambda)$ should be more accurate than those for the function $\phi(\lambda)$, since now only roughly half of the terms appear in the function to be interpolated. There is also the additional benefit that both the smallest and the largest roots are now farther removed from the nearest singularity in the equation so that once again an improved approximation can be expected. All this is borne out by our numerical experiments.

Better upper bounds can be obtained if a positive lower bound is known on the smallest eigenvalue. The only difference in that case is that the approximations are performed at that lower bound, rather than at $\lambda = 0$. As was mentioned before, all our results can be applied in this case to the same spectral equations but with the origin translated to the lower bound.

Before presenting numerical comparisons in the next section, we will first establish a theoretical result. We denote the smallest even and odd eigenvalues of T by λ^e_{min} and λ^o_{min}, respectively, and its smallest eigenvalue by λ_{min}. We note that $\lambda_{min} = \min\{\lambda^e_{min}, \lambda^o_{min}\}$. The theoretical comparisons between the various bounds are then given in the following theorem.

THEOREM 5.1. *The upper bounds on the smallest eigenvalue of T satisfy*

$$
\begin{aligned}
&\lambda_{min} \le r_i \le p_i \qquad (i = 1, 2, 3),\\
&\lambda^e_{min} \le r^e_i \le p^e_i \qquad (i = 1, 2, 3),\\
&\lambda^o_{min} \le r^o_i \le p^o_i \qquad (i = 1, 2, 3),\\
&\lambda_{min} \le r_3 \le r_2 \le r_1,\\
&\lambda^e_{min} \le r^e_3 \le r^e_2 \le r^e_1,\\
&\lambda^o_{min} \le r^o_3 \le r^o_2 \le r^o_1,\\
&\lambda_{min} \le p_3 \le p_2 \le p_1,\\
&\lambda^e_{min} \le p^e_3 \le p^e_2 \le p^e_1,\\
&\lambda^o_{min} \le p^o_3 \le p^o_2 \le p^o_1.
\end{aligned}
$$

Proof. The proof follows immediately from the properties of the approximations that define the bounds, which were proved in Theorem 4.1. ∎

This theorem shows that the bounds, obtained by rational approximations, are always superior to those obtained by polynomial approximations, which should not be surprising, as the functions they approximate are themselves rational. It also confirms the intuitive result that, as the order of the approximations increases, then so does the accuracy of the bounds. This also means that the bounds obtained in [11] (as far as we were able to verify, the best currently available), which are all based on polynomial approximations and correspond to our p_1, p_2, and p_3, are inferior to those produced by rational approximations.

Let us now consider lower bounds on the largest eigenvalue. The largest eigenvalue of T can be bounded from below, given an upper bound δ on it. This can be accomplished by translating the origin in the spectral equations to δ, replacing the resulting new variable by its opposite, and multiplying the equation by (-1), thus obtaining the exact same type of spectral equation for the matrix $(\delta I - T)$, which is positive definite. Computing an upper bound on the smallest eigenvalue of this new matrix then leads

to the desired bound on the largest eigenvalue, since $\lambda_{min}(\delta I - T) = \delta - \lambda_{max}(T)$. One possible value for δ is the Frobenius norm of T, defined as (see [15])

$$\|T\|_F = \left(\sum_{i,j=1}^{n} T_{ij}^2 \right)^{1/2},$$

which for a Toeplitz matrix can be computed in $\mathcal{O}(n)$ flops. An exact analogue of Theorem 5.1 holds for the maximal eigenvalues.

To conclude this section we briefly consider the fact that the same procedure for obtaining bounds for real symmetric positive-definite matrices can be used for general real symmetric matrices as well, provided that a lower bound on the smallest eigenvalue is available. Any known lower bound can be used (see, e.g., [11] or [16]), or one could be obtained by a process where a trial value is iteratively lowered until it falls below the smallest eigenvalue. Calling such a trial value ϵ, Sylvester's law of inertia can then be applied to the decomposition of $(T - \epsilon I)$, obtained in the course of the LDA algorithm (see section 3), to determine its position relative to the smallest eigenvalue of T. Such a procedure is extensively described and used in, e.g., [8] and [17], and we refer to these papers for further details.

6. Numerical results. In this section we will test our methods on three classes of positive semidefinite matrices. For each class and for each of the dimensions $n = 100, 200, 400$, we have run 200 experiments to examine the quality of the bounds on the smallest eigenvalue and 200 separate experiments doing the same for the maximal eigenvalue. Tables 6.1–6.6 report the average values (with their standard deviations in parentheses) of the bound-to-eigenvalue ratio for the smallest eigenvalue and eigenvalue-to-bound ratio for the largest eigenvalue. The closer this ratio is to one, the better the bound. Each entry in the table has a left and right part, separated by a slash.

The left part pertains to the use of ϕ^e and ϕ^o (i.e., the bound is obtained by taking the minimum of the bounds on the even and odd extreme eigenvalues), whereas the right part represents the use of ϕ. The polynomial approximation-based bounds are denoted by "Taylor," followed by the order of the approximation, and the rational ones by "Rational." Let us now list those three classes of matrices.

(1) *CVL matrices*. These are the matrices defined in [8] (whence their name) as

$$T = \mu \sum_{k=1}^{n} \xi_k T_{2\pi\theta_k},$$

where n is the dimension of T, μ is such that $T_{kk} = 1$, $k = 1, \ldots, n$, and

$$(T_\theta)_{ij} = \cos(\theta(i-j)).$$

These matrices are positive semidefinite of rank two. We generated random matrices of this kind by taking the value of θ to be uniformly distributed on $(0, 1)$.

(2) *KMS matrices*. These are the Kac–Murdock–Szegö matrices (see [19]), defined as $T_{ij} = \nu^{|i-j|}$, where $0 < \nu < 1$, $i, j = 1, \ldots, n$, and n is the dimension of the matrix. These matrices are positive definite and are characterized by the fact that their even and odd eigenvalues lie extremely close together. Random matrices of this kind were generated by taking the value of ν to be uniformly distributed on (0, 1).

(3) *UNF matrices*. We define UNF matrices by first defining a random vector v of length n whose components are uniformly distributed on $(-10, 10)$. We then modify that vector by adding to its first component 1.1 times the absolute value of the smallest eigenvalue of the Toeplitz matrix generated by v. Finally, the vector v is normalized by dividing it by its first component, provided that it is different from zero. The Toeplitz matrix generated by this normalized vector is then called a UNF matrix. From their construction, these matrices are positive semidefinite.

Theoretically, some of the matrices that we generated might be singular, although we never encountered this situation in practice.

The experiments clearly show that exploiting the even and odd spectra yields better bounds. The magnitude of the improvement diminishes the closer the even and odd eigenvalues are lying together, as is obviously true for the KMS matrices. The superiority of rational bounds is also clearly demonstrated, both in their smaller average ratios and smaller standard deviations. They may yield a ratio of up to three times smaller than polynomial ones and in many cases, lower-order rational bounds are better than higher-order polynomial ones. This is especially true for larger matrix dimensions. These results also confirm our previous remark that the bounds obtained in [11] are inferior to rational approximation-based bounds.

Although we did not report results on bounds for the even and odd eigenvalues separately, we did verify that they are virtually identical to those obtained for the smallest eigenvalue proper.

All experiments were run in MATLAB on an Intel Pentium II 233MHz machine.

We conclude that computing separate, rational approximation-based bounds on the even and odd spectra leads to a significant improvement over existing bounds.

LIDSKII'S THEOREM VIA NONSMOOTH ANALYSIS*

A. S. LEWIS†

Abstract. Lidskii's theorem on eigenvalue perturbation is proved via a nonsmooth mean value theorem.

Key words. Lidskii's theorem, eigenvalue optimization, nonsmooth analysis, Clarke generalized gradient

AMS subject classifications. Primary, 90C31, 15A18; Secondary, 49K40, 26B05

PII. S0895479898338676

One of the central tools for studying perturbation theory for the eigenvalues of symmetric matrices is Lidskii's theorem. This states that any matrices Z and Y in $\mathbf{S}^n$, the Euclidean space of $n \times n$ real symmetric matrices (with trace inner product), satisfy

$$\lambda(Z+Y) - \lambda(Z) \prec \lambda(Y), \tag{0.1}$$

where $\lambda(Z) \in \mathbf{R}^n$ is the column vector of eigenvalues of Z written by multiplicity and in decreasing order. The symbol $\prec$ denotes *majorization*: $u \prec v$ for vectors u and v in $\mathbf{R}^n$ means

$$u \in \operatorname{conv}\{Pv : P \in \mathbf{P}^n\},$$

where $\mathbf{P}^n$ is the group of $n \times n$ permutation matrices and "conv" denotes convex hull. A standard separation argument (see [6], for example) shows this inclusion is equivalent to the condition

$$x^T u \leq \bar{x}^T \bar{v} \quad \text{for all } x \in \mathbf{R}^n,$$

where $\bar{x}$ is the vector in $\mathbf{R}^n$ with the same components as x arranged in decreasing order. Lidskii's theorem is, for example, one of the unifying themes of the recent book [1].

This note approaches Lidskii's theorem via nonsmooth analysis, using the *Clarke generalized gradient* (see [2]). For a real, locally Lipschitz function g defined close to a point p in a Euclidean space, we can define the generalized gradient $\partial g(p)$ as the convex hull of the set of cluster points of gradients of g at points near p in a set of full measure [2, Thm. 2.5.1]. Thus for a smooth function g, the generalized gradient coincides with the usual gradient $g'(p)$.

For a smooth function g, the classical mean value theorem states that, given points q and r, there is a point p on the line segment between q and r satisfying the equation

$$g(q) - g(r) = \langle g'(p), q - r \rangle.$$

†Department of Combinatorics and Optimization, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1 (aslewis@orion.uwaterloo.ca, http://orion.uwaterloo.ca/∼aslewis).

If g is merely locally Lipschitz, the Lebourg mean value theorem [2, Thm. 2.3.7] generalizes this result, asserting the existence of an element s of $\partial g(p)$ satisfying the equation

$$g(q) - g(r) = \langle s, q - r \rangle.$$

We apply this mean value theorem to derive Lidskii's theorem from a powerful variational result about eigenvalues. This variational result calculates the Clarke generalized gradient of the function $f \circ \lambda$ for an arbitrary locally Lipschitz *permutation-invariant* function $f : \mathbf{R}^n \to \mathbf{R}$ (that is, $f(Px) = f(x)$ for all matrices P in $\mathbf{P}^n$ and vectors x in $\mathbf{R}^n$). Specifically, the result (see [4]) considers diagonalizations of any matrix X in $\mathbf{S}^n$,

$$X = U^T(\operatorname{Diag} x)U, \quad U \in \mathbf{O}^n, \quad x \in \mathbf{R}^n, \tag{0.2}$$

where $\mathbf{O}^n$ is the group of $n \times n$ orthogonal matrices, and states

$$\partial(f \circ \lambda)(X) = \{U^T(\operatorname{Diag} y)U : (0.2) \text{ holds and } y \in \partial f(x)\}. \tag{0.3}$$

The approach of this note is certainly not the simplest proof of Lidskii's theorem, formula (0.3) being a relatively difficult result (see also [5]). However, the approach is delightfully transparent, and it reveals the increasing possibilities of applying nonsmooth analytic techniques in matrix analysis.

Lidskii's theorem (0.1) is equivalent to the inequality

$$w^T(\lambda(Z + Y) - \lambda(Z)) \leq \bar{w}^T\lambda(Y) \text{ for all } w \in \mathbf{R}^n. \tag{0.4}$$

Fix w and consider the (nonconvex) locally Lipschitz, permutation-invariant function defined by

$$f(x) = w^T\bar{x}.$$

Note the relationship

$$(f \circ \lambda)(X) = w^T\lambda(X) \text{ for all } X \in \mathbf{S}^n.$$

Whenever x has distinct components (a subset of $\mathbf{R}^n$ of full measure), f is differentiable at x with gradient $f'(x) = Pw$ for some matrix P in $\mathbf{P}^n$. Hence at *any* point x in $\mathbf{R}^n$ we have the inclusion

$$\partial f(x) \subset \operatorname{conv}\{Pw : P \in \mathbf{P}^n\}, \tag{0.5}$$

by our definition of the generalized gradient. (There are more elementary although less concise ways to see this inclusion.)

By the Lebourg mean value theorem applied to $f \circ \lambda$, there is a matrix X in $\mathbf{S}^n$ (between Z and $Z + Y$) and a matrix V in $\partial(f \circ \lambda)(X)$ satisfying

$$w^T(\lambda(Z + Y) - \lambda(Z)) = \operatorname{tr}(VY) \leq \lambda(V)^T\lambda(Y),$$

the last inequality following from von Neumann's trace theorem (see [3, Eq. (7.4.14)]). But now we can apply the generalized gradient formulae (0.3) and (0.5) to deduce

$$\lambda(V) \in \operatorname{conv}\{Pw : P \in \mathbf{P}^n\}$$

(or in other words, $\lambda(V) \prec \bar{w}$). Hence $\lambda(V)^T\lambda(Y) \leq \bar{w}^T\lambda(Y)$, and Lidskii's theorem (0.4) follows.

Acknowledgment. The author thanks the School of Operations Research and Industrial Engineering at Cornell University, where this work was completed.

SECOND LOGARITHMIC DERIVATIVE OF A COMPLEX MATRIX IN THE CHEBYSHEV NORM*

L. KOHAUPT†

Abstract. The second logarithmic derivative $\mu_\infty^{(2)}[A]$ of a complex $n \times n$ matrix A in the Chebyshev norm is defined as the second right derivative of $\|\Phi(t)\|_\infty = \|e^{At}\|_\infty$ at $t = 0$, where $\|\cdot\|_\infty$ denotes the operator norm corresponding to the norm $\|\cdot\|_\infty$ in $\mathbb{C}^n$. The obtained formula is illustrated by a numerical example. The result may be of interest in applications such as stability theory.

1. Introduction.

For a given complex $n \times n$ matrix A, consider the initial-value problem $\dot{x}(t) = A\,x(t),\ x(0) = x_0$. It is well known that the solution can be expressed in the form $x(t) = \Phi(t)\,x_0$, where $\Phi(t) = e^{At}$ is the so-called *fundamental matrix* or *evolution*.

For many purposes, e.g., in error estimates, the operator norm $\|\Phi(t)\| = \|e^{At}\|$ of $\Phi(t) = e^{At}$ corresponding to a vector norm $\|\cdot\|$ in $\mathbb{C}^n$ is needed. An upper bound on $\|\Phi(t)\|$ is given by $e^{\mu^{(1)}[A]t}$, where $\mu^{(1)}[A]$ is the (first) logarithmic derivative of the matrix A in a matrix operator norm. The quantity $\mu^{(1)}[A]$ is first defined and investigated in [5]. For the inequality $\|\Phi(t)\| \le e^{\mu^{(1)}[A]t},\ t \ge 0$, see [5, Formula (12), pp. 59–60] and [1, p. 59]. In [1] and [3], $\mu^{(1)}[A]$ is called *matrix measure* and it is applied there to bound solutions of ordinary differential equations; it is also used for other purposes.

Formulae for the first logarithmic derivative $\mu_p^{(1)}[A]$ in the p-norm with $p \in \{1, 2, \infty\}$ are derived in [5, Lemma 4, pp. 59–60]; these formulae are also stated without proof in [1, p. 41] and [2, p. 11].

In the present paper, the second logarithmic derivative $\mu_\infty^{(2)}[A]$ is defined and an associated formula is derived. The case $p = 1$ can be treated by interchanging the roles of the row index and column index of the matrix A; this case is therefore omitted. The case $p = 2$ has not yet been resolved.

The paper is structured as follows. In section 2, it is shown that a real analytic function $\hat{\Phi}(\cdot)$ exists, defined on some neighborhood $[0, t_0]$ of $t = 0$, such that $\hat{\Phi}(\cdot)$ and $\|\Phi(\cdot)\|_\infty$ coincide on $[0, t_0]$. In section 3, $\mu_\infty^{(2)}[A]$ is defined and an explicit formula is derived for it. In section 4, the result obtained in section 3 is illustrated by a numerical example.

2. Local regularity.

In this section, it is shown that the mapping $t \mapsto \|\Phi(t)\|_\infty$, $0 \le t \le t_0$, is real analytic for sufficiently small $t_0 > 0$, or, more precisely, that a real analytic function $\hat{\Phi}(\cdot)$ exists, defined on some neighborhood $[0, t_0]$ of $t = 0$, such that

*Received by the editors February 3, 1997; accepted for publication (in revised form) by U. Helmke February 19, 1999; published electronically October 26, 1999.
http://www.siam.org/journals/simax/21-2/31607.html
†Prager Str. 9, D-10779 Berlin, Germany (kohaupt@tfh-berlin.de).

$\hat{\Phi}(\cdot)$ and $\|\Phi(\cdot)\|_\infty$ coincide on $[0,t_0]$. In this article, when we speak of the real analytic function $t \mapsto \|\Phi(t)\|_\infty$, $0 \le t \le t_0$, we mean the mapping $t \mapsto \hat{\Phi}(t)$, $0 \le t \le t_0$.

It follows that the kth logarithmic derivative $\mu_\infty^{(k)}[A] := D_+^k \|\Phi(0)\|_\infty$ (with $k \in \mathbb{N}$) exists, where $D_+^k \|\Phi(0)\|_\infty$ denotes the kth right derivative of the mapping $t \mapsto \|\Phi(t)\|_\infty$ at $t = 0$.

In the next section, we calculate the second logarithmic derivative of a complex matrix A, $\mu_\infty^{(2)}[A]$, explicitly, where the continuous differentiability of the function $t \mapsto \|\Phi(t)\|_\infty$, $0 \le t \le t_0$, up to the second order is used.

As a preparation to the proof of Lemma 2.2 and Theorem 3.1, we need the following lemma.

LEMMA 2.1. *Let $n \in \mathbb{N}$ and $a_i \in \mathbb{R}$, $i = 1, \dots, n$. Further, let $t_0 > 0$ and $t \mapsto b_i(t)$, $0 \le t \le t_0$, be real continuous functions with $b_i(0) = 0$, $i = 1, \dots, n$. Moreover, let $I_0 = \{1, \dots, n\}$ and I_1 be the set of all indices $i_1 \in I_0$, where a_i attains its maximum, i.e.,*

$$I_1 := \left\{ i_1 \in I_0 \,|\, a_{i_1} = \max_{i \in I_0} a_i \right\}.$$

Then, there exists a number $t_1 > 0$ with $t_1 \le t_0$ such that

$$\max_{i \in I_0} \{a_i + b_i(t)\} = \max_{i \in I_0} a_i + \max_{i \in I_1} b_i(t), \quad 0 \le t \le t_1.$$

Proof. Case 1. $I_1 = I_0$. Here, for $0 \le t \le t_0$,

$$\max_{i \in I_0} \{a_i + b_i(t)\} = \max_{i \in I_0} \left\{ \max_{i \in I_0} a_i + b_i(t) \right\} = \max_{i \in I_0} a_i + \max_{i \in I_0} b_i(t) = \max_{i \in I_0} a_i + \max_{i \in I_1} b_i(t).$$

Case 2. $I_1 \neq I_0$. In this case,

$$\max_{i \in I_0 \setminus I_1} a_i < \max_{i \in I_1} a_i.$$

Thus, there exists a number $t_1 > 0$ with $t_1 \le t_0$ such that

$$\max_{i \in I_0 \setminus I_1} \{a_i + b_i(t)\} < \max_{i \in I_1} \{a_i + b_i(h)\}, \quad 0 \le t \le t_1.$$

Consequently, for $0 \le t \le t_1$,

$$\max_{i \in I_0} \{a_i + b_i(t)\} = \max_{i \in I_1} \{a_i + b_i(t)\} = \max_{i \in I_1} \left\{ \max_{i \in I_0} a_i + b_i(t) \right\} = \max_{i \in I_0} a_i + \max_{i \in I_1} b_i(t). \qquad \square$$

LEMMA 2.2. *There exists a number $t_0 > 0$ and a function $t \mapsto \hat{\Phi}(t)$, which is real analytic on $[0, t_0]$, such that $\hat{\Phi}(t) = \|\Phi(t)\|_\infty$ for all $t \in [0, t_0]$.*

Proof. We have

$$\|\Phi(t)\|_\infty = \max_{i=1,\dots,n} \sum_{j=1}^{n} |\Phi_{ij}(t)| = \max_{i=1,\dots,n} \Psi_i(t) \tag{1}$$

with

$$\Psi_i(t) = \sum_{j=1}^{n} |\Phi_{ij}(t)| = \sum_{j=1}^{n} \sqrt{[\operatorname{Re} \Phi_{ij}(t)]^2 + [\operatorname{Im} \Phi_{ij}(t)]^2}, \; i = 1, \dots, n,$$

where the range of t is restricted to $t \geq 0$. Further,

$$\Phi_{ij}(t) = \sum_{k=0}^{\infty} (A^k)_{ij} \frac{t^k}{k!}, \quad i,j = 1,\dots,n,$$

so that the functions $t \mapsto \operatorname{Re} \Phi_{ij}(t)$ and $t \mapsto \operatorname{Im} \Phi_{ij}(t)$ are real analytic for $t \geq 0$. Therefore, if we choose $t_1 > 0$ sufficiently small, the function $t \mapsto \Psi_i(t),\ 0 \leq t \leq t_1$, also is real analytic. Consequently, there exist real numbers $\lambda_i^{(k)}$ such that

$$\Psi_i(t) = \sum_{k=0}^{\infty} \lambda_i^{(k)} \frac{t^k}{k!}, \quad 0 \leq t \leq t_1; \quad i = 1,\dots,n,$$

where

$$\lambda_i^{(0)} = 1, \quad i = 1,\dots,n,$$

and

$$\lambda_i^{(k)} = D_+^k \Psi_i(0), \quad k = 1,2,\dots, \quad i = 1,\dots,n.$$

Thus, we have

$$\|\Phi(t)\|_\infty = \max_{i=1,\dots,n} \left\{ \sum_{k=0}^{\infty} \lambda_i^{(k)} \frac{t^k}{k!} \right\}, \quad 0 \leq t \leq t_1.$$

Let $I_0 := \{1,\dots,n\}$ and I_k be the set of all indices $i_k \in I_{k-1}$, where $\lambda_i^{(k)}$ attains its maximum, i.e.,

$$I_k := \left\{ i_k \in I_{k-1} \,|\, \lambda_{i_k}^{(k)} = \max_{i \in I_{k-1}} \lambda_i^{(k)} \right\}, \quad k = 1,2,\dots.$$

Then,

$$I_0 \supset I_1 \supset \cdots \supset I_k \supset \cdots. \tag{2}$$

Since I_0 contains only a finite number of elements, there is an index N such that

$$I_i = I_N, \quad i \geq N. \tag{3}$$

Choose any indices $i_k \in I_k,\ k = 0,1,\dots,N$. Then, by a repeated application of Lemma 2.1, we obtain a number $t_2 \in (0,t_1]$ such that

$$\|\Phi(t)\|_\infty = \max_{i=1,\dots,n} \Psi_i(t) = \max_{i \in I_0} \left\{ \sum_{k=0}^{\infty} \lambda_i^{(k)} \frac{t^k}{k!} \right\} = \sum_{k=0}^{N-1} \lambda_{i_k}^{(k)} \frac{t^k}{k!} + \sum_{k=N}^{\infty} \lambda_{i_N}^{(k)} \frac{t^k}{k!} =: \hat{\Phi}(t),$$

$0 \leq t \leq t_2$. Consequently, the assertion follows with $t_0 := t_2$. □

Remark. Lemma 2.2 is illustrated by the following example:

$$A := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \Phi(t) = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}, \quad \|\Phi(t)\|_\infty = 1 + |t|, \quad \hat{\Phi}(t) = 1 + t.$$

Thus, $\|\Phi(\cdot)\|_\infty$ is not real analytic at $t = 0$, but it coincides with a real analytic function $\hat{\Phi}(\cdot)$ on $[0,t_0]$ for every $t_0 > 0$.

3. Second logarithmic derivative in the Chebyshev norm. In [5], the *first logarithmic derivative* of a complex $n \times n$ matrix $A = (A_{ij})$ in the p-norm is defined by the right-hand limit

$$\mu_p^{(1)}[A] = D_+^1 \|\Phi(0)\|_p := \lim_{\Delta t \to 0+} \frac{\|\Phi(\Delta t)\|_p - \|\Phi(0)\|_p}{\Delta t} = \lim_{\Delta t \to 0+} \frac{\|E + A\Delta t\|_p - 1}{\Delta t}, \tag{4}$$

where E is the $n \times n$ identity matrix.

For $p \in \{1, 2, \infty\}$, in [5, pp. 59–60, Lemma 4] the following explicit formulae are stated and proved:

$$\mu_\infty^{(1)}[A] = \max_{i=1,\dots,n} \left\{ \operatorname{Re} A_{ii} + \sum_{\substack{j=1 \\ j \neq i}}^{n} |A_{ij}| \right\}, \tag{5}$$

$$\mu_1^{(1)}[A] = \max_{j=1,\dots,n} \left\{ \operatorname{Re} A_{jj} + \sum_{\substack{i=1 \\ i \neq j}}^{n} |A_{ij}| \right\}, \tag{6}$$

$$\mu_2^{(1)}[A] = \lambda_{\max} \left(\frac{A^* + A}{2} \right), \tag{7}$$

where $\lambda_{\max}(\frac{A^*+A}{2})$ denotes the largest eigenvalue of $\frac{A^*+A}{2}$. These formulae can also be found (without proof) in [1, p. 41] and [2, p. 11].

The *second logarithmic derivative* in the Chebyshev norm is defined by the right-hand limit

$$\mu_\infty^{(2)}[A] = D_+^2 \|\Phi(0)\|_\infty := \lim_{\Delta t \to 0+} \frac{D_+^1 \|\Phi(\Delta t)\|_\infty - D_+^1 \|\Phi(0)\|_\infty}{\Delta t}, \tag{8}$$

where the existence of this limit follows from section 2.

To prove Theorem 3.1, we do not use (8), but we compute the coefficient of $\frac{t^2}{2!}$ in the power series expansion of $\|\Phi(t)\|_\infty$ to obtain a formula for $\mu_\infty^{(2)}[A]$. This seems to be more convenient than the direct use of formula (8).

Now, define the following functionals on $\mathbb{C}^{n \times n}$:

$$\nu_{ij}[A] := \begin{cases} \dfrac{\operatorname{Re} A_{ij} \operatorname{Re} (A^2)_{ij} + \operatorname{Im} A_{ij} \operatorname{Im} (A^2)_{ij}}{|A_{ij}|}, & A_{ij} \neq 0, \\ |(A^2)_{ij}|, & A_{ij} = 0, \end{cases}$$

$$\lambda_i^{(1)}[A] := \operatorname{Re} A_{ii} + \sum_{\substack{j=1 \\ j \neq i}}^{n} |A_{ij}|, \tag{9}$$

$$\lambda_i^{(2)}[A] := \operatorname{Re} (A^2)_{ii} + (\operatorname{Im} A_{ii})^2 + \sum_{\substack{j=1 \\ i \neq j}}^{n} \nu_{ij}[A] \tag{10}$$

and observe that the first logarithmic derivative is given by

$$\mu_\infty^{(1)}[A] = \max_{i=1,\ldots,n} \lambda_i^{(1)}[A].$$

Then, we obtain the following theorem.

THEOREM 3.1. *Let $A \in \mathbb{C}^{n\times n}$ and I_1 be the set of all indices $i_1 \in I_0 := \{1,\ldots,n\}$ where $\lambda_i^{(1)}[A]$ attains its maximum, i.e.,*

$$I_1 := \left\{ i_1 \in I_0 \,|\, \lambda_{i_1}^{(1)}[A] = \max_{i\in I_0} \lambda_i^{(1)}[A] \right\}.$$

Then, the second logarithmic derivative of A is given by

$$\mu_\infty^{(2)}[A] = \max_{i\in I_1} \lambda_i^{(2)}[A],$$

where $\lambda_i^{(1)}[A]$ and $\lambda_i^{(2)}[A]$ are given by (9) *and* (10)*, respectively.*

Proof. We obtain

$$\begin{aligned} \|\Phi(t)\|_\infty &= \left\| E + A\,t + \frac{1}{2}\,A^2\,t^2 + O(t^3) \right\|_\infty \\ &= \max_{i=1,\ldots,n} \left\{ \left| 1 + A_{ii}\,t + \frac{1}{2}\,(A^2)_{ii}\,t^2 + O(t^3) \right| \right. \\ &\qquad \left. + \sum_{\substack{j=1\\ j\neq i}}^{n} \left| A_{ij}\,t + \frac{1}{2}\,(A^2)_{ij}\,t^2 + O(t^3) \right| \right\}. \end{aligned} \tag{11}$$

Let $i \in \{1,\ldots,n\}$ be fixed, $t > 0$ be sufficiently small, and

$$\begin{aligned} U_i &:= \left| 1 + A_{ii}\,t + \frac{1}{2}\,(A^2)_{ii}\,t^2 + O(t^3) \right| \\ &\quad + \sum_{\substack{j=1\\ j\neq i}}^{n} \left| A_{ij}\,t + \frac{1}{2}\,(A^2)_{ij}\,t^2 + O(t^3) \right|. \end{aligned} \tag{12}$$

Then,

$$U_i = u_{ii}^{(2)}(A) + \sum_{\substack{j=1\\ j\neq i}}^{n} u_{ij}^{(2)}(A) \tag{13}$$

with

$$\begin{aligned} u_{ii}^{(2)}(A) &:= \left\{ \left[1 + \operatorname{Re} A_{ii}\,t + \frac{1}{2}\operatorname{Re}(A^2)_{ii}\,t^2 + O(t^3) \right]^2 \right. \\ &\quad \left. + \left[\operatorname{Im} A_{ii}\,t + \frac{1}{2}\operatorname{Im}(A^2)_{ii}\,t^2 + O(t^3) \right]^2 \right\}^{\frac{1}{2}} \end{aligned} \tag{14}$$

and

$$u_{ij}^{(2)}(A) := \left\{ \left[\operatorname{Re} A_{ij} + \frac{1}{2} \operatorname{Re} (A^2)_{ij}\, t + O(t^2) \right]^2 + \left[\operatorname{Im} A_{ij} + \frac{1}{2} \operatorname{Im} (A^2)_{ij}\, t + O(t^2) \right]^2 \right\}^{\frac{1}{2}} t, \tag{15}$$

$i \neq j,\ j \in \{1, \ldots, n\}$.

To evaluate (14) and (15), the relation

$$(1+x)^{\frac{1}{2}} = 1 + \frac{1}{2}\, x - \frac{1}{8}\, x^2 + O(x^3), \tag{16}$$

$x \in \mathbb{R},\ |x| \leq 1$, is used. For sufficiently small $t > 0$, we obtain

$$u_{ii}^{(2)}(A) = 1 + \{\operatorname{Re} A_{ii}\}\, t + \frac{1}{2} \{\operatorname{Re} (A^2)_{ii} + (\operatorname{Im} A_{ii})^2\}\, t^2 + O(t^3). \tag{17}$$

To determine $u_{ij}^{(2)}(A)$ in (15), we consider two cases.

Case 1. $A_{ij} \neq 0$, where $i \neq j$.

Here, we get

$$u_{ij}^{(2)}(A) = |A_{ij}|\, t + \frac{1}{2} \left\{ \frac{\operatorname{Re} A_{ij} \operatorname{Re} (A^2)_{ij} + \operatorname{Im} A_{ij} \operatorname{Im} (A^2)_{ij}}{|A_{ij}|} \right\} t^2 + O(t^3). \tag{18}$$

Case 2. $A_{ij} = 0$, where $i \neq j$.

From (15), we infer

$$u_{ij}^{(2)}(A) = \frac{1}{2}\, |(A^2)_{ij}|\, t^2 + O(t^3). \tag{19}$$

Thus, we find

$$U_i = 1 + U_i^{'}\, t + \frac{1}{2}\, U_i^{''}\, t^2 + O(t^3) \tag{20}$$

with

$$U_i^{'} = \lambda_i^{(1)}[A] \tag{21}$$

and

$$U_i^{''} = \lambda_i^{(2)}[A], \tag{22}$$

where $\lambda_i^{(1)}[A]$ and $\lambda_i^{(2)}[A]$ are defined by (9) and (10), respectively.

Now, let I_2 be the set of all indices $i_2 \in I_1$, where $U_i^{''}$ attains its maximum, i.e.,

$$I_2 := \left\{ i_2 \in I_1 \,|\, U_{i_2}^{''} = \max_{i \in I_1} U_i^{''} \right\}. \tag{23}$$

Then, by a repeated application of Lemma 2.1, for sufficiently small $t > 0$ and arbitrary indices $i_1 \in I_1$ and $i_2 \in I_2$ we obtain

$$\begin{aligned} \|\Phi(t)\|_\infty = \left\| E + A\, t + \frac{1}{2}\, A^2\, t^2 + O(t^3) \right\|_\infty &= \max_{i=1,\ldots,n} U_i = \max_{i \in I_0} U_i \\ &= 1 + U_{i_1}^{'}\, t + \frac{1}{2}\, U_{i_2}^{''}\, t^2 + O(t^3) \end{aligned} \tag{24}$$

since $I_1 \supset I_2$. From (24), it follows that

$$\mu_{2,\infty}[A] = U_{i_2}^{''} = \max_{i \in I_1} U_i^{''} \tag{25}$$

for every index $i_2 \in I_2$. This is the asserted formula for $\mu_\infty^{(2)}[A]$. □

Remark. The formula for the first logarithmic derivative, $\mu_\infty^{(1)}[A]$, as stated in (5), is given by the coefficient of t in the power series expansion of $\|\Phi(t)\|_\infty$. This coefficient reads $\max_{i \in I_0} U_i^{'}$ with $U_i^{'}$ from (21). □

In the special case of *real matrices*, a unified formula for all logarithmic derivatives can be given. To see this, define the following sign functionals:

$$s_{ij}^{(1)}(A) := \operatorname{sgn}(A_{ij}) \tag{26}$$

and

$$s_{ij}^{(k)}(A) := \begin{cases} \operatorname{sgn}(A_{ij}), & A_{ij} \neq 0, \\ \operatorname{sgn}((A^2)_{ij}), & A_{ij} = 0, \quad (A^2)_{ij} \neq 0, \\ \operatorname{sgn}((A^3)_{ij}), & A_{ij} = 0, \quad (A^2)_{ij} = 0, \quad (A^3)_{ij} \neq 0, \\ \quad \vdots & \\ \operatorname{sgn}((A^k)_{ij}), & (A^l)_{ij} = 0, \quad l = 1, \ldots, k-1 \end{cases} \tag{27}$$

for $k = 2, 3, \ldots$. The relation (27) can also be written as

$$s_{ij}^{(k)}(A) = \begin{cases} s_{ij}^{(k-1)}(A), & s_{ij}^{(k-1)}(A) \neq 0, \\ \operatorname{sgn}((A^k)_{ij}), & s_{ij}^{(k-1)}(A) = 0 \end{cases}$$

for $k = 2, 3, \ldots$. With these sign functionals, define the further functionals

$$\lambda_i^{(k)}[A] = (A^k)_{ii} + \sum_{\substack{j=1 \\ j \neq i}}^{n} s_{ij}^{(k)}(A)\,(A^k)_{ij}, \tag{28}$$

$k = 1, 2, \ldots$. Then, the logarithmic derivatives for *real matrices* read as follows.

LEMMA 3.2. *Let $A \in \mathbb{R}^{n \times n}$, $I_0 = \{1, \ldots, n\}$, and I_k be the set of all indices $i_k \in I_{k-1}$ where $\lambda_i^{(k)}[A]$ from (28) attains its maximum, i.e.,*

$$I_k := \left\{ i_k \in I_{k-1} \,|\, \lambda_{i_k}^{(k)}[A] = \max_{i \in I_{k-1}} \lambda_i^{(k)}[A] \right\}, \tag{29}$$

$k = 1, 2, \ldots$. Then, the logarithmic derivatives are given by

$$\mu_\infty^{(k)}[A] = \max_{i \in I_{k-1}} \lambda_i^{(k)}[A], \tag{30}$$

$k = 1, 2, \ldots$. □

The proof of Lemma 3.2 is left to the reader.

4. Numerical example. We take matrix A from [4, p. 114, Example 6.1], that is,

$$A = \begin{bmatrix} 2 & -i & 0 \\ i & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}.$$

Then,

$$\mu_\infty^{(1)}[A] = \max\{2+1, 2+1, 3\} = 3$$

and

$$I_1 = \{1, 2, 3\}.$$

Further,

$$A^2 = \begin{bmatrix} 5 & -4i & 0 \\ 4i & 5 & 0 \\ 0 & 0 & 9 \end{bmatrix}.$$

Thus,

$$\mu_\infty^{(2)}[A] = \max\left\{5 + \frac{0\cdot 0 + (-1)(-4)}{1} + 0,\ 5 + \frac{0\cdot 0 + 1\cdot 4}{1} + 0,\ 9 + 0 + 0\right\}$$

$$= \max\{9, 9, 9\} = 9$$

and

$$I_2 = I_1 = \{1, 2, 3\}. \qquad \square$$

Remark. If the element A_{22} of A is replaced by $A_{22} = 1$, we obtain the same values for the first and second logarithmic derivatives as before, but the index sets are different; namely, they read

$$I_1 = \{1, 3\}, \qquad I_2 = \{3\}. \qquad \square$$

Acknowledgment. The author would like to thank the referees for their valuable suggestions.

NONSINGULARITY OF THE DIFFERENCE OF TWO OBLIQUE PROJECTORS*

JÜRGEN GROß† AND GÖTZ TRENKLER†

Abstract. For two real projectors $\mathbf{P}$ and $\mathbf{Q}$ of the same order it is shown that the difference $\mathbf{P}-\mathbf{Q}$ is nonsingular if and only if the column spaces of $\mathbf{P}$ and $\mathbf{Q}$ are complementary and the row spaces of $\mathbf{P}$ and $\mathbf{Q}$ are complementary. Moreover, it is demonstrated that nonsingularity of $\mathbf{P}-\mathbf{Q}$ implies nonsingularity of $\mathbf{P}+\mathbf{Q}$, $\mathbf{I}-\mathbf{QP}$, and $\mathbf{P}+\mathbf{Q}-\mathbf{QP}$.

Key words. oblique projector, rank, complementary subspaces

AMS subject classifications. 15A03, 15A24

1. Notation and preliminaries. For an $m\times n$ real matrix $\mathbf{A}$, the symbols $\mathbf{A}'$, $\mathcal{R}(\mathbf{A})$, $\mathcal{N}(\mathbf{A})$, and $\mathrm{rk}(\mathbf{A})$ will stand for the transpose, the column space, the null space, and the rank, respectively, of $\mathbf{A}$. An $n\times n$ matrix $\mathbf{P}$ is called an (oblique) projector if $\mathbf{P}=\mathbf{P}^2$, or equivalently $\mathcal{N}(\mathbf{P})=\mathcal{R}(\mathbf{I}_n-\mathbf{P})$, in which case $\mathbf{P}$ projects on $\mathcal{R}(\mathbf{P})$ along $\mathcal{N}(\mathbf{P})$. If $\mathbf{P}$ projects on $\mathcal{R}(\mathbf{P})$ along $\mathcal{R}(\mathbf{P})^{\perp}$, then $\mathbf{P}$ is an orthogonal projector. It is readily verified that $\mathbf{P}$ is an orthogonal projector if and only if $\mathbf{P}=\mathbf{P}^2=\mathbf{P}'$.

Throughout this paper, we will repeatedly refer to Marsaglia and Styan [5] for results on equalities for ranks of matrices. An often-applied result is [5, Corollary 6.2], which reads

$$\mathrm{rk}(\mathbf{B})=\mathrm{rk}(\mathbf{AB})+\dim[\mathcal{N}(\mathbf{A})\cap\mathcal{R}(\mathbf{B})]$$

for matrices $\mathbf{A}$ and $\mathbf{B}$ of appropriate dimension. Moreover, we will use the identities $\mathcal{N}(\mathbf{P})=\mathcal{R}(\mathbf{I}_n-\mathbf{P})$ and $\mathrm{rk}(\mathbf{I}_n-\mathbf{P})=n-\mathrm{rk}(\mathbf{P})$ for a projector $\mathbf{P}$ without explicitly mentioning it each time.

2. Rank of the difference. Our first result gives the rank of the difference $\mathbf{P}-\mathbf{Q}$ of two projectors $\mathbf{P}$ and $\mathbf{Q}$, which enables us to establish nonsingularity of $\mathbf{P}-\mathbf{Q}$ as an easy consequence.

THEOREM 1. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n\times n$ *projectors. Then*

$$\mathrm{rk}(\mathbf{P}-\mathbf{Q})=\mathrm{rk}\begin{pmatrix}\mathbf{P}\\ \mathbf{Q}\end{pmatrix}+\mathrm{rk}(\mathbf{P},\mathbf{Q})-\mathrm{rk}(\mathbf{P})-\mathrm{rk}(\mathbf{Q}) \tag{2.1}$$

$$=n-\dim[\mathcal{N}(\mathbf{P})\cap\mathcal{N}(\mathbf{Q})]-\dim[\mathcal{R}(\mathbf{P})\cap\mathcal{R}(\mathbf{Q})]. \tag{2.2}$$

Proof. From Marsaglia and Styan [5, Theorem 8] we conclude that

$$\mathrm{rk}(\mathbf{P}-\mathbf{Q})=\mathrm{rk}\begin{pmatrix}\mathbf{0} & \mathbf{P} & -\mathbf{Q}\\ \mathbf{P} & \mathbf{P} & \mathbf{0}\\ -\mathbf{Q} & \mathbf{0} & -\mathbf{Q}\end{pmatrix}-\mathrm{rk}(\mathbf{P})-\mathrm{rk}(\mathbf{Q}).$$

In view of

$$\begin{pmatrix} \mathbf{I}_n & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & -\mathbf{I}_n & \mathbf{0} \\ -\mathbf{Q} & \mathbf{0} & \mathbf{I}_n \end{pmatrix} \begin{pmatrix} \mathbf{0} & \mathbf{P} & -\mathbf{Q} \\ \mathbf{P} & \mathbf{P} & \mathbf{0} \\ -\mathbf{Q} & \mathbf{0} & -\mathbf{Q} \end{pmatrix} \begin{pmatrix} -\mathbf{I}_n & -\mathbf{P} & \mathbf{0} \\ \mathbf{0} & \mathbf{I}_n & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & -\mathbf{I}_n \end{pmatrix} = \begin{pmatrix} \mathbf{0} & \mathbf{P} & \mathbf{Q} \\ \mathbf{P} & \mathbf{0} & \mathbf{0} \\ \mathbf{Q} & \mathbf{0} & \mathbf{0} \end{pmatrix},$$

(2.1) follows. Moreover, by the identities

$$\mathrm{rk}\begin{pmatrix} \mathbf{P} \\ \mathbf{Q} \end{pmatrix} - \mathrm{rk}(\mathbf{P}) = \mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = n - \mathrm{rk}(\mathbf{P}) - \dim[\mathcal{N}(\mathbf{P}) \cap \mathcal{N}(\mathbf{Q})]$$

and

$$\mathrm{rk}(\mathbf{P}, \mathbf{Q}) - \mathrm{rk}(\mathbf{Q}) = \mathrm{rk}[(\mathbf{I}_n - \mathbf{Q})\mathbf{P}] = \mathrm{rk}(\mathbf{P}) - \dim[\mathcal{R}(\mathbf{P}) \cap \mathcal{R}(\mathbf{Q})]$$

(cf. Marsaglia and Styan [5, Theorem 19 and Corollary 6.2]) (2.2) follows from (2.1). □

As it will be easily seen from the above Theorem 1, $\mathbf{P} - \mathbf{Q}$ is nonsingular if and only if the column spaces of $\mathbf{P}$ and $\mathbf{Q}$ are complementary and the row spaces of $\mathbf{P}$ and $\mathbf{Q}$ are complementary.

COROLLARY 1. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n \times n$ *projectors. Then the following statements are equivalent*:

(i) $\mathrm{rk}(\mathbf{P} - \mathbf{Q}) = n$,

(ii) $\mathcal{R}(\mathbf{P}) \cap \mathcal{R}(\mathbf{Q}) = \{\mathbf{0}\}$ *and* $\mathcal{N}(\mathbf{P}) \cap \mathcal{N}(\mathbf{Q}) = \{\mathbf{0}\}$,

(iii) $\mathcal{R}(\mathbf{P}) \oplus \mathcal{R}(\mathbf{Q}) = \mathbb{R}^n$ *and* $\mathcal{R}(\mathbf{P}') \oplus \mathcal{R}(\mathbf{Q}') = \mathbb{R}^n$.

Proof. The equivalence between (i) and (ii) follows immediately from (2.2). Clearly (iii) implies $\mathcal{R}(\mathbf{P}) \cap \mathcal{R}(\mathbf{Q}) = \{\mathbf{0}\}$ and $[\mathcal{R}(\mathbf{P}') + \mathcal{R}(\mathbf{Q}')]^{\perp} = \{\mathbf{0}\}$, i.e., (ii). On the other hand, if (ii) holds, then from the equivalence between (ii) and (i) we have $\mathrm{rk}(\mathbf{P}' - \mathbf{Q}') = n$, and thus, in addition to (ii), we obtain $\mathcal{R}(\mathbf{P}') \cap \mathcal{R}(\mathbf{Q}') = \{\mathbf{0}\}$ and $\mathcal{N}(\mathbf{P}') \cap \mathcal{N}(\mathbf{Q}') = \{\mathbf{0}\}$. But then (iii) also holds. □

When $\mathbf{P}$ and $\mathbf{Q}$ are orthogonal projectors, then from condition (iii) in Corollary 1 we note that $\mathrm{rk}(\mathbf{P} - \mathbf{Q}) = n$ if and only if $\mathcal{R}(\mathbf{P}) \oplus \mathcal{R}(\mathbf{Q}) = \mathbb{R}^n$. This fact has been established by Ipsen and Meyer [4] and in connection with Hilbert spaces by Buckholtz [1].

From condition (iii) of Corollary 1 it is clear that nonsingularity of the difference $\mathbf{P} - \mathbf{Q}$ entails existence of the oblique projector on $\mathcal{R}(\mathbf{P})$ along $\mathcal{R}(\mathbf{Q})$ as well as existence of the oblique projector on $\mathcal{R}(\mathbf{P}')$ along $\mathcal{R}(\mathbf{Q}')$. Computation of these projectors is quite easy, as shown by the following corollary.

COROLLARY 2. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n \times n$ *projectors. If* $\mathbf{P} - \mathbf{Q}$ *is nonsingular, then* $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}$ *is the projector on* $\mathcal{R}(\mathbf{P})$ *along* $\mathcal{R}(\mathbf{Q})$ *and* $\mathbf{P}'(\mathbf{P}' - \mathbf{Q}')^{-1}$ *is the projector on* $\mathcal{R}(\mathbf{P}')$ *along* $\mathcal{R}(\mathbf{Q}')$.

Proof. The identity $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}(\mathbf{P} - \mathbf{Q}) = \mathbf{P}$ may be reformulated as

$$\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}\mathbf{P} - \mathbf{P} = \mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}\mathbf{Q}.$$

By noting that $\mathcal{R}(\mathbf{P}') \cap \mathcal{R}(\mathbf{Q}') = \{\mathbf{0}\}$, this identity is seen to hold if and only if $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}\mathbf{P} = \mathbf{P}$, and $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}\mathbf{Q} = \mathbf{0}$. Thus $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}$ is the projector on $\mathcal{R}(\mathbf{P})$ along $\mathcal{R}(\mathbf{Q})$; cf. Trenkler [7, Theorem 7(iii)]. Similarly $\mathbf{P}'(\mathbf{P}' - \mathbf{Q}')^{-1}$ is seen to be the projector on $\mathcal{R}(\mathbf{P}')$ along $\mathcal{R}(\mathbf{Q}')$. □

The following result shows that the difference of two commuting projectors can only be nonsingular when the projectors add up to identity. In other words, for a given

projector $\mathbf{P}$, there exists only one projector $\mathbf{Q}$ with the property that $\mathbf{Q}$ commutes with $\mathbf{P}$ and $\mathbf{P}-\mathbf{Q}$ is nonsingular, namely, $\mathbf{Q}=\mathbf{I}_n-\mathbf{P}$.

COROLLARY 3. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two commuting* $n\times n$ *projectors. Then the following statements are equivalent*:

(i) $\mathrm{rk}(\mathbf{P}-\mathbf{Q})=n$,

(ii) $\mathbf{P}-\mathbf{Q}$ *is an involution, i.e.,* $(\mathbf{P}-\mathbf{Q})^2=\mathbf{I}_n$,

(iii) $\mathbf{P}+\mathbf{Q}=\mathbf{I}_n$.

Proof. Since projectors are diagonalizable, it is clear that $\mathbf{P}$ and $\mathbf{Q}$ commute if and only if they are simultaneously diagonalizable. Then, however, the equivalence between the statements follows immediately. □

3. Rank of the sum. As in the previous section, we will now derive the rank of the sum $\mathbf{P}+\mathbf{Q}$ of two projectors $\mathbf{P}$ and $\mathbf{Q}$. From our derivations, it will become obvious that nonsingularity of $\mathbf{P}-\mathbf{Q}$ implies nonsingularity of $\mathbf{P}+\mathbf{Q}$.

THEOREM 2. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n\times n$ *projectors. Then*

$$\mathrm{rk}(\mathbf{P}+\mathbf{Q})=\mathrm{rk}(\mathbf{P})+\mathrm{rk}[(\mathbf{I}_n-\mathbf{P})\mathbf{Q}(\mathbf{I}_n-\mathbf{P})] \tag{3.1}$$

$$=n-\dim\left(\mathcal{N}[(\mathbf{I}_n-\mathbf{P})\mathbf{Q}]\cap\mathcal{N}(\mathbf{P})\right), \tag{3.2}$$

where $\mathcal{N}[(\mathbf{I}_n-\mathbf{P})\mathbf{Q}]=\mathcal{N}(\mathbf{Q})\oplus[\mathcal{R}(\mathbf{P})\cap\mathcal{R}(\mathbf{Q})]$.

Proof. From Marsaglia and Styan [5, Theorem 8] we see that

$$\mathrm{rk}(\mathbf{P}+\mathbf{Q})=\mathrm{rk}\begin{pmatrix}\mathbf{0}&\mathbf{P}&\mathbf{Q}\\ \mathbf{P}&\mathbf{P}&\mathbf{0}\\ \mathbf{Q}&\mathbf{0}&\mathbf{Q}\end{pmatrix}-\mathrm{rk}(\mathbf{P})-\mathrm{rk}(\mathbf{Q}).$$

In view of

$$\begin{pmatrix}\mathbf{I}_n&\mathbf{0}&\mathbf{0}\\ \mathbf{0}&\mathbf{I}_n&\mathbf{0}\\ \mathbf{Q}&\mathbf{0}&\mathbf{I}_n\end{pmatrix}\begin{pmatrix}\mathbf{0}&\mathbf{P}&\mathbf{Q}\\ \mathbf{P}&\mathbf{P}&\mathbf{0}\\ \mathbf{Q}&\mathbf{0}&\mathbf{Q}\end{pmatrix}\begin{pmatrix}\mathbf{I}_n&-\mathbf{P}&\mathbf{0}\\ \mathbf{0}&\mathbf{I}_n&\mathbf{0}\\ \mathbf{0}&\mathbf{0}&\mathbf{I}_n\end{pmatrix}=\begin{pmatrix}\mathbf{0}&\mathbf{P}&\mathbf{Q}\\ \mathbf{P}&\mathbf{0}&\mathbf{0}\\ \mathbf{Q}&\mathbf{0}&\mathbf{2Q}\end{pmatrix},$$

we obtain

$$\mathrm{rk}(\mathbf{P}+\mathbf{Q})=\mathrm{rk}\begin{pmatrix}\mathbf{0}&\mathbf{X}\\ \mathbf{Y}&\mathbf{S}\end{pmatrix}-\mathrm{rk}(\mathbf{P})-\mathrm{rk}(\mathbf{Q}),$$

where

$$\mathbf{X}=(\mathbf{P},\mathbf{Q}),\mathbf{Y}=\begin{pmatrix}\mathbf{P}\\ \mathbf{Q}\end{pmatrix}\quad\text{and}\quad\mathbf{S}=\begin{pmatrix}\mathbf{0}&\mathbf{0}\\ \mathbf{0}&2\mathbf{Q}\end{pmatrix}.$$

By using

$$\mathbf{S}^-=\begin{pmatrix}\mathbf{0}&\mathbf{0}\\ \mathbf{0}&(1/2)\mathbf{Q}\end{pmatrix}$$

as a generalized inverse for $\mathbf{S}$, i.e., $\mathbf{S}\mathbf{S}^-\mathbf{S}=\mathbf{S}$, and by applying Marsaglia and Styan [5, Theorem 19, equation (8.4)], it follows that

$$\mathrm{rk}(\mathbf{P}+\mathbf{Q})=\mathrm{rk}(\mathbf{S})+\mathrm{rk}(\mathbf{U})+\mathrm{rk}(\mathbf{V})+\mathrm{rk}(\mathbf{W})-\mathrm{rk}(\mathbf{P})-\mathrm{rk}(\mathbf{Q}),$$

where

$$\mathbf{U} = \mathbf{X}(\mathbf{I}_{2n} - \mathbf{S}^{-}\mathbf{S}) = (\mathbf{P}, \mathbf{0}), \qquad \mathbf{V} = (\mathbf{I}_{2n} - \mathbf{S}\mathbf{S}^{-}) \begin{pmatrix} \mathbf{P} \\ \mathbf{Q} \end{pmatrix} = \begin{pmatrix} \mathbf{P} \\ \mathbf{0} \end{pmatrix}$$

and

$$\mathbf{W} = (\mathbf{I}_n - \mathbf{U}\mathbf{U}^{-})\mathbf{X}\mathbf{S}^{-}\mathbf{Y}(\mathbf{I}_n - \mathbf{V}^{-}\mathbf{V}) = (1/2)(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})$$

for the choices $\mathbf{U}^{-} = (\mathbf{P}', \mathbf{0})'$ and $\mathbf{V}^{-} = (\mathbf{P}, \mathbf{0})$. In view of $\mathrm{rk}(\mathbf{S}) = \mathrm{rk}(\mathbf{Q})$ and $\mathrm{rk}(\mathbf{U}) = \mathrm{rk}(\mathbf{V}) = \mathrm{rk}(\mathbf{P})$, (3.1) follows. Since, in view of Marsaglia and Styan [5, Corollary 6.2],

$$\mathrm{rk}(\mathbf{I}_n - \mathbf{P}) - \mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \dim \left(\mathcal{N}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}] \cap \mathcal{N}(\mathbf{P}) \right),$$

(3.2) follows from (3.1). The inclusion $\mathcal{N}(\mathbf{Q}) \oplus [\mathcal{R}(\mathbf{P}) \cap \mathcal{R}(\mathbf{Q})] \subseteq \mathcal{N}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}]$ has, for example, been proven in Groß and Trenkler [3, Lemma 2(b)]. The reverse inclusion is also easy. □

We may now give a characterization of the nonsingularity of the sum $\mathbf{P} + \mathbf{Q}$ of two projectors $\mathbf{P}$ and $\mathbf{Q}$ in terms of disjointedness of subspaces similar to the characterization of nonsingularity of $\mathbf{P} - \mathbf{Q}$ in Corollary 1(ii).

COROLLARY 4. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n \times n$ *projectors. Then the following statements are equivalent*:

(i) $\mathrm{rk}(\mathbf{P} + \mathbf{Q}) = n$,

(ii) $\mathcal{R}(\mathbf{P}) \cap \mathcal{R}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \{\mathbf{0}\}$ *and* $\mathcal{N}(\mathbf{P}) \cap \mathcal{N}(\mathbf{Q}) = \{\mathbf{0}\}$.

Proof. By using $\mathcal{N}(\mathbf{P}) = \mathcal{R}(\mathbf{I}_n - \mathbf{P})$, it follows from Marsaglia and Styan [5, Corollary 6.2] that the condition $\mathcal{N}(\mathbf{P}) \cap \mathcal{N}(\mathbf{Q}) = \{\mathbf{0}\}$ is equivalent to $\mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}(\mathbf{I}_n - \mathbf{P})$. Similarly, the condition $\mathcal{R}(\mathbf{P}) \cap \mathcal{R}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \{\mathbf{0}\}$ is seen to be equivalent to $\mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})]$. Hence, statement (ii) implies $\mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] + \mathrm{rk}(\mathbf{P}) = n$, which in view of (3.1) from Theorem 2 gives (i). Conversely, from Theorem 2, statement (i) implies $\mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}(\mathbf{I}_n - \mathbf{P})$ and equivalently $\mathcal{N}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}] \cap \mathcal{N}(\mathbf{P}) = \{\mathbf{0}\}$. Since the latter obviously entails $\mathcal{N}(\mathbf{Q}) \cap \mathcal{N}(\mathbf{P}) = \{\mathbf{0}\}$, i.e., $\mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}(\mathbf{I}_n - \mathbf{P})$, it also follows $\mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})]$, showing that (i) implies (ii). □

Note that for two orthogonal projectors $\mathbf{P}$ and $\mathbf{Q}$ we always have $\mathrm{rk}[(\mathbf{I}_n - \mathbf{P})\mathbf{Q}(\mathbf{I}_n - \mathbf{P})] = \mathrm{rk}[\mathbf{Q}(\mathbf{I}_n - \mathbf{P})]$, and therefore condition (ii) of Corollary 4 would reduce to $\mathcal{N}(\mathbf{P}) \cap \mathcal{N}(\mathbf{Q}) = \{\mathbf{0}\}$, i.e., $\mathcal{R}(\mathbf{P}) + \mathcal{R}(\mathbf{Q}) = \mathbb{R}^n$.

By comparing the respective conditions (ii) of Corollaries 1 and 4, it is clear that nonsingularity of $\mathbf{P} - \mathbf{Q}$ implies nonsingularity of $\mathbf{P} + \mathbf{Q}$. The fact that nonsingularity of the sum of two projectors does *not* imply nonsingularity of the difference can be seen, for example, from

$$\mathbf{P} = \begin{pmatrix} 1 & 0 & a \\ 0 & 1 & b \\ 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \mathbf{Q} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

for arbitrary scalars a and b. Obviously nonsingularity of $\mathbf{P} + \mathbf{Q}$ implies neither disjointness of $\mathcal{R}(\mathbf{P})$ and $\mathcal{R}(\mathbf{Q})$ nor disjointness of $\mathcal{R}(\mathbf{P}')$ and $\mathcal{R}(\mathbf{Q}')$, both conditions being necessary for nonsingularity of $\mathbf{P} - \mathbf{Q}$.

4. Rank of other transforms. In this section we give the rank of the transforms $\mathbf{I}_n - \mathbf{QP}$ and $\mathbf{P} + \mathbf{Q} - \mathbf{QP}$ of two projectors $\mathbf{P}$ and $\mathbf{Q}$. As it will turn out, the rank of $\mathbf{P} + \mathbf{Q} - \mathbf{QP}$ coincides with the rank of $\mathbf{P} + \mathbf{Q}$. Moreover nonsingularity of $\mathbf{P} + \mathbf{Q} - \mathbf{QP}$ and $\mathbf{I}_n - \mathbf{QP}$ are seen to be equivalent to nonsingularity of $\mathbf{P} - \mathbf{Q}$.

THEOREM 3. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n \times n$ *projectors. Then*

$$\operatorname{rk}(\mathbf{I}_n - \mathbf{QP}) = \operatorname{rk}[(\mathbf{I}_n - \mathbf{P}) + (\mathbf{I}_n - \mathbf{Q})], \tag{4.1}$$

$$\operatorname{rk}(\mathbf{P} + \mathbf{Q} - \mathbf{QP}) = \operatorname{rk}(\mathbf{P} + \mathbf{Q}). \tag{4.2}$$

Proof. From (3.1) in Theorem 2,

$$\begin{aligned}\operatorname{rk}[(\mathbf{I}_n - \mathbf{P}) + (\mathbf{I}_n - \mathbf{Q})] &= \operatorname{rk}(\mathbf{I}_n - \mathbf{P}) + \operatorname{rk}[\mathbf{P}(\mathbf{I}_n - \mathbf{Q})\mathbf{P}] \\ &= \operatorname{rk}(\mathbf{I}_n - \mathbf{P}) + \operatorname{rk}[\mathbf{P}(\mathbf{I}_n - \mathbf{QP})].\end{aligned}$$

On the other hand,

$$\operatorname{rk}[\mathbf{P}(\mathbf{I}_n - \mathbf{QP})] = \operatorname{rk}(\mathbf{I}_n - \mathbf{QP}) - \dim[\mathcal{N}(\mathbf{P}) \cap \mathcal{R}(\mathbf{I}_n - \mathbf{QP})];$$

cf. Marsaglia and Styan [5, Corollary 6.2]. Since obviously $\mathcal{N}(\mathbf{P}) \subseteq \mathcal{R}(\mathbf{I}_n - \mathbf{QP})$, we have

$$\dim[\mathcal{N}(\mathbf{P}) \cap \mathcal{R}(\mathbf{I}_n - \mathbf{QP})] = \dim[\mathcal{N}(\mathbf{P})] = \operatorname{rk}(\mathbf{I}_n - \mathbf{P}),$$

which shows (4.1). Equation (4.2) follows from (4.1) by noting that $\mathbf{P} + \mathbf{Q} - \mathbf{QP} = \mathbf{I}_n - (\mathbf{I}_n - \mathbf{Q})(\mathbf{I}_n - \mathbf{P})$. □

We may now give a characterization of the nonsingularity of $\mathbf{P} - \mathbf{Q}$ in terms of the transforms $\mathbf{I}_n - \mathbf{QP}$ and $\mathbf{P} + \mathbf{Q} - \mathbf{QP}$.

COROLLARY 5. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n \times n$ *projectors. Then the following statements are equivalent*:

(i) $\operatorname{rk}(\mathbf{P} - \mathbf{Q}) = n$,

(ii) $\operatorname{rk}(\mathbf{I}_n - \mathbf{QP}) = n$ *and* $\operatorname{rk}(\mathbf{P} + \mathbf{Q} - \mathbf{QP}) = n$.

Proof. As mentioned before, by comparing the corresponding conditions (ii) in Corollaries 1 and 4, it is clear that (i) implies $\operatorname{rk}(\mathbf{P} + \mathbf{Q}) = n$, where $\operatorname{rk}(\mathbf{P} + \mathbf{Q}) = \operatorname{rk}(\mathbf{P} + \mathbf{Q} - \mathbf{QP})$ by Theorem 3. Since $\operatorname{rk}(\mathbf{P} - \mathbf{Q}) = \operatorname{rk}[(\mathbf{I}_n - \mathbf{P}) - (\mathbf{I}_n - \mathbf{Q})]$, (i) implies $\operatorname{rk}[(\mathbf{I}_n - \mathbf{P}) + (\mathbf{I}_n - \mathbf{Q})] = n$, where $\operatorname{rk}[(\mathbf{I}_n - \mathbf{P}) + (\mathbf{I}_n - \mathbf{Q})] = \operatorname{rk}(\mathbf{I}_n - \mathbf{QP})$ from Theorem 3. Hence (i) implies (ii). Conversely, if (ii) is satisfied, then in view of $\operatorname{rk}(\mathbf{P}+\mathbf{Q}) = \operatorname{rk}(\mathbf{P}+\mathbf{Q}-\mathbf{QP})$ we obtain $\mathcal{N}(\mathbf{P})\cap\mathcal{N}(\mathbf{Q}) = \{\mathbf{0}\}$ from Corollary 4. Similarly in view of $\operatorname{rk}(\mathbf{I}_n-\mathbf{QP}) = \operatorname{rk}[(\mathbf{I}_n-\mathbf{P})+(\mathbf{I}_n-\mathbf{Q})]$ we obtain $\mathcal{N}(\mathbf{I}_n-\mathbf{P})\cap\mathcal{N}(\mathbf{I}_n-\mathbf{Q}) = \{\mathbf{0}\}$. Hence by Corollary 1(ii), statement (ii) implies (i). □

In addition to Corollary 2, we may state the following result.

COROLLARY 6. *Let* $\mathbf{P}$ *and* $\mathbf{Q}$ *be two* $n\times n$ *projectors. If* $\mathbf{P}-\mathbf{Q}$ *is nonsingular, then the projector on* $\mathcal{R}(\mathbf{P})$ *along* $\mathcal{R}(\mathbf{Q})$ *may be written in the form* $(\mathbf{I}_n - \mathbf{QP})^{-1}(\mathbf{I}_n - \mathbf{Q})$ *or in the form* $\mathbf{P}(\mathbf{P} + \mathbf{Q} - \mathbf{QP})^{-1}$.

Proof. Since $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}(\mathbf{P} - \mathbf{QP}) = \mathbf{P}$ and $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}\mathbf{Q} = \mathbf{0}$, cf. the proof of Corollary 2, we obtain $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1}(\mathbf{P} + \mathbf{Q} - \mathbf{QP}) = \mathbf{P}$, such that by Corollary 5 we have $\mathbf{P}(\mathbf{P} - \mathbf{Q})^{-1} = \mathbf{P}(\mathbf{P} + \mathbf{Q} - \mathbf{QP})^{-1}$, which by Corollary 2 is the projector on $\mathcal{R}(\mathbf{P})$ along $\mathcal{R}(\mathbf{Q})$. □

Corollary 6 generalizes a result by Greville [2], who has shown the assertion for orthogonal projectors $\mathbf{P}$ and $\mathbf{Q}$. Recall that for orthogonal projectors the condition $\operatorname{rk}(\mathbf{P} - \mathbf{Q}) = n$ is equivalent to $\mathcal{R}(\mathbf{P}) \oplus \mathcal{R}(\mathbf{Q}) = \mathbb{R}^n$, which in turn is necessary and sufficient for existence of an (oblique) projector on $\mathcal{R}(\mathbf{P})$ along $\mathcal{R}(\mathbf{Q})$.

Acknowledgments. The authors are grateful to an anonymous referee for delivering rank formulas for transforms of projectors, which improved the presentation of the main results considerably.

TRANSFORMATION OF FAMILIES OF MATRICES TO NORMAL FORMS AND ITS APPLICATION TO STABILITY THEORY*

ALEXEI A. MAILYBAEV†

Abstract. Families of matrices smoothly depending on a vector of parameters are considered. Arnold [*Russian Math. Surveys*, 26 (1971), pp. 29–43] and Galin [*Uspekhi Mat. Nauk*, 27 (1972), pp. 241–242] have found and listed normal forms of families of complex and real matrices (miniversal deformations), to which any family of matrices can be transformed in the vicinity of a point in the parameter space by a change of basis, smoothly dependent on a vector of parameters, and by a smooth change of parameters. In this paper a constructive method of determining functions describing a change of basis and a change of parameters, transforming an arbitrary family to the miniversal deformation, is suggested. Derivatives of these functions with respect to parameters are determined from a recurrent procedure using derivatives of the functions of lower orders and derivatives of the family of matrices. Then the functions are found as Taylor series. Examples are given. The suggested method allows using efficiently miniversal deformations for investigation of different properties of matrix families. This is shown in the paper where tangent cones (linear approximations) to the stability domain at the singular boundary points are found.

Key words. family of matrices, normal form, versal deformation, stability, tangent cone

1. Introduction.

The paper deals with the study of families of complex and real matrices (a family of matrices is a matrix-valued function $A(p)$ holomorphically (smoothly) depending on a vector p of complex (real) parameters). It is known that from all families of matrices we can select such families that transformation of any family to them can be carried out by a change of basis, smoothly depending on parameters, and by a smooth change of parameters [1, 2, 3]. Such families are called versal deformations. Versal deformations with the minimum possible number of parameters are called miniversal deformations or normal forms. Miniversal deformations of complex matrices have been found by Arnold [1, 2, 3]. He showed that the miniversal deformation, to which a family of matrices $A(p)$ can be transformed in the vicinity of a point $p = p_0$, is determined by the Jordan form of the matrix $A(p_0)$. Miniversal deformations of real matrices have been studied by Galin [8].

The important part of the transformation of a family of matrices to the normal form is to find functions describing a change of basis, depending on parameters, and a change of parameters. Determination of these functions is necessary for effective use of normal forms, but no general algorithm for finding them is available yet. Efforts of construction of the transformation functions required in a specific case have been done in [5, 12]. In the case when the matrix $A_0 = A(p_0)$ has only nonderogatory eigenvalues, the problem of construction of transformation to the normal form has been discussed in [13]. However, the method of finding the transformation functions suggested in [13] can be used only for matrices of small dimensions or in the case when the matrix A_0 has only one nonderogatory eigenvalue. Otherwise it leads to a

†Institute of Mechanics, Moscow State Lomonosov University, Michurinsky pr. 1, 117192 Moscow, Russia (mailybaev@inmech.msu.su).

complicated system of nonlinear equations containing parameters of the family and parameters of the normal form.

Another approach has been suggested in [14], where the transformation functions have been found at a specific value of the parameter vector p by solving a nonlinear implicit matrix equation using secant, updating secant, or using Newton's method. Such a numerical approach, though useful for finding functions in a finite domain (functions are calculated at several points and then approximated), is not efficient in the case under consideration. This is connected with the local character of miniversal deformations, which are defined in the vicinity of a point in the parameter space and used for investigation of local properties of matrix families (singularities, bifurcations, etc.). For local analysis, information about derivatives of the transformation functions with respect to parameters is required. Computation of these derivatives by means of approximate methods of [14] is very time-consuming and leads to numerical errors (especially when the size of the matrix A is not small). In [14] also a method for computation of derivatives of the transformation functions for a case of one-parameter matrix family has been suggested. This family had a special form allowing transformation to a normal form which was simpler than a miniversal deformation.

In the present paper a constructive method of finding functions describing the transformation of any given family of matrices to the normal form is suggested. The functions are found as Taylor series. Derivatives of the functions with respect to parameters, to determine coefficients of Taylor series, are found from a recurrent procedure using the derivatives of lower orders of these functions and derivatives of the family at the initial value of the vector of parameters. The recurrent procedure is convenient for numerical implementation, since it consists of elementary arithmetic operations. Proofs are based on properties of centralizers of matrices transformed to the Jordan form.

Transformation of a family of matrices to the normal form has great significance for applications. It allows studying specific families (normal forms), which consist usually of sparse matrices depending on parameters in a simple way, and then obtaining results for arbitrary families of matrices. Miniversal deformations (without knowledge about transformation to them) have been used in [1, 2, 3] for classification of singularities of bifurcation diagrams, decrement diagrams, and boundaries of the stability domains in the case of two and three parameters. In [10] miniversal deformations have been used for finding tangent cones (linear approximations) to the stability domain at singular boundary points up to a diffeomorphism. All previous results were qualitative. To obtain quantitative results we need information about the transformation. In [4] specific linear combinations of first derivatives of the functions describing a change of parameters have been found and used to obtain necessary conditions for the stable perturbations of matrices. Other applications of miniversal deformations can be found in [6, 7], where a bound for a distance to a less generic matrix pencil and backward error bound in the procedure of calculation of polynomial roots are obtained.

The method of finding functions of transformation, suggested in this paper, allows using miniversal deformations for quantitative study of different properties of matrices depending on parameters. Efficiency of the method for applications is illustrated by the problem of finding tangent cones (or parts of tangent cones) to the stability domain for singular boundary points. All types of singular boundary points are considered. The obtained results represent an extension of the paper [11], where, using another approach, tangent cones for singular boundary points of the stability domain of two- and three-parameter generic families of matrices have been found.

The paper is organized as follows. In section 2 the method for determining derivatives of functions describing the transformation of a family of complex matrices to miniversal deformation is formulated and proved. Section 3 discusses the case of families of real matrices. Section 4 uses results of the previous sections to find tangent cones to the stability domain at singular boundary points. The conclusion gives a brief overview of the results obtained and discusses possibilities for their application to different problems.

2. Transformation of families of complex matrices to normal forms. For the following presentation we need definitions given by Arnold [1, 2], [3, p. 237].

DEFINITION 2.1. *A family of complex matrices is a holomorphic mapping* $A : P \longrightarrow \mathbf{C}^{n^2}$, *where* P *is the vicinity of some point* p_0 *in the parameter space* $\mathbf{C}^m$ *and* $\mathbf{C}^{n^2}$ *is the space of* $n \times n$ *complex matrices.*

Let us consider an arbitrary family of matrices $A(p),\ p = (p_1, \dots, p_m)^T \in \mathbf{C}^m$. Denote by λ_i the eigenvalues of the matrix $A_0 = A(p_0)$ and let $n_1(\lambda_i) \geq n_2(\lambda_i) \geq \cdots$ be the dimensions of the Jordan blocks belonging to λ_i, beginning with the largest one. Let the Jordan form J of the matrix A_0 be given by

$$A_0 = C_0 J C_0^{-1}, \tag{2.1}$$

where

$$J = \begin{pmatrix} J_1 & & \\ & J_2 & \\ & & \ddots \end{pmatrix},$$

$$J_i = \begin{pmatrix} J_i^1 & & \\ & J_i^2 & \\ & & \ddots \end{pmatrix},$$

and the Jordan block

$$J_i^k = \begin{pmatrix} \lambda_i & 1 & & & \\ & \cdot & \cdot & & \\ & & \cdot & \cdot & \\ & & & \cdot & 1 \\ & & & & \lambda_i \end{pmatrix}$$

has dimension $n_k(\lambda_i)$.

Denote by X_{ij}^{kl} the block of a square $n \times n$ matrix X, which is situated on the intersection of the rows corresponding to the block J_i^k and columns corresponding to the block J_j^l; see, for example, Figure 2.1. Denote elements of each block X_{ij}^{kl} by $x_{ij}^{kl}(r,s),\ r = 1, \dots, n_k(\lambda_i),\ s = 1, \dots, n_l(\lambda_j)$, where r, s are the numbers of a row and a column in X_{ij}^{kl} corresponding to $x_{ij}^{kl}(r,s)$. In the case $i = j$ we will leave only one number in the subscript, e.g., X_i^{kl}, $x_i^{kl}(r,s)$. The block of the matrix X which corresponds to the block J_i of the Jordan form J will be denoted by X_i.

DEFINITION 2.2. *A versal deformation of a matrix* A_0 *is a family of matrices* $A'(p'),\ p' \in \mathbf{C}^d$ *such that any family* $A(p),\ A(p_0) = A_0$ *in the vicinity of the point* $p = p_0$ *can be represented in the form*

$$A(p) = C(p) A'(\varphi(p)) C^{-1}(p), \tag{2.2}$$

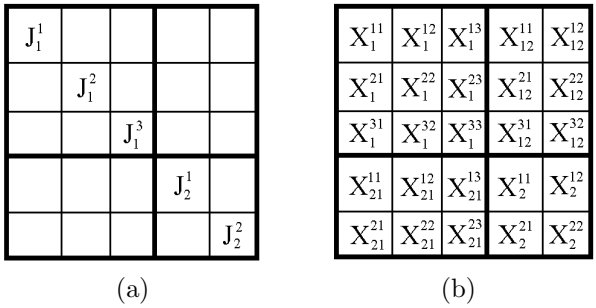

FIG. 2.1. *Block decomposition of a square matrix X according to the Jordan form J.*

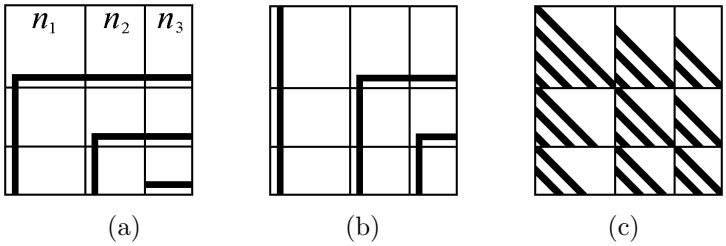

FIG. 2.2. *Location of parameters in blocks of a miniversal deformation.*

where $p' = \varphi(p)$, $\varphi(p_0) = \mathbf{0}$ is a holomorphic mapping from the vicinity of the point $p = p_0$ in the parameter space $\mathbf{C}^m$ into the vicinity of the origin of coordinate in the space $\mathbf{C}^d$; $C(p)$ is a family of nonsingular matrices describing a change of basis. A versal deformation is said to be miniversal if the dimension d of the parameter space is the smallest possible for a versal deformation [1, 2], [3, p. 237].

It is shown in [1, 2], [3, p. 238], that a miniversal deformation is determined by the Jordan form of the matrix A_0 and can be chosen in the form of a sum $J+B(p')$, where $B(p') = \operatorname{Diag}(B_1, B_2, \ldots)$ is a family of block-diagonal matrices with blocks $B_i(p')$ corresponding to the blocks J_i of the matrix J. There are different ways of choosing the blocks $B_i(p')$. Three possible types are shown in Figure 2.2, where the block $B_i(p')$ has all zeros except at the places indicated. In cases (a) and (b), the indicated places are filled by different components of the vector p' (parameters of the miniversal deformation); in case (c) each slanted segment is filled by a corresponding component of the vector p'. Other types of blocks are also possible, e.g., blocks whose elements are all zero, except for one element on each slanted segment in Figure 2.2(c) which is an independent parameter. In all cases, each block B_i^{kl} contains exactly $n_l(\lambda_i)$, if $k \le l$, and $n_k(\lambda_i)$, if $k > l$, different components of p' (one on each slanted segment in Figure 2.2(c)). Denote these components by $b_i^{kl}(t)$, $t = 1, \ldots, \min(n_k(\lambda_i), n_l(\lambda_i))$ numbered inside each block from the top and from the right (see examples for the case of two Jordan blocks of the size 3 and 2 in Figure 2.3). Components $b_i^{kl}(t)$ compose the vector of parameters of the miniversal deformation p' of the dimension $d = \sum_i (n_1(\lambda_i) + 3n_2(\lambda_i) + \cdots)$ [1, 2], [3, p. 237].

DEFINITION 2.3. *Define a generalized trace of a $k \times l$ matrix F denoted by $\operatorname{tr}^{(t)} F$ as a sum of elements on that diagonal of F which is $(\min(k, l) - t)$ positions above the left lower element*

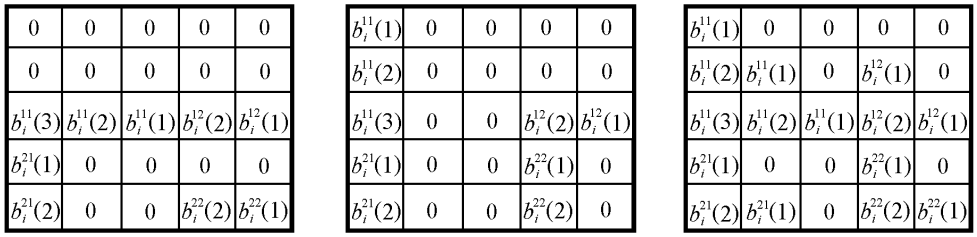

FIG. 2.3. *Numbering of parameters of a miniversal deformation.*

$$\operatorname{tr}^{(t)} F = \sum_{r=t}^{\min(k,l)} f(k - \min(k,l) + r,\ r - t + 1). \tag{2.3}$$

In the case of a square matrix ($k = l$), Definition 2.3 coincides with the definition of a generalized trace given in [4]. In particular, a generalized trace $\operatorname{tr}^{(\min(k,l))} F$ is equal to the left lower element of the matrix F, and a generalized trace $\operatorname{tr}^{(1)} F$ of a square matrix F coincides with the ordinary trace $\operatorname{tr} F$, which is equal to the sum of elements on the main diagonal. In the case of an $n \times n$ matrix F a generalized trace $\operatorname{tr}^{(t)}$ of a block F_i^{kl} is equal to the sum of elements on that slanted segment which is $(t-1)$ positions below the longest one in this block; see Figure 2.2,

$$\operatorname{tr}^{(t)} F_i^{kl} = \sum_{r=t}^{n'} f_i^{kl}(n_k(\lambda_i) - n' + r,\ r - t + 1), \quad n' = \min(n_k(\lambda_i), n_l(\lambda_i)).$$

For blocks of the matrix $B(p')$ we have $\operatorname{tr}^{(t)} B_i^{kl} = \alpha_i^{kl}(t) b_i^{kl}(t)$, where $\alpha_i^{kl}(t) = 1$, if B_i is a block of the type (a) or (b), and $\alpha_i^{kl}(t) = n' - t + 1$, if B_i is a block of the type (c); see Figure 2.2.

Denote by D^h the derivative

$$D^h = \frac{\partial^{|h|}}{\partial p_1^{h^1} \cdots \partial p_m^{h^m}}$$

taken at the point $p = p_0$, where $h = (h^1, \ldots, h^m)$, $h^i \geq 0$, is a vector whose components h^i denote the order of the partial derivative with respect to p_i ($h^i = 0$ means that the derivative with respect to p_i is not taken), $|h| = h^1 + \cdots + h^m$ is the order of the derivative.

Transformation of the family of matrices $A(p)$ to the normal form (miniversal deformation) (2.2) includes finding the family $A'(p')$ corresponding to the Jordan form J of the matrix A_0, families $C(p)$, $C^{-1}(p)$, and holomorphic mapping $p' = \varphi(p)$ (functions $b_i^{kl}(t)(p)$). To obtain $C(p)$, $C^{-1}(p)$, and $b_i^{kl}(t)(p)$, it is sufficient to determine derivatives $D^h C$, $D^h C^{-1}$, and $D^h b_i^{kl}(t)$ for all h. Then the desired functions are found locally as Taylor series (by virtue of holomorphy).

THEOREM 2.4. *Let $A(p)$ be a family of matrices. Then the following expressions are valid for derivatives D^h, $|h| > 0$ of the functions $C(p)$, $C^{-1}(p)$, $b_i^{kl}(t)(p)$ transforming the family of matrices $A(p)$ to the miniversal deformation $A'(p')$ described above* (2.2).

1°.

$$D^h b_i^{kl}(t) = \frac{\operatorname{tr}^{(t)} F_i^{kl}}{\alpha_i^{kl}(t)}, \tag{2.4}$$

$$\begin{aligned} F = C_0^{-1}\Bigg(D^h A - \sum_{\substack{h_1+h_2+h_3=h \\ h_1,h_2,h_3\neq h}} C_h^{h_1h_2h_3} D^{h_1}C\, D^{h_2}A'\, D^{h_3}C^{-1} \\ + A_0 \sum_{\substack{h_1+h_2=h \\ h_1,h_2\neq h}} C_h^{h_1h_2} D^{h_1}C\, D^{h_2}C^{-1} \Bigg) C_0, \end{aligned} \tag{2.5}$$

$$C_h^{h_1h_2h_3} = \prod_{i=1}^{m} \frac{h^i!}{h_1^i!h_2^i!h_3^i!}, \quad C_h^{h_1h_2} = \prod_{i=1}^{m} \frac{h^i!}{h_1^i!h_2^i!}.$$

2°.

$$D^h C = C_0 X, \tag{2.6}$$

$$x_{ij}^{kl}(r,s) = \sum_{r_1=r}^{n_k(\lambda_i)} \sum_{s_1=1}^{s} \frac{(-1)^{r_1-r}}{(\lambda_i-\lambda_j)^{r_1-r+s-s_1+1}}\, C_{r_1-r+s-s_1}^{r_1-r} g_{ij}^{kl}(r_1,s_1),\ i\neq j, \tag{2.7}$$

$$C_n^k = \frac{n!}{k!(n-k)!},$$

$$x_i^{kl}(r,s) = \begin{cases} 0, & k\le l,\ r=1, \\ \displaystyle\sum_{\substack{s_1=s'(r,s) \\ r'(r,s)}} g_i^{kl}(r-s+s_1-1,s_1), & k\le l,\ r\neq 1, \\ \displaystyle -\sum_{r_1=r} g_i^{kl}(r_1,s-r+r_1+1), & k>l,\ s\neq n_l(\lambda_i), \\ 0, & k>l,\ s=n_l(\lambda_i), \end{cases} \tag{2.8}$$

$$s'(r,s) = \max(1, s-r+2), \quad r'(r,s) = \min(n_k(\lambda_i), r-s+n_l(\lambda_i)-1),$$

$$G = D^h A' - F. \tag{2.9}$$

3°.

$$D^h C^{-1} = -C_0^{-1} \sum_{\substack{h_1+h_2=h \\ h_2\neq h}} C_h^{h_1h_2} D^{h_1}C\, D^{h_2}C^{-1}. \tag{2.10}$$

The zero order derivatives D^h, $h=\mathbf{0}$ of functions C, C^{-1}, A' (values of functions at $p=p_0$) are $D^0C = C_0$, $D^0C^{-1} = C_0^{-1}$, $D^0A' = J$. Theorem 2.4 allows finding

derivatives D^h of the order $|h| > 0$ of functions C, C^{-1}, and $b_i^{kl}(t)$, using only derivatives of these functions of a lower order and the derivative $D^h A$. Thus, (2.4)–(2.10) represent a recurrent procedure for determining the derivatives $D^h C$, $D^h C^{-1}$, and $D^h b_i^{kl}(t)$ for any h using derivatives $D^{h_1} A$ of the order $|h_1| < |h|$ and $h_1 = h$.

If all derivatives $D^h C$, $D^h C^{-1}$, and $D^h b_i^{kl}(t)$ of the order $|h| \le s$ are determined, the desired functions can be found approximately as Taylor series containing terms with derivatives D^h of the order $|h| \le s$

$$C(p) = \sum_{0 \le |h| \le s} D^h C \prod_{r=1}^{m} \frac{(p_r - p_{0r})^{h^r}}{h^r!} + o(\|p - p_0\|^s),$$

$$C^{-1}(p) = \sum_{0 \le |h| \le s} D^h C^{-1} \prod_{r=1}^{m} \frac{(p_r - p_{0r})^{h^r}}{h^r!} + o(\|p - p_0\|^s),$$

$$b_i^{kl}(t)(p) = \sum_{0 \le |h| \le s} D^h b_i^{kl}(t) \prod_{r=1}^{m} \frac{(p_r - p_{0r})^{h^r}}{h^r!} + o(\|p - p_0\|^s).$$

Here $\|p\|$ is the norm in $\mathbf{C}^m$. Denoting these approximations by $\widetilde{C}(p)$, $\widetilde{C}^{-1}(p)$, and $\widetilde{\varphi}(p)$ we can represent the family of matrices $A(p)$ in the form $A(p) = \widetilde{C}(p) A'(\widetilde{\varphi}(p)) \widetilde{C}^{-1}(p) + o(\|p - p_0\|^s)$; that is, the recurrent procedure allows transforming an arbitrary given family of matrices $A(p)$ to the normal form in the vicinity of the point $p = p_0$ with the accuracy up to small terms of an arbitrary order.

Note that Burke and Overton [4] obtained the formulae for calculation specific sums of the first order derivatives of functions $b_i^{kl}(t)(p)$ in the case of one parameter $p \in \mathbf{R}$. These formulae can be derived from expressions (2.4) and (2.5).

2.1. Example. As an example let us consider a one-parameter family of 3×3 matrices $A(z)$ which has at the point $z = 0$ eigenvalues $\lambda_1 = 0$, $\lambda_2 = 2i$ with corresponding Jordan blocks of the order $n_1(\lambda_1) = 2$, $n_1(\lambda_2) = 1$, respectively,

$$A(z) = \begin{pmatrix} 2i + z & -8z & z^2 \\ 2iz & 4iz & 1 - iz^2 \\ 2z^2 & -2z & z^2 \end{pmatrix}.$$

The Jordan form of the matrix $A_0 = A(0)$ and matrices C_0, C_0^{-1} have the form

$$J = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 2i \end{pmatrix}, \quad C_0 = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad C_0^{-1} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}.$$

For the first iteration ($h = 1$, $D^h = d/dz$) we have

$$F = \begin{pmatrix} f_1^{11}(1,1) & f_1^{11}(1,2) & f_{12}^{11}(1,1) \\ f_1^{11}(2,1) & f_1^{11}(2,2) & f_{12}^{11}(2,1) \\ f_{21}^{11}(1,1) & f_{21}^{11}(1,2) & f_2^{11}(1,1) \end{pmatrix} = \begin{pmatrix} 4i & 0 & 2i \\ -2 & 0 & 0 \\ -8 & 0 & 1 \end{pmatrix},$$

$$G = \begin{pmatrix} -4i & 0 & -2i \\ 0 & 4i & 0 \\ 8 & 0 & 0 \end{pmatrix}, \quad X = \begin{pmatrix} 0 & 0 & 1 \\ -4i & 0 & 0 \\ -4i & -2 & 0 \end{pmatrix}.$$

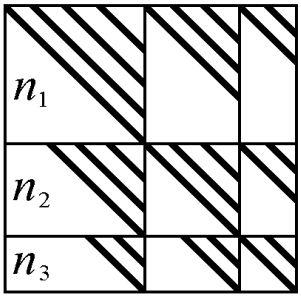

FIG. 2.4. *Block of a matrix commuting with the Jordan form J.*

These matrices are used in (2.4), (2.6), and (2.10) to determine the first derivatives of the desired functions. Then these derivatives are used in the second iteration to find the derivatives $D^h = d^2/dz^2$. As a result, the normal form $A'(p')$ of the family $A(z)$ and, determined by Theorem 2.4, the functions $p' = \varphi(z)$, $C(z)$, $C^{-1}(z)$ have the form

$$A'(p') = \begin{pmatrix} 0 & 1 & 0 \\ b_1(2) & b_1(1) & 0 \\ 0 & 0 & 2i + b_2(1) \end{pmatrix}, \quad p' = (b_1(1), b_1(2), b_2(1))^T,$$

$$b_1(1) = 4iz + 9z^2 + o(z^2), \quad b_1(2) = -2z + o(z^2), \quad b_2(1) = z - 8z^2 + o(z^2),$$

$$C(z) = \begin{pmatrix} -4iz + (2 - 2i)z^2 & -2z - (5 + 1.5i)z^2 & 1 \\ 1 & 0 & z + (2 + 0.5i)z^2 \\ -4iz - 8z^2 & 1 + 5iz^2 & 0 \end{pmatrix} + o(z^2),$$

$$C^{-1}(z) = \begin{pmatrix} -z - (2 + 0.5i)z^2 & 1 - 4iz^2 & -2z^2 \\ -4iz^2 & 4iz + 8z^2 & 1 - 5iz^2 \\ 1 - 4iz^2 & 4iz - (2 - 10i)z^2 & 2z + (5 + 1.5i)z^2 \end{pmatrix} + o(z^2).$$

2.2. Proof of the theorem.

DEFINITION 2.5. *The centralizer of a square matrix X is the set of all matrices commuting with X. The notation is as follows:*

$$Z_X = \{Y : [X, Y] = 0\},$$

where $[X, Y] = XY - YX$ [1, 2, 3].

A centralizer Z_J of the Jordan form J consists of block-diagonal matrices $Y = \text{Diag}\,(Y_1, Y_2, \ldots)$ whose blocks Y_i correspond to the blocks J_i and have the form shown in Figure 2.4 [1, 2, 3, 7]. In Figure 2.4 every slanted segment denotes a sequence of equal numbers, while other elements are all zeros. The centralizer Z_J is a plane in the space of all matrices $\mathbf{C}^{n^2}$ which passes through the zero and identity matrix.

LEMMA 2.6. *For any $n \times n$ matrix X and any i, k, l, t the following equality is valid:*

$$\text{tr}^{(t)}\left([J, X]_i^{kl}\right) = 0.$$

Proof. For any matrix $Y \in Z_J$ we have

$$\begin{aligned} &\operatorname{tr}([J,X]Y) = \operatorname{tr}(JXY - XJY) = \\ &\operatorname{tr}(YJX - JYX) = -\operatorname{tr}([J,Y]X) = 0. \end{aligned} \tag{2.11}$$

Consider the matrix Y which has units on the tth slanted segment (beginning from the largest one) in the block Y_i^{lk} (see Figure 2.4), while the other components are all zeros. Then, using (2.11), we obtain $0 = \operatorname{tr}([J,X]Y) = \operatorname{tr}^{(t)}\big([J,X]_i^{kl}\big)$. ∎

LEMMA 2.7. *For any $n \times n$ matrix G, which satisfies the condition $\operatorname{tr}^{(t)} G_i^{kl} = 0$ for all i,k,l,t, the equation*

$$[J,X] = G \tag{2.12}$$

has the unique solution (2.7), (2.8), *satisfying*

$$\begin{aligned} x_i^{kl}(1,s) &= 0, \qquad k \le l, \\ x_i^{kl}(s, n_l(\lambda_i)) &= 0, \quad k > l, \end{aligned} \tag{2.13}$$

for all i,k,l,s.

Proof. In the case when G is the zero matrix a set of solutions of (2.12) is the centralizer Z_J. To satisfy conditions (2.13) the matrix $X \in Z_J$ must have zeros on the sth slanted segment (beginning from the smallest one for $k \le l$ and from the largest one for $k > l$) of the block X_i^{kl}; see Figure 2.4. Hence, the equation $[J,X] = 0$ has the unique solution $X = 0$ satisfying all conditions (2.13). Due to the linearity of equation (2.12) and conditions (2.13), if two matrices X_1 and X_2 are solutions of (2.12) and (2.13) for nonzero matrix G, then the matrix $X = X_1 - X_2$ satisfies the equations $[J,X] = 0$ and (2.13). Consequently, $X = X_1 - X_2 = 0$; that is, if a solution of (2.12) and (2.13) exists, it is unique.

By substituting the explicit form of J into (2.12) we obtain equations on the elements of the matrix X

$$(\lambda_i - \lambda_j) x_{ij}^{kl}(r,s) + x_{ij}^{kl}(r+1,s) - x_{ij}^{kl}(r,s-1) = g_{ij}^{kl}(r,s), \tag{2.14}$$

where, instead of all elements x_{ij}^{kl} with coordinates $(r+1,s)$ or $(r,s-1)$, which don't belong to the block X_{ij}^{kl}, we take zeros. The fact that (2.7) and (2.8) is a solution to equations (2.12) and (2.13) can be verified by substitution of expressions (2.7) and (2.8) into (2.13) and (2.14). After substitution, equations (2.14) for $i = j$, $r = n_k(\lambda_i)$, $s = n_l(\lambda_i) - t + 1$, $k \le l$ and for $i = j$, $r = t$, $s = 1$, $k > l$ take the form $\operatorname{tr}^{(t)} G_i^{kl} = 0$. They are satisfied by virtue of the conditions of the lemma. Other equations are satisfied identically. ∎

Proof of Theorem 2.4. The proof is divided into three parts according to the items of the theorem. Each part is denoted by a corresponding item number.

Item 3°. Let us take the derivative $D^h, |h| > 0$ from both sides of the equality $C(p)C^{-1}(p) = I$, where I is the identity matrix:

$$\sum_{h_1+h_2=h} C_h^{h_1 h_2} D^{h_1} C \, D^{h_2} C^{-1} = 0, \quad C_h^{h_1 h_2} = \prod_{i=1}^{m} \frac{h^i!}{h_1^i! h_2^i!}.$$

After expressing $C_0 D^h C^{-1}$ in terms of the other summands and multiplying both sides of the equation from the left by C_0^{-1}, we will prove item 3° of the theorem.

Item 1°. Let us take the derivative D^h from both sides of expression (2.2)

$$D^hA = \sum_{h_1+h_2+h_3=h} C_h^{h_1h_2h_3} D^{h_1}C\, D^{h_2}A' D^{h_3}C^{-1}, \quad C_h^{h_1h_2h_3} = \prod_{i=1}^{m} \frac{h^i!}{h_1^i!h_2^i!h_3^i!}.$$

Expressing $C_0D^hA'C_0^{-1}$ in terms of other summands and then multiplying both sides of the equation by C_0^{-1} and C_0 from left and from right, respectively, we obtain

$$D^hA' = C_0^{-1}D^hAC_0 - C_0^{-1} \sum_{\substack{h_1+h_2+h_3=h \\ h_2\neq h}} C_h^{h_1h_2h_3} D^{h_1}C\, D^{h_2}A' D^{h_3}C^{-1}\, C_0.$$

Using equation (2.10), proved above for the term containing D^hC^{-1}, we get

$$D^hA' = [J, C_0^{-1}D^hC] + F, \tag{2.15}$$

where the matrix F is defined in (2.5). Using Lemma 2.6 and taking into account that $\mathrm{tr}^{(t)}(D^hA_i'^{kl}) = \mathrm{tr}^{(t)}(D^hB_i^{kl}) = \alpha_i^{kl}(t)D^hb_i^{kl}(t)$ for $|h| > 0$, we will prove item 1° of the theorem.

Item 2°. Rearranging (2.15), we obtain

$$[J, C_0^{-1}D^hC] = G, \tag{2.16}$$

where a matrix G is defined in (2.9).

Note that $C_0^{-1}D^hC = D^h(C_0^{-1}C)$ is a derivative of the family of matrices $C_J = C_0^{-1}C$, $C_J(p_0) = I$, which describe a change of basis transforming the family $A_J(p) = C_0^{-1}A(p)C_0$ to the normal form, that is,

$$A_J(p) = C_0^{-1}A(p)C_0 = C_0^{-1}C(p)A'(\varphi(p))C^{-1}(p)C_0 = C_J(p)A'(\varphi(p))C_J^{-1}(p).$$

At the point $p = p_0$ the matrix $A_J(p_0) = C_0^{-1}A_0C_0 = J$ is in the Jordan form. In the proof of the versality theorem [1, 2], [3, pp. 238–241] it was shown that in this case the family C_J can be chosen lying on an arbitrary smooth surface of the dimension $n^2 - d$ in the space of all matrices which passes through the identity matrix and transversal at this point to the centralizer Z_J. For each such a surface the family C_J can be chosen in the unique way. In particular, the plane $I + \Pi$, where Π is the set of all matrices X satisfying conditions (2.13), has all these properties. The planes Z_J and $I + \Pi$ are transversal, because the only matrix from Z_J which satisfies conditions (2.13) (intersection of the planes) is the identity matrix and the sum of dimensions of the planes is equal to the dimension of the space n^2. If we choose the plane $I + \Pi$ for determining C_J, we obtain that all derivatives $D^hC_J = C_0^{-1}D^hC = X$ must satisfy conditions (2.13), which can be regarded as normality conditions. Then the formulae of item 2° follow from Lemma 2.7 applied to (2.16) (conditions $\mathrm{tr}^{(t)}G_i^{kl} = \mathrm{tr}^{(t)}(D^hA_i'^{kl}) - \mathrm{tr}^{(t)}F_i^{kl} = \alpha_i^{kl}(t)D^hb_i^{kl}(t) - \mathrm{tr}^{(t)}F_i^{kl} = 0$ are fulfilled by virtue of equality (2.4)). □

Note that instead of normality conditions (2.13) one can take the same amount of any other linearly independent homogeneous equations such that the only matrix from Z_J which satisfies them is the zero matrix. Theorem 2.4 and Lemma 2.7 will remain valid if (2.8) is changed in accordance with the new normality conditions by solving (2.14) for $i = j$, which determines elements of the blocks X_i^{kl}.

The case of families of complex matrices $A(p)$ depending on a vector of real parameters $p \in \mathbf{R}^m$ is the same as considered above except that the holomorphic dependence on parameters is changed to the smooth one. In this case, Theorem 2.4 is valid and allows finding derivatives D^h of functions C, C^{-1}, $b_i^{kl}(t)$ of the order $|h| \le s$, where s is the degree of smoothness of the family $A(p)$.

3. Transformation of families of real matrices to normal forms. Let us consider a family of real matrices $A : P \longrightarrow \mathbf{R}^{n^2}$, $P \subset \mathbf{R}^m$ smoothly depending on a vector of real parameters $p \in \mathbf{R}^m$ and determined in the vicinity of a point $p = p_0$. Let the matrix $A_0 = A(p_0)$ have real eigenvalues λ_i, $i = 1, \ldots, q$ and complex eigenvalues λ_i, $\overline{\lambda_i}$, $i = q+1, q+2, \ldots$ (overline denotes the complex conjugate operation). Then the Jordan form of the matrix A_0 is given by $J = \mathrm{Diag}\,(J_1, \ldots, J_q, J_{q+1}, \overline{J_{q+1}}, J_{q+2}, \overline{J_{q+2}}, \ldots)$, where the blocks J_i correspond to the eigenvalues λ_i and have the form $J_i = \mathrm{Diag}\,(J_i^1, J_i^2, \ldots)$; J_i^k are the Jordan blocks of dimensions $n_k(\lambda_i)$ beginning with the largest one.

Denote by X^{kl}_{ijA}, X^{kl}_{ijB}, X^{kl}_{ijC}, X^{kl}_{ijD} blocks of an arbitrary matrix X of the dimension $n \times n$ which are situated on the intersection of rows and columns belonging to the blocks J_i^k and J_j^l, J_i^k and $\overline{J_j^l}$, $\overline{J_i^k}$ and J_j^l, $\overline{J_i^k}$ and $\overline{J_j^l}$, respectively. Denote elements of these blocks by $x^{kl}_{ijA}(r,s)$, $x^{kl}_{ijB}(r,s)$, $x^{kl}_{ijC}(r,s)$, and $x^{kl}_{ijD}(r,s)$. In the case $i = j$ we will leave only one number in the subscript, e.g., X^{kl}_{iA}, $x^{kl}_{iA}(r,s)$.

Denote by $\mathrm{Rl}\,Y$ a decomplexification of a complex matrix Y [3, pp. 244–245]

$$\mathrm{Rl}\,Y = \begin{pmatrix} \mathrm{Re}\,Y & -\mathrm{Im}\,Y \\ \mathrm{Im}\,Y & \mathrm{Re}\,Y \end{pmatrix}.$$

Define a matrix $J_R = \mathrm{Diag}\,(J_1, \ldots, J_q, \mathrm{Rl}\,J_{q+1}, \mathrm{Rl}\,J_{q+2}, \ldots)$. The matrices J_R and J are connected by the relation $J_R = RJR^{-1}$, where $R = \mathrm{Diag}\,(I_1, \ldots, I_q, I'_{q+1}, I'_{q+2}, \ldots)$, $R^{-1} = \overline{R} = \mathrm{Diag}\,(I_1, \ldots, I_q, \overline{I'_{q+1}}, \overline{I'_{q+2}}, \ldots)$. The blocks I'_j have the form

$$I'_j = \frac{1+i}{2}\begin{pmatrix} I_j & -i\,I_j \\ -i\,I_j & I_j \end{pmatrix}, \quad i = \sqrt{-1},$$

where I_j is the identity matrix of the same dimension as J_j. Let us choose the matrix C_0 transforming A_0 to the Jordan form J (2.1) such that the matrices $C_{R0} = C_0 R^{-1}$ and $C_{R0}^{-1} = RC_0^{-1}$ are real. For this purpose it is sufficient to choose the matrix C_0 so that its columns, passing through the blocks corresponding to real eigenvalues J_j, $j = 1, \ldots, q$, are real, and columns, passing through the blocks corresponding to complex conjugate eigenvalues J_j and $\overline{J_j}$, $j = q+1, q+2, \ldots$, are complex conjugate. This is possible due to the reality of A_0. Then each column of the matrix C_{R0} will be equal to the sum of the real and imaginary parts of the corresponding column of the matrix C_0. Using C_{R0} the matrix A_0 can be transformed to the form J_R

$$A_0 = C_0 J C_0^{-1} = C_{R0} J_R C_{R0}^{-1}.$$

It is shown in [8], [3, pp. 244–245] that the real miniversal deformation $A'_R(p')$, $p' \in \mathrm{R}^d$, to which an arbitrary family of real matrices $A(p)$, $A(p_0) = A_0$ can be transformed by a smooth change of basis $C_R(p)$ and a smooth change of parameters $p' = \varphi(p)$, $\varphi(p_0) = \mathbf{0}$, can be chosen in the form $A'_R(p') = J_R + B_R(p')$, $B_R = \mathrm{Diag}\,(B_1, \ldots, B_q, \mathrm{Rl}\,B_{q+1}, \mathrm{Rl}\,B_{q+2}, \ldots)$. Here B_j is a block corresponding to the block J_j whose elements are all zero, except at the places indicated in Figure 2.3 (a, b, or c). In the blocks B_j, $j = 1, \ldots, q$, the indicated places are filled by independent parameters $b_j^{kl}(t)_a$, and in the blocks B_j, $j = q+1, q+2, \ldots$, by complex numbers $b_j^{kl}(t) = b_j^{kl}(t)_a + ib_j^{kl}(t)_b$, where $b_j^{kl}(t)_a$ and $b_j^{kl}(t)_b$ are independent parameters. Numbering of parameters $b_j^{kl}(t)_a$, $b_j^{kl}(t)_b$ is carried out in the same way as in section 2. Let us introduce families of matrices $C = C_R R$, $C^{-1} = R^{-1}C_R^{-1}$,

$A' = J + B$, and $B = \operatorname{Diag}(B_1, \dots, B_q, B_{q+1}, \overline{B_{q+1}}, B_{q+2}, \overline{B_{q+2}}, \dots)$. Using expressions $A'_R = J_R + B_R = R(J+B)R^{-1} = RA'R^{-1}$, we obtain

$$A(p) = C_R(p)A'_R(\varphi(p))C_R^{-1}(p) = C(p)A'(\varphi(p))C^{-1}(p). \tag{3.1}$$

The family $A'(p')$ has the same structure as the complex miniversal deformation in section 2. This family as well as $A'_R(p')$ is a miniversal deformation to which any family of real matrices $A(p)$, $A(p_0) = A_0$ can be transformed in the vicinity of the point $p = p_0$, but it and the families C, C^{-1} contain complex elements. For derivatives D^h of the functions $p' = \varphi(p)$, $C(p)$, and $C^{-1}(p)$ transforming the family $A(p)$ to the form $A'(p')$ the formulae of Theorem 2.4 are valid if we assume $b_j^{kl}(t) = b_j^{kl}(t)_a$ for $j \le q$ and $b_j^{kl}(t) = b_j^{kl}(t)_a + ib_j^{kl}(t)_b$ for $j > q$. Using the relations $C_R = CR^{-1}$, $C_R^{-1} = RC^{-1}$ and Theorem 2.4, analogous formulae can be found for the derivatives D^hC_R, $D^hC_R^{-1}$, $D^hb_j^{kl}(t)_a$, and $D^hb_j^{kl}(t)_b$.

THEOREM 3.1. *Let $A(p)$, $p \in \mathbf{R}^n$ be a family of real matrices. Then the following formulae are valid for derivatives D^h, $|h| > 0$ of the functions $C_R(p)$, $C_R^{-1}(p)$, $b_j^{kl}(t)_a(p)$, and $b_j^{kl}(t)_b(p)$ transforming the family $A(p)$ to the real miniversal deformation $A'_R(p')$ described above* (3.1)

1°.

$$D^hb_j^{kl}(t)_a = \operatorname{Re}\frac{\operatorname{tr}^{(t)}\left[(R^{-1}F_RR)_{jA}^{kl}\right]}{\alpha_j^{kl}(t)}, \quad D^hb_j^{kl}(t)_b = \operatorname{Im}\frac{\operatorname{tr}^{(t)}\left[(R^{-1}F_RR)_{jA}^{kl}\right]}{\alpha_j^{kl}(t)},$$

$$F_R = C_{R0}^{-1}\Bigg(D^hA - \sum_{\substack{h_1+h_2+h_3=h\\ h_1,h_2,h_3\ne h}} C_h^{h_1h_2h_3}D^{h_1}C_R\,D^{h_2}A'_R\,D^{h_3}C_R^{-1} + A_0\sum_{\substack{h_1+h_2=h\\ h_1,h_2\ne h}} C_h^{h_1h_2}D^{h_1}C_R\,D^{h_2}C_R^{-1}\Bigg)C_{R0}.$$

2°.

$$D^hC_R = C_{R0}RXR^{-1},$$
$$G = R^{-1}(D^hA'_R - F_R)R.$$

3°.

$$D^hC_R^{-1} = -C_{R0}^{-1}\sum_{\substack{h_1+h_2=h\\ h_2\ne h}} C_h^{h_1h_2}D^{h_1}C_R\,D^{h_2}C_R^{-1}.$$

Here elements of the blocks X_{iA}^{kl} and X_{iD}^{kl} are expressed in terms of elements of the blocks G_{iA}^{kl} and G_{iD}^{kl}, respectively, by formulae (2.8), *and elements of other blocks of the matrix X are expressed in terms of elements of the corresponding blocks of the matrix G by formulae* (2.7). *In the last case it is necessary to take into account that the complex conjugate eigenvalues λ_i, $\overline{\lambda_i}$ are considered independently (for example, to obtain the formulae for elements of the block X_{ijC}^{kl}, it is necessary to replace in* (2.7) *$(\lambda_i - \lambda_j)$ by $(\overline{\lambda_i} - \lambda_j)$ and $g_{ij}^{kl}(r_1, s_1)$ by $g_{ijC}^{kl}(r_1, s_1)$).*

Proof. The proof is based on the connection of the real and complex miniversal deformations (3.1). First let us consider a structure of the complex miniversal

deformation $A'(p')$ more thoroughly. As shown above, the matrix A' has a block-diagonal form with blocks A'_{jA}, $j \le q$ and A'_{jA}, A'_{jD}, $j > q$ corresponding to the real and complex eigenvalues $\lambda_j \in \mathbf{R}$, $j \le q$ and λ_j, $\overline{\lambda_j} \in \mathbf{C}$, $j > q$, respectively. The blocks A'_{jA} depend on parameters $b_j^{kl}(t) = b_j^{kl}(t)_a$ for $j \le q$ and on parameters $b_j^{kl}(t) = b_j^{kl}(t)_a + ib_j^{kl}(t)_b$ for $j > q$. The blocks $A'_{jD} = \overline{A'_{jA}}$, $j > q$ depend on parameters $\overline{b_j^{kl}(t)} = b_j^{kl}(t)_a - ib_j^{kl}(t)_b$. Thus, we have a connection between the real and complex miniversal deformations, as well as transformation functions in the form

$$A' = R^{-1}A'_R R, \quad C = C_R R, \quad C^{-1} = R^{-1}C_R^{-1}, \tag{3.2}$$

$$b_j^{kl}(t) = \begin{cases} b_j^{kl}(t)_a, & j \le q, \\ b_j^{kl}(t)_a + ib_j^{kl}(t)_b, & j > q. \end{cases} \tag{3.3}$$

The formulae of theorem 2.4 are valid for derivatives of functions $b_j^{kl}(t)(p)$, $C(p)$, and $C^{-1}(p)$. Combining these formulae with equalities (3.2) and (3.3), we can obtain expressions for derivatives of $b_j^{kl}(t)_a$, $b_j^{kl}(t)_b$, C_R, and C_R^{-1}.

Substituting relations (3.2) into formulae (2.5), (2.6), and (2.9), we obtain

$$F = R^{-1}F_R R, \tag{3.4}$$

$$D^h C_R = C_{R0} R X R^{-1}, \tag{3.5}$$

$$G = R^{-1}(D^h A'_R - F_R)R. \tag{3.6}$$

It follows from expressions (3.3) and Theorem 2.4 that the derivatives $D^h b_j^{kl}(t)_a$ and $D^h b_j^{kl}(t)_b$ can be found by taking the real and imaginary parts of the right-hand side of relation (2.4) and using expression (3.4) for the matrix F. This proves item 1° of the theorem.

Item 2° follows directly from relations (3.5), (3.6), and Theorem 2.4. The fact that the matrix $D^h C_R$ calculated by these formulae will be real can be proved in the following way. Elements of the matrix $G = R^{-1}G_R R$, where $G_R = D^h A'_R - F_R$ is a real matrix, have the properties $g_{ijA}^{kl}(r,s) = \overline{g_{ijD}^{kl}(r,s)}$, $g_{ijB}^{kl}(r,s) = \overline{g_{ijC}^{kl}(r,s)}$. It can be shown that elements of the matrix X obtained from such a matrix G have the same properties. It remains to note that then the matrix RXR^{-1} and, consequently, the matrix $D^h C_R = C_{R0}RXR^{-1}$ will be real.

For the proof of remaining item 3° of the theorem it is sufficient to substitute the relations $C = C_R R$ and $C^{-1} = R^{-1}C_R^{-1}$ into expression (2.10). □

For derivatives of the zero order $h = \mathbf{0}$ we have $D^0 A'_R = J_R$, $D^0 C_R = C_{R0}$, and $D^0 C_R^{-1} = C_{R0}^{-1}$. The recurrent procedure described in Theorem 3.1 allows finding derivatives D^h of the real functions C_R, C_R^{-1}, φ, transforming the family of matrices $A(p)$ to the real miniversal deformation $A'_R(p')$, for any h. Using these derivatives, the real family $A(p)$ can be transformed to the normal form with the accuracy up to $o(\|p - p_0\|^s)$, where s is the degree of smoothness of the family.

3.1. Example. Let us consider a one-parameter family of real matrices $A(x)$ of the order 4×4 having at the point $x = 0$ the pair of complex conjugate eigenvalues

$\lambda = 1 + i$, $\overline{\lambda} = 1 - i$ with corresponding Jordan blocks of the order $n(\lambda) = 2$:

$$A(x) = \begin{pmatrix} 1 - 4x^2 & 1 + x & 2x^2 & 1 \\ -1 + 2x & 1 - x & 1 - 2x^2 & 3x + 2x^2 \\ 2x^2 & 2x^2 & 1 - 2x & -1 + x \\ -x & 3x & 1 + 4x^2 & 1 + x \end{pmatrix}.$$

The normal forms $A'(p')$ and $A'_R(p')$ of this family and the function $p' = \varphi(x)$ determined using the recurrent procedure of Theorem 3.1 (up to $o(x^2)$) have the form

$$A'_R(p') = \begin{pmatrix} 1 & 1 & -1 & 0 \\ b(2)_a & 1 + b(1)_a & -b(2)_b & -1 - b(1)_b \\ 1 & 0 & 1 & 1 \\ b(2)_b & 1 + b(1)_b & b(2)_a & 1 + b(1)_a \end{pmatrix},$$

$$A'(p') = \begin{pmatrix} 1 + i & 1 & 0 & 0 \\ b(2) & 1 + i + b(1) & 0 & 0 \\ 0 & 0 & 1 - i & 1 \\ 0 & 0 & \overline{b(2)} & 1 - i + \overline{b(1)} \end{pmatrix},$$

$$p' = (b(1)_a,\ b(1)_b,\ b(2)_a,\ b(2)_b)^T,$$

$$b(1) = b(1)_a + ib(1)_b = -x - 2x^2 + i\Big(-x - \frac{21}{8}x^2\Big) + o(x^2),$$

$$b(2) = b(2)_a + ib(2)_b = -\frac{x}{2} + \frac{25}{8}x^2 + i\Big(\frac{3}{2}x - \frac{7}{4}x^2\Big) + o(x^2).$$

4. Application to stability theory. As an application of miniversal deformations to the stability theory, let us consider a problem of investigation of the stability domain of a family of real $n \times n$ matrices $A(p)$, $p \in \mathbf{R}^m$ in the vicinity of a singular boundary point. The stability domain of a family of matrices $A(p)$ is a set of values of the vector of parameters p at which all eigenvalues λ of the matrix $A(p)$ have negative real parts $\operatorname{Re}\lambda < 0$. A boundary of the stability domain is characterized by matrices $A(p)$ having pure imaginary eigenvalues $\operatorname{Re}\lambda = 0$, while for all other eigenvalues $\operatorname{Re}\lambda < 0$. Nonsingular points of the stability boundary are characterized by the existence of only one simple zero eigenvalue $\lambda = 0$ or one pair of simple complex conjugate eigenvalues $\lambda = \pm i\omega$ on the imaginary axis. Otherwise the boundary point is singular [2], [3, pp. 255–256]. A linear approximation of the stability domain at the boundary point is described by a tangent cone introduced by Levantovskii [10].

DEFINITION 4.1. *A tangent cone to the stability domain at the boundary point is a set of direction vectors* $e = dp/d\varepsilon\big|_{\varepsilon=0}$ *of the curves* $p(\varepsilon)$, $\varepsilon > 0$, *which start at this point and lie in the stability domain.*

A concept of the tangent cone can be illustrated by a simple example; see Figure 4.1. Here the tangent cone to the stability domain $S = \{p = (p_1, p_2)^T :\ 2p_2 > p_1 + p_1^2,\ 2p_1 + p_1^2 > p_2\}$ at the origin has the form of an angle $K = \{e = (e_1, e_2)^T :$

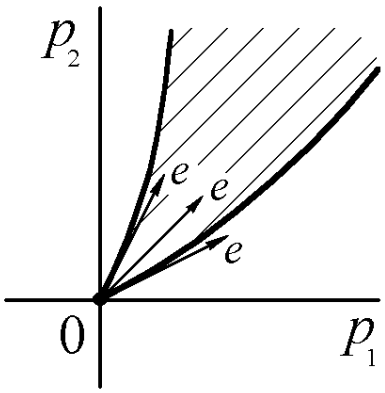

FIG. 4.1. *A tangent cone to the stability domain.*

$2e_2 \geq e_1$, $2e_1 \geq e_2\}$. Thus, the tangent cone consists of all vectors directed into the stability domain or tangent to its boundary.

In [10], using the miniversal deformation tangent cones have been described for some types of singular boundary points up to a linear diffeomorphism. In this section using the miniversal deformations and Theorem 2.4 expressions for tangent cones in the parameter space are found for all types of boundary points. It is shown that for determining the tangent cone we need only the Jordan form of the matrix A and its first derivatives with respect to parameters at the boundary point under consideration.

Let $p = p_0$ be a boundary point of the stability domain and let $\lambda_0 = 0$, $\lambda_j = i\omega_j \neq 0$, $\overline{\lambda_j} = -i\omega_j$, $j = 1, \ldots, k$ be pure imaginary eigenvalues of the matrix $A(p_0)$ (i is the imaginary unit).

THEOREM 4.2. *Assume that each pure imaginary eigenvalue λ_0, λ_j, $\overline{\lambda_j}$, $j = 1, \ldots, k$ of the matrix $A(p_0)$ has exactly one corresponding Jordan block of the dimension n_j, $j = 0, \ldots, k$. If the system of vectors $f(l_1)$, $g_j(l_2)$, $h_j(l_3) \in \mathbf{R}^m$, $l_1 = 1, \ldots, n_0$, $l_2 = 1, \ldots, n_j$, $l_3 = 2, \ldots, n_j$, $j = 1, \ldots, k$, is linearly independent, where*

$$
\begin{aligned}
f(l_1) &= \left(\mathrm{tr}^{(l_1)}[F(1)_0^{11}], \ldots, \mathrm{tr}^{(l_1)}[F(m)_0^{11}]\right)^T, \\
g_j(l_2) &= \left(\mathrm{Re}\,\mathrm{tr}^{(l_2)}[F(1)_j^{11}], \ldots, \mathrm{Re}\,\mathrm{tr}^{(l_2)}[F(m)_j^{11}]\right)^T, \\
h_j(l_3) &= \left(\mathrm{Im}\,\mathrm{tr}^{(l_3)}[F(1)_j^{11}], \ldots, \mathrm{Im}\,\mathrm{tr}^{(l_3)}[F(m)_j^{11}]\right)^T, \\
F(r) &= C_0^{-1}\frac{\partial A}{\partial p_r}C_0,
\end{aligned}
\tag{4.1}
$$

and derivatives are taken at $p = p_0$, then the tangent cone to the stability domain of the family $A(p)$ at the point $p = p_0$ has the form

$$
\begin{aligned}
K \;=\; \{e \in \mathbf{R}^m :\; & \\
& (f(1), e) \leq 0,\ (f(2), e) \leq 0,\ (f(3), e) = \cdots = (f(n_0), e) = 0, \\
& (g_j(1), e) \leq 0,\ (g_j(2), e) \leq 0,\ (g_j(3), e) = \cdots = (g_j(n_j), e) = 0, \\
& (h_j(2), e) = \cdots = (h_j(n_j), e) = 0,\ j = 1, \ldots, k\ \}.
\end{aligned}
\tag{4.2}
$$

Here $(x, y) = x^1y^1 + \cdots + x^my^m$ is the scalar product in $\mathbf{R}^m$. In the case when zero

is not an eigenvalue of the matrix $A(p_0)$ *the expressions containing the vectors* $f(l)$ *have to be excluded from* (4.2).

For the proof of the theorem we need the following lemmas.

LEMMA 4.3. *The tangent cone to the stability domain of the family of polynomials* $x^n - a_1x^{n-1} - \cdots - a_n$ *at the point* $a_1 = \cdots = a_n = 0$ *in the parameter space* $p = (a_1, \ldots, a_n)^T \in \mathbf{R}^n$ *is equal to the set* $\{a_1 \le 0,\ a_2 \le 0,\ a_3 = \cdots = a_n = 0\}$.

LEMMA 4.4. *The tangent cone to the stability domain of the family of polynomials* $z^n - (a_1 + ib_1)z^{n-1} - \cdots - (a_n + ib_n)$ *at the point* $a_1 = b_1 = \cdots = a_n = b_n = 0$ *in the parameter space* $p = (a_1, b_1, \ldots, a_n, b_n)^T \in \mathbf{R}^{2n}$ *is equal to the set* $\{a_1 \le 0,\ b_1 \in \mathbf{R},\ a_2 \le 0,\ b_2 = a_3 = \cdots = a_n = b_n = 0\}$.

A polynomial is said to be stable if real parts of all its roots are negative. Lemmas 4.3 and 4.4 have been formulated and proved in [10].

LEMMA 4.5. *For any* $\alpha_1^j \le 0$, $\alpha_2^j \le 0$, $j = 0, \ldots, k$, *there exists a curve* $q_1(\varepsilon)$, $q_1(0) = \mathbf{0}$ *in the space* $q_1 = (a_{l_1}^{j_1},\ b_{l_2}^{j_2},\ l_2 \ne 1)^T$ *of all coefficients (except* $b_1^1, \ldots, b_1^k$*) of the polynomials*

$$\begin{gathered} x^{n_0} - a_1^0 x^{n_0-1} - \cdots - a_{n_0}^0, \\ z^{n_j} - (a_1^j + ib_1^j)z^{n_j-1} - \cdots - (a_{n_j}^j + ib_{n_j}^j), \quad j = 1, \ldots, k, \end{gathered} \tag{4.3}$$

such that all polynomials (4.3) *are stable along the curve at* $\varepsilon > 0$, *the vector of coefficients* $q_2 = (b_1^1, \ldots, b_1^k)^T$ *is related with* q_1 *and* ε *by an arbitrary given smooth function* $q_2 = Q_2(q_1, \varepsilon)$, $Q_2(\mathbf{0}, 0) = \mathbf{0}$, *and the following conditions are fulfilled:*

$$\begin{gathered} \frac{da_1^j}{d\varepsilon} = \alpha_1^j,\ \frac{da_2^j}{d\varepsilon} = \alpha_2^j,\ \frac{da_3^j}{d\varepsilon} = \cdots = \frac{da_{n_j}^j}{d\varepsilon} = 0,\ j = 0, \ldots, k, \\ \frac{db_2^j}{d\varepsilon} = \cdots = \frac{db_{n_j}^j}{d\varepsilon} = 0,\ j = 1, \ldots, k. \end{gathered} \tag{4.4}$$

Proof. Let us consider polynomials of the form

$$\begin{gathered} (x + \varepsilon^2)^{n_0-2}\big(x^2 + (-\alpha_1^0\varepsilon + \varepsilon^2)x - \alpha_2^0\varepsilon + \varepsilon^2\big), \\ (z + \varepsilon^2)^{n_j-2}\big(z^2 + (-(\alpha_1^j + ib_1^j)\varepsilon + \varepsilon^2)z - \alpha_2^j\varepsilon + \varepsilon^2\big). \end{gathered} \tag{4.5}$$

These polynomials are stable at $\varepsilon > 0$ and their coefficients, obtained after performing multiplication, satisfy conditions (4.4). Expressing these coefficients through $q_2 = (b_1^1\varepsilon, \ldots, b_1^k\varepsilon)^T$, ε and then substituting the obtained expressions into the relation $q_2 = Q_2(q_1, \varepsilon)$, we obtain $q_2 = Q_2'(q_2, \varepsilon)$. Moreover, the matrix of the derivatives $\partial Q_2'/\partial q_2$ is the zero matrix at $\varepsilon = 0$. Hence, by the implicit function theorem the vector q_2 is a smooth function $q_2 = Q_2''(\varepsilon)$ in the vicinity of $\varepsilon = 0$. If we substitute the function $q_2 = (b_1^j)^T = Q_2''(\varepsilon)$ into (4.5), the coefficients of polynomials (4.5) will form the desired curve $q_1 = q_1(\varepsilon)$. □

Proof of Theorem 4.2. Using expression (2.2) the characteristic equation of the matrix $A(p)$ in the vicinity of the point p_0 can be written in the form

$$\det(A(p) - \lambda E) = \det(C(p)A'(\varphi(p))C^{-1}(p) - \lambda E) = \det(A'(\varphi(p)) - \lambda E) = 0,$$

where $A'(p')$ is the miniversal deformation of the matrix $A(p_0)$. Hence, stability of the matrix $A(p)$ is equivalent to stability of the matrix $A'(\varphi(p))$ (normal form) and, by virtue of the block-diagonal structure of A', it is equivalent to simultaneous stability of

all its blocks. The blocks corresponding to eigenvalues of the matrix A_0 with negative real parts are stable at the point p_0 and, consequently, in the vicinity of this point. Thus, stability in the vicinity of p_0 is characterized by stability of the blocks A_0', A_j', $\overline{A_j'}$, $j = 1, \dots, k$, corresponding to pure imaginary eigenvalues or, since the blocks A_j' and $\overline{A_j'}$ are stable or unstable simultaneously (because of complex conjugacy; see section 3), by stability of the blocks A_0', A_j', $j = 1, \dots, k$. Choosing the blocks A_0', A_j' as the blocks of the type (a) (see Figure 2.2), and taking into account that there is only one Jordan block corresponding to each eigenvalue, their characteristic equations take the form

$$\begin{aligned} &\det(A_0' - \lambda E) = \lambda^{n_0} - b_0^{11}(1)_a \lambda^{n_0-1} - \dots - b_0^{11}(n_0)_a = 0, \\ &\det(A_j' - \lambda E) = \eta^{n_j} - (b_j^{11}(1)_a + i\, b_j^{11}(1)_b)\eta^{n_j-1} - \dots \\ &\qquad \dots - (b_j^{11}(n_j)_a + i\, b_j^{11}(n_j)_b) = 0, \\ &\qquad \eta = \lambda - i\,\omega_j, \quad j = 1, \dots, k, \end{aligned} \tag{4.6}$$

where $b_0^{11}(l_1)_a$, $b_j^{11}(l_2)_a$, and $b_j^{11}(l_3)_b$ are parameters of the miniversal deformation smoothly depending on p. By Theorem 2.4, and using expressions (4.1), we get

$$\nabla b_0^{11}(l_1)_a = f(l_1), \quad \nabla b_j^{11}(l_2)_a = g_j(l_2), \quad \nabla b_j^{11}(l_3)_b = h_j(l_3), \tag{4.7}$$

$$\nabla = \left(\frac{\partial}{\partial p_1}, \dots, \frac{\partial}{\partial p_m} \right)^T.$$

Let us consider an arbitrary smooth curve $p = p(\varepsilon)$ with a direction $e = dp/d\varepsilon$. Coefficients of polynomials (4.6) along this curve have the form

$$\begin{aligned} b_0^{11}(l_1)_a(\varepsilon) &= (f(l_1), e)\varepsilon + O(\varepsilon^2), \\ b_j^{11}(l_2)_a(\varepsilon) &= (g_j(l_2), e)\varepsilon + O(\varepsilon^2), \\ b_j^{11}(l_2)_b(\varepsilon) &= (h_j(l_2), e)\varepsilon + O(\varepsilon^2). \end{aligned} \tag{4.8}$$

Applying Lemmas 4.3 and 4.4 to polynomials (4.6) and taking into account expressions (4.8), we obtain that conditions (4.2) are necessary for the curve $p(\varepsilon)$ to lie in the stability domain.

Let us prove that conditions (4.2) are also sufficient. Denote by q a vector whose components are $b_0^{11}(l_1)_a$, $b_j^{11}(l_2)_a$, and $b_j^{11}(l_3)_b$, and by q_1, q_2 the parts of q so that $q_2 = (b_1^{11}(1)_b, \dots, b_k^{11}(1)_b)^T$ and q_1 consists of $d' = n_0 + 2n_1 + \dots + 2n_k - k$ remaining components of the vector q. The vectors q, q_1, and q_2 are connected with p by smooth functions $q = Q(p)$, $q_1 = Q_1(p)$, and $q_2 = Q_2(p)$, which are parts of the mapping $p' = \varphi(p)$. The Jacobian dQ_1/dp is a $d' \times m$ matrix whose rows $f(l_1)$, $g_j(l_2)$, $h_j(l_3)$, $l_3 \neq 1$ form, according to the conditions of the theorem, a linear independent system. Let p_1 be the vector consisting of d' components of the vector p, which corresponds to a linearly independent system of columns of this Jacobian, and denote by p_2 the vector consisting of the remaining components of p. Then $\det[dQ_1/dp_1] \neq 0$ at the point $p = p_0$, and by the implicit function theorem $p_1 = P_1(q_1, p_2)$ in the vicinity of the point $p = p_0$, $q_1 = \mathbf{0}$. By substituting this relation into $q_2 = Q_2(p_1, p_2)$, we get $q_2 = Q_2'(q_1, p_2)$. Let us consider an arbitrary direction e satisfying conditions (4.2) and assume that $p_2 = e_2\varepsilon$, where e_1 and e_2 are the parts of the vector e corresponding to p_1 and p_2, respectively. Then $q_2 = Q_2'(q_1, e_2\varepsilon) = Q_2''(q_1, \varepsilon)$. By Lemma 4.5 there exists

a curve $q_1 = q_1(\varepsilon)$ such that $dq_1/d\varepsilon = (dQ_1/dp)e$, $q_2 = Q_2''(q_1, \varepsilon)$ and all polynomials (4.6) are stable at $\varepsilon > 0$ (conditions (4.4) of the lemma are fulfilled due to (4.2), (4.8)). Then the curve $p = p(\varepsilon)$, $\varepsilon > 0$ such that $p_1 = P_1(q_1(\varepsilon), e_2\varepsilon)$, $p_2 = e_2\varepsilon$ lies in the stability domain of the family $A(p)$ and has the direction e, which was chosen as an arbitrary direction from the set (4.2). □

Theorem 4.2 covers a case when all pure imaginary eigenvalues of $A(p_0)$ are non-derogatory (have only one corresponding Jordan block). In the general case, when some pure imaginary eigenvalues of $A(p_0)$ have several corresponding Jordan blocks, the tangent cone to the stability domain is no longer a product of lines and half-lines as in (4.2). Investigation of this case is much more complicated. However, using an approach presented in the proof of Theorem 4.2, it is possible to find sets of directions belonging to the tangent cone for a boundary point of an arbitrary type.

THEOREM 4.6. *Let $\lambda_0 = 0$, λ_j, $\overline{\lambda_j}$, $j = 1, \dots, k$ be pure imaginary eigenvalues of the matrix $A(p_0)$ and let each eigenvalue λ_j, $j = 0, \dots, k$ have corresponding Jordan blocks of the dimensions $n_1(\lambda_j) \geq n_2(\lambda_j) \geq \cdots$. Assume that the system of vectors $f^{rs}(l_1)$, $g_j^{rs}(l_2)$, $h_j^{rs}(l_3) \in \mathbf{R}^m$ for $r \geq s$ and $l_3 \neq 1$ at $r = s$ is linearly independent, where*

$$
\begin{aligned}
f^{rs}(l_1) &= \Big(\operatorname{tr}^{(l_1)}[F(1)_0^{rs}], \dots, \operatorname{tr}^{(l_1)}[F(m)_0^{rs}]\Big)^T, \\
g_j^{rs}(l_2) &= \Big(\operatorname{Re}\operatorname{tr}^{(l_2)}[F(1)_j^{rs}], \dots, \operatorname{Re}\operatorname{tr}^{(l_2)}[F(m)_j^{rs}]\Big)^T, \\
h_j^{rs}(l_3) &= \Big(\operatorname{Im}\operatorname{tr}^{(l_3)}[F(1)_j^{rs}], \dots, \operatorname{Im}\operatorname{tr}^{(l_3)}[F(m)_j^{rs}]\Big)^T, \\
F(r) &= C_0^{-1}\frac{\partial A}{\partial p_r}C_0,
\end{aligned}
\tag{4.9}
$$

and the derivatives are taken at $p = p_0$. Then the set

$$
\begin{aligned}
K_1 = \{ & e \in \mathbf{R}^m : \\
& (f^{rr}(1), e) \leq 0,\ (f^{rr}(2), e) \leq 0,\ (f^{rr}(3), e) = \cdots = (f^{rr}(n_r(\lambda_0)), e) = 0, \\
& (g_j^{rr}(1), e) \leq 0,\ (g_j^{rr}(2), e) \leq 0,\ (g_j^{rr}(3), e) = \cdots = (g_j^{rr}(n_r(\lambda_j)), e) = 0, \\
& (h_j^{rr}(2), e) = \cdots = (h_j^{rr}(n_r(\lambda_j)), e) = 0, \\
& (f^{rs}(l_1), e) = (g_j^{rs}(l_2), e) = (h_j^{rs}(l_2), e) = 0,\ r > s,\ j = 1, \dots, k\ \}
\end{aligned}
\tag{4.10}
$$

belongs to the tangent cone to the stability domain at the point p_0. Analogously, if the system of vectors (4.9) for $r \leq s$ and $l_3 \neq 1$ at $r = s$ is linearly independent, then the set

$$
\begin{aligned}
K_2 = \{ & e \in \mathbf{R}^m : \\
& (f^{rr}(1), e) \leq 0,\ (f^{rr}(2), e) \leq 0,\ (f^{rr}(3), e) = \cdots = (f^{rr}(n_r(\lambda_0)), e) = 0, \\
& (g_j^{rr}(1), e) \leq 0,\ (g_j^{rr}(2), e) \leq 0,\ (g_j^{rr}(3), e) = \cdots = (g_j^{rr}(n_r(\lambda_j)), e) = 0, \\
& (h_j^{rr}(2), e) = \cdots = (h_j^{rr}(n_r(\lambda_j)), e) = 0, \\
& (f^{rs}(l_1), e) = (g_j^{rs}(l_2), e) = h_j^{rs}(l_2), e) = 0,\ r < s,\ j = 1, \dots, k,\ \}
\end{aligned}
\tag{4.11}
$$

belongs to the tangent cone.

Proof. Characteristic equations of the blocks A'_j in this case cannot be written explicitly as in (4.6). However, if we consider curves $p = p(\varepsilon)$ lying on the surface determined by the equations

$$b_0^{rs}(l_1)_a(p) = b_j^{rs}(l_2)_a(p) = b_j^{rs}(l_2)_b(p) = 0, \quad r > s, \quad j = 1, \dots, k, \tag{4.12}$$

the blocks A'_j will have block-triangular form, and their characteristic equations along these curves will take the form

$$\det(A'_0 - \lambda E) = \prod_r \left(\lambda^{n_r(\lambda_0)} - b_0^{rr}(1)_a \lambda^{n_r(\lambda_0)-1} - \dots - b_0^{rr}(n_r(\lambda_0))_a\right) = 0$$

$$\det(A'_j - \lambda E) = \prod_r \big(\eta^{n_r(\lambda_j)} - (b_j^{rr}(1)_a + i\, b_j^{rr}(1)_b)\eta^{n_r(\lambda_j)-1} - \dots \tag{4.13}$$

$$\dots - (b_j^{rr}(n_r(\lambda_j))_a + i\, b_j^{rr}(n_r(\lambda_j))_b)\big) = 0, \quad \eta = \lambda - i\,\omega_j, \quad j = 1, \dots, k.$$

By Theorem 2.4 and using expressions (4.9), we obtain

$$\nabla b_0^{rs}(l_1)_a = f^{rs}(l_1), \quad \nabla b_j^{rs}(l_2)_a = g_j^{rs}(l_2), \quad \nabla b_j^{rs}(l_3)_b = h_j^{rs}(l_3).$$

Since the system of the vectors $f^{rs}(l_1)$, $g_j^{rs}(l_2)$, $h_j^{rs}(l_2)$, $r > s$ is linearly independent, by the implicit function theorem (4.12) can be solved with respect to a part of variables $p_1 = P_1(p_2)$, where p_1 and p_2 are parts of the vector p. Then the coefficients of polynomials (4.13) depend only on the vector of parameters p_2, and the direction of any curve $p_1 = P_1(p_2(\varepsilon))$, $p_2 = p_2(\varepsilon)$ satisfies all the conditions standing in the last row of (4.10). For the proof of the theorem it is sufficient to find a curve $p_2 = p_2(\varepsilon)$ having an arbitrary chosen direction e_2 such that the vector e consisting of $e_1 = (dP_1/dp_2)e_2$ and e_2 satisfies all conditions (4.10), and all polynomials (4.13) are stable along this curve (conditions in the last row of (4.10) are satisfied automatically due to the choice of e_1). This problem coincides with the problem solved in the proof of Theorem 4.2.

To prove that the set (4.11) belongs to the tangent cone, one should consider curves lying in the surface

$$b_0^{rs}(l_1)_a(p) = b_j^{rs}(l_2)_a(p) = b_j^{rs}(l_2)_b(p) = 0, \quad r < s, \quad j = 1, \dots, k.$$

Then the proof is carried out analogously. ∎

The relations determining sets (4.10) and (4.11) are sufficient conditions that a direction belongs to the tangent cone. Note that Burke and Overton [4] obtained necessary conditions for the stable perturbations of the matrix in the general case, which can be used as necessary conditions that a direction belongs to the tangent cone.

In the nonderogatory case, sets (4.10) and (4.11) coincide and are equal to the tangent cone by Theorem 4.2. Theorems 4.2 and 4.6 give a constructive method for determining the tangent cone to the stability domain at the boundary point. For this purpose we need only information about the matrix A and its first derivatives with respect to parameters at the point under consideration.

In the case of Theorem 4.2 for determining the tangent cone, we need to transform the matrix $A_0 = A(p_0)$ to the Jordan form (2.1) and find the derivatives $\partial A/\partial p_r$ at the point under consideration. Note that components of vectors (4.1) are sums of products of some row of the matrix C_0^{-1} by the matrix $\partial A/\partial p_r$ and by some column of the matrix C_0. Moreover, only the columns and rows of the matrices C_0 and C_0^{-1},

corresponding to the blocks of pure imaginary eigenvalues, are used. This fact can be used to reduce the amount of calculations for determining the tangent cone.

It is well known that the columns of the matrix C_0 corresponding to the block A'_j (in the nonderogatory case) are the eigenvector and associated vectors $u_j^0, \dots, u_j^{n_j-1}$ (also called generalized eigenvectors) of the eigenvalue λ_j

$$\begin{aligned} A_0 u_j^0 &= \lambda_j u_j^0, \\ A_0 u_j^1 &= \lambda_j u_j^1 + u_j^0, \\ &\vdots \\ A_0 u_j^{n_j-1} &= \lambda_j u_j^{n_j-1} + u_i^{n_j-2}. \end{aligned} \tag{4.14}$$

Then the rows of the matrix C_0^{-1} corresponding to the same block are determined as the left eigenvector and associate vectors $v_j^{n_j-1}, \dots, v_j^0$, taken in reverse order,

$$\begin{aligned} v_j^0 A_0 &= \lambda_j v_j^0, \\ v_j^1 A_0 &= \lambda_j v_j^1 + v_j^0, \\ &\vdots \\ v_j^{n_j-1} A_0 &= \lambda_j v_j^{n_j-1} + v_i^{n_j-2}, \end{aligned} \tag{4.15}$$

and satisfying the normalization conditions

$$v_j^0 u_j^{n_j-1} = 1, \quad v_j^l u_j^{n_j-1} = 0, \quad l = 1, \dots, n_j - 1. \tag{4.16}$$

Using these properties of the matrices C_0 and C_0^{-1} expressions (4.1) can be written in the form

$$\begin{aligned} f(l_1) &= \left(\sum_{t=0}^{n_0-l_1} v_0^t \frac{\partial A}{\partial p_1} u_0^{n_0-l_1-t}, \dots, \sum_{t=0}^{n_0-l_1} v_0^t \frac{\partial A}{\partial p_m} u_0^{n_0-l_1-t} \right)^T, \\ g_j(l_2) &= \left(\operatorname{Re} \sum_{t=0}^{n_j-l_2} v_j^t \frac{\partial A}{\partial p_1} u_j^{n_j-l_2-t}, \dots, \operatorname{Re} \sum_{t=0}^{n_j-l_2} v_j^t \frac{\partial A}{\partial p_m} u_j^{n_j-l_2-t} \right)^T, \\ h_j(l_3) &= \left(\operatorname{Im} \sum_{t=0}^{n_j-l_3} v_j^t \frac{\partial A}{\partial p_1} u_j^{n_j-l_3-t}, \dots, \operatorname{Im} \sum_{t=0}^{n_j-l_3} v_j^t \frac{\partial A}{\partial p_m} u_j^{n_j-l_3-t} \right)^T. \end{aligned} \tag{4.17}$$

According to (4.17), for determining the vectors $f(l_1)$, $g_j(l_2)$, and $h_j(l_3)$ we need to know only right and left eigenvectors and associated vectors corresponding to pure imaginary eigenvalues and satisfying normalization conditions (4.16), and the derivatives $\partial A/\partial p_r$, $r = 1, \dots, m$ at the point $p = p_0$.

Analogous expressions can be obtained for vectors (4.9). For this purpose in expressions (4.17) one should substitute $f^{rs}(l_1)$, $g_j^{rs}(l_2)$, $h_j^{rs}(l_3)$, u_{js}^t, v_{jr}^t, n'_0, n'_j instead of $f(l_1)$, $g_j(l_2)$, $h_j(l_3)$, u_j^t, v_j^t, n_0, n_j, respectively, where $n'_0 = \min(n_r(\lambda_0), n_s(\lambda_0))$, $n'_j = \min(n_r(\lambda_j), n_s(\lambda_j))$, and u_{jr}^t v_{jr}^t, $t = 0, \dots, n_r(\lambda_j) - 1$ are right and left eigenvectors and associated vectors corresponding to the Jordan block J_j^r of the eigenvalue λ_j. In this case the normalization conditions for the vectors $u_{jr}^{t_1}$, $v_{jr}^{t_2}$ take the form (4.16), while the normalization conditions for the vectors $u_{jr}^{t_1}$, $v_{js}^{t_2}$, $r \neq s$ are

$$v_{jr}^{n_r(\lambda_j)-1} u_{js}^{n_s(\lambda_j)-t} = 0, \quad t = 1, \dots, n'_j, \quad j = 0, \dots, k.$$

Note that Theorems 4.2 and 4.6 are valid in the case of families of complex matrices smoothly depending on a vector of real parameters, if the vectors $g_j(l_1)$, $h_j(l_2)$, and $g_j^{rs}(l_1)$, $h_j^{rs}(l_2)$ are determined separately for each pure imaginary eigenvalue of the matrix A_0 (also for the zero eigenvalue and for each of the complex conjugate eigenvalues, if any) and the expressions containing the vectors $f(l)$ and $f^{rs}(l)$ are excluded from (4.2), (4.10), and (4.11).

If we consider generic families of matrices [1, 2, 3] the condition of linearly independence of the system of vectors in Theorem 4.2 is satisfied. It follows from the fact that, in the generic case, the codimension of a surface in the parameter space $\mathbf{R}^m$ (stratum), on which all the matrices $A(p)$ have the same type of Jordan structure of pure imaginary eigenvalues of the matrix A_0, is equal to $d' = n_0 + 2n_1 + \cdots + 2n_k - k$ (the number of parameters of the miniversal deformation, which correspond to the blocks of pure imaginary eigenvalues minus the number of nonzero pure imaginary eigenvalues, whose magnitudes are arbitrary on the stratum). There is a field of vectors (4.1) determined on this surface (d' vectors at each point). The condition that the system of these vectors is linearly dependent leads to m equations at each point of the surface, where components of one vector are expressed as a linear combination of corresponding components of the other vectors with $(d' - 1)$ arbitrary coefficients. These equations are equivalent to $(m - d' + 1)$ equations which do not contain these coefficients. But, since the dimension of the stratum is equal to $m - d'$ (less than the number of equations), in the generic case these equations have no solution on the stratum. This means that the system of vectors is linearly independent. The analogous statement is correct in the case of Theorem 4.6. Thus, Theorems 4.2 and 4.6 can be applied to all points of a boundary of the stability domain of a generic family of matrices.

5. Conclusion. In this paper the problem of transformation of families of matrices to the Arnold's and Galin's normal forms (miniversal deformations) is solved. A constructive method determining a change of basis and a change of parameters, transforming a family of real or complex matrices to the normal form in the vicinity of the initial value of the parameter vector, is suggested. Finding the miniversal deformation of a family of matrices and describing the transformation to it represent a complete procedure of transformation to the normal form (2.2). The first step in this procedure is transformation of the matrix $A_0 = A(p_0)$ to the Jordan form (2.1) and finding the miniversal deformation $A'(p')$ according to [1, 2, 3]. Then, using Theorems 2.4 or 3.1, the derivatives of the families $C(p)$, $C^{-1}(p)$ and of the mapping $p' = \varphi(p)$, with respect to the parameters at the point $p = p_0$, are determined. At this step a recurrent procedure is used. Note that the procedure consists of only explicit relations containing elementary arithmetic operations. Using the obtained derivatives, the desired functions $p' = \varphi(p)$ and $C(p)$, $C^{-1}(p)$ (describing a change of parameters and a change of basis) are found as Taylor series. Thus, the procedure of transformation of a matrix family to the normal form is complete.

The spectrum of the normal form $A'(\varphi(p))$ coincides with the spectrum of the family $A(p)$, but $A'(p')$ is a family of sparse matrices depending on parameters in a quite simple way. This makes it efficient to apply normal forms (if the mapping $p' = \varphi(p)$ is known) to investigation of different properties of the spectrum of the family $A(p)$. In section 4 the stability domain of a family of matrices in the vicinity of the singular boundary point $p = p_0$ is studied. In the cases when all pure imaginary eigenvalues of the matrix $A(p_0)$ are nonderogatory, tangent cones to the stability domain at the point $p = p_0$ are found. In the case of an arbitrary Jordan structure

of $A(p_0)$, sufficient conditions, which describe directions belong to the tangent cone, are found. These conditions describe subsets of the tangent cones. It turns out that tangent cones are determined by the right and left eigenvectors and associated vectors corresponding to pure imaginary eigenvalues and the first derivatives of the matrix $A(p)$ with respect to parameters at the point $p = p_0$. Expressions determining the tangent cone are explicit and simple. They can be used in different stability problems studying dependence on parameters.

Moreover, by means of using transformation to the normal form, it is possible to investigate local properties of the spectral radius, to solve the problems of finding eigenvalues of perturbed matrices, etc. In this connection it is convenient to investigate the collapse of nonderogatory multiple eigenvalues. In this case the perturbed eigenvalues are determined as roots of a polynomial whose coefficients are obtained from Theorem 2.4.

Acknowledgments. The author thanks Alexander P. Seyranian for his attention to this work and helpful discussions, and Wolfhard Kliem and Michael L. Overton for useful comments.

CONVERGENCE OF SUBDIVISION SCHEMES ASSOCIATED WITH NONNEGATIVE MASKS*

RONG-QING JIA† AND DING-XUAN ZHOU‡

Abstract. This paper is concerned with refinement equations of the type

$$f = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) f(M \cdot - \alpha),$$

where f is the unknown function defined on the s-dimensional Euclidean space $\mathbb{R}^s$, a is a finitely supported sequence on $\mathbb{Z}^s$, and M is an $s \times s$ dilation matrix with $m := |\det M|$. The solution of a refinement equation can be obtained by using the subdivision scheme associated with the mask. In this paper we give a characterization for the convergence of the subdivision scheme when the mask is nonnegative. Our method is to relate the problem of convergence to m column-stochastic matrices induced by the mask. In this way, the convergence of the subdivision scheme can be determined in a finite number of steps by checking whether each finite product of those column-stochastic matrices has a positive row. As a consequence of our characterization, we show that the convergence of the subdivision scheme with a nonnegative mask depends only on the location of its positive coefficients. Several examples are provided to demonstrate the power and applicability of our approach.

Key words. subdivision schemes, refinement equations, stochastic matrices, convergent matrix products

1. Introduction.

We are interested in functional equations of the form

$$f = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) f(M \cdot - \alpha), \tag{1.1}$$

where f is the unknown function defined on the s-dimensional Euclidean space $\mathbb{R}^s$, a is a finitely supported sequence on $\mathbb{Z}^s$, and M is an $s \times s$ integer matrix such that $\lim_{n\to\infty} M^{-n} = 0$. Equation (1.1) is called a *refinement equation*, and the matrix M is called a *dilation matrix*. Correspondingly, the sequence a is called the *refinement mask*. The support of a is defined as $\operatorname{supp} a := \{\alpha \in \mathbb{Z}^s : a(\alpha) \neq 0\}$. Throughout this paper we assume that the mask a satisfies

$$\sum_{\alpha \in \mathbb{Z}^s} a(\alpha) = m := |\det M|. \tag{1.2}$$

In order to solve the refinement equation (1.1), we start with a compactly supported continuous function ϕ and use the iteration scheme $f_n := Q_a^n \phi$, $n = 0, 1, 2, \ldots$,

where Q_a is the *cascade operator* on $C(\mathbb{R}^s)$ given by

$$Q_a\phi := \sum_{\alpha\in\mathbb{Z}^s} a(\alpha)\phi(M\cdot - \alpha), \qquad \phi \in C(\mathbb{R}^s). \tag{1.3}$$

This iteration scheme is called a *subdivision scheme*. In particular, we choose ϕ to be the function ϕ_0 given by

$$\phi_0(x) := \prod_{j=1}^{s} \chi(x_j) \qquad \text{for } x = (x_1, \ldots, x_s) \in \mathbb{R}^s, \tag{1.4}$$

where

$$\chi(t) = \max\{1 - |t|, 0\}, \qquad t \in \mathbb{R}.$$

We say that the subdivision scheme associated with mask a *converges* (uniformly) if there is a continuous function f such that

$$\lim_{n\to\infty} \|Q_a^n\phi_0 - f\|_\infty = 0,$$

where ϕ_0 is the function given in (1.4). If the subdivision scheme converges, then the limit function f is a solution of the refinement equation.

In many problems arising from computer-aided geometric design, the mask is nonnegative (see [6] and [12]). The purpose of this paper is to give a characterization for the convergence of subdivision schemes associated with nonnegative masks.

Before proceeding further we introduce some notation. Let $\ell(\mathbb{Z}^s)$ denote the linear space of all real sequences on $\mathbb{Z}^s$, and let $\ell_0(\mathbb{Z}^s)$ denote the linear space of all finitely supported sequences on $\mathbb{Z}^s$. For a finite subset K of $\mathbb{Z}^s$, we denote by $\ell(K)$ the linear subspace of $\ell_0(\mathbb{Z}^s)$ consisting of all sequences supported on K. For $\beta \in \mathbb{Z}^s$ we use δ_β to denote the sequence on $\mathbb{Z}^s$ given by

$$\delta_\beta(\alpha) = \begin{cases} 1 & \text{if } \alpha = \beta, \\ 0 & \text{if } \alpha \in \mathbb{Z}^s \setminus \{\beta\}. \end{cases}$$

In particular, we write δ for δ_0. For a vector $y \in \mathbb{Z}^s$ we use ∇_y to denote the difference operator on $\ell(\mathbb{Z}^s)$ given by

$$\nabla_y u = u - u(\cdot - y), \qquad u \in \ell(\mathbb{Z}^s).$$

Let $e_1, \ldots, e_s$ denote the unit coordinate vectors in $\mathbb{R}^s$. For $j = 1, \ldots, s$, we write ∇_j for ∇_{e_j}.

For $\varepsilon \in \mathbb{Z}$, let A_ε denote the bi-infinite matrix given by

$$A_\varepsilon(\alpha, \beta) := a(\varepsilon + M\alpha - \beta), \qquad \alpha, \beta \in \mathbb{Z}^s. \tag{1.5}$$

We also use A_ε to denote the linear operator on $\ell_0(\mathbb{Z}^s)$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}^s} a(\varepsilon + M\alpha - \beta)v(\beta), \qquad v \in \ell_0(\mathbb{Z}^s),\ \alpha \in \mathbb{Z}^s. \tag{1.6}$$

We observe that the set $\mathbb{Z}^s$ is an Abelian group under addition, and $M\mathbb{Z}^s$ is a subgroup of $\mathbb{Z}^s$. Let E be a complete set of representatives of the distinct cosets of the

quotient group $\mathbb{Z}^s/M\mathbb{Z}^s$. A necessary condition (see [2] and [9]) for the subdivision scheme associated with mask a to converge is that a satisfies the *basic sum rule*:

$$\sum_{\beta\in\mathbb{Z}^s} a(\varepsilon + M\beta) = 1 \qquad \forall\, \varepsilon \in E.$$

A finite subset K of $\mathbb{Z}^s$ is said to be *admissible* for A_ε if $\ell(K)$ is invariant under A_ε. For example, if $s = 1$, $M = (2)$, and a is supported in $[0, N]$, where N is a positive integer, then the set $\{0, 1, \ldots, N-1\}$ is admissible for both A_0 and A_1. Suppose G is a finite subset of $\mathbb{Z}^s$. Let $H := MG \cup (-E + \operatorname{supp} a) \cup \{0\}$, and let

$$K := \left(\sum_{n=1}^{\infty} M^{-n} H\right) \cap \mathbb{Z}^s.$$

In other words, an element $\alpha \in \mathbb{Z}^s$ belongs to K if and only if $\alpha = \sum_{n=1}^{\infty} M^{-n} h_n$ for some sequence of elements $h_n \in H$. Then $K \supseteq G$ and K is admissible $\forall\, A_\varepsilon$, $\varepsilon \in E$ (see [9, Lemma 2.3]).

Suppose K is an admissible set for every A_ε, $\varepsilon \in E$, and $\ell(K)$ contains $\nabla_j \delta$ for $j = 1, \ldots, s$. Let $r := \#K$ and $k := 2^{r^2}$. The following theorem gives the main result of this paper.

THEOREM 1.1. *Let a be a nonnegative mask satisfying* (1.2). *Then the subdivision scheme associated with mask a converges if and only if*

(a) *a satisfies the basic sum rule, and*

(b) *for each k-tuple $(\varepsilon_1, \ldots, \varepsilon_k) \in E^k$, the finite matrix $((A_{\varepsilon_1} \cdots A_{\varepsilon_k})(\alpha, \beta))_{\alpha,\beta\in K}$ has a positive row.*

As a consequence of Theorem 1.1 we have the following useful result.

THEOREM 1.2. *Let a and b be two nonnegative masks satisfying the basic sum rule. Suppose $b(\alpha) > 0$ whenever $a(\alpha) > 0$. If the subdivision scheme associated with mask a converges, then the subdivision scheme associated with mask b also converges.*

Proof. For $\varepsilon \in E$, let B_ε be the linear operator on $\ell_0(\mathbb{Z}^s)$ defined in a way similar to (1.6). Let K be a finite subset of $\mathbb{Z}^s$ such that $\ell(K)$ contains $\nabla_j \delta$ for $j = 1, \ldots, s$, and K is admissible $\forall\, A_\varepsilon$ and B_ε, $\varepsilon \in E$. We also use A_ε and B_ε to denote the matrices $(A_\varepsilon(\alpha, \beta))_{\alpha,\beta\in K}$ and $(B_\varepsilon(\alpha, \beta))_{\alpha,\beta\in K}$, respectively. Since the subdivision scheme associated with mask a converges, for each k-tuple $(\varepsilon_1, \ldots, \varepsilon_k) \in E^k$, the matrix $A_{\varepsilon_1} \cdots A_{\varepsilon_k}$ has a positive row, by Theorem 1.1. By the assumption, $b(\alpha) > 0$ whenever $a(\alpha) > 0$. Hence, for $\alpha, \beta \in K$, $(B_{\varepsilon_1} \cdots B_{\varepsilon_k})(\alpha, \beta) > 0$ whenever $(A_{\varepsilon_1} \cdots A_{\varepsilon_k})(\alpha, \beta) > 0$. Thus, for each k-tuple $(\varepsilon_1, \ldots, \varepsilon_k) \in E^k$, the matrix $B_{\varepsilon_1} \cdots B_{\varepsilon_k}$ has a positive row. By using Theorem 1.1 again, we conclude that the subdivision scheme associated with mask b also converges. □

Here is a brief outline of this paper. In section 2 we review some results on stochastic matrices, which will be needed later. The proof of Theorem 1.1 is given in section 3. In section 4 we provide several examples to illustrate applications of Theorems 1.1 and 1.2.

2. Stochastic matrices. A square matrix $(a_{ij})_{1\le i,j\le r}$ is called a *column-stochastic* matrix if

$$a_{ij} \ge 0 \quad \forall\, i, j = 1, \ldots, r \quad \text{and} \quad \sum_{i=1}^{r} a_{ij} = 1 \quad \forall\, j = 1, \ldots, r.$$

The product of two column-stochastic matrices is column-stochastic.

A column-stochastic matrix A is called *scrambling* if each pair of columns of A have positive entries in some common row. In particular, if A is a column-stochastic matrix and has a positive row, then A is scrambling. Scrambling matrices have the property that the product AB is scrambling if one of A and B is scrambling. Similarly, if A and B are two column-stochastic matrices of the same order, then AB has a positive row provided one of A and B does.

We equip $\mathbb{R}^r$ with the ℓ_1-norm defined by

$$\|u\| := \sum_{j=1}^{r} |u_j| \qquad \text{for } u = (u_1, \ldots, u_r)^T \in \mathbb{R}^r.$$

An $r \times r$ matrix A can be viewed as a linear operator on $\mathbb{R}^r$. The norm of A is induced by the norm in $\mathbb{R}^r$:

$$\|A\| := \sup_{\|u\|=1} \|Au\|.$$

A column-stochastic matrix A always has $\|A\| = 1$. Let V be the subspace of $\mathbb{R}^r$ given by

$$V := \left\{ (v_1, \ldots, v_r)^T \in \mathbb{R}^r \,:\, \sum_{j=1}^{r} v_j = 0 \right\}.$$

The norm in V is inherited from the norm in $\mathbb{R}^r$. Clearly, for $1 \le j, k \le r$, the vector $e_j - e_k$ lies in V.

LEMMA 2.1. *A column-stochastic matrix $A = (a_{ij})_{1\le i,j\le r}$ is scrambling if and only if*

$$\|A|_V\| < 1.$$

Proof. If A is not scrambling, then there exist j and k $(j \ne k)$ such that $a_{ij}a_{ik} = 0$ for $i = 1, \ldots, r$. Let $w := e_j - e_k$. Then $\|w\| = 2$ and

$$Aw = \sum_{i=1}^{r} (a_{ij} - a_{ik}) e_i.$$

Since $a_{ij}a_{ik} = 0$ for $i = 1, \ldots, r$, it follows that

$$\|Aw\| = \sum_{i=1}^{r} |a_{ij} - a_{ik}| = \sum_{i=1}^{r} (a_{ij} + a_{ik}) = 2.$$

Consequently, $\|Aw\|/\|w\| = 1$. This shows $\|A|_V\| = 1$.

Now suppose A is a scrambling matrix. For $1 \le j < k \le r$, let $\lambda_{jk} := \|A(e_j - e_k)\|$. Since A is a scrambling matrix, there exists some i such that $a_{ij}a_{ik} > 0$. For this i we have $|a_{ij} - a_{ik}| < a_{ij} + a_{ik}$. It follows that

$$\lambda_{jk} = \|A(e_j - e_k)\| = \sum_{i=1}^{r} |a_{ij} - a_{ik}| < \sum_{i=1}^{r} (a_{ij} + a_{ik}) = 2.$$

Let $\lambda := \max\{\lambda_{jk} : 1 \le j < k \le r\}$. Then $\lambda < 2$. Pick a nonzero vector $v = (v_1, \ldots, v_r)^T$ from the space V. Let

$$J_+ := \{j \in \{1, \ldots, r\} : v_j > 0\} \quad \text{and} \quad J_- := \{j \in \{1, \ldots, r\} : v_j < 0\}.$$

Observe that $\sum_{j=1}^{r} v_j = 0$. We have

$$\sum_{j\in J_+} v_j = -\sum_{j\in J_-} v_j = (1/2)\sum_{j=1}^{r} |v_j| = \|v\|/2.$$

Since $v = -\frac{2}{\|v\|}\sum_{j\in J_+}\sum_{k\in J_-} v_j v_k (e_j - e_k)$, there exist real numbers c_{jk} $(1 \le j < k \le r)$ such that

$$v = \sum_{1\le j<k\le r} c_{jk}(e_j - e_k) \quad \text{and} \quad \sum_{1\le j<k\le r} |c_{jk}| = \sum_{j\in J_+} v_j = \|v\|/2.$$

It follows that

$$\|Av\| \le \sum_{1\le j<k\le r} |c_{jk}|\,\|A(e_j - e_k)\| = \sum_{1\le j<k\le r} |c_{jk}|\lambda_{jk} \le \lambda \sum_{1\le j<k\le r} |c_{jk}| = (\lambda/2)\|v\|.$$

This shows that $\|A|_V\| \le \lambda/2 < 1$, as desired. □

For a nonnegative matrix $A = (a_{ij})_{1\le i,j\le r}$, its *signum* is the matrix of the same size defined by

$$\sigma(A)_{ij} := \begin{cases} 1 & \text{if } a_{ij} > 0, \\ 0 & \text{if } a_{ij} = 0. \end{cases}$$

For two nonnegative matrices A and B of the same size, we have $\sigma(AB) = \sigma(A)\sigma(B)$. There is a total of 2^{r^2} distinct signum matrices of order r.

A finite multiset of square matrices $\Sigma = \{A_i : i = 1, \ldots, m\}$ is called an *RCP* set (right-convergent product set) if all infinite products with each element drawn from Σ converge.

The following result was established in [14, Theorem 2.1]. Also, see [4, Theorem 6.1] and the references cited there.

LEMMA 2.2. *Let $\Sigma = \{A_i : i = 1, \ldots, m\}$ be an RCP set of column-stochastic matrices. Suppose that, for each sequence $(\varepsilon_n)_{n=1,2,\ldots}$ $(1 \le \varepsilon_n \le m,\ n = 1, 2, \ldots)$, all the columns of the limit matrix*

$$L := \lim_{n\to\infty} A_{\varepsilon_1} \cdots A_{\varepsilon_n}$$

are the same. Then there exists a positive integer $k \le 2^{r^2}$ such that $A_{\varepsilon_1} \cdots A_{\varepsilon_k}$ possesses a positive row $\forall\, \varepsilon_1, \ldots, \varepsilon_k \in \{1, \ldots, m\}$.

Proof. Let $k := 2^{r^2}$. Among the $k+1$ matrices $A_{\varepsilon_1} \cdots A_{\varepsilon_l}$, $l = 1, \ldots, k+1$, there exist two matrices having the same signum. In other words, there exist two integers p and q, $1 \le p < q \le k+1$, such that

$$\sigma(A_{\varepsilon_1} \cdots A_{\varepsilon_p}) = \sigma(A_{\varepsilon_1} \cdots A_{\varepsilon_q}).$$

Let $A := A_{\varepsilon_1} \cdots A_{\varepsilon_p}$ and $B := A_{\varepsilon_{p+1}} \cdots A_{\varepsilon_q}$. Then $\sigma(A) = \sigma(AB)$. For $n = 2, 3, \ldots$, we have

$$\sigma(AB^n) = \sigma((AB)B^{n-1}) = \sigma(AB)\sigma(B^{n-1}) = \sigma(A)\sigma(B^{n-1}) = \sigma(AB^{n-1}).$$

Consequently, $\sigma(AB^n) = \sigma(AB^{n-1}) = \cdots = \sigma(A)$.

Since Σ is an RCP set, $\lim_{n\to\infty} AB^n$ exists. Let $G = (g_{ij})_{1\le i,j\le r}$ be the limit matrix. Then G is a column-stochastic matrix. It follows that $g_{i1} > 0$ for some i. By

our hypothesis, all the columns of G are the same. Hence, $g_{ij} = g_{i1} > 0 \ \ \forall\, j = 1, \ldots, r$. In other words, row i of the matrix G is positive. But $G := \lim_{n\to\infty} AB^n$. So row i of the matrix AB^n is positive for sufficiently large n. On the other hand, $\sigma(A) = \sigma(AB^n)$. It follows that row i of the matrix $A = A_{\varepsilon_1} \cdots A_{\varepsilon_p}$ is positive. Note that $p < q \le k+1$ implies $p \le k$. Consequently, row i of the matrix

$$A_{\varepsilon_1} \cdots A_{\varepsilon_k} = \left(A_{\varepsilon_1} \cdots A_{\varepsilon_p}\right)\left(A_{\varepsilon_{p+1}} \cdots A_{\varepsilon_k}\right)$$

is positive. Since this is true for all possible choices of $(\varepsilon_1, \ldots, \varepsilon_k) \in \{1, \ldots, m\}^k$, the proof of the lemma is complete. □

It was pointed out in [4, Theorem 6.1] that, for a finite set $\Sigma = \{A_1, \ldots, A_m\}$ of $r \times r$ column-stochastic matrices, the following two conditions are equivalent:

(i) There exists a positive integer μ such that $\forall\, n \ge \mu$ all products $A_{\varepsilon_1} \cdots A_{\varepsilon_n}$ $(1 \le \varepsilon_1, \ldots, \varepsilon_n \le m)$ have a positive row.

(ii) There exists a positive integer ν such that $\forall\, n \ge \nu$ all products $A_{\varepsilon_1} \cdots A_{\varepsilon_n}$ $(1 \le \varepsilon_1, \ldots, \varepsilon_n \le m)$ are scrambling.

It was shown in [15, Theorem 4] that if the statement in (ii) is true, then it holds with $\nu \le (3^r - 2^{r+1} + 1)/2$ and this bound is sharp. Thus, condition (b) in Theorem 1.1 can be replaced by the statement in (ii) with $\nu = (3^r - 2^{r+1} + 1)/2$. This reduces the complexity of computation in checking the convergence of the subdivision scheme.

3. Convergence of subdivision schemes. This section is devoted to a proof of Theorem 1.1.

The joint spectral radius of matrices introduced in [16] was used in [3] to investigate refinement equations. Let us recall the definition of the joint spectral radius. Suppose $\mathcal{A}$ is a finite collection of linear operators on a *finite-dimensional* vector space V. A vector norm $\|\cdot\|$ on V induces a norm on the linear operators on V as follows. For a linear operator A on V, define

$$\|A\| := \max_{\|v\|=1} \{\|Av\|\}.$$

For a positive integer n we denote by $\mathcal{A}^n$ the Cartesian power of $\mathcal{A}$:

$$\mathcal{A}^n = \{(A_1, \ldots, A_n) : A_1, \ldots, A_n \in \mathcal{A}\}.$$

When $n = 0$, we interpret $\mathcal{A}^0$ as the set $\{I\}$, where I is the identity mapping on V. Let

$$\|\mathcal{A}^n\|_\infty := \max\{\|A_1 \cdots A_n\| : (A_1, \ldots, A_n) \in \mathcal{A}^n\}.$$

Then the joint spectral radius of $\mathcal{A}$ is defined to be

$$\rho(\mathcal{A}) := \lim_{n\to\infty} \|\mathcal{A}^n\|_\infty^{1/n}.$$

It is easily seen that this limit indeed exists, and

$$\lim_{n\to\infty} \|\mathcal{A}^n\|_\infty^{1/n} = \inf_{n\ge 1} \|\mathcal{A}^n\|_\infty^{1/n}.$$

Now let M be a dilation matrix with $m := |\det M|$, and let a be a refinement mask satisfying (1.2) (a is not necessarily nonnegative). For $\varepsilon \in E$, let A_ε be the bi-infinite matrix given in (1.5). We also view A_ε as the linear operator on $\ell_0(\mathbb{Z}^s)$ defined

in (1.6). Suppose K is an admissible set for every A_ε, $\varepsilon \in E$, and $\ell(K)$ contains $\nabla_j \delta$ for $j = 1, \dots, s$. Let

$$V := \left\{ v \in \ell(K) : \sum_{\alpha \in \mathbb{Z}^s} v(\alpha) = 0 \right\}. \tag{3.1}$$

It was proved in [9, Theorem 3.3] that the subdivision scheme associated with a converges if and only if a satisfies the basic sum rule and $\rho(\{A_\varepsilon|_V : \varepsilon \in E\}) < 1$.

The *subdivision operator* S_a associated with a (see [2]) is the linear operator on $\ell(\mathbb{Z}^s)$ given by

$$S_a u(\alpha) := \sum_{\beta \in \mathbb{Z}^s} a(\alpha - M\beta) u(\beta), \qquad u \in \ell(\mathbb{Z}^s),\ \alpha \in \mathbb{Z}^s.$$

Let Q_a be the cascade operator defined in (1.3). Then for $\phi \in C(\mathbb{R}^s)$ we have

$$Q_a^n \phi = \sum_{\alpha \in \mathbb{Z}^s} S_a^n \delta(\alpha) \phi(M^n \cdot - \alpha). \tag{3.2}$$

This can be easily proved by induction on n.

The following lemma was first proved in [7]. For the reader's convenience, we repeat the proof given in [9].

LEMMA 3.1. *Suppose that α can be written as $\varepsilon_1 + M\varepsilon_2 + \cdots + M^{n-1}\varepsilon_n + M^n\gamma$, where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n, \gamma \in \mathbb{Z}^s$. Then for any $\beta \in \mathbb{Z}^s$,*

$$S_a^n \delta(\alpha - \beta) = A_{\varepsilon_n} \cdots A_{\varepsilon_1}(\gamma, \beta).$$

Proof. The proof proceeds by induction on n. For $n = 1$ and $\alpha = \varepsilon_1 + M\gamma$, we have

$$S_a \delta(\alpha - \beta) = a(\varepsilon_1 + M\gamma - \beta) = A_{\varepsilon_1}(\gamma, \beta).$$

Suppose $n > 1$ and the lemma has been verified for $n - 1$. For $\alpha = \varepsilon_1 + M\alpha_1$, where $\alpha_1, \varepsilon \in \mathbb{Z}^s$, we have

$$S_a^n \delta(\alpha - \beta) = \sum_{\eta \in \mathbb{Z}^s} a(\alpha - \beta - M\eta) S_a^{n-1} \delta(\eta) = \sum_{\eta \in \mathbb{Z}^s} a(\varepsilon_1 + M\eta - \beta) S_a^{n-1} \delta(\alpha_1 - \eta). \tag{3.3}$$

Suppose $\alpha_1 = \varepsilon_2 + \cdots + M^{n-2}\varepsilon_n + M^{n-1}\gamma$. Then by the induction hypothesis we have

$$S_a^{n-1} \delta(\alpha_1 - \eta) = A_{\varepsilon_n} \cdots A_{\varepsilon_2}(\gamma, \eta).$$

This in connection with (3.3) gives

$$S_a^n \delta(\alpha - \beta) = \sum_{\eta \in \mathbb{Z}^s} A_{\varepsilon_n} \cdots A_{\varepsilon_2}(\gamma, \eta) A_{\varepsilon_1}(\eta, \beta) = A_{\varepsilon_n} \cdots A_{\varepsilon_2} A_{\varepsilon_1}(\gamma, \beta),$$

thereby completing the induction procedure. □

LEMMA 3.2. *Suppose the subdivision scheme associated with mask a converges to a limit function f on $\mathbb{R}^s$. Then for any sequence $(\varepsilon_n)_{n=1,2,\dots}$ in E,*

$$\lim_{n \to \infty} A_{\varepsilon_1} \cdots A_{\varepsilon_n}(\alpha, \beta) = f(x + \alpha) \qquad \forall\, \alpha, \beta \in \mathbb{Z}^s, \tag{3.4}$$

where $x := \sum_{j=1}^{\infty} M^{-j}\varepsilon_j$.

Proof. For $n = 1, 2, \ldots$, let $\phi_n := Q_a^n \phi_0$, where ϕ_0 is the function given in (1.4). By (3.2) we have

$$\phi_n(x) = \sum_{\beta \in \mathbb{Z}^s} (S_a^n \delta)(\beta) \phi_0(M^n x - \beta), \qquad x \in \mathbb{R}^s.$$

Write a_n for $S_a^n \delta$, $n = 1, 2, \ldots$. Setting $x = M^{-n}\alpha$ for $\alpha \in \mathbb{Z}^s$ in the above equation, we obtain

$$\phi_n(M^{-n}\alpha) = a_n(\alpha), \qquad \alpha \in \mathbb{Z}^s. \tag{3.5}$$

Let $(\varepsilon_n)_{n=1,2,\ldots}$ be a sequence in E. By Lemma 3.1 we have

$$A_{\varepsilon_1} \cdots A_{\varepsilon_n}(\alpha, \beta) = a_n\left(\varepsilon_n + M\varepsilon_{n-1} + \cdots + M^{n-1}\varepsilon_1 + M^n\alpha - \beta\right), \qquad \alpha, \beta \in \mathbb{Z}^s.$$

This in connection with (3.5) yields

$$A_{\varepsilon_1} \cdots A_{\varepsilon_n}(\alpha, \beta) = \phi_n\left(\alpha + M^{-1}\varepsilon_1 + \cdots + M^{-n+1}\varepsilon_{n-1} + M^{-n}\varepsilon_n - M^{-n}\beta\right). \tag{3.6}$$

But

$$M^{-1}\varepsilon_1 + \cdots + M^{-n+1}\varepsilon_{n-1} + M^{-n}\varepsilon_n - M^{-n}\beta \to x \quad \text{as } n \to \infty.$$

Moreover, since the subdivision scheme associated with mask a converges to f, we have $\|\phi_n - f\|_\infty \to 0$ as $n \to \infty$. Letting n go to ∞ in (3.6), we obtain (3.4), as desired. □

Now let a be a nonnegative mask satisfying the basic sum rule. Suppose K is a finite subset of $\mathbb{Z}^s$ such that K is admissible $\forall\, A_\varepsilon$, $\varepsilon \in E$. Since a satisfies the basic sum rule, we have

$$\sum_{\alpha \in \mathbb{Z}^s} a(\varepsilon + M\alpha - \beta) = 1 \qquad \forall\, \beta \in K.$$

But $\ell(K)$ is invariant under A_ε. So $\beta \in K$ and $a(\varepsilon + M\alpha - \beta) \neq 0$ implies $\alpha \in K$. Consequently,

$$\sum_{\alpha \in K} a(\varepsilon + M\alpha - \beta) = \sum_{\alpha \in \mathbb{Z}^s} a(\varepsilon + M\alpha - \beta) = 1 \qquad \forall\, \beta \in K.$$

This shows that the matrix $(A_\varepsilon(\alpha, \beta))_{\alpha,\beta \in K}$ is a column-stochastic matrix. Lemma 3.2 tells us that $\{(A_\varepsilon(\alpha, \beta))_{\alpha,\beta \in K} : \varepsilon \in E\}$ is an RCP set.

We are in a position to establish the main result of this paper.

Proof of Theorem 1.1. Suppose K is an admissible set for every A_ε, $\varepsilon \in E$, and $\ell(K)$ contains $\nabla_j \delta$ for $j = 1, \ldots, s$. The norm on $\ell(K)$ is chosen to be the ℓ_1-norm. Let V be the subspace of $\ell(K)$ given in (3.1). Let $r := \#K$ and $k := 2^{r^2}$. We also use A_ε to denote the matrix $(A_\varepsilon(\alpha, \beta))_{\alpha,\beta \in K}$. Suppose that conditions (a) and (b) in Theorem 1.1 are satisfied. In particular, for each k-tuple $(\varepsilon_1, \ldots, \varepsilon_k) \in E^k$, the finite matrix $A_{\varepsilon_1} \cdots A_{\varepsilon_k}$ has a positive row. By Lemma 2.1 we have

$$\|(A_{\varepsilon_1} \cdots A_{\varepsilon_k})\,|_V\| < 1.$$

It follows that

$$\rho(\{A_\varepsilon|_V : \varepsilon \in E\}) < 1.$$

Therefore, the subdivision scheme associated with mask a converges.

Suppose conversely that the subdivision scheme associated with mask a converges. Then $\{A_\varepsilon : \varepsilon \in E\}$ is an RCP set. Moreover, from (3.4) we see that, for each sequence $(\varepsilon_n)_{n=1,2,\ldots}$ in E, all the columns of the limit matrix

$$\lim_{n\to\infty} A_{\varepsilon_1} \cdots A_{\varepsilon_n}$$

are the same. By Lemma 2.2 we conclude that, for each k-tuple $(\varepsilon_1, \ldots, \varepsilon_k) \in E^k$, the finite matrix $A_{\varepsilon_1} \cdots A_{\varepsilon_k}$ has a positive row. □

4. Examples. In this section, we give four examples to illustrate applications of Theorems 1.1 and 1.2.

Our first example is concerned with the refinement equation

$$\phi(x) = \sum_{j=0}^{N} a(j)\phi(2x - j), \qquad x \in \mathbb{R},$$

where N is an integer greater than 1. Suppose that the mask a is nonnegative and satisfies the basic sum rule. In [13, Corollary 5.1], the convergence of the subdivision scheme was established under the condition that $a(j) > 0$ for $j = 0, 1, \ldots, N$. In [8] this condition was relaxed to $a(j) > 0$ for $j = 0, 1, N-1, N$. The following example gives a more general result, which was also obtained in [11, Theorem 8] by using a different method.

EXAMPLE 4.1. *Suppose that the mask a is nonnegative and satisfies the basic sum rule. Then the subdivision scheme associated with mask a converges, provided $0 < a(0) < 1$, $a(1) > 0$, and $0 < a(N) < 1$.*

Proof. Let $K := \{0, 1, \ldots, N-1\}$. Then $\nabla\delta \in \ell(K)$ and K is admissible for both A_0 and A_1. Let

$$A_\varepsilon := (a(\varepsilon + 2i - j))_{i,j=0}^{N-1}, \qquad \varepsilon = 0, 1.$$

By Theorem 1.1, it suffices to show that the matrix $A_{\varepsilon_1} A_{\varepsilon_2} \cdots A_{\varepsilon_N}$ has a positive row for each $(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_N) \in \{0, 1\}^N$.

We claim that for $2^n \ge N - 1$, $\varepsilon_1 = 1$, and $\varepsilon_2, \ldots, \varepsilon_n \in \{0, 1\}$,

$$A_{\varepsilon_1} A_{\varepsilon_2} \cdots A_{\varepsilon_n}(0, j) > 0, \qquad j = 0, 1, \ldots, N-1.$$

To justify our claim, we set $j_n := j$ and $j_{k-1} := \lfloor (j_k + 1 - \varepsilon_k)/2 \rfloor$ for $k = n, \ldots, 2$, where $\lfloor x \rfloor$ denotes the integer part of a real number x. By our choice of j_k we have $0 \le \varepsilon_k + 2j_{k-1} - j_k \le 1$ for $k = 2, \ldots, n$; hence $A_{\varepsilon_k}(j_{k-1}, j_k) = a(\varepsilon_k + 2j_{k-1} - j_k) > 0$. Moreover, we have

$$2^n j_1 \le 2^{n-1} j_2 + 2^{n-1} \le \cdots \le j_n + 1 + \cdots + 2^{n-1} < j_n + 2^n \le 2^{n+1}.$$

It follows that $0 \le j_1 \le 1$. Consequently, $A_1(0, j_1) = a(1 - j_1) > 0$. Therefore, we obtain

$$A_{\varepsilon_1} A_{\varepsilon_2} \cdots A_{\varepsilon_n}(0, j) \ge A_1(0, j_1) A_{\varepsilon_2}(j_1, j_2) \cdots A_{\varepsilon_n}(j_{n-1}, j_n) > 0.$$

Similarly, if $2^n \ge N - 1$, then $A_0^n(1, j) > 0$ for $j = 1, \ldots, N-1$. Indeed, set $j_n := j$ and $j_{k-1} := \lfloor (j_k + 1)/2 \rfloor$ for $k = n, \ldots, 2$. Then $j_1 = 1$ and

$$A_0^n(1, j) \ge A_0(1, j_1) A_0(j_1, j_2) \cdots A_0(j_{n-1}, j_n) > 0.$$

Since the mask a satisfies the basic sum rule, there exists a positive integer l such that $2l \le N$ and $a(2l) > 0$. It follows that $A_0(l,0) = a(2l) > 0$ and

$$A_0^{n+1}(1,0) \ge A_0^n(1,l)A_0(l,0) > 0.$$

Now consider the product $A_{\varepsilon_1} \cdots A_{\varepsilon_N}$, where $\varepsilon_1, \ldots, \varepsilon_N \in \{0,1\}$. Let $n := \lfloor N/2 \rfloor$. Then $2^n \ge N-1$. If $\varepsilon_1 = \cdots = \varepsilon_n = \varepsilon_{n+1} = 0$, then row 1 of $A_{\varepsilon_1} \cdots A_{\varepsilon_{n+1}} = A_0^{n+1}$ is positive. Otherwise, $\varepsilon_i = 1$ for some i, $1 \le i \le n+1$. Note that the length of the product $A_{\varepsilon_i} \cdots A_{\varepsilon_N}$ is $N - i + 1 \ge N - (n+1) + 1 \ge n$. By what has been proved, row 0 of $A_{\varepsilon_i} \cdots A_{\varepsilon_N}$ is positive. In both cases, $A_{\varepsilon_1} \cdots A_{\varepsilon_N}$ has a positive row. □

EXAMPLE 4.2. *Consider the refinement equation*

$$\phi(x) = \sum_{j \in \mathbb{Z}} a(j)\phi(mx - j), \qquad x \in \mathbb{R},$$

where m is an integer greater than 1. Suppose that the mask a is nonnegative and supported on $[0,N]$, where N is an integer and $N \ge 2m-1$. In addition, we assume that

$$a(j) > 0 \qquad \text{for } j = 0, \ldots, m-1 \quad \text{or} \quad j = N-m+1, \ldots, N,$$

and a satisfies the basic sum rule:

$$\sum_{j \in \mathbb{Z}} a(mj) = \sum_{j \in \mathbb{Z}} a(mj+1) = \cdots = \sum_{j \in \mathbb{Z}} a(mj+m-1) = 1.$$

Then the subdivision scheme associated with mask a converges.

Proof. Let b be the mask given by

$$b(0) = \cdots = b(m-1) = 1/2, \qquad b(N-m+1) = \cdots = b(N) = 1/2,$$

and $b(j) = 0$ for $j \in \mathbb{Z} \setminus \{0, \ldots, m-1, N-m+1, \ldots, N\}$. By Theorem 1.2, in order to prove that the subdivision scheme associated with mask a converges, it suffices to show that the subdivision scheme associated with mask b converges.

The symbol of b is

$$\tilde{b}(z) := \sum_{j=0}^{N} b(j)z^j = \frac{1}{2}(1 + z + \cdots + z^{m-1})(1 + z^{N-m+1}).$$

For $n = 1, 2, \ldots$, let $b_n := S_b^n \delta$, where S_b is the subdivision operator associated with b. It is easily seen that

$$\tilde{b}_n(z) = \tilde{b}(z)\tilde{b}(z^m) \cdots \tilde{b}(z^{m^{n-1}}).$$

Let ∇ denote the difference operator on $\ell(\mathbb{Z})$ given by $\nabla u := u - u(\cdot - 1)$ for $u \in \ell(\mathbb{Z})$. Then the symbol of ∇b_n is

$$\widetilde{\nabla b_n}(z) = (1-z)\tilde{b}_n(z) = \left(\frac{1}{2}\right)^n \left(1 - z^{m^n}\right) \prod_{k=0}^{n-1} \left(1 + z^{(N-m+1)m^k}\right).$$

We observe that $\prod_{k=0}^{n-1}(1 + z^{(N-m+1)m^k})$ is a polynomial of z whose coefficients are either 0 or 1. By using the expression of $\widetilde{\nabla b_n}(z)$ we obtain

$$|\nabla b_n(j)| \le (1/2)^n \cdot 2 = (1/2)^{n-1}.$$

Hence, we have the following estimate for the ℓ_∞-norm of the sequence ∇b_n:

$$(1/2)^n \le \|\nabla b_n\|_\infty \le (1/2)^{n-1}, \qquad n = 1, 2, \ldots.$$

It follows that

$$\lim_{n\to\infty} \|\nabla b_n\|_\infty^{1/n} = 1/2 < 1.$$

By Theorem 3.2 of [9] or [10], we conclude that the subdivision scheme associated with mask b converges. □

EXAMPLE 4.3. *Let X be a multiset of vectors $x^1, \ldots, x^n$ in $\mathbb{R}^s$ whose components are integers. We also use X to denote the $s \times n$ matrix with $x^1, \ldots, x^n$ as its columns. We say that X is* unimodular *if each $s \times s$ submatrix of X has determinant -1, 0, 1. The zonotope generated by the vectors in X is defined by*

$$Z[X] := \left\{ \sum_{j=1}^n t_j x^j \ : \ 0 \le t_1, \ldots, t_n \le 1 \right\}.$$

Let a be a nonnegative sequence on $\mathbb{Z}^s$ such that $a(\alpha) > 0$ if and only if $\alpha \in \mathbb{Z}^s \cap Z[X]$. Suppose a satisfies the basic sum rule. Then the subdivision scheme associated with mask a converges, provided the matrix X is unimodular and $X \setminus x^j$ spans $\mathbb{R}^s$ for every $j = 1, \ldots, n$.

Proof. Let B_X be the box spline associated with X. Precisely, B_X is the distribution on $\mathbb{R}^s$ given by

$$\langle B_X, \varphi \rangle := \int_{[0,1]^n} \varphi\left(u_1 x^1 + \cdots + u_n x^n\right) \, du_1 \cdots du_n, \qquad \varphi \in C(\mathbb{R}^s).$$

By our assumption, $X \setminus x^j$ spans $\mathbb{R}^s$ for every $j = 1, \ldots, n$. Hence, B_X is a compactly supported continuous function. Moreover, B_X is refinable:

$$B_X(x) = \sum_{\alpha\in\mathbb{Z}^s} b(\alpha) B_X(2x - \alpha), \qquad x \in \mathbb{R}^s,$$

where the mask b is nonnegative and $b(\alpha) > 0$ if and only if $\alpha \in \mathbb{Z}^s \cap Z[X]$. Since X is unimodular, the subdivision scheme associated with mask b converges (see, e.g., Theorem 23 in [1, Chapter 7]). In particular, b satisfies the basic sum rule. Since $a(\alpha) > 0$ whenever $b(\alpha) > 0$, by Theorem 1.2 we conclude that the subdivision scheme associated with mask a converges. □

The subdivision scheme associated with a mask supported on a central zonotope was discussed in [2]. Let a be a nonnegative mask on $\mathbb{Z}^s$ satisfying the basic sum rule. Suppose that $a(\alpha) > 0$ if and only if $\alpha \in \mathbb{Z}^s \cap Z[X \cup (-X)]$. It was proved in [2, Theorem 3.4] that the subdivision scheme associated with mask a converges, provided X is unimodular and X spans $\mathbb{R}^s$. Clearly, the conclusion in Example 4.3 extends their result.

EXAMPLE 4.4. *Consider the refinement equation*

$$f(x) = \sum_{\alpha\in\mathbb{Z}^2} a(\alpha) f(Mx - \alpha), \qquad x \in \mathbb{R}^2,$$

where

$$M = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

Let t be a real number such that $0 < t < 1$. Suppose that $a(0,0) = 1$, $a(1,0) = t$, $a(0,1) = 1 - t$, and $a(\alpha) = 0$ for $\alpha \in \mathbb{Z}^2 \setminus \{(0,0),(1,0),(0,1)\}$. Then the subdivision scheme associated with mask a and dilation matrix M converges.

Proof. By Theorem 1.2 it suffices to deal with the special case $t = 1/2$. Let A_0 and A_1 be the linear operators on $\ell_0(\mathbb{Z}^2)$ given by

$$A_0 v(\alpha) = \sum_{\beta \in \mathbb{Z}^2} a(M\alpha - \beta) v(\beta) \quad \text{and} \quad A_1 v(\alpha) = \sum_{\beta \in \mathbb{Z}^2} a((1,0) + M\alpha - \beta) v(\beta),$$

where $\alpha \in \mathbb{Z}^2$ and $v \in \ell_0(\mathbb{Z}^2)$. Let K be the set

$$([-1,2] \times [-2,2]) \cap \left(\mathbb{Z}^2 \setminus \{(-1,-2),(2,-2),(2,2),(-1,2)\}\right).$$

Then K is admissible for both A_0 and A_1. Clearly, $\ell(K)$ contains $\nabla_1 \delta$ and $\nabla_2 \delta$. We also use A_0 and A_1 to denote the matrices

$$\left(a(M\alpha - \beta)\right)_{\alpha,\beta \in K} \quad \text{and} \quad \left(a((1,0) + M\alpha - \beta)\right)_{\alpha,\beta \in K},$$

respectively. Then A_0 and A_1 are 16×16 matrices. By a computation, we find that, for each $(\varepsilon_1, \ldots, \varepsilon_8) \in \{0,1\}^8$, the matrix $A_{\varepsilon_1} \cdots A_{\varepsilon_8}$ has a positive row. By Theorem 1.1 we conclude that the subdivision scheme associated with mask a and dilation matrix M converges. □

This example was treated in [9, Example 3.6] by using a different method. In [5] a different mask was considered. Their mask is given by

$$b(0,0) = 1, \quad b(1,0) = b(0,1) = b(-1,0) = b(0,-1) = 1/4,$$

and $b(\alpha) = 0$ for $\alpha \in \mathbb{Z}^2 \setminus \{(0,0),(1,0),(0,1),(-1,0),(0,-1)\}$. By Theorem 1.2, the convergence of the subdivision scheme associated with mask b and dilation matrix M can be derived from Example 4.4.

ANY CIRCULANT-LIKE PRECONDITIONER FOR MULTILEVEL MATRICES IS NOT SUPERLINEAR*

S. SERRA CAPIZZANO† AND E. TYRTYSHNIKOV‡

Abstract. Superlinear preconditioners (those that provide a proper cluster at 1) are very important for the cg-like methods since they make these methods converge superlinearly. As is well known, for Toeplitz matrices generated by a continuous symbol, many circulant and circulant-like (related to different matrix algebras) preconditioners were proved to be superlinear. In contrast, for multilevel Toeplitz matrices there has been no proof of the superlinearity of any multilevel circulants. In this paper we show that such a proof is not possible since any multilevel circulant preconditioner is not superlinear, in the general case of multilevel Toeplitz matrices. Moreover, for matrices not necessarily Toeplitz, we present some general results proving that many popular structured preconditioners cannot be superlinear.

Key words. preconditioner, cluster, conjugate gradient, circulants

1. Introduction.

The phenomenon of superlinear convergence for the cg-like methods was scrutinized, first of all, in [2, 27] and has become one of the most topical subjects in papers discussing how to make the cg-like iterations converge superlinearly within a constant number of iterations [5, 8, 10, 14, 15, 16, 17, 18, 19, 22, 25, 28, 29]. The key concept behind these papers is that of a cluster. From some naive approach in the beginning it has eventually developed into a rigorous notion [6, 30, 31, 32, 33] as follows.

Consider a sequence of matrices $A_n \in \mathbb{C}^{n\times n}$ and a set M in the complex plane. Denote by M_ε the ε-extension of M, which is the union of all balls of radius ε centered at points of M. Let $\gamma_n(\varepsilon)$ count those eigenvalues of A_n that do not belong to M_ε. Assume that, for any $\varepsilon > 0$,

$$\gamma_n(\varepsilon) = o(n), \quad n \to \infty.$$

Then M is called a general (some say weak) cluster. If $o(n) = O(1)$, then M is called a proper (some say strong) cluster.

Of course, we are interested in the clusters that are as narrow as possible. In this paper we deal only with one-point clusters and primarily those of the singular values rather than the eigenvalues.

If A_n are Hermitian positive definite matrices and C_n are their Hermitian positive definite preconditioners, then the superlinear convergence for the preconditioned conjugate gradient (PCG) method is guaranteed whenever the eigenvalues of $C_n^{-1}A_n$

have a proper cluster at 1. In the non-Hermitian case, the PCG method can be applied to the symmetrized preconditioned system, and the superlinear convergence can be seen as long as the singular values of $C_n^{-1}A_n$ have a proper cluster at 1 [1, 2].

We would have called a preconditioner C_n for A_n superlinear if the singular values of $C_n^{-1}A_n$ had a proper cluster at 1. However, we will require a little more detail.

A preconditioner C_n for A_n is said to be *sublinear* if the singular values of $C_n^{-1}A_n - I_n$ have a cluster at 0 (I_n is the identity matrix of order n) and *superlinear* if this cluster at 0 is proper.

Useful equivalent definitions also exist in terms of convenient matrix relations. A preconditioner C_n for A_n is sublinear iff, for any $\varepsilon > 0$, there exist matrices $E_{n\,\varepsilon}$ and $R_{n\,\varepsilon}$ such that

$$C_n^{-1}A_n - I_n = E_{n\,\varepsilon} + R_{n\,\varepsilon} \tag{1}$$

with

$$||E_{n\,\varepsilon}||_2 \le c_1(\varepsilon), \qquad \lim_{\varepsilon\to 0} c_1(\varepsilon) = 0; \tag{2}$$

$$\operatorname{rank} R_{n\,\varepsilon} \le c_2(n,\varepsilon), \qquad \lim_{n\to\infty} \frac{c_2(n,\varepsilon)}{n} = 0 \quad \forall\, \varepsilon > 0. \tag{3}$$

A sublinear preconditioner C_n is superlinear iff $c_2(n,\varepsilon)$ is uniformly bounded in n (which is equivalent to the claim that some bound c_2 does not depend on n, and so we may write $c_2 = c_2(\varepsilon)$).

For the singular values of $C_n^{-1}A_n$, it is easy to prove that a sublinear preconditioner provides a general cluster at 1 while a superlinear preconditioner provides a proper cluster, and hence the superlinear convergence. However, beware of claiming the reverse, because a preconditioner providing a proper cluster at 1 for the singular values of $C_n^{-1}A_n$ is not necessarily superlinear according to our definition.

In applications, superlinear preconditioners may not be easily available. Still, some important cases exist for when they are.

If $A_n = A_n(f) = [a_{i-j}]_{ij=1}^n$ are Toeplitz matrices associated with an absolutely convergent Fourier series for a positive symbol

$$f(x) = \sum_{k=-\infty}^{\infty} a_k e^{\mathrm{i}kx},$$

then the circulant preconditioners proposed by Chan and Strang are superlinear [6]. More precisely, this is true for the Strang preconditioner when f belongs to the Dini–Lipschitz class [20], while for the Chan preconditioner this is true when f is merely continuous [7, 20, 21]. Moreover, many other preconditioners related to different matrix algebras [3, 4, 9, 11, 13, 21, 23, 24] can be proved to be optimal or superlinear even in the ill-conditioned case, where the symbol f has zeros [9, 20].

From the practical point of view, the profusion of research devoted to preconditioners for Toeplitz matrices is likely to proceed with the hope of using the same ideas for multilevel Toeplitz matrices (see [29]). In the multilevel case, the constructions similar to those of the unilevel case have led only to sublinear preconditioners [31, 21].

As yet, all attempts to construct a superlinear multilevel circulant or circulant-like preconditioner were unsuccessful. In this paper we show that this construction is impossible.

We thus propose a negative result that can be summarized as follows. If a preconditioner C_n for A_n is sought in the form $C_n = U_n D_n V_n$, with unitary matrices U_n and

V_n (still subject to some assumptions) given beforehand and so independent of A_n, and a diagonal matrix D_n to be chosen, then there are multilevel Toeplitz matrices A_n associated with a multivariate symbol, for which the preconditioner C_n cannot be superlinear.

All the same, much of what we discuss has little to do with the Toeplitz property itself; we use, instead, some general ergodic assumptions (that follow from the Szegő-like theorems in the Toeplitz case). Moreover, our results might apply also to the preconditioners for unilevel matrices.

In section 2, we present the basic theoretical tools allowing us to prove that a preconditioner is not superlinear. Then, in section 3 we recollect the notion, common toolkit, and some ergodic results for the multilevel matrices. In section 4, we present our main negative results concerning superlinear circulant-like preconditioners.

2. Basic statements. All matrices, for the time being, are unilevel of order n (with different n). The following two lemmas are almost evident, so they are stated without proofs.

LEMMA 2.1. *Assume that matrices C_n are nonsingular and uniformly bounded in n, in the spectral norm, together with C_n^{-1}. Then a preconditioner C_n for A_n is sublinear iff the singular values of $A_n - C_n$ have a general cluster at zero, and it is superlinear iff this cluster is proper.*

We will say that A_n and C_n are ε-close up to the rank bound $r = r(n,\varepsilon)$ if, $\forall\, \varepsilon > 0$ and $\forall\, n$, there exist matrices $E_{n\,\varepsilon}$ and $R_{n\,\varepsilon}$ such that

$$A_n - C_n = E_{n\,\varepsilon} + R_{n\,\varepsilon}, \quad ||E_{n\,\varepsilon}||_2 \le \varepsilon, \quad \operatorname{rank} R_{n\,\varepsilon} \le r(n,\varepsilon). \tag{4}$$

LEMMA 2.2. *The singular values of $A_n - C_n$ have a cluster at zero iff the matrices A_n and C_n are ε-close up to the rank bound $r(n,\varepsilon)$ which enjoys the relation*

$$\lim_{n\to\infty} \frac{r(n,\varepsilon)}{n} = 0 \quad \forall\, \varepsilon > 0. \tag{5}$$

The cluster at 0 is proper iff $r(n,\varepsilon)$ does not depend on n.

We call a matrix *equimodular* if all its entries are equal in modulus. It is clear that any unitary equimodular matrix of order n has all its entries equal to $1/\sqrt{n}$ in modulus.

LEMMA 2.3. *Let $C_n = U_n D_n V_n$, where matrices D_n are diagonal, U_n and V_n are unitary, and V_n are equimodular. Assume that, for any $\varepsilon > 0$ and for all sufficiently large n, there exists a column $e_{\varepsilon\,n}$ of I_n such that $||C_n e_{\varepsilon\,n}||_2 \le \varepsilon$. Then the singular values of C_n are clustered at zero.*

Proof. If $D_n = \operatorname{diag}\{d_{1n}, \ldots, d_{nn}\}$, then the singular values of C_n are equal to $|d_{jn}|$, $1 \le j \le n$. From the contrary, assume that zero is not a cluster for them. Then, there are positive δ and c such that

$$\gamma_n(\delta) \ge cn \tag{6}$$

for infinitely many n. In line with the previous notation, $\gamma_n(\delta)$ counts those indices j for which $|d_{jn}| > \delta$. Take up any n for which (6) is valid, and set $v^n_{\varepsilon\,n} = [v_{1,\varepsilon\,n}, \ldots, v_{n,\varepsilon\,n}]^T \equiv V_n\, e_{\varepsilon\,n}$. Then, for those n,

$$||C_n e_{\varepsilon\,n}||_2 \;=\; ||D_n v^n_{\varepsilon\,n}||_2 \;=\; \sqrt{\sum_{j=1}^{n} |d_{jn} v_{j,\varepsilon\,n}|^2} \;\ge\; \sqrt{c}\,\delta,$$

and hence, this cannot be less than ε for an arbitrary $\varepsilon > 0$. □

We will say that A_n are ε-zeroed on $\rho = \rho(n, \varepsilon)$ columns of the identity matrix I_n if, first, they are uniformly bounded in n in the spectral norm, and second, $\forall\ \varepsilon > 0$ and $\forall\ n$, for some $\rho(n, \varepsilon)$ columns $e_{jn\,\varepsilon}$ of I_n it holds that

$$||A_n\, e_{jn\,\varepsilon}||_2 \ \le\ \varepsilon, \quad j = 1, \ldots, \rho(n, \varepsilon).$$

LEMMA 2.4. *Let matrices A_n and C_n be ε-close with the rank bound $r(n, \varepsilon)$, and let A_n be ε-zeroed on $\rho(n, \varepsilon)$ columns of I_n so that*

$$\lim_{n\to\infty} \frac{r(n, \varepsilon)}{\rho(n, \varepsilon)} = 0. \tag{7}$$

Suppose $||C_n||_2$ are uniformly bounded in n. Then, $\forall\ \varepsilon > 0$ and all sufficiently large n, there is a column $e_{n\,\varepsilon}$ of I_n such that

$$||C_n\, e_{n\,\varepsilon}||_2 \ \le\ 3\,\varepsilon.$$

Proof. By contradiction, assume that

$$||C_n\, e_{jn\,\varepsilon}||_2 \ >\ 3\,\varepsilon, \quad j = 1, \ldots, \rho(n, \varepsilon).$$

Since A_n are ε-zeroed on the vectors $e_{jn\,\varepsilon}$, it implies that

$$||(A_n - C_n)\, e_{jn\,\varepsilon}||_2 \ >\ 2\,\varepsilon.$$

Denote by $\sigma_{1n} \ge \cdots \ge \sigma_{nn}$ the singular values of $A_n - C_n$. Then, as is well known,

$$\sum_{j=1}^{\rho} \sigma_{jn}^2 \ \ge\ \sum_{j=1}^{\rho} ||(A_n - C_n)\, e_{jn\,\varepsilon}||_2^2.$$

Since A_n and C_n are ε-close with the rank bound $r(n, \varepsilon)$, it follows that

$$\sigma_{jn} \le \varepsilon \quad \text{for} \quad j > r = r(n, \varepsilon).$$

Using this and taking into account the preceding inequalities, we obtain

$$r\ \sigma_{1n}^2 \ \ge\ 4\varepsilon^2 \cdot \rho - \varepsilon^2\ (\rho - r),$$

and hence

$$\frac{r(n, \varepsilon)}{\rho(n, \varepsilon)}\ ||A_n - C_n||_2^2 \ \ge\ 3\,\varepsilon^2.$$

On the strength of (7), and because the spectral norms of the matrices are bounded, the right-hand side must vanish as $n \to \infty$, which is at odds with the last inequality. □

THEOREM 2.1. *Suppose that $C_n = U_n D_n V_n$, where matrices D_n are diagonal, U_n and V_n are unitary, and V_n are equimodular. Let matrices A_n and C_n be ε-close with the rank bound $r(n, \varepsilon)$, and let A_n be ε-zeroed on $\rho(n, \varepsilon)$ columns of I_n. If the singular values of A_n are not clustered at zero, then* (7) *does not stand; that is,*

$$r(n, \varepsilon) \quad \neq \quad o(\rho(n, \varepsilon)), \qquad n \to \infty. \tag{8}$$

Proof. We do not lose generality if we assume that C_n are bounded in the spectral norm uniformly in n. If it is not the case, we transfer to other matrices $\tilde{C}_n$ satisfying the same premises with $r(n,\varepsilon)$ being possibly replaced by $2\,r(n,\varepsilon)$. Indeed, the number of singular values for C_n that are greater than $||A_n||_2 + \varepsilon$ cannot exceed $r(n,\varepsilon)$, and we may thus get to $\tilde{C}_n$ by cutting off the largest diagonal entries of D_n in the equation $C_n = U_n D_n V_n$.

Assume that the relation (7) is still fulfilled. Then, since all the premises of Lemma 2.4 are fulfilled, we conclude that, for any $\varepsilon > 0$ and for any n, there exists a column $e_{\varepsilon\, n}$ of I_n such that $||C_n e_{\varepsilon\, n}||_2 \le \varepsilon$. From Lemma 2.3, we now deduce that the singular values of C_n have a cluster at 0.

Allowing for (7), we have also $r(n,\varepsilon) = o(n)$, which implies that A_n and C_n have the same one-point clusters [31, 33]. However, the matrices A_n have no singular value cluster at 0, and this cannot be reconciled with the above conclusion that C_n have the cluster at 0. □

THEOREM 2.2. *Under the hypotheses of Theorem* 2.1, *assume that*

$$\lim_{n\to\infty} \rho(n,\varepsilon) = \infty \qquad \forall\, \varepsilon > 0.$$

Then the singular values of $A_n - C_n$ *cannot have a proper cluster at* 0.

Proof. From Lemma 2.2, $r(n,\varepsilon)$ is bounded uniformly in n. Then, obviously, $r(n,\varepsilon) = o(\rho(n,\varepsilon))$, which contradicts (8). □

THEOREM 2.3. *Under the hypotheses of Theorem* 2.2, *consider any matrices* P_n *such that* $P_n + A_n$ *and* $P_n + C_n$ *are nonsingular and uniformly bounded in* n, *in the spectral norm, together with their inverses. Then the matrices* $P_n + C_n$ *cannot be superlinear preconditioners for* $P_n + A_n$.

Proof. According to Lemma 2.1, the preconditioner $P_n + C_n$ for $P_n + A_n$ is superlinear iff the singular values of $A_n - C_n$ have a proper cluster at 0. All now reduces to applying Theorem 2.2. □

It might be useful to consider also *quasi-equimodular* matrices instead of equimodular ones. A sequence of matrices $V_n = [v_{ij}^n]$ of order n is referred to as quasi-equimodular if

$$\frac{c_1}{\sqrt{n}} \;\le\; |v_{ij}^n| \;\le\; \frac{c_2}{\sqrt{n}} \quad \forall\, i,j,$$

for some $0 < c_1 \le c_2$ independent of n. It is clear that the above statements remain valid for a quasi-equimodular sequence of matrices.

However, the same statements also stand in an even more general case of *sub-equimodular* matrices. In addition, this notion applies to a sequence of matrices, not to an individual matrix.

A sequence of matrices $V_n = [v_1^n, \ldots, v_n^n]$ is said to be subequimodular if, for any sequence of indices $j(n)$, $1 \le j(n) \le n$, $n = 1, 2, \ldots$, there exists $\delta > 0$ such that the set $[\delta, +\infty]$ is a cluster for $\{\sqrt{n}|v_{1\,j(n)}^n|, \ldots, \sqrt{n}|v_{n\,j(n)}^n|\}_n$, the absolute values of the entries of the $j(n)$th column times $\sqrt{n}$. It is not difficult to show that the above statements hold true for subequimodular matrices V_n.

3. Multilevel preliminaries. We call a matrix multilevel if it can be viewed as one with a nested block structure: A is a p-level matrix of multiorder $n = (n_1, \ldots, n_p)$ if it is a matrix with $n_1 \times n_1$ blocks, if each of them consists of $n_2 \times n_2$ blocks, and so on. Hence, A is of order $N(n) \equiv n_1 \cdots n_p$. The rows and columns of A can naturally be pointed to through multi-indices $i = (i_1, \ldots, i_p)$ and $j = (j_1, \ldots, j_p)$. Thus,

$$A = [a_{ij}], \quad 1 \le i, j \le n,$$

where $1 = (1, \dots, 1)$, and inequalities between multi-indices are understood in the entrywise sense.

Multilevel matrices may possess some structure: A_n is called a p-level Toeplitz matrix if $A_n = [a_{i-j}]$, and A_n is called a p-level circulant if $A_n = [a_{i-j \,(\mathrm{mod}\, n)}]$, where $i(\mathrm{mod}\, n) \equiv (i_1(\mathrm{mod}\, n_1), \dots, i_p(\mathrm{mod}\, n_p))$.

Given two sequences of p-level matrices A_n and B_n of multiorder n, we call their singular values equally distributed if, for any function F continuous with a bounded support,

$$\frac{1}{N(n)}\Sigma(A_n, F) - \frac{1}{N(n)}\Sigma(B_n, F) = o(1), \quad n \to \infty,$$

where

$$\Sigma(A_n, F) \equiv \sum_{1 \le i \le n} F(\sigma_i(A_n)),$$

and $n \to \infty$ means that every component of the multi-index n tends to infinity.

The singular values of multilevel matrices A_n are called distributed as $f(z)$ for $z \in \Pi$ if, for any F continuous with a bounded support,

$$\frac{1}{N(n)}\Sigma(A_n, F) \to \frac{1}{\mathrm{mes}\,\Pi} \int_\Pi F(f(z))dz.$$

Here, Π is a Lebesgue-measurable set and f is a Lebesgue-measurable function on Π.

If $f(z) = 1$, then the above means that the singular values of A_n have a general cluster at 1. It is not necessarily a proper cluster.

Let $z \in \Pi \equiv [-\pi, \pi]^p$, and consider $f \in L_1(\Pi)$ with the formal Fourier expansion

$$f(z) \sim \sum_k a_k \, e^{\mathrm{i}(k,z)},$$

where

$$k = (k_1, \dots, k_p), \quad (k, z) = k_1 z_1 + \cdots + k_p z_p.$$

Such a function f (we call it a symbol) naturally generates the p-level Toeplitz matrices as follows:

$$A_n(f) = [a_{i-j}], \quad 1 \le i, j \le n.$$

For the unilevel Hermitian–Toeplitz case, the classical distribution results can be found in [12]. The Szegő-like theorem [12] for the singular values of $A_n(f)$ obtained in [34] reads as follows: If a symbol $f \in L_1(\Pi)$ is a complex-valued function of $z \in \Pi = [-\pi, \pi]^p$, then the singular values of $A_n(f)$ are distributed as $|f(z)|$ with $z \in \Pi$.

4. Main negative results. Consider a p-variable symbol $f(x_1, \dots, x_p) = \frac{1}{2}\exp\{\mathrm{i}x_1 + \cdots + \mathrm{i}x_p\}$ and the corresponding p-level Toeplitz matrices $A_n = A_n(f)$, where $n = (n_1, \dots, n_p)$.

THEOREM 4.1. *For $I_n + A_n$, any preconditioner of the form $I_n + C_n$, where C_n is a p-level circulant, is not superlinear.*

Proof. As it is not difficult to verify, the matrices A_n are zeroed (ε-zeroed with $\varepsilon = 0$) on $\rho(n)$ columns of the identity matrix of order $N(n) = n_1 \cdots n_p$, where

$$\rho(n) \;\geq\; c\, N(n) \sum_{k=1}^{p} \frac{1}{n_k} \tag{9}$$

and $c \geq 2^{1-p}$ provided that $n_k \geq 2 \;\forall\, k$.

For example, consider the multilevel Toeplitz matrices A_n with $p = 2$ generated by $f(x_1, x_2) = \frac{1}{2}\, \exp\{\mathrm{i}x_1 + \mathrm{i}x_2\}$. In line with the above,

$$A_n = \frac{1}{2} \begin{bmatrix} 0 & J & & \\ & \ddots & \ddots & \\ & & 0 & J \\ & & & 0 \end{bmatrix},$$

where 0 and J are of order n_2 as $n = (n_1, n_2)$ and J is a Jordan block with $J_{i,i+1} = 1$ for $i = 1, \ldots, n_2 - 1$ and zero otherwise. It is evident that the first n_2 columns of A_n are zero columns. Moreover, each of the $n_1 - 1$ blocks J appearing in A_n has one zero column. Therefore, $\rho(n) = n_2 + n_1 - 1$, which is in accordance with (9).

Clearly, $\rho(n) \to \infty$ as $n \to \infty$ (which means, by definition, that every n_k tends to infinity). Note also that $C_n = V_n^* D_n V_n$, where V_n is a unitary equimodular matrix, for it is the Kronecker product of Fourier matrices. Therefore, we may have recourse to Theorem 2.3, and this completes the proof. □

In effect, the above proof enables us to claim much more. In particular, we can propose a lower estimate on the rank of $R_{n\,\varepsilon}$ in the splitting for $A_n - C_n$ concerning the ε-closeness of A_n and C_n. What is more, it is possible to cover a more general case when C_n is not necessarily a multilevel circulant. We call matrices C_n *circulant-like* if, for any n, it holds that $C_n = V_n^* D_n V_n$, where D_n is a diagonal matrix, and matrices V_n are unitary subequimodular matrices.

THEOREM 4.2. *For $I_n + A_n$, any sublinear preconditioner of the form $I_n + C_n$, where C_n are p-level circulant-like matrices, provides the singular value cluster for which, for some $c(\varepsilon) > 0$ and infinitely many n, it holds that*

$$\gamma_n(\varepsilon) \;\geq\; c(\varepsilon)\, \rho(n),$$

where $\rho(n)$ is defined by (9).

To demonstrate this, we follow the previous proof with the reference, in the end, to Theorem 2.1.

We know that, when using the multilevel T. Chan preconditioner [8], the number of outliers is $O(N(n) \sum_{k=1}^{p} \frac{1}{n_k})$ for any A_n generated by a continuous function f [21]. Therefore, we can say that this preconditioning technique, which is not satisfactory for large p, is the best that we may obtain when quasi-equimodular algebras are considered.

The last theorem apparently pertains to many popular matrix algebra preconditioners. We now have a rigorous proof stating that they cannot be superlinear, at least for the particular multilevel Toeplitz matrix-sequence A_n. However, all is not lost for the multilevel preconditioning in algebra.

Sometimes, it is possible to prove that

(a) multilevel circulant preconditioners cause the singular values to march inside some constant, separated from a zero interval;

(b) moreover, there is a general cluster at 1.

The combination of (a) and (b) can result in a very fast convergence in practice (see [5, 22]). We have as much as (a) and (b) together rather often. For example, if the convex hull of the range of f (complex-valued) is separated from zero, then the singular values of the Toeplitz matrices preconditioned by circulants behave in line with (a) [26]. At the same time, (b) is also valid for this case. Apart from its efficiency in experiments, a rigorous description of the effect of combining (a) and (b) is still to be found.

Note also that the basic results of section 2 allow us to construct many other examples. In particular, there are Hermitian multilevel Toeplitz matrices (generated by a multivariable symbol) for which any Hermitian multilevel circulant-like preconditioner is not superlinear.

To see this, take up the previous $f(x_1, \ldots, x_p)$ and consider the symbols

$$g_1 = \operatorname{Re} f(x_1, \ldots, x_p), \quad g_2 = \operatorname{Im} f(x_1, \ldots, x_p).$$

At least one of the sequences $I + A_n(g_1)$ or $I + A_n(g_2)$ cannot have circulant-like superlinear preconditioners. By contradiction, if both of them have superlinear preconditioners $I + C_{n,1}$ and $I + C_{n,2}$, then the circulant-like preconditioner $I + C_{n,1} + \mathrm{i}C_{n,2}$ is superlinear for $I + A_n(f)$ and this contradicts the main negative results of this section.

A BOUND ON THE SOLUTION TO A STRUCTURED SYLVESTER EQUATION WITH AN APPLICATION TO RELATIVE PERTURBATION THEORY*

REN-CANG LI†

Abstract. Assuming only that the spectra of A and B are disjoint as opposed to the more restrictive assumption previously used, we obtain a bound in all unitarily invariant norms on the solution to the *structured* Sylvester equation $AX - XB = A^{1/2}EB^{1/2}$. This bound is the first of its kind in all unitarily invariant norms under only the disjointedness assumption. An application of the bound to the relative perturbation theory for scaled Hermitian eigenvalue problems is given.

Key words. structured Sylvester equation, unitarily invariant norm, relative perturbation theory, eigenspace

The operator (matrix) equation $AX - XB = S$, known as the Sylvester equation, appears frequently in the studies of operator theory, stability, and numerical linear algebra; see Bhatia and Rosenthal [6] and references therein for a history of it and its applications. The equation plays a unique role in eigenspace variations as illustrated by Davis and Kahan [7], where it was shown that the singular values of an associated Sylvester equation are the sines of angles between an eigenspace and its perturbation, and consequently, theorems, now known as the Davis–Kahan $\sin\theta$ and $\sin 2\theta$ theorems, were obtained.

Let A and B be Hermitian, and $\lambda(\cdot)$ denote the spectrum of a matrix. It can be proved that for the Frobenius norm $\|X\|_{\mathrm{F}} \stackrel{\mathrm{def}}{=} \sqrt{\sum_{i,j} |(X)_{ij}|^2}$,

$$\|X\|_{\mathrm{F}} \le \|S\|_{\mathrm{F}}/\delta, \quad \delta \stackrel{\mathrm{def}}{=} \min_{\omega\in\lambda(A),\,\gamma\in\lambda(B)} |\omega - \gamma|. \tag{1}$$

This holds under the most mild assumption, i.e., $\lambda(A)\cap\lambda(B) = \emptyset$ as in Figure 1. But to derive bounds for other norms, Davis and Kahan [7] imposed a restriction on how $\lambda(A)$ and $\lambda(B)$ are relatively distributed; see Figure 2. With that restriction Davis and Kahan proved that

$$|||X||| \le |||S|||/\delta \tag{2}$$

for all unitarily invariant norms $|||\cdot|||$ [3, 14], including the spectral (operator) norm $\|\cdot\|_2$. It remained open what kinds of bounds we may have for $|||X|||$ under the situation of Figure 1 until Bhatia, Davis, and McIntosh [4] extended (2) to cover the situation of Figure 1 and proved[1]

$$|||X||| \le (\pi/2)\cdot|||S|||/\delta. \tag{3}$$

(In [4], the constant $\pi/2$ was not given explicitly; see [6] for details.)

[1] Bhatia, Davis, and McIntosh proved a more general result for the case when A and B are normal.

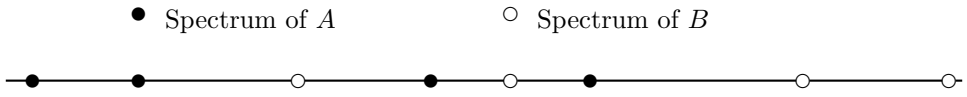

FIG. 1. *The spectrum of A and that of B are disjoint.*

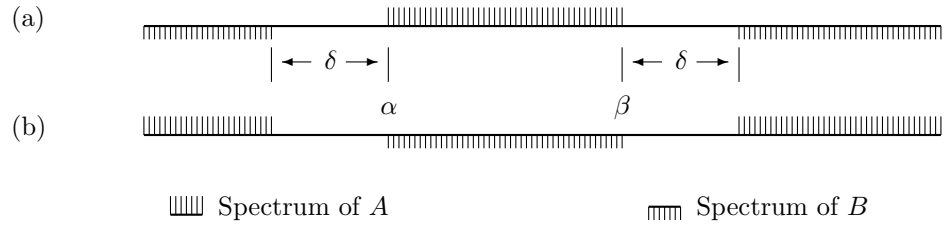

FIG. 2. *The spectrum of A and that of B are separated by two intervals.*

Interestingly, Li [13], in creating a relative perturbation theory for eigenvectors (see also [10]), showed that the sines of angles between an eigenspace and its perturbation are the singular values of an associated *structured* Sylvester equation $AX - XB = S$ in the sense that S takes one of the following forms:

$$AE, FB, AE + FB, \text{ or } A^{1/2}EB^{1/2}, \tag{4}$$

where E and F are some error matrices. Bounds on the norms of X that are inversely proportional to relative gaps between $\lambda(A)$ and $\lambda(B)$ measured by one of[2] $(1 \le p \le \infty)$

$$\frac{|\omega-\gamma|}{|\omega|}, \frac{|\omega-\gamma|}{|\gamma|}, \frac{|\omega-\gamma|}{\sqrt[p]{|\omega|^p+|\gamma|^p}}, \text{ or } \frac{|\omega-\gamma|}{\sqrt{|\omega|\cdot|\gamma|}}, \tag{5}$$

as opposed to the absolute gap δ measured by $|\omega - \gamma|$, are therefore obtained. (Here $A^{1/2}$ can be taken to be any one of A's many square roots. Usually for a positive semidefinite A, it is defined to be the unique square root that is also positive semidefinite.) This was done for the Frobenius norm under the situation of Figure 1, but for all other unitarily invariant norms, a restriction similar to Figure 2 was assumed; see Figure 3. Notice the difference between Figure 2 and Figure 3: in Figure 3, either the spectrum of A or that of B has to scatter around the origin. This is for a good reason: the absolute difference is shift invariant while the relative differences are shift varying; see Li [13] for more discussions. For a sample bound, let $S = A^{1/2}EB^{1/2}$, then under the condition of Figure 3,

$$\|\!|X|\!\| \le \|\!|E|\!\| / \eta, \quad \eta \stackrel{\text{def}}{=} \min_{\omega\in\lambda(A),\,\gamma\in\lambda(B)} \frac{|\omega-\gamma|}{\sqrt{|\omega|\cdot|\gamma|}} \ge \delta/\sqrt{\alpha(\alpha+\delta)}. \tag{6}$$

A natural question arises: under the condition of Figure 1, can we have, e.g., for $AX - XB = A^{1/2}EB^{1/2}$, something like

$$\|\!|X|\!\| \le c\,\|\!|E|\!\| / \eta? \tag{7}$$

[2]It was proved that $\frac{|\omega-\gamma|}{\sqrt[p]{|\omega|^p+|\gamma|^p}}$ is a metric on the set of real numbers in [12] which also conjectured that it might even be a metric on the set of complex numbers. The conjecture was confirmed by Day [8] for $p = \infty$ and recently by Barrlund [2] for all $1 \le p \le \infty$.

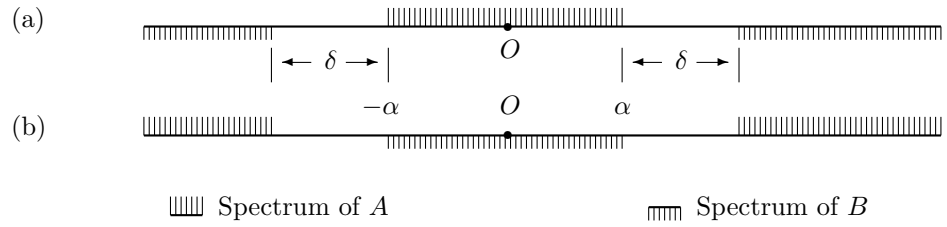

FIG. 3. *The spectrum of A and that of B are separated by two intervals, and one of the spectra scatters around the origin.*

Here $c \geq 1$ is a constant, and $\eta \stackrel{\text{def}}{=} \min_{\omega\in\lambda(A),\,\gamma\in\lambda(B)} \frac{|\omega-\gamma|}{\sqrt{|\omega|\cdot|\gamma|}}$. Similar questions with η defined accordingly for S being of any other forms in (4) can be asked.

While we are not able to give a complete answer to this question, in this note we shall prove something that is very much like it. However, we have no answers for S being of any other forms in (4).

THEOREM 1. *Assume that A and B are positive semidefinite and that $\lambda(A) \cap \lambda(B) = \emptyset$. Then $AX - XB = A^{1/2}EB^{1/2}$ has a unique solution X, and moreover for all unitarily invariant norm $\|\!|\cdot|\!\|$,*

$$|\!|\!| X |\!|\!| \leq (\pi/2) \cdot |\!|\!| E |\!|\!| / \widetilde{\eta}, \quad \widetilde{\eta} \stackrel{\text{def}}{=} \min_{\omega\in\lambda(A),\,\gamma\in\lambda(B)} |\ln(\omega/\gamma)|. \tag{8}$$

It has been proved that all relative measures in (5) are topologically equivalent [12], so they are equally good. The first two in (5) are the classical measures usually used in numerical computations, and the last two were introduced later [1, 9, 12, 13] as circumstances called for. What we see now in (8) is yet another relative measure $|\ln(\omega/\gamma)|$. To see this, let us assume ω and γ are close enough such that $|1-\omega/\gamma| < 1$. (As a matter of fact, $|1-\omega/\gamma| \leq 1/2$ if the most significant binary digit of ω and that of γ are the same; $|1-\omega/\gamma| \leq 1/10$ if the most significant decimal digit of ω and that of γ are the same.) Then

$$\begin{aligned} |\ln(\omega/\gamma)| &= |\ln(1-(1-\omega/\gamma)| \\ &= |(1-\omega/\gamma) + (1-\omega/\gamma)^2/2 + \cdots + (1-\omega/\gamma)^k/k + \cdots|, \end{aligned}$$

and thus the topological equivalence of $|\ln(\omega/\gamma)|$ to any of the measures in (5) is easily established.

Proof of Theorem 1. Without loss of generality, we may assume that both A and B are positive definite; we can always handle the singular case by the often used continuity argument. Our proof relies on the following inequality:

$$|\!|\!| (\ln A)X - X(\ln B) |\!|\!| \leq \left|\!\left|\!\left| A^{1/2}XB^{-1/2} - A^{-1/2}XB^{1/2} \right|\!\right|\!\right|, \tag{9}$$

due to Kosaki [11]; see [5] for another proof. It follows from the equation $AX - XB = A^{1/2}EB^{1/2}$ that $E = A^{1/2}XB^{-1/2} - A^{-1/2}XB^{1/2}$. Thus

$$|\!|\!| E |\!|\!| \geq |\!|\!| (\ln A)X - X(\ln B) |\!|\!| .$$

Now we apply (3), a result of Bhatia, Davis, and McIntosh [4], to complete the proof. ∎

Now let us briefly discuss how Theorem 1 can be applied to the relative perturbation theory. From now on, we shall assume $A = S^*HS$ is an $n \times n$ matrix, perturbed to $\widetilde{A} = S^*\widetilde{H}S$, where S is a scaling matrix and usually diagonal. But this is not necessary to the theorem below. S^* is the complex conjugate transpose of S. The elements of S can vary wildly. H is nonsingular and usually better conditioned than A itself. Set $\Delta H \stackrel{\text{def}}{=} \widetilde{H} - H$, and assume $\|H^{-1}\|_2\|\Delta H\|_2 < 1$. Let A and $\widetilde{A}$ admit eigendecompositions

(10)
$$A = (U_1, U_2)\begin{pmatrix} \Lambda_1 & \\ & \Lambda_2 \end{pmatrix}\begin{pmatrix} U_1^* \\ U_2^* \end{pmatrix} \quad \text{and} \quad \widetilde{A} = (\widetilde{U}_1, \widetilde{U}_2)\begin{pmatrix} \widetilde{\Lambda}_1 & \\ & \widetilde{\Lambda}_2 \end{pmatrix}\begin{pmatrix} \widetilde{U}_1^* \\ \widetilde{U}_2^* \end{pmatrix},$$

where $U = \overset{k}{\begin{pmatrix} U_1 \end{pmatrix}} \overset{n-k}{\begin{pmatrix} U_2 \end{pmatrix}}$, $\widetilde{U} = \overset{k}{\begin{pmatrix} \widetilde{U}_1 \end{pmatrix}} \overset{n-k}{\begin{pmatrix} \widetilde{U}_2 \end{pmatrix}}$ are unitary, and

$$\Lambda_1 = \operatorname{diag}(\lambda_1, \ldots, \lambda_k), \quad \Lambda_2 = \operatorname{diag}(\lambda_{k+1}, \ldots, \lambda_n), \tag{11}$$

$$\widetilde{\Lambda}_1 = \operatorname{diag}(\widetilde{\lambda}_1, \ldots, \widetilde{\lambda}_k), \quad \widetilde{\Lambda}_2 = \operatorname{diag}(\widetilde{\lambda}_{k+1}, \ldots, \widetilde{\lambda}_n). \tag{12}$$

Notice that

$$\begin{aligned} A &= S^*HS = (H^{1/2}S)^*\, H^{1/2}S, \\ \widetilde{A} &= S^*H^{1/2}\big(I + H^{-1/2}(\Delta H)H^{-1/2}\big)H^{1/2}S \\ &= \Big(\big(I + H^{-1/2}(\Delta H)H^{-1/2}\big)^{1/2}H^{1/2}S\Big)^*\, \big(I + H^{-1/2}(\Delta H)H^{-1/2}\big)^{1/2}H^{1/2}S. \end{aligned}$$

Set $B = S^*H^{1/2}$ and $\widetilde{B} = S^*H^{1/2}\big(I + H^{-1/2}(\Delta H)H^{-1/2}\big)^{1/2} \stackrel{\text{def}}{=} BD$, where $D = \big(I + H^{-1/2}(\Delta H)H^{-1/2}\big)^{1/2}$. Then $A = BB^*$ and $\widetilde{A} = \widetilde{B}\widetilde{B}^*$. Given the eigendecompositions of A and $\widetilde{A}$ as in (10)–(12), it can be seen that B and $\widetilde{B}$ admit the following singular value decompositions:

$$B = (U_1, U_2)\begin{pmatrix} \Lambda_1^{1/2} & \\ & \Lambda_2^{1/2} \end{pmatrix}\begin{pmatrix} V_1^* \\ V_2^* \end{pmatrix} \text{ and } \widetilde{B} = (\widetilde{U}_1, \widetilde{U}_2)\begin{pmatrix} \widetilde{\Lambda}_1^{1/2} & \\ & \widetilde{\Lambda}_2^{1/2} \end{pmatrix}\begin{pmatrix} \widetilde{V}_1^* \\ \widetilde{V}_2^* \end{pmatrix},$$

where U_i, $\widetilde{U}_i$ are the same as in (10), $\overset{k}{\begin{pmatrix} V_1 \end{pmatrix}} \overset{n-k}{\begin{pmatrix} V_2 \end{pmatrix}}$ and $\overset{k}{\begin{pmatrix} \widetilde{V}_1 \end{pmatrix}} \overset{n-k}{\begin{pmatrix} \widetilde{V}_2 \end{pmatrix}}$ are unitary. We have

$$\widetilde{A} - A = \widetilde{B}\widetilde{B}^* - BB^* = \widetilde{B}D^*B^* - \widetilde{B}D^{-1}B^* = \widetilde{B}(D^* - D^{-1})B^*.$$

Pre- and post-multiply the equations by $\widetilde{U}_2^*$ and U_1, respectively, to get

$$\widetilde{\Lambda}_2\widetilde{U}_2^*U_1 - \widetilde{U}_2^*U_1\Lambda_1 = \widetilde{\Lambda}_2^{1/2}\widetilde{V}_2^*(D^* - D^{-1})V_1\Lambda_1^{1/2}, \tag{13}$$

a *structured* Sylvester equation for $\widetilde{U}_2^*U_1$. Notice that for any unitarily invariant norm

$$\begin{aligned}
\left|\!\left|\!\left| \widetilde{V}_2^*(D^* - D^{-1})V_1 \right|\!\right|\!\right| &\le \left|\!\left|\!\left| D^* - D^{-1} \right|\!\right|\!\right| \\
&= \left|\!\left|\!\left| \left(I + H^{-1/2}(\Delta H)H^{-1/2}\right)^{1/2} - \left(I + H^{-1/2}(\Delta H)H^{-1/2}\right)^{-1/2} \right|\!\right|\!\right| \\
&\le \left\| \left(I + H^{-1/2}(\Delta H)H^{-1/2}\right)^{-1/2} \right\|_2 \left|\!\left|\!\left| H^{-1/2}(\Delta H)H^{-1/2} \right|\!\right|\!\right| \\
&\le \frac{\|H^{-1}\|_2 \left|\!\left|\!\left| \Delta H \right|\!\right|\!\right|}{\sqrt{1 - \|H^{-1}\|_2 \|\Delta H\|_2}}.
\end{aligned}$$

It is known that $|||\sin\Theta(U_1, \widetilde{U}_1)||| \equiv |||\widetilde{U}_2^* U_1|||$ for all unitarily invariant norms [14]. The following theorem is now a consequence of (13) and Theorem 1.

THEOREM 2. *Let $A = S^*HS$ and $\widetilde{A} = S^*\widetilde{H}S$ be two $n \times n$ Hermitian matrices with eigendecompositions* (10)–(12), *where H is positive definite and $\|H^{-1}\|_2\|\Delta H\|_2 < 1$. If*

$$\widetilde{\eta} \stackrel{\text{def}}{=} \min_{\mu \in \lambda(\Lambda_1),\, \widetilde{\mu} \in \lambda(\widetilde{\Lambda}_2)} |\ln(\mu/\widetilde{\mu})| > 0,$$

then for any unitarily invariant norm $|||\cdot|||$

$$\left|\!\left|\!\left| \sin\Theta(U_1, \widetilde{U}_1) \right|\!\right|\!\right| \le (\pi/2) \cdot \frac{\left|\!\left|\!\left| D - D^{-1} \right|\!\right|\!\right|}{\widetilde{\eta}}, \tag{14}$$

$$\le (\pi/2) \cdot \frac{\|H^{-1}\|_2}{\sqrt{1 - \|H^{-1}\|_2\|\Delta H\|_2}} \frac{\left|\!\left|\!\left| \Delta H \right|\!\right|\!\right|}{\widetilde{\eta}}, \tag{15}$$

where $D = (I + H^{-1/2}(\Delta H)H^{-1/2})^{1/2} = D^*$.

An analogous theorem for all unitarily invariant norms except those under the condition of Figure 3 is given in [13].

We have obtained a bound in all unitarily invariant norms on a *structured* Sylvester equation $AX - XB = A^{1/2}EB^{1/2}$. Though its proof is rather simple once we realize the two crucial results due to Kosaki [11] and to Bhatia, Davis, and McIntosh [4], respectively, it is significant in that for *structured* Sylvester equations it is the first of its kind in all unitarily invariant norms under the weakest assumption on A's and B's spectrum distributions. It remains to be seen whether similar results can be proved for other kinds of *structured* Sylvester equations.

Acknowledgment. I would like to thank Professor R. Bhatia for bringing the inequality (9) to my attention and for his constructive suggestions which improved the presentation considerably.

THE SOLUTION TO A STRUCTURED MATRIX APPROXIMATION PROBLEM USING GRASSMAN COORDINATES*

CRAIG S. MACINNES†

Abstract. A method for finding the best approximation of a matrix A by a full rank Hankel matrix is given. The initial problem of best approximation of one matrix by another is transformed to a problem involving best approximation of a given vector by a second vector whose elements are constrained so that its inverse image is a Hankel matrix. The map from a matrix to a vector is the invertible map between a subspace represented as the row space of the matrix A and the Grassman vector representing that subspace. The relation between the principle angles associated with a pair of subspaces and the angle between the Grassman vectors associated with the subspaces is established.

Key words. Grassman vector, principal angle, symmetric polynomial, Hankel matrix

1. Introduction. The structured matrix approximation problem is of particular interest in signal processing [3], [10], where replacing a data matrix corresponding to a signal plus noise with a matrix known to have the correct underlying structure is used as a means of increasing the relative signal strength. This paper deals with the approximation of an arbitrary matrix, A, by a full rank Hankel matrix of the same dimensions. The approximation is accomplished by first finding the vector v whose entries are the Grassman coordinates for the subspace represented by the rows of A. Then, a Grassman vector g is fitted to v, where g is structured so that its inverse image is a matrix H', which is then premultiplied by a certain Hankel matrix, giving the entire matrix a Hankel structure.

Grassman coordinates are introduced in section 2. A relation between a vector subspace in $\mathbf{C}^N$ and the corresponding Grassman vector representing that subspace can be made whenever certain constraints are placed on the elements of the vectors. In general these constraints are the Plücker relations [6]. For the case where the matrix is Hankel, more restrictive relations are satisfied by the elements of the corresponding Grassman vectors. In section 3 it is shown that these relations are equivalent to requiring that the elements of the Grassman vectors be specific functions of the elementary symmetric polynomials. In section 4, a relation between the principal angles between two subspaces and the inner product of the corresponding Grassman vectors is established. Conclusions are given in section 5.

2. Grassman coordinates. Let U be a K-dimensional subspace of an N-dimensional vector space V, and let U be expressed as a $K \times N$ matrix A of *row vectors* [6]. Then, the Grassman vector $\varphi(U)$ associated with the subspace U is the Kth compound matrix of A [7]. As an example, consider the following matrix of row

†Department of Physics, Informatics and Mathematics, Universidad Peruana Cayetano Heredia, Av. Honorio Delgado 430, Lima 31, Peru (ximefe@tsi.com.pe).

vectors representing a two-dimensional subspace in $\mathbf{R}^4$:

$$A = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}. \tag{2.1}$$

Then, the Grassman (Plücker) coordinates of A are

$$\varphi(A) = \left(\begin{vmatrix} 1 & 2 \\ 5 & 6 \end{vmatrix}, \begin{vmatrix} 1 & 3 \\ 5 & 7 \end{vmatrix}, \begin{vmatrix} 1 & 4 \\ 5 & 8 \end{vmatrix}, \begin{vmatrix} 2 & 3 \\ 6 & 7 \end{vmatrix}, \begin{vmatrix} 2 & 4 \\ 6 & 8 \end{vmatrix}, \begin{vmatrix} 3 & 4 \\ 7 & 8 \end{vmatrix} \right).$$

The components of $\varphi(A)$ are ordered lexicographically:

$$\varphi(A) = (p_{12}, p_{13}, p_{14}, p_{23}, p_{24}, p_{34}).$$

The Grassman vectors corresponding to any two sets of row vectors spanning the same space differ only by a scalar multiple. There is an inverse map φ^{-1} taking a Grassman vector to a corresponding subspace. In general the matrix representing the subspace can be formed by choosing any element $p_{i_1,i_2,\ldots,i_N}$ of the Grassman vector. The jth row of the matrix representing the subspace is then given by the elements

$$p_{i_1,\ldots,i_{j-1},1,i_{j+1},\ldots,i_N}, p_{i_1,\ldots,i_{j-1},2,i_{j+1},\ldots,i_N}, \ldots, p_{i_1,\ldots,i_{j-1},N,i_{j+1},\ldots,i_N}.$$

The subspace corresponding to the Grassman vector $\varphi(A)$ above can be found by choosing any nonzero element, say, p_{12}, and forming the following row matrix:

$$\widehat{A} \overset{\text{def}}{=} \begin{pmatrix} \cdots & p_{i2} & \cdots \\ \cdots & p_{1j} & \cdots \end{pmatrix} \equiv \begin{pmatrix} p_{12} & p_{22} & p_{32} & p_{42} \\ p_{11} & p_{12} & p_{13} & p_{14} \end{pmatrix} = \begin{pmatrix} -4 & 0 & 4 & 8 \\ 0 & -4 & -8 & -12 \end{pmatrix}, \tag{2.2}$$

where the row spaces of A and $\hat{A}$ coincide. It should be noted that in general, not all vectors are Grassman vectors, i.e., represent subspaces.

3. The power sum relations. Consider a $K \times N$ Hankel matrix, H. The $K + N - 1$ distinct elements of H,

$$\{h_{11},\ h_{21}, \ldots, h_{K1},\ h_{K2},\ \ldots,\ h_{KN}\},$$

occur in the first column and last row. The following theorem states that these elements may be considered to be weighted sums of exponentials; see Grenander [5].

THEOREM 3.1 (due to Carathéodory). *Let $c_1, c_2, \ldots, c_n$ be given complex constants not all zero, with $n > 1$. There exist an integer m, $1 \le m \le n$, and certain constants $\rho_k, e_k,\ k = 1, 2, \ldots, m$, such that $\rho_k > 0,\ \|e_k\| = 1,\ e_k \ne e_l, k \ne l$, and such that*

$$c_\nu = \sum_{k=1}^{m} \rho_k e_k^\nu, \quad \nu = 1, 2, \ldots, n.$$

The integer m and the constants $\rho_k,\ e_k$ are uniquely determined.

Lanczos [8] called this type of term a *weighted power sum* and this terminology will be used here.

The relationship between a Hankel (or Toeplitz) matrix and power sums is of practical interest because Hankel matrices with elements which are power sums occur in many signal processing applications. One of these applications involves the so-called

frequencies of sinusoids problem [12], as follows. Consider a sequence $\{b_n\}$ with each term consisting of the weighted sum of K complex exponentials, with frequencies f_j, magnitudes a_j, and phases φ_j, for $j = 1, 2, \ldots, K$ and $n = 1, 2, \ldots$:

$$b_n \stackrel{\text{def}}{=} a_1 \exp(i(2\pi f_1 n + \varphi_1)) + \cdots + a_K \exp(i(2\pi f_K n + \varphi_K)) = \sum_{j=1}^{K} \alpha_j z_j^n, \tag{3.1}$$

where

$$\alpha_j = a_j \exp(i\varphi_j) \text{ and } z_j = \exp(i2\pi f_j), \quad j = 1, 2, \ldots, K \quad \text{with } i \stackrel{\text{def}}{=} \sqrt{-1}.$$

Given the sequence $\{b_n\}$, there are various methods for finding the parameters $\{\alpha_j,\ z_j\}$. The linear prediction method begins by arranging the elements of the sequence in Hankel or Toeplitz matrix form [11].

When a Hankel matrix A representing a subspace has entries as in (3.1) which are weighted power sums, any Grassman vector which represents the corresponding subspace satisfies conditions in addition to the Plücker relations. These conditions will be called the *power sum relations* and will now be derived.

Let $s_i,\ i = 1, \ldots, K$, denote the ith elementary symmetric polynomial; see Lang [9] where it is shown that any symmetric polynomial is a polynomial function of the elementary symmetric polynomials.

Let A be a $K \times N$, $(K \leq N)$, Hankel matrix whose entries are power sums, where $M = K$:

$$A \stackrel{\text{def}}{=} \begin{pmatrix} \sum_{i=1}^{M} \alpha_i z_i^1 & \sum_{i=1}^{M} \alpha_i z_i^2 & \cdots & \sum_{i=1}^{M} \alpha_i z_i^N \\ \sum_{i=1}^{M} \alpha_i z_i^2 & \sum_{i=1}^{M} \alpha_i z_i^3 & \cdots & \sum_{i=1}^{M} \alpha_i z_i^{N+1} \\ \vdots & \vdots & & \vdots \\ \sum_{i=1}^{M} \alpha_i z_i^K & \sum_{i=1}^{M} \alpha_i z_i^{K+1} & \cdots & \sum_{i=1}^{M} \alpha_i z_i^{N+K-1} \end{pmatrix}. \tag{3.2}$$

Consider the matrix consisting of the first K columns of A: $P = [a_1\ a_2, \ldots, a_K]$. Then, $\det P$ is the first element $p_{1\ 2,\ldots,K}$ in the Grassman vector $\varphi(A)$.

LEMMA 3.2. *The determinant of the power sum matrix P is*

$$\det P = \left(\prod_{i=1}^{K} \alpha_i \right) \left(\prod_{i=1}^{K} z_i \right) (\det V)^2, \tag{3.3}$$

where V is the Vandermonde matrix

$$\begin{pmatrix} 1 & 1 & \cdots & 1 \\ z_1 & z_2 & \cdots & z_K \\ \vdots & \vdots & & \vdots \\ z_1^{K-1} & z_2^{K-1} & \cdots & z_K^{K-1}, \end{pmatrix}.$$

Proof. We have that $\det V = \prod_{\substack{i,j=1 \\ i>j}}^{K} (z_i - z_j)$. Note that the determinant is a multilinear function of its columns. By viewing each column of $\det P$ as a sum of K

columns, we deduce that $\det P$ is a sum of K^K terms, $K!$ of which are nonvanishing. These terms occur whenever $z_i \neq z_j,\ i \neq j$, from the expression for the determinant above.

The entire determinant $\det P$ is

$$\det P = \left(\prod_{i=1}^{K} \alpha_i\right) \left\{ \sum_{\sigma \in S_K} \left(\prod_{i=1}^{K} z_{\sigma(i)}^{i}\right) (-1)^{\sigma} \right\} \det V. \tag{3.4}$$

Here, the subscript $\sigma(i)$ of $z_{\sigma(i)}^{i}$ is an index and the superscript, i, is an exponent. S_K is the group of permutations on K letters.

The second factor in (3.4) is simply the Vandermonde determinant again times the product of the $z_i's$:

$$\left\{ \sum_{\sigma \in S_K} \left(\prod_{i=1}^{K} z_{\sigma(i)}^{i}\right) (-1)^{\sigma} \right\} = \left(\prod_{i=1}^{K} z_i\right) \det V. \qquad \square$$

Consider a general power sum matrix $GP = [a_{q_1}, a_{q_2}, \ldots, a_{q_K}]$ where the K columns $\{q_1, q_2, \ldots, q_K\}$ are from the original Hankel matrix, A, given in equation (3.2). Assume without loss of generality that $1 \leq q_1 < q_2 < \cdots < q_K \leq N$:

$$GP \stackrel{\text{def}}{=} \begin{pmatrix} \sum_{i=1}^{M} \alpha_i z_i^{q_1} & \sum_{i=1}^{M} \alpha_i z_i^{q_2} & \cdots & \sum_{i=1}^{M} \alpha_i z_i^{q_K} \\ \sum_{i=1}^{M} \alpha_i z_i^{q_1+1} & \sum_{i=1}^{M} \alpha_i z_i^{q_2+1} & \cdots & \sum_{i=1}^{M} \alpha_i z_i^{q_K+1} \\ \vdots & \vdots & & \vdots \\ \sum_{i=1}^{M} \alpha_i z_i^{q_1+K-1} & \sum_{i=1}^{M} \alpha_i z_i^{q_2+K-1} & \cdots & \sum_{i=1}^{M} \alpha_i z_i^{q_K+K-1} \end{pmatrix}.$$

Here, $\det GP$ corresponds to the Grassman vector element $p_{q_1 \ \cdots \ q_K}$. Following the same line of argument as above, the factorization can be shown to be

$$\det GP = \left(\prod_{i=1}^{N} \alpha_i\right) \left\{ \sum_{\sigma \in S_K} \left(\prod_{i=1}^{K} z_{\sigma(i)}^{q_i}\right) (-1)^{\sigma} \right\} \det V.$$

The second term involves the determinant of what will be called the *general Vandermonde matrix*, GV:

$$\left\{ \sum_{\sigma \in S_K} \left(\prod_{i=1}^{K} z_{\sigma(i)}^{q_i}\right) (-1)^{\sigma} \right\} = \left(\prod_{i=1}^{K} z_i^{q_1}\right) \det \begin{pmatrix} 1 & 1 & \cdots & 1 \\ z_1^{r_2} & z_2^{r_2} & \cdots & z_K^{r_2} \\ \vdots & \vdots & & \vdots \\ z_1^{r_K} & z_2^{r_K} & \cdots & z_K^{r_K} \end{pmatrix}.$$

Here, r_i is defined as $(q_i - q_1),\ i = 2, \ldots, K$. The entire factorization of the determinant of the general power sum matrix GP is then

$$\det GP = \left(\prod_{i=1}^{N} \alpha_i\right) \left(\prod_{i=1}^{K} z_i^{q_1}\right) \det V \det GV. \tag{3.5}$$

We now have the following lemma.

LEMMA 3.3. *Let a Grassman vector, g, be derived from a Hankel matrix. Then the elements of g normalized by the first element are symmetric polynomials.*

Proof. Divide the factorization for $\det GP$ in equation (3.5) by the factorization of $\det P$ in (3.3):

$$\frac{p_{q_1\ q_2\ \cdots\ q_K}}{p_{1\ 2\ \cdots\ K}} = \frac{\det GP}{\det P} = \frac{\left(\prod_{i=1}^K \alpha_i\right)\left(\prod_{i=1}^K z_i^{q_1}\right)(\det V)(\det GV)}{\left(\prod_{i=1}^K \alpha_i\right)\left(\prod_{i=1}^K z_i\right)(\det V)^2} = \left(\prod_{i=1}^K z_i^{q_1-1}\right)\frac{\det GV}{\det V}. \tag{3.6}$$

If $z_i = z_j$, $i \neq j$, then $\det GV = 0$. Therefore, the polynomial $\det GV$ is divisible by $z_i - z_j$ and it follows that $\frac{\det GV}{\det V}$ is a polynomial. Interchanging z_i and z_j, $i \neq j$, the numerator and denominator in (3.6) can be seen to be skew-symmetric. ∎

Using the result of Theorem 3.1, it follows that the elements of a normalized Grassman vector corresponding to any full rank Hankel matrix are symmetric polynomials. Consider the normalized Grassman vector for a 2×4 Hankel matrix A_1 with elements $(A_1)_{ij} = x^n + y^n,\ n = i + j - 1;\ i = 1, 2;\ j = 1, \ldots, 4$. The normalization of the vector $\varphi(A_1)$ can be written in terms of the elementary symmetric polynomials $s_1 = x + y$ and $s_2 = xy$ as

$$\begin{aligned}\varphi(A_1)(1/p_{12}) &= (1/p_{12})(p_{12}, p_{13}, p_{14}, p_{23}, p_{24}, p_{34}) \\ &= (1,\ s_1,\ s_1^2 - s_2,\ s_2,\ s_1 s_2,\ s_2^2).\end{aligned} \tag{3.7}$$

The normalized Grassman vector corresponding to a subspace represented by a 2×5 Hankel matrix A_2 can be written as

$$\begin{aligned}\varphi(A_2)/(1/p_{12}) &= (1/p_{12})(p_{12}, p_{13}, p_{14}, p_{15}, p_{23}, p_{24}, p_{25}, p_{34}, p_{35}, p_{45}) \\ &= (1, s_1, s_1^2 - s_2, s_1(s_1^2 - 2s_2), s_2, s_1 s_2, s_2(s_1^2 - s_2), s_2^2, s_1 s_2^2, s_2^3).\end{aligned}$$

4. Formulation of an alternate problem. Consider a $K \times N$ complex Hankel matrix, A, and corresponding Grassman vector

$$\varphi(A) = \tilde{v} = (p_{1\ 2\ \cdots\ K}, \ldots, p_{N-K+1\ N-K+2\ \cdots\ N}).$$

Let $v = \tilde{v}/p_{12\cdots K}$.

The *distance* between two subspaces A and B of equal dimension can be defined as

$$\operatorname{dist}(A, B) \stackrel{\text{def}}{=} \|P_A - P_B\|_2,$$

where P_A and P_B are the unique orthogonal projections onto A and B, respectively.

What is desired is a matrix, C, with Hankel structure (denote this by $C \in \mathcal{H}$) such that

$$\|P_A - P_C\|_2 = \min_{B \in \mathcal{H}} \|P_A - P_B\|_2. \tag{4.1}$$

The problem in (4.1) will be transformed to the maximization of the inner product of two vectors. In order to do this the notion of *principal angles* [1], [4] will now be introduced.

Let U and W be subspaces with

$$p = \dim(U) \geq \dim(W) = q \geq 1.$$

The *principal angles* $\theta_1, \ldots, \theta_q \in [0, \pi/2]$ between U and W are defined recursively by

$$\cos(\theta_k) = \max_{u \in U} \max_{w \in W} |u^H w|,$$

subject to

$$\begin{aligned} \|u\|_2 = \|w\|_2 &= 1, \\ u^H u_i &= 0, \qquad i = 1, \ldots, k-1, \\ w^H w_i &= 0, \qquad i = 1, \ldots, k-1. \end{aligned}$$

Note that $0 \leq \theta_1 \leq \cdots \leq \theta_q \leq \pi/2$. The vectors $\{u_1, \ldots, u_p\}$ and $\{w_1, \ldots, w_q\}$ are called the *principal vectors* of the subspace pair (U, W). Although the principal vectors aren't unique, the principal angles are. The largest principal angle is related to the distance between equidimensional subspaces given above. If $p = q$, then

$$\text{dist } (U, W) = \sqrt{1 - \cos(\theta_q)^2} = \sin \theta_q.$$

The norm in (4.1) is therefore $\sin \theta_k$, where θ_k is the largest principal angle between the subspaces represented by the row spaces of A and B.

Consider a second subspace distance involving the product of the cosines of all the principal angles:

$$\text{dist}_x(U, W) \stackrel{\text{def}}{=} 1 - \left| \prod_{i=1}^{q} \cos \theta_i \right|. \tag{4.2}$$

We now show that this distance arises naturally when the principal angles associated with the subspaces are related to the angle between the Grassman vectors corresponding to the subspaces. In the following let A^H denote the conjugate transpose of the matrix, A. Let the singular value decomposition of the $N \times M$ matrix A be $A = Y \Sigma Z^H$ where Y and Z are unitary and where the $N \times M$ diagonal matrix, Σ, consists of the singular values in order of decreasing magnitude: $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_p$, where $p = \min\{N, M\}$. A generalization of the Courant–Fischer minimax theorem for symmetric matrices is the following [4].

LEMMA 4.1. *If $A \in \mathbf{C}^{N \times M}$, then for $k = 1$ to $\min\{M, N\}$,*

$$\sigma_k(A) = \max_{\substack{\dim(S)=k \\ \dim(T)=k}} \min_{\substack{x \in S \\ y \in T}} \frac{|y^H A x|}{\|x\|_2 \|y\|_2} = \max_{\dim S = k} \min_{x \in S} \frac{\|Ax\|_2}{\|x\|_2}.$$

We now have the following theorem [4].

THEOREM 4.2. *Let $Q_U \in \mathbf{C}^{\mathbf{m} \times \mathbf{p}}$ and $Q_W \in \mathbf{C}^{\mathbf{m} \times \mathbf{q}}$ be orthogonal bases for the subspaces U and W, respectively. Let the principal vectors of U and W be $[u_1 \ \cdots \ u_p]$ and $[w_1 \ \cdots \ w_q]$, respectively. From the minimax characterization of singular values above, if $Y \Sigma Z^H$ is the singular value decomposition of $Q_U^H Q_W$, then the following are true:*

$$\begin{aligned} [u_1 \ \cdots \ u_p] &= Q_U Y, \\ [w_1 \ \cdots \ w_q] &= Q_W Z, \\ \cos(\theta_k) &= \sigma_k, \ k = 1, \ldots, q, \end{aligned}$$

where $\Sigma = \text{diag}\,(\sigma_1, \ldots, \sigma_q)$ *and where* $\theta_1, \ldots, \theta_k$ *are the principal angles associated with the subspaces* U *and* W.

The following result is related to a theorem by Brualdi, Friedland, and Pothem [2] concerning the angle between two Grassman vectors.

THEOREM 4.3. *Let* A *and* B *be matrices of equal dimensions. Then the cosine of the angle between the Grassman vectors* $\varphi(A)$ *and* $\varphi(B)$ *corresponding to the row spaces of* A *and* B *is equal to the product of the cosines of the principal angles between* A *and* B.

Proof. Consider $K \times N$ full rank matrices A and B, $K \leq N$. Then, A can be written as $A = R_A\, Q_A$ where Q_A has orthonormal rows. Note that $\|\varphi(Q_A)\|_2 = 1$ and so $\|\varphi(A)\|_2 = |\det(R_A)|$. In a similar manner, $B = R_B Q_B$ and $\|\varphi(B)\|_2 = |\det(R_B)|$. Then, the cosine of the angle between $\varphi(A)$ and $\varphi(B)$ is

$$\frac{\left|\varphi(A)\varphi(B)^H\right|}{\|\varphi(A)\|_2\|\varphi(B)\|_2} = \frac{\left|\det(R_A)\ \varphi(Q_A)\ \det(R_B)^H\ \varphi(Q_B)^H\right|}{\|\varphi(R_A)\|_2\ \|\varphi(R_B)\|_2}$$

$$= |\varphi(Q_A Q_B^H)| = |\det(Q_A Q_B^H)|.$$

Now, use Theorem 4.2. ∎

Let the principal angles between the subspaces represented by the rows of A and B be $0 \leq \theta_1 \leq \cdots \leq \theta_q \leq \pi/2$, where $p = \dim(R(A^T)) \geq \dim(R(B^T)) = q \geq 1$. The number r, $1 \leq r \leq q$, of the cosines of the principal angles that are equal to one is the dimension of the subspace $A \cap B$. If the number s of cosines of principle angles that are 0 is greater than 0, then there is a subspace $C \subset A$ of dimension $p - q + s$ such that $C \bigcap B = \emptyset$.

We now return to the formulation of the alternate optimization problem. Consider A from (2.1):

$$v \stackrel{\text{def}}{=} \varphi(A) = (-4, -8, -12, -4, -8, -4).$$

The normalized Grassman vector, g, is, from (3.7),

$$g = (1,\ s_1,\ s_1^2 - s_2,\ s_2,\ s_1 s_2,\ s_2^2).$$

The alternate problem is then

$$\max_{s_1, s_2} \frac{|v\ g(s_1, s_2)^H|}{\|v\|_2 \|g(s_1, s_2)\|_2}.$$

Once g is found, the Hankel matrix H is obtained by substituting s_1 and s_2 in $H = \varphi^{-1}(p_{12})\ \varphi^{-1}(g)$, where

$$\varphi^{-1}(p_{12}) = \begin{pmatrix} s_1 & s_1^2 - 2s_2 \\ s_1^2 - 2s_2 & s_1^3 - 3s_1 s_2 \end{pmatrix}$$

and $\varphi^{-1}(g)$ is found using (2.2).

5. Conclusion. The set of constraints which a Grassman vector must satisfy in order for its inverse image to be a Hankel matrix have been developed. A new subspace distance has been introduced and its use in transforming the original matrix approximation problem into a simpler vector approximation problem has been demonstrated.

Acknowledgments. The author would like to thank G. Martin for advice and guidance during the work on this paper and the anonymous reviewers for their helpful suggestions.

CONDENSED FORMS FOR SKEW-HAMILTONIAN/HAMILTONIAN PENCILS*

CHRISTIAN MEHL†

Abstract. In this paper we consider real or complex skew-Hamiltonian/Hamiltonian pencils $\lambda S - H$, i.e., pencils where S is a skew-Hamiltonian and H is a Hamiltonian matrix. These pencils occur, for example, in the theory of continuous time, linear quadratic optimal control problems. We reduce these pencils to canonical and Schur-type forms under structure-preserving transformations, i.e., J-congruence-transformations $(\lambda S-H) \mapsto -JP^*J(\lambda S-H)P$, where P is nonsingular or unitary.

Key words. Hamiltonian matrices, skew-Hamiltonian matrices, matrix pencils, canonical forms, Schur forms, Riccati equations, descriptor systems, optimal control

1. Introduction.

The motivation for the study of pencils $\lambda S - H$, where S is a skew-Hamiltonian and H is a Hamiltonian matrix, comes mainly from the linear quadratic optimal control problem; see [10], [13], [14], and the references therein. This is the problem of minimizing the cost functional

$$\frac{1}{2}\int_{t_0}^{\infty} \Big(y(t)^*Qy(t) + u(t)^*Ru(t)\Big)dt$$

subject to the dynamics

$$E\dot{x}(t) = Ax(t) + Bu(t), \tag{1}$$

$$x(t_0) = x_0, \tag{2}$$

$$y(t) = Cx(t), \tag{3}$$

where $A, E \in \mathcal{C}^{n\times n}, Q \in \mathcal{C}^{p\times p}, B \in \mathcal{C}^{n\times m}, C \in \mathcal{C}^{p\times n}, R \in \mathcal{C}^{m\times m}$, B with full column rank, C with full row rank, Q Hermitian, and R Hermitian positive definite. Solutions of (1) can be obtained via the solution of the *generalized continuous algebraic Riccati equation*

$$C^*QC + A^*XE + E^*XA - (B^*XE)^*R^{-1}(B^*XE) = 0, \tag{4}$$

or directly via the computation of deflating subspaces of the pencil

$$\lambda S_0 - H_0 = \lambda \begin{bmatrix} E & 0 \\ 0 & E^* \end{bmatrix} - \begin{bmatrix} A & BR^{-1}B^* \\ C^*QC & -A^* \end{bmatrix}; \tag{5}$$

see again [10], [13], [14], and the references therein.

From (5) we obtain immediately that S_0 is a skew-Hamiltonian and H_0 is a Hamiltonian matrix.

DEFINITION 1.1. *Let* $J_n := \left[\begin{smallmatrix} 0 & I_n \\ -I_n & 0 \end{smallmatrix}\right]$. *(We drop the index* n *if the dimension is clear from the context.)*

1. *A matrix* $H \in \mathcal{C}^{2n\times 2n}$ *is called* Hamiltonian *if*

$$HJ + JH^* = 0.$$

The set of Hamiltonian matrices is denoted by $\mathcal{H}_{2n}$.

2. *A matrix* $S \in \mathcal{C}^{2n\times 2n}$ *is called* skew-Hamiltonian *if*

$$SJ - JS^* = 0.$$

The set of skew-Hamiltonian matrices is denoted by $\mathcal{SH}_{2n}$.

3. *A pencil* $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ *is called* skew-Hamiltonian/Hamiltonian *if* S *is skew-Hamiltonian and* H *is Hamiltonian.*

The set of Hamiltonian matrices and the set of skew-Hamiltonian matrices have a special algebraic structure. The first is a Lie algebra (see, e.g., [21]), and the latter is a Jordan algebra; see [1]. If the matrices under consideration are complex, there exists a vector space isomorphism between these two algebras.

LEMMA 1.2. *The map* $A \mapsto iA$ *is a vector space isomorphism between* $\mathcal{H}_{2n}$ *and* $\mathcal{SH}_{2n}$.

Proof. The proof follows directly from the definition. ∎

If E in (5) is the identity matrix, then the study of the pencil $\lambda S_0 - H_0$ reduces to the study of a Hamiltonian matrix. Condensed forms for Hamiltonian matrices have been extensively studied in recent years; see, e.g., [2], [3], [4], [11], [17], or [5] for a more general approach concerning elements from classical Lie or Jordan algebras. There also have been extensive studies concerning symplectic matrices and symplectic pencils that occur in the context of the discrete algebraic Riccati equation corresponding to (5); see, e.g., [6], [11], [22].

If E in (5) is nonsingular, then it is well known that

$$S_0^* \begin{bmatrix} 0 & E^{-*} \\ -E^{-1} & 0 \end{bmatrix} H_0 = -H_0^* \begin{bmatrix} 0 & E^{-*} \\ -E^{-1} & 0 \end{bmatrix} S_0; \tag{6}$$

i.e., $\lambda(iS_0) - H_0$ is an $i\left[\begin{smallmatrix} 0 & E^{-*} \\ -E^{-1} & 0 \end{smallmatrix}\right]$-self-adjoint pencil or in the real case $\lambda S_0 - H_0$ is a $\left[\begin{smallmatrix} 0 & E^{-*} \\ -E^{-1} & 0 \end{smallmatrix}\right]$-skew-symmetric pencil in the sense of [10], where canonical forms for these kinds of pencils were discussed. Obviously this terminology cannot be used if E in (5) is singular. But in recent years, there has been great interest in the singular case; see [13] and the references therein. Therefore we use in this paper the concept of skew-Hamiltonian/Hamiltonian pencils. The case that E is singular is included here.

In the following we will look for condensed forms, i.e., forms from which the eigenvalues of the pencil can be read off in a simple way. For an arbitrary pencil these are the Kronecker canonical form (see [8]) that yields the eigenvalues and eigenvectors and the (generalized) Schur form (see [9]) that yields the eigenvalues and a nested set of invariant subspaces and that is obtained by a transformation $(\lambda A - B) \mapsto U(\lambda A - B)V$, where U and V are unitary matrices. Following the notation in [13] we use the term "Kronecker canonical form" also in the case of regular pencils, but we note that in this case the canonical form is due to Weierstraß; see [8].

The following lemma is helpful in finding out what kind of structure-preserving transformations we may use to obtain corresponding forms for skew-Hamiltonian/ Hamiltonian pencils.

LEMMA 1.3. *The map* $H \mapsto JH$ *is a bijection between* $\mathcal{H}_{2n}$ *and the set of* $2n \times 2n$ *Hermitian matrices.*

Proof. The proof follows directly from the definitions. ∎

The general structure-preserving equivalence transformations for Hermitian matrices are the congruence transformations $A \mapsto P^*AP$, where P is nonsingular. Lemma 1.3 implies that the transformations $H \mapsto -JP^*JHP$, where P is nonsingular, preserve the Hamiltonian structure. We will call these transformations J-congruence transformations by analogy to the congruence transformations. More general are the transformations $H \mapsto \mu JP^*JHP$, where P is nonsingular and $\mu \in \mathcal{R}$. These transformations are the analogue of the μ-congruence transformations $A \mapsto \mu P^*AP$ (see also [16] for related μ-symplectic transformations).

DEFINITION 1.4.

1. *Two matrices $A, B \in \mathcal{C}^{2n\times 2n}$ are called* J-congruent *if there exists a nonsingular matrix $P \in \mathcal{C}^{n\times n}$ such that*

$$-JP^*JAP = B. \tag{7}$$

2. *Two pencils $\lambda A - B, \lambda C - D \in \mathcal{C}^{2n\times 2n}$ are called* J-congruent *if there exists a nonsingular matrix $P \in \mathcal{C}^{n\times n}$ such that*

$$-JP^*J(\lambda A - B)P = \lambda C - D. \tag{8}$$

Analogously we define μ-J-congruence. We easily obtain the following lemma.

LEMMA 1.5. *Let $S \in \mathcal{C}^{2n\times 2n}$ be a skew-Hamiltonian, $H \in \mathcal{C}^{2n\times 2n}$ a Hamiltonian, and $P \in \mathcal{C}^{2n\times 2n}$ an arbitrary matrix and let $\mu \in \mathcal{R}$. Then*

1. *μJP^*JSP is skew-Hamiltonian,*
2. *μJP^*JHP is Hamiltonian,*
3. *$\mu JP^*J(\lambda S - H)P$ is skew-Hamiltonian/Hamiltonian.*

Proof. The proof follows directly from the definitions. ∎

If $\lambda S - H$ is a skew-Hamiltonian/Hamiltonian pencil, then $\lambda(iJS) - (JH)$ is a Hermitian pencil in the sense of [19], where a canonical form for Hermitian pencils is given. In the theory of Hermitian pencils this form is the analogue of the Kronecker canonical form in the theory of general matrix pencils. The numerical computation of the Kronecker canonical form is in general ill-conditioned (see, e.g., [9]), in contrast to the computation of the Schur form; see again [9]. But for a Hermitian matrix the Schur form and the Jordan canonical from coincide; i.e., a triangular form of a Hermitian pencil would be diagonal. Thus, the problem of finding a triangular form for a Hermitian pencil under unitary congruence transformations is equivalent to the problem of the simultaneous diagonalization of two Hermitian matrices. This is possible if and only if the matrices commute; see [18].

In contrast to this, the concept of skew-Hamiltonian/Hamiltonian pencils enables us to obtain both a canonical form and a Schur-type form under J-congruence. After stating some preliminary results in section 2 we discuss this canonical form in section 3. In regard to our interest in finding eigenvalues we restrict our examination to regular pencils. In section 4 we discuss under which conditions it is possible to obtain a structured Schur form under unitary J-congruence transformations, i.e., J-congruence transformations, where the matrix P in (8) is unitary. We will call this form a J-Schur form. Since in general not every skew-Hamiltonian/Hamiltonian pencil has a J-Schur form, we present in section 5 a closely related form that is almost a Schur form and that is obtained by using also some nonunitary J-congruence transformations.

Throughout the paper we use the following notation and expressions:

1. By the *direct sum* of two square matrices A, B, we mean the matrix $\left[\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right]$. Analogously we define the direct sum of square pencils.

2. By $\mathrm{Span}(x_1, \ldots, x_m)$ we denote the subspace of $\mathcal{C}^k$ spanned by the vectors $x_1, \ldots, x_m \in \mathcal{C}^k$.
3. By e_i we denote the ith unit vector.
4. By $\sim_c$ we denote the equivalence relation by congruence.
5. Let $\lambda A - B \in \mathcal{C}^{n\times n}$ be a regular pencil. Introducing homogeneous parameters, $\alpha A - \beta B$ (see [8]), the eigenvalues of $\alpha A - \beta B$ can be represented by pairs $(\alpha, \beta) \in \mathcal{C}^2 \backslash \{0\}$, such that

$$\alpha A x - \beta B x = 0 \quad \text{for an } x \in \mathcal{C}^n \backslash \{0\}.$$

Obviously $(t\alpha, t\beta)$ represents the same eigenvalue for all $t \in \mathcal{C}\backslash\{0\}$; thus, we denote them by $\lambda = \frac{\alpha}{\beta}$ if $\beta \neq 0$. Pairs $(\alpha, 0), \alpha \neq 0$ represent the eigenvalue infinity of $\alpha A - \beta B$ that we will denote by ∞. We note that we always include the eigenvalue ∞ when we are talking about real or about purely imaginary eigenvalues.

2. Preliminaries. We first review some properties of the pencils under consideration.

LEMMA 2.1. *Let $\lambda S - H$ be a skew-Hamiltonian/Hamiltonian pencil. If λ_0 is an eigenvalue of $\lambda S - H$, then so is $-\lambda_0^*$ with the same partial multiplicities.*

Proof. Since S is skew-Hamiltonian and H is Hamiltonian we find that

$$J(\lambda S - H)J = -\lambda S^* - H^*;$$

i.e., $\lambda S - H$ and $-\lambda S^* - H^*$ are equivalent. Thus, these two pencils have the same Kronecker canonical form. ∎

To every block associated with an eigenvalue λ_0 with nonzero real part in the Kronecker canonical form, we find by Lemma 2.1 a paired block of the same size associated with the eigenvalue $-\lambda_0^*$. In general we have no pairing of blocks for the purely imaginary eigenvalues.

In the following we will use the concept of principle vectors of matrix pencils (see [7], [8], and [13]) that is analogous to the concept of principle vectors of matrices or the concept of Jordan chains. Since the chains of principle vectors lead in the pencil case to the Kronecker canonical form, we call them Kronecker chains.

DEFINITION 2.2. *Let $\lambda A - B \in \mathcal{C}^{n\times n}$ be a regular pencil.*

1. *A* Kronecker chain *associated with a finite eigenvalue λ_0 of $\lambda A - B$ is a tuple $(x_1, \ldots, x_m)$ of vectors from $\mathcal{C}^n\backslash\{0\}$ such that*

$$\lambda_0 A x_1 = B x_1 \tag{9}$$

$$\text{and} \quad \lambda_0 A x_i - B x_i = -A x_{i-1} \quad \text{for } i = 2, \ldots, m. \tag{10}$$

2. *A* Kronecker chain *associated with the eigenvalue ∞ of $\lambda A - B$ is a tuple $(y_1, \ldots, y_k)$ of vectors from $\mathcal{C}^n\backslash\{0\}$ such that*

$$A y_1 = 0 \tag{11}$$

$$\text{and} \quad A y_i = B y_{i-1} \quad \text{for } i = 2, \ldots, k. \tag{12}$$

It is clear that if the Kronecker chains in Definition 2.2 are of maximal length, we find a block $\lambda_0 I_m - J_m(\lambda)$ in the Kronecker canonical form of $\lambda A - B$, whose associated deflating subspace is spanned by $x_1, \ldots, x_m$ and a block $\lambda J_k(0) - I_k$, whose associated deflating subspace is spanned by $y_1, \ldots, y_k$. Here $J_l(\mu)$ denotes an $l \times l$ Jordan block

with eigenvalue μ:

$$J_l(\mu) = \begin{bmatrix} \mu & 1 & 0 & \dots & 0 \\ 0 & \mu & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ \vdots & & \ddots & \ddots & 1 \\ 0 & \dots & \dots & 0 & \mu \end{bmatrix}.$$

Furthermore, we have the following property.

LEMMA 2.3. *Let $\lambda A - B \in \mathcal{C}^{n\times n}$ be a regular pencil. If $(x_1, \dots, x_m)$ is a Kronecker chain associated with the eigenvalue 0 of $\lambda A - B$, then $(x_1, \dots, x_m)$ is a Kronecker chain associated with the eigenvalue ∞ of $\lambda B - A$.*

Proof. The proof follows directly from Definition 2.2. ∎

The structure of skew-Hamiltonian/Hamiltonian pencils leads to special properties of the Kronecker chains.

LEMMA 2.4. *Let $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Furthermore let $(x_1, \dots, x_m)$ be a Kronecker chain associated with the eigenvalue $\lambda_0 \in \mathcal{C} \cup \{\infty\}$ and $(y_1, \dots, y_l)$ a Kronecker chain associated with the eigenvalue $\mu_0 \in \mathcal{C} \cup \{\infty\}$, where $\mu_0 \neq -\lambda_0^*$. Then for all i, j, where $1 \le i \le l$ and $1 \le j \le m$, we have*

$$y_i^* JSx_j = y_i^* JHx_j = 0. \tag{13}$$

Proof. The proof proceeds via induction on $k = i + j$.

1. $k = 2$, i.e., $i = j = 1$: Since $\mu \neq -\lambda^*$, at most one of these eigenvalues is infinite. Thus, we may assume without loss of generality (w.l.o.g.) that $\lambda \neq \infty$.

(a) In the case $\mu = \infty$, we have $Sy_1 = 0$. Since S is skew-Hamiltonian, we have

$$y_1^* JSx_1 = y_1^* S^* Jx_1 = 0.$$

Furthermore, we obtain from $\lambda Sx_1 = Hx_1$ that

$$y_1^* JHx_1 = \lambda y_1^* JSx_1 = 0.$$

(b) In the case $\mu \neq \infty$, we have

$$\mu Sy_1 = Hy_1.$$

Noting that S is skew-Hamiltonian and H is Hamiltonian, we see that this implies

$$\begin{aligned} \mu^* y_1^* JSx_1 &= (\mu x_1^* JSy_1)^* \\ &= (x_1^* JHy_1)^* \\ &= -y_1^* JHx_1. \end{aligned}$$

Since we also have $\lambda y_1^* JSx_1 = y_1^* JHx_1 = 0$, we obtain

$$(\lambda + \mu^*) y_1^* JSx_1 = 0.$$

Thus, we obtain $y_1^* JSx_1 = 0$, since $\mu \neq -\lambda^*$, and therefore also $y_1^* JHx_1 = 0$.

2. $k \Rightarrow k + 1$: Suppose that we have already proved (13) for all i, j, where $i \le l$, $j \le m$, and $i + j = k$. Obviously it is sufficient to show that

$$y_i^* JSx_{j+1} = y_i^* JHx_{j+1} = 0$$

for all i, j, where $i \leq l$, $j < m$, and $i + j = k$. Now assume again w.l.o.g. that $\lambda \neq \infty$ and let $y_0 := 0$.

(a) In the case $\mu = \infty$ we have $Sy_i = Hy_{i-1}$. Note that this holds also in the case $i = 1$, since $y_0 = 0$. By this or in the case $i > 1$ by induction, we obtain

$$\begin{aligned} y_i^* JSx_{j+1} &= y_i^* S^* Jx_{j+1} \\ &= y_{i-1}^* H^* Jx_{j+1} \\ &= 0. \end{aligned}$$

From $\lambda Sx_{j+1} - Hx_{j+1} = -Sx_j$ we also obtain

$$y_i^* JHx_{j+1} = \lambda y_i^* JSx_{j+1} + y_i^* JSx_j = 0.$$

(b) In the case $\mu \neq \infty$ we have $\mu Sy_i - Hy_i = -Sy_{i-1}$. Since $x_{j+1}^* JSy_{i-1} = 0$, this yields

$$\begin{aligned} \mu^* y_i^* JSx_{j+1} &= (\mu x_{j+1}^* JSy_i)^* \\ &= (x_{j+1}^* JHy_i)^* \\ &= -y_i^* JHx_{j+1}, \end{aligned}$$

once more using the fact that S is skew-Hamiltonian and that H is Hamiltonian. Noting that $y_i^* JSx_j = 0$, we also have

$$\lambda y_i^* JSx_{j+1} = y_i^* JHx_{j+1}.$$

Therefore, we obtain

$$(\lambda + \mu^*) y_i^* JSx_{j+1},$$

and finally

$$y_i^* JSx_{j+1} = y_i^* JHx_{j+1} = 0. \qquad \square$$

LEMMA 2.5. *Let $\lambda S - H \in \mathcal{C}^{2n \times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Furthermore let $(x_1, \ldots, x_m)$ be a Kronecker chain associated with the eigenvalue $\lambda \in \mathcal{C} \cup \{\infty\}$ and $(y_1, \ldots, y_l)$ a Kronecker chain associated with the eigenvalue μ, where $\mu = -\lambda^*$. Then for all i, j where $1 \leq i \leq l$, $1 \leq j \leq m$ and $i + j \leq \max(l, m)$, we have*

$$y_i^* JSx_j = y_i^* JHx_j = 0.$$

Proof. If $\lambda = \infty$, then Lemma 2.3 implies that $(x_1, \ldots, x_m)$ and $(y_1, \ldots, y_l)$ are Kronecker chains of $\lambda H - S$ associated with the eigenvalue zero. This also holds for the skew-Hamiltonian/Hamiltonian pencil $\lambda(iH) - (iS)$. Thus, it remains to prove the assertion for the case that $\lambda \neq \infty$.

1. First of all we prove that for all i, j, where $1 \leq i \leq l$ and $0 \leq j < m$, we have

$$y_i^* JSx_j = -y_{i-1}^* JSx_{j+1} \quad \text{and} \quad y_i^* JHx_j = -y_{i-1}^* JHx_{j+1}, \tag{14}$$

where $x_0 := 0$ and $y_0 := 0$. Since $(x_1, \ldots, x_m)$ and $(y_1, \ldots, y_l)$ are Kronecker chains we have

$$\lambda Sx_{j+1} - Hx_{j+1} = -Sx_j \quad \text{and} \quad -\lambda^* Sy_i - Hy_i = -Sy_{i-1}. \tag{15}$$

Note that this is also true for $i = 1$ and $j = 0$. From (15) and since S is skew-Hamiltonian and H is Hamiltonian, we obtain

$$\begin{aligned} -y_{i-1}^* JSx_{j+1} &= -y_{i-1}^* S^* Jx_{j+1} \\ &= -\lambda y_i^* S^* Jx_{j+1} - y_i^* H^* Jx_{j+1} \\ &= -\lambda y_i^* JSx_{j+1} + y_i^* JHx_{j+1} \\ &= y_i^* JSx_j \end{aligned}$$

and analogously

$$\begin{aligned} -y_{i-1}^* JHx_{j+1} &= -\lambda y_{i-1}^* JSx_{j+1} - y_{i-1}^* JSx_j \\ &= \lambda y_i^* JSx_j - y_{i-1}^* JSx_j \\ &= (\lambda y_i^* S^* - y_{i-1}^* S^*)Jx_j \\ &= -y_i^* H^* Jx_j \\ &= y_i^* JHx_j. \end{aligned}$$

2. Now assume w.l.o.g. that $l = \max(l, m)$. Since $i + j \leq l$ and $x_0 = 0$ we obtain by (14) that

$$y_i^* JSx_j = (-1)^j y_{i+j}^* JSx_0 = 0$$

and

$$y_i^* JHx_j = (-1)^j y_{i+j}^* JHx_0 = 0. \qquad \square$$

3. A canonical form under *J*-congruence. In this section we present a canonical form for skew-Hamiltonian/Hamiltonian pencils under J-congruence. In the study of skew-Hamiltonian/Hamiltonian pencils this form is the analogue of the Kronecker canonical form in the study of general matrix pencils.

THEOREM 3.1. *Let $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Then there exists a nonsingular matrix $P \in \mathcal{C}^{2n\times 2n}$ such that*

$$\begin{aligned} &-JP^*J(\lambda S - H)P \\ &\quad = \lambda \begin{bmatrix} S_{11} & 0 & 0 & 0 \\ 0 & S_{22} & 0 & S_{24} \\ 0 & 0 & S_{11}^* & 0 \\ 0 & S_{42} & 0 & S_{22}^* \end{bmatrix} - \begin{bmatrix} H_{11} & 0 & 0 & 0 \\ 0 & H_{22} & 0 & H_{24} \\ 0 & 0 & -H_{11}^* & 0 \\ 0 & H_{42} & 0 & -H_{22}^* \end{bmatrix}, \end{aligned} \tag{16}$$

where

1. *$\lambda S_{11} - H_{11}$ is a pencil in Kronecker canonical form and has only eigenvalues with positive real part.*
2. *$\lambda\hat{S} - \hat{H} := \lambda\left[\begin{smallmatrix} S_{22} & S_{24} \\ S_{42} & S_{22}^* \end{smallmatrix}\right] - \left[\begin{smallmatrix} H_{22} & H_{24} \\ H_{42} & -H_{22}^* \end{smallmatrix}\right]$ is a skew-Hamiltonian/Hamiltonian pencil such that $J(\lambda\hat{S} - \hat{H})$ is the direct sum of blocks of the form*

$$\lambda\varepsilon \begin{bmatrix} 0 & & & i \\ & & \cdot & \\ & \cdot & & \\ i & & & 0 \end{bmatrix} - \varepsilon \begin{bmatrix} 0 & & & \mu \\ & & \cdot & 1 \\ & \cdot & \cdot & \\ \mu & 1 & & 0 \end{bmatrix} \in \mathcal{C}^{k\times k} \tag{17}$$

or

$$\lambda\varepsilon \begin{bmatrix} 0 & & & 0 \\ & & \cdot & i \\ & \cdot & \cdot & \\ 0 & i & & 0 \end{bmatrix} - \varepsilon \begin{bmatrix} 0 & & & 1 \\ & & \cdot & \\ & \cdot & & \\ 1 & & & 0 \end{bmatrix} \in \mathcal{C}^{k\times k}, \tag{18}$$

where μ is real and $\varepsilon = \pm 1$.

Proof.

1. We first prove that $\lambda S - H$ is, up to the permutation of rows and columns, J-congruent to the direct sum of two skew-Hamiltonian/Hamiltonian pencils such that the eigenvalues of one pencil have all nonzero real part and the eigenvalues of the other pencil are all purely imaginary.

Let us consider a basis $(x_1, \ldots, x_m, y_1, \ldots, y_m, v_1, \ldots, v_{2(n-m)})$ of $\mathcal{C}^{2n}$ consisting of Kronecker chains of $\lambda S - H$ such that $(x_1, \ldots, x_m)$ is a basis of the deflating subspace associated with the eigenvalues with positive real part, $(y_1, \ldots, y_m)$ is a basis of the deflating subspace associated with the eigenvalues with negative real part, and $(v_1, \ldots, v_{2(n-m)})$ is a basis of the deflating subspace associated with the purely imaginary eigenvalues. Setting

$$Q = [x_1, \ldots, x_m, v_1, \ldots, v_{n-m}, y_1, \ldots, y_m, v_{n-m+1}, \ldots, v_{2(n-m)}],$$

we find by Lemma 2.4 that

$$\begin{aligned} &-JQ^*J(\lambda S - H)Q \\ &\quad = \lambda \begin{bmatrix} \tilde{S}_{11} & 0 & 0 & 0 \\ 0 & \tilde{S}_{22} & 0 & \tilde{S}_{24} \\ 0 & 0 & \tilde{S}_{11}^* & 0 \\ 0 & \tilde{S}_{42} & 0 & \tilde{S}_{22}^* \end{bmatrix} - \begin{bmatrix} \tilde{H}_{11} & 0 & 0 & 0 \\ 0 & \tilde{H}_{22} & 0 & \tilde{H}_{24} \\ 0 & 0 & -\tilde{H}_{11}^* & 0 \\ 0 & \tilde{H}_{42} & 0 & -\tilde{H}_{22}^* \end{bmatrix}, \end{aligned} \tag{19}$$

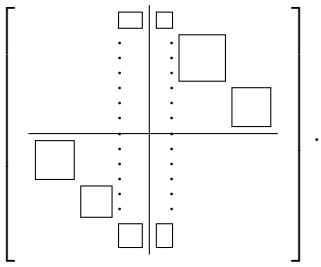
where $\lambda\tilde{S}_{11} - \tilde{H}_{11}$ has only eigenvalues with positive real part and the skew-Hamiltonian/Hamiltonian pencil $\lambda\tilde{S} - \tilde{H} := \lambda\left[\begin{smallmatrix} \tilde{S}_{22} & \tilde{S}_{24} \\ \tilde{S}_{42} & \tilde{S}_{22}^* \end{smallmatrix}\right] - \left[\begin{smallmatrix} \tilde{H}_{22} & \tilde{H}_{24} \\ \tilde{H}_{42} & -\tilde{H}_{22}^* \end{smallmatrix}\right]$ has only purely imaginary eigenvalues.

2. For the proof of (16) we note that $J(\lambda(i\tilde{S}) - \tilde{H})$ is a Hermitian pencil that has only purely imaginary eigenvalues. Thus, applying Lemma 2 from [19], we find that there exists a nonsingular matrix $X = \left[\begin{smallmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{smallmatrix}\right]$, where $X_{jk} \in \mathcal{C}^{(n-m)\times(n-m)}$, such that $X^*J(\lambda\tilde{S} - \tilde{H})X$ is a direct sum of blocks of the form (17) or (18). Furthermore, we find nonsingular matrices R, T such that $R(\lambda\tilde{S}_{11} - \tilde{H}_{11})T$ is in Kronecker canonical form. Hence we obtain (16) by setting

$$P = Q \cdot \begin{bmatrix} R & 0 & 0 & 0 \\ 0 & X_{11} & 0 & X_{12} \\ 0 & 0 & -T^* & 0 \\ 0 & X_{21} & 0 & X_{22} \end{bmatrix}. \qquad \square$$

Note that the blocks of the submatrices $\hat{S}$ and $\hat{H}$ in (16) in general occur in

patterns such as



In general it is not possible to reduce the subpencil $\lambda\hat{S} - \hat{H}$ to a direct sum of skew-Hamiltonian/Hamiltonian pencils that have only one eigenvalue. As an example, consider the pencil

$$\lambda \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix} - \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

Further reduction is impossible, since the pencil has purely imaginary eigenvalues with odd algebraic multiplicity.

LEMMA 3.2. *Let $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil with pairwise distinct eigenvalues $\lambda_1, \ldots, \lambda_k$ that are all purely imaginary. Then the following statements are equivalent:*

1. *The eigenvalues $\lambda_1, \ldots, \lambda_k$ all have even algebraic multiplicity.*
2. *There exists a nonsingular matrix P such that*

$$-JP^*JSP = \left[\begin{array}{ccc|ccc} S_{11} & & 0 & S_{1,k+1} & & 0 \\ & \ddots & & & \ddots & \\ 0 & & S_{kk} & 0 & & S_{k,2k} \\ \hline S_{k+1,1} & & 0 & S_{k+1,k+1} & & 0 \\ & \ddots & & & \ddots & \\ 0 & & S_{2k,k} & 0 & & S_{2k,2k} \end{array}\right]$$

and

$$-JP^*JHP = \left[\begin{array}{ccc|ccc} H_{11} & & 0 & H_{1,k+1} & & 0 \\ & \ddots & & & \ddots & \\ 0 & & H_{kk} & 0 & & H_{k,2k} \\ \hline H_{k+1,1} & & 0 & H_{k+1,k+1} & & 0 \\ & \ddots & & & \ddots & \\ 0 & & H_{2k,k} & 0 & & H_{2k,2k} \end{array}\right],$$

where $\lambda\left[\begin{smallmatrix} S_{ii} & S_{i,k+i} \\ S_{k+i,i} & S_{k+i,k+i} \end{smallmatrix}\right] - \left[\begin{smallmatrix} H_{ii} & H_{i,k+i} \\ H_{k+i,i} & H_{k+i,k+i} \end{smallmatrix}\right], i = 1, \ldots, k$, is a skew-Hamiltonian/Hamiltonian pencil having only one eigenvalue.

Proof. $1 \Rightarrow 2$: For the deflating subspace associated with λ_i, we find a basis $(x_1, \ldots, x_{m_i})$ consisting of Kronecker chains. Now set

$$P_{i1} = [x_1, \ldots, x_{\frac{m_i}{2}}] \quad \text{and} \quad P_{i2} = [x_{\frac{m_i}{2}+1}, \ldots, x_{m_i}].$$

This is possible, since every eigenvalue has even algebraic multiplicity. Setting

$$P = [P_{11}, \ldots, P_{k1}, P_{12}, \ldots, P_{k2}],$$

Lemma 2.4 implies the required result.

$2 \Rightarrow 1$: is clear, since the subpencils

$$\lambda \begin{bmatrix} S_{ii} & S_{i,k+i} \\ S_{k+i,i} & S_{k+i,k+i} \end{bmatrix} - \begin{bmatrix} H_{ii} & H_{i,k+i} \\ H_{k+i,i} & H_{k+i,k+i} \end{bmatrix}$$

have even sizes. □

There exists a real analogue to Theorem 3.1.

THEOREM 3.3. *Let $\lambda S - H \in \mathcal{R}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Then there exists a nonsingular matrix $P \in \mathcal{R}^{2n\times 2n}$ such that*

$$\begin{aligned} &-JP^*J(\lambda S - H)P \\ &\quad = \lambda \begin{bmatrix} S_{11} & 0 & 0 & 0 \\ 0 & S_{22} & 0 & S_{24} \\ 0 & 0 & S_{11}^* & 0 \\ 0 & S_{42} & 0 & S_{22}^* \end{bmatrix} - \begin{bmatrix} H_{11} & 0 & 0 & 0 \\ 0 & H_{22} & 0 & H_{24} \\ 0 & 0 & -H_{11}^* & 0 \\ 0 & H_{42} & 0 & -H_{22}^* \end{bmatrix}, \end{aligned} \tag{20}$$

where

1. *$\lambda S_{11} - H_{11}$ is a pencil in real Kronecker canonical form and has only eigenvalues with positive real part.*
2. *$\lambda \hat{S} - \hat{H} := \lambda \left[\begin{smallmatrix} S_{22} & S_{24} \\ S_{42} & S_{22}^* \end{smallmatrix}\right] - \left[\begin{smallmatrix} H_{22} & H_{24} \\ H_{42} & -H_{22}^* \end{smallmatrix}\right]$ is a skew-Hamiltonian/Hamiltonian pencil such that $J(\lambda \hat{S} - \hat{H})$ is the direct sum of blocks either of the form*

$$\lambda\varepsilon \begin{bmatrix} & & R \\ & R & \\ R & & \end{bmatrix} - \varepsilon \begin{bmatrix} & & \mu I_2 \\ & \mu I_2 & I_2 \\ \mu I_2 & I_2 & \end{bmatrix} \in \mathcal{C}^{2k\times 2k}, \tag{21}$$

where $\mu > 0$, $R = \left[\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right]$ and $I_2 = \left[\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right]$, or of one of the forms

$$\lambda\varepsilon \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & \Delta_k \\ 0 & -\Delta_k & 0 \end{bmatrix} - \varepsilon\Delta_{2k+1},\ k \in \mathcal{N}, \tag{22}$$

$$\lambda \begin{bmatrix} 0 & \Lambda_k \\ -\Lambda_k & 0 \end{bmatrix} - \begin{bmatrix} 0 & \Delta_k \\ \Delta_k & 0 \end{bmatrix},\ k \text{ even}, \tag{23}$$

$$\lambda\varepsilon \begin{bmatrix} 0 & \Delta_k \\ -\Delta_k & 0 \end{bmatrix} - \varepsilon\Lambda_{2k},\ k \in \mathcal{N}, \tag{24}$$

or

$$\lambda \begin{bmatrix} 0 & \Delta_k \\ -\Delta_k & 0 \end{bmatrix} - \begin{bmatrix} 0 & \Lambda_k \\ \Lambda_k & 0 \end{bmatrix},\ k \text{ odd}, \tag{25}$$

where $\varepsilon = \pm 1$ and furthermore

$$\Delta_k := \begin{bmatrix} 0 & & 1 \\ & \iddots & \\ 1 & & 0 \end{bmatrix} \quad \text{and} \quad \Lambda_k := \begin{bmatrix} 0 & & & 0 \\ & & \iddots & 1 \\ & \iddots & \iddots & \\ 0 & 1 & & 0 \end{bmatrix}.$$

Proof. The proof is similar to the proof of Theorem 3.1 using results on pencils $\lambda A - B$, where A is skew symmetric and B is symmetric; see, e.g., [20]. ∎

COROLLARY 3.4. *Let $\lambda S - H$ be a real skew-Hamiltonian/Hamiltonian pencil. Then the following conditions apply:*

1. *Every block of odd size belonging to the eigenvalue zero in the (general) Kronecker canonical form occurs with even multiplicity.*
2. *Every block of even size belonging to the eigenvalue ∞ in the (general) Kronecker canonical form occurs with even multiplicity.*

Proof. This follows directly from the structures of the blocks (23) and (25) in the structured canonical form (20). ∎

4. The existence of *J*-Schur forms. As shown in [17] not every Hamiltonian matrix can be reduced by unitary symplectic similarity transformations to a matrix in a Schur-type form that is called Schur–Hamiltonian form in [17] or Hamiltonian Schur form in [13]. This is a Hamiltonian matrix

$$\begin{bmatrix} T & R \\ 0 & -T^* \end{bmatrix}, \tag{26}$$

where $T \in \mathcal{C}^{n\times n}$ is upper triangular and $R \in \mathcal{C}^{n\times n}$ is Hermitian. The analogous Schur-type form for a skew-Hamiltonian matrix is

$$\begin{bmatrix} T & R \\ 0 & T^* \end{bmatrix}, \tag{27}$$

where $T \in \mathcal{C}^{n\times n}$ is upper triangular and $R \in \mathcal{C}^{n\times n}$ is skew-Hermitian. We call matrices of the form (26) or (27) matrices in J-Schur form. In [12] and [15] a necessary and sufficient condition for the existence of the Hamiltonian Schur form, resp., J-Schur form, is presented.

THEOREM 4.1. *Let $H \in \mathcal{C}^{2n\times 2n}$ be a Hamiltonian matrix and let $\lambda_1, \dots, \lambda_m$ be the pairwise distinct purely imaginary eigenvalues of H with algebraic multiplicities $p_1, \dots, p_m$. Then the following statements are equivalent:*

1. *There exists a unitary symplectic matrix $P \in \mathcal{C}^{2n\times 2n}$ such that PHP^{-1} is in J-Schur form* (26).
2. *If the columns of $U_k \in \mathcal{C}^{2n\times p_k}$, $k = 1, \dots, m$, form a basis of the invariant subspace associated with λ_k, then*

$$U_k^* J U_k \sim_c J_{p_k/2}. \tag{28}$$

Note that (28) implies that the multiplicities p_k are even.

Proof. See [12] or [15].

An analogous result holds in the case that H is skew-Hamiltonian.

THEOREM 4.2. *Let $S \in \mathcal{C}^{2n\times 2n}$ be a skew-Hamiltonian matrix and let $\lambda_1, \dots, \lambda_m$ be the pairwise distinct real eigenvalues of S with algebraic multiplicities $p_1, \dots, p_m$. Then the following statements are equivalent:*

1. *There exists a unitary symplectic matrix $P \in \mathcal{C}^{2n\times 2n}$ such that PSP^{-1} is in J-Schur form* (27).
2. *If the columns of $U_k \in \mathcal{C}^{2n\times p_k}$, $k = 1, \dots, m$, form a basis of the invariant subspace associated with λ_k, then*

$$U_k^* J U_k \sim_c J_{p_k/2}. \tag{29}$$

Proof. The proof follows directly from Lemma 1.2 and Theorem 4.1. ∎

We also obtain a similar result for the skew-Hamiltonian/Hamiltonian pencils. For the proof of this result, we need the following lemma.

LEMMA 4.3. *Let $P \in \mathcal{C}^{2n\times 2n}$. Then there exists a factorization*

$$P = Q \cdot \begin{bmatrix} R_{11} & R_{12} \\ 0 & R_{22}^* \end{bmatrix}, \tag{30}$$

where $Q \in \mathcal{C}^{2n\times 2n}$ is unitary and $R_{11}, R_{22} \in \mathcal{C}^{n\times n}$ are upper triangular.

Proof. After performing n steps of the QR Householder algorithm (see, e.g., [9]), we find a unitary matrix $Q_1 \in \mathcal{C}^{n\times n}$ such that

$$P = Q_1 \cdot \begin{bmatrix} R_{11} & \tilde{P}_{12} \\ 0 & \tilde{P}_{22} \end{bmatrix},$$

where $R_{11} \in \mathcal{C}^{n\times n}$ is upper triangular. Then we compute the QL factorization

$$\tilde{P}_{22} = Q_2 \cdot R_{22}^*,$$

where $Q_2 \in \mathcal{C}^{n\times n}$ is unitary and $R_{22}^* \in \mathcal{C}^{n\times n}$ is lower triangular; see again [9]. Thus, setting $Q = Q_1 \cdot \left[\begin{smallmatrix} I_n & 0 \\ 0 & Q_2 \end{smallmatrix}\right]$ implies (30). ∎

THEOREM 4.4. *Let $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ be a skew-Hamiltonian/Hamiltonian pencil. Let $\lambda_1, \ldots, \lambda_m$ be the pairwise distinct, finite, purely imaginary eigenvalues of $\lambda S - H$ with algebraic multiplicities $p_1, \ldots, p_m$ and let p_∞ be the algebraic multiplicity of the eigenvalue ∞. Then the following statements are equivalent:*

1. *There exists a nonsingular matrix $P \in \mathcal{C}^{2n\times 2n}$ such that*

$$-JP^*J(\lambda S - H)P = \lambda \begin{bmatrix} S_{11} & S_{12} \\ 0 & S_{11}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{12} \\ 0 & -H_{11}^* \end{bmatrix}, \tag{31}$$

   where S_{11} and H_{11} are upper triangular.

2. *There is a unitary matrix $Q \in \mathcal{C}^{2n\times 2n}$ such that*

$$-JQ^*J(\lambda S - H)Q = \lambda \begin{bmatrix} \hat{S}_{11} & \hat{S}_{12} \\ 0 & \hat{S}_{11}^* \end{bmatrix} - \begin{bmatrix} \hat{H}_{11} & \hat{H}_{12} \\ 0 & -\hat{H}_{11}^* \end{bmatrix}, \tag{32}$$

   where $\hat{S}_{11}$ and $\hat{H}_{11}$ are upper triangular.

3. *If the columns of $U_k \in \mathcal{C}^{2n\times p_k}$, $k = 1, \ldots, m$, form a basis of the deflating subspace associated with λ_k, then*

$$U_k^* J S U_k \sim_c J_{p_k/2}. \tag{33}$$

   Furthermore, if $p_\infty \neq 0$ and if the columns of $U_\infty \in \mathcal{C}^{2n\times p_\infty}$ form a basis of the deflating subspace associated with the eigenvalue ∞, then

$$U_\infty^* J H U_\infty \sim_c i J_{p_\infty/2}. \tag{34}$$

Proof. 1 ⇒ 2: If $P \in \mathcal{C}^{2n\times 2n}$ is nonsingular such that (31) holds, Lemma 4.3 implies that there exists a factorization (30). Using this we obtain from (31), that

$$\begin{aligned} &-JQ^*J(\lambda S - H)Q \\ &\quad = J \begin{bmatrix} R_{11} & R_{12} \\ 0 & R_{22}^* \end{bmatrix}^{-*} J \left(\lambda \begin{bmatrix} S_{11} & S_{12} \\ 0 & S_{11}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{12} \\ 0 & -H_{11}^* \end{bmatrix} \right) \begin{bmatrix} R_{11} & R_{12} \\ 0 & R_{22}^* \end{bmatrix}^{-1} \\ &\quad = \lambda \begin{bmatrix} -R_{22}^{-1} S_{11} R_{11}^{-1} & * \\ 0 & -R_{11}^{-*} S_{11}^* R_{22}^{-*} \end{bmatrix} - \begin{bmatrix} -R_{22}^{-1} H_{11} R_{11}^{-1} & * \\ 0 & R_{11}^{-*} H_{11}^* R_{22}^{-*} \end{bmatrix}, \end{aligned}$$

where the upper left subpencil $-R_{22}^{-1}(\lambda S_{11} - H_{11})R_{11}^{-1}$ is still upper triangular.

$2 \Rightarrow 3$: Let $\lambda S - H$ be in the form (32). First we show that the pencil is (up to the permutation of rows and columns) J-congruent to a direct sum of skew-Hamiltonian/Hamiltonian pencils in the form (32) that have only one eigenvalue. Therefore, consider a 4×4 subpencil

$$\lambda \check{S} - \check{H} = \lambda \begin{bmatrix} s_{11} & s_{12} & s_{13} & s_{14} \\ 0 & s_{22} & -s_{14}^* & s_{24} \\ 0 & 0 & s_{11}^* & 0 \\ 0 & 0 & s_{12}^* & s_{22}^* \end{bmatrix} - \begin{bmatrix} h_{11} & h_{12} & h_{13} & h_{14} \\ 0 & h_{22} & h_{14}^* & h_{24} \\ 0 & 0 & -h_{11}^* & 0 \\ 0 & 0 & -h_{12}^* & -h_{22}^* \end{bmatrix}$$

of the pencil in (32) such that $\lambda s_{11} - h_{11}$ has the eigenvalue λ_0 and such that $\lambda s_{22} - h_{22}$ has the eigenvalue μ_0. Furthermore, let $\lambda_0 \neq \mu_0, -\mu_0^*$. Next we show that the (1,2)-elements of $\check{S}$ and $\check{H}$, respectively, can be simultaneously set to zero. Therefore, let

$$P = \begin{bmatrix} 1 & x & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & y & 1 \end{bmatrix},$$

where $x, y \in \mathcal{C}$, and consider $-JP^*J\check{S}P$ and $-JP^*J\check{H}P$. If we want to set the (1,2)-elements of both matrices to zero, we have to solve the equations

$$\begin{aligned} s_{12} + s_{22}y^* + s_{11}x &= 0, \\ \text{and} \quad h_{12} + h_{22}y^* + h_{11}x &= 0. \end{aligned}$$

This implies $(h_{22}s_{11} - h_{11}s_{22})x = s_{22}h_{12} - h_{22}s_{12}$. Since $\lambda_0 \neq \mu_0$, it follows that $h_{22}s_{11} - h_{11}s_{22} \neq 0$. Therefore, x (and y) can be chosen such that the (1,2)-elements of both $-JP^*J\hat{S}P$ and $-JP^*J\hat{H}P$ are zero. In an analogous way we show that using a J-congruence transformation with the matrix

$$P = \begin{bmatrix} 1 & 0 & 0 & x \\ 0 & 1 & y & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

the (1,4)-elements of $\check{S}$ and $\check{H}$ can also be simultaneously set to zero. Here, we need $\lambda_0 \neq -\mu^*$. (We note that this transformation has no effect on the 2×2 diagonal blocks of $\lambda\check{S} - \check{H}$.) Now it is clear that a sequence of J-congruence transformations can be used to obtain a pencil that is (up to the permutation of rows and columns) a direct sum of skew-Hamiltonian/Hamiltonian pencils in the form (32) such that each pencil has only one eigenvalue, and we may consider the blocks separately.

Furthermore, we may assume w.l.o.g. that the bases U_k and U_∞ are canonical, for if (33) holds for a special basis U_k, it holds for every basis of the deflating subspace associated with λ_k, because a change of basis means the transition from U_k to $U_k X$, where $X \in \mathcal{C}^{p_k \times p_k}$ is nonsingular. (The same argument holds for U_∞.) Thus, if

$$\lambda\tilde{S} - \tilde{H} = \lambda \begin{bmatrix} \tilde{S}_{11} & \tilde{S}_{12} \\ 0 & \tilde{S}_{11}^* \end{bmatrix} - \begin{bmatrix} \tilde{H}_{11} & \tilde{H}_{12} \\ 0 & -\tilde{H}_{11}^* \end{bmatrix}$$

is a skew-Hamiltonian/Hamiltonian pencil satisfying (31) and that has only one eigenvalue that is finite and purely imaginary, it remains to show that $J\tilde{S}$ is congruent to

J. This also proves (34), for we can reduce the case of the eigenvalue ∞ to the case of the eigenvalue zero by considering $\lambda(i\tilde{H}) - (i\tilde{S})$ according to Lemma 2.3. Now we obtain

$$\begin{aligned}
&\begin{bmatrix} \tilde{S}_{11}^{-1} & -\frac{1}{2}\tilde{S}_{11}^{-1}\tilde{S}_{12} \\ 0 & I \end{bmatrix}^* J\tilde{S} \begin{bmatrix} \tilde{S}_{11}^{-1} & -\frac{1}{2}\tilde{S}_{11}^{-1}\tilde{S}_{12} \\ 0 & I \end{bmatrix} \\
&\quad = \begin{bmatrix} \tilde{S}_{11}^{-*} & 0 \\ -\frac{1}{2}\tilde{S}_{12}^{*}\tilde{S}_{11}^{-*} & I \end{bmatrix} \begin{bmatrix} 0 & \tilde{S}_{11}^{*} \\ -\tilde{S}_{11} & -\tilde{S}_{12} \end{bmatrix} \begin{bmatrix} \tilde{S}_{11}^{-1} & -\frac{1}{2}\tilde{S}_{11}^{-1}\tilde{S}_{12} \\ 0 & I \end{bmatrix} \\
&\quad = \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} = J,
\end{aligned}$$

i.e., $J\tilde{S}$ is congruent to J.

$3 \Rightarrow 1$: Since (33) and (34) imply that all the algebraic multiplicities of the purely imaginary eigenvalues are even, it is by Theorem 3.1 and Lemmas 3.2 and 2.3 again sufficient to consider the case that $\lambda S - H$ has only one eigenvalue that is finite and purely imaginary. Since JS is congruent to J we have that S is J-congruent to the identity matrix. Thus there exists $P_1 \in \mathcal{C}^{2n\times 2n}$ nonsingular such that

$$-JP_1^*J(\lambda S - H)P_1 = \lambda I - \hat{H},$$

where $\hat{H}$ is a Hamiltonian matrix having only one eigenvalue, which is purely imaginary. Thus, $\hat{H}$ trivially satisfies (28) and by Theorem 4.1 we find a symplectic matrix $P_2 \in \mathcal{C}^{2n\times 2n}$, i.e., $P_2^{-1} = -JP_2^*J$, such that $P_2^{-1}\hat{H}P_2$ is in J-Schur form (26). We obtain (31) by setting $P = P_1P_2$. ∎

We call a pencil of the form (31) a pencil in J-Schur form.

5. An almost-Schur form under *J*-congruence. We have seen in section 4 that not every skew-Hamiltonian/Hamiltonian pencil can be reduced to a J-Schur form by unitary J-congruence transformation. Thus, if we want to obtain a condensed form from which the eigenvalues can be read off in a simple way, we have to use also nonunitary J-congruence transformations. In this section we will present a condensed form that we will call almost-Schur form and that can be obtained by applying J-congruence transformations, where P in (8) is a product of unitary or *almost-unitary* matrices.

DEFINITION 5.1. *Let $P = [p_1, \ldots, p_n] \in \mathcal{C}^n$ be nonsingular. Then P is called* almost unitary *if there exists an index k such that $(p_1, \ldots, p_{k-1}, p_{k+1}, \ldots, p_n)$ is an orthonormal tuple of vectors.*

THEOREM 5.2. *Let $\lambda S - H \in \mathcal{C}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Then there exists a nonsingular matrix $P \in \mathcal{C}^{2n\times 2n}$ and $k \in \mathcal{N}$ such that*

$$\begin{aligned}
&-JP^*J(\lambda S - H)P \\
&\quad = \lambda \begin{bmatrix} S_{11} & S_{12} & S_{13} & S_{14} \\ 0 & 0 & -S_{14}^* & S_{24} \\ 0 & 0 & S_{11}^* & 0 \\ 0 & S_{42} & S_{12}^* & 0 \end{bmatrix} - \begin{bmatrix} H_{11} & H_{12} & H_{13} & H_{14} \\ 0 & 0 & H_{14}^* & H_{24} \\ 0 & 0 & -H_{11}^* & 0 \\ 0 & H_{42} & -H_{12}^* & 0 \end{bmatrix},
\end{aligned} \tag{35}$$

where the following conditions hold:

1. *$\lambda S_{11} - H_{11} \in \mathcal{C}^{k\times k}$ is an upper triangular pencil having only eigenvalues with nonnegative real part.*

2. $S_{24}, S_{42}, H_{24}, H_{42} \in \mathcal{C}^{(n-k)\times(n-k)}$ *are diagonal and all the eigenvalues of the skew-Hamiltonian/Hamiltonian pencil*

$$\lambda \begin{bmatrix} 0 & S_{24} \\ S_{42} & 0 \end{bmatrix} - \begin{bmatrix} 0 & H_{24} \\ H_{42} & 0 \end{bmatrix}$$

are purely imaginary.

3. *The spectrum of* $\lambda S - H$ *is equal to the union of the spectra of*

$$\lambda \begin{bmatrix} S_{11} & S_{13} \\ 0 & S_{11}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{13} \\ 0 & -H_{11}^* \end{bmatrix} \quad \text{and} \quad \lambda \begin{bmatrix} 0 & S_{24} \\ S_{42} & 0 \end{bmatrix} - \begin{bmatrix} 0 & H_{24} \\ H_{42} & 0 \end{bmatrix}.$$

4. P *is a product of unitary and almost unitary matrices.*

Proof. We consider two cases:

(a) Let us assume that there exists an eigenvector $x \neq 0$ associated with an eigenvalue λ_0 of $\lambda S - H$ such that

$$x^* JSx = 0 \ \text{ and } \ x^* JHx = 0. \tag{36}$$

Since $\lambda S - H$ is regular, we have $JSx \neq 0$ or $JHx \neq 0$. Assume that $JSx \neq 0$; i.e., $\lambda_0 \neq \infty$. (Otherwise the argument proceeds analogously by exchanging JSx and JHx.) Then (36) implies in particular that x and JSx are linearly independent. Let $(q_2, \ldots, q_n, q_{n+2}, \ldots, q_{2n})$ be an orthonormal basis of $\mathrm{Span}(x, JSx)^\perp$. We assume that $\mathrm{Re}(\lambda_0) \geq 0$ and set

$$Q := [x, q_2, \ldots, q_n, JSx, q_{n+2}, \ldots, q_{2n}]. \tag{37}$$

(In the case $\mathrm{Re}(\lambda_0) < 0$ we set $Q = [JSx, q_2, \ldots, q_n, x, q_{n+2}, \ldots, q_{2n}]$, and the argument proceeds analogously.)

Note that (after having normalized x and JSx) the matrix Q is unitary by (36) and by definition of the q_i. We obtain

$$-JQ^* JSQe_1 = \begin{bmatrix} -(JSx)^* JSx \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \begin{bmatrix} -x^* S^* Sx \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

and

$$-JQ^* JHQe_1 = \begin{bmatrix} -(JSx)^* JHx \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \begin{bmatrix} -x^* S^* Hx \\ 0 \\ \vdots \\ 0 \end{bmatrix}.$$

Since $-JQ^* J(\lambda S - H)Q$ is still skew-Hamiltonian/Hamiltonian, we obtain

$$\begin{aligned} &-JQ^* J(\lambda S - H)Q \\ &\quad = \lambda \begin{bmatrix} s_{11} & * & * & * \\ 0 & S_{22} & * & S_{24} \\ 0 & 0 & s_{11}^* & 0 \\ 0 & S_{42} & * & S_{22}^* \end{bmatrix} - \begin{bmatrix} h_{11} & * & * & * \\ 0 & H_{22} & * & H_{24} \\ 0 & 0 & -h_{11}^* & 0 \\ 0 & H_{42} & * & -H_{22}^* \end{bmatrix}, \end{aligned}$$

where $S_{22}, S_{24}, S_{42}, H_{22}, H_{24}, H_{42} \in \mathcal{C}^{(n-1)\times(n-1)}$, and furthermore $s_{11} = -x^*S^*Sx$ and $h_{11} = -x^*S^*Hx$. Obviously the pencil $\lambda s_{11} - h_{11}$ has the eigenvalue λ_0 and by permutation of rows and columns we see that the spectrum of $\lambda S - H$ is equal to the union of the spectra of

$$\lambda \begin{bmatrix} s_{11} & * \\ 0 & s_{11}^* \end{bmatrix} - \begin{bmatrix} h_{11} & * \\ 0 & -h_{11}^* \end{bmatrix} \quad \text{and} \quad \lambda \begin{bmatrix} S_{22} & S_{24} \\ S_{42} & S_{22}^* \end{bmatrix} - \begin{bmatrix} H_{22} & H_{24} \\ H_{42} & -H_{22}^* \end{bmatrix}.$$

(b) If the assumption in (a) does not hold, then for every eigenvector $x \neq 0$ associated with an eigenvalue of $\lambda S - H$ we have

$$x^*JSx \neq 0 \quad \text{or} \quad x^*JHx \neq 0. \tag{38}$$

In this case we see by Lemma 2.4 that all the eigenvalues of $\lambda S - H$ are purely imaginary and by Lemma 2.5 they all have partial multiplicities equal to one. Once again we assume $x^*JSx \neq 0$. (Otherwise the argument proceeds analogously by exchanging JSx and JHx.) Let $(q_1, \ldots, q_{n-1}, q_{n+1}, \ldots, q_{2n})$ be an orthonormal basis of $\mathrm{Span}(JSx)^\perp$. Then

$$P_1 := [q_1, \ldots, q_{n-1}, x, q_{n+1}, \ldots, q_{2n}] \tag{39}$$

is invertible. This follows, since if $\alpha_1, \ldots, \alpha_{2n} \in \mathcal{C}$ are such that

$$\alpha_1 q_1 + \cdots + \alpha_{n-1} q_{n-1} + \alpha_n x + \alpha_{n+1} q_{n+1} + \cdots + \alpha_{2n} q_{2n} = 0, \tag{40}$$

then multiplying (40) from the left by x^*S^*J we obtain $\alpha_{2n} = 0$, since $x^*JSx \neq 0$, and therefore $\alpha_i = 0$ for all $i = 1, \ldots, 2n$, since the q_i form a basis. Hence we obtain

$$-JP_1^*JSx = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ s_{42} \end{bmatrix} \quad \text{and} \quad -JP_1^*JHx = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ h_{42} \end{bmatrix},$$

where $s_{42} = x^*JSx$ and $h_{42} = x^*JHx$. This implies that

$$\begin{aligned} &-JP_1^*J(\lambda S - H)P_1 \\ &\quad = \lambda \begin{bmatrix} S_{11} & 0 & S_{13} & S_{14} \\ S_{21} & 0 & -S_{14}^* & S_{24} \\ S_{31} & 0 & S_{11}^* & S_{21}^* \\ 0 & s_{42} & 0 & 0 \end{bmatrix} - \begin{bmatrix} H_{11} & 0 & H_{13} & H_{14} \\ H_{21} & 0 & H_{14}^* & H_{24} \\ H_{31} & 0 & -H_{11}^* & -H_{21}^* \\ 0 & h_{42} & 0 & 0 \end{bmatrix}, \end{aligned} \tag{41}$$

where $S_{11}, H_{11} \in \mathcal{C}^{(n-1)\times(n-1)}$ and the other blocks have corresponding sizes. Now set

$$\lambda\tilde{S} - \tilde{H} := \lambda \begin{bmatrix} S_{11} & S_{13} & S_{14} \\ S_{21} & -S_{14}^* & S_{24} \\ S_{31} & S_{11}^* & S_{21}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{13} & H_{14} \\ H_{21} & H_{14}^* & H_{24} \\ H_{31} & -H_{11}^* & -H_{21}^* \end{bmatrix} \tag{42}$$

and let y be an eigenvalue of $\lambda\tilde{S} - \tilde{H}$ associated with the eigenvalue μ_0. By (38) we find

$$y^*J\tilde{S}y \neq 0 \quad \text{or} \quad y^*J\tilde{H}y \neq 0,$$

which implies, in particular, that also μ_0 is purely imaginary with partial multiplicity equal to one. Again we assume $y^*J\tilde{S}y \neq 0$ and choose an orthonormal basis $(p_1, \dots, p_{2n-2})$ of $\mathrm{Span}(J\tilde{S}x)^\perp$. Analogous to the proof of the nonsingularity of (39), we can show that the vectors y and $(p_1, \dots, p_{2n-2})$ are linearly independent. Embedding these vectors canonically in $\mathcal{C}^n$ and then setting

$$P_2 := [p_1, \dots, p_{n-1}, e_n, p_n, \dots, p_{2n-2}, y],$$

we obtain

$$\begin{aligned} &-JP_2^*P_1^*J(\lambda S - H)P_1P_2 \\ &\qquad = \lambda \begin{bmatrix} \tilde{S}_{11} & 0 & \tilde{S}_{13} & 0 \\ 0 & 0 & 0 & s_{24} \\ \tilde{S}_{31} & 0 & \tilde{S}_{11}^* & 0 \\ 0 & s_{42} & 0 & 0 \end{bmatrix} - \begin{bmatrix} \tilde{H}_{11} & 0 & \tilde{H}_{13} & 0 \\ 0 & 0 & 0 & h_{24} \\ \tilde{H}_{31} & 0 & -\tilde{H}_{11}^* & 0 \\ 0 & h_{42} & 0 & 0 \end{bmatrix}, \end{aligned} \tag{43}$$

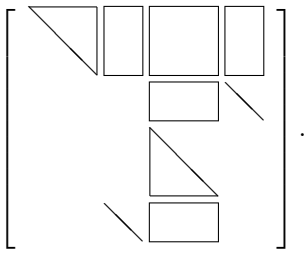
where $\tilde{S}_{11}, \tilde{S}_{13}, \tilde{S}_{31}, \tilde{H}_{11}, \tilde{H}_{13}, \tilde{H}_{31} \in \mathcal{C}^{(n-1)\times(n-1)}$, and furthermore $s_{24} = y^*J\tilde{S}y$ and $h_{24} = y^*J\tilde{H}y$. Thus, the spectrum of $\lambda S - H$ is equal to the union of the spectra of

$$\lambda \begin{bmatrix} \tilde{S}_{11} & \tilde{S}_{13} \\ \tilde{S}_{31} & \tilde{S}_{11}^* \end{bmatrix} - \begin{bmatrix} \tilde{H}_{11} & \tilde{H}_{13} \\ \tilde{H}_{31} & -\tilde{H}_{11}^* \end{bmatrix} \quad \text{and} \quad \lambda \begin{bmatrix} 0 & s_{24} \\ s_{42} & 0 \end{bmatrix} - \begin{bmatrix} 0 & h_{24} \\ h_{42} & 0 \end{bmatrix},$$

and the eigenvalues of $\lambda\left[\begin{smallmatrix} 0 & s_{24} \\ s_{42} & 0 \end{smallmatrix}\right] - \left[\begin{smallmatrix} 0 & h_{24} \\ h_{42} & 0 \end{smallmatrix}\right]$ are λ_0 and μ_0.

In both cases we have reduced the problem to a problem of smaller dimension and the proof follows by induction. □

REMARK 5.3. The matrices $-JP^*JSP$ and $-JP^*JHP$ in (35) have the pattern



.

REMARK 5.4. The proof of Theorem 5.2 also suggests a procedure to compute the almost-Schur form (35). But during the computation the following difficulties may occur:

1. In the first step we may compute only one eigenvalue and then reduce the pencil as indicated in part (a) or (b) of the proof of Theorem 5.2. This means that if we compute an eigenvector satisfying (38), we do not know whether (38) holds for all the eigenvalues or if there exists an eigenvalue such that (36) holds. In particular we might fail in finding an eigenvector of the subpencil (42) that satisfies (38). Consider, for example, the pencil

$$\lambda \begin{bmatrix} 0 & 0 & i & i \\ i & 0 & i & 0 \\ 0 & 0 & 0 & -i \\ 0 & -i & 0 & 0 \end{bmatrix} - \begin{bmatrix} 0 & 0 & 1 & 2 \\ 1 & 0 & 2 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \end{bmatrix}.$$

The subpencil

$$\lambda \begin{bmatrix} 0 & i & i \\ i & i & 0 \\ 0 & 0 & -i \end{bmatrix} - \begin{bmatrix} 0 & 1 & 2 \\ 1 & 2 & 0 \\ 0 & 0 & -1 \end{bmatrix}$$

has the eigenvalue i with partial multiplicity 3. Thus, Lemma 2.5 implies that we do not find an eigenvector satisfying (38). Therefore, the following observation may be helpful.

Given a skew-Hamiltonian/Hamiltonian pencil in the form (41) and an eigenvector x satisfying (36), we can perform a step as indicated in part (a) of the proof of Theorem 5.2 by choosing the basis of $\mathrm{Span}(x, JSx)^{\perp}$ (resp., $\mathrm{Span}(x, JHx)^{\perp}$) such that q_n in (37) is equal to e_n. This is always possible, since e_n is an eigenvector. Then we obtain by Lemmas 2.4 or 2.5 that

$$e_n^* JSx = 0$$

and by the special structure of the pencil (41) also

$$e_n^* x = 0.$$

Hence we can proceed reducing the matrix as indicated in (a) until we find another eigenvector y satisfying (38).

2. If we compute an eigenvector satisfying (38) during the reduction of $\lambda S - H$, we do not achieve the J-Schur form by proceeding as indicated in part (b) of the proof of Theorem 5.2. But this does in general not mean that there is no J-Schur form. Consider as an example the skew-Hamiltonian matrix

$$S := \begin{bmatrix} -1 - 0.5i & 0 & 0.5i & 0 \\ 0 & -1 - 0.5i & 0 & 0.5i \\ -0.5i & 0 & -1 + 0.5i & 0 \\ 0 & -0.5i & 0 & -1 + 0.5i \end{bmatrix}$$

and the skew-Hamiltonian/Hamiltonian pencil $\lambda S - (iS)$. We note that e_1 and e_3 are eigenvectors associated with the eigenvalue i. Now we have

$$e_1^* JSe_1 \neq 0 \quad \text{and} \quad e_3^* JSe_3 \neq 0,$$

but

$$(e_1 + e_3)^* JS(e_1 + e_3) = 0 = (e_1 + e_3)^* JH(e_1 + e_3).$$

Thus, if we choose the eigenvector e_1 instead of $(e_1 + e_3)$ for the reduction of the pencil, we would create the almost-Schur form, although there exists a J-Schur form. Setting

$$U := \frac{1}{\sqrt{2}} J \begin{bmatrix} 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{bmatrix}$$

we obtain

$$-JU^* J(\lambda S - iS)U = -\lambda \begin{bmatrix} 1 & 0 & -i & 0 \\ 0 & 1 & 0 & -i \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} i & 0 & 1 & 0 \\ 0 & i & 0 & 1 \\ 0 & 0 & i & 0 \\ 0 & 0 & 0 & i \end{bmatrix}.$$

Since we do not know how to compute an eigenvector satisfying (36), if it exists, we currently see no method to avoid this problem.

In the real case we obtain a result similar to Theorem 5.2.

DEFINITION 5.5. *Let $P = [p_1, \dots, p_n] \in \mathcal{R}^n$ be nonsingular. Then P is called* almost orthogonal *if there exists indices k, l such that*

$$(p_1, \dots, p_{k-1}, p_{k+1}, \dots, p_{l-1}, p_{l+1}, \dots, p_n)$$

is an orthonormal tuple of vectors.

THEOREM 5.6. *Let $\lambda S - H \in \mathcal{R}^{2n\times 2n}$ be a regular skew-Hamiltonian/Hamiltonian pencil. Then there exists a nonsingular matrix $P \in \mathcal{R}^{2n\times 2n}$ and $k \in \mathcal{N}$ such that*

$$\begin{aligned} &-JP^*J(\lambda S - H)P \\ &\quad = \lambda \begin{bmatrix} S_{11} & S_{12} & S_{13} & S_{14} \\ 0 & 0 & -S_{14}^* & S_{24} \\ 0 & 0 & S_{11}^* & 0 \\ 0 & S_{42} & S_{12}^* & 0 \end{bmatrix} - \begin{bmatrix} H_{11} & H_{12} & H_{13} & H_{14} \\ 0 & 0 & H_{14}^* & H_{24} \\ 0 & 0 & -H_{11}^* & 0 \\ 0 & H_{42} & -H_{12}^* & 0 \end{bmatrix}, \end{aligned} \tag{44}$$

where the following conditions hold:

1. *$\lambda S_{11} - H_{11} \in \mathcal{R}^{k\times k}$ is a quasi upper triangular pencil having only eigenvalues with nonnegative real part.*
2. *The pencils $\lambda S_{24} - H_{24}, \lambda S_{42} - H_{42} \in \mathcal{R}^{(n-k)\times(n-k)}$ are block diagonal and the diagonal blocks are either of the form*

$$\lambda \begin{bmatrix} 0 & & \\ & \ddots & \\ & & 0 \end{bmatrix} - \begin{bmatrix} 1 & & \\ & \ddots & \\ & & 1 \end{bmatrix} \in \mathcal{R}^{m\times m} \tag{45}$$

for $m \in \mathcal{N}$ or of the form

$$\lambda \begin{bmatrix} 0 & s \\ -s & 0 \end{bmatrix} - \begin{bmatrix} h & 0 \\ 0 & h \end{bmatrix}, \tag{46}$$

where $s, h \in \mathcal{R}\backslash\{0\}$. In particular, all the eigenvalues of the skew-Hamiltonian/Hamiltonian pencil

$$\lambda \begin{bmatrix} 0 & S_{24} \\ S_{42} & 0 \end{bmatrix} - \begin{bmatrix} 0 & H_{24} \\ H_{42} & 0 \end{bmatrix} \tag{47}$$

are nonzero and purely imaginary.

3. *The spectrum of $\lambda S - H$ is equal to the union of the spectra of*

$$\lambda \begin{bmatrix} S_{11} & S_{13} \\ 0 & S_{11}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{13} \\ 0 & -H_{11}^* \end{bmatrix} \quad \text{and} \quad \lambda \begin{bmatrix} 0 & S_{24} \\ S_{42} & 0 \end{bmatrix} - \begin{bmatrix} 0 & H_{24} \\ H_{42} & 0 \end{bmatrix}.$$

4. *P is a product of orthogonal and almost orthogonal matrices.*

Proof. Analogous to the proof of Theorem 5.2 we distinguish two cases.

(a) Let us assume that there exists an eigenvector $x \in \mathcal{C}^n\backslash\{0\}$ associated with an eigenvalue $\lambda_0 \in \mathcal{C}$ of $\lambda S - H$ such that

$$x^*JSx = 0 \ \text{ and } \ x^*JHx = 0. \tag{48}$$

If λ_0 and x are real we can proceed as in the proof of Theorem 5.2. So let us assume that λ_0 has nonzero real part and that $x = y + iz$, where $y, z \in \mathcal{R}^n$. Furthermore we assume once again w.l.o.g. that $JSx \neq 0$. (Otherwise the argument proceeds analogously by exchanging JSx and JHx.) This means in particular that both JSy and JSz do not vanish. Otherwise y or z would be an eigenvector associated with the eigenvalue ∞. It is well known that y, z form a basis of a two-dimensional subspace; i.e., in particular y and z are linearly independent. Furthermore, we have by (48) that

$$\begin{aligned} y^*JSy + z^*JSz + i(y^*JSz - z^*JSy) \\ = (y + iz)^*JS(y + iz) = 0. \end{aligned} \tag{49}$$

Since $\lambda_0^* \neq -\lambda_0^*$ and $y - iz$ is an eigenvalue associated with λ_0^*, we also have by Lemma 2.4 that

$$\begin{aligned} y^*JSy - z^*JSz + i(y^*JSz - z^*JSy) \\ = (y - iz)^*JS(y + iz) = 0. \end{aligned} \tag{50}$$

Hence by adding, resp., subtracting (49) and (50) we obtain

$$y^*JSy = z^*JSz = z^*JSy = y^*JSz = 0.$$

If we choose a real orthonormal basis (r_1, r_2) of $\mathrm{Span}(y, z)$, we still have

$$r_1, r_2 \perp JSr_1, JSr_2.$$

Now let $(q_1, \ldots, q_{2n-4})$ be a real orthonormal basis of $\mathrm{Span}(r_1, r_2, JSr_1, JSr_2)$. Then (assuming again w.l.o.g. that λ_0 has nonnegative real part and after having normalized r_1, r_2, JSr_1, and JSr_2) the matrix

$$Q := [r_1, r_2, q_1, \ldots, q_{n-2}, JSr_1, JSr_2, q_{n-1}, \ldots, q_{2n-4}]$$

is orthogonal and we obtain

$$\begin{aligned} &-JQ^*J(\lambda S - H)Q \\ &\quad = \lambda \begin{bmatrix} S_{11} & * & * & * \\ 0 & S_{22} & * & S_{24} \\ 0 & 0 & S_{11}^* & 0 \\ 0 & S_{42} & * & S_{22}^* \end{bmatrix} - \begin{bmatrix} H_{11} & * & * & * \\ 0 & H_{22} & * & H_{24} \\ 0 & 0 & -H_{11}^* & 0 \\ 0 & H_{42} & * & -H_{22}^* \end{bmatrix}, \end{aligned}$$

where $S_{11}, H_{11} \in \mathcal{R}^{2\times 2}$ and $S_{22}, S_{24}, S_{42}, H_{22}, H_{24}, H_{42} \in \mathcal{R}^{(n-2)\times(n-2)}$. Obviously the pencil $\lambda S_{11} - H_{11}$ has the eigenvalues λ_0 and λ_0^* and the spectrum of $\lambda S - H$ is equal to the union of the spectra of

$$\lambda \begin{bmatrix} S_{11} & * \\ 0 & S_{11}^* \end{bmatrix} - \begin{bmatrix} H_{11} & * \\ 0 & -H_{11}^* \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} S_{22} & S_{24} \\ S_{42} & S_{22}^* \end{bmatrix} - \begin{bmatrix} H_{22} & H_{24} \\ H_{42} & -H_{22}^* \end{bmatrix}.$$

(b) If the assumption in (a) does not hold, then for every eigenvector $x \in \mathcal{C}^n \backslash \{0\}$ associated with an eigenvalue of $\lambda S - H$ we have

$$x^*JSx \neq 0 \quad \text{or} \quad x^*JHx \neq 0. \tag{51}$$

This means again that all the eigenvalues of $\lambda S - H$ are purely imaginary and all their partial multiplicities are one. In addition we have that $\lambda S - H$ cannot have the

eigenvalue zero, for if $w \in \mathcal{R}^n$ is an eigenvector associated with zero, i.e., $Hw = 0$, since S is skew-Hamiltonian, we obtain

$$w^*JSw = (w^*JSw)^* = w^*S^*Jw = -w^*JSw;$$

i.e., $w^*JSw = 0 = w^*JHw$. In the case of the eigenvalue ∞, we can find a real eigenvector and so we proceed as in the proof of Theorem 5.2. Thus it remains to consider the case that x is an eigenvector associated with the eigenvalue $i\mu$ for a $\mu \in \mathcal{R}\backslash\{0\}$ and that $x = y + iz$, where $y, z \in \mathcal{R}^n$. Again y and z are linearly independent and we have both $JSy \neq 0$ and $JSz \neq 0$. Now let $(q_1, \ldots, q_{n-2}, q_{n+1}, \ldots, q_{2n})$ be a real orthonormal basis of $\mathrm{Span}(JSy, JSz)^\perp$. Analogous to the proof of the nonsingularity of (39) we can show that

$$\tilde{P} := [q_1, \ldots, q_{n-2}, y, z, q_{n+1}, \ldots, q_{2n}]$$

is nonsingular. We obtain

$$\begin{aligned} &-J\tilde{P}^*J(\lambda S - H)\tilde{P} \\ &\quad = \lambda \begin{bmatrix} S_{11} & 0 & S_{13} & S_{14} \\ S_{21} & 0 & -S_{14}^* & S_{24} \\ S_{31} & 0 & S_{11}^* & S_{21}^* \\ 0 & S_{42} & 0 & 0 \end{bmatrix} - \begin{bmatrix} H_{11} & 0 & H_{13} & H_{14} \\ H_{21} & 0 & H_{14}^* & H_{24} \\ H_{31} & 0 & -H_{11}^* & -H_{21}^* \\ 0 & H_{42} & 0 & 0 \end{bmatrix}, \end{aligned} \tag{52}$$

where

$$S_{42} = \begin{bmatrix} y^*JSy & y^*JSz \\ z^*JSy & z^*JSz \end{bmatrix} \quad \text{and} \quad H_{42} = \begin{bmatrix} y^*JHy & y^*JHz \\ z^*JHy & z^*JHz \end{bmatrix},$$

and $S_{11}, H_{11} \in \mathcal{R}^{(n-2)\times(n-2)}$. The other blocks have corresponding sizes. Since S_{42} is skew symmetric and $y^*JSz = -z^*JSy$ we obtain

$$S_{42} = \begin{bmatrix} 0 & s \\ -s & 0 \end{bmatrix},$$

where $s := -y^*JSz$. This yields in particular that $y^*JSy = 0$. On the other hand, we have $i\mu S(y + iz) = H(y + iz)$; i.e.,

$$-\mu Sz = Hy \quad \text{and} \quad \mu Sy = Hz.$$

Therefore, we obtain that

$$y^*JHz = \mu y^*JSy = 0$$

and

$$y^*JHy = -\mu y^*JSz = \mu z^*S^*Jy = \mu z^*JSy = z^*JHz.$$

Thus,

$$H_{42} = \begin{bmatrix} h & 0 \\ 0 & h \end{bmatrix},$$

where $h := -y^*JHy$. The rest of the proof of (b) follows analogous to the proof of Theorem 5.2, reducing the subpencil

$$\lambda \begin{bmatrix} S_{11} & S_{13} & S_{14} \\ S_{21} & -S_{14}^* & S_{24} \\ S_{31} & S_{11}^* & S_{21}^* \end{bmatrix} - \begin{bmatrix} H_{11} & H_{13} & H_{14} \\ H_{21} & H_{14}^* & H_{24} \\ H_{31} & -H_{11}^* & -H_{21}^* \end{bmatrix}$$

by choosing a nonreal eigenvector associated with an eigenvalue $i\tilde{\mu}, \tilde{\mu} \in \mathcal{R}$, or two real eigenvectors associated with the eigenvalue ∞. (Note that the eigenvalue ∞ must have even algebraic multiplicity, since all the other eigenvalues of the pencil occur in pairs and the size of the pencil is even.)

In both cases we have reduced the problem to a problem of smaller dimension and the proof follows by induction. □

LEMMA 5.7. *Let $\lambda S - H$ be a real skew-Hamiltonian/Hamiltonian pencil. Then the following conditions hold:*

1. *Every block of odd size belonging to the eigenvalue zero in the Kronecker canonical form occurs with even multiplicity.*
2. *Every block of even size belonging to the eigenvalue ∞ in the Kronecker canonical form occurs with even multiplicity.*

Proof. See the proof in [20] of the analogous result for pencils $\lambda A - B$, where A is symmetric and B is skew symmetric. □

6. Conclusions. We have discussed canonical forms and almost-Schur forms for skew-Hamiltonian/Hamiltonian pencils under J-congruence. Also a necessary and sufficient condition for the existence of a J-Schur form has been given.

Acknowledgment. We thank V. Mehrmann for helpful discussions and for initiating this research.

ON OPTIMAL BANDED PRECONDITIONERS FOR THE FIVE-POINT LAPLACIAN*

ZHANYE TONG† AND AHMED SAMEH†

Abstract. We prove the following theorem, which includes a conjecture by Greenbaum and Rodrigue [*BIT*, 29 (1989), pp. 610–634] as a special case:

Let A_h be the five-point Laplace matrix on a unit square for grid size h, and let M_h be any symmetric positive definite preconditioner for A_h with half bandwidth $k = O(1)$. Then the condition number $\kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}})$ satisfies $\kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}) = O(h^{-2})$.

Key words. optimal, preconditioner, tridiagonal

1. Introduction.

In Greenbaum and Rodrigue [1], optimal preconditioners of a given sparsity pattern are discussed. By using the Overton optimization code [3], optimal tridiagonal preconditioners are computed for the five-point Laplacian on a unit square

$$A_h = \begin{bmatrix} T & -I & & \\ -I & T & \ddots & \\ & \ddots & \ddots & -I \\ & & -I & T \end{bmatrix}_{n^2 \times n^2}, \quad T = \begin{bmatrix} 4 & -1 & & \\ -1 & 4 & \ddots & \\ & \ddots & \ddots & -1 \\ & & -1 & 4 \end{bmatrix}_{n \times n}, \tag{1.1}$$

where I is the identity matrix of order n and $h = 1/(n+1)$ is the mesh size. It turns out that the optimal tridiagonal preconditioner for A_h is slightly better than the block diagonal of A_h which is the optimal block diagonal preconditioner. Based on the numerical results, they made the following conjecture.

Conjecture. Let A_h be the five-point Laplace matrix of (1.1) for grid size h, and let M_h be any symmetric positive definite tridiagonal preconditioner for A_h. Then the condition number of the preconditioned matrix $M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}$ satisfies

$$\kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}) = O(h^{-2}). \tag{1.2}$$

In this short note, we show that the conjecture is indeed true. Actually, we shall prove the following theorem.

THEOREM 1.1. *Let A_h be the five-point Laplace matrix of* (1.1) *for grid size h, and let M_h be any symmetric positive definite preconditioner for A_h with half bandwidth $k = O(1)$. Then the condition number of the preconditioned matrix $M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}$ satisfies*

$$\kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}) = O(h^{-2}). \tag{1.3}$$

†Department of Computer Sciences, Purdue University, West Lafayette, IN 47907 (tong@cs.purdue.edu, sameh@purdue.edu).

Moreover, for $k = 1$, we have

$$\kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}) \geq \frac{5}{13}\kappa(A_h).$$

2. The proof of Theorem 1.1. We first introduce two lemmas.

LEMMA 2.1. *Let n be a positive integer, $h = \frac{1}{n+1}$. Then for any $k, 1 \leq k \leq n-1$, the matrix*

$$\begin{bmatrix} \sin[2(n-k+1)h\pi] & \sin[3(n-k+1)h\pi] & \cdots & \sin[(k+1)(n-k+1)h\pi] \\ \sin[2(n-k+2)h\pi] & \sin[3(n-k+2)h\pi] & \cdots & \sin[(k+1)(n-k+2)h\pi] \\ \vdots & \vdots & & \vdots \\ \sin[2nh\pi] & \sin[3nh\pi] & \cdots & \sin[(k+1)nh\pi] \end{bmatrix} \tag{2.1}$$

is invertible.

Proof. Let $\theta = h\pi$. It suffices to prove that the matrix

$$C = \begin{bmatrix} \sin[2\theta] & \sin[3\theta] & \cdots & \sin[(k+1)\theta] \\ \sin[4\theta] & \sin[6\theta] & \cdots & \sin[2(k+1)\theta] \\ \vdots & \vdots & & \vdots \\ \sin[2k\theta] & \sin[3k\theta] & \cdots & \sin[k(k+1)\theta] \end{bmatrix} \tag{2.2}$$

is invertible. It is well known that for any integer $s \geq 1$

$$\sin(s\phi) = \sin(\phi)\left(c_s \cos^{s-1}(\phi) + p_{s-2}(\cos(\phi))\right),$$

in which $c_s \neq 0$ is a constant independent of ϕ and p_{s-2} is a polynomial of order $s-2$. It follows that

$$\det(C) = c\prod_{i=2}^{k+1} \sin(i\theta) \times \det \begin{vmatrix} 1 & 1 & \cdots & 1 \\ \cos[2\theta] & \cos[3\theta] & \cdots & \cos[(k+1)\theta] \\ \vdots & \vdots & & \vdots \\ \cos^{k-1}[2\theta] & \cos^{k-1}[3\theta] & \cdots & \cos^{k-1}[(k+1)\theta] \end{vmatrix} \neq 0. \quad \square$$

LEMMA 2.2. *Let n be a positive integer, $h = \frac{1}{n+1}$. Then we have*

$$\frac{\left(\sin^2(\frac{nh\pi}{2}) + \sin^2(\frac{h\pi}{2})\right)\sin^2(2h\pi) + \left(\sin^2(\frac{nh\pi}{2}) + \sin^2(\frac{2h\pi}{2})\right)\sin^2(h\pi)}{\left(\sin^2(\frac{h\pi}{2}) + \sin^2(\frac{h\pi}{2})\right)\sin^2(2h\pi) + \left(\sin^2(\frac{h\pi}{2}) + \sin^2(\frac{2h\pi}{2})\right)\sin^2(h\pi)} \geq \frac{5}{13} \times \frac{\cos^2(\frac{h\pi}{2})}{\sin^2(\frac{h\pi}{2})}.$$

Proof. The proof is straightforward and hence omitted. $\square$

Now, let us prove Theorem 1.1. By the definition of the condition number, we have

$$\begin{aligned} \kappa(M_h^{-\frac{1}{2}} A_h M_h^{-\frac{1}{2}}) &= \frac{\lambda_{\max}(M_h^{-1}A_h)}{\lambda_{\min}(M_h^{-1}A_h)} \\ &= \frac{\max_{x\neq 0} \frac{x^T A_h x}{x^T M_h x}}{\min_{y\neq 0} \frac{y^T A_h y}{y^T M_h y}} \\ &\geq \frac{x^T A_h x}{y^T A_h y} \times \frac{y^T M_h y}{x^T M_h x} \text{ for any } x, y \neq 0. \end{aligned}$$

For any matrix M_h with half bandwidth $k = O(1)$, we are going to construct two vectors, x_0 and y_0, such that

$$\frac{x_0^T A_h x_0}{y_0^T A_h y_0} = O(h^{-2}) \quad \text{and} \quad x_0^T M_h x_0 = y_0^T M_h y_0. \tag{2.3}$$

The eigenvalues and the corresponding eigenvectors of A_h are [2]

$$\lambda^{(i,j)} = 4\left(\sin^2\left(\frac{ih\pi}{2}\right) + \sin^2\left(\frac{jh\pi}{2}\right)\right), \quad 1 \le i, j \le n,$$

and

$$v^{(i,j)} = \begin{bmatrix} \sin(ih\pi)V_j \\ \sin(2ih\pi)V_j \\ \vdots \\ \sin(nih\pi)V_j \end{bmatrix}, \quad V_j = \begin{bmatrix} \sin(jh\pi) \\ \sin(2jh\pi) \\ \vdots \\ \sin(njh\pi) \end{bmatrix}, \quad 1 \le i, j \le n.$$

Particularly, for any $j, 1 \le j \le n$, we have

$$v^{(1,j)} = \begin{bmatrix} \sin(h\pi)V_j \\ \sin(2h\pi)V_j \\ \vdots \\ \sin(nh\pi)V_j \end{bmatrix}, \quad v^{(n,j)} = \begin{bmatrix} \sin(h\pi)V_j \\ -\sin(2h\pi)V_j \\ \vdots \\ (-1)^{n+1}\sin(nh\pi)V_j \end{bmatrix}.$$

Let us consider two vectors

$$x_0 = v^{(n,1)} + \sum_{i=1}^{k} a_i v^{(n,i+1)} = [X_1^T, X_2^T, \ldots, X_n^T]^T, \tag{2.4}$$

$$y_0 = v^{(1,1)} + \sum_{i=1}^{k} a_i v^{(1,i+1)} = [Y_1^T, Y_2^T, \ldots, Y_n^T]^T, \tag{2.5}$$

which are partitioned conformally with A_h. It is easy to see that x_0 and y_0 have the following properties:

(1) For any a_i, $1 \le i \le k$, we have $X_i = (-1)^{i+1} Y_i$, $1 \le i \le n$.
(2) For $k = O(1)$, each eigenvector component in x_0 corresponds to an eigenvalue of order $O(1)$, and each eigenvector component in y_0 corresponds to an eigenvalue of order $O(h^2)$.
(3) There exists a set of $a_i, 1 \le i \le k$, such that the last k components in X_i and Y_i are zeros for $1 \le i \le n$. This is because the linear system

$$\begin{bmatrix} \sin[2(n-k+1)h\pi] & \cdots & \sin[(k+1)(n-k+1)h\pi] \\ \vdots & & \vdots \\ \sin[2nh\pi] & \cdots & \sin[(k+1)nh\pi] \end{bmatrix} \begin{bmatrix} a_1 \\ \vdots \\ a_k \end{bmatrix} = -\begin{bmatrix} \sin[(n-k+1)h\pi] \\ \cdots \\ \sin[nh\pi] \end{bmatrix},$$

has a unique nonzero solution for any k, $1 \le k \le n-1$.

Suppose the constants $a_i's$ in (2.4) and (2.5) are chosen such that the last k components in X_i and Y_i are zeros for $1 \le i \le n$. Then, it is easy to verify that

$$x_0^T M_h x_0 = y_0^T M_h y_0$$

for any symmetric matrix M_h with half bandwidth k.

On the other hand,

$$\begin{aligned}\frac{x_0^T A_h x_0}{y_0^T A_h y_0} &= \frac{\lambda^{(n,1)} + \sum_{i=1}^{k} \lambda^{(n,i+1)} a_i^2}{\lambda^{(1,1)} + \sum_{i=1}^{k} \lambda^{(1,i+1)} a_i^2} \\ &\ge \frac{\left(\min_{i=1}^{k+1} \lambda^{(n,i)}\right)(1 + a_1^2 + \cdots + a_k^2)}{\left(\max_{i=1}^{k+1} \lambda^{(1,i)}\right)(1 + a_1^2 + \cdots + a_k^2)} \\ &= O(h^{-2}) \qquad \text{for } k = O(1).\end{aligned}$$

In the case of $k = 1$, we have

$$a_1 = -\frac{\sin(h\pi)}{\sin(2h\pi)}.$$

Direct computation shows that

$$\begin{aligned}\frac{x_0^T A_h x_0}{y_0^T A_h y_0} &= \frac{\lambda^{(n,1)} + \lambda^{(n,2)} a_1^2}{\lambda^{(1,1)} + \lambda^{(1,2)} a_1^2} \\ &= \frac{\left(\sin^2(\frac{nh\pi}{2}) + \sin^2(\frac{h\pi}{2})\right)\sin^2(2h\pi) + \left(\sin^2(\frac{nh\pi}{2}) + \sin^2(\frac{2h\pi}{2})\right)\sin^2(h\pi)}{\left(\sin^2(\frac{h\pi}{2}) + \sin^2(\frac{h\pi}{2})\right)\sin^2(2h\pi) + \left(\sin^2(\frac{h\pi}{2}) + \sin^2(\frac{2h\pi}{2})\right)\sin^2(h\pi)} \\ &\ge \frac{5}{13} \times \frac{\cos^2(\frac{h\pi}{2})}{\sin^2(\frac{h\pi}{2})} \\ &= \frac{5}{13}\kappa(A_h).\end{aligned}$$

This completes the proof of Theorem 1.1.

The bound for $k = 1$ is not sharp, but it is very tight for $h = \frac{1}{5}, \frac{1}{6}, \frac{1}{7}$ according to the calculated bounds in [1].

CLASSIFICATION OF LINEAR PERIODIC DIFFERENCE EQUATIONS UNDER PERIODIC OR KINEMATIC SIMILARITY*

I. GOHBERG†, M. A. KAASHOEK‡, AND J. KOS§

Abstract. In this paper linear periodic systems of difference equations are classified with respect to periodic similarity and kinematic similarity. Complete sets of invariants of periodic difference equations relative to such similarity transformations are given, and corresponding canonical forms are described. Also the irreducible periodic difference equations, i.e., those that cannot be reduced by such similarities to a nontrivial direct sum, are identified.

Key words. linear periodic difference equations, periodic similarity, kinematic similarity, invariants, canonical forms

AMS subject classifications. 39A10, 15A21

PII. S0895479898334307

Introduction and main results. This paper deals with the problem of classifying linear N-periodic systems of difference equations. Such equations have the form

$$x_{n+1} = A_n x_n, \quad n \in \mathbb{Z} \quad (A_n : \mathbb{C}^{r_n} \to \mathbb{C}^{r_{n+1}},\ n \in \mathbb{Z}), \tag{0.1}$$

with $A_n = A_{n+N}$ for $n \in \mathbb{Z}$. The coefficient A_n in (0.1) is assumed to be a linear transformation and, by N-periodicity, $r_{n+N} = r_n$ for each n.

Our aim is to classify N-periodic difference equations under two types of time-variant basis transformations. The first is that of kinematic similarity. The system (0.1) is said to be *kinematically similar* to the system

$$y_{n+1} = B_n y_n, \quad n \in \mathbb{Z} \quad (B_n : \mathbb{C}^{r_n} \to \mathbb{C}^{r_{n+1}},\ n \in \mathbb{Z}), \tag{0.2}$$

if there exists a time-variant change of basis $y_n = F_n^{-1} x_n$, where F_n is an invertible linear transformation on $\mathbb{C}^{r_n}$, which transforms (0.1) into (0.2), i.e., $B_n = F_{n+1}^{-1} A_n F_n$ for each n, and which satisfies an additional boundedness condition, namely,

$$\sup_{n \in \mathbb{Z}} \{\|F_n\|, \|F_n^{-1}\|\} < \infty. \tag{0.3}$$

The second type of basis transformation appears if, in place of (0.3), we require that $F_n = F_{n+N}$ for $n \in \mathbb{Z}$; in this case (0.1) and (0.2) are called *N-periodically similar*. Obviously, any periodic similarity is kinematic.

In this paper we give necessary and sufficient conditions for two N-periodic difference equations to be kinematically similar or N-periodically similar. Complete sets

of invariants for N-periodic difference equations relative to both types of similarities are given and corresponding canonical forms are described. We also give necessary and sufficient conditions so that a periodic difference equation is periodically or kinematically similar to a periodic difference equation with a different period.

In connection with the construction of canonical forms, the question of whether the N-periodic difference equation (0.1) is kinematically similar to a nontrivial direct sum

$$x_{n+1} = \begin{pmatrix} A_{1,n} & 0 \\ 0 & A_{2,n} \end{pmatrix} x_n, \quad n \in \mathbb{Z},$$

plays an important role. Here nontrivial means that the space $\mathbb{C}^{r_{1,n}}$ on which $A_{1,n}$ acts is nonzero for at least one n and different from $\mathbb{C}^{r_n}$ for at least one (possibly different) n. We say that the N-periodic difference equation (0.1) is *irreducible* (or *N-periodically irreducible*) *in the class of N-periodic difference equations* if (0.1) is not kinematically similar (or not N-periodically similar) to a nontrivial direct sum of N-periodic difference equations. A complete description of these irreducible and N-periodically irreducible difference equations will be given.

For square N-periodic difference equations, i.e., when all the coefficients are square matrices, we have a special interest in (N-periodic) irreducibility in the class of square N-periodic difference equations. A square N-periodic difference equation is called *irreducible* (or *N-periodically irreducible*) *in the class of square N-periodic difference equations* if it is not kinematically similar (or not N-periodically similar) to a nontrivial direct sum of square N-periodic difference equations. These squarely irreducible systems will be described too.

Let us now review our results in more detail. For this purpose we need the linear transformation $A_N \cdots A_1$, which will be referred to as the *monodromy operator* of the N-periodic equation (0.1). We associate with the monodromy operator a Jordan matrix, denoted by $[J_{A_N \cdots A_1}]$, which has nonnegative eigenvalues only, and which is obtained by replacing the diagonal entries in the Jordan normal form $J_{A_N \cdots A_1}$ of $A_N \cdots A_1$ by their absolute values. We are now ready to state our first two theorems.

THEOREM 0.1. *The N-periodic difference equations* (0.1) *and* (0.2) *are kinematically similar if and only if, for each $n \in \{1, 2, \ldots, N\}$,*

$$\operatorname{rank}(A_{j+n-1}A_{j+n-2}\cdots A_n) = \operatorname{rank}(B_{j+n-1}B_{j+n-2}\cdots B_n),\ 1 \le j \le N(\max_{1\le n\le N} r_n), \tag{0.4}$$

and the Jordan matrices $[J_{A_N \cdots A_1}]$ and $[J_{B_N \cdots B_1}]$ are similar.

THEOREM 0.2. *The N-periodic difference equations* (0.1) *and* (0.2) *are N-periodically similar if and only if, for each $n \in \{1, 2, \ldots, N\}$, the rank conditions* (0.4) *are satisfied and the monodromy matrices $A_N A_{N-1} \cdots A_1$ and $B_N B_{N-1} \cdots B_1$ are similar.*

To describe the irreducible equations, we need some additional notation. Given the N-periodic difference equation (0.1), we define the nonnegative integers

$$s_{n,j} = \begin{cases} \operatorname{rank}(A_{n+j-1}\cdots A_{n+1}) - \operatorname{rank}(A_{n+j-1}\cdots A_{n+1}A_n), & j \ge 2,\ n = 1, 2, \ldots, N, \\ r_{n+1} - \operatorname{rank} A_n, & j = 1,\ n = 1, 2, \ldots, N. \end{cases} \tag{0.5}$$

Notice that these numbers do not change under kinematic similarity.

THEOREM 0.3. *The N-periodic difference equation* (0.1) *is irreducible in the class of N-periodic difference equations (either by N-periodic similarity or by kinematic*

similarity) if and only if $A_N A_{N-1} \cdots A_1$ *is an invertible matrix of which the Jordan form has one block only or* $A_N A_{N-1} \cdots A_1$ *is nilpotent and there exist integers* m *and* q *with* $1 \le m \le N$ *and* $q \ge 1$ *such that*

$$s_{n,j} = \begin{cases} 1 & \text{if } 1 \le j \le q \text{ and } n = m, \\ 0 & \text{otherwise}, \end{cases} \tag{0.6}$$

where the numbers $s_{n,j}$ *are defined by* (0.5).

In particular, an N-periodic difference equation is N-periodically irreducible in the class of N-periodic difference equations if and only if it is kinematically irreducible in this class.

Next we shall define three types of N-periodic difference equations. We shall say that the N-periodic difference equation (0.1) is of *type* I if A_n does not depend on n and is equal to a single Jordan block with a nonzero eigenvalue λ satisfying $0 \le \arg \lambda < \frac{2\pi}{N}$. Similarly, we say that (0.1) is a N-periodic difference equation of *type* I_+ if A_n does not depend on n and is equal to a single Jordan block with a nonzero eigenvalue λ satisfying $\lambda > 0$. By Theorem 0.3 the N-periodic difference equations of types I and I_+ are irreducible.

We proceed with the second type. We say that the N-periodic difference equation (0.1) is of type II if there exist nonnegative integers m, p, and r with $1 \le m \le N$ and $m < p < m + N$ such that

$$A_n = \begin{cases} \begin{pmatrix} I_r \\ 0 \end{pmatrix} : \mathbb{C}^r \to \mathbb{C}^{r+1} & \text{if } n = m, \\ I_{r+1} : \mathbb{C}^{r+1} \to \mathbb{C}^{r+1} & \text{if } n = m+1, \dots, p-1, \\ (\,0 \quad I_r\,) : \mathbb{C}^{r+1} \to \mathbb{C}^r & \text{if } n = p, \\ I_r : \mathbb{C}^r \to \mathbb{C}^r & \text{if } n = p+1, \dots, m+N-1. \end{cases} \tag{0.7}$$

Here I_r stands for the identity operator on $\mathbb{C}^r$. In particular, if (0.1) is an N-periodic difference equation of type II, then the N coefficients $A_1, A_2, \dots, A_N$ are all identity operators except for two of them. The latter two coefficients are the canonical projection on the last r coordinates and the canonical embedding on the first r coordinates. The order of these two coefficients in $A_1, A_2, \dots, A_N$ depends on whether $p > N$. Notice that for a N-periodic difference equation of type II the monodromy operator is nilpotent, and one computes that if for the N-periodic system (0.1) the coefficients are given by (0.7), then the equalities (0.6) hold true with $q = p - m + rN$. It follows from Theorem 0.3 that systems of type II are irreducible.

Finally, we say that the N-periodic difference equation (0.1) is of type III if there exist $1 \le m \le N$ and $r \ge 1$ such that

$$A_n = \begin{cases} \begin{pmatrix} 0 & I_{r-1} \\ 0 & 0 \end{pmatrix} : \mathbb{C}^r \to \mathbb{C}^r & \text{if } n = m, \\ I_r : \mathbb{C}^r \to \mathbb{C}^r & \text{if } n = m+1, \dots, m+N-1. \end{cases} \tag{0.8}$$

Again in this case the monodromy operator is nilpotent and one computes that equalities (0.6) holds true with $q = rN$. Hence, by Theorem 0.3, systems of type III are also irreducible.

THEOREM 0.4. *Systems of type* I_+, II, *or* III *are irreducible in the class of* N*-periodic difference equations under kinematic similarity. Any* N*-periodic difference equation is kinematically similar to a unique (up to reordering) direct sum of difference equations of types* I_+, II, *and* III.

THEOREM 0.5. *Systems of type* I, II, *or* III *are irreducible under N-periodic similarity. Any N-periodic difference equation is N-periodically similar to a unique (up to reordering) direct sum of difference equations of types* I, II, *and* III.

We shall also describe precisely how many times each of the irreducible difference equations I, I_+, II, and III appears in the direct sums referred to in Theorems 0.4 and 0.5. Analogues of Theorems 0.4 and 0.5 for square periodic difference equations will also be given.

The present paper consists of seven sections not counting this introduction. Section 1 presents a canonical form for N-periodic difference equations under N-periodic similarity and contains the proof of Theorem 0.2. In section 2 a similar program is carried out, but with kinematic similarity in place of N-periodic similarity. In particular, in this section Theorem 0.1 is proved. Furthermore, an open question in section 8 of [4] is answered for periodic difference equations. The third section concerns the notion of reducibility in the class of N-periodic difference equations. Here we prove Theorems 0.3–0.5. Results on reducibility by kinematic similarity in the general class of time-varying systems are also given. Reducibility in the class of square periodic systems is the main topic of section 4. In section 5 similarity of periodic difference equations with different periods is analyzed. In section 6 the results of section 1 are restated in terms of a certain class of finite block matrices. The final section presents an example illustrating how the canonical forms referred to in Theorems 0.4 and 0.5 can be constructed and how one can compute the corresponding kinematic and N-periodic similarities.

Problems that are equivalent to classification problems for periodic difference equations have been studied in different settings. The problem of classifying 2-periodic difference equations under 2-periodic similarity may be restated as the problem of classifying pairs of matrices under the following equivalence relation:

$$(A_1, A_2) \simeq (B_1, B_2) \Leftrightarrow \exists X, Y : Y^{-1}A_1X = B_1,\ X^{-1}A_2Y = B_2. \tag{0.9}$$

In this form, the problem has been fully treated by Dobrovol'skaja and Ponomarev in [1], which contains a description of a complete set of invariants, a decomposition into irreducible pairs of matrices, and canonical forms. The classification problem related with (0.9) (or, equivalently, the classification problem for 2-periodic difference equations) can also been seen as a special case of the problem of classifying quadruples of subspaces (see Gel'fand and Ponomarev [3]). In more recent papers by Lenard [8] and Horn and Merino [7] the classification problem related with (0.9) is studied independently. Chapter 2 of [7] gives a canonical form and invariants, and [8] presents the decomposition into irreducible pairs; these results are similar to those obtained in [1].

The problems of classifying N-periodic difference equations under N-periodic similarity may be seen as classification problems for certain block matrices under block diagonal similarity (see Proposition 6.1). The latter classification problems may be restated as problems of classifying representations of a special type of quivers. These problems for quiver representations are studied in Nazarova [9]. (A quiver is a directed graph, possibly with loops and multiple edges.) In terms of N-periodic difference equations, the results of [9] mean that the number of N-periodically irreducible equations is infinite and that it is possible to describe the latter equations. Our results include, additionally, explicit descriptions of a complete set of invariants, canonical forms, the irreducible equations, and geometric methods to obtain the corresponding similarities. Problems related to the classification of N-periodic difference equations under

N-periodic similarity are also studied in Gel'fand and Ponomarev [2] in connection with the representations of the Lorentz group.

Periodic difference equations have also been studied in Van Dooren and Sreedhar [10], where necessary and sufficient conditions are given so that a periodic difference equation is periodically similar to a time-invariant one.

The problem of classifying general (not necessarily periodic) systems of difference equations of the form $x_{n+1} = A_n x_n$ $(n \in \mathbb{Z})$ under kinematic similarity has been studied by the authors in [4]. That paper covers in detail the scalar case, the time invariant case (when the coefficients A_n do not depend on n), the case of finitely supported difference equations (when the number of nonzero coefficients A_n is finite), and some other examples. The present paper and [4] are complementary.

1. Invariants and a canonical form under periodic similarity. In this section a canonical form for N-periodic difference equations under N-periodic similarity will be presented. Furthermore, Theorem 0.2 will be proved. To introduce the canonical form, we need the following lemma.

LEMMA 1.1. *Let $(A_n)_{n=-\infty}^{\infty}$ be an N-periodic sequence of linear operators A_n from $\mathbb{C}^{r_n}$ to $\mathbb{C}^{r_{n+1}}$. Put $s = N \max_{1\le n\le N} r_n$. For each $1 \le n \le N$ the space $\mathbb{C}^{r_n}$ admits a direct sum decomposition*

$$\mathbb{C}^{r_n} = \mathcal{N}_{n,1} \oplus \mathcal{N}_{n,2} \oplus \cdots \oplus \mathcal{N}_{n,s+1} \tag{1.1}$$

such that relative to the decomposition (1.1) *the operator A_n has the block matrix representation*

$$A_n = \left(\begin{array}{cccc|c} 0 & A_{n,1,2} & \dots & A_{n,1,s} & 0 \\ \vdots & 0 & \ddots & \vdots & \vdots \\ \vdots & \vdots & \ddots & A_{n,s-1,s} & 0 \\ 0 & 0 & \dots & 0 & 0 \\ \hline 0 & 0 & \dots & 0 & A_{n,s+1} \end{array}\right) : \oplus_{j=1}^{s+1}\mathcal{N}_{n,j} \to \oplus_{j=1}^{s+1}\mathcal{N}_{n+1,j}, \tag{1.2}$$

where $A_{n,j,j+1}$ is injective, $j = 1, 2, \dots, s-1$, $A_{n,s+1}$ is invertible, and $\mathcal{N}_{N+p,j} = \mathcal{N}_{p,j}$, for all $p \ge 1$ and $j = 1, 2, \dots, s+1$.

Proof. The proof is divided into three steps.

Step 1. In the first step of the proof, the subspaces $\mathcal{N}_{n,j}$ will be defined. Put

$$\mathcal{M}_{n,j} = \operatorname{Ker}(A_{n+j-1} \cdots A_{n+1} A_n),\ j \ge 0,\ n \in \mathbb{Z}. \tag{1.3}$$

By definition, $\mathcal{M}_{n,0} = \{0\}$. Fix $1 \le n \le N$. Notice that $\mathcal{M}_{n,j-1} \subset \mathcal{M}_{n,j}$, $j \ge 1$. For $1 \le j \le s$, let $\mathcal{N}_{n,j}$ be a complement of $\mathcal{M}_{n,j-1}$ into $\mathcal{M}_{n,j}$, i.e.,

$$\mathcal{M}_{n,j-1} \oplus \mathcal{N}_{n,j} = \mathcal{M}_{n,j}. \tag{1.4}$$

To define $\mathcal{N}_{n,s+1}$ for $1 \le n \le N$, let $\mathcal{N}_{1,s+1}$ be the maximum invariant subspace of the monodromy operator $A_N \cdots A_1$ on which $A_N \cdots A_1$ is invertible. Put $\mathcal{N}_{n,s+1} = A_{n-1} \cdots A_1 \mathcal{N}_{1,s+1},\ n = 2, 3, \dots, N$.

Step 2. In this step of the proof it will be shown that

$$\mathcal{M}_{n,s} \oplus \mathcal{N}_{n,s+1} = \mathbb{C}^{r_n},\ n = 1, 2, \dots, N. \tag{1.5}$$

To see (1.5), fix $1 \le n \le N$. Notice that $\mathcal{M}_{n,N(r_n+j)} = \mathcal{M}_{n,N(r_n+j+1)}$, $j = 0, 1, \dots$. In particular, $\mathcal{M}_{n,s} = \mathcal{M}_{n,Nr_n} = \operatorname{Ker}(A_{n+N-1} \cdots A_n)^{r_n}$. Thus it suffices to show that

$\mathcal{N}_{n,s+1}$ is the maximum $(A_{n+N-1}\cdots A_n)$-invariant subspace on which $A_{n+N-1}\cdots A_n$ is invertible. Indeed, if this property has been proved, then

$$\mathcal{N}_{n,s+1} = \operatorname{Im}(A_{n+N-1}\cdots A_n)^{r_n}$$

and (1.5) follows trivially. Notice that the subspace $\mathcal{N}_{n,s+1}$ is $(A_{n+N-1}\cdots A_n)$-invariant, since

$$A_{n+N-1}\cdots A_n\mathcal{N}_{n,s+1} = A_{n-1}\cdots A_1A_N\cdots A_1\mathcal{N}_{1,s+1} = A_{n-1}\cdots A_1\mathcal{N}_{1,s+1} = \mathcal{N}_{n,s+1}.$$

Assume that $\mathcal{N}$ is an $(A_{n+N-1}\cdots A_n)$-invariant subspace on which $A_{n+N-1}\cdots A_n$ is invertible. It follows that $A_N\cdots A_n\mathcal{N}$ is an $(A_N\cdots A_1)$-invariant subspace and hence $\dim A_N\cdots A_n\mathcal{N} \le \dim \mathcal{N}_{1,s+1}$. The left-hand side of this equality is equal to $\dim \mathcal{N}$; the right-hand side is equal to $\dim \mathcal{N}_{n,s+1}$. So $\dim \mathcal{N} \le \dim \mathcal{N}_{n,s+1}$, and hence $\mathcal{N}_{n,s+1}$ is the maximum $(A_{n+N-1}\cdots A_n)$-invariant subspace on which $A_{n+N-1}\cdots A_n$ is invertible.

Step 3. In this step the proof will be finished. Since $\mathcal{M}_{n,0} = \{0\}$, it follows from (1.4) that

$$\mathcal{N}_{n,1} \oplus \mathcal{N}_{n,2} \oplus \cdots \oplus \mathcal{N}_{n,j} = \mathcal{M}_{n,j},\ 1 \le j \le s. \tag{1.6}$$

In particular, (1.5) and $j = s$ in (1.6) give the partitioning (1.1). Next set $\mathcal{N}_{N+1,j} = \mathcal{N}_{1,j}$, $j = 1, 2, \ldots, s$. It can be easily seen that the following identities are satisfied:

$$A_n\mathcal{N}_{n,s+1} = \mathcal{N}_{n+1,s+1},\ n = 1, 2, \ldots, N-1. \tag{1.7}$$

Furthermore, from (1.6) and $A_n\mathcal{N}_{n,j} \subset A_n\mathcal{M}_{n,j} \subset \mathcal{M}_{n+1,j-1}$ it follows that

$$A_n\mathcal{N}_{n,1} = \{0\}, \quad A_n\mathcal{N}_{n,j} \subset \mathcal{N}_{n+1,1} \oplus \cdots \oplus \mathcal{N}_{n+1,j-1},\ j = 1, 2, \ldots, s,\ n = 1, 2, \ldots, N. \tag{1.8}$$

Finally, the maps

$$\pi_{n+1,j-1}A_n \mid \mathcal{N}_{n,j} : \mathcal{N}_{n,j} \to \mathcal{N}_{n+1,j-1},\ j = 1, 2, \ldots, s,\ n = 1, 2, \ldots, N, \tag{1.9}$$

are injective, where $\pi_{n+1,j-1} : \mathbb{C}^{r_{n+1}} \to \mathcal{N}_{n+1,j-1}$ is the canonical projection with respect to the decomposition (1.1). To see this, assume that $x \in \mathcal{N}_{n,j}$ with $\pi_{n+1,j-1}A_nx = 0$. It follows from (1.8) that $A_nx \in \mathcal{M}_{n+1,j-2}$, and hence $x \in \mathcal{M}_{n,j-1}$. Thus $x = 0$ and we conclude that the map (1.9) is injective.

The partitioning (1.2) now follows from (1.7), (1.8), the injectivity of the map (1.9), and the invertibility of the monodromy operator $A_N\cdots A_1 \mid \mathcal{N}_{1,s+1} : \mathcal{N}_{1,s+1} \to \mathcal{N}_{1,s+1}$. ∎

For Lemma 1.1 to hold, it is not necessary to take $s = N\max_{1\le n\le N} r_n$; other choices with smaller s are also good. In fact, from the proof of Lemma 1.1 it can be seen that Lemma 1.1 holds for any $s \ge s'$, where s' is the smallest integer such that $\mathcal{M}_{n,j-1} = \mathcal{M}_{n,j}$ for $j \ge s'$ and $n = 1, 2, \ldots, N$. Here $\mathcal{M}_{n,j}$ is as in (1.3).

From the partitioning induced by the lines in the block matrix in (1.2), the following theorem is immediately obtained.

THEOREM 1.2. *Each N-periodic system is N-periodically similar to the direct sum of an N-periodic system with invertible coefficients and an N-periodic system with a nilpotent monodromy operator.*

By Theorem 1.2, to find canonical forms for N-periodic systems of difference equations it suffices to consider two special cases, namely, the case of N-periodic

systems with invertible coefficients and the case of N-periodic systems with nilpotent monodromy operators. The following two theorems present canonical forms for these two cases.

THEOREM 1.3. *An N-periodic system with invertible coefficients is N-periodically similar to a unique (up to reordering) direct sum of N-periodic difference equations of type* I. *This direct sum is the time-invariant system*

$$x_{n+1} = Jx_n,\ n \in \mathbb{Z}, \tag{1.10}$$

where J is the Jordan matrix which one obtains if in the Jordan normal form of the monodromy matrix the diagonal entries are replaced by their Nth roots in the sector $\{z \in \mathbb{C} | 0 \le \arg z < 2\pi/N\}$.

For the second theorem we need to introduce the following notation. For nonnegative integers m, p, and r with $1 \le m \le N$, $m < p < m + N$, and $r \ge 0$, we denote by $\Sigma_{\mathrm{II}}(m, p, r)$ the N-periodic difference equation (0.1) with the coefficients A_n being given by (0.7). Similarly, for nonnegative integers m and r with $1 \le m \le N$ and $r \ge 0$, we denote by $\Sigma_{\mathrm{III}}(m, r)$ the N-periodic difference equation (0.1) with the coefficients A_n being given by (0.8). With the N-periodic difference equation (0.1) we associate the numbers $\eta_{j,k}((A_n))$ given by

$$\eta_{j,k}((A_n)) = \begin{cases} \operatorname{rank}(A_{j+1}A_j) - \operatorname{rank} A_j - (\operatorname{rank} A_{j+1} - r_{j+1}), & j = k, \\ \operatorname{rank}(A_{j+1} \cdots A_k) - \operatorname{rank}(A_j \cdots A_k) & \\ \quad - (\operatorname{rank}(A_{j+1} \cdots A_{k+1}) - \operatorname{rank}(A_j \cdots A_{k+1})), & j \ge k+1. \end{cases} \tag{1.11}$$

THEOREM 1.4. *An N-periodic system $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, with a nilpotent monodromy operator is N-periodically similar to a unique (up to reordering) direct sum of N-periodic systems of the forms $\Sigma_{\mathrm{II}}(m, p, r)$ and $\Sigma_{\mathrm{III}}(m, r)$. The number of times the system $\Sigma_{\mathrm{II}}(m, p, r)$ appears in the direct sum is equal to $\eta_{p-1+rN,m}((A_n))$; the number of times the system $\Sigma_{\mathrm{III}}(m, r)$ appears is equal to $\eta_{m-1+rN,m}((A_n))$, where the numbers $\eta_{j,k}((A_n))$ are given by* (1.11).

Theorem 1.4 will be proved in section 3. In the remaining part of this section, we prove Theorems 1.3 and 0.2.

Proof of Theorem 1.3. We split the proof into two parts. The first part concerns the uniqueness statement.

Part 1. Let $\tilde{J}$ be a Jordan matrix with nonzero eigenvalues λ in the sector $0 \le \arg \lambda < \frac{2\pi}{N}$, and assume that the system $y_{n+1} = \tilde{J} y_n$, $n \in \mathbb{Z}$, is N-periodically similar to the system (1.10). We have to prove that $\tilde{J}$ is equal to J up to a reordering of the blocks. By N-periodic similarity, $\tilde{J} = E_{n+1}^{-1} J E_n$, $n \in \mathbb{Z}$, where E_n is invertible and $E_n = E_{n+N}$ for each n. It follows that

$$\tilde{J}^N = E_{N+1}^{-1} J^N E_1 = E_1^{-1} J^N E_1.$$

Hence $\tilde{J}^N$ is equal to J^N up to a reordering of the blocks. Notice that the Jordan normal form of the Nth power of a Jordan matrix with nonzero eigenvalues is obtained by replacing each diagonal entry of the Jordan matrix by its Nth power (which can be proved by reduction to the case of a single Jordan block with a nonzero eigenvalue). Since the eigenvalues λ of $\tilde{J}$ and J are in the sector $0 \le \arg \lambda < \frac{2\pi}{N}$, we conclude that $\tilde{J}$ is equal to J up to a reordering of the blocks.

Part 2. In this part we show that the N-periodic equation (0.1) with A_n invertible for each n is N-periodically similar to the time-invariant difference equation (1.10). Let E_1 be an invertible matrix such that $E_1^{-1} A_N \cdots A_1 E_1$ is a Jordan matrix $J_{A_N \cdots A_1}$

of $A_N \cdots A_1$. Define E_n to be the invertible matrix $E_n = A_{n-1} \cdots A_1 E_1$ for $1 \leq n \leq N$. Extend the sequence $(E_n)_{n=1}^N$ to a N-periodic sequence $(E_n)_{n=-\infty}^\infty$. The N-periodic similarity $(E_n)_{n=-\infty}^\infty$ transforms $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, into the N-periodic difference equation

$$\hat{x}_{n+1} = \hat{A}_n \hat{x}_n,\ n \in \mathbb{Z}, \tag{1.12}$$

where $\hat{A}_n = I$ for $1 \leq n \leq N-1$ and $\hat{A}_N = J_{A_N \cdots A_1}$.

Finally, we define an N-periodic similarity $(F_n)_{n=-\infty}^\infty$ which transforms (1.12) into (1.10). Notice that $\hat{A}_N$ is similar to J^N. Let F_1 be an invertible matrix satisfying $F_1^{-1} \hat{A}_N F_1 = J^N$, and put

$$F_n = F_1 J^{-n+1},\ n = 1, 2, \ldots, N.$$

Recall that $\hat{A}_n = I$ for $1 \leq n \leq N-1$. So we obtain the identities

$$F_{n+1}^{-1} \hat{A}_n F_n = J,\ n = 1, 2, \ldots, N,$$

where $F_{N+1} = F_1$. Extend the sequence $(F_n)_{n=1}^N$ to an N-periodic sequence $(F_n)_{n=-\infty}^\infty$. We conclude that the difference equations (1.12) and (1.10) are N-periodically similar, and hence (0.1) and (1.10) are N-periodically similar. □

Proof of Theorem 0.2. We split the proof into two parts. In the first part we prove the necessity of the conditions.

Part 1. Assume that $B_n = E_{n+1}^{-1} A_n E_n$, $n \in \mathbb{Z}$, where $(E_n)_{n=-\infty}^\infty$ is an N-periodic similarity. Iterating these equations, we obtain that

$$E_{n+j}^{-1} A_{n+j-1} \cdots A_n E_n = B_{n+j-1} \cdots B_n, \quad j \geq 1,\ 1 \leq n \leq N. \tag{1.13}$$

In particular, taking ranks in (1.13), we get the equalities (0.4). Substitution of $j = N$ and $n = 1$ in (1.13) yields the identity $E_{N+1}^{-1} A_N \cdots A_1 E_1 = B_N \cdots B_1$. But $E_{N+1} = E_1$, since $(E_n)_{n=-\infty}^\infty$ is N-periodic. Hence $A_N \cdots A_1$ is similar to $B_N \cdots B_1$.

Part 2. Assume that the monodromy matrices of (0.1) and (0.2) are similar and that the rank conditions (0.4) are satisfied. We have to show that the systems (0.1) and (0.2) are N-periodically similar. By Lemma 1.1 and Theorem 1.3 we may assume, without loss of generality, that the monodromy matrices are nilpotent. It suffices to show that the N-periodic difference equation (0.1) with nilpotent monodromy matrix is N-periodically similar to a N-periodic difference equation with coefficients of the form (1.2) with, for each $n = 1, 2, \ldots, N$, the additional properties

$$\mathcal{N}_{n,s+1} = \{0\},\ A_{n,j,k} = 0,\ j < k-1, \tag{1.14}$$

$$A_{n,j,j+1} = \begin{pmatrix} I \\ 0 \end{pmatrix} : \mathcal{N}_{n,j+1} \to \mathcal{N}_{n,j+1} \oplus \mathcal{K}_{n,j+1} = \mathcal{N}_{n+1,j},\ j = 1, 2, \ldots, s-1 \tag{1.15}$$

for some subspaces $\mathcal{K}_{n,j}$, $j = 1, 2, \ldots, s-1$. Indeed, the form (1.2) with the properties (1.14), (1.15) for $n = 1, 2, \ldots, N$ is completely determined by the ranks in the left-hand side of (0.4). Similarly, the N-periodic difference equation (0.2) with nilpotent monodromy matrix is N-periodically similar to a N-periodic difference equation which is completely determined by the ranks in the right-hand side of (0.4). Thus (0.1) and (0.2) are N-periodically similar.

To show that (0.1) with nilpotent monodromy matrix is N-periodically similar to a N-periodic difference equation with coefficients of the form (1.2) with, for each

$n = 1, 2, \ldots, N$, the properties (1.14), (1.15), we construct complements $\mathcal{N}_{n,j}$ as in (1.4) in a special way. The construction is as follows.

Fix $1 \le n \le N$. Let $\mathcal{N}_{n,s}$ be a complement of $\mathcal{M}_{n,s-1}$ into $\mathcal{M}_{n,s}$, i.e., $\mathcal{M}_{n,s-1} \oplus \mathcal{N}_{n,s} = \mathcal{M}_{n,s}$. We proceed recursively. Assume that $\mathcal{N}_{m,j+1}$ is a complement of $\mathcal{M}_{m,j}$ into $\mathcal{M}_{m,j+1}$ for some nonnegative integers m and j with the properties $1 \le m \le N$, $1 \le j \le s-1$, $m + j + 1 = n + s$ modulo N. Notice that $\mathcal{N}_{m,j+1}$ has the following properties:

$$A_m \mathcal{N}_{m,j+1} \subset A_m \mathcal{M}_{m,j+1} \subset \mathcal{M}_{m+1,j}, \tag{1.16}$$

$$A_m \mathcal{N}_{m,j+1} \cap \mathcal{M}_{m+1,j-1} \subset A_m[\mathcal{M}_{m,j} \cap \mathcal{N}_{m,j+1}] = \{0\}. \tag{1.17}$$

Hence there exists a subspace $\mathcal{K}_{m+1,j}$ such that

$$\mathcal{M}_{m+1,j-1} \oplus A_m \mathcal{N}_{m,j+1} \oplus \mathcal{K}_{m+1,j} = \mathcal{M}_{m+1,j}.$$

Now we define $\mathcal{N}_{m+1,j}$ to be equal to $A_m \mathcal{N}_{m,j+1} \oplus \mathcal{K}_{m+1,j}$. If in this process $m = N$, and hence $\mathcal{N}_{m+1,j} = \mathcal{N}_{N+1,j}$, we put $\mathcal{N}_{1,j} = \mathcal{N}_{N+1,j}$ and continue the recursive procedure with $\mathcal{N}_{1,j}$.

Carry out the above recursive procedure for $1 \le n \le N$. We obtain subspaces $\mathcal{N}_{n,j}$ such that

$$\mathcal{M}_{n,j-1} \oplus \mathcal{N}_{n,j} = \mathcal{M}_{n,j},\ j = 1, 2, \ldots, s,\ n = 1, 2, \ldots, N. \tag{1.18}$$

Thus the subspaces $\mathcal{N}_{n,j}$ decompose $\mathbb{C}^{r_n}$ as in (1.1) with $\mathcal{N}_{n,s+1} = \{0\}$, $n = 1, 2, \ldots, N$. Furthermore, for each $1 \le n \le N$, the subspaces $\mathcal{N}_{n,j}$ have the properties

$$A_n \mathcal{N}_{n,j+1} \subset \mathcal{N}_{n+1,j},\ j = 1, 2, \ldots, s-1, \tag{1.19}$$

$$\pi_{n+1,j} A_n | \mathcal{N}_{n,j+1} = \begin{pmatrix} I \\ 0 \end{pmatrix} : \mathcal{N}_{n,j+1} \to A_n \mathcal{N}_{n,j+1} \oplus \mathcal{K}_{n+1,j} = \mathcal{N}_{n+1,j},\ j = 1, 2, \ldots, s-1, \tag{1.20}$$

where $\pi_{n+1,j}$ is the projection of $\mathbb{C}^{r_{n+1}}$ onto $\mathcal{N}_{n+1,j}$ according to the decomposition (1.1), $\mathcal{N}_{N+1,j} = \mathcal{N}_{1,j}$, $j = 1, 2, \ldots, s$, and $\pi_{N+1,j} = \pi_{1,j}$, $j = 1, 2, \ldots, s$. By Lemma 1.1 and (1.18), (1.19), (1.20) the N-periodic difference equation (0.1) with nilpotent monodromy matrix is N-periodically similar to the N-periodic difference equation with coefficients given by (1.2) and (1.14), (1.15). ∎

2. Invariants and a canonical form under kinematic similarity. In this section a canonical form for N-periodic difference equations under kinematic similarity will be presented. Furthermore, Theorem 0.1 will be proven. Finally, we shall answer an open question in [4] for periodic systems. First, we state the analogues of Theorems 1.2–1.4 for N-periodic similarity replaced by kinematic similarity.

THEOREM 2.1. *Each N-periodic system is kinematically similar to the direct sum of an N-periodic system with invertible coefficients and an N-periodic system with a nilpotent monodromy operator.*

THEOREM 2.2. *An N-periodic system with invertible coefficients is kinematically similar to a unique (up to reordering) direct sum of N-periodic difference equations of type* I_+. *This direct sum is the time-invariant system*

$$x_{n+1} = Jx_n,\ n \in \mathbb{Z}, \tag{2.1}$$

where J is the Jordan matrix which one obtains if in the Jordan normal form of the monodromy matrix the diagonal entries are replaced by the positive Nth roots of their absolute values.

THEOREM 2.3. *An N-periodic system $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, with a nilpotent monodromy operator is kinematically similar to a unique (up to reordering) direct sum of N-periodic systems of the forms $\Sigma_{\mathrm{II}}(m,p,r)$ and $\Sigma_{\mathrm{III}}(m,r)$. The number of times the system $\Sigma_{\mathrm{II}}(m,p,r)$ appears in the direct sum is equal to $\eta_{p+rN,m}((A_n))$; the number of times the system $\Sigma_{\mathrm{III}}(m,r)$ appears is equal to $\eta_{m+rN,m}((A_n))$, where the numbers $\eta_{j,k}((A_n))$ are given by* (1.11).

From Theorems 1.4 and 2.3 the following corollary is immediate.

COROLLARY 2.4. *Two N-periodic difference equations with nilpotent monodromy operators are kinematically similar if and only if they are N-periodically similar.*

Theorem 2.3 will be proved in section 3. Since an N-periodic similarity is a kinematic similarity, Theorem 2.1 is an immediate consequence of Theorem 1.2.

Proof of Theorem 2.2. To prove Theorem 2.2 we shall use Theorem 4.1 in [4]. Indeed, according to Theorem 1.3 an N-periodic system is kinematically similar to a time-invariant system $x_{n+1} = \tilde{J}x_n$, $n \in \mathbb{Z}$, where $\tilde{J}$ is the Jordan matrix which one obtains if in the Jordan normal form of the monodromy matrix the diagonal entries are replaced by their Nth roots in the sector $\{z \in \mathbb{C} \mid 0 \le \arg z < \frac{2\pi}{N}\}$. By Theorem 4.1 in [4] the system $x_{n+1} = \tilde{J}x_n$, $n \in \mathbb{Z}$, is kinematically similar to the time-invariant system $x_{n+1} = Jx_n$, $n \in \mathbb{Z}$, where J is obtained from $\tilde{J}$ by replacing the diagonal entries in $\tilde{J}$ by their absolute values. This yields Theorem 2.2, except for the statement about uniqueness. The latter, however, also follows directly from Theorem 4.1 in [4]. □

Proof of Theorem 0.1. We split the proof into two parts.

Part 1. In this part we prove the necessity of the condition in Theorem 0.1. Assume that $B_n = E_{n+1}^{-1} A_n E_n$, $n \in \mathbb{Z}$, where $(E_n)_{n=-\infty}^{\infty}$ is a kinematic similarity. Iterating the last equations, we obtain that

$$E_{n+j}^{-1} A_{n+j-1} \cdots A_n E_n = B_{n+j-1} \cdots B_n,\ j \ge 1,\ 1 \le n \le N. \tag{2.2}$$

In particular, taking ranks in (2.2), we get the equalities (0.4). Substitution of $n = Nm + 1$ and $j = N$ into (2.2) yields the identities

$$E_{N(m+1)+1}^{-1} A_N \cdots A_1 E_{Nm+1} = B_N \cdots B_1,\ m \in \mathbb{Z}. \tag{2.3}$$

Thus the time-invariant difference equations $x_{n+1} = A_N \cdots x_n$, $n \in \mathbb{Z}$, and $y_{n+1} = B_N \cdots B_1 y_n$, $n \in \mathbb{Z}$, are kinematically similar. From Theorem 4.1 in [4] it follows that the Jordan matrices $[J_{A_N \cdots A_1}]$ and $[J_{B_N \cdots B_1}]$ are similar.

Part 2. Assume that the rank conditions (0.4) are satisfied and that the Jordan matrices $[J_{A_N \cdots A_1}]$ and $[J_{B_N \cdots B_1}]$ are similar. We shall show that the systems (0.1) and (0.2) are kinematically similar. By Theorem 2.1 the system (0.1) is kinematically similar to the direct sum of the two N-periodic difference equations

$$x_{n+1} = A_n^{(1)} x_n,\ n \in \mathbb{Z}, \tag{2.4}$$

$$x_{n+1} = A_n^{(2)} x_n,\ n \in \mathbb{Z}, \tag{2.5}$$

with $A_n^{(1)}$ being invertible for each n and the monodromy matrix $A_N^{(2)} \cdots A_1^{(2)}$ being nilpotent. Similarly, (0.2) is kinematically similar to the direct sum of the two N-periodic difference equations

$$y_{n+1} = B_n^{(1)} y_n,\ n \in \mathbb{Z}, \tag{2.6}$$

$$y_{n+1} = B_n^{(2)} y_n,\ n \in \mathbb{Z}, \tag{2.7}$$

with $B_n^{(1)}$ being invertible for each n and the monodromy matrix $B_N^{(2)} \cdots B_1^{(2)}$ being nilpotent. Notice that the Jordan matrices $[J_{A_N^{(1)} \cdots A_1^{(1)}}]$ and $[J_{B_N^{(1)} \cdots B_1^{(1)}}]$ are similar. Thus it follows from Theorem 2.2 that the systems (2.4) and (2.6) are kinematically similar. In addition notice that the matrices $A_n^{(2)}$ and $B_n^{(2)}$ are of the same sizes for each n and that for each $n \in \{1, 2, \ldots, N\}$

$$\operatorname{rank}(A_{j+n-1}^{(2)} A_{j+n-2}^{(2)} \cdots A_n^{(2)}) = \operatorname{rank}(B_{j+n-1}^{(2)} B_{j+n-2}^{(2)} \cdots B_n^{(2)}),\ 1 \le j \le N(\max_{1 \le n \le N} r_n).$$

From Theorem 0.2 it follows that the systems (2.5) and (2.7) are N-periodically similar and, consequently, kinematically similar. We conclude that the direct sum of (2.4) and (2.5) is kinematically similar to the direct sum of (2.6) and (2.7). Hence the systems (0.1) and (0.2) are kinematically similar. □

Theorem 0.1 allows us to answer an open question in section 8 of [4] for periodic difference equations. To state the result, we recall that two families $(a_n)_{n \in \tau}$ and $(b_n)_{n \in \tau}$ of nonnegative real numbers are called *strongly equivalent* if there exists $M \ge 1$ such that $b_n/M \le a_n \le M b_n$, $n \in \tau$. Furthermore, we denote by $s_k(A)$ the kth singular value of the matrix A.

THEOREM 2.5. *Let $(A_n)_{n=-\infty}^{\infty}$ and $(B_n)_{n=-\infty}^{\infty}$ be N-periodic sequences of linear operators $A_n, B_n : \mathbb{C}^{r_n} \to \mathbb{C}^{r_{n+1}}$. Assume that the families*

$$(s_k(A_j A_{j-1} \cdots A_i))_{i,j \in \mathbb{Z},\, i \le j}, \quad (s_k(B_j B_{j-1} \cdots B_i))_{i,j \in \mathbb{Z},\, i \le j} \tag{2.8}$$

are strongly equivalent for each k. Then the N-periodic difference equations $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, and $y_{n+1} = B_n y_n$, $n \in \mathbb{Z}$, are kinematically similar.

Proof. Assume that the families (2.8) are strongly equivalent. In particular, by N-periodicity, the families

$$(s_k(A_N \cdots A_1)^j)_{j=0}^{\infty}, \quad (s_k(B_N \cdots B_1)^j)_{j=0}^{\infty}$$

are strongly equivalent for each k. According to Theorem 4.1 in [4], the Jordan matrices $[J_{A_N \cdots A_1}]$ and $[J_{B_N \cdots B_1}]$ are similar. The strong equivalence of the families (2.8) also yields that

$$s_k(A_j \cdots A_i) = 0 \Leftrightarrow s_k(B_j \cdots B_i) = 0$$

for all $i \le j$ and all k. Hence $\operatorname{rank}(A_j \cdots A_i) = \operatorname{rank}(B_j \cdots B_i)$ for all $i \le j$. From Theorem 0.1 we conclude that the systems $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, and $y_{n+1} = B_n y_n$, $n \in \mathbb{Z}$, are kinematically similar. □

The converse of Theorem 2.5 is also true; see section 8 of [4].

3. Reducibility. In this section we shall prove Theorems 0.3, 0.4, 0.5, 1.4, and 2.3, which are all related to reducibility in the class of N-periodic systems. In the final paragraph reducibility by kinematic similarity in the general class of time-varying systems is analyzed.

The key lemma in the proofs follows.

LEMMA 3.1. *Let $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, be an N-periodic system with a nilpotent monodromy matrix $A_N A_{N-1} \cdots A_1$. Let the numbers $s_{n,j}$ be given by (0.5). The system $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, is reducible in the class of N-periodic systems by N-periodic (or kinematic) similarity if and only if there exists an integer m, $1 \le m \le N$, such that the numbers $s_{m,j}$ may be decomposed as*

$$s_{m,j} = s_{m,j}^{(1)} + s_{m,j}^{(2)},\ j \ge 1, \tag{3.1}$$

where for $i = 1, 2$ the nonnegative integer $s_{m,1}^{(i)}$ is nonzero and where the nonnegative integers $s_{m,j}^{(i)}$ are ordered in a decreasing way:

$$s_{m,j}^{(i)} \geq s_{m,j+1}^{(i)},\ j \geq 1. \tag{3.2}$$

We introduce the following terminology. An array $(s_{n,j})_{n=1,j=1}^{N,\ \infty}$ will be called *admissible* if, for $n = 1, 2, \ldots, N$,

$$s_{n,j} \geq 0,\ j \geq 1, \tag{3.3}$$

$$s_{n,j} = 0,\ j \geq J \text{ for some nonnegative integer } J, \tag{3.4}$$

$$s_{n,j} \geq s_{n,j+1},\ j \geq 1. \tag{3.5}$$

Notice that (3.3) follows from (3.4) and (3.5).

LEMMA 3.2. *For an N-periodic system of the form* (0.1) *the array $(s_{n,j})_{n=1,j=1}^{N\ \infty}$ defined by* (0.5) *is admissible.*

Proof. The properties (3.3) and (3.4) can be easily shown for all n. The number J in (3.4) can be taken equal to $N \max_{1 \leq n \leq N} r_n$. To see that (3.5) is satisfied, we use Lemma 1.1 and its proof. The operators $A_{n,j,j+1}$ in Lemma 1.1 are injective and hence $\dim \mathcal{N}_{n,j} \geq \dim \mathcal{N}_{n+1,j-1}$ for all j and n. From the direct sum decomposition (1.4) we obtain the identity $\dim \mathcal{M}_{n,j} - \dim \mathcal{M}_{n,j-1} \geq \dim \mathcal{M}_{n+1,j-1} - \dim \mathcal{M}_{n+1,j-2}$. This identity may be rewritten as

$$\dim \mathcal{M}_{n,j} - \dim \mathcal{M}_{n+1,j-1} \geq \dim \mathcal{M}_{n,j-1} - \dim \mathcal{M}_{n+1,j-2},\ j \geq 2. \tag{3.6}$$

The left-hand side of (3.6) is equal to $r_n - r_{n+1} - s_{n,j}$; the right-hand side of (3.6) is equal to $r_n - r_{n+1} - s_{n,j-1}$. We conclude that $s_{n,j-1} \geq s_{n,j}$ for all n and $j \geq 2$. □

An admissible array will be called *reducible* if it can be written as the sum of two nonzero admissible arrays. Here the sum of two arrays is the componentwise sum, and an array is called *nonzero* if at least one of its entries is nonzero. Notice that an admissible array $(s_{n,j})_{n=1,j=1}^{N,\ \infty}$ is reducible if and only if there exists an integer m, $1 \leq m \leq N$, for which the numbers $s_{m,j}$ may be decomposed as in (3.1) such that for $i = 1, 2$ the nonnegative integer $s_{m,1}^{(i)}$ is nonzero, and the nonnegative integers $s_{m,j}^{(i)}$ are ordered in a decreasing way as in (3.2). Thus Lemma 3.1 may be restated: "The N-periodic difference equation (0.1) with nilpotent monodromy matrix is reducible in the class of N-periodic systems by N-periodic (or kinematic) similarity if and only if the admissible array $(s_{n,j})_{n=1,j=1}^{N\ \infty}$ is reducible, where the numbers $s_{n,j}$ are defined by (0.5)." It can be easily seen that an admissible array $(s_{n,j})_{n=1,j=1}^{N,\ \infty}$ is irreducible if and only if there exist nonnegative integers m and q, $1 \leq m \leq N$ and $q \geq 1$, such that

$$s_{n,j} = \begin{cases} 1 & \text{if } n = m, 1 \leq j \leq q, \\ 0 & \text{otherwise.} \end{cases}$$

Proof of Lemma 3.1. The proof consists of two parts.

Part 1. Assume that the N-periodic difference equation (0.1) with nilpotent monodromy matrix is kinematically similar to the nontrivial direct sum of the N-periodic difference equations

$$x_{n+1} = A_n^{(1)} x_n,\ n \in \mathbb{Z}, \quad (A_n^{(1)} : \mathbb{C}^{r_{n,1}} \to \mathbb{C}^{r_{n+1,1}}), \tag{3.7}$$

$$x_{n+1} = A_n^{(2)} x_n,\ n \in \mathbb{Z}, \quad (A_n^{(2)} : \mathbb{C}^{r_{n,2}} \to \mathbb{C}^{r_{n+1,2}}). \tag{3.8}$$

In particular, the monodromy matrices of the N-periodic difference equations (3.7), (3.8) are nilpotent. For $i = 1, 2$ let $s_{n,j}^{(i)}$ be given by the right-hand side of (0.5) with A_m replaced by $A_m^{(i)}$ for each $m \in \mathbb{Z}$. It is evident that $s_{n,j} = s_{n,j}^{(1)} + s_{n,j}^{(2)}$ for all n and j. Moreover, $s_{n,j}^{(i)} \geq s_{n,j+1}^{(i)}$ for all n and j by Lemma 3.2. Thus it suffices to show that the arrays $(s_{n,j}^{(i)})_{n=1,j=1}^{N\ \infty}, i = 1, 2$, are nonzero. Suppose that $s_{n,j}^{(1)} = 0$ for all j and n. Thus rank $(A_{n+j-1}^{(1)} \cdots A_n^{(1)})$ does not depend on $j \geq 0$. In particular $r_{n,1} = \text{rank}\,(A_{n+N-1}^{(1)} \cdots A_n^{(1)})^{r_{n,1}}$ for all n. The monodromy matrix of (3.7) is nilpotent and hence the latter ranks are zero for all n. But then $r_{n,1} = 0$ for all n and the difference equation (3.7) is trivial. We conclude that the array $(s_{n,j}^{(1)})_{n=1,j=1}^{N\ \infty}$ is nonzero. In a similar way it can be shown that the array $(s_{n,j}^{(2)})_{n=1,j=1}^{N\ \infty}$ is nonzero.

Part 2. Suppose that the admissible array $(s_{n,j})_{n=1,j=1}^{N\ \infty}$ is reducible. Decompose it as a sum of nonzero irreducible admissible arrays

$$s_{n,j} = s_{n,j}^{(1)} + \cdots + s_{n,j}^{(M)}. \tag{3.9}$$

So for each $i = 1, 2, \ldots, M$ there exists nonnegative integers m_i and q_i, $1 \leq m_i \leq N$, $q_i \geq 1$, such that

$$s_{n,j}^{(i)} = \begin{cases} 1 & \text{if } n = m_i, 1 \leq j \leq q_i, \\ 0 & \text{otherwise.} \end{cases} \tag{3.10}$$

For $i = 1, 2, \ldots, M$, write $m_i + q_i$ as $m_i + q_i = p_i + r_i N$ for nonnegative integers p_i and r_i with $m_i \leq p_i < m_i + N$. Notice that $m_i = p_i$ if and only if q_i is divisible by N. Let $x_{n+1} = A_n^{(0)} x_n$, $n \in \mathbb{Z}$, be the direct sum of the N-periodic difference equations $\Sigma_{\text{II}}(m_i, p_i, r_i) : x_{n+1} = A_n^{(i)} x_n$, $n \in \mathbb{Z}$, where i runs over all integers $1, 2, \ldots, M$ for which q_i not divisible by N and of the N-periodic difference equations $\Sigma_{\text{III}}(m_i, r_i) : x_{n+1} = A_n^{(i)} x_n$, $n \in \mathbb{Z}$, where i runs over all integers $1, 2, \ldots, M$ for which q_i divisible by N. Put for $i = 0, 1, \ldots, M$ and $n = 1, 2, \ldots, N$

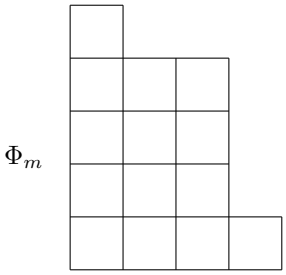
$$t_{n,j}^{(i)} = \begin{cases} \text{rank}\,(A_{n+j-1}^{(i)} \cdots A_{n+1}^{(i)}) - \text{rank}\,(A_{n+j-1}^{(i)} \cdots A_{n+1}^{(i)} A_n^{(i)}), & j \geq 2, \\ r_{n+1}^{(i)} - \text{rank}\, A_n^{(i)}, & j = 1, \end{cases}$$

where $r_{n+1}^{(i)}$ is the dimension of the space on which $A_{n+1}^{(i)}$ acts. Notice that $t_{n,j}^{(0)} = t_{n,j}^{(1)} + \cdots + t_{n,j}^{(M)}$. Furthermore, from the definition of $t_{n,j}^{(i)}$ and the definitions of the systems $x_{n+1} = A_n^{(i)} x_n$, $n \in \mathbb{Z}$, for $i = 1, 2, \ldots, M$, it can easily be computed that $t_{n,j}^{(i)}$ is equal to the right-hand side of (3.10) for $n = 1, 2, \ldots, N$, $j = 1, 2, \ldots$, and $i = 1, 2, \ldots, M$. Thus, according to the decomposition (3.9), $t_{n,j}^{(0)} = s_{n,j}$ for all n and j. The matrix $A_N \cdots A_1$ is nilpotent and hence the numbers $s_{n,j}$ are in a one-to-one relation with the numbers r_n, $n = 1, 2, \ldots, N$, and the ranks in the left-hand side of (0.4). Thus it follows from Theorem 0.2 that the N-periodic difference equations (0.1) and $x_{n+1} = A_n^{(0)} x_n$, $n \in \mathbb{Z}$, are N-periodically similar. The latter N-periodic difference equation is reducible and hence (0.1) is reducible as well. □

Part 2 of the proof of Lemma 3.1 shows that any N-periodic difference equation of the form (0.1) with nilpotent monodromy matrix is N-periodically similar to the

direct sum of N-periodic difference equations of types II and III. To find these N-periodic difference equations, one may decompose the admissible array $(s_{n,j})_{n=1,j=1}^{N\ \infty}$ into irreducible admissible arrays, as in (3.9). Such a decomposition can be made as follows. For each $1 \leq n \leq N$ make a Young tableau of the sequence $(s_{n,j})_{j=1}^{\infty}$ by representing each nonzero number $s_{n,j}$ as a rectangle with height $s_{n,j}$ and width 1 and putting these rectangles one next to another (cf. [5, p. 131]). The result is a ladder-like figure Φ_n. For instance, if $n = m$ and $s_{m,1} = 5$, $s_{m,2} = s_{m,3} = 4$, $s_{m,4} = 1$, and $s_{m,j} = 0$ for $j > 4$, then Φ_m is the following figure:

(3.11)



Now view Φ_m as a set of rectangles of height 1, which are put one above another. The widths of these rectangles determine a decomposition

$$s_{m,j} = \tilde{s}_{m,j}^{(1)} + \cdots + \tilde{s}_{m,j}^{M_m},\ j \geq 1. \tag{3.12}$$

For instance, if Φ_m is as in (3.11), then the decomposition (3.12) is given by $M_m = 5$ and

$$\tilde{s}_{m,j}^{(1)} = \begin{cases} 1, & 1 \leq j \leq 4, \\ 0, & j > 4, \end{cases} \qquad \tilde{s}_{m,j}^{(i)} = \begin{cases} 1, & 1 \leq j \leq 3, \\ 0, & j > 3, \end{cases} \quad i = 2, 3, 4,$$

$$\tilde{s}_{m,j}^{(5)} = \begin{cases} 1, & j = 1, \\ 0, & j > 1. \end{cases}$$

In this way we find integers $\tilde{s}_{m,j}^{(i)}$ for $m = 1, 2, \ldots, N$ and for $i = 1, 2, \ldots, M_m$, $j \geq 1$. Next put $S_m = \sum_{n=1}^{m} M_n$ for $M = 1, 2, \ldots, N$ and put $M = S_N$. For integers i between $1 + S_m$ and S_{m+1}, $1 + S_m \leq i \leq S_{m+1}$, we define numbers $s_{n,j}^{(i)}$, $n = 1, 2, \ldots, N$, $j \geq 1$, by

$$s_{n,j}^{(i)} = \begin{cases} \tilde{s}_{m,j}^{(i-S_m)} & \text{if } n = m \text{ and } j \geq 1, \\ 0 & \text{if } n \neq m \text{ and } j \geq 1. \end{cases}$$

The numbers $s_{n,j}^{(i)}$ satisfy the decomposition (3.9) and the array $(s_{n,j}^{(i)})_{n=1,j=1}^{N\ \infty}$ is irreducible for all i.

Proof of Theorem 1.4. The proof is divided into two steps.

Step 1. In the first step we make a little computation. Let the N-periodic difference equation (0.1) be of type II or of type III, i.e., (0.1) is equal to $\Sigma_{\mathrm{II}}(m, p, r)$ or (0.1) is equal to $\Sigma_{\mathrm{III}}(m, r)$. In the latter case, put $p = m$. In both cases the numbers $\eta_{j,k}((A_n))$ in (1.11) are given by

$$\eta_{j,k,m,p,r} := \eta_{j,k}((A_n)) = \begin{cases} 1 & \text{if } k = m \text{ and } j = p - 1 + rN, \\ 0 & \text{otherwise.} \end{cases} \tag{3.13}$$

Step 2. Assume that the N-periodic difference equation (0.1) has a nilpotent monodromy matrix. By the paragraph preceding the present proof, (0.1) is N-periodically similar to the direct sum Σ of N-periodic difference equations of types II and III, say,

$$\Sigma = \oplus_{i=1}^{t} \alpha_i \Sigma_{\mathrm{II}}(m_i, p_i, r_i) \oplus \oplus_{i=t+1}^{t'} \alpha_i \Sigma_{\mathrm{III}}(m_i, r_i)$$

with $(m_i, p_i, r_i) \neq (m_j, p_j, r_j)$ for all $i \neq j$, $1 \leq i, j \leq t$ and $(m_i, r_i) \neq (m_j, r_j)$ for $i \neq j$, $t+1 \leq i, j \leq t'$. Let B_n be the nth coefficient of Σ. According to the direct sum decomposition of Σ,

$$\eta_{j,k}((B_n)) = \sum_{i=1}^{t'} \alpha_i \eta_{j,k,m_i,p_i,r_i} \tag{3.14}$$

for all j and k. By N-periodic similarity the number $\eta_{j,k}((A_n))$ is also equal to the right-hand side of (3.14) for each j and k. It follows from the computation in Step 1 that the numbers α_i, $i = 1, \ldots, t'$, are uniquely determined and given by $\alpha_i = \eta_{p_i - 1 + r_i N, m_i}((A_n))$ for $i = 1, 2, \ldots t'$. □

Proof of Theorem 2.3. Theorem 2.3 may be proved in a similar way as Theorem 1.4 by replacing N-periodic similarity by kinematic similarity. □

Proofs of Theorems 0.4 *and* 0.5. Equations of types II and III are irreducible under N-periodic or kinematic similarity by Lemma 3.1. Equations of type I are kinematically irreducible by Theorem 4.3 in [4]. Hence they are also irreducible under N-periodic similarity, and equations of type I_+ are kinematically irreducible.

From Theorems 1.2–1.4 it follows that any N-periodic difference equation is N-periodically similar to a direct sum of equations of types I, II, and III. According to Theorems 2.1–2.3, any N-periodic difference equation is kinematically similar to a direct sum of equations of types I_+, II, and III.

It remains to show the uniqueness of the direct sums in Theorems 0.4 and 0.5. We shall show the uniqueness in the former theorem; the uniqueness in the latter theorem can be shown similarly. So assume that (0.1) and (0.2) are N-periodically similar and that both of them are direct sums of systems of types I, II, and III. System (0.1) is the direct sum of the N-periodic difference equations $\Sigma_{1,1}$ and $\Sigma_{1,2}$, where $\Sigma_{1,1}$ is the sum of all systems of type I in (0.1) and $\Sigma_{1,2}$ is the sum of all systems of types II and III in (0.1). In a similar way system (0.2) is the direct sum of the N-periodic difference equations $\Sigma_{2,1}$ and $\Sigma_{2,2}$, where $\Sigma_{2,1}$ is the direct sum of all systems of type I in (0.2) and $\Sigma_{2,2}$ is the direct sum of all systems of types II and III in (0.2). From Theorem 0.2 we obtain that the systems $\Sigma_{1,1}$ and $\Sigma_{2,1}$ are N-periodically similar. According to Theorem 1.3, the direct sums $\Sigma_{1,1}$ and $\Sigma_{2,1}$ are the same up to reordering. Theorem 0.2 also yields that the systems $\Sigma_{1,2}$ and $\Sigma_{2,2}$ are N-periodically similar. By Theorem 1.4 the direct sums $\Sigma_{1,2}$ and $\Sigma_{2,2}$ are the same up to reordering. We conclude that the direct sums (0.1) and (0.2) are the same up to reordering. □

Proof of Theorem 0.3. By Theorem 0.5 the system (0.1) is irreducible under N-periodic similarity if and only if it is either N-periodically similar to a system of type I or N-periodically similar to a system of type II or III. According to Theorem 0.2, the system (0.1) is N-periodically similar to a system of type I if and only if the monodromy matrix of (0.1) is invertible and its Jordan form has one block only. The system (0.1) is N-periodically similar to a system of type II or III if and only if (0.6) holds for some integers m and q with $1 \leq m \leq N$ and $q \geq 1$. □

Finally, we come to reducibility of N-periodic difference equations by kinematic similarity in the general class of time-varying (possibly non-N-periodic) difference equations.

THEOREM 3.3. *The N-periodic difference equation* (0.1) *is irreducible by kinematic similarity in the class of time-varying difference equations if and only if the monodromy matrix $A_N \cdots A_1$ is invertible and the Jordan form of $A_N \cdots A_1$ consists of one block only.*

Proof. The proof is split into two parts.

Part 1. Assume that the monodromy matrix of the system (0.1) is invertible and has one Jordan block only. By Theorem 0.1 the system (0.1) is kinematically similar to a time-invariant system $x_{n+1} = Jx_n$, $n \in \mathbb{Z}$, where J is the Jordan matrix of the monodromy matrix of (0.1). The latter system is kinematically irreducible in the class of time-varying systems by Theorem 4.3 in [4]. Hence (0.1) is kinematically irreducible in the class of time-varying systems.

Part 2. Assume that the system (0.1) is kinematically irreducible in the class of time-varying systems. By Theorem 0.4 the system (0.1) is either kinematically similar to a system of type I_+ or kinematically similar to a system of type II or type III. If (0.1) is kinematically similar to a system of type I_+, then, according to Theorem 0.2, the monodromy matrix of (0.1) is invertible and its Jordan form has one block only. So it suffices to show that any system of type II or type III is the direct sum of time-varying (non-N-periodic) systems. Let (0.1) be equal to $\Sigma_{\mathrm{II}}(m,p,r)$ or to $\Sigma_{\mathrm{III}}(m,r)$. In the latter case, put $p = m$. Let $\Sigma^{(1)} : x_{n+1} = A_n^{(1)} x_n$, $n \in \mathbb{Z}$, and $\Sigma^{(2)} : x_{n+1} = A_n^{(2)} x_n$, $n \in \mathbb{Z}$, be the time-varying systems defined by

$$A_n^{(1)} = \begin{cases} A_n : \mathbb{C}^{r_n} \to \mathbb{C}^{r_{n+1}} & \text{if } n \le p, \\ I : \mathbb{C}^{r-k} \to \mathbb{C}^{r-k} & \text{if } p + kN < n < p + (k+1)N \text{ for some} \\ & k \in \{0, 1, \dots, r-1\}, \\ \begin{pmatrix} 0 & I \end{pmatrix} : \mathbb{C}^{r-k} \to \mathbb{C}^{r-k-1} & \text{if } n = p + (k+1)N \text{ for some} \\ & k \in \{0, 1, \dots, r-1\}, \\ 0 : \{0\} \to \{0\} & \text{if } n > p + rN, \end{cases}$$

$$A_n^{(2)} = \begin{cases} 0 : \{0\} \to \{0\} & \text{if } n < m + N, \\ I : \mathbb{C}^{\ell+1} \to \mathbb{C}^{\ell+1} & \text{if } m + (\ell+1)N < n < m + (\ell+2)N \text{ for some} \\ & \ell \in \{0, 1, \dots, r-1\}, \\ \begin{pmatrix} I \\ 0 \end{pmatrix} : \mathbb{C}^{\ell} \to \mathbb{C}^{\ell+1} & \text{if } n = m + (\ell+1)N \text{ for some } \ell \in \{0, 1, \dots, r-1\}, \\ A_n & \text{if } n \ge m + (r+1)N. \end{cases}$$

The N-periodic difference equation (0.1) is the direct sum of the time-varying difference equations $\Sigma^{(1)}$ and $\Sigma^{(2)}$. ∎

4. Reducibility in the class of square periodic systems. In this section we consider square reducibility in the class of N-periodic systems.

In the first two theorems we shall describe the squarely irreducible systems. For this purpose we call the square N-periodic system $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, a *system of type* IV if precisely one of the coefficients A_n is a singular single Jordan block and each of the other coefficients A_n is either the identity matrix or an identity matrix in which precisely one of the 1's is replaced by a 0. Recall that the system (0.1) is called a system of type I if it is time-invariant and if $A_n = A$ is an invertible single Jordan block with a nonzero eigenvalue λ satisfying $0 \le \arg \lambda < \frac{2\pi}{N}$, and that (0.1) is called a system of type I_+ if, additionally, $A_n = A$ has positive eigenvalues only.

THEOREM 4.1. *Square N-periodic systems of type* I_+ *or* IV *are irreducible in the class of square N-periodic systems under kinematic similarity. Any square N-periodic*

system is kinematically similar to a unique (up to reordering) direct sum of systems of types I_+ *and* IV.

THEOREM 4.2. *Square* N*-periodic systems of type* I *or* IV *are irreducible in the class of square* N*-periodic systems under* N*-periodic similarity. Any square* N*-periodic system is* N*-periodically similar to a unique (up to reordering) direct sum of systems of types* I *and* IV.

In the proofs of Theorems 4.1 and 4.2 we shall use some terminology from graph theory (see, e.g., Chapter 1 in [6]). Let $\mathcal{G} = (V, E)$ be a directed graph with loops and multiple arcs. A sequence $v_1, v_2, \dots, v_n$ of vertices in V is called a *circuit* if $(v_j, v_{j+1}) \in E$ for $1 \le j \le n-1$, and $v_n = v_1$. A circuit $v_1, v_2, \dots, v_n$ is called *elementary* if $v_i \ne v_j$ for $n \ne i \ne j \ne n$. Let $E' \subset E$ be a subset of arcs of $\mathcal{G}$. The *subgraph spanned by* E' is defined to be the graph $\mathcal{G}' = (V', E')$ with V' the set of vertices which are initial point or terminal point of the arcs in E'.

Proofs of Theorems 4.1 *and* 4.2. According to Theorem 0.5, any square N-periodic system is N-periodically similar to a unique direct sum of systems of types I, II, and III. A similar result holds under kinematic similarity (Theorem 0.4). Notice that each system of type III is also of type IV. Hence, in order to prove Theorems 4.1 and 4.2, it suffices to show that systems of type IV are kinematically irreducible in the class of square N-periodic systems and that any direct sum of systems of type II that is a square system may be seen as a unique direct sum of systems of type IV by changing the order in the direct sum. We shall first show the latter statement.

Let $\Sigma(q_i, t_i)$, $i = 1, 2, \dots, M$, be a collection of systems $x_{n+1} = C_n^{(2,i)} x_n$, $n \in \mathbb{Z}$, of type II. Here, for $i = 1, 2, \dots, M$, the numbers q_i, t_i denote the unique indices between 1 and N of the coefficients $C_q^{(2,i)}$ and $C_t^{(2,i)}$, respectively, which are of the form

$$C_q^{(2,i)} = (\,0 \quad I\,) : \mathbb{C}^{r+1} \to \mathbb{C}^r, \quad C_t^{(2,i)} = \begin{pmatrix} I \\ 0 \end{pmatrix} : \mathbb{C}^r \to \mathbb{C}^{r+1}$$

for some r. Notice that $t_i \ne q_i$ for systems of type II. With this collection $\Sigma(q_i, t_i)$, $i = 1, 2, \dots, M$, of systems of type II we associate a directed graph $\mathcal{G} = (V, E)$, which may have loops and multiple arcs. Namely, let

$$V = \{q_i\}_{i=1}^M \cup \{t_i\}_{i=1}^M, \ E = \{(q_i, t_i) \mid i = 1, 2, \dots, M\},$$

where equal elements of the vertex set V are taken only once and equal elements of the edge set E are taken as often as they appear when i runs from 1 to M. Thus a subset E' of E corresponds with a direct sum of the systems $\Sigma(q_i', t_i')$, where (q_i', t_i') runs through E'. Notice that a direct sum of systems of the form $\Sigma(q_i, t_i)$ is square if and only if the corresponding set of arcs spans a circuit in $\mathcal{G}$.

Assume that the direct sum of all systems $\Sigma(q_i, t_i)$, $i = 1, 2, \dots, M$, is a square system. Hence the graph $\mathcal{G}$ is a circuit. It may be easily seen that the arc set E (i.e., the set E consisting of all arcs of $\mathcal{G}$) allows a unique decomposition

$$E = E_1 \cup E_2 \cup \cdots \cup E_P \tag{4.1}$$

into mutually disjoint arc sets E_i, $i = 1, 2, \dots, P$, such that for each $1 \le i \le P$ the subgraph of $\mathcal{G}$ spanned by E_i is an elementary circuit. We claim that the direct sum that corresponds to an elementary circuit is a system of type IV. To see this, let the graph spanned by $\{(q_i, t_i) \mid i = 1, 2, \dots, M'\}$ be an elementary circuit. The direct sum

$\oplus_{i=1}^{M'}\Sigma(q_i,t_i)$ of the systems $\Sigma(q_i,t_i)$ is the N-periodic system $x_{n+1}=C_nx_n$, $n\in\mathbb{Z}$, with

$$C_n=\begin{cases} J_{0,r} & \text{if } n=q_1,\\ \tilde{I}_r & \text{if } n=q_j,\ j\neq 1,\\ I_r & \text{if } n\neq q_j,\ j=1,2,\dots,M', \end{cases} \qquad 1\le n\le N,$$

for some r, where $\tilde{I}_r$ denotes a matrix that is obtained by replacing a 1 by a 0 in the $r\times r$ identity matrix. So the direct sum $\oplus_{i=1}^{M'}\Sigma(q_i,t_i)$ is a system of type IV. We conclude from the decomposition (4.1) that the direct sum of all systems $\Sigma(q_i,t_i)$, $i=1,2,\dots,M$, is a unique direct sum of P systems of type IV.

To see that any system of type IV is kinematically irreducible in the class of square N-periodic systems, notice that any system of type IV is (kinematically similar) to a direct sum of systems of types II and III and that the circuit in $\mathcal{G}$ that corresponds to this direct sum is elementary. Thus any system of type IV is kinematically irreducible in the class of square N-periodic systems. ∎

5. Similarity of difference equation with different periods. In this section we will study periodic difference equations that are kinematically (or periodically) similar to periodic systems with a different period. The main result is as follows.

THEOREM 5.1. *Let $x_{n+1}=A_nx_n$, $n\in\mathbb{Z}$, be an N-periodic difference equation with $A_n:\mathbb{C}^{r_n}\to\mathbb{C}^{r_{n+1}}$ for $n\in\mathbb{Z}$. Let M be a positive integer. The following statements are equivalent:*

(i) *The difference equation $x_{n+1}=A_nx_n$, $n\in\mathbb{Z}$, is kinematically similar to an M-periodic difference equation.*

(ii) *The difference equation $x_{n+1}=A_nx_n$, $n\in\mathbb{Z}$, is N-periodically similar to an M-periodic difference equation.*

(iii) *The numbers r_n are M-periodic in n, and for each $1\le j\le M(\max_{1\le n\le M} r_n)$ the ranks*

$$\operatorname{rank}\left(A_{n+j-1}A_{n+j-2}\cdots A_n\right),\ n\in\mathbb{Z}, \tag{5.1}$$

are M-periodic in n.

(iv) *The numbers r_n are M-periodic in n, and for each $1\le j\le N(\max_{1\le n\le N} r_n)$ the ranks (5.1) are M-periodic in n.*

Proof. (ii) ⇒ (i). The proof is evident.

(i) ⇒ (iii). Assume that $x_{n+1}=A_nx_n$, $n\in\mathbb{Z}$, is kinematically similar to the M-periodic difference equation $\tilde{x}_{n+1}=B_n\tilde{x}_n$, $n\in\mathbb{Z}$. It is evident that the numbers r_n are M-periodic in n. Let $(E_n)_{n=-\infty}^{\infty}$ be a sequence of invertible matrices which satisfy $E_{n+1}^{-1}A_nE_n=B_n$, $n\in\mathbb{Z}$. Iterating these equations, we obtain the identities

$$E_{n+j}^{-1}A_{n+j-1}\cdots A_nE_n=B_{n+j-1}\cdots B_n,\ n=1,2,\dots,\ j=1,2,\dots. \tag{5.2}$$

The product in the right-hand side of (5.2) is M-periodic in n. Thus, taking ranks in (5.2), we obtain that the ranks in (5.1) are M-periodic in n.

(iv) ⇒ (ii). Assume that the numbers r_n and the ranks (5.1) are M-periodic in n. By Theorem 0.5 the system (0.1) is N-periodically similar to a direct sum Σ of systems of types I, II, and III. Let P be the greatest common divisor of M and N. The ranks (5.1) are also P-periodic in n, and hence

$$\eta_{j+\ell P,k+\ell P}((A_n))=\eta_{j,k}((A_n)),\ \ell\in\mathbb{Z},$$

for all j and k. Hence, according to Theorem 1.4, the number of systems $\Sigma_{\mathrm{II}}(m,p,r)$ in the direct sum Σ is equal to the number of systems $\Sigma_{\mathrm{II}}(m+\ell P, p+\ell P, r)$ in the direct sum Σ for all ℓ. Thus the coefficients 1 to N of the system $\Sigma_{\mathrm{II}}(m,p,r)$ in Σ are P-periodic. We conclude that the system $\Sigma_{\mathrm{II}}(m,p,r)$ in the direct sum Σ is P-periodic for all triples (m,p,r). In a similar way the system $\Sigma_{\mathrm{III}}(m,r)$ in the direct sum Σ is P-periodic for all pairs (m,r). Since systems of type I are time-invariant, we conclude that, in particular, Σ is M-periodic.

(iii) $\Rightarrow$ (iv). Put $t_{n,k} = \sum_{j=1}^{k} s_{n-j+1,j}$ for $n \in \mathbb{Z}$ and $k = 1, 2, \ldots$, where $s_{n,j}$ is defined by (0.5). Notice that, by definition, $t_{n,k} = r_{n+1} - \operatorname{rank}(A_n A_{n-1} \cdots A_{n-j+1}) \leq r_{n+1}$ for each n and k.

Assume that (iii) holds. It suffices to show that $s_{n,j} = 0$ for all n and for all $j > M \max_{1\leq n\leq M} r_n$. Indeed, in this case the ranks (5.1) are independent of j for $j \geq M \max_{1\leq n\leq M} r_n$, and hence (iv) follows immediately. To see that $s_{n,j} = 0$ for all n and for all $j > M \max_{1\leq n\leq M} r_n$, assume that $s_{m,i} \neq 0$ for some $m \in \mathbb{Z}$ and $i > M \max_{1\leq n\leq M} r_n$. Let ℓ be the entier of $\frac{i-1}{M}$. Notice that $\ell \geq \max_{1\leq n\leq M} r_n$. The array $(s_{n,j})_{n=1,j=1}^{N\ \infty}$ is admissible (Lemma 3.2), and hence (3.3) and (3.5) are satisfied. Notice that

$$t_{m+i-1,i} \geq \sum_{k=0}^{\ell} s_{m+kM,i-kM}, \tag{5.3}$$

because of (3.3). By M-periodicity of the numbers r_n and of the ranks (5.1), the right-hand side of (5.3) is equal to $\sum_{k=0}^{\ell} s_{m,i-kM}$. According to (3.5) the latter sum is larger than or equal to $(\ell+1)s_{m,i}$. We conclude that

$$t_{m+i-1,i} \geq (\ell+1)s_{m,i} \geq \ell + 1 \geq 1 + \max_{1\leq n\leq M} r_n \geq 1 + r_{m+i-1}.$$

However, in the first lines of the proof of (iii) $\Rightarrow$ (iv) we have shown that $t_{m+i-1,i} \leq r_{m+i-1}$. We conclude that $s_{n,j} = 0$ for all n and all $j > M \max_{1\leq n\leq M} r_n$. □

For $M = 1$ the equivalence of (ii) and (iii) in Theorem 5.1 appeared recently in Van Dooren–Sreedhar [10].

6. Special similarities for a class of finite block matrices. The following proposition shows that the problem of N-periodic similarity may be restated as a problem for finite-dimensional matrices.

PROPOSITION 6.1. *Two N-periodic difference equations $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, and $y_{n+1} = B_n y_n$, $n \in \mathbb{Z}$, are N-periodically similar if and only if the $N \times N$ block matrices*

$$A = \begin{pmatrix} 0 & \ldots & \ldots & \ldots & 0 & A_N \\ A_1 & 0 & \ldots & \ldots & \ldots & 0 \\ 0 & A_2 & \ddots & & & \vdots \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 & A_{N-1} & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & \ldots & \ldots & \ldots & 0 & B_N \\ B_1 & 0 & \ldots & \ldots & \ldots & 0 \\ 0 & B_2 & \ddots & & & \vdots \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 & B_{N-1} & 0 \end{pmatrix} \tag{6.1}$$

are block-diagonally similar.

Proof. Let $(E_n)_{n=-\infty}^{\infty}$ be an N-periodic similarity that transforms the difference equation $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, into $\tilde{x}_{n+1} = B_n \tilde{x}_n$, $n \in \mathbb{Z}$. So, we have the

identities $E_{n+1}^{-1}A_nE_n = B_n$, $n = 1, 2, \ldots, N-1$, and $E_1^{-1}A_NE_N = B_N$. Hence $E := \operatorname{diag}(E_n)_{n=1}^N$ satisfies $E^{-1}AE = B$.

Conversely, assume that the block matrices A and B are block-diagonally similar. Let $E = \operatorname{diag}(E_n)_{n=1}^N$ satisfy $E^{-1}AE = B$. Extend the sequence $(E_n)_{n=1}^N$ to an N-periodic sequence $(E_n)_{n=-\infty}^{\infty}$. From $E^{-1}AE = B$ we obtain the identities $E_{n+1}^{-1}A_nE_n = B_n$, $n = 1, 2, \ldots, N$. We conclude that $(E_n)_{n=-\infty}^{\infty}$ is an N-periodic similarity that transforms $x_{n+1} = A_nx_n$, $n \in \mathbb{Z}$, into $\tilde{x}_{n+1} = B_n\tilde{x}_n$, $n \in \mathbb{Z}$. ∎

Notice that block-diagonal similarity of A and B in (6.1) is not the same as similarity of A and B. To see this, let

$$A = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

where $N = 3$, $r_1 = r_2 = r_3 = 1$. For this example, clearly A and B are similar, but they are not diagonally similar. Necessary and sufficient conditions both for similarity and for block-diagonal similarity of the block matrices in (6.1) will be given in Theorem 6.2 below.

In what follows, we use the following notation and definition. Given a Jordan matrix J of order r, we denote by J^{inv} an invertible Jordan matrix of which the Jordan blocks are the nonsingular Jordan blocks of J. The nonsingular Jordan matrix J^{inv} is referred to as the *nonsingular* (or *invertible*) *part* of J.

From now on we fix a positive integer N and nonnegative integers r_n, $1 \le n \le N$. Put $s = N \max_{1\le n\le N} r_n$. Other choices for s are possible (cf. the discussion that follows the proof of Lemma 1.1).

THEOREM 6.2. *Let A and B be the $N \times N$ block matrices*

$$A = \begin{pmatrix} 0 & \ldots & \ldots & \ldots & 0 & A_N \\ A_1 & 0 & \ldots & \ldots & \ldots & 0 \\ 0 & A_2 & \ddots & & & \vdots \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 & A_{N-1} & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & \ldots & \ldots & \ldots & 0 & B_N \\ B_1 & 0 & \ldots & \ldots & \ldots & 0 \\ 0 & B_2 & \ddots & & & \vdots \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 & B_{N-1} & 0 \end{pmatrix}, \tag{6.2}$$

where, for $1 \le i \le N$, the zero in the ith block-diagonal entry is a square matrix of order r_i. The matrices A and B are block-diagonally similar if and only if $A_NA_{N-1}\cdots A_1$ and $B_NB_{N-1}\cdots B_1$ are similar, and for each $1 \le n \le N$

$$\operatorname{rank}(A_{j+n-1}A_{j+n-2}\cdots A_n) = \operatorname{rank}(B_{j+n-1}B_{j+n-2}\cdots B_n), \ j = 1, 2, \ldots, s, \tag{6.3}$$

where $A_{n+N} = A_n$, $n = 1, 2, \ldots$, and $B_{n+N} = B_n$, $n = 1, 2, \ldots$. Furthermore, let $J^{\mathrm{inv}}_{A_NA_{N-1}\cdots A_1}$ (resp., $J^{\mathrm{inv}}_{B_NB_{N-1}\cdots B_1}$) be the nonsingular part of a Jordan matrix of $A_NA_{N-1}\cdots A_1$ (resp., $B_NB_{N-1}\cdots B_1$). The matrices A and B are similar if and only if $J^{\mathrm{inv}}_{A_NA_{N-1}\cdots A_1}$ is similar to $J^{\mathrm{inv}}_{B_NB_{N-1}\cdots B_1}$, and for each $1 \le j \le s$

$$\sum_{n=1}^{N} \operatorname{rank}(A_{n+j-1}A_{n+j-2}\cdots A_n) = \sum_{n=1}^{N} \operatorname{rank}(B_{n+j-1}B_{n+j-2}\cdots B_n), \tag{6.4}$$

where $A_{n+N} = A_n$, $n = 1, 2, \ldots$, and $B_{n+N} = B_n$, $n = 1, 2, \ldots$.

From Proposition 6.1 and Theorem 1.4 we may obtain a canonical form for block matrices of the form (6.2) under block-diagonal similarity.

Proof of Theorem 6.2. By Proposition 6.1 the block matrices A and B in (6.2) are block-diagonally similar if and only if the N-periodic difference equations $x_{n+1} = A_n x_n$, $n \in \mathbb{Z}$, and $\tilde{x}_{n+1} = B_n \tilde{x}_n$, $n \in \mathbb{Z}$, are N-periodically similar. So from Theorem 0.2 we conclude that A and B are block-diagonally similar if and only if $A_N \cdots A_1$ is similar to $B_N \cdots B_1$, and for each $1 \le n \le N$ the rank conditions (6.3) are satisfied.

Let us consider the block matrix A in the left-hand side of (6.2). By Proposition 6.1 and Theorems 1.2 and 0.2 it is (block-diagonally) similar to a block matrix C_A of the form

$$C_A = \begin{pmatrix} 0 & \dots & \dots & \dots & 0 & C_N \\ C_1 & 0 & \dots & \dots & \dots & 0 \\ 0 & C_2 & \ddots & & & \vdots \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & \dots & 0 & C_{N-1} & 0 \end{pmatrix},$$

where $C_n = \begin{pmatrix} C_n^{(1)} & 0 \\ 0 & C_n^{(2)} \end{pmatrix}$ with

$$C_n^{(1)} = \begin{cases} I & 1 \le n \le N-1, \\ J^{\mathrm{inv}}_{A_N \cdots A_1}, & n = N, \end{cases}$$

and with the product $C_N^{(2)} \cdots C_1^{(2)}$ being nilpotent. Put

$$C_{A,1} = \begin{pmatrix} 0 & \dots & \dots & 0 & J^{\mathrm{inv}}_{A_N \cdots A_1} \\ I & \ddots & & \ddots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & I & 0 \end{pmatrix}, \quad C_{A,2} = \begin{pmatrix} 0 & \dots & \dots & 0 & C^{(2)}_{A,N} \\ C^{(2)}_{A,1} & \ddots & & \ddots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & C^{(2)}_{A,N-1} & 0 \end{pmatrix}.$$

Let us redecompose C_A as a $2N \times 2N$ block matrix using the 2×2 decompositions of the C_n's. With respect to this decomposition of C_A, the block matrix $C_{A,1}$ is the submatrix in the odd block rows and columns, and $C_{A,2}$ is the submatrix in the even block rows and columns. Hence C_A is similar to $\tilde{C}_A = \begin{pmatrix} C_{A,1} & 0 \\ 0 & C_{A,2} \end{pmatrix}$. Notice that $C_{A,2}$ is nilpotent.

Following the preceding paragraph, the block matrix B in the right-hand side of (6.2) is similar to $\tilde{C}_B = \begin{pmatrix} C_{B,1} & 0 \\ 0 & C_{B,2} \end{pmatrix}$ with $C_{B,1}$ an invertible $N \times N$ block matrix and $C_{B,2}$ a nilpotent matrix of the forms

$$C_{B,1} = \begin{pmatrix} 0 & \dots & \dots & 0 & J^{\mathrm{inv}}_{B_N \cdots B_1} \\ I & \ddots & & \ddots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & I & 0 \end{pmatrix}, \quad C_{B,2} = \begin{pmatrix} 0 & \dots & \dots & 0 & C^{(2)}_{B,N} \\ C^{(2)}_{B,1} & \ddots & & \ddots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & C^{(2)}_{B,N-1} & 0 \end{pmatrix}.$$

Now the matrices A and B are similar if and only if the 2×2 block matrices $\tilde{C}_A$ and $\tilde{C}_B$ are similar. Both $C_{A,1}$ and $C_{B,1}$ are invertible, and both $C_{A,2}$ and $C_{B,2}$ are nilpotent. Hence A and B are similar if and only if $C_{A,1}$ is similar to $C_{B,1}$ and $C_{A,2}$ is similar to $C_{B,2}$. It suffices to show that

(i) the matrices $C_{A,1}$ and $C_{B,1}$ are similar if and only if the Jordan matrices $J^{\mathrm{inv}}_{A_N \cdots A_1}$ and $J^{\mathrm{inv}}_{B_N \cdots B_1}$ are similar, and

(ii) if $C_{A,1}$ and $C_{B,1}$ are of the same order, then the matrices $C_{A,2}$ and $C_{B,2}$ are similar if and only if the rank conditions (6.4) are satisfied.

To see (i), assume that $C_{A,1}$ is similar to $C_{B,1}$. It is evident that $C^N_{A,1}$ and $C^N_{B,1}$ are similar. From the form of these two block-diagonal matrices we conclude that $J^{\mathrm{inv}}_{A_N \cdots A_1}$ is similar to $J^{\mathrm{inv}}_{B_N \cdots B_1}$. Conversely, if the latter two Jordan matrices are similar, the block matrices $C_{A,1}$ and $C_{B,1}$ are (block-diagonally) similar.

To see (ii), assume that $C_{A,1}$ and $C_{B,1}$ are of the same order. Hence $C_{A,2}$ and $C_{B,2}$ are of the same order. Both of them are nilpotent. Thus they are similar if and only if $\operatorname{rank} C^j_{A,2} = \operatorname{rank} C^j_{B,2}$ for $j = 1, 2, \ldots, s$. These identities may be rewritten as

$$\sum_{n=1}^{N} \operatorname{rank} (C^{(2)}_{A,n+j-1} \cdots C^{(2)}_{A,n}) = \sum_{n=1}^{N} \operatorname{rank} (C^{(2)}_{B,n+j-1} \cdots C^{(2)}_{B,n}), \ j = 1, 2, \ldots, s. \tag{6.5}$$

Since both $C_{A,1}$ and $C_{B,1}$ are invertible the rank conditions (6.5) hold if and only if the rank conditions (6.4) hold. □

With $A_N = B_N = 0$, the matrices A and B in (6.2) are finite block-weighted shift matrices as in section 5 of [4]. Hence all results for kinematic similarity of finitely supported difference equations in section 5 of [4] may be derived from the present results for N-periodic similarity of N-periodic difference equations.

7. An example. We conclude the paper with an example to illustrate how canonical forms of N-periodic systems are computed (cf. the results in Theorems 0.4, 0.5, 1.2–1.4, and 2.1–2.3) and how the corresponding N-periodic and kinematic similarities can be constructed.

Let (0.1) be the 2-periodic system given by

$$A_1 = \begin{pmatrix} 0 & 1 & -1 & 0 \\ 0 & -2 & 2 & 0 \\ 0 & 3 & -2 & 1 \\ 0 & -2 & 1 & 0 \end{pmatrix}, \ A_2 = \begin{pmatrix} -4 & -2 & -2 & -3 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 \end{pmatrix}. \tag{7.1}$$

Both r_1 and r_2 are 4, and $s = 8$. By direct computation we obtain that

$$A_2A_1 = \begin{pmatrix} 0 & 0 & 1 & -2 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \ A_1A_2A_1 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix},$$

$$A_1A_2 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & -1 & -1 & -1 \end{pmatrix}.$$

TABLE 7.1

3	-	-	-1	-1	-1	0	0	0	0

First, we show how the canonical form under N-periodic similarity in Theorem 0.5 can be computed. The system (0.1) is 2-periodically similar to a unique direct sum of 2-periodic systems of types I, II, and III. This direct sum will be denoted by

$$x_{n+1} = C_n x_n, \quad n \in \mathbb{Z}. \tag{7.2}$$

To compute the systems of type I in the direct sum (7.2), notice that -1 is the only nonzero eigenvalue of the monodromy operator A_2A_1 and that both the algebraic and geometric multiplicity of -1 are 1. It follows from Theorems 1.2 and 1.3 that

$$x_{n+1} = ix_n, \quad n \in \mathbb{Z}, \tag{7.3}$$

is the only system of type I in the direct sum (7.2). Next we compute the systems of types II and III in the direct sum (7.2). Tables 7.1 and 7.2 can be computed easily, where the second table has been derived from the first one.

By Table 7.2 the triples (m, p, r) of positive integers which satisfy $1 \le m \le 2$, $m < p < m + 2$, and $\eta_{p-1+2r,m}((A_n)) > 0$ are $(m, p, r) = (2, 3, 1)$ and $(m, p, r) = (1, 2, 0)$. Thus, according to Theorem 1.4, the direct sum (7.2) contains the following two 2-periodic systems of types II:

$$x_{n+1} = C_n^{(\mathrm{II}),1} x_n, \quad n \in \mathbb{Z}, \qquad x_{n+1} = C_n^{(\mathrm{II}),2} x_n, \quad n \in \mathbb{Z},$$

where the coefficients are given by

$$C_n^{(\mathrm{II}),1} = \begin{cases} \begin{pmatrix} 0 & 1 \end{pmatrix} : \mathbb{C}^2 \to \mathbb{C}, & n = 1, \\ \begin{pmatrix} 1 \\ 0 \end{pmatrix} : \mathbb{C} \to \mathbb{C}^2, & n = 2, \end{cases} \qquad C_n^{(\mathrm{II}),2} = \begin{cases} 0 : \{0\} \to \mathbb{C}, & n = 1, \\ 0 : \mathbb{C} \to \{0\}, & n = 2. \end{cases}$$

By Table 7.2 the only pair (m, r) of positive integers which satisfies $1 \le m \le 2$ and $\eta_{m-1+2r,m} > 0$ is $(m, r) = (2, 1)$. Thus, according to Theorem 1.4, the direct sum (7.2) contains the following 2-periodic system of type III:

$$x_{n+1} = C_n^{(\mathrm{III})} x_n, \quad n \in \mathbb{Z},$$

where the coefficients $C_n^{(\mathrm{III})}$ are given by

$$C_n^{(\mathrm{III})} = \begin{cases} 1, & n = 1, \\ 0, & n = 2. \end{cases} \tag{7.4}$$

We conclude that the canonical system (7.2) is given by

$$C_1 = \left(\begin{array}{c|cc||c} i & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 1 \end{array}\right), \quad C_2 = \left(\begin{array}{c|c|c|c} i & 0 & 0 & 0 \\ \hline 0 & 1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ \hline\hline 0 & 0 & 0 & 0 \end{array}\right). \tag{7.5}$$

Next we show how to compute the 2-periodic similarity that brings (0.1) with coefficients being given by (7.1) into the canonical form (7.2) with coefficients given by (7.5). In the computation two 2-periodic similarities are constructed. The first 2-periodic similarity $(E_n)_{n=-\infty}^{\infty}$ is obtained by applying the constructions in the proof of Theorem 1.3 and in Part 2 of the proof of Theorem 0.2 to the system (0.1) with coefficients being given by (7.1). Following the proof of Theorem 1.3, the first column $e_{1,1}$ of E_1 is defined to be an eigenvector of A_2A_1 with eigenvalue -1. So we take

$$e_{1,1} = (\,3 \quad -1 \quad -1 \quad 1\,)^T.$$

Furthermore, we define the first column $e_{2,1}$ of E_2 to be the vector

$$e_{2,1} = A_1e_{1,1} = (\,0 \quad 0 \quad 0 \quad 1\,)^T.$$

Let the kernels $\mathcal{M}_{n,j}$ be defined as in (1.3). So

$$\mathcal{M}_{1,3} = \cdots = \mathcal{M}_{1,8} = \operatorname{span}\{(\,1 \quad 0 \quad 0 \quad 0\,)^T, (\,0 \quad 1 \quad 0 \quad 0\,)^T, (\,0 \quad 0 \quad 1 \quad 0\,)^T\}, \tag{7.6}$$

$$\mathcal{M}_{2,2} = \cdots = \mathcal{M}_{2,8} = \operatorname{span}\{(\,1 \quad -1 \quad 0 \quad 0\,)^T, (\,0 \quad 1 \quad -1 \quad 0\,)^T, (\,0 \quad 0 \quad 1 \quad -1\,)^T\}.$$

Now we follow the construction of the complements $\mathcal{N}_{n,j}$ in Part 2 of the proof of Theorem 0.2. We define

$$\mathcal{N}_{1,8} = \mathcal{K}_{1,8} = \mathcal{N}_{2,7} = \mathcal{K}_{2,7} = \mathcal{N}_{1,6} = \mathcal{K}_{1,6} = \mathcal{N}_{2,5}$$

$$= \mathcal{K}_{2,5} = \mathcal{N}_{1,4} = \mathcal{K}_{1,4} = \mathcal{N}_{2,3} = \mathcal{K}_{2,3} = \{0\}.$$

The kernels $\mathcal{M}_{1,1}$ and $\mathcal{M}_{1,2}$ are given by

$$\mathcal{M}_{1,1} = \operatorname{span}\{(\,1 \quad 0 \quad 0 \quad 0\,)^T\}, \quad \mathcal{M}_{1,2} = \operatorname{span}\{(\,1 \quad 0 \quad 0 \quad 0\,)^T, (\,0 \quad 1 \quad 0 \quad 0\,)^T\}, \tag{7.7}$$

and thus we set

$$\mathcal{N}_{1,2} = \mathcal{K}_{1,2} = \operatorname{span}\{(\,0 \quad 1 \quad 0 \quad 0\,)^T\}.$$

Notice that $A_1\mathcal{N}_{1,2} = \operatorname{span}\{(\,1 \quad -2 \quad 3 \quad -2\,)^T\}$ and

$$\mathcal{M}_{2,0} \oplus A_1\mathcal{N}_{1,2} \oplus \mathcal{K}_{2,1} = \mathcal{M}_{2,1}$$

with $\mathcal{K}_{2,1} = \operatorname{span}\{(\,0 \quad 1 \quad -1 \quad 0\,)^T\}$. Thus we put

$$\mathcal{N}_{2,1} = A_1\mathcal{N}_{1,3} \oplus \mathcal{K}_{2,1} = \operatorname{span}\{(\,1 \quad -2 \quad 3 \quad -2\,)^T, (\,0 \quad 1 \quad -1 \quad 0\,)^T\}.$$

Next we define

$$\mathcal{N}_{2,8} = \mathcal{K}_{2,8} = \mathcal{N}_{1,7} = \mathcal{K}_{1,7} = \mathcal{N}_{2,6} = \mathcal{K}_{2,6} = \mathcal{N}_{1,5} = \mathcal{K}_{1,5} = \mathcal{N}_{2,4} = \mathcal{K}_{2,4} = \{0\}.$$

Equations (7.6) for $\mathcal{M}_{1,2}$ and (7.7) for $\mathcal{M}_{1,3}$ suggest that we define $\mathcal{N}_{1,3}$ and $\mathcal{K}_{1,3}$ by

$$\mathcal{N}_{1,3} = \mathcal{K}_{1,3} = \operatorname{span}\{(\,0 \quad 0 \quad 1 \quad 0\,)^T\}.$$

We compute that $A_1\mathcal{N}_{1,3} = \operatorname{span}\{(\,-1 \quad 2 \quad -2 \quad 1\,)^T\}$ and that

$$\mathcal{M}_{2,1} = \operatorname{span}\{(\,1 \quad 1 \quad 0 \quad -2\,)^T, (\,0 \quad 1 \quad -1 \quad 0\,)^T\}.$$

Hence we obtain the identity

$$\mathcal{K}_{2,2} = \{0\}, \quad \mathcal{N}_{2,2} = \operatorname{span}\{(-1, 2, -2, 1)^T\}.$$

Finally, notice that $A_2\mathcal{N}_{2,2} = \operatorname{span}\{(1, 0, 0, 0)^T\} = \operatorname{span}\mathcal{M}_{1,1}$. So we get that

$$\mathcal{N}_{1,1} = \operatorname{span}\{(1, 0, 0, 0)^T\}.$$

Now we collect the above basis vectors of the complements $\mathcal{N}_{1,j}$, $j = 1, 2, \ldots, 8$, in the second, third, and fourth columns of E_1 and we collect the above basis vectors of the complements $\mathcal{N}_{2,j}$, $j = 1, 2, \ldots 8$, in the second, third, and fourth columns of E_2, i.e.,

$$E_1 = \begin{pmatrix} 3 & 1 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ -1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \; E_2 = \begin{pmatrix} 0 & 1 & 0 & -1 \\ 0 & -2 & 1 & 2 \\ 0 & 3 & -1 & -2 \\ 1 & -2 & 0 & 1 \end{pmatrix}.$$

Put $B_1 = E_2^{-1}A_1E_1$ and $B_2 = E_1^{-1}A_2E_2$. According to the proofs of Theorems 1.3 and 0.2, we get the identities

$$B_1 = \left(\begin{array}{c|c|c|c} 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 1 \end{array}\right), \quad B_2 = \left(\begin{array}{c|c|c|c} -1 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \end{array}\right).$$

The second 2-periodic similarity $(F_n)_{n=-\infty}^{\infty}$ is obtained by applying the constructions in the proofs of Theorems 1.2 and 0.2 to the canonical 2-periodic system (7.2) with the coefficients being given by (7.5). Following these constructions we obtain, after making computations as in the previous paragraph, the matrices

$$F_1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad F_2 = \begin{pmatrix} i & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

and the identities $F_2^{-1}C_1F_1 = B_1$ and $F_1^{-1}C_2F_2 = B_2$. Let $(G_n)_{n=-\infty}^{\infty}$ be the 2-periodic sequence given by $G_n = E_nF_n^{-1}$, $n = 1, 2$, i.e.,

$$G_1 = \begin{pmatrix} 3 & 1 & 0 & 0 \\ -1 & 0 & 0 & 1 \\ -1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad G_2 = \begin{pmatrix} 0 & -1 & 1 & 0 \\ 0 & 2 & -2 & 1 \\ 0 & -2 & 3 & -1 \\ -i & -1 & -2 & 0 \end{pmatrix}.$$

By construction the 2-periodic sequence $(G_n)_{n=-\infty}^{\infty}$ transforms the system (0.1) with the coefficients being given by (7.1) into the system (7.2) with the coefficients being given by (7.5).

The canonical form of the system (0.1) with the coefficients being given by (7.1) under kinematic similarity in Theorem 0.4 is obtained in the following way: In the systems of type I appearing in the canonical form under N-periodic similarity, one replaces the diagonal entries by their absolute values. Thus the canonical form in Theorem 0.4 is the 2-periodic system $x_{n+1} = \tilde{C}_n x_n$, $n \in \mathbb{Z}$, where

$$\tilde{C}_1 = \left(\begin{array}{c|cc||c} 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 1 \end{array}\right), \quad \tilde{C}_2 = \left(\begin{array}{c|c|c|c} 1 & 0 & 0 & 0 \\ \hline 0 & 1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ \hline\hline 0 & 0 & 0 & 0 \end{array}\right).$$

The corresponding kinematic similarity $(\tilde{G}_n)_{n=-\infty}^{\infty}$ is obtained from $(G_n)_{n=-\infty}^{\infty}$ by multiplying G_n from the right by the diagonal matrix diag $(i^{n-1}, 1, 1, 1)$ (cf. the proof of Theorem 4.1 in [4]). Hence $(\tilde{G}_n)_{n=-\infty}^{\infty}$ is the 4-periodic sequence given by

$$\tilde{G}_1 = \begin{pmatrix} 3 & 1 & 0 & 0 \\ -1 & 0 & 0 & 1 \\ -1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{G}_2 = \begin{pmatrix} 0 & -1 & 1 & 0 \\ 0 & 2 & -2 & 1 \\ 0 & -2 & 3 & -1 \\ 1 & -1 & -2 & 0 \end{pmatrix},$$

$$\tilde{G}_3 = \begin{pmatrix} -3 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}, \quad \tilde{G}_4 = \begin{pmatrix} 0 & -1 & 1 & 0 \\ 0 & 2 & -2 & 1 \\ 0 & -2 & 3 & -1 \\ -1 & -1 & -2 & 0 \end{pmatrix}.$$

Since the system considered in this section is square, we may also apply the results of section 4. For instance, in the class of square periodic systems the canonical form for the present example is a direct sum of three square periodic systems, namely, of the time-invariant system (7.3), the 2-periodic system $x_{n+1} = C_n^{(\mathrm{III})} x_n$, $n \in \mathbb{Z}$, where $C_n^{(\mathrm{III})}$ is given by (7.4), and the 2-periodic system $x_{n+1} = C_n^{(\mathrm{II})} x_n$, $n \in \mathbb{Z}$, where

$$C_1^{(\mathrm{II})} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad C_2^{(\mathrm{II})} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

Let us also remark that from Theorem 5.1 it follows that our example is not kinematically similar to one that is time-invariant.

ANALYSIS OF ITERATIVE LINE SPLINE COLLOCATION METHODS FOR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS*

A. HADJIDIMOS†‡, E. N. HOUSTIS†, J. R. RICE†, AND E. VAVALIS†‡

Abstract. In this paper we present the convergence analysis of iterative schemes for solving linear systems resulting from discretizing multidimensional linear second-order elliptic partial differential equations (PDEs) defined in a hyperparallelepiped Ω and subject to Dirichlet boundary conditions on some faces of Ω and Neumann on the others, using line cubic spline collocation (LCSC) methods. Specifically, we derive analytic expressions or obtain sharp bounds for the spectral radius of the corresponding Jacobi iteration matrix and from this we determine the convergence ranges and compute the optimal parameters for the extrapolated Jacobi and successive overrelaxation (SOR) methods. Experimental results are also presented.

Key words. SOR iterative method, elliptic partial differential equations, collocation methods

1. Introduction.

We consider the following second-order linear elliptic PDE,

$$Lu \equiv \sum_{i=1}^{k} \alpha_i \frac{\partial^2 u}{\partial x_i^2} + \sum_{i=1}^{k} \beta_i \frac{\partial u}{\partial x_i} + \gamma u = f \quad \text{in} \quad \Omega, \tag{1.1a}$$

subject to Dirichlet and/or Neumann boundary conditions

$$Bu = g \text{ on } \partial\Omega \equiv \text{boundary of } \Omega, \tag{1.1b}$$

where Bu is u or $\frac{\partial u}{\partial x_i}$, $\Omega \equiv \prod_{i=1}^{k} \otimes [a_i, b_i]$ is a rectangular domain in R^k (the space of k real variables), and $\alpha_i (< 0)$, β_i, $\gamma (\geq 0)$, f, and g are functions of k variables.

If line cubic spline collocation (LCSC) methods are used to solve (1.1a), (1.1b), then the differential operator is discretized along lines in each direction independently and then the line discretization stencils are combined into one large linear system. Although not extensively analyzed yet, collocation methods combine certain desirable algorithmic and computational characteristics of both finite element and finite difference discretization schemes and compete well with them in accuracy, efficiency, and applicability. In particular the LCSC methods exploit the general idea of being alternating direction implicit (ADI), without being real ADI schemes, in a convenient and natural way. In contrast to ADI methods LCSC can be applied to any PDE operator that can be formulated in a tensor product form. Relative to other methods, their efficiency increases with the dimensionality of the PDE problem, and their implementation is relatively easy. Certain additional desirable properties (inherent

parallelism, methodology for choosing the proper directions of the lines, etc.) of LCSC already have been exploited [5]. In section 2 we briefly describe LCSC discretization procedures. We also present and discuss the resulting coefficient linear system of collocation equations which is nonsymmetric and lacks many of the properties found in Ritz–Galerkin-type finite element methods.

In [5], we were able to formulate and analyze iterative schemes for solving the LCSC linear systems in the case of general elliptic second-order PDE with Dirichlet boundary conditions and constant coefficients; that is,

$$Lu \equiv \sum_{i=1}^{k} \alpha_i D_{x_i}^2 u + \gamma u = f \qquad \text{in } \Omega, \tag{1.2a}$$

$$u = g \qquad \text{on } \partial\Omega, \tag{1.2b}$$

where $D_x^2 u$ denotes $\partial^2 u/\partial x^2$. Unfortunately the convergence analysis presented in [5], as it stands, cannot be applied in the case of the presence of Neumann boundary conditions on some of the faces of Ω. In section 3 we present a convergence analysis of block Jacobi, extrapolated Jacobi (EJ), and successive overrelaxation (SOR) schemes for the iterative solution of the collocation equations that arise from discretizing elliptic problems (1.2a) subject to Neumann (N) boundary conditions on one or more (but not on all if $\gamma = 0$) faces of Ω and Dirichlet (D) ones on the others. More specifically, analytic expressions or sharp bounds for the spectral radius of the corresponding block Jacobi iteration matrix are derived and from these we determine the convergence ranges and compute the optimal parameters for the extrapolated Jacobi and SOR methods. Furthermore, based on our analysis, certain conclusions of significant practical importance are drawn.

Finally, in section 4 we present the results of various numerical experiments designed for the verification of the theoretical behavior of the iterative LCSC solvers. The experiments show very good agreement with the theoretical predictions regarding the convergence of the iterative method used. Although the theoretical results presented here hold for the model problem (1.2a), (1.2b), our experimental results indicate that the behavior of the iterative LCSC solvers on the general problem (1.1a), (1.1b) is similar.

2. The LCSC method. In this section we briefly describe the LCSC discretization method and introduce some notation to be used later. We start by introducing one extra point beyond each end of the intervals $[a_i,b_i]$. Each of these enlarged intervals is then discretized uniformly with step size h_i by

$$\Delta_i \equiv \left\{ \tau_\ell^i = a_i + \ell h_i \ ; \ \ell = -1, \ldots, N_i + 1 \text{ with } h_i = \frac{b_i - a_i}{N_i} \right\}.$$

The tensor product of these discretized lines, $\Delta \equiv \prod_{i=1}^{k} \otimes \Delta_i$, provides an extended uniform partition of Ω. A collocation approximation u_Δ of u in the space $S_{3,\Delta}$ of cubic splines in k dimensions is defined by requiring that it satisfies (1.1a) at all the mesh points of Δ and (1.1b) on the boundary mesh points. In the sequel the interior mesh points are denoted by $(\tau_{n_1}^1, \tau_{n_2}^2, \ldots, \tau_{n_k}^k)$ for all $\mathbf{n} \in \prod_{i=1}^{k} \otimes I_i$, where $I_i \equiv \{n_i \ : \ 1 \le n_i \le N_i - 1\}$.

In the line cubic spline collocation methods we consider in this paper the collocation approximation is made on each set $\mathcal{L}^i$ of lines parallel to the x_i axis. More

specifically, this collocation approximation $u^i_\Delta \in S_{3,\Delta}$ on each line in $\mathcal{L}^i$ is represented as follows:

$$u^i_\Delta(\mathbf{x}) = \sum_{\ell=-1}^{N_i+1} U^i_\ell(\mathbf{x}^i) B^i_\ell(x_i), \tag{2.1}$$

where $B^i_\ell(x_i)$ are the B-spline bases defined on Δ_i, $\mathbf{x} = (x_1, x_2, \ldots, x_k)$ and $\mathbf{x}^i = (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_k)$. Observe that (2.1) is the sum of one-dimensional splines in the x_i variable whose coefficients $U^i(\mathbf{x}^i)$ are functions of the other $k-1$ variables. Furthermore, this approximation is *redundant* in that there are k choices for representing $u^i_\Delta(\mathbf{x})$, one for each coordinate direction.

2.1. The second-order LCSC method. From the assumed representation (2.1) of u^i_Δ and the nature of the B-spline basis functions we conclude easily (see also [9] and [5]) that

$$D^2_{x_i} u^i_\Delta|_{\mathbf{P}^i_\ell} = [U^i_{\ell-1}(\mathbf{n}_i) - 2U^i_\ell(\mathbf{n}_i) + U^i_{\ell+1}(\mathbf{n}_i)]/h_i^2, \tag{2.2}$$

$$D_{x_i} u^i_\Delta|_{\mathbf{P}^i_\ell} = [U^i_{\ell-1}(\mathbf{n}_i) - U^i_{\ell+1}(\mathbf{n}_i)]/2h_i, \tag{2.3}$$

and

$$u^i_\Delta|_{\mathbf{P}^i_\ell} = [U^i_{\ell-1}(\mathbf{n}_i) + 4U^i_\ell(\mathbf{n}_i) + U^i_{\ell+1}(\mathbf{n}_i)]/6 \tag{2.4}$$

at the mesh (collocation) points $\mathbf{P}^i_\ell$ for $\ell = 1, 2, \ldots, N_i - 1$ on each line of $\mathcal{L}^i$. These points are represented by the vectors

$$\mathbf{P}^i_\ell \equiv (\tau^1_{n_1}, \ldots, \tau^{i-1}_{n_{i-1}}, \tau^i_\ell, \tau^{i+1}_{n_{i+1}}, \ldots, \tau^k_{n_k}), \quad \ell = 0, \ldots, N_i,$$

where $\mathbf{n}_i \equiv (n_1, \ldots, n_{i-1}, n_{i+1}, \ldots, n_k)$ indexes the $\mathcal{L}^i$ lines.

First, we observe that the collocation equations obtained from the boundary conditions and the differential equation at the end points of each line can be explicitly determined as follows.

Dirichlet (D) boundary conditions on $\mathbf{P}^i_0$:

$$U^i_0 = \frac{h_i^2 f(\mathbf{P}^i_0)}{6\alpha_i}, \qquad U^i_{-1} = -U^i_1 + \frac{2h_i^2 f(\mathbf{P}^i_0)}{3\alpha_i}; \tag{2.5}$$

Neumann (N) boundary conditions on $\mathbf{P}^i_0$:

$$U^i_0 = U^i_1 + \frac{h_i^2 f(\mathbf{P}^i_0)}{2\alpha_i}, \qquad U^i_{-1} = U^i_1; \tag{2.6}$$

Dirichlet (D) boundary conditions on $\mathbf{P}^i_{N_i}$:

$$U^i_{N_i} = \frac{h_i^2 f(\mathbf{P}^i_{N_i})}{6\alpha_i}, \qquad U^i_{N_i+1} = -U^i_{N_i-1} + \frac{2h_i^2 f(\mathbf{P}^i_{N_i})}{3\alpha_i}; \tag{2.7}$$

Neumann (N) boundary conditions on $\mathbf{P}^i_{N_i}$:

$$U^i_{N_i} = U^i_{N_i-1} + \frac{h_i^2 f(\mathbf{P}^i_{N_i})}{2\alpha_i}, \quad U^i_{N_i+1} = U^i_{N_i-1}, \tag{2.8}$$

where for simplicity we have assumed that all boundary conditions are homogeneous. The rest of the unknowns are determined by solving the so-called *interior collocation equations*, that is, on those lines of $\mathcal{L}^i$ not in $\partial\Omega$,

$$\left(\sum_{i=1}^{k} \alpha_i \, D^2_{x_i} \, u^i_\Delta + \gamma u^1_\Delta\right)\Bigg|_{\mathbf{P}^i_\ell} = f\,|_{\mathbf{P}^i_\ell} \quad \text{for} \quad \ell = 1, 2, \ldots, N_i - 1. \tag{2.9}$$

Equations (2.9) *away* ($2 \le \ell \le N_i - 2$) from the boundary are given by

$$\begin{aligned} &\sum_{i=1}^{k} \frac{\alpha_i}{h_i^2}\left[U^i_{\ell-1}(\mathbf{n}_i) - 2U^i_\ell(\mathbf{n}_i) + U^i_{\ell+1}(\mathbf{n}_i)\right] \\ &+ \frac{\gamma}{6}[U^1_{\ell-1}(\mathbf{n}_1) + 4U^1_\ell(\mathbf{n}_1) + U^1_{\ell+1}(\mathbf{n}_1)] = f|_{\mathbf{P}^i_\ell}, \end{aligned} \tag{2.10}$$

while for lines next to the boundary they have similar form with appropriately modified right sides [5]. The full matrix form of these equations is given in section 3. After eliminating the predetermined (from equations (2.5)–(2.8)) boundary unknowns, each collocation approximation $u^i_\Delta(\mathbf{x})$ involves $\mathcal{K} = \Pi_i(N_i - 1)$ unknown coefficients U^i_ℓ. This redundancy is handled by requiring that all these approximations agree on the mesh points; that is,

$$u^1_\Delta = u^2_\Delta = \cdots = u^k_\Delta \quad \text{on the mesh} \quad \Delta. \tag{2.11}$$

It has been shown [5, 7, 9] that the above-described method leads to a second-order collocation approximation of u.

2.2. The fourth-order LCSC method. To derive the fourth-order LCSC method we use high-order approximations of the derivatives $D^j_{x_i} u$, $j = 1, 2$, defined as appropriate linear combinations of the spline interpolant and its derivatives at the mesh points [7]. Specifically, we approximate the second derivatives in the PDE operator by the difference scheme

$$\begin{aligned} &D^2_{x_i} u^i_\Delta \Big|_{\mathbf{P}^i_\ell} \\ &= \left(U^i_{\ell-2}(\mathbf{n}_i) + 8U^i_{\ell-1}(\mathbf{n}_i) - 18U^i_\ell(\mathbf{n}_i) + 8U^i_{\ell+1}(\mathbf{n}_i) + U^i_{\ell+1}(\mathbf{n}_i)\right)/(12h_i^2). \end{aligned} \tag{2.12}$$

The collocation equations corresponding to the mesh points on a line $\mathcal{L}^i$ *away* ($2 \le \ell \le N_i - 2$) from the boundary are written at the point $\mathbf{P}^i_\ell$ as

$$\begin{aligned} &\sum_{i=1}^{k} \frac{\alpha_i}{12h_i^2}\left[U^i_{\ell-2}(\mathbf{n}_i) + 8U^i_{\ell-1}(\mathbf{n}_i) - 18U^i_\ell(\mathbf{n}_i) + 8U^i_{\ell+1}(\mathbf{n}_i) + U^i_{\ell+2}(\mathbf{n}_i)\right] \\ &+ \frac{\gamma}{6}[U^1_{\ell-1}(\mathbf{n}_i) + 4U^1_\ell(\mathbf{n}_i) + U^1_{\ell+1}(\mathbf{n}_1)] = f|_{\mathbf{P}^i_\ell}. \end{aligned} \tag{2.13}$$

The redundancy on the coefficients is handled in the same way as in the second-order case, with the only basic difference being that the stencils now have five, rather than three, points along each coordinate direction.

3. Iterative solution of the interior LCSC equations. The LCSC equations can be written in the form

$$\sum_{i=1}^{k} A_i \mathbf{U}^i(\mathbf{n}) = \mathbf{F}^1, \tag{3.1}$$

where the coefficient matrices are defined by

$$A_i \equiv \left(\prod_{j=1}^{k-i} \otimes I\right) \otimes \mathcal{E}_i \otimes \left(\prod_{j=k-i+2}^{k} \otimes I\right), \ i = 1, \ldots, k, \tag{3.2}$$

where I denotes a unit matrix of appropriate order and

$$\mathcal{E}_1 = \frac{\alpha_1}{h_1^2}\mathcal{H}_1 + \frac{\gamma}{6}\mathbf{T}_4^1 \quad \text{and} \quad \mathcal{E}_i = \frac{\alpha_i}{h_i^2}\mathcal{H}_i \ , \ i = 2, \ldots, k. \tag{3.3}$$

The matrix $\mathcal{H}_i$ depends both on the discretization scheme applied and the nature (Dirichlet (D) or Neumann (N)) of the boundary conditions on the *left* and *right* end points of the line direction with which the matrix $\mathcal{H}_i, i = 1, \ldots, k$, is associated. Specifically, $\mathcal{H}_i = T^i_{\alpha,\beta}$ for the second-order discretization and $\mathcal{H}_i = \frac{1}{12}T^i_{10}T^i_{\alpha,\beta}$ for the fourth-order one. The matrices $T^i_{\alpha,\beta}$, T^i_4, and T^i_{10} are given by

$$T^i_{\alpha,\beta} := \begin{pmatrix} \alpha & 1 & & & & \\ 1 & -2 & 1 & & & \\ & 1 & -2 & 1 & & \\ & & & \ddots & & \\ & & & 1 & -2 & 1 \\ & & & & 1 & \beta \end{pmatrix}_{(N_i-1)\times(N_i-1)}, \tag{3.4}$$

$$T^i_4 = 6I + T^i_{\alpha,\beta} \text{ and } T^i_{10} = 12I + T^i_{-2,-2},$$

where

$$(\alpha, \beta) = \begin{cases} (-2,-2) & \text{in case of (D) conditions on both ends,} \\ (-1,-2) & \text{in case of (N) conditions on the } \textit{left} \text{ and} \\ & \text{(D) conditions on the } \textit{right} \text{ end,} \\ (-2,-1) & \text{in case of (D) conditions on the } \textit{left} \text{ and} \\ & \text{(N) conditions on the } \textit{right} \text{ end,} \\ (-1,-1) & \text{in case of (N) conditions on both ends.} \end{cases} \tag{3.5}$$

Note. Since in the analysis that will follow the existence of A_1^{-1} is a necessary requirement, we assume, without loss of generality, that on at least one of the faces of Ω perpendicular to the x_1-direction (D) boundary conditions have been imposed so that the invertibility of A_1 is guaranteed even if $\gamma = 0$.

Equation (3.1), coupled with the $k-1$ interpolation conditions (2.11) leads us to the order-kK system of linear equations which, if we order according to the ordering of unknowns $\mathbf{U}^1(\mathbf{n})$, is given by

$$\begin{pmatrix} A_1 & A_2 & A_3 & \ldots & A_k \\ -B_2 & D_2 & & & \\ -B_3 & & D_3 & & \\ \vdots & & & \ddots & \\ -B_k & & & & D_k \end{pmatrix} \begin{pmatrix} \mathbf{U}^1 \\ \mathbf{U}^2 \\ \mathbf{U}^3 \\ \vdots \\ \mathbf{U}^k \end{pmatrix} = \begin{pmatrix} \mathbf{F}^1 \\ \mathbf{F}^2 \\ \mathbf{F}^3 \\ \vdots \\ \mathbf{F}^k \end{pmatrix}, \tag{3.6}$$

where for $i = 2, \ldots, k$ we have that

$$B_i = \left(\prod_{j=1}^{k-1} \otimes I\right) \otimes T_4^1 \ , \ D_i = \left(\prod_{j=1}^{k-i} \otimes I\right) \otimes T_4^i \otimes \left(\prod_{j=k-i+2}^{k} \otimes I\right). \tag{3.7}$$

The matrices in (3.3) and (3.7) may be linear or quadratic functions of the matrix $T^i_{-2,-2}$ if *all* the boundary conditions are Dirichlet (D). With some Neumann (N) conditions present, this is no longer the case. Besides, in the case of the fourth-order discretization scheme, the product $T^i_{10}T^i_{\alpha,\beta}$ is not a symmetric matrix in the case where $(\alpha,\beta) \neq (-2,-2)$. So, the analysis presented in section 3 of [5] does not always apply to the present case. We present a unified analysis for all cases based on the following three lemmas. The first one is a well-known result. For the proofs of the second and the third the reader is referred to [11] and [6, Theorem 4.2.12].

LEMMA 3.1. *If A and B are Hermitian positive definite matrices of the same order, then* (i) *AB (and BA) possesses a complete set of linearly independent eigenvectors.* (ii) *Further, let $X \in \mathcal{C}^{n,n}$ and $\sigma(X) \subset \mathcal{R}$, where $\sigma(.)$ denotes the spectrum of a matrix. Let also λ_X, $\lambda_{X,m}$, and $\lambda_{X,M}$ denote any, the smallest, and the largest eigenvalue of X, respectively. Then for the eigenvalues of the matrix AB there holds*

$$0 < \lambda_{A,m}\lambda_{B,m} \leq \lambda_{AB,m} \leq \lambda_{AB,M} \leq \lambda_{A,M}\lambda_{B,M}. \tag{3.8}$$

Note. The assertions of Lemma 3.1 hold even if one of A or B is nonnegative definite. The only difference is that the two leftmost inequalities in (3.8) become equalities; that is, $0 = \lambda_{A,m}\lambda_{B,m} = \lambda_{AB,m}$, since $\det(AB) = \det(A)\det(B) = 0$.

LEMMA 3.2. *Consider the real symmetric tridiagonal matrix $T_{\alpha,\beta}$ of order m given by*

$$T_{\alpha,\beta} := \begin{pmatrix} \alpha & 1 & & & & & \\ 1 & -2 & 1 & & & & \\ & 1 & -2 & 1 & & & \\ & & & \ddots & & & \\ & & & 1 & -2 & 1 \\ & & & & 1 & \beta \end{pmatrix}, \tag{3.9}$$

where $(\alpha,\beta) = (-2,-2), (-2,-1), (-1,-2)$, or $(-1,-1)$. Its eigenvalues $\lambda_{T_{\alpha,\beta}}$ are given for $\ell = 0,\ldots,m-1$ by the expressions

$$\begin{aligned} &\text{(i) } \textit{If } (\alpha,\beta) = (-2,-2), \textit{ then } \lambda_{T_{\alpha,\beta}} = -4\sin^2\left(\frac{(\ell+1)\pi}{2(m+1)}\right), \\ &\text{(ii) } \textit{If } (\alpha,\beta) = (-2,-1) \textit{ or } (-1,-2), \textit{ then } \lambda_{T_{\alpha,\beta}} = -4\sin^2\left(\frac{(2\ell+1)\pi}{2(2m+1)}\right), \\ &\text{(iii) } \textit{If } (\alpha,\beta) = (-1,-1), \textit{ then } \lambda_{T_{\alpha,\beta}} = -4\sin^2\left(\frac{\ell\pi}{2m}\right). \end{aligned} \tag{3.10}$$

LEMMA 3.3. *Let the $n \times n$ matrices A_i, $i = 1,\ldots,k$, possess complete sets of linearly independent eigenvectors $\mathbf{y}^{(i,j)}$, with corresponding eigenvalues $\lambda^{(j)}_{A_i}$ ($j = 1,\ldots,k$, $i = 1,\ldots,k$). Then the matrix $A \equiv A_1 \otimes A_2 \otimes \cdots \otimes A_k$ possesses the n^k linearly independent eigenvectors $\mathbf{y}^{(\underline{j})} \equiv \mathbf{y}^{(1,j_1)} \otimes \mathbf{y}^{(2,j_2)} \otimes \cdots \otimes \mathbf{y}^{(k,j_k)}$, where $\underline{j} \equiv (j_1,\ldots,j_k)$ and $j_i = 1,\ldots,n$, $i = 1,\ldots,k$, with corresponding eigenvalues $\lambda^{(\underline{j})} = \lambda^{(j_1)}_{A_i}\lambda^{(j_2)}_{A_2}\ldots\lambda^{(j_k)}_{A_k}$.*

Having developed the background material required we are able to go on with the analysis of the three methods associated with the linear system (3.6): block Jacobi (J),

$$K\mathbf{U}^{(s+1)} = (L+M)\mathbf{U}^{(s)} + \mathbf{F}\ ,\ s = 0,1,2,\ldots;$$

block EJ,

$$K\mathbf{U}^{(s+1)} = (1-\omega)K\mathbf{U}^{(s)} + \omega(L+M)\mathbf{U}^{(s)} + \omega\mathbf{F}\ ,\ s = 0, 1, 2, \ldots;$$

and block SOR,

$$K\mathbf{U}^{(s+1)} = (1-\omega)K\mathbf{U}^{(s)} + \omega L\mathbf{U}^{(s+1)} + \omega M\mathbf{U}^{(s)} + \omega\mathbf{F}\ ,\ s = 0, 1, 2, \ldots,$$

where

$$K \equiv \mathrm{diag}(A_1, D_2, D_3, \ldots, D_k),$$

and $-L$ and $-M$ are the strictly lower and the strictly upper triangular parts of the matrix coefficient in (3.6).

The block Jacobi iteration matrix $J \equiv K^{-1}(L+M) = \{J_{i,j}\}$, associated with the matrix coefficient in (3.6), can be described as

$$\begin{aligned} J_{1,1} = 0,\ \{\{J_{i,j}\}_{j=2}^{k}\}_{i=2}^{k} = 0,\ \{J_{i,j} := H_j = -A_1^{-1}A_j\}_{j=2}^{k}, \\ \{J_{i,1} := G_i = D_i^{-1}B_i\}_{i=2}^{k}. \end{aligned} \tag{3.11}$$

Let H and G denote the matrices

$$H := [H_2, H_3, \ldots, H_k]\,,\ G := \left[G_2^T, G_3^T, \ldots, G_k^T\right]^T \tag{3.12}$$

of dimensions $\mathcal{K} \times (k-1)\mathcal{K}$ and $(k-1)\mathcal{K} \times \mathcal{K}$, respectively. Consider then the matrix J^2 which, apparently, is a block diagonal matrix with diagonal blocks HG and GH of orders $\mathcal{K}$ and $(k-1)\mathcal{K}$, respectively. Therefore, we have (see [12, Theorem 1.12, p. 16]) that

$$\sigma(J^2) \setminus \{0\} = \sigma(HG) \setminus \{0\} = \sigma(GH) \setminus \{0\}. \tag{3.13}$$

However, we have

$$HG = \sum_{j=2}^{k} H_j G_j \tag{3.14}$$

and each term in the above sum can be found by using (3.11), (3.2), (3.7) and simple tensor product properties to be

$$H_jG_j = -\Pi_{\ell=1}^{k-j}(\otimes I) \otimes (\mathcal{H}_j D_j^{-1}) \otimes (\Pi_{\ell=k-j+2}^{k-1} \otimes I) \otimes (A_1^{-1}T_4^1),\ j = 2, \ldots, k. \tag{3.15}$$

For the second-order LCSC, we introduce the matrices S_j and find their value to be

$$S_j := \mathcal{H}_j D_j^{-1} = \frac{\alpha_j}{h_j^2} T_{\alpha,\beta}^j \left(6I + T_{\alpha,\beta}^j\right)^{-1},\ j = 2, \ldots, k, \tag{3.16}$$

$$S_1 := A_1^{-1}T_4^1 = \left[\frac{\alpha_1}{h_1^2} T_{\alpha,\beta}^1 \left(6I + T_{\alpha,\beta}^1\right)^{-1} + \frac{\gamma}{6} I\right]^{-1}. \tag{3.17}$$

For the fourth-order LCSC, we have similarly

$$S_j := \mathcal{H}_j D_j^{-1} = \frac{1}{12}\left(12I + T_{-2,-2}^j\right) \frac{\alpha_j}{h_j^2} T_{\alpha,\beta}^j \left(6I + T_{\alpha,\beta}^j\right)^{-1},\ j = 2, \ldots, k, \tag{3.18}$$

$$S_1 := A_1^{-1}T_4^1 = \left[\left(6I + T^1_{\alpha,\beta}\right)^{-1} \frac{1}{12}\left(12I + T^1_{-2,-2}\right) \frac{\alpha_1}{h_1^2} T^1_{\alpha,\beta} + \frac{\gamma}{6} I\right]^{-1}. \tag{3.19}$$

Due to the presence of the unit matrix factors in the tensor product form (3.15), all H_jG_j's possess a linearly independent set of $\mathcal{K}$ common eigenvectors if and only if each $\mathcal{H}_j D_j^{-1}$, $j = 2, \ldots, k$, and $A_1^{-1}T_4^1$ possess complete sets of linearly independent eigenvectors. For the matrices in (3.17) this is obvious because $T^j_{\alpha,\beta}$, $j = 2, \ldots, k$, is real symmetric negative (or nonpositive) definite, $T^1_{\alpha,\beta}$ is real symmetric negative definite, and, in addition, $\sigma(T^j_{\alpha,\beta}) \subset (-4, 0]$, $j = 1, \ldots, k$ (see Lemma 3.2), $\alpha_j < 0$, $j = 1, \ldots, k$, and $\gamma \geq 0$. As one can readily see, each of the matrices S_j in (3.18) is the product of the two real symmetric positive definite matrices $\frac{1}{12}(12I + T^j_{-2,-2})$ and $\frac{\alpha_j}{h_j^2} T^j_{\alpha,\beta}(6I + T_{\alpha,\beta})^{-1}$. (The second matrix factor might also be nonnegative definite.) Therefore Lemma 3.1 (or its note) applies. For the matrix $A_1^{-1}T_4^1$ in (3.19) first observe that the first matrix term in the brackets is similar to

$$\frac{1}{12}(12I + T^1_{-2,-2}) \frac{\alpha_1}{h_1^2} T^1_{\alpha,\beta}(6I + T^1_{\alpha,\beta})^{-1},$$

which, in turn, is of exactly the same form as the matrices S_j in (3.18), except that the second matrix factor considered previously is now always positive definite. Consequently, in all possible cases of the LCSC matrices, all terms $H_j\ G_j$ in (3.15) possess a linearly independent set of $\mathcal{K}$ common eigenvectors. By virtue of this result and in view of Lemma 3.3, it is implied from (3.15) that

$$\lambda_{HG} = -\lambda_{S_1} \sum_{j=2}^{k} \lambda_{S_j}, \tag{3.20}$$

where λ_X is used to denote any eigenvalue of the matrix X. However, from the previous discussion it follows that $\lambda_{S_i} \geq 0$, $j = 2, \ldots, k$, while $\lambda_{S_1} > 0$. Therefore $\lambda_{HG} \leq 0$. So, from (3.13) it is implied that J^2 possesses nonpositive eigenvalues and hence the block Jacobi matrix J has a purely imaginary spectrum. From the analysis so far it becomes clear that the eigenvalues of J^2 and therefore those of J can be given analytically in the following cases:

(1) In all the cases of the second-order LCSC we are dealing with when Dirichlet *and/or* Neumann boundary conditions are imposed on the faces of $\partial\Omega$.
(2) In the fourth-order one when *only* Dirichlet boundary conditions are imposed on the faces of $\partial\Omega$.

This is an immediate consequence of the fact that each matrix S_j, $j = 1, \ldots, k$, in (3.16)–(3.19) is a simple *real rational* matrix function of the matrix $T^j_{\alpha,\beta}$, $j = 1, \ldots, k$, in case (1) and of the matrix $T^j_{\alpha,\beta}$, $j = 2, \ldots, k$, and $T^1_{-2,-2}$ in case (2), respectively.

Having in mind the various conclusions we have arrived at in the analysis so far, one can state the following theorem which gives analytic expressions for the eigenvalues of the block Jacobi matrix J in (3.11).

THEOREM 3.4. *The eigenvalues μ of the block Jacobi iteration matrix $K^{-1}(L+M)$ defined in* (3.11) *are as follows. We have $\mu = 0$ of multiplicity $(k-2)\mathcal{K}$. For the second-order collocation scheme the others are pure imaginary:*

$$\mu = \pm i \left\{ \frac{\sum_{j=2}^{k} \frac{\alpha_j}{h_j^2} \lambda^j_{\alpha,\beta}(6 + \lambda^j_{\alpha,\beta})^{-1}}{\frac{\alpha_1}{h_1^2} \lambda^1_{\alpha,\beta}(6 + \lambda^1_{\alpha,\beta})^{-1} + \frac{\gamma}{6}} \right\}^{1/2}. \tag{3.21}$$

For the fourth-order scheme, where (2.1) *is assumed to be subjected to Dirichlet boundary conditions only, the others are pure imaginary:*

$$\mu = \pm i \left\{ \frac{\sum_{j=2}^{k} \frac{1}{12}(12+\lambda_{-2,-2}^{j})\frac{\alpha_j}{h_j^2}\lambda_{-2,-2}^{j}(6+\lambda_{-2,-2}^{j})^{-1}}{\frac{1}{12}(12+\lambda_{-2,-2}^{1})\frac{\alpha_1}{h_1^2}\lambda_{-2,-2}^{1}(6+\lambda_{-2,-2}^{1})^{-1}+\frac{\gamma}{6}} \right\}^{-1/2}. \tag{3.22}$$

In (3.21) *and* (3.22) $\lambda_{\alpha,\beta}^{j}$, $j=1,\ldots,k$, *with* $(\alpha,\beta)=(-2,-2)$, $(-2,-1)$, $(-1,-2)$, $(-1,-1)$, *are the* $n=N_j-1$ *eigenvalues of the matrix* $T_{\alpha,\beta}^{j}$, $j=1,\ldots,k$, *as obtained by the application of Lemma* 3.2. □

Note. It should be pointed out that analytic expressions for the eigenvalues of J *cannot* be derived, in terms of the matrices $T_{\alpha,\beta}^{j}$ involved, in the case of the fourth-order LCSC where at least on one face of $\partial\Omega$ the Neumann (N) boundary conditions are imposed. This is due to the noncommutativity of the matrices $T_{-2,-2}^{j}$ and $T_{\alpha,\beta}^{j}$ for $(\alpha,\beta)\neq(-2,-2)$. However, one can trivially give analytic expressions in terms of the eigenvalues of the matrices $(12I+T_{2,-2}^{j})\,T_{\alpha,\beta}^{j}\,(6I+T_{\alpha,\beta}^{j})^{-1}$, $j=1,\ldots,k$, and also, by virtue of Lemma 3.1, lower and upper bounds can be given for the eigenvalues of H_j G_j, $j=1,\ldots,k$, in terms of the extreme eigenvalues of $T_{-2,-2}^{j}$ and $T_{\alpha,\beta}^{j}$, $j=1,\ldots,k$, of Lemma 3.2.

To derive the spectral radii of the Jacobi matrices of Theorem 3.4 and also upper bounds in the case of the previous note, we introduce some notation first. Let, then, $\lambda_{\alpha,\beta}^{j}$ denote an eigenvalue of the matrices $T_{\alpha,\beta}^{j}$, $j=1,\ldots,k$, as in Theorem 3.4. To simplify the notation we omit using another index on the generic $\lambda_{\alpha,\beta}^{j}$ and we omit the index j from the pair of subscripts (α,β). Let also

$$c_j := c_j(\alpha,\beta) := \min \lambda_{\alpha,\beta}^{j}, \tag{3.23}$$

$$s_j := s_j(\alpha,\beta) := \max \lambda_{\alpha,\beta}^{j} \tag{3.24}$$

denote the smallest and the largest eigenvalues in $\lambda_{\alpha,\beta}^{j}$, $j=1,\ldots,k$, respectively. Finally, define the functions

$$y_j := y_j(\lambda_{\alpha,\beta}^{j}) := \frac{\alpha_j}{h_j^2}\lambda_{\alpha,\beta}^{j}(6+\lambda_{\alpha,\beta}^{j})^{-1}, \tag{3.25}$$

$$z_j := z_j(\lambda_{-2,-2}^{j},\lambda_{\alpha,\beta}^{j}) := \frac{1}{12}(12+\lambda_{-2,-2}^{j})y_j \tag{3.26}$$

in terms of the eigenvalues $\lambda_{\alpha,\beta}^{j}$ of the matrices $T_{\alpha,\beta}^{j}$, $j=1,\ldots,k$. Then we have Theorem 3.5

THEOREM 3.5. (i) *The squares of the spectral radii of the block Jacobi matrices corresponding to the collocation schemes considered in Theorem* 3.4 *are given by the following expressions.*

Second order:

$$\rho^2(J) \equiv \sum_{j=2}^{k} y_j(c_j) \Big/ \left(y_1(s_1)+\frac{\gamma}{6}\right). \tag{3.27}$$

Fourth order:

$$\rho^2(J) \equiv \frac{\sum_{j=2}^{k} z_j\,(c_j(-2,-2),c_j(\alpha,\beta))}{z_1\,(s_1(-2,-2),s_1(\alpha,\beta))+\frac{\gamma}{6}}. \tag{3.28}$$

(ii) *Moreover the expression* (3.28) *is also a strict upper bound for the square of the spectral radius of the block Jacobi matrix in the case of the fourth-order scheme corresponding to an elliptic problem* (1.2a) *where at least on one of the faces of* $\partial\Omega$ *the Neumann* (N) *boundary conditions are imposed.*

Proof. We notice that in (3.21) and (3.22) $\alpha_j < 0$, $\lambda^j_{\alpha,\beta} \in [c_j, s_j]$, $j = 1, \ldots, k$, and $\gamma \geq 0$. Hence the functions $y_j := y_j(\lambda^j_{\alpha,\beta}) := y_j(\lambda)$ in (3.23) and (3.24) are nonnegative and independent of each other, and so are the expressions $z_j := z_j(\lambda^j_{-2,-2}, \lambda^j_{-2,-2}) := z(\lambda, \lambda)$ in (3.26). To determine the spectral radius of the block Jacobi matrix of the second-order collocation scheme we examine the extreme values of $y_j(\lambda)$, $\lambda \in [c_j, s_j]$, $j = 1, \ldots, k$. By differentiation we have

$$\frac{\partial y_j}{\partial \lambda} = \frac{6}{(6+\lambda)^2} \frac{\alpha_j}{h_j^2} < 0$$

and, consequently,

$$\max y_j = y_j(c_j), \quad \min y_j = y_j(s_j). \tag{3.29}$$

For the corresponding quantity of the fourth-order scheme of Theorem 3.4, working in a similar way, we obtain

$$\frac{\partial z_j}{\partial \lambda} = \frac{1}{12(6+\lambda)^2} \frac{\alpha_j}{h_j^2} [(6+\lambda)^2 + 36] < 0,$$

which implies that

$$\begin{aligned} \max z_j &= z_j \left(c_j(-2,-2), c_j(-2,-2)\right), \\ \min z_j &= z_j \left(s_j(-2,2), s_j(-2,-2)\right). \end{aligned} \tag{3.30}$$

It is obvious now using (3.21)–(3.26) and (3.29), (3.30) that the results (3.27) and (3.28) follow. This concludes the proof for part (i) of the theorem.

For part (ii) we use the analysis preceding the statement of Theorem 3.4 and refer to the matrices in (3.18) and (3.19), especially for those indices $j = 1, \ldots, k$ for which $(\alpha, \beta) \neq (-2, -2)$, and also recall the note immediately following Theorem 3.4. It follows from this and Lemma 3.1, its note, and Lemma 3.2 that the lower and upper bounds for the eigenvalues of the matrices in (3.18) and (3.19) depend directly on the extreme eigenvalues of the two matrices

$$\frac{1}{12}(12I + T^j_{-2,-2}) \quad \text{and} \quad \frac{\alpha_j}{h_j^2} T^j_{\alpha,\beta} (6I + T^j_{\alpha,\beta})^{-1}.$$

These are readily seen to be

$$\frac{1}{12}(12 + c_j(-2,2)) \quad \text{and} \quad \frac{1}{12}(12 + s_j(-2,-2))$$

for the minimum and the maximum eigenvalues for the former matrix and $y_j(c_j)$ and $y_j(s_j)$ for the latter one, where c_j, s_j, and y_j are the expressions in (3.23) and (3.24). From Lemma 3.1, its note, and using the expressions (3.26), the bound for the spectral radius of the corresponding block Jacobi matrix is readily shown to be the expression in the right-hand side of (3.28). □

Remark. The analysis so far has been made on the assumption that the x_1-direction is somehow predetermined. However, since there are k possible choices for

the x_1-direction in any particular case, the choice should be made in such a way as to give the smallest possible values in (3.27) and (3.28). Consider then the quantities

$$\min_i \left(\sum_{\substack{j=1 \\ j\neq i}}^{k} y_j(c_j) / \left(y_i(s_i) + \frac{\gamma}{6} \right) \right) \tag{3.31}$$

taken over all $i = 1, \ldots, k$ for which they are well defined and also the quantities

$$\min_i \left(\sum_{\substack{j=1 \\ j\neq i}}^{\kappa} \frac{z_j\left(c_j(-2,2), c_j(\alpha,\beta)\right)}{z_i\left(s_i(-2,-2), s_i(\alpha,\beta)\right) + \frac{\gamma}{6}} \right) \tag{3.32}$$

considered in the same way. The indices i in (3.31) and (3.32) for which the corresponding minima take place should be interchanged with the index 1 and therefore the x_i-direction should be taken as the x_1-direction. If, in either case (3.31) or (3.32), more than one index i gives the same minimum value, then any such i will do. It should be noted that after having chosen the x_1-direction this way, the expressions in (3.27) and (3.28) give then the smallest possible values for the spectral radius or for an upper bound on it, as was explained, for the particular problem at hand. □

From this point on, the analysis is almost identical with that in [5], and the interested reader is referred to it. For completeness, we simply mention some of the theoretical results obtained in [5], which are based on the corresponding theory developed in [12, 13] and in [1, 2, 3, 4, 10].

(i) The block EJ method and the block SOR method corresponding to the block Jacobi method of this paper converge for values of their parameters varying in some open intervals whose left end is 0 and the right one is a function of $\rho(J)$. However, the optimum SOR is always superior to the optimum EJ, and the corresponding optimal parameters for the SOR method are given by

$$\omega_{opt} = \frac{2}{1 + \sqrt{1 + \rho^2(J)}}, \ \rho(\mathcal{L}_{\omega_{opt}}) = 1 - \omega_{opt}. \tag{3.33}$$

(ii) For the efficiency of both the serial and the parallel iterative solution of the linear system (3.6), a cyclic natural ordering of the unknowns U^i, $i = 2, \ldots, k$, is adopted according to which

$$\mathcal{U}^i \equiv \left\{ \ldots \left\{ \left\{ \ldots \left\{ U^i_{j_1,\ldots,j_{i-1},j_i,\ldots,j_k} \right\}_{j_i=1}^{N_i-1} \cdots \right\}_{j_k=1}^{N_k-1} \right\}_{j_1=1}^{N_1-1} \cdots \right\}_{j_{i-1}=1}^{N_{i-1}-1}. \tag{3.34}$$

The equations in (3.1) are reordered according to the ordering of $\mathcal{U}^1$, and each block of the auxiliary conditions is reordered according to the ordering of the unknowns $\mathcal{U}^i$. It is then proved that the new coefficient matrix $\mathcal{A}$ is obtained by a permutation similarity transformation of the matrix coefficient A in (3.6) having the same $k \times k$ block structure, and, therefore, the associated block Jacobi matrix $\mathcal{J}$ is similar to the previous one J. Consequently, the convergence results are identically the same so that all the formulas in connection with eigenvalues, spectral radii, etc., of the Jacobi, the EJ, and the SOR method studied in this section remain unchanged when these reorderings are made.

(iii) The new structure of the collocation coefficient matrix $\mathcal{A}$, for the second-order and fourth-order scheme in two dimensions, is given in [5].

4. Numerical experiments. In this section we summarize the results of some numerical experiments that verify the convergence properties of the iterative solution methods analyzed in section 3. We mention that although we present numerical data for only the $O(h^2)$, 3-dimensional case, these are very representative of problems with different dimensionality or with $O(h^4)$ discretization schemes. For experimental data on the convergence properties of the LCSC method and the iterative solvers in the case of only Dirichlet boundary conditions the reader is referred to [5] and [7]. The parallel implementation details and the performance of the iterative LCSC schemes, for two-dimensional problems, on several multiprocessing systems can be found in [8].

We have applied the LCSC discretization techniques with uniform (NGRID by NGRID by NGRID) meshes to approximate the known solution of the following set of PDEs:

PDE 1. $D_x^2u + D_y^2u + D_z^2u = -f$.

PDE 2. $4D_x^2u + 2D_y^2u + D_z^2u - 10u = -f$.

PDE 3. $D_x^2u + \frac{.1+x-y+z}{8}D_y^2u + \frac{x+z}{9}D_z^2u + e^{x+y+z}u = -f$.

Each is defined on the unit cube and subject to one of the following types of boundary conditions:

BC 1. Dirichlet conditions on all faces of Ω.

BC 2. Neumann conditions on the faces $y = 1$ and $z = 0$ of Ω and Dirichlet ones on the rest.

BC 3. Neumann conditions on the face $x = 1$ of Ω and Dirichlet on the rest.

These PDEs and boundary conditions are combined to give nine problems; our theory is applicable only to six of these (those excluding PDE 3). The right-hand side f is selected so that the true solution is always

$$u(x, y, z) = e^{x+y+z}(x^2 - x)(y^2 - y)(z^2 - z).$$

The linear systems from the LCSC discretization were solved by the proposed SOR iteration method with the termination criterion being that $||\mathbf{U}^{(s+1)} - \mathbf{U}^{(s)}||_\infty$ is within the interval $(0, 10^{-7})$. All experiments were performed, in double precision, on a SUN4-110 workstation.

In Figure 4.1 we present the theoretically estimated (using the material developed in section 3 when applicable) and the experimentally determined (by systematic search) values of the optimum SOR relaxation parameter ω_{opt}. Specifically, the points we plot are the experimentally observed optimal values of ω for various values of $NGRID$. The lines we plot show the relation (determined using (3.33) and (3.28) of Theorem 3.5) between ω_{opt} and the discretization parameter $NGRID$. Since our theory cannot be directly used to determine such relation in the case of PDE 3 we plot only the experimentally determined ω_{opt}.

Our first observation is that there is a good agreement between our theory and the experiments in the six cases where it applies. The theoretical values for ω_{opt} are close to (although always larger than) the measured ones and exhibit the same dependence on the discretization and PDE problem parameters. Besides confirming our theory, these experiments also show that for PDEs where our analysis is not applicable the proposed SOR scheme still converges. Furthermore, relaxing with ω_{opt} determined by our theory leads us to comparable rates of convergence.

Another interesting observation is that ω_{opt} seems to go fast and asymptotically to a number in the interval $[.03, .08]$. It is therefore expected that the rate of convergence will not decrease rapidly as $NGRID$ increases beyond 30. This is confirmed

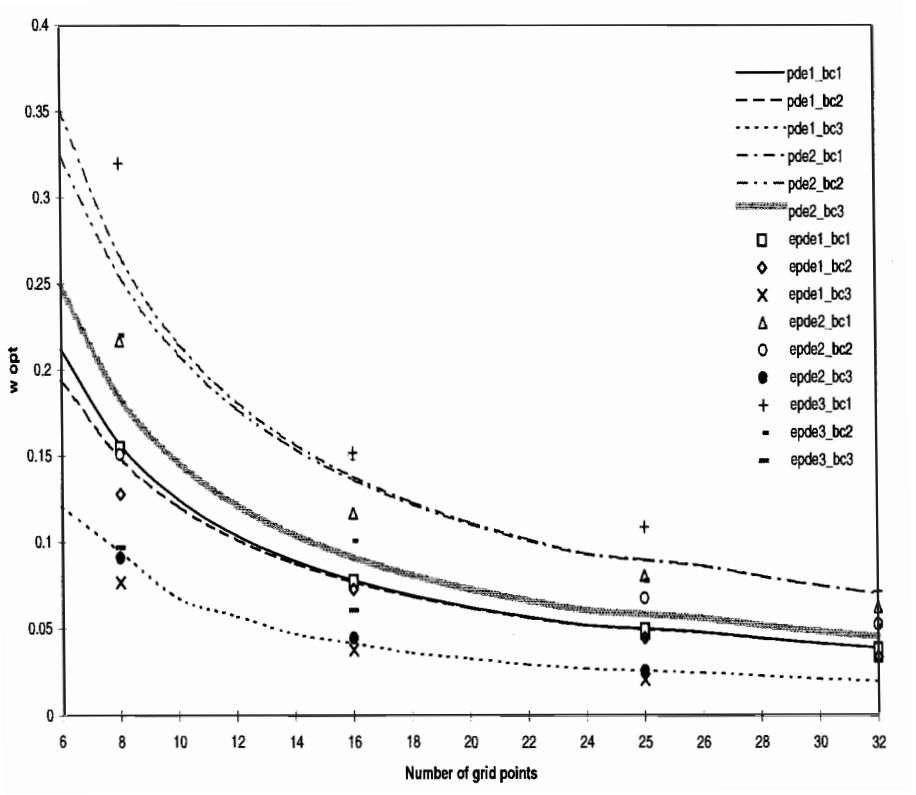

FIG. 4.1. *The graph of the ω_{opt} vs. the number of grid points for the second-order LCSC method applied to the three three-dimensional PDE operators, with different types of boundary conditions on faces of $\partial\Omega$. The text pde1_bc2, etc., indicates the combination of the PDE operator and the boundary condition. Experimental values have "e" in front in the legend; the others are theoretically established values. Experimentally determined ω_{opt} values are given by the "symbol" points alone. Theoretical ω_{opt} values are given by lines.*

TABLE 4.1
The required number of SOR iterations to solve the LCSC equations for PDE 2 and various boundary conditions.

NGRID	BC 1	BC 2	BC 3
8	42	55	85
16	63	98	172
24	73	125	255
32	105	169	320

in Table 4.1, where we observe that increasing $NGRID$ from 24 to 32 increases the number of iterations only by at most 30%.

Table 4.1 presents the SOR iterations required to solve the discretized equations using the optimal value for the relaxation parameter ω and a 10^{-7} stopping criterion for the problems defined by PDE 2 and various boundary conditions. We also note here that the measured discretization errors for all the experiments confirm the expected second order of convergence of the collocation discretization scheme. Specifically, the measured order in all cases is in the interval $[1.8, 2.1]$.

MATRICES WITH LOW-RANK-PLUS-SHIFT STRUCTURE: PARTIAL SVD AND LATENT SEMANTIC INDEXING*

HONGYUAN ZHA† AND ZHENYUE ZHANG‡

Abstract. We present a detailed analysis of matrices satisfying the so-called *low-rank-plus-shift* property in connection with the computation of their partial singular value decomposition (SVD). The application we have in mind is latent semantic indexing for information retrieval, where the term-document matrices generated from a text corpus approximately satisfy this property. The analysis is motivated by developing more efficient methods for computing and updating partial SVD of large term-document matrices and gaining deeper understanding of the behavior of the methods in the presence of noise.

Key words. singular value decomposition, low-rank approximation, latent semantic indexing, perturbation analysis, large sparse matrix

1. Introduction.

In many applications, such as compression of multiple-spectral image cubes, regularization methods for ill-posed problems, and latent semantic indexing (LSI) in information retrieval for large document collections, it is necessary to find a low-rank approximation of a given large and/or sparse matrix $A \in \mathcal{R}^{m\times n}$ [1, 11]. The theory of singular value decomposition (SVD) provides the following characterization of the best low-rank approximation of A in terms of Frobenius norm $\|\cdot\|_F$ [6].

THEOREM 1.1. *Let the singular value decomposition of $A \in \mathcal{R}^{m\times n}$ be $A = P\Sigma Q^T$ with $\Sigma = \operatorname{diag}(\sigma_1, \ldots, \sigma_{\min(m,n)})$, $\sigma_1 \geq \cdots \geq \sigma_{\min(m,n)}$, and P and Q orthogonal. Then for $1 \leq j \leq \min(m, n)$,*

$$\sum_{i=j+1}^{\min(m,n)} \sigma_i^2 = \min\{\ \|A - B\|_F^2 \mid \operatorname{rank}(B) \leq j\}.$$

And the minimum is achieved with $A_j \equiv P_j \operatorname{diag}(\sigma_1, \ldots, \sigma_j) Q_j^T$, where P_j and Q_j are the matrices formed by the first j columns of P and Q, respectively.

It follows from Theorem 1.1 that once the SVD of A is available, the best rank-j approximation of A is readily computed. We call $A_j = P_j \operatorname{diag}(\sigma_1, \ldots, \sigma_j) Q_j^T$ a partial SVD of A. The state-of-the-art methods for computing the partial SVD of large

and/or sparse matrices are based on variants of Lanczos algorithms and the core computation at each iterative step involves matrix-vector multiplications [9].[1] In order to deal effectively with large-scale problems, one is required to exploit various structures of the matrices. Despite its importance, the exploitation of structures so far has been restricted to (i) using the sparsity of a sparse matrix, and (ii) using displacement-rank structures such as Toeplitz or Hankel structures of the matrix to accelerate the matrix-vector multiplications used in the Lanczos process. In this paper, however, we propose to explore an alternative structure that is based on the singular value spectrum of a matrix. Specifically, we investigate matrices possessing the so-called *low-rank-plus-shift* structure, i.e., those matrices A (approximately) satisfying

$$A^T A = \text{a low-rank matrix} + \text{a multiple of the identity matrix}. \tag{1.1}$$

The particular application we have in mind is LSI for information retrieval, and we will show by way of examples that the term-document matrices generated from text corpora approximately satisfy (1.1). In large-scale LSI applications such as the World Wide Web, the term-document matrix generated is usually very large and cannot be kept in RAM or disk. In [15, 16] we have shown that the low-rank-plus-shift structure of the term-document matrix A allows us to compute its partial SVD in a block-wise fashion whereby partial SVD of submatrices of A are computed separately and then merged to obtain a partial SVD of A. The purpose of this paper is to further analyze the properties of matrices with low-rank-plus-shift structure, especially when (1.1) is only approximately satisfied. Our analysis will provide deeper insights into this special class of matrices which will enable us to develop more efficient methods for computing their partial SVD. We should emphasize that although our main results are motivated by problems arising from LSI in information retrieval, they may also be applied in other areas such as array signal processing and solving ill-posed problems.

The rest of the paper is organized as follows. In section 2, we provide a brief background on LSI and review some of the results in [14, 15, 16] related to computing the partial SVD of term-document matrices. In section 3, we discuss some matrix approximation problems associated with the low-rank-plus-shift structure and show by way of examples that the term-document matrices generated from text corpora approximately satisfy (1.1). In section 4 we prove a result on the partial SVD of a block-column partitioned matrix with low-rank-plus-shift structure. This result enables us to efficiently compute the partial SVD either with an incremental approach or a divide-and-conquer approach. We will also discuss the ramification of the result in dealing with LSI updating problems. In section 5 we provide a perturbation analysis of the result when the low-rank-plus-shift property is only satisfied approximately. In section 6 we conclude the paper with some remarks on future research.

2. Latent semantic indexing. The generic problem in information retrieval is the following: given a query, find all the relevant documents in a text collection. The text collection can be a homogeneous one such as the MEDLINE collection for medical information or it can be a heterogeneous one such as the World Wide Web. Variations of the standard keyword-matching methods are still employed by many of the commercial search engines. LSI is a concept-based automatic indexing method that aims at overcoming the two fundamental problems which plague traditional keyword-matching indexing schemes: synonymy and polysemy [2, 5]. Synonymy refers to the problem where several different words can be used to express a concept and the

[1] In the literature *truncated* SVD is also used for what we call partial SVD.

keywords in a user's query may not match those in the relevant documents, while polysemy means that words can have multiple meanings and the user's words may match those in irrelevant documents [8]. LSI is an extension of the vector space model for information retrieval [7, 10]. In the vector space model, the collection of text documents is represented by a *term-document* matrix $A = [a_{ij}] \in \mathcal{R}^{m\times n}$, where a_{ij} is the number of times term i appears in document j, m is the number of terms, and n is the number of documents in the collection. Consequently, a document becomes a column vector and a user's query can also be represented as a vector q of the same dimension. We then compute the score vector $s = q^T A$ and return to the user a list of ranked documents in decreasing order of the scores. Instead of using the raw term frequency for the entries of A, we can also apply many weighting schemes to change the relative importance of terms [10]. LSI extends this vector space model by modeling the term-document relationship using the SVD of the term-document matrix A. Specifically, using the notation in Theorem 1.1, we substitute A by its best rank-k approximation $A_k \equiv P_k \Sigma_k Q_k^T$, where Σ_k is the kth leading principal submatrix of Σ and the score vector is computed as $s = q^T A_k$. Corresponding to each of the k reduced dimensions is a latent concept which may not have any explicit semantic content yet helps to discriminate documents [2, 5].

Large text corpora such as those generated from World Wide Web give rise to very large term-document matrices, and the computation of their partial SVD poses a very challenging problem. Fortunately the term-document matrices possess certain useful properties besides sparsity that can be exploited for this matter. In [15, 16], we developed a theoretical foundation for LSI using the concept of subspaces, and we showed that the model we proposed imposes a so-called *low-rank-plus-shift* structure that is approximately satisfied by the cross-product of the term-document matrices.[2] Specifically, we showed that the term-document matrix $A \in \mathcal{R}^{m\times n}$ satisfies

$$A^T A/m \approx CWC^T + \sigma^2 I_n, \tag{2.1}$$

where $C \in \mathcal{R}^{n\times k}$ is the matrix whose columns represent latent concepts, $W \in \mathcal{R}^{k\times k}$ is a symmetric positive definite matrix, and σ is the variance of the noise. In LSI applications $k \ll \min\{m, n\}$, justifying the use of the terminology *low-rank-plus-shift* structure. As is shown before, we do not need to explicitly compute C, we only need to compute A_k in the factored form $A_k = U_k \Sigma_k V_k^T$.

In [14], we considered the updating problems for LSI: Let A be the term-document matrix for the original text collection and D represent a collection of new documents. The goal is to compute the partial SVD of $[A, D]$. However, in LSI applications, only A_k for some chosen k is available and the matrix A has been discarded. Since updating in this situation is based on a low-rank approximation of A, it has been argued in the literature that one will not be able to get an accurate partial SVD of $[A, D]$. In section 4, we show, however, that this is not the case since $[A, D]$ has the low-rank-plus-shift structure [14]. We will show that no retrieval accuracy degradation will occur if updating is done with a proper implementation. In [15, 16], we also discussed how to compute the partial SVD of a term-document matrix in a block-column partitioned form $A = [A_1, A_2]$ using a divide-and-conquer approach whereby the partial SVDs of A_1 and A_2 are first computed and the results are then merged into a partial SVD of A. This approach is rich in coarse-grain parallelism and can be used to handle very large term-document matrices. The justification for this divide-and-conquer approach will

[2] The low-rank-plus-shift structure was first discussed in the context of array signal processing [12, 13, 17].

be discussed in greater detail in section 4, and perturbation analysis will be provided to show that the approach is still valid even if the term-document matrix A only approximately satisfies the low-rank-plus-shift structure.

3. A matrix approximation problem. From the discussion in section 2 we know that the term-document matrix A approximately satisfies the low-rank-plus-shift property, and therefore A should have flat trailing singular values. In this section we use several example text collections to illustrate this issue. In order to assess whether a given matrix has the low-rank-plus-shift property, we investigate the following matrix approximation problem: Given a general rectangular matrix, what is the *closest* matrix that has the low-rank-plus-shift property? To proceed we first define a matrix set for a given $k > 0$,

$$\mathcal{J}_k = \{B \in \mathcal{R}^{m\times n} \mid \sigma_1(B) \geq \cdots \geq \sigma_{\min\{m,n\}}(B),\ \sigma_{k+1}(B) = \cdots = \sigma_{\min\{m,n\}}(B)\}.$$

With this notation, the matrix approximation problem reduces to finding the distance between a general matrix A and the set $\mathcal{J}_k$. In the following we consider the cases where distance is defined either by Frobenius norm $\|\cdot\|_F$ or by spectral norm $\|\cdot\|_2$.

THEOREM 3.1. *Let the SVD of A be $A = U\Sigma V^T$, $\Sigma = \mathrm{diag}(\sigma_1, \ldots, \sigma_{\min\{m,n\}})$, and U and V orthogonal. Then for $k \leq \min\{m, n\}$,*

$$\arg\min_{J\in\mathcal{J}_k} \|A - J\|_p = U_k\Sigma_k V_k^T + \tau_p U_k^{\perp}(V_k^{\perp})^T, \tag{3.1}$$

where $\Sigma_k = \mathrm{diag}(\sigma_1, \ldots, \sigma_k)$, $U = [U_k, U_k^{\perp}]$, and $V = [V_k, V_k^{\perp}]$. Furthermore,

$$\tau_p = \begin{cases} \sum_{i=k+1}^{\min\{m,n\}} \sigma_i/(\min\{m, n\} - k), & p = F, \\ (\sigma_{k+1} + \sigma_{\min\{m,n\}})/2, & p = 2. \end{cases}$$

Proof. First define

$$\min_p = \begin{cases} \|a_k - \tau_p\|, & p = F, \\ \|a_k - \tau_p\|_\infty, & p = 2, \end{cases}$$

where $a_k = [\sigma_{k+1}, \ldots, \sigma_{\min\{m,n\}}]$. It is readily checked that $\min_p$ is achieved by the right-hand side of (3.1). Therefore, all we need to prove is $\|A - J\|_p \geq \min_p$ for $p = 2, F$ and for any $J \in \mathcal{J}_k$.

To this end we use standard perturbation analysis of singular values which states that [6]

$$|\sigma_i(A) - \sigma_i(J)| \leq \|A - J\|_2, \qquad i = 1, \ldots, \min\{m, n\},$$

and

$$\sum_{i=1}^{\min\{m,n\}} (\sigma_i(A) - \sigma_i(J))^2 \leq \|A - J\|_F^2.$$

It follows that

$$\max_{k+1\leq i\leq \min\{m,n\}} |\sigma_i(A) - \sigma_i(J)| \leq \max_{1\leq i\leq \min\{m,n\}} |\sigma_i(A) - \sigma_i(J)| \leq \|A - J\|_2$$

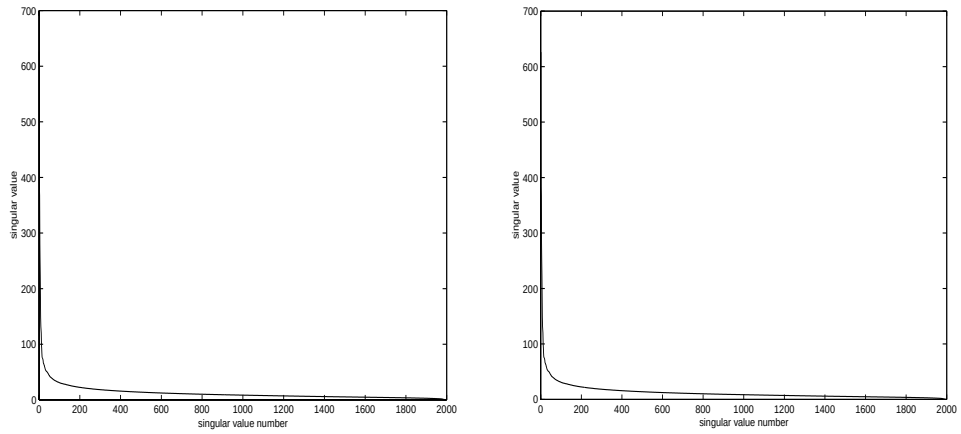

FIG. 3.1. *Singular value distributions:* 3681×1033 *term-document matrix of MEDLINE collection (left) and* 33583×1997 *NEWSGROUP collection (right).*

and

$$\sum_{i=k+1}^{\min\{m,n\}} (\sigma_i(A) - \sigma_i(J))^2 \leq \sum_{i=1}^{\min\{m,n\}} (\sigma_i(A) - \sigma_i(J))^2 \leq \|A - J\|_F^2.$$

Notice that since $\sigma_{k+1}(J) = \cdots = \sigma_{\min\{m,n\}}(J)$, it can be readily verified that the minima of the left-hand sides of the above two inequalities, i.e., $\min_p$, $p = 2, F$, are achieved by τ_2 and τ_F, respectively. □

Examples. In the following we will apply the above theorem to two example text collections and see how close the associated term-document matrices are to the set of matrices with low-rank-plus-shift structure. Our first example is the MEDLINE collection from the Cornell SMART system [3]. The term-document matrix is of size 3681×1033 and weighted by entropy weighting scheme [7]. The singular value distribution is plotted on the left of Figure 3.1. Our second example is from a collection consisting of news articles from 20 newsgroups [4]. The term-document matrix is of size 33583×1997. Its singular values are plotted on the right of Figure 3.1. From Theorem 3.1, the best approximation from $\mathcal{J}_k$ to A is given by

$$A^{(k)} \equiv U_k \Sigma_k V_k^T + \tau_p U_k^{\perp} (V_k^{\perp})^T.$$

For the MEDLINE collection we have $\|A - A^{(100)}\|_F / \|A\|_F = 0.2909$ and for the NEWSGROUP collection we have $\|A - A^{(100)}\|_2 / \|A\|_2 = 0.0491$. Several other text collections from the Cornell SMART system have also been tested and we observed similar singular value distributions: initially the singular values decrease rapidly and then the spectrum curve levels off, but the singular values are never close to zero (unless the sparse term-document matrix is *structurally* rank-deficient). The last point is very important: we usually should not treat those matrices simply as near rank-deficient and it is more appropriate that the more general low-rank-plus-shift structure with a nonzero σ be used (cf. (2.1)).

4. The low-rank-plus-shift structure. We start with an examination of the changes of the singular values of a matrix when its elements undergo certain types of modifications. If some of the elements of a general matrix are set to zero, generally it is

not possible to tell whether the singular values of the matrix will increase or decrease. However, a result we will show below states that the singular values of a matrix will always decrease if some submatrices of the matrix are replaced by its low-rank approximations. To proceed we introduce some notation: for any matrix $A \in \mathcal{R}^{m\times n}$, we will use $\text{best}_k(A)$ to denote its best rank-k approximation (cf. Theorem 1.1), and its singular values are assumed to be arranged in nonincreasing order,

$$\sigma_1(A) \geq \sigma_2(A) \geq \cdots \geq \sigma_m(A).$$

As a convention, when we compare the singular values of two matrices with the same number of rows but different number of columns, we will count the singular values according to the number of rows. With the above preparation we present our first result. The proof is similar to that of a slightly special case presented in [14] and therefore is omitted.

THEOREM 4.1. *Let $A \in \mathcal{R}^{m\times n}$ and write $A = [A_1, A_2]$. Then for any k_1 and k_2, we have*

$$\sigma_i([\text{best}_{k_1}(A_1), \text{best}_{k_2}(A_2)]) \leq \sigma_i([A_1, A_2]), \qquad i = 1, \ldots, m.$$

Remark. It is not true that replacing *arbitrary* submatrices of a matrix by their low-rank approximations will result in the decrease of its singular values, as is illustrated in the following example: Let

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \qquad \hat{A} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Notice that $\hat{A}$ is obtained from A by replacing its $(1,1)$ and $(2,2)$ elements by zero (a best rank-zero approximation). Even though the largest singular value decreases, its smallest singular value increases.

It is rather easy to find examples for which strict *inequalities* hold in Theorem 4.1. In the following we show that this will not be the case if A has the low-rank-plus-shift structure.

THEOREM 4.2. *Let $A = [A_1, A_2] \in \mathcal{R}^{m\times n}$ with $m \geq n$. Furthermore assume that*

$$A^T A = X + \sigma^2 I, \qquad \sigma > 0, \tag{4.1}$$

where X is symmetric and positive semidefinite with $\text{rank}(X) = k$. *Then there are integers $k_1 \leq k$ and $k_2 \leq k$ with $k_1 + k_2 \geq k$ such that*

$$\text{best}_k([\text{best}_{k_1}(A_1), \text{best}_{k_2}(A_2)]) = \text{best}_k([A_1, A_2]). \tag{4.2}$$

Proof. The general idea of the proof is to show that what is discarded when A_1 is replaced by $\text{best}_k(A_1)$ and A_2 is replaced by $\text{best}_k(A_2)$ will also be discarded when $\text{best}_k([A_1, A_2])$ is computed from $[A_1, A_2]$. To this end write

$$A^T A - \sigma^2 I = \begin{bmatrix} A_1^T A_1 - \sigma^2 I & A_1^T A_2 \\ A_2^T A_1 & A_2^T A_2 - \sigma^2 I \end{bmatrix}.$$

Since $\text{rank}(X) = k$, it follows that $\text{rank}(A_1^T A_1 - \sigma^2 I) \leq k$ and $\text{rank}(A_2^T A_2 - \sigma^2 I) \leq k$. Let the eigendecompositions of

$$A_1^T A_1 - \sigma^2 I = V_{A_1} \,\text{diag}(\Sigma_{A_1}^2, 0) V_{A_1}^T, \qquad A_2^T A_2 - \sigma^2 I = V_{A_2} \,\text{diag}(\Sigma_{A_2}^2, 0) V_{A_2}^T,$$

where $\Sigma_{A_1} \in \mathcal{R}^{k_1 \times k_1}, \Sigma_{A_2} \in \mathcal{R}^{k_2 \times k_2}$ are nonsingular with $k_1 \leq k, k_2 \leq k$. We can write the SVD of A_1 and A_2 as follows:

$$A_1 = U_{A_1} \operatorname{diag}(\hat{\Sigma}_{A_1}, \sigma I_{t_1}) V_{A_1}^T = [U_{A_1}^{(1)}, U_{A_1}^{(2)}] \operatorname{diag}(\hat{\Sigma}_{A_1}, \sigma I_{t_1}) [V_{A_1}^{(1)}, V_{A_1}^{(2)}]^T, \tag{4.3}$$

$$A_2 = U_{A_2} \operatorname{diag}(\hat{\Sigma}_{A_2}, \sigma I_{t_2}) V_{A_2}^T = [U_{A_2}^{(1)}, U_{A_2}^{(2)}] \operatorname{diag}(\hat{\Sigma}_{A_2}, \sigma I_{t_2}) [V_{A_2}^{(1)}, V_{A_2}^{(2)}]^T, \tag{4.4}$$

where $\hat{\Sigma}_{A_1} = (\Sigma_{A_1}^2 + \sigma^2 I_{k_1})^{1/2}, \hat{\Sigma}_{A_2} = (\Sigma_{A_2}^2 + \sigma^2 I_{k_2})^{1/2}, U_{A_1}^{(1)} \in \mathcal{R}^{m \times k_1}, U_{A_2}^{(1)} \in \mathcal{R}^{m \times k_2}$, and $t_1 = n_1 - k_1, t_2 = n_2 - k_2$, respectively, where n_i is the column dimension of $A_i, i = 1, 2$. Now write $V_{A_1}^T A_1^T A_2 V_{A_2}$ in a partitioned form as

$$V_{A_1}^T A_1^T A_2 V_{A_2} = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix}, \qquad S_{11} \in \mathcal{R}^{k_1 \times k_2}. \tag{4.5}$$

Since $X = A^T A - \sigma^2 I$ is symmetric positive semidefinite and $\operatorname{rank}(X) = k$, it follows that $S_{12} = 0, S_{21} = 0, S_{22} = 0$, and $k_1 + k_2 \geq \operatorname{rank}(X) = k$. Using the SVD of A_1 and A_2 in (4.3) and (4.4), (4.5) becomes

$$[U_{A_1}^{(1)} \Sigma_{A_1}, \sigma U_{A_1}^{(2)}]^T [U_{A_2}^{(1)} \Sigma_{A_2}, \sigma U_{A_2}^{(2)}] = \begin{bmatrix} S_{11} & 0 \\ 0 & 0 \end{bmatrix},$$

which leads to[3]

$$U_{A_1}^{(1)} \perp U_{A_2}^{(2)}, \qquad U_{A_1}^{(2)} \perp U_{A_2}^{(1)}, \qquad U_{A_1}^{(2)} \perp U_{A_2}^{(2)}.$$

Let $\hat{U}$ be an orthonormal basis of $\mathcal{R}([U_{A_1}^{(1)}, U_{A_2}^{(1)}])$, where $\mathcal{R}(\cdot)$ denotes the column space of a matrix. Then we can write

$$[A_1, A_2] = [\hat{U}, U_{A_1}^{(2)}, U_{A_2}^{(2)}] \operatorname{diag}(\tilde{B}, \sigma I_{t_1}, \sigma I_{t_2}) \begin{bmatrix} (V_{A_1}^{(1)})^T & 0 \\ 0 & (V_{A_2}^{(1)})^T \\ (V_{A_1}^{(2)})^T & 0 \\ 0 & (V_{A_2}^{(2)})^T \end{bmatrix},$$

where $\tilde{B} \in \mathcal{R}^{\hat{k} \times (k_1 + k_2)}$ with all its singular values greater than σ, and $k \leq \hat{k} \leq k_1 + k_2$. Therefore,

$$[A_1, A_2] = \hat{U} \tilde{B} \begin{bmatrix} (V_A^{(1)})^T & 0 \\ 0 & (V_D^{(1)})^T \end{bmatrix} + \sigma [U_{A_1}^{(2)}, U_{A_2}^{(2)}] \begin{bmatrix} (V_{A_1}^{(2)})^T) & 0 \\ 0 & (V_{A_2}^{(2)})^T) \end{bmatrix}.$$

The first term in the right-hand side of the above is easily seen to be the matrix $[\text{best}_{k_1}(A_1), \text{best}_{k_2}(A_2)]$, and the relation in (4.2) therefore holds. □

Remark. Generically we will have $k_1 + k_2 = k$. In the following we give an example that shows the possibility of the case $k_1 + k_2 > k$. Given any two positive numbers a and b, choose θ_1 and θ_2 such that

$$\cos(\theta_1 - \theta_2) = \sqrt{ab/(a + \sigma^2)(b + \sigma^2)}.$$

[3]We use $S \perp T$ to denote $S^T T = 0$.

Construct two matrices U_1 and U_2 as follows,

$$U_1 = \begin{bmatrix} c_1 & 0 \\ s_1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}, \qquad U_2 = \begin{bmatrix} c_2 & 0 \\ s_2 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix},$$

where $c_i = \cos(\theta_i)$ and $s_i = \sin(\theta_i)$ for $i = 1, 2$. Now construct the matrix $A = [A_1, A_2]$ with

$$A_1 = U_1 \operatorname{diag}(\sqrt{a + \sigma^2}, \sigma), \qquad A_2 = U_2 \operatorname{diag}(\sqrt{b + \sigma^2}, \sigma).$$

We obtain that

$$A^T A - \sigma^2 I = \begin{bmatrix} a & 0 & \sqrt{ab} & 0 \\ 0 & 0 & 0 & 0 \\ \sqrt{ab} & 0 & b & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

and therefore $k = 1$. However, we also have

$$A_1^T A_1 - \sigma^2 I = \begin{bmatrix} a & 0 \\ 0 & 0 \end{bmatrix}, \qquad A_2^T A_2 - \sigma^2 I = \begin{bmatrix} b & 0 \\ 0 & 0 \end{bmatrix},$$

and thus $k_1 = k_2 = 1$. So we have the case $k_1 + k_2 > k$.

Remark. In essence the result in Theorem 4.2 states that if A has the low-rank-plus-shift structure, then an optimal low-rank approximation of A can be computed by merging the optimal low-rank approximations of its two submatrices A_1 and A_2. The result can be generalized to the case where A is partitioned into several blocks $A = [A_1, A_2, \ldots, A_s]$.

Remark. In general k_1 and k_2 are not available; they exist in the analysis in the proof of Theorem 4.2 but are never explicitly computed. However, since $k_i \leq k, i = 1, 2$, the relation in (4.2) still holds if we replace $k_i, i = 1, 2$, by k, i.e.,

$$\text{best}_k([\text{best}_k(A_1), \text{best}_k(A_2)]) = \text{best}_k([A_1, A_2]).$$

Referring back to our discussion on LSI updating problem in section 2, we see that Theorem 4.2 justifies the replacement of A by its best rank-k approximation because

$$\text{best}_k[\text{best}_k(A), D]) = \text{best}_k([A, D]),$$

assuming $[A, D]$ has the low-rank-plus-shift structure. That is to say, we will obtain the same best low-rank approximation even though A is replaced by $\text{best}_k(A)$. Numerical results conducted on several text collections show that no retrieval accuracy degradation occurs when updating is computed using a proper implementation [14].

On the other hand, Theorem 4.2 also leads to some novel approaches for computing a low-rank approximation of a large matrix. There are at least two general approaches to pursue ideas based on Theorem 4.2:

- *An incremental method.* The first is what we call an incremental approach, whereby we can use certain sampling methods to divide the whole collection of documents into several groups: Start with one group and compute its rank-k approximation, add the second group using the updating algorithm to produce a new rank-k approximation, then repeat the whole process. This incremental process can be very useful when the data collection is very large and the whole term-document matrix cannot reside completely in the main memory. Some computational results of this approach can be found in [14].

- *A divide-and-conquer method.* The second is what we call a divide-and-conquer approach. We can again divide the whole collection of documents into several groups and compute the rank-k approximation for *each group* and then combine the results together into a rank-k approximation for the whole data collection. Recursively, the rank-k approximation for each group can also be computed using this divide-and-conquer approach, and so on. The approach has the property that computation can be organized with a high degree of coarse-grain parallelism. A parallel implementation of this method is currently under investigation.

5. Perturbation analysis. In this section, we consider the case where A only approximately satisfies the low-rank-plus-shift property. Our main goal is to see to what extent the result in Theorem 4.2 still holds in the presence of perturbation. We first present some lemmas which are of their own interests as well. In what follows, $\|\cdot\|$ denotes 2-norm and $\|\cdot\|_F$ denotes Frobenius norm. We will use MATLAB notation for submatrices: `A(i:j,k:l)` denotes rows i to j and columns k to l of A.

LEMMA 5.1. *Assume that the matrix X defined below is symmetric positive semi-definite,*

$$X = \begin{bmatrix} A & B^T \\ B & C \end{bmatrix} - E.$$

Then we have

$$\|B\| \le \sqrt{(\|A\| + \|E\|)(\|C\| + \|E\|)}.$$

Proof. Without loss of generality we assume that the matrix B is diagonal. (The result still holds even if B is rectangular.) Write

$$B = \operatorname{diag}(\sigma_1, \ldots, \sigma_n), \qquad \sigma_1 \ge \cdots \ge \sigma_n.$$

Let a_{11} and c_{11} be the $(1,1)$ element of A and C, respectively. Then

$$\begin{bmatrix} a_{11} & \sigma_1 \\ \sigma_1 & c_{11} \end{bmatrix} = X_1 + E_1,$$

for some 2-by-2 symmetric positive semidefinite X_1 and E_1 with $\|E_1\| \le \|E\|$. Since the smallest eigenvalue of $X_1 + E_1$ is no smaller than $-\|E_1\|$, it follows that

$$\begin{aligned} \sigma_1^2 &\le ((a_{11} + c_{11})/2 + \|E_1\|)^2 - ((a_{11} - c_{11})/2)^2 \\ &\le (\|A\| + \|E\|)(\|C\| + \|E\|), \end{aligned}$$

thus completing the proof. ∎

LEMMA 5.2. *Let the matrix X be partitioned as*

$$X = \begin{bmatrix} A & B^T \\ B & C \end{bmatrix}.$$

Then $\|X\| \le \max\{\|A\|, \|C\|\} + \|B\|$.

Proof. The proof is straightforward and is therefore omitted. ∎

THEOREM 5.3. *Let $A = [A_1, A_2] \in \mathcal{R}^{m \times n}, m \ge n$ satisfy*

$$A^T A = X + \sigma^2 I + E,$$

where X is symmetric positive semidefinite with $\operatorname{rank}(X) = k$. *If*

$$\lambda_k(X) > 3\|E\| + 2\sqrt{\|E\|(\|X\| + 2\|E\|)},$$

then for some $k_1 \le k$, $k_2 \le k$, and $k_1 + k_2 \ge k$, we have

$$\operatorname{best}_k([A_1, A_2]) = \operatorname{best}_k([\operatorname{best}_{k_1}(A_1), \operatorname{best}_{k_2}(A_2)]) + \Delta$$

with

$$\|\Delta\| \le \alpha(\|E\| + 4\sqrt{\|E\|(\|X\| + 2\|E\|)})$$

and

$$\alpha = \frac{\sigma_1(A) + 2\sigma_{k+1}(A)}{\sigma_k^2(A) - \sigma^2}.$$

Proof. The proof is divided into several parts.

(1) We first write the eigendecomposition of the following matrices:

$$A^T A - \sigma^2 I = X + E = V \operatorname{diag}(\lambda_1, \ldots, \lambda_n) V^T,$$

$$A_i^T A_i - \sigma^2 I = X_i + E_i = V_i \operatorname{diag}(\lambda_1^{(i)}, \ldots, \lambda_{n_i}^{(i)}) V_i^T, \qquad i = 1, 2,$$

where X and X_i are symmetric positive semidefinite and V and V_i are orthogonal for $i = 1, 2$. The eigenvalues $\{\lambda_k\}$ and $\{\lambda_k^{(i)}\}$ are arranged in nonincreasing order. It follows that, for $i = 1, 2$, there are orthogonal matrices U_i such that

$$\begin{aligned} A_i &= U_i \operatorname{diag}(d_1^{(i)}, \ldots, d_{n_i}^{(i)}) V_i^T, \\ &= U_i \operatorname{diag}(D_{i1}, D_{i2}) V_i^T, \end{aligned}$$

where $d_j^{(i)} = \sqrt{\lambda_j^{(i)} + \sigma^2}$ and

$$\begin{aligned} D_{i1} &= \operatorname{diag}(d_1^{(i)}, \ldots, d_{k_i}^{(i)}), \\ D_{i2} &= \operatorname{diag}(d_{k_i+1}^{(i)}, \ldots, d_{n_i}^{(i)}), \end{aligned}$$

where $k_i = \operatorname{rank}(X_i), i = 1, 2$. The definition of best low-rank approximation leads to

$$\operatorname{best}_{k_i}(A_i) = U_i D_{i1} V_i, \qquad i = 1, 2.$$

(2) Using the above decompositions we now write the matrix A in several different forms: $A = [A_1, A_2] = B[W_1, W_2]^T = [B_1, B_2] W^T$, where

$$B_1 = [U_{11} D_{11}, U_{21} D_{21}], \qquad B_2 = [U_{12} D_{12}, U_{22} D_{22}],$$

and

$$W_1 = \begin{bmatrix} V_{11} & 0 \\ 0 & V_{21} \end{bmatrix}, \qquad W_2 = \begin{bmatrix} V_{12} & 0 \\ 0 & V_{22} \end{bmatrix}.$$

It can be readily verified that

$$B_1 W_1^T = [\operatorname{best}_{k_1}(A_1), \operatorname{best}_{k_2}(A_2)].$$

Now partition

$$B^TB - \sigma^2 I = \begin{bmatrix} B_1^TB_1 - \sigma^2 I & B_1^TB_2 \\ B_2^TB_1 & B_2^TB_2 - \sigma^2 I \end{bmatrix}. \tag{5.1}$$

(3) Let the eigendecomposition of $B_1^TB_1 - \sigma^2 I$ be

$$B_1^TB_1 - \sigma^2 I = G\,\mathrm{diag}(\alpha_1, \ldots, \alpha_s)G^T,$$

where $\alpha_1 \geq \cdots \geq \alpha_s, s = k_1 + k_2$. Now partition $\mathrm{diag}(G^T, I)B^TB\,\mathrm{diag}(G, I)$ as

$$\mathrm{diag}(G^T, I)B^TB\,\mathrm{diag}(G, I) = \begin{bmatrix} C & E_1^T \\ E_1 & E_2 \end{bmatrix},$$

where $C = \mathrm{diag}(\alpha_1, \ldots, \alpha_k)$ and the matrix E has the form

$$[E_1, E_2] = \begin{bmatrix} [0, \mathrm{diag}(\alpha_{k+1}, \ldots, \alpha_s)] & (G^TB_1^TB_2)\texttt{(k+1:m,:)} \\ B_2^TB_1G & B_2^TB_2 - \sigma^2 I \end{bmatrix}. \tag{5.2}$$

Furthermore, let the eigendecomposition of

$$\begin{bmatrix} C & E_1^T \\ E_1 & E_2 \end{bmatrix} = Q\Lambda Q^T, \qquad \Lambda = \mathrm{diag}(\lambda_1, \ldots, \lambda_n).$$

Now partition conformally,

$$Q = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix}, \qquad \Lambda = \mathrm{diag}(\Lambda_1, \Lambda_2)$$

with $\Lambda_1 = \mathrm{diag}(\lambda_1, \ldots, \lambda_k)$. It can be verified that

$$Q_{21} = [E_1, E_2] \begin{bmatrix} Q_{11} \\ Q_{21} \end{bmatrix} \Lambda_1^{-1}. \tag{5.3}$$

It follows that we can find U orthogonal such that

$$B = [B_1, B_2] = U(\Lambda + \sigma^2 I)^{1/2} Q^T\,\mathrm{diag}(G^T, I),$$

which leads to

$$B_1W_1^T = U(\Lambda + \sigma^2 I)^{1/2} Q^T \begin{bmatrix} G^TW_1^T \\ 0 \end{bmatrix} = H + \Delta_1,$$

where

$$H = U\texttt{(:,1:k)}(\Lambda_1 + \sigma^2 I)^{1/2} Q_{11}^T G^T W_1^T$$

and

$$\Delta_1 = U\texttt{(:,K+1:n)}(\Lambda_2 + \sigma^2 I)^{1/2} Q_{12}^T G^T W_1^T.$$

Hence

$$\begin{aligned} \|\mathrm{best}_k(B_1W_1^T) - H\| &= \|\mathrm{best}_k(B_1W_1^T) - B_1W_1^T + \Delta_1\| \\ &\leq \|\mathrm{best}_k(B_1W_1^T) - B_1W_1^T\| + \|\Delta_1\| \leq 2\|\Delta_1\|. \end{aligned}$$

(4) On the other hand, let

$$\Delta = \text{best}_k(A) - \text{best}_k(B_1 W_1^T).$$

Then

$$\begin{aligned}
\|\Delta\| &\le \|\text{best}_k(A) - H\| + \|H - \text{best}_k(B_1 W_1^T)\| \\
&\le \|U(:,1:k)(\Lambda_1 + \sigma^2 I)^{1/2} Q_{21}^T W_2^T\| + 2\|\Delta_1\| \\
&\le \sqrt{\lambda_1 + \sigma^2}\|Q_{21}\| + 2\sqrt{\lambda_{k+1} + \sigma^2}\|Q_{12}\| \\
&= (\sqrt{\lambda_1 + \sigma^2} + 2\sqrt{\lambda_{k+1} + \sigma^2})\|Q_{21}\| \\
&\le (\sqrt{\lambda_1 + \sigma^2} + 2\sqrt{\lambda_{k+1} + \sigma^2})\|[E_1, E_2]\|/\lambda_k \\
&= \alpha\|[E_1, E_2]\|,
\end{aligned}$$

where

$$\alpha = \frac{\sqrt{\lambda_1 + \sigma^2} + 2\sqrt{\lambda_{k+1} + \sigma^2}}{\lambda_k} = \frac{\sigma_1(A) + 2\sigma_{k+1}(A)}{\sigma_k^2(A) - \sigma^2}.$$

Now we need to bound $\|[E_1, E_2]\|$, and this will be done in the following steps.

(5) Applying Lemma 5.1 to the matrix

$$B_2^T B_2 - \sigma^2 I = \begin{bmatrix} D_{12}^2 - \sigma^2 I & D_{11}^T U_{12}^T U_{22} D_{22} \\ D_{22}^T U_{22}^T U_{12} D_{11} & D_{22}^2 - \sigma^2 I \end{bmatrix},$$

we obtain the bound

$$\|D_{11}^T U_{12}^T U_{22} D_{22}\|^2 \le (\|D_{12}^2 - \sigma^2 I\| + \|E\|)(\|D_{22}^2 - \sigma^2 I\| + \|E\|) \le 4\|E\|^2,$$

where we have used $\|D_{i2}^2 - \sigma^2 I\| \le \|E\|, i = 1, 2$. By Lemma 5.2 we obtain

$$\|B_2^T B_2 - \sigma^2 I\| \le 3\|E\|.$$

(6) Now applying Lemma 5.1 to $B^T B - \sigma^2 I$ in (5.1) we obtain

$$\|B_2^T B_1\|^2 \le 4\|E\|(\|B_1^T B_1 - \sigma^2 I\| + \|E\|) \le 4\|E\|(\|X\| + 2\|E\|),$$

where we have bounded

$$\|B_1^T B_1 - \sigma^2 I\| \le \|B^T B - \sigma^2 I\| \le \|X\| + \|E\|.$$

(7) Using (5.2), the results in parts (5) and (6), and Lemma 5.2, we have

$$\|[E_1, E_2]\| \le \max\{|\alpha_{k+1}|, 3\|E\|\} + 2\sqrt{\|E\|(\|X\| + 2\|E\|)}.$$

(8) Now we are ready to complete the proof of the theorem by showing that

$$|\alpha_{k+1}| \le \|E\| + 2\sqrt{\|E\|(\|X\| + 2\|E\|)}.$$

In fact, by definition, $\lambda_j = \lambda_j(B^T B - \sigma^2 I)$, and therefore

$$|\lambda_{k+1} - \lambda_{k+1}(\text{diag}(B_1^T B_1 - \sigma^2 I, B_2^T B_2 - \sigma^2 I))| \le \|B_2^T B_1\|.$$

On the other hand, we have

$$|\lambda_{k+1}(B_2^T B_2 - \sigma^2 I)| \le \|B_2^T B_2 - \sigma^2 I\| \le 3\|E\|.$$

The assumption of the theorem implies that

$$\lambda_k > \|B_2^T B_1\| + 3\|E\|,$$

and therefore, for $j \le k$,

$$\lambda_j(\mathrm{diag}(B_1^T B_1 - \sigma^2 I, B_2^T B_2 - \sigma^2 I)) = \lambda_j(B_1^T B_1 - \sigma^2 I) = \alpha_j.$$

Now there is $i > k$ such that $|\alpha_{k+1} - \lambda_i| \le \|B_2^T B_1\|$ and thus

$$|\alpha_{k+1}| \le |\lambda_i| + \|B_2^T B_1\| \le \|E\| + 2\sqrt{\|E\|(\|X\| + 2\|E\|)},$$

completing the proof. □

Remark. In many of our numerical experiments, we observed that $\|\Delta\| = O(\|E\|)$, versus the bound $\|\Delta\| = O(\|E\|^{1/2})$ given in the above theorem. Here we give an example for which we do have $\|\Delta\| = O(\|E\|^{1/2})$. Let ϵ be small, and define $t = \sqrt{2\epsilon}$. Denote

$$\begin{aligned}
\mu_1 &= (1 + \epsilon + \sqrt{(1+\epsilon)^2 + 4\epsilon})/2 = 1 + 2\epsilon - 2\epsilon^2 + O(\epsilon^3),\\
\mu_2 &= (1 + \epsilon - \sqrt{(1+\epsilon)^2 + 4\epsilon})/2 = -\epsilon + 2\epsilon^2 + O(\epsilon^3),\\
a &= (\mu_1 - 1)/t = t(1 - \epsilon + O(\epsilon^2)).
\end{aligned}$$

Then it can be readily verified that

$$\begin{bmatrix} 1 & t \\ t & \epsilon \end{bmatrix} = (1/(1+a^2)) \begin{bmatrix} 1 & a \\ a & -1 \end{bmatrix} \begin{bmatrix} \mu_1 & 0 \\ 0 & \mu_2 \end{bmatrix} \begin{bmatrix} 1 & a \\ a & -1 \end{bmatrix}.$$

Now let

$$X = (\mu_1/(1+a^2)) \begin{bmatrix} 1 & 0 \\ 0 & a \\ 0 & 1 \\ a & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & a & 1 & 0 \end{bmatrix},$$

$$E = (\mu_2/(1+a^2)) \begin{bmatrix} 0 & a \\ 1 & 0 \\ -a & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 0 & 1 & -a & 0 \\ a & 0 & 0 & -1 \end{bmatrix}.$$

With $k = \mathrm{rank}(X) = 2$ and $\|E\| = |\mu_2| = \epsilon(1 - 2\epsilon + O(\epsilon^2))$, it is easy to see that

$$X + E = V\,\mathrm{diag}(\mu_1, \mu_1, \mu_2, \mu_2)V,$$

where

$$V = (1/\sqrt{1+a^2}) \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & a & 1 & 0 \\ 0 & 1 & -a & 0 \\ a & 0 & 0 & -1 \end{bmatrix}$$

is orthogonal and symmetric. For a given $\sigma > 0$, define

$$c_1 = \sqrt{\mu_1 + \sigma^2}, \qquad c_2 = \sqrt{\mu_2 + \sigma^2}.$$

Now construct matrix A as $A = [A_1, A_2]$, where

$$A_1 = [e_1, e_3, e_2, e_4]DV\texttt{(:,1:2)}, \qquad A_2 = [e_1, e_3, e_2, e_4]DV\texttt{(:,3:4)},$$

with $D = \mathrm{diag}(c_1, c_1, c_2, c_2)$, and $I_4 = [e_1, e_2, e_3, e_4]$ is the identity matrix. It can be verified that $k_1 = k_2 = 2$. Then we have

$$\mathrm{best}_k(A) = (c_1/\sqrt{1+a^2})[e_1, e_3]V\texttt{(1:2,:)}.$$

Since $a < 1$, it can be verified that

$$\mathrm{best}_1(A_1) = (1/\sqrt{1+a^2}) \begin{bmatrix} c_1 & 0 \\ 0 & 0 \\ 0 & 0 \\ c_2 a & 0 \end{bmatrix}, \qquad \mathrm{best}_1(A_2) = (1/\sqrt{1+a^2}) \begin{bmatrix} 0 & 0 \\ -c_2 a & 0 \\ c_1 & 0 \\ 0 & 0 \end{bmatrix}.$$

It follows that

$$\mathrm{best}_k([\mathrm{best}_1(A_1), \mathrm{best}_1(A_2)]) = (1/\sqrt{1+a^2}) \begin{bmatrix} c_1 & 0 & 0 & 0 \\ 0 & 0 & -c_2 a & 0 \\ 0 & 0 & c_1 & 0 \\ c_2 a & 0 & 0 & 0 \end{bmatrix},$$

and therefore

$$\begin{aligned} \Delta &= \mathrm{best}_k(A) - \mathrm{best}_k([\mathrm{best}_1(A_1), \mathrm{best}_1(A_2)]) \\ &= a/\sqrt{1+a^2}\,\mathrm{diag}(c_1, c_2, c_1, c_2)[-e_4, e_3, e_2, e_1], \end{aligned}$$

which leads to $\|\Delta\| = ac_1/\sqrt{1+a^2}$. Then we see that

$$\lim_{\epsilon \to 0} \|\Delta\|/\sqrt{\|E\|} = \sqrt{2(1+\sigma^2+2\epsilon+O(\epsilon^2))}/[(1+O(\epsilon^2))(1-\epsilon+O(\epsilon^2)) = \sqrt{2(1+\sigma^2)}.$$

6. Concluding remarks. This paper presented a detailed analysis of matrices with a low-rank-plus-shift structure. We placed emphasis on justifying some novel methods for partial SVD computation and partial SVD updating problems arising from LSI in information retrieval. Our perturbation analysis demonstrated that the results we had derived were still valid even though the low-rank-plus-shift structure was approximately satisfied. The results we have proved provided theoretical justifications for the novel LSI updating algorithms and the incremental and divide-and-conquer approaches proposed in [14, 16].

DISTRIBUTION OF ENTRIES IN A SUBSTOCHASTIC MATRIX HAVING EIGENVALUES NEAR 1*

D. J. HARTFIEL†

Abstract. This paper gives a quantitative result that if A is a substochastic matrix and has r eigenvalues which are sufficiently close to 1, then A has r disjoint principal submatrices which are nearly stochastic.

Key words. substochastic matrices, nearly stochastic blocks, canonical forms, condition

PII. S0895479897323440

The condition of a Markov chain, having transition matrix A and stochastic eigenvector π, has been studied by numerous researchers. Condition numbers were given by Meyer (see [6]) and Seneta (see [7]). Meyer uses $K(A) = \max_{i,j} |a_{ij}^{\#}|$, where $A^{\#} = (I - A + e\pi)^{-1} - e\pi$, e denoting the column vector of 1's. (Here, $A^{\#}$ denotes the group inverse of $I - A$.) Seneta uses $\mathcal{T}(A^{\#})$, where $\mathcal{T}(B) = \frac{1}{2} \max_{i,j} \sum_{k=1}^{n} |b_{ik} - b_{jk}|$ for any $n \times n$ matrix B. Neither of these condition numbers is given in terms of the entries of A, although both papers provide bounds on the condition numbers in terms of the eigenvalues of A. Those bounds show that if a subdominant eigenvalue of A is close to 1, then A is ill-conditioned; the converse is also true.

In [4], Hartfiel and Meyer show qualitatively that if a subdominant eigenvalue of A is sufficiently close to 1, then A has two nearly uncoupled principal submatrices. Qualitatively, this links the condition of a Markov chain to the appearance of nearly uncoupled principal submatrices within A. In this paper, with a somewhat technically intricate argument, we show the first results quantifying these remarks.

Results. Our major result rests on a sequence of preliminary theorems. We provide these theorems below. Throughout the presentation, A is an $n \times n$ irreducible substochastic matrix (necessary for our inductive argument) with positive dominant eigenvalue λ_1 and remaining eigenvalues $\lambda_2, \ldots, \lambda_n$. We suppose $\min_{k \neq 1} |\lambda_1 - \lambda_k| = |\lambda_1 - \lambda_2|$. Let x denote the stochastic eigenvector belonging to λ_1. In addition, we use the terms defined below.

Let B be an $m \times m$ substochastic matrix and $\epsilon, \epsilon \geq 0$, a scalar. Define $r_i(B)$ as the ith row sum of B.

(i) If $1 - r_i(B) \leq \epsilon$ for all i, then B is called an ϵ *nearly stochastic matrix*.

(ii) If there is a permutation matrix P such that, in partitioned form,

$$PBP^t = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix},$$

and B_{11} is an ϵ nearly stochastic matrix, then we say that B_{11} is an ϵ nearly stochastic matrix of B.

*Received by the editors June 25, 1997; accepted for publication (in revised form) by G. Styan November 7, 1998; published electronically December 3, 1999.

†Department of Mathematics, Texas A&M University, College Station, TX 77843-3368 (hartfiel@math.tamu.edu).

(iii) If there is a permutation matrix Q such that, in partitioned form,

$$QBQ^t = \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ B_{21} & B_{22} & B_{23} \\ B_{31} & B_{32} & B_{33} \end{bmatrix}$$

and B_{11} and B_{22} are ϵ nearly stochastic matrices, then we say that B has two *disjoint ϵ nearly stochastic matrices*. Of course, this definition can be extended to r disjoint ϵ nearly stochastic matrices.

(iv) Let $K = \{1, \ldots, m\}$. Let $R, C \subseteq K$ be such that $R \cup C = K$ and $R \cap C = \emptyset$. Define $\mu(B) = \min_{R,C}(\max_{i \in R, j \in C} b_{ij})$, called the *measure of irreducibility* of B [2], [3]. Note that $\mu(B) \leq 1$.

(v) Let P be a permutation matrix such that

$$PBP^t = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix},$$

where B_{11} is square and the largest entry in B_{12} is μ. Then B_{12} is called a μ-block of B.

We now begin with the preliminary work. The first theorem ensures the existence of a small μ-block in A. We need a lemma.

LEMMA 1. *Let λ be a complex number where $|\lambda| \leq 1$ and $|1 - \lambda| \leq \delta$ for some scalar δ. Then $(1 + \mu)^n - |\lambda + \mu|^n \leq n2^n\delta$ for all μ, $0 \leq \mu \leq 1$.*

Proof. First note that

$$\begin{aligned} 2 = |2 - \lambda + \lambda| &\leq |1 - \lambda| + |1 + \lambda| \text{ so} \\ 2 - |1 + \lambda| &\leq |1 - \lambda| < \delta. \\ \text{Set } \ 2 - |1 + \lambda| &= x \text{ so} \\ 2 - x &= |1 + \lambda|. \end{aligned}$$

Now, $0 \leq x \leq 2$ and

$$2^n - |1 + \lambda|^n = 2^n - (2 - x)^n.$$

Set $f(x) = 2^n - (2 - x)^n$ and $g(x) = n2^n x$. Then $f(0) = 0$ and $g(0) = 0$. Further,

$$f'(x) = n(2 - x)^{n-1} \quad \text{and} \quad g'(x) = n2^n.$$

Since $f'(x) \leq g'(x)$, it follows that $f(x) \leq g(x)$ for all x, $0 \leq x \leq 2$. In particular,

$$2^n - (2 - x)^n \leq n2^n x.$$

Thus, by substituting,

$$2^n - |1 + \lambda|^n \leq n2^n\delta.$$

Finally, since $(1 + \mu)^n - |\lambda + \mu|^n$ is nondecreasing in μ, the result follows. □

THEOREM 1. *Suppose $|1 - \lambda_2| < \delta$. Then, for some scalar μ, $0 \leq \mu \leq 1$, A has a μ-block where $\mu^n \leq n2^n\delta$. (Since we know that $\mu \leq 1$, this bound and those that follow are useful only if δ is sufficiently small.)*

Proof. A corollary to Theorem 2.2 in [5] is that if A is positive and m is the smallest entry in A, then

$$|\lambda_2| \leq \lambda_1 - m.$$

Applying the conversion technique described in [2] to this inequality shows that if μ is the measure of irreducibility of A,

$$|\lambda_2 + \mu|^n \leq (\lambda_1 + \mu)^n - \mu^n.$$

Thus,

$$\mu^n \leq (1 + \mu)^n - |\lambda_2 + \mu|^n.$$

By Lemma 1,

$$\mu^n \leq n2^n\delta. \qquad \square$$

Without loss of generality, we now assume that

$$A = \begin{bmatrix} A_1 & U \\ A_{21} & A_2 \end{bmatrix},$$

where A_1 is square and $\max_{i,j} u_{ij} = \mu$.

The next theorem shows the closeness of the eigenvalues of A_1, A_2 and those of A. We need a lemma.

LEMMA 2. *Let $B = (b_{ij})$ be an $n \times n$ matrix with $e = \max_{i<j} b_{ij}$ and $b = \max_{i>j} b_{ij}$. If λ is any eigenvalue of B, then*

$$|\lambda - b_{ii}| \leq \sqrt[n]{eb^{n-1}} + \cdots + \sqrt[n]{e^{n-1}b}$$

for some i.

Proof. Set $D = \operatorname{diag}(1, \sqrt[n]{(e/b)}, \ldots, \sqrt[n]{(e/b)^{n-1}})$ and $C = DBD^{-1}$. Since C is similar to B, C and B have the same list of eigenvalues. Applying Gershgorin's theorem [1] to B yields that for any eigenvalue λ of B,

$$\begin{aligned}
|\lambda - b_{ii}| &\leq \sum_{k \neq i} c_{ik} \\
&\leq \sum_{k<i} (\sqrt[n]{(e/b)^{i-1}}) b (\sqrt[n]{(e/b)^{k-1}})^{-1} \\
&\quad + \sum_{k>i} (\sqrt[n]{(e/b)^{i-1}}) \epsilon (\sqrt[n]{(e/b)^{k-1}})^{-1} \\
&= \sqrt[n]{e^{i-1}b^{n+1-i}} + \cdots + \sqrt[n]{e^1 b^{n-1}} \\
&\quad + \sqrt[n]{e^{n-1}b^1} + \cdots + \sqrt[n]{e^i b^{n-i}} \\
&= \sqrt[n]{eb^{n-1}} + \cdots + \sqrt[n]{e^{n-1}b}
\end{aligned}$$

for some i. $\square$

THEOREM 2. *Suppose $\mu \leq \frac{1}{n}$ and A has r eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_r$ within δ of 1. Then $\bar{A} = \begin{bmatrix} A_1 & 0 \\ A_{21} & A_2 \end{bmatrix}$ has r eigenvalues $\mu_1, \ldots, \mu_r$ within $n^3\mu^{\frac{1}{n}} + \delta$ of 1.*

Proof. Using Schur's theorem [1], let U_i be a unitary matrix so that $U_i^* A_i U_i = T_i$, where T_i is lower triangular for $i = 1, 2$. Set $\overline{U} = \operatorname{diag}(U_1, U_2)$ and

$$T = \overline{U}^* A \overline{U} = \begin{bmatrix} T_1 & T_{12} \\ T_{21} & T_2 \end{bmatrix}.$$

Since any unitary matrix preserves lengths, using $\beta(B) = (\sum_{i,j} b_{ij}^2)^{\frac{1}{2}}$ for any matrix B, we have for

$$\beta_{\bar{A}} = \beta\left(\begin{bmatrix} A_1 & 0 \\ A_{21} & A_2 \end{bmatrix}\right), \quad \beta\left(\begin{bmatrix} T_1 & 0 \\ T_{21} & T_2 \end{bmatrix}\right) = \beta_{\bar{A}}$$

and for

$$\beta_u = \beta\left(\begin{bmatrix} 0 & U \\ 0 & 0 \end{bmatrix}\right), \quad \beta\left(\begin{bmatrix} 0 & T_{12} \\ 0 & 0 \end{bmatrix}\right) = \beta_u.$$

Thus, if the main diagonal entries of T are $\alpha_1, \ldots, \alpha_n$ (these are also the eigenvalues of $\begin{bmatrix} A_1 & 0 \\ A_{21} & A_2 \end{bmatrix}$), it follows from Lemma 2 that if λ is an eigenvalue of A,

$$|\lambda - \alpha_i| \leq \sqrt[n]{\beta_u \beta_{\bar{A}}^{n-1}} + \cdots + \sqrt[n]{\beta_n^{n-1} \beta_{\bar{A}}}$$

for some i. Since $|\cdot|_2 < |\cdot|_1$,

$$|\lambda - \alpha_i| \leq \sqrt[n]{\sigma_u \sigma_{\bar{A}}^{n-1}} + \cdots + \sqrt{\sigma_u^{n-1} \sigma_{\bar{A}}},$$

where $\sigma_u = \sum_{i,j} u_{ij}$ and $\sigma_{\bar{A}} = \sum_{i,j} \bar{a}_{ij}$. Since A is substochastic, $\sigma_{\bar{A}} \leq n$ and $\sigma_u \leq n\mu$. Thus

$$\begin{aligned} |\lambda - \alpha_i| &\leq \sqrt[n]{(n\mu)n^{n-1}} + \cdots + \sqrt[n]{(n\mu)^{n-1} n} \\ &\leq n[(n\mu)n^{n-1}]^{\frac{1}{n}}, \quad \text{since} \quad \mu \leq \frac{1}{n}, \\ &= n^2 \mu^{\frac{1}{n}}. \end{aligned}$$

Each eigenvalue of A is in a disk

$$|\lambda - \alpha_i| \leq n^2 \mu^{\frac{1}{n}}.$$

And, by arguing as in Gershgorin's theorem, if there are k disks in a component of the union of these disks, then that component contains k eigenvalues of A. Thus, there are r eigenvalues, say, $\alpha_1, \ldots, \alpha_r$ of $\bar{A}$, such that

$$|\lambda_i - \alpha_i| \leq n(n^2 \mu^{\frac{1}{n}}) = n^3 \mu^{\frac{1}{n}} \quad \text{for} \quad i = 1, \ldots, r.$$

Finally, since $\lambda_1, \ldots, \lambda_r$ are within δ of 1, it follows $\alpha_1, \ldots, \alpha_r$ are within $n^3 \mu^{\frac{1}{n}} + \delta$ of 1. □

To obtain the major theorem of the paper requires an additional lemma. The lemma uses the notation

$$d = \min \frac{x_i}{x_j}.$$

LEMMA 3. *Let α be a scalar with $\alpha < \frac{1}{2}$ and suppose $2^n - (\lambda_1 + 1)^n = \alpha^2$. Then*

(i) *A has a μ-block with $\mu \leq \alpha^{1/n}$, or*

(ii) *A is an ϵ nearly stochastic matrix with $\epsilon \leq \alpha^2(1 + 2n)$.*

Proof. Using Corollary 7 in [3], we know that

$$(\lambda_1 + \mu)^n \leq (1+\mu)^n - \mu^n(1-d).$$

Rearranging yields

$$\begin{aligned}\mu^n(1-d) &\leq (1+\mu)^n - (\lambda_1+\mu)^n \\ &\leq 2^n - (\lambda_1+1)^n \\ &= \alpha^2.\end{aligned}$$

Thus, either $\mu^n \leq \alpha$ or $1-d \leq \alpha$. We look at the cases.

Case (i) $\mu^n \leq \alpha$.

In this case, $\mu \leq \alpha^{1/n}$ and so A has a μ-block with $\mu \leq \alpha^{\frac{1}{n}}$.

Case (ii) $1-d \leq \alpha$.

Here we have that

$$1-\alpha \leq \min \frac{x_i}{x_j}.$$

Now, using $e = (1,\ldots,1)^t$, since

$$\begin{aligned}xA &= \lambda_1 x, \\ xAe &= \lambda_1 xe.\end{aligned}$$

Using that $Ae = r = (r_1,\ldots,r_n)^t$, we get

$$xr = \lambda_1,$$

that is,

$$x_1r_1 + \cdots + x_nr_n = \lambda_1.$$

Now let

$$\begin{aligned}x_m &= \min x_i, \qquad & x_M &= \max x_i, \\ r_m &= \min r_i, \qquad & r_M &= \max r_i.\end{aligned}$$

Then

$$(1-x_m)r_M + x_m r_m \geq \lambda_1.$$

Thus,

$$r_M - \lambda_1 \geq x_m(r_M - r_m).$$

Since $\frac{x_m}{x_M} \geq 1-\alpha$ and $xe = 1$, it follows that $x_M \leq \frac{x_m}{1-\alpha}$ and so

$$1 = xe \leq n\frac{x_m}{1-\alpha},$$

that is,

$$(1-\alpha)\frac{1}{n} \leq x_m.$$

Substituting this expression yields

$$r_M - \lambda_1 \geq (1-\alpha)\frac{1}{n}(r_M - r_m).$$

Since $1 \geq r_M$, we have

$$1 - \lambda_1 \geq (1-\alpha)\frac{1}{n}(r_M - r_m).$$

Thus,

$$2 - (\lambda_1 + 1) \geq (1-\alpha)\frac{1}{n}(r_M - r_m)$$

and so

$$2^n - (\lambda_1 + 1)^n \geq (1-\alpha)\frac{1}{n}(r_M - r_m).$$

Hence, by hypothesis,

$$\alpha^2 \geq (1-\alpha)\frac{1}{n}(r_M - r_m),$$

that is,

$$\frac{\alpha^2}{1-\alpha} \geq \frac{1}{n}(r_M - r_m).$$

Continuing, since $\alpha < \frac{1}{2}$ we have

$$2\alpha^2 \geq \frac{1}{n}(r_M - r_m)$$

and so

$$2n\alpha^2 \geq r_M - r_m.$$

Thus,

$$r_m + 2n\alpha^2 \geq r_M.$$

Finally, since

$$\alpha^2 = 2^n - (\lambda_1 + 1)^n \geq 2 - (\lambda_1 + 1) = 1 - \lambda_1,$$

it follows that

$$\lambda_1 \geq 1 - \alpha^2.$$

Using the Perron–Frobenius theory, we have

$$r_M \geq \lambda_1;$$

thus

$$r_M \geq 1 - \alpha^2.$$

Substituting, we have

$$r_m + 2n\alpha^2 \geq 1 - \alpha^2,$$

that is,

$$r_m \geq 1 - \alpha^2(1 + 2n).$$

Thus, A is an ϵ nearly stochastic matrix where $\epsilon \leq \alpha^2(1 + 2n)$. □

THEOREM 3. *If* $1 - \lambda_1 < \delta$ *and* $4^n n^{3n} \delta^{\frac{1}{n^{2n}}} < \frac{1}{4}$, *then* A *has an* ϵ *nearly stochastic matrix where* $\epsilon \leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}$.

Proof. The proof is by induction on n. If $n = 1$, then

$$A = [\lambda_1].$$

Thus, A is an ϵ nearly stochastic matrix where $\epsilon = 1 - \lambda_1$, and since $\epsilon \leq \delta$, the result follows.

Now suppose that the theorem is true for all $k < n$. Suppose that A is an $n \times n$ matrix satisfying the hypothesis. Then, since $1 - \lambda_1 < \delta$, by Lemma 1,

$$2^n - (\lambda_1 + 1)^n \leq n2^n\delta.$$

Thus, by Lemma 3,

(i) A has a μ-block with $\mu \leq \alpha^{1/n}$, or

(ii) A is an ϵ nearly stochastic matrix where $\epsilon \leq \alpha^2(1 + 2n)$, where $\alpha^2 \leq n2^n\delta$ and, from the hypothesis, $\sqrt{n2^n\delta} < \frac{1}{2}$.

Suppose (ii) holds. Then

$$\begin{aligned}
\alpha^2(1 + 2n) &\leq n2^n\delta(1 + 2n) \\
&\leq n2^n\delta(3n) \\
&\leq 3n^2 2^n\delta \text{ and since } n \geq 2 \\
&\leq n^4 2^n\delta \\
&\leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}.
\end{aligned}$$

Thus, A has a ϵ nearly stochastic matrix where $\epsilon \leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}$, and the theorem follows.

Now, suppose that (i) holds. Then A has an μ-block where $\mu \leq \alpha^{\frac{1}{n}}$ and where $\alpha^2 \leq n2^n\delta$. Let P be a permutation matrix where

$$PAP^t = \begin{bmatrix} A_1 & U \\ A_{21} & A_2 \end{bmatrix}$$

and $\mu(U) = \mu \leq [n2^n\delta]^{\frac{1}{2n}}$. Then, by Theorem 2, noting $\mu \leq \frac{1}{n}$ from the hypothesis, the dominant eigenvalue μ_1 of

$$\bar{A} = \begin{bmatrix} A_1 & 0 \\ A_{21} & A_2 \end{bmatrix}$$

is such that

$$1 - \mu_1 \leq n^3((n2^n\delta)^{\frac{1}{2n}})^{\frac{1}{n}} + \delta.$$

Since $n^{\frac{1}{n}} \leq 3^{\frac{1}{3}}$ for all n,

$$n^3((n2^n\delta)^{\frac{1}{2n}})^{\frac{1}{n}} + \delta \leq 4n^3\delta^{\frac{1}{2n^2}}.$$

Since μ_1 is an eigenvalue of A_1 or A_2, without loss of generality, we will assume that μ_1 is an eigenvalue of A_1 and that A_1 is $m \times m$.

Applying the induction hypothesis to A_1 yields that A_1 has an ϵ nearly stochastic matrix with

$$\begin{aligned}\epsilon &\leq 4^m m^{3m}[4n^3\delta^{\frac{1}{2n^2}}]^{\frac{1}{m^{2m}}} \\ &= 4^m m^{3m} 4^{\frac{1}{m^{2m}}} n^{\frac{3}{m^{2m}}} \delta^{\frac{1}{2n^2 m^{2m}}},\end{aligned}$$

and, using that $2n^2(n-1)^{2(n-1)} \leq n^{2n}$ (which follows by the binomial formula to show $2k^{2k} \leq (k+1)^{2k}$),

$$\begin{aligned}&\leq 4^m m^{3m} 4n^3 \delta^{\frac{1}{n^{2n}}} \\ &\leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}.\end{aligned}$$

This concludes the induction. □

This result extends to the major result of the paper.

THEOREM 4. *If $|1-\lambda_k| < \delta$ for $k = 1, \ldots, r$ and $4^n n^{3n} \delta^{\frac{1}{n^{2n}}} < \frac{1}{4}$, then A has r disjoint ϵ nearly stochastic matrices with $\epsilon \leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}$.*

Proof. The proof is by induction on n. For $n = 1$, the proof follows from Theorem 3.

Now, suppose the theorem is true for all $n \times n$ substochastic matrices where $m < n$. Let A denote an $n \times n$ substochastic matrix with $|1-\lambda_k| < \delta$ for $k = 1, \ldots, r$. If $r = 1$, the proof follows from Theorem 3. Thus, we can assume $r \geq 2$.

By Lemma 1, since $|1-\lambda_2| < \delta$, it follows that

$$2^n - |1+\lambda_2|^n \leq n2^n\delta.$$

By Theorem 1, A has a μ-block where $\mu \leq 2n^{\frac{1}{n}}\delta^{\frac{1}{n}}$. Let P be a permutation matrix such that

$$PAP^t = \begin{bmatrix} A_1 & U \\ A_{21} & A_2 \end{bmatrix},$$

where U is a μ-block, A_1 is $n_1 \times n_1$, and A_2 is $n_2 \times n_2$.

Now, by Theorem 2, since $\mu \leq \frac{1}{n}$, by using the hypothesis,

$$\bar{A} = \begin{bmatrix} A_1 & 0 \\ A_{21} & A_2 \end{bmatrix}$$

has r eigenvalues $\mu_1, \ldots, \mu_r$ such that

$$\begin{aligned}|1-\mu_i| &\leq n^3\mu^{\frac{1}{n}} + \delta \\ &\leq n^3[2n^{\frac{1}{n}}\delta^{\frac{1}{n}}]^{\frac{1}{n}} + \delta \\ &\leq 3n^3\delta^{\frac{1}{n^2}} + \delta \\ &\leq 4n^3\delta^{\frac{1}{n^2}}.\end{aligned}$$

Without loss of generality, suppose $\mu_1, \ldots, \mu_s$ are eigenvalues of A_1 while $\mu_{s+1}, \ldots, \mu_r$ are eigenvalues of A_2. Then, by the induction hypothesis, A_1 has s and A_2 has $r-s$ disjoint ϵ nearly stochastic matrices with

$$\epsilon \leq 4^{n_1} n_1^{3n_1} [4n^3 \delta^{\frac{1}{n^2}}]^{\frac{1}{n_1^{2n_1}}}, \qquad \epsilon \leq 4^{n_2} n_2^{3n_2} [4n^4 \delta^{\frac{1}{n^2}}]^{\frac{1}{n_2^{2n_2}}},$$

respectively. Thus A has r disjoint ϵ nearly stochastic matrices with $\epsilon \leq 4^n n^{3n} \delta^{\frac{1}{n^{2n}}}$, the result of the theorem. □

In [7], Seneta gave an upper bound for his condition number, namely,

$$\mathcal{T}(A^{\#}) \leq \frac{n}{|1-\lambda_2|}.$$

Theorem 4 assures us that

$$\epsilon \leq 4^n n^{3n} |1-\lambda_2|^{\frac{1}{n^{2n}}}$$

or

$$\Big[\frac{\epsilon}{4^n n^{3n}}\Big]^{n^{2n}} \leq |1-\lambda_2|.$$

Substitution yields

$$\mathcal{T}(A^{\#}) \leq \frac{n[4^n n^{3n}]^{n^{2n}}}{\epsilon^{n^{2n}}}.$$

Thus, for fixed n, if $\mathcal{T}(A^{\#})$ is sufficiently large, the appearance of two disjoint ϵ nearly stochastic occurs. Of course, we would like much better bounds. Using Theorem 1, in a like manner, we have

$$\mathcal{T}(A^{\#}) \leq \frac{n^2 2^n}{\mu^n},$$

where μ small implies one ϵ nearly stochastic matrix where $\epsilon \leq (n-1)\mu$. However, it is hoped that better bounds can still be found.

Finally, Seneta [7, p. 166] proves that

$$\mathcal{T}(A^{\#}) = \max_{i,j} \sum_{s=1}^{n} \max(a_{is}^{\#}, a_{js}^{\#}).$$

Using this expression, it is easy to see that

$$K(A) \leq \mathcal{T}(A^{\#}) \leq nK(A).$$

Thus, the results we have given in terms of $\mathcal{T}$ can be converted to ones involving K.

NORMS OF LARGE TOEPLITZ BAND MATRICES*

A. BÖTTCHER†, S. GRUDSKY‡, A. KOZAK‡, AND B. SILBERMANN†

Abstract. Let $T(b_{jk})$ be a finite collection of infinite Toeplitz band matrices, let $T_n(b_{jk})$ denote their $(n+1)\times(n+1)$ truncations, and put

$$A_n = \sum_j \prod_k T_n(b_{jk}), \quad M_p = \lim_{n\to\infty} \|A_n\|_p,$$

where $\|\cdot\|_p$ stands for the operator norm associated with the l^p-norm ($1 \le p < \infty$) on $\mathbf{C}^{n+1}$. We establish tight two-sided estimates for the difference $M_p - \|A_n\|_p$. It is well known that if $T(b)$ is a Hermitian Toeplitz band matrix and $A_n = T_n(b)$, then $M_2 - \|A_n\|_2$ goes to zero with polynomial speed. We show that such a slow convergence rate is, in a sense, an exceptional case, and we prove that in the generic case $M_p - \|A_n\|_p$ approaches zero with exponential speed. Our results yield good error estimates when computing the norms of certain infinite matrices via their large truncations and, conversely, when determining the norms of certain large matrices by having recourse to known norms of infinite matrices.

Key words. Toeplitz matrix, band matrix, matrix norm

1. Introduction and main results.

For $1 \le p < \infty$, we denote by $l^p := l^p(\mathbf{Z}_+)$ and $l^p[0,n]$ the usual l^p spaces over $\mathbf{Z}_+ := \{0,1,2,\ldots\}$ and $\{0,1,\ldots,n\}$, respectively. Given a trigonometric polynomial

$$b(t) = \sum_{j=-s}^{s} b_j\, t^j, \quad t = e^{i\theta} \in \mathbf{T} \tag{1.1}$$

on the complex unit circle $\mathbf{T}$, we let

$$T(b) := (b_{j-k})_{j,k=0}^{\infty} \quad \text{and} \quad T_n(b) := (b_{j-k})_{j,k=0}^{n}$$

stand for the infinite and $(n+1)\times(n+1)$ Toeplitz matrices generated by b. Clearly, $T(b)$ and $T_n(b)$ are band matrices. The matrices $T(b)$ and $T_n(b)$ induce bounded linear operators on l^p and $l^p[0,n]$ in the natural manner. The norms of these operators will be denoted by $\|T(b)\|_p$ and $\|T_n(b)\|_p$:

$$\|T(b)\|_p := \sup_{\substack{x\in l^p \\ \|x\|_p=1}} \|T(b)x\|_p, \quad \|T_n(b)\|_p := \sup_{\substack{x\in l^p[0,n] \\ \|x\|_p=1}} \|T_n(b)x\|_p.$$

We may think of $l^p[0,n]$ as a subspace of l^p by identifying $l^p[0,n]$ with the image of the canonical projection

$$P_n : l^p \to l^p, \ \ (x_0, x_1, x_2, \ldots) \mapsto (x_0, \ldots, x_n, 0, 0, \ldots).$$

Accordingly, we can write $T_n(b) = P_n T(b) P_n|\mathrm{Im}\, P_n$. Since $\|P_n\|_p = 1$ and $P_n \to I$ strongly on l^p as $n \to \infty$, it follows that $\|T_n(b)\|_p \le \|T(b)\|_p$ for all n and that $\|T(b)\|_p \le \liminf_{n\to\infty} \|T_n(b)\|_p$. Consequently,

$$\lim_{n\to\infty} \|T_n(b)\|_p = \|T(b)\|_p.$$

The purpose of this paper is to establish tight estimates for the difference $\|T(b)\|_p - \|T_n(b)\|_p$ and the difference of the norms of related operators.

The norm of the operator A induced by the matrix (a_{jk}) on l^1 is given by

$$\|A\|_1 = \sup_k \sum_j |a_{jk}|. \tag{1.2}$$

This implies that

$$\|T_n(b)\|_1 = \|T(b)\|_1 = \sum_{j=-s}^{s} |b_j| \ \text{ for } \ n \ge 2s+1.$$

Hence, in the case $p = 1$, our problem is trivial. For $p = 2$, we have

$$\|T(b)\|_2 = \|b\|_\infty := \max_{t\in\mathbf{T}} |b(t)|,$$

but in general $\|T_n(b)\|_2$ is not explicitly available. We prove the following.

THEOREM 1.1. *There exists a constant c depending only on b such that*

$$\|b\|_\infty (1 - c/n^2) \le \|T_n(b)\|_2 \le \|b\|_\infty \ \textit{for all } n.$$

Thus, $\|T_n(b)\|_2$ approaches $\|T(b)\|_2 = \|b\|_\infty$ at least as $O(1/n^2)$. The eigenvalues of the Hermitian matrix $T_n(b)$ generated by $b(t) = 3 - t - t^{-1}$ are

$$\lambda_k^{(n)} = 3 + 2\cos\frac{k\pi}{n+2} \quad (k = 1, 2, \ldots, n+1).$$

Since $\|T_n(b)\| = \lambda_1^{(n)}$ and $\|b\|_\infty = 5$, it follows that

$$\|b\|_\infty - \|T_n(b)\|_2 = 2\left(1 - \cos\frac{\pi}{n+2}\right) = \frac{\pi^2}{(n+2)^2} + O\left(\frac{1}{n^4}\right),$$

which shows that Theorem 1.1 is sharp.

In case we know more about b, we can say more about the speed with which $\|T_n(b)\|_2$ converges to $\|b\|_\infty$. The function $\|b\|_\infty - |b(t)|$ has finitely many zeros on $\mathbf{T}$, and each zero is of even order.

THEOREM 1.2. *Let 2γ be the maximal order of the zeros of $\|b\|_\infty - |b(t)|$; that is, let $\gamma \ge 1$ be the maximal integer for which there are $t_0 \in \mathbf{T}$ and $D \in (0,\infty)$ such that*

$$\|b\|_\infty - |b(t)| \le D|t - t_0|^{2\gamma} \ \textit{for all } t \in \mathbf{T}. \tag{1.3}$$

Then there exist constants $0 < d_1 < d_2 < \infty$ *independent of* n *such that*

$$\|b\|_\infty(1 - d_2/n^{2\gamma}) \le \|T_n(b)\|_2 \le \|b\|_\infty(1 - d_1/n^{2\gamma}) \text{ for all } n. \tag{1.4}$$

Since b is a trigonometric polynomial, estimate (1.3) is always true with $\gamma = 1$, if only $|b(t_0)| = \|b\|_\infty$. Thus, Theorem 1.1 is a direct consequence of Theorem 1.2. We remark that Theorem 1.2 is well known where case b is real-valued and, hence, $T_n(b)$ is Hermitian; see Kac, Murdock, and Szegő [6]; Grenander and Szegő [4]; Widom [10]; Parter [7]; and Serra [8], [9], for example. In this case, $\|T_n(b)\|_2$ is the maximal eigenvalue of $T_n(b)$, and in the aforementioned works it is shown that if 2γ is the maximal order of the zeros of $\|b\|_\infty - b(t)$, then estimate (1.4) holds.

The matrices one has to deal with in practice are frequently not pure Toeplitz band matrices but perturbed Toeplitz band matrices. Let R_n be the operator

$$R_n : \ l^p \to l^p, \ (x_0, x_1, x_2, \ldots) \mapsto (x_n, x_{n-1}, \ldots, x_0, 0, 0, \ldots).$$

We consider band matrices of the form

$$B_n = T_n(b) + P_nKP_n + R_nLR_n, \tag{1.5}$$

where b is a trigonometric polynomial of the form (1.1) and where the infinite matrices K and L have only a finite number of nonzero entries, which means that

$$P_{n_0}KP_{n_0} = K, \quad P_{n_0}LP_{n_0} = L \tag{1.6}$$

for some n_0. Of course, in (1.5) we identify the images of P_n and R_n with $l^p[0, n]$, while in (1.6) we think of P_n and R_n as acting in l^p. Thus, matrix (1.5) differs from $T_n(b)$ by the $(n_0 + 1) \times (n_0 + 1)$ block K in the upper left and the $(n_0 + 1) \times (n_0 + 1)$ block $R_{n_0}LR_{n_0}$ in the lower right corners. For example, if b_{jk} is a finite collection of trigonometric polynomials, then $B_n = \sum_j \prod_k T_n(b_{jk})$ can be shown to be of the form (1.1), (1.5), and (1.6).

Define $\tilde{b}$ by $\tilde{b}(t) := b(1/t)$ $(t \in \mathbf{T})$. If B_n is given by (1.5) and (1.6), then

$$B_n \to T(b) + K =: B, \quad R_nB_nR_n \to T(\tilde{b}) + L =: \tilde{B} \tag{1.7}$$

strongly as $n \to \infty$. Put

$$M_p^0 := \|T(b)\|_p, \quad M_p := \max\Big(\|B\|_p, \ \|\tilde{B}\|_p\Big).$$

Since $\|T(a)+K\|_p \ge \|T(a)\|_p$ for every trigonometric polynomial a and every compact operator K, and since $\|T(a)\|_p = \|T(\tilde{a})\|_p$ for every trigonometric polynomial a (see, e.g., [3, 6.2(a),(b),(c)]), we always have $M_p^0 \le M_p$.

With s and n_0 given by (1.1) and (1.6), put $m_0 := \max(s, n_0)$. Using (1.2), it is easy to see that

$$\|B_n\|_1 = M_1 \text{ for all } n \ge 2m_0 + 1,$$

so that the case $p = 1$ is again uninteresting. For general p, we will prove the following.

THEOREM 1.3. *Suppose* $M_p^0 < M_p$. *If* $s \ge 1$ *and* $n \ge 4(m_0 + s + 1)$, *then*

$$M_p(1 - c_p\varrho_p^n) \le \|B_n\|_p \le M_p(1 + c_p\varrho_p^n), \tag{1.8}$$

where

$$c_p := 2s\left(\frac{M_p}{M_p^0}\right)^{\frac{m_0+2s+2}{2s}}, \quad \varrho_p := \left(\frac{M_p^0}{M_p}\right)^{\frac{1}{4s}}.$$

As $0 < \varrho_p < 1$, it follows that $\|B_n\|_p$ converges to M_p with exponential speed.

To have a simple concrete example, let

$$B = T(b) + K := \begin{pmatrix} 3 & 84 & 0 & \dots \\ -1 & 3 & -1 & \dots \\ 0 & -1 & 3 & \dots \\ \dots & \dots & \dots & \dots \end{pmatrix}$$

and put $B_n := T_n(b) + P_nKP_n$. We have

$$M_2^0 = \|T(b)\|_2 = \|T(\tilde{b})\|_2 = \|b\|_\infty = 5, \quad \|K\|_2 = 85,$$

whence

$$80 = \|K\|_2 - \|T(b)\|_2 \le \|T(b) + K\|_2 \le \|K\|_2 + \|T(b)\|_2 = 90,$$

and thus $M_2^0 < M_2 = \max\Big(\|T(b) + K\|_2, \|T(\tilde{b})\|_2\Big)$. Furthermore,

$$c_2 = 2\left(\frac{M_2}{M_2^0}\right)^{\frac{m_0+2s+2}{2s}} \le 2\left(\frac{90}{5}\right)^{\frac{1+2+2}{2}} < 2750,$$
$$\varrho_2 = \left(\frac{M_2^0}{M_2}\right)^{\frac{1}{4s}} \le \left(\frac{5}{80}\right)^{\frac{1}{4}} = \frac{1}{2}$$

and therefore, by Theorem 1.3,

$$\Big|\, \|B_n\|_2 - \|B\|_2 \Big| \le M_2 c_2 \varrho_2^n \le 90 \cdot 2750 \cdot \left(\frac{1}{2}\right)^n = \frac{247\,500}{2^n}.$$

In particular,

$$\Big|\, \|B_{31}\|_2 - \|B\|_2 \Big| < 0.00011526.$$

Matlab gives $\|B_{31}\|_2 = 84.11171884\ldots$, and hence we arrive at the following fairly precise information on the norm of the infinite matrix B:

$$\|B\|_2 = 84.11171884 \pm 0.00011526.$$

The crucial assumption of Theorem 1.3 is the strict inequality $M_p^0 < M_p$. Let $\mathcal{A}_p$ be the set of all operators on l^p that are of the form $T(a) + K$ with a trigonometric polynomial a and an operator K whose matrix has only finitely many nonzero entries. We remark that if $T(a) + K = T(b) + L \in \mathcal{A}_p$, then necessarily $a = b$ and $K = L$. Furthermore, let $\mathcal{A}_p^0$ be the set of all operators $T(a)+K \in \mathcal{A}_p$ such that $\|T(a)+K\|_p > \|T(a)\|_p$.

PROPOSITION 1.4. *The set $\mathcal{A}_2^0$ is an open and dense subset of $\mathcal{A}_2$.*

If $p = 2$, the operators B and $\tilde{B}$ defined by (1.7) belong to $\mathcal{A}_2$. Proposition 1.4 therefore tells us that the strict inequality $M_2^0 < M_2$ represents the generic case,

whereas the equality $M_2^0 = M_2$ is the exceptional case. Thus, Theorem 1.3 says that generically $\|B_n\|_2 - M_2$ approaches zero with exponential speed.

In concrete situations, we nevertheless often encounter the exceptional case $M_p^0 = M_p$. For instance, we are in this case whenever $B_n = T_n(b)$. The following theorem does certainly not give sharp estimates, but it provides us with a universal estimate with good constants.

THEOREM 1.5. *Suppose $M_p^0 = M_p$. If $s \geq 1$ and $n \geq 4\max(n_0, 72s)$, then*

$$M_p\Big(1 - \frac{291}{p}\frac{s}{n}\Big) \leq \|B_n\|_p \leq M_p\Big(1 + \frac{8}{p}\frac{s}{n}\Big).$$

Full proofs of the results cited above will be given in sections 2, 3, and 4.

The present paper emerged from our papers [1], [2], [5], in which we studied the behavior of the norms of the inverses of (not necessarily band) Toeplitz matrices. In [5], we gave estimates for the speed with which $\|T_n^{-1}(a)\|_1$ approaches $\|T^{-1}(a)\|_1$, provided $T(a)$ is invertible (notice that in the $p = 1$ case we can have recourse to (1.2)). In [1], we considered the case where $T(a)$ is not invertible but still semidefinite, and we established results which show that the spectral condition numbers $\kappa(T_n(a)) := \|T_n(a)\|_2\,\|T_n^{-1}(a)\|_2$ can grow like $\log n$, n^α, or even $e^{\alpha n}$ as $n \to \infty$. Finally, in [2] we were able to prove that $\|T_n(a)\|_p\|T_n^{-1}(a)\|_p$ converges to $\|T^{-1}(a)\|_p\,\|T^{-1}(a)\|_p$. To estimate the *speed* of convergence, we need know the speed with which $\|T_n(a)\|_p$ converges to $\|T(a)\|_p$ and the speed with which $\|T_n^{-1}(a)\|_p$ goes to $\|T^{-1}(a)\|_p$. The former problem (for band matrices) is the subject of the present paper. The latter question can be answered by combining the results of this paper with appropriate approximation arguments, which will be dealt with in a forthcoming paper.

To prove estimates like (1.4) and (1.8), we need sufficiently precise techniques. The techniques employed in sections 2, 3, and 4 are essential refinements of those developed in [1], [2], [5]. These techniques allow us to give nearly self-contained proofs of the results quoted above.

2. Pure Toeplitz matrices. This section is devoted to the proof of Theorem 1.2.

Proof. Let b be given by (1.1). We have

$$T_n(b)T_n(\overline{b}) = T_n(|b|^2) + P_nKP_n + R_nLR_n$$

where $K = -H(b)H(\tilde{\overline{b}})$, $L = -H(\tilde{b})H(\overline{b})$, and $H(a)$ is the Hankel matrix $H(a) := (a_{j+k+1})_{j,k=0}^\infty$; also recall that $\tilde{a}(t) := a(1/t)$.

Since $(Kx, x) \leq 0$ and $(Lx, x) \leq 0$ for all $x \in l^2$, it follows that $(T_n(b)T_n(\overline{b})x, x) \leq (T_n(|b|^2)x, x)$ for all $x \in l^2$, whence

$$\|T_n(b)\|_2^2 = \|T_n(b)T_n(\overline{b})\|_2 \leq \|T_n(|b|^2)\|_2.$$

As the estimate (1.4) is known for Hermitian matrices (see Serra [8], [9]), we obtain

$$\|T_n(b)\|_2^2 \leq \|\,|b|^2\|_\infty\Big(1 - d/n^{2\gamma}\Big) = \|b\|_\infty^2\Big(1 - d/n^{2\gamma}\Big),$$

which implies that $\|T_n(b)\|_2 \leq \|b\|_\infty(1 - d_1/n^{2\gamma})$ with $d_1 := d/2 \in (0, \infty)$.

We are left with the estimate $\|T_n(b)\|_2 \geq \|b\|_\infty(1 - d_2/n^{2\gamma})$. Obviously, (1.6) is satisfied with $n_0 = s - 1$. Put $M = \|b\|_\infty^2$. Since

$$T_n\Big(b(t/t_0)\Big) = \operatorname{diag}(1, t_0^{-1}, \ldots, t_0^{-n})T_n(b)\,\operatorname{diag}(1, t_0, \ldots, t_0^n),$$

we can, without loss of generality, assume that $M = |b(1)|^2$. By virtue of (1.3), there exists a constant $C \in (0,\infty)$ such that

$$M - |b(e^{i\theta})|^2 \le C|\theta|^{2\gamma} \quad \text{for all} \quad \theta \in [-\pi,\pi]. \tag{2.1}$$

For $f \in l^2[0,n]$,

$$\begin{aligned} \|T_n(b)\|_2^2\|f\|_2^2 &= \|T_n(b)T_n(\overline{b})\|_2\|f\|_2^2 \ge |(T_n(b)T_n(\overline{b})f,f)| \\ &\ge M(f,f) - \Big|\Big((M - T_n(|b|^2))f,f\Big)\Big| - |(P_nKP_nf,f)| - |(R_nLR_nf,f)|. \end{aligned} \tag{2.2}$$

We identify $l^2[0,n]$ with the polynomials of degree at most n and, accordingly,

$$(f,g) = \frac{1}{2\pi}\int\limits_{-\pi}^{\pi} f(e^{i\theta})\,\overline{g(e^{i\theta})}\,d\theta \quad \text{for} \quad f,g \in l^2[0,n].$$

Put $j = \gamma+1$, let m be the integer satisfying $mj \le n < (m+1)j$, and define $f \in l^2[0,n]$ by

$$f(e^{i\theta}) = (1 + e^{i\theta} + \cdots + e^{im\theta})^j. \tag{2.3}$$

It is easily seen that

$$f(e^{i\theta}) = e^{imj\theta/2}\left(\frac{\sin((m+1)\theta/2)}{\sin(\theta/2)}\right)^j, \tag{2.4}$$

and in [1] it was shown that

$$\|f\|_2 > \frac{4}{3\sqrt{\pi}}j^{-1/4}(m+1)^{j-1/2}. \tag{2.5}$$

We now estimate the terms on the right of (2.2). By (1.6),

$$|(P_nKP_nf,f)| = |(P_{n_0}KP_{n_0}f,f)| = |(KP_{n_0}f,P_{n_0}f)| \le \|K\|_2\|P_{n_0}f\|_2^2,$$

and from (2.3) we infer that $\|P_{n_0}f\|_2$ is independent on n if only n (and thus m) is large enough. Consequently, by (2.5),

$$\frac{|(P_nKP_nf,f)|}{\|f\|_2^2} \le \frac{C_1}{(m+1)^{2j-1}} < \frac{C_1j^{2j-1}}{n^{2j-1}} = \frac{C_1(\gamma+1)^{2\gamma+1}}{n^{2\gamma+1}} \tag{2.6}$$

with some $C_1 \in (0,\infty)$ independent of n. Analogously,

$$\frac{|(R_nLR_nf,f)|}{\|f\|_2^2} \le \frac{C_2(\gamma+1)^{2\gamma+1}}{n^{2\gamma+1}} \tag{2.7}$$

where $C_2 \in (0,\infty)$ does not depend on n. From (2.1) and (2.4) we get

$$\begin{aligned} \Big|\Big((M - T_n(|b|^2))f,f\Big)\Big| &= \Big|\Big((M - |b|^2)f,f\Big)\Big| \\ &= \frac{1}{2\pi}\int\limits_{-\pi}^{\pi}\Big(M - |b(e^{i\theta})|^2\Big)\left|\frac{\sin((m+1)\theta/2)}{\sin(\theta/2)}\right|^{2j}d\theta \end{aligned}$$

$$\leq \frac{1}{2\pi}\int\limits_{|\theta|<1/(m+1)} C|\theta|^{2\gamma}\left(\frac{(m+1)|\theta|}{2}\right)^{2j}\left(\frac{\pi}{2}\frac{2}{|\theta|}\right)^{2j}d\theta$$
$$+\frac{1}{2\pi}\int\limits_{|\theta|>1/(m+1)} C|\theta|^{2\gamma}\left(\frac{\pi}{2}\frac{2}{|\theta|}\right)^{2j}d\theta$$
$$\leq C_3\frac{(m+1)^{2j}}{(m+1)^{2\gamma+1}}+C_4\frac{1}{(m+1)^{2j-2\gamma}}$$
$$= C_3\frac{(m+1)^{2\gamma+2}}{(m+1)^{2\gamma+1}}+C_4\frac{1}{(m+1)^2}\leq C_5 n$$

with constants $C_3, C_4, C_5 \in (0,\infty)$ independent on n. Taking into account (2.5) we therefore obtain

$$\frac{|((M-T_n(|b|^2))f,f)|}{\|f\|^2}\leq C_6\frac{n}{n^{2j-1}}=C_6\frac{1}{n^{2\gamma}}, \tag{2.8}$$

where $C_6 \in (0,\infty)$ is independent on n. Combining (2.2), (2.6), (2.7), and (2.8), we arrive at the estimate

$$\|T_n(b)\|_2^2\geq M\left(1-C_7\frac{1}{n^{2\gamma}}\right),$$

where $C_7 \in (0,\infty)$ is independent of n, whence

$$\|T_n(b)\|_2\geq\|b\|_\infty\left(1-C_7\frac{1}{n^{2\gamma}}\right) \tag{2.9}$$

whenever $n^{2\gamma} > C_7$. This completes the proof of Theorem 1.2. □

3. The exceptional case. The purpose of this section is to prove Theorem 1.5 and to prepare the proof of Theorem 1.3.

The following result extends a weakened version of Theorem 1.1 to general p.

PROPOSITION 3.1. *Let b given by* (1.1). *If $n \geq 144s$, then*

$$\|T(b)\|_p\left(1-\frac{144}{p}\frac{s}{n}\right)\leq\|T_n(b)\|_p\leq\|T(b)\|_p.$$

Proof. The case $s = 0$ is trivial. So let $s \geq 1$. Put $M_0 := \|T(b)\|_p$ and $\varepsilon_n := M_0 - \|T_n(b)\|_p$. It is clear that ε_n decreases monotonously to zero. Given n, pick $x \in l^p[0,n]$ so that

$$\|x\|_p=\left(\sum_{j=0}^{n}|x_j|^p\right)^{1/p}=1 \text{ and } \|T_n(b)x\|_p=M_0-\varepsilon_n. \tag{3.1}$$

Let $l := [n/4]$, where here and in what follows $[\alpha]$ is the integral part of the number α. We claim that there is a natural number m such that

$$l+s\leq m\leq 3l-s \text{ and } \sum_{j=m-s+1}^{m+s}|x_j|^p<\left[\frac{l}{s}\right]^{-1}. \tag{3.2}$$

Indeed, we have

$$1 \geq \sum_{j=l+1}^{3l} |x_j|^p \geq \sum_{k=0}^{d-1} \Big(\sum_{j=l+2ks+1}^{l+2(k+1)s} |x_j|^p \Big),$$

where $d := [l/s]$, which shows that there exists a k_0 such that $0 \leq k_0 \leq d-1$ and the inner sum does not exceed d^{-1}. Letting $m := l + (2k_0+1)s$, we obtain our claim (3.2).

Define $P_{[j,k]} := P_k - P_{j-1}$. Thus, $P_{[j,k]}$ acts by the rule

$$P_{[j,k]} : l^p \to l^p,\ (x_0, x_1, x_2, \ldots) \mapsto (0, \ldots, 0, x_j, \ldots, x_k, 0, 0, \ldots).$$

Since $T_n(b)$ has only $2s+1$ nonzero diagonals, we get

$$\begin{aligned} T_n(b)x &= P_m T_n(b)x + P_{[m+1,n]} T_n(b)x \\ &= P_m T_n(b)(x_j)_{j=0}^{m+s} + P_{[m+1,n]} T_n(b)(x_j)_{j=m-s+1}^{n}, \end{aligned}$$

where $m = l + (2k_0+1)s$ is as above. Hence

$$\|T_n(b)x\|_p^p = \|P_m T_n(b)(x_j)_{j=0}^{m+s}\|_p^p + \|P_{[m+1,n]} T_n(b)(x_j)_{j=m-s+1}^{n}\|_p^p.$$

It can be directly verified that

$$R_n P_{[m+1,n]} T_n(b) P_{[m-s+1,n]} R_n = P_{n-m-1} T_{n-m+s-1}(\tilde{b}).$$

Because R_n is isometric on $l^p[0,n]$ and $P_m = P_m P_{m+s}$, it follows that

$$\begin{aligned} \|T_n(b)x\|_p^p &\leq \|T_{m+s}(b)(x_j)_{j=0}^{m+s}\|_p^p + \|T_{n-m+s-1}(\tilde{b})(x_{n-j})_{j=0}^{n-m+s-1}\|_p^p \\ &\leq (M_0 - \varepsilon_{m+s})^p \sum_{j=0}^{m+s} |x_j|^p + (M_0 - \varepsilon_{n-m+s-1})^p \sum_{j=m-s+1}^{n} |x_j|^p. \end{aligned}$$

As $\max(m+s, n-m+s-1) \leq n-l$ and as ε_n goes monotonously to zero, we see that

$$\begin{aligned} \|T_n(b)x\|_p^p &\leq (M_0 - \varepsilon_{n-l})^p \Big(\sum_{j=0}^{m+s} |x_j|^p + \sum_{j=m-s+1}^{n} |x_j|^p \Big) \\ &\leq (M_0 - \varepsilon_{n-l})^p + M_0^p [l/s]^{-1}, \end{aligned}$$

the last inequality resulting from (3.1) and (3.2). The second equality of (3.1) now gives

$$(M_0 - \varepsilon_n)^p \leq (M_0 - \varepsilon_{n-l})^p + M_0^p [l/s]^{-1}$$

or, equivalently,

$$\Big(1 - \frac{\varepsilon_n}{M_0}\Big)^p - \Big(1 - \frac{\varepsilon_{n-l}}{M_0}\Big)^p \leq \Big[\frac{l}{s}\Big]^{-1}. \tag{3.3}$$

Recall that $l = [n/4]$ and put $n_1 = [4n/3]$. Taking into account the identity

$$n = [4n/3] - \Big[\frac{[4n/3]}{4}\Big]$$

and the inequality

$$\left[\left[\frac{[4n/3]}{4}\right]\Big/ s\right]^{-1} \le \frac{12s}{n} \quad \text{for} \quad n > 5 + 4s,$$

and replacing in (3.3) the number n by n_1, we arrive at the inequality

$$\left(1 - \frac{\varepsilon_{n_1}}{M_0}\right)^p - \left(1 - \frac{\varepsilon_n}{M_0}\right)^p \le \frac{12s}{n} \quad \text{for} \quad n > 5 + 4s. \tag{3.4}$$

Now substitute the n in (3.4) consecutively by

$$n_1 = \left[\frac{4}{3}n\right],\ n_2 = \left[\frac{4}{3}n_1\right], \ldots, n_j = \left[\frac{4}{3}n_{j-1}\right],$$

add the corresponding inequalities, and then pass to the limit $j \to \infty$. What results is

$$1 - \left(1 - \frac{\varepsilon_n}{M_0}\right)^p \le \frac{12s}{n} + \sum_{j=1}^{\infty} \frac{12s}{n_j}.$$

As $[4n/3] > 6n/5$ for $n \ge 8$, we get

$$1 - \left(1 - \frac{\varepsilon_n}{M_0}\right)^p \le \frac{12s}{n} \sum_{j=0}^{\infty} \left(\frac{5}{6}\right)^j = \frac{72s}{n}.$$

Thus, if $n \ge 72s$, then

$$\varepsilon_n \le \left(1 - \left(1 - \frac{72s}{n}\right)^{1/p}\right) M_0.$$

Because $(1-x)^{1/p} \ge 1 - 2x/p$ for $0 \le x \le 1/2$, we finally obtain $\varepsilon_n \le 144 M_0 s/(pn)$ for $n \ge 144s$. Since $n > 5 + 4s$ and $n \ge 8$ whenever $n \ge 144s$ and $s \ge 1$, the proof is complete. □

Now let B_n be given by (1.1), (1.5), and (1.6). The following result gives a universal estimate of $\|B_n\|_p$ from above and shows that the right estimate of Theorem 1.5 is true without the additional hypothesis $M_p^0 = M_p$.

PROPOSITION 3.2. *If $s \ge 1$ and $n \ge 4\max(n_0, 2s+2)$, then*

$$\|B_n\|_p \le M_p\left(1 + \frac{8}{p}\frac{s}{n}\right).$$

Proof. Choose $x = (x_j)_{j=0}^n$ so that $\|x\|_p = 1$. Put $l := [n/4]$. By assumption, $l \ge \max(n_0, s)$. As in the proof of Proposition 3.1, there is a natural number m satisfying (3.2) and we obtain

$$\|B_n x\|_p^p = \|P_m B_n (x_j)_{j=0}^{m+s}\|_p^p + \|P_{[m+1,n]} B_n (x_j)_{j=m-s+1}^n\|_p^p.$$

We have

$$R_n P_{[m+1,n]} B_n P_{[m-s+1,n]} R_n = P_{n-m-1} R_n B_n R_n P_{n-m+s-1},$$

which shows that

$$\begin{aligned}\|B_n x\|_p^p &= \Big\|P_m\Big(T(b)+K\Big)(x_j)_{j=0}^{m+s}\Big\|_p^p \\ &\quad +\Big\|P_{n-m-1}\Big(T(\tilde b)+L\Big)(x_{n-j})_{j=0}^{n-m+s-1}\Big\|_p^p \\ &\le \|B\|_p^p \sum_{j=0}^{m+s}|x_j|^p + \|\tilde B\|_p^p \sum_{j=m-s+1}^{n}|x_j|^p \\ &\le \max\Big(\|B\|_p^p,\ \|\tilde B\|_p^p\Big)\Big(1+\sum_{j=m-s+1}^{m+s}|x_j|^p\Big) \\ &\le M_p^p\Big(1+[l/s]^{-1}\Big);\end{aligned}$$

here we made use of the notation (1.7), of the equality $\|x\|_p = 1$, and of (3.2). If $n \ge 8+8s$ (which is satisfied by assumption), then $[l/s]^{-1} \le 8s/n$, whence

$$\|B_n\|_p \le M_p\Big(1+\frac{8s}{n}\Big)^{1/p} \le M_p\Big(1+\frac{8}{p}\frac{s}{n}\Big).$$

This completes the proof. □

Here now is the *proof of Theorem* 1.5.

The upper estimate is immediate from Proposition 3.2. We are thus left with the estimate from below. By Proposition 3.1, there is an $x \in l^p[0,[n/2]]$ such that $\|x\|_p = 1$ and

$$\|T_{[n/2]}(b)x\|_p \ge M_p^0\Big(1-\frac{144}{p}\frac{s}{[n/2]}\Big).$$

Let $l = [n/4]$ and define $y \in l^p[0,n]$ by

$$y = (\underbrace{0,\dots,0}_{l}, x_0, x_1, \dots, x_{[n/2]}, \underbrace{0,\dots,0}_{l'}).$$

By assumption, $l \ge n_0$ and $l' \ge n_0$. From (1.6) we therefore deduce that $B_n y = T_n(b)y$, whence

$$\begin{aligned}\|B_n y\|_p &= \|T_n(b)y\|_p \ge \|P_{[l+1,l+[n/2]+1]}T_n(b)y\|_p \\ &= \|T_{[n/2]}(b)x\|_p \ge M_p^0\Big(1-\frac{144}{p}\frac{s}{[n/2]}\Big) \\ &\ge M_p^0\Big(1-\frac{288}{p}\frac{s}{n-2}\Big) \ge M_p^0\Big(1-\frac{291}{p}\frac{s}{n}\Big),\end{aligned}$$

the last estimate resulting from the assumption that $n \ge 288s \ge 288$. As $M_p^0 = M_p$, the proof of Theorem 1.5 is complete.

4. The generic case. We begin with the proof of Proposition 1.4.

Proof. It is clear that $\mathcal{A}_2^0$ is an open subset of $\mathcal{A}_2$. To show that $\mathcal{A}_2^0$ is dense in $\mathcal{A}_2$, pick $T(a)+K \in \mathcal{A}_2$ and suppose $\|T(a)+K\|_2 = \|T(a)\|_2 = \|a\|_\infty$. Given any number $\varepsilon > 0$, we can find a complex number λ such that $|\lambda| < \varepsilon$ and $\|a+\lambda\|_\infty > \|a\|_\infty$. Then

$$\|T(a)+K+\lambda I\|_2 = \|T(a+\lambda)+K\|_2 \ge \|T(a+\lambda)\|_2 = \|a+\lambda\|_\infty > \|a\|_\infty,$$

and since $T(a)+K+\lambda P_n$ converges strongly to $T(a)+K+\lambda I$, it follows that

$$\liminf_{n\to\infty}\|T(a)+K+\lambda P_n\|_2 \geq \|T(a)+K+\lambda I\|_2 > \|a\|_\infty.$$

Consequently, letting $K_0 := K+\lambda P_n$, we see that $\|T(a)+K_0\|_2 > \|T(a)\|_2$ for all sufficiently large n, while

$$\Big\|\Big(T(a)+K_0\Big)-\Big(T(a)+K\Big)\Big\|_2 \leq |\lambda|\,\|P_n\|_2 = |\lambda| < \varepsilon.$$

This completes the proof of Proposition 1.4. □

To prove Theorem 1.3, we need the following lemma, which is of interest on its own. Recall that $B = T(b)+K$, where b is given by (1.1) and K satisfies (1.6). Also, let $s \geq 1$ without loss of generality. Put $m_0 := \max(s, n_0)$.

LEMMA 4.1. *If $\|T(b)\|_p < \|B\|_p$, then there exists an $x_0 = \big(x_j^{(0)}\big)_{j=0}^{\infty} \in l^p$ such that*

$$\|x_0\|_p = 1, \quad \|Bx_0\|_p = \|B\|_p \tag{4.1}$$

and

$$\Big(\sum_{j=m+1}^{\infty} |x_j^{(0)}|^p\Big)^{1/p} < \Big(\|T(b)\|_p \Big/ \|B\|_p\Big)^{\frac{m-(m_0+s)}{2s}} \tag{4.2}$$

for every $m > m_0 + s$.

Proof. Let $M_0 := \|T(b)\|_p$ and $M := \|B\|_p$. There are $x_k = \big(x_j^{(k)}\big)_{j=0}^{\infty} \in l^p$ such that

$$\|x_k\|_p = 1 \ \text{ and } \ \|Bx_k\|_p^p = M^p - \delta_k, \tag{4.3}$$

where δ_k goes monotonously to zero as $k \to \infty$. Pick any natural number $m \geq m_0$. By (1.6),

$$Bx_k = P_m\Big(T(b)+K\Big)\Big(x_j^{(k)}\Big)_{j=0}^{m+s} + P_{[m+1,\infty)}T(b)\Big(x_j^{(k)}\Big)_{j=m-s+1}^{\infty},$$

whence

$$M^p - \delta_k = \|Bx_k\|_p^p \leq M^p \sum_{j=0}^{m+s} |x_j^{(k)}|^p + M_0^p \sum_{j=m-s+1}^{\infty} |x_j^{(k)}|^p. \tag{4.4}$$

Defining

$$O_m^{(k)} := \sum_{j=m+1}^{\infty} |x_j^{(k)}|^p,$$

we can rewrite (4.4) in the form

$$1 - \gamma_k \leq \Big(1 - O_{m+s}^{(k)}\Big) + qO_{m-s}^{(k)},$$

where $\gamma_k := \delta_k/M^p$ and $q := (M_0/M)^p$. Thus,

$$O_{m+s}^{(k)} \leq qO_{m-s}^{(k)} + \gamma_k \ \text{ for all } \ m \geq m_0. \tag{4.5}$$

Application of (4.5) to $m = m_0, m_0 + 2s, \dots, m_0 + 2js$ gives

$$\begin{aligned} O^{(k)}_{m_0+(2j+1)s} &\le q^{j+1} O^{(k)}_{m_0-s} + (q^j + q^{j-1} + \cdots + 1)\gamma_k \\ &= q^{j+1} O^{(k)}_{m_0-s} + \frac{1-q^{j+1}}{1-q}\gamma_k. \end{aligned}$$

As $O^{(k)}_{m_0-s} \le 1$ and $q \in (0,1)$, we get

$$O^{(k)}_{m_0+(2j+1)s} \le q^{j+1} + \frac{\gamma_k}{1-q}. \tag{4.6}$$

Analogously, putting $m = m_0 + 1 + 2js, m_0 + 2 + 2js, \dots, m_0 + (2s-1) + 2js$ in (4.5), we arrive at the inequalities

$$O^{(k)}_{m_0+v+(2j+1)s} \le q^{j+1} + \frac{\gamma_k}{1-q} \tag{4.7}$$

for $v \in \{1, 2, \dots, 2s-1\}$. Letting $r := q^{1/(2s)}$, the inequalities (4.6) and (4.7) can be rewritten in the form

$$O^{(k)}_{m_0+s+j} \le r^j + \frac{\gamma_k}{1-q} \quad (j = 0, 1, 2, \dots). \tag{4.8}$$

We now show that $\{x_k\}_{k=1}^\infty$ is a Cauchy sequence in l^p. Without loss of generality, we can assume that $\{P_m x_k\}_{k=1}^\infty$ is a convergent sequence in $l^p[0,m]$ for each m (if this is not the case, we can pass to a subsequence of $\{x_k\}$ by a diagonalization process). Given $\varepsilon > 0$, choose natural numbers N, k_1, and k_2 so that

$$r^{(N-(m_0+s))/p} < \frac{\varepsilon}{4}, \quad \sum_{j=0}^{N} |x_j^{(k_1)} - x_j^{(k_2)}|^p < \left(\frac{\varepsilon}{4}\right)^p, \quad \frac{\gamma_{k_1} + \gamma_{k_2}}{1-q} < \frac{\varepsilon}{4}.$$

Then, by (4.8), $\|x_{k_1} - x_{k_2}\|_p$ is at most

$$\begin{aligned} &\left(\sum_{j=0}^{N} |x_j^{(k_1)} - x_j^{(k_2)}|^p\right)^{1/p} + \left(\sum_{j=N+1}^{\infty} |x_j^{(k_1)}|^p\right)^{1/p} + \left(\sum_{j=N+1}^{\infty} |x_j^{(k_2)}|^p\right)^{1/p} \\ &\quad \le \frac{\varepsilon}{4} + \left(O_N^{(k_1)}\right)^{1/p} + \left(O_N^{(k_2)}\right)^{1/p} \\ &\quad \le \frac{\varepsilon}{4} + r^{(N-(m_0+s))/p} + r^{(N-(m_0+s))/p} + \frac{\gamma_{k_1} + \gamma_{k_2}}{1-q} \\ &\quad < \frac{\varepsilon}{4} + \frac{\varepsilon}{4} + \frac{\varepsilon}{4} + \frac{\varepsilon}{4} = \varepsilon. \end{aligned}$$

This shows that $\{x_k\}$ is a Cauchy sequence.

Let $x_0 \in l^p$ be the limit of x_k as $k \to \infty$. Passing to the limit $k \to \infty$ in (4.3) we arrive at (4.1). Repeating the above arguments with x_k replaced by x_0, we get the analogue of (4.8) for x_0; that is,

$$\sum_{i=m_0+s+j+1}^{\infty} |x_i^{(0)}|^p \le r^j \quad (j = 0, 1, 2, \dots),$$

which is equivalent to (4.2). ∎

Here now is the *proof of Theorem* 1.3.

Put $M_0 := M_p^0$ and $M := M_p$. Proposition 3.2 implies that $\limsup_{n\to\infty} \|B_n\|_p \le M$, and from (1.7) we infer that $M \le \liminf_{n\to\infty} \|B_n\|_p$. Consequently,

$$\lim_{n\to\infty} \|B_n\|_p = M.$$

It follows that there are $x_n = (x_j^{(n)})_{j=0}^n \in l^p[0,n]$ such that

$$\|x_n\|_p = 1,\ \|B_n x_n\|_p = \|B_n\|_p,\ \|B_n x_n\|_p^p = M^p + \varepsilon_n, \tag{4.9}$$

where $\varepsilon_n \in \mathbf{R}$ and $\varepsilon_n \to 0$ as $n \to \infty$. Again set $l = [n/4]$ and note that $l > m_0 := \max(s, n_0)$ by assumption. For $l < m < 2l$, we have

$$\begin{aligned}\|B_n x_n\|_p^p = &\Big\|P_m\Big(T_n(b) + K\Big)\Big(x_j^{(n)}\Big)_{j=0}^{m+s}\Big\|_p^p \\ &+ \Big\|P_{[m+1,n-(m+1)]}T_n(b)\Big(x_j^{(n)}\Big)_{j=m-s+1}^{n-(m+1)+s}\Big\|_p^p \\ &+ \Big\|P_{[n-m,n]}\Big(T_n(b) + R_nLR_n\Big)\Big(x_j^{(n)}\Big)_{j=n-m-s}^{n}\Big\|_p^p.\end{aligned}$$

Since R_n is isometric on $l^p[0,n]$, we therefore obtain from (4.9) that

$$M^p + \varepsilon_n \le M^p\Big(\sum_{j=0}^{m+s} |x_j^{(n)}|^p\Big) + M_0^p\Big(\sum_{j=m-s+1}^{n-(m+1)+s} |x_j^{(n)}|^p\Big) + M^p\Big(\sum_{j=n-m-s}^{n} |x_j^{(n)}|^p\Big).$$

With

$$O_m^{(n)} := \sum_{j=m+1}^{n-(m+1)} |x_j^{(n)}|^p$$

we get $M^p + \varepsilon_n \le M^p(1 - O_{m+s}^{(n)}) + M_0^p O_{m-s}^{(n)}$, whence

$$O_{m+s}^{(n)} \le qO_{m-s}^{(n)} - \gamma_n,$$

where $q := (M_0/M)^p$ and $\gamma_n := \varepsilon_n/M^p$. The last inequality is of the form (4.5); consequently, analogous to (4.8), we have

$$O_{m_0+s+j}^{(n)} \le r^j - \frac{1-r^j}{1-q}\gamma_n, \quad r := (M_0/M)^{p/(2s)} \tag{4.10}$$

as long as $O_{m_0+s+j}^{(n)}$ is well defined, i.e., for all j satisfying $2(m_0 + s + j + 1) \le n$ or, equivalently, for

$$j \le n/2 - 1 - m_0 - s. \tag{4.11}$$

As the left-hand side of (4.10) is nonnegative provided (4.11) holds, we get

$$\gamma_n \le \frac{1-q}{1-r} r^{n/2-2-m_0-s} \le 2s\left(\frac{M_0}{M}\right)^{\frac{p(n-2m_0-2s-4)}{4s}}.$$

Thus,

$$\varepsilon_n = M^p\gamma_n \le M^p 2s\Big(\frac{M_0}{M}\Big)^{\frac{p(n-2m_0-2s-4)}{4s}}.$$

Put $\eta_n := \|B_n\|_p - M$. By (4.9), $\eta_n = (M^p+\varepsilon_n)^{1/p} - M$. Hence, if $\varepsilon_n \ge 0$, then $\eta_n \le \varepsilon_n/(M^{p-1}p)$, while $\eta_n < 0$ if $\varepsilon_n < 0$. In summary, we arrive at the estimate

$$\eta_n \le \frac{M}{p}2s\Big(\frac{M_0}{M}\Big)^{\frac{p(n-2m_0-2s-4)}{4s}} \le 2sM\Big(\frac{M_0}{M}\Big)^{\frac{n-2m_0-2s-4}{4s}} = Mc_p\varrho_p^n,$$

which is the estimate from above in (1.8).

To prove the left inequality of (1.8), we make use of Lemma 4.1. For the sake of definiteness, suppose $M = \|T(b)+K\|_p$. (The proof is analogous to the case $M = \|T(\tilde{b})+L\|_p$.) Let x_0 satisfy (4.1) and (4.2). Put $v := [n/2]$ ($> m_0$) and $y_n := P_v x_0$. By (1.6),

$$\begin{aligned}
\|B_n y_n\|_p &= \|P_n\Big(T(b)+K\Big)y_n\|_p \\
&= \Big\|\Big(T(b)+K\Big)\Big(x_j^{(0)}\Big)_{j=0}^{\infty} - P_{[n+1,\infty)}\Big(T(b)+K\Big)\Big(x_j^{(0)}\Big)_{j=v-s+1}^{v} \\
&\quad - \Big(T(b)+K\Big)\Big(x_j^{(0)}\Big)_{j=v+1}^{\infty}\Big\|_p \\
&\ge \Big\|\Big(T(b)+K\Big)x_0\Big\|_p - \Big\|P_{[n+1,\infty)}\Big(T(b)+K\Big)\Big(x_j^{(0)}\Big)_{j=v-s+1}^{v} \\
&\quad + \Big(T(b)+K\Big)\Big(x_j^{(0)}\Big)_{j=v+1}^{\infty}\Big\|_p \\
&\ge M - 2M\Big(\sum_{j=v-s+1}^{\infty}|x_j^{(0)}|^p\Big)^{1/p}.
\end{aligned}$$

From (4.2) and the equality $v = [n/2]$ we now infer that

$$\|B_n y_n\|_p \ge M - 2M\Big(\frac{M_0}{M}\Big)^{\frac{v-s-m_0-s}{2s}} \ge M - 2M\Big(\frac{M_0}{M}\Big)^{\frac{n-2m_0-4s-4}{2s}} \ge M - Mc_p\varrho_p^n.$$

Because $\|y_n\|_p \le 1$, we finally obtain

$$\|B_n\|_p \ge \|B_n y_n\|_p/\|y_n\|_p \ge \|B_n y_n\|_p \ge M - Mc_p\varrho_p^n,$$

and this is the lower estimate in (1.8).

ACCURATE SINGULAR VALUE DECOMPOSITIONS OF STRUCTURED MATRICES*

JAMES DEMMEL†

Abstract. We present new $O(n^3)$ algorithms to compute very accurate singular value decompositions of Cauchy matrices, Vandermonde matrices, and related "unit-displacement-rank" matrices. These algorithms compute all the singular values with guaranteed relative accuracy, independent of their dynamic range. In contrast, previous $O(n^3)$ algorithms can potentially lose all relative accuracy in the tiniest singular values.

Key words. singular value decomposition, high accuracy, Cauchy matrix, Vandermonde matrix, displacement rank

1. Introduction.

A *singular value decomposition (SVD)* of a real matrix G is the factorization $G = U\Sigma V^T$, where U and V are orthogonal matrices and Σ is nonnegative and diagonal. If G is m-by-n, with $m \geq n$ (otherwise transpose G), then U is m-by-n, $\Sigma = \mathrm{diag}(\sigma_1, \ldots, \sigma_n)$ with $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$, and V is n-by-n. We call the columns u_i of $U = [u_1, \ldots, u_n]$ the *left singular vectors*, the columns v_i of $V = [v_1, \ldots, v_n]$ the *right singular vectors*, and the σ_i the *singular values*. When G is complex we write instead $G = U\Sigma V^H$ and take U and V unitary.

Our goal is to compute the SVD (i.e., the u_i, v_i, and σ_i) to *high relative accuracy* and with cost $O(n^3)$, i.e., roughly the same cost as prior, less accurate dense matrix algorithms. By high relative accuracy we mean the following:

- The error $|\sigma_i - \hat{\sigma}_i|$ in the computed singular value $\hat{\sigma}_i$ is bounded by $O(\varepsilon)\sigma_i$, where ε is machine precision, i.e., the relative error is small.
- The angle $\theta(u_i, \hat{u}_i)$ between the true left singular vector u_i and the computed vector $\hat{u}_i$ is bounded by $O(\varepsilon)/\mathrm{relgap}_i$, where $\mathrm{relgap}_i = \min_{j \neq i} |\sigma_j - \sigma_i|/\sigma_i$ is the relative gap between σ_i and the nearest other singular value. An analogous statement holds for the computed right singular vectors $\hat{v}_i$.

In contrast, conventional numerical algorithms (QR iteration, divide and conquer, bisection and inverse iteration, traditional Jacobi, etc.) only compute the SVD with *high absolute accuracy*. This means that the error in the singular value is bounded only by $O(\varepsilon)\sigma_1$ instead of $O(\varepsilon)\sigma_i$. Thus the largest singular values are computed with high relative accuracy, but the tiniest singular values (those near or less than $\varepsilon\sigma_1$) may have no relative accuracy at all. Similarly, the error in the computed singular vectors can also be σ_1/σ_i times as large.

In an earlier paper [8] we showed that if we were given a *rank-revealing decomposition* (RRD) $G = XDY^T$, i.e., a decomposition where D is diagonal and X and

Y are full column rank and well conditioned (but otherwise arbitrary), then we could compute the SVD of G to high relative accuracy from X, D, and Y in $O(n^3)$ time. For this to work, the computed $\hat{X}$, $\hat{D}$, and $\hat{Y}$ must be sufficiently accurate:

- Each entry of $\hat{D}$ is known to high relative accuracy: $|D_{ii} - \hat{D}_{ii}| = O(\varepsilon)|D_{ii}|$.
- $\hat{X}$ and $\hat{Y}$ have small norm errors, i.e., $\|X - \hat{X}\| = O(\varepsilon)\|X\|$ and $\|Y - \hat{Y}\| = O(\varepsilon)\|Y\|$.

To summarize, our high accuracy SVD algorithm consists of two steps:

1. Compute the RRD $G = XDY^T$ sufficiently accurate.
2. Compute the SVD of XDY^T using the algorithm from [8] (see also section 2 below).

In [8] a variety of matrix classes were described that permitted the RRD $G = XDY^T$ to be computed sufficiently accurately. In particular we considered the RRD provided by Gaussian elimination with complete pivoting (GECP): X and Y are both unit triangular matrices with off-diagonals bounded by one in magnitude. However, the usual implementation of GECP will often not compute X, D, and Y as accurately as required; a new way to compute the triangular factors is needed.

In particular, suppose C is a square Cauchy matrix: $C_{ij} = 1/(x_i + y_j)$, where the x_i and y_j are given floating point numbers. There is a well-known formula for the determinant of C:

$$\det(C) = \frac{\prod_{1 \le i < j \le n}(x_j - x_i)(y_j - y_i)}{\prod_{1 \le i,j \le n}(x_i + y_j)} \quad . \tag{1}$$

Every factor $x_j - x_i$, $y_j - y_i$, or $x_i + y_j$ is computable to high relative accuracy, as well as their products and quotients, in floating point arithmetic. Thus $\det(C)$ is computable to high relative accuracy. Since every submatrix of a Cauchy matrix is Cauchy, every minor of C can be computed to high relative accuracy. The same is true of the *quasi-Cauchy matrix* $G = D_1 C D_2$, where D_1 and D_2 are diagonal. Finally, since every entry of every Schur complement of G is the quotient of minors of G (or just a minor), all the intermediate and final results of GECP on G can be computed to high relative accuracy using (1). In other words, we can compute the triangular factors of G, and thus its SVD, to high relative accuracy, where G is defined by the x_i, y_j, and diagonal entries of D_1 and D_2. This extends straightforwardly to rectangular Cauchy matrices.

This does *not* mean that small relative changes in these parameters cause small relative changes in the singular values. Indeed, the 1-by-1 example with $x_1 = 1$ and $y_1 = -1 + \varepsilon$ shows that this is not true. It does mean that our algorithm is forward stable, and simply gets an accurate answer for the floating point values of the parameters stored in the machine, whether or not the answer is sensitive to small changes in the parameters. Section 7 addresses the separate perturbation theory question of how small changes in the input data can affect the SVD. We will see, for example, that the Hilbert matrix is nearly perfectly conditioned, in the sense that small relative changes in its Cauchy parameters $x_i = i$ and $y_j = j - 1$ cause only small relative changes in its SVD. Ours is the only algorithm not using expensive high precision arithmetic that can accurately compute the SVD of matrices like the Hilbert matrix, which are very ill conditioned from the conventional point of view. Also, there are some rational interpolation problems where the data is known exactly, in which case our algorithm is most appropriate [17].

Unfortunately, using (1) in the most straightforward way to implement GECP would cost $O(n^5)$ operations by using it to compute each of the $O(n^3)$ intermediate

results that would be produced by Gaussian elimination. The first main result in this paper is an algorithm that reduces the cost from $O(n^5)$ to $\frac{4}{3}n^3$. Similar observations were made for several closely related (noneigenvalue and non-SVD) factorizations in work on predictive pivoting for low displacement rank matrices [17, 4, 15, 3, 30, 21], where the goal was generally to reduce the complexity to $O(n^2)$. In particular, see Theorem 4.1 in [15]. But with complete pivoting it appears impossible to reduce the complexity below $\Theta(n^3)$. Our algorithm can be derived straightforwardly from (1), which is the approach we take here.

Among other examples, we compute the SVD of a 100-by-100 Hilbert matrix. The computed singular values range over 150 orders of magnitude and agree to 15 decimal digits with the singular values computed using a conventional algorithm with 200-decimal digit arithmetic; the singular vectors agree to 14 or more digits. This result is presented in section 4.

The second result is a similar high accuracy RRD for Vandermonde matrices. It is based on the observation that if V is Vandermonde, so that $V_{ij} = x_i^{j-1}$, and $F_{ij} = \exp(2\sqrt{-1}\pi(i-1)(j-1)/n)/\sqrt{n}$ is the discrete Fourier transform matrix, then VF is (essentially) quasi-Cauchy, and the parameters determining the quasi-Cauchy structure can be computed to sufficient accuracy to use the previous algorithm. The observation that VF is quasi-Cauchy was also exploited in the displacement rank literature [16, (3.1)], [15, Section 7], but we again derive it from first principles. This result is presented in section 5.

We observe more generally that if G is defined by the Sylvester equation (also called *displacement equation*)

$$XG + GY = d_1 d_2^T, \tag{2}$$

where

- X and Y are diagonalizable matrices with accurately known eigendecompositions, and
- d_1 and d_2 are column vectors,

then G can be accurately transformed into a quasi-Cauchy matrix, and the above techniques applied. (If X and Y are normal matrices, this process is slightly simpler than if they are not.) This result is presented in section 6.

A matrix satisfying (2) is said to have *displacement rank* equal to 1, because the right-hand side has rank 1. It is natural to ask about the possibility of computing accurate SVDs of matrices with higher displacement rank. For example, general Toeplitz matrices have displacement rank 2. We do not currently see any way to extend our results to higher displacement rank than 1. In section 6 we argue that no high accuracy SVD for general Toeplitz matrices can exist, in the sense that they exist for Cauchy and Vandermonde matrices, and describe conditions under which such algorithms can exist.

In section 7 we describe a simple estimator for the relative error in the SVD we compute, in the case where the input data is uncertain.

2. Computing an accurate SVD of $G = XDY^T$. For completeness, we restate Algorithm 3.1 from [8] (see also [10]) for computing a high accuracy SVD of the RRD $G = XDY^T$.

ALGORITHM 1. Compute a high accuracy SVD of $G = XDY^T$.

1. Perform QR factorization with pivoting on XD to get $XD = QRP$, where P is a permutation. Thus $G = QRPY^T$.

2. Multiply to get $W = RPY^T$. This must be *conventional* matrix multiplication, e.g., Strassen's method [22] may not be used. Thus $G = QW$.

3. Compute the SVD of $W = \bar{U}\Sigma V^T$ using one-sided Jacobi [9]. Thus $G = Q\bar{U}\Sigma V^T$.

4. Multiply $U = Q\bar{U}$. Thus $G = U\Sigma V^T$ is the desired SVD.

The statements of Theorems 3.1 and 3.2 from [8] which describes the accuracy of this algorithm are as follows.

THEOREM 2.1 (see [8, Theorem 3.1]). *Let D' be a diagonal matrix, chosen so that $R' = D'^{-1}R$ is as well conditioned as possible. Then in floating point arithmetic with machine precision ε, Algorithm* 1 *computes the SVD of G with relative accuracy $\eta = O(\varepsilon\kappa(R') \cdot \max(\kappa(X), \kappa(Y)))$.*

In practice $\kappa(R')$ is usually close to 1 so that the error bound is close to the minimum $O(\varepsilon \max(\kappa(X), \kappa(Y)))$ given by the perturbation bound in [8, Theorem 2.1]. But the best we can prove is as shown below.

THEOREM 2.2 (see [8, Theorem 3.2]). *D' can be chosen so that $\kappa(R') = O(\min(n2^n, n^{3/2}\kappa(X)))$.*

In theory [10, 29, 9, 28, 11] the Jacobi rotations during the one-sided Jacobi in step (3) must be applied to the right side of W to guarantee the bounds. But in practice, applying them from the left is significantly faster, and has never been found to be significantly less accurate (see the comments on speed in section 4.1 below).

The factor $\kappa(R')$ in the error bound depends on how well the pivoting during the QR decomposition of XD "reveals the rank" of XD. The bound $O(n2^n)$ comes from the standard column-pivoting algorithm [18] and choosing $D'_{ii} = R_{ii}$, but better alternatives are available [34, 1, 5, 6, 20, 24, 32]. For example, M. Gu has a pivoting scheme that reduces $O(2^n)$ to $O(n^{1+(1/4)\log_2 n})$, analogous to the pivot growth bound for GECP [19] (see also [31]). For our numerical experiments in section 4.1, $\kappa(R')$ never exceeded 5.

We can eliminate the factor $\kappa(R')$, yielding the relative error bound $\eta = O(\varepsilon \cdot \max(\kappa(X), \kappa(Y)))$, by using the more expensive Algorithm 3.2 from [8].

ALGORITHM 2. Compute a high accuracy SVD of $G = XDY^T$.

1. Compute the SVD of $XD = \bar{U}\bar{\Sigma}\bar{V}^T$ using one-sided Jacobi. Thus $G = \bar{U}\bar{\Sigma}\bar{V}^T Y^T$.

2. Multiply $W = \bar{\Sigma}(\bar{V}^T Y^T)$, respecting parentheses. Strassen may be used inside the parentheses. Thus $G = \bar{U}W$.

3. Compute the SVD $W = \bar{\bar{U}}\Sigma V^T$ using one-sided Jacobi. Thus $G = \bar{U}\bar{\bar{U}}\Sigma V^T$.

4. Multiply $U = \bar{U}\bar{\bar{U}}$. Thus $G = U\Sigma V^T$ is the desired SVD.

However, Algorithm 2 is likely to be up to twice as expensive as Algorithm 1 because it does two Jacobi SVDs instead of one (although we note recent work that has made Jacobi-based SVDs about as fast as the QR-based algorithm [13]). Since R' is unlikely to be large, we cannot recommend Algorithm 2 for general use.

3. Assumptions about floating point arithmetic. We use the conventional error model for floating point arithmetic:

$$\mathrm{fl}(a \odot b) = (a \odot b)(1 + \delta), \tag{3}$$

where $\odot \in \{+, -, \times, /\}$, and $|\delta| \le \varepsilon$, where ε is machine precision. In particular, we assume that neither overflow nor underflow occur, since both can destroy relative accuracy in the result.

This assumption implies that expressions like the one in (1) can be evaluated to high relative accuracy. Products and quotients of many floating point numbers

such as in (1) can in principle be quite susceptible to over/underflow; this was not a problem in any test that we ran (once we replaced expressions like $(\prod_i a_i)/(\prod_i b_i)$ with $\prod_i (a_i/b_i)$) but could be guarded against by testing and scaling, or use of IEEE over/underflow flags.

Furthermore, for our algorithm for Vandermonde matrices we further assume that floating point arithmetic is implemented with a guard digit, so that $\mathrm{fl}(a \pm b)$ is exactly $a \pm b$ when cancellation occurs, i.e., when $.5 < a/b < 2$ in binary arithmetic. Almost all existing machines (except the Cray C90 and its predecessors and emulators) satisfy these conditions.

When a and b are complex numbers, we assume that (3) continues to hold, with δ a tiny complex number bounded by $|\delta| = O(\varepsilon)$ [22]. This is true for any reasonable implementation of complex arithmetic. Note that this is weaker than requiring that both real and imaginary parts be computed to high relative accuracy.

4. Quasi-Cauchy matrices. We begin with the simple observation that GECP on G can be implemented as follows. We write this decomposition as $G = XDY^T$, where X and Y are (possibly row permuted) unit lower triangular matrices. Suppose without loss of generality that the first k pivot rows and columns have been chosen as the leading k rows and columns. Then the kth Schur complement $S^{(k)} = G_{22} - G_{21}G_{11}^{-1}G_{12}$ satisfies

$$G = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} = \begin{bmatrix} I & 0 \\ G_{21}G_{11}^{-1} & I \end{bmatrix} \cdot \begin{bmatrix} G_{11} & G_{12} \\ 0 & S^{(k)} \end{bmatrix}.$$

The next pivot row and column is chosen by finding the largest entry in $S^{(k)}$; assume without loss of generality that it is in the (1,1) position of $S^{(k)}$. Finally, $D_{k+1,k+1} = S_{11}^{(k)}$, the $(k+1)$st column of X below the diagonal is first column of $S^{(k)}$ divided by $S_{11}^{(k)}$, and the $(k+1)$st row of Y^T to the right of the diagonal is the first row of $S^{(k)}$ divided by $S_{11}^{(k)}$. Therefore, if we can derive a formula for computing all the entries of $S^{(k)}$ in c operations per entry, we will have an algorithm requiring $\sum_{i=1}^{n} ci^2 = \frac{c}{3}n^3 + O(n^2)$ operations to compute the same triangular factorization as GECP.

We use the fact that

$$S_{rs}^{(k)} = \det(G([1:k, r], [1:k, s]))/\det(G(1:k, 1:k)),$$

where we use Matlab notation for submatrices of $G = D_1 C D_2$. Substituting (1) into this expression and canceling terms, we get that

$$\begin{aligned} S_{rs}^{(k)} &= D_{1,r} \cdot D_{2,s} \cdot \frac{\prod_{1 \le i \le k}(x_r - x_i)(y_s - y_i)}{(x_r + y_s)\prod_{1 \le i \le k}(x_i + y_s)(x_r + y_i)} \\ &= S_{rs}^{(k-1)} \frac{(x_r - x_k)(y_s - y_k)}{(x_k + y_s)(x_r + y_k)}, \end{aligned}$$

where $S_{rs}^{(0)} = D_{1,r}D_{2,s}/(x_r + y_s)$ is the original matrix entry [15, Eq. (2.10)]. Thus, updating each entry of the Schur complement from the previous Schur complement costs $c = 8$ operations, or few as $c = 4$ operations if all $2n^2$ possible values of $x_r - x_s$, $y_r - y_s$, and $1/(x_r + y_s)$ are precomputed. This makes the overall cost of the algorithm range from $\frac{8}{3}n^3$ (when done in place, with no extra storage) to $\frac{4}{3}n^3$ (with an extra $2n^2$ storage). The $\frac{8}{3}n^3$ operations include $\frac{2}{3}n^3$ divisions, which are very expensive,

whereas the $\frac{4}{3}n^3$ operations are all multiplications. To complete the algorithm, each time the Schur complement is updated, it must be pivoted so that $S_{11}^{(k)}$ is the largest entry; this requires $\frac{1}{3}n^3$ comparisons. Also, after completing the factorization the kth row and column must be divided by the kth diagonal entry. The entire algorithm is shown below.

ALGORITHM 3. HIGH ACCURACY GECP OF A QUASI-CAUCHY MATRIX.

for $r = 1 : n$ and $s = 1 : n$
  $G_{rs} = D_{1,r}D_{2,s}/(x_r + y_s)$
endfor
for $k = 1 : n - 1$
  Find the largest absolute entry in $G(k : n, k : n)$
  Swap rows and columns of G, and entries of x and y, so that G_{kk} is largest
  for $r = k + 1 : n$ and $s = k + 1 : n \ldots$ overwrite $G(k + 1 : n, k + 1 : n)$ by $S^{(k)}$
    $G_{rs} = G_{rs}(x_r - x_k)(y_s - y_k)/[(x_k + y_s)(x_r + y_k)]$
  endfor
endfor
$D = \mathrm{diag}(G)$
$X = \mathrm{tril}(G) * D^{-1} + I$ ... tril means strict lower triangle
$Y = (D^{-1} * \mathrm{triu}(G) + I)^T$ ... triu means strict upper triangle

All operations involve multiplication, division, and sums and differences of input data and so are accurate to high relative accuracy.

4.1. Numerical experiments. Our challenge is to test the accuracy of a routine that we claim is more accurate than any other. We do this in several ways:

1. We can compute the SVD using a conventional algorithm implemented in very high precision arithmetic, and compare the answers to our new algorithm (implemented in Matlab on a SPARC 10, running IEEE double precision arithmetic with $\varepsilon = 2^{-53} \approx 10^{-16}$). We have only performed this rather expensive test for the 100-by-100 Hilbert matrix, using Mathematica [37] with 200-decimal digit software floating-point, and rounding the final answers back to 16 decimal digits, using the command

```
N[SingularValues[N[Table[1/(i+j-1),{i,100},{j,100}],200],
   Tolerance->10^(-200)],16].
```

The singular values range from about 2.2 down to $5.8 \cdot 10^{-151}$, as shown in the top of Figure 1. If we were to plot the pivots from Algorithm 3 (the $D_{i,i}$) on the same graph, they would be visually nearly indistinguishable; the ratios $D_{i,i}/\sigma_i$ of pivots to singular values all lie in the range [1/16, 16], and 86% are in [1/4,4]. The relative gaps all exceed .6, so we expect all singular vectors from both Mathematica and from our new algorithm to be very accurate. The largest relative difference between a singular value from Mathematica and from our new algorithm was less than $4 \cdot 10^{-15}$ or about 34ε. The largest angle between a right singular vector from Mathematica and from our new algorithm was less than $6.5 \cdot 10^{-15}$, or 58ε. The largest angle between a left singular vector from Mathematica and from our algorithm was less than $2.8 \cdot 10^{-14}$, or 255ε. A surface plot of the singular vector (or equivalently eigenvector) matrix is shown in the bottom of Figure 1, which reveals interesting patterns of "parallel valleys." This is shown in a different way in Figure 2, which plots dark dots for positive eigenvector components and leaves white space for the negative eigenvectors components. This amounts to a low resolution contour plot of the eigenvector matrix. The top of Figure 2 shows

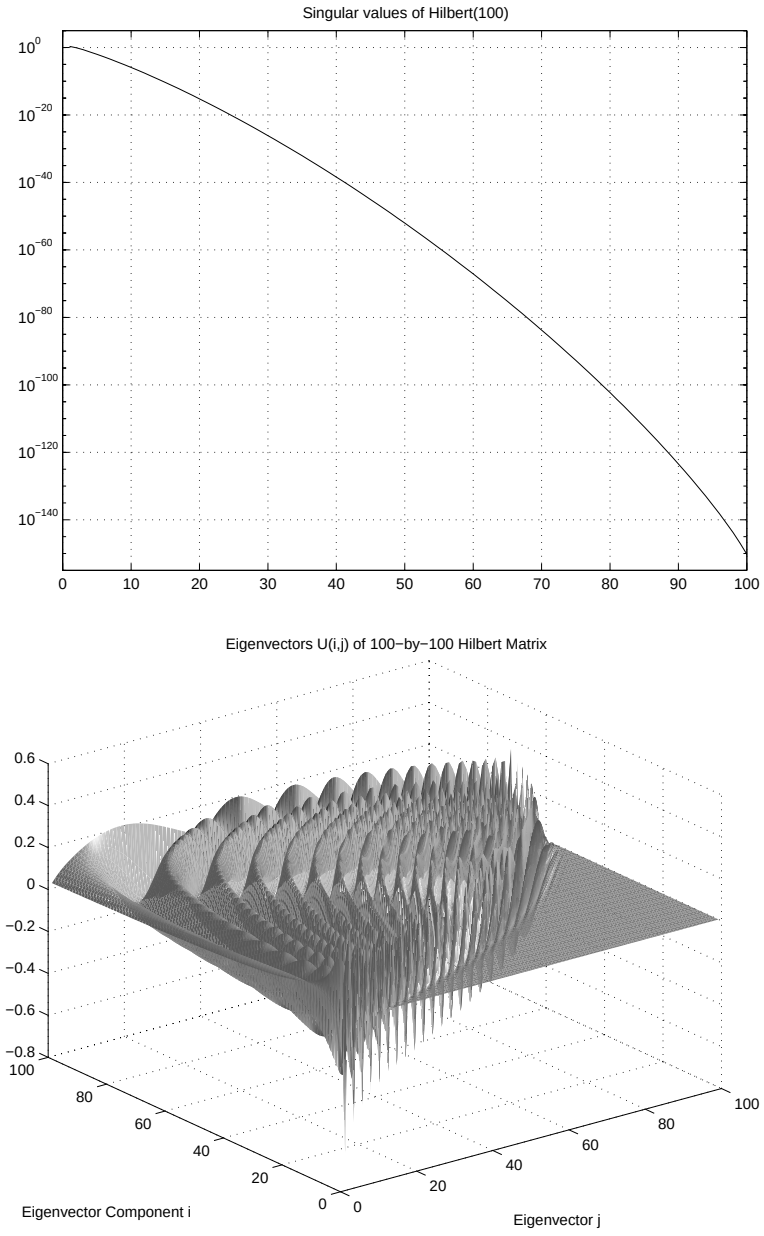

FIG. 1. *Singular values and vectors of the* 100*-by-*100 *Hilbert matrix.*

the results from Mathematica. Although it is somewhat difficult to see, the number of sign changes in eigenvector j (the number of transitions from a positive (black) component to a negative (white) component, or white to black, in column j) is equal to $j-1$. For example, the first column is entirely black (no sign changes) and the last column alternates signs (99 sign changes). Furthermore, the sign changes in eigenvector j interlace those in eigenvector $j+1$ (in the sense that the zero crossings of the piecewise linear curve with corners $(i, U_{i,j})$ interlace the zero crossings of the curve with corners

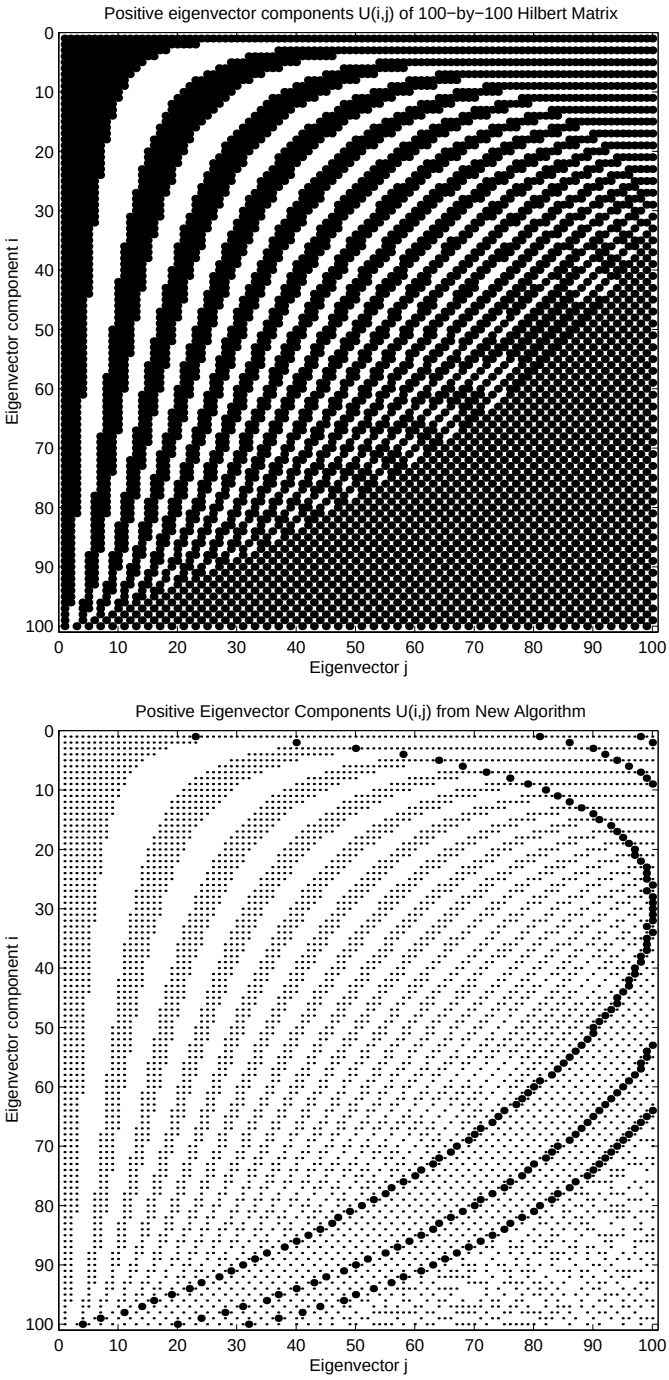

FIG. 2. *Positive components of the singular vectors of the* 100-*by*-100 *Hilbert matrix. The top picture shows the results from Mathematica, and the lower picture shows the results from the new algorithm. In the lower picture, the gray entries are the positive components. The leftmost contour of black dots corresponds to entries of size* .2*, the next contour of black dots corresponds to entries of size* 10^{-7}*, and the rightmost contour of black dots corresponds to entries of size* 10^{-14}*. The* $O(10^{-14})$ *errors can make the smallest entries, those below the rightmost contour, have incorrect signs, as can be seen by the irregular pattern of gray dots below the rightmost contour.*

$(i, U_{i,j+1})$). These properties are as predicted by the theory of totally positive (or oscillation) matrices [14, 26], of which the Hilbert matrix is an example. (Totally nonnegative (positive) matrices are those matrices whose every minor is nonnegative (positive). Oscillation matrices are totally nonnegative matrices A such that A^k is totally positive for some positive k.) The bottom of Figure 2 shows the results from the new algorithm. They agree everywhere except for the components whose magnitudes are less than 10^{-14}, which are on the bottom right, below the contour of black dots. The magnitudes of the components quickly drop from 10^{-14} to near 10^{-74} in this part of the eigenvector matrix. The 200-decimal digit computation with Mathematica computed all these correctly, but the new algorithm has an $O(\varepsilon)$ absolute error in each component, so the signs of such small components are uncertain. In contrast, a conventional SVD algorithm in double precision arithmetic (as implemented in Matlab) loses all significant figures for the 79 singular values less than ε, and most of these are wrong by many orders of magnitude.
The next seven tests use only conventional floating point.

2. We confirm that we have computed an accurate SVD in the conventional sense by measuring

$$Q_1 = \frac{\|G - U\Sigma V^T\|}{\varepsilon\|G\|} + \frac{\|UU^T - I\|}{\varepsilon} + \frac{\|VV^T - I\|}{\varepsilon}$$

and confirming that it is $O(1)$ or perhaps $O(n)$.

3. We compute the SVD of G using a conventional algorithm and confirm that the singular values agree with the singular values computed by our new algorithm to within $\pm O(\varepsilon)\sigma_1$. We measure this as follows:

$$Q_2 = \max_i \frac{|\sigma_{conventional,i}(G) - \sigma_{new,i}(G)|}{\varepsilon\sigma_{conventional,1}(G)} \quad .$$

Note that Q_2 should be $O(1)$ to confirm that our new algorithm computes the largest singular values (those between σ_1 and $\varepsilon\sigma_1$) at least as accurately as a conventional algorithm. We also confirm that the singular vectors are at least as accurate as those from a conventional algorithm by measuring whether Q_3 is $O(1)$:

$$Q_3 = \max_i \frac{\max(\theta(u_{conventional,i}(G), u_{new,i}(G)), \theta(v_{conventional,i}(G), v_{new,i}(G)))}{\varepsilon / \left(\frac{\min j \neq i |\sigma_{new,i}(G) - \sigma_{new,j}(G)|}{\sigma_{new,1}(G)}\right)} \quad .$$

4. We compute each entry of G^{-1} to high relative accuracy using a well-known formula similar to (1) and compute the SVD of G^{-1} using a conventional algorithm. We confirm that these singular values agree with the reciprocals of the singular values computed by our new algorithm to within $\pm O(\varepsilon)/\sigma_n$, by measuring

$$Q_4 = \max_i \frac{|1/\sigma_{new,i}(G) - \sigma_{conventional,i}(G^{-1})|}{\varepsilon/\sigma_{new,n}(G)}$$

to see if it is $O(1)$. This confirms that the smallest singular values of G (those between σ_n and σ_n/ε) are computed accurately. We also confirm that

the singular vectors are at least as accurate as those from the conventional algorithm, by confirming that the following quantity is $O(1)$:

$$Q_5 = \max_i \frac{\max(\theta(u_{conventional,i}(G^{-1}), v_{new,i}(G)), \theta(v_{conventional,i}(G^{-1}), u_{new,i}(G)))}{\varepsilon / \left(\frac{\min j \neq i |\sigma^{-1}_{new,i}(G) - \sigma^{-1}_{new,j}(G)|}{\sigma^{-1}_{new,n}(G)} \right)}.$$

5. We use the fact that G^{-1} is quasi-Cauchy to compute its SVD using our new algorithm, and confirm that it agrees (after reciprocating the singular values) with the SVD computed from G. This is measured by

$$Q_6 = \max_i \frac{|\sigma_{new,i}(G) - \sigma^{-1}_{new,i}(G^{-1})|}{\varepsilon \sigma_{new,i}(G)} \quad .$$

We also confirm that the singular vectors agree to within the error bound determined by the relative gap, via

$$Q_7 = \max_i \frac{\max(\theta(u_{new,i}(G^{-1}), v_{new,i}(G)), \theta(v_{new,i}(G^{-1}), u_{new,i}(G)))}{\varepsilon / \left(\frac{\min j \neq i |\sigma^{-1}_{new,i}(G) - \sigma^{-1}_{new,j}(G)|}{\sigma^{-1}_{new,i}(G)} \right)} \quad .$$

Here are our test cases:

1. 10 Hilbert matrices of dimensions $10, 20, 30, \ldots, 100$ ($x_i = i$, $y_i = i - 1$, $D_{1,i} = D_{2,i} = 1$);
2. 10 Hilbert matrices of dimensions $10, 20, \ldots, 100$, with strong diagonal scaling ($x_i = i$, $y_i = i - 1$, $D_{1,i} = 10^{20u}$, $D_{2,i} = 10^{20u}$, where u is a random number uniformly distributed from 0 to 1);
3. 10 random Cauchy matrices of dimensions $10, 20, \ldots, 100$ ($x_i = u$, $y_i = -u$, $D_{1,i} = D_{2,i} = 1$, where u is a random number uniformly distributed from 0 to 1);
4. 10 random Cauchy matrices of dimensions $10, 20, \ldots, 100$ ($x_i = 10^{10u}$, $y_i = -10^{10u}$, $D_{1,i} = D_{2,i} = 1$, where u is a random number uniformly distributed from 0 to 1);
5. 10 random Cauchy matrices of dimensions $10, 20, \ldots, 100$ with strong diagonal scaling ($x_i = 10^{10u}$, $y_i = -10^{10u}$, $D_{1,i} = 10^{10u}$, $D_{2,i} = 10^{10u}$, where u is a random number uniformly distributed from 0 to 1).

The results were as follows (given as the maximum values over all 50 test cases). As shown, the results were about as accurate as expected.

$\max Q_1$	$\max Q_2$	$\max Q_3$	$\max Q_4$	$\max Q_5$	$\max Q_6$	$\max Q_7$
2752	21	30	21	101	98	137

In addition, we measured some other quantities of numerical interest. The condition numbers of the matrices tested ranged from about 10^8 to 10^{182}, a very wide range. The relative gaps all exceeded 10^{-3}, meaning that all singular vectors were computed with small norm errors, about $10^3\varepsilon$. The condition numbers of the triangular factors X and Y, which limit the accuracy of Algorithm 1, never exceeded 379. Indeed, in tens of thousands of other examples run using a direct search technique [23] in an attempt to maximize $\mu = \max(\max_{ij} |X^{-1}|_{ij}, \max_{ij} |Y^{-1}|_{ij})$, μ never exceeded 7 for $n \leq 20$. Another factor that limits the accuracy of Algorithm 1, the condition number of R' in the statement of Theorem 3.1 from [8], never exceeded 5. The number of Jacobi sweeps required for convergence in Algorithm 1 depends very much on how

we do one-sided Jacobi. The matrix W to which we apply one-sided Jacobi consists of a well conditioned matrix premultiplied by a diagonal matrix with widely varying entries, so that the rows of W vary widely in norm. If we apply Jacobi rotations to W from the left (the algorithm analyzed in [9]), then convergence is rapid, with never more than 8 Jacobi sweeps required, and an average of 4.6 sweeps (including one just to confirm convergence, which does not apply any rotations). If we apply Jacobi rotations to W from the right, which has a more satisfying theoretical analysis [10, 29, 28], then convergence is much slower, with the number of sweeps being 50 for modest sized examples and growing rapidly with n. The above results were run with Jacobi rotations applied on the left.

4.2. The symmetric positive definite case. Significant simplifications are possible in this case, although the overall algorithm is still $O(n^3)$. If G is symmetric and positive definite, the largest pivot is always on the diagonal. Thus, only the diagonal entries of the $S^{(k)}$ need to be computed to determine the pivot order. This leads to the following algorithm:

Algorithm 4. High Accuracy SVD of a Symmetric Positive Definite Quasi-Cauchy Matrix G.

1. Compute only the diagonals of each $S^{(k)}$, and use this to determine the pivot order. This costs just $O(n^2)$.

2. Reorder the data determining G in the correct order, and compute the reordered G's LDU factorization using Algorithm 2.5 of [3]. This costs $O(n^2)$, and is forward stable for the same reasons as Algorithm 3.

3. Rewrite $LDU = \hat{L}\hat{L}^T$, the Cholesky factorization. This also costs $O(n^2)$.

4. Apply one-sided Jacobi to $\hat{L}$ to compute its SVD. The left singular vectors of L are the eigenvectors of G. This costs $O(n^3)$.

Algorithm 2.5 in [3] and Algorithm 3 above are quite similar, but Algorithm 2.5 takes advantage of a fixed pivot order to compute the final entries of L column by column, and final entries of U row by row, rather than computing all the $S^{(k)}$. To see how, note that all the following factors of entries of $S^{(k)}$ can be computed and then combined in $O(n^2)$ time:

$$\begin{aligned}
&\prod_{1\le i\le k}(x_r - x_i) && \text{for all } 1 \le k < r \le n,\\
&\prod_{1\le i\le k}(y_s - y_i) && \text{for all } 1 \le k < s \le n,\\
&x_r + y_s && \text{for all } 1 \le r, s \le n,\\
&\prod_{1\le i\le k}(x_i + y_s) && \text{for all } 1 \le k < s \le n,\\
&\prod_{1\le i\le k}(x_r + y_i) && \text{for all } 1 \le k < r \le n.
\end{aligned}$$

Algorithm 2.5 uses only $O(n)$ extra storage, rather than $O(n^2)$.

It is possible to recognize symmetric positive definite quasi-Cauchy matrices quite easily. Suppose $D_1 = D_2$ and $x_i = y_i$ for all i, so that G is symmetric. (This last condition can be weakened slightly, since replacing each x_i by $x_i - c$ and each y_i by $y_i + c$ leaves G unchanged. But this must be done without rounding error to guarantee accuracy. This is possible for the Hilbert matrix, with $c = .5$.) Then G is positive definite if and only if all $x_i > 0$, as can be seen from (1) applied to all leading principal submatrices. Furthermore, G's rows and columns can be symmetrically permuted (so

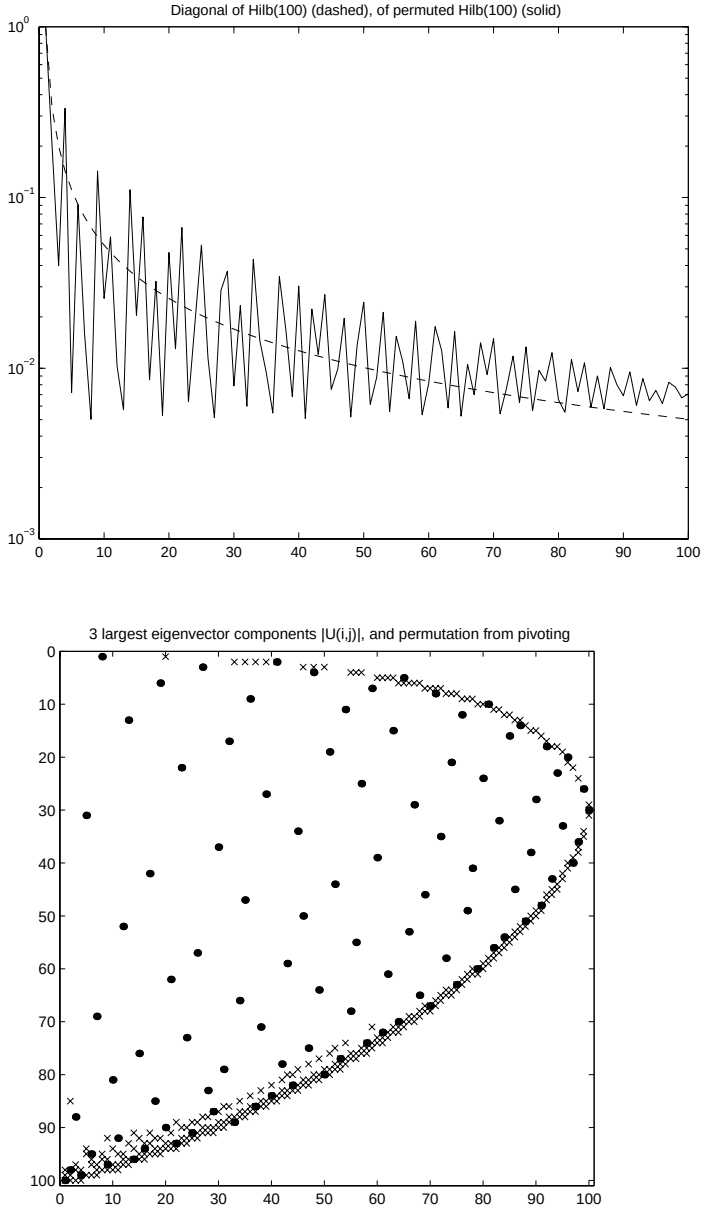

FIG. 3. *Complete pivoting of the* 100-*by*-100 *Hilbert matrix. The top plot shows the diagonal of the Hilbert matrix before (dashed line) and after (solid line) pivoting. The bottom plot superimposes a "spy-plot" of the locations of the three largest entries of each eigenvector (as x's) and the permutation matrix corresponding to complete pivoting (as black dots).*

$x_i < x_{i+1}$) and multiplied by -1 (if any $D_{1,i} < 0$) to make G totally positive. We note that this order is in general not the same as the order determined by pivoting during the algorithm.

A similar approach was also applied to the Hilbert matrix in [29], but using a

formula for the Cholesky factor of the Hilbert matrix without pivoting. When $n = 100$, the corresponding L has a condition number in excess of 10^{20}, so relative accuracy is not guaranteed. Complete pivoting is essential. The top of Figure 3 shows both the diagonal of the unpivoted Hilbert matrix H (dashed line) and the diagonal of the Hilbert matrix PHP^T after applying the permutation P corresponding to complete pivoting; they differ greatly. To better understand the permutation P, in the bottom of Figure 3 we superimpose a "spy-plot" of the nonzero entries of P and the three largest entries in absolute value of each eigenvector; the permutation P frequently corresponds to the location of one of the three largest matrix entries, and otherwise usually corresponds to one of the larger eigenvector entries (which fall to the left of the curve of x's). We do not entirely understand this phenomenon.

5. Vandermonde matrices. Let V be an n-by-n Vandermonde matrix, so that $V_{ij} = x_i^{j-1}$. Let F be the n-by-n discrete Fourier transform matrix, so that $F_{ij} = \omega^{(i-1)(j-1)}/\sqrt{n}$, where $\omega = \exp(2\pi\sqrt{-1}/n)$ is a primitive nth root of unity. Assume for now that no x_i is equal to one of the roots of unity in F; we eliminate this assumption later. Then it is easy to see that VF is quasi-Cauchy by computing

$$\begin{aligned}(VF)_{ij} &= \frac{1}{\sqrt{n}} \sum_{k=0}^{n-1} x_i^k \omega^{(j-1)k} \\ &= \frac{1}{\sqrt{n}} \frac{1-(x_i\omega^{j-1})^n}{1-x_i\omega^{j-1}} \\ &= \frac{1-x_i^n}{\sqrt{n}\omega^{j-1}} \frac{1}{\omega^{1-j}-x_i} \quad .\end{aligned}$$

Thus, provided we can compute all of $D_{1,i} = 1 - x_i^n$, $D_{2,j} = \omega^{1-j}/\sqrt{n}$, $\omega^{1-j} - x_i$, and $\omega^{1-j} - \omega^{1-k}$ to high relative accuracy, we can use Algorithm 3 to compute the triangular factorization of VF to high relative accuracy, and then the SVD $VF = U\Sigma\widetilde{V}^T$ to high relative accuracy. We compute the final SVD via $V = U\Sigma(F\widetilde{V})^T$; multiplying $F\widetilde{V}$ increases the angular error in the right singular vectors by only $O(\varepsilon)$.

Now consider that case when some x_i is a root of unity appearing in F. Since x_i is a (real or complex) floating point number, i.e., rational, the only possible roots of unity that x_i can equal are ± 1 and $\pm\sqrt{-1}$. In this case, the ith row of VF will contain all zeros except for one entry equal to $\sqrt{n}$; thus VF is not quasi-Cauchy. Here is how to incorporate such rows into the GECP process. Since all entries but one are zero, the row will not participate in any operations until either 1. $\sqrt{n}$ is itself selected as the pivot or 2. $\sqrt{n}$ is eliminated by another larger pivot in the same column. In case 1, this simply results in eliminating all other entries in its column, without updating any other nonzero entries. The remaining matrix is quasi-Cauchy (with possibly other rows with a single nonzero), so the elimination can proceed as before. In case 2, the zero row entries are filled in, but it is straightforward to show that the resulting overall matrix with the newly filled row is still quasi-Cauchy, so elimination can again proceed as before.

Now we consider how to compute $\omega^{1-j} - \omega^{1-k}$ to high relative accuracy. Given a table of powers of ω, we can simply compute $\omega^{1-j} - \omega^{1-k}$ in the obvious way. Since $|\omega^{1-j} - \omega^{1-k}| \geq 2\sin(\pi/n)$ the difference cannot be too small (unless n is truly enormous), so it is computed with relative accuracy $O(n\epsilon)$. One can do better by using formulas like $\cos(\alpha) - \cos(\beta) = 2\sin(\frac{\beta+\alpha}{2})\sin(\frac{\beta-\alpha}{2})$.

Next we discuss how to compute $x_i^n - 1$ and $\omega^{1-j} - x_i$ to high relative accuracy. We distinguish between the cases of x_i real and x_i complex, and deal with the easier

real case first. First consider $x_i^n - 1$ when x_i is real. When $x_i^n \leq 0$, we just compute $x_i^n - 1$ straightforwardly since there is no cancellation. When $x_i^n > 0$, we can either use the formula $(|x_i| - 1)\sum_{j=0}^{n-1} |x_i|^j$ for an $O(n)$ cost or use a repeated-squaring-like algorithm for $O(\log n)$ cost [25], or use $\mathrm{expm1}(n \cdot \log_e(x_i))$ for $O(1)$ cost, provided that good implementations of $\mathrm{expm1}(z) \equiv e^z - 1$ and $\log_e(z)$ are available [35, 36]. Next consider $\omega^{1-j} - x_i$. Assume that we have a table of values of ω^{1-j} which are accurate to high relative accuracy in the sense of (3) (with a tiny complex δ). Assume further that the real values of ω^{1-j} ($+1$ or -1) are *exact* in the table; the complex values can be computed using any reasonable implementations of sine and cosine. Then $\omega^{1-j} - x_i$ can be computed straightforwardly to high relative accuracy for the following reason: if ω^{1-j} is real, then it is exact, and the difference is computed to high relative accuracy. If ω^{1-j} is complex, its imaginary part is at least $\sin(2\pi/n)$, so $\omega^{1-j} - x_i$ cannot be any smaller in magnitude; therefore the difference is again small in the sense of a tiny complex δ in (3).

When x_i is complex, the situation is more complicated. We assume that we have a table of powers of ω, represented as follows: for each ω^k we store $w_{1,k} = \mathrm{round}(\omega^k)$ (the real and imaginary components being rounded to the *nearest* floating point numbers; a slightly larger error can be tolerated too) and $w_{2,k} = \mathrm{round}(\omega^k - w_{1,k})$ (rounding here may be less careful; a few units of error in the last place is tolerable). Later we will return to the computation of this table.

Using this table, we compute $\omega^k - x_i$ as $d_{k,i} = \mathrm{round}(\mathrm{round}(w_{1,k} - x_i) + w_{2,k})$, i.e., with two floating point operations. We claim that $d_{k,i}$ is accurate to high relative accuracy in both real and imaginary components independently. To see this, there are three cases. (The argument should be applied to the real and imaginary parts separately.)

1. If $x_i = w_{1,k}$ exactly, then $\mathrm{round}(w_{1,k} - x_i) = 0$. Then $d_{k,i} = w_{2,k}$ is correct to as many digits as $w_{2,k}$.
2. If $.5 < w_{1,k}/x_i < 2$ but $x_i \neq w_{1,k}$, then cancellation occurs in $\mathrm{round}(w_{1,k} - x_i)$. Because we assume arithmetic has a guard digit, this nonzero difference is exact, and at least about twice as large in magnitude as $w_{2,k}$ (we use the fact that $w_{1,k} = \mathrm{round}(\omega^k)$ is (nearly) the *nearest* floating point number to ω^k). This means that there is no significant cancellation in $\mathrm{round}(\mathrm{round}(w_{1,k} - x_i) + w_{2,k}) = \mathrm{round}((w_{1,k} - x_i) + w_{2,k})$, so it is computed to high relative accuracy.
3. If $w_{1,k}/x_i \leq .5$ or $2 \leq w_{1,k}/x_i$, then $\mathrm{round}(w_{1,k} - x_i)$ is accurate to high relative accuracy, and since it is at least half as large in magnitude as $w_{1,k}$, adding $w_{2,k}$ does not change it significantly.

To compute $x_i^n - 1$ accurately, we can evaluate it as $\prod_{i=0}^{n-1}(x_i - \omega^i)$, evaluating each difference as described above.

Now we return to the computation of the table of values of $w_{1,k}$ and $w_{2,k}$. The obvious algorithm is to compute $w = \mathrm{round_to_double}(\omega^k)$ to double precision, let $w_{1,k} = \mathrm{round_to_single}(w)$, and $w_{2,k} = \mathrm{round_to_single}(w - w_{1,k})$. The trouble is that $w_{2,k}$ may be much smaller than εw, so that it may have few or no significant digits when computed this way, whereas we rely on it being accurate to single precision. For example, $\cos(2 \cdot 99 \cdot \pi/3565) \approx .9848162531852694$. Rounding this to single yields the real part of $w_{1,99} \approx .9848162531852722$, and subtracting to get the real part of $w_{2,99}$ yields $\approx -2.776 \cdot 10^{-15}$, which only has 5 significant bits. In other words, high precision arithmetic may be needed to compute the table. But since we can empirically confirm that the above example is the worst case up to $n = 10000$, we can

assert that *triple* precision is enough up to $n = 10000$ for input data in IEEE single precision.

Since this table needs only to be computed once and for all for each n, and *not* for each input matrix, its cost should not be considered part of the algorithm. Since its cost is only $O(n)$ as opposed to $O(n^3)$ for the rest of the algorithm anyway, one could in practice recompute the table for each input. A similar issue arises for the FFT itself, where one can precompute and store the ω^k, or compute them on the fly (the latter of which may actually be faster because it uses less memory bandwidth).

The following observation [2] indicates why we expect triple precision to be enough except perhaps in rare cases. By the theory of continued fractions [27, Thm. 19], a rational approximation $p/q \approx \Re\omega^k$ (the real part of ω^k) can satisfy only $|p/q - \omega^k| < 1/(2q^2)$ if p/q is a *convergent* of $\Re\omega^k$, i.e., a truncation of the infinite continued fraction expansion of $\Re\omega^k$ (the same is true for the imaginary part). Therefore, unless the floating point approximation $\Re w_{1,k}$ happens to equal this convergent, which seems unlikely, we will have

$$|\Re w_{2,k}| \approx |\Re w_{1,k} - \Re\omega^k| \geq 1/(2q^2).$$

Since $\Re w_{1,k} = p/q$ is a floating point number, $q = 2^e$, where $e \approx |\log_2 \Re\omega^k| + b$, where b is the number of bits in the floating point fraction, and $p \approx 2^b$, since the floating point fraction is normalized. The nontrivial values of $\Re\omega^k$ satisfy $|\Re\omega^k| \gtrapprox 2\pi/n$, so

$$\frac{|\Re w_{2,k}|}{|\Re\omega^k|} \gtrapprox \frac{1}{(2q^2)} \cdot \frac{q}{p} = \frac{1}{2pq} \gtrapprox 2^{-2b}(\pi/n).$$

This says that computing ω^k to triple precision means that $\Re w_{2,k}$ will be determined with relative error at most $(n/\pi)2^{-b}$, i.e., nearly single precision.

It is an open problem to avoid the need for this high precision table entirely.

6. Unit displacement rank matrices. The most general situation for which the above high accuracy SVD technique works is described as follows. Assume that G satisfies the Sylvester equation (or *displacement equation* [4, 15, 3, 30])

$$XG + GY = d_1 d_2^T,$$

where X and Y are diagonal matrices with diagonal entries x_i and y_j, respectively, and d_1 and d_2 are column vectors. Then it is immediate to see that G is quasi-Cauchy with $G_{ij} = d_{1i}d_{2j}/(x_i + y_j)$.

Now suppose that X and Y are normal matrices with eigendecompositions $X = U_X D_X U_X^T$ and $Y = U_Y D_Y U_Y^T$. Then we can premultiply the above equation by U_X^T and postmultiply it by U_Y to transform it to

$$D_X(U_X^T G U_Y) + (U_X^T G U_Y)D_Y = (U_X^T d_1)(U_Y^T d_2)^T$$

or

$$D_X G' + G' D_Y = d_1' d_2'^T$$

so that G' is quasi-Cauchy. Thus, if this transform can be performed accurately enough, then we can compute the SVD of $G' = U\Sigma V^T$, and backtransform using U_X and U_Y to get the SVD of $G = (U_X U)\Sigma(U_Y V)^T$.

For example, Vandermonde matrices satisfy the displacement equation with X diagonal and Y a circular shift. The eigenvector matrix of Y is the discrete Fourier

transform matrix F, and its eigenvalues are roots of unity. The entries of d_1 are $x_i^n - 1$. This is the transformation used in the previous section.

One can imagine other possibilities besides X and Y diagonal or circular shifts, but it is important that $d_1' = U_X^T d_1$ and $d_2' = U_Y^T d_2$ be computable to high relative accuracy (alternatively, one could say that d_1' and d_2' are the parameters of G that determine its SVD to high relative accuracy).

Now consider the case of X and Y diagonalizable, but not necessarily normal, so that $X = U_X D_X U_X^{-1}$ and $Y = U_Y D_Y U_Y^{-1}$. Then given the SVD $G' = U\Sigma V^T$, $G = (U_X U)\Sigma(U_Y^{-T} V)^T$ is *not* the SVD of G, because U_X and U_Y are not unitary. Instead, we simply convert the RRD $G' = XDY^T$ obtained by Algorithm 3 into the RRD $G = (U_X X)D(U_Y^{-T} Y)^T$ and then apply Algorithm 1 [12].

What about matrices satisfying displacement equations with higher than rank-1 matrices on the right-hand side? For example, Toeplitz matrices satisfy such an equation with rank 2. We argue that no high relative accuracy algorithm like ours can exist for general Toeplitz matrices, and we believe it is unlikely that they exist for higher displacement rank in general.

It is tricky to argue impossibility results in floating point arithmetic, because one can simulate arbitrary precision floating point using just standard floating point, without "bit-fiddling" [33]. Still, we may argue informally as follows. Consider just a 2-by-2 Toeplitz matrix:

$$T = \begin{bmatrix} a & b \\ c & a \end{bmatrix}.$$

If we could compute the singular values of T to high relative accuracy, then by multiplying them we could compute the determinant of T to high relative accuracy (actually just its absolute value, but that is enough for this argument). In other words, we would have a floating point algorithm for evaluating $a^2 - b \cdot c$ to high relative accuracy, without any tricks like splitting a, b, or c into half-precision parts and combining them separately. But since $a^2 - b \cdot c$ does not factor into products and quotients of factors we can compute to high relative accuracy (like $x_i - x_j$ for Cauchy and Vandermonde matrices) – indeed, it does not factor at all – we believe that there is no forward stable SVD algorithm for Toeplitz matrices. Furthermore, it appears that n-by-n Toeplitz determinants have irreducible factors whose degrees grow with n, which means that higher precision would be needed as n grew.

To illustrate the difficulties in formalizing this argument, consider a matrix of the form $G_{ij} = d_{1i} d_{2j}/(x_i w_j + y_j z_i)$. This is quasi-Cauchy, since we can also write $G_{ij} = (d_{1i}/z_i)(d_{2j}/w_j)/((x_i/z_i) + (y_j/w_j))$. The sums and differences that we would need to compute to high relative accuracy in the algorithm of section 4 look like $(x_i/z_i) + (y_j/w_j) = (x_i w_j + y_j z_i)/(w_j z_i)$. These can be evaluated to high relative accuracy using double precision, or in single precision using the techniques in [33].

More generally, if *every* minor of G factors into products and quotients of 1 or 2 term polynomials of degree at most d in the original parameters ($d = 1$ for the quasi-Cauchy matrices in section 4, $d = 1$ for acyclic matrices [8, 7], and $d = 2$ for the matrix in the last paragraph), then a high accuracy SVD algorithm requiring at most d-tuple precision (for the LU factorization) exists. As stated above, d appears to grow with dimension of Toeplitz matrices, so no fixed precision would suffice in the Toeplitz case. Whether an acceptably fast algorithm ($O(n^3)$ or better) exists to compute the LU factorization this way is a different question that depends on another structure of the matrix, like its sparsity pattern or whether it has low displacement rank.

One might object that our required table of high accuracy roots of unity in section 5 violates the spirit of our impossibility argument. The difference is that the table need only be computed once and for all for all complex Vandermonde matrices, that the precision (two significant words) is independent of the Vandermonde data, and that the cost is $O(n)$, in contrast to the $O(n^3)$ overall cost. In contrast, for Toeplitz matrices $O(n^3)$ extra precise operations are required for each matrix, real or complex, and the precision seems to grow with dimension.

Matrices which are simultaneously Cauchy and Toeplitz deserve special mention. The accuracy question depends on which parameters are used to represent these matrices. Either the Cauchy data alone (x_i and y_j), or the Toeplitz data alone (the entries $a_{i,j} \equiv t_{j-i}$ of the first row and column) is redundant. It is not hard to see that two parameters, α and β, form a minimal parameterization of such matrices: $a_{i,j} = 1/(\alpha + \beta(j-i))$. A quasi-Cauchy-Toeplitz matrix is determined by three parameters: $a_{i,j} = \gamma^{j-i}/(\alpha + \beta(j-i))$. Either parameterization determines $x_i - x_j = (j-i)\beta = y_j - y_i$ to as much relative accuracy as β is known. But it may or may not determine $x_i + y_j = \gamma^{j-i}/t_{j-i} = \alpha + (j-i)\beta$ accurately, depending on cancellation. A better parameterization would be the *smallest* $\alpha + k\beta$ in absolute value for any $-n < k < n$, the value k (which is exact) at which the minimum is attained, β, and γ. This way all values of $1/t_{j-i}$ can be determined to high relative accuracy, and small relative changes in $\alpha + k\beta$, β, and γ can cause only small relative changes in the SVD.

7. Estimating the error when the input is uncertain. So far we have considered only exact inputs, and shown that we compute the SVD to high relative accuracy, as defined in the introduction. When the parameters x_i, y_i, D_{1i}, and D_{2i} defining a quasi-Cauchy matrix are themselves uncertain, then we may easily compute a relative error bound on the SVD using Theorem 2.1 from [8].

THEOREM 7.1 (see [8, Theorem 2.1]). *Let $G = XDY^T$ be an RRD with SVD $G = U\Sigma V^T$, and let $\hat{G} = \hat{X}\hat{D}\hat{Y}^T$ with SVD $\hat{G} = \hat{U}\hat{\Sigma}\hat{V}^T$, where $\hat{X}$, $\hat{D}$, and $\hat{Y}$ are defined as follows:*

$$\hat{X} = X + \delta X, \quad \textit{where} \quad \frac{\|\delta X\|}{\|X\|} \le \epsilon,$$

$$\hat{D} = D + \delta D, \quad \textit{where} \quad \delta D \ \textit{is diagonal and} \ \frac{|\delta D_{ii}|}{|D_{ii}|} \le \epsilon,$$

$$\hat{Y} = Y + \delta Y, \quad \textit{where} \quad \frac{\|\delta Y\|}{\|Y\|} \le \epsilon,$$

where $0 \le \epsilon < 1$. Let $\eta = \epsilon(2+\epsilon)\max(\kappa(X), \kappa(Y))$ and $\eta' = 2\eta + \eta^2$, where $\kappa(Z) = \sigma_{\max}(Z)/\sigma_{\min}(Z)$ is the condition number of Z. Then the difference between the singular values of G and $\hat{G}$ is bounded as follows:

$$\frac{|\sigma_i - \hat{\sigma}_i|}{\sigma_i} \le \eta'. \tag{4}$$

Furthermore, the angle θ between u_i and $\hat{u}_i$ (or between v_i and $\hat{v}_i$) is bounded by

$$\sin\theta \le \sqrt{2}\left(\frac{1+\eta'}{1-\eta'} \cdot \frac{\eta'}{\min(\text{relgap}_i, 2) - \eta'} + \eta\right) \tag{5}$$

provided that $\min(\text{relgap}_i, 2) \ge \eta'$.

It is easy to see that relative errors of size ϵ in the D_{1i} and D_{2i} can increase the relative errors in the singular values by at most ϵ, and the errors in the singular vectors by at most about ϵ divided by the relative gap. Given uncertainty bounds $x_i \pm \delta x_i$ and $y_i \pm \delta y_i$, we can also easily bound the maximum relative error in any factor like $x_i + y_j$ (namely $\varepsilon + (|\delta x_i| + |\delta y_j|)/|x_i + y_j|$) appearing in the algorithm in section 4. The maximum such factor-wise relative error can be used as an estimate of ϵ in Theorem 2.1 above. (This ignores factors depending on the dimension n, which are often pessimistic anyway.)

From this point of view the Hilbert matrix is very well conditioned, since small relative changes in the values of $x_i = i$ and $y_i = i-1$ cause only small relative changes in the SVD.

More generally, consider a totally positive Cauchy matrix, where $0 < x_1 < \cdots < x_m$ and $0 < y_1 < \cdots < y_n$. In this case small relative changes in the x_i and y_j cause only small relative changes in the $x_i + y_j$, so the relative accuracy depends only on the *relative gaps* $(x_{i+1} - x_i)/(x_{i+1} + x_i) < 1$ and $(y_{j+1} - y_j)/(y_{j+1} + y_j) < 1$; if these are not small, small relative changes in the x_i and y_j cause only small relative changes in the SVD. (The most general characterization of totally positive Cauchy matrices reduces the requirements $0 < x_1$ and $0 < y_1$ to just $0 < x_1 + y_1$ [14], but this allows cancellation, which is why we used the stronger conditions $0 < x_1$ and $0 < y_1$.)

Acknowledgments. The author thanks Ming Gu and Vadim Olshevsky for discussion of and pointers to relevant displacement rank literature, Doug Priest, W. Kahan, and Peter Tang for discussions of floating point issues, Zlatko Drmač for simplifying and improving some of the algorithms, David Blackston for pointing out the connection with continued fractions, and the three referees for many useful comments.

INTERLACING INEQUALITIES AND CARTAN SUBSPACES OF CLASSICAL REAL SIMPLE LIE ALGEBRAS*

TIN-YAU TAM†

Abstract. The well-known interlacing inequalities are examined in the framework of classical real simple Lie algebras.

Key words. interlacing inequalities, Cartan subspaces, real simple Lie algebras

AMS subject classifications. 15A42, 17B20

PII. S0895479898343528

1. Introduction.

Let A be an $n \times n$ Hermitian matrix with eigenvalues

$$\alpha_1 \geq \cdots \geq \alpha_n \tag{1.1}$$

and let B be a $k \times k$ principal submatrix of A, having eigenvalues

$$\beta_1 \geq \cdots \geq \beta_k. \tag{1.2}$$

The well-known Cauchy interlacing inequalities [7] are

$$\alpha_i \geq \beta_i \geq \alpha_{i+n-k}, \qquad i = 1, \ldots, k. \tag{1.3}$$

When $k = n - 1$, (1.3) becomes

$$\alpha_1 \geq \beta_1 \geq \alpha_2 \geq \beta_2 \geq \cdots \geq \alpha_{n-1} \geq \beta_{n-1} \geq \alpha_n, \tag{1.4}$$

which are genuinely interlacing inequalites. The interlacing inequalites (1.3) are closely related to the Poincaré inequality and the Courant–Fischer–Weyl minimax principle. Indeed they can be derived from each other [1], [2]. The following converse is true. Given two sets of real numbers (1.1) and (1.2) satisfying the interlacing inequalites (1.3), there exists an $n \times n$ real symmetric (thus Hermitian) matrix A with a $k \times k$ principal submatrix B, having eigenvalues (1.1) and (1.2), respectively. Fan and Pall [4] were apparently the first to publish a proof of the converse, and according to them, in 1953 H. Wielandt had an unpublished proof of the same result based on a different idea; see also [8] and [9]. The essential case is (1.4), as observed by Fan and Pall [4, p. 299], in the sense that (1.3) and its converse will then follow. For if (1.3) holds, sequences of eigenvalues can be inserted such that two consecutive sequences are genuinely interlaced as in (1.4). Then, by the result for $k = n-1$, there exists a chain of Hermitian matrices having prescribed eigenvalues such that each is a principal submatrix of the next.

Thompson [12] obtained similar interlacing inequalites for an arbitrary $p \times q$ complex matrix A, but now the role of the eigenvalues is played by the singular values. Let B be a $k_1 \times k_2$ submatrix of A. Let

$$\alpha_1 \geq \cdots \geq \alpha_{\min\{p,q\}} \tag{1.5}$$

be the singular values of A and let

$$\beta_1 \geq \cdots \geq \beta_{\min\{k_1,k_2\}} \tag{1.6}$$

be the singular values of B. Then [12, p. 4]

$$\alpha_i \geq \beta_i, \qquad i = 1, \ldots, \min\{k_1, k_2\} \tag{1.7}$$

$$\beta_i \geq \alpha_{i+(p-k_1)+(q-k_2)}, \qquad i \leq \min\{k_1 + k_2 - p, k_1 + k_2 - q\}. \tag{1.8}$$

When $p = q$ and $k_1 = k_2 = p - 1$, i.e., we have the singular values of a $p \times p$ matrix and its $(p-1) \times (p-1)$ submatrices, (1.7) and (1.8) become

$$\begin{gathered} \alpha_1 \geq \beta_1 \geq \alpha_3, \\ \alpha_2 \geq \beta_2 \geq \alpha_4, \\ \vdots \\ \alpha_{p-2} \geq \beta_{p-2} \geq \alpha_p, \\ \alpha_{p-1} \geq \beta_{p-1}. \end{gathered} \tag{1.9}$$

The index drops by two in (1.9) instead of one. However, if we just delete one row or one column at a time, then we do have the genuine interlacing inequalities

$$\alpha_1 \geq \beta_1 \geq \alpha_2 \geq \beta_2 \geq \cdots. \tag{1.10}$$

Similar to the Hermitian case, given (1.5) and (1.6) satisfying (1.7) and (1.8), there exists a $p \times q$ real (indeed, the proof of Thompson [12, Theorem 2] also works for the real case) matrix A with a $k_1 \times k_2$ submatrix B having singular values (1.5) and (1.6), respectively.

There are orbital descriptions of the above two results.

THEOREM 1.1 (see Cauchy–Fan–Pall [3], [4]). *Let A be an $n \times n$ Hermitian (respectively, real symmetric) matrix with eigenvalues* (1.1). *The eigenvalues of $(UAU^*)[1, \ldots, k|1, \ldots, k]$ fill out the values permitted by* (1.3) *as U runs through the unitary group $U(n)$ (respectively, the orthogonal group $O(n)$).*

THEOREM 1.2 (Thompson [12]). *If A is a $p \times q$ complex (respectively, real) matrix, then the singular values of $(UAV)[1, \ldots, k_1|1, \ldots, k_2]$ fill out the values permitted by* (1.7) *and* (1.8) *as U and V run through the unitary groups $U(p)$ and $U(q)$ (respectively, $O(p)$ and $O(q)$) independently.*

This orbital point of view turns out to be very useful when we study a similar problem in a more general setting.

Thompson [13] suggested that the index on the lower side of each inequality (1.9) drops by two instead of one, as in (1.4), due to the fact that the number of degrees of freedom in the singular value case is doubled, since one considers UAV when A is a complex matrix, in contrast to UAU^* when A is Hermitian. But the explanation is not satisfactory since Thompson [13] also discovered the following result for a complex symmetric matrix somewhat unexpectedly. Thus, counting the degrees of freedom is not always a reliable guide [14, p. 119] in the study of interlacing inequalities.

THEOREM 1.3 (see Thompson [13]). *Let A be an $n \times n$ complex symmetric matrix having singular values* (1.1). *The singular values of $(UAU^T)[1, \ldots, n-1|1, \ldots, n-1]$, $U \in U(n)$, fill out all values permitted by* (1.9) *where $p = n$.*

We will see that the number of deleted rows and columns is a contributing factor to the above phenomenon when we encounter $\mathfrak{sp}_{2n}(\mathbb{R})$.

Let $\mathfrak{g} = \mathfrak{k} + \mathfrak{p}$ be a Cartan decomposition of a real semisimple Lie algebra $\mathfrak{g}$ whose analytic group is G. Let K be the analytic subgroup of G (it is unique once we fix G), whose Lie algebra is $\mathfrak{k}$. Here $\mathfrak{p}$, which will be called the Cartan subspace of $\mathfrak{g}$, is the orthogonal complement of $\mathfrak{k}$ in $\mathfrak{g}$ with respect to the Killing form $B(\cdot, \cdot)$. The group K acts on $\mathfrak{p}$ via adjoint representation Ad, i.e., $x \mapsto \mathrm{Ad}(k)x$, if $x \in \mathfrak{p}$. Denote by $O(x)$ the orbit of x under the action of K, i.e., $O(x) = \{\mathrm{Ad}(k)x : k \in K\}$. It is known that

$$O(x) \cap \mathfrak{a}_+ \neq \phi, \qquad x \in \mathfrak{p}, \tag{1.11}$$

where $\mathfrak{a}_+$ is a fundamental Weyl chamber of the maximal abelian subalgebra $\mathfrak{a}$ in $\mathfrak{p}$. See [5]. Indeed the set $O(x) \cap \mathfrak{a}_+$ is merely a singleton set whose element will be denoted by $\mathfrak{a}_+(x)$. Since we will study only the classical real simple Lie algebras, the adjoint action is just conjugation, i.e., $\mathrm{Ad}(k)x = kxk^{-1}$. The idea of recovering interlacing inequalities is that we pick any element $x \in \mathfrak{p}$ and consider an appropriate compression P from $\mathfrak{p}$ to a lower dimensional space $\mathfrak{p}'$, which is a Cartan subspace of a simple $\mathfrak{g}'$, where $\mathfrak{g}'$ and $\mathfrak{g}$ are of the same classical series. Then we consider the compression of the orbit $O(x)$, $O'(x) := PO(x) \subset \mathfrak{p}'$. Now we want to describe $\mathfrak{a}'_+(O'(x))$. It turns out that the appropriate interlacing inequalities are the complete description.

The classical real simple Lie algebras [10, p. 233] are isomorphic to one of the following real forms $\mathfrak{h} \subset \mathfrak{g}$ and $\mathfrak{g}^{\mathbb{R}}$ (the realification of $\mathfrak{g}$).

1. $\mathfrak{g} = \mathfrak{sl}_n(\mathbb{C})$, $n \geq 2$
   (a) $\mathfrak{h} = \mathfrak{sl}_n(\mathbb{R})$,
   (b) $\mathfrak{h} = \mathfrak{sl}_m(\mathbb{H})$, $n = 2m$,
   (c) $\mathfrak{h} = \mathfrak{su}_{p,q}$ $(p = 0, 1, \ldots, [\frac{n}{2}]$, $p + q = n)$.
2. $\mathfrak{g} = \mathfrak{so}_{2n+1}(\mathbb{C})$, $n \geq 2$
   (a) $\mathfrak{h} = \mathfrak{so}_{p,q}$ $(p = 0, 1, \ldots, n$, $p + q = 2n + 1)$.
3. $\mathfrak{g} = \mathfrak{sp}_{2n}(\mathbb{C})$, $n = 2m$, $m \geq 3$
   (a) $\mathfrak{h} = \mathfrak{sp}_{2n}(\mathbb{R})$, $n = 2m$,
   (b) $\mathfrak{h} = \mathfrak{sp}_{p,q}$ $(p = 0, 1, \ldots, [m/2]$, $p + q = m)$.
4. $\mathfrak{g} = \mathfrak{so}_{2n}(\mathbb{C})$, $n \geq 4$
   (a) $\mathfrak{h} = \mathfrak{so}_{p,q}$ $(p = 0, 1, \ldots, n$, $p + q = 2n)$,
   (b) $\mathfrak{h} = \mathfrak{so}^*(2n)$.

2. The real forms of $\mathfrak{sl}_n(\mathbb{C})$. We will see that the real forms of $\mathfrak{sl}_n(\mathbb{C})$ are related to the interlacing results for real symmetric, Hermitian, quaternionic Hermitian, and complex matrices. The group $SL(n, \mathbb{F}) \subset GL(n, \mathbb{F})$ is the special linear group consisting of $n \times n$ matrices with determinant 1. The Lie algebra is $\mathfrak{sl}_n(\mathbb{F})$, i.e., the traceless $n \times n$ matrices with elements in $\mathbb{F}$. The Cartan decomposition of $\mathfrak{sl}_n(\mathbb{F})$ is $\mathfrak{sl}_n(\mathbb{F}) = \mathfrak{k} + \mathfrak{p}$, where $\mathfrak{p}$ is the space of traceless real symmetric, Hermitian, and quaternionic Hermitian matrices (i.e., $A = A^*$, where $A^* = \overline{A}^T$ and $\overline{a_1 + ia_2 + ja_3 + ka_4} = a_1 - ia_2 - ja_3 - ka_4$) when $\mathbb{F} = \mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$, respectively. The group K is $SU_n(\mathbb{F})$ and $\mathfrak{k}$ is the algebra of real skew symmetric, traceless skew Hermitian, and traceless quaternionic skew Hermitian matrices accordingly; $\mathfrak{a} \subset \mathfrak{p}$ is the subset of real diagonal matrices; $\mathfrak{a}_+ \subset \mathfrak{a}$ can be chosen as the subset of real diagonal matrices with decreasing diagonal entries. Then (1.11) is simply the spectral decomposition, though the quaternionic spectral decomposition is less well known. Now (1.11) means that a quaternionic Hermitian matrix is quaternionic unitarily similar to a real diagonal matrix whose diagonal elements are called the (right) eigenvalues of A.

When $\mathbb{F} = \mathbb{C}$ or $\mathbb{R}$, we have Cauchy–Fan–Pall's result. Of course one can consider general Hermitian or real symmetric matrices which correspond to the reductive algebras $\mathfrak{gl}_n(\mathbb{F}) = \mathfrak{sl}_n(\mathbb{F}) + \mathbb{R}I$, $\mathbb{F} = \mathbb{C}$, $\mathbb{R}$, respectively. The groups $SU_n(\mathbb{C})$ and $SU_n(\mathbb{R})$ act trivially on the center $\mathbb{R}I$. So the study of traceless cases is sufficient. Indeed one can replace $SU_n(\mathbb{F})$ by $U_n(\mathbb{F})$, as they will give the same orbit $O(A)$. The following result is for the quaternionic case, due to Thompson [14], and we will give another proof.

THEOREM 2.1 (see [14, pp. 132–133]). *Let A be an $n \times n$ quaternionic Hermitian matrix with eigenvalues* (1.1); *then the eigenvalues of $(UAU^*)[1, \dots, k|1, \dots, k]$ fill out the values permitted by* (1.3) *as U runs through the quaternionic unitary group $U_n(\mathbb{H})$.*

Proof. It suffices to consider $A \in \mathfrak{sl}_n(\mathbb{H})$. We identify $\mathfrak{sl}_n(\mathbb{H})$ with $\mathfrak{su}^*(2n)$ via the standard isomorphism $\mathbb{H} = \mathbb{C} + \mathbb{C}j = \mathbb{C}^2$, such that $a + bj \mapsto (a, b)$, $a, b \in \mathbb{C}$ ([6], pp. 26–27), i.e., $A + Bj \in \mathfrak{sl}_n(\mathbb{H})$ is identified with

$$\varphi(A + Bj) := \begin{pmatrix} A & -\overline{B} \\ B & \overline{A} \end{pmatrix} \in \mathfrak{su}^*(2n).$$

Notice that $\varphi(XY) = \varphi(X)\varphi(Y)$ and $\varphi(X^*) = \varphi(X)$ for any $X, Y \in \mathbb{H}_{n\times n}$. With this isomorphism, $SU_n(\mathbb{H})$ is identified with $Sp(n) \cap SU(2n)$. Since $U(n)$ acts on Hermitian matrices in the same way as $SU(n)$, we can simply use $Sp(n)$ instead of $Sp(n) \cap SU(2n)$. Indeed,

$$\begin{aligned}
\mathfrak{su}^*(2n) &= \left\{ \begin{pmatrix} X & Y \\ -\overline{Y} & \overline{X} \end{pmatrix} : \operatorname{Re} \operatorname{tr} X = 0,\ X, Y \in \mathbb{C}_{n\times n} \right\}, \\
K = Sp(n) &= \left\{ \begin{pmatrix} U & V \\ -\overline{V} & \overline{U} \end{pmatrix}, U, V \in \mathbb{C}_{n\times n} \right\} \cap U(2n), \\
\mathfrak{k} = \mathfrak{sp}(n) &= \left\{ \begin{pmatrix} X & Y \\ -\overline{Y} & \overline{X} \end{pmatrix} : X^* = -X,\ Y^T = Y \right\}, \\
\mathfrak{p} &= \left\{ \begin{pmatrix} X & Y \\ -\overline{Y} & \overline{X} \end{pmatrix} : X^* = X,\ \operatorname{tr} X = 0,\ Y^T = -Y \right\}, \\
\mathfrak{a} &= \left\{ \operatorname{diag}(a_1, \dots, a_n, a_1, \dots, a_n), a_1, \dots, a_n \in \mathbb{R},\ \sum_{i=1}^{n} a_i = 0 \right\}.
\end{aligned}$$

The study of $(U(A + Bj)U^*)[1, \dots, k|1, \dots, k]$ is reduced to that of

$$(\varphi(U)\varphi(A + Bj)\varphi(U)^*)[1, \dots, k, n+1, \dots, n+k|1, \dots, k, n+1, \dots, n+k],$$

a Hermitian case. We notice that the eigenvalues of $\varphi(A + Bj)$ appear in pairs, i.e., $\alpha_1, \alpha_1, \dots, \alpha_n, \alpha_n$, but the number of deleted rows and columns is $2(n - k)$. So we have (1.3) by Cauchy's interlacing inequality. For the converse, we just consider the orbit $\{(U \oplus U)\Lambda(U^T \oplus U^T) : U \in O(n)\}$, where $\Lambda = \operatorname{diag}(\alpha_1, \dots, \alpha_n, \alpha_1, \dots, \alpha_n)$ and apply Fan–Pall's result. ∎

Summarizing the above results we arrive at the following theorem.

THEOREM 2.2 (Cauchy–Fan–Pall–Thompson). *Let A be an $n \times n$ Hermitian matrix over the field $\mathbb{F}$, where $\mathbb{F} = \mathbb{R}$, $\mathbb{C}$, or $\mathbb{F}$, with $\mathfrak{a}_+(A) = (\alpha_1, \dots, \alpha_n)$. Then*

$$\{\mathfrak{a}_+((UAU^*)[1, \dots k|1, \dots, k]) : U \in SU_n(\mathbb{F})\} = \prod_{i=1}^{k} [\alpha_{i+n-k}, \alpha_i].$$

We remark that the set in the above theorem is a "rectangular solid" in $\mathbb{R}^k$.

Let us consider the last real form of the $\mathfrak{sl}_n(\mathbb{C})$, namely, $\mathfrak{su}_{p,q}$, which corresponds to the case of $p \times q$ complex matrices. It is known that [10]

$$\begin{aligned}
\mathfrak{su}_{p,q} &= \left\{ \begin{pmatrix} X_1 & Y \\ Y^* & X_2 \end{pmatrix} : X_1^* = -X_1,\ X_2^* = -X_2,\ \operatorname{tr} X_1 = \operatorname{tr} X_2 = 0,\ Y \in \mathbb{C}_{p\times q} \right\}, \\
K = SU(p,q) &= \left\{ \begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix} : U \in U(p), V \in U(q),\ \det U \det V = 1 \right\}, \\
\mathfrak{k} &= \mathfrak{su}_{p,q},\ \text{i.e.,}\ Y = 0, \\
\mathfrak{p} &= \left\{ \begin{pmatrix} 0 & Y \\ Y^* & 0 \end{pmatrix}, Y \in \mathbb{C}_{p\times q} \right\},\ \text{i.e.,}\ X_1 = X_2 = 0, \\
\mathfrak{a} &= \oplus_{1\le j\le p} \mathbb{R}(E_{j,p+j} + E_{p+j,j}), \\
\mathfrak{a}_+ &= \{\oplus_{1\le j\le p} a_j(E_{j,p+j} + E_{p+j,j}) : a_1 \ge \cdots \ge a_p \ge 0\}.
\end{aligned}$$

Now the orbit of an element in $\mathfrak{p}$ under the adjoint action of K is

$$\begin{aligned}
&\left\{ \begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix} \begin{pmatrix} 0 & A \\ A^* & 0 \end{pmatrix} \begin{pmatrix} U & 0 \\ 0 & V \end{pmatrix}^* : U \in U(p), V \in U(q),\ \det U \det V = 1 \right\} \\
&\quad = \left\{ \begin{pmatrix} 0 & UAV^* \\ VA^*U^* & 0 \end{pmatrix} : U \in U(p), V \in U(q),\ \det U \det V = 1 \right\} \\
&\quad = \left\{ \begin{pmatrix} 0 & UAV \\ (UAV)^* & 0 \end{pmatrix} : U \in U(p), V \in U(q) \right\}.
\end{aligned}$$

The last equality comes from

$$\begin{aligned}
&\{UAV^* : U \in U(p), V \in U(q), \det U \det V = 1\} \\
&= \{UAV^* : U \in U(p), V \in U(q), \det U = \det V^*\} \\
&= \{UAV : U \in U(p), V \in U(q)\}.
\end{aligned}$$

So (1.11) is the singular value decomposition of a $p \times q$ complex matrix. Notice that

$$\begin{aligned}
&\begin{pmatrix} 0 & A[1,\dots,k_1|1,\dots,k_2] \\ A[1,\dots,k_1|1,\dots,k_2]^* & 0 \end{pmatrix} \\
&\quad = \begin{pmatrix} 0 & A \\ A^* & 0 \end{pmatrix} [1,\dots,k_1,p+1,\dots,p+k_2|1,\dots,k_1,p+1,\dots p+k_2].
\end{aligned}$$

The eigenvalues of the matrix

$$\begin{pmatrix} 0 & A \\ A^* & 0 \end{pmatrix} \tag{2.1}$$

are $\alpha_1 \ge \alpha_2 \ge \cdots \ge \alpha_{\min\{p,q\}} \ge 0 \ge \cdots \ge 0 \ge -\alpha_{\min\{p,q\}} \ge \cdots \ge -\alpha_2 \ge -\alpha_1$, where α's are the singular values of A and there are $p+q-2\min\{p,q\}$ zeros. So the missing lower bound in the last inequality of (1.9) is indeed $-\alpha_p$, which is too superficial to write down. The matrix (2.1) is also used in [12] as a means to deduce the interlacing inequalities. Theorem 1.2 is the following corresponding interlacing result:

$$\begin{aligned}
&\{\mathfrak{a}_+((UAV)[1,\dots k_1|1,\dots,k_2]) : U \in U(p), V \in U(q)\} \\
&\quad = \prod_{i \le \min\{k_1+k_2-p,\, k_1+k_2-q\}} [\alpha_{i+(p-k_1)+(q-k_2)}, \alpha_i] \\
&\qquad \times \prod_{\min\{k_1+k_2-p,\, k_1+k_2-q\} < i \le \min\{k_1,k_2\}} [0, \alpha_i].
\end{aligned}$$

It is interesting to notice that the proof of Theorem 1.2 in [12] also relies on Theorem 1.1. However, [11] provides another proof without using Theorem 1.

3. The real forms of $\mathfrak{sp}_{2n}(\mathbb{C})$. The Cartan decomposition of

$$\mathfrak{sp}_{2n}(\mathbb{C}) = \left\{ \begin{pmatrix} X & Y_1 \\ Y_2 & -X^T \end{pmatrix} : \ X, Y_1, Y_2 \in \mathbb{C}_{n\times n},\ Y_1^T = Y_1, Y_2^T = Y_2 \right\}$$

is $\mathfrak{sp}_{2n}(\mathbb{C})^{\mathbb{R}} = \mathfrak{sp}(n) + i\mathfrak{sp}(n)$, i.e., $\mathfrak{k} = \mathfrak{sp}(n)$ and $\mathfrak{p} = i\mathfrak{sp}(n)$, where

$$\mathfrak{sp}(n) = \left\{ \begin{pmatrix} A_1 & -\overline{A}_2 \\ A_2 & \overline{A}_1 \end{pmatrix} : A_1, A_2 \in \mathbb{C}_{n\times n},\ A_1^* = -A_1,\ A_2^T = A_2 \right\},$$

and K is the symplectic group $Sp(n)$. Now

$$\begin{aligned} \mathfrak{a} &= \{\mathrm{diag}\,(a_1, \ldots, a_n, -a_1, \ldots, -a_n) : a_1, \ldots, a_n \in \mathbb{R}\} \\ \mathfrak{a}_+ &= \{\mathrm{diag}\,(a_1, \ldots, a_n, -a_1, \ldots, -a_n) : a_1 \geq \cdots \geq a_n \geq 0\}, \end{aligned}$$

which will be identified with $\mathbb{R}^n$ and $\{(a_1, \ldots, a_n) : a_1 \geq \cdots \geq a_n \geq 0\}$, respectively. Thus (1.11) means that if $C \in i\mathfrak{sp}(n)$, then there exists $U \in Sp(n)$ such that

$$U^*CU = \mathrm{diag}\,(c_1, \ldots, c_n, -c_1, \ldots, -c_n),$$

where $c_i \geq 0$ are the singular values of C, $i = 1, \ldots, n$. In the following we identify $i\mathfrak{sp}(n)$ and $\mathfrak{sp}(n)$ in the obvious way.

THEOREM 3.1. *Let $A \in \mathfrak{sp}(n)$ with $\mathfrak{a}_+(A) = (\alpha_1, \cdots, \alpha_n)$. Then*

$$\begin{aligned} &\{\mathfrak{a}_+((UAU^*)[1, \ldots, k, n+1, \ldots, n+k | 1, \ldots, k, n+1, \ldots, n+k]) : U \in Sp(n)\} \\ &\quad = \prod_{i \leq 2k-n} [\alpha_{i+(n-k)+(n-k)}, \alpha_i] \times \prod_{2k-n < i \leq k} [0, \alpha_i]. \end{aligned}$$

Proof. By Theorem 1.1 we have the inequalities since the matrix A is Hermitian. By considering the set

$$\{(U \oplus U)\mathrm{diag}\,(\alpha_1, \ldots, \alpha_n, -\alpha_1, \ldots, -\alpha_n)(U^T \oplus U^T) : U \in O(n)\}$$

and using Theorem 1.1 again, we have the desired result. □

We now consider $\mathfrak{sp}_{2n}(\mathbb{R})$, which will yield the interlacing inequalities for complex symmetric matrices. It is known that

$$\begin{aligned} \mathfrak{sp}_{2n}(\mathbb{R}) &= \left\{ \begin{pmatrix} X & Y_1 \\ Y_2 & -X^T \end{pmatrix} : Y_1^T = Y_1,\ Y_2^T = Y_2,\ X, Y_1, Y_2 \in \mathbb{R}_{n\times n} \right\}, \\ K &= \left\{ \begin{pmatrix} A & B \\ -B & A \end{pmatrix} : A^TA + B^TB = I,\ A^TB = B^TA,\ A, B \in \mathbb{R}_{n\times n} \right\}, \\ \mathfrak{k} &= \left\{ \begin{pmatrix} X & Y \\ -Y & X \end{pmatrix} : Y^T = Y,\ X^T = -X,\ X, Y \in \mathbb{R}_{n\times n} \right\}, \\ \mathfrak{p} &= \left\{ \{ \begin{pmatrix} X & Y \\ Y & -X \end{pmatrix} : Y^T = Y,\ X^T = X,\ X, Y \in \mathbb{R}_{n\times n} \right\}, \\ \mathfrak{a} &= \{\mathrm{diag}\,(a_1, \ldots, a_n, -a_1, \ldots, -a_n) : a_1, \ldots, a_n \geq 0\}. \end{aligned}$$

Notice that

$$\begin{pmatrix} U & V \\ -V & U \end{pmatrix} \in K$$

if and only if $U+iV \in U(n)$. Hence we identify K with $U(n)$ via the map

$$\begin{pmatrix} U & V \\ -V & U \end{pmatrix} \mapsto U+iV.$$

Now we identify $\mathfrak{p}$ with the space of $n \times n$ complex symmetric matrices via the map

$$\begin{pmatrix} X & Y \\ Y & -X \end{pmatrix} \mapsto Y+iX, \qquad X,Y \in \mathbb{R}_{n\times n},\ X^T=X,\ Y^T=Y.$$

Notice that with this identification, the group K acting on $\mathfrak{p}$ contains just those transformations of the form $x \mapsto cxc^T$. Hence the maximal abelian subalgebra $\mathfrak{a}$ can then be identified with the space of real diagonal matrices. We then pick $\mathfrak{a}_+$ to be the set of diagonal matrices $\operatorname{diag}(a_1,\dots,a_n)$, where $a_1 \geq \cdots \geq a_n$. Thus (1.11) means Takagi decomposition: a complex symmetric matrix is unitarily congruent to a diagonal matrix whose diagonal entries are the singular values of the matrix. The following is apparently an extension of Theorem 1.3. But it can also be proved by using the same technique in the proof [13] for Theorem 1.3, or it follows from Theorem 1.3 by the remark of Fan and Pall, analogously. We now give a proof according to our setting.

THEOREM 3.2 (see Thompson [13]). *Let A be an $n \times n$ complex symmetric matrix having singular values* (1.1). *The singular values of $(UAU^T)[1,\dots,k|1,\dots,k]$, $U \in U(n)$, denoted by* (1.2), *fill out all values permitted by* (1.7) *and* (1.8).

Proof. The eigenvalues of the real symmetric matrix

$$\begin{pmatrix} X & Y \\ Y & -X \end{pmatrix}$$

appear in pairs but in opposite signs, i.e, $\alpha_1 \geq \cdots \geq \alpha_n \geq -\alpha_n \geq \cdots \geq -\alpha_1$. But now taking a $k\times k$ principal submatrix of an $n\times n$ complex symmetric matrix $Y+iX$, say, $(Y+iX)[1,\dots,k|1,\dots,k]$, amounts to taking a $(2k)\times(2k)$ principal submatrix of the $(2n)\times(2n)$ matrix

$$\begin{pmatrix} X & Y \\ Y & -X \end{pmatrix}$$

corresponding to the rows and columns $1,\dots,k,n+1,\dots,n+k$. So we have (1.7) and (1.8) by Theorem 1.1, with $p=q=k$ and $m=n$. The converse can be established by using Theorem 1.1 again while considering the following set:

$$\{(U\oplus U)\operatorname{diag}(\alpha_1,\dots,\alpha_n,-\alpha_1\dots,-\alpha_n)(U^T\oplus U^T) : U \in O(n)\}. \qquad \square$$

The deficiency of 2 in Theorem 1.3 can now be viewed as a result of deleting 2 rows and 2 columns of the real symmetric matrix

$$\begin{pmatrix} X & Y \\ Y & -X \end{pmatrix}.$$

The last real form of $\mathfrak{sp}(n,\mathbb{C})$ is $\mathfrak{sp}_{p,q}$. Without loss of generality, we may assume that $p \leq q$. It is known that

$$\mathfrak{sp}_{p,q} = \left\{ \begin{pmatrix} X_{11} & X_{12} & X_{13} & X_{14} \\ X_{12}^* & X_{22} & X_{14}^T & X_{24} \\ -\overline{X}_{13} & \overline{X}_{14} & \overline{X}_{11} & -\overline{X}_{12} \\ X_{14}^* & -\overline{X}_{24} & -X_{12}^T & \overline{X}_{22} \end{pmatrix} : X_{11}^* = -X_{11} \in \mathbb{C}_{p\times p},\right.$$

$$X_{22}^* = -X_{22} \in \mathbb{C}_{q\times q},\ X_{13}^T = X_{13},\ X_{24}^T = X_{24} \Bigg\},$$

$$\mathfrak{k} = \left\{ \begin{pmatrix} X_{11} & 0 & X_{13} & 0 \\ 0 & X_{22} & 0 & X_{24} \\ -\overline{X}_{13} & 0 & \overline{X}_{11} & 0 \\ 0 & -\overline{X}_{24} & 0 & \overline{X}_{22} \end{pmatrix} : X_{11}^* = -X_{11} \in \mathbb{C}_{p\times p},\right.$$

$$\left. X_{22}^* = -X_{22} \in \mathbb{C}_{q\times q},\ X_{13}^T = X_{13},\ X_{24}^T = X_{24} \right\},$$

$$\mathfrak{p} = \left\{ \begin{pmatrix} 0 & X_{12} & 0 & X_{14} \\ X_{12}^* & 0 & X_{14}^T & 0 \\ 0 & \overline{X}_{14} & 0 & -\overline{X}_{12} \\ X_{14}^* & 0 & -X_{12}^T & 0 \end{pmatrix} \right\},$$

$$\mathfrak{a} = \oplus_{1\le j\le p}\mathbb{R}(E_{j,p+j} + E_{p+j,j} - E_{p+q+j,2p+q+j} - E_{2p+q+j,p+q+j}),$$

$$\mathfrak{a}_+ = \{\oplus_{1\le j\le p} a_j(E_{j,p+j} + E_{p+j,j} - E_{p+q+j,2p+q+j} - E_{2p+q+j,p+q+j}) : a_1 \ge \cdots \ge a_p \ge 0\}.$$

We then identify $\mathfrak{a}$ with $\mathbb{R}$ and $\mathfrak{a}_+$ with $\{(a_1,\dots,a_n) : a_1 \ge \cdots \ge a_n \ge 0\}$, respectively. The group K is

$$\left\{ \begin{pmatrix} U_1 & 0 & -\overline{V}_1 & 0 \\ 0 & U_2 & 0 & -\overline{V}_2 \\ V_1 & 0 & \overline{U}_1 & 0 \\ 0 & V_2 & 0 & \overline{U}_2 \end{pmatrix} : \begin{pmatrix} U_1 & -\overline{V}_1 \\ V_1 & \overline{U}_1 \end{pmatrix} \in Sp(p),\ \begin{pmatrix} U_2 & -\overline{V}_2 \\ V_2 & \overline{U}_2 \end{pmatrix} \in Sp(q) \right\},$$

which can be viewed as the image of $Sp(p)\times Sp(q)$ under the map γ:

$$\left(\begin{pmatrix} A_1 & B_1 \\ C_1 & D_1 \end{pmatrix}, \begin{pmatrix} A_2 & B_2 \\ C_2 & D_2 \end{pmatrix} \right) \mapsto \begin{pmatrix} A_1 & 0 & B_1 & 0 \\ 0 & A_2 & 0 & B_2 \\ C_1 & 0 & D_1 & 0 \\ 0 & C_2 & 0 & D_2 \end{pmatrix}.$$

Given $C \in \mathfrak{sp}_{p,q}$, there exists $W \in Sp(p,q)$ such that W^*CW is of the following form:

$$\begin{pmatrix} 0 & C_1 & 0 & 0 \\ C_1^T & 0 & 0 & 0 \\ 0 & 0 & 0 & -C_1 \\ 0 & 0 & -C_1^T & 0 \end{pmatrix},$$

where $C_1 = c_1E_{11} \oplus \cdots \oplus c_pE_{pp}$ with $c_i \ge 0$ for all $i = 1,\dots,p$. So the eigenvalues of $C \in \mathfrak{p}$ appear as double pairs but opposite in signs.

THEOREM 3.3. *With the above notations, let $A \in \mathfrak{p}$ and let*

$$\mathfrak{a}_+(A) = (\alpha_1,\dots,\alpha_{\min\{p,q\}}).$$

Then

$$\{\mathfrak{a}_+((UAU^*)[1,\dots,k_1,p+q+1,\dots,p+q+k_2|1,\dots,k_1,p+q+1,\dots,p+q+k_2]) : U \in K\}$$

consists of the elements $(\beta_1, \ldots, \beta_{\min\{k_1,k_2\}})$ *permitted by* (1.7) *and* (1.8).

Proof. Without loss of generality, we may assume that $p \le q$. Apply Thompson's interlacing inequalities (1.7) and (1.8) to show one inclusion. Then consider the set

$$\{W\hat{A}W^{-1} : W = \gamma((U \oplus U), (V \oplus V)), U \in O(p), V \in O(q)\},$$

where

$$\hat{A} = \begin{pmatrix} 0 & A_1 & 0 & 0 \\ A_1^T & 0 & 0 & 0 \\ 0 & 0 & 0 & -A_1 \\ 0 & 0 & -A_1^T & 0 \end{pmatrix},$$

and $A_1 = \alpha_1 E_{11} \oplus \cdots \oplus \alpha_p E_{pp}$ with $\alpha_i \ge 0$ for all $i = 1, \ldots, p$. Apply Theorem 1.2 to obtain the desired conclusion. □

4. The real forms of $\mathfrak{so}_{2n}(\mathbb{C})$ and $\mathfrak{so}_{2n+1}(\mathbb{C})$. We will consider the even and odd cases together in this section. The Cartan decomposition of the algebra of complex skew symmetric matrices $\mathfrak{so}_n(\mathbb{C})^{\mathbb{R}}$ is $\mathfrak{so}_n(\mathbb{C})^{\mathbb{R}} = \mathfrak{so}(n) + i\mathfrak{so}(n)$, where $\mathfrak{so}(n)$ is the algebra of real skew symmetric matrices. The group K is $SO(n)$, the special orthogonal group. The orbit of $C \in \mathfrak{so}(n)$ is $O(C) = \{OCO^T : O \in SO(n)\}$. Thus,

$$\mathfrak{p} = i\mathfrak{so}(n)$$

and

$$\mathfrak{a} = i\mathbb{R}(E_{12} - E_{21}) \oplus i\mathbb{R}(E_{34} - E_{43}) \oplus \cdots \oplus i\mathbb{R}(E_{[\frac{n}{2}]-1,[\frac{n}{2}]} - E_{[\frac{n}{2}],[\frac{n}{2}]-1}) \oplus (0),$$

where the trivial block exists for the odd case. For the odd case $\mathfrak{so}_{2n+1}(\mathbb{C})$,

$$\mathfrak{a}_+ = \{i(a_1(E_{12} - E_{21}) \oplus a_2(E_{34} - E_{43}) \oplus \cdots \oplus a_n(E_{2n-1,2n} - E_{2n,2n-1}) \oplus 0) : a_1 \ge \cdots \ge a_n \ge 0\},$$

which can then be identified with $\{(a_1, \ldots, a_n) : a_1 \ge \cdots \ge a_n \ge 0\}$. However, for the even case $\mathfrak{so}_{2n}(\mathbb{C})$,

$$\mathfrak{a}_+ = \{i(a_1(E_{12} - E_{21}) \oplus a_2(E_{34} - E_{43}) \oplus \cdots \oplus a_n(E_{2n-1,2n} - E_{2n,2n-1})) : a_1 \ge \cdots \ge a_{n-1} \ge |a_n|\},$$

which can then be identified with $\{(a_1, \ldots, a_n) : a_1 \ge \cdots \ge a_{n-1} \ge |a_n|\}$. In either case, the absolute values of α's (each appears twice) are the singular values of the real skew symmetric matrix. We shall identify $\mathfrak{so}(n)$ and $i\mathfrak{so}(n)$ in the obvious way. The following theorem has been established by Thompson [13, p. 251] when $k = n - 1$.

THEOREM 4.1. *Let A be an $n \times n$ real skew symmetric matrix with singular values $\alpha_1 \ge \alpha_1 \ge \alpha_2 \ge \alpha_2 \ge \cdots \ge \alpha_{[\frac{n}{2}]} \ge \alpha_{[\frac{n}{2}]} \ge (0)$ where the zero is a singular value if n is odd, i.e.,*

$$\mathfrak{a}_+(A) = \begin{cases} (\alpha_1, \ldots, \alpha_{[\frac{n}{2}]}) & \text{if } n \text{ is odd,} \\ (\alpha_1, \ldots, \alpha_{\frac{n}{2}-1}, \pm\alpha_{\frac{n}{2}}) & \text{if } n \text{ is even.} \end{cases}$$

Then the set $\{\mathfrak{a}_+((UAU^T)[1, \ldots, k|1, \ldots, k]) : U \in SO(n)\}$ consists of the elements $(\beta_1, \ldots, \beta_{[\frac{k}{2}]})$, where

1. *If k is odd,*

$$\alpha_i \geq \beta_i, \quad i = 1, \ldots, \left[\frac{k}{2}\right], \qquad \beta_i \geq \begin{cases} \alpha_{i+n-k} & \text{if } i+n-k \leq [\frac{n}{2}], \\ 0 & \text{otherwise.} \end{cases}$$

2. *If k is even,*

$$\alpha_i \geq \beta_i, \quad i = 1, \ldots, \frac{k}{2} - 1, \quad \alpha_{\frac{k}{2}} \geq |\beta_{\frac{k}{2}}|,$$

and, when $i \neq \frac{k}{2}$,

$$\beta_i \geq \begin{cases} \alpha_{i+n-k} & \text{if } i+n-k \leq [\frac{n}{2}], \\ 0 & \text{otherwise.} \end{cases}$$

Proof. Notice that the special orthogonal group $SO(n)$ in the following set

$$\{\mathfrak{a}_+((UAU^T)[1, \ldots, k|1, \ldots, k] : U \in SO(n)\}$$

can be replaced by $O(n)$, providing that $k < n$. Notice also that the orbits of the real skew symmetric matrix under the actions of $SO(n)$ and $O(n)$ are not the same, but the compressions are identical. The eigenvalues of the Hermitian iA and the eigenvalues of its $k \times k$ principal submatrix are

$$\alpha_1 \geq \cdots \geq \alpha_{[\frac{n}{2}]-1} \geq \alpha_{[\frac{n}{2}]} \geq (0) \geq -\alpha_{[\frac{n}{2}]} \geq -\alpha_{[\frac{n}{2}]-1} \cdots \geq -\alpha_1,$$
$$\beta_1 \geq \cdots \geq \beta_{[\frac{k}{2}]-1} \geq \beta_{[\frac{k}{2}]} \geq (0) \geq -\beta_{[\frac{k}{2}]} \geq -\beta_{[\frac{k}{2}]-1} \cdots \geq -\beta_1,$$

respectively, where the zero exists if n (k) is odd. We will denote them by $\alpha'_1 \geq \cdots \geq \alpha'_n$ and $\beta'_1 \geq \cdots \geq \beta'_k$. By Theorem 1.1, $\alpha'_i \geq \beta'_i \geq \alpha'_{i+n-k}$, $i = 1, \ldots, [\frac{k}{2}]$. But $\alpha'_i = \alpha_i$ and $\beta'_i = \beta_i$ when $i = 1, \ldots, [\frac{k}{2}]$. Moreover, if $1 \leq i+n-k \leq [\frac{n}{2}]$, then $\alpha'_{i+n-k} = \alpha_{i+n-k}$; if $i+n-k > [\frac{n}{2}]$, then $\alpha'_{i+n-k} = -\alpha_{k-i+1}$ when $i+n-k > [\frac{n}{2}]+1$ and $\alpha'_{[\frac{n}{2}]+1} = 0$. The rest follows from a result of Thompson [13] (which is the case $k = n-1$; see the remark on p. 251 and the proof of Theorem 3 in [13]) and the remark of Fan and Pall analogously. The converse of the interlacing inequalities corresponding to the even k needs special care and can be done easily by suitably adjusting $U \in O(n)$. □

We notice that if $n-k$ is even, then the submatrix is in the Cartan subspace associated with the same series. But if $n-k$ is odd, the submatrix belongs to the Cartan subspace of another series, i.e., switches from B-series to D-series or from D-series to B-series.

The real forms $\mathfrak{so}_{p,q}$ ($q+p$ can be $2n$ or $2n+1$) give the interlacing result for real $p \times q$ matrices (with loss of generality, we assume that $p \leq q$) and the treatment is exactly the same as the $\mathfrak{su}_{p,q}$ case once we see that

$$\mathfrak{so}_{p,q} = \left\{ \begin{pmatrix} X_1 & Y \\ Y^T & X_2 \end{pmatrix} : X_1^T = -X_1,\ X_2^T = -X_2,\ Y \in \mathbb{R}_{p\times q} \right\},$$
$$K = SO(p) \times SO(q),$$
$$\mathfrak{k} = \mathfrak{so}(p) \oplus \mathfrak{so}(q),\ \text{i.e.,}\ Y = 0,$$
$$\mathfrak{p} = \{ \begin{pmatrix} 0 & Y \\ Y^T & 0 \end{pmatrix}, Y \in \mathbb{R}_{p\times q} \},\ \text{i.e.,}\ X_1 = X_2 = 0,$$
$$\mathfrak{a} = \oplus_{1\leq j\leq p} \mathbb{R}(E_{j,p+j} + E_{p+j,j}).$$

If $p < q$, then

$$\mathfrak{a}_+ = \{\oplus_{1\le j\le p} a_j(E_{j,p+j} + E_{p+j,j}) : a_1 \ge \cdots \ge a_p \ge 0\},$$

which can then be identified with $\{(a_1, \ldots, a_p) : a_1 \ge \cdots \ge a_p \ge 0\}$. If $p = q$, then

$$\mathfrak{a}_+ = \{\oplus_{1\le j\le p} a_j(E_{j,p+j} + E_{p+j,j}) : a_1 \ge \cdots \ge a_p \ge 0\},$$

which can then be identified with $\{(a_1, \ldots, a_p) : a_1 \ge \cdots \ge \alpha_{p-1} \ge |a_p| \ge 0\}$.

THEOREM 4.2. *Let A be a $p \times q$ real matrix with*

$$\mathfrak{a}_+(A) = \begin{cases} (\alpha_1, \ldots, \alpha_{\min\{p,q\}}) & \text{if } p \ne q, \\ (\alpha_1, \ldots, \alpha_{p-1}, \mathit{sign}(\det\ A)\alpha_p) & \text{if } p = q, \end{cases}$$

where $\alpha_1 \ge \cdots \alpha_{\min\{p,q\}} \ge 0$ are the singular values of A.

1. *If $k_1 \ne k_2$, then $\{\mathfrak{a}_+((UAV)[1, \ldots, k_1|1, \ldots, k_2]) : U \in SO(p), V \in SO(q)\}$ consists of the elements $(\beta_1, \ldots, \beta_{\min\{k_1,k_2\}})$ permitted by* (1.7) *and* (1.8).
2. *If $k_1 = k_2 = k$, then $\{\mathfrak{a}_+((UAV)[1, \ldots, k|1, \ldots, k]) : U \in SO(p), V \in SO(q)\}$ consists of the elements $(\beta_1, \ldots, \beta_k)$ permitted by* (1.7) *and* (1.8)*, where the last inequality of* (1.8) *is replaced by $\alpha_k \ge |\beta_k|$.*

Proof. Notice that the special orthogonal groups $SO(p)$ and $SO(q)$ in the following set

$$\{\mathfrak{a}_+((UAV)[1, \ldots, k_1|1, \ldots, k_2]) : U \in SO(p), V \in SO(q)\}$$

can be replaced by $O(p)$ and $O(q)$, respectively, provided that $(k_1, k_2) \ne (p, q)$. The rest follows from the real case of Theorem 1.2. ∎

Theorem 4.2, when $k_1 = k_2 = k$, says that a real $p \times q$ matrix can be constructed so that the $k \times k$ submatrix has the prescribed singular values, β's, and nonnegative or nonpositive determinants if the interlacing inequalities are satisfied.

The real form $\mathfrak{so}^*(2n)$ of $\mathfrak{so}_{2n}(\mathbb{C})$ yields the interlacing result for the complex skew symmetric matrices. It is known that

$$\begin{aligned}
\mathfrak{so}^*(2n) &= \left\{ \begin{pmatrix} X & Y \\ -\overline{Y} & \overline{X} \end{pmatrix} : X^T = -X,\ Y^* = Y,\ X, Y \in \mathbb{C}_{n\times n} \right\}, \\
K &= \left\{ \begin{pmatrix} A & B \\ -B & A \end{pmatrix} : A^TA + B^TB = I,\ A^TB = B^TA,\ A, B \in \mathbb{R}_{n\times n} \right\}, \\
\mathfrak{k} &= \left\{ \begin{pmatrix} X & Y \\ -Y & X \end{pmatrix} : X^T = -X,\ Y^T = Y,\ X, Y \in \mathbb{R}_{n\times n} \right\}, \\
\mathfrak{p} &= \left\{ \begin{pmatrix} X & Y \\ Y & -X \end{pmatrix} : X^T = -X,\ Y^T = -Y,\ X, Y \in i\mathbb{R}_{n\times n} \right\}, \\
\mathfrak{a} &= i\mathbb{R}((E_{12} - E_{21}) - (E_{n+1,n+2} - E_{n+2,n+1})) \\
&\quad \oplus\ i\mathbb{R}((E_{34} - E_{43}) - (E_{n+3,n+4} - E_{n+4,n+3})) \oplus \cdots.
\end{aligned}$$

Analogous to $\mathfrak{sp}_{2n}(\mathbb{R})$, we identify K with $U(n)$ and identify $\mathfrak{p}$ with the space of $n \times n$ complex skew symmetric matrices via the map

$$\begin{pmatrix} X & Y \\ Y & -X \end{pmatrix} \mapsto Y + iX, \qquad X, Y \in i\mathbb{R}_{n\times n},\ X^T = -X,\ Y^T = -Y.$$

Then $\mathfrak{a}$ is identified with $i \oplus_{1\le j\le [\frac{n}{2}]} \mathbb{R}(E_{2j-1,2j} - E_{2j,2j-1})$ and the action of K on $\mathfrak{p}$ is $A \to UAU^T$. Now (1.11) is the Autonne decomposition for a complex skew symmetric matrix.

THEOREM 4.3 (see Thompson [13]). *Let A be an $n \times n$ complex skew symmetric matrix having singular values $\alpha_1 \geq \alpha_1 \geq \alpha_2 \geq \alpha_2 \geq \cdots \alpha_{[\frac{n}{2}]} \geq \alpha_{[\frac{n}{2}]} \geq (0)$. (The zero is a singular value if n is odd.) The singular values of $(UAU^T)[1,\ldots,k|1,\ldots,k]$, $U \in U(n)$, denoted by $\beta_1 \geq \beta_1 \geq \beta_2 \geq \beta_2 \geq \cdots \geq \beta_{[\frac{k}{2}]} \geq \beta_{[\frac{k}{2}]} \geq (0)$ (the zero is a singular value if k is odd), fill out all values permitted by*

$$\alpha_i \geq \beta_i, \quad i = 1,\ldots,\left[\frac{k}{2}\right], \qquad \beta_i \geq \begin{cases} \alpha_{i+n-k} & \text{if } i+n-k \leq [\frac{n}{2}], \\ 0 & \text{otherwise.} \end{cases}$$

Proof. The case $k = n-1$ has been established by Thompson [13, Theorem 2]. The other cases follow by the remark of Fan and Pall analogously. The following is a reason for interlacing inequalities. Each element in $\mathfrak{p}$ is a $(2n) \times (2n)$ Hermitian matrix. The eigenvalues appear in double pairs but opposite in signs, i.e., $\alpha_1 \geq \alpha_1 \geq \cdots \geq \alpha_{[\frac{n}{2}]} \geq \alpha_{[\frac{n}{2}]} \geq (0) \geq (0) \geq -\alpha_{[\frac{n}{2}]} \geq -\alpha_{[\frac{n}{2}]} \geq \cdots \geq -\alpha_1 \geq -\alpha_1$. (If n is odd, the two zeros are included as eigenvalues.) But now taking a $k \times k$ principal submatrix of an $n \times n$ complex skew symmetric matrix $Y + iX$, say, $(Y+iX)[1,\ldots,k|1,\ldots,k]$, amounts to taking a $(2k) \times (2k)$ principal submatrix of the $(2n) \times (2n)$ Hermitian matrix

$$\begin{pmatrix} X & Y \\ -Y & X \end{pmatrix}$$

corresponding to the rows and columns $1,\ldots,k,n+1,\ldots,n+k$. Hence we have the desired interlacing inequalities. □

MORE RESULTS ON EIGENVECTOR SADDLEPOINTS AND EIGENPOLYNOMIALS*

MARK A. MENDLOVITZ†

Abstract. This paper extends the author's earlier work which proved that, for a certain class of Hermitian eigenproblems $AP = \lambda BP$ (including, most notably, the Toeplitz eigenproblem), the eigenvectors can be represented as saddlepoints of a special form of the Rayleigh quotient. Each saddlepoint solves a min-max/max-min optimization problem whose optimal value is the eigenvalue. The zeros of the eigenpolynomial factors are located with respect to the unit circle. These results were proved, in part, by using an inertia theorem for Stein equations. For another class of Hermitian eigenproblems $AP = \lambda BP$, an analogous set of results are derived here using an inertia theorem for Lyapunov equations. In this case, the zeros of the eigenpolynomial factors are located with respect to the imaginary axis, and sufficient conditions for the eigenpolynomial factors to have only extended imaginary zeros are established. The highlight of the article is an important theorem that yields a general factorization of saddlepoint eigenpolynomials and parameterizes all eigenvector saddlepoint representations for an m-dimensional eigenspace. Several key extensions to the theory are also presented.

Key words. eigenvectors, eigenpolynomials, saddlepoints, zeros, Lyapunov equation, Rayleigh quotient, Toeplitz matrix, inertia, perturbation

NOTATION.

$\mathbb{R}^{n\times m}$	the space of real $n \times m$ matrices ($\mathbb{R}^n \triangleq \mathbb{R}^{n\times 1}$)
$\mathbb{C}^{n\times m}$	the space of complex $n \times m$ matrices ($\mathbb{C}^n \triangleq \mathbb{C}^{n\times 1}$)
$\mathbb{C}_e$	the extended complex plane, $\mathbb{C} \cup \{\infty\}$
$\overline{[G]}_m$	the upper left $m \times m$ submatrix of the $n \times n$ matrix G, i.e., $[g_{ij}]$ $i = 1, \ldots, m$, $j = 1, \ldots, m$
$\underline{[G]}_m$	the lower right $m \times m$ submatrix of the $n \times n$ matrix G, i.e., $[g_{ij}]$ $i = n-m+1, \ldots, n$, $j = n-m+1, \ldots, n$
$G\rceil$	the upper right principal submatrix of the $n \times n$ matrix G, i.e., $[g_{ij}]$ $i = 1, \ldots, n-1$, $j = 2, \ldots, n$
$\lfloor G$	the lower left principal submatrix of the $n \times n$ matrix G, i.e., $[g_{ij}]$ $i = 2, \ldots, n$, $j = 1, \ldots, n-1$
H^*	the complex conjugate transpose of H
$\det(\cdot)$	the determinant of $(\cdot)$
I	the identity matrix
e_i	the ith column of the identity matrix
$\mathcal{I}(G(\lambda))$	an open interval in $\mathbb{R}$ containing $\{\lambda \mid \det G(\lambda) = 0\}$
$H > 0$ $(H < 0)$	H is a positive (negative) definite matrix
$H \geq 0$ $(H \leq 0)$	H is a positive (negative) semidefinite matrix
$\tilde{P} * \hat{P}$	the convolution of $\tilde{P}$ and $\hat{P}$
$\mathcal{P}_m(R)$	the $(n+m) \times m$ convolution matrix formed from $R = [\ r(0) \quad r(1) \quad \cdots \quad r(n)\ ]^T$; the ijth element is $r(i-j)$ for $0 \leq i-j \leq n$, and 0 otherwise
$\arg\min_x f(x)$	an argument x which minimizes $f(x)$
$\lvert z\rvert < 1$ (> 1)	the region of the complex plane interior (exterior) to the unit circle

$X_{(i:j)}$	$\stackrel{\triangle}{=} [\ x(i) \quad \cdots \quad x(j)\ ]^T$

1. Introduction. The Hermitian eigenproblem is one of the most widely studied topics in linear algebra [5]. This important problem can be stated as follows: For Hermitian matrices $A, B \in \mathbb{C}^{(N+1)\times(N+1)}$, where $B \neq 0$, determine a basis set of finite eigenvalue/eigenvector pairs or *eigenpairs* $\{(\lambda_k, P_k) \in \mathbb{R} \times \mathbb{C}^{N+1} \mid k = 1, \dots, j \leq N+1\}$ which solve

$$AP = \lambda BP. \tag{1}$$

The eigenvalues are the zeros of the jth order λ-polynomial $\det(A - \lambda B)$.[1] It can be shown that if an eigenvector P_k satisfies (1) and $P_k^* B P_k \neq 0$, then P_k is a stationary point of the Rayleigh quotient $\rho(P) = P^*AP/P^*BP$, i.e., the gradient $\nabla\rho(P_k) = 0$, and the eigenvalue $\lambda_k = \rho(P_k)$ is the corresponding stationary value. Conversely, all stationary points and stationary values of $\rho(P)$ are eigenvectors and eigenvalues, respectively. In general, a stationary point may be a maximizing point, a minimizing point, a saddlepoint, or none of these. An example of the last case is a *point of inflection*, such as the one at $(x, y) = (0, 0)$ for the function $f(x, y) = x^3 + y^3$ defined on $\{(x, y) \in \mathbb{R} \times \mathbb{R}\}$.

For eigenvector P_k to be a *saddlepoint eigenvector*, there must exist a point $(\tilde{P}_k, \hat{P}_k)$ contained in a real or complex Cartesian product space $\tilde{\mathcal{S}}_k \times \hat{\mathcal{S}}_k$ and a map $\mathcal{F} : \tilde{\mathcal{S}}_k \times \hat{\mathcal{S}}_k \longrightarrow \mathbb{C}^{N+1}$ such that $P_k = \mathcal{F}(\tilde{P}_k, \hat{P}_k)$, and

$$\rho(\mathcal{F}(\tilde{P}_k, \hat{P})) \leq \rho(\mathcal{F}(\tilde{P}_k, \hat{P}_k)) \leq \rho(\mathcal{F}(\tilde{P}, \hat{P}_k))$$

for all $\tilde{P} \in \tilde{\mathcal{S}}_k$ and $\hat{P} \in \hat{\mathcal{S}}_k$. Any point $(\tilde{P}_k, \hat{P}_k)$ satisfying this inequality is said to be a *saddlepoint representation* of the eigenvector or, simply, an *eigenvector saddlepoint*. It is easy to see from the inequality that an eigenvector saddlepoint is a stationary point of a differentiable function $\rho(\mathcal{F}(\cdot, \cdot))$. An equivalent definition is given by the so-called *minimax theorem* [14], which states that $(\tilde{P}_k, \hat{P}_k)$ is a saddlepoint if and only if

$$\max_{\hat{P} \in \hat{\mathcal{S}}_k} \min_{\tilde{P} \in \tilde{\mathcal{S}}_k} \rho(\mathcal{F}(\tilde{P}, \hat{P})) = \rho(\mathcal{F}(\tilde{P}_k, \hat{P}_k)) = \min_{\tilde{P} \in \tilde{\mathcal{S}}_k} \max_{\hat{P} \in \hat{\mathcal{S}}_k} \rho(\mathcal{F}(\tilde{P}, \hat{P})),$$

$$\tilde{P}_k = \arg \min_{\tilde{P} \in \tilde{\mathcal{S}}_k} \left\{ \max_{\hat{P} \in \hat{\mathcal{S}}_k} \rho(\mathcal{F}(\tilde{P}, \hat{P})) \right\},$$

[1] $\det(A - \lambda B)$ of degree j implies that there are j finite eigenvalues and $N + 1 - j$ infinite eigenvalues. If $\det(A - \lambda B)$ is identically zero, every number is an eigenvalue.

and

$$\hat{P}_k = \arg\max_{\hat{P}\in\hat{\mathcal{S}}_k} \left\{ \min_{\tilde{P}\in\tilde{\mathcal{S}}_k} \rho(\mathcal{F}(\tilde{P},\hat{P})) \right\}.$$

The optimal value of the objective function at the eigenvector saddlepoint solution is the eigenvalue, i.e., $\lambda_k = \rho(\mathcal{F}(\tilde{P}_k,\hat{P}_k))$.

Now let $\rho(\tilde{P},\hat{P})$ denote the special Rayleigh quotient obtained by choosing $\mathcal{F}$ to be the convolution map, i.e., $\rho(\mathcal{F}(\tilde{P},\hat{P})) = \rho(\tilde{P}*\hat{P}) \stackrel{\triangle}{=} \rho(\tilde{P},\hat{P})$ or, equivalently,

$$\begin{aligned}\rho(\tilde{P},\hat{P}) &= \frac{\tilde{P}^*\left[\mathcal{P}^*(\hat{P})A\mathcal{P}(\hat{P})\right]\tilde{P}}{\tilde{P}^*\left[\mathcal{P}^*(\hat{P})B\mathcal{P}(\hat{P})\right]\tilde{P}} \\ &= \frac{\hat{P}^*\left[\mathcal{P}^*(\tilde{P})A\mathcal{P}(\tilde{P})\right]\hat{P}}{\hat{P}^*\left[\mathcal{P}^*(\tilde{P})B\mathcal{P}(\tilde{P})\right]\hat{P}} \\ &= \rho(\hat{P},\tilde{P}),\end{aligned}$$

where $\tilde{P}\in\mathbb{C}^k$, $\hat{P}\in\mathbb{C}^{N-k+2}$,[2] and $\mathcal{P}(\cdot)$ is the matrix representation of the convolution operator. Since convolution is commutative, $\mathcal{P}(\hat{P})\tilde{P} = \mathcal{P}(\tilde{P})\hat{P}$. The subscript of $\mathcal{P}$, which indicates column dimension, is dropped to reduce notational complexity whenever the dimension is clear from the context, as it is here.

Let us express the Hermitian eigenproblem as

$$G(\lambda)P \stackrel{\triangle}{=} (A-\lambda B)P = 0, \tag{2}$$

with $A, B\in\mathbb{C}^{(N+1)\times(N+1)}$ and $B>0$, and let $\underline{[G(\lambda)]}_m$ and $\overline{[G(\lambda)]}_m$ denote the lower right and upper left $m\times m$ submatrices of $G(\lambda)$, respectively. In the earlier work [9], it was proved, using an inertia theorem for Stein equations and some basic matrix perturbation theory, that when $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N \le 0$ or $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N \ge 0$ for all $\lambda\in\mathcal{I}(G(\lambda))$ (an open interval in $\mathbb{R}$ containing all of the eigenvalues), an eigenvector P_k corresponding to the kth largest eigenvalue of (2) has a *factorization* $P_k = \tilde{P}_k * \hat{P}_k$ such that $(\tilde{P}_k,\hat{P}_k)\in\mathbb{C}^k\times\mathbb{C}^{N-k+2}$ is a saddlepoint of the Rayleigh quotient $\rho(\tilde{P},\hat{P})$. (Note that since convolution and polynomial multiplication are equivalent operations, we can also say that the *eigenpolynomial* $P_k(z)\stackrel{\triangle}{=} p_k(0)+\cdots+p_k(N)z^{-N}$ has a factorization $P_k(z) = \tilde{P}_k(z)\hat{P}_k(z)$.) If $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N \le 0$ (≥ 0),[3] the eigenpolynomial factor $\tilde{P}_k(z)$ has all of its zeros in $|z|\ge 1$ ($|z|\le 1$), and the factor $\hat{P}_k(z)$ has all of its zeros in $|z|\le 1$ ($|z|\ge 1$). Additionally, it was shown that real $\tilde{P}_k$ and $\hat{P}_k$ exist whenever A and B are real. Eigenvector saddlepoints for this class of problems are called *saddlepoints of the first kind* or *type*-1 *saddlepoints*. Included in this class of eigenproblems are the important special cases in which A is a Hermitian Toeplitz or a Hankel-conjugate–transpose-Hankel matrix [3, 4]. Sufficient conditions for the eigenpolynomial factors to have all of their zeros on $|z|=1$ when A and B are Toeplitz were also developed.

[2] For the sake of notational brevity, we shall implicitly assume that the spaces containing the arguments of ρ exclude the possibility of $\rho(0)$, since ρ is not defined at the origin. For example, $\min_{\tilde{P}\in\mathbb{C}^k}\rho(\tilde{P},\hat{P})$ actually means $\min_{\tilde{P}\in\mathbb{C}^k-\{0\}}\rho(\tilde{P},\hat{P})$.

[3] A convention frequently used here is the placement of a parallel condition and its corresponding result in parentheses.

Here we study another set of eigenproblems for which $\rho(\tilde{P}, \hat{P})$ has eigenvector saddlepoints, and results analogous to the ones summarized above are obtained by applying an inertia theorem for Lyapunov equations instead. These eigenvector saddlepoints, termed *saddlepoints of the second kind* or *type-2 saddlepoints*, are shown to exist when the sum of the lower left principal submatrix of $G(\lambda)$, $\lfloor G(\lambda) \in \mathbb{C}^{N\times N}$, and the upper right principal submatrix of $G(\lambda)$, $G(\lambda)\rceil \in \mathbb{C}^{N\times N}$, satisfies either $\lfloor G(\lambda) + G(\lambda)\rceil \leq 0$ or $\lfloor G(\lambda)+G(\lambda)\rceil \geq 0$ for all $\lambda \in \mathcal{I}(G(\lambda))$. The zeros of the eigenpolynomial factors in this case are located with respect to the imaginary axis rather than the unit circle, and sufficient conditions for the eigenpolynomial factors to have all of their zeros on the extended imaginary axis $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$ are proved. Again, perturbation methods are needed to prove existence of the saddlepoints. This paper also serves to resolve some subtle issues not dealt with in [9], such as the correct way to define the eigenpolynomial zeros. The highlight of the paper is an important theorem that gives a general factorization of any saddlepoint eigenpolynomial and parameterizes all eigenvector saddlepoint representations for an m-dimensional eigenspace. This result is significant because it provides a very elegant and useful characterization of the eigenstructure for many problems of practical interest, including the case where A and B are Hermitian Toeplitz matrices. It also leads to a new set of bounds on the number of zeros that an eigenpolynomial factor may have on the extended imaginary axis or unit circle.

2. Preliminaries. Some foundational theory and definitions, primarily derived from [2, 8, 9], are presented in this section.

LEMMA 2.1. *The eigenvalues of the $n \times n$ companion matrix*

$$C_R \triangleq \begin{bmatrix} -r(1) & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ -r(n-1) & 0 & \dots & 1 \\ -r(n) & 0 & \dots & 0 \end{bmatrix}$$

are the zeros of the monic polynomial $R(s) = s^n + r(1)s^{n-1} + \cdots + r(n)$.

A more detailed discussion of the "zeros" of polynomials $R(s)$ and $R(z)$ is dealt with later. For the moment, however, as long as $r(0) \neq 0$, it is safe to assume the zeros of $R(s)$ are the set of points $\{s_i \in \mathbb{C} \mid R(s_i) = 0, \ \ i = 1, \dots, n\}$.

DEFINITION 2.2. *$(U, V) \in \mathbb{C}^{n\times n} \times \mathbb{C}^{n\times m}$ is said to be a controllable pair if and only if*

$$[\ U - \lambda I \quad V\ ]$$

has full row rank for all $\lambda \in \mathbb{C}$.

The pair (U, V) is always controllable if V is definite or invertible or has full row rank.

DEFINITION 2.3. *If $H \in \mathbb{C}^{n\times n}$, then $\pi(H)$, $\nu(H)$, and $\delta(H)$ denote the number of eigenvalues of H with positive, negative, and zero real parts, respectively, and $\pi(H) + \nu(H) + \delta(H) = n$. The ordered triple $\{\pi(H), \nu(H), \delta(H)\}$ is called the inertia of H with respect to the imaginary axis.*

If $r(0) \neq 0$, the inertia of a polynomial $R(s)$ with respect to the imaginary axis is similarly defined to be the triple containing the number of zeros of $R(s)$ in $\mathrm{Re}[s] > 0$, $\mathrm{Re}[s] < 0$, and on $\mathrm{Re}[s] = 0$, respectively, while the inertia of polynomial $R(z)$ with respect to the unit circle is given by the triple containing the number of zeros of $R(z)$ in $|z| > 1$, $|z| < 1$, and on $|z| = 1$, respectively.

THEOREM 2.4. *Let* $(U^*, V) \in \mathbb{C}^{n\times n} \times \mathbb{C}^{n\times n}$ *be a controllable pair, and assume the Lyapunov equation* $U^*H + HU = V$ *holds for some Hermitian* $H \in \mathbb{C}^{n\times n}$.

(a) *If* $V \geq 0$, *then* $\det H \neq 0$, $\delta(U) = \delta(H) = 0$, $\pi(U) = \pi(H)$, *and* $\nu(U) = \nu(H)$.

(b) *If* $V \leq 0$, *then* $\det H \neq 0$, $\delta(U) = \delta(H) = 0$, $\pi(U) = \nu(H)$, *and* $\nu(U) = \pi(H)$.

Theorem 2.4 is an inertia theorem for Lyapunov equations which originates from the work of Chen [1] and Wimmer [13].

DEFINITION 2.5. $G(\lambda, \tilde{P}_k) \triangleq \mathcal{P}^*_{N-k+2}(\tilde{P}_k)(A - \lambda B)\mathcal{P}_{N-k+2}(\tilde{P}_k)$ *for* $\tilde{P}_k \in \mathbb{C}^k$, $k = 1, \ldots, N+1$.

DEFINITION 2.6. $G(\lambda, \hat{P}_k) \triangleq \mathcal{P}^*_k(\hat{P}_k)(A - \lambda B)\mathcal{P}_k(\hat{P}_k)$ *for* $\hat{P}_k \in \mathbb{C}^{N-k+2}$, $k = 1, \ldots, N+1$.

It is clear from the definitions that the stationary points $\tilde{P}$ of $\rho(\tilde{P}, \hat{P}_k)$ are the eigenvector solutions of $G(\lambda, \hat{P}_k)\tilde{P} = 0$ and vice versa, and the stationary points $\hat{P}$ of $\rho(\hat{P}, \tilde{P}_k)$ are the eigenvector solutions of $G(\lambda, \tilde{P}_k)\hat{P} = 0$ and vice versa. Also, $G(\lambda_k)P_k = 0$ and $P_k = \tilde{P}_k * \hat{P}_k$ imply $G(\lambda_k, \hat{P}_k)\tilde{P}_k = 0$ and $G(\lambda_k, \tilde{P}_k)\hat{P}_k = 0$.

LEMMA 2.7. *Let* (λ_*, R_*) *be an eigenpair satisfying the eigenproblem* $G'(\lambda)R = 0$, *where* $G'(\lambda) \in \mathbb{C}^{n\times n}$ *and* R_* *is scaled so that* $r_*(0) = 1$. *Then*

$$\underline{[G'(\lambda_*)]}_{n-1} C_{R_*} = \lfloor G'(\lambda_*).$$

Proof. The result follows from the definition of C_{R_*} and the equation $G'(\lambda_*)R_* = 0$. □

In a similar way, $C^*_{R_*}\underline{[G'(\lambda_*)]}_{n-1} = G'(\lambda_*)\rceil$.

As in [9], basic matrix perturbation theory is used in some of the proofs. A good introduction to this subject can be found in [8]; however, a more extensive treatment is given by Rellich [12]. Classical matrix perturbation theory generally deals with perturbations which are *analytic functions* of a real parameter ϵ. For our purposes, an analytic function is a function which has a power series expansion convergent on a neighborhood of $\epsilon = 0$. Thus, analytic functions are a proper subset of the set of infinitely differentiable functions. An example of a function which is infinitely differentiable at $\epsilon = 0$ but nonanalytic is $f(\epsilon) = e^{-1/\epsilon^2}\sin(2/\epsilon)$ [12].

It can be shown that if $A(\epsilon), B(\epsilon) \in \mathbb{C}^{n\times n}$ are Hermitian analytic matrix functions of a real parameter ϵ, and $B(\epsilon) > 0$ on a neighborhood of $\epsilon = 0$, then there exists a complete set of analytic eigenpairs $\{(\lambda_{k\epsilon}, P_{k\epsilon}) \in \mathbb{R} \times \mathbb{C}^n \mid k = 1, \ldots, n\}$ satisfying the eigenproblem $(A(\epsilon) - \lambda B(\epsilon))P = 0$. As a result, $P_{k\epsilon}$ and any of its factors are continuous at $\epsilon = 0$. This simple but important fact is invoked in subsequent arguments.

Finally, we shall continue to assume that an eigenvalue's (first) subscript indicates its relative rank, i.e., $\lambda_{k-1} \geq \lambda_k \geq \lambda_{k+1}$ for $k = 2, \ldots, N$. If an eigenvalue is not equal to any other eigenvalues, it is said to be *distinct* (its multiplicity equals one); otherwise, it is *repeated* (its multiplicity is greater than one). If a stationary point of a Rayleigh quotient is an element of a one-dimensional eigenspace, i.e., it corresponds to a distinct stationary value, the stationary point is said to be *unique*.

3. Main results. The first theorem in this section is fundamental.

THEOREM 3.1. *If* (λ_k, P_k) *is an eigenpair which satisfies* $G(\lambda)P = 0$, *where* $B > 0$, $p_k(0) = 1$,

$$\lfloor G(\lambda) + G(\lambda)\rceil \geq 0 \ \ (\leq 0) \quad \forall\, \lambda \in \mathcal{I}(G(\lambda)),$$

and $(C^*_{P_k}, \lfloor G(\lambda_k) + G(\lambda_k)\rceil)$ *is a controllable pair, then*

(a) λ_k *is distinct;*
(b) $P_k(s)$ *has* $k-1$ *zeros in* $\mathrm{Re}[s] > 0$ ($\mathrm{Re}[s] < 0$) *and* $N-k+1$ *zeros in* $\mathrm{Re}[s] < 0$ ($\mathrm{Re}[s] > 0$).

Proof. The proof closely follows the proof of Theorem 5 in [9], so it is shortened here. From Lemma 2.7 and our assumption,

$$C_{P_k}^* \underline{[G(\lambda_k)]}_N + \underline{[G(\lambda_k)]}_N C_{P_k} = \lfloor G(\lambda_k) + G(\lambda_k) \rceil \geq 0 \ \ (\leq 0). \tag{3}$$

The Lyapunov equation (3) satisfies the hypothesis of Theorem 2.4(a) (Theorem 2.4(b)), so $\mathrm{rank}\{\underline{[G(\lambda_k)]}_N\} = N$. This implies that $N \leq \mathrm{rank}\{G(\lambda_k)\} \leq N+1$, but since $G(\lambda_k)$ is singular by definition, $\mathrm{rank}\{G(\lambda_k)\} = N$. Thus, λ_k is distinct.

It can be shown that $\pi(\underline{[G(\lambda_k)]}_N) = k-1$ and $\nu(\underline{[G(\lambda_k)]}_N) = N-k+1$ [9, Theorem 5]. Again, by Theorem 2.4(a) (Theorem 2.4(b)), C_{P_k} satisfying (3) must have $k-1$ eigenvalues in $\mathrm{Re}[s] > 0$ ($\mathrm{Re}[s] < 0$) and $N-k+1$ eigenvalues in $\mathrm{Re}[s] < 0$ ($\mathrm{Re}[s] > 0$). Lemma 2.1 implies (b). ∎

If the hypotheses of Theorem 3.1 are satisfied for every eigenpair, then each of the eigenpolynomials has a different inertia. An important consequence of this is that the inertia of an eigenpolynomial can be used to determine the relative rank of its corresponding eigenvalue with respect to the other eigenvalues. For example, knowing only that an eigenpolynomial has zeros entirely in $\mathrm{Re}[s] < 0$ when $\lfloor G(\lambda) + G(\lambda) \rceil > 0$ for all $\lambda \in \mathbb{R}$ indicates that the eigenvector must correspond to the largest eigenvalue; thus it maximizes the Rayleigh quotient. Note that both the controllability and semidefiniteness conditions in Theorem 3.1 are satisfied for all of the eigenpairs if $\lfloor G(\lambda) + G(\lambda) \rceil$ is definite on an interval of λ containing the eigenvalues, e.g., $\mathcal{I}(G(\lambda))$. (See the remark after Definition 2.2.) The corollary is now apparent.

COROLLARY 3.2. *Let* $G'(\lambda)R \triangleq (A' - \lambda B')R = 0$, *where* $A', B' \in \mathbb{C}^{n\times n}$ *are Hermitian,* $B' > 0$, *and assume*

$$\lfloor G'(\lambda) + G'(\lambda) \rceil > 0 \ \ (< 0) \ \ \forall\, \lambda \in \mathcal{I}(G'(\lambda)).$$

Also, let $\rho'(R) \triangleq R^* A' R / R^* B' R$ *and assume* $(\rho'(R_*), R_*)$ *is an eigenpair, with* $r_*(0) \neq 0$. *If* $R_*(s)$ *has all of its zeros in* $\mathrm{Re}[s] < 0$ ($\mathrm{Re}[s] > 0$), *then* R_* *is a unique maximizer of* $\rho'(R)$. *If* $R_*(s)$ *has all of its zeros in* $\mathrm{Re}[s] > 0$ ($\mathrm{Re}[s] < 0$), *then* R_* *is a unique minimizer of* $\rho'(R)$.

Even if an eigenproblem fails to satisfy the controllability or definiteness conditions in Theorem 3.1 and Corollary 3.2, *we can still find eigenproblems that are arbitrarily close to the original which do satisfy these conditions*, i.e., we can analytically perturb the problem with an arbitrarily small perturbation matrix in a way which satisfies the definiteness (and in turn the controllability) condition. The ultimate purpose of introducing a perturbation here is to enable us to draw conclusions about the original eigenproblem, which may be difficult to analyze directly, by examining the characteristics of a more easily analyzed perturbed problem as the perturbation approaches zero.

Consider the perturbed matrix

$$G_\epsilon(\lambda) \triangleq G(\lambda) + \Delta(\epsilon),$$

where the perturbation matrix $\Delta(\epsilon)$ is a Hermitian analytic matrix function of the real scalar parameter ϵ and $\lim_{\epsilon\to 0} \Delta(\epsilon) = 0$. If we choose the elements of $\Delta(\epsilon)$ to be

$$\Delta_{ij}(\epsilon) \triangleq \begin{cases} \epsilon & |i-j| = 1, \\ 0 & \text{otherwise}, \end{cases}$$

then

$$\lfloor \Delta(\epsilon) + \Delta(\epsilon) \rceil = \begin{cases} 2\epsilon & i = j, \\ \epsilon & |i-j| = 2, \\ 0 & \text{otherwise}, \end{cases}$$
$$= \mathcal{P}_N^T(R)\mathcal{P}_N(R),$$

where $R = [\ \sqrt{\epsilon}\ \ 0\ \ \sqrt{\epsilon}\ \ 0\ \ \cdots\ \ 0\ ]^T$. Note that $\lfloor \Delta(\epsilon) + \Delta(\epsilon) \rceil = \mathcal{P}_N^T(R)\mathcal{P}_N(R)$ is positive definite when $\epsilon > 0$ and negative definite when $\epsilon < 0$. Thus, if $\lfloor G(\lambda)+G(\lambda) \rceil \geq 0$ (≤ 0) on $\lambda \in \mathcal{I}(G(\lambda))$,

$$\lfloor G_\epsilon(\lambda) + G_\epsilon(\lambda) \rceil = (\lfloor G(\lambda) + G(\lambda) \rceil) + (\lfloor \Delta(\epsilon) + \Delta(\epsilon) \rceil) > 0\ (< 0)$$

for $\lambda \in \mathcal{I}(G(\lambda))$ and $\epsilon > 0$ $(\epsilon < 0)$. Since the eigenvalues of $G_\epsilon(\lambda)P = 0$ are continuously variable with respect to ϵ, and $\mathcal{I}(G(\lambda))$ is open (by assumption), there exists an $\mathcal{I}(G_\epsilon(\lambda)) \subset \mathcal{I}(G(\lambda))$ for $|\epsilon| > 0$ sufficiently small, so

$$\lfloor G_\epsilon(\lambda) + G_\epsilon(\lambda) \rceil > 0\ (< 0) \tag{4}$$

for $\lambda \in \mathcal{I}(G_\epsilon(\lambda))$ and sufficiently small $|\epsilon| > 0$.

It is worth noting that the choice of $\Delta(\epsilon)$ above is by no means the only one possible. The perturbation matrix

$$\Delta(\epsilon) = \epsilon\Delta_1 + \sum_{i=2}^{\infty} \epsilon^i \Delta_i \quad \in \mathbb{C}^{(N+1)\times(N+1)}$$

meets the criteria, for sufficiently small $|\epsilon| > 0$, if $\epsilon\Delta_1$ is any Hermitian matrix satisfying the condition $\lfloor \epsilon\Delta_1 + \epsilon\Delta_1 \rceil > 0$ (< 0) and Δ_i are *arbitrary*, bounded Hermitian matrices for $i \geq 2$. The Δ_i for $i \geq 2$ can be arbitrary because $\epsilon\Delta_1$ dominates the higher-order terms for sufficiently small $|\epsilon| > 0$.

The following theorem proves the existence of eigenvector saddlepoints of the second kind and characterizes some properties of the eigenpolynomial factors.

THEOREM 3.3. *Consider the Hermitian eigenproblem* (2) *in which* $\lfloor G(\lambda) + G(\lambda) \rceil \geq 0$ (≤ 0) *for all* $\lambda \in \mathcal{I}(G(\lambda))$ *and* $B > 0$. *Let* $G_\epsilon(\lambda)P = [G(\lambda) + \Delta(\epsilon)]\,P = 0$ *be an analytically perturbed version of this problem such that for some* ϵ' *and each* $\epsilon \in (0, \epsilon')$,

1. $\lfloor \Delta(\epsilon) + \Delta(\epsilon) \rceil > 0\ (< 0)$;
2. $G_\epsilon(\lambda_{k\epsilon})P_{k\epsilon} = 0$, $\lambda_{k\epsilon}$ *is the* k*th largest eigenvalue, and* $\lim_{\epsilon\to 0} p_{k\epsilon}(0) \neq 0$.

For the eigenpair of $G(\lambda)P = 0$,

$$(\lambda_k, P_k) \stackrel{\triangle}{=} \lim_{\epsilon\to 0} (\lambda_{k\epsilon}, P_{k\epsilon}),$$

there exists a factorization

$$P_k(s) = \tilde{P}_k(s)\hat{P}_k(s),$$

where $\tilde{P}_k \in \mathbb{C}^k$ *and* $\hat{P}_k \in \mathbb{C}^{N-k+2}$, *such that*

(a)

$$\rho(\tilde{P}_k, \hat{P}) \leq \rho(\tilde{P}_k, \hat{P}_k) \leq \rho(\tilde{P}, \hat{P}_k) \quad \forall\ \tilde{P} \in \mathbb{C}^k, \hat{P} \in \mathbb{C}^{N-k+2}, \tag{5}$$

or, equivalently,

$$\max_{\hat{P}\in\mathbb{C}^{N-k+2}} \min_{\tilde{P}\in\mathbb{C}^{k}} \rho(\tilde{P},\hat{P}) = \lambda_k = \min_{\tilde{P}\in\mathbb{C}^{k}} \max_{\hat{P}\in\mathbb{C}^{N-k+2}} \rho(\tilde{P},\hat{P}),$$

where

$$\tilde{P}_k = \arg\min_{\tilde{P}\in\mathbb{C}^{k}} \left\{ \max_{\hat{P}\in\mathbb{C}^{N-k+2}} \rho(\tilde{P},\hat{P}) \right\}$$

and

$$\hat{P}_k = \arg\max_{\hat{P}\in\mathbb{C}^{N-k+2}} \left\{ \min_{\tilde{P}\in\mathbb{C}^{k}} \rho(\tilde{P},\hat{P}) \right\};$$

(b) $\tilde{P}_k(s)$ *has all of its zeros in* $\mathrm{Re}[s] \geq 0$ $(\mathrm{Re}[s] \leq 0)$ *and* $\hat{P}_k(s)$ *has all of its zeros in* $\mathrm{Re}[s] \leq 0$ $(\mathrm{Re}[s] \geq 0)$;

(c) $A,\ B \in \mathbb{R}^{(N+1)\times(N+1)} \Longrightarrow \exists \tilde{P}_k \in \mathbb{R}^k, \hat{P}_k \in \mathbb{R}^{N-k+2}$.

Proof. We can begin the proof of part (a) by using Theorem 3.1 to factor the perturbed eigenpolynomial $P_{k\epsilon}(s)$ as $P_{k\epsilon}(s) = \tilde{P}_{k\epsilon}(s)\hat{P}_{k\epsilon}(s)$, such that $\tilde{P}_{k\epsilon}(s)$ has all $k-1$ of its zeros in $\mathrm{Re}[s] > 0$ $(\mathrm{Re}[s] < 0)$ and $\hat{P}_{k\epsilon}(s)$ has all $N-k+1$ of its zeros in $\mathrm{Re}[s] < 0$ $(\mathrm{Re}[s] > 0)$. (Note that for $k=1$, $\tilde{P}_{k\epsilon}$ is a scalar, and for $k=N+1$, $\hat{P}_{k\epsilon}$ is a scalar.) The assumption $\lim_{\epsilon\to 0} p_{k\epsilon}(0) \neq 0$ implies that $p_{k\epsilon}(0)$, $\tilde{p}_{k\epsilon}(0)$, and $\hat{p}_{k\epsilon}(0)$ are all nonzero on a neighborhood of $\epsilon = 0$.

Now $G_\epsilon(\lambda,\tilde{P}_{k\epsilon})$ and $G_\epsilon(\lambda,\hat{P}_{k\epsilon})$ are defined by Definitions 2.5 and 2.6, but with $A+\Delta(\epsilon)$ replacing A. The corresponding Rayleigh quotients are $\rho_\epsilon(\cdot,\tilde{P}_{k\epsilon})$ and $\rho_\epsilon(\cdot,\hat{P}_{k\epsilon})$, respectively. Assumption 1 implies (4), so that

$$\begin{aligned} \lfloor G_\epsilon(\lambda,\hat{P}_{k\epsilon}) + G_\epsilon(\lambda,\hat{P}_{k\epsilon})\rceil &= \mathcal{P}^*(\hat{P}_{k\epsilon})\lfloor G_\epsilon(\lambda)\mathcal{P}(\hat{P}_{k\epsilon}) + \mathcal{P}^*(\hat{P}_{k\epsilon})G_\epsilon(\lambda)\rceil\mathcal{P}(\hat{P}_{k\epsilon}) \\ &= \mathcal{P}^*(\hat{P}_{k\epsilon})\left(\lfloor G_\epsilon(\lambda) + G_\epsilon(\lambda)\rceil\right)\mathcal{P}(\hat{P}_{k\epsilon}) \\ &> 0 \ \ (<0) \end{aligned} \tag{6}$$

for $k = 2,\ldots,N+1$, $\lambda \in \mathcal{I}(G_\epsilon(\lambda))$, and $\epsilon \in (0,\epsilon'')$, where $|\epsilon''| \leq |\epsilon'|$. Since

$$\min_{P\in\mathbb{C}^{N+1}} \rho_\epsilon(P) \leq \min_{\tilde{P}\in\mathbb{C}^{k}} \rho_\epsilon(\tilde{P},\hat{P}_{k\epsilon}) \leq \max_{\tilde{P}\in\mathbb{C}^{k}} \rho_\epsilon(\tilde{P},\hat{P}_{k\epsilon}) \leq \max_{P\in\mathbb{C}^{N+1}} \rho_\epsilon(P),$$

it follows that the range of eigenvalues for $G_\epsilon(\lambda,\hat{P}_{k\epsilon})\tilde{P} = 0$ are contained within the range of eigenvalues for $G_\epsilon(\lambda)P = 0$. In other words, there exists an $\mathcal{I}(G_\epsilon(\lambda,\hat{P}_{k\epsilon})) \subset \mathcal{I}(G_\epsilon(\lambda))$, so (6) can be rewritten as

$$\lfloor G_\epsilon(\lambda,\hat{P}_{k\epsilon}) + G_\epsilon(\lambda,\hat{P}_{k\epsilon})\rceil > 0 \ \ (<0) \tag{7}$$

for $k = 2,\ldots,N+1$, $\lambda \in \mathcal{I}(G_\epsilon(\lambda,\hat{P}_{k\epsilon}))$, and $\epsilon \in (0,\epsilon'')$. In a similar way, we can show that

$$\lfloor G_\epsilon(\lambda,\tilde{P}_{k\epsilon}) + G_\epsilon(\lambda,\tilde{P}_{k\epsilon})\rceil > 0 \ \ (<0) \tag{8}$$

for $k = 1,\ldots,N$, $\lambda \in \mathcal{I}(G_\epsilon(\lambda,\tilde{P}_{k\epsilon}))$, and $\epsilon \in (0,\epsilon'')$.

Since $(\lambda_{k\epsilon},\tilde{P}_{k\epsilon})$ is an eigenpair satisfying $G_\epsilon(\lambda,\hat{P}_{k\epsilon})\tilde{P} = 0$, $\tilde{P}_{k\epsilon}(s)$ has all of its zeros in $\mathrm{Re}[s] > 0$ $(\mathrm{Re}[s] < 0)$ for $k = 2,\ldots,N+1$, $\tilde{p}_{k\epsilon}(0) \neq 0$, and (7) is true, then by Corollary 3.2, $\tilde{P}_{k\epsilon}$ is a unique minimizer of $\rho_\epsilon(\tilde{P},\hat{P}_{k\epsilon})$, i.e.,

$$\rho_\epsilon(\tilde{P}_{k\epsilon},\hat{P}_{k\epsilon}) \leq \rho_\epsilon(\tilde{P},\hat{P}_{k\epsilon}) \tag{9}$$

for all $\tilde{P} \in \mathbb{C}^k$, $k = 1, \ldots, N+1$ and $\epsilon \in (0, \epsilon'')$. (For $k = 1$, (9) is trivially true since $\tilde{P}$ is a scalar.) Since $(\lambda_{k\epsilon}, \hat{P}_{k\epsilon})$ is an eigenpair satisfying $G_\epsilon(\lambda, \tilde{P}_{k\epsilon})\hat{P} = 0$, $\hat{P}_{k\epsilon}(s)$ has all of its zeros in $\mathrm{Re}[s] < 0$ ($\mathrm{Re}[s] > 0$) for $k = 1, \ldots, N$, $\hat{p}_{k\epsilon}(0) \neq 0$, and (8) is true, then by Corollary 3.2, $\hat{P}_{k\epsilon}$ is a unique maximizer of $\rho_\epsilon(\hat{P}, \tilde{P}_{k\epsilon})$, i.e.,

$$\rho_\epsilon(\hat{P}_{k\epsilon}, \tilde{P}_{k\epsilon}) \geq \rho_\epsilon(\hat{P}, \tilde{P}_{k\epsilon}) \tag{10}$$

for all $\hat{P} \in \mathbb{C}^{N-k+2}$, $k = 1, \ldots, N+1$ and $\epsilon \in (0, \epsilon'')$. (For $k = N+1$, (10) is trivially true since $\hat{P}$ is a scalar.) Reordering the arguments of (10) and combining with (9) yields

$$\rho_\epsilon(\tilde{P}_{k\epsilon}, \hat{P}) \leq \rho_\epsilon(\tilde{P}_{k\epsilon}, \hat{P}_{k\epsilon}) \leq \rho_\epsilon(\tilde{P}, \hat{P}_{k\epsilon}) \tag{11}$$

for all $\tilde{P} \in \mathbb{C}^k$, $\hat{P} \in \mathbb{C}^{N-k+2}$ and $\epsilon \in (0, \epsilon'')$. Since (11) holds for all $\epsilon \in (0, \epsilon'')$, and the limit of each term exists as $\epsilon \to 0$, then (5) is true and (a) follows.

Part (b) is fairly obvious from the definitions of $\tilde{P}_{k\epsilon}$ and $\hat{P}_{k\epsilon}$ and their continuity at $\epsilon = 0$, though it should be noted that at $\epsilon = 0$, the zeros of the eigenpolynomial and its factors may lie on the imaginary axis. Since $\tilde{p}_k(0)$, $\hat{p}_k(0)$, and $p_k(0)$ are nonzero, all of the eigenpolynomial zeros must be finite. Allowing these leading coefficients to be zero complicates matters a bit, so this case is considered separately.

To prove (c), we can assume that $G_\epsilon(\lambda)$ is real, without loss of generality. Thus there is a real eigenpolynomial $P_{k\epsilon}(s)$ whose complex zeros (if there are any) must exist in conjugate pairs. Since the zeros of $\tilde{P}_{k\epsilon}(s)$ and $\hat{P}_{k\epsilon}(s)$ are separated by the imaginary axis, their complex zeros must be in conjugate pairs; thus they are real polynomials. By continuity of the factors at $\epsilon = 0$, (c) follows. □

Without perturbation in Theorem 3.3, many important problems for which the controllability condition of Theorem 3.1 naturally fails to hold would be unjustly excluded since factorization of the unperturbed eigenpolynomial into recognizable maximizing and minimizing factors could be difficult or impossible (e.g., if any eigenpolynomial zeros are on the imaginary axis). An obvious example is when $\lfloor G(\lambda) + G(\lambda) \rceil = 0$. Clearly, perturbation is critical to the scope of the theorem.

Because the eigenproblem is perturbed, however, special care is required in the statement of Theorem 3.3. Note that while every eigenvector (in the original problem) corresponding to a distinct eigenvalue is the limit of an analytically perturbed eigenvector as $\epsilon \to 0$, an arbitrary element of the eigenspace of a repeated eigenvalue may not necessarily be the limit of an analytically perturbed eigenvector [12], so the eigenvectors cannot, in general, be specified a priori. Rather, they are determined by the perturbation matrix, and this is the reason for defining $P_k = \lim_{\epsilon \to 0} P_{k\epsilon}$.

Theorem 3.3 and its analogue, [9, Theorem 6], should not be confused with the well-known Courant–Fischer theorem [8], which also contains a min-max equals max-min result, nor do they follow from it. The Courant–Fischer theorem, in contrast, is applicable to a larger set of eigenproblems, but it is not a saddlepoint theorem in general. Also, Theorem 3.3 and [9, Theorem 6] clearly imply that each saddlepoint eigenvector is, in principle, *independently computable*. In other words, computation of the saddlepoint eigenvector P_k need not rely on the computation of any other eigenvectors or any larger eigenspaces containing P_k.

In both Theorem 3.3 and [9, Theorem 6], it is assumed that $p_k(0) = \lim_{\epsilon \to 0} p_{k\epsilon}(0) \neq 0$. Proving the existence of an eigenvector saddlepoint $(\tilde{P}_k, \hat{P}_k)$ when $p_k(0) = 0$ simply involves choosing an admissible perturbation (for either a type-1 or type-2 saddlepoint problem) such that $p_{k\epsilon}(0) \neq 0$ for $\epsilon \in (0, \epsilon')$. Since a perturbed eigenvector $P_{k\epsilon}$ with $p_{k\epsilon}(0) = 0$ would be an element of the set of vectors

$[0 \ \ (\mathbb{C}^N)^T]^T$ which has *zero measure* in $\mathbb{C}^{N+1}$, then $p_{k\epsilon}(0) \neq 0$ for almost every $P_{k\epsilon}$. Thus, almost every perturbation will ensure that this condition is satisfied. The steps in proving Theorem 3.3(a) (or [9, Theorem 6(a)]) for this case are the same otherwise. An example of an eigenproblem having saddlepoint eigenvectors of the first kind with coefficients $p_k(0) = 0$ for $k \leq N$ is

$$\left(\begin{bmatrix} e_1 & 2e_2 & \cdots & (N+1)e_{N+1} \end{bmatrix} - \lambda I \right) P = 0,$$

where e_i denotes the ith column of the identity matrix. It is easily verified that $\lambda_k = N - k + 2$, $P_k = e_{N-k+2} \in \mathbb{R}^{N+1}$, $\hat{P}_k = e_{N-k+2} \in \mathbb{R}^{N-k+2}$, and $\tilde{P}_k = e_1 \in \mathbb{R}^k$ for $k = 1, \ldots, N+1$.

The issue that remains to be addressed when $p_k(0) = 0$ concerns the definition of the "zeros" of the eigenpolynomial and its factors. In [9], it was implicitly assumed that for $R \in \mathbb{C}^{n+1}$ with $r(0) \neq 0$, $R(z) \stackrel{\triangle}{=} r(0) + \cdots + r(n)z^{-n}$ has exactly n poles at $z = 0$ and n zeros in the complex plane $\mathbb{C}$, i.e., $R(z)$ is an nth order *rational function* [6]. In this paper, the zeros are again understood to mean the zeros of a rational function. To include the possibility of $r(0) = 0$, however, the zero domain of $R(z)$ must be expanded to the *extended complex plane* $\mathbb{C}_e \stackrel{\triangle}{=} \mathbb{C} \cup \{\infty\}$ [6]. Thus, if j is the largest integer such that $r(j) \neq 0$, then the zeros of the rational function $R(z)$ (with n poles at $z = 0$) are the set of (possibly nondistinct) points given by either

$$\{z_i \in \mathbb{C}_e \mid R(z_i) = 0, \ i = 1, \ldots, n\} \quad \text{if} \quad j = n$$

or

$$\{z_i \in \mathbb{C}_e \mid R(z_i) = 0, \ i = 1, \ldots, j\} \cup \{z_i = 0 \mid i = j+1, \ldots, n\} \quad \text{if} \quad 0 < j < n$$

or

$$\{z_i = 0 \mid i = 1, \ldots, n\} \quad \text{if} \quad j = 0.$$

Given the same R, an identical set of zeros can be obtained by the following equivalent definition: Let j be the smallest number such that $r(j) \neq 0$. Then the zeros of the rational function $R(s)$ (with n poles at $s = \infty$) are the set of (possibly nondistinct) points given by either

$$\{s_i \in \mathbb{C} \mid R(s_i) = 0, \ i = 1, \ldots, n\} \quad \text{if} \quad j = 0$$

or

$$\{s_i = \infty \mid i = 1, \ldots, j\} \cup \{s_i \in \mathbb{C} \mid R(s_i) = 0, \ i = j+1, \ldots, n\} \quad \text{if} \quad 0 < j < n$$

or

$$\{s_i = \infty \mid i = 1, \ldots, n\} \quad \text{if} \quad j = n.$$

The assumption of rationality is critical for several reasons. First, it is entirely valid to allow a zero to exist at a pole location (in this case, either $z = 0$ or $s = \infty$), particularly when convenience and consistency necessitate it. Pole-zero cancellation is a well-established concept in linear system theory [2]. Second, the assumption that the number of zeros is the same for all $R \in \mathbb{C}^{n+1}$ is especially important as R varies within $\mathbb{C}^{n+1}$, e.g., from perturbation of the coefficients. For instance, a zero of $R(z)$

which would otherwise "disappear" as $r(n) \to 0$ is instead viewed as moving to the origin. Third, by our definition of the zeros, we ensure that the eigenvalues of the companion matrix C_R are always considered zeros of $R(z)$ or $R(s)$. If, instead, the zeros were to be defined as the points where $R(\cdot) = 0$, then an awkward exception would have to be made for $R(z)$ when C_R has a zero eigenvalue, since $R(z) \neq 0$ at $z = 0$. Finally, and perhaps most importantly, it ensures that for a given eigenvector R, the locations of the zeros of the eigenpolynomial are *independent of whether the eigenpolynomial is realized as* $R(z)$ *or* $R(s)$.[4] Using either definition, we can see, for example, that a polynomial $R(\cdot)$ generated from $R = e_k \in \mathbb{R}^{n+1}$ has $k-1$ zeros at infinity and $n-k+1$ zeros at the origin, regardless of whether we write $R(z) = z^{-(k-1)}$ or $R(s) = s^{n-k+1}$.[5]

Irrespective of whether the zeros are defined in the manner just discussed or by a more restrictive definition, the results in Theorem 3.3(b) and [9, Theorem 6(b)] remain correct for eigenvectors where $p_k(0) \neq 0$. With the extension made for eigenvectors with $p_k(0) = 0$, however, part (b) in each of these theorems must be modified to allow for zeros at infinity. Specifically, $\mathrm{Re}[s] \geq 0$, $\mathrm{Re}[s] \leq 0$, and $|z| \geq 1$ are replaced by $\{\mathrm{Re}[s] \geq 0\} \cup \{\infty\}$, $\{\mathrm{Re}[s] \leq 0\} \cup \{\infty\}$, and $\{|z| \geq 1\} \cup \{\infty\}$, respectively. Additionally, with the general definition of a zero, Theorem 3.3 and [9, Theorem 6] can be further strengthened to say that $\tilde{P}_k(\cdot)$ has exactly $k-1$ zeros and $\hat{P}_k(\cdot)$ has exactly $N-k+1$ zeros.

The next theorem provides one set of sufficient conditions for the zeros of the eigenpolynomial factors to lie on the extended imaginary axis.

THEOREM 3.4. *Let* $(\tilde{P}_k, \hat{P}_k) \in \mathbb{C}^k \times \mathbb{C}^{N-k+2}$ *be an eigenvector saddlepoint for* $G(\lambda)P = 0$ *corresponding to eigenvalue* λ_k *and assume that* $\lfloor G(\lambda) + G(\lambda) \rceil = 0$.

(a) *If* λ_k *is a distinct eigenvalue of* $G(\lambda, \hat{P}_k)\tilde{P} = 0$, *then all* $k-1$ *zeros of* $\tilde{P}_k(s)$ *are on* $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$.

(b) *If* λ_k *is a distinct eigenvalue of* $G(\lambda, \tilde{P}_k)\hat{P} = 0$, *then all* $N-k+1$ *zeros of* $\hat{P}_k(s)$ *are on* $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$.

Proof. The proofs to (a) and (b) are similar, so only (a) is proved. Assume that j is the smallest integer such that $\tilde{p}_k(j) \neq 0$. By our definition of the eigenpolynomial zeros, there are j zeros at ∞. If $j = k-1$, all zeros are at ∞. If $j < k-1$, then let $\tilde{P}_{k(j:k-1)} \stackrel{\triangle}{=} [\ \tilde{p}_k(j) \ \cdots \ \tilde{p}_k(k-1)\ ]^T$, and assume $\tilde{P}_{k(j:k-1)}$ is scaled so that $\tilde{p}_{k(j:k-1)}(0) = \tilde{p}_k(j) = 1$. Since the zeros of $\tilde{P}_{k(j:k-1)}(s)$ are the finite zeros of $\tilde{P}_k(s)$, our goal is to show that $\tilde{P}_{k(j:k-1)}(s)$ has zeros only on $\mathrm{Re}[s] = 0$.

From (5), λ_k is the minimum $\rho(\tilde{P}, \hat{P}_k)$, i.e., $\rho(\tilde{P}, \hat{P}_k) \geq \lambda_k$ for all $\tilde{P} \in \mathbb{C}^k$. This implies that

$$\tilde{P}^* G(\lambda_k, \hat{P}_k)\tilde{P} = \tilde{P}^* \left[\mathcal{P}^*(\hat{P}_k) A \mathcal{P}(\hat{P}_k) - \lambda_k \mathcal{P}^*(\hat{P}_k) B \mathcal{P}(\hat{P}_k)\right] \tilde{P} \geq 0 \ \ \forall \tilde{P} \in \mathbb{C}^k.$$

Thus, $G(\lambda_k, \hat{P}_k) \geq 0$. Since $\tilde{P}_k^* G(\lambda_k, \hat{P}_k)\tilde{P}_k = 0$ and λ_k is distinct by assumption, then $X^* G(\lambda_k, \hat{P}_k) X > 0$ for all nontrivial X not in the eigenspace containing $\tilde{P}_k$. An arbitrary $\bar{X} \in \mathbb{C}^k$ of the form

$$\bar{X} = [\ 0 \ \cdots \ 0 \ \ \bar{x}(j+1) \ \cdots \ \bar{x}(k-1)\ ]^T = [\ 0 \ \cdots \ 0 \ \ \bar{X}^T_{(j+1:k-1)}\ ]^T$$

[4] Whether R is realized as $R(z)$ or $R(s)$ is essentially arbitrary. It is traditionally assumed, however, that complex functions of z (or z^{-1}) and complex functions of s have different inertial definitions.

[5] Henrici redefined the meaning of the term "polynomial" to be entirely consistent with our definition of the term "zeros" [6, p. 464].

cannot be in the eigenspace of $\tilde{P}_k$ since $\bar{x}(j) = 0$ and $\tilde{p}_k(j) \neq 0$, so

$$\bar{X}^* G(\lambda_k, \hat{P}_k)\bar{X} = \bar{X}^*_{(j+1:k-1)} \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} \bar{X}_{(j+1:k-1)} > 0$$

for all nontrivial $\bar{X}_{(j+1:k-1)} \in \mathbb{C}^{k-j-1}$. Thus $\underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} > 0$.

The equation

$$\begin{aligned} \lfloor G(\lambda_k, \hat{P}_k) + G(\lambda_k, \hat{P}_k) \rceil &= \mathcal{P}^*(\hat{P}_k) \lfloor G(\lambda_k)\mathcal{P}(\hat{P}_k) + \mathcal{P}^*(\hat{P}_k) G(\lambda_k) \rceil \mathcal{P}(\hat{P}_k) \\ &= \mathcal{P}^*(\hat{P}_k) \left(\lfloor G(\lambda_k) + G(\lambda_k) \rceil \right) \mathcal{P}(\hat{P}_k) \\ &= 0 \end{aligned}$$

is equivalent to the condition that the sum of the (i, j)th and $(i+1, j-1)$th elements of $G(\lambda_k, \hat{P}_k) \in \mathbb{C}^{k \times k}$ is zero. The same relationship must hold for the elements in a submatrix of $G(\lambda_k, \hat{P}_k)$, so

$$\left\lfloor \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j} + \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j} \right\rceil = 0. \tag{12}$$

$G(\lambda_k, \hat{P}_k)\tilde{P}_k = 0$ implies $\underline{[G(\lambda_k, \hat{P}_k)]}_{k-j} \tilde{P}_{k(j:k-1)} = 0$; hence Lemma 2.7 and (12) allow us to obtain the Lyapunov equation

$$\underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} C_{\tilde{P}_{k(j:k-1)}} + C^*_{\tilde{P}_{k(j:k-1)}} \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} = 0. \tag{13}$$

Now let $(\sigma, Y) \in \mathbb{C} \times \mathbb{C}^{k-j-1}$ be an *arbitrary* eigenpair of $C_{\tilde{P}_{k(j:k-1)}}$. Premultiplication and postmultiplication of (13) by Y^* and Y, respectively, yields

$$Y^* \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} Y\sigma + \sigma^* Y^* \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} Y = 0.$$

Since $\underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} > 0$, then $Y^* \underline{[G(\lambda_k, \hat{P}_k)]}_{k-j-1} Y > 0$; hence $\frac{1}{2}(\sigma + \sigma^*) = \mathrm{Re}[\sigma] = 0$. Finally, the proof is completed by noting that σ is a zero of $\tilde{P}_{k(j:k-1)}(s)$ and thus $\tilde{P}_k(s)$. □

A few comments about Theorem 3.4 are in order:

- Part (a) (part (b)) is satisfied when λ_{N+1} (λ_1) is a distinct eigenvalue of $G(\lambda)P = 0$ since $\hat{P}_{N+1}$ ($\tilde{P}_1$) is a scalar.
- Theorem 3.4 is analogous to [9, Theorem 7], which provides sufficient conditions for the zeros of eigenpolynomial factors to exist on the unit circle.[6] The difference is that here we replace $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N = 0$ with the parallel condition $\lfloor G(\lambda) + G(\lambda) \rceil = 0$.
- The Hermitian matrices $W \in \mathbb{C}^{n \times n}$ which satisfy $\lfloor W + W \rceil = 0$ are of the general pattern

$$W = \begin{bmatrix} w_1 & jw_2 & w_3 & jw_4 & & & \cdots & \\ -jw_2 & -w_3 & -jw_4 & & \cdots & & & \vdots \\ w_3 & jw_4 & & \cdots & & & & \\ -jw_4 & & \cdots & & & & \cdots & \\ & & & & \cdots & & & w_{2n-3} \\ \vdots & & & \cdots & & -w_{2n-3} & jw_{2n-2} & \\ & & \cdots & & w_{2n-3} & -jw_{2n-2} & w_{2n-1} & \end{bmatrix},$$

[6] The unit circle and extended imaginary axis are clearly related since there is a one-to-one mapping between the two sets of points via the bilinear transformation (also known as the linear fractional or Moebius transformation [6]) pair $z = (1+s)/(1-s)$ and $s = (1-z^{-1})/(1+z^{-1})$ [10]. The point $z = -1$ corresponds to the point $s = \infty$.

where $j \triangleq \sqrt{-1}$ and all w_i are real. Matrices having the form of W (*W-matrices*) are to eigenvector saddlepoint problems of the second kind what Hermitian Toeplitz matrices are to eigenvector saddlepoint problems of the first kind. Of course, a Toeplitz matrix $T \in \mathbb{C}^{n\times n}$ satisfies the analogous condition $\underline{[T]}_{n-1} - \overline{[T]}_{n-1} = 0$. Interestingly, the connection between W-matrices and Hermitian Toeplitz matrices extends further. In fact, the covariance matrix of a stationary, continuous random process is a W-matrix, while the covariance matrix of a stationary, discrete random process is a Hermitian Toeplitz matrix. Covariance matrices arise, for example, in the subjects of spectral estimation and linear prediction of continuous or discrete-time autoregressive processes [7, 11].

The remaining theorems relate to both types of saddlepoint eigenproblems. The first of these relaxes an earlier condition that B be positive definite.

THEOREM 3.5. *Consider the eigenproblem* (1)*, in which* $B \geq 0$*. If there exists a Hermitian* $\bar{B}$ *such that* $B+\epsilon\bar{B} > 0$ *and* $AP = \lambda(B+\epsilon\bar{B})P$ *has saddlepoint eigenvectors of the first or second kind for all* $\epsilon \in (0, \epsilon')$*, then the eigenvectors of* (1) *corresponding to finite eigenvalues are also saddlepoint eigenvectors.*

Proof. Let $\rho_\epsilon(P) \triangleq P^*AP/P^*(B+\epsilon\bar{B})P$. By assumption, for each $\epsilon \in (0,\epsilon')$, there is a set of saddlepoints $\{(\tilde{P}_{k\epsilon}, \hat{P}_{k\epsilon}) \mid k = 1, \ldots, N+1\}$ which satisfy (11) for all $\tilde{P} \in \mathbb{C}^k$ and $\hat{P} \in \mathbb{C}^{N-k+2}$. Since the perturbation is analytic,

$$\lim_{\epsilon\to 0}(\tilde{P}_{k\epsilon}, \hat{P}_{k\epsilon}) = (\tilde{P}_k, \hat{P}_k) \in \mathbb{C}^k \times \mathbb{C}^{N-k+2}$$

for $k = 1, \ldots, N+1$, but

$$\lim_{\epsilon\to 0} \rho_\epsilon(\tilde{P}_{k\epsilon}, \hat{P}_{k\epsilon}) = \rho(\tilde{P}_k, \hat{P}_k) \in \mathbb{R}$$

if and only if $(\tilde{P}_k * \hat{P}_k)^* B(\tilde{P}_k * \hat{P}_k) \neq 0$ or, equivalently, $\tilde{P}_k * \hat{P}_k$ is not an eigenvector corresponding to an infinite eigenvalue.

Now for each k such that $\rho(\tilde{P}_k, \hat{P}_k) \in \mathbb{R}$, the continuity of ρ implies there is a neighborhood of $\tilde{P}_k$, denoted by $\tilde{\mathcal{N}}_k$, such that $\rho(\tilde{P}, \hat{P}_k)$ is bounded for all $\tilde{P} \in \tilde{\mathcal{N}}_k$, and a neighborhood of $\hat{P}_k$, denoted by $\hat{\mathcal{N}}_k$, such that $\rho(\tilde{P}_k, \hat{P})$ is bounded for all $\hat{P} \in \hat{\mathcal{N}}_k$. Thus, the limit of (11)

$$\rho(\tilde{P}_k, \hat{P}) \leq \rho(\tilde{P}_k, \hat{P}_k) \leq \rho(\tilde{P}, \hat{P}_k)$$

holds for all $\tilde{P} \in \tilde{\mathcal{N}}_k$ and $\hat{P} \in \hat{\mathcal{N}}_k$, so $(\tilde{P}_k, \hat{P}_k)$ is an eigenvector saddlepoint corresponding to the finite eigenvalue of (1), $\rho(\tilde{P}_k, \hat{P}_k)$. ∎

As an example, when $B \geq 0$ is Hermitian Toeplitz and $\underline{[A]}_N - \overline{[A]}_N \leq 0$ (≥ 0), the eigenvectors in (1) corresponding to finite eigenvalues must be saddlepoint eigenvectors since the eigenvectors of $AP = \lambda(B+\epsilon I)P$ for $\epsilon > 0$ are clearly type-1 saddlepoint eigenvectors under the original criteria. Note that the eigenvector saddlepoints in Theorem 3.5 were demonstrated only to be *local* rather than *global*, i.e., the saddlepoint inequalities were shown to hold over a neighborhood of the saddlepoint, $\tilde{\mathcal{N}}_k \times \hat{\mathcal{N}}_k$, rather than the entire domain $\mathbb{C}^k \times \mathbb{C}^{N-k+2}$. A local saddlepoint is analogous to a local maximum or a local minimium. An example is the saddlepoint $(0,0)$ of the function $f(x,y) = (x^2-2)^2 - (y^2-2)^2$, which satisfies the inequalities $f(x,0) \leq f(0,0) \leq f(0,y)$ for all $x \in [-2,2]$ and $y \in [-2,2]$. Of course, every global saddlepoint is a local one as well.

The next theorem reveals the existence of a general factorization for eigenpolynomials corresponding to eigenvalues of multiplicity m and parameterizes all eigenvector saddlepoint representations.

THEOREM 3.6. *If $G(\lambda)P = 0$ is a type-1 or type-2 saddlepoint eigenproblem with an eigenvalue of multiplicity m, e.g., $\lambda_{k+1} = \cdots = \lambda_{k+m}$, then the m-dimensional eigenspace can be represented as the set*

$$\Xi \stackrel{\triangle}{=} \{P = \tilde{P}_{k+1} * \hat{P}_{k+m} * \bar{P} \mid \bar{P} \in \mathbb{C}^m - \{0\}\},$$

where

$$\tilde{P}_{k+1} \stackrel{\triangle}{=} \arg \min_{\tilde{P} \in \mathbb{C}^{k+1}} \left\{ \max_{\hat{P} \in \mathbb{C}^{N-k+1}} \rho(\tilde{P}, \hat{P}) \right\}$$

and

$$\hat{P}_{k+m} \stackrel{\triangle}{=} \arg \max_{\hat{P} \in \mathbb{C}^{N-k-m+2}} \left\{ \min_{\tilde{P} \in \mathbb{C}^{k+m}} \rho(\tilde{P}, \hat{P}) \right\}.$$

In other words, all of the eigenpolynomials generated from the m-dimensional eigenspace share a common polynomial factor, of degree no greater than $N - m + 1$, given by

$$P_{k+1,k+m}(\cdot) \stackrel{\triangle}{=} \tilde{P}_{k+1}(\cdot)\hat{P}_{k+m}(\cdot).$$

Furthermore, every eigenvector in Ξ has saddlepoint representations of the form

$$(\tilde{P}_{k+1} * \bar{P}_1, \hat{P}_{k+m} * \bar{P}_2) \in \mathbb{C}^{k+j+1} \times \mathbb{C}^{N-k-j+1},$$

where $\bar{P}_1 \in \mathbb{C}^{j+1}$ and $\bar{P}_2 \in \mathbb{C}^{m-j}$, for $j = 0, \ldots, m-1$.

Proof. To prove that the m-dimensional set Ξ is actually the eigenspace, our goal is to show that every vector $P \in \Xi$ has saddlepoint representations (in the form shown) for each of the Cartesian product spaces and that $\rho(P) = \lambda_{k+1} = \cdots = \lambda_{k+m}$. Since λ_{k+1} corresponds to an eigenvector saddlepoint with a minimizing factor $\tilde{P}_{k+1}$,

$$\begin{aligned} \min_{\tilde{P} \in \mathbb{C}^{k+1}} \max_{\hat{P} \in \mathbb{C}^{N-k+1}} \rho(\tilde{P}, \hat{P}) &= \max_{\hat{P} \in \mathbb{C}^{N-k+1}} \rho(\tilde{P}_{k+1}, \hat{P}) \\ &= \lambda_{k+1} \\ &\geq \rho(\tilde{P}_{k+1}, \hat{P}) \ \ \forall \hat{P} \in \mathbb{C}^{N-k+1}. \end{aligned} \tag{14}$$

Using the assumption that λ_{k+m} corresponds to an eigenvector saddlepoint with a maximizing factor $\hat{P}_{k+m}$,

$$\begin{aligned} \max_{\hat{P} \in \mathbb{C}^{N-k-m+2}} \min_{\tilde{P} \in \mathbb{C}^{k+m}} \rho(\tilde{P}, \hat{P}) &= \min_{\tilde{P} \in \mathbb{C}^{k+m}} \rho(\tilde{P}, \hat{P}_{k+m}) \\ &= \lambda_{k+m} \\ &\leq \rho(\tilde{P}, \hat{P}_{k+m}) \ \ \forall \tilde{P} \in \mathbb{C}^{k+m}. \end{aligned} \tag{15}$$

With an *arbitrary* nontrivial $\bar{P} \in \mathbb{C}^m$, let $\hat{P} \stackrel{\triangle}{=} \hat{P}_{k+m} * \bar{P}$ and $\tilde{P} \stackrel{\triangle}{=} \tilde{P}_{k+1} * \bar{P}$. Substitution into (14) and (15) yields

$$\rho(\tilde{P}_{k+1}, \hat{P}_{k+m} * \bar{P}) \leq \lambda_{k+1} = \cdots = \lambda_{k+m} \leq \rho(\tilde{P}_{k+1} * \bar{P}, \hat{P}_{k+m}). \tag{16}$$

Since $\rho(\tilde{P}_{k+1}, \hat{P}_{k+m} * \bar{P}) = \rho(\tilde{P}_{k+1} * \bar{P}, \hat{P}_{k+m})$, (16) is actually an equality, so clearly

$$\rho(P) = \lambda_{k+1} = \cdots = \lambda_{k+m} \quad \forall P \in \Xi. \tag{17}$$

Now let $\bar{P} = \bar{P}_1 * \bar{P}_2$ be *any* factorization of $\bar{P}$, where $\bar{P}_1 \in \mathbb{C}^{j+1}$, $\bar{P}_2 \in \mathbb{C}^{m-j}$, and $j \in \{0, \ldots, m-1\}$. From (14) and (17) we have

$$\rho(\tilde{P}_{k+1}, \hat{P}' * \bar{P}_1) \leq \rho(\tilde{P}_{k+1} * \bar{P}_1, \hat{P}_{k+m} * \bar{P}_2) \quad \forall \hat{P}' \in \mathbb{C}^{N-k-j+1}, \tag{18}$$

and from (15) and (17) we have

$$\rho(\tilde{P}_{k+1} * \bar{P}_1, \hat{P}_{k+m} * \bar{P}_2) \leq \rho(\tilde{P}' * \bar{P}_2, \hat{P}_{k+m}) \quad \forall \tilde{P}' \in \mathbb{C}^{k+j+1}. \tag{19}$$

Combining (18) and (19) and rearranging terms yields

$$\rho(\tilde{P}_{k+1} * \bar{P}_1, \hat{P}') \leq \rho(\tilde{P}_{k+1} * \bar{P}_1, \hat{P}_{k+m} * \bar{P}_2) \leq \rho(\tilde{P}', \hat{P}_{k+m} * \bar{P}_2) \tag{20}$$

for all $\tilde{P}' \in \mathbb{C}^{k+j+1}$ and $\hat{P}' \in \mathbb{C}^{N-k-j+1}$. Since every $P = \tilde{P}_{k+1} * \bar{P}_1 * \hat{P}_{k+m} * \bar{P}_2 \in \Xi$ satisfies the saddlepoint inequality (20), then every $P \in \Xi$ is a stationary point of ρ, and since (17) is also true, then Ξ must be the m-dimensional eigenspace corresponding to eigenvalues $\lambda_{k+1} = \cdots = \lambda_{k+m}$. ∎

There are some other interesting items to note from the last theorem and its proof:

- $\tilde{P}_{k+1}$ and $\hat{P}_{k+m}$ are the lowest dimensional minimizing and maximizing saddlepoint factors, respectively.
- In the case where $m = 1$, $\bar{P}$ is a scalar, and the eigenpolynomial factorization reduces to $P_{k+1}(\cdot) = \tilde{P}_{k+1}(\cdot)\hat{P}_{k+1}(\cdot)$.
- In the case where $m > 1$, a particular eigenvector may have multiple saddlepoint representations in each one of the Cartesian product spaces. Also, since $\bar{P}$ is arbitrary, an eigenpolynomial can have $m-1$ arbitrary zeros.
- Assuming the hypotheses are satisfied, Theorem 3.3 and [9, Theorem 6] only guarantee the existence of a set of eigenvector saddlepoints

$$\mathcal{S} \triangleq \{(\tilde{P}_j, \hat{P}_j) \in \mathbb{C}^j \times \mathbb{C}^{N-j+2} \mid j = k+1, \ldots, k+m\}$$

  for the m-dimensional eigenspace corresponding to eigenvalues $\lambda_{k+1}, \ldots, \lambda_{k+m}$. On the other hand, Theorem 3.6 above proves that the existence of the set $\mathcal{S}$ implies that *all* of the eigenvectors in the eigenspace are saddlepoint eigenvectors, i.e., they all have saddlepoint representations.
- Finally, Theorem 3.6 extends the known results on eigenpolynomial factorization for Hermitian Toeplitz and Hankel-conjugate–transpose-Hankel eigenproblems [3, 4].

As we will demonstrate, Theorem 3.6 can be used to derive estimates of the number of zeros on the extended imaginary axis or the unit circle for each eigenpolynomial factor when $\lfloor G(\lambda) + G(\lambda) \rceil = 0$ or when $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N = 0$, respectively. The following preliminary theorem is also needed.

THEOREM 3.7. *Let $\{\lambda_i \mid \lambda_1 \geq \cdots \geq \lambda_{N+1}\}$ be the set of eigenvalues for $G(\lambda)P = 0$, and let $\{\mu_i \mid \mu_1 \geq \cdots \geq \mu_j\}$ be the set of eigenvalues for a related eigenproblem $Q^*G(\mu)QR = 0$, where $Q \in \mathbb{C}^{(N+1)\times j}$ is a constant matrix with full column rank. Then*

$$\lambda_i \geq \mu_i \geq \lambda_{i+(N+1-j)} \quad \forall\, i = 1, \ldots, j.$$

We will not give a formal proof to this theorem, which appears in a slightly different form in [8, p. 292], but the essence of the proof is contained in the relationships

$$\mu_i = \max_{\mathcal{Q}_i} \min_{P \in \mathcal{Q}_i} \rho(P) \leq \max_{\mathcal{L}_i} \min_{P \in \mathcal{L}_i} \rho(P) = \lambda_i$$

and

$$\mu_i = \min_{\mathcal{Q}_{j-i+1}} \max_{P \in \mathcal{Q}_{j-i+1}} \rho(P) \geq \min_{\mathcal{L}_{j-i+1}} \max_{P \in \mathcal{L}_{j-i+1}} \rho(P) = \lambda_{i+(N+1-j)},$$

where $\mathcal{L}_i$ denotes an arbitrary i-dimensional subspace and $\mathcal{Q}_i$ denotes an i-dimensional subspace in the range of Q.

THEOREM 3.8. *Assume $\lambda_{k+1} = \cdots = \lambda_{k+m}$ is an eigenvalue of multiplicity m for the saddlepoint eigenproblem $G(\lambda)P = 0$ and that $\tilde{P}_{k+1}$ and $\hat{P}_{k+m}$ are defined as in Theorem* 3.6.

1. *If $\lfloor G(\lambda) + G(\lambda) \rceil = 0$,*
   (a) *$\tilde{P}_{k+1}(s)$ has at least $\max\{0, -N+2k+m-1\}$ zeros and at most k zeros on $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$. If λ_{k+m} is a minimum eigenvalue, i.e., $k+m = N+1$, then all $N-m+1$ zeros of $\tilde{P}_{k+1}(s)$ are on $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$.*
   (b) *$\hat{P}_{k+m}(s)$ has at least $\max\{0, N-2k-m+1\}$ zeros and at most $N-k-m+1$ zeros on $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$. If λ_{k+1} is a maximum eigenvalue, i.e., $k = 0$, then all $N-m+1$ zeros of $\hat{P}_{k+m}(s)$ are on $\{\mathrm{Re}[s] = 0\} \cup \{\infty\}$.*
2. *If $\underline{[G(\lambda)]}_N - \overline{[G(\lambda)]}_N = 0$,*
   (a) *$\tilde{P}_{k+1}(z)$ has at least $\max\{0, -N+2k+m-1\}$ zeros and at most k zeros on $|z| = 1$. If λ_{k+m} is a minimum eigenvalue, i.e., $k+m = N+1$, then all $N-m+1$ zeros of $\tilde{P}_{k+1}(z)$ are on $|z| = 1$.*
   (b) *$\hat{P}_{k+m}(z)$ has at least $\max\{0, N-2k-m+1\}$ zeros and at most $N-k-m+1$ zeros on $|z| = 1$. If λ_{k+1} is a maximum eigenvalue, i.e., $k = 0$, then all $N-m+1$ zeros of $\hat{P}_{k+m}(z)$ are on $|z| = 1$.*

Proof. We begin with the proof of 1(a). From the inequality

$$\lambda_{k+m} = \rho(\tilde{P}_{k+m}, \hat{P}_{k+m}) \leq \rho(\tilde{P}, \hat{P}_{k+m})$$

obtained from (5), we can see that the eigenproblem

$$G(\sigma, \hat{P}_{k+m})\tilde{P} = \mathcal{P}^*_{k+m}(\hat{P}_{k+m})G(\sigma)\mathcal{P}_{k+m}(\hat{P}_{k+m})\tilde{P} = 0 \tag{21}$$

has a minimum eigenvalue $\sigma = \lambda_{k+m}$ of multiplicity, say, $\tilde{m}$. Since (21) must obey Theorem 3.6, the $\tilde{m}$-dimensional eigenspace of the minimum eigenvalue can be given by

$$\tilde{\Xi}' \triangleq \{\tilde{P} = \tilde{P}' * \bar{P}' \in \mathbb{C}^{k+m} \mid \bar{P}' \in \mathbb{C}^{\tilde{m}} - \{0\}\}$$

for some $\tilde{P}' \in \mathbb{C}^{k+m-\tilde{m}+1}$. It should also be apparent from Theorem 3.6 that the m-dimensional set

$$\tilde{\Xi} \triangleq \{\tilde{P} = \tilde{P}_{k+1} * \bar{P} \in \mathbb{C}^{k+m} \mid \bar{P} \in \mathbb{C}^{m} - \{0\}\}$$

satisfies (21) for $\sigma = \lambda_{k+m}$, so it follows that $\tilde{\Xi}' \supseteq \tilde{\Xi}$, $m \leq \tilde{m}$, and $\tilde{P}'$ is a factor of $\tilde{P}_{k+1}$.

The next step is to prove that all of the zeros of $\tilde{P}'(s)$ are on the extended imaginary axis. First, define j to be the lowest integer such that $\tilde{p}'(j) \neq 0$, and let

$$\tilde{P}'_{(j:k+m-\tilde{m})} \triangleq [\ \tilde{p}'(j) \quad \cdots \quad \tilde{p}'(k+m-\tilde{m})\ ]^T \in \mathbb{C}^{k+m-\tilde{m}-j+1}.$$

Then $\tilde{P}'(s)$ has j zeros at $s=\infty$ and $k+m-\tilde{m}-j$ finite zeros which are the zeros of $\tilde{P}'_{(j:k+m-\tilde{m})}(s)$. Next, define $\tilde{\Xi}'_0$ to be the subset of $\tilde{\Xi}'$ containing vectors of the form

$$Y = [\ Y^T_{(0:\tilde{m}+j-2)} \quad Y^T_{(\tilde{m}+j-1:k+m-1)}\ ]^T \in \mathbb{C}^{k+m}$$

such that $Y_{(0:\tilde{m}+j-2)}$ is the zero vector or the empty vector, i.e.,

$$Y_{(0:\tilde{m}+j-2)} = \begin{cases} 0 & \text{if } \tilde{m}+j-2 \geq 0, \\ [\ ] & \text{if } \tilde{m}+j-2 < 0. \end{cases}$$

Since $X_{(0:\tilde{m}+j-2)}$ is zero or empty when $X = \tilde{P}' * e_{\tilde{m}} \in \tilde{\Xi}'$, then

$$X = \alpha_{\tilde{m}} \tilde{P}' * e_{\tilde{m}} \Longrightarrow X \in \tilde{\Xi}'_0 \tag{22}$$

for any $\alpha_{\tilde{m}} \neq 0$. The set $\{\tilde{P}' * e_1, \ldots, \tilde{P}' * e_{\tilde{m}} \mid e_i \in \mathbb{R}^{\tilde{m}}\}$ is a basis for $\tilde{\Xi}'$, so

$$X \in \tilde{\Xi}'_0 \subseteq \tilde{\Xi}' \implies X = \alpha_1 \tilde{P}' * e_1 + \cdots + \alpha_{\tilde{m}} \tilde{P}' * e_{\tilde{m}}$$

for some set of coefficients $\{\alpha_1, \ldots, \alpha_{\tilde{m}}\}$, not all of which are zero. If $\alpha_i \neq 0$ for any $i \neq \tilde{m}$, then $X_{(0:\tilde{m}+j-2)} \neq 0$; therefore

$$X \in \tilde{\Xi}'_0 \Longrightarrow X = \alpha_{\tilde{m}} \tilde{P}' * e_{\tilde{m}} \tag{23}$$

for some nontrivial $\alpha_{\tilde{m}}$. Thus, (22) and (23) imply

$$X \in \tilde{\Xi}'_0 \Longleftrightarrow X = \alpha_{\tilde{m}} \tilde{P}' * e_{\tilde{m}},$$

so $\tilde{\Xi}'_0$ has dimension one. Since $G(\lambda_{k+m}, \hat{P}_{k+m}) \geq 0$ and $\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}-j+1} \geq 0$, $(\lambda_{k+m}, X_{(\tilde{m}+j-1:k+m-1)})$ is an eigenpair of

$$\underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}-j+1} R = 0 \tag{24}$$

if and only if $X \in \tilde{\Xi}'_0$. This means the eigenspace of (24) corresponding to eigenvalue $\sigma = \lambda_{k+m}$ is also one-dimensional, and $\sigma = \lambda_{k+m}$ is distinct. Theorem 3.7 implies that the minimum eigenvalue of (24) cannot be less than the minimum eigenvalue of (21); therefore, $\sigma = \lambda_{k+m}$ is the distinct, minimum eigenvalue of (24). By the same argument used to get (12), we obtain

$$\left\lfloor \underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}-j+1} + \underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}-j+1} \right\rfloor = 0.$$

It now follows from Theorem 3.4(a) that, for the eigenproblem (24), the eigenpolynomial $\tilde{P}'_{(j:k+m-\tilde{m})}(s)$ must have all $k+m-\tilde{m}-j$ of its zeros on $\mathrm{Re}[s]=0$. Thus, $\tilde{P}'(s)$ has all $k+m-\tilde{m}$ zeros on $\{\mathrm{Re}[s]=0\} \cup \{\infty\}$.

We now want to determine usable bounds on the number of zeros of $\tilde{P}'(s)$,

$$k+m-\tilde{m} \stackrel{\triangle}{=} \tilde{n}'. \tag{25}$$

To do that, we need to derive an upper bound on $\tilde{m}$. (The lower bound is known.) Thus, if $\{\sigma_i \mid \sigma_1 \geq \cdots \geq \sigma_{k+m}\}$ are the eigenvalues of (21), we must find the *lowest* index i such that $\sigma_i = \cdots = \sigma_{k+m} = \lambda_{k+1} = \cdots = \lambda_{k+m}$ is possible. If that index is denoted by i_{min}, then

$$m \leq \tilde{m} \leq (k+m) - (i_{min} - 1). \tag{26}$$

From Theorem 3.7, we know that $\sigma_i \geq \lambda_{i+N+1-(k+m)}$, so we can write

$$\sigma_{i_{min}} \geq \lambda_{i_{min}+N-k-m+1} = \lambda_{k+1},$$

which yields $i_{min} + N - k - m + 1 = k + 1$, or

$$i_{min} = 2k - N + m. \tag{27}$$

Therefore, by (26) and (27),

$$m \leq \tilde{m} \leq N - k + 1. \tag{28}$$

By combining (25), (28), and the fact that $\tilde{n}' \geq 0$, we obtain

$$\max\{0, -N + 2k + m - 1\} \leq \tilde{n}' \leq k.$$

Since $\tilde{P}'(s)$ is a factor of $\tilde{P}_{k+1}(s)$, and $\tilde{P}_{k+1}(s)$ has exactly k zeros, the bounds on $\tilde{n}'$ are also the bounds on the number of extended imaginary zeros of $\tilde{P}_{k+1}(s)$. Finally, note that when $k + m = N + 1$, the upper and lower bounds on $\tilde{n}'$ are both equal to $k = N - m + 1$; hence the estimate is exact for that case.

To prove 1(b), we proceed in the same fashion as before. From the inequality

$$\rho(\tilde{P}_{k+1}, \hat{P}) \leq \rho(\tilde{P}_{k+1}, \hat{P}_{k+1}) = \lambda_{k+1}$$

obtained from (5), we can see that the eigenproblem

$$G(\theta, \tilde{P}_{k+1})\hat{P} = \mathcal{P}^*_{N-k+1}(\tilde{P}_{k+1})G(\theta)\mathcal{P}_{N-k+1}(\tilde{P}_{k+1})\hat{P} = 0 \tag{29}$$

has a maximum eigenvalue $\theta = \lambda_{k+1}$ of multiplicity, say, $\hat{m}$. Since (29) must obey Theorem 3.6, the $\hat{m}$-dimensional eigenspace of the maximum eigenvalue can be given by

$$\hat{\Xi}' \triangleq \{\hat{P} = \hat{P}' * \bar{P}' \in \mathbb{C}^{N-k+1} \mid \bar{P}' \in \mathbb{C}^{\hat{m}} - \{0\}\}$$

for some $\hat{P}' \in \mathbb{C}^{N-k-\hat{m}+2}$. It should also be apparent from Theorem 3.6 that the m-dimensional set

$$\hat{\Xi} \triangleq \{\hat{P} = \hat{P}_{k+m} * \bar{P} \in \mathbb{C}^{N-k+1} \mid \bar{P} \in \mathbb{C}^{m} - \{0\}\}$$

satisfies (29) for $\theta = \lambda_{k+1}$, so it follows that $\hat{\Xi}' \supseteq \hat{\Xi}$, $m \leq \hat{m}$, and $\hat{P}'$ is a factor of $\hat{P}_{k+m}$.

The procedure needed to prove that $\hat{P}'(s)$ has all of its zeros on the extended imaginary axis is much like the one used for $\tilde{P}'(s)$, so we will continue with the step which bounds the number of zeros of $\hat{P}'(s)$,

$$N - k - \hat{m} + 1 \triangleq \hat{n}'. \tag{30}$$

To do that, we need to derive an upper bound on $\hat{m}$. (The lower bound is known.) Thus, if $\{\theta_i \mid \theta_1 \geq \cdots \geq \theta_{N-k+1}\}$ are the eigenvalues of (29), we must find the *highest* index i such that $\theta_1 = \cdots = \theta_i = \lambda_{k+1} = \cdots = \lambda_{k+m}$ is possible. If that index is denoted by i_{max}, then

$$m \leq \hat{m} \leq i_{max}. \tag{31}$$

From Theorem 3.7, we know that $\lambda_i \geq \theta_i$, so we can write

$$\lambda_{k+m} = \lambda_{i_{max}} \geq \theta_{i_{max}},$$

which yields

$$i_{max} = k + m. \tag{32}$$

Therefore, by (31) and (32),

$$m \leq \hat{m} \leq k + m. \tag{33}$$

By combining (30), (33), and the fact that $\hat{n}' \geq 0$, we obtain

$$\max\{0, N - 2k - m + 1\} \leq \hat{n}' \leq N - k - m + 1.$$

Since $\hat{P}'(s)$ is a factor of $\hat{P}_{k+m}(s)$, and $\hat{P}_{k+m}(s)$ has exactly $N - k - m + 1$ zeros, the bounds on $\hat{n}'$ are also the bounds on the number of extended imaginary zeros of $\hat{P}_{k+m}(s)$. Finally, note that when $k = 0$, the upper and lower bounds on $\hat{n}'$ are both equal to $N - m + 1$; hence the estimate is exact for that case.

The proof of 2(a) is similar to the proof of 1(a) except for one step. Instead, we need to show that all of the zeros of $\tilde{P}'(z)$ are on the unit circle. Because $G(\lambda_{k+m}, \hat{P}_{k+m})$ is a positive semidefinite Toeplitz matrix, it contains $\tilde{m} + 1$ overlapping, positive semidefinite Toeplitz submatrices identical to $\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}}$ embedded along the diagonal. If we assume $\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}}$ is singular and that

$$\bar{V}^* \underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}} \bar{V} = 0,$$

then the set of vectors $\{\bar{V} * e_1, \ldots, \bar{V} * e_{\tilde{m}+1} \mid e_i \in \mathbb{R}^{\tilde{m}+1}\}$ generates an $(\tilde{m} + 1)$-dimensional null space of $G(\lambda_{k+m}, \hat{P}_{k+m})$. Observe, however, that $G(\lambda_{k+m}, \hat{P}_{k+m})$ cannot have a null space of dimension $\tilde{m}+1$, since it would contradict the fact that $\sigma = \lambda_{k+m}$ is an eigenvalue of (21) with multiplicity $\tilde{m}$. Therefore, $\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}}$ is nonsingular, which implies that

$$k + m - \tilde{m} \leq \operatorname{rank}\{\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1}\} \leq k + m - \tilde{m} + 1. \tag{34}$$

Also, since $(\lambda_{k+m}, \tilde{P}' * e_{\tilde{m}})$ is an eigenpair of (21), then

$$\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1} \tilde{P}' = 0. \tag{35}$$

It follows from (34) and (35) that

$$\operatorname{rank}\{\underline{[G(\lambda_{k+m}, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1}\} = k + m - \tilde{m}.$$

Thus, $\sigma = \lambda_{k+m}$ is the distinct, minimum eigenvalue of

$$\underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1} R = 0 \tag{36}$$

and $\tilde{P}'$ is the corresponding eigenvector. Since $G(\sigma, \hat{P}_{k+m})$ and all of its submatrices along the diagonal are Toeplitz,

$$\underline{\left[\underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1}\right]}_{k+m-\tilde{m}} - \overline{\left[\underline{[G(\sigma, \hat{P}_{k+m})]}_{k+m-\tilde{m}+1}\right]}_{k+m-\tilde{m}} = 0.$$

It now follows from [9, Theorem 7(a)] that, for the eigenproblem (36), the eigenpolynomial $\tilde{P}'(z)$ must have all $k+m-\tilde{m}$ of it zeros on $|z|=1$. The remainder of the proof of 2(a) follows that of 1(a). The proof of 2(b) follows those of 1(b) and 2(a). □

For the product $\tilde{P}_{k+1}(\cdot)\hat{P}_{k+m}(\cdot)$, the lower bound on the number of zeros located on the unit circle or extended imaginary axis is $|N-2k-m+1|$, and the upper bound is $N-m+1$. This lower bound is consistent with the one given in [4] for eigenpolynomials of Toeplitz eigenproblems.

4. Summary. Using an inertia theorem for Lyapunov equations, among other techniques, a new class of eigenproblems was shown to have saddlepoint eigenvectors. Sufficient conditions were given for the eigenpolynomial factors to have zeros in $\mathrm{Re}[s]>0\,(\geq 0)$, $\mathrm{Re}[s]<0\,(\leq 0)$, and on $\{\mathrm{Re}[s]=0\}\cup\{\infty\}$. An important theorem that gives a general factorization for an m-dimensional saddlepoint eigenspace was also proved. In the final result, estimates of the number of zeros located on the extended imaginary axis or unit circle were derived for the eigenpolynomial factors in W-matrix and Hermitian Toeplitz eigenproblems.

This paper complements the earlier work in [9], and it provides new perspective on the material there. The usefulness of classical inertia theory in the study of certain types of eigenproblems has been exhibited in both of the discussions as well.

ITERATIVE REGULARIZATION AND MINRES*

MISHA KILMER† AND G. W. STEWART‡

Abstract. In this paper we present three theorems which give insight into the regularizing properties of MINRES. While our theory does not completely characterize the regularizing behavior of the algorithm, it provides a partial explanation of the observed behavior of the method. Unlike traditional attempts to explain the regularizing properties of Krylov subspace methods, our approach focuses on convergence properties of the residual rather than on convergence analysis of the harmonic Ritz values. The import of our analysis is illustrated by two examples. In particular, our theoretical and numerical results support the following important observation: in some circumstances the dimension of the optimal Krylov subspace can be much smaller than the number of the components of the truncated spectral solution that must be computed to attain comparable accuracy.

Key words. regularization, ill-posed problem, MINRES, iterative regularization

1. Introduction.

The discretization of a compact self-adjoint operator equation with errors in the right-hand side results in a linear system whose exact solution bears no relation to the solution of the original error-free system. Specifically, in the spectral domain — that is, in the coordinate system of the eigenvectors of the matrix — the exact linear system can be written in the form

$$\Lambda x = b,$$

where

$$\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_n), \qquad 1 = \lambda_1 > \cdots > \lambda_n > 0.$$

Note that we assume that the system is positive definite and has been scaled so that $\lambda_1 = 1$. To the extent that the quantities in this equation track the corresponding quantities in the original operator, they have the following properties:

(1) If the operator is smooth, the eigenvalues λ_i of the discrete operator will eventually decay rapidly to zero.
(2) If the solution of the original problem is square integrable, then the components ξ_i of x decay to zero.
(3) Since the components β_i of the right-hand side satisfy $\beta_i = \xi_i \lambda_i$, they decay faster than either the components of the solution or the eigenvalues of the operator.

The system with error is

$$\Lambda \tilde{x} = b + e \equiv \tilde{b}.$$

If we model the error as white noise, then we can append the following condition to the above list.

(4) The components ϵ_i of e are random variables with mean zero and standard deviation ϵ.

The components of the solution for the perturbed right-hand side are

$$\tilde{\xi}_i = \frac{\beta_i + \epsilon_i}{\lambda_i}. \tag{1.1}$$

Since the β_i decay rapidly, they soon fall below the error level. The subsequent components of the solution are effectively random variables with standard deviation ϵ/λ_i. The division by λ_i magnifies the originally small error so that it dominates the solution.

As long as the β_i are larger than the errors ϵ_i, the $\tilde{\xi}_i$ contain useful information. The process of extracting this information is called *regularization.* There are many regularization schemes. A natural one is to stop computing components of x when the β_i get near the error level. We will call this procedure *truncated spectral regularization.*[1]

In this paper we will be concerned with regularization based on the iterative method MINRES [9]. The method can be described briefly as follows. Let

$$K_k = (\tilde{b}\ \Lambda\tilde{b}\ \cdots\ \Lambda^{k-1}\tilde{b})$$

be the kth *Krylov matrix*. Then we seek an approximation to x in the form

$$x_k = K_k a_k,$$

where a_k is determined so that

$$\rho_k^2 \equiv \|\tilde{b} - \Lambda x_k\|^2 = \min.$$

Here $\|\cdot\|$ denotes the usual Euclidean norm.

The residual $r_k = \tilde{b} - \Lambda x_k$ has an alternate expression that is used in the analysis of the algorithm. Given a vector $a_k = (\alpha_1, \ldots, \alpha_k)^{\mathrm{T}}$, let a polynomial p be defined by

$$p(t) = 1 - \alpha_1 t - \alpha_2 t^2 - \cdots - \alpha_k t^k.$$

Then the residual $r_k = \tilde{b} - \Lambda K_k a_k$ can be written in the form $r_k = p_k(\Lambda)\tilde{b}$, where p_k is the polynomial associated with a_k. Since MINRES minimizes $\|r_k\|$, we have

$$\rho_k \equiv \|r_k\| = \min_{\substack{\deg(p_k)=k \\ p_k(0)=1}} \|p(\Lambda)\tilde{b}\|. \tag{1.2}$$

Because the ith component of the residual is the value of a polynomial at λ_i, we will often call it the value of the residual at λ_i.

It has been widely observed that up to a certain index k_0 the MINRES solutions x_k are increasingly accurate approximates to the exact solution x, after which their accuracy rapidly deteriorates. Thus if we can determine k_0 (a difficult problem), MINRES can be used as a regularization method. What seems less well known is that

[1] In the nonsymmetric case this process is also known as truncated SVD regularization (see [7] and the references therein).

in some circumstances the critical index k_0 can be quite small — much smaller than the number of components of the truncated spectral solution that must be computed to attain the same accuracy.[2]

In this paper we give three theorems that help explain the regularizing properties of MINRES. The phrase "help explain" is a deliberate warning to the reader not to expect a complete analysis. The theorems do not say that MINRES has to behave in a particular way. Nonetheless, they give considerable insight into the method.

There is a vast body of literature on regularization, much of which is devoted to determining the asymptotic behavior of the error in the optimally regularized solution as the error in the right-hand side approaches zero. (This literature has been admirably surveyed by Engl, Hanke, and Neubauer [4].) There is also a body of literature for well-posed problems in which the asymptotic convergence of Krylov methods like MINRES are analyzed (see, for example, the recent book by Greenbaum [5]). Our approach, which consists of leaving the error in b fixed and determining how the solution behaves as the regularization parameter varies, is essentially nonasymptotic and fits in neither of these categories. On the other hand, our work is closely related to analyses that attempt to find the optimal value of the regularization parameter. (For a survey of this literature see Hansen [8].)

In the next section we give a toy example that will be used to illustrate the subsequent results. We will also describe in a general way what is happening. The next three sections are devoted to establishing our three results. In section 6 we apply our results to another example. The paper concludes with a discussion of the results and suggestions for future work.

A little informal terminology will help in our discussions. We will call the part of the spectrum for which the $\tilde{\beta}_i$ are little affected by the error the *initial part* of the spectrum. We will call the part where they are fully contaminated the *terminal part* of the spectrum. The part of the spectrum lying between will be called the *intermediate part* or the *transitional part.*

2. An example. In this section we will introduce a simple-minded example from image processing. Let $\underline{x}(t)$ represent an "image" on $[0, 1]$, and consider the Gaussian blurring operator

$$\underline{b}(t) = \int_0^1 \underline{x}(s) e^{-\left(\frac{s-t}{\sigma}\right)^2} \, ds.$$

We will discretize this operator by choosing an integer n and setting

$$t_i = \frac{i-1}{n}, \qquad i = 1, \ldots, n+1,$$

and generating a matrix K whose elements are

$$\kappa_{ij} = e^{-\left(\frac{t_j - t_i}{\sigma}\right)^2}.$$

The resulting matrix is then scaled so that its dominant eigenvalue is one. Although this problem is highly simplified, its regularization properties are typical of more realistic problems.

In the following experiments, we took $n = 40$ and $\epsilon = 0.1$. Our function was $\underline{x}(t) = 1 + t + t^2$, and it was discretized by evaluating it at the points t_i to give the components x_i of x. The vector b was generated in the form Ax. Figure 2.1 is a plot

[2] Martin Hanke has also observed this phenomenon [6].

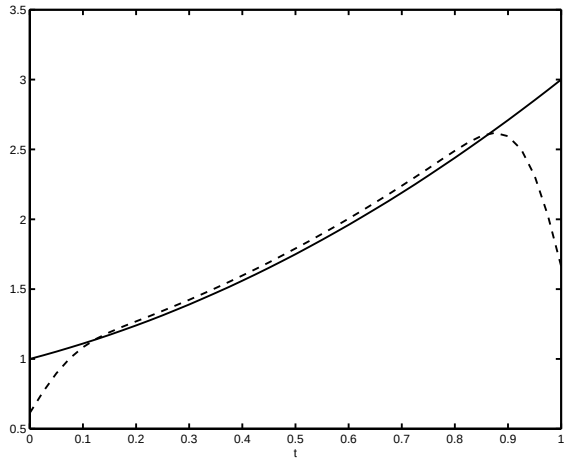

FIG. 2.1. *$x(t)$ (solid) and $b(t)$ (dashed).*

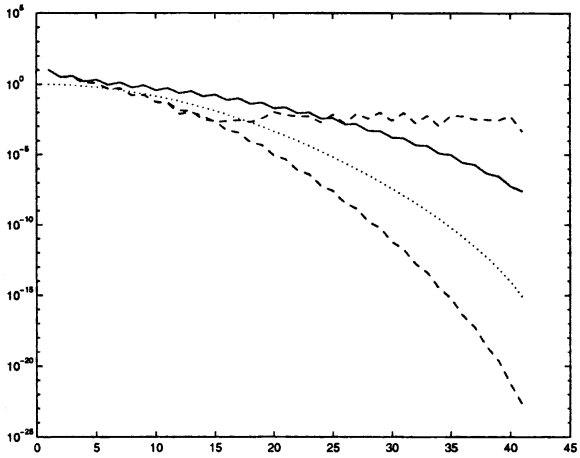

FIG. 2.2. *ξ_i (solid), λ_i (dotted), and β_i, $\tilde{\beta}_i$ (dashed).*

of $\underline{x}(t)$ and $\underline{b}(t)$. The divergence at the ends of the intervals is due to the fact that at those points the part of the blurring distribution that lies outside $[0, 1]$ becomes significant.

Figure 2.2 shows the vectors b, $\tilde{b}$, and x after they have been transformed to the spectral coordinates. Note that for $i > 15$ values $\tilde{\beta}_i$ are significantly contaminated with error. The plot also shows the eigenvalues of A, which decrease slowly at first and then rapidly plunge to about 10^{-15}. This rapid decrease is typical of smooth operators.

Truncated spectral regularization and MINRES regularization behave quite differently for this problem. Figure 2.3 plots the norms of the errors at the kth step of each method. The error for truncated spectral regularization decreases slowly until $k = 15$, after which it increases rapidly. The error in the MINRES iterates decreases rapidly until $k = 5$ and then rises. Truncated spectral regularization produces a bet-

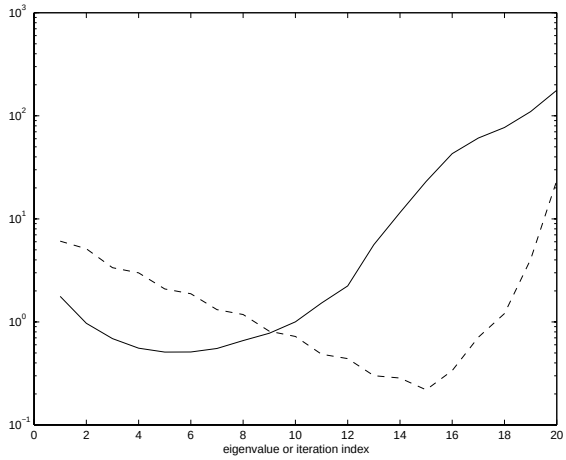

FIG. 2.3. *Errors from spectral regularization (dashed) and MINRES regularization (solid).*

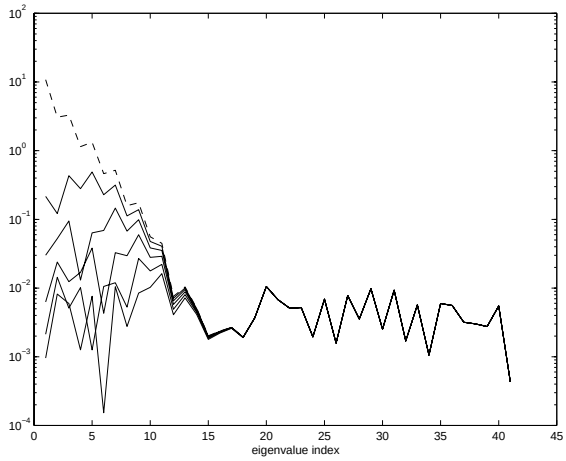

FIG. 2.4. *First five MINRES residuals and $\tilde{b}$ (dashed line).*

ter solution with about half the error but arrives at it more slowly.[3] In fact, not until $k = 11$ does it produce a solution as accurate as the MINRES solution for $k = 5$.

It is informative to examine the behavior of the MINRES residuals. Figure 2.4 displays the magnitudes of the residuals at the eigenvalues λ_i as a function of i for the first five MINRES approximations along with the magnitudes of the components of $\tilde{b}$. It is seen that they decrease in the initial part of the spectrum. At other points in the spectrum, they change very little. The plot in Figure 2.5 shows the same thing in terms of the residual polynomials that satisfy (1.2).[4] The polynomials are small in

[3]The relative quality of the solutions depends on the throw of the dice in constructing the random vector e. For ten other simulations the ratio of the minimum error for truncated spectral regularization to that for MINRES was the following: 0.80, 0.57, 0.76, 0.41, 1.14, 0.65, 0.67, 0.67, 0.82, 0.68. These numbers show the solutions to be usually comparable, with the MINRES solution actually better in a single case.

[4]The plots are not strictly the polynomials. The values between i and $i + 1$ were obtained by evaluating the polynomial at ten equally spaced points between λ_i and λ_{i+1}.

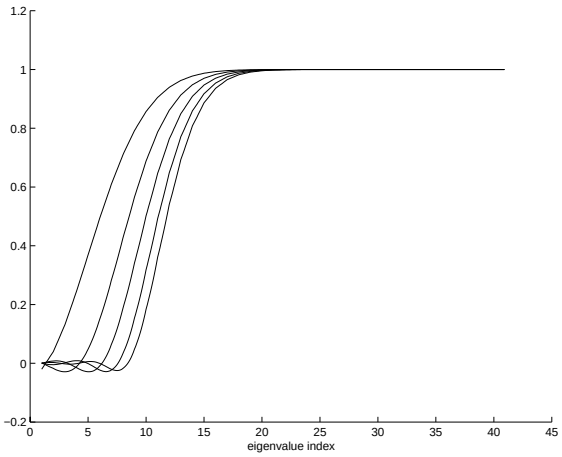

FIG. 2.5. *First five MINRES residual polynomials.*

the initial part of the spectrum and then rise swiftly to a value of one.

Stepping back from this example, we see that three factors are operating to give the fast regularization.

(1) From (1.1) it follows that the residual cannot be reduced indefinitely without harming the solution.
(2) The plot in Figure 2.4 shows that the residual decreases rapidly to a point where further reduction is harmful.
(3) Notice in Figure 2.4 that the values of the first five residuals corresponding to terminal eigenvalues λ_i coincide with $\tilde{\beta}_i$. Equation (1.1) implies that if we reduce the residual at λ_i from $\tilde{\beta}_i$ to $\tilde{\beta}_i(1-\alpha)$, where $0 < \alpha < 1$, then the corresponding component of the approximate solution is $\alpha\tilde{\beta}_i/\lambda_i$. Now in the terminal part of the spectrum $\tilde{\beta}_i \cong \epsilon_i$, and hence the component of the approximate solution is essentially $\alpha\epsilon_i/\lambda_i$. Because the terminal eigenvalues are extremely small compared to the error, even a very small reduction of the residual at a terminal eigenvalue must result in a large component in the approximate solution. Thus if MINRES is to produce an acceptably regularized solution, it must not reduce the residuals at the terminal part of the spectrum while it is still reducing the residuals at the initial part. As it turns out (see Figure 2.5), the first 5 residual polynomials for our running example are very near one on the terminal spectrum, so there is virtually no reduction of the residual there.

In the next three sections we will establish results that give quantitative substance to these observations.

3. The residual and the error. The first of our results concerns the relation between the size of the error in a purported solution and the size of the corresponding residual. We have already noted that if the residual is required to be too small, the error must be large. However, we can be more precise.

Specifically, let y be a purported solution with residual norm δ. There are many such solutions, and among them one must give minimum error; i.e., there must be a

vector y that solves the following problem. Given $\delta > 0$,

$$\begin{aligned} &\text{minimize } \|x - y\|^2 \\ &\text{subject to } \|\tilde{\beta} - \Lambda y\|^2 = \delta^2. \end{aligned} \tag{3.1}$$

The following theorem shows when the solution to this problem has a large error. Below we have assumed $\lambda_1 = 1$.

THEOREM 3.1. *If $\tau > -1$ is the solution of the equation*

$$\sum_i \frac{\epsilon_i^2}{(1+\tau\lambda_i^2)^2} = \delta^2, \tag{3.2}$$

then

$$\eta_i = \xi_i + \frac{\tau\lambda_i\epsilon_i}{1+\tau\lambda_i^2} \tag{3.3}$$

is a solution of (3.1). *In this case*

$$\|x - y\|^2 = \sum_i \left(\frac{\tau\lambda_i}{1+\tau\lambda_i^2}\right)^2 \epsilon_i^2. \tag{3.4}$$

Proof. Consider the Lagrangian

$$\sum_i (\xi_i - \eta_i)^2 + \tau\left[\sum_i (\tilde{\beta}_i - \lambda_i\eta_i)^2 - \delta^2\right],$$

where τ is the Lagrange multiplier. Differentiating with respect to η_i and setting the results to zero, we get

$$\xi_i - \eta_i + \tau\lambda_i(\tilde{\beta}_i - \lambda_i\eta_i) = 0.$$

Equation (3.3) follows on solving this equation for η_i and using the fact that $\tilde{\beta}_i = \lambda_i\xi_i + \epsilon_i$. Equation (3.2) defines the value of τ for which the solution satisfies the constraint. Finally, (3.4) follows by direct computation. ∎

The best way to understand this theorem is to consider the solution y_τ generated as τ varies from -1 to ∞. From (3.2) we see that the residual norm δ decreases monotonically from ∞ to 0. The error norm $\|x - y_\tau\|$ decreases from ∞ to 0 at $\tau = 0$, where $\delta = \|e\|$. Thereafter, small reductions in the residual cause large increases in the error. To see this, consider the term

$$\frac{\epsilon_i^2}{(1+\tau\lambda_i^2)^2}$$

in (3.2). For this term to be reduced by a factor of four from its value ϵ_i^2 at $\tau = 0$, a very modest reduction in the total, we must have $\tau\lambda_i^2 = 1$. The corresponding term in the square of the error norm (3.4) is

$$\left(\frac{\tau\lambda_i\epsilon_i}{1+\tau\lambda_i^2}\right)^2 = \frac{\epsilon_i^2}{4\lambda_i^2},$$

which for small λ_i is large. It is worth noting that these observations depend only on Λ and e and not on x or b.

The above comments suggest that an attempt to reduce the residual norm below $\|e\|$ will increase the error in the solution. This is certainly true of our example, for which $\|e\| = 0.033$. The error turns around at $k = 5$. The residual norms are $\rho_4 = 0.055$ $\rho_5 = 0.039$, and $\rho_6 = 0.031$. Thereafter the error increases sharply, as it must (see Figure 2.3).

It is worth noting that Theorem 3.1 supports the discrepancy principle of Morozov, which says that a regularization parameter should be chosen to make the norm of the residual approximately the size of the norm of the error (see [4, section 4.3]). However, the rapid increase of the error when the residual becomes too small suggests that methods based on the discrepancy principle will be extremely sensitive to variations in the estimate of the error norm (see the experiments in section 7.7.1 of [8]).

4. Reduction of the residual. We now turn to the reduction of the residual. The usual analysis of MINRES is based on (1.2). Specifically, given any polynomial p_k of degree k satisfying $p_k(0) = 1$, we have

$$\|r_k\|^2 \leq \sum_{i=1}^{n} p_k(\lambda_i)^2 \tilde{\beta}_i^2. \tag{4.1}$$

One convergence result amounts to choosing a sequence of polynomials p_k such that

$$\lambda \in [\lambda_n, \lambda_1] \implies p_k(\lambda) \to 0.$$

The rate at which the p_k approach zero on $[\lambda_n, \lambda_1]$ is an upper bound on the convergence rate of MINRES.

The key to analyzing the regularizing properties of MINRES is to note that we are not interested in the convergence of the method on the terminal part of the spectrum. In fact (1.1) shows that MINRES *must not* converge there until after a reasonable regularized solution has been formed. We can therefore restrict our attention to an interval, say, $[\lambda_m, \lambda_1]$ in which the $\tilde{\beta}_i$ are relatively error free. Since the interval is farther removed from the origin, the convergence will be faster.[5]

The polynomial $p_{k,m}$ for this analysis is constructed in the usual way from the Chebychev polynomials $c_k(\tau)$. Specifically, let

$$s_m(t) = -\frac{2t - \lambda_1 - \lambda_m}{\lambda_1 - \lambda_m} \tag{4.2}$$

and set

$$p_{k,m}(t) = \frac{c_k[s_m(t)]}{c_k[s_m(0)]}. \tag{4.3}$$

By bounding the values of these polynomials we obtain the following theorem.

THEOREM 4.1. *Let $m > 1$ and set*

$$\kappa = \frac{\lambda_1}{\lambda_m}$$

[5] For the standard analysis see [5, Chapter 3]. In fact, one reviewer has pointed out that Björck and Eldén [2] used polynomials of this kind to construct regularizing iterative methods. Here, on the other hand, we use them to analyze the regularizing properties of a particular iterative method.

and

$$\tilde{b}_m = (\tilde{\beta}_1, \ \ldots, \ \tilde{\beta}_m)^{\mathrm{T}}.$$

Then

$$\begin{aligned} \|r_k\|^2 &\le \|p_{k,m}(\Lambda)\tilde{b}\|^2 \\ &\le 4\left(\tfrac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1}\right)^{2k} \|\tilde{b}_m\|^2 \\ &\quad + \textstyle\sum_{i=m+1}^{n} \left(1 - 2\frac{\lambda_i}{(\sqrt{\lambda_1}+\sqrt{\lambda_i})^2}\right)^{2k} \tilde{\beta}_i^2. \end{aligned} \tag{4.4}$$

The proof of this theorem is highly technical and will be found in the appendix. The first term in (4.4) is of the same form as the bound from the usual analysis of MINRES mentioned above. However, for that bound κ is λ_1/λ_n, which is larger than λ_1/λ_m and implies slower convergence. The first factor in the remaining terms is essentially one for small eigenvalues. However, for eigenvalues near λ_m it has a reducing effect on the corresponding part of the residual.

The bound is too crude to use in applications, but it provides insight into the way MINRES converges. In our running example, when m is small, κ is near one, and the polynomials $p_{k,m}$ rapidly reduce the residual on $\lambda_1, \ldots, \lambda_m$. But this is precisely the place where there is a large residual to reduce. Since the reduction by $p_{k,m}$ bounds the MINRES reduction, we conclude that initially MINRES will rapidly reduce the residual.

But the bound implies more. As k increases, for fixed m, $p_{k,m}$ will reach a point of diminishing returns when there is not enough residual to reduce. This can be seen by looking at the upper bound in (4.4). Consider m fixed at 4. Since κ is effectively 1, the first term becomes insignificant for $k \ge 2$, and we have a tight bound on the residual for $k = 2$. Yet as k increases and the residual continues to be reduced, the bound stagnates because the second term decreases slowly. However, if we increase m a little, the first term remains small while the second term becomes smaller (since there are fewer indices over which to sum). Thus with increasing k one should increase m to get the smallest possible upper bound. The following table shows that this is precisely what happens in our example.

k	1	2	3	4	5
m	2	4	5	6	7
$\|p_{k,m}(\Lambda)\tilde{b}\|$	8.8e−01	2.8e−01	1.3e−01	7.1e−02	4.7e−02
$\max_{[\lambda_m,\lambda_1]} p_{k,m}$	8.0e−02	2.9e−02	1.0e−02	6.1e−03	5.2e−03
ρ_k	8.7e−01	2.5e−01	1.0e−01	5.5e−02	3.9e−02

For each value of k, the value of m for which $p_{k,m}$ minimizes the residual $\|p_{k,m}(\Lambda)\tilde{b}\|$ was determined. As the table shows, the value of m increases with k. This increase is accompanied by a modest decrease in the size of $p_{k,m}$ on $[\lambda_m, \lambda_1]$. Note that by holding m fixed one can obtain a dramatic decrease in the size of $p_{k,m}$ over $[\lambda_m, \lambda_1]$, but this strategy is not as effective at reducing the bound on the residual norm as the strategy of increasing m and putting up with a modest decrease in $p_{k,m}$. For example, if m is fixed at two, then $\max_{[\lambda_2,\lambda_1]} p_{5,2} = 1.5\text{e}{-09}$, but the residual norm is only 8.9e−02.

The last line in the table shows the MINRES residual norms. They are well approximated by the values in the third line, which suggests that MINRES is following a similar strategy. Figure 2.5 supports our contention that MINRES reduces the residual by increasing the interval in which the polynomial is small.

5. Nonreduction of the residual. Let $\alpha \in [0,1]$, and suppose we wish to reduce the residual at λ_i from $\tilde{\beta}_i$ to $\tilde{\beta}_i(1-\alpha)$. We have already noted that the corresponding component of $\tilde{x}$ is then

$$\tilde{\xi}_i = \frac{\alpha\tilde{\beta}_i}{\lambda_i}.$$

If λ_i is small, then $\tilde{\xi}_i$ is large and the solution will be unsatisfactory. Thus while MINRES is producing a regularized solution, it must not reduce the residuals on the terminal part of the spectrum. From Figure 2.5 we see that this is precisely what is happening in our example. The residual polynomials are effectively one at small λ_i.

The reason MINRES behaves in this manner is that if any polynomial is small at a small eigenvalue, it must be very large at the initial eigenvalues, say $\lambda_1, \ldots, \lambda_m$. Specifically, we have the following theorem.

THEOREM 5.1. *Let $p_{k,m}$ be defined by* (4.3). *If p is any polynomial of degree k satisfying $p(0) = 1$, $p(\lambda_i) = 1-\alpha$ for some $i > m$, and*

$$\frac{p_{k-1,m}(\lambda_i)\lambda_i}{p_{k-1,m}(\lambda_i) - 1 + \alpha} < \lambda_m, \tag{5.1}$$

then there is a point $t_{\text{big}} \in [\lambda_m, \lambda_1]$ such that

$$|p(t_{\text{big}})| \geq \left| 1 - \frac{p_{k-1,m}(\lambda_i) - 1 + \alpha}{p_{k-1,m}(\lambda_i)} \frac{\lambda_m}{\lambda_i} \right| |p_{k-1,m}(\lambda_m)|. \tag{5.2}$$

Proof. The proof is a variant of the standard proof of the theorem of de laVallée Poussin [1, p. 191]. Consider the polynomial

$$q(t) = \left[1 - \frac{p_{k-1,m}(\lambda_i) - 1 + \alpha}{p_{k-1,m}(\lambda_i)} \frac{t}{\lambda_i} \right] p_{k-1,m}(t).$$

This polynomial satisfies the conditions $p(0) = 1$ and $p(\lambda_i) = 1-\alpha$. If, in addition, (5.1) is satisfied, the root of the linear term in brackets is less than λ_m, and the polynomial $q(t)$ alternates in sign at k points

$$\lambda_m = t_1, t_2, \ldots, t_k = 1$$

on the interval $[\lambda_m, \lambda_1]$.

Now let p also satisfy the conditions of the theorem. We claim that $|p(t_i)| \geq |q(t_i)|$ for at least one t_i. For if not, the polynomial $p - q$ alternates in sign at the t_i and hence has $k-1$ zeros in the interval $[\lambda_m, \lambda_1]$. But by the conditions of the theorem $p - q$ is zero at zero and λ_i. Hence $p - q$ is a polynomial of degree not greater than k with $k+1$ zeros and must be identically zero — a contradiction.

Because the values of $|p_{k-1,m}(t_i)|$ are equal, the absolute value of $q(t_i)$ is smallest at λ_m, and evaluating $|q(\lambda_m)|$ gives the lower bound (5.2). ∎

Note that when i is large the condition (5.1) is not very restrictive. For in that case, the right-hand side is near λ_i/α, which cannot approach λ_m unless α is very small.

The import of this theorem is that the cost of reducing the residual at the small eigenvalues is to make the polynomial large on an interval containing the initial eigenvalues. This is because the factor λ_m/λ_i in (5.2) becomes enormous for i large. For

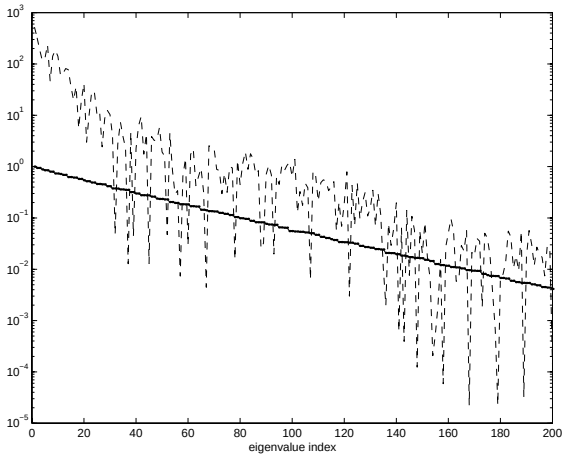

FIG. 6.1. *Eigenvalues (solid line) and components of b (dashed line).*

example, Theorem 5.1 implies that if $m = 8$ and $k = 5$ in our running example, then to get a reduction of .9 ($\alpha = .1$) in the residual at $\lambda_{25} = 6.8\text{e}{-6}$, the absolute value of the residual polynomial will have to be to be greater than 71 at some point in $[\lambda_8, \lambda_1]$. Such a large polynomial is more likely to cause a residual magnification than a residual reduction in $[\lambda_8, \lambda_1]$. This likelihood is increased by the fact that for our example the roots of p_k are spread out over $[\lambda_m, \lambda_1]$, where $m > k$, and the zeros of p_k cannot be near all m of these eigenvalues.

On the other hand, in our example, suppose we wish to reduce the residual at λ_{15} from $\tilde{\beta}_{15}$ to $\tilde{\beta}_{15}(1 - \alpha)$ for $\alpha = 0.11$. The lower bound (5.2) for the residual polynomial is 0.0086. The maximum value of the residual polynomial in $[\lambda_8, \lambda_1]$ is, in fact, 0.037, which is insufficiently greater than 0.0086 to render the reduction at λ_{15} harmless. Once again, the dispersal of the roots of $p_{k,m}$ has a beneficial effect — this time allowing a modest decrease in the residual at the intermediate eigenvalues.

In the last section we observed that MINRES eschews a quick reduction of the residual polynomials over a limited range in favor of expanding the range in which they are moderately small. The theory of this section shows that the deferred reduction has another benefit: it gives the algorithm an opportunity to reduce the residual by a modest amount on the intermediate eigenvalues.

6. Another example. To confirm our analysis of MINRES, we consider a two dimensional blurring operator. Specifically, the original matrix A is the Kronecker product $T \otimes T$, where T is a symmetric Toeplitz matrix whose first row is given by

$$t_{1k} = e^{-0.1(1-k)^2}, \qquad k = 1, \ldots, 32.$$

Figure 6.1 exhibits the first 200 eigenvalues of the matrix and the absolute values components of b in the spectral coordinate system. The error e consists of white noise scaled so that $\|e\|/\|b\| = 0.01$.

Figure 6.2 plots the errors from spectral regularization and MINRES. The contrast is dramatic. The MINRES iteration reduces the error to a minimum of 195 in four iterations. Spectral regularization requires the first 100 components of the solution be computed to reduce the error to a minimum of 192. (However, the plot shows that acceptable accuracy is attained for, say, 30 components.)

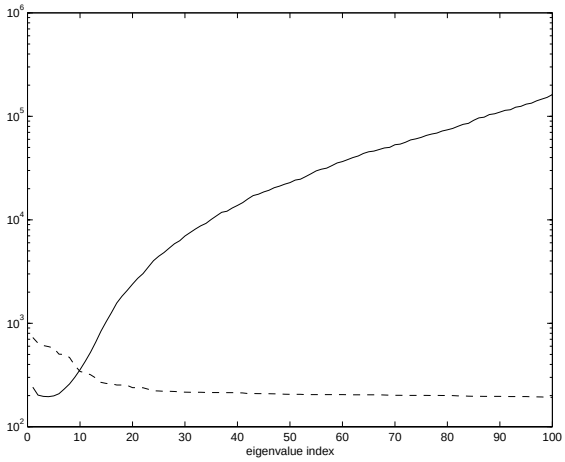

FIG. 6.2. *Errors from spectral regularization (dashed line) and MINRES regularization (solid line).*

The analysis of section 3 suggests that the solution will deteriorate when the residual norm becomes less than the error norm. In fact, the fourth, fifth, and sixth residual norms are 8.66, 7.86, and 7.52. This should be compared with the error norm 7.78.

From the comments in section 4 we would expect that residual polynomials would reduce the error by spreading their roots over a number of eigenvalues rather than by approximating specific eigenvalues. The roots for the first five residual polynomials are given below.

(1)	9.3e−01				
(2)	9.8e−01	7.3e−01			
(3)	9.9e−01	8.1e−01	5.7e−01		
(4)	9.9e−01	8.7e−01	6.9e−01	3.6e−01	
(5)	1.0e+00	9.0e−01	7.4e−01	5.4e−01	2.2e−01

The largest root is converging to one, which in our normalization is an eigenvalue of A. But otherwise, the roots are dispersed. For example, the smallest root of p_4 is 0.36, which corresponds to λ_{34}.

7. Conclusions. In the introduction to this paper we emphasized that this work would not provide a complete analysis of MINRES as a regularization technique. We can analyze MINRES applied to well-posed problems because asymptotic bounds become applicable long before a solution of the desired accuracy is attained. On the other hand, for ill-posed problems in our examples, MINRES does not have a chance to settle down before the optimal solution is obtained. In effect, we are analyzing the early transient behavior of the algorithm — always a difficult problem.

In spite of not concluding with a general theorem, our analysis sheds considerable light on the behavior of MINRES as a regularizer. Theorem 3.1 is a very general result about ill-posed problems. It suggests that attempting to reduce the residual norm below the error norm will result in a worsened solution. As we have already noted, the theorem can be taken as a justification of the Morozov discrepancy principle.

We have mentioned that the bound (4.4) on the residual norm is too crude to be used in practical applications. Nonetheless, it is good enough to suggest the strategy that MINRES uses to obtain rapid reduction of the residual norm. The free parameter m in the bound is essentially a measure of the spread of the zeros of the residual polynomial. As we have seen, the bound is optimized by keeping m greater than the iteration number k. This suggests that MINRES will attempt to minimize the residual by spreading the roots of its residual polynomials over a larger number of eigenvalues. Our numerical examples support this conjecture.

Finally, Theorem 5.1 shows us why MINRES does not tend to reduce the residual at a small eigenvalue while homing in on the regularized solution. Essentially, a small value of the residual polynomial at a small eigenvalue causes the polynomial to be large on the larger eigenvalues — just where it is most desirable to obtain a decrease in the residuals.

For definiteness, we have restricted ourselves to MINRES applied to a positive definite system. Obviously, some of our results apply to other systems and methods — e.g., least squares regularization of overdetermined systems. Such generalizations, however, will be subject for future work.

8. Appendix. *Proof of Theorem* 4.1. Let $c_k(\tau)$ denote the Chebychev polynomial of degree k and define $s_m(t)$ and $p_{k,m}(t)$ as in (4.2) and (4.3), respectively. Now $p_{k,m}$ is a polynomial of degree k satisfying $p_{k,m}(0) = 1$, and therefore from (4.1), we have

$$\|r^{(k)}\|_2^2 \leq \sum_{i=1}^{n} p_{k,m}^2(\lambda_i)\tilde{\beta}_i = \|p_{k,m}(\Lambda)\tilde{b}\|_2^2. \tag{8.1}$$

When $i \leq m$, $c_k^2(s_m(\lambda_i)) \leq 1$. Moreover, one can show that the denominator of $p_{k,m}$, which is independent of i, is bounded above [10]:

$$\left| \frac{1}{c_k(\frac{\lambda_1+\lambda_m}{\lambda_1-\lambda_m})} \right| \leq 2\left(\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1}\right)^k. \tag{8.2}$$

Thus, it remains to determine an upper bound for the values $c_k(s_m(\lambda_i)),\ i > m$.

For notational convenience, we fix i, let $d = \frac{\lambda_i}{\lambda_1}$, and note that since $\kappa = \frac{\lambda_1}{\lambda_m}$, $\frac{\lambda_i}{\lambda_m} = d\kappa$. Using this notation, we write $s_{m,i} \equiv s_m(\lambda_i) = (\frac{\kappa+1-2d\kappa}{\kappa-1})$.

Now $c_k(s) = \cosh(k \cosh^{-1} s)$. We use the formulas

$$\cosh x = \frac{e^x + e^{-x}}{2} \tag{8.3}$$

and

$$\ln z = \cosh^{-1}\left(\frac{z + z^{-1}}{2}\right) \text{ when } x = \ln z \tag{8.4}$$

to determine our upper bound as outlined below. We note that this type of proof technique was used at least as early as the 1960s (see [3]).

(1) Find a z such that $(\frac{z+z^{-1}}{2}) = s_{m,i}, i > m$.
(2) Use z and (8.3) to determine $c_k(s_{m,i}), i > m$.
(3) Find an upper bound for $c_k^2(s_{m,i}), i > m$.
(4) Use this bound and (8.2) to deduce an upper bound for $p_{k,m}^2(s_{m,i})$ $i > m$.
(5) Use the above information to obtain the upper bound on the right-hand side of (8.1).

Step 1. We first set

$$\frac{z + z^{-1}}{2} = s_{m,i}$$

to obtain

$$z^2 - 2s_{m,i}z + 1 = 0.$$

Since this is a quadratic equation, z is given by

$$\begin{aligned} z &= \frac{2s_{m,i} \pm \sqrt{4s_{m,i}^2 - 4}}{2} \\ &= \left(\frac{\kappa + 1 - 2d\kappa}{\kappa - 1}\right) \pm \sqrt{\left(\frac{\kappa + 1 - 2d\kappa}{\kappa - 1}\right)^2 - 1} \\ &= \frac{1}{\kappa - 1}\left(\kappa + 1 - 2d\kappa \pm 2\sqrt{(\kappa - \kappa d)(1 - \kappa d)}\right) \\ &= \frac{(\sqrt{\kappa - \kappa d} \pm \sqrt{1 - \kappa d})^2}{\kappa - 1}. \end{aligned}$$

(8.5)

For convenience, we take z to be

$$z = \frac{(\sqrt{\kappa - \kappa d} + \sqrt{1 - \kappa d})^2}{\kappa - 1}. \tag{8.6}$$

Step 2. Now $c_k(s_{m,i}) = \cosh(k \ln z) = \cosh(\ln z^k)$. Using (8.3), we obtain

$$\begin{aligned} c_k(s_{m,i}) &= \frac{z^k + z^{-k}}{2} \\ &= \frac{z^{2k} + 1}{2z^k}. \end{aligned}$$

(8.7)

Step 3. Therefore,

$$c_k^2(s_{m,i}) = \frac{1}{4}\left(z^{2k} + \frac{1}{z^{2k}} + 2\right).$$

(8.8)

To get an upper bound on $c_k^2(s_{m,i})$, let us first try to get an upper bound on $\frac{1}{z^{2k}}$ by getting a lower bound on z. Observe that the numerator of z in (8.6) is bounded below by $\kappa - d\kappa$, so our lower bound for z is $\frac{\kappa - d\kappa}{\kappa - 1}$. Since $d\kappa \leq 1$, we therefore obtain

$$\frac{1}{z} \leq \frac{\kappa - 1}{\kappa - d\kappa} \leq 1,$$

and so $\frac{1}{z^{2k}} \leq 1$.

Next, we have the following expression for z^{2k}:

$$z^{2k} = \left(\frac{\kappa + 1 + 2\left((\kappa - d\kappa)(1 - d\kappa)\right)^{1/2} - 2d\kappa}{\kappa - 1} \right)^{2k}.$$

Therefore, we have the following bound on $c_k^2(s_{m,i})$:

$$c_k^2(s_{m,i}) \leq \frac{1}{4} \left(3 + \left(\frac{\kappa + 1 + 2\left((\kappa - d\kappa)(1 - d\kappa)\right)^{1/2} - 2d\kappa}{\kappa - 1} \right)^{2k} \right). \tag{8.9}$$

Step 4. Now we may use (8.2) and (8.9) to determine an upper bound on $p_{k,m}^2(s_{m,i})$ for $i > m$:

$$p_{k,m}^2(s_{m,i}) \leq \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} \left(3 + \left(\frac{\kappa + 1 + 2\left((\kappa - d\kappa)(1 - d\kappa)\right)^{1/2} - 2d\kappa}{\kappa - 1} \right)^{2k} \right).$$

Using $\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1} = \frac{\kappa-1}{\kappa+2\sqrt{\kappa}+1}$, we cancel like terms on the right-hand side above and factor out $\sqrt{\kappa}$ from the radical to obtain

$$p_{k,m}^2(s_{m,i}) \leq 3 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} + \left(\frac{\kappa + 1 + 2\sqrt{\kappa}\left((1 - \frac{\lambda_i}{\lambda_1})(1 - \frac{\lambda_i}{\lambda_m}) \right)^{1/2} - 2\frac{\lambda_i}{\lambda_m}}{\kappa + 1 + 2\sqrt{\kappa}} \right)^{2k}.$$

The second term of the right-hand side above can be bounded above by

$$\left(1 - \frac{2\frac{\lambda_i}{\lambda_m}}{\kappa + 1 + 2\sqrt{\kappa}} \right)^{2k} = \left(1 - 2\frac{\lambda_i}{\lambda_1 + \lambda_m + 2\sqrt{\lambda_1 \lambda_m}} \right)^{2k}.$$

Thus,

$$p_{k,m}^2(s_{m,i}) \leq 3 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} + \left(1 - 2\frac{\lambda_i}{\lambda_1 + \lambda_m + 2\sqrt{\lambda_1 \lambda_m}} \right)^{2k}. \tag{8.10}$$

Step 5. From (8.2) when $i \leq m$,

$$p_{k,m}^2(s_{m,i}) \leq \left(\frac{l}{c_k(s_{m,i})} \right)^2 \leq 4 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k}.$$

Breaking up the sum over the first m and last $n - m$ terms from (8.1) and (8.10), we observe

$$\|r_k\|_2^2 \leq 4 \left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1} \right)^{2k} \|\tilde{b}_m\|_2^2 + \sum_{i=m+1}^{n} \left(1 - 2\frac{\lambda_i}{(\sqrt{\lambda_1} + \sqrt{\lambda_m})^2} \right)^{2k} \tilde{\beta}_i^{\,2}.$$

9. Acknowledgments. We wish to thank Per Christian Hansen and Dianne O'Leary for their useful comments on the first draft of this paper.

THE MOORE–PENROSE GENERALIZED INVERSE FOR SUMS OF MATRICES*

JAMES ALLEN FILL† AND DONNIELL E. FISHKIND‡

Abstract. In this paper we exhibit, under suitable conditions, a neat relationship between the Moore–Penrose generalized inverse of a sum of two matrices and the Moore–Penrose generalized inverses of the individual terms. We include an application to the parallel sum of matrices.

Key words. Moore–Penrose generalized inverse, Sherman–Morrison–Woodbury formula, singular value decomposition, rank additivity, parallel sum

1. Background and main result. In the late 1940s and the 1950s Sherman and Morrison [11], [12], Woodbury [13], Bartlett [2], and Bodewig [4] discovered the following result. As in [7], $M_{m,n}$ denotes the space of complex-valued $m \times n$ matrices and, when $m = n$, this is shortened to M_n.

THEOREM 1 (Sherman–Morrison–Woodbury). *For $s \leq n$, let $A \in M_n$ and $G \in M_s$ both be invertible, and let $Y, Z \in M_{n,s}$. Then $A + YGZ^*$ is invertible if and only if $G^{-1} + Z^*A^{-1}Y$ is invertible, in which case*

$$(A + YGZ^*)^{-1} = A^{-1} - A^{-1}Y(G^{-1} + Z^*A^{-1}Y)^{-1}Z^*A^{-1}.$$

The Sherman–Morrison–Woodbury (SMW) formula and related formulas are reviewed in Henderson and Searle [6]. The SMW formula has been used in a wide variety of applications; an excellent review by Hager [5] describes some of the applications to statistics, networks, structural analysis, asymptotic analysis, optimization, and partial differential equations.

In 1992, Riedel [10] proved an analogous formula (Theorem 2) for some cases where A is singular. All matrices, including singular and even nonsquare matrices, have a *Moore–Penrose generalized inverse. Given a matrix $A \in M_{m,n}$, the Moore–Penrose generalized inverse* of A, denoted $A^\dagger$, is the unique matrix in $M_{n,m}$ satisfying the conditions

$$AA^\dagger A = A, \tag{1}$$

$$A^\dagger AA^\dagger = A^\dagger, \tag{2}$$

$$AA^\dagger \text{ is Hermitian, and} \tag{3}$$

$$A^\dagger A \text{ is Hermitian.} \tag{4}$$

In particular, if $A = U\Sigma V^*$ is a singular value decomposition of A (that is, if $U \in M_m$ and $V \in M_n$ are unitary and $\Sigma \in M_{m,n}$ has $\Sigma_{i,i} \geq 0$ for $1 \leq i \leq \min(m,n)$ and $\Sigma_{i,j} = 0$ otherwise), then it may be verified (by checking (1)–(4)) that $A^\dagger = V\Sigma^\dagger U^*$, where $\Sigma^\dagger$ is defined by

$$\Sigma^\dagger_{i,j} := \begin{cases} \frac{1}{\Sigma_{i,i}} & \text{if } i = j \text{ and } \Sigma_{i,i} \neq 0, \\ 0 & \text{otherwise.} \end{cases}$$

Classical references on generalized inverses are [3] and [9].

THEOREM 2 (Riedel). *Let s and n be positive integers with $s \leq n$; $A \in M_n$; $G \in M_s$; $Y, Y_p \in M_{n,s}$; $Z, Z_p \in M_{n,s}$. Assume $R(Y) \subseteq R(A)$, $R(Y_p) \perp R(A)$, $R(Z) \subseteq R(A^*)$, $R(Z_p) \perp R(A^*)$, G is invertible, Y_p is of full rank, and Z_p is of full rank. Assume also that $R(Y_p) = R(Z_p)$. Then*

$$(A + (Y + Y_p)G(Z + Z_p)^*)^\dagger = A^\dagger - DZ^*A^\dagger - A^\dagger YC^* + D(G^{-1} + Z^*A^\dagger Y)C^*,$$

where $C := Y_p(Y_p^*Y_p)^{-1}$ and $D := Z_p(Z_p^*Z_p)^{-1}$.

The matrices $(Y + Y_p)G(Z + Z_p)^*$ in Theorem 2 and YGZ^* in Theorem 1 are referred to as the *update matrices* to the *initial matrix* A. A version of Riedel's theorem (Theorem 2) for the special case where we seek the Moore–Penrose generalized inverse of a rank-one update to the initial matrix can be found in [9].

Riedel verifies Theorem 2 by checking conditions (1)–(4). It must, however, be noted that the hypothesis $R(Y_p) = R(Z_p)$ of Theorem 2 is nowhere used in the verification of Theorem 2, and thus *Theorem 2 is true without this part of the hypothesis.* It is this key observation that allows us to make use of Theorem 2 in this paper. *When we refer to Theorem 2 henceforth, we will be referring to this theorem without the aforementioned unnecessary hypothesis.*

The purpose of this paper, given matrices A and B and suitable conditions, is to relate $(A + B)^\dagger$ cleanly to $A^\dagger$ and $B^\dagger$. This is done in Theorem 3, our main result, using Riedel's theorem. (For a subspace Ω we denote by P_Ω the orthogonal projection onto Ω.)

THEOREM 3. *Let $A, B \in M_n$ with $\operatorname{rank}(A + B) = \operatorname{rank} A + \operatorname{rank} B$. Then*

$$(A + B)^\dagger = (I - S)\, A^\dagger\, (I - T) + SB^\dagger T, \tag{5}$$

where

$$S := (P_{R(B^*)}P_{R(A^*)^\perp})^\dagger \qquad \text{and}$$
$$T := (P_{R(A)^\perp}P_{R(B)})^\dagger.$$

EXAMPLE 4. Without the rank-additivity hypothesis [$\operatorname{rank}(A + B) = \operatorname{rank} A + \operatorname{rank} B$], the conclusion of Theorem 3 is (generally) false. For example, let A and B be 1×1 matrices with 1 as their only entry. In the notation of Theorem 3, we compute $S = ([1][0])^\dagger = [0]$ and $T = ([0][1])^\dagger = [0]$. Hence,

$$(I - S)A^\dagger(I - T) + SB^\dagger T = [1][1]^\dagger[1] + [0][1]^\dagger[0] = [1]$$

while $(A + B)^\dagger = [\frac{1}{2}]$, contrary to the assertion of Theorem 3. But note $\operatorname{rank}[2] = 1 \neq 2 = \operatorname{rank}[1] + \operatorname{rank}[1]$.

Is it possible, however, that the rank-additivity hypothesis in the statement of Theorem 3 can be eliminated in favor of a weaker condition? We show in Proposition 5

that the rank-additivity hypothesis cannot be avoided in any proof of Theorem 3 which employs Riedel's theorem (Theorem 2), since rank additivity is shown to be implied by the hypotheses of Riedel's theorem. (As mentioned, our proof of Theorem 3 relies on Theorem 2.)

For conditions when $\operatorname{rank}(A+B) = \operatorname{rank} A + \operatorname{rank} B$, see [8].

Remark. The matrices S and T appearing in (5) are far from determined by (5). For example, let x and y be orthonormal vectors in $\mathbf{C}^n$ with $n \geq 3$, and let

$$A := xx^*, \quad B := yy^*.$$

Applying Theorem 3, we obtain

$$(A+B)^\dagger = (I-yy^*)A(I-yy^*) + (yy^*)B(yy^*),$$

which simplifies to

$$(xx^* + yy^*)^\dagger = xx^* + yy^*. \tag{6}$$

But applying Theorem 3 with the roles of A and B reversed, we obtain the different formula

$$(A+B)^\dagger = (xx^*)A(xx^*) + (I-xx^*)B(I-xx^*)$$

which, however, also simplifies to (6).

1.1. Derivation of main result (Theorem 3). Our proof of Theorem 3 is based on the following proposition.

PROPOSITION 5. *Let s and n be positive integers with $s \leq n$; $A \in M_n$; $G \in M_s$; $Y, Y_p \in M_{n,s}$; $Z, Z_p \in M_{n,s}$. Assume $R(Y) \subseteq R(A)$, $R(Y_p) \perp R(A)$, $R(Z) \subseteq R(A^*)$, and $R(Z_p) \perp R(A^*)$.*

Of the following statements, 1 *implies* 2. *Conversely,* 2 *and* 3 *imply* 1.

1. *Y_p and Z_p are of full rank.*
2. $\operatorname{rank}[A + (Y+Y_p)G(Z+Z_p)^*] = \operatorname{rank} A + \operatorname{rank}[(Y+Y_p)G(Z+Z_p)^*]$.
3. $\operatorname{rank}[(Y+Y_p)G(Z+Z_p)^*] = s$.

Proposition 5 is used in proving Theorem 3, but it also demonstrates that rank additivity (of the initial matrix and the update matrix) is implied by the hypotheses of Theorem 2; since our proof of Theorem 3 relies on Theorem 2, the rank-additivity hypothesis of Theorem 3 is, for us, unavoidable.

Proof of Proposition 5. Using the assumption $R(Y) \subseteq R(A)$, we find

$$R[A + (Y+Y_p)G(Z+Z_p)^*] \subseteq R(A) + R(Y) + R(Y_p) = R(A) + R(Y_p).$$

Thus, if statements 2 and 3 hold, then

$$\operatorname{rank} A + s = \operatorname{rank}[A + (Y+Y_p)G(Z+Z_p)^*] \leq \operatorname{rank} A + \operatorname{rank} Y_p,$$

from which we conclude that $\operatorname{rank} Y_p \geq s$, that is, that Y_p (and similarly Z_p) is of full rank (statement 1).

Conversely, suppose Y_p and Z_p are of full rank (statement 1). We have

$$\operatorname{rank} Y_p = s \geq \operatorname{rank} G \geq \operatorname{rank}\left[(Y+Y_p)G(Z+Z_p)^*\right]. \tag{7}$$

In [10], Riedel points out that (when Y_p and Z_p are of full rank)

$$[A + (Y+Y_p)G(Z+Z_p)^*]\,[A + (Y+Y_p)G(Z+Z_p)^*]^\dagger = AA^\dagger + Y_pY_p^\dagger.$$

By the orthogonality of $R(A)$ and $R(Y_p)$, we have $\operatorname{rank}(AA^\dagger + Y_pY_p^\dagger) = \operatorname{rank}(AA^\dagger) + \operatorname{rank}(Y_pY_p^\dagger)$. (Without loss of generality, $AA^\dagger$ and $Y_pY_p^\dagger$ share the same unitary matrices in their singular value decompositions because of this orthogonality.) Thus,

$$\begin{aligned}\operatorname{rank}[A + (Y + Y_p)G(Z + Z_p)^*] &= \operatorname{rank}(AA^\dagger + Y_pY_p^\dagger)\\ &= \operatorname{rank}(AA^\dagger) + \operatorname{rank}(Y_pY_p^\dagger)\\ &= \operatorname{rank} A + \operatorname{rank} Y_p\\ &\geq \operatorname{rank} A + \operatorname{rank}[(Y + Y_p)G(Z + Z_p)^*],\end{aligned}$$

the last inequality holding by (7). Because (trivially)

$$\operatorname{rank}[A + (Y + Y_p)G(Z + Z_p)^*] \leq \operatorname{rank} A + \operatorname{rank}[(Y + Y_p)G(Z + Z_p)^*],$$

we conclude

$$\operatorname{rank}[A + (Y + Y_p)G(Z + Z_p)^*] = \operatorname{rank} A + \operatorname{rank}[(Y + Y_p)G(Z + Z_p)^*],$$

that is, statement 2 holds. □

In proving Theorem 3 we will need also the following three facts about the Moore–Penrose generalized inverse that can be verified directly from (1)–(4). For positive integers t and n such that $t \leq n$, let $L_{n,t}$ denote a matrix of size $n \times t$ with ones on the diagonal and zeros elsewhere. Let r, s, p, and q be positive integers with $s \leq p$ and $r \leq q$, and let $A \in M_{r,s}$, $U \in M_r$, and $V \in M_s$ with U and V unitary. Then

$$(L_{q,r}AL_{p,s}^*)^\dagger = L_{p,s}A^\dagger L_{q,r}^* \tag{8}$$

and

$$(UAV^*)^\dagger = VA^\dagger U^*. \tag{9}$$

If A is of full rank with $r \geq s$, then

$$A^\dagger = (A^*A)^{-1}A^*. \tag{10}$$

Proof of Theorem 3. To simplify notation, and since n is fixed, we shorten $L_{n,t}$ to L_t for $t \leq n$. Let A and B have respective singular value decompositions $U_A\Sigma_AV_A^*$ and $U_B\Sigma_BV_B^*$, where, without loss of generality, exactly the first s diagonal entries of Σ_B are nonzero and exactly the first r diagonal entries of Σ_A are zero.

Note that

$$A + B = A + U_BL_sL_s^*\Sigma_BL_sL_s^*V_B^* = A + (Y + Y_p)G(Z + Z_p)^*, \tag{11}$$

where we define

$$\begin{aligned}G &:= L_s^*\Sigma_BL_s,\\ Y &:= P_{R(A)}U_BL_s = [U_A(I - L_rL_r^*)U_A^*]U_BL_s,\\ Y_p &:= P_{R(A)^\perp}U_BL_s = [U_AL_rL_r^*U_A^*]U_BL_s,\\ Z &:= P_{R(A^*)}V_BL_s = [V_A(I - L_rL_r^*)V_A^*]V_BL_s,\\ Z_p &:= P_{R(A^*)^\perp}V_BL_s = [V_AL_rL_r^*V_A^*]V_BL_s.\end{aligned}$$

Note that G, Y, Y_p, Z, and Z_p satisfy all of the hypotheses of Theorem 2 since Y_p and Z_p are of full rank by Proposition 5 (because $\operatorname{rank} B = s$ and $\operatorname{rank}(A + B) = \operatorname{rank} A + \operatorname{rank} B$).

We next observe that (with D and C defined as in Theorem 2)

$$\begin{aligned} DG^{-1}C^* &= DL_s^*\Sigma_B^\dagger L_s C^* \\ &= DL_s^*V_B^*V_B\Sigma_B^\dagger U_B^*U_BL_sC^* \\ &= DL_s^*V_B^*B^\dagger U_BL_sC^* \\ &= D(Z^*+Z_p^*)B^\dagger(Y+Y_p)C^*, \end{aligned} \tag{12}$$

and thus by Theorem 2 and (12) we have that

$$(A+B)^\dagger = (I-DZ^*)A^\dagger(I-YC^*)+(DZ^*+DZ_p^*)B^\dagger(YC^*+Y_pC^*). \tag{13}$$

This is the basic form of $(A+B)^\dagger$ that we seek, and we proceed to compute DZ^*, YC^*, DZ_p^*, and Y_pC^*.

Because

$$n \geq \operatorname{rank}(A+B) = \operatorname{rank}A + \operatorname{rank}B = n-r+s,$$

we have $r \geq s$. By this, the fact that projection matrices are Hermitian and idempotent, and (8)–(10), we get

$$\begin{aligned} YC^* &= Y(Y_p^*Y_p)^{-1}Y_p^* \\ &= P_{R(A)}U_BL_s(L_s^*U_B^*P_{R(A)^\perp}^*P_{R(A)^\perp}U_BL_s)^{-1}L_s^*U_B^*P_{R(A)^\perp}^* \\ &= P_{R(A)}U_BL_s(L_s^*U_B^*P_{R(A)^\perp}U_BL_s)^{-1}L_s^*U_B^*P_{R(A)^\perp} \\ &= P_{R(A)}U_BL_s(L_s^*U_B^*U_AL_rL_r^*U_A^*U_BL_s)^{-1}L_s^*U_B^*U_AL_rL_r^*U_A^* \\ &= P_{R(A)}U_BL_s[(L_r^*U_A^*U_BL_s)^*(L_r^*U_A^*U_BL_s)]^{-1}(L_r^*U_A^*U_BL_s)^*L_r^*U_A^* \\ &= P_{R(A)}U_BL_s(L_r^*U_A^*U_BL_s)^\dagger L_r^*U_A^* \\ &= P_{R(A)}U_B(L_rL_r^*U_A^*U_BL_sL_s^*)^\dagger U_A^* \\ &= P_{R(A)}(U_AL_rL_r^*U_A^*U_BL_sL_s^*U_B^*)^\dagger \\ &= P_{R(A)}(P_{R(A)^\perp}P_{R(B)})^\dagger \\ &= P_{R(A)}T \end{aligned} \tag{14}$$

and also

$$\begin{aligned} DZ^* &= Z_p(Z_p^*Z_p)^{-1}Z^* \\ &= P_{R(A^*)^\perp}V_BL_s(L_s^*V_B^*P_{R(A^*)^\perp}^*P_{R(A^*)^\perp}V_BL_s)^{-1}L_s^*V_B^*P_{R(A^*)}^* \\ &= P_{R(A^*)^\perp}V_BL_s(L_s^*V_B^*P_{R(A^*)^\perp}V_BL_s)^{-1}L_s^*V_B^*P_{R(A^*)} \\ &= V_AL_rL_r^*V_A^*V_BL_s[L_s^*V_B^*V_AL_rL_r^*V_A^*V_BL_s]^{-1}L_s^*V_B^*P_{R(A^*)} \\ &= V_AL_r(L_r^*V_A^*V_BL_s)[(L_r^*V_A^*V_BL_s)^*(L_r^*V_A^*V_BL_s)]^{-1}L_s^*V_B^*P_{R(A^*)} \\ &= V_AL_r(L_r^*V_A^*V_BL_s)^{*\dagger}L_s^*V_B^*P_{R(A^*)} \\ &= V_AL_r(L_s^*V_B^*V_AL_r)^\dagger L_s^*V_B^*P_{R(A^*)} \\ &= V_A(L_sL_s^*V_B^*V_AL_rL_r^*)^\dagger V_B^*P_{R(A^*)} \\ &= (V_BL_sL_s^*V_B^*V_AL_rL_r^*V_A^*)^\dagger P_{R(A^*)} \\ &= (P_{R(B^*)}P_{R(A^*)^\perp})^\dagger P_{R(A^*)} \\ &= SP_{R(A^*)}. \end{aligned} \tag{15}$$

Similarly, we get

$$Y_p C^* = P_{R(A)^\perp} T \qquad \text{and}$$
$$DZ_p^* = S P_{R(A^*)^\perp}. \tag{16}$$

By plugging (14)–(16) into (13), and noting that $P_{R(A^*)} A^\dagger = A^\dagger$ and $A^\dagger P_{R(A)} = A^\dagger$, the assertion of Theorem 3 follows. □

2. Application to the parallel sum. It is well known in elementary electronics that if two resistors with resistances r_1 and r_2 are placed in parallel, then the cumulative resistance r is computed by the formula

$$r = r_1 (r_1 + r_2)^{-1} r_2 = \left(\frac{1}{r_1} + \frac{1}{r_2} \right)^{-1}. \tag{17}$$

With the idea of generalizing this notion to matrices, Anderson and Duffin [1] define, for $A, B \in M_n$, the *parallel sum* of A and B as

$$A : B := A(A + B)^\dagger B, \tag{18}$$

which, in the case that A and B are (scalar) resistances, is exactly the formula in (17). An alternative definition for the parallel sum of A and B can be found in Rao and Mitra [9], where it is defined as

$$A \| B := \left(A^\dagger + B^\dagger \right)^\dagger, \tag{19}$$

which, in the case that A and B are (scalar) resistances, is again exactly the formula in (17). Given some assumptions on A and B, [9] presents necessary and sufficient conditions for the two definitions of parallel sum to agree.

The following result uses Theorem 3 to provide, under certain conditions, a neat equation relating $A \| B$ to A and B.

COROLLARY 6. *Let* $A, B \in M_n$ *with* $\operatorname{rank}(A \| B) = \operatorname{rank} A + \operatorname{rank} B$. *Then*

$$A \| B = (I - R) A (I - W) + RBW,$$

where

$$R := \left(P_{R(B)} P_{R(A)^\perp} \right)^\dagger \qquad \textit{and}$$
$$W := \left(P_{R(A^*)^\perp} P_{R(B^*)} \right)^\dagger.$$

Corollary 6 is an immediate corollary of Theorem 3, where $A^\dagger$ and $B^\dagger$ of Theorem 6 play the roles of A and B in Theorem 3.

Acknowledgments. The authors thank Adi Ben-Israel, Shih-Ping Han, Roger Horn, and Kurt Riedel for valuable discussions and also thank two anonymous referees for their helpful suggestions.

A NOTE ON P_1- AND LIPSCHITZIAN MATRICES*

G. S. R. MURTHY†, S. K. NEOGY‡, AND F. THUIJSMAN§

Abstract. The linear complementarity problem (q, A) with data $A \in R^{n\times n}$ and $q \in R^n$ involves finding a nonnegative $z \in R^n$ such that $Az+q \geq 0$ and $z^t(Az+q) = 0$. Cottle and Stone introduced the class of P_1-matrices and showed that if A is in $P_1\backslash Q$, then $K(A)$ (the set of all q for which (q, A) has a solution) is a half-space and (q, A) has a unique solution for every q in the interior of $K(A)$. Extending the results of Murthy, Parthasarathy, and Sriparna [*Ann. Dynamic Games*, to appear], we present a number of equivalent characterizations of $P_1\backslash Q$. Also, we present yet another characterization of P-matrices. This widens the range of matrix classes for which a conjecture raised by Murthy, Parthasarathy, and Sriparna [*SIAM J. Matrix Anal. Appl.*, 19 (1998), pp. 898–905] characterizing the class of Lipschitzian matrices is true.

Key words. linear complementarity problem, matrix classes, Lipschitz property

1. Introduction.

The linear complementarity problem (LCP) with data $A \in \boldsymbol{R}^{n\times n}$ and $q \in \boldsymbol{R}^n$ involves finding a vector $z \in \boldsymbol{R}^n$ such that

$$Az + q \geq 0, \quad z \geq 0, \quad \text{and } z^t(Az + q) = 0.$$

Many have tackled a number of problems on existence and solvability of LCP by studying the properties of A; this has lead to the evolution of a wide range of matrix classes. Good background material on the subject can be found in [2, 13].

We shall briefly introduce the concepts and notation required for presentation of the results of this paper. For $A \in \boldsymbol{R}^{n\times n}$, $q \in \boldsymbol{R}^n$, let $F(q, A) = \{z \in \boldsymbol{R}^n_+ : Az+q \geq 0\}$, $S(q, A) = \{z \in F(q, A) : (Az + q)^t z = 0\}$, and $K(A) = \{p \in \boldsymbol{R}^n : S(p, A) \neq \emptyset\}$. For most of the other notation, we shall follow that used in [2]. Let $\bar{n} = \{1, 2, \ldots, n\}$ and for $\alpha, \beta \subseteq \bar{n}$, let $A_{\alpha\beta}$ denote the submatrix of A obtained by retaining only rows corresponding to α and columns corresponding to β. A similar notation is used for vectors. The complement of $\alpha \subseteq \bar{n}$ with respect to $\bar{n}$ will be denoted by $\bar{\alpha}$. The vector e will denote the vector of ones (of appropriate order).

We define a number of matrix classes studied extensively in the literature of LCPs. Say that $A \in \boldsymbol{Q}$ if $S(q, A) \neq \phi$ for all $q \in \boldsymbol{R}^n$; $A \in \boldsymbol{Q}_0$ if for all q, $F(q, A) \neq \phi \Rightarrow S(q, A) \neq \phi$; $A \in \boldsymbol{P}_0(\boldsymbol{P})$ (A is nondegenerate) if $\det A_{\alpha\alpha} \geq 0 (> 0)(\neq 0)$ for all $\alpha \subseteq \bar{n}$; $A \in \boldsymbol{P}_1$ if $A \in \boldsymbol{P}_0$ and $\det A_{\alpha\alpha} = 0$ for some unique α; $A \in \boldsymbol{INS}_k$ if $|S(q, A)| = k$ for all $q \in \text{int } K(A)$; $A \in \boldsymbol{R}_0$ if $|S(0, A)| = 1$; $A \in \boldsymbol{E}_0(\boldsymbol{E})$ if $|S(q, A)| = 1$ for all $q > 0\, (q \geq 0)$; and $A \in \boldsymbol{E'}$ if $|S(q, A)| = 1$ for all $q \geq 0$ and $|S(0, A)| \geq 2$. The class $\boldsymbol{INS}_1$ is denoted by $\boldsymbol{U}$. Next, say that $A \in \boldsymbol{Q}$ if $A_{\alpha\alpha} \in \boldsymbol{Q}$ for all $\alpha \subseteq \bar{n}$. Similar notation is used for other classes.

For $A \in \boldsymbol{R}^{n\times n}$ with $\det A_{\alpha\alpha} \neq 0$ for an α, the principal pivotal transform (PPT) of A with respect to α, denoted by $\wp_\alpha(A)$, is defined as $M = \wp_\alpha(A)$, where $M_{\alpha\alpha} =$

$(A_{\alpha\alpha})^{-1}$, $M_{\alpha\bar{\alpha}} = -(A_{\alpha\alpha})^{-1}A_{\alpha\bar{\alpha}}$, $M_{\bar{\alpha}\alpha} = A_{\bar{\alpha}\alpha}(A_{\alpha\alpha})^{-1}$, and $M_{\bar{\alpha}\bar{\alpha}} = A_{\bar{\alpha}\bar{\alpha}} - M_{\bar{\alpha}\alpha}A_{\alpha\bar{\alpha}}$. Whenever we refer to PPTs, we mean only those which are well defined. It is a well-established result that if A belongs to $\boldsymbol{Q}$, $\boldsymbol{Q}_0$, $\boldsymbol{P}_0$, $\boldsymbol{P}$, $\boldsymbol{P}_1$, or $\boldsymbol{INS}_k$, then every PPT of A is also in the respective class.

For any $A \in \boldsymbol{R}^{m\times n}$, the associated two-person zero-sum matrix game is described as follows. There are two players: row player R and column player C. R chooses a row i, C chooses a column j, and R pays C an amount equal to a_{ij}. A mixed strategy for $R(C)$ is a probability vector $p \in \boldsymbol{R}^m (q \in \boldsymbol{R}^n)$. The fundamental theorem of von Neumann asserts that there exist strategies $\bar{p}$ and $\bar{q}$, called optimal strategies for R and C, respectively, and a real number v, called the value of the game (denoted by $v(A)$), such that

$$\bar{p}^t A \le ve \quad \text{and} \quad A\bar{q} \ge ve.$$

A strategy is said to be completely mixed if all its coordinates are positive. A game is said to be completely mixed if all the optimal strategies are completely mixed. We shall refer to the game by the matrix itself.

Cottle and Stone [3] showed that if $A \in \boldsymbol{P}_1\backslash\boldsymbol{Q}$, then $A \in \boldsymbol{U}$ and that $K(A)$ is a half-space. They further showed that if, in addition, $\det A = 0$, then the support of the half-space $K(A)$ can be chosen to be a positive vector. Murthy, Parthasarathy, and Sriparna [11] showed that if A is a completely mixed game with $v(A) = 0$, then $A \in \boldsymbol{P}_1\backslash\boldsymbol{Q}$ if and only if $A \in \boldsymbol{U}$. In section 2, we show that $A \in \boldsymbol{P}_1\backslash\boldsymbol{Q}$ if and only if $A \in \boldsymbol{U}$ and $K(A)$ is a half-space with a positive support. Indeed, we give a number of equivalent conditions of the statement that $A \in \boldsymbol{P}_1\backslash\boldsymbol{Q}$ and $\det A = 0$.

In section 3, we provide some results relating to the conjecture raised by Murthy, Parthasarathy, and Sriparna [12] concerning a constructive characterization of Lipschitzian matrices. In particular, we show that a certain (constructive) property is necessarily satisfied by Lipschitzian matrices as well as nondegenerate ***INS***-matrices and that the converse is true with an additional assumption.

2. Results on $\boldsymbol{P}_1$-matrices. For the sake of completeness, we state relevant portions of some known theorems.

THEOREM 1 (see Cottle and Stone [3]). *Suppose $A \in \boldsymbol{R}^{n\times n} \cap \boldsymbol{P}_1$. The following statements hold:*

(i) *There exists a unique α such that $\wp_\alpha(A) \in \boldsymbol{P}_1$ and $\det \wp_\alpha(A) = 0$.*
(ii) *A is in $\boldsymbol{Q}_0$.*
(iii) *If $A \notin \boldsymbol{Q}$ and $\det A = 0$, then $A \in \boldsymbol{U}$ and $K(A) = \{q : \pi^t q \ge 0\}$ for some $\pi > 0$.*

THEOREM 2 (see Kaplansky [7]). *Suppose $A \in \boldsymbol{R}^{m\times n}$. The following statements hold for the matrix game A:*

(i) *If the row player R has a completely mixed strategy, then $Aq = v(A)e$ for all optimal strategies q of the column player C.*
(ii) *If $v(A) = 0$, then the game is completely mixed if and only if [$m = n$, $\operatorname{rank}(A) = n - 1$, and all cofactors of A are different from zero and have the same sign].*
(iii) *If the matrix game A is completely mixed, then $v(A) = \det A/$(sum of all cofactors). If, in addition, $v(A) = 0$, then $K(A) = \{q : \pi^t q \ge 0\}$ for some $\pi > 0$.*

THEOREM 3 (see Murthy, Parthasarathy, and Sriparna [11]). *Suppose $A \in \boldsymbol{R}^{m\times n}$. If the matrix game A is completely mixed with $v(A) = 0$, then $A \in \boldsymbol{Q}_0$ and $K(A) = \{q : \pi^t q \ge 0\}$ for some $\pi > 0$.*

Remark 4. It is easy to see that if A is in $\boldsymbol{P}_1$ and $\det A = 0$, then A is a completely mixed game with $v(A) = 0$. However, the converse is not true. This is not true even with an additional assumption that A is a $\boldsymbol{P}_0$-matrix. Consider the example

$$A = \begin{bmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ -1 & 1 & 0 \end{bmatrix}.$$

Note that A is a completely mixed game with $A \in \boldsymbol{P}_0$ but $A \notin \boldsymbol{P}_1$.

LEMMA 5. *Suppose $A \in \boldsymbol{R}^{n\times n}$, $n \geq 2$. If $A \in \boldsymbol{E'}$, then for every proper subset α of $\bar{n}$ such that* $\det A_{\alpha\alpha} = 0$, *$A_{\alpha\alpha} \notin \boldsymbol{P}_1$.*

Proof. Suppose for some proper subset α, $A_{\alpha\alpha} \in \boldsymbol{P}_1$ and $\det A_{\alpha\alpha} = 0$. Then $A_{\alpha\alpha}$ is a completely mixed game with value 0. So there exists a positive vector z_α such that $A_{\alpha\alpha}z_\alpha = 0$. Let $q_{\bar{\alpha}}$ be such that $A_{\bar{\alpha}\alpha}z_\alpha + q_{\bar{\alpha}} > 0$ and $q_{\bar{\alpha}} > 0$. Then z is a nontrivial solution of (q, A), where $z^t = (z_\alpha^t, 0_{\bar{\alpha}}^t)$ and $q = (0_\alpha^t, q_{\bar{\alpha}}^t)$. Since q is a nonzero nonnegative vector, this contradicts the assumption that $A \in \boldsymbol{E'}$. This completes the proof. □

THEOREM 6. *Suppose $A \in \boldsymbol{R}^{n\times n}$, $n \geq 2$. The following statements are equivalent:*

(i) $A \in \boldsymbol{P}_1\backslash Q$ *and* $\det A = 0$.
(ii) $A \in \boldsymbol{U}$ *and* $K(A) = \{q : \pi^t q \geq 0\}$ *for some positive vector* π.
(iii) $A \in \boldsymbol{E'} \cap \boldsymbol{P}_1$.
(iv) $A \in \boldsymbol{E'} \cap \bar{U}$.
(v) $A \in \boldsymbol{U}$ *and* A *is completely mixed with value zero.*
(vi) A^t *satisfies any one of the above conditions* (i)–(v).
(vii) A^t *satisfies all of the above conditions* (i)–(v).

Proof. Cottle and Stone [3] have already proved that (i) implies (ii).

Suppose (ii) holds. Then, as $K(A)$ is a half-space, it is convex and hence $A \in \boldsymbol{Q}_0\backslash\boldsymbol{Q}$ (see [5]). So $A \in \boldsymbol{P}_0$ (see Theorem 4 of [3]). Since $\boldsymbol{P} \subseteq \boldsymbol{Q}$, $\det A_{\alpha\alpha} = 0$ for at least one α. If possible, let α be a proper subset of $\bar{n}$ such that $\det A_{\alpha\alpha} = 0$. There exists $d_\alpha \neq 0$ such that $A_{\alpha\alpha}d_\alpha = 0$. We may assume that $e_\alpha + d_\alpha > 0$. Let $q_\alpha = -A_{\alpha\alpha}e_\alpha$. Choose $q_{\bar{\alpha}}$ to be any positive vector satisfying (*a*) $A_{\bar{\alpha}\alpha}e_\alpha + q_{\bar{\alpha}} > 0$, (*b*) $A_{\bar{\alpha}\alpha}(e_\alpha + d_\alpha) + q_{\bar{\alpha}} > 0$, and (*c*) $\pi_\alpha^t q_\alpha + \pi_{\bar{\alpha}}^t q_{\bar{\alpha}} > 0$. Let $q^t = (q_\alpha^t, q_{\bar{\alpha}}^t)$, $z^t = (z_\alpha^t, 0_{\bar{\alpha}}^t)$, and $d^t = (d_\alpha^t, 0_{\bar{\alpha}}^t)$. It is easy to check that z and $z + d$ are two distinct solutions of (q, A). However, since $\pi^t q > 0$, $q \in \operatorname{int} K(A)$, this contradicts that $A \in \boldsymbol{U}$. It follows that $\det A = 0$ and $A \in \boldsymbol{P}_1$. From the corollary of Lemma 1 of [1], $(0, A)$ has at least two solutions. Now it is easy to see that $A \in \boldsymbol{E'}$ (also see Danao [4]).

Suppose (iii) holds. Since $A \in \boldsymbol{E'}$, $A \notin \boldsymbol{R}_0$. So $A \in \boldsymbol{P}_1\backslash\boldsymbol{Q}$. Let z be a nontrivial solution of $(0, A)$. From Lemma 5, it follows that $z > 0$ and hence $Az = 0$. From Theorem 1(iii), $A \in U$. As $A \in \boldsymbol{P}_1$ and $\det A = 0$, all proper principal submatrices of A are in $\boldsymbol{P}$ and hence in $\boldsymbol{U}$. Hence $A \in \bar{\boldsymbol{U}}$.

Suppose (iv) holds. Since $A \in \boldsymbol{E'}$ and $n \geq 2$, all diagonal entries of A are positive (if $a_{11} < 0$, then $(1, 0, \ldots, 0)^t$ is a nontrivial solution of (q, A) for some nonzero nonnegative q). Now, if for some α all proper principal submatrices of $A_{\alpha\alpha}$ are all $\boldsymbol{P}$-matrices and $\det A_{\alpha\alpha} < 0$, then $(A_{\alpha\alpha})^{-1}$ is an $\boldsymbol{N}$-matrix and hence a $\boldsymbol{Q}_0$-matrix (if $A_{\alpha\alpha} \leq 0$, then obviously $(A_{\alpha\alpha})^{-1} \in \boldsymbol{Q}_0$, and if $A_{\alpha\alpha} \not\leq 0$, then from Theorem 6.6.4 of [2] $(A_{\alpha\alpha})^{-1} \in \boldsymbol{Q}$). Since $\boldsymbol{U} \cap \boldsymbol{Q}_0 \subseteq \boldsymbol{P}_0$, this would contradict the hypothesis. So $\det A_{\alpha\alpha} \geq 0$. From Lemma 5, it follows that $\det A_{\alpha\alpha} > 0$ for all proper subsets α. Since $A \notin \boldsymbol{R}_0$, it follows that $A \in \boldsymbol{P}_1$, $\det A = 0$, and, from Remark 4, A is completely mixed.

Suppose (v) holds. From Theorem 2, $\det A = 0$. From Theorem 3, $A \in \boldsymbol{Q}_0$ and $K(A) = \{q : \pi^t q \geq 0\}$ for some positive vector π. Since $A \in \boldsymbol{U} \cap \boldsymbol{Q}_0$, $A \in \boldsymbol{P}_0$. Suppose $\det A_{\alpha\alpha} = 0$ for some α with $|\alpha| < n$. Then there exists $d_\alpha \neq 0$ such that $A_{\alpha\alpha} d_\alpha = 0$. Let $q_\alpha = -A_{\alpha\alpha} e_\alpha$. Then, for $q_{\bar{\alpha}}$ positive and sufficiently large, we observe $q \in \text{int } K(A)$ and (q, A) has two solutions, that is, $(e^t_\alpha, 0^t_{\bar{\alpha}})$ and $(e^t_\alpha + \lambda d^t_\alpha, 0^t_{\bar{\alpha}})$ for some λ sufficiently small but positive. This contradicts that $A \in \boldsymbol{U}$, and thus all proper principal minors of A are positive. Since $K(A)$ is a half-space, $A \notin \boldsymbol{Q}$.

To complete the rest of the proof, we will show that (i) holds if and only if (i) holds for A^t. It suffices to show that (i) implies $A^t \notin \boldsymbol{Q}$. Suppose (i) holds. From the proof of Lemma 5 it follows that there exists $z > 0$ such that $Az = 0$. Then $z^t A^t = 0$. Note that this implies $S(q, A) = \emptyset$ for all $q < 0$. Hence $A \notin \boldsymbol{Q}$. □

3. Block property. The study of stability of solution sets in LCPs leads to the class of Lipschitzian matrices. A matrix $A \in \boldsymbol{R}^{n\times n}$ is said to be Lipschitzian if there exists a real number $\lambda > 0$ such that for every $p, q \in K(A)$ and every $z \in S(q, A)$ there exists an $x \in S(p, A)$ such that $\|x - z\| \leq \lambda \|p - q\|$. Mangasarian and Shiau [8] showed that $\boldsymbol{P}$-matrices are Lipschitzian. Gowda [6] showed that if A is Lipschitzian and (q, A) has a unique solution for some nondegenerate q (q is said to be nondegenerate if $z + Az + q > 0$ for all $z \in S(q, A)$), then A is in $\boldsymbol{P}$. Later, Murthy, Parthasarathy, and Sabatini [9] showed that a $\boldsymbol{Q}$-matrix is Lipschitzian if it is a $\boldsymbol{P}$-matrix. Stone [15] showed that Lipschitzian matrices are nondegenerate ***INS***-matrices and conjectured that the converse is also true. Murthy, Parthasarathy, and Sriparna [12] introduced the block property and showed that Lipschitzian as well as nondegenerate ***INS***-matrices satisfy the block property; they further conjectured that if a matrix has block property, then it must be Lipschitzian. In this article, we modify the definition of block property and show that the revised property is also a necessary condition for both Lipschitzian and nondegenerate ***INS***-matrices. Furthermore, we show that if a matrix A has the revised block property and (q, A) has a unique solution for some nondegenerate q, then A is Lipschitzian.

The main significance of block property (as well as the revised one) is that it can be checked in finite number of steps by examining the sign structures of all PPTs. It must be mentioned here that no finite characterization is known for checking whether a given matrix is a Lipschitzian matrix or not. Thus, if the conjecture is true, one would have a finite condition for checking the Lipschitzian property.

DEFINITION 7. *Say that $A \in \boldsymbol{R}^{n\times n}$ has block property $(B^\star)$ if for every PPT M of A there exists a partition $\alpha_1, \alpha_2, \ldots, \alpha_k$ of $\{1, 2, \ldots, n\}$ such that the following hold:*

(i) *$M_{\alpha_i\alpha_i}$, are negative $\boldsymbol{N}$-matrices for $i = 1, 2, \ldots, k-1$, $M_{\alpha_i\alpha_j} = 0$ for $i \neq j$, $i, j = 1, 2, \ldots, k-1$, and the diagonal entries of $M_{\alpha_k\alpha_k}$ are positive.*

(ii) *For any index sets α and β such that $\alpha \Delta \beta = \{i\}$ for some i, $\det M_{\alpha\alpha} \det M_{\beta\beta} > 0$ provided $\{x \in \boldsymbol{R}^{n-1}_+ : [-M_{.\alpha} I_{.\bar{\alpha}}]_{.(i)} x > 0\} \neq \emptyset$.*

THEOREM 8. *Suppose $A \in \boldsymbol{R}^{n\times n}$ is a nondegenerate ***INS***-matrix. Then A has property $(B^\star)$.*

Proof. In [12] it was shown that A satisfies condition (i) of Definition 7. From Theorem 6.6.20 of [2], it follows that M does not have any reflecting facets (see also Definition 6.2.10 and Definition 6.6.14 of [2]). From this, the second condition of the definition follows. □

COROLLARY 9. *Suppose $A \in \boldsymbol{R}^{n\times n}$ is a Lipschitzian matrix. Then A has property $(B^\star)$.*

Proof. The proof follows from the fact that Lipschitzian matrices are nondegenerate ***INS***-matrices. □

THEOREM 10. *Suppose $A \in \boldsymbol{R}^{n\times n} \cap \boldsymbol{E}_0$. Assume that A has property $(B^\star)$. Then $A \in \boldsymbol{P}$.*

Proof. We will prove this by induction. Since $A \in \boldsymbol{E}_0$, $a_{ii} > 0$ for all i. Assume that $A_{\alpha\alpha} \in \boldsymbol{P}$ for all α such that $|\alpha| = k-1$, $k \geq 2$. Let β be any arbitrary index set such that $|\beta| = k$. Suppose $\det A_{\beta\beta} < 0$. Then the inverse of $A_{\beta\beta}$ is an $\boldsymbol{N}$-matrix. From (i) of property $(B^\star)$, $(A_{\beta\beta})^{-1} \leq 0$ and all its diagonal entries are negative. This would imply that $v((A_{\beta\beta})^{-1}) < 0$ and hence $v(A_{\beta\beta}) < 0$. However, this is not possible, as $A \in \boldsymbol{E}_0$ (see Definition 3.9.4 and Corollary 3.9.7 of [2]). □

THEOREM 11. *Suppose $A \in \boldsymbol{R}^{n\times n}$ has property $(B^\star)$. Assume that (q, A) has a unique solution for some nondegenerate q. Then $A \in \boldsymbol{P}$.*

Proof. We may assume without loss of generality that $q > 0$. If (p, A) has a unique solution for every positive vector p, then $A \in \boldsymbol{E}_0$ and hence $A \in \boldsymbol{P}$. Suppose, to the contrary, that (p, A) has a nontrivial solution for some $p > 0$. This means there exists a facet in the positive orthant and an open ball B of positive vectors such that for every $q' \in B \cap H^+$, (q', A) has a unique solution, and for every $q' \in B \cap H^-$, (q', A) has at least two solutions, where H^+ and H^- are the half-spaces containing the facets. Let α be the index set corresponding to the facet. Then $\alpha \neq \emptyset$. Since the facet intersects the nonnegative orthant in the interior, the system defined in condition (ii) of Definition 7 is nonempty. Condition (ii) of the definition implies for $i \notin \alpha$, $-A_{.i}$ and $I_{.i}$ are on the opposing sides of the facet in question. But then it would mean that (q', A) has at least two solutions for some $q' \in B \cap H^+$—a contradiction. It follows that (p, A) has a unique solution for every positive vector p. Hence $A \in \boldsymbol{E}_0$ and the rest follows from Theorem 10. □

From the above we have a characterization of $\boldsymbol{P}$-matrices (see [2] for characterizations of $\boldsymbol{P}$-matrices), namely, $A \in \boldsymbol{P}$ if and only if A has property $(B^\star)$ and (q, A) has a unique solution for some nondegenerate q.

Acknowledgments. The authors wish to thank Prof. O. J. Vrieze for some useful discussions and for inviting the first two authors to visit the Department of Mathematics, University of Maastricht. The first author offers special thanks to Prof. K. G. Murty, University of Michigan at Ann Arbor, for partially supporting his foreign tour.

REAL SOLUTIONS OF THE EQUATION $\Phi^t(A) = \frac{1}{n}J_n$*

ZHANG XIAN†, YANG ZHONGPENG‡, AND CAO CHONGGUANG‡

Abstract. For nonsingular $n \times n$ matrices A, $\Phi(A) = A \circ A^{-T}$ ($\circ$ denotes the Hadamard product and A^{-T} the inverse transpose, $(A^{-1})^T$, of A) arises in mathematical control theory associated with chemical engineering design problems and in a matrix theoretic problem involving the relation between the diagonal entries and eigenvalues. For any positive integer t, we show that the equation

$$\Phi^t(A) = \frac{1}{n}J_n$$

has at least 2^{t-1} and 2^t mutually Φ-distinct real solutions for the case $n = 4$ and $n > 4$, respectively, and that these solutions can be determined by an inverted iteration. We also prove that the above equation has only one Φ-distinct real solution $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ for $t = 1$ and has no real solutions for $t \geq 2$ when $n = 2$. The above results answer the problem that has been proposed by Johnson and Shapiro in [*SIAM J. Algebraic Discrete Methods*, 7 (1986), pp. 627–644]. When does the equation $\Phi(A) = A \circ A^{-T} = \frac{1}{n}J_n$ have a real solution?

Key words. Hadamard product, Φ-distinct, H–matrix

1. Introduction.

The Hadamard product of two matrices $B = (b_{ij})$ and $C = (c_{ij})$ is defined by $B \circ C = (b_{ij}c_{ij})$. For a nonsingular $n \times n$ matrix A, we investigate the map

$$\Phi(A) = A \circ A^{-T},$$

where A^{-T} means the inverse transpose, $\left(A^{-1}\right)^T$, of A. The matrix $\Phi(A)$ arises in mathematical control theory in chemical engineering design problems, where it is known as the relative gain array, and also in a matrix theoretic problem involving the relation between the diagonal entries and eigenvalues. A basic question about the map Φ is to determine its range.

Let $M_n(\mathbf{R})$ and $\sigma(A)$ be the set of $n \times n$ matrices over real number field $\mathbf{R}$ and eigenvalues of matrix A, respectively. We denote by I_n and J_n the $n \times n$ identity matrix and all-one matrix, respectively.

From the definition of Φ, it is easy to see that every matrix in the range of Φ has row and column sums of 1. Johnson and Shapiro [1, p. 634], however, showed that not every matrix with row and column sums 1 lying in the range of Φ is true by the equation $\Phi(A) = \frac{1}{3}J_3$. Thus it has no real solution and they proposed the open problem: When does the equation

$$(\star) \qquad \Phi(A) = \frac{1}{n}J_n$$

have a real solution? In this paper we study the more general problem: the existence of real solutions of the equation

$$(\star\star) \qquad \Phi^t(A) = \frac{1}{n}J_n$$

for any positive integer t, where Φ^t is the map Φ applied t times. Obviously, the above open problem is only a special case when $t = 1$.

Johnson and Shapiro showed that $(\star)$ has no real solutions when $n = 3$ (see [1, Example 2]), and hence $(\star\star)$ also has no real solutions. Hence we consider the case $n \neq 3$.

The main results are given in sections 2 and 3 for the case $n \geq 4$ and $n = 2$, respectively. An open problem is proposed in section 4.

2. The case $n \geq 4$. In this section, we assume that $n \geq 4$.

LEMMA 1 [1, Observations 2 and 4]. *For every nonsigular $A \in M_n(\mathbf{R})$,*

(i) *if D and E are $n \times n$ diagonal, nonsingular matrices, then $\Phi(DAE) = \Phi(A)$;*

(ii) *if P and Q are $n \times n$ permutation matrices, then $\Phi(PAQ) = P\Phi(A)Q$.*

DEFINITION 1. *Suppose A and B in $M_n(\mathbf{R})$. If there exist diagonal, nonsingular matrices D and E such that $A = DBE$, then A and B are said to be diagonally equivalent.*

LEMMA 2. *For $\lambda \neq 0$, let $A(\lambda) = \frac{1}{\lambda}[(\lambda + n)I_n - J_n]$.*

(i) *The matrix $A(\lambda)$ is nonsingular if $\lambda \neq -n$. When $\lambda = -n$ we get $A(-n) = \frac{1}{n}J_n$.*

(ii) *If $\lambda \neq -n$, we have $\Phi(A(\lambda)) = A(\mu)$, where $\mu = \lambda(\lambda + n)$.*

(iii) *If $\alpha \neq \beta$, then $A(\alpha)$ and $A(\beta)$ are not diagonally equivalent.*

Proof. (i) Let $e = (1, \ldots, 1)^T$. Then $\sigma(J_n) = \{n, 0, \ldots, 0\}$ because ee^T and e^Te have the same nonzero eigenvalues (see [2, Theorem 1.3.20]), and hence $\sigma(A(\lambda)) = \{1, 1 + \frac{n}{\lambda}, \ldots, 1 + \frac{n}{\lambda}\}$. Thus $A(\lambda)$ is nonsingular if $\lambda \neq -n$. It is easy to see that $A(-n) = \frac{1}{n}J_n$ from the definition of $A(\lambda)$.

(ii) Since $\lambda \neq -n$, $A(\lambda)$ is nonsingular from part (i) of the lemma. Thus

$$\Phi(A(\lambda)) = A(\lambda) \circ A(\lambda)^{-T} = \left\{\frac{1}{\lambda}[(\lambda + n)I_n - J_n]\right\} \circ \left\{\lambda[\frac{1}{\lambda + n}I_n + \frac{1}{\lambda(\lambda + n)}J_n]\right\}.$$

By a direct computation, we obtain $\Phi(A(\lambda)) = A(\mu)$, where $\mu = \lambda(\lambda + n)$.

(iii) Suppose there exist nonsingular matrices $D = \operatorname{diag}(d_1, \ldots, d_n)$ and $E = \operatorname{diag}(e_1, \ldots, e_n)$ such that $A(\alpha) = DA(\beta)E$. Then $d_ie_j = \frac{\beta}{\alpha}$ for any $i \neq j$ and $d_ie_i = \frac{\beta(\alpha+n-1)}{\alpha(\beta+n-1)}$ for any i. This is impossible.

The lemma follows.

LEMMA 3. *Let $f(\lambda) = \lambda(\lambda + n)$, and let t be a positive integer. If $n > 4$, in the interval $(-\frac{n^2}{4}, 0]$ there are 2^t distinct, real solutions to the equation $f^t(\lambda) = -n$, where f^t is the map f applied t times. If $n = 4$, in the interval $(-\frac{n^2}{4}, 0]$ there are 2^{t-1} distinct, real solutions to the equation $f^t(\lambda) = -n$.*

Proof. We only prove the lemma by induction on t when $n > 4$ (because the proof is similar when $n = 4$). $t = 1$ being obvious, we may assume the result for $t - 1$ $(t \geq 2)$.

Let $\mu = f(\lambda)$. Then $f^t(\lambda) = f^{t-1}(\mu)$. By the inductive hypothesis, in the interval $(-\frac{n^2}{4}, 0]$ there are 2^{t-1} real, distinct solutions to the equation $f^{t-1}(\mu) = -n$ (i.e., there are mutually distinct $\mu_1, \mu_2, \ldots, \mu_{2^{t-1}} \in (-\frac{n^2}{4}, 0]$ such that $f^{t-1}(\mu_i) = -n$).

For $i = 1, 2, \ldots, 2^{t-1}$, the solutions to the equation $f(\lambda) = \mu_i$ are

$$\lambda_{i,1} = \frac{-n + \sqrt{n^2 + 4\mu_i}}{2} \quad \text{and} \quad \lambda_{i,-1} = \frac{-n - \sqrt{n^2 + 4\mu_i}}{2}. \tag{1}$$

Obviously, $\lambda_{1,1}, \lambda_{1,-1}, \lambda_{2,1}, \lambda_{2,-1}, \ldots, \lambda_{2^{t-1},1}$ and $\lambda_{2^{t-1},-1}$ are 2^t real solutions, in the interval $(-\frac{n^2}{4}, 0]$, to the equation $f^t(\lambda) = -n$. Now we will show that $\lambda_{1,1}$, $\lambda_{1,-1}$, $\lambda_{2,1}$, $\lambda_{2,-1}, \ldots, \lambda_{2^{t-1},1}$ and $\lambda_{2^{t-1},-1}$ are mutually distinct.

Case 1. Suppose there exist $p, q \in \{1, -1\}$ and distinct $i, j \in \{1, 2, \ldots, 2^{t-1}\}$ such that $\lambda_{i,p} = \lambda_{j,q}$. Then $\mu_i = \mu_j$ from (1), which contradicts $\mu_i \neq \mu_j$.

Case 2. Suppose $\lambda_{i,1} = \lambda_{i,-1}$ for some $i \in \{1, 2, \ldots, 2^{t-1}\}$. Then $\mu_i = -\frac{n^2}{4}$ from (1), which contradicts $\mu_i \in (-\frac{n^2}{4}, 0]$.

Summarizing, $\lambda_{1,1}, \lambda_{1,-1}, \lambda_{2,1}, \lambda_{2,-1}, \ldots, \lambda_{2^{t-1},1}$ and $\lambda_{2^{t-1},-1}$, in the interval $(-\frac{n^2}{4}, 0]$, are 2^t distinct, real solutions to the equation $f^t(\lambda) = -n$. The lemma follows.

THEOREM 1. *Let t be a positive integer. Then if $n > 4$, there are 2^t distinct, real values of λ such that $\Phi^t(A(\lambda)) = \frac{1}{n}J_n$ and hence the equation $\Phi^t(A) = \frac{1}{n}J_n$ has at least 2^t nondiagonally equivalent solutions. When $n = 4$, there are 2^{t-1} distinct, real values of λ such that $\Phi^t(A(\lambda)) = \frac{1}{4}J_4$ and hence the equation $\Phi^t(A) = \frac{1}{4}J_4$ has at least 2^{t-1} nondiagonally equivalent solutions.*

Proof. If $\lambda \neq -n$, part (ii) of Lemma 2 tells us that $\Phi(A(\lambda)) = A(f(\lambda))$. Thus, $\Phi^t(A(\lambda)) = A(f^t(\lambda))$ and the result follows from Lemma 3 and parts (i) and (iii) of Lemma 2.

Remark 1. *We can find 2^t and 2^{t-1} mutually nondiagonally equivalent real solutions $A(\lambda_0)$ to the equation $\Phi^t(A) = \frac{1}{n}J_n$ for the case $n > 4$ and $n = 4$, respectively, where λ_0 satisfies the following inverted iteration:*

$$\begin{cases} \lambda_t = -n, \\ \lambda_k = \frac{-n \pm \sqrt{n^2 + 4\lambda_{k+1}}}{2}, \quad k = 0, 1, \ldots, t-1. \end{cases} \tag{2}$$

In particular, the equation $\Phi(A) = \frac{1}{n}J_n$ has at least two nondiagonally equivalent real solutions $\frac{2}{-n+\epsilon\sqrt{n^2-4n}}(\frac{-n+\epsilon\sqrt{n^2-4n}}{2}I_n - J_n)$ if $n > 4$, where $\epsilon = \pm 1$. When $n = 4$, the equation $\Phi(A) = \frac{1}{4}J_4$ has at least one nondiagonally equivalent real solution $-I_4 + \frac{1}{2}J_4$.

Proof. We consider only the case $n > 4$. (The proof is similar for $n = 4$.) From the proof of Lemma 3, it is easy to see that the equation $f^t(\lambda) = -n$ has 2^t distinct real solutions and these solutions can be obtained from the inverted iteration (2). Again applying $\Phi^t(A(\lambda)) = A(f^t(\lambda))$ and parts (i) and (iii) of Lemma 2, we can obtain 2^t mutually distinct real solutions $A(\lambda_0)$ to the equation $\Phi^t(A) = \frac{1}{n}J_n$, where λ_0 follows from (2). In particular, if $t = 1$, $A(\lambda_0) = -I_4 + \frac{1}{2}J_4$.

3. The case $n = 2$. In this section, we assume that $n = 2$.

THEOREM 2. *Let $A = (a_{ij}) \in M_2(\mathbf{R})$. Then A is a real solution to the equation $\Phi(A) = \frac{1}{2}J_2$ if and only if A and $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ are diagonally equivalent. Hence, there is only one nondiagonally equivalent solution to the equation $\Phi(A) = \frac{1}{2}J_2$.*

Proof. A calculation shows that if $A \in M_2(\mathbf{R})$, then $\Phi(A) = \frac{1}{2}J_2$ if and only if $a_{11}a_{22} = -a_{12}a_{21} \neq 0$. Let $D = \operatorname{diag}(1, \frac{a_{11}}{a_{21}})$ and $E = \operatorname{diag}(\frac{1}{a_{11}}, \frac{1}{a_{12}})$. Then $DAE = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$; i.e., A and $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ are diagonally equivalent.

The converse is evident by applying part (i) of Lemma 1.

THEOREM 3. *Suppose $t \geq 2$. Then the equation $\Phi^t(A) = \frac{1}{2}J_2$ has no real solutions.*

Proof. Suppose $A = (a_{ij}) \in M_2(\mathbf{R})$ is a real solution of the equation $\Phi^t(A) = \frac{1}{2}J_2$. Then $\Phi(A)$ is nonsingular, and hence $a_{11}a_{22} \neq -a_{12}a_{21}$. Let $B = \Phi(A)$.

Case 1. If $|a_{11}a_{22}| > |a_{12}a_{21}|$, then B is an H-matrix. By applying Theorem 2 in [1], we have $\lim_{k\to\infty} \Phi^k(A) = \lim_{k\to\infty} \Phi^{k-1}(B) = I_2$. This contradicts $\Phi^t(A) = \frac{1}{2}J_2$.

Case 2. If $|a_{11}a_{22}| < |a_{12}a_{21}|$, then BP is an H-matrix, where $P = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. Hence $\lim_{k\to\infty} \Phi^k(BP) = I_2$ from Theorem 2 in [1]. Again applying part (ii) of Lemma 1, we obtain $\lim_{k\to\infty} \Phi^k(B) = P$. Further, $\lim_{k\to\infty} \Phi^k(A) = \lim_{k\to\infty} \Phi^{k-1}(B) = P$. This contradicts $\Phi^t(A) = \frac{1}{2}J_2$.

Remark 2. From Theorems 1 and 2, we obtain that the equation $\Phi(A) = \frac{1}{n}J_n$ has at least one real solution for $n \neq 3$. This answers the open problem that has been proposed by Johnson and Shapiro [1].

4. An open problem. Are there real solutions to the equation $\Phi^t(A) = \frac{1}{n}J_n$, which are not diagonally equivalent to those found by the authors when $n \geq 4$?

Acknowledgment. The author wishes to thank the referee for providing helpful reports.

MATRIX ALGEBRAS AND DISPLACEMENT DECOMPOSITIONS*

CARMINE DI FIORE†

Abstract. A class ξ of algebras of symmetric $n \times n$ matrices, related to Toeplitz-plus-Hankel structures and including the well-known algebra $\mathcal{H}$ diagonalized by the Hartley transform, is investigated. The algebras of ξ are then exploited in a general displacement decomposition of an arbitrary $n \times n$ matrix A. Any algebra of ξ is a 1-*space*, i.e., it is spanned by n matrices having as first rows the vectors of the canonical basis. The notion of 1-space (which generalizes the previous notions of $\mathcal{L}_1$ space [Bevilacqua and Zellini, *Linear and Multilinear Algebra*, 25 (1989), pp. 1–25] and Hessenberg algebra [Di Fiore and Zellini, *Linear Algebra Appl.*, 229 (1995), pp. 49–99]) finally leads to the identification in ξ of three new (non-Hessenberg) matrix algebras close to $\mathcal{H}$, which are shown to be associated with fast *Hartley-type* transforms. These algebras are also involved in new efficient centrosymmetric Toeplitz-plus-Hankel inversion formulas.

1. Introduction.

It is well known that the inverse of any nonsingular Toeplitz matrix $T = (t_{i-j})_{i,j=1}^{n}$ can be represented using lower and upper triangular Toeplitz matrices L_m, U_m via the Gohberg–Semencul formula $T^{-1} = L_1U_1 + L_2U_2$ [23]. Kailath, Kung, and Morf [28] extended this result by showing that any $n \times n$ matrix A can be decomposed as

$$A = \sum_{m=1}^{\alpha} L_m U_m \tag{1.1}$$

with α equal to the *displacement rank* of A, i.e., $\alpha = \operatorname{rank}(A - ZAZ^T)$, where $Z = (\delta_{i,\,j+1})_{i,\,j=1}^{n}$. On the basis of the ideas introduced in [28], different fast algorithms for the inversion or the factorization of structured matrices such as Toeplitz-like [27, 31, 33], Cauchy-like [19, 24], and polynomial Vandermonde-like matrices [29, 30] have been developed (see also [7, 25, 31]).

Besides the triangular Toeplitz used in [23, 28], other algebras have been exploited in *displacement formulas* of type (1.1), for example, ε-circulant [1, 18, 20], τ algebra [6, 16, 32], and algebras of dimension greater than n [8, 9]. In [16], most of these algebras appear as special instances of Hessenberg algebras, which allows one to regain the known displacement formulas in a more general context and to obtain new decompositions of high efficiency (especially if A is the inverse of a Toeplitz-plus-Hankel matrix) [16, 10, 17].

If A is a *Toeplitz-like* matrix, that is, A has a *small* displacement rank α, then the known displacement formulas let one compute the matrix-vector product $A\mathbf{f}$, $\mathbf{f} \in \mathbb{C}^n$, by means of a small number of fast discrete transforms (assuming preprocessing on A). These transforms are discrete Fourier transforms (DFT) in cases of formulas

involving triangular Toeplitz or ε-circulant matrices [1, 9, 17, 21, 22] and are sine or cosine transforms in cases of formulas involving τ or $\tau_{\varepsilon,\varphi}$ matrices [6, 10, 16, 17, 32], and therefore they are all associated with Hessenberg algebras [16].

In this paper we further extend the results of [6, 9, 10, 16, 17, 18, 20, 21, 22, 28, 32] in the sense that we introduce a new class of matrix algebras $\mathbb{L}$, including Hessenberg and other algebras of matrices diagonalized by means of Hartley [11, 12] or *Hartley-type* transforms, which have not been yet considered in displacement literature. This extension requires the study of matrix algebras containing the matrix $T^{\beta,\beta}_{\varepsilon,\varphi}$ displayed at the beginning of section 2. Notice that the algebra $\mathcal{H}$ of the matrices diagonalized by the Hartley transform (see [5]) contains the matrix $T^{1,1}_{0,0}$. The appropriate mechanism for capturing algebras $\mathbb{L}$ such that $\mathbb{L} \supset T^{\beta,\beta}_{\varepsilon,\varphi}$, which are generally not Hessenberg, is the notion of 1-*space* (which is an extension of the notions of $\mathcal{L}_1$ space [4] and Hessenberg algebra [16]).

A 1-space is a space of $n \times n$ matrices A spanned by n matrices J_k having as first rows the vectors of the canonical basis of $\mathbb{C}^n$. If $[z_1 z_2 \cdots z_n]$ is the first row of A, then each a_{ij} is a linear combination in $\mathbb{C}$ of $z_1, z_2, \ldots, z_n$. Any space of matrices simultaneously diagonalized by a nonsingular matrix M whose first row has all nonzero entries can be easily checked to be a 1-space. This is the main reason why the introduction of 1-spaces allows one to extend the range of algebras which could be used, in principle, in (possibly) efficient displacement formulas. In particular, the algebra $\mathcal{H}$ diagonalized by the Hartley transform [5] is a 1-space even though it is not a Hessenberg algebra.

The results of this paper are now described in detail.

In section 2 we state some properties of commutative 1-spaces used throughout the paper. Then we define a class of symmetric 1-spaces $\xi(\varphi, \beta, \mathbf{p})$, $\varphi, \beta \in \mathbb{C}$, $\mathbf{p} \in \mathbb{C}^n - 1$ in terms of matrices of different dimensions from the algebra τ (τ is the algebra generated by $T^{0,0}_{0,0}$). The main result of section 2 is Theorem 2.5, where the symmetric 1-algebras (closed 1-spaces), including the matrix $T^{\beta,\beta}_{\varepsilon,\varphi}$, are shown to be the spaces $\xi(\varphi, \beta, \mathbf{p})$ with $\mathbf{p}$ running among the solutions of a linear system with coefficients depending upon φ, β, and ε.

In section 3 a *general* displacement formula for a matrix A in terms of 2α matrices from two arbitrary symmetric 1-algebras $\mathbb{L} \supset T^{\beta,\beta}_{\varepsilon,\varphi}$ and $\mathbb{L}' \supset T^{\beta',\beta'}_{\varepsilon',\varphi'}$ is obtained under the assumption that the rank of $AT^{\beta,\beta}_{\varepsilon,\varphi} - T^{\beta,\beta}_{\varepsilon,\varphi}A$ is α (see Theorem 3.2). This formula extends some formulas of [10] to the case of non-Hessenberg algebras.

In sections 4 and 5 the results of Theorems 2.5 and 3.2 are investigated and specialized. In particular it is shown that the Hartley algebra $\mathcal{H}$ introduced in [5] is an element of the class of 1-algebras ξ characterized in Theorem 2.5 and that there are at least three other algebras of ξ, called η, μ, and $\mathcal{K}$, which are associated with fast Hartley-type discrete transforms (see Theorem 5.2 and the following remark). Moreover, new decompositions of the inverse of an arbitrary centrosymmetric Toeplitz-plus-Hankel matrix $T + H = (t_{i-j} + h_{i+j} - 2)^n_{i,\,j} = 1$ in terms of matrices from $\mathcal{H}$, $\mathcal{K}$, η, and μ are obtained. In particular it is shown that there exist $\mathbf{a}, \mathbf{b} \in \mathbb{C}^n$ such that

$$(T + H)^{-1} = [\mu(\mathbf{a}) + I]\eta(\mathbf{b}) - \mu(\mathbf{b})[\eta(\mathbf{a}) - I]. \tag{1.2}$$

(Here $\mathbb{L}(\mathbf{z})$ denotes the matrix of $\mathbb{L}$ whose first row is $\mathbf{z}^T$.) Under the assumption that the vectors $\mathbf{a}$ and $\mathbf{b}$ are known, formula (1.2) lets one calculate the matrix-vector product $(T+H)^{-1}\mathbf{f}$, $\mathbf{f} \in \mathbb{C}^n$, by means of 10 fast discrete transforms reducible to 8 in case $H = 0$, $[T^{-1}]_{11} \neq 0$, matching both best limits known so far [1, 10, 16]. In any case, the number of transforms reduces to 6 (as in [1, 10, 16, 21, 22]) if the transforms

of vectors not depending upon $\mathbf{f}$ are included in the preprocessing stage, where $\mathbf{a}$ and $\mathbf{b}$ are computed.

2. A class of algebras of symmetric matrices. The main result of this section (Theorem 2.5) is a characterization of all spaces $\mathbb{L}$ of $n \times n$ matrices containing the matrix

$$T_{\varepsilon,\varphi}^{\beta,\beta} = \begin{pmatrix} \varepsilon & 1 & 0 & \cdot & \cdot & 0 & \beta \\ 1 & 0 & 1 & . & & & 0 \\ 0 & 1 & . & . & . & & \cdot \\ . & . & . & . & . & . & \cdot \\ . & & . & . & . & 1 & 0 \\ 0 & & & . & 1 & 0 & 1 \\ \beta & 0 & \cdot & \cdot & 0 & 1 & \varphi \end{pmatrix}, \quad \varepsilon, \varphi, \beta \in \mathbb{C} \tag{2.1}$$

and satisfying the following three properties: $A = A^T$, $\forall\, A \in \mathbb{L}$; $AB \in \mathbb{L}$, $\forall\, A,\, B \in \mathbb{L}$; $\mathbb{L}$ is a 1-space (see Definition 2.1). Notice that the properties of symmetry and closure imply the commutativity of $\mathbb{L}$. Moreover, requiring $\mathbb{L}$ to be a 1-space essentially means that any matrix of $\mathbb{L}$ is determined once its first row is given.

The interest of matrix algebras including $T_{\varepsilon,\varphi}^{\beta,\beta}$ and of possible *displacement* decompositions involving them (see sections 3 and 4) is in the fact that for a Toeplitz-plus-Hankel matrix $T + H$, $[T + H]_{ij} = t_{i-j} + h_{i+j-2}$, $i, j = 1, \ldots, n$, the rank of $(T + H)T_{\varepsilon,\varphi}^{\beta,\beta} - T_{\varepsilon,\varphi}^{\beta,\beta}(T + H)$ is 4 for all values of ε, φ, β (see [26] for the case $\varepsilon = \varphi = \beta = 0$). In section 5, this fact finally leads to efficient inversion formulas for $T + H$ involving Hartley-type matrix algebras. The appropriate mechanism with which to capture algebras including $T_{\varepsilon,\varphi}^{\beta,\beta}$ is the notion of 1-space introduced below.

Let $M_n(\mathbb{C})$ be the space of $n \times n$ matrices with entries in the complex field $\mathbb{C}$ and let $\mathbf{e}_k$, $k = 1, \ldots, n$, be the vectors of $\mathbb{C}^n$ $\mathbf{e}_k = [0 \cdots 0 \underset{k}{1} 0 \cdots 0]^T$.

DEFINITION 2.1. *A subset $\mathbb{L}$ of $M_n(\mathbb{C})$ is a 1-space if there exist n $n \times n$ matrices $J_{\mathbf{k}} \in \mathbb{L}$, $k = 1, \ldots, n$, such that $\mathbb{L} = \{\sum_{k=1}^{n} a_k J_k : a_k \in \mathbb{C}\}$ and*

$$\mathbf{e}_1^T J_k = \mathbf{e}_k^T, \quad k = 1, \ldots, n.$$

Closed (under matrix multiplication) 1-spaces are also called 1-algebras.

Many significant classes of spaces of matrices have 1-space structure. Some examples are the group (or, more generally, hypergroup) matrix algebras [18, 3] and the intersection algebras of the association schemes [2, pp. 52–57]; a simple example is the space of all symmetric Toeplitz matrices (which is not a matrix algebra).

Moreover, every space $H_X = \{\sum_{k=1}^{n} a_k X^{k-1} : a_k \in \mathbb{C}\}$, where X is an $n \times n$ lower Hessenberg matrix, is a 1-space if the entries $[X]_{i,\, i+1}$ are all nonzero. In this case we also have that $H_X = \{A \in M_n(\mathbb{C}) : AX = XA\}$ because X is nonderogatory. In [16] H_X is called Hessenberg algebra (HA) and, for $\mathbf{z} = [z_1 \cdots z_n]^T \in \mathbb{C}^n$, $H_X(\mathbf{z})$ denotes the matrix of H_X whose first row is $\mathbf{z}^T$. For our purposes it is useful to recall the HAs corresponding to the choices $X = T_{\varepsilon,\varphi}$ and $X = P_\beta$, where

$$T_{\varepsilon,\varphi} = \begin{pmatrix} \varepsilon & 1 & 0 & \cdot & \cdot & \cdot & 0 \\ 1 & 0 & 1 & . & & & . \\ 0 & 1 & . & . & . & & . \\ \cdot & \cdot & . & . & . & . & . \\ . & & . & . & . & 1 & 0 \\ & & & . & 1 & 0 & 1 \\ 0 & \cdot & \cdot & \cdot & 0 & 1 & \varphi \end{pmatrix} \quad \text{and} \quad P_\beta = \begin{pmatrix} 0 & 1 & 0 & \cdot & \cdot & \cdot & 0 \\ \cdot & 0 & 1 & . & & & . \\ \cdot & & \cdot & \cdot & \cdot & & . \\ \cdot & & & \cdot & \cdot & . & . \\ \cdot & & & & . & 1 & 0 \\ 0 & & & & & 0 & 1 \\ \beta & 0 & \cdot & \cdot & \cdot & \cdot & 0 \end{pmatrix}. \tag{2.2}$$

These HAs are denoted, respectively, by $\tau_{\varepsilon,\varphi}$ and C_β in conformity with [10, 16, 17, 20]. In fact the (non-Hessenberg) algebras containing $T^{\beta,\beta}_{\varepsilon,\varphi}$ studied in Theorem 2.5 and in section 4 are defined in terms of matrices from $\tau_{\varepsilon,\varphi}$ and C_β. Notice that the matrices of $\tau_{\varepsilon,\varphi}$ and of C_β are, respectively, symmetric and persymmetric, in particular $C_\beta(\mathbf{z}) = \sum_{i=1}^n z_i P_\beta^{i-1}$. C_β is the space of β-circulant matrices, and $C = C_1$ is the well-known space of circulant matrices [14].

Finally, observe that any space $\mathbb{L}$ defined as the set of all matrices diagonalized by a nonsingular matrix M is a 1-space if $[M]_{1,i} \neq 0\ \forall i$, because, in this case, $\mathbb{L} = \{Md(M^T\mathbf{z})d(M^T\mathbf{e}_1)^{-1}M^{-1} : \mathbf{z} \in \mathbb{C}^n\}$, where for $\mathbf{z} \in \mathbb{C}^n$ $d(\mathbf{z}) = \mathrm{diag}(z_i, i = 1, \ldots, n)$. As a consequence, the algebra $\mathcal{H}$ diagonalized by the Hartley transform (see [5]) is a 1-space even though it is not an HA. Recall that matrices from $\mathcal{H}$ are symmetric and that $\mathcal{H}$ contains the matrix $T^{1,1}_{0,0}$. Thus $\mathcal{H}$ is an example of a symmetric 1-algebra including $T^{\beta,\beta}_{\varepsilon,\varphi}$ for $\beta \neq 0$.

Following the notation used for HAs, if $\mathbb{L}$ is a 1-space and $\mathbf{z} \in \mathbb{C}^n$, $\mathbb{L}(\mathbf{z})$ denotes the matrix of $\mathbb{L}$ whose first row is $\mathbf{z}^T$, i.e., $\mathbb{L}(\mathbf{z}) = \sum_{i=1}^n z_i J_i$, where J_i are the matrices in Definition 2.1. Notice that $A \in \mathbb{L}$ iff $A = \mathbb{L}(A^T\mathbf{e}_1)$.

PROPOSITION 2.2. *Let $\mathbb{L}$ be a commutative 1-space. Then*

(i) *$\mathbb{L}$ is closed under matrix multiplication and $I \in \mathbb{L}$;*

(ii) $\mathbf{x}^T\mathbb{L}(\mathbf{y}) = \mathbf{y}^T\mathbb{L}(\mathbf{x}) \quad \forall \mathbf{x}, \mathbf{y} \in \mathbb{C}^n$;

(iii) $\mathbb{L}(\mathbb{L}(\mathbf{x})^T\mathbf{y}) = \mathbb{L}(\mathbf{y})\mathbb{L}(\mathbf{x}) \quad \forall \mathbf{x}, \mathbf{y} \in \mathbb{C}^n$.

Proof. As $J_kJ_s = J_sJ_k\ \forall s, k$, we have that $\mathbf{e}_k^T J_s = \mathbf{e}_s^T J_k\ \forall s, k$. Consequently, $J_1 \equiv \mathbb{L}(\mathbf{e}_1)$ is the identity matrix I. Moreover, for all i, j, $\mathbf{e}_i^T(\sum_{r=1}^n [J_s]_{kr} J_r)\mathbf{e}_j = \sum_{r=1}^n [J_s]_{kr}[J_r]_{ij} = \sum_{r=1}^n [J_s]_{kr}[J_i]_{rj} = [J_sJ_i]_{kj} = [J_iJ_s]_{kj} = [J_kJ_s]_{ij}$ and thus

$$J_kJ_s = \sum_{r=1}^n [J_s]_{kr} J_r \quad \forall\, s, k,$$

that is, assertion (i) holds. For (iii) observe that, by (i), both $\mathbb{L}(\mathbf{y})\mathbb{L}(\mathbf{x})$ and $\mathbb{L}(\mathbb{L}(\mathbf{x})^T\mathbf{y})$ are in $\mathbb{L}$ and have $\mathbf{y}^T\mathbb{L}(\mathbf{x})$ as first row. Finally, for (ii) use (iii) and the commutativity of $\mathbb{L}$. ∎

Proposition 2.2 and the following notation are used throughout the paper. The symbol I^i_j, $1 \leq i,\ j \leq n$, denotes the $(|j - i| + 1) \times n$ $(0, 1)$ matrix, which maps a vector $\mathbf{z} = [z_1 \cdots z_n]^T \in \mathbb{C}^n$ into the vector $I^i_j\mathbf{z} = [z_i \cdots z_j]^T \in \mathbb{C}^{|j-i|+1}$. Thus $I = I^1_n$ and $J = I^n_1$ are, respectively, the $n \times n$ identity and the reversion matrix. I and J also denote, respectively, identity and reversion matrices of dimensions different from n. Also, set $e_k = I^1_{n-1}\mathbf{e}_k$, $k = 1, \ldots, n-1$, and $\hat{\mathbf{z}} = [z_k \cdots z_1]^T = J\mathbf{z}$ if $\mathbf{z} \in \mathbb{C}^k$.

Now we state Theorem 2.5, where the symmetric closed 1-spaces containing $T^{\beta,\beta}_{\varepsilon,\varphi}$ are shown to be the spaces $\xi(\varphi, \beta, \mathbf{p})$ in Definition 2.4 obtained by choosing as $\mathbf{p}$ the solutions of (2.6). As a consequence (see section 4) for given ε, φ, β, there are as many symmetric 1-algebras including $T^{\beta,\beta}_{\varepsilon,\varphi}$ as the solutions of equation (2.6), i.e., none, an infinite number, or only one, depending upon the values of ε, φ, β. A preliminary Lemma 2.3 follows.

LEMMA 2.3. (i) *Let A be an $n \times n$ matrix and $\mathbf{x}_m$ and $\mathbf{y}_m$, $m = 1, \ldots, \alpha$, vectors of $\mathbb{C}^n$ such that $AT_{\varepsilon,0} - T_{\varepsilon,0}A = \sum_{m=1}^\alpha \mathbf{x}_m\mathbf{y}_m^T$. Then*

$$A = \sum_{m=1}^{\alpha} \begin{pmatrix} 0 & \cdots\cdots & 0 \\ \vdots & & \\ \vdots & \tau(I^2_n\mathbf{x}_m) & \\ 0 & & \end{pmatrix} \Omega_\varepsilon(\mathbf{y}_m) + \Omega_\varepsilon(A^T\mathbf{e}_1), \tag{2.3}$$

where $\tau = \tau_{0,0}$ and $\Omega_\varepsilon = \tau_{\varepsilon,0}$.

(ii) *In particular, for* $\mathbf{z} \in \mathbb{C}^n$,

$$\Omega_\varepsilon(\mathbf{z}) = \tau(\mathbf{z}) - \varepsilon \begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 \\ \vdots & & & & \\ \vdots & & \tau(I_n^2\mathbf{z}) & & \\ 0 & & & & \end{pmatrix}. \tag{2.4}$$

Proof. For (i) see [16]. (ii) follows from the identities

$$\tau(\mathbf{z})T_{\varepsilon,0} - T_{\varepsilon,0}\tau(\mathbf{z}) = \tau(\mathbf{z})T_{0,0} - T_{0,0}\tau(\mathbf{z}) + \varepsilon[\tau(\mathbf{z})\mathbf{e}_1\mathbf{e}_1^T - \mathbf{e}_1\mathbf{e}_1^T\tau(\mathbf{z})] = \varepsilon(\mathbf{z}\mathbf{e}_1^T - \mathbf{e}_1\mathbf{z}^T)$$

and from assertion (i) for $A = \tau(\mathbf{z})$. □

DEFINITION 2.4. *For* φ, $\beta \in \mathbb{C}$, $\mathbf{p} \in \mathbb{C}^{n-1}$, *define the space of* $n \times n$ *matrices*

$$\begin{aligned} \xi &\equiv \xi(\varphi, \beta, \mathbf{p}) \\ &= \left\{ \tau(\mathbf{z}) - \begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 \\ & \vdots\, \tau(I_{n-1}^2\mathbf{z})\, \vdots & & & \\ 0 & \cdot & \cdot & \cdot & 0 \end{pmatrix} (\varphi I + \beta J) + \begin{pmatrix} 0 & \cdot & \cdot & \cdot & \cdot & \cdot & 0 \\ \vdots & & & & & & \\ 0 & & & J\Omega_\varphi(I_2^n\mathbf{z})\Omega_\varphi(\mathbf{p})\, J & & & \end{pmatrix} : \mathbf{z} \in \mathbb{C}^n \right\} \end{aligned} \tag{2.5}$$

and denote by $\xi(\mathbf{z})$ *the matrix of* ξ *whose first row is* $\mathbf{z}^T$.

THEOREM 2.5. *If* $\mathbb{L}$ *is a symmetric closed* 1*-space containing the matrix* $T_{\varepsilon,\varphi}^{\beta,\beta}$ *for some* ε, φ, $\beta \in \mathbb{C}$, *then* $\mathbb{L} = \xi(\varphi, \beta, \mathbf{p})$ *with* $\mathbf{p}$ *such that*

$$\Omega_\varphi(\beta e_1 + e_{n-1})\mathbf{p} = (\varphi - \varepsilon)e_1. \tag{2.6}$$

Conversely, every space of matrices $\xi(\varphi, \beta, \mathbf{p})$ *with* $\mathbf{p}$ *solving* (2.6) *for some* $\varepsilon \in \mathbb{C}$ *is a symmetric closed* 1*-space containing the matrix* $T_{\varepsilon,\varphi}^{\beta,\beta}$*; moreover,* $\xi(\varphi, \beta, \mathbf{p}) = \{A \in M_n(\mathbb{C}) : AT_{\varepsilon,\varphi}^{\beta,\beta} = T_{\varepsilon,\varphi}^{\beta,\beta}A$ *and* $A\xi(\mathbf{e}_n) = \xi(\mathbf{e}_n)A\}$.

Proof. Let $\mathbb{L}$ be a symmetric closed 1-space containing the matrix $T_{\varepsilon,\varphi}^{\beta,\beta}$ and let A be an arbitrary element of $\mathbb{L}$. Notice that $AT_{\varepsilon,\varphi}^{\beta,\beta} = T_{\varepsilon,\varphi}^{\beta,\beta}A$ and therefore $I_n^2A\mathbf{e}_1(e_1 + \beta e_{n-1})^T + BT_{0,\varphi}^{()} = (e_1 + \beta e_{n-1})(I_n^2A\mathbf{e}_1)^T + T_{0,\varphi}^{()}B$, where B and $T_{0,\varphi}^{()}$ are the $(n-1)\times(n-1)$ lower-right submatrices of A and $T_{\varepsilon,\varphi}^{\beta,\beta}$, respectively. Right- and left-multiply this equality by the matrix J to obtain

$$JBJT_{\varphi,0}^{()} - T_{\varphi,0}^{()}JBJ = (\beta e_1 + e_{n-1})(I_2^nA\mathbf{e}_1)^T - (I_2^nA\mathbf{e}_1)(\beta e_1 + e_{n-1})^T \tag{2.7}$$

($T_{\varphi,0}^{()} = JT_{0,\varphi}^{()}J$). The identity (2.7) and Lemma 2.3(i) (with n replaced by $n-1$) yield

$$JBJ = \begin{pmatrix} 0 & \cdot\cdot & 0 \\ \vdots & & \\ 0 & J & \end{pmatrix}\Omega_\varphi(I_2^nA\mathbf{e}_1) - \begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 \\ \vdots & & & & \\ 0 & \tau(I_2^{n-1}A\mathbf{e}_1) & & & \end{pmatrix} \Omega_\varphi(\beta e_1 + e_{n-1}) + \Omega_\varphi(I_2^nA\mathbf{e}_n).$$

Therefore,

$$B = \begin{pmatrix} & J & 0 \\ & & \vdots \\ 0 & \cdot\cdot & 0 \end{pmatrix} J\Omega_\varphi(I_2^nA\mathbf{e}_1)J - \begin{pmatrix} \tau(I_2^{n-1}A\mathbf{e}_1) & 0 \\ & \vdots \\ 0 & \cdot\cdot\cdot\cdot\ 0 \end{pmatrix} J\Omega_\varphi(\beta e_1 + e_{n-1})J + J\Omega_\varphi(I_2^nA\mathbf{e}_n)J$$

and, by the equality (2.4),

$$B = \begin{pmatrix} & J & 0 \\ & & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \tau(I_2^n A\mathbf{e}_1) - \begin{pmatrix} \tau(I_2^{n-1}A\mathbf{e}_1)\, 0 \\ \vdots \\ 0 \quad \cdots \quad 0 \end{pmatrix} J$$

$$- \beta \begin{pmatrix} \tau(I_2^{n-1}A\mathbf{e}_1)\, 0 \\ \vdots \\ 0 \quad \cdots \quad 0 \end{pmatrix} + J\Omega_\varphi(I_2^n A\mathbf{e}_n)J. \tag{2.8}$$

As a consequence of (2.8) we have

$$\begin{pmatrix} 0 & (I_n^2 A\mathbf{e}_1)^T \\ \vdots & B \\ 0 & \end{pmatrix} = J \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & \tau(I_2^n A\mathbf{e}_1) & \end{pmatrix} - \beta \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I_2^{n-1}A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix}$$

$$- \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I_2^{n-1}A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & J \\ 0 & & \end{pmatrix}$$

$$+ \begin{pmatrix} 0 & \cdots & \cdots & 0 \\ \vdots & & & J\Omega_\varphi(I_2^n A\mathbf{e}_n)\, J \\ 0 & & & \end{pmatrix}. \tag{2.9}$$

As $A = \mathbb{L}(A\mathbf{e}_1)$, by Proposition 2.2(ii), $A\mathbf{e}_n = \mathbb{L}(\mathbf{e}_n)A\mathbf{e}_1$, i.e., $A\mathbf{e}_n = (J + \left(\begin{smallmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & Q & \end{smallmatrix}\right))A\mathbf{e}_1$, for a certain $(n-1)\times(n-1)$ matrix Q not depending upon A. Thus $I_2^n A\mathbf{e}_n = I_{n-1}^1 A\mathbf{e}_1 + JQJI_2^n A\mathbf{e}_1$ and (2.9) becomes

$$\begin{pmatrix} 0 & (I_n^2 A\mathbf{e}_1)^T \\ \vdots & B \\ 0 & \end{pmatrix} = J \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & \tau(I_2^n A\mathbf{e}_1) & \end{pmatrix} - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I_2^{n-1}A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & J \\ 0 & & \end{pmatrix}$$

$$+ \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & \tau(I_{n-1}^1 A\mathbf{e}_1) & \end{pmatrix}$$

$$- \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I_{n-1}^2 A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix} (\varphi I + \beta J) + \begin{pmatrix} 0 & \cdots & \cdots & 0 \\ \vdots & & & J\Omega_\varphi(JQJI_2^n A\mathbf{e}_1)J \\ 0 & & & \end{pmatrix}. \tag{2.10}$$

Notice that the sum of the first three matrices on the right-hand side of (2.10) plus $A\mathbf{e}_1\mathbf{e}_1^T$ is the matrix $\tau(A\mathbf{e}_1)$. In fact the identity $\tau(A\mathbf{e}_1)T_{0,0} = T_{0,0}\tau(A\mathbf{e}_1)$ implies that (2.7) holds for $\varphi = \beta = 0$ and for B ($T_{0,0}^{()}$) the $(n-1)\times(n-1)$ lower-right submatrix of $\tau(A\mathbf{e}_1)$ ($T_{0,0}$); the thesis follows from (2.10), which then holds for $\varphi = \beta = 0$ and $Q = 0$. Thus we have an explicit expression of $A \in \mathbb{L}$:

$$A = \tau(A\mathbf{e}_1) - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I_{n-1}^2 A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix} (\varphi I + \beta J) + \begin{pmatrix} 0 & \cdots & \cdots & 0 \\ \vdots & & & J\Omega_\varphi(JQJI_2^n A\mathbf{e}_1)\, J \\ 0 & & & \end{pmatrix}.$$

By exploiting it for $A = \mathbb{L}(\mathbf{e}_n) = J + \left(\begin{smallmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & Q & \end{smallmatrix}\right)$, we realize that $JQJ = \Omega_\varphi(JQJe_1)$ or, equivalently, that $JQJ = \Omega_\varphi(\mathbf{p})$ for some $\mathbf{p} \in \mathbb{C}^{n-1}$ not depending upon A.

Therefore, by Proposition 2.2(iii), the generic matrix A of a symmetric closed 1-space containing $T^{\beta,\beta}_{\varepsilon,\varphi}$ has the expression

$$A = \tau(A\mathbf{e}_1) - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I^2_{n-1}A\mathbf{e}_1) & \vdots \\ 0 & \cdots & 0 \end{pmatrix}(\varphi I + \beta J) + \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & J\Omega_\varphi(I^n_2 A\mathbf{e}_1)\Omega_\varphi(\mathbf{p})\, J & \\ 0 & & \end{pmatrix} \tag{2.11}$$

for some $\mathbf{p} \in \mathbb{C}^{n-1}$. In particular, (2.11) must be verified for $A = T^{\beta,\beta}_{\varepsilon,\varphi}$ and thus $\mathbf{p}$ must verify (2.6).

Now let us prove the second part of Theorem 2.5. Consider the space $\xi = \xi(\varphi, \beta, \mathbf{p})$ in Definition 2.4 and assume that $\mathbf{p}$ solves equation $\Omega_\varphi(\beta e_1 + e_{n-1})\mathbf{p} = (\varphi - \varepsilon)e_1$ for some $\varepsilon \in \mathbb{C}$. The matrix $T^{\beta,\beta}_{\varepsilon,\varphi}$ is an element of ξ; in fact, by Proposition 2.2(iii), $\xi(\varepsilon\mathbf{e}_1 + \mathbf{e}_2 + \beta\mathbf{e}_n) = T^{\beta,\beta}_{\varepsilon,\varphi}$. Obviously, ξ is a symmetric 1-space. Thus we have to prove only that ξ is equal to the space $\mathbb{A}$ defined as

$$\mathbb{A} = \left\{A \in M_n(\mathbb{C}) : AT^{\beta,\beta}_{\varepsilon,\varphi} = T^{\beta,\beta}_{\varepsilon,\varphi}A \quad \text{and} \quad A\xi(\mathbf{e}_n) = \xi(\mathbf{e}_n)A\right\} \tag{2.12}$$

since the closure of ξ follows from the closure of $\mathbb{A}$. Observe that $\mathbb{A}$ is a linear space whose dimension is not greater than n. In fact, let A_i, $i = 1, \ldots, k$, be k linearly independent matrices of $\mathbb{A}$. If $k > n$, then there exist k elements of $\mathbb{C}$, z_i, $i = 1, \ldots, k$, not all null and such that $\sum_{i=1}^k z_i \mathbf{e}_1^T A_i = \mathbf{0}^T$. The matrix $\sum_{i=1}^k z_i A_i$ is an element of $\mathbb{A}$ and $\mathbf{e}_1^T(\sum_{i=1}^k z_i A_i) = \mathbf{0}^T$. However, if a matrix $A \in \mathbb{A}$, then it satisfies the identities

$$\begin{aligned} &\mathbf{e}_1^T AT^{\beta,\beta}_{\varepsilon,\varphi} = \varepsilon\mathbf{e}_1^T A + \mathbf{e}_2^T A + \beta\mathbf{e}_n^T A, \qquad \mathbf{e}_1^T A\xi(\mathbf{e}_n) = \mathbf{e}_n^T A, \\ &\mathbf{e}_i^T AT^{\beta,\beta}_{\varepsilon,\varphi} = \mathbf{e}_{i-1}^T A + \mathbf{e}_{i+1}^T A, \quad i = 2, \ldots, n-1. \end{aligned} \tag{2.13}$$

If, moreover, $\mathbf{e}_1^T A = \mathbf{0}^T$ from (2.13), it follows that $A = 0$. Thus the matrix $\sum_{i=1}^k z_i A_i$ above must be null and the A_i's are linearly dependent, that is, a contradiction. Now we show that $\xi \subset \mathbb{A}$. As a consequence of this fact and of the inequalities $\dim \xi = n$ and $\dim \mathbb{A} \le n$, we have that $\xi = \mathbb{A}$.

For $\mathbf{z} \in \mathbb{C}^n$, set

$$M(\mathbf{z}) = \tau(\mathbf{z}) - \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \tau(I^2_{n-1}\mathbf{z}) & \vdots \\ 0 & \cdots & 0 \end{pmatrix}(\varphi I + \beta J), \quad N(\mathbf{z}) = \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & J\Omega_\varphi(I^n_2\mathbf{z})\Omega_\varphi(\mathbf{p})\, J & \\ 0 & & \end{pmatrix}$$

and notice that $\xi(\mathbf{z}) = M(\mathbf{z}) + N(\mathbf{z})$. By exploiting the equality $T^{\beta,\beta}_{\varepsilon,\varphi} = T^{\beta,\beta}_{\varphi,\varphi} + (\varepsilon - \varphi)\mathbf{e}_1\mathbf{e}_1^T$, as well as the fact that the first row and the first column of $N(\mathbf{z})$ are null, and the equality $M(\mathbf{z})T^{\beta,\beta}_{\varphi,\varphi} = T^{\beta,\beta}_{\varphi,\varphi}M(\mathbf{z})$ (the proof of this identity is obvious and mechanical and thus is omitted), we have

$$\xi(\mathbf{z})T^{\beta,\beta}_{\varepsilon,\varphi} - T^{\beta,\beta}_{\varepsilon,\varphi}\xi(\mathbf{z}) = (\varepsilon - \varphi)(\mathbf{z}\mathbf{e}_1^T - \mathbf{e}_1\mathbf{z}^T) + N(\mathbf{z})T^{\beta,\beta}_{\varphi,\varphi} - T^{\beta,\beta}_{\varphi,\varphi}N(\mathbf{z}).$$

As

$$N(\mathbf{z})T^{\beta,\beta}_{\varphi,\varphi} - T^{\beta,\beta}_{\varphi,\varphi}N(\mathbf{z}) = \begin{pmatrix} 0 & -\mathbf{p}^T\Omega_\varphi(\beta e_1 + e_{n-1})\Omega_\varphi(I^n_2\mathbf{z})J \\ J\Omega_\varphi(I^n_2\mathbf{z})\Omega_\varphi(\beta e_1 + e_{n-1})\mathbf{p} & O \end{pmatrix}$$

the assumption $\Omega_\varphi(\beta e_1 + e_{n-1})\mathbf{p} = (\varphi - \varepsilon)e_1$ yields

$$N(\mathbf{z})T^{\beta,\beta}_{\varphi,\varphi} - T^{\beta,\beta}_{\varphi,\varphi}N(\mathbf{z}) = (\varphi - \varepsilon)(\mathbf{z}\mathbf{e}_1^T - \mathbf{e}_1\mathbf{z}^T),$$

and therefore $\xi(\mathbf{z})T^{\beta,\beta}_{\varepsilon,\varphi} = T^{\beta,\beta}_{\varepsilon,\varphi}\xi(\mathbf{z})\ \ \forall \mathbf{z} \in \mathbb{C}^n$.

Now set $Q = \xi(\mathbf{z})\xi(\mathbf{e}_n) - \xi(\mathbf{e}_n)\xi(\mathbf{z})$. Notice that $\mathbf{e}_1^T Q = \mathbf{z}^T N(\mathbf{e}_n) - \mathbf{e}_n^T N(\mathbf{z}) = \mathbf{0}^T$. Therefore, as $Q^T = -Q$, the first row and the first column of Q are null. Moreover, $QT^{\beta,\beta}_{\varepsilon,\varphi} = T^{\beta,\beta}_{\varepsilon,\varphi}Q$, which implies

$$Q = \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & & \tau_{0,\varphi}(\mathbf{x}) \end{pmatrix}$$

for some $\mathbf{x} \in \mathbb{C}^{n-1}$. Thus Q is simultaneously symmetric and skewsymmetric; therefore, $Q = \xi(\mathbf{z})\xi(\mathbf{e}_n) - \xi(\mathbf{e}_n)\xi(\mathbf{z}) = 0\ \forall \mathbf{z} \in \mathbb{C}^n$. □

3. 1-algebras and displacement formulas. The algebras characterized in Theorem 2.5 are now involved in a *general* decomposition formula (see Theorem 3.2 below) which leads, in the next section, to new significant displacement decompositions corresponding to special choices of these matrix algebras. A preliminary Lemma 3.1 generalizing related results on HAs [16, 10, 17] follows below. The role of this lemma in the proof of Theorem 3.2 is analogous to the role of *orthogonality relations* in the proof of displacement decompositions involving group matrices [18]. In Lemma 3.1 and Theorem 3.2 A denotes an arbitrary $n \times n$ matrix.

LEMMA 3.1. *Let $\mathbb{L}$ be a commutative 1-space and let $X \in \mathbb{L}$. If $\mathbf{x}_m$, $\mathbf{y}_m \in \mathbb{C}^n$, $m = 1, \ldots, \alpha$, are such that $AX - XA = \sum_{m=1}^{\alpha} \mathbf{x}_m\mathbf{y}_m^T$, then $\sum_{m=1}^{\alpha} \mathbf{x}_m^T\mathbb{L}(\mathbf{y}_m)^T = \mathbf{0}^T$.*

Proof. By Proposition 2.2(ii), for $r = 1, \ldots, n$,

$$\sum_{m=1}^{\alpha} \mathbf{x}_m^T\mathbb{L}(\mathbf{y}_m)^T\mathbf{e}_r = \sum_{m=1}^{\alpha} \mathbf{x}_m^T J_r^T\mathbf{y}_m = \sum_{m=1}^{\alpha}\sum_{i,j=1}^{n} [\mathbf{x}_m]_i[\mathbf{y}_m]_j[J_r^T]_i$$

$$= \sum_{i,j=1}^{n} [AX - XA]_{ij}[J_r]_{ji} = \sum_{i=1}^{n}[(AX - XA)J_r]_{ii} = \sum_{i=1}^{n}[(AJ_r)X - X(AJ_r)]_{ii} = 0. \quad \square$$

THEOREM 3.2. *Let $\mathbb{L}$ and $\mathbb{L}'$ be two symmetric closed 1-spaces containing the matrices $T^{\beta,\beta}_{\varepsilon,\varphi}$ and $T^{\beta',\beta'}_{\varepsilon',\varphi'}$, respectively. If $AT^{\beta,\beta}_{\varepsilon,\varphi} - T^{\beta,\beta}_{\varepsilon,\varphi}A = \sum_{m=1}^{\alpha} \mathbf{x}_m\mathbf{y}_m^T$, then*

$$\begin{aligned} &(\varepsilon - \varepsilon')A + (\beta - \beta')(A\mathbb{L}(\mathbf{e}_n) + \mathbb{L}'(\mathbf{e}_n)A) + (\varphi - \varphi')\mathbb{L}'(\mathbf{e}_n)A\mathbb{L}(\mathbf{e}_n) \\ &\quad = \sum_{m=1}^{\alpha} \mathbb{L}'(\mathbf{x}_m)\mathbb{L}(\mathbf{y}_m) + \mathbb{L}'((\varepsilon - \varepsilon')\mathbf{e}_1 + (\beta - \beta')\mathbf{e}_n)\mathbb{L}(A^T\mathbf{e}_1) \\ &\qquad + \mathbb{L}'((\beta - \beta')\mathbf{e}_1 + (\varphi - \varphi')\mathbf{e}_n)\mathbb{L}(A^T\mathbf{e}_n). \end{aligned} \tag{3.1}$$

Proof. Let X be a symmetric $n \times n$ matrix such that if $AX = XA$ and $\mathbf{e}_1^T A = \mathbf{e}_n^T A = \mathbf{0}^T$, then $A = 0$. Set $[X]_{1n} = [X]_{n1} = \beta$, $[X]_{11} = \varepsilon$, and $[X]_{nn} = \varphi$ and let X' be the $n \times n$ matrix defined by $X = X' + (\varepsilon - \varepsilon')\mathbf{e}_1\mathbf{e}_1^T + (\beta - \beta')(\mathbf{e}_1\mathbf{e}_n^T + \mathbf{e}_n\mathbf{e}_1^T) + (\varphi - \varphi')\mathbf{e}_n\mathbf{e}_n^T$. The assertion of Theorem 3.2 is now shown for X and X' instead of for $T^{\beta,\beta}_{\varepsilon,\varphi}$ and $T^{\beta',\beta'}_{\varepsilon',\varphi'}$, respectively. The thesis will follow because $T^{\beta,\beta}_{\varepsilon,\varphi}$ and $T^{\beta',\beta'}_{\varepsilon',\varphi'}$ satisfy the hypotheses on X and X'. (The simple proof of this fact is left to the reader.)

Let M and N be the matrices on the left-hand side and on the right-hand side in equality (3.1), respectively. We shall prove that if $AX - XA = \sum_{m=1}^{\alpha} \mathbf{x}_m\mathbf{y}_m^T$, then

$(M-N)X = X(M-N)$ and $\mathbf{e}_1^T(M-N) = \mathbf{e}_n^T(M-N) = \mathbf{0}^T$, and therefore, by the hypothesis on X, $M = N$.

The equality $\mathbf{e}_1^T M = \mathbf{e}_1^T N$ is easily verifiable by exploiting Lemma 3.1. The equalities $(M-N)X = X(M-N)$ and $\mathbf{e}_n^T M = \mathbf{e}_n^T N$ are equivalent to the equalities

$$\begin{aligned}[(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]&\left\{\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right\}\\ &= [(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\{(\varepsilon-\varepsilon')[\mathbf{e}_n^T A - \mathbf{e}_1^T A\mathbb{L}(\mathbf{e}_n)]\\ &\quad + \mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)[(\beta-\beta')(A-\mathbb{L}(A^T\mathbf{e}_1)) + (\varphi-\varphi')(A\mathbb{L}(\mathbf{e}_n)-\mathbb{L}(A^T\mathbf{e}_n))]\}\end{aligned}$$

and

$$\begin{aligned}\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m) &= (\varepsilon-\varepsilon')[\mathbf{e}_n^T A - \mathbf{e}_1^T A\mathbb{L}(\mathbf{e}_n)]\\ &\quad + \mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)[(\beta-\beta')(A-\mathbb{L}(A^T\mathbf{e}_1)) + (\varphi-\varphi')(A\mathbb{L}(\mathbf{e}_n)-\mathbb{L}(A^T\mathbf{e}_n))],\end{aligned} \tag{3.2}$$

respectively. The proof of the second equivalence is simple. Let us prove the first one.

$$\begin{aligned}NX-XN = \sum_{m=1}^{\alpha}&[\mathbb{L}'(\mathbf{x}_m)X - X\mathbb{L}'(\mathbf{x}_m)]\mathbb{L}(\mathbf{y}_m) + (\beta-\beta')[\mathbb{L}'(\mathbf{e}_n)X - X\mathbb{L}'(\mathbf{e}_n)]\mathbb{L}(A^T\mathbf{e}_1)\\ &+ (\varphi-\varphi')[\mathbb{L}'(\mathbf{e}_n)X - X\mathbb{L}'(\mathbf{e}_n)]\mathbb{L}(A^T\mathbf{e}_n).\end{aligned}$$

For the sake of simplicity, set $Q = \mathbb{L}'(\mathbf{e}_n)X - X\mathbb{L}'(\mathbf{e}_n)$ and then exploit the equality $X = X' + (\varepsilon-\varepsilon')\mathbf{e}_1\mathbf{e}_1^T + (\beta-\beta')(\mathbf{e}_1\mathbf{e}_n^T + \mathbf{e}_n\mathbf{e}_1^T) + (\varphi-\varphi')\mathbf{e}_n\mathbf{e}_n^T$ to obtain

$$\begin{aligned}NX - XN &= \sum_{m=1}^{\alpha}\{(\varepsilon-\varepsilon')(\mathbf{x}_m\mathbf{e}_1^T - \mathbf{e}_1\mathbf{x}_m^T) + (\beta-\beta')\\ &\qquad\times[\mathbf{x}_m\mathbf{e}_n^T + \mathbb{L}'(\mathbf{e}_n)\mathbf{x}_m\mathbf{e}_1^T - \mathbf{e}_1\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n) - \mathbf{e}_n\mathbf{x}_m^T]\\ &\qquad+(\varphi-\varphi')[\mathbb{L}'(\mathbf{e}_n)\mathbf{x}_m\mathbf{e}_n^T - \mathbf{e}_n\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)]\}\mathbb{L}(\mathbf{y}_m)\\ &\qquad+(\beta-\beta')Q\mathbb{L}(A^T\mathbf{e}_1) + (\varphi-\varphi')Q\mathbb{L}(A^T\mathbf{e}_n)\\ &= \sum_{m=1}^{\alpha}\{(\varepsilon-\varepsilon')[\mathbf{x}_m\mathbf{y}_m^T - \mathbf{e}_1\mathbf{x}_m^T\mathbb{L}(\mathbf{y}_m)]\\ &\qquad+(\beta-\beta')[\mathbf{x}_m\mathbf{y}_m^T\mathbb{L}(\mathbf{e}_n) + \mathbb{L}'(\mathbf{e}_n)\mathbf{x}_m\mathbf{y}_m^T\\ &\qquad\quad-\mathbf{e}_1\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m) - \mathbf{e}_n\mathbf{x}_m^T\mathbb{L}(\mathbf{y}_m)]\\ &\qquad+(\varphi-\varphi')[\mathbb{L}'(\mathbf{e}_n)\mathbf{x}_m\mathbf{y}_m^T\mathbb{L}(\mathbf{e}_n) - \mathbf{e}_n\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)]\}\\ &\qquad+(\beta-\beta')Q\mathbb{L}(A^T\mathbf{e}_1) + (\varphi-\varphi')Q\mathbb{L}(A^T\mathbf{e}_n).\end{aligned}$$

By exploiting the assumption $AX - XA = \sum_{m=1}^{\alpha}\mathbf{x}_m\mathbf{y}_m^T$ and Lemma 3.1, the last expression becomes

$$\begin{aligned}&(\varepsilon-\varepsilon')(AX-XA) + (\beta-\beta')\\ &\times\left[(AX-XA)\mathbb{L}(\mathbf{e}_n) + \mathbb{L}'(\mathbf{e}_n)(AX-XA) - \mathbf{e}_1\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right]\end{aligned}$$

$$
\begin{aligned}
&+ (\varphi-\varphi')\left[\mathbb{L}'(\mathbf{e}_n)(AX-XA)\mathbb{L}(\mathbf{e}_n) - \mathbf{e}_n\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right]\\
&+ (\beta-\beta')Q\mathbb{L}(A^T\mathbf{e}_1) + (\varphi-\varphi')Q\mathbb{L}(A^T\mathbf{e}_n)\\
=\ & (\varepsilon-\varepsilon')(AX-XA) + (\beta-\beta')\\
&\times\left[A\mathbb{L}(\mathbf{e}_n)X - XA\mathbb{L}(\mathbf{e}_n) + \mathbb{L}'(\mathbf{e}_n)AX - X\mathbb{L}'(\mathbf{e}_n)A - QA - \mathbf{e}_1\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right]\\
&+ (\varphi-\varphi')\left[\mathbb{L}'(\mathbf{e}_n)A\mathbb{L}(\mathbf{e}_n)X - X\mathbb{L}'(\mathbf{e}_n)A\mathbb{L}(\mathbf{e}_n) - QA\mathbb{L}(\mathbf{e}_n)\right.\\
&-\ \left.\mathbf{e}_n\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right] + (\beta-\beta')Q\mathbb{L}(A^T\mathbf{e}_1) + (\varphi-\varphi')Q\mathbb{L}(A^T\mathbf{e}_n)\\
=\ & MX - XM + (\beta-\beta')Q[\mathbb{L}(A^T\mathbf{e}_1) - A] + (\varphi-\varphi')Q[\mathbb{L}(A^T\mathbf{e}_n) - A\mathbb{L}(\mathbf{e}_n)]\\
&- [(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m).
\end{aligned}
$$

By replacing $\mathbf{x}_m$ with $\mathbf{e}_n$ in the expression of $\mathbb{L}'(\mathbf{x}_m)X - X\mathbb{L}'(\mathbf{x}_m)$ obtained above, we have $Q = (\varepsilon-\varepsilon')(\mathbf{e}_n\mathbf{e}_1^T - \mathbf{e}_1\mathbf{e}_n^T) + (\beta-\beta')[\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_1^T - \mathbf{e}_1\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)] + (\varphi-\varphi')[\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_n^T - \mathbf{e}_n\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)]$. Thus

$$
\begin{aligned}
NX-XN = MX-XM &+ (\beta-\beta')\{[(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)[A - \mathbb{L}(A^T\mathbf{e}_1)]\\
&+ [(\varepsilon-\varepsilon')\mathbf{e}_1 - (\varphi-\varphi')\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n][\mathbf{e}_n^TA - \mathbf{e}_1^TA\mathbb{L}(\mathbf{e}_n)]\}\\
&+ (\varphi-\varphi')\{[(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)[A\mathbb{L}(\mathbf{e}_n) - \mathbb{L}(A^T\mathbf{e}_n)]\\
&+ [(\varepsilon-\varepsilon')\mathbf{e}_n + (\beta-\beta')\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n][\mathbf{e}_n^TA - \mathbf{e}_1^TA\mathbb{L}(\mathbf{e}_n)]\}\\
&- [(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\\
= MX - XM &+ [(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\{(\varepsilon-\varepsilon')[\mathbf{e}_n^TA - \mathbf{e}_1^TA\mathbb{L}(\mathbf{e}_n)]\\
&+ \mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)[(\beta-\beta')(A - \mathbb{L}(A^T\mathbf{e}_1)) + (\varphi-\varphi')(A\mathbb{L}(\mathbf{e}_n) - \mathbb{L}(A^T\mathbf{e}_n))]\}\\
&- [(\beta-\beta')\mathbf{e}_1 + (\varphi-\varphi')\mathbf{e}_n]\left\{\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\right\}
\end{aligned}
$$

and the first equivalence is proved. Now we have to prove (3.2) and the proof of Theorem 3.2 will be complete, because then the equality preceding (3.2)—identical to (3.2), but a factor—is satisfied. For $s = 1, \ldots, n$

$$
\begin{aligned}
&\sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{y}_m)\mathbf{e}_s = \sum_{m=1}^{\alpha}\mathbf{x}_m^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{e}_s)\mathbf{y}_m = \sum_{m=1}^{\alpha}\sum_{i,\,j=1}^{n}[\mathbf{x}_m]_i[\mathbf{y}_m]_j[\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{e}_s)]_{ij}\\
&= \sum_{i,\,j=1}^{n}[AX-XA]_{ij}[\mathbb{L}(\mathbf{e}_s)\mathbb{L}'(\mathbf{e}_n)]_{ji} = \sum_{i=1}^{n}[A\mathbb{L}(\mathbf{e}_s)X\mathbb{L}'(\mathbf{e}_n) - XA\mathbb{L}(\mathbf{e}_s)\mathbb{L}'(\mathbf{e}_n)]_{ii}
\end{aligned}
$$

$$
\begin{aligned}
&= \sum_{i=1}^{n}[-A\mathbb{L}(\mathbf{e}_s)(\mathbb{L}'(\mathbf{e}_n)X - X\mathbb{L}'(\mathbf{e}_n))]_{ii}\\
&= \sum_{i=1}^{n}[-A\mathbb{L}(\mathbf{e}_s)\{(\varepsilon-\varepsilon')(\mathbf{e}_n\mathbf{e}_1^T - \mathbf{e}_1\mathbf{e}_n^T) + (\beta-\beta')[\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_1^T - \mathbf{e}_1\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)]\\
&\quad + (\varphi-\varphi')[\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_n^T - \mathbf{e}_n\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)]\}]_{ii}\\
&= -(\varepsilon-\varepsilon')\sum_{i=1}^{n}\mathbf{e}_1^T[A\mathbb{L}(\mathbf{e}_n)\mathbf{e}_s\mathbf{e}_1^T - A\mathbf{e}_s\mathbf{e}_n^T]\mathbf{e}_i - (\beta-\beta')\sum_{i=1}^{n}\mathbf{e}_i^T[A\mathbb{L}(\mathbf{e}_s)\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_1^T\\
&\quad - A\mathbf{e}_s\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)]\mathbf{e}_i - (\varphi-\varphi')\sum_{i=1}^{n}\mathbf{e}_i^T[A\mathbb{L}(\mathbf{e}_s)\mathbb{L}'(\mathbf{e}_n)\mathbf{e}_n\mathbf{e}_n^T - A\mathbb{L}(\mathbf{e}_n)\mathbf{e}_s\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)]\mathbf{e}_i\\
&= (\varepsilon-\varepsilon')[\mathbf{e}_n^TA\mathbf{e}_s - \mathbf{e}_1^TA\mathbb{L}(\mathbf{e}_n)\mathbf{e}_s] + (\beta-\beta')[\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)A\mathbf{e}_s - \mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{e}_s)A^T\mathbf{e}_1]\\
&\quad + (\varphi-\varphi')[\mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)A\mathbb{L}(\mathbf{e}_n)\mathbf{e}_s - \mathbf{e}_n^T\mathbb{L}'(\mathbf{e}_n)\mathbb{L}(\mathbf{e}_s)A^T\mathbf{e}_n],
\end{aligned}
$$

that is, (3.2) holds. □

Remark. It is clear that Theorem 3.2 holds unchanged if $T_{\varepsilon,\varphi}^{\beta,\beta} = T_{\varepsilon,\varphi} + \beta(\mathbf{e}_1\mathbf{e}_n^T + \mathbf{e}_n\mathbf{e}_1^T)$ is replaced by $M = Y + \beta(\mathbf{e}_1\mathbf{e}_n^T + \mathbf{e}_n\mathbf{e}_1^T)$, where Y is a generic symmetric tridiagonal matrix having at least $n-2$ nonzero entries $[Y]_{i,\,i+1}$, and $T_{\varepsilon',\varphi'}^{\beta',\beta'}$ is replaced by $M' = Y' + \beta'(\mathbf{e}_1\mathbf{e}_n^T + \mathbf{e}_n\mathbf{e}_1^T)$, where $Y' = Y + (\varepsilon'-\varepsilon)\mathbf{e}_1\mathbf{e}_1^T + (\varphi'-\varphi)\mathbf{e}_n\mathbf{e}_n^T$ (set $[Y]_{11} = \varepsilon$, $[Y]_{nn} = \varphi$). (In fact M and M' satisfy the assumptions on X and X' at the beginning of the proof.) This result includes Theorems 3.2 ($i = 1$, $i = n$) and 3.4 of [10].

For $\beta = \beta' = 0$ the result stated in Theorem 3.2 leads to displacement decompositions exploiting symmetric HAs that include, as special instances, some of the most significant formulas stated in [10] (see Corollaries 4.1 and 4.2 in [10]). In the next section it is shown that formula (3.1) also leads to significant decompositions exploiting 1-spaces which are not HAs. More specifically, in these last decompositions some Hartley-type matrix algebras will be involved.

4. The algebras $\boldsymbol{\eta, \mu, \mathcal{H}, \mathcal{K}}$. Theorem 3.2 can be exploited in order to obtain—as special cases of formula (3.1)—effective displacement decompositions of a generic matrix A. To this end we need to know if, and under what assumptions, there exist symmetric 1-algebras containing matrices of the form $T_{\varepsilon,\varphi}^{\beta,\beta}$. Theorem 2.5 relates the existence of such spaces $\xi(\varphi,\beta,\mathbf{p})$ to the existence of vectors $\mathbf{p}$ solving the linear system

$$I_{\beta\varphi}\mathbf{p} = (\varphi-\varepsilon)e_1, \tag{4.1}$$

where $I_{\beta\varphi}$ is the $(n-1)\times(n-1)$ matrix

$$I_{\beta\varphi} = \Omega_\varphi(\beta e_1 + e_{n-1}) = \begin{pmatrix} \beta & & & & \\ & \ddots & & & \\ & & \ddots & & \\ & & & \ddots & \\ & & & & \beta \end{pmatrix} + \begin{pmatrix} & & & & 1 \\ & & & 1 & -\varphi \\ & & \iddots & \iddots & \\ & 1 & \iddots & & \\ 1 & -\varphi & & & \end{pmatrix}. \tag{4.2}$$

Equation (4.1) may have no solution, infinite solutions, or only one solution; these three cases and the corresponding 1-spaces $\xi(\varphi,\beta,\mathbf{p})$ are studied in Proposition 4.2. For the sake of simplicity, for U, V $n\times n$ matrices, set $\mathcal{C}_V(U) = UV - VU$.

LEMMA 4.1. *$I_{\beta\varphi}$ is nonsingular iff $\exists\ \mathbf{z} \in \mathbb{C}^{n-1}$ and $\delta \in \mathbb{C}$, $\delta \neq 0$, such that $\mathbf{z}^T I_{\beta\varphi} = \delta e_1^T$. In this case $I_{\beta,\varphi}^{-1} = \delta^{-1}\Omega_\varphi(\mathbf{z})$.*

Proof. The assertion holds for any matrix A of a commutative 1-space $\mathbb{L}$; in fact, if $\mathbf{z}^T A = \delta e_1^T$, then $e_i^T \mathbb{L}(\mathbf{z})A = \mathbf{z}^T \mathbb{L}(e_i)A = \mathbf{z}^T A \mathbb{L}(e_i) = \delta e_i^T$, $i = 1, \ldots, n-1$, that is, $\delta^{-1}\mathbb{L}(\mathbf{z})A = I$. ∎

PROPOSITION 4.2. *We have the following three cases.*

(i) *$I_{\beta\varphi}$ singular and $\varepsilon \neq \varphi$: There is no symmetric 1-algebra containing $T_{\varepsilon,\varphi}^{\beta,\beta}$.*

(ii) *$I_{\beta\varphi}$ singular and $\varepsilon = \varphi$: There are infinite symmetric 1-algebras containing $T_{\varphi,\varphi}^{\beta,\beta}$ and therefore $T_{\varphi,\varphi}^{\beta,\beta}$ is derogatory. More specifically, these spaces are the $\xi(\varphi, \beta, \mathbf{p})$ (in (2.5)) where $\mathbf{p}$ is such that $I_{\beta\varphi}\mathbf{p} = \mathbf{0}$, and they can be represented as*

$$\xi(\varphi, \beta, \mathbf{p}) = \left\{ A \in M_n(\mathbb{C}) : \mathcal{C}_A\left(T_{\varphi,\varphi}^{\beta,\beta}\right) = \mathcal{C}_A(\xi(\mathbf{e}_n)) = 0 \right\}. \tag{4.3}$$

Only one of them is also persymmetric, and we call it $\tau_{\varphi,\varphi}^{\beta,\beta}$. We have

$$\tau_{\varphi,\varphi}^{\beta,\beta} = \xi(\varphi, \beta, \mathbf{0}) = \left\{ A \in M_n(\mathbb{C}) : \mathcal{C}_A\left(T_{\varphi,\varphi}^{\beta,\beta}\right) = \mathcal{C}_A(J) = 0 \right\}. \tag{4.4}$$

(iii) *$I_{\beta\varphi}$ nonsingular: For any $\varepsilon \in \mathbb{C}$ there exists a unique symmetric 1-algebra containing $T_{\varepsilon,\varphi}^{\beta,\beta}$. Moreover, if $\tau_{\varepsilon,\varphi}^{\beta,\beta}$ denotes such a space, we have*

$$\tau_{\varepsilon,\varphi}^{\beta,\beta} = \xi\left(\varphi, \beta, (\varphi - \varepsilon) I_{\beta\varphi}^{-1} e_1\right) = \left\{ A \in M_n(\mathbb{C}) : \mathcal{C}_A\left(T_{\varepsilon,\varphi}^{\beta,\beta}\right) = 0 \right\}. \tag{4.5}$$

Therefore, $T_{\varepsilon,\varphi}^{\beta,\beta}$ is nonderogatory and $\tau_{\varepsilon,\varphi}^{\beta,\beta}$ is the set of all polynomials in $T_{\varepsilon,\varphi}^{\beta,\beta}$.

Proof of Proposition 4.2(i). Assume that $I_{\beta\varphi}$ is singular and that $\varepsilon \neq \varphi$. By the first part of Theorem 2.5, a symmetric 1-algebra containing $T_{\varepsilon,\varphi}^{\beta,\beta}$ is equal to $\xi(\varphi, \beta, \mathbf{p})$, where $\mathbf{p}$ is such that $I_{\beta\varphi}\mathbf{p} = (\varphi - \varepsilon)e_1$. Then, by Lemma 4.1, $I_{\beta\varphi}$ is invertible, that is, a contradiction.

Proof of Proposition 4.2(ii). Assume that $I_{\beta\varphi}$ is singular and that $\varepsilon = \varphi$. Then the vectors $\mathbf{p} \in \mathbb{C}^{n-1}$ satisfying the equality $I_{\beta\varphi}\mathbf{p} = (\varphi - \varepsilon)e_1 = \mathbf{0}$ are infinite and, by the second part of Theorem 2.5, every space $\xi(\varphi, \beta, \mathbf{p})$ is a symmetric 1-algebra containing $T_{\varphi,\varphi}^{\beta,\beta}$, and it can be represented as in (4.3). The matrix $T_{\varphi,\varphi}^{\beta,\beta}$ is derogatory, because otherwise the set of all polynomials in $T_{\varphi,\varphi}^{\beta,\beta}$ should be an n-dimensional subspace of each $\xi(\varphi, \beta, \mathbf{p})$, which is absurd. Finally, among the $\xi(\varphi, \beta, \mathbf{p})$'s, there is only one containing the matrix J (or, equivalently, for which $\xi(\mathbf{e}_n) = J$), that is, $\xi(\varphi, \beta, \mathbf{0})$.

Proof of Proposition 4.2(iii). Assume that $I_{\beta\varphi}$ is nonsingular. By the second part of Theorem 2.5, $\xi(\varphi, \beta, (\varphi - \varepsilon)I_{\beta\varphi}^{-1}e_1)$ is a symmetric 1-algebra containing $T_{\varepsilon,\varphi}^{\beta,\beta}$. By the first part of Theorem 2.5, there is no other symmetric 1-algebra containing $T_{\varepsilon,\varphi}^{\beta,\beta}$. As regards the identity (4.5), notice that $\tau_{\varepsilon,\varphi}^{\beta,\beta} \subset \{A \in M_n(\mathbb{C}) : \mathcal{C}_A(T_{\varepsilon,\varphi}^{\beta,\beta}) = 0\}$. Conversely, let A be a matrix commuting with $T_{\varepsilon,\varphi}^{\beta,\beta}$ and consider the space $\tau_{\varepsilon',\varphi}^{\beta,\beta} = \xi(\varphi, \beta, (\varphi - \varepsilon')I_{\beta\varphi}^{-1}e_1)$, $\varepsilon' \neq \varepsilon$. Then apply Theorem 3.2 for $\mathbb{L} = \tau_{\varepsilon,\varphi}^{\beta,\beta}$ and $\mathbb{L}' = \tau_{\varepsilon',\varphi}^{\beta,\beta}$ to the matrix A to obtain $(\varepsilon - \varepsilon')A = (\varepsilon - \varepsilon')\tau_{\varepsilon,\varphi}^{\beta,\beta}(A^T\mathbf{e}_1)$. ∎

Now two interesting classes of matrix algebras $\mathcal{S}$ and $\mathcal{R}$, both corresponding to case (ii) in Proposition 4.2, are investigated. These algebras are also exploited to state, as special instances of formula (3.1), new efficient decompositions of a generic centrosymmetric matrix A (Theorem 4.3). Notice that the algebra $\mathcal{H}$, studied in [5] and related to the *Hartley transform*, is a particular element of $\mathcal{S}$.

The class $\mathcal{S}$. Let $\varphi = \varepsilon = 0$ and $\beta = 1$ in (4.1)–(4.2). As $\Omega_0(e_1 + e_{n-1}) = \tau(e_1 + e_{n-1}) = I + J$ is singular, by Proposition 4.2(ii) there are infinite symmetric 1-algebras containing the matrix $T^{1,1}_{0,0}$, i.e., the spaces $\xi(0, 1, \mathbf{p}^{\mathrm{SK}})$, where $\mathbf{p}^{\mathrm{SK}}$ is an arbitrary skewsymmetric vector ($\hat{\mathbf{p}}^{\mathrm{SK}} = -\mathbf{p}^{\mathrm{SK}}$). These spaces are denoted by $\mathcal{S}(\cdot; \mathbf{p}^{\mathrm{SK}})$ and can be represented as

$$\mathcal{S}(\cdot; \mathbf{p}^{\mathrm{SK}}) = \xi(0, 1, \mathbf{p}^{\mathrm{SK}}) = \{A \in M_n(\mathbb{C}) : \mathcal{C}_A(T^{1,1}_{0,0}) = \mathcal{C}_A(\mathcal{S}(\mathbf{e}_n; \mathbf{p}^{\mathrm{SK}})) = 0\}. \tag{4.6}$$

Each algebra $\mathcal{S}(\cdot; \mathbf{p}^{\mathrm{SK}})$ contains the algebra C^{S} of all $n \times n$ symmetric circulant matrices; therefore, by the identity $\{A : \mathcal{C}_A(T^{1,1}_{0,0}) = 0\} = C + JC$ (found in [9]), $\mathcal{S}(\cdot; \mathbf{p}^{\mathrm{SK}})$ must be equal to $C^{\mathrm{S}} + J\tilde{C}$ for some subset $\tilde{C}$ (depending upon $\mathbf{p}^{\mathrm{SK}}$) of the space C of circulant matrices.

Algebra η. If $\mathbf{p}^{\mathrm{SK}} = \mathbf{0}$ we have the space

$$\eta = \mathcal{S}(\cdot; \mathbf{0}) = \xi(0, 1, \mathbf{0}) = \tau^{1,1}_{0,0} = \{A \in M_n(\mathbb{C}) : \mathcal{C}_A(T^{1,1}_{0,0}) = \mathcal{C}_A(J) = 0\}. \tag{4.7}$$

Notice that $\eta = C^{\mathrm{S}} + JC^{\mathrm{S}}$; in fact $C^{\mathrm{S}} + JC^{\mathrm{S}} \subset \eta$ and

$$\begin{aligned}\dim(C^{\mathrm{S}} + JC^{\mathrm{S}}) &= \dim C^{\mathrm{S}} + \dim JC^{\mathrm{S}} - \dim C^{\mathrm{S}} \cap JC^{\mathrm{S}} = 2\dim C^{\mathrm{S}} - \dim C^{\mathrm{S}} \cap JC^{\mathrm{S}} \\ &= \begin{cases} 2\left(\dfrac{n}{2} + 1\right) - 2 & \text{if } n \text{ is even,} \\ 2\left(\dfrac{n+1}{2}\right) - 1 & \text{if } n \text{ is odd,} \end{cases}\end{aligned}$$

that is, $\dim(C^{\mathrm{S}} + JC^{\mathrm{S}}) = n$.

Algebra $\mathcal{H}$. If $\mathbf{p}^{\mathrm{SK}} = \frac{1}{2}(e_2 - e_{n-2})$, we have the space

$$\mathcal{H} = \mathcal{S}\left(\cdot; \frac{1}{2}(e_2 - e_{n-2})\right) = \xi\left(0, 1, \frac{1}{2}(e_2 - e_{n-2})\right). \tag{4.8}$$

Notice that $\mathcal{H} = C^{\mathrm{S}} + JPC^{\mathrm{SK}}$, where P is the circulant matrix whose first row is $\mathbf{e}_2^T$ ($P = P_1 = C(\mathbf{e}_2)$) and C^{SK} is the set of all $n \times n$ skewsymmetric circulant matrices (a matrix A is skewsymmetric if $A^T = -A$). To prove this fact, first observe that $C^{\mathrm{S}} + JPC^{\mathrm{SK}}$ is commutative and that the matrices $T^{1,1}_{0,0}$ and

$$\mathcal{H}(\mathbf{e}_n) = \mathcal{S}\left(\mathbf{e}_n; \frac{1}{2}(e_2 - e_{n-2})\right) = J + \frac{1}{2}\begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \\ 0 & \tau(e_2 - e_{n-2}) & \end{pmatrix} \tag{4.9}$$

are elements of $C^{\mathrm{S}} + JPC^{\mathrm{SK}}$. The commutativity follows from the commutativity of the space C. Moreover, the matrices $\frac{1}{2}T^{1,1}_{0,0}$ and $JP\left(-\frac{1}{2}(P - P^T)\right)$ are elements of C^{S} and JPC^{SK}, respectively, and their sum is the matrix in (4.9). Thus $C^{\mathrm{S}} + JPC^{\mathrm{SK}} \subset \mathcal{H}$. But

$$\begin{aligned}\dim(C^{\mathrm{S}} + JPC^{\mathrm{SK}}) &= \dim C^{\mathrm{S}} + \dim JPC^{\mathrm{SK}} - \dim C^{\mathrm{S}} \cap JPC^{\mathrm{SK}} \\ &= \begin{cases} \left(\dfrac{n}{2} + 1\right) + \left(\dfrac{n}{2} - 1\right) - 0 & \text{if } n \text{ is even,} \\ \left(\dfrac{n+1}{2}\right) + \left(\dfrac{n-1}{2}\right) - 0 & \text{if } n \text{ is odd,} \end{cases}\end{aligned}$$

that is, $\dim(C^{\mathrm{S}} + JPC^{\mathrm{SK}}) = n$, and the identity $\mathcal{H} = C^{\mathrm{S}} + JPC^{\mathrm{SK}}$ is proved. In [5] it is shown that the matrices of $\mathcal{H}$ are simultaneously diagonalized by a similarity

transformation known as Hartley transform (see also Theorem 5.2 in the next section). A greater attention has been devoted to this particular *real* transform since Bracewell [11, 12] introduced the fast Hartley transform (FHT).

Observe that the proper inclusion $\mathcal{H} \supset C^{\mathrm{S}}$ is exploited in [5] to determine a new preconditioner of symmetric Toeplitz systems, competitive with the more usual circulant preconditioners (see also [13]). All algebras $\mathcal{S}(\cdot;\mathbf{p}^{\mathrm{SK}})$ include C^{S} and, besides $\mathcal{H}$, there may be other algebras $\mathcal{S}(\cdot;\mathbf{p}^{\mathrm{SK}})$ whose matrices are simultaneously diagonalized by a fast transform (this is, the case of $\eta = \mathcal{S}(\cdot;\mathbf{0})$; see Theorem 5.2). As it will be shown in a forthcoming paper, some of the algebras $\mathcal{S}(\cdot;\mathbf{p}^{\mathrm{SK}})$ (together with some other $\mathcal{R}(\cdot;\mathbf{p}^{\mathrm{S}})$ algebras described below) can lead to other efficient preconditioners of Toeplitz systems.

The class $\mathcal{R}$. The choice $\varphi = \varepsilon = 0$, $\beta = -1$ leads to symmetric 1-algebras—containing $T_{0,0}^{-1,-1}$—naturally related to those of the class $\mathcal{S}$. These are the following:

$$\mathcal{R}(\cdot;\mathbf{p}^{\mathrm{S}}) = \xi(0,-1,\mathbf{p}^{\mathrm{S}}) = \left\{A \in M_n(\mathbb{C}) : \mathcal{C}_A\left(T_{0,0}^{-1,-1}\right) = \mathcal{C}_A(\mathcal{R}(\mathbf{e}_n;\mathbf{p}^{\mathrm{S}})) = 0\right\}, \tag{4.10}$$

where $\mathbf{p}^{\mathrm{S}}$ is an arbitrary symmetric vector ($\hat{\mathbf{p}}^{\mathrm{S}} = \mathbf{p}^{\mathrm{S}}$). Each algebra $\mathcal{R}(\cdot;\mathbf{p}^{\mathrm{S}})$ contains the algebra C_{-1}^{S} of all $n \times n$ symmetric (-1)-circulant matrices; therefore, by the identity $\{A : \mathcal{C}_A(T_{0,0}^{-1,-1}) = 0\} = C_{-1} + JC_{-1}$ (found in [9]), $\mathcal{R}(\cdot;\mathbf{p}^{\mathrm{S}}) = C_{-1}^{\mathrm{S}} + J\tilde{C}_{-1}$ for some subset $\tilde{C}_{-1}$ (depending on $\mathbf{p}^{\mathrm{S}}$) of the space C_{-1} of (-1)-circulant matrices.

Algebra μ. If $\mathbf{p}^{\mathrm{S}} = \mathbf{0}$, we have the space

$$\mu = \mathcal{R}(\cdot;\mathbf{0}) = \xi(0,-1,\mathbf{0}) = \tau_{0,0}^{-1,-1} = \{A \in M_n(\mathbb{C}) : \mathcal{C}_A(T_{0,0}^{-1,-1}) = \mathcal{C}_A(J) = 0\} \tag{4.11}$$

naturally related to η. Notice that $\mu = C_{-1}^{\mathrm{S}} + JC_{-1}^{\mathrm{S}}$; in fact $C_{-1}^{\mathrm{S}} + JC_{-1}^{\mathrm{S}} \subset \mu$ and

$$\begin{aligned}
\dim(C_{-1}^{\mathrm{S}} + JC_{-1}^{\mathrm{S}}) &= \dim C_{-1}^{\mathrm{S}} + \dim JC_{-1}^{\mathrm{S}} - \dim C_{-1}^{\mathrm{S}} \cap JC_{-1}^{\mathrm{S}} \\
&= 2\dim C_{-1}^{\mathrm{S}} - \dim C_{-1}^{\mathrm{S}} \cap JC_{-1}^{\mathrm{S}} \\
&= \begin{cases} 2\left(\dfrac{n}{2}\right) - 0 & \text{if } n \text{ is even,} \\ 2\left(\dfrac{n+1}{2}\right) - 1 & \text{if } n \text{ is odd,} \end{cases}
\end{aligned}$$

that is, $\dim(C_{-1}^{\mathrm{S}} + JC_{-1}^{\mathrm{S}}) = n$.

Algebra $\mathcal{K}$. If $\mathbf{p}^{\mathrm{S}} = -\frac{1}{2}(e_2 + e_{n-2})$, we have the space

$$\mathcal{K} = \mathcal{R}\left(\cdot; -\frac{1}{2}(e_2 + e_{n-2})\right) = \xi\left(0,-1,-\frac{1}{2}(e_2 + e_{n-2})\right) \tag{4.12}$$

naturally related to $\mathcal{H}$. Notice that $\mathcal{K} = C_{-1}^{\mathrm{S}} + JP_{-1}C_{-1}^{\mathrm{SK}}$, where $P_{-1} = C_{-1}(\mathbf{e}_2)$ and C_{-1}^{SK} is the set of all $n \times n$ skewsymmetric (-1)-circulant matrices. In order to prove this fact, first show (by proceeding as for $\mathcal{H}$) the inclusion $C_{-1}^{\mathrm{S}} + JP_{-1}C_{-1}^{\mathrm{SK}} \subset \mathcal{K}$, and then use the identity

$$\begin{aligned}
\dim(C_{-1}^{\mathrm{S}} + JP_{-1}C_{-1}^{\mathrm{SK}}) &= \dim C_{-1}^{\mathrm{S}} + \dim JP_{-1}C_{-1}^{\mathrm{SK}} - \dim C_{-1}^{\mathrm{S}} \cap JP_{-1}C_{-1}^{\mathrm{SK}} \\
&= \begin{cases} \left(\dfrac{n}{2}\right) + \left(\dfrac{n}{2}\right) - 0 & \text{if } n \text{ is even,} \\ \left(\dfrac{n+1}{2}\right) + \left(\dfrac{n-1}{2}\right) - 0 & \text{if } n \text{ is odd,} \end{cases} = n.
\end{aligned}$$

The matrices of $\mathcal{K}$ are simultaneously diagonalized by a similarity transformation analogue to the Hartley transform (skew-Hartley transform). Also the algebra μ is associated with a fast discrete transform. (See Theorem 5.2 and the following remark.) In Theorem 4.3 the most significant displacement decompositions are stated in terms of the algebras η, μ, $\mathcal{H}$, and $\mathcal{K}$.

THEOREM 4.3. *If* $AT_{0,0}^{1,1} - T_{0,0}^{1,1}A = \sum_{m=1}^{\alpha} \mathbf{x}_m \mathbf{y}_m^T$, *then*

$$A\mathcal{S}(\mathbf{e}_n;\mathbf{p}^{\mathrm{SK}}) + \mathcal{R}(\mathbf{e}_n;\mathbf{p}^{s})A = \frac{1}{2}\sum_{m=1}^{\alpha} \mathcal{R}(\mathbf{x}_m;\mathbf{p}^{\mathrm{S}})\mathcal{S}(\mathbf{y}_m;\mathbf{p}^{\mathrm{SK}}) + \mathcal{S}(A^T\mathbf{e}_n;\mathbf{p}^{\mathrm{SK}}) + \mathcal{R}(\mathbf{e}_n;\mathbf{p}^{s})\mathcal{S}(A^T\mathbf{e}_1;\mathbf{p}^{\mathrm{SK}}) \tag{4.13}$$

and, in particular,

$$AJ + JA = \frac{1}{2}\sum_{m=1}^{\alpha} \mu(\mathbf{x}_m)\eta(\mathbf{y}_m) + \eta((AJ+JA)^T\mathbf{e}_1), \tag{4.14}$$

$$AJ + \mathcal{K}(\mathbf{e}_n)A = \frac{1}{2}\sum_{m=1}^{\alpha} \mathcal{K}(\mathbf{x}_m)\eta(\mathbf{y}_m) + \eta(A^T\mathbf{e}_n) + \mathcal{K}(\mathbf{e}_n)\eta(A^T\mathbf{e}_1), \tag{4.15}$$

$$A\mathcal{H}(\mathbf{e}_n) + JA = \frac{1}{2}\sum_{m=1}^{\alpha} \mu(\mathbf{x}_m)\mathcal{H}(\mathbf{y}_m) + \mathcal{H}(A^T\mathbf{e}_n) + J\mathcal{H}(A^T\mathbf{e}_1), \tag{4.16}$$

$$A\mathcal{H}(\mathbf{e}_n) + \mathcal{K}(\mathbf{e}_n)A = \frac{1}{2}\sum_{m=1}^{\alpha} \mathcal{K}(\mathbf{x}_m)\mathcal{H}(\mathbf{y}_m) + \mathcal{H}(A^T\mathbf{e}_n) + \mathcal{K}(\mathbf{e}_n)\mathcal{H}(A^T\mathbf{e}_1). \tag{4.17}$$

Proof. For (4.13) set $\varepsilon = \varphi = \varepsilon' = \varphi' = 0$, $\beta = 1$, $\beta' = -1$ in Theorem 3.2. The particular cases (4.14)–(4.17) correspond, respectively, to the choices $\mathbf{p}^{\mathrm{S}} = \mathbf{p}^{\mathrm{SK}} = \mathbf{0}$, $\mathbf{p}^{\mathrm{S}} = -\frac{1}{2}(e_2 + e_{n-2})$ and $\mathbf{p}^{\mathrm{SK}} = \mathbf{0}$, $\mathbf{p}^{\mathrm{S}} = \mathbf{0}$ and $\mathbf{p}^{\mathrm{SK}} = \frac{1}{2}(e_2 - e_{n-2})$, and $\mathbf{p}^{\mathrm{S}} = -\frac{1}{2}(e_2 + e_{n-2})$ and $\mathbf{p}^{\mathrm{SK}} = \frac{1}{2}(e_2 - e_{n-2})$. □

If the matrix A is *centrosymmetric* (i.e., $AJ = JA$) the formulas (4.14)–(4.16) give explicit representations of A in terms of the algebras μ, η, $\mathcal{H}$, and $\mathcal{K}$. In fact the matrices $2J$, $J + \mathcal{K}(\mathbf{e}_n)$, and $J + \mathcal{H}(\mathbf{e}_n)$ are invertible. (It can be shown that $\det(J + \mathcal{H}(\mathbf{e}_n)) = \det(J + \mathcal{K}(\mathbf{e}_n)) = (-1)^{(n-1)/2}2n$ if n is odd; $\det(J + \mathcal{H}(\mathbf{e}_n)) = (-1)^{n/2}n^2$, $\det(J + \mathcal{K}(\mathbf{e}_n)) = (-1)^{n/2}4$ if n is even.) Notice that by Proposition 4.2(i) a symmetric 1-algebra containing $T_{\varepsilon,0}^{\beta,\beta}$, where $\beta = 1$ or $\beta = -1$, may exist only if $\varepsilon = 0$. As a (nonobvious) consequence of this fact, Theorem 3.2 cannot yield effective representations of a *generic* matrix A including algebras $\mathcal{S}(\cdot;\mathbf{p}^{\mathrm{SK}})$ or $\mathcal{R}(\cdot;\mathbf{p}^{\mathrm{S}})$. However, Theorem 3.2 yields such generic formulas, also in terms of non-Hessenberg algebras, if we let both $\mathbb{L}$ and $\mathbb{L}'$ be matrix algebras of the type considered in Proposition 4.2(iii). An example is easily obtained by choosing $\varphi' = \varphi$, $\beta' = \beta$ (in Theorem 3.2) and then—in order to ensure the existence of symmetric 1-algebras $\mathbb{L} \supset T_{\varepsilon,\varphi}^{\beta,\beta}$ and $\mathbb{L}' \supset T_{\varepsilon',\varphi}^{\beta,\beta}$ for $\varepsilon \neq \varepsilon'$—by requiring $I_{\beta\varphi}$ in (4.2) to be nonsingular (see Proposition 4.2). For the sake of brevity we mention only some values of β and φ for which $I_{\beta\varphi}$ is nonsingular and $I_{\beta\varphi}^{-1}$ is known (in the sense of Lemma 4.1) for any value of n: φ arbitrary, $\beta = 0$ [10]; $\varphi = 0$, $\beta^2 \neq 1$; $\varphi = 2$, $\beta = 1$; $\varphi = -2$, $\beta = -1$.

Formula (4.14) is exploited in section 5 to state a simple espression of the inverse of a centrosymmetric Toeplitz-plus-Hankel matrix $T + H$. This expression allows us to calculate $(T+H)^{-1}\mathbf{f}$, $\mathbf{f} \in \mathbb{C}^n$, by performing essentially 10 DFTs reducible to 8 in the case $H = 0$, $[T^{-1}]_{11} \neq 0$, matching both best limits known so far.

5. Toeplitz-plus-Hankel inversion formulas. Theorem 3.2, the results of the previous section, and the fact that the rank of $\mathcal{C}_{T_{\varepsilon,\varphi}^{\beta,\beta}}((T+H)^{-1})$ is 4 for all values of ε, φ, β (see [26] for the case $\varepsilon=\varphi=\beta=0$) yield new representations of the inverse of a Toeplitz-plus-Hankel matrix $T+H$ (or, more generally, of $(T+H)$-like matrices, that is, structured matrices A for which $\operatorname{rank}\mathcal{C}_{T_{\varepsilon,\varphi}^{\beta,\beta}}(A)$ is small with respect to n). These are similar to other formulas found in [1, 6, 9, 10, 16, 17, 20, 23, 32], but they involve new n-dimensional matrix algebras different from HAs. The formulas so obtained can be used to solve a linear system $(T+H)\mathbf{x}=\mathbf{f}$, $\mathbf{f}=\mathbb{C}^n$, in $O(n\log n)$ arithmetic operations (via the computation of $(T+H)^{-1}\mathbf{f}$), provided the 8 vectors defining $\mathcal{C}_{T_{\varepsilon,\varphi}^{\beta,\beta}}((T+H)^{-1})$ are known. Here only the centrosymmetric case is considered in detail.

This approach (compared to a direct triangular factorization of $T+H$ [33, 27]) is significant especially in case a distinction is emphasized between a preprocessing stage—where only operations on elements of $T+H$ are performed—and a successive stage of complexity $O(n\log n)$, where the linear system $(T+H)\mathbf{x}=\mathbf{f}$, $\mathbf{f}\in\mathbb{C}^n$, is solved. This distinction is justified when many different linear systems $(T+H)\mathbf{x}=\mathbf{f}_i$ have to be solved. The same point of view is assumed by Gohberg and Olshevsky in [21, 22], where the complexity of the computation of $A\mathbf{f}$ with preprocessing on A is studied for different types of structured matrices A, including the case $A=T^{-1}$ for a generic Toeplitz T. (Some results on the complexity of the preprocessing stage are also given in [21, 22].) In particular, they show that the application of T^{-1} to the vector $\mathbf{f}$ can be accomplished with a cost of 6 DFTs of order n and thus generalize the analogous result obtained by Ammar and Gader in the Hermitian case [1]. We mention the fact that if T is symmetric, the above limit can be reduced to 11 DFTs of order $\frac{n}{2}$ by using a formula for T^{-1} involving circulant and (-1)-circulant matrices of order $\frac{n}{2}$ (see [15, 17]). Moreover, it is known [10, 16] that 6 discrete transforms are also enough to compute the product $(T+H)^{-1}\mathbf{f}$, where $T+H$ is a centrosymmetric Toeplitz-plus-Hankel matrix. This fact is also shown in the present paper by using a decomposition of $(T+H)^{-1}$ in terms of Hartley-type matrix algebras (see the remarks after Theorems 5.1 and 5.2).

Let T, $[T]_{ij}=t_{i-j}$, and H, $[H]_{ij}=h_{i+j-2}$, $i,j=1,\dots,n$, be, respectively, a symmetric Toeplitz and a persymmetric Hankel matrix with complex elements, and assume that $T+H$ is nonsingular. Then [26]

$$\begin{aligned}(T+H)^{-1}T_{\varphi,\varphi}^{\beta,\beta}-T_{\varphi,\varphi}^{\beta,\beta}(T+H)^{-1}&=(\mathbf{x}_1-\varphi\mathbf{e}_1-\beta\mathbf{e}_n)\mathbf{w}_1^T+(\hat{\mathbf{x}}_1-\varphi\mathbf{e}_n-\beta\mathbf{e}_1)\hat{\mathbf{w}}_1^T\\&\quad-\mathbf{w}_1(\mathbf{x}_1-\varphi\mathbf{e}_1-\beta\mathbf{e}_n)^T-\hat{\mathbf{w}}_1(\hat{\mathbf{x}}_1-\varphi\mathbf{e}_n-\beta\mathbf{e}_1)^T,\end{aligned}\tag{5.1}$$

where $\mathbf{w}_1$ and $\mathbf{x}_1$ are such that

$$(T+H)\mathbf{w}_1=\mathbf{e}_1\quad\text{and}\quad(T+H)\mathbf{x}_1=[t_1+h_{-1}\ t_2+h_0\cdots t_n+h_{n-2}]^T, h_{-1},t_n\in\mathbb{C}$$

(see also [16, 10]). Equality (5.1) for $\beta=0$, $\varphi=1$ and Theorem 3.2 for $\varepsilon=\varphi=1$, $\varepsilon'=\varphi'=-1$, $\beta=\beta'=0$ let us regain the decomposition of $(T+H)^{-1}$

$$2(T+H)^{-1}=\tau_{-1,-1}(\mathbf{x}_1+\mathbf{e}_1)\tau_{1,1}(\mathbf{w}_1)-\tau_{-1,-1}(\mathbf{w}_1)\tau_{1,1}(\mathbf{x}_1-\mathbf{e}_1)\tag{5.2}$$

found in [10]. Moreover, Theorem 3.2 (via Theorem 4.3) yields new decompositions of $(T+H)^{-1}$ in terms of the matrix algebras η, μ, $\mathcal{H}$, and $\mathcal{K}$ studied in section 4.

THEOREM 5.1.

$$(T+H)^{-1}=\frac{1}{2}\{\mu(\hat{\mathbf{x}}_1+\mathbf{e}_1)\eta(\mathbf{w}_1)-\mu(\mathbf{w}_1)\eta(\hat{\mathbf{x}}_1-\mathbf{e}_1)\},\tag{5.3}$$

$$(T+H)^{-1} = \frac{1}{2}(J+\mathcal{K}(\mathbf{e}_n))^{-1}\{[\mathcal{K}(\mathbf{x}_1+\mathbf{e}_n)+\mathcal{K}(\hat{\mathbf{x}}_1+\mathbf{e}_1)J]\eta(\mathbf{w}_1)$$

$$-[\mathcal{K}(\mathbf{w}_1)+\mathcal{K}(\hat{\mathbf{w}}_1)J]\eta(\mathbf{x}_1-\mathbf{e}_n)\}, \tag{5.4}$$

$$(T+H)^{-1} = \{\mu(\mathbf{x}_1+\mathbf{e}_n)[\mathcal{H}(\mathbf{w}_1)+J\mathcal{H}(\hat{\mathbf{w}}_1)]$$

$$-\mu(\mathbf{w}_1)[\mathcal{H}(\mathbf{x}_1-\mathbf{e}_n)+J\mathcal{H}(\hat{\mathbf{x}}_1-\mathbf{e}_1)]\}\frac{1}{2}(J+\mathcal{H}(\mathbf{e}_n))^{-1}. \tag{5.5}$$

Proof. Exploit (5.1) for $\varphi = 0$, $\beta = 1$ and formulas (4.14), (4.15), and (4.16) of Theorem 4.3, respectively. ∎

Formulas (5.2)–(5.5) can be used to compute $(T+H)^{-1}\mathbf{f}$ by means of a constant number of DFTs, Hartley-type transforms, trigonometric transforms, or mixed-type transforms all computable in $O(n\log n)$ arithmetic operations (see [5, 11, 10, 34], Theorem 5.2, and the following remark). In particular, formula (5.3) is competitive with the formulas found in [16, 10]. In fact, as an immediate consequence of Theorem 5.2, the matrix by vector product $(T+H)^{-1}\mathbf{f}$, $\mathbf{f}\in\mathbb{C}^n$, can be calculated by performing essentially 10 order n DFTs if $(T+H)^{-1}$ is replaced by its expression in (5.3) and if $\mathbf{x}_1$ and $\mathbf{w}_1$ are assumed as known. Moreover, we shall see that, for $H=0$ and $w_{11}=[T^{-1}]_{11}\neq 0$, the number of DFTs can be reduced to 8. The limits 10 and 8 are identical to those obtained in [10] with (5.2); however, here the limit 8 is obtained without the further assumption that the entries of T are real, and the coefficient of n in the surplus of $O(n)$ operations is smaller. Recall that the limit 8 has been obtained for the first time by Ammar and Gader in [1]. Both in [1, 16, 10] and in (5.3) the number of discrete transforms is in any case 6 if the transforms of vectors not depending upon $\mathbf{f}$ are included in the preprocessing stage. Moreover, notice that Rost [32] obtains a simple representation for the "classical" Hankel Bezoutian (and therefore for H^{-1}) in terms of $\tau_{0,0}$ and $\tau_{0,1}$ matrices and refers to a future work concerning with the Toeplitz-plus-Hankel case and with the study of computational properties of these representations.

In the next theorem, $d(\mathbf{z})$, $\mathbf{z}\in\mathbb{C}^n$, denotes the $n\times n$ diagonal matrix whose (k,k) element is z_k, $k=1,\dots,n$, and $\mathbf{i}$ is the imaginary unit. Moreover, if A is an $n\times n$ matrix with complex entries, then A^H denotes the transposed conjugate of A.

THEOREM 5.2. *Set* $\rho=\exp(-\mathbf{i}\pi/n)$, $\bar{\rho}=\rho^{-1}$, $\omega=\rho^2$, $[F]_{ij}=\frac{1}{\sqrt{n}}\,\omega^{(i-1)(j-1)}$, $i,j=1,\dots,n$, $D_\rho=\mathrm{diag}(\rho^{i-1}, i=1,\dots,n)$, *and* $D_\omega=D_\rho^2$. *Then, for all* $\mathbf{z}\in\mathbb{C}^n$,

$$\eta(\mathbf{z}) = M_\eta\Lambda(M_\eta^T\mathbf{z})M_\eta^H, \qquad \Lambda(M_\eta^T\mathbf{z}) = d(M_\eta^T\mathbf{z})d(M_\eta^T\mathbf{e}_1)^{-1}, \tag{5.6}$$

$$\mu(\mathbf{z}) = M_\mu\Lambda(M_\mu^T\mathbf{z})M_\mu^H, \qquad \Lambda(M_\mu^T\mathbf{z}) = d(M_\mu^T\mathbf{z})d(M_\mu^T\mathbf{e}_1)^{-1}, \tag{5.7}$$

where M_η *and* M_μ *are the unitary matrices:*

$$M_\eta = \frac{1}{\sqrt{2}}F\begin{pmatrix} \sqrt{2} & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\ 0 & 1 & & & & & -\omega & \\ \vdots & & \ddots & & & \iddots & & \vdots \\ \vdots & & & 1 & 0 & -\omega^{\frac{n}{2}-1} & & \vdots \\ \vdots & & & 0 & \sqrt{2} & 0 & & \vdots \\ \vdots & & & \omega^{\frac{n}{2}+1} & 0 & 1 & & \vdots \\ & \iddots & & & & & \ddots & \\ 0 & \cdots & \cdots & \cdots & \cdots & 0 & \omega^{n-1} & 1 \end{pmatrix}, \tag{5.8}$$

$$M_\mu = \frac{1}{\sqrt{2}} D_\rho F \begin{pmatrix} 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & -\overline{\rho}^{n-1} \\ 0 & 1 & \ddots & & & & & \iddots & \iddots & 0 \\ \vdots & \ddots & \ddots & \ddots & & & \iddots & \iddots & \iddots & \vdots \\ \vdots & \iddots & \ddots & \ddots & 0 & 0 & -\overline{\rho}^{3} & \iddots & \iddots & \vdots \\ \vdots & & \iddots & 0 & 1 & -\overline{\rho} & 0 & & & \vdots \\ \vdots & & & 0 & -\overline{\rho}^{n-1} & 1 & 0 & & & \vdots \\ \vdots & & \iddots & \iddots & 0 & 0 & 1 & \ddots & \iddots & \vdots \\ \vdots & \iddots & \iddots & \iddots & & & \ddots & \ddots & \ddots & \vdots \\ 0 & -\overline{\rho}^{3} & \iddots & & & & & \ddots & \ddots & 0 \\ -\overline{\rho} & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & 1 \end{pmatrix} \tag{5.9}$$

for n even, and

$$M_\eta = \frac{1}{\sqrt{2}} F \begin{pmatrix} \sqrt{2} & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\ 0 & 1 & \ddots & & & & & & \iddots & -\omega \\ \vdots & \ddots & \ddots & \ddots & & & & \iddots & \iddots & 0 \\ \vdots & \iddots & \ddots & \ddots & 0 & 0 & \iddots & \iddots & \iddots & \vdots \\ \vdots & & \iddots & 0 & 1 & -\omega^{\frac{n-1}{2}} & 0 & \iddots & \iddots & \vdots \\ \vdots & & & \iddots & \omega^{\frac{n+1}{2}} & 1 & \iddots & \iddots & \iddots & \vdots \\ \vdots & & 0 & \iddots & \ddots & \ddots & \ddots & 0 & \iddots & \vdots \\ \vdots & \iddots & \iddots & \iddots & 0 & 0 & \iddots & \iddots & \iddots & \vdots \\ \vdots & \iddots & & \iddots & \iddots & \iddots & \iddots & \iddots & 0 & \vdots \\ 0 & \omega^{n-1} & 0 & \cdots & \cdots & \cdots & \cdots & 0 & 1 & 0 \end{pmatrix}, \tag{5.10}$$

$$M_\mu = \frac{1}{\sqrt{2}} D_\rho F \begin{pmatrix} 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & -\omega^{\frac{n+1}{2}} \\ 0 & \ddots & \ddots & & & & \iddots & \iddots & 0 \\ \vdots & \ddots & \ddots & \ddots & & & \iddots & \iddots & \vdots \\ \vdots & \iddots & 1 & 0 & -\omega^{n-1} & \iddots & \iddots & \iddots & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \ddots & \iddots & \iddots & \vdots \\ \vdots & & 0 & \sqrt{2} & 0 & \iddots & \iddots & \iddots & \vdots \\ \vdots & \iddots & \iddots & \ddots & \ddots & \ddots & \iddots & \iddots & \vdots \\ \vdots & \iddots & \iddots & \omega & 0 & 1 & \iddots & \iddots & \vdots \\ 0 & \ddots & & \ddots & & \ddots & \ddots & \ddots & 0 \\ \vdots & & \ddots & & \ddots & & \ddots & \ddots & \vdots \\ \omega^{\frac{n-1}{2}} & 0 & \cdots & \cdots & \cdots & \cdots & 0 & 1 & 0 \end{pmatrix} \tag{5.11}$$

for n odd. Moreover, for all $\mathbf{z} \in \mathbb{C}^n$,

$$\mathcal{H}(\mathbf{z}) = \sqrt{n}\ H_+ d(H_+\mathbf{z}) H_+ = \sqrt{n}\ H_- d(H_-\mathbf{z}) H_-, \tag{5.12}$$

$$\mathcal{K}(\mathbf{z}) = \sqrt{n}\ K_+ d(K_+^T\mathbf{z}) K_+^T = \sqrt{n}\ K_- d(K_-^T\mathbf{z}) K_-^T, \tag{5.13}$$

where H_+, H_-, K_+, and K_- are the orthonormal matrices defined by

$$[H_\pm]_{ij} = (1/\sqrt{n}\,) \left(\cos \frac{2\pi(i-1)(j-1)}{n} \pm \sin \frac{2\pi(i-1)(j-1)}{n} \right), \tag{5.14}$$

$$[K_\pm]_{ij} = (1/\sqrt{n}\,) \left(\cos \frac{\pi(i-1)(2j-1)}{n} \pm \sin \frac{\pi(i-1)(2j-1)}{n} \right), \tag{5.15}$$

$i, j = 1, \ldots, n$.

Proof. The equalities (5.6) and (5.7) are shown only in the case n even ($n = 2m$). In the case n odd, the proof is similar. Notice that in order to find the matrices in (5.8), (5.10) and (5.9), (5.11), we had to look for a matrix diagonalizing J among the matrices diagonalizing $T_{0,0}^{1,1}$ and $T_{0,0}^{-1,-1}$, respectively.

Let us prove (5.6). Set $\mathbf{c}_i = \sqrt{n}\,F\mathbf{e}_i$, $i = 1, \ldots, n$. By using the identities $\hat{\mathbf{c}}_i = \omega^{n-i+1}\mathbf{c}_{n-i+2}$, $i = 2, \ldots, m$ (recall that, for a vector $\mathbf{z}$, $\hat{\mathbf{z}} = J\mathbf{z}$), one can easily show that

$$M_\eta = \frac{1}{\sqrt{2n}}\,[\sqrt{2}\mathbf{c}_1\ \mathbf{c}_2 + \hat{\mathbf{c}}_2 \cdots \mathbf{c}_m + \hat{\mathbf{c}}_m\ \sqrt{2}\mathbf{c}_{m+1}\ \ \mathbf{c}_{m+2} - \hat{\mathbf{c}}_{m+2} \cdots \mathbf{c}_n - \hat{\mathbf{c}}_n]. \tag{5.16}$$

Moreover, as $T_{0,0}^{1,1} = P_1 + P_1^H$ and $P_1 = FD_\omega F^H$, $T_{0,0}^{1,1}F = F(D_\omega + D_\omega^H)$, i.e.,

$$T_{0,0}^{1,1}[\mathbf{c}_1\ \mathbf{c}_2 \cdots \mathbf{c}_n] = [\mathbf{c}_1\ \mathbf{c}_2 \cdots \mathbf{c}_n]\,\mathrm{diag}(2\cos\frac{2\pi(j-1)}{n}, \quad j = 1, \ldots, n). \tag{5.17}$$

By the centrosymmetry of $T_{0,0}^{1,1}$ (besides $\mathbf{c}_j$) also $\hat{\mathbf{c}}_j$ is an eigenvector of $T_{0,0}^{1,1}$ with associated eigenvalue $2\cos\frac{2\pi(j-1)}{n}$. This remark and equalities (5.17) and (5.16) allow us to say that

$$T_{0,0}^{1,1}M_\eta = M_\eta\,\mathrm{diag}\left(2\cos\frac{2\pi(j-1)}{n},\ j = 1, \ldots, n\right). \tag{5.18}$$

From (5.16) it also follows that

$$\eta(\mathbf{e}_n)M_\eta = JM_\eta = M_\eta \begin{pmatrix} I & O \\ O & -I \end{pmatrix}, \tag{5.19}$$

where the I in (5.19) is the $m \times m$ identity matrix ($\hat{\mathbf{c}}_1 = \mathbf{c}_1$, $\hat{\mathbf{c}}_{m+1} = -\mathbf{c}_{m+1}$). By exploiting, respectively, (5.18) and (5.19), we have that the matrix $M_\eta d(M_\eta^T\mathbf{z})\,d(M_\eta^T\mathbf{e}_1)^{-1}M_\eta^H$ commutes with the matrices $T_{0,0}^{1,1}$ and J $\forall\mathbf{z} \in \mathbb{C}^n$. Moreover, as $M_\eta M_\eta^H = I$, its first row is $\mathbf{z}^T$, and therefore, by (4.7), we have $\eta(\mathbf{z}) = M_\eta d(M_\eta^T\mathbf{z})\,d(M_\eta^T\mathbf{e}_1)^{-1}M_\eta^H$.

Let us prove (5.7). Set $\mathbf{c}_i = \sqrt{n}D_\rho F\mathbf{e}_i$, $i = 1, \ldots, n$. The identities $\hat{\mathbf{c}}_i = -\bar{\rho}^{2i-1}\mathbf{c}_{n+1-i}$, $i = 1, \ldots, m$, yield

$$M_\mu = \frac{1}{\sqrt{2n}}\,[\mathbf{c}_1 + \hat{\mathbf{c}}_1 \cdots \mathbf{c}_m + \hat{\mathbf{c}}_m\ \ \mathbf{c}_{m+1} - \hat{\mathbf{c}}_{m+1} \cdots \mathbf{c}_n - \hat{\mathbf{c}}_n]. \tag{5.20}$$

Moreover, as $T_{0,0}^{-1,-1} = P_{-1} + P_{-1}^H$ and $P_{-1} = D_\rho F\rho D_\omega F^H D_\rho^H$, we have $T_{0,0}^{-1,-1}D_\rho F = D_\rho F(\rho D_\omega + \bar{\rho}D_\omega^H)$, i.e.,

$$T_{0,0}^{-1,-1}[\mathbf{c}_1\ \mathbf{c}_2 \cdots \mathbf{c}_n] = [\mathbf{c}_1\ \mathbf{c}_2 \cdots \mathbf{c}_n]\,\mathrm{diag}\left(2\cos\frac{\pi(2j-1)}{n}, \quad j = 1, \ldots, n\right). \tag{5.21}$$

As in the case of (5.6), the equalities (5.21) and (5.20) yield

$$T_{0,0}^{-1,-1}M_\mu = M_\mu\,\mathrm{diag}\left(2\cos\frac{\pi(2j-1)}{n}, \quad j = 1, \ldots, n\right),$$

$$\mu(\mathbf{e}_n)M_\mu = JM_\mu = M_\mu \begin{pmatrix} I & O \\ O & -I \end{pmatrix},$$

where I is the $m \times m$ identity matrix. Thus the matrix $M_\mu d(M_\mu^T \mathbf{z}) d(M_\mu^T \mathbf{e}_1)^{-1} M_\mu^H$ commutes with the matrices $T_{0,0}^{-1,-1}$ and J $\forall \mathbf{z} \in \mathbb{C}^n$. Moreover, as $M_\mu M_\mu^H = I$, its first row is $\mathbf{z}^T$ and therefore, by (4.11), we have $\mu(\mathbf{z}) = M_\mu d(M_\mu^T \mathbf{z}) d(M_\mu^T \mathbf{e}_1)^{-1} M_\mu^H$.

Finally, let us prove (5.13). This proof is analogous to the proof of the first equality in (5.12), which is in [5]. Notice that $D_\rho F = \frac{1}{\sqrt{n}} (M - \mathbf{i}N)$, where $[M]_{ij} = \cos \frac{\pi(i-1)(2j-1)}{n}$ and $[N]_{ij} = \sin \frac{\pi(i-1)(2j-1)}{n}$, $i, j = 1, \ldots, n$. Moreover, from the identities $(D_\rho F)^H D_\rho F = I$ and $(D_\rho F)^T D_\rho F = J$, we have

$$M^T M + N^T N = nI \quad \text{and} \quad M^T N + N^T M = 0,$$

respectively. Observe that $K_+ = \frac{1}{\sqrt{n}} (M + N)$ $\left[K_- = \frac{1}{\sqrt{n}} (M - N)\right]$. Thus, by the above equalities, $K_+^T K_+ = I$ $[K_-^T K_- = I]$. Moreover $M = MJ = -JP_{-1}M$ and $-N = NJ = -JP_{-1}N$; therefore, $K_+ J = -JP_{-1}K_+$ $[K_- J = -JP_{-1}K_-]$.

Let A be a generic (-1)-circulant matrix. We know that $(D_\rho F)^H A D_\rho F = D_A$, where D_A is a diagonal matrix and thus

$$\text{(5.22)} \qquad \mathrm{Re}D_A = \frac{1}{n}(M^T A M + N^T A N), \quad \mathrm{Im}D_A = \frac{1}{n} (N^T A M - M^T A N).$$

From (5.22) it follows that if A is a (-1)-circulant matrix, then

$$K_+^T A K_+ = \mathrm{Re}D_A - J\mathrm{Im}D_A \quad [K_-^T A K_- = \mathrm{Re}D_A + J\mathrm{Im}D_A].$$

Now let E be a generic element of $\mathcal{K} = C_{-1}^{\mathrm{S}} + JP_{-1}C_{-1}^{\mathrm{SK}}$ and assume that the entries of E are real, i.e., $E = E_{-1}^{\mathrm{S}} + JP_{-1}E_{-1}^{\mathrm{SK}}$, where E_{-1}^{S} is a real symmetric (-1)-circulant matrix and E_{-1}^{SK} is a real skewsymmetric (-1)-circulant matrix. Observe that the eigenvalues of E_{-1}^{S} is a real skewsymmetric (-1)-circulant matrix. Observe that the eigenvalues of E_{-1}^{S} and E_{-1}^{SK} are, respectively, real and purely imaginary. Thus

$$\begin{aligned} K_+^T E K_+ &= K_+^T E_{-1}^{\mathrm{S}} K_+ + K_+^T J P_{-1} E_{-1}^{\mathrm{SK}} K_+ = K_+^T E_{-1}^{\mathrm{S}} K_+ - J K_+^T E_{-1}^{\mathrm{SK}} K_+ \\ &= \mathrm{Re}D_{E_{-1}^{\mathrm{S}}} + \mathrm{Im}D_{E_{-1}^{\mathrm{SK}}} \\ &\left[K_-^T E K_- = \mathrm{Re}D_{E_{-1}^{\mathrm{S}}} - \mathrm{Im}D_{E_{-1}^{\mathrm{SK}}}\right]. \end{aligned}$$

We have proved that $K_\pm^T E K_\pm = d(\mathbf{z}_E^\pm)$ for some $\mathbf{z}_E^\pm \in \mathbb{R}^n$. The thesis, in the real case, follows from the equalities $\mathbf{e}_1^T E K_\pm = \mathbf{e}_1^T K_\pm d(\mathbf{z}_E^\pm) = \mathbf{z}_E^{\pm T} d(K_\pm^T \mathbf{e}_1) = \frac{1}{\sqrt{n}}\, \mathbf{z}_E^{\pm T}$. For the complex case, simply observe that if $\mathbf{z} \in \mathbb{C}^n$, then $\mathbf{z} = \mathbf{z}_1 + \mathbf{i}\mathbf{z}_2$, where $\mathbf{z}_1, \mathbf{z}_2 \in \mathbb{R}^n$, and that $\mathcal{K}(\mathbf{z}) = \mathcal{K}(\mathbf{z}_1 + \mathbf{i}\mathbf{z}_2) = \mathcal{K}(\mathbf{z}_1) + \mathbf{i}\mathcal{K}(\mathbf{z}_2)$. ∎

Remark. If n is an integer power of 2, then the *skew-Hartley* transform $\sqrt{n}\, K_\pm \mathbf{z}$ $(\sqrt{n}\, K_\pm^T \mathbf{z})$, $\mathbf{z} \in \mathbb{R}^n$, can be computed in at most $\frac{3}{2} n \log_2 n$ additions and $n \log_2 n$ multiplications of real numbers, i.e., with the same cost of the Hartley transform $\sqrt{n}\, H_\pm \mathbf{z}$. (For this last transform, see [5] and the references cited therein.) In fact, for $K_\pm^{(n)} = K_\pm$ we have

$$K_\pm^{(n)} = \frac{1}{\sqrt{2}} Q \begin{pmatrix} K_\pm^{\left(\frac{n}{2}\right)} & K_\pm^{\left(\frac{n}{2}\right)} \\ K_\pm^{\left(\frac{n}{2}\right)} R_\pm & -K_\pm^{\left(\frac{n}{2}\right)} R_\pm \end{pmatrix},$$

where $R_\pm = \mathrm{diag}(\cos \frac{(2j-1)\pi}{n}, j = 1, \ldots, \frac{n}{2}) \pm J\, \mathrm{diag}(\sin \frac{(2j-1)\pi}{n}, j = 1, \ldots, \frac{n}{2})$ and Q is the permutation matrix $Q\mathbf{e}_j = \mathbf{e}_{2j-1}$, $Q\mathbf{e}_{n-j+1} = \mathbf{e}_{n-2j+2}$, $j = 1, \ldots, \frac{n}{2}$. (For

$H_{\pm}^{(n)} = H_{\pm}$ an analogous identity holds, where $R_{\pm} = \operatorname{diag}(\cos \frac{2\pi(j-1)}{n},\ j = 1, \ldots, \frac{n}{2}) \pm JP_{\beta} \operatorname{diag}(\sin \frac{2\pi(j-1)}{n},\ j = 1, \ldots, \frac{n}{2})$.

If $H = 0$ and $w_{11} = [T^{-1}]_{11} \neq 0$, then $\mathbf{x}_1 = -(1/w_{11})P_0\mathbf{w}_1$ [25] (see also [16]). By exploiting this fact and the identities (5.6) and (5.7) in Theorem 5.2, formula (5.3) becomes

$$T^{-1} = \frac{1}{2w_{11}}\{\mu(\mathbf{w}_1)\eta(JP_1\mathbf{w}_1) - \mu(JP_{-1}\mathbf{w}_1)\eta(\mathbf{w}_1)\} \tag{5.23}$$

$$= \frac{1}{2w_{11}} M_{\mu}\{\Lambda(M_{\mu}^T\mathbf{w}_1)M_{\mu}^H M_{\eta}\Lambda(M_{\eta}^T JP_1\mathbf{w}_1)$$

$$- \Lambda(M_{\mu}^T JP_{-1}\mathbf{w}_1)M_{\mu}^H M_{\eta}\Lambda(M_{\eta}^T\mathbf{w}_1)\}M_{\eta}^H.$$

Observe that the vectors $\mathbf{z}$ in the four matrices $\Lambda(\mathbf{z})$ appearing in this last formula can be computed in $O(n)$ arithmetic operations once that $F\mathbf{w}_1$ and $FD_{\rho}\mathbf{w}_1$ are calculated (use the identities $F(JP_1)\mathbf{w}_1 = (JP_1)F\mathbf{w}_1$ and $FD_{\rho}(JP_{-1})\mathbf{w}_1 = -JFD_{\rho}\mathbf{w}_1$). Thus, if $\mathbf{w}_1$ is known, the vector $T^{-1}\mathbf{f}$, $\mathbf{f} \in \mathbb{C}^n$, can be computed by performing eight DFTs plus $\mathrm{O}(n)$ arithmetic operations.

In [1] Ammar and Gader obtain the same result by exploiting the representation in terms of circulant and (-1)-circulant matrices

$$T^{-1} = \frac{1}{2w_{11}}\{C_{-1}(\mathbf{w}_1)C(\mathbf{w}_1)^T + C_{-1}(\mathbf{w}_1)^T C(\mathbf{w}_1)\}, \tag{5.24}$$

which is a consequence of the following formula, holding for a *generic* nonsingular Toeplitz matrix $T = (t_{i-j})_{i,j=1}^n$,

$$T^{-1} = \frac{1}{2}\{C_{-1}(\hat{\mathbf{w}}_n)C(\mathbf{e}_1 - \hat{\mathbf{x}}_1) + C_{-1}(\mathbf{e}_1 + \hat{\mathbf{x}}_1)C(\hat{\mathbf{w}}_n)\}, \tag{5.25}$$

where $\mathbf{w}_n = T^{-1}\mathbf{e}_n$ and $T\mathbf{x}_1 = [t_1\ t_2 \cdots t_n]^T$, $t_n \in \mathbb{C}$ (see also [16]). Formulas of type (5.25), generalizing the Ammar–Gader formula (5.24), were first derived by Gohberg and Olshevsky in [20, 22]. Notice that, by using formula (5.25) or the analogous formulas in [20, 22], the product $T^{-1}\mathbf{f}$ for a generic T can be calculated with essentially 10 order n DFTs [21, 22], i.e., with the same amount of computation required to compute $(T+H)^{-1}\mathbf{f}$ for $T = T^T$ and $H = JHJ$ via (5.3). Both in (5.24), (5.25) and in (5.3), (5.23) the number of discrete transforms is 6 if the transforms of vectors not depending upon $\mathbf{f}$ are included in the preprocessing stage. Thus formulas (5.3) and (5.23) seem to be the analogues of the Ammar–Gader–Gohberg–Olshevsky-type formulas for the centrosymmetric Toeplitz-plus-Hankel case.

Acknowledgments. I wish to thank Professor Paolo Zellini for proposing the problem and for his comments and suggestions. I would also like to thank the referees for their useful comments.

CONVEXITY OF THE JOINT NUMERICAL RANGE*

CHI-KWONG LI† AND YIU-TUNG POON‡

Dedicated to Professor Yik-Hoi Au-Yeung on the occasion of his retirement.

Abstract. Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times n$ Hermitian matrices. For $1 \le k \le n$, the kth *joint numerical range* of A is defined by

$$W_k(A) = \{(\mathrm{tr}\,(X^*A_1X), \ldots, \mathrm{tr}\,(X^*A_mX)) : X \in \mathbf{C}^{n\times k}, X^*X = I_k\}.$$

We consider linearly independent families of Hermitian matrices $\{A_1, \ldots, A_m\}$ so that $W_k(A)$ is convex. It is shown that m can reach the upper bound $2k(n-k)+1$. A key idea in our study is relating the convexity of $W_k(A)$ to the problem of constructing rank k orthogonal projections under linear constraints determined by A. The techniques are extended to study the convexity of other generalized numerical ranges and the corresponding matrix construction problems.

Key words. convexity, numerical range, matrix constriction

1. Introduction.

Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times n$ Hermitian matrices. For $1 \le k \le n$, the kth *joint numerical range* of A is defined as

$$W_k(A) = \{(\mathrm{tr}\,(X^*A_1X), \ldots, \mathrm{tr}\,(X^*A_mX)) : X \in \mathbf{C}^{n\times k},\ X^*X = I_k\}.$$

When $k = 1$, it reduces to the usual joint numerical range of A that is useful in the study of various pure and applied subjects (see [2, 3, 4, 5, 7]). In particular, in the study of structured singular values arising in robust stability (see [6, 7, 15]), it is important that $W_1(A)$ is convex. Unfortunately, $W_1(A)$ is not always convex if $m > 3$ (see, e.g., [1]). We modify the example in [1] to show that the same conclusion holds for $W_k(A)$ in the following example.

Example 1.1. Let $A_1 = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right) \oplus 0_{n-2}$, $A_2 = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) \oplus 0_{n-2}$, $A_3 = \left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right) \oplus 0_{n-2}$, $A_4 = I_2 \oplus 2I_{k-1} \oplus 0_{n-k-1}$, $A_j = I_n$ for all other $j \le m$. Then $W_k(A)$ is not convex.

Proof. Suppose $W_k(A)$ is convex. Note that $2k-1$ is the sum of the k largest eigenvalues of A_4. If $X \in \mathbf{C}^{n\times k}$ with $X^*X = I_k$ such that $\mathrm{tr}\,(X^*A_4X) = 2k-1$, then (see, e.g., [10]) the column space of X must be spanned by k eigenvectors of A_4 corresponding to the k largest eigenvalues. Thus, there exists a $k \times k$ unitary matrix V such that XV has columns $\alpha e_1 + \beta e_2, e_3, \ldots, e_{k+1}$, where $|\alpha|^2 + |\beta|^2 = 1$. Then one can check that the subset

$$S = \{(a_1, \ldots, a_m) \in W_k(A) : a_4 = 2k-1\} = \{(a, b, c, 2k-1, k, \ldots, k) : a^2+b^2+c^2 = 1\}$$

of $W_k(A)$ is not convex, which is a contradiction. ∎

Apart from these negative results, one would still hope to get the convexity conclusion if A has some special structure. In this paper, we consider linearly independent

families $\{A_1, \ldots, A_m\}$ so that $W_k(A)$ is convex. In particular, we show that the maximum value of m is $2k(n-k)+1$, which is much larger than 3 as ensured by the general theorem (see [2]).

A key idea in our study is to view $W_k(A)$ as the image of the set of all rank k projections under the linear map

$$\phi(P) = (\operatorname{tr} A_1 P, \ldots, \operatorname{tr} A_m P).$$

To make this claim precise, denote by

$$\mathcal{U}(C) = \{U^* C U : U^* U = I_n\}$$

the *unitary similarity orbit* of a given Hermitian matrix C. If

$$J_k = I_k \oplus 0_{n-k},$$

then $\mathcal{U}(J_k)$ is the set of rank k orthogonal projections. Since a matrix P belongs to $\mathcal{U}(J_k)$ if and only if $P = XX^*$ for some $X \in \mathbf{C}^{n\times k}$ satisfying $X^*X = I_k$, we have

$$W_k(A) = \{(\operatorname{tr} A_1 P, \ldots, \operatorname{tr} A_m P) : P \in \mathcal{U}(J_k)\}.$$

Thus, $W_k(A)$ is just the image of $\mathcal{U}(J_k)$ under the linear projection onto the linear space spanned by $\{A_1, \ldots, A_m\}$. With this new formulation of $W_k(A)$, its convex hull can be written as

$$\operatorname{conv} W_k(A) = \{(\operatorname{tr} A_1 X, \ldots, \operatorname{tr} A_m X) : X \in \operatorname{conv} \mathcal{U}(J_k)\}.$$

Consequently, we have the following theorem.

THEOREM 1.2. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times n$ Hermitian matrices. Then $W_k(A)$ is convex if and only if for any $X \in \operatorname{conv} \mathcal{U}(J_k)$ there exists $P \in \mathcal{U}(J_k)$ so that $\operatorname{tr} A_j P = \operatorname{tr} A_j X$ for all $j = 1, \ldots, m$.*

This rather simple observation turns out to be very useful in our study. Moreover, if $A_1, \ldots, A_m$ are chosen from the standard basis for $n \times n$ Hermitian matrices, then the constraints $\operatorname{tr} A_j P = \operatorname{tr} A_j X$ for all $j = 1, \ldots, m$, are just specifications of certain entries of P. Thus, the problem reduces to construction of a rank k orthogonal projection P with some specified entries.

We shall use $\{E_{11}, E_{12}, \ldots, E_{nn}\}$ to denote the standard basis for $\mathbf{C}^{n\times n}$ in our discussion. Moreover, the following observations will be used frequently:

1. $W_k(A) = W_k(V^* A_1 V, \ldots, V^* A_m V)$ for any unitary V.
2. $W_k(A)$ is convex if and only if $W_k(I, A_1, \ldots, A_m)$ is convex.
3. Let $\{B_1, \ldots, B_s\}$ be a basis for $\operatorname{span}\{A_1, \ldots, A_m\}$. Then $W_k(A)$ is convex if and only if $W_k(B_1, \ldots, B_s)$ is convex.
4. Suppose $W_k(A)$ is convex. If $B_j \in \operatorname{span}\{I, A_1, \ldots, A_m\}$ for $1 \le j \le s$, then $W_k(B_1, \ldots, B_s)$ is convex.

2. The *k*th numerical range and orthogonal projections. In this section, we study linearly independent families $\{A_1, \ldots, A_m\}$ for which $W_k(A_1, \ldots, A_m)$ is convex. We call such a family a *linearly independent convex family* for the kth numerical range. In particular, we would like to study maximal (in the sense of set inclusion) linearly independent convex families.

We begin with the following result on the completion of a certain partial Hermitian matrix to a rank k orthogonal projection.

THEOREM 2.1. *Let $1 \le k < n$ and $X \in \mathbf{C}^{k\times(n-k)}$. There exists a rank k orthogonal projection of the form $\left(\begin{smallmatrix} * & X \\ X^* & * \end{smallmatrix}\right)$ if and only if $\|X\| \le 1/2$.*

Proof. Suppose X is an off-diagonal submatrix of a rank k orthogonal projection. Then $\|X\| \le 1/2$ by the result in [12]. For the converse, let $m = \min\{k, n-k\}$. Suppose $2X$ has singular value decomposition UDV, where U and V are unitary and

$$D_{rs} = \begin{cases} \sin t_r & \text{if } r = s \le m, \\ 0 & \text{otherwise,} \end{cases}$$

with $\pi/2 \ge t_1 \ge \cdots \ge t_m \ge 0$. Set

$$P = \begin{cases} U\,\mathrm{diag}\,(1+\cos t_1, \ldots, 1+\cos t_k)U^*/2 & \text{if } k \le n/2, \\ U(\mathrm{diag}\,(1+\cos t_1, \ldots, 1+\cos t_m) \oplus I_{2k-n})U^*/2 & \text{otherwise,} \end{cases}$$

and

$$Q = \begin{cases} V^*(\mathrm{diag}\,(1-\cos t_1, \ldots, 1-\cos t_k) \oplus 0_{n-2k})V/2 & \text{if } k \le n/2, \\ V^*\mathrm{diag}\,(1-\cos t_1, \ldots, 1-\cos t_m)V/2 & \text{otherwise.} \end{cases}$$

One easily checks that $\left(\begin{smallmatrix} P & X \\ X^* & Q \end{smallmatrix}\right)$ is a rank k orthogonal projection. ∎

Clearly, the set of $k \times (n-k)$ matrices X satisfying $\|X\| \le 1/2$ is convex. By observations 1 and 2, we have the following result.

THEOREM 2.2. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times n$ Hermitian matrices. Suppose $1 \le k < n$ and*

$$\mathcal{S} = \left\{ \alpha I + \begin{pmatrix} 0 & X \\ X^* & 0 \end{pmatrix} : \alpha \in \mathbf{R},\ X \in \mathbf{C}^{k\times(n-k)} \right\}.$$

If there exists a unitary U such that $U^*A_jU \in \mathcal{S}$ for all j, then $W_k(A)$ is convex.

Let $1 \le k < n$. Since all matrices in $\mathcal{U}(J_k)$ have Frobenius norm equal to $\sqrt{k}$, the set $\mathcal{U}(J_k)$ is highly nonconvex in the sense that no three points in $\mathcal{U}(J_k)$ are collinear [18]. It is somewhat surprising that the projection of $\mathcal{U}(J_k)$ to a subspace of dimension $2k(n-k)+1$ can be convex. In particular, if $n = 2k$, then $2k(n-k)+1 = n^2/2+1$, which is more than half of the dimension of the space of $n \times n$ Hermitian matrices! In any event, we have the following result showing that $2k(n-k)+1$ is indeed the upper limit.

THEOREM 2.3. *The unitary orbit $\mathcal{U}(J_k)$ is a homogeneous manifold, and the tangent space at J_k equals*

$$\{i(HJ_k - J_kH) : H = H^*\} = \left\{ \begin{pmatrix} 0 & X \\ X^* & 0 \end{pmatrix} : X \in \mathbf{C}^{k\times(n-k)} \right\},$$

which has dimension $2k(n-k)$. Consequently, if $A = (A_1, \ldots, A_m)$ is such that

$$\dim\,(\mathrm{span}\,\{I, A_1, \ldots, A_m\}) > 2k(n-k)+1,$$

then $W_k(A)$ is not convex.

Proof. The set $\mathcal{U}(J_k)$ is the orbit of J_k under the group action $(U, C) \mapsto U^*CU$ for any unitary U and Hermitian C. Thus $\mathcal{U}(J_k)$ is a homogeneous manifold.

Since every unitary matrix admits a representation of the form e^{iH} for some Hermitian H, every smooth path of unitary matrices $U(t)$, $-1 \le t \le 1$, $U(0) = I$, is

of the form $U(t) = e^{iH(t)}$, where $H(t)$, $-1 \le t \le 1$, is a smooth path of Hermitian matrices such that $H(0) = 0$. Thus we have

$$\left.\frac{d(e^{iH(t)}J_k e^{-iH(t)})}{dt}\right|_{t=0} = i(H'(0)J_k - J_k H'(0))$$

and the tangent space of $\mathcal{U}(J_k)$ at J_k is equal to

$$\{i(HJ_k - J_k H) : H = H^*\} = \left\{ \begin{pmatrix} 0 & X \\ X^* & 0 \end{pmatrix} : X \in \mathbf{C}^{k\times(n-k)} \right\},$$

which has dimension $2k(n-k)$.

Let $A = (A_1, \ldots, A_m)$ and $\mathcal{S} = \operatorname{span}\{I, A_1, \ldots, A_m\}$ with $\dim \mathcal{S} > 2k(n-k)+1$. We prove that $W_k(A)$ is not convex. Suppose $W_k(A)$ is indeed convex. By observation 4, we can find a linearly independent subset $\{I, B_1, \ldots, B_s\}$ of $\{I, A_1, \ldots, A_m\}$ with $s = 2k(n-k)+1$ such that $W_k(B_1, \ldots, B_s)$ is also convex.

We claim that $W_k(B_1, \ldots, B_s)$ has a nonempty interior in $\mathbf{R}^s$. If this isn't true, then the convex set $W_k(B_1, \ldots, B_s)$ must lie in a certain hyperplane

$$\mathcal{P} = \{v \in \mathbf{R}^s : v^t w = d\},$$

for some unit vector $w = (w_1, \ldots, w_s)^t \in \mathbf{R}^s$ and $d \in \mathbf{R}$. But then we have

$$\operatorname{tr}\left(\left(\sum_{j=1}^{s} w_j B_j\right) X\right) = d$$

for all $X \in \mathcal{U}(J_k)$, i.e., $W_k(\sum_{j=1}^s w_j B_j) = \{d\}$. It follows that (see [10]) $\sum_{j=1}^s w_j B_j = dI/k$, contradicting the fact that $\{I, B_1, \ldots, B_s\}$ is linearly independent.

Now $\mathcal{U}(J_k)$ is a homogeneous manifold of (real) dimension $2k(n-k)$ and $\phi(\mathcal{U}(J_k)) = W_k(B_1, \ldots, B_s)$ with

$$\phi(P) = (\operatorname{tr} B_1 P, \ldots, \operatorname{tr} B_s P).$$

The set $W_k(B_1, \ldots, B_s) \subseteq \mathbf{R}^s$ with $s = 2k(n-k)+1$ cannot have a nonempty interior. So, the assumption that $\dim \mathcal{S} > 2k(n-k)+1$ cannot be true. □

By the last two theorems, we see that a basis for the tangent space of $\mathcal{U}(J_k)$ at any point, together with the identity matrix, form a maximal linearly independent convex family for the kth generalized numerical range.

Next we turn to other linearly independent families $\{A_1, \ldots, A_m\}$ so that $W_k(A)$ is convex. By the result in [14], we have the following theorem.

THEOREM 2.4. *Let $1 \le k \le n/2$ and $P \in \mathbf{C}^{k\times k}$ be Hermitian. Then there exists a rank k orthogonal projection of the form $\begin{pmatrix} P & * \\ * & * \end{pmatrix}$ if and only if all eigenvalues of P lie in $[0,1]$.*

Clearly, the set of matrices $P \in \mathbf{C}^{k\times k}$ with eigenvalues lying in $[0,1]$ is convex. Using Theorem 1.2, observations 1 and 2, we obtain the following theorem.

THEOREM 2.5. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of Hermitian matrices. Suppose*

$$\mathcal{S} = \{P \oplus \alpha I_{n-k} : \alpha \in \mathbf{R},\ P \text{ is } k \times k \text{ Hermitian }\}.$$

If there exists a unitary U such that $U^* A_j U \in \mathcal{S}$ for all j, then $W_k(A)$ is convex.

3. Convex families for the first joint numerical range. We first identify a maximal linearly independent convex family for the first joint numerical range which is different from those constructed in the previous section.

THEOREM 3.1. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of Hermitian matrices. Suppose*

$$\mathcal{S} = \text{span}\,(\{E_{jj} : 1 \le j \le n\} \cup \{E_{j,j+1} + E_{j+1,j} : 1 \le j \le n-1\}).$$

If there exists a unitary U such that $U^* A_j U \in \mathcal{S}$ for all j, then $W_1(A)$ is convex.

Proof. Let $A = (A_1, \ldots, A_{2n-1})$ so that $A_j = E_{jj}$ for $1 \le j \le n$ and $A_{n+j} = (E_{j,j+1} + E_{j+1,j})/2$ for $1 \le j \le n-1$. Then $(x_1, \ldots, x_{2n-1}) \in W_1(A)$ if and only if there is a unit vector $v = (v_1, \ldots, v_n)^t \in \mathbf{C}^n$ such that

$$\begin{aligned} x_j &= |v_j|^2, && \text{if } 1 \le j \le n, \\ x_{n+j} &= (v_j \bar{v}_{j+1} + \bar{v}_j v_{j+1})/2, && \text{if } 1 \le j < n. \end{aligned}$$

These conditions hold if and only if $(x_1, \ldots, x_{2n-1})$ satisfies

$$\sum_{j=1}^{n} x_j = 1, \quad x_j \ge 0 \ \text{ for } 1 \le j \le n, \ \text{ and}$$

$$|x_{n+j}|^2 \le x_j x_{j+1} \text{ for } 1 \le j \le n-1.$$

Now suppose that $x = (x_1, \ldots, x_{2n-1})$, $y = (y_1, \ldots, y_{2n-1}) \in W_1(A)$, and $z = (z_1, \ldots, z_{2n-1})$ equals $(x+y)/2$. Clearly, we have

$$\sum_{j=1}^{n} z_j = 1, \quad z_j \ge 0 \ \text{ for } \ j = 1, \ldots, n.$$

Moreover, for $j = 1, \ldots, n-1$,

$$4|z_{n+j}|^2 = |x_{n+j} + y_{n+j}|^2 \le (\sqrt{x_j x_{j+1}} + \sqrt{y_j y_{j+1}})^2 \le (x_j + y_j)(x_{j+1} + y_{j+1}).$$

Hence $z \in W_1(A)$. Since $W_1(A)$ is closed, we conclude that it is a convex set. ∎

A result of Horn [8] implies that $W_1(E_{11}, E_{22}, \ldots, E_{nn})$ is convex. Theorem 3.1 strengthens this statement.

Note that a maximal linearly independent convex family of the first joint numerical range may not have $2(n-1)+1$ elements as shown in the following example.

Example 3.2. Suppose $(k, n) = (1, 3)$. Then $\{I_3, A_1, A_2, A_3\}$ with

$$A_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \ A_2 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \ A_3 = \begin{pmatrix} 0 & i & 0 \\ -i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

is a maximal linearly independent convex family for $W_1(A)$.

Proof. Suppose there exists A_4 such that $\{I, A_1, \ldots, A_4\}$ is linearly independent and $W_1(I_3, A_1, \ldots, A_4)$ is convex. One may replace A_4 by a matrix of the form $A_4 - (a_0 I_3 + a_1 A_1 + a_2 A_2 + a_3 A_3)$ so that the leading 2×2 principal submatrix is zero. Since $W_1(I_3, A_1, \ldots, A_4)$ is convex if and only if $W_1(A)$ is convex with $A = (A_1, \ldots, A_4)$, we can focus on $W_1(A) \subseteq \mathbf{R}^4$. Using the unit vectors $(1, 0, 0)^t$ and $(0, 1, 0)^t$, we see

that $(1,0,0,0),(-1,0,0,0) \in W_1(A)$. By convexity, we see that $(0,0,0,0) \in W_1(A)$. One easily checks that a unit vector giving rise to the point $(0,0,0,0) \in W_1(A)$ must be of the form $(0,0,\mu) \in \mathbf{C}^3$. As a result, the $(3,3)$ entry of A_4 must be 0. Let U be a unitary matrix of the form $U = \hat{U} \oplus [1]$ so that $\hat{A}_4 = U^* A_4 U = E_{13} + E_{31}$. Then

$$\operatorname{span}\{A_1, A_2, A_3, \hat{A}_4\} = \operatorname{span}\{U^* A_j U : 1 \le j \le 4\}.$$

Thus $W_1(A)$ is convex if and only if $W_1(\hat{A})$ is convex, where $\hat{A} = (A_1, A_2, A_3, \hat{A}_4)$. Note that

$$W_1(\hat{A}) = \left\{ \begin{array}{c} (|v_1|^2 - |v_2|^2, v_1\bar{v}_2 + v_2\bar{v}_1, i(v_2\bar{v}_1 - v_1\bar{v}_2), v_1\bar{v}_3 - v_3\bar{v}_1) : \\ v_1, v_2, v_3 \in \mathbf{C}, \sum_{j=1}^3 |v_j|^2 = 1 \end{array} \right\}.$$

Using the unit vectors $(1/2, \pm 1/2, 1/\sqrt{2})^t$, we see that $(0, \pm 1/2, 0, 1/\sqrt{2}) \in W_1(\hat{A})$. However, their midpoint $(0,0,0,1/\sqrt{2}) \notin W_1(\hat{A})$, which is a contradiction. ∎

In connection with the above discussion, it would be interesting to solve the following problems.

Problem 3.3. Characterize maximal linearly independent convex families for the first (or the kth) joint numerical range.

Problem 3.4. Determine maximal linearly independent convex families with the smallest number of elements.

4. A theorem on nonconvexity. Let $n \ge 3$. Then there exists a 4-tuple A of $n \times n$ Hermitian matrices such that $W_1(A)$ is not convex as mentioned in the introduction. Suppose A_1, A_2, A_3 are $n \times n$ Hermitian matrices such that $\{I, A_1, A_2, A_3\}$ is linearly dependent, say, $\operatorname{span}\{I, A_1, A_2, A_3\} = \operatorname{span}\{I, A_1, A_2\}$. Then for any Hermitian matrix A_4, $W(A_1, A_2, A_4)$ is convex, and so is $W(I, A_1, A_2, A_3, A_4)$ by observations 2 and 3.

In the following, we show that as long as $\{I, A_1, A_2, A_3\}$ is linearly independent, one can find A_4 so that $W_1(A_1, A_2, A_3, A_4)$ is not convex. We first establish the following auxiliary result, which is of independent interest.

THEOREM 4.1. *Let A_1, A_2, A_3 be $n \times n$ Hermitian matrices. If $\{I, A_1, A_2, A_3\}$ is linearly independent, then there exists $X \in \mathbf{C}^{n\times 2}$ with $X^*X = I_2$ such that $\{I_2, X^*A_1X, X^*A_2X, X^*A_3X\}$ is linearly independent.*

Proof. We assume that $n > 2$ to avoid trivial consideration. Since I, A_1, A_2 are linearly independent, the complex matrix $A_1 + iA_2$ cannot be written as $\alpha H + \beta I$ for any $\alpha, \beta \in \mathbf{C}$ and Hermitian matrix H. By [14, Theorem 3.5], there exists $X \in \mathbf{C}^{n\times 2}$ such that $X^*(A_1 + iA_2)X$ is not normal. By [9, Lemma 1.3.1], we may assume that $X^*(A_1 + iA_2)X$ has equal diagonal entries $\gamma_1 + i\gamma_2$ with $\gamma_1, \gamma_2 \in \mathbf{R}$. Replace A_1 and A_2 by suitable linear combinations of $A_1 - \gamma_1 I$ and $A_2 - \gamma_2 I$; we may assume that

$$X^*A_1X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad X^*A_2X = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}.$$

If $\{I_2, X^*A_1X, X^*A_2X, X^*A_3X\}$ is linearly independent, then we are done. If not, we may replace A_3 by a suitable linear combination of I, A_1, A_2, A_3 so that $X^*A_3X = 0$ and $\{I, A_1, A_2, A_3\}$ is still linearly independent. Since $A_3 \ne 0$, there exists $Y = [X|y] \in \mathbf{C}^{n\times 3}$ such that $Y^*Y = I_3$ and

$$\hat{A}_1 = Y^*A_1Y = \begin{pmatrix} 0 & 1 & a_1 \\ 1 & 0 & a_2 \\ \bar{a}_1 & \bar{a}_2 & a_3 \end{pmatrix}, \quad \hat{A}_2 = Y^*A_2Y = \begin{pmatrix} 0 & i & b_1 \\ -i & 0 & b_2 \\ \bar{b}_1 & \bar{b}_2 & b_3 \end{pmatrix},$$

$$\text{and} \qquad \hat{A}_3 = Y^* A_3 Y = \begin{pmatrix} 0 & 0 & c_1 \\ 0 & 0 & c_2 \\ \bar{c}_1 & \bar{c}_2 & c_3 \end{pmatrix} \neq 0.$$

We may assume that $c_2 \geq |c_1|$; otherwise, we may replace $\hat{A}_3$ by $D^* \hat{A}_3 D$ with $D = \text{diag}(1, \mu, 1)$ or $D = \left(\begin{smallmatrix} 0 & \mu \\ 1 & 0 \end{smallmatrix}\right) \oplus [1]$ for some suitable $\mu \in \mathbf{C}$ with $|\mu| = 1$. One can then replace $\hat{A}_1$ and $\hat{A}_2$ by suitable linear combinations of $D^* \hat{A}_1 D$ and $D^* \hat{A}_2 D$, and assume that $\hat{A}_1$ and $\hat{A}_2$ are still of the form in the display.

Now consider $P = \left(\begin{smallmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & \sin\theta \end{smallmatrix}\right)^t$ with $\theta \in (0, \pi/2)$. Then

$$P^* A_1 P = \sin\theta \begin{pmatrix} 0 & \cot\theta + a_1 \\ \cot\theta + \bar{a}_1 & (a_2 + \bar{a}_2)\cos\theta + a_3 \sin\theta \end{pmatrix},$$

$$P^* A_2 P = \sin\theta \begin{pmatrix} 0 & i\cot\theta + b_1 \\ -i\cot\theta + \bar{b}_1 & (b_2 + \bar{b}_2)\cos\theta + b_3 \sin\theta \end{pmatrix},$$

$$P^* A_3 P = \sin\theta \begin{pmatrix} 0 & c_1 \\ \bar{c}_1 & 2c_2 \cos\theta + c_3 \sin\theta \end{pmatrix}.$$

We claim that there exists $\theta \in (0, \pi/2)$ such that $\{I_2, P^* \hat{A}_1 P, P^* \hat{A}_2 P, P^* \hat{A}_3 P\}$ is linearly independent, and hence the conclusion of the theorem follows. Since all the $(1,1)$ entries of $P^* \hat{A}_1 P$, $P^* \hat{A}_2 P$, and $P^* \hat{A}_3 P$ equal 0, I_2 is not a linear combination of these three matrices. To establish our claim, we need only show that there exists $\theta \in (0, \pi/2)$ such that $P^* \hat{A}_1 P$, $P^* \hat{A}_2 P$, and $P^* \hat{A}_3 P$ are linearly independent. To this end, construct the following matrix B, whose rows contain the real and imaginary parts of the entries of $P^* \hat{A}_j P$:

$$B = \sin\theta \begin{pmatrix} \cot\theta + (a_1 + \bar{a}_1)/2 & i(\bar{a}_1 - a_1)/2 & (a_2 + \bar{a}_2)\cos\theta + a_3 \sin\theta \\ (b_1 + \bar{b}_1)/2 & \cot\theta + i(\bar{b}_1 - b_1)/2 & (b_2 + \bar{b}_2)\cos\theta + b_3 \sin\theta \\ (c_1 + \bar{c}_1)/2 & i(\bar{c}_1 - c_1)/2 & 2c_2 \cos\theta + c_3 \sin\theta \end{pmatrix}.$$

Now,

$$\det(B)/\sin^4\theta = \det \begin{pmatrix} \cot\theta + (a_1 + \bar{a}_1)/2 & i(\bar{a}_1 - a_1)/2 & (a_2 + \bar{a}_2)\cot\theta + a_3 \\ (b_1 + \bar{b}_1)/2 & \cot\theta + i(\bar{b}_1 - b_1)/2 & (b_2 + \bar{b}_2)\cot\theta + b_3 \\ (c_1 + \bar{c}_1)/2 & i(\bar{c}_1 - c_1)/2 & 2c_2 \cot\theta + c_3 \end{pmatrix}$$

can be viewed as $p(\cot\theta)$ for some real polynomial p of degree 3. If $\det(B) = 0$ for all $\theta \in (0, \pi/2)$, then the coefficient of $\cot^3\theta$ in $p(\cot\theta)$ is 0, which is just $2c_2$ by expanding $\det(B)/\sin^4\theta$. Since $c_2 \geq |c_1|$, we see that $c_1 = 0$ as well. Now, consider the coefficient of $\cot^2\theta$ in $p(\cot\theta)$, which is just c_3. Again, it has to be 0. It follows that $\hat{A}_3 = 0$, which is a contradiction. ∎

Now we are ready to state the nonconvexity result of the joint numerical range.

THEOREM 4.2. *Suppose A_1, A_2, A_3 are $n \times n$ Hermitian matrices such that $\{I, A_1, A_2, A_3\}$ is linearly independent. Then there exists an $n \times n$ Hermitian matrix A_4 such that $W_1(A_1, A_2, A_3, A_4)$ is not convex.*

Proof. By the previous theorem, there exists $X \in \mathbf{C}^{n \times 2}$ such that $X^* X = I_2$ and $\{I_2, X^* A_1 X, X^* A_2 X, X^* A_3 X\}$ is linearly independent. Let $A_4 = XX^*$. Then by [11, Lemma 4.1] we have $(a, b, c, 1) \in W_1(A_1, A_2, A_3, A_4)$ if and only if $(a, b, c) \in W_1(X^* A_1 X, X^* A_2 X, X^* A_3 X)$, which is not convex [1]. The result follows. ∎

We remark that Theorem 4.1 and its proof can be easily modified to deal with infinite dimensional self-adjoint operators A_1, A_2, A_3. In general, it is interesting to solve the following problem.

Problem 4.3. If a linearly independent family $\{A_1, \ldots, A_m\}$ of (finite- or infinite-dimensional) self-adjoint operators is given, where $(r-1)^2 < m \le r^2$, does there exist an X such that $X^*X = I_r$ and $\{X^*A_jX : j = 1, \ldots, m\}$ is linearly independent?

By private communication, Doug Farenick pointed out that this problem can be studied in the context of unital completely positive maps on C^*-algebras.

5. Related results and questions. There are many variations of our problems. We mention a few of them in what follows.

5.1. Real symmetric matrices. In applications, one often has to consider real symmetric matrices instead of complex Hermitian matrices. One can modify the results and proofs on complex Hermitian matrices and get the following analogues for real symmetric matrices.

THEOREM 5.1. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of real symmetric matrices. Suppose $1 \le k \le n/2$ and*

$$\mathcal{S} = \left\{ \alpha I + \begin{pmatrix} 0_k & X \\ X^t & 0_{n-k} \end{pmatrix} : \alpha \in \mathbf{R},\ X \in \mathbf{R}^{k\times(n-k)} \right\},$$

or

$$\mathcal{S} = \{ P \oplus \alpha I_{n-k} : \alpha \in \mathbf{R},\ P \text{ is } k \times k \text{ real symmetric} \}.$$

If there is a real orthogonal Q such that $Q^tA_jQ \in \mathcal{S}$, then $W_k(A)$ is convex.

THEOREM 5.2. *The orthogonal similarity orbit $\mathcal{O}(J_k)$ is a homogeneous manifold, and the tangent space at J_k equals*

$$\{(KJ_k - J_kK) : K = -K^t\} = \left\{ \begin{pmatrix} 0 & X \\ X^t & 0 \end{pmatrix} : X \in \mathbf{R}^{k\times(n-k)} \right\},$$

which has dimension $k(n-k)$. Consequently, if $A = (A_1, \ldots, A_m)$ such that

$$\dim(\operatorname{span}\{I, A_1, \ldots, A_m\}) > k(n-k) + 1,$$

then $W_k(A)$ is not convex.

By this theorem and a result of Horn [8], we have the following corollary.

COROLLARY 5.3. *The elements of $A = (E_{11}, E_{22}, \ldots, E_{nn})$ form a maximal linearly independent convex family for $W_1(A)$.*

5.2. Rectangular matrices. Suppose $A = (A_1, \ldots, A_m)$, where $A_1, \ldots, A_m$ are $n \times r$ matrices over $\mathbf{F} = \mathbf{R}$ or $\mathbf{C}$. To be specific, we assume that $n \le r$ in our discussion. Otherwise, consider the transposes of $A_1, \ldots, A_m$. For $1 \le k \le n$, define

$$V_k(A) = \left\{ \left(\sum_{j=1}^{k} x_j^* A_i y_j \right)_{i=1}^{m} : \begin{matrix} \{x_1, \ldots, x_k\} \text{ is an orthonormal set of } \mathbf{F}^n \\ \{y_1, \ldots, y_k\} \text{ is an orthonormal set of } \mathbf{F}^r \end{matrix} \right\},$$

which is a subset of $\mathbf{F}^m$. Let $\mathcal{V}_k$ be the collection of $n \times r$ matrices X such that X^*X is a rank k orthogonal projection. It is not hard to see that

$$V_k(A) = \{(\operatorname{tr} X^*A_1, \ldots, \operatorname{tr} X^*A_m) : X \in \mathcal{V}_k\}.$$

It was shown in [13, Theorems 14 and 41] that $V_k(A)$ is not convex in general if $m > 2$. Again, if $A_1, \ldots, A_m$ belong to a certain subset, then one can get convexity for a much larger m as shown in the following result.

THEOREM 5.4. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times r$ matrices. Suppose*

$$\mathcal{S} = \left\{ \begin{pmatrix} X & 0 \\ 0 & 0 \end{pmatrix} \in \mathbf{F}^{n\times r} : X \in \mathbf{F}^{p\times q} \right\},$$

where $\min\{p, q\} \le k \le n + r - p - q$. If there exist square matrices U and V with $U^*U = I_n$ and $V^*V = I_r$ such that $UA_jV \in \mathcal{S}$ for all j, then $V_k(A)$ is convex.

The proof of this theorem depends on the following theorem.

THEOREM 5.5. *Let $(p, q) \le (n, r)$ in the entrywise sense, and $\min\{p, q\} \le k \le n + r - p - q$. Then a $p \times q$ matrix X can be embedded in an $n \times r$ matrix Y so that Y^*Y is a rank k orthogonal projection if and only if $\|X\| \le 1$. Hence, the collection of all such $X \in \mathbf{F}^{p\times q}$ is a convex set.*

Proof. By a result of Thompson [17] and our assumptions on the positive integers n, r, p, q, k, we see that a $p \times q$ matrix X with singular values $s_1 \ge \cdots \ge s_k$ can be embedded in an $n \times r$ matrix with the k largest singular values equal to 1 and the rest equal to 0 if and only if $s_i \le 1$. The result follows. □

Let $R_k = E_{11} + E_{22} + \cdots + E_{kk} \in \mathbf{F}^{n\times r}$. In the complex case, the tangent space of the manifold $\mathcal{V}_k$ at R_k is

$$\begin{aligned} \mathcal{T}(R_k) &= \{i(R_kH + GR_k) : H = H^*,\ G = G^*\} \\ &= \left\{ \begin{pmatrix} iX & Y \\ Z & 0_{(n-k)\times(r-k)} \end{pmatrix} : X = X^* \in \mathbf{C}^{k\times k} \right\} \end{aligned}$$

and has real dimension $k^2 + 2k(n + r - 2k)$. In the real case, the tangent space of the manifold $\mathcal{V}_k$ at R_k is

$$\begin{aligned} \mathcal{T}(R_k) &= \left\{R_kH + GR_k : H = -H^t,\ G = -G^t\right\} \\ &= \left\{ \begin{pmatrix} X & Y \\ Z & 0_{(n-k)\times(r-k)} \end{pmatrix} : X = -X^t \in \mathbf{R}^{k\times k} \right\} \end{aligned}$$

and has real dimension $k(k-1)/2 + k(n + r - 2k)$. It would be interesting to see whether one can construct a maximal linearly independent convex family for $V_k(A)$ of this size.

5.3. Complex symmetric matrices. Let $A = (A_1, \ldots, A_m)$, where $A_1, \ldots, A_m$ are $n \times n$ complex symmetric matrices. For $1 \le k \le n$, let $J_k = I_k \oplus 0_{n-k}$, and define

$$W_k^t(A) = \{(\operatorname{tr} J_kU^tA_1U, \ldots, \operatorname{tr} J_kU^tA_mU) : U^*U = I\}.$$

Then Theorem 5.1 is valid for the complex case. However, the tangent space of the manifold at J_k is

$$\begin{aligned} \mathcal{U}^t(J_k) &= \left\{i(J_kH + H^tJ_k) : H = H^*\right\} \\ &= \left\{ i \begin{pmatrix} X & Y \\ Y^t & 0_{n-k} \end{pmatrix} : X = X^t \in \mathbf{R}^{k\times k},\ Y \in \mathbf{C}^{k\times(n-k)} \right\} \end{aligned}$$

and has real dimension $k(k+1)/2 + 2k(n-k)$. It is interesting to know whether one can find a maximal linearly independent convex family for $W_k^t(A)$ of this size.

Note that one may consider $W_k^t(A)$ for an m-tuple of complex matrices $A = (A_1, \ldots, A_m)$. However, it is easy to check that $W_k^t(A)$ is the same as $W_k^t(\hat{A}_1, \ldots, \hat{A}_m)$, where $\hat{A}_j$ is the symmetric part of A_j for all j. For skew-symmetric matrices, one needs a different treatment, as shown in the next subsection.

5.4. Skew-symmetric matrices. Suppose $A_1, \ldots, A_m$ are skew-symmetric matrices over $\mathbf{F} = \mathbf{R}$ or $\mathbf{C}$. For $1 \le k \le n/2$, let $T_k = \left(\begin{smallmatrix} 0_k & I_k \\ -I_k & 0_k \end{smallmatrix}\right) \oplus 0_{n-2k}$, and define

$$W_k^t(A) = \{(\operatorname{tr} T_k U^t A_1 U, \ldots, \operatorname{tr} T_k U^t A_m U) : U^* U = I\}.$$

We have the following convexity theorem.

THEOREM 5.6. *Let $A = (A_1, \ldots, A_m)$ be an m-tuple of $n \times n$ skew-symmetric matrices. Suppose*

$$\mathcal{S} = \{E_{j,k+j} : j = 1, \ldots, k\}, \qquad \text{or}$$

$$\mathcal{S} = \left\{ \begin{pmatrix} 0_p & 0 & X \\ 0 & 0 & 0 \\ -X^t & 0 & 0_q \end{pmatrix} : X \in \mathbf{F}^{p \times q},\ \|X\| \le 1 \right\}$$

for some positive integers p and q such that $n - (p+q) \ge k \ge \min\{p, q\}$. If there exists a square matrix U with $U^*U = I_n$ such that $U^t A_j U \in \mathcal{S}$ for all j, then $W_k^t(A)$ is convex.

The proof of this theorem depends on the following two results. First we have the following (see [16] and its references).

THEOREM 5.7. *Let $(d_1, \ldots, d_k) \in \mathbf{F}^k$. There exists U with $U^*U = I_n$ such that the $(1, k+1), (2, k+2), \ldots, (k, 2k)$ entries of $U^t T_k U$ equal $d_1, \ldots, d_k$ if and only if $|d_j| \le 1$ for all j. Hence, the collection of such $(d_1, \ldots, d_k)$ forms a convex set.*

Note that the singular values of the matrix $\left(\begin{smallmatrix} 0_k & X \\ -X^t & 0_{n-k} \end{smallmatrix}\right)$ are just two copies of those of X. Applying the result on rectangular matrices to the $k \times (n-k)$ right top corner of a skew-symmetric matrix, we have the following result.

THEOREM 5.8. *Let p and q be positive integers with $n - (p+q) \ge k \ge \min\{p, q\}$. Then a $p \times q$ matrix X can be embedded in the right top corner of an $n \times n$ skew-symmetric matrix with the $2k$ largest singular values equal to 1 and the rest equal to 0 if $\|X\| \le 1$. Hence, the collection of all such X is a convex set.*

Acknowledgment. The first author would like to express his thanks to Professor M. D. Choi for making the visit to the University of Toronto possible and to the staff of the University of Toronto for their warm hospitality.

Note added in proof. Professor M. D. Choi pointed out that the answer of Problem 4.3 is negative. For instance, the 10×10 Hermitian matrices $A_j = E_{1j} + E_{j1}$, $j = 2, \ldots, 10$, are linearly independent, but it is impossible to have a 10×3 matrix V with $V^*V = I_3$ so that $\{V^* A_j V : j = 2, \ldots, 10\}$ is linearly independent. A modified problem would be the following: Given linearly independent Hermitian operators $A_1, \ldots, A_m$, find the smallest positive integer r so that there exists V with $V^*V = I_r$ for which the set $\{V^* A_j V : j = 1, \ldots, m\}$ is still linearly independent.

CONDITIONING OF RECTANGULAR VANDERMONDE MATRICES WITH NODES IN THE UNIT DISK*

FERMÍN S. V. BAZÁN†

Abstract. Let $W_N = W_N(z_1, z_2, \ldots, z_n)$ be a rectangular Vandermonde matrix of order $n \times N$, $N \geq n$, with distinct nodes z_j in the unit disk and z_j^{k-1} as its (j,k) entry. Matrices of this type often arise in frequency estimation and system identification problems. In this paper, the conditioning of W_N is analyzed and bounds for the spectral condition number $\kappa_2(W_N)$ are derived. The bounds depend on n, N, and the separation of the nodes. By analyzing the behavior of the bounds as functions of N, we conclude that these matrices may become well conditioned, provided the nodes are close to the unit circle but not extremely close to each other and provided the number of columns of W_N is large enough. The asymptotic behavior of both the conditioning itself and the bounds is analyzed and the theoretical results arising from this analysis verified by numerical examples.

Key words. Vandermonde matrices, singular values, almost normal matrices, exponential modeling

1. Introduction.

Let $W_N = W_N(z_1, z_2, \ldots, z_n)$ be a Vandermonde matrix of order $n \times N$, $N \geq n$, with distinct nonzero complex nodes in the unit disk and z_j^{k-1} as its (j,k) entry, that is,

$$W_N = W_N(z_1, z_2, \ldots, z_n) = \begin{bmatrix} 1 & z_1 & z_1^2 & \cdots & z_1^{N-1} \\ 1 & z_2 & z_2^2 & \cdots & z_2^{N-1} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & z_n & z_n^2 & \cdots & z_n^{N-1} \end{bmatrix}, \tag{1.1}$$

and let $\kappa_2(W_N) = \|W_N\|\|W_N^\dagger\|$ be its 2-norm condition number, where † stands for Moore–Penrose pseudoinverse. These matrices arise in approximation theory and polynomial interpolation, but their most frequent use is in the framework of signal processing.

The purpose of this work is to derive bounds for $\kappa_2(W_N)$ and to analyze their behavior for fixed $n, z_1, \ldots, z_n$ and increasing N. Motivation for this analysis can be encountered in problems related to frequency estimation, parameter identification, and quantitative analysis of time domain nuclear magnetic resonance (NMR) data, among others; see, for instance, Van Huffel [17], Van Huffel et al. [18], and Bazán and Bavastri [1]. For illustration purposes, suppose we have a set of data h_l ($l = 0, 1, \ldots M-1$) involving $2n$ unknown parameters $r_j, z_j \in \mathbb{C}$ through the model

$$h_l = r_1 z_1^l + r_2 z_2^l + \cdots + r_n z_n^l,$$

and suppose we wish to determine these parameters from the available data. This is a separable problem that can be solved as follows. First, note that if all z_j are available then the r_j can be estimated by solving the least squares problem

$$\min \|W_M^T r - h\|, \tag{1.2}$$

where T denotes the transpose of a matrix, W_M is as before, and $h \in \mathbb{C}^M$ contains the data h_l. The sensitivity of the r_j to perturbations in the data is governed by $\kappa_2(W_M)$. If both r_j and z_j are unknown instead, then one starts by finding first the z_j. For instance, these z_j can be found from the roots of a polynomial $p_N(z) = a_0 + a_1 z + \cdots + a_{N-1} z^{N-1} + z^N$, whose coefficients are computed by solving a least squares problem of type

$$\min \|Ha + b\|, \tag{1.3}$$

where H is an $L \times N$ Hankel matrix with h_{i+j-2} as its (i, j) entry, $n \le L, N \le M - n$, and $b = [h_N, h_{N+1}, \ldots, h_{N+L-1}]^T$ (Wei and Majda [19]). Once the z_j are found, the r_j are readily computed by solving (1.2). In this case, one can prove that the sensitivity of the roots z_j to perturbations in the coefficients depends on $\|W_N^\dagger\|$ (see, for instance, Bazán, Toint, and Zambaldi [4]), and once more $\kappa_2(W_N)$ is important.

Although there are many other applications in signal processing where $\kappa_2(W_N)$ plays a crucial role, little is known about the behavior of $\kappa_2(W_N)$ for $N > n$, which is in contrast with the well-known fact that square Vandermonde matrices are in general ill conditioned (see, e.g., Gautschi [7], Gautschi and Inglese [8], Cordoba, Gautschi, and Ruscheweyh [5], and Tyrtyshnikov [15]). This justifies our interest to analyze this condition number.

Rectangular Vandermonde matrices also appear in trigonometric polynomial interpolation problems, but we shall restrict ourselves to analyzing the conditioning of those Vandermonde matrices that appear implicitly in frequency estimation and parameter identification. The term *implicitly* is used because in these applications the nodes z_j are known only approximately: the z_j appear after preliminary computations involving data h_l that is noise corrupted. Thus, what we pursue is a theoretical prediction of the sensitivity of these problems to perturbations in the data rather than an effective computation of $\kappa_2(W_N)$.

An interesting feature often numerically observed in the above problems is that $\kappa_2(W_N)$ is substantially better than the bad condition number $\kappa_2(W_n)$ when N is large enough, but a mathematical explanation for this phenomenon is still lacking. In this paper, we intend to substantiate this observation by exhibiting lower and upper bounds for $\kappa_2(W_N)$ which say much about the condition number itself. The bounds depend on n, z_j, and N, and their quality essentially depends on the separation of the nodes in the unit disk. In particular, we show that the numbers $\kappa_2(W_N)$ become rather small for large N, provided the nodes are not extremely close to each other and of modulus not much smaller than one. On the other hand, to evaluate the quality of the bounds as N grows, we analyze the asymptotic value of both the bounds and the condition number itself as N grows infinitely. As a by-product, we obtain that if all $|z_j| = 1$, then the asymptotic value of the bounds is equal to 1.

The paper is organized as follows. In section 2 we describe preliminary background information. The main results are presented in section 3 where we derive our bounds and perform an analyzis about the behavior of them as N grows infinitely. In section 4 we describe some numerical results involving Vandermonde matrices related to signal processing applications. Finally, we present some conclusions in section 5.

2. An estimate for $\|\mathbf{W}_\mathbf{N}^\dagger\|$ and other preliminaries. In this section we perform a preliminary analysis of the behavior of $\|W_N^\dagger\|$ as a function of N and present a few basic results. In what follows the singular values of a matrix $A \in \mathbb{C}^{M\times N}$ are denoted by $\sigma_i(A)$ and arranged in increasing order, i.e., $\sigma_1(A) \geq \sigma_2(A) \geq \cdots \geq \sigma_q(A)$, where $q = \min(M, N)$. The spectrum of $A \in \mathbb{C}^{N\times N}$ is denoted by $\lambda(A)$. Also, $\|A\|$ and $\|A\|_F$ denote the spectral and the Frobenius norm of A, respectively; A^* denotes the transpose conjugate of A.

The following result, whose proof follows from the Rayleigh characterization of $\sigma_n^2(W_N)$ as an eigenvalue of $W_N W_N^*$, provides information about the behavior of $\|W_N^\dagger\|$ as a function of N.

THEOREM 1. *Let W_N be a Vandermonde matrix as in* (1.1) *but with distinct nodes in the complex plane. Then for $N > n$, $\|W_N^\dagger\|$ decreases monotonically with N and this decrease is strict along the subsequence $\{n, 2n, \ldots\}$. Moreover, if $N = p\cdot n$, $p \geq 1$, then*

$$\|W_{p\cdot n}^\dagger\| \leq \frac{\|W_n^{-1}\|}{\sqrt{1+\beta^{2n}+\beta^{4n}+\cdots+\beta^{2(p-1)n}}}, \tag{2.1}$$

where $\beta = \min|z_j|$, $j = 1, \ldots, n$.

This preliminary result suggests that, since $\|W_N^\dagger\|$ decreases monotonically with N, it is not unreasonable to expect improvements of $\kappa_2(W_N)$ as N increases, though the behavior of $\kappa_2(W_N)$ as a function of N may be not always monotonic, as illustrated in section 4. We also observe that the bound (2.1) as a function of N may be very pessimistic if W_n is very ill conditioned. In spite of this, it can be very useful for theoretical purposes as we illustrate below.

THEOREM 2. *Let $\widehat{f}_N$ be the minimum 2-norm solution of the underdetermined system*

$$W_N f = Z^N e,$$

where $Z = \operatorname{diag}(z_1, \ldots, z_n)$ and e is the vector in $\mathbb{R}^n$ of all ones. Suppose that all nodes z_j satisfy either $|z_j| = 1$ or $|z_j| < 1$; then, whenever $N \to \infty$ we have

$$\|\widehat{f}_N\| \to 0.$$

Proof. It is sufficient to note that $\|\widehat{f}_N\| = \|W_N^\dagger Z^N e\| \leq \|W_N^\dagger\|\sqrt{n}\alpha^N$, where $\alpha = \max_j|z_j|$, $j = 1, 2, \ldots, n$, and then to use Theorem 1. ∎

The vector $\widehat{f}_N$ we have just described appears in connection with linear prediction problems and autoregressive modeling of time series. It is currently referred to as *vector of predictor parameters*; see Bazán and Bezerra [2] or Cybenko [6] for details. In our context, it predicts the last column of W_{N+1}. This fact yields the following interesting relationship:

$$ZW_N = W_N\mathcal{F}_N, \tag{2.2}$$

where $\mathcal{F}_N$ is an $N \times N$ companion matrix of the form

$$\mathcal{F}_N = [e_2, e_3, \ldots, e_{N-1}, \widehat{f}_N],$$

in which e_i denotes the ith canonical vector in $\mathbb{R}^N$.

Define F_N by

$$F_N = V_N^* \mathcal{F}_N V_N, \tag{2.3}$$

where

$$V_N = W_N^*(W_N W_N^*)^{-1/2}.$$

Note that F_N is well defined for $W_N W_N^*$ is positive definite. Then the following result is obtained.

THEOREM 3. *The matrix F_N introduced in* (2.3) *has an eigenvalue decomposition given by*

$$F_N = Q_N Z Q_N^{-1}, \tag{2.4}$$

where $Q_N = (W_N W_N^*)^{-1/2}$. Furthermore, this eigenvector matrix satisfies $\kappa_2(Q_N) = \kappa_2(W_N)$.

Proof. The proof is straightforward. □

Much of our results concerning bounds for $\kappa_2(W_N)$ depend on the eigenvalue and singular value spectra of F_N. The following theorem characterizes the singular spectrum of F_N.

THEOREM 4. *Let F_N be as in* (2.3). *Then its singular spectrum is described by*

$$\begin{aligned}
\sigma_1^2(F_N) &= \frac{2 + \|\widehat{f}_N\|^2 - \|p_1\|^2 + \sqrt{(\|\widehat{f}_N\|^2 + \|p_1\|^2)^2 - 4|f_1|^2}}{2}, \\
\sigma_j^2(F_N) &= 1, \quad j = 2, n-1, \\
\sigma_n^2(F_N) &= \frac{2 + \|\widehat{f}_N\|^2 - \|p_1\|^2 - \sqrt{(\|\widehat{f}_N\|^2 + \|p_1\|^2)^2 - 4|f_1|^2}}{2},
\end{aligned} \tag{2.5}$$

where p_1 is the first column of $\mathcal{P}_N$, the orthogonal projector onto $\mathcal{R}(W_N^*)$, and f_1 the first component of the vector $\widehat{f}_N$ introduced in Theorem 2.

Proof. Using (2.4) we have that

$$F_N F_N^* = Q_N Z Q_N^{-2} Z^* Q_N = Q_N^* Z W_N W_N^* Z^* Q_N = V_N^* \mathcal{F}_N \mathcal{F}_N^* V_N,$$

where the last equality is because of (2.2). Since $\mathcal{F}_N$ is a companion matrix, this can be now rewritten as

$$F_N F_N^* = I + xx^* - yy^*, \tag{2.6}$$
