$$\frac{\hat{u}^{m+1} - \hat{u}^m}{\delta} + i\xi c_s^2\hat{n}^m + \frac{i}{\varepsilon^2\xi}\hat{n}^{m+1} = 0. \tag{3.15}$$

It is easy to see that this scheme can be recast into an implicit scheme for the wave-equation (3.4) expressed in Fourier variables, i.e.,

$$\partial_{tt}^2\hat{n} + c_s^2\xi^2\hat{n} + \frac{1}{\varepsilon^2}\hat{n} = 0. \tag{3.16}$$

Indeed, taking the time difference of (3.14) and combining it with (3.15) to eliminate the velocity leads to

$$\frac{\hat{n}^{m+1} - 2\hat{n}^m + \hat{n}^{m-1}}{\delta^2} + c_s^2\xi^2\hat{n}^m + \frac{1}{\varepsilon^2}\hat{n}^{m+1} = 0. \tag{3.17}$$

By contrast, let us consider the following explicit scheme for the wave-equation formulation:

$$\frac{\hat{n}^{m+1} - 2\hat{n}^m + \hat{n}^{m-1}}{\delta^2} + c_s^2 \xi^2 \hat{n}^m + \frac{1}{\varepsilon^2}\hat{n}^m = 0. \tag{3.18}$$

This scheme can be obtained by eliminating the velocity from the original formulation of the LEP system. Two schemes for the original LEP system lead to the same scheme (3.18). The first one is implicit in the mass flux and explicit in the momentum flux and in the source term:

$$\frac{\hat{n}^{m+1} - \hat{n}^m}{\delta} + i\xi \hat{u}^{m+1} = 0, \tag{3.19}$$

$$\frac{\hat{u}^{m+1} - \hat{u}^m}{\delta} + i\xi c_s^2 \hat{n}^m + \frac{i}{\varepsilon^2 \xi}\hat{n}^m = 0. \tag{3.20}$$

The second one is explicit in the mass flux and implicit in the momentum flux and the source term:

$$\frac{\hat{n}^{m+1} - \hat{n}^m}{\delta} + i\xi \hat{u}^m = 0, \tag{3.21}$$

$$\frac{\hat{u}^{m+1} - \hat{u}^m}{\delta} + i\xi c_s^2 \hat{n}^{m+1} + \frac{i}{\varepsilon^2 \xi}\hat{n}^{m+1} = 0. \tag{3.22}$$

We see that the schemes (3.14)–(3.15) and (3.19)–(3.20) are both implicit in the mass flux. The first one is also implicit in the source term while the second one is explicit. For these reasons, we shall refer to the first scheme as the II scheme (for implicit-implicit) while the second one is the IE scheme (for implicit-explicit). What the equivalence of scheme (3.21), (3.22) with the scheme (3.18) shows is that if the mass flux is taken to be explicit, there is no way to obtain a uniformly stable scheme, no matter how implicit one takes the momentum flux or the source term to be.

If additionally the momentum flux is taken as explicit and only the source term is taken as implicit, one is led to the following scheme:

$$\frac{\hat{n}^{m+1} - \hat{n}^m}{\delta} + i\xi \hat{u}^m = 0, \tag{3.23}$$

$$\frac{\hat{u}^{m+1} - \hat{u}^m}{\delta} + i\xi c_s^2 \hat{n}^m + \frac{i}{\varepsilon^2 \xi}\hat{n}^{m+1} = 0, \tag{3.24}$$

which is equivalently written in the wave-equation formulation as follows:

$$\frac{\hat{n}^{m+1} - 2\hat{n}^m + \hat{n}^{m-1}}{\delta^2} + c_s^2 \xi^2 \hat{n}^{m-1} + \frac{1}{\varepsilon^2}\hat{n}^m = 0. \tag{3.25}$$

In this scheme the mass flux is taken as explicit and the source term as implicit. For this reason, we call this scheme the EI scheme. We shall analyze the stability of this scheme in the next section in relation to decentered space-differencing. Indeed, we know already that with a centered space-differencing, the hydrodynamic part of this scheme will be unconditionally unstable and that it is unlikely that the implicit source term restores stability, and if it does so, it will do it only marginally.

For all the reasons previously exposed, in the remainder of this paper, we will always treat the momentum flux explicitly. We will consider various combinations of

explicit or implicit schemes for the mass flux and the source term, and the terminology will refer to these terms. For instance, the IE scheme refers to a scheme that is implicit in the mass flux but explicit in the source term.

Looking at the stability of a time-semidiscretized scheme in Fourier space gives a good indication of the behavior of a fully discretized scheme associated with a space-centered discretization. Indeed, the symbol of a space-centered discretization is purely imaginary, like the symbol of the continuous space derivative. Of course, there might exist some quantitative differences between the fully discrete scheme and the semidiscrete scheme in Fourier space, but we believe that this analysis gives a correct rough picture. Using the space continuous Fourier transform allows us also to considerably simplify the computations and to express the results in a more compact form, which makes them easier to interpret.

In view of a space discretization of mesh size Δx, we assume that the range of admissible wave-numbers ξ is $|\xi| \le \xi^* = \pi/\Delta x$.

We can show (the proof is technical and is omitted) that a sufficient stability condition for the II scheme for a given wave-number ξ is

$$\delta \le \delta_{ii}(\xi) := \frac{2(\frac{1}{\varepsilon^2} + c_s^2\xi^2)^{1/2}}{c_s^2\xi^2}. \tag{3.26}$$

The II scheme is stable over the range of admissible wave-numbers ξ as soon as

$$\delta \le \delta_{ii}^* := \delta_{ii}(\xi^*) = 2\left(\frac{\Delta x}{\pi c_s}\right)^2\left(\frac{1}{\varepsilon^2} + \left(\frac{\pi c_s}{\Delta x}\right)^2\right)^{1/2}. \tag{3.27}$$

By contrast, the stability domain of the IE scheme for a given wave-number ξ is given by

$$\delta \le \delta_{ie}(\xi) := \frac{2}{(\frac{1}{\varepsilon^2} + c_s^2\xi^2)^{1/2}}. \tag{3.28}$$

The IE scheme is stable over the range of admissible wave-numbers iff

$$\delta \le \delta_{ie}^* := \delta_{ie}(\xi^*) = \frac{2}{(\frac{1}{\varepsilon^2} + \left(\frac{\pi c_s}{\Delta x}\right)^2)^{1/2}}. \tag{3.29}$$

The stability domain of the IE scheme shrinks when $\varepsilon \to 0$, while that of the II scheme turns out to be uniformly stable with respect to ε. Furthermore, the II scheme is also consistent with the limit model when $\varepsilon \to 0$ (AP property) as we have seen in section 2.2 in the case of the fully nonlinear equation (the proof is the same for the linearized equation and is left to the reader).

Indeed, we see that $\delta_{ie}^* = O(\varepsilon)$ as $\varepsilon \to 0$ with a fixed Δx, while $\delta_{ii}^* = O(\varepsilon^{-1})$, showing the announced behavior. More precisely, $\delta_{ii}^* \sim 2(\frac{\Delta x}{2\pi c_s})^2\frac{1}{\varepsilon}$. We note that this increased stability with respect to ε is paid for by a more restrictive CFL condition of diffusion type with respect to the acoustic waves. By contrast, in the absence of a source term or, equivalently, when $\Delta x \to 0$ for a fixed ε, the stability constraints for both the IE and II schemes reduce to $\delta \le 2\frac{\Delta x}{\pi c_s}$, which is similar to a CFL condition. We can also show that the II scheme damps the plasma oscillations. At each time step, the amplitude of the oscillation is multiplied by a factor ε/δ (in the limit $\varepsilon \to 0$ for fixed δ). When ε is very small, the damping is very strong. At each time step, the phase of the solution is multiplied by the factor $e^{\pm i\theta}$ with

$$\theta = \cos^{-1}\frac{(1 - \frac{1}{2}\delta^2 c_s^2\xi^2)}{(1 + \frac{\delta^2}{\varepsilon^2})^{1/2}} \quad \overset{\varepsilon\to 0}{\longrightarrow} \quad \frac{\pi}{2}, \tag{3.30}$$

which means that, in the limit $\varepsilon \to 0$, a shift of $\pi/2$ is added to the phase of the oscillation at each time step. In this limit, the period of the plasma oscillations stays bounded, equal to 4δ.

To support the conclusions of this Fourier analysis of the scheme, we show below that the same stability and dissipation properties are still valid when we use a fully discretized scheme in both time and space.

We denote by $D^2u = \frac{u_{i+1}-2u_i+u_{i-1}}{h^2}$ the standard second order difference operator and by $D_-u = \frac{u_i-u_{i-1}}{h}$ and $D_+u = \frac{u_{i+1}-u_i}{h}$ the standard one-sided difference operator. Then $D^2 = D_+D_- = D_-D_+$. Denote $\tilde{D} = (D_+ + D_-)/2$. Here h is the space step.

We consider a space discretization of (3.4) by replacing the continuous second order space derivative by the discrete operator D^2:

$$\partial_{tt}^2 n - c_s^2 D^2 n + \frac{1}{\varepsilon^2} n = 0. \tag{3.31}$$

Applying the II time-difference scheme (3.17) to this equation leads to

$$\frac{n^{m+1} - 2n^m + n^{m-1}}{\delta^2} - c_s^2 D^2 n^m + \frac{1}{\varepsilon^2} n^{m+1} = 0. \tag{3.32}$$

This scheme can be viewed as a wave-type version of the following scheme for the original LEP system (3.1)–(3.3):

$$\frac{n^{m+1} - n^m}{\delta} + D_- u^{m+1} = 0, \tag{3.33}$$

$$\frac{u^{m+1} - u^m}{\delta} + c_s^2 D_+ n^m = D_+ \phi^{m+1}, \tag{3.34}$$

$$\varepsilon^2 D^2 \phi^{m+1} = n^{m+1}. \tag{3.35}$$

Indeed, eliminating u between (3.33) and (3.34), one has

$$\frac{n^{m+1} - 2n^m + n^{m-1}}{\delta^2} - c_s^2 D^2 n^m + D^2 \phi^{m+1} = 0, \tag{3.36}$$

and using (3.35) we get (3.32). We can also eliminate n^{m+1} from (3.36) using (3.35) and get a discretization of the reformulated Poisson equation (2.7) (in linearized form):

$$\left(\frac{\varepsilon^2}{\delta^2} + 1\right) D^2 \phi^{m+1} = \frac{2n^m - n^{m-1}}{\delta^2} + c_s^2 D^2 n^m. \tag{3.37}$$

We can show (the proof is technical and is omitted) that this scheme is stable provided that $2\varepsilon c_s \le h$. We observe that the scheme is asymptotically stable in the limit $\varepsilon \to 0$ but is not stable if ε is large. This feature can easily be explained. When $\varepsilon \to \infty$ the electric field term disappears and we are left with the standard LEP system discretized via centered differences. A time explicit discretization will be unconditionally unstable. Here, the time-differencing is implicit in the mass flux term but still explicit in the momentum flux. This semi-implicit discretization is not implicit enough to stabilize the space-centered discretization. It is a remarkable fact that the electric field contributes to stabilize the instability of the space-centered scheme. However, this scheme cannot be used in a far from quasineutrality regime,

which is a severe drawback in situations close to quasineutrality in some regions but far from it in others. This unpleasant feature will also be found via Fourier analysis when linearizing the Euler–Poisson system about a nonzero velocity (see section 4). This drawback will be overcome by means of a space-decentered discretization.

We also note that the implicit treatment of the last term in (3.32) gives a strong dissipation (like in the Fourier analysis case). This can be seen from the use of the so-called equivalent equation (i.e., the equation obtained by retaining the leading order term in the Taylor expansion of the time semidiscrete scheme). This equivalent equation is written

$$\partial_{tt}^2 n - c_s^2 \partial_{xx}^2 n + \frac{1}{\varepsilon^2} n + \frac{\delta}{\varepsilon^2} n_t = 0, \tag{3.38}$$

which can be recast as an LEP system with a damping term

$$\partial_t n + \partial_x u = -\tfrac{\delta}{\varepsilon^2} n, \tag{3.39}$$

$$\partial_t u + c_s^2 \partial_x n = \partial_x \phi, \tag{3.40}$$

$$\varepsilon^2 \partial_{xx}^2 \phi = n. \tag{3.41}$$

The energy estimate (3.13) for (3.38) becomes

$$\partial_t \int_a^b \left((\partial_t n)^2 + c_s^2 (\partial_x n)^2 + \frac{1}{\varepsilon^2} n^2 \right) dx + \frac{2\delta}{\varepsilon^2} \int_a^b (\partial_t n)^2 \, dx = 0, \tag{3.42}$$

and we observe the strong damping of the energy with a rate which tends to infinity as $\varepsilon \to 0$ (for fixed δ) as fast as $1/\varepsilon^2$.

The use of centered differencing associated with only a partial implicit time-differencing may lead to stability problems when the coupling with the field term is weak, i.e., ε is large. This will be particularly clear with the analysis of the LEP system about a nonzero velocity in section 4. For this reason, we now analyze schemes associated with decentered space-differencing, which we shall mimic by looking at the LEP system with diffusion.

3.3. AP strategy associated with upwind space-decentered differencing. In order to mimic the influence of a decentered space-difference, we consider the following two viscous perturbation of the LEP system. The linearized viscous Euler–Poisson (LVEP) system reads either as

$$\partial_t n + \partial_x u = 0, \tag{3.43}$$

$$\partial_t u + c_s^2 \partial_x n = \nu \partial_{xx}^2 u + \partial_x \phi, \tag{3.44}$$

$$\varepsilon^2 \partial_{xx} \phi = n \tag{3.45}$$

if numerical diffusion is added only to the momentum balance equation or as

$$\partial_t n + \partial_x u = \beta \partial_{xx}^2 n, \tag{3.46}$$

$$\partial_t u + c_s^2 \partial_x n = \nu \partial_{xx}^2 u + \partial_x \phi, \tag{3.47}$$

$$\varepsilon^2 \partial_{xx} \phi = n \tag{3.48}$$

if we also consider numerical diffusion in the mass conservation equation. Here, β and ν are artificial viscosity coefficients. These systems will be referred to below, respectively, as the LVEP-1 and LVEP-2 systems. The LVEP-1 system is of course a particular case of the LVEP-2 system by taking $\beta = 0$.

Eliminating u and ϕ, the LVEP-1 system reduces to the following Klein–Gordon equation with a viscoelastic term:

$$\partial_{tt}^2 n = c_s^2 \partial_{xx}^2 n - \frac{1}{\varepsilon^2} n + \nu \partial_{txx}^3 n. \tag{3.49}$$

For the LVEP-2 system, following Slemrod, we introduce $v = u - \beta \partial_x n$. Then the above system is equivalent to

$$\partial_t n + \partial_x v = 0, \tag{3.50}$$

$$\partial_t v + c_s^2 \partial_x n = (\nu + \beta) \partial_{xx}^2 u + \nu\beta \partial_{xxx}^3 n + \partial_x \phi, \tag{3.51}$$

$$\varepsilon^2 \partial_{xx}^2 \phi = n. \tag{3.52}$$

Eliminating v and ϕ, we are led to the following Klein–Gordon equation with viscoelastic and capillary-type terms:

$$\partial_{tt}^2 n = c_s^2 \partial_{xx}^2 n - \frac{1}{\varepsilon^2} n + (\nu + \beta) \partial_{txx}^3 n - \nu\beta \partial_{xxxx}^4 n. \tag{3.53}$$

We now perform Fourier and energy analyses for the LVEP-2 system which includes the LVEP-1 system as a particular case. After a partial Fourier transform with respect to x, the system reads

$$\partial_t \hat{n} + i\xi \hat{u} + \beta \xi^2 \hat{n} = 0, \tag{3.54}$$

$$\partial_t \hat{u} + i\xi c_s^2 \hat{n} + \nu \xi^2 \hat{u} = i\xi \hat{\phi}, \tag{3.55}$$

$$-\varepsilon^2 \xi^2 \hat{\phi} = \hat{n}, \tag{3.56}$$

or, equivalently, after elimination of $\hat{\phi}$,

$$\begin{pmatrix} \partial_t \hat{n} \\ \partial_t \hat{u} \end{pmatrix} + \begin{pmatrix} \beta\xi^2 & i\xi \\ i\xi c_s^2 + \frac{i}{\varepsilon^2 \xi} & \nu\xi^2 \end{pmatrix} \begin{pmatrix} \hat{n} \\ \hat{u} \end{pmatrix} = 0. \tag{3.57}$$

For $|\xi|$ not too large, the eigenmodes of the LVEP-2 system are given by

$$s^{\pm} = r_{\beta,\nu}(\xi) \pm i\theta_\varepsilon(\xi) := \frac{\beta + \nu}{2} \xi^2 \pm i \left(\frac{1}{\varepsilon^2} + c_s^2 \xi^2 - \frac{(\beta + \nu)^2}{4} \xi^4 \right)^{1/2}. \tag{3.58}$$

Now the oscillations are damped by an exponential factor $e^{-r_{\beta,\nu}t}$ which is independent of ε and proportional to $\beta+\nu$. Moreover, the phase oscillates with a frequency $O(\frac{1}{\varepsilon})$ when $\varepsilon \to 0$, independently of ξ.

In order to derive energy estimates, we multiply (3.53) with $\partial_t n$ and get

$$\partial_t\Big(\tfrac{1}{2}(\partial_t n)^2\Big) = c_s^2\,\partial_t n\,\partial_{xx}^2 n - \tfrac{1}{\varepsilon^2}\partial_t\Big(\tfrac{1}{2}n^2\Big) + (\nu+\beta)\,\partial_t n\,\partial_{txx}^3 n - \nu\beta\,\partial_t n\,\partial_{xxxx}^4 n.$$

Simple computations give

$$\begin{aligned}
\partial_t n\,\partial_{xx}^2 n &= \partial_x(\partial_x n\,\partial_t n) - \partial_x n\,\partial_{tx}^2 n = \partial_x(\partial_x n\,\partial_t n) - \partial_t\Big(\tfrac{1}{2}(\partial_x n)^2\Big),\\
\partial_t n\,\partial_{txx}^3 n &= \partial_x(\partial_{tx}^2 n\,\partial_t n) - (\partial_{tx}^2 n)^2,\\
\partial_t n\,\partial_{xxxx}^4 n &= \partial_x(\partial_{xxx}^3 n\,\partial_t n - \partial_{tx}^2 n\,\partial_{xx}^2 n) + \partial_{txx}^3 n\,\partial_{xx}^2 n\\
&= \partial_x(\partial_{xxx}^3 n\,\partial_t n - \partial_{tx}^2 n\,\partial_{xx}^2 n) + \partial_t\Big(\tfrac{1}{2}(\partial_{xx}^2 n)^2\Big).
\end{aligned}$$

Summing up, we get

$$\begin{aligned}
&\partial_t\tfrac{1}{2}\Big((\partial_t n)^2 + c_s^2(\partial_x n)^2 + \tfrac{1}{\varepsilon^2}n^2 + \nu\beta(\partial_{xx}^2 n)^2\Big) + (\beta+\nu)(\partial_{tx}^2 n)^2\\
&= \partial_x\Big(c_s^2 n_x\partial_t n + (\nu+\beta)\partial_{tx}^2 n\,\partial_t n - \nu\beta(\partial_{xxx}^3 n\,\partial_t n - \partial_{tx}^2 n\,\partial_{xx}^2 n)\Big).
\end{aligned}$$

For periodic or homogeneous Neumann boundary conditions, we obtain

$$\partial_t\tfrac{1}{2}\int_a^b \Big((\partial_t n)^2 + c_s^2(\partial_x n)^2 + \tfrac{1}{\varepsilon^2}n^2 + \nu\beta(\partial_{xx}^2 n)^2\Big)\,dx + (\beta+\nu)\int_a^b (\partial_{tx}^2 n)^2\,dx = 0.$$

Again we see that the second order dissipative coefficient is dependent only on $\nu+\beta$.

This energy estimate is still true for a space-discrete version of the LVEP-2 system with $\beta=\nu$ (simply referred to as the LVEP system). Indeed, the natural finite difference space discretization for the LVEP system is given by (with the same notation as above):

$$\partial_t n + \tilde{D}u = \beta D^2 n, \tag{3.59}$$

$$\partial_t u + c_s^2\tilde{D}n = \beta D^2 u + \tilde{D}\phi, \tag{3.60}$$

$$\varepsilon^2 D^2\phi = n, \tag{3.61}$$

where $\tilde{D} = (D_+ + D_-)/2$ and $D^2 = D_+D_-$.

Both the upwinding and Lax–Friedrichs schemes for LEP (3.1)–(3.3) take the same form with $\beta = c_s h/2$ and $\beta = \frac{h^2}{2\delta}$, respectively, as we will explain below. This is also true for the modified Lax–Friedrichs scheme used in [7] and [9], because in the linearized case, the modified Lax–Friedrichs scheme and the upwind scheme coincide. Indeed, for the upwinding scheme, we first diagonalize the LEP system (3.1)–(3.3) and then take upwind difference as follows:

$$\begin{aligned}
\partial_t(u+c_s n) + c_s D_-(u+c_s n) &= \tilde{D}\phi,\\
\partial_t(u-c_s n) - c_s D_+(u-c_s n) &= \tilde{D}\phi,\\
\varepsilon^2 D^2\phi &= n.
\end{aligned}$$

Recast to the original form, it can be written

$$\partial_t n + \tilde{D}u = \frac{c_s}{2}(D_+ - D_-)n,$$

$$\partial_t u + c_s^2 \tilde{D}n = \frac{c_s}{2}(D_+ - D_-)u + \tilde{D}\phi,$$

$$\varepsilon^2 D^2 \phi = n.$$

Note that $D_+ - D_- = hD^2$. The above is the same as (3.59)–(3.61) with $\beta = c_s h/2$. For the Lax–Friedrichs scheme we first write the scheme in its usual form:

$$(n^{m+1} - n^m)/\delta + \tilde{D}u^m = \frac{h^2}{2\delta} D^2 n^m,$$

$$(u^{m+1} - u^m)/\delta + c_s^2 \tilde{D}n^m = \frac{h^2}{2\delta} D^2 u^m + \tilde{D}\phi^{m+1},$$

$$\varepsilon^2 D^2 \phi^{m+1} = n^{m+1}.$$

We can regard it as a time discretization scheme of (3.59)–(3.61) with $\beta = \frac{h^2}{2\delta}$.

We can show that the time continuous scheme (3.59)–(3.61) has the following energy estimate for the periodic boundary condition case:

$$\partial_t \tfrac{1}{2}\left(c_s^2 \|D_- n\|^2 + \|D_- u\|^2 + \frac{1}{\varepsilon^2}\|n\|^2\right) + \beta(c_s^2 \|D^2 n\|^2 + \|D^2 u\|^2) + \frac{1}{\varepsilon^2}\|D_- n\|^2 = 0. \tag{3.62}$$

This indicates that the space discretization has the same behavior as the space-continuous model. For this reason, from now on, we shall consider only the problem of the stability of the time discretization and replace the influence of the space discretization by a Fourier transform, limiting the admissible wave-numbers to a bounded interval (the latter being related to the space step Δx).

In the remainder of this analysis, we will be using the LVEP-2 system (3.46)–(3.48) with $\beta = \nu$ and will simply refer to it as the LVEP system. The coefficient β is linked with numerical diffusion. For most schemes,

$$\beta = O(c_s \Delta x). \tag{3.63}$$

Again, we suppose that $|\xi| \le \xi^* = \pi/\Delta x$, having in mind that this mimics a space discretization of mesh step Δx. Therefore, assuming (3.63), there exists a constant $C^* > 0$ such that

$$\frac{\beta|\xi|}{c_s} \le C^*. \tag{3.64}$$

The AP strategy (II scheme) for the LVEP system reads as follows:

$$\frac{\hat{n}^{m+1} - \hat{n}^m}{\delta} + i\xi \hat{u}^{m+1} + \beta \xi^2 \hat{n}^m = 0, \tag{3.65}$$

$$\frac{\hat{u}^{m+1} - \hat{u}^m}{\delta} + i\xi c_s^2 \hat{n}^m + \beta \xi^2 \hat{u}^m + \frac{i}{\varepsilon^2 \xi}\hat{n}^{m+1} = 0. \tag{3.66}$$

We shall compare this strategy with an explicit time-differencing of the mass flux term that is still implicit in the Poisson source term. Such a scheme (EI scheme) reads

$$\frac{\hat{n}^{m+1}-\hat{n}^m}{\delta}+i\xi\hat{u}^m+\beta\xi^2\hat{n}^m=0, \tag{3.67}$$

$$\frac{\hat{u}^{m+1}-\hat{u}^m}{\delta}+i\xi c_s^2\hat{n}^m+\beta\xi^2\hat{u}^m+\frac{i}{\varepsilon^2\xi}\hat{n}^{m+1}=0. \tag{3.68}$$

Note that in section 3.2, we mentioned the converse strategy (implicit in the mass flux, and explicit in the Poisson source term; see system (3.19), (3.20)) called the IE scheme and we showed that in the nonviscous case, the stability requirement scales down to 0 as $\varepsilon\to 0$. It is unlikely that the use of an artificial viscosity can cure this instability, since the cause of this instability is clearly linked to the coupling with the field (because of its dependence with respect to ε) while the motivation of the artificial viscosity is to compensate for the instability of the space-centered scheme of the purely hydrodynamic part of the model. For this reason and for the sake of conciseness, we do not consider the IE scheme in the viscous case.

For completeness, we mention the full explicit scheme, in both mass flux and Poisson source term. This scheme (EE scheme) reads as follows:

$$\frac{\hat{n}^{m+1}-\hat{n}^m}{\delta}+i\xi\hat{u}^m+\beta\xi^2\hat{n}^m=0, \tag{3.69}$$

$$\frac{\hat{u}^{m+1}-\hat{u}^m}{\delta}+i\xi c_s^2\hat{n}^m+\beta\xi^2\hat{u}^m+\frac{i}{\varepsilon^2\xi}\hat{n}^m=0. \tag{3.70}$$

We mention that the EE and EI schemes for the nonviscous system would be unconditionally unstable because of the well-known instability of space-centered schemes for hydrodynamics. It is easy to check this instability directly. The computation is left to the reader.

For these schemes, a stability analysis (omitted) leads to the following conclusions. The AP II scheme shows a uniform stability condition with respect to the parameter ε, as expected. More precisely, a sufficient stability condition is

$$\delta\le\frac{2\beta}{c_s^2}F(C^*), \tag{3.71}$$

where $F(C^*)$ is a convenient function of the constant C^* (see (3.64)). Again, this looks like a CFL condition, which depends only on the purely hydrodynamic part of the scheme and not on ε.

By contrast, the EI scheme has a stability domain which shrinks down to 0 as $\varepsilon\to 0$. The analysis is simplified by making the following assumption:

$$\delta\le\frac{2\beta}{c_s^2}\,\frac{1}{1+C^{*2}}:=\delta^*, \tag{3.72}$$

where C^* is given by (3.64). This condition is again similar to a CFL condition (see (3.63)). Under this condition, a sufficient stability constraint for this scheme is of the form

$$\delta\le\frac{2}{\sqrt{1+C^{*2}}}\,\varepsilon\quad\forall\varepsilon\in\left[0,\frac{\beta}{c_s^2\sqrt{1+C^{*2}}}\right]. \tag{3.73}$$

Additionally if δ satisfying (3.72) is such that $\delta > 2\varepsilon$, the scheme is unstable. Therefore, the stability domain is an interval of size exactly $O(\varepsilon)$. This scheme is the linearized version of the standard scheme used for the Euler–Poisson problem. The conditional stability of this scheme in a fully discrete version was proved earlier by Fabre in [16].

Finally, the fully explicit EE scheme has disastrous behavior. Its stability condition for a given wave-number ξ is given by

$$\delta \leq \delta_{ee}(\xi) := \frac{2\beta\xi^2}{\beta^2\xi^4 + c_s^2\xi^2 + \frac{1}{\varepsilon^2}}. \tag{3.74}$$

Over the range of admissible wave-numbers $[0, \xi^*]$, the minimal value of $\delta_{ee}(\xi)$ is zero, showing that the scheme is actually unstable. Therefore, numerical diffusion is not sufficient to stabilize the EE scheme. This was proved by Fabre for a fully discrete version of the scheme in [16].

To summarize, the EE scheme is unconditionally unstable, even used in conjunction with a decentered space discretization of the hydrodynamic fluxes. The EI scheme is conditionally stable: the time step must be kept proportional to ε. Finally, the II scheme is asymptotically stable when $\varepsilon \to 0$. Its stability requirement involves only a CFL condition related to the space discretization of the hydrodynamic part of the model.

In the next section, we investigate if these conclusions remain true when the LEP system is linearized about a nonzero velocity. We show that the II scheme remains uniformly stable in the viscous case (i.e., for a space-decentered discretization) but not in the nonviscous case (for a space-centered scheme).

4. The LEP system about nonzero velocity. Linearizing system (2.1)–(2.3) about the stationary homogeneous solution $n_0 = 1$, $u_0 = a$, a being constant (but not equal to 0), and $\partial_x\phi_0 = 0$, leads to the following LEP system:

$$\partial_t n + a\partial_x n + \partial_x u = 0, \tag{4.1}$$

$$\partial_t u + a\partial_x u + c_s^2\partial_x n = \partial_x\phi, \tag{4.2}$$

$$\varepsilon^2\partial_{xx}^2\phi = n. \tag{4.3}$$

When $|a| < |c_s|$, it can be reduced to a wave-like formulation (specifically a Klein–Gordon equation with mass equal to $1/\varepsilon^2$):

$$\partial_{tt}^2 n + 2a\partial_{tx}^2 n - (c_s^2 - a^2)\partial_{xx}^2 n + \frac{1}{\varepsilon^2}n = 0. \tag{4.4}$$

We can get an energy estimate for this system by multiplying by $\partial_t n$. We have

$$\partial_t\Big((\partial_t n)^2 + (c_s^2 - a^2)(\partial_x n)^2 + \frac{1}{\varepsilon^2}n^2\Big) = 2(c_s^2 - a^2)\partial_x\Big(\partial_x n\,\partial_t n\Big) - 2a\partial_x\Big((\partial_t n)^2\Big). \tag{4.5}$$

If periodic or homogeneous Dirichlet boundary conditions are imposed at the boundary points, conservation of energy follows:

$$\partial_t \int_a^b \Big((\partial_t n)^2 + (c_s^2 - a^2)(\partial_x n)^2 + \frac{1}{\varepsilon^2}n^2\Big)\,dx = 0. \tag{4.6}$$

We consider a space discretization of (4.4) by replacing the continuous second order space derivative by the discrete operator D^2, with the same meaning as above for $\tilde{D}$:

$$\partial_{tt}^2 n + 2a\partial_t \tilde{D} n - (c_s^2 - a^2) D^2 n + \frac{1}{\varepsilon^2} n = 0. \tag{4.7}$$

Applying the II time-difference scheme (3.17) to this equation leads to

$$\frac{n^{m+1} - 2n^m + n^{m-1}}{\delta^2} + 2a \frac{\tilde{D} n^m - \tilde{D} n^{m-1}}{\delta} + a^2 D^2 n^{m-1} - c_s^2 D^2 n^m + \frac{1}{\varepsilon^2} n^{m+1} = 0. \tag{4.8}$$

This scheme can be viewed as a wave-type version of the following scheme for the original LEP system (4.1)–(4.3):

$$\frac{n^{m+1} - n^m}{\delta} + a D_- n^m + D_- u^{m+1} = 0, \tag{4.9}$$

$$\frac{u^{m+1} - u^m}{\delta} + a D_+ u^m + c_s^2 D_+ n^m = D_+ \phi^{m+1}, \tag{4.10}$$

$$\varepsilon^2 D^2 \phi^{m+1} = n^{m+1}. \tag{4.11}$$

Indeed, eliminating u between (4.9) and (4.10), one has

$$\frac{n^{m+1} - 2n^m + n^{m-1}}{\delta^2} + 2a \frac{\tilde{D} n^m - \tilde{D} n^{m-1}}{\delta} + a^2 D^2 n^{m-1} - c_s^2 D^2 n^m + D^2 \phi^{m+1} = 0, \tag{4.12}$$

and using (4.11), we get (4.8). We can also eliminate n^{m+1} from (4.12) using (4.11) and get a discretization of the reformulated Poisson equation (2.7) (in linearized form):

$$\left(\frac{\varepsilon^2}{\delta^2} + 1 \right) D^2 \phi^{m+1} = \frac{2n^m - n^{m-1}}{\delta^2} + c_s^2 D^2 n^m - 2a \frac{\tilde{D} n^m - \tilde{D} n^{m-1}}{\delta} - a^2 D^2 n^{m-1}. \tag{4.13}$$

We also note that the implicit treatment of the last term in (4.8) gives a strong dissipation (like in the Fourier analysis case). This can be seen from the use of the so-called equivalent equation (i.e., the equation obtained by retaining the leading order term in the Taylor expansion of the time semidiscrete scheme). This equivalent equation is written

$$\partial_{tt}^2 n + 2a\partial_{tx}^2 n - (c_s^2 - a^2)\partial_{xx}^2 n + \frac{1}{\varepsilon^2} n = -\frac{\delta}{\varepsilon^2} \partial_t n + a^2 \delta \partial_{txx}^3 n + a\delta \partial_{ttx}^3 n. \tag{4.14}$$

The first two terms on the right-hand side are dissipative terms, while the nature of the last term is less clear.

By examining the LEP system about zero velocity, we have shown that schemes that are implicit in both the mass flux term and the electric field source term are asymptotically stable in the small Debye length limit $\varepsilon \to 0$.

Two schemes have been shown to have this property. A first scheme is associated with centered space-differencing: the II scheme for the LEP system without diffusion. A second scheme is associated with a decentered shock-capturing–type space discretization: the II scheme for the viscous linearized Euler–Poisson (LVEP) system (see section 3.3). We have seen in section 3.2 that the II scheme for the inviscid LEP system is not uniformly stable with respect to ε when $\varepsilon \to \infty$ and that this lack of uniformity is related to the space-centered differencing.

We are now concerned with the stability of these two schemes for the LEP problem about nonzero velocity. This analysis will confirm that the II scheme without diffusion is uniformly stable in the limit $\varepsilon \to 0$ but not in the limit $\varepsilon \to \infty$ while the II scheme with diffusion is uniformly stable for all values of ε, however small or large.

We linearize system (2.1)–(2.3) about the stationary homogeneous solution $n_0 = 1$, $q_0 =$ Constant (but not equal to 0), and $\partial_x \phi_0 = 0$. We denote by $\zeta \ll 1$ the size of the initial perturbation to this stationary state. Then, we can formally expand the solution as follows: $n = 1+\zeta n' + O(\zeta^2)$, $q = q_0 + \zeta(q_0 n' + u') + O(\zeta^2)$, $\phi = \zeta\phi' + O(\zeta^2)$. Retaining only terms of order ζ, we are led to the following LEP system (where the primes have been dropped for the sake of clarity):

$$\partial_t n + \partial_x u = 0, \tag{4.15}$$

$$\partial_t u + \partial_x(2q_0 u - q_0^2 n) + c_s^2 \partial_x n = \partial_x \phi, \tag{4.16}$$

$$\varepsilon^2 \partial_{xx}\phi = n. \tag{4.17}$$

After a Fourier transform in space, the system reads

$$\partial_t \hat{n} + i\xi \hat{u} = 0, \tag{4.18}$$

$$\partial_t \hat{u} + i\xi(2q_0 u - q_0^2 n) + i\xi c_s^2 \hat{n} = i\xi\hat{\phi}, \tag{4.19}$$

$$-\varepsilon^2 \xi^2 \hat{\phi} = \hat{n}. \tag{4.20}$$

After elimination of $\hat{\phi}$, the system reduces to a 2×2 system of the form

$$\begin{pmatrix} \partial_t \hat{n} \\ \partial_t \hat{u} \end{pmatrix} + \begin{pmatrix} 0 & i\xi \\ -iq_0^2\xi + i\xi c_s^2 + \frac{i}{\varepsilon^2 \xi} & 2iq_0\xi \end{pmatrix} \begin{pmatrix} \hat{n} \\ \hat{u} \end{pmatrix} = 0. \tag{4.21}$$

Its solutions are of the form

$$\begin{pmatrix} \hat{n}(\xi,t) \\ \hat{u}(\xi,t) \end{pmatrix} = \begin{pmatrix} \hat{n}_+(\xi) \\ \hat{u}_+(\xi) \end{pmatrix} e^{i\theta_+^\varepsilon(\xi)t} + \begin{pmatrix} \hat{n}_-(\xi) \\ \hat{u}_-(\xi) \end{pmatrix} e^{i\theta_-^\varepsilon(\xi)t}, \tag{4.22}$$

where

$$\theta_\pm^\varepsilon(\xi) = -q_0\xi \pm \left(c_s^2\xi^2 + \frac{1}{\varepsilon^2}\right)^{1/2}. \tag{4.23}$$

These eigenmodes are obtained by shifting the phase by the quantity $-q_0\xi$. Indeed, the linearization about a uniform nonzero velocity can be deduced from a linearization about a zero velocity by a Galilean transformation $x' = x + q_0 t$, $v' = v$ thanks to the Galilean invariance of the nonlinear Euler problem. A Galilean shift translates in Fourier space into a constant phase shift.

It should not be inferred, however, that the stability of the schemes for the linearization about a nonzero velocity can be deduced from considerations concerning the linearized system about a zero velocity. Indeed, the mass and momentum flux terms are treated differently (one is implicit while the other one is explicit), which breaks this Galilean invariance.

Now, the II scheme for the inviscid Euler–Poisson system linearized about nonzero velocity reads

$$\frac{\hat{n}^{m+1}-\hat{n}^m}{\delta}+i\xi\hat{u}^{m+1}=0, \tag{4.24}$$

$$\frac{\hat{u}^{m+1}-\hat{u}^m}{\delta}+i\xi(2q_0u^m-q_0^2n^m)+i\xi c_s^2\hat{n}^m+\frac{i}{\varepsilon^2\xi}\hat{n}^{m+1}=0, \tag{4.25}$$

while the II scheme for the viscous system is written

$$\frac{\hat{n}^{m+1}-\hat{n}^m}{\delta}+i\xi\hat{u}^{m+1}+\beta\xi^2\hat{n}^m=0, \tag{4.26}$$

$$\frac{\hat{u}^{m+1}-\hat{u}^m}{\delta}+i\xi(2q_0u^m-q_0^2n^m)+i\xi c_s^2\hat{n}^m+\beta\xi^2\hat{u}^m+\frac{i}{\varepsilon^2\xi}\hat{n}^{m+1}=0. \tag{4.27}$$

We recall that the inviscid linearized system in Fourier space mimics a centered spatial discretization while the viscous system mimics a decentered spatial discretization associated with a numerical diffusion equal to β.

We can prove that the II scheme for the inviscid system is uniformly stable in the limit $\varepsilon \to 0$. But ε must be large enough. To state a more precise result, we recall that the range of admissible wave-numbers ξ is limited to the interval $|\xi| \le \xi^* = \frac{\pi}{\Delta x}$ in order to mimic the influence of a space discretization Δx. Then, for all $K < 1$, there exists a $\delta^* > 0$ such that for all $\delta < \delta^*$ and all ε such that $\varepsilon < K\delta$, the II scheme for the inviscid system is stable. We note that as K gets closer to 1, δ^* tends to 0. In particular, the scheme is not stable when $\varepsilon = O(1)$ and $\delta \to 0$, which would be the situation if we wanted to resolve the plasma period scale. We can show that if $\varepsilon = 0$, the scheme is unstable. Therefore, the II scheme for the inviscid system cannot be of practical usefulness.

We now turn to the II scheme for the viscous system. We assume that the diffusion constant β is proportional to the time step: $\beta = B\delta$. Then, the result we can prove is that if B is large enough (depending only on q_0 and c_s), then there exists an interval of time steps $[0, \delta^*]$ (again, depending only on q_0 and c_s) such that for all δ's in this interval, all admissible wave-numbers ξ (i.e., such that $|\xi| \le \xi^*$) and all $\varepsilon \ge 0$, the scheme is stable. Usually, the diffusion constant is taken proportional to Δx (or to $\Delta x^2/\delta$ in the case of the Lax–Friedrichs scheme) rather than to δ. The result would also remain true in this case, but the proof would be more complex. Indeed, supposing that $\beta = O(\delta)$ allows us to express the problem in terms of the CFL variable, $X = \xi\delta$ only, which simplifies the (already quite technical) proof. Also, the result in itself is interesting as it shows that the scheme is stable even with a vanishingly small diffusion proportional to δ.

These results show that, at least for the linearized problem about any uniform state (of zero or nonzero velocity), the II scheme associated with a decentered space-differencing is uniformly stable with respect to all values of ε small or large.

5. Burgers–Poisson equation. In a preliminary attempt to analyze the nonlinear effects, we consider the following model consisting of a nonlinear Burgers–Poisson system:

$$\partial_t u + u\partial_x u = -\partial_x \phi, \tag{5.1}$$

$$\varepsilon^2 \partial_{xx}^2 \phi = u. \tag{5.2}$$

This equation appears as a model describing high-frequency wave propagation in relaxing media [30, 17]. In [30], special soliton solutions called "loop solitons" are constructed using inverse scattering theory. However, these solutions are multivalued and cannot be computed by the method developed below. Note that the quasineutral limit has been investigated theoretically in [17].

This system owns the entropy pair $(\frac{u^2}{2}, \frac{u^3}{3} + \frac{\varepsilon^2 \phi_x^2}{2})$. Indeed, simple computations show that

$$\partial_t \left(\frac{u^2}{2} \right) + \partial_x \left(\frac{u^3}{3} + \frac{\varepsilon^2 (\partial_x \phi)^2}{2} \right) = 0. \tag{5.3}$$

The theoretical study of this equation will be reported in a future paper.

We consider the conservative scheme

$$\partial_t u_j + \frac{u_{j+1} + u_j + u_{j-1}}{3} \frac{u_{j+1} - u_{j-1}}{2h} = -\frac{\phi_{j+1} - \phi_{j-1}}{2h}, \tag{5.4}$$

$$\varepsilon^2 \frac{\phi_{j+1} - 2\phi_j + \phi_{j-1}}{h^2} = u_j, \tag{5.5}$$

where $h = \Delta x$ is the grid size. The above scheme may generate some oscillations near shocks due to the dispersive nature of the scheme. We can recast the above scheme in a conservative form,

$$\partial_t u_j + \frac{f_{j+1/2} - f_{j-1/2}}{h} = -\frac{\phi_{j+1} - \phi_{j-1}}{2h}, \tag{5.6}$$

$$\varepsilon^2 \frac{\phi_{j+1} - 2\phi_j + \phi_{j-1}}{h^2} = u_j, \tag{5.7}$$

where $f_{j+1/2} = \frac{1}{6}(u_j^2 + u_j u_{j+1} + u_{j+1}^2)$. We have a discrete entropy pair

$$\partial_t \left(\frac{u_j^2}{2} \right) + \frac{g_{j+1/2} - g_{j-1/2}}{h} = 0, \tag{5.8}$$

where $g_{j+1/2} = \frac{1}{6}(u_j^2 u_{j+1} + u_j u_{j+1}^2) + \frac{\varepsilon^2}{2}(\frac{\phi_{j+1} - \phi_j}{h})^2$. As a direct consequence, we can prove a stability result for the space semidiscretization of this model. We can also get some convergence results assuming the solution is smooth.

More precisely, we consider only the periodic boundary condition case for simplicity. Let $\phi(x), u(x)$ be the exact solution. Let $\Phi_j = \phi(x_j)$, $U_j = \varepsilon^2 \frac{\Phi_{j+1} - 2\Phi_j + \Phi_{j-1}}{h^2}$. Assuming that the initial data are approximated up to second order, we have

$$\|u_h - u\| = \sqrt{\sum_j (u_j - u(x_j))^2 h} \le Ch^2$$

and

$$\varepsilon\|\phi_h - \phi\| = \varepsilon\sqrt{\sum_j (\phi_j - \phi(x_j))^2 h} \le Ch^2$$

for all $\varepsilon \le \varepsilon_0$, with arbitrary $\varepsilon_0 > 0$ and where $C = C(u, \phi, \varepsilon_0)$.

This analysis indicates that a similar implicit time discretization as in the LVEP system will provide asymptotic stability with respect to $\varepsilon \to 0$. The investigation of this problem will be the topic of future work.

6. Conclusion. In this paper, we have analyzed the stability property of a recently proposed numerical scheme for the Euler–Poisson system [9]. For this analysis, we have considered the linearized Euler–Poisson system about both zero and nonzero velocities, and, after a Fourier transform in space, we have applied the time discretization under scrutiny. We have mimicked the influence of a space-decentered discretization by adding viscosity terms in both the mass and momentum conservation equations. We have shown that the resulting scheme is uniformly stable with respect to the Debye parameter ε. By contrast, other schemes with less implicit treatment or with centered space-differencing are shown to lose the uniform stability property. Elements of a nonlinear stability analysis have been given by considering a model Burgers–Poisson problem. The analysis of this strategy for the kinetic version of this model [10] is in progress.

THE FABER–MANTEUFFEL THEOREM FOR LINEAR OPERATORS*

V. FABER†, J. LIESEN‡, AND P. TICHÝ§

Abstract. A short recurrence for orthogonalizing Krylov subspace bases for a matrix A exists if and only if the adjoint of A is a low-degree polynomial in A (i.e., A is normal of low degree). In the area of iterative methods, this result is known as the Faber–Manteuffel theorem [V. Faber and T. Manteuffel, *SIAM J. Numer. Anal.*, 21 (1984), pp. 352–362]. Motivated by the description by J. Liesen and Z. Strakoš, we formulate here this theorem in terms of linear operators on finite dimensional Hilbert spaces and give two new proofs of the necessity part. We have chosen the linear operator rather than the matrix formulation because we found that a matrix-free proof is less technical. Of course, the linear operator result contains the Faber–Manteuffel theorem for matrices.

Key words. cyclic subspaces, Krylov subspaces, orthogonal bases, orthogonalization, short recurrences, normal matrices

DOI. 10.1137/060678087

1. Introduction.

At the Householder Symposium VIII held in Oxford in July 1981, Golub posed as an open question to characterize necessary and sufficient conditions on a matrix A for the existence of a three-term conjugate gradient–type method for solving linear systems with A (cf. *SIGNUM Newsletter*, vol. 16, no. 4, 1981). This important question was answered by Faber and Manteuffel in 1984 [4]. They showed that an $(s+2)$-term conjugate gradient type method for A, based on some given inner product, exists if and only if the adjoint of A with respect to the inner product is a polynomial of degree s in A (i.e., A is normal of degree s). In the area of iterative methods this result is known as the Faber–Manteuffel theorem; see, e.g., [7, Chapter 6] or [13, Chapter 6.10].

The theory of [4] and some further developments have recently been surveyed in [12]. There the Faber–Manteuffel theorem is formulated independently of the conjugate gradient context and solely as a result on the existence of a short recurrence for generating orthogonal bases for Krylov subspaces of the matrix A. A new proof of the sufficiency part is given, and the normality condition on A is thoroughly characterized. For the proof of the (significantly more difficult) necessity part, however, the authors refer to [4]. In particular, they suggest that, in light of the fundamental nature of the result, it is desirable to find an alternative, and possibly simpler, proof. Note that a proof similar to the one of Faber and Manteuffel but for other classes of matrices has been given in [14].

Motivated by the description in [12], we here take a new approach to formulate and prove the necessity part of the Faber–Manteuffel theorem. Instead of a matrix

we consider a given linear operator A on a finite dimensional Hilbert space V. By the cyclic decomposition theorem, the space V decomposes into cyclic invariant subspaces, i.e., Krylov subspaces, of A (see section 2 for details). The Faber–Manteuffel theorem then gives a necessary (and sufficient) condition on A, so that the standard Gram–Schmidt algorithm for generating orthogonal bases of the cyclic subspaces reduces from a full to a short recurrence.

We have chosen this setting because we believe that the proof of necessity is easier to follow when we use linear operators rather than matrices. In this paper we give two different proofs of the necessity part, both based on restriction of the linear operator A to certain cyclic invariant subspaces. The resulting technicalities in the matrix formulation would obstruct rather than help the understanding. Moreover, our formulation may serve as a starting point for extending the results to infinite dimensional spaces. We are not aware that any such extensions have been obtained yet.

The paper is organized as follows. In section 2 we introduce the notation and the required background from the theory of linear operators. In section 3 we translate the matrix concepts introduced in [12] into the language of linear operators. In section 4 we state and prove several technical lemmas that are required in the proof of the main result, which is given in section 5. In section 6 we give an alternative proof, which we consider elementary and constructive. This proof involves structure-preserving orthogonal transformations of Hessenberg matrices, which may be of interest beyond our context here. In section 7 we discuss our rather theoretical analysis in the preceeding sections. This discussion includes a matrix formulation of the Faber–Manteuffel theorem, a high-level description of the strategies of our two proofs of the necessity part, and our reasoning why necessity is more difficult to prove than sufficiency. For obtaining a more detailed overview of the results in this paper, section 7 may be read before the other sections.

2. Notation and background. In this section we introduce the notation and recall some basic results from the theory of linear operators; see Gantmacher's book [6, Chapters VII and IX] for more details.

Let V be a finite dimensional Hilbert space, i.e., a complex vector space equipped with a (fixed) inner product $(\cdot,\cdot)$. Let $A : V \to V$ be a given invertible linear operator. For any vector $v \in V$, we can form the sequence

$$v, Av, A^2v, \ldots . \tag{2.1}$$

Since V is finite dimensional, there exists an integer $d = d(A, v)$ such that the vectors $v, Av, \ldots, A^{d-1}v$ are linearly independent, while $A^d v$ is a linear combination of them. This means that there exist scalars, $\alpha_1, \ldots, \alpha_{d-1}$, not all equal to zero, such that

$$A^d v \;=\; -\sum_{j=0}^{d-1} \alpha_j A^j v\,. \tag{2.2}$$

Defining the monic polynomial $\phi(z) = z^d + \alpha_{d-1} z^{d-1} + \cdots + \alpha_0$, we can rewrite (2.2) as

$$\phi(A)v \;=\; 0\,. \tag{2.3}$$

We say that ϕ *annihilates* v. It would be more accurate to say "ϕ annihilates v with respect to A," but when it is clear which operator A is meant, the reference to A is

omitted for the sake of brevity. The monic polynomial ϕ is the uniquely determined monic polynomial of smallest degree that annihilates v, and it is called the *minimal polynomial of* v. Its degree, equal to $d(A, v)$, is called the *grade of* v, and v is said to be of grade $d(A, v)$.

Consider any basis of V, and define the polynomial Φ as the least common multiple of the minimal polynomials of the basis vectors. Then Φ is the uniquely defined (independent of the choice of the basis!) monic polynomial of smallest degree that annihilates all vectors $v \in V$, and it is called the *minimal polynomial of* A. We denote its degree by $d_{\min}(A)$. Apparently, $d_{\min}(A) \geq d(A, v)$ for all $v \in V$, and Φ is divisible by the minimal polynomial of every vector $v \in V$.

If $v \in V$ is any vector of grade d, then

$$\text{span}\{v, \dots\ A^{d-1}v\} \ \equiv\ \mathcal{K}_d(A, v) \tag{2.4}$$

is a d-dimensional invariant subspace of A. Because of (2.2) and the special character of the basis vectors, the subspace $\mathcal{K}_d(A, v)$ is called *cyclic*. The letter $\mathcal{K}$ has been chosen because this space is often called the *Krylov subspace* of A and v. The vector v is called the *generator* of this subspace.

A central result in the theory of linear operators on finite dimensional vector spaces is that the space V can be decomposed into cyclic subspaces. This result has several equivalent formulations, and in this paper we will use the one from [6, Chapter VII, section 4, Theorem 3]: there exist vectors $w_1, \dots, w_j \in V$ of respective grades $d_1, \dots, d_j$ such that

$$V \ =\ \mathcal{K}_{d_1}(A, w_1) \oplus \cdots \oplus \mathcal{K}_{d_j}(A, w_j)\,, \tag{2.5}$$

where the minimal polynomial of w_1 is equal to the minimal polynomial of A, and for $k = 1, \dots, j-1$, the minimal polynomial of w_k is divisible by the minimal polynomial of w_{k+1}.

Since the decomposition (2.5) is an important tool in this paper, we illustrate it by a simple example (adapted from [9, section 7.2]; also see [10] for a short and self-contained proof of the decomposition (2.5)). Suppose that A is the linear operator on $V = \mathbb{R}^3$ whose matrix representation in the canonical basis of $\mathbb{R}^3$ is

$$\begin{bmatrix} 2 & -3 & -3 \\ -3 & 2 & 3 \\ 3 & -3 & -4 \end{bmatrix}.$$

The characteristic polynomial of A is $(z-2)(z+1)^2$, while the minimal polynomial is $\Phi = (z-2)(z+1)$, so that $d_{\min}(A) = 2$. Any nonzero vector in $\mathbb{R}^3$ is either of grade one (and hence is an eigenvector) or of grade two. It is easy to see that the first canonical basis vector is not an eigenvector. Thus, $w_1 \equiv [1,\ 0,\ 0]^T$ is of grade $d_1 = 2$, i.e., $\mathcal{K}_{d_1}(A, w_1)$ has dimension two, and the minimal polynomial of w_1 is Φ. Note that

$$\mathcal{K}_{d_1}(A, w_1) \ =\ \text{span}\left\{ \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 2 \\ -3 \\ 3 \end{bmatrix} \right\} \ =\ \left\{ \begin{bmatrix} \alpha \\ \beta \\ -\beta \end{bmatrix} \,:\, \alpha, \beta \in \mathbb{R} \right\}.$$

Since $V = \mathbb{R}^3$ has dimension three, it remains to find a vector $w_2 \notin \mathcal{K}_{d_1}(A, w_1)$ that is of grade one and has minimal polynomial $z+1$, i.e., w_2 is an eigenvector with respect to the eigenvalue -1, that is not contained in $\mathcal{K}_{d_1}(A, w_1)$. These requirements are satisfied by $w_2 \equiv [1,\ 0,\ 1]^T$, giving

$$\mathbb{R}^3 \ =\ \mathcal{K}_{d_1}(A, w_1) \oplus \mathcal{K}_{d_2}(A, w_2) \ =\ \text{span}\,\{w_1,\ Aw_1\} \oplus \text{span}\,\{w_2\}\,.$$

In the basis of $\mathbb{R}^3$ given by w_1, Aw_1, w_2, the linear operator A has the matrix representation

$$\left[\begin{array}{cc|c} 0 & 2 & \\ 1 & 1 & \\ \hline & & -1 \end{array}\right].$$

Here the two diagonal blocks correspond to the decomposition (2.5), where each block is the companion matrix of the minimal polynomial of the respective cyclic subspace generators. This matrix representation is sometimes called the *rational canonical form*. When this canonical form consists of a single diagonal block in companion form, A is called *nonderogatory*. Hence in our example A is derogatory, but the restriction of A to the cyclic subspace generated by w_1 is nonderogatory. Loosely speaking, this restriction is the "largest nonderogatory part" of A.

3. Orthogonalization of a cyclic subspace basis. Let $v \in V$ be a vector of grade d. For theoretical as well as practical purposes it is often convenient to *orthogonalize* the basis $v, \ldots, A^{d-1}v$ of the cyclic subspace $\mathcal{K}_d(A, v)$. The classical approach to orthogonalization, which appears in different mathematical areas (see, e.g., [2, p. 15], [5, p. 74]) is the Gram–Schmidt algorithm:

$$v_1 = v\,, \tag{3.1}$$

$$v_{n+1} = Av_n - \sum_{m=1}^{n} h_{m,n} v_m\,, \tag{3.2}$$

$$h_{m,n} = \frac{(Av_n, v_m)}{(v_m, v_m)}\,, \quad m = 1, \ldots, n\,, \quad n = 1, \ldots, d-1\,. \tag{3.3}$$

The resulting vectors $v_1, \ldots, v_d$ are mutually orthogonal, and for $n = 1, \ldots, d$ they satisfy $\operatorname{span}\{v_1, \ldots, v_n\} = \operatorname{span}\{v, \ldots, A^{n-1}v\}$. We call v (or v_1) the *initial vector* of the algorithm (3.1)–(3.3). When A is a (square) matrix, this algorithm is usually referred to as Arnoldi's method [1]. It can be equivalently written as

$$v_1 = v\,, \tag{3.4}$$

$$A \underbrace{[v_1, \ldots, v_{d-1}]}_{\equiv V_{d-1}} = \underbrace{[v_1, \ldots, v_d]}_{\equiv V_d} \underbrace{\begin{bmatrix} h_{1,1} & \cdots & h_{1,d-1} \\ 1 & \ddots & \vdots \\ & \ddots & h_{d-1,d-1} \\ & & 1 \end{bmatrix}}_{\equiv H_{d,d-1}}, \tag{3.5}$$

$$(v_i, v_j) = 0 \quad \text{for } i \neq j\,, \quad i, j = 1, \ldots, d\,. \tag{3.6}$$

The matrix $H_{d,d-1}$ is an unreduced upper Hessenberg matrix of size $d \times (d-1)$. Its band structure determines the length of the recurrence (3.2) that generates the orthogonal basis. To state this formally, we need the following definition [12, Definition 2.1].

DEFINITION 3.1. *An unreduced upper Hessenberg matrix is called $(s+2)$-band Hessenberg when its sth superdiagonal contains at least one nonzero entry and all its entries above its sth superdiagonal are zero.*

If $H_{d,d-1}$ is $(s+2)$-band Hessenberg, then for $n = 1, \ldots, d-1$, the recurrence (3.2) reduces to

$$v_{n+1} \;=\; Av_n \;-\; \sum_{m=n-s}^{n} h_{m,n} v_m \,, \tag{3.7}$$

and thus the orthogonal basis is generated by an $(s+2)$-*term recurrence*. Since precisely the latest $s+1$ basis vectors $v_n, \ldots, v_{n-s}$ are required to determine v_{n+1}, and only one operation with A is performed, an $(s+2)$-term recurrence of the form (3.7) is called *optimal*.

DEFINITION 3.2 (linear operator version of [12, Definition 2.4]). *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space, and let s be a nonnegative integer, $s+2 \le d_{\min}(A)$.*

1. *If for an initial vector the matrix $H_{d,d-1}$ in (3.4)–(3.6) is $(s+2)$-band Hessenberg, then we say that A admits for the given initial vector an optimal $(s+2)$-term recurrence.*
2. *If A admits for any given initial vector an optimal recurrence of length at most $s+2$, while it admits for at least one given initial vector an optimal $(s+2)$-term recurrence, then we say that A admits an optimal $(s+2)$-term recurrence.*

We denote the *adjoint of* A by A^*. This is the uniquely determined operator that satisfies $(Av, w) = (v, A^*w)$ for all vectors v and w in the given Hilbert space. The operator A is called *normal* if it commutes with its adjoint, $AA^* = A^*A$. This holds if and only if A has a complete orthonormal system of eigenvectors. Equivalently, A^* can be written as a polynomial in A, $A^* = p(A)$, where p is completely determined by the condition that $p(\lambda_j) = \overline{\lambda}_j$ for all eigenvalues λ_j of A (cf. [6, Chapter IX, section 10]). We will be particularly interested in the degree of this polynomial.

DEFINITION 3.3. *Let A be an invertible linear operator on a finite dimensional Hilbert space. If the adjoint of A satisfies $A^* = p(A)$, where p is a polynomial of smallest degree s having this property, then A is called normal of degree s, or, shortly, normal(s).*

The condition that A is normal(s) is *sufficient* for A to admit an optimal $(s+2)$-term recurrence. The precise formulation of this statement is the following.

THEOREM 3.4. *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space. Let s be a nonnegative integer, $s+2 < d_{\min}(A)$. If A is normal(s), then A admits an optimal $(s+2)$-term recurrence.*

Proof. A matrix version of this result is given in [12, Theorem 2.9], and the proof given there can be easily adapted from matrices to linear operators. ∎

The main result we will prove in this paper is that the condition that A is normal(s) also is *necessary*.

THEOREM 3.5. *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space. Let s be a nonnegative integer, $s+2 < d_{\min}(A)$. If A admits an optimal $(s+2)$-term recurrence, then A is normal(s).*

4. Technical lemmas. We prove Theorem 3.5 in section 5. To do so, we need several technical lemmas that are stated and proved in this section.

LEMMA 4.1. *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space. If $1 < i < n \le d_{\min}(A)$ and $(u_1, Au_i) = 0$ for every initial vector u_1 of grade n, then $(v_1, Av_i) = 0$ for every initial vector v_1 of grade m, where $i \le m \le n$.*

(Here u_i, v_i are the ith basis vectors generated by (3.1)–(3.3) *with initial vectors u_1, v_1, respectively.)*

Proof. If $m = n$, there is nothing to prove. Hence, suppose that $m < n$, and let v_1 be a vector of grade m, and u_1 be a vector of grade n, such that the minimal polynomial of v_1 divides the minimal polynomial of u_1. Define

$$x_1 \equiv x_1(\gamma) \equiv v_1 + \gamma u_1 , \tag{4.1}$$

where γ is a scalar parameter. It is clear that, except for finitely many choices of γ, the vector x_1 is of grade n.

Suppose that γ has been chosen so that x_1 is of grade n, and consider the corresponding ith basis vector x_i, where $1 < i \le m$. By construction, $x_i = p(A)x_1$, where p is a polynomial of (exact) degree $i-1$. The vector x_i is defined uniquely (up to scaling) by the conditions

$$(A^j x_1, x_i) = (A^j x_1, p(A)x_1) = 0 , \quad j = 0, \ldots, i-2 .$$

The hypothesis

$$(x_1, Ax_i) = (x_1, Ap(A)x_1) = 0$$

gives one additional condition. We thus have i conditions that translate into i homogeneous linear equations for the i coefficients of the polynomial p. The existence of x_i implies that the determinant of the matrix $M(x_1)$ of these equations must be zero, where

$$M(x_1) = \begin{bmatrix} (x_1, x_1) & (x_1, Ax_1) & \cdots & (x_1, A^{i-1}x_1) \\ (Ax_1, x_1) & (Ax_1, Ax_1) & \cdots & (Ax_1, A^{i-1}x_1) \\ \vdots & \vdots & \vdots & \vdots \\ (A^{i-2}x_1, x_1) & (A^{i-2}x_1, Ax_1) & \cdots & (A^{i-2}x_1, A^{i-1}x_1) \\ (x_1, Ax_1) & (x_1, A^2x_1) & \cdots & (x_1, A^i x_1) \end{bmatrix} .$$

Now note that $\det M(x_1)$ is a continuous function of γ. By construction, this function is zero for all but a finite number of choices of γ. Therefore $\det M(x_1) = 0$ for all γ, and in particular, $\det M(v_1) = 0$. Consequently, there exists a nontrivial solution of the linear system with $M(v_1)$, defining a vector $w = p(A)v_1$, where p is a polynomial of degree at most $i-1$. The first $i-1$ rows mean that w is orthogonal to $v_1, \ldots, A^{i-2}v_1$, so w is a multiple of v_i. The last row means that Aw and hence Av_i is orthogonal to v_1. ∎

The decomposition (2.5) shows that for any linear operator A on a finite dimensional Hilbert space V, there exists a vector in V whose minimal polynomial coincides with the minimal polynomial of A. The following result shows that there in fact exists a basis of V consisting of vectors with this property.

LEMMA 4.2. *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space V. Then there exists a basis of V consisting of vectors that all are of grade $d_{\min}(A)$.*

Proof. From the cyclic decomposition theorem, cf. (2.5), we know that there exist vectors $w_1, \ldots, w_j$ with minimal polynomials $\phi_1, \ldots, \phi_j$ of respective degrees $d_1, \ldots, d_j$, such that the space V can be decomposed as

$$V = \mathcal{K}_{d_1}(A, w_1) \oplus \cdots \oplus \mathcal{K}_{d_j}(A, w_j) ,$$

where ϕ_1 equals the minimal polynomial of A, and ϕ_k is divisible by ϕ_{k+1} for $k = 1, \ldots, j-1$. In particular, $d_1 = d_{\min}(A)$. Consequently, a basis of V is given by

$$w_1, \ldots, A^{d_1-1}w_1, \quad w_2, \ldots, A^{d_2-1}w_2, \quad \ldots, \quad w_j, \ldots, A^{d_j-1}w_j\,.$$

But then it is easy to see that

$$w_1, \ldots, A^{d_1-1}w_1, \quad w_2+w_1, \ldots, A^{d_2-1}w_2+w_1, \quad \ldots, \quad w_j+w_1, \ldots, A^{d_j-1}w_j+w_1$$

is a basis of V consisting of vectors that all are of grade d_1. ∎

The following result is a generalization of [11, Lemma 4.1], which in turn can be considered a (considerably) strengthened version of [4, Lemma 2].

LEMMA 4.3. *Let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space. Let B be a linear operator on the same space, and let s be a nonnegative integer, $s+2 \le d_{\min}(A)$. If*

$$Bv \in \operatorname{span}\{v, \ldots, A^s v\} \quad \textit{for all vectors } v \textit{ of grade } d_{\min}(A)\,, \tag{4.2}$$

then $AB = BA$. In particular, if $B = A^*$, then A is normal(t) for some $t \le s$.

Proof. For notational convenience, we denote $\delta = d_{\min}(A)$. Let v be any vector of grade δ. Since A is invertible, $\mathcal{K}_\delta(A, v) = \mathcal{K}_\delta(A, Av)$. In addition, except possibly when γ is an eigenvalue of A, the vector $w = (A-\gamma I)v$ satisfies $\mathcal{K}_\delta(A, w) = \mathcal{K}_\delta(A, v)$. In the following, we exclude those values of γ. By assumption, there exist polynomials p_γ, q, and r of degree at most s, which satisfy

$$Bw = p_\gamma(A)w, \quad B(Av) = q(A)(Av), \quad Bv = r(A)v,$$

where p_γ depends on γ, but q and r do not. We can then write Bw as

$$Bw \;=\; p_\gamma(A)w \;=\; p_\gamma(A)Av - \gamma p_\gamma(A)v$$

and

$$Bw \;=\; BAv - \gamma Bv \;=\; q(A)Av - \gamma r(A)v\,.$$

Combining these two identities yields

$$t_\gamma(A)v \;=\; 0\,, \quad \text{where} \quad t_\gamma(z) = z(p_\gamma(z) - q(z)) - \gamma(p_\gamma(z) - r(z))\,.$$

The polynomial t_γ is of degree at most $s+1 < s+2 \le \delta$. Thus, except for finitely many γ, $t_\gamma = 0$. Some straightforward algebraic manipulation gives, for all but these γ,

$$\gamma(q(z) - r(z)) \;=\; (z-\gamma)\widehat{p}_\gamma(z)\,,$$

where $\widehat{p}_\gamma \equiv p_\gamma - q$ is of degree at most $s-1$. Therefore, every γ that is not an eigenvalue of A is a root of the polynomial $r-q$, which consequently must be identically zero.

But then

$$B(Av) \;=\; q(A)(Av) \;=\; Aq(A)v \;=\; Ar(A)v \;=\; A(Bv)\,.$$

By Lemma 4.2, there exists a basis consisting of vectors of grade δ. Hence $BAv = ABv$ for a basis of vectors v, so that $BA = AB$.

Finally, if $B = A^*$, then $AA^* = A^*A$, so that A is normal and hence $A^* = p(A)$ for some polynomial. From (4.2) we see that the degree of p is at most s, so that A is normal(t) for some $t \le s$. ∎

5. Proof of Theorem 3.5. Let A be an invertible linear operator on a finite dimensional Hilbert space, and let s be a nonnegative integer, $s+2 < d_{\min}(A)$. Suppose that A admits an optimal $(s+2)$-term recurrence.

Step 1. *Restriction to a cyclic subspace of dimension* $s+2$.

If u_1 is any vector of grade $s+3$, then (with the obvious meaning of u_{s+2})

$$0 \;=\; h_{1,s+2} \;=\; (u_1, Au_{s+2})\,. \tag{5.1}$$

Consider any v_1 of grade $s+2$, and the corresponding cyclic subspace $\mathcal{K}_{s+2}(A, v_1)$. Let $\widehat{A}$ be the restriction of A to $\mathcal{K}_{s+2}(A, v_1)$, i.e., the invertible linear operator

$$\widehat{A} : \mathcal{K}_{s+2}(A, v_1) \to \mathcal{K}_{s+2}(A, v_1)\,, \qquad v \mapsto Av \;\text{ for } v \in \mathcal{K}_{s+2}(A, v_1)\,.$$

Clearly, $d_{\min}(\widehat{A}) = s+2$. Let $\mathcal{K}_{s+2}(A, v_1)$ be equipped with the same inner product as the whole space.

Let $y_1 \in \mathcal{K}_{s+2}(A, v_1)$ be any vector of grade $s+2$. Obviously, the grade of y_1 with respect to A is the same as the grade of y_1 with respect to $\widehat{A}$. Since (5.1) holds for any u_1 of grade $s+3$ (with respect to A), Lemma 4.1 (with $i = m = s+2$ and $n = s+3$) implies that (with the obvious meaning of y_{s+2})

$$0 \;=\; (y_1, Ay_{s+2}) \;=\; (y_1, \widehat{A}y_{s+2}) \;=\; (\widehat{A}^* y_1, y_{s+2})\,, \tag{5.2}$$

where $\widehat{A}^* : \mathcal{K}_{s+2}(A, v_1) \to \mathcal{K}_{s+2}(A, v_1)$ is the adjoint operator of $\widehat{A}$. But this means that

$$\widehat{A}^* y_1 \;\in\; \operatorname{span}\{y_1, \ldots, \widehat{A}^s y_1\}\,. \tag{5.3}$$

Since this holds for any vector $y_1 \in \mathcal{K}_{s+2}(A, v_1) = \mathcal{K}_{s+2}(\widehat{A}, v_1)$ of grade $s+2 = d_{\min}(\widehat{A})$, Lemma 4.3 implies that $\widehat{A}$ is normal(t) for some $t \le s$. In particular, $\widehat{A}$ is normal, and has $s+2$ distinct eigenvalues, λ_k, $k = 1, \ldots, s+2$, with corresponding eigenvectors that are mutually orthogonal. Moreover, there exists a polynomial of degree at most s such that $p(\lambda_k) = \overline{\lambda}_k$, $k = 1, \ldots, s+2$. By definition, any eigenpair of $\widehat{A}$ is an eigenpair of A. Therefore, A acting on *any* vector of grade $s+2$ has $s+2$ distinct eigenvalues, and the corresponding eigenvectors are mutually orthogonal in the given inner product.

Step 2. *Extension to the whole space.*

Consider the cyclic decomposition of the whole space as in (2.5). Then the cyclic subspace $\mathcal{K}_{d_1}(A, w_1)$, where w_1 has the same minimal polynomial as A, can be further decomposed into

$$\mathcal{K}_{d_1}(A, w_1) \;=\; \mathcal{K}_{c_1}(A, z_1) \oplus \cdots \oplus \mathcal{K}_{c_\ell}(A, z_\ell)\,,$$

where the minimal polynomial of z_k is $(z - \lambda_k)^{c_k}$, $k = 1, \ldots, \ell$, and $\lambda_1, \ldots, \lambda_\ell$ are the distinct eigenvalues of A (see, e.g., [6, Chapter VII, section 2, Theorem 1]). In other words, $\mathcal{K}_{d_1}(A, w_1)$ is decomposed into ℓ cyclic invariant subspaces of A, where each of these corresponds to one of the ℓ distinct eigenvalues of A. (Recall that the restriction of A to $\mathcal{K}_{d_1}(A, w_1)$ is nonderogatory; see the example at the end of section 2.) In particular, if A is diagonalizable, then $\ell = d_{\min}(A)$, and $c_1 = \cdots = c_\ell = 1$, and $z_1, \ldots, z_\ell$ are eigenvectors of A corresponding to $\lambda_1, \ldots, \lambda_\ell$, respectively. In general, we can assume that $c_1 \ge c_2 \ge \cdots \ge c_\ell$. If $c_1 \ge s+2$, we can determine a vector v_1 of grade $s+2$ in $\mathcal{K}_{c_1}(A, z_1)$. But then the above implies that A acting on v_1 has $s+2$

distinct eigenvalues, which is a contradiction. Hence $c_1 < s+2$. We therefore can find an index m so that $c_1 + \cdots + c_{m-1} + \tilde{c}_m = s+2$, $0 \le \tilde{c}_m \le c_m$. Let $\tilde{z}_m$ be any vector of grade $\tilde{c}_m$ in $\mathcal{K}_{c_m}(A, z_m)$; then $w = z_1 + \cdots + z_{m-1} + \tilde{z}_m$ is of grade $s+2$. Hence A acting on w has $s+2$ distinct eigenvalues, which shows that $c_1 = c_2 = \cdots = c_\ell = 1$. To these eigenvalues correspond $s+2$ eigenvectors that are mutually orthogonal in the given inner product.

In the cyclic decomposition (2.5), the minimal polynomial of w_k is divisible by the minimal polynomial of w_{k+1}. Therefore the whole space completely decomposes into one-dimensional cyclic subspaces of A, i.e., A has a complete system of eigenvectors. We know that any $s+2$ of these corresponding to distinct eigenvalues of A must be mutually orthogonal. In the subspaces corresponding to a multiple eigenvalue we can find an orthogonal basis. Therefore A has a complete orthonormal system of eigenvectors, and hence A is normal. For every subset of $s+2$ distinct eigenvalues there exists a polynomial p of degree at most s that satisfies $p(\lambda_k) = \overline{\lambda}_k$ for all eigenvalues λ_k in the subset. If we take any two subsets having $s+1$ eigenvalues in common, the two corresponding polynomials must be identical. Thus all the polynomials are identical, so that A is normal(t) for some $t \le s$.

If $t < s$, then by the sufficiency result in Theorem 3.4, A admits an optimal $(t+2)$-term recurrence, which contradicts our initial assumption. Hence $t = s$, so that A is normal(s), which concludes the proof. ∎

6. Another proof based on the Rotation Lemma. In this section we discuss an elementary and more constructive approach to proving Theorem 3.5, which is based on orthogonal transformations ("rotations") of upper Hessenberg matrices. With this approach, we can prove Theorem 3.5 with the assumption $s+2 < d_{\min}(A)$ replaced by $s+3 < d_{\min}(A)$. We discuss the missing case $s+3 = d_{\min}(A)$ in section 7.

As above, let A be an invertible linear operator with minimal polynomial degree $d_{\min}(A)$ on a finite dimensional Hilbert space. Let s be a given nonnegative integer, $s+3 < d_{\min}(A)$. We assume that

(6.1) A admits an $(s+2)$-term recurrence, but A is *not* normal(s),

and derive a contradiction.

For deriving the contradiction we need some notation. Suppose that the space is decomposed into cyclic invariant subspaces of A as in (2.5). Let $\widehat{A}$ be the restriction of A to $\mathcal{K}_{d_1}(A, w_1)$, i.e., the invertible linear operator defined by

$$\widehat{A} \,:\, \mathcal{K}_{d_1}(A, w_1) \to \mathcal{K}_{d_1}(A, w_1)\,, \qquad v \mapsto Av \ \text{ for } v \in \mathcal{K}_{d_1}(A, w_1)\,.$$

The operator $\widehat{A}$ depends on the choice of w_1, which we consider fixed here, so $\widehat{A}$ is fixed as well. It is clear that $d_1 = d_{\min}(A) = d_{\min}(\widehat{A})$. We denote $d = d_1$ for simplicity. Now let $v_1 \in \mathcal{K}_d(\widehat{A}, w_1)$ be any initial vector of grade d, and let $v_1, \ldots, v_d$ be the corresponding orthogonal basis of $\mathcal{K}_d(\widehat{A}, v_1) = \mathcal{K}_d(\widehat{A}, w_1)$ generated by (3.1)–(3.3). Then the matrix representation of the operator $\widehat{A}$ with respect to this particular basis is a $d \times d$ unreduced upper Hessenberg matrix H_d, which is defined by the equation

$$\widehat{A}\,[v_1, \ldots, v_d] \;=\; [v_1, \ldots, v_d]\, H_d\,. \tag{6.2}$$

The matrix formed by the first $d-1$ columns of H_d coincides with the $d \times (d-1)$ upper Hessenberg matrix generated by (3.1)–(3.3) with $\widehat{A}$ and the initial vector v_1,

while the last column of H_d is given by the vector

$$h_d \;=\; \begin{bmatrix} h_{1,d} \\ \vdots \\ h_{d,d} \end{bmatrix}, \quad \text{where} \quad h_{m,d} \;=\; \frac{(\widehat{A}v_d, v_m)}{(v_m, v_m)}, \quad m = 1, \ldots, d\,. \tag{6.3}$$

In short, $H_d = [H_{d,d-1}, h_d]$. We now proceed in two steps.

Step 1. *Show that there exists a basis for which* $h_{1,d} \neq 0$.

We first show that under assumption (6.1) there exists an initial vector $v_1 \in \mathcal{K}_d(\widehat{A}, w_1)$ of grade $d = d_{\min}(\widehat{A})$ for which the matrix representation H_d of $\widehat{A}$ has $h_{1,d} \neq 0$. Suppose not, i.e., for all $v_1 \in \mathcal{K}_d(\widehat{A}, w_1)$ of grade $d_{\min}(\widehat{A})$, we have for the resulting entry $h_{1,d}$,

$$0 \;=\; h_{1,d} \;=\; \frac{(\widehat{A}v_d, v_1)}{(v_1, v_1)} \;=\; \frac{(v_d, \widehat{A}^* v_1)}{(v_1, v_1)}\,,$$

where $\widehat{A}^*$ is the adjoint of $\widehat{A}$. In particular, this implies that for all vectors $v_1 \in \mathcal{K}_d(\widehat{A}, w_1)$ of grade $d = d_{\min}(\widehat{A})$,

$$\widehat{A}^* v_1 \;\in\; \{v_1, \ldots, \widehat{A}^{d-2} v_1\}\,.$$

By Lemma 4.3, $\widehat{A}$ is normal(t) for some $t \leq d_{\min}(\widehat{A}) - 2$. Therefore, A acting on any vector of grade $d_{\min}(A)$ has $d_{\min}(A)$ distinct eigenvalues and corresponding eigenvectors that are mutually orthogonal. From this it is easy to see that A is normal(t). By the sufficiency result in Theorem 3.4, A admits an optimal $(t+2)$-term recurrence. However, we have assumed in (6.1) that A admits an optimal $(s+2)$-term recurrence, so $t = s$. But then A is normal(s), which contradicts the second part of the assumption. In summary, there exists an initial vector v_1 of grade $d = d_{\min}(A)$, such that (6.2) holds with $H_d = [H_{d,d-1}, h_d]$, where $H_{d,d-1}$ is $(s+2)$-band Hessenberg (this follows from the first part of our assumption), while $h_{1,d} \neq 0$.

Step 2. *Rotation of the nonzero entry* $h_{1,d}$.

The following result is called the Rotation Lemma for reasons apparent from its proof.

LEMMA 6.1 (Rotation Lemma). *Let* s, d *be nonnegative integers,* $s + 3 < d$. *Let* H_d *be a* $d \times d$ *unreduced upper Hessenberg matrix with* $h_{1,d} \neq 0$ *and* $H_{d,d-1}$, *the matrix formed by the first* $d-1$ *columns of* H_d, *being an* $(s+2)$*-band Hessenberg matrix. Then there exists a unitary matrix* G *such that* $\widetilde{H}_d \equiv G^* H_d G$ *is a* $d \times d$ *unreduced upper Hessenberg matrix with* $[\widetilde{h}_{1,d-1}, \widetilde{h}_{2,d-1}] \neq [0, 0]$.

Proof. The main idea of this proof is to find $d-1$ (complex) Givens rotations of the form

$$G_i \equiv \begin{bmatrix} I_{d-1-i} & & & \\ & c_i & \overline{s}_i & \\ & -s_i & c_i & \\ & & & I_{i-1} \end{bmatrix}, \quad c_i^2 + |s_i|^2 = 1, \quad c_i \in \mathbb{R}, \quad i = 1, \ldots, d-1, \tag{6.4}$$

which, applied symmetrically to H_d, "rotate" the nonzero entry $h_{1,d}$ to the $(d-1)$st column of the resulting matrix $\widetilde{H}_d = (G_1 \cdots G_{d-1})^* H_d (G_1 \cdots G_{d-1})$. To prove the assertion it suffices to show the following. First, $\widetilde{H}_d$ must be an unreduced upper Hessenberg matrix, and, second, at least one of its entries $\widetilde{h}_{1,d-1}, \widetilde{h}_{2,d-1}$ is nonzero. See Figure 6.1 for an illustration of this idea.

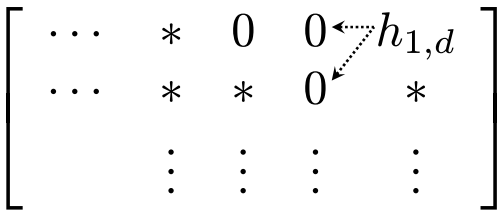

FIG. 6.1. *Graphical illustration of the Rotation Lemma. Shown is the upper-right-hand corner of* $H_d = [H_{d,d-1}, h_d]$. *We know that* $H_{d,d-1}$ *is* $(s+2)$*-band Hessenberg with* $s+3 < d$ *and that* $h_{1,d} \neq 0$. *We construct an orthogonal transformation* G *such that the matrix* $\widetilde{H}_d = G^* H_d G$ *remains unreduced upper Hessenberg, while the nonzero entry* $h_{1,d} \neq 0$ *is "rotated" to the last column of* $\widetilde{H}_{d,d-1}$, *so that at least one of its entries* $\widetilde{h}_{1,d-1}$ *and* $\widetilde{h}_{2,d-1}$ *is nonzero.*

Proceeding in an inductive manner, we denote $H^{(0)} \equiv H_d$. To start, choose $s_1 \in \mathbb{R} \setminus \{0\}$ and $c_1 \in \mathbb{R}$ such that $c_1^2 + s_1^2 = 1$. We have explicitly chosen real parameters s_1, c_1 since this simplifies our arguments below. These two parameters determine our first Givens rotation G_1 of the form (6.4). By construction, the matrix $H^{(1)} \equiv G_1^* H^{(0)} G_1$ is upper Hessenberg except for its entry

$$h_{d,d-2}^{(1)} = s_1 h_{d-1,d-2}^{(0)}.$$

Since $s_1 \neq 0$ and $h_{d-1,d-2}^{(0)} \neq 0$ ($H^{(0)}$ is unreduced), we have $h_{d,d-2}^{(1)} \neq 0$. The transformation by G_1 modifies only the last two rows and columns of $H^{(0)}$, so that the entries on the subdiagonal of $H^{(1)}$ satisfy $h_{i+1,i}^{(1)} = h_{i+1,i}^{(0)} \neq 0$, $i = 1, \ldots, d-3$. Next, we determine G_2 such that its application from the right to $H^{(1)}$ eliminates the nonzero entry in position $(d, d-2)$. Application of G_2^* from the left then introduces a nonzero entry in position $(d-1, d-3)$, which we will subsequently eliminate using G_3, and so forth.

In a general step $j = 2, \ldots, d-1$, suppose that $s_{j-1} \neq 0$, $h_{i+1,i}^{(j-1)} = h_{i+1,i}^{(0)} \neq 0$, $i = 1, \ldots, d-j-1$, and $h_{i+1,i}^{(j-1)} \neq 0$ for $i = d-j+2, \ldots, d-1$. Next suppose that

$$H^{(j-1)} \equiv G_{j-1}^* H^{(j-2)} G_{j-1}$$

is an upper Hessenberg matrix except for its entry

$$h_{d-j+2,d-j}^{(j-1)} = s_{j-1} h_{d-j+1,d-j}^{(0)} \neq 0.$$

The next Givens rotation G_j is (uniquely) determined to eliminate this nonzero entry, i.e., we determine c_j and s_j by the equation

$$[h_{d-j+2,d-j}^{(j-1)}, h_{d-j+2,d-j+1}^{(j-1)}] \begin{bmatrix} c_j & \overline{s}_j \\ -s_j & c_j \end{bmatrix} = [0, h_{d-j+2,d-j+1}^{(j)}]. \tag{6.5}$$

Since $h_{d-j+2,d-j}^{(j-1)} \neq 0$, it is clear that $s_j \neq 0$ and $h_{d-j+2,d-j+1}^{(j)} \neq 0$. As a result, the matrix

$$H^{(j)} \equiv G_j^* H^{(j-1)} G_j$$

is an upper Hessenberg except for its entry

$$h_{d-j+1,d-j-1}^{(j)} = s_j h_{d-j,d-j-1}^{(0)} \neq 0.$$

The unitary transformation determined by G_j modifies only $(d-j)$th and $(d-j+1)$st rows and columns of $H^{(j-1)}$. Therefore, the subdiagonal entries of $H^{(j)}$ satisfy $h^{(j)}_{i+1,i} = h^{(0)}_{i+1,i} \neq 0$ for $i = 1, \ldots, d-j-2$, and, since $h^{(j)}_{d-j+2,d-j+1} \neq 0$, we have shown inductively that indeed $h^{(j)}_{i+1,i} \neq 0$ for $i = d-j+1, \ldots, d-1$. In the end, we receive the unitary matrix $G = G_1 \cdots G_{d-1}$ and the upper Hessenberg matrix $H^{(d-1)} = G^* H^{(0)} G$ with $h^{(d-1)}_{i+1,i} \neq 0$ for $i = 2, \ldots, d-1$. To complete the proof we need to show that the initial parameters s_1, c_1 can be chosen so that, first, $h^{(d-1)}_{2,1} \neq 0$ ($H^{(d-1)}$ is unreduced), and, second, $[\, h^{(d-1)}_{1,d-1}, h^{(d-1)}_{2,d-1}\,] \neq [0,0]$.

First, if $h^{(d-1)}_{2,1} = 0$, then we must have $h^{(d-1)}_{1,1} \neq 0$, for if otherwise $H^{(d-1)}$ would be singular. From $H^{(d-1)} = G^* H^{(0)} G$ we receive $H^{(0)} G = G H^{(d-1)}$, and thus the first column of G is an eigenvector of $H^{(0)}$ corresponding to the eigenvalue $h^{(d-1)}_{1,1}$. Note that the first column of G depends on our choice of s_1, while the matrix $H^{(0)}$ is fixed and has at most d linearly independent eigenvectors. Apparently, the case $h^{(d-1)}_{2,1} = 0$ happens only for a finite number of values of s_1 (if any); almost every initial choice of s_1 will yield $h^{(d-1)}_{2,1} \neq 0$.

Second, we have assumed that the first $d-1$ columns of $H^{(0)}$ form an unreduced $(s+2)$-band Hessenberg matrix with $s+3 < d$, and therefore $h^{(0)}_{1,d-2} = h^{(0)}_{1,d-1} = 0$ (see Figure 6.1). Denote the entries of the (lower Hessenberg) matrix G by $g_{i,j}$. It is easy to see that $g_{d,d-1} = -c_2 s_1$. Again consider the matrix equation $H^{(0)} G = G H^{(d-1)}$. Comparing the entries in position $(1, d-1)$ on both sides shows that

$$-c_2 s_1 h^{(0)}_{1,d} \;=\; g_{1,1} h^{(d-1)}_{1,d-1} + g_{1,2} h^{(d-1)}_{1,d-1}\,, \tag{6.6}$$

where $h^{(0)}_{1,d} \neq 0$ and $s_1 \neq 0$. Therefore, to show that $[h^{(d-1)}_{1,d-1}, h^{(d-1)}_{2,d-1}] \neq [0,0]$, it suffices to show that $c_2 \neq 0$. For c_2 it holds that (cf. (6.5))

$$h^{(1)}_{d,d-2} c_2 - h^{(1)}_{d,d-1} s_2 \;=\; 0.$$

We know that $h^{(1)}_{d,d-2} \neq 0 \neq s_2$. Thus, $c_2 = 0$ if and only if $h^{(1)}_{d,d-1} = 0$, which holds if and only if

$$c_1 s_1 h^{(0)}_{d-1,d-1} + c_1^2 h^{(0)}_{d,d-1} - s_1^2 h^{(0)}_{d-1,d} - c_1 s_1 h^{(0)}_{d,d} \;=\; 0.$$

We write $s_1 = \sin(\theta)$, $c_1 = \cos(\theta)$ and apply standard identities for trigonometric functions to see that the above equation is equivalent with

$$\left(h^{(0)}_{d-1,d-1} - h^{(0)}_{d,d}\right) \sin(2\theta) + \left(h^{(0)}_{d,d-1} + h^{(0)}_{d-1,d}\right) \cos(2\theta) + \left(h^{(0)}_{d,d-1} - h^{(0)}_{d-1,d}\right) \;=\; 0\,.$$

The left-hand side in this equation is a nontrivial trigonometric polynomial of degree two, which has at most two roots in the interval $[0, 2\pi)$. Consequently, for almost all choices of s_1 we receive $c_2 \neq 0$, giving a nonzero right-hand side in (6.6). Hence, for almost all choices of s_1, we must have $[h^{(d-1)}_{1,d-1}, h^{(d-1)}_{2,d-1}] \neq [0,0]$. ∎

We can now derive the contradiction to (6.1). Consider the relation (6.2), where H_d is of the form assumed in the Lemma 6.1. Without loss of generality we may assume that the columns of V_d are normalized (normalization does not alter the nonzero pattern of H_d). By Lemma 6.1, there exists a unitary matrix G such that $\widetilde{H}_d = G^* H_d G$ is unreduced upper Hessenberg with either $\widetilde{h}_{1,d-1}$ or $\widetilde{h}_{2,d-1}$ nonzero. Then (6.2) is equivalent with

$$\widehat{A}(V_d G) \;=\; (V_d G) \widetilde{H}_d\,. \tag{6.7}$$

Denote the entries of G by $g_{i,j}$, and let $V_d G \equiv [y_1, \ldots, y_d]$. Then, since the basis $v_1, \ldots, v_d$ is orthonormal and the matrix G is unitary, the basis $y_1, \ldots, y_d$ is orthonormal,

$$(y_i, y_j) \;=\; \left(\sum_{k=1}^{d} v_k g_{k,i}, \sum_{k=1}^{d} v_k g_{k,j} \right) \;=\; \sum_{k=1}^{d} \overline{g}_{k,j} g_{k,i} \;=\; \delta_{i,j}\,,$$

where $\delta_{i,j}$ is the Kronecker delta. By (6.7), the vectors $y_1, \ldots, y_d$ form the unique (up to scaling) basis of $\mathcal{K}_d(\widehat{A}, y_1)$ generated by (3.1)–(3.3) with $\widehat{A}$ and starting vector y_1. But since $[\widetilde{h}_{1,d-1}, \widetilde{h}_{2,d-1}] \neq [0, 0]$, we see that $\widehat{A}$ (and hence A) admits for the given y_1 an optimal recurrence of length at least $d-1$. Since we have assumed that A admits an optimal $(s+2)$-term recurrence, we must have $d - 1 \leq s + 2$, or, equivalently, $d = d_{\min}(A) \leq s + 3$. This is a contradiction since $s + 3 < d_{\min}(A)$.

As claimed at the beginning of this section, we now have shown Theorem 3.5, with the assumption $s + 2 < d_{\min}(A)$ replaced by $s + 3 < d_{\min}(A)$.

7. Concluding discussion. In this section we discuss our rather theoretical analysis above.

1. *Matrix formulation and the Faber–Manteuffel theorem.*

When formulated in terms of matrices rather than linear operators, Theorems 3.4 and 3.5 make up the Faber–Manteuffel theorem [4] in the formulation given in [12, section 2]. We state this result here for completeness.

THEOREM 7.1. *Let A be an $N \times N$ nonsingular matrix with minimal polynomial degree $d_{\min}(A)$. Let B be an $N \times N$ Hermitian positive definite matrix, and let s be a nonnegative integer, $s + 2 < d_{\min}(A)$. Then A admits for the given B an optimal $(s+2)$-term recurrence if and only if A is B-normal(s).*

In this formulation, the Hilbert space from Theorems 3.4 and 3.5 is $\mathbb{C}^N$, equipped with the inner product generated by the Hermitian positive definite matrix B. (In case A is real, we consider B to be real as well, and the adjoint A^* is the regular transpose A^T.) The matrix A is B-normal(s) if its B-adjoint, i.e., the matrix $A^+ \equiv B^{-1} A^* B$, is a polynomial of degree s in A, and s is the smallest degree for which this is true. A complete characterization of the matrices A and B for which A is B-normal(s) is given in [12, section 3].

In this paper we have chosen the linear operator rather than the matrix formulation, because it appears to be a natural generalization. Moreover, both proofs we have given use the restriction of the linear operator A to certain cyclic invariant subspaces. In the matrix formulation, such restrictions lead to nonsquare as well as square but singular matrices. This involves a more complicated notation, which obstructs rather than helps the theoretical understanding. For instance, the restriction $\widehat{A}$ of a nonsingular $N \times N$ matrix A to a cyclic invariant subspace of A with (orthonormal) basis $v_1, \ldots, v_d$ can be represented as $\widehat{A} = VHV^*$, where $V = [v_1, \ldots, v_d]$ and H is a $d \times d$ nonsingular matrix. If $d < N$, $\widehat{A}$ is a singular $N \times N$ matrix (more precisely, $\widehat{A}$ has rank $d < N$). Any vector w in the cyclic invariant subspace can be represented as $w = V\omega$, where ω is a vector of length d containing the coefficients of w in the basis, so that $Aw = \widehat{A}w = VH\omega$, where VH is a (nonsquare) matrix of size $N \times d$. On the other hand, in the linear operator formulation, $\widehat{A}$ is invertible, and we may simply write $\widehat{A}w$ for the application of $\widehat{A}$ to any vector w in the space.

2. *On the strategies of the two different proofs of Theorem* 3.5.

The two different proofs of Theorem 3.5 given in this paper (with the second one excluding the case $s + 3 = d_{\min}(A)$; see below) follow two different strategies.

The first proof, given in section 5, is based on vectors of grade $s+2$, and works its way up to vectors of full grade $d_{\min}(A)$. This general strategy is similar to the one in the original paper of Faber and Manteuffel [4]. The details of our proof here, however, are quite different from [4]. In particular, simple arguments about the number of roots of certain polynomials (particularly in Lemmas 4.1 and 4.3) have replaced the continuity and topology arguments in the proof of [4]. We therefore consider this a simpler proof than the one given in [4].

The second proof, given in section 6, works immediately with vectors of full grade $d_{\min}(A)$. We consider this approach more elementary than our first proof. We assume that the assertion of Theorem 3.5 is false, i.e., that A admits an optimal $(s+2)$-term recurrence but is not normal(s). We show that if A is not normal(s), there must exist at least one initial vector v_1 of full grade $d = d_{\min}(A)$, for which the corresponding matrix H_d has a nonzero entry above its sth superdiagonal. If this nonzero entry already is in $H_{d,d-1}$, we are done. However, we cannot guarantee this, and therefore we need the Rotation Lemma to rotate a nonzero from the dth column of H_d into the $(d-1)$st column. This shows that A cannot admit an optimal $(s+2)$-term recurrence, contradicting our initial assumption.

3. *The Rotation Lemma and the missing case* $s+3 = d_{\min}(A)$.

In the Rotation Lemma we rotate the nonzero entry $h_{1,d}$, where $d = d_{\min}(A)$, to give $\widetilde{h}_{1,d-1} \neq 0$ *or* $\widetilde{h}_{2,d-1} \neq 0$; see Figure 6.1. Therefore, the matrix $\widetilde{H}_{d,d-1}$ is *at least* $(d-1)$-band Hessenberg. The shortest possible optimal recurrence that A may admit hence is of length $d-1$, or $s+2$ for $s = d-3$. The assumption that A admits an optimal recurrence of length $s+3 < d_{\min}(A)$ then leads to a contradiction.

To prove also the missing case $s+3 = d_{\min}(A)$, we need to guarantee that there exists a choice of s_1 so that $\widetilde{h}_{1,d-1} \neq 0$, giving a d-band Hessenberg matrix $\widetilde{H}_{d,d-1}$. Since Theorem 3.5 also holds for the case $s+3 = d_{\min}(A)$, we know that such s_1 *must exist*, but we were unable to prove the existence without using Theorem 3.5. Note, however, that in practical applications we are interested in recurrences of length $s+2 \ll d_{\min}(A)$. Therefore the missing case of the Rotation Lemma is only of rather theoretical interest.

We point out that the construction given in the Rotation Lemma, namely, the structure-preserving unitary transformation of an upper Hessenberg matrix, may be of interest beyond its application in our current context. To state this idea in a more general way, we introduce some notation. Let Ω_d be the set of the $d \times d$ unreduced upper Hessenberg matrices, and let $\Omega_d(s+2)$ be the subset consisting of the $(s+2)$-band Hessenberg matrices (these are unreduced by assumption; cf. Definition 3.1). Consider a *fixed* $H \in \Omega_d$, and define the set

$$\mathcal{R}_H \equiv \{\, G^* H G \in \Omega_d \;:\; G \text{ is unitary} \,\}.$$

Hence $\mathcal{R}_H$ is the set of all unitary transformations of H that are unreduced upper Hessenberg. Note that since $H \in \mathcal{R}_H$, the set $\mathcal{R}_H$ is nonempty. Using the Rotation Lemma (for $s+3 < d$) and Theorem 3.5 (for $s+3 = d$) the following result can be proved.

THEOREM 7.2. *Let s, d be given nonnegative integers, $s+2 < d$. For any $H \in \Omega_d$, the following assertions are equivalent:*

(1) *H is I-normal(s), i.e., $H^* = p(H)$ for a polynomial of (smallest possible) degree s;*
(2) *$\mathcal{R}_H \subset \Omega_d(s+2)$.*

This result means that an unreduced upper Hessenberg matrix H is I-normal(s) if and only if H is $(s+2)$-band Hessenberg, and all unitary transformations that preserve the unreduced upper Hessenberg structure of H also preserve the $(s+2)$-band structure of H.

4. *What distinguishes Theorem* 3.5 *from other results about normal operators.*

Theorem 3.5 gives a *necessary* condition when an operator A is normal (of some degree s). This condition is also *sufficient*, as shown by Theorem 3.4. Hence this condition might be taken as a *definition* of normality, and it might be included among the numerous equivalent definitions in [8, 3]. We believe, however, that the nature of the result distinguishes it from the many other equivalent ones. This distinction is clear from the second proof given in section 6.

Consider the linear operator A, and any cyclic invariant subspace $\mathcal{K}_d(A, v_1)$. Then the matrix representation of A with respect to the orthogonal basis $v_1, \ldots, v_d$ of $\mathcal{K}_d(A, v_1)$ generated by (3.1)–(3.3) is a $d \times d$ unreduced upper Hessenberg matrix H_d (cf. (6.2), where this is shown for the restriction of A to $\mathcal{K}_d(A, v_1)$). Typically, equivalent results for normality are derived using knowledge of *the whole matrix*, H_d in this case. But Theorem 3.5 is based only on knowledge of *a part of the matrix*, namely, the first $d-1$ columns of H_d. Our experience in this area shows that this difference also is the reason why Theorem 3.5 is rather difficult to prove, particularly when compared with other results about normal matrices or operators.

Acknowledgments. We thank Tom Manteuffel and an anonymous referee for suggestions that helped us to improve the presentation of the results.

A FINITE ELEMENT METHOD FOR THE MAGNETOSTATIC PROBLEM IN TERMS OF SCALAR POTENTIALS*

ALFREDO BERMÚDEZ†, RODOLFO RODRÍGUEZ‡, AND PILAR SALGADO†

Abstract. The aim of this paper is to analyze a numerical method for solving the magnetostatic problem in a three-dimensional bounded domain containing prescribed currents and magnetic materials. The method discretizes a well-known formulation of this problem based on two scalar potentials: the total potential, defined in magnetic materials, and the reduced potential, defined in dielectric media and in nonmagnetic conductors carrying currents. The topology of the domain of each material is not assumed to be trivial. The resulting variational problem is proved to be well posed and is discretized by means of standard piecewise linear finite elements. Transmission conditions are imposed by means of a piecewise linear Lagrange multiplier on the surface separating the domains of both potentials. Error estimates for the numerical method are proved and the results of some numerical tests are reported to assess the performance of the method.

1. Introduction.

The goal of this paper is to analyze a finite element method to solve the magnetostatic problem in terms of scalar potentials in a three-dimensional bounded domain.

Several finite element methods have been developed to solve the magnetostatic problem in the last decades; see, for instance, [1, 5, 6, 10, 15, 16, 17, 21, 25, 26]. The main difference in the numerical methods lies in the choice of the primary unknowns. Indeed, formulations based on the magnetic vector potential [5, 10], on the magnetic field [15], on the magnetic and the magnetic induction fields [1, 20], or on different scalar potentials [6, 12, 17, 25, 26] can be found in engineering and mathematical journals.

The published numerical results show that the scalar potential formulations are specially efficient. In particular, the combination of two different potentials, the so-called *reduced scalar potential* and *total scalar potential* (see [16, 21]) seems to be the most effective in terms of accuracy and computer cost. In this approach, the total potential is defined in magnetic materials without current sources, while the reduced potential is defined in dielectric media and in nonmagnetic materials carrying currents.

This formulation, which was introduced by Simkin and Trowbridge in [25] for two-dimensional domains and extended to three-dimensional domains in [26], is very well known in the engineering literature and has been used in linear and nonlinear

cases. There exist several papers dealing with this formulation in bounded domains by using finite element methods (FEMs) (see [12, 16, 21, 31]) and others in unbounded domains by using boundary element methods (BEMs) or coupled BEM-FEM (see [3, 22, 23]).

However, to the best of the authors' knowledge, the approximation of the total scalar potential/reduced scalar potential formulation in bounded domains by standard finite elements has not been analyzed yet from a mathematical point of view. This is the aim of the present paper in the context of three-dimensional domains.

We notice that the magnetostatic problem in terms of scalar potentials leads to Poisson problems defined in different domains with suitable interface conditions. At this point, we will describe an amenable procedure to impose these conditions by means of a Lagrange multiplier. On the other hand, the topological structure of the region occupied by the magnetic materials plays a very important role, because the total potential is defined in this set from a curl-free magnetic field. We will allow for multiply connected domains, which leads to consider a total scalar potential with constant jumps on certain "cut" surfaces (see [2, 31]).

The outline of the paper is as follows. In section 2 we introduce the magnetostatic problem and the geometrical framework for our analysis. We recall the Biot–Savart law and deduce the differential equations of the total potential/reduced potential formulation on a bounded domain. In section 3 we obtain a weak formulation of the problem. We prove that it is well posed and that its solution satisfies the classical magnetostatic equations in a weak form. In section 4 we introduce a discretization based on standard finite elements, with the interface constraint between both potentials being imposed as an essential condition. This approach, although unfeasible from the implementation viewpoint, allows us to prove optimal-order error estimates. In section 5 we introduce a Lagrange multiplier to impose conveniently the interface constraint at the discrete level. We prove that the resulting mixed problem is equivalent to the previously analyzed discrete problem. Finally, in section 6, we report some numerical results which confirm the order of convergence predicted by the theory and allow us to assess the performance of the method.

2. The magnetostatic problem in terms of scalar potentials. The classical magnetostatic model is obtained by neglecting the time derivatives in Maxwell's equations. Thus, given a divergence-free stationary source current density $\boldsymbol{J}$, the magnetic field $\boldsymbol{H}$ and the magnetic induction $\boldsymbol{B}$ satisfy the following equations:

$$\mathbf{curl}\,\boldsymbol{H} = \boldsymbol{J}, \tag{2.1}$$

$$\operatorname{div}\boldsymbol{B} = 0. \tag{2.2}$$

The vector fields $\boldsymbol{H}$ and $\boldsymbol{B}$ are linked by the constitutive relation

$$\boldsymbol{B} = \mu\boldsymbol{H}, \tag{2.3}$$

where μ is the magnetic permeability which satisfies

$$0 < \mu_{\min} \le \mu \le \mu_{\max}. \tag{2.4}$$

Throughout the paper we use boldface letters to denote vector fields and variables, as well as vector-valued operators. We also use standard notation for Sobolev spaces and norms.

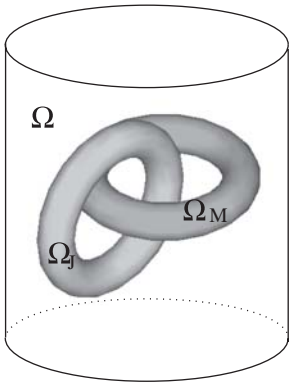

FIG. 2.1. *Sketch of the domains. Case* $\overline{\Omega}_{\rm J} \subset \Omega$.

The typical magnetostatic problem involves magnetic materials with permeability $\mu \neq \mu_0$ (where μ_0 is the magnetic permeability of vacuum), current sources, and eventually magnets. In this paper we focus on solving the magnetostatic problem in a bounded three-dimensional domain Ω containing prescribed currents and linear magnetic materials, but not magnets. This domain is assumed to be simply connected with a Lipschitz-continuous connected boundary Γ.

We denote by $\Omega_{\rm M}$ an open subset of Ω containing all the magnetic materials (i.e., all the points of Ω where $\mu \neq \mu_0$) and by $\Omega_{\rm J}$ another open subset of Ω such that $\overline{\Omega}_{\rm J}$ contains the support of the current source $\boldsymbol{J}$ in $\overline{\Omega}$. We assume that $\Omega_{\rm M} \cap \Omega_{\rm J} = \emptyset$, so that $\boldsymbol{J}|_{\Omega_{\rm M}} = \boldsymbol{0}$. This is a very typical case, for instance, in electromagnets like that of the second numerical test in section 6.2. The set $\Omega_{\rm M}$ is assumed to be connected although in general not simply connected. Moreover, we assume for simplicity that the boundary of $\Omega_{\rm M}$ is connected. The analysis of this paper extends with minimal changes to sets $\Omega_{\rm M}$ with disconnected boundaries; we discuss briefly this point in Remark 5.2 (see also Remark 3.1).

We further assume that $\overline{\Omega}_{\rm M} \subset \Omega$, which in practice is not restrictive at all. However, concerning $\Omega_{\rm J}$, it is useful not to impose a similar restriction, in order to allow for eventual current flows through the boundary of the domain Ω. Our analysis covers problems in which the domain Ω contains all the source currents (*closed circuits*), as that shown in Figure 2.1, and also problems in which there is a current flow through a part $\Gamma_{\rm J} := \partial\Omega_{\rm J} \cap \Gamma$ of the boundary (*open circuits*), as that shown in Figure 2.2. In any case, since the source current is divergence free, the net current flux through the boundary of Ω has to vanish.

To pose the magnetostatic problem in the bounded domain Ω, we have to add adequate boundary conditions to (2.1)–(2.3). In particular, we consider the following one:

$$\boldsymbol{B} \cdot \boldsymbol{n} = g \qquad \text{on } \Gamma,$$

where g is a given data function and $\boldsymbol{n}$ the outward unit normal vector to Γ. Notice that, by virtue of (2.2), the data g must have zero mean, i.e., $\int_\Gamma g = 0$. Let us remark that mixed boundary conditions, including $\boldsymbol{H} \times \boldsymbol{n} = \boldsymbol{0}$ on part of the boundary, can be dealt with the techniques of this paper, as well. However, for simplicity, we restrict our analysis to the simpler case above. We refer to Remark 5.1 for a brief discussion about how to proceed to deal with the boundary condition $\boldsymbol{H} \times \boldsymbol{n} = \boldsymbol{0}$.

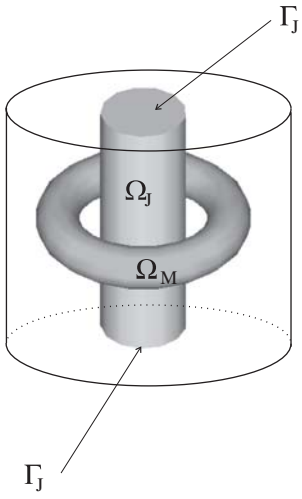

FIG. 2.2. *Sketch of the domains. Case* $\Gamma_J := \partial\Omega_J \cap \Gamma \neq \emptyset$.

Therefore, the magnetostatic problem that we are going to analyze, written in terms of the magnetic field, consists of finding $\boldsymbol{H}$ satisfying

$$\mathbf{curl}\,\boldsymbol{H} = \boldsymbol{J} \qquad \text{in } \Omega, \tag{2.5}$$

$$\operatorname{div}(\mu\boldsymbol{H}) = 0 \qquad \text{in } \Omega, \tag{2.6}$$

$$\mu\boldsymbol{H}\cdot\boldsymbol{n} = g \qquad \text{on } \Gamma. \tag{2.7}$$

This problem has a unique solution. In fact, let $\varphi \in \mathrm{H}^1(\Omega)/\mathbb{R}$ be the unique solution of $\operatorname{div}(\mu\,\mathbf{grad}\,\varphi) = 0$ in Ω with $\mu\frac{\partial\varphi}{\partial\boldsymbol{n}} = g$ on Γ. Clearly $\boldsymbol{H}$ is a solution of (2.5)–(2.7) if and only if $\hat{\boldsymbol{H}} := \boldsymbol{H} - \mathbf{grad}\,\varphi$ is a solution of the analogue of (2.5)–(2.7) with $g = 0$, and the latter has a unique solution (see [10, Remark p. 295], for instance).

Simkin and Trowbridge have introduced in [25] a formulation of this problem in the two-dimensional case based on two scalar potentials defined in different regions of the domain. The same authors have extended this formulation to the three-dimensional case in [26]. The aim of this paper is to analyze this formulation and a finite element method to compute its solution in the three-dimensional case.

Before introducing these potentials, we recall the Biot–Savart law. Given a current density $\widehat{\boldsymbol{J}} \in \mathrm{L}^2(\mathbb{R}^3)^3$ such that $\operatorname{div}\widehat{\boldsymbol{J}} = 0$ in $\mathbb{R}^3$, let $\boldsymbol{T}$ be defined as follows:

$$\boldsymbol{T}(\boldsymbol{x}) := \frac{1}{4\pi}\int_{\mathbb{R}^3} \widehat{\boldsymbol{J}}(\boldsymbol{y}) \times \frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3}\,\mathrm{d}\boldsymbol{y}\,, \qquad \boldsymbol{x} \in \mathbb{R}^3.$$

So defined, $\boldsymbol{T}$ turns out to be a divergence-free vector potential of $\widehat{\boldsymbol{J}}$ (see, for instance, [18, Lemma 2.2(b)]), namely,

$$\mathbf{curl}\,\boldsymbol{T} = \widehat{\boldsymbol{J}} \qquad \text{in } \mathbb{R}^3,$$

$$\operatorname{div}\boldsymbol{T} = 0 \qquad \text{in } \mathbb{R}^3.$$

Moreover, if the support of $\widehat{\boldsymbol{J}}$ is compact, then $\boldsymbol{T} \in \mathrm{H}^1(\mathbb{R}^3)^3$ and

$$\|\boldsymbol{T}\|_{1,\mathbb{R}^3} \leq C\,\|\widehat{\boldsymbol{J}}\|_{0,\mathbb{R}^3}$$

with C a strictly positive constant independent of $\widehat{\boldsymbol{J}}$ (see again [18, Lemma 2.2(b)]).

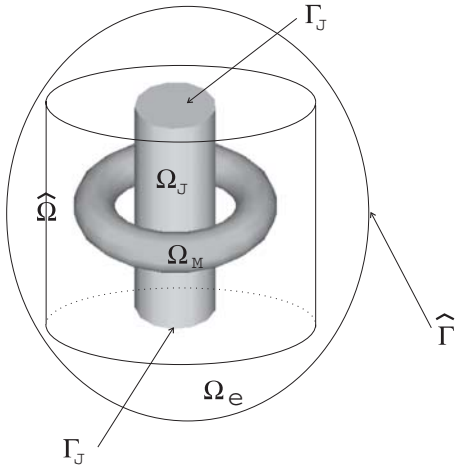

FIG. 2.3. *Auxiliary domains* $\widehat{\Omega}$ *and* $\Omega_{\rm e}$.

In our problem, the current density $\boldsymbol{J}$ is a divergence-free vector field defined only in Ω. In case that $\boldsymbol{J}\cdot\boldsymbol{n}=0$ on Γ (which necessarily happens if $\overline{\Omega}_{\rm J}\subset\Omega$, for instance), $\boldsymbol{J}$ can be extended by zero to the whole $\mathbb{R}^3$ in order to apply the previous results. Indeed, in such a case, if we denote this extension by $\widehat{\boldsymbol{J}}$, then $\operatorname{div}\widehat{\boldsymbol{J}}=0$ in $\mathbb{R}^3$. Thus, all the conclusions above hold true for the vector field $\boldsymbol{T}$ defined by the Biot–Savart law, which in this case reads

$$\boldsymbol{T}(\boldsymbol{x}):=\frac{1}{4\pi}\int_{\Omega_{\rm J}}\boldsymbol{J}(\boldsymbol{y})\times\frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3}\,\mathrm{d}\boldsymbol{y}\,,\qquad \boldsymbol{x}\in\mathbb{R}^3. \tag{2.8}$$

However, we are interested in solving the magnetostatic problem also in cases where $\boldsymbol{J}\cdot\boldsymbol{n}$ does not vanish on the whole Γ. In such a case we consider an auxiliary larger bounded domain $\widehat{\Omega}\supset\overline{\Omega}$ to obtain a vector potential for $\boldsymbol{J}$ (see Figure 2.3).

Let $\Omega_{\rm e}:=\widehat{\Omega}\setminus\overline{\Omega}$ and consider the following Neumann problem:

$$\begin{aligned}-\operatorname{div}(\mathbf{grad}\,\zeta)&=0 && \text{in } \Omega_{\rm e},\\ \mathbf{grad}\,\zeta\cdot\boldsymbol{n}&=\boldsymbol{J}\cdot\boldsymbol{n} && \text{on } \Gamma,\\ \mathbf{grad}\,\zeta\cdot\widehat{\boldsymbol{n}}&=0 && \text{on } \widehat{\Gamma}\end{aligned}$$

with $\widehat{\boldsymbol{n}}$ the outward unit normal vector to $\widehat{\Gamma}:=\partial\widehat{\Omega}$. This problem is well posed because $\int_\Gamma\boldsymbol{J}\cdot\boldsymbol{n}=\int_\Omega\operatorname{div}\boldsymbol{J}=0$. Moreover, it is straightforward to show that $\|\mathbf{grad}\,\zeta\|_{0,\Omega_{\rm e}}\leq C\,\|\boldsymbol{J}\|_{0,\Omega}$, with $C>0$ independent of $\boldsymbol{J}$.

Next, we define

$$\widehat{\boldsymbol{J}}:=\begin{cases}\boldsymbol{J} & \text{in } \Omega,\\ \mathbf{grad}\,\zeta & \text{in } \Omega_{\rm e},\\ \boldsymbol{0} & \text{in } \mathbb{R}^3\setminus\Omega_{\rm e},\end{cases}$$

so that $\operatorname{div}\widehat{\boldsymbol{J}}=0$ in $\mathbb{R}^3$. Thus, all the conclusions above also hold true in this case for the vector potential $\boldsymbol{T}$ defined by the Biot–Savart law, which now reads

$$\boldsymbol{T}(\boldsymbol{x})=\frac{1}{4\pi}\int_{\Omega_{\rm J}}\boldsymbol{J}(\boldsymbol{y})\times\frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3}\,\mathrm{d}\boldsymbol{y}+\frac{1}{4\pi}\int_{\Omega_{\rm e}}\mathbf{grad}\,\zeta(\boldsymbol{y})\times\frac{\boldsymbol{x}-\boldsymbol{y}}{|\boldsymbol{x}-\boldsymbol{y}|^3}\,\mathrm{d}\boldsymbol{y}\,,\qquad \boldsymbol{x}\in\mathbb{R}^3. \tag{2.9}$$

We collect these results in the following lemma.

LEMMA 2.1. *Let* $\boldsymbol{J} \in \mathrm{L}^2(\Omega)^3$ *be such that* $\operatorname{div} \boldsymbol{J} = 0$ *in* Ω. *Let* $\boldsymbol{T}$ *be defined by the Biot–Savart law* (2.8) *if* $\boldsymbol{J} \cdot \boldsymbol{n} = 0$ *on* Γ, *or by* (2.9) *otherwise. Then,* $\boldsymbol{T}$ *satisfies*

$$\mathbf{curl}\, \boldsymbol{T} = \boldsymbol{J} \qquad \text{in } \Omega, \tag{2.10}$$

$$\operatorname{div} \boldsymbol{T} = 0 \qquad \text{in } \Omega. \tag{2.11}$$

Moreover, $\boldsymbol{T}|_\Omega \in \mathrm{H}^1(\Omega)^3$ *with*

$$\|\boldsymbol{T}\|_{1,\Omega} \leq C \, \|\boldsymbol{J}\|_{0,\Omega}\,, \tag{2.12}$$

where C *is a strictly positive constant independent of* $\boldsymbol{J}$.

We can use $\boldsymbol{T}$ to obtain a potential formulation of problem (2.5)–(2.7). For this purpose notice that $\mathbf{curl}\,(\boldsymbol{H} - \boldsymbol{T}) = \boldsymbol{0}$ because of (2.5) and (2.10). Therefore, since Ω is simply connected, there exists a scalar potential ϕ^{R} such that

$$\boldsymbol{H} = \boldsymbol{T} - \mathbf{grad}\, \phi^{\mathrm{R}} \qquad \text{in } \Omega. \tag{2.13}$$

The scalar field ϕ^{R} is known as the *reduced scalar potential*.

In principle the magnetostatic problem (2.5)–(2.7) can be written in terms of ϕ^{R}, which leads to an important saving in computational effort. However, this possibility is not recommended in the literature because its numerical approximation leads to the so-called *cancellation error*. The origin of this error is that, often, the two terms $\boldsymbol{T}$ and $\mathbf{grad}\, \phi^{\mathrm{R}}$ in (2.13) are almost of the same size and opposite direction within the magnetic materials, which leads to large cancellation errors when computing the magnetic field $\boldsymbol{H}$ (see, for instance, [16, 17]). An alternative proposed by several authors consists of introducing an additional scalar potential in the domain Ω_{M} containing the magnetic materials (see [16, 25]).

To do this, let $\Omega_{\mathrm{R}} := \Omega \setminus \overline{\Omega}_{\mathrm{M}}$ and recall that $\mu = \mu_0$ (constant) in Ω_{R}. Also, let $\Gamma_{\mathrm{I}} := \partial\Omega_{\mathrm{R}} \cap \partial\Omega_{\mathrm{M}}$ be the interface between Ω_{R} and Ω_{M}, and $\boldsymbol{\nu}$ the unit normal vector to Γ_{I} pointing outwards Ω_{M}. Notice that $\Gamma_{\mathrm{I}} = \partial\Omega_{\mathrm{M}}$, because we have chosen $\Omega \supset \overline{\Omega}_{\mathrm{M}}$. Another consequence of this and the connectedness of $\partial\Omega_{\mathrm{M}}$ is that Ω_{R} is connected, too. As stated above, we restrict our analysis to domains Ω_{M} with a connected boundary, only for simplicity. If $\partial\Omega_{\mathrm{M}}$ were disconnected, then Ω_{R} would be disconnected, as well. We discuss briefly in Remarks 3.2 and 4.1 the main differences arising in such a case.

The domain Ω_{M} is supposed to be connected although in general not simply connected. However, we assume that there exists a finite number of open connected surfaces (so-called *cuts*) Σ_j, $j = 1, \ldots, J$, such that

- $\Sigma_j \subset \Omega_{\mathrm{M}}$ and $\partial\Sigma_j \subset \partial\Omega_{\mathrm{M}}$,
- $\overline{\Sigma}_j \cap \overline{\Sigma}_k = \emptyset$ for $j \neq k$,
- the open set $\widetilde{\Omega}_{\mathrm{M}} := \Omega_{\mathrm{M}} \setminus \bigcup_{j=1}^{J} \Sigma_j$ is pseudo-Lipschitz and simply connected.

Any set of surfaces satisfying these assumptions is called "an admissible set of cuts" (see [2], for instance, where the proper definition of *pseudo-Lipschitz* domains also appears in Definition 3.1). Figure 2.4 shows a particular case for $J = 1$.

We assume that for each of these cuts Σ_j there exists a simple closed curve $\gamma_j \subset \partial\Omega_{\mathrm{M}}$, crossing $\overline{\Sigma}_j$ once and only once, and such that γ_j is the boundary of an open surface $S_j \subset \Omega_{\mathrm{R}}$ (see again Figure 2.4).

Let $\widetilde{\Omega}_{\mathrm{M}}^j := \Omega_{\mathrm{M}} \setminus \Sigma_j$, $j = 1, \ldots, J$. We fix a unit normal vector $\boldsymbol{n}_j$ on Σ_j and denote its two faces by Σ_j^- and Σ_j^+, with $\boldsymbol{n}_j$ being the "outer" normal to $\widetilde{\Omega}_{\mathrm{M}}^j$ along

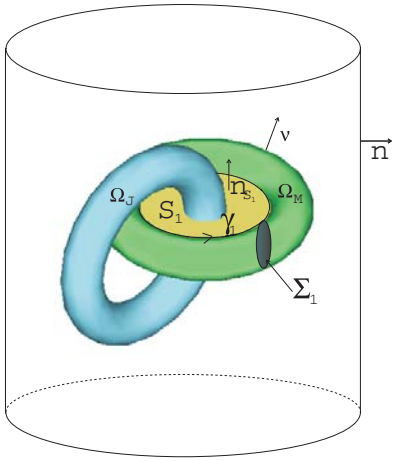

FIG. 2.4. *Cut surface and geometry description.*

Σ_j^+. We choose an orientation for each γ_j by taking its initial and end points on $\overline{\Sigma}_j^-$ and $\overline{\Sigma}_j^+$, respectively. We denote by $\boldsymbol{t}_j$ the unit vector tangent to γ_j.

For any function $\widetilde{\psi} \in \mathrm{H}^1(\widetilde{\Omega}_{\mathrm{M}})$, we denote by

$$[\![\widetilde{\psi}]\!]_{\Sigma_j} := \widetilde{\psi}|_{\Sigma_j^-} - \widetilde{\psi}|_{\Sigma_j^+}$$

the jump of $\widetilde{\psi}$ through Σ_j along $\boldsymbol{n}_j$. The gradient of $\widetilde{\psi}$ in $\mathcal{D}'(\widetilde{\Omega}_{\mathrm{M}})$ can be extended to $\mathrm{L}^2(\Omega_{\mathrm{M}})^3$ and will be denoted by $\widetilde{\mathbf{grad}}\,\widetilde{\psi}$.

Let Θ be the subspace of $\mathrm{H}^1(\widetilde{\Omega}_{\mathrm{M}})$ defined by

$$\Theta := \left\{ \widetilde{\psi} \in \mathrm{H}^1(\widetilde{\Omega}_{\mathrm{M}}) : \ [\![\widetilde{\psi}]\!]_{\Sigma_j} = \text{constant}, \ j = 1, \ldots, J \right\}.$$

For all $\widetilde{\psi} \in \mathrm{H}^1(\widetilde{\Omega}_{\mathrm{M}})$, we have that $\widetilde{\psi} \in \Theta$ if and only if $\mathbf{curl}\left(\widetilde{\mathbf{grad}}\,\widetilde{\psi}\right) = \mathbf{0}$ in Ω_{M} (see [2, Lemma 3.11]). More precisely, the operator $\mathbf{curl}: \ \mathrm{H}(\mathbf{curl}, \Omega_{\mathrm{M}}) \longrightarrow \mathrm{L}^2(\Omega_{\mathrm{M}})^3$ has a null space given by

$$\mathrm{Ker}\,(\mathbf{curl}) = \widetilde{\mathbf{grad}}\,\Theta. \tag{2.14}$$

Moreover, given $\widetilde{\psi} \in \Theta$, we have that $\widetilde{\psi} \in \mathrm{H}^1(\Omega_{\mathrm{M}})$ if and only if $[\![\widetilde{\psi}]\!]_{\Sigma_j} = 0$, $j = 1, \ldots, J$ (see [4]).

Now we are in a position to introduce the additional scalar potential that will be used to solve problem (2.5)–(2.7). Indeed, since $\boldsymbol{J}$ vanishes in Ω_{M}, by virtue of (2.14) the solution of this problem can be written in this subdomain as follows:

$$\boldsymbol{H}|_{\Omega_{\mathrm{M}}} = -\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}, \qquad \widetilde{\phi} \in \Theta.$$

The scalar function $\widetilde{\phi}$ is known as the *total scalar potential*.

Remark 2.1. The jumps of this potential have a precise physical meaning. Indeed, provided $\boldsymbol{H}$ is sufficiently smooth, by using the Stokes theorem, (2.5), and the fact that $\gamma_j \subset \Gamma_{\mathrm{I}}$, we have that

$$[\![\widetilde{\phi}]\!]_{\Sigma_j} = -\int_{\gamma_j} \widetilde{\mathbf{grad}}\,\widetilde{\phi} \cdot \boldsymbol{t}_j = \int_{\gamma_j} \boldsymbol{H} \cdot \boldsymbol{t}_j = \int_{S_j} \mathbf{curl}\,\boldsymbol{H} \cdot \boldsymbol{n}_{S_j} = \int_{S_j} \boldsymbol{J} \cdot \boldsymbol{n}_{S_j} =: I_j,$$

with $\boldsymbol{n}_{S_j}$ being a unit vector normal to S_j, as shown in Figure 2.4. Thus, the jump of the total scalar potential $\widetilde{\phi}$ across each cut surface Σ_j is completely determined by the net current intensity I_j flowing through the surface S_j (as defined in the equation above). Notice that, in particular, if $S_j \cap \Omega_{\mathrm{J}} = \emptyset$, then $[\![\widetilde{\phi}]\!]_{\Sigma_j} = 0$.

Our next step is to write the magnetostatic problem (2.5)–(2.7) in terms of the reduced and the total scalar potentials, $\widetilde{\phi} \in \Theta$ and $\phi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})$, so that

$$\boldsymbol{H} = \begin{cases} -\,\widetilde{\mathbf{grad}}\,\widetilde{\phi} & \text{in } \Omega_{\mathrm{M}}, \\ \boldsymbol{T} - \mathbf{grad}\,\phi^{\mathrm{R}} & \text{in } \Omega_{\mathrm{R}}. \end{cases} \tag{2.15}$$

Boundary and interface conditions must be written in terms of these potentials, as well. With this purpose, notice that for $\boldsymbol{J} \in \mathrm{L}^2(\Omega_{\mathrm{J}})^3$ we have from (2.10) that $\boldsymbol{H} \in \mathrm{H}(\mathbf{curl}, \Omega)$ and, hence, $\boldsymbol{H} \times \boldsymbol{\nu}$ does not have jumps across Γ_{I}. Analogously, $\mu \boldsymbol{H} \cdot \boldsymbol{\nu}$ does not have jumps across Γ_{I} either, because of (2.6). Consequently, we have to search for $\widetilde{\phi} \in \Theta$ and $\phi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})$ satisfying the following equations:

$$-\operatorname{div}\left(\mu_0\,\mathbf{grad}\,\phi^{\mathrm{R}}\right) = 0 \qquad \text{in } \Omega_{\mathrm{R}}, \tag{2.16}$$

$$-\operatorname{div}\left(\mu\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}\right) = 0 \qquad \text{in } \Omega_{\mathrm{M}}, \tag{2.17}$$

$$-\mu\,\mathbf{grad}\,\phi^{\mathrm{R}} \cdot \boldsymbol{n} = g - \mu_0\,\boldsymbol{T} \cdot \boldsymbol{n} \qquad \text{on } \Gamma, \tag{2.18}$$

$$\mu_0\,\mathbf{grad}\,\phi^{\mathrm{R}} \cdot \boldsymbol{\nu} - \mu\,\widetilde{\mathbf{grad}}\,\widetilde{\phi} \cdot \boldsymbol{\nu} = \mu_0\,\boldsymbol{T} \cdot \boldsymbol{\nu} \qquad \text{on } \Gamma_{\mathrm{I}}, \tag{2.19}$$

$$\mathbf{grad}\,\phi^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\,\widetilde{\phi} \times \boldsymbol{\nu} = \boldsymbol{T} \times \boldsymbol{\nu} \qquad \text{on } \Gamma_{\mathrm{I}}. \tag{2.20}$$

3. Well-posedness of the reduced/total potential formulation of the magnetostatic problem. The aim of this section is to obtain a weak formulation of the magnetostatic problem in terms of the total and the reduced scalar potentials and to prove its well-posedness.

To obtain the weak formulation, we multiply (2.16) and (2.17) by a sufficiently smooth test function ψ, integrate by parts, and use (2.18) and (2.19). Thus, we obtain

$$\int_{\Omega_{\mathrm{M}}} \mu\,\widetilde{\mathbf{grad}}\,\widetilde{\phi} \cdot \mathbf{grad}\,\psi + \int_{\Omega_{\mathrm{R}}} \mu_0\,\mathbf{grad}\,\phi^{\mathrm{R}} \cdot \mathbf{grad}\,\psi = \int_{\Gamma} \mu_0 \boldsymbol{T} \cdot \boldsymbol{n}\,\psi - \int_{\Gamma_{\mathrm{I}}} \mu_0 \boldsymbol{T} \cdot \boldsymbol{\nu}\,\psi - \int_{\Gamma} g\psi$$

as long as g is sufficiently smooth for the last integral to make sense.

For the subsequent analysis, (2.20) will be imposed as an essential condition. We introduce the space

$$\mathcal{X} := \Theta/\mathbb{R} \times \mathrm{H}^1(\Omega_{\mathrm{R}})/\mathbb{R},$$

endowed with the norm

$$\left\|(\widetilde{\psi}, \psi^{\mathrm{R}})\right\|_{\mathcal{X}} := \left(\left\|\,\widetilde{\mathbf{grad}}\,\widetilde{\psi}\,\right\|^2_{0,\Omega_{\mathrm{M}}} + \left\|\mathbf{grad}\,\psi^{\mathrm{R}}\right\|^2_{0,\Omega_{\mathrm{R}}}\right)^{1/2},$$

and the closed linear manifold

$$\mathcal{V}(\boldsymbol{T}) := \left\{(\widetilde{\psi}, \psi^{\mathrm{R}}) \in \mathcal{X} :\ \mathbf{grad}\,\psi^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\,\widetilde{\psi} \times \boldsymbol{\nu} = \boldsymbol{T} \times \boldsymbol{\nu} \text{ on } \Gamma_{\mathrm{I}}\right\}.$$

In what follows we prove a couple of lemmas involving this manifold and the corresponding subspace

$$\mathcal{V}(\boldsymbol{0}) := \left\{(\widetilde{\psi}, \psi^{\mathrm{R}}) \in \mathcal{X} :\ \mathbf{grad}\,\psi^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\,\widetilde{\psi} \times \boldsymbol{\nu} = \boldsymbol{0} \text{ on } \Gamma_{\mathrm{I}}\right\}.$$

LEMMA 3.1. $\mathcal{V}(\boldsymbol{T}) \cap \left[\mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})/\mathbb{R} \times \mathrm{H}^2(\Omega_{\mathrm{R}})/\mathbb{R}\right] \neq \emptyset$.

Proof. Because of Lemma 2.1, since $\boldsymbol{J}$ vanishes in Ω_{M}, $\mathbf{curl}\,\boldsymbol{T} = \mathbf{0}$ in Ω_{M}. Hence, according to (2.14), there exists $\widetilde{\xi} \in \Theta$ such that $\boldsymbol{T}|_{\Omega_{\mathrm{M}}} = -\,\widetilde{\mathbf{grad}}\,\widetilde{\xi}$. Moreover, $\widetilde{\xi} \in \mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})/\mathbb{R}$, because $\boldsymbol{T} \in \mathrm{H}^1(\Omega_{\mathrm{M}})^3$ (by virtue of Lemma 2.1, again). Consequently, the pair $\left(\widetilde{\xi}, 0\right)$ belongs to $\mathcal{V}(\boldsymbol{T}) \cap \left[\mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})/\mathbb{R} \times \mathrm{H}^2(\Omega_{\mathrm{R}})/\mathbb{R}\right]$. ∎

LEMMA 3.2. $\left(\widetilde{\psi}, \psi^{\mathrm{R}}\right) \in \mathcal{V}(\mathbf{0})$ *if and only if there exists* $\psi \in \mathrm{H}^1(\Omega)/\mathbb{R}$ *such that* $\widetilde{\psi} = \psi|_{\Omega_{\mathrm{M}}}$ *and* $\psi^{\mathrm{R}} = \psi|_{\Omega_{\mathrm{R}}}$.

Proof. Given $(\widetilde{\psi}, \psi^{\mathrm{R}}) \in \mathcal{V}(\mathbf{0})$, let ψ^{R}_* be an H^1-extension to the whole Ω of a representative of ψ^{R} (that we also denote by ψ^{R}); i.e., $\psi^{\mathrm{R}}_* \in \mathrm{H}^1(\Omega)$ and $\psi^{\mathrm{R}}_*|_{\Omega_{\mathrm{R}}} = \psi^{\mathrm{R}}$. Hence, $\widetilde{\mathbf{grad}}\left(\widetilde{\psi} - \psi^{\mathrm{R}}_*|_{\Omega_{\mathrm{M}}}\right) \in \mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}})$, where

$$\mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}}) := \{\boldsymbol{G} \in \mathrm{H}(\mathbf{curl}, \Omega_{\mathrm{M}}) :\ \boldsymbol{G} \times \boldsymbol{\nu} = \mathbf{0} \text{ on } \partial\Omega_{\mathrm{M}} \text{ and } \mathbf{curl}\,\boldsymbol{G} = \mathbf{0} \text{ in } \Omega_{\mathrm{M}}\}.$$

As we show below, $\mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}}) \subset \mathbf{grad}\left(\mathrm{H}^1(\Omega_{\mathrm{M}})\right)$. Consequently, we have that $\widetilde{\mathbf{grad}}\,\widetilde{\psi} = \mathbf{grad}\left(\psi^{\mathrm{R}}_*|_{\Omega_{\mathrm{M}}}\right) + \widetilde{\mathbf{grad}}\left(\widetilde{\psi} - \psi^{\mathrm{R}}_*|_{\Omega_{\mathrm{M}}}\right) \in \mathbf{grad}\left(\mathrm{H}^1(\Omega_{\mathrm{M}})\right)$. Thus $\widetilde{\psi} \in \mathrm{H}^1(\Omega_{\mathrm{M}})/\mathbb{R}$ and $\widetilde{\mathbf{grad}}\,\widetilde{\psi}$ is the actual gradient of $\widetilde{\psi}$ in the whole Ω_{M} and not only in $\widetilde{\Omega}_{\mathrm{M}}$.

Now, from this and the definition of $\mathcal{V}(\mathbf{0})$, $\mathbf{grad}\,\psi^{\mathrm{R}} \times \boldsymbol{\nu} = \mathbf{grad}\,\widetilde{\psi} \times \boldsymbol{\nu}$ on Γ_{I}. Therefore, any pair of representatives of $\psi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})/\mathbb{R}$ and $\widetilde{\psi} \in \mathrm{H}^1(\Omega_{\mathrm{M}})/\mathbb{R}$ only differ by a constant on Γ_{I}. Hence, we may choose these representatives (which we also denote by ψ^{R} and $\widetilde{\psi}$) coinciding on Γ_{I}. Thus, if we define ψ in Ω by $\psi|_{\Omega_{\mathrm{M}}} = \widetilde{\psi} \in \mathrm{H}^1(\Omega_{\mathrm{M}})$ and $\psi|_{\Omega_{\mathrm{R}}} = \psi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})$, then $\psi \in \mathrm{H}^1(\Omega)$. The converse is clearly true.

There only remains to prove that $\mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}}) \subset \mathbf{grad}\left(\mathrm{H}^1(\Omega_{\mathrm{M}})\right)$. Indeed, given $\boldsymbol{G} \in \mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}})$, let $\xi \in \mathrm{H}^1_0(\Omega_{\mathrm{M}})$ be the unique solution of

$$\int_{\Omega_{\mathrm{M}}} \mathbf{grad}\,\xi \cdot \mathbf{grad}\,\eta = \int_{\Omega_{\mathrm{M}}} \boldsymbol{G} \cdot \mathbf{grad}\,\eta \qquad \forall \eta \in \mathrm{H}^1_0(\Omega_{\mathrm{M}}).$$

Then $\boldsymbol{G} - \mathbf{grad}\,\xi$ belongs to the space of *Dirichlet harmonic fields* in Ω_{M}, $\boldsymbol{\mathcal{H}} := \left\{\boldsymbol{F} \in \mathrm{H}_0(\mathbf{curl}^{\mathbf{0}}, \Omega_{\mathrm{M}}) :\ \mathrm{div}\,\boldsymbol{F} = 0 \text{ in } \Omega_{\mathrm{M}}\right\}$, which is trivial for $\partial\Omega_{\mathrm{M}}$ connected. Hence $\boldsymbol{G} = \mathbf{grad}\,\xi \in \mathbf{grad}\left(\mathrm{H}^1_0(\Omega_{\mathrm{M}})\right)$. ∎

Remark 3.1. This lemma remains true even for domains Ω_{M} with a not connected boundary. Indeed, in any case $\boldsymbol{\mathcal{H}} \subset \mathbf{grad}\left(\mathrm{H}^1(\Omega_{\mathrm{M}})\right)$ (see [2, Proposition 3.18]). Hence, $\boldsymbol{G} \in \mathbf{grad}\left(\mathrm{H}^1(\Omega_{\mathrm{M}})\right)$ in this case too.

The last lemma allows us to write in a more symmetric form the variational formulation of the magnetostatic problem in terms of the total and the reduced scalar potentials as follows.

PROBLEM P. *Find* $\left(\widetilde{\phi}, \phi^{\mathrm{R}}\right) \in \mathcal{V}(\boldsymbol{T})$ *such that*

$$\begin{aligned}(3.1)\qquad &\int_{\Omega_{\mathrm{M}}} \mu\,\widetilde{\mathbf{grad}}\,\widetilde{\phi} \cdot \widetilde{\mathbf{grad}}\,\widetilde{\psi} + \int_{\Omega_{\mathrm{R}}} \mu_0\,\mathbf{grad}\,\phi^{\mathrm{R}} \cdot \mathbf{grad}\,\psi^{\mathrm{R}} \\ &\qquad = \int_{\Gamma} \mu_0 \boldsymbol{T} \cdot \boldsymbol{n}\,\psi^{\mathrm{R}} - \int_{\Gamma_{\mathrm{I}}} \mu_0 \boldsymbol{T} \cdot \boldsymbol{\nu}\,\psi^{\mathrm{R}} - \left\langle g, \psi^{\mathrm{R}}\right\rangle_{\Gamma} \qquad \forall \left(\widetilde{\psi}, \psi^{\mathrm{R}}\right) \in \mathcal{V}(\mathbf{0}).\end{aligned}$$

Let us remark that according to Lemma 3.2, for all test functions $\left(\widetilde{\psi}, \psi^{\mathrm{R}}\right) \in \mathcal{V}(\mathbf{0})$, the total potential $\widetilde{\psi} \in \mathrm{H}^1(\Omega_{\mathrm{M}})$ and, consequently, the jumps $[\![\widetilde{\psi}]\!]_{\Sigma_j}$ actually vanish. (We denote $\widetilde{\mathbf{grad}}\,\widetilde{\psi}$ instead of $\mathbf{grad}\,\psi$ in the problem above, just to emphasize the symmetry of the formulation.) This does not happen for the trial functions $\left(\widetilde{\psi}, \psi^{\mathrm{R}}\right) \in$

$\mathcal{V}(\boldsymbol{T})$. However, the jumps of such $\widetilde{\psi}$ are completely determined through $\boldsymbol{T}$ by the intensities I_j defined in Remark 2.1. In fact, provided $\boldsymbol{J}$ is smooth enough,

$$\begin{aligned}[\![\widetilde{\psi}]\!]_{\Sigma_j} &= -\int_{\gamma_j} \widetilde{\mathbf{grad}}\,\widetilde{\psi}\cdot\boldsymbol{t}_j = \int_{\gamma_j}\left(\mathbf{grad}\,\psi^{\mathrm{R}} - \widetilde{\mathbf{grad}}\,\widetilde{\psi}\right)\cdot\boldsymbol{t}_j = \int_{\gamma_j}\boldsymbol{T}\cdot\boldsymbol{t}_j \\ &= \int_{S_j}\mathbf{curl}\,\boldsymbol{T}\cdot\boldsymbol{n}_{S_j} = \int_{S_j}\boldsymbol{J}\cdot\boldsymbol{n}_{S_j} = I_j,\end{aligned}$$

where we have used the Stokes theorem and (2.10).

Note that, according to the definition of $\mathcal{X}$, the test functions in Problem P are determined up to two arbitrary additive constants, whereas, according to Lemma 3.2, the trial functions seem to be determined up to one constant. However, there is no contradiction. Indeed, the equalities $\widetilde{\psi} = \psi|_{\Omega_{\mathrm{M}}}$ and $\psi^{\mathrm{R}} = \psi|_{\Omega_{\mathrm{R}}}$ from Lemma 3.2 have to be understood in $\mathrm{H}^1(\Omega_{\mathrm{R}})/\mathbb{R}$ and $\mathrm{H}^1(\Omega_{\mathrm{M}})/\mathbb{R}$, respectively, since $\widetilde{\psi}$ and ψ^{R} belong to these quotient spaces. Therefore, two arbitrary constants appear anyway.

The expression $\langle\cdot,\cdot\rangle_\Gamma$ in Problem P refers to the standard duality pairing between $\mathrm{H}^{1/2}(\Gamma)$ and its dual space $\mathrm{H}^{-1/2}(\Gamma)$. The data g is only assumed to belong to $\mathrm{H}^{-1/2}(\Gamma)$ and to satisfy $\langle g, 1\rangle_\Gamma = 0$, so that $\langle g, \psi^{\mathrm{R}}\rangle_\Gamma$ is well defined for $\psi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})/\mathbb{R}$. Recall that this last assumption is actually necessary from the very beginning for (2.6) and (2.7) to hold true. On the other hand, $\int_\Gamma \mu_0\boldsymbol{T}\cdot\boldsymbol{n}\,\psi^{\mathrm{R}} - \int_{\Gamma_{\mathrm{I}}}\mu_0\boldsymbol{T}\cdot\boldsymbol{\nu}\,\psi^{\mathrm{R}}$ is also well defined for $\psi^{\mathrm{R}} \in \mathrm{H}^1(\Omega_{\mathrm{R}})/\mathbb{R}$, because $\int_\Gamma \mu_0\boldsymbol{T}\cdot\boldsymbol{n} - \int_{\Gamma_{\mathrm{I}}}\mu_0\boldsymbol{T}\cdot\boldsymbol{\nu} = \int_{\Omega_{\mathrm{R}}}\mathrm{div}\,(\mu_0\boldsymbol{T}) = 0$, as a consequence of (2.11) (recall that μ_0 is constant). Finally, the bilinear form in the left-hand side above,

$$a\big((\widetilde{\phi},\phi^{\mathrm{R}}),(\widetilde{\psi},\psi^{\mathrm{R}})\big) := \int_{\Omega_{\mathrm{M}}}\mu\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}\cdot\widetilde{\mathbf{grad}}\,\widetilde{\psi} + \int_{\Omega_{\mathrm{R}}}\mu_0\,\mathbf{grad}\,\phi^{\mathrm{R}}\cdot\mathbf{grad}\,\psi^{\mathrm{R}},$$

is clearly continuous and elliptic in $\mathcal{X}$, as a consequence of (2.4). Therefore, we have the following result.

THEOREM 3.3. *Problem* P *has a unique solution.*

Proof. The result follows from Lax–Milgram's lemma, because a is $\mathcal{X}$-elliptic in $\mathcal{V}(\boldsymbol{0})$, the linear functional in the left-hand side of (3.1) is bounded in the same subspace, and $\mathcal{V}(\boldsymbol{T})$ is a nonempty closed linear manifold of $\mathcal{X}$ (Lemma 3.1). ∎

Once the total and the reduced scalar potentials are known, the magnetic field $\boldsymbol{H}$ can be readily computed by means of (2.15). In the following theorem we show that this vector field actually satisfies the equations of the magnetostatic problem (2.5)–(2.7).

THEOREM 3.4. *Let* $\big(\widetilde{\phi},\phi^{\mathrm{R}}\big)$ *be the solution of Problem* P *and let* $\boldsymbol{H}$ *be defined by* (2.15)*; namely,* $\boldsymbol{H} := -\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}$ *in* Ω_{M} *and* $\boldsymbol{H} := \boldsymbol{T} - \mathbf{grad}\,\phi^{\mathrm{R}}$ *in* Ω_{R}*. Then,*

$$\mathbf{curl}\,\boldsymbol{H} = \boldsymbol{J} \qquad \text{in } \Omega, \tag{3.2}$$

$$\mathrm{div}\,(\mu\boldsymbol{H}) = 0 \qquad \text{in } \Omega, \tag{3.3}$$

$$\mu\boldsymbol{H}\cdot\boldsymbol{n} = g \qquad \text{on } \Gamma_{\mathrm{I}}. \tag{3.4}$$

Proof. For $\boldsymbol{H}$ defined by (2.15), $\boldsymbol{H}|_{\Omega_{\mathrm{M}}} \in \mathrm{H}(\mathbf{curl},\Omega_{\mathrm{M}})$ because of (2.14), and $\boldsymbol{H}|_{\Omega_{\mathrm{R}}} \in \mathrm{H}(\mathbf{curl},\Omega_{\mathrm{R}})$ because of Lemma 2.1. Moreover, from the definition of $\mathcal{V}(\boldsymbol{T})$, $\boldsymbol{H}|_{\Omega_{\mathrm{M}}}\times\boldsymbol{\nu} = \boldsymbol{H}|_{\Omega_{\mathrm{R}}}\times\boldsymbol{\nu}$ on Γ_{I}. Hence $\boldsymbol{H} \in \mathrm{H}(\mathbf{curl},\Omega)$ and (3.2) holds true as a consequence of (2.10).

For the second equation, let $\psi \in \mathcal{D}(\Omega)$. From Lemma 3.2, $(\psi|_{\Omega_{\rm M}}, \psi|_{\Omega_{\rm R}}) \in \mathcal{V}(\mathbf{0})$. Then

$$\begin{aligned}
-\int_\Omega \mu \boldsymbol{H} \cdot \mathbf{grad}\, \psi &= \int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi} \cdot \mathbf{grad}\, \psi - \int_{\Omega_{\rm R}} \left(\mu_0 \boldsymbol{T} - \mu_0\, \mathbf{grad}\, \phi^{\rm R}\right) \cdot \mathbf{grad}\, \psi \\
&= \int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi} \cdot \mathbf{grad}\, \psi + \int_{\Omega_{\rm R}} \mu_0\, \mathbf{grad}\, \phi^{\rm R} \cdot \mathbf{grad}\, \psi \\
&\quad + \int_{\Omega_{\rm R}} \mathrm{div}\, (\mu_0 \boldsymbol{T})\, \psi - \int_{\Gamma_{\rm I}} \mu_0 \boldsymbol{T} \cdot \boldsymbol{n}\, \psi \\
&= 0,
\end{aligned}$$

the latter holds because of (3.1) and (2.11). Hence, $\mu \boldsymbol{H} \in \mathrm{H}(\mathrm{div}, \Omega)$ and (3.3) holds true.

Finally, to prove the last equation, let $v \in \mathrm{H}^{1/2}(\Gamma)$ and $\psi \in \mathrm{H}^1(\Omega)$ be such that $\psi|_\Gamma = v$. According to Lemma 3.2, $(\psi|_{\Omega_{\rm M}}, \psi|_{\Omega_{\rm R}}) \in \mathcal{V}(\mathbf{0})$ and, hence, it can be used as a test function in (3.1). Therefore,

$$\begin{aligned}
\langle g, v \rangle_\Gamma &= -\int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi} \cdot \mathbf{grad}\, \psi - \int_{\Omega_{\rm R}} \mu_0\, \mathbf{grad}\, \phi^{\rm R} \cdot \mathbf{grad}\, \psi \\
&\quad + \int_\Gamma \mu_0 \boldsymbol{T} \cdot \boldsymbol{n}\, \psi - \int_{\Gamma_{\rm I}} \mu_0 \boldsymbol{T} \cdot \boldsymbol{\nu}\, \psi \\
&= -\int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi} \cdot \mathbf{grad}\, \psi - \int_{\Omega_{\rm R}} \mu_0\, \mathbf{grad}\, \phi^{\rm R} \cdot \mathbf{grad}\, \psi \\
&\quad + \int_{\Omega_{\rm R}} \mathrm{div}\, (\mu_0 \boldsymbol{T})\, \psi + \int_{\Omega_{\rm R}} \mu_0 \boldsymbol{T} \cdot \mathbf{grad}\, \psi \\
&= -\int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi} \cdot \mathbf{grad}\, \psi + \int_{\Omega_{\rm R}} \left(\mu_0 \boldsymbol{T} - \mu_0\, \mathbf{grad}\, \phi^{\rm R}\right) \cdot \mathbf{grad}\, \psi \\
&= \int_\Omega \mu \boldsymbol{H} \cdot \mathbf{grad}\, \psi \\
&= -\int_\Omega \mathrm{div}\, (\mu \boldsymbol{H})\, \psi + \langle \mu \boldsymbol{H} \cdot \boldsymbol{n}, \psi \rangle_\Gamma \\
&= \langle \mu \boldsymbol{H} \cdot \boldsymbol{n}, v \rangle_\Gamma\,,
\end{aligned}$$

where we have used (2.11) and (3.3). Hence (3.4) holds true in $\mathrm{H}^{-1/2}(\Gamma)$, and we conclude the proof. ∎

Remark 3.2. We have restricted the analysis of this section to connected sets $\Omega_{\rm R}$. However, it extends with minor modifications to a disconnected $\Omega_{\rm R}$. In such a case, let us denote by $\Omega_{\rm R}^1, \ldots, \Omega_{\rm R}^K$ its connected components. The reduced potential $\phi^{\rm R}$ is uniquely defined up to an additive constant for each of these connected components. Therefore, the function space for the pair of scalar potentials must be defined as follows: $\mathcal{X} := \Theta/\mathbb{R} \times \Pi_{k=1}^K \left[\mathrm{H}^1(\Omega_{\rm R}^k)/\mathbb{R}\right]$.

4. Finite element discretization. In this section we introduce a discretization of Problem P and prove an error estimate.

In what follows we assume that Ω, $\Omega_{\rm M}$, and $\Omega_{\rm R}$ are Lipschitz polyhedra and consider a family $\{\mathcal{T}_h\}$ of regular tetrahedral meshes of Ω such that each element $K \in \mathcal{T}_h$ is contained either in $\overline{\Omega}_{\rm M}$ or in $\overline{\Omega}_{\rm R}$ (h stands as usual for the corresponding mesh size). We define $\mathcal{T}_h^{\Omega_{\rm R}} := \left\{K \in \mathcal{T}_h :\ K \subset \overline{\Omega}_{\rm R}\right\}$ and $\mathcal{T}_h^{\Omega_{\rm M}} := \left\{K \in \mathcal{T}_h :\ K \subset \overline{\Omega}_{\rm M}\right\}$.

We assume that the cut surfaces Σ_j are polyhedral and that the meshes are compatible with them, in the sense that each $\overline{\Sigma}_j$ is a union of faces of tetrahedra for each mesh $\mathcal{T}_h$. Therefore, $\mathcal{T}_h^{\Omega_{\rm M}}$ can also be seen as a mesh of $\widetilde{\Omega}_{\rm M}$.

We introduce the following finite element spaces:

$$\begin{aligned}
\mathcal{L}_h(\widetilde{\Omega}_{\rm M}) &:= \left\{ \widetilde{\psi}_h \in \mathcal{C}(\widetilde{\Omega}_{\rm M}) :\ \widetilde{\psi}_h|_K \in \mathcal{P}_1(K)\ \forall K \in \mathcal{T}_h^{\Omega_{\rm M}} \right\},\\
\Theta_h &:= \left\{ \widetilde{\psi}_h \in \mathcal{L}_h(\widetilde{\Omega}_{\rm M}) :\ [\![\widetilde{\psi}_h]\!]_{\Sigma_j} = \text{constant},\ j = 1, \dots, J \right\},\\
\mathcal{L}_h(\Omega_{\rm R}) &:= \left\{ \psi_h^{\rm R} \in \mathcal{C}(\Omega_{\rm R}) :\ \psi_h^{\rm R}|_K \in \mathcal{P}_1(K)\ \forall K \in \mathcal{T}_h^{\Omega_{\rm R}} \right\},\\
\mathcal{X}_h &:= \Theta_h/\mathbb{R} \times \mathcal{L}_h(\Omega_{\rm R})/\mathbb{R}.
\end{aligned}$$

Definitions analogous to that of $\mathcal{L}_h(\Omega_{\rm R})$ hold for $\mathcal{L}_h(\Omega_{\rm M})$, $\mathcal{L}_h(\Omega)$, etc.

We also have to introduce suitable approximations of $\boldsymbol{T}$ to be used on $\Gamma_{\rm I}$ and Γ for the discrete problem. Notice that only the normal component of $\boldsymbol{T}$ is needed on Γ, whereas the tangential and normal components are needed on $\Gamma_{\rm I}$. We will use the Nédélec interpolant of $\boldsymbol{T}$ for the former and its Raviart–Thomas interpolant for the latter. In what follows we recall their definitions and some basic properties (see, for instance, [19] for more details and proofs).

The lowest-order Nédélec edge finite element space is defined as follows:

$$\boldsymbol{\mathcal{N}}_h(\Omega) := \{ \boldsymbol{G}_h \in {\rm H}(\mathbf{curl}, \Omega) :\ \boldsymbol{G}_h|_K \in \boldsymbol{\mathcal{N}}(K)\ \forall K \in \mathcal{T}_h \},$$

where $\boldsymbol{\mathcal{N}}(K) := \left\{ \boldsymbol{G}_h \in \mathcal{P}_1(K)^3 :\ \boldsymbol{G}_h(\boldsymbol{x}) = \boldsymbol{a} \times \boldsymbol{x} + \boldsymbol{b},\ \boldsymbol{a}, \boldsymbol{b} \in \mathbb{R}^3,\ \boldsymbol{x} \in K \right\}$. If $\boldsymbol{G}$ is smooth enough, then its Nédélec interpolant $\boldsymbol{G}_{\rm N}$ is well defined by

$$\boldsymbol{G}_{\rm N} \in \boldsymbol{\mathcal{N}}_h(\Omega) :\quad \int_\ell \boldsymbol{G}_{\rm N} \cdot \boldsymbol{t}_\ell = \int_\ell \boldsymbol{G} \cdot \boldsymbol{t}_\ell \quad \forall \ell \text{ edge of } \mathcal{T}_h,$$

where $\boldsymbol{t}_\ell$ denotes a unit vector tangent to ℓ. The results of [2] allow extending the above definition to the space ${\rm H}^r(\mathbf{curl}, \Omega) := \{ \boldsymbol{G} \in {\rm H}^r(\Omega) :\ \mathbf{curl}\, \boldsymbol{G} \in {\rm H}^r(\Omega) \}$ with $r > \frac{1}{2}$.

On the other hand, the lowest-order Raviart–Thomas finite element space is defined as follows:

$$\boldsymbol{\mathcal{R}}_h(\Omega) := \{ \boldsymbol{G}_h \in {\rm H}(\mathrm{div}, \Omega) :\ \boldsymbol{G}_h|_K \in \boldsymbol{\mathcal{R}}(K)\ \forall K \in \mathcal{T}_h \},$$

where $\boldsymbol{\mathcal{R}}(K) := \left\{ \boldsymbol{G}_h \in \mathcal{P}_1(K)^3 :\ \boldsymbol{G}_h(\boldsymbol{x}) = a\boldsymbol{x} + \boldsymbol{b};\ a \in \mathbb{R},\ \boldsymbol{b} \in \mathbb{R}^3,\ \boldsymbol{x} \in K \right\}$. For $\boldsymbol{G}$ sufficiently smooth, its Raviart–Thomas interpolant $\boldsymbol{G}_{\rm RT}$ is defined by

$$\boldsymbol{G}_{\rm RT} \in \boldsymbol{\mathcal{R}}_h(\Omega) :\quad \int_T \boldsymbol{G}_{\rm RT} \cdot \boldsymbol{n}_T = \int_T \boldsymbol{G} \cdot \boldsymbol{n}_T \quad \forall T \text{ face of } \mathcal{T}_h,$$

where $\boldsymbol{n}_T$ denotes a unit vector normal to T. The following error estimate holds for all $\boldsymbol{G} \in {\rm H}^1(\Omega)^3$:

$$\|\boldsymbol{G} - \boldsymbol{G}_{\rm RT}\|_{0,\Omega} \le Ch\, \|\boldsymbol{G}\|_{1,\Omega}\,. \tag{4.1}$$

Here and thereafter, C denotes a strictly positive constant, not necessarily the same at each occurrence, but always independent of h.

One basic property that will be used in what follows is that the Raviart–Thomas interpolant of a divergence free field is divergence free:

$$\mathrm{div}\, \boldsymbol{G} = 0 \quad \text{in } \Omega \qquad \Longrightarrow \qquad \mathrm{div}\, \boldsymbol{G}_{\rm RT} = 0 \quad \text{in } \Omega. \tag{4.2}$$

Next, we introduce the following finite-dimensional approximations of $\mathcal{V}(\boldsymbol{T})$ and $\mathcal{V}(\boldsymbol{0})$:

$$\mathcal{V}_h(\boldsymbol{T}) := \left\{ \left(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\right) \in \mathcal{X}_h : \ \mathbf{grad}\, \psi_h^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\, \widetilde{\psi}_h \times \boldsymbol{\nu} = \boldsymbol{T}_{\mathrm{N}} \times \boldsymbol{\nu} \text{ on } \Gamma_{\mathrm{I}} \right\},$$

$$\mathcal{V}_h(\boldsymbol{0}) := \left\{ \left(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\right) \in \mathcal{X}_h : \ \mathbf{grad}\, \psi_h^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\, \widetilde{\psi}_h \times \boldsymbol{\nu} = \boldsymbol{0} \text{ on } \Gamma_{\mathrm{I}} \right\}.$$

Let us remark that the Nédélec interpolant $\boldsymbol{T}_{\mathrm{N}}$ in the definition of $\mathcal{V}_h(\boldsymbol{T})$ is well defined, because $\boldsymbol{T} \in \mathrm{H}^1(\Omega_{\mathrm{M}})$ and $\mathbf{curl}\, \boldsymbol{T} = \boldsymbol{0}$ in Ω_{M} (Lemma 2.1).

Thus we arrive to the following discrete version of Problem P.

Problem DP. *Find* $\left(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\right) \in \mathcal{V}_h(\boldsymbol{T})$ *such that*

$$\begin{aligned} (4.3) \quad & \int_{\Omega_{\mathrm{M}}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi}_h \cdot \widetilde{\mathbf{grad}}\, \widetilde{\psi}_h + \int_{\Omega_{\mathrm{R}}} \mu_0\, \mathbf{grad}\, \phi_h^{\mathrm{R}} \cdot \mathbf{grad}\, \psi_h^{\mathrm{R}} \\ & \quad = \int_{\Gamma} \mu_0 \boldsymbol{T}_{\mathrm{RT}} \cdot \boldsymbol{n}\, \psi_h^{\mathrm{R}} - \int_{\Gamma_{\mathrm{I}}} \mu_0 \boldsymbol{T}_{\mathrm{RT}} \cdot \boldsymbol{\nu}\, \psi_h^{\mathrm{R}} - \left\langle g, \psi_h^{\mathrm{R}} \right\rangle_{\Gamma} \qquad \forall \left(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\right) \in \mathcal{V}_h(\boldsymbol{0}). \end{aligned}$$

Notice that the right-hand side above is well defined for $\psi_h^{\mathrm{R}} \in \mathcal{L}_h(\Omega_{\mathrm{R}})/\mathbb{R}$. Indeed, $\int_{\Gamma} \mu_0 \boldsymbol{T}_{\mathrm{RT}} \cdot \boldsymbol{n} - \int_{\Gamma_{\mathrm{I}}} \mu_0 \boldsymbol{T}_{\mathrm{RT}} \cdot \boldsymbol{\nu} = \int_{\Omega_{\mathrm{R}}} \operatorname{div}(\mu_0 \boldsymbol{T}_{\mathrm{RT}}) = 0$, because of (4.2), since $\operatorname{div} \boldsymbol{T} = 0$ in Ω_{R} and μ_0 is constant. On the other hand, g has been assumed to satisfy $\langle g, 1 \rangle_{\Gamma} = 0$.

The following lemmas will be used to prove the existence and uniqueness of solution for this problem, as well as an error estimate.

Lemma 4.1. $\mathcal{V}_h(\boldsymbol{T}) \neq \emptyset$.

Proof. According to Lemma 3.1, there exists $\left(\widetilde{\psi}, \psi^{\mathrm{R}}\right) \in \mathcal{V}(\boldsymbol{T})$ such that $\widetilde{\psi} \in \mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})/\mathbb{R}$ and $\psi^{\mathrm{R}} \in \mathrm{H}^2(\Omega_{\mathrm{R}})/\mathbb{R}$. Thus, the Lagrange interpolants of these functions, $\widetilde{\psi}_{\mathrm{L}}$ and $\psi_{\mathrm{L}}^{\mathrm{R}}$, are well defined and $\left(\widetilde{\psi}_{\mathrm{L}}, \psi_{\mathrm{L}}^{\mathrm{R}}\right) \in \mathcal{X}_h$. Moreover, since the Nédélec interpolant of a gradient is the gradient of the Lagrange interpolant (see, for instance, again [19]), we have

$$\mathbf{grad}\, \psi_{\mathrm{L}}^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\, \widetilde{\psi}_{\mathrm{L}} \times \boldsymbol{\nu} = \left(\mathbf{grad}\, \psi^{\mathrm{R}}\right)_{\mathrm{N}} \times \boldsymbol{\nu} - \left(\widetilde{\mathbf{grad}}\, \widetilde{\psi}\right)_{\mathrm{N}} \times \boldsymbol{\nu} = \boldsymbol{T}_{\mathrm{N}} \times \boldsymbol{\nu} \qquad \text{on } \Gamma_{\mathrm{I}}.$$

Thus, $\left(\widetilde{\psi}_{\mathrm{L}}, \psi_{\mathrm{L}}^{\mathrm{R}}\right) \in \mathcal{V}_h(\boldsymbol{T})$. ∎

Lemma 4.2. *The following properties hold true:*

(i) *there exists* $\widetilde{\xi} \in \Theta \cap \mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})$ *such that* $\boldsymbol{T} = -\widetilde{\mathbf{grad}}\, \widetilde{\xi}$ *in* Ω_{M}*;*

(ii) *there exists* $\widetilde{\xi}_{\mathrm{L}} \in \Theta_h$ *such that* $\boldsymbol{T}_{\mathrm{N}} = -\widetilde{\mathbf{grad}}\, \widetilde{\xi}_{\mathrm{L}}$ *in* Ω_{M}*;*

(iii) $\left\| \widetilde{\mathbf{grad}}\, \widetilde{\xi} - \widetilde{\mathbf{grad}}\, \widetilde{\xi}_{\mathrm{L}} \right\|_{0,\Omega_{\mathrm{M}}} \leq Ch \left\| \boldsymbol{T} \right\|_{1,\Omega_{\mathrm{M}}}$.

Proof. Property (i) has been already shown in the proof of Lemma 3.1. To prove (ii), let $\widetilde{\xi}_{\mathrm{L}}$ be the Lagrange interpolant of $\widetilde{\xi}$, which is well defined because $\widetilde{\xi} \in \mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})$. For all the vertices P of the mesh lying on a given cut surface Σ_j,

$$[\![\widetilde{\xi}_{\mathrm{L}}(P)]\!]_{\Sigma_j} = [\![\widetilde{\xi}(P)]\!]_{\Sigma_j} = \text{constant (the same for all such } P).$$

Then $[\![\widetilde{\xi}_{\mathrm{L}}]\!]_{\Sigma_j}$ is constant too and, hence, $\widetilde{\xi}_{\mathrm{L}} \in \Theta_h$. Now, using again the relation between the Nédélec and the Lagrange interpolants, we have

$$-\widetilde{\mathbf{grad}}\, \widetilde{\xi}_{\mathrm{L}} = -\left(\widetilde{\mathbf{grad}}\, \widetilde{\xi}\right)_{\mathrm{N}} = \boldsymbol{T}_{\mathrm{N}} \qquad \text{in } \Omega_{\mathrm{M}},$$

and we conclude (ii).

Finally (iii) is a consequence of the standard approximation properties of the Lagrange interpolant (see, for instance, [19]) and of (i). ∎

LEMMA 4.3. *Let* $\left(\widetilde{\phi}, \phi^{\mathrm{R}}\right) \in \mathcal{V}(\boldsymbol{T})$ *be such that* $\widetilde{\phi} \in \mathrm{H}^{1+r}(\widetilde{\Omega}_{\mathrm{M}})/\mathbb{R}$ *and* $\phi^{\mathrm{R}} \in \mathrm{H}^{1+r}(\Omega_{\mathrm{R}})/\mathbb{R}$ *with* $0 < r \leq 1$. *Then, there exists* $\left(\widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}}_{\mathrm{I}}\right) \in \mathcal{V}_h(\boldsymbol{T})$ *such that*

$$\left\|\left(\widetilde{\phi} - \widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}} - \phi^{\mathrm{R}}_{\mathrm{I}}\right)\right\|_{\mathcal{X}} \leq Ch^r \left(\left\| \widetilde{\mathbf{grad}}\, \widetilde{\phi} \right\|_{r,\widetilde{\Omega}_{\mathrm{M}}} + \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}} + \|\boldsymbol{J}\|_{0,\Omega}\right).$$

Proof. Let $\phi^{\mathrm{R}}_{*} \in \mathrm{H}^{1+r}(\Omega_{\mathrm{R}})$ be an extension to the whole Ω of a representative of $\phi^{\mathrm{R}} \in \mathrm{H}^{1+r}(\Omega_{\mathrm{R}})/\mathbb{R}$ such that $\left\|\mathbf{grad}\, \phi^{\mathrm{R}}_{*}\right\|_{r,\Omega} \leq C \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}}$. From now on, we will not distinguish between classes modulo $\mathbb{R}$ and their representatives.

Let $\widetilde{\xi} \in \Theta \cap \mathrm{H}^2(\widetilde{\Omega}_{\mathrm{M}})$ be as in Lemma 4.2(i) and let $\widetilde{\eta} := \widetilde{\phi} - \phi^{\mathrm{R}}_{*}|_{\Omega_{\mathrm{M}}} + \widetilde{\xi} \in \mathrm{H}^{1+r}(\widetilde{\Omega}_{\mathrm{M}})$. For $\left(\widetilde{\phi}, \phi^{\mathrm{R}}\right) \in \mathcal{V}(\boldsymbol{T})$, we have $\widetilde{\mathbf{grad}}\, \widetilde{\eta} \times \boldsymbol{\nu} = \widetilde{\mathbf{grad}}\, \widetilde{\phi} \times \boldsymbol{\nu} - \mathbf{grad}\, \phi^{\mathrm{R}} \times \boldsymbol{\nu} - \boldsymbol{T} \times \boldsymbol{\nu} = \mathbf{0}$ on the connected set Γ_{I}; hence, $\widetilde{\eta}|_{\Gamma_{\mathrm{I}}}$ is constant. Therefore, for each cut surface Σ_j, $\widetilde{\eta}|_{\partial\Sigma_j^+}$ and $\widetilde{\eta}|_{\partial\Sigma_j^-}$ are identical functions in $\mathrm{H}^r(\partial\Sigma_j)$. Consequently, $[\![\widetilde{\eta}]\!]_{\Sigma_j} = [\![\widetilde{\eta}]\!]_{\partial\Sigma_j} = 0$, so that $\widetilde{\eta}$ lies in $\mathrm{H}^{1+r}(\Omega_{\mathrm{M}})$, rather than in $\mathrm{H}^{1+r}(\widetilde{\Omega}_{\mathrm{M}})$. Moreover,

$$\left\| \mathbf{grad}\, \widetilde{\eta} \right\|_{r,\Omega_{\mathrm{M}}} \leq \left\| \widetilde{\mathbf{grad}}\, \widetilde{\phi} \right\|_{r,\Omega_{\mathrm{M}}} + C \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{M}}} + \|\boldsymbol{T}\|_{r,\Omega_{\mathrm{M}}}.$$

Let $\widetilde{\eta}_{\mathrm{C}} \in \mathcal{L}_h(\Omega_{\mathrm{M}})$ be a Clément-like interpolant of $\widetilde{\eta} \in \mathrm{H}^{1+r}(\Omega_{\mathrm{M}})$ such that $\widetilde{\eta}_{\mathrm{C}}|_{\Gamma_{\mathrm{I}}} = \widetilde{\eta}|_{\Gamma_{\mathrm{I}}}$ (constant) and

$$\left\| \mathbf{grad}\, \widetilde{\eta} - \mathbf{grad}\, \widetilde{\eta}_{\mathrm{C}} \right\|_{0,\Omega_{\mathrm{M}}} \leq Ch^r \left\| \mathbf{grad}\, \widetilde{\eta} \right\|_{r,\Omega_{\mathrm{M}}}$$

(see [27]). Let $\phi^{\mathrm{R}}_{*\mathrm{C}} \in \mathcal{L}_h(\Omega)$ be a Clément interpolant of $\phi^{\mathrm{R}}_{*} \in \mathrm{H}^{1+r}(\Omega_{\mathrm{R}})$ such that

$$\left\|\mathbf{grad}\, \phi^{\mathrm{R}}_{*} - \mathbf{grad}\, \phi^{\mathrm{R}}_{*\mathrm{C}}\right\|_{0,\Omega} \leq Ch^r \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}}.$$

Let $\widetilde{\xi}_{\mathrm{L}} \in \Theta_h$ be as in Lemma 4.2(ii), so that from property (iii) of the same lemma

$$\left\| \widetilde{\mathbf{grad}}\, \widetilde{\xi} - \widetilde{\mathbf{grad}}\, \widetilde{\xi}_{\mathrm{L}} \right\|_{0,\Omega_{\mathrm{M}}} \leq Ch \left\|\boldsymbol{T}\right\|_{1,\Omega_{\mathrm{M}}}.$$

Let $\widetilde{\phi}_{\mathrm{I}} := \widetilde{\eta}_{\mathrm{C}} + \phi^{\mathrm{R}}_{*\mathrm{C}}|_{\Omega_{\mathrm{M}}} - \widetilde{\xi}_{\mathrm{L}} \in \Theta_h$ and $\phi^{\mathrm{R}}_{\mathrm{I}} := \phi^{\mathrm{R}}_{*\mathrm{C}}|_{\Omega_{\mathrm{R}}} \in \mathcal{L}_h(\Omega_{\mathrm{R}})$. Hence

$$\widetilde{\mathbf{grad}}\, \widetilde{\phi}_{\mathrm{I}} \times \boldsymbol{\nu} - \mathbf{grad}\, \phi^{\mathrm{R}}_{\mathrm{I}} \times \boldsymbol{\nu} = \widetilde{\mathbf{grad}}\, \widetilde{\eta}_{\mathrm{C}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\, \widetilde{\xi}_{\mathrm{L}} \times \boldsymbol{\nu} = \boldsymbol{T}_{\mathrm{N}} \times \boldsymbol{\nu} \qquad \text{on } \Gamma_{\mathrm{I}},$$

the last equality follows because $\widetilde{\mathbf{grad}}\, \widetilde{\eta}_{\mathrm{C}} \times \boldsymbol{\nu} = 0$ on Γ_{I}, since the Clément-like interpolant $\widetilde{\eta}_{\mathrm{C}}$ was defined as constant on Γ_{I}. Thus, $\left(\widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}}_{\mathrm{I}}\right) \in \mathcal{V}_h(\boldsymbol{T})$.

On the other hand,

$$\begin{aligned}\left\| \widetilde{\mathbf{grad}}\, \left(\widetilde{\phi} - \widetilde{\phi}_{\mathrm{I}}\right) \right\|_{0,\Omega_{\mathrm{M}}} &= \left\| \widetilde{\mathbf{grad}}\, \left(\widetilde{\eta} + \phi^{\mathrm{R}}_{*} - \widetilde{\xi}\right) - \widetilde{\mathbf{grad}}\, \left(\widetilde{\eta}_{\mathrm{C}} + \phi^{\mathrm{R}}_{*\mathrm{C}} - \widetilde{\xi}_{\mathrm{L}}\right) \right\|_{0,\Omega_{\mathrm{M}}} \\ &\leq Ch^r \left(\left\| \widetilde{\mathbf{grad}}\, \widetilde{\phi} \right\|_{r,\widetilde{\Omega}_{\mathrm{M}}} + \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}} + \|\boldsymbol{T}\|_{1,\Omega}\right)\end{aligned}$$

and

$$\left\|\mathbf{grad}\, \left(\phi^{\mathrm{R}} - \phi^{\mathrm{R}}_{\mathrm{I}}\right)\right\|_{0,\Omega_{\mathrm{R}}} \leq \left\|\mathbf{grad}\, \phi^{\mathrm{R}}_{*} - \mathbf{grad}\, \phi^{\mathrm{R}}_{*\mathrm{C}}\right\|_{0,\Omega} \leq Ch^r \left\|\mathbf{grad}\, \phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}}.$$

Finally, the last two inequalities and (2.12) allow us to conclude the proof. ∎

Now, we are in a position to prove the main result of this section.

THEOREM 4.4. *Problem* DP *has a unique solution* $\left(\widetilde{\phi}_h, \phi^{\mathrm{R}}_h\right)$. *Moreover, if the solution* $(\widetilde{\phi}, \phi^{\mathrm{R}})$ *of Problem* P *is such that* $\boldsymbol{H}|_{\Omega_{\mathrm{M}}} = -\widetilde{\mathbf{grad}}\, \widetilde{\phi} \in \mathrm{H}^r(\Omega_{\mathrm{M}})^3$ *and* $\boldsymbol{H}|_{\Omega_{\mathrm{R}}} =$

$\boldsymbol{T}|_{\Omega_{\mathrm{R}}} - \mathbf{grad}\,\phi^{\mathrm{R}} \in \mathrm{H}^r(\Omega_{\mathrm{R}})^3$, with $0 < r \leq 1$, then there exists a strictly positive constant C such that

$$\left\|\left(\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{\mathcal{X}} \leq Ch^r \left(\left\|\boldsymbol{H}\right\|_{r,\Omega_{\mathrm{M}}} + \left\|\boldsymbol{H}\right\|_{r,\Omega_{\mathrm{R}}} + \|\boldsymbol{J}\|_{0,\Omega}\right).$$

Proof. The existence and uniqueness of the solution follows from Lax–Milgram's lemma, since the bilinear form a is $\mathcal{X}$-elliptic in $\mathcal{V}_h(\mathbf{0})$ and $\mathcal{V}_h(\boldsymbol{T})$ is a nonempty closed linear manifold of $\mathcal{X}_h$ (Lemma 4.1).

To prove the error estimate, we start noticing that, as a consequence of the assumptions of this theorem and Lemma 2.1, the solution $\left(\widetilde{\phi}, \phi^{\mathrm{R}}\right)$ of Problem P satisfies the hypotheses of Lemma 4.3. Then, let $\left(\widetilde{\phi}_{\mathrm{I}}, \phi_{\mathrm{I}}^{\mathrm{R}}\right)$ be as in that lemma. By using the ellipticity of a, we have that

$$\begin{aligned}\mu_{\min}\left\|\left(\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{\mathcal{X}}^2 &\leq a\big((\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}), (\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}})\big)\\ &= a\big((\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}), (\widetilde{\phi} - \widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}} - \phi_{\mathrm{I}}^{\mathrm{R}})\big)\\ &\quad + a\big((\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}), (\widetilde{\phi}_{\mathrm{I}} - \widetilde{\phi}_h, \phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}})\big).\end{aligned}$$

We estimate the first term on the right-hand side above by using the continuity of a and Lemma 4.3:

$$\begin{aligned}&a\big((\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}), (\widetilde{\phi} - \widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}} - \phi_{\mathrm{I}}^{\mathrm{R}})\big)\\ &\quad\leq \mu_{\max}\left\|\left(\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{\mathcal{X}}\left\|\left(\widetilde{\phi} - \widetilde{\phi}_{\mathrm{I}}, \phi^{\mathrm{R}} - \phi_{\mathrm{I}}^{\mathrm{R}}\right)\right\|_{\mathcal{X}}\\ &\quad\leq Ch^r\left\|\left(\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{\mathcal{X}}\left(\left\|\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}\,\right\|_{r,\widetilde{\Omega}_{\mathrm{M}}} + \left\|\mathbf{grad}\,\phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}} + \|\boldsymbol{J}\|_{0,\Omega_{\mathrm{J}}}\right).\end{aligned}$$

For the second term, notice that $\left(\widetilde{\phi}_{\mathrm{I}} - \widetilde{\phi}_h, \phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right) \in \mathcal{V}_h(\mathbf{0})$, because $\left(\widetilde{\phi}_{\mathrm{I}}, \phi_{\mathrm{I}}^{\mathrm{R}}\right)$ and $\left(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\right)$ both belong to $\mathcal{V}_h(\boldsymbol{T})$. Then, from (3.1) and (4.3) we obtain

$$\begin{aligned}&a\big((\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}), (\widetilde{\phi}_{\mathrm{I}} - \widetilde{\phi}_h, \phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}})\big)\\ &\quad= \int_{\Gamma} \mu_0\,(\boldsymbol{T} - \boldsymbol{T}_{\mathrm{RT}}) \cdot \boldsymbol{n}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right) - \int_{\Gamma_{\mathrm{I}}} \mu_0\,(\boldsymbol{T} - \boldsymbol{T}_{\mathrm{RT}}) \cdot \boldsymbol{\nu}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\\ &\quad= \int_{\Omega_{\mathrm{R}}} \mu_0\,(\boldsymbol{T} - \boldsymbol{T}_{\mathrm{RT}}) \cdot \mathbf{grad}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\\ &\quad\leq \mu_0\,\|\boldsymbol{T} - \boldsymbol{T}_{\mathrm{RT}}\|_{0,\Omega_{\mathrm{R}}}\left\|\mathbf{grad}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{0,\Omega_{\mathrm{R}}}.\end{aligned}$$

For the last equality, we have used integration by parts and that $\operatorname{div}\boldsymbol{T} = \operatorname{div}\boldsymbol{T}_{\mathrm{RT}} = 0$ in Ω_{R}, because of (2.11) and (4.2), respectively. Next, using (4.1) and (2.12), we have

$$\|\boldsymbol{T} - \boldsymbol{T}_{\mathrm{RT}}\|_{0,\Omega_{\mathrm{R}}} \leq Ch\,\|\boldsymbol{T}\|_{1,\Omega_{\mathrm{R}}} \leq Ch\,\|\boldsymbol{J}\|_{0,\Omega_{\mathrm{J}}}.$$

On the other hand, from Lemma 4.3, there holds

$$\begin{aligned}\left\|\mathbf{grad}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{0,\Omega_{\mathrm{R}}} &\leq \left\|\mathbf{grad}\,\left(\phi_{\mathrm{I}}^{\mathrm{R}} - \phi^{\mathrm{R}}\right)\right\|_{0,\Omega_{\mathrm{R}}} + \left\|\mathbf{grad}\,\left(\phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{0,\Omega_{\mathrm{R}}}\\ &\leq Ch^r\left(\left\|\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}\,\right\|_{r,\widetilde{\Omega}_{\mathrm{M}}} + \left\|\mathbf{grad}\,\phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}} + \|\boldsymbol{J}\|_{0,\Omega_{\mathrm{J}}}\right)\\ &\quad + \left\|\left(\widetilde{\phi} - \widetilde{\phi}_h, \phi^{\mathrm{R}} - \phi_h^{\mathrm{R}}\right)\right\|_{\mathcal{X}}.\end{aligned}$$

Finally, the estimate of the theorem follows from all these inequalities, basic algebraic manipulations, and the fact that $\left\|\,\widetilde{\mathbf{grad}}\,\widetilde{\phi}\,\right\|_{r,\widetilde{\Omega}_{\mathrm{M}}} + \left\|\mathbf{grad}\,\phi^{\mathrm{R}}\right\|_{r,\Omega_{\mathrm{R}}} = \|\boldsymbol{H}\|_{r,\Omega_{\mathrm{M}}} + \|\boldsymbol{H} - \boldsymbol{T}\|_{r,\Omega_{\mathrm{R}}} \leq \|\boldsymbol{H}\|_{r,\Omega_{\mathrm{M}}} + \|\boldsymbol{H}\|_{r,\Omega_{\mathrm{R}}} + C\,\|\boldsymbol{J}\|_{0,\Omega_{\mathrm{J}}}$ (Lemma 2.1). ∎

Remark 4.1. As in the case of the continuous problem (see Remark 3.2), the analysis of this section also extends with minor modifications to a disconnected set Ω_{R}. In particular, if $\Omega_{\mathrm{R}}^1, \ldots, \Omega_{\mathrm{R}}^K$ are its connected components, then the discrete space for the pair of scalar potentials must be $\mathcal{X}_h := \Theta_h/\mathbb{R} \times \Pi_{k=1}^K \left[\mathcal{L}_h(\Omega_{\mathrm{R}}^k)/\mathbb{R}\right]$.

5. Implementation of the interface constraint by means of a Lagrange multiplier. The numerical solution of Problem DP requires to impose somehow the constraint on Γ_{I} appearing in the definition of $\mathcal{V}_h(\boldsymbol{T})$. For this purpose one could use standard techniques proposed in the literature (see, for instance, [7, 31]). As an alternative, in what follows we will introduce a Lagrange multiplier to handle this interface condition in a weak sense. While this approach would be in principle more expensive in terms of degrees of freedom, it has the advantage that its computer implementation is quite straightforward and only needs the usual data structures for FEMs.

Let us denote by $\mathcal{T}_h^{\Gamma_{\mathrm{I}}}$ the mesh induced by $\mathcal{T}_h$ on the polyhedral surface Γ_{I}: $\mathcal{T}_h^{\Gamma_{\mathrm{I}}} := \{T \subset \Gamma_{\mathrm{I}} :\ T \text{ face of } K \in \mathcal{T}_h\}$. Let $\widetilde{\Gamma}_{\mathrm{I}} := \Gamma_{\mathrm{I}} \setminus \bigcup_{j=1}^J \partial\Sigma_j$. Notice that, since each $\overline{\Sigma}_j$ is a union of faces of $K \in \mathcal{T}_h$, $\mathcal{T}_h^{\Gamma_{\mathrm{I}}}$ can also be seen as a mesh on $\widetilde{\Gamma}_{\mathrm{I}}$. Let

$$\mathcal{L}_h(\Gamma_{\mathrm{I}}) := \left\{\eta_h \in \mathcal{C}(\Gamma_{\mathrm{I}}) :\ \eta_h|_T \in \mathcal{P}_1(T)\ \forall T \in \mathcal{T}_h^{\Gamma_{\mathrm{I}}}\right\},$$
$$\mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{I}}) := \left\{\widetilde{\eta}_h \in \mathcal{C}(\widetilde{\Gamma}_{\mathrm{I}}) :\ \widetilde{\eta}_h|_T \in \mathcal{P}_1(T)\ \forall T \in \mathcal{T}_h^{\Gamma_{\mathrm{I}}}\right\}.$$

Given $\widetilde{\eta}_h \in \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{I}})$, clearly $\widetilde{\eta}_h \in \mathcal{L}_h(\Gamma_{\mathrm{I}})$ if and only if $[\![\widetilde{\eta}_h]\!]_{\partial\Sigma_j} = 0$, $j = 1, \ldots, J$.

To define the Lagrange multipliers, it is useful to introduce the surface gradient operator. Since we will use it acting only on piecewise linear functions defined on polyhedral surfaces, we give a simple definition valid in this case (see [9] for a more general definition):

$$\widetilde{\mathbf{grad}}_\Gamma :\ \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{I}}) \longrightarrow \mathrm{L}^2_{\mathbf{t}}(\Gamma_{\mathrm{I}})^3 := \left\{\boldsymbol{G} \in \mathrm{L}^2(\Gamma_{\mathrm{I}})^3 :\ \boldsymbol{G} \cdot \boldsymbol{\nu} = 0 \text{ on } \Gamma_{\mathrm{I}}\right\}$$

is defined on each element $T \in \mathcal{T}_h^{\Gamma_{\mathrm{I}}}$ by

$$\left(\widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\eta}_h\right)|_T := \nabla\left(\widetilde{\eta}_h|_T\right),$$

where ∇ denotes the usual gradient of a function of two variables. More precisely, if $\{\boldsymbol{e}_1, \boldsymbol{e}_2, \boldsymbol{\nu}\}$ is an orthonormal coordinate system (i.e., $\boldsymbol{e}_1$ and $\boldsymbol{e}_2$ are orthonormal tangent vectors to T) and $(\zeta_1, \zeta_2, \zeta_3)$ denote the coordinates in this system, then

$$\left(\widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\eta}_h\right)|_T := \frac{\partial\left(\widetilde{\eta}_h|_T\right)}{\partial\zeta_1}\,\boldsymbol{e}_1 + \frac{\partial\left(\widetilde{\eta}_h|_T\right)}{\partial\zeta_2}\,\boldsymbol{e}_2.$$

Let us remark that the tangential component of $\widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\eta}_h$ is continuous along all the edges of triangles on Γ_{I}, except eventually for those lying on the boundary $\partial\Sigma_j$ of a cut surface. Of course, the same definition also holds for $\eta_h \in \mathcal{L}_h(\Gamma_{\mathrm{I}}) \subset \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{I}})$; moreover, in this case, the tangential components are continuous even along the edges on $\partial\Sigma_j$. To help remember this, we write $\mathbf{grad}_\Gamma\, \eta_h$ instead of $\widetilde{\mathbf{grad}}_\Gamma\, \eta_h$, when $\eta_h \in \mathcal{L}_h(\Gamma_{\mathrm{I}})$.

It is straightforward to show that, for all $(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}) \in \mathcal{X}_h$, there holds

$$\widetilde{\psi}_h|_{\Gamma_{\mathrm{I}}} \in \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{I}}) \quad \text{and} \quad \widetilde{\mathbf{grad}}_\Gamma\left(\widetilde{\psi}_h|_{\Gamma_{\mathrm{I}}}\right) = \boldsymbol{\nu} \times \left(\widetilde{\mathbf{grad}}\,\widetilde{\psi}_h \times \boldsymbol{\nu}\right) \quad \text{on } \widetilde{\Gamma}_{\mathrm{I}},$$
$$\psi_h^{\mathrm{R}}|_{\Gamma_{\mathrm{I}}} \in \mathcal{L}_h(\Gamma_{\mathrm{I}}) \quad \text{and} \quad \mathbf{grad}_\Gamma\left(\psi_h^{\mathrm{R}}|_{\Gamma_{\mathrm{I}}}\right) = \boldsymbol{\nu} \times \left(\mathbf{grad}\,\psi_h^{\mathrm{R}} \times \boldsymbol{\nu}\right) \quad \text{on } \Gamma_{\mathrm{I}}.$$

From now on, for simplicity we write $\widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h := \widetilde{\mathbf{grad}}_\Gamma\,(\widetilde{\psi}_h|_{\Gamma_{\rm I}})$ and $\mathbf{grad}_\Gamma\,\psi_h^{\rm R} := \mathbf{grad}_\Gamma\,(\psi_h^{\rm R}|_{\Gamma_{\rm I}})$. Thus, the constraint in the definition of $\mathcal{V}_h(\boldsymbol{T})$ can be equivalently written as follows:

$$\mathbf{grad}_\Gamma\,\psi_h^{\rm R} - \widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h = \boldsymbol{\nu}\times(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu}) \qquad \text{on } \Gamma_{\rm I}.$$

The following lemma will allow us to write an equivalent weak form of this constraint. We recall that

$$I_j := \int_{S_j} \boldsymbol{J}\cdot\boldsymbol{n}_{S_j}, \qquad j=1,\dots,J,$$

was already defined in Remark 2.1 and it corresponds to the total current flux through S_j in the direction of $\boldsymbol{n}_{S_j}$ (see Figure 2.4). Note that, since $\operatorname{div}\boldsymbol{J}=0$ in Ω, the integral in the definition has a weak sense as long as $\boldsymbol{J}\in \mathrm{H}^s(\Omega)^3$ for any $s>0$ (see [8, section III.3.3]). From now on, we assume this with $0<s<\frac{1}{2}$.

LEMMA 5.1. *Let $\widetilde{\psi}_h\in\mathcal{L}_h(\widetilde{\Gamma}_{\rm I})$ be such that*

$$[\![\widetilde{\psi}_h]\!]_{\partial\Sigma_j} = I_j, \qquad j=1,\dots,J. \tag{5.1}$$

Then, $\widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h = \boldsymbol{\nu}\times(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu})$ on $\Gamma_{\rm I}$ if and only if

$$\int_{\Gamma_{\rm I}} \widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h\cdot\mathbf{grad}_\Gamma\,\eta_h = \int_{\Gamma_{\rm I}} \boldsymbol{\nu}\times(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu})\cdot\mathbf{grad}_\Gamma\,\eta_h \qquad \forall\eta_h\in\mathcal{L}_h(\Gamma_{\rm I}). \tag{5.2}$$

Proof. Clearly, for all $\widetilde{\psi}_h\in\mathcal{L}_h(\widetilde{\Gamma}_{\rm I})$, $\widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h = \boldsymbol{\nu}\times(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu})$ on $\Gamma_{\rm I}$ implies (5.2).

Conversely, let $\widetilde{\psi}_h\in\mathcal{L}_h(\widetilde{\Gamma}_{\rm I})$ be such that (5.1) and (5.2) hold true. We are going to prove that there exists $\eta_h\in\mathcal{L}_h(\Gamma_{\rm I})$ such that $\mathbf{grad}_\Gamma\,\eta_h = \widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\psi}_h - \nu\times(\boldsymbol{T}_{\rm N}\times\nu)$, so that we can take it as a test function in (5.2) to conclude the lemma.

Let $\widetilde{\xi}_{\rm L}\in\Theta_h$ be as in Lemma 4.2(ii). Hence,

$$-\widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\xi}_{\rm L} = -\boldsymbol{\nu}\times\big(\widetilde{\mathbf{grad}}\,\widetilde{\xi}_{\rm L}\times\boldsymbol{\nu}\big) = \boldsymbol{\nu}\times\big(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu}\big) \qquad \text{on } \Gamma_{\rm I},$$

and therefore

$$[\![\widetilde{\xi}_{\rm L}]\!]_{\partial\Sigma_j} = -\int_{\gamma_j}\widetilde{\mathbf{grad}}_\Gamma\,\widetilde{\xi}_{\rm L}\cdot\boldsymbol{t}_j = \int_{\gamma_j}\boldsymbol{\nu}\times\big(\boldsymbol{T}_{\rm N}\times\boldsymbol{\nu}\big)\cdot\boldsymbol{t}_j = \int_{\gamma_j}\boldsymbol{T}_{\rm N}\cdot\boldsymbol{t}_j.$$

On the other hand, from (5.1), because of (2.10) and Stokes' theorem we have

$$[\![\widetilde{\psi}_h]\!]_{\partial\Sigma_j} = I_j = \int_{S_j}\boldsymbol{J}\cdot\boldsymbol{n}_{S_j} = \int_{S_j}\mathbf{curl}\,\boldsymbol{T}\cdot\boldsymbol{n}_{S_j} = \int_{\gamma_j}\boldsymbol{T}\cdot\boldsymbol{t}_j.$$

The integrals above have a precise weak sense since we are assuming $\boldsymbol{J}\in\mathrm{H}^s(\Omega)^3$, $0<s<\frac{1}{2}$, and consequently $\mathbf{curl}\,\boldsymbol{T}=\boldsymbol{J}\in\mathrm{H}^s(\Omega)^3$ as well (see [2]). The curve γ_j joining $\overline{\Sigma}_j^-$ with $\overline{\Sigma}_j^+$ can always be chosen formed by edges of the mesh. In such a case, from the definition of the Nédélec interpolant,

$$\int_{\gamma_j}\boldsymbol{T}\cdot\boldsymbol{t}_j = \int_{\gamma_j}\boldsymbol{T}_{\rm N}\cdot\boldsymbol{t}_j, \qquad j=1,\dots,J.$$

Now, let $\eta_h := \widetilde{\psi}_h - \widetilde{\xi}_{\rm L}|_{\widetilde{\Gamma}_{\rm I}}\in\mathcal{L}_h(\widetilde{\Gamma}_{\rm I})$. From the equations above,

$$[\![\eta_h]\!]_{\partial\Sigma_j} = [\![\widetilde{\psi}_h]\!]_{\partial\Sigma_j} - [\![\widetilde{\xi}_{\rm L}]\!]_{\partial\Sigma_j} = 0, \qquad j=1,\dots,J,$$

and consequently $\eta_h \in \mathcal{L}_h(\Gamma_{\rm I})$. Moreover,

$$\mathbf{grad}_\Gamma\, \eta_h = \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h - \boldsymbol{\nu} \times (\boldsymbol{T}_{\rm N} \times \boldsymbol{\nu}) \qquad \text{on } \Gamma_{\rm I}.$$

Thus, using η_h in (5.2), we obtain

$$\int_{\Gamma_{\rm I}} \left| \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h - \boldsymbol{\nu} \times (\boldsymbol{T}_{\rm N} \times \boldsymbol{\nu}) \right|^2 = 0,$$

which yields

$$\widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h = \boldsymbol{\nu} \times (\boldsymbol{T}_{\rm N} \times \boldsymbol{\nu}) \qquad \text{on } \Gamma_{\rm I},$$

and we conclude the proof. ∎

Next, we impose the constraint in the definition of $\mathcal{V}_h(\boldsymbol{T})$ by using the previous lemma to rewrite Problem DP as follows.

PROBLEM DLP. *Find* $\big((\widetilde{\phi}_h, \phi_h^{\rm R}), \lambda_h\big) \in \mathcal{X}_h \times \mathcal{L}_h(\Gamma_{\rm I})/\mathbb{R}$ *such that*

$$[\![\widetilde{\phi}_h]\!]_{\Sigma_j} = I_j, \qquad j = 1, \dots, J, \tag{5.3}$$

$$\begin{aligned} &\int_{\Omega_{\rm M}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\phi}_h \cdot \widetilde{\mathbf{grad}}\, \widetilde{\psi}_h + \int_{\Omega_{\rm R}} \mu_0\, \mathbf{grad}\, \phi_h^{\rm R} \cdot \mathbf{grad}\, \psi_h^{\rm R} \\ &\quad + \int_{\Gamma_{\rm I}} \big(\mathbf{grad}_\Gamma\, \psi_h^{\rm R} - \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h\big) \cdot \mathbf{grad}_\Gamma\, \lambda_h \\ &\qquad = \int_\Gamma \mu_0 \boldsymbol{T}_{\rm RT} \cdot \boldsymbol{n}\, \psi_h^{\rm R} - \int_{\Gamma_{\rm I}} \mu_0 \boldsymbol{T}_{\rm RT} \cdot \boldsymbol{\nu}\, \psi_h^{\rm R} - \big\langle g, \psi_h^{\rm R} \big\rangle_\Gamma \qquad \forall \big(\widetilde{\psi}_h, \psi_h^{\rm R}\big) \in \mathcal{X}_h, \end{aligned} \tag{5.4}$$

$$\begin{aligned} &\int_{\Gamma_{\rm I}} \big(\mathbf{grad}_\Gamma\, \phi_h^{\rm R} - \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\phi}_h\big) \cdot \mathbf{grad}_\Gamma\, \eta_h \\ &\qquad = \int_{\Gamma_{\rm I}} \boldsymbol{\nu} \times (\boldsymbol{T}_{\rm N}|_{\Gamma_{\rm I}} \times \boldsymbol{\nu}) \cdot \mathbf{grad}_\Gamma\, \eta_h \qquad \forall \eta_h \in \mathcal{L}_h(\Gamma_{\rm I})/\mathbb{R}. \end{aligned} \tag{5.5}$$

THEOREM 5.2. *Problem* DLP *has a unique solution.*

Proof. Problem DLP reduces to a linear system with the same number of equations and unknowns, so that it is enough to prove that, for vanishing data, this problem attains only the null solution. Let $\big((\widetilde{\phi}_o, \phi_o^{\rm R}), \lambda_o\big) \in \mathcal{X}_h \times \mathcal{L}_h(\Gamma_{\rm I})/\mathbb{R}$ be a solution of (5.3)–(5.5) with $I_j = 0$, $j = 1, \dots, J$, $\boldsymbol{T} = \boldsymbol{0}$, and $g = 0$.

In such a case $[\![\widetilde{\phi}_o]\!]_{\Sigma_j} = 0$, $j = 1, \dots, J$, because of (5.3). Thus, if we define $\eta_h := \big(\phi_o^{\rm R} - \widetilde{\phi}_o\big)|_{\widetilde{\Gamma}_{\rm I}}$, then $[\![\eta_h]\!]_{\partial\Sigma_j} = 0$, $j = 1, \dots, J$, and hence $\eta_h \in \mathcal{L}_h(\Gamma_{\rm I})/\mathbb{R}$. Then, by testing (5.5) with η_h, we obtain

$$\mathbf{grad}_\Gamma\, \phi_o^{\rm R} - \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\phi}_o = \boldsymbol{0}.$$

Therefore, by testing (5.4) with $\big(\widetilde{\phi}_o, \phi_o^{\rm R}\big)$, we have

$$\int_{\Omega_{\rm M}} \mu \left| \widetilde{\mathbf{grad}}\, \widetilde{\phi}_o \right|^2 + \int_{\Omega_{\rm R}} \mu_0 \left| \mathbf{grad}\, \phi_o^{\rm R} \right|^2 = 0,$$

which implies that $\widetilde{\phi}_o = 0$ in $\Theta_h/\mathbb{R}$ and $\phi_o^{\rm R} = 0$ in $\mathcal{L}_h(\Omega_{\rm R})/\mathbb{R}$.

Thus, there only remains to prove that $\lambda_o = 0$. For this purpose, let ψ_h^{R} be any function in $\mathcal{L}_h(\Omega_{\mathrm{R}})/\mathbb{R}$ such that $\psi_h^{\mathrm{R}}|_{\Gamma_{\mathrm{I}}} = \lambda_o$, and let $\widetilde{\psi}_h = 0$ in $\Theta_h/\mathbb{R}$. Then $\mathbf{grad}_\Gamma\, \psi_h^{\mathrm{R}} - \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h = \mathbf{grad}_\Gamma\, \lambda_o$ on Γ_{I}, and by testing (5.4) with $\big(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\big)$ we obtain

$$\int_{\Gamma_{\mathrm{I}}} |\mathbf{grad}_\Gamma\, \lambda_o|^2 = 0.$$

Therefore, $\lambda_o = 0$ in $\mathcal{L}_h(\Gamma_{\mathrm{I}})/\mathbb{R}$, and we conclude the proof. ∎

The final result of this section is that Problems DP and DLP are equivalent.

THEOREM 5.3. *If* $\big((\widetilde{\phi}_h, \phi_h^{\mathrm{R}}), \lambda_h\big)$ *is the solution of Problem* DLP*, then* $\big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big)$ *is the solution of Problem* DP*.*

Conversely, if $\big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big)$ *is the solution of Problem* DP*, then there exists* λ_h *such that* $\big((\widetilde{\phi}_h, \phi_h^{\mathrm{R}}), \lambda_h\big)$ *is the solution of Problem* DLP*.*

Proof. Let $\big((\widetilde{\phi}_h, \phi_h^{\mathrm{R}}), \lambda_h\big)$ be the solution of Problem DLP. Because of (5.3), (5.5), and Lemma 5.1, we have that $\big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big) \in \mathcal{V}_h(\boldsymbol{T})$. Now, let $\big(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\big) \in \mathcal{V}_h(\mathbf{0})$. Since $\mathbf{grad}_\Gamma\, \psi_h^{\mathrm{R}} - \widetilde{\mathbf{grad}}_\Gamma\, \widetilde{\psi}_h = \mathbf{0}$, by testing (5.4) with such $\big(\widetilde{\psi}_h, \psi_h^{\mathrm{R}}\big)$, we obtain (4.3). Thus, $\big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big)$ is the solution of Problem DP.

Conversely, let $\big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big)$ be the solution of Problem DP and $\big((\widetilde{\phi}'_h, \phi_h^{\mathrm{R}\prime})), \lambda_h\big)$ the solution of Problem DLP. We have just proved that $\big(\widetilde{\phi}'_h, \phi_h^{\mathrm{R}\prime}\big)$ is also a solution of Problem DP. Since this solution is unique because of Theorem 4.4, then $\big(\widetilde{\phi}'_h, \phi_h^{\mathrm{R}\prime}\big) = \big(\widetilde{\phi}_h, \phi_h^{\mathrm{R}}\big)$, and we conclude the proof. ∎

Remark 5.1. We have restricted our analysis to the magnetostatic problem with a boundary condition $\mu \boldsymbol{H} \cdot \boldsymbol{n} = g$ on the whole Γ. However, as stated above, the method can deal with a condition $\boldsymbol{H} \times \boldsymbol{n} = \mathbf{0}$ on a piece Γ_{D} of the boundary, as well. In such a case, an additional Lagrange multiplier must be used to impose

$$\mathbf{grad}\, \phi_h^{\mathrm{R}} \times \boldsymbol{n} - \boldsymbol{T}_{\mathrm{N}} \times \boldsymbol{n} = \mathbf{0} \qquad \text{on } \Gamma_{\mathrm{D}}.$$

Remark 5.2. We have also restricted the analysis of this section to domains Ω_{M} with a connected boundary, and consequently to Ω_{R} a connected set. However, it also extends with minor modifications to the case $\Gamma_{\mathrm{I}} = \partial\Omega_{\mathrm{M}}$ disconnected (and hence Ω_{R} disconnected too). We have already pointed out in Remark 4.1 how to deal with a disconnected set Ω_{R}. Regarding Γ_{I}, if $\Gamma_1, \ldots, \Gamma_K$ are its connected components, then the constraint in the definition of $\mathcal{V}_h(\boldsymbol{T})$, $\mathbf{grad}\, \psi_h^{\mathrm{R}} \times \boldsymbol{\nu} - \widetilde{\mathbf{grad}}\, \widetilde{\psi}_h \times \boldsymbol{\nu} = \boldsymbol{T}_{\mathrm{N}} \times \boldsymbol{\nu}$ on Γ_{I}, must be imposed by means of a Lagrange multiplier on each connected component. Therefore, the functional space for λ_h and η_h in Problem DLP must be $\Pi_{k=1}^K [\mathcal{L}_h(\Gamma_k)/\mathbb{R}]$.

6. Numerical results. In this section we present some numerical results obtained with a MATLAB code which implements the method described above.

Notice that the implementation requires the computation of $\boldsymbol{T}_{\mathrm{N}}$ and $\boldsymbol{T}_{\mathrm{RT}}$ on Γ_{I}. Since we have assumed that $\Omega_{\mathrm{M}} \cap \Omega_{\mathrm{J}} = \emptyset$, the integral involved in the definition of $\boldsymbol{T}$ does not include singular terms on this boundary. However, to compute the magnetic field $\boldsymbol{H} = \boldsymbol{T} - \mathbf{grad}\, \phi^{\mathrm{R}}$ in the source region, we have to deal with singular integrals. There exists an important list of papers devoted to the numerical evaluation of the Biot–Savart integral; some of these techniques are based on assumptions on the shape of the source region or on the current density $\boldsymbol{J}$ (see, for instance, [13, 29, 30] and the references therein), while other works are based on the transformation of the volume integral into line integrals [28]. Specifically, we have used the techniques developed in [13] in the numerical test in section 6.2.

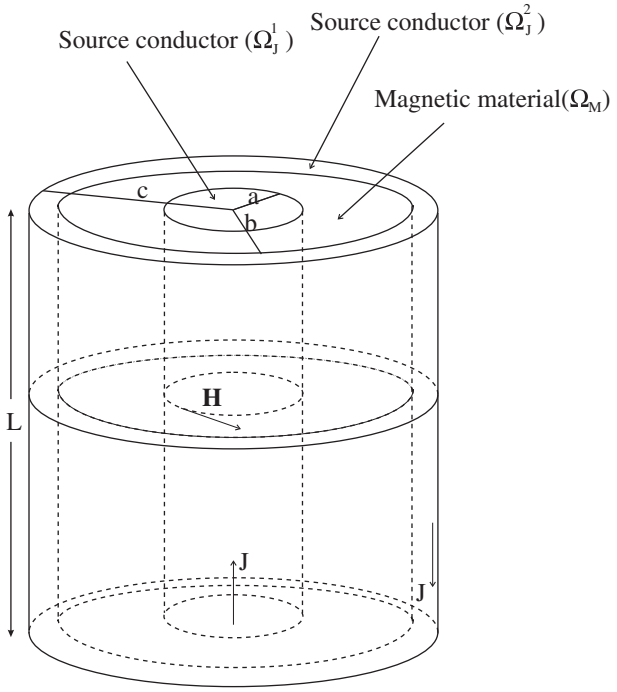

FIG. 6.1. *Geometric data for the verification test.*

6.1. Verification of the FEM. First, in order to test the convergence properties settled in the previous sections, we report the results obtained by applying the method to a simple problem with a known analytical solution.

Consider the magnetostatic problem in a cylindrical domain Ω, which consists of a current source region with two concentric connected components, Ω_J^1 and Ω_J^2, separated by a magnetic material Ω_M, as shown in Figure 6.1. These sets are assumed to be sections of height L of respective infinite cylinders. This assumption allows us to obtain the analytical solution of the problem.

The magnetic permeability of $\Omega_R := \Omega_J^1 \cup \Omega_J^2$ is taken equal to that of vacuum ($\mu_0 = 4\pi\,10^{-7}\,\mathrm{Hm}^{-1}$), whereas that of Ω_M is taken constant and equal to $10^4\mu_0$. The conductors Ω_J^1 and Ω_J^2 carry uniformly distributed currents $\boldsymbol{J}$ of the same intensity $I = 70000\,\mathrm{A}$, but in opposite directions (see Figure 6.1).

Consider a cylindrical coordinate system (r, θ, z), with the z-axis coinciding with the common axis of the cylinders, and denote by $\boldsymbol{e}_r$, $\boldsymbol{e}_\theta$, and $\boldsymbol{e}_z$ the unit vectors in the corresponding coordinate directions. Simple calculus (see [14, Example 5.1, p. 260]) shows that

$$\boldsymbol{H}(r,\theta,z) = \begin{cases} \dfrac{rI}{2\pi a^2}\,\boldsymbol{e}_\theta, & 0 \le r \le a, \\ \dfrac{I}{2\pi r}\,\boldsymbol{e}_\theta, & a \le r \le b, \\ \left\{ \dfrac{rI}{2\pi\,(c^2-b^2)} + \dfrac{1}{r}\left[\dfrac{I}{2\pi} - \dfrac{b^2 I}{2\pi\,(c^2-b^2)} \right] \right\} \boldsymbol{e}_\theta, & b < r < c. \end{cases}$$

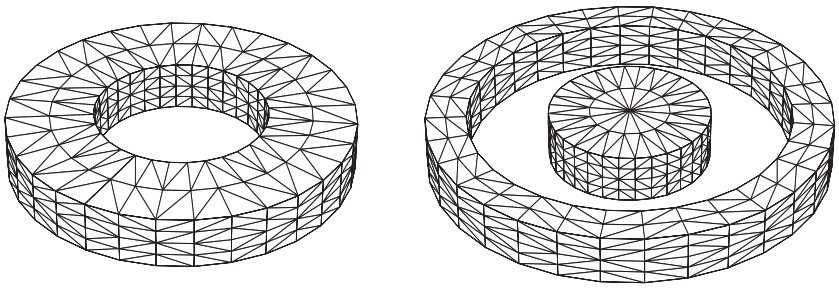

FIG. 6.2. *Initial mesh $\mathcal{T}_h$ for the verification test: $\mathcal{T}_h^{\Omega_M}$ (left) and $\mathcal{T}_h^{\Omega_R}$ (right).*

TABLE 6.1
Verification test. $L^2(\Omega)$*-norms of computed solution and error for the magnetic field.*

Mesh size	d.o.f.	$\|\boldsymbol{H}_h\|_{0,\Omega}$	$\|\boldsymbol{H}-\boldsymbol{H}_h\|_{0,\Omega}$	Relative error (%)
h	1220	23746.15	2757.19	11.61
$h/2$	7254	23704.27	1390.96	5.87
$h/3$	21944	23696.28	930.31	3.93
$h/4$	49130	23693.46	698.50	2.95
$h/5$	92652	23692.13	559.18	2.36

Taking into account the expression of the gradient operator of a scalar field in cylindrical coordinates, we have that

$$\boldsymbol{H} = -\,\widetilde{\mathbf{grad}}\,\widetilde{\phi} \qquad \text{in } \Omega_M$$

with

$$\widetilde{\phi}\,(r,\theta,z) = -\frac{I}{2\pi}\,\theta, \qquad r \in (a,b)\,, \quad \theta \in [0,2\pi]\,, \quad z \in \mathbb{R}.$$

Notice that this scalar potential has a jump of magnitude I across the cut surface Σ on the half-plane $\theta = 0$.

In this example, we have taken $\boldsymbol{T} = \boldsymbol{H}$ in Ω_R, so that ϕ^R is constant, and the boundary condition

$$\mu\boldsymbol{H}\cdot\boldsymbol{n} = 0 \qquad \text{on } \partial\Omega,$$

which is fulfilled by the exact solution on the whole boundary.

The geometrical data has been taken as follows: $a = 0.5\,\text{m}$, $b = 1\,\text{m}$, $c = 1.25\,\text{m}$, and $L = 0.5\,\text{m}$.

The numerical method has been used with a sequence of meshes obtained by uniformly refining the mesh $\mathcal{T}_h$ shown in Figure 6.2. We denote by h, $h/2$, $h/3$, etc. the corresponding mesh sizes.

The computed solutions have been compared with the analytical one to determine the orders of convergence. Table 6.1 shows the $L^2(\Omega)$-norms of the computed magnetic field $\boldsymbol{H}_h$ and the corresponding errors. The total number of degrees of freedom (d.o.f.) for the potentials (i.e., total number of vertices) is also included for each mesh.

Figure 6.3 shows a log-log plot of the relative error of the computed magnetic field in $L^2(\Omega)$-norm versus the number of d.o.f. of each mesh.

A linear dependence on the mesh size can be clearly observed from Figure 6.3. Let us remark that this norm coincides with the $\mathcal{X}$-norm of the potentials, for which

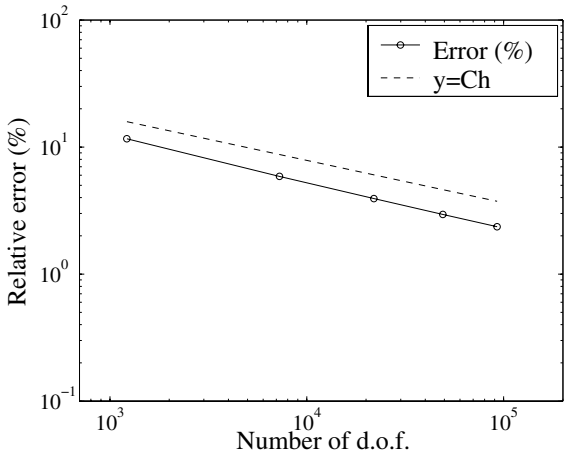

FIG. 6.3. *Verification test.* $\|\boldsymbol{H} - \boldsymbol{H}_h\|_{0,\Omega} / \|\boldsymbol{H}_h\|_{0,\Omega}$ *versus number of d.o.f. (log-log scale).*

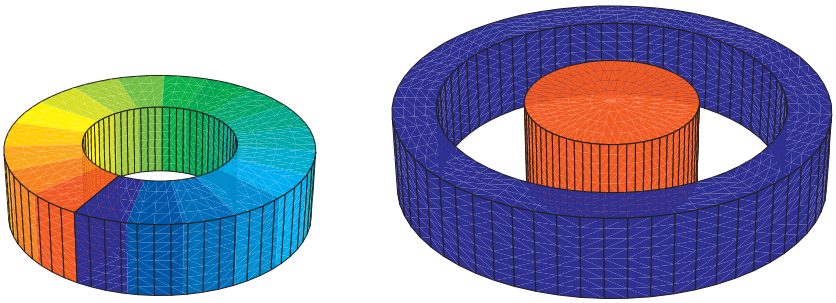

FIG. 6.4. *Verification test. Total and reduced potential in* Ω_{M} *(left) and* Ω_{J} *(right).*

Theorem 4.4 provides error estimates. The observed linear dependence agrees with the theoretically predicted order of convergence, even though this problem does not fully satisfy the geometrical assumptions of the previous sections.

Finally, Figure 6.4 shows the computed total and reduced potentials in the sets Ω_{M} and Ω_{J}, respectively.

6.2. The magnetostatic problem in an electromagnet. The second test corresponds to an axisymmetric electromagnet. This example has been taken from [12], where the magnetostatic problem is solved also in terms of total and reduced scalar potentials by using an adaptive finite element code.

The problem consists of a ferromagnetic cylindrical core (iron) surrounded by a toroidal coil (copper) with a rectangular cross section. A two-dimensional section of the geometry and the dimensions are shown in Figure 6.5.

A stationary uniform current with intensity $I = 1\,\mathrm{A}$ flows through the coil. The magnetic permeabilities have been taken as follows: $\mu_0 = 4\pi\,10^{-7}\,\mathrm{Hm}^{-1}$ for the air and the copper coil (Ω_{R}) and $10^4\mu_0$ for the iron core (Ω_{M}). We have used a homogeneous boundary condition $\mu\boldsymbol{H}\cdot\boldsymbol{n} = 0$ on the whole boundary. The vector potential $\boldsymbol{T}$ has been computed as proposed in [13].

Figure 6.6 shows the coarser meshes used to solve the problem.

Figure 6.7 shows the total and reduced scalar potentials on a plane containing the symmetry axis.

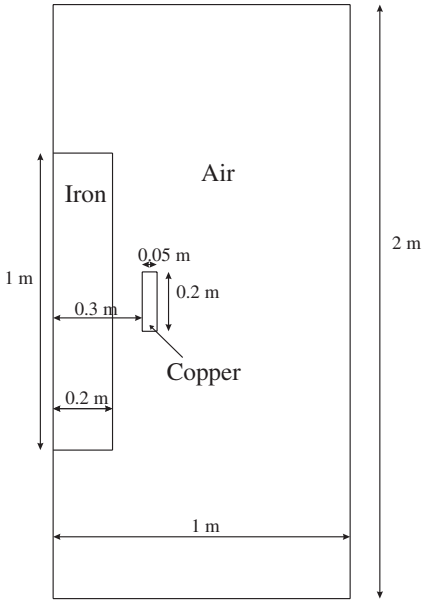

FIG. 6.5. *Electromagnet. Axial section of the domain.*

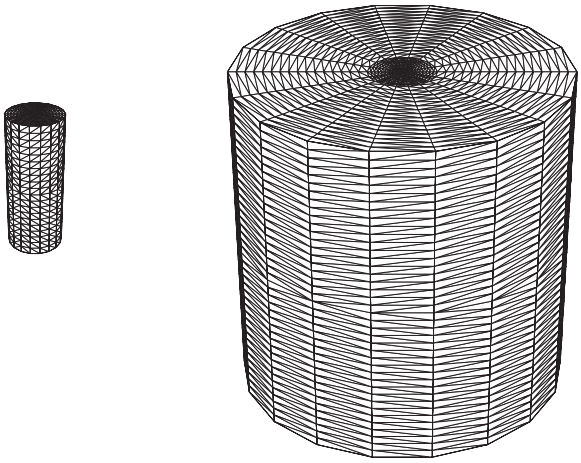

FIG. 6.6. *Electromagnet. Meshes in* Ω_{M} *(left) and* Ω_{R} *(right).*

Figure 6.8 shows the intensity of the magnetic induction field, $|\boldsymbol{B}| = |\mu \boldsymbol{H}|$, on the same plane.

To validate the proposed method, we have also solved this magnetostatic problem by means of the commercial code *FLUX2D* (see [24]), which takes advantage of the axial symmetry of the problem. We have computed the magnetic energy (see, for instance, [14])

$$W = \frac{1}{2} \int_D \boldsymbol{B} \cdot \boldsymbol{H} = \frac{1}{2} \int_D \mu \, |\boldsymbol{H}|^2 \,,$$

where D represents a generic domain occupied by any of the three media: air, copper, or iron.

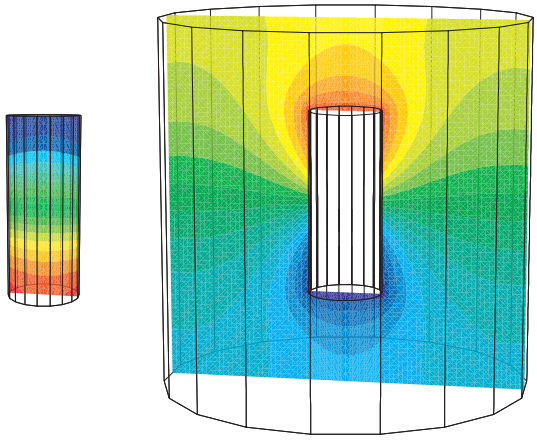

FIG. 6.7. *Electromagnet. Total potential* $\widetilde{\phi}_h$ *in* Ω_{M} *(left) and reduced potential* ϕ_h^{R} *in* Ω_{R} *(right).*

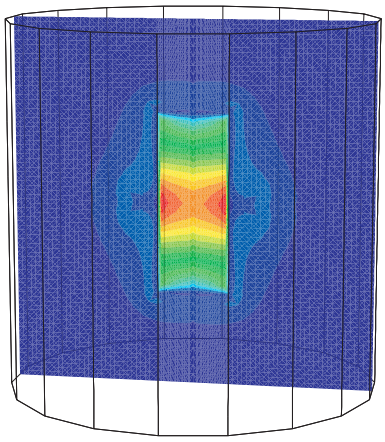

FIG. 6.8. *Electromagnet. Intensity of the magnetic induction field,* $|\boldsymbol{B}|$ *in* Ω.

TABLE 6.2
Electromagnet. Computed magnetic energies and relative errors.

	Medium	Air	Iron	Copper
Mesh 1	Magnetic Energy (J)	9.13e-07	4.93e-10	2.60e-08
19933 d.o.f.	Relative error (%)	0.43	4.23	27.07
Mesh 2	Magnetic Energy (J)	9.10e-07	4.83e-10	3.37e-08
37159 d.o.f.	Relative error (%)	0.15	2.11	6.65
FLUX2D	Magnetic Energy (J)	9.09e-07	4.73e-10	3.61e-08

We report in Table 6.2 the values of the magnetic energy computed with our method on two different meshes and the corresponding values computed with *FLUX2D* on a highly refined two-dimensional mesh. We include the total numbers of d.o.f. for each three-dimensional mesh and the relative errors obtained by using the values computed with *FLUX2D* as "exact."

Table 6.2 shows that the error of the computed magnetic energy in each medium goes to zero as the mesh is refined. On the other hand, the agreement between the values obtained with the proposed method on the coarser mesh and *FLUX2D* is excellent in the magnetic material (which is typically the domain of interest), very good in the air, but not so good in the conducting domain. A similar behavior has been already reported in [11].

Acknowledgment. The numerical computations have been performed on the system HPC320 at "Centro de Supercomputación de Galicia" (CESGA).

ERROR ESTIMATES FOR THE RUNGE–KUTTA DISCONTINUOUS GALERKIN METHOD FOR THE TRANSPORT EQUATION WITH DISCONTINUOUS INITIAL DATA*

BERNARDO COCKBURN† AND JOHNNY GUZMÁN†

Abstract. We study the approximation of nonsmooth solutions of the transport equation in one space dimension by approximations given by a Runge–Kutta discontinuous Galerkin method of order two. We take an initial datum, which has compact support and is smooth except at a discontinuity, and show that, if the ratio of the time step size to the grid size is less than 1/3, the error at the time T in the $L^2(\mathbb{R}\setminus\mathcal{R}_T)$-*norm* is the optimal order two when $\mathcal{R}_T$ is a region of size $O(T^{1/2}\,h^{1/2}\,\log 1/h)$ to the right of the discontinuity and of size $O(T^{1/3}\,h^{2/3}\,\log 1/h)$ to the left. Numerical experiments validating these results are presented.

Key words. discontinuous Galerkin methods, error estimates, hyperbolic problems

DOI. 10.1137/060668936

1. Introduction.

In this paper, we present the first error estimates for the Runge–Kutta discontinuous Galerkin (RKDG) method for the transport equation with *discontinuous* initial data. These results are obtained for a formally second-order accurate RKDG method applied to the model problem

$$U_t + U_x = 0 \qquad \text{in } \mathbb{R}\times(0,T), \tag{1.1a}$$

$$U(\cdot,0) = U_0(\cdot) \quad \text{on } \mathbb{R}, \tag{1.1b}$$

where the initial condition U_0 has compact support; it has a discontinuity at $x = 0$ and is smooth everywhere else. Roughly speaking, we show that the quality of the approximation at time T is of second order in the size of the mesh h *outside* a region of size $O(T^{1/2}\,h^{1/2}\,\log 1/h)$ to the right of the discontinuity and of size $O(T^{1/3}\,h^{2/3}\,\log 1/h)$ to the left. An illustration of this result can be seen in Figure 1.1.

The RKDG method was introduced by Cockburn, Shu, and co-workers in a series of papers [10, 9, 8, 6, 11]; see also the monographs [4, 5] and the review [12]. Most a priori and a posteriori error analyzes of discontinuous Galerkin (DG) methods for hyperbolic problems have been carried out either for the semidiscrete version of the method or for DG methods using space-time elements; see [7], where the development of the DG methods up to the end of past century is described. To the knowledge of the authors, the only a priori error analysis for the RKDG method is due to Shu and Zhang [19], who proved, among other things, that the same method considered here (but applied to nonlinear scalar conservation laws in several space dimensions) converges with order two in the $L^\infty(0,T;L^2(\mathbb{R}^d))$-norm, provided that the solution is *smooth*. In this paper, we continue this effort to understand the RKDG method and analyze it

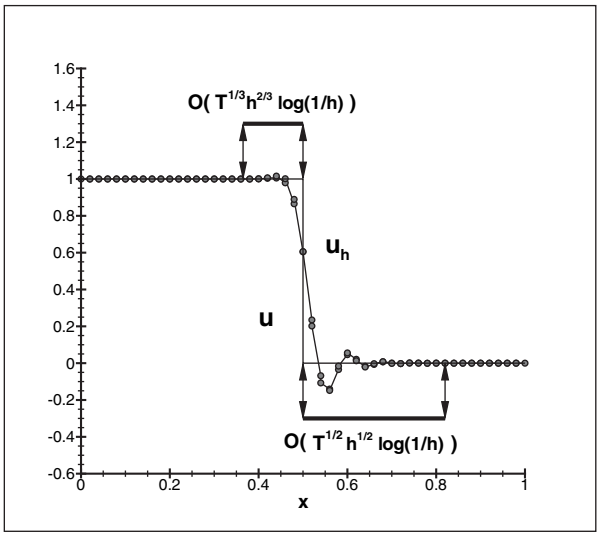

FIG. 1.1. *The two parts of the region $\mathcal{R}_T$ containing the numerical layer of the RKDG method: to the left (top) and to the right (bottom) of the discontinuity of the exact solution u. The approximate solution u_h was obtained by using $h = 1/100$ and $k/h = 0.3$. The time T is* 0.5.

in the case of solutions that have *discontinuities*. As a stepping stone towards the goal of solving the much more complicated case of nonlinear scalar conservation laws in several space dimensions, we consider here the simpler model problem (1.1) and find, for each time T, the region $\mathcal{R}_T$ around the discontinuity of the exact solution $U(\cdot, T)$ such that the approximate solution $u_h(\cdot, T)$ given by the RKDG method converges with the optimal order of two in the $L^2(\mathbb{R} \setminus \mathcal{R}_T)$-norm.

To do that, we use an approach which is a modification of the classical L^2-argument to obtain error estimates in the $L^\infty(0, T; L^2(\mathbb{R}^d))$-norm; see, for example, subsection 2.7 of [5], where the semidiscrete case is treated. The modification has three main features. The first is the use of the decomposition of the error of the approximation given by the RKDG method proposed by Shu and Zhang [19]. The second is the use of special projections that allow us to obtain the full order of convergence of the approximation; see [3]. In our technique, without these projections, the order of convergence is reduced by 1/2. The third is the introduction of suitably chosen *weights* thanks to which we can localize the estimates and make the difference between the region to the left of the discontinuity and that to the right of it.

Similar weights were originally used by Johnson, Nävert, and Pitkäranta [16] to prove local L^2 error estimates for a singularly perturbed reaction-convection-diffusion problem approximated by the streamline diffusion (SD) method; see [17] for L^∞ results. Recently, Guzmán [13] proved similar results for a DG method. Moreover, if one approximates (1.1) with either the standard SD or the DG method and linear space-time elements, one can show by using techniques in [16, 13] that the numerical layer resulting from discontinuous initial data is contained in a region whose size is at most $O(\log(1/h)h^{1/2})$ from either side of the discontinuity. In this article we show that, in one side of the discontinuity, the size of the numerical layer can be reduced to $O(\log(1/h)h^{2/3})$ for the RKDG method. We accomplish this by taking advantage of the monotonicity of one of the two weight functions that we use; see Theorem 4.11 below.

Results of this type were obtained many years ago for finite difference methods for the model problem (1.1) with discontinuous initial data; see [1, 14, 2, 15]. Indeed,

by using Fourier techniques, the size of the numerical layer to the left of the discontinuity was shown to be different to the size of the numerical layer to its right for some schemes; see (1.13) in [15]. In particular, the results concerning the size of the numerical layer for second-order accurate finite difference methods with fourth-order dissipation in [15] are exactly the same result we prove in this paper for the RKDG method.

The organization of the paper is as follows. In section 2, we introduce the RKDG method under consideration and state and discuss the main result, which is Theorem 2.1. In section 4, we prove the theorem, and, in section 5, we display numerical results showing that the result is sharp. We end in section 6 with some concluding remarks.

2. The main result. To state our main result, we first give a precise definition of the RKDG under consideration. The RKDG method is obtained by discretizing the equations in space by means of the DG method and then discretizing the resulting system of ODEs by a second-order TVD Runge–Kutta time stepping [18]; see [9].

We take uniform grids in both space and time. Let $\{I_j\}_j$ be a uniform partition of the real line, where $I_j = (x_{j-1/2}, x_{j+1/2})$. Denote the mesh size by $h = x_{j+1/2} - x_{j-1/2}$ and the midpoint by $x_j = (x_{j+1/2} + x_{j-1/2})/2$. Accordingly, the RKDG approximation at each time $t^n = k\,n$, where k denotes the time step, is taken in the space

$$V_h = \{v \in L^2(\mathbb{R}), v|_{I_j} \in P^1(I_j) \ \ \forall j \in \mathbb{Z}\}.$$

For any function $v \in V_h$, we define the jump in v at the nodal point $x_{j+1/2}$ by

$$[v]_{j+1/2} = v(x^+_{j+1/2}) - v(x^-_{j+1/2}).$$

The RKDG approximation $\{\, u_h^n \,\}_{n=0}^{\infty}$ is defined as follows. For $n \geq 0$, u_h^{n+1} is the element of V_h such that

$$\sum_j (u_h^{n+1}, v_h)_j = \sum_j \left\{ \frac{1}{2}(u_h^n, v_h)_j + \frac{1}{2}(w_h^n, v_h)_j \right\} + k\, H(w_h^n, v_h), \tag{2.1a}$$

where $w_h^n \in V_h$ is given by

$$\sum_j (w_h^n, v_h)_j = \sum_j (u_h^n, v_h)_j + kH(u_h^n, v_h) \tag{2.1b}$$

and

$$H(p, q) = \sum_j (p, q_x)_j + p(x^-_{j+1/2})[q]_{j+1/2}. \tag{2.1c}$$

Here $(w, v)_j = \int_{I_j} w\, v\, dx$. For $n = 0$, we set

$$u_h^0 = P_-(U_0). \tag{2.1d}$$

Here the projection $P_-(v)$ of a function v in the space

$$H_h^1(\mathbb{R}) = \{v : \mathbb{R} \mapsto \mathbb{R} \text{ such that } v|_{I_j} \in H^1(I_j)\ \forall j \in \mathbb{Z}\}$$

is defined as the element of V_h satisfying, on each interval I_j, $j \in \mathbb{Z}$,

$$(P_-(v), 1)_j = (v, 1)_j \quad \text{ and } \quad P_-(v)(x^-_{j+1/2}) = v(x^-_{j+1/2}).$$

This projection was introduced in [20] in the framework of DG methods for ODEs and was later used in [3] to obtain optimal error estimates for DG methods for one-dimensional convection-diffusion problems.

We can now state our main result.

THEOREM 2.1. *Let U be the solution of the initial value problem* (1.1)*, and let u_h^N be the solution of the* RKDG *method* (2.1) *at time $T = N\,k$. Suppose that $\lambda := \frac{k}{h} \le 1/3 - \epsilon$ for some fixed $\epsilon \in (0, 1/3)$, and then there exist constants $\beta > 0$ and $C > 0$ such that for any $s \ge 4$*

$$\| U(T) - u_h^N \|_{L^2(\mathbb{R}\setminus\mathcal{R}_T)} \le C\,T\,h^2 \left(1 + \left(\frac{k}{T\,\epsilon}\right)^{1/2}\right) + Ch^s + ||U(T) - P_-(U(T))||_{L^2(\mathbb{R}\setminus\mathcal{R}_T)},$$

where the interval $\mathcal{R}_T$ is given by

$$\mathcal{R}_T = T + \beta\,s\,\log(1/h)\epsilon^{-1}\,(-\lambda^{-7/3}T^{1/3}\,h^{2/3}, \lambda^{-1/2}T^{1/2}\,h^{1/2})$$

and C is independent of h, k, T, and ϵ.

A couple of remarks are in order. The first is that our hypothesis that the CFL condition $\lambda \le 1/3 - \epsilon$ is reasonable, since it is well known that the RKDG under consideration is L^2-stable under the CFL condition

$$\lambda \le 1/3;$$

see, for example, [9, 12]. Taking $\epsilon > 0$ allows us to take advantage of the damping properties of the RKDG method. We would have to significantly modify our approach to deal with the case $\epsilon = 0$, and the result might be very different.

The second remark is that this error estimate extends the result by Shu and Zhang [19] for smooth solutions to nonsmooth solutions, in the special case considered here, of course. Indeed, in our case such a result would read

$$\| U(T) - u_h^N \|_{L^2(\mathbb{R})} \le C\,h^2,$$

provided the initial condition U_0 is smooth. Our results say that the same rate of convergence in h holds if the region $\mathcal{R}_T$ around the discontinuity $x = t$ is removed from $\mathbb{R}$.

3. Idea of the proof. Since the proof of Theorem 2.1 is very technical, we explain here the idea upon which it is based. Suppose that we are interested in establishing error estimates to the left of the line $t = x$; that is, suppose that we want to prove

$$\begin{aligned} \| U(T) - u_h^N \|_{L^2(\mathbb{R}\setminus\mathcal{R}_T^-)} &\le C||U(T) - P_-(U(T))||_{L^2(\mathbb{R}\setminus\mathcal{R}_T^-)} \\ &\quad + C\,T\,h^2 \left(1 + \left(\frac{k}{T\,\epsilon}\right)^{1/2}\right) + Ch^s, \end{aligned} \tag{3.1}$$

where $\mathcal{R}_T^- = (T - \beta\,s\,\log(1/h)\epsilon^{-1}\lambda^{-7/3}T^{1/3}\,h^{2/3}, -\infty)$.

To do this, we do not bound $U(T) - u_h^N$ directly. Instead, we compare u_h^N with a smooth approximation u of U so that

$$\| U(T) - u_h^N \|_{L^2(\mathbb{R}\setminus\mathcal{R}_T^-)} = \|u(T) - u_h^N\|_{L^2(\mathbb{R}\setminus\mathcal{R}_T^-)}.$$

We then obtain a bound of the form

$$\|u(T) - u_h^N\|_{L^2(\mathbb{R}\setminus\mathcal{R}_T^-)} \le C\|\phi_1(T)(u(T) - u_h^N)\|_{L^2(\mathbb{R})},$$

where ϕ_1 is a suitably chosen positive weight function.

The function ϕ_1 will be of order one in the region of interest and will satisfy

$$(\phi_1)_t + (\phi_1)_x = 0.$$

It will be a decreasing function in x which is exponentially small near the line $x = t$; as a consequence, it will have an internal layer. Moreover, ϕ_1 will satisfy

$$\left| \frac{D_x^l(\phi_1(x,t))}{\phi_1(x,t)} \right| \leq \frac{C}{M^l} \quad \text{for all } (x,t), l = 1,2,3,4. \tag{3.2}$$

It is clear that the parameter M is nothing but the size of the above-mentioned layer.

In this way, we reduce the original problem to that of showing a weighted stability result for the error. In solving this problem, we will try to match the size of the layer of the weight function M with that of the internal layer produced by the numerical scheme to the left of the discontinuity. Indeed, roughly speaking, we will show that, if we take $M = \epsilon^{-1}\lambda^{-7/3}T^{1/3}\,h^{2/3}$, we obtain

(3.3)
$$\|\phi_1(T)(u(T) - u_h^N)\|_{L^2(\mathbb{R})} \leq C\|\phi_1(0)(u(0) - u_h^0)\|_{L^2(\mathbb{R})} + C\,T\,h^2\left(1 + \left(\frac{k}{T\,\epsilon}\right)^{1/2}\right).$$

Finally, if we take $u_0 = U_0$ in the region of interest, and since $\phi_1(0)$ is exponentially small when $u_0 \neq U_0$, we would arrive at (3.1).

A similar argument is used to estimate the error to the right of the discontinuity. In this case, however, it turns out that we cannot choose the corresponding weight function ϕ_2 to be a decreasing function in x. This leads to a larger numerical layer to the right.

Most of this paper is dedicated to proving a result similar to (3.3) for the two different weights ϕ_1 and ϕ_2. Next we illustrate one of the main ideas behind the proof of such an estimate by proving a similar result for a continuous problem; the techniques will be similar but more simple.

To this end, we have to find a continuous model for the equation satisfied by the error $\boldsymbol{e}$. Although the model equation for stable second-order accurate finite difference methods with constant coefficients is of the form

$$\boldsymbol{e}_t + \boldsymbol{e}_x = c_2\,h^2\boldsymbol{e}_{xxx} - c_3\,h^3\boldsymbol{e}_{xxxx},$$

where $c_3 > 0$ (see [15]) we are going to work with a simpler equation in order to simplify the computations; the final result will be the same. Thus, let $\boldsymbol{e}$ be the solution of

$$\boldsymbol{e}_t + \boldsymbol{e}_x = h^2\boldsymbol{e}_{xxx} \quad \text{in } \mathbb{R}\times(0,T), \tag{3.4a}$$
$$\boldsymbol{e}(x,0) = \boldsymbol{e}_0(x) \quad \text{on } \mathbb{R}, \tag{3.4b}$$

where $\boldsymbol{e}_0$ is smooth with compact support, and suppose that we are interested in proving a weighted stability result of the form

$$\|\phi(T)\boldsymbol{e}(T)\|_{L^2(\mathbb{R})} \leq C\|\phi(0)\boldsymbol{e}_0\|, \tag{3.5}$$

where ϕ solves $\phi_t + \phi_x = 0$, is a decreasing function in x, and satisfies (3.2).

In obtaining the estimate (3.5), one important question is how to pick M in an optimal way. To answer this question, we proceed as follows. First, we multiply both sides of (3.4a) by $\phi^2 \boldsymbol{e}$, integrate in space and time, and obtain

$$||\phi(T)\boldsymbol{e}(T)||^2_{L^2(\mathbb{R})} = ||\phi(0)\boldsymbol{e}(0)||^2_{L^2(\mathbb{R})} + h^2 \int_0^T (\boldsymbol{e}_{xxx}(t), \phi^2(t)\boldsymbol{e})\, dt.$$

By using the fact that $\boldsymbol{e}_{xxx}\boldsymbol{e} = \frac{1}{2}(\boldsymbol{e}^2)_{xxx} - \frac{3}{2}((\boldsymbol{e}_x)^2)_x$,

$$\begin{aligned} h^2 \int_0^T (\boldsymbol{e}_{xxx}(t), \phi^2(t)\boldsymbol{e})\, dt &= \frac{h^2}{2} \int_0^T (\phi^2(t), (\boldsymbol{e}^2(t))_{xxx})\, dt - \frac{3h^2}{2} \int_0^T ((\phi(t))^2, ((\boldsymbol{e}_x)^2)_x)\, dt \\ &= \frac{h^2}{2} \int_0^T ((\phi^2(t))_{xxx}, \boldsymbol{e}^2(t))\, dt + \frac{3h^2}{2} \int_0^T ((\phi^2(t))_x, (\boldsymbol{e}_x)^2)\, dt. \end{aligned}$$

In the last equation we used integration by parts and the fact that $\boldsymbol{e}$ has compact support. Now we use the fact that $(\phi^2(t))_x < 0$ to get

$$\begin{aligned} ||\phi(T)\boldsymbol{e}(T)||^2_{L^2(\mathbb{R})} &\le ||\phi(0)\boldsymbol{e}(0)||^2_{L^2(\mathbb{R})} + \frac{h^2}{2} \int_0^T ((\phi^2(t))_{xxx}, \boldsymbol{e}^2(t))\, dt \\ &\le ||\phi(0)\boldsymbol{e}(0)||^2_{L^2(\mathbb{R})} + \frac{Ch^2}{M^3} \int_0^T \|\phi(t)\boldsymbol{e}^2(t)\|^2_{L^2(\mathbb{R})}\, dt. \end{aligned}$$

In the last equation we used (3.4a). Finally, by Gronwall's inequality, we have

$$||\phi(T)\boldsymbol{e}(T)||^2_{L^2(\mathbb{R})} \le ||\phi(0)\boldsymbol{e}_0||^2_{L^2(\mathbb{R})} \left(1 + \frac{CTh^2}{M^3} e^{\frac{CTh^2}{M^3}}\right),$$

and we see that we must choose $M = CT^{1/3}h^{2/3}$ to obtain the wanted estimate.

Note that if ϕ is not a decreasing function in x, then M will have to be larger in order to prove stability. This actually happens when dealing with the numerical layer to the right of the discontinuity. This is why the layer to the left of the discontinuity is smaller.

4. Proof. In this section we give a detailed proof of Theorem 2.1. We proceed in several steps.

4.1. Step 1: The error equations. First we define a suitable approximation u to U. The smooth approximation u will satisfy

$$u_t + u_x = 0 \qquad \text{in } \mathbb{R} \times (0,T), \tag{4.1a}$$

$$u(x,0) = u_0(x) \quad \text{on } \mathbb{R}, \tag{4.1b}$$

where u_0 is a smooth function which agrees with U_0 on $(-\infty, -h) \cup (h, \infty)$ such that

$$|D^l u_0(x)| \le Ch^{-l} \quad \text{for } x \in [-h,h],\ l = 1,2,3,4. \tag{4.2}$$

We then obtain the equations satisfied by the error $e_u^n = u(t^n) - u_h^n$. To capture the two-step nature of the RKDG method under consideration, we follow [19] and introduce the function

$$w(x,t) = u(x,t) - k\, u_x(x,t) \tag{4.3}$$

and the corresponding error, namely, $e_w^n = w(t^n) - w_h^n$. Finally, we write, for $p = u$ and $p = w$,

$$e_p^n = \xi_p^n - \eta_p^n, \tag{4.4a}$$

$$\xi_p^n = P_-(p(t^n)) - p_h^n \qquad \text{(projection of the error } e_p^n\text{)}, \tag{4.4b}$$

$$\eta_p^n = P_-(p(t^n)) - p(t^n) \quad \text{(interpolation error)}. \tag{4.4c}$$

In addition to the projection P_-, we also have to introduce the similar projection P_+ given on I_j by

$$(P_+(v), 1)_j = (v, 1)_j \quad \text{and} \quad P_+(v)(x_{j-1/2}^+) = v(x_{j-1/2}^+).$$

The projections $P_\pm$ are strongly related to the bilinear form $H(\cdot,\cdot)$ defined by (2.1c), as we can see in the next result.

LEMMA 4.1. *We have, for any $w \in H_h^1(\mathbb{R})$ and any $v_h \in V_h$,*

$$H(w - P_-(w), v_h) = 0, \tag{4.5a}$$

$$H(v_h, w - P_+(w)) = 0. \tag{4.5b}$$

Proof. The identity (4.5a) follows from the definitions of H and P_-. By using integration by parts we can rewrite $H(p, q)$ as

$$H(p, q) = -\sum_j \{(p_x, q)_j + q(x_{j+1/2}^+)[p]_{j+1/2}\}.$$

The identity (4.5b) now follows from the above equation and the definition of P_+. ∎

The equations for the error are contained in the following result.

LEMMA 4.2. *We have, for any $v \in H_h^1(\mathbb{R})$,*

$$\sum_j (\xi_w^n, v)_j = \sum_j (\xi_u^n, v)_j + k\, H(\xi_u^n, v) + E_2(v) + E_3(v), \tag{4.6a}$$

$$\begin{aligned} \sum_j (\xi_u^{n+1}, v)_j = &\sum_j (\xi_u^n, v)_j + \frac{k}{2} H(\xi_w^n, v) + \frac{k}{2} H(\xi_u^n, v) \\ &+ E_1(P_+(v)) + \frac{1}{2} E_2(v) + \frac{1}{2} E_3(v) + E_4(v) + E_5(v), \end{aligned} \tag{4.6b}$$

where

$$E_1(v) = \frac{k^3}{6} \sum_j (u_{ttt}(\zeta^n), v)_j,$$

$$E_2(v) = \sum_j (\xi_w^n - \xi_u^n, v - P_+(v))_j,$$

$$E_3(v) = \sum_j (\eta_w^n - \eta_u^n, P_+(v))_j,$$

$$E_4(v) = \sum_j (\xi_u^{n+1} - (\xi_u^n + \xi_w^n)/2, v - P_+(v))_j,$$

$$E_5(v) = \sum_j (\eta_u^{n+1} - (\eta_u^n + \eta_w^n)/2, P_+(v))_j.$$

Here ζ^n is a function of x lying in the interval (t^n, t^{n+1}).

Proof. Let us begin by proving the identity (4.6a). For any function v in $H_h^1(\mathbb{R})$, we have, by the definition of ξ_p and η_p—(4.4)—

$$\begin{aligned}\sum_j (\xi_w^n, v)_j &= \sum_j \{(e_w^n, v)_j + (\eta_w^n, v)_j\} \\ &= \sum_j \{(e_w^n, P_+(v))_j + (e_w^n, v - P_+(v))_j + (\eta_w^n, v)_j\} \\ &= \sum_j \{(e_w^n, P_+(v))_j + (\xi_w^n, v - P_+(v))_j + (\eta_w^n, P_+ v)_j\}.\end{aligned}$$

To suitably rewrite the first term of the right-hand side, we notice that, by the definition of w—(4.3)—and since u is smooth, we have

$$\sum_j (w(t^n), v_h)_j = \sum_j (u(t^n), v_h)_j + k\, H(u(t^n), v_h)$$

for any $v_h \in V_h$. Hence, by subtracting the equation defining w_h^n—(2.1b)—we obtain

$$\sum_j (e_w^n, v_h)_j = \sum_j (e_u^n, v_h)_j + k\, H(e_u^n, v_h). \tag{4.7}$$

Now, by taking $v_h = P_+(v)$, we immediately get

$$\begin{aligned}\sum_j (e_w^n, P_+(v))_j &= \sum_j (e_u^n, P_+(v))_j + k\, H(e_u^n, P_+(v)) \\ &= \sum_j (e_u^n, P_+(v))_j + k\, H(\xi_u^n, v),\end{aligned}$$

since, by the properties (4.5a) and (4.5b), we have

$$H(e_u^n, P_+(v)) \;=\; H(P_-(e_u^n), P_+(v)) \;=\; H(\xi_u^n, P_+(v)) \;=\; H(\xi_u^n, v).$$

As a consequence, we get

$$\begin{aligned}\sum_j (\xi_w^n, v)_j &= \sum_j (e_u^n, P_+(v))_j + k\, H(\xi_u^n, v) \\ &\quad + \sum_j \{(\xi_w^n, v - P_+(v))_j + (\eta_w^n, P_+(v))_j\} \\ &= \sum_j (\xi_u^n, v)_j + k\, H(\xi_u^n, v) \\ &\quad + \sum_j \{(\xi_w^n - \xi_u^n, v - P_+(v))_j + (\eta_w^n - \eta_u^n, P_+(v))_j\} \\ &= \sum_j (\xi_u^n, v)_j + k\, H(\xi_u^n, v) + E_2(v) + E_3(v)\end{aligned}$$

by the definition of $E_2(v)$ and $E_3(v)$. This proves the identity (4.6a).

It remains to prove the identity (4.6b). For any function v in $H_h^1(\mathbb{R})$ we have

$$\begin{aligned}\sum_j (\xi_u^{n+1}, v)_j &= \sum_j \{(\xi_u^{n+1}, P_+(v))_j + (\xi_u^{n+1}, v - P_+(v))_j\} \\ &= \sum_j \{(e_u^{n+1}, P_+(v))_j + (\eta_u^{n+1}, P_+(v))_j + (\xi_u^{n+1}, v - P_+(v))_j\}\end{aligned}$$

by the definition of ξ_p and η_p—(4.4).

Next, we rewrite the first term of the right-hand side. By Taylor's theorem

$$u(x,t+k)=\frac{1}{2}u(x,t)+\frac{1}{2}w(x,t)-\frac{k}{2}w_x(x,t)+\frac{k^3}{6}u_{ttt}(x,\zeta),$$

where ζ depends on x and is $t\le\zeta\le t+k$. After a simple integration by parts, we have

$$\sum_j(u(t^{n+1}),v)_j=\sum_j\frac{1}{2}(u(t^n),v)_j+\frac{1}{2}(w(t^n),v)_j+\frac{k}{2}H(w(t^n),v)+E_1(v).$$

By subtracting the equation defining u_h^{n+1}—(2.1a)—we get for any $v_h\in V_h$

$$\sum_j(e_u^{n+1},v_h)_j=\sum_j\frac{1}{2}(e_u^n,v_h)_j+\frac{1}{2}(e_w^n,v_h)_j+\frac{k}{2}H(e_w^n,v_h)+E_1(v_h),$$

and, by using (4.7), we obtain

$$\sum_j(e_u^{n+1},v_h)_j=\sum_j(e_u^n,v_h)_j+\frac{k}{2}H(e_w^n,v_h)+\frac{k}{2}H(e_u^n,v_h)+E_1(v_h).$$

Finally, by taking $v_h=P_+(v)$ and using (4.5b), this equation becomes

$$\sum_j(e_u^{n+1},P_+(v))_j=\sum_j(e_u^n,P_+(v))_j+\frac{k}{2}H(\xi_w^n,v)_j+\frac{k}{2}H(\xi_u^n,v)+E_1(P_+(v)).$$

This implies that

$$\begin{aligned}\sum_j(\xi_u^{n+1},v)_j&=\sum_j(e_u^n,P_+(v))_j+\frac{k}{2}H(\xi_w^n,v)+\frac{k}{2}H(\xi_u^n,v)+E_1(P_+(v))\\&\quad+\sum_j\{(\eta_u^{n+1},P_+(v))_j+(\xi_u^{n+1},v-P_+(v))_j\}\\&=\sum_j(\xi_u^n,v)_j+\frac{k}{2}H(\xi_w^n,v)+\frac{k}{2}H(\xi_u^n,v)+E_1(P_+(v))\\&\quad+\sum_j\{(\eta_u^{n+1}-\eta_u^n,P_+(v))_j+(\xi_u^{n+1}-\xi_u^n,v-P_+(v))_j\}\\&=\sum_j(\xi_u^n,v)_j+\frac{k}{2}H(\xi_w^n,v)+\frac{k}{2}H(\xi_u^n,v)+E_1(P_+(v))\\&\quad+\frac{1}{2}E_2(v)+\frac{1}{2}E_3(v)+E_4(v)+E_5(v).\qquad\square\end{aligned}$$

4.2. Step 2: The weights. Theorem 2.1 will follow from estimates of quantities of the form

$$\|\phi(\cdot,t^n)(u(t^n)-u_h^n)\|_{L^2(\mathbb{R})},$$

where $\phi(x,t)$ is a suitably chosen weight function. Here we describe the weights with which we are going to work.

Since, as we stated in the introduction, we have different results on the left and on the right of the discontinuity, we consider two slightly different weight functions

ϕ_1 and ϕ_2. The weight ϕ_1 will be of order one in the region $x < t + x_1$ for some number $x_1 < 0$ and "small" in the region $x > t + x_1 + d_1$ for some $d_1 > 0$, whereas the weight ϕ_2 is of order one on the region $x > t + x_2$ for some number $x_2 > 0$ and small in the region $x < t + x_2 - d_2$ for some $d_2 > 0$. A very important property that will allow better results to the left of the discontinuity is that $\phi_1(x,t)$ can be chosen as a decreasing function in x.

We take the functions ϕ_i, for $i = 1, 2$, as solutions of

$$\begin{aligned} \phi_{i,t} + \phi_{i,x} &= 0 \qquad \text{in } R \times (0,T), \\ \phi_i(x,0) &= b_i(x) \quad \text{on } R \end{aligned}$$

for some initial conditions b_1 and b_2. We choose the initial conditions b_1 and b_2 so that ϕ_1 and ϕ_2 satisfy the following.

PROPOSITION 4.3. *We have*

$$c \le \phi_i(x,t) \le C \qquad \text{for } (x,t) \in \Omega_i(0), \tag{4.8a}$$

$$\phi_i(x,t) \le h^s \qquad \text{for } (x,t) \in \mathbb{R}^2 \backslash \Omega_i(d_i), \tag{4.8b}$$

$$(-1)^{i+1}\phi_{i,x}(x,t) < 0 \qquad \text{for all } (x,t), \tag{4.8c}$$

$$\left|\frac{D_x^{l+1}(\phi_i(x,t))}{(\phi_i(x,t))_x}\right| + \left|\frac{D_x^{l}(\phi_i(x,t))}{\phi_i(x,t)}\right| \le \frac{C}{(\tilde{K}_i \tilde{T}^{1-\gamma_i} h^{\gamma_i})^l} \qquad \text{for all } (x,t), l = 1,2,3, \tag{4.8d}$$

$$RO(S,\phi_i) + RO(S,(\phi_i)_x) \le C \qquad \text{for all squares } S \text{ with sides of length } \tilde{T}^{1-\gamma_i} h^{\gamma_i}, \tag{4.8e}$$

where

$$\begin{aligned} \Omega_1(d) &= \{(x,t) : x \le t + x_1 + d\}, \\ \Omega_2(d) &= \{(x,t) : x \ge t + x_2 - d\}, \\ d_i &= s \log(1/h) \tilde{K}_i \tilde{T}^{1-\gamma_i} h^{\gamma_i}, \end{aligned}$$

$RO(D,\chi) = \max_{r\in D} |\chi(r)| \,/\, \min_{r\in D} |\chi(r)|$ *for any domain* D, *and* c *and* C *are positive constants independent of* h, λ, *and* T. *Here* $\tilde{T} = \frac{T}{\lambda}$ *and* $\tilde{K}_i = \frac{K_i}{\lambda^{m_i}}$. *The parameters* K_i, γ_i, *and* m_i *satisfy* $K_i \ge 1$, $0 \le \gamma_i \le 1$, *and* $m_i \ge 0$ *for* $i = 1, 2$.

In the rest of this paper we assume that the CFL number satisfies $\lambda \le 1/3$. Therefore, often we will use the fact that $\frac{1}{\tilde{K}_i} \le \frac{1}{K_i} \le 1$. Also, since $\tilde{T}^{1-\gamma_i} h^{\gamma_i} = (\frac{T}{k})^{1-\gamma_i} h \ge h$, we see that $RO(S,\phi_i)$ and $RO(S,(\phi_i)_x)$ are bounded for squares S with sides of size h.

The construction of b_1 and b_2 is very similar to the construction of weight functions used in [16]. We include it in the appendix for completeness.

4.3. Step 3: The error in one time step. Next, we find how the weighted error changes in a single time step. This information is captured in a key identity contained in the following result.

LEMMA 4.4. *Let* ϕ *be any solution of the equation* $\phi_t + \phi_x = 0$. *Then we have*

$$\|\phi(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} + \mathbb{J}_h = \|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \frac{k}{2}\Theta((\phi^2)_x) + \Psi_h(\phi) + E_h, \tag{4.9}$$

where

$$\begin{aligned}\mathbb{J}_h :=& \frac{k}{2}\sum_j \{[\phi(t^n)\xi_u^n]^2_{j+1/2} + [\phi(t^{n+1})\xi_w^n]^2_{j+1/2}\}\\ \Theta(v) :=& \sum_j \Theta_j(v), \quad \Theta_j(v) := (\xi_w^n - \xi_u^n, v(t^n)(\xi_w^n - \xi_u^n))_j,\\ \Psi_h(\phi) :=& \|\phi(t^{n+1})(\xi_u^{n+1} - \xi_w^n)\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

Moreover,

$$\begin{aligned}E_h :=& 2\,E_1(P_+(\phi^2(t^{n+1})\xi_w^n)) + 2\,E_4(\phi^2(t^{n+1})\xi_w^n) + 2\,E_5(\phi^2(t^{n+1})\xi_w^n)\\ &+ E_2(\phi^2(t^n)\xi_u^n) + E_3(\phi^2(t^n)\xi_u^n) - \frac{k^2}{2}\sum_j (\xi_w^n - \xi_u^n, (\phi^2(t^n))_{xx}\xi_w^n)_j\\ &+ S_1 + S_2,\end{aligned}$$

where

$$S_1 = -\frac{k^3}{6}\sum_j (\xi_u^n, (\phi^2)_{xxx}(\theta_1^n)\xi_w^n)_j \quad \textit{and} \quad S_2 = \frac{k^3}{4}\sum_j (\xi_w^n, (\phi^2)_{xxx}(\theta_2^n)\xi_w^n)_j.$$

Here θ_i^n, $i = 1, 2$, depend on x and $t^n \le \theta_i^n \le t^{n+1}$.

Before proving this result, let us briefly discuss some of its salient features. Notice the following:

• This result is completely independent of the fact that the approximate solution is piecewise linear in space. It takes into account only the nature of the Runge–Kutta time-stepping method we are considering.

• The term $\mathbb{J}_h$ containing the jumps across interelement boundaries captures the dissipative nature of the DG-space discretization. In the analysis, it will allow us to control the terms of the right-hand side.

• The term $\Theta((\phi^2)_x)$ will allow us to distinguish between the behavior of the error to the right and that to the left of the discontinuity. Since $\Theta((\phi_1^2)_x) \le 0$, this term enhances the damping properties of the method to the left of the discontinuity. This property does not hold for $\Theta((\phi_2^2)_x)$, which will have to be controlled by the jumps in $\mathbb{J}_h$. This is the technicality that captures the fact that the approximation properties to the left and to the right of the discontinuity of the exact solution are very different. This results in a region $\mathcal{R}_T$ whose size is significantly *smaller* to the left of the discontinuity than to its right.

• If the initial condition U_0 were smooth, we could then take $\phi \equiv 1$, and the above result would be the first step in the L^2-error analysis; see [19]. In such a case, the estimates of the terms of the right-hand side play a crucial role, with the exception of the term $\Theta((\phi^2)_x)$, which is identically equal to zero.

• Note that this lemma also contains the first step of the L^2-stability analysis of the RKDG method under consideration, which we obtain by setting $\phi \equiv 1$ and $u = 0$. In this case, (4.9) becomes

$$||u_h^{n+1}||^2_{L^2(\mathbb{R})} + \frac{k}{2}\sum_j \{[u_h^n]_j^2 + [w_h^n]_j^2\} = ||u_h^n||^2_{L^2(\mathbb{R})} + ||u_h^{n+1} - w_h^n||^2_{L^2(\mathbb{R})}. \tag{4.10}$$

The second term of the left-hand side reflects the dissipative nature of the DG-space discretization of the method, whereas the second term of the right-hand side captures the *antidissipative* nature typical of explicit schemes. The condition that the dissipative term dominates the antidissipative is nothing but the CFL condition. As we are going to see, a sharp estimate of the term $||u_h^{n+1} - w_h^n||_{L^2(\mathbb{R})}$ allows us to see that the method is L^2-stable, provided $\lambda \leq 1/3$.

Let us now prove Lemma 4.4.

Proof. We begin by considering the trivial identity

$$\begin{aligned}\|\phi(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} =& \|\phi(t^{n+1})(\xi_u^{n+1} - \xi_w^n)\|^2_{L^2(\mathbb{R})} \\ &+ 2\sum_j (\xi_u^{n+1}, \phi^2(t^{n+1})\xi_w^n)_j - \|\phi(t^{n+1})\xi_w^n\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

If we subtract (4.6a) from two times (4.6b), we get

$$\begin{aligned}2\sum_j (\xi_u^{n+1}, v)_j = &\sum_j \{(\xi_w^n, v)_j + (\xi_u^n, v)_j\} + kH(\xi_w^n, v) \\ &+ 2E_1(P_+(v)) + 2E_4(v) + 2E_5(v).\end{aligned}$$

By taking $v = \phi^2(t^{n+1})\, \xi_w^n$ in this equation and $v = \phi^2(t^n)\, \xi_u^n$ in (4.6a), we obtain

$$\begin{aligned}2\sum_j (\xi_u^{n+1}, \phi^2(t^{n+1})\xi_w^n)_j = &\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \|\phi(t^{n+1})\xi_w^n\|^2_{L^2(\mathbb{R})} \\ &+ kH(\xi_u^n, \phi^2(t^n)\xi_u^n) + kH(\xi_w^n, \phi^2(t^{n+1})\xi_w^n) \\ &+ 2E_1(P_+(\phi^2(t^{n+1})\xi_w^n)) + 2E_4(\phi^2(t^{n+1})\xi_w^n) \\ &+ 2E_5(\phi^2(t^{n+1})\xi_w^n) + E_2(\phi^2(t^n)\xi_u^n) \\ &+ E_3(\phi^2(t^n)\xi_u^n) + \sum_j (\xi_w^n, (\phi^2(t^{n+1}) - \phi^2(t^n))\xi_u^n)_j,\end{aligned}$$

and hence

$$\begin{aligned}\|\phi(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} = &\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \|\phi(t^{n+1})(\xi_u^{n+1} - \xi_w^n)\|^2_{L^2(\mathbb{R})} \\ &+ kH(\xi_u^n, \phi^2(t^n)\xi_u^n) + kH(\xi_w^n, \phi^2(t^{n+1})\xi_w^n) \\ &+ 2E_1(P_+(\phi^2(t^{n+1})\xi_w^n)) + 2E_4(\phi^2(t^{n+1})\xi_w^n) \\ &+ 2E_5(\phi^2(t^{n+1})\xi_w^n) + E_2(\phi^2(t^n)\xi_u^n) \\ &+ E_3(\phi^2(t^n)\xi_u^n) + \sum_j (\xi_u^n, (\phi^2(t^{n+1}) - \phi^2(t^n))\xi_w^n)_j.\end{aligned}$$

Since, for any $v \in H_h^1(\mathbb{R})$,

$$\begin{aligned}H(v, \phi^2(t)v) =& H(\phi(t)v, \phi(t)v) + \frac{1}{2}\sum_j (v, (\phi^2(t))_x v)_j \\ =& -\frac{1}{2}\sum_j [\phi(t)v]^2_{j+1/2} + \frac{1}{2}\sum_j (v, (\phi^2(t))_x v)_j,\end{aligned}$$

we get

$$\begin{aligned}\|\phi(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} + \mathbb{J}_h = \|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \Psi_h(\phi)\\ +\frac{k}{2}\sum_j\{(\xi_u^n,(\phi^2(t^n))_x\xi_u^n)_j + (\xi_w^n,(\phi^2(t^{n+1}))_x\xi_w^n)_j\}\\ +2E_1(P_+(\phi^2(t^{n+1})\xi_w^n)) + 2E_4(\phi^2(t^{n+1})\xi_w^n)\\ +2E_5(\phi^2(t^{n+1})\xi_w^n) + E_2(\phi^2(t^n)\xi_u^n)\\ +E_3(\phi^2(t^n)\xi_u^n) + \sum_j(\xi_u^n,(\phi^2(t^{n+1})-\phi^2(t^n))\xi_w^n)_j.\end{aligned} \tag{4.11}$$

By using Taylor's expansion, we see that

$$\begin{aligned}\sum_j(\xi_u^n,(\phi^2(t^{n+1})-\phi^2(t^n))\xi_w^n)_j = -k\sum_j(\xi_u^n,(\phi^2(t^n))_x\xi_w^n)_j\\ +\frac{k^2}{2}\sum_j(\xi_u^n,(\phi^2(t^n))_{xx}\xi_w^n)_j + S_1.\end{aligned}$$

Here we used that $(\phi^2)_t = -(\phi^2)_x$. Similarly,

$$\begin{aligned}\frac{k}{2}\sum_j(\xi_w^n,(\phi^2(t^{n+1}))_x\xi_w^n)_j = \frac{k}{2}\sum_j(\xi_w^n,(\phi^2(t^n))_x\xi_w^n)_j\\ -\frac{k^2}{2}\sum_j(\xi_w^n,(\phi^2(t^n))_{xx}\xi_w^n)_j + S_2.\end{aligned}$$

Therefore,

$$\begin{aligned}&\frac{k}{2}\sum_j\{(\xi_u^n,(\phi^2(t^n))_x\xi_u^n)_j + (\xi_w^n,(\phi^2(t^{n+1}))_x\xi_w^n)_j\}\\ &\quad+\sum_j(\xi_u^n,(\phi^2(t^{n+1})-\phi^2(t^n))\xi_w^n)_j\\ &=\frac{k}{2}\sum_j\{(\xi_u^n,(\phi^2(t^n))_x\xi_u^n)_j + (\xi_w^n,(\phi^2(t^n))_x\xi_w^n)_j\}\\ &\quad-k\sum_j(\xi_u^n,(\phi^2(t^n))_x\xi_w^n)_j - \frac{k^2}{2}\sum_j(\xi_w^n-\xi_u^n,(\phi^2(t^n))_{xx}\xi_w^n) + S_1 + S_2\\ &=\frac{k}{2}\Theta((\phi^2)_x) - \frac{k^2}{2}\sum_j(\xi_w^n-\xi_u^n,(\phi^2(t^n))_{xx}\xi_w^n) + S_1 + S_2.\end{aligned}$$

The result follows after inserting the above identity into (4.11). This completes the proof. ∎

4.4. Step 4: Bound for Ψ_h. In order to bound Ψ_h we first need a bound for $||\xi_u^{n+1}-\xi_w^n||_{I_j}$ for each interval I_j. By exploiting the fact that $\xi_u^{n+1}-\xi_w^n$ is linear on each element, we express $\xi_u^{n+1}-\xi_w^n$ in terms of its mean and derivative on each element. More precisely, if $v\in V_h$, then for $x\in I_j$ we have

$$v(x) = \bar{v}(x_j) + v_x(x_j)(x-x_j), \tag{4.12}$$

where the average of v on I_j is $\bar{v}(x_j) = \frac{1}{h}(v,1)_j$. The representation we are seeking is contained in the following lemma, which is proved in the appendix. For the rest of

this paper θ^n will denote a number satisfying $t^n \le \theta^n \le t^{n+1}$ which depends on x; the values of θ^n may be different in separate occurrences. It will appear in different places when we use Taylor's theorem.

LEMMA 4.5. *For $x \in I_j$, we have*

$$(\xi_u^{n+1} - \xi_w^n)(x) = \frac{-3k^2}{h^2}[\xi_u^n]_{j-1/2} - \frac{k}{2h}[\xi_w^n - \xi_u^n]_{j-1/2} + \frac{k^3}{6h}R_{3,j} - \frac{k}{2h^3}R_{1,j}$$
$$+ \left(\frac{3k}{h^2}[\xi_w^n - \xi_u^n]_{j-1/2} + \frac{k^3}{6h^3}R_{4,j} - \frac{6}{h^3}R_{1,j} + \frac{6}{h^3}R_{2,j}\right)(x - x_j) \tag{4.13a}$$

and

$$(\xi_w^n - \xi_u^n)(x) = -k(\xi_u^n)_x(x_j) - \frac{k}{h}[\xi_u^n]_{j-1/2} + \left(6\frac{k}{h^2}[\xi_u^n]_{j-1/2} + \frac{12}{h^3}R_{1,j}\right)(x - x_j), \tag{4.13b}$$

where

$$R_{1,j} = \int_{I_j} (\eta_w^n - \eta_u^n)(x - x_j)dx, \quad R_{2,j} = \int_{I_j} (\eta_u^{n+1} - (\eta_w^n + \eta_u^n)/2)(x - x_j)dx,$$
$$R_{3,j} = \int_{I_j} u_{ttt}(\theta^n)dx, \qquad R_{4,j} = \int_{I_j} u_{ttt}(\theta^n)(x - x_j)dx.$$

Now we calculate the term $\|(\xi_u^{n+1} - \xi_w^n)\|^2_{L^2(I_j)}$. We are going to express it in terms of the vector $[\boldsymbol{\xi}^n]_{j-1/2} := ([\xi_u^n]_{j-1/2}, [\xi_w^n]_{j-1/2})$.

LEMMA 4.6. *If $\lambda = \frac{k}{h}$, then*

$$\|\xi_u^{n+1} - \xi_w^n\|^2_{L^2(I_j)} = k\,[\boldsymbol{\xi}^n]_{j-1/2}\mathbb{A}[\boldsymbol{\xi}^n]^t_{j-1/2} + Y_j, \tag{4.14}$$

where

$$\mathbb{A} := \begin{pmatrix} Q(\lambda) & \frac{1}{2}Z(\lambda) \\ \frac{1}{2}Z(\lambda) & \lambda \end{pmatrix}, \quad Q(\lambda) = 9\lambda^3 - 3\lambda^2 + \lambda, \quad Z(\lambda) = 3\lambda^2 - 2\lambda,$$

and

$$Y_j = h\left(\frac{k^3}{6h}R_{3,j} - \frac{k}{2h^3}R_{1,j}\right)^2 + \frac{h^3}{12}\left(\frac{k^3}{6h^3}R_{4,j} - \frac{6}{h^3}R_{1,j} + \frac{6}{h^3}R_{2,j}\right)^2$$
$$+ 2h\left(\frac{-3k^2}{h^2}[\xi_u^n]_{j-1/2} - \frac{k}{2h}[\xi_w^n - \xi_u^n]_{j-1/2}\right)\left(\frac{k^3}{6h}R_{3,j} - \frac{k}{2h^3}R_{1,j}\right)$$
$$+ 2\frac{h^3}{12}\left(\frac{3k}{h^2}[\xi_w^n - \xi_u^n]_{j-1/2}\right)\left(\frac{k^3}{6h^3}R_{4,j} - \frac{6}{h^3}R_{1,j} + \frac{6}{h^3}R_{2,j}\right).$$

Proof. By using (4.13a) and the fact that $\int_{I_j}(x - x_j)^2 = \frac{h^3}{12}$ and $\int_{I_j}(x - x_j)dx = 0$, we get

$$\|\xi_u^{n+1} - \xi_w^n\|^2_{L^2(I_j)} = h\,(\overline{(\xi_u^{n+1} - \xi_w^n)}(x_j))^2 + \frac{h^3}{12}((\xi_u^{n+1} - \xi_w^n)_x(x_j))^2$$
$$= h\left(\frac{-3k^2}{h^2}[\xi_u^n]_{j-1/2} - \frac{k}{2h}[\xi_w^n - \xi_u^n]_{j-1/2} + \frac{k^3}{6h}R_{3,j} - \frac{k}{2h^3}R_{1,j}\right)^2$$
$$+ \frac{h^3}{12}\left(\frac{3k}{h^2}[\xi_w^n - \xi_u^n]_{j-1/2} + \frac{k^3}{6h^3}R_{4,j} - \frac{6}{h^3}R_{1,j} + \frac{6}{h^3}R_{2,j}\right)^2,$$

and the result follows after a few simple algebraic manipulations. ∎

Note that, by simply setting $\phi = 1$ and $u = 0$, we obtain an identity which is used for the L^2-stability analysis, namely,

$$\|u_h^{n+1} - w_h^n\|^2_{L^2(I_j)} = k \sum_j [\boldsymbol{u}^n]_{j-1/2} \, \mathbb{A} [\boldsymbol{u}^n]^t_{j-1/2},$$

where $[\boldsymbol{u}^n]_{j-1/2} := ([u_h^n]_{j-1/2}, [w_h^n]_{j-1/2})$. Indeed, by inserting this expression in the identity (4.10), we get

$$\|u_h^{n+1}\|^2_{L^2(\mathbb{R})} + k \sum_j [\boldsymbol{u}^n]_{j-1/2} \left(\frac{1}{2} \mathbb{I} - \mathbb{A} \right) [\boldsymbol{u}^n]^t_{j-1/2} = \| \, u_h^n \, \|^2_{L^2(\mathbb{R})},$$

where $\mathbb{I}$ is the 2×2 identity matrix. Therefore, the method is L^2-stable if the matrix $\frac{1}{2}\mathbb{I} - \mathbb{A}$ is positive semidefinite. This occurs precisely for $\lambda \leq 1/3$.

Note also that, although we do not need to take $\lambda < 1/3$ to achieve L^2-stability, we need to take this choice in our error analysis. As we are going to see, taking $\lambda \leq 1/3 - \epsilon$, with $\epsilon > 0$, ensures that the matrix $\frac{1}{2}\mathbb{I} - \mathbb{A}$ is positive definite, and, as a consequence, the terms involving the jumps of ξ_u^n and ξ_w^n in the right-hand side of the identity (4.9) of Lemma 4.4 can be controlled by the term $\mathbb{J}_h$.

We now state and prove the bound for $\Psi_h(\phi_i)$. We will need the following notation:

$$[\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2} := ([\phi(t^n)\, \xi_u^n]_{j-1/2}, \, [\phi(t^{n+1})\, \xi_w^n]_{j-1/2}).$$

LEMMA 4.7. *We have*

$$\begin{aligned}
\Psi_h(\phi_i) \leq k \sum_j & [\boldsymbol{\phi}_i \boldsymbol{\xi}^n]_{j-1/2} \, \mathbb{B}_i [\boldsymbol{\phi}_i \boldsymbol{\xi}^n]^t_{j-1/2} \\
& + C \, K_i \|\phi_i(t^n)(\eta_w^n - \eta_u^n)\|^2_{L^2(I_j)} \\
& + C \, K_i \|\phi_i(t^n)(\eta_u^{n+1} - (\eta_u^n + \eta_w^n)/2)\|^2_{L^2(I_j)} \\
& + C \, K_i k^6 \|\phi_i(t^n) u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})},
\end{aligned}$$

where

$$\mathbb{B}_i = \mathbb{A} + \frac{C}{K_i} \, \mathbb{I}.$$

Proof. To simplify the notation, we drop the subindex i. We have

$$\Psi_h(\phi) = T_1 + T_2,$$

where

$$\begin{aligned}
T_1 &= \sum_j \phi^2(x_{j-1/2}, t^{n+1}) \|(\xi_u^{n+1} - \xi_w^n)\|^2_{L^2(I_j)}, \\
T_2 &= \sum_j \int_{I_j} (\phi^2(x, t^{n+1}) - \phi^2(x_{j-1/2}, t^{n+1}))(\xi_u^{n+1} - \xi_w^n)^2(x) \, dx.
\end{aligned}$$

We first estimate the term T_1. We multiply (4.14) by $\phi^2(x_{j-1/2}, t^{n+1})$, and we bound the terms of the resulting right-hand side separately. Since

$$\begin{aligned}
\phi^2(x_{j-1/2}, t^{n+1}) &= \phi^2(x_{j-1/2}, t^n) + k(\phi^2)_t(x_{j-1/2}, \theta^n), \\
\phi(x_{j-1/2}, t^{n+1}) &= \phi(x_{j-1/2}, t^n) + k\phi_t(x_{j-1/2}, \theta^n),
\end{aligned}$$

by using inequalities (4.8d) and (4.8e), we have

$$k\phi^2(x_{j-1/2},t^{n+1})[\boldsymbol{\xi}^n]_{j-1/2}\mathbb{A}[\boldsymbol{\xi}^n]^t_{j-1/2} \le k[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{A}[\boldsymbol{\phi\xi}^n]^t_{j-1/2} + k\left(\frac{Ch^{1-\gamma}}{\tilde{T}^{1-\gamma}\tilde{K}}\right)[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}.$$

Here we used the fact that the entries of $\mathbb{A}$ are bounded for $\lambda \in [0, 1/3]$.

By using (4.8e) and the Cauchy–Schwarz inequality, we get, from the definition of $R_{l,j}$ for $l = 1, \cdots, 4$,

$$\begin{aligned}&\phi(x_{j-1/2},t^n)\left(\frac{k^6}{h}|R_{3,j}|^2 + \frac{1}{h^3}|R_{1,j}|^2 + \frac{k^6}{h^3}|R_{4,j}|^2 + \frac{1}{h^3}|R_{2,j}|^2\right)\\ &\le C(\|\phi(t^n)(\eta^n_w - \eta^n_u)\|^2_{L^2(I_j)} + \|\phi(t^n)(\eta^{n+1}_u - (\eta^n_u + \eta^n_w)/2)\|^2_{L^2(I_j)})\\ &\quad + Ck^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(I_j)}.\end{aligned}$$

Therefore, if we again apply (4.8e), multiply and divide each term of Y_j by $K^{1/2}$, and apply Young's inequality, we obtain

$$\begin{aligned}|\phi^2(x_{j-1/2},t^{n+1})Y_j| \le{}& \frac{1}{K}k[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}\\ &+ C\,K\|\phi(t^n)(\eta^n_w - \eta^n_u)\|^2_{L^2(I_j)}\\ &+ C\,K\|\phi(t^n)(\eta^{n+1}_u - (\eta^n_u + \eta^n_w)/2)\|^2_{L^2(I_j)}\\ &+ C\,Kk^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(I_j)}.\end{aligned}$$

Hence,

$$\begin{aligned}T_1 \le{}& k\sum_j[\boldsymbol{\phi\xi}^n]_{j-1/2}\left(\mathbb{A} + \left(\left(\frac{h}{\tilde{T}}\right)^{1-\gamma}\frac{C}{\tilde{K}} + \frac{C}{K}\right)\mathbb{I}\right)[\boldsymbol{\phi\xi}^n]^t_{j-1/2}\\ &+ C\,K\|\phi(t^n)(\eta^n_w - \eta^n_u)\|^2_{L^2(I_j)}\\ &+ C\,K\|\phi(t^n)(\eta^{n+1}_u - (\eta^n_u + \eta^n_w)/2)\|^2_{L^2(I_j)} + C\,K\,k^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

To bound T_2 we see from (4.14) that

$$T_2 \le \sum_j \|\phi^2(x_{j-1/2},t^{n+1}) - \phi^2(t^{n+1})\|_{L^\infty(I_j)}(k[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{A}[\boldsymbol{\phi\xi}^n]^t_{j-1/2} + Y_j).$$

By using the inequality

$$\|\phi^2(x_{j-1/2},t^{n+1}) - \phi^2(t^{n+1})\|_{L^\infty(I_j)} \le \frac{Ch^{1-\gamma}}{\tilde{T}^{1-\gamma}\tilde{K}}\|\phi^2(t^{n+1})\|_{L^\infty(I_j)},$$

the inequality (4.8e), and Young's inequality, we obtain

$$\begin{aligned}&\|\phi^2(x_{j-1/2},t^{n+1}) - \phi^2(t^{n+1})\|_{L^\infty(I_j)}(k[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{A}[\boldsymbol{\phi\xi}^n]^t_{j-1/2})\\ &\le \frac{Ch^{1-\gamma}}{\tilde{T}^{1-\gamma}\tilde{K}}k[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}.\end{aligned}$$

By the triangle inequality and (4.8e) we have

$$\|\phi^2(x_{j-1/2},t^{n+1}) - \phi^2(t^{n+1})\|_{L^\infty(I_j)}|Y_j| \le C|\phi^2(x_{j-1/2},t^{n+1})Y_j|.$$

Therefore,

$$T_2 \le k\sum_j [\boldsymbol{\phi\xi}^n]_{j-1/2}\left(\left(\frac{h}{\bar{\bar{T}}}\right)^{1-\gamma}\frac{C}{\bar{\bar{K}}}+\frac{C}{K}\right)\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}$$
$$+C\,K\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(I_j)}$$
$$+C\,K\|\phi(t^n)(\eta_u^{n+1}-(\eta_u^n+\eta_w^n)/2)\|^2_{L^2(I_j)}+M(\epsilon)k^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})}.$$

Combining the estimates of T_1 and T_2 and using $\frac{h}{\bar{\bar{T}}}\le 1$, $\gamma\le 1$, and $\frac{1}{\bar{\bar{K}}}\le\frac{1}{K}$ concludes the proof. ∎

4.5. Step 6: Estimates of E_h. We state two slightly different estimates for $E_h(\phi_i)$. One would be applied with the weight ϕ_1 and the other for ϕ_2. To simplify notation, for the rest of this section we let $\phi=\phi_i$, $K=K_i$, $m=m_i$, and $\gamma=\gamma_i$ for $i=1$ or $i=2$.

LEMMA 4.8. *If K is sufficiently large, then*

$$E_h(\phi)\le(1+\lambda^{m-2})\frac{Ck}{K}\sum_j[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}+\frac{k}{4}\Theta(|(\phi^2)_x|)$$
$$+\left\{\frac{k}{4T}+\left(1+\left(\frac{h}{\bar{\bar{T}}}\right)^{(3-4\gamma)}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}\right)\frac{C\,k}{K\,T}\right\}||\phi(t^n)\xi_u^n||^2_{L^2(\mathbb{R})}$$
$$+\left(1+\left(\frac{h}{\bar{\bar{T}}}\right)^{2(3/2-2\gamma)}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}\right)\frac{C\,T}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||^2_{L^2(\mathbb{R})}$$
$$+\frac{C\,T}{k}(||\phi(t^n)(\eta_u^{n+1}-\eta_u^n)||^2_{L^2(\mathbb{R})}+k^6||\phi(t^n)u_{ttt}(\theta^n)||^2_{L^2(\mathbb{R})})$$

and

$$E_h(\phi)\le\frac{Ck}{K}\sum_j[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]^t_{j-1/2}+\frac{k}{4}\Theta(|(\phi^2)_x|)$$
$$+\left\{\frac{k}{4T}+\left(1+\left(\frac{h}{\bar{\bar{T}}}\right)^{2(3/2-2\gamma)}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}+\left(\frac{h}{\bar{\bar{T}}}\right)^{1-2\gamma}\right)\frac{C\,k}{K\,T}\right\}||\phi(t^n)\xi_u^n||^2_{L^2(\mathbb{R})}$$
$$+\left(1+\left(\frac{h}{\bar{\bar{T}}}\right)^{2(3/2-2\gamma)}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}+\left(\frac{h}{\bar{\bar{T}}}\right)^{1-2\gamma}\right)\frac{C\,T}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||^2_{L^2(\mathbb{R})}$$
$$+\frac{C\,T}{k}(||\phi(t^n)(\eta_u^{n+1}-\eta_u^n)||^2_{L^2(\mathbb{R})}+k^6||\phi(t^n)u_{ttt}(\theta^n)||^2_{L^2(\mathbb{R})}).$$

The proof of this lemma is contained in the appendix. Here we would like to point out that the main tool in proving this result is superapproximation. The superapproximation result involving weights are similar to the ones used in [16, 13]. For the sake of completeness we include the proof of the following superapproximation lemma in the appendix.

LEMMA 4.9. *If $P = P_-$ or $P = P_+$ and $l = 0, 1, 2$, then there exists $C > 0$ independent of h such that for all $v \in V_h$ the following estimates hold:*

$$\|\phi^{-1}(t)(\phi^2(t)v - P(\phi^2(t)v))\|_{L^2(I_j)} + h\|\phi^{-1}(t)(\phi^2(t)v - P(\phi^2(t)v))_x\|_{L^2(I_j)}$$
$$\leq \frac{Ch^{2-2\gamma}}{\tilde{T}^{2(1-\gamma)}\tilde{K}^2}\|\phi(t)v\|_{L^2(I_j)}$$

(4.15a)
$$+ \frac{Ch^{2-\gamma/2}}{\tilde{T}^{(1-\gamma)/2}\tilde{K}^{1/2}}\|(|\phi(t)\phi_x(t)|)^{1/2}v_x\|_{L^2(I_j)}, \|\phi^{-1}(t)(D_x^l(\phi^2(t))v$$
$$- P(D_x^l(\phi^2(t))v))\|_{L^2(I_j)} + h\|\phi^{-1}(t)(D_x^l(\phi^2(t))v - P(D_x^l(\phi^2(t))v))_x\|_{L^2(I_j)}$$

(4.15b)
$$\leq \left(\frac{Ch^{2-(l+2)\gamma}}{\tilde{T}^{(1-\gamma)(l+2)}\tilde{K}^{2+l}} + \frac{Ch^{1-(l+1)\gamma}}{\tilde{T}^{(1-\gamma)(l+1)}\tilde{K}^{l+1}}\right)\|\phi(t)v\|_{L^2(I_j)}.$$

Let us illustrate how we can use Lemma 4.9 to prove Lemma 4.8 by showing how we can bound one of the terms appearing in the definition of E_h.

LEMMA 4.10. *Let $t^n \leq t \leq t^{n+1}$ and $v_h \in V_h$, and then for $l = 0, 1, 2$,*

$$h^l|E_2(D_x^l(\phi^2(t))v_h)| + h^l|E_4(D_x^l(\phi^2(t))v_h)| \leq \frac{C\,k}{K^{l+1}}\sum_j [\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2}^t$$
$$+ \left(1 + \left(\frac{h}{\tilde{T}}\right)^{2(l+1/2-(l+1)\gamma)} + \left(\frac{h}{\tilde{T}}\right)^{2(l+3/2-(l+2)\gamma)}\right)\frac{C\,k}{K^{l+1}\,T}\|\phi(t^n)v_h\|_{L^2(\mathbb{R})}^2$$

$$+ \frac{CT}{k}(\|\phi(t^n)(\eta_w^n - \eta_u^n)\|_{L^2(\mathbb{R})}^2 + \|\phi(t^n)(\eta_u^{n+1} - \eta_u^n)\|_{L^2(\mathbb{R})}^2 + k^6\|u_{ttt}(\theta^n)\|_{L^2(\mathbb{R})}^2). \tag{4.16}$$

If we take $l = 0$, $v_h = \xi_u^n$, and $t = t^n$, then we get the E_2 term appearing in the definition of E_h.

Proof. By using (4.13b) and the properties of P_+ we get

$$h^l|E_2(D_x^l(\phi^2(t))v_h)| = h^l\left|\sum_j(\xi_w^n - \xi_u^n, D_x^l(\phi^2(t))v_h - P_+(D_x^l(\phi^2(t))v_h))_j\right|$$
$$= h^l\left|\sum_j\left(\frac{6k}{h^2}[\xi_u^n]_{j-1/2} + \frac{12}{h^3}R_{1,j}\right)\right.$$
$$\left.\times\,(x - x_j, D_x^l(\phi^2(t))v_h - P_+(D_x^l(\phi^2(t))v_h))_j\right|.$$

By multiplying and dividing the last equation by $\phi(t^n, x_{j-1/2})$ and using (4.8e), we get

$$h^l|E_2(D_x^l(\phi^2(t))v_h)| \leq h^{l+3/2}\sum_j\left(\frac{6k}{h^2}|[\phi(t^n)\xi_u^n]_{j-1/2}| + \frac{12}{h^3}|R_{1,j}\phi(t^n, x_{j-/2})|\right)$$
$$\times\,||\phi^{-1}(t)(D_x^l(\phi^2(t))v_h - P_+(D_x^l(\phi^2(t))v_h))||_{L^2(I_j)}, \tag{4.17}$$

where we used the fact that $||x-x_j||_{L^2(I_j)} \le Ch^{3/2}$. If we use (4.15b), we see that

$$\begin{aligned}
&kh^{l-1/2}\sum_j |[\phi(t^n)\xi_u^n]_{j-1/2}|\ ||\phi^{-1}(t)(D_x^l(\phi^2(t))v_h - P_+(D_x^l(\phi^2(t))v_h))||_{L^2(I_j)}\\
&\le \left(\frac{C}{K^{l+1}}+\frac{C}{K^{l+2}}\right)k\sum_j [\phi(t^n)\xi_u^n]_{j-1/2}^2\\
&\left(\left(\frac{h}{\bar{\bar{T}}}\right)^{2(l+1/2-(l+1)\gamma)}\frac{C}{K^{l+1}}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2(l+3/2-(l+2)\gamma)}\frac{C}{K^{l+2}}\right)\frac{k}{T}\|\phi(t^n)v_h\|_{L^2(\mathbb{R})}^2. \qquad (4.18)
\end{aligned}$$

By the Cauchy–Schwarz inequality we get $|R_{1,j}| \le Ch^{3/2}\|\eta_w^n - \eta_u^n\|_{L^2(I_j)}$. Hence,

$$\begin{aligned}
&h^{l-3/2}\sum_j |R_{1,j}\phi(t^n,x_{j-1/2})|\ ||\phi^{-1}(t)(D_x^l(\phi^2(t))v_h - P_+(D_x^l(\phi^2(t))v_h))||_{L^2(I_j)}\\
&\le \left(\frac{C}{K^{2(l+1)}}+\frac{C}{K^{2(l+2)}}\right)\frac{k}{T}\|\phi(t^n)v_h\|_{L^2(\mathbb{R})}^2\\
&\quad+\left(\left(\frac{h}{\bar{\bar{T}}}\right)^{2(1-\gamma)(l+1)}+\left(\frac{h}{\bar{\bar{T}}}\right)^{2(1-\gamma)(l+2)}\right)\frac{CT}{k}\|\eta_w^n-\eta_u^n\|_{L^2(I_j)}^2. \qquad (4.19)
\end{aligned}$$

Therefore, if we plug (4.18) and (4.19) into (4.17) and use $\frac{h}{\bar{\bar{T}}} \le 1$, $\gamma \le 1$, and $K \ge 1$, we can bound $h^l|E_2(D_x^l(\phi^2(t))v_h)|$ by the right-hand side of (4.16). In a similar fashion we can bound $h^l|E_4(D_x^l(\phi^2(t))v_h)|$ to conclude the proof. ∎

4.6. Step 7: Estimates for $\Theta((\phi^2)_x)$ and the final estimates for the error in one time step.

4.6.1. Case 1: The weight ϕ_1. In this case, the only estimate we need for $\Theta((\phi_1^2)_x)$ is simply

$$\Theta((\phi_1^2)_x) < 0, \qquad (4.20)$$

which follows from (4.8c). By collecting the estimates for Ψ_h and E_h and $\Theta((\phi_1^2)_x)$, we can give the right bound for the weighted ϕ_1 error produced after one time step.

THEOREM 4.11. *Let $0 < \epsilon < \frac{1}{3}$, and suppose that $\lambda \le 1/3 - \epsilon$. If $\gamma_1 = 2/3$, $m_1 = 2$, and*

$$\frac{1}{K_1} = c\,\epsilon \qquad (4.21)$$

for a sufficiently small fixed constant $c > 0$, then

$$\begin{aligned}
\|\phi_1(t^{n+1})\xi_u^{n+1}\|_{L^2(\mathbb{R})}^2 \le{}& \left(1+\frac{k}{T}\right)\|\phi_1(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)\|\phi_1(t^n)(\eta_u^{n+1}-\eta_u^n)\|_{L^2(\mathbb{R})}^2\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)\|\phi_1(t^n)(\eta_w^n-\eta_u^n)\|_{L^2(\mathbb{R})}^2\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)k^6\,\|\phi_1(t^n)u_{ttt}(\theta^n)\|_{L^2(\mathbb{R})}^2.
\end{aligned}$$

Proof. To simplify notation we let $\phi = \phi_1$, $\gamma = \gamma_1$, $m_1 = m$, and $K = K_1$. If we insert (4.20), the result of Lemma 4.7, and (4.15) into Lemma 4.4, we get

$$\begin{aligned}
&\|\phi(t^{n+1})\xi_u^{n+1}\|_{L^2(\mathbb{R})} + \frac{k}{4}\Theta(|(\phi^2)_x|) \\
&+ k\sum_j [\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2}\left(\left(\frac{1}{2} - \frac{C}{K}(1+\lambda^{m-2})\right)\mathbb{I} - \mathbb{A}\right)[\boldsymbol{\phi}\boldsymbol{\xi}^n]^t_{j-1/2} \\
&+ \left\{1 + \frac{k}{4T} + \left(1 + \left(\frac{h}{\bar{\bar{T}}}\right)^{2(3/2-2\gamma)} + \left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}\right)\frac{C\,k}{K\,T}\right\}||\phi(t^n)\xi_u^n||^2_{L^2(\mathbb{R})} \\
&+ \left\{CK + \left(1 + \left(\frac{h}{\bar{\bar{T}}}\right)^{2(3/2-2\gamma)} + \left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}\right)\frac{C\,T}{k}\right\}||\phi(t^n)(\eta_w^n - \eta_u^n)||^2_{L^2(\mathbb{R})} \\
&+ \left\{CK + \frac{C\,T}{k}\right\}(||\phi(t^n)(\eta_u^{n+1} - \eta_u^n)||^2_{L^2(\mathbb{R})} + k^6||\phi(t^n)u_{ttt}(\theta^n)||^2_{L^2(\mathbb{R})}),
\end{aligned}$$

where we used the fact that $|(\phi^2)_x| = -(\phi^2)_x$ in this case where $\phi = \phi_1$. We see from the term

$$\left(\frac{h}{\bar{\bar{T}}}\right)^{2-3\gamma}\frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}$$

that we are forced to take $\gamma = 2/3$. By substituting $\gamma = 2/3$ and $m = 2$ and using our hypothesis (4.21), we see that

$$\begin{aligned}
\|\phi(t^{n+1})\xi_u^{n+1}\|_{L^2(\mathbb{R})} + k\sum_j [\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2}\mathbb{D}[\boldsymbol{\phi}\boldsymbol{\xi}^n]^t_{j-1/2} &\le \left(1 + \frac{k}{T}\right)\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} \\
+ \left(\frac{CT}{k}1 + C\epsilon^{-1}\right)(\|\phi(t^n)(\eta_w^n - \eta_u^n)\|^2_{L^2(\mathbb{R})} &+ \|\phi(t^n)(\eta_u^{n+1} - (\eta_u^n + \eta_w^n)/2)\|^2_{L^2(\mathbb{R})}) \\
+ \left(\frac{CT}{k}1 + C\epsilon^{-1}\right)k^6\,\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})},&
\end{aligned}$$

where

$$\mathbb{D} = \left(\left(\frac{1}{2} - \epsilon\right)\mathbb{I} - \mathbb{A}\right). \tag{4.22}$$

Here we used the fact that $\frac{h}{\bar{\bar{T}}} \le 1$.

The proof will be complete if we can show that

$$k\sum_j [\boldsymbol{\phi}\boldsymbol{\xi}^n]_{j-1/2}\mathbb{D}[\boldsymbol{\phi}\boldsymbol{\xi}^n]^t_{j-1/2} \ge 0.$$

This occurs when $\mathbb{D}$ is positive semidefinite. This is guaranteed by our hypothesis $\lambda \le 1/3 - \epsilon$. ∎

4.6.2. Case 2: The weight ϕ_2. In this case we do not have $\Theta((\phi_2^2)_x) < 0$, and therefore we must find an appropriate bound for this term. The bound actually is true for both ϕ_1 and ϕ_2.

LEMMA 4.12. *Let $\phi=\phi_i$, $K=K_i$, and $\gamma=\gamma_i$ for either $i=1$ or $i=2$. Then*

$$
\begin{aligned}
k\Theta((\phi^2)_x) &\le \frac{Ck}{K}\sum_j [\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]_{j-1/2}^t\\
&+\left\{\frac{k}{4\,T}+\left(1+\left(\frac{h}{\tilde{\bar{T}}}\right)^{(1-2\gamma)}+\left(\frac{h}{\tilde{T}}\right)^{(3-4\gamma)}+\left(\frac{h}{\tilde{\bar{T}}}\right)^{(5-6\gamma)}\right)\frac{C\,k}{K\,T}\right\}\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}\\
&+\left(1+\left(\frac{h}{\bar{\tilde{T}}}\right)^{2(1/2-\gamma)}+\left(\frac{h}{\tilde{T}}\right)^{(3-4\gamma)}+\left(\frac{h}{\bar{\tilde{T}}}\right)^{(5-6\gamma)}\right)\frac{C\,T}{k}\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\
&+\frac{C\,T}{k}(\|\phi(t^n)(\eta_u^{n+1}-\eta_u^n)\|^2_{L^2(\mathbb{R})}+\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})}).
\end{aligned}
$$

Proof. By using (4.6a), we have

$$
\begin{aligned}
\frac{k}{2}\sum_j(\xi_w^n-\xi_u^n,(\phi^2(t^n))_x(\xi_w^n-\xi_u^n))_j &= \frac{k^2}{2}H(\xi_u^n,(\phi^2(t^n))_x(\xi_w^n-\xi_u^n))\\
&+\frac{k}{2}E_2((\phi^2(t^n))_x(\xi_w^n-\xi_u^n))+\frac{k}{2}E_3((\phi^2(t^n))_x(\xi_w^n-\xi_u^n)).
\end{aligned}
$$

The result now follows if we apply Lemmas 7.9, 4.10, 7.7, and 7.3. ∎

Now we can bound the weighted ϕ_2 error in one time step.

THEOREM 4.13. *Let $0<\epsilon<\frac{1}{3}$, and suppose that $\lambda\le 1/3-\epsilon$. If $\gamma_2=1/2$, $m_2=0$, and*

$$
\frac{1}{K_2}=c\,\epsilon \tag{4.23}
$$

for a sufficiently small fixed constant $c>0$, then

$$
\begin{aligned}
\|\phi_2(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} &\le \left(1+\frac{k}{T}\right)\|\phi_2(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)\|\phi_2(t^n)(\eta_u^{n+1}-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)\|\phi_2(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\
&+C\left(\frac{T}{k}+\epsilon^{-1}\right)k^6\,\|\phi_2(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})}.
\end{aligned}
$$

Proof. Again to simplify notation we let $\phi=\phi_2$, $\gamma=\gamma_2$, $m=m_2$, and $K=K_2$. If we insert (4.15) and the results of Lemmas 4.12 and 4.7 into Lemma 4.4, we get

$$
\begin{aligned}
&\|\phi(t^{n+1})\xi_u^{n+1}\|_{L^2(\mathbb{R})}+k\sum_j[\boldsymbol{\phi\xi}^n]_{j-1/2}\left(\left(\frac{1}{2}-\frac{C}{K}\right)\mathbb{I}-\mathbb{A}\right)[\boldsymbol{\phi\xi}^n]_{j-1/2}^t\\
&\le\left(1+\frac{k}{2\,T}+\frac{C\,k}{K\,T}\right)\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}\\
&\quad+\left(C\,K+\frac{C\,T}{k}\right)(\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}+\|\phi(t^n)(\eta_u^{n+1}-\eta_u^n)\|^2_{L^2(\mathbb{R})})\\
&\quad+\left(C\,K+\frac{C\,T}{k}\right)k^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})},
\end{aligned}
$$

where we used $\frac{h}{T} \le 1$ and our hypothesis $\gamma = 1/2$ and $m = 0$. In fact, we needed only our original assumption $m \ge 0$ for this inequality. We choose $m = 0$, which minimizes the numerical layer. If we now use our hypothesis (4.23), we see that

$$\begin{aligned}\|\phi_2(t^{n+1})\xi_u^{n+1}\|^2_{L^2(\mathbb{R})} + k\sum_j [\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{D}[\boldsymbol{\phi\xi}^n]^t_{j-1/2} &\le \left(1+\frac{k}{T}\right)\|\phi_2(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}\\ &+ \left(\frac{C\,T}{k} + C\epsilon^{-1}\right)\|\phi(t^n)(\eta_u^{n+1}-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\ &+ \left(\frac{C\,T}{k} + C\epsilon^{-1}\right)\|\phi(t^n)(\eta_w^{n}-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\ &+ \left(\frac{C\,T}{k} + C\epsilon^{-1}\right)k^6\,\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})},\end{aligned}$$

where $\mathbb{D}$ is defined in (4.22). By our hypothesis $\lambda \le 1/3 - \epsilon$, $\mathbb{D}$ is positive definite. This proves Theorem 4.13. ∎

4.7. Step 9: Conclusion of the proof of Theorem 2.1. Let K_1 and ϕ_1 be as in Theorem 4.11. Choose $x_1 = -2sK_1\log(1/h)\lambda^{-7/3}T^{1/3}h^{2/3}$ for some $s > 0$, where x_1 appears in the definition of ϕ_1. We choose s sufficiently large below. Since $x_1 < -h$,

$$\begin{aligned}&\|U(T) - u_h^N\|_{L^2(-\infty,T+x_1)} = \|u(T) - u_h^N\|_{L^2(-\infty,T+x_1)}\\ &\le \|\eta_u^N\|_{L^2(-\infty,T+x_1)} + \|\xi_u^N\|^2_{L^2(-\infty,T+x_1)}\\ &= ||P_-(U(T)) - U(T)||_{L^2(-\infty,T+x_1)} + \|\xi_u^N\|_{L^2(-\infty,T+x_1)}.\end{aligned}$$

By (4.8a), we have $\|\xi_u^N\|_{L^2(-\infty,T+x_1)} \le C\|\phi_1(t^N)(\xi_u^N)\|_{L^2(\mathbb{R})}$. Hence, we need only to bound $\|\phi_1(t^N)\xi_u^N\|_{L^2(\mathbb{R})}$. Now we apply Theorem 4.11 for $n \le N$, and

$$\begin{aligned}\|\phi_1(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} &\le \left(1+\frac{k}{T}\right)\|\phi_1(t^{n-1})\xi_u^{n-1}\|^2_{L^2(\mathbb{R})}\\ &\quad+\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)(\|\phi_1(t^{n-1})(\eta_u^n-\eta_u^{n-1})\|^2_{L^2(\mathbb{R})}\\ &\quad+\|\phi_1(t^{n-1})(\eta_w^{n-1}-\eta_u^{n-1})\|^2_{L^2(\mathbb{R})})\\ &\quad+\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)k^6\,\|\phi_1(t^{n-1})u_{ttt}(\theta^{n-1})\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

We decompose the real line as $\mathbb{R} = S_n \cup S_n^c$, where $S_n = (-\infty,\ t^n + x_1 + sK_1\log(1/h)\lambda^{-7/3}T^{1/3}h^{2/3}) = (-\infty,\ t^n - sK_1\log(1/h)\lambda^{-7/3}T^{1/3}h^{2/3})$. Notice that $u(\cdot,t^n) = U(\cdot,t^n)$ in S_n. Hence, by the approximation properties of the projection operator P_-, we have

$$\begin{aligned}&\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)\|\phi_1(t^{n-1})(\eta_u^n-\eta_u^{n-1})\|^2_{L^2(S_{n-1})}\\ &\quad+\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)\|\phi_1(t^{n-1})(\eta_w^{n-1}-\eta_u^{n-1})\|^2_{L^2(S_{n-1})}\\ &\quad+\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)k^6\,\|\phi_1(t^{n-1})u_{ttt}(\theta^n)\|^2_{L^2(S_{n-1})} \le \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right)k^2\,h^4.\end{aligned}$$

It follows from (4.8b) that $\phi(x,t^{n-1}) \le h^s$ for $x \in \mathbb{R}\backslash S_{n-1}$. By using (4.2) and choosing $s \ge 4$, we can easily show that

$$\left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) \|\phi(t^{n-1})(\eta_u^n - \eta_u^{n-1})\|^2_{L^2(\mathbb{R}\backslash S_{n-1})}$$
$$+ \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) \|\phi(t^{n-1})(\eta_w^{n-1} - \eta_u^{n-1})\|^2_{L^2(\mathbb{R}\backslash S_{n-1})}$$
$$+ \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) k^6\, \|\phi(t^{n-1})u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R}\backslash S_{n-1})} \le \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) k^2\, h^4.$$

Hence,

$$\|\phi_1(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} \le \left(1 + \frac{k}{T}\right) \|\phi_1(t^{n-1})\xi_u^{n-1}\|^2_{L^2(\mathbb{R})} + \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) k^2\, h^4,$$

and it follows by Gronwall's inequality that

$$\|\phi_1(T)\xi_u^N\|^2_{L^2(\mathbb{R})} \le (1+e)\|\phi_1(0)\xi_u^0\|^2_{L^2(\mathbb{R})} + \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) T\,k\,h^4$$
$$= (1+e)\|\phi_1(0)(P_-(U_0) - P_-(u_0))\|^2_{L^2(\mathbb{R})} + \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) T\,k\,h^4.$$

Again, by using the fact that $U_0 = u_0$ in $(-\infty, -h)$ and using the decay properties of $\phi_1(0)$, we have

$$\|\phi_1(t^N)\xi_u^N\|^2_{L^2(\mathbb{R})} \le \left(\frac{C\,T}{k} + C\,\epsilon^{-1}\right) T\,k\,h^4 + Ch^s.$$

Therefore, by using this result and (4.8a) we get

$$\|U(T) - u_h^N\|_{L^2(-\infty,\, T - 2\,s\,K_1\,\log(1/h)\lambda^{-7/3}T^{1/3}h^{2/3})} \le CTh^2 + C\left(\frac{Tk}{\epsilon}\right)^{1/2} h^2 + Ch^s$$
$$+ \|P_-(U(T)) - U(T)\|_{L^2(-\infty,\, T - 2\,s\,K_1\,\log(1/h)\lambda^{-7/3}T^{1/3}h^{2/3})}.$$

Since $K_1 = \frac{1}{c\,\epsilon}$, we can choose $\beta = \frac{2}{c}$ to obtain

$$\|U(T) - u_h^N\|_{L^2(-\infty,\, T - \beta\,s\log(1/h)\lambda^{-7/3}\epsilon^{-1}T^{1/3}h^{2/3})} \le CTh^2 + C\left(\frac{Tk}{\epsilon}\right)^{1/2} h^2 + Ch^s$$
$$+ \|P_-(U(T)) - U(T)\|_{L^2(-\infty,\, T - \beta\,s\log(1/h)\lambda^{-7/3}\epsilon^{-1}T^{1/3}h^{2/3})}.$$

The estimate in the region $x > T + \beta\,s\log(1/h)\lambda^{-1/2}\epsilon^{-1}T^{1/2}h^{1/2}$ can be established in a similar fashion.

5. Numerical eperiments. The purpose of this section is to verify our main result (Theorem 2.1) and to present numerical evidence suggesting that it is sharp.

5.1. L^2-errors. To verify the estimate of Theorem 2.1, we consider the problem (1.1) with periodic initial condition $U_0(x) = \sin(2\pi x) + \chi(x)$ for $x \in [0,1]$, where χ is the characteristic function of the interval $(\frac{1}{4}, \frac{3}{4})$. We use uniform spatial meshes and uniform time stepping and take $CFL = \lambda = k/h = 0.33$.

TABLE 5.1
Error to the left and to the right of the singularity.

ℓ	eL_ℓ	oL_ℓ	eR_ℓ	oR_ℓ
1	.44e-8	-	.58e-8	-
2	.11e-8	1.98	.15e-8	1.96
3	.28e-9	1.99	.38e-9	1.98
4	.70e-10	1.99	.95e-10	1.99
5	.18e-10	2.00	.24e-10	1.99
6	.44e-11	2.00	.60e-11	1.99
7	.20e-11	2.00	.15e-11	2.00

We will investigate the error at time $T = 1$. The mesh ℓ will denote a mesh with size $h_l = \frac{2^{-\ell}}{1000}$. We compute the L^2-error to the left and right of the singularity $x = \frac{1}{4}$ and $T = 1$. Specifically, we compute the following errors:

$$eL_\ell := \|U(T) - u_h(T)\|_{L^2(0,\frac{1}{4}-5h_l^{2/3})},$$
$$eR_\ell := \|U(T) - u_h(T)\|_{L^2(\frac{1}{4}+5h_l^{1/2},\frac{7}{10})}.$$

We then compute the orders of convergence defined by

$$oL_\ell := \frac{\log(\frac{eL_\ell}{eL_{\ell+1}})}{\log(2)},$$
$$oR_\ell := \frac{\log(\frac{eR_\ell}{eR_{\ell+1}})}{\log(2)}.$$

We list the results in Table 5.1. As we can see, the optimal orders of convergence are realized; this confirms the prediction of Theorem 2.1. Note that we did not use a logarithmic factor in this computational experiment. We simply took the region around the discontinuity as $\mathcal{R}_T = \frac{1}{4} + (-5\,h^{2/3}, 5\,h^{1/2})$.

5.2. Behavior of the error near discontinuities. To show that our results are sharp, we explore a very precise form of the error near the discontinuity for the special periodic initial condition $U_0(x) = \chi(x)$ for $x \in [0, 1]$.

We would study the error *near* the discontinuity $x = 1/4$ and $T = 1$. We do this by scaling the error near the discontinuity and plotting the results for different h. To the left of the discontinuity, for each fix mesh size h we plot the scaled error

$$\text{errorL}(y, h) := \left|U(1/4 + h^{2/3}\, y, T) - u_h(1/4 + h^{2/3}\, y, T)\right|.$$

Note that here $y \le 0$. The results are given in the top panel of Figure 5.1. Note that as we decrease h the graphs seem to be converging. This reflects the fact that the scaling $h^{2/3}$ is the correct one and that our results are sharp.

Similarly, to the right of the discontinuity we define, for $y \ge 0$,

$$\text{errorR}(y, h) := \left|U(1/4 + h^{1/2}\, y, T) - u_h(1/4 + h^{1/2}\, y, T)\right|.$$

Since the above function is very oscillatory, we are going to consider its "envelope" which we denote by "envelopeR(y, h)"; see the middle panel of Figure 5.1. In the bottom panel of Figure 5.1, we plot those envelopes for various h in Figure 5.1. Notice that the graphs seem to be converging as we decrease h. Again, this reflects the fact that the scaling $h^{1/2}$ is the correct one and that our results are sharp.

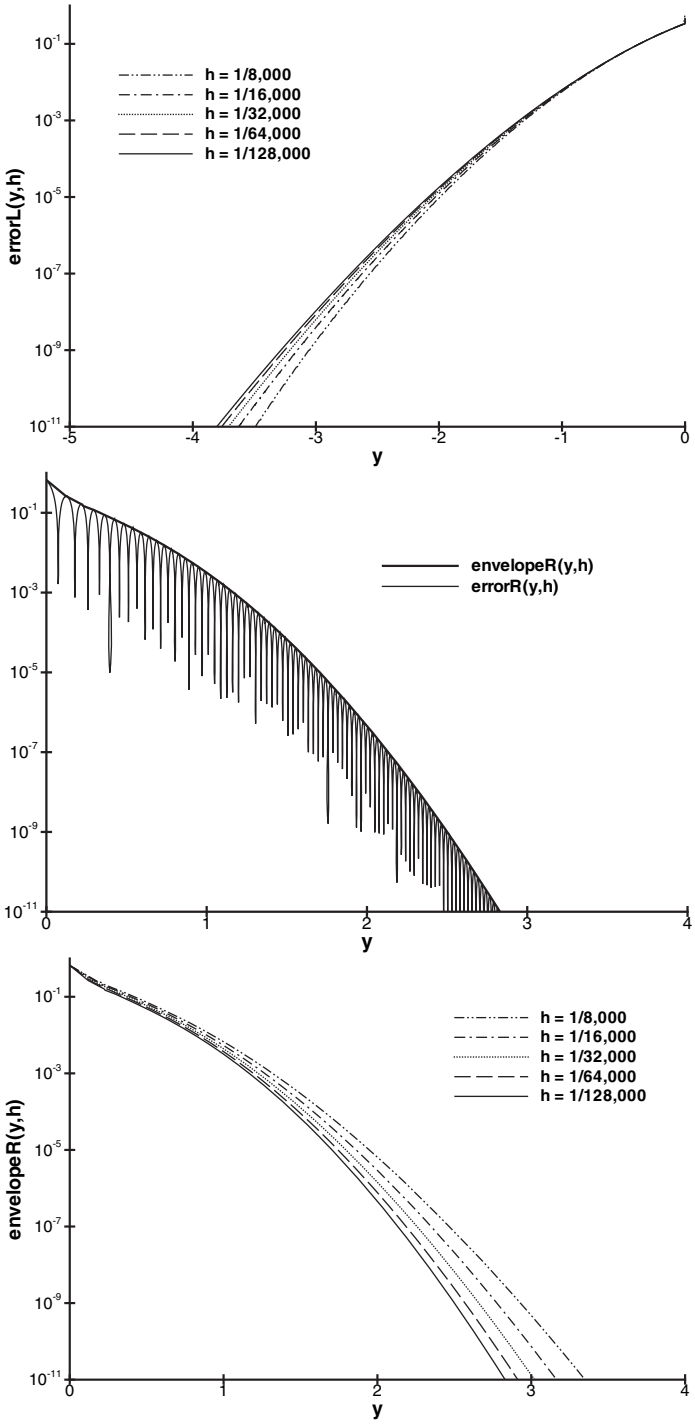

FIG. 5.1. *History of convergence of the scaled error to the left of the discontinuity (top) and of the envelope of the scaled error to the right of the discontinuity (bottom) for different values of the mesh size h. In the middle, we see an example of the scaled error to the right of the discontinuity and its envelope.*

6. Concluding remarks. The approach developed in this paper could be applied to the study of general RKDG methods for the model problem under consideration. The only difficulty in carrying out such a task is that the use of high-order accurate Runge–Kutta methods quickly complicates the calculations. If we solve exactly in time, however, a characterization of the region containing the numerical layer should be fairly easy to obtain for any given polynomial degree p for the DG discretization in space. This constitutes the subject of ongoing work.

7. Appendix.

7.1. Construction of weights. To finish the construction of the weights ϕ_1 and ϕ_2, we need only to construct the initial conditions b_1 and b_2:

$$b_1(x) = \psi\left((x - x_1)/\tilde{K}_1\tilde{T}^{1-\gamma_1}\, h^{\gamma_1}\right) \quad \text{and} \quad b_2(x) = \psi\left((x_2 - x)/\tilde{K}_2\tilde{T}^{1-\gamma_2}\, h^{\gamma_2}\right).$$

The function ψ is given by

$$\psi(r) = \int_r^\infty e^{-g(s)} ds,$$

where $g \in C^5(\mathbb{R})$ and is such that $g(s) = |s|$ for $|s| \geq 1$.

Now we can prove Proposition 4.3.

Proof. Since we have the following representation of ϕ for $i = 1, 2$:

$$\phi_1(x,t) = b_1(x-t) = \psi\left(((x-t) - x_1)/\tilde{K}_1\tilde{T}^{1-\gamma_1}\, h^{\gamma_1}\right),$$
$$\phi_2(x,t) = b_2(x-t) = \psi\left((x_2 - (x-t))/\tilde{K}_2\tilde{T}^{1-\gamma_2}\, h^{\gamma_2}\right),$$

it is not difficult to show that these results can be easily obtained by using the following properties of ψ:

$$\begin{aligned} c \leq \psi(r) \leq C \ \text{ for } \ r \leq 1, \\ \psi'(x) < 0 \ \text{ for } \ x \in \mathbb{R} \\ \psi(r) = e^{-r} \quad \text{for } \ r > 1, \\ |\psi'(r)| + |\psi''(r)| + |\psi'''(r)| \leq C|\psi(r)| \quad \text{for } \ r \in \mathbb{R}, \\ |\psi''(r)| + |\psi'''(r)| + |\psi''''(r)| \leq C|\psi'(r)| \quad \text{for } \ r \in \mathbb{R} \end{aligned}$$

and that, for any interval I of unit length, $RO(I,\psi) + RO(I,\psi') \leq C$. This completes the sketch of the proof. ∎

7.2. Proof of Lemma 4.9. The proof is very similar to the superapproximation proofs contained in [16, 13].

Proof. To simplify notation we drop t. By the approximation properties of P, we have

$$\begin{aligned} &\|D_x^l(\phi^2)v - P(D_x^l(\phi^2)v)\|_{L^2(I_j)} + h\|(D_x^l(\phi^2)v)_x - P(D_x^l(\phi^2)v)_x\|_{L^2(I_j)} \\ &\leq Ch^2\|(D_x^l(\phi^2)v)_{xx}\|_{L^2(I_j)}. \end{aligned}$$

Since $v_{xx} = 0$, we have

$$h^2\|(D_x^l(\phi^2)v)_{xx}\|_{L^2(I_j)} \leq h^2\|D_x^{l+2}(\phi^2)v\|_{L^2(I_j)} + 2h^2\|D_x^{l+1}(\phi^2)v_x\|_{L^2(I_j)}.$$

By using (4.8d), we obtain

$$\begin{aligned}&\|D_x^l(\phi^2)v - P(D_x^l(\phi^2)v)\|_{L_h^2(I_j)} + h\|(D_x^l(\phi^2)v)_x - P(D_x^l(\phi^2)v)_x\|_{L^2(I_j)}\\ &\le \frac{Ch^{2-(l+1)\gamma}}{\tilde{T}^{(1-\gamma)(l+2)}\tilde{K}^{l+2}}\|\phi^2 v\|_{L^2(I_j)} + \frac{h^{2-\frac{1}{2}(l+1)\gamma}}{\bar{T}^{(1-\gamma)(l+1/2)}K^{(l+1/2)}}\|\phi|\phi\phi_x|^{1/2}v_x\|_{L^2(I_j)}.\end{aligned} \tag{7.1}$$

If we multiply both sides by ϕ^{-1} (here we use (4.8e)) and set $l = 0$, we arrive at (4.15a). The inequality (4.15b) follows from (7.1), (4.8d), (4.8e), and (7.4). ∎

7.3. Proof of Lemma 4.5. We start by proving (4.13b). If χ_j is the characteristic function of I_j, then

$$\overline{\xi_w^n - \xi_u^n}(x_j) = \frac{1}{h}(\xi_w^n - \xi_u^n, 1)_j = \frac{k}{h}H(\xi_u^n, \chi_j) + \frac{1}{h}(E_2(\chi_j) + E_3(\chi_j)).$$

Since $\chi_j \in V_h$, $E_2(\chi_j) = 0$. By the properties of P_- we have $E_3(\chi_j) = 0$. Also, from the definition of H we have $H(\xi_u^n, \chi_j) = -h(\xi_u^n)_x(x_j) - [\xi_u^n]_{j-1/2}$. This shows that

$$\overline{\xi_w^n - \xi_u^n}(x_j) = -k(\xi_u^n)_x(x_j) - \frac{k}{h}[\xi_u^n]_{j-1/2}. \tag{7.2}$$

By using (4.12), we have

$$\begin{aligned}(\xi_w^n - \xi_u^n)_x(x_j) &= (\xi_w^n - \xi_u^n, x - x_j)_j / \int_{I_j}(x - x_j)^2 dx\\ &= \frac{12}{h^3}\{kH(\xi_u^n, \chi_j(x - x_j)) + E_2(\chi_j(x - x_j)) + E_3(\chi_j(x - x_j))\}.\end{aligned}$$

We used the fact that $\int_{I_j}(x - x_j)^2 = \frac{h^3}{12}$.

Again, since $\chi_j(x - x_j) \in V_h$, we see that $E_2(\chi_j(x - x_j)) = 0$. By the definition of E_3, we have $E_3(\chi_j(x - x_j)) = R_{1,j}$. Also, $H(\xi_u^n, \chi_j(x - x_j)) = -\int_{I_j}(x - x_j)(\xi_u^n)_x dx - (x - x_j)(x_{j-1/2}^+)[\xi_u^n]_{j-1/2} = \frac{h}{2}[\xi_u^n]_{j-1/2}$, since $(\xi_u^n)_x$ is constant on I_j and $\int_{I_j}(x - x_j)dx = 0$.

Therefore,

$$(\xi_w^n - \xi_u^n)_x(x_j) = \frac{6k}{h^2}[\xi_u^n]_{j-1/2} + \frac{12}{h^3}R_{1,j}.$$

Equation (4.13b) now follows from (4.12), (7.2), and the above identity.

By subtracting (4.6a) from (4.6b) we have

$$\begin{aligned}(\xi_u^{n+1} - \xi_w^n, v) = \frac{k}{2}H(\xi_w^n - \xi_u^n, v) + E_1(P_+(v)) - E_2(v)/2 - E_3(v)/2\\ + E_4(v) + E_5(v).\end{aligned}$$

By using this representation and following the techniques used to prove (4.13b), we can easily show (4.13a).

7.4. Proof of Lemma 4.8. In order to prove Lemma 4.8 we will state and prove a series of lemmas. Most of these lemmas are bounds for the terms of E_h. We first state standard inverse estimates.

LEMMA 7.1. *There exists a $C > 0$ such that for every $v \in P^1(I_j)$*

$$|v(x_{j+1/2})| + |v(x_{j-1/2})| \le Ch^{-1/2}\|v\|_{L^2(I_j)} \tag{7.3}$$

and

$$\|v'\|_{L^2(I_j)} \le Ch^{-1}\|v\|_{L^2(I_j)}. \tag{7.4}$$

We also need the following preliminary estimates.

LEMMA 7.2. *Let $t^n \le t \le t^{n+1}$; then for $v_h \in V_h$*

$$\|\phi^{-1}(t)(P_+(\phi^2(t)v_h) - \phi^2(t)v_h)\|_{L^2(I_j)} \le \frac{C}{K}\|\phi(t^n)v_h\|_{L^2(I_j)}, \tag{7.5}$$

and for K sufficiently large

$$\|\phi^{-1}(t)P_+(\phi^2(t)v_h)\|_{L^2(I_j)} \le 2\|\phi(t^n)v_h\|_{L^2(I_j)}. \tag{7.6}$$

Proof. By (4.15b) we have

$$\|\phi^{-1}(t)(P_+(\phi^2(t)v_h) - \phi^2(t)v_h)\|_{L^2(I_j)} \le \left(\left(\frac{h}{\bar{T}}\right)^{1-\gamma}\frac{C}{K} + \left(\frac{h}{\bar{T}}\right)^{2(1-\gamma)}\frac{C}{K^2}\right)\|\phi(t^n)v_h\|_{L^2(I_j)}.$$

The inequality (7.5) now follows from $K \ge 1$ and $\frac{h}{\bar{T}} \le 1$. The inequality (7.6) easily follows from (7.5). ∎

The following result compares ξ_w^n to ξ_u^n.

LEMMA 7.3. *If $t^n \le t \le t^{n+1}$ and K is sufficiently large, then*

$$\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})} \le C\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + C\|\phi(t^n)(\eta_w^n - \eta_u^n)\|^2_{L^2(\mathbb{R})}.$$

Proof. By using (4.6a), we have

$$\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})} = \sum_j (\xi_u^n, \phi^2(t)\xi_w^n)_j + kH(\xi_u^n, \phi^2(t)\xi_w^n) + E_2(\phi^2(t)\xi_w^n) + E_3(\phi^2(t)\xi_w^n).$$

By applying (4.8e) and the Cauchy–Schwarz inequality, we get

$$\sum_j (\xi_u^n, \phi^2(t)\xi_w^n)_j \le C\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \frac{1}{8}\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})}.$$

If we use (4.8e), (7.3), and (7.4), we get

$$kH(\xi_u^n, \phi^2(t)\xi_w^n) \le C\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \frac{1}{8}\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})}.$$

By using (7.5) and taking K sufficiently large, we get

$$E_2(\phi^2(t^n)\xi_w^n) \le C\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \frac{1}{8}\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})}.$$

If we use (7.6), we get

$$E_3(\phi^2(t)\xi_w^n) \le C\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \frac{1}{8}\|\phi(t)\xi_w^n\|^2_{L^2(\mathbb{R})}.$$

Combining the last four inequalities proves Lemma 7.3. ∎

We will need a different bound than what is given in Lemma 4.10 for the case $l = 0$ and $v_h = \xi_u^n$ or $v_h = \xi_w^n$.

LEMMA 7.4. *Let $t^n \le t \le t^{n+1}$, and then*

$$\begin{aligned}
&|E_2(\phi^2(t)\xi_u^n)| + |E_4(\phi^2(t)\xi_w^n)| \\
&\le (1+\lambda^{m-2})\frac{Ck}{K}\sum_j [\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]_{j-1/2}^t + \frac{k}{6}\Theta(|(\phi^2)_x|) \\
&\quad + \left(1+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right)\frac{C\,k}{K\,T}||\phi(t^n)\xi_u^n||_{L^2(\mathbb{R})}^2 \\
&\quad + \left(1+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right)\frac{T}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||_{L^2(\mathbb{R})}^2 \\
&\quad + \frac{C\,T}{k}(||\phi(t^n)(\eta_u^{n+1}-\eta_u^n)||_{L^2(\mathbb{R})}^2 + k^6||\phi(t^n)u_{ttt}(\theta^n)||_{L^2(\mathbb{R})}^2).
\end{aligned}$$

Proof. As was done in the proof of Lemma 4.10, we see that

$$\begin{aligned}
|E_2(\phi^2(t)\xi_u^n)| &= \left|\sum_j\left(\frac{6k}{h^2}[\xi_u^n]_{j-1/2}(\phi(t)(x-x_j),\phi^{-1}(t)(\phi^2(t)\xi_u^n - P_+(\phi^2(t)\xi_u^n)))_j\right)\right. \\
&\qquad \left. + \sum_j \frac{12}{h^3}R_{1,j}(\phi(t)(x-x_j),\phi^{-1}(t)(\phi^2(t)\xi_u^n - P_+(\phi^2(t)\xi_u^n)))_j\right| \\
&\le M_1 + M_2,
\end{aligned}$$

where

$$\begin{aligned}
M_1 &:= \frac{C\,k}{h^{1/2}}\sum_j |[\phi(t^n)\xi_u^n]_{j-1/2}|\,\|\phi^{-1}(t)(\phi^2(t)\xi_u^n - P_+(\phi^2(t)\xi_u^n))\|_{L^2(I_j)}, \\
M_2 &:= \frac{C}{h^{3/2}}\sum_j |R_{1,j}\phi(t^n,x_{j-1/2})|\,\|\phi^{-1}(t)(\phi^2(t)\xi_u^n - P_+(\phi^2(t)\xi_u^n))\|_{L^2(I_j)}.
\end{aligned}$$

We first bound M_2. By using (4.19) with $v_h = \xi_u^n$ and $l = 0$ combined with the inequalities $K \ge 1$, $\frac{h}{\tilde{T}} \le 1$, and $\gamma \le 1$, we have

$$M_2 \le \frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 + \frac{C\,T}{k}\|\phi(t^n)(\eta_w^n-\eta_u^n)\|_{L^2(I_j)}^2. \tag{7.7}$$

For the next term we use (4.8e) and (4.15a) to obtain

$$\begin{aligned}
M_1 &\le \frac{Ckh^{3/2-2\gamma}}{\tilde{T}^{2(1-\gamma)}\tilde{K}^2}\sum_j |[\phi(t^n)(\xi_u^n)]_{j-1/2}|\,\|\phi(t^n)\xi_u^n\|_{L^2(I_j)} \\
&\quad + \frac{Ckh^{3/2-\gamma/2}}{\tilde{T}^{(1-\gamma)/2}\tilde{K}^{1/2}}\sum_j |[\phi(t^n)(\xi_u^n)]_{j-1/2}|\,\|(|\phi(t^n)(\phi)_x(t^n)|)^{1/2}(\xi_u^n)_x\|_{L^2(I_j)}.
\end{aligned}$$

By using Young's inequality, we have

$$\begin{aligned}
&\frac{Ckh^{3/2-2\gamma}}{\tilde{T}^{2(1-\gamma)}\tilde{K}^2}\sum_j |[\phi(t^n)(\xi_u^n)]_{j-1/2}|\,\|\phi(t^n)\xi_u^n\|_{L^2(I_j)} \\
&\le \frac{C}{K^2}k\sum_j [\phi(t^n)\xi_u^n]_{j+1/2}^2 + \left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\frac{C\,k}{K^2\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2.
\end{aligned} \tag{7.8}$$

If we use (4.13b), the triangle inequality, and the fact that $|x-x_j| \le h$ for $x \in I_j$, then

$$\|(|\phi(t^n)(\phi)_x(t^n)|)^{1/2}(\xi_u^n)_x\|_{L^2(I_j)} \le \frac{1}{k}\Theta_j(|(\phi^2)_x|)^{1/2} + \frac{Ch^{-(1+\gamma)/2}}{\tilde{K}^{1/2}\tilde{T}^{(1-\gamma)/2}}|[\phi(t^n)\xi_u^n]_{j-1/2}| + \frac{Ch^{-\gamma/2}}{k\tilde{K}^{1/2}\tilde{T}^{(1-\gamma)/2}}||\phi(t^n)(\eta_w^n-\eta_u^n)||_{L^2(I_j)},$$

where we also used $|R_{1,j}| \le h^{3/2}||\eta_w^n-\eta_u^n||_{L^2(I_j)}$, (4.8d), and (4.8e).

Therefore,

$$\begin{aligned}
&\frac{Ckh^{3/2-\gamma/2}}{\tilde{T}^{(1-\gamma)/2}\tilde{K}^{1/2}}\sum_j |[\phi(t^n)(\xi_u^n)]_{j-1/2}|\ \|(|\phi(t^n)(\phi)_x(t^n)|)^{1/2}(\xi_u^n)_x\|_{L^2(I_j)}\\
&\le \left(\frac{C\lambda^{-2}}{\tilde{K}}\left(\frac{h}{\tilde{T}}\right)^{1-\gamma} + \frac{C}{\tilde{K}}\left(\frac{h}{\tilde{T}}\right)^{2(1-\gamma)} + \frac{C\lambda^{-1}}{\tilde{K}^2}\left(\frac{h}{\tilde{T}}\right)^{2(3/2-\gamma)}\right)k\sum_j[\phi(t^n)\xi_u^n]_{j-1/2}^2\\
&\quad + \frac{k}{12}\Theta(|(\phi^2)_x|) + \frac{T}{k}||\eta_w^n-\eta_u^n||_{L^2(\mathbb{R})}^2\\
&\le (\lambda^{m-2}+\lambda^m+\lambda^{2m-1})\frac{Ck}{K}\sum_j[\phi(t^n)\xi_u^n]_{j-1/2}^2 + \frac{k}{12}\Theta(|(\phi^2)_x|)\\
&\quad + \frac{CT}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||_{L^2(\mathbb{R})}^2.
\end{aligned}$$

Here we used the fact that $\tilde{K} = \lambda^{-m}K$, $\frac{h}{\tilde{T}} \le 1$, $\gamma \le 1$, and $K \ge 1$. By combining this inequality with (7.8) we get

$$\begin{aligned}
M_1 &\le (1+\lambda^{m-2})\frac{Ck}{K}\sum_j[\phi(t^n)\xi_u^n]_{j-1/2}^2 + \frac{k}{12}\Theta(|(\phi^2)_x|)\\
&\quad + \left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\frac{Ck}{KT}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2\\
&\quad + \frac{CT}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||_{L^2(\mathbb{R})}^2,
\end{aligned}$$

where we used the fact that $K \ge 1$, $\lambda \le 1$, and $m \ge 0$. Therefore, combining the estimate of M_1 and M_2 gives the right bound for $|E_2(\phi^2(t)\xi_u^n)|$. We are left to bound $|E_4(\phi^2(t)\xi_w^n)|$. To this end, we write

$$|E_4(\phi^2(t)\xi_w^n)| = |E_4(\phi^2(t)\xi_u^n) + E_4(\phi^2(t)(\xi_w^n-\xi_u^n))|.$$

We can follow the proof of the bound for $E_2(\phi^2(t)\xi_u^n)$ to obtain

$$\begin{aligned}
|E_4(\phi^2(t)\xi_u^n)| &\le (1+\lambda^{m-2})\frac{Ck}{K}\sum_j[\phi(t^n)\xi_w^n]_{j-1/2}^2\\
&\quad + \frac{k}{24}\Theta(|(\phi^2)_x|) + \left(1+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right)\frac{Ck}{TK}||\phi(t^n)\xi_u^n||_{L^2(\mathbb{R})}^2\\
&\quad + \left(1+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right)\frac{CT}{k}||\phi(t^n)(\eta_w^n-\eta_u^n)||_{L^2(\mathbb{R})}^2\\
&\quad + \frac{CT}{Kk}(||\phi(t^n)(\eta_u^{n+1}-\eta_u^n)||_{L^2(\mathbb{R})}^2 + k^6||\phi(t^n)u_{ttt}(\theta^n)||_{L^2(\mathbb{R})}^2).
\end{aligned}$$

If we use (4.13a), (4.13b), and the properties of P_+, we have

$$\begin{aligned}|E_4(\phi^2(t)(\xi_w^n-\xi_u^n))| &= \sum_j \left(\frac{3k}{h^2}[\xi_w^n]_{j-1/2}+\frac{k^3}{6h^3}R_{4,j}+\frac{12}{h^3}R_{2,j}\right)\\ &\qquad \times (x-x_j,\ \phi^2(t)(\xi_w^n-\xi_u^n)-P_+(\phi^2(t)(\xi_w^n-\xi_u^n)))_j\\ &\le Q_1+Q_2+Q_3,\end{aligned}$$

where

$$\begin{aligned}Q_1 &:= \frac{C}{h^{3/2}}\sum_j |R_{2,j}\phi(t^n,x_{j-1/2})|\,D_j,\\ Q_2 &:= \frac{C\,k^3}{h^{3/2}}\sum_j |R_{4,j}\phi(t^n,x_{j-1/2})|\,D_j,\\ Q_3 &:= \frac{C\,k}{h^{1/2}}\sum_j |[\phi(t^n)\xi_w^n]_{j-1/2}|\,D_j,\end{aligned}$$

and

$$D_j := \|\phi^{-1}(t)(\phi^2(t)(\xi_w^n-\xi_u^n)-P_+(\phi^2(t)(\xi_w^n-\xi_u^n)))\|_{L^2(I_j)}.$$

By following the proof of the bound for M_2, we can show that

$$Q_1 \le \frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}+\frac{C\,T}{k}(\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}+\|\phi(t^n)(\eta_u^{n+1}-\eta_u^n)\|^2_{L^2(\mathbb{R})}),$$

where in addition we used Lemma 7.3. Similarly, we can show that

$$Q_2 \le \frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}+\frac{C\,T}{k}(\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}+k^6\|\phi(t^n)u_{ttt}(\theta^n)\|^2_{L^2(\mathbb{R})}).$$

In order to bound Q_3 we first bound D_j by using (4.15a):

$$\begin{aligned}|D_j| &\le \frac{Ch^{2-2\gamma}}{\tilde{T}^{2(1-\gamma)}\tilde{K}^2}(||\phi(t^n)\xi_u^n||_{L^2(I_j)}+||\phi(t^n)\xi_w^n||_{L^2(I_j)})\\ &\quad+\frac{Ch^{2-\gamma/2}}{\tilde{T}^{(1-\gamma)/2}\tilde{K}^{1/2}}||(|\phi(t^n)(\phi(t^n))_x|)^{1/2}(\xi_w^n-\xi_u^n)_x||_{L^2(I_j)}\\ &\le \frac{Ch^{2-2\gamma}}{\tilde{T}^{2(1-\gamma)}\tilde{K}}(||\phi(t^n)\xi_u^n||_{L^2(I_j)}+\|\phi(t^n)(\eta_w^n-\eta_u^n)\|_{L^2(I_j)})\\ &\quad+\frac{Ch^{1-\gamma/2}}{\tilde{T}^{(1-\gamma)/2}\tilde{K}^{1/2}}\Theta_j(|(\phi^2)_x|)^{1/2}.\end{aligned}$$

In the last inequality we used Lemma 7.3 and the inverse estimate (7.4). Therefore,

$$\begin{aligned}Q_3 &\le \frac{Ck}{K}\sum_j[\phi(t^{n+1})\xi_w^n]^2_{j-1/2}+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\frac{C\,k}{KT}||\phi\xi_u^n||^2_{L^2(\mathbb{R})}\\ &\quad+\left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\frac{C\,T}{k}\|\phi(t)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}\\ &\quad+\frac{k}{24}\Theta(|(\phi^2)_x|),\end{aligned}$$

where we used the fact that $\gamma \le 1$, $K \ge 1$, and $\lambda \le 1$. Hence,

$$
\begin{aligned}
|E_4(\phi^2(t)(\xi_w^n - \xi_u^n))| &\le \frac{Ck}{K} \sum_j [\phi(t^{n+1})\xi_w^n]_{j-1/2}^2 \\
&+ \frac{k}{24}\Theta(|(\phi^2)_x|) + \left(1 + \left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right) \frac{C\,k}{KT} ||\phi(t^n)\xi_u^n||_{L^2(\mathbb{R})}^2 \\
&+ \left(1 + \left(\frac{h}{\tilde{T}}\right)^{2(3/2-2\gamma)}\right) \frac{C\,T}{k} \|\phi(t^n)(\eta_w^n - \eta_u^n)\|_{L^2(\mathbb{R})}^2 \\
&+ \frac{CT}{k}(\|\phi(t^n)(\eta_u^{n+1} - \eta_w^n)\|_{L^2(\mathbb{R})}^2 + k^6 ||\phi(t^n)u_{ttt}(\theta^n)||_{L^2(\mathbb{R})}^2).
\end{aligned}
$$

This completes the proof of Lemma 7.4. ∎

LEMMA 7.5.

$$
\begin{aligned}
\left|\frac{k^2}{2}\sum_j (\xi_w^n - \xi_u^n, (\phi^2(t^n))_{xx}\xi_w^n)_j\right| &\le \left(\frac{h}{\tilde{T}}\right)^{2-3\gamma} \frac{C\,k}{K^3\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 + \frac{k}{12}\Theta(|(\phi^2)_x|) \\
&+ \left(\frac{h}{\tilde{T}}\right)^{2-3\gamma} \frac{C\,T}{K^3\,k}\|\phi(t^n)(\eta_w^n - \eta_u^n)\|_{L^2(\mathbb{R})}^2
\end{aligned} \tag{7.9}
$$

and

$$
\begin{aligned}
\left|\frac{k^2}{2}\sum_j (\xi_w^n - \xi_u^n, (\phi^2(t^n))_{xx}\xi_w^n)_j\right| &\le \left(\frac{h}{\tilde{T}}\right)^{1-2\gamma} \frac{C\,k}{K^2\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 \\
&+ \left(\frac{h}{\tilde{T}}\right)^{1-2\gamma} \frac{C\,T}{K^2\,k}\|\phi(t^n)(\eta_w^n - \eta_u^n)\|_{L^2(\mathbb{R})}^2.
\end{aligned} \tag{7.10}
$$

Proof. The results are simple consequences of (4.8d), (4.8e), the Cauchy–Schwarz inequality, and Lemma 7.3. ∎

LEMMA 7.6. *For K sufficiently large*

$$
|E_1(P_+(\phi^2(t^{n+1})\xi_w^n))| \le \frac{k}{8\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 + CTk^5\|\phi(t^n)u_{ttt}(\theta^n)\|_{L^2(\mathbb{R})}^2.
$$

Proof. By applying the Cauchy–Schwarz inequality, (7.6), and Young's inequality, we obtain Lemma 7.6. ∎

LEMMA 7.7. *Let $t^n \le t \le t^{n+1}$ and $v_h = \xi_u^n$ or $v_h = \xi_w^n$. For $l = 0, 1, 2$, we have*

$$
\begin{aligned}
&h^l|E_3(D_x^l(\phi^2(t))v_h)| + h^l|E_5(D_x^l(\phi^2(t))v_h)| \\
&\le \frac{k}{16\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 + \frac{C\,T}{k}(\|\phi(t^n)(\eta_u^{n+1} - \eta_u^n)\|_{L^2(\mathbb{R})}^2 + \|\phi(t^n)(\eta_w^n - \eta_u^n)\|_{L^2(\mathbb{R})}^2).
\end{aligned}
$$

Proof. This result easily follows from the Cauchy–Schwarz inequality, (7.6), Lemma 7.3, and Young's inequality. ∎

LEMMA 7.8. *We have*

$$
|S_1| + |S_2| \le \left(\frac{h}{\tilde{T}}\right)^{2-3\gamma} \frac{Ck}{K^3T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2 + \left(\frac{h}{\tilde{T}}\right)^{2-3\gamma} \frac{CT}{k}||\phi(t^n)(\eta_w^n - \eta_u^n)||_{L^2(\mathbb{R})}^2.
$$

Proof. This follows from (4.8d), (4.8e), the Cauchy–Schwarz inequality, and Lemma 7.3. ∎

Now we can prove Lemma 4.8, which is a simple consequence of the lemmas of this section.

Proof. We start with the proof of (4.15). If we apply Lemmas 7.6, 7.4, and 7.7, (7.9), and Lemma 7.8, we get (4.15).

To prove (4.15) we proceed as in the proof for (4.15), but instead of using Lemma 7.4 we apply Lemma 4.10 only, and we use (7.10) rather than (7.9). We also use Lemma 7.3. ∎

7.5. Auxiliary lemma. The following lemma is used to prove (4.12).

LEMMA 7.9. *Let $\phi = \phi_i$, $\gamma = \gamma_i$, and $K = K_i$ for $i = 1$ or $i = 2$. If $t^n < t < t^{n+1}$, then*

$$k^2|H(\xi_u^n,(\phi^2(t))_x(\xi_w^n-\xi_u^n))| \le \frac{Ck}{K}\sum_j [\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]_{j-1/2}^t$$
$$+\left(\left(\frac{h}{\tilde{\tilde{T}}}\right)^{2(1/2-\gamma)}+1\right)\frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2$$
$$+\left(1+\left(\frac{h}{\tilde{\tilde{T}}}\right)^{2(1/2-\gamma)}\right)\frac{C\,T}{k}\|\phi(t^n)(\eta_w^n-\eta_u^n)\|_{L^2(\mathbb{R})}^2.$$

Proof.

$$k^2|H(\xi_u^n,(\phi^2(t))_x(\xi_w^n-\xi_u^n))|$$
$$= k^2\left|\sum_j(\xi_u^n,((\phi^2)_x(t)(\xi_w^n-\xi_u^n))_x)_j+\xi_u^n(x_{j+1/2}^-)[(\phi^2)_x(t)(\xi_w^n-\xi_u^n)]_{j+1/2}\right|.$$

By applying the Cauchy–Schwarz inequality, (4.8d), (4.8e), (7.3), and Young's inequality, we have

$$k^2\left|\sum_j \xi_u^n(x_{j+1/2}^-)[(\phi^2)_x(t)(\xi_w^n-\xi_u^n)]_{j+1/2}\right|$$
$$\le \frac{C\,k}{K}\sum_j[\boldsymbol{\phi\xi}^n]_{j-1/2}\mathbb{I}[\boldsymbol{\phi\xi}^n]_{j-1/2}^t+\left(\frac{h}{\tilde{\tilde{T}}}\right)^{2(1/2-\gamma)}\frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|_{L^2(\mathbb{R})}^2.$$

The product rule gives

$$\left|\sum_j(\xi_u^n,((\phi^2)_x(t)(\xi_w^n-\xi_u^n))_x)_j\right| = \left|\sum_j\{(\xi_u^n,(\phi^2)_{xx}(t)(\xi_w^n-\xi_u^n))_j\right.$$
$$\left.+(\xi_u^n,(\phi^2)_x(t)(\xi_w^n-\xi_u^n)_x)_j\}\right|.$$

By applying the Cauchy–Schwarz inequality, (4.8d), Lemma 7.3, and Young's inequality, we have

$$k^2\left|\sum_j(\xi_u^n,(\phi^2)_{xx}(t^n)(\xi_w^n-\xi_u^n))_j\right| \le \left(\frac{h}{\tilde{T}}\right)^{1-2\gamma}\frac{C\,k}{K^2T}(\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})} + \|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}).$$

If we use (4.13b), (4.8e), (4.8d), and Young's inequality, we see that

$$\begin{aligned}k^2\left|\sum_j(\xi_u^n,(\phi^2)_x(t)(\xi_w^n-\xi_u^n)_x)_j\right| &\le \frac{C\,k}{K}\sum_j[\phi(t^n)\xi_u^n]^2_{j-1/2}\\ &\quad+\left(\left(\frac{h}{\tilde{T}}\right)^{2(1/2-\gamma)}+1\right)\frac{C\,k}{K\,T}\|\phi(t^n)\xi_u^n\|^2_{L^2(\mathbb{R})}\\ &\quad+\frac{C\,T}{k}\|\phi(t^n)(\eta_w^n-\eta_u^n)\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

This concludes the proof. ∎

A CONVERGENT IMPLICIT FINITE ELEMENT DISCRETIZATION OF THE MAXWELL–LANDAU–LIFSHITZ–GILBERT EQUATION*

L'UBOMÍR BAŇAS†, SÖREN BARTELS‡, AND ANDREAS PROHL§

Abstract. We propose an implicit, fully discrete scheme for the numerical solution of the Maxwell–Landau–Lifshitz–Gilbert equation which is based on linear finite elements and satisfies a discrete sphere constraint as well as a discrete energy law. As numerical parameters tend to zero, solutions weakly accumulate at weak solutions of the Maxwell–Landau–Lifshitz–Gilbert equation. A practical linearization of the nonlinear scheme is proposed and shown to converge for certain scalings of numerical parameters. Computational studies are presented to indicate finite-time blow-up behavior and to study combined electromagnetic phenomena in ferromagnets for benchmark problems.

Key words. ferromagnetism, Maxwell–Landau–Lifshitz–Gilbert equation, finite elements, convergence

DOI. 10.1137/070683064

1. Introduction.

The Maxwell–Landau–Lifschitz–Gilbert equation (MLLG) describes certain electromagnetic phenomena in a ferromagnet occupying the domain $\omega \Subset \Omega \subseteq \mathbb{R}^d$, $d = 2, 3$. For a parameter $\alpha > 0$ which serves as a damping factor, the magnetization field $\mathbf{m} : (0,T) \times \omega \to \mathbb{S}^2$, where $\mathbb{S}^2 = \{\mathbf{x} \in \mathbb{R}^3 | \, |\mathbf{x}| = 1\}$ is the unit sphere, and the electric and magnetic fields $(\mathbf{E}, \mathbf{H}) : (0,T) \times \Omega \to \mathbb{R}^3$ satisfy for all $T > 0$

$$\mathbf{m}_t + \alpha\, \mathbf{m} \times \mathbf{m}_t = (1+\alpha^2)\, \mathbf{m} \times \mathbf{H}_{\text{eff}} \quad \text{in } \omega_T := (0,T) \times \omega\,, \tag{1.1}$$

$$\varepsilon_0\, \mathbf{E}_t - \nabla \times \mathbf{H} + \sigma\, \chi_\omega \mathbf{E} = -\mathbf{J} \quad \text{in } \Omega_T := (0,T) \times \Omega\,, \tag{1.2}$$

$$\mu_0\, \mathbf{H}_t + \nabla \times \mathbf{E} = -\mu_0\, \mathbf{m}_t \qquad \text{in } \Omega_T \tag{1.3}$$

for the (simplified) effective field $\mathbf{H}_{\text{eff}} = \Delta \mathbf{m} + \mathbf{H}$. This choice of $\mathbf{H}_{\text{eff}}$ comprises the most relevant contributions to the more general version (5.1) below. The constants $\varepsilon_0, \mu_0 \geq 0$ denote, respectively, the electric and magnetic permeability of free space, while $\sigma \geq 0$ describes the conductivity of the ferromagnet. The field $\mathbf{J} : \Omega_T \to \mathbb{R}^3$ denotes an applied current density and $\chi_\omega : \Omega \to \{0,1\}$ is the characteristic function of ω. For simplicity we suppose that $\Omega \subset \mathbb{R}^3$ is a bounded cavity with a perfectly conducting outer surface $\partial\Omega$ into which the ferromagnet $\omega \Subset \Omega$ is embedded, and $\Omega \setminus \overline{\omega}$ is assumed to be a vacuum [15]. The system (1.1)–(1.3) is supplemented with

initial conditions

$$\mathbf{m}(0,\cdot)=\mathbf{m}_0 \quad \text{in } \omega\,, \qquad \mathbf{E}(0,\cdot)=\mathbf{E}_0\,, \quad \mathbf{H}(0,\cdot)=\mathbf{H}_0 \quad \text{in } \Omega \tag{1.4}$$

and boundary conditions

$$\partial_{\mathbf{n}}\mathbf{m}=0 \quad \text{on } \partial\omega_T\,, \qquad \mathbf{E}\times\mathbf{n}=0 \quad \text{on } \partial\Omega_T\,. \tag{1.5}$$

We remark that the inclusion of a damping term is necessary to permit the magnetic field to align with the effective field, and we refer the reader to [5, 23, 12] for a more detailed discussion of the mathematical model. Interesting computational studies of the model (1.1)–(1.5) can be found in [15, 22].

The construction of convergent numerical schemes for the Maxwell–Landau-Lifshitz–Gilbert system (1.1)–(1.5) is difficult due to the nonlinear character of (1.1). Moreover, the limited flexibility of piecewise polynomial finite elements and the artificial damping of implicit time-discretization schemes make it hard to appropriately account for the constraint $|\,\mathbf{m}\,|=1$ a.e. in ω_T. The semidiscrete scheme proposed in [15] uses numerical integration to guarantee that the constraint is satisfied at the nodes of a triangulation. Stability of that scheme is proved in [15], but its convergence has not been discussed in the literature so far.

According to Landau and Lifshitz [11], damped precession ($\alpha>0$) of the magnetization $\mathbf{m}:\omega_T\to\mathbb{S}^2$ is governed by

$$\mathbf{m}_t=\mathbf{m}\times\mathbf{H}_{\text{eff}}-\alpha\,\mathbf{m}\times(\mathbf{m}\times\mathbf{H}_{\text{eff}})\,. \tag{1.6}$$

Gilbert's approach modifies the undamped precession equation by a damping term which is proportional to the rate of change of magnetization; see (1.1). Both approaches are analytically equivalent for smooth magnetization fields, and weak solutions to MLLG exist in both cases [23, 6]. The numerical analysis differs significantly, and Gilbert's approach turns out to be attractive from a numerical viewpoint. Explicit and implicit discretizations for the simplest choice $\mathbf{H}_{\text{eff}}=\Delta\mathbf{m}$ have been proposed and analyzed in [1, 3, 4], and approximations are known to respectively converge conditionally and unconditionally with respect to discretization parameters to weak solutions of (1.1). Corresponding results for (1.6) are so far only available for (locally existing) strong solutions; cf. [18, 7]. The articles [14, 21] study convergence for the simplification $\mathbf{H}_{\text{eff}}=\mathbf{H}$ for cases where smooth solutions to (1.1)–(1.5) exist. Convergence of iterates of the following scheme to weak solutions of (1.1) for $\mathbf{H}_{\text{eff}}=\Delta\mathbf{m}$ is verified in [4]; the proof relies on conservation of $|\,\mathbf{m}_h^j\,|=1$ at all mesh points and for all $j\geq 0$ as well as a discrete energy law.

ALGORITHM 1.1. *Let $\mathbf{m}_h^0\in\mathbf{V}_h$. Given $j\geq 0$ and $\mathbf{m}_h^j\in\mathbf{V}_h$, let $\mathbf{m}_h^{j+1}\in\mathbf{V}_h$ solve*

$$(d_t\mathbf{m}_h^{j+1},\boldsymbol{\phi}_h)_h+\alpha\,(\mathbf{m}_h^j\times d_t\mathbf{m}_h^{j+1},\boldsymbol{\phi}_h)_h=(1+\alpha^2)(\overline{\mathbf{m}}_h^{j+1/2}\times\tilde{\Delta}_h\overline{\mathbf{m}}_h^{j+1/2},\boldsymbol{\phi}_h)_h$$
$$\forall\,\boldsymbol{\phi}_h\in\mathbf{V}_h\,.$$

Here, $\mathbf{V}_h\subset W^{1,2}(\omega;\mathbb{R}^3)$ is the finite element space subordinate to a triangulation $\mathcal{T}_h$ of ω consisting of piecewise linear functions, and $(\cdot,\cdot)_h$ denotes a discrete version (numerical integration) of the inner product in $L^2(\omega;\mathbb{R}^3)$. Moreover, $\tilde{\Delta}_h:W^{1,2}(\omega;\mathbb{R}^3)\to\mathbf{V}_h$ is an approximation of the Laplace operator. For a time-step size $k>0$ we write $d_t\varphi^j:=k^{-1}\big(\varphi^j-\varphi^{j-1}\big)$ for $j\geq 1$, and $\overline{\varphi}^{j+1/2}:=\frac{1}{2}\big(\varphi^{j+1}+\varphi^j\big)$ for $j\geq 0$ and a sequence $\{\varphi^j\}_{j\geq 0}$; we refer the reader to section 2 for details.

The goal of this work is (i) to propose a discretization of (1.1)–(1.3) based on linear finite elements which satisfies a discrete sphere constraint and a discrete energy identity, (ii) to verify convergence of iterates toward a weak solution of (1.1)–(1.3), and (iii) to propose a reliable solver for the nonlinear system of equations in each time step. This program is motivated by possible finite-time blow-up behavior of solutions to (1.1)–(1.3) (see section 5), whose numerical simulation requires reliable numerical schemes. Our strategy is to appropriately modify Algorithm 1.1 and to extend its analysis from [4].

The discretization of (1.1)–(1.3) requires a proper choice of Ansatz spaces for the approximation of $(\mathbf{E}, \mathbf{H})$. Suitable pairs can be found in [14, 15], and we let $\mathbf{X}_h \subset \mathbf{H}_0(\mathbf{curl}; \Omega)$ and $\mathbf{Y}_h \subset L^2(\Omega, \mathbb{R}^3)$ be finite dimensional spaces satisfying $\nabla \times \mathbf{X}_h \subset \mathbf{Y}_h$. We then aim at analyzing the following algorithm for the numerical approximation of MLLG.

ALGORITHM 1.2. *Let* $(\mathbf{m}_h^0, \mathbf{E}_h^0, \mathbf{H}_h^0) \in \mathbf{V}_h \times \mathbf{X}_h \times \mathbf{Y}_h$. *For* $j \geq 0$ *and* $(\mathbf{m}_h^j, \mathbf{E}_h^j, \mathbf{H}_h^j) \in \mathbf{V}_h \times \mathbf{X}_h \times \mathbf{Y}_h$, *let* $(\mathbf{m}_h^{j+1}, \mathbf{E}_h^{j+1}, \mathbf{H}_h^{j+1}) \in \mathbf{V}_h \times \mathbf{X}_h \times \mathbf{Y}_h$ *solve*

$$(1.7)\quad (d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h + \alpha\, (\mathbf{m}_h^j \times d_t \mathbf{m}_h^{j+1}, \boldsymbol{\phi}_h)_h = (1+\alpha^2) \Big(\overline{\mathbf{m}}_h^{j+1/2} \times (\tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}_h} \overline{\mathbf{H}}_h^{j+1/2}), \boldsymbol{\phi}_h \Big)_h \quad \forall\, \boldsymbol{\phi}_h \in \mathbf{V}_h\,,$$

$$(1.8)\quad \varepsilon_0\, (d_t \mathbf{E}_h^{j+1}, \boldsymbol{\varphi}_h) - (\overline{\mathbf{H}}_h^{j+1/2}, \nabla \times \boldsymbol{\varphi}_h) + \sigma\, (\chi_\omega \overline{\mathbf{E}}_h^{j+1/2}, \boldsymbol{\varphi}_h) = -(\overline{\mathbf{J}}_h^{j+1/2}, \boldsymbol{\varphi}_h) \qquad \forall\, \boldsymbol{\varphi}_h \in \mathbf{X}_h\,,$$

$$(1.9)\quad \mu_0\, (d_t \mathbf{H}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) + (\nabla \times \overline{\mathbf{E}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h) = -\mu_0\, (d_t \mathbf{m}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) \qquad \forall\, \boldsymbol{\mathfrak{Z}}_h \in \mathbf{Y}_h\,.$$

Here, $\mathbf{P}_{\mathbf{V}_h} : L^2(\omega, \mathbb{R}^3) \to \mathbf{V}_h$, with $(\mathbf{P}_{\mathbf{V}_h} \mathbf{u}, \boldsymbol{\varphi}_h)_h = (\mathbf{u}, \boldsymbol{\varphi}_h)$ for all $\boldsymbol{\varphi}_h \in \mathbf{V}_h$, denotes the L^2-projection into $\mathbf{V}_h$.

Lemma 3.1 below establishes conservation of $|\, \mathbf{m}_h^j\, | = 1$, $j \geq 0$, at nodes of the triangulation $\mathcal{T}_h$, and a discrete energy law for solutions to Algorithm 1.2. Our first main result is Theorem 3.1, which states unconditional convergence of subsequences of outputs of Algorithm 1.2. A simple fixed-point iteration for the approximate solution of the nonlinear system of equations in each step of Algorithm 1.2, which preserves the unit-length constraint, is proposed in Algorithm 4.1. Its convergence is proved under the mesh constraint $k = \mathcal{O}(h^2)$ in Lemma 4.1. Numerical studies which indicate possible finite-time blow-up of weak solutions of (1.1)–(1.5) are reported in section 5. Simulations of benchmark problems from [8] are also reported.

2. Preliminaries. Throughout this paper we assume that $\mathcal{T}_h$ is a regular triangulation of the polygonal or polyhedral bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$ into triangles or tetrahedra of maximal mesh-size (maximal diameter of triangles or tetrahedra) $h > 0$ for $d = 2$ or $d = 3$, respectively, and $\mathcal{T}_h\big|_\omega$ denotes its restriction to $\omega \Subset \Omega$. We define the lowest order conforming finite element space $\mathbf{V}_h \subset W^{1,2}(\omega; \mathbb{R}^3)$ by

$$\mathbf{V}_h = \big\{ \boldsymbol{\phi}_h \in C(\overline{\omega}; \mathbb{R}^3) : \boldsymbol{\phi}_h|_K \in \mathcal{P}_1(K; \mathbb{R}^3) \quad \forall\, K \in \mathcal{T}_h\big|_\omega \big\}\,,$$

where $\mathcal{P}_1(K; \mathbb{R}^3)$ denotes the set of polynomials of total degree less than or equal to one if restricted to the element $K \in \mathcal{T}_h$. Given the set of nodes $\{\mathbf{x}_\ell : \ell \in L\}$ of the triangulation $\mathcal{T}_h\big|_\omega$, the nodal interpolation operator $\boldsymbol{\mathcal{I}}_{\mathbf{V}_h} : C(\overline{\omega}; \mathbb{R}^3) \to \mathbf{V}_h$ satisfies

$\boldsymbol{\mathcal{I}}_{\mathbf{V}_h}\boldsymbol{\phi}(\mathbf{x}_\ell) = \boldsymbol{\phi}(\mathbf{x}_\ell)$ for all $\ell \in L$. We let $\langle\cdot,\cdot\rangle$ denote the inner product in $\mathbb{R}^d$, and we define

$$\big(\mathbf{f},\mathbf{g}\big) = \int_\Omega \langle \mathbf{f},\mathbf{g}\rangle \,\mathrm{d}\mathbf{x} \qquad \text{and} \qquad \big(\boldsymbol{\phi},\boldsymbol{\mathfrak{Z}}\big)_h = \int_\omega \boldsymbol{\mathcal{I}}_{\mathbf{V_h}}\big(\langle\boldsymbol{\phi},\boldsymbol{\mathfrak{Z}}\rangle\big)\,\mathrm{d}\mathbf{x} = \sum_{\ell\in L}\beta_\ell\langle\boldsymbol{\phi}(\mathbf{x}_\ell),\boldsymbol{\mathfrak{Z}}(\mathbf{x}_\ell)\rangle$$

for $\mathbf{f},\mathbf{g} \in L^2(\Omega;\mathbb{R}^d)$, certain weights $\beta_\ell > 0$, $\ell \in L$, and continuous functions $\boldsymbol{\phi}, \boldsymbol{\mathfrak{Z}} \in C(\overline{\omega};\mathbb{R}^3)$. Note that we use the notation $(\cdot,\cdot)$ for the inner product in $L^2(\Omega)$ as well as in $L^2(\omega)$—it will always be clear from the context which of them it represents. For each $\ell \in L$ we let $\varphi_\ell \in C(\overline{\omega})$ denote the nodal basis function in $\mathbf{V}_h$ which is $\mathcal{T}_h$-elementwise affine and satisfies $\varphi_\ell(\mathbf{x}_m) = \delta_{\ell m}$ for all $m,\ell \in L$, and we define $\beta_\ell = \int_\omega \varphi_\ell \,\mathrm{d}\mathbf{x}$. We write $||\boldsymbol{\phi}||_h^2 = \big(\boldsymbol{\phi},\boldsymbol{\phi}\big)_h$ and notice that

$$\|\,\boldsymbol{\phi}_h\,\|_{L^2}^2 \le \|\,\boldsymbol{\phi}_h\,\|_h^2 \le (d+2)\,\|\,\boldsymbol{\phi}_h\,\|_{L^2}^2 \qquad \forall\,\boldsymbol{\phi}_h \in \mathbf{V}_h\,. \tag{2.1}$$

Basic interpolation estimates yield for all $\boldsymbol{\phi}_h, \boldsymbol{\mathfrak{Z}}_h \in \mathbf{V}_h$ that

$$\big|(\boldsymbol{\phi}_h,\boldsymbol{\mathfrak{Z}}_h)_h - (\boldsymbol{\phi}_h,\boldsymbol{\mathfrak{Z}}_h)\big| \le Ch\|\boldsymbol{\phi}_h\|\,\|\nabla\boldsymbol{\mathfrak{Z}}_h\|\,. \tag{2.2}$$

We define a discrete Laplace operator $\tilde{\Delta}_h : W^{1,2}(\omega;\mathbb{R}^3) \to \mathbf{V}_h$ by

$$(-\tilde{\Delta}_h\boldsymbol{\phi},\boldsymbol{\chi}_h)_h = (\nabla\boldsymbol{\phi},\nabla\boldsymbol{\chi}_h) \quad \forall\,\boldsymbol{\chi}_h \in \mathbf{V}_h\,. \tag{2.3}$$

It is well known that there exist constants $c_1, c_2 > 0$ such that for all $\boldsymbol{\phi}_h \in \mathbf{V}_h$ and all $\ell \in L$ we have (see, e.g., [4])

$$||\tilde{\Delta}_h\boldsymbol{\phi}_h||_h \le c_1 h_{min}^{-1}||\nabla\boldsymbol{\phi}_h||_{L^2} \le c_2 h_{min}^{-2}||\boldsymbol{\phi}_h||_{L^2}\,, \tag{2.4}$$

$$|\tilde{\Delta}_h\boldsymbol{\phi}_h(\mathbf{x}_\ell)| \le c_3 h_{min}^{-2}||\boldsymbol{\phi}_h||_{L^\infty}\,, \tag{2.5}$$

where $h_{min} > 0$ is the minimal diameter of elements in $\mathcal{T}_h$.

To discretize Maxwell's equations, we employ finite element spaces $\mathbf{X}_h \subset \mathbf{H}_0(\mathbf{curl};\Omega)$, $\mathbf{Y}_h \subset L^2(\Omega;\mathbb{R}^3)$ subordinate to $\mathcal{T}_h$ such that $\nabla\times\mathbf{X}_h \subset \mathbf{Y}_h$; common examples are Nédélec's first and second family of edge elements on tetrahedra, where we choose the latter subsequently; cf. [13, Chapter 8.5]

$$\mathbf{X}_h = \big\{\boldsymbol{\varphi}_h \in \mathbf{H}_0(\mathbf{curl};\Omega) : \boldsymbol{\varphi}_h|_K \in \mathcal{P}_1(K;\mathbb{R}^3) \quad \forall\,K \in \mathcal{T}_h\big\}$$

and

$$\mathbf{Y}_h = \big\{\boldsymbol{\mathfrak{Z}}_h \in L^2(\Omega;\mathbb{R}^3) : \boldsymbol{\mathfrak{Z}}_h|_K \in \mathcal{P}_0(K;\mathbb{R}^3) \quad \forall\,K \in \mathcal{T}_h\big\}\,,$$

where global interpolants of sufficiently smooth functions ($\delta > 0$, $p > 2$)

$$\boldsymbol{\mathcal{I}}_{\mathbf{X}_h} : W^{1/2+\delta,2}(\Omega,\mathbb{R}^3) \cap W^{1,p}(\Omega,\mathbb{R}^3) \to \mathbf{X}_h \quad \text{and} \quad \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} : W^{1/2+\delta,2}(\Omega,\mathbb{R}^3) \to \mathbf{Y}_h$$

exist and satisfy [13, Theorem 8.15, Remark 8.8]

$$\|\,\boldsymbol{\varphi} - \boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\boldsymbol{\varphi}\,\|_{L^2} + h\,\|\,\nabla\times(\boldsymbol{\varphi} - \boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\boldsymbol{\varphi})\,\|_{L^2} \le Ch^2\,\|\,\nabla^2\boldsymbol{\varphi}\,\|_{L^2}\,, \tag{2.6}$$

$$\|\,\boldsymbol{\mathfrak{Z}} - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\boldsymbol{\mathfrak{Z}}\,\|_{L^2} \le Ch\,\|\,\boldsymbol{\mathfrak{Z}}\,\|_{H^1} \tag{2.7}$$

for all $\boldsymbol{\varphi} \in W^{2,2}(\Omega,\mathbb{R}^3)$ and $\boldsymbol{\mathfrak{Z}} \in W^{1,2}(\Omega,\mathbb{R}^3)$.

To define weak solutions of (1.1)–(1.3), we assume that the given data satisfy

$$\mathbf{m}_0 \in W^{1,2}(\omega, \mathbb{S}^2)\,, \quad \mathbf{H}_0,\, \mathbf{E}_0 \in L^2(\Omega, \mathbb{R}^3)\,, \quad \mathbf{J} \in L^2(\Omega_T, \mathbb{R}^3)\,. \tag{2.8}$$

We assume that the set of initial data satisfies $\operatorname{div} \mathbf{H}_0 = 0$ and is consistent in the sense that

$$\operatorname{div}(\mathbf{H}_0 + \chi_\omega \mathbf{m}_0) = 0 \quad \text{in } \Omega\,, \qquad \langle \mathbf{H}_0 + \chi_\omega \mathbf{m}_0, \mathbf{n}\rangle = 0 \quad \text{on } \partial\Omega\,. \tag{2.9}$$

Definition 2.1. *Suppose* (2.8)–(2.9) *hold. Then* $(\mathbf{m}, \mathbf{E}, \mathbf{H})$ *is called a weak solution to MLLG if, for all* $T > 0$,

(1) $\mathbf{m} \in L^\infty\big(0,T; W^{1,2}(\omega, \mathbb{R}^3)\big)$, *such that* $\mathbf{m}_t \in L^2(\omega_T, \mathbb{R}^3)$ *and* $|\,\mathbf{m}\,| = 1$ *a.e. in* ω_T, *and* $\mathbf{E}, \mathbf{H} \in L^\infty\big(0,T; L^2(\Omega, \mathbb{R}^3)\big)$;

(2) *for all* $\boldsymbol{\phi} \in C^\infty\big(\overline{\omega_T}; \mathbb{R}^3\big)$ *and* $\boldsymbol{\mathfrak{Z}} \in \mathcal{D}\big([0,T); C^\infty(\Omega, \mathbb{R}^3) \cap \mathbf{H}_0(\mathbf{curl}, \Omega)\big)$,

$$\begin{aligned}(2.10)\quad &\int_{\omega_T} \langle \mathbf{m}_t, \boldsymbol{\phi}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t + \alpha \int_{\omega_T} \langle \mathbf{m}\times\mathbf{m}_t, \boldsymbol{\phi}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t \\ &\qquad = -(1+\alpha^2)\left[\int_{\omega_T} \langle \mathbf{m}\times\nabla\mathbf{m}, \nabla\boldsymbol{\phi}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t - \int_{\omega_T} \langle \mathbf{m}\times\mathbf{H}, \boldsymbol{\phi}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t\right],\end{aligned}$$

$$\begin{aligned}(2.11)\quad &-\varepsilon_0 \int_{\Omega_T} \langle \mathbf{E}, \boldsymbol{\mathfrak{Z}}_t\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t - \int_{\Omega_T} \langle \mathbf{H}, \nabla\times\boldsymbol{\mathfrak{Z}}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t \\ &\qquad + \sigma \int_{\omega_T} \langle \mathbf{E}, \boldsymbol{\mathfrak{Z}}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t = -\int_{\Omega_T} \langle \mathbf{J}, \boldsymbol{\mathfrak{Z}}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t + \varepsilon_0 \int_\Omega \langle \mathbf{E}_0, \boldsymbol{\mathfrak{Z}}(0,\cdot)\rangle \,\mathrm{d}\mathbf{x}\,,\end{aligned}$$

$$\begin{aligned}(2.12)\quad &-\mu_0 \int_{\Omega_T} \langle \mathbf{H} + \chi_\omega \mathbf{m}, \boldsymbol{\mathfrak{Z}}_t\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t + \int_{\Omega_T} \langle \mathbf{E}, \nabla\times\boldsymbol{\mathfrak{Z}}\rangle \,\mathrm{d}\mathbf{x}\,\mathrm{d}t \\ &\qquad = \mu_0 \int_\Omega \langle \mathbf{H}_0, \boldsymbol{\mathfrak{Z}}(0,\cdot)\rangle \,\mathrm{d}\mathbf{x} + \mu_0 \int_\omega \langle \mathbf{m}_0, \boldsymbol{\mathfrak{Z}}(0,\cdot)\rangle \,\mathrm{d}\mathbf{x}\,;\end{aligned}$$

(3) *we have* $\mathbf{m}(0,\cdot) = \mathbf{m}_0$ *in the sense of traces;*

(4) *for almost all* $T' \in (0,T)$ *we have*

$$\begin{aligned}&\mathcal{E}_{(\mathbf{m},\mathbf{H},\mathbf{E})}(T') + \int_{\omega_{T'}} \left(\frac{\alpha\mu_0}{1+\alpha^2}\,|\,\mathbf{m}_t\,|^2 + \sigma|\,\mathbf{E}\,|^2\right) \mathrm{d}\mathbf{x}\,\mathrm{d}t \\ &\qquad \le \mathcal{E}_{(\mathbf{m},\mathbf{H},\mathbf{E})}(0) - \int_{\Omega_{T'}} (\mathbf{J}, \mathbf{E}) \,\mathrm{d}\mathbf{x}\,\mathrm{d}t\,,\end{aligned}$$

where

$$\begin{aligned}&\mathcal{E}_{(\mathbf{m},\mathbf{H},\mathbf{E})}(T') \\ &\qquad = \frac{\mu_0}{2} \int_\omega |\,\nabla\mathbf{m}(T',\cdot)\,|^2 \,\mathrm{d}\mathbf{x} + \int_\Omega \Big[\frac{\mu_0}{2}|\,\mathbf{H}(T',\cdot)\,|^2 + \frac{\varepsilon_0}{2}|\,\mathbf{E}(T',\cdot)\,|^2\Big] \,\mathrm{d}\mathbf{x}\,.\end{aligned}$$

Existence of weak solutions was first shown in [6].

3. Stability and convergence. The following lemma provides a discrete counterpart of (4) in Definition 2.1 for Algorithm 1.2. Solvability of (1.7)–(1.9) follows from a contraction argument, which employs (i) the discrete energy law (Lemma 3.1), (ii) the isomorphism property of the mapping $\mathbf{v} \mapsto \mathbf{v} - \mathbf{u} \times \mathbf{v}$ in $\mathbb{R}^3$ (cf. [2, p. 1079]), and, in particular, (iii) the isomorphism property for the linear problem (1.8)–(1.9). For a less general proof of existence of a solution, see section 4.

LEMMA 3.1. *Suppose that* $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ *for all* $\ell \in L$. *Then the sequence* $\{(\mathbf{m}_h^j, \mathbf{E}_h^j, \mathbf{H}_h^j)\}_{j\geq 0}$ *produced by Algorithm* 1.2 *satisfies for all* $j \geq 0$

$$\text{(i)} \quad |\,\mathbf{m}_h^{j+1}(\mathbf{x}_\ell)\,| = 1 \quad \forall\, \ell \in L\,,$$

$$\text{(ii)} \quad \mathcal{E}_h\big(\{\mathbf{m}_h^{j+1}, \mathbf{H}_h^{j+1}, \mathbf{E}_h^{j+1}\}\big) + k\sum_{\ell=0}^{j} \frac{\alpha\mu_0}{1+\alpha^2} \| \, d_t\mathbf{m}_h^{\ell+1} \, \|_h^2 + \sigma \, \| \, \overline{\mathbf{E}}_h^{\ell+1/2} \, \|_{L^2(\omega)}^2$$

$$= \mathcal{E}_h\big(\{\mathbf{m}_h^0, \mathbf{H}_h^0, \mathbf{E}_h^0\}\big) - k\sum_{\ell=0}^{j} (\overline{\mathbf{J}}_h^{\ell+1/2}, \overline{\mathbf{E}}_h^{\ell+1/2})\,,$$

where

$$\mathcal{E}_h\big(\{\mathbf{m}_h^j, \mathbf{H}_h^j, \mathbf{E}_h^j\}\big) = \frac{\mu_0}{2}\int_\omega |\,\nabla \mathbf{m}_h^j\,|^2 \,\mathrm{d}\mathbf{x} + \int_\Omega \Big[\frac{\mu_0}{2}\,|\,\mathbf{H}_h^j\,|^2 + \frac{\varepsilon_0}{2}\,|\,\mathbf{E}_h^j\,|^2\Big]\,\mathrm{d}\mathbf{x}\,.$$

Proof. Verification of (i) follows from choosing $\boldsymbol{\phi}_h = \varphi_\ell \overline{\mathbf{m}}_h^{j+1/2}(\mathbf{x}_\ell) \in \mathbf{V}_h$ for $\ell \in L$ in (1.7): with the properties of the discrete inner product and the cross product we infer

$$\beta_\ell d_t \big|\mathbf{m}_h^{j+1}(\mathbf{x}_\ell)\big|^2 = \beta_\ell \langle d_t\mathbf{m}_h^{j+1}(\mathbf{x}_\ell), \overline{\mathbf{m}}_h^{j+1/2}(\mathbf{x}_\ell)\rangle = \big(d_t\mathbf{m}_h^{j+1}, \varphi_\ell \overline{\mathbf{m}}_h^{j+1/2}(\mathbf{x}_\ell)\big)_h = 0.$$

Hence, if $|\mathbf{m}_h^j(\mathbf{x}_\ell)| = 1$, then also $|\mathbf{m}_h^{j+1}(\mathbf{x}_\ell)| = 1$. To verify (ii), we first choose $\boldsymbol{\phi}_h = -\big(\tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}_h} \overline{\mathbf{H}}_h^{j+1/2}\big)$ to obtain

$$\frac{1}{2} d_t \| \, \nabla \mathbf{m}_h^{j+1} \, \|_{L^2}^2 - (d_t\mathbf{m}_h^{j+1}, \mathbf{P}_{\mathbf{V}_h} \overline{\mathbf{H}}_h^{j+1/2})_h$$

$$= \alpha\big(\overline{\mathbf{m}}_h^{j+1/2} \times d_t\mathbf{m}_h^{j+1}, \tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}_h} \overline{\mathbf{H}}_h^{j+1/2}\big)_h\,.$$

Choosing $\boldsymbol{\phi}_h = d_t\mathbf{m}_h^{j+1}$ yields

$$\frac{\alpha}{1+\alpha^2} \| \, d_t\mathbf{m}_h^{j+1} \, \|_h^2 = \alpha\Big(\overline{\mathbf{m}}_h^{j+1/2} \times (\tilde{\Delta}_h \overline{\mathbf{m}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}_h} \overline{\mathbf{H}}_h^{j+1/2}), d_t\mathbf{m}_h^{j+1}\Big)_h\,.$$

Adding the last two identities and using the definition of $\mathbf{P}_{\mathbf{V}_h}$ lead to

$$\frac{1}{2} d_t \| \, \nabla \mathbf{m}_h^{j+1} \, \|_{L^2}^2 + \frac{\alpha}{1+\alpha^2} \| \, d_t\mathbf{m}_h^{j+1} \, \|_h^2 = (d_t\mathbf{m}_h^{j+1}, \overline{\mathbf{H}}_h^{j+1/2})\,.$$

In a second step, we choose $(\boldsymbol{\varphi}_h, \boldsymbol{\mathfrak{Z}}_h) = (\overline{\mathbf{E}}_h^{j+1/2}, \overline{\mathbf{H}}_h^{j+1/2})$ in (1.8)–(1.9) and add the resulting identities,

$$d_t\Big(\frac{\mu_0}{2} \| \, \mathbf{H}_h^{j+1} \, \|_{L^2}^2 + \frac{\varepsilon_0}{2} \| \, \mathbf{E}_h^{j+1} \, \|_{L^2}^2\Big) + \sigma \| \, \chi_\omega \overline{\mathbf{E}}_h^{j+1/2} \, \|_{L^2}^2$$

$$= -\mu_0\,(d_t\mathbf{m}_h^{j+1}, \overline{\mathbf{H}}_h^{j+1/2}) - (\overline{\mathbf{J}}_h^{j+1/2}, \overline{\mathbf{E}}_h^{j+1/2})\,.$$

Summation of last two identities then proves assertion (ii). ∎

DEFINITION 3.1. *For* $\mathbf{x} \in \Omega$ *and* $t \in [t_j, t_{j+1})$ *define for* $\boldsymbol{\xi}^\ell = \mathbf{m}_h^\ell, \mathbf{H}_h^\ell, \mathbf{E}_h^\ell, \mathbf{J}_h^\ell$, *and* $\ell = j, j+1$,

$$\tilde{\boldsymbol{\xi}}(t,\mathbf{x}) := \frac{t-t_j}{k}\boldsymbol{\xi}_h^{j+1}(\mathbf{x}) + \frac{t_{j+1}-t}{k}\boldsymbol{\xi}_h^{j}(\mathbf{x})\,,$$

$$\tilde{\boldsymbol{\xi}}^-(t,\mathbf{x}) := \boldsymbol{\xi}_h^j(\mathbf{x})\,, \quad \tilde{\boldsymbol{\xi}}^+(t,\mathbf{x}) := \boldsymbol{\xi}_h^{j+1}(\mathbf{x})\,, \quad \overline{\tilde{\boldsymbol{\xi}}}(t,\mathbf{x}) := \overline{\boldsymbol{\xi}}_h^{j+1/2}\,.$$

Given any $T' \geq 0$, equation (ii) in Lemma 3.1 may be rewritten as

$$\mathcal{E}_{(\tilde{\mathbf{m}}^+,\tilde{\mathbf{H}}^+,\tilde{\mathbf{E}}^+)}(T') + \frac{\alpha\mu_0}{1+\alpha^2}\int_0^{T'} ||\tilde{\mathbf{m}}_t||_h^2\,\mathrm{d}t + \sigma\int_0^{T'} \|\,\overline{\tilde{\mathbf{E}}}\,\|_{L^2(\omega)}^2\,\mathrm{d}t \leq \mathcal{E}_{(\tilde{\mathbf{m}}_0,\tilde{\mathbf{H}}_0,\tilde{\mathbf{E}}_0)}(0) + \int_0^{T'} (\overline{\tilde{\mathbf{J}}}, \overline{\tilde{\mathbf{E}}})\,\mathrm{d}t\,. \tag{3.1}$$

We define $\mathbf{P}_{\mathbf{Y}_h} : L^2(\Omega,\mathbb{R}^3) \to \mathbf{Y}_h$ through $(\mathbf{u} - \mathbf{P}_{\mathbf{Y}_h}\mathbf{u}, \boldsymbol{\varphi}_h) = 0$ for all $\boldsymbol{\varphi}_h \in \mathbf{Y}_h$ and all $\mathbf{u} \in L^2(\Omega,\mathbb{R}^3)$. Letting $\big(\boldsymbol{\phi}_h, \boldsymbol{\varphi}_h, \boldsymbol{\mathfrak{Z}}_h\big)(t,\cdot) := \big(\boldsymbol{\mathcal{I}}_{\mathbf{V}_h}\boldsymbol{\phi}, \boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\boldsymbol{\varphi}, \mathbf{P}_{\mathbf{Y}_h}\boldsymbol{\mathfrak{Z}}\big)(t,\cdot)$ for $\boldsymbol{\phi} \in C^\infty(\omega_T;\mathbb{R}^3)$ and $\boldsymbol{\mathfrak{Z}}, \boldsymbol{\varphi} \in \mathcal{D}\big([0,T); C^\infty(\Omega,\mathbb{R}^3) \cap \mathbf{H}_0(\mathbf{curl},\Omega)\big)$ we may rewrite Algorithm 1.2 as follows:

$$\int_0^T (\tilde{\mathbf{m}}_t, \boldsymbol{\phi}_h)_h\,\mathrm{d}t + \alpha\int_0^T (\tilde{\mathbf{m}}^- \times \tilde{\mathbf{m}}_t, \boldsymbol{\phi}_h)_h\,\mathrm{d}t = (1+\alpha^2)\int_0^T \big(\overline{\tilde{\mathbf{m}}} \times (\tilde{\Delta}_h\overline{\tilde{\mathbf{m}}} + \mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}}), \boldsymbol{\phi}_h\big)_h\,\mathrm{d}t\,, \tag{3.2}$$

$$\varepsilon_0\int_0^T (\tilde{\mathbf{E}}_t, \boldsymbol{\varphi}_h)\,\mathrm{d}t - \int_0^T (\overline{\tilde{\mathbf{H}}}, \nabla\times\boldsymbol{\varphi}_h)\,\mathrm{d}t + \sigma\int_0^T (\chi_\omega\overline{\tilde{\mathbf{E}}}, \boldsymbol{\varphi}_h)\,\mathrm{d}t = \int_0^T (\overline{\tilde{\mathbf{J}}}, \boldsymbol{\varphi}_h)\,\mathrm{d}t\,, \tag{3.3}$$

$$\mu_0\int_0^T (\tilde{\mathbf{H}}_t, \boldsymbol{\mathfrak{Z}}_h)\,\mathrm{d}t + \int_0^T (\nabla\times\overline{\tilde{\mathbf{E}}}, \boldsymbol{\mathfrak{Z}}_h)\,\mathrm{d}t = -\mu_0\int_0^T (\tilde{\mathbf{m}}_t, \boldsymbol{\mathfrak{Z}}_h)\,\mathrm{d}t\,. \tag{3.4}$$

The a priori bounds in Lemma 3.1 provide the existence of a triple

$$(\,\mathbf{m},\mathbf{H},\mathbf{E}\,) \in \big[L^\infty\big(0,T;W^{1,2}(\omega,\mathbb{S}^2)\big) \cap W^{1,2}(\omega_T;\mathbb{R}^3)\big] \times \big[L^\infty\big(0,T;L^2(\Omega;\mathbb{R}^3)\big)\big]^2,$$

which is the weak limit (as $k,h \to 0$) of a subsequence $\big\{(\,\tilde{\mathbf{m}},\tilde{\mathbf{H}},\tilde{\mathbf{E}}\,)\big\}_{k,h}$, such that

$$\tilde{\mathbf{m}}, \tilde{\mathbf{m}}^\pm, \overline{\tilde{\mathbf{m}}} \overset{*}{\rightharpoonup} \mathbf{m} \ \text{ in } L^\infty\big(0,T;W^{1,2}(\omega,\mathbb{R}^3)\big)\,, \quad \tilde{\mathbf{m}} \rightharpoonup \mathbf{m} \ \text{ in } W^{1,2}(\omega_T,\mathbb{R}^3)\,,$$

$$\tilde{\mathbf{m}}, \tilde{\mathbf{m}}^\pm\,\overline{\tilde{\mathbf{m}}} \to \mathbf{m} \ \text{ in } L^2(\omega_T,\mathbb{R}^3)\,,$$

$$(\,\tilde{\mathbf{H}}, \tilde{\mathbf{H}}^\pm, \overline{\tilde{\mathbf{H}}}; \tilde{\mathbf{E}}, \tilde{\mathbf{E}}^\pm, \overline{\tilde{\mathbf{E}}}\,) \overset{*}{\rightharpoonup} (\,\mathbf{H};\mathbf{E}\,) \ \text{ in } \big[L^\infty\big((0,T);L^2(\Omega,\mathbb{R}^3)\big)\big]^2\,.$$

Since $|\,\tilde{\mathbf{m}}^+(\mathbf{x}_\ell)\,| = 1$ for all $\ell \in L$ and all $t \in (0,T)$ by Lemma 3.1(i), we deduce with a discrete Poincaré inequality that

$$\begin{aligned}\big\||\tilde{\mathbf{m}}^+|^2 - 1\big\|_{L^2(K)} &\leq Ch\,\big\|\nabla\big[|\tilde{\mathbf{m}}^+|^2 - 1\big]\big\|_{L^2(K)}\\ &\leq Ch\,\|(\tilde{\mathbf{m}}^+)^T\nabla\tilde{\mathbf{m}}^+\|_{L^2(K)}^2 \leq Ch\,\|\nabla\tilde{\mathbf{m}}^+\|_{L^2(K)}^2\end{aligned}$$

for all $K \in \mathcal{T}_h$ and hence that $|\tilde{\mathbf{m}}^+| \to 1$ a.e. in Ω_T. In particular, we deduce that $|\mathbf{m}| = 1$ a.e. in Ω_T. Owing to item (ii) of Lemma 3.1 and weak lower semicontinuity of norms we verify that $(\,\mathbf{m}, \mathbf{H}, \mathbf{E}\,)$ satisfies part (4) of Definition 2.1. If $\mathbf{m}_h^0 \to \mathbf{m}_0$ in $L^2(\omega;\mathbb{R}^3)$ as $h \to 0$, then weak continuity of the trace operator yields that $\mathbf{m}(0,\cdot) = \mathbf{m}_0$ in the sense of traces.

Identification of limits in (3.2) apart from the last term can be done as in [4], and we discuss the term which involves $\mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}}$. By definition of $\mathbf{P}_{\mathbf{V}_h}$,

$$\begin{aligned}(\overline{\tilde{\mathbf{m}}} \times \mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}}, \boldsymbol{\phi}_h)_h &= -(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h, \mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}})_h = -\big(\boldsymbol{\mathcal{I}}_{\mathbf{V}_h}(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h), \mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}}\big)_h \\ &= -\big(\boldsymbol{\mathcal{I}}_{\mathbf{V}_h}(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h), \overline{\tilde{\mathbf{H}}}\big) \\ &= -\big((\boldsymbol{\mathcal{I}}_{\mathbf{V}_h} - \mathbf{Id})(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h), \overline{\tilde{\mathbf{H}}}\big) - \big(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h, \overline{\tilde{\mathbf{H}}}\big).\end{aligned}$$

Noting that

$$\begin{aligned}\big((\boldsymbol{\mathcal{I}}_{\mathbf{V}_h} - \mathbf{Id})(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h), \overline{\tilde{\mathbf{H}}}\big) &\le Ch^2 \sum_{K\in\mathcal{T}_h} \| D^2(\overline{\tilde{\mathbf{m}}} \times \boldsymbol{\phi}_h) \|_{L^2(K)} \| \overline{\tilde{\mathbf{H}}} \|_{L^2(K)} \\ &\le Ch^2 \| \nabla\overline{\tilde{\mathbf{m}}} \|_{L^2} \| \nabla\boldsymbol{\phi}_h \|_{L^\infty} \| \overline{\tilde{\mathbf{H}}} \|_{L^2},\end{aligned}$$

we deduce that

$$\int_0^T \big(\overline{\tilde{\mathbf{m}}} \times \mathbf{P}_{\mathbf{V}_h}\overline{\tilde{\mathbf{H}}}, \boldsymbol{\phi}_h\big)_h \,\mathrm{d}t \to \int_0^T (\mathbf{m} \times \mathbf{H}, \boldsymbol{\phi})$$

as $h, k \to 0$. To identify the limit in (3.3), we use the identity

$$\int_0^T (\tilde{\mathbf{E}}_t, \boldsymbol{\varphi}_h)\,\mathrm{d}t = -\int_0^T \big(\tilde{\mathbf{E}}, (\boldsymbol{\varphi}_h)_t\big)\,\mathrm{d}t + \big(\mathbf{E}(T,\cdot), \boldsymbol{\varphi}_h(T,\cdot)\big) - \big(\mathbf{E}(0,\cdot), \boldsymbol{\varphi}_h(0,\cdot)\big),$$

and a passage to the limits in the terms on the right-hand side is straightforward owing to their linearity and the convergence properties of $\tilde{\mathbf{E}}$; we proceed accordingly with the leading term in (3.3). It remains to consider the second term in (3.4). Owing to $\nabla \times \mathbf{X}_h \subset \mathbf{Y}_h$, $\mathfrak{Z}_h = \mathbf{P}_{\mathbf{Y}_h}\mathfrak{Z}$, and the properties of $\overline{\tilde{\mathbf{E}}}$, we verify

$$\int_0^T \big(\nabla \times \overline{\tilde{\mathbf{E}}}, \mathfrak{Z}_h\big)dt = \int_0^T \big(\nabla \times \overline{\tilde{\mathbf{E}}}, \mathfrak{Z}\big)dt = \int_0^T (\overline{\tilde{\mathbf{E}}}, \nabla \times \mathfrak{Z})\,\mathrm{d}t \to \int_0^T (\mathbf{E}, \nabla \times \mathfrak{Z})\,\mathrm{d}t.$$

Finally, weak lower semicontinuity of norms and strong convergence of discrete initial data imply the energy inequality in item (4) of Definition 2.1 for the limit $(\,\mathbf{m}, \mathbf{E}, \mathbf{H}\,)$. We have thus proved the following theorem.

THEOREM 3.1. *Let* (2.8)–(2.9) *be valid. Suppose that we have* $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ *for all* $\ell \in L$ *and let* $\{(\,\mathbf{m}_h^j, \mathbf{E}_h^j, \mathbf{H}_h^j\,)\}_{j\ge 0}$ *solve Algorithm* 1.2. *Assume that* $\mathbf{m}_h^0 \to \mathbf{m}_0$ *in* $W^{1,2}(\omega)$ *and* $(\,\tilde{\mathbf{H}}_h^0, \tilde{\mathbf{E}}_h^0\,) \to (\,\mathbf{H}_0, \mathbf{E}_0\,)$ *in* $L^2(\Omega,\mathbb{R}^3)$ *as* $h \to 0$, *and let* $T > 0$ *be a fixed constant. As* $k, h \to 0$, *a subsequence of* $(\,\tilde{\mathbf{m}}, \tilde{\mathbf{H}}, \tilde{\mathbf{E}}\,)$ *converges weakly to* $(\,\mathbf{m}, \mathbf{H}, \mathbf{E}\,)$ *in* $\big[L^\infty\big(0,T;W^{1,2}(\Omega,\mathbb{S}^2)\big) \cap W^{1,2}(\omega_T,\mathbb{R}^3)\big] \times \big[L^\infty\big((0,T);L^2(\Omega,\mathbb{R}^3)\big)\big]^2$, *and* $(\,\mathbf{m}, \mathbf{H}, \mathbf{E}\,)$ *is a weak solution of* (1.1)–(1.3).

In fact, every weak accumulation point of $(\,\tilde{\mathbf{m}}, \tilde{\mathbf{H}}, \tilde{\mathbf{E}}\,)$ solves (1.1)–(1.3). Note also that no discrete version of the compatibility assumption (2.9) is assumed for $(\,\tilde{\mathbf{H}}_h^0, \tilde{\mathbf{E}}_h^0, \mathbf{m}_h^0\,)$.

4. Solving the nonlinear system. We employ a fixed-point iteration to solve the nonlinear system in each step of Algorithm 1.2: Given $\mathbf{m}_h^j$, $\mathbf{H}_h^j$, and $\mathbf{E}_h^j$ (or approximations $\tilde{\mathbf{m}}_h^j$, $\tilde{\mathbf{H}}_h^j$, and $\tilde{\mathbf{E}}_h^j$), we aim at approximating $\mathbf{w}_h := \overline{\mathbf{m}}_h^{j+1/2}$, $\mathbf{F}_h := \overline{\mathbf{E}}_h^{j+1/2}$, and $\mathbf{G}_h := \overline{\mathbf{H}}_h^{j+1/2}$. The time derivative $d_t\mathbf{m}_h^{j+1}$ is replaced by $\frac{2}{k}(\mathbf{w}_h - \mathbf{m}_h^j)$ and similar expressions for $d_t\mathbf{E}_h^{j+1}$ and $d_t\mathbf{H}_h^{j+1}$. A linearization of the nonlinear term $\big(\mathbf{w}_h \times (\tilde\Delta_h \mathbf{w}_h + \mathbf{P}_{\mathbf{L}^2}\mathbf{G}_h), \boldsymbol{\phi}_h\big)_h$ and the identity $\mathbf{m}_h^j \times d_t\mathbf{m}_h^{j+1} = -\frac{2}{k}\overline{\mathbf{m}}_h^{j+1/2} \times \mathbf{m}_h^j$ lead to the following algorithm.

ALGORITHM 4.1. *Set* $(\mathbf{w}_h^0, \mathbf{F}_h^0, \mathbf{G}_h^0) := (\tilde{\mathbf{m}}_h^j, \tilde{\mathbf{E}}_h^j, \tilde{\mathbf{H}}_h^j)$ *and* $\ell := 0$.

(i) *Compute* $(\mathbf{w}_h^{\ell+1}, \mathbf{F}_h^{\ell+1}, \mathbf{G}_h^{\ell+1}) \in \mathbf{V}_h \times \mathbf{X}_h^0 \times \mathbf{Y}_h$ *such that for all* $(\boldsymbol{\phi}_h, \boldsymbol{\varphi}_h, \boldsymbol{\mathfrak{Z}}_h) \in \mathbf{V}_h \times \mathbf{X}_h^0 \times \mathbf{Y}_h$ *there holds*

$$
\begin{aligned}
&\frac{2}{k}(\mathbf{w}_h^{\ell+1}, \boldsymbol{\phi}_h)_h - \frac{2\alpha}{k}(\mathbf{w}_h^{\ell+1} \times \tilde{\mathbf{m}}_h^j, \boldsymbol{\phi}_h)_h \\
&-(1+\alpha^2)\big(\mathbf{w}_h^{\ell+1} \times (\tilde\Delta_h \mathbf{w}_h^\ell + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^\ell), \boldsymbol{\phi}_h\big)_h = \frac{2}{k}(\tilde{\mathbf{m}}_h^j, \boldsymbol{\phi}_h)_h,
\end{aligned} \tag{4.1}
$$

$$
\frac{2\varepsilon_0}{k}(\mathbf{F}_h^{\ell+1}, \boldsymbol{\varphi}_h) - (\mathbf{G}_h^{\ell+1}, \nabla \times \boldsymbol{\varphi}_h) + \sigma(\chi_\omega \mathbf{F}_h^{\ell+1}, \boldsymbol{\varphi}_h) = \frac{2\varepsilon_0}{k}(\tilde{\mathbf{E}}_h^j, \boldsymbol{\varphi}_h) - (\overline{\mathbf{J}}_h^{j+1/2}, \boldsymbol{\varphi}_h),
$$

$$
\frac{2\mu_0}{k}(\mathbf{G}_h^{\ell+1}, \boldsymbol{\mathfrak{Z}}_h) + (\nabla \times \mathbf{F}_h^{\ell+1}, \boldsymbol{\mathfrak{Z}}_h) + \frac{2\mu_0}{k}(\mathbf{w}_h^{\ell+1}, \boldsymbol{\mathfrak{Z}}_h) = \frac{2\mu_0}{k}(\tilde{\mathbf{H}}_h^j, \boldsymbol{\mathfrak{Z}}_h) + \frac{2\mu_0}{k}(\tilde{\mathbf{m}}_h^j, \boldsymbol{\mathfrak{Z}}_h).
$$

(ii) *Stop and set* $(\tilde{\mathbf{m}}_h^{j+1}, \tilde{\mathbf{E}}_h^{j+1}, \tilde{\mathbf{H}}_h^{j+1}) := 2(\mathbf{w}_h^{\ell+1}, \mathbf{F}_h^{\ell+1}, \mathbf{G}_h^{\ell+1}) - (\tilde{\mathbf{m}}_h^j, \tilde{\mathbf{E}}_h^j, \tilde{\mathbf{H}}_h^j)$ *once*

$$
||\tilde\Delta_h(\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell)||_h + ||\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell||_{L^2} \le \varepsilon. \tag{4.2}
$$

(iii) *Set* $\ell := \ell + 1$ *and go to* (i).

For $\varepsilon \to 0$, the output of the iteration converges to the solution of (1.7)–(1.9) (in case $\tilde{\mathbf{m}}_h^j = \mathbf{m}_h^j$, $\tilde{\mathbf{E}}_h^j = \mathbf{E}_h^j$, and $\tilde{\mathbf{H}}_h^j = \mathbf{H}_h^j$) provided that $k \le ch_{min}^2/(1+\alpha^2)$ with a factor $c > 0$ that depends only on the geometry of $\mathcal{T}_h$.

LEMMA 4.1. *Suppose that* $||\tilde{\mathbf{m}}_h^j||_{L^\infty} \le c_0$. *For all* $\ell \ge 0$ *there exists a unique* $(\mathbf{w}_h^{\ell+1}, \mathbf{F}_h^{\ell+1}, \mathbf{G}_h^{\ell+1})$ *solving* (4.1) *and there holds*

$$
\begin{aligned}
&\sqrt{\mu_0/2}||\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell||_h + \sqrt{2\varepsilon_0}||\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell||_{L^2} + \sqrt{\mu_0}||\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell||_{L^2} \\
&\qquad \le \Theta\Big(\sqrt{\mu_0/2}||\mathbf{w}_h^\ell - \mathbf{w}_h^{\ell-1}||_h + \sqrt{\mu_0}||\mathbf{G}_h^\ell - \mathbf{G}_h^{\ell-1}||_{L^2}\Big)
\end{aligned} \tag{4.3}
$$

with $\Theta = c_1^2 c_0 \sqrt{15}(1+\alpha^2)kh_{min}^{-2}$ *provided that* $c_1^2\sqrt{5}h_{min}^{-2} \ge 1$. *Let* $(\tilde{\mathbf{m}}_h^{j+1}, \tilde{\mathbf{E}}_h^{j+1}, \tilde{\mathbf{H}}_h^{j+1})$ *be the output of Algorithm* 4.1. *There exists a function* $\mathbf{R}^j \in \mathbf{V}_h$ *satisfying* $||\mathbf{R}^j||_h \le \varepsilon$ *such that for all* $(\boldsymbol{\phi}_h, \boldsymbol{\varphi}_h, \boldsymbol{\mathfrak{Z}}_h) \in \mathbf{V}_h \times \mathbf{X}_h^0 \times \mathbf{Y}_h$ *there holds*

$$
\begin{aligned}
&(d_t\tilde{\mathbf{m}}_h^{j+1}, \boldsymbol{\phi}_h)_h + \alpha(\tilde{\mathbf{m}}_h^j \times d_t\tilde{\mathbf{m}}_h^{j+1}, \boldsymbol{\phi}_h)_h \\
&\quad - (1+\alpha^2)\big(\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times (\tilde\Delta_h \overline{\tilde{\mathbf{m}}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}^h}\overline{\tilde{\mathbf{H}}}_h^{j+1/2}), \boldsymbol{\phi}_h\big)_h \\
&\quad = (1+\alpha^2)\big(\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times \mathbf{R}^j, \boldsymbol{\phi}_h\big)_h,
\end{aligned} \tag{4.4}
$$

$$
\frac{\varepsilon_0}{k}(d_t\tilde{\mathbf{E}}_h^{j+1}, \boldsymbol{\varphi}_h) - (\overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \nabla \times \boldsymbol{\varphi}_h) + \sigma(\chi_\omega \overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \boldsymbol{\varphi}_h) = -(\overline{\mathbf{J}}_h^{j+1/2}, \boldsymbol{\varphi}_h),
$$

$$
\frac{\mu_0}{k}(d_t\tilde{\mathbf{H}}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) + (\nabla \times \overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h) + \frac{\mu_0}{k}(d_t\tilde{\mathbf{m}}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) = 0.
$$

Moreover, if $|\tilde{\mathbf{m}}_h^j(\mathbf{x}_m)| = 1$ *for all* $m \in L$*, then there holds* $|\tilde{\mathbf{m}}_h^{j+1}(\mathbf{x}_m)| = 1$ *for all* $m \in L$.

Proof. Step 1. For $(\boldsymbol{\phi}_h, \boldsymbol{\varphi}_h, \mathfrak{Z}_h) = (\mathbf{w}_h^{\ell+1}, \mathbf{F}_h^{\ell+1}, \mathbf{G}_h^{\ell+1})$ the sum of the left-hand sides in (4.1) (after multiplication of the first equation by μ_0) equals

$$\frac{2\mu_0}{k}||\mathbf{w}_h^{\ell+1}||_h^2 + \frac{2\varepsilon_0}{k}||\mathbf{F}_h^{\ell+1}||_{L^2}^2 + \sigma||\chi_\omega \mathbf{F}_h^{\ell+1}||_{L^2}^2 + \frac{2\mu_0}{k}||\mathbf{G}_h^{\ell+1}||_{L^2}^2 + \frac{2\mu_0}{k}(\mathbf{w}_h^{\ell+1}, \mathbf{G}_h^{\ell+1}).$$

Since $2(\mathbf{w}_h^{\ell+1}, \mathbf{G}_h^{\ell+1}) \geq -||\mathbf{w}_h^{\ell+1}||_h^2 - ||\mathbf{G}_h^{\ell+1}||_{L^2}^2$, the bilinear form defined by the left-hand side of (4.1) is positive definite on $\big[\mathbf{V}_h \times \mathbf{X}_h^0 \times \mathbf{Y}_h\big]^2$ and (4.1) admits a unique solution.

Step 2. We next control $||\mathbf{w}_h^{\ell+1}||_{L^\infty}$ uniformly for all $\ell \geq 0$: Let $m \in L$ be such that $||\mathbf{w}_h^{\ell+1}||_{L^\infty} = |\mathbf{w}_h^{\ell+1}(\mathbf{x}_m)|$. Putting $\boldsymbol{\phi}_h = \varphi_m \mathbf{w}_h^{\ell+1}(\mathbf{x}_m)$ in the first equation of (4.1) leads to

$$||\mathbf{w}_h^{\ell+1}||_{L^\infty} = |\mathbf{w}_h^{\ell+1}(\mathbf{x}_m)| \leq |\tilde{\mathbf{m}}_h^j(\mathbf{x}_m)| \leq ||\tilde{\mathbf{m}}_h^j||_{L^\infty} \leq c_0. \tag{4.5}$$

Step 3. Subtraction of two subsequent equations of iteration (4.1) shows

$$\begin{aligned}
&\frac{2}{k}(\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell, \boldsymbol{\phi}_h)_h - \frac{2\alpha}{k}\big((\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell) \times \tilde{\mathbf{m}}_h^j, \boldsymbol{\phi}_h\big)_h \\
&\quad -(1+\alpha^2)\big((\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell) \times (\tilde{\Delta}_h \mathbf{w}_h^\ell + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^\ell), \boldsymbol{\phi}_h\big)_h \\
&\quad -(1+\alpha^2)\big(\mathbf{w}_h^\ell \times [(\tilde{\Delta}_h \mathbf{w}_h^\ell + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^\ell) - (\tilde{\Delta}_h \mathbf{w}_h^{\ell-1} + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^{\ell-1})], \boldsymbol{\phi}_h\big)_h = 0, \\
&\frac{2\varepsilon_0}{k}(\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell, \boldsymbol{\varphi}_h) - (\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell, \nabla \times \boldsymbol{\varphi}_h) + \sigma\big(\chi_\omega(\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell), \boldsymbol{\varphi}_h\big) = 0, \\
&\frac{2\mu_0}{k}(\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell, \mathfrak{Z}_h) + \big(\nabla \times (\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell), \mathfrak{Z}_h\big) + \frac{2\mu_0}{k}(\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell, \mathfrak{Z}_h) = 0.
\end{aligned}$$

Adding the three identities (after multiplying the first equation by μ_0) and choosing $(\boldsymbol{\phi}_h, \boldsymbol{\varphi}_h, \mathfrak{Z}_h) = (\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell, \mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell, \mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell)$ provides

$$\begin{aligned}
&\frac{2\mu_0}{k}||\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell||_h^2 + \frac{2\varepsilon_0}{k}||\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell||_{L^2}^2 + \sigma||\chi_\omega(\mathbf{F}_h^{\ell+1} - \mathbf{F}_h^\ell)||_{L^2}^2 \\
&\quad + \frac{2\mu_0}{k}||\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell||_{L^2}^2 \\
&= -\frac{2\mu_0}{k}(\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell, \mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell) \\
&\quad + \mu_0(1+\alpha^2)\big(\mathbf{w}_h^\ell \times [(\tilde{\Delta}_h \mathbf{w}_h^\ell + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^\ell) - (\tilde{\Delta}_h \mathbf{w}_h^{\ell-1} + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^{\ell-1})], \mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell\big)_h \\
&\leq \frac{3\mu_0}{2k}||\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^\ell||_h^2 + \frac{\mu_0}{k}||\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^\ell||_{L^2}^2 \\
&\quad + k\frac{\mu_0}{2}(1+\alpha^2)^2 c_0^2\big(||\tilde{\Delta}_h(\mathbf{w}_h^\ell - \mathbf{w}_h^{\ell-1})||_h + ||\mathbf{P}_{\mathbf{V}^h}(\mathbf{G}_h^\ell - \mathbf{G}_h^{\ell-1})||_h\big)^2.
\end{aligned}$$

The estimates $||\tilde{\Delta}_h \boldsymbol{\phi}_h||_h \leq c_1^2\sqrt{5}h_{min}^{-2}||\boldsymbol{\phi}_h||_h$ and $||\mathbf{P}_{\mathbf{V}^h}\mathfrak{Z}_h||_h \leq ||\mathfrak{Z}_h||_{L^2}$ imply (4.3).

Step 4. In order to prove (4.4) we replace $d_t\tilde{\mathbf{m}}_h^{j+1} = \frac{2}{k}(\mathbf{w}_h^{\ell+1} - \tilde{\mathbf{m}}_h^j)$, $\overline{\tilde{\mathbf{m}}}_h^{j+1/2} = \mathbf{w}_h^{\ell+1}$, etc. in (4.1) to verify with $\mathbf{R}^j := (\tilde{\Delta}_h \mathbf{w}_h^\ell + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^\ell) - (\tilde{\Delta}_h \mathbf{w}_h^{\ell+1} + \mathbf{P}_{\mathbf{V}^h}\mathbf{G}_h^{\ell+1})$

$$
\begin{aligned}
&(d_t\tilde{\mathbf{m}}_h^{j+1}, \boldsymbol{\phi}_h)_h - \frac{2\alpha}{k}(\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times \tilde{\mathbf{m}}_h^j, \boldsymbol{\phi}_h)_h \\
&\qquad - (1+\alpha^2)\big(\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times (\tilde{\Delta}_h \overline{\tilde{\mathbf{m}}}_h^{j+1/2} + \mathbf{P}_{\mathbf{V}^h}\overline{\tilde{\mathbf{H}}}_h^{j+1/2}), \boldsymbol{\phi}_h\big)_h \\
&\qquad = (1+\alpha^2)\big(\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times \mathbf{R}^j, \boldsymbol{\phi}_h\big)_h, \\
&\frac{\varepsilon_0}{k}\,(d_t\tilde{\mathbf{E}}_h^{j+1}, \boldsymbol{\varphi}_h) - (\overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \nabla \times \boldsymbol{\varphi}_h) + \sigma(\chi_\omega \overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \boldsymbol{\varphi}_h) = -(\overline{\mathbf{J}}_h^{j+1/2}, \boldsymbol{\varphi}_h), \\
&\frac{\mu_0}{k}\,(d_t\tilde{\mathbf{H}}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) + (\nabla \times \overline{\tilde{\mathbf{E}}}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h) + \frac{\mu_0}{k}\,(d_t\tilde{\mathbf{m}}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) = 0.
\end{aligned}
$$

Using $\frac{2}{k}\overline{\tilde{\mathbf{m}}}_h^{j+1/2} \times \tilde{\mathbf{m}}_h^j = -\tilde{\mathbf{m}}_h^j \times d_t\tilde{\mathbf{m}}_h^{j+1}$ we verify (4.4), and the stopping criterion implies $||\mathbf{R}||_h \le \varepsilon$.

Step 5. We choose $\boldsymbol{\phi}_h = \varphi_m \overline{\tilde{\mathbf{m}}}_h^{j+1/2}(\mathbf{x}_m)$ in (4.4) to verify $d_t|\tilde{\mathbf{m}}_h^{j+1}(\mathbf{x}_m)|^2 = 0$. ∎

Remark 4.1. Convergence to a weak solution of MLLG of approximations satisfying (4.4) as $(k, h, \varepsilon) \to 0$ such that $\varepsilon = o(h_{min}^2)$ is verified as in section 3. The only difference is a perturbed energy law: instead of (ii) in Lemma 3.1 one has

$$
\begin{aligned}
&\mathcal{E}_h\big(\{\tilde{\mathbf{m}}_h^{j+1}, \tilde{\mathbf{H}}_h^{j+1}, \tilde{\mathbf{E}}_h^{j+1}\}\big) + k\sum_{\ell=0}^{j}(1-\varepsilon)\frac{\alpha\mu_0}{1+\alpha^2}\| d_t\tilde{\mathbf{m}}_h^{\ell+1} \|_h^2 + \sigma \| \overline{\tilde{\mathbf{E}}}_h^{\ell+1/2} \|_{L^2(\omega)}^2 \\
&\qquad \le \mathcal{E}_h\big(\{\tilde{\mathbf{m}}_h^0, \tilde{\mathbf{H}}_h^0, \tilde{\mathbf{E}}_h^0\}\big) - k\sum_{\ell=0}^{j}(\overline{\mathbf{J}}_h^{\ell+1/2}, \overline{\tilde{\mathbf{E}}}_h^{\ell+1/2}) \\
&\qquad + k\sum_{\ell=0}^{j}\left\{(1+\alpha^2)\| \mathbf{R}^\ell \|_h\big(c_3 h_{min}^{-2} + \| \tilde{\mathbf{H}}_h^{\ell+1/2} \|\big) + \frac{1}{4\varepsilon}(1+\alpha^2)\alpha \| \mathbf{R}^\ell \|_h^2\right\}.
\end{aligned}
$$

5. Computational experiments.

5.1. Physical model. Below, let $\mathbf{j} = \frac{\mathbf{J}}{M_s}$, $\mathbf{h} = \frac{\mathbf{H}}{M_s}$, and $\mathbf{e} = \frac{\mathbf{E}}{M_s}$ denote the scaled electric current, magnetic field, and electric field, respectively.

In practical computations, the following physical constants have to be included in the model: the permeability of vacuum μ_0^*, the permittivity of vacuum ε_0^*, the exchange constant A^*, the anisotropy constant K^*, the saturation magnetization M_s, and the gyromagnetic ratio γ. The direction of the uniaxial anisotropy is characterized by a unit vector $\mathbf{p} \in \mathbb{S}^2$. Without loss of generality, we assume that $\mathbf{p}$ is parallel to one of the coordinate axes. The effective field then becomes

$$
\mathbf{h}_{\text{eff}} = A\Delta\mathbf{m} + K\langle \mathbf{m}, \mathbf{p}\rangle \mathbf{p} + \mathbf{h}, \tag{5.1}
$$

with constants

$$
A = \frac{2A^*}{\mu_0^* M_s^2}, \quad K = \frac{2K^*}{\mu_0^* M_s^2}.
$$

The Landau–Lifshitz–Gilbert equation (LLG), which after rescaling in time takes a dimensionless form

$$\mathbf{m}_t + \alpha\,\mathbf{m}\times\mathbf{m}_t = (1+\alpha^2)\,\mathbf{m}\times\mathbf{h}_{\rm eff} \quad \text{in} \quad \omega_T\,, \tag{5.2}$$

now corresponds to a fully physical situation with time measured in units of $(\gamma M_s)^{-1}$s; cf., e.g., [20].

To have the same time scales for the whole MLLG system, the Maxwell equations have to be rescaled in time appropriately. After a change of the time variable and an additional scaling by factor M_s^{-1}, we obtain

$$\varepsilon_0\,\mathbf{e}_t + \nabla\times\mathbf{h} + \sigma\,\chi_\omega\mathbf{e} = -\mathbf{j} \quad \text{on} \quad \Omega_{T^*}, \tag{5.3}$$

$$\mu_0\,\mathbf{h}_t - \nabla\times\mathbf{e} = -\mu_0\,\mathbf{m}_t \qquad \text{on} \quad \Omega_{T^*}\,, \tag{5.4}$$

where $\varepsilon_0 = \gamma M_s\varepsilon_0^*$, $\mu_0 = \gamma M_s\mu_0^*$, and $T^* = \gamma M_s\,T$.

A counterpart of Lemma 3.1 for (5.2)–(5.4) reads as follows.

LEMMA 5.1. *Suppose that* $|\mathbf{m}_h^0(\mathbf{x}_\ell)| = 1$ *for all* $\ell \in L$. *Then the sequence* $\{(\,\mathbf{m}_h^j, \mathbf{E}_h^j, \mathbf{H}_h^j)\}_{j\ge 0}$ *produced by Algorithm* 1.2 *satisfies for all* $j \ge 0$

(i) $\quad |\,\mathbf{m}_h^{j+1}(\mathbf{x}_\ell)\,| = 1 \quad \forall\,\ell \in L\,,$

(ii) $$\mathcal{E}_T := \mathcal{E}_h^*\big(\{\mathbf{m}_h^{j+1}, \mathbf{h}_h^{j+1}, \mathbf{e}_h^{j+1}\}\big) + k\sum_{\ell=0}^{j}\frac{\alpha\mu_0 M_s}{1+\alpha^2}\|\,d_t\mathbf{m}_h^{\ell+1}\,\|_h^2 + \sigma\,\|\,\overline{\mathbf{e}}_h^{\ell+1/2}\,\|_{L^2(\omega)}^2$$

$$= \mathcal{E}_h^*\big(\{\mathbf{m}_h^0, \mathbf{h}_h^0, \mathbf{e}_h^0\}\big) - k\sum_{\ell=0}^{j}(\bar{\mathbf{j}}_h^{\ell+1/2}, \overline{\mathbf{e}}_h^{\ell+1/2})\,,$$

where

$$\begin{aligned}\mathcal{E}_h^*\big(\{\mathbf{m}_h^j, \mathbf{h}_h^j, \mathbf{e}_h^j\}\big) &= \frac{\mu_0 M_s}{2}\int_\omega\Big[A|\,\nabla\mathbf{m}_h^j\,|^2 + K\boldsymbol{\mathcal{I}}_{\mathbf{V}_h}\Big(1-\langle\mathbf{m}_h^j,\mathbf{p}\rangle^2\Big)\Big]\,d\mathbf{x}\\ &\quad + \int_\Omega\Big[\frac{\mu_0}{2}\,|\,\mathbf{h}_h^j\,|^2 + \frac{\varepsilon_0}{2}\,|\,\mathbf{e}_h^j\,|^2\Big]\,d\mathbf{x}\\ &:= \mathcal{E}_{ex} + \mathcal{E}_{anis} + \mathcal{E}_H + \mathcal{E}_E\,.\end{aligned}$$

In the following we refer to $\mathcal{E}_T$ as the total energy and to the terms $\mathcal{E}_{ex}$, $\mathcal{E}_{an}$, $\mathcal{E}_H$, and $\mathcal{E}_E$ as the exchange energy, anisotropy energy, magnetic field energy, and electric field energy, respectively.

Remark 5.1. To obtain physically relevant results, the initial condition for the LLG system should satisfy the "divergence-free" constraint from, i.e., $\mathrm{div}_h(\mathbf{h}_h^0 + \chi_\omega\mathbf{m}_h^0) = 0$. This can be achieved by taking $\mathbf{h}_h^0 = \mathbf{h}_*^0 - \chi_\omega(\mathbf{P}_h^*\mathbf{m}_h^0)$, with $\mathbf{h}_*^0 \in \mathbf{Y}_h$ such that $\mathrm{div}_h\mathbf{h}_*^0 = 0$. The projection $\mathbf{P}_h^* : \mathbf{V}_h \to \mathbf{Y}_h$ is for $\mathbf{u}_h \in \mathbf{V}_h$ defined through $(\mathbf{P}_h^*\mathbf{u}_h, \boldsymbol{\mathfrak{Z}}_h) = (\mathbf{u}_h, \boldsymbol{\mathfrak{Z}}_h)$ for all $\boldsymbol{\mathfrak{Z}}_h \in \mathbf{Y}_h$. Since $\mathbf{m}_h^j$ is piecewise linear, we have that the value of $\mathbf{P}_h^*\mathbf{m}_h^j$ on an element $K \in \mathcal{T}_h\big|_\omega$ corresponds to the value of $\mathbf{m}_h^j$ in the barycenter of K. Further, we have from (1.9) that

$$\begin{aligned}&\frac{\mu_0}{k}\,(\mathbf{h}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h) + \frac{\mu_0}{k}\,(\mathbf{P}_h^*\mathbf{m}_h^{j+1}, \boldsymbol{\mathfrak{Z}}_h)\\ &\qquad = -(\nabla\times\mathbf{e}_h^{j+1/2}, \boldsymbol{\mathfrak{Z}}_h) + \frac{\mu_0}{k}\,(\mathbf{h}_h^j, \boldsymbol{\mathfrak{Z}}_h) + \frac{\mu_0}{k}\,(\mathbf{P}_h^*\mathbf{m}_h^j, \boldsymbol{\mathfrak{Z}}_h) \quad \forall\,\boldsymbol{\mathfrak{Z}}_h \in \mathbf{Y}_h.\end{aligned}$$

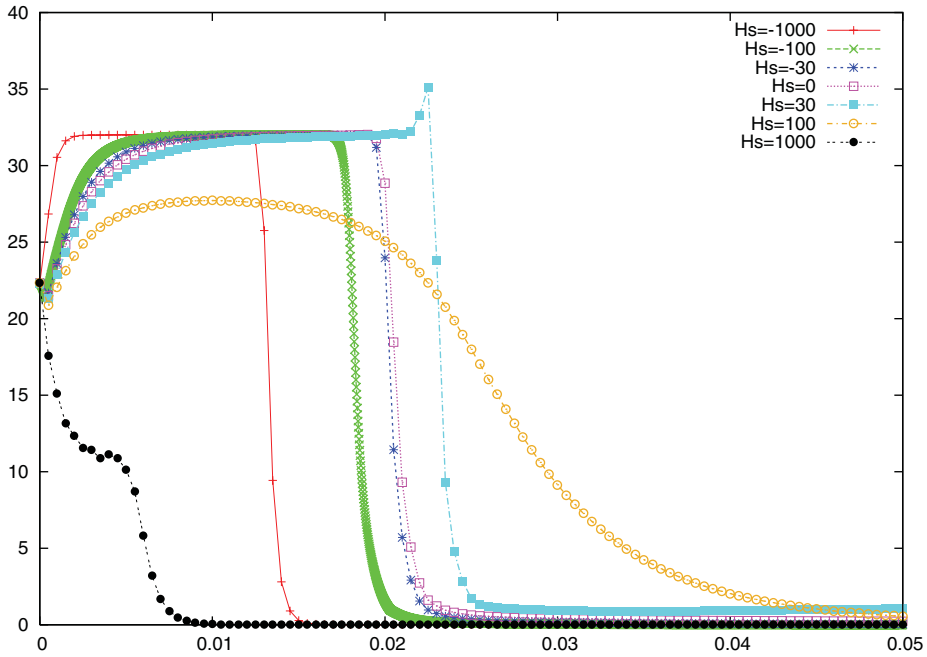

FIG. 1. *Example* 5.1: *Plot of* $t \mapsto \|\nabla \mathbf{m}_h(t,\cdot)\|_\infty$.

From the previous equation, it can be deduced by induction that $\mathrm{div}_h(\mathbf{h}_h^{j+1} + \chi_\omega(\mathbf{P}_{\mathbf{Y}_h}\mathbf{m}_h^{j+1})) = 0$ is satisfied pointwise in Ω. The above arguments remain valid for (4.1). In our experiments, we simply take $\mathbf{h}_*^0$ to be a constant vector field.

5.2. Solution of the discrete system. Without loss of generality, we consider the discrete system with $\sigma = 0$. The first equation from (4.1), corresponding to the discrete LLG equation, is efficiently solved by the biconjugate gradient stabilized (BiCGStab) method. The solution of the second and third equations from (4.1) is equivalent to solving a discrete algebraic system of the form

$$\begin{pmatrix} \mathbf{A} & -\mathbf{C}^T \\ \mathbf{C} & \mathbf{B} \end{pmatrix} \begin{pmatrix} \overline{\mathbf{e}} \\ \overline{\mathbf{h}} \end{pmatrix} = \begin{pmatrix} \overline{\mathbf{f}} \\ \overline{\mathbf{g}} \end{pmatrix}, \tag{5.5}$$

where

$$\mathbf{A}_{ij} = \frac{2\varepsilon_0}{k}(\boldsymbol{\varphi}_h^i, \boldsymbol{\varphi}_h^j), \quad \mathbf{B}_{ij} = \frac{2\mu_0}{k}(\boldsymbol{\mathfrak{Z}}_h^i, \boldsymbol{\mathfrak{Z}}_h^j), \quad \mathbf{C}_{ij} = (\nabla \times \boldsymbol{\varphi}_h^j, \boldsymbol{\mathfrak{Z}}_h^i),$$

and the vectors of unknowns $\overline{\mathbf{e}} = \{e_i\}$, $\overline{\mathbf{h}} = \{h_i\}$ are defined through

$$\mathbf{F}_h = \sum_i e_i \boldsymbol{\varphi}_h^i, \quad \mathbf{G}_h = \sum_i h_i \boldsymbol{\mathfrak{Z}}_h^i.$$

Similarly, we define $\overline{\mathbf{f}} = \{f_i\}$, $\overline{\mathbf{g}} = \{g_i\}$, where $\mathbf{f} = \sum_i f_i \boldsymbol{\varphi}_h^i$ and $\mathbf{g} = \sum_i g_i \boldsymbol{\mathfrak{Z}}_h^i$ represent the right-hand sides of the discrete problem.

The system (5.5) can be effectively solved by a preconditioned inexact Uzawa method which consists of two steps:

1. $\overline{\mathbf{h}}^n = \mathbf{B}^{-1}(\overline{\mathbf{g}} - \mathbf{C}\overline{\mathbf{e}}^n)$,

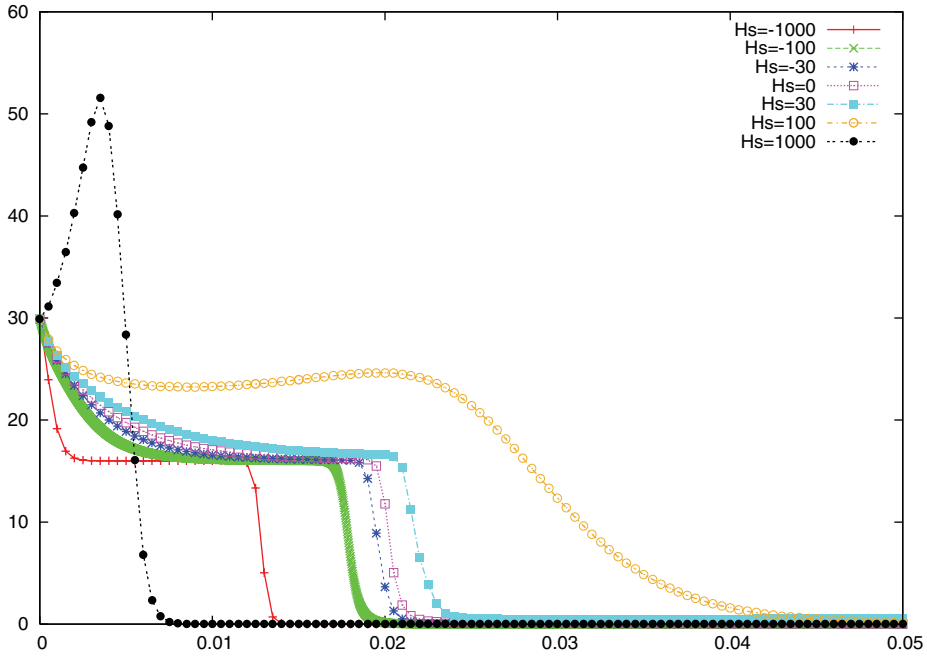

FIG. 2. *Example* 5.1: *Plot of* $t \mapsto \|\nabla \mathbf{m}_h(t,\cdot)\|_2$.

2. $\overline{\mathbf{e}}^{n+1} = \overline{\mathbf{e}}^n + \rho \mathbf{S}^{-1}(\overline{\mathbf{f}} + \mathbf{C}^T \overline{\mathbf{h}}^n - \mathbf{A}\overline{\mathbf{e}}^n)$.

Here, $\rho > 0$ is a constant (we set $\rho = 1$ below), and $\mathbf{S}^{-1}$ is a suitably chosen preconditioner that can considerably speed up the convergence of the Uzawa iterations. Note that the computation of $\mathbf{B}^{-1}$ in the first step of the above Uzawa algorithm is trivial, since the matrix $\mathbf{B}$ is diagonal, owing to the choice of piecewise constant functions.

The preconditioner $\mathbf{S}$ is an approximation of the Schur complement, i.e.,

$$\mathbf{S} \approx (\mathbf{C}^T \mathbf{B}^{-1} \mathbf{C}) + \mathbf{A}\,.$$

The construction of the preconditioner is motivated by the fact that our formulation can be (formally) considered as a mixed approximation of an eddy current problem of the form

$$\frac{2\varepsilon_0}{k}(\mathbf{F}_h^*, \boldsymbol{\varphi}) + \frac{k}{2\mu_0}(\nabla \times \mathbf{F}_h^*, \nabla \times \boldsymbol{\varphi}) = (\mathbf{f}, \boldsymbol{\varphi}) + \frac{k}{2\mu_0}(\nabla \times \mathbf{g}, \boldsymbol{\varphi}) \qquad \forall \boldsymbol{\varphi} \in \mathbf{H}_0(\mathbf{curl}; \Omega).$$

In matrix notation we have $\mathbf{S} = \mathbf{M} + \mathbf{R}$, with matrices

$$\mathbf{M}_{ij} = \frac{2\varepsilon_0}{k}(\boldsymbol{\varphi}_h^i, \boldsymbol{\varphi}_h^j)\,, \quad \mathbf{R}_{ij} = \frac{k}{2\mu_0}(\nabla \times \boldsymbol{\varphi}_h^i, \nabla \times \boldsymbol{\varphi}_h^j)\,.$$

We compute the approximation of $\mathbf{S}^{-1}$ by the BiCGStab algorithm with at most 50 iterations for every substep. A better approximation of $\mathbf{S}^{-1}$ can be obtained by using a multigrid method for eddy current equations (see, e.g., [9]), which together with the moderate number of outer Uzawa iterations gives an effective method with multigrid complexity.

It is possible to eliminate $\overline{\mathbf{h}}$ from (5.5), which leads to a system of equations in the Schur complement form

$$\big(\mathbf{C}^T \mathbf{B}^{-1} \mathbf{C} + \mathbf{A}\big)\,\overline{\mathbf{e}} = \overline{\mathbf{f}} + \mathbf{C}^T \mathbf{B}^{-1} \overline{\mathbf{g}}\,. \tag{5.6}$$

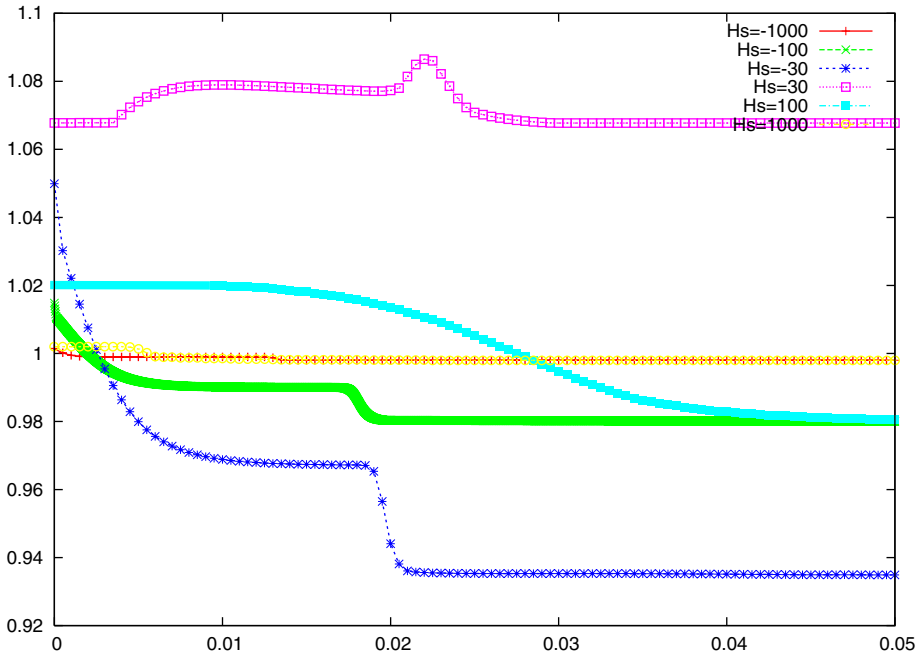

FIG. 3. *Example* 5.1: *Plot of* $t \mapsto \|\mathbf{h}_h(t,\cdot)\|_\infty/|H_s|$.

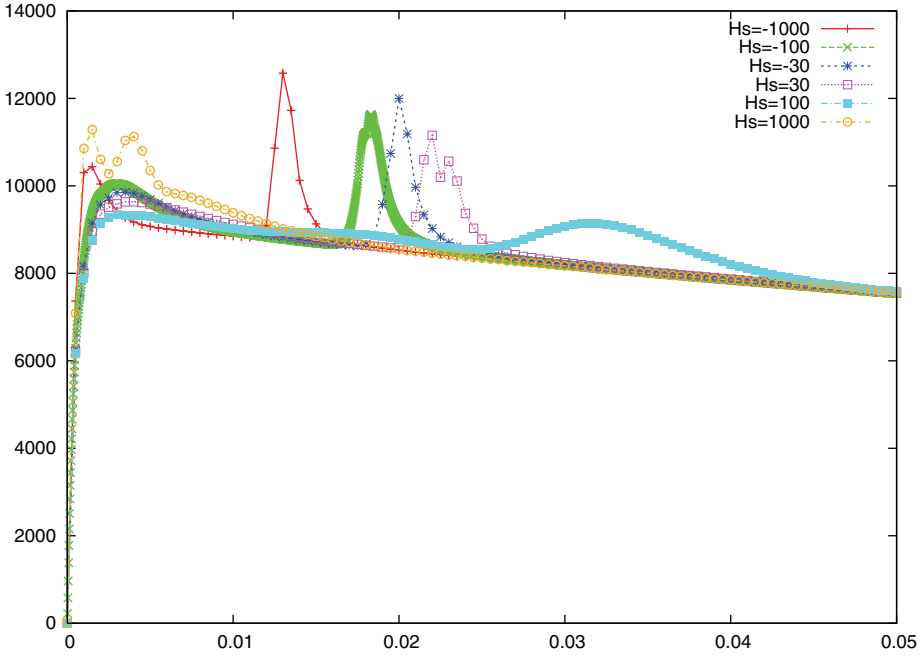

FIG. 4. *Example* 5.1: *Plot of* $t \mapsto \|\mathbf{e}_h(t,\cdot)\|_\infty$.

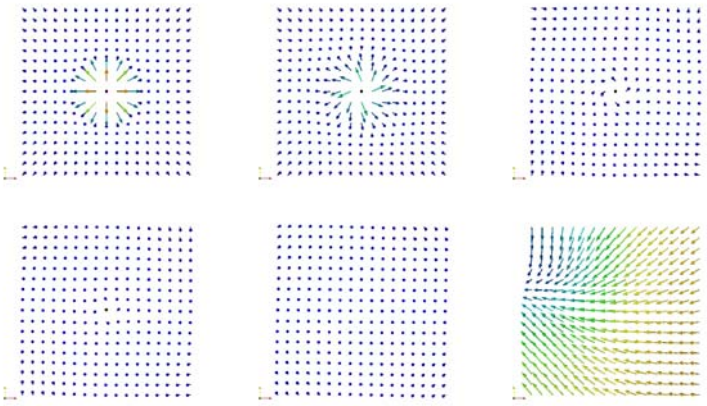

FIG. 5. *Example* 5.1: *Magnetization for* $H_s = 30$ *at times* $t = 0, 0.01, 0.015, 0.020, 0.030, 0.214$ *for* $h = 1/2^4$ *(from left to right, from top to bottom).*

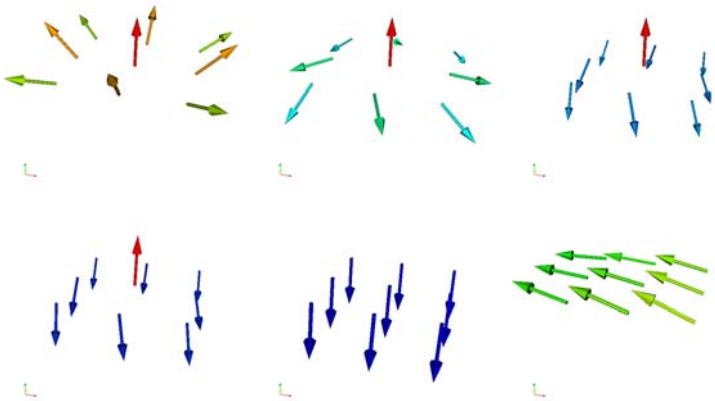

FIG. 6. *Example* 5.1: *Details of the magnetization for* $H_s = 30$ *near* $\mathbf{x} = (0.5, 0.5, 0.5)$ *at times* $t = 0, 0.01, 0.015, 0.020, 0.030, 0.214$ *for* $h = 1/2^4$ *(from left to right, from top to bottom).*

An alternative approach to the Uzawa algorithm is to solve (5.6) by the conjugate gradient method; see, e.g., [17] and the references therein. The conjugate gradient algorithm needs to evaluate $\mathbf{B}^{-1}$, which is trivial, since $\mathbf{B}$ is diagonal. We can speed up the convergence of the conjugate gradient algorithm by using a suitable preconditioner. In our case, one could use the same preconditioner as for the Uzawa algorithm. We use the conjugate gradient algorithm for (5.6) without preconditioning in our experiments, since it proves to be slightly faster than the preconditioned Uzawa algorithm. We expect both methods to have comparable performance with effective multigrid preconditioners; cf. [17].

Remark 5.2. We observe slow convergence of the algebraic solvers for domains of size $\mathcal{O}(10^{-6})$, i.e., in practical applications. The convergence properties of the solvers improve for larger values of the gyromagnetic ratio γ or for smaller sizes of the time step k. We believe that the convergence rates can be substantially improved with a suitable multigrid preconditioner. Note that similar problems with solver

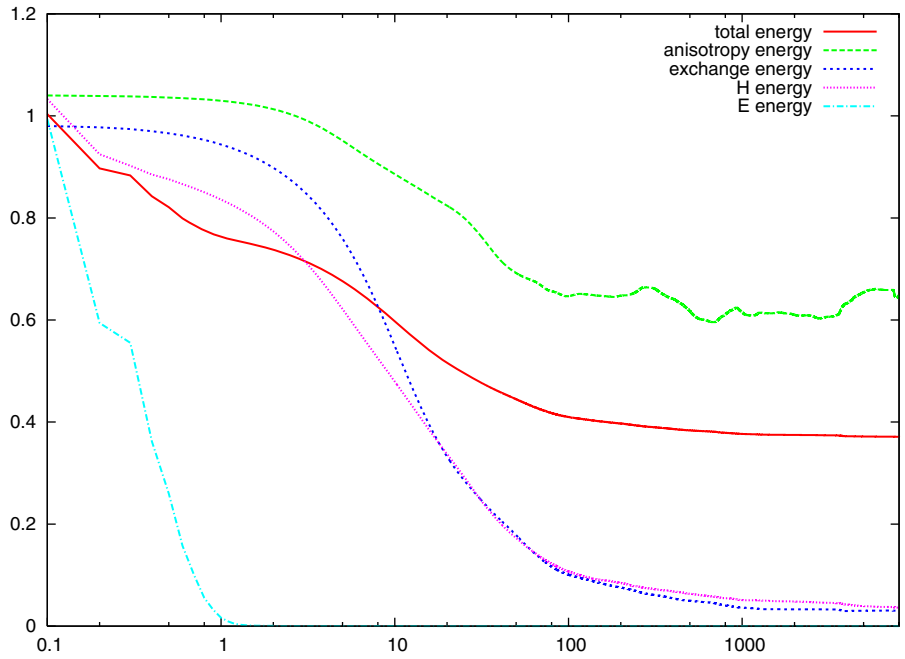

FIG. 7. *Example* 5.2: *Evolution of the energies,* $\log(t) \mapsto \mathcal{E}_T(t)/22$, $\mathcal{E}_{ex}(t)/11$, $\mathcal{E}_{an}(t)/0.04$, $\mathcal{E}_H(t)/7$, $\mathcal{E}_E(t)/4$.

convergence in micromagnetic applications are reported in [22], where a conjugate gradient algorithm is applied to the eddy current formulation of Maxwell's equations.

5.3. Computational results. Our computational code is based on the finite element package ALBERT (see [19]) with tetrahedral meshes in three dimensions. We use standard piecewise linear elements for the discretization of $\mathbf{m}_h$, with degrees of freedom (DOFs) located at the vortices of the mesh, and piecewise constant elements for $\mathbf{h}_h$, with DOFs located at the barycenters of the mesh elements. We discretize $\mathbf{e}_h$ by edge elements of the first kind, with one DOF per every edge of the mesh. The edge elements of the first kind have only slightly worse approximation properties than the edge elements of the second kind; however, the latter need two DOFs per edge. In our code we replace (4.2) in Algorithm 4.1 by a slightly more practical stopping criterion for the fixed-point iterations, i.e.,

$$\begin{aligned} ||\mathbf{w}_h^{\ell+1} - \mathbf{w}_h^{\ell}||_h &\leq h^2\varepsilon, \\ ||\mathbf{G}_h^{\ell+1} - \mathbf{G}_h^{\ell}||_{L^2} &\leq \varepsilon. \end{aligned}$$

We choose $\varepsilon = 10^{-8}$ in our computations. The convergence of the fixed-point iterations is attained after at most six steps in all presented experiments. We observe monotone decrease of the discrete energy from Lemma 5.1 in all experiments, which confirms good numerical convergence of Algorithm 4.1.

The first example is academic and studies possible finite-time blow-up behavior of weak solutions to (1.1)–(1.5) with the help of Algorithm 1.2. We say that (discrete) finite-time blow-up occurs if the sequence $\left\{||\nabla \mathbf{m}_h^j||_{L^\infty}\right\}_j$ attains the maximum value of the mapping $\mathbf{v}_h \mapsto ||\nabla \mathbf{v}_h||_{L^\infty}$ among functions $\mathbf{v}_h \in \mathbf{V}_h$ satisfying $|\mathbf{v}_h(\mathbf{x}_\ell)| = 1$ for all $\ell \in L$. Corresponding studies are reported in [4, 3] for $\mathbf{h}_{\text{eff}} = \Delta\mathbf{m}$ and $\omega \subset \mathbb{R}^2$, where blow-up is computationally evidenced for supercritical (initial) data. Here, we

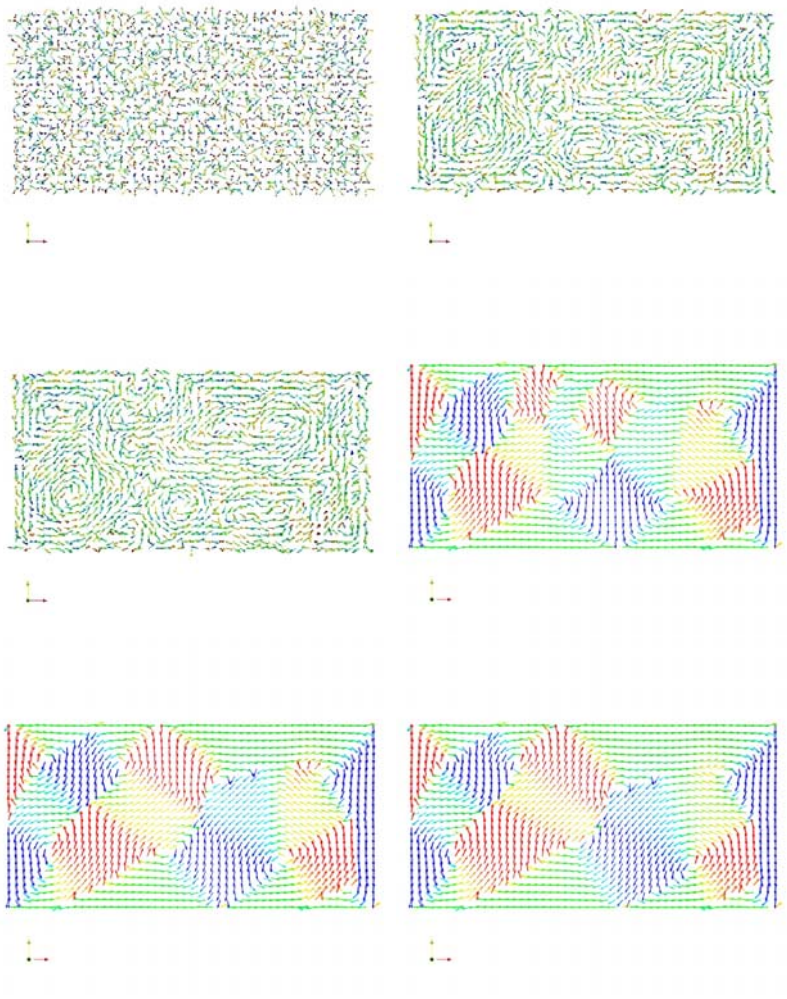

FIG. 8. *Example* 5.2: *Magnetization at times* $t = 0, 100, 200, 2500, 5000, 8000$ *(from left to right, from top to bottom).*

study the influence of the electromagnetic field $(\mathbf{e}^0, \mathbf{h}^0) : \Omega \to \mathbb{R}^3$ on the supercritical $\mathbf{m}^0 : \omega \to \mathbb{S}^2$.

Example 5.1. Let $(0,1)^3 = \omega = \Omega$ and $\mathbf{j} \equiv 0$. Let $\mathbf{m}^0 : \omega \to \mathbb{S}^2$ and $(\mathbf{e}^0, \mathbf{h}^0) : \Omega \to \left[\mathbb{R}^3\right]^2$ be defined by

$$\mathbf{m}^0(\mathbf{x}) = \begin{cases} (0,0,-1) & \text{for } |\mathbf{x}^*| \geq 1/2, \\ (2\mathbf{x}^* A, A^2 - |\mathbf{x}^*|^2)/(A^2 + |\mathbf{x}^*|^2) & \text{for } |\mathbf{x}^*| \leq 1/2 \text{ and } \mathbf{x}^* \in \omega, \end{cases}$$

$$\mathbf{h}^0_*(\mathbf{x}) = (0,0,H_s) \qquad \text{in } \Omega\,,$$

$$\mathbf{e}^0(\mathbf{x}) = (0,0,0) \qquad \text{in } \Omega,$$

with $\mathbf{x}^* = (x_1 - 0.5, x_2 - 0.5, 0)$ and $A = (1 - 2|\mathbf{x}^*|)^4/4$. The computational domain

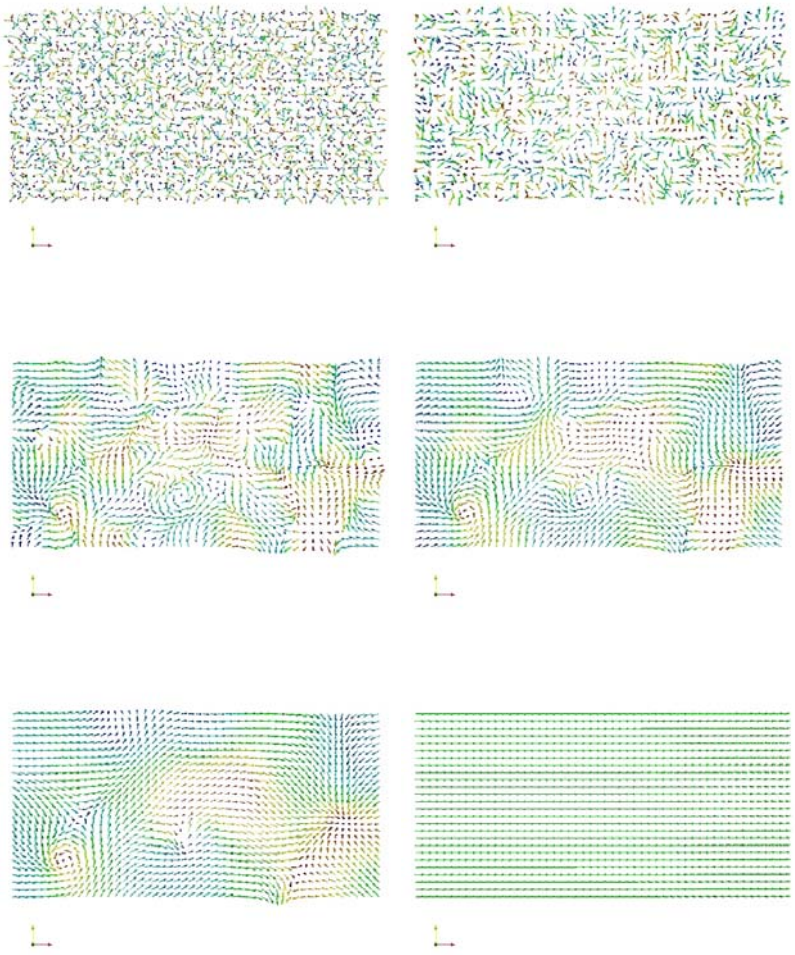

FIG. 9. *Example* 5.2: *Magnetization without the magnetic field at times* $t = 0, 10, 50, 100, 200, 2500$ *(from left to right, from top to bottom).*

$\Omega = \omega = (0,1)^3$ is partitioned into uniform cubes with side h, each cube consisting of six tetrahedra. We choose the time step $k = 10^{-5}$ and set the other parameters $\alpha = \gamma = M_s = \mu_0 = 1$, $\varepsilon_0 = 10^{-6}$, $K = 0$.

The constant H_s represents the strength of initial field in the x_3-direction. We computed the experiments for $H_s = -30, 0, 30$ on meshes with $h = 1/2^4$ and $h = 1/2^5$. The evolution of $\|\nabla \mathbf{m}_h\|_\infty$ is depicted in Figure 1. The evolution of the exchange energy can be found in Figure 2. Figure 3 displays the evolution of $\|\mathbf{h}_h\|_\infty / H_s$. We deduce from Figures 1 and 3 that variations of $\|\nabla \mathbf{m}_h\|_\infty$ close to a certain time $T^* > 0$ ("blow-up time") correspond to variations of $\|\mathbf{h}_h\|_\infty$ close to the same time T^*. Similar behavior is found for the evolution of $\|\mathbf{e}_h\|_\infty$, which is depicted in Figure 4. Further, we observe that the mesh-size not only determines the quantity $\max_t \|\nabla \mathbf{m}_h(t,\cdot)\|_\infty$ (cf. [4, 3]), but also influences the evolution of $\|\mathbf{h}_h\|_\infty$, $\|\mathbf{e}_h\|_\infty$. The computations with $H_s = -30$ show that a negative initial magnetic field accelerates the blow-up of

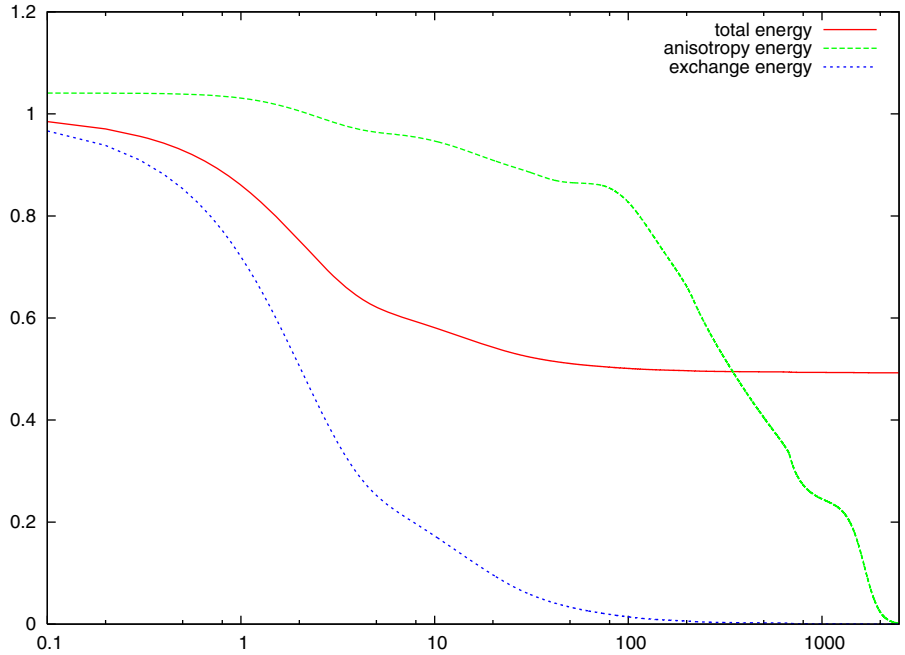

FIG. 10. *Example* 5.2: *Evolution of the energies,* $\log(t) \mapsto \mathcal{E}_T(t)/11$, $\mathcal{E}_{ex}(t)/11$, $\mathcal{E}_{an}(t)/0.04$.

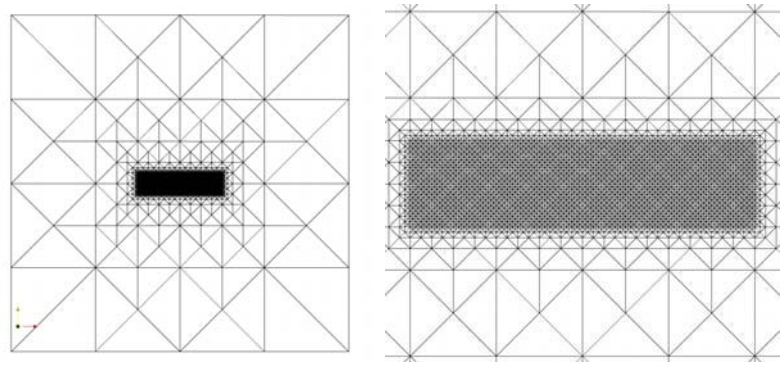

FIG. 11. *Example* 5.3: *Mesh for the domain* Ω *at* $x_3 = 0$ *(left) and zoom at the mesh for the domain* ω *at* $x_3 = 0$ *(right).*

the solution. The evolution becomes more complex for $H_s = 30$; the blow-up time is slightly delayed. Beyond the instability, when the magnetization is aligned along the $(0, 0, -1)$-direction, the influence of the magnetic field on the evolution prevails and the magnetization starts to rotate in the opposite direction, i.e., $(0, 0, 1)$; see Figure 5 for $h = 2^{-4}$. We did not compute beyond the time $t = 0.214$; however, it is reasonable to expect that the magnetization will be aligned in the $(0, 0, 1)$-direction after the steady state is reached. The details of the solution for $H_s = 30$, $h = 2^{-4}$ near $\mathbf{x} = (0.5, 0.5, 0.5)$ are depicted in Figure 6. There was only a little variation of the magnetization in the x_3-direction; we therefore present all results on the cross-cut through the domain at $x_3 = 0.5$.

For comparison, Figure 9 shows the evolution of magnetization with the same

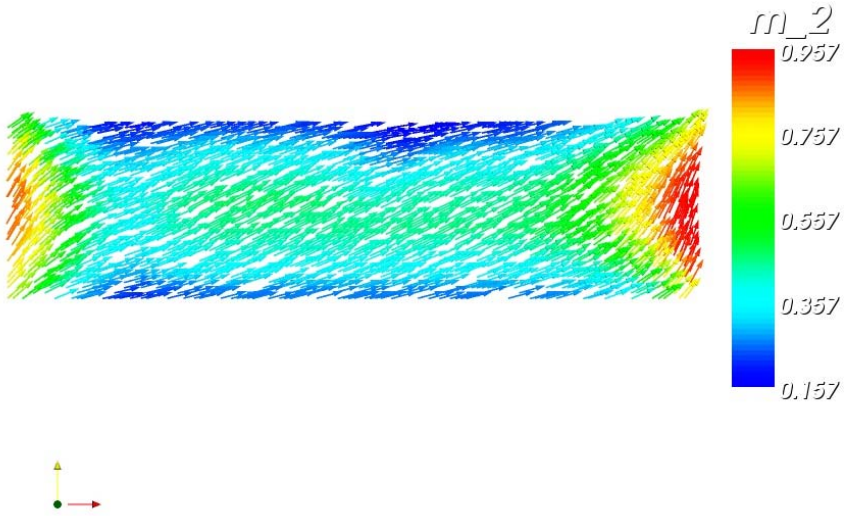

FIG. 12. *Example* 5.3: *Magnetization at time* $t = 300$*, near the S-state.*

initial condition computed without taking the coupling with Maxwell's equations into account. The evolution of the discrete energies $\mathcal{E}_T$, $\mathcal{E}_{ex}$, $\mathcal{E}_{an}$ is displayed in Figure 10 (note that $\mathcal{E}_H = \mathcal{E}_E \equiv 0$). The figures show a clear difference between the two cases.

The following example is derived from a benchmark problem [8, Problem #1] of a thin uniaxial ferromagnetic film, for which long-time dynamics is studied in [15], in the case $d = 2$. Here, we study the dynamics of the problem for $d = 3$. According to our knowledge, there are no comparable studies for $d = 3$ in the existing literature.

Example 5.2. Let $\omega = (0, 2) \times (0, 1) \times (0, 0.02)$ and $\Omega = (-0.2, 2.2) \times (-0.2, 1.2) \times (-0.04, 0.06)$ (the domain dimensions are in μm), with

$$\alpha = 0.5, \quad \gamma = 2.2 \times 10^9, \quad M_s = 8 \times 10^5, \quad K^* = 5 \times 10^2, \quad A^* = 1.3 \times 10^{-11},$$
$$\mathbf{p} = (1, 0, 0), \quad \varepsilon_0^* = 0.88422 \times 10^{-11}, \quad \mu_0^* = 1.25667 \times 10^{-6}, \quad \sigma = 0,$$

and ($\mathbf{j} \equiv \mathbf{0}$)

$$(\mathbf{e}^0, \mathbf{h}^0) = (\mathbf{0}, \mathbf{0}) \quad \text{in } \Omega.$$

The initial condition $\mathbf{m}_h^0$ is defined by assigning unit vectors with random orientation to every vortex of the mesh.

The domains Ω and ω are partitioned into bricks of dimension $0.04 \times 0.04 \times 0.02$. Subsequently, the corresponding computational meshes are obtained by subdivision of each brick into six tetrahedra. This partition results in 7956 DOFs for $\mathbf{m}_h$ on ω and

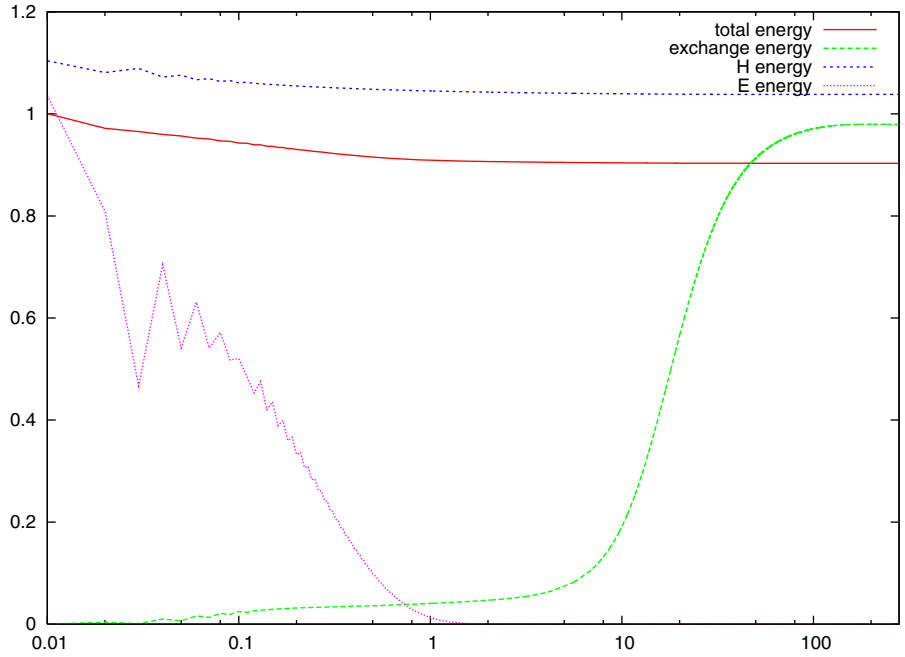

FIG. 13. *Example* 5.3: *Evolution of the energies,* $\log(t) \mapsto \mathcal{E}_T(t)/2.3$, $\mathcal{E}_{ex}(t)/0.0004$, $\mathcal{E}_H(t)/2$, $\mathcal{E}_E(t)/0.09$.

189000, 81325 DOFs for $\mathbf{e}_h$, $\mathbf{h}_h$ on Ω, respectively. We compute on a time interval $(0, 8000)$ using a uniform time step $k = 0.1$.

The evolution of the discrete energies $\mathcal{E}_T$, $\mathcal{E}_{ex}$, $\mathcal{E}_{an}$, $\mathcal{E}_H$, $\mathcal{E}_E$ (i.e., the total, exchange, anisotropy, magnetic field energy, and electric field energy) from Lemma 5.1 is depicted in Figure 7. Snapshots of the magnetization at different time levels can be found in Figure 8; the vectors are colored according to the value of the x_2-component of the magnetization vector.

The data for the last example are taken from [8, Problem #4]. Here we study the evolution of the magnetization toward a steady state, the so-called S-state; cf. [8, Problem #4].

Example 5.3. Let $\omega = (0, 0.5) \times (0, 0.125) \times (0, 0.003)$ and $\Omega = (-0.75, 1.25) \times (-0.9375, 1.0625) \times (-0.7665, 0.7695)$ (in μm), with

$$\alpha = 1, \quad \gamma = 2.2 \times 10^9, \quad M_s = 8 \times 10^5, \quad K^* = 0, \quad A^* = 1.3 \times 10^{-11},$$
$$\varepsilon_0^* = 0.88422 \times 10^{-11}, \quad \mu_0^* = 1.25667 \times 10^{-6}, \quad \sigma = 0,$$

and ($\mathbf{j} \equiv \mathbf{0}$)

$$\mathbf{m}^0 = (\,1, 0, 0\,) \quad \text{in } \omega\,,$$
$$\mathbf{h}_*^0 = (0.01, 0.01, 0.01), \quad \mathbf{e}^0 = \mathbf{0} \quad \text{in } \Omega\,.$$

The domain ω is partitioned uniformly into cubes of dimensions $0.00390625 \times 0.00390625 \times 0.003$, where each cube consists of six tetrahedra. The nonuniform mesh for the domain Ω is constructed in such a way that it is identical to the mesh for ω in the region $\Omega \cap \omega$ and the mesh-size gradually increases away from the overlapping region. A cross-cut through the mesh at $x_3 = 0$ is displayed in Figure 11.

The above discretization of the computational domains results in $25,542$ DOFs for $\mathbf{m}_h$ on ω and $138,302$, $353,568$ DOFs for $\mathbf{e}_h$, $\mathbf{h}_h$, respectively. We employ a uniform time stepping, with $k = 0.01$.

The magnetization at time $T = 300$ is displayed in Figure 12; the vectors are colored according to the x_2-component of the magnetization. Convergence toward the S-state (cf. [8, Problem #4]) can be observed from the results. No steady state has yet been reached at the final time; however, the convergence toward the steady state after the time $T = 300$ has been very slow. The evolution of the discrete energies from Lemma 5.1 is depicted in Figure 13.

6. Concluding remarks. We devised an implicit discretization of the MLLG system which is based on linear finite elements. For pairs of time-step sizes and mesh-sizes tending simultaneously but independently to zero, we showed that every accumulation point of the sequence of numerical approximations is a weak solution of the continuous equations satisfying an energy inequality. An iterative solver for the solution of the nonlinear system of equations in each time step is proposed, and its convergence is proved under the time-step restriction $k \leq Ch^2$. The convergence of the nonlinear solver is robust for small values of the damping parameters α. Owing to expected nonuniqueness and possible occurrence of singularities, strong convergence of the (whole) sequence or error estimates cannot be expected unless additional assumptions on an exact solution are made. The use of higher order finite elements for the discretization of $\mathbf{m}$ are beyond the scope of this paper and remain to be analyzed in future work. Our numerical experiments confirm the theoretical results and indicate that finite-time blow-up for MLLG is possible and hence that singular solutions can develop from smooth initial data. Two examples based on standard micromagnetic benchmark problems are computed to demonstrate the potential of the method for practical applications. Further, we constructed a Schur complement preconditioner for a saddle point system of algebraic equations which arise in every iteration of the nonlinear solver. We observed that the preconditioning dramatically reduced the number of iterations needed for the convergence of the linear solver on structured and unstructured meshes. A multigrid-type preconditioner, which is robust with respect to the time-step size, is subject to our current research.

NONDEGENERACY AND WEAK GLOBAL CONVERGENCE OF THE LLOYD ALGORITHM IN $\mathbb{R}^{D*}$

MARIA EMELIANENKO†, LILI JU‡, AND ALEXANDER RAND§

Abstract. The Lloyd algorithm originated in the context of optimal quantization and represents a fixed point iteration for computing an optimal quantizer. Reducing average distortion at every step, it constructs a Voronoi partition of the domain and replaces each generator with the centroid of the corresponding Voronoi cell. Optimal quantization is obtained in the case of a centroidal Voronoi tessellation (CVT), which is a special Voronoi tessellation of a domain $\Omega \in \mathbb{R}^d$ having the property that the generators of the Voronoi diagram are also the centers of mass, with respect to a given density function $\rho \geq 0$, of the corresponding Voronoi cells. The Lloyd iteration is currently the most popular and elegant algorithm for computing CVTs and optimal quantizers, but many questions remain about its convergence, especially in d-dimensional spaces ($d > 1$). In this paper, we prove that any limit point of the Lloyd iteration in any dimensional spaces is nondegenerate provided that Ω is a convex and bounded set and ρ belongs to $L^1(\Omega)$ and is positive almost everywhere. This ensures that the fixed point map remains closed and hence the standard theory of descent methods guarantees weak global convergence of the Lloyd iteration to the set of nondegenerate fixed point quantizers. While previously only conjectured, the convergence properties of the Lloyd iteration are rigorously justified under such minimal regularity assumptions on the density functional. The results presented in this paper go beyond existing convergence theories for CVTs and optimal quantization related algorithms and should be of interest to both the mathematical and engineering communities.

Key words. centroidal Voronoi tessellations, quantization, Lloyd algorithm, global convergence

1. Introduction.

Given a bounded domain $\Omega \in \mathbb{R}^d$ and a set of distinct points $\mathbf{Z} = \{\mathbf{z}_i\}_{i=1}^n \subset \Omega$, for each point $\mathbf{z}_i$, $i = 1, \ldots, n$, define the corresponding Voronoi region $V_i(\mathbf{Z})$, $i = 1, \ldots, n$, by

$$V_i(\mathbf{Z}) = \big\{\mathbf{z} \in \Omega \;\mid\; |\mathbf{z} - \mathbf{z}_i| < |\mathbf{z} - \mathbf{z}_j| \quad \text{for } j = 1, \ldots, n \quad \text{and} \quad j \neq i\big\},$$

where $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^d$. Clearly $V_i(\mathbf{Z}) \cap V_j(\mathbf{Z}) = \emptyset$ for $i \neq j$, and $\cup_{i=1}^n \overline{V}_i(\mathbf{Z}) = \overline{\Omega}$ so that $\{V_i(\mathbf{Z})\}_{i=1}^n$ is a tessellation of Ω. We refer to $\mathbf{V}(\mathbf{Z}) = \{V_i(\mathbf{Z})\}_{i=1}^n$ as the *Voronoi tessellation* of Ω associated with the point set $\mathbf{Z}$. A point $\mathbf{z}_i$ is called a *generator*; a subdomain $V_i(\mathbf{Z}) \subset \Omega$ is referred to as the *Voronoi region* corresponding to the generator $\mathbf{z}_i$. It is well known that the dual tessellation (in a graph-theoretical sense) to a Voronoi tessellation of Ω is the so-called *Delaunay triangulation* (DT). All Voronoi regions $V_i(\mathbf{Z})$'s are convex (especially convex polygons/polyhedra, except for their part on the boundary) if Ω is convex.

Given a density function $\rho(\mathbf{z}) \geq 0$ defined on Ω, for any region $V \subset \Omega$, define $\mathbf{c}_V$, the *mass center* or *centroid* of V, by

$$\mathbf{c}_V = \frac{\int_V \mathbf{y}\rho(\mathbf{y})\,\mathrm{d}\mathbf{y}}{\int_V \rho(\mathbf{y})\,\mathrm{d}\mathbf{y}}.$$

Then a special family of Voronoi tessellations can be defined in the following.

DEFINITION 1.1 (see [6]). *We refer to a Voronoi tessellation* $(\mathbf{Z}, \mathbf{V}(\mathbf{Z}))$ *of* Ω *as a* centroidal Voronoi tessellation *(CVT) if and only if the points* $\mathbf{Z} = \{\mathbf{z}_i\}_{i=1}^n$ *which serve as the generators of the associated Voronoi regions* $\mathbf{V}(\mathbf{Z}) = \{V_i(\mathbf{Z})\}_{i=1}^n$ *are also the centroids of those regions, i.e., if and only if we have that*

$$\mathbf{z}_i = \mathbf{c}_{V_i(\mathbf{Z})} \quad \textit{for} \;\; i = 1, \ldots, n\,.$$

General Voronoi tessellations do not satisfy the CVT property. It is worth noting that for a given domain and density, at least one CVT exists [1] but may not be unique [6]. The CVT concept can be generalized to very broad settings that range from abstract spaces and distance metrics to discrete point sets [6]. In the latter setting, it can be recognized as being closely related to the k-means and h-means algorithms in clustering and quantization applications [10]. Its extension to general surfaces and manifolds has also been studied in [7, 8]. CVTs are very useful in many applications, including but not limited to image and data analysis, vector quantization, resource optimization, design of experiments, optimal placement of sensors and actuators, cell biology, territorial behavior of animals, numerical partial differential equations, point sampling, meshless computing, mesh generation and optimization, reduced-order modeling, computer graphics, and mobile sensing networks.

CVTs possess an optimization property that can be used as a basis for an alternate definition. Given any set of points $\mathbf{Z} = \{\mathbf{z}_i\}_{i=1}^n$ in Ω and any tessellation $\mathbf{V} = \{V_i\}_{i=1}^n$ of Ω, define the *energy* by

$$\mathcal{E}(\mathbf{Z}, \mathbf{V}) = \sum_{i=1}^{n} \int_{V_i} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_i|^2\,\mathrm{d}\mathbf{y}. \tag{1.1}$$

Then it can be shown that $\mathcal{E}$ is minimized only if $(\mathbf{Z}, \mathbf{V})$ forms a CVT of Ω [6]. Notice that $(\mathbf{Z}, \mathbf{V})$ still may not be a minimizer of $\mathcal{E}$ although $(\mathbf{Z}, \mathbf{V})$ is a CVT. For some properties of the minimizers of the energy functional $\mathcal{E}$ (i.e., CVTs or optimal quantizations), see discussions in [6, 2, 21]. Although the energy $\mathcal{E}$ may not be directly identified with the energy of some physical system, it is often naturally associated with quantities such as *error distortion*, *variance*, and *cost* in many applications.

Currently the most popular and effective algorithm for construction of CVTs is the so-called Lloyd algorithm [18] that is a simple iteration between constructing Voronoi diagrams and mass centroids.

ALGORITHM 1.1 (Lloyd algorithm). *We are given a domain* Ω*, a density function* $\rho(\mathbf{x})$ *defined on* Ω*, and a positive integer* n*.*

0. *Select an initial set of* n *distinct points* $\mathbf{Z} = \{\mathbf{z}_i\}_{i=1}^n$ *on* Ω*.*
1. *Construct the Voronoi regions* $\mathbf{V}(\mathbf{Z}) = \{V_i(\mathbf{Z})\}_{i=1}^n$ *of* Ω *associated with* $\mathbf{Z}$*.*
2. *Determine the centroids of the Voronoi regions* $\mathbf{V}(\mathbf{Z})$*; these centroids form the new set of points* $\mathbf{Z}$*.*

3. *If the new points meet some convergence criterion, return* $(\mathbf{Z}, \mathbf{V}(\mathbf{Z}))$ *and terminate; otherwise, go to step* 1.

The Lloyd algorithm also coincides with the simplest version of the k-means algorithm in clustering and quantization fields [10, 12, 18, 15]. A commonly used stopping criterion is to test whether $\|\mathbf{Z}^k - \mathbf{Z}^{k-1}\| \leq \epsilon$ holds for some predefined tolerance ϵ at some iteration k. It is worth noting that the energy $\mathcal{E}(\mathbf{Z}, \mathbf{V}(\mathbf{Z}))$ decreases monotonically along the Lloyd iteration. Some acceleration schemes based on multigrid techniques are proposed in [4]. A probabilistic version of the Lloyd method for computing CVTs and its parallel implementation have also been studied in [14]. One famous generalization in the vector quantization setting is the Linde–Buzo–Gray algorithm [17], widely used in statistics and data mining applications.

Since Lloyd's pioneering work, many studies have been done on convergence properties of the Lloyd iteration [6, 5, 13, 16, 19]. Despite the algorithm's long history and wide popularity in many applications, its convergence theory is far from being complete. Many researchers addressed the question of existence and uniqueness of an optimal quantizer. Most notably, in [9] and later in [24] and [16], it was shown that the Lloyd method is a local contraction (thus *locally* convergent) in the one-dimensional space when the density function is logarithmically concave. This result was reiterated in [6] with a much simpler proof. In [25], this result was extended to all continuous and positive densities in the one-dimensional setting of scalar quantization. A different approach was used in [5], where the fixed point map was shown to be closed and a weak global convergence result was presented for all continuous and positive density functionals along with some numerical studies and precise theoretic estimates of the local convergence rate.

In higher dimensions, convergence results are much more limited. For discrete distributions, the algorithm is shown to converge and, moreover, reach a CVT in a finite number of steps [23, 11]. In the case of continuous distributions, [11, 22] show convergence of the energy functional by defining the value of the Lloyd map on degenerate points. In order to ensure that the algorithm is closed, this requires that degenerate points be *defined* as fixed points in the definition of the algorithm. So, while standard theory of descent methods ensures that this extended Lloyd algorithm will converge to a fixed point, these limit points could be degenerate. Similarly, the multidimensional global convergence of a subsequence argument presented in [5] implicitly assumed nondegeneracy of the Lloyd map and hence suffered from a similar deficiency. We seek to apply the theory of descent methods to the Lloyd algorithm without any extension to degenerate points. This makes sense as it will be shown that points of degeneracy locally maximize the energy in some sense. Moreover, this is necessary in order to ensure that limit points are in fact CVTs.

In this paper we prove that for an arbitrary, positive density function under a mild L^1 regularity assumption, the fixed point mapping remains closed, which guarantees weak global convergence of the Lloyd iteration. Although we rely on the standard global convergence theory for descent algorithms as discussed in previous investigations (see, e.g., [22, 24]), we take a more direct approach of rigorously justifying the nondegeneracy of the limiting and intermediate iteration points, an approach that much simplifies the analysis of the method and that addresses a question that escaped rigorous treatment until now. These results ensure that Lloyd iterates do not approach degenerate points and that any limit point of the algorithm is a CVT with n distinct generators.

The rest of the paper is organized as follows. In section 2, we introduce some

necessary notation and give an overview of some relevant results and properties. In subsection 3.1, we derive precise estimates on the distance from a centroid to the boundary of the domain and obtain an upper bound on the difference of two Voronoi regions. In subsection 3.2 we present the proof of nondegeneracy of the limit points of the Lloyd iteration, followed in section 3.3 by the main result of the weak global convergence of Lloyd algorithm. Conclusions and some open questions are given in section 4.

2. Preliminaries. For any set $V \subset \Omega$, let us denote by $m(V)$ the measure of V, i.e.,

$$m(V) := \int_V \mathrm{d}\mathbf{y},$$

and by $M(V)$ the mass of V, i.e.,

$$M(V) := \int_V \rho(\mathbf{y})\, \mathrm{d}\mathbf{y}.$$

The fact that ρ is positive almost everywhere means that $M(V) > 0$ if $m(V) > 0$. We also define $\hat{\Omega}^n$ as follows:

$$\hat{\Omega}^n := \{\mathbf{Z} = (\mathbf{z}_1, \ldots, \mathbf{z}_n) \in \overline{\Omega}^n \mid \mathbf{z}_i \neq \mathbf{z}_j \ \ \forall\, i \neq j\}.$$

The so-called Lloyd map is the function $\mathbf{T} : \hat{\Omega}^n \to \hat{\Omega}^n$ that takes a tuple of generators into the tuple of the centroids of its Voronoi regions (exactly the iteration used in the Lloyd algorithm). More precisely, let $\mathbf{T} = (\mathbf{T}_1, \ldots, \mathbf{T}_n)$; then, for any $\mathbf{Z} \in \hat{\Omega}^n$,

$$\mathbf{T}_i(\mathbf{Z}) = \frac{\displaystyle\int_{V_i(\mathbf{Z})} \mathbf{y}\rho(\mathbf{y})\, \mathrm{d}\mathbf{y}}{\displaystyle\int_{V_i(\mathbf{Z})} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y}}$$

for $i = 1, \ldots, n$. The Lloyd map is continuous from $\hat{\Omega}^n$ to $\hat{\Omega}^n$ [6, 5] but not defined on $\bar{\Omega}^n \setminus \hat{\Omega}^n$. The Lloyd algorithm is then the process generating a sequence of point sets:

$$\mathbf{Z}, \mathbf{T}(\mathbf{Z}), \mathbf{T}^2(\mathbf{Z}), \ldots, \mathbf{T}^k(\mathbf{Z}), \ldots .$$

Clearly, the resulting Lloyd iterates are bounded.

For any $\mathbf{Z} \in \hat{\Omega}^n$, the *quantization energy* is defined as

$$\mathcal{G}(\mathbf{Z}) = \mathcal{E}(\mathbf{Z}, \mathbf{V}(\mathbf{Z})) = \sum_{i=1}^{n} \int_{V_i(\mathbf{Z})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_i|^2\, \mathrm{d}\mathbf{y}.$$

The quantization energy function is also continuous on $\hat{\Omega}^n$. Furthermore, this energy can be extended continuously to $\overline{\Omega}^n$. When $\mathbf{Z} \notin \hat{\Omega}^n$, the value of $\mathcal{G}$ is given by the same formula except we consider $\mathbf{Z}$ without duplicate components. For example, in the case of $n = 2$, if $\mathbf{Z} = (\mathbf{z}_1, \mathbf{z}_2)$ and $\mathbf{z}_1 \neq \mathbf{z}_2$, then

$$\mathcal{G}(\mathbf{Z}) = \int_{V_1(\mathbf{Z})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_1|^2\, \mathrm{d}\mathbf{y} + \int_{V_2(\mathbf{Z})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_2|^2\, \mathrm{d}\mathbf{y}.$$

In the degenerate case, we have $\mathbf{Z} = (\mathbf{z}_1, \mathbf{z}_1)$, so that

$$\mathcal{G}(\mathbf{Z}) = \mathcal{G}((\mathbf{z}_1)) = \int_\Omega \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_1|^2 \, \mathrm{d}\mathbf{y}.$$

The derivative of $\mathcal{G}$ in $\hat{\Omega}^n$ is given [6] by

$$\frac{\partial \mathcal{G}}{\partial \mathbf{z}_i}(\mathbf{Z}) = 2M(V_i(\mathbf{Z}))(\mathbf{Z}_i - \mathbf{T}_i(\mathbf{Z})), \tag{2.1}$$

and thus the set of critical points of $\mathcal{G}$ in $\hat{\Omega}^n$ is exactly the set of fixed points of the Lloyd map and thus is the set of CVTs.

For convenience of discussion, a more general energy $\mathcal{H}$ is defined in [5] as follows: for any $(\mathbf{Y}, \mathbf{Z}) \in (\hat{\Omega}^n, \hat{\Omega}^n)$,

$$\mathcal{H}(\mathbf{Y}, \mathbf{Z}) = \mathcal{E}(\mathbf{Z}, \mathbf{V}(\mathbf{Y})) = \sum_{i=1}^{n} \int_{V_i(\mathbf{Y})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}_i|^2 \, \mathrm{d}\mathbf{y}.$$

Notice that $\mathcal{H}$ cannot be continuously extended to $(\overline{\Omega}^n, \overline{\Omega}^n)$ like the function $\mathcal{G}$. The Lloyd algorithm is in fact a dual minimization process [5]: for any $\mathbf{Z} \in \hat{\Omega}^n$,

$$\mathcal{H}(\mathbf{Z}, \mathbf{T}(\mathbf{Z})) = \min_{\mathbf{Y} \in \hat{\Omega}^n} \mathcal{H}(\mathbf{Z}, \mathbf{Y}),$$

$$\mathcal{H}(\mathbf{Z}, \mathbf{Z}) = \min_{\mathbf{Y} \in \hat{\Omega}^n} \mathcal{H}(\mathbf{Y}, \mathbf{Z}).$$

As long as ρ is positive almost everywhere, the above minimization problems on the right-hand side both have a unique solution. Thus we have that

$$\mathcal{G}(\mathbf{T}(\mathbf{Z})) = \mathcal{H}(\mathbf{T}(\mathbf{Z}), \mathbf{T}(\mathbf{Z})) \le \mathcal{H}(\mathbf{Z}, \mathbf{T}(\mathbf{Z})) \le \mathcal{H}(\mathbf{Z}, \mathbf{Z}) = \mathcal{G}(\mathbf{Z}). \tag{2.2}$$

Uniqueness of the centroid implied by the positive density in a convex set ensures that if $(\mathbf{Z}, \mathbf{V}(\mathbf{Z}))$ is not a CVT, then $\mathcal{G}(\mathbf{T}(\mathbf{Z})) < \mathcal{G}(\mathbf{Z})$.

The following definition of weak convergence will be used throughout the paper.

DEFINITION 2.1. *Denote by $\sigma(x, S)$ a distance between a point $x \in \Omega$ and a set S and by Γ the set of fixed points of $\mathbf{T}$. We will say that the sequence of Lloyd iterates $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ is* weakly convergent *if $\lim_{i \to +\infty} \nabla \mathcal{G}(\mathbf{Z}^i) = \mathbf{0}$ and $\lim_{i \to +\infty} \sigma(\mathbf{Z}^i, \Gamma) = 0$.*

In other words, the sequence of Lloyd iterates converges in a weak sense if the energy values asymptotically approach some limit and the sequence of Lloyd iteration points approaches the set of fixed points of $\mathbf{T}$.

In order to analyze *global* convergence of the Lloyd algorithm in general dimensional spaces, we recall the following result.

THEOREM 2.1 (see [5, 20]). *If the iterates in the Lloyd algorithm stay in a compact set where the Lloyd map $\mathbf{T}$ is continuous, then the algorithm is weakly globally convergent, i.e., $\lim_{i \to +\infty} \nabla \mathcal{G}(\mathbf{Z}^i) = \mathbf{0}$ for the Lloyd iterates $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ starting from any initial guess (in other words, any limit point of $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ is a critical point of $\mathcal{G}$).*

Theorem 2.1 was proved in [5] using the properties of $\mathcal{H}$ and the (weak) global convergence theorem stated in [20]. It was also shown in [5] and [25] that the Lloyd algorithm has to converge to the set of critical points of the energy in one-dimensional space provided that ρ is strictly positive and smooth, but for higher dimensional cases, this question is still open, as discussed earlier in the introduction.

It has also never been rigorously justified that the set of limit points cannot contain more than one point, except for the case of log-concave density in the one-dimensional case, restricting the convergence in the aforementioned result to the "weak" sense as given in Definition 2.1. Although we conjecture that a stronger convergence result can be obtained in most practical cases, this question requires a separate rigorous treatment, while at present we focus our attention on extending Theorem 2.1 to higher dimensions.

More precisely, the goal of this paper is to present a proof for the weak global convergence of the Lloyd algorithm in any dimensional space. We do this by showing that limit points of the Lloyd method in $\mathbb{R}^d$ are nondegenerate, and hence the algorithm converges in the sense of Definition 2.1 for any L^1 density functions in any dimension.

3. Weak global convergence of Lloyd iteration. In the following part of this paper, we assume that the following conditions hold.

Assumption 3.1. (1) The domain $\Omega \in \mathbb{R}^d$ is a convex and bounded set with the diameter

$$\operatorname{diam}(\Omega) := \sup_{\mathbf{z},\mathbf{y}\in\Omega} |\mathbf{z}-\mathbf{y}| = R_\Omega < +\infty.$$

(2) The density function ρ belongs to $L^1(\Omega)$ and is positive almost everywhere. Consequently, we have that

$$0 < M(\Omega) = \|\rho\|_{L^1(\Omega)} = \int_\Omega \rho(\mathbf{y})\mathrm{d}\mathbf{y} < +\infty.$$

For the proof of weak global convergence of the Lloyd algorithm, we will show that any limit point of the algorithm is nondegenerate (in $\hat{\Omega}^n$) and thus the iterates stay inside a compact set in $\hat{\Omega}^n$. The weak global convergence of the algorithm will then follow from Theorem 2.1. This ensures that any limit point of the algorithm does in fact correspond to a CVT. Before these results can be shown, a number of technical intermediate lemmas must be shown. The goal of these lemmas is to estimate how the quantization energy changes between iterations of the Lloyd map when iterates approach the boundary of $\hat{\Omega}^n$. As iterates approach the boundary of $\hat{\Omega}^n$, some generator approaches the boundary of its Voronoi region. As all Voronoi regions are convex sets, it becomes important to bound the distance between the boundary and the centroid of a generic convex set in Ω with a prescribed mass.

3.1. Some lemmas. First, let us present a classic result from measure theory.

LEMMA 3.1. *Let Assumption* 3.1 *be satisfied. Then for any $\epsilon > 0$, there exists a constant $\eta > 0$ such that*

$$M(V) = \int_V \rho(\mathbf{y})\ \mathrm{d}\mathbf{y} \le \epsilon \tag{3.1}$$

for any set $V \subset \Omega$ with $m(V) \le \eta$.

The proof of this lemma is given in the appendix. For any $\epsilon \ge 0$, define

$$E_\epsilon = \{\eta \in [0, m(\Omega)] \ \mid\ M(V) \le \epsilon \ \text{ if } \ V \subset \Omega \text{ with } m(V) \le \eta\},$$

and Lemma 3.1 tells us that E_ϵ is a nonempty set, so that

$$\eta_\epsilon := \sup_{\eta\in E_\epsilon} \eta \tag{3.2}$$

is well defined and satisfies that $\eta_{\epsilon_1} \le \eta_{\epsilon_2}$ if $\epsilon_1 \le \epsilon_2$. It is also obvious that $\eta_\epsilon > 0$ if $\epsilon > 0$. For a given $\epsilon \ge 0$, η_ϵ is often difficult to compute, but here we assert only its existence.

Now we estimate the distance from the boundary to the centroid of a general convex set. The important feature of the estimate below is that the lower bound on the distance between the centroid and the boundary of a general convex set depends only on the set through the mass of the set.

For any $V \in \Omega$, let $R_V := \mathrm{diam}(V)$ denote the diameter of V (clearly $R_V \le R_\Omega$), and define the V-dependent constant δ_V by

$$\delta_V := \frac{\eta^2_{M(V)/4}}{64 R_V^{2d-1}},$$

where $\eta_{M(V)/4}$ is the constant defined in (3.2) with $\epsilon = \frac{M(V)}{4}$. Then the following result holds.

LEMMA 3.2. *Let Assumption* 3.1 *be satisfied. Then for any convex set $V \subset \Omega$, it holds that*

$$\mathrm{dist}(\mathbf{c}_V, \partial V) \ge \delta_V, \tag{3.3}$$

where $\mathrm{dist}(\mathbf{c}_V, \partial V)$ *denotes the shortest distance from the centroid of V denoted by $\mathbf{c}_V$ to the boundary of V.*

Proof. Without loss of generality, we assume that the origin is the nearest boundary point to the centroid $\mathbf{c}_V$, and we let $\mathbf{c}_V$ have the coordinate $(\mathbf{0}, x)$ for some $x > 0$, where $\mathbf{0}$ denotes the zero vector in $\mathbb{R}^{d-1}$. Since V is convex and $\sup_{\mathbf{z},\mathbf{y}\in\Omega} |\mathbf{z}-\mathbf{y}| = R_V$, we must have $R_V \ge y_d \ge 0$ for any $\mathbf{y} = (y_1, \ldots, y_d) \in V$. Further, the dth coordinate of $\mathbf{c}_V$ exactly equals $\mathrm{dist}(\mathbf{c}_V, \partial V)$. Then, from the definition of the centroid, we have that

$$\begin{aligned}
\mathrm{dist}(\mathbf{c}_V, \partial V) &= \frac{\int_V \rho(\mathbf{y}) y_d \, \mathrm{d}\mathbf{y}}{\int_V \rho(\mathbf{y}) \, \mathrm{d}\mathbf{y}} \\
&= \frac{\int_0^{R_V} \int_{A(y_d)} \rho(\tilde{\mathbf{y}}, y_d) y_d \, \mathrm{d}\tilde{\mathbf{y}} \mathrm{d}y_d}{M(V)} \\
&= \frac{\int_0^{R_V} y_d [\int_{A(y_d)} \rho(\tilde{\mathbf{y}}, y_d) \, \mathrm{d}\tilde{\mathbf{y}}] \, \mathrm{d}y_d}{M(V)}, \qquad (3.4)
\end{aligned}$$

where $\tilde{\mathbf{y}} = (y_1, \ldots, y_{d-1})$ and $A(y_d) = \{\tilde{\mathbf{y}} \in \mathbb{R}^{d-1} \mid (\tilde{\mathbf{y}}, y_d) \in V\}$. Let us define

$$f_\rho(y_d) := \int_{A(y_d)} \rho(\tilde{\mathbf{y}}, y_d) \, \mathrm{d}\tilde{\mathbf{y}}.$$

The representation above has essentially reduced the problem to a similar one-dimensional problem. To bound (3.4) from below, follow the following steps. In the first step, we find a set such that $\int_S f_\rho(y_d) \, \mathrm{d}y_d$ is sufficiently large and f_ρ is bounded below away from 0. Second, a lower bound on this Lebesgue measure of this set is found. Finally, the third step is to combine these estimates to get a lower bound on (3.4) in terms of the mass of V.

Step 1. For any number $\mu > 0$, define $S_\mu = \{y_d \mid f_\rho(y_d) > \mu R_V^{d-1}\}$ and let $L(S_\mu)$ denote the measure of S_μ. First, we have

$$\begin{aligned} M(V) &= \int_V \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} \\ &= \int_0^{R_V} f_\rho(y_d)\, \mathrm{d}y_d \\ &= \int_{S_\mu} f_\rho(y_d)\, \mathrm{d}y_d + \int_{[0,R_V]-S_\mu} f_\rho(y_d)\, \mathrm{d}y_d \\ &\le \int_{S_\mu} f_\rho(y_d)\, \mathrm{d}y_d + \mu R_V^d. \end{aligned}$$

Set $\mu_1 = \frac{M(V)}{2R_V^d}$; then the above inequality gives us

$$\int_{S_{\mu_1}} f_\rho(y_d)\, \mathrm{d}y_d \ge M(V) - \mu_1 R_V^d = M(V) - \frac{M(V)}{2} = \frac{M(V)}{2}. \tag{3.5}$$

Step 2. From the fact that

$$M(V) \ge \int_{S_\mu} f_\rho(y_d)\, \mathrm{d}y_d \ge L(S_\mu)\mu R_V^{d-1},$$

it is easy to deduce that

$$L(S_\mu) \le \frac{M(V)}{\mu R_V^{d-1}},$$

and so that

$$m(V_\mu) \le L(S_\mu) R_V^{d-1} \le \frac{M(V)}{\mu},$$

where $V_\mu = \{(\tilde{\mathbf{y}}, y_d) \in V \mid y_d \in S_\mu,\ \tilde{\mathbf{y}} \in A(y_d)\}$. Setting $\mu_2 = \frac{M(V)}{\eta_{M(V)/4}}$, we have

$$m(V_{\mu_2}) \le \frac{M(V)}{\mu_2} = \eta_{M(V)/4}.$$

Then, by Lemma 3.1, we obtain that

$$\int_{S_{\mu_2}} f_\rho(y_d)\, \mathrm{d}y_d = \int_{S_{\mu_2}} \int_{A(y_d)} \rho(\tilde{\mathbf{y}}, y_d)\, \mathrm{d}\tilde{\mathbf{y}} \mathrm{d}y_d = \int_{V_{\mu_2}} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} \le \frac{M(V)}{4}. \tag{3.6}$$

According to (3.5) and (3.6), we get

$$\int_{S_{\mu_1}-S_{\mu_2}} f_\rho(y_d)\, \mathrm{d}y_d \ge \frac{M(V)}{2} - \frac{M(V)}{4} \ge \frac{M(V)}{4}. \tag{3.7}$$

Notice that we also have

$$\int_{S_{\mu_1}-S_{\mu_2}} f_\rho(y_d)\, \mathrm{d}y_d \le \mu_2 R_V^{d-1} L(S_{\mu_1}). \tag{3.8}$$

The combination of (3.7) and (3.8) gives us

$$L(S_{\mu_1}) \geq \frac{M(V)}{4\mu_2 R_V^{d-1}}. \tag{3.9}$$

Step 3. Using (3.4) and (3.9), we get

$$\begin{aligned}
\operatorname{dist}(\mathbf{c}_V, \partial V) &= \frac{\int_0^{R_V} y_d f_\rho(y_d)\, \mathrm{d}y_d}{M(V)} \\
&\geq \frac{\int_{S_{\mu_1}} y_d \mu_1 R_V^{d-1}\, \mathrm{d}y_d}{M(V)} \\
&\geq \frac{\mu_1 R_V^{d-1} \int_0^{L(S_{\mu_1})} y_d\, \mathrm{d}y_d}{M(V)} \\
&\geq \frac{\mu_1 R_V^{d-1} [L(S_{\mu_1})]^2}{2M(V)} \\
&\geq \frac{\mu_1 M(V)}{32\mu_2^2 R_V^{d-1}} \\
&\geq \frac{\eta^2_{M(V)/4}}{64 R_V^{2d-1}},
\end{aligned}$$

which completes the proof. □

Remark 3.1. If $\rho \in L^q(\Omega)$ for some $q > 1$, then δ_V can be selected such that it does not depend on the constant $\eta_{M(V)/4}$ such as

$$\delta_V := \frac{M(V)^{2q/(q-1)}}{4^{(5q-3)/(q-1)} \|\rho\|^{2q/(q-1)}_{L^q(V)} R_V^{2d-1}}.$$

This follows from that fact that applying the Hölder inequality to $\int_{S_\mu} f_\rho(y_d)\, \mathrm{d}y_d$ gives us that

$$\int_{S_\mu} f_\rho(y_d)\, \mathrm{d}y_d \leq \frac{\|\rho\|_{L^q(V)} [M(V)]^{(q-1)/q}}{\mu^{(q-1)/q}},$$

and so that

$$\int_{S_{\mu_2}} f_\rho(y_d)\, \mathrm{d}y_d \leq \frac{M(V)}{4},$$

where $\mu_2 = \frac{(4\|\rho\|_{L^q(V)})^{q/(q-1)}}{[M(V)]^{1/(q-1)}}$.

The next lemma is a local estimate on the difference in the quantization energy over a particular set with respect to different generators. For our purposes, it is important to compare the energy with respect to the centroid to the energy generated by a point near the boundary. To prove this, the previous lemma is essential; it ensures that the centroid is sufficiently far away from the boundary. This again leads to an estimate that depends on the particular convex set V through $M(V)$.

For any convex set $V \subset \Omega$, let us define the V-dependent constant γ_V by

$$\gamma_V := \frac{M(V)\delta_V^2}{4}.$$

LEMMA 3.3. *Let Assumption* 3.1 *be satisfied and $V \subset \Omega$ be a convex set. Then for any $\mathbf{z} \in V$ with $\operatorname{dist}(\mathbf{z}, \partial V) \leq \frac{\delta_V}{2}$, it holds that*

$$\int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{c}_V|^2 \, \mathrm{d}\mathbf{y} \leq \int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}|^2 \, \mathrm{d}\mathbf{y} - \gamma_V, \tag{3.10}$$

where $\mathbf{c}_V$ is the centroid of V.

Proof. First, from Lemma 3.2, it is obvious that

$$|\mathbf{z} - \mathbf{c}_V| \geq \operatorname{dist}(\mathbf{c}_V, \partial V) - \operatorname{dist}(\mathbf{z}, \partial V) \geq \frac{\delta_V}{2}.$$

We have

$$\begin{aligned}
&\int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}|^2 \, \mathrm{d}\mathbf{y} - \int_V \rho(\mathbf{y})|\mathbf{y} - c_V|^2 \, \mathrm{d}\mathbf{y} \\
&\quad = \int_V \rho(\mathbf{y})\langle \mathbf{y} - \mathbf{z}, \mathbf{y} - \mathbf{z}\rangle \mathrm{d}\mathbf{y} - \int_V \rho(\mathbf{y})\langle \mathbf{y} - \mathbf{c}_V, \mathbf{y} - \mathbf{c}_V\rangle \mathrm{d}\mathbf{y} \\
&\quad = \int_V \rho(\mathbf{y})(|\mathbf{y}|^2 + |\mathbf{z}|^2 - 2\langle \mathbf{y}, \mathbf{z}\rangle) \mathrm{d}\mathbf{y} \\
&\qquad - \int_V \rho(\mathbf{y})(|\mathbf{y}|^2 + |\mathbf{c}_V|^2 - 2\langle \mathbf{y}, \mathbf{c}_V >\rangle \mathrm{d}\mathbf{y} \\
&\quad = \int_V \rho(\mathbf{y})(|\mathbf{z}|^2 - |\mathbf{c}_V|^2) \, \mathrm{d}\mathbf{y} + 2\int_V \rho(\mathbf{y})\langle \mathbf{y}, \mathbf{c}_V - \mathbf{z}\rangle \mathrm{d}\mathbf{y}.
\end{aligned}$$

Notice that

$$\int_V \rho(\mathbf{y})(|\mathbf{z}|^2 - |\mathbf{c}_V|^2) \, \mathrm{d}\mathbf{y} = M(V)(|\mathbf{z}|^2 - |\mathbf{c}_V|^2) \tag{3.11}$$

and

$$\begin{aligned}
\int_V \rho(\mathbf{y})\langle \mathbf{y}, \mathbf{c}_V - \mathbf{z}\rangle \mathrm{d}\mathbf{y} &= \left\langle \int_V \mathbf{y}\rho(\mathbf{y}) \, \mathrm{d}\mathbf{y}, \mathbf{c}_V - \mathbf{z} \right\rangle \\
&= \langle M(V)\mathbf{c}_V, \mathbf{c}_V - \mathbf{z}\rangle \\
&= M(V)(|\mathbf{c}_V|^2 - \langle \mathbf{c}_V, \mathbf{z}\rangle). \qquad (3.12)
\end{aligned}$$

Using (3.11) and (3.12), we go further and get

$$\begin{aligned}
&\int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{z}|^2 \, \mathrm{d}\mathbf{y} - \int_V \rho(\mathbf{y})|\mathbf{y} - \mathbf{c}_V|^2 \, \mathrm{d}\mathbf{y} \\
&\quad = M(V)(|\mathbf{z}|^2 + |\mathbf{c}_V|^2 - 2\langle \mathbf{c}_V, \mathbf{z}\rangle) \\
&\quad = M(V)|\mathbf{z} - \mathbf{c}_V|^2 \\
&\quad \geq \frac{M(V)\delta_V^2}{4},
\end{aligned}$$

which deduces (3.10) and completes the proof. ∎

Before presenting the next lemma, we need to define some notation. For any point set $\mathbf{Z} \in \Omega^n$, denote by $\mathbf{Z}_i$ the ith point of $\mathbf{Z}$.

DEFINITION 3.1. *Let $k, n \in \mathbb{N}$. For any points $\mathbf{Z} \in \hat{\Omega}^k$ and $\mathbf{Y} \in \hat{\Omega}^n$, define the d_*-distance from $\mathbf{Z}$ to $\mathbf{Y}$ by*

$$d_*(\mathbf{Y}, \mathbf{Z}) = \max_{1 \le j \le k} \min_{1 \le i \le n} |\mathbf{Z}_j - \mathbf{Y}_i|.$$

Then the natural definition of the distance between $\mathbf{Z}$ and $\mathbf{Y}$ is given by

$$d(\mathbf{Y}, \mathbf{Z}) = \max(d_*(\mathbf{Y}, \mathbf{Z}), d_*(\mathbf{Z}, \mathbf{Y})).$$

This is a generalization of the regular Euclidean difference between two elements of Ω^n to the case of vectors of a different length. This definition will become useful for us when we consider a degenerate set of generators in the proof of our main theorem. Provided with this definition, let us consider the set theoretic difference of the two Voronoi tessellations generated by the vectors $\mathbf{Z}$ and $\mathbf{Y}$ as

$$\sum_{i=1}^{k} M\left(V_i(\mathbf{Z}) - \cup_{j \in S_i} V_j(\mathbf{Y})\right).$$

This definition is illustrated in Figure 3.1 below.

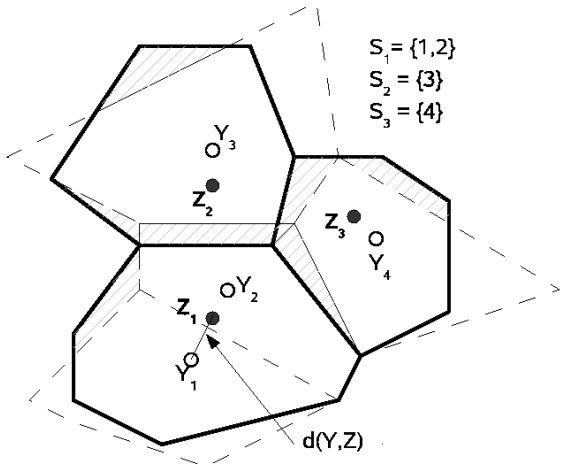

FIG. 3.1. *An illustration of the definition of $d(\mathbf{Y}, \mathbf{Z})$ and the difference of Voronoi tessellations generated by $\mathbf{Z}$ and $\mathbf{Y}$, where $\mathbf{Z} \in \hat{\Omega}_3$ and $\mathbf{Y} \in \hat{\Omega}_4$ (shaded).*

The next lemma for quantifies the fact that if two possibly degenerate points in Ω^n are close together in the sense of Definition 3.1, then the corresponding Voronoi regions of these points are also close together in some sense. The appropriate measurement of how far apart these Voronoi regions are is the total mass of the difference of corresponding Voronoi regions.

LEMMA 3.4. *Let Assumption 3.1 be satisfied. Fix $\mathbf{Z} \in \hat{\Omega}^k$ for $k \le n$. For any $\epsilon > 0$, there exists a $\delta_\epsilon > 0$ such that if $\mathbf{Y} \in \hat{\Omega}^n$ and $d(\mathbf{Z}, \mathbf{Y}) \le \delta_\epsilon$, then*

$$\sum_{i=1}^{k} M\left(V_i(\mathbf{Z}) - \cup_{j \in S_i} V_j(\mathbf{Y})\right) \le \epsilon,$$

where $\{S_i\}_{i=1}^k$ *is any partition of* $\{1,\dots,n\}$ *satisfying* $S_i \in \{j \mid |\mathbf{Z}_i - \mathbf{Y}_j| \le |\mathbf{Z}_m - \mathbf{Y}_j|$ *for all* $m \in \{1,\dots,k\}\}$.

Proof. Let us suppose that $\mathbf{Y} \in \hat{\Omega}^n$ and $d(\mathbf{Z},\mathbf{Y}) < \delta$ for some $\delta > 0$. Since $\mathbf{Z} \in \hat{\Omega}^k$ is fixed, let us define the constant $d_{\mathbf{Z}}$ by

$$d_{\mathbf{Z}} = \min_{i \neq j} \frac{|\mathbf{Z}_i - \mathbf{Z}_j|}{2}.$$

We let δ be small enough such that $\delta \le \frac{d_{\mathbf{Z}}}{2}$; then it is not difficult to verify that S_i is a nonempty set for each $1 \le i \le k$. From Definition 3.1, it is also obvious that for any $1 \le i \le k$,

$$|\mathbf{y} - \mathbf{Z}_i| - \delta \le |\mathbf{y} - \mathbf{Y}_j| \le |\mathbf{y} - \mathbf{Z}_i| + \delta \quad \forall\, \mathbf{y} \in \Omega,\ j \in S_i.$$

For any $\mathbf{y}$, if $\mathbf{y} \in V_i(\mathbf{Z}) - \cup_{j\in S_i} V_j(\mathbf{Y})$ (i.e., $\mathbf{y} \in V_i(\mathbf{Z})$ and $\mathbf{y} \notin \cup_{j\in S_i} V_j(\mathbf{Y})$), then we will argue by contradiction that $\operatorname{dist}(\mathbf{y}, \partial V_i(\mathbf{Z}))$, the shortest distance from $\mathbf{y}$ to the boundary of $V_i(\mathbf{Z})$, satisfies

$$\operatorname{dist}(\mathbf{y}, \partial V_i(\mathbf{Z})) < \sigma = \frac{3\delta}{\alpha_{\mathbf{Z}}}, \tag{3.13}$$

where $\alpha_{\mathbf{Z}} = \frac{2}{\sqrt{(1+R_\Omega/d_{\mathbf{Z}})^2 + (R_\Omega/d_{\mathbf{Z}})^2}}$ is a constant depending only on $\mathbf{Z}$ and R_Ω. Let us first assume that $\operatorname{dist}(\mathbf{y}, \partial V_i(\mathbf{Z})) \ge \sigma$. We will show that $\mathbf{y} \in \cup_{j\in S_i} V_j(\mathbf{Y})$. Take any $1 \le j \le k$ with $j \neq i$; without loss of generality, assume that $V_i(\mathbf{Z})$ and $V_j(\mathbf{Z})$ are neighbor Voronoi cells. Notice that $V_i(\mathbf{Z})$ and $V_j(\mathbf{Z})$ are both convex polygons/polyhedra except for the part belonging to the boundary of Ω; see Figure 3.2 for an illustration of two-dimensional cases.

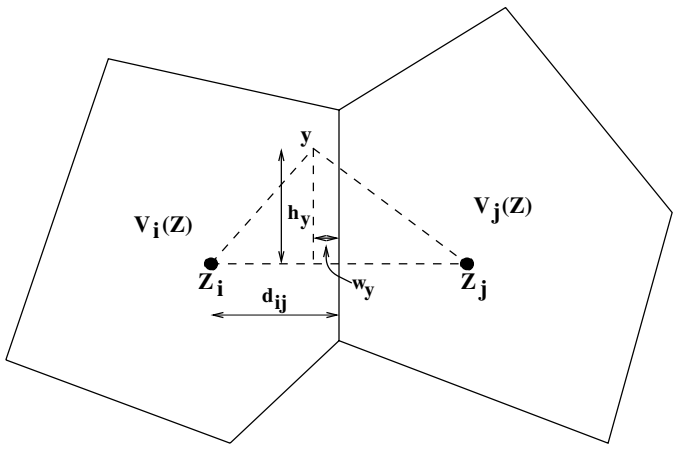

FIG. 3.2. *Two neighboring Voronoi regions.*

One can easily verify that

$$\begin{aligned}|\mathbf{y}-\mathbf{Z}_j|-|\mathbf{y}-\mathbf{Z}_i| &= \sqrt{(d_{ij}+w_{\mathbf{y}})^2+h_{\mathbf{y}}^2}-\sqrt{(d_{ij}-w_{\mathbf{y}})^2+h_{\mathbf{y}}^2}\\ &\geq \frac{2d_{ij}w_{\mathbf{y}}}{\sqrt{(d_{ij}+w_{\mathbf{y}})^2+h_{\mathbf{y}}^2}}\\ &= \frac{2w_{\mathbf{y}}}{\sqrt{(1+w_{\mathbf{y}}/d_{ij})^2+(h_{\mathbf{y}}/d_{ij})^2}}.\end{aligned}$$

Since $d_{ij}\geq d_{\mathbf{Z}}$, $R_\Omega\geq w_{\mathbf{y}}>\sigma$, and $h_{\mathbf{y}}\leq R_\Omega$, we obtain

$$\begin{aligned}|\mathbf{y}-\mathbf{Z}_j|-|\mathbf{y}-\mathbf{Z}_i| &\geq \frac{2\sigma}{\sqrt{(1+R_\Omega/d_{\mathbf{Z}})^2+(R_\Omega/d_{\mathbf{Z}})^2}}\\ &= 3\delta.\end{aligned}$$

Then, for any $j\in S_i$ and any $m\in S_l$ with $l\neq i$, it holds that

$$\begin{aligned}|\mathbf{y}-\mathbf{Y}_j| &\leq |\mathbf{y}-\mathbf{Z}_i|+\delta\\ &\leq |\mathbf{y}-\mathbf{Z}_l|-3\delta+\delta\\ &\leq |\mathbf{y}-\mathbf{Y}_m|+\delta-2\delta\\ &\leq |\mathbf{y}-\mathbf{Y}_m|-\delta\\ &< |\mathbf{y}-\mathbf{Y}_m|.\end{aligned}$$

This means that $\mathbf{y}\in\cup_{j\in S_i}V_j(\mathbf{Y})$ and gives us a contradiction with $\mathbf{y}\notin\cup_{j\in S_i}V_j(\mathbf{Y})$, so that the inequality (3.13) holds. Since $V_i(\mathbf{Z})\subset\Omega$ is convex and $\operatorname{diam}(\Omega)=R_\Omega<+\infty$, it holds that

$$m(\partial V_i(\mathbf{Z}))\leq S_d\left(\frac{R_\Omega}{2}\right)^{d-1}, \tag{3.14}$$

where $S_d=\frac{2\pi^{d/2}}{\Gamma(d/2)}$ denotes the hypersurface area of an d-sphere of unit radius; see [3] for details. Then the inequality (3.13) with (3.14) implies that

$$m(V_i(\mathbf{Z})-\cup_{j\in S_i}V_j(\mathbf{Y}))\leq\frac{\sigma S_d R_\Omega^{d-1}}{2^{d-1}}.$$

Then selecting

$$\delta=\delta_\epsilon:=\min\left(\frac{d_{\mathbf{Z}}}{2},\ \frac{2^{d-1}\eta_{\epsilon/k}\alpha_{\mathbf{Z}}}{3S_dR_\Omega^{d-1}}\right)$$

ensures that $m(V_i(\mathbf{Z})-\cup_{j\in S_i}V_j(\mathbf{Y}))\leq\eta_{\epsilon/k}$. Due to Lemma 3.1, this means that

$$\begin{aligned}\sum_{i=1}^k M\left(V_i(\mathbf{Z})-\cup_{j\in S_i}V_j(\mathbf{Y})\right) &= \sum_{i=1}^k\int_{V_i(\mathbf{Z})-\cup_{j\in S_i}V_j(\mathbf{Y})}\rho(\mathbf{y})\,\mathrm{d}\mathbf{y}\\ &\leq \sum_{i=1}^k\frac{\epsilon}{k}\\ &\leq \epsilon,\end{aligned}$$

and thus the result holds. ∎

Remark 3.2. In the case that $\rho \in L^q(\Omega)$ for some $q > 1$, the Hölder inequality again can be used to find a δ_ϵ in the above lemma which does not depend on the constant $\eta_{\epsilon/k}$ such as

$$\delta = \delta_\epsilon := \min\left(\frac{d_{\mathbf{Z}}}{2}, \frac{2^{d-1}\alpha_{\mathbf{Z}}}{3S_d R_\Omega^{d-1}}\left(\frac{\epsilon}{k\|\rho\|_{L^q(\Omega)}}\right)^{q/(q-1)}\right).$$

3.2. Nondegeneracy of limit points. Now, let us present our first important result.

THEOREM 3.5. *Let Assumption* 3.1 *be satisfied. Given $n \in \mathbb{N}$ and any initial point $\mathbf{Z}^0 \in \hat{\Omega}^n$, let $\{\mathbf{Z}^i\}_{i=0}^\infty$ be the iterates of the Lloyd algorithm starting with $\mathbf{Z}^0$. Then any limit point $\mathbf{Z}$ of these iterates is nondegenerate (i.e., $\mathbf{Z} \in \hat{\Omega}^n$).*

Proof. Let $\mathbf{Z} \in \overline{\Omega}^n$ be any limit point of these iterates $\{\mathbf{Z}^i\}_{i=0}^\infty$. We will argue by contradiction that $\mathbf{Z} \in \hat{\Omega}^n$. Let us first assume that $\mathbf{Z} = (\mathbf{Z}_1, \ldots, \mathbf{Z}_n)$ is degenerate, i.e., in the sense that several of its components are equal. Without loss of generality, assume that $\mathbf{Z}_1 = \cdots = \mathbf{Z}_r$ for some $1 < r \le n$.

Since $\mathbf{Z}^i$'s are Lloyd iterates, by the continuity of $\mathcal{G}$ on $\overline{\Omega}^n$ and the monotone decrease of $\mathcal{G}$ along $\mathbf{Z}^i$'s due to (2.2), we know that

$$\mathcal{G}(\mathbf{Z}^i) \searrow_{i\to+\infty} \mathcal{G}(\mathbf{Z}); \tag{3.15}$$

i.e., $\mathcal{G}(\mathbf{Z}^i)$ monotonically decreases and converges to $\mathcal{G}(\mathbf{Z})$. Let $\tilde{\mathbf{Z}} \in \hat{\Omega}^k$ ($k = n-r+1 < n$) be the set of points in $\mathbf{Z}$ without duplication; i.e.,

$$\tilde{\mathbf{Z}} = (\tilde{\mathbf{Z}}_1, \ldots, \tilde{\mathbf{Z}}_k) = (\mathbf{Z}_1, \mathbf{Z}_{r+1}, \ldots, \mathbf{Z}_n).$$

It is obvious that $\mathcal{G}(\tilde{\mathbf{Z}}) = \mathcal{G}(\mathbf{Z})$. From $\{\mathbf{Z}^i\}_{i=0}^\infty$, select a subsequence $\{\mathbf{Z}^{i_j}\}_{j=0}^\infty$ such that $\mathbf{Z}^{i_j} \to \mathbf{Z}$ as $j \to +\infty$.

Now define

$$\alpha = \frac{M(V_1(\tilde{\mathbf{Z}}))}{2r}, \quad \beta = \frac{\eta_{\alpha/4}^2}{64R_\Omega^{2d-1}}, \quad \text{and} \quad \gamma = \frac{\alpha\beta^2}{4}.$$

Obviously we have $\alpha, \beta, \gamma > 0$ since $(V_1(\tilde{\mathbf{Z}}))$ is a convex set with positive measure.

Now let us select a j^* large enough such that the following inequalities hold:

$$M(\cup_{m=1}^r V_m(\mathbf{Z}^{i_{j^*}})) > \frac{M(V_1(\tilde{\mathbf{Z}}))}{2}, \tag{3.16}$$

$$\mathcal{G}(\mathbf{Z}^{i_{j^*}}) - \mathcal{G}(\tilde{\mathbf{Z}}) < \frac{\gamma}{2}, \tag{3.17}$$

$$|\mathbf{Z}_m^{i_{j^*}} - \mathbf{Z}_m| < \frac{\beta}{4}, \quad m = 1, 2, \ldots, n. \tag{3.18}$$

Inequality (3.16) holds for large j^* by Lemma 3.4 using $\epsilon = \frac{M(V_1(\tilde{\mathbf{Z}}))}{2}$. Further, that also means that for some $m \in \{1, \ldots, r\}$, $M(V_m(\mathbf{Z}^{i_{j^*}})) > \alpha$. Without loss of generality, assume this m is 1, i.e., $M(V_1(\mathbf{Z}^{i_{j^*}})) > \alpha$. That gives us

$$\delta_{V_1(\mathbf{Z}^{i_{j^*}})} \ge \beta, \qquad \gamma_{V_1(\mathbf{Z}^{i_{j^*}})} \ge \gamma. \tag{3.19}$$

The inequalities (3.18) and (3.19) imply

$$\operatorname{dist}(\mathbf{Z}_1^{i_{j^*}}, \partial V_1(\mathbf{Z}^{i_{j^*}})) \le |\mathbf{Z}_1^{i_{j^*}} - \mathbf{Z}_1| + |\mathbf{Z}_2^{i_{j^*}} - \mathbf{Z}_1| < \frac{\beta}{2} \le \frac{\delta_{V_1(\mathbf{Z}^{i_{j^*}})}}{2}.$$

Then by Lemma 3.3 and (3.19), we immediately obtain

$$\begin{aligned}
&\int_{V_1(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{c}_{V_1(\mathbf{Z}^{i_{j^*}})}|^2 \, \mathrm{d}\mathbf{y} \\
&\qquad \le \int_{V_1(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{Z}_1^{i_{j^*}}|^2 \, \mathrm{d}\mathbf{y} - \gamma_{V_1(\mathbf{Z}^{i_{j^*}})} \\
&\qquad \le \int_{V_1(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{Z}_1^{i_{j^*}}|^2 \, \mathrm{d}\mathbf{y} - \gamma. \qquad (3.20)
\end{aligned}$$

Now, let us estimate the quantization energy $\mathcal{G}(\mathbf{T}(\mathbf{Z}^{i_{j^*}}))$. Using the dual minimization property, we get

$$\begin{aligned}
\mathcal{G}(\mathbf{T}(\mathbf{Z}^{i_{j^*}})) &= \mathcal{H}(\mathbf{T}(\mathbf{Z}^{i_{j^*}}), \mathbf{T}(\mathbf{Z}^{i_{j^*}})) \\
&\le \mathcal{H}(\mathbf{Z}^{i_{j^*}}, \mathbf{T}(\mathbf{Z}^{i_{j^*}})) \\
&= \int_{V_1(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{T}_1(\mathbf{Z}^{i_{j^*}})|^2 \, \mathrm{d}\mathbf{y} \\
&\qquad + \sum_{k=2}^{n} \int_{V_k(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{T}_k(\mathbf{Z}^{i_{j^*}})|^2 \, \mathrm{d}\mathbf{y}.
\end{aligned}$$

It is easy to see that

$$\sum_{k=2}^{n} \int_{V_k(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{T}_k(\mathbf{Z}^{i_{j^*}})|^2 \, \mathrm{d}\mathbf{y} \le \sum_{k=2}^{n} \int_{V_k(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{Z}_k^{i_{j^*}}|^2 \, \mathrm{d}\mathbf{y} \qquad (3.21)$$

since $\mathbf{T}_k(\mathbf{Z}^{i_{j^*}})$ is the centroid of $V_k(\mathbf{Z}^{i_{j^*}})$. With (3.17), (3.20), and (3.21), we have

$$\begin{aligned}
\mathcal{G}(\mathbf{T}(\mathbf{Z}^{i_{j^*}})) &\le \int_{V_1(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{Z}_1^{i_{j^*}}|^2 \, \mathrm{d}\mathbf{y} - \gamma \\
&\qquad + \sum_{k=2}^{n} \int_{V_k(\mathbf{Z}^{i_{j^*}})} \rho(\mathbf{y})|\mathbf{y} - \mathbf{Z}_k^{i_{j^*}}|^2 \, \mathrm{d}\mathbf{y} \\
&= \mathcal{G}(\mathbf{Z}^{i_{j^*}}) - \gamma \\
&< \mathcal{G}(\tilde{\mathbf{Z}}) + \frac{\gamma}{2} - \gamma \\
&= \mathcal{G}(\tilde{\mathbf{Z}}) - \frac{\gamma}{2},
\end{aligned}$$

which contradicts the fact (3.15). We conclude that $\mathbf{Z} \in \hat{\Omega}^n$; i.e., any limit point of the Lloyd iteration cannot be a degenerate point. ∎

THEOREM 3.6. *Let Assumption* 3.1 *be satisfied. Given* $n \in \mathbb{N}$ *and any initial point* $\mathbf{Z}^0 \in \hat{\Omega}^n$, *let* $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *be the iterates of the Lloyd algorithm starting with* $\mathbf{Z}^0$. *Then there exists a constant* $D_{\mathbf{Z}^0} > 0$ *depending only on* n, Ω, ρ, *and* $\mathbf{Z}^0$ *such that for any* $i \geq 0$,

$$|\mathbf{Z}_j^i - \mathbf{Z}_k^i| > D_{\mathbf{Z}^0}$$

for all $j, k \in \{1, \dots, n\}$ *and* $j \neq k$.

Proof. We will use the contradiction argument again. Let us assume that the theorem is not true, then for all $m \in \mathbb{N}$, there always exist an index i_m, some $j_m, k_m \in \{1, \dots, n\}$, and $j_m \neq k_m$ such that

$$|\mathbf{Z}_{j_m}^{i_m} - \mathbf{Z}_{k_m}^{i_m}| < \frac{1}{m}.$$

Let us consider the subsequence $\{\mathbf{Z}^{i_m}\}_{m=1}^{\infty}$. Without loss of generality, assume the index set $I = \{i_m\}_{m=1}^{\infty}$ is a monotonically increasing sequence (otherwise we can do that by adding some restriction such as $i_{k+1} > i_k$ during choosing $\{\mathbf{Z}^{i_m}\}_{m=1}^{\infty}$). Notice that the set $JK = \{(j_m, k_m)\}_{m=1}^{\infty}$ has at most $n(n-1)$ different elements, so there exists a pair $\{(j^*, k^*)\} \in JK$ that appears infinitely many times along the increasing of m, and let us record their appearances by the increasing sequence $\{m_1, m_2, \dots\} \subset \mathbb{N}$. This means that

$$|\mathbf{Z}_{j^*}^{i_{m_p}} - \mathbf{Z}_{k^*}^{i_{m_p}}| < \frac{1}{m_p} \quad \forall\, p \in \mathbb{N}. \tag{3.22}$$

Since $\{\mathbf{Z}^{i_{m_p}}\}$ are bounded, there always exists a convergent subsequence of $\{\mathbf{Z}^{i_{m_p}}\}$, and assume $\mathbf{Z}$ is the corresponding limit point. Due to (3.22), we must have $\mathbf{Z}_{j^*} = \mathbf{Z}_{k^*}$, which means that $\mathbf{Z}$ is a degenerate point. However, $\mathbf{Z}$ is also a limit point of the original Lloyd iterates $\{\mathbf{Z}^i\}_{i=0}^{\infty}$, and according to Theorem 3.5, $\mathbf{Z}$ could not be a degenerate point. We then get a contradiction, and so the theorem holds. ∎

Remark 3.3. In Theorem 3.6, we are only able to show existence of the lower bound of the distances between any pair of generators of all Lloyd iterates starting with $\mathbf{Z}^0$. For the one-dimensional case, an explicit estimate was derived in [5] when the density function is strictly positive and smooth.

A direct consequence of Theorem 3.6 is the following corollary.

COROLLARY 3.7. *Let Assumption* 3.1 *be satisfied. Given* $n \in \mathbb{N}$ *and any initial point* $\mathbf{Z}^0 \in \hat{\Omega}^n$, *let* $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *be the iterates of the Lloyd algorithm starting with* $\mathbf{Z}^0$. *Then the Lloyd map is continuous at any of the iterates* $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *and* $m(V_j(\mathbf{Z}^i)) \geq (\frac{D_{\mathbf{Z}^0}}{2})^d$ *for any* $1 \leq j \leq n$ *and* $i \geq 0$.

3.3. Main result. Finally, let us present our main result in the following theorem.

THEOREM 3.8 (weak global convergence). *Let Assumption* 3.1 *be satisfied. Given* $n \in \mathbb{N}$ *and any initial point* $\mathbf{Z}^0 \in \hat{\Omega}^n$, *let* $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *be the iterates of the Lloyd algorithm starting with* $\mathbf{Z}^0$. *Then the following hold:*

1. $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *is weakly convergent (i.e.,* $\lim_{i \to +\infty} \nabla \mathcal{G}(\mathbf{Z}^i) = 0$*) and any limit point of* $\{\mathbf{Z}^i\}_{i=0}^{\infty}$ *is also a nondegenerate critical point of the quantization energy* $\mathcal{G}$ *(and thus a CVT).*
2. *Moreover, it also holds that* $\lim_{i \to +\infty} \|\mathbf{Z}^{i+1} - \mathbf{Z}^i\| = 0$.

Proof. Using the result of Corollary 3.7, we see that we can define a compact set (away from the degenerate points) such that for any initial point $\mathbf{Z}^0 \in \hat{\Omega}^n$, the Lloyd

iterates (the images of the Lloyd maps) will stay in such a compact set. Thus, we can apply Theorem 2.1 and Corollary 3.7 to deduce the weak global convergence of the Lloyd iterations. The first part of the theorem is then complete with the help of Theorem 3.5.

From Corollary 3.7, we also know that for any $1 \le k \le n$ and $i \ge 0$,

$$m(V_k(\mathbf{Z}^i)) \ge \left(\frac{D_{\mathbf{Z}^0}}{2}\right)^d > 0.$$

Together with Lemma 3.1 and the assumption that ρ is positive almost everywhere, we know that there exists some constant $M^* > 0$ such that

$$M(V_k(\mathbf{Z}^i)) \ge M^* > 0. \tag{3.23}$$

Using (2.1), we then get

$$\begin{aligned}
\|\nabla \mathcal{G}(\mathbf{Z}^i)\| &= \left(\sum_{k=1}^{n} \Big|\frac{\partial \mathcal{G}}{\partial \mathbf{z}_k}(\mathbf{Z}^i)\Big|^2\right)^{1/2} \\
&= \left(\sum_{k=1}^{n} |2M(V_k(\mathbf{Z}^i))(\mathbf{Z}_k^i - \mathbf{T}_k(\mathbf{Z}^i))|^2\right)^{1/2} \\
&\ge 2M^* \left(\sum_{k=1}^{n} |\mathbf{Z}_k^i - \mathbf{T}_k(\mathbf{Z}^i)|^2\right)^{1/2} \\
&= 2M^* \|\mathbf{Z}^i - \mathbf{Z}^{i+1}\|. \qquad (3.24)
\end{aligned}$$

Consequently, we get

$$0 \le \lim_{i \to +\infty} \|\mathbf{Z}^{i+1} - \mathbf{Z}^i\| \le \frac{1}{2M^*} \lim_{i \to +\infty} \|\nabla \mathcal{G}(\mathbf{Z}^i)\| = 0,$$

which deduces the second part of this theorem. □

Remark 3.4. It is a consequence of part (1) of Theorem 3.8 that the generators of any limit point configuration of the Lloyd algorithm cannot lie on the boundary of the convex domain, since the limit point is a CVT and the density function ρ is positive almost everywhere.

Remark 3.5. Part (2) of Theorem 3.8 in fact tells us that the Lloyd method always terminates under general practical stopping criteria.

4. Conclusions and open questions. In this paper, we prove that any limit point of the Lloyd iteration is nondegenerate provided that Ω is a convex and bounded set and ρ belongs to $L^1(\Omega)$ and is positive almost everywhere in any dimensional space. It follows that, for every initial point set, the Lloyd iteration always approaches the set of nondegenerate critical points of the so-called quantization energy (which is exactly the set of CVTs). These results go beyond those presented in earlier papers; they enlarge the class of densities in the one-dimensional case and assign a stronger meaning to the statement of global convergence of the Lloyd iteration by eliminating the possibility of degeneracy. Although the proofs in their generality hold for all L^1 density functions, we have been able to provide a more constructive characterization

for the constants δ_V and δ_ϵ in the case of $L^q, q > 1$, which possess their own merit from a practical point of view.

There are still some open questions. Throughout our proof, the convexity of Ω is required in many places. The first question is whether this condition is really necessary or whether Ω can be a nonconvex set with some constraints. Another question is under which conditions weak convergence transforms into a strong single limit-point convergence. Also, it remains to explore whether the proof can be extended to replace the density function with a more general measure; ideally, it would be extended to a set of measures more general than those considered in [22]. Finally, it is also very meaningful and interesting to study the convergence properties of the Lloyd algorithm when the CVT is defined under some other error weighting functions, such as the very commonly used l^1 and l^∞ that arise in many engineering applications. The geometric proof provided here clearly provides room for such generalizations; however, the detailed analysis would complicate current presentation and hence is left to a separate treatment. These questions and generalizations are the focus of current research and will be addressed in subsequent publications.

Appendix. Proof of Lemma 3.1.

Proof. Suppose that the claim is false. Then there exists an $\epsilon_0 > 0$ such that for all $k \in \mathbb{N}$, $\exists A_k \subset \Omega$ with $m(A_k) \leq (1/2)^{k+1}$, it holds that $\int_{A_k} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} > \epsilon_0$. Let $B_k = \cup_{i=k}^{\infty} A_i$; clearly $m(B_k) \leq \sum_{k=1}^{\infty} m(A_i) \leq (1/2)^k$ and $\int_{B_k} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} > \epsilon_0$ for all $k \in \mathbb{N}$. Since $\{\int_{B_k} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y}\}_{k=1}^{\infty}$ is a positive nonincreasing sequence, it is easy to see that

$$\lim_{k \to +\infty} \int_{B_k} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} \geq \epsilon_0 > 0.$$

On the other hand, notice that $B_1 \supset B_2 \supset \cdots$. By the dominated convergence theorem in measure theory, we have

$$\begin{aligned} \lim_{k \to +\infty} \int_{B^*} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y} &= \lim_{k \to +\infty} \int_{\Omega} (\mathbf{1}_{B_k}(\mathbf{y}) \rho(\mathbf{y}))\, \mathrm{d}\mathbf{y} \\ &= \int_{\Omega} \lim_{k \to +\infty} (\mathbf{1}_{B_k}(\mathbf{y}) \rho(\mathbf{y}))\, \mathrm{d}\mathbf{y} \\ &= 0, \end{aligned}$$

which gives us a contradiction, and so this lemma holds. ∎

ERROR ESTIMATES FOR THE RAVIART–THOMAS INTERPOLATION UNDER THE MAXIMUM ANGLE CONDITION*

RICARDO G. DURÁN† AND ARIEL L. LOMBARDI†

Abstract. The classical error analysis for the Raviart–Thomas interpolation on triangular elements requires the so-called regularity of the elements, or equivalently, the minimum angle condition. However, in the lowest order case, optimal order error estimates have been obtained in [G. Acosta and R. G. Durán, *SIAM J. Numer. Anal.*, 37 (2000), pp. 18–36] replacing the regularity hypothesis by the maximum angle condition, which was known to be sufficient to prove estimates for the standard Lagrange interpolation. In this paper we prove error estimates on triangular elements for the Raviart–Thomas interpolation of any order under the maximum angle condition. Also, we show how our arguments can be extended to the three-dimensional case to obtain error estimates for tetrahedral elements under the regular vertex property introduced in [G. Acosta and R. G. Durán, *SIAM J. Numer. Anal.*, 37 (2000), pp. 18–36].

Key words. mixed finite elements, Raviart–Thomas, anisotropic finite elements

AMS subject classification. 65N30

DOI. 10.1137/060665312

1. Introduction.

The classical error analysis for finite element approximations is based on the so-called regularity assumption on the elements. In other words, the constants in the error estimates obtained depend on the ratio between outer and inner diameter of the elements and blow up when this ratio goes to infinity (see, for example, [4, 5]).

However, it is well known that the regularity assumption can be relaxed for standard finite element approximations. For example, in the two-dimensional (2d) case, optimal order error estimates have been proved for triangular elements under the weaker maximum angle condition (i.e., angles bounded away from π). This condition allows the use of the so-called anisotropic elements which is of interest in several applications, for example in problems with boundary or interior layers.

Error estimates under the maximum angle condition were first obtained in [3, 9]. After these pioneering works many papers have considered different generalizations of their results (see, for example, [2] and the references therein).

The usual error analysis for mixed finite element methods also makes use of the regularity assumption [12, 14]. In view of the results for the standard method mentioned above, it is a natural question whether the regularity hypothesis on the elements can be relaxed in this case also. A positive answer for the Raviart–Thomas space of lowest order $\mathcal{R}T_0$ is given in [1], where an optimal error estimate is proved under the maximum angle condition. However, it is not straightforward to extend the arguments given in that paper to higher order approximations. In [7] it is proved that the maximum angle condition is also sufficient to obtain optimal error estimates for the Raviart–Thomas space $\mathcal{R}T_1$.

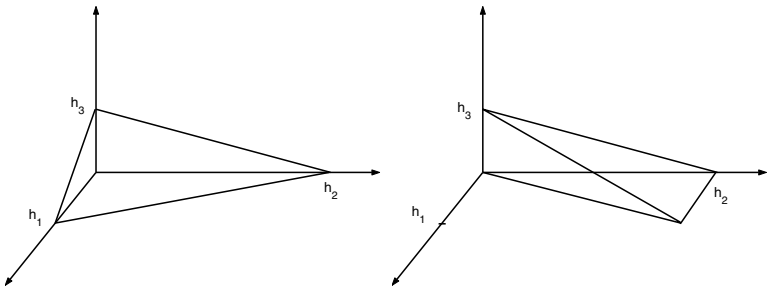

FIG. 1. *Two families of reference elements in the* 3*d case.*

The goal of this paper is to prove that the maximum angle condition is also sufficient to obtain optimal error estimates for the approximation using the Raviart–Thomas space $\mathcal{R}T_k$ for arbitrary k.

The three-dimensional (3d) case presents some important differences with the 2d case. Results for the standard finite element approximations in three dimensions were obtained in several papers (see, for example, [2, 6, 8, 10, 13]). In [10] Krízek proved optimal order error estimates for the Lagrange interpolation on a tetrahedron K for smooth functions, namely $u \in W^{2,\infty}$, provided the angles between faces and the angles in the faces are bounded away from π.

The Krízek condition seems to be a natural extension of the 2d maximum angle condition. However, there is another possible extension: the regular vertex property introduced in [1]. Roughly speaking, a family of tetrahedral elements satisfies this condition if for each element there is at least one vertex such that the unit vectors in the direction of the edges sharing that vertex are "uniformly" linearly independent, in the sense that the volume determined by them is uniformly bounded away from zero.

It is easy to see that in the 2d case the maximum angle condition and the regular vertex property are equivalent. However, in three dimensions this is not the case. Indeed, the Krízek condition allows for more general elements. To understand better these two possible extensions of the maximum angle condition, consider the two families of elements given in Figure 1, where h_1, h_2, and h_3 are arbitrary positive numbers.

It is easy to see that both families satisfy the maximum angle condition, but the second family does not satisfy the regular vertex property. Moreover, it was proved in [1] that the family of all elements satisfying the Krízek condition with a constant $\psi < \pi$ (i.e., angles between faces and angles in the faces are less than or equal to ψ) can be obtained by transforming both families in the figure by affine transformations with bounded condition number. On the other hand, the family of all elements satisfying the regular vertex property with a given constant (see section 3 for the formal definition of this condition) is obtained by transforming in the same way only the first family in the figure.

In [1], optimal error estimates under the Krízek condition were obtained for the $\mathcal{R}T_0$ spaces in three dimensions. In this paper we prove optimal error estimates for the general $\mathcal{R}T_k$ spaces under the regular vertex property. The more general case of elements satisfying the Krízek condition requires a different argument and will be the subject of future research.

To simplify the exposition we present first the proofs in the 2d case in section 2. Then, in section 3 we show how the arguments can be easily generalized to the 3d case for elements satisfying the regular vertex property.

2. Error estimates in the 2d case. We use the standard notation $\mathcal{P}_k$ for the space of polynomials of degree less than or equal to k. Then the local Raviart–Thomas space of order $k \geq 0$ on a triangle T [12] is defined by

$$\mathcal{R}T_k(T) = \mathcal{P}_k^2(T) + (x, y)\mathcal{P}_k(T). \tag{2.1}$$

It is known that there exists an operator

$$\Pi_k : H^1(T)^2 \longrightarrow \mathcal{R}T_k(T)$$

such that

$$\int_\ell \Pi_k \mathbf{v} \cdot \mathbf{n} p_k = \int_\ell \mathbf{v} \cdot \mathbf{n} p_k \quad \forall p_k \in \mathcal{P}_k(\ell) \quad \forall \ell \,\text{side of } T \tag{2.2}$$

and, if $k \geq 1$,

$$\int_T \Pi_k \mathbf{v} \cdot \mathbf{p}_{k-1} = \int_T \mathbf{v} \cdot \mathbf{p}_{k-1} \quad \forall \mathbf{p}_{k-1} \in \mathcal{P}_{k-1}^2(T). \tag{2.3}$$

Introducing the L^2 orthogonal projection

$$P_k \ : L^2(T) \longrightarrow \mathcal{P}_k(T),$$

it is not difficult to check that Π_k and P_k satisfy the following commutative diagram:

$$\begin{array}{lll} H^1(T)^2 & \xrightarrow{\text{div}} & L^2(T) \\ \Pi_k \big\downarrow & & \big\downarrow P_k \\ \mathcal{R}T_k(T) & \xrightarrow{\text{div}} & \mathcal{P}_k(T) \quad \longrightarrow 0 \end{array} \tag{2.4}$$

where the right bottom arrow in this diagram indicates that the divergence operator is surjective.

In the rest of the paper the letter C will denote a generic constant independent of the element T and of the functions involved in the estimates.

The error estimates for Π_k will be a consequence of the generalized Poincaré inequality given in the next lemma.

LEMMA 2.1. *Let T be a triangle and ξ_1 and ξ_2 unit vectors in the directions of two sides of T that have lengths h_1 and h_2. Assume that for one side ℓ of T and $f \in H^{k+1}(T)$ we have*

$$\int_\ell f\, q = 0 \qquad \forall q \in \mathcal{P}_k(\ell) \tag{2.5}$$

and, if $k \geq 1$,

$$\int_T f\, p = 0 \qquad \forall p \in \mathcal{P}_{k-1}(T). \tag{2.6}$$

Then, there exists a constant C independent of T and f such that

$$\|f\|_{L^2(T)} \leq C \sum_{i+j=k+1} h_1^i h_2^j \left\| \frac{\partial^{k+1} f}{\partial \xi_1^i \partial \xi_2^j} \right\|_{L^2(T)}. \tag{2.7}$$

Proof. First we prove the result for the reference element $\widehat{T}$ which has vertices at $(0,0)$, $(1,0)$, and $(0,1)$. Namely, we will show that if $\hat{f} \in H^{k+1}(\widehat{T})$ satisfies

$$\int_{\hat{\ell}} \hat{f}\, q = 0 \qquad \forall q \in \mathcal{P}_k(\hat{\ell}) \tag{2.8}$$

and, if $k \geq 1$,

$$\int_{T} \hat{f}\, p = 0 \qquad \forall p \in \mathcal{P}_{k-1}(\widehat{T}), \tag{2.9}$$

where $\hat{\ell}$ is one of the sides of $\widehat{T}$, then

$$\|\hat{f}\|_{L^2(\widehat{T})} \leq C \sum_{i+j=k+1} \left\| \frac{\partial^{k+1} \hat{f}}{\partial \hat{x}^i \partial \hat{y}^j} \right\|_{L^2(\widehat{T})}. \tag{2.10}$$

Let $\mathcal{S}_0 = \mathcal{P}_0(\widehat{T})$ and, for $k \geq 1$, let $\mathcal{S}_k$ be the orthogonal complement of $\mathcal{P}_{k-1}(\widehat{T})$ in $\mathcal{P}_k(\widehat{T})$. Then, $\|\,.\,\|_{L^2(\hat{\ell})}$ is a norm on $\mathcal{S}_k$. For $k = 0$ this is trivial and to see this for $k \geq 1$ it is enough to check that if $p \in \mathcal{S}_k$ satisfies $\|p\|_{L^2(\hat{\ell})} = 0$, then $p = 0$. But, $\|p\|_{L^2(\hat{\ell})} = 0$ implies that p vanishes on $\hat{\ell}$ and therefore $p = \lambda_1 q$ with $q \in \mathcal{P}_{k-1}(\widehat{T})$, where $\lambda_1 \in \mathcal{P}_1$ is the function such that $\lambda_1 = 0$ is the equation of the line containing the side $\hat{\ell}$ (i.e., the so-called barycentric coordinate). Now, since $p \in \mathcal{S}_k$ we have

$$\int_{\widehat{T}} \lambda_1\, q^2 = 0$$

and, since λ_1 does not change sign in $\hat{T}$, it follows that $q = 0$ and so $p = 0$ as we wanted to see.

In view of (2.9), the L^2 orthogonal projection of $\hat{f}$ on $\mathcal{P}_k(\widehat{T})$, namely $\widehat{P}_k \hat{f}$, belongs to $\mathcal{S}_k$. Then, since $\mathcal{S}_k$ is a finite-dimensional space, there exists a constant C depending only on k and $\widehat{T}$ such that

$$\|\widehat{P}_k \hat{f}\|_{L^2(\widehat{T})} \leq C \|\widehat{P}_k \hat{f}\|_{L^2(\hat{\ell})}. \tag{2.11}$$

On the other hand, using (2.8) we have

$$\|\hat{P}_k \hat{f}\|^2_{L^2(\hat{\ell})} = \int_{\hat{\ell}} \widehat{P}_k \hat{f}\, (\widehat{P}_k \hat{f} - \hat{f}) \leq \|\widehat{P}_k \hat{f}\|_{L^2(\hat{\ell})} \|\widehat{P}_k \hat{f} - \hat{f}\|_{L^2(\hat{\ell})}$$

which, together with (2.11), gives

$$\|\widehat{P}_k \hat{f}\|_{L^2(\widehat{T})} \leq C \|\widehat{P}_k \hat{f} - \hat{f}\|_{L^2(\hat{\ell})}$$

and then, using a standard trace theorem to bound the right-hand side and known error estimates for the L^2 projection, we obtain

$$\|\widehat{P}_k \hat{f}\|_{L^2(\widehat{T})} \leq C \|\widehat{P}_k \hat{f} - \hat{f}\|_{H^1(\widehat{T})} \leq C \sum_{i+j=k+1} \left\| \frac{\partial^{k+1} \hat{f}}{\partial \hat{x}^i \partial \hat{y}^j} \right\|_{L^2(\widehat{T})}$$

with another constant C depending only on k and $\widehat{T}$. Therefore, (2.10) follows using the triangular inequality.

Assume, without loss of generality, that the vertex shared by the sides of T in the directions ξ_1 and ξ_2 is at the origin. Then, T is the image of $\widehat{T}$ by the linear map

$$\begin{pmatrix} x \\ y \end{pmatrix} = B \begin{pmatrix} \hat{x} \\ \hat{y} \end{pmatrix},$$

where the columns of B are given by $h_1\xi_1$ and $h_2\xi_2$. Therefore, if $\hat{f}(\hat{x},\hat{y}) = f(x,y)$, then

$$\frac{\partial^{k+1}\hat{f}}{\partial\hat{x}^i\partial\hat{y}^j} = h_1^i h_2^j \frac{\partial^{k+1} f}{\partial\xi_1^i\partial\xi_2^j}.$$

Then, (2.7) follows from (2.10) by changing variables. ∎

Our next goal is to prove a result for the L^2 orthogonal projection which will be needed in our main theorem. For clarity we divide the proof in the following two lemmas.

LEMMA 2.2. *Let $\widehat{T}$ be the triangle with vertices at $(0,0)$, $(1,0)$, and $(0,1)$. Given (i,j) such that $i+j=k$ we define*

$$q_{ij} := \frac{\partial^k}{\partial x^i \partial y^j}\big(x^i y^j (1-x-y)^k\big).$$

Then, for any $f \in H^k(\widehat{T})$,

$$\int_{\widehat{T}} q_{ij}\, f = (-1)^k \int_{\widehat{T}} \big(x^i y^j (1-x-y)^k\big) \frac{\partial^k f}{\partial x^i \partial y^j}. \tag{2.12}$$

Proof. We want to prove that

$$\int_{\widehat{T}} \frac{\partial^k}{\partial x^i \partial y^j}\big(x^i y^j\ (1-x-y)^k\big)\, f = (-1)^k \int_{\widehat{T}} \big(x^i y^j (1-x-y)^k\big) \frac{\partial^k f}{\partial x^i \partial y^j}$$

so, it is enough to see that the boundary terms arising in the integration by parts vanish. For example, when we integrate by parts in the x variable the boundary terms will be of the form

$$\int_{\partial\widehat{T}} \frac{\partial^{l+j}}{\partial x^l \partial y^j}\big(x^i y^j (1-x-y)^k\big)\, \frac{\partial^{i-1-l} f}{\partial x^{i-1-l}}\, n_1,$$

where n_1 is the first component of the unit normal at the boundary and $l = 0,\dots,i-1$. Since $n_1 = 0$ on the side contained in the line $\{y=0\}$, it is enough to see that

$$\frac{\partial^{l+j}}{\partial x^l \partial y^j}\big(x^i y^j (1-x-y)^k\big) = 0 \tag{2.13}$$

on the other two sides of $\widehat{T}$. This derivative can be written as a sum of terms which, up to a multiplicative constant, are of the form

$$x^{i-m} y^{j-n} (1-x-y)^{k+m+n-l-j}$$

with $m = 0,\dots,l$ and $n = 0,\dots,j$. But, since $l < i$, we have $m < i$ and $l+j < i+j = k$ and so in all of these terms the exponents of x and $(1-x-y)$ are positive. Therefore,

(2.13) holds on the sides of $\widehat{T}$ contained in $\{x = 0\}$ and $\{1 - x - y = 0\}$ as we wanted to show. ∎

LEMMA 2.3. *If T is the right triangle with vertices at $(0,0)$, $(h_1,0)$, and $(0,h_2)$, then, for any $f \in H^k(T)$ and any i,j such that $i+j=k$,*

$$\left\| \frac{\partial^k P_k f}{\partial x^i \partial y^j} \right\|_{L^2(T)} \leq C \left\| \frac{\partial^k f}{\partial x^i \partial y^j} \right\|_{L^2(T)}$$

with a constant C independent of the right triangle T.

Proof. We prove the estimate for the reference triangle $\widehat{T}$ with vertices at $(0,0)$, $(1,0)$, and $(0,1)$. Then, the result follows by making the change of variables $(x,y) = (h_1\hat{x}, h_2\hat{y})$.

Since the result is trivial for $k = 0$ we can assume that $k \geq 1$. Fix (i,j) such that $i + j = k$ and let $\{p_1, \ldots, p_N\}$ be an orthonormal basis of the subspace $\mathcal{S} \subset \mathcal{P}_k(\widehat{T})$ expanded by

$$\{x^m y^n \,:\, m + n \leq k, (m,n) \neq (i,j)\}.$$

From the definition of q_{ij} given in the previous lemma it is easy to check that $q_{ij} \in \mathcal{P}_k$. Moreover, since $\frac{\partial^k p}{\partial x^i \partial y^j} = 0$ for all $p \in \mathcal{S}$, it follows from (2.12) that q_{ij} is orthogonal to $\mathcal{S}$.

Then, defining $p_{N+1} := q_{ij}/\|q_{ij}\|_{L^2(\widehat{T})}$, we have that $\{p_1, \ldots, p_{N+1}\}$ is an orthonormal basis of $\mathcal{P}_k(\widehat{T})$. Then

$$P_k f = \sum_{s=1}^{N+1} \left(\int_{\widehat{T}} f p_s \right) p_s$$

and, since $\frac{\partial^k p_s}{\partial x^i \partial y^j} = 0$ for $s = 1, \ldots, N$, we have

$$\frac{\partial^k P_k f}{\partial x^i \partial y^j} = \left(\int_{\widehat{T}} f p_{N+1} \right) \frac{\partial^k p_{N+1}}{\partial x^i \partial y^j}, \tag{2.14}$$

but it follows from (2.12) that

$$\int_{\widehat{T}} f p_{N+1} = \frac{(-1)^k}{\|q_{ij}\|_{L^2(\widehat{T})}} \int_{\widehat{T}} \left(x^i y^j (1-x-y)^k \right) \frac{\partial^k f}{\partial x^i \partial y^j}$$

which, together with (2.14) and an application of the Schwarz inequality, gives

$$\left\| \frac{\partial^k P_k f}{\partial x^i \partial y^j} \right\|_{L^2(\widehat{T})} \leq \widehat{C} \left\| \frac{\partial^k f}{\partial x^i \partial y^j} \right\|_{L^2(\widehat{T})}$$

as we wanted to prove. ∎

To end with the preliminary results we give in the next lemma a relation between derivatives of a function in $\mathcal{RT}_k(T)$ and derivatives of its divergence.

LEMMA 2.4. *If T is a triangle and $\mathbf{u} \in \mathcal{RT}_k(T)$, then*

$$\frac{\partial^{k+1} \mathbf{u}}{\partial x^{k+1}} = \left(\frac{k+1}{k+2} \frac{\partial^k (\operatorname{div} \mathbf{u})}{\partial x^k}, 0 \right), \qquad \frac{\partial^{k+1} \mathbf{u}}{\partial y^{k+1}} = \left(0, \frac{k+1}{k+2} \frac{\partial^k (\operatorname{div} \mathbf{u})}{\partial y^k} \right)$$

and for $i+j=k+1$, with $i>0$ and $j>0$,

$$\frac{\partial^{k+1}\mathbf{u}}{\partial x^i\partial y^j}=\left(\frac{i}{2+k}\frac{\partial^k \mathrm{div}\,\mathbf{u}}{\partial x^{i-1}\partial y^j}\,,\frac{j}{2+k}\frac{\partial^k \mathrm{div}\,\mathbf{u}}{\partial x^i\partial y^{j-1}}\right).$$

Proof. Any function $\mathbf{u}\in\mathcal{R}T_k(T)$ can be written as $\mathbf{u}=\mathbf{p}+(xq,yq)$ with $\mathbf{p}\in\mathcal{P}_k^2$ and $q\in\mathcal{P}_k$. An elementary computation shows that

$$\frac{\partial^{k+1}\mathbf{u}}{\partial x^{k+1}}=\Big((k+1)\frac{\partial^k q}{\partial x^k}\,,\,0\Big)\quad,\qquad \frac{\partial^{k+1}\mathbf{u}}{\partial y^{k+1}}=\Big(0\,,\,(k+1)\frac{\partial^k q}{\partial y^k}\Big)$$

and, for any positive i,j such that $i+j=k+1$,

$$\frac{\partial^{k+1}\mathbf{u}}{\partial x^i\partial y^j}=\Big(i\frac{\partial^k q}{\partial x^{i-1}\partial y^j}\,,j\frac{\partial^k q}{\partial x^i\partial y^{j-1}}\Big).$$

On the other hand, for $l+m=k$

$$\frac{\partial^k(\mathrm{div}\,\mathbf{u})}{\partial x^l\partial y^m}=(k+2)\frac{\partial^k q}{\partial x^l\partial y^m}\,.$$

Then the lemma is easily obtained. ∎

Now we are ready to prove our main result. Given a triangle T we call h_T the longest side of T. We will also use the notation

$$D^m f=\sum_{i+j=m}\left|\frac{\partial^m f}{\partial x^i\partial y^j}\right|$$

and a tilde over operators will indicate that the derivatives are taken with respect to $(\tilde{x},\tilde{y})$.

THEOREM 2.5. *Let T be a triangle with maximum angle α. Let h_1 and h_2 be the lengths of the sides adjacent to α and let ξ_1 and ξ_2 be unit vectors in the directions of those sides. Then, for any function $\mathbf{v}\in H^{k+1}(T)^2$,*

(2.15)
$$\|\mathbf{v}-\Pi_k\mathbf{v}\|_{L^2(T)}\le\frac{C}{\sin\alpha}\left\{\sum_{i+j=k+1}h_1^ih_2^j\left\|\frac{\partial^{k+1}\mathbf{v}}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)}+h_T^{k+1}\|D^k\mathrm{div}\,\mathbf{v}\|_{L^2(T)}\right\}$$

with a constant C independent of T.

Proof. In view of (2.2) and (2.3), for any side ℓ_s of T the function $(\mathbf{v}-\Pi_k\mathbf{v})\cdot\mathbf{n}_s$, where $\mathbf{n}_s$ denotes the unit exterior normal on ℓ_s, satisfies conditions (2.6) and (2.5) of Lemma 2.1, and therefore

$$\|(\mathbf{v}-\Pi_k\mathbf{v})\cdot\mathbf{n}_s\|_{L^2(T)}\le C\sum_{i+j=k+1}h_1^ih_2^j\left\|\frac{\partial^{k+1}\left[(\mathbf{v}-\Pi_k\mathbf{v})\cdot\mathbf{n}_s\right]}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)}.$$

But, choosing ℓ_1 and ℓ_2 as the sides with directions ξ_1 and ξ_2, it is not difficult to see that

$$\|\mathbf{v}-\Pi_k\mathbf{v}\|_{L^2(T)}\le\frac{C}{\sin\alpha}\left\{\|(\mathbf{v}-\Pi_k\mathbf{v})\cdot\mathbf{n}_1\|_{L^2(T)}+\|(\mathbf{v}-\Pi_k\mathbf{v})\cdot\mathbf{n}_2\|_{L^2(T)}\right\}$$

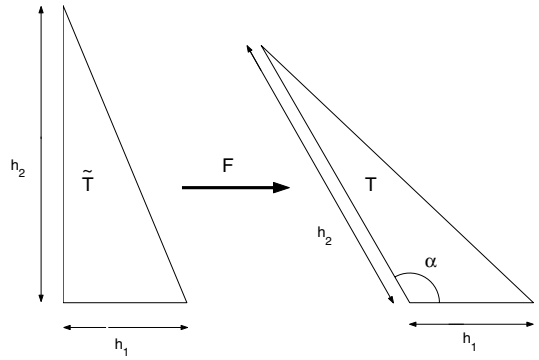

FIG. 2. *The map F applying $\widetilde{T}$ on T.*

and then,

$$\|\mathbf{v}-\Pi_k\mathbf{v}\|_{L^2(T)} \le \frac{C}{\sin\alpha}\sum_{i+j=k+1} h_1^i h_2^j \left\| \frac{\partial^{k+1}(\mathbf{v}-\Pi_k\mathbf{v})}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)}. \tag{2.16}$$

Then (2.15) is obtained from the inequality

$$\sum_{i+j=k+1}\left\| \frac{\partial^{k+1}\Pi_k\mathbf{v}}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)} \le C\left\|D^k\mathrm{div}\,\mathbf{v}\right\|_{L^2(T)}, \tag{2.17}$$

that we will prove in what follows.

Without loss of generality, we can assume that T has vertices at $(0,0)$, $(h_1,0)$, and (a,b) and that the vertex corresponding to the maximum angle is at (0,0). Then $\xi_1=(1,0)$ and $\xi_2=(\frac{a}{h_2},\frac{b}{h_2})$.

Consider the right triangle $\widetilde{T}$ with vertices at $(0,0)$, $(h_1,0)$, and $(0,h_2)$. Then, the linear transformation $(x,y)=F(\tilde{x},\tilde{y})$ defined as

$$\begin{pmatrix} x\\ y\end{pmatrix} = B\begin{pmatrix}\tilde{x}\\ \tilde{y}\end{pmatrix}$$

with

$$B=\begin{pmatrix} 1 & \frac{a}{h_2}\\ 0 & \frac{b}{h_2}\end{pmatrix}$$

maps $\widetilde{T}$ onto T (see Figure 2). We have

$$\|B\|_2 \le \sqrt{2}, \tag{2.18}$$

where $\|\,.\,\|_2$ denotes the matrix norm associated with the euclidean norm.

Now, given $\mathbf{v}\in H^{k+1}(T)^2$, we define the corresponding function $\tilde{\mathbf{v}}\in H^{k+1}(\widetilde{T})^2$ via the Piola transform, that is,

$$\mathbf{v}(x,y)=\frac{1}{|\det B|}B\,\tilde{\mathbf{v}}(\tilde{x},\tilde{y}),\quad (x,y)\in T.$$

Then, we have

$$\operatorname{div} \mathbf{v} = \frac{1}{|\det B|} \widetilde{\operatorname{div}}\, \tilde{\mathbf{v}}. \tag{2.19}$$

Denoting by $\widetilde{\Pi}_k$ the Raviart–Thomas interpolation on $\widetilde{T}$, it is proved in [12, page 303] that

$$\Pi_k \mathbf{v}(x,y) = \frac{1}{|\det B|} B\, \widetilde{\Pi}_k \tilde{\mathbf{v}}(\tilde{x},\tilde{y}), \quad (x,y) \in T.$$

Then, we have

$$\frac{\partial^{k+1} \Pi_k \mathbf{v}}{\partial \xi_1^i \partial \xi_2^j}(x,y) = \frac{1}{|\det B|} B\, \frac{\partial^{k+1} \widetilde{\Pi}_k \tilde{\mathbf{v}}}{\partial \tilde{x}^i \partial \tilde{y}^j}(\tilde{x},\tilde{y}),$$

and, therefore,

$$\left\| \frac{\partial^{k+1} \Pi_k \mathbf{v}}{\partial \xi_1^i \partial \xi_2^j} \right\|_{L^2(T)} \leq \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \left\| \frac{\partial^{k+1} \widetilde{\Pi}_k \tilde{\mathbf{v}}}{\partial \tilde{x}^i \partial \tilde{y}^j} \right\|_{L^2(\tilde{T})}.$$

Now, since $\widetilde{\Pi}_k \tilde{\mathbf{v}} \in \mathcal{R}T_k(\widetilde{T})$, using Lemma 2.4, the commutative diagram property (2.4) for $\widetilde{\Pi}_k$, Lemma 2.3 in $\widetilde{T}$, and (2.19), we have

$$\begin{aligned}
\sum_{i+j=k+1} \left\| \frac{\partial^{k+1} \Pi_k \mathbf{v}}{\partial \xi_1^i \partial \xi_2^j} \right\|_{L^2(T)} &\leq \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \sum_{i+j=k+1} \left\| \frac{\partial^{k+1} \widetilde{\Pi}_k \tilde{\mathbf{v}}}{\partial \tilde{x}^i \partial \tilde{y}^j} \right\|_{L^2(\tilde{T})} \\
&\leq C \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \left\| \widetilde{D}^k \widetilde{\operatorname{div}}\, \widetilde{\Pi}_k \tilde{\mathbf{v}} \right\|_{L^2(\tilde{T})} \\
&\leq C \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \left\| \widetilde{D}^k \widetilde{P}_k \widetilde{\operatorname{div}}\, \tilde{\mathbf{v}} \right\|_{L^2(\tilde{T})} \\
&\leq C \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \left\| \widetilde{D}^k \widetilde{\operatorname{div}}\, \tilde{\mathbf{v}} \right\|_{L^2(\tilde{T})} \\
&\leq C \|B\|_2^{k+1} \left\| D^k \operatorname{div} \mathbf{v} \right\|_{L^2(T)},
\end{aligned}$$

then (2.17) follows using (2.18). ∎

Remark 2.1. It is possible to prove error estimates for the Raviart–Thomas interpolation under the maximum angle condition without using the Piola transform. However, the dependence of the constant on the maximum angle of T obtained in this way is worse than that in Theorem 2.5.

Indeed, using the same change of variables from a right triangle $\widetilde{T}$ onto T as in Theorem 2.5, and the estimate given in Lemma 2.3 we can prove, for any $f \in H^k(T)$,

$$\|D^k P_k f\|_{L^2(T)} \leq \frac{C}{(\sin \alpha)^k} \|D^k f\|_{L^2(T)}, \tag{2.20}$$

where α is the maximum angle of T.

Then, using Lemma 2.4, the commutative diagram property for Π_k (2.4), and (2.20) we have

$$\begin{aligned}\sum_{i+j=k+1}\left\|\frac{\partial^{k+1}\Pi_k\mathbf{v}}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)} &\le \|B\|_2^{k+1}\sum_{i+j=k+1}\left\|\frac{\partial^{k+1}\Pi_k\mathbf{v}}{\partial x^i\partial y^j}\right\|_{L^2(T)}\\ &\le C\|B\|_2^{k+1}\sum_{i+j=k+1}\left\|D^k\operatorname{div}\Pi_k\mathbf{v}\right\|_{L^2(T)}\\ &= C\|B\|_2^{k+1}\sum_{i+j=k+1}\left\|D^kP_k\operatorname{div}\mathbf{v}\right\|_{L^2(T)}\\ &\le \frac{C}{(\sin\alpha)^k}\|B\|_2^{k+1}\sum_{i+j=k+1}\left\|D^k\operatorname{div}\mathbf{v}\right\|_{L^2(T)}.\end{aligned}$$

This inequality, together with (2.16) and (2.18), gives

$$\|\mathbf{v}-\Pi_k\mathbf{v}\|_{L^2(T)} \le \frac{C}{\sin\alpha}\left\{\sum_{i+j=k+1}h_1^ih_2^j\left\|\frac{\partial^{k+1}\mathbf{v}}{\partial\xi_1^i\partial\xi_2^j}\right\|_{L^2(T)} + \frac{h_T^{k+1}}{(\sin\alpha)^k}\|D^k\operatorname{div}\mathbf{v}\|_{L^2(T)}\right\}.$$

3. The 3d case. The Raviart–Thomas spaces have been generalized to the 3d case by Nedelec [11]. In this section we briefly explain how to extend the results previously obtained to a class of tetrahedral elements satisfying a condition which is weaker than regularity.

Following [1], we say that a tetrahedron K satisfies the *regular vertex property* with a constant $\bar{c}>0$ if there exist a vertex $\mathbf{Z}$ of K, called the *regular vertex*, unit vectors ξ_i, and scalars h_i, $i=1,2,3$, such that K is the convex hull of $\{\mathbf{Z}\}\cup\{\mathbf{Z}+h_i\xi_i, i=1,2,3\}$, and the matrix B made up with ξ_i as its columns verifies $|\det B|\ge\bar{c}$.

Given a tetrahedron K the spaces introduced in [11] are given, for $k\ge 0$, by

$$\mathcal{R}T_k(K)=\mathcal{P}_k(K)^3+(x,y,z)\mathcal{P}_k(K).$$

Also in [11] it is proved that there exists an operator

$$\Pi_k : H^1(K)^3 \longrightarrow \mathcal{R}T_k(K)$$

such that

$$\int_F \Pi_k\mathbf{v}\cdot\mathbf{n}p_k=\int_F\mathbf{v}\cdot\mathbf{n}p_k \quad \forall p_k\in\mathcal{P}_k(F),\ \forall F \ \text{ face of } \ K$$

and, if $k\ge 1$,

$$\int_K \Pi_k\mathbf{v}\cdot\mathbf{p}_{k-1}=\int_K\mathbf{v}\cdot\mathbf{p}_{k-1}\quad\forall\mathbf{p}_{k-1}\in\mathcal{P}_{k-1}^3(K).$$

In what follows we state, for tetrahedral elements satisfying the regular vertex property, an error estimate for Π_k analogous to that given in Theorem 2.5. We will mention without proof the 3d versions of Lemmas 2.1 and 2.3 that can be obtained following the same arguments as in the 2d case.

We define the tetrahedron $\widetilde{K}$ with vertices at $(0,0,0)$, $(h_1,0,0)$, $(0,h_2,0)$, and $(0,0,h_3)$. We denote by $\mathbf{n}_1$, $\mathbf{n}_2$, and $\mathbf{n}_3$ the normals to the faces of $\widetilde{K}$ contained in

the planes $x = 0$, $y = 0$, and $z = 0$, respectively. For a tetrahedron K we call h_K its diameter.

THEOREM 3.1. *Let K be a tetrahedron satisfying the regular vertex property with a constant $\bar{c}$ and let h_i and ξ_i, $i = 1, 2, 3$, be the lengths and unit directions corresponding to the edges sharing the regular vertex $\mathbf{Z}$. Then, for any function $\mathbf{v} \in H^{k+1}(K)^3$,*

$$\|\mathbf{v} - \Pi_k \mathbf{v}\|_{L^2(K)} \leq C \left\{ \sum_{i+j+l=k+1} h_1^i h_2^j h_3^l \left\| \frac{\partial^{k+1} \mathbf{v}}{\partial \xi_1^i \partial \xi_2^j \partial \xi_3^l} \right\|_{L^2(K)} + h_K^{k+1} \|D^k \operatorname{div} \mathbf{v}\|_{L^2(T)} \right\}$$

with a constant C depending only on $\bar{c}$.

Proof. From [1, Lemma 5.2] there exists a constant C depending only on $\bar{c}$ such that

$$\|\mathbf{v} - \Pi_k \mathbf{v}\|_{L^2(K)} \leq C \sum_{s=1}^{3} \|(\mathbf{v} - \Pi_k \mathbf{v}) \cdot \mathbf{n}_s\|_{L^2(K)}.$$

We can apply to $(\mathbf{v} - \Pi_k \mathbf{v}) \cdot \mathbf{n}_s$ a straightforward generalization of Lemma 2.1 to obtain

$$\|\mathbf{v} - \Pi_k \mathbf{v}\|_{L^2(K)} \leq C \sum_{i+j+l=k+1} h_1^i h_2^j h_3^l \left\| \frac{\partial^{k+1} (\mathbf{v} - \Pi_k \mathbf{v})}{\partial \xi_1^i \partial \xi_2^j \partial \xi_3^l} \right\|_{L^2(K)}. \tag{3.1}$$

Hence, we have to prove

$$\sum_{i+j+l=k+1} \left\| \frac{\partial^{k+1} \Pi_k \mathbf{v}}{\partial \xi_1^i \partial \xi_2^j \partial \xi_3^l} \right\|_{L^2(K)} \leq C \left\| D^k \operatorname{div} \mathbf{v} \right\|_{L^2(K)}.$$

Without loss of generality, we can assume that K has vertices $(0, 0, 0)$, $(h_1, 0, 0)$, $(a_2, b_2, 0)$, and (a_3, b_3, c_3) and that it satisfies the definition of the regular vertex property with $\mathbf{Z} = (0, 0, 0)$, $\xi_1 = (1, 0, 0)$, $\xi_2 = \frac{1}{h_2}(a_2, b_2, 0)$, and $\xi_3 = \frac{1}{h_3}(a_3, b_3, c_3)$.

The linear transformation

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = B \begin{pmatrix} \tilde{x} \\ \tilde{y} \\ \tilde{z} \end{pmatrix}$$

with

$$B = \begin{pmatrix} 1 & \frac{a_2}{h_2} & \frac{a_3}{h_3} \\ 0 & \frac{b_2}{h_2} & \frac{b_3}{h_3} \\ 0 & 0 & \frac{c_3}{h_3} \end{pmatrix}$$

maps $\widetilde{K}$ onto K.

Moreover, it is easy to check that

$$\|B\|_2 \leq 3\sqrt{3}.$$

For $\mathbf{v} \in H^{k+1}(K)^3$ we can consider $\tilde{\mathbf{v}} \in H^{k+1}(\widetilde{K})^3$ defined by the Piola transform

$$\mathbf{v} = \frac{1}{|\det B|} B \, \tilde{\mathbf{v}}.$$

Then, as in the proof of Theorem 2.5, we have

$$\left\| \frac{\partial^{k+1}\Pi_k \mathbf{v}}{\partial\xi_1^i \partial\xi_2^j \partial\xi_3^l} \right\|_{L^2(K)} \leq \frac{\|B\|_2}{|\det B|^{\frac{1}{2}}} \left\| \frac{\partial^{k+1}\widetilde{\Pi}_k \tilde{\mathbf{v}}}{\partial\tilde{x}^i \partial\tilde{y}^j \partial\tilde{z}^l} \right\|_{L^2(\widetilde{K})}.$$

But, as in the 2d case, for any tetrahedral element T we can write the derivatives of order $k+1$ of $\mathbf{u} \in \mathcal{R}T_k(T)$ in terms of the derivatives of its divergence, namely,

$$\begin{aligned}
\frac{\partial^{k+1}\mathbf{u}}{\partial x^{k+1}} &= \left(\frac{k+1}{k+3} \frac{\partial^k(\operatorname{div}\mathbf{u})}{\partial x^k}, 0, 0 \right), \\
\frac{\partial^{k+1}\mathbf{u}}{\partial y^{k+1}} &= \left(0, \frac{k+1}{k+3} \frac{\partial^k(\operatorname{div}\mathbf{u})}{\partial y^k}, 0 \right), \\
\frac{\partial^{k+1}\mathbf{u}}{\partial z^{k+1}} &= \left(0, 0, \frac{k+1}{k+3} \frac{\partial^k(\operatorname{div}\mathbf{u})}{\partial z^k} \right)
\end{aligned}$$

and for $i+j+l = k+1$, with $i > 0$, $j > 0$, and $l > 0$,

$$\frac{\partial^{k+1}\mathbf{u}}{\partial x^i \partial y^j \partial z^l} = \left(\frac{i}{k+3} \frac{\partial^k \operatorname{div}\mathbf{u}}{\partial x^{i-1} \partial y^j \partial z^l}, \frac{j}{k+3} \frac{\partial^k \operatorname{div}\mathbf{u}}{\partial x^i \partial y^{j-1} \partial z^l}, \frac{l}{k+3} \frac{\partial^k \operatorname{div}\mathbf{u}}{\partial x^i \partial y^j \partial z^{l-1}} \right).$$

We conclude, as in the last part of the proof of Theorem 2.5, by using the commutative diagram property of $\widetilde{\Pi}_k$ and by observing that Lemma 2.3 has a straightforward extension to the element $\widetilde{K}$. ∎

FINITE-DIMENSIONAL APPROXIMATION SETTINGS FOR INFINITE-DIMENSIONAL MOORE–PENROSE INVERSES*

NAILIN DU†

Abstract. After a brief survey of basic results about finite-dimensional approximation settings (such as mathematical frameworks of various projection methods, including the least-squares method, the dual least-squares method, and the Galerkin method) for infinite-dimensional Moore–Penrose inverses, this paper proceeds to a detailed study from the following aspects: For projection methods, we investigate convergence and weak convergence of their approximation setting to develop a unified theory on projection methods for infinite-dimensional Moore–Penrose inverses; this investigation yields a fundamental convergence theorem (Theorem 2.2), from which the criterion for convergence, the criterion for weak convergence, and the generalized dual least-squares method are derived. We also derive general results on the least-squares method, by which two flaws in Groestch's results are corrected. For nonprojection methods (whose approximation setting is a more general framework), we investigate weak perfect convergence of their approximation setting and provide a necessary and sufficient condition of such convergence holding (Theorem 3.2). Several examples are proposed as counterexamples to illustrate the differences between some important concepts or as concrete algorithms to show how the present work can help to analyze their behavior.

Key words. convergence, weak convergence, weak perfect convergence, stability

1. Introduction.

Let X and Y be Hilbert spaces over the same scalars and $T \in \mathcal{B}(X,Y)$, i.e., $T : X \to Y$ is a bounded linear operator. If X_0 and Y_0 are closed subspaces of X and Y, respectively, P_{X_0} and Q_{Y_0} will denote the orthogonal projections from X onto X_0 and from Y onto Y_0, respectively. Let $\{X_n\}$ and $\{Y_n\}$ be sequences of closed subspaces of X and Y, respectively, which satisfy the completeness conditions, that is,

$$\operatorname*{s-lim}_{n\to\infty} P_n = I_X, \qquad \operatorname*{s-lim}_{n\to\infty} Q_n = I_Y,$$

where $P_n := P_{X_n}$ and $Q_n := Q_{Y_n}$; for each $n \in \mathbb{N}$, let $T_n \in \mathcal{B}(X_n, Y_n)$ with closed range $\mathcal{R}(T_n)$. Consider the operator equation of the first kind

$$Tu = b, \quad u \in X, \tag{1.1}$$

with its approximations

$$T_n u_n = b_n, \quad u_n \in X_n, \tag{1.2}$$

where $b \in Y$, $b_n \in Y_n$, and $b_n \to b$ in Y as $n \to \infty$. A practical case of interest is that $\dim X_n < \infty$ $(n \in \mathbb{N})$, $\dim \mathcal{R}(T) = \infty$, and X_n $(n \in \mathbb{N})$ are increasing and eventually dense in X, that is,

$$X_n \subseteq X_{n+1} \quad \text{and} \quad \overline{\bigcup_{n=1}^{\infty} X_n} = X.$$

We are interested in the problem of approximating the best-approximate solution of (1.1), i.e., the least-squares solution of the minimal norm of (1.1), which is that vector $u_\infty \in X$ of smallest norm satisfying

$$\|Tu_\infty - b\| = \inf\{\|Tx - b\| \,|\, x \in X\}.$$

The vector u_∞ exists if and only if $Q_{\overline{\mathcal{R}(T)}} b \in \mathcal{R}(T)$, and u_∞ is given by $u_\infty = T^\dagger b$, where $T^\dagger$ is the Moore–Penrose generalized inverse of T. $T^\dagger$ is, in general, a closed linear operator with

$$\mathcal{D}\left(T^\dagger\right) = \mathcal{R}(T) + \mathcal{R}(T)^\perp, \quad \mathcal{N}\left(T^\dagger\right) = \mathcal{R}(T)^\perp, \quad \text{and} \quad \mathcal{R}\left(T^\dagger\right) = \mathcal{N}(T)^\perp.$$

Note that $\mathcal{D}\left(T^\dagger\right) = Y$ if and only if $\mathcal{R}(T)$ is closed. Here we remark that, since $T_n \in \mathcal{B}(X_n, Y_n)$ is with closed range $\mathcal{R}(T_n)$ in Y_n, the generalized inverse $T_n^\dagger$ of T_n is a bounded linear operator with

$$\mathcal{D}\left(T_n^\dagger\right) = Y_n, \quad \mathcal{N}\left(T_n^\dagger\right) = \mathcal{R}(T_n)^\perp \cap Y_n, \quad \text{and} \quad \mathcal{R}\left(T_n^\dagger\right) = \mathcal{N}(T_n)^\perp \cap X_n.$$

See [11, 22, 28] for comprehensive information about generalized inverses. For infinite-dimensional problems with the approximation setting (1.1) and (1.2), the questions of finite-dimensional approximations of the infinite-dimensional Moore–Penrose inverse $T^\dagger$ and their convergence naturally arise, so we formulate the following conditions:

- (H1) (*consistency*):

$$\lim_{n\to\infty} \|Q_n (T_n - T) P_n x\| = 0 \quad (\forall\, x \in X).$$

- (H1)$^{\mathrm{u}}$ (*uniform consistency*):

$$\lim_{n\to\infty} \|Q_n (T_n - T) P_n\| = 0.$$

- (H2) (*stability*): There is a constant $C > 0$ such that

$$\left\|T_n^\dagger\right\|_n := \sup\left\{\left\|T_n^\dagger y\right\| \,\middle|\, y \in Y_n, \|y\| = 1\right\} \leqslant C \quad (\forall\, n \in \mathbb{N}).$$

- (H3)$^{\mathrm{s}}$ (*convergence*):

$$\lim_{n\to\infty} T_n^\dagger Q_n y = T^\dagger y \quad \left(\forall\, y \in \mathcal{D}\left(T^\dagger\right)\right).$$

- (H3)$^{\mathrm{w}}$ (*weak convergence*):

$$\operatorname*{w\text{-}lim}_{n\to\infty} T_n^\dagger Q_n y = T^\dagger y \quad \left(\forall\, y \in \mathcal{D}\left(T^\dagger\right)\right).$$

- (H3)$^{\mathrm{s}}_{\mathrm{p}}$ (*perfect convergence*):

$$\mathcal{D}\left(T^\dagger\right) = Y \quad \text{and} \quad \operatorname*{s\text{-}lim}_{n\to\infty} T_n^\dagger Q_n = T^\dagger.$$

- (H3)$^{\mathrm{u}}_{\mathrm{p}}$ (*uniform perfect convergence*):

$$\mathcal{D}\left(T^\dagger\right) = Y \quad \text{and} \quad \lim_{n\to\infty} T_n^\dagger Q_n = T^\dagger.$$

- (H3)$^{\mathrm{w}}_{\mathrm{p}}$ (*weak perfect convergence*):

$$\mathcal{D}\left(T^\dagger\right) = Y \quad \text{and} \quad \operatorname*{w\text{-}lim}_{n\to\infty} T_n^\dagger Q_n = T^\dagger.$$

In addition, we introduce the following notation:

$$\operatorname*{s\text{-}lim}_{n\to\infty} S_n := \{\, x \mid \text{there is a sequence } \{x_n\} \text{ such that } S_n \ni x_n \to x \},$$

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} S_n := \left\{ x \mid \text{there is a sequence } \{x_n\} \text{ such that } \bigcup_{k=n}^{\infty} S_k \ni x_n \rightharpoonup x \right\},$$

where $\{S_n\}$ is a sequence of nonempty subsets of a Banach space, and

$$A^{\perp} := \{\, x \in X \text{ (or } Y) \mid \langle x, u\rangle = 0 \ (\forall\ u \in A)\},$$
$$B^{\perp_n} := \{\, x \in X_n \text{ (or } Y_n) \mid \langle x, u\rangle = 0 \ (\forall\ u \in B)\},$$

where $A \subseteq X$ (or Y) and $B \subseteq X_n$ (or Y_n). The notation in the paper can generally be found in [4] except when noted specifically.

In practice, to solve the best-approximate solution of (1.1) numerically we naturally reduce (1.1) to the finite system of (1.2) whose best-approximate solution is available, where the approximation setting (1.1) and (1.2) is usually designed to be with (H1) or $(\mathrm{H1})^{\mathrm{u}}$, which falls into the category of projection methods (see [17, pp. 199–321] for the theory of projection methods). For projection methods, the convergence and stability of their approximation settings are usually major objectives to study, so in this work we are interested in various convergence settings, such as the setting (1.1) and (1.2) with $(\mathrm{H3})^{\mathrm{s}}$, $(\mathrm{H3})^{\mathrm{w}}$, $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$, $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$, or $(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}}$, etc.

Next, in this section we give a brief survey of basic results about various convergence settings and then present new work. We will discuss the approximation setting (1.1) and (1.2) with $(\mathrm{H1})^{\mathrm{u}}$ or (H1) in the following situations:

Situation 1: $\mathcal{R}(T)$ is closed; that is, (1.1) is a well-posed problem.

Situation 2: $\mathcal{R}(T)$ is nonclosed; that is, (1.1) is an ill-posed problem.

1.1. Well-posed problems. For well-posed problems with the approximation setting (1.1) and (1.2), $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$, $(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}}$, and $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ are the three kinds of convergence to be considered (in this situation $(\mathrm{H3})^{\mathrm{s}}$ and $(\mathrm{H3})^{\mathrm{w}}$ are equivalent to $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$ and $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$, respectively). The works [2, 3, 4, 14, 19, 20, 21, 23, 25, 29] may be viewed as research involving $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$, $(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}}$, and $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$, in which the basic results, due to Izumino [14], are as follows.

THEOREM 1.1 (see [14, Proposition 2.3]). *Let $\{T_n\}$ be a sequence in $\mathcal{CR}(X,Y)$, and let $T_n \xrightarrow{\mathrm{u}} T \in \mathcal{CR}(X,Y)$ $[(\mathrm{H1})^{\mathrm{u}}]$, where $\mathcal{CR}(X,Y)$ is the set of all operators in $\mathcal{B}(X,Y)$ with closed range. Then the following conditions are equivalent:*

(a) $T_n^{\dagger} \xrightarrow{\mathrm{u}} T^{\dagger}$ $[(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}}]$;

(b) $\sup_n \|T_n^{\dagger}\| < \infty$ [(H2)];

(c) $T_n^{\dagger}T_n \xrightarrow{\mathrm{u}} T^{\dagger}T$;

(d) $T_nT_n^{\dagger} \xrightarrow{\mathrm{u}} TT^{\dagger}$.

THEOREM 1.2 (see [14, Proposition 2.4]). *Let $\{T_n\}$ be a sequence in $\mathcal{CR}(X,Y)$, and let $T_n \xrightarrow{\mathrm{s}} T \in \mathcal{CR}(X,Y)$ [(H1)]. Then the following conditions are equivalent:*

(a) $T_n^{\dagger} \xrightarrow{\mathrm{s}} T^{\dagger}$ $[(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}]$;

(b) $\sup_n \|T_n^{\dagger}\| < \infty$ [(H2)], $T_n^{\dagger}T_n \xrightarrow{\mathrm{s}} T^{\dagger}T$, *and* $T_nT_n^{\dagger} \xrightarrow{\mathrm{s}} TT^{\dagger}$.

From the computational point of view the above results may be at best regarded as academic, for T_n and T are defined on the same maybe infinite-dimensional space. Let us recall two results more convenient for numerical analysis.

THEOREM 1.3 (see [4, Theorem 2.1]). *For the approximation setting* (1.1) *and* (1.2), *suppose* (H1). *Then the following propositions hold:*

(a) $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Longleftrightarrow \begin{cases} (\mathrm{H2}), \\ \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n) \subseteq \mathcal{N}(T) + \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{N}(T_n), \\ \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{R}(T_n) \subseteq \overline{\mathcal{R}(T)}. \end{cases}$

(b) $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Longrightarrow \begin{cases} \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{N}(T_n) = \mathcal{N}(T), \\ \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{R}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{R}(T_n) = \mathcal{R}(T). \end{cases}$

THEOREM 1.4 (see [4, Theorem 3.1]). *For the approximation setting* (1.1) *and* (1.2), *suppose* $(\mathrm{H1})^{\mathrm{u}}$. *Then the following propositions hold:*

(a) $(\mathrm{H2}) \Longrightarrow \begin{cases} \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{N}(T_n) = \mathcal{N}(T), \\ \mathrm{w}\text{-}\widetilde{\lim}_{n\to\infty}\mathcal{R}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{R}(T_n) = \mathcal{R}(T). \end{cases}$

(b) $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Longleftrightarrow (\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}} \Longleftrightarrow (\mathrm{H2})$.

(c) $(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}} \Longleftrightarrow \begin{cases} (\mathrm{H2}), \\ \lim_{n\to\infty}\|T - Q_nTP_n\| = 0. \end{cases}$

As a corollary of Theorem 1.4, the following practical result holds.

COROLLARY 1.5 (see [4, Theorem 3.4]). *Let* $\{X_n\}$ *and* $\{Y_n\}$ *be sequences of finite-dimensional subspaces of* X *and* Y *which are increasing and eventually dense in* X *and* Y, *respectively. Suppose that* $T \in \mathcal{B}(X,Y)$ *and*

$$T_n := Q_nTP_n : X_n \to Y_n \quad (\forall\ n \in \mathbb{N}).$$

Then Theorem 1.4 *holds under the given conditions.*

Remark 1.6. By [4, Lemmas 2.12 and 2.13], there hold

$$\mathrm{w}\text{-}\widetilde{\lim_{n\to\infty}}\mathcal{N}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{N}(T_n) = \mathcal{N}(T) \Longleftrightarrow \mathrm{s}\text{-}\lim_{n\to\infty}P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)},$$
$$\mathrm{w}\text{-}\widetilde{\lim_{n\to\infty}}\mathcal{R}(T_n) = \mathrm{s}\text{-}\lim_{n\to\infty}\mathcal{R}(T_n) = \mathcal{R}(T) \Longleftrightarrow \mathrm{s}\text{-}\lim_{n\to\infty}Q_{\mathcal{R}(T_n)} = Q_{\mathcal{R}(T)}.$$

1.2. Ill-posed problems. For ill-posed problems with the approximation setting (1.1) and (1.2), one needs to consider $(\mathrm{H3})^{\mathrm{s}}$ and $(\mathrm{H3})^{\mathrm{w}}$ of the two kinds of convergence (because $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$, $(\mathrm{H3})^{\mathrm{u}}_{\mathrm{p}}$, and $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ are meaningless in this situation). There are two natural and practical approaches to approximating $T^{\dagger}$, namely, the least-squares method and the dual least-squares method, which have been studied by many authors, e.g., [6, 8, 9, 12, 13, 15, 24, 26]. Note that the two methods fit into the framework of the setting (1.1) and (1.2) with $(\mathrm{H1})^{\mathrm{u}}$. We recall some basic results about the two methods, which are the assertions concerning $(\mathrm{H3})^{\mathrm{s}}$ and $(\mathrm{H3})^{\mathrm{w}}$.

1.2.1. The basic results on the least-squares method. The least-squares method (see, e.g., [9, 12, 10]) is to find the minimum-norm solution of (1.1) in a finite-dimensional subspace of X. That is, given a sequence $\{X_n\}_{n=1}^{\infty}$ of finite-dimensional subspaces of X which satisfies that X_n $(n \in \mathbb{N})$ are increasing and eventually dense in X, let x_n be the minimal norm least-squares solution of (1.1) in the subspace X_n. Obviously,

$$x_n = T_n^{\dagger}b,$$

where $T_n := T|_{X_n} \in \mathcal{B}(X_n, Y)$. Note that, since T_n has closed range,

$$\mathcal{D}\left(T_n^{\dagger}\right) = Y, \quad T_n^{\dagger} \in \mathcal{B}(Y, X_n) \subseteq \mathcal{B}(Y, X), \quad T_n^{\dagger} = (TP_n)^{\dagger}.$$

Here we recall the basic results of Groetsch and Neubauer [9, 12].

THEOREM 1.7 (see [9, Proposition 0]). *The sequence $\{x_n\}$ converges (to $T^\dagger b$) for all $b \in \mathcal{D}\left(T^\dagger\right)$ if and only if the sequence $\{\|R_n\|\}$ is bounded. Here $R_n := T_n^\dagger Q_{\mathcal{R}(T_n)} T$.*

Remark 1.8. The approximation setting (1.1) and (1.2) with X_n being as above, $Y_n := Y$, and $T_n := T|_{X_n}$ provides the mathematical framework of the least-squares method, and the above theorem says that:

$$(\mathrm{H3})^{\mathrm{s}} \iff (\mathrm{H3})^{\mathrm{w}} \iff \sup_n \left\|T_n^\dagger T\right\| < \infty\,.$$

THEOREM 1.9 (see [12, Theorem 1]). *For a given $g \in \mathcal{D}\left(T^\dagger\right)$, let $f_n := T_n^\dagger g$. Then $\{f_n\}$ converges weakly to $f_0 := T^\dagger g$ if and only if $\{\|f_n\|\}$ is bounded.*

Remark 1.10. The above theorem is incomplete because there is an absence of a condition in its statement. We should note that, without that condition, the theorem would be false. We will explain this observation by giving a counterexample.

1.2.2. The basic result on the dual least-squares method. The dual least-squares method (see, e.g., [6, 7, 10, 26]), different from the least-squares method, is to look to the range space itself for finite-dimensional subspaces in order to form finite rank approximations to $T^\dagger$. That is, given a sequence

$$V_1 \subseteq V_2 \subseteq V_3 \subseteq \cdots$$

of finite-dimensional subspaces of $\overline{\mathcal{R}(T)} = \mathcal{N}(T^*)^\perp \subseteq Y$ whose union is dense in $\mathcal{N}(T^*)^\perp$, let x_n be now defined as the least-squares solution of minimal norm of the equation

$$T_n u = b_n, \qquad T_n := Q_{V_n} T, \quad b_n := Q_{V_n} b.$$

Note that $T_n \in \mathcal{B}(X,Y) \cap \mathcal{B}(X,V_n)$ (with closed range), and therefore

$$T_n^\dagger \in \mathcal{B}(Y,X) \cap \mathcal{B}(V_n,X)\,, \quad x_n = T_n^\dagger b = T_n^\dagger b_n.$$

The basic result on the dual least-squares method is the following (see, e.g., [7, Theorem 3.24], [10, Theorems 4.1.2 and 4.1.3], and [26, Theorem 2.1]).

THEOREM 1.11. (a) *Let $b \in \mathcal{D}\left(T^\dagger\right)$ and x_n as above. Then $x_n = P_{U_n} x^\dagger$, where $U_n := T^*(V_n)$, $x^\dagger := T^\dagger b$. Moreover, $x_n \to x^\dagger$ as $n \to \infty$.*

(b) *If $b \notin \mathcal{D}\left(T^\dagger\right)$ and x_n is as above, then $\|x_n\| \to \infty$ as $n \to \infty$.*

Remark 1.12. Set $X_n := X$, $Y_n := V_n + \mathcal{N}(T^*)$, $P_n := I_X$, $Q_n := Q_{V_n} + Q_{\mathcal{N}(T^*)}$, and $T_n := Q_{V_n} T$. Then

$$\operatorname*{s-lim}_{n\to\infty} P_n = I_X, \quad \operatorname*{s-lim}_{n\to\infty} Q_n = I_Y, \quad T_n = Q_n T,$$

so that the approximation setting (1.1) and (1.2) in this case provides the mathematical framework of the dual least-squares method. Theorem 1.11 shows that, for the dual least-squares method, $(\mathrm{H3})^{\mathrm{s}}$ as well as $(\mathrm{H3})^{\mathrm{w}}$ are always guaranteed. However, the finite-dimensional subspaces V_n, whose union is dense in $\overline{\mathcal{R}(T)}$, are sometimes not easy to come by. In fact, the subspaces V_n can be replaced by more convenient finite-dimensional subspaces of Y that might be desirable; we notice that the special choice of V_n is only to result in $\sup_n \left\|T_n^\dagger Q_n T\right\| < \infty$ (see Corollaries 2.4 and 2.5).

1.2.3. Projection methods. The least-squares method and the dual least-squares method belong to the class of projection methods. The unified approximation

setting of projection methods is the following: For the approximation setting (1.1) and (1.2), let $\{X_n\}$ and $\{Y_n\}$ be sequences of finite-dimensional subspaces of X and Y, respectively, which are increasing and eventually dense in X and Y, and let

$$T_n := Q_n T P_n : X_n \to Y_n \quad (\forall\, n \in \mathbb{N})\,;$$

for a given vector $b \in \mathcal{D}\left(T^\dagger\right)$, let

$$x^\dagger := T^\dagger b, \qquad x_n := T_n^\dagger Q_n b \quad (\forall\, n \in \mathbb{N})\,.$$

Note that, since T_n has closed range, the operator $T_n^\dagger$ is bounded, and x_n is a stable approximation of $x^\dagger$; but, without additional assumptions, it cannot be guaranteed that x_n converges to $x^\dagger$ whether strongly or weakly, as the example from Seidman [27] shows. Naturally, it is interesting for us to look for criteria for $(\mathrm{H3})^{\mathrm{s}}$ and $(\mathrm{H3})^{\mathrm{w}}$ of the unified projection approximation setting. In this direction the author hasn't seen a desirable general result; but, in the special case of "$\mathcal{N}(T_n) = \{0\}$ $(n \in \mathbb{N})$," there holds

$$T_n^\dagger Q_n T x = P_n x + T_n^\dagger Q_n T\,(I - P_n)\,x,$$

and therefore

$$\lim_{n\to\infty} x_n = x^\dagger \ \ (\forall\, b \in \mathcal{R}(T)) \iff \sup_n \left\|T_n^\dagger Q_n T\right\| < \infty \implies \mathcal{N}(T) = \{0\}\,.$$

Here we refer to [16, Theorem 3.7] and [18, Theorem 17.1].

Of course, there are many other methods for obtaining stable approximations of infinite-dimensional Moore–Penrose inverses, the important ones including iterative methods, the conjugate gradient method, the Tikhonov regularization method, and various discretization forms of the above methods. Since there has already been much research about them (see [7, 10, 11, 22, 24, 26, 28], and the references cited therein), the present paper is not going to involve those methods.

The above is a brief survey of basic results about various convergences of the finite-dimensional approximation settings for infinite-dimensional Moore–Penrose inverses.

1.3. New work. The dual least-squares method is sometimes suggested in discretization of regularization methods for ill-posed problems. The approximation setting of this method as well as the least-squares method is with the special projection scheme (see Remarks 1.12 and 1.8), and therefore $(\mathrm{H3})^{\mathrm{s}}$ and $(\mathrm{H3})^{\mathrm{w}}$ are always guaranteed (see Theorem 1.11). Naturally, one wants to generalize this characterization to more general projection schemes. In section 2, we develop a unified theory on the general projection methods for infinite-dimensional Moore–Penrose inverses, which contains:

- fundamental convergence theorems (see Theorem 2.2 and its corollaries), which are generalizations of Theorems 1.11 and 1.7, and with a wider scope of application;
- the criterion for $(\mathrm{H3})^{\mathrm{s}}$, the criterion for $(\mathrm{H3})^{\mathrm{w}}$, etc. (see Theorem 2.6);
- general results for the least-squares method (see Theorem 2.8), by which the flaws in [9, Proposition 0] and [12, Theorem 1] are corrected (see Remark 2.9).

In section 3, we investigate $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ for the approximation setting (1.1) and (1.2) with (H1). Note that, for such a general approximation setting, $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ is equivalent neither to (H2) nor to $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$; the relation among the three is

$$(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \implies (\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}} \implies (\mathrm{H2}).$$

We present a result to characterize $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ by use of (H2) with other necessary compensated conditions (see Theorem 3.2), which is further explained by four examples. A corollary of the result is also presented, which can be applied to an interesting special case.

In section 4, we summarize the conclusions of the paper. Theorems 2.2 and 3.2 are the fundamental results obtained.

2. Projection methods for Moore–Penrose inverses. In this section, the approximation setting (1.1) and (1.2) satisfies that, for each $n \in \mathbb{N}$,

$$T_n := Q_n T P_n : X_n \to Y_n, \qquad \mathcal{R}(T_n) \text{ is closed}, \qquad R_n := T_n^{\dagger} Q_n T\,. \tag{2.1}$$

In such a case, the setting (1.1) and (1.2) provides the unified mathematical framework of projection methods (including the least-squares method and the dual least-squares method as special cases), which is with $(\mathrm{H1})^{\mathrm{u}}$ automatically. For this approximation setting, we will present a general convergence theory, which can be applied to ill-posed problems.

2.1. The fundamental convergence theorem for projection methods. We prepare a lemma first.

LEMMA 2.1. *Let H be a Hilbert space and $\{H_n\}$ a sequence of closed subspaces of H.*

(a) *There holds*

$$\{P_{H_n}\} \text{ is strongly convergent} \iff \operatorname*{s\,-lim}_{n\to\infty} H_n = \operatorname*{w\,-\widetilde{lim}}_{n\to\infty} H_n\,;$$

in the case that $\{P_{H_n}\}$ is strongly convergent,

$$\operatorname*{s\,-lim}_{n\to\infty} P_{H_n} = P_M\,, \quad \text{where } M := \operatorname*{s\,-lim}_{n\to\infty} H_n\,.$$

(b) *If N is a closed subspace of H, then*

$$\begin{aligned} \operatorname*{s\,-lim}_{n\to\infty} P_{H_n} = P_N &\iff \operatorname*{w\,-lim}_{n\to\infty} P_{H_n} = P_N \\ &\iff \lim_{n\to\infty} \|P_{H_n} x\| = \|P_N x\| \ \ (\forall\, x \in X)\,. \end{aligned}$$

Proof. See [4, Lemma 2.13] or [5, Theorem 2.1] for the proof of (a).

In order to prove (b) we need only to show that

$$\lim_{n\to\infty} \|P_{H_n} x\| = \|P_N x\| \ \ (\forall\ x \in X) \implies \operatorname*{s\,-lim}_{n\to\infty} P_{H_n} = P_N. \tag{2.2}$$

Indeed, by the polarization identities (see, e.g., [1, p. 20]) and the fact of "$P_N^2 = P_N = P_N^*$," it is easy to see that

$$\lim_{n\to\infty} \|P_{H_n} x\| = \|P_N x\| \ \ (\forall\ x \in X) \iff \operatorname*{w\,-lim}_{n\to\infty} P_{H_n} = P_N. \tag{2.3}$$

Thus, (2.2) follows with (2.3) and [30, Theorem 8 on p. 124]. ∎

Now we present the fundamental convergence theorem for projection methods, which is one of the main results in the paper.

THEOREM 2.2. *Let the approximation setting* (1.1) *and* (1.2) *satisfy* (2.1). *If* $\sup_n \|R_n\| < \infty$, *then:*

(a) $\text{s-lim}_{n\to\infty} \mathcal{N}(T_n) = \text{w-}\widetilde{\lim}_{n\to\infty} \mathcal{N}(T_n) = \mathcal{N}(T)$*; that is,*

$$\operatorname*{s\,-lim}_{n\to\infty} P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)};$$

(b) *for all* $b \in \mathcal{D}\left(T^{\dagger}\right)$,

$$\left\|T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T^{\dagger} b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^{\dagger} b\right\| + \|R_n - I_X\| \operatorname{dist}\left(T^{\dagger} b, X_n\right) \to 0;$$

(c) $\text{s-lim}_{n\to\infty} Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} = Q_{\overline{\mathcal{R}(T)}}$, *and*

$$\lim_{n\to\infty} \left\|T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} y\right\| = \begin{cases} \left\|T^{\dagger} y\right\|, & \text{as } y \in \mathcal{D}\left(T^{\dagger}\right), \\ \infty, & \text{as } y \notin \mathcal{D}\left(T^{\dagger}\right). \end{cases}$$

Proof. The proof will be carried out in three steps.

Step 1 (to prove (a)). Let $x \in \mathcal{N}(T)$. Then

$$R_n P_n x + R_n (I - P_n) x = 0.$$

Since

$$R_n P_n x = T_n^{\dagger} T_n P_n x = P_n x - P_{\mathcal{N}(T_n)} x,$$

and since $\sup_n \|R_n\| < \infty$, we then have

$$P_{\mathcal{N}(T_n)} x = P_n x + R_n (I - P_n) x \to x \quad \text{as } n \to \infty.$$

Thus, it follows that

$$\mathcal{N}(T) \subseteq \operatorname*{s\text{-}lim}_{n\to\infty} \mathcal{N}(T_n). \tag{2.4}$$

Now let $x \in \text{w-}\widetilde{\lim}_{n\to\infty} \mathcal{N}(T_n)$. Then, by the definition of $\text{w-}\widetilde{\lim}_{n\to\infty} \mathcal{N}(T_n)$, there exists a sequence $\{x_n\}$ such that

$$x_n \in \bigcup_{k \geqslant n} \mathcal{N}(T_k) \ (\forall\, n) \quad \text{and} \quad x_n \rightharpoonup x \text{ as } n \to \infty. \tag{2.5}$$

Since for each $n \in \mathbb{N}$ there is a $k_n \in \mathbb{N}$ such that $k_n \geqslant n$ and $x_n \in \mathcal{N}(T_{k_n})$, and since $T_{k_n} = Q_{k_n} T P_{k_n}$ (see (2.1)), we then have

$$\begin{aligned} |\langle Tx, u\rangle| &\leqslant |\langle T(x - x_n), u\rangle| + |\langle T_{k_n} x_n, u\rangle| + |\langle Tx_n, (I_Y - Q_{k_n}) u\rangle| \\ &\leqslant |\langle T(x - x_n), u\rangle| + \|T\| \|x_n\| \|(I_Y - Q_{k_n}) u\| \qquad (\forall\, u \in X). \end{aligned} \tag{2.6}$$

So it follows from (2.5) and (2.6) that $x \in \mathcal{N}(T)$. Thus, we obtain

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \mathcal{N}(T_n) \subseteq \mathcal{N}(T). \tag{2.7}$$

From (2.4) and (2.7), together with Lemma 2.1 or Remark 1.6, we conclude that (a) holds.

Step 2 (to prove (b)). Let $b \in \mathcal{D}\left(T^{\dagger}\right)$. Then

$$\begin{aligned} T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T^{\dagger} b &= \left(T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T_n^{\dagger} T_n P_n T^{\dagger} b\right) + \left(T_n^{\dagger} T_n P_n T^{\dagger} b - T^{\dagger} b\right) \\ &= \left(T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T_n^{\dagger} Q_n T P_n T^{\dagger} b\right) + \left(T_n^{\dagger} T_n P_n T^{\dagger} b - T^{\dagger} T T^{\dagger} b\right) \\ &= T_n^{\dagger} Q_n \left(T T^{\dagger} b - T P_n T^{\dagger} b\right) + \left(T_n^{\dagger} T_n P_n - T^{\dagger} T\right) T^{\dagger} b \\ &= R_n (I_X - P_n) T^{\dagger} b + \left(P_n - P_{\mathcal{N}(T_n)} - I_X + P_{\mathcal{N}(T)}\right) T^{\dagger} b \\ &= -P_{\mathcal{N}(T_n)} T^{\dagger} b + (R_n - I_X)(I_X - P_n) T^{\dagger} b, \end{aligned}$$

so that

$$\left\|T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b - T^\dagger b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^\dagger b\right\| + \|R_n - I_X\| \operatorname{dist}\left(T^\dagger b, X_n\right) . \tag{2.8}$$

Thus, (b) follows from (2.8) and (a).

Step 3 (to prove (c)). By (b), there holds

$$\lim_{n\to\infty} T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b = T^\dagger b \quad \left(\forall\ b \in \mathcal{D}\left(T^\dagger\right)\right) .$$

Hence, for any $v \in Y$ and $b \in \mathcal{D}\left(T^\dagger\right)$,

$$\begin{aligned}\left\langle Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} b\,, v\right\rangle &= \left\langle T_n T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b\,, v\right\rangle \\ &= \left\langle Q_n T T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b\,, v\right\rangle \\ &= \left\langle T T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b\,, Q_n v\right\rangle \to \left\langle Q_{\overline{\mathcal{R}(T)}} b\,, v\right\rangle \qquad \text{as } n \to \infty;\end{aligned}$$

that is,

$$\operatorname*{w\text{-}lim}_{n\to\infty} Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} b = Q_{\overline{\mathcal{R}(T)}} b \qquad \left(\forall\ b \in \mathcal{D}\left(T^\dagger\right)\right) . \tag{2.9}$$

Since $\overline{\lim}_{n\to\infty} \|Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} b\| \leqslant \|Q_{\overline{\mathcal{R}(T)}} b\|$ is always valid, by [30, Theorem 1 on p. 120], (2.9) implies that

$$\lim_{n\to\infty} \left\|Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} b\right\| = \left\|Q_{\overline{\mathcal{R}(T)}} b\right\| \qquad \left(\forall\ b \in \mathcal{D}\left(T^\dagger\right)\right) . \tag{2.10}$$

Now, by [30, Theorem 8 on p. 124], it follows from (2.9) and (2.10) that

$$\operatorname*{s\text{-}lim}_{n\to\infty} Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} b = Q_{\overline{\mathcal{R}(T)}} b \qquad \left(\forall\ b \in \mathcal{D}\left(T^\dagger\right)\right) .$$

Notice that $\mathcal{D}\left(T^\dagger\right)$ is a dense subspace of Y, so, by the Banach–Steinhaus theorem [1, Theorem 2.4.5 on p. 58], we obtain

$$\operatorname*{s\text{-}lim}_{n\to\infty} Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} = Q_{\overline{\mathcal{R}(T)}} . \tag{2.11}$$

Next, let $y \notin \mathcal{D}\left(T^\dagger\right)$, and we need only to show that

$$\lim_{n\to\infty} \left\|T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} y\right\| = \infty . \tag{2.12}$$

Assume that there is a sequence $n_k \to \infty$ $(k \to \infty)$ such that

$$\sup_k \left\|T_{n_k}^\dagger Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\right\| < \infty ,$$

so that $\{T_{n_k}^\dagger Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\}$ has a subsequence (denoted again by $\{T_{n_k}^\dagger Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\}$) which converges weakly to an $x_\infty \in X$. Since T is also weakly sequentially continuous,

$$T T_{n_k}^\dagger Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y \rightharpoonup T x_\infty \quad \text{as } k \to \infty . \tag{2.13}$$

On the other hand, for any $v \in Y$ it follows from (2.11) and (2.13) that

$$\begin{aligned}\left\langle TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, v \right\rangle &= \left\langle TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, Q_{n_k} v \right\rangle \\ &\qquad + \left\langle TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, (I_Y - Q_{n_k})\, v \right\rangle \\ &= \left\langle T_{n_k} T_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, v \right\rangle + \left\langle TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, (I_Y - Q_{n_k})\, v \right\rangle \\ &= \left\langle Q_{\mathcal{R}\left(T_{n_k}\right)} Q_{\overline{\mathcal{R}(T)}} y\,, v \right\rangle + \left\langle TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\,, (I_Y - Q_{n_k})\, v \right\rangle \\ &\to \left\langle Q_{\overline{\mathcal{R}(T)}} y\,, v \right\rangle \qquad \text{as } k \to \infty\,.\end{aligned}$$

This implies that

$$TT_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y \rightharpoonup Q_{\overline{\mathcal{R}(T)}} y \quad \text{as } k \to \infty\,. \tag{2.14}$$

From (2.13) and (2.14) we obtain that $Q_{\overline{\mathcal{R}(T)}} y = T x_\infty \in \mathcal{R}(T)$, so that $y \in \mathcal{D}\left(T^{\dagger}\right)$. Thus, if $y \notin \mathcal{D}\left(T^{\dagger}\right)$, no bounded sequence $\{\|T_{n_k}^{\dagger} Q_{n_k} Q_{\overline{\mathcal{R}(T)}} y\|\}$ (where $n_k \to \infty$ $(k \to \infty)$) can exist; hence (2.12) holds. ∎

2.2. Corollaries of the fundamental convergence theorem. The following three results are simple corollaries of Theorem 2.2.

COROLLARY 2.3 (the least-squares method). *Let $T \in \mathcal{B}(X,Y)$, X_n $(n \in \mathbb{N})$ be finite-dimensional subspaces of X such that*

$$X_1 \subseteq X_2 \subseteq X_3 \subseteq \cdots\,, \quad \overline{\bigcup_{n=1}^{\infty} X_n} = X\,.$$

Let $T_n := T|_{X_n} : X_n \to Y$ $(n \in \mathbb{N})$. If $\sup_n \left\|T_n^{\dagger} T\right\| < \infty$, then:

(a) *there hold*

$$\mathcal{N}(T_n) = \mathcal{N}(T) \cap X_n, \qquad \overline{\bigcup_{n=1}^{\infty} \mathcal{N}(T_n)} = \mathcal{N}(T)\;;$$

(b) *for all $b \in \mathcal{D}\left(T^{\dagger}\right)$,*

$$\left\|T_n^{\dagger} b - T^{\dagger} b\right\| \leqslant \left\|T_n^{\dagger} T - I_X\right\| \operatorname{dist}\left(T^{\dagger} b, X_n\right) \to 0\,;$$

(c) *there hold*

$$\mathcal{R}(T_n) = T(X_n)\;, \qquad \overline{\bigcup_{n=1}^{\infty} \mathcal{R}(T_n)} = \overline{\mathcal{R}(T)}\,,$$

and

$$\lim_{n\to\infty} \left\|T_n^{\dagger} y\right\| = \begin{cases} \left\|T^{\dagger} y\right\|, & \text{as } y \in \mathcal{D}\left(T^{\dagger}\right), \\ \infty, & \text{as } y \notin \mathcal{D}\left(T^{\dagger}\right). \end{cases}$$

COROLLARY 2.4 (the dual least-squares method). *Let $T \in \mathcal{B}(X,Y)$, V_n $(n \in \mathbb{N})$ be finite-dimensional subspaces of $\overline{\mathcal{R}(T)}$ such that*

$$V_1 \subseteq V_2 \subseteq V_3 \subseteq \cdots\,, \quad \overline{\bigcup_{n=1}^{\infty} V_n} = \overline{\mathcal{R}(T)}\,.$$

Let $T_n := Q_{V_n} T : X \to V_n$ $(n \in \mathbb{N})$. Then:

(a) *there hold*

$$\mathcal{N}(T_n) = T^*(V_n)^\perp \quad \text{and} \quad \bigcap_{n=1}^{\infty} \mathcal{N}(T_n) = \mathcal{N}(T)\,;$$

(b) *for all $b \in \mathcal{D}\left(T^\dagger\right)$,*

$$\left\|T_n^\dagger Q_{V_n} b - T^\dagger b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^\dagger b\right\| = \operatorname{dist}\left(T^\dagger b,\, T^*(V_n)\right) \to 0\,,$$

and therefore

$$T_n^\dagger Q_{V_n} b = P_{T^*(V_n)} T^\dagger b\,;$$

(c) *there hold*

$$\mathcal{R}(T_n) = V_n \quad \text{and} \quad \lim_{n\to\infty} \left\|T_n^\dagger Q_{V_n} y\right\| = \begin{cases} \left\|T^\dagger y\right\|, & \text{as } y \in \mathcal{D}\left(T^\dagger\right), \\ \infty, & \text{as } y \notin \mathcal{D}\left(T^\dagger\right); \end{cases}$$

(d) *$\mathcal{R}(T)$ is closed if and only if $\sup_n \left\|T_n^\dagger\right\|_n < \infty$, where*

$$\left\|T_n^\dagger\right\|_n := \sup\left\{\left\|T_n^\dagger y\right\| \;\middle|\; y \in V_n,\, \|y\| = 1\right\}.$$

Corollary 2.5 (the generalized dual least-squares method). *Let $T \in \mathcal{B}(X,Y)$, Y_n $(n \in \mathbb{N})$ be finite-dimensional subspaces of Y such that*

$$\operatorname*{s\,-\,lim}_{n\to\infty} Q_n = I_Y, \qquad \text{where} \quad Q_n := Q_{Y_n} \;\; (n \in \mathbb{N})\,.$$

Let $T_n := Q_n T : X \to Y_n$ $(n \in \mathbb{N})$. Then:

(a) $\text{s-}\lim_{n\to\infty} \mathcal{N}(T_n) = \widetilde{\text{w-}\lim}_{n\to\infty} \mathcal{N}(T_n) = \mathcal{N}(T)$, *with* $\mathcal{N}(T_n) = T^*(Y_n)^\perp$, *and*

$$\operatorname*{s\,-\,lim}_{n\to\infty} P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)};$$

(b) *for all $b \in \mathcal{D}\left(T^\dagger\right)$,*

$$\left\|T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b - T^\dagger b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^\dagger b\right\| = \operatorname{dist}\left(T^\dagger b, T^*(Y_n)\right) \to 0\,,$$

and therefore

$$T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} b = P_{T^*(Y_n)} T^\dagger b\,;$$

(c) $\text{s-}\lim_{n\to\infty} Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} = Q_{\overline{\mathcal{R}(T)}}$ *and*

$$\lim_{n\to\infty} \left\|T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} y\right\| = \begin{cases} \left\|T^\dagger y\right\|, & \text{as } y \in \mathcal{D}\left(T^\dagger\right), \\ \infty, & \text{as } y \notin \mathcal{D}\left(T^\dagger\right). \end{cases}$$

Proof. Since $T_n := Q_n T$, we have

$$\mathcal{N}(T_n) = \mathcal{R}(T^* Q_n)^\perp = T^*(Y_n)^\perp\,.$$

Let $R_n := T_n^\dagger Q_n T$. Then

$$R_n = T_n^\dagger T_n = P_{T^*(Y_n)}, \qquad \|R_n\| \leqslant 1\,.$$

Therefore the corollary is a consequence of Theorem 2.2, with $X_n = X$ $(n \in \mathbb{N})$. ∎

2.3. The criteria for (H3)$^{\mathrm{s}}$ and (H3)$^{\mathrm{w}}$ on projection methods. We can obtain the following result by use of Theorem 2.2.

THEOREM 2.6. *Let the approximation setting* (1.1) *and* (1.2) *satisfy* (2.1). *Then:*

(a) $\lim_{n\to\infty} T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} y = T^\dagger y \ \left(\forall\ y \in \mathcal{D}\left(T^\dagger\right)\right) \iff \sup_{n\in\mathbb{N}} \left\|T_n^\dagger Q_n T\right\| < \infty$;

(b) $(\mathrm{H3})^{\mathrm{s}} \iff \begin{cases} \sup_{n\in\mathbb{N}} \left\|T_n^\dagger Q_n T\right\| < \infty, \\ T_n^\dagger Q_n y \to 0 \text{ if } T_n^* Q_n y \to 0 \end{cases}$ *(criterion for* (H3)$^{\mathrm{s}}$*);*

(c) $(\mathrm{H3})^{\mathrm{w}} \iff \begin{cases} \sup_{n\in\mathbb{N}} \left\|T_n^\dagger Q_n T\right\| < \infty, \\ T_n^\dagger Q_n y \rightharpoonup 0 \text{ if } T_n^* Q_n y \to 0 \end{cases}$ *(criterion for* (H3)$^{\mathrm{w}}$*);*

(d) $(\mathrm{H3})^{\mathrm{w}} \implies \begin{cases} \mathrm{s}\text{-}\lim_{n\to\infty} P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)}, \\ \mathrm{s}\text{-}\lim_{n\to\infty} Q_{\mathcal{R}(T_n)} = Q_{\overline{\mathcal{R}(T)}}. \end{cases}$

Remark 2.7. The two conditions of characterizing (H3)$^{\mathrm{s}}$ or (H3)$^{\mathrm{w}}$, in (b) or (c), are independent (see Examples 3.6 and 4.2).

Proof. It is clear that (a) holds by use of the uniform boundedness principle [30, Theorem 1 on p. 68] and Theorem 2.2.

Notice that for any $b \in \mathcal{D}\left(T^\dagger\right)$ there holds

$$T_n^\dagger Q_n b - T^\dagger b = T_n^\dagger Q_n Q_{\mathcal{R}(T)^\perp} b - P_{\mathcal{N}(T_n)} T^\dagger b + \left(R_n - I_X\right)\left(I_X - P_n\right) T^\dagger b\,. \tag{2.15}$$

From (2.15), by the uniform boundedness principle and Theorem 2.2, we have

$$(\mathrm{b}') \quad (\mathrm{H3})^{\mathrm{s}} \iff \begin{cases} \sup_{n\in\mathbb{N}} \left\|T_n^\dagger Q_n T\right\| < \infty, \\ T_n^\dagger Q_n y \to 0 \text{ if } y \in \mathcal{R}\left(T\right)^\perp; \end{cases}$$

$$(\mathrm{c}') \quad (\mathrm{H3})^{\mathrm{w}} \iff \begin{cases} \sup_{n\in\mathbb{N}} \left\|T_n^\dagger Q_n T\right\| < \infty, \\ T_n^\dagger Q_n y \rightharpoonup 0 \text{ if } y \in \mathcal{R}\left(T\right)^\perp. \end{cases}$$

So, to prove (b) and (c) we need only to show that

$$\mathcal{R}\left(T\right)^\perp = \left\{\, y \in Y \mid T_n^* Q_n y \to 0 \ \ (n \to \infty)\right\}. \tag{2.16}$$

Because for any $x \in X$ and $y \in Y$ there holds

$$\left\langle x\,, T^* y\right\rangle = \left\langle x\,, T_n^* Q_n y\right\rangle + \left\langle x - P_n x\,, T^* y\right\rangle + \left\langle T P_n x\,, y - Q_n y\right\rangle,$$

this implies that

$$y \in \mathcal{N}\left(T^*\right) \iff T_n^* Q_n y \rightharpoonup 0 \ \ (n \to \infty)\,. \tag{2.17}$$

Notice that

$$T_n^* = P_n T^* Q_n : Y_n \to X_n\,.$$

This implies that

$$y \in \mathcal{N}\left(T^*\right) \implies T_n^* Q_n y = P_n T^* \left(Q_n - I_Y\right) y \to 0 \ \ (n \to \infty)\,. \tag{2.18}$$

Now, from (2.17) and (2.18), we obtain

$$y \in \mathcal{N}\left(T^*\right) \iff T_n^* Q_n y \to 0 \ \ (n \to \infty)\,.$$

Since $\mathcal{R}\left(T\right)^\perp = \mathcal{N}\left(T^*\right)$, (2.16) follows.

To prove (d), we note that (H3)$^{\mathrm{w}}$ implies that $\sup_{n\in\mathbb{N}}\left\|T_n^{\dagger}Q_nT\right\|<\infty$, and therefore (by Theorem 2.2)

$$\operatorname*{s\text{-}lim}_{n\to\infty}P_{\mathcal{N}(T_n)}=P_{\mathcal{N}(T)}\,,\quad \operatorname*{s\text{-}lim}_{n\to\infty}Q_{\mathcal{R}(T_n)}Q_{\overline{\mathcal{R}(T)}}=Q_{\overline{\mathcal{R}(T)}}\,. \tag{2.19}$$

Hence, we need only to show that

$$\operatorname*{s\text{-}lim}_{n\to\infty}Q_{\mathcal{R}(T_n)}=Q_{\overline{\mathcal{R}(T)}}\,. \tag{2.20}$$

Notice that

$$\begin{aligned}Q_{\mathcal{R}(T_n)}Q_{\mathcal{R}(T)^{\perp}}&=T_nT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}\\&=TT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}-\left(I_Y-Q_n\right)TT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}\,.\end{aligned}$$

Since (H3)$^{\mathrm{w}}$ implies that

$$TT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}\rightharpoonup TT^{\dagger}Q_{\mathcal{R}(T)^{\perp}}=0\quad\text{as}\quad n\to\infty\,,$$

by which $\sup_n\left\|TT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}\right\|<\infty$ holds, and since this implies that

$$\left(I_Y-Q_n\right)TT_n^{\dagger}Q_nQ_{\mathcal{R}(T)^{\perp}}\rightharpoonup 0\quad\text{as}\quad n\to\infty\,,$$

we then obtain

$$Q_{\mathcal{R}(T_n)}Q_{\mathcal{R}(T)^{\perp}}\rightharpoonup 0\quad\text{as}\quad n\to\infty\,.$$

This together with (2.19) gives

$$\operatorname*{w\text{-}lim}_{n\to\infty}Q_{\mathcal{R}(T_n)}=Q_{\overline{\mathcal{R}(T)}}.$$

Thus, (2.20) follows by Lemma 2.1. □

2.4. General results for the least-squares method. We especially investigate the least-squares method and correct flaws in the Groetsch results in the present subsection.

THEOREM 2.8. *Let $T\in\mathcal{B}(X,Y)$, X_n $(n\in\mathbb{N})$ be finite-dimensional subspaces of X such that*

$$X_1\subseteq X_2\subseteq X_3\subseteq\cdots\,,\quad \overline{\bigcup_{n=1}^{\infty}X_n}=X\,.$$

Let $T_n:=T|_{X_n}:X_n\to Y$ $(n\in\mathbb{N})$. Then:

(a) *for any $y\in Y$ there holds*

$$\lim_{n\to\infty}\left\|TT_n^{\dagger}y-Q_{\overline{\mathcal{R}(T)}}y\right\|=0;$$

if $\varliminf_{n\to\infty}\left\|T_n^{\dagger}y\right\|<\infty$, then $y\in\mathcal{D}\left(T^{\dagger}\right)$ and

$$\varnothing\neq\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty}\left\{T_n^{\dagger}y\right\}\subseteq T^{-1}\left(Q_{\overline{\mathcal{R}(T)}}y\right)\,.$$

(b) *If*

$$\overline{\bigcup_{n=1}^{\infty}\left(\mathcal{N}(T)\cap X_n\right)}=\mathcal{N}(T) \tag{$\star$}$$

and $y \in Y$ is given, then

$$\left\{ y \in \mathcal{D}\left(T^{\dagger}\right),\ \operatorname*{w\text{-}lim}_{n\to\infty} T_n^{\dagger} y = T^{\dagger} y \right\} \Longleftrightarrow \sup_n \left\| T_n^{\dagger} y \right\| < \infty .$$

(c) *If* $\sup_n \|R_n\| < \infty$ *($R_n := T_n^{\dagger} T$), then condition ($\star$) holds.*
(d) $(\mathrm{H3})^{\mathrm{s}} \Longleftrightarrow (\mathrm{H3})^{\mathrm{w}} \Longleftrightarrow \sup_n \|R_n\| < \infty$.
(e) $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Longleftrightarrow (\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}} \Longleftrightarrow (\mathrm{H2}) \Longleftrightarrow \{\sup_n \|R_n\| < \infty$, *and* $\mathcal{R}(T)$ *is closed*$\}$.

Remark 2.9. Assertion (b) is Theorem 1.9 (due to Groetsch–Neubauer [12, Theorem 1]). Note that condition ($\star$) is missing in the original statement of the theorem, and without that condition the theorem would be false. We will explain this observation by giving a counterexample (see Example 2.10 below).

Assertion (d) is Theorem 1.7 (due to Groetsch [9, Proposition 0]). Its proof given in [9] (or [10, Theorem 4.1.1]) applies only to the case of "$\mathcal{N}(T_n) = \{0\} (n \in \mathbb{N})$."

Proof. (a) Note that $\mathcal{R}(T_n)$ is closed (since X_n is finite-dimensional) and that

$$\mathcal{R}(T_n) \subseteq \mathcal{R}(T_{n+1}) \subseteq \mathcal{R}(T)\ \ (n \in \mathbb{N}) \quad \text{and} \quad \overline{\bigcup_{n\in\mathbb{N}} \mathcal{R}(T_n)} = \overline{\mathcal{R}(T)} .$$

This implies that

$$T T_n^{\dagger} = Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}} \quad \text{as} \quad n \to \infty . \tag{2.21}$$

Assume that $\varliminf_{n\to\infty} \left\| T_n^{\dagger} y \right\| < \infty$. Then $\left\{ T_n^{\dagger} y \right\}$ has a bounded subsequence $\left\{ T_{n_k}^{\dagger} y \right\}$ and therefore has a subsequence, again denoted by $\left\{ T_{n_k}^{\dagger} y \right\}$, converging weakly to some $u \in X$ by the Eberlein–Shmulyan theorem (see, e.g., [30, p. 141]). Since T is bounded, we have

$$Q_{\mathcal{R}\left(T_{n_k}\right)} y = T T_{n_k}^{\dagger} y \rightharpoonup T u \quad \text{as} \quad k \to \infty. \tag{2.22}$$

From (2.21) and (2.22) it follows that $Q_{\overline{\mathcal{R}(T)}} y = T u$, that is, $y \in \mathcal{D}(T^{\dagger})$ and $u \in T^{-1}(Q_{\overline{\mathcal{R}(T)}} y)$. Clearly, we can prove that

$$\varnothing \neq \operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \left\{ T_n^{\dagger} y \right\} \subseteq T^{-1} \left(Q_{\overline{\mathcal{R}(T)}} y \right) . \tag{2.23}$$

(b) We need only to show that if condition ($\star$) is satisfied and $y \in Y$ is with $\sup_n \left\| T_n^{\dagger} y \right\| < \infty$, then

$$y \in \mathcal{D}\left(T^{\dagger}\right) \quad \text{and} \quad \operatorname*{w\text{-}lim}_{n\to\infty} T_n^{\dagger} y = T^{\dagger} y . \tag{2.24}$$

Indeed, by (a) we obtain immediately $y \in \mathcal{D}\left(T^{\dagger}\right)$ and (2.23). Since

$$\mathcal{N}(T_n) = \mathcal{N}(T) \cap X_n, \quad \mathcal{N}(T_n)^{\perp_n} = \mathcal{N}(T_n)^{\perp} \cap X_n,$$

by condition ($\star$) we have that

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \left\{ T_n^{\dagger} y \right\} \subseteq \operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \mathcal{N}(T_n)^{\perp_n} \subseteq \bigcap_{n\in\mathbb{N}} (\mathcal{N}(T) \cap X_n)^{\perp} = \mathcal{N}(T)^{\perp} . \tag{2.25}$$

Hence, it follows from (2.23) and (2.25) that

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \left\{ T_n^{\dagger} y \right\} = \mathcal{N}(T)^{\perp} \cap T^{-1} \left(Q_{\overline{\mathcal{R}(T)}} y \right) .$$

This together with $\sup_n \|T_n^\dagger y\| < \infty$ implies that w-$\lim_{n\to\infty} T_n^\dagger y = T^\dagger y$, completing the proof of (2.24).

(c) Assume that $\sup_n \|R_n\| < \infty$. Then, by (a) of Corollary 2.3, condition $(\star)$ holds.

(d) We need only to prove that $\sup_n \|R_n\| < \infty$ implies $(\mathrm{H3})^{\mathrm{s}}$. This is obvious by (b) of Corollary 2.3 or by using the assertions (b) and (c).

(e) By Corollary 1.5 and (c) of Corollary 2.3, (e) holds obviously. □

Example 2.10. Let $X := l^2$, $X_n := \operatorname{span}\{e_1, e_2, \dots, e_n\}$, where

$$e_k = (0, \dots, 0, \underset{\substack{\uparrow \\ k\,\mathrm{th}}}{1}, 0, \dots) \quad (\forall\, k \in \mathbb{N}).$$

We define an operator $T : X \to X$ as follows:

$$Tx := x - \langle x, e\rangle\, e \qquad (x \in X),$$

where $\langle\cdot,\cdot\rangle$ is the inner product on X and

$$e := \frac{\sqrt{3}}{2}e_1 + \frac{\sqrt{3}}{2^2}e_2 + \cdots + \frac{\sqrt{3}}{2^k}e_k + \cdots.$$

This operator satisfies

$$T = T^2 = T^* = T^\dagger \quad \text{and} \quad \mathcal{N}(T) = \operatorname{span}\{e\};$$

that is, T is the orthogonal projection of X onto $e^\perp$. Now, let

$$T_n := T|_{X_n} : X_n \to X.$$

Then we have the following three propositions (whose proofs are in the appendix):

(A.1) $\mathcal{N}(T_n) = \mathcal{N}(T) \cap X_n = \{0\}$, $\overline{\bigcup_{n=1}^{\infty} (\mathcal{N}(T) \cap X_n)} \subsetneqq \mathcal{N}(T)$.

(A.2) $T_n^\dagger y = P_n y - 4^n \langle (I - P_n)\, y, e\rangle\, P_n e \quad (\forall\, y \in X)$.

(A.3) If $y \in X$, then

$$\sup_n \left\|T_n^\dagger y\right\| < \infty \Longleftrightarrow \sup_n 4^n \left|\langle (I - P_n)\, y, e\rangle\right| < \infty,$$

$$T_n^\dagger y \rightharpoonup T^\dagger y \Longleftrightarrow 4^n \langle (I - P_n)\, y, e\rangle \longrightarrow \langle y, e\rangle.$$

Note that by (A.1) condition $(\star)$ does not hold. We take, for example,

$$y = \left(\frac{\sqrt{3}}{4}, \frac{3\sqrt{3}}{4^2}, \dots, \underset{\substack{\uparrow \\ n\,\mathrm{th}}}{\frac{(2^n - 1)\sqrt{3}}{4^n}}, \dots\right)$$

and notice that

$$\langle y, e\rangle = 1 - \frac{3}{7} \quad \text{and} \quad \langle (I - P_n)\, y, e\rangle = \frac{1}{4^n} - \frac{3}{7 \times 8^n}.$$

Then

$$\begin{cases} \sup_n 4^n \left|\langle (I - P_n)\, y, e\rangle\right| = \sup_n 4^n \left(\frac{1}{4^n} - \frac{3}{7\times 8^n}\right) < \infty, \\ 4^n \langle (I - P_n)\, y, e\rangle = 4^n \left(\frac{1}{4^n} - \frac{3}{7\times 8^n}\right) \longrightarrow 1 \neq \langle y, e\rangle. \end{cases}$$

Therefore, by (A.3) we conclude that

$$\sup_n \left\|T_n^\dagger y\right\| < \infty \quad \text{and} \quad \operatorname*{w\text{-}lim}_{n\to\infty} T_n^\dagger y \neq T^\dagger y.$$

This indicates that Theorem 1.9 would be false without condition $(\star)$.

3. Weak perfect convergence for nonprojection methods. To make it clear, the discretization methods with the approximation setting (1.1) and (1.2) are called "generalized projection methods" or "nonprojection methods" if their approximation setting is with $(\mathrm{H1})^{\mathrm{u}}$ or (H1), respectively. For generalized projection methods, by Theorem 1.4, we have

$$(\mathrm{H3})_{\mathrm{p}}^{\mathrm{s}} \iff (\mathrm{H3})_{\mathrm{p}}^{\mathrm{w}} \iff (\mathrm{H2}).$$

But for nonprojection methods $(\mathrm{H3})_{\mathrm{p}}^{\mathrm{w}}$ is neither equivalent to (H2) nor to $(\mathrm{H3})_{\mathrm{p}}^{\mathrm{s}}$, and the relation among the three is

$$(\mathrm{H3})_{\mathrm{p}}^{\mathrm{s}} \implies (\mathrm{H3})_{\mathrm{p}}^{\mathrm{w}} \implies (\mathrm{H2}).$$

In this section, for nonprojection methods we present a criterion for $(\mathrm{H3})_{\mathrm{p}}^{\mathrm{w}}$ by (H2) with other necessary compensated conditions, which is further explained by four examples.

3.1. A criterion for weak perfect convergence. We need a lemma as follows.

LEMMA 3.1. *Suppose that the approximation setting* (1.1) *and* (1.2) *is with* (H1). *Then:*

(a) $\text{s-lim}_{n\to\infty} T_nP_n = T$, $\sup_n \|T_n\|_{\widetilde{n}} = \sup_n \|T_nP_n\| < \infty$;

(b) $\text{s-lim}_{n\to\infty} \mathcal{N}(T_n) \subseteq \mathcal{N}(T) \cap \text{w-}\widetilde{\lim}_{n\to\infty} \mathcal{N}(T_n)$;

(c) $\overline{\mathcal{R}(T)} \subseteq \text{s-lim}_{n\to\infty} \mathcal{R}(T_n) \subseteq \text{w-}\widetilde{\lim}_{n\to\infty} \mathcal{R}(T_n)$;

(d) $\mathcal{G}(T) = \text{s-lim}_{n\to\infty} \mathcal{G}(T_n)$, *where* $\mathcal{G}(\cdot)$ *stands for "graph of";*

(e) $(\mathrm{H2}) \Longrightarrow \text{s-lim}_{n\to\infty} \mathcal{N}(T_n) = \mathcal{N}(T)$;

(f) $\mathcal{N}(T^*) = \{ y \in Y \mid T_n^* Q_n y \rightharpoonup 0 \ (n \to \infty) \}$.

Proof. (a) follows from the fact that for any $x \in X$ there holds

$$\|T_nP_nx - Tx\| \leqslant \|Q_n(T_n - T)P_nx\| + \|T\|\,\|(I - P_n)x\| + \|(I - Q_n)Tx\|.$$

To prove (b), let $x \in \text{s-lim}_{n\to\infty} \mathcal{N}(T_n)$. We need only to show that $x \in \mathcal{N}(T)$. By the definition of $\text{s-lim}_{n\to\infty} \mathcal{N}(T_n)$ there exists a sequence $\{x_n\}$ such that

$$x_n \in \mathcal{N}(T_n) \ (\forall\, n) \quad \text{and} \quad x_n \to x \text{ as } n \to \infty. \tag{3.1}$$

Notice that

$$\|Tx\| \leqslant \|Tx - T_nP_nx\| + M\,\|P_nx - x_n\| \quad (M = \sup_{k\in\mathbb{N}} \|T_k\|_k). \tag{3.2}$$

By putting $n \to \infty$, by (a), it follows from (3.1) and (3.2) that $x \in \mathcal{N}(T)$.

To prove (c), we need only to show that $\mathcal{R}(T) \subseteq \text{s-lim}_{n\to\infty} \mathcal{R}(T_n)$ (note that $\text{s-lim}_{n\to\infty} \mathcal{R}(T_n)$ is closed [4, Lemma 2.7]). Let $y \in \mathcal{R}(T)$. Then there is an $x \in X$ such that $Tx = y$. By (a) we have

$$T_nP_nx \to y \text{ as } n \to \infty,$$

which implies that $y \in \text{s-lim}_{n\to\infty} \mathcal{R}(T_n)$.

(d) follows from (a), because we have the following:

$$(x,y) \in \mathcal{G}(T) \overset{\text{(a)}}{\Longrightarrow} \begin{cases} P_nx \to x \\ T_nP_nx \to y \end{cases} \implies (x,y) \in \underset{n\to\infty}{\text{s-}\lim} \mathcal{G}(T_n);$$

$$(x,y)\in \operatorname*{s\,-\,lim}_{n\to\infty}\mathcal{G}(T_n)\Longrightarrow \exists x_n\in X_n:\begin{cases} x_n\to x\\ T_nx_n\to y\end{cases}$$

$$\overset{\text{(a)}}{\Longrightarrow}\begin{cases} T_nx_n-T_nP_nx\to 0\\ T_nP_nx\to Tx\\ T_nx_n\to y\end{cases}\Longrightarrow Tx=y,\ \text{i.e.,}\ (x,y)\in\mathcal{G}(T)\ .$$

Assume that (H2) holds. Then for any $x\in\mathcal{N}(T)$ there holds

$$P_nx-T_n^{\dagger}T_nP_nx\to x\quad \text{as } n\to\infty\,.$$

Note that, for any $x\in\mathcal{N}(T)$, $P_nx-T_n^{\dagger}T_nP_nx\in\mathcal{N}(T_n)$ $(\forall\ n\in\mathbb{N})$, so that we have $x\in\text{s-lim}_{n\to\infty}\mathcal{N}(T_n)$. Thus, (e) holds.

Finally, because we have the identity

$$\begin{aligned}\langle u,T^*v\rangle=\langle u,T_n^*Q_nv\rangle+\langle u-P_nu,T^*v\rangle+\langle TP_nu,v-Q_nv\rangle\\ +\langle Q_n(T-T_n)P_nu,v\rangle\qquad(\forall u\in X,\,\forall v\in Y),\end{aligned}$$

and because (H1) holds, (f) follows. □

THEOREM 3.2. *Suppose that the approximation setting* (1.1) *and* (1.2) *is with* (H1). *Then the following propositions hold:*

(a) *If* (H2) *and* $\text{w-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n)\subseteq\mathcal{N}(T)+\text{s-lim}_{n\to\infty}\mathcal{N}(T_n)$ *are valid, then:*

(i) $\text{s-lim}_{n\to\infty}\mathcal{N}(T_n)=\text{w-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n)=\mathcal{N}(T)$*; that is,*

$$\operatorname*{s\,-\,lim}_{n\to\infty}P_{\mathcal{N}(T_n)}=P_{\mathcal{N}(T)}\,;$$

(ii) $\mathcal{R}(T)$ *is closed, and*

$$\begin{aligned}\left\|T_n^{\dagger}Q_nQ_{\mathcal{R}(T)}y-T^{\dagger}y\right\|\leqslant\left\|T_n^{\dagger}Q_nT-I\right\|\operatorname{dist}\left(T^{\dagger}y,X_n\right)+\left\|P_{\mathcal{N}(T_n)}T^{\dagger}y\right\|\\ +\left\|T_n^{\dagger}\right\|_n\left\|Q_n(T_n-T)P_nT^{\dagger}y\right\|\qquad(\forall\ y\in Y)\,;\end{aligned}$$

(iii) *there hold*

$$\operatorname*{s\,-\,lim}_{n\to\infty}T_n^{\dagger}Q_nQ_{\mathcal{R}(T)}=T^{\dagger}\,,\quad \operatorname*{s\,-\,lim}_{n\to\infty}Q_{\mathcal{R}(T_n)}Q_{\mathcal{R}(T)}=Q_{\mathcal{R}(T)}.$$

(b) *Criterion for* $(\text{H3})_{\text{p}}^{\text{w}}$*:*

$$(\text{H3})_{\text{p}}^{\text{w}}\Longleftrightarrow\begin{cases}\text{(H2) }\textit{and}\ \operatorname*{w\,-\,\widetilde{lim}}_{n\to\infty}\mathcal{N}(T_n)\subseteq\mathcal{N}(T)+\operatorname*{s\,-\,lim}_{n\to\infty}\mathcal{N}(T_n)\,,\\ \operatorname*{w\,-\,lim}_{n\to\infty}T_n^{\dagger}Q_ny=0\ \textit{if}\ \operatorname*{w\,-\,lim}_{n\to\infty}T_n^{*}Q_ny=0\,.\end{cases}$$

Proof. The proof will be carried out in two steps.

Step 1 (to prove (a)). By (e) in Lemma 3.1, (H2) together with $\text{w-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n)\subseteq\mathcal{N}(T)+\text{s-lim}_{n\to\infty}\mathcal{N}(T_n)$ implies that

$$\operatorname*{s\,-\,lim}_{n\to\infty}\mathcal{N}(T_n)=\operatorname*{w\,-\,\widetilde{lim}}_{n\to\infty}\mathcal{N}(T_n)=\mathcal{N}(T)\ . \tag{3.3}$$

Assume that $\{y^{(m)}\}\subseteq\mathcal{R}(T)$ satisfies $\text{s-lim}_{n\to\infty}y^{(m)}=y$. By (d) in Lemma 3.1, $\mathcal{G}(T)=\text{s-lim}_{n\to\infty}\mathcal{G}(T_n)$. Hence, for every $m\in\mathbb{N}$ there exists a sequence $\{(x_n^{(m)},y_n^{(m)})\}_{n=1}^{\infty}$ in $X\times Y$ such that

$$y_n^{(m)}=T_n\left(x_n^{(m)}\right)\quad(\forall\ n\in\mathbb{N}) \tag{3.4}$$

and

$$x_n^{(m)} \to T^\dagger\left(y^{(m)}\right), \quad y_n^{(m)} \to y^{(m)} \quad \text{as } n \to \infty\,. \tag{3.5}$$

It follows from (3.4) and (3.5) that, for every $m \in \mathbb{N}$,

$$\sup_n \left\|T_n^\dagger\left(y_n^{(m)}\right)\right\| \le \sup_n \left\|x_n^{(m)}\right\| < \infty\,. \tag{3.6}$$

For every $m \in \mathbb{N}$, because the sequence $\{T_n^\dagger(y_n^{(m)})\}_{n=1}^\infty$ is bounded (by (3.6)), $\{T_n^\dagger(y_n^{(m)})\}_{n=1}^\infty$ contains a subsequence $\{T_{n_j}^\dagger(y_{n_j}^{(m)})\}_{j=1}^\infty$ which converges weakly to an element $x^{(m)}$ of X by the Eberlein–Shmulyan theorem [30, p. 141], and therefore, with the use of (3.5), we have

$$x_{n_j}^{(m)} - T_{n_j}^\dagger\left(y_{n_j}^{(m)}\right) \rightharpoonup T^\dagger\left(y^{(m)}\right) - x^{(m)} \quad \text{as } j \to \infty \tag{3.7}$$

and (by [30, Theorem 1, p. 120])

$$\left\|x^{(m)}\right\| \le \varliminf_{j\to\infty} \left\|T_{n_j}^\dagger\left(y_{n_j}^{(m)}\right)\right\|\,. \tag{3.8}$$

Notice that $\{x_{n_j}^{(m)} - T_{n_j}^\dagger(y_{n_j}^{(m)})\}_{m=1}^\infty \subseteq \mathcal{N}(T_{n_j})$ for every $j \in \mathbb{N}$ (by (3.4)), so it follows from (3.7) that

$$\left\{T^\dagger\left(y^{(m)}\right) - x^{(m)}\right\}_{m=1}^\infty \subseteq \operatorname{w}\text{-}\widetilde{\varliminf_{n\to\infty}}\mathcal{N}\left(T_n\right).$$

This together with (3.3) implies that

$$T\left(x^{(m)}\right) = y^{(m)} \quad (\forall\ m \in \mathbb{N})\,. \tag{3.9}$$

Note that from (3.8) and (3.5) it follows that

$$\begin{aligned}\sup_m \left\|x^{(m)}\right\| &\le \sup_m \varliminf_{j\to\infty} \left\|T_{n_j}^\dagger\left(y_{n_j}^{(m)}\right)\right\| \\ &\le \sup_n \left\|T_n^\dagger\right\| \sup_m \varliminf_{j\to\infty} \left\|y_{n_j}^{(m)}\right\| \\ &= \sup_n \left\|T_n^\dagger\right\| \sup_m \left\|y^{(m)}\right\| < \infty.\end{aligned}$$

This implies that $\{x^{(m)}\}$ contains a subsequence $\{x^{(m_j)}\}_{j=1}^\infty$ which converges weakly to some $x^{(\infty)}$ in X. Furthermore, note that, by the Mazur lemma (see [30, Theorem 2 (Mazur), p. 120] or [1, Theorem 3.2.11, p. 109]), for every $j \in \mathbb{N}$ there exists a convex combination

$$x_j = \sum_{i=1}^{k_j} \alpha_i^{(j)} x^{(m_{j+i})} \quad \left(\alpha_i^{(j)} \ge 0,\ \sum_{i=1}^{k_j} \alpha_i^{(j)} = 1\right) \tag{3.10}$$

such that

$$\left\|x^{(\infty)} - x_j\right\| \le \frac{1}{j}. \tag{3.11}$$

By (3.9) and (3.10), we have

$$\begin{aligned}\|T(x_j)-y\| &= \left\|\sum_{i=1}^{k_j}\alpha_i^{(j)}T\left(x^{(m_{j+i})}\right)-y\right\| \\ &= \left\|\sum_{i=1}^{k_j}\alpha_i^{(j)}y^{(m_{j+i})}-y\right\| \\ &\le \sum_{i=1}^{k_j}\alpha_i^{(j)}\left\|y^{(m_{j+i})}-y\right\| \\ &\le \sup_{m\ge j}\left\|y^{(m)}-y\right\|.\end{aligned} \tag{3.12}$$

By putting $j\to\infty$, by (3.11) and (3.12) we conclude that $T\left(x^{(\infty)}\right)=y$ and therefore $y\in\mathcal{R}(T)$. Thus, $\mathcal{R}(T)$ is closed. This implies that $T^\dagger\in\mathcal{B}(Y,X)$.

Next, because

$$\begin{aligned}&T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}}-T^\dagger = T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}}-T_n^\dagger T_n P_n T^\dagger+T_n^\dagger T_n P_n T^\dagger-T^\dagger T T^\dagger \\ &= T_n^\dagger Q_n\left(Q_{\overline{\mathcal{R}(T)}}-TP_nT^\dagger\right)-T_n^\dagger Q_n(T_n-T)P_nT^\dagger+\left(T_n^\dagger T_nP_n-T^\dagger T\right)T^\dagger \\ &= T_n^\dagger Q_nT(I_X-P_n)T^\dagger-T_n^\dagger Q_n(T_n-T)P_nT^\dagger+\left(P_n-P_{\mathcal{N}(T_n)}-I_X+P_{\mathcal{N}(T)}\right)T^\dagger \\ &= \left(T_n^\dagger Q_nT-I_X\right)(I_X-P_n)T^\dagger-T_n^\dagger Q_n(T_n-T)P_nT^\dagger-P_{\mathcal{N}(T_n)}T^\dagger,\end{aligned}$$

and because $\mathcal{R}(T)$ is closed, we have

$$\begin{aligned}\left\|T_n^\dagger Q_nQ_{\mathcal{R}(T)}y-T^\dagger y\right\| \le{}& \left\|T_n^\dagger Q_nT-I\right\|\operatorname{dist}\left(T^\dagger y,X_n\right)+\left\|P_{\mathcal{N}(T_n)}T^\dagger y\right\| \\ &+\left\|T_n^\dagger\right\|_n\left\|Q_n(T_n-T)P_nT^\dagger y\right\| \qquad (\forall\, y\in Y).\end{aligned} \tag{3.13}$$

Since (3.3) gives (by Lemma 2.1 or Remark 1.6)

$$\operatorname*{s-lim}_{n\to\infty}P_{\mathcal{N}(T_n)}=P_{\mathcal{N}(T)},$$

and since (by (H1) and (H2))

$$\lim_{n\to\infty}\|P_nx-x\|=\lim_{n\to\infty}\|Q_n(T_n-T)P_nx\|=0,\quad \sup_n\left\|T_n^\dagger\right\|_n<\infty,$$

it follows from (3.13) that

$$\operatorname*{s-lim}_{n\to\infty}T_n^\dagger Q_nQ_{\mathcal{R}(T)}=T^\dagger.$$

This implies, by (a) in Lemma 3.1, that

$$\operatorname*{s-lim}_{n\to\infty}T_nT_n^\dagger Q_nQ_{\mathcal{R}(T)}=TT^\dagger,\quad \text{that is,}\quad \operatorname*{s-lim}_{n\to\infty}Q_{\mathcal{R}(T_n)}Q_{\mathcal{R}(T)}=Q_{\mathcal{R}(T)}.$$

Thus, (a) follows.

Step 2 (to prove (b)). Assume that $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ holds. Then (H2) holds by the uniform boundedness principle. Because for any $x, u \in X$ there holds

$$\begin{aligned}\left|\left\langle (T_nP_n)^\dagger (T_nP_n)\, x - T^\dagger Tx, u\right\rangle\right| &\leqslant \left|\left\langle (T_nP_n)^\dagger Q_n (T_n - T) P_n x, u\right\rangle\right| \\ &\quad + \left|\left\langle (T_nP_n)^\dagger Q_n T P_n x - T^\dagger Tx, u\right\rangle\right| \\ &\leqslant \left|\left\langle T_n^\dagger Q_n (T_n - T) P_n x, u\right\rangle\right| + \left|\left\langle T_n^\dagger Q_n T P_n x - T_n^\dagger Q_n Tx, u\right\rangle\right| \\ &\quad + \left|\left\langle T_n^\dagger Q_n Tx - T^\dagger Tx, u\right\rangle\right| \\ &\leqslant \left\|T_n^\dagger\right\|_n \|Q_n (T_n - T) P_n x\| \|u\| + \left\|T_n^\dagger Q_n\right\| \|T\| \|P_n x - x\| \|u\| \\ &\quad + \left|\left\langle \left(T_n^\dagger Q_n - T^\dagger\right) Tx, u\right\rangle\right| ,\end{aligned}$$

we obtain

$$(T_nP_n)^\dagger (T_nP_n) \rightharpoonup T^\dagger T \quad \text{as} \quad n \to \infty ,$$

so that

$$P_{\mathcal{N}(T_nP_n)} \rightharpoonup P_{\mathcal{N}(T)} \quad \text{as} \quad n \to \infty . \tag{3.14}$$

Notice that

$$P_{\mathcal{N}(T_nP_n)} = I - P_n + P_{\mathcal{N}(T_n)} .$$

By Lemma 2.1, this with (3.14) implies that

$$\operatorname*{s\text{-}lim}_{n\to\infty} P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)}, \quad \text{i.e.,} \quad \operatorname*{s\text{-}lim}_{n\to\infty} \mathcal{N}(T_n) = \operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \mathcal{N}(T_n) = \mathcal{N}(T) . \tag{3.15}$$

This implies that

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \mathcal{N}(T_n) \subseteq \mathcal{N}(T) + \operatorname*{s\text{-}lim}_{n\to\infty} \mathcal{N}(T_n) . \tag{3.16}$$

Next, let $y \in Y$ satisfy $T_n^* Q_n y \rightharpoonup 0$. Then $y \in \mathcal{N}(T^*)$ by (f) in Lemma 3.1; that is, $y \in \mathcal{N}\left(T^\dagger\right)$. Therefore, it follows from $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ that

$$T_n^\dagger Q_n y \rightharpoonup 0 \quad \text{if} \quad T_n^* Q_n y \rightharpoonup 0 . \tag{3.17}$$

So $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ implies (H2), (3.16), and (3.17).

Inversely, assume (H2), (3.16), and (3.17). Then, by (a), (H2) together with (3.16) implies that $\mathcal{R}(T)$ is closed and that (3.13) and (3.15) hold. By (f) in Lemma 3.1, (3.17) implies that

$$T_n^\dagger Q_n y \rightharpoonup 0 \quad \text{if} \quad y \in \mathcal{N}(T^*) = \mathcal{R}(T)^\perp . \tag{3.18}$$

Hence, it follows from (3.13), (3.15), and (3.18) that

$$T_n^\dagger Q_n y \rightharpoonup T^\dagger y \quad \text{if} \quad y \in \mathcal{D}\left(T^\dagger\right) ,$$

that is, $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ holds. □

Corollary 3.3. *Suppose that the approximation setting* (1.1) *and* (1.1) *is with* (H1). *If* $X = Y$, $X_n = Y_n$, *and* T *and* T_n *are both self-adjoint, then*

$$(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Longleftrightarrow (\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}} \Longleftrightarrow \left\{(\mathrm{H2}) \text{ and } \operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty} \mathcal{N}(T_n) \subseteq \mathcal{N}(T) + \operatorname*{s\text{-}lim}_{n\to\infty} \mathcal{N}(T_n)\right\} .$$

Proof. By Theorem 3.2, we need only to show that

$$\left\{\text{(H2) and } \operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty}\mathcal{N}(T_n)\subseteq\mathcal{N}(T)+\operatorname*{s\text{-}lim}_{n\to\infty}\mathcal{N}(T_n)\right\}\Longrightarrow(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}\,.$$

Assume that the left side of the above implication is valid. Then $\mathcal{R}(T)$ is closed, and (3.3) holds, that is,

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty}\mathcal{N}(T_n)=\operatorname*{s\text{-}lim}_{n\to\infty}\mathcal{N}(T_n)=\mathcal{N}(T)\,.$$

Since T_n $(n\in\mathbb{N})$ and T are all self-adjoint, we hence have

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty}\mathcal{R}(T_n)^{\perp_n}=\operatorname*{s\text{-}lim}_{n\to\infty}\mathcal{R}(T_n)^{\perp_n}=\mathcal{R}(T)^{\perp}\,,$$

that is (by Lemma 2.1),

$$\operatorname*{s\text{-}lim}_{n\to\infty}\left(P_n-P_{\mathcal{R}(T_n)}\right)=I-P_{\mathcal{R}(T)}\,.$$

Here we note that $P_n-P_{\mathcal{R}(T_n)}$ is the orthogonal projection from X onto $\mathcal{R}(T_n)^{\perp_n}$. Hence, we obtain

$$\operatorname*{s\text{-}lim}_{n\to\infty}P_{\mathcal{R}(T_n)}=P_{\mathcal{R}(T)}\,,$$

that is (by Lemma 2.1),

$$\operatorname*{w\text{-}\widetilde{lim}}_{n\to\infty}\mathcal{R}(T_n)=\operatorname*{s\text{-}lim}_{n\to\infty}\mathcal{R}(T_n)=\mathcal{R}(T)\,. \tag{3.19}$$

Now $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$ follows from (H2), (3.3), and (3.19) by Theorem 1.3. ∎

3.2. Examples on weak perfect convergence. In this subsection we will give some examples to indicate that the three conditions of characterizing $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$ in Theorem 3.2 are independent. The three conditions are

- (H2);
- $\text{w-}\widetilde{\lim}_{n\to\infty}\mathcal{N}(T_n)\subseteq\mathcal{N}(T)+\text{s-}\lim_{n\to\infty}\mathcal{N}(T_n)$, *denoted by* (CH1);
- $\text{w-}\lim_{n\to\infty}T_n^{\dagger}Q_ny=0$ if $\text{w-}\lim_{n\to\infty}T_n^{*}Q_ny=0$, *denoted by* (CH2).

In fact, for the approximation setting (1.1) and (1.2) with (H1), the following three cases arise:

$$\text{case 1: }\begin{cases}\text{(H2)},\\ \text{(CH1)},\\ \neg\text{(CH2)};\end{cases}\qquad\text{case 2: }\begin{cases}\text{(H2)},\\ \neg\text{(CH1)},\\ \text{(CH2)};\end{cases}\qquad\text{case 3: }\begin{cases}\neg\text{(H2)},\\ \text{(CH1)},\\ \text{(CH2)}.\end{cases}$$

Here the negation of a statement P is written by $\neg P$.

Example 3.4. We define $T:l^2\to l^2$ and $T_n:l^2\to l^2$ $(n\in\mathbb{N})$ as follows:

$$T(\mathbf{x}):=(0,x_1,x_2,\dots)\,,$$

$$T_n(\mathbf{x}):=(\underset{\substack{\uparrow\\1\text{st}}}{x_n},\underset{\substack{\uparrow\\2\text{nd}}}{x_1-x_n},\underset{\substack{\uparrow\\3\text{rd}}}{x_2},\dots,\underset{\substack{\uparrow\\n\text{th}}}{x_{n-1}},\underset{\substack{\uparrow\\(n+1)\text{th}}}{x_{n+1}},\dots),$$

where $\mathbf{x}=(x_1,x_2,\dots)\in l^2$. Then

(i) $T_n\xrightarrow{\mathrm{s}}T$; that is, the approximation setting is with (H1);

(ii) $\mathcal{N}(T_n) = \{\mathbf{0}\}$, $\mathcal{R}(T_n) = l^2$, and

$$T_n^\dagger(\mathbf{y}) = (y_1 + y_2,\ y_3, \dots,\ \underset{(n-1)\text{th}}{y_n},\ y_1,\ \underset{n\text{th}}{y_{n+1}}, \dots);$$

(iii) $\sup_n \left\|T_n^\dagger\right\|_n < \infty$; that is, the setting is with (H2);
(iv) $\mathcal{N}(T) = \{\mathbf{0}\}$, $\mathcal{R}(T) = \mathbf{e}_1^\perp$, where $\mathbf{e}_1 = (1, 0, 0, \dots)$, and

$$T^\dagger(\mathbf{y}) = (y_2, y_3, \dots);$$

(v) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{N}(T_n) = \text{s-lim}_{n\to\infty}\mathcal{N}(T_n) = \mathcal{N}(T)$, and the setting is with (CH1);
(vi) $T_n^*\mathbf{y} \rightharpoonup \mathbf{0}$ if and only if $\mathbf{y} \in \text{span}\{\mathbf{e}_1\}$, where

$$T_n^*(\mathbf{y}) = (y_2, \dots, y_n, y_1 - y_2, y_{n+1}, \dots);$$

it is clear that

$$T_n^\dagger(y_1, 0, 0, \dots) = (y_1,\ \underset{1\text{st}}{0},\ \underset{2\text{nd}}{0}, \dots,\ \underset{(n-1)\text{th}}{0},\ y_1,\ \underset{n\text{th}}{0},\ \underset{(n+1)\text{th}}{0}, \dots),$$

and therefore the setting is not with (CH2);
(vii) $T_n^\dagger \rightharpoonup T^\dagger + P_{\text{span}\{\mathbf{e}_1\}}$.

Example 3.5. Let $T, T_n \in \mathcal{B}(l^2)$ $(n \in \mathbb{N})$ be defined by

$$T(\mathbf{x}) := \mathbf{x}, \quad T_n(\mathbf{x}) := (x_1 - x_{n+1}, x_2, \dots, x_n, 0, \dots),$$

where $\mathbf{x} = (x_1, x_2, \dots) \in l^2$. Then
(i) $T_n \xrightarrow{\text{s}} T$; that is, the approximation setting is with (H1);
(ii)
$$\begin{cases} \mathcal{N}(T_n) = \{\mathbf{x} \mid x_1 = x_{n+1},\ x_2 = \cdots = x_n = 0\}, \\ \mathcal{R}(T_n) = \{\mathbf{x} \mid x_k = 0\ \ (k \geqslant n+1)\}, \\ T_n^\dagger(\mathbf{x}) = (\frac{1}{2}x_1, x_2, \dots, x_n, -\frac{1}{2}x_1, 0, 0, \dots); \end{cases}$$
(iii) $\sup_n \left\|T_n^\dagger\right\|_n < \infty$; that is, the setting is with (H2);
(iv) $\mathcal{N}(T) = \{\mathbf{0}\}$, $\mathcal{R}(T) = l^2$, and $T^\dagger = T$;
(v) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{N}(T_n) \supsetneqq \mathcal{N}(T) = \text{s-lim}_{n\to\infty}\mathcal{N}(T_n)$, and the setting is not with (CH1);
(vi) $T_n^*(\mathbf{y}) = (y_1, y_2 \dots, y_n, -y_1, 0, 0, \dots)$; hence we have

$$T_n^*\mathbf{y} \rightharpoonup \mathbf{0} \iff \mathbf{y} = \mathbf{0},$$

and the setting is with (CH2);
(vii) $T_n^\dagger \rightharpoonup T^\dagger - \frac{1}{2}P_{\text{span}\{\mathbf{e}_1\}}$, where $\mathbf{e}_1 = (1, 0, 0, \dots)$.

Example 3.6. Take Example 2.10. Then
(i) the approximation setting is with $(\text{H1})^{\text{u}}$ (uniform consistency);
(ii) $\mathcal{N}(T_n) = \{0\}$, $\mathcal{R}(T_n) = T(X_n)$, and

$$T_n^\dagger y = P_n y - 4^n \langle (I - P_n)\, y, e\rangle\, P_n e \quad (\forall y \in X);$$

(iii) $\sup_n \left\|T_n^\dagger\right\|_n = \infty$ (in fact, $\sup_n \left\|T_n^\dagger T\right\| = \infty$ since $T_n^\dagger T = T_n^\dagger$) because

$$\sup_n \left\|T_n^\dagger\right\|_n \geqslant \left\|T_m^\dagger e_{m+1}\right\| = 2^{m-1}\left(1 - \frac{1}{4^m}\right)\sqrt{3} \to \infty \quad \text{as} \quad m \to \infty;$$

hence the setting is not with (H2);

(iv) $\mathcal{N}(T) = \operatorname{span}\{e\}$, $\mathcal{R}(T) = e^{\perp}$, and $T^{\dagger} = T^{*} = T$;

(v) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{N}(T_n) = \text{s-lim}_{n\to\infty}\mathcal{N}(T_n) \subsetneqq \mathcal{N}(T)$, and the setting is with (CH1);

(vi) $T_n^{*} = P_n T$ and therefore

$$T_n^{*} y \rightharpoonup 0 \iff y \in \mathcal{N}(T) \ (\Longleftrightarrow T_n^{*} y \to 0) \ ,$$

and the setting is with (CH2) (in fact, $T_n^{\dagger} Q_n y = 0$ if $y \in \mathcal{N}(T)$; here $Q_n = I$);

(vii) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{R}(T_n) = \text{s-lim}_{n\to\infty}\mathcal{R}(T_n) = \mathcal{R}(T)$;

(viii) the setting is not with $(\text{H3})^{\text{w}}$.

The above examples, together with Theorem 3.2, indicate that, for characterizing $(\text{H3})_{\text{p}}^{\text{w}}$ of the approximation setting (1.1) and (1.2) with (H1), the conditions (H2), (CH1), and (CH2) are not only necessary and sufficient but also independent.

A natural problem left is: For such an approximation setting, is there a case that $(\text{H3})_{\text{p}}^{\text{w}}$ holds and $(\text{H3})_{\text{p}}^{\text{s}}$ fails? The answer is yes.

Example 3.7. Let $T, T_n \in \mathcal{B}\left(l^2\right)$ $(n \in \mathbb{N})$ be defined by

$$T\mathbf{x} = (0, x_1, x_2, \dots) \ ,$$

$$T_n\mathbf{x} = (x_n, x_1, \dots, x_{n-1}, x_{n+1}, \dots) \ ,$$

where $\mathbf{x} = (x_1, x_2, \dots) \in l^2$. Then

(i) $T_n \overset{\text{s}}{\to} T$; that is, the approximation setting is with (H1);

(ii) $\mathcal{N}(T_n) = \{\mathbf{0}\}$, $\mathcal{R}(T_n) = l^2$, and

$$T_n^{\dagger}\mathbf{y} = (\underset{\substack{\uparrow\\ 1\text{st}}}{y_2}, \underset{\substack{\uparrow\\ 2\text{nd}}}{y_3}, \dots, \underset{\substack{\uparrow\\ (n-1)\text{th}}}{y_n}, \underset{\substack{\uparrow\\ n\text{th}}}{y_1}, \underset{\substack{\uparrow\\ (n+1)\text{th}}}{y_{n+1}}, \dots);$$

(iii) $\sup_n \left\|T_n^{\dagger}\right\|_n < \infty$; that is, the setting is with (H2);

(iv) $\mathcal{N}(T) = \{\mathbf{0}\}$, $\mathcal{R}(T) = \mathbf{e}_1^{\perp}$, where $\mathbf{e}_1 = (1, 0, 0, \dots)$, and

$$T^{\dagger}\mathbf{y} = (y_2, y_3, \dots) \ ;$$

(v) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{N}(T_n) = \text{s-lim}_{n\to\infty}\mathcal{N}(T_n) = \mathcal{N}(T)$, and the setting is with (CH1);

(vi) $T_n^{*}\mathbf{y} = T_n^{\dagger}\mathbf{y}$, and therefore the setting is with (CH2);

(vii) $\widetilde{\text{w-lim}}_{n\to\infty}\mathcal{R}(T_n) = \text{s-lim}_{n\to\infty}\mathcal{R}(T_n) \supsetneqq \overline{\mathcal{R}(T)}$.

Note: By Theorems 1.3 and 3.2, the approximation setting is not with $(\text{H3})_{\text{p}}^{\text{s}}$, but it is with $(\text{H3})_{\text{p}}^{\text{w}}$.

4. Conclusions. Fundamental results on projection methods of Moore–Penrose inverses for well- and ill-posed problems have been obtained (see Corollary 1.5 and Theorems 2.2, 2.6, and 2.8 with their corollaries). Therefore, Tables 4.1 and 4.2 are produced. We come to the following conclusions:

- Stable projection methods (whose approximation setting is with (H2)) apply only to well-posed problems, which means that the projection methods applied to ill-posed problems are unstable (whose approximation setting must be with $\lim_{n\to\infty} \left\|T_n^{\dagger}\right\|_n = \infty$ by Corollary 1.5)!
- The projection methods that can cope with ill-posed problems have first to be with scheme regularization, which means that their approximation setting has to provide a regularization scheme (on the basis of which one chooses a regular strategy). Table 4.1 indicates that the scheme regularization of projection methods should have four degrees:

TABLE 4.1
Projection methods.

$(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$	$\Rightarrow$	$(\mathrm{H3})^{\mathrm{s}}$	$\Rightarrow$	$T_n^\dagger Q_n Q_{\mathcal{R}(T)^\perp} \xrightarrow{\mathrm{s}} 0$
$\Updownarrow$		$\Downarrow$		
$(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$	$\Rightarrow$	$(\mathrm{H3})^{\mathrm{w}}$	$\Rightarrow$	$Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}}$
$\Updownarrow$		$\Downarrow$		$\Downarrow$
(H2)	$\Rightarrow$	$\sup_n \|R_n\| < \infty$	$\Rightarrow$	$Q_{\mathcal{R}(T_n)} Q_{\overline{\mathcal{R}(T)}} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}}$
$\Downarrow$		$\Downarrow$		
$\overline{\mathcal{R}(T)} = \mathcal{R}(T)$		$P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)}$	$\Rightarrow$	$P_{\mathcal{N}(T_n)} T^\dagger \xrightarrow{\mathrm{s}} 0$ on $\mathcal{D}(T^\dagger)$

Note: (1) $\sup_n \|R_n\| < \infty \Longleftrightarrow T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} y \to T^\dagger y \ \ (y \in \mathcal{D}(T^\dagger))$;
(2) If $\mathcal{R}(T_n) \subseteq \overline{\mathcal{R}(T)}$ $(n \in \mathbb{N})$, $(\mathrm{H3})^{\mathrm{s}} \iff (\mathrm{H3})^{\mathrm{w}} \iff \sup_n \|R_n\| < \infty$.

	$\overline{\mathcal{R}(T)} = \mathcal{R}(T)$		$P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)}$ [**T**]	$P_{\mathcal{N}(T_n)} T^\dagger \xrightarrow{\mathrm{s}} 0$ [**T**]
Note	**T** := true (always holds).			

– "$P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)}$"-regularization, *denoted by* (R0)-regularization;
– "$\sup_n \|R_n\| < \infty$"-regularization, *denoted by* (R1)-regularization;
– $(\mathrm{H3})^{\mathrm{w}}$-regularization;
– $(\mathrm{H3})^{\mathrm{s}}$-regularization.

It remains unknown whether the four degrees of scheme regularization occur. But it is certain that the case without any scheme regularization appears. See Examples 4.1, 4.2 (below), and 3.6. Besides, a conjecture is proposed (Conjecture 4.3). As special cases, by Table 4.2, the least-squares methods (LS) have two degrees of scheme regularization: (R0)- and $(\mathrm{H3})^{\mathrm{s}}$-regularization; the generalized dual least-squares methods (GDLS) have three degrees: (R1)-, $(\mathrm{H3})^{\mathrm{w}}$-, and $(\mathrm{H3})^{\mathrm{s}}$-regularization (the first one always holds);

the dual least-squares methods (DLS) are always with the highest degree: $(\mathrm{H3})^{\mathrm{s}}$-regularization. The criteria for $(\mathrm{H3})^{\mathrm{w}}$- and $(\mathrm{H3})^{\mathrm{s}}$-regularization are given by Theorem 2.6.

- Theorem 2.2 provides a general error estimate on projection methods of Moore–Penrose inverses: For all $b \in \mathcal{D}\left(T^{\dagger}\right)$,

$$\left\|T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T^{\dagger} b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^{\dagger} b\right\| + \|R_n - I_X\| \operatorname{dist}\left(T^{\dagger} b, X_n\right). \tag{4.1}$$

  It follows that, for all $b \in \mathcal{D}\left(T^{\dagger}\right)$ and $b_n \in Y_n$,

$$\begin{aligned}\left\|T_n^{\dagger} b_n - T^{\dagger} b\right\| &\leqslant \left\|T_n^{\dagger}\right\|_n \left\|Q_n\left(b_n - b\right)\right\| + \left\|T_n^{\dagger} Q_n Q_{\mathcal{R}(T)^{\perp}} b\right\| \\ &\quad + \left\|P_{\mathcal{N}(T_n)} T^{\dagger} b\right\| + \|R_n - I_X\| \operatorname{dist}\left(T^{\dagger} b, X_n\right) \\ &= \left\|T_n^{\dagger}\right\|_n \left\|Q_n\left(b_n - b\right)\right\| + \left\|T_n^{\dagger} Q_n \left(Q_{\mathcal{R}(T_n)} - Q_{\overline{\mathcal{R}(T)}}\right) b\right\| \\ &\quad + \left\|\left(P_{\mathcal{N}(T_n)} - P_{\mathcal{N}(T)}\right) T^{\dagger} b\right\| + \|R_n - I_X\| \operatorname{dist}\left(T^{\dagger} b, X_n\right),\end{aligned}$$

  which is fundamental to design regularization schemes by projection including regular strategies for ill-posed problems or to design stable schemes by projection for well-posed problems.
- When one designs a discretization method by projection, for a well-posed problem, (H2) is the most important condition; for an ill-posed problem, scheme regularization and strategy regularization are both important conditions; here (R1)-regularization should be emphasized, which is convenient for application.
- By observing the approximation settings of various projection methods, one can see that LS and GDLS are two extreme cases of projection methods, and DLS is the best case of GDLS (in the sense of scheme regularization). We remark that, for LS, DLS, and GDLS, the error estimate (4.1) becomes

$$\left\|T_n^{\dagger} b - T^{\dagger} b\right\| \leqslant \|R_n - I_X\| \operatorname{dist}\left(T^{\dagger} b, X_n\right) \quad \left(\forall\ b \in \mathcal{D}\left(T^{\dagger}\right)\right),$$

$$\left.\begin{aligned}\left\|T_n^{\dagger} Q_n b - T^{\dagger} b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^{\dagger} b\right\| \quad \left(\forall\ b \in \mathcal{D}\left(T^{\dagger}\right)\right), \\ \text{where } Q_n := Q_{\mathcal{R}(T_n)} + Q_{\mathcal{R}(T)^{\perp}}\end{aligned}\right\},$$

  and

$$\left\|T_n^{\dagger} Q_n Q_{\overline{\mathcal{R}(T)}} b - T^{\dagger} b\right\| \leqslant \left\|P_{\mathcal{N}(T_n)} T^{\dagger} b\right\| \quad \left(\forall\ b \in \mathcal{D}\left(T^{\dagger}\right)\right),$$

  respectively. Tables 4.1 and 4.2 illustrate the differences and relations among the results for LS, DLS, GDLS, and general projection methods.

Example 4.1 (see [7, Example 3.19]). Let $\{e_n\}$ be any orthonormal basis of a infinite-dimensional Hilbert space X, and let $X_n := \operatorname{span}\{e_1, \ldots, e_n\}$ $(n \in \mathbb{N})$. We define an operator $T : X \to Y := X$ as follows:

$$T : \sum_{i=1}^{\infty} \xi_i e_i \mapsto \sum_{i=1}^{\infty} \left(a_i \xi_i + b_i \xi_1\right) e_i,$$

with

$$a_i := \begin{cases} i^{-1}, & i \text{ odd}, \\ i^{-\frac{5}{2}}, & i \text{ even}, \end{cases} \qquad b_i := \begin{cases} 0, & i = 1, \\ i^{-1}, & i > 1. \end{cases}$$

TABLE 4.3
Nonprojection methods.

$(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}}$	$\Rightarrow$	$(\mathrm{H3})^{\mathrm{s}}$	$\Rightarrow$	$T_n^\dagger Q_n Q_{\mathcal{R}(T)^\perp} \xrightarrow{\mathrm{s}} 0$
$\Downarrow$		$\Downarrow$		
$(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}}$	$\Rightarrow$	$(\mathrm{H3})^{\mathrm{w}}$	$\not\Rightarrow$	$Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}}$
$\Downarrow$		$\Downarrow$		
$\left\{(\mathrm{H2}) \text{ and } P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)}\right\}$	$\Rightarrow$	$\sup_n \|R_n\| < \infty$		
$\Downarrow$				
$\overline{\mathcal{R}(T)} = \mathcal{R}(T)$				

Note: (1) $(\mathrm{H3})^{\mathrm{s}}_{\mathrm{p}} \Leftrightarrow \left\{(\mathrm{H2}),\ P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)},\ \text{and } Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}}\right\}$;
(2) $(\mathrm{H3})^{\mathrm{w}}_{\mathrm{p}} \not\Rightarrow Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} Q_{\overline{\mathcal{R}(T)}}$ (see Example 3.7);
(3) $(\mathrm{H2}) \not\Rightarrow P_{\mathcal{N}(T_n)} \xrightarrow{\mathrm{s}} P_{\mathcal{N}(T)}$ (see Example 3.5).

This operator is linear, injective, and compact. If $T_n := T|_{X_n} : X_n \to X$, then

$$P_{\mathcal{N}(T_n)} = P_{\mathcal{N}(T)} = 0 \ (\forall\ n)\,, \qquad \sup_n \|R_n\| = \infty.$$

This gives such an example of LS whose approximation setting is with (R0)- but without (R1)-regularization.

Example 4.2. Let $T : X \to Y$ defined as Example 2.10, where $X = Y = l^2$. If $T_n := Q_n T : X \to Y_n := \operatorname{span}\{e_1, e_2, \ldots, e_n\}$, then

$$\mathcal{R}(T_n) = Y_n\,, \qquad \overline{\mathcal{R}(T)} = \mathcal{R}(T) = e^\perp\,, \qquad Q_{\mathcal{R}(T_n)} \xrightarrow{\mathrm{s}} I \neq Q_{\overline{\mathcal{R}(T)}}\,.$$

This provides such an example of GDLS whose approximation setting is, by Theorem 2.6, with (R1)- but without $(\mathrm{H3})^{\mathrm{w}}$-regularization. In addition, the example demonstrates that "$(\mathrm{H2}) \Longleftrightarrow \overline{\mathcal{R}(T)} = \mathcal{R}(T)$" is not valid for GDLS; however, this proposition holds for DLS (see Corollary 2.4).

CONJECTURE 4.3. *Let the approximation setting* (1.1) *and* (1.2) *satisfy* (2.1). *Then*

$$(\mathrm{H3})^{\mathrm{s}} \iff (\mathrm{H3})^{\mathrm{w}} \iff \begin{cases} \sup_n \|R_n\| < \infty\,, \\ Q_{\mathcal{R}(T_n)} \xrightarrow{s} Q_{\overline{\mathcal{R}(T)}}\,. \end{cases}$$

Fundamental results on nonprojection methods of Moore–Penrose inverses for well-posed problems are also given (see Theorems 1.3 and 3.2). Therefore, Table 4.3 is produced, and the following error estimates hold: For all $y \in \mathcal{D}\left(T^\dagger\right)$ and $y_n \in Y_n$,

$$\begin{aligned} \left\|T_n^\dagger Q_n Q_{\overline{\mathcal{R}(T)}} y - T^\dagger y\right\| &\leqslant \left\|T_n^\dagger\right\|_n \left\|Q_n\left(T_n - T\right) P_n T^\dagger y\right\| + \left\|P_{\mathcal{N}(T_n)} T^\dagger y\right\| \\ &\quad + \left\|T_n^\dagger Q_n T - I\right\| \operatorname{dist}\left(T^\dagger y, X_n\right), \end{aligned} \tag{4.2}$$

$$\begin{aligned} \left\|T_n^\dagger y_n - T^\dagger y\right\| &\leqslant \left\|T_n^\dagger\right\|_n \left(\left\|Q_n\left(y_n - y\right)\right\| + \left\|Q_n\left(T_n - T\right) P_n T^\dagger y\right\|\right) + \left\|P_{\mathcal{N}(T_n)} T^\dagger y\right\| \\ &\quad + \left\|T_n^\dagger Q_n Q_{\mathcal{R}(T)^\perp} y\right\| + \left\|T_n^\dagger Q_n T - I\right\| \operatorname{dist}\left(T^\dagger y, X_n\right) \\ &= \left\|T_n^\dagger\right\|_n \left(\left\|Q_n\left(y_n - y\right)\right\| + \left\|Q_n\left(T_n - T\right) P_n T^\dagger y\right\|\right) \\ &\quad + \left\|\left(P_{\mathcal{N}(T_n)} - P_{\mathcal{N}(T)}\right) T^\dagger y\right\| + \left\|T_n^\dagger Q_n \left(Q_{\mathcal{R}(T_n)} - Q_{\overline{\mathcal{R}(T)}}\right) y\right\| \\ &\quad + \left\|T_n^\dagger Q_n T - I\right\| \operatorname{dist}\left(T^\dagger y, X_n\right). \end{aligned}$$

We remark that the above estimates can be also applied to ill-posed problems, based on which regularization nonprojection schemes including regular strategies can be designed and analyzed.

Clearly, nonprojection methods are with a wider scope of application than projection methods; but the latter are more convenient for application than the former. By observing Tables 4.1 and 4.3 with the error estimates (4.1) and (4.2), one can see the difference and relation between projection methods and nonprojection methods.

Appendix. The proof of the three propositions in Example 2.10.

Let $X := l^2$, $X_n := \operatorname{span}\{e_1, e_2, \dots, e_n\}$, where

$$e_k = (0, \dots, 0, \underset{k\,\text{th}}{\overset{\uparrow}{1}}, 0, \dots) \quad (\forall\ k \in \mathbb{N}).$$

We define an operator $T : X \to X$ as follows:

$$Tx := x - \langle x, e\rangle\, e \qquad (x \in X),$$

where $\langle\cdot,\cdot\rangle$ is the inner product on X and

$$e := \frac{\sqrt{3}}{2}e_1 + \frac{\sqrt{3}}{2^2}e_2 + \cdots + \frac{\sqrt{3}}{2^k}e_k + \cdots.$$

This operator satisfies

$$T^2 = T = T^* \quad \text{and} \quad \mathcal{N}(T) = \operatorname{span}\{e\}; \tag{A.1}$$

that is, T is the orthogonal projection of X onto $e^{\perp}$. Therefore, we have

$$T^{\dagger} = T. \tag{A.2}$$

Now set $T_n := T|_{X_n} : X_n \to X$. Then the following three propositions are valid.

PROPOSITION A.1. $\mathcal{N}(T_n) = \mathcal{N}(T) \cap X_n = \{0\}$, $\overline{\bigcup_{n=1}^{\infty} (\mathcal{N}(T) \cap X_n)} \subsetneqq \mathcal{N}(T)$.

Proof. This proposition is clear by (A.1). ∎

PROPOSITION A.2. *Let P_n denote the orthogonal projection onto X_n. Then*

$$T_n^{\dagger} y = P_n y - 4^n \langle (I - P_n)\, y, e\rangle\, P_n e \quad (\forall\ y \in X).$$

Proof. Note that

$$\|e\| = 1, \quad \langle P_n e, e\rangle = \|P_n e\|^2 = 1 - \frac{1}{4^n}. \tag{A.3}$$

Define $S_n : X \to X$ as follows:

$$S_n y := y - 4^n \langle (I - P_n)\, y, e\rangle\, e \quad (\forall\ y \in X). \tag{A.4}$$

Then it follows from (A.4), (A.1), and (A.3) that

$$\mathcal{N}(T) \subseteq \mathcal{N}(S_n), \quad \mathcal{R}((I - P_n)\, S_n) \subseteq e^{\perp}. \tag{A.5}$$

By use of (A.4), (A.5), and (A.3) we have

$$S_n|_{X_n} = P_n|_{X_n}, \quad S_n T = S_n, \quad T S_n = T, \tag{A.6}$$

and

$$T(I - P_n)\, S_n = (I - P_n)\, S_n, \quad [(I - P_n)\, S_n]^* = (I - P_n)\, S_n. \tag{A.7}$$

It follows from (A.6) that the operator $P_nS_n : X \to X_n$ satisfies

$$\text{(A.8)} \qquad \begin{cases} T_n\,(P_nS_n)\,T_n = T_n\,P_n|_{X_n} = T_n, \\ (P_nS_n)\,T_n\,(P_nS_n) = P_n|_{X_n}\,(P_nS_n) = P_nS_n, \\ [(P_nS_n)\,T_n]^* = I_n^* = I_n = (P_nS_n)\,T_n. \end{cases}$$

It follows from (A.7), (A.6), and (A.1) that $P_nS_n : X \to X_n$ also satisfies

$$\text{(A.9)} \qquad [T_n\,(P_nS_n)]^* = [T - (I - P_n)\,S_n]^* = T - (I - P_n)\,S_n = T_n\,(P_nS_n)\,.$$

Therefore, by (A.8) and (A.9), we have

$$T_n^\dagger = P_nS_n.$$

Thus, the proposition is proved. ∎

PROPOSITION A.3. *If $y \in X$, then*

$$\sup_n \left\|T_n^\dagger y\right\| < \infty \Longleftrightarrow \sup_n 4^n\,|\langle (I - P_n)\,y, e\rangle| < \infty\,,$$
$$T_n^\dagger y \rightharpoonup T^\dagger y \Longleftrightarrow 4^n\,\langle (I - P_n)\,y, e\rangle \longrightarrow \langle y, e\rangle\ .$$

Proof. By Proposition A.2, it follows that

$$\begin{cases} \left\|T_n^\dagger y\right\| \leqslant 4^n\,|\langle (I - P_n)\,y, e\rangle|\,\|P_ne\| + \|P_ny\|\,, \\ 4^n\,|\langle (I - P_n)\,y, e\rangle|\,\|P_ne\| \leqslant \left\|T_n^\dagger y\right\| + \|P_ny\|\,, \end{cases}$$

so that we obtain (notice that $\frac{\sqrt{3}}{2} \leqslant \|P_ne\| \leqslant 1$ and $\|P_ny\| \leqslant \|y\|$)

$$\sup_n \left\|T_n^\dagger y\right\| < \infty \Longleftrightarrow \sup_n 4^n\,|\langle (I - P_n)\,y, e\rangle| < \infty\,.$$

By Proposition A.2 and (A.2), it follows that for any $x \in X$ there holds

$$\begin{aligned} \left\langle x, T_n^\dagger y - T^\dagger y\right\rangle &= \langle x, (P_n - I)\,y - 4^n\,\langle (I - P_n)\,y, e\rangle\,P_ne + \langle y, e\rangle\,e\rangle \\ &= \langle x, e\rangle\,\overline{\langle y, e\rangle} - 4^n\,\langle P_nx, e\rangle\,\overline{\langle (I - P_n)\,y, e\rangle} - \langle x, (I - P_n)\,y\rangle\,. \end{aligned}$$

This implies that

$$\begin{aligned} T_n^\dagger y \rightharpoonup T^\dagger y &\Longleftrightarrow 4^n\,\langle P_nx, e\rangle\,\overline{\langle (I - P_n)\,y, e\rangle} \longrightarrow \langle x, e\rangle\,\overline{\langle y, e\rangle}\ \ (\forall\ x \in X) \\ &\Longleftrightarrow 4^n\,\langle (I - P_n)\,y, e\rangle \longrightarrow \langle y, e\rangle\ . \end{aligned}$$

The proof is complete. ∎

Acknowledgment. I am glad to acknowledge the very detailed suggestions of the referee and the editor for improving my manuscript. Their comments and suggestions were very helpful to me.

UNIFORM CONVERGENCE OF A NONLINEAR ENERGY-BASED MULTILEVEL QUANTIZATION SCHEME*

QIANG DU† AND MARIA EMELIANENKO‡

Abstract. A popular vector quantization scheme can be constructed by centroidal Voronoi tessellations (CVTs) which also have many other applications in diverse areas of science and engineering. The development of efficient algorithms for their construction is a key to the successful applications of CVTs in practice. This paper studies the details of a new optimization-based multilevel algorithm for the numerical computation of CVTs. The rigorous proof of its uniform convergence in one space dimension and the results of computational simulations are provided. They substantiate recent claims on the significant speedup demonstrated by the new scheme in comparison with traditional methods.

Key words. optimal quantization, centroidal Voronoi tessellations, Lloyd's method, multilevel method, uniform convergence

1. Introduction.

Optimal vector quantization is used in many applications such as image and data compression, pattern recognition, and image rendering [24]. A vector quantizer maps N-dimensional vectors in the domain $\Omega \subset \mathbb{R}^N$ into a finite set of vectors $\{\mathbf{z}_i\}_{i=1}^k$. Each vector $\mathbf{z}_i$ is called a code vector or a *codeword*, and the set of all the codewords is called a codebook. A special quantization scheme is given by the Voronoi tessellation which associates with each codeword $\mathbf{z}_i$ (also called a *generator*) a nearest neighbor region that is called a Voronoi region $\{V_i\}_{i=1}^k$. That is, for each i, V_i consists of all points in the domain Ω that are closer to $\mathbf{z}_i$ than to all the other generating points, and a Voronoi tessellation refers to the tessellation of a given domain by the Voronoi regions $\{V_i\}_{i=1}^k$ associated with a set of given generating points $\{\mathbf{z}_i\}_{i=1}^k \subset \Omega$ [1, 34].

With a suitably defined distortion measure, an optimal quantizer can be described as a centroidal Voronoi tessellation. For a given density function ρ defined on Ω, we may define the centroids, or mass centers, of regions $\{V_i\}_{i=1}^k$ by

$$\mathbf{z}_i^* = \Big(\int_{V_i} \mathbf{y}\rho(\mathbf{y})\,d\mathbf{y}\Big)\Big(\int_{V_i} \rho(\mathbf{y})\,d\mathbf{y}\Big)^{-1}. \tag{1.1}$$

Then an *optimal quantization* may be constructed through a *centroidal Voronoi tessellation* (CVT) for which the generators of the Voronoi tessellation are the centroids of their respective Voronoi regions; in other words, $\mathbf{z}_i = \mathbf{z}_i^*$ for all i. Such a connection between CVTs and optimal quantization schemes has been explored extensively in the literature [13].

‡Department of Mathematical Sciences, George Mason University, Fairfax, VA 22030 (memelian@gmu.edu).

Given a set of points $\{\mathbf{z}_i\}_{i=1}^k$ and a tessellation $\{V_i\}_{i=1}^k$ of the domain, we may define the *energy functional* or the *distortion value* for the pair $(\{\mathbf{z}_i\}_{i=1}^k, \{V_i\}_{i=1}^k)$ by

$$\mathcal{G}\Big(\{\mathbf{z}_i\}_{i=1}^k, \{V_i\}_{i=1}^k\Big) = \sum_{i=1}^k \int_{V_i} \rho(\mathbf{y})|\mathbf{y}-\mathbf{z}_i|^2\, d\mathbf{y}\,. \tag{1.2}$$

The minimizer of $\mathcal{G}$, that is, the optimal quantizer, necessarily forms a CVT which illustrates the optimization property of the CVT [13]. The terms optimal quantizer and CVT are thus to be used interchangeably in what follows. For more studies on optimal quantization schemes, we refer to [23, 24, 38]. We note that, besides providing an optimal least squares vector quantizer design in electrical engineering applications, the CVT concept also has applications in diverse areas such as astronomy, biology, image and data analysis, resource optimization, sensor networks, geometric design, and numerical partial differential equations [5, 8, 13, 14, 15, 16, 17, 18, 26, 27, 33, 39, 40]. We refer to [13] for a more comprehensive review of the mathematical theory and diverse applications of CVTs.

In the seminal work of Lloyd on least squares quantization [32], one of the algorithms proposed for computing optimal quantizers is a fixed point–type iterative algorithm consisting of the following simple steps: Starting from an initial quantization (a Voronoi tessellation corresponding to an old set of generators), a new set of generators is defined by the mass centers of the Voronoi regions. This process is continued until a certain stopping criterion is met. For algorithms on the computation of Voronoi tessellations, we refer to [1, 19, 21]. It is easy to see that the Lloyd algorithm is an energy descent iteration of the energy functional (1.2), which gives strong indications to its practical convergence. We refer to [11, 20] for some discussions on the recent development of a rigorous convergence theory.

Lloyd's algorithms and their variants have been proposed and studied in many contexts for different applications [15, 24, 31, 36]. A particular extension using parallel and probabilistic sampling was given in [27] which allows efficient and mesh-free implementation of the Lloyd algorithm. Still, the Lloyd algorithm is at best linearly convergent. Moreover, it slows down as the number of generators increases.

For modern applications of the CVT concept in large scale scientific and engineering problems such as data communication, vector quantization, and mesh generation, efficient algorithms for computing the CVTs play crucial roles.

Recently, a new multilevel approach to the optimal quantization problem has been developed [10, 12]. The new multilevel scheme offers considerable speedup over traditional methods such as the celebrated Lloyd iteration. It can be combined with other techniques to accelerate the computation of CVTs and the optimal vector quantizers. In this paper, we present a rigorous mathematical theory for the new algorithm. We focus on the main characteristics of this multilevel scheme, namely, the uniform convergence with respect to the problem size. Though the result is shown in one space dimension only, such a result is the first of its type in the vector quantization field and on the computation of CVTs. Proofs for higher-dimensional cases are more involved, and they are now being worked out in our ongoing study [12].

The rest of the paper is organized as follows. In section 2, the optimization-based nonlinear multilevel algorithm is introduced. In section 3, the uniform convergence theory is established in the one-dimensional case. Numerical results demonstrating its superiority over traditional methods are given in section 4. Final conclusions are made in section 5.

2. Optimization-based nonlinear multilevel algorithm. Since the original concept of CVTs is related to the solution of a nonlinear optimization problem, and the monotone energy descent property is preserved by the Lloyd iteration [13], we may thus investigate whether monotone energy reduction can be achieved in a multilevel procedure which would also improve the performance of the simple-minded iteration.

The problem of constructing a CVT is nonlinear in nature, and hence standard linear multigrid theory cannot be directly applied. There are still several ways one could implement a nonlinear multilevel scheme in this context (see [9, 10, 28, 29]). A Newton-type acceleration method, studied earlier in [9], is based on some global linearization as the outer loop, coupled with other fast solvers in the inner loop. Alternatively, we now study an approach that overcomes the difficulties of the nonlinearity by essentially relying on direct energy minimization without any type of global linearization.

The optimization formulation of CVTs is not new [13]. CVTs and optimal quantizers are known to be closely related to the problem of minimizing the functional $\mathcal{G}\big(\{\mathbf{z}_i\}_{i=1}^k, \{V_i\}_{i=1}^k\big)$ with $\{V_i\}_{i=1}^k$ forming the Voronoi tessellation corresponding to the generators $\{\mathbf{z}_i\}_{i=1}^k$. In fact, we may note that the vector of generators of a CVT forms a critical point of the energy, and vice versa [13]. This is one of the important characterizations of CVTs which will be used in the later discussion. In our study here, we follow the ideas presented in the literature on the extension of multigrid ideas to nonlinear optimization problems (see [6, 22, 25, 30, 37] and the references cited therein). However, we observe that a direct application of multilevel schemes to the minimization of the original energy is not the best strategy. We illustrate later in this section that an alternative minimization formulation can be introduced to make the problem of computing CVTs more amenable for the multilevel framework.

2.1. Preconditioned formulation. Let $\mathbf{V} = \{V_i\}_{i=1}^k$ denote a Voronoi tessellation corresponding to some choice of iteration points $\mathbf{Z}$ in Ω. For any Voronoi cell $V_i \subset \Omega$, let us denote by R_i the mass of V_i, i.e.,

$$R_i := \int_{V_i} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y}.$$

The fact that ρ is positive almost everywhere implies that $R_i > 0$ for all $i = 1, \ldots, k$.

We define the set of iteration points $\mathbf{W}$ by

$$\mathbf{W} = \{(w_i)|_{i=0}^{k+1} | \quad 0 = w_0 \le w_i \le w_{i+1} \le w_{k+1} = 1 \quad \forall\, 0 \le i \le k\}\,, \tag{2.1}$$

which includes the generators and the end points. The so-called Lloyd map is the function $\mathbf{T} : \mathbf{W} \to \mathbf{W}$ that takes a tuple of generators into the tuple of the centroids of its Voronoi regions (exactly the iteration used in the Lloyd algorithm). More precisely, let $\mathbf{T} = (T_1, \ldots, T_k)$; then for any $z \in \mathbf{W}$,

$$T_i(z) = \frac{\int_{V_i(z)} \mathbf{y}\rho(\mathbf{y})\, \mathrm{d}\mathbf{y}}{\int_{V_i(z)} \rho(\mathbf{y})\, \mathrm{d}\mathbf{y}}$$

for $i = 1, \ldots, k$. The Lloyd map is continuous from $\mathbf{W}$ to $\mathbf{W}$ [13, 11].

For any $z \in \mathbf{W}$, the *Lloyd energy* is defined as

$$\mathcal{H}(z) = \mathcal{G}(z, \mathbf{V}(z)) = \sum_{i=0}^{n} \int_{V_i(z)} \rho(\mathbf{y}) |\mathbf{y} - z_i|^2\, \mathrm{d}\mathbf{y}.$$

The Lloyd energy function is also continuous on $\mathbf{W}$. The derivative of $\mathcal{H}$ is given [13] by

$$\frac{\partial \mathcal{H}}{\partial z_i}(z) = 2R(V_i(z))(z_i - \mathbf{T}_i(z)) \,. \tag{2.2}$$

To perform rigorous analysis of our nonlinear multigrid scheme, it is desirable if the energy functional is locally convex and satisfies some spectral equivalence properties in the appropriate norm. In general, we cannot expect these properties to hold. However, relating our problem to an equivalent optimization problem through a technique that mimics the role of a dynamic nonlinear preconditioner turns out to be very effective. More precisely, denote by P a nonsingular matrix playing the role of a preconditioner. It is easy to deduce that $P\nabla\mathcal{H} = 0$ at a CVT. Hence we arrive at an equivalent formulation of the minimization problem: $\min ||P\nabla\mathcal{H}||^2$, with respect to the standard Euclidean norm. In particular, we can choose $P = (\mathbf{I} - S)^{-1/2}R^{-1}$, where R is a diagonal matrix $R = \mathtt{diag}(R_1, R_2, \ldots, R_k)$, where, as before, the R_i's are the masses of the corresponding Voronoi cells. As we will show later, this preconditioning strategy renders the problem convex and shares some spectral equivalence properties in an appropriately chosen norm for a class of densities, say of the form $\rho(x) = 1 + \epsilon g(x)$. For such densities, the energy functional $\mathcal{H}$ may not be locally convex; however, the equivalent preconditioned strategy successfully eliminates this difficulty. Notice that for this type of density we have $\frac{\partial \mathbf{T}}{\partial z} = S + \epsilon\widetilde{S}(z)$, where

$$S = \begin{pmatrix} 1/4 & 1/4 & 0 & & 0 & 0 & 0 \\ 1/4 & 1/2 & 1/4 & \ldots & 0 & 0 & 0 \\ 0 & 1/4 & 1/2 & & 0 & 0 & 0 \\ & \ldots & & \ldots & & \ldots & \\ 0 & 0 & 0 & & 1/2 & 1/4 & 0 \\ 0 & 0 & 0 & \ldots & 1/4 & 1/2 & 1/4 \\ 0 & 0 & 0 & & 0 & 1/4 & 1/4 \end{pmatrix}$$

is the derivative of the Lloyd map corresponding to the case of the constant density. This preconditioned formulation leads to a multilevel algorithm based on the following nonlinear optimization problem:

$$\min_{z\in\mathbf{W}} \widetilde{\mathcal{H}}(z), \text{ where } \widetilde{\mathcal{H}}(z = \{z_i\}_{i=0}^{k+1}) = ||P\nabla\mathcal{H}(\{\mathbf{z}_i\}_{i=1}^{k})||^2 \,. \tag{2.3}$$

The functional $\widetilde{\mathcal{H}}$ may be regarded as a preconditioned energy, and with the above choice of the preconditioner P, we have

$$\widetilde{\mathcal{H}}(z) = ||2(\mathbf{I} - S)^{-1/2}R^{-1}R(z - \mathbf{T}(z))||^2 = 2[z - \mathbf{T}(z)]^T[(\mathbf{I} - S)^{-1}(z - \mathbf{T}(z))] \tag{2.4}$$

and the gradient can be computed as

$$\begin{aligned} \nabla\widetilde{\mathcal{H}}(z) &= 4\left(\mathbf{I} - \frac{\partial \mathbf{T}}{\partial z}\right)(\mathbf{I} - S)^{-1}(z - \mathbf{T}(z)) = 4(\mathbf{I} - \epsilon\widehat{S}(z))(z - \mathbf{T}(z)) \\ &= 4(z - \mathbf{T}(z)) - 4\epsilon\beta(z), \end{aligned} \tag{2.5}$$

where $\widehat{S}(z) = \widetilde{S}(z)(I - S)^{-1}$ and $\beta(z) = \widehat{S}(z)(z - \mathbf{T}(z))$.

A key observation is that as R varies with respect to the generators, the above transformation or *dynamic preconditioning* keeps the modified objective functional convex in a suitably large neighborhood of the minimizer and therefore makes the new formulation more amenable to analysis than the original problem.

2.2. Space decomposition. Suppose that without loss of generality we start with an odd number of generators $k = 2^{n_J} - 1$. Now, we define the set of iteration points $\mathbf{W}$ by (2.1).

While the set of iteration points will be dynamically updated at each step of the algorithm, we want to construct a domain decomposition that will not be affected by these changes. Namely, we can denote by $\mathbf{X} = \mathbf{X}^J$ the set of uniformly distributed grid nodes in the unit interval, and by $\mathbf{X}^i$ the sequence of grid nodes $\mathbf{X}^i = \{x_j^i\}_{j=0}^{n_i}$, obtained via uniform subdivision $x_j^i = j/2^{n_i}$. A set of nonoverlapping grid points at the ith level would consist of $\overline{\mathbf{X}}^i = \mathbf{X}^i/\mathbf{X}^{i-1}$. Next we define by $\mathcal{T} = \mathcal{T}_J$ a mesh corresponding to $\mathbf{X}$ and consider a sequence of nested uniform finite element meshes $\mathcal{T}_1 \subset \mathcal{T}_2 \subset \cdots \mathcal{T}_J$, where $\mathcal{T}_i$ consists of all finite element meshes $\{\tau_j^i\}_{j=1}^{n_i-1}$ with mesh parameters $h_i = h_{i-1}/2$, such that $\cup_{j=1}^{n_i} \tau_j^i = \Omega = [0,1]$ and $n_i = 2n_{i-1}$. Corresponding to each partition $\mathcal{T}_i$ $(i = 1, \ldots, J)$, there is a finite element space $\mathbf{Y}_i$ defined by

$$\mathbf{Y}_i = \{v \in H_0^1(\Omega) \ \mid \ v|_\tau \in \mathcal{P}_1(\tau) \ \forall \tau \in \mathcal{T}_i\} \ .$$

For each $\mathbf{Y}_i$, there corresponds a nodal basis $\{\psi_j^i\}_{j=1}^{n_i}$, such that $\psi_j^i(x_k^i) = \delta_{jk}$, where δ_{jk} is the usual Kronecker delta function and $\{x_k^i\}_{k=1}^{n_i}$ is the set of all nodes of the elements of $\mathcal{T}_i$ with $x_1^J = 0, x_{n_J}^J = 1$. Define the corresponding one-dimensional subspaces $\mathbf{Y}_{i,j} = \text{span}\{\psi_j^i\}$. Then the decomposition can be regarded as

$$\mathbf{Y}_J = \sum_{i=1}^{J} \sum_{j=1}^{n_i} \mathbf{Y}_{i,j} = \bigoplus_{i=1}^{J} \overline{\mathbf{Y}}_i,$$

where $\overline{\mathbf{Y}}_i = \mathbf{Y}_i/\mathbf{Y}_{i-1}$ for $i > 1$ and $\overline{\mathbf{Y}}_1 = \mathbf{Y}_1$, following the standard multigrid construction given in [4]. Now clearly for each $\psi_j^i \in \mathbf{Y}_i$, we can find a vector $w_j^i = \{\bar{\psi}_{jm}^i\}_{m=1}^{n_J-1} \in \mathbb{R}^{n_J}$, such that $\psi_j^i(x) = \sum_{m=1}^{n_J-1} \bar{\psi}_{jm}^i \psi_m^J(x)$ for $x \in \Omega$.

Figure 2.1 gives an illustration of this decomposition. Notice that this configuration is independent of the positions of generators and relies entirely on the grids $\mathcal{T}_i$ that are chosen to be uniform.

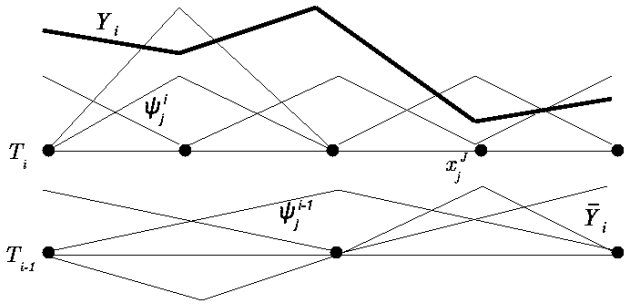

FIG. 2.1. *The structure of the space decomposition subordinate to the uniform mesh* $\mathbf{X}$ *in* $[0,1]$.

Using the linear interpolation coefficients $w_j^i = \{\bar{\psi}_{jm}^i\}_{m=1}^{n_j} \in \mathbb{R}^{n_J}$ defined above, we can decompose the space of iteration points as follows:

$$\mathbf{W} = \sum_{i=1}^{J} \mathbf{W}_i = \bigoplus_{i=1}^{J} \overline{\mathbf{W}}_i,$$

where $\mathbf{W}_i = \text{span}\{w_j^i\}$ and $\overline{\mathbf{W}}_i = \mathbf{W}_i/\mathbf{W}_{i-1}$ for $i > 1$. The vector spaces defined this way provide all the information necessary to fully describe the iteration procedure given below.

Note that once a mesh coarsening procedure is described, the above setup naturally applies to higher-dimensional cases, where $\mathbf{X}$ consists of grids points in a higher-dimensional domain and is discussed in more detail in [12]. Here we will restrict our attention to the one-dimensional case. It may then be noted that the set of basis functions $[w_1^i, \ldots, w_{n_i}^i]^T \in \mathbb{R}^{n_i \times k}$ used at each iteration can be pregenerated using the recursive procedure $[w_1^J, \ldots, w_{nJ}^J]^T = I_{k\times k}$ and $[w_1^{J-s}, \ldots, w_{nJ-s}^{J-s}]^T = (\Pi_{i=1}^s P_{J-i})$, where P_i is the basis transformation from space $\mathbf{W}_{i+1}$ to $\mathbf{W}_i$ which plays the role of a restriction operator.

2.3. Description of the algorithm. Using the above notation, we design Algorithm 2.2, which is a multilevel successive subspace correction algorithm [6, 41]. Each step of the procedure outlined below involves solving a system of nonlinear equations, which plays the role of relaxation. We can use the Newton iteration to solve this nonlinear system. Solution at current iterate is updated after each nonlinear solve by the Gauss–Seidel-type procedure, and hence the resulting scheme is successive in nature. The algorithm uses the procedure *CoarseGridSolve*, which, as the name indicates, refers to finding the solution at the coarsest level. In our implementation, this procedure consists of applying the Lloyd method to the $2^m - 1$ coarsest generators for a few steps (given by $imax$) or until saturation. In the implementation, we mostly use $m = 2$ so that there are only three coarsest generators.

ALGORITHM 2.1. $\mathbf{U}$ = CoarseGridSolve($\mathbf{U}$,tol).
Input: A set of k iteration points $\mathbf{U} = \{u_i\}_{i=1}^k$ *on* Ω.
Method:
Define the set of coarsest grid nodes: $z = \{z_j\}_{j=1}^{2^m-1}$, *where* $z_j = u_{\frac{j(k+1)}{2^m}}$.
For `iter` $= 1 : imax$
Perform Lloyd iterations with $2^m - 1$ *generators:*
1. *Construct the Voronoi regions* $\{V_j(z)\}_{j=1}^{2^m-1}$ *of* Ω *associated with z;*
2. *Determine the centroids* $\mathbf{T}(z)$ *of the Voronoi regions* $V_j(z)$*;*
these centroids form the new set of points z;
3. *If* $||z - \mathbf{T}(z)|| <$ tol, *return z and terminate the cycle;*
otherwise, goto step 1.

endfor.
Update $\mathbf{U}$ *by* $u_{\frac{j(k+1)}{2^m}} = z_j, j = 1, 2, \ldots, 2^m - 1$.

In general, other efficient optimization methods, as well as Newton's method, can be used in order to quickly damp the error, since the number of unknowns on the coarsest grid remains relatively small.

The "slash" cycle can be defined as follows.

ALGORITHM 2.2. Successive correction $V(\nu)$ scheme.
Input:
k, number of generators; $u_1 = \{z_i\}_{i=1}^k$, *the ends plus the initial set of generators.*
tol, *tolerance for the coarse grid solution accuracy.*
Output after n cycles:
$u_n = \{z_i\}_{i=0}^{k+1}$, *the ends plus the set of generators for CVT.*
Method: For $n > 1$, *given* u_n, *do*
1. *For* $i = 1 : J$
$\bar{u}_{n+\frac{i-1}{J}} = u_{n+\frac{i-1}{J}}$

Perform ν smoothings:

$\bar{u}_{n+\frac{i-1}{J}} = \bar{u}_{n+\frac{i-1}{J}} + \alpha^0_{j\,l} w^i_j \in \overline{\mathbf{W}}_i$ *sequentially for* $1 \le j \le n_i$,

such that $\widetilde{\mathcal{H}}(\bar{u}_{n+\frac{i-1}{J}} + \alpha^0_{j\,l} w^i_j) = \min_{\alpha_{jl}} \widetilde{\mathcal{H}}(\bar{u}_{n+\frac{i-1}{J}} + \alpha_{j\,l} w^i_j)$,

Update the solution at ith level:

$$u_{n+\frac{i}{J}} = \bar{u}_{n+\frac{i-1}{J}} = u_{n+\frac{i-1}{J}} + e^i_n, \text{ where } e^i_n = \sum_{l=1}^{\nu_1} \sum_{j=1}^{n_i - 1} \alpha^0_{j\,l} w^i_j$$

endfor.

2. *On the coarsest level,* $u_{n+1} \leftarrow$*CoarseGridSolve(*u_{n+1},tol*).*
3. *Set* $n = n + 1$ *repeat procedure* 1 *to* 2 *until some stopping criterion is met.*

Here, the parameter ν denotes the number of Gauss–Seidel iterations (smoothings) used at each level. Although it is enough to have $\nu = 1$ in theory, larger values are used in practice due to the inexact nonlinear solver. The values $\nu \le 3$ usually suffice for the optimization to reach saturation. In the above description, no postsmoothings are used to make the analysis more transparent. A complete $V(\nu_1, \nu_2)$ cycle with ν_1 presmoothings and ν_2 postsmoothings can be defined and analyzed in a similar fashion. The algorithm essentially depends only on the proper space decompositions and its relation to the set of generators, and thus it is applicable in any dimension. The more general forms, including detailed description of the grid coarsening procedure, will be discussed in our subsequent works.

3. The uniform convergence theory. The uniform convergence of the new multilevel scheme can be rigorously proved, at least, for a large class of density functions in one-dimensional space. This is the first step toward a more comprehensive theoretical analysis of this type of multilevel scheme in general. Here, let us first establish some important properties of the energy functional defined in (2.3). Then we introduce our main convergence results. Without further notice, all the analysis in this section is restricted to the one-dimensional case only, and we further assume without loss of generality that the domain is simply the unit interval $\Omega = (0, 1)$, which can always be transformed into any other intervals.

3.1. Notation. First, for each $u, v \in \mathbf{W}$, we adopt the following H^1 inner product:

$$\langle u, v \rangle_{\mathbf{W}} = \frac{1}{k} \sum_{i=1}^{k+1} (u_i - u_{i-1})(v_i - v_{i-1}).$$

Next, if $y = u - v$, we have $y_0 = y_{k+1} = 0$ and

$$||y||^2_{\mathbf{W}} = \frac{1}{k} \sum_{i=1}^{k+1} (y_i - y_{i-1})^2$$

defines a $\mathbf{W}$-norm that we will be using throughout the rest of the paper.

To simplify the presentation, let us introduce the following notation: for $i = 1, \ldots, k$,

$$u^-_i = \frac{u_i + u_{i-1}}{2}, \qquad u^+_{i-1} = \frac{u_{i-1} + u_i}{2}$$

with $a_i = u_i - u_{i-1}, b_i = w_i - w_{i-1}, x_i = u_i - w_i$, and $u_0 = w_0 = 0$, $u_{k+1} = w_{k+1} = 1$ being the fixed ends of the interval.

3.2. Technical lemmas. In the discussion that follows we say that a functional F satisfies the *convexity* and *continuity* properties in $\mathbf{W}$ if there exist constants $K > 0$, $L > 0$ satisfying

$$(\nabla F(w) - \nabla F(v), w - v) \geq K||w - v||^2_{\mathbf{W}} \quad \forall w, v \in \mathbf{W} \,, \tag{3.1}$$

$$(\nabla F(w) - \nabla F(v), w - v) \leq L||w - v||^2_{\mathbf{W}} \quad \forall w, v \in \mathbf{W} \,, \tag{3.2}$$

where $(\cdot, \cdot)$ denotes the regular Euclidean inner product.

Let us first turn our attention to the case of a constant density. In this simple case, with the above notation, we get the following result for the preconditioned energy functional.

PROPOSITION 3.1. *Let $\rho(x) = 1$ be the density function on $[0, 1]$. Then the following relation holds for all $u, w \in \mathbf{W}$:*

$$(\nabla\widetilde{\mathcal{H}}(u) - \nabla\widetilde{\mathcal{H}}(w), u - w) = \frac{1}{2}\sum_{i=1}^{k+1}(a_i - b_i)^2 \,.$$

Proof. Following (2.5), we have

$$\frac{\partial\widetilde{\mathcal{H}}}{\partial u_i} = 2(u_i - T_i) = 2\Big(u_i - \frac{u_i^+ + u_i^-}{2}\Big) = \frac{1}{2}(a_i - a_{i+1}) \,.$$

Thus,

$$\begin{aligned}(\nabla\widetilde{\mathcal{H}}(u) - \nabla\widetilde{\mathcal{H}}(w), u - w) &= \frac{1}{2}\sum_{i=1}^{k}(u_i - w_i)(a_i - a_{i+1} - b_i + b_{i+1}) \\ = \frac{1}{2}\sum_{i=1}^{k}(u_i - w_i)(a_i - b_i) - \frac{1}{2}\sum_{i=1}^{k}(u_{i-1} - w_{i-1})(a_i - b_i) &= \frac{1}{2}\sum_{i=1}^{k+1}(a_i - b_i)^2 \,. \qquad \square\end{aligned}$$

COROLLARY 3.1. *For a constant density, the functional $F = k^{-1}\widetilde{\mathcal{H}}$ satisfies the continuity and convexity conditions with $K = L = 1/2$ for all points in $\mathbf{W}$.*

Note that this is a simple consequence of the fact $\sum_{i=1}^{k+1}(a_i - b_i)^2 = k||u - w||^2_{\mathbf{W}}$.

One can extend the above result to a broader class of density functions. First, the following auxiliary lemma can be verified.

LEMMA 3.2. *Let $M_g = \sup_{x\in[0,1]}|g(x)|$ and $M' = \sup_{x\in[0,1]}|g'(x)|$ on $[0, 1]$, and define*

$$Q_i(u) = \frac{\int_{u_i^-}^{u_i^+}(2x - (u_i^+ + u_i^-))g(x)dx}{(u_i^+ - u_i^-) + \epsilon\int_{u_i^-}^{u_i^+} g(x)dx} \,. \tag{3.3}$$

Then

$$|Q_i(u)| \leq \frac{4M_g|u_i^+ - u_i^-|}{1 - 2\epsilon M_g} \tag{3.4}$$

and

$$|Q_i(u) - Q_i(w)| \leq C_Q\alpha_i \,, \tag{3.5}$$

where $\alpha_i = |u_i^+ - w_i^+| + |u_i^- - w_i^-|$ and $C_Q = M_g + M' + \epsilon M_g^2 + 3\epsilon M_g M'$.

Proof. Denote

$$Q_i(u) = \frac{\int_{u_i^-}^{u_i^+} (2x - (u_i^+ + u_i^-))g(x)dx}{(u_i^+ - u_i^-) + \epsilon \int_{u_i^-}^{u_i^+} g(x)dx} = \frac{N_i}{D_i} .$$

In order to represent the above expression in a more convenient form, we employ the following change of variables argument:

$$\int_\alpha^\beta f(x)\,dx = (\beta - \alpha)\int_{-1}^{1} f\Big(\frac{\alpha+\beta}{2} + \frac{s}{2}(\beta-\alpha)\Big)\,ds . \tag{3.6}$$

Introducing $-1 \le s \le 1$, we can rewrite $x_u(s) = \frac{u_i^+ + u_i^-}{2} + \frac{s}{2}(u_i^+ - u_i^-)$ and $x_w(s) = \frac{w_i^+ + w_i^-}{2} + \frac{s}{2}(w_i^+ - w_i^-)$. Then for the numerator we have

$$\begin{aligned} N_i(u) &= \int_{u_i^-}^{u_i^+} (2x - (u_i^+ + u_i^-))g(x)dx \\ &= (u_i^+ - u_i^-)\int_{-1}^{1} s(u_i^+ - u_i^-)g(x_u(s))\,ds \\ &= (u_i^+ - u_i^-)^2 \int_{-1}^{1} g(x_u(s))s\,ds, \end{aligned}$$

while the denominator is equal to

$$D_i(u) = (u_i^+ - u_i^-)\Big(1 + \epsilon\int_{-1}^{1} g(x_u(s))\,ds\Big) .$$

For the ratio $Q_i = N_i/D_i$ we have

$$Q_i(u) = \frac{N_i(u)}{D_i(u)} = \frac{(u_i^+ - u_i^-)\int_{-1}^{1} g(x_u(s))s\,ds}{1 + \epsilon\int_{-1}^{1} g(x_u(s))\,ds} .$$

We thus can use the bound on g to get (3.4). Now, for simplicity let us redefine the modified numerator and denominator as

$$\widetilde{N}_i(u) = (u_i^+ - u_i^-)\int_{-1}^{1} g(x_u(s))s\,ds , \quad \widetilde{D}_i(u) = 1 + \epsilon\int_{-1}^{1} g(x_u(s))\,ds .$$

In the new notation,

$$\begin{aligned} |Q_i(u) - Q_i(w)| &\le \frac{1}{\widetilde{D}_i(u)\widetilde{D}_i(w)}\Big|\widetilde{N}_i(u)\widetilde{D}_i(w) - \widetilde{N}_i(w)\widetilde{D}_i(u)\Big| \\ &\le \frac{1}{2}\Big|\widetilde{N}_i(u) - \widetilde{N}_i(w)\Big|\Big(\widetilde{D}_i(u) + \widetilde{D}_i(w)\Big) \\ &\quad + \frac{1}{2}\Big(\widetilde{N}_i(u) + \widetilde{N}_i(w)\Big)\Big|\widetilde{D}_i(u) - \widetilde{D}_i(w)\Big| . \end{aligned}$$

Notice further that $|x_u(s) - x_w(s)| \le |u_i^+ - w_i^+| + |u_i^- - w_i^-| = \alpha_i$. It follows that

$$\left|\widetilde{D}_i(u) - \widetilde{D}_i(w)\right| = \epsilon\left|\int_{-1}^{1} (g(x_u(s)) - g(x_w(s)))\, ds\right| \le \epsilon M_g' \alpha_i \ ,$$

$$\begin{aligned}\left|\widetilde{N}_i(u) - \widetilde{N}_i(w)\right| &= \Big|\int_{-1}^{1} ((u_i^+ - u_i^-)g(x_u(z)) - (w_i^+ - w_i^-)g(x_w(s)))s\, ds\Big| \\ &\le 2(M_g + M_g')\alpha_i \ .\end{aligned}$$

Finally, since $|\widetilde{D}_i| \le 1 + \epsilon M_g$ and $\widetilde{N}_i \le 2M_g$, we have

$$|Q_i(u) - Q_i(w)| \le \Big((M_g + M')(1 + \epsilon M_g) + 2\epsilon M_g M'\Big)\alpha_i = C_Q \alpha_i,$$

which leads to (3.5). This proves the lemma. ∎

In a similar fashion, by employing the change of variables argument, we can easily prove the following.

LEMMA 3.3. *With the same assumptions (and notation) as the previous lemma,*

$$|\mathbf{T}_i(u) - \mathbf{T}_i(w)| \le C_T \alpha_i \quad \textit{and} \quad \sum_j |\widetilde{S}_{ij}(u) - \widetilde{S}_{ij}(w)| \le C_S \alpha_i.$$

Proof. The proofs for both $\mathbf{T}$ and $\widetilde{S}$ are analogous and follow along the lines of Lemma 3.2. For instance, direct calculation yields

$$\begin{aligned}\mathbf{T}_i(u) &= u_i - \Big(\int \rho(x)dx\Big)^{-1}\Big(\int (u_i - x)dx + \epsilon\int (u_i - x)g(x)dx\Big) \\ &= u_i - \frac{(u_i^+ - u_i^-)(2x_i - u_i^+ - u_i^-) + 2\epsilon\int (u_i - x)g(x)dx}{2(u_i^+ - u_i^-) + 2\epsilon\int g(x)dx} \\ &= \frac{u_i^+ + u_i^-}{2} - \frac{2\epsilon\int (u_i - x)g(x)dx - \epsilon(u_i^+ - u_i^-)\int g(x)dx}{2(u_i^+ - u_i^-) + 2\epsilon\int g(x)dx} \\ &= \frac{1}{2}\Big(u_i^+ + u_i^-\Big) + \epsilon\Big(\frac{\int (2x - (u_i^+ + u_i^-))g(x)dx}{2(u_i^+ - u_i^-) + 2\epsilon\int g(x)dx}\Big) \ ,\end{aligned}$$

where the integrals all refer to the integral over $[u_i^-, u_i^+]$. By the definition (3.3), we have

$$\mathbf{T}_i(u) = \frac{u_i^+ + u_i^-}{2} + \frac{1}{2}\epsilon Q_i \ . \tag{3.7}$$

One may then use estimates on Q_i to derive similar estimates for $\mathbf{T}_i$. We omit the rest of the details. ∎

With the help of Lemmas 3.2 and 3.3 we can finally derive the following general result.

PROPOSITION 3.2. *For any $\rho(x) = 1 + \epsilon g(x)$ with ϵ suitably small, there exist constants $C_l > 0$ and $C_u > 0$ dependent only on k, such that for any $u, w \in \mathbf{W}$ and with the notation defined earlier*

$$kC_l(k)||u - w||_{\mathbf{W}}^2 \le (\nabla\widetilde{\mathcal{H}}(u) - \nabla\widetilde{\mathcal{H}}(w), u - w) \le kC_u(k)||u - w||_{\mathbf{W}}^2 \ .$$

Proof. Recall from (2.5) that $\frac{\partial \widetilde{\mathcal{H}}}{\partial u_i} = 4[(u_i - \mathbf{T}_i(u)) - \epsilon\beta_i(u)]$. By (3.7), we get

$$\frac{\partial \widetilde{\mathcal{H}}}{\partial u_i}(u) = \Big(a_i - a_{i+1}\Big) - 2\epsilon(Q_i(u) + 2\beta_i(u))$$

and hence

$$(\nabla\widetilde{\mathcal{H}}(u) - \nabla\widetilde{\mathcal{H}}(w), u - w) = \sum_{i=1}^{k} (a_i - b_i)^2 - 2\epsilon(Q(u) - Q(w), u - w)$$

$$- 4\epsilon(\beta(u) - \beta(w), u - w)\ . \tag{3.8}$$

The first term in (3.8) comes from the constant part of the density and hence complies with the results of the previous theorem.

For the second term, from the Cauchy inequality and Lemma 3.2, we have

$$|\epsilon(Q(u) - Q(w), u - w)| \le \sum_{i=1}^{k} \epsilon|Q_i(u) - Q_i(w)|\,|u_i - w_i| \le C_q\epsilon k\|u - w\|^2_{\mathbf{W}} \tag{3.9}$$

for some constant C_q.

Finally, for the last term in (3.8), we note that by (2.5) and (3.7)

$$\beta(u) = \widehat{S}(u)(u - \mathbf{T}(u)) = \widehat{S}(u)\left[(I - S)u - \frac{1}{2}\epsilon Q(u)\right] = \widetilde{S}(u)\left[u - \frac{\epsilon}{2}(I - S)^{-1}Q(u)\right].$$

Hence, $(u - w)^T(\beta(u) - \beta(w)) = B_1 - B_2 + B_3 - B_4$, where

$$B_1 = (u - w)^T\widetilde{S}(u)(u - w), \qquad B_2 = \frac{\epsilon}{2}(u - w)^T\widetilde{S}(u)(I - S)^{-1}[Q(u) - Q(w)],$$

$$B_3 = (u - w)^T[\widetilde{S}(u) - \widetilde{S}(w)]w, \quad B_4 = \frac{\epsilon}{2}(u - w)^T[\widetilde{S}(u) - \widetilde{S}(w)](I - S)^{-1}Q(u).$$

Using the fact that $\widetilde{S}(u)$ is uniform bounded, we get from the Cauchy inequality that

$$|B_1| \le C_{b1}k\|u - w\|^2_{\mathbf{W}}$$

for some constant C_{b1}. Similarly for B_2, we apply the Cauchy inequality along with Lemma 3.2 and the spectral bound on $(1 - S)^{-1}$ (which is of the order k^2) to get

$$|B_2| \le \epsilon C_{b2}k^3\|u - w\|^2_{\mathbf{W}}$$

for some constant C_{b2}. As for B_3, we may use the estimates on $\widetilde{S}(u) - \widetilde{S}(w)$ in Lemma 3.3 and apply the Cauchy inequality to get

$$|B_3| \le C_{b3}k\|u - w\|^2_{\mathbf{W}}$$

for some constant C_{b3}. In addition, for ϵ small, it is easy to see that $Q_i(u)$ is uniformly bounded (independent of k). Hence we use the Cauchy inequality, the estimates for $\widetilde{S}(u) - \widetilde{S}(w)$ in Lemma 3.3, along with the same spectral bound on $(1 - S)^{-1}$ we used in B_2 estimation to get

$$|B_4| \le C_{b4}\epsilon k^3\|u - w\|^2_{\mathbf{W}}$$

for some constant C_{b4}. Hence, we get for some constant C_β, independent of k,

$$|\epsilon(\beta(u)-\beta(w),u-w)| \le C_\beta k(\epsilon+\epsilon^2k^2)||u-w||^2_{\mathbf{W}} \ . \tag{3.10}$$

Combining (3.5), (3.8), (3.9), and (3.10), we get

$$\begin{aligned} kC_l||u-w||^2_{\mathbf{W}} &= k[1-2\epsilon C_q-4C_\beta(\epsilon+\epsilon^2k^2)]\|u-w\|^2_{\mathbf{W}} \\ &\le (\nabla\widetilde{\mathcal{H}}(u)-\nabla\widetilde{\mathcal{H}}(w),u-w) \\ &\le k[1+2\epsilon C_q+4C_\beta(\epsilon+\epsilon^2k^2)]\|u-w\|^2_{\mathbf{W}} \\ &= kC_u||u-w||^2_{\mathbf{W}} \ , \end{aligned}$$

with constants $C_l = 1-2\epsilon C_q-4C_\beta(\epsilon+\epsilon^2k^2)]$ and $C_u = 1+2\epsilon C_q+4C_\beta(\epsilon+\epsilon^2k^2)$.

So, if ϵ is small such that ϵk is also small, independent of k, then we have the proposition. □

Note that it follows from Proposition 3.2 that the functional $F = k^{-1}\widetilde{\mathcal{H}}$ preserves the continuity and convexity for the class of densities considered here. Consequently, the preconditioned energy is guaranteed to be convex as long as the perturbations to a constant density $\rho(x) = 1+\epsilon g(x)$ remain small enough with $\epsilon = o(k^{-1})$. In other words, we obtain the following.

COROLLARY 3.4. *For any $\rho(x) = 1+\epsilon g(x)$ with ϵ suitably small, the functional $F = k^{-1}\widetilde{\mathcal{H}}$ satisfies the continuity and convexity conditions with $K = C_l, L = C_u$ for all points in $\mathbf{W}$.*

In addition to the convexity and continuity properties, we also need the following conditions on the space decomposition to be satisfied.

Condition A. For all $v \in \mathbf{W}$, there exists $v_i \in \overline{\mathbf{W}}_i$ such that $\sum_{i=1}^J v_i = v$, and $(\sum_{i=1}^J ||v_i||^2_{\mathbf{W}})^{1/2} \le C_1||v||_{\mathbf{W}}$ for some C_1 independent of k.

Condition B. *Strengthened Cauchy–Schwarz.* For all $w_{ij} \in \mathbf{W}, u_i \in \overline{\mathbf{W}}_i, v_j \in \overline{\mathbf{W}}_j \Rightarrow$

$$\sum_{i,j=1}^J (\nabla F(w_{ij}+u_i)-\nabla F(w_{ij}),v_j) \le C_2\left(\sum_{i=1}^J ||u_i||^2_{\mathbf{W}}\right)^{1/2}\left(\sum_{j=1}^J ||v_j||^2_{\mathbf{W}}\right)^{1/2}$$

for some $C_2 \le cL$, where c is independent of k.

These conditions are verified below. First, the following result follows from a simple accounting and the properties of the uniform domain decomposition we defined in section 2.2. Here and later supp denotes the support set of a function.

LEMMA 3.5. *For the one-dimensional* "hat" *basis, for all $u \in \overline{\mathbf{W}}_j$ and all $v \in \overline{\mathbf{W}}_l$ such that $j > l$, the following scaling of the supports relationship holds:*

$$\operatorname{supp}(u) \cap \operatorname{supp}(v) = 2^{-|j-l|}\operatorname{supp}(v).$$

In addition, denote the connected set of common indices $\mathcal{I} = \{0 \le i \le k+1|\ x_i^J \in \operatorname{supp}(u)\cap\operatorname{supp}(v)\}$ and define a restricted norm to be

$$||v||^2_{\mathbf{W},\operatorname{supp}(u)\cap\operatorname{supp}(v)} = \frac{1}{k}\sum_{i\in\mathcal{I}}(v_i-v_{i-1})^2 \ .$$

Then the following norm equivalence up to scaling is satisfied:

$$||v||_{\mathbf{W},\operatorname{supp}(u)\cap\operatorname{supp}(v)} = 2^{-|j-l|}||v||_{\mathbf{W}}. \tag{3.11}$$

The result of this lemma follows by counting the number of common nodes in the intersection of the supports of functions at different levels of the hierarchical decomposition and from the properties of the piecewise linear functions.

With the help of Lemma 3.5, we can show that for the chosen decomposition, both Conditions A and B are satisfied.

THEOREM 3.6. *For the nested subspace decomposition with the choice of the "hat" basis functions,* $(\sum_{i=1}^{J} ||v_i||_{\mathbf{W}}^2)^{1/2} = ||v||_{\mathbf{W}}$, *so that* $C_1 = 1$. *Moreover, for* $F = k^{-1}\widetilde{\mathcal{H}}$, C_2 *can be estimated as* $C_2 = L \cdot \max_j (\sum_{l=1}^{J} 2^{-|j-l|}) \le 2L$.

Proof. Notice that "hat" functions form an orthogonal basis, so

$$\left(\sum_{i=1}^{J} ||v_i||_{\mathbf{W}}^2 \right)^{1/2} = ||v||_{\mathbf{W}}$$

follows easily from calculation. As for the C_2, without loss of generality fix $j > l$ and take any $w \in \mathbf{W}$ and $u \in \overline{\mathbf{W}}_j$, $v \in \overline{\mathbf{W}}_l$. Now, adopting a similar argument for those in the proofs of Propositions 3.1 and 3.2 and taking notice that the contributions are confined in the support regions of u and v, we get

$$\begin{aligned}
&(\nabla\widetilde{\mathcal{H}}(u+w) - \nabla\widetilde{\mathcal{H}}(w), v) \\
&= \sum_{i=1}^{k+1} \{a_i\, b_i - 2\epsilon[(Q_i(u+w) - Q_i(w))v_i + 2(\beta_i(u+w) - \beta_i(w))v_i]\} \\
&= \sum_{i\in\mathcal{I}} (v_i - v_{i-1})(u_i - u_{i-1}) - 2\epsilon[(Q_i(u+w) - Q_i(w))v_i + 2(\beta_i(u+w) - \beta_i(w))v_i] \\
&\le k||u||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)}||v||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)} \\
&\quad + 2\epsilon C_q||u||_{\mathbf{W},\mathrm{supp}(u)\cap supp(v)}||v||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)} \\
&\quad + 4kC_\beta(\epsilon + \epsilon^2 k^2)||u||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)}||v||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)} \\
&\le kL||u||_{\mathbf{W}} \cdot ||v||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)},
\end{aligned}$$

where $\mathcal{I}$ is the same as in Lemma 3.5, $L = 1 + 2\epsilon C_q + 4C_\beta(\epsilon + \epsilon^2 k^2)$ is the continuity constant defined in Corollary 3.4, and C_β, C_q are as defined in Proposition 3.2.

Now by Lemma 3.5, $||v||_{\mathbf{W},\mathrm{supp}(u)\cap\mathrm{supp}(v)} = 2^{-|j-l|}||v||_{\mathbf{W}}$. It follows that, since for any symmetric matrix $||Ax|| \le \rho(A)||x|| \le \max_i (\sum_{j=1}^{n} |a_{ij}|)||x||$,

$$\begin{aligned}
\sum_{i,j=1}^{J} (\nabla\widetilde{\mathcal{H}}(w_{ij} + u_i) - \nabla\widetilde{\mathcal{H}}(w_{ij}), v_j) &\le kL \sum_{i,j=1}^{J} 2^{-|i-j|}||u_i||_{\mathbf{W}}||v_j||_{\mathbf{W}} \\
&\le kL \left(\max_j \sum_{i=1}^{J} 2^{-|i-j|} \right) \left(\sum_{i=1}^{J} ||u_i||_{\mathbf{W}}^2 \right)^{1/2} \left(\sum_{j=1}^{J} ||v_j||_{\mathbf{W}}^2 \right)^{1/2}.
\end{aligned}$$

Henceforth, we have $C_2 = L \cdot \max_j \sum_{i=1}^{J} 2^{-|i-j|} \le 2L$.

Note that although the proof above is presented for the special case of the "hat" basis that we used in our numerical implementation, similar arguments can be used to show that Conditions A and B hold for other suitable bases. Indeed, since the energy part of the argument does not depend on the decomposition, Conditions A and B will remain true for any basis as long as

$$\left(\sum_{i=1}^{J} ||v_i||_{\mathbf{W}}^2 \right)^{1/2} \le C_1||v||_{\mathbf{W}}$$

and

$$||v||_{\mathbf{W},\mathrm{supp}(v)\cap\mathrm{supp}(u)} \le C\cdot 2^{-|j-l|}||v||_{\mathbf{W}}$$

hold for some constants C, C_1 independent of k.

3.3. Uniform convergence theorem. Finally, putting together Conditions A and B and using convexity and continuity of $F = k^{-1}\widetilde{\mathcal{H}}$ in $\mathbf{W}$, we are ready to prove the following uniform convergence result.

THEOREM 3.7. *Under Conditions* A *and* B *on space decomposition, Algorithm* 2.1 *converges uniformly in* $\mathbf{W}$ *for any density of type* $\rho(x) = 1 + \epsilon g(x)$ *with sufficiently small* ϵ. *Moreover,* $d_n = \widetilde{\mathcal{H}}(u_n) - \widetilde{\mathcal{H}}(u)$ *satisfies*

$$d_n \le r d_{n-1}, \quad r \in (0,1),$$

where $r = \frac{C}{1+C}$ *and* $C = C_1^2 C_2^2 L/K^3$.

Before proceeding to its proof, let us first state a consequence.

COROLLARY 3.8. *In the case of a "hat" basis, the constants* C_1 *and* C_2 *can be estimated as* $C_1 = 1$ *and* $C_2 = 2L$, *so, for example, when* $\rho(x) = 1$, $C = 4$.

The proof of this result is similar to the one given in [37] and relies on the following inequality:

$$F(u) - F(v) - (\nabla F(v), u - v) = \int_0^1 (u - v, \nabla F(u + t(v-u)) - \nabla F(v))dt$$

$$\ge K\int_0^1 ||(1-t)(u-v)||_{\mathbf{W}}^2 \frac{dt}{1-t} = \frac{K}{2}||u-v||_{\mathbf{W}}^2 . \tag{3.12}$$

3.4. Proof of Theorem 3.7. Denote u to be the exact solution of (2.3). Consider u_n as the approximate solution after one J-level iteration of the Algorithm 2.2. At the ith level, since the supports of the basis functions w_j^i are disjoint in $\overline{\mathbf{W}}_i$, we have

$$u_{n+\frac{i}{J}} = u_{n+\frac{i-1}{J}} + e_n^i, \quad \widetilde{\mathcal{H}}(u_{n+\frac{i-1}{J}} + e_n^i) \le \widetilde{\mathcal{H}}(u_{n+\frac{i-1}{J}} + v_i) \quad \forall v_i \in \overline{\mathbf{W}}_i,$$

where in the notation of the algorithm, $e_n^i = \sum_{l=1}^{\nu_1}\sum_{j=1}^{n_i}\alpha_{jl}^0 w_j^i \in \overline{\mathbf{W}}_i$.

First notice that since the minimizer $u_{n+\frac{i}{J}}$ satisfies $(\nabla\widetilde{\mathcal{H}}(u_{n+\frac{i}{J}}), v) = 0$ for all $v \in \overline{\mathbf{W}}_i$, it follows from (3.12) that

$$\begin{aligned}
\widetilde{\mathcal{H}}(u_n) - \widetilde{\mathcal{H}}(u_{n+1}) &= \sum_{i=1}^{J}(\widetilde{\mathcal{H}}(u_{n+\frac{i-1}{J}}) - \widetilde{\mathcal{H}}(u_{n+\frac{i}{J}})) \\
&\ge \sum_{i=1}^{J}\left((\nabla\widetilde{\mathcal{H}}(u_{n+\frac{i}{J}}), u_{n+\frac{i-1}{J}} - u_{n+\frac{i}{J}}) + \frac{K}{2}||u_{n+\frac{i-1}{J}} - u_{n+\frac{i}{J}}||_{\mathbf{W}}^2\right) \\
&= \frac{K}{2}\sum_{i=1}^{J}||e_n^i||_{\mathbf{W}}^2 .
\end{aligned}$$

Next, let us use Condition A to decompose $u_{n+1} - u = \sum_{i=1}^{J} v_i$. Then

$$\begin{aligned}(\nabla\widetilde{\mathcal{H}}(u_{n+1}) - \nabla\widetilde{\mathcal{H}}(u), u_{n+1} - u) &= (\nabla\widetilde{\mathcal{H}}(u_{n+1}), u_{n+1} - u)\\ &= \sum_{i=1}^{J} (\nabla\widetilde{\mathcal{H}}(u_{n+1}), v_i) = \sum_{i=1}^{J} (\nabla\widetilde{\mathcal{H}}(u_{n+1}) - \nabla\widetilde{\mathcal{H}}(u_{n+\frac{i}{J}}), v_i)\\ &= \sum_{i=1}^{J}\sum_{j\geq i+1}^{J} (\nabla\widetilde{\mathcal{H}}(u_{n+\frac{j}{J}}) - \nabla\widetilde{\mathcal{H}}(u_{n+\frac{j-1}{J}}), v_i)\\ &\leq C_2\Big(\sum_{j=1}^{J} ||e_n^j||_{\mathbf{W}}^2\Big)^{1/2}\Big(\sum_{i=1}^{J} ||v_i||_{\mathbf{W}}^2\Big)^{1/2}.\end{aligned}$$

Hence

$$\begin{aligned}(\nabla\widetilde{\mathcal{H}}(u_{n+1}) - \nabla\widetilde{\mathcal{H}}(u), u_{n+1} - u) &\leq C_1C_2\Big(\sum_{j=1}^{J} ||e_n^j||_{\mathbf{W}}^2\Big)^{1/2} ||u_{n+1} - u||_{\mathbf{W}}\\ &\leq C_1C_2\left(\frac{2}{K}(\widetilde{\mathcal{H}}(u_n) - \widetilde{\mathcal{H}}(u_{n+1}))\right)^{1/2} ||u_{n+1} - u||_{\mathbf{W}}\,.\end{aligned}$$

Denote $d_n = \widetilde{\mathcal{H}}(u_n) - \widetilde{\mathcal{H}}(u)$; then $\widetilde{\mathcal{H}}(u_n) - \widetilde{\mathcal{H}}(u_{n+1}) = d_n - d_{n+1}$, and it follows from the inequality above that

$$\left(\frac{2}{K}(d_n - d_{n+1})\right)^{1/2} \geq \frac{(\nabla\widetilde{\mathcal{H}}(u_{n+1}) - \nabla\widetilde{\mathcal{H}}(u), u_{n+1} - u)}{C_1C_2||u_{n+1} - u||_{\mathbf{W}}}\,.$$

Thus,

$$\begin{aligned}d_n - d_{n+1} &\geq \frac{K}{2}\left(\frac{(\nabla\widetilde{\mathcal{H}}(u_{n+1}) - \nabla\widetilde{\mathcal{H}}(u), u_{n+1} - u)}{C_1C_2||u_{n+1} - u||_{\mathbf{W}}}\right)^2\\ &\geq \frac{K}{2}(C_1C_2)^{-2}K^2||u_{n+1} - u||_{\mathbf{W}}^2 \geq \frac{K^3}{C_1^2C_2^2L}d_{n+1}\,.\end{aligned}$$

The last step of the argument uses (3.2) and an inequality similar to (3.12) for the upper bound:

$$d_{n+1} = \widetilde{\mathcal{H}}(u_{n+1}) - \widetilde{\mathcal{H}}(u) \leq \frac{L}{2}||u_{n+1} - u||_{\mathbf{W}}^2\,.$$

As a consequence, we get

$$d_{n+1} \leq \frac{C_1^2C_2^2L}{K^3}(d_n - d_{n+1}) \Rightarrow d_{n+1} \leq \frac{C}{1+C}d_n, \quad \text{where } C = \frac{C_1^2C_2^2L}{K^3}\,.$$

Since for any basis satisfying Conditions A and B, $C_1^2C_2^2L/K^3 = O(L^3/K^3)$, the convergence is uniform as long as the ratio L/K does not depend on k. By looking at the L and K estimates obtained in Proposition 3.2, it is easy to see that this condition is satisfied for any smooth perturbation of the constant density $1 + \epsilon g(x)$ with ϵ of the order of $O(1/k)$. This concludes the proof of the main theorem. ∎

It follows that, for a suitable choice of decomposition in one dimension, the asymptotic convergence factor of our multilevel algorithm is independent of the size of the problem and the number of grid levels, which gives a significant speedup compared to other methods, like the traditional Lloyd iteration. This claim is further substantiated by the following numerical examples. Although for the sake of simplicity we have presented the detailed theory only for the case of the $V(\nu)$ multigrid cycle with no postsmoothings, same conclusions can be drawn for the case of the full $V(\nu_1, \nu_2)$ cycle, and the results of the numerical experiments in both cases are outlined below.

4. Numerical examples. We now report some numerical results obtained using the new multilevel algorithm.

First we compare the results of our $V(1,1)$ multigrid implementation with the usual Lloyd iteration for the one-dimensional problem. Then we present some results for a two-dimensional test problem in a parallelogram domain. The results are obtained with the MATLAB 6.5 implementation of the new algorithm. The test runs were performed on a PC with a Pentium IV processor and 512MB RAM.

The one-dimensional implementation is very straightforward. Here, we take the unit interval and test a couple of different density functions, like $\rho(x) = 1$ and $\rho(x) = 1 + x$. We plot the convergence factor $\rho \approx |z_{n+1} - z_n|/|z_n - z_{n-1}|$ for each $V(1,1)$ cycle with respect to the total number of generators (grid points) involved.

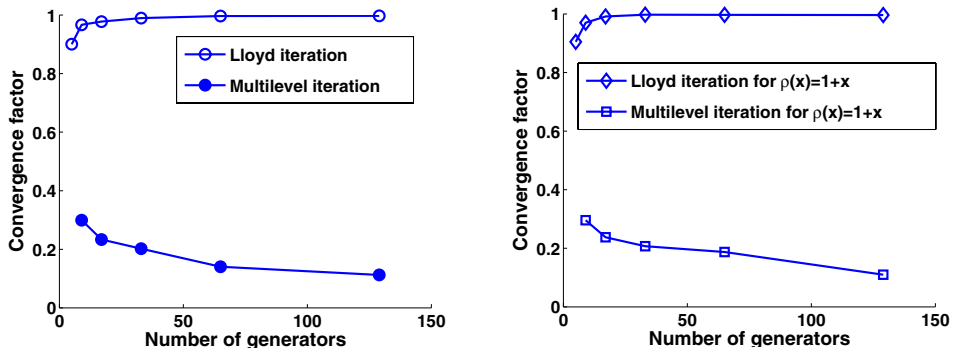

FIG. 4.1. *Plot of the convergence factor vs. the number of generators for the regular Lloyd (upper) and the multilevel (lower curves) iterations for* $\rho(x) = 1$ *(left) and* $\rho(x) = 1 + 0.1x$ *(right).*

Figure 4.1 substantiates the fact that the speed of convergence for the proposed scheme remains nearly constant as the number of generators increases. In Figure 4.2, the computational time needed for the $V(1,0)$ implementation of the multilevel method to reach 10^{-12} accuracy is given for $\rho(x) = 1$ and $\rho(x) = 1 + x$, respectively. The graph shows that in the one-dimensional case, the computational time *scales almost linearly* with the problem size.

The data in Table 4.1 shows the stabilization of the number of multigrid cycles $V(\nu_1, \nu_2)$ needed to reduce the error to $\epsilon = 10^{-12}$ in the constant density case. While there is a visible difference between the number of iterations required for $V(1,1)$ and $V(2,2)$ cycles, respectively, saturation occurs if the values of the relaxation parameters are increased, which is why $\nu_{1,2} \leq 2$ in most of our calculations. The geometric rate of the energy and error reduction asserted by Theorem 3.7 are confirmed by the experiments. Indeed, Figure 4.3 shows the convergence history of a $V(1,1)$ cycle against the total number of relaxations for the $k = 129$ case.

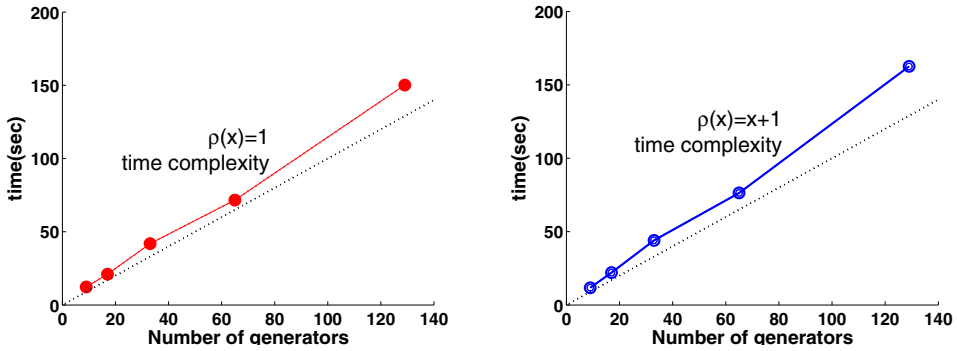

FIG. 4.2. *Computational time vs. problem size for the one-dimensional implementation.*

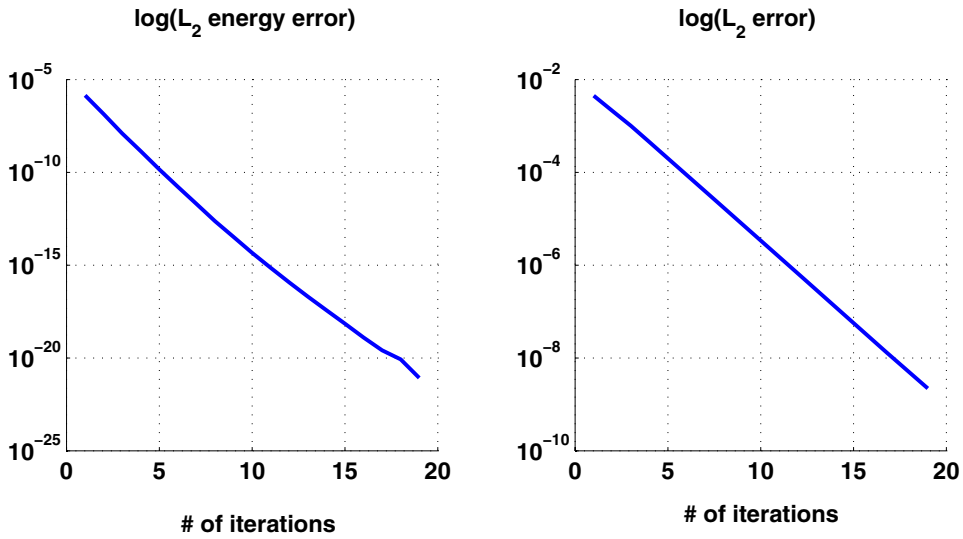

FIG. 4.3. *The energy reduction (left) and the convergence history (right) for* 129 *generators in the log-normal scale.*

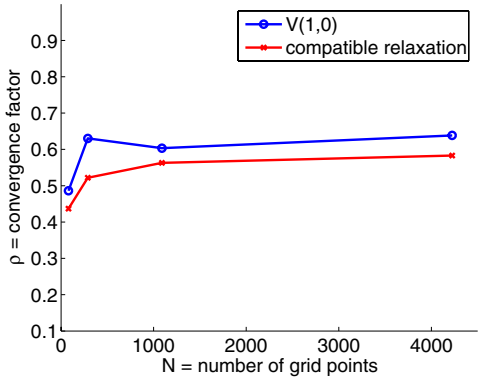

FIG. 4.4. *Comparison of the convergence factors for the compatible relaxation and a* $V(1,0)$ *cycle for* $\rho = 1$ *on a two-dimensional parallelogram-shaped domain.*

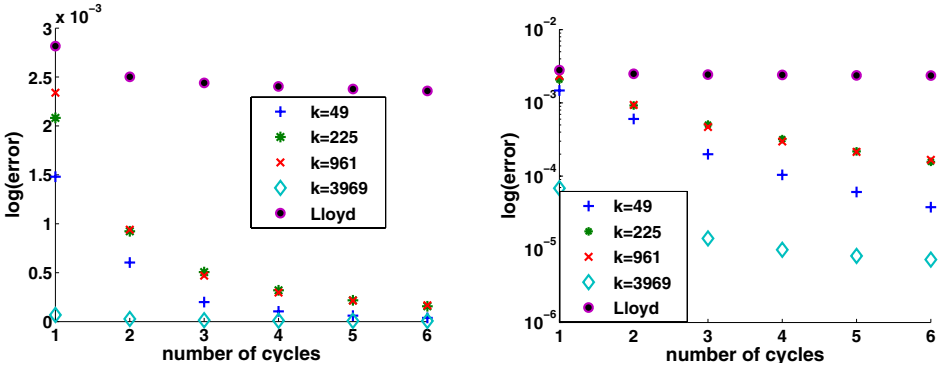

FIG. 4.5. *Convergence history for the two-dimensional multigrid scheme for* $\rho = 1$ *on a parallelogram-shaped domain compared to the Lloyd scheme shown on the top curve in the normal scale (left) and log-normal scale (right).*

Next, the convergence factors for a two-dimensional problems with $\rho = 1$ on a parallelogram domain are compared in Figure 4.4. The lower line in the graph shows the convergence factor for the compatible relaxation, that is, a relaxation performed on the grid with the exact solution given at the coarse nodes (see [2] for discussions on the compatible relaxation). This factor can serve as a lower bound on the convergence factor of the full multigrid cycle, and the quality of the coarse grid influences the distance between the two graphs. As we can see from Figure 4.4, the result of the compatible relaxation in this case is in good agreement with the convergence factor of the whole $V(1,0)$ cycle given on top, which is an indication of a good quality for the coarsening procedure.

The convergence history plots are given in Figure 4.5. The top curves in both graphs depict the error reductions given by the Lloyd iteration, while those below correspond to the convergence of the multigrid scheme for various problem sizes. One can clearly see that the slopes of error reduction on the logarithmic scale do not depend on the number of generators. Hence, even though our theoretical results here are proved only in one dimension, the proposed algorithm preserves its characteristics in certain higher-dimensional implementations.

5. Conclusion. Recently, several methods have been proposed for accelerating the convergence of the classical Lloyd iteration commonly used in the context of quantization and in the construction of centroidal Voronoi tessellations [9, 10]. These algorithmic advances are important for making the computation of optimal quantizers more efficient and for many other successful applications of CVTs. A few possible extensions that use multilevel techniques to accelerate the convergence of the CVTs have been suggested. One of such extensions uses some algebraic multigrid solvers in the spirit of [3, 7, 35] as preconditioners to accelerate the solution of the linear system at every Newton iteration [9], while the other adopts an energy-based nonlinear multigrid approach with the use of a dynamic nonlinear preconditioning [10]. In this paper, we focus on the latter approach, and for the first time, a rigorous analysis of its convergence properties is presented for a class of one-dimensional density functions, with the results of several numerical experiments given for both one- and two-dimensional cases. A more detailed analysis in the higher-dimensional cases as well as more efficient and robust implementations of the energy-based nonlinear multigrid approach are presently under investigation [12]. We conclude by commenting that there is obviously a great potential in using such multigrid methods to accelerate the optimal quantizer design and more generally the computation of CVTs.

Acknowledgment. The authors would like to thank M. Gunzburger of FSU and L. Zikatanov and J. Xu of PSU for interesting discussions on the subject, and anonymous referees for constructive criticism that helped to make current presentation more consistent.

A HYBRID POLYNOMIAL SYSTEM SOLVING METHOD FOR MIXED TRIGONOMETRIC POLYNOMIAL SYSTEMS*

BO YU† AND BO DONG†

Abstract. Mixed trigonometric polynomial systems arise in many fields of science and engineering. Commonly, this class of systems is transformed into polynomial systems by variable substituting and adding some quadratic equations, and then solved by some polynomial system solving method. In this paper, by exploiting the special structure of the additional quadratic equations, an efficient hybrid method for solving polynomial systems coming from mixed trigonometric polynomial systems is presented. It combines the homotopy method, in which the homotopy is a combination of coefficient parameter homotopy and the random product homotopy, with decomposition, variable substitution, and reduction techniques. Numerical tests are given to show its effectiveness, and it is applied to solve a practical problem.

Key words. homotopy method, polynomial system, mixed trigonometric polynomial system, symbolic-numeric computation

1. Introduction.

In this paper, we consider the task of finding all solutions of mixed trigonometric polynomial systems. Commonly, this class of systems is transformed into polynomial systems by variable substituting and adding some quadratic equations, and then solved by some polynomial solving method, symbolic or numeric. In this paper, by exploiting the special structure of the additional quadratic equations, an efficient hybrid method for solving polynomial systems coming from mixed trigonometric polynomial systems is presented. It combines the homotopy method, in which the homotopy is a combination of coefficient parameter homotopy and the random product homotopy, with decomposition, variable substitution, and reduction techniques.

The paper is organized as following: The problem with some examples of applications and an introduction to homotopy methods for solving polynomial systems are given in the rest of this section. A hybrid method for solving polynomial systems coming from mixed trigonometric polynomial systems is given in section 2. The main theorem with proof is given in section 3. Numerical examples with application are given in section 4.

1.1. Mixed trigonometric polynomial systems.

Mixed trigonometric polynomial systems (MTPS) are shown as follows:

$$F(y,\theta) = (f_1(y,\theta),\ldots,f_{n+m}(y,\theta))^T = 0, \tag{1.1}$$

where $y = (y_1,\ldots,y_n)$, $\theta = (\theta_1,\ldots,\theta_m)$, and for $1 \le i \le n+m$,

$$f_i(y,\theta) = \sum_{\alpha\in S_i} b_{i\alpha} y^{\beta} \sin^{\mu}\theta \cos^{\nu}\theta + b_i, \tag{1.2}$$

where $\alpha = (\beta,\ \mu,\ \nu)$, $S_i \subset \mathcal{N}^{n+2m}$ (here, for convenience, we write the constant term of $f_i(y,\theta)$ explicitly, i.e., for all i, $0 \notin S_i$), and

$$\begin{cases} y^{\beta} = y_1^{\beta_1} \cdots y_n^{\beta_n}, \\ \sin^{\mu}\theta = \sin^{\mu_1}\theta_1 \cdots \sin^{\mu_m}\theta_m, \\ \cos^{\nu}\theta = \cos^{\nu_1}\theta_1 \cdots \cos^{\nu_m}\theta_m. \end{cases} \tag{1.3}$$

This class of systems is common in many fields of science and engineering; see, for example, its application in neurophysiology [33], the inverse position and kinematics problems [33, 8], and the PUMA robot [26, 27].

In the following we give two examples of MTPS.

Example 1.1. This is a simple example in two dimensions.

$$F(y,\theta) = \begin{pmatrix} \sin^3\theta + y^2 + 1 \\ \cos^3\theta + y\sin\theta - 2 \end{pmatrix} = 0. \tag{1.4}$$

Example 1.2. This is a practical problem we meet in signal processing of sonar and radar, which is the original motivation of this research.

$$\begin{cases} \sum\limits_{i=1}^{n} y_i = b_1, & \sum\limits_{i=1}^{n} y_i^2 = b_2, \\ \sum\limits_{i=1}^{n} y_i \sin\theta_i = b_3, & \sum\limits_{i=1}^{n} y_i \cos\theta_i = b_4, \\ \sum\limits_{i=1}^{n} y_i \sin^2\theta_i = b_5, & \sum\limits_{i=1}^{n} y_i \sin\theta_i \cos\theta_i = b_6, \\ \sum\limits_{i=1}^{n} y_i^2 \sin\theta_i = b_7, & \sum\limits_{i=1}^{n} y_i^2 \cos\theta_i = b_8, \\ \sum\limits_{i=1}^{n} y_i^2 \sin^2\theta_i = b_9, & \sum\limits_{i=1}^{n} y_i^2 \sin\theta_i \cos\theta_i = b_{10}, \end{cases} \tag{1.5}$$

where $n = 3$ to 5 (if $n < 5$, then only the first $2n$ equations are needed).

By the variable substitution

$$\begin{cases} x_i = y_i, & i = 1, \ldots, n, \\ x_{n+j} = \sin\theta_j, & j = 1, \ldots, m, \\ x_{n+m+k} = \cos\theta_k, & k = 1, \ldots, m, \end{cases} \tag{1.6}$$

and adding m quadratic equations,

$$x_{n+k}^2 + x_{n+m+k}^2 - 1 = 0, \quad k = 1, \ldots, m,$$

the MTPS $F(y,\theta) = 0$ in (1.1), (1.2), and (1.3) can be transformed into the polynomial system

$$P(x) = \begin{pmatrix} p_1(x) + b_1 \\ \cdots \\ p_{n+m}(x) + b_{n+m} \\ x_{n+1}^2 + x_{n+m+1}^2 - 1 \\ \cdots \\ x_{n+m}^2 + x_{n+2m}^2 - 1 \end{pmatrix} = 0, \tag{1.7}$$

where

$$p_i(x) = \sum_{\alpha \in S_i} b_{ij} x^{\alpha}. \tag{1.8}$$

The transformed polynomial systems from Examples 1.1 and 1.2 are as follows.

Example 1.1 (continued).

$$P(x) = \begin{pmatrix} x_2^3 + x_1^2 + 1 \\ x_3^3 + x_2 x_1 - 2 \\ x_2^2 + x_3^2 - 1 \end{pmatrix} = 0. \tag{1.9}$$

Example 1.2 (continued).

$$\begin{cases} \sum_{i=1}^{n} x_i = b_1, & \sum_{i=1}^{n} x_i^2 = b_2, \\ \sum_{i=1}^{n} x_i x_{n+i} = b_3, & \sum_{i=1}^{n} x_i x_{n+m+i} = b_4, \\ \sum_{i=1}^{n} x_i x_{n+i}^2 = b_5, & \sum_{i=1}^{n} x_i x_{n+i} x_{n+m+i} = b_6, \\ \sum_{i=1}^{n} x_i^2 x_{n+i} = b_7, & \sum_{i=1}^{n} x_i^2 x_{n+m+i} = b_8, \\ \sum_{i=1}^{n} x_i^2 x_{n+i}^2 = b_9, & \sum_{i=1}^{n} x_i^2 x_{n+i} x_{n+m+i} = b_{10}, \\ x_{n+1}^2 + x_{2n+1}^2 = 1, & \\ \cdots & \\ x_{2n}^2 + x_{3n}^2 = 1. & \end{cases} \tag{1.10}$$

1.2. Methods for solving polynomial systems. The primary methods for solving polynomial systems include some elimination methods, e.g., Gröbner methods [3]; Wu's method [45]; (sparse) resultant methods [4]; and the numerical homotopy method. The homotopy method is an efficient numerical method for solving polynomial systems suggested independently by Garcia and Zangwill [6] and Drexler [5] in 1977. The typical homotopy method for solving $P(x) = 0$ is to construct a homotopy

$$H(x,t) = (1-t)Q(x) + tP(x).$$

If the system $Q(x) = 0$, known as the start system, is chosen correctly, the following three properties hold:

Triviality. The solutions of $Q(x) = 0$ are known.

Smoothness. The solution set of $H(x,t) = 0$ for $0 \le t \le 1$ consists of a finite number of smooth paths, called homotopy paths, each parameterized by $t \in [0,1)$.

Accessibility. Every isolated solutions of $H(x,1) = P(x) = 0$ can be reached by some paths originating at a solution of $H(x,0) = Q(x) = 0$.

Tracing numerically homotopy paths for t from 0 to 1, we can find all isolated solutions of $P(x) = 0$.

Many homotopies with triviality, smoothness, and accessibility have been constructed [4, 5, 8, 9, 14, 15, 16, 17, 18, 19, 23, 24, 25, 26, 27, 32, 34, 35, 38, 39, 43, 44]. To solve a polynomial system $P(x) = (p_1(x), \ldots, p_n(x))^T = 0$ of n polynomials in n

unknowns with deg $p_i(x) = d_i$, the standard homotopies [15, 25, 44, 48], whose start system is

$$Q(x) = \begin{pmatrix} a_1 x_1^{d_1} - b_1 \\ \cdots \\ a_n x_n^{d_n} - b_n \end{pmatrix},$$

need to trace a Bézout number of paths to get all isolated solutions of the polynomial system. However, for most applications, the polynomial system is deficient; i.e., the actual number of solutions is less than the Bézout number. For deficient systems, standard homotopies generate many paths that tend to infinity and hence make wasted computation. So studies on homotopy methods for solving polynomial systems are now focused on exploiting the sparsity of the system, i.e., constructing better homotopy such that the number of homotopy paths to be traced is proportional to the actual number of isolated solutions of the target system.

In [18, 19], Li, Sauer, and Yorke presented the random product homotopy for solving deficient polynomial systems whose solutions at infinity are the union of some linear subspace. In [21], Li and Wang proposed a homotopy keeping subschemes at infinity invariant, which can serve as a general theoretical base of homotopy methods for solving deficient polynomial systems. In [26, 27], Morgan and Sommese suggested the use of multihomogeneous homotopy, i.e., keeping multihomogeneous structures. Some homotopies that keep multihomogeneous structures are given in [35, 36, 41, 46, 47]. In [46], a two-stage homotopy method is proposed for deficient polynomial systems. Verschelde derived the GBQ-algorithm in [37] by taking for different equations different partitions of the sets of unknowns. In [29], Morgan, Sommese, and Wampler presented polynomial product homotopies, in which every component of the start system is the product of some polynomials.

Polynomial systems arising in science and engineering are often parameterized. We have to solve repeatedly polynomial systems with different parameters. For this class of systems, one may first solve a system with generic parameters, then take this system as the start system and construct the homotopy, and then finally trace numerically homotopy paths to get the solution of the desired system with special parameters. In [20, 22, 28], some homotopies for parameterized systems were suggested.

In the mid-seventies, Bernstein [1], Kushnirenko [13], and Khovanskii [11] presented a root count in $(\mathcal{C}^*)^n$ $(\mathcal{C}^* = \mathcal{C} \setminus \{0\})$ for systems of Laurent polynomials. Canny and Rojas [2] named this root count the BKK bound. In [40], based on the idea of Bernstein [1], Verschelde, Verlinden, and Cools presented homotopies exploiting Newton polytopes for solving sparse polynomial systems. The polyhedral homotopy method can solve polynomial systems by applying their special structures. In [9], a more general polyhedral homotopy method was presented when some of the p_i's share the same support, and in fact, the homotopy defined in [9] can be used to establish an independent proof of Bernstein's theorem. A root count in $\mathcal{C}^n$ was presented in [23] by Li and Wang. In [10], Huber and Sturmfels gave a tighter upper bound for the root number of the polynomial system $P(x) = 0$ in $\mathcal{C}^n$. Based on this tighter upper bound, a more efficient homotopy method was presented. We refer to [16, 17] for developments of polyhedral homotopies for polynomial systems.

There are several freely available packages for solving polynomial systems. PHCpack, written by Verschelde [34], implements a variety of homotopies mentioned above, with the exception of polynomial product homotopies. In addition to isolated solutions, an algorithm for handling positive dimensional solutions is implemented. HomLab [32], written by Wampler, runs in the MATLAB environment and

implements the product homotopies and coefficient-parameter homotopy. PHoM, by Kojima et al. [12], is a C++ code and applies polyhedral homotopy to solve square systems (same number of equations as variables). HOMPACK [42, 30] and POLSYS_PLP [43] are a sequence of increasingly sophisticated continuation algorithms written in Fortran. MVOLgl, by Li et al. [14], implements efficient algorithms for the computation of mixed volumes. BERTINI [31] is a C code and features a high-level interface for parameter homotopies (including automatic differentiation) and multiple-precision routines that can adjust precision on the fly.

2. A hybrid polynomial system solving method for MTPS. For its essential complexity, the polynomial system solving problem is far from satisfactorily solved. The above-mentioned symbolic methods and homotopy methods still cannot efficiently solve practical polynomial systems of moderate size. Further effort needs to be made to solve polynomial systems more efficiently by exploiting their special structures and sparsity.

Polynomial systems coming from the mixed trigonometric polynomial system, as in (1.7), have a special structure: the last m equations are $x_{n+i}^2 + x_{n+m+i}^2 - 1 = 0, i = 1, \ldots, m$. Based on this special structure, we present a hybrid method to solve them more efficiently.

2.1. The hybrid homotopy. To solve (1.7) and (1.8), we construct the homotopy as

$$H(x,t) = \gamma(1-t)Q(x) + tP(x), \tag{2.1}$$

where

$$Q(x) = \begin{pmatrix} p_1(x) + a_1 \\ \cdots \\ p_{n+m}(x) + a_{n+m} \\ (a_{11}^1 x_{n+1} + a_{12}^1 x_{n+m+1} + a_{10}^1)(a_{11}^2 x_{n+1} + a_{12}^2 x_{n+m+1} + a_{10}^2) \\ \cdots \\ (a_{m1}^1 x_{n+m} + a_{m2}^1 x_{n+2m} + a_{m0}^1)(a_{m1}^2 x_{n+m} + a_{m2}^2 x_{n+2m} + a_{m0}^2) \end{pmatrix}, \tag{2.2}$$

and γ, $a_1, \ldots, a_{n+m}, a_{10}^1, \ldots, a_{m2}^2$ are random numbers in $\mathcal{C}^*$.

Remark 2.1. We call (2.1) a *hybrid homotopy*, because the upper part of its first $n+m$ components is a special coefficient parameter homotopy, and the lower part of its last m components is a random linear product homotopy.

Remark 2.2. The upper part of the start system keeps the sparse structure of the target system invariant to keep as much information, e.g., solution number and mixed volume, of the target system as possible, which is very useful for solving polynomial systems by the homotopy method. We set a_i $(i = 1, \ldots, n+m)$ as random numbers to ensure nonsingularity of the homotopy. If some components of the target system lack constant terms, we can keep them 0 such that the solution number of the start system is as small as possible.

2.2. The solution procedure. Using the hybrid homotopy, combined with decomposition, variable substitution, and some reduction techniques, we suggest a hybrid solution procedure for MTPS as follows.

HYBRID POLYNOMIAL SYSTEM SOLVING METHOD FOR MTPS.

Step 1. Construct the hybrid homotopy as in (2.1).

Step 2. Decompose the start system into 2^m subsystems:

$$Q_\sigma(x) = \begin{pmatrix} p_1(x) + a_1 \\ \cdots \\ p_{n+m}(x) + a_{n+m} \\ a_{11}^{\sigma_1} x_{n+1} + a_{12}^{\sigma_1} x_{n+m+1} + a_{10}^{\sigma_1} \\ \cdots \\ a_{m1}^{\sigma_m} x_{n+m} + a_{m2}^{\sigma_m} x_{n+2m} + a_{m0}^{\sigma_m} \end{pmatrix} = 0,$$

where $\sigma \in \mathfrak{S} \triangleq \{(\sigma_1, \ldots, \sigma_m) | \sigma_i \in \{1, 2\}\}$.

Step 3. By variable substitution

$$x_{n+m+i} = l_i(x_{n+i}) \triangleq -\frac{a_{11}^{\sigma_1}}{a_{12}^{\sigma_1}} x_{n+i} - \frac{a_{10}^{\sigma_1}}{a_{12}^{\sigma_1}} \tag{2.3}$$

for $i = 1, \ldots, m$, $Q_\sigma(x) = 0$ can be transformed into a new simpler system with fewer variables and equations:

$$\widehat{Q}_\sigma(\widehat{x}) = \begin{pmatrix} q_1(\widehat{x}) + a_1 \\ \cdots \\ q_{n+m}(\widehat{x}) + a_{n+m} \end{pmatrix} = 0,$$

where $\widehat{x} = (x_1, \ldots, x_{n+m})$ and for all $1 \le i \le n + m$,

$$q_i(\widehat{x}) = \sum_{\alpha \in S_i} b_{i\alpha} (x_1, \ldots, x_{n+m}, l_1(x_{n+1}), \ldots, l_m(x_{n+m}))^\alpha.$$

Hence solving $Q(x) = 0$ is equivalent to solving 2^m subsystems $\widehat{Q}_\sigma(\widehat{x}) = 0$, whose Bézout number is $\deg(p_1) \cdots \deg(p_{n+m})$.

Step 4. Reduction: reduce subsystems $\widehat{Q}_\sigma(\widehat{x}) = 0$, if possible, by using some symbolic reduction procedure (e.g., [32, 39]) or by hand, so that they will have fewer Bézout numbers or, in some extreme case, assert that some of them have no solution.

Step 5. Solve the reduced systems of $\widehat{Q}_\sigma(\widehat{x}) = 0$ by one of the homotopy methods given in [15, 16, 17, 18, 19, 20, 24, 26, 27, 36, 37, 38, 40, 48] to obtain all isolated solutions to $Q(x) = 0$. These solutions serve as start points of the homotopy (2.1).

Step 6. Trace homotopy paths generated by the homotopy (2.1) to get all isolated solutions of the target system $P(x) = 0$.

Remark 2.3. If the system $P(x) = 0$ is sparse enough, its solution number as well as the solution number of $Q(x)$ are much less than its Bézout number and multi-homogeneous Bézout number. Then the main work in the solution procedure is to solve the start system $Q(x) = 0$. In Steps 2 and 3, the start system is decomposed into some simpler subsystems and then transformed by variable substitution into systems whose dimensions are reduced by m; when m is big, the hybrid solution procedure will take much less computational time than existing homotopy methods for sparse polynomial systems, e.g., linear product homotopy or polyhedral homotopy, for the following three reasons:

(1) Tracing homotopy paths in $(n + m)$-dimensional space will be considerably faster than doing so in $(n + 2m)$-dimensional space.

(2) Finding the best multihomogeneous structure or mixed subdivision of initial subsystems with less dimension and lower total degree is much easier than that of the target system.

(3) Further potential for saving computational time is in Step 4, since sometimes the subsystems $Q_\sigma(\widehat{x})$ can be considerably reduced in Bézout number even when the target system $P(x)$ can hardly be reduced, as in the following example.

Example 2.1. We consider the system in (1.9). Its total degree and multihomogeneous Bézout number are both 18, and applying standard homotopy or multihomogeneous homotopy to solve $P(x) = 0$ requires tracing 18 homotopy paths.

Applying our new method, the start system is constructed as follows:

$$\begin{pmatrix} x_2^3 + x_1^2 + 1 \\ x_3^3 + x_1x_2 - 2 \\ (x_2 + \mathbf{i}\, x_3)(\mathbf{i}\, x_2 + x_3) \end{pmatrix} = 0. \tag{2.4}$$

Here, for simplicity of expression, without loss of generality, we have fixed random coefficients as $a_{11}^1 = 1$, $a_{12}^1 = \mathbf{i}$, $a_{10}^1 = 0$, $a_{11}^2 = \mathbf{i}$, $a_{12}^2 = 1$, $a_{10}^2 = 0$, where $\mathbf{i} = \sqrt{-1}$. The start system $Q(x) = 0$ can be decomposed into the following two subsystems:

$$Q_{\sigma_1} = \begin{pmatrix} x_2^3 + x_1^2 + 1 \\ x_3^3 + x_1x_2 - 2 \\ x_2 + \mathbf{i}\, x_3 \end{pmatrix} = 0 \tag{2.5}$$

and

$$Q_{\sigma_2} = \begin{pmatrix} x_2^3 + x_1^2 + 1 \\ x_3^3 + x_1x_2 - 2 \\ \mathbf{i}\, x_2 + x_3 \end{pmatrix} = 0. \tag{2.6}$$

By eliminating variable x_2, (2.5) can be equivalently transformed into

$$\begin{pmatrix} x_2^3 + x_1^2 + 1 \\ -\mathbf{i}\, x_2^3 + x_1x_2 - 2 \end{pmatrix} = 0. \tag{2.7}$$

By simple elimination, (2.7) is equivalent to

$$\widehat{Q}_{\sigma_1}(\widehat{x}) = \begin{pmatrix} x_1^3 + x_3^2 + 1 \\ \mathbf{i}\, x_1^2 + x_1x_2 + \mathbf{i} - 2 \end{pmatrix} = 0, \tag{2.8}$$

whose total degree is 6. Performing the same calculations on (2.6), we get

$$\widehat{Q}_{\sigma_2}(\widehat{x}) = \begin{pmatrix} x_1^3 + x_3^2 + 1 \\ \mathbf{i}\, x_1^2 - x_1x_2 + \mathbf{i} + 2 \end{pmatrix} = 0, \tag{2.9}$$

whose total degree is also 6. Hence, applying the standard homotopy to solve (2.8) and (2.9), the total number of homotopy paths that must be traced is 12, which is just the actual solution number of (1.9).

3. The homotopy theorem with proof. The following theorem shows that the hybrid homotopy (2.1) and (2.2) can be used to find all isolated solutions to polynomial systems coming from MTPS.

THEOREM 3.1. *There exists an open dense full-measure subset U of $\mathcal{C}^{n+7m}$, such that for all $\{a_1, \ldots, a_{n+m}, a_{10}^1, \ldots, a_{m2}^2\} \in U$, the solutions to $Q(x) = 0$ in (2.2) are all isolated and regular, and the homotopy map $H(x,t)$ in (2.1) possess the following properties:*

Smoothness. *The solution set to $H(x,t) = 0$ for $0 \le t \le 1$ consists of a finite number of smooth paths, each parameterized by t.*

Accessibility. *Every isolated solution to* $P(x) = 0$ *in* (1.7) *and* (1.8) *can be reached by some path originating at a solution to* $Q(x) = 0$.

The proof of Theorem 3.1 is inspired by [20]. The following preliminary results are needed.

A *linear system* $\mathcal{L}$ is a complex vector space

$$\mathcal{L} = \left\{ \sum_{i=1}^{r} c_i m_i(z) : (c_1, \ldots, c_r) \in \mathcal{C}^r \right\} \tag{3.1}$$

spanned by homogeneous polynomials $m_1(z), \ldots, m_r(z)$ of some fixed degree and parameterized by $\mathcal{C}^r$. The *base locus* of $\mathcal{L}$ is the set

$$\{z \in \mathcal{CP}^n : m_i(z) = 0, i = 1, \ldots, r\}.$$

LEMMA 3.2 (Bertini's theorem [7]). *Let* $\mathcal{Z}$ *be a nonsingular quasi-projective subvariety of* $\mathcal{CP}^n$ *of dimension* k. *Let* $\mathcal{L}$ *be a linear system as in* (3.1). *Then there exists a nonzero homogeneous polynomial* G *in* r *variables such that* $G(c_1, \ldots, c_r) \neq 0$ *implies that the intersection of* $\mathcal{Z}$ *with the hypersurface*

$$\sum_{i=1}^{r} c_i m_i(z) = 0$$

is of dimension $k-1$ *and is nonsingular at each point not in the base locus of* $\mathcal{L}$.

Let $\langle f_1, \ldots, f_n \rangle$ denote the ideal of homogeneous polynomials generated by $f_1, \ldots, f_n$, let $\langle f_1, \ldots, f_n \rangle_M$ denote the subset of $\langle f_1, \ldots, f_n \rangle$ consisting of degree M polynomials, and let $V(f_1, \ldots, f_n)$ denote the variety defined by $f_1, \ldots, f_n$.

LEMMA 3.3 (see [20]). *Let* $f_1, \ldots, f_n$ *be homogeneous polynomials in the variables* $z_0, \ldots, z_n$ *such that the set*

$$S = \{(z_0, \ldots, z_n) \in V(f_1, \ldots, f_n) : z_0 \neq 0\}$$

consists of isolated points. Then there exists a positive integer K_0 *such that for* $K \geq K_0$,

$$\langle f_1, \ldots, f_n, z_0^{K_0} \rangle_M = \langle f_1, \ldots, f_n, z_0^{K} \rangle_M$$

for sufficiently large integers M.

The key lemma we need to detect paths diverging to infinity is the following.

LEMMA 3.4 (see [19]). *Let* $H : \mathcal{C}^n \times T \to \mathcal{C}^n$, *where* $T \subset \mathcal{R}$ *is an open subset,* H *is continuous in* t, *and* $H(x,t)$ *is a polynomial map for each* t, *and* $\widetilde{h}_i$ *is the homogenization of the* i*th polynomial of* $H(x,t) = 0$. *Suppose there are integers* $K < m$ *such that* $\dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_n, {z_0}^K \rangle_m$ *is independent of* $t \in U$ *and* $k \in \{K, K+1\}$. *Then no path of solutions of* $H(x,t) = 0$ *parameterized by* t *tends to infinity as* $t \to t_0 \in U$.

Proof of Theorem 3.1. (1) Rewrite $H(x)$ as

$$H(x) = \begin{pmatrix} \widehat{p}_1(x) + c_1 \\ \cdots \\ \widehat{p}_{n+m}(x) + c_{n+m} \\ \widehat{p}_{n+m+1}(x) + c_{n+m+1} \\ \cdots \\ \widehat{p}_{n+2m}(x) + c_{n+2m} \end{pmatrix},$$

where

$$\begin{aligned}
c_j &= tb_j + \gamma(1-t)a_j,\\
c_{n+m+i} &= \gamma(1-t)a^1_{i0}a^2_{i0} - t,\\
\widehat{p}_j(x) &= (\gamma(1-t)+t)p_j(x),\\
\widehat{p}_{n+m+i}(x) &= (\gamma(1-t)a^1_{i1}a^2_{i1}+t)x^2_{n+i} + (\gamma(1-t)a^1_{i2}a^2_{i2}+t)x^2_{n+m+i}\\
&\quad + \gamma(1-t)(a^1_{i1}a^2_{i2}+a^1_{i2}a^2_{i1})x_{n+i}x_{n+m+i}\\
&\quad + \gamma(1-t)((a^1_{i0}a^2_{i1}+a^1_{i1}a^2_{i0})x_{n+i} + (a^1_{i0}a^2_{i2}+a^1_{i2}a^2_{i0})x_{n+m+i})
\end{aligned}$$

for all $i = 1, \ldots, m,\ j = 1, \ldots, n+m$.

Let $d_i = \deg(p_i)$ and let $\widetilde{p}_i(z)$ be the homogenization of $\widehat{p}_i(x)$ $(i = 1, \ldots, n+2m)$. For any $t \in [0, 1)$ and $i = 1, \ldots, n+2m$, define

$$g_i(z) = \xi_i \widetilde{p}_i(z) + \eta_i z_0^{d_i}.$$

Let $\mathcal{Z}_0 = \mathcal{CP}^{n+2m} \setminus V(z_0) = \mathcal{C}^{n+2m}$ be the quasi-projective variety. The base locus of the linear system

$$\mathcal{L}_1 = \{\xi_1 \widetilde{p_1}(z) + \eta_1 z_0^{d_1}, \xi_1, \eta_1 \in \mathcal{C}\}$$

is contained in $V(z_0)$. Hence, by Bertini's theorem, there exists a nonzero homogeneous polynomial $G_1(\xi_1, \eta_1)$ such that $\mathcal{Z}_0 \cap V(g_1)$ is an $(n+2m-1)$-dimensional nonsingular quasi-projective variety for $G_1(\xi_1, \eta_1) \neq 0$. G_1 is homogeneous, so the polynomial $\widehat{G}_1(\eta_1) = G_1(1, \eta_1)$ is not identically zero. $V(\widehat{G}_1)$ consists of finite complex numbers. $\mathcal{Z}_0 \cap V(\widetilde{p}_1(z) + c_1 z_0^{d_1})$ is an $(n+2m-1)$-dimensional quasi-projective variety for all $1 \neq t \in R$ and $c_1 \in U_1 = \mathcal{C} \setminus V(\widehat{G}_1)$ which is an open dense full-measure subset of $\mathcal{C}$, and hence $\mathcal{Z}_1 = \mathcal{Z}_0 \cap V(\widehat{p}_1(x) + c_1)$ is also an $(n+2m-1)$-dimensional nonsingular quasi-variety.

The process is repeated. At every step, the base locus is contained in $V(z_0)$ and so does not intersect $\mathcal{Z}_i$. Applying Bertini's theorem, there exists an open dense full-measure subset U_i of $\mathcal{C}$, and for all $c_i \in V_i$, $\mathcal{Z}_i = \mathcal{Z}_{i-1} \cap V(\widehat{p}_i(x) + c_i)$ is an $(n+2m-i)$-dimensional nonsingular quasi-projective variety. When the process is repeated $n+2m$ times, the Jacobian of $H(x,t)$ is nonsingular and the solution set to $H(x,t) = 0$ consists of isolated complex numbers for all real $t \neq 1$. Thus the smoothness is proved.

(2) Denote by S_e the complex vector space of degree e homogeneous polynomials in $z_0, \ldots, z_{n+2m}$ with complex coefficients. Let $h_i(x) = \widehat{p}_i(x) + c_i$, and $\widetilde{h}_1(z), \ldots, \widetilde{h}_{n+2m}(z)$ is the homogenization of $h_1(x), \ldots, h_{n+2m}(x)$, $\widetilde{h}_i(z) \in S_{d_i}$. For $e \geq \max\{d_i\}$, define the linear transformation

$$T_e(\widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, z_0^K) : S_{e-d_1} \times \cdots \times S_{e-d_{n+2m}} \times S_{e-K} \to S_e,$$

$$T_e(\widetilde{h}_1, \cdots, \widetilde{h}_{n+2m}, z_0^K)(r_1, \ldots, r_{n+2m+1}) = \widetilde{h}_1 r_1 + \cdots + \widetilde{h}_{n+2m} r_{n+2m} + z_0^K r_{n+2m+1}.$$

Let $\mathfrak{T}_e$ be the matrix representation of T_e using the basis of all degree e monomials for each S_e. It follows that

$$\operatorname{rank}_{\mathcal{C}} \mathfrak{T}_e(\widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, z_0^K) = \dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, z_0^K \rangle_e. \tag{3.2}$$

The following discussion shows that the homotopy map (2.1) satisfies accessibility if choosing $a_1, \ldots, a_{n+m}, a^1_{10}, \ldots, a^2_{m2}$ from an open dense full-measure subset U of $\mathcal{C}^{n+7m}$.

For a given e, let A be a highest-rank submatrix of $\mathfrak{T}_e(\widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, z_0^K)$ $(K < e)$. Then $\det(A)$ is a polynomial $D(a_1, \ldots, a_{n+m}, a_{10}^1, \ldots, a_{m2}^2, t)$ in variables $a_1, \ldots, a_{n+m}$, $a_{10}^1, \ldots, a_{m2}^2, t$ and not identically zero. $\det(A)$, if considered as a polynomial in the variables $a_1, \ldots, a_{n+m}, a_{10}^1, \ldots, a_{m2}^2$, has leading monomial

$$b(1-t)^s {a_1}^{\alpha_1} {a_{n+m}}^{\alpha_{n+m}} {a_{10}^1}^{\alpha_{n+m+1}} \cdots {a_{m2}^2}^{\alpha_{n+7m}}$$

for some nonnegative integer $\alpha_1, \ldots, \alpha_{n+7m}$ and $b \in \mathcal{C}^*$, so $\det(A)$ is not identically zero for each $t_0 \neq 1$ and vanishes on a complex codimension 1 subset $\mathcal{Z}_{t_0}$ of $\mathcal{C}^{n+7m}$. The union $\mathcal{Z} = \cup_{t_0 \in \mathcal{R} \setminus \{1\}} \mathcal{Z}_{t_0}$ of the $\mathcal{Z}_{t_0}$ is of real codimension 1 in $\mathcal{C}^{n+7m}$, and hence the complement $U^{'}$ of the closure is an open dense full-measure subset of $\mathcal{C}^{n+7m}$. For all $(a_1, \ldots, a_{n+m}, a_{10}^1, \ldots, a_{m2}^2) \in U^{'}$,

$$\operatorname{rank}_{\mathcal{C}} \mathfrak{T}_e(\widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, z_0^K)$$

is independent of $t \in \mathcal{R} \setminus \{1\}$. Since (3.2) holds,

$$\dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^K \rangle_e \tag{3.3}$$

is independent of $t \in \mathcal{R} \setminus \{1\}$.

Replacing K by $K+1$ in the above, the same argument holds for $K+1$ on an open dense full-measure subset $U^{''}$ of $\mathcal{C}^{n+3m}$.

The solution to $Q(x) = 0$ are all nonsingular, thus by Lemma 3.3,

$$\langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^K \rangle_e = \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^{K+1} \rangle_e$$

holds for $t = 0$. Hence

$$\dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^{K+1} \rangle_e = \dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^K \rangle_e$$

also holds for $t = 0$. Because (4.2) is independent of $t \in \mathcal{R} \setminus \{1\}$,

$$\dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^{K+1} \rangle_e = \dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^K \rangle_e$$

holds for all $t \in \mathcal{R} \setminus \{1\}$. Therefore, for all $(a_1, \ldots, a_{n+m}, s_{10}, \ldots, s_{2m}) \in U = U^{'} \cap U^{''}$,

$$\dim_{\mathcal{C}} \langle \widetilde{h}_1, \ldots, \widetilde{h}_{n+2m}, {z_0}^k \rangle_e$$

is independent of $t \in \mathcal{R} \setminus \{1\}$ and $k \in \{K, K+1\}$. By Lemma 3.4, all homotopy paths remain finite for $t \neq 1$. Thus each path must cross $t = 0$ in a finite solution to $Q(x) = 0$. The accessibility follows.

4. Numerical examples and applications. We have done some numerical tests and solved the practical problem (1.10) in Example 1.2 using our new hybrid

TABLE 4.1

method, and we also compared our method with some other homotopy methods, such as multihomogeneous homotopy and polyhedral homotopy, mentioned in section 1.2. In this section, we will list some numerical results for several deficient polynomial systems coming from MTPS which appeared in the literature [8, 24, 27] and the practical problem (1.10) for $n = 3, 4, 5$. All our numerical results were obtained by PHCpack [34] running on a desktop with the Windows XP Professional operating system, Intel Core2 1.86GHz processor, and 960 megabytes of memory.

Problems are listed in Examples 4.1 to 4.6. Sizes of target systems, including numbers of variables, Bézout numbers, multi-Bézout numbers, mixed volumes, and solution numbers, are listed in Tables 4.1(a) to 4.6(a). Comparison of elapsed time of our hybrid method with multihomogeneous homotopy and polyhedral homotopy are listed in Tables 4.1(b) to 4.6(b). In Tables 4.1(a) to 4.6(a), "BN" and "MBN" denote the Bézout number and multihomogeneous Bézout number of the target system, "MV" is the mixed volume, and "SN" is the number of the isolated solutions of the target systems. In Tables 4.1(b) to 4.6(b) the numbers in the "MHH" column are the elapsed time of solving the target system by the multihomogeneous homotopies, and the numbers in the "PH" column are the elapsed time of solving the target system by the polyhedral homotopies. The numbers in the "Hybrid-MHH" column are the elapsed time of solving the target system by our hybrid method, in which we apply multihomogeneous homotopy to solve the simpler subsystems coming from the start system; the numbers in the "T_1" column are the elapsed time for solving the start system, the numbers in the "T_2" column are the elapsed time for tracing homotopy paths generated by (2.1) from $t = 0$ to $t = 1$, and the numbers in the "T" column are the total elapsed time. The numbers in the "Hybrid-PH" column are the elapsed time of solving the target system by our hybrid method, in which we apply polyhedral homotopy to solve the simpler subsystems coming from the start system. All times in the tables are in seconds.

Example 4.1. The PUMA system in [24] (see Table 4.1).

$$\begin{cases} -0.7623x_1 + 0.2238x_2 + 0.3461 = 0; \\ x_6x_8 + 0.3578x_1 + 0.004731x_2 = 0; \\ 0.2238x_1x_3 + 0.7623x_2x_3 + 0.2638x_1 - 0.07745x_2 - 0.6734x_4 - 0.6022 = 0; \\ 0.004731x_1x_3 - 0.3578x_2x_3 - 0.1238x_1 - 0.001637x_2 - 0.9338x_4 + x_7 - 0.3571 = 0; \\ x_1^2 + x_2^2 - 1 = 0; \\ x_3^2 + x_4^2 - 1 = 0; \\ x_5^2 + x_6^2 - 1 = 0; \\ x_7^2 + x_8^2 - 1 = 0. \end{cases}$$

Example 4.4. The system in (1.10) for $n = 3$ (see Table 4.4).

Example 4.5. The system in (1.10) for $n = 4$ (see Table 4.5).

Example 4.6. The system in (1.10) for $n = 5$ (see Table 4.6).

Remark 4.1. Numerical results show that for MTPS, the hybrid method we proposed in this paper is more efficient, especially for high dimensional and highly sparse problems, such as Example 4.6.

Remark 4.2. As mentioned above, our start system can be decomposed into some subsystems whose dimension is reduced by m. Applying another homotopy method, e.g., polyhedral homotopy, to solve the target system, computing the mixed volume, and tracing the homotopy paths have to be done in $(n + 2m)$-dimensional space. However, applying our hybrid method, our main work is proceeded in $(n+m)$-dimensional space; thus when m is larger, our method is more efficient than other homotopy methods.

Remark 4.3. As mentioned in section 1.2, there is much freely variable software for solving polynomial systems. All of this software can be used to solve target systems and subsystems coming from our start system. We can choose one of them as a tool to compare our hybrid method with other homotopy methods. Maybe there is some difference in the computational time, but the comparison result of our hybrid method with other homotopy methods will not remarkably change due to the reasons mentioned in Remark 4.2.

Remark 4.4. In Examples 4.4 to 4.6, in practice, it is necessary to solve this problem for various parameters b_i $(i = 1, \ldots, 2n)$ and in real time. To achieve this aim, we can apply coefficient parameter homotopy, or cheater's homotopy, to solve the target system. We construct a start system whose constant terms are random nonzero complex numbers, and we solve it using our hybrid method. The solutions obtained by our hybrid method were used as start points of coefficient parameter homotopy or cheater's homotopy.

5. Conclusion. A hybrid polynomial system solving method for mixed trigonometric polynomial systems is proposed, which hybridizes the homotopy method and the elimination method and uses a hybrid homotopy that combines linear product homotopy and coefficient parameter homotopy or cheater's homotopy. It is more efficient for high dimensional and highly sparse problems.

Acknowledgment. The authors are grateful to the anonymous referee for his helpful suggestions.

WALSH SPACES CONTAINING SMOOTH FUNCTIONS AND QUASI–MONTE CARLO RULES OF ARBITRARY HIGH ORDER*

JOSEF DICK†

Abstract. We define a Walsh space which contains all functions whose partial mixed derivatives up to order $\delta \geq 1$ exist and have finite variation. In particular, for a suitable choice of parameters, this implies that certain Sobolev spaces are contained in these Walsh spaces. For this Walsh space we then show that quasi–Monte Carlo rules based on digital (t, α, s)-sequences achieve the optimal rate of convergence of the worst-case error for numerical integration. This rate of convergence is also optimal for the subspace of smooth functions. Explicit constructions of digital (t, α, s)-sequences are given, hence providing explicit quasi–Monte Carlo rules which achieve the optimal rate of convergence of the integration error for arbitrarily smooth functions.

Key words. numerical integration, quasi–Monte Carlo, digital nets and sequences, Walsh functions

DOI. 10.1137/060666639

1. Introduction.

Quasi–Monte Carlo rules are quadrature rules which aim to approximate an integral $\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$ by the average of the N function values $f(\boldsymbol{x}_n)$ at the quadrature points $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1} \in [0,1]^s$ (and hence are equal weight quadrature rules). The dimension s can be arbitrarily large. The task here is to find ways of choosing those quadrature points in order to obtain a fast convergence of the approximation to the integral. Until now, explicit constructions of quadrature points in arbitrary high dimensions have been available for the following two cases:

1. for sufficiently smooth periodic functions, arbitrary high convergence can be achieved using Kronecker sequences [18, Theorem 5.3] or a modification of digital nets recently introduced in [2];
2. a convergence of $\mathcal{O}(N^{-1}(\log N)^{s-1})$ can be achieved for functions of bounded variation (in this case the functions are not required to be periodic).

For nonperiodic functions no explicit constructions have been established which can fully exploit the smoothness of the integrand. This paper provides a complete solution to this problem.

Among other things we show that an explicit construction of suitable point sets and sequences can be obtained in the following way: let $d \geq 1$ be an integer and let $\boldsymbol{x}_0, \boldsymbol{x}_1, \ldots \in [0,1)^{ds}$ be the points of a digital (t, m, ds)-net or digital (t, ds)-sequence over a finite field $\mathbb{F}_q$ in dimension ds (see [20] for the definition of digital nets and sequences and see, for example, [9, 20, 21, 23, 31] for explicit constructions of suitable digital nets and sequences). Let $\boldsymbol{x}_n = (x_{n,1}, \ldots, x_{n,ds})$ with $x_{n,j} = x_{n,j,1}q^{-1} + x_{n,j,2}q^{-2} + \cdots$ and $x_{n,j,i} \in \{0, \ldots, q-1\}$ (i.e., $x_{n,j,i}$ are the digits in the base q representation of $x_{n,j}$). Then for $n \geq 0$ we define $\boldsymbol{y}_n = (y_{n,1}, \ldots, y_{n,s})$ with

$$y_{n,j} = \sum_{i=1}^{\infty} \sum_{k=1}^{d} x_{n,(j-1)d+k,i} q^{-k-(i-1)d} \quad \text{for } j = 1, \ldots, s.$$

†School of Mathematics and Statistics, University of New South Wales, Sydney 2052, Australia (josef.dick@unsw.edu.au).

(Note that the addition here is carried out in $\mathbb{R}$ and that the sum over i above is often finite as $x_{n,j,i} = 0$ for i large enough.) We point out here that the quality of the point set or sequence is directly related to the t-value of the underlying (t, m, ds)-net or (t, ds)-sequence; see Theorems 4.11 and 4.12.

Corollary 5.5 now shows that quasi–Monte Carlo rules using the points $\boldsymbol{y}_0, \dots, \boldsymbol{y}_{N-1}$ (with $N = q^m$ for some $m \geq 1$) achieve the optimal rate of convergence of the integration error of $\mathcal{O}(N^{-\vartheta}(\log N)^{\vartheta s})$ for functions which have partial mixed derivatives up to order ϑ which are square integrable as long as $1 \leq \vartheta \leq d$ (Corollary 5.5 is actually more general). If $\vartheta > d$, no improvement of the convergence rate is obtained compared to functions with smoothness $\vartheta = d$; i.e., we obtain a convergence of $\mathcal{O}(N^{-d}(\log N)^{ds})$. Similar but less general results for periodic functions compared to those in this paper have been shown in [2] by a different proof method. (The construction above is an example of a construction method which can be used. In section 4 we outline the general algebraical properties required for the construction of suitable point sets.)

The quasi–Monte Carlo algorithm based on digital nets and sequences proposed here has also some further useful properties. For example, our results also hold if one randomizes the point set by, say, a random digital shift (see, for example, [4, 5, 17]). (This follows easily because the worst-case error (see section 5) is invariant with respect to digital shifts in the Walsh space, and hence we obtain the same upper bounds for randomized digital nets and sequences.) In summary the quadrature rules have the following properties:

- The quadrature rules introduced in this paper are equal weight quadrature rules which achieve the optimal rate of convergence up to some $\log N$ factors, and the result holds for deterministic and randomly digitally shifted quadrature rules.
- The construction of the underlying point set is explicit, and suitable point sets are available in arbitrary high dimensions and arbitrary high number of points.
- The quadrature rules automatically adjust themselves to the optimal rate of convergence $\mathcal{O}(N^{-\vartheta}(\log N)^{s\vartheta})$ as long as $1 \leq \vartheta \leq d$.
- The underlying point set is extensible in the dimension as well as in the number of points; i.e., one can always add some coordinates or points to an existing point set such that the quality of the point set is preserved.

In the following we lay out some of the underlying principles used in this work which stem from the behavior of the Walsh coefficients of smooth functions. Walsh functions are piecewise constant wavelets which form an orthonormal set of $\mathcal{L}_2([0,1]^s)$. In their simplest form, for a nonnegative integer k with base 2 representation $k = \kappa_0 + \cdots + \kappa_{m-1}2^{m-1}$ and an $x \in [0,1)$ with base 2 representation $x = x_1 2^{-1} + x_2 2^{-2} + \cdots$, the kth Walsh function in base 2 is given by

$$\mathrm{wal}_k(x) = (-1)^{\kappa_0 x_1 + \cdots + \kappa_{m-1} x_m}.$$

(Later on we will use the more general definition of Walsh functions over groups.)

The behavior of the Fourier coefficients of smooth periodic functions is well known; i.e., the smoother the function, the faster the Fourier coefficients go to zero (see, for example, [34]). An analogous result for Walsh functions has, to the best of the author's knowledge, not been known until now (see Fine [10], who, for example, shows that the only absolute continuous functions whose kth Walsh coefficients decay faster than $1/k$ are constant functions). This will be established here and subsequently be exploited to obtain quasi–Monte Carlo rules with arbitrary high order of convergence.

To give a glimpse of how the Walsh coefficients of smooth functions behave, consider, for example, the Walsh series for $1/2 - x$:

$$1/2 - x = \sum_{k=0}^{\infty} c_k \mathrm{wal}_k(x) = \sum_{a=0}^{\infty} 2^{-a-2} \mathrm{wal}_{2^a}(x).$$

Although the function is infinitely smooth, in general the decay of the Walsh coefficient is only of order $1/k$. But note that most of the Walsh coefficients are actually 0. For example, when we consider $(1/2 - x)^2$, then typically we would have that the Walsh coefficient of $k = 2^a$ is of order 2^{-a}, the Walsh coefficient of $k = 2^{a_1} + 2^{a_2}$ $(a_1 > a_2)$ is of order $2^{-a_1-a_2}$, and for $k = 2^{a_1} + 2^{a_2} + \cdots + 2^{a_v}$ with $a_1 > \cdots > a_v$ and $v > 2$ the kth Walsh coefficient would be 0. By considering $(1/2 - x)^3, (1/2 - x)^4, \ldots$, or more generally polynomials, one can now realize that the speed of convergence of the Walsh coefficients depends on how many nonzero digits k has. This is the basic feature which we will relate to the speed of convergence of the Walsh coefficients for smooth functions.

Subsequently we will explicitly state and use the behavior of the Walsh coefficients of smooth functions. In general the Walsh functions depend on the base q digit expansion of the wavenumber k and also of the point x where the Walsh function is to be evaluated. Hence, maybe not surprisingly, the value of the kth Walsh coefficient of a smooth function depends also on the q-adic expansion of k. We show that the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ introduced in section 3 contains all functions whose partial mixed derivatives up to order $\delta < \vartheta$ exist and have finite variation, where ϑ is a parameter restricting the behavior of the Walsh coefficients of the function space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$. (We use a similar, though much more general, technique to that which Fine [10] used for showing that the Walsh coefficients of a differentiable function cannot decay faster than $1/k$.)

The concept of digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences (see section 4 and also [2] for a similar concept) is now designed to yield point sets which work well for the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$, just in the same way as the digital nets and sequences from [9, 19, 20, 23, 31] are designed to work well for the spaces considered, for example, in [4, 11] (or as lattice rules are designed to work well for periodic Korobov spaces). Here the power of the result that the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ contains smooth functions comes into play: it follows that we can fully exploit the smoothness of an integrand using digital $(t, \alpha, \alpha, m, s)$-nets or digital (t, α, α, s)-sequences. As the construction of the points $\boldsymbol{y}_0, \boldsymbol{y}_1, \ldots$ introduced at the beginning yields explicit examples of digital $(t, \alpha, \alpha, m, s)$-nets or digital (t, α, α, s)-sequences as shown in section 4 we therefore obtain explicit constructions of quasi–Monte Carlo rules which can achieve the optimal order of convergence for arbitrary smooth functions.

In the next section we introduce Walsh functions over groups and state some of their essential properties.

2. Walsh functions over groups. In this section we give the definition of Walsh functions over groups and present some essential properties. Walsh functions in base 2 were first introduced by Walsh [33], though a similar but noncomplete set of functions had already been studied by Rademacher [27]. Further important results were obtained in [10]. We follow [26] in our presentation.

2.1. Definition of Walsh functions over groups. An essential tool for the investigation of digital nets are Walsh functions. A very general definition, corresponding to the most general construction of digital nets over finite rings, was given

in [15]. There, Walsh functions over a finite abelian group G, using some bijection φ, were defined. Here we restrict ourselves to the additive groups of the finite fields $\mathbb{F}_{p^r}$, p prime, and $r \geq 1$. We restate the definitions for this special case here for the sake of convenience. In the following let $\mathbb{N}$ denote the set of positive integers and $\mathbb{N}_0$ the set of nonnegative integers.

DEFINITION 2.1 (Walsh functions). *Let $q = p^r$, p prime, $r \in \mathbb{N}$, and let $\mathbb{F}_q$ be the finite field with q elements. Let $\mathbb{Z}_q = \{0, 1, \ldots, q-1\} \subset \mathbb{Z}$ and let $\varphi : \mathbb{Z}_q \longrightarrow \mathbb{F}_q$ be a bijection such that $\varphi(0) = 0$, the neutral element of addition in $\mathbb{F}_q$. Moreover denote by ψ the canonical isomorphism (described below) of additive groups $\psi : \mathbb{F}_q \longrightarrow \mathbb{Z}_p^r$ and define $\eta := \psi \circ \varphi$. For $1 \leq i \leq r$ denote by π_i the projection $\pi_i : \mathbb{Z}_p^r \longrightarrow \mathbb{Z}_p$, $\pi_i(x_1, \ldots, x_r) = x_i$.*

$$\begin{array}{ccc} \mathbb{Z}_q & \xrightarrow{\varphi} & \mathbb{F}_q \\ & \searrow^{\eta} & \downarrow{\scriptstyle \psi} \\ & & \mathbb{Z}_p^r \xrightarrow{\pi_i} \mathbb{Z}_p \end{array}$$

Now let $k \in \mathbb{N}_0$ with base q representation $k = \kappa_0 + \kappa_1 q + \cdots + \kappa_{m-1} q^{m-1}$ where $\kappa_l \in \mathbb{Z}_q$ and let $x \in [0,1)$ with base q representation $x = x_1/q + x_2/q^2 + \cdots$ (unique in the sense that infinitely many x_l must be different from $q-1$). Then the kth Walsh function over the additive group of the finite field $\mathbb{F}_q$ with respect to the bijection φ is defined by

$$_{\mathbb{F}_q,\varphi}\mathrm{wal}_k(x) = \exp\left(\frac{2\pi \mathtt{i}}{p} \sum_{l=0}^{m-1} \sum_{i=1}^{r} (\pi_i \circ \eta)(\kappa_l)(\pi_i \circ \eta)(x_{l+1})\right).$$

For convenience we will in the rest of the paper omit the subscript and simply write wal_k *if there is no ambiguity.*

Multivariate Walsh functions are defined by multiplication of the univariate components, i.e., for $s > 1$, $\boldsymbol{x} = (x_1, \ldots, x_s) \in [0,1)^s$ and $\boldsymbol{k} = (k_1, \ldots, k_s) \in \mathbb{N}_0^s$, we set

$$\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \prod_{j=1}^{s} \mathrm{wal}_{k_j}(x_j).$$

We now briefly describe the canonical isomorphism. Let $\mathbb{F}_q = \mathbb{Z}_p[\theta]$, such that $\{1, \theta, \ldots, \theta^{r-1}\}$ is a basis of $\mathbb{F}_q$ over $\mathbb{Z}_p$ as a vector space. Then the isomorphism ψ between $\mathbb{F}_q$ and $\mathbb{Z}_p^r$ shall be given by

$$\psi(x) = (x_1, \ldots, x_r)^\top \text{ for } x = \sum_{i=1}^{r} x_i \theta^{i-1},\ x_i \in \mathbb{Z}_p.$$

For more information on the Walsh functions defined above see [26].

We summarize some important properties of Walsh functions over the additive group of a finite field which will be used throughout the paper. The proofs of the subsequent results can be found, e.g., in [16, 25] (see also [1]). In the following we call $x \in [0,1)$ a q-adic rational if x can be represented by a finite base q expansion.

PROPOSITION 2.2. *Let p, q, $\mathbb{F}_q$, and φ be as in Definition 2.1. For x, y with q-adic representations $x = \sum_{i=w}^{\infty} x_i q^{-i}$ and $y = \sum_{i=w}^{\infty} y_i q^{-i}$, $w \in \mathbb{Z}$ (taking w negative, hence the following operations are also defined for integers), define $x \oplus_\varphi y :=$*

$\sum_{i=w}^{\infty} z_i q^{-i}$, *where* $z_i := \varphi^{-1}(\varphi(x_i) + \varphi(y_i))$, *and* $\ominus_\varphi x := \sum_{i=w}^{\infty} v_i q^{-i}$, *where* $v_i := \varphi^{-1}(-\varphi(x_i))$. *Further we set* $x \ominus_\varphi y := x \oplus_\varphi (\ominus_\varphi y)$. *For vectors* $\boldsymbol{x}, \boldsymbol{y}$ *we define the operations componentwise. Then we have the following:*

1. *For all* $k, l \in \mathbb{N}_0$ *and all* $x, y \in [0,1)$, *with the restriction that if* x, y *are not* q*-adic rationals, then* $x \oplus_\varphi y$ *is not allowed to be a* q*-adic rational, we have*

$$\mathrm{wal}_k(x) \cdot \mathrm{wal}_l(x) = \mathrm{wal}_{k \oplus_\varphi l}(x), \quad \mathrm{wal}_k(x) \cdot \mathrm{wal}_k(y) = \mathrm{wal}_k(x \oplus_\varphi y)$$

and, with the restriction that if x, y *are not* q*-adic rationals, then* $x \ominus_\varphi y$ *is not allowed to be a* q*-adic rational,*

$$\mathrm{wal}_k(x) \cdot \overline{\mathrm{wal}_l(x)} = \mathrm{wal}_{k \ominus_\varphi l}(x), \quad \mathrm{wal}_k(x) \cdot \overline{\mathrm{wal}_k(y)} = \mathrm{wal}_k(x \ominus_\varphi y).$$

2. *We have*

$$\sum_{k=0}^{q-1} \mathrm{wal}_l(k/q) = \begin{cases} 0 & \text{if } l \neq 0, \\ q & \text{if } l = 0. \end{cases}$$

3. *We have*

$$\int_0^1 \mathrm{wal}_0(x)\,\mathrm{d}x = 1 \quad \text{and} \quad \int_0^1 \mathrm{wal}_k(x)\,\mathrm{d}x = 0 \text{ if } k > 0.$$

4. *For all* $\boldsymbol{k}, \boldsymbol{l} \in \mathbb{N}_0^s$ *we have the following orthogonality properties:*

$$\int_{[0,1)^s} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\overline{\mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{x})}\,\mathrm{d}\boldsymbol{x} = \begin{cases} 1 & \text{if } \boldsymbol{k} = \boldsymbol{l}, \\ 0 & \text{otherwise.} \end{cases}$$

5. *For any* $f \in \mathcal{L}_2([0,1)^s)$ *and any* $\boldsymbol{\sigma} \in [0,1)^s$ *we have*

$$\int_{[0,1)^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} = \int_{[0,1)^s} f(\boldsymbol{x} \oplus_\varphi \boldsymbol{\sigma})\,\mathrm{d}\boldsymbol{x}.$$

6. *For any integer* $s \geq 1$ *the system* $\{\mathrm{wal}_{\boldsymbol{k}} : \boldsymbol{k} \in \mathbb{N}_0^s\}$ *is a complete orthonormal system in* $\mathcal{L}_2([0,1)^s)$.

Remark 2.3. The restrictions in item 1 were added to exclude cases like $x = (0.010101\ldots)_2$, $y = (0.0010101\ldots)_2$, and $x \oplus y = (0.1)_2$, for which the result is of course not true. On the other hand, the result holds for $x \oplus y = (0.0111111\ldots)_2$.

Throughout the paper we will use a fixed bijection φ, and a fixed finite field $\mathbb{F}_q$ is used for Walsh functions and $\oplus_\varphi$ and $\ominus_\varphi$. Hence we will often write $\oplus$ and $\ominus$ instead of $\oplus_\varphi$ and $\ominus_\varphi$.

In the following section we will deal with Walsh series and Walsh coefficients, which we briefly describe in the following: functions $f \in \mathcal{L}_2([0,1)^s)$ have an associated Walsh series

$$f(\boldsymbol{x}) \sim \sum_{\boldsymbol{k} \in \mathbb{N}_0^s} \hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}),$$

where the Walsh coefficients $\hat{f}(\boldsymbol{k})$ are given by

$$\hat{f}(\boldsymbol{k}) = \int_{[0,1)^s} f(\boldsymbol{x})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}.$$

For smooth functions the Walsh series converges to the function, which is shown in section 3.3.

3. Walsh spaces containing smooth functions. In the following we investigate how the Walsh coefficients of smooth functions decay, and subsequently we use this to define function classes based on Walsh functions which contain smooth functions. But first we introduce a suitable variation.

3.1. A generalized weighted Hardy and Krause variation. In the following we generalize the Hardy and Krause variation, which suits our purposes later on.

3.1.1. Hölder condition. A function $f : [0,1) \to \mathbb{R}$ satisfies a Hölder condition with coefficient $0 < \lambda \le 1$ if there is a constant $C_f > 0$ such that

$$|f(x) - f(y)| \le C_f |x-y|^\lambda \quad \text{for all } x, y \in [0,1).$$

The right-hand side of the above inequality forms a metric on $[0,1)$. When one considers the higher-dimensional domain $[0,1)^s$ then $|x-y|$ is changed to some other metric on $[0,1)^s$. Here we consider tensor product spaces and generalize the Hölder condition to higher dimensions in a way which is suitable for tensor product spaces in our context. Consider, for example, the function $f(\boldsymbol{x}) = \prod_{j=1}^s f_j(x_j)$, where $\boldsymbol{x} = (x_1, \dots, x_s)$ and each $f_j : [0,1) \to \mathbb{R}$ satisfies a Hölder condition with coefficient $0 < \lambda \le 1$. Then it follows that for all $\emptyset \ne u \subseteq \mathcal{S} := \{1, \dots, s\}$ we have

$$\prod_{j \in u} |f_j(x_j) - f_j(y_j)| \le \prod_{j \in u} C_{f_j} \prod_{j \in u} |x_j - y_j|^\lambda \tag{3.1}$$

for all $x_j, y_j \in [0,1)$ with $j \in u$. But here $\prod_{j=1}^s |x_j - y_j|$ is not a metric on $[0,1)^s$.

Note that we have

$$\prod_{j \in u} |f_j(x_j) - f_j(y_j)| = \left| \sum_{v \subseteq u} (-1)^{|v|-|u|} \prod_{j \in v} f_j(x_j) \prod_{j \in u \setminus v} f_j(y_j) \right|, \tag{3.2}$$

which can be described in words in the following way: for given $\emptyset \ne u \subseteq \mathcal{S}$ let $x_j, y_j \in [0,1)$ with $x_j \ne y_j$ for all $j \in u$; consider the box J with vertices $\{(a_j)_{j \in u} : a_j = x_j \text{ or } a_j = y_j \text{ for } j \in u\}$. Then (3.2) is the alternating sum of the function $\prod_{j \in u} f_j$ at the vertices of J where adjacent vertices have opposite signs. This sum can also be defined for functions on $[0,1)^s$ which are not of product form.

Indeed, for a subinterval $J = \prod_{j=1}^s [x_j, y_j)$ with $0 \le x_j < y_j \le 1$ and a function $f : [0,1)^s \to \mathbb{R}$, let the function $\Delta(f, J)$ denote the alternating sum of f at the vertices of J where adjacent vertices have opposite signs. (Hence for $f = \prod_{j=1}^s f_j$ we have $\Delta(f, J) = \prod_{j=1}^s (f_j(x_j) - f_j(y_j))$.)

3.1.2. Generalized Vitali variation. Let $\mathfrak{p} \ge 1$. Then we define the generalized variation in the sense of Vitali with coefficient $0 < \lambda \le 1$ by

$$V^{(s)}_{\lambda,\mathfrak{p}}(f) = \sup_{\mathcal{P}} \left(\sum_{J \in \mathcal{P}} \mathrm{Vol}(J) \left| \frac{\Delta(f, J)}{\mathrm{Vol}(J)^\lambda} \right|^{\mathfrak{p}} \right)^{1/\mathfrak{p}}, \tag{3.3}$$

where the supremum is extended over all partitions $\mathcal{P}$ of $[0,1]^s$ into subintervals and $\mathrm{Vol}(J)$ denotes the volume of the subinterval J.

Note that for $\lambda = 1$ and $\mathfrak{p} = 1$ one obtains the usual definition of the Vitali variation; see, for example, [20]. If we take $\mathfrak{p} = \infty$, then we obtain a condition of the

form (3.1) where $u = \mathcal{S}$ and where we can take the constant $\prod_{j=1}^{s} C_{f_j} = V^{(s)}_{\lambda,\infty}(f)$. For $s = 1$ and $\mathfrak{p} = \infty$ we obtain a Hölder condition with coefficient $0 < \lambda \le 1$. In this sense we can view (3.3) as a fractional Vitali variation of order λ.

For $\lambda = 1$ and if the partial derivatives of f are continuous on $[0,1]^s$ we also have the formula

$$V^{(s)}_{1,\mathfrak{p}}(f) = \left(\int_{[0,1]^s} \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s} \right|^{\mathfrak{p}} \, \mathrm{d}\boldsymbol{x} \right)^{1/\mathfrak{p}} \tag{3.4}$$

for all $\mathfrak{p} \ge 1$. Indeed we have

$$|\Delta(f,J)| = \left| \int_J \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x} \right| = \mathrm{Vol}(J) \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{\zeta}_J) \right|$$

for some $\boldsymbol{\zeta}_J \in \overline{J}$, which follows by applying the mean value theorem to the inequality

$$\min_{\boldsymbol{x} \in \overline{J}} \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{x}) \right| \le \mathrm{Vol}(J)^{-1} \left| \int_J \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x} \right| \le \max_{\boldsymbol{x} \in \overline{J}} \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{x}) \right|.$$

Therefore we have

$$\sum_{J \in \mathcal{P}} \mathrm{Vol}(J) \left| \frac{\Delta(f,J)}{\mathrm{Vol}(J)} \right|^{\mathfrak{p}} = \sum_{J \in \mathcal{P}} \mathrm{Vol}(J) \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s}(\boldsymbol{\zeta}_J) \right|^{\mathfrak{p}},$$

which is just a Riemann sum for the integral $\int_{[0,1]^s} \left| \frac{\partial^s f}{\partial x_1 \cdots \partial x_s} \right|^{\mathfrak{p}} \mathrm{d}\boldsymbol{x}$, and thus the equality follows.

Using Hölder's inequality and the fact that $\left(\sum_{J \in \mathcal{P}} (\mathrm{Vol}(J)^{1-1/\mathfrak{p}})^{\mathfrak{p}/(\mathfrak{p}-1)} \right)^{1-1/\mathfrak{p}} = \left(\sum_{J \in \mathcal{P}} \mathrm{Vol}(J) \right)^{1-1/\mathfrak{p}} = 1$, it follows that

$$V^{(s)}_{\lambda,1}(f) \le V^{(s)}_{\lambda,\mathfrak{p}}(f) \quad \text{for all } \mathfrak{p} \ge 1.$$

3.1.3. Generalized Hardy and Krause variation. Until now we did not take projections to lower-dimensional faces into account (in (3.1) we did take projections into account as we considered all $\emptyset \ne u \subseteq \mathcal{S}$).

For $\emptyset \ne u \subseteq \mathcal{S}$, let $V^{(|u|)}_{\lambda,\mathfrak{p}}(f_u; u)$ be the generalized Vitali variation with coefficient $0 < \lambda \le 1$ of the $|u|$-dimensional function $f_u(\boldsymbol{x}_u) = \int_{[0,1)^{s-|u|}} f(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x}_{\mathcal{S} \setminus u}$. For $u = \emptyset$ we have $f_\emptyset = \int_{[0,1)^s} f(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x}_{\mathcal{S}}$ and we define $V^{(|\emptyset|)}_{\lambda,\mathfrak{p}}(f_\emptyset; \emptyset) = |f_\emptyset|$. Let $\mathfrak{q} \ge 1$. Then

$$V_{\lambda,\mathfrak{p},\mathfrak{q}}(f) = \left(\sum_{u \subseteq \mathcal{S}} \left(V^{(|u|)}_{\lambda,\mathfrak{p}}(f_u; u) \right)^{\mathfrak{q}} \right)^{1/\mathfrak{q}} \tag{3.5}$$

is called the generalized Hardy and Krause variation of f on $[0,1]^s$.

For $\lambda = \mathfrak{p} = \mathfrak{q} = 1$ one obtains an unanchored version of the usual definition of the Hardy and Krause variation; see [20]. A function f for which $V_{\lambda,\mathfrak{p},\mathfrak{q}}(f) < \infty$ is said to be of finite variation with coefficient λ. (We remark that in some cases it might be appropriate to leave out the term corresponding to $u = \emptyset$ in (3.5), but here this term will be needed later on, and hence we include it already in the definition of the variation.)

3.1.4. Generalized weighted Hardy and Krause variation. As first suggested in [30] (see also [6]) different coordinates might have different importance, hence we can also define a weighted variation. In the spirit of the weighted Sobolev spaces in [6], let $\boldsymbol{\gamma} = (\gamma_u)_{u \subset \mathbb{N}}$ be an indexed set of nonnegative real numbers. Then we define the weighted variation $V_{\lambda,\mathfrak{p},\mathfrak{q},\boldsymbol{\gamma}}(f)$ of f with coefficient $0 < \lambda \le 1$ by

$$V_{\lambda,\mathfrak{p},\mathfrak{q},\boldsymbol{\gamma}}(f) = \left(\sum_{u \subseteq \mathcal{S}} \gamma_u^{-1} \left(V_{\lambda,\mathfrak{p}}^{(|u|)}(f_u; u) \right)^{\mathfrak{q}} \right)^{1/\mathfrak{q}}.$$

Note that for $\lambda = 1$ and $\mathfrak{p} = \mathfrak{q} = 2$ the weighted variation $V_{\lambda,\mathfrak{p},\mathfrak{q},\boldsymbol{\gamma}}(f)$ coincides with the norm in a weighted unanchored Sobolev space for any function in this Sobolev space; i.e., we have the identity $V_{1,2,2,\boldsymbol{\gamma}}(f) = \|f\|_{\mathrm{sob}}$, where

$$\|f\|_{\mathrm{sob}} = \left(\sum_{u \subseteq \mathcal{S}} \gamma_u^{-1} \int_{[0,1)^{|u|}} \left| \int_{[0,1)^{s-|u|}} \frac{\partial^{|u|} f(\boldsymbol{x})}{\partial \boldsymbol{x}_u} \, \mathrm{d}\boldsymbol{x}_{\mathcal{S}\setminus u} \right|^2 \mathrm{d}\boldsymbol{x}_u \right)^{1/2}$$

denotes the norm in the weighted Sobolev space (see [6] for more information on this Sobolev space).

3.2. The decay of the Walsh coefficients of smooth functions. We are now ready to show how the Walsh coefficients of smooth functions decay. This behavior is essentially captured in Definition 3.5 below. But before we get there we need several lemmas to prove the result. The following lemma is needed to show how the Walsh coefficients of functions with bounded variation decay. A simpler version of it was shown in [25, Lemma 4].

LEMMA 3.1. *Let $f \in \mathcal{L}_1([0,1)^s)$ and let $\boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{N}^s$ with $k_j = \kappa_j q^{a_j - 1} + k_j'$, where $a_j \in \mathbb{N}$, $\kappa_j \in \{1, \dots, q-1\}$, $0 \le k_j' < q^{a_j-1}$, and let $0 \le c_j < q^{a_j-1}$ for $j = 1, \dots, s$. Then*

$$\left| \int_{\prod_{j=1}^s [c_j q^{-a_j+1}, (c_j+1)q^{-a_j+1})} f(\boldsymbol{x}) \, \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})} \, \mathrm{d}\boldsymbol{x} \right| \le q^{-\sum_{j=1}^s (a_j - 1)} \sup_J |\Delta(f, J)|,$$

where the supremum is taken over all boxes of the form

$$J = \prod_{j=1}^s [d_j, e_j) \subseteq \prod_{j=1}^s [c_j q^{-a_j+1}, (c_j+1)q^{-a_j+1})$$

with $q^{a_j} |e_j - d_j| \in \{1, \dots, q-1\}$.

Proof. We have $\overline{\mathrm{wal}_{k_j}} = \overline{\mathrm{wal}_{\kappa_j q^{a_j-1}}} \, \overline{\mathrm{wal}_{k_j'}}$ and the function $\overline{\mathrm{wal}_{k_j'}}$ is constant on each subinterval $[c_j q^{-a_j+1}, (c_j+1)q^{-a_j+1})$. Hence we have

$$\begin{aligned} &\left| \int_{\prod_{j=1}^s [c_j q^{-a_j+1}, (c_j+1)q^{-a_j+1})} f(\boldsymbol{x}) \, \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})} \, \mathrm{d}\boldsymbol{x} \right| \\ &= \left| \int_{\prod_{j=1}^s [c_j q^{-a_j+1}, (c_j+1)q^{-a_j+1})} f(\boldsymbol{x}) \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j q^{a_j-1}}(x_j)} \, \mathrm{d}\boldsymbol{x} \right|. \end{aligned}$$

Note that the function $\overline{\mathrm{wal}_{\kappa_j q^{a_j-1}}}$ is constant on each of the subintervals $[r_j q^{-a_j}, (r_j+1)q^{-a_j})$ for $r_j = 0, \dots, q^{a_j} - 1$ for $j = 1, \dots, s$. Without loss of generality we

may assume that $c_j = 0$; for all other c_j the result follows by the same arguments. Thus we have

$$\int_{\prod_{j=1}^s [0,q^{-a_j+1})} f(\boldsymbol{x}) \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j q^{a_j-1}}(x_j)}\,\mathrm{d}\boldsymbol{x}$$

$$= \sum_{r_1,\ldots,r_s=0}^{q-1} \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j}(r_j/q)} \int_{\prod_{j=1}^s [r_j q^{-a_j},(r_j+1)q^{-a_j})} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}.$$

Now let $a_{(r_1,\ldots,r_s)} = \int_{\prod_{j=1}^s [r_j q^{-a_j},(r_j+1)q^{-a_j})} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$ and for a given $0 \le r_1,\ldots,r_s < q$ let

$$A(r_1,\ldots,r_s) = q^{-s} \sum_{t_1,\ldots,t_s=0}^{q-1} \sum_{\emptyset \ne u \subseteq \{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u, \boldsymbol{r}_{\{1,\ldots,s\}\setminus u})}, \tag{3.6}$$

where $(\boldsymbol{t}_u, \boldsymbol{r}_{\{1,\ldots,s\}\setminus u})$ denotes the vector obtained by setting the jth coordinate to t_j if $j \in u$ and r_j if $j \notin u$. Further let

$$B(r_1,\ldots,r_s) = q^{-s} \sum_{t_1,\ldots,t_s=0}^{q-1} \sum_{u \subseteq \{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u, \boldsymbol{r}_{\{1,\ldots,s\}\setminus u})}.$$

Then we have

$$\sum_{r_1,\ldots,r_s=0}^{q-1} \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j}(r_j/q)} a_{(r_1,\ldots,r_s)}$$

$$= -\sum_{r_1,\ldots,r_s=0}^{q-1} \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j}(r_j/q)} A(r_1,\ldots,r_s)$$

$$+ \sum_{r_1,\ldots,r_s=0}^{q-1} \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j}(r_j/q)} (a_{(r_1,\ldots,r_s)} + A(r_1,\ldots,r_s)).$$

Since $\sum_{r=0}^{q-1} \overline{\mathrm{wal}_\kappa(r/q)} = 0$ and $A(r_1,\ldots,r_s)$ is a sum where each summand does not depend on at least one r_j, i.e., the case $u = \emptyset$ is excluded in (3.6), it follows that the first sum on the right-hand side above is zero. Further we have $a_{(r_1,\ldots,r_s)} + A(r_1,\ldots,r_s) = B(r_1,\ldots,r_s)$ and thus

$$\left| \sum_{r_1,\ldots,r_s=0}^{q-1} \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j}(r_j/q)} a_{(r_1,\ldots,r_s)} \right| \le \sum_{r_1,\ldots,r_s=0}^{q-1} |B(r_1,\ldots,r_s)|.$$

We have

$$|B(r_1,\ldots,r_s)| \le \max_{\boldsymbol{t} \in \{0,\ldots,q-1\}^s} \left| \sum_{u \subseteq \{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u, \boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right|.$$

Therefore we have

$$\begin{aligned}
&\left| \int_{\prod_{j=1}^s [0,q^{-a_j+1})} f(\boldsymbol{x}) \prod_{j=1}^s \overline{\mathrm{wal}_{\kappa_j q^{a_j-1}}(x_j)}\,\mathrm{d}\boldsymbol{x} \right| \\
&\le \sum_{r_1,\ldots,r_s=0}^{q-1} \max_{\boldsymbol{t}\in\{0,\ldots,q-1\}^s} \left| \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u,\boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right| \\
&\le q^s \max_{\boldsymbol{r},\boldsymbol{t}\in\{0,\ldots,q-1\}^s} \left| \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u,\boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right|.
\end{aligned}$$

Note that if in the above maximum there is a j such that $r_j = t_j$, then it follows that

$$\left| \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u,\boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right| = 0.$$

Hence we may in the following assume without loss of generality that the maximum in the last line of the inequality above is taken on for $\boldsymbol{r} = (r_1,\ldots,r_s)$ and $\boldsymbol{t} = (t_1,\ldots,t_s)$, which satisfy $r_j \ne t_j$ for $j = 1,\ldots,s$.

We have

$$\begin{aligned}
&\left| \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u,\boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right| \\
&= \left| \int_{\prod_{j=1}^s [r_j q^{-a_j},(r_j+1)q^{-a_j})} \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} f(\boldsymbol{x}+\boldsymbol{y}_u)\,\mathrm{d}\boldsymbol{x} \right|,
\end{aligned}$$

where $\boldsymbol{y}_u = (y_1,\ldots,y_s)$ with $y_j = 0$ for $j \notin u$ and $y_j = (t_j - r_j)q^{-a_j}$ for $j \in u$. We can write

$$\sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} f(\boldsymbol{x}+\boldsymbol{y}_u) = \Delta(f, J_{\boldsymbol{x}}),$$

where $J_{\boldsymbol{x}} = \prod_{j=1}^s [\min(x_j, x_j + (t_j - r_j)q^{-a_j}), \max(x_j, x_j + (t_j - r_j)q^{-a_j}))$. Therefore it follows that

$$\left| \sum_{u\subseteq\{1,\ldots,s\}} (-1)^{|u|} a_{(\boldsymbol{t}_u,\boldsymbol{r}_{\{1,\ldots,s\}\setminus u})} \right| \le q^{-\sum_{j=1}^s a_j} \sup_{\boldsymbol{x}\in\prod_{j=1}^s [r_j q^{-a_j},(r_j+1)q^{-a_j})} |\Delta(f, J_{\boldsymbol{x}})|.$$

The result follows. □

In the following lemma we now obtain a bound on the Walsh coefficients for functions of bounded variation. It is a generalization of [25, Proposition 6].

LEMMA 3.2. *Let $0 < \lambda \le 1$ and let $f \in \mathcal{L}_2([0,1)^s)$ satisfy $V_{\lambda,1,1,\boldsymbol{\gamma}}(f) < \infty$. Then for any $\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}$ the $\boldsymbol{k}$th Walsh coefficient of f satisfies*

$$|\hat{f}(\boldsymbol{k})| \le q^{|u|-\lambda\sum_{j\in u}(a_j-1)} V_{\lambda,1}^{(|u|)}(f_u; u),$$

where $\boldsymbol{k} = (k_1, \dots, k_s)$, $u = \{1 \le j \le s : k_j \ne 0\}$, *and for* $j \in u$ *we have* $k_j = \kappa_j q^{a_j - 1} + k_j'$, *where* $\kappa_j \in \{1, \dots, q-1\}$, $a_j \in \mathbb{N}$, *and* $0 \le k_j' < q^{a_j - 1}$.

Proof. Let $f \in \mathcal{L}_2([0,1)^s)$ with $\boldsymbol{k}$th Walsh coefficient $\hat{f}(\boldsymbol{k})$. First note that it suffices to show the result for $\boldsymbol{k} \in \mathbb{N}^s$, as otherwise we only need to replace the function f with the function $f_u(\boldsymbol{x}_u) = \int_{[0,1)^{s-|u|}} f(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x}_{\mathcal{S}\setminus u}$. Hence now let $\boldsymbol{k} \in \mathbb{N}^s$ be given and let $\boldsymbol{k}' = (k_1', \dots, k_s')$. Then we have

$$\begin{aligned}
&\left| \int_{[0,1)^s} f(\boldsymbol{x}) \, \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})} \, \mathrm{d}\boldsymbol{x} \right| \\
&\le \sum_{\substack{0 \le c_j < q^{a_j - 1} \\ 1 \le j \le s}} \left| \int_{c_1 q^{-a_1 + 1}}^{(c_1+1) q^{-a_1+1}} \cdots \int_{c_s q^{-a_s+1}}^{(c_s+1) q^{-a_s+1}} f(\boldsymbol{x}) \, \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})} \, \mathrm{d}\boldsymbol{x} \right|.
\end{aligned}$$

Now we use Lemma 3.1 and thereby obtain that the above sum is bounded by

$$\sum_{0 \le c_1 < q^{a_1 - 1}} \cdots \sum_{0 \le c_s < q^{a_s - 1}} q^{-\sum_{j=1}^s (a_j - 1)} \sup_J |\Delta(f, J)|,$$

where the supremum is taken over all boxes $J = \prod_{j=1}^s [d_j, e_j) \subseteq \prod_{j=1}^s [c_j q^{-a_j+1}, (c_j + 1) q^{-a_j+1})$ with $q^{a_j} |e_j - d_j| \in \{1, \dots, q-1\}$. Now we have

$$q^{-\sum_{j=1}^s (a_j - 1)} \sup_J |\Delta(f, J)| \le \sup_{\mathcal{P}_{\mathbf{c}}} \sum_{I \in \mathcal{P}_{\mathbf{c}}} \mathrm{Vol}(I)^{1-\lambda} |\Delta(f, I)| \frac{q^{-\sum_{j=1}^s (a_j - 1)}}{\mathrm{Vol}(I)^{1-\lambda}},$$

where the supremum on the right-hand side is taken over all partitions $\mathcal{P}_{\mathbf{c}}$ of the cube $\prod_{j=1}^s [c_j q^{-a_j+1}, (c_j+1) q^{-a_j+1})$ and where each $I \in \mathcal{P}_{\mathbf{c}}$ is of the form $I = \prod_{j=1}^s [x_j, y_j)$ with $q^{a_j} |y_j - x_j| \in \{1, \dots, q-1\}$. We have $q^{-\sum_{j=1}^s a_j} \le \mathrm{Vol}(I) \le q^{-\sum_{j=1}^s (a_j - 1)}$ and therefore

$$\frac{q^{-\sum_{j=1}^s (a_j - 1)}}{\mathrm{Vol}(I)^{1-\lambda}} \le \mathrm{Vol}(I)^{\lambda} q^s \le q^{s - \lambda \sum_{j=1}^s (a_j - 1)}$$

and hence

$$q^{-\sum_{j=1}^s (a_j - 1)} \sup_J |\Delta(f, J)| \le q^{s - \lambda \sum_{j=1}^s (a_j - 1)} \sup_{\mathcal{P}_{\mathbf{c}}} \sum_{I \in \mathcal{P}_{\mathbf{c}}} \mathrm{Vol}(I)^{1-\lambda} |\Delta(f, I)|.$$

Note that

$$\sum_{\substack{0 \le c_j < q^{a_j - 1} \\ 1 \le j \le s}} \sup_{\mathcal{P}_{\mathbf{c}}} \sum_{I \in \mathcal{P}_{\mathbf{c}}} \mathrm{Vol}(I)^{1-\lambda} |\Delta(f, I)| \le \sup_{\mathcal{P}} \sum_{J \in \mathcal{P}} \mathrm{Vol}(J) \frac{|\Delta(f, J)|}{\mathrm{Vol}(J)^{\lambda}},$$

where the supremum on the left-hand side is taken over all partitions $\mathcal{P}$ of the cube $\prod_{j=1}^s [c_j q^{-a_j+1}, (c_j + 1) q^{-a_j+1})$ into subintervals and the supremum on the right-hand side is taken over all partitions of $[0,1)^s$ into subintervals. Thus the result follows. ∎

For the next lemma we will need the following two functions. For $\kappa \in \{1, \dots, q-1\}$ now let

$$\upsilon_\kappa = \sum_{r=0}^{q-1} r \, \mathrm{wal}_\kappa(r/q).$$

If q is chosen to be a prime number and the bijections φ and η are chosen to be the identity, then $\upsilon_\kappa = q(\mathrm{e}^{2\pi \mathrm{i}\kappa/q}-1)^{-1}$; see [4, Appendix A].

Further for $l \in \{1,\dots,q-1\}$ we define the function $\zeta_a(x) = \sum_{r=0}^{x_a-1} \overline{\mathrm{wal}_l(r/q)}$, where $a \geq 1$ and $x = x_1 q^{-1} + x_2 q^{-2} + \cdots$ and where for $x_a = 0$ we set $\zeta_a(x) = 0$. The function ζ_a depends on x only through x_a, thus it is a step-function which is constant on the intervals $[cq^{-a}, (c+1)q^{-a})$ for $c = 0,\dots,q^a-1$. By [25, Proposition 5] it follows that ζ_a can be represented by a finite Walsh series. Indeed, there are numbers $c_0,\dots,c_{q-1}$ (which depend on l but not on a) such that

$$\zeta_a(x) = \sum_{z=0}^{q-1} c_z \overline{\mathrm{wal}_{zq^{a-1}}(x)}.$$

If q is chosen to be a prime number and the bijections φ and η are chosen to be the identity, then $\zeta_a(x) = (1-\overline{\mathrm{wal}_{lq^{a-1}}(x)})(1-\overline{\mathrm{wal}_l(1/q)})^{-1}$, i.e., $c_0 = (1-\overline{\mathrm{wal}_l(1/q)})^{-1}$, $c_l = (\overline{\mathrm{wal}_l(1/q)}-1)^{-1}$, and $c_z = 0$ for $z \neq 0, l$.

The following lemma will be used in the induction step for differentiable functions. For example, for a differentiable function $F:\mathbb{R}\to\mathbb{R}$ given by $F(x) = \int_0^x f(y)\,\mathrm{d}y$ we can calculate the Walsh coefficients using integration by parts in the following way: For $k > 0$ we have

$$\begin{aligned}\hat{F}(k) &= \int_0^1 F(x)\overline{\mathrm{wal}_k(x)}\,\mathrm{d}x = \left[\int_0^x \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y F(x)\right]_0^1 - \int_0^1 f(x)\int_0^x \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y\,\mathrm{d}x \\ &= -\int_0^1 f(x)\int_0^x \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y\,\mathrm{d}x, \qquad (3.7)\end{aligned}$$

where we used $\int_0^0 \overline{\mathrm{wal}_k(x)}\,\mathrm{d}x = \int_0^1 \overline{\mathrm{wal}_k(x)}\,\mathrm{d}x = 0$. For $k = 0$ on other hand we obtain

$$\begin{aligned}\hat{F}(0) &= \int_0^1 F(x)\overline{\mathrm{wal}_0(x)}\,\mathrm{d}x = \left[\int_0^x \overline{\mathrm{wal}_0(y)}\,\mathrm{d}y F(x)\right]_0^1 - \int_0^1 f(x)\int_0^x \overline{\mathrm{wal}_0(y)}\,\mathrm{d}y\,\mathrm{d}x \\ &= \int_0^1 f(x)\,\mathrm{d}x - \int_0^1 f(x)\int_0^x \overline{\mathrm{wal}_0(y)}\,\mathrm{d}y\,\mathrm{d}x. \qquad (3.8)\end{aligned}$$

Thus if we know the Walsh series for f, then we can easily calculate the Walsh series for F, provided that we know the Walsh series for $\int_0^x \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y$. This will be calculated in the following lemma. It appeared in a simpler form in [10].

LEMMA 3.3. *For $k \in \mathbb{N}_0$ and $x \in [0,1)$ define $J_k(x) = \int_0^x \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y$. For $k \geq 1$ let $k = lq^{a-1}+k'$, where $l \in \{1,\dots,q-1\}$, $a \geq 1$, and $0 \leq k' < q^{a-1}$. Then J_k can be represented by a Walsh series which is given by*

$$J_k(x) = q^{-a}\left(\sum_{z=0}^{q-1} c_z \overline{\mathrm{wal}_{zq^{a-1}+k'}(x)} + 2^{-1}\overline{\mathrm{wal}_k(x)} + \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa \overline{\mathrm{wal}_{\kappa q^{a+c-1}+k}(x)}\right).$$

Further we have

$$J_0(x) = 1/2 + \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa\,\overline{\mathrm{wal}_{\kappa q^{c-1}}(x)}.$$

Proof. Let $k = lq^{a-1}+k'$ with $a \geq 1$, $0 \leq k' < q^{a-1}$, and $l \in \{1,\dots,q-1\}$. The function $\overline{\mathrm{wal}_{lq^{a-1}}(y)}$ is constant on each interval $[rq^{-a},(r+1)q^{-a})$ and

$\overline{\mathrm{wal}_{k'}(y)}$ is constant on each interval $[cq^{-a+1},(c+1)q^{-a+1})$. We have $\overline{\mathrm{wal}_k(y)} = \overline{\mathrm{wal}_{lq^{a-1}}(y)}\,\overline{\mathrm{wal}_{k'}(y)}$. For any $0 \le c < q^{a-1}$ we have

$$\begin{aligned}\int_{[cq^{-a+1},(c+1)q^{-a+1})} \overline{\mathrm{wal}_k(y)}\,\mathrm{d}y &= \overline{\mathrm{wal}_{k'}(cq^{-a+1})}\int_{[cq^{-a+1},(c+1)q^{-a+1})} \overline{\mathrm{wal}_{lq^{a-1}}(y)}\,\mathrm{d}y\\ &= \overline{\mathrm{wal}_{k'}(cq^{-a+1})}q^{-a}\sum_{r=0}^{q-1}\mathrm{wal}_l(r/q)\\ &= 0.\end{aligned}$$

Thus we have

$$J_k(x) = \overline{\mathrm{wal}_{k'}(x)}J_{lq^{a-1}}(x).$$

Let $x = x_1q^{-1} + x_2q^{-2} + \cdots$ and $y = x_{a+1}q^{-1} + x_{a+2}q^{-2} + \cdots$; then we have

$$J_{lq^{a-1}}(x) = q^{-a}\sum_{r=0}^{x_a-1}\overline{\mathrm{wal}_l(r/q)} + q^{-a}\overline{\mathrm{wal}_l(x_a/q)}y.$$

We now investigate the Walsh series representation of the function $J_{lq^{a-1}}(x)$. First note that $\overline{\mathrm{wal}_l(x_a/q)} = \overline{\mathrm{wal}_{lq^{a-1}}(x)}$. Further, by a slight adaption of [4, eq. (30)] we obtain

$$y = 1/2 + \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa\,\overline{\mathrm{wal}_{\kappa q^{c-1}}(y)}. \tag{3.9}$$

As $\overline{\mathrm{wal}_{\kappa q^{c-1}}(y)} = \overline{\mathrm{wal}_{\kappa q^{a+c-1}}(x)}$ we obtain

$$y = 1/2 + \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa\,\overline{\mathrm{wal}_{\kappa q^{a+c-1}}(x)}.$$

As noted above, the Walsh series of $\zeta_a(x) = \sum_{r=0}^{x_a-1}\overline{\mathrm{wal}_l(r/q)}$, where for $x_a = 0$ we set $\zeta_a(x) = 0$, can be written as

$$\zeta_a(x) = \sum_{z=0}^{q-1} c_z\overline{\mathrm{wal}_{zq^{a-1}}(x)}.$$

Altogether we obtain

$$\begin{aligned}q^aJ_{lq^{a-1}}(x) = \sum_{z=0}^{q-1} c_z\overline{\mathrm{wal}_{zq^{a-1}}(x)} &+ 2^{-1}\overline{\mathrm{wal}_{lq^{a-1}}(x)}\\ &+ \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa\overline{\mathrm{wal}_{\kappa q^{a+c-1}+lq^{a-1}}(x)}\end{aligned}$$

and therefore

$$q^aJ_k(x) = \sum_{z=0}^{q-1} c_z\overline{\mathrm{wal}_{zq^{a-1}+k'}(x)} + 2^{-1}\overline{\mathrm{wal}_k(x)} + \sum_{c=1}^{\infty}\sum_{\kappa=1}^{q-1} q^{-c-1}\upsilon_\kappa\overline{\mathrm{wal}_{\kappa q^{a+c-1}+k}(x)}.$$

The result for $k = 0$ follows easily from (3.9). □

Note that Lemma 3.3 can easily be generalized to arbitrary dimensions s, since for $\boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{N}_0^s$ we have for any $\boldsymbol{x} = (x_1, \dots, x_s) \in [0,1)^s$ that

$$J_{\boldsymbol{k}}(\boldsymbol{x}) = \int_{[0,\boldsymbol{x})} \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{y})}\, \mathrm{d}\boldsymbol{y} = \prod_{j=1}^{s} J_{k_j}(x_j),$$

where $[0, \boldsymbol{x}) = \prod_{j=1}^{s} [0, x_j)$.

The next lemma shows how the Walsh coefficients of a function $F = \int f$ can be obtained from the Walsh coefficients of f.

LEMMA 3.4. *Let $f \in \mathcal{L}_2([0,1)^s)$ and let $F(\boldsymbol{x}) = \int_{[0,\boldsymbol{x})} f(\boldsymbol{y})\, \mathrm{d}\boldsymbol{y}$, where $[0, \boldsymbol{x}) = \prod_{j=1}^{s} [0, x_j)$ with $\boldsymbol{x} = (x_1, \dots, x_s)$. Further let $\hat{F}(\boldsymbol{k})$ denote the $\boldsymbol{k}$th Walsh coefficient of F. Let $\boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{N}_0^s$ and let $U = \{1 \le j \le s : k_j \ne 0\}$. For $j \in U$ let $k_j = l_j q^{a_j - 1} + k_j'$, $0 < l_j < q$ and $0 \le k_j' < q^{a_j - 1}$, and further let $\boldsymbol{k}' = (k_1', \dots, k_s')$, where $k_j' = 0$ for $j \notin U$. Then we have*

$$\hat{F}(\boldsymbol{k}) = q^{-\sum_{j \in U} a_j} \sum_{U \subseteq v \subseteq \mathcal{S}} (-1)^{|v|} \sum_{\boldsymbol{h}_v \in \mathbb{N}_0^{|v|}} \hat{f}(\boldsymbol{k}' + (\boldsymbol{h}_v, \boldsymbol{0}))\, \chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v),$$

where $(\boldsymbol{h}_v, \boldsymbol{0})$ denotes the s-dimensional vector whose jth component is h_j for $j \in v$ and 0 otherwise and where for $\boldsymbol{h}_v = (h_j)_{j \in v} \in \mathbb{N}_0^{|v|}$ we set

$$\chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v) = \prod_{j \in U} \rho_{k_j}(h_j) \prod_{j \in v \setminus U} \phi(h_j).$$

Here

$$\rho_{k_j}(h_j) = \begin{cases} c_z + 2^{-1} 1_{z = l_j} & \text{for } h_j = z q^{a_j - 1}, \\ \upsilon_z q^{-i-1} & \text{for } h = z q^{a_j - 1 + i} + l_j q^{a_j - 1},\ i > 0,\ 0 < z < q, \\ 0 & \text{otherwise,} \end{cases}$$

where $1_{z = l_j} = 1$ for $z = l_j$ and 0 otherwise, and

$$\phi(h_j) = \begin{cases} 2^{-1} & \text{for } h_j = 0, \\ \upsilon_z q^{-i-1} & \text{for } h = z q^{a_j - 1 + i},\ i > 0,\ 0 < z < q, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. Using integration by parts in each coordinate, Fubini's theorem, and $J_k(0) = J_k(1) = 0$ for any $k \in \mathbb{N}$ (see (3.7) and (3.8) for one-dimensional examples), it follows that

$$\hat{F}(\boldsymbol{k}) = \int_{[0,1)^s} F(\boldsymbol{x}) \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})}\, \mathrm{d}\boldsymbol{x} = \sum_{U \subseteq v \subseteq \mathcal{S}} (-1)^{|v|} \int_{[0,1)^s} J_{\boldsymbol{k}_v}(\boldsymbol{x}_v) f(\boldsymbol{x})\, \mathrm{d}\boldsymbol{x},$$

where for $\boldsymbol{k} = (k_1, \dots, k_s)$ and $\boldsymbol{x} = (x_1, \dots, x_s)$ we have $J_{\boldsymbol{k}_v}(\boldsymbol{x}_v) = \prod_{j \in v} J_{k_j}(x_j)$.

Using the Walsh series expansion of $J_{\boldsymbol{k}}$ given by Lemma 3.3 we can now express the Walsh coefficient $\hat{F}(\boldsymbol{k})$ as a sum of the Walsh coefficients $\hat{f}(\boldsymbol{h})$, from which the result follows. □

The following definition now captures the essence of the decay of the Walsh coefficients of smooth functions and will be used in the statement of subsequent lemmas, theorems, and corollaries.

DEFINITION 3.5. *Let $k = k(v; a_1, \dots, a_v) = \kappa_1 q^{a_1 - 1} + \cdots + \kappa_v q^{a_v - 1}$ with $v \geq 1$, let $\kappa_1, \dots, \kappa_v \in \{1, \dots, q-1\}$, and let $1 \leq a_v < \cdots < a_1$ be a natural number. For $k = 0$ we set $v = 0$, i.e., $k(0) = 0$. A function $\mathcal{B} : \mathbb{N}_0 \to \mathbb{R}$ is called q-adically nonincreasing if $\mathcal{B}(k) = \mathcal{B}(k(v; a_1, \dots, a_v))$ is nonincreasing in v and each a_i for $i = 1, \dots, v$; that is, for any $v \geq 0$ we have*

$$\mathcal{B}(k(v; a_1, \dots, a_v)) \geq \mathcal{B}(k(v+1; a'_1, \dots, a'_{v+1}))$$

with $1 \leq a'_{v+1} < \cdots < a'_1$ and $a_1, \dots, a_v \in \{a'_1, \dots, a'_{v+1}\}$ and for an arbitrary $1 \leq i \leq v$ we have

$$\mathcal{B}(k(v; a_1, \dots, a_v)) \geq \mathcal{B}(k(v; a_1, \dots, a_{i-1}, a_i + 1, a_{i+1}, \dots, a_v)),$$

provided that $a_i + 1 < a_{i-1}$ in case $1 < i \leq v$.

In the following lemma we give a bound on the Walsh coefficients of F if f satisfies some smoothness condition.

LEMMA 3.6. *Let $\mathcal{B} : \mathbb{N}_0^s \to [0, \infty)$ be a q-adically nonincreasing function in each variable. Let $f \in \mathcal{L}_2([0,1)^s)$ and let the Walsh coefficients of f satisfy*

$$|\hat{f}(\boldsymbol{k})| \leq \mathcal{B}(\boldsymbol{k}) \quad \text{for all } \boldsymbol{k} \in \mathbb{N}_0^s.$$

Let $F(\boldsymbol{x}) = \int_{[0,\boldsymbol{x})} f(\boldsymbol{y}) \, \mathrm{d}\boldsymbol{y}$, where $[0, \boldsymbol{x}) = \prod_{j=1}^s [0, x_j)$ with $\boldsymbol{x} = (x_1, \dots, x_s)$. Further let $\hat{F}(\boldsymbol{k})$ denote the $\boldsymbol{k}$th Walsh coefficient of F. Let $\boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}$ and let $U = \{1 \leq j \leq s : k_j \neq 0\}$. For $j \in U$ let $k_j = l_j q^{a_j - 1} + k'_j$ and $0 \leq k'_j < q^{a_j - 1}$ and further let $\boldsymbol{k}' = (k'_1, \dots, k'_s)$, where $k'_j = 0$ for $j \notin U$. Then there is a constant $C_{s,U} > 0$ independent of $\boldsymbol{k}$ such that

$$|\hat{F}(\boldsymbol{k})| \leq C_{s,U} \, q^{-\sum_{j \in U} a_j} \mathcal{B}(\boldsymbol{k}').$$

Proof. Using Lemma 3.4 we obtain that

$$|\hat{F}(\boldsymbol{k})| \leq q^{-\sum_{j \in U} a_j} \mathcal{B}(\boldsymbol{k}') \sum_{U \subseteq v \subseteq \mathcal{S}} \sum_{\boldsymbol{h}_v \in \mathbb{N}_0^{|v|}} |\chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v)|,$$

as $|\hat{f}(\boldsymbol{k}' + (\boldsymbol{h}_v, \boldsymbol{0}))| \leq \mathcal{B}(\boldsymbol{k}' + (\boldsymbol{h}_v, \boldsymbol{0})) \leq \mathcal{B}(\boldsymbol{k}')$ for all values of $\boldsymbol{h}_v \in \mathbb{N}_0^{|v|}$ for which $\chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v) \neq 0$, since $\mathcal{B}$ is q-adically nonincreasing in each variable.

Thus it remains to bound $\sum_{U \subseteq v \subseteq \mathcal{S}} \sum_{\boldsymbol{h}_v \in \mathbb{N}_0^{|v|}} |\chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v)|$ independently of $\boldsymbol{k}$. We only prove the case where q is chosen to be a prime number and the bijections φ and η are chosen to be the identity, as in this case we can obtain an explicit constant $C_{s,U} > 0$. The general case can be obtained by similar arguments using the result from Lemma 3.4.

Using the notation from Lemma 3.4 we have

$$\begin{aligned}\sum_{h \in \mathbb{N}_0} |\rho_{k_j}(h)| &= |1 - \omega_q^{-l_j}|^{-1} + 2^{-1} |1 + \omega_q^{-l_j}| |\omega_q^{-l_j} - 1|^{-1} \\ &\quad + \sum_{i=1}^{\infty} q^{-i} \sum_{z=1}^{q-1} |\mathrm{e}^{2\pi \mathrm{i} z/q} - 1|^{-1} \\ &\leq 3(2 - 2\cos(2\pi/q))^{-1/2}\end{aligned}$$

and

$$\sum_{h=0}^{\infty} |\phi(h)| = 2^{-1} + \sum_{i=1}^{\infty} q^{-i} \sum_{z=1}^{q-1} |\mathrm{e}^{2\pi \mathrm{i} z/q} - 1|^{-1} \leq 2^{-1} + (2 - 2\cos(2\pi/q))^{-1/2}.$$

Therefore we have

$$\sum_{U\subseteq v\subseteq S}\sum_{\boldsymbol{h}_v\in\mathbb{N}_0^{|v|}}|\chi_{U,v,\boldsymbol{k}}(\boldsymbol{h}_v)|$$

$$\le 3^{|U|}(2-2\cos(2\pi/q))^{-|U|/2}(3/2+(2-2\cos(2\pi/q))^{-1/2})^{s-|U|}$$

and hence we can choose

$$C_{s,U}=3^{|U|}(2-2\cos(2\pi/q))^{-|U|/2}(3/2+(2-2\cos(2\pi/q))^{-1/2})^{s-|U|} \tag{3.10}$$

in Lemma 3.6 for this case. □

We use the above results now to establish an upper bound on the Walsh coefficients of a polynomial. The proof will give a glimpse of how the argument will work for more general function classes.

LEMMA 3.7. *Let $k=\kappa_1q^{a_1-1}+\cdots+\kappa_vq^{a_v-1}$ with $v\ge 1$, $\kappa_1,\dots,\kappa_v\in\{1,\dots,q-1\}$ and $1\le a_v<\cdots<a_1$. For $v=0$ let $k=0$. Let $f:[0,1)\to\mathbb{R}$ be the polynomial $f(x)=f_0+f_1x+\cdots+f_ix^i$ with $f_i\ne 0$ and let $\hat f(k)$ denote the kth Walsh coefficient of f. Then for $v\ge 0$ there are constants $0<C_{f,i,v}<\infty$ such that*

$$|\hat f(k)|\le C_{f,i,v}q^{-a_1-\cdots-a_v},$$

where we can choose $C_{f,i,v}=0$ for $v>i$.

Proof. Let $f(x)=f_0+f_1x+\cdots+f_ix^i$, where $i=\deg(f)$ (that is, $f_i\ne 0$). Then we have $f^{(i)}(x)=i!f_i\ne 0$. As $f^{(i)}$ is a constant function, its Walsh series representation is simply given by $f^{(i)}(x)=i!f_i$. Now we use Lemma 3.6. The dimension s in our case is 1, and we can choose the function $\mathcal{B}_1$ by $\mathcal{B}_1(0)=i!|f_i|$ and for $k>0$ we set $\mathcal{B}_1(k)=0$. Note the function $\mathcal{B}_1$ defined this way is a q-adically nonincreasing function. Then it follows that there is a constant $C_1>0$ such that the Walsh coefficients of the function $\int_0^x f^{(i)}(t)\,\mathrm{d}t=f^{(i-1)}(x)-f^{(i-1)}(0)$ are bounded by $C_1q^{-a_1}i!|f_i|$ for all k where $v=1$ and the Walsh coefficients are 0 for $v>1$. The Walsh coefficient for $k=0$ is given by $f^{(i-2)}(1)-f^{(i-2)}(0)-f^{(i-1)}(0)$.

Now consider the function $\int_0^x f^{(i-1)}(t)\,\mathrm{d}t=f^{(i-2)}(x)-f^{(i-2)}(0)$. It follows from the above and Lemma 3.6 that the Walsh coefficients of $f^{(i-2)}(x)-f^{(i-2)}(0)$ can be bounded by a q-adically nonincreasing function $\mathcal{B}_2$. Indeed there are constants $C_2,C_3>0$ such that we can choose $\mathcal{B}_2(0)=|f^{(i-2)}(1)-f^{(i-2)}(0)-f^{(i-1)}(0)|$, $\mathcal{B}_2(k)=C_2q^{-a_1}$ for $v=1$, $\mathcal{B}_2(k)=C_3q^{-a_1-a_2}$ for $v=2$, and $\mathcal{B}_2(k)=0$ for $v>2$. Again $\mathcal{B}_2$ is a q-adically nonincreasing function and Lemma 3.6 can again be used.

By using the above argument iteratively we obtain that there is a constant $C>0$ such that $|\hat f(k)|\le Cq^{-a_1-\cdots-a_v}$ for $k=\kappa_1q^{a_1-1}+\cdots+\kappa_vq^{a_v-1}$ with $\kappa_1,\dots,\kappa_v\in\{1,\dots,q-1\}$ and $1\le a_v<\cdots<a_1$. The result thus follows. □

For the case where q is chosen to be a prime number and the bijections φ and η are chosen to be the identity and for $0\le v\le i$ we can choose

$$C_{f,i,v}=\bar C^v\sum_{l=v}^{i}C'^{i-l}l!|f_l|, \tag{3.11}$$

where $\bar C=(2-2\cos(2\pi/q))^{-1/2}$ and $C'=3/2+(2-2\cos(2\pi/q))^{-1/2}$ in Lemma 3.7.

Let $f : [0,1)^s \to \mathbb{R}$ be such that the partial mixed derivatives up to order $\delta \geq 1$ in each variable exist and are continuous. We need some further notation: Let $\boldsymbol{\tau} = (\tau_1, \ldots, \tau_s)$ and

$$f^{(\boldsymbol{\tau})}(\boldsymbol{x}) = \frac{\partial^{\tau_1+\cdots+\tau_s}}{\partial x_1^{\tau_1} \cdots \partial x_s^{\tau_s}} f(\boldsymbol{x}).$$

For $\boldsymbol{\tau} \in \{0, \ldots, \delta\}^s$ let $u(\boldsymbol{\tau}) = \{1 \leq j \leq s : \tau_j = \delta\}$. Let $\boldsymbol{\gamma} = (\gamma_v)_{v \subset \mathbb{N}}$ be an indexed set of nonnegative real numbers. Let $v(\boldsymbol{\tau}) = \{1 \leq j \leq s : \tau_j > 0\}$. Then for $0 < \lambda \leq 1$ and $\mathfrak{p}, \mathfrak{q}, \mathfrak{r} \geq 1$ ($\mathfrak{p}, \mathfrak{q}, \mathfrak{r}$ do not appear in the subscript of N as they do not have influence on our subsequent bounds—we assume only that they are greater than or equal to 1) we define

$$N_{\delta,\lambda,\boldsymbol{\gamma}}(f) = \left(\sum_{\boldsymbol{\tau} \in \{0,\ldots,\delta\}^s} \gamma_{v(\boldsymbol{\tau})}^{-1} \left[V_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}^{(|u(\boldsymbol{\tau})|)} (f^{(\boldsymbol{\tau})}(\cdot, \mathbf{0}_{\mathcal{S}\setminus u(\boldsymbol{\tau})})) \right]^{\mathfrak{r}} \right)^{1/\mathfrak{r}}, \tag{3.12}$$

where, for clarity, we introduce the additional superscript $(|u(\boldsymbol{\tau})|)$ in the Hardy and Krause variation $V_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}^{(|u(\boldsymbol{\tau})|)}$ which indicates the dimension of the function and where for $u(\boldsymbol{\tau}) = \emptyset$ we set $V_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}^{(|u(\boldsymbol{\tau})|}(f^{(\boldsymbol{\tau})}(\cdot, \mathbf{0}_{\mathcal{S}\setminus u(\boldsymbol{\tau})})) = |f^{(\boldsymbol{\tau})}(\mathbf{0})|$.

The weights $\boldsymbol{\gamma}$ are introduced to modify the importance of various coordinate projections and were first introduced in [30]; see also [6, 7]. If for some $v' \subseteq \mathcal{S}$ the weight $\gamma_{v'} = 0$, then we assume that the function f satisfies $V_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}^{(|v'|)}(f^{(\boldsymbol{\tau})}(\cdot, \mathbf{0}_{\mathcal{S}\setminus v'})) = 0$ for all $\boldsymbol{\tau} \in \{0, \ldots, \delta\}^s$ with $v(\boldsymbol{\tau}) = v'$, and in (3.12) we formally set $0/0 = 0$.

The parameters in the definition of $N_{\delta,\lambda,\boldsymbol{\gamma}}$ have the following meaning:

- δ denotes the order of partial derivatives of f required in order for $N_{\delta,\lambda,\boldsymbol{\gamma}}(f)$ to make sense;
- λ is a Hölder-type parameter or fractional order–type parameter of the generalized Hardy and Krause variation; roughly, f needs to have partial derivatives up to order $\delta + \lambda$, where for $0 < \lambda < 1$ this means some type of fractional smoothness or in dimension one a Hölder condition of order λ;
- the Vitali variation is in $\mathfrak{p}$ norm;
- $\mathfrak{q}$ is the norm in the summation of the generalized Hardy and Krause variation;
- $\mathfrak{r}$ is the norm in the summation over the $\boldsymbol{\tau}$;
- $\boldsymbol{\gamma}$ are the weights which regulate the importance of different coordinate projections.

Note that for $\lambda = 1$ and $\mathfrak{p} = \mathfrak{q} = \mathfrak{r} = 2$ the functional $N_{\delta,\lambda,\boldsymbol{\gamma}}$ is just the norm in a weighted reproducing kernel Sobolev space with continuous partial mixed derivatives up to order $\delta + 1$ in each variable. In one dimension the unweighted norm in this reproducing kernel Sobolev space is given by

$$\begin{aligned} &\langle f, g \rangle_{\mathrm{sob,an},\delta+1} \\ &\quad = f(0)g(0) + \cdots + f^{(\delta-1)}(0)g^{(\delta-1)}(0) \\ &\qquad + \int_0^1 f^{(\delta)}(x)\,\mathrm{d}x \int_0^1 g^{(\delta)}(x)\,\mathrm{d}x + \int_0^1 f^{(\delta+1)}(x) g^{(\delta+1)}(x)\,\mathrm{d}x \end{aligned} \tag{3.13}$$

and for higher dimensions one just takes the weighted tensor product of the one-dimensional reproducing kernel Sobolev spaces (see [7] for examples of weighted tensor product reproducing kernel Sobolev spaces). Let the s-dimensional weighted inner

product be denoted by $\langle\cdot,\cdot\rangle_{\mathrm{sob,an},s,\delta+1,\boldsymbol{\gamma}}$ and the corresponding norm $\|\cdot\|_{\mathrm{sob,an},s,\delta+1,\boldsymbol{\gamma}}$ (indeed if the partial mixed derivatives up to order $\delta+1$ of f are continuous on $[0,1]^s$, then we have $\|f\|_{\mathrm{sob,an},s,\delta+1,\boldsymbol{\gamma}} = N_{\delta,1,\boldsymbol{\gamma}}(f)$).

In the following we define a function μ which will be used throughout the paper: Let $\delta \geq 1$ be an integer and let $0 < \lambda \leq 1$ be a real number. Then for $\boldsymbol{k} = (k_1, \ldots, k_s)$ we set

$$\mu_{q,\delta+\lambda}(\boldsymbol{k}) = \sum_{j=1}^{s} \mu_{q,\delta+\lambda}(k_j) \tag{3.14}$$

with

$$\mu_{q,\delta+\lambda}(k) = \begin{cases} 0 & \text{for } k = 0, \\ a_1 + \cdots + a_v & \text{for } v \leq \delta, \\ a_1 + \cdots + a_\delta + \lambda a_{\delta+1} & \text{for } v > \delta, \end{cases} \tag{3.15}$$

where for $k \in \mathbb{N}$ we write $k = \kappa_1 q^{a_1-1} + \cdots + \kappa_v q^{a_v-1}$ with $v \geq 1$, $\kappa_1, \ldots, \kappa_v \in \{1, \ldots, q-1\}$, and $1 \leq a_v < \cdots < a_1$.

THEOREM 3.8. *Let $\delta \geq 1$ be an integer, let $0 < \lambda \leq 1$, let $\mathfrak{p}, \mathfrak{q}, \mathfrak{r} \geq 1$ be real numbers, and let an indexed set $\boldsymbol{\gamma} = (\gamma_v)_{v \subset \mathbb{N}}$ of nonnegative real numbers be given. Let $f : [0,1)^s \to \mathbb{R}$ be such that the partial mixed derivatives up to order δ in each variable exist and such that $N_{\delta,\lambda,\boldsymbol{\gamma}}(f) < \infty$. Then for any $\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\mathbf{0}\}$ it follows that there is a constant $C_{f,q,s,\boldsymbol{\gamma}} > 0$ independent of $\boldsymbol{k}$ such that*

$$|\hat{f}(\boldsymbol{k})| \leq C_{f,q,s,\boldsymbol{\gamma}} q^{-\mu_{q,\delta+\lambda}(\boldsymbol{k})}.$$

Proof. In order to prove the result we use the Taylor series expansion of the function f. We have

$$\begin{aligned} f(\boldsymbol{x}) = {} & \sum_{\boldsymbol{\tau} \in \{0,\ldots,\delta-1\}^s} \frac{\boldsymbol{x}^{\boldsymbol{\tau}}}{\boldsymbol{\tau}!} f^{(\boldsymbol{\tau})}(\mathbf{0}) + \sum_{\emptyset \neq u \subseteq \mathcal{S}} \sum_{\boldsymbol{\tau}_{\mathcal{S}\setminus u} \in \{0,\ldots,\delta-1\}^{s-|u|}} ((\delta-1)!)^{-|u|} \\ & \times \frac{\prod_{j \in \mathcal{S}\setminus u} x_j^{\tau_j}}{\prod_{j \in \mathcal{S}\setminus u} \tau_j!} \int_{[\mathbf{0}_u, \boldsymbol{x}_u)} f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{\mathcal{S}\setminus u})}(\boldsymbol{y}_u, \mathbf{0}_{\mathcal{S}\setminus u}) \prod_{j \in u} (x_j - y_j)^{\delta-1} \, \mathrm{d}\boldsymbol{y}_u. \end{aligned} \tag{3.16}$$

First note that the first sum in (3.16) is a polynomial in $\boldsymbol{x}$ and therefore the Walsh coefficients of this polynomial satisfy the desired bound by Lemma 3.7.

Now we consider the second sum. Let $\emptyset \neq u \subseteq \mathcal{S}$ with $u = \{j_1, \ldots, j_{|u|}\}$ be given. Then for $j \notin u$ the Walsh coefficients satisfy the desired bound by Lemma 3.7. Hence it remains to consider the Walsh coefficients of

$$\begin{aligned} G_u(\boldsymbol{x}_u) &= \int_{[\mathbf{0}_u, \boldsymbol{x}_u)} f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{\mathcal{S}\setminus u})}(\boldsymbol{y}_u, \mathbf{0}_{\mathcal{S}\setminus u}) \prod_{j \in u} (x_j - y_j)^{\delta-1} \, \mathrm{d}\boldsymbol{y}_u \\ &= \int_{[\mathbf{0}_u, \mathbf{1}_u)} f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{\mathcal{S}\setminus u})}(\boldsymbol{y}_u, \mathbf{0}_{\mathcal{S}\setminus u}) \prod_{j \in u} (x_j - y_j)_+^{\delta-1} \, \mathrm{d}\boldsymbol{y}_u, \end{aligned}$$

where $(x-y)_+ = \max(0, x-y)$.

By differentiating the function G_u in each variable $0 \leq k < \delta$ times we obtain (see [32, pp. 153, 154])

$$\frac{\partial^{k|u|}}{\partial \boldsymbol{x}_u^k} G_u(\boldsymbol{x}_u) = \left(\frac{(\delta-1)!}{(\delta-1-k)!} \right)^{|u|} \int_{[\mathbf{0}_u, \boldsymbol{x}_u)} f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{S\setminus u})}(\boldsymbol{y}_u, \mathbf{0}_{S\setminus u}) \prod_{j \in u} (x_j - y_j)^{\delta-1-k} \, \mathrm{d}\boldsymbol{y}_u.$$

Hence $\frac{\partial^{k|u|}}{\partial \boldsymbol{x}_u^k} G_u(\boldsymbol{x}_u) = 0$ if there is at least one $j \in u$ such that $x_j = 0$. Further we have

$$\frac{\partial^{\delta|u|}}{\partial \boldsymbol{x}_u^\delta} G_u(\boldsymbol{x}_u) = ((\delta-1)!)^{|u|} f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{S\setminus u})}(\boldsymbol{x}_u, \mathbf{0}_{S\setminus u}).$$

From $N_{\delta,\lambda,\boldsymbol{\gamma}}(f) < \infty$ it follows that the Walsh coefficients of $f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{\mathcal{S}\setminus u})}(\boldsymbol{x}_u, \mathbf{0}_{\mathcal{S}\setminus u})$ decay with order $\mu_{q,0+\lambda}(k)$ in each variable. Further we have

$$G_u(\boldsymbol{x}_u) = \int_{[\mathbf{0},\boldsymbol{x}_u)} \int_{[\mathbf{0},\boldsymbol{y}_1)} \cdots \int_{[\mathbf{0},\boldsymbol{y}_{\delta-1})} G_u^{(\boldsymbol{\delta}_u)}(\boldsymbol{y}_\delta)\, \mathrm{d}\boldsymbol{y}_\delta \cdots \mathrm{d}\boldsymbol{y}_1$$

as the function G_u, and its derivatives are 0 if at least one $x_j = 0$ for $j \in u$; i.e., we have

$$\int_{[\mathbf{0},\boldsymbol{x}_u)} G_u^{(\boldsymbol{\tau})}(\boldsymbol{y})\, \mathrm{d}\boldsymbol{y} = \sum_{v \subseteq u} (-1)^{u\setminus v} G_u^{(\boldsymbol{\tau}-\mathbf{1})}(\boldsymbol{x}_v, \mathbf{0}_{u\setminus v}) = G_u^{(\boldsymbol{\tau}-\mathbf{1})}(\boldsymbol{x}_u).$$

Hence it follows by repeated use of Lemma 3.6 that the desired bound holds for G_u and thus the result follows from (3.16). □

For the case where q is chosen to be a prime number and the bijections φ and η are chosen to be the identity, we can also obtain an explicit constant in Theorem 3.8. Indeed, using Lemmas 3.2 and 3.6 together with the explicit constant (3.10) and Lemma 3.7 together with the explicit constant (3.11), we obtain that the constant $C_{q,\boldsymbol{\gamma}}$ can be chosen as

$$\begin{aligned} C_{f,q,s,\boldsymbol{\gamma}} = {} & \sum_{\substack{\boldsymbol{\tau} \in \{0,\ldots,\delta-1\}^s \\ \gamma_{v(\boldsymbol{\tau})} \neq 0}} |f^{(\boldsymbol{\tau})}(\mathbf{0})| \hat{C}^{\tau_1+\cdots+\tau_s} + \sum_{\emptyset \neq u \subseteq \mathcal{S}} q^{|u|} C_{s,u}^\delta \\ & \times \sum_{\substack{\boldsymbol{\tau}_{\mathcal{S}\setminus u} \in \{0,\ldots,\delta-1\}^{s-|u|} \\ \gamma_{u\cup v(\boldsymbol{\tau}_{\mathcal{S}\setminus u})} \neq 0}} \hat{C}^{\sum_{j\in\mathcal{S}\setminus u} \tau_j} V_{\lambda,1}^{(|u|)}(f^{(\boldsymbol{\delta}_u, \boldsymbol{\tau}_{\mathcal{S}\setminus u})}(\cdot, \mathbf{0}_{\mathcal{S}\setminus u})), \end{aligned}$$

where $\hat{C} = 1$ for $2 \le q < 6$ and $\hat{C} = (2 - 2\cos(2\pi/q))^{-1/2}$ for $q > 6$ (note that for $q > 6$ we have $\hat{C} > 1$) and

$$C_{s,u} = 3^{|u|}(2 - 2\cos(2\pi/q))^{-|u|/2}(3/2 + (2 - 2\cos(2\pi/q))^{-1/2})^{s-|u|}.$$

As noted above, under certain conditions we can write $V_{\lambda,1}^{(|u|)}$ also as an integral; see (3.4).

We give a further useful estimation of the constant by separating the dependence of the function from the constants. This way we obtain

$$C_{f,q,s,\boldsymbol{\gamma}} \le C_{\delta,q,s,\boldsymbol{\gamma}} N_{\delta,\lambda,\boldsymbol{\gamma}}(f),$$

where

$$\begin{aligned} C_{\delta,q,s,\boldsymbol{\gamma}} = {} & \sum_{\boldsymbol{\tau} \in \{0,\ldots,\delta-1\}^s} \gamma_{v(\boldsymbol{\tau})} \hat{C}^{\tau_1+\cdots+\tau_s} \\ & + \sum_{\emptyset \neq u \subseteq \mathcal{S}} q^{|u|} C_{s,u}^\delta \sum_{\boldsymbol{\tau}_{\mathcal{S}\setminus u} \in \{0,\ldots,\delta-1\}^{s-|u|}} \gamma_{u\cup v(\boldsymbol{\tau}_{\mathcal{S}\setminus u})} \hat{C}^{\sum_{j\in\mathcal{S}\setminus u} \tau_j}. \end{aligned} \tag{3.17}$$

Consider now the case where the weights are of product form (see [7]); i.e., there is a sequence of positive real numbers $(\gamma_j)_{j\in\mathbb{N}}$ such that $\gamma_v = \prod_{j\in v}\gamma_j$ for all $v \subset \mathbb{N}$ and for $v = \emptyset$ we set $\gamma_v = 1$. If q is now prime with $2 \le q < 6$, then

$$C_{\delta,q,s,\boldsymbol{\gamma}} = \prod_{j=1}^{s}(1+\gamma_j(\delta-1)) + \prod_{j=1}^{s}\left[(1+\gamma_j(\delta-1))(3/2+\hat{C}) + \gamma_j 3q\hat{C}\right]$$
$$- \prod_{j=1}^{s}\left[(1+\gamma_j(\delta-1))(3/2+\hat{C})\right].$$

For example, for $q = 2$, $\delta = 1$ and product weights we obtain

$$C_{1,2,s,\boldsymbol{\gamma}} = 1 - 2^s + 2^s\prod_{j=1}^{s}(1+6\gamma_j).$$

The approach used here for prime q and φ the identity map can also be used for arbitrary prime powers q and arbitrary mappings φ with $\varphi(0) = 0$. Hence we obtain the following corollary.

COROLLARY 3.9. *Under the assumptions of Theorem* 3.8 *there exists a constant* $C_{\delta,q,s,\boldsymbol{\gamma}} > 0$ *independent of* $\boldsymbol{k}$ *and* f *such that*

$$|\hat{f}(\boldsymbol{k})| \le C_{\delta,q,s,\boldsymbol{\gamma}} N_{\delta,\lambda,\boldsymbol{\gamma}}(f) q^{-\mu_{q,\delta+\lambda}(\boldsymbol{k})} \quad \text{for all } \boldsymbol{k} \in \mathbb{N}_0^s,$$

where $\mu_{q,\delta+\lambda}$ *is given by* (3.14) *and* (3.15).

Remark 3.10. The results in this section also hold for the following generalization. In the definition of $N_{\delta,\lambda,\boldsymbol{\gamma}}$ we anchored the function and its derivatives at 0, i.e., we used $V^{(|u(\boldsymbol{\tau})|)}_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}(f(\cdot,\mathbf{0}_{\mathcal{S}\setminus u(\boldsymbol{\tau})}))$. This can be generalized by choosing an arbitrary $\boldsymbol{a} \in [0,1]^s$ and using $V^{(|u(\boldsymbol{\tau})|)}_{\lambda,\mathfrak{p},\mathfrak{q},\mathbf{1}}(f(\cdot,\boldsymbol{a}_{S\setminus u(\boldsymbol{\tau})}))$ in the definition of $N_{\delta,\lambda,\boldsymbol{\gamma}}$. It can be shown that in this case we also have Theorem 3.8 and Corollary 3.9.

3.3. Convergence of the Walsh series. For our purposes here we need strong assumptions on the convergence of the Walsh series $S(f)(\boldsymbol{x}) = \sum_{\boldsymbol{k}\in\mathbb{N}_0^s}\hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})$ to the function f, i.e., we require that the partial series $S_m(f)(\boldsymbol{x}) = \sum_{\substack{\boldsymbol{k}\in\mathbb{N}_0^s\\ k_j<m}}\hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})$ converge to $f(\boldsymbol{x})$ at every point $\boldsymbol{x} \in [0,1)^s$ as $m \to \infty$. (Note that the Walsh series $S(f)$ for the functions considered in this paper is always absolutely convergent, i.e., $\sum_{\boldsymbol{k}\in\mathbb{N}_0^s}|\hat{f}(\boldsymbol{k})| < \infty$; hence the Walsh series $S(f)(\boldsymbol{x})$ is uniformly bounded by $\sum_{\boldsymbol{k}\in\mathbb{N}_0^s}|\hat{f}(\boldsymbol{k})|$ and therefore $S(f)(\boldsymbol{x})$ itself converges at every point $\boldsymbol{x} \in [0,1)^s$.) This is necessary as we want to approximate the integral at function values $\boldsymbol{x}_n$, and for our analysis we deal with the Walsh series rather than the function itself; hence it is paramount that the function and its Walsh series coincide at every point $\boldsymbol{x} \in [0,1)^s$.

As the functions considered here are at least differentiable it follows that they are continuous, and using the argument in [10, p. 373] it follows that the Walsh series really converges at every point $\boldsymbol{x} \in [0,1)^s$ to the function value $f(\boldsymbol{x})$. Indeed, for a given $\boldsymbol{x} \in [0,1)^s$ we have

$$S_{q^m}(f)(\boldsymbol{x}) = \sum_{\boldsymbol{k}\in\{0,\dots,q^m-1\}^s}\hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \mathrm{Vol}(J_{\boldsymbol{x}})^{-1}\int_{J_{\boldsymbol{x}}} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x},$$

where $J_{\boldsymbol{x}} = \prod_{j=1}^{s}[q^{-m}\lfloor q^m x_j\rfloor, q^{-m}\lfloor q^m x_j\rfloor + q^{-m})$. The last equality follows from

$$\sum_{\boldsymbol{k}\in\{0,\dots,q^m-1\}^s} \hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \int_{[0,1)^s} f(\boldsymbol{y}) \sum_{\boldsymbol{k}\in\{0,\dots,q^m-1\}^s} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{y})}\,\mathrm{d}\boldsymbol{y}$$

$$= \mathrm{Vol}(J_{\boldsymbol{x}})^{-1} \int_{J_{\boldsymbol{x}}} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}.$$

As the function f is continuous, it immediately follows that $S_{q^m}(f)(\boldsymbol{x})$ converges to $f(\boldsymbol{x})$ as m goes to infinity, and the result follows.

3.4. A function space based on Walsh functions containing smooth functions. In this section we use the above results to define a function space based on Walsh functions which contains smooth functions for smoothness conditions considered in the previous section.

Let $\vartheta > 1$ be a real number and q a prime power. Then for $\boldsymbol{k} \in \mathbb{N}_0^s$ we set $r_{q,\vartheta}(\boldsymbol{k}) = q^{-\mu_{q,\vartheta}(\boldsymbol{k})}$, where $\mu_{q,\vartheta}$ is given by (3.14) and (3.15) (if ϑ is an integer, then choose $\lambda = 1$ and $\delta = \vartheta - 1$ and otherwise $\delta = \lfloor\vartheta\rfloor$ and $\lambda = \vartheta - \lfloor\vartheta\rfloor$).

Now we define a function space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}} \subseteq \mathcal{L}_2([0,1)^s)$ with norm $\|\cdot\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}}$ given by

$$\|f\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}} = \max_{\substack{u\subseteq\mathcal{S}\\ \gamma_u\neq 0}} \gamma_u^{-1} \sup_{\boldsymbol{k}_u\in\mathbb{N}^{|u|}} \frac{|\hat{f}(\boldsymbol{k}_u, \boldsymbol{0}_{\mathcal{S}\setminus u})|}{r_{q,\vartheta}(\boldsymbol{k}_u)},$$

where again for $\gamma_u = 0$ we assume that $\hat{f}(\boldsymbol{k}_u, \boldsymbol{0}_{\mathcal{S}\setminus u}) = 0$ for all $\boldsymbol{k}_u \in \mathbb{N}^{|u|}$.

The following result follows now directly from Corollary 3.9.

COROLLARY 3.11. *Let $\delta \geq 1$, let $0 < \lambda \leq 1$, let $\mathfrak{p}, \mathfrak{q}, \mathfrak{r} \geq 1$, and let an indexed set $\boldsymbol{\gamma} = (\gamma_v)_{v\subset\mathbb{N}}$ of nonnegative real numbers be given. Then there exists a constant $C_{\delta,q,s,\boldsymbol{\gamma}} > 0$ such that for every function $f : [0,1)^s \to \mathbb{R}$, whose partial mixed derivatives up to order δ exist, we have*

$$\|f\|_{\mathcal{E}_{s,q,\delta+\lambda,\boldsymbol{\gamma}}} \leq C_{\delta,q,s,\boldsymbol{\gamma}} N_{\delta,\lambda,\boldsymbol{\gamma}}(f),$$

where $\mu_{q,\delta+\lambda}$ is given by (3.14) *and* (3.15).

Again, using (3.17), an explicit constant in Corollary 3.11 can be obtained for q prime and φ the identity map. For all other cases (i.e., arbitrary prime powers q and mappings φ with $\varphi(0) = 0$) explicit constants can be obtained as well, but in this case the constant may also depend on the particular choice of q and φ. Further, as noted above, for $\lambda = 1$ and $\mathfrak{p} = \mathfrak{q} = \mathfrak{r} = 2$ the functional $N_{\delta,\lambda,\boldsymbol{\gamma}}$ coincides with the norm in a certain Sobolev space (the one-dimensional inner product for this Sobolev space is given by (3.13), and for higher dimensions one just considers tensor products of the one-dimensional space), and hence it follows that $\mathcal{E}_{s,q,\delta+1,\boldsymbol{\gamma}}$ contains certain Sobolev spaces. Hence Corollary 3.11 shows that if we want to prove results for smooth functions, it is enough to consider $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$. (In the following we design quasi–Monte Carlo rules which work well for $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ rather than directly for smooth functions, so the results for smooth functions come as a byproduct.)

A function $f \in \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ can be written as a sum of their anova terms $f = \sum_{u\subseteq\mathcal{S}} f_u$ (see [8]). For a function $f \in \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ given by $f(\boldsymbol{x}) = \sum_{\boldsymbol{k}\in\mathbb{N}_0^s} \hat{f}(\boldsymbol{k})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})$ the anova term f_u corresponding to a subset $u \subseteq \mathcal{S}$ is simply given by

$$f_u(\boldsymbol{x}_u) = \sum_{\boldsymbol{k}_u\in\mathbb{N}^{|u|}} \hat{f}(\boldsymbol{k}_u, \boldsymbol{0}_{\mathcal{S}\setminus u})\mathrm{wal}_{\boldsymbol{k}_u}(\boldsymbol{x}_u).$$

If for some $u \subseteq \mathcal{S}$ we have $\gamma_u = 0$, then this implies that the anova term corresponding to u satisfies $f_u \equiv 0$. Hence the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ consists only of functions whose anova term belonging to a subset u is zero for all subsets u with $\gamma_u = 0$ (see also [7]).

4. Digital $(t, \alpha, \beta, n \times m, s)$-nets and digital $(t, \alpha, \beta, \sigma, s)$-sequences. In this section we give the definition of digital $(t, \alpha, \beta, n \times m, s)$-nets and digital $(t, \alpha, \beta, \sigma, s)$-sequences. Similar point sets were introduced in [2].

4.1. The digital construction scheme. The construction of the point set used here is a slight generalization of the digital construction scheme introduced by Niederreiter [20] by breaking with the tradition of having square generating matrices.

DEFINITION 4.1. *Let q be a prime power and let $n, m, s \geq 1$ be integers. Let $C_1, \dots, C_s$ be $n \times m$ matrices over the finite field $\mathbb{F}_q$ of order q. Now we construct q^m points in $[0,1)^s$: for $0 \leq h \leq q^m - 1$ let $h = h_0 + h_1 q + \cdots + h_{m-1} q^{m-1}$ be the q-adic expansion of h. Consider an arbitrary but fixed bijection $\varphi : \{0, 1, \dots, q-1\} \longrightarrow \mathbb{F}_q$. Identify h with the vector $\vec{h} = (\varphi(h_0), \dots, \varphi(h_{m-1}))^\top \in \mathbb{F}_q^m$, where $\top$ means the transpose of the vector (note that we write $\vec{h}$ for vectors in the finite field $\mathbb{F}_q^m$ and $\boldsymbol{h}$ for vectors of integers or real numbers). For $1 \leq j \leq s$ multiply the matrix C_j by $\vec{h}$, i.e.,*

$$C_j \vec{h} =: (y_{j,1}(h), \dots, y_{j,n}(h))^\top \in \mathbb{F}_q^n,$$

and set

$$x_{h,j} := \frac{\varphi^{-1}(y_{j,1}(h))}{q} + \cdots + \frac{\varphi^{-1}(y_{j,n}(h))}{q^n}.$$

The point set $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{q^m-1}\}$ is called a digital net (over $\mathbb{F}_q$) (with generating matrices $C_1, \dots, C_s$).

For $n, m = \infty$ we obtain a sequence $\{\boldsymbol{x}_0, \boldsymbol{x}_1, \dots\}$, which is called a digital sequence (over $\mathbb{F}_q$) (with generating matrices $C_1, \dots, C_s$).

Niederreiter's concept of a digital (t, m, s)-net and a digital (t, s)-sequence will appear as a special case in the subsequent section. Further, the digital nets considered below all satisfy $n \geq m$.

For a digital net with generating matrices $C_1, \dots, C_s$ let $\mathcal{D} = \mathcal{D}(C_1, \dots, C_s)$ be the dual net given by

$$\mathcal{D} = \{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\} : C_1^\top \vec{k}_1 + \cdots + C_s^\top \vec{k}_s = \vec{0}\},$$

where for $\boldsymbol{k} = (k_1, \dots, k_s)$ with $k_j = \kappa_{j,0} + \kappa_{j,1} q + \cdots$ and $\kappa_{j,i} \in \{0, \dots, q-1\}$ let $\vec{k}_j = (\varphi(\kappa_{j,0}), \dots, \varphi(\kappa_{j,n-1}))^\top$. Further, for $\emptyset \neq u \subseteq \mathcal{S}$ let $\mathcal{D}_u = \mathcal{D}((C_j)_{j \in u})$ and $\mathcal{D}_u^* = \mathcal{D}_u \cap \mathbb{N}^{|u|}$.

Note that throughout the paper Walsh functions and digital nets are defined using the same finite field $\mathbb{F}_q$ and the same bijection φ.

The following lemma is a slight generalization of [26, Lemma 2.5].

LEMMA 4.2. *Let $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{q^m-1}\}$ be a digital net over $\mathbb{F}_q$ with bijection φ, where $\varphi(0) = 0$, generated by the $n \times m$ matrices $C_1, \dots, C_s$ over $\mathbb{F}_q$, $n, m \geq 1$. Then for any vector $\boldsymbol{k} = (k_1, \dots, k_s)$ of nonnegative integers $0 \leq k_1, \dots, k_s < q^n$ we have*

$$\sum_{h=0}^{q^m-1} {}_{\mathbb{F}_q, \varphi}\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_h) = \begin{cases} q^m & \text{if } \boldsymbol{k} \in \mathcal{D} \cup \{\boldsymbol{0}\}, \\ 0 & \text{else}, \end{cases}$$

where $\boldsymbol{0}$ is the zero vector in $\mathbb{N}_0^s$.

4.2. $(t, \alpha, \beta, n \times m, s)$-nets and $(t, \alpha, \beta, \sigma, s)$-sequences. Digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences were first introduced in [2]. Those point sets were used for quasi–Monte Carlo rules which achieve the optimal rate of convergence of the worst-case error in Korobov spaces (which are reproducing kernel Hilbert spaces of smooth periodic functions). By a slight generalization of digital (t, α, β, m, s)-nets we will show that those digital nets also achieve the optimal convergence of the worst-case error in the space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ for all $1 < \vartheta \le \alpha$.

The t-value of a (t, m, s)-net is a quality parameter for the distribution properties of the net. A low t-value yields well-distributed point sets, and it has been shown (see, for example, [4, 20]) that a small t-value also guarantees a small worst-case error for integration in Sobolev spaces for which the partial first derivatives are square integrable. In [2] it was shown how the definition of the t-value needs to be modified in order to obtain faster convergence rates for periodic Sobolev spaces for which the partial derivatives up to order $\delta \le \beta$ are square integrable. Here we extend those result in several ways. First we generalize the digital (t, α, β, m, s)-nets used in [2] to digital $(t, \alpha, \beta, n \times m, s)$-nets and show that we then can remove the periodicity assumption necessary in [2]. Further, if the derivatives up to order δ also have bounded variation with coefficient $0 < \lambda \le 1$, then we have shown that such functions are in $\mathcal{E}_{s,q,\delta+\lambda,\boldsymbol{\gamma}}$.

In the following we repeat some definitions and results from [2] and give the definition of digital $(t, \alpha, \beta, n \times m, s)$-nets and digital $(t, \alpha, \beta, \sigma, s)$-sequences.

For a real number $\vartheta > 1$ the definition of the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ suggests that we define the metric $\mu_{q,\vartheta}(\boldsymbol{k}, \boldsymbol{l}) = \mu_{q,\vartheta}(\boldsymbol{k} \ominus \boldsymbol{l})$ on $\mathbb{N}_0^s$, where $\mu_{q,\vartheta}(\boldsymbol{k} \ominus \boldsymbol{l})$ is given by (3.14) and (3.15), which is an extension of the metric introduced in [19]; see also [28] (the metric for $\vartheta = 1$ can be used for Walsh spaces, for example, as considered in [4]; for this case one basically obtains the metric in [19, 28]). As we will see later, in order to obtain a small worst-case error in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ we need digital nets for which $\min\{\mu_{q,\vartheta}(\boldsymbol{k}) : \boldsymbol{k} \in \mathcal{D}\}$ is large. By translating this property into a linear independence property of the row vectors of the generating matrices $C_1, \dots, C_s$ we arrive at the following definition.

DEFINITION 4.3. *Let $n, m, \alpha \ge 1$ be natural numbers, let $0 < \beta \le \alpha m/n$ be a real number, and let $0 \le t \le \beta n$ be a natural number. Let $\mathbb{F}_q$ be the finite field of prime power order q and let $C_1, \dots, C_s \in \mathbb{F}_q^{n \times m}$ with $C_j = (c_{j,1}, \dots, c_{j,n})^\top$. If for all $1 \le i_{j,\nu_j} < \cdots < i_{j,1} \le n$, where $0 \le \nu_j \le m$ for all $j = 1, \dots, s$, with*

$$\sum_{j=1}^{s} \sum_{l=1}^{\min(\nu_j, \alpha)} i_{j,l} \le \beta n - t$$

the vectors

$$c_{1,i_{1,\nu_1}}, \dots, c_{1,i_{1,1}}, \dots, c_{s,i_{s,\nu_s}}, \dots, c_{s,i_{s,1}}$$

are linearly independent over $\mathbb{F}_q$, then the digital net with generating matrices $C_1, \dots, C_s$ is called a digital $(t, \alpha, \beta, n \times m, s)$-net over $\mathbb{F}_q$. Further we call a digital $(t, \alpha, \beta, n \times m, s)$-net over $\mathbb{F}_q$ with the largest possible value of β, i.e., $\beta = \alpha m/n$, a digital $(t, \alpha, n \times m, s)$-net over $\mathbb{F}_q$.

If t is the smallest nonnegative integer such that the digital net generated by $C_1, \dots, C_s$ is a digital $(t, \alpha, \beta, n \times m, s)$-net, then we call the digital net a strict digital $(t, \alpha, \beta, n \times m, s)$-net or a strict digital $(t, \alpha, n \times m, s)$-net if $\beta = \alpha m/n$.

Remark 4.4. Using duality theory (see [22]) it follows that for a digital $(t, \alpha, \beta, n \times m, s)$-net we have $\min_{\boldsymbol{k} \in \mathcal{D}} \mu_{q,\alpha}(\boldsymbol{k}) > \beta n - t$ and for a strict digital $(t, \alpha, \beta, n \times m, s)$-net

we have $\min_{\boldsymbol{k}\in\mathcal{D}} \mu_{q,\alpha}(\boldsymbol{k}) = \beta n - t + 1$. Hence digital $(t, \alpha, \beta, n \times m, s)$-nets with high quality have a large value of $\beta n - t$.

Remark 4.5. In summary the parameters $t, \alpha, \beta, n, m, s$ have the following meaning:

- s denotes the dimension of the point set.
- n and m denote the size of the generating matrices for digital nets, i.e., the generating matrices are of size $n \times m$; in particular this means the point set has q^m points.
- t denotes the quality parameter of the point set; a low t-value means high quality. In the upper bound, t is a quality parameter related to the constant in the upper bound.
- β is also a quality parameter. We will see later that the integration error is roughly q^{-n}. This is of course true only within boundaries, which is the reason for the parameter β, i.e., the integration error is roughly $q^{-\beta n}$. Hence β is a quality parameter related to the convergence rate.
- α is the smoothness parameter of the point set.

We can group the parameters also in the following way:

- m, n, s are fixed parameters, i.e., they specify the number and size of the generating matrices.
- α is a variable parameter, i.e., given (fixed) generating matrices, we can, for example, generate a $(t_1, 1, \beta_1, 10 \times 5, 5)$-net, a $(t_2, 2, \beta_2, 10 \times 5, 5)$-net, and so on (note the point set is always the same in each instance; the values $t_1, t_2, \ldots, \beta_1, \beta_2, \ldots$ may differ). This is necessary as in the upper bounds α will be the smoothness of the integrand, which may not be known explicitly.
- t and β are dependent parameters; they will depend on the generating matrices and on α. For given generating matrices, it is desirable to know the values of β and t for each value of $\alpha \in \mathbb{N}$.

Digital $(t, \alpha, \beta, n \times m, s)$-nets do not exist for arbitrary choices of the parameters $t, \alpha, \beta, n, m, s$; see [2]. The digital nets considered in [2] had the restriction that $n = m$, and special attention was paid to those digital nets with high quality, i.e., where $\alpha = \beta$. In this paper, a special role will be played by those digital nets for which $n = \alpha m$ and $\beta = 1$. The restriction on the linear independence of the digital nets comprises now $n - t = \alpha m - t$ row vectors, which is the same as in [2], with the only difference being that the size of the generating matrices is now bigger since now each generating matrix has $n = \alpha m$ rows. Because those digital nets play a special role in this work, we have the following definition.

DEFINITION 4.6. *A digital $(t, \alpha, 1, \alpha m \times m, s)$-net over $\mathbb{F}_q$ is called a digital $(t, \alpha, \alpha m \times m, s)$-net over $\mathbb{F}_q$. A strict digital $(t, \alpha, 1, \alpha m \times m, s)$-net over $\mathbb{F}_q$ is called a strict digital $(t, \alpha, \alpha m \times m, s)$-net over $\mathbb{F}_q$.*

Remark 4.7. For practical purposes we would like to explicitly know digital $(t, \alpha, \alpha m \times m, s)$-nets for all $\alpha, m, s \geq 1$ with t as small as possible. (As will be shown later, they achieve the optimal rate of convergence of the integration error of integrands for which all mixed partial derivatives of order α are, for example, square integrable, thus their usefulness.)

Further, for given $\alpha, m, s \geq 1$ and a given digital $(t, \alpha, \alpha m \times m, s)$-net P, we would then also like to know the t'- and β'-values of this point set P when viewed as a digital $(t', \delta, \beta', \alpha m \times m, s)$-net for all values $\delta \in \mathbb{N}$, i.e., t' and β' are functions of δ. (This is because we would also like to know how well such a digital net P performs if the integrand has partial mixed derivatives of order up to δ, because we might not

know the smoothness of the integrand, but still would wish that P performs as well as possible.)

We can also define sequences of points for which the first q^m points form a digital $(t, \alpha, \beta, n \times m, s)$-net. In the classical case [20] one can just consider the left-upper $m \times m$ submatrices of the generating matrices of a digital sequence and determine the net properties of these for each $m \in \mathbb{N}$. Here, on the other hand, we are considering digital nets whose generating matrices are $n \times m$ matrices. So we would have to consider the left-upper $n_m \times m$ submatrices of the generating matrices of the digital sequence for each $m \in \mathbb{N}$ and where $(n_m)_{m\in\mathbb{N}}$ is a sequence of natural numbers. For our purposes here it is enough to consider only n_m of the form σm for some given $\sigma \in \mathbb{N}$.

DEFINITION 4.8. *Let $\alpha, \sigma \geq 1$ and $t \geq 0$ be integers and let $0 < \beta \leq \alpha/\sigma$ be a real number. Let $\mathbb{F}_q$ be the finite field of prime power order q and let $C_1, \ldots, C_s \in \mathbb{F}_q^{\infty\times\infty}$ with $C_j = (c_{j,1}, c_{j,2}, \ldots)^\top$. Further let $C_{j,\sigma m\times m}$ denote the left upper $\sigma m \times m$ submatrix of C_j. If for all $m > t/(\beta\sigma)$ the matrices $C_{1,\sigma m\times m}, \ldots, C_{s,\sigma m\times m}$ generate a digital $(t, \alpha, \beta, \sigma m \times m, s)$-net, then the digital sequence with generating matrices $C_1, \ldots, C_s$ is called a digital $(t, \alpha, \beta, \sigma, s)$-sequence over $\mathbb{F}_q$. Further we call a digital $(t, \alpha, 1, \alpha, s)$-sequence over $\mathbb{F}_q$ a digital (t, α, s)-sequence over $\mathbb{F}_q$.*

If t is the smallest nonnegative integer such that the digital sequence generated by $C_1, \ldots, C_s$ is a digital $(t, \alpha, \beta, \sigma, s)$-sequence, then we call the digital sequence a strict digital $(t, \alpha, \beta, \sigma, s)$-sequence or a strict digital (t, α, s)-sequence if $\alpha = \sigma$ and $\beta = 1$.

For brevity we will often write $(t, \alpha, \beta, n \times m, s)$-net instead of digital $(t, \alpha, \beta, n \times m, s)$-net over $\mathbb{F}_q$. The same applies to the other notions defined above.

Remark 4.9. Note that the definition of a digital $(t, 1, m\times m, s)$-net coincides with the definition of a digital (t, m, s)-net and the definition of a digital $(t, 1, s)$-sequence coincides with the definition of a digital (t, s)-sequence as defined by Niederreiter [20]. Further note that the t-value depends on α, β, and σ, i.e., $t = t(\alpha, \beta, \sigma)$ or $t = t(\alpha)$ if $\alpha = \sigma$ and $\beta = 1$.

The definition of (t, α, s)-sequences here differs slightly from the definition in [2]. Indeed the definition of a (t, α, s)-sequence in [2] corresponds to a $(t, \alpha, \alpha, 1, s)$-sequence in the terminology of this paper, whereas here we call a $(t, \alpha, 1, \alpha, s)$-sequence a (t, α, s)-sequence. On the other hand note that the condition of linear independence in Definition 4.3 is the same in both cases; i.e., the sum $i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha)}$ needs to be bounded by $\alpha m - t$ for all m for $(t, \alpha, 1, \alpha, s)$-sequences and also for $(t, \alpha, \alpha, 1, s)$-sequences.

4.3. Some properties of $(t, \alpha, \beta, n \times m, s)$-nets and $(t, \alpha, \beta, \sigma, s)$-sequences. The properties of such digital nets and sequences shown in [2] also hold here. For example, it was shown there that a digital (t, α, m, s)-net is also a digital $(\lceil t\alpha'/\alpha\rceil, \alpha', m, s)$-net for all $1 \leq \alpha' \leq \alpha$ and every digital (t, α, s)-sequence is also a digital $(\lceil t\alpha'/\alpha\rceil, \alpha', s)$-sequence for all $1 \leq \alpha' \leq \alpha$. In the same way we have the following theorem.

THEOREM 4.10. *Let P be a digital $(t, \alpha, \beta, n \times m, s)$-net over $\mathbb{F}_q$ and let S be a digital $(t, \alpha, \beta, \sigma, s)$-sequence over $\mathbb{F}_q$. Then we have the following:*

(i) *P is a digital $(t', \alpha, \beta', n \times m, s)$-net for all $1 \leq \beta' \leq \beta$ and all $t \leq t' \leq \beta' m$, and S is a digital $(t', \alpha, \beta', \sigma, s)$-sequence for all $1 \leq \beta' \leq \beta$ and all $t \leq t'$.*

(ii) *P is a digital $(t', \alpha', \beta', n \times m, s)$-net for all $1 \leq \alpha' \leq n$ where $\beta' = \beta \min(\alpha, \alpha')/\alpha$ and $t' = \lceil t \min(\alpha, \alpha')/\alpha\rceil$, and S is a digital $(t', \alpha', \beta', \sigma, s)$-sequence for all $\alpha' \geq 1$ where $\beta' = \beta \min(\alpha, \alpha')/\alpha$ and where $t' = \lceil t \min(\alpha, \alpha')/\alpha\rceil$.*

(iii) *Any digital* $(t, \alpha, n \times m, s)$*-net is a digital* $(\lceil t\alpha'/\alpha \rceil, \alpha', n \times m, s)$*-net for all* $1 \le \alpha' \le \alpha$ *and every digital* (t, α, σ, s)*-sequence is a digital* $(\lceil t\alpha'/\alpha \rceil, \alpha', \sigma, s)$*-sequence for all* $1 \le \alpha' \le \alpha$.

(iv) *If* $C_1, \dots, C_s \in \mathbb{Z}_b^{n \times m}$ *are the generating matrices of a digital* $(t, \alpha, \beta, n \times m, s)$*-net, then the matrices* $C_1^{(n')}, \dots, C_s^{(n')}$*, where* $C_j^{(n')}$ *consists of the first* n' *rows of* C_j*, generate a digital* $(t, \alpha, \beta, n' \times m, s)$*-net for all* $1 \le n' \le n$.

(v) *Any digital* $(t, \alpha, \beta, \sigma, s)$*-sequence is a digital* $(t, \alpha, \beta, \sigma', s)$*-sequence for all* $1 \le \sigma' \le \sigma$.

4.4. Constructions of $(t, \alpha, \beta, n \times m, s)$-nets and (t, α, σ, s)-sequences. In this section we show how explicit examples of $(t, \alpha, \beta, n \times m, s)$-nets and $(t, \alpha, \beta, \sigma, s)$-sequences can be constructed. The idea for the construction is based on the construction method presented in [2].

Let $d \ge 1$ and let $C_1, \dots, C_{sd}$ be the generating matrices of a digital (t, m, sd)-net. Note that many explicit examples of such generating matrices are known; see, for example, [9, 20, 23, 31] and the references therein. For the construction of a (t, α, m, s)-net any of the above-mentioned explicit constructions can be used, but as will be shown below the quality of the (t, α, m, s)-net obtained depends on the quality of the underlying digital (t, m, sd)-net on which our construction is based on.

Let $C_j = (c_{j,1}, \dots, c_{j,m})^\top$ for $j = 1, \dots, sd$; i.e., $c_{j,l}$ are the row vectors of C_j. Now let the matrix $C_j^{(d)}$ be made of the first rows of the matrices $C_{(j-1)d+1}, \dots, C_{jd}$, then the second rows of $C_{(j-1)d+1}, \dots, C_{jd}$, and so on. The matrix $C_j^{(d)}$ is then a $dm \times m$ matrix; i.e., $C_j^{(d)} = (c_{j,1}^{(d)}, \dots, c_{j,dm}^{(d)})^\top$, where $c_{j,l}^{(d)} = c_{u,v}$ with $l = (v-j)d + u$, $1 \le v \le m$, and $(j-1)d < u \le jd$ for $l = 1, \dots, dm$ and $j = 1, \dots, s$. The following result is a slight generalization of [2, Theorem 3] and can be obtained using the same proof technique.

THEOREM 4.11. *Let* $d \ge 1$ *be a natural number and let* $C_1, \dots, C_{sd}$ *be the generating matrices of a digital* (t', m, sd)*-net over the finite field* $\mathbb{F}_q$ *of prime power order* q*. Let* $C_1^{(d)}, \dots, C_s^{(d)}$ *be defined as above. Then for any* $\alpha \ge 1$ *the matrices* $C_1^{(d)}, \dots, C_s^{(d)}$ *are generating matrices of a digital* $(t, \alpha, \min(1, \alpha/d), dm \times m, s)$*-net over* $\mathbb{F}_q$ *with*

$$t = \min(\alpha, d)\, t' + \left\lceil \frac{s(d-1)\min(\alpha, d)}{2} \right\rceil.$$

The above construction and Theorem 4.11 can easily be extended to $(t, \alpha, \beta, \sigma, s)$-sequences. Indeed, let $d \ge 1$ and let $C_1, \dots, C_{sd}$ be the generating matrices of a digital (t, sd)-sequence. Again many explicit generating matrices are known; see, for example, [9, 20, 23, 31]. Let $C_j = (c_{j,1}, c_{j,2}, \dots)^\top$ for $j = 1, \dots, sd$; i.e., $c_{j,l}$ are the row vectors of C_j. Now let the matrix $C_j^{(d)}$ be made of the first rows of the matrices $C_{(j-1)d+1}, \dots, C_{jd}$, then the second rows of $C_{(j-1)d+1}, \dots, C_{jd}$, and so on, i.e.,

$$C_j^{(d)} = (c_{(j-1)d+1,1}, \dots, c_{jd,1}, c_{(j-1)d+1,2}, \dots, c_{jd,2}, \dots)^\top.$$

The following theorem states that the matrices $C_1^{(d)}, \dots, C_s^{(d)}$ are the generating matrices of a digital $(t, \alpha, \min(1, \alpha/d), d, s)$-sequence; cf. [2, Theorem 4].

THEOREM 4.12. *Let* $d \ge 1$ *be a natural number and let* $C_1, \dots, C_{sd}$ *be the generating matrices of a digital* (t', sd)*-sequence over the finite field* $\mathbb{F}_q$ *of prime power order* q*. Let* $C_1^{(d)}, \dots, C_s^{(d)}$ *be defined as above. Then for any* $\alpha \ge 1$ *the matrices* $C_1^{(d)}, \dots, C_s^{(d)}$ *are generating matrices of a digital* $(t, \alpha, \min(1, \alpha/d), d, s)$*-sequence over* $\mathbb{F}_q$ *with*

$$t = \min(\alpha, d)\, t' + \left\lceil \frac{s(d-1)\min(\alpha, d)}{2} \right\rceil.$$

The last result shows that $(t, \alpha, \beta, \sigma m \times m, s)$-nets indeed exist for $\beta = 1$ and any $0 < \sigma \leq \alpha$ and for m arbitrarily large. We have even shown that digital $(t, \alpha, \beta, \alpha m \times m, s)$-nets exist which are extensible in m and s. This can be achieved by using an underlying (t', sd)-sequence which is itself extensible in m and s. If the t'-value of the original (t', m, s)-net or (t', s)-sequence is known explicitly, then we also know the t-value of the digital $(t, \alpha, \beta, \alpha m \times m, s)$-net or $(t, \alpha, \beta, \sigma, s)$-sequence. Furthermore it has also been shown how such digital nets can be constructed in practice. Further results on such sequences are established in [2].

5. Numerical integration in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$. In this section we investigate numerical integration in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ using quasi–Monte Carlo rules,

$$Q_{q^m,s}(f) = \frac{1}{q^m} \sum_{n=0}^{q^m-1} f(\boldsymbol{x}_n),$$

where $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{q^m-1}$ are the points of a digital (t, α, β, m, s)-net over $\mathbb{F}_q$. More precisely, we want to approximate the integral

$$I_s(f) = \int_{[0,1]^s} f(\boldsymbol{x})\, \mathrm{d}\boldsymbol{x}$$

by the quasi–Monte Carlo rule $Q_{q^m,s}(f)$. As a quality measure for our rule we introduce the worst-case error in the next section.

5.1. The worst-case error in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$. The worst-case error for the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ using the quasi–Monte Carlo rule $Q_{q^m,s}$ is given by

$$e(Q_{q^m,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) = \sup_{\substack{f \in \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}} \\ \|f\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}} \leq 1}} |I_s(f) - Q_{q^m,s}(f)|.$$

The initial error is given by

$$e(Q_{0,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) = \sup_{\substack{f \in \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}} \\ \|f\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}} \leq 1}} |I_s(f)|.$$

In the following we use digital nets generated by the matrices $C_1, \ldots, C_s$ as quadrature points for the quadrature rule $Q_{q^m,s}$. Let $f \in \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$. Using Lemma 4.2 it follows that

$$\begin{aligned} |I_s(f) - Q_{q^m,s}(f)| &= \left| \sum_{\boldsymbol{k} \in \mathcal{D}} \hat{f}(\boldsymbol{k}) \right| \\ &\leq \sum_{\boldsymbol{k} \in \mathcal{D}} |\hat{f}(\boldsymbol{k})| = \sum_{\emptyset \neq u \subseteq \mathcal{S}} \sum_{\boldsymbol{k}_u \in \mathcal{D}_u^*} |\hat{f}(\boldsymbol{k}_u, \boldsymbol{0}_{\mathcal{S}\setminus u})|. \end{aligned}$$

Now we have $|\hat{f}(\boldsymbol{k}_u, \boldsymbol{0}_{\mathcal{S}\setminus u})| \leq \gamma_u r_{q,\vartheta}(\boldsymbol{k}_u) \|f\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}}$ and thus we obtain

$$|I_s(f) - Q_{q^m,s}(f)| \leq \|f\|_{\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}} \sum_{\emptyset \neq u \subseteq \mathcal{S}} \gamma_u \sum_{\boldsymbol{k}_u \in \mathcal{D}_u^*} r_{q,\vartheta}(\boldsymbol{k}_u). \tag{5.1}$$

By choosing $\hat{f}(\boldsymbol{k}_u, \mathbf{0}_{\mathcal{S}\setminus u}) = \gamma_u r_{q,\vartheta}(\boldsymbol{k}_u)$ for all u and $\boldsymbol{k}_u$ we can also obtain equality in (5.1). Thus we have

$$e(Q_{q^m,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) = \sum_{\emptyset\neq u\subseteq\mathcal{S}} \gamma_u \sum_{\boldsymbol{k}_u\in\mathcal{D}_u^*} r_{q,\vartheta}(\boldsymbol{k}_u). \tag{5.2}$$

From the last formula we can now see that essentially a large value of $\min\{\mu_{q,\vartheta}(\boldsymbol{k}) : \boldsymbol{k}\in\mathcal{D}\}$ guarantees a small worst-case error. Further it can be shown that

$$e(Q_{0,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) = \gamma_\emptyset. \tag{5.3}$$

We have shown the following theorem.

THEOREM 5.1. *The initial error for multivariate integration in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ is given by* (5.3)*, and the worst-case error for multivariate integration in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ using a digital net as quadrature points is given by* (5.2).

In the following lemma we establish an upper bound on the sum $\sum_{\boldsymbol{k}_u\in\mathcal{D}_u^*} r_{q,\vartheta}(\boldsymbol{k}_u)$ for digital $(t,\alpha,\beta,n\times m,s)$-nets over $\mathbb{F}_q$. The proof is similar to that of [2, Lemma 6].

LEMMA 5.2. *Let $\vartheta > 1$ be a real number, let $q \geq 2$ be a prime power, let $C_1,\ldots,C_s \in \mathbb{F}_q^{n\times m}$ be the generating matrices of a digital $(t,\lceil\vartheta\rceil,\beta,n\times m,s)$-net over $\mathbb{F}_q$ with $0<\beta\leq 1$, and let $\mathcal{D}_u^* = \mathcal{D}_u^*((C_j)_{j\in u})$. For all $\emptyset\neq u\subseteq\mathcal{S}$ we have that if ϑ is not an integer, it follows that*

$$\sum_{\boldsymbol{k}_u\in\mathcal{D}_u^*} r_{q,\vartheta}(\boldsymbol{k}_u) \leq C_{|u|,q,\vartheta}(\beta n - t + \lceil\vartheta\rceil)^{|u|\lceil\vartheta\rceil-1} q^{-\vartheta\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor},$$

where

$$C_{|u|,q,\vartheta} = q^{|u|\lceil\vartheta\rceil}((q-q^{\vartheta-\lfloor\vartheta\rfloor})^{-1} + (1-q^{(1-\vartheta)/\lceil\vartheta\rceil})^{-|u|\lceil\vartheta\rceil}),$$

and if ϑ is an integer, it follows that

$$\sum_{\boldsymbol{k}_u\in\mathcal{D}_u^*} r_{q,\vartheta}(\boldsymbol{k}_u) \leq C'_{|u|,q,\vartheta}(\beta n - t + \vartheta)^{|u|\vartheta} q^{-(\beta n-t)},$$

where

$$C'_{|u|,q,\vartheta} = q^{|u|\vartheta}(q^{-1} + (1-q^{1/\vartheta-1})^{-|u|\vartheta}).$$

Proof. To simplify the notation we prove the result only for $u=\mathcal{S}$. For all other subsets the result follows by the same arguments.

We first consider the case where $\vartheta>1$ is not an integer. We partition the set $\mathcal{D}_{\mathcal{S}}^*$ into parts where the highest digits of k_j are prescribed, and we count the number of solutions of $C_1^\top\vec{k}_1+\cdots+C_s^\top\vec{k}_s=\vec{0}$. For $j=1,\ldots,s$ now let $i_{j,\lceil\vartheta\rceil}<\cdots<i_{j,1}$ with $i_{j,1}\geq 1$. Note that we now allow $i_{j,l}<1$, in which case the contributions of those $i_{j,l}$ are to be ignored. This notation is adopted in order to avoid considering many special cases. Further we write $\boldsymbol{i}_{s,\lceil\vartheta\rceil} = (i_{1,1},\ldots,i_{1,\lceil\vartheta\rceil},\ldots,i_{s,1},\ldots,i_{s,\lceil\vartheta\rceil})$ and define

$$\begin{aligned}\mathcal{D}_{\mathcal{S}}^*(\boldsymbol{i}_{s,\lceil\vartheta\rceil}) = \{\boldsymbol{k}\in\mathcal{D}_{\mathcal{S}}^* : k_j = \lfloor \kappa_{j,1}q^{i_{j,1}-1}+\cdots+\kappa_{j,\lceil\vartheta\rceil}q^{i_{j,\lceil\vartheta\rceil}-1}+l_j\rfloor \\ \text{with } 0\leq l_j<q^{i_{j,\lceil\vartheta\rceil}-1}\text{and } 1\leq\kappa_{j,l}<q \text{ for } j=1,\ldots,s\},\end{aligned}$$

where $\lfloor\cdot\rfloor$ just means that the contributions of $i_{j,l}<1$ are to be ignored. Let $\mu(\boldsymbol{i}_{s,\lceil\vartheta\rceil}) = i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil-1}+(\vartheta-\lfloor\vartheta\rfloor)i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil-1}+(\vartheta-\lfloor\vartheta\rfloor)i_{s,\lceil\vartheta\rceil}$.

Then we have

$$\sum_{\boldsymbol{k}_{\mathcal{S}}\in\mathcal{D}^*_{\mathcal{S}}} r_{q,\vartheta}(\boldsymbol{k}_{\mathcal{S}}) = \sum_{i_{1,1}=1}^{\infty}\cdots\sum_{i_{1,\lceil\vartheta\rceil}=1}^{i_{1,\lceil\vartheta\rceil-1}-1}\cdots\sum_{i_{s,1}=1}^{\infty}\cdots\sum_{i_{s,\lceil\vartheta\rceil}=1}^{i_{s,\lceil\vartheta\rceil-1}-1}\frac{|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})|}{q^{\mu(\boldsymbol{i}_{s,\lceil\vartheta\rceil})}}. \tag{5.4}$$

Some of the sums above can be empty, in which case we just set the corresponding summation index $i_{j,l}=0$.

Note that by the $(t,\lceil\vartheta\rceil,\beta,n\times m,s)$-net property we have that $|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})|=0$ as long as $i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil}\le\beta n-t$. Hence now let $0\le i_{1,1},\dots,i_{s,\lceil\vartheta\rceil}$ be given such that $i_{1,1},\dots,i_{s,1}\ge 1$, $i_{j,\lceil\vartheta\rceil}<\cdots<i_{j,1}$ for $j=1,\dots,s$ and where if $i_{j,l}<1$, we set $i_{j,l}=0$ (in which case we also have $i_{j,l+1}=i_{j,l+2}=\cdots=0$ and the inequalities $i_{j,l}>\cdots>i_{j,\lceil\vartheta\rceil}$ are ignored) and $i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil}>\beta n-t$. We now need to estimate $|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})|$, that is, we need to count the number of $\boldsymbol{k}\in\mathcal{D}^*_{\mathcal{S}}$ with $k_j=\lfloor\kappa_{j,1}b^{i_{j,1}-1}+\cdots+\kappa_{j,\lceil\vartheta\rceil}b^{i_{j,\lceil\vartheta\rceil}-1}+l_j\rfloor$.

There are at most $(q-1)^{\lceil\vartheta\rceil s}$ choices for $\kappa_{1,1},\dots,\kappa_{s,\lceil\vartheta\rceil}$ (we say "at most" because if $i_{j,l}<1$, then the corresponding $\kappa_{j,l}$ does not have any effect and therefore need not to be included).

Now let $1\le\kappa_{1,1},\dots,\kappa_{s,\lceil\vartheta\rceil}<q$ be given and define

$$\vec{g}=\kappa_{1,1}c^{\top}_{1,i_{1,1}}+\cdots+\kappa_{1,\lceil\vartheta\rceil}c^{\top}_{1,i_{1,\lceil\vartheta\rceil}}+\cdots+\kappa_{s,1}c^{\top}_{s,i_{s,1}}+\cdots+\kappa_{s,\lceil\vartheta\rceil}c^{\top}_{s,i_{s,\lceil\vartheta\rceil}},$$

where we set $c^{\top}_{j,l}=0$ if $l<1$ or $l>n$. Further let

$$B=(c^{\top}_{1,1},\dots,c^{\top}_{1,i_{1,\lceil\vartheta\rceil}-1},\dots,c^{\top}_{s,1},\dots,c^{\top}_{s,i_{s,\lceil\vartheta\rceil}-1}).$$

Now the task is to count the number of solutions $\vec{l}$ of $B\vec{l}=\vec{g}$.

As long as the columns of B are linearly independent the number of solutions can at most be 1. By the $(t,\lceil\vartheta\rceil,\beta,n\times m,s)$-net property this is certainly the case if (we write $(x)_+=\max(x,0)$)

$$\begin{aligned}(i_{1,\lceil\vartheta\rceil}-1)_+&+\cdots+(i_{1,\lceil\vartheta\rceil}-\lceil\vartheta\rceil)_+\\ &+(i_{s,\lceil\vartheta\rceil}-1)_+\cdots+(i_{s,\lceil\vartheta\rceil}-\lceil\vartheta\rceil)_+\le\lceil\vartheta\rceil(i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil})\\ &\le\beta n-t,\end{aligned}$$

that is, as long as

$$i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil}\le\frac{\beta n-t}{\lceil\vartheta\rceil}.$$

Now let $i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil}>\frac{\beta n-t}{\lceil\vartheta\rceil}$. Then by considering the rank of the matrix B and the dimension of the space of solutions of $B\vec{l}=\vec{0}$ it follows that the number of solutions of $B\vec{l}=\vec{g}$ is smaller than or equal to $q^{i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil}-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor}$. Thus we have

$$|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})|=0$$

if $\sum_{j=1}^{s}\sum_{l=1}^{\lceil\vartheta\rceil}i_{j,l}\le\beta n-t$, we have

$$|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})|=(q-1)^{s\lceil\vartheta\rceil}$$

if $\sum_{j=1}^{s}\sum_{l=1}^{\lceil\vartheta\rceil}i_{j,l}>\beta n-t$ and $\sum_{j=1}^{s}i_{j,\lceil\vartheta\rceil}\le\frac{\beta n-t}{\lceil\vartheta\rceil}$, and finally we have

$$|\mathcal{D}^*_{\mathcal{S}}(\boldsymbol{i}_{s,\lceil\vartheta\rceil})| \le (q-1)^{s\lceil\vartheta\rceil} q^{i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil}-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor}$$

if $\sum_{j=1}^{s}\sum_{l=1}^{\lceil\vartheta\rceil} i_{j,l} > \beta n - t$ and $\sum_{j=1}^{s} i_{j,\lceil\vartheta\rceil} > \frac{\beta n-t}{\lceil\vartheta\rceil}$.

We estimate the sum (5.4) now. Let S_1 be the sum in (5.4) where $i_{1,1}+\cdots+i_{s,\lceil\vartheta\rceil} > \beta n - t$ and $i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil} \le \frac{\beta n-t}{\lceil\vartheta\rceil}$. Let $l_1 = i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil-1}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil-1}$ and let $l_2 = i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil}$. Let $A(l_1+l_2)$ denote the number of admissible choices of $i_{1,1},\ldots,i_{s,\lceil\vartheta\rceil}$ such that $l_1+l_2 = i_{1,1}+\cdots+i_{s,\lceil\vartheta\rceil}$. Then we have

$$S_1 = (q-1)^{s\lceil\vartheta\rceil} \sum_{l_2=0}^{\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor} \frac{1}{q^{(\vartheta-\lfloor\vartheta\rfloor)l_2}} \sum_{l_1=\beta n-t+1-l_2}^{\infty} \frac{A(l_1+l_2)}{b^{l_1}}.$$

We have $A(l_1+l_2) \le \binom{l_1+l_2+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1}$ and hence we obtain

$$S_1 \le (q-1)^{s\lceil\vartheta\rceil} \sum_{l_2=0}^{\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor} \frac{1}{q^{(\vartheta-\lfloor\vartheta\rfloor)l_2}} \sum_{l_1=\beta n-t+1-l_2}^{\infty} \frac{1}{q^{l_1}} \binom{l_1+l_2+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1}.$$

From a result by Matoušek [17, Lemma 2.18] (see also [4, Lemma 6]), we have

$$\begin{aligned}(q-1)^{s\lceil\vartheta\rceil} &\sum_{l_1=\beta n-t+1-l_2}^{\infty} \frac{1}{q^{l_1}} \binom{l_1+l_2+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1} \\ &\le q^{l_2-\beta n+t-1+s\lceil\vartheta\rceil} \binom{\beta n-t+s\lceil\vartheta\rceil}{s\lceil\vartheta\rceil-1}\end{aligned}$$

and further we have

$$\sum_{l_2=0}^{\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor} \frac{q^{l_2}}{q^{(\vartheta-\lfloor\vartheta\rfloor)l_2}} = \sum_{l_2=0}^{\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor} q^{l_2(\lceil\vartheta\rceil-\vartheta)} = \frac{q^{(\lceil\vartheta\rceil-\vartheta)(\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor+1)}-1}{q^{\lceil\vartheta\rceil-\vartheta}-1}.$$

Thus we obtain

$$\begin{aligned}S_1 &\le \frac{q^{(\lceil\vartheta\rceil-\vartheta)(\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor+1)}-1}{q^{\lceil\vartheta\rceil-\vartheta}-1} q^{-\beta n+t-1+s\lceil\vartheta\rceil} \binom{\beta n-t+s\lceil\vartheta\rceil}{s\lceil\vartheta\rceil-1} \\ &\le \frac{q^{s\lceil\vartheta\rceil-1}}{1-q^{\vartheta-\lceil\vartheta\rceil}} \binom{\beta n-t+s\lceil\vartheta\rceil}{s\lceil\vartheta\rceil-1} q^{-\vartheta\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor}.\end{aligned}$$

Let S_2 be the part of (5.4) for which $i_{1,1}+\cdots+i_{s,\lceil\vartheta\rceil} > \beta n - t$ and $i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil} > \frac{\beta n-t}{\lceil\vartheta\rceil}$, i.e., we have

$$\begin{aligned}S_2 \le (q-1)^{s\lceil\vartheta\rceil} &\sum_{i_{1,1}=1}^{\infty} \cdots \sum_{i_{1,\lceil\vartheta\rceil}=1}^{i_{1,\lceil\vartheta\rceil-1}-1} \cdots \\ &\sum_{i_{s,1}=1}^{\infty} \cdots \sum_{i_{s,\lceil\vartheta\rceil}=1}^{i_{s,\lceil\vartheta\rceil-1}-1} \frac{q^{-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor} q^{(i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil})(\lceil\vartheta\rceil-\vartheta)}}{q^{i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil-1}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil-1}}},\end{aligned}$$

where we have the additional conditions $i_{1,1}+\cdots+i_{s,\lceil\vartheta\rceil} > \beta n - t$ and $i_{1,\lceil\vartheta\rceil}+\cdots+i_{s,\lceil\vartheta\rceil} > \frac{\beta n-t}{\lceil\vartheta\rceil}$. As above let $l_1 = i_{1,1}+\cdots+i_{1,\lceil\vartheta\rceil-1}+\cdots+i_{s,1}+\cdots+i_{s,\lceil\vartheta\rceil-1}$ and

let $l_2 = i_{1,\lceil\vartheta\rceil} + \cdots + i_{s,\lceil\vartheta\rceil}$. Let $A(l_1+l_2)$ denote the number of admissible choices of $i_{1,1},\dots,i_{s,\lceil\vartheta\rceil}$ such that $l_1+l_2 = i_{1,1}+\cdots+i_{s,\lceil\vartheta\rceil}$. Note that $l_1 > \lfloor\vartheta\rfloor l_2$. Then we have $A(l_1+l_2) \le \binom{l_1+l_2+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1}$ and hence obtain

$$\begin{aligned}
S_2 &\le (q-1)^{s\lceil\vartheta\rceil} q^{-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor} \\
&\quad\times \sum_{l_2=\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor+1}^{\infty} q^{(\lceil\vartheta\rceil-\vartheta)l_2} \sum_{l_1=\lfloor\vartheta\rfloor l_2+1}^{\infty} \frac{1}{q^{l_1}} \binom{l_1+l_2+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1} \\
&= (q-1)^{s\lceil\vartheta\rceil} q^{-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor} \\
&\quad\times \sum_{l_2=\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor+1}^{\infty} \sum_{l_1=0}^{\infty} q^{-l_1+l_2-1-l_2\vartheta} \binom{l_1+l_2+\lfloor\vartheta\rfloor l_2-1+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1}.
\end{aligned}$$

By using again Matoušek [17, Lemma 2.18] (see also [4, Lemma 6]), we have

$$\begin{aligned}
&(q-1)^{s\lceil\vartheta\rceil} \sum_{l_1=0}^{\infty} q^{-l_1+l_2-1-l_2\vartheta} \binom{l_1+l_2+\lfloor\vartheta\rfloor l_2-1+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1} \\
&\qquad\qquad \le q^{s\lceil\vartheta\rceil} q^{l_2(1-\vartheta)-1} \binom{l_2\lceil\vartheta\rceil-1+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1}
\end{aligned}$$

and also

$$\begin{aligned}
&q^{s\lceil\vartheta\rceil-1-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor} \sum_{l_2=\lfloor\frac{\beta n-t}{\lceil\vartheta\rceil}\rfloor+1}^{\infty} q^{l_2(1-\vartheta)} \binom{l_2\lceil\vartheta\rceil-1+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1} \\
&\le q^{s\lceil\vartheta\rceil-1-\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor} \sum_{l_2=\beta n-t}^{\infty} q^{l_2(1-\vartheta)/\lceil\vartheta\rceil} \binom{l_2+\lceil\vartheta\rceil-1+s\lceil\vartheta\rceil-1}{s\lceil\vartheta\rceil-1} \\
&\le q^{s\lceil\vartheta\rceil} (1-q^{(1-\vartheta)/\lceil\vartheta\rceil})^{-s\lceil\vartheta\rceil} \binom{\beta n-t+\lceil\vartheta\rceil-2+s\lceil\vartheta\rceil}{s\lceil\vartheta\rceil-1} q^{-\vartheta(\beta n-t)/\lceil\vartheta\rceil}.
\end{aligned}$$

Hence we have

$$S_2 \le q^{s\lceil\vartheta\rceil} (1-q^{(1-\vartheta)/\lceil\vartheta\rceil})^{-s\lceil\vartheta\rceil} \binom{\beta n-t+\lceil\vartheta\rceil-2+s\lceil\vartheta\rceil}{s\lceil\vartheta\rceil-1} q^{-\vartheta(\beta n-t)/\lceil\vartheta\rceil}.$$

Note that we have $\sum_{\boldsymbol{k}_S\in\mathcal{D}_S^*} r_{q,\vartheta}(\boldsymbol{k}_S) = S_1 + S_2$. Let $a \ge 1$ and $b \ge 0$ be integers; then we have

$$\binom{a+b}{b} = \prod_{i=1}^{b} \left(1+\frac{a}{i}\right) \le (1+a)^b.$$

Therefore we obtain

$$S_1 \le \frac{q^{s\lceil\vartheta\rceil-1}}{1-q^{\vartheta-\lceil\vartheta\rceil}} (\beta n-t+2)^{s\lceil\vartheta\rceil-1} q^{-\vartheta\lfloor(\beta n-t)/\lceil\vartheta\rceil\rfloor}$$

and

$$S_2 \le q^{s\lceil\vartheta\rceil} (1-q^{(1-\vartheta)/\lceil\vartheta\rceil})^{-s\lceil\vartheta\rceil} (\beta n-t+\lceil\vartheta\rceil)^{s\lceil\vartheta\rceil-1} q^{-\vartheta(\beta n-t)/\lceil\vartheta\rceil}.$$

Thus we have

$$\sum_{\boldsymbol{k}_{\mathcal{S}} \in \mathcal{D}^*_{\mathcal{S}}} r_{q,\vartheta}(\boldsymbol{k}_{\mathcal{S}}) \le C_{s,q,\vartheta}(\beta n - t + \lceil \vartheta \rceil)^{s\lceil \vartheta \rceil - 1} q^{-\vartheta \lfloor (\beta n - t)/\lceil \vartheta \rceil \rfloor},$$

where

$$C_{s,q,\vartheta} = q^{s\lceil \vartheta \rceil}((q - q^{\vartheta - \lfloor \vartheta \rfloor})^{-1} + (1 - q^{(1-\vartheta)/\lceil \vartheta \rceil})^{-s\lceil \vartheta \rceil}).$$

The result follows for the case $0 < \vartheta - \lfloor \vartheta \rfloor < 1$.

Now let $\vartheta > 1$ be an integer. Then using the same arguments as above it can be shown that

$$S_1 \le (\beta n - t + 2)^{s\vartheta} q^{-(\beta n - t) - 1 + s\vartheta}$$

and

$$S_2 \le q^{s\vartheta}(1 - q^{1/\vartheta - 1})^{-s\vartheta}(\beta n - t + \vartheta)^{s\vartheta - 1} q^{-(\beta n - t)}.$$

Thus we have

$$\sum_{\boldsymbol{k}_{\mathcal{S}} \in \mathcal{D}^*_{\mathcal{S}}} r_{q,\vartheta}(\boldsymbol{k}_{\mathcal{S}}) \le C'_{s,q,\vartheta}(\beta n - t + \vartheta)^{s\vartheta} q^{-(\beta n - t)},$$

where

$$C'_{s,q,\vartheta} = q^{s\vartheta}(q^{-1} + (1 - q^{1/\vartheta - 1})^{-s\vartheta}).$$

The result now follows. □

Remark 5.3. We note that the above lemma does not hold for $\beta > 1$ in general. Indeed, take, for example, $u = \{1\}$; then $\boldsymbol{k}_u = (k_1)$ and choose $k_1 = q^n$. Then the digit vector of the first n digits of q^n is $(0, \dots, 0)^\top$; therefore $C_1^\top \vec{k}_1 = \vec{0}$ and hence $\boldsymbol{k}_{(1)} \in \mathcal{D}^*_{(1)}$. Thus

$$\sum_{\boldsymbol{k}_{(1)} \in \mathcal{D}^*_{(1)}} r_{q,\vartheta}(\boldsymbol{k}_{(1)}) \ge q^{-n-1}$$

and hence a counterexample can be obtained for some choices of n, β, ϑ.

In [2] we did allow $\beta > 1$, but therein we had the additional assumption that the functions are periodic. In this case we were able to show that the Walsh coefficients $r_{q,\alpha}(\boldsymbol{k}, \boldsymbol{l}) = \prod_{j=1}^s r_{q,\alpha}(k_j, l_j)$ of the reproducing kernel also satisfy the additional property that $r_{q,\alpha}(q^m k_j, q^m k_j) = r_{q,\alpha}(q^m k_j) = q^{-2\alpha m} r_{q,\alpha}(k_j, k_j)$ for all $k_j, m \in \mathbb{N}$; see [2, Lemma 15]. Similarly, if we would also assume here that $r_{q,\vartheta}(q^n k) = q^{-\vartheta n} r_{q,\vartheta}(k)$ and $r_{q,\vartheta}(k)$ given as above if $q \not| k$, then the above counterexample would fail as then $r_{q,\vartheta}(q^n) = r_{q,\vartheta}(1q^n) = q^{-\vartheta(n+1)} r_{q,\vartheta}(1)$.

Using the above lemma we can now obtain an upper bound on the worst-case error.

THEOREM 5.4. *Let $\vartheta > 1$ be a real number and let $q \ge 2$ be a prime power. The worst-case error for multivariate integration in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ using a digital $(t, \lceil \vartheta \rceil, \beta, n \times m, s)$-net over $\mathbb{F}_q$, with $0 < \beta \le 1$, as quadrature points is for nonintegers ϑ bounded by*

$$e(Q_{q^m,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) \le q^{-\vartheta \lfloor (\beta n - t)/\lceil \vartheta \rceil \rfloor} \sum_{\emptyset \ne u \subseteq \mathcal{S}} \gamma_u C_{|u|,q,\vartheta}(\beta n - t + \lceil \vartheta \rceil)^{|u|\lceil \vartheta \rceil - 1},$$

where

$$C_{|u|,q,\vartheta} = q^{|u|\lceil\vartheta\rceil}((q - q^{\vartheta-\lfloor\vartheta\rfloor})^{-1} + (1 - q^{(1-\vartheta)/\lceil\vartheta\rceil})^{-|u|\lceil\vartheta\rceil}),$$

and if ϑ is an integer, the worst-case error is bounded by

$$e(Q_{q^m,s}, \mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}) \le q^{-(\beta n - t)} \sum_{\emptyset \ne u \subseteq \mathcal{S}} \gamma_u C'_{|u|,q,\vartheta} (\beta n - t + \vartheta)^{|u|\vartheta},$$

where

$$C'_{|u|,q,\vartheta} = q^{|u|\vartheta}(q^{-1} + (1 - q^{1/\vartheta - 1})^{-|u|\vartheta}).$$

As a direct consequence of Corollary 3.11 we obtain the following result.

COROLLARY 5.5. *Let $\delta \ge 1$ be an integer, let $0 < \lambda \le 1$, and let $q \ge 2$ be a prime power. Then for any function $f : [0,1)^s \to \mathbb{R}$ whose partial mixed derivatives up to order δ exist it follows that the integration error using a digital $(t, \delta+1, \beta, n \times m, s)$-net over $\mathbb{F}_q$ with $0 < \beta \le 1$ as quadrature points is for $0 < \lambda < 1$ bounded by*

$$\begin{aligned} |I_s(f) - Q_{q^m,s}(f)| &\le q^{-(\delta+\lambda)\lfloor(\beta n - t)/(\delta+1)\rfloor} C_{\delta,s,q,\boldsymbol{\gamma}} N_{\delta,\lambda,\boldsymbol{\gamma}}(f) \\ &\quad \times \sum_{\emptyset \ne u \subseteq \mathcal{S}} \gamma_u C_{|u|,q,\delta+\lambda} (\beta n - t + \delta + 1)^{|u|(\delta+1)-1} \end{aligned}$$

and for $\lambda = 1$ the integration error is bounded by

$$\begin{aligned} |I_s(f) - Q_{q^m,s}(f)| &\le q^{-(\beta n - t)} C_{\delta,s,q,\boldsymbol{\gamma}} N_{\delta,\lambda,\boldsymbol{\gamma}}(f) \\ &\quad \times \sum_{\emptyset \ne u \subseteq \mathcal{S}} \gamma_u C'_{|u|,q,\delta+1} (\beta n - t + \delta + 1)^{|u|\delta+1}, \end{aligned}$$

where the constant $C_{\delta,s,q,\boldsymbol{\gamma}}$ is given in Corollary 3.11 and the constants $C_{|u|,q,\delta+\lambda}$ and $C'_{|u|,q,\delta+1}$ are given in Theorem 5.4.

Explicit constructions of digital $(t, \alpha, \min(1, \alpha/d), dm \times m, s)$-nets over $\mathbb{F}_q$ for all prime powers q and integers $\alpha, d, m, s > 1$ are given in section 4.4. By choosing $d = \alpha = \lceil\vartheta\rceil = \delta + 1$, by Theorem 5.4 and Corollary 5.5 we obtain a convergence of $\mathcal{O}(q^{-\vartheta m} m^{s\lceil\vartheta\rceil+1})$, which is optimal even for the smooth functions contained in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$; see [29], where a lower bound for smooth periodic functions was shown.

Remark 5.6. In [2, Remark 4] it was noted that if $m = n$ and $\beta > \alpha$, the t-value must grow with m and hence the restriction $\beta \le \alpha$ was added. A similar argument yields in our case that the t-value must grow with n if $\beta n > \alpha m$, as Theorem 5.4 shows a convergence of $\mathcal{O}(q^{-\beta n + t})$, but the best possible convergence rate is $q^{-\alpha m}$; hence the restriction $\beta \le \alpha m/n$ was added.

In case the smoothness of the function is not known, our constructions adjust themselves automatically up to a certain degree in the following way: for the construction of the digital net we choose some value of $d \ge 1$ and construct a digital $(t, \alpha, \min(1, \alpha/d), dm \times m, s)$-net or a digital $(t, \alpha, \min(1, \alpha/d), d, s)$-sequence for all $\alpha \ge 1$. The values $\delta \ge 1$ and $0 < \lambda \le 1$ determine the real smoothness of the function, which we now assume is not known. The value of α is the smoothness analogue for the digital net, i.e., we need to choose $\alpha = \delta + 1$. First assume that $\delta + \lambda \le d$; then $\min(1, \alpha/d) = (\delta + 1)/d$, and therefore we have $\beta = (\delta + 1)/d$. As $n = dm$ it follows

that $\beta n = (\delta+1)m$, and therefore Corollary 5.5 shows that we achieve a convergence of $\mathcal{O}(q^{-(\delta+\lambda)m} m^{s(\delta+1)+1})$, which is optimal. Now assume on the other hand that $\delta + \lambda > d$; then $\min(1, \alpha/d) = 1$ and therefore $\beta = 1$. Again we have $n = dm$ and hence $\beta n = dm$. In this case Corollary 5.5 shows that our construction achieves a convergence of $\mathcal{O}(q^{-dm} m^{s(\delta+1)+1})$.

Note that numerical integration of functions with less smoothness, i.e., for example functions with partial mixed derivatives up to degree 1 in $\mathcal{L}_2([0,1)^s)$ or functions with bounded variation, has been considered in many papers and monographs; see, for example, [3, 4, 6, 7, 14, 20, 30, 31]. Using the notation from above, basically those results are concerned with the case where $\delta = 0$ and $\lambda = 1$, and hence the results here are a direct continuation of what was previously known. The construction of digital nets proposed here for $d = 1$ yields obviously digital (t, m, s)-nets and (t, s)-sequences as, for example, defined in [20]. In view of Corollary 5.5 and the explanation which followed it is hence not surprising that the classical examples and theory (see, for example, [3, 4, 12, 13, 14, 20, 26, 31]) yielded only a convergence of $\mathcal{O}(q^{m(-1+\varepsilon)})$ for any $\varepsilon > 0$ (the ε here is used to hide the powers of m).

Note that the worst-case error in the Walsh space $\mathcal{E}_{s,q,\vartheta,\boldsymbol{\gamma}}$ is invariant with respect to a digital shift (see [4]); hence Corollary 5.5 also holds for digitally shifted digital nets. Thus, if one wants to use randomized digital nets, one can also use randomly digitally shifted digital nets. The root mean square worst-case error for this case would of course be bounded by the bound in Corollary 5.5, as this bound holds for any digital shift; i.e., our result here is even stronger in that we have shown that even for the worst digital shift we still have the bound of Corollary 5.5. From this, it follows that for our situation here, there is, in some sense, no bad digital shift. Other more sophisticated scrambling methods which do not destroy the essential properties of the point set can be used as well (for example, a digital shift of depth m; see [5, 17]); see [24] for some ideas in this direction.

A CONVERGENT FINITE DIFFERENCE SCHEME FOR THE CAMASSA–HOLM EQUATION WITH GENERAL H^1 INITIAL DATA*

G. M. COCLITE†, K. H. KARLSEN‡, AND N. H. RISEBRO‡

Abstract. We suggest a finite dfference scheme for the Camassa–Holm equation that can handle general H^1 initial data. The form of the difference scheme is judiciously chosen to ensure that it satisfies a total energy inequality. We prove that the difference scheme converges strongly in H^1 towards a dissipative weak solution of the Camassa–Holm equation.

Key words. Camassa–Holm equation, hyperbolic-elliptic system, weak solution, finite difference scheme, convergence

1. Introduction.

In this paper we present and analyze a finite difference scheme for the Camassa–Holm partial differential equation [7]

$$\partial_t u - \partial^3_{txx} u + 3u\partial_x u = 2\partial_x u \partial^2_{xx} u + u\partial^3_{xxx} u, \qquad (t,x) \in \mathbb{R}_+ \times \mathbb{R}, \tag{1.1}$$

which we augment with an initial condition:

$$u|_{t=0} = u_0 \in H^1(\mathbb{R}). \tag{1.2}$$

By rewriting (1.1) as

$$(1-\partial^2_{xx})\left[\partial_t u + u\partial_x u\right] + \partial_x\left(u^2 + \frac{1}{2}(\partial_x u)^2\right) = 0,$$

we see that (for smooth solutions) (1.1) is equivalent to the elliptic-hyperbolic system

$$\partial_t u + u\partial_x u + \partial_x P = 0, \qquad -\partial^2_{xx} P + P = u^2 + \frac{1}{2}(\partial_x u)^2. \tag{1.3}$$

By recalling that $e^{-|x|}/2$ is the Green's function of the operator $1-\partial^2_{xx}$, (1.3) can be written as

$$\partial_t u + \partial_x F(u, \partial_x u) = 0, \quad F(u,\partial_x u) = \frac{1}{2}\left[u^2 + e^{-|x|} \star \left(u^2 + \frac{1}{2}(\partial_x u)^2\right)\right], \tag{1.4}$$

which can be viewed as a conservation law with a nonlocal flux function. In this paper the relevant formulation of the Camassa–Holm equation (1.1) is the one provided by the hyperbolic-elliptic system (1.3).

The Camassa–Holm equation (1.1) can be viewed as a model for the propagation of unidirectional shallow water waves [7, 32]. The equation is a member of the class of weakly nonlinear and weakly dispersive shallow water models, a class which already contains the Korteweg–de Vries (KdV) and Benjamin–Bona–Mahony (BBM) equations. The Camassa–Holm equation contains higher order nonlinear dispersive/nonlocal balances not present in the KdV and BBM equations. As is the case with the BBM equation but not in the KdV equation, the linear dispersion relation in the Camassa–Holm equation remains bounded for large wave numbers.

In another interpretation the Camassa–Holm equation models finite length, small-amplitude radial deformation waves in cylindrical compressible hyperelastic rods [21]. It arises also in the context of differential geometry as an equation for geodesics of the H^1-metric on the diffeomorphism group; see [17, 18, 30, 36].

The Camassa–Holm equation possesses several extraordinary properties such as an infinite number of conserved integrals, a bi-Hamiltonian structure, and complete integrability [2, 7, 19, 13, 26]. Moreover, it enjoys an infinite number of nonsmooth solitary wave solutions, called peakons, which have to be interpreted as weak solutions of (1.4).

From a mathematical point of view the Camassa–Holm equation has by now become rather well studied. While it is impossible to give a complete overview of the mathematical literature, we shall here mention a few typical results, starting with local(-in-time) existence results [14, 35, 37]. For $u_0 \in H^s(\mathbb{R})$, with $s > \frac{3}{2}$, there exists a unique solution $u \in C([0,T]; H^s(\mathbb{R})) \cap C^1([0,T]; H^{s-1}(\mathbb{R}))$ of (1.1)–(1.2) for some T that depends on $\|u_0\|_{H^s(\mathbb{R})}$. Furthermore, the flow map is continuous from $H^s(\mathbb{R})$ to the class defined above. The proof of this result is based on the "momentum" formulation of the Camassa–Holm equation,

$$\partial_t m + u\partial_x m + 2m\partial_x u = 0, \qquad m := (1 - \partial_{xx}^2)u. \tag{1.5}$$

to which one applies Kato's theory for quasi-linear hyperbolic equations. For local well-posedness results based on Besov spaces, see [23, 22].

The Camassa–Holm equation posseses an infinite number of conservation laws, but none of them control the H^s-norm for $s > 1$. Hence these local existence results cannot (in general) be turned into global ones. Indeed, it is well known that global (strong) solutions do not exist and wave breaking occurs [7]. Wave breaking means that the solution itself stays bounded while the spatial derivative $\partial_x u$ tends to $-\infty$ as $t \uparrow T^*$, where T^* denotes the maximal time of existence. More precisely, the following results are proved in [14, 16]. Assume that $u_0 \in H^3(\mathbb{R})$ is odd with $\partial_x u_0(0) < 0$. Then the solution of of (1.1)–(1.2) does not exist globally, and T^* is estimated above by $1/(2\,|\partial_x u_0(0)|)$. Another result says that if the initial function $u_0 \in H^3(\mathbb{R})$ has at some point a slope which is less than $-(1/\sqrt{2})\,\|u_0\|_{H^1(\mathbb{R})}$, then T^* is finite and wave breaking occurs. It was observed in [14] that the solutions are global if $m_0 := (1 - \partial_{xx}^2)u_0$ (cf. (1.5)) is a bounded measure with a definitive sign.

In view of what we have said so far (peakon solutions/wave breaking), it is clear that a theory based on weak solutions is essential. In the literature there are a number of results on weak solutions of the Camassa–Holm equation. Here we will mention only a few of them, starting with the results obtained in [15, 20]. Suppose that $u_0 \in H^1(\mathbb{R})$ with $m_0 := (1 - \partial_{xx}^2)u_0 \in \mathcal{M}(\mathbb{R})$. Then the authors prove that there exists a final time $T = T(\|m_0\|_{\mathcal{M}}) > 0$ and a unique weak solution $u \in C([0,T]; H^1(\mathbb{R})) \cap L^\infty(0,T; W^{1,1}(\mathbb{R}))$, with $\partial_x u \in L^\infty(0,T; BV(\mathbb{R}))$, of (1.1)–(1.2); i.e., u is a distributional solution of (1.4)–(1.2). Additionally, the following

two time-dependent quantities remain constant: $E(u) := \int_{\mathbb{R}} \left[u^2 + (\partial_x u)^2\right] dx$ and $F(u) := \int_{\mathbb{R}} \left[u^3 + u(\partial_x u)^2\right] dx$. In particular, this weak solution is total energy conserving; i.e., $E(u(t,\cdot)) = E(u_0)$. Finally, if m_0 has a definite sign, then u is global in time. The sign of m_0 is maintained by $m(t,\cdot)$ at all times t. It is possible to prove the existence of local weak solutions without the sign assumption on m_0; see [22]. The proofs in [15, 20] are based on the momentum formulation (1.5).

For other approaches to conservative weak solutions, we refer to [4, 5, 29].

More relevant from the point of view of the present paper is the result of Xin and Zhang [38], which states the existence of a global (dissipative) weak solution for any H^1 initial data (see [11, 12] for similar results for a generalized Camassa–Holm equation). These solutions are global in the sense that they are defined even past the blow-up time (wave breaking). More precisely, suppose that $u_0 \in H^1(\mathbb{R})$. Then there exists a global weak solution $u \in C(\mathbb{R}_+ \times \mathbb{R}) \cap L^\infty(0,T;H^1(\mathbb{R}))$ of (1.1)–(1.2), satisfying the following properties:

$$\begin{aligned} &\|u(t,\cdot)\|_{H^1(\mathbb{R})} \le \|u_0\|_{H^1(\mathbb{R})}, \\ &\partial_x u \in L^p_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R}), \quad p < 3, \\ &\partial_x u(t,x) \le \frac{2}{t} + C, \quad t > 0, \end{aligned} \tag{1.6}$$

where C is a positive constant that depends only on $\|u_0\|_{H^1(\mathbb{R})}$. The proof of the existence result is based on the vanishing viscosity method; see [38].

We remark that the last item in (1.6) serves as an "entropy condition" that singles out a (presumably) unique weak solution after the occurrence of wave breaking. This solution is often referred to as a *dissipative* weak solution as the total energy is merely nonincreasing in time: $E(u(t,\cdot)) \le E(u_0)$. The entropy condition is (formally) seen to hold by inspecting the equation satisfied by the spatial derivative $q := \partial_x u$ (cf. [38] for details), which reads

$$\partial_t q + u\partial_x q + \frac{q^2}{2} - u^2 + P = 0, \qquad -\partial_{xx}^2 P + P = u^2 + \frac{q^2}{2}. \tag{1.7}$$

Currently there is no uniqueness result for weak solutions of the type constructed in [38]. The problem appears to be connected to a lack of temporal integrability (of the L^∞-norm) of the spatial derivative. Indeed, if one furthermore knows the existence of a function $b \in L^2_{\mathrm{loc}}(\mathbb{R}_+)$ such that $\|\partial_x u(t,\cdot)\|_{L^\infty(\mathbb{R})} \le b(t)$, then the weak solution of Xin and Zhang is unique (in a particular class) [39]. For example, if m_0 is a positive bounded Radon measure, then $\partial_x u$ is pointwise bounded [20], and uniqueness thus holds.

For a different approach to dissipative weak solutions, see the recent work [3].

Let us now turn to the main topic of the present paper, namely, convergent numerical schemes for the Camassa–Holm equation. Although there are few works on convergent numerical schemes, there are several authors that employ numerical schemes to obtain approximate solutions. The first numerical results are presented in [8], where a pseudospectral scheme is utilized. Additional numerical simulations with pesudospectral schemes are reported in [25, 31]. Numerical schemes based on multi-peakons (thereby exploiting the Hamiltonian structure of the Camassa–Holm equation) are examined in [6, 9, 10]. In a different direction, an adaptive high-resolution finite volume scheme is developed and used in [1].

Regarding works that provide numerical schemes with some sort of theoretical foundation, we know only of the papers [27, 28, 33]. In [28], the authors prove that

the multipeakon algorithm from [9, 10] converges to the solution of the Camassa–Holm equation (1.1) as the number of peakons tends to infinity (in an appropriate way). This convergence result applies to the situation where the initial function $u_0 \in H^1$ is such that $(1 - \partial_{xx}^2)u_0$ is a positive measure. In [33], the authors establish error estimates for a spectral projection scheme, though under the (unrealistic) assumption of smooth solutions.

It seems rather difficult to construct numerical schemes for which one can prove rigorously the convergence to a solution of the Camassa–Holm equation, a fact that is related to the nonlinear and nonlocal features of the equation. It has been observed in [27] that certain "natural" schemes either diverge or converge to a wrong solution. Indeed, a priori it is not even clear which one of the three formulations of the Camassa–Holm equation—(1.1), (1.3), or (1.5)—should be used as a starting point for discretization. Nevertheless, in [27] the authors commence from the momentum formulation (1.5) and thereby restrict themselves to initial data u_0 in H^1 for which $m_0 = (1-\partial_{xx}^2)u_0$ is a positive measure, in which case also $m(t,\cdot)$ remains positive and consequently so does u. They prove that the following difference scheme converges strongly in H^1 to the weak solution identified in [15, 20]:

$$\frac{d}{dt}m_j + D_-(m_j u_j) + m_j D u_j = 0, \quad m_j = u_j - D_- D_+ u_j, \quad t > 0,\ j \in \mathbb{Z},$$

where D_-, D, and D_+ denote, respectively, the backward, central, and forward difference operators and $m_j(t) \approx m(t, x_j)$, $u_j(t) \approx u(t, x_j)$, $x_j = j\Delta x$, and $\Delta x > 0$.

The main aim of this paper is to provide a convergent finite difference scheme that works for any H^1 initial data and not merely the subclass considered in [27]. Neither the scheme nor the analysis presented in [27] works in the general case.

At variance with [27], we shall herein take as a starting point the hyperbolic-elliptic formulation (1.3). From the point of view of conservation laws (e.g., the inviscid Burgers equation) and their shock wave (discontinuous) solutions, it might seem natural to employ a conservative finite difference scheme of the upwind type [34] to the u-equation in (1.3). As is well known, the upwinding will render a scheme stable since the difference stencil utilizes information only from the side from which the (discontinuous) waves are coming. However, here one should keep in mind that solutions to the Camassa–Holm equation are continuous and that prospective discontinuities occur only in the variable $q = \partial_x u$, which satisfies the transport equation in (1.7). Thus, herein we will not opt for this strategy.

Instead we will devise a tailored difference scheme for the u-equation in (1.3) that yields an upwind difference scheme for the q-equation in (1.7). A key feature of the scheme is that it satisfies a total energy inequality in which only the q-part of the total energy is dissipated (not the u-part!). To avoid complicating further the convergence analysis, we restrict our attention to a semidiscrete finite difference scheme. To turn the difference scheme into a fully discrete one, we can rely on a variety of different time-discretization techniques.

Now we outline the finite difference scheme (here only briefly since the details can be found in section 3). To this end, we start with discretizing the spatial domain $\mathbb{R}$ by specifying the mesh points $x_j = j\Delta x$, $x_{j+1/2} = (j + 1/2)\Delta x$ for $j = 0, \pm 1, \pm 2, \ldots$, where $\Delta x > 0$ is the length between two consecutive mesh points (the mesh size). Our numerical scheme will generate approximations $u_{j+1/2}(t) \approx u(t, x_{j+1/2})$, $P_j(t) \approx P(t, x_j)$ for $t \geq 0$ and $j \in \mathbb{Z}$, where we remark that the discretization of P is shifted (staggered) one half-cell compared to that of u. Our finite difference scheme for

$\{u_{j+1/2}(t)\}_{j\in\mathbb{Z}}$ reads

$$\frac{d}{dt}u_{j+1/2} + \left(u_{j+1/2}\vee 0\right) D_- u_{j+1/2} + \left(u_{j+1/2}\wedge 0\right) D_+ u_{j+1/2} + D_+ P_j = 0, \tag{1.8}$$

while the difference scheme for $\{P_j(t)\}_{j\in\mathbb{Z}}$ takes the form

$$-D_-D_+P_j + P_j = \left(u_{j+1/2}\vee 0\right)^2 + \left(u_{j-1/2}\wedge 0\right)^2 + \frac{1}{2}\left(D_- u_{j+1/2}\right)^2.$$

Of course, as we have already alluded to above, from the point of view of the inviscid Burgers equation, (1.8) is not a reasonable discretization. However, the quantity $q_j := D_- u_{j+1/2}$ automatically satisfies the difference scheme

$$\begin{aligned} q_j' + \left(u_{j-1/2}\vee 0\right) D_- q_j + \left(u_{j+1/2}\wedge 0\right) D_+ q_j + \frac{q_j^2}{2} \\ - \left(u_{j+1/2}\vee 0\right)^2 - \left(u_{j-1/2}\wedge 0\right)^2 + P_j = 0, \end{aligned} \tag{1.9}$$

which contains proper upwinding of the transport term in (1.7). In our situation (compare with [27]) u does not have a definite sign, hence the splitting of u into positive and negative parts. As with the "pressure" P, the discretization of q is staggered compared to that of the "velocity" u.

By properly extending $\{u_{j+1/2}\}_{j\in\mathbb{Z}}$, $\{q_j\}_{j\in\mathbb{Z}}$ to functions $u_{\Delta x}$, $q_{\Delta x}$ defined at all points (t,x) in the domain, we prove that $u_{\Delta x}$ converges strongly in H^1 to a dissipative weak solution of the Camassa–Holm equation, which constitutes the main result of the present paper. Regarding the proof, we derive several a priori estimates in Lebesgue and Sobolev spaces as well as a uniform upper bound on q_j serving as a discrete version of the "entropy condition," among which a discrete total energy inequality constitutes the key building block. The total energy inequality ensures only weak compactness of the sequence $\left\{q_{\Delta x}^2\right\}_{\Delta x>0}$. However, it is crucial to know that this sequence is strongly compact. Strong compactness is needed if we want to recover the original equation (1.4) when sending $\Delta x \downarrow 0$ in the finite difference scheme. To establish the strong compactness property we apply ideas from the theory of renormalized solutions (in the sense of DiPerna and Lions) to the finite difference scheme (1.9). As a part of establishing strong compactness, a higher integrability estimate for $q_{\Delta x}$ is needed to ensure that weak limit points of $q_{\Delta x}^2$ do not contain singular measures. Our convergence proof can be best understood as a discrete variant of the proof used in [38] for the vanishing viscosity method.

This paper is organized as follows: In section 2 we state some relevant notations. The difference scheme and its main convergence theorem are presented in section 3. This theorem is a consequence of the results proved in sections 4–9.

Throughout this paper we use C to denote a generic constant; the actual value of C may change from one line to the next in a calculation.

2. Preliminaries. In this section we introduce some notations to be used throughout this paper and a few basic mathematical results that will be relevant to the convergence analysis of the numerical scheme.

The notations $a\vee 0 = \max\{a,0\} = \frac{a+|a|}{2}$ and $a\wedge 0 = \min\{a,0\} = \frac{a-|a|}{2}$ will be used frequently. In what follows, unless otherwise stated, the index j will run over $\mathbb{Z}$. For such an index we set $x_{j+1/2} = (j+1/2)\Delta x$ and introduce the grid cells $I_j = [x_{j-1/2}, x_{j+1/2})$, where Δx is a small positive number ("the discretization

parameter"). The grid cells I_j are centered around the points $x_j = j\Delta x$. For any sequence $\{v_j\}_{j\in\mathbb{Z}}$ we introduce the following difference operators:

$$D_+v_j := \frac{v_{j+1}-v_j}{\Delta x},\ D_-v_j := \frac{v_j - v_{j-1}}{\Delta x},\ Dv_j := \frac{D_+v_j + D_-v_j}{2} = \frac{v_{j+1}-v_{j-1}}{2\Delta x}.$$

We also use the notations

$$\left\|\{v_j\}_j\right\|_{\ell^p} := \left(\Delta x \sum_{j\in\mathbb{Z}} |v_j|^p\right)^{\frac{1}{p}},\ 1<p<\infty, \quad \left\|\{v_j\}_j\right\|_{\ell^\infty} := \sup_j |v_j|,$$

$$\left\|\{v_j\}_j\right\|_{h^1} := \left(\Delta x \sum_{j\in\mathbb{Z}} \left[v_j^2 + (D_-v_j)^2\right]\right)^{\frac{1}{2}}.$$

Let $\{v_j\}_{j\in\mathbb{Z}}$ be a sequence such that $\|\{v_j\}_j\|_{\ell^1\cap\ell^2} < \infty$. Then $\|\{v_j\}_j\|_{\ell^\infty} \le \frac{1}{\sqrt{\Delta x}}\|\{v_j\}_j\|_{\ell^2} \le \frac{1}{\Delta x}\|\{v_j\}_j\|_{\ell^1}$. Let $\{v_j\}_{j\in\mathbb{Z}}$ be such that $\|\{v_j\}_j\|_{h^1} < \infty$. It is easy to see that the following discrete Sobolev inequality holds:

$$\left\|\{v_j\}_j\right\|_{\ell^\infty} \le \frac{1}{\sqrt{2}}\left\|\{v_j\}_j\right\|_{h^1}. \tag{2.1}$$

Let $\{v_j\}_{j\in\mathbb{Z}}, \{w_j\}_{j\in\mathbb{Z}}$ be two sequences. Then the discrete Leibniz rule reads

$$D_\pm(v_jw_j) = v_jD_\pm w_j + D_\pm v_j w_{j\pm1}, \tag{2.2}$$

while the discrete chain rule states that for any C^2 function f there holds

$$D_\pm f(v_j) = f'(v_j)D_\pm v_j \pm \frac{\Delta x}{2} f''(\xi_j^\pm)(D_\pm v_j)^2 \tag{2.3}$$

for some $\xi_j^\pm$ between $v_{j\pm1}$ and v_j. A key difficulty in designing converging difference schemes for nonlinear equations is that there is no exact chain rule for discrete derivatives but merely the formula (2.3) showing that the chain rule holds only up to a certain error term.

3. Difference scheme and convergence theorem. In this section we present the semidiscrete upwind difference scheme for the Camassa–Holm equation and state the main convergence result.

For $t>0$, we let $\{u_{j+1/2}(t)\}_{j\in\mathbb{Z}}$, where $u_{j+1/2}(t) \approx u(t, x_{j+1/2})$, solve the following system of ODEs:

$$\frac{d}{dt}u_{j+1/2} + \left(u_{j+1/2}\vee 0\right)D_-u_{j+1/2} + \left(u_{j+1/2}\wedge 0\right)D_+u_{j+1/2} + D_+P_j = 0, \tag{3.1}$$

where we specify the initial values as follows:

$$u_{j+1/2}(0) = u_0(x_{j+1/2}). \tag{3.2}$$

For $t\ge 0$, we let $\{P_j(t)\}_{j\in\mathbb{Z}}$, where $P_j(t) \approx P(t, x_j)$, solve

$$-D_-D_+P_j + P_j = \left(u_{j+1/2}\vee 0\right)^2 + \left(u_{j-1/2}\wedge 0\right)^2 + \frac{1}{2}\left(D_-u_{j+1/2}\right)^2. \tag{3.3}$$

By introducing $f_j := (u_{j+1/2} \vee 0)^2 + (u_{j-1/2} \wedge 0)^2 + \frac{q_j^2}{2}$, $h := (1 + 2\frac{1-e^{-\kappa}}{(\Delta x)^2})^{-1}$, and $\kappa := \ln(1 + \frac{\Delta x^2}{2} + \frac{\Delta x}{2}\sqrt{4 + \Delta x^2})$, it is not difficult to verify that the solution of (3.3) has the form

$$P_j = h \sum_i e^{-\kappa|j-i|} f_i, \qquad j \in \mathbb{Z}. \tag{3.4}$$

For later use, one should observe that

$$h = \frac{\Delta x}{2} + \mathcal{O}(\Delta x^2), \quad \frac{|e^{\kappa} - 1|}{\Delta x} = 1 + \mathcal{O}(\Delta x), \quad \frac{|e^{-\kappa} - 1|}{\Delta x} = 1 + \mathcal{O}(\Delta x).$$

Since $\{P_j\}_{j\in\mathbb{Z}}$ can be expressed solely in terms of $\{u_{j+1/2}(t)\}_{j\in\mathbb{Z}}$, we see that (3.1) constitutes an infinite-dimensional system of ODEs of the form

$$\frac{d}{dt} u_{j+1/2}(t) = F\left(\left\{u_{j+1/2}(t)\right\}_{j\in\mathbb{Z}}\right). \tag{3.5}$$

The proof of the next lemma is standard and is therefore omitted.

LEMMA 3.1. *For each fixed $\Delta x > 0$, the ODE system* (3.1)*, or* (3.5)*, has a continuously differentiable solution defined for all $t > 0$.*

Next, let us derive the difference scheme satisfied by

$$q_j = D_- u_{j+1/2}. \tag{3.6}$$

This will be done by applying the difference operator D_- to the u-equation (3.1). To this end, by applying the discrete Leibniz rule we get

$$D_-\left[\left(u_{j+1/2} \vee 0\right) D_- u_{j+1/2}\right] = \left(u_{j-1/2} \vee 0\right) D_- q_j + D_-\left(u_{j+1/2} \vee 0\right) q_j$$

and

$$D_-\left[\left(u_{j+1/2} \wedge 0\right) D_+ u_{j+1/2}\right] = \left(u_{j+1/2} \wedge 0\right) D_+ q_j + D_-\left(u_{j+1/2} \wedge 0\right) q_j,$$

so that

$$\begin{aligned} D_-\left[\left(u_{j+1/2} \vee 0\right) D_- u_{j+1/2} + \left(u_{j+1/2} \wedge 0\right) D_+ u_{j+1/2}\right] \\ = \left(u_{j-1/2} \vee 0\right) D_- q_j + \left(u_{j+1/2} \wedge 0\right) D_+ q_j + q_j^2. \end{aligned} \tag{3.7}$$

The P-equation (3.3) rephrased in terms of q reads

$$-D_+ D_- P_j + P_j = \left(u_{j+1/2} \vee 0\right)^2 + \left(u_{j-1/2} \wedge 0\right)^2 + \frac{1}{2} q_j^2. \tag{3.8}$$

Employing (3.7) and (3.8) when applying D_- to the u-equation in (3.1) yields

$$\begin{aligned} q_j' + \left(u_{j-1/2} \vee 0\right) D_- q_j + \left(u_{j+1/2} \wedge 0\right) D_+ q_j \\ + \frac{q_j^2}{2} + P_j - \left(u_{j+1/2} \vee 0\right)^2 - \left(u_{j-1/2} \wedge 0\right)^2 = 0. \end{aligned} \tag{3.9}$$

Inasmuch as q can be discontinuous, (3.9) is a natural discretization of the q-equation in (1.7). Regarding the initial values, it easy to see that

$$q_j(0) = \frac{1}{\Delta x} \int_{I_j} \partial_x u_0(x)\, dx, \quad j \in \mathbb{Z}. \tag{3.10}$$

The main aim of this paper is to prove that the numerical scheme defined in section 3 converges to a solution of the Camassa–Holm equation. Before we can do that, we need to define what we mean by a "solution."

DEFINITION 3.1. *We call a function* $u = u(t,x) : [0,\infty)\times\mathbb{R} \to \mathbb{R}$ *a weak solution of the Cauchy problem* (1.1)–(1.2) *provided*

(i) $u \in L^\infty(\mathbb{R}_+; H^1(\mathbb{R})) \cap C([0,\infty)\times\mathbb{R})$*;*

(ii) u *satisfies* (1.4) *in the sense of distributions; that is,* $\forall \phi \in C_c^\infty(\mathbb{R}_+\times\mathbb{R})$

$$\int_{\mathbb{R}_+}\int_{\mathbb{R}} u\partial_t\phi + F(u,\partial_x u)\partial_x\phi\, dxdt = 0; \tag{3.11}$$

(iii) $u(0,x) = u_0(x)$ *for every* $x \in \mathbb{R}$*;*

(iv) $\|u(t,\cdot)\|_{H^1(\mathbb{R})} \le \|u_0\|_{H^1(\mathbb{R})}$ *for each* $t > 0$.

If, in addition, there is a constant $C \ge 0$ *depending only on* $\|u_0\|_{H^1(\mathbb{R})}$ *such that*

$$u_x(t,x) \le \frac{2}{t} + C, \qquad (t,x) \in (0,\infty)\times\mathbb{R}, \tag{3.12}$$

then we call u *a dissipative weak solution of the Cauchy problem* (1.1)–(1.2).

The existence of a dissipative solution has been previously established in [38]; see also [39] for a partial uniqueness result.

Supplied with the sequences $\{u_{j+1/2}(t)\}_{j\in\mathbb{Z}}$, $\{q_j(t)\}_{j\in\mathbb{Z}}$ defined by (3.1)–(3.3) and (3.6), we introduce the function

$$u_{\Delta x}(t,x) = q_j(t)(x - x_{j+1/2}) + u_{j-1/2}(t), \quad t \ge 0,\ x \in I_j,\ j \in \mathbb{Z}. \tag{3.13}$$

Observe that $u_{\Delta x}(t,\cdot)$ is piecewise linear and continuous. Besides,

$$\begin{aligned} &u_{\Delta x}(t, x_{j\pm1/2}) = u_{j\pm1/2}(t), \quad t \ge 0,\ j \in \mathbb{Z},\\ &\partial_x u_{\Delta x}(t,x) = q_j(t), \qquad t \ge 0,\ x \in I_j\ j \in \mathbb{Z}. \end{aligned}$$

We are now in a position to state our main result.

THEOREM 3.1. *Suppose that* (1.2) *holds. Let* $\{u_{\Delta x}\}_{\Delta x>0}$ *be a sequence of difference solutions defined by* (3.13), (3.1)–(3.3), *and* (3.6). *Then, along a subsequence as* $\Delta x \downarrow 0$,

$$u_{\Delta x} \to u \text{ in } H^1_{\mathrm{loc}}(\mathbb{R}_+\times\mathbb{R}),$$

where u *is a dissipative weak solution of the Cauchy problem* (1.1)–(1.2).

This theorem is a consequence of the results stated and proved in sections 4–9.

4. Discrete total energy estimate. The finite difference scheme (3.1)–(3.6) is designed to admit the discrete total energy estimate stated below, which contains a dissipation term resulting from the upwind nature of the scheme for the q-variable (notice that there is no dissipation associated with the u-variable).

LEMMA 4.1. *For each* $t \ge 0$,

$$\begin{aligned} &\left\|\left\{u_{j+1/2}(t)\right\}_j\right\|_{h^1}^2 + \Delta x^2 \sum_j \int_0^t \left|u_{j+1/2}(s)\right| \left(D_+D_- u_{j+1/2}(s)\right)^2 ds \\ &\qquad = \left\|\left\{u_{j+1/2}(0)\right\}_j\right\|_{h^1}^2. \end{aligned} \tag{4.1}$$

Proof. We multiply the u-equation in (3.1) by $u_{j+1/2}$ and use $q_j = D_- u_{j+1/2}$ to obtain

$$\begin{aligned}\frac{d}{dt}\left(\frac{u_{j+1/2}^2}{2}\right) &+ \left(u_{j+1/2}\vee 0\right)^2 q_j \\ &+ \left(u_{j+1/2}\wedge 0\right)^2 q_{j+1} + \left(D_+ P_j\right) u_{j+1/2} = 0,\end{aligned} \tag{4.2}$$

while multiplying the q-equation in (3.9) by q_j yields

$$\begin{aligned}\frac{d}{dt}\left(\frac{q_j^2}{2}\right) &+ \left(u_{j-1/2}\vee 0\right)\left(D_- q_j\right) q_j + \left(u_{j+1/2}\wedge 0\right)\left(D_+ q_j\right) q_j \\ &+ \frac{q_j^3}{2} - \left(u_{j+1/2}\vee 0\right)^2 q_j - \left(u_{j-1/2}\wedge 0\right)^2 q_j + P_j q_j = 0.\end{aligned} \tag{4.3}$$

Adding (4.2) and (4.3), multiplying the result with Δx, and summing over j yields

$$\frac{d}{dt}\left[\Delta x \sum_j \left(\frac{u_{j+1/2}^2}{2} + \frac{q_j^2}{2}\right)\right] + \mathrm{I} + \mathrm{II} + \mathrm{III} = 0,$$

where

$$\begin{aligned}\mathrm{I} &= \Delta x \sum_j \left(u_{j-1/2}\vee 0\right)\left(D_- q_j\right) q_j + \Delta x \sum_j \left(u_{j+1/2}\wedge 0\right)\left(D_+ q_j\right) q_j + \Delta x \sum_j \frac{q_j^3}{2}, \\ \mathrm{II} &= \Delta x \sum_j \left(u_{j+1/2}\vee 0\right)^2 q_j + \Delta x \sum_j \left(u_{j+1/2}\wedge 0\right)^2 q_{j+1} \\ &\quad - \Delta x \sum_j \left(u_{j+1/2}\vee 0\right)^2 q_j - \Delta x \sum_j \left(u_{j-1/2}\wedge 0\right)^2 q_j \equiv 0 \quad \text{(by shifting indices)}, \\ \mathrm{III} &= \Delta x \sum_j D_+ P_j u_{j+1/2} + \Delta x \sum_j P_j q_j \equiv 0 \quad \text{(by summation by parts)}.\end{aligned}$$

Let us now deal with term I. The discrete chain rule implies that

$$\left(D_\pm q_j\right) q_j = D_\pm\left(\frac{q_j^2}{2}\right) \mp \frac{\Delta x}{2}\left(D_\pm q_j\right)^2.$$

Hence

$$\begin{aligned}\mathrm{I} &= \Delta x \sum_j \left(u_{j-1/2}\vee 0\right)\left[D_-\left(\frac{q_j^2}{2}\right) + \frac{\Delta x}{2}\left(D_- q_j\right)^2\right] \\ &\quad + \Delta x \sum_j \left(u_{j+1/2}\wedge 0\right)\left[D_+\left(\frac{q_j^2}{2}\right) - \frac{\Delta x}{2}\left(D_+ q_j\right)^2\right] + \Delta x \sum_j \frac{q_j^3}{2} \\ &= \mathrm{I}_1 + \mathrm{I}_2,\end{aligned}$$

where

$$\begin{aligned}
\mathrm{I}_1 &= \Delta x \sum_j \left(u_{j-1/2} \vee 0\right) D_- \left(\frac{q_j^2}{2}\right) + \Delta x \sum_j \left(u_{j+1/2} \wedge 0\right) D_+ \left(\frac{q_j^2}{2}\right) + \Delta x \sum_j \frac{q_j^3}{2}, \\
\mathrm{I}_2 &= \frac{\Delta x^2}{2} \sum_j \Big[\left(u_{j-1/2} \vee 0\right) (D_- q_j)^2 - \left(u_{j+1/2} \wedge 0\right) (D_+ q_j)^2\Big] \\
&= \frac{\Delta x^2}{2} \sum_j \Big[\left(u_{j+1/2} \vee 0\right) (D_- q_{j+1})^2 - \left(u_{j+1/2} \wedge 0\right) (D_+ q_j)^2\Big] \\
&= \frac{\Delta x^2}{2} \sum_j |u_{j+1/2}| (D_+ q_j)^2 \geq 0.
\end{aligned}$$

To handle the I_1-term, we use the discrete Leibniz rule, which implies that

$$\begin{aligned}
D_- \left[\left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2}\right] &= \left(u_{j-1/2} \vee 0\right) D_- \left(\frac{q_j^2}{2}\right) + D_- \left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2}, \\
D_+ \left[\left(u_{j-1/2} \wedge 0\right) \frac{q_j^2}{2}\right] &= \left(u_{j+1/2} \wedge 0\right) D_+ \left(\frac{q_j^2}{2}\right) + D_+ \left(u_{j-1/2} \vee 0\right) \frac{q_j^2}{2} \\
&= \left(u_{j+1/2} \wedge 0\right) D_+ \left(\frac{q_j^2}{2}\right) + D_- \left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2},
\end{aligned}$$

to obtain

$$\begin{aligned}
\mathrm{I}_1 = {} & \Delta x \sum_j D_- \left[\left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2}\right] - \Delta x \sum_j D_- \left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2} \\
& + \Delta x \sum_j D_+ \left[\left(u_{j-1/2} \wedge 0\right) \frac{q_j^2}{2}\right] - \Delta x \sum_j D_- \left(u_{j+1/2} \vee 0\right) \frac{q_j^2}{2} + \Delta x \sum_j \frac{q_j^3}{2} \\
= {} & - \Delta x \sum_j D_- u_{j+1/2} \frac{q_j^2}{2} + \Delta x \sum_j \frac{q_j^3}{2} - \Delta x \sum_j \frac{q_j^3}{2} + \Delta x \sum_j \frac{q_j^3}{2} = 0.
\end{aligned}$$

Summarizing our findings, the following discrete energy estimate holds:

$$\frac{d}{dt}\left[\Delta x \sum_j \left(\frac{u_{j+1/2}^2}{2} + \frac{q_j^2}{2}\right)\right] + \frac{\Delta x^2}{2} \sum_j \left|u_{j+1/2}\right| \left(D_+ q_j\right)^2 = 0.$$

Finally, by integrating over $[0,t]$ we get (4.1). □

Remark 4.1. In view of (4.1) and (2.1)

$$\left\| \left\{u_{j+1/2}(t)\right\}_j \right\|_{\ell^\infty} \leq C \left\|u_0\right\|_{H^1(\mathbb{R})}, \qquad t \geq 0, \tag{4.4}$$

where $C > 0$ is a constant that is independent of Δx.

Later we will need the strong L^p convergence of the numerical approximations of the "pressure" P. We now collect some estimates on $\{P_j\}_{j\in\mathbb{Z}}$ implying this convergence; the estimates are all straightforward consequences of (4.1) and (3.4).

LEMMA 4.2. *For each $t \geq 0$,*

$$\left\| \{P_j(t)\}_j \right\|_{\ell^\infty}, \left\| \{P_j(t)\}_j \right\|_{\ell^1} \leq C \left\| u_0 \right\|^2_{H^1(\mathbb{R})}, \tag{4.5}$$

$$\left\| \{D_+P_j(t)\}_j \right\|_{\ell^\infty}, \left\| \{D_+P_j(t)\}_j \right\|_{\ell^1} \leq C \left\| u_0 \right\|^2_{H^1(\mathbb{R})}, \tag{4.6}$$

where $C > 0$ is a constant independent of Δx.

5. Discrete Oleĭnik estimate. The aim of this section is to prove that the quantity $q_j = D_- u_{j+1/2}$ is uniformly upper bounded on $\{t > 0\}$, thereby revealing the dissipative nature of our scheme.

LEMMA 5.1. *For $t > 0$, $j \in \mathbb{Z}$,*

$$q_j(t) \leq \frac{2}{t} + C \tag{5.1}$$

for some positive constant C that is independent of Δx.

Proof. By (4.4) and (4.5), it follows from (1.9) that

$$q_j' + \frac{q_j^2}{2} \leq L - \left[\left(u_{j-1/2} \vee 0 \right) D_- q_j + \left(u_{j+1/2} \wedge 0 \right) D_+ q_j \right], \quad j \in \mathbb{Z},\ t > 0, \tag{5.2}$$

for some constant $L > 0$. Since $\lim_{j \to \pm\infty} q_j(t) = 0$ there is an index $i(t) \in \mathbb{Z}$ such that

$$q_{i(t)}(t) = \sup_{j \in \mathbb{Z}} q_j(t), \qquad t > 0. \tag{5.3}$$

At $j = i(t)$ for $t > 0$ there holds $D_+ q_{i(t)}(t) \leq 0 \leq D_- q_{i(t)}(t)$, so that

$$\left(u_{i(t)-1/2}(t) \vee 0 \right) D_- q_{i(t)}(t) + \left(u_{i(t)+1/2}(t) \wedge 0 \right) D_+ q_{i(t)}(t) \geq 0, \qquad t > 0,$$

which inserted into (5.2) yields

$$q_{i(t)}'(t) + \frac{q_{i(t)}^2(t)}{2} \leq L, \qquad t > 0. \tag{5.4}$$

One can check that $f(t) := \frac{2}{t} + \sqrt{2L}$ is a supersolution of the ODE $y' + \frac{y^2}{2} = L$ on $\{t > 0\}$, while (5.4) shows that $q_{i(t)}(t)$ is a subsolution. Hence, by the comparison principle for ODEs and (5.3), $q_j(t) \leq q_{i(t)}(t) \leq \frac{2}{t} + \sqrt{2L}$ for $j \in \mathbb{Z}$, $t > 0$. ∎

6. Discrete higher integrability estimate. In view of (4.1) we infer that $(\partial_x u_{\Delta x})^2$ converges (in the sense of measures) along a subsequence as $\Delta x \downarrow 0$. To ensure that the limit does not contain concentration effects (singular measures), we shall derive a discrete higher integrability estimate.

To prepare for the derivation of this estimate (but also for later use), we will derive a "renormalized form" of the finite difference scheme for q_j. To this end, let f be a nonlinear function (renormalization) of appropriate regularity and growth. By multiplying (3.9) by $f'(q_j)$ and using the discrete chain rule, which in the present context reads

$$(D_\pm q_j) f'(q_j) = D_\pm f(q_j) \mp \frac{\Delta x}{2} f''(\xi_j^\pm) \left(D_\pm q_j \right)^2,$$

for some numbers $\xi_j^{\pm}$ between q_j and $q_{j\pm1}$, we obtain the following renormalized difference scheme:

$$\begin{aligned}\frac{d}{dt}f(q_j)+\big(u_{j-1/2}\vee 0\big)\,D_-f(q_j)+\big(u_{j+1/2}\wedge 0\big)\,D_+f(q_j)+\frac{q_j^2}{2}f'(q_j)\\ +\Big[P_j-\big(u_{j+1/2}\vee 0\big)^2-\big(u_{j-1/2}\wedge 0\big)^2\Big]f'(q_j)+I_{\Delta x,f'',j}=0,\end{aligned}\tag{6.1}$$

where

$$I_{\Delta x,f'',j}:=\frac{\Delta x}{2}\Big\{\big(u_{j-1/2}\vee 0\big)\,f''(\xi_j^-)(D_-q_j)^2-\big(u_{j+1/2}\wedge 0\big)\,f''(\xi_j^+)(D_+q_j)^2\Big\}.$$

Let us now write (6.1) in divergence form. To this end, observe that the discrete Leibniz rule (2.2) implies the following relations:

$$\begin{aligned}D_-\left[\big(u_{j+1/2}\vee 0\big)\,f(q_j)\right]&=\big(u_{j-1/2}\vee 0\big)\,D_-f(q_j)+D_-\big(u_{j+1/2}\vee 0\big)\,f(q_j),\\ D_+\left[\big(u_{j-1/2}\wedge 0\big)\,f(q_j)\right]&=\big(u_{j+1/2}\wedge 0\big)\,D_+f(q_j)+D_+\big(u_{j-1/2}\wedge 0\big)\,f(q_j)\\ &=\big(u_{j+1/2}\wedge 0\big)\,D_+f(q_j)+D_-\big(u_{j+1/2}\wedge 0\big)\,f(q_j),\end{aligned}$$

and therefore, by using that $q_j=D_-u_{j+1/2}$,

$$\begin{aligned}&\big(u_{j-1/2}\vee 0\big)\,D_-f(q_j)+\big(u_{j+1/2}\wedge 0\big)\,D_+f(q_j)\\ &\qquad=D_-\left[\big(u_{j+1/2}\vee 0\big)\,f(q_j)\right]+D_+\left[\big(u_{j-1/2}\wedge 0\big)\,f(q_j)\right]-q_jf(q_j).\end{aligned}$$

Hence, we end up with the following divergence-form variant of the renormalized difference scheme (6.1):

$$\begin{aligned}&\frac{d}{dt}f(q_j)+D_-\left[\big(u_{j+1/2}\vee 0\big)\,f(q_j)\right]+D_+\left[\big(u_{j-1/2}\wedge 0\big)\,f(q_j)\right]\\ &\qquad+\frac{q_j^2}{2}f'(q_j)-q_jf(q_j)+\Big[P_j-\big(u_{j+1/2}\vee 0\big)^2-\big(u_{j-1/2}\wedge 0\big)^2\Big]f'(q_j)\\ &\qquad\qquad+I_{\Delta x,f'',j}=0.\end{aligned}\tag{6.2}$$

We are now in a position to prove the following lemma.

LEMMA 6.1. *Let $\alpha\in(0,1)$, $T>0$, and j_a,j_b be integers such that $j_a<j_b$. Set $a:=j_a\Delta x$ and $b:=j_b\Delta x$. There exists a positive constant C, depending only on u_0,α,T,a,b, such that*

$$\int_0^T\Delta x\sum_{j=j_a}^{j_b}|q_j(t)|^{2+\alpha}\,dt\le C.\tag{6.3}$$

Proof. Our proof exploits (5.1). We start by introducing the notations

$$\begin{gathered}\mathcal{J}=\{j_a,\dots,j_b\},\\ \mathcal{N}(t)=\big\{j\in\mathcal{J}\;\big|\;q_j(t)<0\big\},\quad \mathcal{P}(t)=\big\{j\in\mathcal{J}\;\big|\;q_j(t)\ge 0\big\},\\ I=\int_0^T\Delta x\sum_{j\in\mathcal{J}}|q_j(t)|^{2+\alpha}\,dt,\\ I_-=\int_0^T\Delta x\sum_{j\in\mathcal{N}(t)}|q_j(t)|^{2+\alpha}\,dt,\quad I_+=\int_0^T\Delta x\sum_{j\in\mathcal{P}(t)}|q_j(t)|^{2+\alpha}\,dt\end{gathered}$$

and observing that

$$\mathcal{J} = \mathcal{N}(t) \cup \mathcal{P}(t), \quad I = I_+ + I_-.$$

By (4.1) and (5.1), and since $\alpha < 1$,

$$I_+ \le \int_0^T \Delta x \sum_{j \in \mathcal{P}(t)} |q_j(t)|^2 \left(\frac{2}{t} + C\right)^\alpha \, dt \le C(T,\alpha) \left\| \{u_j(0)\}_j \right\|_{h^1}^2 .$$

We have to estimate I_-. With $f(\xi) = |\xi|^{1+\alpha}$, (6.2) reads

$$\begin{aligned}
&\frac{d}{dt} |q_j|^{1+\alpha} + D_- \left[\left(u_{j+1/2} \vee 0\right) |q_j|^{1+\alpha} \right] + D_+ \left[\left(u_{j-1/2} \wedge 0\right) |q_j|^{1+\alpha} \right] \\
&\quad + \frac{\alpha - 1}{2} \operatorname{sign}(q_j) |q_j|^{2+\alpha} + (1+\alpha) P_j \operatorname{sign}(q_j) |q_j|^\alpha \\
&\quad - (1+\alpha) \left[\left(u_{j+1/2} \vee 0\right)^2 + \left(u_{j-1/2} \wedge 0\right)^2 \right] \operatorname{sign}(q_j) |q_j|^\alpha = -I_{\Delta x, f'', j} \le 0,
\end{aligned}$$

where we used the convexity of f to conclude the inequality. Let χ be a smooth cutoff function such that

$$0 \le \chi \le 1, \quad \xi \in [a, b+1] \Longrightarrow \chi(\xi) = 1, \quad \xi \notin [a-1, b+2] \Longrightarrow \chi(\xi) = 0.$$

By multiplying by $\Delta x \chi(j\Delta x)$, summing over $j \in \mathbb{Z}$, and integrating over $t \in (0,T)$, we arrive at

$$\begin{aligned}
0 \le\ & \Delta x \sum_j \left(|q_j(0)|^{1+\alpha} - |q_j(T)|^{1+\alpha} \right) \chi(j\Delta x) \\
& + \frac{1-\alpha}{2} \int_0^T \Delta x \sum_j \operatorname{sign}(q_j) |q_j|^{2+\alpha} \chi(j\Delta x) \, dt \\
& - \int_0^T \Delta x \sum_j D_- \left[\left(u_{j+1/2} \vee 0\right) |q_j|^{1+\alpha} \right] \chi(j\Delta x) \, dt \\
& - \int_0^T \Delta x \sum_j D_+ \left[\left(u_{j-1/2} \wedge 0\right) |q_j|^{1+\alpha} \right] \chi(j\Delta x) \, dt \\
& - (1+\alpha) \int_0^T \Delta x \sum_j |P_j| |q_j|^\alpha \chi(j\Delta x) \, dt \\
& + (1+\alpha) \int_0^T \Delta x \sum_j \left(u_{j+1/2} \vee 0\right)^2 |q_j|^\alpha \chi(j\Delta x) \, dt \\
& + (1+\alpha) \int_0^T \Delta x \sum_j \left(u_{j-1/2} \wedge 0\right)^2 |q_j|^\alpha \chi(j\Delta x) \, dt.
\end{aligned} \tag{6.4}$$

Next, we introduce the notations

$$\widetilde{\mathcal{N}}(t) = \left\{ j \in \mathbb{Z} \;\middle|\; q_j(t) < 0 \right\}, \qquad \widetilde{\mathcal{P}}(t) = \left\{ j \in \mathbb{Z} \;\middle|\; q_j(t) \ge 0 \right\}$$

and observe that, since $\mathcal{N}(t) \subset \widetilde{\mathcal{N}}(t)$ and $\widetilde{\mathcal{N}}(t) \cup \widetilde{\mathcal{P}}(t) = \mathbb{Z}$, there holds

$$\begin{aligned}
&\int_0^T \Delta x \sum_j \operatorname{sign}(q_j)\, |q_j|^{2+\alpha}\, \chi(j\Delta x)\, dt \\
&\quad = \Delta x \int_0^T \sum_{j \in \mathcal{P}(t)} |q_j|^{2+\alpha}\, dt - \int_0^T \Delta x \sum_{j \in \mathcal{N}(t)} |q_j|^{2+\alpha}\, dt \\
&\quad \le \int_0^T \Delta x \sum_{j \in \mathcal{P}(t)} |q_j|^{2+\alpha}\, dt - I_-.
\end{aligned}$$

Therefore, from (6.4),

$$\frac{1-\alpha}{2} I_- \le I_1 + I_2 + I_3 + I_4, \tag{6.5}$$

where

$$\begin{aligned}
I_1 &= \frac{1-\alpha}{2} \int_0^T \Delta x \sum_{j \in \mathcal{P}(t)} |q_j|^{2+\alpha}\, dt, \\
I_2 &= \Delta x \sum_j \left(|q_j(0)|^{1+\alpha} - |q_j(T)|^{1+\alpha} \right) \chi(j\Delta x), \\
I_3 &= -\int_0^T \Delta x \sum_j D_- \left[\left(u_{j+1/2} \vee 0 \right) |q_j|^{1+\alpha} \right] \chi(j\Delta x)\, dt \\
&\qquad - \int_0^T Dx \sum_j D_+ \left[\left(u_{j-1/2} \wedge 0 \right) |q_j|^{1+\alpha} \right] \chi(j\Delta x)\, dt, \\
I_4 &= -(1+\alpha) \int_0^T \Delta x \sum_j |P_j|\, |q_j|^{\alpha}\, \chi(j\Delta x)\, dt \\
&\qquad + (1+\alpha) \int_0^T \Delta x \sum_j \left(u_{j+1/2} \vee 0 \right)^2 |q_j|^{\alpha}\, \chi(j\Delta x)\, dt \\
&\qquad + (1+\alpha) \int_0^T \Delta x \sum_j \left(u_{j-1/2} \wedge 0 \right)^2 |q_j|^{\alpha}\, \chi(j\Delta x)\, dt.
\end{aligned}$$

For I_1 we repeat what we did for I_+. Indeed, due to (4.1), (5.1), and $\alpha < 1$,

$$I_1 \le \frac{1}{2} \int_0^T \Delta x \sum_{j \in \mathcal{P}(t)} |q_j|^2 \left(\frac{2}{t} + C \right)^{\alpha} dt \le C(T, \alpha) \left\| \{u_{j+1/2}(0)\}_j \right\|_{h^1}^2.$$

For the other terms we use Hölder's inequality for sums, the discrete Leibniz rule,

(4.1), (4.4), and (4.5):

$$
\begin{aligned}
I_2 &\le \left(\left\| \left\{ |q_j(0)|^{1+\alpha} \right\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} + \left\| \left\{ |q_j(T)|^{1+\alpha} \right\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} \right) \left\| \{\chi(j\Delta x)\}_j \right\|_{\ell^{\frac{2}{1-\alpha}}} \\
&= \left(\left\| \{q_j(0)\}_j \right\|_{\ell^2}^{1+\alpha} + \left\| \{q_j(T)\}_j \right\|_{\ell^2}^{1+\alpha} \right) \left\| \{\chi(j\Delta x)\}_j \right\|_{\ell^{\frac{2}{1-\alpha}}} \\
&\le C_1 \left\| \{u_j(0)\}_j \right\|_{h^1}^{1+\alpha} \left\| \{\chi(j\Delta x)\}_j \right\|_{\ell^{\frac{2}{1-\alpha}}}, \\
I_3 &= \int_0^T \Delta x \sum_j \left(u_{j+1/2} \vee 0 \right) |q_j|^{1+\alpha} D_- \chi((j-1)\Delta x)\, dt \\
&\qquad + \int_0^T \Delta x \sum_j \left(u_{j-1/2} \wedge 0 \right) |q_j|^{1+\alpha} D_+ \chi((j+1)\Delta x)\, dt \\
&\le \int_0^T \left\| \left\{ u_{j+1/2}(t) \right\}_j \right\|_{\ell^\infty} \left\| \{q_j(t)\}_j \right\|_{\ell^2}^{1+\alpha} \\
&\qquad \times \left(\left\| \{D_-\chi((j-1)\Delta x)\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} + \left\| \{D_+\chi((j+1)\Delta x) dt\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} \right) dt \\
&\le C_2 T \left\| \{u_j(0)\}_j \right\|_{h^1}^{2+\alpha} \\
&\qquad \times \left(\left\| \{D_-\chi((j-1)\Delta x)\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} + \left\| \{D_+\chi((j+1)\Delta x)\}_j \right\|_{\ell^{\frac{2}{1+\alpha}}} \right), \\
I_4 &\le (1+\alpha) \int_0^T \Delta x \sum_j \left(\left\| \{P_j\}_j \right\|_{\ell^\infty} + 2 \left\| \left\{ u_{j+1/2} \right\}_j \right\|_{\ell^\infty}^2 \right) |q_j|^\alpha \chi(j\Delta x)\, dt \\
&\le C_3 \left\| \{u_j(0)\}_j \right\|_{h^1}^2 \int_0^T \left\| \{q_j(t)_j\}_j \right\|_{\ell^2}^\alpha \left\| \{\chi(j\Delta x)\}_j \right\|_{\ell^{\frac{2}{2-\alpha}}} dt \\
&\le C_4 \left\| \{u_j(0)\}_j \right\|_{h^1}^{2+\alpha} T \left\| \{\chi(j\Delta x)\}_j \right\|_{\ell^{\frac{2}{2-\alpha}}},
\end{aligned}
$$

where the constants $C_1, \dots, C_4$ are independent of Δx. Now a bound on I_- follows from (6.5), and thereby the proof is concluded. ∎

7. Basic convergence results. In this section we present some convergence results that are straightforward consequences of the a priori estimates established earlier.

LEMMA 7.1. *There exists a limit function $u \in L^\infty(\mathbb{R}_+; H^1(\mathbb{R})) \cap C([0,\infty) \times \mathbb{R})$ such that along a subsequence as $\Delta x \downarrow 0$*

$$
u_{\Delta x} \overset{\star}{\rightharpoonup} u \text{ in } L^\infty(\mathbb{R}_+; H^1(\mathbb{R})), \tag{7.1}
$$

$$
u_{\Delta x} \to u \text{ uniformly on } [0,T] \times [a,b] \tag{7.2}
$$

for each set $[0,T] \times [a,b] \subset \mathbb{R}^2$. Additionally,

$$
u(t,x) \overset{t \downarrow 0}{\to} u_0(x) \text{ for each } x \in \mathbb{R}. \tag{7.3}
$$

Proof. It is not hard to see that (3.13) implies that

$$
\left| \int_{\mathbb{R}} u_{\Delta x}^2\, dx - \Delta x \sum_j u_{j+1/2}^2 \right| \le \left(\Delta x \sum_j q_j^2 \right) \Delta x, \qquad t \ge 0,
$$

and

$$\int_{\mathbb{R}} (\partial_x u_{\Delta x})^2 \, dx = \Delta x \sum_j q_j^2, \qquad t \geq 0,$$

so, by (4.1),

$$\begin{aligned} &\int_{\mathbb{R}} \Big[(u_{\Delta x})^2 + (\partial_x u_{\Delta x})^2 \Big] \, dx \\ &\leq \int_{\mathbb{R}} \Big[(u_{\Delta x}(0,x))^2 + (\partial_x u_{\Delta x}(0,x))^2 \Big] \, dx + \mathcal{O}(\Delta x) \\ &\leq C \left(\|u_0\|^2_{H^1(\mathbb{R})} + \Delta x \right), \qquad t \geq 0, \end{aligned} \tag{7.4}$$

where C is independent of Δx. Claim (7.1) is an outcome of (7.4).

To verify claim (7.2) we will show that

$$\{u_{\Delta x}\}_{\Delta x > 0} \text{ is bounded in } W^{1,2+\alpha}((0,T) \times (a,b)) \tag{7.5}$$

for any (fixed) set $(0,T) \times (a,b) \subset \mathbb{R}^2$, where α is provided by Lemma 6.1.

Without loss generality, let us assume that $a = j_a \Delta x$ and $b = j_b \Delta x$ for some integers j_a and j_b. Then Lemma 6.1 tells us that

$$\int_0^T \int_a^b |\partial_x u_{\Delta x}|^{2+\alpha} \, dx \, dt = \Delta x \sum_{j=j_a}^{j_b} \int_0^T |q_j(t)|^{2+\alpha} \, dt \leq C \tag{7.6}$$

for some constant $C = C(u_0, \alpha, T, a, b)$ independent of Δx.

By taking into account (3.13), (3.1), and (3.9), there holds for any $x \in I_j$, $j \in \mathbb{Z}$,

$$\begin{aligned} |\partial_t u_{\Delta x}(t,x)| &= \Big| q_j'(t)(x - x_{j-1/2}) + u_{j-1/2}'(t) \Big| \\ &\leq \Big| u_{j-1/2}'(t) \Big| + \big| q_j'(t) \big| \, \Delta x \\ &\leq \big| u_{j+1/2} q_j \big| + \big| u_{j+1/2} q_{j+1} \big| + |D_+ P_j| \\ &\quad + \Delta x \Big(\big| u_{j-1/2} D_- q_j \big| + \big| u_{j+1/2} D_+ q_j \big| \\ &\qquad + \frac{q_j^2}{2} + u_{j+1/2}^2 + u_{j-1/2}^2 + |P_j| \Big). \end{aligned} \tag{7.7}$$

Observe that $\Delta x \, q_j = \mathcal{O}(1)$ for all j, which is clearly true thanks to (3.6) and (4.4). By using this and (4.4) and (4.6) in (7.7) we acquire the pointwise estimate

$$|\partial_t u_{\Delta x}| \leq C \left(1 + |q_{j-1}| + |q_j| + |q_{j+1}|\right) \quad \text{for each } x \in I_j, \, j \in \mathbb{Z}, \tag{7.8}$$

for some constant C independent of Δx. Consequently, in view of (6.3),

$$\int_0^T \int_a^b |\partial_t u_{\Delta x}|^{2+\alpha} \, dx \, dt \leq C \left(1 + \Delta x \sum_{j=j_a}^{j_b} \int_0^T |q_j|^{2+\alpha} \, dt \right) \leq C$$

for some constant $C = C(u_0, \alpha, T, a, b)$ independent of Δx.

In summary, we have proved that (7.5) holds. Since $W^{1,2+\alpha}((0,T)\times(a,b))$ is compactly embedded into $C^{0,\ell}([0,T]\times[a,b])$, with $\ell = 1-2/(2+\alpha)$, there exists a continuous function $u:[0,\infty)\times\mathbb{R}\to\mathbb{R}$ such that along a subsequence

$$u_{\Delta x}\to u \text{ uniformly on } [0,T]\times[a,b] \text{ and pointwise in } \mathbb{R}_+\times\mathbb{R} \text{ as } \Delta x\downarrow 0.$$

By combining this with a diagonal argument we conclude that claim (7.2) is true.

Finally, let us prove that the limit u satisfies the initial condition. We fix an arbitrary point $x_0\in\mathbb{R}$ and let $t\in(0,1)$. Then we proceed as follows:

$$\begin{aligned}|u(t,x_0)-u_0(x_0)| &\le |u(t,x_0)-u_{\Delta x}(t,x_0)|\\ &\quad + |u_{\Delta x}(t,x_0)-u_{\Delta x}(0,x_0)| + |u_{\Delta x}(0,x_0)-u_0(x_0)|\\ &\le |u(t,x_0)-u_{\Delta x}(t,x_0)|\\ &\quad + Ct^{\ell} + |u_{\Delta x}(0,x_0)-u_0(x_0)|\,,\quad \ell = 1-\frac{2}{2+\alpha},\end{aligned}$$

where we used (7.5) to derive the last inequality (C does not depend on Δx). Equipped with (7.2), (1.2), and (3.2), we deduce (7.3) by sending first $\Delta x\downarrow 0$ and second $t\downarrow 0$. This concludes the proof of the lemma. ∎

Equipped with the sequence $\{P_j\}_{j\in\mathbb{Z}}$ defined by (3.1)–(3.6), we introduce the piecewise linear and continuous function

$$P_{\Delta x}(t,x) = P_j(t) + (x-x_j)D_+P_j(t),\quad t\ge 0,\ x\in I_{j+1/2},\ j\in\mathbb{Z}. \tag{7.9}$$

Observe that $\partial_x P_{\Delta x}(t,x) = D_+P_j(t)$ for $t\ge 0$, $x\in I_{j+1/2}$, $j\in\mathbb{Z}$.

LEMMA 7.2. *There exists a limit $P\in L^\infty(\mathbb{R}_+;W^{1,\infty}(\mathbb{R}))\cap L^\infty(\mathbb{R}_+;W^{1,1}(\mathbb{R}))$ such that along a subsequence as $\Delta x\downarrow 0$*

$$P_{\Delta x}\to P \text{ in } L^p_{\mathrm{loc}}(\mathbb{R}_+\times\mathbb{R}) \text{ for each } 1\le p<\infty. \tag{7.10}$$

Proof. First of all, it is not difficult to see from (7.9) and Lemma 4.2 that

$$\{P_{\Delta x}\}_{\Delta x>0} \text{ is bounded in } L^\infty(\mathbb{R}_+;W^{1,\infty}(\mathbb{R}))\cap L^\infty(\mathbb{R}_+;W^{1,1}(\mathbb{R})).$$

Next, we prove that $\{\partial_t P_{\Delta x}\}_{\Delta x>0}$ is bounded in $L^1([0,T]\times\mathbb{R})$ for each fixed $T>0$. To this end, we write $P_j = P_{1,j}+P_{2,j}$ (cf. (3.4)) where

$$\begin{aligned}P_{1,j} &= h\sum_{i\in\mathbb{Z}}\left(e^{-\kappa|j-i|}\right)\left((u_{i+1/2}\vee 0)^2 + (u_{i-1/2}\wedge 0)^2\right),\\ P_{2,j} &= \frac{h}{2}\sum_{i\in\mathbb{Z}}\left(e^{-\kappa|j-i|}\right)q_i^2.\end{aligned}$$

We shall prove that there is a constant C, independent of Δx, such that

$$\int_0^T \Delta x\sum_j\left|\frac{d}{dt}P_{1,j}\right|\,dt\le C, \tag{7.11}$$

$$\int_0^T \Delta x\sum_j\left|\Delta x\,D_+\left(\frac{d}{dt}P_{1,j}\right)\right|\,dt\le C, \tag{7.12}$$

$$\int_0^T \Delta x\sum_j\left|\frac{d}{dt}P_{2,j}\right|\,dt\le C, \tag{7.13}$$

$$\int_0^T \Delta x\sum_j\left|\Delta x\,D_+\left(\frac{d}{dt}P_{2,j}\right)\right|\,dt\le C. \tag{7.14}$$

Note that (7.12) and (7.14) follow from (7.11) and (7.13), respectively, since if $|a_j| \le C$ for all j, then $|\Delta x D_\pm a_j| \le |a_j| + |a_{j\pm1}| \le 2C$ for all j.

To prove (7.11) observe that

$$\begin{aligned} P'_{1,j} &= h\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\left((u_{i+1/2}\vee 0)u'_{i+1/2} + (u_{i-1/2}\wedge 0)u'_{i-1/2}\right) \\ &\le \frac{h}{2}\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\left(u^2_{i+1/2} + (u'_{i+1/2})^2 + u^2_{i-1/2} + (u'_{i-1/2})^2\right), \end{aligned}$$

and thus

$$\begin{aligned} \Delta x\sum_j |P'_{1,j}| &\le h\Delta x\sum_{i,j} \left(e^{-\kappa|j-i|}\right)\left(u^2_{i+1/2} + (u'_{i+1/2})^2 + u^2_{i-1/2} + (u'_{i-1/2})^2\right) \\ &\le C\left(\left\|\left\{e^{-\kappa|j|}\right\}_j\right\|_{\ell^1} + 1\right)\left(\left\|\left\{u_{j+1/2}\right\}_j\right\|^2_{\ell^2} + \left\|\left\{u'_{j+1/2}\right\}_j\right\|^2_{\ell^2}\right), \end{aligned}$$

where $C > 0$ is a constant independent of Δx. From (7.8) and (4.1) it follows that $\{u'_{j+1/2}\}_{j\in\mathbb{Z}}$ is bounded in $L^2(0,T;\ell^2)$, which implies (7.11).

To prove (7.13) we use (6.2) with $f(q) = \frac{q^2}{2}$ to obtain

$$\begin{aligned} P'_{2,j} &= h\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\frac{d}{dt}\left(\frac{q_i^2}{2}\right) \\ &= -h\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\left(D_-\left[\left(u_{i+1/2}\vee 0\right)\frac{q_i^2}{2}\right] + D_+\left[\left(u_{i-1/2}\wedge 0\right)\frac{q_i^2}{2}\right]\right) \\ &\quad - h\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\left[P_i q_i - \left(u_{j+1/2}\vee 0\right)^2 q_i - \left(u_{i-1/2}\wedge 0\right)^2 q_i \right. \\ &\qquad\qquad \left. + \frac{\Delta x}{2}\left[\left(u_{i-1/2}\vee 0\right)(D_- q_i)^2 - \left(u_{i+1/2}\wedge 0\right)(D_+ q_i)^2\right]\right] \\ &= -h\sum_{i\in\mathbb{Z}} \left(D_-\left(e^{-\kappa|j-i|}\right)\right)\left(u_{i-1/2}\vee 0\right)\frac{q_{i-1}^2}{2} \\ &\quad - h\sum_{i\in\mathbb{Z}} \left(D_+\left(e^{-\kappa|j-i|}\right)\right)\left(u_{i+1/2}\wedge 0\right)\frac{q_{i+1}^2}{2} \\ &\quad - h\sum_{i\in\mathbb{Z}} \left(e^{-\kappa|j-i|}\right)\left[P_i q_i - \left(u_{i+1/2}\vee 0\right)^2 q_i - \left(u_{i-1/2}\wedge 0\right)^2 q_i \right. \\ &\qquad\qquad \left. + \frac{\Delta x}{2}\left[\left(u_{i-1/2}\vee 0\right)(D_- q_i)^2 - \left(u_{i+1/2}\wedge 0\right)(D_+ q_i)^2\right]\right], \end{aligned}$$

and hence (7.13) follows from (4.1) and (4.4).

Since $\partial_t P_{\Delta x}(t,x) = P'_j(t) + (x - x_j)D_+ P'_j(t)$, $t \ge 0$, $x \in I_{j+1/2}$, the bound on $\{\partial_t P_{\Delta x}\}_{\Delta x>0}$ follows from (7.11)–(7.14). As a result the sequence $\{P_{\Delta x}\}_{\Delta x>0}$ is bounded in $W^{1,1}_{\mathrm{loc}}(\mathbb{R}_+\times\mathbb{R})$. Combining this with the L^∞-bound in Lemma 4.2 yields the existence of a subsequence that converges as claimed in (7.10). ∎

8. Strong convergence result. Endowed with the sequence $\{q_j(t)\}_{j\in\mathbb{Z}}$ defined in terms of (3.1)–(3.3) and (3.6), we introduce the function

$$q_{\Delta x}(t,x) = q_j(t), \quad t \ge 0,\ x \in I_j,\ j \in \mathbb{Z}. \tag{8.1}$$

Observe that

$$\partial_x u_{\Delta x}(t,x) = q_{\Delta x}(t,x), \quad t \geq 0,\, x \in I_j,\, j \in \mathbb{Z}. \tag{8.2}$$

Additionally, by (3.10) (cf. also (3.13))

$$\|q_0 - q_{\Delta x,0}\|_{L^2(\mathbb{R})} \to 0 \quad \text{as } \Delta x \to 0 \quad (q_0 := \partial_x u_0,\, q_{\Delta x,0} := \partial_x u_{\Delta x}|_{t=0}). \tag{8.3}$$

The ensuing lemma is a simple consequence of the main estimates established in earlier sections.

LEMMA 8.1. *Fix any $1 \leq p < 3$ and $1 \leq r < \frac{3}{2}$. Then there exist two functions $q \in L^p_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R})$, $\overline{q^2} \in L^r_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R})$ such that along a subsequence as $\Delta x \downarrow 0$*

$$q_{\Delta x} \overset{\star}{\rightharpoonup} q \text{ in } L^\infty_{\mathrm{loc}}(\mathbb{R}_+; L^2(\mathbb{R})), \qquad q_{\Delta x} \rightharpoonup q \text{ in } L^p_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R}), \tag{8.4}$$

$$q^2_{\Delta x} \rightharpoonup \overline{q^2} \text{ in } L^r_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R}). \tag{8.5}$$

Moreover,

$$q^2(t,x) \leq \overline{q^2}(t,x) \text{ for a.e. } (t,x) \in \mathbb{R}_+ \times \mathbb{R} \tag{8.6}$$

and

$$\partial_x u = q \quad \text{in the sense of distributions on } [0,\infty) \times \mathbb{R}. \tag{8.7}$$

Finally, there is a positive constant C depending only on $\|u_0\|_{H^1(\mathbb{R})}$ such that

$$q(t,x) \leq \frac{2}{t} + C, \qquad t > 0,\, x \in \mathbb{R}. \tag{8.8}$$

Remark 8.1. Throughout the paper we use overbars to denote weak limits. Below and later we routinely use some well known results related to weak convergence, which are listed, for example, in [24, Chapter 2]).

Proof. Claims (8.4) and (8.5) are direct consequences of (8.1), (3.6), and Lemmas 4.1 and 6.1. Claim (8.6) is true thanks to (8.5), while (8.7) is a consequence of (8.2) and Lemma 7.1. Finally, by (5.1), $q_{\Delta x}(t,x) \leq \frac{2}{t} + C$, $t \geq 0$, $x \in \mathbb{R}$, and hence, because of (8.4), claim (8.8) follows. □

In view of the weak convergences stated in (8.4), we can assume that for any function $f \in C^1(\mathbb{R})$ with f' bounded

$$\begin{aligned} &f(q_{\Delta x}) \overset{\star}{\rightharpoonup} \overline{f(q)} \quad \text{in } L^\infty_{\mathrm{loc}}(\mathbb{R}_+; L^2(\mathbb{R})), \\ &f(q_{\Delta x}) \rightharpoonup \overline{f(q)} \text{ in } L^p_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R}),\, 1 \leq p < 3, \end{aligned} \tag{8.9}$$

where the same subsequence of $\Delta x \downarrow 0$ applies to any f from the specified class.

In what follows, we let $\overline{qf(q)}$ and $\overline{f'(q)q^2}$ denote the weak limits of $q_{\Delta x} f(q_{\Delta x})$ and $f'(q_{\Delta x}) q^2_{\Delta x}$, respectively, in $L^r_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R})$, $1 \leq r < \frac{3}{2}$.

LEMMA 8.2. *For any convex function $f \in C^1(\mathbb{R})$ with f' bounded we have*

$$\begin{aligned} &\iint_{\mathbb{R}_+ \times \mathbb{R}} \left(\overline{f(q)} \partial_t \varphi + u \overline{f(q)} \partial_x \varphi \right) dx\, dt + \int_{\mathbb{R}} f(q_0(x)) \varphi(x,0)\, dx \\ &\qquad \geq \iint_{\mathbb{R}_+ \times \mathbb{R}} \left(\frac{1}{2} \overline{f'(q) q^2} - \overline{qf(q)} + \left(P - u^2\right) \overline{f'(q)} \right) \varphi\, dx\, dt \end{aligned} \tag{8.10}$$

for any nonnegative $\varphi \in C^\infty_c([0,\infty) \times \mathbb{R})$.

Proof. Set $\varphi_j(t) = \frac{1}{\Delta x}\int_{I_j}\varphi(x,t)\,dx$. We multiply (6.2) by $\Delta x\varphi_j$, sum over $j\in\mathbb{Z}$, integrate over $t\in\mathbb{R}_+$, and take into account the convexity of f. After a partial integration and a partial summation, the final result reads

$$\begin{aligned}
&\Delta x\sum_j f(q_j(0))\varphi_j(0) + \int_{\mathbb{R}_+}\Delta x\sum_j f(q_j)\varphi_j'\,dt\\
&+\int_{\mathbb{R}_+}\Delta x\sum_j\Big[\big(u_{j+1/2}\vee 0\big)\,f(q_j)D_+\varphi_j + \big(u_{j-1/2}\wedge 0\big)\,f(q_j)D_-\varphi_j\Big]\,dt\\
&+\int_{\mathbb{R}_+}\Delta x\sum_j\Big[q_jf(q_j) - \frac{q_j^2}{2}f'(q_j)\Big]\varphi_j\,dt\\
&+\int_{\mathbb{R}_+}\Delta x\sum_j\Big[\big(u_{j+1/2}\vee 0\big)^2 + \big(u_{j-1/2}\wedge 0\big)^2 - P_j\Big]f'(q_j)\varphi_j\,dt\ge 0.
\end{aligned}$$

We write this inequality as

$$E_0+E_1+E_2+E_3+E_4\ge 0.$$

By (8.3),

$$\Delta x\sum_j f(q_j(0))\varphi_j(0)\to\int_{\mathbb{R}} f(q_0(x))\varphi(x,0)\,dx\quad\text{as }\Delta x\downarrow 0.$$

Clearly, by the choice of φ_j and (8.9),

$$E_1=\int_{\mathbb{R}_+}\int_{\mathbb{R}} f(q_{\Delta x})\partial_t\varphi\,dx\,dt\to\int_{\mathbb{R}_+}\int_{\mathbb{R}}\overline{f(q)}\partial_t\varphi\,dxdt\quad\text{as }\Delta x\downarrow 0.$$

Next,

$$E_2=\int_{\mathbb{R}_+}\int_{\mathbb{R}} u_{\Delta x}f(q_{\Delta x})\partial_x\varphi\,dx\,dt+E_{2,1}+E_{2,2},$$

where

$$E_{2,1}=\int_{\mathbb{R}_+}\sum_j\int_{I_j}\Big[\big(u_{j+1/2}\vee 0\big)\,f(q_j)D_+\varphi_j-(u_{\Delta x}\vee 0)f(q_{\Delta x})\partial_x\varphi\Big]\,dx\,dt$$

and

$$E_{2,2}=\int_{\mathbb{R}_+}\sum_j\int_{I_j}\Big[\big(u_{j-1/2}\wedge 0\big)\,f(q_j)D_-\varphi_j-(u_{\Delta x}\wedge 0)f(q_{\Delta x})\partial_x\varphi\Big]\,dx\,dt.$$

We decompose $E_{2,1}$ as follows:

$$\begin{aligned}
E_{2,1}=&\int_{\mathbb{R}_+}\sum_j\int_{I_j}\Big[\big(u_{j+1/2}\vee 0\big)-(u_{\Delta x}\vee 0)\Big]f(q_{\Delta x})\partial_x\varphi\,dx\,dt\\
&+\int_{\mathbb{R}_+}\sum_j\int_{I_j}\big(u_{j+1/2}\vee 0\big)\,f(q_{\Delta x})\Big[D_+\phi-\partial_x\varphi\Big]\,dx\,dt=:E_{2,1,1}+E_{2,1,2}.
\end{aligned}$$

For $x \in I_j$, we have by (3.13)

$$\left|\left(u_{j+1/2} \vee 0\right) - \left(u_{\Delta x} \vee 0\right)\right| \leq \left|u_{j+1/2} - u_{\Delta x}\right| \leq C_1 \Delta x \left|q_j\right|. \tag{8.11}$$

Hence, by keeping in mind that $|f(q)| = \mathcal{O}(1+|q|)$ for all $q \in \mathbb{R}$ and using (8.1) and (4.1),

$$|E_{2,1,1}| \leq C_2 \Delta x \left\|\partial_x \varphi\right\|_{L^\infty(\mathbb{R}_+ \times \mathbb{R})} \iint_{\mathrm{supp}(\varphi)} q_{\Delta x}^2 \, dx \, dt \leq C_2 \Delta x,$$

where C_2 depends on φ but not on Δx. For $x \in I_j$, $|D_+\phi - \partial_x \varphi| \leq C_3 \Delta x$, where C_3 depends on φ but not Δx, and thus by (8.1) and (4.1),

$$|E_{2,1,2}| \leq C_4 \Delta x \iint_{\mathrm{supp}(\varphi)} q_{\Delta x} \, dx \, dt \leq C_5 \Delta x,$$

where the final constant C_5 depends on φ but not on Δx. To summarize, we have proved that $|E_{2,1}| = \mathcal{O}(\Delta x) \to 0$ as $\Delta x \downarrow 0$. Similarly, we can prove that $|E_{2,2}| = \mathcal{O}(\Delta x) \to 0$ as $\Delta x \downarrow 0$. Consequently, by (7.2) and (8.9),

$$E_2 \to \int_{\mathbb{R}_+} \int_{\mathbb{R}} u \overline{f(q)} \partial_x \varphi \, dx \, dt \quad \text{as } \Delta x \downarrow 0.$$

We can take the limit in E_3 directly:

$$\begin{aligned} E_3 &= \iint_{\mathbb{R}_+ \times \mathbb{R}} \left[q_{\Delta x} f(q_{\Delta x}) - \frac{q_{\Delta x}^2}{2} f'(q_{\Delta x}) \right] dx \, dt \\ &\overset{\Delta x \downarrow 0}{\longrightarrow} \iint_{\mathbb{R}_+ \times \mathbb{R}} \left[\overline{q f(q)} - \overline{f'(q) q^2} \right] dx \, dt. \end{aligned}$$

Finally, let us analyze E_4, which we write as the sum of four terms:

$$E_4 = \iint_{\mathbb{R}_+ \times \mathbb{R}} \left[u_{\Delta x}^2 - P_{\Delta x} \right] f'(q_{\Delta x}) \varphi \, dx \, dt + E_{4,1} + E_{4,2} - E_{4,3},$$

where

$$\begin{aligned} E_{4,1} &= \int_{\mathbb{R}_+} \sum_j \int_{I_j} \left[\left(u_{j+1/2} \vee 0\right)^2 f'(q_j) \varphi_j - \left(u_{\Delta x} \vee 0\right)^2 f'(q_{\Delta x}) \varphi \right] dx \, dt, \\ E_{4,2} &= \int_{\mathbb{R}_+} \sum_j \int_{I_j} \left[\left(u_{j-1/2} \wedge 0\right)^2 f'(q_j) \varphi_j - \left(u_{\Delta x} \wedge 0\right)^2 f'(q_{\Delta x}) \varphi \right] dx \, dt, \\ E_{4,3} &= \int_{\mathbb{R}_+} \sum_j \int_{I_j} \left[P_j f'(q_j) \varphi_j - P_{\Delta x} f'(q_{\Delta x}) \varphi \right] dx \, dt. \end{aligned}$$

Let us write

$$\begin{aligned} E_{4,1} = &\underbrace{\int_{\mathbb{R}_+} \sum_j \int_{I_j} \left[\left(u_{j+1/2} \vee 0\right)^2 - \left(u_{\Delta x} \vee 0\right)^2 \right] f'(q_{\Delta x}) \varphi \, dx \, dt}_{E_{4,1,1}} \\ &+ \underbrace{\int_{\mathbb{R}_+} \sum_j \int_{I_j} \left(u_{j+1/2} \vee 0\right)^2 f'(q_{\Delta x}) \left[\varphi_j - \varphi \right] dx \, dt}_{E_{4,1,2}}. \end{aligned}$$

In view of (4.4) and (8.11), we have the following estimate for $x \in I_j$:

$$\left|\left(u_{j+1/2} \vee 0\right)^2 - (u_{\Delta x} \vee 0)^2\right| \leq \left|u_{j+1/2} - u_{\Delta x}\right| \, \left|u_{j+1/2} + u_{\Delta x}\right| \leq C\Delta x \, |q_j| \, ,$$

where the constant C does not depend on Δx. Hence we infer that $|E_{4,1,1}| = \mathcal{O}(\Delta x)$ (cf. the treatment of $E_{2,1,1}$). As $|\varphi_j - \varphi| = \mathcal{O}(\Delta x)$, we can argue as we did with $E_{2,1,2}$ to reach the conclusion that $E_{4,1,2} = O(\Delta x)$. Therefore, $E_{4,1} = \mathcal{O}(\Delta x)$.

Along the same lines we can prove that $E_{4,2} = O(\Delta x)$.

Similarly to the estimates of $E_{4,1}$ and $E_{4,2}$ we can show that $E_{4,3} = \mathcal{O}(\Delta x)$, by exploiting (7.9) and (4.6) to conclude that $|P_j - P_{\Delta x}| = \mathcal{O}(\Delta x)$ for $x \in I_{j+1/2}$.

By the previous calculations,

$$E_4 \to \iint_{\mathbb{R}_+ \times \mathbb{R}} \left[u^2 - P\right] \overline{f'(q)} \varphi \, dx \, dt \quad \text{as } \Delta x \downarrow 0.$$

This concludes the proof of (8.10). □

We know that $\{q^2_{\Delta x}\}_{\Delta x > 0}$ is a subset of $L^\infty(\mathbb{R}_+; L^1(\mathbb{R})) \cap L^r_{\mathrm{loc}}(\mathbb{R}_+ \times \mathbb{R})$ for $1 \leq r < \frac{3}{2}$. Additionally, from (6.2) with $f(q) = \frac{q^2}{2}$ (cf. the proof of Lemma 8.2), it follows that $\{\partial_t q^2_{\Delta x}\}_{\Delta x > 0}$ is bounded in $L^1(0, T; W^{-1,1}(\mathbb{R}))$ for each $T > 0$. The Ascoli–Arzelà theorem then implies the following convergence for each $\varphi \in C_c^\infty(\mathbb{R})$:

$$\int_{\mathbb{R}} q^2_{\Delta x} \varphi \, dx \to \int_{\mathbb{R}} \overline{q^2} \varphi \, dx \quad \text{uniformly on compact subsets of } [0, \infty), \tag{8.12}$$

and thus

$$[0, \infty) \ni t \mapsto \int_{\mathbb{R}} \overline{q^2} \varphi \, dx \quad \text{is continuous on } [0, \infty). \tag{8.13}$$

The statements (8.12) and (8.13) hold with $q^2_{\Delta x}$ and $\overline{q^2}$ replaced, respectively, by $f(q_{\Delta x})$ and $\overline{f(q_{\Delta x})}$ for any convex function $f \in C^1(\mathbb{R})$ with f' bounded.

LEMMA 8.3. *Let q and $\overline{q^2}$ be the weak limits identified in Lemma* 8.1. *Then*

$$\begin{aligned} &\iint_{\mathbb{R}_+ \times \mathbb{R}} (q \partial_t \varphi + u q \partial_x \varphi) \, dx \, dt + \int_{\mathbb{R}} q_0(x) \varphi(x, 0) \, dx \\ &\quad = \iint_{\mathbb{R}_+ \times \mathbb{R}} \left(-\frac{1}{2} \overline{q^2} + \left(P - u^2\right) \right) \varphi \, dx \, dt, \quad \varphi \in C_c^\infty([0, \infty) \times \mathbb{R}). \end{aligned} \tag{8.14}$$

Proof. By starting off from (6.2) with $f(q) = q$, we argue as in the proof of Lemma 8.2 to conclude the validity of (8.14). □

The succeeding lemma tells us in which sense the weak limits singled out in Lemma 8.1 satisfy the initial data.

LEMMA 8.4. *Let q and $\overline{q^2}$ be the weak limits identified in Lemma* 8.1. *Then*

$$\lim_{t \downarrow 0} \int_{\mathbb{R}} q^2(t, x) \, dx = \int_{\mathbb{R}} (\partial_x u_0)^2 \, dx, \quad \lim_{t \downarrow 0} \int_{\mathbb{R}} \overline{q^2}(t, x) \, dx = \int_{\mathbb{R}} (\partial_x u_0)^2 \, dx. \tag{8.15}$$

Proof. In view of previous results, $q \in C\left(0, T; L^2_{\mathrm{weak}}(\mathbb{R})\right)$. Hence, it follows from (8.14) that $q(t, \cdot) \rightharpoonup q_0$ $(= \partial_x u_0)$ in $L^2(\mathbb{R})$ as $t \downarrow 0$. Consequently,

$$\int_{\mathbb{R}} (\partial_x u_0)^2 \, dx \leq \liminf_{t \downarrow 0} \int_{\mathbb{R}} q^2(t, x) \, dx. \tag{8.16}$$

On the other hand, (7.1) tells us that $u_{\Delta x}(t,\cdot) \rightharpoonup u(t,\cdot)$ in $H^1(\mathbb{R})$ for a.e. $t>0$, and thereby, by using also (7.2), (7.4), and (8.5),

$$\int_{\mathbb{R}} (u(t,x))^2\,dx + \int_{\mathbb{R}} \overline{q^2}(t,x)\,dx \le \int_{\mathbb{R}} u_0^2\,dx + \int_{\mathbb{R}} (\partial_x u_0)^2\,dx. \tag{8.17}$$

Since (8.13) holds, this inequality is valid for all $t>0$. By exploiting the continuity of u (see Lemma 7.1), (8.17) yields

$$\limsup_{t\downarrow 0} \int_{\mathbb{R}} \overline{q^2}(t,x)\,dx \le \int_{\mathbb{R}} \left(\partial_x u_0\right)^2\,dx. \tag{8.18}$$

Clearly, (8.6), (8.16), and (8.18) imply (8.15). ∎

We are now in a position to conclude the strong convergence of $\{q_{\Delta x}\}_{\Delta x>0}$.

LEMMA 8.5. *Let q and $\overline{q^2}$ be the weak limits identified in Lemma* 8.1. *Then*

$$\overline{q^2}(t,x) = q^2(t,x) \text{ for a.e. } (t,x)\in\mathbb{R}_+\times\mathbb{R}. \tag{8.19}$$

Consequently, as $\Delta x\downarrow 0$,

$$q_{\Delta x}\to q \text{ in } L^2_{\mathrm{loc}}(\mathbb{R}_+\times\mathbb{R}) \text{ and a.e. in } \mathbb{R}_+\times\mathbb{R}. \tag{8.20}$$

Proof. Lemma 8.2 tells us that for any convex function $f\in C^1(\mathbb{R})$ with f' bounded there holds

$$\partial_t \overline{f(q)} + \partial_x\left(u\overline{f(q)}\right) \le \overline{qf(q)} - \frac{1}{2}\overline{f'(q)q^2} + \left(u^2-P\right)\overline{f'(q)}, \tag{8.21}$$

in the sense of distributions on $\mathbb{R}_+\times\mathbb{R}$. Moreover, by Lemma 8.3,

$$\partial_t q + \partial_x(uq) = \frac{1}{2}\overline{q^2} + u^2 - P, \tag{8.22}$$

in the sense of distributions on $\mathbb{R}_+\times\mathbb{R}$. Equipped with (8.21), (8.22), Lemma 8.15, and (8.8), we can argue exactly as in Xin and Zhang [38] to arrive at (8.19). In view of standard functional analysis considerations, claim (8.20) now follows immediately from (8.19) and (7.6). ∎

9. Concluding the proof of Theorem 3.1. Lemmas 7.1 and 8.1 and (3.12) show that the strong H^1-limit u satisfies conditions (i), (iii), (iv), and (3.12) of Definition 3.1. It remains to prove that u satisfies condition (ii), i.e., the weak formulation (3.1).

We start by deriving a divergence-form version of the scheme (3.1). To this end, introduce the functions $f_\vee$, $f_\wedge$ defined by $f_\vee'(u)=u\vee 0$, $f_\vee(0)=0$, $f_\wedge'(u)=u\wedge 0$, $f_\wedge(0)=0$, i.e., $f_\vee(u)=\frac{1}{2}(u\vee 0)^2$ and $f_\wedge(u)=\frac{1}{2}(u\wedge 0)^2$. Observe that $f_\vee, f_\wedge$ are piecewise C^2, and the absolute values of the second derivatives are bounded (by 1). By the discrete chain rule,

$$\left(u_{j+1/2}\vee 0\right) D_- u_{j+1/2} = D_- f_\vee(u_{j+1/2}) + \mathcal{O}\left(\Delta x\left(D_- u_{j+1/2}\right)^2\right)$$

and

$$\left(u_{j+1/2}\wedge 0\right) D_+ u_{j+1/2} = D_+ f_\wedge(u_{j+1/2}) + \mathcal{O}\left(\Delta x\left(D_+ u_{j+1/2}\right)^2\right).$$

Consequently, we can replace (3.1) by

$$\begin{aligned} &u'_{j+1/2} + D_- f_\vee(u_{j+1/2}) + D_+ f_\wedge(u_{j+1/2}) + D_+ P_j \\ &\qquad = \mathcal{O}\left(\Delta x \left\{ \left(D_- u_{j+1/2}\right)^2 + \left(D_+ u_{j+1/2}\right)^2 \right\}\right). \end{aligned} \tag{9.1}$$

We can restate (9.1) as

$$\begin{aligned} &u'_{j+1/2} + D_- \left[\frac{u_{j+1/2}^2}{4} + \frac{1}{2}\left(f_\vee(u_{j+1/2}) - f_\wedge(u_{j+1/2}) \right) \right] \\ &\quad + D_+ \left[\frac{u_{j+1/2}^2}{4} + \frac{1}{2}\left(f_\wedge(u_{j+1/2}) - f_\vee(u_{j+1/2}) \right) \right] + D_+ P_j \\ &\qquad = \mathcal{O}\left(\Delta x \left\{ \left(D_- u_{j+1/2}\right)^2 + \left(D_+ u_{j+1/2}\right)^2 \right\}\right). \end{aligned} \tag{9.2}$$

By using the relation

$$\begin{aligned} &D_-\left(f_\vee(u_{j+1/2}) - f_\wedge(u_{j+1/2}) \right) + D_+\left(f_\wedge(u_{j+1/2}) - f_\vee(u_{j+1/2}) \right) \\ &\quad = \Delta x D_- D_+ f_\wedge(u_{j+1/2}) - \Delta x D_- D_+ f_\vee(u_{j+1/2}), \end{aligned}$$

(9.2) becomes

$$\begin{aligned} &u'_{j+1/2} + D\left(\frac{u_{j+1/2}^2}{2} \right) + D_+ P_j \\ &\qquad = \mathcal{O}\left(\Delta x \left\{ \left(D_- u_{j+1/2}\right)^2 + \left(D_+ u_{j+1/2}\right)^2 \right\}\right) \\ &\qquad\quad + \Delta x \left\{ D_- D_+ f_\vee(u_{j+1/2}) - D_- D_+ f_\wedge(u_{j+1/2}) \right\}. \end{aligned} \tag{9.3}$$

Fix $\varphi \in C_c^\infty(\mathbb{R}_+ \times \mathbb{R})$, and set $\varphi_j(t) = \frac{1}{\Delta x}\int_{I_j} \varphi(x,t)\,dx$. We multiply (9.3) by $\Delta x \varphi_j$, sum over $j \in \mathbb{Z}$, and integrate over $t \in \mathbb{R}_+$. After a partial integration and a partial summation, the final result reads

$$\begin{aligned} &\underbrace{\int_{\mathbb{R}_+} \Delta x \sum_j u_{j+1/2} \varphi'_j \,dt}_{=:E_1} + \underbrace{\int_{\mathbb{R}_+} \Delta x \sum_j \frac{u_{j+1/2}^2}{2} D\varphi_j \,dt}_{=:E_2} \\ &\qquad + \underbrace{\int_{\mathbb{R}_+} \Delta x \sum_j P_j D_- \varphi_j \,dt}_{=:E_3} = \mathcal{O}(\Delta x), \end{aligned} \tag{9.4}$$

where the right-hand side is a consequence of (4.1).

First, since $\left|u_{j+1/2} - u_{\Delta x}\right| \le C\Delta x\,|q_j|$ (cf. (3.13)) and by Lemmas 4.1 and 7.1,

$$\begin{aligned} E_1 &= \int_{\mathbb{R}_+}\int_{\mathbb{R}} u_{\Delta x} \partial_t \varphi \,dt + \int_{\mathbb{R}_+} \sum_j \int_{I_j} \left(u_{j+1/2} - u_{\Delta x}\right) \partial_t \varphi \,dx\,dt \\ &= \iint_{\mathbb{R}_+\times\mathbb{R}} u_{\Delta x} \partial_t \varphi \,dx\,dt + \mathcal{O}(\Delta x) \overset{\Delta x \downarrow 0}{\longrightarrow} \iint_{\mathbb{R}_+\times\mathbb{R}} u \partial_t \varphi \,dx\,dt. \end{aligned}$$

Next,

$$E_2 = \underbrace{\iint_{\mathbb{R}_+\times\mathbb{R}} \frac{u_{\Delta x}^2}{2} u_{\Delta x} \partial_t \varphi \, dt}_{E_{2,1}} + \underbrace{\int_{\mathbb{R}_+} \sum_j \int_{I_j} \left(\frac{u_{j+1/2}^2}{2} D\varphi_j - \frac{u_{\Delta x}^2}{2} \partial_x \varphi \right) dx \, dt}_{E_{2,2}}.$$

Let us analyze the term $E_{2,2}$. We have $E_{2,2} = E_{2,2,1} + E_{2,2,2}$, where

$$E_{2,2,1} = \int_{\mathbb{R}_+} \sum_j \int_{I_j} \left(\frac{u_{j+1/2}^2}{2} - \frac{u_{\Delta x}^2}{2} \right) \partial_x \varphi \, dx \, dt,$$

$$E_{2,2,2} = \int_{\mathbb{R}_+} \sum_j \int_{I_j} \frac{u_{j+1/2}^2}{2} \left(D\varphi_j - \partial_x \varphi \right) dx \, dt.$$

Since, by (4.4),

$$\left| \frac{u_{j+1/2}^2}{2} - \frac{u_{\Delta x}^2}{2} \right| \le C \Delta x \left| q_j \right|, \quad \left| D\varphi_j - \partial_x \varphi \right| \le C \Delta x, \quad x \in I_j, \, j \in \mathbb{Z},$$

where C does not depend on Δx, we use again (4.1) to conclude that $|E_{2,2}| = \mathcal{O}(\Delta x)$.

It remains to analyze E_3. By (3.4), we have

$$E_3 = \int_{\mathbb{R}_+} h \Delta x \sum_{j,i} \left(e^{-\kappa |j-i|} \right) \left((u_{i+1/2} \vee 0)^2 + (u_{i-1/2} \wedge 0)^2 + \frac{q_i^2}{2} \right) D_- \varphi_j \, dt.$$

By Lemmas 7.1, 8.5, and 8.1,

$$\lim_{\Delta x \downarrow 0} E_3 = \frac{1}{2} \iint_{\mathbb{R}_+\times\mathbb{R}} \left[\int_{\mathbb{R}} e^{-|x-y|} \left((u(t,y))^2 + \frac{1}{2} (q(t,y))^2 \right) dy \right] \partial_x \varphi(t,x) \, dx \, dt.$$

In summary, our calculations show that by sending $\Delta x \downarrow 0$ in (9.4) we obtain (3.11). This concludes the proof of Theorem 3.1. □

MAXIMAL USE OF CENTRAL DIFFERENCING FOR HAMILTON–JACOBI–BELLMAN PDEs IN FINANCE*

J. WANG† AND P. A. FORSYTH†

Abstract. In order to ensure convergence to the viscosity solution, the standard method for discretizing Hamilton–Jacobi–Bellman partial differential equations uses forward/backward differencing for the drift term. In this paper, we devise a monotone method which uses central weighting as much as possible. In order to solve the discretized algebraic equations, we have to maximize a possibly discontinuous objective function at each node. Nevertheless, convergence of the overall iteration can be guaranteed. Numerical experiments on two examples from the finance literature show higher rates of convergence for this approach compared to the use of forward/backward differencing only.

Key words. stochastic control, nonlinear Hamilton–Jacobi–Bellman partial differential equations, central differencing, monotone scheme, finance

1. Introduction.

There are a number of financial models which result in nonlinear Hamilton–Jacobi–Bellman (HJB) partial differential equations (PDEs). These problems usually arise in the context of optimal stochastic control. Some examples of these HJB-type equations include transaction cost/uncertain volatility models [21, 3, 27], passport options [2, 29], unequal borrowing/lending costs [12], large investor effects [1], risk control in reinsurance [23], pricing options and insurance in incomplete markets using an instantaneous Sharpe ratio [31, 22, 10], minimizing ruin probability in insurance [28, 13], and optimal consumption [11, 15]. A recent survey article on the theoretical aspects of this topic is given in [25].

In many cases, classical solutions to these PDEs do not exist, and we seek to find the viscosity solution of the HJB equation [17]. It is important to ensure that the discrete solution converges to the viscosity solution as the mesh size and timestep are reduced (see [27] for an example where seemingly reasonable discretization methods can converge to nonviscosity solutions). In order to guarantee convergence to the viscosity solution, the discrete scheme must be pointwise consistent, l_∞ stable, and monotone [9, 4].

A monotone scheme is usually constructed by using a positive coefficient method [20, 24, 7, 18]. Typically, a positive coefficient method is developed using forward or backward differencing for the drift term. The choice of forward or backward differencing depends on the control variable. This has the disadvantage that the truncation error in the space-like direction is only first order.

If implicit timestepping is used, then the nonlinear discretized algebraic equations are solved by an iterative method. The usual iterative approach [20, 18] requires solution of a local optimization problem for the optimal control at each grid node and at every iteration. Since the discretization at each node is a function of the control

variable at that node, the type of discretization (i.e., forward or backward differencing) may change at each iteration. Use of forward/backward differencing means that the local objective function at each node is a continuous function of the control variable but nonsmooth.

In this paper, we take a slightly different approach compared to the standard technique. We will use a combination of central/forward/backward differencing at each node. Given a value of the control variable at a node, we use the following criteria to select the differencing method:

- Central differencing is used if the discretization is a positive coefficient method (for this particular choice of control).
- Forward/backward differencing is used only if central differencing does not result in a positive coefficient method. One of forward or backward differencing must satisfy the positive coefficient condition.

This method has the advantage that central differencing is used as much as possible, so that use of a locally second order method is maximized. However, in general, the local objective function at each grid node is now a discontinuous function of the control. It would appear that iterative solution of the discretized equations would be problematic in this case.

In this paper we note that the proof of convergence of the iterative scheme for solution of the discretized algebraic equations does not, in fact, require continuity of the local objective function. Hence, convergence of the iterative method for solution of the discrete equations can be guaranteed, even if the local objective function is a discontinuous function of the control. Nevertheless, it is not clear that, in practice,

- the use of a locally second order method as much as possible will result in improved convergence as the mesh is refined for practical parameter values;
- the rate of convergence of the nonlinear iteration will be acceptable if the local objective function is a discontinuous function of the control.

We report the results of several numerical experiments for passport options [2] and optimal asset allocation [14]. These experiments show that we can often obtain higher rates of convergence using central differencing as much as possible, although at some additional cost compared to the standard approach.

2. General form for the example problems. To avoid repetition, we will carry out our analysis for a general form for the example problems.

As is typically the case with finance problems, we solve backwards in time from the expiry date of the contract $t = T$ to $t = 0$ by use of the variable $\tau = T - t$. Set

$$\mathcal{L}^Q V \equiv a(S,\tau,Q)V_{SS} + b(S,\tau,Q)V_S - c(S,\tau,Q)V, \tag{2.1}$$

where the control parameter Q is in general a vector, that is, $Q = (q_1, q_2, \dots)'$. We write our problems in the general form

$$V_\tau = \sup_{Q\in\hat{Q}} \left\{ \mathcal{L}^Q V + d(S,\tau,Q) \right\},$$

$$S \in [S_{\min}, S_{\max}], \quad 0 \le \tau \le T. \tag{2.2}$$

Here we include the $d(S,t,Q)$ term in (2.2) for generality, although in the examples in this paper, we will always have $d \equiv 0$. We can also replace the sup in (2.2) by an inf, and all the results of this paper hold in this case as well.

2.1. Boundary conditions. We assume the boundary and payoff conditions satisfy the following conditions.

Assumption 2.1 (payoff and boundary conditions). At $\tau = 0$, we set $V(S, 0)$ to the specified contract payoff. As $S \to S_{\min}, S \to S_{\max}$, we assume that either

- a Dirichlet boundary condition is specified and $a(S, \tau, Q) > 0$;
- the coefficient $a(S, \tau, Q)$ vanishes, and the sign of $b(S, \tau, Q)$ is such that no boundary condition is required [8]; i.e., the boundary condition is the limit of the PDE from the interior.

Note that it may be the case that the original problem has $S_{\max} = +\infty$ or $S_{\min} = -\infty$. In these cases, we will use a finite computational domain, and we assume that financial reasoning can be used to determine an appropriate Dirichlet condition. This is clearly an approximation and introduces a *localization error*. However, as pointed out in [6], we can expect any errors incurred by imposing approximate boundary conditions at finite values of $S_{\min}, S_{\max}$ to be small in areas of interest if $|S_{\min}|$, $|S_{\max}|$ are selected sufficiently large. We will assume in the following that the original problem has been localized to a finite domain.

An alternative approach is introduced by [32] for handling the infinite domain problem, in which reversion conditions for stochastic models are defined. At $S = S_{\min}$, a reversion condition would be $a(S_{\min}, \tau, Q) = 0$ and $b(S_{\min}, \tau, Q) \geq 0$. The authors in [32] prove that if the models satisfy reversion conditions, then the financial PDEs have a unique solution and their numerical solutions can be obtained without using any artificial boundary conditions. However, as discussed in [32], in general this may require modification of the PDE coefficients for extreme values of S.

Assumption 2.2 (properties of the HJB PDE). We make the assumption that the coefficients a, b, c, d are Lipschitz continuous functions of (S, τ, Q), with $a \geq 0$, and $c \geq 0$, that a, b, c, d are bounded on $S_{\min} \leq S \leq S_{max}$, and that the set of admissible controls $\hat{Q}$ is compact.

Remark 2.1. Since we restrict ourselves to a finite computational domain $S_{\min} \leq S \leq S_{max}$, we avoid difficulties associated with coefficients that grow with S as $|S| \to \infty$. It follows from [16, 8] that solutions to (2.2), satisfying Assumptions 2.1 and 2.2, satisfy the strong comparison property. Hence, a unique viscosity solution exists for (2.2).

3. Implicit controls. Define a grid $\{S_0, S_1, \ldots, S_p\}$ with $S_0 = S_{\min}$, $S_p = S_{\max}$, and let V_i^n be a discrete approximation to $V(S_i, \tau^n)$. Let $V^n = [V_0^n, \ldots, V_p^n]'$, and let $(\mathcal{L}_h^Q V^n)_i$ denote the discrete form of the differential operator (2.1) at node (S_i, τ^n). The operator (2.1) can be discretized using forward, backward, or central differencing in the S direction to give

$$(\mathcal{L}_h^Q V^{n+1})_i = \alpha_i^{n+1} V_{i-1}^{n+1} + \beta_i^{n+1} V_{i+1}^{n+1} - (\alpha_i^{n+1} + \beta_i^{n+1} + c_i^{n+1}) V_i^{n+1}. \tag{3.1}$$

Here α_i, β_i are defined in Appendix A.

It is important that central, forward, or backward discretizations be used to ensure that (3.3) is a positive coefficient discretization. To be more precise, this condition is given as follows.

Condition 3.1 (positive coefficient condition).

$$\alpha_i^{n+1} \geq 0, \quad \beta_i^{n+1} \geq 0, \quad c_i^{n+1} \geq 0, \quad i = 0, \ldots, p-1. \tag{3.2}$$

We will assume that all models have $c_i^{n+1} \geq 0$. Consequently, we choose central, forward, or backward differencing at each node to ensure that $\alpha_i^{n+1},\ \beta_i^{n+1} \geq 0$. Note that different nodes can have different discretization schemes.

Equation (2.2) can now be discretized using fully implicit timestepping along with the discretization (3.1) to give

$$\frac{V_i^{n+1} - V_i^n}{\Delta\tau} = \sup_{Q^{n+1} \in \hat{Q}} \left\{ (\mathcal{L}_h^{Q^{n+1}} V^{n+1})_i + d_i^{n+1} \right\}. \tag{3.3}$$

Note that $\alpha_i^{n+1} = \alpha_i^{n+1}(Q_i^{n+1})$, $\beta_i^{n+1} = \beta_i^{n+1}(Q_i^{n+1})$, $c_i^{n+1} = c_i^{n+1}(Q_i^{n+1})$, and $d_i^{n+1} = d_i^{n+1}(Q_i^{n+1})$; that is, the discrete equation coefficients are functions of the local optimal control Q_i^{n+1}. This makes (3.3) highly nonlinear in general. We refer to methods which use an implicit timestepping method where the control is handled implicitly as an *implicit control* method in the following.

3.1. Matrix form of the discrete equations. It will be convenient to use matrix notation for (3.3), coupled with boundary conditions.

If a Dirichlet condition is specified at $S = S_{\min}, \tau = \tau^n$ $(i = 0)$, then we denote this value by G_0^n. If a Dirichlet boundary condition is specified at $S = S_{\max}, \tau = \tau^n$ $(i = p)$, then we denote this value by G_p^n. Set $Q^n = [Q_0^n, Q_1^n, \ldots, Q_p^n]'$, with each Q_i^n a local optimal control. We can write the discrete operator $(\mathcal{L}_h^Q V^n)_i$ as

$$\begin{aligned} (\mathcal{L}_h^Q V^n)_i &= [A^n(Q^n)V^n]_i \\ &= \left[\alpha_i^n V_{i-1}^n + \beta_i^n V_{i+1}^n - (\alpha_i^n + \beta_i^n + c_i^n) V_i^n\right], \qquad 1 < i < p. \end{aligned} \tag{3.4}$$

The first and last rows of A are modified as needed to handle the boundary conditions. The boundary conditions at $S = S_{\min}, S_{\max}$ can be enforced by specifying a boundary condition vector $G^n = [G_0^n, 0, \ldots, 0, G_p^n]'$. If a Dirichlet condition is specified at $i = p$, we set G_p^n to the appropriate value and set the last row in A^n to be zero. With a slight abuse of notation, we denote this last row in this case as $(A^n)_p \equiv 0$. Conversely, if no boundary condition is required at $i = p$, then we use backward differencing at node $i = p$ (which means that $\beta_p = 0$) and set $G_p^n = 0$. The boundary condition at $S = S_{\min}$, $i = 0$, is handled in a similar fashion. Let D^n be the vector with entries

$$[D]_i^n = \begin{cases} d_i^n, & 1 < i < p, \\ 0, & i = 0, p \quad \text{if a Dirichlet condition is specified,} \\ d_i^n, & i = 0, p \quad \text{if no boundary condition is required.} \end{cases}$$

Let

$$F^n(Q, V^n) = A^n(Q)V^n + D^n(Q). \tag{3.5}$$

As we shall see in section 6.3, $[F^n(Q, V^n)]_i$, regarded as a function of Q, can have a finite number of discontinuities at points where the differencing scheme changes. Recall that an upper semicontinuous ($\mathcal{USC}$) function $g(x)$ has the property that

$$\limsup_{x \to y} g(x) \leq g(y). \tag{3.6}$$

In particular, we will define $F(Q, V^n)$ so that it is an $\mathcal{USC}$ function of Q, i.e.,

$$\limsup_{X \to Q} [F^n(X, V^n)]_i \ \leq [F^n(Q, V^n)]_i, \tag{3.7}$$

where

$$F^n(Q, V^n) = A^n(Q, V^n)V^n + D^n(Q), \tag{3.8}$$

and we now note that the definition of A^n may depend on V^n. We will give an algorithm for determining $A^n(Q, V^n)$ for a specific case so that $F^n(Q, V^n)$ is $\mathcal{USC}$ in section 6.2.

Since $F^n(Q, V^n)$ is $\mathcal{USC}$, and $\hat{Q}$ is compact, the discrete equations (3.3) can then be written as

$$\left[I - \Delta\tau A^{n+1}(Q^{n+1}, V^{n+1})\right] V^{n+1} = V^n + \Delta\tau D^{n+1} + (G^{n+1} - G^n),$$

$$\text{where } Q_i^{n+1} = \arg\max_{Q\in\hat{Q}} \left\{ \left[F^{n+1}(Q, V^{n+1})\right]_i \right\}. \tag{3.9}$$

Here the term $(G^{n+1} - G^n)$ enforces possible Dirichlet boundary conditions at $S = S_0, S_p$. Note also that the discrete equations (3.9) are nonlinear since $Q^{n+1} = Q^{n+1}(V^{n+1})$.

4. Convergence to the viscosity solution. In [27], examples were given in which seemingly reasonable discretizations of nonlinear option pricing PDEs were unstable or converged to the incorrect solution. It is important to ensure that we can generate discretizations which are guaranteed to converge to the viscosity solution [4, 17]. Assuming that (2.2) satisfies the strong comparison property [5, 8, 16], then, from [9, 4], a numerical scheme converges to the viscosity solution if the method is pointwise consistent, stable (in the l_∞ norm), and monotone.

It is straightforward, using the methods in [7, 18], to show that scheme (3.3) is monotone, pointwise consistent, and stable.

THEOREM 4.1 (convergence to the viscosity solution). *Provided that the original HJB satisfies Assumptions* 2.1 *and* 2.2 *and discretization* (3.9) *satisfies the positive coefficient Condition* 3.1*, then scheme* (3.9) *converges to the viscosity solution of* (2.2).

Proof. Using the methods in [7, 18], this can be shown to follow from results in [9, 4]. We give a brief overview of the proof.

Monotonicity: From the positive coefficient Condition 3.1 and following the same method as in [7, 18], we can show that scheme (3.9) is monotone.

Pointwise consistency: From Appendix A, a simple Taylor series verifies consistency.

Stability: Using the same technique as in [18], we can show that scheme (3.9) is l_∞ stable by a maximum analysis.

As shown in [9], if a discretization scheme is monotone, pointwise consistent, and l_∞ stable, then that scheme converges to the viscosity solution. ∎

Remark 4.1 (rate of convergence). If $\Delta S = \max_i(S_{i+1} - S_i)$ and $\Delta\tau = C_1 h$, $\Delta S = C_2 h$, where C_1, C_2 are positive constants, then there has been considerable effort in recent years to determine rates of convergence for monotone finite difference

schemes for HJB equations. Typically, one obtains estimates of the error of the form $O(h^\rho)$, where ρ varies from 1/27 to 1/2 depending on assumptions about regularity of the solution and the PDE coefficients. See [7] for an overview of recent work along these lines. These results seem generally pessimistic when compared with numerical experiments.

It is also useful to note the following property of the matrix $[I - \Delta\tau A^n(Q, V^n)]$.

LEMMA 4.2 (M-matrix). *If the positive coefficient condition* (3.2) *is satisfied, and either Dirichlet boundary conditions are specified or no boundary condition is required, then* $[I - \Delta\tau A^n(Q, V^n)]$ *is an M-matrix for any* $Q \in \hat{Q}$.

Proof. The positive coefficient condition (3.2) implies that $\alpha_i^n, \beta_i^n, c_i^n$ in (3.4) are nonnegative $\forall Q \in \hat{Q}$. Hence $[I - \Delta\tau A^n(Q, U)]$ has positive diagonals, has nonpositive off diagonals, and is diagonally dominant. As a result, it is an M-matrix. ∎

4.1. Discretization of the control. Suppose we have a single control $q \in \hat{Q}$, where $\hat{Q} = [q_{\min}, q_{\max}]$, with $q_{\min}, q_{\max}$ bounded. It is sometimes convenient to discretize the control; i.e., we replace $\hat{Q}$ by $\hat{Y}$, where $\hat{Y} = [y_0, y_1, y_2, \ldots, y_k]$, with $y_0 = q_{\min}, y_k = q_{\max}$, and $y_{i+1} > y_i$. Let $\max_i(y_{i+1} - y_i) = C_3 h$, where C_3 is a positive constant. Then we have the following lemma.

LEMMA 4.3 (consistency of discrete control approximation). *If the HJB equation satisfies Assumption* 2.2, *then the discretized control problem with* $\max_i(y_{i+1} - y_i) = C_3 h$

$$V_\tau = \sup_{Q \in \hat{Y}} \left\{ \mathcal{L}^Q V + d(S, \tau, Q) \right\} \tag{4.1}$$

is consistent with (2.2) *as* $h \to 0$.

Proof. Let $\phi(S, \tau)$ be a smooth test function possessing bounded derivatives of appropriate order; then, in view of the fact that the coefficients of (2.2) are assumed to be Lipschitz continuous, bounded functions of Q,

$$\left| \phi_\tau - \sup_{Q \in \hat{Q}} \left\{ \mathcal{L}^Q \phi + d(S, \tau, Q) \right\} - \left(\phi_\tau - \max_{Q \in \hat{Y}} \left\{ \mathcal{L}^Q \phi + d(S, \tau, Q) \right\} \right) \right|$$

$$= O(h), \quad h \to 0. \tag{4.2}$$ ∎

PROPOSITION 4.4 (discrete control approximation: convergence to the viscosity solution). *Let* $\Delta\tau = C_1 h$, $\max_i(S_{i+1} - S_i) = C_2 h$, $\max_i(y_{i+1} - y_i) = C_3 h$, *with* C_i *being positive constants. Provided the conditions for Theorem* 4.1 *and Lemma* 4.3 *are satisfied, then the discretization* (3.9) *with* $\hat{Q}$ *replaced by the discrete control set* $\hat{Y}$ *converges to the viscosity solution of* (2.2) *as* $h \to 0$.

Proof. This follows immediately from Theorem 4.1 and Lemma 4.3. ∎

5. Solution of algebraic discrete equations. Although we have established that discretization (3.9) is consistent, l_∞ stable, and monotone, it is not obvious that this is a practical scheme, since the implicit timestepping method requires solution of highly nonlinear algebraic equations at each timestep.

5.1. Iterative method. Recall the definitions of $F^n(Q, V^n)$ and $A^n(Q, V^n)$ in (3.8). Consider the following iteration scheme:

ITERATIVE SOLUTION OF THE DISCRETE EQUATIONS

Let $(V^{n+1})^0 = V^n$

Let $\hat{V}^k = (V^{n+1})^k$

For $k = 0, 1, 2, \ldots$ until convergence

Solve

$$\left[I - \Delta\tau A^{n+1}(Q^k, \hat{V}^k)\right] \hat{V}^{k+1} = V^n + (G^{n+1} - G^n) + \Delta\tau D^{n+1}(Q^k) \tag{5.1}$$

$$Q_i^k = \arg\max_{Q \in \hat{Q}} \left\{ \left[F^{n+1}(Q, \hat{V}^k) \right]_i \right\}$$

If $(k > 0)$ and $\left(\max_i \dfrac{\left| \hat{V}_i^{k+1} - \hat{V}_i^k \right|}{\max\left(scale, \left| \hat{V}_i^{k+1} \right| \right)} < tolerance \right)$, then quit

EndFor

The term *scale* in scheme (5.1) is used to ensure that unrealistic levels of accuracy are not required when the value is very small. Typically, $scale = 1$ for financial problems priced in dollars.

Some manipulation of algorithm (5.1) results in

$$\begin{aligned} &\left[I - \Delta\tau A^{n+1}(Q^k, \hat{V}^k)\right] (\hat{V}^{k+1} - \hat{V}^k) \\ &= \Delta\tau \Big[\left(A^{n+1}(Q^k, \hat{V}^k)\hat{V}^k + D^{n+1}(Q^k) \right) \\ &\qquad - \left(A^{n+1}(Q^{k-1}, \hat{V}^{k-1})\hat{V}^k + D^{n+1}(Q^{k-1}) \right) \Big]. \end{aligned} \tag{5.2}$$

The proof of convergence of the iteration scheme (5.1) is given in [26, 18]. Since scheme (5.1) can be regarded as a variant of policy iteration for infinite horizon Markov chains, the convergence proof is similar to the proof of convergence for policy iteration [20]. For the convenience of the reader, we sketch the proof below.

In order to prove the convergence of algorithm (5.1), we first need an intermediate result.

LEMMA 5.1 (sign of right-hand side (5.2)). *If* $A^{n+1}(Q^k, \hat{V}^k)$ *is given by* (3.8), (3.9), *with the control parameter determined by*

$$Q_i^k = \arg\max_{Q \in \hat{Q}} \left\{ \left[F^{n+1}(Q, \hat{V}^k) \right]_i \right\}, \tag{5.3}$$

then every element of the right-hand side of (5.2) *is nonnegative, that is,*

$$\left[\left(A^{n+1}(Q^k, \hat{V}^k)\hat{V}^k + D^{n+1}(Q^k) \right) - \left(A^{n+1}(Q^{k-1}, \hat{V}^{k-1})\hat{V}^k + D^{n+1}(Q^{k-1}) \right) \right]_i \geq 0. \tag{5.4}$$

Proof. Recall that Q^k is selected to maximize $A^{n+1}(Q^k, \hat{V}^k)\hat{V}^k + D^{n+1}(Q^k)$ for given $\hat{V}^k$. Hence, any other choice of coefficients, for example $A^{n+1}(Q^{k-1}, \hat{V}^{k-1})\hat{V}^k + D^{n+1}(Q^{k-1})$, cannot exceed $A^{n+1}(Q^k, \hat{V}^k)\hat{V}^k + D^{n+1}(Q^k)$. ∎

It is now easy to show that iteration (5.1) always converges.

THEOREM 5.2 (convergence of iteration (5.1)). *Provided that the conditions for Lemmas* 4.2 *and* 5.1 *are satisfied, then the iteration* (5.1) *converges to the unique solution of* (3.9) *for any initial iterate* $\hat{V}^0$. *Moreover, the iterates converge monotonically.*

Proof. Given Lemmas 5.1 and 4.2, the proof of this result is similar to the proof of convergence given in [27]. We give a brief outline of the steps in this proof and refer the reader to [27] for details. A straightforward maximum analysis of scheme (5.1) can be used to bound $\|\hat{V}^k\|_\infty$ independent of iteration k. From Lemma 5.1, we have that the right-hand side of (5.2) is nonnegative. Noting that $[I - \Delta\tau A^{n+1}(Q^k, \hat{V}^k)]$ is an M-matrix (from Lemma 4.2) and hence $[I - \Delta\tau A^{n+1}(Q^k, \hat{V}^k)]^{-1} \geq 0$, it is easily seen that the iterates form a bounded nondecreasing sequence. In addition, if $\hat{V}^{k+1} = \hat{V}^k$, the residual is zero. Hence the iteration converges to a solution. It follows from the M-matrix property of $[I - \Delta\tau A^{n+1}(Q^k, \hat{V}^k)]$ that the solution is unique. ∎

Remark 5.1 (Q dependent discretizations). Note that we obtain convergence of iteration (5.1) even if the discrete equations, regarded as a function of the control Q, are discontinuous. We do, however, require that the coefficients a, b, c, d in (2.1)–(2.2) are bounded functions of the control Q, in order to ensure that A^{n+1}, D^{n+1} are bounded.

Remark 5.2 (uniqueness of solution). The above argument shows that the solution for V^{n+1} is unique. However, this does not imply that the controls Q^{n+1} are unique. As a simple counterexample, consider the case where a, b, c, d in (2.1)–(2.2) are independent of Q, in which case the solution for V is unique for any choice of $Q \in \hat{Q}$.

6. Passport options. Passport options are financial derivative contracts which allow the holder to take profit from a trading account while obligating the writer to cover losses [2, 29]. The holder is allowed to trade an underlying asset S at any time during the option lifetime, say T. Let q denote the number of shares of the underlying the holder holds at time t, $0 \leq t \leq T$. q is limited to an amount C, i.e., $|q| \leq C$. At the maturity T, the holder keeps any net gain, while any loss is covered by the writer.

In [2], this problem is solved using central weighting and Crank–Nicolson timestepping. While the results appear to converge to the correct solution, convergence to the viscosity solution cannot be guaranteed, since this is a nonmonotone method. In [26], it is shown that, for passport options, it is not possible to preselect central, forward, or backward differencing at a node, independent of the control, and guarantee a positive coefficient scheme. In other words, the scheme must depend on the control.

6.1. The pricing model for passport options. Let S be the underlying asset price which follows the stochastic process

$$dS = \mu S\, dt + \sigma S\, dZ, \tag{6.1}$$

where dZ is the increment of a Wiener process, σ is volatility, and μ is the drift rate. Let $V(S, W, t)$ denote the option value at time t with underlying price S and

wealth W. Under the process (6.1), the pricing PDE for passport options can be written as [30]

$$(6.2)\quad -V_t = -rV + (r-\gamma)SV_S + \sup_{|q|\le 1}\left[-((\gamma - r + r_c)qS - r_tW)V_W + \frac{\sigma^2S^2}{2}(V_{SS} + 2qV_{SW} + q^2V_{WW})\right],$$

where the following are defined:

W is the accumulated wealth of the underlying trading account.

r is the risk-free interest rate.

γ is the dividend rate on the underlying asset S.

r_c is a cost of carry rate.

r_t is an interest rate for the trading account.

q is the number of shares of S that an investor holds, which is also termed a trading strategy. q is limited to $|q| \le 1$ in (6.2). Different position limits can be handled by scaling [19].

We consider two types of payoff at $t = T$. The standard payoff is

$$(6.3)\qquad V(S, W, t = T) = \max(W, 0),$$

and the *asset or nothing* payoff [2] is

$$(6.4)\qquad V(S, W, t = T) = \begin{cases} S & \text{if } W \ge 0, \\ 0 & \text{otherwise.} \end{cases}$$

The above payoff can be generalized to specify a nonzero strike, but we assume the form (6.4) in this paper.

For both of these payoffs, we can reduce the problem to solving for $V(S, W, t) = Su(x, \tau)$, where $x = W/S$ and $\tau = T - t$ [2], so that (6.2) can be reduced to a one-dimensional problem for u:

$$(6.5)\quad u_\tau = -\gamma u + \sup_{|q|\le 1}\left[((r - \gamma - r_c)q - (r - \gamma - r_t)x)u_x + \frac{\sigma^2}{2}(x - q)^2u_{xx}\right],$$

where $x \in [-\infty, +\infty]$. The standard payoff becomes

$$(6.6)\qquad u(x, \tau = 0) = \max(x, 0),$$

with boundary conditions

$$(6.7)\qquad u(x \to -\infty, \tau) = 0, \quad u(x \to \infty, \tau) = x,$$

while the asset or nothing payoff is

$$(6.8)\qquad u(x, \tau = 0) = \begin{cases} 1 & \text{if } x \ge 0, \\ 0 & \text{otherwise} \end{cases}$$

with boundary conditions

$$u(x \to -\infty, \tau) = 0, \quad u(x \to \infty, \tau) = \exp(-\gamma\tau). \tag{6.9}$$

For computational purposes, we truncate the domain to $x \in [x_{\min}, x_{\max}]$ and apply the boundary conditions (6.7) and (6.9) at $x_{\min}, x_{\max}$.

6.2. Discretization. Passport option valuation is a special case of the general HJB equation (2.2) if we note that in this case

$$Q = (q), \quad \hat{Q} = [-1, +1], \quad a(x,\tau,Q) = \frac{\sigma^2}{2}(x-q)^2, \tag{6.10}$$

$$b(x,\tau,Q) = (r-\gamma-r_c)q - (r-\gamma-r_t)x, \quad c(x,\tau,Q) = \gamma, \quad d(x,\tau,Q) = 0,$$

where $Q,\ \hat{Q},\ a,\ b,\ c,\ d$ are defined in section 2. Let the discrete approximation for $u(x_i, \tau^n)$ be denoted by u_i^n with $U^n = [u_0^n, u_1^n, \ldots, u_{imax}^n]'$. Let $\hat{U}^k$ be the $k'th$ estimate for U^n; then the local objective function which must be maximized in algorithm (5.1) is

(6.11)

$$[F^{n+1}(Q, \hat{U}^k)]_i = [A^{n+1}(Q, \hat{U}^k)\hat{U}^k + D^{n+1}(Q)]_i$$

$$= ((r-\gamma-r_c)q - (r-\gamma-r_t)x_i)[(\hat{u}^k)_x]_i + \frac{\sigma^2}{2}(x_i-q)^2[(\hat{u}^k)_{xx}]_i^{n+1},$$

where $[\cdot]_i^{n+1}$ refers to the discrete form for $[\cdot]$. We need a positive coefficient scheme to solve the pricing PDE (6.5). Given node $x = x_i$, with current solution estimate $\hat{U}^k$, suppose the sets of q's, which give a positive coefficient scheme for central, forward, and backward differencing, respectively, are $P_i^{cent},\ P_i^{fwd},\ P_i^{bwd}$. Since central differencing is the most accurate, it should be used as much as possible. Consequently, given a q, if central differencing satisfies positive coefficient conditions, central differencing will be used for that q (with the constraint that F^{n+1} is $\mathcal{USC}$). In other words, the proper ranges of q for various differencings are $Range_i^{cent} = P_i^{cent}$, $Range_i^{fwd} = P_i^{fwd} - (P_i^{cent} \cap P_i^{fwd})$, and $Range_i^{bwd} = P_i^{bwd} - (P_i^{cent} \cap P_i^{bwd})$. Note that

$$Range_i^j \cap Range_i^k = \emptyset, \quad \text{where } j,k \in \{cent, bwd, fwd\} \text{ and } j \neq k,$$

$$Range_i^{bwd} \cup Range_i^{fwd} \cup Range_i^{cent} = \hat{Q}. \tag{6.12}$$

Let $\overline{Range}_i^j$ denote the closure of $Range_i^j$. For a given asset grid and the option values at the current iteration, algorithm (6.13) is used to determine the optimal control and to decide which differencing should be applied. This choice of differencing method uses central differencing as much as possible and determines $A^{n+1}(Q, \hat{U}^k)$ so that $F^{n+1}(Q, \hat{U}^k)$ is $\mathcal{USC}$.

For a given differencing method, the range of possible values of the control is divided into closed line segments where the objective function is smooth. Standard methods are then used to determine the maximum within each segment. If an analytic form for the local objective function is not available, then an alternate approach is discussed in section 7.4.

DETERMINING THE OPTIMAL CONTROL AND THE DIFFERENCING METHOD

(6.13)

Apply boundary conditions at the first node x_0 and the last node x_p
For each $x_0 < x_i < x_p$
  Compute the positive coefficient sets $Range_i^{cent}$, $Range_i^{fwd}$, $Range_i^{bwd}$
  diff = cent, $q^* = 0$, $F_{\max} = -\infty$
  For j = cent, fwd, bwd
    Compute $[A^{n+1}(q, \hat{V}^k)]_i$ with scheme $= j$
    Solve $q_j^* = \underset{q \in \overline{Range_i^j}}{\arg\max} \{[F^{n+1}(q, \hat{V}^k)]_i\}$
    If $[F^{n+1}(q_j^*, \hat{V}^k)]_i > F_{\max}$
      diff $= j$, $q^* = q_j^*$
      $F_{\max} = [F^{n+1}(q_j^*, \hat{V}^k)]_i$
    EndIf
  EndFor
EndFor

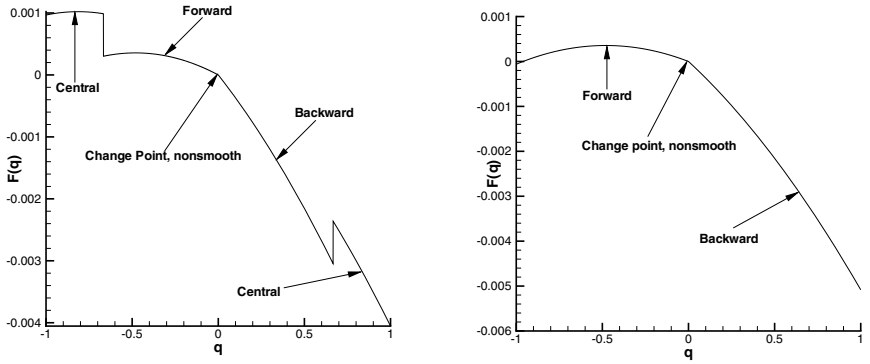
6.3. Discontinuity of the objective function. When we use central differencing as much as possible, the local objective function at each node is in general a discontinuous function of the control q. However, the proof of convergence of the iterative scheme for solution of the discretized algebraic equations (Theorem 5.2) does not require continuity of the local objective function. If forward/backward differencing are applied, the local objective function is continuous but not smooth. Figure 1 shows these features for a given grid and solution values.

Note that algorithm (6.13) requires determination of the maximum of the local objective function for each set of points where central, forward, or backward differencing is used. For example, as shown in Figure 1, central differencing can be used on two disjoint intervals of the control space. On each of the subintervals, the objective function is a smooth function of the control, and hence we can use standard methods to maximize the objective function. Determination of the range of controls where central, forward, and backward differencing give rise to a positive coefficient method is generally only possible if we have an analytic expression for the objective function. If this is not available, we can discretize the control and use a linear search to find the maximum as described in section 7.4. This is, of course, much more computationally expensive compared to analytic maximization.

6.4. Numerical results. In this section, we will examine the convergence as the grid and timesteps are refined for various differencing methods.

We use a convergence tolerance of 10^{-7} in algorithm (5.1), and we truncate the computational domain to $[x_{\min}, x_{\max}] = [-3, 4]$. Numerical experiments show that increasing the size of the computational domain does not affect solution values to six digits.

In [2, 26], input parameters in Table 1 are used for testing. An unequally spaced grid in the x direction is used, and new fine grid nodes are added between each two



(a) **(b)**

FIG. 1. *Local objective function* (6.11) *for the passport option at* $x_i = 0$. (a) *Using central differencing as much as possible;* (b) *using forward/backward differencing only. Parameters:* $r = 0.05$, $\sigma = 0.03$, *dividend* $= 0.04$, $r_c = 0.07$, $r_t = 0.03$. *Nodes:* $x_{i-1} = -0.01$, $u_{i-1} = 0.173298$; $x_i = 0.$, $u_i = 0.173888$; $x_{i+1} = 0.01$, $u_{i+1} = 0.174135$.

coarse grid nodes at each level of refinement. In Table 2, *ratio* refers to the ratio of successive changes in the solution as the grid is refined by a factor of two, and the timestep sizes are reduced by a factor of four. Since fully implicit timestepping is used, this allows us to isolate the effect of the use of central weighting as much as possible, compared to forward/backward differencing only. Local second order convergence (in terms of x node spacing) would be consistent with a ratio of four, while first order convergence would be consistent with a ratio of two.

For this particular set of parameters an analytical solution is known [2], $V(S_0, 0, \tau = T) = \$13.1381$ (to six figures). Table 2 shows that our numerical solution

converges to the analytical solution. The numerical solutions in [2, 26] also converge to that value. However, the discretization schemes in [2, 26] are not monotone so that convergence to the viscosity solution is not guaranteed. As shown in Theorem 4.1, our numerical method guarantees convergence to the viscosity solution.

We now compare the results from two differencing methods—using central differencing as much as possible and using forward/backward differencing only. Using the input parameters in Table 3, Table 4 presents a convergence study, which also reports the actual initial option values, i.e., $V = S_0\, u(x = W_0/S_0, \tau = T)$.

The payoff type is a call (convex payoff). As expected, Table 4 indicates that quadratic convergence is obtained by using central differencing as much as possible, and first order convergence is obtained by using forward/backward differencing.

For a convex payoff, it is always optimal to choose $q = -1$ or 1 [26]. But for a nonconvex payoff, q can be any value in $[-1, 1]$. Table 5 presents a convergence study using the parameters in Table 3, but the payoff type is an asset or nothing, nonconvex payoff (this is a digital call in terms of u; see (6.8)). For the asset or nothing payoff, if $W_0 \geq 0$, the option value will be very high (close to the initial stock value) and insensitive to the grid refinement, and so it is difficult to carry out a convergence study. In this example, option values are reported at $W_0 = -25$ (initial wealth is $-\$25$). When central differencing as much as possible is applied, the convergence rate is close to second order. First order convergence is obtained by using forward/backward differencing.

From the numerical results, we can conclude that generally we can obtain higher rates of convergence using central weighting as much as possible, compared to forward/backward differencing only. Of course, we cannot guarantee that this will always

TABLE 4

occur, but we can rarely obtain second order convergence using forward/backward differencing. In all our numerical experiments, we have never seen a case where central weighting as much as possible converges at a slower rate compared to forward/backward differencing only.

Note that in both these examples, forward/backward differencing requires only about 60% of the CPU time compared to central differencing as much as possible. This is simply because of the additional tests required to determine the ranges of possible central weighting in algorithm (6.13).

Both Tables 4 and 5 show that the number of nonlinear iterations per timestep is about two, indicating that algorithm (5.1) converges rapidly, in spite of the discontinuous objective function that is maximized at each node.

7. Defined contribution pension plan. The second example in this paper concerns an optimal dynamic asset allocation strategy for a defined contribution pension plan. A traditional asset allocation strategy for a defined contribution pension plan is *deterministic lifestyling*. Initially, the contributions of the plan are invested entirely in equities. Beginning on a predetermined date, say N years prior to retirement, the contributions are switched into bonds at a rate of $1/N$ per year. Then all assets are invested in bonds by the date of retirement. Deterministic lifestyling can reduce the losses of the plan in case of a sudden fall in the stock market just before the date of retirement. This strategy is simple and widely used. However, obviously it is not the optimal strategy.

We will follow the approach given in [14] to find the optimal dynamic asset allocation strategy for a defined contribution pension plan. The objective of the strategy is to maximize the plan member's utility at retirement. It is assumed that the utility is a function of the plan member's wealth to yearly income ratio [14].

We give a brief derivation of the model equations; for details we refer the reader to [14].

7.1. Stochastic model. Suppose there are two underlying assets in the pension plan: one is risk-free (e.g., a government bond) and the other is risky (e.g., a stock

market fund). The risky asset S follows the stochastic process

$$dS = (r + \xi_1\sigma_1)S\ dt + \sigma_1 S\ dZ_1, \tag{7.1}$$

where dZ_1 is the increment of a Wiener process, σ_1 is volatility, r is the interest rate, and ξ_1 is the market price of risk. Suppose that the plan member continuously pays into the pension plan at a fraction π of his/her yearly salary Y, which follows the process

$$dY = (r + \mu_Y)Y\ dt + \sigma_{Y_0} Y\ dZ_0 + \sigma_{Y_1} Y\ dZ_1, \tag{7.2}$$

where μ_Y, σ_{Y_0}, and σ_{Y_1} are constants, and dZ_0 is another increment of a Wiener process, which is independent of dZ_1. Let $W(t)$ denote the wealth accumulated in the pension plan, let p denote the proportion of this wealth invested in the risky asset S, and let $1 - p$ denote the fraction of wealth invested in the risk-free asset. Then

$$dW = (r + p\xi_1\sigma_1)W\ dt + p\sigma_1 W dZ_1 + \pi Y dt. \tag{7.3}$$

Assume the plan member has a power utility function $u(W(T), Y(T))$ at retirement time T, which is defined as a function of the wealth-income ratio,

$$u(W(T), Y(T)) = \begin{cases} \frac{1}{\gamma}\left(\frac{W(T)}{Y(T)}\right)^{\gamma}, & \text{where } \gamma < 1 \text{ and } \gamma \neq 0, \\ \log\left(\frac{W(T)}{Y(T)}\right) & \text{when } \gamma = 0. \end{cases} \tag{7.4}$$

Our goal is to find the optimal asset allocation strategy to maximize the expected terminal utility. Define a new state variable $X(t) = W(t)/Y(t)$; then by Itô's lemma, we obtain

$$\begin{aligned} dX = [\pi + X(-\mu_Y + p\sigma_1(\xi_1 - \sigma_{Y_1}) + \sigma_{Y_0}^2 + \sigma_{Y_1}^2)]dt \\ - \sigma_{Y_0} X dZ_0 + X(p\sigma_1 - \sigma_{Y_1})dZ_1. \end{aligned} \tag{7.5}$$

Let $J(t, x, p) = E[u(X_p(T))|X(t) = x]$, where $X(t)$ is the path of X given the asset allocation strategy $p = p(t, x)$, and $E[\cdot]$ is the expectation operator. We define

$$V(x, \tau) = \sup_{p \in \hat{P}} E[u(X_p(T))|X(T - \tau) = x] = \sup_{p \in \hat{P}} J(T - \tau, x, p), \tag{7.6}$$

where $\hat{P}$ is the set of all admissible asset allocation strategies, and $\tau = T - t$. Then $V(x, \tau)$ satisfies the HJB equation

$$V_\tau = \sup_{p \in \hat{P}} \left\{ \mu_X^p V_x + \frac{1}{2}(\sigma_X^p)^2 V_{xx} \right\}, \quad x \in [0, \infty], \tag{7.7}$$

with terminal condition

$$V(x, \tau = 0) = \begin{cases} \gamma^{-1} x^{\gamma}, & \text{where } \gamma < 1 \text{ and } \gamma \neq 0, \\ \log(x) & \text{when } \gamma = 0, \end{cases} \tag{7.8}$$

and where

$$\begin{aligned} \mu_X^p &= \pi + x(-\mu_Y + p\sigma_1(\xi_1 - \sigma_{Y_1}) + \sigma_{Y_0}^2 + \sigma_{Y_1}^2), \\ (\sigma_X^p)^2 &= x^2(\sigma_{Y_0}^2 + (p\sigma_1 - \sigma_{Y_1})^2), \end{aligned} \tag{7.9}$$

TABLE 6

Computational parameters, pension plan. Convergence tolerance used in algorithm (5.1). ϵ *is used to adjust the terminal condition* (7.12). $p_{\max}$ *is the maximum value of the equity proportion* (7.11). $x_{\max}$ *is the maximum* x *value in the finite computational domain.*

convergence tolerance	10^{-7}
ϵ	10^{-3}
$p_{\max}$	200
$x_{\max}$	80

with boundary conditions

$$V_\tau(x=0,\tau) = \pi V_x, \quad V(x\to\infty,\tau) = 0. \tag{7.10}$$

For computational purposes, we truncate the domain to $[0, x_{\max}]$ and impose the boundary conditions (7.10) on this finite domain. In order to ensure that Assumption 2.2 holds, we define the range of controls to be

$$\hat{P} = [0, p_{\max}]. \tag{7.11}$$

Note that in the original problem in [14], $\hat{P} = [0,\infty]$. A value of $p > 1$ indicates that the holder borrows to invest in risky assets. As a practical matter, it is unlikely that anyone could borrow an unlimited amount relative to his/her wealth to invest in risky assets. We will choose $p_{\max}$ sufficiently large so that the computed solution is insensitive to $p_{\max}$.

The terminal condition (7.4) is undefined for $x = 0$ if, for example, $\gamma < 0$. We adopt the simple expedient of replacing condition (7.4) by

$$V(x,\tau=0) = \begin{cases} \frac{1}{\gamma}\max(x,\epsilon)^\gamma & \text{if } \gamma < 0, \\ \log(\max(x,\epsilon)) & \text{if } \gamma = 0, \end{cases} \tag{7.12}$$

where $\epsilon > 0, \epsilon \ll 1$. We choose ϵ sufficiently small so that the computed results are insensitive to this value. Table 6 shows the computational parameters used in our numerical tests.

Note that the HJB equation (7.7) becomes independent of p at $x = 0$. This nonuniqueness of p does not affect the solution value u. It will be understood in the following that if we refer to a value of, say, $(p\ x)$ at $x = 0$, then we are really referring to

$$\lim_{x\to 0}(p\ x). \tag{7.13}$$

7.2. Discretization. The pension plan asset allocation model is a special case of the general HJB equation (2.2) if we make the identification

$$Q = (p)\ , \quad \hat{Q} = [0, p_{\max}],$$

$$a(x,\tau,Q) = \frac{1}{2}(\sigma_X^p)^2, \quad b(x,\tau,Q) = \mu_X^p, \quad c(x,\tau,Q) = 0, \quad d(x,\tau,Q) = 0, \tag{7.14}$$

where Q, a, b, c, d are defined in (2.2). Given node $x = x_i$, with specified solution estimate $\hat{V}^k = [\hat{v}_0^k, \ldots, \hat{v}_{imax}^k]'$, the objective function which is maximized at each node in algorithm (5.1) is

$$\begin{aligned}[F^{n+1}(Q,\hat{V}^k)]_i &= [A^{n+1}(Q,\hat{V}^k)\hat{V}^k + D^{n+1}(Q)]_i \\ &= [\mu_X^p]_i[(\hat{v}^k)_x]_i + \frac{1}{2}([\sigma_X^p]_i)^2[(\hat{v}^k)_{xx}]_i^{n+1}, \end{aligned} \tag{7.15}$$

TABLE 7

Parameters used in the pension plan examples. The time units in this problem are years, so that the ratio of wealth to salary x has the units of years.

μ_y	0.	ξ_1	0.2
σ_1	0.2	σ_{Y1}	0.05
σ_{Y0}	0.05	π	0.1
T	20 years	γ	-5

where $\hat{V}^k$ is the vector containing the current estimate of the discrete solution values. Similar to the passport option case, if we want to apply central differencing as much as possible, algorithm (6.13) is used to decide which differencing scheme is used (which depends on Q and $\hat{V}^k$).

7.3. Numerical results. Given the parameters in Table 7, Table 8 shows the numerical results. Recall that as we refine the grid, by inserting a fine grid node between two coarse grid nodes, we reduce the timestep size by four. Since fully implicit timestepping is used (which guarantees a monotone scheme), then the ratio of successive changes in the solution, as the grid is refined, should be four for quadratic convergence and two for linear convergence. As expected, Table 8 shows that quadratic convergence is obtained by using central differencing as much as possible, and first order convergence is obtained by using forward/backward differencing. As for the passport option case, convergence of algorithm (5.1) is rapid.

TABLE 8

Convergence study, pension plan example. Fully implicit timestepping is applied, using constant timesteps. On each refinement, new fine grid nodes are inserted between each coarse grid node, and the timestep size is reduced by four. Parameters are given in Table 7. The utility values are given at $x = 1$ and $x = 0$. Ratio is the ratio of successive changes in computed solution as the discretization parameters are reduced.

1377	40960	81920	103.09	-4.40348×10^{-4}	2.06

Numerical tests with the parameters in Table 6 indicated that increasing the truncated domain size $x_{\max}$, increasing the maximum value of the control $p_{\max}$, and decreasing the convergence tolerance and ϵ resulted in no change to the results in Table 8 to six figures.

In the passport option case, particularly with a convex payoff, numerical experiments indicate that using central differencing only does converge to the viscosity solution [2, 26]. However, this cannot be guaranteed. In contrast, in the pension plan case, the numerical scheme does not appear to converge at all using central differencing only. In this respect, the pension plan problem appears to be more challenging than passport option valuation.

Given the parameters in Table 7, Figure 2 shows the expected terminal utility at $t = 0$ and the corresponding optimal asset allocation strategy p as a function of the wealth to salary ratio x. Note that as $x \to 0$, the proportion invested in the risky asset becomes very large. However, as noted in [14], the amount actually invested in the risky asset $(p\ x)$, tends to zero as $x \to 0$. This is clearly illustrated Figure 2(d). Moreover, [14] points out that $(p\ x)$ converges to 0 at the same rate as $\sqrt{x}$. Using

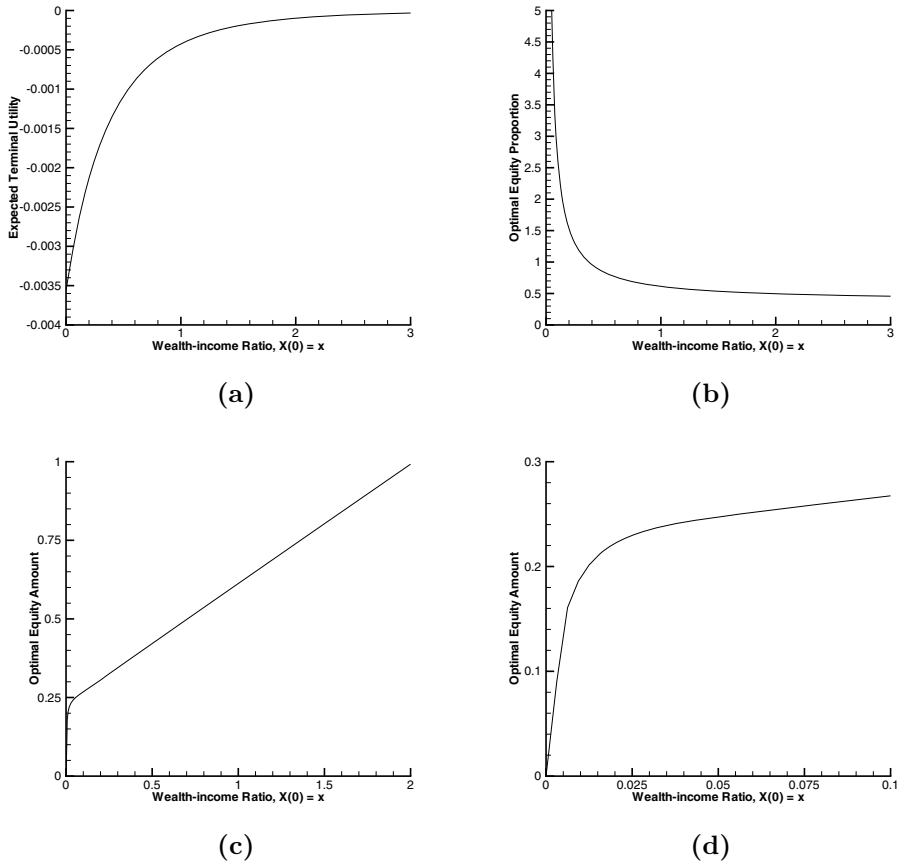

FIG. 2. *Utility and optimal asset allocation strategy at* $t = 0$*, pension plan example. Parameters are given in Table* 7. (a) *Expected terminal utility;* (b) *optimal asset allocation strategy;* (c) *optimal equity amount* $(p\ x)$*;* (d) *magnified graph of* (c).

the parameters in Table 7, we find that $\lim_{x\to 0} \frac{px}{\sqrt{x}} \simeq 1.59$. In [14], the authors do not give details about their numerical method and present only graphical results. We can comment only that the results in Figure 2 are qualitatively similar to the results in [14].

7.4. Discretization of the control. In some cases, if the form of the HJB equation is complex, then it may be difficult to implement algorithm (6.13). In this case, a simpler approach is desirable. Suppose there is one control q at each node, and we discretize the possible control values as described in section 4.1. From Lemma 4.3, we have that a scheme using discrete controls will converge to the viscosity solution of the original HJB equation. To determine the optimal control at each node, as required in algorithm (5.1), we simply perform a linear search of the discrete control values. For a given q, we use central weighting if this results in a positive coefficient method; otherwise, forward/backward differencing is used.

Note that since we cannot assume that the objective function is a continuous function of the control, linear search is the only way to find the optimal value of q. This method has the obvious advantage that it is very easy to implement, especially in the case where central differencing is used as much as possible.

The numerical results obtained using this method for the pension plan problem are given in Table 9. The results are very close to the results reported in Table 8. Of course, this method requires much more CPU time compared to algorithm (6.13). This is simply due to the comparatively crude method used to find the optimal control at each grid node.

In an effort to do better than linear search, we experimented with various approximate methods for finding the optimal control (assuming a discrete set of controls). Seemingly reasonable methods based on smooth approximations to the objective function were very unreliable, and algorithm (5.1) typically failed to converge. This is simply because the smooth approximation may not find the global maximum of the local objective function, and hence the argument used to prove the convergence of the iteration (Theorem 5.2) breaks down.

TABLE 9

Convergence study, pension plan example, discretized control. x-nodes refers to the number of nodes in the x grid. p-nodes refers to the number of nodes in the discretization of the range of control values. Fully implicit timestepping is used with constant timesteps. On each refinement, new fine grid nodes are inserted between each coarse grid node, and the timestep is reduced by four. Central differencing is used as much as possible. Ratio is the ratio of successive changes in computed solution as the discretization parameters are reduced. Problem data is given in Table 7.

x-nodes	p-nodes	Timesteps	Nonlinear iterations	CPU (sec)	Utility	Ratio
			$x = 0$			
173	113	640	1317	1.9	-3.65307×10^{-3}

689	449	10240	20511	457	-4.25619×10^{-4}	3.93
1377	897	40961	82016	7240	-4.25306×10^{-4}	3.92

8. Extension to multidimensional models. We have fully discussed the solution of one-factor cases. Many financial problems are modelled as multifactor HJB equations. Our scheme can, in principal, be extended to multifactor problems. For example, for two-factor models, the operator $\mathcal{L}$ (defined by (2.1)) changes to

$$\begin{aligned}\mathcal{L}^Q V \equiv\ & a_1(X,Y,\tau,Q)V_{XX} + a_2(X,Y,\tau,Q)V_{YY} + a_3(X,Y,\tau,Q)V_{XY} \\ & + a_4(X,Y,\tau,Q)V_X + a_5(X,Y,\tau,Q)V_Y - a_6(X,Y,\tau,Q)V, \end{aligned} \tag{8.1}$$

where

$$\begin{bmatrix} a_1 & a_3/2 \\ a_3/2 & a_2 \end{bmatrix} \tag{8.2}$$

is positive semidefinite. Consequently, the general form of our pricing PDE changes to

$$\begin{aligned} V_\tau = \sup_{Q\in\hat{Q}} \left\{ \mathcal{L}^Q V + d(X,Y,\tau,Q) \right\}, \\ X \in [X_{\min}, X_{\max}], \quad Y \in [Y_{\min}, Y_{\max}], \quad 0 \le \tau \le T. \end{aligned} \tag{8.3}$$

If we can find a positive coefficient discretization scheme for (8.3), we can solve this problem using the same methods as described for the single factor case. All the proofs follow without change.

However, the difficulty results from the fact that it is not trivial to find a positive coefficient discretization for the term $a_3 V_{XY}$. One possible approach is discussed in [7], where if certain grid spacing conditions are satisfied, then a positive coefficient discretization can be obtained if a seven point finite difference method is used to approximate the V_{XY} term (the orientation of the seven point operator depends on the sign of a_3). Note that forward/backward differencing for the first order terms is suggested in [7].

9. Conclusions. Many financial models result in nonlinear HJB PDEs. Classical solutions to these PDEs do not usually exist. In order to ensure convergence to the viscosity solution, monotone difference methods must be used. The standard approach simply uses forward/backward differencing to ensure monotonicity. Clearly, this method can be at most first order accurate.

However, in many financial applications, it is often the case that central differencing can be used at many nodes. This possibility seems to have been ignored in previous work. In this paper, we use central differencing as much as possible. When we use central differencing as much as possible, the local objective function at each node is a discontinuous function of the control. However, the proof of convergence of the iterative scheme for solution of the fully implicit discretized algebraic equations does not require continuity of the local objective function. Hence convergence of the iterative algorithm for solving the nonlinear discretized equations is guaranteed.

We have reported numerical experiments for pricing passport options and optimal asset allocation for defined contribution pension plans. In all cases, use of central differencing as much as possible converges at a higher rate than use of forward/backward differencing only. We have seen this same effect in many numerical experiments. Use of central differencing as much as possible is never worse (in terms of convergence rate) and almost always superior to forward/backward differencing only. Note that

these higher rates cannot be guaranteed, but convergence to the viscosity solution is guaranteed.

However, use of central differencing as much as possible is more costly than simply using forward/backward differencing. This is due to the fact that the possible discontinuity points of the objective function must be identified, so that standard methods can be used to maximize the objective function on intervals where the objective function is smooth. This also adds somewhat to implementation complexity.

In cases where it is not possible to analytically maximize the objective function, a very straightforward approach is to discretize the control and to maximize the objective function using a linear search. This method is very easy to implement and is also guaranteed to converge to the viscosity solution, but this technique is much more computationally expensive. In these cases, it is clearly advantageous to use central differencing as much as possible, so that higher rates of convergence may compensate for the increased computational cost.

The methods developed in this article can be extended to multifactor problems if a monotone scheme is used to discretize the differential operator. However, in this case it may be nontrivial to satisfy the monotonicity requirement, due to the presence of a cross-derivative term.

Appendix A. Discrete equation coefficients. Let Q_i^n denote the vector of optimal controls at node i and time level n, and set

$$a_i^n = a(S_i, \tau^n, Q_i^n), \quad b_i^n = b(S_i, \tau^n, Q_i^n), \quad c_i^n = c(S_i, \tau^n, Q_i^n). \tag{A.1}$$

Then we can use central, forward, or backward differencing at any node.

Central differencing:

$$\alpha^n_{i,central} = \left[\frac{2a_i^n}{(S_i - S_{i-1})(S_{i+1} - S_{i-1})} - \frac{b_i^n}{S_{i+1} - S_{i-1}} \right],$$

$$\beta^n_{i,central} = \left[\frac{2a_i^n}{(S_{i+1} - S_i)(S_{i+1} - S_{i-1})} + \frac{b_i^n}{S_{i+1} - S_{i-1}} \right]. \tag{A.2}$$

Forward/backward differencing ($b_i^n > 0/\ b_i^n < 0$):

$$\alpha^n_{i,forward/backward} = \left[\frac{2a_i^n}{(S_i - S_{i-1})(S_{i+1} - S_{i-1})} + \max\left(0, \frac{-b_i^n}{S_i - S_{i-1}}\right) \right],$$

$$\beta^n_{i,forward/backward} = \left[\frac{2a_i^n}{(S_{i+1} - S_i)(S_{i+1} - S_{i-1})} + \max\left(0, \frac{b_i^n}{S_{i+1} - S_i}\right) \right]. \tag{A.3}$$

MAXIMUM NORM A POSTERIORI ERROR ESTIMATE FOR A 2D SINGULARLY PERTURBED SEMILINEAR REACTION-DIFFUSION PROBLEM*

NATALIA KOPTEVA†

Abstract. A singularly perturbed semilinear reaction-diffusion equation, posed in the unit square, is discretized on arbitrary nonuniform tensor-product meshes. We establish a second-order maximum norm a posteriori error estimate that holds true uniformly in the small diffusion parameter. No mesh aspect ratio assumption is made. Numerical results are presented that support our theoretical estimate.

Key words. reaction-diffusion, singular perturbation, a posteriori error estimate, maximum norm, no mesh aspect ratio condition, finite differences, layer-adapted mesh

AMS subject classifications. 65N06, 65N15, 65N50

DOI. 10.1137/060677616

1. Introduction.

Solutions of singularly perturbed differential equations typically exhibit sharp boundary and interior layers, which are narrow regions where solutions change rapidly. To obtain reliable numerical approximations of layer solutions in an efficient way, one has to use locally refined meshes that are fine in layer regions and standard outside. Furthermore, as is shown in [20, 19, 7, 13] by the numerical analysis of model problems, for which the location and width of the layers are known a priori, optimal layer-adapted meshes have extremely high maximum aspect ratios (typically $O(\varepsilon^{-1})$, where ε is the layer width).

In contrast, a posteriori error estimates, which underlie any reliable a posteriori mesh construction, are typically obtained under the minimum angle condition, which is equivalent to the bounded-mesh-aspect-ratio condition; see, e.g., [2, 21]. But the minimum angle condition seems rather restrictive and makes a posteriori error estimates less practical for layer solutions, for which a posteriori mesh generation is most needed.

The aim of the present paper is to establish an a posteriori error estimate for one singularly perturbed problem under *no mesh aspect ratio condition*. Note that our error estimate is in the maximum norm, which is sufficiently strong to capture layers and hence seems most appropriate for singularly perturbed problems.

Consider the singularly perturbed semilinear reaction-diffusion problem posed in the unit square:

$$\begin{aligned} Tu := -\varepsilon^2 \triangle u + b(x,y,u) = 0, \qquad & (x,y) \in \Omega = (0,1)\times(0,1), \\ u(x,y) = 0, \qquad & (x,y) \in \partial\Omega. \end{aligned} \tag{1.1}$$

†Department of Mathematics and Statistics, University of Limerick, Limerick, Ireland (natalia.kopteva@ul.ie).

Here ε is a small positive parameter, $\triangle = \partial^2/\partial x^2 + \partial^2/\partial y^2$ is the Laplace operator, the function b is sufficiently smooth, and

$$0 < \beta < b_u(x, y, u) \le \bar{\beta} \qquad \text{for all } (x, y, u) \in [0, 1]^2 \times \mathbb{R}. \tag{1.2}$$

Under condition (1.2), problem (1.1) has a unique solution, which exhibits sharp boundary layers of width $O(\varepsilon|\ln\varepsilon|)$ along the boundary $\partial\Omega$.

We discretize (1.1) using the standard second-order five-point difference scheme—see (2.2) for details—on an arbitrary tensor-product mesh $\{(x_i, y_j)\}$, where $0 = x_0 < x_1 < \cdots < x_N = 1$ and $0 = y_0 < y_1 < \cdots < y_M = 1$, while $h_i = x_i - x_{i-1}$ and $k_j = y_j - y_{j-1}$ are the local mesh sizes.

This is an idealized situation in the a posteriori mesh construction context since an irregular mesh, rather than a tensor-product mesh, seems more suitable for a practical a posteriori mesh construction algorithm. Therefore the error estimate, which we present, is more interesting from a theoretical point of view. In particular, it shows that the bounded-mesh-aspect-ratio condition/minimal-angle condition is not essential in the a posteriori error estimation. Furthermore, if tensor-product meshes are used at least in crucial layer regions, where the mesh adaptation is most needed, one might conjecture that in such regions, local analogues of our a posteriori error estimate would apply.

Our main result is the following maximum norm *a posteriori error estimate*, in which the error is understood as the difference between the exact solution and the bilinear interpolant of the computed solution:

$$\|U^{\mathrm{B}} - u\|_\infty \le C_0 \left[\max_{\substack{i=1,\dots,N \\ j=0,\dots,M}} \left\{ h_i^2 M_{1,ij} \right\} + \max_{\substack{i=0,\dots,N \\ j=1,\dots,M}} \left\{ k_j^2 M_{2,ij} \right\} \right] \tag{1.3}$$

—see Theorem 2.1—where, roughly speaking,

$$M_{1,ij} \approx |D_x^2 U_{ij}| \ln\bigl(2 + \varepsilon/\kappa\bigr) + 1, \qquad M_{2,ij} \approx |D_y^2 U_{ij}| \ln\bigl(2 + \varepsilon/\kappa\bigr) + 1, \tag{1.4}$$

with $\kappa := \min\{\min_i\{h_i\}, \min_j\{k_j\}\}$. Here U^{B} is the bilinear interpolant of the computed solution U (the finite difference computed solution is originally defined at the mesh nodes only; hence to measure the error in the entire domain, one first has to interpolate the computed solution there). The quantities $D_x^2 U_{ij}$ and $D_y^2 U_{ij}$ are the standard discrete approximations of $\partial^2 u/\partial x^2$ and $\partial^2 u/\partial y^2$ defined in (2.3). In (1.4), a few terms are skipped, for which the one-dimensional analysis [12] and the numerical results of section 6 show that they are less important; see Theorem 2.1 for the precise definitions of $M_{1,ij}$ and $M_{2,ij}$.

The error constant C_0 in (1.3) is independent of ε, the mesh, and aspect ratios of its elements, although this constant is not specified. In a posteriori error estimation, much attention focuses on specifying the error constants. Note that for singularly perturbed problems, the error constant might blow up as ε becomes small, and hence the existence of an ε-uniform error constant is more significant than its precise value.

Note that, roughly speaking, the a posteriori error estimate (1.3), (1.4) might be viewed as a discrete analogue of the linear interpolation error estimates [8, 6], which imply that a suitable anisotropic mesh should be quasi-uniform under the metric induced by the Hessian matrix. An example of this idea being exploited for mesh generation is given, e.g., in [10], where anisotropic meshes, defined as mappings of regular uniform grids, are obtained via functional minimization.

The present paper follows [11] and in particular [12], where certain maximum norm a posteriori error estimates were derived for one-dimensional singularly perturbed convection-diffusion and reaction-diffusion problems; see also a more recent paper [18] for a similar one-dimensional a posteriori error estimate. Note that the papers [11, 12, 18] report one-dimensional error estimates, while now we extend the one-dimensional analysis [12] to a two-dimensional case.

Problem (1.1) has often been addressed in the numerical analysis literature. In particular, we refer the reader to [5], where iterative techniques for the standard finite difference discretization of (1.1) are developed, and [15, 16], where certain a posteriori error estimates for a linear version of (1.1) are obtained on anisotropic meshes in the energy norm.

The paper is organized as follows. In section 2, we describe the numerical method, present our a posteriori error estimate in Theorem 2.1, and outline its proof. Next, in section 3, we establish some estimates for the Green's function of a linearized version of (1.1). They imply certain stability properties of the differential operator T from (1.1), which are presented in section 4. Then in section 5, we complete the proof of Theorem 2.1. Finally, in section 6, numerical results are given that support our theoretical estimate.

Notation. Let $\|\cdot\|_{p;\tilde\Omega}$, where $1 \le p \le \infty$, denote the standard $L_p(\tilde\Omega)$ norm for any domain $\tilde\Omega$. Furthermore, the standard notation $W^{k,p}(\tilde\Omega)$ is used for the Sobolev spaces with the norm $\|\cdot\|_{k,p;\tilde\Omega}$ defined, for a function $v(x,y)$ in a domain $\tilde\Omega$, by

$$\|v\|_{k,p;\tilde\Omega} = \|v\|_{p;\tilde\Omega} + \sum_{l=1}^{k} |v|_{l,p;\tilde\Omega}, \qquad k = 1, 2,$$

$$|v|_{1,p;\tilde\Omega} = \|v_x\|_{p;\tilde\Omega} + \|v_y\|_{p;\tilde\Omega}\,, \qquad |v|_{2,p;\tilde\Omega} = \|v_{xx}\|_{p;\tilde\Omega} + \|v_{xy}\|_{p;\tilde\Omega} + \|v_{yy}\|_{p;\tilde\Omega}\,;$$

see, e.g., [9]. We shall use the notation $\|\cdot\|_p$ and $\|\cdot\|_{k,p}$ for $\|\cdot\|_{p;\Omega}$ and $\|\cdot\|_{k,p;\Omega}$ when there is no ambiguity. Sometimes the domain of interest will be an open ball $B(a,b;\rho) = \{(x,y) : (x-a)^2 + (y-b)^2 < \rho^2\}$ centered at (a,b) of radius ρ.

Throughout the paper we let C denote a generic positive constant that may take different values in different formulas but is always independent of the mesh and ε. A subscripted C (e.g., C_1) denotes a positive constant that is independent of h and ε and takes a fixed value.

Remark 1.1. The assumption $b_u(x,y,u) \le \bar\beta$ in (1.2) can be omitted since it follows, for some constant $\bar\beta$, from $0 < \beta < b_u(x,y,u)$ and u being a unique and bounded solution of (1.1); see, e.g., [22, section 12]. Note that assumption (1.2) enables us to linearize (1.1) and then invoke the Green's function in our analysis. On the other hand, this assumption implies that our problem has a unique solution and thus excludes the possibility of multiple solutions. Hence, strictly speaking, our results are not applicable to the multiple-solution case. Having said this, we still believe that the present paper provides some insight into the numerical solution of a more general multiple-solution version of (1.1), considered, e.g., in [10].

2. Numerical method. Main result. Let our problem (1.1) satisfy the standard compatibility conditions at the corners of the domain Ω:

$$b(0,0,0) = b(0,1,0) = b(1,0,0) = b(1,1,0) = 0, \tag{2.1}$$

which guarantee that $u \in C^3(\bar\Omega)$.

Numerical method. We require the computed solution U to satisfy the standard five-point finite difference discretization of problem (1.1):

$$-\varepsilon^2 D_x^2 U_{ij} - \varepsilon^2 D_y^2 U_{ij} + b(x_i, y_j, U_{ij}) = 0, \tag{2.2}$$

for $i = 1, \dots N-1$, $j = 1, \dots, M-1$, where $U_{0,j} = U_{N,j} = U_{i,0} = U_{i,M} = 0$. Here, as usual, U_{ij} is associated with the mesh node (x_i, y_j), and we use the standard finite difference operators, defined for a discrete function V_{ij} by

$$\begin{aligned} D_x^- V_{ij} &= \frac{V_{ij} - V_{i-1,j}}{h_i}, \qquad D_x^2 V_{ij} = \frac{D_x^- V_{i+1,j} - D_x^- V_{i,j}}{(h_i + h_{i+1})/2}, \\ D_y^- V_{ij} &= \frac{V_{ij} - V_{i,j-1}}{k_j}, \qquad D_y^2 V_{ij} = \frac{D_y^- V_{i,j+1} - D_y^- V_{i,j}}{(k_j + k_{j+1})/2}. \end{aligned} \tag{2.3}$$

By condition (1.2), there exists a unique solution of the discrete problem (2.2) on an arbitrary mesh $\{(x_i, y_j)\}$; see, e.g., [5].

Clearly, $D_x^2 U_{ij}$ is defined for $i = 1, \dots, N-1$, $j = 0, \dots, M$, while $D_y^2 U_{ij}$ is defined for $i = 0, \dots, N$, $j = 1, \dots, M-1$. We now extend $D_x^2 U_{ij}$ to the mesh nodes $i = 0, N$ as follows. First, formally extend the discrete equation (2.2) to $i = 0$ and $i = N$, in which, using the zero boundary conditions, we set $D_y^2 U_{0,j} = D_y^2 U_{N,j} = 0$. This yields

$$D_x^2 U_{0,j} := \varepsilon^{-2} b(0, y_j, 0), \qquad D_x^2 U_{N,j} := \varepsilon^{-2} b(1, y_j, 0), \qquad j = 0, \dots, M. \tag{2.4a}$$

Similarly, extend $D_x^2 U_{ij}$ to $j = 0, M$ by

$$D_y^2 U_{i,0} := \varepsilon^{-2} b(x_i, 0, 0), \qquad D_y^2 U_{i,M} := \varepsilon^{-2} b(x_i, 1, 0), \qquad i = 0, \dots, N. \tag{2.4b}$$

Note that by (2.1), the above relations (2.4) imply that $D_x^2 U_{ij} = D_y^2 U_{ij} = 0$ if (x_i, y_j) is $(0,0)$, $(0,1)$, $(1,0)$, or $(1,1)$, which is consistent with the boundary condition in (1.1).

Remark 2.1. Now that $D_x^2 U_{ij}$ and $D_y^2 U_{ij}$ are extended by (2.4) to all i, j, our discrete equation (2.2) holds true for all $i = 0, \dots, N$ and $j = 0, \dots, M$.

Bilinear interpolation notation. Let $U^{\mathrm{B}} = U^{\mathrm{B}}(x, y)$ be the standard bilinear interpolant of the computed solution U_{ij}; i.e., U^{B} is continuous in $\bar{\Omega}$, bilinear on each $[x_{i-1}, x_i] \times [y_{j-1}, y_j]$, and equal to U_{ij} at the mesh nodes:

$$U^{\mathrm{B}}(x_i, y_j) = U_{ij} \qquad \text{for} \quad i = 0, \dots, N, \ j = 0, \dots, M. \tag{2.5}$$

Similarly, we introduce the bilinear interpolant $v^{\mathrm{B}}(x, y)$ for any discrete function v_{ij} or any continuous function $v(x, y)$.

Furthermore, we shall use the standard one-dimensional linear interpolants v^{I} and v^{J} with respect to x and y, respectively, that are defined, for any function v, as follows. For each fixed y in the domain of v, we have $v^{\mathrm{I}}(x_i, y) = v(x_i, y)$, and $v^{\mathrm{I}}(x, y)$ is linear on each $[x_{i-1}, x_i]$. Similarly, for each fixed x in the domain of v, we have $v^{\mathrm{J}}(x, y_j) = v(x, y_j)$, and $v^{\mathrm{J}}(x, y)$ is linear on each $[y_{j-1}, y_j]$.

In particular, consider the bilinear interpolant U^{B} of U_{ij} and the linear one-dimensional interpolants $U^{\mathrm{I}}(x, y_j)$ and $U^{\mathrm{J}}(x_i, y)$. Clearly,

$$[U^{\mathrm{I}}(x, y_j)]^{\mathrm{J}} = [U^{\mathrm{J}}(x_i, y)]^{\mathrm{I}} = U^{\mathrm{B}}(x, y). \tag{2.6}$$

Now we state a maximum norm a posteriori error estimate, which is the main result of the present paper.

THEOREM 2.1. *Let $u(x,y)$ be a solution of problem* (1.1), (1.2), (2.1), *U_{ij} a solution of problem* (2.2) *on an arbitrary mesh $\{(x_i,y_j)\}$, and $U^{\rm B}(x,y)$ its piecewise bilinear interpolant* (2.5). *Then*

$$\|U^{\rm B}-u\|_\infty \le C_0 \left[\max_{\substack{i=1,\dots,N\\ j=0,\dots,M}} \bigl\{h_i^2 M_{1,ij}\bigr\} + \max_{\substack{i=0,\dots,N\\ j=1,\dots,M}} \bigl\{k_j^2 M_{2,ij}\bigr\} \right], \tag{2.7}$$

where

$$M_{1,ij} := \min\bigl\{|D_x^2 U_{i-1,j}|, |D_x^2 U_{ij}|\bigr\} \ln\bigl(2+\varepsilon/\kappa\bigr) + \varepsilon |D_x^- D_x^2 U_{ij}| + |D_x^- U_{ij}|^2 + 1,$$
$$M_{2,ij} := \min\bigl\{|D_y^2 U_{i,j-1}|, |D_y^2 U_{ij}|\bigr\} \ln\bigl(2+\varepsilon/\kappa\bigr) + \varepsilon |D_y^- D_y^2 U_{ij}| + |D_y^- U_{ij}|^2 + 1,$$

with $\kappa := \min\{\min_i\{h_i\}, \min_j\{k_j\}\}$, while the constant C is independent of ε and the mesh.

Proof outline. By (1.1), we have

$$TU^{\rm B} - Tu = -\varepsilon^2 \left[\partial^2/\partial x^2 + \partial^2/\partial y^2\right] U^{\rm B} + b(x,y,U^{\rm B}),$$

where $\partial^2 U^{\rm B}/\partial x^2$ and $\partial^2 U^{\rm B}/\partial y^2$ are understood in the sense of distributions. Define an auxiliary function

$$q(x,y) := b(x,y,U^{\rm B}(x,y))$$

and let $q^{\rm B}$ denote its piecewise bilinear interpolant on the mesh $\{(x_i,y_j)\}$. Hence

$$TU^{\rm B} - Tu = -\varepsilon^2 \left[\partial^2/\partial x^2 + \partial^2/\partial y^2\right] U^{\rm B} + q^{\rm B} + \bigl[q - q^{\rm B}\bigr].$$

Noting that $q_{ij} := q(x_i,y_j) = b(x_i,y_j,U_{ij})$ and recalling the discrete equation (2.2) combined with Remark 2.1 yields $q_{ij} = \varepsilon^2 D_x^2 U_{ij} + \varepsilon^2 D_y^2 U_{ij}$ for $i=0,\dots,N$, $j=0,\dots,M$. Next, decompose this as $q_{ij} = q_{1,ij} + q_{2,ij}$, where

$$q_{1,ij} := \varepsilon^2 D_x^2 U_{ij}, \qquad q_{2,ij} := \varepsilon^2 D_y^2 U_{ij}, \qquad i=0,\dots,N,\ j=0,\dots,M. \tag{2.8}$$

Furthermore, using analogues of (2.6) for q_1 and q_2, we get

$$q^{\rm B}(x,y) = q_1^{\rm B}(x,y) + q_2^{\rm B}(x,y) = \bigl[q_1^{\rm I}(x,y_j)\bigr]^{\rm J} + \bigl[q_2^{\rm J}(x_i,y)\bigr]^{\rm I}, \qquad (x,y)\in\bar\Omega.$$

Therefore

$$TU^{\rm B} - Tu = \left[-\varepsilon^2 \frac{\partial^2 U^{\rm I}(x,y_j)}{\partial x^2} + q_1^{\rm I}(x,y_j)\right]^{\rm J} + \left[-\varepsilon^2 \frac{\partial^2 U^{\rm J}(x_i,y)}{\partial y^2} + q_2^{\rm J}(x_i,y)\right]^{\rm I} + \bigl[q - q^{\rm B}\bigr].$$

Here we used

$$\frac{\partial^2 U^{\rm B}(x,y)}{\partial x^2} = \left[\frac{\partial^2 U^{\rm I}(x,y_j)}{\partial x^2}\right]^{\rm J}, \qquad \frac{\partial^2 U^{\rm B}(x,y)}{\partial y^2} = \left[\frac{\partial^2 U^{\rm J}(x_i,y)}{\partial y^2}\right]^{\rm I}, \tag{2.9}$$

which follow from (2.6); see also Remark 2.2.

The proof is completed in section 5. First, the residual $TU^{\rm B} - Tu$ is represented as

$$TU^{\rm B} - Tu = \frac{\partial}{\partial x} F_1(x,y) + \frac{\partial}{\partial y} F_2(x,y) + \bigl[q - q^{\rm B}\bigr], \tag{2.10}$$

where F_1 and F_2 are functions of the current mesh and computed solution. This will enable us to estimate the error $U^{\mathrm{B}} - u$ in the maximum norm by linearizing the operator T and invoking its stability properties, which are obtained in section 4 using sharp estimates of the Green's function of section 3.

Remark 2.2. We understand $\partial^2 U^{\mathrm{B}}/\partial x^2$ and $\partial^2 U^{\mathrm{B}}/\partial y^2$ in the sense of distributions. To be more precise, in (2.9) we use $\partial^2 U^{\mathrm{I}}(x, y_j)/\partial x^2 = \sum_{i=1}^{N-1} \upsilon_i(y_j)\delta(x - x_i)$, and $[\partial^2 U^{\mathrm{I}}(x, y_j)/\partial x^2]^{\mathrm{J}} = \sum_{i=1}^{N-1} \upsilon_i^{\mathrm{J}}(y)\delta(x - x_i)$, where $\delta(\cdot)$ is the Dirac δ-distribution, while $\upsilon_i(y_j) := D^2 U_{ij}\,(h_i + h_{i+1})/2$.

3. Green's function. Assumption (1.2) enables us to linearize (1.1) and then invoke the Green's function in our analysis. Hence we start with a linear case of (1.1), where $b(x, y, u) := p(x, y)u - f(x, y)$:

$$Lu := -\varepsilon^2 \triangle u + p(x, y)u = f(x, y) \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega. \tag{3.1}$$

Here $p \in L_\infty(\Omega)$ and, in accordance with (1.2),

$$0 < \beta \le p(x, y) \le \bar{\beta}. \tag{3.2}$$

Introduce the Green's function $G(x, y; \xi, \eta)$ of the linear self-adjoint operator L that, for each $(x, y) \in \Omega$, satisfies

$$\begin{aligned} LG = -\varepsilon^2 \big[G_{\xi\xi} + G_{\eta\eta}\big] + p(\xi, \eta)G = \delta(x - \xi)\,\delta(y - \eta), \qquad (\xi, \eta) \in \Omega, \\ G(x, y; \xi, \eta) = 0, \qquad (\xi, \eta) \in \partial\Omega, \end{aligned} \tag{3.3}$$

where $\delta(\cdot)$ is the Dirac δ-distribution. Then the unique solution u of problem (3.1) is

$$u(x, y) = \int_\Omega G(x, y; \xi, \eta)\, f(\xi, \eta)\, d\xi\, d\eta. \tag{3.4}$$

Starting from (3.3), throughout the present section, the differential operators L and $\bar{L}$ are understood as differential operators in the variables (ξ, η). Furthermore, all norms are understood as norms of functions of (ξ, η).

THEOREM 3.1. *The Green's function $G(x, y; \xi, \eta)$ from* (3.3) *satisfies*

$$\big|G(x, y; \cdot)\big|_{1,1\,;\Omega} \le C\varepsilon^{-1}. \tag{3.5a}$$

Furthermore, for any ball $B(a, b\,; \rho)$ of radius ρ we have

$$\big|\,G(x, y; \cdot)\big|_{1,1\,;B(a,b\,;\rho)\cap\Omega} \le C\varepsilon^{-2}\rho, \tag{3.5b}$$

while for the ball $B(x, y\,; \rho)$ centered at (x, y) of radius ρ we have

$$\big|\,G(x, y; \cdot)\big|_{2,1\,;\Omega\setminus B(x,y\,;\rho)} \le C\varepsilon^{-2} \ln(2 + \varepsilon/\rho). \tag{3.5c}$$

3.1. Constant-coefficient case. First, we shall establish a particular case of Theorem 3.1. Let $p := \gamma^2$, where $\gamma = \text{const} > 0$, and let Ω be the quarter plane $\mathbb{R}^2_+ = \{x, y > 0\}$. In this particular case we denote the differential operator by $\bar{L}$ and the Green's function by $\bar{G}$, and for each (x, y) we have

$$\bar{L}\bar{G}(x, y; \xi, \eta) := -\varepsilon^2 \big[\bar{G}_{\xi\xi} + \bar{G}_{\eta\eta}\big] + \gamma^2 \bar{G} = \delta(x - \xi)\,\delta(y - \eta), \qquad \xi, \eta > 0. \tag{3.6}$$

The fundamental solution for the differential operator $\bar{L}$ is

$$g(x, y; \xi, \eta) := \frac{1}{2\pi\varepsilon^2} K_0\left(\frac{\gamma r}{\varepsilon}\right), \qquad r := \sqrt{(x - \xi)^2 + (y - \eta)^2}, \tag{3.7}$$

where K_0 is the modified Bessel function of the second kind of order zero [1]. Hence the Green's function for this differential operator over the quarter plane is

$$\bar{G}(x,y;\xi,\eta) = g(x,y;\xi,\eta) - g(-x,y;\xi,\eta) - g(x,-y;\xi,\eta) + g(-x,-y;\xi,\eta). \tag{3.8}$$

LEMMA 3.2. *For $\bar{G}(x,y;\xi,\eta)$ of* (3.8)*, estimates* (3.5) *hold true, in which G is replaced by $\bar{G}$ and Ω is replaced by $\mathbb{R}^2_+$.*

Proof. We shall prove estimates (3.5) only for $\|\bar{G}_\xi\|_1$ and $\|\bar{G}_{\xi\xi}\|_1$ here, since the estimates for $\|\bar{G}_\eta\|_1$ and $\|\bar{G}_{\eta\eta}\|_1$ with $\|\bar{G}_{\xi\eta}\|_1$ are obtained similarly. Furthermore, it suffices to show (3.5) with $\bar{G}$ replaced by the first term $g(x,y;\xi,\eta)$ of the representation (3.8) of $\bar{G}$, as the estimates for the other three terms are similar.

Since $K_0' = -K_1$, where K_1 is the modified Bessel function of the second kind of order one, and $\partial r/\partial\xi = -(x-\xi)/r$, we get

$$g_\xi(x,y;\xi,\eta) = \frac{\gamma}{2\pi\varepsilon^3} K_1\left(\frac{\gamma r}{\varepsilon}\right)\frac{x-\xi}{r}.$$

Furthermore, a similar calculation invoking $K_1'(s) = -K_0(s) - s^{-1}K_1(s)$ yields

$$g_{\xi\xi}(x,y;\xi,\eta) = \frac{\gamma^2}{2\pi\varepsilon^4}\left[K_0\left(\frac{\gamma r}{\varepsilon}\right) + \frac{K_1(\gamma r/\varepsilon)}{\gamma r/\varepsilon}\right]\frac{(x-\xi)^2}{r^2} - \frac{\gamma}{2\pi\varepsilon^3}K_1\left(\frac{\gamma r}{\varepsilon}\right)\frac{(y-\eta)^2}{r^3}.$$

Hence we have

$$|g_\xi| \le C\varepsilon^{-3}K_1(s), \qquad |g_{\xi\xi}(x,y;\xi,\eta)| \le C\varepsilon^{-4}\left[K_0(s) + \frac{K_1(s)}{s}\right], \qquad s := \frac{\gamma r}{\varepsilon}.$$

To obtain the desired bounds for $\|g_\xi\|_1$ and $\|g_{\xi\xi}\|_1$, we represent these integral norms in polar coordinates and then substitute $r = \varepsilon\gamma^{-1}s$; note that $d\xi\,d\eta = r\,dr\,d\varphi = C\varepsilon^2 s\,ds\,d\varphi$. For $\|g_\xi\|_{1;\mathbb{R}^2}$, this yields

$$\big\|g_\xi(x,y;\cdot)\big\|_{1;\mathbb{R}^2} \le C\varepsilon^{-3}\int_{\mathbb{R}^2} K_1(s)\,d\xi\,d\eta \le C\varepsilon^{-1}\int_0^\infty sK_1(s)\,ds \le C\varepsilon^{-1},$$

where we also used $0 < K_1(s) < Cs^{-1}e^{-s}$ [1]. Similarly,

$$\big\|g_\xi(x,y;\cdot)\big\|_{1;B(a,b;\rho)} \le C\varepsilon^{-3}\int_{B(x,y;\rho)} K_1(s)\,d\xi\,d\eta \le C\varepsilon^{-1}\int_0^{\gamma\rho/\varepsilon} sK_1(s)\,ds \le C\varepsilon^{-2}\rho.$$

Here replacing the integral over $B(a,b;\rho)$ by the integral over $B(x,y;\rho)$ yields an upper bound since K_1 is a positive decreasing function. Thus we obtained the desired estimates for $\|g_\xi\|_1$, which imply estimates (3.5a) and (3.5b) for $\|\bar{G}_\xi\|_1$.

Next, in a similar manner, we estimate $\|g_{\xi\xi}\|_1$:

$$\begin{aligned}\big\|g_{\xi\xi}(x,y;\cdot)\big\|_{1;\mathbb{R}^2\setminus B(x,y;\rho)} &\le C\varepsilon^{-2}\int_{\gamma\rho/\varepsilon}^\infty s\left[K_0(s) + \frac{K_1(s)}{s}\right]ds \le C\varepsilon^{-2}\left[1 + K_0\left(\frac{\rho}{\varepsilon}\right)\right]\\ &\le C\varepsilon^{-2}\ln\left(2 + \frac{\varepsilon}{\rho}\right),\end{aligned}$$

where, to get the second inequality, we used $0 < K_0(s) < Cs^{-1}e^{-s}$ and $K_1 = -K_0'$, while to get the final bound, we invoked $0 < K_0(s) < C\ln(2+s^{-1})$ [1]. This implies estimate (3.5c) for $\|\bar{G}_{\xi\xi}\|_1$. ∎

Remark 3.1. An inspection of the proof of Lemma 3.2, in which we used the explicit representation (3.8), (3.7) of the Green's function in the constant-coefficient case, shows that the estimates of the Green's function in Theorem 3.1 are sharp.

3.2. Smooth-coefficient case. Next, we shall use Lemma 3.2 to establish a variable-coefficient case of Theorem 3.1 under the additional assumption that

$$\|p\|_{C^{0,1}(\bar{\Omega})} \le C, \tag{3.9}$$

where $C^{0,1}(\bar{\Omega})$ is a standard Hölder space.

LEMMA 3.3. *Under condition* (3.9)*, the Green's function* $G(x,y\,;\xi,\eta)$ *from* (3.3) *satisfies estimates* (3.5a) *and* (3.5c)*.*

Proof. Fix $(x,y) \in \Omega$. Without loss of generality consider only the case of $x \le 1/2$ and $y \le 1/2$, as the other cases are similar. Let $\bar{G}$ be defined by (3.7), (3.8) with the frozen coefficient $\gamma^2 := p(x,y)$. By Lemma 3.2, estimates (3.5) hold true for $\bar{G}$. Hence is suffices to show that the function

$$v = v(x,y;\xi,\eta) := G(x,y;\xi,\eta) - \omega(\xi,\eta)\,\bar{G}(x,y;\xi,\eta), \tag{3.10}$$

where $\omega(\xi,\eta)$ is a smooth cut-off function that equals 1 on $[0,3/4] \times [0,3/4]$ and vanishes on the boundaries $\xi = 1$ and $\eta = 1$, satisfies

$$\varepsilon^2 \big|v(x,y;\cdot)\big|_{2,1\,;\Omega} + \varepsilon \big|v(x,y;\cdot)\big|_{1,1\,;\Omega} \le C. \tag{3.11}$$

Clearly, $v = 0$ for $(\xi,\eta) \in \partial\Omega$. Furthermore, using $LG = \bar{L}\bar{G}$ and (3.6), it is easy to check that $Lv = (\gamma^2 - p)\bar{G} + L[(\bar{G} - \omega\bar{G}]$, i.e.,

$$Lv = -\varepsilon^2[v_{\xi\xi} + v_{\eta\eta}] + p(\xi,\eta)\,v = \phi, \tag{3.12a}$$

$$\phi = \phi_1 + \phi_2, \quad \phi_1 := \big[\gamma^2 - p(\xi,\eta)\big]\bar{G}, \quad \phi_2 := L\big[(1-\omega)\bar{G}\big]. \tag{3.12b}$$

Let the stretching transformation from (ξ,η) to the new coordinates $\hat{\xi} := (\xi - x)/\varepsilon$ and $\hat{\eta} := (\eta - y)/\varepsilon$ map the original domain Ω into the domain $\hat{\Omega}$. Using the notation $\hat{w}(\hat{\xi},\hat{\eta}) := w(x,y;\xi,\eta)$ for any function w, rewrite (3.12a) as $-\triangle\hat{v} + \hat{p}\,\hat{v} = \hat{\phi}$. Combining this with $\hat{v} = 0$ on $\partial\hat{\Omega}$ yields $\|\hat{v}\|_{2;\hat{\Omega}} \le \beta^{-1/2}\|\hat{\phi}\|_{2;\hat{\Omega}}$ and, more importantly,

$$\big\|\hat{v}\big\|_{2,2\,;\hat{\Omega}} \le C_1\Big(\big\|\hat{\phi}\big\|_{2;\hat{\Omega}} + \big\|\hat{v}\big\|_{2;\hat{\Omega}}\Big) \le C_1\big(1 + \beta^{-1/2}\big)\,\big\|\hat{\phi}\big\|_{2;\hat{\Omega}}\,, \tag{3.13}$$

where the constant C_1 is independent of the size of the domain $\hat{\Omega}$ [17, Chapter 3, Lemma 8.1, p. 175]. Estimate (3.13), rewritten in the original variables (ξ,η), implies that

$$\varepsilon^2 \big|v(x,y;\cdot)\big|_{2,2\,;\Omega} + \varepsilon \big|v(x,y;\cdot)\big|_{1,2\,;\Omega} \le C\big\|\phi(x,y;\cdot)\big\|_{2\,;\Omega}\,. \tag{3.14}$$

Next, we claim that for ϕ from (3.12b) we have $\|\phi(x,y;\cdot)\|_{2\,;\Omega} \le C$. Indeed, $\phi_2 = 0$ for $(\xi,\eta) \in [0,3/4] \times [0,3/4]$ and $|\phi_2| \le C$ outside. Furthermore, condition (3.9) implies that $|\gamma^2 - p(\xi,\eta)| \le Cr$, where $\gamma^2 = p(x,y)$. Hence $|\phi_1| \le C\varepsilon^{-2} r K_0(\gamma r/\varepsilon)$, while

$$\big\|\phi_1\big\|_2^2 \le C\,\varepsilon^{-2}\int_\Omega (r/\varepsilon)^2 K_0^2(\gamma r/\varepsilon)\,d\xi\,d\eta \le C\int_0^\infty s^3\,K_0^2(s)\,ds \le C.$$

Thus we have established that $\|\phi\|_{L_2(\Omega)} \le C$. Combining this with (3.14) and $|v|_{k,1} \le C|v|_{k,2}$ for $k = 1,2$, we obtain (3.11) and complete the proof. ∎

Note that condition (3.9), under which we now proved Theorem 3.1, is suitable for the particular linear case (3.1) of problem (1.1). However, if we consider the semilinear case (1.1) and linearize (2.10) to the form (3.1), then the coefficient p depends on u and U and assumption (3.9) becomes unrealistic. Hence, we still have to prove Theorem 3.1 for the general case of p satisfying only (3.2).

3.3. General case. Proof of Theorem 3.1. Let $\bar G$ be defined by (3.8), (3.7) with the coefficient $\gamma^2 := \beta$. Then, by the maximum/comparison principle, $L[\bar G - G] = [p(\xi,\eta) - \beta]\,\bar G \ge 0$ combined with $\bar G - G \ge 0$ on $\partial\Omega$ implies that $0 \le G \le \bar G$.

Imitating the proof of Lemma 3.3, we arrive at (3.14), in which again $\|\phi_2\|_2 \le C$, while $|\gamma^2 - p(\xi,\eta)| \le C$ implies only that $|\phi_1| \le C\varepsilon^{-2}K_0(\gamma r/\varepsilon)$. Hence $\|\phi_1\|_2 \le C\varepsilon^{-1}$ and $\|\phi\|_2 \le C\varepsilon^{-1}$. Combining this with (3.14) and $|v|_{k,1\,;B(a,b\,;\rho)} \le C\rho|v|_{k,2\,;\Omega}$ or $|v|_{k,1\,;B(x,y\,;\varepsilon)} \le C\varepsilon|v|_{k,2\,;\Omega}$ for $k = 1, 2$, we obtain

$$\varepsilon\big|v(x,y;\cdot)\big|_{1,1\,;B(a,b\,;\rho)} \le C\varepsilon^{-1}\rho \tag{3.15}$$

and

$$\varepsilon^2\big|v(x,y;\cdot)\big|_{2,1\,;B(x,y\,;\varepsilon)} + \varepsilon\big|v(x,y;\cdot)\big|_{1,1\,;B(x,y\,;\varepsilon)} \le C\,; \tag{3.16}$$

compare with (3.11).

Combining (3.15) and (3.16) with Lemma 3.2, we observe that $G = v + \omega\bar G$ satisfies (3.5b), and furthermore, G satisfies (3.5a) and (3.5c), with Ω replaced by $B(x,y\,;\varepsilon)$. Hence, to complete the proof, it suffices to show that

$$\varepsilon^2\big|G(x,y;\cdot)\big|_{2,1\,;\Omega\setminus B(x,y\,;\varepsilon)} + \varepsilon\big|G(x,y;\cdot)\big|_{1,1\,;\Omega\setminus B(x,y\,;\varepsilon)} \le C\,. \tag{3.17}$$

Next, divide the domain $\Omega\setminus B(x,y\,;\varepsilon)$ into the subdomains $\mathcal{D}_j := \{(\xi,\eta) \in \Omega : \rho_j < r < \rho_{j+1}\}$, where $j = 0, 1, \dots$ and $\rho_j := 2^j\varepsilon$. Furthermore, $\mathcal{D}_j \subset \mathcal{D}'_j := \mathcal{D}_{j-1} \cup \bar{\mathcal{D}}_j \cup \mathcal{D}_{j+1}$ so that $\operatorname{dist}(\partial\mathcal{D}_j\setminus\partial\Omega\,,\partial\mathcal{D}'_j\setminus\partial\Omega) \ge \varepsilon/2$.

Let the stretching transformation from (ξ,η) to the new coordinates $\hat\xi := (\xi - x)/\varepsilon$ and $\hat\eta := (\eta - y)/\varepsilon$ map $\mathcal{D}_j$ into $\hat{\mathcal{D}}_j$. Imitating the proof of Lemma 3.3, we use the notation $\hat G(\hat\xi,\hat\eta) := G(x,y;\xi,\eta)$ and rewrite the equation from (3.3) as $-\triangle\hat G + \hat p\,\hat G = 0$ to get the local estimate

$$\big\|\hat G\big\|_{2,2\,;\hat{\mathcal{D}}_j} \le C_2\big\|\hat G\big\|_{2;\hat{\mathcal{D}}'_j} \tag{3.18}$$

[17, Chapter 3, estimate (8.6), p. 171]; compare with the global estimate (3.13). Here the constant C_2 is independent of ε since $\operatorname{dist}(\partial\hat{\mathcal{D}}_j\setminus\partial\hat\Omega\,,\partial\hat{\mathcal{D}}'_j\setminus\partial\hat\Omega) \ge 1/2$. Rewriting the above estimate in the variables (ξ,η) yields

$$\varepsilon^2\big|G(x,y;\cdot)\big|_{2,2;\mathcal{D}_j} + \varepsilon\big|G(x,y;\cdot)\big|_{1,2;\mathcal{D}_j} \le C\big\|G(x,y;\cdot)\big\|_{2,\mathcal{D}'_j} \le C\|g(x,y;\cdot)\|_{2,\mathcal{D}'_j}.$$

Here we also used $|G| \le \bar G \le 4g$; see (3.7), (3.8). Finally, since $|G|_{k,1\,;\mathcal{D}_j} \le C\rho_j|G|_{k,2\,;\mathcal{D}_j}$ for $k = 1, 2$, we arrive at

$$\varepsilon^2\big|G(x,y;\cdot)\big|_{2,1;\mathcal{D}_j} + \varepsilon\big|G(x,y;\cdot)\big|_{1,1;\mathcal{D}_j} \le C\rho_j\big\|g(x,y;\cdot)\big\|_{2,\mathcal{D}'_j}\,. \tag{3.19}$$

Note that

$$\big\|g(x,y;\cdot)\big\|^2_{2,\mathcal{D}'_j} \le C\varepsilon^{-2}\int_{\gamma\rho_{j-1}/\varepsilon}^{\gamma\rho_{j+1}/\varepsilon} sK_0^2(s)\,ds \le C\varepsilon^{-2}e^{-2s}\Big|_{\gamma\rho_{j+1}/\varepsilon}^{\gamma\rho_{j-1}/\varepsilon} \le C\varepsilon^{-2}e^{-\gamma\rho_j/\varepsilon}$$

since for $r \ge \varepsilon/2$ we have $g \le C\varepsilon^{-2}s^{-1/2}e^{-s}$, where $s = \gamma r/\varepsilon$. Furthermore,

$$\sum_{j=0}^{\infty} \rho_j \big\| g(x,y;\cdot) \big\|_{2,\mathcal{D}'_j} \le C \sum_{j=0}^{\infty} \frac{\gamma(\rho_j - \rho_{j-1})}{2\varepsilon}\, e^{-\gamma\rho_j/(2\varepsilon)} \le C \int_{\gamma/4}^{\infty} s e^{-s}\, ds \le C \tag{3.20}$$

since $\rho_j = 2(\rho_j - \rho_{j-1})$, while e^{-s} is decreasing. Combining (3.20) with (3.19), we get (3.17) and thus complete the proof. ∎

4. Stability properties of differential operators. The main result of the present section is the following stability theorem for the semilinear differential operator T from (1.1), which we shall further apply to relation (2.10).

Consider the right-hand side f in the special form

$$f(x,y) = -\frac{\partial}{\partial x}\big[F_1(x,y) + \bar{F}_1(x,y)\big] - \frac{\partial}{\partial y}\big[F_2(x,y) + \bar{F}_2(x,y)\big] + \bar{f}(x,y), \tag{4.1a}$$

where F_1, $\bar{F}_1$, F_2, $\bar{F}_2$, $f \in L_\infty(\Omega)$ and

$$F_1(x,y) = A_i(y)(x - x_{i-1/2}) \quad \text{for } (x,y) \in (x_{i-1}, x_i) \times [0,1], \quad i = 1, \dots, N, \tag{4.1b}$$

$$F_2(x,y) = B_j(x)(y - y_{j-1/2}) \quad \text{for } (x,y) \in [0,1] \times (y_{j-1}, y_j), \quad j = 1, \dots, M, \tag{4.1c}$$

while $x_{i-1/2} := x_i - h_i/2$ and $y_{j-1/2} := y_j - k_j/2$.

THEOREM 4.1. *Let the function b in* (1.1) *satisfy* (1.2). *Then, for any v, $w \in W^{1,2}(\Omega)$ such that $Tv(x,y) - Tw(x,y) = f(x,y)$, where f is defined by* (4.1), *and $v(x,y) = w(x,y)$ for $(x,y) \in \partial\Omega$, we have*

$$\begin{aligned} \|v - w\|_\infty \le{}& C\varepsilon^{-1}\big(\|\bar{F}_1\|_\infty + \|\bar{F}_2\|_\infty\big) + \beta^{-1}\|\bar{f}\|_\infty \\ &+ C\left[\max_{i=1,\dots,N}\left\{\frac{h_i^2}{\varepsilon^2}\max_{y\in[0,1]}\big|A_i(y)\big|\right\} + \max_{j=1,\dots,M}\left\{\frac{k_j^2}{\varepsilon^2}\max_{x\in[0,1]}\big|B_j(x)\big|\right\}\right]\ln\left(2 + \frac{\varepsilon}{\kappa}\right). \end{aligned}$$

The proof is deferred to section 4.2

4.1. Linear reaction-diffusion. First, we address the linear problem (3.1), (3.2) with the right-hand side (4.1). Since the differential operator L is linear, it is convenient to establish stability of u with respect to various components of f separately.

LEMMA 4.2. *There exists a unique solution $u \in L_\infty(\Omega)$ of problem* (3.1), (3.2) *with the right-hand side* (4.1a). *Furthermore, if $F_1 = F_2 := 0$, then*

$$\|u\|_\infty \le \beta^{-1}\|\bar{f}\|_\infty + C\varepsilon^{-1}\big(\|\bar{F}_1\|_\infty + \|\bar{F}_2\|_\infty\big). \tag{4.2}$$

Proof. Since L is linear, it suffices to establish the desired estimate in the following two cases. Case A: $f = \bar{f}$, while $\bar{F}_1 = \bar{F}_2 := 0$. Then estimate (4.2) is well known and follows from the maximum/comparison principle extended to functions in the Sobolev space $W^{1,2}$ [9, section 8.1]. Case B: $\bar{f} := 0$. Now the desired estimate (4.2) follows from (3.4) combined with estimate (3.5a). ∎

LEMMA 4.3. *Let $\bar{F}_1 = \bar{F}_2 = \bar{f} := 0$ in* (4.1a). *Then the solution $u \in L_\infty(\Omega)$ of problem* (3.1), (3.2) *with the right-hand side* (4.1) *satisfies*

$$\|u\|_\infty \le C\left[\max_{i=1,\dots,N}\left\{\frac{h_i^2}{\varepsilon^2}\max_{y\in[0,1]}\big|A_i(y)\big|\right\} + \max_{j=1,\dots,M}\left\{\frac{k_j^2}{\varepsilon^2}\max_{x\in[0,1]}\big|B_j(x)\big|\right\}\right]\ln\left(2 + \frac{\varepsilon}{\kappa}\right),$$

where $\kappa := \min\{\min_i\{h_i\}, \min_j\{k_j\}\}$.

Proof. It suffices to consider only the case of $f := -\partial F_1/\partial x$, i.e., $F_2 := 0$, as the case of $f := -\partial F_2/\partial y$ is considered similarly, while our differential operator L is linear.

Fix (x, y) and denote $v(\xi, \eta) := G(x, y; \xi, \eta)$. Then, by (3.4), we have

$$u(x,y) = \int_\Omega F_1(\xi,\eta) v_\xi(\xi,\eta)\, d\xi\, d\eta = \sum_{i=1}^N \int_{\Omega_i} A_i(\eta)(\xi - x_{i-1/2})\, v_\xi(\xi)\, d\xi\, d\eta, \tag{4.3}$$

where $\Omega_i := (x_{i-1}, x_i) \times (0,1),\ i = 1, \dots, N$. Furthermore, let $x \in [x_{m-1/2}, x_{m+1/2}]$ for some $0 < m < N$ (the cases of $x \in [0, x_{1/2}]$ and $x \in [x_{N-1/2}, 1]$ are similar) and introduce the rectangular domain

$$\Omega' := (x_{m-1}, x_{m+1}) \times (y - \tilde h_m, y + \tilde h_m), \quad \text{where } \tilde h_m := \min\{h_m, h_{m+1}\}/2,$$

so that

$$B(x, y\,; \tilde h_m) \subset \Omega' \subset B(x_{m-1/2}, y\,; h_m) \cup B(x_{m+1/2}, y; h_{m+1}). \tag{4.4}$$

Clearly, (4.3) can be written as $u(x, y) = S_1 + S_2$, where

$$S_1 = \sum_{i=1}^N \int_{\Omega_i} A_i(\eta)(\xi - x_{i-1/2})\, \tilde v_\xi(\xi,\eta)\, d\xi\, d\eta\,,$$

with $\tilde v := v$ in $\Omega_i \setminus \Omega'$ and $\tilde v := 0$ in Ω', while

$$S_2 = \sum_{i=m}^{m+1} \int_{\Omega_i \cap \Omega'} A_i(\eta)(\xi - x_{i-1/2})\, v_\xi(\xi,\eta)\, d\xi\, d\eta\,.$$

To estimate S_1, note that

$$\tilde v_\xi(\xi,\eta) = \tilde v_\xi(x_{i-1},\eta) + \int_{x_{i-1}}^\xi \tilde v_{\xi\xi}(s,\eta)\, ds \qquad \text{for } \ \xi \in (x_{i-1}, x_i). \tag{4.5}$$

Here $\tilde v_{\xi\xi}$ is well defined, since the singularity of v occurs at (x, y), which is inside Ω', and furthermore, for each i and η either $\tilde v_{\xi\xi} = v_{\xi\xi}$ or $\tilde v_{\xi\xi} = 0$ for all $\xi \in (x_{i-1}, x_i)$. Combining (4.5) with $\int_{x_{i-1}}^{x_i} (\xi - x_{i-1/2})\, d\xi = 0$ yields

$$\begin{aligned}\left| \int_{x_{i-1}}^{x_i} (\xi - x_{i-1/2})\, \tilde v_\xi(\xi,\eta)\, d\xi \right| &= \left| \int_{x_{i-1}}^{x_i} d\xi\, (\xi - x_{i-1/2}) \int_{x_{i-1}}^\xi \tilde v_{\xi\xi}(s,\eta)\, ds \right| \\ &\le \frac{h_i^2}{4} \int_{x_{i-1}}^{x_i} \left|\tilde v_{\xi\xi}(s,\eta)\right| ds\,.\end{aligned}$$

Hence

$$\begin{aligned}|S_1| &\le \sum_{i=1}^N \frac{h_i^2}{4} \int_0^1 |A_i(\eta)| d\eta \int_{x_{i-1}}^{x_i} |\tilde v_{\xi\xi}(s,\eta)|\, ds \\ &\le \max_{i=1,\dots,N} \left\{ \frac{h_i^2}{4} \max_{\eta\in[0,1]} |A_i(\eta)| \right\} \int_\Omega |\tilde v_{\xi\xi}(\xi,\eta)|\, d\xi\, d\eta\,.\end{aligned}$$

Finally, recalling (4.4) and estimate (3.5c) for $v_{\xi\xi} = G_{\xi\xi}$, we get

$$\int_\Omega |\tilde{v}_{\xi\xi}(\xi,\eta)|\,d\xi\,d\eta \le \int_{\Omega\setminus B(x,y;\tilde{h}_m)} |v_{\xi\xi}(\xi,\eta)|\,d\xi\,d\eta \le C\varepsilon^{-2}\ln(2+\varepsilon/\tilde{h}_m)$$

and thus the desired estimate for S_1:

$$|S_1| \le C \max_{i=1,\dots,N}\left\{\frac{h_i^2}{\varepsilon^2}\max_{\eta\in[0,1]}\bigl|A_i(\eta)\bigr|\right\}\ln\left(2+\frac{\varepsilon}{\kappa}\right).$$

It remains to obtain a similar estimate for S_2:

$$\begin{aligned} S_2 &\le \sum_{i=m}^{m+1} h_i \max_{\eta\in[0,1]}|A_i(\eta)| \int_{B(x_{i-1/2},y;h_i)} |v_\xi(\xi,\eta)|\,d\xi\,d\eta \le \sum_{i=m}^{m+1}\max_{\eta\in[0,1]}|A_i(\eta)|h_i\frac{Ch_i}{\varepsilon^2} \\ &\le C\max_i\left\{\frac{h_i^2}{\varepsilon^2}\max_{\eta\in[0,1]}|A_i(\eta)|\right\}. \end{aligned}$$

Here we used (4.4) and estimate (3.5b) for $v_\xi = G_\xi$. ∎

4.2. Semilinear reaction-diffusion. Proof of Theorem 4.1. Using the standard linearization technique, we have $Tv(x,y) - Tw(x,y) = L\bigl[v(x,y) - w(x,y)\bigr]$, where the operator L is linear and defined by (3.1) with the coefficient $p(x,y) = \int_0^1 b_u(x,y,w(x,y)+s[v(x,y)-w(x,y)])\,ds$, which, by (1.2), satisfies condition (3.2). Hence the desired estimate follows from Lemmas 4.2 and 4.3. ∎

5. Analysis of the numerical method. Proof of Theorem 2.1. To complete the proof of Theorem 2.1, which we started in section 2, we shall invoke the following lemma.

LEMMA 5.1. *We have*

$$-\varepsilon^2\frac{\partial^2 U^{\mathrm{I}}(x,y_j)}{\partial x^2} + q_1^{\mathrm{I}}(x,y_j) = \frac{\partial}{\partial x}F_1(x,y_j), \quad -\varepsilon^2\frac{\partial^2 U^{\mathrm{J}}(x_i,y)}{\partial y^2} + q_2^{\mathrm{J}}(x_i,y) = \frac{\partial}{\partial y}F_2(x_i,y),$$

where

$$F_1(x,y_j) := q_{1,ij}(x-x_{i-1/2}) + \frac{D_x^- q_{1,ij}}{2}(x_i-x)^2, \qquad x\in(x_{i-1},x_i), \tag{5.1a}$$

for $i = 1,\dots,N$, $j = 0,\dots,M$, *and*

$$F_2(x_i,y) := q_{2,ij}(y-y_{j-1/2}) + \frac{D_y^- q_{2,ij}}{2}(y_j-y)^2, \qquad y\in(y_{i-1},y_i), \tag{5.1b}$$

for $i = 0,\dots,N$, $j = 1,\dots,M$.

Proof. We closely imitate the one-dimensional argument used in the proof of [12, Theorem 3.3] and give the proof here only for completeness.

It suffices to obtain the first desired relation, as the other one is similar. To simplify the presentation, within this proof, fix y_j and use the notation $U^{\mathrm{I}}(x) := U^{\mathrm{I}}(x,y_j)$, $q_1^{\mathrm{I}}(x) := q_1^{\mathrm{I}}(x,y_j)$, $q_{1,i} := q_{1,ij}$, and $F_1(x) := F(x,y_j)$. Furthermore, for any function v, let $v' := \partial v/\partial x$. Thus we intend to show that $-\varepsilon^2(U^{\mathrm{I}})'' + q_1^{\mathrm{I}} = F_1'$.

First, note that

$$-\varepsilon^2(U^{\mathrm{I}})'' + q_1^I = -\left[\varepsilon^2(U^{\mathrm{I}})' + \int_x^1 q_1^I(s)\,\mathrm{d}s\right]'. \tag{5.2}$$

Recalling (2.3) and (2.8), we observe that

$$\varepsilon^2(U^{\mathrm{I}})' = \varepsilon^2 D_x^- U_i^{\mathrm{I}} = \varepsilon^2 D_x^- U_N^{\mathrm{I}} - \sum_{m=i}^{N-1} q_{1,m} \frac{h_m + h_{m+1}}{2}\,, \quad x \in (x_{i-1}, x_i), \quad i = 1, \dots, N.$$

Now, substituting the above representation in (5.2) and omitting the derivative of the constant $\varepsilon^2 D^- U_N^{\mathrm{I}}$, we arrive at $-\varepsilon^2(U^{\mathrm{I}})'' + q_1^I = \tilde{F}_1'$, where

$$\tilde{F}_1(x) := \sum_{m=i}^{N-1} q_{1,m} \frac{h_m + h_{m+1}}{2} - \int_x^1 q_1^I(s)\,\mathrm{d}s, \quad x \in (x_{i-1}, x_i), \quad i = 1, \dots, N.$$

A calculation shows that

$$\sum_{m=i}^{N-1} q_{1,m} \frac{h_m + h_{m+1}}{2} = q_{1,i} \frac{h_i}{2} + \int_{x_i}^1 q_1^I(s)\,\mathrm{d}s - q_{1,N} \frac{h_N}{2},$$

and, omitting the derivative of another constant $q_{1,N} h_N/2$, we obtain $\tilde{F}_1' = F_1'$, where

$$F_1(x) := q_{1,i} \frac{h_i}{2} - \int_x^{x_i} q_1^I(s)\,\mathrm{d}s, \quad x \in (x_{i-1}, x_i), \quad i = 1, \dots, N. \tag{5.3}$$

Thus we have obtained the desired relation $-\varepsilon^2(U^{\mathrm{I}})'' + q_1^I = F_1'$, in which F_1 is defined by (5.3), and it remains to show that the definition of F_1 in (5.1a) is equivalent to (5.3). Indeed, by computing $\int_x^{x_i} q^I(s)\,\mathrm{d}s$ in (5.3) using $q_1^I(x) = q_{1,i} - (x_i - x)\, D^- q_{1,i}$, we get (5.1a). □

Remark 5.1. One can easily check that F_1 and F_2 or (5.1) allow an alternative representation:

$$F_1(x, y_j) := q_{1,i-1,j}(x - x_{i-1/2}) + \frac{D_x^- q_{1,ij}}{2}\, O(h_i^2), \qquad x \in (x_{i-1}, x_i),$$

$$F_2(x_i, y) := q_{2,i,j-1}(y - y_{j-1/2}) + \frac{D_y^- q_{2,ij}}{2}\, O(k_j^2), \qquad y \in (y_{i-1}, y_i).$$

E.g., the new representation of F_1 follows from $q_{1,ij} = q_{1,i-1,j} + h_i\, D_x^- q_{1,ij}$.

Proof of Theorem 2.1 (continued from section 2). Extending F_1 and F_2 of (5.1) onto the whole domain $\bar{\Omega}$ by linear interpolation,

$$F_1(x, y) := \big[F_1(x, y_j)\big]^{\mathrm{J}}, \qquad F_2(x, y) := \big[F_2(x_i, y)\big]^{\mathrm{I}},$$

we obtain (2.10). Now, invoking Theorem 4.1 yields

$$\begin{aligned}\|U^{\mathrm{B}} - u\|_\infty \le C &\left[\max_{\substack{i=1,\dots,N\\ j=0,\dots,M}} \left\{ \frac{h_i^2}{\varepsilon^2} |q_{1,ij}| \right\} + \max_{\substack{i=0,\dots,N\\ j=1,\dots,M}} \left\{ \frac{k_j^2}{\varepsilon^2} |q_{2,ij}| \right\} \right] \ln\Big(2 + \frac{\varepsilon}{\kappa}\Big) \\ &+ C \left[\max_{\substack{i=1,\dots,N\\ j=0,\dots,M}} \left\{ \frac{h_i^2}{\varepsilon} |D_x^- q_{1,ij}| \right\} + \max_{\substack{i=0,\dots,N\\ j=1,\dots,M}} \left\{ \frac{k_j^2}{\varepsilon} |D_y^- q_{2,ij}| \right\} \right] + \beta^{-1} \|q - q^{\mathrm{B}}\|_\infty.\end{aligned} \tag{5.4}$$

Combining this with (2.8) and the bilinear interpolation estimate

$$\|q - q^{\mathrm{B}}\|_\infty \le C \left[\max_{\substack{i=1,\dots,N\\ j=0,\dots,M}} \big\{ h_i^2 (1 + |D_x^- U_{ij}|^2) \big\} + \max_{\substack{i=0,\dots,N\\ j=1,\dots,M}} \big\{ k_j^2 (1 + |D_y^- U_{ij}|^2) \big\} \right], \tag{5.5}$$

we obtain a version of the desired a posteriori error estimate (2.7) in which the quantities $\min\{|D_x^2 U_{i-1,j}|, |D_x^2 U_{ij}|\}$ and $\min\{|D_y^2 U_{i,j-1}|, |D_y^2 U_{ij}|\}$ are replaced by $|D_x^2 U_{ij}|$ and $|D_y^2 U_{ij}|$, respectively.

By Remark 5.1, the quantities $|q_{1,ij}|$ and $|q_{2,ij}|$ in (5.4) can be replaced by $\min\{|q_{1,i-1,j}|, |q_{1,ij}|\}$ and $\min\{|q_{2,i,j-1}|, |q_{2,ij}|\}$, respectively. Combining this sharper version of (5.4) with (2.8) and (5.5) yields the desired estimate (2.7).

Finally, note that the interpolation error estimate (5.5), which we used, follows from $q - q^B = [q - q^I] + [q^I - (q^I)^J]$ combined with $|\partial^2 q(x, y_j)/\partial x^2| \le C(1 + |D_x^- U_{ij}|^2)$ for $x \in (x_{i-1}, x_i)$ and $|\partial^2 q(x_i, y)/\partial y^2| \le C(1 + |D_y^- U_{ij}|^2)$ for $y \in (y_{j-1}, y_j)$; see [3, Comment 2.15] for a similar argument. ∎

6. Numerical results. The maximum norm a posteriori error estimate of Theorem 2.1 implies that

$$e := \|U^{\mathrm{B}} - u\|_\infty \le \tilde{C}\eta, \qquad \eta := \max\{\eta_0, \eta_1, \eta_2, \eta_3\}, \tag{6.1}$$

$$\eta_l := \max\left\{ \max_{\substack{i=1,\dots,N \\ j=0,\dots,M}} \{h_i^2 M_{1,ij}^{(l)}\} \; ; \; \max_{\substack{i=0,\dots,N \\ j=1,\dots,M}} \{k_j^2 M_{2,ij}^{(l)}\} \right\}, \qquad l = 0, 1, 2, 3,$$

where $\tilde{C} = C \ln\bigl(2 + \varepsilon/\kappa\bigr)$, while $M_{1,ij}^{(0)} = M_{2,ij}^{(0)} = 1$,

$$M_{1,ij}^{(1)} := |D_x^- U_{ij}|^2, \quad M_{1,ij}^{(2)} := \min\{|D_x^2 U_{i-1,j}|\,, |D_x^2 U_{ij}|\}, \quad M_{1,ij}^{(3)} := \varepsilon |D_x^- D_x^2 U_{ij}|,$$

$$M_{2,ij}^{(1)} := |D_y^- U_{ij}|^2, \quad M_{2,ij}^{(2)} := \min\{|D_y^2 U_{i,j-1}|\,, |D_y^2 U_{ij}|\}, \quad M_{2,ij}^{(3)} := \varepsilon |D_y^- D_y^2 U_{ij}|.$$

Here η_l and $M^{(l)}$, $l = 1, 2, 3$, involve discrete analogues of lth-order derivatives.

In this section we present numerical results on a priori chosen meshes to investigate the efficiency of the upper maximum norm error estimator η in (6.1) and its components η_l. It is also of interest which of η_l is the principal component in η if any. We shall examine the errors e and, more importantly, the quantities η, e/η, η_l, e/η_l and their dependence on ε, $N = M$, and particular mesh choices.

We consider $\varepsilon = 10^{-k}$, $k = 1, \dots, 10$, and two tensor-product meshes with $M = N$: a variant of the layer-adapted mesh by Bakhvalov [4] and a simple uniform mesh; see Tables 6.1–6.5. Note that a Bakhvalov-type layer-adapted mesh was chosen for the numerical experiments, since it yields ε-uniform second-order accuracy [4, 13]. Furthermore, we expect a robust adaptive algorithm to generate a mesh that is very close to a Bakhvalov mesh, as in [14, section 6 and Figure 2].

To be precise, if $\varepsilon \le \bar{\varepsilon}$, our Bakhvalov-type mesh is given by $x_i = y_i := x(i/N)$ for $i = 0, 1, \dots, N$, where $x(\xi) := \varepsilon\lambda \ln[b/(b - \xi)]$ for $\xi \in [0, \theta]$, $x(1) := 1$, and $x(\xi)$ is continuous on $[0, 1]$ and linear on $[\theta, 1]$. We use the constants $b = 1/2$, $\bar{\varepsilon} = b/\lambda$, and $\theta = b - \varepsilon\lambda$. The constant λ will be specified later. For $\varepsilon > \bar{\varepsilon}$, the Bakhvalov mesh is defined to be a simple uniform mesh.

Our test problem is the linear problem (3.1), in which $p(x, y) := 1$, and whose exact solution

$$u(x, y) := \left(\cos(\pi x) - \frac{e^{-x/\varepsilon} - e^{-1/\varepsilon}}{1 - e^{-1/\varepsilon}}\right)\left(1 - y - \frac{e^{-y/\varepsilon} - e^{-1/\varepsilon}}{1 - e^{-1/\varepsilon}}\right)$$

exhibits boundary layers and a corner layer.

Tables 6.1 and 6.2 present numerical results for the Bakhvalov mesh with $\lambda = 3$. This mesh yields ε-uniform second-order accuracy in the maximum norm; i.e., ultimately, we would like to be able to construct a similar adaptive mesh. We observe agreement with our theoretical estimate (6.1). Not only does e/η stabilize—see Table 6.1—but it becomes very close to the linear interpolation error constant $1/8 = 1.25e - 1$. Table 6.2 is given to compare the components η_l of η. We observe that $\eta_2 \approx \eta_3 = \eta$. Furthermore, for $\varepsilon \leq 10^{-2}$ we have $\eta_1 \approx \eta_2 \approx \eta_3$, while for $\varepsilon = 10^{-1}$ the quantity η_1 is dominated by η_2 and η_3. The quantity η_0 is not presented, since it is negligible and, furthermore, known a priori.

When uniform meshes are used—see Tables 6.3 and 6.4—the boundary layers are not resolved and $e = O(1)$. This is indicated by $\eta = \eta_3$ blowing up even more significantly than e. Unlike η_3 the component η_2 remains bounded. Thus both η_2 and η_3 not being small correctly indicates that the method is inaccurate. But η_2 better reflects the actual errors since $e/\eta_2 \approx \text{const} = 0.58$ in Table 6.4.

Finally we consider the Bakhvalov mesh with $\lambda = 1$; see Table 6.5. Since the condition $\lambda > 2$, which implies ε-uniform second-order accuracy for our test problem [4, 13], is violated, the errors slightly decrease as $\varepsilon \to 0$. We observe that η_1 is too small compared to η and e.

In summary, for our test problem on the meshes considered, the error estimator η indicates correctly whether or not the method is ε-uniformly accurate. Furthermore, we observe that the quantity $\eta = \eta_3$ might blow up (see Table 6.4), while the component η_1 is sometimes too optimistic (see Table 6.5). The component η_2 seems the most relevant estimator for the actual error e. Besides, η_2 does not blow up, like η_3, and hence seems a suitable error indicator for a posteriori mesh construction.

WEIGHTED-NORM FIRST-ORDER SYSTEM LEAST-SQUARES (FOSLS) FOR DIV/CURL SYSTEMS WITH THREE DIMENSIONAL EDGE SINGULARITIES*

E. LEE†, T. A. MANTEUFFEL‡, AND C. R. WESTPHAL§

Abstract. A weighted-norm first-order system least-squares (FOSLS) method for div/curl problems with edge singularities is presented. Traditional finite element methods, including least-squares methods, often suffer from a global loss of accuracy due to the influence of a nonsmooth solution near polyhedral edges. By minimizing a modified least-squares functional, optimal accuracy in weighted and nonweighted norms is recovered. Error estimates with and without mesh refinements are presented, and numerical results are given to confirm the theory.

Key words. singularities, weighted Sobolev spaces, least-squares, finite element methods

1. Introduction. In this paper, a weighted-norm first-order system least-squares (FOSLS) method for problems with edge singularities is studied. The least-squares finite element method is well suited for many problems with first-order differential operators. Such systems often arise naturally from physical laws or can be formulated from a higher-order system (cf. [18]). The numerical solution is found by minimizing the norm of the residual of the system over an appropriate finite element space. Thus, to approximate a solution to the first-order system, the goal of a least-squares method is largely to choose the correct norm and finite element space. Under sufficient smoothness assumptions, many least-squares functionals induce a norm that can be shown to be equivalent to the product H^1-norm, indicating that H^1-conforming finite elements and multigrid can be used to solve the equations efficiently (cf. [9], [10]). However, the presence of boundary singularities may cause a loss of H^1-equivalence, and the use of H^1-finite element spaces may cause a loss of global accuracy in the approximate solution.

We focus on problems posed in polyhedral domains where the boundary contains edges with an inner angle larger than π or edges upon which different types of boundary conditions meet with an inner angle larger than $\pi/2$. Such problems generally require special consideration and have been the focus of study in both Galerkin and least-squares methods. One of the most common approaches is to use $H(div)$- or $H(curl)$-conforming finite elements, for example, Raviart–Thomas or Nédélec edge elements (see [29]). In papers [15] and [7], finite element spaces having a grid decomposition property and $H(div)$-conforming finite element spaces to get optimal

convergence were investigated. In the classical paper [14], singular functions were added to standard finite element spaces, admitting optimal approximations at minimal additional cost. This approach in the context of a FOSLS formulation was explained in [6] and [5]. A weighted regularization in which weight functions were used in the divergence integral was presented in [13]. In [8], the H^{-1}-norm least-squares approach in discrete space was introduced in a weak variational formulation. In [24] and [22], two different types of modified first-order system LL* methods were developed that allow an accurate approximation using H^1-conforming finite elements for equations having singular boundaries in two and three dimensions, respectively. The latter of these employed partially weighted functionals.

In [23], two dimensional div/curl problems with boundary singularities are solved by minimizing a functional weighted according to the distance from the singular point. Here, we extend our earlier work to three dimensional problems with edge singularities and further consider local mesh refinement. Since many properties do not follow the two dimensional ones, this extension requires the investigation of the three dimensional singular solutions in the proper weighted Sobolev spaces and the establishment of certain new Poincaré-type bounds in scalar and vector forms. The goal of this paper is retaining the global L^2-accuracy and achieving the optimal order discretization accuracy in the induced weighted Sobolev spaces. In section 2, we introduce notation, definitions, and our model problem. Some regularity results in weighted Sobolev spaces are described in section 3. In section 4, we investigate Poincaré inequalities in weighted Sobolev spaces. We prove optimal L^2- and H^1-error convergence away from the singularities and the optimal L^2-error convergence globally by error estimates in weighted norms and L^2-norms in section 5. Establishing error estimates in weighted L^2- and H^1-norms with graded mesh refinement are presented in section 6. In section 7, we report several numerical examples. The theory applies for a range of values for the power of the weight function. Our numerical results show remarkable agreement with theory within this range and somewhat outside this range as well, indicating the possibility that the theory can be extended.

2. Weighted-norm least squares. Let Q be a polygon in $\mathbb{R}^2$ and $I \subset \mathbb{R}$ be a bounded interval. Then, consider the prototype domain

$$\Omega := Q \times I \subset \mathbb{R}^3, \tag{2.1}$$

which is a polyhedral cylinder. In this paper, we restrict ourselves to the case where the domain has one singular edge, which means

- the polygon Q has a corner with inner angle in $(\pi/2, \pi]$, or
- the polygon Q has a corner with inner angle $> \pi$, or
- different types of boundary condition meet at the edge with inner angle $> \pi/2$;

however, the general case follows by considering our approach as a local result. In this paper, we focus on resolving the difficulties from the second and the third case above. The first case gives more regular solution than the second or the third case, but it can still reduce the rate of convergence, and the treatment will be similar to the other two cases. We refer to the edge that causes the boundary singularity as E and the inner angle of the edge E as ω. From now on, the value λ indicates π/ω. We assume that $E = (x_0, y_0) \times I \subset \partial\Omega$. By translation and rotation, we may suppose that E coincides with the z-axis. Without loss of generality, we further assume that $diam(\Omega) \leq 1$.

We denote $\langle \cdot, \cdot \rangle$ the L^2-inner product defined by $\langle u, v \rangle = \int_\Omega u\ v\ d\Omega$, for $u, v \in L^2(\Omega)$, and denote $\| \cdot \|$ the L^2-norm defined by $||u|| = \langle u, u \rangle^{\frac{1}{2}}$. Let $H^k(\Omega)$ be the

standard Sobolev space with the norm $\|\cdot\|_k$ and the seminorm $|\cdot|_k$. Denote by $H^k_\beta(\Omega)$ the weighted Sobolev space of functions u such that

$$\|u\|^2_{k,\beta} = \sum_{|m|=0}^{k} \int_\Omega r^{2(\beta+|m|-k)} \left|D^m u\right|^2 d\Omega < \infty,$$

where $r := r(\mathbf{x})$ is the distance of $\mathbf{x} \in \Omega$ from the singular edge, E, and $|D^m u|^2 = \sum_{a_1+a_2+a_3=m} |\partial_x^{a_1}\partial_y^{a_2}\partial_z^{a_3} u|^2$. The corresponding seminorm is $|\cdot|_{k,\beta} := \|D^k \cdot\|_{0,\beta}$. Characters in bold represent vector functions, and components are subscripted by integers. For example, $\mathbf{u} = (u_1, u_2, u_3)^t$, and the vector L^2-norm is given by $\|\mathbf{u}\| = (\|u_1\|^2 + \|u_2\|^2 + \|u_3\|^2)^{\frac{1}{2}}$. Define Hilbert spaces $H(\nabla\cdot)$ and $H(\nabla\times)$ as the spaces of L^2 vector functions, $\mathbf{u}$, satisfying $\nabla \cdot \mathbf{u} \in L^2(\Omega)$ and $\nabla \times \mathbf{u} \in L^2(\Omega)^3$, respectively.

For convenience, we omit the superscript t for vector transpose. Throughout this paper, c is a generic constant that is used to denote various constants, and its dependence on other quantities will be indicated if necessary.

Consider the div/curl system

$$\begin{aligned} \nabla \times \mathbf{u} &= \mathbf{f} \quad && \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} &= g \quad && \text{in} \quad \Omega, \\ \mathbf{n} \times \mathbf{u} &= \mathbf{0} \quad && \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot \mathbf{u} &= 0 \quad && \text{on} \quad \Gamma_N, \end{aligned} \tag{2.2}$$

where $\mathbf{n}$ is the outward unit normal and Γ_D, Γ_N are a finite number of connected pieces satisfying $\Gamma_D \cap \Gamma_N = \emptyset$, $\Gamma_D \cup \Gamma_N = \partial\Omega$. The above system can be rewritten as

$$L\mathbf{u} = \begin{bmatrix} \nabla\times \\ \nabla\cdot \end{bmatrix} \mathbf{u} = \begin{bmatrix} \mathbf{f} \\ g \end{bmatrix} = \mathbf{F}, \tag{2.3}$$

where L is a linear operator from $\mathcal{U}$ to $L^2(\Omega)^4$ with

$$\mathcal{U} = \{\mathbf{v} \in H(\nabla\cdot) \cap H(\nabla\times) : \mathbf{n} \times \mathbf{v} = 0 \text{ on } \Gamma_D,\ \mathbf{n} \cdot \mathbf{v} = 0 \text{ on } \Gamma_N\}.$$

This type of div/curl system appears in many applications, including electromagnetics, porous media flow, and solid and fluid mechanics. Thus, solving $L\mathbf{u} = \mathbf{F}$ in nonsmooth domains is of wide interest. The traditional least-squares method solves system (2.3) by minimizing the residual functional

$$G(\mathbf{v}; \mathbf{F}) = \|L\mathbf{v} - \mathbf{F}\|^2 = \|\nabla \times \mathbf{v} - \mathbf{f}\|^2 + \|\nabla \cdot \mathbf{v} - g\|^2$$

over $\mathcal{U}$ in the weak sense: find $\mathbf{u} \in \mathcal{U}$ satisfying

$$\langle L\mathbf{u}, L\mathbf{v}\rangle = \langle \mathbf{F}, L\mathbf{v}\rangle \qquad \text{for all } \mathbf{v} \in \mathcal{U}.$$

The FOSLS method includes the design of functionals whose bilinear part is equivalent to an appropriate norm, often the H^1-norm when possible. As briefly mentioned in the introduction, if the domain is not convex and the boundary is not $\mathcal{C}^{1,1}$ or different types of boundary conditions meet at an edge with an inner angle larger than $\pi/2$, then the space $\mathcal{U}$ is not continuously embedded into $H^1(\Omega)^3$; therefore, the solution may not be in $H^1(\Omega)^3$. This would seem to preclude the use of H^1-conforming finite element spaces even though the solution is smooth away from the edge. To overcome this difficulty, we introduce the following weighted-norm functional:

$$G_w(\mathbf{u}; \mathbf{F}) = \|w(L\mathbf{u} - \mathbf{F})\|^2 = \|w\nabla \times (\mathbf{u} - \mathbf{f})\|^2 + \|w(\nabla \cdot \mathbf{u} - g)\|^2, \tag{2.4}$$

where the weight function has the form $w = r^\beta$ for some $\beta > 0$, and we define

$$\|L\mathbf{u}\|_{0,\beta}^2 = \|r^\beta \nabla \times \mathbf{u}\|^2 + \|r^\beta \nabla \cdot \mathbf{u}\|^2.$$

Of course, one can restrict the weight function to some small region by use of scaling or a smooth cut-off function; that is, one can define a weight function local to each of the singular edges of an arbitrary polyhedral domain. It is reasonable to provide a local treatment since while the pollution effect produces global errors, its cause is a local loss of smoothness. In this presentation, we assumed $diam(\Omega) \leq 1$ and use the weight function as above for convenience of presentation.

3. Coercivity of L in weighted Sobolev spaces. In this section, we show that the operator L defined in (2.3) is coercive in certain weighted Sobolev spaces, leading to the norm equivalence between $\|L\mathbf{u}\|_{0,\beta}$ and $\|\nabla \mathbf{u}\|_{0,\beta}$.

LEMMA 3.1. *Let the operator L be defined as in* (2.3) *and* $(\mathbf{f}, g) \in H_\beta^0(\Omega)^4$.

(i) *If* $\mathbf{f} = \mathbf{0}$, *then* $L : H_\beta^1(\Omega)^3 \cap \mathcal{U} \to H_\beta^0(\Omega)^4$ *is injective for*

$$\beta \in \begin{cases} (1-\lambda, 1+\lambda) & \text{when } \partial\Omega = \Gamma_D, \\ (1-\lambda, 1) & \text{when } \partial\Omega = \Gamma_N, \\ (1-\lambda/2, 1+\lambda/2) & \text{when } \Gamma_D \neq \emptyset \text{ and } \Gamma_N \neq \emptyset. \end{cases} \tag{3.1}$$

(ii) *If* $g = 0$, *then* $L : H_\beta^1(\Omega)^3 \cap \mathcal{U} \to H_\beta^0(\Omega)^4$ *is injective for*

$$\beta \in \begin{cases} (1-\lambda, 1+\lambda) & \text{when } \partial\Omega = \Gamma_D, \\ (1-\lambda, 1) & \text{when } \partial\Omega = \Gamma_N \text{ and the sides of the domain} \\ & \quad \text{are parallel to the coordinate axes}, \\ (1-\lambda/2, 1+\lambda/2) & \text{when } \Gamma_D \neq \emptyset \text{ and } \Gamma_N \neq \emptyset \text{ and the sides of the} \\ & \quad \text{domain are parallel to the coordinate axes.} \end{cases} \tag{3.2}$$

(iii) *If* $\mathbf{f} \neq \mathbf{0}$ *and* $g \neq 0$, *then* $L : H_\beta^1(\Omega)^3 \cap \mathcal{U} \to H_\beta^0(\Omega)^4$ *is injective for*

$$\beta \in \begin{cases} (1-\lambda, 1+\lambda) & \text{when } \partial\Omega = \Gamma_D, \\ (1-\lambda, 1) & \text{when } \partial\Omega = \Gamma_N \text{ and the sides of the domain} \\ & \quad \text{are parallel to the coordinate axes.} \end{cases} \tag{3.3}$$

Proof. The result is proved by establishing a decomposition of $\mathbf{u} \in H_\beta^1(\Omega)^3 \cap \mathcal{U}$ and then demonstrating that components of the decomposition each satisfy a Poisson equation, for which known results apply (cf. [25], [26], [28]). The two dimensional orthogonal decomposition of $\mathbf{u}$ with boundary conditions in (2.2) naturally provides Poisson equations with Dirichlet or Neumann boundary conditions [23]. But, it is not true that each component of the orthogonal decomposition of $\mathbf{u}$ can be easily induced to Dirichlet or Neumann Poisson equations in three dimensional space. So, we consider things in several cases as presented in Lemma 3.1.

(i) If $\mathbf{f} = \mathbf{0}$, then there exists a unique $p \in H^1(\Omega)$ satisfying $\mathbf{u} = \nabla p$ and

$$\begin{cases} \Delta p \;=\; \nabla \cdot \mathbf{u} \;\text{ in } \Omega, \\ p \;=\; c \;\text{ on } \Gamma_D, \quad \mathbf{n} \cdot \nabla p \;=\; 0 \;\text{ on } \Gamma_N, \end{cases} \tag{3.4}$$

where c is any constant. The above Poisson problem (3.4) is an isomorphism from $H_\beta^2(\Omega)$ to $H_\beta^0(\Omega)$ for $\beta \in (1-\lambda, 1+\lambda)$ if $\partial\Omega = \Gamma_D$ [26], for $\beta \in (1-\lambda, 1)$ if $\partial\Omega = \Gamma_N$ [26], and for $\beta \in (1-\lambda/2, 1+\lambda/2)$ if $\Gamma_D \neq \emptyset$ and $\Gamma_N \neq \emptyset$ [25], [28]. Also, there exists a constant C satisfying

$$\|p\|_{2,\beta} \;\leq\; C\|\nabla \cdot \mathbf{u}\|_{0,\beta} \tag{3.5}$$

under the above assumptions on β and boundary conditions. The inequality (3.5) implies that $\|\mathbf{u}\|_{1,\beta} \le c\|L\mathbf{u}\|_{0,\beta}$; therefore, L is injective.

(ii) If $g = 0$, then there exists a vector potential $\phi = (\phi_1, \phi_2, \phi_3) \in H(\nabla\times)$ such that $\mathbf{u} = \nabla \times \phi$ and $\nabla \cdot \phi = 0$. Suppose $\partial\Omega = \Gamma_D$; then $\nabla \times \mathbf{u} = \nabla \times \nabla \times \phi = -\Delta\phi + \nabla\nabla \cdot \phi = -\Delta\phi$ and the boundary conditions $\mathbf{n} \times \phi = \mathbf{0}$, $\mathbf{n} \times \nabla \times \phi = \mathbf{0}$ yield, for $i = 1, 2$,

$$\begin{cases} -\Delta\phi_i = (\nabla \times \mathbf{u})_i & \text{in } \Omega, \\ \phi_i = 0 & \text{on } \partial\Omega \end{cases} \quad \text{and} \quad \begin{cases} -\Delta\phi_3 = (\nabla \times \mathbf{u})_3 & \text{in } \Omega, \\ \phi_3 = 0 & \text{on the side walls,} \\ \mathbf{n} \cdot \nabla\phi_3 = 0 & \text{on top and bottom,} \end{cases}$$

where $(\nabla \times \mathbf{u})_i$ is the ith component of $\nabla \times \mathbf{u}$. Since the inner angle between top and side walls is $\pi/2$, there are no singularities around those edges. Therefore, L is injective for $\beta \in (1 - \lambda, 1 + \lambda)$. Analogously, L is injective for $\beta \in (1 - \lambda, 1)$ when $\partial\Omega = \Gamma_N$ and the sides of the domain are parallel to the coordinate axes, in which $\mathbf{n}$ is of the form $(n_1, 0, 0), (0, n_2, 0)$, and $(0, 0, n_3)$. For the case when $\Gamma_D \neq \emptyset$ and $\Gamma_N \neq \emptyset$, we use the following decomposition in [1]: a function $\mathbf{u}$ satisfies $\nabla \cdot \mathbf{u} = 0$ and $\mathbf{n} \cdot \mathbf{u} = 0$ on Γ_N if and only if there exists a function $\phi \in H(\nabla\times)$ such that

$$\begin{cases} \mathbf{u} = \nabla \times \phi, \quad \nabla \cdot \phi = 0 \ \text{ in } \Omega, \\ \mathbf{n} \times \phi = \mathbf{0} \text{ on } \Gamma_N, \quad \text{and} \quad \mathbf{n} \cdot \phi = 0 \text{ on } \Gamma_D. \end{cases} \tag{3.6}$$

If the sides of the domain are parallel to the coordinate axes, then we can derive a Poisson equation with mixed boundary conditions from (3.6). Hence, L is injective for $\beta \in (1 - \lambda/2, 1 + \lambda/2)$.

(iii) Let $\mathbf{u} \in H^1_\beta(\Omega)^3 \cap \mathcal{U}$; then $\mathbf{u}$ has the orthogonal decomposition [16]

$$\mathbf{u} = \nabla \times \phi + \nabla p,$$

where $\phi \in H(\nabla\times)$ with $\nabla \cdot \phi = 0$ and $\mathbf{n} \times \phi = \mathbf{0}$, and $p \in H^1_0(\Omega)$ is the solution of

$$\langle \nabla p, \nabla\xi \rangle = \langle \mathbf{u}, \nabla\xi \rangle \quad \text{for all } \xi \in H^1_0(\Omega).$$

Similarly to (i) and (ii), one can establish the results. ∎

Remark 3.2. Note that the above restrictions on β are sufficient but may not be necessary. In the remainder of the paper, we establish results that depend on L being injective. While the above theorem establishes sufficient conditions, the operator L may be injective for a much wider range of values for the weight β. Extension of the range is beyond the scope of this paper, but we remark that numerical results seem to indicate that it may be possible.

If the div/curl system is derived from the Poisson equation, then the problem easily matches to the first case in Lemma 3.1.

LEMMA 3.3. *Let $\mathbf{u} \in H^1_\beta(\Omega)^3 \cap \mathcal{U}$; then there exists a constant c satisfying*

$$\|\mathbf{u}\|_{1,\beta} \le c \left(\|L\mathbf{u}\|_{0,\beta} + \|\mathbf{u}\|_{0,\beta-1} \right) \tag{3.7}$$

for any $\beta > 0$.

Proof. Since the norms $\|u\|_{1,\beta}$ and $\|r^\beta u\|_1$ are equivalent (see [25]) and $\|r^\beta u\| \le \|u\|_{0,\beta-1}$, it is enough to show that $\|\nabla(r^\beta \mathbf{u})\|$ is less than the right-hand side of (3.7). Since $r^\beta \mathbf{u} \in H^1(\Omega)^3$, the result in [12] and the triangle inequality yield $\|\nabla(r^\beta \mathbf{u})\| \le c\, \|L(r^\beta \mathbf{u})\| \le c\, (\|L\mathbf{u}\|_{0,\beta} + \|\mathbf{u}\|_{0,\beta-1})$. ∎

Based on Lemmas 3.1 and 3.3, we achieve the goal of this section in the following theorem by using a modified compactness argument.

THEOREM 3.4. *Let $L : H^1_\beta(\Omega)^3 \cap \mathcal{U} \to H^0_\beta(\Omega)^4$ be injective and $\mathbf{u} \in H^1_\beta(\Omega)^3 \cap \mathcal{U}$. Then, there exists a constant $c = c(\Omega, \beta)$ such that*

$$\|\mathbf{u}\|_{1,\beta} \leq c \, \|L\mathbf{u}\|_{0,\beta}. \tag{3.8}$$

Proof. First, we let

$$\Omega_R = \{\mathbf{x} = (r, \theta, z) \in \Omega \ : \ r > R\}$$

and define a norm $\|\mathbf{u}\|^2_{1,\beta,\Omega_R} = |\mathbf{u}|^2_{1,\beta,\Omega_R} + \|\mathbf{u}\|^2_{0,\beta-1,\Omega_R}$ for any $R \geq 0$. Define Ω_{2R} and a norm $\|\mathbf{u}\|_{1,\beta,\Omega_{2R}}$ in the same way by replacing R with $2R$. Let $\delta(r)$ be a smooth cut-off function,

$$\delta(r) = \begin{cases} 0 & \text{if} \quad r \leq R, \\ 1 & \text{if} \quad r \geq 2R, \end{cases}$$

where $|\delta| \leq 1$, $|\delta'| \leq cR^{-1}$, and δ' has support only for $r \in (R, 2R)$. By the fact that, for any $\mathbf{u} \in H^1_\beta(\Omega)^3$, we have $\delta r^\beta \mathbf{u} \in H^1(\Omega)^3$ and the triangle inequality, we have the first (cf. [12]) and the second inequalities, respectively, of the following:

$$\begin{aligned} \|\nabla(\delta r^\beta \mathbf{u})\| &\leq c\|L(\delta r^\beta \mathbf{u})\| \leq c(\|\delta r^\beta L\mathbf{u}\| + \|\nabla(\delta r^\beta) \cdot \mathbf{u}\|) \\ &\leq c(\|L\mathbf{u}\|_{0,\beta,\Omega_R} + c\|\mathbf{u}\|_{0,\beta-1,\Omega_R}), \end{aligned} \tag{3.9}$$

where c is independent of R. We also have

$$\begin{aligned} \|\nabla \mathbf{u}\|_{0,\beta,\Omega_{2R}} &\leq \|\delta r^\beta \nabla \mathbf{u}\| \leq \|\delta r^\beta \nabla \mathbf{u} + \nabla(\delta r^\beta) \cdot \mathbf{u}\| + \|\nabla(\delta r^\beta) \cdot \mathbf{u})\| \\ &\leq \|\nabla(\delta r^\beta \mathbf{u})\| + c\|\mathbf{u}\|_{0,\beta-1,\Omega_R}, \end{aligned} \tag{3.10}$$

where c is independent of R. Putting (3.9) and (3.10) together we have

$$\|\nabla \mathbf{u}\|_{0,\beta,\Omega_{2R}} \leq c(\|L\mathbf{u}\|_{0,\beta,\Omega_R} + \|\mathbf{u}\|_{0,\beta-1,\Omega_R}). \tag{3.11}$$

Here, we use a modified compactness argument: Assume that (3.8) is not true; that is, there is a sequence $\{\mathbf{u}_j\}_{j=1,\infty} \subset H^1_\beta(\Omega)^3 \cap \mathcal{U}$ such that

$$\|\mathbf{u}_j\|_{1,\beta} = 1 \quad \text{and} \quad \|L\mathbf{u}_j\|_{0,\beta} \to 0 \ \text{ as } n \to \infty. \tag{3.12}$$

Since $H^1_\beta(\Omega)$ is compactly embedded into $H^0_\beta(\Omega)$ [25], there is a subsequence $\{\mathbf{u}_{j_\ell}\}_{\ell=1,\infty}$, which we shall denote by $\{\mathbf{u}_\ell\}_{\ell=1,\infty}$, that is Cauchy in $H^0_\beta(\Omega)^3$ and, thus, has limit $\tilde{\mathbf{u}} \in H^0_\beta(\Omega)^3$. That is, $\|\mathbf{u}_\ell - \tilde{\mathbf{u}}\|_{0,\beta} \to 0$. Now, for any $R > 0$, the norms $\|\cdot\|_{0,\beta,\Omega_R}$ and $\|\cdot\|_{0,\beta-1,\Omega_R}$ are equivalent. This implies that $\{\mathbf{u}_\ell\}_{\ell=1,\infty}$ is Cauchy in $H^0_{\beta-1}(\Omega_R)$ and

$$\|\mathbf{u}_\ell - \tilde{\mathbf{u}}\|_{0,\beta-1,\Omega_R} \to 0.$$

Using (3.11) we have

$$|\mathbf{u}_\ell - \mathbf{u}_m|_{1,\beta,\Omega_{2R}} \leq c\left(\|L(\mathbf{u}_\ell - \mathbf{u}_m)\|_{0,\beta,\Omega_R} + \|\mathbf{u}_\ell - \mathbf{u}_m\|_{0,\beta-1,\Omega_R}\right), \tag{3.13}$$

which implies that $\{\mathbf{u}_\ell\}_{\ell=1,\infty}$ is Cauchy in $H^1_\beta(\Omega_{2R})^3$ and, thus, $\tilde{\mathbf{u}} \in H^1_\beta(\Omega_{2R})^3$ and

$$\|\mathbf{u}_\ell - \tilde{\mathbf{u}}\|_{1,\beta,\Omega_{2R}} \to 0. \tag{3.14}$$

The triangle inequality yields

$$\begin{aligned}\|L\tilde{\mathbf{u}}\|_{0,\beta,\Omega_{2R}} &\le c\|L(\tilde{\mathbf{u}}-\mathbf{u}_\ell)\|_{0,\beta,\Omega_{2R}} + c\|L\mathbf{u}_\ell\|_{0,\beta,\Omega_{2R}}\\ &\le c\|(\tilde{\mathbf{u}}-\mathbf{u}_\ell)\|_{1,\beta,\Omega_{2R}} + c\|L\mathbf{u}_\ell\|_{0,\beta,\Omega_{2R}}\end{aligned}$$

for every ℓ, which implies that $L\tilde{\mathbf{u}}=0$ on Ω_{2R}. Since this is true for every $R>0$, we have

$$L\tilde{\mathbf{u}}=0 \qquad \text{on} \quad \Omega. \tag{3.15}$$

To summarize what we now know, $\tilde{\mathbf{u}}\in H^0_\beta(\Omega)^3$, $\tilde{\mathbf{u}}\in H^1_\beta(\Omega_R)^3$ for every $R>0$, and $L\tilde{\mathbf{u}}=0$ on Ω. If $\tilde{\mathbf{u}}\in H^0_{\beta-1}(\Omega)^3$, using Lemma 3.3 and the fact that $L\tilde{\mathbf{u}}=0$, we have $\tilde{\mathbf{u}}\in H^1_\beta(\Omega)^3$, which would contradict the assumption that L is injective on $H^1_\beta(\Omega)^3\cap\mathcal{U}$. So, we assume that $\tilde{\mathbf{u}}\notin H^0_{\beta-1}(\Omega)^3$, that is,

$$\lim_{R\to 0}\|\tilde{\mathbf{u}}\|_{0,\beta-1,\Omega_R}=\infty.$$

However,

$$\begin{aligned}\|\tilde{\mathbf{u}}\|_{0,\beta-1,\Omega_R} &\le \|\tilde{\mathbf{u}}-\mathbf{u}_\ell\|_{0,\beta-1,\Omega_R} + \|\mathbf{u}_\ell\|_{0,\beta-1,\Omega_R} \le \|\tilde{\mathbf{u}}-\mathbf{u}_\ell\|_{0,\beta-1,\Omega_R} + \|\mathbf{u}_\ell\|_{0,\beta-1,\Omega}\\ &\le \|\tilde{\mathbf{u}}-\mathbf{u}_\ell\|_{0,\beta-1,\Omega_R} + \|\mathbf{u}_\ell\|_{1,\beta,\Omega} \le \|\tilde{\mathbf{u}}-\mathbf{u}_\ell\|_{0,\beta-1,\Omega_R}+1\end{aligned}$$

for every ℓ independent of R. Thus, $\|\tilde{\mathbf{u}}\|_{0,\beta-1,\Omega_R}\le 1$ for all $R>0$. This is a contradiction, and the result is proved. ∎

The above theorem implies that the corresponding weak formulation of the least-squares method is coercive, whenever L is injective, in the proper weighted Sobolev space. The continuity is obtained easily by the triangle inequality. Since the solution is in $H^1_\beta(\Omega)$, that is, the weighted L^2-norm of gradient of the solution is finite, it is reasonable to minimize the residual functional in the weighted norm to approximately solve the problem when using H^1-conforming finite elements.

4. Poincaré inequalities. In this section, we develop several types of Poincaré inequalities, which are useful in various settings. Recall that E is the singular edge and $diam(\Omega)<1$. From now on, we consider the domain in the cylindrical coordinate system for convenience. The domain, Ω, can be rewritten as

$$\Omega=\{\mathbf{x}=(r,\theta,z): 0<r<R(\theta),\ 0<\theta<\omega<2\pi,\ a<z<b\},$$

where $R(\theta)$ is the distance from the singular edge, E, to boundary points depending on the angle θ. Then, $\partial\Omega=\{(r,\theta,z): r=R(\theta), 0\le\theta\le\omega\}\cup\{(r,\theta,z):\theta=0, 0\le r\le R(0)\}\cup\{(r,\theta,z):\theta=\omega, 0\le r\le R(\omega)\}\cup\{(r,\theta,z): z=a \text{ or } z=b\}$. The following lemma is known from [20].

LEMMA 4.1. *If $q\in H^1_\beta(\Omega)$ vanishes on $\partial\Omega$, then, for any β,*

$$\|q\|_{0,\beta-1} \ \le\ c\ \|\nabla q\|_{0,\beta}.$$

Now, we show several generalized Poincaré-type inequalities.

LEMMA 4.2. *For $p\in H^1_\beta(\Omega)$, there exists a constant c such that*

$$\|p\|_{0,\beta-1}\ \le\ c\ (\|p\|_{0,\beta}+\|\nabla p\|_{0,\beta})$$

when $\beta>0$.

Proof. Let $R_0 = (\min_{0<\theta<\omega} R(\theta))/4$ and let χ be a smooth function defined in Ω such that $\chi(r) = 1$ when $r < R_0$ and $\chi(r) = 0$ when $r > 2R_0$ and $|\chi'| \le cR_0^{-1}$ for some constant c. Since $1 = \chi + 1 - \chi$,

$$\int_0^{R(\theta)} r^{2\beta-2}|p|^2 r dr = \int_0^{R(\theta)} r^{2\beta-2}\left|\chi p + (1-\chi)p\right|^2 r dr \le 2\int_0^{R(\theta)} r^{2\beta-2}\left(|\chi p|^2 + |(1-\chi)p|^2\right) r dr.$$

By the modified Hardy inequality in [19], for $\beta > 0$,

$$\int_0^{R(\theta)} r^{2\beta-2}|\chi p|^2 r dr \le c\int_0^{R(\theta)} r^{2\beta}\left|\frac{\partial(\chi p)}{\partial r}\right|^2 r dr \le c\int_0^{2R_0} r^{2\beta}\left(\frac{1}{R_0^2}|p|^2 + \left|\frac{\partial p}{\partial r}\right|^2\right) r dr.$$

Since $(1-\chi)p$ has nonzero values only on $(R_0, R(\theta))$,

$$\begin{aligned}\int_0^{R(\theta)} r^{2\beta-2}|(1-\chi)p|^2 r dr &= \int_{R_0}^{R(\theta)} r^{2\beta-2}|(1-\chi)p|^2 r dr \\ &\le {R_0}^{-2}\int_{R_0}^{R(\theta)} r^{2\beta}|(1-\chi)p|^2 r dr \le {R_0}^{-2}\int_0^{R(\theta)} r^{2\beta}|p|^2 r dr.\end{aligned}$$

Hence, by Fubini's theorem,

$$\int_\Omega r^{2\beta-2}|p|^2 d\Omega \le c\ R_0^{-2}\int_\Omega r^{2\beta}|p|^2 d\Omega + c\int_\Omega r^{2\beta}|\nabla p|^2 d\Omega. \qquad \square$$

The above lemma is useful in establishing weighted-norm Poincaré inequalities since they are guaranteed if we can show that

$$\|p\|_{0,\beta} \le c\|\nabla p\|_{0,\beta}. \tag{4.1}$$

Combining Lemma 4.2 with the following lemma provides a Poincaré inequality when there are no given boundary conditions.

LEMMA 4.3. *Let $\epsilon > 0$, $\beta > -1$, and $\beta + 1 - \epsilon > 0$. If $p \in H^1_{\beta+1-\epsilon}(\Omega)$, then there exist constants b and $c = c(\Omega, \beta, \epsilon)$ such that*

$$\|p - b\|_{0,\beta} \ \le\ c\ \|\nabla p\|_{0,\beta+1-\epsilon}.$$

Proof. Here, we show an outline of the proof. The details can be found in [21]. If $p \in H^1_{\beta+1-\epsilon}(\Omega)$ when $\beta + 1 - \epsilon > 0$, then $p \in H^1(S)$, where $S \subset \Omega$ and $\bar{S} \cap E = \emptyset$. Then, we can consider the following expression for p: for $(r, \theta, z), (r_0, \theta_0, z_0) \in \Omega$,

$$\begin{aligned}&p(r,\theta,z) - p(r_0,\theta_0,z_0)\\ &= p(r,\theta,z) - p(r,\theta_0,z) + p(r,\theta_0,z) - p(r_0,\theta_0,z) + p(r_0,\theta_0,z) - p(r_0,\theta_0,z_0)\\ &= \int_{\theta_0}^{\theta} \frac{\partial p}{\partial\tilde{\theta}}(r,\tilde{\theta},z)\ d\tilde{\theta}\ +\ \int_{r_0}^{r} \frac{\partial p}{\partial\tilde{r}}(\tilde{r},\theta_0,z)\ d\tilde{r}\ +\ \int_{z_0}^{z} \frac{\partial p}{\partial\tilde{z}}(r_0,\theta_0,\tilde{z})\ d\tilde{z}.\end{aligned}$$

Multiply by $r_0^{\beta+\frac{1}{2}}$ and perform the integration $\int_\Omega r_0 dr_0 d\theta_0 dz_0$ on both sides:

$$\begin{aligned}c_1 p(r,\theta,z) = &\int_\Omega r_0^{\beta+\frac{1}{2}} p(r_0,\theta_0,z_0) r_0 dr_0 d\theta_0 dz_0 + \int_\Omega r_0^{\beta+\frac{1}{2}}\left\{\int_{t_0}^{\theta} \frac{\partial p}{\partial\tilde{\theta}}(r,\tilde{\theta},z)\ d\tilde{\theta}\right.\\ &\left. + \int_{r_0}^{r} \frac{\partial p}{\partial\tilde{r}}(\tilde{r},\theta_0,z)\ d\tilde{r}\ +\ \int_{z_0}^{z} \frac{\partial p}{\partial\tilde{z}}(r_0,\theta_0,\tilde{z})\ d\tilde{z}\right\} r_0 dr_0 d\theta_0 dz_0,\end{aligned} \tag{4.2}$$

where $c_1 = \int_\Omega r_0^{\beta+\frac{1}{2}} r_0 dr_0 d\theta_0 dz_0$. Let

$$b = \frac{1}{c_1} \int_\Omega r_0^{\beta+\frac{1}{2}} p(r_0, \theta_0, z_0)\ r_0 dr_0 d\theta_0 dz_0;$$

then $|b| \le c\|p\| < \infty$. Subtracting b from both sides in (4.2), applying Fubini's theorem, inserting $\tilde{r}^{\frac{-1+2\epsilon}{2}} \cdot \tilde{r}^{\frac{1-2\epsilon}{2}} = 1$ into group $\tilde{r}^{\frac{1-2\epsilon}{2}}$ with the $\frac{\partial p}{\partial \tilde{r}}$ term, using the Cauchy–Schwarz inequality, and squaring both sides yields

$$|p(r,\theta,z) - b|^2 \le c \left\{ \int_0^\omega \left| \frac{\partial p}{\partial \tilde{\theta}}(r, \tilde{\theta}, z) \right|^2 d\tilde{\theta} + \int_0^\omega \int_0^R \tilde{r}^{2\beta+3} \left| \frac{\partial p}{\partial \tilde{r}}(\tilde{r}, \theta_0, z) \right|^2 d\tilde{r} d\theta_0 \right.$$
$$\left. + \int_0^\omega \left\{ \frac{R^{2\epsilon}}{\epsilon} \int_r^R \tilde{r}^{1-2\epsilon} \left| \frac{\partial p}{\partial \tilde{r}}(\tilde{r}, \theta_0, z) \right|^2 d\tilde{r} + \int_0^R r_0^{2\beta+3} \int_a^b \left| \frac{\partial p}{\partial \tilde{z}}(r_0, \theta_0, \tilde{z}) \right|^2 d\tilde{z} dr_0 \right\} d\theta_0 \right\}.$$

To establish the weighted L^2-norm of $|p-b|$, multiply by $r^{2\beta}$ and take an integration over Ω. Then, we have

$$\int_\Omega r^{2\beta} |p(r,\theta,z) - b|^2 d\Omega \le c \int_\Omega r^{2\beta+2} \left(\left| \frac{1}{r} \frac{\partial p}{\partial \theta} \right|^2 + \left| \frac{\partial p}{\partial r} \right|^2 + \left| \frac{\partial p}{\partial z} \right|^2 \right) + r^{2\beta+2-2\epsilon} \left| \frac{\partial p}{\partial r} \right|^2 d\Omega$$
$$\le c \int_\Omega r^{2\beta+2-2\epsilon} |\nabla p\ |^2 d\Omega,$$

where $c = c(\Omega, \beta, \epsilon, (\beta+1)^{-1}, \epsilon^{-1}) \to \infty$ as $\epsilon \to 0$ and $\beta \to -1$. ∎

The next result follows from setting $\epsilon = 1$ in Lemma 4.3.

THEOREM 4.4. *Let $\beta > 0$ and $p \in H^1_\beta(\Omega)$; then there exist constants b, c satisfying*

$$\|p - b\|_{0,\beta-1} \le c \|\nabla p\|_{0,\beta}.$$

Proof. From Lemmas 4.2 and 4.3 (set $\epsilon = 1$), we deduce the result. ∎

COROLLARY 4.5. *If $p \in H^1_\beta(\Omega) \cap H^1(\Omega)/\mathbb{R}$ is the solution of Poisson equation with Neumann boundary condition, then for $\beta > 0$, by Theorem 4.4, p satisfies*

$$\|p\|_{0,\beta-1} \le c \|\nabla p\|_{0,\beta}. \tag{4.3}$$

We now consider functions with zero boundary conditions given on a nonempty portion of the boundary. The following theorem shows that the weighted-norm Poincaré inequality holds wherever the zero boundary conditions are located.

THEOREM 4.6. *Let $\beta > 0$ and $p \in H^1_\beta(\Omega)$. If $p = 0$ on $\Gamma_0 \neq \emptyset$, then*

$$\|p\|_{0,\beta-1} \ \le \ c\ \|\nabla p\|_{0,\beta}. \tag{4.4}$$

Proof. In order to prove (4.4), by Lemma 4.2, it is enough to show (4.1). Here, we show (4.1) for p satisfying $p = 0$ on $\Gamma_0 \subset \{\mathbf{x} \in \partial\Omega : z = a\}$; however, the other cases can be proved in the same manner. Consider the following expression for p:

$$p(r,\theta,z) = \int_{r_0}^r \frac{\partial p(\tilde{r}, \theta, z)}{\partial \tilde{r}} d\tilde{r} + \int_{\theta_0}^\theta \frac{\partial p(r_0, \tilde{\theta}, z)}{\partial \tilde{\theta}} d\tilde{\theta} + \int_a^z \frac{\partial p(r_0, \theta_0, \tilde{z})}{\partial \tilde{z}} d\tilde{z},$$

where $(r_0, \theta_0, a) \in \Gamma_0$. If $r \geq r_0$, then squaring both sides, applying the Cauchy inequality, and multiplying by $r_0^{2\beta+1}$ yields

$$\begin{aligned} r_0^{2\beta+1}|p(r,\theta,z)|^2 &\leq c\int_{r_0}^{r} \tilde{r}^{2\beta+1}\left|\frac{\partial p(\tilde{r},\theta,z)}{\partial \tilde{r}}\right|^2 d\tilde{r} + c\int_{\theta_0}^{\theta} r_0^{2\beta+1}\left|\frac{1}{r_0}\frac{\partial p(r_0,\tilde{\theta},z)}{\partial \tilde{\theta}}\right|^2 d\tilde{\theta} \\ &\quad + c\int_{a}^{z} r_0^{2\beta+1}\left|\frac{\partial p(r_0,\theta_0,\tilde{z})}{\partial \tilde{z}}\right|^2 d\tilde{z} \\ &\leq c\int_{0}^{R(\theta)} \tilde{r}^{2\beta+1}\left|\frac{\partial p(\tilde{r},\theta,z)}{\partial \tilde{r}}\right|^2 d\tilde{r} + c\int_{0}^{\omega} r_0^{2\beta+1}\left|\frac{1}{r_0}\frac{\partial p(r_0,\tilde{\theta},z)}{\partial \tilde{\theta}}\right|^2 d\tilde{\theta} \\ &\quad + c\int_{a}^{b} r_0^{2\beta+1}\left|\frac{\partial p(r_0,\theta_0,\tilde{z})}{\partial \tilde{z}}\right|^2 d\tilde{z}. \end{aligned}$$

First, integrate with respect to r_0, θ_0 and then multiply by $r^{2\beta+1}$ on both sides and integrate over Ω with respect to r, θ, and z, respectively. Then, by Fubini's theorem,

$$\int_\Omega r^{2\beta}|p|^2 d\Omega \leq c\left(\int_\Omega \tilde{r}^{2\beta}\left|\frac{\partial p}{\partial \tilde{r}}\right|^2 d\Omega + \int_\Omega r_0^{2\beta}\left|\frac{1}{r_0}\frac{\partial p}{\partial \tilde{\theta}}\right|^2 d\Omega + \int_\Omega r_0^{2\beta}\left|\frac{\partial p}{\partial \tilde{z}}\right|^2 d\Omega\right),$$

which yields (4.1).

If $r < r_0$, similarly, we square both sides, use the Cauchy inequality, and multiply by $r_0^{2\beta+1} r^{2\beta+1}$. Then, we have

$$\begin{aligned} &r_0^{2\beta+1} r^{2\beta+1}|p(r,\theta,z)|^2 \leq c r_0^{2\beta+1}\int_{r}^{r_0} \tilde{r}^{2\beta+1}\left|\frac{\partial p(\tilde{r},\theta,z)}{\partial \tilde{r}}\right|^2 d\tilde{r} \\ &+ c r^{2\beta+1}\int_{\theta_0}^{\theta} r_0^{2\beta+1}\left|\frac{1}{r_0}\frac{\partial p(r_0,\tilde{\theta},z)}{\partial \tilde{\theta}}\right|^2 d\tilde{\theta} + c r^{2\beta+1}\int_{a}^{z} r_0^{2\beta+1}\left|\frac{\partial p(r_0,\theta_0,\tilde{z})}{\partial \tilde{z}}\right|^2 d\tilde{z} \\ &\leq c r_0^{2\beta+1}\int_{0}^{R(\theta)} \tilde{r}^{2\beta+1}\left|\frac{\partial p}{\partial \tilde{r}}\right|^2 d\tilde{r} + c r^{2\beta+1}\int_{0}^{\omega} r_0^{2\beta+1}\left|\frac{1}{r_0}\frac{\partial p}{\partial \tilde{\theta}}\right|^2 d\tilde{\theta} + c r^{2\beta+1}\int_{a}^{b} r_0^{2\beta+1}\left|\frac{\partial p}{\partial \tilde{z}}\right|^2 d\tilde{z}. \end{aligned}$$

Taking integrations with respect to r_0, θ_0, r, θ, and z implies (4.1). ∎

So far, Poincaré inequalities in weighted Sobolev spaces for scalar functions have been established. We now extend these to vector functions.

THEOREM 4.7. *Let $\beta > 0$ and $\mathbf{u} \in H^1_\beta(\Omega)^3$ with $\mathbf{n} \times \mathbf{u} = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot \mathbf{u} = 0$ on Γ_N; then there exists a constant c such that*

$$\|\mathbf{u}\|_{0,\beta-1} \leq c\, \|\nabla \mathbf{u}\|_{0,\beta} \tag{4.5}$$

except for the case with $\Gamma_D = \{\mathbf{x} \in \partial\Omega : z = a \text{ and } b\}$ and $\Gamma_N = \partial\Omega \backslash \Gamma_D$.

Proof. Here, we prove (4.5) only for the case $\partial\Omega = \Gamma_N$. However, all the other cases can be proved easily by using the same methodology.

First, we rotate the domain so that the side $\theta = 0$ lies on the x-axis. Since $\mathbf{n}\cdot\mathbf{u} = 0$ on $\partial\Omega$, $\mathbf{n} \cdot \mathbf{u} = (n_1, n_2, n_3) \cdot (u_1, u_2, u_3) = n_3 u_3 = 0$ on the top and bottom of the domain, that is, where $z = a$ and b. Then, by Theorem 4.6, $\|u_3\|_{0,\beta-1} \leq c\|\nabla u_3\|_{0,\beta}$. From $\mathbf{n} = (0, n_2, 0)$ on $\theta = 0$, we have $\mathbf{n} \cdot \mathbf{u} = n_2 u_2 = 0$, which yields $u_2 = 0$; therefore, Theorem 4.6 yields $\|u_2\|_{0,\beta-1} \leq c\|\nabla u_2\|_{0,\beta}$. On the boundary that has

nonzero n_1-component, we have $n_1u_1 + n_2u_2 = 0$. Then, the triangle inequality leads to

$$\begin{aligned}\|\mathbf{u}\|^2_{0,\beta-1} &= \|u_1\|^2_{0,\beta-1} + \|u_2\|^2_{0,\beta-1} + \|u_3\|^2_{0,\beta-1}\\ &\le c\frac{1}{n_1^2}\|n_1u_1 + n_2u_2\|^2_{0,\beta-1} + c\frac{n_2^2}{n_1^2}\|u_2\|^2_{0,\beta-1} + \|u_2\|^2_{0,\beta-1} + \|u_3\|^2_{0,\beta-1}\\ &\le c\frac{1}{n_1^2}\|\nabla(n_1u_1 + n_2u_2)\|^2_{0,\beta} + c\|u_2\|^2_{0,\beta-1} + \|u_3\|^2_{0,\beta-1}\\ &\le c(\|\nabla u_1\|^2_{0,\beta} + \|\nabla u_2\|^2_{0,\beta} + \|\nabla u_3\|^2_{0,\beta}) = c\|\nabla\mathbf{u}\|^2_{0,\beta}. \qquad (4.6)\end{aligned}$$

If $\Gamma_D = \{\mathbf{x} \in \partial\Omega : z = a,\ b\}$ and $\Gamma_N = \partial\Omega\backslash\{\mathbf{x} \in \partial\Omega : z = a,\ b\}$, then $\mathbf{n} \times \mathbf{u} = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot \mathbf{u} = 0$ on Γ_N do not provide any information about boundary condition for u_3. Therefore, we exclude this case. ∎

5. Error bounds. Let $\mathcal{T}_h$ be a quasi-uniform partition of the domain $\bar{\Omega} = \cup_{\tau\in\mathcal{T}_h}\tau$ and each finite element $\tau \in \mathcal{T}_h$ be a closed subset of $\bar{\Omega}$ with $h := \max\{h_\tau : h_\tau = diam(\tau)\}$. Assume that the partition $\mathcal{T}_h$ is regular so that we may choose a finite element basis that is conforming and satisfies the standard approximation properties (see [11]). We also assume that there exists a constant, ρ, satisfying $h \le \rho \min_\tau h_\tau$. Let $\mathcal{P}^h$ denote the space of $\mathcal{C}^0$ piecewise polynomials on each finite element and $\mathcal{W}^h$ be a subspace of $\mathcal{P}^h$ such that

$$\mathcal{W}^h = \{\mathbf{v}^h \in \mathcal{P}^h : \mathbf{n} \times \mathbf{v}^h = \mathbf{0} \text{ on } \Gamma_D,\ \ \mathbf{n} \cdot \mathbf{v}^h = 0 \text{ on } \Gamma_N\}.$$

Here, the normal vector is defined to be normal to the corresponding boundary face. On the edge where the Dirichlet and Neumann boundary conditions meet, for example, $\mathbf{n} \times \mathbf{v}^h = \mathbf{0}$ on Γ_1, $\mathbf{n} \cdot \mathbf{v}^h = 0$ on Γ_2, $\Gamma_1 \cap \Gamma_2 \neq \emptyset$, and Γ_1 includes the edge, the normal vector on the edge can be defined as a normal to the boundary face Γ_1 or the average of two normal vectors corresponding to Γ_1 and Γ_2. Either case provides the same numerical results. The discrete weighted-norm least-squares approximation minimizes the functional

$$G_w(\mathbf{u}^h; f) = \min_{\mathbf{v}^h\in\mathcal{W}^h} G_w(\mathbf{v}^h; f). \qquad (5.1)$$

For ease of discussion, we will consider cubes. However, arbitrary triangulations can be handled in a similar manner. Let $\mathcal{I}^h$ be a standard polynomial interpolation operator such that $\mathcal{I}^h p = p$, for any $p \in \mathbb{Q}_k(\tau)$, where $\mathbb{Q}_k(\tau)$ is a set of kth order polynomials with respect to each variable on τ. Define $\mathcal{I}^h_0$ by

$$\mathcal{I}^h_0 u|_\tau \ = \ \begin{cases} \mathcal{I}^h u|_\tau = \sum_{i=1}^{(k+1)^3} u(a_i)\phi_i & \text{if } \tau \text{ does not meet the singular edge, } E,\\ \sum_{a_i\notin N} u(a_i)\phi_i & \text{if } \tau \text{ meets the singular edge, } E,\end{cases}$$

where ϕ_i are the basis functions, a_i are the nodal points corresponding to ϕ_i, and $N = \{a_j : a_j = (0, 0, z_j)\}$ is the set of $k + 1$ nodes seated along the singular edge, E. Here, it is easy to see that $\mathcal{I}^h_0\mathbf{u} \in \mathcal{W}^h$ for $\mathbf{u} \in H^1_\beta(\Omega)^3$ with $\mathbf{n} \times \mathbf{u} = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot \mathbf{u} = 0$ on Γ_N since we can consider $\mathcal{I}^h_0\mathbf{u}$ as $\mathcal{I}^h(\xi\mathbf{u})$, where the smooth function ξ satisfies $\xi = 0$ when $r < \epsilon$ and $\xi = 1$ when $r \ge 2\epsilon$ for sufficiently small positive ϵ.

LEMMA 5.1. *Let $u \in H^m_\beta(\Omega)$; then*

$$\|u - \mathcal{I}^h_0 u\|_{1,\beta} \ \le \ c\ h^{m-1}\|u\|_{m,\beta}, \qquad (5.2)$$

for $3/2 < m$ and any $0 < \beta$, where $\mathcal{I}_0^h$ is the modified interpolation operator into piecewise polynomials of degree $m-1 \le k$.

Proof. We rewrite

$$\|u - \mathcal{I}_0^h u\|_{1,\beta}^2 \;=\; \sum_{\tau \in \mathcal{T}_h} \|u - \mathcal{I}_0^h u\|_{1,\beta,\tau}^2,$$

where $\|u\|_{1,\beta,\tau} = \left(\int_\tau r^{2\beta-2}|u|^2 + r^{2\beta}|\nabla u|^2 d\tau\right)^{\frac{1}{2}}$. Consider $\|u - \mathcal{I}_0^h u\|_{1,\beta,\tau}^2$ on each element τ. If τ does not touch the singular edge, then, by the definition of $\mathcal{I}_0^h$, $\mathcal{I}_0^h u|_\tau = \mathcal{I}^h u|_\tau$. Let $r_{min} = \inf\{r : (x,y,z) \in \tau\}$ and $r_{max} = \sup\{r : (x,y,z) \in \tau\}$ in τ. Then, $ch \le r_{min} \le r = (x^2+y^2)^{\frac{1}{2}} \le r_{max} \le r_{min} + \sqrt{3}h$ and the standard interpolation property yield

$$\begin{aligned}
\|u - \mathcal{I}_0^h u\|_{1,\beta,\tau}^2 &= \|u - \mathcal{I}^h u\|_{1,\beta,\tau}^2 = \int_\tau r^{2\beta}|\nabla(u - \mathcal{I}^h u)|^2 + r^{2(\beta-1)}|u - \mathcal{I}^h u|^2 d\tau \\
&\le r_{max}^{2\beta} \int_\tau |\nabla(u - \mathcal{I}^h u)|^2 d\tau + r_{max}^{2\beta} r_{min}^{-2} \int_\tau |u - \mathcal{I}^h u|^2 d\tau \\
&\le c r_{max}^{2\beta} h^{2(m-1)} |u|_{m,\tau}^2 + c r_{max}^{2\beta} r_{min}^{-2} h^{2m} |u|_{m,\tau}^2 = c r_{max}^{2\beta} h^{2(m-1)} (1 + r_{min}^{-2} h^2) |u|_{m,\tau}^2 \\
&\le c r_{max}^{2\beta} h^{2(m-1)} |u|_{m,\tau}^2 \le c h^{2(m-1)} r_{max}^{2\beta} r_{min}^{-2\beta} \int_\tau r^{2\beta} |D^m u|^2 d\tau \\
(5.3) &\le c h^{2(m-1)} \left(\frac{r_{min} + \sqrt{3}h}{r_{min}}\right)^{2\beta} \int_\tau r^{2\beta} |D^m u|^2 d\tau \le c h^{2(m-1)} \|D^m u\|_{0,\beta,\tau}^2.
\end{aligned}$$

Next, consider the case in which $\tau \cap E \neq \emptyset$. Let $\delta \in \mathcal{C}^\infty$ be a cut-off function defined by

$$\delta(r) = \begin{cases} 1 & \text{if} \quad r \le \frac{h}{3k}, \\ 0 & \text{if} \quad r > \frac{h}{2k}, \end{cases} \tag{5.4}$$

with $|\delta^{(m)}| \le ch^{-m}$, where $\delta^{(m)}$ is the mth derivative of δ. By the triangle inequality,

$$\|u - \mathcal{I}_0^h u\|_{1,\beta,\tau}^2 \le c(\|\delta u - \mathcal{I}_0^h(\delta u)\|_{1,\beta,\tau}^2 + \|(1-\delta)u - \mathcal{I}_0^h((1-\delta)u)\|_{1,\beta,\tau}^2). \tag{5.5}$$

On these τ, $\mathcal{I}_0^h(\delta u) = 0$. Thus, for the first term in (5.5), the properties in δ and Fubini's theorem imply that

$$\begin{aligned}
&\|\delta u - \mathcal{I}_0^h(\delta u)\|_{1,\beta,\tau}^2 = \|\delta u\|_{1,\beta,\tau}^2 = \int_\tau r^{2\beta}|\nabla(\delta u)|^2 + r^{2(\beta-1)}|\delta u|^2 d\tau \\
&\le c \int_\tau r^{2\beta}(|\nabla\delta \cdot u|^2 + |\delta \nabla u|^2) + r^{2(\beta-1)}|\delta u|^2 d\tau \\
&\le c \iiint_{\frac{h}{3k}}^{\frac{h}{2k}} r^{2\beta} h^{-2} |u|^2 d\tau + c \iiint_0^{\frac{h}{3k}} r^{2\beta}|\nabla u|^2 + r^{2(\beta-1)}|u|^2 d\tau \\
&\le c \iiint_{\frac{h}{3k}}^{\frac{h}{2k}} r^{2(\beta-1)} |u|^2 d\tau + c \iiint_0^{\frac{h}{3k}} r^{2\beta}|\nabla u|^2 + r^{2(\beta-1)}|u|^2 d\tau \\
&\le c \int_\tau r^{2(m-1)}(r^{2(\beta-m+1)}|\nabla u|^2 + r^{2(\beta-m)}|u|^2) d\tau \le c h^{2(m-1)} \|u\|_{m,\beta,\tau}^2.
\end{aligned}$$

For the second term in (5.5), use $\mathcal{I}_0^h((1-\delta)u) = \mathcal{I}^h((1-\delta)u)$ and Theorem 4.6 to obtain

$$\|(1-\delta)u - \mathcal{I}_0^h((1-\delta)u)\|_{1,\beta,\tau}^2 \le c|(1-\delta)u - \mathcal{I}^h((1-\delta)u)|_{1,\beta,\tau}^2.$$

Since $(1-\delta)u \in H^m(\tau)$, we use the standard interpolation property, Fubini's theorem, and the properties of δ to obtain

$$\begin{aligned}
&|(1-\delta)u - \mathcal{I}^h((1-\delta)u)|_{1,\beta,\tau}^2 \le ch^{2\beta}\int_\tau |\nabla((1-\delta)u - \mathcal{I}^h((1-\delta)u))|^2 d\tau \\
&\le ch^{2\beta}h^{2(m-1)}\int_\tau |D^m((1-\delta)u)|^2 d\tau \le ch^{2(\beta+m-1)}\int_\tau \sum_{j=0}^{m} |D^{m-j}(1-\delta)D^j u|^2 d\tau \\
&\le ch^{2(\beta+m-1)}\left(\iiint_{\frac{h}{3k}}^{\frac{h}{2k}} \sum_{j=0}^{m-1} |h^{j-m}D^j u|^2 d\tau + \iiint_{\frac{h}{3k}}^{r(\theta)} |(1-\delta)D^m u|^2 d\tau\right) \\
&\le ch^{2(\beta+m-1)}\left(\sum_{j=0}^{m-1}\iiint_{\frac{h}{3k}}^{\frac{h}{2k}} h^{-2\beta}r^{2(\beta+j-m)}|D^j u|^2 d\tau + \iiint_{\frac{h}{3k}}^{r(\theta)} h^{-2\beta}r^{2\beta}|D^m u|^2 d\tau\right) \\
&= ch^{2(m-1)}\sum_{j=0}^{m}\int_\tau r^{2(\beta+j-m)}|D^j u|^2 d\tau = ch^{2(m-1)}\|u\|_{m,\beta,\tau}^2.
\end{aligned}$$

Hence, we have

$$\|u - \mathcal{I}_0^h u\|_{1,\beta}^2 = \sum_{\tau\in\mathcal{T}_h} \|u - \mathcal{I}_0^h u\|_{1,\beta,\tau}^2 \le ch^{2(m-1)}\sum_{\tau\in\mathcal{T}_h}\|u\|_{m,\beta,\tau}^2 \le ch^{2(m-1)}\|u\|_{m,\beta}^2. \qquad \square$$

LEMMA 5.2. *Let $\mathbf{u}^h \in \mathcal{W}^h$; then there exists a constant c such that*

$$\|\mathbf{u}^h\|_{0,\gamma} \le ch^{-\eta}\|\mathbf{u}^h\|_{0,\gamma+\eta} \tag{5.6}$$

for any real $\gamma \ge 0$ and any $\eta > 0$.

Proof. In [23], inequality (5.6) is shown in two dimensions. The analogous three dimensional result can be proved in the same manner. $\square$

Lemma 5.1 shows that there exists an approximation of the solution in the finite dimensional subspace $\mathcal{W}^h$ that yields an optimal weighted H^1-convergence. By using this, we can show the following error estimates.

THEOREM 5.3. *Let $\mathbf{u} \in \mathcal{U}$ be the solution of* (2.3) *and $\mathbf{u}^h \in \mathcal{W}^h$ be the solution of* (5.1). *Assume $\mathbf{u} \in H_\beta^{\alpha+\beta}(\Omega)^3$ and L satisfies Theorem* 3.4. *Then,*

$$\|\mathbf{u} - \mathbf{u}^h\|_{l,\beta} \le c\, h^{\alpha+\beta-l}\|\mathbf{u}\|_{\alpha+\beta,\beta} \quad \text{for } l = 0, 1, \tag{5.7}$$

$$\|\mathbf{u} - \mathbf{u}^h\| \le c\, h^{\alpha}\|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{5.8}$$

where $3/2 < \alpha + \beta \le k + 1$ and k is the degree of the piecewise polynomials in $\mathcal{W}^h$.

Proof. First, we prove (5.7) for $l = 1$. Since $\mathbf{u}^h$ is the minimizer of (5.1), by Theorem 3.4, the triangle inequality, and Lemma 5.1, we have

$$\begin{aligned}
\|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} &\le c\|L(\mathbf{u} - \mathbf{u}^h)\|_{0,\beta} \le c\|L(\mathbf{u} - \mathcal{I}_0^h\mathbf{u})\|_{0,\beta} \le c\|\mathbf{u} - \mathcal{I}_0^h\mathbf{u}\|_{1,\beta} \\
&\le ch^{\alpha+\beta-1}\|\mathbf{u}\|_{\alpha+\beta,\beta}.
\end{aligned} \tag{5.9}$$

In order to prove the result for $l = 0$, we consider the weighted L^2-norm on each element. We have

$$\|\mathbf{u} - \mathbf{u}^h\|_{0,\beta}^2 = \sum_{\tau \in \mathcal{T}_h} \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta,\tau}^2.$$

By the Cauchy inequality, we have

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}^h\|_{0,\beta,\tau}^2 &= \int_\tau r^{2\beta} |\mathbf{u} - \mathbf{u}^h|^2 d\tau \le \left(\int_\tau 1^{\frac{3}{2}} d\tau \right)^{\frac{2}{3}} \left(\int_\tau \left(r^{2\beta} |\mathbf{u} - \mathbf{u}^h|^2 \right)^3 d\tau \right)^{\frac{1}{3}} \\ &\le c\, h^{3 \cdot \frac{2}{3}} \left(\int_\tau \left(r^\beta |\mathbf{u} - \mathbf{u}^h| \right)^6 d\tau \right)^{\frac{1}{6} \cdot 2} = c\, h^2 \|r^\beta (\mathbf{u} - \mathbf{u}^h)\|_{L^6(\tau)}^2. \end{aligned} \tag{5.10}$$

Since $H^1(\Omega)$ is continuously embedded into $L^6(\Omega)$ [11] and $r^\beta \mathbf{u} \in H^1(\Omega)^3$,

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}^h\|_{0,\beta}^2 &\le c\, h^2 \sum_{\tau \in \mathcal{T}_h} \|r^\beta (\mathbf{u} - \mathbf{u}^h)\|_{L^6(\tau)}^2 \le c\, h^2 \|r^\beta (\mathbf{u} - \mathbf{u}^h)\|_{L^6(\Omega)}^2 \\ &\le c\, h^2 \|r^\beta (\mathbf{u} - \mathbf{u}^h)\|_1^2 \le c\, h^2 \|\mathbf{u} - \mathbf{u}^h\|_{1,\beta}^2.\end{aligned}$$

Applying (5.9) to the above implies that

$$\|\mathbf{u} - \mathbf{u}^h\|_{0,\beta} \le ch \|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} \le chh^{\alpha+\beta-1} \|\mathbf{u}\|_{\alpha+\beta,\beta} = ch^{\alpha+\beta} \|\mathbf{u}\|_{\alpha+\beta,\beta}.$$

To establish (5.8), we let $K = \{\tau \in \mathcal{T}_h : \tau \cap E \neq \emptyset\}$ and separate the norm $\|\mathbf{u} - \mathbf{u}^h\|$ into two parts:

$$\|\mathbf{u} - \mathbf{u}^h\|^2 = \sum_{\tau \in K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 + \sum_{\tau \in \mathcal{T}_h \backslash K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2.$$

First, we consider the case $\beta < 1$. We have $r \le ch$ when $\tau \in K$; therefore,

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}^h\|^2 &= \sum_{\tau \in K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 + \sum_{\tau \in \mathcal{T}_h \backslash K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 \\ &\le \sum_{\tau \in K} h^{2(1-\beta)} \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta-1,\tau}^2 + \sum_{\tau \in \mathcal{T}_h \backslash K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2. \end{aligned} \tag{5.11}$$

When $\tau \in \mathcal{T}_h \backslash K$, similarly to (5.10), we have

$$\|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 \le c\, h^2 \|\mathbf{u} - \mathbf{u}^h\|_{L^6(\tau)}^2.$$

Then, the continuous embedding from H^1 into L^6 and $h \le cr$ when $\tau \in \mathcal{T}_h \backslash K$ yields

$$\begin{aligned}&\sum_{\tau \in \mathcal{T}_h \backslash K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 \le c\, h^2 \sum_{\tau \in \mathcal{T}_h \backslash K} \|\mathbf{u} - \mathbf{u}^h\|_{L^6(\tau)}^2 \le c\, h^2 \|\mathbf{u} - \mathbf{u}^h\|_{L^6(\mathcal{T}_h \backslash K)}^2 \\ &\le ch^2 \|\mathbf{u} - \mathbf{u}^h\|_{H^1(\mathcal{T}_h \backslash K)}^2 \le c\, h^2 h^{-2\beta} \int_{\mathcal{T}_h \backslash K} r^{2\beta} \left(|\mathbf{u} - \mathbf{u}^h|^2 + |\nabla(\mathbf{u} - \mathbf{u}^h)|^2 \right) d\Omega \\ &\le\ ch^{2(1-\beta)} \|\mathbf{u} - \mathbf{u}^h\|_{1,\beta}^2.\end{aligned}$$

Combining the above with (5.11) and using (5.9) gives

$$\|\mathbf{u} - \mathbf{u}^h\| \le ch^{1-\beta} \|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} \le ch^\alpha \|\mathbf{u}\|_{\alpha+\beta,\beta}.$$

For $\beta \geq 1$, by the triangle inequality, Lemma 5.2, and (5.9), we have

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}^h\|^2 &\leq c\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|^2 + c\|\mathcal{I}_0^h\mathbf{u}-\mathbf{u}^h\|^2 \leq c\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|^2 + ch^{2(1-\beta)}\|\mathcal{I}_0^h\mathbf{u}-\mathbf{u}^h\|_{0,\beta-1}^2 \\ &\leq c\sum_{\tau\in\mathcal{T}_h}\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\tau}^2 + ch^{2(1-\beta)}\left(\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\beta-1}^2 + \|\mathbf{u}-\mathbf{u}^h\|_{0,\beta-1}^2\right) \\ &\leq c\sum_{\tau\in\mathcal{T}_h}\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\tau}^2 + ch^{2(1-\beta)}\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{1,\beta}^2. \qquad (5.12)\end{aligned}$$

If $\tau \in \mathcal{T}_h \backslash K$, then we simply use $h \leq cr$ to obtain

$$\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\tau}^2 \leq ch^{2(1-\beta)}\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\beta-1,\tau}^2. \qquad (5.13)$$

If $\tau \in K$, we recall the definition of the operator $\mathcal{I}_0^h$ and let δ be a smooth cut-off function defined in (5.4). By the triangle inequality,

$$\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{0,\tau}^2 \leq c\|(1-\delta)\mathbf{u}-\mathcal{I}_0^h((1-\delta)\mathbf{u})\|_{0,\tau}^2 + c\|\delta\mathbf{u}-\mathcal{I}_0^h(\delta\mathbf{u})\|_{0,\tau}^2.$$

Since $(1-\delta)\mathbf{u} \in H^{\alpha+\beta}(\tau)^3$ and $\mathcal{I}_0^h((1-\delta)\mathbf{u}) = \mathcal{I}^h((1-\delta)\mathbf{u})$ from the definition, the analogous calculation in the proof of Lemma 5.1 provides

$$\begin{aligned}\|(1-\delta)\mathbf{u}-\mathcal{I}_0^h((1-\delta)\mathbf{u})\|_{0,\tau}^2 &= \|(1-\delta)\mathbf{u}-\mathcal{I}^h((1-\delta)\mathbf{u})\|_{0,\tau}^2 \\ &\leq ch^{2(\alpha+\beta)}\int_\tau \left|D^{\alpha+\beta}((1-\delta)\mathbf{u})\right|^2 d\tau = ch^{2(\alpha+\beta)}\iiint_{\frac{h}{3k}}^{r(\theta)}\left|D^{\alpha+\beta}((1-\delta)\mathbf{u})\right|^2 d\tau \\ &\leq ch^{2(\alpha+\beta)}h^{-2\beta}\iiint_{\frac{h}{3k}}^{r(\theta)} r^{2\beta}\left|D^{\alpha+\beta}((1-\delta)\mathbf{u})\right|^2 d\tau \\ &\leq ch^{2\alpha}\sum_{l=0}^{\alpha+\beta}\int_\tau r^{2(\beta-(\alpha+\beta)+l)}\left|D^l\mathbf{u}\right|^2 d\tau = ch^{2\alpha}\|\mathbf{u}\|_{\alpha+\beta,\beta,\tau}^2. \qquad (5.14)\end{aligned}$$

By the definition of $\mathcal{I}_0^h$ and $\|\mathbf{u}\|_{0,\beta-(\alpha+\beta)} \leq \|\mathbf{u}\|_{\alpha+\beta,\beta}$, we have

$$\begin{aligned}\|\delta\mathbf{u}-\mathcal{I}_0^h(\delta\mathbf{u})\|_{0,\tau}^2 = \|\delta\mathbf{u}\|_{0,\tau}^2 &\leq \int_\tau r^{2\alpha}r^{-2\alpha}|\mathbf{u}|^2 d\tau \leq ch^{2\alpha}\int_\tau r^{-2\alpha}|\mathbf{u}|^2 d\tau \\ &= ch^{2\alpha}\int_\tau r^{2(\beta-(\alpha+\beta))}|\mathbf{u}|^2 d\tau = ch^{2\alpha}\|\mathbf{u}\|_{0,\beta-(\alpha+\beta),\tau}^2 \leq ch^{2\alpha}\|\mathbf{u}\|_{\alpha+\beta,\beta,\tau}^2. \qquad (5.15)\end{aligned}$$

Substituting (5.13), (5.14), and (5.15) into (5.12) and applying Lemma 5.1 yields

$$\|\mathbf{u}-\mathbf{u}^h\|^2 \leq ch^{2\alpha}\sum_{\tau\in K}\|\mathbf{u}\|_{\alpha+\beta,\beta,\tau}^2 + ch^{2(1-\beta)}\|\mathbf{u}-\mathcal{I}_0^h\mathbf{u}\|_{1,\beta}^2 \leq ch^{2\alpha}\|\mathbf{u}\|_{\alpha+\beta,\beta}. \qquad \square$$

Minimizing the least-squares functional in the weighted norm using H^1-conforming elements and appropriate values of the weight allows the approximate solution to converge. The above theorem also implies optimal L^2-error convergence with H^1-conforming finite elements. In the next section, we consider error bounds using graded mesh refinements.

6. Graded mesh refinement. The paper [4] is one of the earliest papers to examine graded mesh refinement in the context of weighted Sobolev spaces. Following that, many have used similar mesh refinements when weighted Sobolev spaces were

considered to overcome the difficulties associated with singularities (see [2], [3]). In this section we show some error estimate results using graded mesh refinements in our methodology.

Assume $\beta < 1$. For the global mesh parameter, h $(0 < h < 1)$, let $\mathcal{T}_h^m$ be a triangulation of the domain $\overline{\Omega} = \cup_{\tau \in \mathcal{T}_h^m} \tau$, where the diameter, $h_\tau = diam(\tau)$, of each tetrahedron, τ, is defined by

$$h_\tau \sim \begin{cases} h^{\frac{1}{1-\beta}} & \text{if} \quad \tau \cap E \neq \emptyset, \\ h r_\tau^\beta & \text{if} \quad \tau \cap E = \emptyset, \end{cases} \tag{6.1}$$

where $r_\tau = \min\{r = \sqrt{x^2+y^2} : (x,y,z) \in \tau\}$. Define $\mathcal{V}^h$ to be a space of $\mathcal{C}^0$ piecewise polynomials on each finite element satisfying $\mathbf{n} \times \mathbf{v}^h = \mathbf{0}$ on Γ_D and $\mathbf{n} \cdot \mathbf{v}^h = 0$ on Γ_N and let $\mathbf{u}^h$ satisfy

$$G_w(\mathbf{u}^h; f) = \min_{\mathbf{v}^h \in \mathcal{V}^h} G_w(\mathbf{v}^h; f). \tag{6.2}$$

THEOREM 6.1. *Let $\mathbf{u} \in H_\beta^{\alpha+\beta}(\Omega)^3 \cap \mathcal{U}$ and $\mathbf{u}^h \in \mathcal{V}^h$ be the solutions of* (2.3) *and* (6.2)*, respectively. Suppose that $\beta < 1$ and the hypotheses of Lemma* 3.1 *are satisfied. Then,*

$$\|\mathbf{u} - \mathbf{u}^h\| \leq c\ h^{\alpha+\beta} \|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{6.3}$$

where $3/2 < \alpha + \beta \leq k+1$ and k is the degree of the piecewise polynomials in $\mathcal{V}^h$.

Proof. Let $K = \{\tau \in \mathcal{T}_h^m : \tau \cap E \neq \emptyset\}$. By the Cauchy inequality and (6.1), we have

$$\begin{aligned}
\|\mathbf{u} - \mathbf{u}^h\|^2 &= \sum_{\tau \in K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 + \sum_{\tau \in \mathcal{T}_h^m \setminus K} \|\mathbf{u} - \mathbf{u}^h\|_{0,\tau}^2 \\
&\leq \sum_{\tau \in K} c h_\tau^{2(1-\beta)} \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta-1,\tau}^2 + \sum_{\tau \in \mathcal{T}_h^m \setminus K} \left(\int_\tau 1 d\tau \right)^{\frac{2}{3}} \left(\int_\tau |\mathbf{u} - \mathbf{u}^h|^6 d\tau \right)^{\frac{1}{3}} \\
&\leq \sum_{\tau \in K} c h^2 \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta-1,\tau}^2 + \sum_{\tau \in \mathcal{T}_h^m \setminus K} c h_\tau^2 ||\mathbf{u} - \mathbf{u}^h||_{L^6(\tau)}^2 \\
&\leq \sum_{\tau \in K} c h^2 \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta-1,\tau}^2 + \sum_{\tau \in \mathcal{T}_h^m \setminus K} c h^2 ||r^\beta(\mathbf{u} - \mathbf{u}^h)||_{L^6(\tau)}^2. \qquad (6.4)
\end{aligned}$$

The continuous embedding of $H^1(\Omega)$ into $L^6(\Omega)$ and $r^\beta \mathbf{u} \in H^1(\Omega)^3$ leads to

$$\begin{aligned}
\sum_{\tau \in \mathcal{T}_h^m \setminus K} c h^2 ||r^\beta(\mathbf{u} - \mathbf{u}^h)||_{L^6(\tau)}^2 &\leq c h^2 ||r^\beta(\mathbf{u} - \mathbf{u}^h)||_{L^6(\Omega)}^2 \leq c h^2 ||r^\beta(\mathbf{u} - \mathbf{u}^h)||_1^2 \\
&\leq c h^2 ||\mathbf{u} - \mathbf{u}^h||_{1,\beta}^2. \qquad (6.5)
\end{aligned}$$

We define $\mathcal{I}_0^h$ in the same manner as in section 5 on each element $\tau \in \mathcal{T}_h^m$. Then, a calculation analogous to the proof of Lemma 5.1 yields

$$\begin{aligned}
\|\mathbf{u} - \mathcal{I}_0^h \mathbf{u}\|_{1,\beta} &\leq c h^{\alpha+\beta-1} |\mathbf{u}|_{\alpha+\beta,(\alpha+\beta)\beta} + c h^{\frac{\alpha+\beta-1}{1-\beta}} \|\mathbf{u}\|_{\alpha+\beta,\beta} \\
&= c h^{\alpha+\beta-1} \left(|\mathbf{u}|_{\alpha+\beta,(\alpha+\beta)\beta} + c h^{\frac{\alpha+\beta-1}{1-\beta}\beta} \|\mathbf{u}\|_{\alpha+\beta,\beta} \right). \qquad (6.6)
\end{aligned}$$

In (6.6), since $r^{(\alpha+\beta)\beta} < r^{\beta}$ and $h^{\frac{\alpha+\beta-1}{1-\beta}\beta} < 1$, we have

$$\|\mathbf{u} - \mathcal{I}_0^h \mathbf{u}\|_{1,\beta} \leq c h^{\alpha+\beta-1} \|\mathbf{u}\|_{\alpha+\beta,\beta}. \tag{6.7}$$

Since $\mathbf{u}^h$ is the minimizer of (6.2), Theorem 3.4 and the triangle inequality yield

$$\|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} \leq c\|L(\mathbf{u} - \mathbf{u}^h)\|_{0,\beta} \leq c\|L(\mathbf{u} - \mathcal{I}_0^h \mathbf{u})\|_{0,\beta} \leq c\|\mathbf{u} - \mathcal{I}_0^h \mathbf{u}\|_{1,\beta}. \tag{6.8}$$

Therefore, (6.4), (6.5), (6.8), and (6.7) imply the error bound (6.3). ∎

In section 5, we demonstrated optimal L^2-error convergence. Now, the above theorem shows that graded mesh refinement provides faster L^2-convergence by doing extra work around the singular area. Graded mesh refinement does the same work locally so that the finer mesh helps the order of convergence. However, in this paper, we want to observe the error convergence without any mesh refinement. Therefore, in the following section, we present numerical tests on uniform grids.

7. Computational results. In this section, we present some numerical examples. By minimizing the weighted-norm least-squares functional, we verify the optimal error convergence given in section 5. As mentioned in the introduction, if the internal angle of the edge, ω, is bigger than π or different types of boundary conditions meet at an edge with the internal angle bigger than $\pi/2$, then the boundary singularities occur. Thus, the solution of the Poisson equation is in H^{1+s}, where $s < \pi/\omega$ if the problem has Dirichlet or Neumann boundary conditions at a reentrant edge or $s < \pi/(2\omega)$ if Dirichlet and Neumann boundary conditions meet at an edge with inner angle ω [17]. Here, we construct our test problems based on the leading term of the singular part of the solution of Poisson's equation.

The software package FOSPACK (cf. [30]) was used to build the discrete system and to solve it by a conjugate gradient iterative method preconditioned by algebraic multigrid using W(1,1)-cycles. The stopping criterion for the iteration was a residual reduction 10^{-8}. This unnecessarily large reduction was used to remove the algebraic error from the calculation of the convergence of the discrete solution. No graded mesh refinement is applied.

The domain of Examples 7.1 and 7.2 is an L-shaped polyhedral cylinder:

$$\Omega = (-0.5, 0.5) \times (-0.5, 0.5) \times (0, 1) \backslash [0, 0.5) \times (-0.5, 0] \times (0, 1).$$

Example 7.1. We choose $\mathbf{u} = \nabla p$, where p has the form

$$p = \delta(r) r^{\frac{2}{3}} \sin(2\theta/3) \sin(\pi z)$$

in the cylindrical coordinate system with $\delta(r)$ a smooth cut-off function satisfying $\delta(r) = 1$ when $r \leq 0.25$ and $\delta(r) = 0$ when $r \geq 0.375$, and choose f by Δp. Then, p satisfies

$$\Delta p = f \quad \text{in } \Omega \tag{7.1}$$

with $p = 0$ on $\partial\Omega$, and $\mathbf{u} \in H^{\frac{2}{3}}(\Omega)^3$ satisfies

$$\nabla \times \mathbf{u} = \mathbf{0}, \quad \nabla \cdot \mathbf{u} = f \quad \text{in } \Omega \tag{7.2}$$

$$\mathbf{n} \times \mathbf{u} = \mathbf{0} \quad \text{on } \partial\Omega. \tag{7.3}$$

TABLE 7.1
Example 1 *with* $\beta = 4/3$.

	$\|\|\mathbf{u}-\mathbf{u}^h\|\|$		$\|\|\mathbf{u}-\mathbf{u}^h\|\|_{0,\beta}$		$\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta}$	
1/8	2.398e-01	rates	3.734e-02	rates	7.775e-01	rates
1/16	1.074e-01	1.16	1.252e-02	1.58	2.223e-01	1.81
1/32	5.532e-02	0.96	3.116e-03	2.01	6.177e-02	1.85
1/64	3.350e-02	0.72	7.891e-04	1.98	1.875e-02	1.72
1/128	2.098e-02	0.68	1.978e-04	2.00	6.855e-03	1.45

It is easy to see that $\mathbf{u}$ in the above example is not in $H^1(\Omega)^3$. Since $\alpha = 2/3$ in this case, our theory holds for any β between 5/6 and 5/3. Here, we choose $\beta = 4/3$ so that $3/2 < \alpha + \beta = 2$ and observe the errors in L^2-, weighted L^2-, and weighted H^1-norms in Table 7.1. The error estimates in Theorem 5.3 predict the asymptotic L^2-error convergence rate to be approximately $O(h^{\frac{2}{3}})$ and the weighted L^2- and weighted H^1-rates at $O(h^2)$ and $O(h)$, respectively. We report the numbers in Table 7.1 to support our theory. The convergence rate of the weighted H^1-seminorm in Table 7.1 shows better convergence than expected at the resolution we are able to compute. However, based on two dimensional test results, it is likely that on increasingly fine meshes the asymptotic rate will approach what theory predicted.

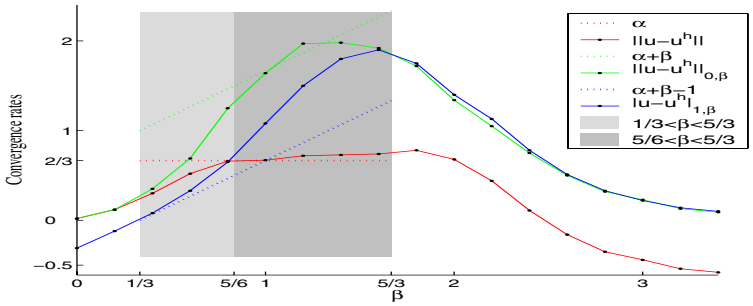

FIG. 7.1. *Finite element convergence rate as a function of* β *for Example* 7.1.

In Figure 7.1, we present the results with more β values when mesh size decreases from 1/64 to 1/128. It shows that the errors in L^2- and weighted H^1-norms behave as expected and better than expected for weighted L^2-norm errors. The darker shaded region is the area where Theorem 5.3 holds.

Example 7.2. In this example, we choose $\mathbf{u} = \nabla p$ and $f = \Delta p$, where

$$p = \delta(r) r^{\frac{2}{3}} \cos(2\theta/3) \cos(\pi z)$$

with the same smooth cut-off function, $\delta(r)$, defined in Example 7.1. Then, p satisfies a Poisson problem with Neumann boundary condition, that is, (7.1) with $\mathbf{n} \cdot \nabla p = 0$ on $\partial\Omega = \Gamma_N$, and $\mathbf{u} \in H^{\frac{2}{3}}(\Omega)^3$ satisfies (7.2) but with $\mathbf{n} \cdot \mathbf{u} = 0$ on $\partial\Omega$.

Example 7.2 is similar to Example 7.1 but with a different type of boundary condition. The range of β satisfying Theorem 5.3 is the interval $(5/6, 1)$, but numerical tests show that $\beta = 1$ gives the best convergence results. Here, we report the numerical results with $\beta = 1$ (see Table 7.2). With $\beta = 1$, we expect the L^2-, weighted L^2-, and weighted H^1-error convergence rates to be approximately $O(h^{\frac{2}{3}})$, $O(h^{\frac{5}{3}})$, and $O(h^{\frac{2}{3}})$, respectively. Figure 7.2 shows behavior similar to Figure 7.1 when the mesh h moves from 1/64 to 1/128. It shows that the convergence rates follow the theory for awhile after β becomes bigger than 1, but soon the rates break down. As briefly mentioned

Example 3 *with* $\beta = 1.4$.

	$\|\|\mathbf{u}-\mathbf{u}^h\|\|$		$\|\|\mathbf{u}-\mathbf{u}^h\|\|_{0,\beta}$		$\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta}$	
1/6	3.702E-01	rates	3.332E-02	rates	6.694E-01	rates
1/12	1.168E-01	1.66	1.106E-02	1.59	2.608E-01	1.36
1/24	6.542E-02	0.84	3.553E-03	1.64	7.157E-02	1.87
1/48	4.447E-02	0.56	8.975E-04	1.99	2.213E-02	1.69
1/96	3.125E-02	0.51	2.301E-04	1.96	8.405E-03	1.40
1/192	2.204E-02	0.50	6.179E-05	1.90	3.975E-03	1.08

in Remark 3.2, the restriction on β is sufficient, and Figure 7.2 shows the possibility that the bounds hold beyond the restriction. However, again, we do not address that issue here.

As the last example, we introduce mixed boundary conditions and the domain $\Omega = (-0.5, 0.5) \times (0, 0.5) \times (0, 0.5)$.

Example 7.3. Let $\mathbf{u} = \nabla p$ and $f = \Delta p$, where p has the form

$$p = \delta(r) r^{\frac{1}{2}} \sin(\theta/2) \sin(2\pi z).$$

Then, $\mathbf{u} \in H^{\frac{1}{2}}(\Omega)^3$ satisfies (7.2) and boundary conditions

$$\mathbf{n} \cdot \mathbf{u} = 0 \quad \text{on } \Gamma_N = \{(r, \theta, z) \in \partial\Omega : \theta = \pi\},$$
$$\mathbf{n} \times \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D = \partial\Omega \backslash \Gamma_N.$$

In Example 7.3, different types of boundary conditions meet at an edge with inner angle π. Still, boundary singularity occurs along this edge, since the internal angle is bigger than $\pi/2$. In this case, the condition $1 < \beta < 3/2$ guarantees that Theorem 5.3 holds. According to Theorem 5.3, asymptotic convergence rates are $O(h^{\frac{1}{2}})$ for L^2-error, $O(h^{\frac{1}{2}+\beta})$ for weighted L^2-error, and $O(h^{\beta-\frac{1}{2}})$ for weighted H^1-error. Table 7.3 shows the error convergence in L^2-, weighted L^2-, and weighted H^1-norms with

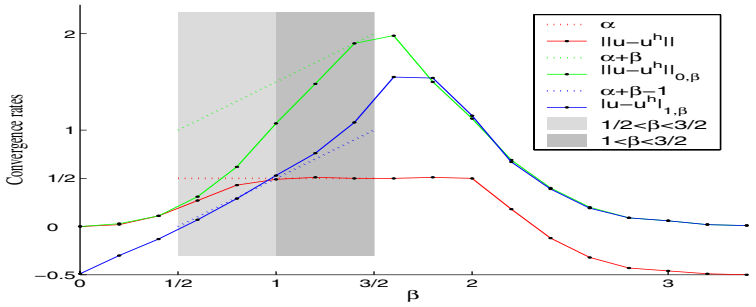

FIG. 7.3. *Finite element convergence rate as a function of* β *for Example* 7.3.

$\beta = 1.4$, where $3/2 < 1/2 + \beta$. In Figure 7.3, the results with more β values when mesh size decreases from 1/96 to 1/192 are presented.

8. Conclusion. Low regularity of the solution caused by singularities on the boundary usually precludes the use of H^1-conforming finite elements in the standard L^2 FOSLS functional. To overcome these difficulties, we use weighted norms in the least-squares functional. This is based on the idea of unweighting the area where the singularity occurs by multiplying by the weight functions. In this paper, we showed that minimization of the least-squares functional in the weighted norm allows us to approximately solve the div/curl system in H^1-conforming finite element spaces with optimal error convergence in L^2-, weighted L^2-, and weighted H^1-norms without using graded mesh refinement. Here, we focused on the case when we have one singular edge. However, in the case when we have several singular edges, we can have the weight function be multi-indexed with r^β at any edge, giving a vector $\beta = (\beta_1, \beta_2, \ldots, \beta_m)$, for a domain with m edges with each of them having inner angle $> \pi/2$. In this paper, we assumed an appropriate weight at each edge and assumed that the analysis is simpler to consider as a "local" result, the way we do to generalize.

A WEIGHTED $H(\mathrm{div})$ LEAST-SQUARES METHOD FOR SECOND-ORDER ELLIPTIC PROBLEMS*

Z. CAI† AND C. R. WESTPHAL‡

Abstract. This paper presents analysis of a weighted-norm least squares finite element method for elliptic problems with boundary singularities. We use $H(\mathrm{div})$ conforming Raviart–Thomas elements and continuous piecewise polynomial elements. With only a rough estimate of the power of the singularity, we employ a simple, locally weighted L^2 norm to eliminate the pollution effect and recover better rates of convergence. Theoretical results are carried out in weighted Sobolev spaces and include ellipticity bounds of the homogeneous least-squares functional, new weighted Raviart–Thomas interpolation results, and error estimates in both weighted and nonweighted norms. Numerical tests are given to confirm the theoretical estimates and to illustrate the practicality of the method

Key words. boundary singularities, least squares, finite element methods, weighted Sobolev spaces

1. Introduction.

The loss of regularity of second-order partial differential equations at corners/edges of polygonal/polyhedral domains is well known. Numerical methods for approximating solutions to these problems often suffer either reduced rates of accuracy or loss of convergence due to the nonsmooth solutions. For finite element methods, the rate of convergence generally depends on both the smoothness of the solution and the approximation properties of the finite element space used. When the rates are diminished due to these boundary singularities, standard rates of convergence can only be recovered with care.

In this paper we present a weighted-norm least-squares method for scalar elliptic problems of the form

$$\begin{cases} -\nabla \cdot A\nabla u + \mathbf{b} \cdot \nabla u + cu = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where A is symmetric, positive definite and $\mathbf{b}$ and c are smooth, bounded functions. For the analysis in this paper we assume homogeneous Dirichlet boundary conditions, though the method may easily be applied to other boundary conditions. It is well known that if Ω is a polygonal/polyhedral domain in $\mathbb{R}^2/\mathbb{R}^3$, then the regularity of system (1.1) may be limited by the geometry of Ω. To illustrate, assume that $\Omega \subseteq \mathbb{R}^2$ has one reentrant corner, which has interior angle ω, and (r, θ) are polar coordinates centered at the corner. For $f \in L^2(\Omega)$, solutions to (1.1) may be decomposed by

$$u = \tilde{u} + r^{\lambda} w,$$

where $\tilde{u} \in H^2(\Omega)$ is the smooth component of u, and $r^\lambda w \in H^{\alpha+1}(\Omega)$ for $\alpha < \lambda$ is the singular component. The function $w = w(\theta)$ and parameter α are characteristic of the operator and the domain. For Poisson's equation the singular functions are multiples of $r^{\pi/\omega}\sin(\pi\theta/\omega)$. Edge singularities in $\mathbb{R}^3$ may be considered analogously, where $w = w(\theta, z)$.

The least-squares finite element approach for a variety of problems affords several unique features. Among these is the freedom to independently choose finite element spaces for different unknowns. In [5], system (1.1) is reformulated as a first-order system by introducing the flux variable $\boldsymbol{\sigma} = -A\nabla u$, and $(u, \boldsymbol{\sigma}) \in H^1 \times H(\mathrm{div})$ are approximated using piecewise polynomial and $H(\mathrm{div})$-conforming Raviart–Thomas elements. See also [4, 9] for results concerning least-squares minimization of this system. For polygonal/polyhedral domains this method results in $O(h^\alpha)$ approximations, even for smooth data or higher-order approximation spaces. Thus, for problems with $\alpha < 1$, the convergence is suboptimal. Moreover, the reduction in convergence rate is generally a global effect—that is, convergence throughout the entire domain is suboptimal. This well-known *pollution effect* is also seen in Galerkin discretizations as well as in div-curl least-squares formulations. We overcome this difficulty by minimizing an appropriately weighted functional. Our approach eliminates the pollution effect with only a trivial modification of the equations, requires only crude a priori knowledge of the power of the singularity (not the singular function itself), and can be used in conjunction with adaptive mesh refinement. A least-squares formulation provides a natural error estimator that can be used in an adaptive mesh refinement strategy. We note that, while many problems are effectively treated with only mesh refinement near boundary singularities, some problems admit solutions much less smooth than considered here. If the approximation space used is not dense in the solution space, then global errors may persist, despite any amount of mesh refinement. In these cases, a weighted-norm method in the spirit of this paper can be effectively used to recover convergence, allowing mesh refinement to be much less aggressive.

In [6], Cox and Fix use a weighted-norm approach similar to our approach, but achieve optimal convergence with continuous P_1 finite elements and specialized graded meshes. In [10, 11], the weighted-norm least-squares approach is presented for div-curl functionals in two and three dimensions. An aggressive weighting is used to recover optimal convergence without relying on mesh refinement. In this paper, using mixed affine finite element spaces allows a less aggressive weighting to achieve optimal results, even with uniform meshes.

The organization of this paper is as follows. We define notation and detail the problem formulation in section 2. In section 3, we show equivalence of the homogeneous least-squares functional to an appropriate weighted norm, present new interpolation bounds for Raviart–Thomas finite element spaces in weighted norms, and show the resulting error bounds. Numerical results are given in section 4 that confirm the theoretical error estimates and demonstrate the practicality of the method.

2. Problem formulation. We use standard notation for the L^2 norm, $\|\cdot\|$, and inner product, $\langle\cdot,\cdot\rangle$, and use $\|\cdot\|_{k;\Omega}$ to denote the norm corresponding to the Sobolev space $H^k(\Omega)^d$, omitting subscript Ω and superscript d when the domain and dimension are clear by context. For noninteger k, $H^k(\Omega)$ represents the standard interpolation space.

For this paper, we assume that Ω is a bounded domain in $\mathbb{R}^d$, $d = 2, 3$, with one boundary corner in $\mathbb{R}^2$ or one boundary edge in $\mathbb{R}^3$ that admits a singularity with $\alpha < 1$. Assume further that this singular point is located at the origin for $d = 2$ or

along the z-axis for $d = 3$, and denote this part of $\partial\Omega$ by $\mathcal{E}$. For simplicity, we consider only one singular point although techniques here may be applied locally to more than one singular point. In section 4 we discuss practical implementation in such cases.

Define the weighted Sobolev norm by

$$\|v\|_{k,\beta;\Omega} = \left(\sum_{|j|\le k} \|r^{\beta-k+|j|} D^j v\|_{0;\Omega}^2 \right)^{1/2}$$

and seminorm by

$$|v|_{k,\beta;\Omega} = \left(\sum_{|j|=k} \|r^{\beta} D^j v\|_{0;\Omega}^2 \right)^{1/2}.$$

For $k = 0$, 1, we have

$$\|v\|_{0,\beta;\Omega} = \|r^{\beta} v\|_{0;\Omega}, \quad \|v\|_{1,\beta;\Omega} = \left(\|r^{\beta}\nabla v\|_{0;\Omega}^2 + \|r^{\beta-1} v\|_{0;\Omega}^2 \right)^{1/2},$$
$$\text{and} \quad |v|_{1,\beta;\Omega} = \|r^{\beta}\nabla v\|_{0;\Omega}.$$

Then the weighted Sobolev space $H_{\beta}^{k}(\Omega)$ is defined by

$$H_{\beta}^{k}(\Omega) = \{v \in L^2(\Omega) : \|v\|_{k,\beta;\Omega} < +\infty\}.$$

The dual spaces are defined by duality in the natural way. Let

$$D_{-\beta}^{1} = \{v \in H_{-\beta}^{1}(\Omega) : v = 0 \text{ on } \partial\Omega\},$$

and define its dual, $H_{\beta}^{-1}(\Omega)$, by the norm

$$\|v\|_{-1,\beta} = \sup_{\phi \in D_{-\beta}^{1}} \frac{\langle v, \phi\rangle}{\|\phi\|_{1,-\beta}}.$$

By introducing the new unknown $\boldsymbol{\sigma} = -A\nabla u$ and denoting the lower-order terms by $Xu = \mathbf{b}\cdot\nabla u + cu$, we may expand system (1.1) to the first-order system

$$\begin{cases} \boldsymbol{\sigma} + A\nabla u = 0 & \text{in } \Omega, \\ \nabla\cdot\boldsymbol{\sigma} + Xu = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

In this paper, we consider the weighted least-squares functional

$$G(u, \boldsymbol{\sigma}; f) = \|A^{-1/2}(\boldsymbol{\sigma} + A\nabla u)\|_{0,\beta_1}^2 + \|\nabla\cdot\boldsymbol{\sigma} + Xu - f\|_{0,\beta_2}^2 \tag{2.2}$$

for functions $(u, \boldsymbol{\sigma}) \in \mathcal{V}\times\mathcal{W}$, where

$$\mathcal{V} = \{v \in H_{\beta_1}^{1}(\Omega) : v = 0 \text{ on } \partial\Omega\}$$

and

$$\mathcal{W} = \{\boldsymbol{\tau} : r^{\beta_1}\boldsymbol{\tau} \in L^2(\Omega),\ r^{\beta_2}\nabla\cdot\boldsymbol{\tau} \in L^2(\Omega)\}.$$

The nonweighted functional (i.e., $\beta_1 = \beta_2 = 0$) yields less-than-optimal global discretization rates for problems with $\alpha < 1$. We thus investigate appropriate values for β_1 and β_2 to recover better rates of convergence and eliminate the pollution effect.

The least-squares minimization problem is to find $(u, \boldsymbol{\sigma}) \in \mathcal{V} \times \mathcal{W}$ such that

$$G(u, \boldsymbol{\sigma}; f) = \inf_{(v,\boldsymbol{\tau}) \in \mathcal{V} \times \mathcal{W}} G(v, \boldsymbol{\tau}; f).$$

It may be noted that the minimization above is equivalent to the symmetric variational problem of finding $(u, \boldsymbol{\sigma}) \in \mathcal{V} \times \mathcal{W}$ such that

$$b(u, \boldsymbol{\sigma}; v, \boldsymbol{\tau}) = f(v, \boldsymbol{\tau}) \qquad \forall\ (v, \boldsymbol{\tau}) \in \mathcal{V} \times \mathcal{W},$$

where the bilinear and linear forms are given by

$$b(u, \boldsymbol{\sigma}; v, \boldsymbol{\tau}) := \langle r^{2\beta_1} A^{-1}(\boldsymbol{\sigma} + A\nabla u), \boldsymbol{\tau} + A\nabla v \rangle + \langle r^{2\beta_2}(\nabla \cdot \boldsymbol{\sigma} + Xu), \nabla \cdot \boldsymbol{\tau} + Xv \rangle$$

and

$$f(v, \boldsymbol{\tau}) := \langle r^{2\beta_2} f, \nabla \cdot \boldsymbol{\tau} + Xv \rangle.$$

Let $\mathcal{T}_h$ be a regular affine triangulation of Ω with a meshsize of $O(h)$, where on element K we denote $h_K = diam(K)$. Denote by $P_k(K)$ the standard space of polynomials of degree $\leq k$ on element K, and consider the Raviart–Thomas space of degree k on element K defined by

$$RT_k(K) = P_k(K)^d + \mathbf{x} P_k(K),$$

where $\mathbf{x} = (x_1, \ldots, x_d)^t$. For this paper we define the spaces

$$\mathcal{V}^h = \{v \in \mathcal{V} \cap C^0(\Omega) : v|_K \in P_1(K)\ \forall\ K \in \mathcal{T}_h\},$$

$$\mathcal{W}^h = \{\boldsymbol{\tau} \in \mathcal{W} : \boldsymbol{\tau}|_K \in RT_0(K)\ \forall\ K \in \mathcal{T}_h\}.$$

The discrete minimization problem is to find $(u^h, \boldsymbol{\sigma}^h) \in \mathcal{V}^h \times \mathcal{W}^h$ such that

$$G(u^h, \boldsymbol{\sigma}^h; f) = \min_{(v^h,\boldsymbol{\tau}^h) \in \mathcal{V}^h \times \mathcal{W}^h} G(v^h, \boldsymbol{\tau}^h; f).$$

This leads to a symmetric, positive definite linear system of equations that can be efficiently solved by standard multigrid methods.

3. Theory. In the following analysis, we assume that A is a $d \times d$ matrix of functions in $L^2(\Omega)$ and that $\mathbf{b}$ and c are smooth, bounded functions. We further assume that A is uniformly symmetric positive definite; that is, there exist positive constants λ_1 and λ_2 such that

$$\lambda_1 \boldsymbol{\xi}^T \boldsymbol{\xi} \leq \boldsymbol{\xi}^T A \boldsymbol{\xi} \leq \lambda_2 \boldsymbol{\xi}^T \boldsymbol{\xi} \tag{3.1}$$

for all $\boldsymbol{\xi} \in \mathbb{R}^d$ and almost all $\boldsymbol{\xi} \in \overline{\Omega}$. Under an ellipticity assumption on the operator for problem (1.1), a general regularity result for second-order problems is established in [1]. We state here an H^1_β estimate sufficient for our purposes.

THEOREM 3.1. *Assume that the operator $L := -\nabla \cdot A\nabla + X$ satisfies the assumptions of Theorem* 5.2 *in* [1] *and that $f \in H^{-1}_\beta(\Omega)$. Then there exists some $\alpha > 0$ such that problem* (1.1) *admits the estimate*

$$\|u\|_{1,\beta} \leq C \|f\|_{-1,\beta}$$

for any $|\beta| < \alpha$. In general, α depends on the operator and domain. If $L = -\Delta$, then $\alpha = \pi/\omega$, where ω is the interior angle at $\mathcal{E}$.

Proof. See Theorem 5.4 in [1]. ∎

We note that values for α are considered in the classic works [7, 8]. In [12], values for α are explicitly shown to satisfy $\alpha \geq 1/2$ for the Stokes and elasticity systems. In general, the value of α for Poisson's equation serves as an upper bound for second-order problems on similar geometries. While the method described in this paper is based on the value of α for the operator of the problem, we note that the exact value of α need not be known for the method to be effective.

Let $\mathcal{I}^h$ be the standard interpolation operator onto $P_k(K)$, where, for all $v \in H^m(K)$,

$$\|v - \mathcal{I}^h v\|_{s;K} \leq C h_K^{m-s} |v|_{m;K} \tag{3.2}$$

holds for $0 \leq s \leq m$ and $1 < m \leq k+1$. A proof of this classical result can be found in [2].

Define the modified interpolation operator, $\mathcal{I}_0^h$, by

$$\mathcal{I}_0^h v|_K = \begin{cases} \mathcal{I}^h v|_K & \text{if } \overline{K} \cap \mathcal{E} = \emptyset, \\ \displaystyle\sum_{a_i \notin \mathcal{E}} v(a_i)\phi_i & \text{if } \overline{K} \cap \mathcal{E} \neq \emptyset, \end{cases}$$

where a_i are the nodal points corresponding to the basis functions, ϕ_i. Thus, the modified interpolation has a value of zero at $\mathcal{E}$ and is identical to $\mathcal{I}^h$ away from $\mathcal{E}$. From [10, 11], if $\beta > 0$, then $\mathcal{I}_0^h$ satisfies

$$\sum_{K \in \mathcal{T}_h} \|v - \mathcal{I}_0^h v\|_{1,\beta;K}^2 \leq C h^2 \|v\|_{2,\beta}^2 \tag{3.3}$$

for $v \in H_\beta^2(\Omega)$.

Let I^h be the standard interpolation operator from $H(\mathrm{div}) \cap L^p(\Omega)$ onto RT_k with $p > 2$. Then the following approximation properties of RT_k hold (see, e.g., [3]) for any $\boldsymbol{\tau} \in (H^m(K))^d$ with $1 \leq m \leq k+1$:

$$\|\boldsymbol{\tau} - I^h \boldsymbol{\tau}\|_{s;K} \leq C h_K^{m-s} |\boldsymbol{\tau}|_{m;K} \quad \text{with} \quad s = 0,\ 1, \tag{3.4}$$

and

$$\|\nabla \cdot (\boldsymbol{\tau} - I^h \boldsymbol{\tau})\|_{0;K} \leq C h_K^m |\nabla \cdot \boldsymbol{\tau}|_{m;K} \tag{3.5}$$

if $\nabla \cdot \boldsymbol{\tau} \in H^m(K)$. For any $\boldsymbol{\tau} \in (H^\alpha(K))^d$ and $\nabla \cdot \boldsymbol{\tau} \in H^\alpha(K)$ with $\alpha < 1$, we assume the following approximation properties:

$$\|\boldsymbol{\tau} - I^h \boldsymbol{\tau}\| \leq C h^{\tilde{\alpha}} |\boldsymbol{\tau}|_\alpha \tag{3.6}$$

and

$$\|\nabla \cdot (\boldsymbol{\tau} - I^h \boldsymbol{\tau})\| \leq C h^{\tilde{\alpha}} |\nabla \cdot \boldsymbol{\tau}|_\alpha \tag{3.7}$$

hold for some constant $\tilde{\alpha} \in (0, \alpha]$.

THEOREM 3.2. *Assume that $\nabla \cdot \boldsymbol{\tau}$ and each $\boldsymbol{\tau}_j$ are in $H_\beta^1(\Omega) \cap H^\alpha(\Omega)$. Then for any $\beta \geq 0$, there exists a positive constant C such that*

$$\|\boldsymbol{\tau} - I^h \boldsymbol{\tau}\|_{0,\beta} \leq C h^{m_1} \left(|\boldsymbol{\tau}|_{1,\beta} + |\boldsymbol{\tau}|_\alpha\right) \tag{3.8}$$

and that

$$\|\nabla\cdot(\boldsymbol{\tau}-I^h\boldsymbol{\tau})\|_{0,\beta}\le Ch^{m_2}\left(|\nabla\cdot\boldsymbol{\tau}|_{1,\beta}+|\nabla\cdot\boldsymbol{\tau}|_{\alpha}\right), \tag{3.9}$$

where $m_1=\min\{1,\beta+\tilde{\alpha}\}$, $m_2=\min\{1,\beta+\alpha\}$, *and* C *depends only on* k, β, *and the shape of* Ω.

Proof. We first prove the bound in (3.8). Note that (3.4) and (3.5) apply since $\boldsymbol{\tau}$ is smooth enough to be in the domain of I^h. Denote the set of elements adjacent to $\mathcal{E}$ by

$$\mathcal{K}_0=\{K\in\mathcal{T}_h:\overline{K}\cap\mathcal{E}\neq\emptyset\}.$$

For any element $K\in\mathcal{T}_h\backslash\mathcal{K}_0$, we note that $\boldsymbol{\tau}\in H^1(K)$ and that

$$\frac{1}{c_K}h_K\le r_{\min}\le r\le r_{\max}\le r_{\min}+c_Kh_K, \tag{3.10}$$

where $r_{\min}$ and $r_{\max}$ are the minimum and maximum distances from K to $\mathcal{E}$, respectively, and c_K depends only on d and the shape of K (e.g., $c_K=\sqrt{d}$ for a uniform mesh). Inequality (3.10) implies

$$\frac{r_{\max}}{r_{\min}}\le 1+c_K^2.$$

Now, it follows from (3.10) and (3.4) with $m=1$ and $s=0$ that

$$\begin{aligned}\|\boldsymbol{\tau}-I^h\boldsymbol{\tau}\|_{0,\beta;K}&=\|r^{\beta}(\boldsymbol{\tau}-I^h\boldsymbol{\tau})\|_{0;K}\le r_{\max}^{\beta}\|\boldsymbol{\tau}-I^h\boldsymbol{\tau}\|_{0;K}\\&\le Cr_{\max}^{\beta}h_K|\boldsymbol{\tau}|_{1;K}\le Cr_{\max}^{\beta}h_K\|(r/r_{\min})^{\beta}\nabla\boldsymbol{\tau}\|_{0;K}\\&=C\left(\frac{r_{\max}}{r_{\min}}\right)^{\beta}h_K|\boldsymbol{\tau}|_{1,\beta;K}=Ch_K|\boldsymbol{\tau}|_{1,\beta;K}.\end{aligned} \tag{3.11}$$

For any element $K\in\mathcal{K}_0$, it follows from the fact that $r\le h_K$ and (3.4) that

$$\begin{aligned}\|\boldsymbol{\tau}-I^h\boldsymbol{\tau}\|_{0,\beta;K}&=\|r^{\beta}(\boldsymbol{\tau}-I^h\boldsymbol{\tau})\|_{0;K}\le h_K^{\beta}\|\boldsymbol{\tau}-I^h\boldsymbol{\tau}\|_{0;K}\\&\le Ch_K^{\beta+\tilde{\alpha}}|\boldsymbol{\tau}|_{\alpha;K},\end{aligned}$$

which, together with (3.11), yields the bound in (3.8).

To prove (3.9), we first consider $K\in\mathcal{T}_h\backslash\mathcal{K}_0$. A calculation identical to (3.11) using (3.5) with $m=1$ gives

$$\|\nabla\cdot(\boldsymbol{\tau}-I^h\boldsymbol{\tau})\|_{0,\beta;K}\le Ch_K|\nabla\cdot\boldsymbol{\tau}|_{1,\beta;K}. \tag{3.12}$$

Now consider $K\in\mathcal{K}_0$. Let Π^h be the L^2-projection onto discontinuous piecewise polynomial of degree k. Working with affine elements allows the use of the well-known commutativity property,

$$\nabla\cdot(I^h\boldsymbol{\tau})=\Pi^h\nabla\cdot\boldsymbol{\tau}.$$

This, (3.5), and the approximation property of Π^h give

$$\begin{aligned}\|\nabla\cdot(\boldsymbol{\tau}-I^h\boldsymbol{\tau})\|_{0,\beta;K}&=\|(I-\Pi^h)\nabla\cdot\boldsymbol{\tau}\|_{0,\beta;K}\\&\le h_K^{\beta}\|(I-\Pi^h)\nabla\cdot\boldsymbol{\tau}\|_{0;K}\\&\le Ch_K^{\beta+\alpha}|\nabla\cdot\boldsymbol{\tau}|_{\alpha;K}.\end{aligned}$$

This and (3.12) lead to the bound in (3.9). The proof of the theorem is now complete. ∎

LEMMA 3.3. *If $\beta \le \gamma$, then*

$$\|\phi\|_{0,\gamma} \le C\,\|\phi\|_{0,\beta} \quad \forall\ \phi \in H^0_\beta(\Omega). \tag{3.13}$$

Proof. Let $\Omega_1 = \Omega \cap \{r < 1\}$. For $r < 1$, since $r^\gamma \le r^\beta$, we then have

$$\|\phi\|_{0,\gamma;\Omega_1} = \|r^\gamma \phi\|_{0;\Omega_1} \le \|r^\beta \phi\|_{0;\Omega_1} = \|\phi\|_{0,\beta;\Omega_1}.$$

Now, (3.13) is a direct consequence of the fact that $\|\phi\|_{0,\gamma;\Omega_2} \le C\,\|\phi\|_{0,\beta;\Omega_2}$, where $\Omega_2 = \Omega \setminus \overline{\Omega}_1$. ∎

The following theorem establishes equivalence of $G(u,\boldsymbol{\sigma};0)^{1/2}$ to the norm

$$|||(u,\boldsymbol{\sigma})|||_{\beta_1,\beta_2} := \left(\|u\|^2_{1,\beta_1} + \|\boldsymbol{\sigma}\|^2_{0,\beta_1} + \|\nabla\cdot\boldsymbol{\sigma}\|^2_{0,\beta_2}\right)^{1/2}.$$

Since $G(u^h,\boldsymbol{\sigma}^h;f) = G(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h;0)$, this equivalence implies that minimizing the functional is equivalent to minimizing the error in this natural norm.

THEOREM 3.4. *For $\beta_1 \le \beta_2 \le \beta_1 + 1$ and $|\beta_1| < \alpha$, there exist positive constants c_0 and c_1 such that*

$$c_0|||(u,\boldsymbol{\sigma})|||^2_{\beta_1,\beta_2} \le G(u,\boldsymbol{\sigma};0) \le c_1|||(u,\boldsymbol{\sigma})|||^2_{\beta_1,\beta_2} \tag{3.14}$$

for all $(u,\boldsymbol{\sigma}) \in \mathcal{V}\times\mathcal{W}$.

Proof. We first recall the definition of the homogeneous functional

$$G(u,\boldsymbol{\sigma};0) = \|A^{-1/2}(\boldsymbol{\sigma} + A\nabla u)\|^2_{0,\beta_1} + \|\nabla\cdot\boldsymbol{\sigma} + Xu\|^2_{0,\beta_2}.$$

Since $\beta_1 - 1 < \beta_1 \le \beta_2$, (3.13) with the respective $\phi = \nabla u$, $\beta = \beta_1$, $\gamma = \beta_2$ and $\phi = u$, $\beta = \beta_1 - 1$, $\gamma = \beta_2$ implies

$$\|\nabla u\|_{0,\beta_2} + \|u\|_{0,\beta_2} \le C\ (\|\nabla u\|_{0,\beta_1} + \|u\|_{0,\beta_1-1}) = C\,\|u\|_{1,\beta_1}. \tag{3.15}$$

These, together with the triangle inequality and the assumptions on A and X, prove the validity of the upper bound in (3.14).

For the lower bound in (3.14), since $|\beta_1| < \alpha$, Theorem 3.1 with $\beta = \beta_1$ and the triangle inequality gives

$$\begin{aligned} \|u\|_{1,\beta_1} &\le C\|-\nabla\cdot A\nabla u + Xu\|_{-1,\beta_1} \\ &\le C(\|\nabla\cdot\boldsymbol{\sigma} + \nabla\cdot A\nabla u\|_{-1,\beta_1} + \|\nabla\cdot\boldsymbol{\sigma} + Xu\|_{-1,\beta_1}). \end{aligned} \tag{3.16}$$

We consider each term on the right side above separately. For the first term, integration by parts and the Cauchy–Schwarz inequality give

$$\begin{aligned} \|\nabla\cdot\boldsymbol{\sigma} + \nabla\cdot A\nabla u\|_{-1,\beta_1} &= \sup_{\phi\in D^1_{-\beta_1}} \frac{\langle\nabla\cdot(\boldsymbol{\sigma} + A\nabla u),\phi\rangle}{\|\phi\|_{1,-\beta_1}} \\ &= \sup_{\phi\in D^1_{-\beta_1}} \frac{\langle -r^{\beta_1}(\boldsymbol{\sigma} + A\nabla u), r^{-\beta_1}\nabla\phi\rangle}{\|\phi\|_{1,-\beta_1}} \\ &\le \|r^{\beta_1}(\boldsymbol{\sigma} + A\nabla u)\| \sup_{\phi\in D^1_{-\beta_1}} \frac{\|\nabla\phi\|_{0,-\beta_1}}{\|\phi\|_{1,-\beta_1}} \\ &\le \|\boldsymbol{\sigma} + A\nabla u\|_{0,\beta_1}. \end{aligned} \tag{3.17}$$

Since $\beta_2 \le \beta_1 + 1$, (3.13) with $\beta = -(\beta_1+1)$ and $\gamma = -\beta_2$ gives

$$\|\phi\|_{0,-\beta_2} \le C\,\|\phi\|_{0,-(\beta_1+1)} = C\,\|r^{-\beta_1-1}\phi\| \le C\,\|\phi\|_{1,-\beta_1}. \tag{3.18}$$

Now, the second term may be bounded similarly using the Cauchy–Schwarz inequality and (3.18),

$$\begin{aligned}
\|\nabla\cdot\boldsymbol{\sigma} + Xu\|_{-1,\beta_1} &= \sup_{\phi\in D^1_{-\beta_1}} \frac{\langle \nabla\cdot\boldsymbol{\sigma} + Xu, \phi\rangle}{\|\phi\|_{1,-\beta_1}} \\
&= \sup_{\phi\in D^1_{-\beta_1}} \frac{\langle r^{\beta_2}(\nabla\cdot\boldsymbol{\sigma} + Xu), r^{-\beta_2}\phi\rangle}{\|\phi\|_{1,-\beta_1}} \\
&\le \|\nabla\cdot\boldsymbol{\sigma} + Xu\|_{0,\beta_2} \sup_{\phi\in D^1_{-\beta_1}} \frac{\|\phi\|_{0,-\beta_2}}{\|\phi\|_{1,-\beta_1}} \\
&\le C\,\|\nabla\cdot\boldsymbol{\sigma} + Xu\|_{0,\beta_2}.
\end{aligned} \tag{3.19}$$

Combining equations (3.16), (3.17), and (3.19) gives

$$\|u\|_{1,\beta_1} \le CG(u,\boldsymbol{\sigma};0)^{1/2}. \tag{3.20}$$

It follows from the triangle inequality, (3.1), (3.20), and (3.15) that

$$\begin{aligned}
&\|\boldsymbol{\sigma}\|_{0,\beta_1} + \|\nabla\cdot\boldsymbol{\sigma}\|_{0,\beta_2} \\
&\le \|\boldsymbol{\sigma} + A\nabla u\|_{0,\beta_1} + \|A\nabla u\|_{0,\beta_1} + \|\nabla\cdot\boldsymbol{\sigma} + Xu\|_{0,\beta_2} + \|Xu\|_{0,\beta_2} \\
&\le CG(u,\boldsymbol{\sigma};0)^{1/2} + C\|u\|_{1,\beta_1} + C(\|\nabla u\|_{0,\beta_2} + \|u\|_{0,\beta_2}) \\
&\le CG(u,\boldsymbol{\sigma};0)^{1/2},
\end{aligned}$$

which, together with (3.20), implies the lower bound in (3.14) and, hence, completes the proof of the theorem. ∎

We may now prove error estimates.

THEOREM 3.5. *Let $(u,\boldsymbol{\sigma}) \in \mathcal{V}\times\mathcal{W}$ be the solution of system (2.1) and let $(u^h,\boldsymbol{\sigma}^h)$ be the minimizer of the weighted functional (2.2) over $\mathcal{V}^h\times\mathcal{W}^h$. Assume that $f\in H^\alpha(\Omega)$. Then for $\beta_1\in[1-\alpha,\alpha)$ and $\beta_2\in[\beta_1,\beta_1+1]$, the following error estimate holds:*

$$|||(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h)|||_{\beta_1,\beta_2} \le Ch^{m_1}\left(\|u\|_{2,\beta_1} + \|u\|_{1+\alpha} + \|f\|_\alpha\right)$$

with $m_1 = \min\{1, \beta_1+\tilde{\alpha}\}$.

Proof. For any $(v,\boldsymbol{\tau})\in\mathcal{V}^h\times\mathcal{W}^h$, it follows from Theorem 3.4 and the orthogonality property that

$$\begin{aligned}
c_0|||(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h)|||^2_{\beta_1,\beta_2} &\le G(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h;0) \\
&= G(u-v^h,\boldsymbol{\sigma}-\boldsymbol{\tau}^h;0) \le c_1|||(u-v^h,\boldsymbol{\sigma}-\boldsymbol{\tau}^h)|||^2_{\beta_1,\beta_2},
\end{aligned}$$

which implies

$$\begin{aligned}
|||(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h)|||^2_{\beta_1,\beta_2} &\le \frac{c_1}{c_0}\inf_{(v,\boldsymbol{\tau})\in\mathcal{V}^h\times\mathcal{W}^h} |||(u-v,\boldsymbol{\sigma}-\boldsymbol{\tau})|||^2_{\beta_1,\beta_2} \\
&\le C\left(\inf_{v\in\mathcal{V}}\|u-v\|^2_{1,\beta_1} + \inf_{\boldsymbol{\tau}\in\mathcal{W}^h}\|\boldsymbol{\sigma}-\boldsymbol{\tau}\|^2_{0,\beta_1} + \inf_{\boldsymbol{\tau}\in\mathcal{W}^h}\|\nabla\cdot(\boldsymbol{\sigma}-\boldsymbol{\tau})\|^2_{0,\beta_2}\right).
\end{aligned}$$

This, with the approximation properties in (3.3), (3.8), and (3.9), results in

$$|||(u-u^h,\boldsymbol{\sigma}-\boldsymbol{\sigma}^h)|||^2_{\beta_1,\beta_2} \le Ch^{2m_1}\left(\|u\|^2_{2,\beta_1}+|\boldsymbol{\sigma}|^2_{1,\beta_1}+|\boldsymbol{\sigma}|^2_{\alpha}+|\nabla\cdot\boldsymbol{\sigma}|^2_{\alpha}\right).$$

Choosing $\beta_1 \ge 1-\alpha$ ensures that $u \in H^2_{\beta_1}(\Omega)$. The terms above involving $\boldsymbol{\sigma}$ each may be bounded as follows:

$$|\boldsymbol{\sigma}|_{1,\beta_1} = |A\nabla u|_{1,\beta_1} \le C\|u\|_{2,\beta_1},$$
$$|\boldsymbol{\sigma}|_{\alpha} = |A\nabla u|_{\alpha} \le C\|u\|_{1+\alpha},$$
$$|\nabla\cdot\boldsymbol{\sigma}|_{\alpha} = |f-Xu|_{\alpha} \le |f|_{\alpha}+|Xu|_{\alpha} \le |f|_{\alpha}+C\|u\|_{1+\alpha},$$

and the theorem follows by combining these bounds above. ∎

Theorem 3.5 shows improvement in the order of approximation by choosing $\beta_1 \in (0,\alpha]$. We note that Theorem 3.5 assumes $\beta_1 \ge 1-\alpha$ to be consistent with interpolation bound (3.3). In practice this restriction is unnecessary. Choosing $\beta_1 = 1-\alpha$ restores exactly $O(h)$ convergence. Since for many elliptic problems (Poisson, Stokes, linear elasticity, etc.) we have $\alpha \in [0.5, 1)$, we may choose $\beta_1 \in [1-\alpha, \alpha)$ or simply $\beta_1 = 0.5$. This flexibility in parameter choice shows that almost no a priori information of the singular solutions is required for this approach to apply. Rough lower bounds on α suffice.

We also may choose to apply the techniques here locally to each singular point in the domain. The loss of smoothness of the solution at irregular boundary points is a local phenomenon, but it causes global difficulties. Our motivation is to provide a local treatment that eliminates the global effect of the irregular boundary point. To this end, let $\Omega_R = \{\mathbf{x} \in \Omega : r > R\}$ be a subdomain of Ω of fixed size that does not include $\mathcal{E}$. Since on Ω_R the norms $|||(u,\boldsymbol{\sigma})|||_{0,0}$ and $|||(u,\boldsymbol{\sigma})|||_{\beta_1,\beta_2}$ are equivalent, Theorem 3.5 indicates that the error is reduced at optimal asymptotic rates away from $\mathcal{E}$—thus eliminating the pollution effect.

We conclude this section with a brief justification of the reduction of the error with respect to a nonweighted norm.

THEOREM 3.6. *Let $\beta_1 \ge 1-\tilde{\alpha}$. Then under the same assumptions as Theorem* 3.5, *the error in approximating $\boldsymbol{\sigma}$ satisfies*

$$\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^h\| \le C\,h^{\tilde{\alpha}}, \tag{3.21}$$

where C is independent of h.

Proof. By the triangle inequality we take

$$\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^h\| \le \|\boldsymbol{\sigma}-I^h\boldsymbol{\sigma}\| + \|\boldsymbol{\sigma}^h-I^h\boldsymbol{\sigma}\| \tag{3.22}$$

and consider the terms above separately. The first term may be bounded by (3.6),

$$\|\boldsymbol{\sigma}-I^h\boldsymbol{\sigma}\| \le Ch^{\tilde{\alpha}}|\boldsymbol{\sigma}|_{\alpha}. \tag{3.23}$$

For the second term, we require an inequality proved in [10]:

$$\|\boldsymbol{\tau}^h\| \le Ch^{-\delta}\|\boldsymbol{\tau}^h\|_{0,\delta} \tag{3.24}$$

for $\delta > 0$ and all $\boldsymbol{\tau}^h \in \mathcal{W}^h$. Now, using (3.24), the triangle inequality, Theorem 3.5, and (3.8) results in

$$\begin{aligned}\|\boldsymbol{\sigma}^h-I^h\boldsymbol{\sigma}\| &\le Ch^{-\beta_1}\|\boldsymbol{\sigma}^h-I^h\boldsymbol{\sigma}\|_{0,\beta_1}\\ &\le Ch^{-\beta_1}\left(\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^h\|_{0,\beta_1}+\|\boldsymbol{\sigma}-I^h\boldsymbol{\sigma}\|_{0,\beta_1}\right)\\ &\le C\,h^{-\beta_1}h^{\beta_1+\tilde{\alpha}} \le C\,h^{\tilde{\alpha}}.\end{aligned} \tag{3.25}$$

Combining (3.22), (3.23), and (3.25) yields the bound in (3.21) and thus completes the theorem. ∎

4. Numerical results. In this section we validate the weighted-norm method by presenting two numerical test problems. Define the domain $\Omega = \{(r, \theta) : r < 1, \theta \in (0, 7\pi/4)\}$ as pictured in Figure 4.1, which results in singularities with $\alpha = 4/7$.

While the analysis in this paper assumes one singular corner with norms weighted by r^{β_1} and r^{β_2}, generalization to more than one singular corner is straightforward. We illustrate that here by defining the local weight functions

$$w_i = \begin{cases} (r/R)^{\beta_i} & \text{for } r < R, \\ 1 & \text{for } r \geq R \end{cases}$$

for $i = 1, 2$ and $R = 0.25$. We minimize the weighted functional

$$G(u, \boldsymbol{\sigma}; f) = \|w_1 A^{-1/2}(\boldsymbol{\sigma} + A\nabla u)\|^2 + \|w_2(\nabla \cdot \boldsymbol{\sigma} + \mathbf{b} \cdot \nabla u + cu - f)\|^2$$

for u^h using continuous P_1 finite elements and $\boldsymbol{\sigma}^h$ using RT_0 elements. We take $\beta_1 = \beta_2 = 0.57 \approx \alpha$ as the power of the weight functions. A regular triangulation of the domain is used, where the meshsize parameter is $h = \min_{K \in \mathcal{T}^h} diam(K)$.

In Table 4.1 we describe a sequence of nested discretizations used to test convergence of the method. Numerical results are summarized in Table 4.2, where we report the computed convergence rate from the two finest meshes (conv. rate), which may be compared with the asymptotic optimal convergence rate that the interpolant admits (asy. opt.).

We denote the exact solution by u, strongly impose Dirichlet boundary conditions on $\partial\Omega$, and compute the right-hand function f by analytically computing

$$f = -\nabla \cdot A\nabla u + \mathbf{b} \cdot \nabla u + cu.$$

We also analytically define $\boldsymbol{\sigma} = -A\nabla u$ for comparison to the numerical approximation, $\boldsymbol{\sigma}^h$.

Problem 1 (*Poisson's equation*). As a baseline case we begin with the Laplace operator,

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad \text{and} \quad c = 0.$$

The exact solution is chosen to be $u = r^\alpha \sin(\alpha\theta)$, and in this case $f = 0$.

Problem 2 (*convection dominated anisotropic diffusion*). We now consider an operator consisting of anisotropic diffusion dominated by a strong convection with a small reaction term,

$$A = \begin{pmatrix} 0.1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} 10 \\ 5 \end{pmatrix}, \quad \text{and} \quad c = 1.$$

The exact solution in this case is chosen to be $u = \tilde{r}^\alpha \sin(\alpha\tilde{\theta})$, where $(\tilde{r}, \tilde{\theta})$ are polar coordinates in the rescaled domain defined by $(\tilde{x}_1, \tilde{x}_2)^t = A^{-1/2}(x_1, x_2)^t$. The resulting data function satisfies $f \in H^k(\Omega)$ for any $k < \alpha$ and takes the form

$$f = 10\alpha\tilde{r}^{\alpha-1} \sin\left((\alpha-1)\tilde{\theta}\right) + 5\alpha\tilde{r}^{\alpha-1} \cos\left((\alpha-1)\tilde{\theta}\right) + \tilde{r}^\alpha \sin\alpha\tilde{\theta}.$$

To distinguish the rates of convergence close to and far from the singular point we define the following partitioning of the domain: $\Omega_0 = \{r < 1/4\} \cap \Omega$ and $\Omega_1 = \Omega \backslash \Omega_0$. Thus, Ω_0 contains the singular point and Ω_1 does not. We solve the problem in Ω but monitor the error in these subdomains as measured in the functional norm, $G^{1/2} = G(u^h, \boldsymbol{\sigma}^h; f)^{1/2}$, the L^2 errors in $\boldsymbol{\sigma}$, and the H^1 seminorm error in u.

Table 4.2 summarizes the computational results of the two problems. In both problems, the weighted functional is reduced at (or very nearly at) optimal $O(h)$, as

predicted by Theorem 3.5. This rate is seen on both partitions of the domain. For both $\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|$ and $|u - u^h|_1$, the optimal rates are $O(h^{4/7})$ and $O(h)$ in Ω_0 and Ω_1, respectively. Both example problems have similar behavior, though Problem 1 approaches the asymptotic rate faster than the more challenging Problem 2. The results also show no pollution effect as evidenced by a clear distinction in convergence rates between partitions Ω_0 and Ω_1.

We also note that in (3.6) and (3.7) we assume $\tilde{\alpha} \in (0, \alpha]$. The rates we achieve in Table 4.2 indicate that $\tilde{\alpha} = \alpha$. We also observe this same result in many numerical tests not shown here.

DISCRETE FOURIER ANALYSIS, CUBATURE, AND INTERPOLATION ON A HEXAGON AND A TRIANGLE*

HUIYUAN LI†, JIACHANG SUN†, AND YUAN XU‡

Abstract. Several problems of trigonometric approximation on a hexagon and a triangle are studied using the discrete Fourier transform and orthogonal polynomials of two variables. A discrete Fourier analysis on the regular hexagon is developed in detail, from which the analysis on the triangle is deduced. The results include cubature formulas and interpolation on these domains. In particular, a trigonometric Lagrange interpolation on a triangle is shown to satisfy an explicit compact formula, which is equivalent to the polynomial interpolation on a planar region bounded by Steiner's hypocycloid. The Lebesgue constant of the interpolation is shown to be in the order of $(\log n)^2$. Furthermore, a Gauss cubature is established on the hypocycloid.

1. Introduction. Approximation by trigonometric polynomials, or equivalently complex exponentials, is at the root of approximation theory. Many problems central to approximation theory were first studied for trigonometric polynomials on the real line or on the unit circle, as illustrated in the classical treatise of Zygmund [26]. Much of the advancement in the theory of trigonometric approximation is due to the periodicity of the function. In the case of one variable, one usually works with 2π periodic functions. A straightforward extension to several variables is the tensor product type, where one works with functions that are 2π periodic in each of their variables. There are, however, other definitions of periodicity in several variables, most notably the periodicity defined by a lattice, which is a discrete subgroup defined by $A\mathbb{Z}^d$, where A is a nonsingular matrix, and the periodic function satisfies $f(x + Ak) = f(x)$ for all $k \in \mathbb{Z}^d$. With such a periodicity, one works with exponentials or trigonometric functions of the form $\mathrm{e}^{i2\pi\alpha\cdot x}$, where α and x are in proper sets of $\mathbb{R}^d$, not necessarily the usual trigonometric polynomials.

If Ω is a bounded open set that tiles $\mathbb{R}^d$ with the lattice $L = A\mathbb{Z}^d$, meaning that $\Omega + A\mathbb{Z}^d = \mathbb{R}^d$, then, according to a theorem of Fuglede [6], the family of exponentials $\{\mathrm{e}^{2\pi i\alpha\cdot x} : \alpha \in L^\perp\}$, where $L^\perp = A^{-\mathrm{tr}}\mathbb{Z}^d$ is the dual lattice of L, forms an orthonormal basis in $L^2(\Omega)$. In particular, this shows that it is appropriate to use such exponentials for approximation. Naturally one can study Fourier series on Ω, defined by these exponentials, which is more or less the usual multivariate Fourier series with a change of variables from $\mathbb{Z}^d$ to $A\mathbb{Z}^d$. Lattices appear prominently in various problems in combinatorics and analysis (see, for example, [2, 5]); the Fourier series associated with them are studied in the context of information science and

physics, such as sampling theory [7, 11] and multivariate signal processing [3]. As far as we are aware, they have not been studied much in approximation theory until recently. Part of the reason may lie in the complexity of the set Ω. In the simplest nontensor product case, it is a regular hexagon region on the plane, not one of those regions that people are used to in classical analysis. It turns out, however, that the results on the hexagon are instrumental to the study of trigonometric functions on the triangle [21, 22]. The Fourier series on the hexagon were studied from scratch in [21], and two families of functions analogous to those of sine and cosine but defined using three directions were identified and studied. In [22] the two generalized trigonometric functions were derived as solutions of the eigenfunctions of the Laplace equation on a triangle, and the Fourier series in terms of them were studied.

The purpose of the present paper is to study discrete Fourier analysis on the hexagon and on the triangle; in particular, we will derive results on cubature and Lagrange interpolation on these domains. We shall follow two approaches. The first one relies on the discrete Fourier transforms associated with the lattices, which leads naturally to an interpolation formula, and the result applies to a general lattice. We then apply the result to the hexagonal tiling. The symmetry group of the hexagon lattice is the reflection group $\mathcal{A}_2$. The generalized cosine and sine are invariant and anti-invariant projections, respectively, of the basic exponential function under $\mathcal{A}_2$, and they can be studied as functions defined on a fundamental domain, which is one of the equilateral triangles inside the hexagon. This allows us to pass from the hexagon to the triangle. The discrete Fourier transform can be regarded as a cubature formula. In the case of a triangle, the trigonometric functions for which such a cubature holds is a graded algebra due to a connection to polynomials of two variables, which shows that the cubature is of Gaussian type.

The second approach uses orthogonal polynomials in two variables. It turns out that the generalized cosine and sine functions were studied earlier by Koornwinder in [9], who also started with eigenfunctions of the Laplace operator and identified them as orthogonal polynomials on the region bounded by Steiner's hypocycloid, which he called Chebyshev polynomials of the first and the second kind, respectively. It is well known that orthogonal polynomials are closely related to cubature formulas and polynomial interpolation (see, for example, [4, 14, 20, 24, 25]). Roughly speaking, a cubature formula of high precision exists if the set of its nodes is an algebraic variety of a polynomial ideal generated by (quasi-)orthogonal polynomials, and the size of the variety is equal to the codimension of the ideal. Furthermore, such a cubature formula arises from an interpolation polynomial. The rich structure of the generalized Chebyshev polynomials allow us to study their common zeros and establish the cubature and the polynomial interpolation. One particular result shows that Gaussian cubature formula exists for one integral on the region bounded by the hypocycloid. It should be mentioned that, unlike the case of one variable, Gaussian cubature formulas rarely exist in several variables.

The most concrete result, in our view, is the trigonometric interpolation on the triangle. For a standard triangle $\Delta := \{(x, y) : x \ge 0, y \ge 0, x + y \le 1\}$, the set of interpolation points are $X_n := \{(\frac{i}{n}, \frac{j}{n}) : 0 \le i \le j \le n\}$ in Δ. We found a compact formula for the fundamental interpolation functions in terms of the elementary trigonometric functions, which ensures that the interpolation can be computed efficiently. Moreover, the uniform operator norm (the Lebesgue constant) of the interpolation is shown to grow in the order of $(\log n)^2$ as n goes to infinity. This is in sharp contrast to the algebraic polynomial interpolation on the set X_n, which also exists and

can be given by simple formulas but has an undesirable convergence behavior (see, for example, [17]). In fact, it is well known that equally spaced points are not good for algebraic polynomial interpolation. For example, a classical result shows that the polynomial interpolation of $f(x) = |x|$ on equally spaced points of $[-1, 1]$ diverges at all points other than $-1, 0, 1$.

The paper is organized as follows. In section 2 we state the basic results on lattices and discrete Fourier transform, and establish the connection to the interpolation formula. Section 3 contains results on the regular hexagon, obtained from applying the general result of the previous section. Section 4 studies the generalized sine and cosine functions, and the discrete Fourier analysis on the triangle. In particular, it contains the results on the trigonometric interpolation. The generalized Chebyshev polynomials and their connection to the orthogonal polynomials of two variables are discussed in section 5 and used to establish the existence of Gaussian cubature and an alternative way to derive interpolation polynomial.

2. Continuous and discrete Fourier analysis with lattice.

2.1. Lattice and Fourier series. A lattice in $\mathbb{R}^d$ is a discrete subgroup that contains d linearly independent vectors,

$$L := \{k_1a_1 + k_2a_2 + \cdots + k_da_d : \quad k_i \in \mathbb{Z},\, i = 1, 2, \ldots, d\}, \tag{2.1}$$

where $a_1, \ldots, a_d$ are linearly independent column vectors in $\mathbb{R}^d$. Let A be the $d \times d$ matrix whose columns are $a_1, \ldots, a_d$. Then A is called a generator matrix of the lattice L. We can write L as L_A and a short notation for L_A is $A\mathbb{Z}^d$; that is,

$$L_A = A\mathbb{Z}^d = \left\{Ak : k \in \mathbb{Z}^d\right\}.$$

Any d-dimensional lattice has a dual lattice $L^\perp$ given by

$$L^\perp = \{x \in \mathbb{R}^d : x \cdot y \in \mathbb{Z} \text{ for all } y \in L\},$$

where $x \cdot y$ denotes the usual Euclidean inner product of x and y. The generator matrix of the dual lattice $L_A^\perp$ is $A^{-\mathsf{tr}} := (A^{\mathsf{tr}})^{-1}$, where A^{tr} denote the matrix transpose of A [2]. Throughout this paper whenever we need to treat $x \in \mathbb{R}^d$ as a vector, we treat it as a column vector, so that $x \cdot y = x^{\mathsf{tr}}y$.

A bounded set Ω of $\mathbb{R}^d$ is said to tile $\mathbb{R}^d$ with the lattice L if

$$\sum_{\alpha \in L} \chi_\Omega(x + \alpha) = 1 \qquad \text{for almost all } x \in \mathbb{R}^d,$$

where χ_Ω denotes the characteristic function of Ω. We write this as $\Omega + L = \mathbb{R}^d$. Tiling and Fourier analysis are closely related; see, for example, [6, 8]. We will need the following result due to Fuglede [6]. Let $\langle \cdot, \cdot \rangle_\Omega$ denote the inner product in the space $L^2(\Omega)$ defined by

$$\langle f, g\rangle_\Omega = \frac{1}{\operatorname{mes}(\Omega)} \int_\Omega f(x)\overline{g(x)}dx. \tag{2.2}$$

THEOREM 2.1 (see [6]). *Let Ω in $\mathbb{R}^d$ be a bounded open domain and let L be a lattice of $\mathbb{R}^d$. Then $\Omega + L = \mathbb{R}^d$ if and only if $\{e^{2\pi i\alpha\cdot x} : \alpha \in L^\perp\}$ is an orthonormal basis with respect to the inner product* (2.2).

The orthonormal property is defined with respect to normalized Lebesgue measure on Ω. If $L = L_A$, then the measure of Ω is equal to $|\det A|$. Furthermore, since $L_A^\perp = A^{-\mathsf{tr}}\mathbb{Z}^d$, we can write $\alpha = A^{-\mathsf{tr}}k$ for $\alpha \in L_A^\perp$ and $k \in \mathbb{Z}^d$, so that $\alpha \cdot x = (A^{-\mathsf{tr}}k)\cdot x = k^{\mathsf{tr}}A^{-1}x$. Hence the orthogonality in the theorem is

$$\frac{1}{|\det(A)|}\int_\Omega \mathrm{e}^{2\pi i k^{\mathsf{tr}}A^{-1}\xi}d\xi = \delta_{k,0}, \qquad k \in \mathbb{Z}^d. \tag{2.3}$$

The set Ω is called a spectral (fundamental) set for the lattice L. If $L = L_A$, we also write $\Omega = \Omega_A$.

A function $f \in L^1(\Omega_A)$ can be expanded into a Fourier series

$$f(x) \sim \sum_{k\in\mathbb{Z}^d} c_k \mathrm{e}^{2\pi i k^{\mathsf{tr}}A^{-1}x}, \qquad c_k = \frac{1}{|\det(A)|}\int_\Omega f(x)\mathrm{e}^{-2\pi i k^{\mathsf{tr}}A^{-1}x}dx,$$

which is just a change of variables away from the usual multiple Fourier series. The Fourier transform $\widehat{f}$ of a function $f \in L^1(\mathbb{R}^d)$ and its inverse are defined by

$$\widehat{f}(\xi) = \int_{\mathbb{R}^d} f(x)\mathrm{e}^{-2\pi i\,\xi\cdot x}dx \quad \text{and} \quad f(x) = \int_{\mathbb{R}^d}\widehat{f}(\xi)\mathrm{e}^{2\pi i\,\xi\cdot x}d\xi.$$

One important tool for us is the Poisson summation formula given by

$$\sum_{k\in\mathbb{Z}^d} f(x+Ak) = \frac{1}{|\det(A)|}\sum_{k\in\mathbb{Z}^d}\widehat{f}(A^{-\mathsf{tr}}k)\mathrm{e}^{2\pi i k^{\mathsf{tr}}A^{-1}x}, \tag{2.4}$$

which holds for $f \in L^1(\Omega_A)$ under the usual assumption on the convergence of the series in both sides. This formula has been used by various authors (see, for example, [1, 5, 7, 9, 19]). An immediate consequence of the Poisson summation formula is the following sampling theorem (see, for example, [7, 11]).

PROPOSITION 2.2. *Let Ω be a spectral set of the lattice $A\mathbb{Z}^d$. Assume that $\widehat{f}$ is supported on Ω and $\widehat{f} \in L^2(\Omega)$. Then*

$$f(x) = \sum_{k\in\mathbb{Z}^d} f(A^{-\mathsf{tr}}k)\Psi_\Omega(x - A^{-\mathsf{tr}}k) \tag{2.5}$$

in $L^2(\Omega)$, where

$$\Psi_\Omega(x) = \frac{1}{|\det(A)|}\int_\Omega \mathrm{e}^{2\pi i x\cdot\xi}d\xi. \tag{2.6}$$

In fact, since $\widehat{f}$ is supported on Ω_A, $\widehat{f}(\xi) = \sum_{k\in\mathbb{Z}^d}\widehat{f}(\xi + Ak)$. Integrating over Ω, the sampling equation follows from (2.4) and Fourier inversion. We note that

$$\Psi_\Omega(A^{-\mathsf{tr}}j) = \delta_{0,j} \qquad \text{for all } j \in \mathbb{Z}^d$$

by (2.3), so that Ψ_Ω can be considered as a cardinal interpolation function.

2.2. Discrete Fourier analysis and interpolation. A function f defined on $\mathbb{R}^d$ is called a periodic function with respect to the lattice $A\mathbb{Z}^d$ if

$$f(x + Ak) = f(x) \qquad \text{for all } k \in \mathbb{Z}^d.$$

For a given lattice L, its spectral set is evidently not unique. The orthogonality (2.3) is independent of the choice of Ω. This can be seen directly from the fact that the function $x \mapsto e^{2\pi i k^{\mathrm{tr}} A^{-1} x}$ is periodic with respect to the lattice $A\mathbb{Z}^d$.

In order to carry out a discrete Fourier analysis with respect to a lattice, we shall fix Ω such that Ω contains 0 in its interior, and we further require in this subsection that the tiling $\Omega + A\mathbb{Z}^d = \mathbb{R}^d$ holds pointwise and without overlapping. In other words, we require

$$\sum_{k\in\mathbb{Z}^d} \chi_\Omega(x + Ak) = 1 \text{ for all } x \in \mathbb{R}^d \quad \text{and} \quad (\Omega + Ak) \cap (\Omega + Aj) = \emptyset \text{ if } k \neq j. \tag{2.7}$$

For example, we can take $\Omega = [-\frac{1}{2}, \frac{1}{2})^d$ for the standard lattice $\mathbb{Z}^d$.

DEFINITION 2.3. *Let A and B be two nonsingular matrices such that Ω_A and Ω_B satisfy* (2.7). *Assume that all entries of $N := B^{\mathrm{tr}}A$ are integers. Denote*

$$\Lambda_N := \{k \in \mathbb{Z}^d : B^{-\mathrm{tr}} k \in \Omega_A\} \quad \textit{and} \quad \Lambda_N^\dagger := \{k \in \mathbb{Z}^d : A^{-\mathrm{tr}} k \in \Omega_B\}.$$

Two points $x, y \in \mathbb{R}^d$ are said to be congruent with respect to the lattice $A\mathbb{Z}^d$ if $x - y \in A\mathbb{Z}^d$, and we write $x \equiv y \mod A$.

THEOREM 2.4. *Let A, B, and N be as in Definition* 2.3. *Then*

$$\frac{1}{|\det(N)|} \sum_{j\in\Lambda_N} \mathrm{e}^{2\pi i k^{\mathrm{tr}} N^{-1} j} = \begin{cases} 1 & \textit{if } k \equiv 0 \mod N^{\mathrm{tr}}, \\ 0 & \textit{otherwise.} \end{cases} \tag{2.8}$$

Proof. Let $f \in L^1(\mathbb{R}^d)$ be such that Poisson summation formula holds. Denote

$$\Phi^A f(x) := \sum_{k\in\mathbb{Z}^d} f(x + Ak).$$

Then the Poisson summation formula (2.4) shows that

$$\Phi^A f(B^{-\mathrm{tr}} j) = \frac{1}{|\det(A)|} \sum_{k\in\mathbb{Z}^d} \widehat{f}(A^{-\mathrm{tr}} k) e^{2\pi i k^{\mathrm{tr}} N^{-1} j}, \qquad j \in \mathbb{Z}^d.$$

Since $\mathbb{R}^d = \Omega_B + B\mathbb{Z}^d$, we can write $A^{-\mathrm{tr}} k = x_B + Bm$ for every $k \in \mathbb{Z}^d$ with $x_B \in \Omega_B$ and $m \in \mathbb{Z}^d$. The fact that N has integer entries shows that $A^{\mathrm{tr}} x_B = l \in \mathbb{Z}^d$. That is, every $k \in \mathbb{Z}^d$ can be written as $k = l + N^{\mathrm{tr}} m$ with $l \in \Lambda_N^\dagger$ and $m \in \mathbb{Z}^d$. It is easy to see that $\mathrm{e}^{2\pi i k^{\mathrm{tr}} N^{-1} j} = \mathrm{e}^{2\pi i l^{\mathrm{tr}} N^{-1} j}$ under this decomposition. Consequently,

$$\begin{aligned} \Phi^A f(B^{-\mathrm{tr}} j) &= \frac{1}{|\det(A)|} \sum_{l\in\Lambda_N^\dagger} \sum_{m\in\mathbb{Z}^d} \widehat{f}(A^{-\mathrm{tr}} l + Bm) \mathrm{e}^{2\pi i l^{\mathrm{tr}} N^{-1} j} \\ &= \frac{1}{|\det(A)|} \sum_{l\in\Lambda_N^\dagger} \Phi^B \widehat{f}(A^{-\mathrm{tr}} l) \mathrm{e}^{2\pi i l^{\mathrm{tr}} N^{-1} j}. \end{aligned} \tag{2.9}$$

Similarly, we have

$$\Phi^B \widehat{f}(A^{-\mathrm{tr}} l) = \frac{1}{|\det(B)|} \sum_{j\in\Lambda_N} \Phi^A f(B^{-\mathrm{tr}} j) \mathrm{e}^{-2\pi i l^{\mathrm{tr}} N^{-1} j}. \tag{2.10}$$

Substituting (2.9) into (2.10) leads to the identity

$$\Phi^B \widehat{f}(A^{-\mathsf{tr}} l) = \frac{1}{|\det(AB)|} \sum_{k \in \Lambda_N^\dagger} \Phi^B \widehat{f}(A^{-\mathsf{tr}} k) \sum_{j \in \Lambda_N} \mathrm{e}^{2\pi i (k-l)^{\mathsf{tr}} N^{-1} j},$$

which holds for f in, say, the Schwartz class of functions, from which (2.8) follows immediately. □

THEOREM 2.5. *Let A, B, and N be as in Definition* 2.3. *Define*

$$\langle f, g \rangle_N = \frac{1}{|\det(N)|} \sum_{j \in \Lambda_N} f(B^{-\mathsf{tr}} j) \overline{g(B^{-\mathsf{tr}} j)}$$

for f, g in $C(\Omega_A)$, the space of continuous functions on Ω_A. Then

$$\langle f, g \rangle_{\Omega_A} = \langle f, g \rangle_N \tag{2.11}$$

for all f, g in the finite-dimensional subspace

$$\mathcal{H}_N := \operatorname{span} \left\{ \phi_k : \phi_k(x) = \mathrm{e}^{2\pi i k^{\mathsf{tr}} A^{-1} x},\ k \in \Lambda_N^\dagger \right\}.$$

Proof. By the definition of $\langle \cdot, \cdot \rangle_N$, (2.8) implies that $\langle \phi_l, \phi_k \rangle_N = \delta_{l,k}$, $l, k \in N^{\mathsf{tr}}$, which shows, by (2.3), that (2.11) holds for $f = \phi_l$ and $g = \phi_k$. Since both inner products are sesquilinear, the stated result follows. □

If Λ is a subset of $\mathbb{Z}^d$, we denote by $\#\Lambda$ the number of points in Λ. Evidently the dimension of $\mathcal{H}_N$ is $\#\Lambda_N^\dagger$.

Let $\mathcal{I}_N f$ denote the Fourier expansion of $f \in C(\Omega_A)$ in $\mathcal{H}_N$ with respect to the inner product $\langle \cdot, \cdot \rangle$. Then

$$\begin{aligned} \mathcal{I}_N f(x) &:= \sum_{j \in \Lambda_N^\dagger} \langle f, \phi_j \rangle_N \phi_j(x) \\ &= \frac{1}{|\det(N)|} \sum_{k \in \Lambda_N} f(B^{-\mathsf{tr}} k) \sum_{j \in \Lambda_N^\dagger} \phi_j(x) \overline{\phi_j(B^{-\mathsf{tr}} k)}. \end{aligned}$$

Hence, analogous to the sampling theorem in Proposition 2.2, we have

$$\mathcal{I}_N f(x) = \sum_{k \in \Lambda_N} f(B^{-\mathsf{tr}} k) \Psi_{\Omega_B}^A (x - B^{-\mathsf{tr}} k), \qquad f \in C(\Omega_A), \tag{2.12}$$

where

$$\Psi_{\Omega_B}^A(x) = \frac{1}{|\det(N)|} \sum_{j \in \Lambda_N^\dagger} \mathrm{e}^{2\pi i j^{\mathsf{tr}} A^{-1} x}. \tag{2.13}$$

THEOREM 2.6. *Let A, B, and N be as in Definition* 2.3. *If $\Lambda_{N^{\mathsf{tr}}} = \Lambda_N^\dagger$, then $\mathcal{I}_N f$ is the unique interpolation operator on N in $\mathcal{H}_N$; that is,*

$$\mathcal{I}_N f(B^{-\mathsf{tr}} j) = f(B^{-\mathsf{tr}} j) \qquad \text{for all } j \in \Lambda_N.$$

In particular, $\#\Lambda_N = \#\Lambda_{N^{\mathsf{tr}}} = |\det(N)|$. Furthermore, the fundamental interpolation function $\Psi_{\Omega_A}^B$ satisfies

$$\Psi_{\Omega_B}^A(x) = \sum_{j \in \mathbb{Z}^d} \Psi_{\Omega_B}(x + Aj). \tag{2.14}$$

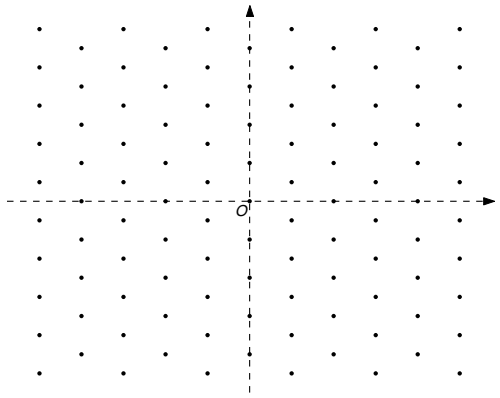

FIG. 1. *The lattice* L_H.

Proof. Using (2.8) with N in place of N^{tr} gives immediately that $\Psi^A_{\Omega_B}(B^{-\mathsf{tr}}k) = \delta_{k,0}$ for $k \in \Lambda_N$, so that the interpolation holds. This also shows that $\{\Psi^A_{\Omega_B}(x - B^{-\mathsf{tr}}k) : k \in \Lambda_N\}$ is linearly independent. Equation (2.8) with $k = 0$ shows immediately that $\#\Lambda_N = |\det(N)|$. Similarly, with N replaced by N^{tr}, we have $\#\Lambda_N = |\det(N^{\mathsf{tr}})|$. This shows that $\#\Lambda_N = |\det(N)| = \#\Lambda_{N^{\mathsf{tr}}}$. Furthermore, let $M = (\phi_k(B^{-\mathsf{tr}}j))_{j,k\in\Lambda_N}$ be the interpolation matrix; then (2.8) shows that M is a unitary matrix, which shows in particular that M is invertible. Consequently the interpolation by $\mathcal{H}_n$ on points in Λ_N is unique.

Finally, since $\widehat{\Psi}_{\Omega_B} = |\det(B)|^{-1}\chi_{\Omega_B}$, we have

$$\begin{aligned}\Psi^A_{\Omega_B}(x) &= \frac{1}{|\det(N)|}\sum_{j\in\mathbb{Z}^d}\phi_j(x)\chi_{\Omega_B}(A^{-\mathsf{tr}}j)\\ &= \frac{1}{|\det(A)|}\sum_{j\in\mathbb{Z}^d}\phi_j(x)\widehat{\Psi}_{\Omega_B}(A^{-\mathsf{tr}}j),\end{aligned}$$

from which (2.14) follows from the Poisson summation formula (2.4). ∎

The result in this section applies to fairly general lattices. In the following section we apply it to the hexagon lattice in two dimensions. We hope to report results for higher dimensional lattices in a future work.

3. Discrete Fourier analysis on the hexagon.

3.1. Hexagon lattice and Fourier analysis. The hexagon lattice is depicted in Figure 1. The generator matrix and the spectral set of the hexagon lattice is given by

$$H = \begin{pmatrix}\sqrt{3} & 0\\ -1 & 2\end{pmatrix}, \qquad \Omega_H = \left\{(x_1,x_2):\ -1 \le x_2, \tfrac{\sqrt{3}}{2}x_1 \pm \tfrac{1}{2}x_2 < 1\right\}.$$

The strict inequality in the definition of Ω_H comes from our assumption in (2.7).

As shown in [21], it is more convenient to use homogeneous coordinates (t_1, t_2, t_3) that satisfy $t_1 + t_2 + t_3 = 0$. We define

$$t_1 = -\frac{x_2}{2} + \frac{\sqrt{3}x_1}{2}, \quad t_2 = x_2, \quad t_3 = -\frac{x_2}{2} - \frac{\sqrt{3}x_1}{2}. \tag{3.1}$$

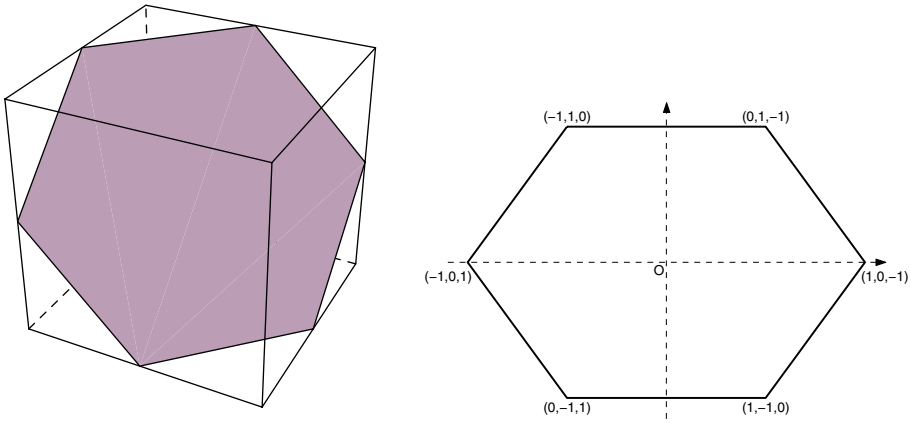

FIG. 2. *The hexagon in homogeneous coordinates.*

Under these homogeneous coordinates, the hexagon Ω_H becomes

$$\Omega = \left\{(t_1, t_2, t_3) \in \mathbb{R}^3 : \ -1 \le t_1, t_2, -t_3 < 1; \, t_1 + t_2 + t_3 = 0\right\},$$

which is the intersection of the plane $t_1 + t_2 + t_3 = 0$ with the cube $[-1, 1]^3$, as shown in Figure 2. Later in the paper we shall depict the hexagon as a two-dimensional figure, but still refer to its points by their homogeneous coordinates, as shown by the right-hand side of Figure 2.

For convenience, we adopt the convention of using bold letters, such as $\mathbf{t}$, to denote points in the space

$$\mathbb{R}^3_H := \{\mathbf{t} = (t_1, t_2, t_3) \in \mathbb{R}^3 : t_1 + t_2 + t_3 = 0\}.$$

In other words, bold letters such as $\mathbf{t}$ stand for homogeneous coordinates. Furthermore, we introduce the notation

$$\mathbb{H} := \mathbb{Z}^3 \cap \mathbb{R}^3_H = \left\{\mathbf{k} = (k_1, k_2, k_3) \in \mathbb{Z}^3 : \ k_1 + k_2 + k_3 = 0\right\}.$$

The inner product on the hexagon under homogeneous coordinates becomes

$$\langle f, g\rangle_H = \frac{1}{|\Omega_H|} \int_{\Omega_H} f(x_1, x_2)\overline{g(x_1, x_2)} dx_1 dx_2 = \frac{1}{|\Omega|} \int_{\Omega} f(\mathbf{t})\overline{g(\mathbf{t})} d\mathbf{t},$$

where $|\Omega|$ denotes the area of Ω.

To apply the general results in the previous section, we choose $A = H$ and $B = \frac{n}{2}H$, where n is a positive integer. Then

$$N = B^{\mathsf{tr}}A = \frac{n}{2}H^T H = \begin{bmatrix} 2n & -n \\ -n & 2n \end{bmatrix}$$

has integer entries. Note that N is a symmetric matrix and $\Lambda_N = \Lambda_N^\dagger$. Using the fact that $B^{-\mathsf{tr}}j = \frac{2}{n}H^{-\mathsf{tr}}j = \frac{1}{n}\left(\frac{2}{\sqrt{3}}j_1 + \frac{1}{\sqrt{3}}j_2, j_2\right)$, it is not hard to see that $B^{-\mathsf{tr}}j \in \Omega_A$, or equivalently $j \in \Lambda_N$, becomes $\mathbf{j} = (j_1, j_2, -j_1 - j_2) \in \mathbb{H}_n$, where

$$\mathbb{H}_n := \{\mathbf{j} \in \mathbb{H} : -n \le j_1, j_2, -j_3 < n\} \qquad \text{and} \qquad \#\mathbb{H}_n = 3n^2.$$

In other words, Λ_N in the previous section becomes $\mathbb{H}_n$ in homogeneous coordinates. The fact that $\#\mathbb{H}_n = 3n^2$ can be easily verified. Moreover, under the change of variables $x = (x_1, x_2) \mapsto (t_1, t_2, t_3)$ in (3.1), it is easy to see that

$$(k_1, k_2)H^{-1}x = \tfrac{1}{3}(k_1, k_2, -k_1 - k_2)\mathbf{t} = \tfrac{1}{3}\mathbf{k}\cdot\mathbf{t}, \tag{3.2}$$

so that $\mathrm{e}^{2\pi i k^{\mathrm{tr}} H^{-1} x} = \mathrm{e}^{\frac{2\pi i}{3}\mathbf{k}^{\mathrm{tr}}\mathbf{t}}$. Therefore, introducing the notation

$$\phi_{\mathbf{j}}(\mathbf{t}) := \mathrm{e}^{\frac{2\pi i}{3}\mathbf{j}^{\mathrm{tr}}\mathbf{t}}, \qquad \mathbf{j} \in \mathbb{H},$$

the orthogonality relation (2.3) becomes

$$\langle \phi_{\mathbf{k}}, \phi_{\mathbf{j}} \rangle_H = \delta_{\mathbf{k},\mathbf{j}}, \qquad \mathbf{k}, \mathbf{j} \in \mathbb{H}. \tag{3.3}$$

The finite-dimensional space $\mathcal{H}_N$ in the previous section becomes

$$\mathcal{H}_n := \operatorname{span}\{\phi_{\mathbf{j}} : \mathbf{j} \in \mathbb{H}_n\} \quad \text{and} \quad \dim \mathcal{H}_n = 3n^2.$$

Under the homogeneous coordinates (3.1), $x \equiv y \pmod{H}$ becomes $\mathbf{t} \equiv \mathbf{s} \mod 3$, where we define

$$\mathbf{t} \equiv \mathbf{s} \mod 3 \quad \Longleftrightarrow \quad t_1 - s_1 \equiv t_2 - s_2 \equiv t_3 - s_3 \mod 3.$$

We call a function f H-periodic if $f(\mathbf{t}) = f(\mathbf{t} + \mathbf{j})$ whenever $\mathbf{j} \equiv 0 \mod 3$. Since $\mathbf{j}, \mathbf{k} \in \mathbb{H}$ implies that $2\mathbf{j}\cdot\mathbf{k} = (j_1 - j_2)(k_1 - k_2) + 3j_3k_3$, we see that $\phi_{\mathbf{j}}$ is H-periodic. The following lemma is convenient in practice.

LEMMA 3.1. *Let $\varepsilon_1 = (2, -1, -1)$, $\varepsilon_2 = (-1, 2, -1)$, $\varepsilon_3 = (-1, -1, 2)$. Then a function $f(\mathbf{t})$ is H-periodic if and only if*

$$f(\mathbf{t} + j\varepsilon_i) = f(\mathbf{t}), \quad j \in \mathbb{Z}, \quad i = 1, 2, 3. \tag{3.4}$$

3.2. Discrete Fourier analysis on the regular hexagon. Using the setup in the previous subsection, Theorem 2.5 becomes, in homogeneous coordinates, the following.

PROPOSITION 3.2. *For $n \ge 0$, define*

$$\langle f, g \rangle_n := \frac{1}{3n^2} \sum_{\mathbf{j} \in \mathbb{H}_n} f(\tfrac{\mathbf{j}}{n})\overline{g(\tfrac{\mathbf{j}}{n})}, \qquad f, g \in C(\Omega). \tag{3.5}$$

Then

$$\langle f, g \rangle_H = \langle f, g \rangle_n, \qquad f, g \in \mathcal{H}_n.$$

The point set $\mathbb{H}_n$, and hence the inner product $\langle \cdot, \cdot \rangle_n$, is not symmetric on Ω in the sense that it contains only part of the points on the boundary, as shown by the left-hand side of Figure 3. We denote by $\mathbb{H}_n^*$ the symmetric point set on Ω,

$$\mathbb{H}_n^* := \{\mathbf{j} \in \mathbb{H} : -n \le j_1, j_2, j_3 \le n\} \quad \text{and} \quad \#\mathbb{H}_n^* = 3n^2 + 3n + 1.$$

The set $\mathbb{H}_n^*$ is shown by the right-hand side of Figure 3.

Using periodicity, we can show that the inner product $\langle \cdot, \cdot \rangle$ is equivalent to a symmetric discrete inner product based on $\mathbb{H}_n^*$. Let

$$\mathbb{H}_n^\circ := \{\mathbf{j} \in \mathbb{H} : -n < j_1, j_2, j_3 < n\}$$

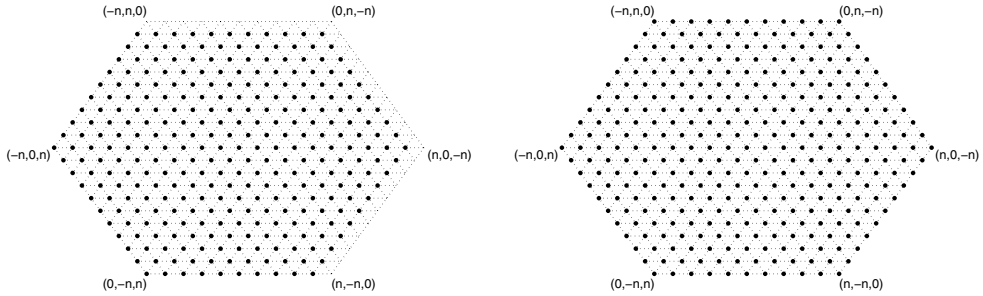

FIG. 3. *The set $\mathbb{H}_n$ (left) and the set $\mathbb{H}_n^*$ (right).*

denote the set of interior points in $\mathbb{H}_n^*$ and $\mathbb{H}_n$. Define

$$\langle f, g\rangle_n^* := \frac{1}{3n^2} \sum_{\mathbf{j}\in\mathbb{H}_n^*} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n})\overline{g(\tfrac{\mathbf{j}}{n})}, \qquad f, g \in C(\Omega), \tag{3.6}$$

where

$$c_{\mathbf{j}}^{(n)} = \begin{cases} 1, & \mathbf{j} \in \mathbb{H}_n^\circ \quad \text{(inner points)}, \\ \frac{1}{2}, & \mathbf{j} \in \mathbb{H}_n^* \setminus \mathbb{H}_n^\circ,\ j_1 j_2 j_3 \neq 0 \quad \text{(edge points)}, \\ \frac{1}{3}, & \mathbf{j} \in \mathbb{H}_n^* \setminus \mathbb{H}_n^\circ,\ j_1 j_2 j_3 = 0 \quad \text{(vertices)}, \end{cases}$$

in which we also include the positions of the points; the only one that needs an explanation is the "edge points," which are the points located on the edges but not on the vertices of the hexagon. In analogy to Proposition 3.2, we have the following theorem.

THEOREM 3.3. *For $n \geq 0$,*

$$\langle f, g\rangle_H = \langle f, g\rangle_n = \langle f, g\rangle_n^*, \qquad f, g \in \mathcal{H}_n.$$

Proof. If f is an H-periodic function, then it follows from (3.4) that

$$\begin{aligned} 6 \sum_{\mathbf{j}\in\mathbb{H}_n^*\setminus\mathbb{H}_n} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) &= 2\left[f(1,-1,0) + f(1,0,-1) + f(0,1,-1) + f(-1,1,0)\right] \\ &\quad + 3 \sum_{1\leq j\leq n-1} \left[f(1, -\tfrac{j}{n}, \tfrac{j}{n} - 1) + f(\tfrac{j}{n} - 1, 1, -\tfrac{j}{n}) + f(1 - \tfrac{j}{n}, \tfrac{j}{n}, -1)\right] \\ &= 3 \sum_{1\leq j\leq n-1} \left[f(-1, 1 - \tfrac{j}{n}, \tfrac{j}{n}) + f(\tfrac{j}{n}, -1, 1 - \tfrac{j}{n}) + f(-\tfrac{j}{n}, \tfrac{j}{n} - 1, 1)\right] \\ &\quad + 4\left[f(0,-1,1) + f(-1,0,1)\right] \\ &= 6 \sum_{\mathbf{j}\in\mathbb{H}_n\setminus\mathbb{H}_{n-1}^*} \left(1 - c_{\mathbf{j}}^{(n)}\right) f(\tfrac{\mathbf{j}}{n}) = 6 \sum_{\mathbf{j}\in\mathbb{H}_n} \left(1 - c_{\mathbf{j}}^{(n)}\right) f(\tfrac{\mathbf{j}}{n}). \end{aligned}$$

Consequently, we have

$$\begin{aligned} \sum_{\mathbf{j}\in\mathbb{H}_n^*} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) &= \sum_{\mathbf{j}\in\mathbb{H}_n} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) + \sum_{\mathbf{j}\in\mathbb{H}_n^*\setminus\mathbb{H}_n} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) \\ &= \sum_{\mathbf{j}\in\mathbb{H}_n} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) + \sum_{\mathbf{j}\in\mathbb{H}_n} \left(1 - c_{\mathbf{j}}^{(n)}\right) f(\tfrac{\mathbf{j}}{n}) = \sum_{\mathbf{j}\in\mathbb{H}_n} f(\tfrac{\mathbf{j}}{n}). \end{aligned}$$

Replacing f by $f\bar{g}$, we have proved that $\langle f, g\rangle_n = \langle f, g\rangle_n^*$ for H-periodic functions, which clearly applies to functions in $\mathcal{H}_n$. ∎

3.3. Interpolation on the hexagon. First we note that by (3.2), Theorem 2.6 when restricted to the hexagon domain becomes the following.

PROPOSITION 3.4. *For $n \ge 0$, define*

$$\mathcal{I}_n f(\mathbf{t}) := \sum_{\mathbf{j}\in\mathbb{H}_n} f(\tfrac{\mathbf{j}}{n})\Phi_n(\mathbf{t} - \tfrac{\mathbf{j}}{n}), \quad \text{where} \quad \Phi_n(\mathbf{t}) = \frac{1}{3n^2}\sum_{\mathbf{j}\in\mathbb{H}_n} \phi_{\mathbf{j}}(\mathbf{t}),$$

for $f \in C(\Omega)$. Then $\mathcal{I}_n f \in \mathcal{H}_n$ and

$$\mathcal{I}_n f(\tfrac{\mathbf{j}}{n}) = f(\tfrac{\mathbf{j}}{n}) \qquad \text{for all } \mathbf{j} \in \mathbb{H}_n.$$

Furthermore, and perhaps much more interesting, there exists another interpolation operator that works for almost all points in $\mathbb{H}_n^*$. First we need a few more definitions. We denote by $\partial\mathbb{H}_n^* := \mathbb{H}_n^* \setminus \mathbb{H}_n^\circ$ the set of points in $\mathbb{H}_n^*$ that are on the boundary of the hexagon $\{\mathbf{t} : -n \le t_1, t_2, t_3 \le n\}$. We further divide $\partial\mathbb{H}_n^*$ as $\mathbb{H}_n^{\mathrm{v}} \cup \mathbb{H}_n^{\mathrm{e}}$, where $\mathbb{H}_n^{\mathrm{v}}$ consists of the six vertices of $\partial\mathbb{H}_n$ and $\mathbb{H}_n^{\mathrm{e}}$ consists of the other points in $\partial\mathbb{H}_n$, i.e., the edge points. For $\mathbf{j} \in \partial\mathbb{H}_n^*$, we define

$$\mathcal{S}_{\mathbf{j}} := \left\{\mathbf{k} \in \mathbb{H}_n^* : \tfrac{\mathbf{k}}{n} \equiv \tfrac{\mathbf{j}}{n} \mod 3\right\}.$$

Because of the tiling property of the hexagon, if $\mathbf{j} \in \mathbb{H}_n^{\mathrm{e}}$, then $\mathcal{S}_{\mathbf{j}}$ contains two points, $\mathbf{j}$ and $\mathbf{j}^* \in \mathbb{H}_n^{\mathrm{e}}$, where j^* is on the opposite edge, relative to j, of the hexagon; while if $\mathbf{j} \in \mathbb{H}_n^{\mathrm{v}}$, then $\mathcal{S}_{\mathbf{j}}$ contains three vertices, $\mathbf{j}$ and its rotations by the angles $2\pi/3$ and $4\pi/3$.

THEOREM 3.5. *For $n \ge 0$ and $f \in C(\Omega)$, define*

$$\mathcal{I}_n^* f(\mathbf{t}) := \sum_{\mathbf{j}\in\mathbb{H}_n^*} f(\tfrac{\mathbf{j}}{n})\ell_{\mathbf{j},n}(\mathbf{t}),$$

where

$$\ell_{\mathbf{j},n}(\mathbf{t}) = \Phi_n^*(\mathbf{t} - \tfrac{\mathbf{j}}{n}) \quad \text{and} \quad \Phi_n^*(\mathbf{t}) = \frac{1}{3n^2}\sum_{\mathbf{j}\in\mathbb{H}_n^*} c_{\mathbf{j}}^{(n)}\phi_{\mathbf{j}}(\mathbf{t}). \tag{3.7}$$

Then $\mathcal{I}_n^* f \in \mathcal{H}_n^* := \{\phi_{\mathbf{j}} : \mathbf{j} \in \mathbb{H}_n^*\}$ and

$$\mathcal{I}_n^* f(\tfrac{\mathbf{j}}{n}) = \begin{cases} f(\tfrac{\mathbf{j}}{n}), & \mathbf{j} \in \mathbb{H}_n^\circ, \\ \sum_{\mathbf{k}\in\mathcal{S}_{\mathbf{j}}} f(\tfrac{\mathbf{k}}{n}), & \mathbf{j} \in \partial\mathbb{H}_n^*. \end{cases} \tag{3.8}$$

Furthermore, $\Phi_n^*(\mathbf{t})$ is a real function and has a compact formula

$$\begin{aligned}\Phi_n^*(\mathbf{t}) = \frac{1}{3n^2}\Bigg[&\frac{1}{2}\big(\Theta_n(\mathbf{t}) - \Theta_{n-2}(\mathbf{t})\big) \\ &-\frac{1}{3}\big(\cos\tfrac{2n\pi}{3}(t_1 - t_2) + \cos\tfrac{2n\pi}{3}(t_2 - t_3) + \cos\tfrac{2n\pi}{3}(t_3 - t_1)\big)\Bigg],\end{aligned} \tag{3.9}$$

where

$$\Theta_n(\mathbf{t}) := \frac{\sin\frac{(n+1)\pi(t_1-t_2)}{3}\sin\frac{(n+1)\pi(t_2-t_3)}{3}\sin\frac{(n+1)\pi(t_3-t_1)}{3}}{\sin\frac{\pi(t_1-t_2)}{3}\sin\frac{\pi(t_2-t_3)}{3}\sin\frac{\pi(t_3-t_1)}{3}}. \tag{3.10}$$

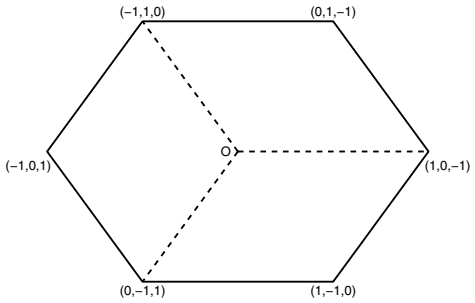

FIG. 4. *The hexagon partitioned into three parallelograms.*

Proof. First let $\mathbf{k} \in \mathbb{H}_n$. From the definition of the inner product $\langle \cdot, \cdot \rangle_n^*$, it follows that if $\mathbf{j} \in \mathbb{H}_n^\circ$, then $\ell_{\mathbf{j},n}(\frac{\mathbf{k}}{n}) = \langle \phi_{\mathbf{k}}, \phi_{\mathbf{j}} \rangle_n^* = \delta_{\mathbf{k},\mathbf{j}}$. If $\mathbf{j} \in \partial\mathbb{H}_n^*$, then one of the points in $\mathcal{S}_{\mathbf{j}}$ will be in $\mathbb{H}_n$, call it $\mathbf{j}^*$, and then $\ell_{\mathbf{j},n}(\frac{\mathbf{k}}{n}) = \delta_{\mathbf{k},\mathbf{j}^*}$. As the roles of $\mathbf{j}$ and $\mathbf{k}$ are symmetric in $\ell_{\mathbf{j},n}(\frac{\mathbf{k}}{n})$, this covers all cases. Putting these cases together, we have proved that

$$\ell_{\mathbf{j},n}(\tfrac{\mathbf{k}}{n}) = \Phi_n^*(\tfrac{\mathbf{k}}{n} - \tfrac{\mathbf{j}}{n}) = \begin{cases} 1 & \text{if } \frac{\mathbf{k}}{n} \equiv \frac{\mathbf{j}}{n} \mod 3, \\ 0 & \text{otherwise,} \end{cases} \qquad \mathbf{k}, \mathbf{j} \in \mathbb{H}_n^*, \tag{3.11}$$

from which the interpolation (3.8) follows immediately.

By the definition of $c_{\mathbf{j}}^{(m)}$, it is easy to see that

$$\Phi_n^*(\mathbf{t}) = \frac{1}{3n^2} \left[\frac{1}{2}\big(D_n(\mathbf{t}) + D_{n-1}(\mathbf{t})\big) - \frac{1}{6} \sum_{\mathbf{j} \in \mathbb{H}_n^{\mathrm{v}}} \phi_{\mathbf{j}}(\mathbf{t}) \right],$$

where D_n is the analogue of the Dirichlet kernel defined by

$$D_n(\mathbf{t}) := \sum_{\mathbf{j} \in \mathbb{H}_n^*} \phi_{\mathbf{j}}(\mathbf{t}). \tag{3.12}$$

By the definitions of $\phi_{\mathbf{k}}$ and $\mathbb{H}_n^{\mathrm{v}}$, we have

$$\sum_{\mathbf{j} \in \mathbb{H}_n^{\mathrm{v}}} \phi_{\mathbf{j}}(\mathbf{t}) = 2\left[\cos \tfrac{2n\pi}{3}(t_1 - t_2) + \cos \tfrac{2n\pi}{3}(t_2 - t_3) + \cos \tfrac{2n\pi}{3}(t_3 - t_1)\right],$$

so that we have to show only that $D_n = \Theta_n - \Theta_{n-1}$, which in fact has already appeared in [21]. Since an intermediate step is needed later, we outline the proof of the identity below. The hexagon domain can be partitioned into three parallelograms, as shown in Figure 4. Accordingly, we split the sum over $\mathbb{H}_n^*$ as

$$D_n(\mathbf{t}) = 1 + \sum_{j_2=-n}^{-1} \sum_{j_1=0}^{n} \phi_{\mathbf{j}}(\mathbf{t}) + \sum_{j_3=-n}^{-1} \sum_{j_2=0}^{n} \phi_{\mathbf{j}}(\mathbf{t}) + \sum_{j_1=-n}^{-1} \sum_{j_3=0}^{n} \phi_{\mathbf{j}}(\mathbf{t}). \tag{3.13}$$

Using the fact that $t_1 + t_2 + t_3 = 0$ and $j_1 + j_2 + j_3 = 0$, each of the three sums can be summed up explicitly. For example,

$$\sum_{j_2=-n}^{-1} \sum_{j_1=0}^{n} \phi_{\mathbf{j}}(\mathbf{t}) \tag{3.14}$$

$$= \frac{\mathrm{e}^{-\frac{\pi i}{3}(n+1)(t_3-t_2)} \sin \frac{n\pi}{3}(t_2 - t_3)}{\sin \frac{\pi}{3}(t_2 - t_3)} \frac{\mathrm{e}^{-\frac{\pi i}{3} n(t_1-t_3)} \sin \frac{(n+1)\pi}{3}(t_1 - t_3)}{\sin \frac{\pi}{3}(t_1 - t_3)}.$$

The formula $D_n = \Theta_n - \Theta_{n-1}$ comes from summing up these terms and carrying out simplification using the fact that if $t_1 + t_2 + t_3 = 0$, then

$$\begin{aligned} \sin 2t_1 + \sin 2t_2 + \sin 2t_3 &= -4 \sin t_1 \sin t_2 \sin t_3, \\ \cos 2t_1 + \cos 2t_2 + \cos 2t_3 &= 4 \cos t_1 \cos t_2 \cos t_3 - 1, \end{aligned} \tag{3.15}$$

which can be easily verified. □

The compact formula of the interpolation function allows us to estimate the operator norm of $\mathcal{I}_n^* : C(\overline{\Omega}) \mapsto C(\overline{\Omega})$ in the uniform norm, which is often referred to as the Lebesgue constant.

THEOREM 3.6. *Let $\|\mathcal{I}_n^*\|_\infty$ denote the operator norm of $\mathcal{I}_n^* : C(\overline{\Omega}) \mapsto C(\overline{\Omega})$. Then there is a constant c, independent of n, such that*

$$\|\mathcal{I}_n^*\|_\infty \le c(\log n)^2.$$

Proof. A standard procedure shows that

$$\|\mathcal{I}_n^*\|_\infty = \max_{\mathbf{t}\in\Omega} \sum_{\mathbf{j}\in\mathbb{H}_n^*} |\Phi_n^*(\mathbf{t} - \tfrac{\mathbf{j}}{n})|.$$

By (3.9) and the fact that $D_n = \Theta_n - \Theta_{n-1}$, it is sufficient to show that

$$\frac{1}{3n^2} \max_{\mathbf{t}\in\Omega} \sum_{\mathbf{j}\in\mathbb{H}_n^*} |D_n(\mathbf{t} - \tfrac{\mathbf{j}}{n})| \le c(\log n)^2, \qquad n \ge 0.$$

By (3.13) and (3.14), the estimate can be further reduced to show that

$$\begin{aligned} J_n(\mathbf{t}) &:= \frac{1}{3n^2} \sum_{\mathbf{j}\in\mathbb{H}_n^*} \left| \frac{\sin \frac{n\pi}{3}(t_2 - t_3 - \frac{j_2 - j_3}{n})}{\sin \frac{\pi}{3}(t_2 - t_3 - \frac{j_2 - j_3}{n})} \frac{\sin \frac{(n+1)\pi}{3}(t_1 - t_3 - \frac{j_1 - j_3}{n})}{\sin \frac{\pi}{3}(t_1 - t_3 - \frac{j_1 - j_3}{n})} \right| \\ &:= \sum_{\mathbf{j}\in\mathbb{H}_n^*} F_n(\mathbf{t} - \tfrac{\mathbf{j}}{n}) \end{aligned} \tag{3.16}$$

and two other similar sums obtained by permuting t_1, t_2, t_3 are bounded by $c(\log n)^2$ for all $\mathbf{t} \in \Omega$. The three sums are similar, so we will work only with (3.16).

Fix a $\mathbf{t} \in \Omega$. If $s_1 + s_2 + s_3 = 0$, then the equations $s_2 - s_3 = t_2 - t_3$ and $s_1 - s_3 = t_1 - t_3$ have the unique solutions $s_2 = t_2$ and $s_3 = t_3$. In particular, there can be at most one $\mathbf{j}$ such that the denominator of $F_n(\mathbf{t} - \frac{\mathbf{j}}{n})$ is zero. Using the well-known inequality $|\sin n\theta / \sin\theta| \le n$ shows that $F_n(\mathbf{t} - \frac{\mathbf{j}}{n}) \le n(n+1)/(3n^2) = \frac{1}{3}(1 + n^{-1})$ for all $\mathbf{j} \in \mathbb{H}_n^*$. We break the summation over $\mathbb{H}_n^*$ into several sums. The first sum is over those $\mathbf{j}$ such that

$$\rho_1(\mathbf{j}) := |t_1 - t_3 - \tfrac{j_1 - j_3}{n}| \quad \text{and} \quad \rho_2(\mathbf{j}) := |t_2 - t_3 - \tfrac{j_2 - j_3}{n}|$$

are both less than n^{-1}. There can be at most 6 such points, so that the sum is bounded by $2(1 + n^{-1})$. The second sum is over those $\mathbf{j}$ such that $\rho_1(\mathbf{j}) < n^{-1}$ but $\rho_2(\mathbf{j}) \ge n^{-1}$. Such $\mathbf{j}$'s are along a line $\rho_1(\mathbf{j}) = 0$, and there are at most $2n$ of them so that this sum is bounded by

$$\begin{aligned} \frac{n+1}{3n^2} \sum_{\rho_2(\mathbf{j})\ge n^{-1}} \left| \frac{\sin \frac{n\pi}{3}(t_2 - t_3 - \frac{j_2 - j_3}{n})}{\sin \frac{\pi}{3}(t_2 - t_3 - \frac{j_2 - j_3}{n})} \right| &\le \frac{c}{n} \sum_{\rho_2(\mathbf{j})\ge n^{-1}} \frac{1}{\rho_2(\mathbf{j})} \\ &\le c \sum_{k=1}^{2n} \frac{1}{k} \le c \log n, \end{aligned}$$

using the fact that $\sin\theta \ge (2/\pi)\theta$ for $0 \le \theta \le \pi/2$. The third sum is over those $\mathbf{j}$ such that $\rho_1(\mathbf{j}) \ge n^{-1}$ but $\rho_2(\mathbf{j}) < n^{-1}$, which can be estimated similarly. The last sum is over those $\mathbf{j}$ such that $\rho_1(\mathbf{j}) \ge n^{-1}$ and $\rho_2(\mathbf{j}) \ge n^{-1}$, which is, using once again the inequalities $\sin\theta \ge (2/\pi)\theta$, bounded by

$$\begin{aligned}\frac{c}{n^2} \sum_{\rho_1(\mathbf{j}),\rho_2(\mathbf{j})\ge n^{-1}} \frac{1}{\rho_1(\mathbf{j})\rho_2(\mathbf{j})} &\le \frac{c}{n^2} \sum_{\rho_1(\mathbf{j})\ge n^{-1}} \frac{1}{\rho_1(\mathbf{j})} \sum_{\rho_2(\mathbf{j})\ge n^{-1}} \frac{1}{\rho_2(\mathbf{j})} \\ &\le c \sum_{k=1}^{2n} \frac{1}{k} \sum_{k=1}^{2n} \frac{1}{k} \le c(\log n)^2.\end{aligned}$$

Putting these estimates together completes the proof. ∎

4. Discrete Fourier analysis on the triangle. Working with functions invariant under the isometries of the hexagon lattice, we can carry out a Fourier analysis on the equilateral triangle based on the analysis on the hexagon.

4.1. Generalized sine and cosine functions. The group $\mathcal{G}$ of isometries of the hexagon lattice is generated by the reflections in the edges of the equilateral triangles inside it, which is the reflection group $\mathcal{A}_2$. In homogeneous coordinates, the three reflections $\sigma_1, \sigma_2, \sigma_3$ are defined by

$$\mathbf{t}\sigma_1 := -(t_1, t_3, t_2), \quad \mathbf{t}\sigma_2 := -(t_2, t_1, t_3), \quad \mathbf{t}\sigma_3 := -(t_3, t_2, t_1).$$

Because of the relations $\sigma_3 = \sigma_1\sigma_2\sigma_1 = \sigma_2\sigma_1\sigma_2$, the group $\mathcal{G}$ is given by

$$\mathcal{G} = \{1, \sigma_1, \sigma_2, \sigma_3, \sigma_1\sigma_2, \sigma_2\sigma_1\}.$$

For a function f in homogeneous coordinates, the action of the group $\mathcal{G}$ on f is defined by $\sigma f(\mathbf{t}) = f(\mathbf{t}\sigma)$, $\sigma \in \mathcal{G}$. Following [9], we call a function f *invariant* under $\mathcal{G}$ if $\sigma f = f$ for all $\sigma \in \mathcal{G}$, and we call it *anti-invariant* under $\mathcal{G}$ if $\sigma f = \rho(\sigma) f$ for all $\sigma \in \mathcal{G}$, where $\rho(\sigma) = -1$ if $\sigma = \sigma_1, \sigma_2, \sigma_3$, and $\rho(\sigma) = 1$ for other elements in $\mathcal{G}$. The following proposition is easy to verify [9].

PROPOSITION 4.1. *Define two operators $\mathcal{P}^+$ and $\mathcal{P}^-$ acting on $f(\mathbf{t})$ by*

$$\mathcal{P}^{\pm} f(\mathbf{t}) = \frac{1}{6}\left[f(\mathbf{t}) + f(\mathbf{t}\sigma_1\sigma_2) + f(\mathbf{t}\sigma_2\sigma_1) \pm f(\mathbf{t}\sigma_1) \pm f(\mathbf{t}\sigma_2) \pm f(\mathbf{t}\sigma_3)\right]. \tag{4.1}$$

Then the operators $\mathcal{P}^+$ and $\mathcal{P}^-$ are projections from the class of H-periodic functions onto the class of invariant, respectively, anti-invariant, functions.

Recall that $\phi_{\mathbf{k}}(\mathbf{t}) = \mathrm{e}^{\frac{2\pi i}{3}\mathbf{k}\cdot\mathbf{t}}$. Following [21], we shall call the functions

$$\begin{aligned}\mathsf{TC}_{\mathbf{k}}(\mathbf{t}) := \mathcal{P}^+\phi_{\mathbf{k}}(\mathbf{t}) =& \frac{1}{6}\left[\phi_{k_1,k_2,k_3}(\mathbf{t}) + \phi_{k_2,k_3,k_1}(\mathbf{t}) + \phi_{k_3,k_1,k_2}(\mathbf{t})\right. \\ &\left. + \phi_{-k_1,-k_3,-k_2}(\mathbf{t}) + \phi_{-k_2,-k_1,-k_3}(\mathbf{t}) + \phi_{-k_3,-k_2,-k_1}(\mathbf{t})\right], \\ \mathsf{TS}_{\mathbf{k}}(\mathbf{t}) := \frac{1}{i}\mathcal{P}^-\phi_{\mathbf{k}}(\mathbf{t}) =& \frac{1}{6i}\left[\phi_{k_1,k_2,k_3}(\mathbf{t}) + \phi_{k_2,k_3,k_1}(\mathbf{t}) + \phi_{k_3,k_1,k_2}(\mathbf{t})\right. \\ &\left. - \phi_{-k_1,-k_3,-k_2}(\mathbf{t}) - \phi_{-k_2,-k_1,-k_3}(\mathbf{t}) - \phi_{-k_3,-k_2,-k_1}(\mathbf{t})\right]\end{aligned}$$

a *generalized cosine* and a *generalized sine*, respectively, where the second equal sign follows from the fact that $\phi_{\mathbf{k}}(\mathbf{t}\sigma) = \phi_{\mathbf{k}\sigma}(\mathbf{t})$ for every $\sigma \in \mathcal{G}$. It follows that $\mathsf{TC}_{\mathbf{k}}$ and $\mathsf{TS}_{\mathbf{k}}$ are invariant and anti-invariant, respectively.

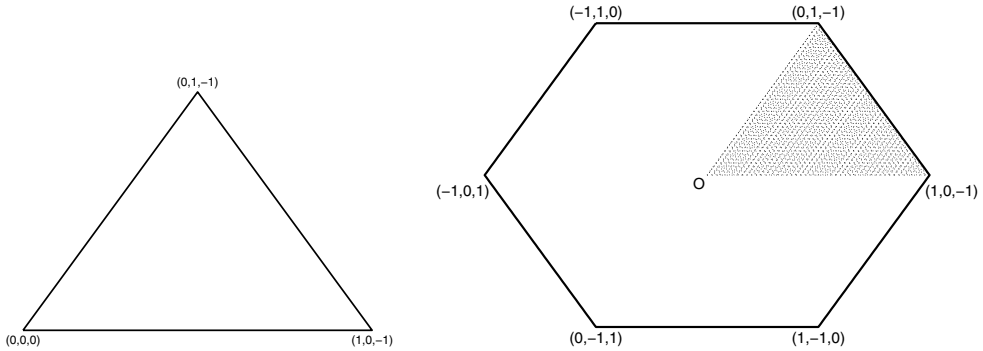

FIG. 5. *The equilateral triangle* Δ *in the hexagon.*

These two functions appear as eigenfunctions of the Laplacian on the triangle and have been studied in [9, 12, 13, 15, 16, 21, 22] under various coordinate systems. In particular, they are shown to share many properties of the classical sine and cosine functions in homogeneous coordinates in [21, 22]. Some of those properties that we shall need will be recalled below. The advantage of homogeneous coordinates lies in the symmetry of the formulas. For example, the equations $t_1 + t_2 + t_3 = 0$ and $k_1 + k_2 + k_3 = 0$ can be used to write $\mathsf{TC}_{\mathbf{k}}$ and $\mathsf{TS}_{\mathbf{k}}$ in several useful forms, such as

$$\begin{aligned}\mathsf{TC}_{\mathbf{k}}(\mathbf{t}) =& \frac{1}{3}\Big[\mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_2-t_3)}\cos k_1\pi t_1 \\ &+ \mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_3-t_1)}\cos k_1\pi t_2 + \mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_1-t_2)}\cos k_1\pi t_3\Big],\end{aligned} \tag{4.2}$$

$$\begin{aligned}\mathsf{TS}_{\mathbf{k}}(\mathbf{t}) =& \frac{1}{3}\Big[\mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_2-t_3)}\sin k_1\pi t_1 \\ &+ \mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_3-t_1)}\sin k_1\pi t_2 + \mathrm{e}^{\frac{i\pi}{3}(k_2-k_3)(t_1-t_2)}\sin k_1\pi t_3\Big],\end{aligned} \tag{4.3}$$

and similar formulas derived from the permutations of t_1, t_2, t_3. In particular, it follows from (4.3) that $\mathsf{TS}_{\mathbf{k}}(\mathbf{t}) \equiv 0$ whenever $\mathbf{k}$ contains one zero component.

For invariant functions, we can use symmetry to translate the results on the hexagon to one of its six equilateral triangles. We shall choose the triangle as

$$\begin{aligned}\Delta :=& \{(t_1,t_2,t_3) : t_1+t_2+t_3 = 0, 0 \le t_1, t_2, -t_3 \le 1\} \\ =& \{(t_1,t_2) : t_1, t_2 \ge 0,\, t_1+t_2 \le 1\}.\end{aligned} \tag{4.4}$$

The region Δ and its relative position in the hexagon is depicted in Figure 5. The inner product on Δ is defined by

$$\langle f, g\rangle_\Delta := \frac{1}{|\Delta|}\int_\Delta f(\mathbf{t})\overline{g(\mathbf{t})}d\mathbf{t} = 2\int_\Delta f(t_1,t_2)\overline{g(t_1,t_2)}dt_1dt_2.$$

If $f\bar{g}$ is invariant under $\mathcal{G}$, then it is easy to see that $\langle f, g\rangle_H = \langle f, g\rangle_\Delta$.

When $\mathsf{TC}_{\mathbf{k}}$ are restricted to the triangle Δ, we only need to consider a subset of $\mathbf{k} \in \mathbb{H}$. In fact, since $\mathsf{TC}_{\mathbf{k}\sigma}(\mathbf{t}) = \mathsf{TC}_{\mathbf{k}}(\mathbf{t}\sigma) = \mathsf{TC}_{\mathbf{k}}(\mathbf{t})$ for $\mathbf{t} \in \Delta$ and $\sigma \in \mathcal{G}$, we can restrict $\mathbf{k}$ to the index set

$$\Lambda := \{\mathbf{k} \in \mathbb{H} : k_1 \ge 0, k_2 \ge 0, k_3 \le 0\}. \tag{4.5}$$

We define the space $\mathcal{T}$ as the collection of finite linear combinations of elements in $\{\mathsf{TC}_{\mathbf{k}}, \mathsf{TS}_{\mathbf{k}} : \mathbf{k} \in \Lambda\}$; that is,

$$\mathcal{T} = \left\{ \sum_{\mathbf{k}\in\Xi} (a_{\mathbf{k}} \mathsf{TC}_{\mathbf{k}} + b_{\mathbf{k}} \mathsf{TS}_{\mathbf{k}}) : a_{\mathbf{k}}, b_{\mathbf{k}} \in \mathbb{C}, \Xi \subset \Lambda, \#\Xi < \infty \right\}. \tag{4.6}$$

Since $\mathsf{TS}_{\mathbf{k}}(\mathbf{t}) = 0$ whenever $\mathbf{k}$ has a zero component, $\mathsf{TS}_{\mathbf{k}}(\mathbf{t})$ are defined only for $\mathbf{k} \in \Lambda^\circ$, where

$$\Lambda^\circ := \{\mathbf{k} \in \mathbb{H} : k_1 > 0, k_2 > 0, k_3 < 0\},$$

which is the set of the interior points of Λ. These functions are orthogonal on Δ.

PROPOSITION 4.2. *For* $\mathbf{k}, \mathbf{j} \in \Lambda$,

$$\langle \mathsf{TC}_{\mathbf{k}}, \mathsf{TC}_{\mathbf{j}} \rangle_\Delta = \delta_{\mathbf{k},\mathbf{j}} \begin{cases} 1, & \mathbf{k} = 0, \\ \frac{1}{3}, & \mathbf{k} \in \Lambda \setminus \Lambda^\circ,\ \mathbf{k} \neq 0, \\ \frac{1}{6}, & \mathbf{k} \in \Lambda^\circ, \end{cases} \tag{4.7}$$

and for $\mathbf{k}, \mathbf{j} \in \Lambda^\circ$,

$$\langle \mathsf{TS}_{\mathbf{k}}, \mathsf{TS}_{\mathbf{j}} \rangle_\Delta = \frac{1}{6}\, \delta_{\mathbf{k},\mathbf{j}}. \tag{4.8}$$

This follows easily from $\langle f, g\rangle_H = \langle f, g\rangle_\Delta$, which holds if $f\bar{g}$ is invariant, the fact that $\mathsf{TC}_{\mathbf{k}}$ is invariant and $\mathsf{TS}_{\mathbf{k}}$ is anti-invariant, and the orthogonality of $\phi_{\mathbf{k}}$ in (3.3). The norms of $\mathsf{TC}_{\mathbf{k}}$ are divided into three cases, since $\mathsf{TC}_0(\mathbf{t}) = 1$ and

$$\mathsf{TC}_{\mathbf{k}}(\mathbf{t}) = \frac{1}{3}\left[\phi_{k_1,k_2,k_3}(\mathbf{t}) + \phi_{k_2,k_3,k_1}(\mathbf{t}) + \phi_{k_3,k_1,k_2}(\mathbf{t})\right], \qquad k_1k_2k_3 = 0.$$

4.2. Discrete inner product on the triangle. Using the fact that $\mathsf{TC}_{\mathbf{k}}$ and $\mathsf{TS}_{\mathbf{k}}$ are invariant and anti-invariant under $\mathcal{G}$ and the orthogonality of $\phi_{\mathbf{k}}$ with respect to the symmetric inner product $\langle\cdot,\cdot\rangle_n^*$, we can deduce a discrete orthogonality for the generalized cosine and sine functions. For this purpose, we define

$$\Lambda_n := \{\mathbf{k} \in \Lambda : -k_3 \le n\} = \{(k_1, k_2) \in \mathbb{Z}^2 : k_1 \ge 0, k_2 \ge 0, k_1 + k_2 \le n\},$$

and we denote by $\Lambda^\circ, \Lambda_n^{\mathrm{e}}, \Lambda_n^{\mathrm{v}}$ the set of points in the interior of Λ_n, on the boundary of Λ_n but not vertices, and at vertices, respectively; that is,

$$\begin{aligned} \Lambda_n^\circ &:= \{\mathbf{k} \in \Lambda_n : k_1 > 0, k_2 > 0, -k_3 < n\}, \\ \Lambda_n^{\mathrm{v}} &:= \{(n, 0, -n), (0, n, -n), (0, 0, 0)\}, \\ \Lambda_n^{\mathrm{e}} &:= \{\mathbf{k} \in \Lambda_n : \mathbf{k} \notin \Lambda_n^\circ \cup \Lambda^{\mathrm{v}}\}. \end{aligned}$$

We then define by $\mathcal{T}C_n$ and $\mathcal{T}S_n$ the subspace of $\mathcal{T}$ defined by

$$\mathcal{T}C_n = \operatorname{span}\{\mathsf{TC}_{\mathbf{k}} : \mathbf{k} \in \Lambda_n\} \quad \text{and} \quad \mathcal{T}S_n = \operatorname{span}\{\mathsf{TS}_{\mathbf{k}} : \mathbf{k} \in \Lambda_n^\circ\},$$

respectively.

THEOREM 4.3. *Let the discrete inner product* $\langle\cdot,\cdot\rangle_{\Delta,n}$ *be defined by*

$$\langle f, g\rangle_{\Delta,n} = \frac{1}{3n^2} \sum_{\mathbf{j}\in\Lambda_n} \lambda_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) \overline{g(\tfrac{\mathbf{j}}{n})},$$

where

$$\lambda_{\mathbf{j}}^{(n)} := \begin{cases} 6, & \mathbf{j} \in \Lambda^\circ, \\ 3, & \mathbf{j} \in \Lambda^{\mathrm{e}}, \\ 1, & \mathbf{j} \in \Lambda^{\mathrm{v}}. \end{cases} \tag{4.9}$$

Then

$$\langle f, g\rangle_\Delta = \langle f, g\rangle_{\Delta,n}, \qquad f, g \in \mathcal{T}C_n. \tag{4.10}$$

Proof. We shall deduce the result from the discrete inner product $\langle \cdot, \cdot \rangle_n^*$ defined in (3.6). Let $\mathbf{j}\mathcal{G}$ denote the orbit of $\mathbf{j}$ under $\mathcal{G}$, which is the set $\{\mathbf{j}\sigma : \sigma \in \mathcal{G}\}$. It is easy to see that for $\mathbf{j} \in \mathbb{H}$,

$$|\mathbf{j}\mathcal{G}| = \begin{cases} 6 & \text{if } j_1 j_2 j_3 \neq 0, \\ 3 & \text{if } j_1 j_2 j_3 = 0 \text{ but } \mathbf{j} \neq (0,0,0), \\ 1 & \text{if } \mathbf{j} = (0,0,0). \end{cases} \tag{4.11}$$

Assume that f is invariant. Using (4.11), we see that

$$\begin{aligned} \sum_{\mathbf{j}\in\mathbb{H}_n^*, j_1 j_2 j_3 \neq 0} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) &= 6 \sum_{\mathbf{j}\in\Lambda_n^\circ} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) + 6 \sum_{\mathbf{j}\in\Lambda_n^{\mathrm{e}}, j_1 j_2 j_3 \neq 0} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) \\ &= \sum_{\mathbf{j}\in\Lambda_n, j_1 j_2 j_3 \neq 0} \lambda_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) \end{aligned}$$

and

$$\begin{aligned} \sum_{\mathbf{j}\in\mathbb{H}_n^*, j_1 j_2 j_3 = 0} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) &= f(0,0,0) + 3 \sum_{j\in\Lambda^{\mathrm{e}}, j_1 j_2 j_3 = 0} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) + 3 \sum_{j\in\Lambda^{\mathrm{v}}, \mathbf{j}\neq 0} c_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}) \\ &= \sum_{\mathbf{j}\in\Lambda_n, j_1 j_2 j_3 = 0} \lambda_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}). \end{aligned}$$

Replacing f by $f\bar{g}$ and adding these two sums, we have proved that $\langle f, g\rangle_n^* = \langle f, g\rangle_{\Delta,n}$ for invariant $f\bar{g}$, which applies to $f, g \in \mathcal{T}C_{n-1}$. Thus, the stated result follows immediately from Theorem 3.3 and the fact that $\langle f, g\rangle_H = \langle f, g\rangle_\Delta$. ∎

The proof of the above proposition also applies to $f, g \in \mathcal{T}S_n$ as $f\bar{g}$ is invariant if both f and g are anti-invariant. Notice also that $\mathcal{T}S_{\mathbf{j}}(\frac{\mathbf{j}}{n}) = 0$ when $\mathbf{j} \in \Lambda^{\mathrm{e}}$, and hence we conclude the following result.

PROPOSITION 4.4. *Let the discrete inner product $\langle \cdot, \cdot \rangle_{\Delta^\circ,n}$ be defined by*

$$\langle f, g\rangle_{\Delta^\circ,n} = \frac{2}{n^2} \sum_{\mathbf{j}\in\Lambda_n^\circ} f(\tfrac{\mathbf{j}}{n}) \overline{g(\tfrac{\mathbf{j}}{n})}.$$

Then

$$\langle f, g\rangle_\Delta = \langle f, g\rangle_{\Delta^\circ,n}, \qquad f, g \in \mathcal{T}S_n. \tag{4.12}$$

The relation (4.10) can be regarded as a cubature formula

$$\frac{1}{|\Delta|} \int_\Delta f(\mathbf{t}) d\mathbf{t} = \frac{1}{3n^2} \sum_{\mathbf{j}\in\Lambda_n} \lambda_{\mathbf{j}}^{(n)} f(\tfrac{\mathbf{j}}{n}),$$

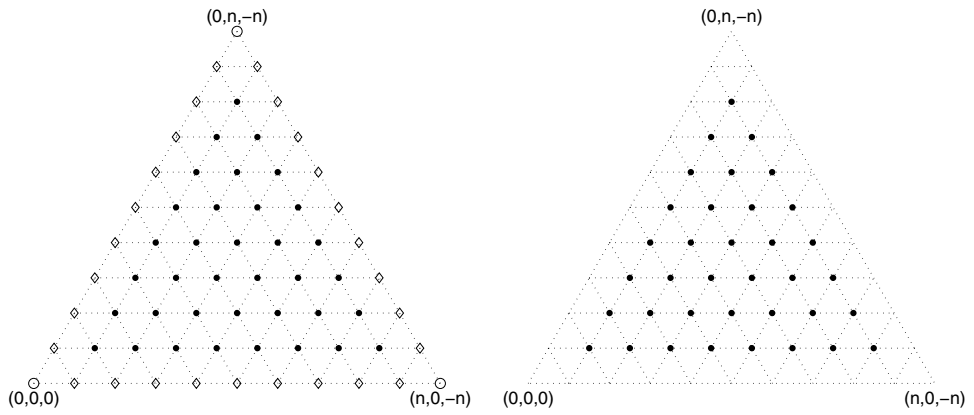

FIG. 6. *Left:* Λ_n *in which* $\bullet$, $\diamond$, *and* $\circ$ *correspond to points of different coefficients in* $\langle\cdot,\cdot\rangle_n^*$. *Right:* $\bullet$ *indicates points in* Λ°.

which is exact for $f = g\bar{h}$, $g, h \in \mathcal{TC}_n$. It turns out, however, that much more is true. We state the following result in terms of the triangle in (t_1, t_2).

THEOREM 4.5. *For* $n \ge 0$, *the cubature formula*

$$2\int_\Delta f(t_1,t_2)dt_1dt_2 = \frac{1}{3n^2}\sum_{j_1=0}^{n}\sum_{j_2=0}^{j_1}\lambda_{\mathbf{j}}^{(n)} f\left(\tfrac{j_1}{n}, \tfrac{j_2}{n}\right) \tag{4.13}$$

is exact for all $f \in \mathcal{TC}_{2n-1}$.

In order to establish such a result, we will need to study the structure of $\mathcal{TC}_n$, which, along with the proof of the theorem, will be given in section 5. One may note that the formulation of the result resembles a Gaussian quadrature. There is indeed a connection, which will also be explored in section 5.

4.3. Interpolation on the triangle. One way to deduce the result on interpolation is by making use of the orthogonality of generalized trigonometric functions with respect to the discrete inner product, as shown in the first theorem below. Recall the operator $\mathcal{P}^\pm$ defined in (4.1).

THEOREM 4.6. *For* $n \ge 0$ *and* $f \in C(\Delta)$ *define*

$$\mathcal{L}_n f(\mathbf{t}) := \sum_{\mathbf{j}\in\Lambda_n^\circ} f(\tfrac{\mathbf{j}}{n})\ell_{\mathbf{j},n}^\circ(\mathbf{t}), \qquad \ell_{\mathbf{j},n}^\circ(\mathbf{t}) = \frac{2}{n^2}\sum_{\mathbf{k}\in\Lambda_n^\circ} \mathsf{TS}_{\mathbf{k}}(\mathbf{t})\overline{\mathsf{TS}_{\mathbf{k}}(\tfrac{\mathbf{j}}{n})}.$$

Then $\mathcal{L}_n$ *is the unique function in* $\mathcal{TS}_n$ *that satisfies*

$$\mathcal{L}_n f(\tfrac{\mathbf{j}}{n}) = f(\tfrac{\mathbf{j}}{n}), \qquad \mathbf{j} \in \Lambda_n^\circ.$$

Furthermore, the fundamental interpolation function $\ell_{\mathbf{j},n}^\circ$ *is real and satisfies*

$$\ell_{\mathbf{j},n}^\circ(\mathbf{t}) = \frac{1}{3n^2}\mathcal{P}_{\mathbf{t}}^-\left[\Theta_{n-1}(\mathbf{t}-\tfrac{\mathbf{j}}{n}) - \Theta_{n-2}(\mathbf{t}-\tfrac{\mathbf{j}}{n})\right],$$

where $\mathcal{P}_{\mathbf{t}}^-$ *means that the operator* $\mathcal{P}^-$ *is acting on the the variable* $\mathbf{t}$ *and* Θ_n *is defined in* (3.10).

Proof. By (4.8) and (4.12), $\langle \mathsf{TS}_{\mathbf{j}}, \mathsf{TS}_{\mathbf{k}}\rangle_{\Delta^\circ,n} = \frac{1}{6}\delta_{\mathbf{k},\mathbf{j}}$, which shows that $\ell_{\mathbf{j},n}^\circ(\frac{\mathbf{k}}{n}) = \delta_{\mathbf{k},\mathbf{j}}$ and verifies the interpolation condition. Furthermore, since $\mathsf{TS}_{\mathbf{k}}(\frac{\mathbf{j}}{n}) = \mathsf{TS}_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = 0$

whenever $\mathbf{k} \in \Lambda_n \setminus \Lambda_n^\circ$, and $\mathsf{TS}_{\mathbf{j}}(\mathbf{t}) = 0$ whenever $j_1 j_2 j_3 = 0$, it follows from the definition of $\mathsf{TS}_{\mathbf{j}}$ that

$$\ell^\circ_{\mathbf{j},n}(\mathbf{t}) = \frac{1}{3n^2}\mathcal{P}^-_{\mathbf{t}}\mathcal{P}^-_{\mathbf{j}} \sum_{\mathbf{k}\in\mathbb{H}^\circ_n} \phi_{\mathbf{k}}(\mathbf{t})\overline{\phi_{\mathbf{k}}(\tfrac{\mathbf{j}}{n})} = \frac{1}{3n^2}\mathcal{P}^-_{\mathbf{t}}\mathcal{P}^-_{\mathbf{j}} D_{n-1}(\mathbf{t} - \tfrac{\mathbf{j}}{n}),$$

where D_n is defined in (3.12). To complete the proof we use the fact that if F is an invariant function, then

$$\mathcal{P}^-_{\mathbf{t}}\mathcal{P}^-_{\mathbf{s}} F(\mathbf{t} - \mathbf{s}) = \mathcal{P}^-_{\mathbf{t}} F(\mathbf{t} - s),$$

which can be easily verified by using the fact that the elements of the group $\mathcal{G}$ satisfy $\sigma_i^2 = 1$, $i = 1, 2, 3$, and $\sigma_3 = \sigma_1\sigma_2\sigma_1 = \sigma_2\sigma_1\sigma_2$. □

We can derive the result of interpolation on the Λ_n using the same approach, but it is more illustrative to derive it from the interpolation on the hexagon given in Theorem 3.5.

THEOREM 4.7. *For $n \ge 0$ and $f \in C(\Delta)$ define*

$$\mathcal{L}^*_n f(\mathbf{t}) := \sum_{\mathbf{j}\in\Lambda_n} f(\tfrac{\mathbf{j}}{n})\ell^\Delta_{\mathbf{j},n}(\mathbf{t}), \qquad \ell^\Delta_{\mathbf{j},n}(\mathbf{t}) = \lambda^{(n)}_{\mathbf{j}}\mathcal{P}^+\ell_{\mathbf{j},n}(\mathbf{t}), \tag{4.14}$$

where $\lambda^{(n)}_{\mathbf{j}}$ and $\ell_{\mathbf{j},n}$ are defined in (4.9) *and* (3.7)*, respectively. Then $\mathcal{L}^*_n$ is the unique function in $\mathcal{T}C_n$ that satisfies*

$$\mathcal{L}^*_n f(\tfrac{\mathbf{j}}{n}) = f(\tfrac{\mathbf{j}}{n}), \qquad \mathbf{j} \in \Lambda_n.$$

Furthermore, the fundamental interpolation function $\ell_{\mathbf{j},n}$ is given by

$$\ell^\Delta_{\mathbf{j},n}(\mathbf{t}) = \frac{\lambda^{(n)}_{\mathbf{j}}}{3n^2}\left[\frac{1}{2}\mathcal{P}^+\big(\Theta_n(\mathbf{t} - \tfrac{\mathbf{j}}{n}) - \Theta_{n-2}(\mathbf{t} - \tfrac{\mathbf{j}}{n})\big) - \Re\left\{\mathsf{TC}_{n,0,-n}(\mathbf{t})\overline{\mathsf{TC}_{n,0,-n}(\tfrac{\mathbf{j}}{n})}\right\}\right].$$

Proof. Throughout this proof, write $\ell_{\mathbf{j}} = \ell_{\mathbf{j},n}$. Recall (3.11), which states that $\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = 1$ if $\mathbf{k} \equiv \mathbf{j} \mod 3$ and $\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = 0$ otherwise. Let $\mathbf{k} \in \Lambda$. If $\mathbf{j} \in \Lambda^\circ$, then we have $\mathcal{P}^+\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \frac{1}{6}\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = [\lambda^{(n)}_{\mathbf{j}}]^{-1}\delta_{\mathbf{k},\mathbf{j}}$. If $\mathbf{j} \in \Lambda^{\mathrm{e}}$ and $j_1 j_2 j_3 \ne 0$, then $\mathcal{P}^+\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \frac{1}{6}[\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) + \ell_{\mathbf{j}}(\frac{\mathbf{k}^*}{n})] = \frac{1}{3}\delta_{\mathbf{k},\mathbf{j}} = [\lambda^{(n)}_{\mathbf{j}}]^{-1}\delta_{\mathbf{k},\mathbf{j}}$, where k^* is defined as in the proof of Theorem 3.5. If $\mathbf{j} \in \Lambda^{\mathrm{e}}$ and $j_1 j_2 j_3 = 0$, then $\mathcal{P}^+\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \frac{1}{3}\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = [\lambda^{(n)}_{\mathbf{j}}]^{-1}\delta_{\mathbf{k},\mathbf{j}}$ since $\mathbf{j} \in \mathbb{H}^\circ_n$. If $\mathbf{j} \in \Lambda^{\mathrm{v}}$ and $\mathbf{j} \ne (0,0,0)$, then $\mathcal{P}^+\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \frac{1}{3}\sum_{\mathbf{l}\in\mathcal{S}_{\mathbf{j}}}\ell_{\mathbf{l}}(\frac{\mathbf{k}}{n}) = \delta_{\mathbf{j},\mathbf{k}} = [\lambda^{(n)}_{\mathbf{j}}]^{-1}\delta_{\mathbf{k},\mathbf{j}}$, where $\mathcal{S}_{\mathbf{j}}$ is defined as in the proof of Theorem 3.5. Finally, if $\mathbf{j} = (0,0,0)$, $\mathcal{P}^+\ell_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \delta_{\mathbf{k},\mathbf{j}} = [\lambda^{(n)}_{\mathbf{j}}]^{-1}\delta_{\mathbf{k},\mathbf{j}}$. Putting these together, we have proved that $\ell^\Delta_{\mathbf{j}}(\frac{\mathbf{k}}{n}) = \delta_{\mathbf{k},\mathbf{j}}$, which verifies the interpolation condition.

The explicit formula of $\ell^\Delta_{\mathbf{j}}$ follows from (3.9) and the fact that

$$\begin{aligned}\mathcal{P}^+ \sum_{\mathbf{k}\in\mathbb{H}^{\mathrm{v}}_n} \phi_{\mathbf{k}}(\mathbf{t} - \tfrac{\mathbf{j}}{n}) &= \mathcal{P}^+ \sum_{\mathbf{k}\in\mathbb{H}^{\mathrm{v}}_n} \phi_{\mathbf{k}}(\mathbf{t})\overline{\phi_{\mathbf{k}}(\tfrac{\mathbf{j}}{n})} = \sum_{\mathbf{k}\in\mathbb{H}^{\mathrm{v}}_n} \mathsf{TC}_{\mathbf{k}}(\mathbf{t})\overline{\phi_{\mathbf{k}}(\tfrac{\mathbf{j}}{n})} \\ &= 3\mathsf{TC}_{n,0,-n}(\mathbf{t})\overline{\mathsf{TC}_{n,0,-n}(\tfrac{\mathbf{j}}{n})} + 3\mathsf{TC}_{0,n,-n}(\mathbf{t})\overline{\mathsf{TC}_{0,n,-n}(\tfrac{\mathbf{j}}{n})},\end{aligned}$$

as well as the fact that $\overline{\mathsf{TC}_{0,n,-n}(\mathbf{t})} = \mathsf{TC}_{n,0,-n}(\mathbf{t})$. □

As a consequence of Theorem 3.6, we immediately have the following.

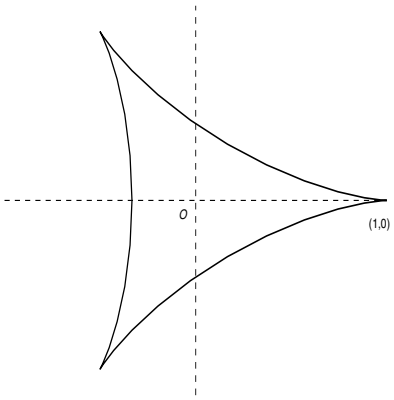

FIG. 7. *The region $\triangle^*$ bounded by Steiner's hypocycloid.*

THEOREM 4.8. *Let $\|\mathcal{L}_n\|$ and $\|\mathcal{L}_n^*\|$ denote the operator norm of $\mathcal{L}_n : C(\Delta) \mapsto C(\Delta)$ and $\mathcal{L}_n^* : C(\Delta) \mapsto C(\Delta)$, respectively. Then there is a constant c, independent of n, such that*

$$\|\mathcal{L}_n\| \le c(\log n)^2 \quad \text{and} \quad \|\mathcal{L}_n^*\| \le c(\log n)^2.$$

In particular, if $f \in C^1(\Omega)$, the class of functions having continuous derivatives on Ω, then both $\mathcal{L}_n f$ and $\mathcal{L}_n^* f$ converge uniformly to f on Ω.

This theorem shows a sharp contrast between interpolation by trigonometric functions on Λ_n or Λ_n° and the interpolation by algebraic polynomials on Λ_n. From the result in one variable [17], the Lebesgue constant for algebraic polynomial interpolation grows exponentially as $n \to \infty$ and, as a consequence, the convergence does not hold in $C^1(\Omega)$.

5. Generalized Chebyshev polynomials and their zeros. Just as in the classical case of one variable, we can use the generalized sine and cosine functions to define analogues of Chebyshev polynomials of the first and the second kind, respectively, which are orthogonal polynomials of the two variables.

5.1. Generalized Chebyshev polynomials. To see the polynomial structure among the generalized trigonometric functions, we make a change of variables. Denote

$$z := \mathsf{TC}_{0,1,-1}(\mathbf{t}) = \tfrac{1}{3}[\phi_{0,1,-1}(\mathbf{t}) + \phi_{1,-1,0}(\mathbf{t}) + \phi_{-1,0,1}(\mathbf{t})], \tag{5.1}$$

whose real part and imaginary part, after simplification using (3.15), are

$$\begin{aligned} x &= \Re z = \tfrac{4}{3}\cos\tfrac{\pi}{3}(t_2 - t_1)\cos\tfrac{\pi}{3}(t_3 - t_2)\cos\tfrac{\pi}{3}(t_1 - t_3) - \tfrac{1}{3}, \\ y &= \Im z = \tfrac{4}{3}\sin\tfrac{\pi}{3}(t_2 - t_1)\sin\tfrac{\pi}{3}(t_3 - t_2)\sin\tfrac{\pi}{3}(t_1 - t_3), \end{aligned} \tag{5.2}$$

respectively. If we change variables $(t_1, t_2) \mapsto (x, y)$, then the region Δ is mapped onto the region Δ^* bounded by Steiner's hypocycloid (see Figure 7),

$$\Delta^* = \{(x, y) : -3(x^2 + y^2 + 1)^2 + 8(x^3 - 3xy^2) + 4 \ge 0\}. \tag{5.3}$$

DEFINITION 5.1. *Under the change of variables* (5.1)*, define*

$$\begin{aligned} T_k^m(z, \bar z) &:= \mathsf{TC}_{k,m-k,-m}(\mathbf{t}), \qquad 0 \le k \le m, \\ U_k^m(z, \bar z) &:= \frac{\mathsf{TS}_{k+1,m-k+1,-m-2}(\mathbf{t})}{\mathsf{TS}_{1,1,-2}(\mathbf{t})}, \qquad 0 \le k \le m. \end{aligned}$$

We will also use the notation $T_k^m(\mathbf{t})$ and $U_k^m(\mathbf{t})$ when it is more convenient to work with $\mathbf{t}$ variable.

These functions are in fact polynomials of degree m in the z and $\bar{z}$ variables since they both satisfy a simple recursive relation.

PROPOSITION 5.2. *Let P_k^m denote either T_k^m or U_k^m. Then*

$$P_{m-k}^m(z,\bar{z}) = \overline{P_k^m(z,\bar{z})}, \qquad 0 \le k \le m, \tag{5.4}$$

and they satisfy the recursion relation

$$P_k^{m+1}(z,\bar{z}) = 3zP_k^m(z,\bar{z}) - P_{k+1}^m(z,\bar{z}) - P_{k-1}^{m-1}(z,\bar{z}) \tag{5.5}$$

for $0 \le k \le m$ and $m \ge 1$, where we use

$$T_{-1}^m(z,\bar{z}) = T_1^{m+1}(z,\bar{z}), \quad T_{m+1}^m(z,\bar{z}) = T_m^{m+1}(z,\bar{z}),$$
$$U_{-1}^m(z,\bar{z}) = 0, \quad U_m^{m-1}(z,\bar{z}) = 0.$$

In particular, we have

$$T_0^0(z,\bar{z}) = 1, \quad T_0^1(z,\bar{z}) = z, \quad T_1^1(z,\bar{z}) = \bar{z},$$
$$U_0^0(z,\bar{z}) = 1, \quad U_0^1(z,\bar{z}) = 3z, \quad U_1^1(z,\bar{z}) = 3\bar{z}.$$

The recursion relation (5.5) follows from a straightforward computation. Together, (5.5) and (5.4) determine all P_k^m recursively, which show that both T_k^m and U_k^m are polynomials of degree m in z and $\bar{z}$. Furthermore, each family inherits an orthogonal relation from the generalized trigonometric functions, so that they are orthogonal polynomials of two variables. They were studied by Koornwinder [9, 10], who called them the generalized Chebyshev polynomials of the first and the second kind, respectively. Moreover, they are special cases of orthogonal polynomials with respect to the weighted inner product

$$\langle f, g\rangle_{w_\alpha} = c_\alpha \int_{\Delta^*} f(x,y)\overline{g(x,y)}w_\alpha(x,y)dxdy,$$

where w_α is the weight function defined in terms of the Jacobian of the change of variables (5.1),

$$w_\alpha(x,y) = \left|\frac{\partial(x,y)}{\partial(t_1,t_2)}\right|^{2\alpha} = \left[\frac{16}{27}\pi^2 \sin\pi t_1 \sin\pi t_2 \sin\pi(t_1+t_2)\right]^{2\alpha}$$
$$= \frac{4^\alpha}{27^\alpha}\pi^{2\alpha}\left[-3(x^2+y^2+1)^2 + 8(x^3-3xy^2) + 4\right]^\alpha,$$

and c_α is a normalization constant, $c_\alpha := 1/\int_\Delta w_\alpha(x,y)dxdy$. We have, in particular, that $c_{-\frac{1}{2}} = 2$ and $c_{\frac{1}{2}} = 81/(8\pi^4)$. Since the change of variables (5.1) shows immediately that

$$\frac{1}{|\Delta|}\int_\Delta f(\mathbf{t})d\mathbf{t} = c_{-\frac{1}{2}}\int_{\Delta^*} f(x,y)w_{-\frac{1}{2}}(x,y)dxdy,$$

it follows from the orthogonality of $\mathsf{TC_j}$ and $\mathsf{TS_j}$ that T_k^m and U_k^m are orthogonal polynomials with respect to $w_{-\frac{1}{2}}$ and $w_{\frac{1}{2}}$, respectively. Furthermore, from Proposition 4.2

we have

$$\langle T_k^m, T_j^m\rangle_{w_{-\frac{1}{2}}} = d_k^m \delta_{k,j}, \quad d_k^m := \begin{cases} 1, & m = k = 0, \\ \frac{1}{3}, & k = 0 \text{ or } k = m,\ m > 0, \\ \frac{1}{6}, & 1 \le k \le m-1,\ m > 0, \end{cases} \tag{5.6}$$

and

$$\langle U_k^m, U_j^m\rangle_{w_{\frac{1}{2}}} = \frac{1}{6}\delta_{k,j}, \qquad 0 \le j,k \le m. \tag{5.7}$$

Let $\widetilde{T}_k^m = \sqrt{d_k^m} T_k^m$ and $\widetilde{U}_k^m = \sqrt{6} U_k^m$. These are orthonormal polynomials. We introduce the notation

$$\mathbb{P}_m = \{P_0^m, P_1^m, \ldots, P_m^m\} \tag{5.8}$$

for either $P_k^m = \widetilde{T}_k^m$ or $\widetilde{U}_k^m$. The polynomials in $\mathbb{P}_n$ consist of an orthonormal basis for the space $\mathcal{V}_n$ of orthogonal polynomials of degree m. Evidently both T_k^m and U_k^m are complex polynomials. As a consequence of (5.4), however, it is easy to derive real orthogonal polynomials with respect to $w_{\pm\frac{1}{2}}(x,y)$ on Δ^*. In fact, let $\mathbb{P}_m$ be as in (5.8). Then the polynomials in the set $\mathbb{P}_m$ defined by

$$\begin{aligned} \mathbb{P}_{2m-1}^R(x,y) &:= \{\sqrt{2}\Re\{P_k^{2m-1}(z,\bar z)\}, \sqrt{2}\Im\{P_k^{2m-1}(z,\bar z)\}, 0 \le k \le \lfloor m-1 \rfloor\}, \\ \mathbb{P}_{2m}^R(x,y) &:= \{P_m^{2m}, \sqrt{2}\Re\{P_k^{2m}(z,\bar z)\}, \sqrt{2}\Im\{P_k^{2m}(z,\bar z)\}, 0 \le k \le \lfloor m \rfloor\} \end{aligned} \tag{5.9}$$

are real orthonormal polynomials and form a basis for $\mathcal{V}_n$ with $n = 2m-1$ or $2m$, respectively.

5.2. Zeros of Chebyshev polynomials and Gaussian cubature formula. Let w be a nonnegative weight function defined on a compact set Ω in $\mathbb{R}^2$. A cubature formula of degree $2n-1$ is a sum of point evaluations that satisfies

$$\int_\Omega f(x,y) w(x,y)\,dxdy = \sum_{j=1}^N \lambda_j f(x_j, y_j), \qquad \lambda_j \in \mathbb{R},$$

for every $f \in \Pi_{2n-1}^2$, where Π_n^2 denote the space of polynomials of degree at most n in two variables. The points (x_j, y_j) are called nodes of the cubature and the numbers λ_i are called weights. It is well known that a cubature formula of degree $2n-1$ exists only if $N \ge \dim \Pi_{n-1}^2$. A cubature that attains such a lower bound is called a Gaussian cubature.

Let $\mathbb{P}_n := \{P_k^n : 0 \le k \le n\}$ denote a basis of orthonormal polynomials of degree n with respect to $w(x,y)dxdy$. It is known that a Gaussian cubature exists if and only if $\mathbb{P}_n$ (every element in $\mathbb{P}_n$) has $\dim \Pi_{n-1}^2$ many common zeros, which are necessarily real and distinct. Furthermore, the weight λ_j in a Gaussian cubature is given by

$$\lambda_j = [K_{n-1}(x_j, y_j)]^{-1}, \qquad K_n(x,y) := \sum_{k=0}^n \sum_{j=0}^k P_j^k(x) P_j^k(y). \tag{5.10}$$

The definition of $K_n(x,y)$ shows that it is the reproducing kernel of Π_n^2 in $L^2(\mu)$, so that it is independent of the choice of the basis.

Unlike the case of one variable, however, Gaussian cubatures do not exist in general. We refer to [4, 14, 20] for results and further discussions. It is sufficient to say that Gaussian cubatures are rare. In fact, the family of weight functions identified in [18] for which the Gaussian cubature exist for all n remains the only known example up to now.

We now test the above theory on the generalized Chebyshev polynomials. Because of the relation (5.9), we can work with the zeros of the complex polynomials in $\mathbb{P}_n$. Furthermore, it follows from (5.4) that the reproducing kernel

$$K_n(z,w) := \sum_{k=0}^{n} \mathbb{P}_k^{\mathsf{tr}}(z,\bar{z})\mathbb{P}_k(w,\bar{w}) = \sum_{k=0}^{n}\sum_{j=0}^{k} P_j^k(z,\bar{z})P_j^k(w,\bar{w})$$

is real and, by (5.9), is indeed the reproducing kernel of Π_n^2.

For the Chebyshev polynomials of the first kind, the polynomials in $\mathbb{P}_n$ do not have common zeros in general. For example, in the case of $m = 2$, we have $T_0^2(z,\bar{z}) = 3z^2 - 2\bar{z}$ and $T_1^2(z,\bar{z}) = (3z\bar{z} - 1)/2$, so that the three real orthogonal polynomials of degree 2 can be given by

$$\left\{3(x^2 - y^2) - 2x, \quad 6xy + 2y, \quad 3(x^2 + y^2) - 1\right\},$$

which has no common zero at all. Therefore, there is no Gaussian cubature for the weigh function $w_{-\frac{1}{2}}$ on Δ^*.

The Chebyshev polynomials of the second kind, on the other hand, do have the maximum number of common zeros, so that a Gaussian cubature exists for $w_{\frac{1}{2}}(\mathbf{t})$. Let

$$X_n := \Lambda_{n+2}^\circ = \{(\tfrac{k_1}{n+2}, \tfrac{k_2}{n+2}) | k_1 \ge 1, k_2 \ge 1, k_1 + k_2 \le n+1\},$$

which is in the interior of Δ, and let X_n^* denote the image of X_n in Δ^* under the mapping (5.2).

THEOREM 5.3. *For the weight function $w_{\frac{1}{2}}$ on Δ^* a Gaussian cubature formula exists; that is,*

(5.11)
$$c_{\frac{1}{2}} \int_{\Delta^*} f(x,y) w_{\frac{1}{2}}(x,y)dxdy = \sum_{j_1=1}^{n+1} \sum_{j_2=1}^{n+1-j_1} \mu_j^{(n)} f(\tfrac{j_1}{n+2}, \tfrac{j_2}{n+2}) \quad \textit{for all } f \in \Pi_{2n-1},$$

where $j = (j_1, j_2)$,

$$\mu_j^{(n)} = \tfrac{32}{9(n+2)^2} \sin^2 \pi \tfrac{j_1}{n+2} \sin^2 \pi \tfrac{j_2}{n+2} \sin^2 \pi \tfrac{j_1+j_2}{n+2}.$$

Proof. The numerator of $U_k^n(\mathbf{t})$ is $\mathsf{TS}_{k+1,n-k+1,-n-2}(\mathbf{t})$, which is zero at all $\frac{j}{n+2}$ according to (4.3). The first equation of (3.15) shows that the denominator of $U_k^n(\mathbf{t})$ is

$$\mathsf{TS}_{1,1,-2}(\mathbf{t}) = \frac{4}{3} \sin \pi t_1 \sin \pi t_2 \sin \pi t_3, \tag{5.12}$$

which vanishes at the integer points on the boundary point of Δ. Consequently, $U_k^n(\mathbf{t})$ does not vanish on the boundary of Δ but vanishes on X_n. It is easy to see that the cardinality of X_n is $\dim \Pi_{n-1}^2$. Consequently, the corresponding $\mathbb{P}_n$ has $\dim \Pi_{n-1}^2$ common zeros in X_n^*, so that the Gaussian cubature with respect to $w_{\frac{1}{2}}$ exists, which

takes the form (5.11). To obtain the formula for $\mu_j^{(n)}$, we note that the change of variables (5.2) shows that (5.11) is the same as

$$\frac{1}{|\Delta|}\int_\Delta f(\mathbf{t})\left[\mathsf{TS}_{1,1,-2}(\mathbf{t})\right]^2 d\mathbf{t} = \frac{2}{(n+2)^2}\sum_{j\in\Lambda^\circ_{n+2}}\left[\mathsf{TS}_{1,1,-2}(\tfrac{\mathbf{j}}{n+2})\right]^2 f(\tfrac{\mathbf{j}}{n+2}),$$

where the last step follows from the fact that $\mathsf{TS}_{1,1,-2}(\mathbf{t})$ vanishes on the boundary of Δ. This is exactly the cubature (4.13) applied to the function $f(\mathbf{t})\left[\mathsf{TS}_{1,1,-2}(\mathbf{t})\right]^2$. ∎

We note that $w_{\frac12}$ is only the second example of a weight function for which a Gaussian cubature exists for all n. Furthermore, the example of $w_{-\frac12}$ shows that the existence of Gaussian cubature does not hold for all weight functions in the family of w_α. In [18], a family of weight functions depending on three parameters that are on a region bounded by a parabola and two lines is shown to ensure Gaussian cubature for all permissible parameters.

The set of nodes of a Gaussian cubature is poised for polynomial interpolation, which shows that there is a unique polynomial P in Π^2_{n-1} such that $P(\xi) = f(\xi)$ for all $\xi \in X_n^*$, where f is an arbitrary function on X_n^*. In fact the general theory (cf. [4]) immediately gives the following result.

PROPOSITION 5.4. *The unique interpolation polynomial of degree n on X_n^* is given by*

$$\mathcal{L}_n f(x) = \sum_{j_1=1}^{n+1}\sum_{j_2=1}^{n+1-j_1} f(\tfrac{j}{n})\mu_j^{(n)} K_n(\mathbf{t}, \tfrac{j}{n}), \tag{5.13}$$

where $x = (x_1, x_2)$ and $z(\mathbf{t}) = x_1 + ix_2$, and $\mathcal{L}_n f$ is of total degree $n-1$ in x.

Under the mapping (5.2), the above interpolation corresponds to a trigonometric interpolation on Λ°_{n+2}. Since $\mu_j^{(n)} = \frac{2}{(n+2)^2}|\mathsf{TS}_{1,1,-2}(\frac{\mathbf{j}}{n})|^2$, it follows readily that

$$\mu_j^{(n)} K_n(\mathbf{t}, \tfrac{j}{n}) = \frac{2}{(n+2)^2}\mathsf{TS}_{1,1,-2}(\tfrac{\mathbf{j}}{n})\sum_{\mathbf{k}\in\Lambda^\circ_{n+2}}\frac{\mathsf{TS}_{\mathbf{k}}(\mathbf{t})\mathsf{TS}_{\mathbf{k}}(\frac{\mathbf{j}}{n})}{\mathsf{TS}_{1,1,-2}(\mathbf{t})},$$

where $\mathbf{j} = (j_1, j_2, -j_1 - j_2)$. Consequently, the interpolation (5.13) is closely related to the trigonometric interpolation on the triangle given in Theorem 4.6.

5.3. Cubature formula and Chebyshev polynomials of the first kind. As discussed in the previous subsection, Gaussian cubature does not exist for $w_{-\frac12}$ on Δ^*. It turns out, however, that there is a Gauss–Lobatto-type cubature for this weight function whose nodes are the points in the set

$$Y_n := \Lambda_n = \left\{\left(\tfrac{k_1}{n}, \tfrac{k_2}{n}\right) | k_1 \ge 0, k_2 \ge 0, k_1 + k_2 \le n\right\},$$

which is located inside Δ. Again we let Y_n^* denote the image of Y_n in Δ^* under the mapping (5.2).

The cardinality of Y_n is $\dim \Pi^2_n$. According to a characterization of cubature formula in the language of ideals and varieties (see [25]), there will be a cubature formula of degree $2n-1$ based on Y_n^* if there are $n+2$ linearly independent polynomials of degree $n+1$ that vanish on Y_n^*. In other words, Y_n^* is the variety of an ideal generated by $n+2$ algebraic polynomials of degree $n+1$, which are necessarily quasi-orthogonal in the sense that they are orthogonal to all polynomials of degree $n-2$. Such an ideal and a basis are described in the following proposition.

PROPOSITION 5.5. *The set Y_n^* is the variety of the polynomial ideal*

$$\langle T_0^{n+1} - T_1^n, \quad T_k^{n+1} - T_{k-1}^{n-1} \quad (1 \le k \le n), \quad T_{n+1}^{n+1} - T_{n-1}^n \rangle. \tag{5.14}$$

Proof. The mapping (5.2) allows us to work with $T_k^n(\mathbf{t})$ on Y_n. Using the explicit formula for $\mathsf{TC}_{k,n-k,-n}$ in (4.2), we have

$$\begin{aligned} T_k^n(\mathbf{t}) = \frac{1}{3}\Big[& e^{\frac{i\pi}{3}(n-2k)(t_2-t_3)} \cos n\pi t_1 \\ & + e^{\frac{i\pi}{3}(n-2k)(t_3-t_1)} \cos n\pi t_2 + e^{\frac{i\pi}{3}(n-2k)(t_1-t_2)} \cos n\pi t_3 \Big]. \end{aligned}$$

Since $n+1-2k = n-1-2(k-1)$, the above formula implies that

$$\begin{aligned} T_k^{n+1}(\mathbf{t}) - T_{k-1}^{n-1}(\mathbf{t}) = \frac{-1}{3}\Big[& e^{\frac{i\pi}{3}(n-2k)(t_2-t_3)} \sin \pi t_1 \sin m\pi t_1 \\ & + e^{\frac{i\pi}{3}(n-2k)(t_3-t_1)} \sin \pi t_2 \sin n\pi t_2 \\ & + e^{\frac{i\pi}{3}(n-2k)(t_1-t_2)} \sin \pi t_3 \sin n\pi t_3 \Big], \end{aligned}$$

from which it follows immediately that $T_k^{n+1} - T_{k-1}^{n+1}$ vanishes on Y_n for $1 \le k \le n$. Furthermore, a tedious computation shows that

$$\begin{aligned} & T_k^n\left(\tfrac{j_1}{n}, \tfrac{j_2}{n}, \tfrac{-j_1-j_2}{n}\right) = \frac{-1}{6} e^{\frac{-2i\pi}{3n}(n+1)j_1 + j_2} \Big[(-2 + e^{2i\pi j_2} + e^{2i\pi(j_1+j_2)}) \\ & + e^{2i\pi \frac{j_2}{n}} (-2e^{2i\pi j_2} + e^{2i\pi(j_1+j_2)} + 1) + e^{2i\pi \frac{j_1+j_2}{n}} (-2e^{2i\pi j_1} + e^{2i\pi j_2} + 1) \Big], \end{aligned}$$

which is evidently zero whenever j_1 and j_2 are integers. Finally, we note that $T_{n+1}^{n+1} - T_{n-1}^n$ is the conjugate of $T_0^{n+1} - T_1^n$. This completes the proof. ∎

As mentioned before, this proposition already implies that a cubature formula of degree $2n-1$ based on the nodes of Y_n^* exists.

THEOREM 5.6. *For the weight function $w_{-\frac{1}{2}}$ on Δ^* the cubature formula*

$$c_{-\frac{1}{2}} \int_{\Delta^*} f(x,y) w_{-\frac{1}{2}}(x,y) dxdy = \frac{1}{3n^2} \sum_{k_1=0}^{n} \sum_{k_2=0}^{k_1} \lambda_k^{(n)} f\left(\tfrac{k_1}{n}, \tfrac{k_2}{n}\right) \quad \text{for all } f \in \Pi_{2n-1} \tag{5.15}$$

holds, where $\lambda_k^{(n)} = \lambda_{k,n-k,-n}^{(n)}$ with $\lambda_{\mathbf{j}}^{(n)}$ given by (4.9).

In fact, the change of variables back to Δ shows that the cubature (5.15) is exactly of the form (4.13), which gives the values of $\lambda_k^{(n)}$. In particular, this gives a proof of Theorem 4.5.

Another way of determining the cubature weight $\lambda_k^{(n)}$ is to work with the reproducing kernel and the polynomial ideal. This approach also gives another way of determining the formula for polynomial interpolation. Furthermore, it fits into a general framework (see [24] and the references therein), and the intermediate results are of independent interest. In the rest of this section, we follow through with this approach.

The recursive relation (5.5) for T_k^m can be conveniently written in matrix form. Recall that for T_k^m, the orthonormal polynomials are

$$P_0^m = \sqrt{3} T_0^m, \quad P_k^m = \sqrt{6} T_k^m \quad (1 \le k \le m-1), \quad P_m^m = \sqrt{3} T_m^m$$

for $m > 0$ and $P_0^0 = 1$. In the following we treat $\mathbb{P}_m$ defined in (5.8) as a column vector. The relation (5.4) shows an important relation

$$\overline{\mathbb{P}_m} = J_{m+1}\mathbb{P}_m, \qquad J_m = \begin{bmatrix} \bigcirc & & 1 \\ & \iddots & \\ 1 & & \bigcirc \end{bmatrix}. \tag{5.16}$$

Using this notation, we have the following three-term relations.

PROPOSITION 5.7. *Define $\mathbb{P}_{-1} = 0$. For $m \ge 0$,*

$$\begin{aligned} z\mathbb{P}_m &= A_m\mathbb{P}_{m+1} + B_m\mathbb{P}_m + C_m\mathbb{P}_{m-1}, \\ \bar{z}\mathbb{P}_m &= C_{m+1}^{\mathsf{tr}}\mathbb{P}_{m+1} + B_m^{\mathsf{tr}}\mathbb{P}_m + A_{m-1}^{\mathsf{tr}}\mathbb{P}_{m-1}, \end{aligned} \tag{5.17}$$

where A_m, B_m, and C_m are given by

$$A_m = \frac{1}{3}\begin{bmatrix} 1 & & & \bigcirc & 0 \\ & \ddots & & & \vdots \\ & & 1 & & \\ \bigcirc & & & \sqrt{2} & 0 \end{bmatrix}, \quad B_m = \frac{1}{3}\begin{bmatrix} 0 & \sqrt{2} & 0 & \dots & \bigcirc \\ 0 & & 1 & & \\ \vdots & & & \ddots & \\ 0 & \bigcirc & & & 1 \quad 0 \\ 0 & 0 & \dots & & 0 \quad \sqrt{2} \end{bmatrix},$$

and $C_m = J_m A_{m-1}^{\mathsf{tr}} J_{m-1}$.

In fact, the first relation is exactly (5.5). To verify the second relation, take the complex conjugate of the first equation and then use (5.16).

In the following we slightly abuse the notation by writing $\mathbb{P}_n(\mathbf{t})$ in place of $\mathbb{P}_n(z)$, when $z = z(\mathbf{t})$ is given by (5.1). Similarly, we write $K_n(\mathbf{t}, \mathbf{s})$ in place of $K_n(z, w)$ when $z = z(\mathbf{t})$ and $w = w(\mathbf{s})$. Just like the case of real orthogonal polynomials, the three-term relation implies a Christoph–Darboux-type formula (see [4]).

PROPOSITION 5.8. *For $m \ge 0$, we have*

$$(z - w)K_n(z, w) := \mathbb{P}_{n+1}^{\mathsf{tr}}(z)A_n^{\mathsf{tr}}\,\overline{\mathbb{P}_n(w)} - \mathbb{P}_n^{\mathsf{tr}}(z)C_{n+1}^{\mathsf{tr}}\overline{\mathbb{P}_{n+1}(w)}. \tag{5.18}$$

Next we incorporate the information on the ideal in (5.14) into the kernel function. The $n + 2$ polynomials in the ideal can be written as a set

$$\mathbb{Q}_{n+1} = \mathbb{P}_{n+1} - \Gamma_0\mathbb{P}_n - \Gamma_1\mathbb{P}_{n-1}, \tag{5.19}$$

which we also treat as a column vector below, where

$$\Gamma_0 = \begin{bmatrix} 0 & \frac{1}{\sqrt{2}} & 0 & \dots & 0 \\ \bigcirc & \cdots & \bigcirc & \cdots & \bigcirc \\ 0 & \dots & 0 & \frac{1}{\sqrt{2}} & 0 \end{bmatrix} \quad \text{and} \quad \Gamma_1 = \begin{bmatrix} 0 & \dots & 0 & \dots & 0 \\ \sqrt{2} & & & & \bigcirc \\ & 1 & & & \\ & & \ddots & & \\ & & & 1 & \\ \bigcirc & & & & \sqrt{2} \\ 0 & \dots & 0 & \dots & 0 \end{bmatrix}.$$

PROPOSITION 5.9. *For $n \ge 0$, define*

$$\Phi_n(\mathbf{t}, \mathbf{s}) := \frac{1}{2}\left[K_n(\mathbf{t}, \mathbf{s}) + K_{n-1}(\mathbf{t}, \mathbf{s})\right] - \frac{1}{2}\left[T_0^n(\mathbf{t})\overline{T_0^n(\mathbf{s})} + \overline{T_0^n(\mathbf{t})}T_0^n(\mathbf{s})\right],$$

and we again write $\Phi_n(z,w)$ *in place of* $\Phi_n(\mathbf{t},\mathbf{s})$ *for* $z = z(\mathbf{t})$ *and* $w = w(\mathbf{s})$. *Then*

$$(z-w)\Phi_n(z,w) = \mathbb{Q}^{\mathsf{tr}}_{n+1}(z)A^{\mathsf{tr}}_n M_n \overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)M_n C^{\mathsf{tr}}_{n+1}\overline{\mathbb{Q}_{n+1}(w)}, \tag{5.20}$$

where $M_n = \operatorname{diag}\{-1/3, 1/2, \ldots, 1/2, -1/3\}$ *is a diagonal matrix.*

Proof. Inserting $\mathbb{P}_{n+1} = \mathbb{Q}_{n+1} + \Gamma_0\mathbb{P}_n + \Gamma_1\mathbb{P}_{n-1}$ into (5.18) gives

$$\begin{aligned}(z-w)K_n(z,w) = {}& \mathbb{Q}^{\mathsf{tr}}_{n+1}(z)A^{\mathsf{tr}}_n\,\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)C^{\mathsf{tr}}_{n+1}\overline{\mathbb{Q}_{n+1}(w)}\\ &+ \mathbb{P}^{\mathsf{tr}}_n(z)\Gamma^{\mathsf{tr}}_0 A^{\mathsf{tr}}_n\,\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)C^{\mathsf{tr}}_{n+1}\Gamma_0\overline{\mathbb{P}_n(w)}\\ &+ \mathbb{P}^{\mathsf{tr}}_{n-1}(z)\Gamma^{\mathsf{tr}}_1 A^{\mathsf{tr}}_n\,\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)C^{\mathsf{tr}}_{n+1}\Gamma_1\overline{\mathbb{P}_{n-1}(w)}.\end{aligned}$$

Let D_n be an $n\times n$ matrix. Then similarly we have

$$\begin{aligned}(z-w)\mathbb{P}^{\mathsf{tr}}_n(z)D_n\overline{\mathbb{P}_n(w)} = {}& \mathbb{Q}^{\mathsf{tr}}_{n+1}(z)A^{\mathsf{tr}}_n D_n\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)D_nC^{\mathsf{tr}}_{n+1}\overline{\mathbb{Q}_{n+1}(w)}\\ &+ \mathbb{P}^{\mathsf{tr}}_n(z)(A_n\Gamma_0 + B_n)^{\mathsf{tr}}D_n\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)D_n(C^{\mathsf{tr}}_{n+1}\Gamma_0 + B^{\mathsf{tr}}_n)\overline{\mathbb{P}_n(w)}\\ &+ \mathbb{P}^{\mathsf{tr}}_{n-1}(z)(A_n\Gamma_1 + C_n)^{\mathsf{tr}}D_n\overline{\mathbb{P}_n(w)} - \mathbb{P}^{\mathsf{tr}}_n(z)D_n(C^{\mathsf{tr}}_{n+1}\Gamma_1 + A^{\mathsf{tr}}_{n-1})\overline{\mathbb{P}_{n-1}(w)}.\end{aligned}$$

In order to prove the stated result, we take the difference of the two equations and choose D_n such that

$$\begin{aligned}&(A_n\Gamma_0 + B_n)^{\mathsf{tr}}D_n - D_n(C^{\mathsf{tr}}_{n+1}\Gamma_0 + B^{\mathsf{tr}}_n) = \Gamma^{\mathsf{tr}}_0 A^{\mathsf{tr}}_n - C^{\mathsf{tr}}_{n+1}\Gamma_1,\\ &(A_n\Gamma_1 + C_n)^{\mathsf{tr}}D_n = \Gamma^{\mathsf{tr}}_1 A^{\mathsf{tr}}_n, \qquad D_n(C^{\mathsf{tr}}_{n+1}\Gamma_1 + A^{\mathsf{tr}}_{n-1}) = C^{\mathsf{tr}}_{n+1}\Gamma_1.\end{aligned} \tag{5.21}$$

It turns out that the unique solution of the above three equations is given by $D_n = \operatorname{diag}\{2/3, 1/2, 1/2, \ldots, 1/2, 2/3\}$, which is completely determined by the last two equations and then verified to satisfy the first equation. As a consequence of this choice of D_n, we obtain

$$\begin{aligned}(z-w)\left[K_n(z,w) - \mathbb{P}^{\mathsf{tr}}_n(z)D_n\overline{\mathbb{P}(w)}\right] = {}& \mathbb{Q}^{\mathsf{tr}}_{n+1}(z)A^{\mathsf{tr}}_n(I-D_n)\overline{\mathbb{P}_n(w)}\\ &- \mathbb{P}^{\mathsf{tr}}_n(z)(I-D_n)C^{\mathsf{tr}}_{n+1}\overline{\mathbb{Q}_{n+1}(w)},\end{aligned}$$

where I denotes the identity matrix. Setting $M_n = I - D_n$ we see that the right-hand side agrees with the right-hand side of (5.20). Finally we note that

$$\begin{aligned}\mathbb{P}^{\mathsf{tr}}_n(z)D_n\overline{\mathbb{P}_n(w)} &= \frac{1}{2}\mathbb{P}^{\mathsf{tr}}_n(z)\overline{\mathbb{P}_n(w)} + \left[P^n_0(z)\overline{P^n_0(w)} + P^n_n(z)\overline{P^n_n(w)}\right]\\ &= \frac{1}{2}\left[K_n(z,w) - K_{n-1}(z,w)\right] + \frac{1}{2}\left[T^n_0(z)\overline{T^n_0(w)} + \overline{T^n_0(z)}T^n_0(z)\right],\end{aligned}$$

which completes the proof. ∎

As a consequence of the above proposition, it is readily seen that $\Phi_n(\frac{j}{n},\frac{k}{n}) = 0$ for $j \neq k$. Furthermore, we note that $\Phi_n(\mathbf{t},\mathbf{s})$ is in fact a real-valued function. Consequently, we have proved the following.

PROPOSITION 5.10. *The unique interpolation polynomial on* Y^*_n *is given by*

$$\mathcal{L}^*_n f(x,y) = \sum_{j_1=0}^{n}\sum_{j_2=0}^{n-j_1} f(\tfrac{j}{n})\frac{\Phi_n(\mathbf{t},\frac{j}{n})}{\Phi_n(\frac{j}{n},\frac{j}{n})},$$

where $z(\mathbf{t}) = x + iy$, and $\mathcal{L}_n^* f$ is of total degree n in x and y.

In fact, upon changing variables (5.1), this interpolation polynomial is exactly the trigonometric interpolation function $\mathcal{L}_n^* f(\mathbf{t})$ at (4.14). Here the uniqueness of the interpolation follows from the general theory. Moreover, integrating $\mathcal{L}_n^* f$ with respect to $w_{-\frac{1}{2}}$ over Δ^* yields the cubature formula (5.15) with

$$\lambda_j^{(n)} = \left[\Phi_n\left(\tfrac{j}{n}, \tfrac{j}{n}\right)\right]^{-1}, \tag{5.22}$$

which can be used to determine $\lambda_j^{(n)}$ if needed. The function $K_n(\mathbf{t}, \mathbf{s})$, and thus $\Phi_n(\mathbf{t}, \mathbf{s})$, enjoys a compact formula, which facilitates the computation of $\Phi_n(\frac{j}{n}, \frac{j}{n})$. The compact formula follows from the following identity.

PROPOSITION 5.11. *Let D_n be defined in* (3.12). *Then*

$$K_n(\mathbf{s}, \mathbf{t}) = \sum_{k=0}^{n} \sum_{j=0}^{k} \widetilde{T}_j^k(\mathbf{t}) \overline{\widetilde{T}_j^k(\mathbf{s})} = \mathcal{P}_t^+ D_n(\mathbf{t} - \mathbf{s}).$$

The identity can be established from the definition of T_j^k and D_n as in the proof of Theorem 4.6 upon using the fact that $\mathcal{P}_{\mathbf{t}}^+ \mathcal{P}_{\mathbf{s}}^+ F(\mathbf{t} - \mathbf{s}) = \mathcal{P}^+ F(\mathbf{t} - \mathbf{s})$. We omit the details. From this identity and (5.22), we immediately have a compact formula for the interpolation polynomial, whose trigonometric counterpart under the change of variables (5.2) is exactly the function $\ell_{\mathbf{j},n}^{\Delta}$ in Theorem 4.7.

Acknowledgment. The authors thank the referees for their meticulous and prudent comments.

CONVERGENCE ANALYSIS OF HIGH ORDER ALGEBRAIC FRACTIONAL STEP SCHEMES FOR TIME-DEPENDENT STOKES EQUATIONS*

PAOLA GERVASIO†

Dedicated to Fausto Saleri

Abstract. In this paper we analyze the family of Yosida algebraic fractional step schemes proposed in [A. Quarteroni, F. Saleri, and A. Veneziani, *Comput. Methods Appl. Mech. Engrg.*, 188 (2000), pp. 505–526], [F. Saleri and A. Veneziani, *SIAM J. Numer. Anal.*, 43 (2005), pp. 174–194], and [P. Gervasio, F. Saleri, and A. Veneziani, *J. Comput. Phys.*, 214 (2006), pp. 347–365] when applied to time-dependent Stokes equations. Under suitable regularity assumptions on the data, splitting error estimates both for velocity and pressure are established. In particular we analyze the first three methods of this family, providing, respectively, convergence (of the fractional step solution towards the numerical solution achieved without any operator splitting) of orders 3/2, 5/2, 7/2 for the velocity and 1, 2, 3 for the pressure. Moreover a general way to set up higher-order schemes is proposed. The present analysis is carried out when spectral element methods are employed for space discretization.

Key words. algebraic fractional step methods, time-dependent Stokes equations, spectral element methods

1. Introduction.

The aim of this paper is to provide convergence estimates for the class of *Yosida* methods proposed in [12, 13, 15, 8] for the numerical solution of time-dependent Stokes equations in the primitive variables velocity and pressure.

Yosida schemes are algebraic fractional step schemes in which the incompressibility constraint is relaxed in order to earn computational efficiency, and they are based on an inexact LU factorization of the matrix $\mathcal{A}$ arising from the full discretization (in space and time) of Stokes equations. The basic Yosida scheme was introduced in [13]. The accuracy analysis, carried out in [12], shows that when the time discretization is based on a backward Euler method, Yosida splitting still maintains the first order accuracy in time both for velocity and pressure (with respect to appropriate norms).

Successively, in [15, 8] two improved versions of the basic Yosida method (named *Yosida*-3 and *Yosida*-4 in the present paper) have been proposed. A pressure correction step is introduced in these schemes, with the aim of increasing the accuracy in time for both velocity and pressure. A preliminary analysis of the consistency error has been carried out for *Yosida*-3 (resp., *Yosida*-4) in [15] (resp., [8]) proving that the perturbation on the discretization matrix $\mathcal{A}$ is of third (resp., fourth) order in time with respect to the time-step. However, a complete splitting error analysis, i.e., the convergence analysis of the fractional step solution towards the numerical solution achieved without any operator splitting, is still missing. The aim of the present paper is essentially to perform such analysis when the space discretization is based on spectral element methods of $\mathbb{Q}_N - \mathbb{Q}_{N-2}$ type [11, 1, 3, 4], but we also emphasize the derivation of Yosida methods from a more general point of view than that given in

[15, 8], suggesting the formulation of higher-order schemes. The main result of the paper is Theorem 3.7, in which we prove that the splitting error induced by Yosida schemes (when they are coupled to BDFq (with $q = 1,\ 2$) for time discretization of the time-dependent Stokes equations) behaves like $\Delta t^{p+3/2}$ (resp., Δt^{p+1}) for the velocity (resp., for the pressure), where $p = 0$ for basic *Yosida*, $p = 1$ for *Yosida*-3, and $p = 2$ for *Yosida*-4. The thesis of Theorem 3.7 when $q = 3, 4$ has not been proved yet. Nevertheless in this paper we consider the more general contest with $q = 1, \ldots, 4$ since numerical results relative to the choice $q = p + 2$ are encouraging and provide global approximation errors on the velocity of order q with respect to Δt. In the present paper no evidence is given to computational aspects concerned with Yosida methods, since the topic has been extensively discussed in [8].

This paper is organized as follows. In section 2 we recall notation and settings about Stokes equations, spectral elements discretization, and some useful properties on symmetric positive definite matrices. In section 3 we present the derivation of Yosida methods for the unsteady Stokes equations, perform the splitting error analysis when spectral element methods are used for space discretization, and give some perspective for extending the analysis to unsteady Navier–Stokes equations. In section 4 we present some numerical results corroborating the convergence analysis developed in section 3. Even if the theory presented in this paper holds in $\mathbb{R}^d$, with $d = 2, 3$, only numerical results for the case $d = 2$ are reported here.

2. Problem statement and settings. We consider time-dependent Stokes equations for Newtonian incompressible fluids in the velocity-pressure formulation. For any open bounded domain $\Omega \subset \mathbb{R}^d$ ($d = 2, 3$) with a Lipschitz boundary $\partial\Omega$, and a positive T fixed, given a solenoidal datum $\mathbf{u}_0 \in [H^1(\Omega)]^d$, an external field $\mathbf{f} \in [L^2(0, T; H^{-1}(\Omega))]^d$, and a boundary datum $\mathbf{g} \in [L^2(0, T; H^{1/2}(\partial\Omega))]^d$, we look for the velocity field $\mathbf{u} \in [L^2(0, T; H^1(\Omega))]^d$ and the pressure field $p \in L^2(0, T; L^2_0(\Omega))$ solutions of

$$\begin{cases} \dfrac{\partial \mathbf{u}}{\partial t} - \nu\Delta\mathbf{u} + \nabla p = \mathbf{f} & \text{in } \Omega \times (0, T), \\ \nabla \cdot \mathbf{u} = 0 & \text{in } \Omega \times (0, T), \\ \mathbf{u} = \mathbf{g} & \text{on } \partial\Omega \times (0, T), \\ \mathbf{u} = \mathbf{u}_0 & \text{in } \Omega \times \{0\}, \end{cases} \tag{2.1}$$

where $\nu > 0$ is the kinematic viscosity. It is well known that problem (2.1) admits a unique solution (see, e.g., [16]).

We approximate the time derivative by a *backward differentiation formula* (BDF) of order q. Given $\Delta t \in (0, T)$, we set $t^0 = 0$, $t^n = t^0 + n\Delta t$ (for any $n \geq 1$) and $N_T = \left[\frac{T}{\Delta t}\right]$; therefore, for any integer $n = n_0 (= q - 1), \ldots, N_T - 1$, we look for the solution $(\mathbf{u}^{n+1}, p^{n+1})$ of the system

$$\begin{cases} \dfrac{\beta_{-1}}{\Delta t}\mathbf{u}^{n+1} - \nu\Delta\mathbf{u}^{n+1} + \nabla p^{n+1} = \mathbf{f}^{n+1} + \displaystyle\sum_{j=0}^{q-1} \frac{\beta_j}{\Delta t}\mathbf{u}^{n-j} & \text{in } \Omega, \\ \nabla \cdot \mathbf{u}^{n+1} = 0 & \text{in } \Omega, \\ \mathbf{u}^{n+1} = \mathbf{g}^{n+1} & \text{on } \partial\Omega, \end{cases} \tag{2.2}$$

where $\mathbf{u}^0 = \mathbf{u}_0$ and β_j (for $j = -1, \ldots, q$) are the coefficients of BDF of order q. When BDF with order greater than one are used, initial data could be provided by suitable explicit schemes (e.g., Runge–Kutta) of the same order as the BDF used.

About the space discretization, we choose quadrilateral conforming spectral elements [11]. In order to overcome instabilities due to the mixed formulation of Stokes equations, we make use of the $\mathbb{Q}_N - \mathbb{Q}_{N-2}$ scheme with staggered grids [1], according to which local polynomials of degree N in each variable are used to approximate every component of the velocity field, and local polynomials of degree $N-2$ in each variable are used to approximate the pressure ($\mathbb{Q}_N$ denotes the space of polynomials of degree less than or equal to N in each variable). By this choice, the inf-sup condition is satisfied with a constant β which is proportional to $N^{(1-d)/2}$ [1].

We introduce a conformal, regular, and quasi-uniform (see, e.g., [14]) partition $\mathcal{T}_h$ of Ω in N_e quadrilaterals T_k such that

$$\overline{\Omega} = \bigcup_{k=1}^{N_e} \overline{T}_k, \quad \text{with} \quad h = \max_{T_k \in \mathcal{T}_h} h_k, \qquad h_k = \operatorname{diam}(T_k), \quad k = 1, \ldots, N_e.$$

Let us assume that every $T_k \in \mathcal{T}_h$ is the image of the reference square $\hat{T} = (-1,1)^2$ through a smooth invertible mapping $\mathbf{F}_k : \hat{T} \mapsto T_k$ with Jacobian J_{F_k} satisfying $\det J_{F_k}(\hat{\mathbf{x}}) > 0 \ \forall \hat{\mathbf{x}} \in \hat{T}$. We set

$$\mathbb{Q}_{\mathcal{H}}(\Omega) = \{v_{\mathcal{H}} \in \mathcal{C}^0(\overline{\Omega}) : \ v_{\mathcal{H}|T_k} \circ \mathbf{F}_k \in \mathbb{Q}_N \quad \forall T_k \in \mathcal{T}_h\} \tag{2.3}$$

and $v_{N,k} := v_{\mathcal{H}|T_k} \ \forall T_k \in \mathcal{T}_h$. The subscript $\mathcal{H}$ represents the discretization level and it stands for the couple (h, N). Given $u_{\mathcal{H}},\ v_{\mathcal{H}} \in \mathbb{Q}_{\mathcal{H}}(\Omega)$, we set

$$(u_{\mathcal{H}}, v_{\mathcal{H}})_{\mathcal{H},\Omega} = \sum_{k=1}^{N_e} (u_{N,k}, v_{N,k})_{N,T_k}, \tag{2.4}$$

where $(\cdot,\cdot)_{N,T_k}$ denotes the discrete inner product in $L^2(T_k)$, based on the Gauss–Lobatto–Legendre (GLL) quadrature formulas [3]. In each element T_k of the partition we define a local GLL grid of $(N+1)^2$ points and a local Gauss–Legendre (GL) grid of $(N-1)^2$ points. The last grid is staggered with respect to the former one and is internal to T_k. The unknowns of the discrete problem will be both the set of the velocity values on the GLL grid and the set of the pressure values on the GL grid [1]. By setting the finite-dimensional spaces

$$\begin{aligned} &\mathbf{V}_{\mathcal{H}} := [\mathbb{Q}_{\mathcal{H}}(\Omega)]^2, \qquad \mathbf{V}^0_{\mathcal{H}} := \left[\mathbb{Q}_{\mathcal{H}}(\Omega) \cap H^1_0(\Omega)\right]^2, \\ &Q_{\mathcal{H}} := \{q_{\mathcal{H}} \in L^2_0(\Omega) : \ q_{\mathcal{H}|T_k} \circ \mathbf{F}_k \in \mathbb{Q}_{N-2} \quad \forall T_k \in \mathcal{T}_h\}, \end{aligned}$$

we reformulate problem (2.1) following the Galerkin approach and replace all exact integrals in $L^2(\Omega)$ with GLL quadrature formulas; the resulting approach is named the *spectral element method with numerical integration* (SEM-NI) [4]. For any $t_n \in (0,T)$, we denote by $\tilde{\mathbf{g}}(t_n) \in [H^1(\Omega)]^2$ the extension of $\mathbf{g}(t_n)$ to Ω by any possible continuous operator from $[H^{1/2}(\partial\Omega)]^2$ to $[H^1(\Omega)]^2$; moreover, we denote its discrete counterpart by $\tilde{\mathbf{g}}^n_{\mathcal{H}} \in \mathbf{V}_{\mathcal{H}}$. At each time-step t_{n+1} (for $n = n_0, \ldots, N_T - 1$) we look for the numerical solution $(\mathbf{u}^{n+1}_{\mathcal{H}}, p^{n+1}_{\mathcal{H}}) \in \mathbf{V}_{\mathcal{H}} \times Q_{\mathcal{H}}$, satisfying $(\mathbf{u}^{n+1}_{\mathcal{H}} - \tilde{\mathbf{g}}^{n+1}_{\mathcal{H}}) \in \mathbf{V}^0_{\mathcal{H}}$ and

$$\begin{cases} \dfrac{\beta_{-1}}{\Delta t}(\mathbf{u}^{n+1}_{\mathcal{H}}, \mathbf{v}_{\mathcal{H}})_{\mathcal{H},\Omega} + \nu(\nabla \mathbf{u}^{n+1}_{\mathcal{H}}, \nabla \mathbf{v}_{\mathcal{H}})_{\mathcal{H},\Omega} \\ \qquad - (p^{n+1}_{\mathcal{H}}, \nabla \cdot \mathbf{v}_{\mathcal{H}})_{\mathcal{H},\Omega} = \left(\mathbf{f}^{n+1} + \displaystyle\sum_{j=0}^{q-1} \frac{\beta_j}{\Delta t} \mathbf{u}^{n-j}_{\mathcal{H}}, \mathbf{v}_{\mathcal{H}} \right)_{\mathcal{H},\Omega} & \forall \mathbf{v}_{\mathcal{H}} \in \mathbf{V}^0_{\mathcal{H}}, \\ (\nabla \cdot \mathbf{u}^{n+1}_{\mathcal{H}}, q_{\mathcal{H}})_{\mathcal{H},\Omega} = 0 & \forall q_{\mathcal{H}} \in Q_{\mathcal{H}}. \end{cases} \tag{2.5}$$

Therefore, we set N_v (resp., N_p) the total number of GLL (resp., GL) grid points in Ω. For any $\mathbf{u}_\mathcal{H} \in \mathbf{V}_\mathcal{H}$, we denote by $\mathbf{U} \in \mathbb{R}^{2N_v}$ the vector of the expansion coefficients of $\mathbf{u}_\mathcal{H}$ with respect to the Lagrange basis $\{\boldsymbol{\varphi}_j\}_{j=1}^{2N_v}$ (defined on the GLL grid) in $\mathbf{V}_\mathcal{H}$ and by $\mathsf{V}_G \subset \mathbb{R}^{2N_v}$ (resp., $\mathsf{V}_G^0 \subset \mathbb{R}^{2N_v}$) the set of the vectors $\mathbf{U}$ corresponding to functions $\mathbf{u}_\mathcal{H} \in \mathbf{V}_\mathcal{H}$ (resp., $\mathbf{V}_\mathcal{H}^0$). In a similar way, for any $p_\mathcal{H} \in Q_\mathcal{H}$ we denote by $\mathbf{P} \in \mathbb{R}^{N_p}$ the vector of the expansion coefficients of $p_\mathcal{H}$ with respect to the Lagrange basis $\{\eta_l\}_{l=1}^{N_p}$ (defined on the GL grid) in $Q_\mathcal{H}$ and by $\mathsf{Q}_G \subset \mathbb{R}^{N_p}$ the set of the arrays $\mathbf{P}$ corresponding to functions $p_\mathcal{H} \in Q_\mathcal{H}$.

We denote by $M \in \mathbb{R}^{2N_v \times 2N_v}$ the mass matrix $M_{ij} = (\boldsymbol{\varphi}_j, \boldsymbol{\varphi}_i)_{\mathcal{H},\Omega}$, by $K \in \mathbb{R}^{2N_v \times 2N_v}$ the stiffness matrix $K_{ij} = (\nabla\boldsymbol{\varphi}_j, \nabla\boldsymbol{\varphi}_i)_{\mathcal{H},\Omega}$, and by $B \in \mathbb{R}^{2N_v \times N_p}$ the matrix related to the discretization of $-\nabla\cdot$: $B_{lj} = -(\nabla \cdot \boldsymbol{\varphi}_j, \eta_l)_{\mathcal{H},\Omega}$, and we set

$$C = \frac{\beta_{-1}}{\Delta t} M + \nu K. \tag{2.6}$$

Remark 1. Matrices M, K, and C are symmetric and positive definite. Moreover, thanks to the fact that the space discretization chosen satisfies the inf-sup condition, the matrix B is a full rank matrix and $\ker(B^T) = \{\mathbf{0}\}$. Finally, we remark that when SEM-NI is used, the mass matrix M is diagonal.

The system is reduced to the unknowns internal to Ω, and the right-hand side is modified accordingly, taking into account the contributions that Lagrange basis functions associated to Dirichlet boundary nodes give to those associated to internal nodes. This step produces a right-hand side $[\mathbf{F}_1^{n+1}, \mathbf{F}_2^{n+1}]^T$ that is nonzero also in the continuity equation.

The algebraic form of (2.5) reads as follows: for $n = n_0, \ldots, N_T - 1$ solve

$$\begin{cases} C\mathbf{U}^{n+1} + B^T\mathbf{P}^{n+1} = \mathbf{F}_1^{n+1} + \dfrac{1}{\Delta t}\displaystyle\sum_{j=0}^{q-1} \beta_j M\mathbf{U}^{n-j}, \\ B\mathbf{U}^{n+1} = \mathbf{F}_2^{n+1}, \end{cases} \tag{2.7}$$

or equivalently, for $n = n_0, \ldots, N_T - 1$ solve

$$\mathcal{A}\mathbf{W}^{n+1} = \mathbf{G}^{n+1}, \qquad \text{with} \qquad \mathcal{A} = \begin{bmatrix} C & B^T \\ B & 0 \end{bmatrix} \tag{2.8}$$

and

$$\mathbf{W}^{n+1} = \begin{bmatrix} \mathbf{U}^{n+1} \\ \mathbf{P}^{n+1} \end{bmatrix}, \quad \mathbf{G}^{n+1} = \begin{bmatrix} \mathbf{G}_1^{n+1} \\ \mathbf{G}_2^{n+1} \end{bmatrix} := \begin{bmatrix} \mathbf{F}_1^{n+1} + \dfrac{1}{\Delta t}\displaystyle\sum_{j=0}^{q-1} \beta_j M\mathbf{U}^{n-j} \\ \mathbf{F}_2^{n+1} \end{bmatrix}.$$

System (2.8) could be solved by a global approach such as a preconditioned Krylov method with either algebraic or differential preconditioners. Alternatively, a block LU factorization of $\mathcal{A}$ can be performed with

$$L = \begin{bmatrix} C & 0 \\ B & -BC^{-1}B^T \end{bmatrix}, \qquad U = \begin{bmatrix} I & C^{-1}B^T \\ 0 & I \end{bmatrix}, \tag{2.9}$$

so that, for any $n = n_0, \ldots, N_T - 1$, system (2.7) reads also

$$
\begin{aligned}
&L\text{-step}: \text{ find } \mathbf{U}^{n+1/2},\ \mathbf{P}^{n+1/2}: && \begin{cases} C\mathbf{U}^{n+1/2} = \mathbf{G}_1^{n+1}, \\ \Sigma\mathbf{P}^{n+1/2} = \mathbf{G}_2^{n+1} - B\mathbf{U}^{n+1/2}, \end{cases} \\
&U\text{-step}: \text{ find } \mathbf{U}^{n+1},\ \mathbf{P}^{n+1}: && \begin{cases} \mathbf{P}^{n+1} = \mathbf{P}^{n+1/2}, \\ C(\mathbf{U}^{n+1/2} - \mathbf{U}^{n+1}) = B^T\mathbf{P}^{n+1}. \end{cases}
\end{aligned} \tag{2.10}
$$

The matrix

$$\Sigma := -BC^{-1}B^T \in \mathbb{R}^{N_p \times N_p} \tag{2.11}$$

is the so-called *pressure Schur complement* matrix and $-\Sigma > 0$. Solving system (2.8) by a block LU factorization offers the advantage of splitting the original problem into subproblems of smaller size, even if the assembling of Σ is, however, quite expensive. The idea of Yosida schemes consists in replacing the block LU factorization (2.9) with an inexact one or, equivalently, in replacing algorithm (2.10) with a more efficient one from the computational point of view. The next section will be devoted to present the derivation of Yosida schemes, starting from (2.8).

We are now going to introduce some notation and report some properties we will use in the next sections, referring to [17] and [9] for an exhaustive treatment of these subjects.

D1. Given a real square matrix $\mathcal{B}$, we write $\mathcal{B} > 0$ if it is symmetric positive definite (s.p.d.), while we write $\mathcal{B} \geq 0$ if it is symmetric semipositive definite. Moreover, if $\mathcal{B}$, $\mathcal{C} \in \mathbb{R}^{n\times n}$ are symmetric, we write $\mathcal{B} > \mathcal{C}$ if $\mathcal{B} - \mathcal{C} > 0$ and $\mathcal{B} \geq \mathcal{C}$ if $\mathcal{B} - \mathcal{C} \geq 0$.

D2. The eigenvalues of a matrix $\mathcal{B} \in \mathbb{R}^{n\times n}$ are denoted by $\lambda_i(\mathcal{B})$ and the *spectral radius* of $\mathcal{B}$ is defined as $\rho(\mathcal{B}) = \max\{|\lambda_i(\mathcal{B})|,\ i = 1, \ldots, n\}$.

D3. For any square matrix $\mathcal{M}$ of the form

$$\mathcal{M} = \begin{bmatrix} \mathcal{C} & \mathcal{B}^T \\ \mathcal{B} & \mathcal{D} \end{bmatrix}$$

the Schur complement of the nonsingular block $\mathcal{C}$ in $\mathcal{M}$ is defined as $\mathcal{M}/\mathcal{C} := \mathcal{D} - \mathcal{B}\mathcal{C}^{-1}\mathcal{B}^T$. Moreover, $\det(\mathcal{M}) = \det(\mathcal{C})\det(\mathcal{M}/\mathcal{C})$ (*Schur's formula* [17, Thm. 2.2]).

D4. The *inertia* $In(\mathcal{B})$ of a square matrix $\mathcal{B}$ is defined to be the ordered triplet (i_+, i_-, i_0), where i_+, i_-, and i_0 are the numbers of positive, negative, and zero real parts of the eigenvalues of $\mathcal{B}$.

D5. For any matrix $\mathcal{B} \in \mathbb{R}^{n\times n}$, whose coefficients depend on Δt, we say that

$$\mathcal{B} = \mathcal{O}(\Delta t^k) \qquad \text{if} \quad |||\mathcal{B}||| = \mathcal{O}(\Delta t^k) \qquad \text{for } \Delta t \to 0,$$

where $|||\cdot|||$ denotes the 2-norm for matrices.

P1. For any invertible matrices $\mathcal{B}$, $\mathcal{C} \in \mathbb{R}^{n\times n}$ it holds that

$$(\mathcal{B} + \mathcal{C})^{-1} = \mathcal{B}^{-1}[\mathcal{B} - (\mathcal{C}^{-1} + \mathcal{B}^{-1})^{-1}]\mathcal{B}^{-1}, \tag{2.12}$$

$$\mathcal{B} - \mathcal{C} = -\mathcal{B}(\mathcal{B}^{-1} - \mathcal{C}^{-1})\mathcal{B}, \tag{2.13}$$

$$\mathcal{B}(\mathcal{B} + \mathcal{C})^{-1}\mathcal{B} = \mathcal{B} - \mathcal{C} + \mathcal{C}(\mathcal{B} + \mathcal{C})^{-1}\mathcal{C}. \tag{2.14}$$

P2. As a consequence of the Courant–Fisher minimax theorem [17], for any real symmetric matrices $\mathcal{B}$, $\mathcal{C} \in \mathbb{R}^{n\times n}$ it holds that $\lambda_i(\mathcal{B}) + \lambda_{min}(\mathcal{C}) \leq \lambda_i(\mathcal{B} + \mathcal{C}) \leq \lambda_i(\mathcal{B}) + \lambda_{max}(\mathcal{C})$, $i = 1, \ldots, n$.

P3. If $\mathcal{B}$, $\mathcal{C} \in \mathbb{R}^{n\times n}$ are s.p.d. and $\mathcal{B}-\mathcal{C} > 0$, then $\mathcal{C}^{-1} - \mathcal{B}^{-1} > 0$.

P4. If $\mathcal{B}$, $\mathcal{C} \in \mathbb{R}^{n\times n}$ are symmetric and $\mathcal{C} > 0$, then the eigenvalues of $\mathcal{BC}$ are all real and $In(\mathcal{BC}) = In(\mathcal{B})$ (see, e.g., [5]).

P5. If a matrix is the product of two s.p.d. matrices, then it is similar to an s.p.d. matrix (this is a consequence of P4).

P6. For any s.p.d. matrix $\mathcal{C} \in \mathbb{R}^{n\times n}$ and $\mathcal{X} \in \mathbb{R}^{m\times n}$ with $\ker(\mathcal{X}^T) = \{\mathbf{0}\}$, it holds [18] that

$$\mathcal{C}^{-1} - \mathcal{X}^T(\mathcal{X}\mathcal{C}\mathcal{X}^T)^{-1}\mathcal{X} \geq 0. \tag{2.15}$$

3. Yosida schemes. Yosida schemes come basically from an inexact block LU factorization of matrix $\mathcal{A}$. The first method of this family was introduced in [12, 13] and consists in replacing the Schur complement Σ by a suitable matrix S.

In [15] and [8] two improved versions of the *Yosida* method (here named *Yosida*-3 and *Yosida*-4) were proposed. Such improved Yosida schemes introduce a correction step on the pressure with the aim of increasing the accuracy in time for both velocity and pressure. In particular, these improved Yosida schemes are defined by a new matrix Q, inside the U-step of (2.10) and acting on the pressure, which corrects the approximation of the Schur complement Σ. All is done at the algebraic level, without a compulsory differential interpretation. This feature allows us to neglect the setting up of boundary conditions for the substeps. All methods and the analysis developed hereafter can be applied to different kinds of boundary conditions as well.

The idea of Yosida schemes is as follows: at each time-step, instead of solving system (2.8) by the block LU factorization set in (2.9), we are interested in solving a new system

$$\hat{\mathcal{A}}\widehat{\mathbf{W}}^{n+1} = \widehat{\mathbf{G}}^{n+1}, \tag{3.1}$$

where $\hat{\mathcal{A}} := \hat{L}\hat{U}$ is generated by a suitable $\hat{L}\hat{U}$ inexact factorization of $\mathcal{A}$, $\widehat{\mathbf{W}}^{n+1}$ is an approximation of $\mathbf{W}^{n+1}$ defined as

$$\widehat{\mathbf{W}}^{n+1} = \begin{bmatrix} \hat{\mathbf{U}}^{n+1} \\ \hat{\mathbf{P}}^{n+1} \end{bmatrix}, \quad \text{while} \qquad \widehat{\mathbf{G}}^{n+1} = \begin{bmatrix} \mathbf{F}_1^{n+1} + \dfrac{1}{\Delta t}\displaystyle\sum_{j=0}^{q-1} \beta_j M \widehat{\mathbf{U}}^{n-j} \\ \mathbf{F}_2^{n+1} \end{bmatrix}. \tag{3.2}$$

Let $H = (\Delta t/\beta_{-1})M^{-1}$; the inexact factors $\hat{L}$ and $\hat{U}$ of $\mathcal{A}$ are chosen as follows:

$$\hat{L} = \begin{bmatrix} C & 0 \\ B & -BHB^T \end{bmatrix}, \quad \hat{U} = \begin{bmatrix} I & C^{-1}B^T \\ 0 & Q \end{bmatrix}, \tag{3.3}$$

where the nonsingular matrix Q may be set up by following different strategies (see section 3.1), and its choice leads the accuracy of the whole scheme. By setting

$$S := -BHB^T, \tag{3.4}$$

matrix $\hat{\mathcal{A}}$ reads

$$\hat{\mathcal{A}} = \begin{bmatrix} C & B^T \\ B & SQ - \Sigma \end{bmatrix}. \tag{3.5}$$

Matrix S is an approximation of the pressure Schur complement Σ of $\mathcal{A}$ and $-S > 0$.

For any $n = n_0, \ldots, N_T - 1$, system (3.1) reads also

$$\text{(3.6)} \qquad \begin{cases} C\widehat{\mathbf{U}}^{n+1} + B^T\widehat{\mathbf{P}}^{n+1} = \mathbf{F}_1^{n+1} + \dfrac{1}{\Delta t}\displaystyle\sum_{j=0}^{q-1}\beta_j M\widehat{\mathbf{U}}^{n-j}, \\ B\widehat{\mathbf{U}}^{n+1} - (\Sigma - SQ)\widehat{\mathbf{P}}^{n+1} = \mathbf{F}_2^{n+1} \end{cases}$$

(this is the Yosida counterpart of (2.7)) or again

$$\text{(3.7)} \qquad \begin{array}{ll} \hat{L}\text{-step}: \text{ find } \widehat{\mathbf{U}}^{n+1/2},\ \widehat{\mathbf{P}}^{n+1/2}: & \begin{cases} C\widehat{\mathbf{U}}^{n+1/2} = \widehat{\mathbf{G}}_1^{n+1}, \\ S\widehat{\mathbf{P}}^{n+1/2} = \widehat{\mathbf{G}}_2^{n+1} - B\widehat{\mathbf{U}}^{n+1/2}, \end{cases} \\ \hat{U}\text{-step}: \text{ find } \widehat{\mathbf{U}}^{n+1},\ \widehat{\mathbf{P}}^{n+1}: & \begin{cases} Q\widehat{\mathbf{P}}^{n+1} = \widehat{\mathbf{P}}^{n+1/2}, \\ C(\widehat{\mathbf{U}}^{n+1/2} - \widehat{\mathbf{U}}^{n+1}) = B^T\widehat{\mathbf{P}}^{n+1} \end{cases} \end{array}$$

(this is the Yosida counterpart of (2.10)).

For any t^n, system (3.1) is well posed iff $\hat{\mathcal{A}}$ is invertible, i.e., iff Q is invertible. As a matter of fact, recalling the definition of $\hat{\mathcal{A}}$ and thanks to Schur's formula, we can write $\det(\hat{\mathcal{A}}) = \det(C)\det(SQ)$.

In the following section we will present some possible choices for nonsingular matrices Q and provide algebraic fractional step schemes supplying different accuracy properties.

3.1. How to set up matrix Q. System (2.7) is equivalent to (3.6) if $\hat{\mathcal{A}} = \mathcal{A}$, i.e., if either $Q = S^{-1}\Sigma$ or $Q^{-1} = \Sigma^{-1}S$, but the exact computation of Q is infeasible, since it would imply computing Σ directly, which is what we want to avoid. Our aim is to set suitable sequences of matrices $\{\tilde{Q}_p\}_{p\geq 0}$ approximating Q such that

$$\text{(3.8)} \qquad \exists C > 0 \qquad |||\Sigma - S\tilde{Q}_p||| \leq C\Delta t^{p+2} \qquad \text{as} \qquad \Delta t \to 0,$$

where $|||\cdot|||$ denotes the 2-norm for matrices. The quantity $|||\Sigma - S\tilde{Q}_p|||$ is named the *consistency error* and is due to the approximation of $\mathcal{A}$ by $\hat{\mathcal{A}}$.

The direct definition of $Q = S^{-1}\Sigma$ and its definition by the inverse $Q^{-1} = \Sigma^{-1}S$ suggest two different strategies for deriving matrices $\tilde{Q}_p$ invoked in (3.8). The first strategy exploits the expansion in series of Σ (through the expansion of C^{-1}) and the matrices so derived will be denoted by $\{Q_p\}_{p\geq 0}$. The second strategy takes advantage of the expansion of Σ^{-1} as well and the resulting matrices will be denoted by $\{\hat{Q}_p\}_{p\geq 0}$.

Let us begin to set up matrices Q_p. If $\rho(\nu HK) < 1$, we can expand Σ as follows:

$$\text{(3.9)} \qquad \Sigma = -BC^{-1}B^T = -B(I + \nu HK)^{-1}HB^T = -\sum_{k\geq 0} B(-\nu HK)^k HB^T.$$

By setting

$$\text{(3.10)} \qquad D_k := B(-\nu HK)^k HB^T = \mathcal{O}(\Delta t^{k+1}) \quad \text{for } k = 0, 1, 2, \ldots$$

we have $\Sigma = -\sum_{k\geq 0} D_k$ and $Q = S^{-1}\Sigma = -S^{-1}\sum_{k\geq 0} D_k$. Therefore, we define

$$\text{(3.11)} \qquad Q_p := -S^{-1}\sum_{k=0}^{p} D_k \quad \text{for } \ p = 0,\ 1,\ 2, \ldots .$$

The explicit forms of the first three items of $\{Q_p\}$ are

$$Q_0 = I, \qquad Q_1 = I - S^{-1}D_1, \qquad Q_2 = I - S^{-1}D_1 - S^{-1}D_2. \tag{3.12}$$

Remark 2. In the case of SEM-NI discretization, the assumption $\rho(\nu HK) < 1$ turns into

$$\nu\frac{\Delta t}{\beta_{-1}}\rho(M^{-1}K) = c\nu\frac{\Delta t}{\beta_{-1}}N^4h^{-2} < 1,$$

where c denotes a generic positive constant independent of Δt, N, and h [3, 4]. It follows that the convergence of the series $\sum_{k\geq 0}(-\nu HK)^k$ to $(I+\nu HK)^{-1}$ is guaranteed if

$$\Delta t < c\frac{\beta_{-1}h^2}{\nu\ N^4}. \tag{3.13}$$

It is worth remarking that condition (3.13) implies the nonsingularity of matrices Q_p as well.

To derive the second sequence of matrices $\{\hat{Q}_p\}$ we note that $S = -D_0$ and we write

$$Q^{-1} = \Sigma^{-1}S = \left(-\sum_{k\geq 0} D_k\right)^{-1} \cdot S = \left(S - \sum_{k\geq 1} D_k\right)^{-1} \cdot S = \left(I - S^{-1}\sum_{k\geq 1} D_k\right)^{-1}.$$

By putting $R := S^{-1}(\sum_{k\geq 1} D_k)$ it holds that $Q^{-1} = (I-R)^{-1}$ and, by assuming that $\rho(R) < 1$, it holds that $Q^{-1} = \sum_{k\geq 0} R^k$ as well. Then we rewrite Q^{-1} as a sum of matrices $\tilde{R}_k$ s.t. $\tilde{R}_k = \mathcal{O}(\Delta t^k)$ in order to highlight the dependence on powers of Δt. We have $Q^{-1} = \sum_{k\geq 0}\tilde{R}_k$ and then we set

$$\hat{Q}_p := \left(\sum_{k=0}^{p}\tilde{R}_k\right)^{-1} \qquad \text{for } p = 0,\ 1,\ 2\ldots. \tag{3.14}$$

To give the explicit form of $\hat{Q}_p$ (for $p = 0, 1, 2$) we compute the powers of R up to degree 3:

$$\begin{aligned} R &= S^{-1}D_1 + S^{-1}D_2 + S^{-1}D_3 + \mathcal{O}(\Delta t^4),\\ R^2 &= (S^{-1}D_1)^2 + S^{-1}D_1S^{-1}D_2 + S^{-1}D_2S^{-1}D_1 + \mathcal{O}(\Delta t^4),\\ R^3 &= (S^{-1}D_1)^3 + \mathcal{O}(\Delta t^4), \end{aligned}$$

and recalling that $D_k = \mathcal{O}(\Delta t^{k+1})$ we have

$$\begin{aligned} &\tilde{R}_0 = I,\\ &\tilde{R}_1 = S^{-1}D_1,\\ &\tilde{R}_2 = S^{-1}D_2 + (S^{-1}D_1)^2,\\ &\tilde{R}_3 = (S^{-1}D_1)^3 + S^{-1}D_1S^{-1}D_2 + S^{-1}D_2S^{-1}D_1 + S^{-1}D_3. \end{aligned} \tag{3.15}$$

From definition (3.14) it follows that

$$\begin{aligned} &\hat{Q}_0 = I,\\ &\hat{Q}_1 = (I + S^{-1}D_1)^{-1} = -D^{-1}S,\\ &\hat{Q}_2 = (I + S^{-1}D_1 + S^{-1}D_2 + (S^{-1}D_1)^2)^{-1}\\ &\qquad = (-D + DS^{-1}D + B(HC)^2HB^T)^{-1}S, \end{aligned} \tag{3.16}$$

where we have set $D = BHCHB^T$ and employed the fact that $C = H^{-1} + \nu K$.

Remark 3. We analyze the bound $\rho(R) < 1$ when SEM-NI are used. By construction, the leading part of R, for $\Delta t \to 0$, is $S^{-1}D_1$, and we can infer that, for sufficiently small Δt,

$$\rho(R) \simeq \rho(S^{-1}D_1) = \frac{\nu\Delta t}{\beta_{-1}}\rho((BM^{-1}B^T)^{-1}BM^{-1}KM^{-1}B^T).$$

It is possible to prove that the condition $\rho(R) < 1$ is satisfied under assumption (3.13). As a matter of fact we set $E_0 = BM^{-1}B^T$, $E_1 = BM^{-1}KM^{-1}B^T$, $E = E_0^{-1}E_1$, and we denote by $(\lambda_i, \mathbf{p}_i)$ an eigenvalue-eigenvector pair of E or, equivalently, an eigenvalue-eigenvector pair of the generalized eigenvalue problem $E_1\mathbf{p} = \lambda E_0\mathbf{p}$. Since $E_0 > 0$, the eigenvectors $\mathbf{p}_i$ can be chosen E_0-orthogonal to one other, i.e., $\mathbf{p}_i^T E_0 \mathbf{p}_j = 0$ if $i \neq j$. Then, for any eigenvector $\mathbf{p}_i$ $(i = 1, \ldots, N_p)$, we set $\mathbf{v}_i := M^{-1/2}B^T\mathbf{p}_i$ and denote by V_E the subspace of $\mathbb{R}^{2N_v}$ spanned by $\{\mathbf{v}_i\}_{i=1}^{N_p}$. It is easy to see that $M^{-1/2}KM^{-1/2}\mathbf{v}_i = \lambda_i\mathbf{v}_i$ holds for any $i = 1, \ldots, N_p$, that is, the eigenvalues λ_i of E are bounded by the eigenvalues of $M^{-1}K$.

PROPOSITION 3.1. *Matrices $\hat{Q}_p$ (for $p = 0, 1, 2$) are nonsingular.*

Proof. $\hat{Q}_0$ is the identity matrix, and $\hat{Q}_1 = -D^{-1}S$ is nonsingular since both D and S are nonsingular matrices. Proving $\hat{Q}_2$ is nonsingular is equivalent to proving $\hat{Q}_2^{-1} = \tilde{R}_0 + \tilde{R}_1 + \tilde{R}_2$ is nonsingular. By definition

$$\begin{aligned}\hat{Q}_2^{-1} &= -S^{-1}D + (S^{-1}D)^2 + S^{-1}B(HC)^2HB^T \\ &= S^{-1}BHC(-C^{-1} - HB^T(BHB^T)^{-1}BH + H)CHB^T\end{aligned}$$

and, since B is a full rank matrix, $\hat{Q}_2^{-1}$ is nonsingular iff the matrix

$$W = H - C^{-1} - HB^T(BHB^T)^{-1}BH \tag{3.17}$$

is nonsingular. By recalling that $H = \frac{\beta_{-1}}{\Delta t}M^{-1} > 0$, $C = H^{-1} + \nu K > 0$, and $K > 0$, we have $C - H^{-1} > 0$, and then $H - C^{-1} > 0$ (see P3 in section 2), which implies that $(H - C^{-1})$ is nonsingular. Since $\ker(B^T) \neq \{\mathbf{0}\}$, also BHB^T is nonsingular. Therefore, we set

$$\mathcal{M} = \begin{bmatrix} BHB^T & BH \\ HB^T & H - C^{-1} \end{bmatrix}, \tag{3.18}$$

and we note that matrix W is nothing more than the Schur complement of BHB^T in $\mathcal{M}$, i.e., $\mathcal{M}/(BHB^T)$.

By applying Schur's formula (D3, section 2), $\det(\mathcal{M}) = \det(BHB^T)\det(W)$ holds. On the other hand we can write $\det(\mathcal{M}) = \det(H - C^{-1})\det(\mathcal{M}/(H - C^{-1}))$ as well. Therefore

$$\det(W) = \det(\mathcal{M}/(BHB^T)) = \frac{\det(H - C^{-1})}{\det(BHB^T)}\det(\mathcal{M}/(H - C^{-1}))$$

and $\det(W) \neq 0$ iff $\det(\mathcal{M}/(H - C^{-1})) \neq 0$.

Recalling (2.12) we have $(H - C^{-1})^{-1} = H^{-1}[H - (-C + H^{-1})^{-1}]H^{-1}$, and since $-C + H^{-1} = -\nu K$, it holds that

$$\begin{aligned}\mathcal{M}/(H - C^{-1}) &= BHB^T - BH(H - C^{-1})^{-1}HB^T \\ &= BHB^T - BHH^{-1}[H + (\nu K)^{-1}]H^{-1}HB^T = -B(\nu K)^{-1}B^T.\end{aligned}$$

The thesis follows since K is nonsingular. ∎

As stated by the following lemma, both sequences of matrices Q_p and $\hat{Q}_p$ yield a consistency error satisfying estimate (3.8). This lemma generalizes the results given in [15, 8].

LEMMA 3.2. *There exist* $\overline{\Delta t} = \overline{\Delta t}(\nu, N, h) > 0$ *and positive constants* $c_p = c_p(\nu, N, h)$ *and* $\hat{c}_p = \hat{c}_p(\nu, N, h)$ *such that for any* $\Delta t \in (0, \overline{\Delta t})$ *and* $p = 0, 1, 2$ *the following estimates hold:*

$$|||\Sigma - SQ_p||| = c_p \Delta t^{p+2} + o(\Delta t^{p+2}), \tag{3.19}$$

$$|||\Sigma - S\hat{Q}_p||| = \hat{c}_p \Delta t^{p+2} + o(\Delta t^{p+2}). \tag{3.20}$$

Proof. By definition (3.12) we have $\Sigma - SQ_p = -\sum_{k \geq p+1} D_k$.

Estimate (3.19), with $c_p = \frac{\nu^{p+1}}{(\beta_{-1})^{p+2}} \rho(B(M^{-1}K)^{p+1} M^{-1} B^T)$, immediately follows by recalling that $D_k = \mathcal{O}(\Delta t^{k+1})$ (for any integer $k \geq 0$).

In order to prove (3.20) we begin to consider the matrix $\Sigma^{-1} - \hat{Q}_p^{-1} S^{-1}$. We set $Z = \sum_{k \geq p+1} \tilde{R}_k$, so that

$$\Sigma^{-1} - \hat{Q}_p^{-1} S^{-1} = \left(\sum_{k \geq 0} \tilde{R}_k - \sum_{k=0}^{p} \tilde{R}_k \right) S^{-1} = Z S^{-1}.$$

By using (2.13) we have

$$\Sigma - S\hat{Q}_p = -\Sigma(\Sigma^{-1} - \hat{Q}_p^{-1} S^{-1}) S\hat{Q}_p = -\Sigma Z \hat{Q}_p. \tag{3.21}$$

Estimate (3.20) proceeds by recalling that $\Sigma = -\sum_{k \geq 0} D_k = \mathcal{O}(\Delta t)$, $Z = \sum_{k \geq p+1} \tilde{R}_k = \mathcal{O}(\Delta t^{p+1})$ and by noting that $\hat{Q}_p = \left(\sum_{k=0}^{p} \tilde{R}_k \right)^{-1} = \mathcal{O}(1)$. ∎

Even though both matrices Q_p and $\hat{Q}_p$ produce consistency errors of the same order with respect to Δt, we are inclined to choose matrices $\hat{Q}_p$ instead of Q_p to set up Yosida schemes, when $p > 0$ (recall that $Q_0 = \hat{Q}_0 = I$). As a matter of fact we can easily prove that

$$\hat{c}_1 < c_1, \tag{3.22}$$

which implies $|||\Sigma - S\hat{Q}_1||| < |||\Sigma - SQ_1|||$ for sufficiently small Δt.

By exploiting the definition of $\hat{Q}_1$ and by using (2.14), with $\mathcal{B} = S = -D_0$ and $\mathcal{C} = D_1$, we write the difference $\Sigma - S\hat{Q}_1$ as follows:

$$\begin{aligned} \Sigma - S\hat{Q}_1 &= -\sum_{k \geq 0} D_k - S(S + D_1)^{-1} S = -\sum_{k \geq 0} D_k + D_0 + D_1 - D_1(D_1 - D_0)^{-1} D_1 \\ &= -D_2 - D_1(D_1 - D_0)^{-1} D_1 + o(\Delta t^3). \end{aligned}$$

On the other hand, $\Sigma - SQ_1 = -D_2 + o(\Delta t^3)$. It is immediate to verify that both D_2 and $D_1(D_1 - D_0)^{-1} D_1$ are symmetric matrices, and then the 2-norm $|||\cdot|||$ coincides with the spectral radius $\rho(\cdot)$; moreover it holds that $D_2 > 0$ and $D_1(D_1 - D_0)^{-1} D_1 < 0$. If we apply P2 of section 2, we can conclude that

$$\lambda_{max}(D_2 + D_1(D_1 - D_0)^{-1} D_1) \leq \lambda_{max}(D_2) + \lambda_{max}(D_1(D_1 - D_0)^{-1} D_1) < \lambda_{max}(D_2),$$

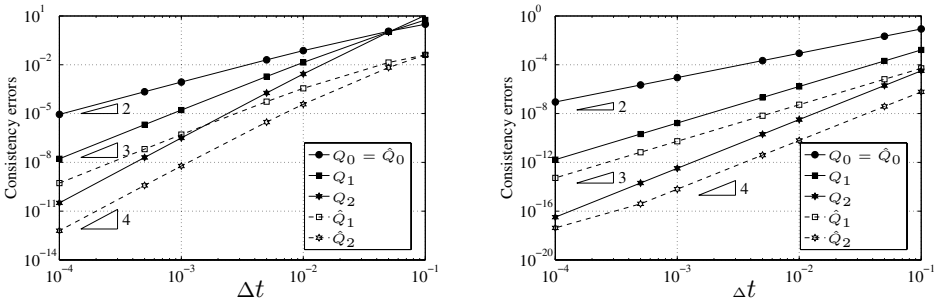

FIG. 3.1. *The consistency errors* $|||\Sigma - SQ_p|||$ *and* $|||\Sigma - S\hat{Q}_p|||$ *for* $p = 0, 1, 2$. *The viscosity is* $\nu = 10^{-2}$ *at left and* $\nu = 10^{-4}$ *at right.* 4×4 *equal square spectral elements with polynomial degree* $N = 5$ *are used.*

that is,

$$\hat{c}_1 \Delta t^3 = \rho(-D_2 - D_1(D_1 - D_0)^{-1} D_1) < \rho(-D_2) = c_1 \Delta t^3.$$

Results shown in Figure 3.1 confirm (3.22). The proof that $\hat{c}_2 < c_2$ (which implies $|||\Sigma - S\hat{Q}_2||| \leq |||\Sigma - SQ_2|||$ for small Δt) is quite long and technical, so we only report numerical results (again in Figure 3.1) confirming such assertion.

In order to compare the two approaches from a computational point of view, we note that both matrices Q_p and $\hat{Q}_p$ are involved in the solution of a linear system like $Q\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$ at each time-step. When $p = 0$ it holds that $Q_0 = \hat{Q}_0 = I$. When $p \geq 1$, solving systems $Q_p\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$ means performing 2 $(N_p \times 2N_v)$-matrix-vector products and solving one linear system whose matrix is $\sum_{k=0}^{p} D_k$. If we choose a direct algebraic solver, the matrix $\sum_{k=0}^{p} D_k$ may be assembled and factorized once, and the computational cost related to the solution of all systems of type $Q\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$ (for any $n = n_0, \ldots, N_T - 1$) is proportional to $N_p^3 + N_p \cdot N_v \cdot N_T$. Otherwise, solving systems $\hat{Q}_p\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$ means performing $2 \cdot p$ $(N_p \times 2N_v)$-matrix-vector products, $2 \cdot p$ $(N_v \times N_v)$-matrix-vector products, and solving p linear systems whose matrix is S. By recalling that matrix S is already assembled and factorized inside the algorithm, since it is used in the $\hat{L}$-substep of (3.7), the computational cost related to the solution of all $\hat{Q}\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$ (for any $n = n_0, \ldots, N_T - 1$) is proportional to $(N_v + N_p) \cdot N_v \cdot N_T$. In conclusion, when we choose a direct algebraic solver to solve $Q\hat{\mathbf{P}}^{n+1} = \hat{\mathbf{P}}^{n+1/2}$, if N_T is large (i.e., $N_T \gtrsim N_v$), the choice $Q = Q_p$ will be more convenient than $Q = \hat{Q}_p$. Nevertheless, matrices $\hat{Q}_p$ (3.14) are preferable to matrices Q_p (3.11) for what concerns accuracy with respect to Δt. In this paper we have preferred accuracy properties and have chosen to approximate Q by $\hat{Q}_p$ inside the definition of $\hat{\mathcal{A}}$ (or equivalently in either (3.6) or (3.7)).

The choice $\hat{Q}_0$ yields the *Yosida* (or *Yosida*-2) method [13, 12], while the choice $\hat{Q}_1$ (resp., $\hat{Q}_2$) provides the *Yosida*-3 (resp., *Yosida*-4) scheme introduced in [15] (resp., [8]). From now on the term *Yosida*-$(p + 2)$ (for $p = 0, 1, 2$) will denote the Yosida method obtained by replacing Q with $\hat{Q}_p$.

Finally, for any $n \geq n_0$ we will denote by $(\hat{\mathbf{u}}_{\mathcal{H},p}^n, \hat{p}_{\mathcal{H},p}^n) \in \mathbf{V}_{\mathcal{H}} \times Q_{\mathcal{H}}$ the numerical solution of (3.6) obtained by replacing Q with $\hat{Q}_p$, while we will denote by $\hat{\mathbf{U}}_p^n$ (resp., $\hat{\mathbf{P}}_p^n$) the vector of the expansion coefficients of $\hat{\mathbf{u}}_{\mathcal{H},p}$ (resp., $\hat{p}_{\mathcal{H},p}$) with respect to the Lagrange basis in $V_{\mathcal{H}}$ (resp., $Q_{\mathcal{H}}$).

3.2. Convergence analysis. We define the *global errors* as the errors between the exact solution of problem (2.1) and the numerical solution $(\hat{\mathbf{u}}_{\mathcal{H},p}, \hat{p}_{\mathcal{H},p})$ obtained with any *Yosida*-$(p+2)$ method, i.e.,

$$\begin{aligned} \|\mathbf{u} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{\ell^2(H^1)} &:= \left(\Delta t \sum_{n=n_0}^{N_T-1} \|\mathbf{u}(t_n) - \hat{\mathbf{u}}^n_{\mathcal{H},p}\|^2_{H^1(\Omega)} \right)^{1/2}, \\ \|p - \hat{p}_{\mathcal{H},p}\|_{\ell^2(L^2)} &:= \left(\Delta t \sum_{n=n_0}^{N_T-1} \|p(t_n) - \hat{p}^n_{\mathcal{H},p}\|^2_{L^2(\Omega)} \right)^{1/2}. \end{aligned} \tag{3.23}$$

We can upper-bound global errors (3.23) as follows:

$$\begin{aligned} \|\mathbf{u} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{\ell^2(H^1)} &\le \|\mathbf{u} - \mathbf{u}_{\mathcal{H}}\|_{\ell^2(H^1)} + \|\mathbf{u}_{\mathcal{H}} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{\ell^2(H^1)}, \\ \|p - \hat{p}_{\mathcal{H},p}\|_{\ell^2(L^2)} &\le \|p - p_{\mathcal{H}}\|_{\ell^2(L^2)} + \|p_{\mathcal{H}} - \hat{p}_{\mathcal{H},p}\|_{\ell^2(L^2)}, \end{aligned}$$

where the first terms on the right-hand sides are the errors due to BDF, while the second ones, induced by the *Yosida*-$(p+2)$ scheme, are named *splitting errors* and are the errors between the solution $(\mathbf{u}_{\mathcal{H}}, p_{\mathcal{H}})$ of (2.10) and the solution $(\hat{\mathbf{u}}_{\mathcal{H},p}, \hat{p}_{\mathcal{H},p})$ obtained by solving (3.6) with $Q \simeq \hat{Q}_p$. Therefore, for $p = 0$, 1, 2, we are interested in analyzing the *splitting errors*:

$$\begin{aligned} \|\mathbf{u}_{\mathcal{H}} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{\ell^2(H^1)} &:= \left(\Delta t \sum_{n=n_0}^{N_T-1} \|\mathbf{u}^n_{\mathcal{H}} - \hat{\mathbf{u}}^n_{\mathcal{H},p}\|^2_{H^1(\Omega)} \right)^{1/2}, \\ \|p_{\mathcal{H}} - \hat{p}_{\mathcal{H},p}\|_{\ell^2(L^2)} &:= \left(\Delta t \sum_{n=n_0}^{N_T-1} \|p^n_{\mathcal{H}} - \hat{p}^n_{\mathcal{H},p}\|^2_{L^2(\Omega)} \right)^{1/2}. \end{aligned} \tag{3.24}$$

Remark 4. From the analysis carried out in [10] it is known that the solution of the Navier–Stokes problem can be regular for $t \to 0$ under unrealistic nonlocal compatibility conditions. On the other hand, accuracy in the usual norms $\ell^2(H^1)$ and $\ell^2(L^2)$ can be attained only if the solution is regular enough, even when using high order discretization schemes. Otherwise, high order in time can be recovered only in suitable weighted norms. In what follows, we will assume that high regularity hypotheses hold. This ensures that when using BDFq time discretization of order $q(>1)$, without the fractional step approach, optimal accuracy is q for both velocity and pressure. Without such high regularity assumptions, optimal convergence estimates given in the present paper will hold only far from $t = 0$. We denote by $||\cdot||_{\ell^2_w(V)}$ a suitable time-weighted norm; the scheme shown in Table 3.1 summarizes results known in literature.

From now on, by $(\cdot,\cdot)$ and $\|\cdot\| = (\cdot,\cdot)^{1/2}$ we will denote the classic Euclidean inner product and the Euclidean norm, respectively, in $\mathbb{R}^n$.

Let $\mathbf{U},\ \mathbf{V} \in \mathsf{V}_G$ be the vectors associated to $\mathbf{u}_{\mathcal{H}},\ \mathbf{v}_{\mathcal{H}} \in \mathbf{V}_{\mathcal{H}}$. By recalling that M and K are the mass and stiffness matrices, respectively, it holds that $(M\mathbf{U}, \mathbf{V}) = \mathbf{V}^T M\mathbf{U} = (\mathbf{u}_{\mathcal{H}}, \mathbf{v}_{\mathcal{H}})_{\mathcal{H},\Omega}$ and $(K\mathbf{U}, \mathbf{U}) = (\nabla\mathbf{u}_{\mathcal{H}}, \nabla\mathbf{v}_{\mathcal{H}})_{\mathcal{H},\Omega}$. Then we set

$$\|\mathbf{U}\|_0 := \sqrt{(M\mathbf{U}, \mathbf{U})}, \qquad \|\mathbf{U}\|_1 := \sqrt{(K\mathbf{U}, \mathbf{U})}.$$

It is worth pointing out that the norm $||\cdot||_1$ is the discrete counterpart to the L^2-norm of $\nabla\mathbf{u}$. Thanks to the Poincaré inequality, which states that, for any function

TABLE 3.1

	Low regularity assumptions on the exact solution (no compatibility conditions imposed)	High regularity assumptions on the exact solution
BDF1 in time	$\|\mathbf{u}-\mathbf{u}_{\mathcal{H}}\|_{\ell^2(H^1)}=\mathcal{O}(\Delta t)$ $\|p-p_{\mathcal{H}}\|_{\ell^2(L^2)}=\mathcal{O}(\Delta t^{1/2})$	$\|\mathbf{u}-\mathbf{u}_{\mathcal{H}}\|_{\ell^2(H^1)}=\mathcal{O}(\Delta t)$ $\|p-p_{\mathcal{H}}\|_{\ell^2(L^2)}=\mathcal{O}(\Delta t)$

$u\in H^1_0(\Omega)$, there exists a positive constant C_Ω such that $\|u\|_{L^2(\Omega)}\le C_\Omega\|\nabla u\|_{L^2(\Omega)}$, and thanks to the equivalence between the continuous L^2-norm and its discrete counterpart induced by the discrete inner product (2.4) [14, 7], $\|u_{\mathcal{H}}\|_{\mathcal{H},\Omega}\le\|u_{\mathcal{H}}\|_{L^2(\Omega)}\le 3\|u_{\mathcal{H}}\|_{\mathcal{H},\Omega}$, the following (discrete) Poincaré inequality holds:

$$\|\mathbf{V}\|_0\le 3C_\Omega\|\mathbf{V}\|_1 \qquad \text{for any } \mathbf{V}\in\mathsf{V}^0_G. \tag{3.25}$$

Moreover, since K is s.p.d., for any $\mathbf{U},\mathbf{V}\in\mathsf{V}_G$ it holds that

$$(K\mathbf{U},\mathbf{V})=(K^{1/2}\mathbf{U},K^{1/2}\mathbf{V})\le\|K^{1/2}\mathbf{U}\|\|K^{1/2}\mathbf{V}\|=\|\mathbf{U}\|_1\|\mathbf{V}\|_1. \tag{3.26}$$

Finally, from Lemma 3.2, we immediately deduce that, for $p=0,1,2$,

$$((\Sigma-S\hat{Q}_p)\mathbf{P},\mathbf{Q})\le\hat{c}_p\Delta t^{p+2}\|\mathbf{P}\|\|\mathbf{Q}\| \qquad \text{for any } \mathbf{P},\mathbf{Q}\in\mathsf{Q}_G. \tag{3.27}$$

Remark 5. In order to prove convergence estimates for the Yosida schemes, we need to prove that matrix $\Sigma-S\hat{Q}_p$ is definite. With Lemmas 3.3, 3.4, and 3.5 we prove that $\Sigma-S\hat{Q}_0>0$, $-(\Sigma-S\hat{Q}_1)\ge 0$ and, under suitable conditions, that $\Sigma-S\hat{Q}_2>0$. Lemma 3.3 has been proved in [13] by using the analogy with the Yosida regularization operator; we present here a shorter proof, based on s.p.d. matrices properties. Lemma 3.4 has been proved in [15] with different arguments. Here we follow an approach exploiting (2.15), yielding a shorter proof.

LEMMA 3.3. $\Sigma-S\hat{Q}_0>0$.

Proof. Inside the proof of Lemma 3.1 we have proved that $(H-C^{-1})>0$. Since $\ker(B^T)=\{\mathbf{0}\}$, it follows that $\Sigma-S\hat{Q}_0=\Sigma-S=B(H-C^{-1})B^T>0$. ∎

LEMMA 3.4. $-(\Sigma-S\hat{Q}_1)\ge 0$.

Proof. By definitions of Σ, S, and $\hat{Q}_1$ we have

$$-(\Sigma-S\hat{Q}_1)=B[C^{-1}-(BH)^T(BHCHB^T)^{-1}BH]B^T$$

and since $\ker(B^T)=\{\mathbf{0}\}$, $-(\Sigma-S\hat{Q}_1)\ge 0$ iff $C^{-1}-(BH)^T(BHCHB^T)^{-1}BH\ge 0$. The thesis follows by putting $\mathcal{X}=BH$ and $\mathcal{C}=C$ in (2.15). ∎

Inside the proof of the following lemma, we will use the matrix

$$\tilde{\tilde{B}}:=-D_3-D_1S^{-1}D_2-D_2S^{-1}D_1-D_1(S^{-1}D_1)^2. \tag{3.28}$$

Matrix $\tilde{\tilde{B}}$ is symmetric, and numerical computations have shown that $\tilde{\tilde{B}}$ has real nonnegative eigenvalues for any space discretization we have considered. Nevertheless

we cannot prove that it is positive definite, even if it is worth noting that nonnegativeness of its eigenvalues does not depend on the time-step (recalling definitions of matrices D_k, all the addend in (3.28) are $\mathcal{O}(\Delta t^3)$).

LEMMA 3.5. *If* $\tilde{\tilde{B}} > 0$ *and if* Δt *is sufficiently small, then* $\Sigma - S\hat{Q}_2 > 0$.

Proof. As a particular case of (3.21) we have

$$\Sigma - S\hat{Q}_2 = -\Sigma(\Sigma^{-1} - \hat{Q}_2^{-1}S^{-1})S\hat{Q}_2, \tag{3.29}$$

and we analyze the sign of the three factors of the right-hand side of (3.29). Let us start by proving that if Δt is small enough, then $-S\hat{Q}_2 > 0$. We set

$$\tilde{B} := D - DS^{-1}D - B(HC)^2HB^T, \tag{3.30}$$

so that $-S\hat{Q}_2 = S\tilde{B}^{-1}S$. Since $\tilde{B}$ is symmetric, then $-S\hat{Q}_2$ is symmetric as well (and $\Sigma - S\hat{Q}_2$ is also symmetric); moreover we can apply Sylvester's law of inertia [9] and conclude that $-S\hat{Q}_2 > 0$ iff $\tilde{B} > 0$. In order to prove that $\tilde{B} > 0$ we apply P2 of section 2. By construction, both D and $-DS^{-1}D - B(HC)^2HB^T$ are symmetric matrices, and we can write that $\lambda_{min}(\tilde{B}) \geq \lambda_{min}(D) + \lambda_{min}(-DS^{-1}D - B(HC)^2HB^T)$. Since $D = -S - D_1 = \mathcal{O}(\Delta t)$ and $-DS^{-1}D - B(HC)^2HB^T = -D_2 - D_1S^{-1}D_1 = \mathcal{O}(\Delta t^3)$, there exist two real constants c_1 and c_2 such that $\lambda_{min}(D) = c_1\Delta t$ and $\lambda_{min}(-DS^{-1}D - B(HC)^2HB^T) = c_2\Delta t^3$; therefore $c_1 + c_2\Delta t^2 > 0$ is a sufficient condition to have $\lambda_{min}(\tilde{B}) > 0$. Since $D = BHCHB^T > 0$, then $c_1 > 0$, while we cannot give any estimate on c_2. If $c_2 > 0$, no restrictions on Δt are required; otherwise if $c_2 < 0$, we have to assume that $\Delta t < \overline{\Delta t} := (-c1/c2)^{1/2}$.

Let us consider now the matrix $-(\Sigma^{-1} - \hat{Q}_2^{-1}S^{-1}) = -\tilde{R}_3S^{-1} - \sum_{k\geq 4}\tilde{R}_kS^{-1}$, where $\tilde{R}_3S^{-1} = \mathcal{O}(\Delta t^2)$ and $\sum_{k\geq 4}\tilde{R}_kS^{-1} = \mathcal{O}(\Delta t^3)$, and we analyze only the sign of $-\tilde{R}_3S^{-1}$. By (3.15) we have $-\tilde{R}_3S^{-1} = S^{-1}\tilde{\tilde{B}}S^{-1}$, so that $-\tilde{R}_3S^{-1} > 0$ since $\tilde{\tilde{B}} > 0$. Whatever the sign of $-\sum_{k\geq 4}\tilde{R}_kS^{-1}$ may be, for sufficiently small Δt, the matrix $-(\Sigma^{-1} - \hat{Q}_2^{-1}S^{-1})$ will be s.p.d.

Finally, starting from (3.29) we can write $(\Sigma - S\hat{Q}_2)(-S\hat{Q}_2)^{-1} = \Sigma(\Sigma^{-1} - \hat{Q}_2^{-1}S^{-1})$ and the thesis follows by noting that the matrix on the right is similar to a s.p.d. matrix (P5 of section 2) and by applying P4 of section 2, with $\mathcal{B} = \Sigma - S\hat{Q}_2$ and $\mathcal{C} = (-S\hat{Q}_2)^{-1}$. ∎

It is worth noting that the stability of BDFq+*Yosida*-$(p+2)$ depends on stability of both BDFq scheme and Yosida splitting. The following lemma extends stability results proved in [12, 15] and highlights the stability of Yosida splitting when the associated BDFq method is absolutely stable, i.e., $q = 1, 2$. On the contrary, when either BDF3 or BDF4 is considered, it is natural to expect that a stability condition due to BDF has to be ensured as well.

LEMMA 3.6 (stability). *BDF*q+*Yosida*-$(p+2)$ *scheme* (3.7) *is unconditionally stable if* $q = 1, 2$ *and* $p = 0$, *while it is conditionally stable if* $q = 1, 2$ *and* $p > 0$.

Proof. We consider system (3.6) with $Q = \hat{Q}_p$, $\mathbf{F}_1 = \mathbf{0}$, $\mathbf{F}_2 = \mathbf{0}$. By using either the identity $2(a-b,a) = a^2 - b^2 + (a-b)^2$ (when $q = 1$) or $2(3a - 4b + c, a) = a^2 - b^2 + (2a-b)^2 - (2b-c)^2 + (a - 2b + c)^2$ (when $q = 2$), by summing from $n = n_0$ up to $N_T - 1$, by Lemma 3.3, and by neglecting some positive terms, it holds that $\|\hat{\mathbf{U}}_p^{N_T}\|_0^2 \leq C$, where C is a positive constant depending only on initial data.

When $q = 1, 2$ and $p = 1$, we proceed as before. In particular, when $p = 1$, in view of Lemma 3.4, a sufficient condition to ensure stability is furnished by $\nu\|\hat{\mathbf{U}}^{n+1}\|_1^2 + ((\Sigma - S\hat{Q}_p)\hat{\mathbf{P}}^{n+1}, \hat{\mathbf{P}}^{n+1}) \geq 0$ for any $n \geq n_0$. By recalling (3.20), the previous estimate

infers a bound on Δt. Finally, when $p = 2$, Lemma 3.5 ensures positiveness of $\Sigma - S\hat{Q}_p$ under suitable restrictions on Δt. ∎

We set $\mathbf{E}^n_{U,p} = \mathbf{U}^n - \hat{\mathbf{U}}^n_p$, $\mathbf{E}^n_{P,p} = \mathbf{P}^n - \hat{\mathbf{P}}^n_p$, and $\mathbf{E}^n_p = [\mathbf{E}^n_{U,p}, \mathbf{E}^n_{P,p}]^T$, recalling that p is the subindex of $\hat{Q}_p$.

THEOREM 3.7 (convergence). *Let us consider systems* (2.7) *and* (3.6) *with either* $q = 1$ *or* $q = 2$, *and* (3.6) *with* $Q = \hat{Q}_p$ *for* $p = 0, 1, 2$. *If* Δt *is sufficiently small, then there exist two positive constants* C_p *and* $\tilde{C}_p$, *depending on space discretization, but independent of* Δt, *such that the following convergence estimates hold:*

$$\|\mathbf{E}^{N_T}_{U,p}\|^2_0 + \nu\Delta t \sum_{n=n_0}^{N_T-1} \|\mathbf{E}^{n+1}_{U,p}\|^2_1 \le C_p \Delta t^{2p+3}, \tag{3.31}$$

$$\Delta t \sum_{n=n_0}^{N_T-1} \|\mathbf{E}^{n+1}_{P,p}\|^2 \le \tilde{C}_p \Delta t^{2p+2}, \tag{3.32}$$

i.e., $\|\mathbf{u}_{\mathcal{H}} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{l^\infty(L^2)} \le C_p \Delta t^{p+3/2}$, $\|\mathbf{u}_{\mathcal{H}} - \hat{\mathbf{u}}_{\mathcal{H},p}\|_{l^2(H^1)} \le C_p \Delta t^{p+3/2}$, *and* $\|p_{\mathcal{H}} - \hat{p}_{\mathcal{H},p}\|_{l^2(L^2)} \le \tilde{C}_p \Delta t^{p+1}$.

*Proof. BDF*1. We start by considering BDF1 for time approximation of both systems (2.7) and (3.6). They read

$$\begin{cases} \dfrac{M}{\Delta t}(\mathbf{U}^{n+1} - \mathbf{U}^n) + \nu K \mathbf{U}^{n+1} + B^T \mathbf{P}^{n+1} = \mathbf{F}^{n+1}_1, \\ B\mathbf{U}^{n+1} = \mathbf{F}^{n+1}_2 \end{cases} \tag{3.33}$$

and

$$\begin{cases} \dfrac{M}{\Delta t}(\hat{\mathbf{U}}^{n+1}_p - \hat{\mathbf{U}}^n_p) + \nu K \hat{\mathbf{U}}^{n+1}_p + B^T \hat{\mathbf{P}}^{n+1}_p = \mathbf{F}^{n+1}_1, \\ B\hat{\mathbf{U}}^{n+1}_p - (\Sigma - S\hat{Q}_p)\hat{\mathbf{P}}^{n+1}_p = \mathbf{F}^{n+1}_2. \end{cases} \tag{3.34}$$

By subtracting (3.34) from (3.33), we obtain

$$\begin{cases} \dfrac{M}{\Delta t}(\mathbf{E}^{n+1}_{U,p} - \mathbf{E}^n_{U,p}) + \nu K \mathbf{E}^{n+1}_{U,p} + B^T \mathbf{E}^{n+1}_{P,p} = \mathbf{0}, \\ B\mathbf{E}^{n+1}_{U,p} - (\Sigma - S\hat{Q}_p)\mathbf{E}^{n+1}_{P,p} = -(\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}, \end{cases} \tag{3.35}$$

then multiply the first and the second equations of (3.35) by $\mathbf{V}^T = 2\Delta t(\mathbf{E}^{n+1}_{U,p})^T$ and $\mathbf{Q}^T = 2\Delta t(\mathbf{E}^{n+1}_{P,p})^T$, respectively, and we subtract the second equation from the first one. We obtain

$$\begin{aligned} &(M(\mathbf{E}^{n+1}_{U,p} - \mathbf{E}^n_{U,p}), \mathbf{E}^{n+1}_{U,p}) + 2\nu\Delta t(K\mathbf{E}^{n+1}_{U,p}, \mathbf{E}^{n+1}_{U,p}) \\ &\quad + 2\Delta t((\Sigma - S\hat{Q}_p)\mathbf{E}^{n+1}_{P,p}, \mathbf{E}^{n+1}_{P,p}) = 2\Delta t((\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}, \mathbf{E}^{n+1}_{P,p}). \end{aligned} \tag{3.36}$$

Moreover, by using the identity $2(a-b,a) = |a|^2 - |b|^2 + |a-b|^2$ and the definite positivity/negativity of $(\Sigma - S\hat{Q}_p)$ (Lemmas 3.3, 3.4, and 3.5), we have

$$\begin{aligned} &\|\mathbf{E}^{n+1}_{U,p}\|^2_0 - \|\mathbf{E}^n_{U,p}\|^2_0 + \|\mathbf{E}^{n+1}_{U,p} - \mathbf{E}^n_{U,p}\|^2_0 + 2\nu\Delta t\|\mathbf{E}^{n+1}_{U,p}\|^2_1 \\ &\quad \le 2\Delta t((\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}, \mathbf{E}^{n+1}_{P,p}) - 2\gamma\Delta t((\Sigma - S\hat{Q}_p)\mathbf{E}^{n+1}_{P,p}, \mathbf{E}^{n+1}_{P,p}), \end{aligned}$$

where $\gamma = 0$ when $p = 0$ or when $p = 2$ and $\tilde{\tilde{B}} > 0$; otherwise $\gamma = 1$ when $p = 1$ or $p = 2$ and $\tilde{\tilde{B}}$ is not positive definite.

By applying the Cauchy–Schwarz inequality, estimate (3.27), and the Young inequality it follows that

$$\begin{aligned}\|\mathbf{E}_{U,p}^{n+1}\|_0^2 - \|\mathbf{E}_{U,p}^{n}\|_0^2 + \|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + 2\nu\Delta t\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \\ \leq \frac{1}{2\varepsilon}\|(\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}\|^2 + 2\varepsilon\Delta t^2\|\mathbf{E}_{P,p}^{n+1}\|^2 + 2\gamma\hat{c}_p^2\Delta t^{p+3}\|\mathbf{E}_{P,p}^{n+1}\|^2 \\ \leq \frac{\hat{c}_p^2}{2\varepsilon}\Delta t^{2p+4}\|\mathbf{P}^{n+1}\|^2 + \left(2\varepsilon\Delta t^2 + 2\gamma\hat{c}_p^2\Delta t^{p+3}\right)\|\mathbf{E}_{P,p}^{n+1}\|^2,\end{aligned}$$

and by summing on $n = n_0, \ldots, N_T - 1$ we obtain

$$\begin{aligned}\|\mathbf{E}_{U,p}^{N_T}\|_0^2 + \sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + 2\nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \\ \leq \frac{\hat{c}_p^2}{2\varepsilon}\Delta t^{2p+3}\left(\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{P}^{n+1}\|^2\right) \\ + \left(2\varepsilon\Delta t^2 + 2\gamma\hat{c}_p^2\Delta t^{p+3}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2.\end{aligned} \tag{3.37}$$

We denote by β the *inf-sup* constant which depends on the space discretization but that is independent of Δt. Thanks to the *inf-sup* condition, to the first equation in (3.35), to (3.25) and (3.26), we have

$$\begin{aligned}\|\mathbf{E}_{P,p}^{n+1}\| &\leq \frac{1}{\beta}\sup_{\substack{\mathbf{V}\in\mathbf{V}_G^0\\ \mathbf{V}\neq\mathbf{0}}}\frac{|(B^T\mathbf{E}_{P,p}^{n+1},\mathbf{V})|}{\|\mathbf{V}\|_1} = \frac{1}{\beta}\sup_{\substack{\mathbf{V}\in\mathbf{V}_G^0\\ \mathbf{V}\neq\mathbf{0}}}\frac{|(\frac{M}{\Delta t}(\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}) + \nu K\mathbf{E}_{U,p}^{n+1},\mathbf{V})|}{\|\mathbf{V}\|_1} \\ &\leq \frac{1}{\beta}\left[\frac{3C_\Omega}{\Delta t}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0 + \nu\|\mathbf{E}_{U,p}^{n+1}\|_1\right]\end{aligned}$$

and then

$$\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2 \leq \frac{\Delta t}{\beta^2}\left[\frac{18C_\Omega^2}{\Delta t^2}\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + 2\nu^2\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2\right]. \tag{3.38}$$

Now we note that there exists a positive constant C_P such that $\Delta t(\sum_{n=n_0}^{N_T-1}\|\mathbf{P}^{n+1}\|^2) \leq C_P$. As a matter of fact, $p \in L^2(0,T;L_0^2(\Omega))$, while the discretization error on the pressure associated to the pure BDF1 scheme (3.33) satisfies the inequality $\Delta t\sum_{n=n_0}^{N_T-1}\|p(t_{n+1}) - p_{\mathcal{H}}(t_{n+1})\|^2 \leq c\Delta t$ [2].

Therefore, we replace (3.38) in (3.37) and obtain

$$\begin{aligned}\|\mathbf{E}_{U,p}^{N_T}\|_0^2 + \sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + 2\nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \\ \leq \frac{\hat{c}_p^2C_P}{2\varepsilon}\Delta t^{2p+3} + \left(\frac{\varepsilon\Delta t}{2} + \gamma\hat{c}_p^2\Delta t^{p+2}\right)\frac{\Delta t}{\beta^2} \\ \times\left[\frac{18C_\Omega^2}{\Delta t^2}\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + 2\nu^2\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2\right].\end{aligned}$$

If $\gamma = 0$, we choose $\varepsilon = \beta^2/(18C_\Omega^2)$, we move on the left the terms depending on $\mathbf{E}_U$, and, under the assumption $\Delta t \le 18C_\Omega^2/\nu$, we obtain

$$\|\mathbf{E}_{U,p}^{N_T}\|_0^2 + \frac{1}{2}\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 + \nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \le \frac{9C_\Omega^2\hat{c}_p^2C_P}{\beta^2}\Delta t^{2p+3}. \tag{3.39}$$

Otherwise, if $\gamma = 1$, we choose $\varepsilon = \beta^2/(27C_\Omega^2)$, again we move on the left the terms depending on $\mathbf{E}_{U,p}$, and we have

$$\begin{aligned}\|\mathbf{E}_{U,p}^{N_T}\|_0^2 &+ \left(\frac{2}{3} - \Delta t^{p+1}\frac{18\hat{c}_p^2C_\Omega^2}{\beta^2}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2\\ &+ \nu\Delta t\left(2 - \frac{\nu\Delta t}{27C_\Omega^2} - \frac{2\nu\hat{c}_p^2\Delta t^{2p+3}}{\beta^2}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \le \frac{27C_\Omega^2\hat{c}_p^2C_P}{2\beta^2}\Delta t^{2p+3}.\end{aligned}$$

If we require that $\Delta t \le \min\left\{\left(\frac{\beta}{6\sqrt{3}\hat{c}_pC_\Omega}\right)^{(p+1)/2}, \frac{27C_\Omega^2}{2\nu}, \left(\frac{\beta}{2\hat{c}_p\sqrt{\nu}}\right)^{1/(2p+3)}\right\}$, an estimate like (3.39), but with a different numeric constant, is true as well.

In conclusion, by neglecting some positive terms the estimate (3.31) holds, that is, the *Yosida*-$(p+2)$ method is $(p+3/2)$th order accurate on the velocity with respect to both $\ell^\infty(L^2)$- and $\ell^2(H^1)$-norms, with $C_p = C_p(C_\Omega, \hat{c}_p, C_P, \beta)$.

Finally, from (3.38) and (3.31), the estimate (3.32) on the pressure holds as well, that is, the *Yosida*-$(p+2)$ is $(p+1)$th order accurate on the pressure with respect to the $\ell^2(L^2)$-norm, with $\tilde{C}_p = \tilde{C}_p(C_\Omega, \hat{c}_p, C_P, \beta)$.

*BDF*2. We take into account both systems (2.7) and (3.6) with $q = 2$ and subtract the second system from the first one, obtaining

$$\begin{cases}\dfrac{M}{2\Delta t}(3\mathbf{E}_{U,p}^{n+1} - 4\mathbf{E}_{U,p}^{n} + \mathbf{E}_{U,p}^{n-1}) + \nu K\mathbf{E}_{U,p}^{n+1} + B^T\mathbf{E}_{P,p}^{n+1} = \mathbf{0},\\ B\mathbf{E}_{U,p}^{n+1} - (\Sigma - S\hat{Q}_p)\mathbf{E}_{P,p}^{n+1} = -(\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}.\end{cases} \tag{3.40}$$

Then we multiply the first and the second equations of (3.40) by $\mathbf{V}^T = 4\Delta t(\mathbf{E}_{U,p}^{n+1})^T$ and $\mathbf{Q}^T = 4\Delta t(\mathbf{E}_{P,p}^{n+1})^T$, respectively, and subtract the second equation from the first one. We obtain

$$\begin{aligned}2(M(3\mathbf{E}_{U,p}^{n+1} - 4\mathbf{E}_{U,p}^{n} + \mathbf{E}_{U,p}^{n-1}), \mathbf{E}_{U,p}^{n+1}) &+ 4\nu\Delta t(K\mathbf{E}_{U,p}^{n+1}, \mathbf{E}_{U,p}^{n+1})\\ &+ 4\Delta t((\Sigma - S\hat{Q}_p)\mathbf{E}_{P,p}^{n+1}, \mathbf{E}_{P,p}^{n+1}) = 4\Delta t((\Sigma - S\hat{Q}_p)\mathbf{P}^{n+1}, \mathbf{E}_{P,p}^{n+1}).\end{aligned} \tag{3.41}$$

Moreover, by using the identity $2(3a - 4b + c, a) = |a|^2 - |b|^2 + |2a - b|^2 - |2b - c|^2 + |a - 2b + c|^2$, working as in the proof for BDF1, and by neglecting some positive terms, we obtain

$$\begin{aligned}\|\mathbf{E}_{U,p}^{N_T}\|_0^2 &+ \sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - 2\mathbf{E}_{U,p}^{n} + \mathbf{E}_{U,p}^{n-1}\|_0^2 + 4\nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2\\ &\le \frac{\hat{c}_p^2}{2\varepsilon}C_P\Delta t^{2p+3} + 4\left(2\varepsilon\Delta t^2 + \gamma\hat{c}_p^2\Delta t^{p+3}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2.\end{aligned} \tag{3.42}$$

By applying the *inf-sup* condition, we have

$$\begin{aligned}\|\mathbf{E}_{P,p}^{n+1}\| &\le \frac{1}{\beta}\sup_{\substack{\mathbf{v}\in\mathbf{v}_G^0\\ \mathbf{v}\neq\mathbf{0}}}\frac{|(B^T\mathbf{E}_{P,p}^{n+1},\mathbf{V})|}{\|\mathbf{V}\|_1}\\ &\le \frac{1}{\beta}\left[\frac{3C_\Omega}{2\Delta t}\|3\mathbf{E}_{U,p}^{n+1}-4\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}\|_0+\nu\|\mathbf{E}_{U,p}^{n+1}\|_1\right]\\ &\le \frac{1}{\beta}\left[\frac{3C_\Omega}{2\Delta t}\|\mathbf{E}_{U,p}^{n+1}-2\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}\|_0+2\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_0+\nu\|\mathbf{E}_{U,p}^{n+1}\|_1\right]\end{aligned}$$

and then

$$\begin{aligned}\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2 \le \frac{3\Delta t}{\beta^2}\Bigg[&\nu^2\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2\\ &+\frac{9C_\Omega^2}{4\Delta t^2}\sum_{n=n_0}^{N_T-1}\left(\|\mathbf{E}_{U,p}^{n+1}-2\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}\|_0^2+4\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_0^2\right)\Bigg].\end{aligned}\tag{3.43}$$

Now we have to estimate the term $\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_0^2$ which is not present on the left-hand side of (3.42). To this aim we multiply the first equation of (3.40) by $4\Delta t(\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n})^T$, the second equation of (3.42) at both time t_{n+1} and t_n by $4\Delta t(\mathbf{E}_{p,p}^{n+1})^T$, and we linearly combine them in order to cut the term $(B\mathbf{E}_{P,p}^{n+1},\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n})$. By rewriting $3\mathbf{E}_{U,p}^{n+1}-4\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}=2(\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n})+(\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n})-(\mathbf{E}_{U,p}^{n}-\mathbf{E}_{U,p}^{n-1})$ by applying $(2a,a-b)=|a|^2-|b|^2+|a-b|^2$, we have

$$\begin{aligned}&5\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_0^2-\|\mathbf{E}_{U,p}^{n}-\mathbf{E}_{U,p}^{n-1}\|_0^2+\|\mathbf{E}_{U,p}^{n+1}-2\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}\|_0^2\\ &\quad+2\nu\Delta t\left(\|\mathbf{E}_{U,p}^{n+1}\|_1^2-\|\mathbf{E}_{U,p}^{n}\|_1^2+\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_1^2\right)\\ &\quad=-4\Delta t((\Sigma-S\hat{Q}_p)(\mathbf{P}^{n+1}-\mathbf{P}^{n}),\mathbf{E}_{P,p}^{n+1})+4\Delta t((\Sigma-S\hat{Q}_p)(\mathbf{E}_{P,p}^{n+1}-\mathbf{E}_{P,p}^{n}),\mathbf{E}_{P,p}^{n+1}).\end{aligned}$$

Therefore, by applying the same techniques as before, we have

$$\begin{aligned}&4\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_0^2+\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}-2\mathbf{E}_{U,p}^{n}+\mathbf{E}_{U,p}^{n-1}\|_0^2\\ &\qquad+2\nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}-\mathbf{E}_{U,p}^{n}\|_1^2\\ &\qquad\le\frac{4}{\varepsilon}\hat{c}_p^2C_P\Delta t^{2p+3}+\left(2\varepsilon\Delta t+3\hat{c}_p\Delta t^{p+2}\right)\left(\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2\right),\end{aligned}\tag{3.44}$$

where we have used $\sum_n\|\mathbf{P}^{n+1}-\mathbf{P}^{n}\|^2\le 2\sum_n\|\mathbf{P}^{n+1}\|^2$ and $\sum_n\|\mathbf{E}_{P,p}^{n+1}-\mathbf{E}_{P,p}^{n}\|^2\le 2\sum_n\|\mathbf{E}_{P,p}^{n+1}\|^2$. By summing inequalities (3.42) and (3.44) and by neglecting some

positive terms, it holds that

$$\begin{aligned}
&\|\mathbf{E}_{U,p}^{N_T}\|_0^2 + 2\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - 2\mathbf{E}_{U,p}^{n} + \mathbf{E}_{U,p}^{n-1}\|_0^2 + 4\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 \\
&\quad + 2\nu\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \\
&\quad \le \frac{9}{2\varepsilon}\hat{c}_p^2 C_P \Delta t^{2p+3} + (10\varepsilon\Delta t + 7\hat{c}_p\Delta t^{p+2})\left(\Delta t\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{P,p}^{n+1}\|^2\right).
\end{aligned} \tag{3.45}$$

By using (3.43) in (3.45) and by moving the terms with $\mathbf{E}_{U,p}$ on the left, we have

$$\begin{aligned}
&\|\mathbf{E}_{U,p}^{N_T}\|_0^2 + \left(4 - \frac{3}{\beta_2}(10\varepsilon\Delta t + 7\hat{c}_p\Delta t^{p+2})\frac{9c_\Omega^2}{4\Delta t}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - \mathbf{E}_{U,p}^{n}\|_0^2 \\
&\quad + \left(2 - \frac{3}{\beta_2}(10\varepsilon\Delta t + 7\hat{c}_p\Delta t^{p+2})\frac{9c_\Omega^2}{4\Delta t}\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1} - 2\mathbf{E}_{U,p}^{n} + \mathbf{E}_{U,p}^{n-1}\|_0^2 \\
&\quad + \left(4\nu\Delta t - \frac{3}{\beta_2}(10\varepsilon\Delta t + 7\hat{c}_p\Delta t^{p+2})\nu^2\Delta t\right)\sum_{n=n_0}^{N_T-1}\|\mathbf{E}_{U,p}^{n+1}\|_1^2 \le \frac{9}{2\varepsilon}\hat{c}_p^2 C_P\Delta t^{2p+3}.
\end{aligned}$$

We choose $\varepsilon = \frac{1}{10}(\beta^2/(27C_\Omega^2) - 7\hat{c}_p\Delta t^{p+1})$ and, under the assumption $\Delta t \le \min\{27\, C_\Omega^2/\nu, (4\beta^2/(189\hat{c}_p C_\Omega^2))^{1/(p+1)}\}$, the estimate (3.31) follows. The estimate (3.32) follows by both (3.31) and (3.43). ∎

Remark 6. It is worth noting that the assumptions required on the time-step by the previous theorem are not very restrictive; note that for $\Omega \subset \mathbb{R}^d$ it holds that $C_\Omega = \frac{2meas(\Omega)}{d}$ and $\beta = \mathcal{O}(N^{(1-d)/2})$. The most restrictive condition on the time-step is that given in (3.13) ensuring the series $-\sum_{k\ge 0} D_k$ converges to Σ.

Remark 7. When either BDF3 or BDF4 are considered, under suitable stability conditions on the time-step, we expect that convergence estimates like (3.31)–(3.32) hold for the couple BDFq-*Yosida*-$(p+2)$, as well as for $q = 3, 4$, as numerical results of the next section show.

Remark 8 (extensions to the Navier–Stokes case). We consider now the semi-discretization of unsteady Navier–Stokes equations by the following semi-implicit scheme: for any $n = n_0, \ldots, N_T - 1$, look for the solution $(\mathbf{u}^{n+1}, p^{n+1})$ of the system

$$\begin{cases}
\dfrac{\beta_{-1}}{\Delta t}\mathbf{u}^{n+1} - \nu\Delta\mathbf{u}^{n+1} + \mathcal{N}(\mathbf{u}^{n-q+1}, \ldots, \mathbf{u}^n; \mathbf{u}^{n+1}) \\
\qquad\qquad + \nabla p^{n+1} = \mathbf{f}^{n+1} + \displaystyle\sum_{j=0}^{q-1}\frac{\beta_j}{\Delta t}\mathbf{u}^{n-j} & \text{in } \Omega, \\
\nabla\cdot\mathbf{u}^{n+1} = 0 & \text{in } \Omega, \\
\mathbf{u}^{n+1} = \mathbf{g}^{n+1} & \text{on } \partial\Omega,
\end{cases} \tag{3.46}$$

where $\mathcal{N}$ represents either a full *explicit* discretization of the convective term if

$$\mathcal{N}(\mathbf{u}^{n-q+1}, \ldots, \mathbf{u}^n; \mathbf{u}^{n+1}) := \sum_{j=0}^{q-1}\alpha_j(\mathbf{u}^{n-j}\cdot\nabla)\mathbf{u}^{n-j} \tag{3.47}$$

or a *semi-implicit* discretization of the convective term if

$$\mathcal{N}(\mathbf{u}^{n-q+1},\dots,\mathbf{u}^n;\mathbf{u}^{n+1}) = (\mathbf{u}^*\cdot\nabla)\mathbf{u}^{n+1}, \qquad \mathbf{u}^* = \sum_{j=0}^{q-1}\alpha_j\mathbf{u}^{n-j}, \tag{3.48}$$

and where $\alpha_j \in \mathbb{R}$ (for $j = 0,\dots,q-1$) are the coefficients of an extrapolation formula of order q. When the convective term is handled by the explicit form (3.47) the Yosida method can be used to solve (3.46), (3.47) and the analysis can be easily extended provided that $\mathcal{N}(\mathbf{u}_{\mathcal{H}}^{n-q+1},\dots,\mathbf{u}_{\mathcal{H}}^{n};\mathbf{u}_{\mathcal{H}}^{n+1}) - \mathcal{N}(\hat{\mathbf{u}}_{\mathcal{H}}^{n-q+1},\dots,\hat{\mathbf{u}}_{\mathcal{H}}^{n};\hat{\mathbf{u}}_{\mathcal{H}}^{n+1})$ is bounded. Otherwise, when the convective term is treated by the semi-implicit form (3.48) the counterpart of (3.6) reads as follows: for $n = n_0,\dots,N_T-1$ solve

$$\begin{cases} \left(\dfrac{\beta_{-1}}{\Delta t}M + C_n(\{\widehat{\mathbf{U}}^{n-j}\}_{j=0}^{q-1})\right)\widehat{\mathbf{U}}^{n+1} + B^T\widehat{\mathbf{P}}^{n+1} = \mathbf{F}_1^{n+1} + \dfrac{1}{\Delta t}\displaystyle\sum_{j=0}^{q-1}\beta_j M\widehat{\mathbf{U}}^{n-j}, \\ B\widehat{\mathbf{U}}^{n+1} - (-B(C_n(\{\widehat{\mathbf{U}}^{n-j}\}_{j=0}^{q-1}))^{-1}B^T - SQ)\widehat{\mathbf{P}}^{n+1} = \mathbf{F}_2^{n+1}, \end{cases} \tag{3.49}$$

where $C_n(\{\mathbf{U}^{n-j}\}_{j=0}^{q-1}) := \frac{\beta_{-1}}{\Delta t}M + \nu K + N(\mathbf{U}^{n-q+1},\dots,\mathbf{U}^n)$, and $N(\mathbf{U}^{n-q+1},\dots,\mathbf{U}^n)$ is the matrix related to the discretization of the convective term. It is immediate to see that matrix Σ is now time-dependent and both the derivation and analysis of Yosida schemes cannot be easily extended starting from the Stokes case.

Nevertheless, many numerical results presented in [8, 7] show that the convergence orders proved in Theorem 3.7 for the Stokes case still hold for Navier–Stokes equations with semi-implicit treatment of the convective term.

4. Numerical results on time-dependent Stokes equations. We consider the computational domain $\Omega = (-1,1)^2$ and $t \in (0,1)$, while the right-hand side, the boundary conditions, and the initial conditions are set so that the exact solution is

$$\begin{aligned} &\mathbf{u}(x,y,t) = [(t+1)\sin(x)\sin((t+1)y), \cos(x)\cos((t+1)y)]^T, \\ &p(x,y,t) = \cos(x)\sin((t+1)y). \end{aligned} \tag{4.1}$$

In Figure 4.1 we report the splitting errors (3.24) obtained by using either BDF1 or BDF2. In Figure 4.2 we show the global errors (3.23) for $p = 0,1,2$ by using

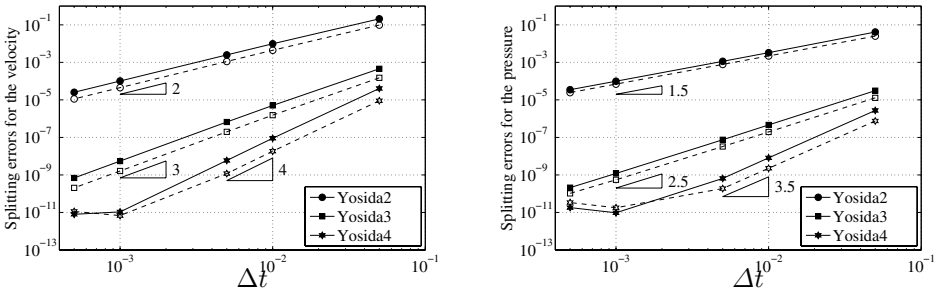

FIG. 4.1. *Splitting errors* (3.24) *for the exact solution* (4.1). *Black symbols refer to runs with BDF*1*, while empty symbols refer to runs with BDF*2. $\nu = 10^{-3}$, $N = 16$, *and* $h = 2$ *(one spectral element). The convergence history of Yosida-*4 *is stopped by the spectral element method discretization error.*

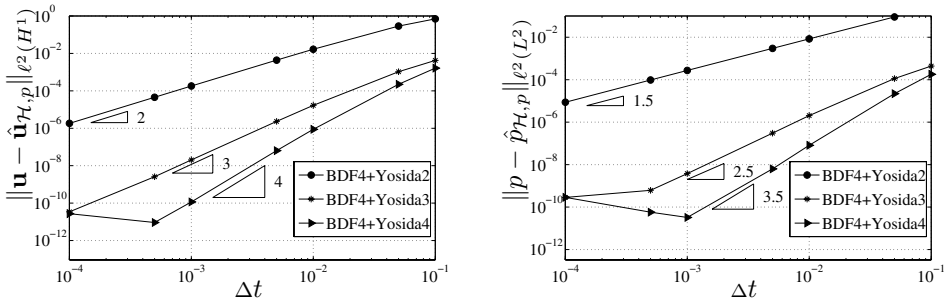

FIG. 4.2. *Global errors* (3.23) *for the exact solution* (4.1). $\nu = 10^{-3}$, $N = 16$, *and* $h = 1$ *(*2×2 *spectral elements). The convergence history of BDF*4 + *Yosida-*4 *is stopped by both spectral element method discretization and rounding errors. The splitting errors prevail over the errors due to BDF*4.

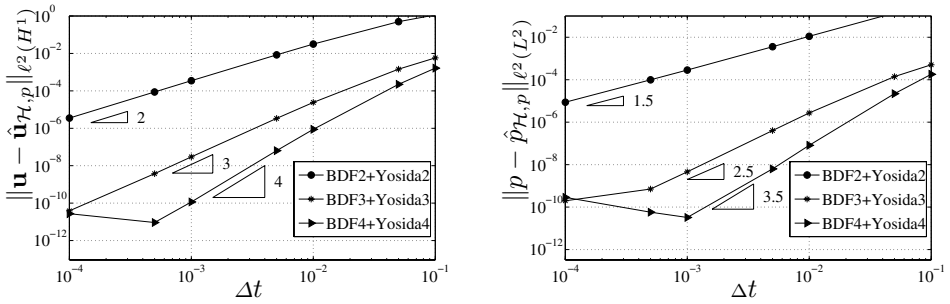

FIG. 4.3. *Global errors* (3.23) *for the exact solution* (4.1). $\nu = 10^{-3}$, $N = 16$, *and* $H = 1$ *(*2×2 *spectral elements). The convergence history of BDF*4 + *Yosida-*4 *is stopped by both spectral element method discretization and rounding errors. The splitting errors due to Yosida-*$(p+2)$ *schemes are of the same order as those produced by BDF*p.

BDF4 time approximation; finally in Figure 4.3 we show the global errors (3.23) for $p = 0, 1, 2$ by using BDFq time approximation, with $q = p + 2$.

Even if Theorem 3.7 ensures that the splitting errors (3.24) behave like $\Delta t^{p+3/2}$ for the velocity and Δt^{p+1} for the pressure, numerical results on the solution (4.1) provide that the splitting errors of *Yosida-*$(p+2)$ schemes behave like Δt^{p+2} for the velocity and like $\Delta t^{p+3/2}$ for the pressure for both BDF1 and BDF2. Global errors depend on convergence order of both BDF and *Yosida-*$(p+2)$ schemes; in particular for the results of Figure 4.2 we have used BDF4, so that, for $p = 0, 1, 2$, splitting errors prevail over the error of BDF. For the results of Figure 4.3 we have coupled *Yosida-*2 with BDF2, *Yosida-*3 with BDF3, and *Yosida-*4 with BDF4 and have obtained a global approximation error of order $p + 2 = q$ for the velocity and of order $p + 3/2$ for the pressure. We refer to [8, 7, 15] for numerical results about the approximation of Navier–Stokes equations.

FINITE ELEMENT APPROXIMATIONS OF THE ERICKSEN–LESLIE MODEL FOR NEMATIC LIQUID CRYSTAL FLOW*

ROLAND BECKER†, XIAOBING FENG‡, AND ANDREAS PROHL§

Abstract. The Ericksen–Leslie model describes dynamics of low molar-mass nematic liquid crystals, where the spatiotemporal distribution of defects defining texture is represented by the director unit vector field $\mathbf{d} : \Omega_T \to \mathbb{S}^2$. It consists of the Navier–Stokes equations with an extra viscous stress tensor, and a convective harmonic map heat flow equation to govern the dynamics of the director field. Two fully discrete finite element methods, for a regularized system using the Ginzburg–Landau regularization and for the limiting Ericksen–Leslie model, are proposed, and well-posedness and related discrete energy laws are established. For the regularized model, unconditional convergence of finite element solutions towards weak solutions of the continuum model as well as convergence towards measure-valued solutions of the limiting Ericksen–Leslie model are verified when the mesh parameters and the regularization parameter successively tend to zero. Computational experiments are also presented to show the importance of balancing numerical and regularization parameters, to compare regularized and direct approaches, and to show numerically the finite-time formation, annihilation, and evolution of point defects.

1. Introduction.

The Ericksen–Leslie continuum theory gives a successful model for describing dynamics of low molar-mass nematic liquid crystals [14, 23, 22, 34]; this intermediate phase in certain materials is characterized by orientational order but positional disorder of anisotropic molecules, with rigid segments in the structure represented by a unit vector field $\mathbf{d} : \Omega_T \to \mathbb{S}^{N-1}$. The presence of order suggests the possibility of defects, and their spatial distribution defines the texture of a liquid crystal, which characterizes the liquid-crystalline phase and significantly influences flow behavior.

In this paper we propose and analyze some fully discrete finite element approximations of the equations [17, 16, 23]

$$\mathbf{u}_t - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p + \lambda\,\mathrm{div}\,(\nabla\mathbf{d}\odot\nabla\mathbf{d}) = \mathbf{g} \quad \text{in } \Omega_T := (0,T)\times\Omega\,, \tag{1.1}$$

$$\mathbf{d}_t + (\mathbf{u}\cdot\nabla)\mathbf{d} - \gamma\Delta\mathbf{d} = \gamma|\nabla\mathbf{d}|^2\mathbf{d} \quad \text{in } \Omega_T, \tag{1.2}$$

$$|\mathbf{d}| = 1, \qquad \mathrm{div}\,\mathbf{u} = 0 \quad \text{in } \Omega_T, \tag{1.3}$$

with the following initial and boundary conditions:

$$\mathbf{u}(0,\mathbf{x}) = \mathbf{u}_0(\mathbf{x}), \qquad \mathbf{d}(0,\mathbf{x}) = \mathbf{d}_0(\mathbf{x}) \qquad \forall\, \mathbf{x} \in \Omega\,, \tag{1.4}$$

$$\mathbf{u}(t,\mathbf{x}) = 0, \qquad \partial_{\mathbf{n}}\mathbf{d}(t,\mathbf{x}) = 0 \qquad \forall\, (t,\mathbf{x}) \in \partial\Omega_T := (0,T)\times\partial\Omega\,. \tag{1.5}$$

Here and below, let $\Omega \subset \mathbb{R}^N\,(N = 2,3)$ be a bounded domain with a Lipschitz boundary $\partial\Omega$ and outward pointing normal $\mathbf{n} \in \mathbb{S}^{N-1}$. The vector $\mathbf{u}(t,\mathbf{x}) \in \mathbb{R}^N$ and the scalar $p(t,\mathbf{x}) \in \mathbb{R}$ denote the velocity and the pressure of the fluid at the space-time point $(t,\mathbf{x})$, respectively. The vector $\mathbf{d}(t,\mathbf{x}) \in \mathbb{S}^{N-1}$ is known as the *local director* and indicates the directions of the molecules of the liquid crystal at $(t,\mathbf{x}) \in \Omega_T$. Let ν, λ, and γ be positive constants. The vector $\mathbf{g}(t,\mathbf{x}) \in \mathbb{R}^N$ represents a body force on the fluid. The (i,j)th entry of the $N\times N$ matrix $\nabla\mathbf{d}$ is $\frac{\partial d_i}{\partial x_j}$, and $\nabla\mathbf{d}\odot\nabla\mathbf{d}$ stands for the $N\times N$ matrix whose (i,j)th entry is $\mathbf{d}_{x_i}\cdot\mathbf{d}_{x_j}$. Equation (1.1) without the extra stress term $\lambda\,\mathrm{div}\,(\nabla\mathbf{d}\odot\nabla\mathbf{d})$ is the Navier–Stokes equation [36], and (1.2) without the convection term $(\mathbf{u}\cdot\nabla)\mathbf{d}$ is the harmonic map heat flow equation [11, 35].

The system (1.1)–(1.3) was derived by Lin [25] from the original equations of the continuum theory of nematic liquid crystals proposed by Ericksen [17, 16] and Leslie [23]. A nematic liquid crystal behaves like a regular liquid with molecules of similar size; however, it displays anisotropic properties due to the molecule alignment, which is usually described by the local director $\mathbf{d}$ as seen in (1.2). The system (1.1)–(1.3) is known as the simplest approximation of the full Ericksen–Leslie model which retains the basic nonlinear structure and the essential features of the full hydrodynamic equations for nematic liquid crystals. However, it turns out that the mathematical techniques developed for studying the system are applicable to treating the general and more complicated Ericksen–Leslie model. We refer to [17, 23, 25, 26, 28] and the references therein for the derivation of the above system and further physical background on the continuum theory of liquid crystals.

In addition to the well-known barriers for analyzing the Navier–Stokes equations, there are two more features which make the system (1.1)–(1.3) more difficult to study. First, the presence of the extra stress term leads to a strong coupling of the equations. Second, the nonconvex side constraint $|\mathbf{d}| = 1$ causes further difficulties (cf. [9, 7]), both analytically and numerically, and is a main source for possible formation of defects of the system at finite times. Hence, a widely used approach is to approximate the constraint $|\mathbf{d}| = 1$ by a penalty function such as the Ginzburg–Landau approximation $\frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d})$ for $0 < \varepsilon \ll 1$, where $[\mathbf{f}(\mathbf{z})]_i = (|\mathbf{z}|^2-1)z_i = \frac{\partial}{\partial z_i}F(\mathbf{z})$ for $F(\mathbf{z}) := \frac{1}{4}(|\mathbf{z}|^2-1)^2$ (cf. [25, 26, 9, 7]). The regularized model then reads as

$$\mathbf{u}^\varepsilon_t - \nu\Delta\mathbf{u}^\varepsilon + (\mathbf{u}^\varepsilon\cdot\nabla)\mathbf{u}^\varepsilon + \nabla p^\varepsilon + \lambda\,\mathrm{div}\,(\nabla\mathbf{d}^\varepsilon\odot\nabla\mathbf{d}^\varepsilon) = \mathbf{g} \quad \text{in } \Omega_T\,, \tag{1.6}$$

$$\mathbf{d}^\varepsilon_t + (\mathbf{u}^\varepsilon\cdot\nabla)\mathbf{d}^\varepsilon - \gamma\big(\Delta\mathbf{d}^\varepsilon - \frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d}^\varepsilon)\big) = 0 \quad \text{in } \Omega_T\,, \tag{1.7}$$

$$\mathrm{div}\,\mathbf{u}^\varepsilon = 0 \quad \text{in } \Omega_T\,, \tag{1.8}$$

subject to initial and boundary conditions (1.4) and (1.5). It is known [28] that as $\varepsilon \searrow 0$, the regularized system (1.6)–(1.8) converges to system (1.1)–(1.3); see section 2 below for more details.

It was observed in [26] that by using the differential identity $\mathrm{div}(\nabla\mathbf{z}\odot\nabla\mathbf{z}) = (\nabla\mathbf{z})^T\Delta\mathbf{z} + \frac{1}{2}\nabla(|\nabla\mathbf{z}|^2)$, (1.6) can be rewritten as

$$\mathbf{u}^\varepsilon_t - \nu\Delta\mathbf{u}^\varepsilon + (\mathbf{u}^\varepsilon\cdot\nabla)\mathbf{u}^\varepsilon + \nabla\widehat{p}^\varepsilon + \lambda\,(\nabla\mathbf{d}^\varepsilon)^T\Delta\mathbf{d}^\varepsilon = \mathbf{g}\,, \quad \widehat{p}^\varepsilon := p^\varepsilon + \frac{\lambda}{2}|\nabla\mathbf{d}^\varepsilon|^2\,. \tag{1.9}$$

This then leads to the key discovery that the system (1.6)–(1.8) satisfies the following basic energy law:

$$\frac{d}{dt}\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}^\varepsilon,\mathbf{d}^\varepsilon)+\int_\Omega\Big(\nu|\nabla\mathbf{u}^\varepsilon|^2+\lambda\gamma\big|\Delta\mathbf{d}^\varepsilon-\frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d}^\varepsilon)\big|^2\Big)\,\mathrm{d}\mathbf{x}=\int_\Omega\langle\mathbf{g},\mathbf{u}^\varepsilon\rangle\,\mathrm{d}\mathbf{x}\,, \tag{1.10}$$

where

$$\mathcal{J}_{\varepsilon,\lambda}(\mathbf{u}^\varepsilon,\mathbf{d}^\varepsilon):=\int_\Omega\Big[\,\frac{1}{2}|\mathbf{u}^\varepsilon|^2+\frac{\lambda}{2}|\nabla\mathbf{d}^\varepsilon|^2+\frac{\lambda}{\varepsilon^2}F(\mathbf{d}^\varepsilon)\,\Big]\,\mathrm{d}\mathbf{x}\,. \tag{1.11}$$

Based on the above energy law, Lin and Liu [26] established, for every fixed $\varepsilon>0$ and under appropriate assumptions on the initial data and Ω, global existence of weak solutions and local existence of classical solutions for the regularized system (1.6)–(1.8). Later, they also proved that the singular set of suitable weak solutions of the system has zero one-dimensional Hausdorff measure [27].

The first numerical studies for the regularized problem (1.6)–(1.8) appeared in [31], where Hermite bicubic finite elements were used to approximate the director field $\mathbf{d}^\varepsilon:\Omega_T\to\mathbb{R}^N$. To avoid using Hermite elements, a mixed finite element method was subsequently developed in [32]. Later, a Fourier spectral method was studied in [15]. However, a priori bounds for the numerical solutions in all these works for quantities on the left-hand side of (1.10) are of order $\mathcal{O}\big(\exp(\frac{t}{\varepsilon^2})\big)$, and no uniform discrete energy law was obtained. Consequently, (i) solvability of these schemes by Brouwer fixed point argument requires very small time steps $k=\mathcal{O}\big(\exp(-\frac{1}{\varepsilon^2})\big)$, (ii) no information about the long-time dynamics for the energy is available for the numerical solutions, and (iii) limiting behavior (as $\varepsilon\to0$) of discretizations is not clear.

The first goal of this paper is to construct a practical, fully discrete finite element discretization for the regularized system (1.6)–(1.8). The main features of the proposed scheme include the following: (i) it is unconditionally solvable (with respect to mesh parameters); (ii) the numerical solution satisfies a discrete energy law; (iii) the numerical solution unconditionally converges to a weak solution of (1.6)–(1.8) (as $k,h\to0$) and to a measure-valued solution of (1.1)–(1.3) (as $\varepsilon\to0$). To achieve the above goal, our main idea is to introduce a new "pressure"

$$\widetilde{p}^\varepsilon:=\widehat{p}^\varepsilon+\frac{\lambda}{\varepsilon^2}F(\mathbf{d}^\varepsilon)\equiv p^\varepsilon+\frac{\lambda}{2}|\nabla\mathbf{d}^\varepsilon|^2+\frac{\lambda}{\varepsilon^2}F(\mathbf{d}^\varepsilon) \tag{1.12}$$

and use the fact that $\nabla F(\mathbf{z})=(\nabla\mathbf{z})^T\mathbf{f}(\mathbf{z})$ to rewrite (1.9), and hence (1.6), as

$$\mathbf{u}_t^\varepsilon-\nu\Delta\mathbf{u}^\varepsilon+(\mathbf{u}^\varepsilon\cdot\nabla)\mathbf{u}^\varepsilon+\nabla\widetilde{p}^\varepsilon-\lambda(\nabla\mathbf{d}^\varepsilon)^T\mathbf{w}^\varepsilon=\mathbf{g}\,,\qquad\mathbf{w}^\varepsilon:=-\Delta\mathbf{d}^\varepsilon+\frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d}^\varepsilon)\,. \tag{1.13}$$

The fully discrete numerical method is then constructed based on this $(\mathbf{u}^\varepsilon,\mathbf{d}^\varepsilon,\widetilde{p}^\varepsilon,\mathbf{w}^\varepsilon)$-formulation (see section 3 for the details). The new formulation allows us to establish a discrete energy law which exactly mimics the differential energy law (1.10). With the help of the discrete energy law, we are able to establish both unconditional well-posedness and convergence of the numerical solution to the solution of system (1.6)–(1.8) for every fixed $\varepsilon>0$ as the mesh parameters independently tend to zero, and to a measure-valued solution of the Ericksen–Leslie model (1.1)–(1.3) as the mesh parameters and successively the parameter ε all approach zero.

It is interesting to note that the sum of the last two terms in the definition of $\widetilde{p}^\varepsilon$ is *exactly* the energy density function for the Ginzburg–Landau equation (cf. [7]). It turns out that this new formulation allows us to use simple Lagrange finite elements to

approximate both $\mathbf{u}^\varepsilon$ and $\mathbf{d}^\varepsilon$ and to avoid using Hermite finite elements or higher order spectral finite elements to approximate $\mathbf{d}^\varepsilon$. From a more practical viewpoint, unless very fine meshes are used, penalization of the sphere constraint $(1.3)_1$ causes some smearing of textures at finite scales of regularization and discretization parameters, which provides motivation to discretize (1.1)–(1.3) directly.

The second goal of this paper concerns the construction of a fully discrete scheme for (1.1)–(1.5) which uses low order finite elements and enjoys a discrete energy law. However, to construct a stable discretization for (1.1)–(1.3) turns out to be even harder than for (1.6)–(1.8), which is now explained. For the differential problem, in order to verify the energy law (for smooth solutions) it is crucial to use the sphere constraint $|\mathbf{d}| = 1$, which is difficult to achieve at the discrete level due to the facts that finite element functions (as well as time differences) have restricted flexibility and lower regularity. In [5], a convergent discretization of the (related nonconvective) harmonic map flow for data $\mathbf{w}_0 : \Omega \to \mathbb{S}^2$ is considered, where $\mathbf{w} : \Omega_T \to \mathbb{S}^2$ satisfies $\mathbf{w}(0,\cdot) = \mathbf{w}_0$ in $\Omega \subset \mathbb{R}^3$, and

$$\mathbf{w}_t - \Delta \mathbf{w} = |\nabla \mathbf{w}|^2 \mathbf{w} \quad \text{in } \Omega_T, \qquad \partial_{\mathbf{n}} \mathbf{w} = 0 \quad \text{on } \partial\Omega_T. \tag{1.14}$$

The construction of a discrete scheme is based on the following reformulation of (1.14):

$$\mathbf{w}_t + \mathbf{w} \times (\mathbf{w} \times \Delta \mathbf{w}) = 0 \quad \text{in } \Omega_T, \qquad \partial_{\mathbf{n}} \mathbf{w} = 0 \quad \text{on } \partial\Omega_T. \tag{1.15}$$

Here, we used the vector identity $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \langle \mathbf{a}, \mathbf{c} \rangle \mathbf{b} - \langle \mathbf{a}, \mathbf{b} \rangle \mathbf{c}$ for all $\mathbf{a}, \mathbf{b}, \mathbf{c} \in \mathbb{R}^3$, together with $|\mathbf{w}| = 1$, to obtain the identity $\mathbf{w} \times (\mathbf{w} \times \Delta \mathbf{w}) = -|\nabla \mathbf{w}|^2 \mathbf{w} - \Delta \mathbf{w}$.

The proposed discretization of (1.15) satisfies a nodal sphere constraint and a discrete energy law (cf. [5]), and hence (subsequences of discrete) solutions unconditionally converge to a weak solution of (1.14) (as $k, h \to 0$). However, the Ericksen–Leslie model is more complicated, mainly due to the convective term in (1.2) which makes it harder to tackle the nodal sphere constraint in a fully discrete context, and due to the strongly nonlinear term $\operatorname{div}\big(\nabla \mathbf{d} \odot \nabla \mathbf{d}\big)$ in (1.1).

Combining reformulations (1.9) and (1.15), we arrive at the following reformulation of (1.1)–(1.3):

$$\mathbf{u}_t - \nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla \hat{p} + \lambda (\nabla \mathbf{d})^T \Delta \mathbf{d} = \mathbf{g} \quad \text{in } \Omega_T, \tag{1.16}$$

$$\mathbf{d}_t + (\mathbf{u} \cdot \nabla)\mathbf{d} + \gamma\, \mathbf{d} \times (\mathbf{d} \times \Delta \mathbf{d}) = 0 \quad \text{in } \Omega_T, \tag{1.17}$$

$$|\mathbf{d}| = 1, \qquad \operatorname{div} \mathbf{u} = 0 \quad \text{in } \Omega_T. \tag{1.18}$$

Multiplying (1.16) and (1.17) with $\mathbf{u}$ and $\Delta \mathbf{d}$, respectively, and using the formula $\langle \mathbf{a} \times \mathbf{b}, \mathbf{c} \rangle = \langle \mathbf{a} \times \mathbf{c}, \mathbf{b} \rangle$ for all $\mathbf{a}, \mathbf{b}, \mathbf{c} \in \mathbb{R}^3$, we obtain the energy law

$$\frac{d}{dt} \mathcal{J}(\mathbf{u}, \mathbf{d}) + \int_\Omega \Big(\nu\, |\nabla \mathbf{u}|^2 + \lambda\gamma\, |\mathbf{d} \times \Delta \mathbf{d}|^2 \Big)\, \mathrm{d}\mathbf{x} = \int_\Omega \langle \mathbf{g}, \mathbf{u} \rangle\, \mathrm{d}\mathbf{x}\,, \tag{1.19}$$

where

$$\mathcal{J}(\mathbf{u}, \mathbf{d}) = \frac{1}{2} \int_\Omega \big\{ |\mathbf{u}|^2 + \lambda |\nabla \mathbf{d}|^2 \big\}\, \mathrm{d}\mathbf{x}.$$

In section 4, we propose a fully discrete scheme for (1.16)–(1.18) using low-order Lagrangian finite elements (see Algorithm 4.1), and prove its conditional solvability, as well as a discrete energy law. The construction uses the midpoint rule for temporal

discretization and a discrete Laplacian. Appropriate limits (as $k, h \to 0$) are shown to satisfy properties in (1.18) and an inequality version of (1.19). Unfortunately, we are not able to identify limits in the PDEs for the discrete velocity and director fields to recover existing measure-valued solutions to (1.1)–(1.3) in the limit $k, h \to 0$ via Algorithm 4.1; the reason for this is mainly due to the additional stress which leads to the last term on the left-hand side of (1.16).

The paper is organized as follows. In section 2, we introduce notation and cite some useful known results. In section 3, we present an unconditionally solvable scheme for (1.6)–(1.8) which satisfies a discrete energy law. Convergence to weak solutions of (1.6)–(1.8) as $k, h \to 0$ and to measure-valued solutions of (1.1)–(1.3) are shown. Section 4 studies a direct discretization of problem (1.1)–(1.3), where conditional solvability and a discrete energy law are proved. Computational experiments are presented in section 5 to compare the two numerical approaches, to study proper scalings between h, k, and ε for optimal convergence of Algorithm 3.1, and to simulate formation, annihilation, and dynamics of point defects admitted by the model (1.1)–(1.3).

2. Preliminaries. Standard Sobolev space notation is used in this paper; we refer to [1, 36, 30] for their precise definitions. In particular, $(\cdot,\cdot)$ denotes the standard $L^2(\Omega)$-inner product, and $\langle\cdot,\cdot\rangle$ denotes the standard inner product in $\mathbb{R}^N$. We also introduce the function spaces

$$L^2_0(\Omega) := \{q \in L^2(\Omega);\, (q,1) = 0\}, \qquad \boldsymbol{\mathcal{V}} := \{\mathbf{v} \in C^\infty_0(\Omega,\mathbb{R}^3);\, \operatorname{div}\mathbf{v} = 0 \text{ in } \Omega\}\,,$$

$$\mathbf{H} := \{\mathbf{v} \in L^2(\Omega,\mathbb{R}^3);\, \operatorname{div}\mathbf{v} = 0 \text{ weakly in } \Omega \text{ and } \langle\mathbf{v},\mathbf{n}\rangle|_{\partial\Omega} = 0\},$$

$$\mathbf{V} := \{\mathbf{v} \in H^1_0(\Omega,\mathbb{R}^3);\, \operatorname{div}\mathbf{v} = 0 \text{ weakly in } \Omega\}.$$

Let $\mathbf{V}'$ denote the dual of $\mathbf{V}$. In the following, we assume $\Omega \subset \mathbb{R}^N$ to be a bounded Lipschitz domain such that $\Delta : W^{1,2}_0(\Omega) \cap W^{2,2}(\Omega) \to L^2(\Omega)$ is an isomorphism; see [19, 20]. In addition, C is used to denote a generic positive constant which is independent of $\mathbf{u}$, p, $\mathbf{d}$, and the regularization and mesh parameters ε, k, and h.

2.1. Solvability of systems (1.4)–(1.8) and (1.1)–(1.5). Letting $N = 2, 3$, we recall the notion of weak solutions for (1.4)–(1.8).

DEFINITION 2.1. *Let* $(\mathbf{u}_0, \mathbf{d}_0) \in \mathbf{H} \times W^{1,2}(\Omega,\mathbb{R}^N)$, $\mathbf{g} \in L^2\big(0,T;\mathbf{V}')\big)$, *and* $\varepsilon > 0$. *Given* $T > 0$, *a tuple* $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ *with*

$$\mathbf{u}^\varepsilon \in L^2\big(0,T;\mathbf{V}\big) \cap W^{1,\frac{4}{3}}\big(0,T;\mathbf{V}'\big),$$

$$\mathbf{d}^\varepsilon \in L^2\big(0,T;W^{2,2}(\Omega,\mathbb{R}^N)\big) \cap W^{1,\frac{4}{3}}\big(0,T;L^2(\Omega,\mathbb{R}^N)\big)$$

is called a weak solution to (1.4)–(1.8) *if* (1.6)–(1.8) *hold in the distributional sense,* (1.4)–(1.5) *are valid in the sense of traces, and for almost every* $t \in [0,T]$ *there holds*

$$\mathcal{J}_{\varepsilon,\lambda}\big(\mathbf{u}^\varepsilon(t,\cdot),\mathbf{d}^\varepsilon(t,\cdot)\big) + \int_{\Omega_t}\Big(\nu\,|\nabla\mathbf{u}|^2 + \lambda\gamma\,|\Delta\mathbf{d}^\varepsilon - \frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d}^\varepsilon)|^2\Big)\,\mathrm{d}\mathbf{x}\mathrm{d}s$$

$$\leq \mathcal{J}_{\varepsilon,\lambda}\big(\mathbf{u}_0,\mathbf{d}_0\big) + \int_{\Omega_t}\langle\mathbf{g},\mathbf{u}^\varepsilon\rangle\,\mathrm{d}\mathbf{x}\mathrm{d}s\,. \tag{2.1}$$

Weak solutions to (1.4)–(1.8) for every $\varepsilon > 0$ were constructed in [26] by the Faedo–Galerkin method. They are locally strong for more regular data, and even global if the fluid viscosity $\nu > 0$ is sufficiently large.

A solution concept for the limiting system (1.1)–(1.3) that uses a Radon measure $\nu = \{\nu_{t,\mathbf{x}}\} \in L^\infty_w\big(\Omega_T; \mathcal{M}(\mathbb{R}^{N\times N})\big) \equiv \big(L^1\big(\Omega_T; C_0(\mathbb{R}^{N\times N})\big)\big)'$ to interpret the limiting behavior ($\varepsilon \to 0$) of the extra stress in (1.6) is defined next.

DEFINITION 2.2. *Let* $(\mathbf{u}_0, \mathbf{d}_0) \in \mathbf{H} \times W^{1,2}(\Omega, \mathbb{R}^N)$, *such that* $|\mathbf{d}_0| = 1$ *a.e. in* Ω, *and* $\mathbf{g} \in L^2\big(0,T; \mathbf{V}'\big)$. *Given* $T > 0$, *a triple* $(\mathbf{u}, \mathbf{d}, \nu)$ *with*

$$\mathbf{u} \in L^2\big(0,T;\mathbf{V}\big) \cap W^{1,\frac{4}{3}}\big(0,T;\mathbf{V}'\big),$$

$$(\mathbf{d}, \nu) \in L^\infty\big(0,T; W^{1,2}(\Omega,\mathbb{R}^N)\big) \times L^\infty_w\big(\Omega_T; \mathcal{M}(\mathbb{R}^{N\times N})\big)$$

is called a generalized solution to (1.1)–(1.5) *if*

(i) $|\mathbf{d}| = 1$ *a.e. in* Ω_T,

(ii) *equation* (1.2) *holds in the distributional sense, and for all* $(\boldsymbol{\varphi}, \boldsymbol{\psi}) \in C_0^\infty\big([0,T); \boldsymbol{\mathcal{V}}\big) \times C_0^\infty\big([0,T); C_0^\infty(\Omega,\mathbb{R}^N)\big)$ *there hold*

$$-\int_{\Omega_T} \Big[\langle \mathbf{u}, \boldsymbol{\varphi}_t\rangle - \nu\langle \nabla\mathbf{u}, \nabla\boldsymbol{\varphi}\rangle + \big\langle (\mathbf{u}\cdot\nabla)\boldsymbol{\varphi}, \mathbf{u}\big\rangle + \lambda\left\langle \nabla\boldsymbol{\varphi}, \int_{\mathbb{R}^{N\times N}} \boldsymbol{\lambda}\odot\boldsymbol{\lambda}\,\mathrm{d}\nu(\boldsymbol{\lambda})\right\rangle\Big]\,\mathrm{d}\mathbf{x}\mathrm{d}t = \int_{\Omega_T}\langle \mathbf{g}, \boldsymbol{\varphi}\rangle\,\mathrm{d}\mathbf{x}\mathrm{d}t + \big(\mathbf{u}_0, \boldsymbol{\varphi}(0,\cdot)\big),$$

$$-\int_{\Omega_T} \langle \mathbf{d}, \boldsymbol{\psi}_t\rangle - \langle \nabla\mathbf{d}, \nabla\boldsymbol{\psi}\rangle + \big\langle (\mathbf{U}\cdot\nabla)\boldsymbol{\psi}, \mathbf{d}\big\rangle + \big\langle |\nabla\mathbf{d}|^2\mathbf{d}, \boldsymbol{\psi}\big\rangle\,\mathrm{d}\mathbf{x}\mathrm{d}t = \big(\mathbf{d}_0, \boldsymbol{\psi}(0,\cdot)\big),$$

and

$$\nabla\mathbf{d}(t,\mathbf{x}) = \int_{\mathbb{R}^{N\times N}} \boldsymbol{\lambda}\,\mathrm{d}\nu_{t,\mathbf{x}}(\boldsymbol{\lambda}) \quad \text{a.e. in } \Omega_T\,.$$

The Radon measure ν can be generated from convergent subsequences $\{\nabla\mathbf{d}^\varepsilon\}_{\varepsilon>0}$ which solve (1.6)–(1.8) in the limit, i.e.,

$$\delta_{\nabla\mathbf{d}^\varepsilon} \overset{*}{\rightharpoonup} \nu \qquad \text{in } L^\infty_w\big(\Omega_T; \mathcal{M}(\mathbb{R}^{N\times N})\big) \qquad (\varepsilon \to 0)\,.$$

Local existence of strong solutions ($N = 2$) to (1.1)–(1.5) for more regular data is verified in [33, Chapter 6]. The next lemma states conservation of the initial sphere constraint for classical solutions to (1.1)–(1.5).

LEMMA 2.3. *Suppose* $(\mathbf{u}_0, \mathbf{d}_0) \in \boldsymbol{\mathcal{V}} \times C^2(\Omega, \mathbb{S}^{N-1})$ *and that* $(\mathbf{u}, \mathbf{d})$ *is a classical solution to* (1.1), (1.2), $(1.3)_2$, (1.4), (1.5). *Then* $|\,\mathbf{d}\,| = 1$ *in* Ω_T.

Proof. Multiply (1.2) by $\mathbf{d}$, and set $z = |\,\mathbf{d}\,|^2$. Because of

$$z_t = 2\langle \mathbf{d}, \mathbf{d}_t\rangle\,, \quad \nabla z = 2(\nabla\mathbf{d})\mathbf{d}\,, \quad \Delta z = 2\langle \mathbf{d}, \Delta\mathbf{d}\rangle + 2|\,\nabla\mathbf{d}\,|^2\,,$$

we find

$$z_t - \Delta z + 2\langle (\mathbf{u}\cdot\nabla)\mathbf{d}, \mathbf{d}\rangle = 2|\,\nabla\mathbf{d}\,|^2\big(|\,\mathbf{d}\,|^2 - 1\big) \quad \text{in } \Omega_T\,.$$

Put $w = z - 1$, and note $w(\cdot, 0) = 0$ everywhere in Ω, and

$$w_t - \Delta w + 2\langle (\mathbf{u}\cdot\nabla)\mathbf{d}, \mathbf{d}\rangle = 2|\,\nabla\mathbf{d}\,|^2 w \qquad \text{in } \Omega_T\,.$$

Testing the above equation with w, integrating over Ω_T, and using $\big((\mathbf{u}\cdot\nabla)w, w\big) = 0$ lead to ($T > 0$)

$$\frac{1}{2}\|\,w(T,\cdot)\,\|^2_{L^2} + \int_{\Omega_T} |\,\nabla w\,|^2\,\mathrm{d}\mathbf{x}\mathrm{d}s \le \frac{1}{2}\|\,w(0,\cdot)\,\|^2_{L^2}\exp\left(\int_{\Omega_T}|\,\nabla\mathbf{d}\,|^2\,\mathrm{d}\mathbf{x}\mathrm{d}s\right) = 0$$

by Gronwall's lemma. Hence, $w \equiv 0$ or $|\mathbf{d}| \equiv 1$. ∎

2.2. Finite element spaces. Throughout this section we assume that $\mathcal{T}_h$ is a quasi-uniform triangulation of a bounded polygonal or polyhedral domain $\Omega \subset \mathbf{R}^N$ into triangles or tetrahedrons of maximal diameter $h > 0$ for $N = 2, 3$, i.e., $\overline{\Omega} = \bigcup_{K \in \mathcal{T}_h} \overline{K}$. Let $\mathcal{N}_h = \{\mathbf{x}_\ell\}_{\ell \in L}$ denote the set of all nodes of $\mathcal{T}_h$. Choose

$$\mathbf{Y}_h = \{\mathbf{a}_h \in C(\overline{\Omega}, \mathbb{R}^N) : \mathbf{a}_h|_K \in P_1(K, \mathbb{R}^N)\},$$

and the nodal interpolation operator $\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} : C(\overline{\Omega}, \mathbb{R}^N) \to \mathbf{Y}_h$, such that $\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\boldsymbol{\psi} := \sum_{\mathbf{z} \in \mathcal{N}_h} \boldsymbol{\psi}(\mathbf{z})\boldsymbol{\varphi}_\mathbf{z}$, where $\{\boldsymbol{\varphi}_\mathbf{z} : \mathbf{z} \in \mathcal{N}_h\} \subset \mathbf{Y}_h$ denotes the nodal basis for $\mathbf{Y}_h$ and $\boldsymbol{\psi} \in C(\overline{\Omega}, \mathbb{R}^N)$.

For functions $\boldsymbol{\phi}, \boldsymbol{\psi} \in C(\overline{\Omega}, \mathbb{R}^N)$, we define

$$(\boldsymbol{\phi}, \boldsymbol{\psi})_h := \int_\Omega \mathcal{I}_h(\langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle)\, \mathrm{d}\mathbf{x} = \sum_{\mathbf{z} \in \mathcal{N}_h} \beta_\mathbf{z} \big\langle \boldsymbol{\phi}(\mathbf{z}), \boldsymbol{\psi}(\mathbf{z}) \big\rangle,$$

$$\|\boldsymbol{\phi}_h\|_h^2 := (\boldsymbol{\phi}_h, \boldsymbol{\phi}_h)_h,$$

where $\beta_\mathbf{z} = \int_\Omega \varphi_\mathbf{z}\, \mathrm{d}\mathbf{x}$ for $\mathbf{z} \in \mathcal{N}_h$. It is easy to check that for all $\boldsymbol{\phi}_h, \boldsymbol{\psi}_h \in \mathbf{Y}_h$,

$$\|\boldsymbol{\phi}_h\|_{L^2} \le \|\boldsymbol{\phi}_h\|_h \le (N+2)^{1/2} \|\boldsymbol{\phi}_h\|_{L^2}, \tag{2.2}$$

$$\big|(\boldsymbol{\phi}_h, \boldsymbol{\psi}_h)_h - (\boldsymbol{\phi}_h, \boldsymbol{\psi}_h)\big| \le Ch \|\boldsymbol{\phi}_h\|_{L^2} \|\nabla \boldsymbol{\psi}_h\|_{L^2}. \tag{2.3}$$

We also define a discrete Laplace operator $\Delta_h : \mathbf{W}^{1,2}(\Omega, \mathbb{R}^N) \to \mathbf{Y}_h$ by

$$(\Delta_h \boldsymbol{\phi}, \boldsymbol{\chi}_h) = -(\nabla \boldsymbol{\phi}, \nabla \boldsymbol{\chi}_h) \qquad \forall\, \boldsymbol{\chi}_h \in \mathbf{Y}_h. \tag{2.4}$$

Note that (see [5]) there exists a constant $C > 0$ such that for all $\boldsymbol{\phi}_h \in \mathbf{Y}_h$ there holds

$$\|\Delta_h \boldsymbol{\phi}_h\|_{L^2} \le Ch^{-2} \|\boldsymbol{\phi}_h\|_{L^2} \quad \text{and} \quad \|\Delta_h \boldsymbol{\phi}_h\|_{L^\infty} \le Ch^{-2} \|\boldsymbol{\phi}_h\|_{L^\infty} \quad \forall\, \boldsymbol{\phi}_h \in \mathbf{Y}_h.$$

The following discrete Sobolev interpolation inequality immediately follows from [21, Lemma 4.4]:

$$\|\nabla \boldsymbol{\phi}_h\|_{L^4} \le C \|\nabla \boldsymbol{\phi}_h\|_{L^2}^{\frac{4-N}{4}} \big[\|\nabla \boldsymbol{\phi}_h\| + \|\Delta_h \boldsymbol{\phi}_h\|_{L^2}\big]^{\frac{N}{4}} \qquad \forall\, \boldsymbol{\phi}_h \in \mathbf{Y}_h. \tag{2.5}$$

The next result is a discrete version of the Aubin–Lions compactness lemma.

LEMMA 2.4. *Let $N = 2, 3$. Suppose $\frac{2N}{N+2} < \ell < \infty$, and let $\mathcal{T}_h$ be a quasi-uniform triangulation of $\Omega \subset \mathbb{R}^N$. Let $\{\boldsymbol{\Phi}_h\}_{h \ge 0} \subset L^2(\Omega_T, \mathbb{R}^N)$ be a sequence of functions, such that $\boldsymbol{\Phi}_h(t, \cdot) \in \mathbf{Y}_h$ for all $t \in [0, T]$, and there holds*

$$\|\boldsymbol{\Phi}_h\|_{W^{1,2}(0,T;L^\ell(\Omega))} + \|\boldsymbol{\Phi}_h\|_{L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;W^{1,2}(\Omega))} + \|\Delta_h \boldsymbol{\Phi}_h\|_{L^2(\Omega_T)} \le C.$$

Then there exist a subsequence $\{\boldsymbol{\Phi}_h\}_{h>0}$ (not relabeled) and $\boldsymbol{\Phi}$, such that

$$\boldsymbol{\Phi}_h \to \boldsymbol{\Phi} \quad \text{in } L^2\big(0, T; W^{1,2}(\Omega, \mathbb{R}^N)\big) \qquad (h \to 0).$$

Proof. For every $T > 0$ and $h > 0$, consider a weak solution $\mathbf{w}_h : \Omega_T \to \mathbb{R}^3$ of

$$\frac{\partial \mathbf{w}_h}{\partial t} - \Delta \mathbf{w}_h = \mathbf{g}_h \equiv \boldsymbol{\Phi}_{h,t} - \Delta_h \boldsymbol{\Phi}_h \quad \text{in } \Omega_T, \quad \partial_\mathbf{n}[\mathbf{w}_h - \boldsymbol{\Phi}_h] = 0 \quad \text{on } \partial\Omega_T, \tag{2.6}$$

such that $\mathbf{w}_h(0,\cdot) = \mathbf{\Phi}_h(0,\cdot)$. The following maximal L^p-L^ℓ-estimates $(1 < p, \ell < \infty)$ for (2.6) are well known [24]:

$$\begin{aligned}\|(\mathbf{w}_h)_t\|_{L^p(L^\ell)} + \|\mathbf{w}_h\|_{L^p(W^{2,\ell})} &\le C\|\mathbf{g}_h\|_{L^p(L^\ell)} \\ &\le C\left[\|\mathbf{\Phi}_{h,t}\|_{L^p(L^\ell)} + \|\Delta_h\mathbf{\Phi}_h\|_{L^p(L^\ell)}\right].\end{aligned}$$

By Sobolev embedding $W^{2,\ell}(\Omega) \overset{c}{\hookrightarrow} W^{1,2}(\Omega)$ for $\ell > \frac{2N}{2+N}$ and the Aubin–Lions compactness lemma we conclude that there exists a subsequence (not relabeled) of $\{\mathbf{w}_h\}$ such that $\mathbf{w}_h \to \mathbf{\Phi}$ in $L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)$.

Next, testing (2.6) with $[\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h - \mathbf{\Phi}_h](t,\cdot) \in \mathbf{Y}_h$ we obtain

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|\mathbf{w}_h - \mathbf{\Phi}_h\|_{L^2}^2 + \|\nabla\big[\mathbf{w}_h - \mathbf{\Phi}_h\big]\|_{L^2}^2 \\ &\quad= \Big([\mathbf{w}_h - \mathbf{\Phi}_h]_t, \mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h\Big) + \Big(\nabla[\mathbf{w}_h - \mathbf{\Phi}_h], \nabla[\mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h]\Big) \\ &\quad\le \big(\|\mathbf{w}_{h,t}\|_{L^\ell} + \|\mathbf{\Phi}_{h,t}\|_{L^\ell}\big)\|\mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h\|_{L^{\ell'}} \\ &\qquad\qquad + \|\nabla[\mathbf{w}_h - \mathbf{\Phi}_h]\|_{L^2}\|\mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h\|_{W^{1,2}}.\end{aligned}$$

Put $p = 2$ in the above estimate. Integrating in time, applying Young's inequality, and using standard interpolation results yield

$$\begin{aligned}&\|\mathbf{w}_h - \mathbf{\Phi}_h\|_{L^\infty(L^2)}^2 + \frac{1}{2}\|\mathbf{w}_h - \mathbf{\Phi}_h\|_{L^2(W^{1,2})}^2 \\ &\qquad\le C\left[\|\mathbf{w}_{h,t}\|_{L^2(L^\ell)} + \|\mathbf{\Phi}_{h,t}\|_{L^2(L^\ell)}\right]\|\mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}_h\|_{L^2(L^{\ell'})} \\ &\qquad\quad + 2\|\mathbf{w}_h - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{w}\|_{L^2(W^{1,2})}^2 \\ &\qquad\le C\Big[h^{2+N\min\{1-\frac{2}{\ell},0\}} + h^{2[1+N\min\{\frac{\ell-2}{2\ell},0\}]}\Big]\|\mathbf{w}_h\|_{L^2(W^{2,\ell})}.\end{aligned}$$

Hence, for $\ell > \frac{2N}{N+2}$, we have $\mathbf{w}_h - \mathbf{\Phi}_h \to 0$ in $L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)$ as $h \to 0$. Consequently, $\mathbf{\Phi}_h \to \mathbf{\Phi}$ in $L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)$. ∎

For a nonnegative integer r, let $P_r(K)$ denote the space of polynomials of degree less than or equal to r on K. Let $(\mathbf{X}_h, M_h)$ be an LBB-stable mixed finite element pair; i.e., $\mathbf{X}_h \subset W_0^{1,2}(\Omega,\mathbb{R}^N)$ and $M_h \subset L_0^2(\Omega)$ satisfy the inf-sup condition

$$\sup_{\mathbf{v}_h \in \mathbf{X}_h} \frac{(\operatorname{div}\mathbf{v}_h, q_h)}{\|\nabla\mathbf{v}_h\|_{L^2}} \ge C\|q_h\|_{L^2} \qquad \forall q_h \in M_h. \tag{2.7}$$

A well-known example that satisfies (2.7) is (see [20, 10])

$$\begin{aligned}\mathbf{X}_h &= \{\mathbf{v}_h \in C^0(\overline{\Omega},\mathbb{R}^N) \cap W_0^{1,2}(\Omega,\mathbb{R}^N);\ \mathbf{v}_h|_K \in P_2(K,\mathbb{R}^N)\},\\ M_h &= \{q_h \in L_0^2(\Omega);\ q_h|_K \in P_0(K)\}.\end{aligned}$$

Let

$$\mathbf{V}_h := \{\mathbf{v}_h \in \mathbf{X}_h :\ (\operatorname{div}\mathbf{v}_h, q_h) = 0\ \forall q_h \in M_h\}.$$

In the following, we use L^2-orthogonal projections $Q_{\mathbf{V}_h} : L^2(\Omega,\mathbb{R}^N)\to\mathbf{V}_h$ and $Q_{\mathbf{Y}_h} : L^2(\Omega,\mathbb{R}^N)\to\mathbf{Y}_h$, i.e., for all $\mathbf{z}\in L^2(\Omega,\mathbb{R}^N)$

$$(\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z},\mathbf{v}_h)=0\qquad\forall\mathbf{v}_h\in\mathbf{V}_h\,,\qquad(\mathbf{z}-Q_{\mathbf{Y}_h}\mathbf{z},\mathbf{a}_h)=0\qquad\forall\mathbf{a}_h\in\mathbf{Y}_h\,,$$

and the $W^{1,2}$-orthogonal projection $R_{\mathbf{Y}_h} : W^{1,2}(\Omega,\mathbb{R}^N)\to\mathbf{Y}_h$ such that for all $\mathbf{z}\in W^{1,2}(\Omega,\mathbb{R}^N)$

$$\big(\nabla[\mathbf{a}-R_{\mathbf{Y}_h}\mathbf{z}],\nabla\mathbf{b}_h\big)+\big(\mathbf{a}-R_{\mathbf{Y}_h}\mathbf{z},\mathbf{b}_h\big)=0\qquad\forall\,\mathbf{b}_h\in\mathbf{Y}_h\,.$$

The following estimates can be found in [21]:

$$\|\,\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z}\,\|_2+h\|\,\nabla(\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z})\,\|_{L^2}\le Ch^2\|\,D^2\mathbf{z}\,\|_{L^2}\quad\forall\mathbf{z}\in\mathbf{V}\cap W^{2,2}(\Omega,\mathbb{R}^N),\tag{2.8}$$

$$\|\,\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z}\,\|_2\le Ch\,\|\,\nabla\mathbf{z}\,\|_{L^2}\quad\forall\,\mathbf{z}\in\mathbf{V}.\tag{2.9}$$

By the inverse inequality, a standard duality argument which gives $\|\,\mathbf{a}-R_{\mathbf{Y}_h}\mathbf{a}\,\|_{L^2}\le Ch\,\|\,\nabla\mathbf{a}\,\|_{L^2}$ for all $\mathbf{a}\in W^{1,2}(\Omega,\mathbb{R}^N)$, together with (2.9) and $W^{1,2}$-stability of $R_{\mathbf{Y}_h}$: $W^{1,2}(\Omega;\,\mathbb{R}^N)\to\mathbf{Y}_h$, we have

$$\begin{aligned}\|\,Q_{\mathbf{V}_h}\mathbf{z}\,\|_{W^{1,2}}&\le\|\,R_{\mathbf{Y}_h}\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z}\,\|_{W^{1,2}}+\|\,R_{\mathbf{Y}_h}\mathbf{z}\,\|_{W^{1,2}}\\&\le Ch^{-1}\|\,R_{\mathbf{Y}_h}\mathbf{z}\pm\mathbf{z}-Q_{\mathbf{V}_h}\mathbf{z}\,\|_{L^2}+\|\,\mathbf{z}\,\|_{W^{1,2}}\\&\le C\|\,\mathbf{z}\,\|_{W^{1,2}}\qquad\forall\,\mathbf{z}\in\mathbf{V}\,.\end{aligned}\tag{2.10}$$

Hence, $Q_{\mathbf{V}_h}$ is stable in $W^{1,2}(\Omega)$.

2.3. Discrete time-derivatives and interpolations. Given a time-step size $k>0$ and a sequence $\{\boldsymbol{\phi}_j\}$ in some Banach space $\mathbf{X}$, we set $d_t\boldsymbol{\phi}^j:=k^{-1}\big(\boldsymbol{\phi}^j-\boldsymbol{\phi}^{j-1}\big)$ and $\boldsymbol{\phi}^{j+1/2}:=\frac12\big(\boldsymbol{\phi}^j+\boldsymbol{\phi}^{j+1}\big)$ for $j\ge0$. Note that $\langle d_t\boldsymbol{\phi}^{j+1},\boldsymbol{\phi}^{j+1/2}\rangle=\frac12 d_t\|\,\boldsymbol{\phi}^{j+1}\,\|_X^2$ if $\mathbf{X}$ is a Hilbert space. Piecewise constant interpolations of $\big\{\boldsymbol{\phi}^j\big\}$ are defined for $t\in[t_j,t_{j+1})$ and $j\in\{0,1,\ldots,J-1\}$ by

$$\overline{\boldsymbol{\Phi}}(t):=\boldsymbol{\phi}^{j+1/2},\quad\boldsymbol{\Phi}^-(t):=\boldsymbol{\phi}^j\,,\quad\boldsymbol{\Phi}^+(t):=\boldsymbol{\phi}^{j+1}\,,$$

and a piecewise linear interpolation on $[t_j,t_{j+1})$ for $j\in\{0,1,\ldots,J-1\}$ is defined by

$$\boldsymbol{\Phi}(t):=\frac{t-t_j}{k}\boldsymbol{\phi}^{j+1}+\frac{t_{j+1}-t}{k}\boldsymbol{\phi}^j.$$

Note that there holds

$$\|\,\boldsymbol{\Phi}^\pm-\boldsymbol{\Phi}\,\|_X+\|\,\overline{\boldsymbol{\Phi}}-\boldsymbol{\Phi}\,\|_X\le2k\,\|\,d_t\boldsymbol{\Phi}\,\|_X.$$

3. Fully discrete finite element methods for the regularized Ericksen–Leslie model (1.6)–(1.8). The plan of this section is as follows. A priori bounds for solutions to the regularized Ericksen–Leslie model are collected in section 3.1. A fully discrete finite element approximation is studied in section 3.2, and unconditional solvability and a discrete energy law are shown in Lemma 3.4 and Theorem 3.5; convergence of numerical solutions to weak solutions of (1.6)–(1.8) and to generalized solutions of (1.1)–(1.3) is proved in Theorem 3.7.

3.1. A priori bounds for regular solutions to (1.6)–(1.8). We recall the basic energy law and derive some additional a priori estimates for solutions of the system (1.6)–(1.8); most of the a priori estimates to be given below were derived in [26] for the case $\nu = \lambda = \gamma = \varepsilon = 1$.

We first state some properties of the differential of the vector-valued function $\mathbf{f}(\mathbf{a}) = \big(|\mathbf{a}|^2 - 1\big)\mathbf{a}$. Since the proofs are elementary, we omit them.

LEMMA 3.1. *Let $\mathbf{a} \in \mathbf{R}^N$; then the following properties hold for the differential $D\mathbf{f}$ of $\mathbf{f}(\mathbf{a}) = (|\mathbf{a}|^2 - 1)\mathbf{a}$:*

(i) $D\mathbf{f}(\mathbf{a}) = (|\mathbf{a}|^2 - 1)I + 2\mathbf{a}\mathbf{a}^T$.

(ii) $\mu_1(|\mathbf{a}|) = 3|\mathbf{a}|^2 - 1$ *and* $\mu_2(|\mathbf{a}|) = |\mathbf{a}|^2 - 1$ *are the only two distinct eigenvalues of $D\mathbf{f}(\mathbf{a})$ with multiplicities 1 and $N-1$, respectively. Moreover, $\mathcal{V}_{\mu_1} = span\{\mathbf{a}\}$ and $\mathcal{V}_{\mu_2} = \mathcal{V}_{\mu_1}^{\perp}$ are the eigenspaces corresponding to μ_1 and μ_2.*

(iii) $D\mathbf{f}(\mathbf{a})$ *is a singular $N \times N$ matrix for $|\mathbf{a}| = 1$.*

(iv) $\langle D\mathbf{f}(\mathbf{a})\mathbf{b}, \mathbf{b}\rangle = (|\mathbf{a}|^2 - 1)|\mathbf{b}|^2 + 2|\langle \mathbf{a}, \mathbf{b}\rangle|^2$ *for all $\mathbf{b} \in \mathbf{R}^N$.*

(v) $\langle D\mathbf{f}(\mathbf{a})A, A\rangle = (|\mathbf{a}|^2 - 1)|A|^2 + 2|A^T\mathbf{a}|^2$ *for all $A \in \mathbf{R}^{N\times N}$.*

The next lemma derives the basic energy law associated with (1.6)–(1.8) and its induced a priori estimates.

LEMMA 3.2. *Let $\Omega \subset \mathbb{R}^N$ $(N = 2, 3)$ be a convex polyhedron and let $T > 0$. Let $\mathbf{g} \in L^2\big((0,T); \mathbf{V}'\big)$ and the initial values $\mathbf{u}_0^\varepsilon \in \mathbf{H}$ and $\mathbf{d}_0^\varepsilon \in W^{1,2}(\Omega, \mathbb{R}^N)$ such that $|\mathbf{d}_0^\varepsilon| \le 1$ a.e. in Ω. Then every regular smooth solution $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ of the system (1.6)–(1.8), (1.4)–(1.5) satisfies*

(i) $\operatorname*{ess\,sup}_{t\in[0,T]} \| \mathbf{d}^\varepsilon(t,\cdot) \|_{L^\infty} \le 1\,,$

(ii) $\operatorname*{ess\,sup}_{t\in[0,T]} \Big\{ \frac{1}{2} \| \mathbf{u}^\varepsilon(t,\cdot) \|_{L^2}^2 + \frac{\lambda}{2} \| \nabla \mathbf{d}^\varepsilon(t,\cdot) \|_{L^2}^2 + \lambda\varepsilon^{-2}\big(F(\mathbf{d}^\varepsilon(t,\cdot)), 1\big) \Big\} \le C\,,$

(iii) $\dfrac{\nu}{2}\displaystyle\int_0^T \| \nabla \mathbf{u}^\varepsilon(t,\cdot) \|_{L^2}^2 \mathrm{d}t + \left\{ \begin{array}{l} \lambda\gamma \displaystyle\int_0^T \| \Delta \mathbf{d}^\varepsilon(t,\cdot) - \varepsilon^{-2}\mathbf{f}(\mathbf{d}^\varepsilon(t,\cdot)) \|_{L^2}^2 \mathrm{d}t \\ \dfrac{\lambda}{\gamma} \displaystyle\int_0^T \| \mathbf{d}_t^\varepsilon(t,\cdot) + (\mathbf{u}^\varepsilon(t,\cdot)\cdot\nabla)\mathbf{d}^\varepsilon(t,\cdot) \|_{L^2}^2 \mathrm{d}t \end{array} \right\} \le C,$

(iv) $\displaystyle\int_0^T \Big\{ \| \mathbf{u}_t^\varepsilon(t,\cdot) \|_{(\mathbf{V}\cap L^\infty)'}^2 + \| \mathbf{d}_t^\varepsilon(t,\cdot) \|_{L^{\frac{3}{2}}}^2 \Big\} \mathrm{d}t \le C,$

(v) $\displaystyle\int_0^T \Big\{ \| \Delta \mathbf{d}^\varepsilon(t,\cdot) \|_{L^2}^2 + \| \mathbf{d}_t^\varepsilon(t,\cdot) \|_{L^2}^{\frac{4}{3}} + \| \mathbf{u}_t^\varepsilon(t,\cdot) \|_{\mathbf{V}'}^{\frac{4}{3}} \Big\} \mathrm{d}t \le C\,\varepsilon^{-2}\,.$

Proof. Assertion (i) follows from a weak maximum principle on testing (1.7) with $(|\mathbf{d}^\varepsilon| - 1)^+\mathbf{d}^\varepsilon/|\mathbf{d}^\varepsilon|$, where

$$\frac{(z-1)^+}{z} := \left\{ \begin{array}{ll} 0 & \text{if } z \in [0,1], \\ \frac{z-1}{z} & \text{if } z \ge 1. \end{array} \right.$$

Next, multiplying (1.13) with $\mathbf{u}^\varepsilon$, and (1.7) with $\lambda\big(-\Delta\mathbf{d}^\varepsilon + \varepsilon^{-2}\mathbf{f}(\mathbf{d}^\varepsilon)\big)$, and adding the resulting equations lead to the basic energy equation (1.10).

The bounds (ii), (iii) follow easily from integrating (1.10) with respect to t from 0 to T on noting the inequality

$$|\langle \mathbf{g}, \mathbf{u}^\varepsilon\rangle| \le \frac{\nu}{2} \| \nabla \mathbf{u}^\varepsilon \|_{L^2}^2 + \frac{C_1}{\nu} \| \mathbf{g} \|_{\mathbf{V}'}^2\,.$$

To show $(\mathrm{iv})_1$, testing (1.13) with $\mathbf{v} \in \mathbf{V} \cap L^\infty(\Omega, \mathbb{R}^3)$ yields

$$\begin{aligned}\big(\mathbf{u}_t^\varepsilon, \mathbf{v}\big) &= -\nu\big(\nabla \mathbf{u}^\varepsilon, \nabla \mathbf{v}\big) + \lambda\big(\mathbf{w}^\varepsilon \nabla \mathbf{d}^\varepsilon, \mathbf{v}\big) - \big((\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{u}^\varepsilon, \mathbf{v}\big) + \langle \mathbf{g}, \mathbf{v}\rangle \\ &\le \nu \| \nabla \mathbf{u}^\varepsilon \|_{L^2} \| \nabla \mathbf{v} \|_{L^2} + \lambda \| \mathbf{w}^\varepsilon \|_{L^2} \| \nabla \mathbf{d}^\varepsilon \|_{L^2} \| \mathbf{v} \|_{L^\infty} \\ &\qquad + \| \nabla \mathbf{u}^\varepsilon \|_{L^2} \| \mathbf{u}^\varepsilon \|_{L^2} \| \mathbf{v} \|_{L^\infty} + \| \mathbf{g} \|_{\mathbf{V}'} \| \mathbf{v} \|_{W^{1,2}},\end{aligned}$$

which together with (ii), (iii) implies the assertion. To verify $(\mathrm{iv})_2$, note that (1.7) can be rewritten as $\mathbf{d}_t^\varepsilon = -\gamma \mathbf{w}^\varepsilon - (\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{d}^\varepsilon$. The second assertion in (iv) then uses (ii), (iii), and the inequality

$$\| (\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{d}^\varepsilon \|_{L^{\frac{3}{2}}} \le \| \mathbf{u}^\varepsilon \|_{L^6} \| \nabla \mathbf{d}^\varepsilon \|_{L^2}.$$

To show $(\mathrm{v})_1$, multiply the equation $\mathbf{w}^\varepsilon = -\Delta \mathbf{d}^\varepsilon + \varepsilon^{-2} \mathbf{f}(\mathbf{d}^\varepsilon)$ with $-\Delta \mathbf{d}^\varepsilon$:

$$\begin{aligned}\| \Delta \mathbf{d}^\varepsilon \|_{L^2}^2 &= -(\mathbf{w}^\varepsilon, \Delta \mathbf{d}^\varepsilon) + \frac{1}{\varepsilon^2}\big(\mathbf{f}(\mathbf{d}^\varepsilon), \Delta \mathbf{d}^\varepsilon\big) \\ &\le \| \mathbf{w}^\varepsilon \|_{L^2} \| \Delta \mathbf{d}^\varepsilon \|_{L^2} - \frac{1}{\varepsilon^2}\big(D\mathbf{f}(\mathbf{d}^\varepsilon)\nabla \mathbf{d}^\varepsilon, \nabla \mathbf{d}^\varepsilon\big) \\ &\le \frac{1}{2} \| \Delta \mathbf{d}^\varepsilon \|_{L^2}^2 + \frac{1}{2} \| \mathbf{w}^\varepsilon \|_{L^2}^2 + \frac{1}{\varepsilon^2} \| \nabla \mathbf{d}^\varepsilon \|_{L^2}^2.\end{aligned}$$

Here we have used (v) of Lemma 3.1 in combination with (i). The result then is a consequence of (iii). Estimate $(\mathrm{v})_2$ is an immediate consequence of (iii), $(\mathrm{v})_1$, and the bounds

$$\| \mathbf{d}_t^\varepsilon \|_{L^2}^{\frac{4}{3}} \le C \left[\| \mathbf{w}_\varepsilon \|_{L^2}^{\frac{4}{3}} + \| (\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{d}^\varepsilon \|_{L^2}^{\frac{4}{3}} \right],$$

$$\| (\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{d}^\varepsilon \|_{L^2}^{\frac{4}{3}} \le C \| \mathbf{u}^\varepsilon \|_{L^4}^{\frac{4}{3}} \| \nabla \mathbf{d}^\varepsilon \|_{L^4}^{\frac{4}{3}} \le C \left[\| \mathbf{u}^\varepsilon \|_{L^2}^{\frac{2}{3}} \| \nabla \mathbf{u}^\varepsilon \|_{L^2}^2 + \| \nabla \mathbf{d}^\varepsilon \|_{L^2}^{\frac{2}{3}} \| \mathbf{d}^\varepsilon \|_{W^{2,2}}^2 \right].$$

Finally, to show $(\mathrm{v})_3$, testing (1.13) with $\mathbf{v} \in \mathbf{V}$ yields

$$\begin{aligned}\big(\mathbf{u}_t^\varepsilon, \mathbf{v}\big) &= -\nu\big(\nabla \mathbf{u}^\varepsilon, \nabla \mathbf{v}\big) + \lambda\big(\mathbf{w}^\varepsilon \nabla \mathbf{d}^\varepsilon, \mathbf{v}\big) - \big((\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{u}^\varepsilon, \mathbf{v}\big) + \langle \mathbf{g}, \mathbf{v}\rangle \\ &\le \nu \| \nabla \mathbf{u}^\varepsilon \|_{L^2} \| \nabla \mathbf{v} \|_{L^2} + \lambda \| \mathbf{w}^\varepsilon \|_{L^2} \| \nabla \mathbf{d}^\varepsilon \|_{L^3} \| \mathbf{v} \|_{L^6} \\ &\qquad + \| \nabla \mathbf{u}^\varepsilon \|_{L^2} \| \mathbf{u}^\varepsilon \|_{L^3} \| \mathbf{v} \|_{L^6} + \| \mathbf{g} \|_{W^{-1,2}} \| \mathbf{v} \|_{W^{1,2}} \\ &\le \nu \| \nabla \mathbf{u}^\varepsilon \|_{L^2} \| \nabla \mathbf{v} \|_{L^2} + \lambda \| \mathbf{w}^\varepsilon \|_{L^2} \| \mathbf{d}^\varepsilon \|_{W^{2,2}}^{\frac{1}{2}} \| \nabla \mathbf{d}^\varepsilon \|_{L^2}^{\frac{1}{2}} \| \mathbf{v} \|_{L^6} \\ &\qquad + \| \nabla \mathbf{u}^\varepsilon \|_{L^2}^{\frac{3}{2}} \| \mathbf{u}^\varepsilon \|_{L^2}^{\frac{1}{2}} \| \mathbf{v} \|_{L^6} + \| \mathbf{g} \|_{W^{-1,2}} \| \mathbf{v} \|_{W^{1,2}},\end{aligned}$$

which together with (ii), (iii), and $(\mathrm{v})_1$ leads to the assertion. ∎

A priori estimates for $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ in higher norms show exponential dependence on $\varepsilon > 0$, in general. Without proof, we collect some bounds for strong solutions to (1.6)–(1.8) for $\Omega \subset \mathbb{R}^2$. For the three-dimensional case, corresponding estimates hold locally in time, unless a smallness assumption for initial data is made.

LEMMA 3.3. *In addition to the assumptions of Lemma* 3.2, *let* $\Omega = (0,1)^2$, *and suppose periodic boundary conditions. Let* $\mathbf{g} \in L^2\big(0, T; L^2(\Omega, \mathbb{R}^2)\big)$ *and* $(\mathbf{u}_0^\varepsilon, \mathbf{d}_0^\varepsilon) \in \mathbf{V} \times W^{2,2}(\Omega, \mathbb{R}^2)$. *Then every regular solution* $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ *of problem* (1.6)–(1.8) *satisfies*

$$\text{(i)}\quad \operatorname*{ess\,sup}_{[0,T]}\left\{\|\nabla\mathbf{u}^\varepsilon\|_{L^2}^2+\frac{\lambda^2}{\gamma}\|\Delta\mathbf{d}^\varepsilon\|_{L^2}^2\right\}$$
$$+\int_0^T\left(\nu\,\|\Delta\mathbf{u}^\varepsilon(s,\cdot)\|_{L^2}^2+\lambda^2\|\nabla\Delta\mathbf{d}^\varepsilon(s,\cdot)\|_{L^2}^2\right)\mathrm{d}s\le C\exp\left(\frac{T}{\varepsilon^2}\right),$$

$$\text{(ii)}\quad \int_0^T\left(\|\mathbf{u}_t^\varepsilon(s,\cdot)\|_{L^2}^2+\|\nabla p^\varepsilon(s,\cdot)\|_{L^2}^2\right)\mathrm{d}s\le C\exp\left(\frac{T}{\varepsilon^2}\right).$$

3.2. A fully discrete scheme for (1.6)–(1.8): Unconditional solvability, discrete energy law, and convergence analysis. As mentioned in section 1, our fully discrete finite element approximation for (1.6)–(1.8) is based on the formulation (1.9) using the new "pressure" $\tilde{p}^\varepsilon$.

ALGORITHM 3.1.

(1) *Set* $\mathbf{u}_h^0=Q_{\mathbf{V}_h}\mathbf{u}_0^\varepsilon$ *and* $\mathbf{d}_h^0:=R_{\mathbf{Y}_h}\mathbf{d}_0^\varepsilon$.

(2) *For* $m=1,\dots,M$, *let* $\mathbf{f}_h^m:=|\mathbf{d}_h^m|^2\mathbf{d}_h^m-\mathbf{d}_h^{m-1}$. *Find* $(\mathbf{u}_h^m,\mathbf{d}_h^m,\tilde{p}_h^m,\mathbf{w}_h^m)\in\mathbf{X}_h\times\mathbf{Y}_h\times M_h\times\mathbf{Y}_h$ *such that for all* $(\mathbf{v}_h,\mathbf{a}_h,\mathbf{b}_h,q_h)\in\mathbf{X}_h\times\big[\mathbf{Y}_h\big]^2\times M_h$

$$\big(d_t\mathbf{u}_h^m,\mathbf{v}_h\big)+\nu\big(\nabla\mathbf{u}_h^m,\nabla\mathbf{v}_h\big)+\big((\mathbf{u}_h^{m-1}\cdot\nabla)\mathbf{u}_h^m,\mathbf{v}_h\big)+\frac{1}{2}\big((\operatorname{div}\mathbf{u}_h^{m-1})\,\mathbf{u}_h^m,\mathbf{v}_h\big)$$
$$-\big(\tilde{p}_h^m,\operatorname{div}\mathbf{v}_h\big)-\lambda\big((\nabla\mathbf{d}_h^{m-1})^T\mathbf{w}_h^m,\mathbf{v}_h\big)=\big\langle\mathbf{g}(t_m,\cdot),\mathbf{v}_h\big\rangle,\tag{3.1}$$

$$\big(d_t\mathbf{d}_h^m,\mathbf{a}_h\big)+\big((\mathbf{u}_h^m\cdot\nabla)\mathbf{d}_h^{m-1},\mathbf{a}_h\big)+\gamma\big(\mathbf{w}_h^m,\mathbf{a}_h\big)=0,\tag{3.2}$$

$$\big(\operatorname{div}\mathbf{u}_h^m,q_h\big)=0,\tag{3.3}$$

$$\big(\nabla\mathbf{d}_h^m,\nabla\mathbf{b}_h\big)+\frac{1}{\varepsilon^2}\big(\mathbf{f}_h^m,\mathbf{b}_h\big)_h-\big(\mathbf{w}_h^m,\mathbf{b}_h\big)=0.\tag{3.4}$$

The crux for proving unconditional solvability and convergence of Algorithm 3.1 is to establish a discrete energy law, which mimics the basic energy law (1.10) for (1.6)–(1.8). Note that not every numerical method possesses such a property. Define $\mathcal{J}_{\varepsilon,\lambda,h}:\mathbf{X}_h\times\mathbf{Y}_h\to\mathbb{R}$ by

$$\mathcal{J}_{\varepsilon,\lambda,h}\big(\boldsymbol{\varphi}_h,\boldsymbol{\psi}_h\big):=\int_\Omega\Big[\frac{1}{2}|\boldsymbol{\varphi}_h|^2+\frac{\lambda}{2}|\nabla\boldsymbol{\psi}_h|^2\Big]\mathrm{d}\mathbf{x}+\frac{\lambda}{\varepsilon^2}\big(F(\boldsymbol{\varphi}_h),1\big)_h.\tag{3.5}$$

LEMMA 3.4. *Let* $\big\{(\mathbf{u}_h^m,\mathbf{d}_h^m,\widetilde{p}_h^m,\mathbf{w}_h^m)\big\}_{m=1}^M$ *be generated by Algorithm* 3.1*; then for all* $1\le\ell\le M$,

$$\mathcal{J}_{\varepsilon,\lambda,h}(\mathbf{u}_h^\ell,\mathbf{d}_h^\ell)+k\sum_{m=1}^{\ell}\Big(\frac{k}{2}\|\,d_t\mathbf{u}_h^m\,\|_{L^2}^2+\frac{k\lambda}{2}\|\,\nabla d_t\mathbf{d}_h^m\,\|_{L^2}^2+\nu\|\,\nabla\mathbf{u}_h^m\,\|_{L^2}^2+\lambda\gamma\|\,\mathbf{w}_h^m\,\|_{L^2}^2\Big)$$
$$\le k\sum_{m=1}^{\ell}\langle\mathbf{g}(t_m,\cdot),\mathbf{u}_h^m\rangle+\mathcal{J}_{\varepsilon,\lambda,h}(\mathbf{u}_h^0,\mathbf{d}_h^0).$$

Proof. Setting $\mathbf{v}_h=\mathbf{u}_h^m$ in (3.1), $\mathbf{a}_h=\lambda\mathbf{w}_h^m$ in (3.2), $q_h=\widetilde{p}_h^m$ in (3.3), $\mathbf{b}_h=\lambda d_t\mathbf{d}_h^m$ in (3.4) and adding the resulting equations lead to

$$\big(d_t\mathbf{u}_h^m,\mathbf{u}_h^m\big)+\nu\|\,\nabla\mathbf{u}_h^m\,\|_{L^2}^2+\big((\mathbf{u}_h^{m-1}\cdot\nabla)\mathbf{u}_h^m,\mathbf{u}_h^m\big)+\frac{1}{2}\big((\operatorname{div}\mathbf{u}_h^{m-1}),|\mathbf{u}_h^m|^2\big)$$
$$+\lambda\gamma\|\,\mathbf{w}_h^m\,\|_{L^2}^2+\lambda\big(\nabla\mathbf{d}_h^m,\nabla(d_t\mathbf{d}_h^m)\big)+\frac{\lambda}{\varepsilon^2}\big(\mathbf{f}_h^m,d_t\mathbf{d}_h^m\big)_h=\langle\mathbf{g}(t_m,\cdot),\mathbf{u}_h^m\rangle.$$

The result of the lemma then follows after applying the summation operator $k\sum_{m=1}^{\ell}$ and using the relationships

$$\big(d_t\mathbf{u}_h^m,\mathbf{u}_h^m\big)=\frac{1}{2}\left\{d_t\|\,\mathbf{u}_h^m\,\|_{L^2}^2+k\,\|\,d_t\mathbf{u}_h^m\,\|_{L^2}^2\right\},$$

$$\big((\mathbf{u}_h^{m-1}\cdot\nabla)\mathbf{u}_h^m,\mathbf{u}_h^m\big)+\frac{1}{2}\big(\operatorname{div}\mathbf{u}_h^{m-1},|\mathbf{u}_h^m|^2\big)=0\,,$$

$$\big(\nabla d_t\mathbf{u}_h^m,\nabla\mathbf{u}_h^m\big)=\frac{1}{2}\left\{d_t\|\,\nabla\mathbf{u}_h^m\,\|_{L^2}^2+k\,\|\,\nabla d_t\mathbf{u}_h^m\,\|_{L^2}^2\right\},$$

$$\begin{aligned}\big(\mathbf{f}_h^m,d_t\mathbf{d}_h^m\big)_h&=\big((|\mathbf{d}_h^m|^2-1)\mathbf{d}_h^m+kd_t\mathbf{d}_h^m,d_t\mathbf{d}_h^m\big)_h\\&\geq\frac{1}{4}\big(d_t\big||\mathbf{d}_h^m|^2-1\big|^2,1\big)_h+\frac{k}{2}\big(|d_t\mathbf{d}_h^m|^2,1\big)_h\\&\geq\frac{1}{k}\big(F(\mathbf{d}_h^m)-F(\mathbf{d}_h^{m-1}),1\big)_h\,.\qquad\square\end{aligned}$$

Solvability of Algorithm 3.1 for every $m\geq 1$ now follows from the discrete energy law and an application of the Brouwer fixed point theorem (cf. Corollary 1.1 on p. 279 of [20]).

THEOREM 3.5. *For all $k,h,\varepsilon>0$, and $m\geq 1$, there exists a solution $(\mathbf{u}_h^m,\mathbf{d}_h^m,\tilde{p}_h^m,\mathbf{w}_h^m)$ to (3.1)–(3.4).*

Remark 3.1. Due to the lack of a discrete energy law in [31, 32, 15], existence for those schemes requires $k=\mathcal{O}(e^{-\frac{1}{\varepsilon^2}})$. In [31, 32, 15], the authors follow the strategy given in [26] to construct weak solutions to (1.6)–(1.8) as proper limits of existing Faedo–Galerkin solutions, where existence of local weak solutions was verified by the Schauder fixed point argument, which was then globally extended by a continuation argument using the basic energy law. However, in order to repeat the fixed point argument as used in section 2 of [26], it requires certain smallness of the time interval, which manifests to the above restrictive mesh constraint in the fully discrete case.

Lemma 3.4 now implies the following uniform (in ε) a priori estimates for $(\mathbf{u}_h^m,\mathbf{d}_h^m,\tilde{p}_h^m,\mathbf{w}_h^m)$.

LEMMA 3.6. *Let $\mathcal{T}_h$ be a quasi-uniform triangulation of $\Omega\subset\mathbb{R}^N$ for $N=2,3$, and let $T>0$. Suppose that $\big\{(\mathbf{u}_h^m,\mathbf{d}_h^m,\widetilde{p}_h^m,\mathbf{w}_h^m)\big\}_{m=1}^N$ solves (3.1)–(3.4), where $\mathbf{g}\in L^2\big(0,T;\mathbf{V}'\big)$ and $\mathcal{J}_{\varepsilon,\lambda,h}(\mathbf{u}_h^0,\mathbf{d}_h^0)\leq C$. Then the following estimate holds:*

$$k\sum_{m=1}^{M}\Big\{\|\,d_t\mathbf{u}_h^m\,\|_{(\mathbf{V}\cap W^{2,2})'}^{\frac{4}{3}}+\|\,d_t\mathbf{d}_h^m\,\|_{L^{\frac{3}{2}}}^2+\varepsilon^4\lambda\gamma\|\,\Delta_h\mathbf{d}_h^m\,\|_{L^2}^2\Big\}\leq C\,.$$

Proof. To bound the first term, choose $\mathbf{v}_h=Q_{\mathbf{V}_h}\mathbf{v}$ with any $\mathbf{v}\in\mathbf{V}\cap W^{2,2}(\Omega,\mathbb{R}^3)$ in (3.1) and use the approximation and stability properties of $Q_{\mathbf{V}_h}$ (cf. (2.8)–(2.10)) to conclude

$$
\begin{aligned}
(3.6)\quad (d_t\mathbf{u}_h^m,\mathbf{v}) &= -\nu\big(\nabla\mathbf{u}_h^m,\nabla Q_{\mathbf{V}_h}\mathbf{v}\big)-\big((\mathbf{u}_h^{m-1}\cdot\nabla)\mathbf{u}_h^m,Q_{\mathbf{V}_h}\mathbf{v}\big)+\langle\mathbf{g}(t_m,\cdot),Q_{\mathbf{V}_h}\mathbf{v}\rangle\\
&\quad-\frac{1}{2}\big((\operatorname{div}\mathbf{u}_h^{m-1})\,\mathbf{u}_h^m,Q_{\mathbf{V}_h}\mathbf{v}\big)+\lambda\big((\nabla\mathbf{d}_h^{m-1})^T\mathbf{w}_h^m,Q_{\mathbf{V}_h}\mathbf{v}\big)\\
&\le C\nu\|\nabla\mathbf{u}_h^m\|_{L^2}\|\nabla\mathbf{v}\|_{L^2}+C\|\mathbf{u}_h^{m-1}\|_{L^3}\|\nabla\mathbf{u}_h^m\|_{L^2}\|\nabla Q_{\mathbf{V}_h}\mathbf{v}\|_{L^2}\\
&\quad+C\|\nabla\mathbf{u}_h^{m-1}\|_{L^2}\|\mathbf{u}_h^m\|_{L^3}\|\nabla\mathbf{v}\|_{L^2}+\|\mathbf{g}(t_m,\cdot)\|_{\mathbf{V}'}\|\mathbf{v}\|_{W^{1,2}}\\
&\quad+\lambda\|\mathbf{w}_h^m\|_{L^2}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}\Big[\|Q_{\mathbf{V}_h}\mathbf{v}\|_{L^\infty}+\|\mathbf{v}-Q_{\mathbf{V}_h}\mathbf{v}\|_{L^\infty}\Big].
\end{aligned}
$$

For the last term above, we use standard interpolation estimates, an inverse estimate, and error bound (2.8).

$$
\begin{aligned}
\|\mathbf{v}-Q_{\mathbf{V}_h}\mathbf{v}\|_{L^\infty}&\le\|\mathbf{v}-\boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\mathbf{v}\|_{L^\infty}+\|Q_{\mathbf{V}_h}\mathbf{v}-\boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\mathbf{v}\|_{L^\infty}\\
&\le Ch^{2-\frac{N}{2}}\|\mathbf{v}\|_{W^{2,2}}+Ch^{-\frac{N}{2}}\|\boldsymbol{\mathcal{I}}_{\mathbf{X}_h}\mathbf{v}-Q_{\mathbf{V}_h}\mathbf{v}\|_{L^2}\\
&\le Ch^{2-\frac{N}{2}}\|\mathbf{v}\|_{W^{2,2}}+Ch^{-\frac{N}{2}}\|\mathbf{v}-Q_{\mathbf{V}_h}\mathbf{v}\|_{L^2}.
\end{aligned}
$$

Together with Sobolev's inequality, the right-hand side of (3.6) can be controlled by

$$
\begin{aligned}
&C\nu\|\nabla\mathbf{u}_h^m\|_{L^2}\|\nabla\mathbf{v}\|_{L^2}+C\|\mathbf{u}_h^m\|_{L^3}\|\mathbf{u}_h^{m-1}\|_{L^6}\|\mathbf{v}\|_{W^{1,2}}+\|\mathbf{g}(t_m,\cdot)\|_{\mathbf{V}'}\|\mathbf{v}\|_{W^{1,2}}\\
&\quad+C\lambda\|\mathbf{w}_h^m\|_{L^2}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}\big(\|\Delta\mathbf{v}\|_{L^2}+\|\nabla\mathbf{v}\|_{L^2}\big),
\end{aligned}
$$

which yields the first assertion, thanks to interpolation of L^3 between L^2 and $W^{1,2}$.

To bound the second term, notice that (3.2) can be rewritten as

$$
d_t\mathbf{d}_h^m=-\gamma\mathbf{w}_h^m-Q_{\mathbf{Y}_h}((\mathbf{u}_h^m\cdot\nabla)\mathbf{d}_h^{m-1})\quad\text{in }\mathbf{Y}_h.
$$

The L^2-stability of $Q_{\mathbf{Y}_h}$, Lemma 3.4, and the inequality

$$
\|(\mathbf{u}_h^m\cdot\nabla)\mathbf{d}_h^{m-1}\|_{L^{\frac{3}{2}}}\le\|\mathbf{u}_h^m\|_{L^6}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}
$$

then lead to the desired estimate.

The estimate for the last term follows from (3.4) with $\mathbf{a}_h=-\Delta_h\mathbf{d}_h^m$. We use (2.2) and L^p-stability of Lagrange interpolation, together with Sobolev's inequality, to conclude

$$
\begin{aligned}
\|\Delta_h\mathbf{d}_h^m\|_{L^2}^2&\le C\|\mathbf{w}_h^m\|_{L^2}^2+\frac{C}{\varepsilon^2}\|\mathbf{f}_h^m\|_h^2\\
&\le C\|\mathbf{w}_h^m\|_{L^2}^2+\frac{C}{\varepsilon^4}\|\nabla\mathbf{d}_h^m\|_{L^2}^6+\frac{C}{\varepsilon^4}\|\mathbf{d}_h^{m-1}\|_{L^2}^2. \qquad \square
\end{aligned}
$$

Let $\mathbf{U}_\varepsilon,\mathbf{D}_\varepsilon:\Omega_T\to\mathbb{R}^N$ and $P_\varepsilon:\Omega_T\to\mathbb{R}$ denote continuous, piecewise linear interpolations in time of the fully discrete solution $\{(\mathbf{u}_h^m,\mathbf{d}_h^m,p_h^m)\}_{m=1}^M$. See section 2.2 for the definition.

We are ready to state the main result of this section.

THEOREM 3.7. *Suppose that the assumptions of Lemma* 3.6 *hold, and* $\varepsilon>0$. *Then there exists a convergent (not relabeled) subsequence of* $\{(\mathbf{U}_\varepsilon,\mathbf{D}_\varepsilon,\mathbf{W}_\varepsilon^+)\}$ *and a triple* $(\mathbf{u}^\varepsilon,\mathbf{d}^\varepsilon,\mathbf{w}^\varepsilon)$ *such that*

(i) $\displaystyle\lim_{k,h\to0}\Big(\|\mathbf{U}_\varepsilon-\mathbf{u}^\varepsilon\|_{L^2(\Omega_T)}+\|\nabla(\mathbf{D}_\varepsilon-\mathbf{d}^\varepsilon)\|_{L^2(\Omega_T)}\Big)=0,$

(ii) $\mathbf{W}_\varepsilon\rightharpoonup\mathbf{w}^\varepsilon$ *in* $L^2(\Omega_T,\mathbb{R}^N)\qquad(k,h\to0).$

Moreover, $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ *is a weak solution of problem* (1.6)–(1.8)*, and* $\mathbf{w}^\varepsilon = -\Delta \mathbf{d}^\varepsilon + \varepsilon^{-2}\mathbf{f}(\mathbf{d}^\varepsilon)$ *holds in distributional sense.*

Proof. Step 1*: Extracting convergent subsequences.* Lemmas 3.4 and 3.6 imply the following estimates (uniform in k, h, and ε):

$$\| \mathbf{U}_\varepsilon^+ \|_{L^\infty(L^2)} + \sqrt{\lambda}\| \nabla \mathbf{D}_\varepsilon^+ \|_{L^\infty(L^2)} + \varepsilon^{-1}\sqrt{\lambda}\| \, | \mathbf{D}_\varepsilon^+ |^2 - 1 \|_{L^\infty(L^2)} \leq C \,, \tag{3.7}$$

$$\sqrt{\nu}\| \nabla \mathbf{U}_\varepsilon^+ \|_{L^2(\Omega_T)} + \sqrt{\lambda\gamma}\| \mathbf{W}_\varepsilon^+ \|_{L^2(\Omega_T)} \leq C \,, \tag{3.8}$$

$$\| \mathbf{U}_{\varepsilon,t} \|_{L^2((\mathbf{V}\cap W^{2,2})')} + \| \mathbf{D}_{\varepsilon,t} \|_{L^2(L^{\frac{3}{2}})} \leq C \,, \tag{3.9}$$

$$\varepsilon^2\sqrt{\lambda\gamma}\| \Delta_h \mathbf{D}_\varepsilon^+ \|_{L^2(L^2)} \leq C \,. \tag{3.10}$$

Then, on noting (3.3), there exist a convergent subsequence of $\{(\mathbf{U}_\varepsilon, \mathbf{D}_\varepsilon, \mathbf{W}_\varepsilon^+)\}$ (still denoted by the same notation) and functions $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon, \mathbf{w}^\varepsilon)$ such that

$$\mathbf{u}^\varepsilon \in L^\infty\big(0,T;\mathbf{H}\big) \cap L^2\big(0,T;\mathbf{V}\big) \cap W^{1,2}\big(0,T;[\mathbf{V}\cap W^{2,2}(\Omega,\mathbb{R}^N)]'\big) \,,$$

$$\mathbf{d}^\varepsilon \in L^\infty(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big) \cap L^4\big(0,T;W^{1,4}(\Omega,\mathbb{R}^N)\big) \cap W^{1,2}\big(0,T;L^{\frac{3}{2}}(\Omega,\mathbb{R}^N)\big) \,,$$

$$\mathbf{w}^\varepsilon \in L^2\big(\Omega_T,\mathbb{R}^N\big) \,,$$

and as $k, h \to 0$

$$\begin{aligned}
\mathbf{U}_\varepsilon, \mathbf{U}_\varepsilon^+ &\overset{*}{\rightharpoonup} \mathbf{u}^\varepsilon \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbb{R}^N)\big) \,,\\
\mathbf{U}_\varepsilon, \mathbf{U}_\varepsilon^+ &\rightharpoonup \mathbf{u}^\varepsilon \quad \text{in } L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)\\
\mathbf{U}_\varepsilon &\rightharpoonup \mathbf{U}_\varepsilon \quad \text{in } W^{1,\frac{4}{3}}\big(0,T;[\mathbf{V}\cap W^{2,2}(\Omega,\mathbb{R}^N)]'\big) \,,\\
\mathbf{U}_\varepsilon &\to \mathbf{u}^\varepsilon \quad \text{in } L^2\big(0,T;L^2(\Omega,\mathbb{R}^N)\big) \,,\\
\mathbf{D}_\varepsilon, \mathbf{D}_\varepsilon^+ &\overset{*}{\rightharpoonup} \mathbf{d}^\varepsilon \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big) \,,\\
\mathbf{D}_\varepsilon, \mathbf{D}_\varepsilon^+ &\rightharpoonup \mathbf{d}^\varepsilon \quad \text{in } L^4\big(0,T;W^{1,4}(\Omega,\mathbb{R}^N)\big)\\
\mathbf{D}_\varepsilon &\rightharpoonup \mathbf{d}^\varepsilon \quad \text{in } W^{1,2}\big(0,T;L^{\frac{3}{2}}(\Omega,\mathbb{R}^N)\big) \,,\\
\mathbf{D}_\varepsilon &\to \mathbf{d}^\varepsilon \quad \text{in } L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big) \,,\\
\mathbf{W}_\varepsilon, \mathbf{W}_\varepsilon^+ &\rightharpoonup \mathbf{w}^\varepsilon \quad \text{in } L^2\big(0,T;L^2(\Omega,\mathbb{R}^N)\big) \,.
\end{aligned} \tag{3.11}$$

Here, we have used the Aubin–Lions lemma to conclude $(3.11)_3$ from (3.3), and $(3.11)_8$ from (2.5) and Lemma 2.4.

From Lemma 3.4 we also have, as $k \to 0$,

$$\begin{aligned}
\| \mathbf{U}_\varepsilon - \mathbf{U}_\varepsilon^+ \|_{L^2(L^2)}^2 &= \sum_{m=1}^M \| \mathbf{u}_h^m - \mathbf{u}_h^{m-1} \|_{L^2}^2 \int_{t_{m-1}}^{t_m} \Big(\frac{s-t_m}{k}\Big)^2 \,\mathrm{d}s\\
&= \frac{k}{3}\sum_{m=1}^M \| \mathbf{u}_h^m - \mathbf{u}_h^{m-1} \|_{L^2}^2 \to 0 \,,
\end{aligned}$$

$$\| \nabla(\mathbf{D}_\varepsilon - \mathbf{D}_\varepsilon^+) \|_{L^2(L^2)}^2 = \frac{k}{3}\sum_{m=1}^M \| \nabla(\mathbf{d}_h^m - \mathbf{d}_h^{m-1}) \|_{L^2}^2 \to 0 \,.$$

Hence, the sequences $\{\mathbf{U}_\varepsilon\}$ and $\{\mathbf{U}_\varepsilon^+\}$ converge to the same limit as $k, h \to 0$, and so do the sequences $\{\mathbf{D}_\varepsilon\}$ and $\{\mathbf{D}_\varepsilon^+\}$. Similarly, we can show that $\{\mathbf{U}_\varepsilon\}$ and $\{\mathbf{U}_\varepsilon^-\}$ have the same limit, as do $\{\mathbf{D}_\varepsilon\}$ and $\{\mathbf{D}_\varepsilon^-\}$.

Step 2*: Passing to the limit.* We now pass to the limit in (3.1)–(3.4) and show that $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ is a weak solution to problem (1.6)–(1.8) with the initial values $\mathbf{u}^\varepsilon(0,\cdot) = \mathbf{u}_0^\varepsilon$ and $\mathbf{d}^\varepsilon(0,\cdot) = \mathbf{d}_0^\varepsilon$. To the end, we rewrite (3.1)–(3.4) as follows: For every $t > 0$, find $\big(\mathbf{U}_\varepsilon(t,\cdot), \mathbf{D}_\varepsilon(t,\cdot)\big) \in \mathbf{V}_h \times \mathbf{Y}_h$, such that for every $(\mathbf{v}_h, \mathbf{a}_h, q_h) \in \mathbf{V}_h \times \mathbf{Y}_h \times M_h$

$$
\begin{aligned}
&(\mathbf{U}_{\varepsilon,t}, \mathbf{v}_h) + \nu\big(\nabla \mathbf{U}_\varepsilon^+, \nabla \mathbf{v}_h\big) + \big((\mathbf{U}_\varepsilon^- \cdot \nabla)\mathbf{U}_\varepsilon^+, \mathbf{v}_h\big) \\
&\qquad + \frac{1}{2}\big((\operatorname{div} \mathbf{U}_\varepsilon^-)\,\mathbf{U}_\varepsilon^+, \mathbf{v}_h\big) + \lambda\big((\nabla \mathbf{D}_\varepsilon^-)^T \mathbf{W}_\varepsilon^+, \mathbf{v}_h\big) = \langle \mathbf{g}^+, \mathbf{v}_h\rangle\,, \\
&(\mathbf{D}_{\varepsilon,t}, \mathbf{a}_h) + \big((\mathbf{U}_\varepsilon^+ \cdot \nabla)\mathbf{D}_\varepsilon^-, \mathbf{a}_h\big) + \gamma\,\big(\mathbf{W}_\varepsilon^+, \mathbf{a}_h\big) = 0\,, \\
&(\nabla \mathbf{D}_\varepsilon^+, \nabla \mathbf{a}_h) + \frac{1}{\varepsilon^2}\big(\,\overline{\mathbf{f}}_\varepsilon, \mathbf{a}_h\,\big)_h + \big(\mathbf{W}_\varepsilon^+, \mathbf{a}_h\big) = 0\,, \\
&(\operatorname{div} \mathbf{U}_\varepsilon^+, q_h) = 0\,.
\end{aligned}
$$

For any $(\mathbf{v}, \mathbf{a}) \in \boldsymbol{\mathcal{V}} \times C^\infty(\Omega, \mathbb{R}^N)$, let $(\mathbf{v}_h, \mathbf{a}_h) \equiv (Q_{\mathbf{V}_h}\mathbf{v}, R_{\mathbf{Y}_h}\mathbf{a}) \in \mathbf{V}_h \times \mathbf{Y}_h$, which satisfy $(\mathbf{v}_h, \mathbf{a}_h) \to (\mathbf{v}, \mathbf{a})$ in $\big[W^{1,p}(\Omega, \mathbb{R}^N)\big]^2$ $(h \to 0)$ for all $1 \le p \le \frac{2N}{N-2}$ (cf. (2.8)). For $k, h \to 0$, we use (3.11) to obtain

$$
\langle \mathbf{u}_t^\varepsilon, \mathbf{v}\rangle + \nu\big(\nabla \mathbf{u}^\varepsilon, \nabla \mathbf{v}\big) + \big((\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{u}^\varepsilon, \mathbf{v}\big) + \lambda\big((\nabla \mathbf{d}^\varepsilon)^T \mathbf{w}^\varepsilon, \mathbf{v}\big) = \langle \mathbf{g}, \mathbf{v}\rangle\,, \tag{3.12}
$$

$$
\big(\mathbf{d}_t^\varepsilon, \mathbf{a}\big) + \big((\mathbf{u}^\varepsilon \cdot \nabla)\mathbf{d}^\varepsilon, \mathbf{a}\big) - \gamma\,\big(\mathbf{w}^\varepsilon, \mathbf{a}\big) = 0\,, \tag{3.13}
$$

$$
\big(\operatorname{div} \mathbf{u}^\varepsilon, q\big) = 0, \tag{3.14}
$$

$$
\big(\nabla \mathbf{d}^\varepsilon, \nabla \mathbf{a}\big) + \frac{1}{\varepsilon^2}\big(\mathbf{f}(\mathbf{d}^\varepsilon), \mathbf{a}\big) + \big(\mathbf{w}^\varepsilon, \mathbf{a}\big) = 0\,, \tag{3.15}
$$

and $\mathbf{u}^\varepsilon(0,\cdot) = \mathbf{u}_0^\varepsilon$, $\mathbf{d}^\varepsilon(0,\cdot) = \mathbf{d}_0^\varepsilon$. Here, we have used $\big(\operatorname{div} \mathbf{u}^\varepsilon, \langle \mathbf{u}^\varepsilon, \mathbf{v}\rangle\big) = 0$, which is a consequence of $\mathbf{u}^\varepsilon(t,\cdot) \in \mathbf{V}$ for almost every $t > 0$.

Equation (3.15) immediately implies that $\mathbf{w}^\varepsilon = -\Delta \mathbf{d}^\varepsilon + \frac{1}{\varepsilon^2}\mathbf{f}(\mathbf{d}^\varepsilon)$ in Ω_T, and $\partial_{\mathbf{n}} \mathbf{d}^\varepsilon = 0$ on $\partial\Omega_T$ in the sense of distribution. Hence, $(\mathbf{u}^\varepsilon, \mathbf{d}^\varepsilon)$ is a weak solution of (1.4)–(1.8). □

Remark 3.2. (a) In the case of unique weak solutions (valid for $N = 2$), the proof also verifies that the limit of *every* convergent subsequence of $\{(\mathbf{U}_\varepsilon, \mathbf{D}_\varepsilon, \mathbf{W}_\varepsilon)\}$ must be a weak solution of (1.6)–(1.8). Hence, the whole sequence $\{(\mathbf{U}_\varepsilon, \mathbf{D}_\varepsilon)\}$ converges to the unique weak solution $(\mathbf{u}_*^\varepsilon, \mathbf{d}_*^\varepsilon)$.

(b) The proof does not provide information about convergence of the pressure $\widetilde{P}_\varepsilon$ as $(k, h) \mapsto 0$, which is in accordance with the general theory for incompressible Navier–Stokes equations (cf. p. 83 of [30]). However, its convergence in L^2 could be proved under additional regularity assumptions on the weak solution $(\mathbf{u}_*^\varepsilon, \mathbf{d}_*^\varepsilon)$.

An immediate consequence of Theorem 3.7 and the convergence result of [28] is the following convergence theorem.

THEOREM 3.8. *Under the assumptions of Theorem* 3.7, *there exist a subsequence of* $\{(\mathbf{U}_\varepsilon, \mathbf{D}_\varepsilon)\}$ *and a triple* $(\mathbf{u}_*, \mathbf{d}_*, \nu_*) \in \big[L^\infty\big(0,T;L^2(\Omega,\mathbb{R}^N)\big) \cap L^2(0,T;\mathbf{V})\big] \times \big[L^\infty\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big) \cap L^2\big(0,T;W^{2,2}(\Omega,\mathbb{R}^N)\big)\big]$ *such that*

$$\lim_{\varepsilon\to 0} \lim_{k,h\to 0} \Big(\| \mathbf{U}_\varepsilon - \mathbf{u}_* \|_{L^2(L^2)} + \| \mathbf{D}_\varepsilon - \mathbf{d}_* \|_{L^2(L^2)} \Big) = 0\,, \tag{3.16}$$

$$\delta_{\nabla \mathbf{D}_\varepsilon} \overset{*}{\rightharpoonup} \nu_* \quad \text{in } L^\infty_w\big(\Omega_T, \mathcal{M}(\mathbb{R}^{N\times N})\big) \quad (\text{first } k,h\to 0, \text{ then } \varepsilon \to 0)\,, \tag{3.17}$$

where $(\mathbf{u}_*, \mathbf{d}_*, \nu_*)$ *is a generalized solution to* (1.1)–(1.5).

The polynomial bound with respect to ε^{-1} in (3.10) suggests that a polynomial scaling law $F(\varepsilon,k,h) \geq 0$ would be sufficient to ensure convergence of the numerical solutions to weak solutions of (1.4)–(1.8) and to generalized solutions of (1.1)–(1.5). This observation is in contrast to convergence results for the schemes proposed in [31, 32, 15], where optimal rates of convergence involve constants that grow exponentially with respect to ε^{-1} (cf. Lemma 3.3 for a priori estimates of strong solutions). We shall investigate this issue further in section 5 and now turn to studying a fully discrete scheme which approximates the original problem (1.1)–(1.5) directly.

4. A fully discrete scheme for (1.1)–(1.5): Conditional solvability and discrete energy law. In this section, we propose and analyze a fully discrete scheme for (1.1)–(1.5) which uses a stable tuple $(\mathbf{X}_h, M_h)$ of finite element spaces for velocity and pressure fields. It also crucially utilizes the discrete Laplacian $\Delta_h : W^{1,2}(\Omega,\mathbb{R}^N) \to \mathbf{Y}_h$ and the midpoint rule for temporal discretization.

ALGORITHM 4.1.

(1) *Let* $\mathbf{u}_h^0 = Q_{\mathbf{V}_h}\mathbf{u}^0$ *and* $\mathbf{d}_h^0 = \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\mathbf{d}^0$.

(2) *Let* $m = 1,\ldots,M$. *Find* $(\mathbf{u}_h^m, \mathbf{d}_h^m) \in \mathbf{X}_h \times \mathbf{Y}_h$ *such that for all* $(\mathbf{v}_h, \mathbf{a}_h, q_h) \in \mathbf{X}_h \times \mathbf{Y}_h \times M_h$ *there holds*

$$\begin{aligned}(d_t\mathbf{u}_h^m, \mathbf{v}_h) + \nu(\nabla\mathbf{u}_h^m, \nabla\mathbf{v}_h) + \big((\mathbf{u}_h^{m-1}\cdot\nabla)\mathbf{u}_h^m, \mathbf{v}_h\big) + \frac{1}{2}\big((\operatorname{div}\mathbf{u}_h^{m-1})\mathbf{u}_h^m, \mathbf{v}_h\big) \\ - (\hat{p}_h^m, \operatorname{div}\mathbf{v}_h) - \lambda\big((\nabla\mathbf{d}_h^{m-1})^T\Delta_h\mathbf{d}^{m-1/2}, \mathbf{v}_h\big) = \big\langle \mathbf{g}(t_m,\cdot), \mathbf{v}_h\big\rangle\,,\end{aligned} \tag{4.1}$$

$$\begin{aligned}(d_t\mathbf{d}_h^m, \mathbf{a}_h) + \big((\mathbf{u}_h^m\cdot\nabla)\mathbf{d}_h^{m-1}, \mathbf{a}_h\big) \\ + \gamma\big(\mathbf{d}_h^{m-1/2}\times(\mathbf{d}_h^{m-1/2}\times\Delta_h\mathbf{d}_h^{m-1/2}), \mathbf{a}_h\big) = 0\,,\end{aligned} \tag{4.2}$$

$$(\operatorname{div}\mathbf{u}_h^m, q_h) = 0\,. \tag{4.3}$$

Note that an implicit treatment of coupling terms is used in (4.1)–(4.2), in contrast to the semi-implicit discretization in Algorithm 3.1. The following lemma verifies a discrete energy law for solutions of Algorithm 4.1.

LEMMA 4.1. *Let* $(\mathbf{u}_h^0, \mathbf{d}_h^0) \in \mathbf{X}_h \times \mathbf{Y}_h$, *such that* $\mathcal{J}(\mathbf{u}_h^0, \mathbf{d}_h^0) \leq C$. *Then for all* $1 \leq \ell \leq M$,

$$\begin{aligned}\mathcal{J}(\mathbf{u}_h^\ell, \mathbf{d}_h^\ell) + k\sum_{m=1}^{\ell}\Big[\frac{k}{2}\|\,d_t\mathbf{u}_h^m\,\|_{L^2}^2 + \nu\,\|\,\nabla\mathbf{u}_h^m\,\|_{L^2}^2 + \|\,\mathbf{d}_h^{m-1/2}\times\Delta_h\mathbf{d}_h^{m-1/2}\,\|_{L^2}^2\Big] \\ = k\sum_{m=1}^{\ell}\langle\mathbf{g}^m, \mathbf{u}_h^m\rangle + \mathcal{J}(\mathbf{u}_h^0, \mathbf{d}_h^0)\,.\end{aligned}$$

Proof. Setting $(\mathbf{v}_h, \mathbf{a}_h, \chi_h) = (\mathbf{u}_h^m, -\lambda\Delta_h \mathbf{d}_h^{m-1/2}, \hat{p}_h^m)$ in (4.1)–(4.3) and adding the resulting equations yield

$$\frac{1}{2} d_t \big[\| \mathbf{u}_h^m \|_{L^2}^2 + \lambda \| \nabla \mathbf{d}_h^m \|_{L^2}^2 \big] + \frac{k}{2} \| d_t \mathbf{u}_h^m \|_{L^2}^2 + \nu \| \nabla \mathbf{u}_h^m \|_{L^2}^2$$

$$+ \lambda\gamma \| \mathbf{d}_h^{m-1/2} \times \Delta_h \mathbf{d}^{m-1/2} \|_{L^2}^2 + \Big[\big((\mathbf{u}_h^{m-1} \cdot \nabla) \mathbf{u}_h^m, \mathbf{u}_h^m \big) + \frac{1}{2} \big((\operatorname{div} \mathbf{u}_h^{m-1}, | \mathbf{u}_h^m |^2 \big) \Big]$$

$$+ \lambda \Big[\big((\nabla \mathbf{d}_h^{m-1})^T \Delta_h \mathbf{d}_h^{m-1/2}, \mathbf{u}_h^m \big) + \big((\mathbf{u}_h^m \cdot \nabla) \mathbf{d}_h^{m-1}, -\Delta_h \mathbf{d}^{m-1/2} \big) \big) \Big] = \langle \mathbf{g}^m, \mathbf{u}_h^m \rangle .$$

Since the two pairs of terms in the brackets on the left-hand side of the equation vanish, hence, the assertion follows by applying the summation operator $k \sum_{m=1}^{\ell}$. ∎

We now verify existence of sequences $\big\{ (\mathbf{u}_h^m, \mathbf{d}_h^m) \big\}_{m=1}^M \subset \mathbf{X}_h \times \mathbf{Y}_h$ in the case of restricted mesh parameters. For each $m \geq 0$, consider the continuous mapping $\boldsymbol{\mathcal{F}} : \mathbf{V}_h \times \mathbf{Y}_h \to \mathbf{V}_h \times \mathbf{Y}_h$ defined as follows: Given $(\mathbf{u}_h^{m-1}, \mathbf{d}_h^{m-1}) \in \mathbf{V}_h \times \mathbf{Y}_h$, find $(\mathbf{U}, \mathbf{D}) \in \mathbf{V}_h \times \mathbf{Y}_h$ such that

$$\big(\boldsymbol{\mathcal{F}}[\mathbf{U}, \mathbf{D}], [\mathbf{v}_h, \mathbf{a}_h] \big) := \big((\boldsymbol{\mathcal{F}}_1[\mathbf{U}, \mathbf{D}], \mathbf{v}_h), (\boldsymbol{\mathcal{F}}_2[\mathbf{U}, \mathbf{D}], \mathbf{a}_h) \big) = \mathbf{0} \tag{4.4}$$

for any $(\mathbf{v}_h, \mathbf{a}_h) \in \mathbf{V}_h \times \mathbf{Y}_h$. Where

$$\big(\boldsymbol{\mathcal{F}}_1[\mathbf{U}, \mathbf{D}], \mathbf{v}_h \big) := \frac{1}{k} \big(\mathbf{U} - \mathbf{u}_h^{m-1}, \mathbf{v}_h \big) + \nu (\nabla \mathbf{U}, \nabla \mathbf{v}_h) + \big((\mathbf{u}_h^{m-1} \cdot \nabla) \mathbf{U}, \mathbf{v}_h \big)$$

$$+ \frac{1}{2} \big((\operatorname{div} \mathbf{u}_h^{m-1}) \mathbf{U}, \mathbf{v}_h \big) - \lambda \big((\nabla \mathbf{d}_h^{m-1})^T \Delta_h \mathbf{D}, \mathbf{v}_h \big) - \langle \mathbf{g}(t_m, \cdot), \mathbf{v}_h \rangle ,$$

$$\big(\boldsymbol{\mathcal{F}}_2[\mathbf{U}, \mathbf{D}], \mathbf{a}_h \big) := \frac{2}{k} \big(\mathbf{D} - \mathbf{d}_h^{m-1}, \mathbf{a}_h \big) + \big((\mathbf{U} \cdot \nabla) \mathbf{d}_h^{m-1}, \mathbf{a}_h \big) + \gamma \big(\mathbf{D} \times (\mathbf{D} \times \Delta_h \mathbf{D}), \mathbf{a}_h \big) .$$

Suppose $\mathcal{T}_h$ is a quasi-uniform triangulation of a bounded polyhedral domain $\Omega \subset \mathbb{R}^N$ for $N = 2, 3$. In what follows, consider tuple $\big(\mathbf{U}, \mathbf{D} \big) \in \mathbf{V}_h \times \mathbf{Y}_h$ which satisfies for existing nonnegative constants $\overline{C} \equiv \overline{C} \big(\| \mathbf{u}_h^{m-1} \|_{L^2}, \| \mathbf{d}_h^{m-1} \|_{W^{1,2}}, \| \mathbf{g}(t_m, \cdot) \|_{\mathbf{V}'} \big)$ and $\hat{C}$

$$\min \big\{ \| \mathbf{U} \|_{L^2}, \| \mathbf{D} \|_{L^2} \big\} \geq \overline{C} \quad \text{and} \quad k \leq \hat{C} h^{2 + \frac{N}{2}} .$$

First, on noting $\langle \mathbf{g}(t_m, \cdot), \mathbf{U} \rangle \leq \| \mathbf{U} \|_{W^{1,2}} \| \mathbf{g}(t_m, \cdot) \|_{W^{-1,2}}$, and by the inverse inequality, we observe that for some $\tilde{C} = \tilde{C}(\Omega) > 0$

$$\begin{aligned} \big| \big((\nabla \mathbf{d}_h^{m-1})^T \Delta_h \mathbf{D}, \mathbf{U} \big) \big| &\leq \| \nabla \mathbf{d}^{m-1} \|_{L^2} \| \Delta_h \mathbf{D} \|_{L^2} \| \mathbf{U} \|_{L^\infty} \\ &\leq \tilde{C} h^{-(2 + \frac{N}{2})} \| \nabla \mathbf{d}^{m-1} \|_{L^2} \| \mathbf{D} \|_{L^2} \| \mathbf{U} \|_{L^2} , \\ \big| \big((\mathbf{U} \cdot \nabla) \mathbf{d}_h^{m-1}, \mathbf{D} \big) \big| &\leq \| \mathbf{U} \|_{L^\infty} \| \nabla \mathbf{d}_h^{m-1} \|_{L^2} \| \mathbf{D} \|_{L^2} \\ &\leq \tilde{C} h^{-\frac{N}{2}} \| \mathbf{U} \|_{L^2} \| \nabla \mathbf{d}_h^{m-1} \|_{L^2} \| \mathbf{D} \|_{L^2} . \end{aligned}$$

By Lemma 4.1 we conclude that for $k = \mathcal{O}(h^{2+\frac{N}{2}})$ the following holds:

$$\begin{aligned}
\big(\boldsymbol{\mathcal{F}}[\mathbf{U},\mathbf{D}],[\mathbf{U},\mathbf{D}]\big) &= \frac{1}{k}\Big[\|\mathbf{U}\|_{L^2}^2 - (\mathbf{u}_h^{m-1},\mathbf{U}) + 2\|\mathbf{D}\|_{L^2}^2 - 2(\mathbf{d}_h^{m-1},\mathbf{D})\Big] \\
&\quad + \nu\|\nabla\mathbf{U}\|_{L^2}^2 - \lambda\big((\nabla\mathbf{d}_h^{m-1})^T\Delta_h\mathbf{D},\mathbf{U}\big) - \langle\mathbf{g}(t_m,\cdot),\mathbf{U}\rangle \\
&\quad + \big((\mathbf{U}\cdot\nabla)\mathbf{d}_h^{m-1},\mathbf{D}\big) \\
&\geq \frac{1}{k}\Big[\|\mathbf{U}\|_{L^2}\Big(\Big[1-\frac{\tilde{C}k}{h^{2+\frac{N}{2}}}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}\Big]\|\mathbf{U}\|_{L^2} - \|\mathbf{u}_h^{m-1}\|_{L^2}\Big) \\
&\quad + 2\|\mathbf{D}\|_{L^2}\Big(\Big[1-\frac{\tilde{C}k}{h^{2+\frac{N}{2}}}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}\Big]\|\mathbf{D}\|_{L^2} - \|\mathbf{d}_h^{m-1}\|_{L^2}\Big)\Big] \\
&\quad + \frac{\nu}{2}\|\nabla\mathbf{U}\|_{L^2}^2 - \frac{2}{\nu}\|\mathbf{g}(t_m,\cdot)\|_{\mathbf{V}'}^2 \geq 0\,.
\end{aligned}$$

Brouwer's fixed point theorem then implies the existence of $(\mathbf{U}^*,\mathbf{D}^*) \in \mathbf{V}_h \times \mathbf{Y}_h$, which solves (4.4) (cf. Corollary 1.1 on p. 279 of [20]), and $(\mathbf{u}_h^m,\mathbf{d}_h^m) := (\mathbf{U}^*, 2\mathbf{D}^* - \mathbf{d}_h^{m-1}) \in \mathbf{V}_h \times \mathbf{Y}_h$ is a solution to Algorithm 4.1. Hence, we have shown the following result.

THEOREM 4.2. *Let $\mathcal{T}_h$ be a quasi-uniform triangulation of a bounded polyhedral domain $\Omega \subset \mathbb{R}^N$ for $N = 2, 3$. There exists $\hat{C} > 0$ such that for all $k \leq \hat{C}h^{2+\frac{N}{2}}$ there exists a solution $(\mathbf{u}_h^m, \mathbf{d}_h^m, \hat{p}_h^m)$ to (4.1)–(4.3).*

The following result provides an estimate for the first order discrete time derivative of $\{\mathbf{d}_h^m\}$.

LEMMA 4.3. *Suppose $(\mathbf{u}_h^0,\mathbf{d}_h^0) \in \mathbf{V}_h \times \mathbf{Y}_h$ and $\mathcal{J}(\mathbf{u}_h^0,\mathbf{d}_h^0) \leq C$. There holds*

$$k\sum_{m=1}^{M}\|d_t\mathbf{d}_h^m\|_{L^p}^2 \leq C \quad \Big(1 \leq p < \frac{N}{N-1}\Big)\,.$$

In the following, we use the L^2-projection $Q_{\mathbf{Y}_h} : L^2(\Omega,\mathbb{R}^N) \to \mathbf{Y}_h$, where for any $\mathbf{b} \in L^2(\Omega,\mathbb{R}^N)$ there holds $(Q_{\mathbf{Y}_h}\mathbf{b} - \mathbf{b}, \mathbf{a}_h) = 0$ for every $\mathbf{a}_h \in \mathbf{Y}_h$.

Proof. We use the L^2-projection $Q_{\mathbf{Y}_h}$ to write $\|d_t\mathbf{d}_h^m\|_{L^p} = \sup_{\boldsymbol{\xi}\in L^{p'}} \frac{(d_t\mathbf{d}_h^m, Q_{\mathbf{Y}_h}\boldsymbol{\xi})}{\|\boldsymbol{\xi}\|_{L^{p'}}}$. On using (4.2), with $\mathbf{a}_h := Q_{\mathbf{Y}_h}\boldsymbol{\xi}$, we find upper bounds ($r > 2$)

$$\begin{aligned}
&\big|\big(\mathbf{d}_h^{m-1/2}\times(\mathbf{d}_h^{m-1/2}\times\Delta_h\mathbf{d}_h^{m-1/2}),\mathbf{a}_h\big)\big| \\
&\qquad\qquad \leq \|\mathbf{d}_h^{m-1/2}\|_{L^r}\|\mathbf{d}_h^{m-1/2}\times\Delta_h\mathbf{d}_h^{m-1/2}\|_{L^2}\|\mathbf{a}_h\|_{L^{\frac{2r}{r-2}}}\,, \\
&\big|\big((\mathbf{u}_h^m\cdot\nabla)\mathbf{d}_h^{m-1},\mathbf{a}_h\big)\big| \leq \|\mathbf{u}_h^m\|_{L^r}\|\nabla\mathbf{d}_h^{m-1}\|_{L^2}\|\mathbf{a}_h\|_{L^{\frac{2r}{r-2}}}\,.
\end{aligned}$$

Then we employ L^q-stability of $Q_{\mathbf{Y}_h}$ (cf. [13]) and Lemma 4.1, which verifies that sequences $\{\mathbf{d}_h^{m-1/2}\} \in \ell^\infty\big(\{t_\ell\}_{\ell=1}^M; L^r(\Omega,\mathbb{R}^N)\big)$ and $\{\mathbf{u}_h^m\} \in \ell^2\big(\{t_\ell\}_{\ell=1}^M; L^r(\Omega,\mathbb{R}^N)\big)$ are bounded uniformly in k,h for all $r < \frac{2N}{N-2}$, which gives the assertion. ∎

Using the notation of section 2.3, by Lemma 4.1, Theorem 4.2, and Lemma 4.3 there exist a convergent subsequence of $\{(\mathbf{U},\mathbf{D})\}$ and a tuple $(\mathbf{u},\mathbf{d})$ such that

$$\begin{aligned}
&\mathbf{u} \in L^\infty(0,T;\mathbf{H}) \cap L^2(0,T;\mathbf{V}), \\
&\mathbf{d} \in L^\infty\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big) \cap W^{1,2}\big(0,T;L^p(\Omega,\mathbb{R}^N)\big)\,,
\end{aligned}$$

and for $k,h \to 0$ and $1 \leq p < \frac{N}{N-1}$

$$\mathbf{U}, \mathbf{U}^+ \overset{*}{\rightharpoonup} \mathbf{u} \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbb{R}^N)\big)\,, \tag{4.5}$$

$$\rightharpoonup \mathbf{u} \quad \text{in } L^2\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)\,,$$

$$\mathbf{D}, \mathbf{D}^+ \overset{*}{\rightharpoonup} \mathbf{d} \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbb{R}^N)\big)\,, \tag{4.6}$$

$$\mathbf{D} \rightharpoonup \mathbf{d} \in W^{1,2}\big(0,T;L^p(\Omega,\mathbb{R}^N)\big)\,,$$

$$\to \mathbf{d} \in L^p\big(0,T;L^2(\Omega,\mathbb{R}^N)\big) \qquad (1 \le p < \infty)\,.$$

Note that due to the viscous stress term no estimate for $\mathbf{u}_t$ is obtained. Moreover, by the weak lower semicontinuity property of norms there holds for almost all $t \in (0,T)$

$$\mathcal{J}\big(\mathbf{u}(t,\cdot),\mathbf{d}(t,\cdot)\big) + \nu \int_0^t \|\nabla \mathbf{u}(s,\cdot)\|_{L^2}^2 \,\mathrm{d}s \le \mathcal{J}\big(\mathbf{u}_0,\mathbf{d}_0\big) + \int_0^t \langle \mathbf{g}(s,\cdot), \mathbf{u}(s,\cdot)\rangle \,\mathrm{d}s\,. \tag{4.7}$$

The next result establishes $|\mathbf{d}| = 1$ a.e. in Ω_T for $N = 2$.

THEOREM 4.4. *Let $T > 0$, $\Omega \subset \mathbb{R}^2$ be a bounded polygonal domain, and let $\mathcal{T}_h$ be a quasi-uniform triangulation of Ω. Suppose $(\mathbf{u}_h^0, \mathbf{d}_h^0) \in \mathbf{V}_h \times \mathbf{Y}_h$ satisfies $\mathcal{J}(\mathbf{u}_h^0, \mathbf{d}_h^0) \le C$ and $|\mathbf{d}_h^0(\mathbf{z})| = 1$ for all $\mathbf{z} \in \mathcal{N}_h$. Assume $k \le \hat{C}h^3$. Then the above limiting director field $\mathbf{d}$ satisfies $|\mathbf{d}| = 1$ a.e. in Ω_T.*

Proof. Choose $\mathbf{a}_h = \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\big[\frac{1}{2}\big(|\,\mathbf{d}_h^m\,|^2 + |\,\mathbf{d}_h^{m-1}\,|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big]$ in (4.2). Rewrite

$$\frac{1}{2}\Big(d_t\mathbf{d}_h^m, \big[\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} \pm \mathbf{Id}\big]\big[\big(|\,\mathbf{d}_h^m\,|^2 + |\,\mathbf{d}_h^{m-1}\,|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big]\Big) = A_1 + A_2\,, \tag{4.8}$$

where

$$A_1 = \frac{1}{4}\Big(d_t\big[|\,\mathbf{d}_h^m\,|^2 - 1\big], |\,\mathbf{d}_h^m\,|^2 + |\,\mathbf{d}_h^{m-1}\,|^2 - 2\Big) = \frac{1}{4}d_t\|\,|\,\mathbf{d}_h^m\,|^2 - 1\,\|_{L^2}^2\,,$$

$$\begin{aligned}
|\,A_2\,| &\le \|\,d_t\mathbf{d}_h^m\,\|_{L^p}\|\,\big[\mathbf{Id} - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\big]\big[\big(|\,\mathbf{d}_h^m\,|^2 + |\,\mathbf{d}_h^{m-1}\,|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big]\,\|_{L^{p'}} \\
&\le Ch\,\|\,d_t\mathbf{d}_h^m\,\|_{L^p} \max_{\eta_i \in \{0,\frac{1}{2},1\}} \Big[\int_\Omega |\,\mathbf{d}_h^{m-\eta_1}\,|^{2p'}\,|\,\nabla \mathbf{d}_h^{m-\eta_2}\,|^{p'}\,\mathrm{d}\mathbf{x}\Big]^{1/p'} \\
&\le Ch\,\|\,d_t\mathbf{d}_h^m\,\|_{L^p} \max_{\eta_i \in \{0,\frac{1}{2},1\}} \big\{\|\,\mathbf{d}_h^{m-\eta_1}\,\|_{L^\infty}^2\,\|\,\nabla \mathbf{d}_h^{m-\eta_2}\,\|_{L^{p'}}\big\}
\end{aligned}$$

for $1 \le p < \infty$. When $N = 2$, it follows from Sobolev's inequality, the inverse inequality, and Lemma 4.1 that

$$k\sum_{m=1}^{M} |\,A_2\,| = o(1) \qquad \text{as } h \to 0.$$

The second term in (4.2) can be bounded as follows:

$$\frac{1}{2}\Big((\mathbf{u}_h^m \cdot \nabla)\mathbf{d}_h^{m-1}, \big[\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} \pm \mathbf{Id}\big]\big[\big(|\,\mathbf{d}_h^m\,|^2 + |\,\mathbf{d}_h^{m-1}\,|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big]\Big) = B_1 + B_2\,, \tag{4.9}$$

where

(4.10)

$$
\begin{aligned}
&k\sum_{m=1}^{M} |\, B_2 \,| \\
&\quad \le k\sum_{m\ge 1}^{M} \| \mathbf{u}_h^m \|_{L^\infty} \| \nabla \mathbf{d}_h^{m-1} \|_{L^2} \| \big[\mathbf{Id} - \boldsymbol{\mathcal{I}}_{\mathbf{Y}_h}\big]\big[\big(|\, \mathbf{d}_h^m \,|^2 + |\, \mathbf{d}_h^{m-1} \,|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big] \|_{L^2} \\
&\quad \le Ch \max_{\eta_i\in\{0,\frac12,1\}} \left[k\sum_{m=1}^{M} \| \mathbf{u}_h^m \|_{L^\infty} \| \mathbf{d}_h^{m-\eta_1} \|_{L^\infty}^2 \| \nabla \mathbf{d}_h^{m-\eta_2} \|_{L^2}^2 \right] \to 0
\end{aligned}
$$

as $h \to 0$. In order to bound $B_1 = \overline{B}_1 + \tilde{B}_1$, we substitute $\mathbf{d}_h^{m-1}$ by $\mathbf{d}_h^{m-1/2} - \frac{k}{2} d_t \mathbf{d}_h^m$ in the first argument in (4.9) and use the inverse inequality and Lemmas 4.1 and 4.3 to get

$$
\overline{B}_1 := k \Big| \Big((\mathbf{u}_h^m \cdot \nabla) d_t \mathbf{d}_h^m, \big(|\, \mathbf{d}_h^m \,|^2 + |\, \mathbf{d}_h^{m-1} \,|^2 - 2\big)\mathbf{d}_h^{m-1/2} \Big) \Big| \to 0
$$

for admissible $k \le \hat{C} h^3$ as $k, h \to 0$. To estimate $\tilde{B}_1$, we first employ the parallelogram identity to rewrite

$$
\begin{aligned}
\tilde{B}_1 &\equiv \frac12 \Big((\mathbf{u}_h^m \cdot \nabla)\mathbf{d}_h^{m-1/2}, \big(|\, \mathbf{d}_h^m \,|^2 + |\, \mathbf{d}_h^{m-1} \,|^2 - 2\big)\mathbf{d}_h^{m-1/2} \Big) \\
&= \frac12 \Big((\mathbf{u}_h^m \cdot \nabla)\big[|\, \mathbf{d}_h^{m-1/2} \,|^2 - 1\big], 2\big[|\, \mathbf{d}_h^{m-1/2} \,|^2 - 1\big] + \frac{k^2}{2} |\, d_t \mathbf{d}_h^m \,|^2 \Big) \\
&= -\Big(\operatorname{div} \mathbf{u}_h^m, \big[|\, \mathbf{d}_h^{m-1/2} \,|^2 - 1\big]^2 \Big) + \frac{k^2}{4} \Big((\mathbf{u}_h^m \cdot \nabla)\big[|\, \mathbf{d}_h^{m-1/2} \,|^2 - 1\big], |\, d_t \mathbf{d}_h^m \,|^2 \Big) \\
&\equiv B_{11} + B_{12} \,.
\end{aligned}
$$

We now use (4.3) to bound B_{11} by

$$
\begin{aligned}
&\Big| \Big(\operatorname{div} \mathbf{u}_h^m, \big[|\mathbf{d}^{m-1/2}|^2 - 1\big]^2 \Big) - P_{M_h}\big[|\mathbf{d}^{m-1/2}|^2 - 1\big]^2 \Big) \Big| \\
&\qquad\qquad \le Ch \, \|\operatorname{div} \mathbf{u}_h^m\|_{L^2} \|\mathbf{d}^{m-1/2}\|_{L^\infty}^2 \|\nabla \mathbf{d}_h^{m-1/2}\|_{L^2} \,.
\end{aligned}
$$

Hence, by Lemma 4.3 we conclude

$$
k\sum_{m=1}^{M} |\, B_{11} \,| = o(1)
$$

for admissible $k, h \to 0$.

To show

$$
k\sum_{m\ge 1} |\, B_{12} \,| \to 0
$$

for admissible $k, h \to 0$, let $\eta_1, \eta_2 \in \{0, \frac12, 1\}$. By the inverse inequality,

$$
\begin{aligned}
|\, B_{12} \,| &\le Ck^2 \| \mathbf{u}_h^m \|_{L^\infty} \| \mathbf{d}_h^{m-\eta_1} \nabla \mathbf{d}^{m-\eta_2} \|_{L^2} \| d_t \mathbf{d}_h^m \|_{L^4}^2 \\
&\le Ck \| \mathbf{u}_h^m \|_{L^\infty} \| \mathbf{d}_h^{m-\eta_1} \|_{L^\infty} \| \nabla \mathbf{d}_h^{m-\eta_2} \|_{L^2} \| d_t \mathbf{d}_h^m \|_{L^2} \sum_{\eta=0}^{1} \| \mathbf{d}_h^{m-\eta} \|_{W^{1,2}} .
\end{aligned}
$$

Convergence to zero for admissible $k, h \to 0$ now follows easily.

For the third term in (4.2), we observe that testing the equation with $\mathbf{a}_h = \big[\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} \pm \mathbf{Id}\big]\big[\big(|\mathbf{d}_h^m|^2 + |\mathbf{d}_h^{m-1}|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big]$ gives only one nonzero term, which can be bounded as follows, on using Lemma 4.1 and Sobolev's inequality ($N = 2$):

$$\begin{aligned}
&\left| k \sum_{m=1}^{M} \Big(\mathbf{d}_h^{m-1/2} \times (\mathbf{d}_h^{m-1/2} \times \Delta_h \mathbf{d}_h^{m-1/2}), \right. \\
&\qquad \left. \big[\boldsymbol{\mathcal{I}}_{\mathbf{Y}_h} - \mathbf{Id}\big]\big[\big(|\mathbf{d}_h^m|^2 + |\mathbf{d}_h^{m-1}|^2 - 2\big)\mathbf{d}_h^{m-1/2}\big] \Big) \right| \\
&\quad \le Chk \sum_{m=1}^{M} \|\mathbf{d}_h^{m-1/2}\|_{L^\infty} \|\mathbf{d}_h^{m-1/2} \times \Delta_h \mathbf{d}_h^{m-1/2}\|_{L^2} \\
&\qquad \Big\| \nabla \Big[|\mathbf{d}_h^m|^2 + |\mathbf{d}_h^{m-1}|^2 - 2\big)\mathbf{d}_h^{m-1/2} \Big] \Big\|_{L^2} \\
&\quad \to 0 \qquad \text{as } k, h \to 0.
\end{aligned}$$

Finally, putting all the pieces together yields for all $M > 0$

$$\| \, |\, \mathbf{d}_h^m \,|^2 - 1 \, \|_{L^2}^2 \le \| \, |\mathbf{d}_h^0|^2 - 1 \, \|_{L^2}^2 + o(1) \, .$$

Hence, $|\, \mathbf{D} \,| \to 1$ a.e. in Ω_T as $k, h \to 0$. ∎

5. Computational experiments. Two new algorithms have been proposed and analyzed in the previous sections for problem (1.1)–(1.5):

(1) Solutions to Algorithm 3.1 satisfy a discrete energy law (Lemma 3.4) and unconditionally converge to weak solutions (Theorem 3.7) of the regularized problem ($\varepsilon > 0$) and generalized solutions (Theorem 3.8) of the limiting problem ($\varepsilon = 0$); we refer again to section 2.1 for a definition of the solution concepts.

(2) Algorithm 4.1 is based on a direct discretization of reformulation (1.16)–(1.18) of problem (1.1)–(1.5) to avoid penalization: Existence of solutions has been proven under a restrictive mesh constraint given in Theorem 4.2; in addition, the solutions satisfy a (modified) discrete energy law (Lemma 4.1). Convergence to generalized solutions of (1.1)–(1.5) is not known so far.

In this section, we present numerical results for two test problems using both algorithms: The first one has a smooth solution and is used to investigate the convergence behavior of the schemes with respect to the discretization parameters. The second example shows annihilation of (regularized) initial singularities.

We use Newton's method for the solution of the nonlinear system at each time step. The stopping criterion used is to require the L^2-norm of the residual to be less than 10^{-10}. For this, approximately three Newton iterations per time step are sufficient in our computations.

5.1. Smooth solution. We approximate smooth solutions of (1.1)–(1.3). Although we did not prove strong convergence with rates in the case of existing smooth solutions, we conjecture this error behavior for both Algorithms 3.1 and 4.1. In particular, Algorithm 4.1 does not employ an additional penalty parameter, which is the motivation for comparing computed solutions for varying $\varepsilon > 0$ of Algorithm 3.1 with those of Algorithm 4.1.

Example 5.1. We consider (1.1)–(1.5) for $\Omega = (-1, 1)^2$, $\mathbf{g} \equiv 0$, and

$$\mathbf{u}_0 \equiv 0 \, , \qquad \mathbf{d}_0 = (\sin(a), \cos(a))^\top, \quad a := 2.0\pi(\cos(x) - \sin(y)) \, .$$

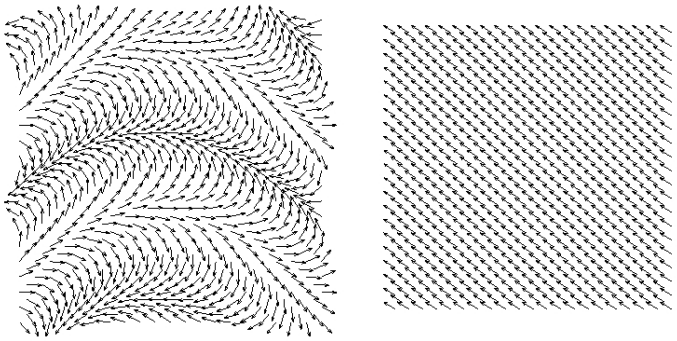

FIG. 5.1. *Example* 5.1*: Initial and final director fields (smooth solution).*

Parameters are set as $\lambda = \gamma = 1$ and $\nu = 0.1$.

The initial condition $\mathbf{d}_0$ and the final state towards which the system evolves are shown in Figure 5.1. We use a uniform crisscross triangulation of Ω with uniform mesh sizes $h = 1/20, 1/40, 1/80$.

First, we investigate the convergence behavior of Algorithm 4.1 with respect to the time-step size k and the mesh size h based on the decay of the elastic energy $\mathcal{J}_{\rm ela}(\mathbf{d}_h^m) = \frac{\lambda}{2}\int_\Omega |\nabla \mathbf{d}_h^m|^2 \,\mathrm{d}\mathbf{x}$. To this end, we compute on the finest mesh with varying $k > 0$, and with varying $h > 0$ for the finest time-step size. The corresponding approximate errors, defined as the difference to the most accurate solution, are shown in Figure 5.2. In addition, the violation of the sphere condition, measured in terms of the penalized energy $\mathcal{J}_{\rm pen}(\mathbf{d}_h^m) = \frac{\lambda}{\varepsilon^2}\big(F(\mathbf{d}_h^m), 1\big)_h$ (here with $\varepsilon = 1$), is shown with respect to varying h. As can be seen from the graphs, the algorithm shows a second order convergence with respect to h; the rate of convergence with respect to k is between first and second order.

Next, we present test results for Algorithm 3.1. For fixed $\varepsilon > 0$, the convergence behavior is similar to that of Algorithm 4.1 depicted in Figure 5.2. It is clear that ε has to be chosen in dependence of h. Figure 5.3 shows that it is quite delicate to balance ε and h in practice. Here, the computation results with a fixed mesh size h and time step k are presented. The discretization parameters are chosen sufficiently small in order to ensure that the difference between the next finer mesh and smaller time step are negligible for Algorithm 4.1. We then compare the different energies of interest with the results of Algorithm 4.1 on the same mesh with the same time step and with varying ε.

As can be seen from Figure 5.3, the correct decay in time of $\mathcal{J}_{\rm ela}$ requires a relatively precise choice of ε. A large choice of ε leads to a significant artificial energy $\mathcal{J}_{\rm pen}(\mathbf{d}_h^m)$; however, a small choice of ε leads to a large elastic energy and a too-small kinetic energy $\mathcal{J}_{\rm kin}(\mathbf{u}_h^m) = \frac{1}{2}\int_\Omega |\mathbf{u}_h^m|^2 \,\mathrm{d}\mathbf{x}$ (for a fixed mesh). Despite the more favorable theoretical results for Algorithm 3.1, it seems nontrivial to correctly capture the dynamics using the algorithm in this example.

5.2. Annihilation. The following example is taken from [31] to study annihilation of (regularized initial) singularities; cf. also [33, p. 284]. Here, the phenomenon critically depends on initial data, which in the limit ($\eta \to 0$) has infinite initial energy.

Example 5.2. Consider (1.1)–(1.5) for $\Omega = (-1,1)^2$, $\mathbf{g} \equiv 0$, and

$$\mathbf{u}_0 \equiv 0\,, \qquad \mathbf{d}_0 = \hat{\mathbf{d}}/\sqrt{|\hat{\mathbf{d}}|^2 + \eta^2} \qquad \text{for} \quad \hat{\mathbf{d}}(x_1, x_2) = (x_1^2 + x_2^2 - 0.25, x_2)^\top .$$

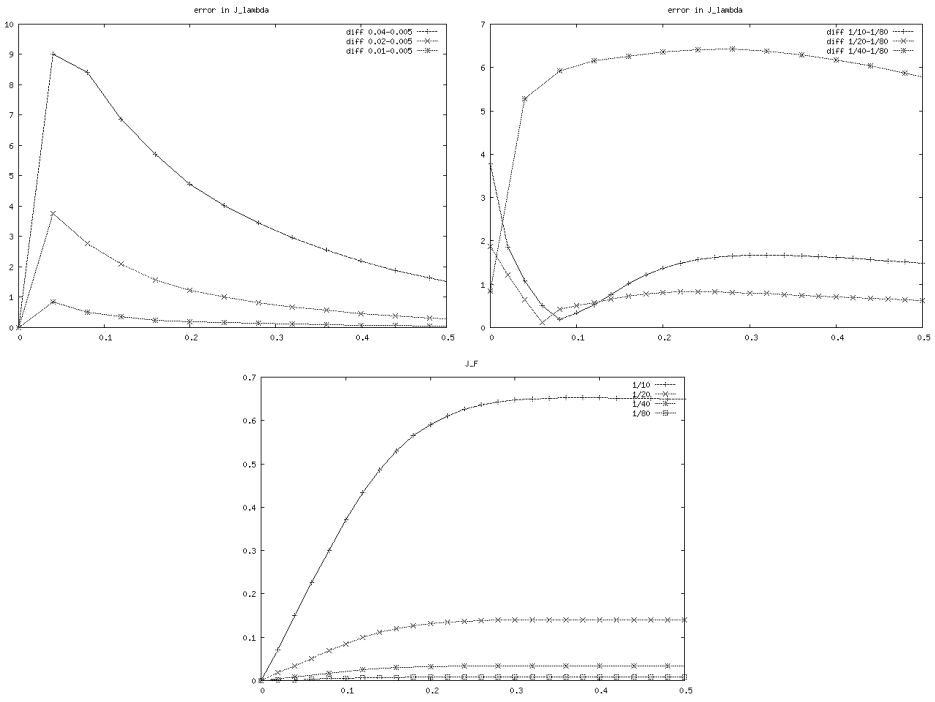

FIG. 5.2. *Example* 5.1*: Approximate errors (as a function of time) in energy* $\mathcal{J}_{\rm ela}$ *for* $k = 0.04, 0.02, 0.01$ *(top left) and* $h = 1/10, 1/20, 1/40$ *(top right);* $\mathcal{J}_{\rm pen}(\mathbf{d}_h^m)$ *for* $h = 1/10, 1/20, 1/40$ *(bottom).*

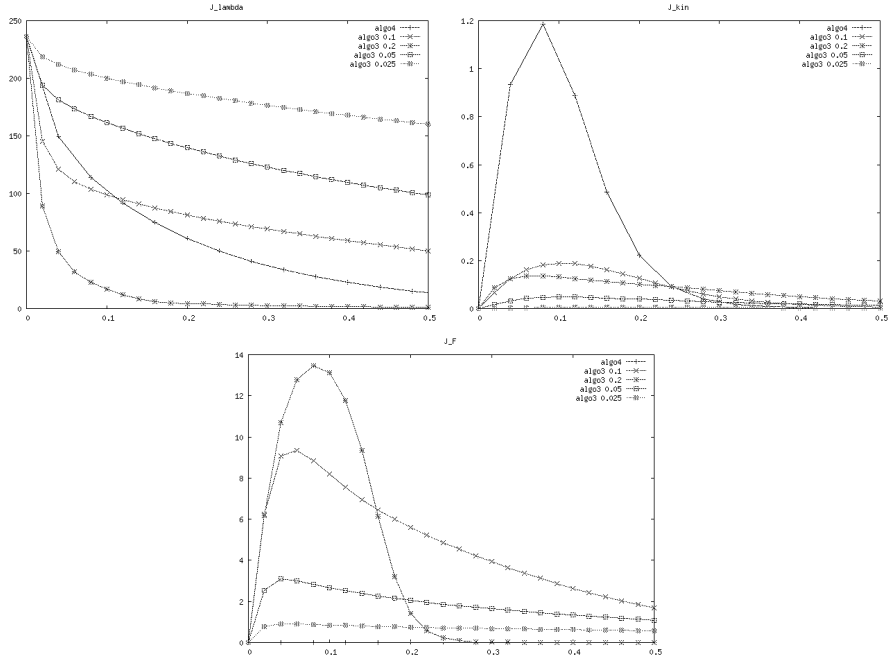

FIG. 5.3. *Example* 5.1*: Comparison of Algorithms* 4.1 *and* 3.1 *for different* $\varepsilon = 0.2, 0.1, 0.05, 0.025$*:* $\mathcal{J}_{\rm ela}$ *(top left),* $\mathcal{J}_{kin}$ *(top right), and* $\mathcal{J}_{\rm pen}(\mathbf{d}_h^m)$ *(bottom).*

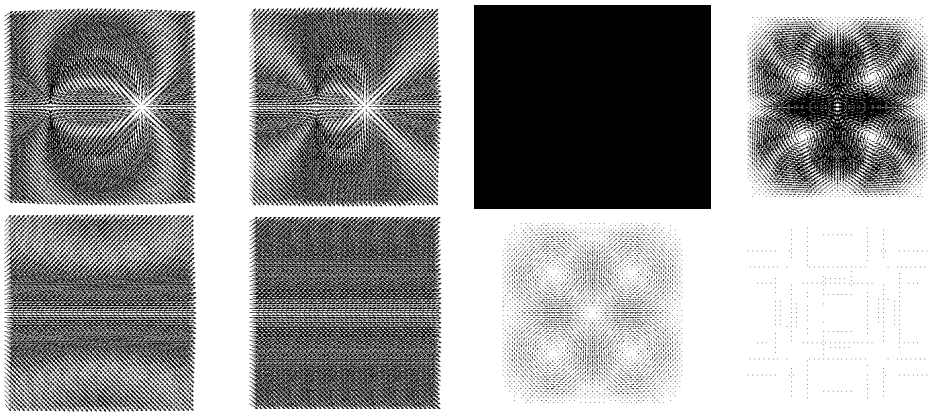

FIG. 5.4. *Example* 5.2, *using Algorithm* 3.1*: Snapshots at times* $t = 0, 0.3, 0.6, 0.9$ *of* $\{\mathbf{d}_h^m\}$ *(left) and* $\{\mathbf{u}_h^m\}$*(right). (The director and velocity fields are scaled by a factor of* 0.1 *and* 2.0*, respectively.)*

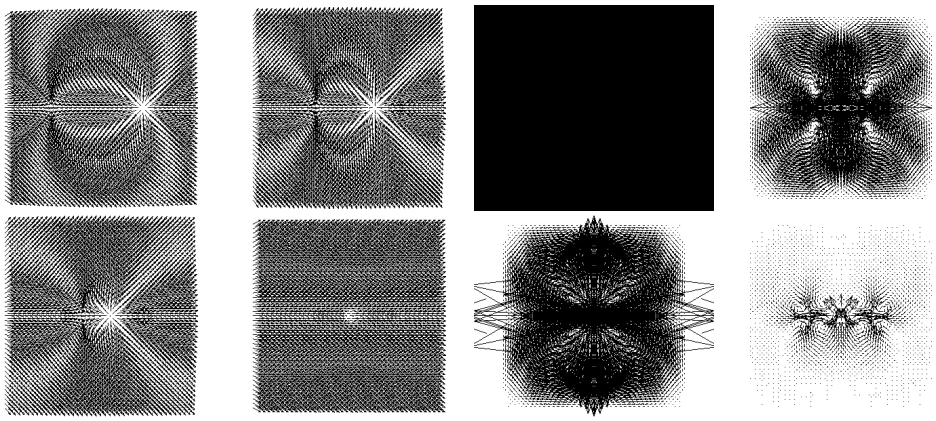

FIG. 5.5. *Example* 5.2, *using Algorithm* 4.1*: Snapshots at times* $t = 0, 0.3, 0.6, 0.9$ *of* $\{\mathbf{d}_h^m\}$ *(left) and* $\{\mathbf{u}_h^m\}$ *(right). (The director and velocity fields are scaled by a factor of* 0.1 *and* 2.0*, respectively.)*

Parameters are set as $\lambda = \gamma = \nu = 1$ and $\eta = 0.05$. We use a uniform crisscross triangulation of Ω, and $(\varepsilon, k, h) = (0.05, 0.01, 0.1)$ if not stated otherwise.

Snapshots of the evolution are displayed in Figure 5.4 for iterates $\{\mathbf{d}_h^m, \mathbf{u}_h^m\}$, which agree well with the computations presented in [31].

Figure 5.6 (first column) displays evolution of kinetic, elastic $\mathcal{J}_{\rm ela}(\mathbf{d}_h^m)$, and penalization $\mathcal{J}_{\rm pen}(\mathbf{d}_h^m)$ energies, as well as the total energy

$$\mathcal{J}_h(\mathbf{u}_h^m, \mathbf{d}_h^m) \equiv \mathcal{J}_{\varepsilon,\lambda,h}(\mathbf{u}_h^m, \mathbf{d}_h^m) := \mathcal{J}_{\rm kin}(\mathbf{u}_h^m) + \mathcal{J}_{\rm ela}(\mathbf{d}_h^m) + \mathcal{J}_{\rm pen}(\mathbf{d}_h^m)\,.$$

In the beginning of the simulation, we observe an oscillatory behavior of nonzero kinetic energy up to an annihilation time $t_{m^*} \approx 0.5$, where $\| \mathbf{u}^{m^*} \|_{L^\infty}$ is large. Both $\| \mathbf{u}^m \|_{L^\infty}$ and $\| \nabla \mathbf{d}^m \|_{L^\infty}$ rapidly approach zero for $m > m^*$; cf. Figure 5.6, first line. The dynamics of $\| \nabla \mathbf{d}_h^m \|_{L^\infty}$ for $m \approx m_*$ and annihilation time t_{m^*} are both sensitive to choices of $\varepsilon = \varepsilon(h)$, as is shown in Figure 5.7.

A drawback of the regularization approach (Algorithm 3.1) is the need to balance

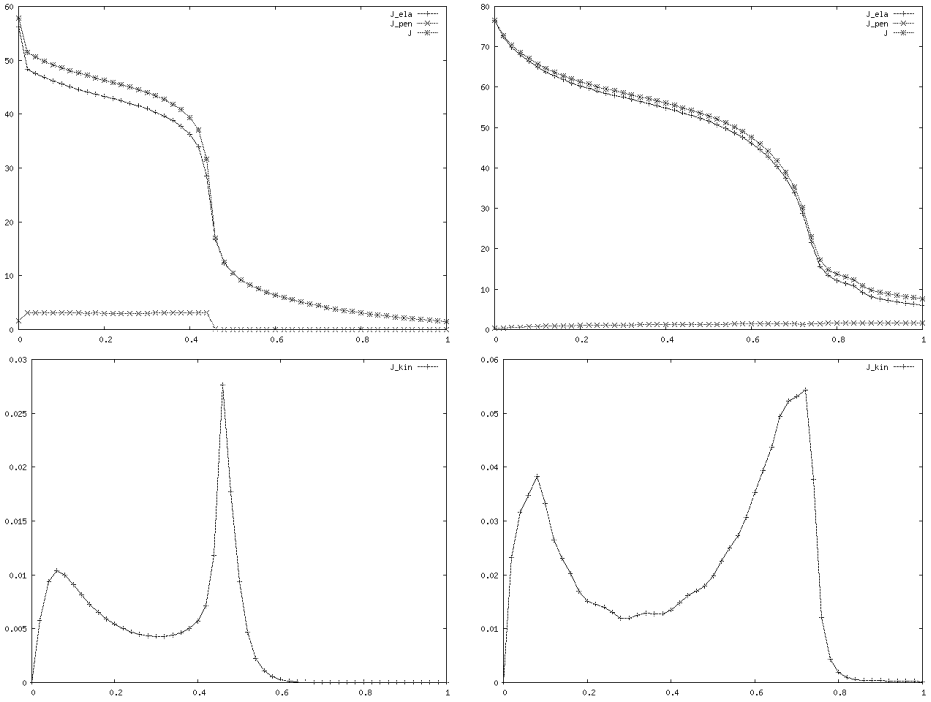

FIG. 5.6. *Example* 5.2*:* (a) *first line: Plot of elastic, penalty and total energies of tuple* $\{\mathbf{d}_h^m, \mathbf{u}_h^m\}$ *for Algorithm* 3.1 *(left) and Algorithm* 4.1 *(right), displayed in Figures* 5.4 *and* 5.5. (b) *second line: (Scaled) Plot of kinetic energies for Algorithm* 3.1 *(left) and Algorithm* 4.1 *(right).*

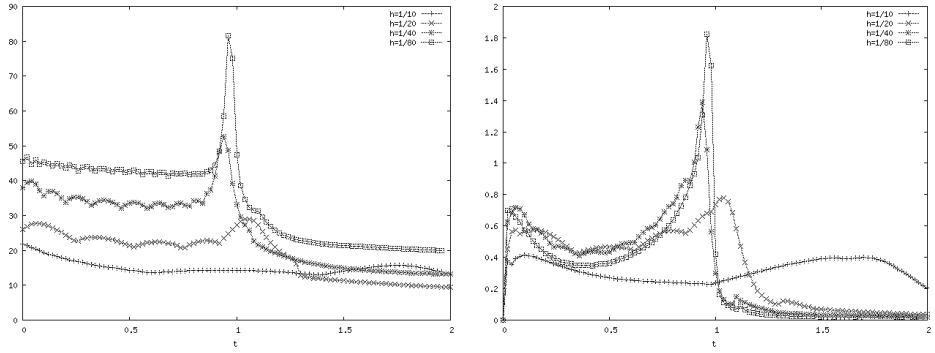

FIG. 5.7. *Example* 5.2*: Plot of* $L^\infty(\Omega)$ *for* $\nabla \mathbf{d}_h^m$ *(left) and* $\mathbf{u}_h^m$ *(right) for varying* $h = 1/10, 1/20, 1/40, 1/80$*, using Algorithm* 4.1.

penalization and discretization parameters $\varepsilon, k, h > 0$, which turned out to be quite subtle. In contrast, computation results of Algorithm 4.1 are much cleaner.

Next we use Algorithm 4.1 to solve the problem stated in Example 5.2. Snapshots of the simulation are collected in Figure 5.5, and the corresponding evolution of energies can be found in Figure 5.6 (second column). Finally, a possible blow-up behavior (simultaneous for $\| \mathbf{u}_h^m \|_{L^\infty}$, $\| \nabla \mathbf{d}_h^m \|_{L^\infty}$, as $m \to m^*$) is evident, with clear blow-up time t_{m^*}.

Finally, we investigate the behavior with respect to the parameter η used to

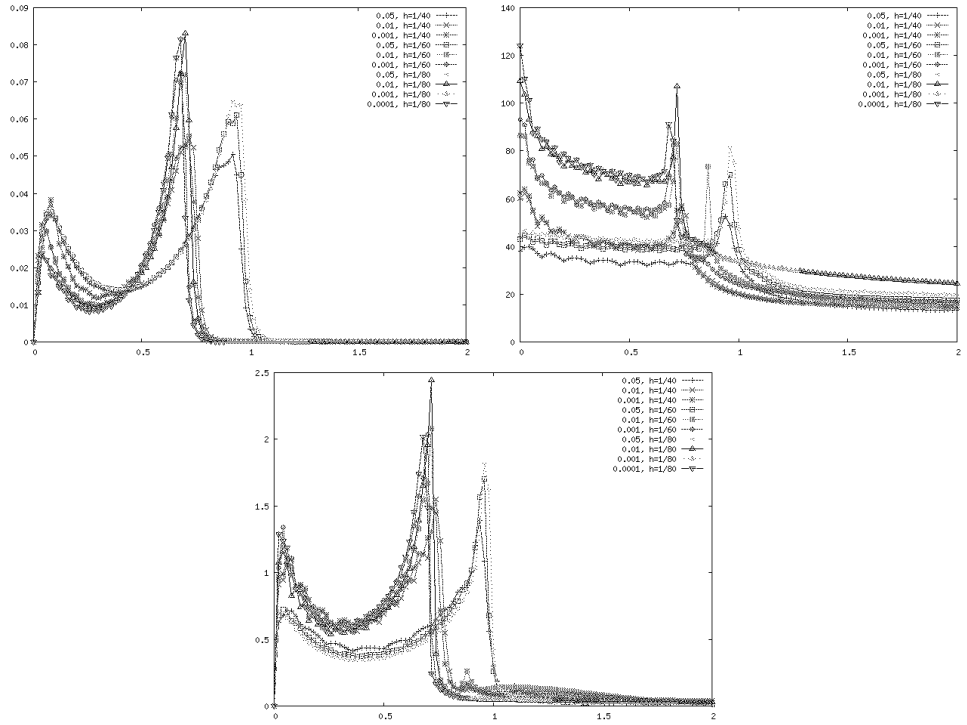

FIG. 5.8. *Example* 5.2*: Plot of* J *(top left),* $L^\infty(\Omega)$ *for* $\nabla \mathbf{d}_h^m$ *(top right), and* $\mathbf{u}_h^m$ *(bottom) for* $h = 1/40, 1/60, 1/80$ *and* $\eta = 0.05, 0.01, 0.001$*, using Algorithm* 4.1.

mollify the initial condition. Computational results based on Algorithm 4.1 are shown in Figure 5.8, where the total energy, velocity, and gradient of director in $L^\infty(\Omega)$ are plotted for varying $\eta = 0.1, 0.01, 0.001$ and mesh sizes $h = 1/20, 1/40, 1/80$.

ADAPTIVE WEAK APPROXIMATION OF DIFFUSIONS WITH JUMPS*

E. MORDECKI†, A. SZEPESSY‡, R. TEMPONE§, AND G. E. ZOURARIS¶

Abstract. This work develops adaptive time stepping algorithms for the approximation of a functional of a diffusion with jumps based on a jump augmented Monte Carlo Euler–Maruyama method, which achieve a prescribed precision. The main result is the derivation of new expansions for the time discretization error, with computable leading order term in a posteriori form, which are based on stochastic flows and discrete dual backward functions. Combined with proper estimation of the statistical error, they lead to efficient and accurate computation of global error estimates, extending the results by A. Szepessy, R. Tempone, and G. E. Zouraris [*Comm. Pure Appl. Math.*, 54 (2001), pp. 1169–1214]. Adaptive algorithms for either deterministic or trajectory-dependent time stepping are proposed. Numerical examples show the performance of the proposed error approximations and the adaptive schemes.

Key words. diffusions with jumps, weak approximation, error control, Euler–Maruyama method, a posteriori error estimates, backward dual functions

1. Introduction.

Since the introduction by Kiyoshi Itô of the theory of stochastic integration [26], diffusion processes have become a benchmark model in the mathematical sciences. Nevertheless, the study of more complex phenomena, including abrupt changes, pathwise features different from the ones of diffusions, and heavy tails, leads to the introduction of models with jumps.

In our view, the introduction of jumps in stochastic modeling is realized at least in the following three major directions. First, diffusions with jumps, the case we consider in this work, are obtained by adding jumps to a diffusion-type dynamics. Jumps have exponentially distributed interarrival times and amplitudes generated by time-dependent mark distributions. This jump structure ensures the unpredictability of the epoch and the magnitude of the jumps, a fact that is observed in financial markets, where it leads to the incompleteness of the market. This first approach was initiated with the work by Merton [37]. For other models we refer to Cont and Tankov [11] and the references therein. In a second approach, the jump intensity depends on the state of the process, implying a certain possibility to predict the jump

epoch. State-dependent jump diffusion processes are intensively used in default risk theory, for instance, in the form of affine jump diffusion processes [13]. The third approach assumes that not only the large movements but also the small movements observed in the dynamics are generated by jumps. In some works even the Brownian driving process is replaced by a stable-type process (i.e., a Lévy process with jump measure with infinite mass around zero). This gives a process with an infinite number of jumps on every bounded time interval, a situation known as *infinite activity*. Initial references to infinite activity are, for instance, [34] and [17]. More recent works include [10].

The computation of functionals of the above-mentioned stochastic processes, when closed solutions are not available, led to the development of time discretization schemes, following the approach by Maruyama [35]. In this wide field of applied mathematics, standard references are the books by Kloeden and Platen [31] and by Milstein and Tretyakov [39]. The main emphasis in these books is on the development of different numerical schemes and the determination of their *order* of convergence. Consider a given functional θ (for instance, an expectation, related to an option price in finance) of a stochastic process defined on a time interval $[0, T]$. Assuming the necessary regularity, we say that a scheme has (weak) order r if it produces a sample average approximate value, $\widehat{\theta}$, such that $|\widehat{\theta}-\theta| = \mathcal{O}\big((\Delta t_{max})^r + M^{-1/2}\big)$, using a time discretization $\{0 = t_0 < t_1 < \cdots < t_N = T\}$ and M independent samples.

Motivated by practical reasons, we formulate in this work a weak approximation problem in the following way: given the functional θ, the numerical scheme for time discretization, and a certain desired accuracy $\mathrm{TOL} > 0$, produce a *computable* sample average estimator $\widehat{\theta}$ such that $|\widehat{\theta} - \theta| \leq \mathrm{TOL}$ with a probability close to one. We also seek to construct $\widehat{\theta}$ using minimal computational effort.

To solve this problem we use the so-called jump augmented Euler–Maruyama scheme (also known as jump adapted Euler–Maruyama scheme; cf. [47]) and develop novel time discretization error estimation formulas. Based on these computable error estimates we propose *a posteriori adaptive* methods that compute the approximation $\widehat{\theta}$ and estimate its numerical error due to time discretization and statistical sampling. If the prescribed accuracy TOL is not yet achieved, the adaptive algorithms decide whether to subdivide a set of time intervals with largest error contribution or to increase the number of realizations, up to the point of achieving the accuracy goal. To the best of our knowledge, there are no references that follow this approach for any class of jump processes.

Regarding the jump intensity λ, we consider a moderate number of jumps, motivated by reported results from the calibration of jump diffusion models in finance. For instance, the value $\lambda = 0.089$ was reported for the calibration of the Merton model with option prices on the S&P 500 index, and $\lambda \approx 1$ for the Kou model applied to the German DAX index; see [1] and [12]. These empirical facts allow us to rely on the augmentation of the grid with the jump times, reported to be more accurate for strong approximation of diffusion with jumps [6]. In Remark 4.1 we discuss the corresponding additional work due to the inclusion of the jump points in the time discretization.

The main contribution in this work is the generalization of the approach proposed by Szepessy, Tempone, and Zouraris for diffusions in [51] to the context of diffusion with large jumps. This generalization is based on the probabilistic properties of diffusions with jumps, performing two steps of simulation. The first step relates to the jump structure, and the second relates to the diffusion part. We provide

corresponding analysis for the approximation errors in each step. In section 2 we present an example with a singularity and many jumps. There, our new algorithms save a factor of one hundred in the number of time steps required to produce the same accuracy as the uniform time stepping algorithm. Furthermore, for one of those algorithms the additional computational work to generate the adaptive time steps is negligible.

The other two cases not considered here, namely, diffusions with state-dependent intensity jumps and high intensity of small jumps, seem to require other techniques and would therefore be interesting for future work; see the end of section 1.2.1.

Efficient adaptive time stepping methods, with theoretical basis, use a posteriori error information, since in general a priori knowledge is not as precise as the a posteriori one. Adaptive time stepping methods can be based on Theorem 2.2 or Theorem 3.1, where error estimates with leading order terms in computable a posteriori form are obtained. These estimations require the use of stochastic flows and dual functions in the presence of jumps. Dual functions are standard in optimal control theory, in particular for adaptive mesh control for ordinary and partial differential equations (see [4], [5], [16], [28], [29], [41], [43], and [44]) and were successfully applied in the probabilistic context in [15], [40], [45], and [51].

Alternative deterministic methods involve the numerical approximation of the Kolmogorov backward equation (2.5), which is a nonlocal partial integrodifferential equation. Direct discretization of such time-dependent integrodifferential equations requires the approximation of integrals at each time step and may suffer from the curse of dimensionality. On the other hand, the Euler–Maruyama method avoids these expensive computations. Examples of this deterministic approach include the work by Andersen and Andreasen [1], which uses operator splitting to approximate the integral term explicitly in Fourier space while approximating the other terms in the equation implicitly, and the work by Matache, von Petersdorff, and Schwab [36], which discretizes the partial integrodifferential equation by the θ-scheme in time and a wavelet Galerkin method in space.

For work which proposes and analyzes numerical methods for diffusions with jumps, we refer the reader to Liu and Li [33], where weak convergence schemes are analyzed, and Higham and Kloeden [22], [23], [24], where implicit methods for diffusion with jumps are presented, analyzing strong convergence and nonlinear stability. We refer also to Bruti-Liberati and Platen [6], [7], [8], [9], Kubilius and Platen [32], and Mikulevičius and Platen [38].

1.1. Problem's setting. Let $d \in \mathbb{N}$, $T > 0$ and let $X : [0,T] \to \mathbb{R}^d$ be a stochastic process solving the following stochastic differential equation:

$$\begin{aligned} X(t) = X(0) &+ \int_0^t a(\, s, X(s^-)\,)\, ds + \sum_{\ell=1}^{\ell_0} \int_0^t b^\ell(\, s, X(s^-)\,)\, dW^\ell(s) \\ &+ \int_0^t \int_{\mathbf{z}} c(\, s, X(s^-), z\,)\, p(ds, dz) \quad \forall\, t \in [0,T] \end{aligned} \tag{1.1}$$

(see [19, Chap. II.2], [27, Chap. III.2c], or [25]), with initial condition $X(0) = x_0$ that we assume deterministic for simplicity (see Remark 2.1 for a random initial condition). The randomness in this equation is generated by the following:

(i) A standard ℓ_0-dimensional Wiener process

$$W = \{W(t) = (W^1(t), \ldots, W^{\ell_0}(t)) \colon t \in [0,T]\},$$

defined on a filtered probability space $(\Omega^W, \mathcal{F}^W, \mathbf{F}^W, P^W)$, where

$$\mathbf{F}^W = \{\mathcal{F}_t^W : t \in [0,T]\}$$

is a filtration and $\mathcal{F}_T^W = \mathcal{F}^W$.

(ii) A Poisson random measure $p(\omega, dt, dz)$ on $[0,T]\times\mathbf{Z}$, where $\mathbf{Z} \equiv \mathbb{R}^{\ell_1}\backslash\{0\}$, with $\ell_1 \in \mathbb{N}$, and deterministic compensator $q(dt,dz) = \lambda(t)\mu(t,dz)dt$. Here $\lambda\colon [0,T] \to [0,\lambda_{\max}]$ is the time intensity of jumps with $\lambda_{\max} \in (0,+\infty)$ and, for each fixed $t \geq 0$, the measure $\mu(t,dz)$ is a probability on $\mathbf{Z}$. The jump measure is defined in a filtered probability space $(\Omega^J, \mathcal{F}^J, \mathbf{F}^J, P^J)$, where $\mathbf{F}^J = \{\mathcal{F}_t^J : t \in [0,T]\}$ is a filtration and $\mathcal{F}_T^J = \mathcal{F}^J$.

As a consequence, the process X is defined on a stochastic basis $(\Omega, \mathcal{F}, \mathbf{F}, P)$, where $\Omega = \Omega^W \times \Omega^J$, $\mathbf{F} = \{\mathcal{F}_t^W \otimes \mathcal{F}_t^J : t \in [0,T]\}$, and $P = P^W \times P^J$; as usual in this framework, the Wiener process and the Poisson random measure are mutually independent. The coefficients $a\colon [0,T]\times\mathbb{R}^d \to \mathbb{R}^d$, $b\colon [0,T]\times\mathbb{R}^d \to \mathbb{R}^{d\times\ell_0}$, and $c\colon [0,T]\times\mathbb{R}^d\times\mathbf{Z} \to \mathbb{R}^d$ are assumed to be Borel functions, satisfying regularity conditions stated in Lemma 2.1.

Given a scalar function $g\colon \mathbb{R}^d \to \mathbb{R}$, a functional of the stochastic process X of the form $\theta = E\big[\, g\big(X(T)\big)\big]$, and a tolerance $\mathrm{TOL} > 0$, the goal of our work is to derive an algorithm that produces a computable approximation $\widehat{\theta}$ to θ such that

$$\big|\, \widehat{\theta} - \theta \,\big| \leq \mathrm{TOL}$$

with a probability close to one and minimal computational effort.

1.2. The jump augmented Euler–Maruyama simulation scheme. The scheme has two steps. After choosing an initial deterministic partition of the time interval $[0,T]$ we sample the jump epochs and magnitudes, to later implement the numerical method in the *augmented* grid, including the original points and the jump points. We first describe the jump structure construction.

1.2.1. Construction of the integral with respect to the Poisson random measure. Consider a sequence $(\mathbf{e}_j)_{j=1}^{\infty}$ of random variables defined on a probability space $(\Omega^J, \mathcal{F}^J, P^J)$, which are independent and have common exponential distribution with parameter one. Define an auxiliary function

$$\Lambda(t) = \int_0^t \lambda(s)\, ds, \quad t \in [0,T]. \tag{1.2}$$

Then the number of jumps of the random Poisson measure $p(dt,dz)$ in an interval $[0,t]$ is

$$\nu(t) = \max\left\{ k\colon \sum_{j=1}^{k} \mathbf{e}_j \leq \Lambda(t) \right\}$$

and the total number of jumps in $[0,T]$ is denoted by $\nu \equiv \nu(T)$. The jump times of the Poisson measure can be defined by $\tau_0 = 0$, and $\tau_k = \Lambda^{-1}(\mathbf{e}_1 + \cdots + \mathbf{e}_k)$ for $k = 1,\ldots,\nu$, and can be computed recursively by solving for τ_k in the equations

$$\mathbf{e}_k = \int_{\tau_{k-1}}^{\tau_k} \lambda(s)\, dt = \Lambda(\tau_k) - \Lambda(\tau_{k-1}) \quad \text{for} \quad k = 1,\ldots,\nu. \tag{1.3}$$

Once the jump times are computed, we proceed to sample the marks $\{Z_k\}$, which, conditionally on the values of the jumps times, are independent random variables distributed respectively according to $\{\mu(\tau_k, dz)\}$. Observe that the random measure $p(dt, dz)$, characterized by its intensity $q(dt, dz) = \lambda(t)\mu(t, dz)dt$, can then be constructed as

$$p(ds, dz) = \sum_{k=1}^{\nu} \delta_{(\tau_k, Z_k)}(ds, dz).$$

Here $\delta_{(t,Z)}(ds, dz)$ is a Dirac distribution at the point (t, Z). As a consequence of this construction, the stochastic integral with respect to the Poisson random measure, i.e., the last term in (1.1), can be computed as a finite sum, i.e.,

$$\int_0^t \int_{\mathbf{z}} c(\, s, X(s^-), z\,)\, p(ds, dz) = \sum_{k=1}^{\nu(t)} c\big(\tau_k, X(\tau_k^-), Z_k\big), \quad t \in [0, T].$$

Some relevant remarks concerning the jump structure and its simulation are in order. First, the number of jumps in the interval $[0, T]$ is almost surely finite, its expectation being $\Lambda(T) = \int_0^T \lambda(s)ds \le \lambda_{\max} T$. Second, since the time intensity $\lambda(t)$ is deterministic, the jump times $\{\tau_k\}$ can be directly obtained before solving for the process X; it is enough to find the function Λ by accurately integrating (1.2) and successively finding $\{\tau_k\}$ by solving (1.3). Furthermore, if λ is a constant, then we simply sample $\tau_k = (\mathbf{e}_1 + \cdots + \mathbf{e}_k)/\lambda$. The jump augmented Euler–Maruyama scheme admits a direct generalization in the case of stochastic intensity, as long as this intensity is independent of the Wiener process and it admits exact simulation. This is the case, for instance, of a regime-switching intensity process (see, for instance, [2]).

In the second approach described before, the jump intensity λ depends on the current value $X(t)$ of the process. Then it is not possible to sample the jump times separately from the process and it is necessary to implement a different algorithm. For instance, see Glasserman and Merener [20], [21], where a rejection algorithm is proposed, reducing the case of uniformly bounded state-dependent intensity $\lambda = \lambda(t, x) \le \lambda_o(t) < \lambda_{\max}$ to the case of a time-dependent intensity $\lambda = \lambda_o(t) < \lambda_{\max}$, which is our case.

Regarding the third approach described above and the possibility of adapting our methodology to the case of infinite activity, a possible approach is to separate small and large jumps, simulating the large jumps and approximating the small jumps by an additional independent Brownian motion, as suggested by Asmussen and Rosiński [3]. Nevertheless, one should be cautious, as the efficient use of the jump augmented Euler–Maruyama method assumes a moderate number of jumps, while the cut-off approximation of the small jump part by a Brownian motion may produce a high intensity compound Poisson process. This delicate tradeoff between "small" and "large" jumps is characteristic in infinite activity Lévy processes problems, should be separately examined, and is out of the scope of the present work (see [50]).

1.2.2. Jump augmented Euler–Maruyama time stepping algorithm. After constructing the jumps and its marks as in section 1.2.1, we simulate the trajectory $\overline{X}$ using the following scheme.

Jump augmented Euler–Maruyama simulation scheme.

Input: Given N, time nodes $0 = \tilde{t}_0 < \tilde{t}_1 < \cdots < \tilde{t}_N = T$, and sample jump times $0 < \tau_1(\omega) < \cdots < \tau_{\nu(\omega)}(\omega) < T$ with corresponding marks $Z_1(\omega), \ldots, Z_{\nu(\omega)}(\omega)$,

set the jump counter $k = 1$.

Time stepping: Consider an augmented partition given by the union

$$\{t_n(\omega)\}_{n=0}^{\kappa(\omega)} = \{\tilde{t}_n\}_{n=0}^{N} \cup \{\tau_n(\omega)\}_{n=0}^{\nu(\omega)},$$

where $\kappa(\omega) = N + \nu(\omega)$ (a.s.) is the number of time steps.

Set the initial condition $\overline{X}(t_0, \omega) = x_0$.

For time steps $n = 0, \ldots, \kappa(\omega) - 1$

Compute the remaining approximate grid values, $\overline{X}(t_{n+1}, \omega)$, by first constructing the left limit value of the approximated process,

$$\begin{aligned}\overline{X}(t_{n+1}^-, \omega) &= \overline{X}(t_n, \omega) + a(t_n, \overline{X}(t_n, \omega))(t_{n+1} - t_n) \\ &\quad + \sum_{\ell=1}^{\ell_0} b^\ell(t_n, \overline{X}(t_n, \omega))(W^\ell(t_{n+1}, \omega) - W^\ell(t_n, \omega)).\end{aligned} \tag{1.4}$$

When needed, introduce the correction due to jump discontinuities:

if $(t_{n+1} = \tau_k(\omega))$ **then**

$$\overline{X}(t_{n+1}, \omega) = \overline{X}(t_{n+1}^-, \omega) + c\big(t_{n+1}, \overline{X}(t_{n+1}^-, \omega), Z_k(\omega)\big), \tag{1.5}$$

increase k to $k + 1$

else

$$\overline{X}(t_{n+1}, \omega) = \overline{X}(t_{n+1}^-, \omega), \tag{1.6}$$

end-if

end-for

Several important particular cases deserve comment. First, taking $c = 0$ we obtain the previous algorithm in [51]. For the other particular case when $a = b = 0$ the approximate process $\overline{X}$ has the same law as X, due to the form of the grid proposed in the numerical method (see [20]). A similar situation occurs when only $b = 0$; there, conditioned on the jumps information, a higher order method for ordinary differential equation integration should be used to approximate $\overline{X}$ between jump times, giving a time discretization error which is essentially negligible with respect to the statistical error.

1.3. Error control. The aim, for a given TOL > 0, is to choose time steps $\{0 = \tilde{t}_0 < \tilde{t}_1 < \cdots < \tilde{t}_N = T\}$ and the number M of independent identically distributed (i.i.d.) samples $\{\overline{X}(\cdot\,, \omega_j)\}_{j=1}^{M}$ such that the computational work, defined as M times the average number of time steps, i.e., $M \times E[\kappa]$ is minimal, constrained by the condition that the computational error, $\mathcal{E}$, defined by

$$\mathcal{E} = E[g(X(T))] - \tfrac{1}{M} \sum_{j=1}^{M} g(\overline{X}(T, \omega_j)), \tag{1.7}$$

is such that the event

$$\big|\mathcal{E}\big| \leq \text{TOL} \tag{1.8}$$

has a probability close to one. The computational error $\mathcal{E}$ naturally splits as the sum of the (deterministic) time discretization error $\mathcal{E}_T$ and the statistical error $\mathcal{E}_S$ given,

respectively, by

$$\mathcal{E}_T = E\big[g(X(T))\big] - E\big[g(\overline{X}(T))\big], \tag{1.9}$$

$$\mathcal{E}_S = E[g(\overline{X}(T))] - \tfrac{1}{M}\sum_{j=1}^{M} g(\overline{X}(T,\omega_j)). \tag{1.10}$$

The number M of independent realizations of $\overline{X}$ is computed from the statistical properties of $\mathcal{E}_S$. Theorems 2.2 and 3.1 state approximations for the time discretization error in terms of error contributions from each time subinterval, that is,

$$\mathcal{E}_T \approx E\left(\sum_m \rho(t_m,\omega)(\Delta t_m)^2\right)$$

(see (2.7) and (3.4)). These approximations are used to estimate the time discretization error in the adaptive algorithms that we propose. The error density $\rho(t_m,\omega_j)$ in (2.8) and (3.5), respectively, are computed through the discrete dual functions that we describe in section 1.4.

1.4. Discrete dual equations. This subsection is dedicated to the determination of the discrete dual functions $\varphi(t) \in \mathbb{R}^d$, $\varphi'(t) \in \mathbb{R}^{d\times d}$, and $\varphi''(t) \in \mathbb{R}^{d\times d\times d}$, where t is a node of the (stochastic) partition of the time interval $[0,T]$. First, we introduce some notation.

DEFINITION 1.1 (local discrete solution operator). *Write the Euler time stepping for the time nodes $t = t_0, t_1^-, t_1, t_2^-, t_2, \dots$ as*

$$\overline{X}(t_{next},\omega) = \Phi(t,\overline{X}(t)), \tag{1.11}$$

where the next computational time is given by

$$t_{next} = \begin{cases} t_n & \text{if} \quad t = t_n^-, \\ t_{n+1}^- & \text{if} \quad t = t_n, \end{cases}$$

and, correspondingly, the previous computational time is

$$t_{prev} = \begin{cases} t_{n-1} & \text{if} \quad t = t_n^-, \\ t_n^- & \text{if} \quad t = t_n. \end{cases}$$

Observe that, depending on ω and t, we may have

$$\Phi(t,x,\omega) = \begin{cases} x + a(t,x)\Delta t + b^\ell(t,x)\Delta W^\ell & \text{if } t = t_n, \\ x + c(t,x,Z_k(\omega)) & \text{if } t = t_n^- \text{ and } t_n \text{ is the } k\text{th jump time}, \\ x & \text{if } t = t_n^- \text{ and } t_n \text{ is not a jump time}. \end{cases}$$

Then, for each realization, φ, φ', and φ'' are constructed by the following algorithm.

DUAL BACKWARD TIME STEPPING ALGORITHM.

Set the initial backward values

$$t = T, \tag{1.12}$$
$$\varphi_i(T) = \partial_i g\big(\overline{X}(T)\big),$$
$$\varphi'_{ik}(T) = \partial_{ik} g\big(\overline{X}(T)\big),$$
$$\varphi''_{ikm}(T) = \partial_{ikm} g\big(\overline{X}(T)\big).$$

while $t > 0$ set $t = t_{prev}$

$$\varphi_i(t) = \partial_i \Phi_j(t, \overline{X}(t))\, \varphi_j(t_{next}), \tag{1.13}$$
$$\varphi'_{ik}(t) = \partial_i \Phi_j(t, \overline{X}(t))\, \partial_k \Phi_p(t, \overline{X}(t))\, \varphi'_{jp}(t_{next}) \tag{1.14}$$
$$+ \partial_{ik} \Phi_j(t, \overline{X}(t))\, \varphi_j(t_{next}), \tag{1.15}$$
$$\begin{aligned}\varphi''_{ikm}(t) = {} & \partial_i \Phi_j(t, \overline{X}(t)) \partial_k \Phi_p(t, \overline{X}(t)) \partial_m \Phi_r(t, \overline{X}(t)) \varphi''_{jpr}(t_{next}) \\ & + \partial_{im} \Phi_j(t, \overline{X}(t)) \partial_k \Phi_p(t, \overline{X}(t)) \varphi'_{jp}(t_{next}) \\ & + \partial_i \Phi_j(t, \overline{X}(t)) \partial_{km} \Phi_p(t, \overline{X}(t)) \varphi'_{jp}(t_{next}) \\ & + \partial_{ik} \Phi_j(t, \overline{X}(t)) \partial_m \Phi_p(t, \overline{X}(t)) \varphi'_{jp}(t_{next}) \\ & + \partial_{ikm} \Phi_j(t, \overline{X}(t)) \varphi_j(t_{next}).\end{aligned} \tag{1.16}$$

end-while

1.5. Adaptivity. After choosing the initial jump augmented grid, we propose two different ways of a posteriori refinement or time stepping in order to achieve the prescribed TOL: a first algorithm that refines simultaneously all the simulated trajectories, which we call *deterministic*, and a second one that refines the simulated trajectories one by one, which we call *stochastic*.

In the deterministic algorithm, the refinement is taken in order to achieve

$$(\Delta \tilde{t}_n)^2 |E[\rho(\tilde{t}_n, \omega)]| = \text{constant}.$$

Observe that we can only control the deterministic points $\tilde{t}_n$ and not the whole augmented grid. This is the basis of our adaptive algorithm in section 4.3.

In the stochastic algorithm the time steps are determined by the condition

$$(\Delta \tilde{t}_n)^2 |\rho(\tilde{t}_n, \omega)| = \text{constant},$$

where, in contrast to the previous algorithm, there is no expectation. This is achieved through a test performed at each interval of each realization, to decide whether to refine the given interval (see section 4.4). In this case, when a node is added, a Brownian bridge is used to obtain the value of both the Wiener process and the approximated process, $\overline{X}$, at this new intermediate time node.

Stochastic time steps are advantageous for problems with singularities at random times, but since their use entails more work per realization than the deterministic time steps they should be judiciously used. A natural application of stochastic time steps appears in the weak approximation of killed diffusions; see [15]. The optimal stochastic steps depend on the whole solution $\overline{X}(t)$, $0 < t < T$, and in particular the step $\Delta t(t)$ at time t depends also on $W(u)$ for $t < u$. In stochastic analysis the concept of *adaptedness* means, intuitively, that the values of the process at time t depend only on the events generated by the sources of randomness up to time t,

i.e., they do not depend on future events. In numerical analysis a method is said to be *adaptive* when the approximate solution is used to control the error, e.g., to determine the time steps. Our stochastic time stepping algorithm is in this sense adaptive and nonadapted, since the time steps $\Delta t(t)$ depend on values of $W(u)$ for $t < u$, i.e., on future values of the Wiener process. The backward evolutions (1.13)–(1.14) of the weight functions φ and φ' avoid solving for the two variables t, s present in $\frac{\partial \overline{X}(t)}{\partial x(s)}$, which appears in the forward t-evolution equation for $\frac{\partial \overline{X}(t)}{\partial x(s)}$ in the identity $\varphi_i(t_n) = \partial_j g(\overline{X}(T)) \frac{\partial \overline{X}_j(T)}{\partial x_i(t_n)}$; see (6.25). A solution with two variables s and t would require work of the order N^2 for each realization, instead of the corresponding work of the order N in Theorem 2.2.

The rest of the paper is organized as follows. Section 2 contains a first error expansion based on the dual functions and their first variations. Section 3 contains a second error expansion based on the duals and their first and second variations. Section 4 presents implementations of adaptive algorithms. Section 5 includes results from numerical experiments, and section 6 presents the proofs.

2. A first estimate of the time discretization error. In this section we present in Theorem 2.2 an error expansion in a posteriori computable form for the time discretization error $\mathcal{E}_T$ in (1.9) based on the first and second dual functions φ and φ'. All the proofs are given in section 6.

Our analysis uses the fact that the simulated process can be extended to the interval $[0, T]$. To do this we first define the piecewise constant coefficients

$$\begin{aligned} &\overline{a}(s; \overline{X}) \equiv a(t_n, \overline{X}(t_n)) \quad \forall\, s \in [t_n, t_{n+1}), \\ &\overline{b}^{\ell}(s; \overline{X}) \equiv b^{\ell}(t_n, \overline{X}(t_n)) \quad \forall\, s \in [t_n, t_{n+1}), \quad \ell = 1, \ldots, \ell_0, \end{aligned} \tag{2.1}$$

for $n = 0, \ldots, \nu - 1$, and then consider the stochastic differential equation

$$\begin{aligned} \overline{X}(t) = \overline{X}(0) &+ \int_0^t \overline{a}(s; \overline{X}) ds + \sum_{\ell=1}^{\ell_0} \int_0^t \overline{b}^{\ell}(s; \overline{X})\, dW^{\ell}(s) \\ &+ \int_0^t \int_{\mathbf{z}} c\big(s, \overline{X}(s^-), z\big)\, p(ds, dz) \quad \forall\, t \in [0, T]. \end{aligned} \tag{2.2}$$

A key point of our approach is the possibility of perfect simulation of the jump structure, avoiding the necessity of the consideration of an approximated jump coefficient $\bar{c}$. For simplicity we introduce the notation $\partial_k \equiv \frac{\partial}{\partial x_k}$, $\partial_{ki} \equiv \frac{\partial^2}{\partial x_k \partial x_i}, \ldots$, $\partial_t \equiv \frac{\partial}{\partial t}$ and use the summation convention, i.e., if the same subscript appears twice in a term, the term denotes the sum over the range of this subscript, e.g., $c_{ik}\partial_k b_j \equiv \sum_{k=1}^{d} c_{ik}\partial_k b_j$, and consequently

$$d_{ij} \equiv \frac{1}{2} \sum_{\ell=1}^{\ell_0} b_i^{\ell} b_j^{\ell} = \frac{1}{2} b_i^{\ell} b_j^{\ell}, \quad \overline{d}_{ij} \equiv \frac{1}{2} \sum_{\ell=1}^{\ell_0} \overline{b}_i^{\ell} \overline{b}_j^{\ell} = \frac{1}{2} \overline{b}_i^{\ell} \overline{b}_j^{\ell}.$$

For a derivative ∂_α the notation $|\alpha|$ is its order.

LEMMA 2.1. (a) *Assume that the following regularity conditions hold:*

(i) *The functions $a(t, x)$, $b(t, x)$, and $c(t, x, z)$ are continuous in (t, x) and are twice continuously differentiable with respect to x.*

(ii) *The partial derivatives of first and second order with respect to x of the functions a and b are uniformly bounded.*

(iii) *The function* $c(t,x,z)$ *satisfies*

(2.3)
$$\int_0^T \int_{\mathbf{z}} \left(|c(t,x,z)| + |\nabla_x c(t,x,z)|^4 + |\nabla_x^2 c(t,x,z)|^2 \right) \lambda(t) \mu(t,dz) dt \leq C,$$

where ∇_x *denotes the gradient with respect to* x*, and the constant* C *is independent of* x*.*

(iv) *The function* g *is twice continuously differentiable, and together with its partial derivatives of first and second order it is uniformly bounded.*

Then the cost to go *function, defined by*

$$u(t,x) = E\big[g(X(T)) \mid X(t) = x\big], \tag{2.4}$$

satisfies the Kolmogorov equation

(2.5)
$$\partial_t u(t,x) + a_k \partial_k u(t,x) + d_{kn} \partial_{kn} u(t,x) + \lambda(t) \int_{\mathbf{z}} [u(t,x+c(t,x,z)) - u(t,x)] \mu(t,dz) = 0,$$

with the boundary condition

$$u(T,\cdot) = g.$$

(b) *Furthermore, if the following regularity conditions are satisfied:*

(i) *the functions* $\partial_\beta a(t,\cdot)$*,* $\partial_\beta b(t,\cdot)$*, and* $\partial_\beta c(t,\cdot,z)$ *are bounded uniformly in* t *and* z *for* $1 \leq |\beta| \leq 8$*;*

(ii) *the jump intensity* $\lambda(t)$ *and the measure* $\mu(t,dz)$ *have continuous time derivatives; in addition, the functions* $a(\cdot,x)$*,* $b(\cdot,x)$*,* $c(\cdot,x,z)$ *have continuous and uniformly bounded first order time derivatives;*

(iii) $\int_0^T \int_{\mathbf{z}} |c(t,0,z)|^{2k} \mu(t,dz) dt < \infty$ *for all* $k \in \mathbb{N}$*;*

(iv) *the function* g *has spatial derivatives* $\partial_\beta g$*, with polynomial growth for* $|\beta| \leq 8$*;*

then the function u *has continuous partial derivatives with respect to* x *up to the order* 8*, satisfying the following polynomial growth condition: for all* $i \in \{0,1,2\}$ *and* $\alpha \in \mathbb{N}^d$ *with* $i + |\alpha| \leq 8$ *there exists* $p_{\alpha,i} \in \mathbb{N}$ *and* $C_{\alpha,i} > 0$ *such that*

$$\max_{0 \leq t \leq T} \left| \partial_t^i \partial_\alpha u(t,x) \right| \leq C_{\alpha,i} \left(1 + |x|^{p_{\alpha,i}} \right) \quad \forall\, x \in \mathbb{R}^d.$$

LEMMA 2.2. *Assume that the regularity conditions described in paragraph* (b) *of Lemma* 2.1 *hold. Then the time discretization error in* (1.9) *satisfies*

$$\begin{aligned} \mathcal{E}_T = & \int_0^T E\Big[\left(a_k(t, \overline{X}(t^-)) - \overline{a}_k(t; \overline{X}) \right) \partial_k u(t, \overline{X}(t^-)) \Big] \, dt \\ & + \int_0^T E\Big[\left(d_{ij}(t, \overline{X}(t^-)) - \overline{d}_{ij}(t; \overline{X}) \right) \partial_{ij} u(t, \overline{X}(t^-)) \Big] \, dt, \end{aligned} \tag{2.6}$$

where $u = u(t,x)$ *is the cost to go function defined in* (2.4)*.*

Remark 2.1. It is possible to relax the assumption of the process departing from a fixed value $x_0 \in \mathbb{R}$. We can assume that it departs from a random variable $X(0)$, independent of the jump structure and the Wiener process, and we can assume that either this initial random variable admits perfect simulation by $\overline{X}(0)$ or it does not. Both situations easily adapt to our approach, giving (in the latter case) an additional term of the form $E[u(0,X(0)) - u(0,\overline{X}(0))]$ in the error expansion in (2.6).

Lemma 2.2 is combined with stochastic flows to derive the a posteriori error expansion in Theorem 2.2 below. This error expansion is based on variations of the processes X and $\overline{X}$. The proof of Theorem 2.2 uses mainly the fact that the error in replacing $g(X(T))$ in Lemma 2.2 by $g(\overline{X}(T))$, in the representation (2.4) of $\partial_\alpha u$, yields the small deterministic remainder term $\int_0^T \mathcal{O}\big((\Delta t)^2\big)dt$ in (2.7) of Theorem 2.2, which is analogous to the $\mathcal{O}(N^{-2})$ term in Talay and Tubaro's expansion, [53], and needs some a priori estimate to be controlled. Lemma 2.2 can be applied to estimate this error. The second important ingredient in the proof is the Markov property of $\overline{X}$ satisfied at the discrete times t_n. Based on the fact that $\overline{X}(t_n)$ is $\mathcal{F}_{t_n}$ measurable, the nested expected values

$$E\big[a_j(t_n, \overline{X}(t_n))\partial_{x_j(t_n)} E[g(\overline{X}(T)) \mid \mathcal{F}_{t_n}]\big]$$

in (2.6) can, by the definition of φ and its implication (6.25), be decoupled to

$$E\big[a_j(t_n, \overline{X}(t_n))\varphi_j(t_n)\big],$$

which reduces the computational complexity substantially; see Lemma 6.3.

THEOREM 2.2 (first error expansion). *Suppose that a, b, g, X, and $\overline{X}$ satisfy the assumptions in Lemma* 2.2. *Then the time discretization error in* (1.9) *has the expansion*

(2.7)
$$\mathcal{E}_T = E\left[\sum_{m=0}^{N-1} \rho(\tilde{t}_m, \omega)(\Delta\tilde{t}_m)^2\right] + E\left[\sum_{m=0}^{N-1} (\Delta\tilde{t}_m)^2 \left\{\mathcal{O}(\Delta\tilde{t}_m) + \sum_{k=m}^{N-1} \mathcal{O}((\Delta\tilde{t}_k)^2)\right\}\right],$$

where the leading order error term is in computable a posteriori form:

(2.8)
$$\begin{aligned}\rho(\tilde{t}_m, \omega) \equiv{}& \frac{1}{2}\sum_{n\in\mathcal{J}_m} \big[\big(a_i(t_{n+1}, \overline{X}(t_{n+1}^-, \omega)) - a_i(t_n, \overline{X}(t_n, \omega))\big)\varphi_i(t_{n+1}^-, \omega)\big]\frac{\Delta t_n}{(\Delta\tilde{t}_m)^2}\\ &+ \frac{1}{2}\sum_{n\in\mathcal{J}_m} \big[\big(d_{ik}(t_{n+1}, \overline{X}(t_{n+1}^-, \omega)) - d_{ik}(t_n, \overline{X}(t_n, \omega))\big)\varphi'_{ik}(t_{n+1}^-, \omega)\big]\frac{\Delta t_n}{(\Delta\tilde{t}_m)^2}\end{aligned}$$

with $\mathcal{J}_m \equiv \{n : \tilde{t}_m \le t_n < \tilde{t}_{m+1}\}$, $m = 0, \ldots, N-1$, and the discrete dual functions $\varphi(t_n) \in \mathbb{R}^d$ and $\varphi'(t_n) \in \mathbb{R}^{d\times d}$ defined in (1.13) *and* (1.14), *respectively.*

Remark 2.3. When implementing a deterministic time stepping algorithm based on this result the expectation of the sum of errors in (2.7) is approximated by the mean of the errors along the M simulated trajectories, i.e.,

$$E\left[\sum_{m=0}^{N-1} \rho(\tilde{t}_m, \omega)(\Delta\tilde{t}_m)^2\right] \approx \frac{1}{M}\sum_{j=1}^{M}\sum_{m=0}^{N-1} \rho(\tilde{t}_m, \omega_j)(\Delta\tilde{t}_m)^2.$$

The statistical error of this approximation can be expressed as

$$E\left[\sum_{m=0}^{N-1} \rho(\tilde{t}_m, \omega)(\Delta\tilde{t}_m)^2\right] - \frac{1}{M}\sum_{j=1}^{M}\sum_{m=0}^{N-1} \rho(\tilde{t}_m, \omega_j)(\Delta\tilde{t}_m)^2 = \int_0^T (I_M + J_M)dt,$$

where the distributions of the statistical errors $\sqrt{M}I_M$ and $\sqrt{M}J_M$ weakly converge to normal distributions with mean zero and time interval–dependent variances given

by

$$\mathrm{Var}\left[\sum_{n\in\mathcal{J}_m}\left(a_i(t_{n+1},\overline{X}(t_{n+1}^-))-a_i(t_n,\overline{X}(t_n))\right)\varphi_i(t_{n+1}^-)\right]=\mathcal{O}(\Delta\tilde{t}_m)$$

and

$$\mathrm{Var}\left[\sum_{n\in\mathcal{J}_m}\left(d_{ik}(t_{n+1},\overline{X}(t_{n+1}^-))-d_{ik}(t_n,\overline{X}(t_n))\right)\varphi'_{ik}(t_{n+1}^-)\right]=\mathcal{O}(\Delta\tilde{t}_m),$$

respectively. Observe that the number of realizations to determine a reliable error estimate is in general TOL^{-1}, much smaller than the—proportional to TOL^{-2}—number of realizations to approximate $E[g(X(T))]$. For more details on this and the statistical approximation of the error density ρ see Remark 2.7 in [51].

3. A second estimate of the time discretization error. In this section we present in Theorem 3.1 an error expansion in a posteriori computable form for the time discretization error $\mathcal{E}_T$ in (1.9) based on the dual functions and its first and second derivatives φ, φ', and φ''. The analysis uses the Malliavin derivative, $\partial_{W(t)}Y$, which is the first variation of a process Y with respect to a perturbation $dW(t)$, at time t of the Wiener process; cf. [46]. As we will see, although computationally more expensive than the expansion in Theorem 2.2, it gives a more precise estimation of the error, measured through its variance.

We shall restrict the analysis to time steps which are constructed by first sampling the jump times to augment an a priori given time discretization $\Delta\tilde{t}$, obtaining $\Delta t[0]$ (see (3.3)). Using the refinement criterion

$$|\rho(t,\omega)|\big(\Delta t(t)\big)^2<\text{constant},\tag{3.1}$$

we construct the partition $\Delta t(t)$ that satisfies

$$\Delta t(t)=\Delta t[0](t)/2^n\ \text{ for some natural number } n=n(t,\omega),$$

with an approximate error density function ρ, satisfying for $s,t\in[0,T]$ and all outcomes ω the uniform upper and lower bounds

$$\begin{aligned}\rho_{low}(\mathrm{TOL})\le|\rho(s,\omega)|\le\rho_{up}(\mathrm{TOL}),\\ |\partial_{W(t)}\rho(s,\omega)|\le\rho_{up}(\mathrm{TOL}).\end{aligned}\tag{3.2}$$

Here ρ_{low} and ρ_{up} are positive functions with $\mathrm{TOL}/\rho_{low}(\mathrm{TOL})\to 0$ as $\mathrm{TOL}\to 0$. For each realization successive subdivisions of the steps yield the largest time steps satisfying (3.1). The corresponding stochastic increments ΔW will have the correct distribution, with the necessary independence, if the increments ΔW related to the new steps are generated by Brownian bridges [30], i.e., the time steps are generated by conditional expected values of the Wiener process.

Let δ be a constant approximating $\frac{\mathrm{TOL}}{E[N]}$, where $E[N]$ is the expected number of steps. The analysis in this section with adaptive nonadapted time steps, satisfying (3.1)–(3.2), is based on the *stochastic time stepping algorithm* described below.

In what follows, Lemma 3.1 and Theorem 3.1 show that although the steps generated by (3.1)–(3.2) are not adapted, the method indeed converges to the correct limit, which is the same as the limit of the forward Euler method with adapted time steps.

LEMMA 3.1 (strong convergence). *Suppose that a, b, c, g, X satisfy the assumptions in Lemma 2.2, that $\overline{X}$ is constructed by the forward Euler method, based on the stochastic time stepping algorithm above, with step sizes Δt_n satisfying (3.1)–(3.2), and that their corresponding ΔW_n are generated by Brownian bridges. Then*

$$\sup_{0\le t\le T}\sqrt{E[|X(t)-\overline{X}(t)|^2]} = \mathcal{O}\left(\sqrt{\Delta t_{\sup}}\right) = \mathcal{O}\left(\sqrt{\frac{\mathrm{TOL}}{\rho_{low}(\mathrm{TOL})}}\right) \to 0$$

as TOL $\to 0$, *where* $\Delta t_{\sup} \equiv \sup_{n,\omega} \Delta t_n(\omega)$.

STOCHASTIC TIME STEPPING ALGORITHM.

Do for M realizations $\omega_j,\ j = 1, \dots, M$:

Sample jump times: $0 < \tau_1(\omega_j) < \cdots < \tau_{\nu(\omega_j)}(\omega_j) < T$.

Consider the initial augmented partition given by the union

$$\Delta t[0] = \{t_n(\omega_j)\}_{n=0}^{\kappa(\omega_j)} = \{\tilde{t}_n\}_{n=0}^{N} \cup \{\tau_n(\omega_j)\}_{n=0}^{\nu(\omega_j)} \tag{3.3}$$

that has $\kappa(\omega_j) = N + \nu(\omega_j)$ (a.s.) time steps.

`STEP 1`: Set $k = 0$. Start with the initial coarse mesh $\Delta t[0]$ and compute $\Delta W[0]$.

`STEP 2`: For the piecewise constant mesh function $\Delta t[k]$ with corresponding noise $\Delta W[k]$, compute $\overline{X}[k]$ and the weight function $\rho[k]$ defined in (3.4)–(3.5).

`STEP 3`: Define $r(t) \equiv |\rho[k](t)|(\Delta t[k](t))^2$ and let for all t

$$\Delta t[k+1](t) = \begin{cases} \Delta t[k](t) & \text{if } r(t) < \delta, \quad (\dagger) \\ \Delta t[k](t)/2 & \text{if } r(t) \ge \delta, \quad (\star) \end{cases}$$

and in the refinement case $(\star)$ construct $\Delta W[k+1]$ by Brownian bridges based on the already known $\Delta W[k]$.

`STEP 4`: **If** at least one step of $\Delta t[k]$ is refined by $(\star)$, increment k by 1 and **goto** Step 2. **Else** all steps of $\Delta t[k]$ satisfy $(\dagger)$; thus accept the approximation $g(\overline{X}(T, \omega_j))$ and **goto** the next realization of p and W.

Enddo

If the statistical error, $E[g(\overline{X}(T))] - \frac{1}{M}\sum_{j=1}^{M} g(\overline{X}(T, \omega_j))$, is sufficiently small **stop**, **else** restart with a larger M.

Endif

For a detailed description of the stochastic time stepping algorithm see section 4.4.

Proof of Lemma 3.1. The proof relies on the two-step simulation scheme that we construct and on the fact that the jump nodes do not contribute to the global error. Observe that $\mathcal{F}^J$ is the σ-algebra generated by the jumps and marks constructed in section 1.2.1. Consider the conditional expectation $E[|X(t) - \overline{X}(t)|^2 \mid \mathcal{F}^J]$ and apply Lemma 3.1 from [51], using also that there is no time discretization error at the jump nodes. ∎

In addition to the dual functions φ and φ' in Theorem 2.2, the new error expansion for stochastic time steps in Theorem 3.1 below also uses, for $t = t_{n+1}^-$, the discrete dual variation $\varphi''(t)$ defined in (1.16). It derives an error estimate applicable both to adaptive deterministic time steps and to the stochastic time stepping algorithm; the assumptions and the proof of the theorem focus on stochastic steps; however, a modification to deterministic time steps is straightforward. The computable error density $\tilde{\rho}$ of this error estimate can then be cut off for small and large values to satisfy (3.2). This truncation procedure is explained in formulas (4.6) and (4.15).

THEOREM 3.1 (second error expansion). *Suppose that the functions a, b, c, g, and the process X satisfy the assumptions in Lemma 2.2 with $X(0)$ deterministic. Let $\overline{X}$ be constructed by the forward Euler method with step sizes Δt_n satisfying (3.1)–(3.2) and let the corresponding ΔW_n be generated by Brownian bridges, following the stochastic time stepping algorithm in Lemma 3.1. Then the time discretization error defined in (1.9) has the following expansion, based on both the drift and diffusion fluxes and the discrete dual functions φ, φ', and φ'' given in (1.13)–(1.16), with computable leading order terms:*

(3.4)
$$\mathcal{E}_T = E\left[\sum_{n=0}^{\kappa-1} \tilde{\rho}(t_n,\omega)(\Delta t_n)^2\right] + \mathcal{O}\left(\Big(\frac{\mathrm{TOL}}{\rho_{low}(\mathrm{TOL})}\Big)^{1/2}\Big(\frac{\rho_{up}(\mathrm{TOL})}{\rho_{low}(\mathrm{TOL})}\Big)^{\epsilon}\right) E\left[\sum_{n=0}^{\kappa-1}(\Delta t_n)^2\right],$$

for any $\epsilon > 0$ and where

$$\begin{aligned}\tilde{\rho}(t_n,\omega) \equiv \frac{1}{2}\Big(&\big(\partial_t a_k + \partial_j a_k a_j + \partial_{ij} a_k d_{ij}\big)\varphi_k(t_{n+1}^-)\\ &+ \big(\partial_t d_{km} + \partial_j d_{km} a_j + \partial_{ij} d_{km} d_{ij} + 2\partial_j a_k d_{jm}\big)\varphi'_{km}(t_{n+1}^-)\\ &+ \big(2\partial_j d_{km} d_{jr}\big)\varphi''_{kmr}(t_{n+1}^-)\Big)\end{aligned} \tag{3.5}$$

and the terms in the sum of (3.5) are evaluated at the a posteriori known points $(t_n, \overline{X}(t_n))$, i.e.,

$$\partial_\alpha a \equiv \partial_\alpha a(t_n, \overline{X}(t_n)), \quad \partial_\alpha b \equiv \partial_\alpha b(t_n, \overline{X}(t_n)), \quad \partial_\alpha d \equiv \partial_\alpha d(t_n, \overline{X}(t_n)).$$

Observe that the constant in $\mathcal{O}$ that appears in (3.4) may not be uniform with respect to the value ϵ. Thus, in practice one chooses $\epsilon = \epsilon(\mathrm{TOL})$ to minimize the contribution of the remainder term to the error expansion (3.4).

4. Adaptive time stepping algorithms. Here, we describe two adaptive time stepping algorithms for the weak approximation problem based on the approximation error formula (3.4). They are very similar to those introduced in [45]. Algorithm D augments a mesh that is the same for all realizations with jump times that are sampled differently for each realization; its adaptive strategy is based on averaged information from the a posteriori error formula. On the other hand, Algorithm S can adapt the mesh differently for each realization. Both adaptive algorithms choose adaptively the number of realizations and the size of time steps to efficiently bound the approximation error by a prescribed error tolerance.

4.1. Computational error splitting. As we described in section 1.3 the weak approximation computational error $\mathcal{E}$ of the jump augmented Euler–Maruyama scheme naturally splits into time discretization and statistical errors, namely, $\mathcal{E} = \mathcal{E}_T + \mathcal{E}_S$. Thus, the control of the computational error is related to the combined control of the time discretization error via the choice of the time steps Δt, and of the statistical error via the choice of the number M of realizations. Therefore, we split a given computational error tolerance, $\mathrm{TOL} > 0$, into a statistical error tolerance TOL_S and a time discretization error tolerance TOL_T (see [51], [45]) by

$$\mathrm{TOL}_T = \frac{1}{3}\,\mathrm{TOL} \quad \text{and} \quad \mathrm{TOL}_S = \frac{2}{3}\mathrm{TOL}. \tag{4.1}$$

4.2. Control of the statistical error. For M independent samples $\{Y(\omega_j)\}_{j=1}^M$ of a random variable Y, with $E\left[\,|Y|^6\,\right] < \infty$, define the sample average by

$$\mathcal{A}(Y;M) \equiv \frac{1}{M}\sum_{j=1}^{M} Y(\omega_j)$$

and the sample standard deviation by

$$\mathcal{S}(Y;M) \equiv \left\{\mathcal{A}(Y^2;M) - (\mathcal{A}(Y;M))^2\right\}^{\frac{1}{2}}.$$

Let $\sigma_Y \equiv \left\{E\left[\left|Y - E[Y]\right|^2\right]\right\}^{\frac{1}{2}}$ and $Z_M \equiv \frac{\sqrt{M}}{\sigma_Y}\left(\mathcal{A}(Y;M) - E[Y]\right)$ with cumulative distribution function $F_{Z_M}(x) \equiv P(Z_M \le x),\ x \in \mathbb{R}$. Let $\gamma \equiv (E[|Y - E[Y]|^3])^{1/3}/\sigma_Y < \infty$. The Berry–Essen theorem [14] gives the following estimation in the central limit theorem:

$$\sup_{x\in\mathbb{R}} |F_{Z_M}(x) - \mathcal{N}(x)| \le \frac{3}{\sqrt{M}}\gamma^3$$

for the rate of convergence of F_{Z_M} to the distribution function $\mathcal{N}$ of a normal random variable with mean zero and variance one, i.e.,

$$\mathcal{N}(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}s^2\right) ds. \tag{4.2}$$

Provided M is sufficiently large, i.e., $M \gg 36\gamma^6$, the statistical error

$$\mathcal{E}_S(Y;M) \equiv E[Y] - \mathcal{A}(Y;M)$$

satisfies, by the Berry–Essen theorem, the probability approximation

$$P\left(\left[|\mathcal{E}_S(Y;M)| \le c_0\frac{\sigma_Y}{\sqrt{M}}\right]\right) \approx 2\mathcal{N}(c_0) - 1.$$

In practice choose some constant $c_0 \ge 1.65$, so the normal distribution satisfies $1 > 2\mathcal{N}(c_0) - 1 \ge 0.901$ and the event

$$|\mathcal{E}_S(Y;M)| \le \mathtt{E}_S(Y;M) \equiv c_0\ \frac{\mathcal{S}(Y;M)}{\sqrt{M}} \tag{4.3}$$

has probability close to one, which involves the additional step to approximate σ_Y by $\mathcal{S}(Y;M)$; cf. [18]. Thus, in the computations $\mathtt{E}_S(Y;M)$ is a good approximation of the statistical error $\mathcal{E}_S(Y;M)$.

For a given $\mathrm{TOL}_S > 0$, the goal is to find M such that $\mathtt{E}_S(Y;M) \le \mathrm{TOL}_S$. The following algorithm adaptively finds the number of realizations M to compute the sample average $\mathcal{A}(Y;M)$ as an approximation to $E[Y]$. With probability close to one, depending on c_0, the statistical error in the approximation is then bounded by TOL_S.

`routine Monte-Carlo`(TOL_S, M_0; EY)
Set the batch counter $m = 1$, $M[m] = M_0$ and $\mathtt{E}_S[m] = +\infty$.
Do while ($\mathtt{E}_S[m] > \mathrm{TOL}_S$)

(4.4)
Compute $M[m]$ new samples of Y, along with the sample average $EY \equiv \mathcal{A}(Y;M[m])$, the sample standard deviation $\mathcal{S}[m] \equiv \mathcal{S}(Y;M[m])$ and the statistical error estimation $\mathtt{E}_S[m+1] \equiv \mathtt{E}_S(Y,M[m])$. Compute $M[m+1]$ by `change_`M ($M[m]$, $\mathcal{S}[m]$, TOL_S; $M[m+1]$).
Increase m by 1.

end-do
`end of Monte-Carlo`

`routine change_`M $(M_{in}, \mathcal{S}_{in}, \mathrm{TOL}_S; M_{out})$

$$\begin{aligned} M^* &= \min\Big\{\text{integer part } \Big(\tfrac{c_0\,\mathcal{S}_{in}}{\mathrm{TOL}_S}\Big)^2,\ \mathrm{MCH}\times M_{in}\Big\},\\ n &= \text{integer part } (\log_2 M^*) + 1,\\ M_{out} &= 2^n. \end{aligned} \tag{4.5}$$

`end of change_`M

Here, M_0 is a given initial value for M, and $\mathrm{MCH} > 1$ is a positive integer parameter introduced to avoid a large new number of realizations in the next batch due to a possibly inaccurate sample standard deviation $\mathcal{S}[m]$. Indeed, $M[m+1]$ cannot be greater than $\mathrm{MCH}\times M[m]$.

4.3. Deterministic time stepping algorithm. Following closely [40] and [45], we present an adaptive algorithm based on the cut-off of the error density $\tilde{\rho}$ in (3.5) of Theorem 3.1 which is defined as

$$\rho_D^n \equiv \min\left(\max\left(\left|\frac{1}{(\Delta\tilde{t}_n)^2}\sum_{\ell\in\mathcal{J}_n}(\Delta t_\ell)^2\tilde{\rho}(t_\ell,\overline{X})\right|, \mathrm{TOL}^{\frac{1}{9}}\right), \mathrm{TOL}^{-1}\right), \quad n=1,\dots,N. \tag{4.6}$$

The error expansion in Theorem 3.1 motivates us to approximate the time discretization error by

$$|\mathcal{E}_T| \lesssim E\left[\sum_{n=1}^{N} r_n\right], \tag{4.7}$$

where the error indicator, r_n, is defined by

$$r_n \equiv \rho_D^n\,(\Delta\tilde{t}_n)^2, \quad n=1,\dots,N. \tag{4.8}$$

The main advantage of the deterministic time stepping algorithm over the stochastic time stepping algorithm is that the number M_T of realizations necessary to determine the optimal deterministic stepping scheme is considerably smaller than M, whereas, in the stochastic time stepping algorithm, a refinement of the partition is carried out in each one of the M trajectories, leading to a considerably larger amount of computational work.

As pointed out before, the error expansion derived in Theorem 3.1 is also valid with deterministic time steps. Therefore, we have some flexibility in the choice of error densities for the adaptive algorithm with deterministic time steps because we can also use the results from Theorem 2.2. There are some practical differences to mention. On the one hand, the variance of the averaged error density from (2.8) is $\mathcal{O}(\frac{1}{\Delta\tilde{t}_n M_T})$. This feature has been observed in [42] and [51], where a local filtering procedure was proposed to reduce the variance of the error density estimator. A positive feature of this error density is that it does not require the computation of the second variation, φ'', which may be computationally expensive for large d. On the other hand, the averaged error density from (3.5) has a much smaller variance $\mathcal{O}(\frac{1}{M_T})$

which does not need filtering but requires the computation of φ''. In this work, based on the comments above and on previous experience (mainly [51]), we do not discuss further this choice and only show numerical results with adaptive deterministic time steps based on the error density (3.5).

The approximation of the time discretization error in the right-hand side of (4.7) can be separated into two parts,

$$E\left[\sum_{n=1}^{N} r_n\right] \leq \mathcal{A}\left(\sum_{n=1}^{N} r_n; M_T\right) + \left|E\left[\sum_{n=1}^{N} r_n\right] - \mathcal{A}\left(\sum_{n=1}^{N} r_n; M_T\right)\right|, \tag{4.9}$$

where the second error term in the right-hand side of (4.9) is with probability close to one asymptotically bounded by

$$\left|E\left[\sum_{n=1}^{N} r_n\right] - \mathcal{A}\left(\sum_{n=1}^{N} r_n; M_T\right)\right| \lesssim \ \mathtt{E}_{TS} \ \equiv c_0 \frac{\mathcal{S}\left(\sum_{n=1}^{N} r_n; M_T\right)}{\sqrt{M_T}} \tag{4.10}$$

and the first term defines $\mathtt{E}_{TT} \equiv \mathcal{A}(\sum_{n=1}^{N} r_n; M_T)$. Then for a given $\mathrm{TOL}_T > 0$, the goal is to construct a partition $\Delta\tilde{t}$ of $[0,T]$ with as few time steps and realizations M_T as possible, such that $\mathtt{E}_{TT} + \mathtt{E}_{TS} \leq \mathrm{TOL}_T$. To this end, first split the time discretization tolerance TOL_T into two positive parts, TOL_{TT} and TOL_{TS} for $\mathtt{E}_{TT}$ and $\mathtt{E}_{TS}$, respectively. The statistical error of the time discretization using the density (4.6) is $\mathcal{O}(\frac{\Delta t_{\sup}}{\sqrt{M_T}})$. Therefore the percentage of the tolerance, TOL, devoted to the control of the statistical time discretization error can be arbitrary small as $\Delta t_{\sup} \to 0$. In practice we choose

$$\mathrm{TOL}_{TT} = \frac{2}{3}\mathrm{TOL}_T = \frac{2}{9}\mathrm{TOL}, \qquad \mathrm{TOL}_{TS} = \frac{1}{3}\mathrm{TOL}_T = \frac{1}{9}\mathrm{TOL}. \tag{4.11}$$

The control of the statistical time discretization error determines the number of realizations M_T necessary to ensure a reliable choice of the time discretization in the deterministic time stepping algorithm. Similarly as in [45], here it is optimal to equidistribute the error contributions from different time intervals. Thus, the goal of the adaptive algorithm described below is to construct a deterministic time partition $\Delta\tilde{t}$ of $[0,T]$ such that

$$\bar{r}_n \equiv \mathcal{A}(r_n; M_T) \leq d_1 \frac{\mathrm{TOL}_{TT}}{N}, \quad n = 1, \ldots, N, \tag{4.12}$$

where $d_1 = 2$; see [45, Remark 3.9].

To achieve (4.12), start with an initial partition $\Delta\tilde{t}[1]$ and then specify iteratively a new partition $\Delta\tilde{t}[k+1]$, from $\Delta\tilde{t}[k]$, using the refinement strategy

for $n = 1, 2, \ldots, N[k]$
if $\bar{r}_n[k] \geq d_1 \frac{\mathrm{TOL}_{TT}}{N[k]}$, **then** divide $\Delta\tilde{t}_n[k]$ into 2 uniform substeps. (4.13)
else let the new step be the same as the old
endif
endfor

until the following stopping criteria is satisfied:

$$\textbf{if } \left(\max_{1 \leq n \leq N[k]} \bar{r}_n[k] < D_1 \frac{\mathrm{TOL}_{TT}}{N[k]}\right) \textbf{ then stop.} \tag{4.14}$$

Here D_1 is a given constant satisfying $D_1 > \frac{2}{\hat{c}} d_1$, where $\hat{c} \approx 1/2$; see [45]. The combination of (4.9) and (4.14) asymptotically guarantees a given level of accuracy, $\mathtt{E}_{TT} < D_1 \mathrm{TOL}_{TT}$. The positive number D_1 is introduced to avoid slow convergence in case almost all $\bar{r}_n$ satisfy (4.14), as in section 4.4.

Now we are ready for the detailed definition of the adaptive algorithm with deterministic steps.

ALGORITHM D.

Initialization Choose:

1. an error tolerance, $\mathrm{TOL} \equiv \mathrm{TOL}_S + \mathrm{TOL}_{TT} + \mathrm{TOL}_{TS}$,
2. a number $N[1]$ of initial uniform steps $\Delta\tilde{t}[1]$ for $[0, T]$,
3. a number $M[1]$ of initial realizations and set $M_T[1] = M[1]$,
4. a number $d_1 = 2$ in (4.13) and $\hat{c} = 1/2 + 1/20$ to compute D_1 using $D_1 > \frac{2}{\hat{c}} d_1$,
5. a constant $c_0 \geq 1.65$ and an integer $\mathrm{MCH} \geq 2$ to determine the number of realizations in (4.5), and
6. a constant $\epsilon = 1/2$ used to control the statistical error in the time discretization error estimate.

Set the iteration counter, k, for time refinement levels, to 1 and set the statistical error, $\mathtt{E}_{TS} = +\infty$ and $\bar{r}[k] = +\infty$.

Do while ($\bar{r}[k]$ violates the stopping criterion (4.14) or $\mathtt{E}_{TS} > \mathrm{TOL}_{TS}$)

Compute the sample averages and the error estimates on $\Delta\tilde{t}[k]$
by calling `Euler`. Set $M_T[k+1] = M_T[k]$ and $\Delta\tilde{t}[k+1] = \Delta\tilde{t}[k]$.

Set $\widetilde{\mathrm{TOL}}_{TS,\epsilon} = \max(\mathrm{TOL}_{TS}, \epsilon\, \mathtt{E}_{TT})$.

If $(\mathtt{E}_{TS} > \widetilde{\mathrm{TOL}}_{TS,\epsilon})$

Update $M_T[k+1]$ by `change_M` $(M_T[k], \mathcal{S}_{TS}[k], \widetilde{\mathrm{TOL}}_{TS,\epsilon}; M_T[k+1])$.

elseif ($\bar{r}[k]$ violates the stopping criterion (4.14))

For all time steps $i = 1, \ldots, N[k]$, do the refinement process (4.13)
to update $\Delta\tilde{t}[k+1]$ from $\Delta\tilde{t}[k]$.

end-if

Increase k by 1.

end-do

Compute an approximation, Eg, for $E[g(\overline{X}(T))]$ with fixed time mesh $\Delta\tilde{t} = \Delta\tilde{t}[k]$ by `Monte-Carlo`$(\mathrm{TOL}_S,\ M_T[k];\ Eg)$ in (4.4).

Accept Eg as an approximation of $E[g(X(T))]$, since the estimate of the computational error is bounded by TOL.

`routine Euler`

For each $M_{\tau}[k]$ new realizations, sample jump times with their corresponding marks.

As described in section 1.2, use $\Delta\tilde{t}[k]$ to compute corresponding realizations of the Euler method.

Update the approximations of the time discretization error indicators $\bar{r}[k]$ and the statistical time discretization error $\mathtt{E}_{TS}[k]$ and compute the sample standard deviation $\mathcal{S}_{TS}[k] \equiv \mathcal{S}(g(\overline{X}(T)); M_T[k])$.

`end of Euler`

4.4. The stochastic time stepping algorithm. Now we describe an adaptive algorithm with stochastic time steps based on a cut-off of the error density $\tilde{\rho}$ introduced in (3.5) of Theorem 3.1, ρ_s, defined as

$$\rho_s^n \equiv \min\left(\max\left(|\tilde{\rho}(t_n, \overline{X})|, \mathrm{TOL}^{\frac{1}{9}}\right), \mathrm{TOL}^{-1}\right), \quad n = 1, \ldots, \kappa. \tag{4.15}$$

Following the error expansion in Theorem 3.1, the time discretization error is approximated by

$$|\mathcal{E}_T| \lesssim E\left[\sum_{n=1}^{\kappa} r_n\right], \tag{4.16}$$

where the error indicator, r_n, is defined by

$$r_n \equiv \rho_S^n \left(\Delta t_n\right)^2, \quad n = 1, \ldots, \kappa. \tag{4.17}$$

In this case it is optimal (cf. [45]) to equidistribute the error contributions among all time steps and all realizations. In other words, the goal of the adaptive algorithm is to construct a time partition Δt of $[0, T]$ for each realization such that

$$r_n \leq s_1 \frac{\mathrm{TOL}_T}{E[\kappa]}, \quad n = 1, \ldots, \kappa, \tag{4.18}$$

where $s_1 = 2$; see Remark 3.1 in [45]. Note that in practice the quantity $E[\kappa]$ is not known and we can only estimate it by a sample average $\mathcal{A}(\kappa; M)$ from the previous batch of realizations. The statistical error $|E[\kappa] - \mathcal{A}(\kappa; M)|$ is then bounded by $\mathtt{E}_S(\kappa; M)$, with probability close to one, by the same argument as in (4.3).

Let $\bar{\kappa}[j] \equiv \mathcal{A}(\kappa; M[j])$ be the sample average of the final number of time steps in the jth batch of $M[j]$ realizations. To achieve (4.18) for each realization, start with an initial partition $\Delta t[1]$ and then specify iteratively a new partition $\Delta t[k+1]$, from $\Delta t[k]$, using the following refinement strategy:

for each realization in the jth batch
for each time step $n = 1, \ldots, \kappa[k]$
if $r_n[k] \geq s_1 \frac{\mathrm{TOL}_T}{\bar{\kappa}[j-1]}$, **then** divide $\Delta t_n[k]$ into 2 uniform substeps.
else let the new step be the same as the old
endif
endfor
endfor (4.19)

The refinement strategy (4.19) motivates the following stopping criteria: for each realization of the jth batch

$$\textbf{if } \left(\max_{1 \leq n \leq \kappa[k]} r_n[k] < S_1 \frac{\mathrm{TOL}_T}{\bar{\kappa}[j-1]}\right) \quad \textbf{then} \quad \text{stop}, \tag{4.20}$$

where $S_1 > \frac{2}{\hat{c}}\, s_1$ with $\hat{c} \approx \frac{1}{2}$; see [45].

Now we are ready for the detailed definition of the adaptive algorithm with stochastic steps.

ALGORITHM S.

Initialization Choose:

1. an error tolerance, $\mathrm{TOL} \equiv \mathrm{TOL}_S + \mathrm{TOL}_T$,
2. a number $N[1]$ of initial uniform steps $\Delta t[1]$ for $[0, T]$ and set $\bar{\kappa} = N[1]$,
3. a number $M[1]$ of initial realizations,
4. a number $s_1 = 2$ in (4.19) and $\hat{c} = \frac{1}{2} + \frac{1}{20}$ to compute S_1 using $S_1 > \frac{2}{\hat{c}}\, s_1$, and

5. a constant $c_0 \geq 1.65$ and an integer MCH≥ 2 to determine the number of realizations in (4.5).

Set the iteration counter for batches $m = 1$ and the stochastic error $\mathtt{E}_S[m] = +\infty$.
Do while ($\mathtt{E}_S[m] > \mathrm{TOL}_S$)
  For realizations $j = 1, \ldots, M[m]$
    Set $k = 1$ and $r[k] = +\infty$.
    Generate the jump times and their marks $(\tau, Z) = \{(\tau_\ell, Z_\ell)\}_{\ell=1}^{\nu}$.
    Start with the initial partition $\Delta t[k]$ and generate $\Delta W[k]$.
    Compute $g(\overline{X}(T))[J]$ and $N[J]$ by `routine Control-Time-Error`.
  end-for
  Compute the sample average $Eg \equiv \mathcal{A}\left(g(\overline{X}(T)); M[m]\right)$, the sample standard deviation $\mathcal{S}[m] \equiv \mathcal{S}(g(\overline{X}(T)); M[m])$ and the a posteriori bound for the statistical error $\mathtt{E}_S[m] \equiv \mathtt{E}_S(g(\overline{X}(T)), M[m])$ in (4.3).
  if ($\mathtt{E}_S[m] > \mathrm{TOL}_S$)
    Compute $M[m+1]$ by `change_`$M(M[m], \mathcal{S}[m], \mathrm{TOL}_S; M[m+1])$, (see (4.5)) and update $\bar{\kappa} = \mathcal{A}(\kappa[J]; M[m])$, where the random variable $\kappa[J]$ is the final number of time steps on each realization.
  end-if
  Increase m by 1.
end-do
Accept Eg as an approximation of $E[g(X(T))]$, since the estimate of the computational error is bounded by TOL.

`routine Control-Time-Error`$(\Delta t[k], \Delta W[k], r[k], (\tau, Z); g(\overline{X}(T))[J], N[J])$
  Do while ($r[k]$ violates the stopping criterion (4.20))
    Compute the Euler approximation $\overline{X}[k]$ in section 1.2 and the error indicator $r[k]$ in (4.8) using the error density (4.15) on $\Delta t[k]$ with the known Wiener increments $\Delta W[k]$.
    If ($r[k]$ violates the stopping criterion (4.20))
      For time steps $i = 1, \ldots, N[k]$
        Do the refinement process (4.19) to compute $\Delta t[k+1]$ from $\Delta t[k]$ and compute $\Delta W[k+1]$ from $\Delta W[k]$ using Brownian bridges.
      end-for
    end-if
    Increase k by 1.
  end-do
  Set the number of the final level $J = k - 1$.
`end of Control-Time-Error`

Remark 4.1 (computational limitations of the jump augmented Euler scheme). Since the Euler method has weak order one, the number of discretization points needed to control the time discretization error is $\mathcal{O}(1/\mathrm{TOL})$. Therefore, as long as the product $\Lambda(T)\mathrm{TOL} \ll 1$, we can still use the jump augmented Euler method to solve the weak approximation problem with an amount of computational work that is similar to that required to solve the same problem without jumps. We still find it important to emphasize that our error approximation theory does not rely on the assumption $\Lambda(T)\mathrm{TOL} \ll 1$; the key point is that it may become too costly to apply it if this condition does not hold. Indeed, if $\Lambda(T)\mathrm{TOL} \approx 1$ (or larger), one can suggest (for overall computational efficiency reasons) using another time discretization which does not include jump times in the computational grid, for instance, one related to those discussed in [22] and [33].

5. Numerical experiments. This section shows numerical results from the implementation of the a posteriori error approximation formula presented in section 2 and of the adaptive algorithms described in section 4. Our implementation uses double-precision FORTRAN 77 and is an extension of the code written for the numerical experiments in [51]. For the numerical simulation of the uniform distribution $\mathcal{U}(0,1)$ and the normal distribution $\mathcal{N}(0,1)$, we implemented a double-precision modification of the functions `ran1` and `gasdev` proposed in [48], with a user-provided initial seed which must be a negative integer. In particular, we use three different seeds for the independent sources of randomness in our equations, namely, `iseed` for the simulation of the Wiener process increments, `zseed` for the simulation of the jump marks, and `tseed` for the simulation of the jump times.

Example 1. Consider the stochastic differential equation (1.1) with $d = 2$, $\ell_0 = \ell_1 = 1$,

$$a(t,x) = \left(-x_2,\, x_1 + \frac{1}{2}\,\lambda(t)\,x_2 \right), \quad b^1(t,x) = \left(\sqrt{\frac{\lambda(t)}{1+t}}\,\sin(x_1),\, 0 \right),$$
$$c(t,x,z) = \left(0,\, z\,\frac{\cos(x_1)}{\sqrt{t+1}} - x_2 \right)$$

and a time-dependent intensity $\lambda(t) = (1+t)^{-1}$. The distribution for the jump marks is time dependent and such that $E[Z_k^2] = 1$. In particular, we use $Z_k = \cos(2\pi\tau_k) + \sin(2\pi\tau_k)\,2\sqrt{3}\,(U_k - \frac{1}{2})$, where $\{\tau_k\}$ are the jumps constructed in section 1.2.1 and $\{U_k\}$ is a sequence of $\mathcal{U}(0,1)$ i.i.d. random variables. In this case, the inverse function Λ^{-1} is given explicitly by $\Lambda^{-1}(s) = \exp(s) - 1$. This example is a generalization of Example 5.1 in [33]. Here, we have both time-dependent jump intensity and mark distribution for the underlying Poisson process. Taking $g(x) = |x|^2$, $T = 1$, and $X(0) = (0,0)$, the exact solution of the corresponding weak approximation problem is given by the formula

$$E\big[g(X(T))\big] = |X(0)|^2 + \int_0^T \frac{\lambda(s)}{1+s}\,ds = 1 - \frac{1}{1+T} = \frac{1}{2}.$$

The value of the parameters needed in the simulations are MCH $= 10$, $c_0 = 1.65$, `iseed` $= -7$, `zseed` $= -101$, and `tseed` $= -20$. We note that the expected value of the number of jump points equals $\Lambda(T) = \Lambda(1) = \log(2) \approx 0.693$. Therefore, the computational cost of including the jump times of the process X in our discretization is fairly low; see the statistic for the sampled number of jumps, ν. In fact, the extra work to simulate the exact jump times of the process is asymptotically negligible as the required accuracy, TOL, tends to zero.

Deterministic time stepping algorithm. First, we perform overkilling runs in order to test how realistic the a posteriori error approximation of the time discretization error described in Theorem 2.2 is. The results, shown in Table 5.1, confirm that the ratio of the computational error and its computable approximation tends to 1 as the number of uniform time steps N increases. For each value of N, we choose the number of realizations M large enough in order to keep the total statistical error at the level of 1% of the size of the obtained approximation of the time discretization error. Then Table 5.2 contains the results of the Algorithm D with an adaptive choice of both the deterministic time steps and the number of realizations. The program starts with $M = 100$ and $N = 5$ subintervals as an initial uniform partition of the time interval $[0,T] = [0,1]$. The tolerance TOL $= 0.02$ is divided into $\text{TOL}_S = 0.01333$,

Adaptive choice of M and Δt with Algorithm D when $\mathrm{TOL} = 0.02$ *in Example* 1.

Iter.	N	M	$\mathcal{E}$	$\mathtt{E}_{TT}$	$\mathtt{E}_{TS}$	$\mathtt{E}_S$
1	5	100	-2.66×10^{-2}	-5.22×10^{-2}	1.82×10^{-2}	1.44×10^{-1}
2	10	100	-9.19×10^{-3}	-2.48×10^{-2}	8.74×10^{-3}	1.35×10^{-1}
3	20	100	9.16×10^{-2}	-1.16×10^{-2}	4.25×10^{-3}	1.30×10^{-1}
4	20	1000	-1.78×10^{-2}	–	–	4.54×10^{-2}
5	20	10000	-1.77×10^{-2}	–	–	1.50×10^{-2}
6	20	14088	-1.29×10^{-2}	–	–	1.23×10^{-2}

$\mathrm{TOL}_T = 0.00444$, and $\mathrm{TOL}_{TS} = 0.00222$. When the algorithm stops, the size of the total approximation error is less than 2TOL according to the stopping criterion (4.14), and it agrees with the size of the computational error.

Stochastic time stepping algorithm. To observe the performance of the stochastic time steps Algorithm S, we apply it for different values of TOL, starting with a number of realizations $M = 100$ and a number of uniform time steps $N = 5$. Table 5.3 contains the obtained results which show that Algorithm S is also effective in giving us an approximation of the quantity of interest within the margin of 2TOL due to the criterion (4.14).

Example 2. The second example motivates the use of adaptivity by applying Algorithm D to a linear one-dimensional ($d = 1$) stochastic differential equation with time-dependent coefficients. It is interesting to observe that although here the evolution of X has many jumps, computing with Algorithm D based on jump augmented grids is still substantially more economical than doing the time stepping on a uniform mesh. The goal of the computation is given by the function $g(x) = x$, the initial condition $x_0 = 1$, and the final time $T = 1$. The coefficients of the equation have the form

$$a(t,x) = a(t)x, \quad b(t,x) = \frac{x}{\sqrt{2}}, \quad c(t,x,z) = c_* xz,$$

where $c_* > 0$ is a given constant defined below. The compensator of the jump measure is given by $q(dt,dz) = \lambda(t)\mu(dz)dt$, where $\mu(dz)$ is the uniform distribution in the interval $[-\sqrt{3},\sqrt{3}]$, and the jump intensity exhibits two different regimes,

$$\lambda(t) = \begin{cases} 0 & \text{if } 0 \le t \le 2/3, \\ 3N_J & \text{if } 2/3 < t \le 1, \end{cases}$$

with $N_J = 32^2 = 1024$. Thus, we expect in the mean $N_J = 1024$ jumps per realization. The time varying drift function is

$$a(t) = \begin{cases} 0 & \text{if } t < 1/3, \\ \frac{1}{2\sqrt{t-1/3+\mathrm{TOL}^4}} & \text{if } 1/3 \le t \le 1. \end{cases}$$

TABLE 5.3
Adaptive runs with Algorithm S corresponding to different required accuracies in Example 1.

TOL	M	$\mathcal{A}(\kappa;M)$	$[\kappa_{\min},\kappa_{\max}]$	$\mathcal{S}(\kappa;M)$	$\nu_{\max}$	E_S	$\mathcal{E}$
0.040	3.2×10^3	8.3	[5, 41]	5.2	6	0.0250	−0.002
0.020	12×10^3	10.9	[5, 73]	9.2	6	0.0130	−0.006
0.010	48×10^3	20.5	[10, 146]	16.9	6	0.0066	−0.010
0.005	186×10^3	30.1	[10, 193]	32.2	7	0.0033	−0.003

Finally, the constant that defines the jump amplitude is $c_* = 1/\sqrt{N_J}$. The exact solution of the corresponding weak approximation problem is

$$E[g(X(T))] = \exp\left(\int_0^T a(t)dt\right) = \exp\left(\sqrt{T - 1/3 + \mathrm{TOL}^4} - \mathrm{TOL}^2\right).$$

Due to the time discontinuity of the drift function and to ensure optimal convergence of the adaptive algorithms, we modify the diffusion step in the Euler method by

$$\overline{X}(t_{n+1}^-) - \overline{X}(t_n) = a(\hat{t}, \overline{X}_n)\Delta t_n + \overline{X}(t_n)\Delta W_n, \quad n = 0, \ldots, \kappa - 1,$$

where we choose the stochastic evaluation time $\hat{t} \in \{t_n, t_{n+1}\}$ by

$$|a(\hat{t}, \overline{X}_n)| = \max(|a(t_n, \overline{X}_n)|, |a(t_{n+1}^-, \overline{X}_n)|).$$

Observe that the use of $\hat{t}$ does not change the adapted nature of the Euler method. To illustrate the problem dynamics, Figure 5.1 shows three realizations of the approximate process, $\overline{X}$, and the backward dual function, $\varphi(t_n)$. The latter represents the pathwise sensitivity of $g(\overline{X}(T))$ with respect to perturbations in the initial data of X at time t_n. It coincides in this example with the first variation of $\overline{X}$, namely, $\overline{X}'(T;t_n)$. Figure 5.2 and Table 5.4 show information related to the adaptive runs for two values of the accuracy tolerance, starting in both cases with $M = 10^2$ realizations and $N = 10$ uniform time steps. In particular, Figure 5.2 shows the adaptive time steps needed to control the numerical error. Observe that these deterministic time steps are prior to the augmentation with the sampled jump times and are the ones we can choose to control the time discretization error. Figure 5.2 shows that although we may have more than a thousand time steps added in the interval $[2/3, 1]$ due to jump times, we still need to significantly refine our deterministic time steps near the singularity at $t = 1/3$. Table 5.4 shows information related to the computational effort necessary to solve the problem. There we can see that the amount of realizations needed to find our deterministic time steps, M_T, is much smaller than the amount needed to solve the problem, M. For instance, when $\mathrm{TOL} = 1.0 \times 10^{-2}$ we need only $M_T \approx M \times 10^{-3}$ realizations to control the time discretization error, making the adaptivity procedure completely inexpensive. Using the approximate error density we have also estimated the number of uniform time steps, N_U, needed to achieve the prescribed accuracy. Table 5.4 shows that N_U is approximately 100 times larger than the number of deterministic time steps, N. This fact motivates further the use of Algorithm D in this problem. Finally, we emphasize that the computational effort due to the augmentation of the time discretization with the jump times decreases as TOL decreases. Even in this case with $N_J = 1024$ jump times in the mean we

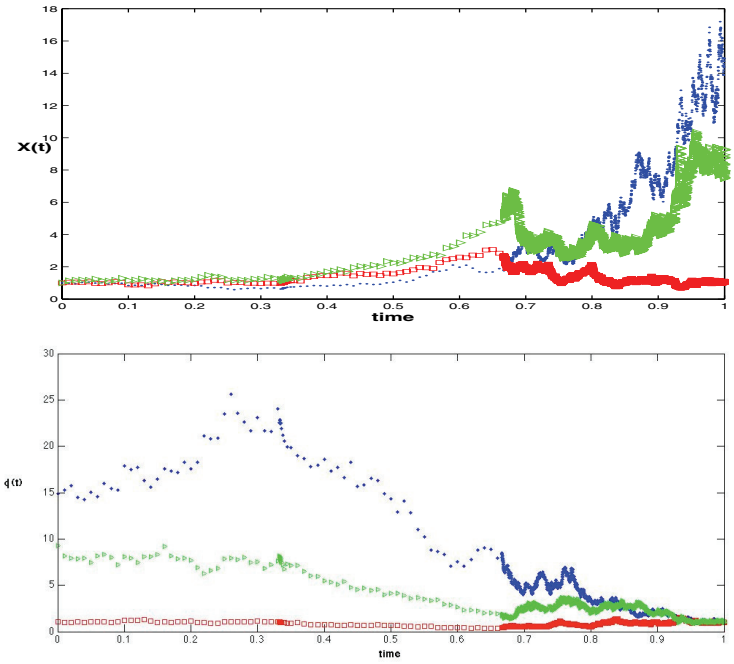

FIG. 5.1. *Three sample realizations of the processes* $\overline{X}$ *(above) and* φ *(below) obtained with modified Euler in Example* 2.

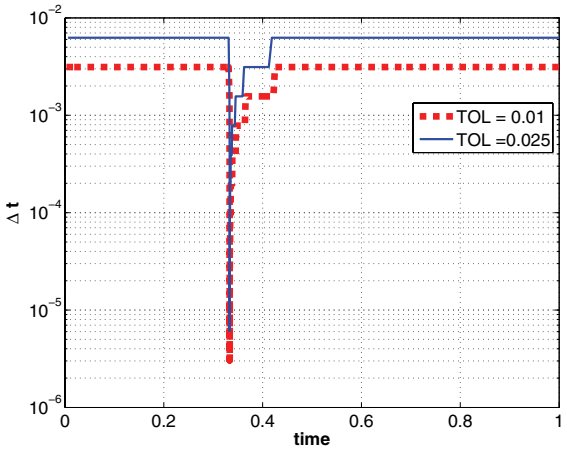

FIG. 5.2. *Final time discretizations (jumps not included) for the adaptive runs with Algorithm D and* $\mathrm{TOL} = 2.5 \times 10^{-2}$, $\mathrm{TOL} = 1 \times 10^{-2}$ *in Example* 2.

TABLE 5.4
Adaptive choice of M *and* Δt *with Algorithm D in Example* 2.

TOL	M	N	M_T	N_U	$\mathcal{E}$
2.5×10^{-2}	2.0×10^{5}	220	1.7×10^{3}	2×10^{4}	-2.0×10^{-2}
1.0×10^{-2}	1.45×10^{6}	450	1.7×10^{3}	6×10^{4}	-1.4×10^{-2}

anticipate that for a smaller value of TOL $\approx 10^{-3}$ the number of deterministic time steps needed to control the discretization error will be approximately 4 times larger than the mean number of jumps.

6. Proofs. This section contains the proofs postponed in the previous sections.

6.1. Proof of Lemma 2.1. The proof follows closely the proof of Corollary II.2.2 to Theorem II.2.6 (pp. 237–238 in [19]). The main two differences with this result are (i) our process has finite Lévy measure, while there a general Lévy measure is considered; (ii) our jump distribution depends on time, while there it does not. Theorem II.2.6 in [19] covers our case, and our regularity conditions on a and b are the same as in the mentioned corollary. Concerning the jumps, it is direct to see that (2.3) replaces the corresponding condition on the jump coefficient in Corollary II.2.2 in [19], following now the result from Theorem II.2.6 [19, p. 237]. The other minor difference consists of the compensation of the jump part of the differential equation (1.1). Defining

$$\alpha(t,x) = a(t,x) + \lambda(t)\int_{\mathbf{z}} c(t,x,z)\mu(t,dz),$$

we see that our equation can be written as

$$\begin{aligned} X(t) = X(0) &+ \int_0^t \alpha(\,s, X(s^-)\,)\,ds + \sum_{\ell=1}^{\ell_0}\int_0^t b^\ell(\,s, X(s^-)\,)\,dW^\ell(s) \\ &+ \int_0^t\int_{\mathbf{z}} c(\,s, X(s^-), z\,)\,\left(p(ds,dz) - q(ds,dz)\right), \end{aligned}$$

which is the form of the equation in [19]. This concludes the proof of part (a).

Part (b) is a consequence of the representation of the derivatives in terms of the fluxes, by application of the chain rule, as developed in formulas (6.9)–(6.12). We apply the Cauchy–Schwarz inequality to each summand in each representation to obtain the estimates based on the respective polynomial growth of the function g and its derivatives, and the boundedness of the moments of the process X and its variations. Since the full proof is somewhat lengthy, we do not include it here. □

6.2. Proof of Lemma 2.2. Based on Lemma 2.1 we know that the cost to go function $u(t,x)$ is the solution of the Kolmogorov backward equation (2.5), satisfying the regularity conditions described in (iv) of part (b) of Lemma 2.2. The Itô formula for processes with jumps (cf. [25, p. 66]) applied to (2.2) gives

$$\begin{aligned} u(T,\overline{X}(T)) = u(0,X(0)) &+ \int_0^T \left[\,\partial_t u(t,\overline{X}(t^-)) + \overline{a}_i(t;\overline{X})\,\partial_i u(t,\overline{X}(t^-))\,\right]\,dt \\ &+ \int_0^T \overline{d}_{ij}(t;\overline{X})\,\partial_{ij}u(t,\overline{X}(t^-))\,dt \\ &+ \int_0^T \overline{b}_i^\ell(t;\overline{X})\,\partial_i u(t,\overline{X}(t^-))\,dW^\ell(t) \\ &+ \int_0^T\int_{\mathbf{z}} \left[\,u\big(t,\overline{X}(t^-) + c(t,\overline{X}(t^-),z)\big) - u(t,\overline{X}(t^-))\,\right]\,p(dt,dz), \end{aligned}$$

which is written equivalently as

$$\begin{aligned}
u(T,\overline{X}(T)) = u(0,X(0)) &+ \int_0^T \big[\,\partial_t u(t,\overline{X}(t^-)) + \overline{a}_i(t;\overline{X})\,\partial_i u(t,\overline{X}(t^-))\,\big]\,dt \\
&+ \int_0^T \overline{d}_{ij}(t;\overline{X})\,\partial_{ij}u(t,\overline{X}(t^-))\,dt \\
&+ \int_0^T \overline{b}_i^{\ell}(t;\overline{X})\,\partial_i u(t,\overline{X}(t^-))\,dW^{\ell}(t) \\
&+ \int_0^T \lambda(t)\int_{\mathbf{z}}\big[\,u\big(t,\overline{X}(t^-)+c(t,\overline{X}(t^-),z)\big)-u(t,\overline{X}(t^-))\,\big]\,\mu(t,dz)dt \\
&+ \int_0^T\int_{\mathbf{z}}[u(t,\overline{X}(t^-)+c(t,\overline{X}(t^-),z))-u(t,\overline{X}(t^-))]\,\big(p(dt,dz)-q(dt,dz)\big),
\end{aligned}$$

where the last equality is obtained by the compensation of the integral with respect to p (remember that $q(dt,dz)=\lambda(t)\mu(t,dz)dt$). Now, use (2.5) to substitute $\partial_t u(t,\overline{X}(t^-))$ in the latter formula to obtain

$$\begin{aligned}
u(0,X(0)) = g(\overline{X}(T)) &+ \int_0^T \big[\,a_i(t,\overline{X}(t^-)) - \overline{a}_i(t;\overline{X})\,\big]\,\partial_i u(t,\overline{X}(t^-))\,dt \\
&+ \int_0^T \big[\,d_{ij}(t,\overline{X}(t^-)) - \overline{d}_{ij}(t;\overline{X})\big]\,\partial_{ij}u(t,\overline{X}(t^-))\,dt \\
&- \int_0^T \overline{b}_i^{\ell}(t;\overline{X})\,\partial_i u(t,\overline{X}(t^-))\,dW^{\ell}(t) \\
&- \int_0^T\int_{\mathbf{z}}\big[\,u(t,\overline{X}(t^-)+c(t,\overline{X}(t^-),z)) - u(t,\overline{X}(t^-))\big]\,\big(p(dt,dz)-q(dt,dz)\big).
\end{aligned} \tag{6.1}$$

The expected value of the last two integrals is zero, the first one by the martingale property of Itô integrals and the second one due to the fact that $p(dt,dz)-q(dt,dz)$ is a compensated random measure (i.e., a martingale measure). Using the representation of u in (2.4) we obtain $E\big[u(0,X(0))\big] = E\big[g(X(T))\big]$. Therefore, taking expected values in both sides of (6.1) we arrive at the error representation (2.6). □

6.3. Proof of Theorem 2.2. The main content of Theorem 2.2 is the replacement of the (noncomputable) error estimate in Lemma 2.2 by an error expansion with computable leading order term. For this purpose the derivatives of the expected value

$$\partial_\alpha u(t,x) = \partial_\alpha E\big[g(X(T))|X(t)=x\big]$$

appearing in the integral in Lemma 2.2 are approximated by the corresponding derivatives of

$$\bar{u}(t,x) \equiv E[g(\overline{X}(T)) \mid \overline{X}(t)=x],$$

which depends on the simulated solution $\overline{X}$. The proof is divided into three steps:

(i) in Lemma 6.1 we estimate the quadrature error;

(ii) in Lemma 6.2 we bound the error in replacing $\partial_\alpha u$ by $\partial_\alpha \bar{u}$ with the use of stochastic flows and its variations;

(iii) in Lemma 6.3 we use the discrete dual functions φ and φ' (which solve the backward evolution problems; see (1.13)–(1.14) in section 1.4) to derive a computable representation of $\partial_\alpha \bar{u}$.

Step 1. We begin with the estimation of the error of the quadrature approximation.

LEMMA 6.1. *Let* $\mathcal{J}_m \equiv \{n : \tilde{t}_m \leq t_n < \tilde{t}_{m+1}\}$ *for* $m = 0, \ldots, N-1$. *If the assumptions in Lemma* 2.2 *hold, then the following quadrature error estimates hold:*

$$\int_{\tilde{t}_m}^{\tilde{t}_{m+1}} E\big[\big(a_i(t, \overline{X}(t^-)) - \overline{a}_i(t; \overline{X})\big)\, \partial_i u(t, \overline{X}(t^-))\big] dt = Q_m(a_i) + \mathcal{O}\big((\Delta \tilde{t}_m)^3\big)$$

and

$$\int_{\tilde{t}_m}^{\tilde{t}_{m+1}} E\big[\big(d_{ij}(t, \overline{X}(t^-)) - \overline{d}_{ij}(t; \overline{X})\big)\partial_{ij} u(t, \overline{X}(t^-))\big] dt = \widetilde{Q}_m(d_{ij}) + \mathcal{O}\big((\Delta \tilde{t}_m)^3\big)$$

for $m = 0, \ldots, N-1$, *where*

$$Q_m(a_i) \equiv E\left[\sum_{n \in \mathcal{J}_m} \frac{\Delta t_n}{2} \left[a_i(t_{n+1}, \overline{X}(t_{n+1}^-)) - a_i(t_n, \overline{X}(t_n))\right] \partial_i u(t_{n+1}, \overline{X}(t_{n+1}^-))\right]$$

and

$$\widetilde{Q}_m(d_{ij}) \equiv E\left[\sum_{n \in \mathcal{J}_m} \frac{\Delta t_n}{2} \left[d_{ij}(t_{n+1}, \overline{X}(t_{n+1}^-)) - d_{ij}(t_n, \overline{X}(t_n))\right] \partial_{ij} u(t_{n+1}, \overline{X}(t_{n+1}^-))\right].$$

Proof. Denote by $\mathcal{F}^J$ the σ-algebra generated by the jumps and marks in $[0, T]$ constructed in section 1.2.1. Observe that in $[t_n, t_{n+1})$ the conditioned process $\overline{X}$ has no jump discontinuities, and introduce the auxiliary functions

$$\begin{aligned} \mathcal{H}(t, \overline{X}(t^-)) &\equiv \left[\, d_{ij}(t, \overline{X}(t^-)) - \overline{d}_{ij}(t; \overline{X}) \,\right] \partial_{ij} u(t, \overline{X}(t^-)), \\ \overline{\mathcal{H}}_n(t) &\equiv \frac{t - t_n}{\Delta t_n}\, \mathcal{H}(t_{n+1}, \overline{X}(t_{n+1}^-)), \quad n = 0, \ldots, \kappa - 1. \end{aligned}$$

Then we have

$$\begin{aligned} \int_{\tilde{t}_m}^{\tilde{t}_{m+1}} E[\mathcal{H}(t, \overline{X}(t^-))]\, dt &= E\left[\sum_{n \in \mathcal{J}_m} \int_{t_n}^{t_{n+1}} E\big[\mathcal{H}(t, \overline{X}(t^-))|\mathcal{F}^J\big]\, dt\right] \\ &= \widetilde{Q}_m(d_{ij}) + E\left[\sum_{n \in \mathcal{J}_m} \int_{t_n}^{t_{n+1}} E\big[\mathcal{H}(t, \overline{X}(t^-)) - \overline{\mathcal{H}}_n(t)|\mathcal{F}^J\big]\, dt\right]. \end{aligned} \tag{6.2}$$

Observing that the function $E\big[\,\overline{\mathcal{H}}_n(t)|\mathcal{F}^J\,\big]$ is the linear interpolant of the smooth function $E\big[\,\mathcal{H}(t, \overline{X}(t^-))|\mathcal{F}^J\big]$ at the nodes $\{t_n, t_{n+1}\}$, a standard interpolation error

estimate yields

$$\begin{aligned}\left|\int_{t_n}^{t_{n+1}} E[\mathcal{H}(t,\overline{X}(t^-)) - \overline{\mathcal{H}}_h(t)|\mathcal{F}^J]\,dt\right| \\ \leq \frac{(\Delta t_n)^2}{8}\int_{t_n}^{t_{n+1}}\left|\frac{d^2}{dt^2}E[\mathcal{H}(t,\overline{X}(t^-))|\mathcal{F}^J]\right|dt.\end{aligned} \tag{6.3}$$

Denoting $\mathcal{L}\mathcal{H} \equiv \partial_t\mathcal{H}+\overline{a}_i\partial_i\mathcal{H}+\overline{d}_{ij}\partial_{ij}\mathcal{H}$, Itô's formula and the conditions in Lemma 2.1 show that there exist constants K_1, K_2 and $p \in \mathbb{N}$ such that

$$\begin{aligned}\frac{d}{dt}E[\mathcal{H}(t,\overline{X}(t^-))|\mathcal{F}^J] &= E[\mathcal{L}\mathcal{H}(t,\overline{X}(t^-))|\mathcal{F}^J] \\ &\leq K_1 + K_2\,E[\max_{t\in[0,T]}|\overline{X}_t|^{2p}|\mathcal{F}^J], \\ \frac{d^2}{dt^2}E[\mathcal{H}(t,\overline{X}(t^-))|\mathcal{F}^J] &= E[\mathcal{L}^2\mathcal{H}(t,\overline{X}(t^-))|\mathcal{F}^J] \\ &\leq K_1 + K_2\,E[\max_{t\in[0,T]}|\overline{X}_t|^{2p}|\mathcal{F}^J],\end{aligned} \tag{6.4}$$

as all the functions involved in the derivatives of $\mathcal{H}(t,x)$ in the computation of $\mathcal{L}\mathcal{H}$ and $\mathcal{L}^2\mathcal{H}$ have polynomial growth, and $\overline{X}$ has bounded moments of all order, uniformly with respect to Δt_{max} (from this fact follows the finiteness of the moments of the supremum of the process). The combination of (6.2), (6.3), and (6.4) proves the estimate of the diffusion term in the lemma. The estimate of the drift term follows analogously. □

Step 2. In the second step of the proof the derivative $\partial_\alpha u$ and its approximation $\partial_\alpha \bar{u}$ are evaluated, respectively, through expected values of *stochastic flows* of X and $\overline{X}$ and its *variations*, which we now introduce. Let

$$\delta_{ik} \equiv \begin{cases} 0, & i \neq k, \\ 1, & i = k. \end{cases}$$

The following equation for the first variation of the process X at time $s > t$ holds:

$$\begin{aligned} dX'_{ij}(s) &= \partial_k a_i(s,X(s^-))\,X'_{kj}(s^-)\,ds + \partial_k b_i^\ell(s,X(s^-))\,X'_{kj}(s^-)\,dW^\ell(s) \\ &\quad + \int_{\mathbf{z}} \partial_k c_i(s,X(s^-),z)\,X'_{kj}(s^-)\,p(ds,dz), \\ X'_{ij}(t) &= \delta_{ij}. \end{aligned} \tag{6.5}$$

Similarly, for the second variation of the process X at time $s > t$ we have

$$\begin{aligned} dX''_{ijn}(s) &= \left[\partial_k a_i(s,X(s^-))\,X''_{kjn}(s^-) + \partial_{kr}a_i(s,X(s^-))\,X'_{kj}(s^-)\,X'_{rn}(s^-)\right]ds \\ &\quad + \left[\partial_k b_i^\ell(s,X(s^-))\,X''_{kjn}(s^-)\right. \\ &\qquad \left. + \partial_{kr}b_i^\ell(s,X(s^-))\,X'_{kj}(s^-)\,X'_{rn}(s^-)\right]dW^\ell(s) \\ &\quad + \int_{\mathbf{z}}\left[\partial_k c_i(s,X(s^-),z)\,X''_{kjn}(s^-)\right. \\ &\qquad \left. + \partial_{kr}c_i(s,X(s^-),z)\,X'_{kj}(s^-)\,X'_{rn}(s^-)\right]p(ds,dz), \\ X''_{ijn}(t) &= 0. \end{aligned} \tag{6.6}$$

For the third variation of the process X at time $s > t$ we have

$$
\begin{aligned}
dX'''_{ijnm}(s) = \Big[& \partial_k a_i(s, X(s^-))\, X'''_{kjnm}(s^-) \\
& + \partial_{kr} a_i(s, X(s^-))\, X'_{kj}(s^-)\, X''_{rnm}(s^-) \\
& + \partial_{kr} a_i(s, X(s^-))\, X'_{kn}(s^-)\, X''_{rjm}(s^-) \\
& + \partial_{kr} a_i(s, X(s^-))\, X'_{km}(s^-)\, X''_{rjn}(s^-) \\
& + \partial_{krv} a_i(s, X(s^-))\, X'_{kj}(s^-)\, X'_{rn}(s^-)\, X'_{vm}(s^-) \Big]\, ds \\
+ \Big[& \partial_k b_i^\ell(s, X(s^-))\, X'''_{kjnm}(s^-) \\
& + \partial_{kr} b_i^\ell(s, X(s^-))\, X'_{kj}(s^-)\, X''_{rnm}(s^-) \\
& + \partial_{kr} b_i^\ell(s, X(s^-))\, X'_{kn}(s^-)\, X''_{rjm}(s^-) \\
& + \partial_{kr} b_i^\ell(s, X(s^-))\, X'_{km}(s^-)\, X''_{rjn}(s^-) \\
& + \partial_{krv} b_i^\ell(s, X(s^-))\, X'_{kj}(s^-)\, X'_{rn}(s^-)\, X'_{vm}(s^-) \Big]\, dW^\ell(s) \\
+ \int_{\mathbf{z}} \Big[& \partial_k c_i(s, X(s^-))\, X'''_{kjnm}(s^-) \\
& + \partial_{kr} c_i(s, X(s^-), z)\, X'_{kj}(s^-) X''_{rnm}(s^-) \\
& + \partial_{kr} c_i(s, X(s^-), z)\, X'_{kn}(s^-)\, X''_{rjm}(s^-) \\
& + \partial_{kr} c_i(s, X(s^-), z)\, X'_{km}(s^-)\, X''_{rjn}(s^-) \\
& + \partial_{krv} c_i(s, X(s^-), z)\, X'_{kj}(s^-)\, X'_{rn}(s^-)\, X'_{vm}(s^-) \Big]\, p(ds, dz), \\
X'''_{ijnm}(t) = & \, 0,
\end{aligned}
\tag{6.7}
$$

and similarly for the fourth variation of the process X at time $s > t$:

$$
dX''''_{ijnmp} = \ldots, \qquad X''''_{ijnmp}(t) = 0. \tag{6.8}
$$

Let $I^{d\times d}$ be the $d \times d$ identity matrix. The equations above imply the representation of the derivatives of expectations with stochastic flows (cf. [19], [49], and [52]) as follows: for the first order derivatives

$$
\partial_k u(t,x) = E\big[\, \partial_i g(X(T))\, X'_{ik}(T) \mid X^{I}(t) = (x, I^{d\times d}) \,\big] \tag{6.9}
$$

with $X^{I} \equiv (X, X')$; for the second order derivatives

$$
\begin{aligned}
\partial_{kn} u(t,x) = E\big[& \partial_i g(X(T))\, X''_{ikn}(T) \\
& + \partial_{ir} g(X(T))\, X'_{ik}(T)\, X'_{rn}(T) \mid X^{II}(t) = (x, I^{d\times d}, 0) \,\big]
\end{aligned}
\tag{6.10}
$$

with $X^{II} \equiv (X, X', X'')$; for the third order derivatives

$$
\begin{aligned}
\partial_{knm} u(t,x) = E\big[& \partial_i g(X(T))\, X'''_{iknm}(T) + \partial_{ir} g(X(T))\, X'_{ik}(T)\, X''_{rnm}(T) \\
& + \partial_{ir} g(X(T))\, X'_{in}(T)\, X''_{rkm}(T) \\
& + \partial_{irv} g(X(T))\, X'_{ik}(T)\, X'_{rn}(T)\, X'_{vm}(T) \\
& + \partial_{ir} g(X(T))\, X'_{im}(T)\, X''_{rkn}(T) \mid X^{III}(t) = (x, I^{d\times d}, 0, 0) \big]
\end{aligned}
\tag{6.11}
$$

with $X^{III} \equiv (X, X', X'', X''')$; and, analogously, for the fourth order derivatives

$$
\partial_{knmp} u(t,x) = \ldots. \tag{6.12}
$$

Let $Y = (X, X', X'', X''', X'''')^T$. Then the system consisting of (1.1) and (6.5)–(6.8) can be written as

$$\begin{aligned} dY(t) &= A(t, Y(t^-))\, dt + B^\ell(t, Y(t^-))\, dW^\ell(t) \\ &\quad + \int_{\mathbf{z}} C(t, Y(t^-), z)\, p(dt, dz), \quad t > t_0, \\ Y(t_0) &= (x, I^{d\times d}, 0, 0, 0)^T. \end{aligned} \tag{6.13}$$

Furthermore, in order to simplify the writing of the formulas (6.9)–(6.12), we introduce below additional notation:

$$\begin{aligned} f_i(Y(T)) &\equiv \partial_k g(X(T))\, X'_{ki}(T), \\ f_{ij}(Y(T)) &\equiv \partial_k g(X(T))\, X''_{kij}(T) + \partial_{kn} g(X(T))\, X'_{ki}(T)\, X'_{nj}(T), \\ f_{ijm}(Y(T)) &\equiv \partial_k g(X(T))\, X'''_{kijm}(T) + \partial_{kn} g(X(T))\, X'_{ki}(T)\, X''_{njm}(T) \\ &\quad + \partial_{kn} g(X(T))\, X'_{kj}(T)\, X''_{nim}(T) \\ &\quad + \partial_{kn} g(X(T))\, X'_{km}(T)\, X''_{nji}(T) \\ &\quad + \partial_{knv} g(X(T))\, X'_{ki}(T)\, X'_{nj}(T)\, X'_{vm}(T), \\ f_{ijmn}(Y(T)) &\equiv \dots. \end{aligned} \tag{6.14}$$

The Euler approximation of Y, the solution of (6.13), is denoted by

$$\overline{Y} = \big(\overline{Y}^0, \overline{Y}^1, \overline{Y}^2, \overline{Y}^3, \overline{Y}^4\big)^\tau$$

and can be extended as the solution of the stochastic differential equation with piecewise constant drift and diffusion fluxes

$$d\overline{Y} = \overline{A}(t; \overline{Y})\, dt + \overline{B}^\ell(t; \overline{Y})\, dW^\ell(t) + \int_{\mathbf{z}} C(t, \overline{Y}, z)\, p(dt, dz), \tag{6.15}$$

defined as in (1.4), (1.6), and (2.2), with coefficients defined as in (2.1).

An important consequence of the Euler method is that the variation and the Euler discretization commute. This yields for each α the representation

$$\begin{aligned} &\partial_\alpha u(t,x) - \partial_\alpha \bar{u}(t,x) \\ &\qquad = E\big[f_\alpha(Y(T)) - f_\alpha(\overline{Y}(T)) \mid Y(t) = \overline{Y}(t) = (x, I^{d\times d}, 0, 0, 0)^T\big]. \end{aligned} \tag{6.16}$$

Now we rely on Lemma 2.2 applied to the process Y to obtain the representation

$$\begin{aligned} &E\big[f_\alpha(Y(T)) - f_\alpha(\overline{Y}(T)) \mid Y(t) = \overline{Y}(t) = (x, I^{d\times d}, 0, 0, 0)^T\big] \\ &\quad = \int_t^T E\Big[(A - \overline{A})_k\, \partial_k \nu^\alpha(s, \overline{Y}(s^-)) \,\Big|\, \overline{Y}(t) = (x, I^{d\times d}, 0, 0, 0)^T\Big]\, ds \\ &\qquad + \int_t^T E\Big[(D - \overline{D})_{kn}\, \partial_{kn} \nu^\alpha(s, \overline{Y}(s^-)) \,\Big|\, \overline{Y}(t) = (x, I^{d\times d}, 0, 0, 0)^T\Big]\, ds \end{aligned} \tag{6.17}$$

to be used in Lemmas 6.2 and 6.3 below, where the cost to go function ν^α is, for each f_α in (6.14), defined as

$$\nu^\alpha(t, y) = E\big[f_\alpha(Y(T)) \mid Y(t) = y\big].$$

We use the notation $D_{kn} = \frac{1}{2}B_k^\ell B_n^\ell$ and $\overline{D}_{kn} = \frac{1}{2}\overline{B}_k^\ell \overline{B}_n^\ell$, and the corresponding Kolmogorov backward equation for $t > T$ is

$$\begin{aligned}\mathcal{L}^Y \nu^\alpha &\equiv \partial_t \nu^\alpha + A_k \partial_k \nu^\alpha + D_{kn}\partial_{kn}\nu^\alpha \\ &\quad + \lambda(t)\int_{\mathbf{z}} [\nu^\alpha(t, Y + C(t,Y,z)) - \nu^\alpha(t,Y)]\,\mu(t,dz) = 0,\\ \nu^\alpha(T,\cdot) &= f_\alpha.\end{aligned}$$

We are ready for the second step.

LEMMA 6.2 (approximation of $\partial_\alpha u$). *Let the piecewise constant mesh function Δt be defined by $\Delta t(s) \equiv \Delta t_n$ for $s \in [t_n, t_{n+1})$ and $n = 0, \ldots, \kappa - 1$. Suppose that the assumptions in Lemma 2.2 hold. Then the discretization errors of the stochastic flows, for $|\alpha| \le 4$, satisfy*

$$\partial_\alpha(u - \bar{u})(t_n, \overline{X}(t_n)) = \int_{t_n}^T E[\mathcal{O}(\Delta t(s)) \mid \mathcal{F}_{t_n}]\, ds = \mathcal{O}(\Delta \tilde{t}_{max}). \tag{6.18}$$

Furthermore

$$\begin{aligned}E\Big[\big[a_i(t_{n+1}, \overline{X}(t_{n+1}^-)) - a_i(t_n, \overline{X}(t_n))\big]\, \partial_i(u-\bar{u})(t_{n+1}, \overline{X}(t_{n+1}^-)) \mid \mathcal{F}^J\Big] \\ = \Delta t_n \int_{t_{n+1}}^T \mathcal{O}(\Delta t(s))\, ds\end{aligned} \tag{6.19}$$

and

$$\begin{aligned}E\Big[\big[\, d_{ij}(t_{n+1}, \overline{X}(t_{n+1}^-)) - d_{ij}(t_n, \overline{X}(t_n))\,\big]\, \partial_{ij}(u-\bar{u})(t_{n+1}, \overline{X}(t_{n+1}^-)) \mid \mathcal{F}^J\Big] \\ = \Delta t_n \int_{t_{n+1}}^T \mathcal{O}(\Delta t(s))\, ds.\end{aligned} \tag{6.20}$$

Proof. The combination of (6.16) and (6.17) gives

$$\begin{aligned}\partial_\alpha(u-\bar{u})(t_n, \overline{X}(t_n)) &= \int_{t_n}^T E\big[(A_i - \overline{A}_i)\,\partial_i \nu^\alpha(s, \overline{Y}(s^-)) \mid \mathcal{F}_{t_n}\big]\, ds \\ &\quad + \int_{t_n}^T E\big[(D_{ij} - \overline{D}_{ij})\,\partial_{ij}\nu^\alpha(s, \overline{Y}(s^-)) \mid \mathcal{F}_{t_n}\big]\, ds.\end{aligned} \tag{6.21}$$

Now, for $t_m \le t < t_{m+1}$, introduce the notation

$$h(t, \overline{Y}(t)) \equiv (A_i - \overline{A}_i)\partial_i \nu^\alpha(t, \overline{Y}(t)) + (D_{ij} - \overline{D}_{ij})\partial_{ij}\nu^\alpha(t, \overline{Y}(t))$$

and

$$\begin{aligned}\mathcal{L}_0 w(t,y) &\equiv \big(\partial_t w + \overline{A}_n \partial_n w + \overline{D}_{kn}\partial_{kn} w\big)(t,y),\\ \mathcal{L}^{\overline{Y}} w(t,y) &\equiv \mathcal{L}_0 w(t,y) + \lambda(t)\int_{\mathbf{z}} [w(t, y + C(t,y,z)) - w(t,y)]\mu(t,dz).\end{aligned}$$

Observe that $h(t_m, \overline{Y}(t_m)) = 0$, and apply Itô's formula in the interval $[t_m, t]$ to obtain

$$E[h(t, \overline{Y}(t^-)) \mid \mathcal{F}_{t_m}] = \int_{t_m}^t E[\mathcal{L}^{\overline{Y}} h(s, \overline{Y}(s^-)) \mid \mathcal{F}_{t_m}] ds = \mathcal{O}(\Delta t_m), \quad t_m \le t < t_{m+1}, \tag{6.22}$$

where the bound follows as in (6.4). Combining (6.22) with (6.21) proves (6.18).

The estimate (6.20) follows similarly by defining now

$$\tilde{h}(t,\overline{X}(t)) \equiv (d_{ij}-\overline{d}_{ij})\partial_{ij}(u-\bar{u})(t,\overline{X}(t)).$$

Then, as in (6.3)–(6.4), the Itô's formula shows

$$E[\tilde{h}(t,\overline{X}(t)) \mid \mathcal{F}^J] = \int_{t_n}^{t} E[\mathcal{L}_0\tilde{h}(s,\overline{X}(s^-)) \mid \mathcal{F}^J]ds, \quad t_n \le t < t_{n+1}.$$

The final step to proving (6.20) is to establish

$$E[\mathcal{L}_0\,\tilde{h}(s,\overline{X}(s^-)) \mid \mathcal{F}^J] = \int_{s}^{T} \mathcal{O}(\Delta t(\tau))d\tau.$$

The function $\mathcal{L}_0\,\tilde{h}(s,\overline{X}(s^-))$ splits into the two types of terms $h_1 \equiv (d-\overline{d})v$ and $h_2 \equiv v\partial_\alpha(u-\bar{u})$, with smooth functions v of $(s,\overline{X}(s))$. The Itô formula again shows that

$$E[h_1(s,\overline{X}(s^-)) \mid \mathcal{F}^J] = \int_{t_n}^{s} E[\mathcal{L}_0 h_1(\tau,\overline{X}(\tau^-)) \mid \mathcal{F}^J]d\tau = \mathcal{O}(\Delta t_n), \quad t_n \le s < t_{n+1}.$$

Moreover (6.18) implies

$$E[h_2(s,\overline{X}(s^-)) \mid \mathcal{F}^J] = \int_{s}^{T} \mathcal{O}(\Delta t(\tau))d\tau,$$

and consequently (6.20) holds. The estimate (6.19) of the drift terms follows analogously. □

Step 3. The last step is to show a result on the representation of the derivative of $\bar{u}$ using discrete duals.

LEMMA 6.3. *Suppose that the assumptions in Lemma* 2.2 *hold. Then the dual functions* φ *and* φ', *defined in* (1.13) *and* (1.14), *satisfy for* $t = t_n$ *and* $t = t_{n+1}^-$

$$\partial_i\bar{u}(t,\overline{X}(t)) = E[\varphi_i(t) \mid \mathcal{F}_t], \tag{6.23}$$

$$\partial_{ij}\bar{u}(t,\overline{X}(t)) = E[\varphi'_{ij}(t) \mid \mathcal{F}_t]. \tag{6.24}$$

Proof. Equations (2.2), (6.5), and (6.9) show that the first variation of the Euler approximation $\overline{X}$ is in fact equal to the Euler approximation of the first variation X', and consequently

$$\partial_i\bar{u}(t,\overline{X}(t)) = E[\partial_j g(\overline{X}(T))\overline{X}'_{ji}(T;t) \mid \mathcal{F}_t],$$

where $\overline{X}'_{ji}(s;t)$ $(s > t)$, is the Euler approximation (6.15) of X' with initial data $\overline{X}'_{ji}(t;t) = \delta_{ji}$.

For $t = \ldots, t_n, t_{n+1}^-, \ldots$, let

$$\varphi_i(t) \equiv \partial_{x_i(t)} g(\overline{X}(T)),$$

i.e.,

$$\varphi_i(t) = \partial_j g(\overline{X}(T))\overline{X}'_{ji}(T;t). \tag{6.25}$$

We prove inductively that $\varphi_i(t)$ is the solution of the corresponding problem in (1.12)–(1.13). Since (1.12) is trivially true it remains to prove the inductive step. By the chain rule we have

$$\partial_k g(\overline{X}(T))\overline{X}'_{ki}(T;t) = \partial_k g(\overline{X}(T))\overline{X}'_{kj}(T;t_{next})\overline{X}'_{ji}(t_{next};t)$$

or, in other words,

$$\varphi_i(t) = \varphi_j(t_{next})\partial_i \Phi_j(t, \overline{X}(t)), \tag{6.26}$$

which is equivalent to (1.12)–(1.13), which is what we wanted to prove.

The equality (6.25) implies that

$$\partial_{ij}\bar{u}(t, \overline{X}(t)) = E\big[\partial_{x_j(t)}\varphi_i(t) \mid \mathcal{F}_t\big].$$

The next step is to verify that the first variation of φ,

$$\varphi'_{ij}(t) \equiv \partial_{x_j(t)}\varphi_i(t) \equiv \frac{\partial \varphi_i(t; \overline{X}(t) = x)}{\partial x_j}, \tag{6.27}$$

satisfies the backward recursive equation (1.14). First, differentiate the equation (6.26) to obtain

$$\begin{aligned} \varphi'_{ik}(t) &= \partial_i \Phi_j \partial_{x_k(t)}\varphi_j(t_{next}) + \partial_k \partial_i \Phi_j \varphi_j(t_{next}), \quad t < T, \\ \varphi'_{ik}(T) &= \partial_{ik} g(\overline{X}(T)). \end{aligned} \tag{6.28}$$

Observe that problem (1.12)–(1.16) shows that $\varphi(t_{next})$ depends only on the point values

$$\{\overline{X}(s) : \ t_{next} \le s \le T\},$$

so that

$$\partial_{x_k(t)}\varphi_j(t_{next}) = \partial_{x_p(t_{next})}\varphi_j(t_{next})\partial_{x_k(t)}\overline{X}_p(t_{next}). \tag{6.29}$$

Finally, the definitions of $\overline{X}$ and Φ in (2.2) and (1.11) imply

$$\partial_k \Phi_p(t, \overline{X}(t)) = \partial_{x_k(t)}\overline{X}_p(t_{next}), \tag{6.30}$$

which together with (6.28)–(6.29) proves that φ' satisfies the recursive equation

$$\begin{aligned} \varphi'_{ik}(t) &= \partial_i \Phi_j \ \ \varphi'_{jp}(t_{next})\partial_k \Phi_p(t, \overline{X}(t)) + \partial_k \partial_i \Phi_j \ \ \varphi_j(t_{next}), \quad t < T, \\ \varphi'_{ik}(T) &= \partial_{ik} g(\overline{X}(T)), \end{aligned} \tag{6.31}$$

which is equivalent to (1.12)–(1.14). ∎

Remark 6.1. The measurability of $\big(a_i(t^-_{n+1}, \overline{X}(t^-_{n+1})) - \overline{a}_i(t_n, \overline{X}(t_n))\big) \in \mathcal{F}_{t^-_{n+1}}$ proves that for $t = t^-_{n+1}$ and any random variable β we have

$$\begin{aligned} E\big[\big(a_i(t, \overline{X}(t)) - \overline{a}_i(t_n, \overline{X}(t_n))\big)E[\beta \mid \mathcal{F}_t]\big] &= E\big[E[\big(a_i(t, \overline{X}(t)) - \overline{a}_i(t_n; \overline{X})\big)\beta \mid \mathcal{F}_t]\big] \\ &= E\big[\big(a_i(t, \overline{X}(t)) - \overline{a}_i(t_n; \overline{X})\big)\beta\big], \end{aligned}$$

and in a completely similar way we obtain the same result for the diffusion terms, i.e.,

$$E\big[\big(d_{ij}(t, \overline{X}(t)) - \overline{d}_{ij}(t_n; \overline{X})\big)E[\beta \mid \mathcal{F}_t]\big] = E\big[\big(d_{ij}(t, \overline{X}(t)) - \overline{d}_{ij}(t_n; \overline{X})\big)\beta\big].$$

The proof of Theorem 2.2 is now concluded by combining Lemmas 6.1, 6.2, and 6.3, Remark 6.1, and the central limit theorem to estimate I_M and J_M. We have

$$\begin{aligned}
&\int_{\tilde{t}_m}^{\tilde{t}_{m+1}} E\big[\big(a_i(t,\overline{X}(t^-)) - \overline{a}_i(t;\overline{X})\big)\,\partial_i u(t,\overline{X}(t^-))\big]dt \\
&\quad = E\left[\sum_{n\in\mathcal{J}_m} \frac{\Delta t_n}{2}\left[a_i(t_{n+1},\overline{X}(t_{n+1}^-)) - a_i(t_n,\overline{X}(t_n))\right]\partial_i u(t_{n+1},\overline{X}(t_{n+1}^-))\right] \\
&\qquad + \sum_{m=0}^{N-1}\mathcal{O}\big((\Delta\tilde{t}_m)^3\big) \\
&\quad = E\left[\sum_{n\in\mathcal{J}_m} \frac{\Delta t_n}{2}\left[\,a_i(t_{n+1},\overline{X}(t_{n+1}^-)) - a_i(t_n,\overline{X}(t_n))\,\right]\partial_i \bar{u}(t_{n+1},\overline{X}(t_{n+1}^-))\right] \\
&\qquad + \sum_{m=0}^{N-1} E\left[\sum_{n\in\mathcal{J}_m}(\Delta t_n)^2\int_{t_{n+1}}^{T}\mathcal{O}(\Delta t(s))\,ds\right] + \sum_{m=0}^{N-1}\mathcal{O}\big((\Delta\tilde{t}_m)^3\big) \\
&\quad = E\left[\sum_{n\in\mathcal{J}_m} \frac{\Delta t_n}{2}\left[\,a_i(t_{n+1},\overline{X}(t_{n+1}^-)) - a_i(t_n,\overline{X}(t_n))\,\right]E\big[\varphi_i(t_{n+1-})\,\big|\,\mathcal{F}_{t_{n+1}^-}\big]\right] \\
&\qquad + \sum_{m=0}^{N-1} E\left[\sum_{n\in\mathcal{J}_m}(\Delta t_n)^2\int_{t_{n+1}}^{T}\mathcal{O}(\Delta t(s))\,ds\right] + \sum_{m=0}^{N-1}\mathcal{O}\big((\Delta\tilde{t}_m)^3\big) \\
&\quad = E\left[\sum_{n\in\mathcal{J}_m} \frac{\Delta t_n}{2}\left[\,a_i(t_{n+1},\overline{X}(t_{n+1}^-)) - a_i(t_n,\overline{X}(t_n))\,\right]\varphi_i(t_{n+1-})\right] \\
&\qquad + \sum_{m=0}^{N-1} E\left[\sum_{n\in\mathcal{J}_m}(\Delta t_n)^2\int_{t_{n+1}}^{T}\mathcal{O}(\Delta t(s))\,ds\right] + \sum_{m=0}^{N-1}\mathcal{O}\big((\Delta\tilde{t}_m)^3\big).
\end{aligned}$$

The expansion of the diffusion term appearing in (2.8) follows analogously. ∎

6.4. Proof of Theorem 3.1. We consider the difference

$$g(X(t)) - g(\overline{X}(t))$$

and apply Theorem 3.3 from [51], using also the fact that there is no time discretization error at the jump nodes. To this end, denote the set of stochastic time nodes by $\mathcal{J} \equiv \{0 = t_0, t_1^-, t_1, t_2^-, t_2, \ldots, t_N = T\}$ and recall that the notation

$$\overline{X}(t_{next}) = \Phi(\overline{X}(t)), \quad t \in \mathcal{J}, \tag{6.32}$$

introduced in Definition 1.1 denotes one step with the Euler method. Write similarly one step with the exact solution

$$X(t_{next}) = \hat{\Phi}(X(t)), \quad t \in \mathcal{J}. \tag{6.33}$$

Introduce the notation $X^t \equiv X(t)$ and $\overline{X}^t \equiv \overline{X}(t)$. Now verify the representation

$$g(X(T)) - g(\overline{X}(T)) = \sum_{n=0}^{\kappa-1}(\hat{\Phi}(\overline{X}(t_n)) - \Phi(\overline{X}(t_n)))_i\tilde{\varphi}_i(t_{n+1}^-), \tag{6.34}$$

where the weight functions are defined recursively by linear backward recursion:

$$\begin{aligned}\tilde{\varphi}_i(T) &= \int_0^1 \partial_i g(sX(T) + (1-s)\overline{X}(T))ds,\\ \tilde{\varphi}_i(t) &= \left(\int_0^1 \partial_i \hat{\Phi}_j(sX(t) + (1-s)\overline{X}(t))ds\right)\tilde{\varphi}_j(t_{next}),\ t \in \mathcal{J}.\end{aligned} \tag{6.35}$$

To verify (6.34), first observe that by construction of the Euler method at every jump point $t = t_n^-$ there is no local error in computing the next $\overline{X}$ value at time t_n, i.e.,

$$\hat{\Phi}(\overline{X}^t) - \Phi(\overline{X}^t) = 0,$$

so (6.34) is equivalent to

$$g(X(T)) - g(\overline{X}(T)) = \sum_{t\in\mathcal{J}} (\hat{\Phi}(\overline{X}^t) - \Phi(\overline{X}^t))_i \tilde{\varphi}_i(t_{next}). \tag{6.36}$$

Then telescoping cancellation gives

$$g(X(T)) - g(\overline{X}(T)) = \sum_{t\in\mathcal{J}} \big((X^{t_{next}} - \overline{X}^{t_{next}})_i \tilde{\varphi}_i(t_{next}) - (X^t - \overline{X}^t)_i \tilde{\varphi}_i(t)\big). \tag{6.37}$$

Use the definitions (6.32) and (6.33) and split the first term in the sum of (6.37) into

$$(\hat{\Phi}(X^t) - \hat{\Phi}(\overline{X}^t) + \hat{\Phi}(\overline{X}^t) - \Phi(\overline{X}^t))_i \tilde{\varphi}_i(t_{next}).$$

The two first terms above and the last term in the sum of (6.37) combine to zero by (6.35):

$$(\hat{\Phi}(X^t) - \hat{\Phi}(\overline{X}^t))_i \tilde{\varphi}_i(t_{next})(X^t - \overline{X}^t)_i \tilde{\varphi}_i(t),$$

which proves (6.34).

The next step is to use the Malliavin derivative to analyze the expectation of the representation (6.34) by studying the dependence of $\overline{X}$ and $\tilde{\varphi}$ on a small increment dW. This follows exactly the lines of the proof of Theorem 3.3 from [51], and it is not reproduced here. □

Remark 6.2. The assumptions in Theorems 2.2 and 3.1 can be relaxed. For instance, the results of Theorem 2.2 also hold when λ and μ are piecewise continuously differentiable, provided that (i) they have a finite number of discontinuities; (ii) those discontinuity times are included in the time discretization; and (iii) for each time subinterval between discontinuities, the first derivatives of λ and μ are bounded and have lateral limits.

Acknowledgment. The authors are indebted to the anonymous referees for their useful comments regarding the manuscript.

FINITE ELEMENT RUNGE–KUTTA DISCRETIZATIONS OF POROUS MEDIUM–TYPE EQUATIONS*

ESKIL HANSEN† AND ALEXANDER OSTERMANN†

Abstract. In this paper we analyze the convergence properties of full discretizations of a class of generalized porous medium equations. For the spatial and time discretizations, we use continuous piecewise linear finite elements and algebraically stable Runge–Kutta methods, respectively. We prove our convergence result without any assumption on the *spatial regularity*. It is shown that, under a certain stability assumption, the *temporal order* of convergence is given by the stage order of the method, whereas the spatial order is essentially one. Numerical experiments illustrate our stability assumption and the convergence result.

Key words. porous medium equation, degenerate parabolic problems, Runge–Kutta time discretization, high order convergence in time

1. Introduction.

Consider the equation

$$\begin{cases} \dot{u} = \Delta\alpha(u) & \text{in } \Omega \times (0,T], \\ \alpha(u) = 0 & \text{on } \partial\Omega \quad \text{and } u(0) = \eta \text{ in } \Omega, \end{cases} \tag{1.1}$$

where Ω is an open and convex polyhedral domain in $\mathbb{R}^d$, with $d = 1$, 2, or 3. We assume that $\alpha : \mathbb{R} \to \mathbb{R}$ is a continuous and strictly increasing map with range $R(\alpha) = \mathbb{R}$, and $\alpha(0) = 0$. The classical example of (1.1) is the porous medium equation (PME),

$$\dot{u} = \Delta|u|^{m-1}u, \quad m > 1,$$

which is found when modeling the flow of an ideal gas through a homogeneous porous medium, where the unknown u represents the (normalized) gas density. Other applications can be found, for example, in nonlinear heat transfers and population dynamics. For further details regarding the applications and the mathematical theory of porous medium–type equations, we refer to the recent book by Vázquez [14].

In order to characterize the nature of the problem class, we temporarily restrict our attention to the PME. Rewriting the equation in divergence form,

$$\dot{u} = \nabla \cdot (m|u|^{m-1}\nabla u),$$

reveals a nonlinear diffusion process where the diffusion coefficient $m|u|^{m-1}$ may vanish, i.e., the PME is a degenerate parabolic equation. Another feature of the PME is that an initial value η with compact support in Ω evolves with a finite speed of propagation. Quite a few families of explicit solutions have been derived for the PME

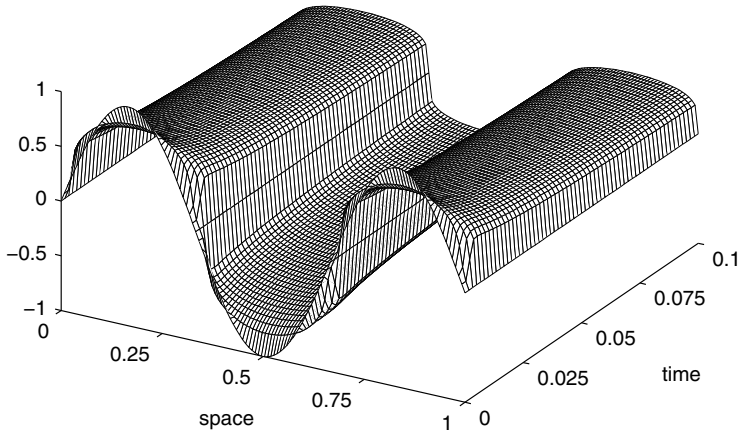

FIG. 1.1. *The evolution of the initial value* $\eta(x) = \sin(3\pi x)$ *in time under the PME with* $m = 5$.

in the context of initial data with compact support, and these solutions usually lack high regularity in space and time.

Due to the lack of regularity, the numerical studies concerning porous medium–type equations (or even more general problems) have predominantly considered discretizations based on continuous piecewise linear finite elements and the implicit Euler method [3, 7, 11, 12, 13]. For these discretizations, Rulla and Walkington [13] have derived an (essentially) optimal convergence of the form $\mathcal{O}(h + k)$ in the space $L^\infty(0, T : H^{-1}(\Omega))$, where h is the mesh width of the finite elements and k is the time step size. For studies of other spatial discretizations, see Eymard, Hilhorst, and Vohralík [8] and the references therein.

Numerical experiments, however, clearly indicate that the *time regularity* is improved for a large class of initial values which are sufficiently regular and do not vanish on open subsets of Ω. For example, consider the evolution presented in Figure 1.1. Here, the gradient of the evolution ∇u is most likely unbounded, whereas the evolution seems to be smooth in time. The same behavior can also be found in higher dimensional problems; see Figure 6.1. In the presence of higher time regularity, one may apply high order time-stepping schemes, e.g., Runge–Kutta methods, which enables the usage of large time steps k without compromising the accuracy of the discretization.

The aim of the present study is to derive an optimal convergence analysis for discretizations based on linear finite elements and high order implicit Runge–Kutta methods. An outline of the paper is as follows: In section 2 we give an appropriate H^{-1} framework for analyzing (1.1). The analogous framework for the spatial discretization is introduced in section 3. In section 4 we investigate the convergence properties of the spatial discretization. The main ingredient of the analysis is to consider auxiliary implicit Euler discretizations in combination with the results of [6, 13]. The convergence of the full discretization is then analyzed in section 5. The analysis will be carried out in a discrete H^{-1} norm in space. Under a certain stability assumption on the spatial discretization, we derive an (essentially) optimal convergence result of the form $\mathcal{O}(h + k^q)$, with q denoting the stage order of the Runge–Kutta method. The time convergence analysis employs results from the first author's paper

[10]. We conclude by proposing an implementation in section 6 which validates our assumptions and the derived convergence orders.

Henceforth, C denotes a generic constant that assumes different values at different occurrences. The inner product of a Hilbert space H is denoted by $(\cdot,\cdot)_H$ and the duality pairing between H and H' is referred to as $\langle\cdot,\cdot\rangle$.

2. Problem setting. We will interpret the porous medium–type equation (1.1) in an H^{-1} framework. For the convenience of the reader, we summarize some basic properties of this space. Recall that $H^{-1}(\Omega)$ is the dual space of $H_0^1(\Omega)$ and the inclusions $H_0^1(\Omega) \subset L^2(\Omega) = L^2(\Omega)' \subset H^{-1}(\Omega)$ are continuous. The related Riesz map $\mathcal{R} : H_0^1(\Omega) \to H^{-1}(\Omega)$ is the isomorphism defined by

$$\langle \mathcal{R}u, v\rangle := (u,v)_{H_0^1(\Omega)} = \int_\Omega \nabla u \cdot \nabla v \, \mathrm{d}x;$$

hence, $\mathcal{R}$ is the Dirichlet Laplacian $-\Delta$ on $H_0^1(\Omega)$. The inner product on $H^{-1}(\Omega)$ can be defined as

$$(u,v)_{H^{-1}(\Omega)} := (\mathcal{R}^{-1}u, \mathcal{R}^{-1}v)_{H_0^1(\Omega)} = \langle u, \mathcal{R}^{-1}v\rangle = \langle \mathcal{R}^{-1}u, v\rangle.$$

In the present H^{-1} context the map $\Delta\alpha$, with domain

$$D(\Delta\alpha) := \{u \in H^{-1}(\Omega) \cap L^1(\Omega) : \alpha(u) \in H_0^1(\Omega)\},$$

has the following properties

(i) $(\Delta\alpha(u) - \Delta\alpha(v), u - v)_{H^{-1}(\Omega)} \le 0$ for all u and v in $D(\Delta\alpha)$;
(ii) $R(I - \lambda\Delta\alpha) = H^{-1}(\Omega)$ for all $\lambda > 0$.

In other words, the map $-\Delta\alpha$ is maximal monotone, and the following existence result is obtained from nonlinear semigroup theory.

LEMMA 2.1. *For any initial value $\eta \in D(\Delta\alpha)$ there exists a unique function $u \in W^{1,\infty}(0,T : H^{-1}(\Omega))$ satisfying*

1. *$u(t) \in D(\Delta\alpha)$ for all $t \in [0,T]$;*
2. *$\dot{u} = \Delta\alpha(u)$ a.e. on $(0,T)$;*
3. *$u(0) = \eta$.*

These results are given in [5]; for a contemporary reference see [2, Proposition 2.2.12 and Theorem 4.1.4]. For the forthcoming error analysis, we assume the following.

Assumption 1. The map $\alpha^{-1} : \mathbb{R} \to \mathbb{R}$ satisfies the bound

$$|\alpha^{-1}(x)| \le C(1 + |x|^r),$$

where C is a positive constant and the parameter r is in the interval $(0,\infty)$ when $\Omega \subset \mathbb{R}^d$, with $d \le 2$, and in the interval $(0,1]$ when $\Omega \subset \mathbb{R}^3$.

This assumption is fulfilled for the PME, where $r = 1/m$, and it implies the inclusions $D(\Delta\alpha) \subset L^p(\Omega)$ for all $p \in [1,\infty)$ when $\Omega \subset \mathbb{R}^d$, with $d \le 2$, and $D(\Delta\alpha) \subset L^6(\Omega)$ when $\Omega \subset \mathbb{R}^3$. The stated inclusions follow by the observations

$$\|u\|_{L^{p/r}(\Omega)} \le C\|1 + |\alpha(u)|^r\|_{L^{p/r}(\Omega)} \le C(1 + \|\alpha(u)\|^r_{L^p(\Omega)})$$

and $\alpha(u) \in H_0^1(\Omega) \subset L^p(\Omega)$, with p given by the Sobolev embedding theorem [1]. Note that the upper bound of r in the three-dimensional case is not optimal. However, we omit these considerations in order to keep the technicalities to a minimum.

3. Spatial discretization. In preparation for the spatial discretization of (1.1), we introduce the standard finite element space $S_h \subset H_0^1(\Omega)$ of continuous piecewise linear functions on Ω, with h denoting the maximum diameter of the related tetrahedral partition; see [4] for further details. As a direct analogue to the continuous case, we identify the Riesz map $\mathcal{R}_h : S_h \to S_h'$ with the discrete Laplacian $-\Delta_h$, where

$$\langle -\Delta_h u, v\rangle = (u, v)_{S_h} = \int_\Omega \nabla u \cdot \nabla v \, \mathrm{d}x.$$

Furthermore, we define the inner product of S_h' as

$$(u, v)_{S_h'} := (\mathcal{R}_h^{-1} u, \mathcal{R}_h^{-1} v)_{S_h} = \langle u, \mathcal{R}_h^{-1} v\rangle = \langle \mathcal{R}_h^{-1} u, v\rangle.$$

Note that $u \in H^{-1}(\Omega)$ can be interpreted as an element in S_h', by mere restriction, and that $u_h \in S_h$ can be seen as an element in both S_h' and $H^{-1}(\Omega)$, via the construction $(u_h, \cdot)_{L^2(\Omega)}$. Next, consider the map $\Delta_h \alpha$, with domain

$$D(\Delta_h \alpha) := \{u \in L^2(\Omega) : \alpha(u) \in S_h\},$$

and the spatial discretization of (1.1),

$$\dot{u}_h = \Delta_h \alpha(u_h), \quad u_h(0) = \eta_h \in D(\Delta_h \alpha). \tag{3.1}$$

Lemma 2.1 is in fact valid for an arbitrary maximal monotone map on a Hilbert space (see [2, Theorem 4.1.4]). Therefore, the very same existence result, as obtained for the original equation (1.1), can be derived for (3.1) by the lemma below.

LEMMA 3.1. *The map $-\Delta_h \alpha$ is maximal monotone.*

Proof. (i) Monotonicity: As $\alpha : \mathbb{R} \to \mathbb{R}$ is an increasing function, it follows that

$$\begin{aligned}(\Delta_h \alpha(u) - \Delta_h \alpha(v), u - v)_{S_h'} &= -\langle \alpha(u) - \alpha(v), u - v\rangle \\ &= -(\alpha(u) - \alpha(v), u - v)_{L^2(\Omega)} \le 0\end{aligned}$$

for all u and v in $D(\Delta_h \alpha)$.

(ii) Range condition: In order to prove that $R(I - \lambda \Delta_h \alpha) = S_h'$ for all $\lambda > 0$, consider the map $\alpha^{-1} - \lambda \Delta_h : S_h \to S_h'$ which is *hemicontinuous*, i.e., $t \mapsto \langle (\alpha^{-1} - \lambda \Delta_h)(u + tv), w\rangle$ is continuous on $[0, 1]$ for all u, v, and w in S_h, and *strongly monotone*, i.e.,

$$\big\langle (\alpha^{-1} - \lambda \Delta_h)(u) - (\alpha^{-1} - \lambda \Delta_h)(v), u - v\big\rangle \ge \lambda \|u - v\|_{S_h}^2$$

for all u and v in S_h. Hence, it follows by the Browder and Minty theorem (see [15, Theorem 26.A]) that $R(\alpha^{-1} - \lambda \Delta_h) = S_h'$, and the range condition is then implied by the identity $I - \lambda \Delta_h \alpha = (\alpha^{-1} - \lambda \Delta_h)\alpha$. ∎

4. Spatial error analysis. The aim of this section is to bound the spatial error, $u(t) - u_h(t)$, generated when passing from (1.1) to (3.1). The key idea of the analysis is to introduce the auxiliary implicit Euler discretizations

$$u^n := (I - \tau \Delta \alpha)^{-n}(\eta) \quad \text{and} \quad u_h^n := (I - \tau \Delta_h \alpha)^{-n}(\eta_h)$$

of (1.1) and (3.1), respectively, where $\tau := t/n$, $u^n \approx u(t)$, and $u_h^n \approx u_h(t)$. The influence of the spatial discretization can then be isolated to a time-independent term, $u^n - u_h^n$, by the decomposition

$$u(t) - u_h(t) = (u(t) - u^n) + (u^n - u_h^n) + (u_h^n - u_h(t)).$$

Before we proceed with the analysis, we again recapitulate a well-known result from nonlinear semigroup theory.

LEMMA 4.1. *Consider the evolution equation*

$$\dot{u} = f(u), \quad u(0) = \eta \in D(f),$$

on the (real) Hilbert space H, and its implicit Euler discretization $u^n = (I - \tau f)^{-n}(\eta)$. If the map $-f$ is maximal monotone, then

$$\|u(t) - u^n\|_H \le C\,\tau^{1/2}\,\|f(\eta)\|_H,$$

with a uniform constant C on the time interval $[0, T]$.

This result is due to [6]. Bounds of the term $u^n - u_h^n$ can also be found in the literature [13].

LEMMA 4.2. *If the initial values η and η_h satisfy $\eta \in L^\infty(\Omega)$, $\alpha(\eta) \in W^{2,1}(\Omega)$, $\|\alpha(\eta_h)\|_{S_h} \le C$, $\|\eta - \eta_h\|_{S_h'} \le Ch$, and Assumption 1 is valid, then*

$$\|u^n - u_h^n\|_{S_h'} \le C\varphi_d(\tau, h)h,$$

where $\varphi_d(\tau, h) = 1 + |\log h|^{1+r/2}$ for $d \le 2$ and $\varphi_3(\tau, h) = \tau^{-r/12}$.

Note that Lemma 4.2 is stated in our problem setting, but the results follow along the lines of the proofs presented in [13], where the one- and two-dimensional results are given in Lemma 2.6, and the three-dimensional result is stated in the remark following Theorem 2.7.

Example 4.3. Assume that the initial value η is Lipschitz continuous. The above hypotheses on η_h are then valid if $\eta_h := \alpha^{-1}(I_h\alpha(\eta))$, where I_h is the linear interpolation operator. Note that in this case the bound of $\eta - \eta_h$ holds even in $L^\infty(\Omega)$. To this end, consider a tetrahedron K of the partition with nodes $\{x_i\}$. As $I_h\eta_h = I_h\eta$ and $\eta_h|_K$ is the image of a linear function under a monotone map, we have the bound $|\eta(x_i) - \eta_h(x)| \le \max_j |\eta(x_i) - \eta(x_j)|$ for all x in K. Hence,

$$|\eta(x) - \eta_h(x)| \le |\eta(x) - \eta(x_i)| + |\eta(x_i) - \eta_h(x)| \le 2\,\mathrm{Lip}(\eta)h$$

for all x in K, and consequently $\|\eta - \eta_h\|_{L^\infty(\Omega)} \le C(\eta)h$.

Combining these results yields the following spatial error bound.

THEOREM 4.4. *Consider the solution u of the porous medium–type equation (1.1) and its spatial approximation u_h, given by (3.1). If $\eta \in L^\infty(\Omega)$, $\alpha(\eta) \in W^{2,1}(\Omega)$, $\|\alpha(\eta_h)\|_{S_h} \le C$, $\|\eta - \eta_h\|_{S_h'} \le Ch$, and Assumption 1 is valid, then*

$$\|u(t) - u_h(t)\|_{S_h'} \le C\phi_d(h)h,$$

where $\phi_d(h) = 1 + |\log h|^{1+r/2}$ for $d \le 2$ and $\phi_3(h) = h^{-r/(6+r)}$. The constant C is uniform in the time interval $[0, T]$.

Proof. By Lemmas 4.1 and 4.2, one obtains the inequality

$$\begin{aligned}\|u(t) - u_h(t)\|_{S_h'} &\le \|u(t) - u^n\|_{H^{-1}(\Omega)} + \|u^n - u_h^n\|_{S_h'} + \|u_h^n - u_h(t)\|_{S_h'} \\ &\le C\left(\tau^{1/2} + \varphi_d(\tau, h)h + \tau^{1/2}\right).\end{aligned}$$

The sought after bound now follows by setting $\tau = h^2$ when $\Omega \subset \mathbb{R}^d$, with $d \le 2$, or $\tau = h^{12/(6+r)}$ when $\Omega \subset \mathbb{R}^3$. ∎

The bound in Theorem 4.4 is close to the optimal form $\mathcal{O}(h)$, as the term $\phi_d(h)$ will not be observable in numerical experiments, e.g., for the three-dimensional PME the term becomes $\phi_3(h) = h^{-1/(6m+1)}$.

5. Full spatial time discretization. In order to obtain a full spatial time approximation of (1.1), we discretize (3.1) in time by an implicit Runge–Kutta method. The main issue when bounding the related error is that the bound of the time discretization must be independent of the stiffness of the problem. This prevents the usage of explicit integrators and the classic ODE theory. We will instead use implicit methods and employ the uniform results of [10].

For fixed h and a sufficiently regular α, (3.1) is a smooth ODE on a finite-dimensional space. Consequently, its solution u_h is smooth with bounded derivatives. For the convergence analysis we have in mind, however, it is essential that we can control the size of certain time derivatives of u_h.

The uniform boundedness of these derivatives cannot be guaranteed, in general. A typical example is given by the Barenblatt solution of the PME (see [14, section 4.4]) for which the time derivatives of u_h grow as $h \to 0$ and become unbounded in the limit. This implies that the error constant of the time discretization grows as $h \to 0$; see the Barenblatt evolution (6.7) in Table 6.2 below.

Extensive numerical experiments, however, indicate that the situation is often more favorable. For example, the evolutions (6.5), (6.6), and (6.8), considered in our simulations in section 6, clearly show that the error constant of the time discretization remains bounded. Even though the current analytic theory does not provide tools to characterize an explicit class of initial values guaranteeing the sought after regularity, the convincing numerical results motivate the following sufficient stability assumption.

Assumption 2. The function $u_h \in C^{q+1}([0,T] : S_h')$ satisfies (3.1) on the interval $(0,T]$ and $\|u_h^{(q+1)}\|_{L^\infty(0,T:S_h')}$ is uniformly bounded in h.

Note that this assumption is of a theoretical nature as some growth of the time derivatives in the error constant can always be compensated for by relating the time step to the spatial grid size.

The s-stage Runge–Kutta approximation u_h^{n+1} of $u_h(t_{n+1})$ is defined by the S_h' difference equation

$$\begin{cases} U^{ni} = u_h^n + k\sum_{j=1}^s a_{ij}\Delta_h\alpha(U^{nj}), \quad i = 1,\dots,s, \\ u_h^{n+1} = u_h^n + k\sum_{i=1}^s b_i\Delta_h\alpha(U^{ni}), \end{cases} \tag{5.1}$$

where $k = T/N$, $t_n = kn$ for $n = 0,\dots,N$, and $u_h^0 = \eta_h$. The stage values U^{ni} approximate the solution at times $t_n + c_i k$ with $c_i = \sum_{j=1}^s a_{ij}$. For further details on Runge–Kutta methods, we refer to [9].

One can characterize a set of matrices $A = \{a_{ij}\}$ for which (5.1) has a unique solution, as we prove in [10, Theorem 5.2]. We recall this result for the convenience of the reader.

LEMMA 5.1. *If the matrix A is invertible and there exists a positive diagonal matrix D such that DA^{-1} is positive definite, then there exists a unique solution $\{U^{ni}\}_{i=1}^s$ of* (5.1).

Implicit Runge–Kutta methods are referred to as *algebraically stable*, and with *stage order* $q \geq 1$, whenever $b_i \geq 0$, the matrix $S = \{b_i a_{ij} + b_j a_{ji} - b_i b_j\}$ is positive semidefinite, and the coefficients satisfy the order conditions

$$\sum_{i=1}^s b_i c_i^{k-1} = 1/k \quad \text{and} \quad \sum_{j=1}^s a_{ij} c_j^{k-1} = c_i^k/k \quad \text{for} \quad k = 1,\dots,q.$$

For these methods one has the following analogue to the global error bounds obtained for stiff ODEs (compare, e.g., with the results of [9, Theorem 15.3]).

LEMMA 5.2. *If there exists a positive diagonal matrix D such that DA^{-1} is positive definite, and Assumption 2 is valid, then*

$$\|u_h(t_n) - u_h^n\|_{S_h'} \le Ck^q,$$

where the constant C is uniform in the time interval $[0,T]$.

The proof is given in [10, Corollary 6.3].

Example 5.3. Some examples of algebraically stable Runge–Kutta methods which satisfy the assumptions imposed on the matrix A in Lemma 5.2 are the Gauss and Radau IIA methods. The explicit expressions of the optimal D matrices are summarized in [9, section IV.14].

We are now able to derive the following bound for the error of the full discretization by combining Theorem 4.4 and Lemma 5.2.

THEOREM 5.4. *Consider the solution u of the porous medium–type equation (1.1) and its full finite element Runge–Kutta approximation u_h^n, given by (5.1). If $\eta \in L^\infty(\Omega)$, $\alpha(\eta) \in W^{2,1}(\Omega)$, $\|\alpha(\eta_h)\|_{S_h} \le C$, $\|\eta - \eta_h\|_{S_h'} \le Ch$, the Runge–Kutta method is algebraically stable with stage order q, there exists a positive diagonal matrix D such that DA^{-1} is positive definite, and Assumptions 1 and 2 are valid, then*

$$\|u(t_n) - u_h^n\|_{S_h'} \le C(\phi_d(h)h + k^q),$$

where $\phi_d(h) = 1 + |\log h|^{1+r/2}$ for $d \le 2$ and $\phi_3(h) = h^{-r/(6+r)}$. The constant C is uniform in the time interval $[0,T]$. ∎

6. Numerical experiments. We finally propose an implementation for the full spatial time discretization and present a series of numerical experiments that validate the regularity assumptions as well as the derived convergence orders.

To ease the notation, we start off by considering the full discretization based on the implicit Euler method,

$$u_h^{n+1} = u_h^n + k\Delta_h \alpha(u_h^{n+1}).$$

The only computable quantity is $\alpha(u_h^{n+1}) \in S_h$, and we therefore rewrite the discretization as

$$\alpha^{-1}(v_h^{n+1}) = \alpha^{-1}(v_h^n) + k\Delta_h v_h^{n+1},$$

where $v_h^n := \alpha(u_h^n) \in S_h$. Introduce a basis $\{\psi_i\}_{i=1}^M$ of S_h and let $v_h^n = \sum_{j=1}^M d_j^n \psi_j$. The discretization is then equivalent to

$$g(d^{n+1}) = g(d^n) - kKd^{n+1}, \tag{6.1}$$

where $d^n = (d_1^n, \dots, d_M^n)^{\mathrm{T}}$, $K = \{(\nabla\psi_j, \nabla\psi_i)_{L^2(\Omega)}\}$ is the stiffness matrix, and

$$g(d^n)_i = \int_\Omega \alpha^{-1}\Big(\textstyle\sum_{j=1}^M d_j^n \psi_j\Big)\,\psi_i \,\mathrm{d}x, \quad i = 1, \dots, M.$$

Next, choose $\{\psi_i\}$ as the standard basis related to linear Lagrange elements [4]. Approximating the integrals in (6.1) by the nodal quadrature rule, i.e., the multidimensional counterpart of the trapezoidal rule, and changing variables, $y^n := \alpha^{-1}(d^n)$, gives the scheme

$$Dy^{n+1} = Dy^n - kK\alpha(y^{n+1}),$$

where the diagonal matrix D is the so-called lumped mass matrix. (The application of α and α^{-1} to a vector is understood componentwise.) Hence, the full discretization u_h^n is approximated by $\tilde{u}_h^n := \alpha^{-1}(\sum_{i=1}^M \alpha(y_i^n)\psi_i)$.

The very same considerations can be made for full discretizations based on stiffly accurate Runge–Kutta methods, i.e., $a_{sj} = b_j$ and $c_s = 1$. A typical example is given by the class of Radau IIA methods. For stiffly accurate methods, the scheme becomes

$$\begin{cases} DY^{ni} = Dy^n - k\sum_{j=1}^s a_{ij} K\alpha(Y^{nj}), \quad i = 1, \dots, s, \\ y^{n+1} = Y^{ns}. \end{cases} \tag{6.2}$$

In the numerical experiments below, where the PME is chosen as the model problem, the map α is differentiable, and we then propose using Newton's method when approximating the solution to (6.2).

Throughout the experiments we will employ the three-stage Radau IIA method and with the discrete initial value η_h chosen as in Example 4.3. In order to approximate the discretization error in S_h', we consider the linear interpolation of the numerical solution $I_h\tilde{u}_h^n = \sum_{i=1}^M y_i^n \psi_i$. For the one- and two-dimensional settings we have the estimate

$$\begin{aligned} \|\tilde{u}_h^n - I_h\tilde{u}_h^n\|_{S_h'} &\le C(1 + |\log h|)\, \|\tilde{u}_h^n - I_h\tilde{u}_h^n\|_{L^1(\Omega)} \\ &\le C(1 + |\log h|)h^d \sum_{\ell=1}^M \max_{K_\ell} |\tilde{u}_h^n(x_i) - \tilde{u}_h^n(x_j)|, \end{aligned}$$

where d is the spatial dimension and K_ℓ denotes the ℓth tetrahedron of the partition with nodes $\{x_i\}$. In the context of the PME, one observes a spatially smooth solution except in regions where the equation degenerates. Hence, the differences $\tilde{u}_h^n(x_i) - \tilde{u}_h^n(x_j)$ are (at least) of the form $\mathcal{O}(h)$ in partitions where the solution is smooth and are of the form $\mathcal{O}(1)$ in partitions where the solution jumps. Furthermore, the solution will degenerate in a fixed number of points or curves and the number of degenerate partitions is therefore proportional to h^{-d+1}. This implies the relation

$$\sum_{\ell=1}^M \max_{K_\ell} |\tilde{u}_h^n(x_i) - \tilde{u}_h^n(x_j)| = \mathcal{O}(h^{-d+1}), \tag{6.3}$$

and we then obtain that $\|\tilde{u}_h^n - I_h\tilde{u}_h^n\|_{S_h'} = \mathcal{O}(|\log h|\, h)$. Note that the sum in (6.3) is dependent only on the nodal values of the numerical solution, and it is easily checked in the simulation runs that the equality (6.3) is valid for our experiments. If we finally compute a reference solution $\tilde{u}_{h_r}^{N_r}$ by solving (6.2) with sufficiently small parameters (h_r, k_r), then the global error can be approximated as

$$\|u(T) - u_h^N\|_{S_h'} \approx \|\tilde{u}_{h_r}^{N_r} - \tilde{u}_h^N\|_{S_h'} \le \|I_{h_r}\tilde{u}_{h_r}^{N_r} - I_h\tilde{u}_h^N\|_{S_h'} + \mathcal{O}(|\log h|\, h),$$

where the second term from the right is explicitly computable:

$$\|I_{h_r}\tilde{u}_{h_r}^{N_r} - I_h\tilde{u}_h^N\|_{S_h'} = (I_{h_r}\tilde{u}_{h_r}^{N_r} - I_h\tilde{u}_h^N, -\Delta_h^{-1}(I_{h_r}\tilde{u}_{h_r}^{N_r} - I_h\tilde{u}_h^N))_{L^2(\Omega)}^{1/2}. \tag{6.4}$$

To validate the convergence result of Theorem 5.4, we consider the one-dimensional PME with

$$\alpha(u) = u^5, \quad \eta(x) = \sin(3\pi x), \quad \Omega = (0, L), \quad L = 1, \quad \text{and} \quad T = 0.1. \tag{6.5}$$

TABLE 6.1

Thm. 5.4		3		1		2

The results of the simulations are presented in Table 6.1, where the scaled spatial parameter h/L was kept at a constant value of 2^{-13}, varied as k/T, or varied proportionally to k^2. As can be seen from the results, the term (6.4) displays a convergence of roughly the form $\mathcal{O}(h^{1.3} + k^3)$. The presence of the third order convergence in time indicates that there is sufficient time regularity present, and the results are indeed in agreement with the convergence of form $\mathcal{O}(h + k^3)$, predicted by Theorem 5.4.

We conclude by investigating which type of initial values yields solutions satisfying Assumption 2. One way to conduct such an investigation is to consider the time discretization error

$$\|u_h(T) - u_h^N\|_{S_h'} \approx \|I_h(\tilde{u}_h^{N_r} - \tilde{u}_h^N)\|_{S_h'} + \mathcal{O}(|\log h|\, h).$$

If the solution of the spatial discretization u_h fulfills Assumption 2, one would expect the error to remain constant as the spatial parameter h tends to zero and, similarly, one expects that $\lim_{h\to 0} \|u_h(T) - u_h^N\|_{S_h'} = \infty$ when $u_h^{(4)}$ is not uniformly bounded with respect to h. For our experiment we consider the example given in (6.5) and the evolutions

$$\alpha(u) = |u|^{2.2}u,\ \eta(x) = \sin(4.5x)(1-x),\ \Omega = (0, L),\ L = 1,\ \text{and } T = 3, \tag{6.6}$$

$$\alpha(u) = u^5,\ \eta(x) = [1 - x^2/15]_+^{1/4},\ \Omega = (-L, L),\ L = 10,\ \text{and } T = 5, \tag{6.7}$$

$$\alpha(u) = u^5,\ \eta(x, y) = \sin(3\pi x)\sin(3\pi y),\ \Omega = (0, L)^2,\ L = 1,\ \text{and } T = 0.1. \tag{6.8}$$

The first problem is chosen in order to illustrate that Assumption 2 is valid for (regular) unsymmetric initial values and noninteger values of the exponent m in the PME. The second evolution (6.7) is equipped with the initial data of the classical Barenblatt solution [14], for which the solution does not possess high time regularity, and the last evolution is the two-dimensional version of (6.5); see Figure 6.1.

The observed values of the term $\|I_h(\tilde{u}_h^{N_r} - \tilde{u}_h^N)\|_{S_h'}$ are presented in Table 6.2, where the spatial parameter was varied. The scaled time steps k/L were chosen as 2^{-6} for (6.5) and (6.6), and as 2^{-8} for (6.7) and (6.8), respectively. It is clear from the simulations that the time discretization error $\|u_h(T) - u_h^N\|_{S_h'}$ remains bounded for the evolutions (6.5), (6.6), (6.8), and grows for the Barenblatt solution (6.7); i.e., Assumption 2 is realistic for the cases with regular initial values.

Acknowledgments. We thank Juan Luis Vázquez for providing us with a preliminary version of his book [14] and Noel Walkington for a proof of the remark following Theorem 2.7 in [13].

CONVERGENCE AND NUMERICS OF A MULTISECTION METHOD FOR SCATTERING BY THREE-DIMENSIONAL ROUGH SURFACES*

ERIC HEINEMEYER†, MARKO LINDNER‡, AND ROLAND POTTHAST‡

Abstract. We introduce a novel *multisection method* for the solution of integral equations on unbounded domains. The method is applied to the rough surface scattering problem in three dimensions, in particular to a Brakhage–Werner-type integral equation for acoustic scattering by an unbounded rough surface with Dirichlet boundary condition, where the fundamental solution is replaced by some appropriate half-space Green's function. The basic idea of the multisection method is to solve an integral equation $A\varphi = f$ by *approximately* solving the equation $P_\varrho A P_\tau \varphi = P_\varrho f$ for some positive constants ϱ, τ. Here P_ϱ is a projection operator that truncates a function to a ball with radius $\varrho > 0$. For a very general class of operators A, for which the Brakhage–Werner equation from acoustic scattering is a particular example, we will show existence of approximate solutions to the multisection equation and show that approximate solutions to the multisection equation approximate the true solution φ_0 of the operator equation $A\varphi = f$. Finally, we describe a numerical implementation of the multisection algorithm and provide numerical examples for the case of rough surface scattering in three dimensions.

1. Introduction. The goal of this work is the introduction and analysis of a new numerical scheme for a class of linear operator equations

$$A\varphi = f, \tag{1}$$

where A has particular decay properties.

Model problem. The basic model problem for our work is the solution of integral equations over unbounded domains which appear in what is usually called the *rough surface scattering problem* in the engineering literature. It denotes scattering of acoustic or electromagnetic waves by a surface which is a nonlocal perturbation of an infinite plane surface. We will restrict our attention to the case where the scattering surface

$$\Gamma = \{x = (x_1, x_2, x_3) \in \mathbb{R}^3 : x_3 = f(x_1, x_2)\} \tag{2}$$

is the graph of some bounded continuous function $f : \mathbb{R}^2 \to \mathbb{R}$. The domain of wave propagation is the upper perturbed half-space

$$D := \{x = (x_1, x_2, x_3) : x_3 > f(x_1, x_2)\}. \tag{3}$$

For this work we will assume that $f \in C^{1,\alpha}$, $\alpha \in (0, 1)$, is a Lyapunov function; i.e., it is continuously differentiable with Hölder continuous first derivative.

Rough surface scattering problems arise in important applications for acoustic and electromagnetic waves. Well-known areas are outdoor sound propagation or optical scattering in nanotechnology. We refer the reader to the extensive literature reviewed in [12], [16], [15], [17], and [5]. Recently, Chandler-Wilde, Heinemeyer, and Potthast [1], [2] provided some rigorous existence theory for the integral equation approach in three dimensions. But to our knowledge there is no rigorous numerical analysis for the solution of these integral equations in three dimensions. This is the starting point of our work.

However, the approach presented here is based only on very general properties of the operator equations under consideration. We expect that it can be used for a whole range of different problems, and it will be the starting point for further research.

The finite section method. If we regard (1) as an equation on the space $Y = L^2(\mathbb{R}^2)$, for example, then the well-known *finite section method* consists in replacing (1) by

$$P_\varrho A P_\varrho \varphi = P_\varrho f, \tag{4}$$

where $\varrho > 0$ and the projection operator $P_\varrho : Y \to Y$ is given by

$$(P_\varrho \psi)(x) := \begin{cases} \psi(x), & |x| < \varrho \\ 0 & \text{otherwise.} \end{cases} \tag{5}$$

The operator P_ϱ truncates a function on $\mathbb{R}^2$ to its values inside the disk

$$B_\varrho := \{x \in \mathbb{R}^2 : |x| < \varrho\}. \tag{6}$$

In these notations $|\cdot|$ denotes an arbitrary norm in $\mathbb{R}^2$. In particular, in our numerical part in section 4 we will use the maximum norm $|x| := \max(|x_1|, |x_2|)$.

So the finite section method (4) simply restricts the right-hand side f, the solution φ, and the resulting function $A\varphi$ all to the same disk B_ϱ. The idea behind this method is, provided (1) is uniquely solvable for every right-hand side f, to hope that also (4) is uniquely solvable (now in $L^2(B_\varrho)$, of course) and that its solution φ approximates the exact solution φ_0 of (1) if only one chooses ϱ large enough. If this is the case, then this method is called applicable. There are, however, simple examples of operators A that show that the finite section method is not necessarily applicable in general.

There are recent results on the applicability of the finite section method for the fairly large class of all so-called band-dominated operators in terms of their limit operators (see [10], [13], and [14]). The operators originating from two-dimensional (2D) rough surface scattering are band-dominated, and we refer the reader to [11], [3], and further literature cited therein for the study and application of the finite section method to these equations. Although, also for three-dimensional (3D) rough surface scattering, the corresponding operators belong to this class, we will leave the finite section method aside and study what we call the multisection method. We underline that the framework for this method not only covers the set of band-dominated operators, it even applies to the much larger class, called $L(Y, \mathcal{P})$ in [10] and [13], that consists of all bounded linear operators A on Y for which

$$\|(I - P_\varrho)AP_\tau\| \to 0 \quad \text{and} \quad \|P_\tau A(I - P_\varrho)\| \to 0 \quad \text{as} \quad \varrho \to \infty \tag{7}$$

for every fixed $\tau > 0$. In fact, the multisection method to be presented here only requires the first condition in (7) to be true.

The multisection method. Already very simple examples like the shift operator

$$(A\varphi)(x) \;=\; \varphi(x-a), \qquad x \in \mathbb{R}^2,$$

on $Y = L^2(\mathbb{R}^2)$ with a fixed $a \in \mathbb{R}^2 \setminus \{0\}$ show that the finite section method fails to apply in general. Indeed, $P_\varrho A P_\varrho$ is neither surjective nor injective on $L^2(B_\varrho)$, however large ϱ is chosen. The new method proposed here will overcome some of these difficulties and will, in fact, apply to all bounded linear operators on Y that are subject to the first condition in (7).

In contrast to exactly solving the truncated equation (4), that is,

$$P_\varrho A P_\varrho \varphi \;=\; P_\varrho f,$$

for large ϱ, we propose to look for a function $\varphi \in Y$ with

$$P_\varrho A P_\tau \varphi \;\approx\; P_\varrho f \tag{8}$$

for large ϱ, τ and a given discrepancy allowance δ in the "$\approx$" sign. So we have two main differences from the finite section method:

(a) We allow two different cutoff parameters ϱ and τ instead of just one.

(b) We work with approximate instead of exact solutions.

Point (a) is the reason why we call this method the *multisection method*. From the matrix perspective it means that we cut rectangular rather than quadratic finite matrices out of the original infinite matrix that represents our operator A.

We will show that for every precision $\delta > 0$ and every sufficiently large parameter $M > 0$, there are positive constants ϱ, τ such that there exists a function $\varphi \in Y$ which satisfies the conditions

$$P_\tau \varphi = \varphi, \tag{9}$$

$$\|P_\varrho A P_\tau \varphi - P_\varrho f\|_Y \le \delta; \tag{10}$$

i.e., φ is supported on B_τ and it approximately satisfies the multisection equation (8).

In our main convergence result we show that, given any $\varepsilon > 0$, we can choose the parameters δ, ϱ, τ such that every solution φ of the multisection method (9)–(10) approximates the true solution φ_0 of the original equation (1) with

$$\|\varphi - \varphi_0\|_Y \le \varepsilon.$$

We would like to clarify the relation between the multisection method and the theory of regularization of ill-posed problems. Clearly, in general, the truncated equation $P_\varrho A P_\tau \varphi = P_\varrho f$ does not have a solution and, thus, describes an ill-posed equation. In the theory of inverse problems such equations are solved approximately by using a family R_α of bounded linear inversion operators which (for injective operators) tend pointwise to the inverse of the equation under consideration; see [6]. However, here we are not interested in the case where $\delta \to 0$ while ρ and τ are fixed, which would be the case interesting in the framework of inverse problems. Here we keep δ fixed and then choose τ, ρ sufficiently large; i.e., we change the equation which we solve.

Contents of the paper. Section 2 introduces the 3D rough surface scattering problems. Here we study the operators arising from this application and prove that they satisfy the conditions on which the multisection method is built. Section 3 contains the main analysis for the multisection method. We provide this analysis in a very general setting which reflects the potential of this method. Section 4 provides details about the algorithmical realization of the multisection method and numerical examples which demonstrate the applicability of the ideas.

2. Scattering by rough surfaces. We restrict our attention to time-harmonic acoustic waves, which are modelled by the *Helmholtz equation*

$$\triangle u + \kappa^2 u = 0. \tag{11}$$

Here, κ denotes the wave number, which for the real-valued case is linked to the speed of sound c and the frequency ω via $\kappa = \omega/c > 0$. Often, κ is admitted to be a complex number $\kappa = \kappa_0 + i\sigma$, where the imaginary part σ models the properties of some lossy medium.

For our scattering surface Γ we assume that $f \in BC^{1,\alpha}(\mathbb{R}^2)$ for some $\alpha \in (0, 1]$. Further, f is assumed to satisfy the bounds

$$0 < f^- \le f(x) \le f^+, \quad x \in \mathbb{R}^2. \tag{12}$$

We consider the scattering of an *incident acoustic wave* u^i by the surface Γ. The *total field* $u := u^i + u^s$ is the sum of the incident field and the *scattered field* u^s. The scattered field is a solution to the Helmholtz equation (11) in D. Further, we assume that u satisfies the *Dirichlet boundary condition*

$$u(x) = 0, \quad x \in \Gamma. \tag{13}$$

The scattered field is required to be bounded in D; i.e.,

$$|u^s(x)| \le c, \quad x \in D, \tag{14}$$

for some constant c. Further, we follow [2] and require that u satisfies the *limiting absorption principle* as follows. If u is considered in its dependence on the complex wave number κ, we write $u = u^{(\kappa)}$. We assume that, for all sufficiently small $\sigma > 0$, a solution of (11), (13), (14) exists and satisfies

$$u^{(\kappa_0+i\sigma)} \to u^{(\kappa_0)}, \quad \sigma \to 0, \tag{15}$$

for all $x \in D$. The limiting absorption principle is a kind of radiation condition which is needed to obtain the physically correct solution to the scattering problem.

The free-space fundamental solution in three dimensions is given by the function

$$\Phi(x, y) = \frac{1}{4\pi} \frac{e^{i\kappa|x-y|}}{|x-y|}, \quad x \ne y \in \mathbb{R}^3. \tag{16}$$

The decay of this function for $|y| \to \infty$ is very weak, and it has not been possible to use it for the solution of scattering problems over unbounded domains in three dimensions. However, in [1] Chandler-Wilde, Heinemeyer, and Potthast employed the Green's function for the half-space $\{x \in \mathbb{R}^3 : \ x_3 > 0\}$,

$$G(x, y) := \Phi(x, y) - \Phi(x, y') \tag{17}$$

with $y' := (y_1, y_2, -y_3)$, to derive an integral equation of the second kind for the solution of the rough surface scattering problem. The decay of the function G is given in [1, equation (3.8)] as

$$\Big|G(x, y)\Big| \le \frac{C}{|x-y|^2} \tag{18}$$

for all $x, y \in \mathbb{R}^3$ with $f^- < x_3, y_3 < f^+$ with some constant C. For the normal derivative of G the estimate

$$\Big|\frac{\partial G(x,y)}{\partial \nu(y)}\Big| \leq \frac{C}{|x-y|^2} \tag{19}$$

holds for all $x, y \in \mathbb{R}^3$ with $f^- < x_3, y_3 < f^+$ with some constant C; compare equation (3.11) in [1].

We are now prepared to formulate the scattering problem under consideration.

DEFINITION 2.1 (point source rough surface scattering problem). *For the incident field $u^i(x) := \Phi(x,z)$ with $z \in D$ we seek a scattered field $u^s \in C^2(D) \cap C(\overline{D})$ which satisfies the Helmholtz equation* (11) *in D, the Dirichlet boundary condition* (13) *on Γ, the bound* (14)*, and the limiting absorption principle* (15).

The rough surface scattering problem is transformed into a boundary value problem via the ansatz

$$u^s(x) = v(x) - \Phi(x, z'), \tag{20}$$

where v satisfies the Helmholtz equation (11), the bound (14), the limiting absorption principle (15), and the boundary condition

$$v(x) = g(x), \quad x \in \Gamma, \tag{21}$$

with

$$g(x) := -(\Phi(x,z) - \Phi(x,z')) = -G(x,z). \tag{22}$$

A solution to the boundary value problem can be found via the single- and double-layer potential approach. We define the *single-layer potential*

$$u_1(x) = \int_\Gamma G(x,y)\varphi(y)\, ds(y), \quad x \in \mathbb{R}^3, \tag{23}$$

and the *double-layer potential*

$$u_2(x) = \int_\Gamma \frac{\partial G(x,y)}{\partial \nu(y)}\varphi(y)\, ds(y), \quad x \in \mathbb{R}^3. \tag{24}$$

The boundary values of these potentials can be calculated using the boundary integral operators S and K defined by

$$(S\varphi)(x) = 2\int_\Gamma G(x,y)\varphi(y)\, ds(y), \quad x \in \Gamma, \tag{25}$$

and the *double-layer potential*

$$(K\varphi)(x) = 2\int_\Gamma \frac{\partial G(x,y)}{\partial \nu(y)}\varphi(y)\, ds(y), \quad x \in \Gamma. \tag{26}$$

It is shown in [1] that the combined single- and double-layer potential

$$v(x) := u_2(x) - i\eta u_1(x), \quad x \in D, \tag{27}$$

with parameter $\eta > 0$ satisfies the boundary value problem (21) if and only if the density $\varphi \in L^2(\Gamma)$ satisfies the integral equation

$$(I + K - i\eta S)\varphi = 2g, \tag{28}$$

which is of the form $(I - W)\varphi = f$ with $W = -K + i\eta S$ and $f = 2g$. The basic uniqueness and existence result is given by Theorem 3.4 of [2] as follows.

THEOREM 2.2. *The operator $I + K - i\eta S$ is boundedly invertible on $L^2(\Gamma)$, and for the norm of its inverse, one has*

$$\|(I + K - i\eta S)^{-1}\| \leq B, \tag{29}$$

where the constant B, as given in (3.4) *in* [2], *depends only on the quotient κ/η and the Lipschitz constant of f.*

As a result of Theorem 2.2 we obtain the existence of the solution for the rough surface scattering problem. In principle, the solution to the scattering problem is given by the combined potential (27) with a density φ which satisfies (28). Our main topic here is the numerical solution of such integral equations in three dimensions. We need to treat the numerical integration of functions over unbounded surfaces.

3. The multisection method (MSM). We will formulate our multisection method (from this point abbreviated by MSM) for the following abstract setting which includes the rough surface scattering problems discussed above.

Let Y be a Banach space, and let $\{P_\varrho\}_{\varrho>0}$ be a family of linear operators on Y with the following three properties:

(P1) $P_\varrho P_\tau = P_\tau = P_\tau P_\varrho$ for all $\varrho \geq \tau > 0$,

(P2) $\|P_\varrho\| = 1$ for all $\varrho > 0$,

(P3) $P_\varrho \to I$ pointwise, which means $P_\varrho\varphi \to \varphi$ for all $\varphi \in Y$, as $\varrho \to \infty$.

From (P1) with $\varrho = \tau$ we get that every P_ϱ is a projection operator. We will also have to deal with the complementary projectors $I - P_\varrho$ which, for brevity, shall be denoted by Q_ϱ for every $\varrho > 0$.

Now suppose A is a bounded linear operator on Y with

(A1) A invertible (and therefore boundedly invertible) on Y,

(A2) $\|Q_\varrho A P_\tau\| \to 0$ as $\varrho \to \infty$ for every fixed $\tau > 0$.

For illustration we give an example of Y, $\{P_\varrho\}_{\varrho>0}$, and A that includes the setting from (28) in section 2.

Example 3.1. Let $Y = L^p(\mathbb{R}^n)$ with $1 \leq p < \infty$ and $n \in \mathbb{N}$, and define P_ϱ as in (5) for every $\varrho > 0$. Then Y and the family $\{P_\varrho\}_{\varrho>0}$ are clearly subject to our assumptions (P1)–(P3).

Now let $A = I - W$, where W is a well-defined and bounded integral operator

$$(W\varphi)(x) = \int_{\mathbb{R}^n} k(x,y)\,\varphi(y)\,dy, \qquad x \in \mathbb{R}^n, \tag{30}$$

on Y. Hence the kernel function $k(\cdot,\cdot)$ must satisfy a decay condition

$$|k(x,y)| \leq \frac{C}{|x-y|^\gamma} \quad \text{for} \quad |x-y| > 1 \tag{31}$$

with constants $\gamma > 0$ and some $C > 0$.

Note that this example, with $p = n = \gamma = 2$, covers the operators in the boundary integral formulation (28) arising from 3D rough surface scattering problems as discussed in section 2.

The following lemma shows that our assumption (A2) automatically holds for the operator A from Example 3.1 if $\gamma p > n$.

LEMMA 3.2. *Let $A = I - W$ act boundedly on $Y = L^p(\mathbb{R}^n)$ with $1 \le p < \infty$, $n \in \mathbb{N}$ and W as in (30) and (31) with $C > 0$ and $\gamma > 0$. Then, for every $\tau > 0$, we have*

$$\|Q_\varrho A P_\tau\| \le \frac{c}{\varrho^{\gamma - n/p}}, \qquad \varrho > 2\tau, \tag{32}$$

with some constant $c > 0$ depending on τ. In particular, if $\gamma p > n$, then assumption (A2) *holds.*

Proof. Let $B_\varrho = \{x \in \mathbb{R}^n : |x| \le \varrho\}$ and $\partial B_\varrho = \{x \in \mathbb{R}^n : |x| = \varrho\}$ be the ball and sphere of radius $\varrho > 0$ in $\mathbb{R}^n$, and denote their n- and $(n-1)$-dimensional measure by $|B_\varrho|$ and $|\partial B_\varrho|$, respectively. Now take some $\varrho > 2\tau > 0$ and first suppose $1 < p < \infty$. Using Hölder's inequality with $1/p + 1/q = 1$ we get the following:

$$\begin{aligned}
\|Q_\varrho A P_\tau \varphi\|^p_{L^p(\mathbb{R}^n)} &= \int_{|x|\ge\varrho} \Big|(AP_\tau\varphi)(x)\Big|^p dx \\
&= \int_{|x|\ge\varrho} \Big|(WP_\tau\varphi)(x)\Big|^p dx \\
&= \int_{|x|\ge\varrho} \Big| \int_{|y|<\tau} k(x,y)\,\varphi(y)\; dy\Big|^p dx \\
&\le \int_{|x|\ge\varrho} \left(\left(\int_{|y|<\tau} |k(x,y)|^q\; dy \right)^{1/q} \cdot \|P_\tau\varphi\|_{L^p(\mathbb{R}^n)} \right)^p dx \\
&\le \int_{|x|\ge\varrho} \left(\int_{|y|||<\tau} |k(x,y)|^q\; dy \right)^{p/q} dx \;\cdot\; \|\varphi\|^p_{L^p(\mathbb{R}^n)}.
\end{aligned}$$

Consequently, using the bound (31) and the inequality

$$|x| \ge \varrho > 2\tau > 2|y|, \quad \text{which implies} \quad |x-y| \ge |x| - |y| > |x|/2,$$

we get

$$\begin{aligned}
\|Q_\varrho A P_\tau\|^p &\le \int_{|x|\ge\varrho} \left(\int_{|y|<\tau} \frac{C^q}{|x-y|^{\gamma q}}\; dy \right)^{p/q} dx \qquad (33) \\
&\le \int_{|x|\ge\varrho} \left(\int_{|y|<\tau} \frac{C^q}{(|x|/2)^{\gamma q}}\; dy \right)^{p/q} dx \\
&= \left(\int_{|x|\ge\varrho} \frac{1}{|x|^{\gamma p}}\; dx \right) \left(\int_{|y|<\tau} dy \right)^{p/q} 2^{\gamma p}\, C^p \\
&= \left(\int_{r=\varrho}^{+\infty} \frac{1}{r^{\gamma p}}\; |\partial B_r|\; dr \right) |B_\tau|^{p/q}\, 2^{\gamma p}\, C^p \\
&= \left(\int_{r=\varrho}^{+\infty} \frac{r^{n-1}}{r^{\gamma p}}\; dr \right) |\partial B_1|\, |B_\tau|^{p/q}\, 2^{\gamma p}\, C^p \\
&= \varrho^{\,n-\gamma p}\; \frac{1}{\gamma p - n}\, |\partial B_1|\, |B_\tau|^{p/q}\, 2^{\gamma p}\, C^p.
\end{aligned}$$

Finally, taking pth roots proves (32). The proof for $p = 1$ is similar. But instead of using Hölder's inequality one immediately arrives at (33), with p/q replaced by 0. ∎

We illustrate the generality of our approach with three more examples of Banach spaces Y with projections P_ϱ and operators A acting on them.

Example 3.3. Let $Y = \ell^p(\mathbb{Z}^n)$ with $1 \le p < \infty$ and $n \in \mathbb{N}$. Define P_ϱ, with $\varrho > 0$, literally as in (5) but with $x \in \mathbb{Z}^n$, of course. Also here, (P1)–(P3) clearly hold.

In this case, in fact every bounded linear operator A on Y is subject to (A2)! This can be seen as follows. Since all P_τ are compact operators on Y, also AP_τ is compact for every $\tau > 0$. But since, by (P3), $Q_\varrho \to 0$ pointwise as $\varrho \to \infty$, and since pointwise convergence on compact sets is uniformly, we get that even (A2) holds.

Example 3.4. Let $Y = C[0, 1]$. For $m \in \mathbb{N}$, let $P_m\varphi$ denote the piecewise linear function which interpolates $\varphi \in Y$ at the points $j/2^m$ with $j = 0, \dots, 2^m$, and for arbitrary $\varrho > 0$, put $P_\varrho = P_{[\varrho]}$ with $[\varrho]$ denoting the integer part of ϱ. Then it is easy to see that (P1)–(P3) are fulfilled.

Example 3.5. Let $Y = L^2(\mathbb{T})$, where $\mathbb{T} := \{z \in \mathbb{C} : |z| = 1\}$ is the complex unit circle. For $m \in \mathbb{N}$, let

$$(P_m\varphi)(t) = \sum_{k=-m}^{m} c_k\, t^k, \quad t \in \mathbb{T},$$

be the truncated Fourier series of φ with c_k denoting its kth Fourier coefficient. And again put $P_\varrho = P_{[\varrho]}$ for arbitrary $\varrho > 0$. Then (P1)–(P3) are fulfilled.

Note that this example is isometrically isomorphic to Example 3.3 with $n = 1$ and $p = 2$, the isomorphism being the Fourier transform. As a result we get that also here every bounded linear operator A on Y is subject to (A2).

Given a Banach space Y and a family of projections $\{P_\varrho\}_{\varrho>0}$ on Y with properties (P1)–(P3), an operator A on Y with properties (A1) and (A2), and an arbitrary element $f \in Y$, we are looking for the (unique) solution $\varphi =: \varphi_0$ of (1); that is,

$$A\varphi = f.$$

For the approximate solution of (1) we propose the following method.

DEFINITION 3.6 (MSM). *For a given precision $\delta > 0$ and sufficiently large cutoff parameters ϱ and τ, calculate a solution $\varphi \in Y$ of the system*

$$\left.\begin{aligned} P_\tau\varphi &= \varphi, \\ \|P_\varrho A P_\tau \varphi - P_\varrho f\| &\le \delta. \end{aligned}\right\} \quad \text{(MSM)}$$

DEFINITION 3.7. *We say that $\tau_0 > 0$ is an* admissible τ-bound *for a given precision $\delta > 0$ if the system (MSM) is solvable in Y for all $\varrho > 0$ and $\tau > \tau_0$.*

THEOREM 3.8 (existence of solutions to (MSM)). *For every $\delta > 0$, there is an admissible τ-bound $\tau_0 = \tau_0(\delta) > 0$.*

Proof of Theorem 3.8. Let $\varrho > 0$ be arbitrary. We demonstrate how to choose τ_0 so that

$$\varphi_1 := P_\tau\varphi_0 = P_\tau A^{-1} f \tag{34}$$

solves the system (MSM) for every $\tau > \tau_0$, with φ_0 being the exact solution of (1).

Since P_τ is a projector, we have

$$P_\tau\varphi_1 = P_\tau^2\varphi_0 = P_\tau\varphi_0 = \varphi_1$$

for every $\tau > 0$.

Furthermore, for all $\varrho > 0$ and $\tau > 0$, we have

$$\begin{aligned}\|P_\varrho A P_\tau \varphi_1 - P_\varrho f\| &= \|P_\varrho A P_\tau^2 A^{-1} f - P_\varrho f\| \\ &\le \|P_\varrho A A^{-1} f - P_\varrho f\| \ + \ \|P_\varrho A Q_\tau A^{-1} f\| \\ &\le 0 \ + \ \|A\| \cdot \|Q_\tau A^{-1} f\|.\end{aligned}$$

But, by assumption (P3), there is a $\tau_0 > 0$ such that

$$\|Q_\tau A^{-1} f\| \le \frac{\delta}{\|A\|} \tag{35}$$

for all $\tau > \tau_0$, so that finally

$$\|P_\varrho A P_\tau \varphi_1 - P_\varrho f\| \le \delta$$

holds, and hence φ_1 is a solution of the system (MSM) for all $\tau > \tau_0$ and $\varrho > 0$. ∎

LEMMA 3.9. *Let $\tau_0 > 0$ be an admissible τ-bound for a given precision $\delta > 0$. If $\tau > \tau_0$ and $\varrho > 0$ are such that $\|Q_\varrho A P_\tau\| < 1/\|A^{-1}\|$, then the set of all solutions of the system (MSM) is a bounded subset of Y. Precisely, every solution $\varphi \in Y$ of the system (MSM) is subject to $\|\varphi\|_Y \le M$ with M given by* (36).

Proof. Suppose $\varphi \in Y$ solves the system (MSM) for given parameters $\delta, \varrho, \tau > 0$. Then

$$\begin{aligned}\|A\varphi\| - \|P_\varrho f\| \le \|A\varphi - P_\varrho f\| \ &= \ \|AP_\tau\varphi - P_\varrho f\| \\ &\le \|AP_\tau\varphi - P_\varrho A P_\tau \varphi\| + \|P_\varrho A P_\tau \varphi - P_\varrho f\| \\ &\le \|Q_\varrho A P_\tau\| \cdot \|\varphi\| + \delta,\end{aligned}$$

together with $\|\varphi\| \le \|A^{-1}\| \cdot \|A\varphi\|$, implies that

$$\begin{aligned}\frac{\|\varphi\|}{\|A^{-1}\|} \ \le \ \|A\varphi\| &\le \|P_\varrho f\| + \|Q_\varrho A P_\tau\| \cdot \|\varphi\| + \delta \\ &\le \|f\| + \|Q_\varrho A P_\tau\| \cdot \|\varphi\| + \delta,\end{aligned}$$

and hence

$$\|\varphi\| \ \le \ M \ := \ \frac{\|f\| \ + \ \delta}{1/\|A^{-1}\| \ - \ \|Q_\varrho A P_\tau\|}. \tag{36}$$ ∎

THEOREM 3.10 (convergence of the MSM). *For every $\varepsilon > 0$, there are parameters δ, ϱ, τ such that every solution $\varphi \in Y$ of the system (MSM) is an approximation*

$$\|\varphi - \varphi_0\|_Y < \varepsilon \tag{37}$$

of the exact solution φ_0 of (1). *Precisely, there are functions $\delta_0, \tau_0 : \mathbb{R}_+ \to \mathbb{R}_+$ and $\varrho_0 : \mathbb{R}_+^3 \to \mathbb{R}_+$ such that if $\delta < \delta_0(\varepsilon)$, $\tau > \tau_0(\delta)$, and $\varrho > \varrho_0(\varepsilon, \delta, \tau)$, then every solution $\varphi \in Y$ of (MSM) is subject to* (37).

Proof. Let $\varepsilon > 0$ be given. We start the proof with three preliminary steps.

(a) Choose $\delta < \delta_0 := \frac{\varepsilon}{3\|A^{-1}\|}$.

(b) Choose $\tau_0 > 0$ such that $\big(\|Q_\tau\varphi_0\| = \big)\|Q_\tau A^{-1}f\| \le \frac{\delta}{\|A\|}$ for all $\tau > \tau_0$, so that τ_0 is an admissible τ-bound for δ (see inequality (35)). Now let $\tau > \tau_0$.

(c) Choose $\varrho_0 > 0$ such that $\|Q_\varrho f\| < \frac{\varepsilon}{3\|A^{-1}\|}$ and

$$\|Q_\varrho A P_\tau\| \;<\; \frac{1}{\|A^{-1}\|}\left(1 - \frac{1}{1 + \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|}}\right) \tag{38}$$

for all $\varrho > \varrho_0$, and fix some $\varrho > \varrho_0$.

Now let $\varphi \in Y$ be a solution of (MSM) with parameters δ, τ, and ϱ as chosen above. From (38) we get $\|Q_\varrho A P_\tau\| < 1/\|A^{-1}\|$, and hence, by Lemma 3.9,

$$\|\varphi\| \;\le\; M \tag{39}$$

with M as defined in (36). Moreover, inequality (38) is equivalent to

$$\|Q_\varrho A P_\tau\| \;<\; \frac{1}{\|A^{-1}\|} \cdot \frac{\frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|}}{1 + \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|}},$$

and hence to

$$\left(1 + \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|}\right) \cdot \|Q_\varrho A P_\tau\| \;<\; \frac{1}{\|A^{-1}\|} \cdot \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|}.$$

This, moreover, is equivalent to

$$\begin{aligned}\|Q_\varrho A P_\tau\| &< \frac{1}{\|A^{-1}\|} \cdot \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|} - \frac{\varepsilon}{3(\|f\|+\delta)\cdot\|A^{-1}\|} \cdot \|Q_\varrho A P_\tau\| \\ &= \frac{\varepsilon\,\big(1/\|A^{-1}\| - \|Q_\varrho A P_\tau\|\big)}{3(\|f\|+\delta)\cdot\|A^{-1}\|} \;=\; \frac{\varepsilon}{3M\|A^{-1}\|} \end{aligned} \tag{40}$$

with M as defined in (36). Then we have

$$\begin{aligned}\|\varphi - \varphi_0\| = \|P_\tau\varphi - \varphi_0\| \;&=\; \|A^{-1}AP_\tau\varphi - A^{-1}f\| \;\le\; \|A^{-1}\| \cdot \|AP_\tau\varphi - f\| \\ &\le \|A^{-1}\| \cdot \big(\|AP_\tau\varphi - P_\varrho AP_\tau\varphi\| \;+\; \|P_\varrho AP_\tau\varphi - P_\varrho f\| \;+\; \|P_\varrho f - f\|\big) \\ &\le \|A^{-1}\| \cdot \big(\|Q_\varrho AP_\tau\| \cdot \|\varphi\| \;+\; \delta \;+\; \|Q_\varrho f\|\big) \\ &\le \frac{\varepsilon}{3} \;+\; \frac{\varepsilon}{3} \;+\; \frac{\varepsilon}{3} \;=\; \varepsilon,\end{aligned}$$

using (40) and (39) and the bounds on δ and $\|Q_\varrho f\|$ in the last step. ∎

Remark 3.11. One way to effectively solve the system (MSM) for given parameters ϱ, τ, and δ is to compute a $\varphi \in Y$ that minimizes the discrepancy in (8), for example, using a gradient method or, if possible, by directly applying the Moore Penrose pseudoinverse $B^\dagger$ of $B := P_\varrho A P_\tau$ to the right-hand side $P_\varrho f$.

If Y is a Hilbert space, then it is well known that $\varphi \in Y$ minimizes the residual $\|B\varphi - P_\varrho f\|$ if and only if $B^*(B\varphi - P_\varrho f) = 0$ with B^* denoting the adjoint operator of B. If, in addition, P_ϱ is self-adjoint for all $\varrho > 0$, then, after resubstituting B, the latter is equivalent to

$$P_\tau A^* P_\varrho A P_\tau \varphi \;=\; P_\tau A^* P_\varrho f. \tag{41}$$

However, if ϱ is sufficiently large, then, by (A2) and (P3), (41) is just a small perturbation of

$$P_\tau A^* A P_\tau \varphi \;=\; P_\tau A^* f, \tag{42}$$

which is nothing but the finite section method for the equation

$$A^* A \varphi \;=\; A^* f. \tag{43}$$

Note that the finite section method (42) is applicable since A^*A is positive definite (see, e.g., Theorem 1.10b in [7]). Clearly, if A is invertible, as we require in (A1), then also its adjoint A^* is invertible, and (43) is equivalent to our original equation (1).

Summarizing, if Y is a Hilbert space and all P_ϱ are self-adjoint, then minimizing $\|P_\varrho A P_\tau \varphi - P_\varrho f\|$ is equivalent to solving a slight perturbation (41) of the finite section method (42) for (43).

The MSM can be applied to the rough surface scattering problem of section 2, as we know from Example 3.1, Lemma 3.2, and inequalities (18) and (19). In particular, note that the bound (29) on $\|A^{-1}\|$ enables us to actually compute the corresponding terms in steps (a) and (c) in the proof of Theorem 3.10.

We summarize the results in the following theorem.

THEOREM 3.12 (MSM for rough surface scattering). *The MSM, as defined in Definition* 3.6, *applied to rough surface scattering* (11), (13), (14), *and* (15), *is convergent in the sense of Theorem* 3.10.

4. Numerical realization and examples. The goal of this final section is to provide a numerical algorithm for the solution of the integral equation (28) using the MSM. For simplicity, we employ a low-order scheme for the treatment of the singularity of the operator, leaving more sophisticated high-order approaches to [8].

Our numerical approach to the solution of the system (MSM) for the concrete operator equation (28) is to choose some large parameters ϱ and τ and to choose the discrepancy δ as small as it possibly can be by looking for a function $\varphi \in L^2(B_\tau)$ that minimizes the MSM residual $\|P_\varrho A P_\tau \varphi - P_\varrho f\|$.

We have implemented both a *direct solver* for the minimization of the corresponding MSM residual and an *iterative scheme* based on a gradient method. In both cases we first transform the truncated approximate equation (8) by numerical quadrature and projection as described in (52)–(56) below into an approximate matrix equation which, for simplicity, we denote by

$$\mathbf{A}\boldsymbol{\varphi} \approx \mathbf{f}. \tag{44}$$

The direct solver then approximately solves this equation via the Moore–Penrose pseudoinverse $\mathbf{A}^\dagger$ of $\mathbf{A}$. Precisely,

$$\boldsymbol{\varphi} = \mathbf{A}^\dagger \circ \mathbf{f} \tag{45}$$

has the smallest norm among all $\boldsymbol{\varphi}$ that minimize the residual $\|\mathbf{A}\boldsymbol{\varphi} - \mathbf{f}\|$.

This scheme is rather quick, but for standard desktop PCs[1] limits the number of unknowns N to several thousands, since we need to store fully occupied matrices of size N^2. This leads to a bound of approximately 10 on the number of wavelengths which can be resolved, since, for example, $N = 2500$ unknowns correspond to a grid

[1]For our computations we used workstations with 2 GB main memory.

size of 50×50 grid points on our surface, and we need at least 5 points per wavelength for its resolution.

For problems with more unknowns we used an iterative solver, where the functional

$$\mu(\boldsymbol{\varphi}) := \|\mathbf{A}\boldsymbol{\varphi} - \mathbf{f}\|^{\mathbf{2}} \tag{46}$$

is minimized. There are well-known schemes available for this task, for example, the CG method, GMRES, or gradient schemes. Here, for the minimization we employed the *gradient method*

$$\boldsymbol{\varphi}_{n+1} \;=\; \boldsymbol{\varphi}_n \;-\; h_n \,\mathrm{grad}_{\boldsymbol{\varphi}}\, \mu(\boldsymbol{\varphi}_n), \quad n = 0, 1, 2, \ldots, \tag{47}$$

with starting value $\boldsymbol{\varphi} = 0$ and adaptive step size $h_n > 0$. Simple calculations show that the gradient of μ with respect to the complex density $\boldsymbol{\varphi}$ is given by

$$\mathrm{grad}_{\boldsymbol{\varphi}}\, \mu(\varphi) \;=\; 2\mathbf{A}^* \circ (\mathbf{A}\boldsymbol{\varphi} - \mathbf{f}). \tag{48}$$

To see this one simply writes $\boldsymbol{\varphi} \in \mathbb{C}^N$ as a function $\tilde{\boldsymbol{\varphi}} \in \mathbb{R}^{2N}$, calculates the gradient in $\mathbb{R}^{2N}$, and converts it back into $\mathbb{C}^N$. The calculation of

$$\mathbf{s_1} := \mathbf{A}\boldsymbol{\varphi}, \tag{49}$$

$$\mathbf{s_2} \;=\; \mathbf{s_1} - \mathbf{f}, \tag{50}$$

$$\mathrm{grad}_{\boldsymbol{\varphi}}\, \mu(\varphi) \;=\; 2\mathbf{A}^* \circ \mathbf{s_2} \tag{51}$$

can be carried out without storing the matrices $\mathbf{A}$ and $\mathbf{A}^*$; i.e., for the gradient method we only need to store vectors of length N. Here, in principle, we can work with up to several million unknowns N if we can invest the time to calculate the updates. In this case we can resolve up to 400 wavelengths with a grid size of 2000×2000.

For the iteration scheme the computation time per iteration scales quadratically in the number of unknowns. If we want to keep the time for one gradient step in the time frame of hours,[2] this limits the size of the problem to approximately $N = 100.000$, which corresponds to a grid of 350×350 or a resolution of 70 wavelengths. It is clear that at this point matrix compression schemes like the fast multipole method need to be employed. Since our main point here is the presentation of the MSM and the proof of its applicability, we leave this to future research.

The main ingredient of (28) is the integral operator $I + K - i\eta S$, which, for the MSM, is applied to some density $P_\tau \varphi$ supported on B_τ and is evaluated on the set B_ϱ. We denote the kernel of $K - i\eta S$ by $k(x, y)$, $x \in B_\varrho$, $y \in B_\tau$.

We employ the basic ideas of Nyström's method, however, applied to the approximate equation (8). We use standard numerical quadrature for the calculation of

$$I(x) := \int_{B_\tau} k(x, y)\varphi(y)\, dy, \quad x \in B_\varrho; \tag{52}$$

i.e., we replace the integral by a finite sum

$$I_N(x) := \sum_{\xi=1}^{N} \alpha_\xi \tilde{k}(x, y_\xi)\varphi(y_\xi), \quad x \in B_\varrho, \tag{53}$$

[2]Calculations have been carried out on a PC with processor speed of 3.6 GHz.

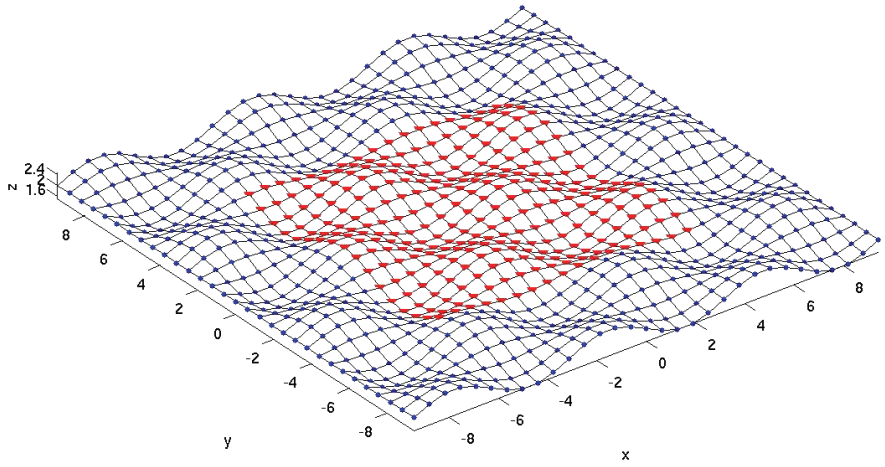

FIG. 1. *Setting for the MSM. The set B_ϱ is shown with dots, the set B_τ with triangles.*

with *quadrature points* $y_\xi \in B_\varrho$ and *weights* α_ξ. For details about a variety of such quadratures we refer the reader to [4] and [9]. Here, we employed a trapezoidal rule, i.e., the exact integration of linear functions, combined with a cutoff of the singular parts of the kernels. For more sophisticated schemes for the treatment of the singularity we refer the reader to [8]. For a convergent quadrature formula the values (53) approximate the integral (52) and we have

$$I_N(x) \to I(x), \quad N \to \infty, \quad x \in B_\varrho. \tag{54}$$

Next, we choose points $x_\eta \in B_\varrho$ for $\eta = 1, \ldots, M$ and define

$$V := \{x_\eta : \ \eta = 1, \ldots, M\}, \qquad L := \{y_\xi : \ \xi = 1, \ldots, N\}. \tag{55}$$

For our numerics of the direct method we chose the points such that $L \subset V$; compare Figure 1 for the case of an equidistant grid. Then we evaluate $I_N(x_\eta)$ at the points x_η, $\eta = 1, \ldots, M$. This leads to the discrete system

$$\|\mathbf{A}\boldsymbol{\varphi} - \mathbf{f}\|_{\mathbf{2}} \le \delta \tag{56}$$

with

$$\mathbf{A} = (\mathbf{I} - \mathbf{W}) \circ \mathbf{P}_\tau \qquad \text{(see Figure 2)}, \tag{57}$$

$$\boldsymbol{\varphi} = \begin{pmatrix} \varphi(x_1) \\ \vdots \\ \varphi(x_M) \end{pmatrix}, \tag{58}$$

$$\mathbf{f} = \begin{pmatrix} f(x_1) \\ \vdots \\ f(x_M) \end{pmatrix}, \tag{59}$$

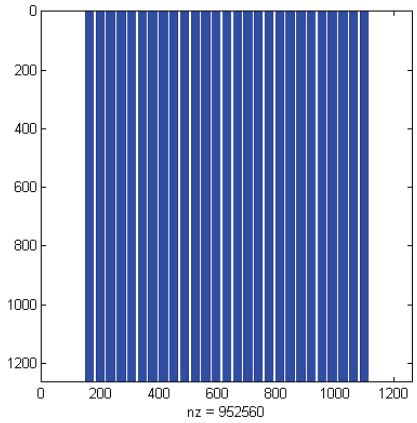

FIG. 2. *Structure of the matrix* $\mathbf{A} = (\mathbf{I} - \mathbf{W}) \circ \mathbf{P}_\tau$.

$$\mathbf{W} = \begin{pmatrix} \alpha_1 k(x_1, x_1) & \dots & \alpha_M k(x_1, x_M) \\ \vdots & & \vdots \\ \alpha_1 k(x_M, x_1) & \dots & \alpha_M k(x_M, x_M) \end{pmatrix}, \tag{60}$$

and the projector $\mathbf{P}_\tau$ is defined by

$$\mathbf{P}_\tau = \operatorname{diag}(\mathbf{v}), \quad \mathbf{v_j} = \begin{cases} 1 & \text{if } x_j \in B_\tau, \\ 0 & \text{otherwise} \end{cases} \tag{61}$$

for $j = 1, \dots, M$.

The solution of (56) is calculated using the Moore–Penrose pseudoinverse $\mathbf{A}^\dagger$ (in MATLAB realized via the function pinv($\mathbf{A}$)) applied to $\mathbf{f}$, i.e., via

$$\boldsymbol{\varphi}_{\text{sol}} := \Big((\mathbf{I} - \mathbf{W}) \circ \mathbf{P}_\tau \Big)^\dagger \mathbf{f}. \tag{62}$$

As a test example for the numerical realization of the MSM we use the surface Γ defined by

$$f(x_1, x_2) := c_0 \cdot \sin(x_1) \cdot \cos(x_2) + 2$$

with $c_0 = 1/2$. Here, we place the source point z of the incident point source $\Phi(\cdot, z)$ below the surface Γ, but above the plane $x_3 = 0$. In this case the scattered field is given by $-\Phi(\cdot, z)$. Thus, we can test the precision of the combined single- and double-layer potential with density φ calculated via the MSM.

Figure 3(top) shows the original fields for an incident point source with source point $(-2, 0, 0.2)$. The reconstructed field is shown in Figure 3(bottom). Here, we worked with the direct method and employed the MSM with $\varrho = 3\pi$ and $\tau = 0.8\,\varrho$. The figures show a grid of 40×40 points.

Figure 4 demonstrates the real part of the scattered field for an incident point source with source point $(-2, 0, 4)$. We employed the direct method and used the same choice of parameters as in Figure 3.

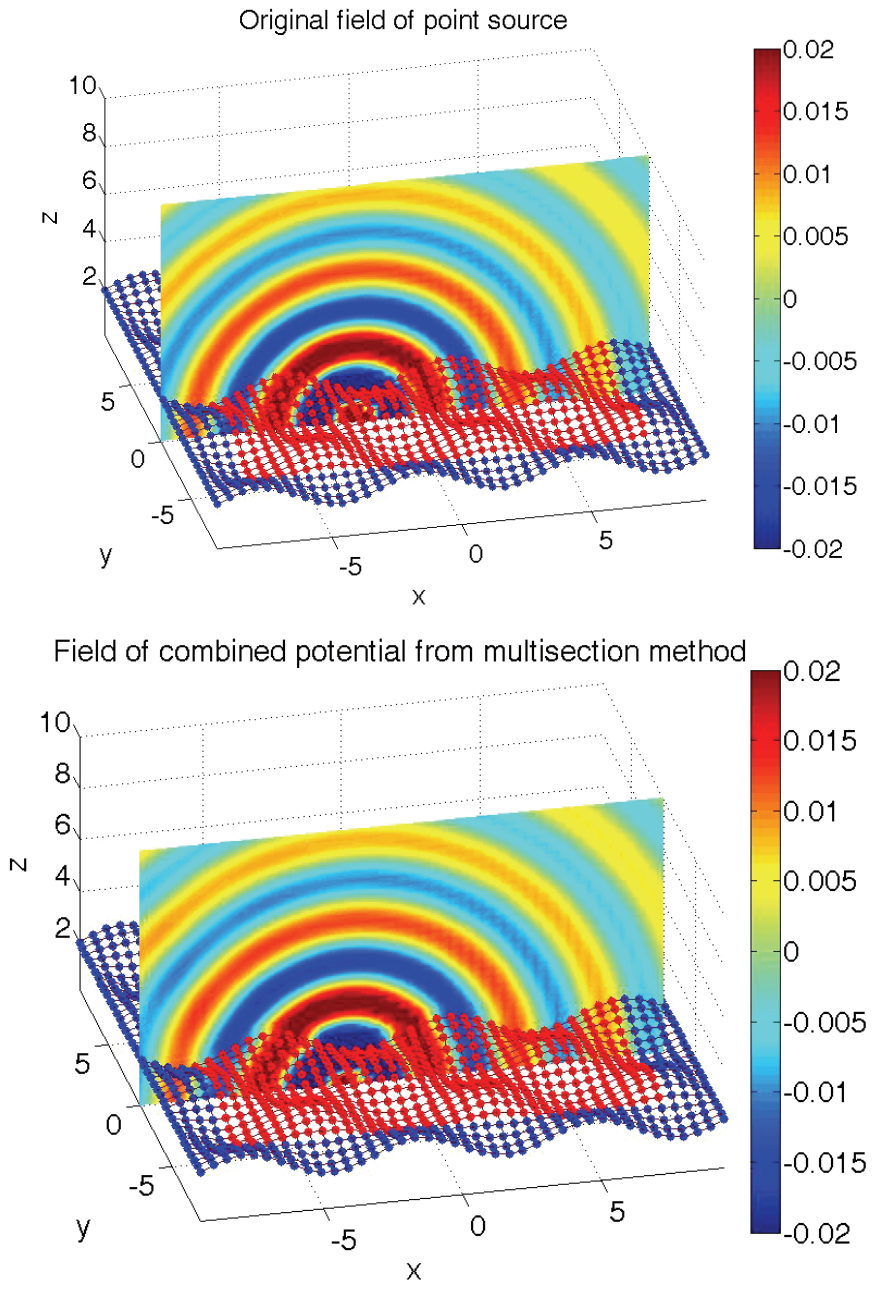

FIG. 3. *Top: Test field of a point source located between the surface and the plane* $x_3 = 0$. *Bottom: Constructed field via the combined layer potential with a density given by the MSM. Here, the relative error for the reconstruction in the points with* $x_3 \geq 3$ *above the set* B_ϱ *is below* 5%.

The behavior of the solution density φ of the MSM is shown in Figure 5. The different sections are indicated in the third row. The right-hand side shows the "true" density, which is calculated using larger patches.

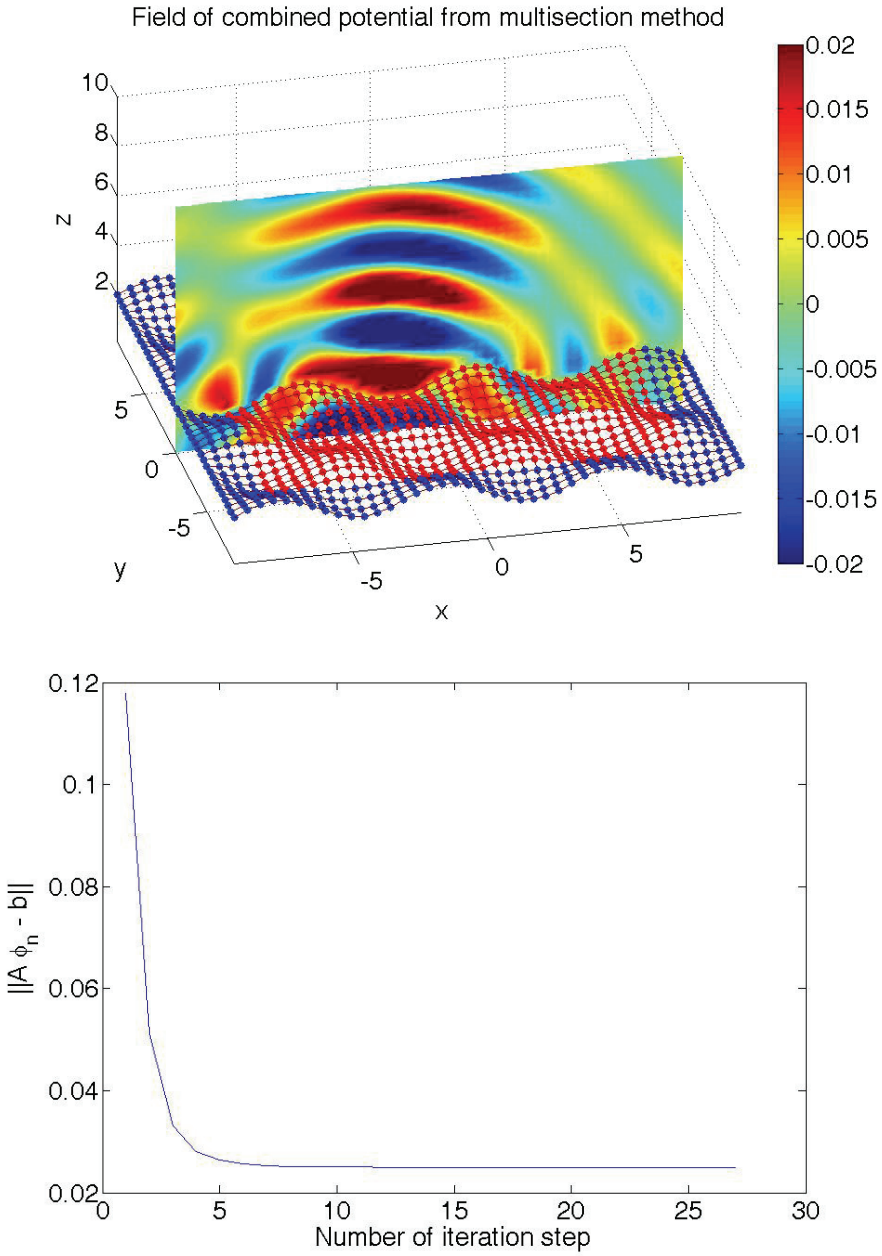

FIG. 4. *Top: Scattered field for an incident point source with source point* $z = (-2, 0, 4)$. *Bottom: Error behavior for the iterates of the gradient method.*

The behavior of the solutions for the *iterative* scheme is demonstrated in Figures 6 and 4. Figure 6(top) is a schematic presentation of the relation between the area ϱ^2 of the calculation domain, the total number of unknowns N, and the one-dimensional step size h. The blue lines are lines of constant step size, where both N and ϱ are increased. To achieve convergence of the numerical method, we need to increase both ϱ and N such that $h = h(\varrho, N)$ tends to zero.

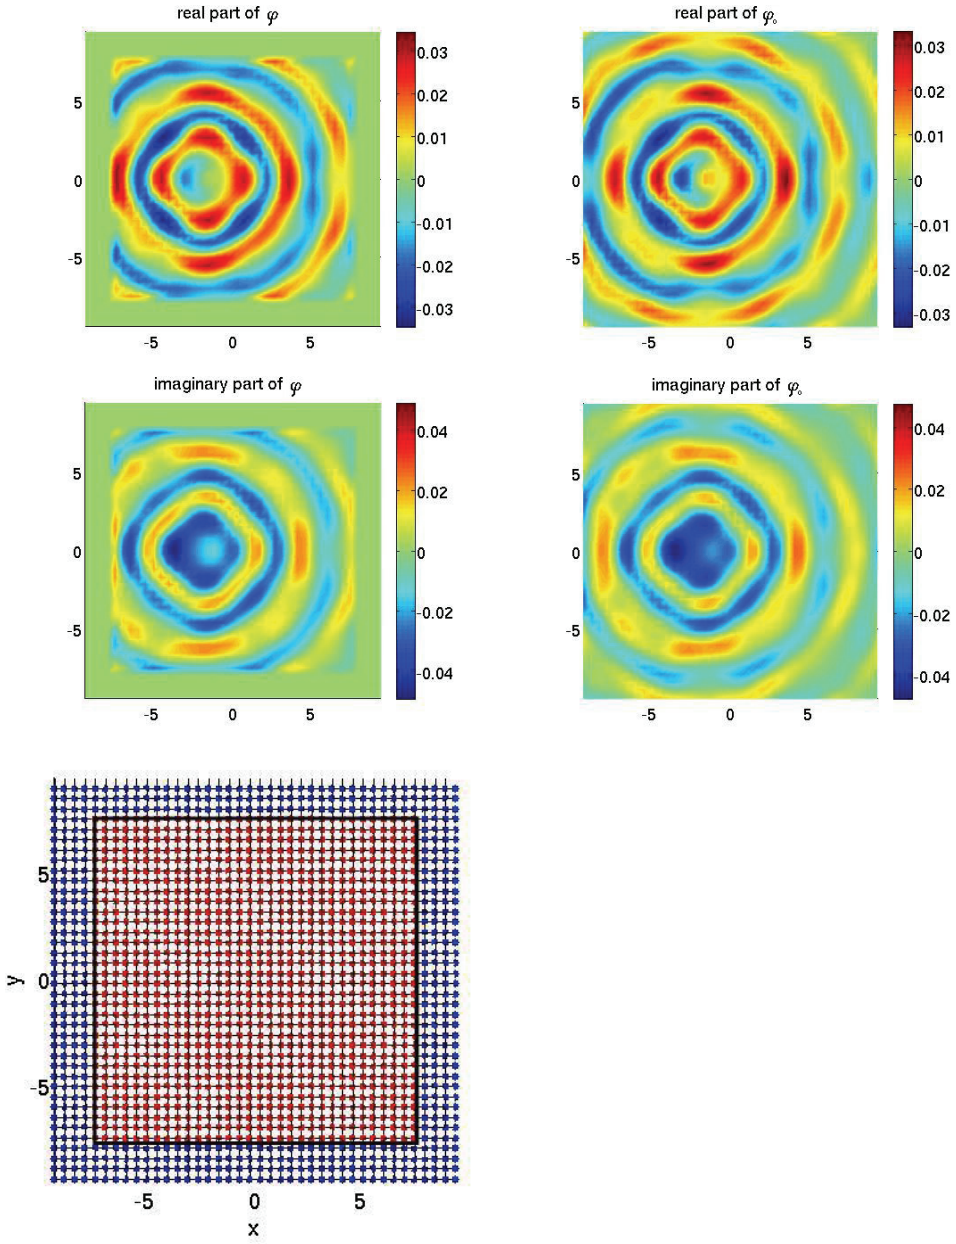

FIG. 5. *The images show the real and imaginary parts of the density φ solving the multisection inequality in the left column and the true density φ_0 in the right column. The location of the two different sections B_τ and B_ϱ is indicated in the image of the third row. On the set B_τ the approximation is good and on $B_\varrho \setminus B_\tau$ the density φ is zero by construction.*

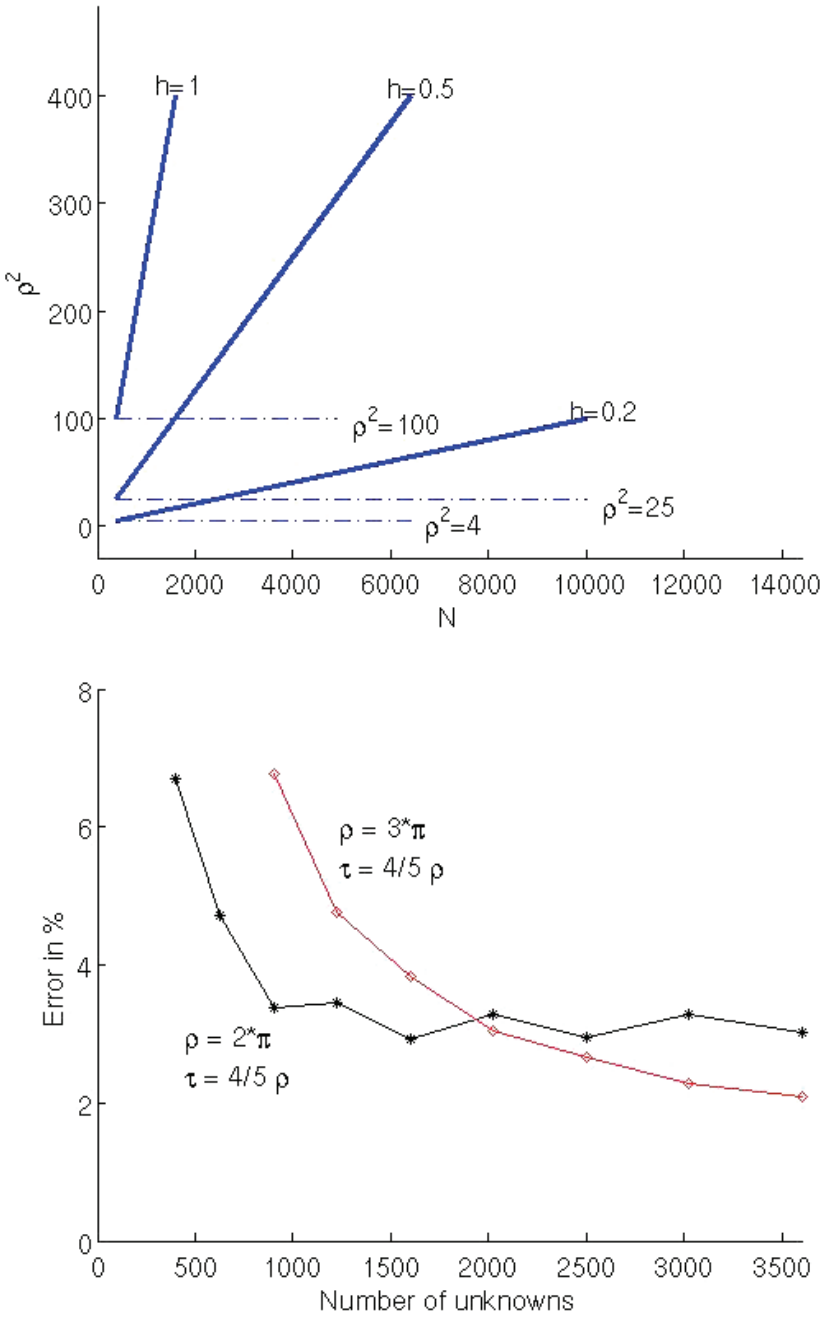

FIG. 6. *Top: Scheme to discuss the discretization and cutoff error and convergence properties of the MSM. Bottom: Illustration of the relative error measured in the calculated field for different choices of cutoff parameters* ϱ *and* τ *dependent on the number of unknowns* N*. In both cases we have chosen a fixed ratio of* $\rho/\tau = 4/5$*. The curve with stars shows the error for* $\rho = 2\pi$*, and the curve with diamonds shows the error for* $\rho = 3\pi$*.*

The relative error for the calculation of the field of Figure 3 for different choices of ϱ and N is demonstrated in Figure 6(bottom). For a fixed small number of unknowns the error for a large calculation domain is larger than for a small calculation domain. This can be explained by the two types of error which add up to the total error:

1. the discretization error from approximating the integral by a quadrature formula,
2. the cutoff error from the limited domain of calculation.

If for a fixed number of unknowns we enlarge the calculation domain, then the cutoff error decreases, but the discretization error increases. Here with $N = 3500$ unknowns and a sufficiently large calculation area we reach an error of 2%.

The behavior of the residual for the gradient method is illustrated in Figure 4(bottom). The error usually quickly drops and then tends to some fixed residual which does not change significantly when further iterating. The residual is caused by the discretization and cutoff error. We usually used 15–20 iterations in our calculations.

A SPLINE PRODUCT QUASI-INTERPOLATION METHOD FOR WEAKLY SINGULAR FREDHOLM INTEGRAL EQUATIONS*

EERO VAINIKKO† AND GENNADI VAINIKKO†

Abstract. A discrete method of accuracy $O(h^m)$ is constructed and justified for a class of Fredholm integral equations of the second kind with kernels that may have weak diagonal and boundary singularities. The method is based on (i) improving the boundary behavior of the kernel with the help of a change of variables, and (ii) the product integration using quasi-interpolation by smooth splines of order m.

Key words. weakly singular integral equations, boundary singularities, spline quasi-interpolation, spline interpolation, product integration methods, Nyström-type methods

AMS subject classifications. 65R20, 65D07, 65D30

DOI. 10.1137/070693308

1. Introduction. In the present paper we call attention to some high order fully discrete methods for a class of Fredholm integral equations of the second kind with different weak singularities. The idea of the method is close to those in [2, 3, 9]. Consider the weakly singular integral equation

$$u(x) = \int_0^1 \big(a(x,y)|x-y|^{-\nu} + b(x,y)\big)\, u(y)dy + f(x), \qquad 0 \le x \le 1, \tag{1.1}$$

depending on the parameter ν, $0 < \nu < 1$. A traditional product integration method (see [2, 3] and the literature quoted there) is based on the approximation of (1.1) by the equation

$$u(x) = \int_0^1 \big(|x-y|^{-\nu} P_{n,m}(a(x,y)u(y)) + P_{n,m}(b(x,y)u(y))\big)\, dy + f(x), \qquad 0 \le x \le 1,$$

where $P_{n,m}$ is an interpolation projector onto the space of piecewise polynomial functions of degree $m-1$ associated with a subdivision of $[0,1]$ into n subintervals by some knots $0 = x_{0,n} < x_{1,n} < \cdots < x_{n,n} = 1$; $P_{n,m}$ is applied to the products $a(x,y)u(y)$ and $b(x,y)u(y)$ as functions of y treating x as a parameter. This results in some Nyström-type methods of accuracy $O(n^{-m})$, provided that the grid $\{x_{0,n}, x_{1,n}, \ldots, x_{n,n}\}$ is properly graded to compensate the generic boundary singularities of the derivatives of the exact solution to (1.1); even the accuracy $O(n^{-m-1+\nu})$ can be achieved for a skilled choice of the interpolation points; see [13]. The approach of [9] is different: the authors first perform a change of variables which improves the boundary behavior of the solution and of the coefficient functions $a(x,y), b(x,y)$. After that, using a polynomial approximation of the solution, they apply a Gauss-type quadrature formula for the integral in the transformed equation.

In our approach we follow the methods of [9, 10], performing a smoothing change of variables and then, instead of discontinuous piecewise polynomial interpolation

by $P_{n,m}$, we use a product quasi-interpolation (or even the real interpolation) by smooth splines of degree $m-1$ on the uniform grid of the step size $h = 1/n$. This leads to some reduction of degrees of freedom compared with the use of piecewise polynomials. Our algorithm still has features of the Nyström method. In Nyström-type methods for weakly singular integral equations, the computation of the quadrature coefficients is a laborious and delicate part of the algorithms. The use of quasi-interpolation (or real interpolation) by smooth splines on uniform grids enables us to obtain simple but still somewhat delicate formulae for the quadrature coefficients, and so we obtain a fully discrete method of accuracy $O(h^m)$. This is the main message of the present paper.

In our considerations, the coefficient functions $a(x,y)$ and $b(x,y)$ may have boundary singularities with respect to y. Denote by T the integral operator of (1.1),

$$(Tu)(x) = \int_0^1 \big(a(x,y)|x-y|^{-\nu} + b(x,y)\big)\, u(y)dy.$$

LEMMA 1.1. *Assume that $a, b \in C([0,1]\times(0,1))$ satisfy the inequalities*

$$|a(x,y)| \le cy^{-\lambda_0}(1-y)^{-\lambda_1}, \quad |b(x,y)| \le cy^{-\mu_0}(1-y)^{-\mu_1}, \quad (x,y)\in[0,1]\times(0,1),$$

where $0<\nu<1$, $\lambda_0, \lambda_1, \mu_0, \mu_1 \in \mathbb{R}$, $\lambda_0+\nu<1$, $\lambda_1+\nu<1$, $\mu_0<1$, $\mu_1<1$. Then T maps $C[0,1]$ into $C[0,1]$, and $T: C[0,1]\to C[0,1]$ is compact.

The proof is standard; cf. [5, 7]; a detailed argument can be found in [11].

For $m\in\mathbb{N}$, θ_0, $\theta_1\in\mathbb{R}$, θ_0, $\theta_1<1$, denote by $C^m_\star(0,1)$ and $C^{m,\theta_0,\theta_1}(0,1)$ the weighted spaces of functions $u\in C[0,1]\cap C^m(0,1)$ such that, respectively,

$$\|u\|_{C^m_\star(0,1)} := \sum_{k=0}^m \sup_{0<x<1} x^k(1-x)^k|u^{(k)}(x)| < \infty,$$

$$\|u\|_{C^{m,\theta_0,\theta_1}(0,1)} := \sum_{k=0}^m \sup_{0<x<1} w_{k-1+\theta_0}(x)w_{k-1+\theta_1}(1-x)|u^{(k)}(x)| < \infty,$$

where

$$w_\rho(r) = \begin{cases} 1, & \rho<0, \\ 1/(1+|\log r|), & \rho=0, \\ r^\rho, & \rho>0, \end{cases} \qquad r,\rho\in\mathbb{R}, r>0.$$

Clearly, $C^m[0,1]\subset C^{m,\theta_0,\theta_1}(0,1)\subset C^m_\star(0,1)$.

LEMMA 1.2 (see [11]). *Let $a, b\in C^m([0,1]\times(0,1))$ and*

$$|\partial_x^k\partial_y^l a(x,y)| \le cy^{-\lambda_0-l}(1-y)^{-\lambda_1-l}, \quad |\partial_x^k\partial_y^l b(x,y)| \le cy^{-\mu_0-l}(1-y)^{-\mu_1-l}, \tag{1.2}$$
$$(x,y)\in[0,1]\times(0,1), k+l\le m,$$

where $m\in\mathbb{N}$, $0<\nu<1$, $\lambda_0+\nu<1$, $\lambda_1+\nu<1$, $\mu_0<1$, $\mu_1<1$. Then T maps $C^m_\star(0,1)$ into $C^m_\star(0,1)$, $T: C^m_\star(0,1)\to C^m_\star(0,1)$ is bounded, and $T^2: C^m_\star(0,1)\to C^m_\star(0,1)$ is compact. Further, T maps $C^{m,\theta_0,\theta_1}(0,1)$ with $\theta_0 = \max\{\lambda_0+\nu, \mu_0\}$, $\theta_1 = \max\{\lambda_1+\nu, \mu_1\}$ into $C^{m,\theta_0,\theta_1}(0,1)$, and $T: C^{m,\theta_0,\theta_1}(0,1)\to C^{m,\theta_0,\theta_1}(0,1)$ is compact.

Here $\partial_x^k\partial_y^l = (\partial/\partial x)^k(\partial/\partial y)^l$. An example of a satisfying (1.2) is given by $a(x,y) = y^{-\lambda_0}(1-y)^{-\lambda_1}\overline{a}(x,y)$, where $\overline{a}\in C^m([0,1]\times[0,1])$.

Denote $\mathcal{N}(I-T)=\{u\in C[0,1]: u=Tu\}$. The following theorem is a consequence of Lemmas 1.1 and 1.2.

THEOREM 1.3. *Assume the conditions of Lemma* 1.2 *and* $\mathcal{N}(I-T)=\{0\}$. *Then for* $f\in C^m_\star(0,1)$, (1.1) *has a solution* $u\in C^m_\star(0,1)$ *which is unique in* $C[0,1]$, *and* $\|u\|_{C^m_\star(0,1)}\le c\|f\|_{C^m_\star(0,1)}$, *where the constant* c *is independent of* f. *Further, if* $f\in C^{m,\theta_0,\theta_1}(0,1)$, $\theta_0=\max\{\lambda_0+\nu,\mu_0\}$, $\theta_1=\max\{\lambda_1+\nu,\mu_1\}$, *then* $u\in C^{m,\theta_0,\theta_1}(0,1)$, *and* $\|u\|_{C^{m,\theta_0,\theta_1}(0,1)}\le c_{m,\theta_0,\theta_1}\|f\|_{C^{m,\theta_0,\theta_1}(0,1)}$, *where the constant* c_{m,θ_0,θ_1} *is independent of* f.

The main results of the paper are established under assumptions of Theorem 1.3. Using the approach of [12], our treatment can be extended to the case where f has a singularity at a point $x=\xi$, $\xi\in(0,1)$, and/or a and b have certain singularities on the lines $x=\xi$ and $y=\xi$ or on a system of such inner points/lines—we can build the approximate solution on $[0,\xi]$ and $[\xi,1]$ in a manner similar to that done on $[0,1]$ in section 4.

The rest of the paper is organized as follows. In section 2 we recall some results about the interpolation and quasi-interpolation of functions by splines with a uniform knot set and, in particular, about the optimality of such approximations. In section 3 we transform (1.1) into a new form by the change of variables. Section 4 is central in the paper—we introduce the product quasi-interpolation method for the transformed equation, examine its accuracy, and present the matrix form of the method. In section 5 we discuss different computational details of the method, and in section 6 we test the algorithms on a numerical example.

Actually the method can be applied to a somewhat more general class of equations rather than (1.1). The case of an integral equation with logarithmic diagonal singularity of the kernel will be treated in a separate work with more attention to the computational environment. In [17] the method is modified for the Volterra integral equation corresponding to (1.1).

2. Approximation tools.

2.1. The father B-spline. The *father* B*-spline* B_m *of order* m in the terminology of [4, 15], or of degree $m-1$ in the terminology of [6, 16], can be defined by the formula

$$B_m(x)=\frac{1}{(m-1)!}\sum_{i=0}^{m}(-1)^i\mathcal{C}_i^{(m)}(x-i)_+^{m-1},\quad x\in\mathbb{R},\quad m\in\mathbb{N}. \tag{2.1}$$

Here, as usual, $0!=1$, $0^0:=\lim_{x\downarrow 0}x^x=1$,

$$\mathcal{C}_i^{(m)}=\left(\begin{array}{c} m\\ i\end{array}\right)=\frac{m!}{i!(m-i)!},\quad (x-i)_+^{m-1}=\begin{cases}(x-i)^{m-1}, & x-i\ge 0,\\ 0, & x-i<0.\end{cases}$$

Let us recall some properties of B_m: $B_m\in C^{(m-2)}(\mathbb{R})$,

$$\mathrm{supp}B_m=[0,m],\quad B_m(x)=B_m(m-x)>0 \text{ for } 0<x<m, \tag{2.2}$$

$$B_m^{(m-1)}(x)=(-1)^l\mathcal{C}_l^{(m-1)} \text{ for } l<x<l+1,\quad l=0,\dots,m-1, \tag{2.3}$$

$$\sum_{j\in\mathbb{Z}}B_m(x-j)=1 \text{ for } x\in\mathbb{R},\quad \int_{\mathbb{R}}B_m(x)dx=1. \tag{2.4}$$

2.2. Spline interpolation on the uniform grid in $\mathbb{R}$. Introduce in $\mathbb{R}$ the uniform grid $h\mathbb{Z} = \{ih : i \in \mathbb{Z}\}$ of the step size $h > 0$. Denote by $S_{h,m}$, $m \in \mathbb{N}$, the space of splines of order m (of degree $m-1$) and defect 1 with the knot set $h\mathbb{Z}$. The family B-spline $B_m(h^{-1}x - j)$, $j \in \mathbb{Z}$, belongs to $S_{h,m}$, and the same is true for $\sum_{j\in\mathbb{Z}} d_j B_m(h^{-1}x - j)$ with arbitrary coefficients d_j; there are no problems with the convergence of the series since it is locally finite: it follows from (2.2) that

$$\sum_{j\in\mathbb{Z}} d_j B_m(h^{-1}x - j) = \sum_{j=i-m+1}^{i} d_j B_m(h^{-1}x - j) \text{ for } x \in [ih, (i+1)h), \quad i \in \mathbb{Z}.$$

Given a function $f \in C(\mathbb{R})$, bounded or of at most polynomial growth as $|x| \to \infty$, we determine the interpolant $Q_{h,m}f \in S_{h,m}$ by the conditions

$$(Q_{h,m}f)(x) = \sum_{j\in\mathbb{Z}} d_j B_m(h^{-1}x - j), \quad x \in \mathbb{R}, \tag{2.5}$$

$$(Q_{h,m}f)\left(\left(k + \frac{m}{2}\right)h\right) = f\left(\left(k + \frac{m}{2}\right)h\right), \qquad k \in \mathbb{Z}. \tag{2.6}$$

For $m = 1$ and $m = 2$, $Q_{h,m}f$ is the usual piecewise constant, respectively, piecewise linear interpolant, which can be determined on every subinterval $[ih, (i+1)h)$, $i \in \mathbb{Z}$, independently of other subintervals. For $m \geq 3$, the value of $Q_{h,m}f$ at a given point $x \in \mathbb{R}$ depends on the values of f at all interpolation knots $(k + \frac{m}{2})h$, $k \in \mathbb{Z}$. It occurs (see [14, 16]) that for $m \geq 3$ conditions (2.5)–(2.6) really determine d_j, $j \in \mathbb{Z}$, uniquely in the space of bounded or polynomially growing bisequences (d_j), namely,

$$d_j = \sum_{k\in\mathbb{Z}} \alpha_{j-k,m} f\left(\left(k + \frac{m}{2}\right)h\right) = \sum_{k\in\mathbb{Z}} \alpha_{k,m} f\left(\left(j - k + \frac{m}{2}\right)h\right), \quad j \in \mathbb{Z}, \tag{2.7}$$

where

$$\alpha_{k,m} = \sum_{l=1}^{m_0} \frac{z_{l,m}^{m_0-1}}{P_m'(z_{l,m})} z_{l,m}^{|k|}, \quad k \in \mathbb{Z}, \quad m_0 = \begin{cases} (m-2)/2 & \text{if } m \text{ is even,} \\ (m-1)/2 & \text{if } m \text{ is odd,} \end{cases} \tag{2.8}$$

and $z_{l,m} \in (-1, 0)$, $l = 1, \ldots, m_0$, are the roots of the characteristic polynomial

$$P_m(z) = \sum_{|k|\leq m_0} B_m\left(k + \frac{m}{2}\right) z^{k+m_0}$$

(it is a polynomial of degree $2m_0$); it occurs that P_m has exactly m_0 simple roots $z_{l,m}$, $l = 1, \ldots, m_0$, in the interval $(-1, 0)$, and the remaining m_0 roots are of the form $z_{l+m_0,m} = 1/z_{l,m} \in (-\infty, -1)$, $l = 1, \ldots, m_0$.

Denote by $BC(\mathbb{R})$ the space of bounded continuous functions on $\mathbb{R}$ equipped with the norm $\|f\|_\infty = \sup_{x\in\mathbb{R}} |f(x)|$, by $V^{m,\infty}(\mathbb{R})$ the space of functions having bounded mth (distributional) derivative in $\mathbb{R}$, by $W^{m,\infty}(\mathbb{R})$ the standard Sobolev space of functions on $\mathbb{R}$ having bounded derivatives of order $\leq m$, and by $W^{m,\infty}_{(0,1)}(\mathbb{R})$ the space of functions $f \in W^{m,\infty}(\mathbb{R})$ with supports in $(0, 1)$.

LEMMA 2.1 (see [6, 21, 22]). *For $f \in V^{m,\infty}(\mathbb{R})$, it holds that $f - Q_{h,m}f \in BC(\mathbb{R})$ and*

$$\|f - Q_{h,m}f\|_\infty \leq \Phi_{m+1}\pi^{-m}h^m\|f^{(m)}\|_\infty, \tag{2.9}$$

where $\Phi_m = \frac{4}{\pi}\sum_{k=0}^{\infty} \frac{(-1)^{km}}{(2k+1)^m}$, $m \in \mathbb{N}$, is the Favard constant,

$$\Phi_1 < \Phi_3 < \Phi_5 < \cdots < 4/\pi < \cdots < \Phi_6 < \Phi_4 < \Phi_2, \quad \lim_{m\to\infty} \Phi_m = 4/\pi.$$

The following lemma tells that, in some sense, the spline interpolation yields the best approximation of the function classes $W^{m,\infty}(\mathbb{R})$ and $V^{m,\infty}(\mathbb{R})$, asymptotically also of $W^{m,\infty}_{(0,1)}(\mathbb{R})$, compared with other methods that use the same information as $Q_{h,m}f$—the values $f|_{\mathbb{Z}_{h,m}}$ of f on the grid $\mathbb{Z}_{h,m} = \{(j + \frac{m}{2})h : j \in \mathbb{Z}\}$. Denote by $C(\mathbb{Z}_{h,m})$ the vector space of all (grid) functions defined on $\mathbb{Z}_{h,m}$.

LEMMA 2.2 (see [21, 22]). *For given $\gamma > 0$, we have by Lemma* 2.1

$$\sup_{f\in V^{m,\infty}(\mathbb{R}),\|f^{(m)}\|_\infty\le\gamma} \|f - Q_{h,m}f\|_\infty \le \Phi_{m+1}\pi^{-m}h^m\gamma,$$

whereas for any mapping $M_h : C(\mathbb{Z}_{h,m}) \to C(\mathbb{R})$ (linear or nonlinear, continuous or discontinuous), it holds that

$$\sup_{f\in W^{m,\infty}(\mathbb{R}),\|f^{(m)}\|_\infty\le\gamma} \|f - M_h(f|_{\mathbb{Z}_{h,m}})\|_\infty \ge \Phi_{m+1}\pi^{-m}h^m\gamma,$$

$$\liminf_{h\to 0} \sup_{f\in W^{m,\infty}_{(0,1)}(\mathbb{R}),\|f^{(m)}\|_\infty\le\gamma} \|f - M_h(f|_{\mathbb{Z}_{h,m}})\|_\infty/(\Phi_{m+1}\pi^{-m}h^m\gamma) \ge 1.$$

2.3. Quasi-interpolation by splines. Let $m \ge 3$. In a quasi-interpolant $Q^{(p)}_{h,m}f$, the infinite sum (2.7) defining the coefficients d_j of the spline interpolant (2.5)–(2.6) is replaced by a finite sum:

$$(Q^{(p)}_{h,m}f)(x) = \sum_{j\in\mathbb{Z}} d^{(p)}_j B_m(h^{-1}x - j), \quad x \in \mathbb{R}, \tag{2.10}$$

$$d^{(p)}_j = \sum_{|k|\le p-1} \alpha^{(p)}_{k,m} f\left(\left(j - k + \frac{m}{2}\right)h\right), \quad p \in \mathbb{N}. \tag{2.11}$$

A simple truncation of the series in (2.7) does not give acceptable results. Using a special difference calculus for fast decaying bisequences, the following formulae for $\alpha^{(p)}_{k,m}$ have been proposed in [8]:

$$\alpha^{(p)}_{k,m} = \sum_{q=|k|}^{p-1} (-1)^{k+q} \begin{pmatrix} 2q \\ k+q \end{pmatrix} \gamma_{q,m}, \quad |k| \le p-1, \tag{2.12}$$

$$\gamma_{0,m} = 1, \quad \gamma_{q,m} = \sum_{l=1}^{m_0} \frac{(1 + z_{l,m})z^{m_0+q-1}_{l,m}}{(1 - z_{l,m})^{2q+1}P'_m(z_{l,m})}, \quad q \ge 1. \tag{2.13}$$

Then it occurs that

$$\|Q_{h,m}f - Q^{(p)}_{h,m}f\|_\infty \le c_{m,p}h^{2p}\|f^{(2p)}\|_\infty \text{ for } f \in V^{2p,\infty}(\mathbb{R}) \tag{2.14}$$

with a constant $c_{m,p}$ that can be described. A consequence of (2.14) is that for $f \in V^{m,\infty}(\mathbb{R})$ with uniformly continuous $f^{(m)}$ and $2p > m$, it holds that $\|Q_{h,m}f - Q^{(p)}_{h,m}f\|_\infty h^{-m} \to 0$ as $h \to 0$, i.e., the quasi-interpolant $Q^{(p)}_{h,m}f$ is asymptotically of the same accuracy as the interpolant $Q_{h,m}f$. It is reasonable to take the smallest $p \in \mathbb{N}$ for which $2p > m$; denote it by m_1,

$$m_1 = \left\{ \begin{array}{ll} \frac{m}{2} + 1, & m \text{ even} \\ \frac{m+1}{2}, & m \text{ odd} \end{array} \right\} = m - m_0. \tag{2.15}$$

Denote also $Q'_{h,m} := Q^{(m_1)}_{h,m}$, $\alpha'_{k,m} := \alpha^{(m_1)}_{k,m}$, $|k| < m_1$. Note that $(Q'_{h,m}f)(x)$ is well defined for $x \in [ih, (i+1)h]$ with an $i \in \mathbb{Z}$ if f is given on $[(i-m+1)h, (i+m)h] \cap \mathbb{Z}_{h,m}$.

LEMMA 2.3 (see [8]). *For $i \in \mathbb{Z}$, $f \in C^m[(i-m+1)h, (i+m)h]$, it holds that*

$$\max_{ih \le x \le (i+1)h} |f(x) - (Q'_{h,m}f)(x)| \le (\Phi_{m+1}\pi^{-m} + q_m c'_m)h^m \sup_{(i-m+1)h \le x \le (i+m)h} |f^{(m)}(x)|. \tag{2.16}$$

For a relatively compact set $\mathcal{M}$ in $C[-\delta, 1+\delta]$, $\delta > 0$, it holds that

$$\sup_{f \in \mathcal{M}} \max_{0 \le x \le 1} |f(x) - (Q'_{h,m}f)(x)| \to 0 \text{ as } h \to 0. \tag{2.17}$$

Formulae for $q_m := \|Q_{h,m}\|_{BC(\mathbb{R}) \to BC(\mathbb{R})}$, $q'_m := \|Q'_{h,m}\|_{BC(\mathbb{R}) \to BC(\mathbb{R})}$, and c'_m from (2.16) are presented in [8] with the following numerical values:

m	3	4	5	6	7	8	9	10	20
c'_m	0.016	0.019	0.015	0.0085	0.0060	0.0030	0.0022	0.0010	6.5e-6
q_m	1.414	1.549	1.706	1.816	1.916	2.000	2.075	2.142	2.583
$q_m c'_m$	0.023	0.029	0.026	0.015	0.012	0.006	0.005	0.002	1.7e-5
q'_m	1.250	1.354	1.329	1.403	1.356	1.413	1.378	1.419	1.514

Relatively small values of the norms q_m and q'_m tell us about good stability properties of interpolation and quasi-interpolation processes.

We assumed that $m \ge 3$. For $m = 1$ and $m = 2$, we may put $Q'_{h,m} = Q_{h,m}$.

3. A smoothing change of variables. In the integral equation (1.1), we perform the change of variables

$$x = \varphi(t), \quad y = \varphi(s), \quad 0 \le t \le 1, \quad 0 \le s \le 1, \tag{3.1}$$

where $\varphi : [0,1] \to [0,1]$ is defined by the formula

$$\varphi(t) = \frac{1}{c_\star} \int_0^t \sigma^{r_0 - 1}(1-\sigma)^{r_1 - 1} d\sigma, \tag{3.2}$$

$$c_\star = \int_0^1 \sigma^{r_0 - 1}(1-\sigma)^{r_1 - 1} d\sigma = \frac{\Gamma(r_0)\Gamma(r_1)}{\Gamma(r_0 + r_1)},$$

Γ is the Euler gamma function. We assume that r_0, $r_1 \in \mathbb{R}$, $r_0 \ge 1$, $r_1 \ge 1$, but we keep in mind that practicable algorithms correspond to the case where at least one of the parameters r_0 and r_1 is natural. If $r_1 \in \mathbb{N}$, (3.2) takes the form

$$\varphi(t) = \frac{1}{c_\star} t^{r_0} \sum_{k=0}^{r_1 - 1} \frac{(-1)^k}{r_0 + k} \mathcal{C}_k^{(r_1 - 1)} t^k, \quad 0 \le t \le 1, \quad c_\star = \frac{(r_1 - 1)!}{r_0(r_0+1)\dots(r_0 + r_1 - 1)},$$

but in our computations, the following expansion of φ with positive terms occurred to be preferable (essentially more stable numerically):

$$\varphi(t) = t^{r_0} \left[1 + \sum_{k=1}^{r_1 - 1} \frac{r_0(r_0+1)\dots(r_0+k-1)}{k!} (1-t)^k \right], \quad 0 \le t \le 1. \tag{3.3}$$

If $r_0, r_1 \in \mathbb{N}$, the integral in (3.2) can be alternatively evaluated [9] in a stable way by an exact Gauss rule, since the integrand is a polynomial of degree $r_0 + r_1 - 2$.

Clearly, $\varphi(0) = 0$, $\varphi(1) = 1$, and $\varphi(t)$ is strictly increasing in $[0,1]$. Hence $\frac{\varphi(t)-\varphi(s)}{t-s} > 0$, $|\varphi(t) - \varphi(s)| = \frac{\varphi(t)-\varphi(s)}{t-s}|t-s|$ for $s \neq t$, and (1.1) takes with respect to $v(t) = u(\varphi(t))$ the form

$$v(t) = \int_0^1 \left(\mathcal{A}(t,s)|t-s|^{-\nu} + \mathcal{B}(t,s)\right) v(s)ds + g(t), \quad 0 \le t \le 1, \tag{3.4}$$

where

$$\mathcal{A}(t,s) = a(\varphi(t),\varphi(s))\Phi(t,s)^{-\nu}\varphi'(s), \qquad \Phi(t,s) = \begin{cases} \frac{\varphi(t)-\varphi(s)}{t-s}, & t \neq s, \\ \varphi'(s), & t = s, \end{cases} \tag{3.5}$$

$$\mathcal{B}(t,s) = b(\varphi(t),\varphi(s))\varphi'(s), \qquad g(t) = f(\varphi(t)). \tag{3.6}$$

Let us characterize the boundary behavior of functions in (3.4). Clearly,

$$\begin{gathered} 0 \le \varphi(t) \le ct^{r_0}, \quad 0 \le 1 - \varphi(t) \le c(1-t)^{r_1}, \\ |\varphi^{(k)}(t)| \le ct^{r_0-k}(1-t)^{r_1-k}, \quad 0 < t < 1, \quad k = 1, \dots, m. \end{gathered} \tag{3.7}$$

LEMMA 3.1. *For $u \in C^m_\star(0,1)$, $v(t) = u(\varphi(t))$, it holds that $v \in C^m_\star(0,1)$ and*

$$\|v\|_{C^m_\star(0,1)} \le c\|u\|_{C^m_\star(0,1)}, \tag{3.8}$$

where the constant c is independent of u. Further, if $u \in C^{m,\theta_0,\theta_1}(0,1)$, $\theta_0 < 1$, $\theta_1 < 1$, then for $j = 1, \dots, m$, $0 < t < 1$,

$$\begin{aligned} |v^{(j)}(t)| &\le c\|u\|_{C^{m,\theta_0,\theta_1}(0,1)} \\ &\times \left\{ \begin{array}{r} t^{r_0-j}, \quad \theta_0 < 0 \\ t^{r_0-j}(1+|\log t|), \quad \theta_0 = 0 \\ t^{(1-\theta_0)r_0-j}, \quad \theta_0 > 0 \end{array} \right\} \left\{ \begin{array}{r} (1-t)^{r_1-j}, \quad \theta_1 < 0 \\ (1-t)^{r_1-j}(1+|\log(1-t)|), \quad \theta_1 = 0 \\ (1-t)^{(1-\theta_1)r_1-j}, \quad \theta_1 > 0 \end{array} \right\}. \end{aligned} \tag{3.9}$$

Proof. Clearly $\|v\|_\infty = \|u\|_\infty$. The proof of (3.8) and (3.9) is based on (3.7) and the formula of Faà di Bruno,

$$\left(\frac{d}{dt}\right)^j u(\varphi(t)) = \sum_{k_1+\cdots+jk_j=j} \frac{j!}{k_1!..k_j!} u^{(k_1+\cdots+k_j)}(\varphi(t)) \left(\frac{\varphi'(t)}{1!}\right)^{k_1} \cdots \left(\frac{\varphi^{(j)}(t)}{j!}\right)^{k_j},$$

where the sum is taken over all $k_1 \ge 0, \dots, k_j \ge 0$ such that $k_1 + 2k_2 + \cdots + jk_j = j$. Here are the details for (3.9). For $0 < t \le \frac{1}{2}$, $1 \le j \le m$, we have

$$\begin{aligned} |v^{(j)}(t)| &\le c \sum_{k_1+2k_2\dots+jk_j=j} \left\{ \begin{array}{cc} 1, & k_1+\cdots+k_j < 1-\theta_0 \\ 1+|\log t|, & k_1+\cdots+k_j = 1-\theta_0 \\ t^{(1-\theta_0-k_1-\cdots-k_j)r_0}, & k_1+\cdots+k_j > 1-\theta_0 \end{array} \right\} \\ &\times \|u\|_{C^{m,\theta_0,\theta_1}} t^{k_1(r_0-1)} t^{k_2(r_0-2)} \dots t^{k_j(r_0-j)} \\ &= c \sum_{k_1+\cdots+jk_j=j} \left\{ \begin{array}{cc} t^{(k_1+\cdots+k_j)r_0-j}, & k_1+\cdots+k_j < 1-\theta_0 \\ t^{(1-\theta_0)r_0-j}(1+|\log t|), & k_1+\cdots+k_j = 1-\theta_0 \\ t^{(1-\theta_0)r_0-j}, & k_1+\cdots+k_j > 1-\theta_0 \end{array} \right\} \|u\|_{C^{m,\theta_0,\theta_1}}. \end{aligned}$$

The condition $k_1+2k_2\cdots+jk_j=j$ implies the following: (i) The relation $k_1+\cdots+k_j<1-\theta_0$ is possible only if $\theta_0<0$, and then t^{r_0-j} is the leading term as $t\to 0$ in the last sum (it corresponds to $k_1=\cdots=k_{j-1}=0$, $k_j=1$). (ii) The relation $k_1+\cdots+k_j=1-\theta_0$ is possible only if $\theta_0\le 0$, $\theta_0\in\mathbb{Z}$; in the case $\theta_0=0$, the leading term is $t^{r_0-j}(1+|\log t|)$, whereas in case $\theta_0\le -1$, similarly as in (i), the leading term is t^{r_0-j}. (iii) If $0<\theta_0<1$, then all terms in the last sum are $t^{(1-\theta_0)r_0-j}$. These considerations prove (3.9) for $0<t\le\frac{1}{2}$. By an analogous argument we obtain (3.9) also for $\frac{1}{2}\le t<1$. □

LEMMA 3.2. *Let a and b satisfy the conditions of Lemma* 1.2. *Then for $j=0,\dots,m$, $0\le t\le 1$, $0<s<1$, it holds that*

$$|\partial_s^j a(\varphi(t),\varphi(s))|\le cs^{-r_0\lambda_0-j}(1-s)^{-r_1\lambda_1-j}, \tag{3.10}$$

$$|\partial_s^j b(\varphi(t),\varphi(s))|\le cs^{-r_0\mu_0-j}(1-s)^{-r_1\mu_1-j}. \tag{3.11}$$

These inequalities elementarily follow by the formula of Faà di Bruno.

The function $\Phi(t,s)^{-\nu}$ has singularities at $(0,0)$ and $(1,1)$, the only zeros of $\Phi(t,s)$ in $[0,1]\times[0,1]$. It is easy to see that

$$\partial_s^k\Phi(t,s)\asymp(t+s)^{r_0-k-1}((1-t)+(1-s))^{r_1-k-1} \text{ as } t,s\to 0 \text{ or as } t,s\to 1,$$

which together with the formula of Faà di Bruno implies the following result.

LEMMA 3.3. *For $j=0,\dots,m$, $0\le t\le 1$, $0<s<1$, it holds that*

$$\left|\partial_s^j\left((\Phi(t,s))^{-\nu}\right)\right|\le c(t+s)^{-\nu(r_0-1)-j}((1-t)+(1-s))^{-\nu(r_1-1)-j}. \tag{3.12}$$

Next we present estimates for functions $\mathcal{A}(t,s)$, $\mathcal{B}(t,s)$, and $\partial_s^m[\mathcal{A}(t,s)v(s)]$, $\partial_s^m[\mathcal{B}(t,s)v(s)]$ in somewhat specific form for the needs of section 4.

COROLLARY 3.4. *Let a and b satisfy the conditions of Lemma* 1.1. *Then the following holds true:* (i) *if*

$$r_0,r_1\ge 1,\quad r_0>(1-\nu)/(1-\nu-\lambda_0),\quad r_1>(1-\nu)/(1-\nu-\lambda_1), \tag{3.13}$$

then with $\delta_0:=(1-\nu-\lambda_0)r_0-(1-\nu)>0$, $\delta_1:=(1-\nu-\lambda_1)r_1-(1-\nu)>0$, it holds that

$$|\mathcal{A}(t,s)|\le cs^{\delta_0}(1-s)^{\delta_1},\quad (t,s)\in[0,1]\times(0,1); \tag{3.14}$$

(ii) *if*

$$r_0,r_1\ge 1,\quad r_0>1/(1-\mu_0),\quad r_1>1/(1-\mu_1), \tag{3.15}$$

then with $\delta_0:=(1-\mu_0)r_0-1>0$, $\delta_1:=(1-\mu_1)r_1-1>0$, it holds that

$$|\mathcal{B}(t,s)|\le cs^{\delta_0}(1-s)^{\delta_1},\quad (t,s)\in[0,1]\times(0,1). \tag{3.16}$$

Proof. These estimates are direct consequences of Lemmas 3.2 and 3.3. By (3.7), (3.10), and (3.12) we have

$$|\mathcal{A}(t,s)|\le cs^{-r_0\lambda_0+r_0-1}(t+s)^{-\nu(r_0-1)}(1-s)^{-r_1\lambda_1+r_1-1}(2-t-s)^{-\nu(r_1-1)},$$

which for r_0, r_1 satisfying (3.13) yields (3.14). Similarly, by (3.7), (3.11), and (3.12),

$$|\mathcal{B}(t,s)|\le cs^{-r_0\mu_0+r_0-1}(1-s)^{-r_1\mu_1+r_1-1},$$

which for r_0, r_1 satisfying (3.15) yields (3.16). □

COROLLARY 3.5. *Let a and b satisfy the conditions of Lemma* 1.2, *and let $u \in C^m_\star(0,1)$, $v(t) = u(\varphi(t))$. Then the following estimates hold true for $(t,s) \in [0,1] \times (0,1)$:* (i) *if*

$$r_0, r_1 \geq 1, \quad r_0 > m/(1-\nu-\lambda_0), \quad r_1 > m/(1-\nu-\lambda_1), \tag{3.17}$$

then with $\delta_0 := (1-\nu-\lambda_0)r_0 - m > 0$, $\delta_1 := (1-\nu-\lambda_1)r_1 - m > 0$,

$$|\mathcal{A}(t,s)| \leq cs^{m-(1-\nu)+\delta_0}(1-s)^{m-(1-\nu)+\delta_1}, \tag{3.18}$$

$$|\partial_s^m[\mathcal{A}(t,s)v(s)]| \leq cs^{-(1-\nu)+\delta_0}(1-s)^{-(1-\nu)+\delta_1}\|u\|_{C^m_\star(0,1)}; \tag{3.19}$$

(ii) *if*

$$r_0, r_1 \geq 1, \quad r_0 > m/(1-\mu_0), \quad r_1 > m/(1-\mu_1), \tag{3.20}$$

then with $\delta_0 := (1-\mu_0)r_0 - m > 0$, $\delta_1 := (1-\mu_1)r_1 - m > 0$,

$$|\mathcal{B}(t,s)| \leq cs^{m-1+\delta_0}(1-s)^{m-1+\delta_1}, \tag{3.21}$$

$$|\partial_s^m[\mathcal{B}(t,s)v(s)]| \leq cs^{-1+\delta_0}(1-s)^{-1+\delta_1}\|u\|_{C^m_\star(0,1)}; \tag{3.22}$$

(iii) *if*

$$r_0, r_1 \geq 1, \quad r_0 > (m+\nu)/(1-\lambda_0), \quad r_1 > (m+\nu)/(1-\lambda_1), \tag{3.23}$$

then with $\delta_0 := (1-\lambda_0)r_0 - m - \nu > 0$, $\delta_1 := (1-\lambda_1)r_1 - m - \nu > 0$,

$$\varphi'(t)^\nu|\mathcal{A}(t,s)| \leq cs^{m-(1-\nu)+\delta_0}(1-s)^{m-(1-\nu)+\delta_1}, \tag{3.24}$$

$$\varphi'(t)^\nu|\partial_s^m[\mathcal{A}(t,s)v(s)]| \leq cs^{-(1-\nu)+\delta_0}(1-s)^{-(1-\nu)+\delta_1}\|u\|_{C^m_\star(0,1)}. \tag{3.25}$$

Proof. These estimates are direct consequences of Lemmas 3.1–3.3. Observe that $|\partial_s^k[\varphi'(t)^\nu\Phi(t,s)^{-\nu}]| \leq c(t+s)^{-k}((1-t)+(1-s))^{-k}$. ∎

Let us extend $\mathcal{A}(t,s)$ and $\mathcal{B}(t,s)$ with respect to s outside $(0,1)$ by the zero value. Under conditions (3.13) and (3.15) we obtain continuous functions on $[0,1] \times \mathbb{R}$; see (3.14) and (3.16).

4. The product quasi-interpolation method.

4.1. The operator form of the method. Let $h = 1/n$, $n \in \mathbb{N}$, $n \geq m$. For $0 \leq s \leq 1$, the quasi-interpolant $Q'_{h,m}w$ of a function $w \in C[-\delta, 1+\delta]$ has the expansion

$$(Q'_{h,m}w)(s) = \sum_{j=-m+1}^{n-1} \sum_{|p|<m_1} \alpha'_{p,m} w\left(\left(j-p+\frac{m}{2}\right)h\right) B_m(ns-j). \tag{4.1}$$

We approximate (3.4) by its discretized version: for $0 \leq t \leq 1$,

$$v_n(t) = \int_0^1 [|t-s|^{-\nu}Q'_{h,m}(\mathcal{A}(t,s)v_n(s)) + Q'_{h,m}(\mathcal{B}(t,s)v_n(s))]ds + g(t), \tag{4.2}$$

where $Q'_{h,m}$ is applied to the products $\mathcal{A}(t,s)v(s)$ and $\mathcal{B}(t,s)v(s)$ as functions of s. This can be done for v given on $[0,1]$ since $\mathcal{A}(t,s) = \mathcal{B}(t,s) = 0$ for $s \leq 0$ and for $s \geq 1$; recall that under conditions (3.13) and (3.15), $\mathcal{A}, \mathcal{B} \in C([0,1] \times \mathbb{R})$.

THEOREM 4.1. (i) *Let a and b satisfy the conditions of Lemma* 1.1, $\mathcal{N}(I-T)=\{0\}$, $f\in C[0,1]$, *and let r_0 and r_1 satisfy conditions* (3.13) *and* (3.15). *Then for sufficiently large n,* (4.2) *has a unique solution v_n, and*

$$\|v-v_n\|_\infty := \max_{0\le t\le 1}|v(t)-v_n(t)|\to 0 \text{ as } n\to\infty, \tag{4.3}$$

where v is the solution of (3.4).

(ii) *Under the assumptions of Theorem* 1.3, $f\in C^m_\star(0,1)$, *and conditions* (3.17) *and* (3.20) *on r_0 and r_1, it holds that*

$$\|v-v_n\|_\infty \le ch^m\|f\|_{C^m_\star(0,1)}. \tag{4.4}$$

(iii) *Under the assumptions of Theorem* 1.3, $f\in C^m_\star(0,1)$, *and conditions* (3.20) *and* (3.23) *on r_0 and r_1, it holds that*

$$\max_{0\le t\le 1}\varphi'(t)^\nu|v(t)-v_n(t)|\le ch^m\|f\|_{C^m_\star(0,1)}. \tag{4.5}$$

The constant c in (4.4) *and* (4.5) *is independent of n and f.*

Proof. Accept the assumptions formulated in (i). Denote by $\mathcal{T}$ and $\mathcal{T}_n$ the integral operators of (3.4) and (4.2),

$$(\mathcal{T}v)(t)=\int_0^1[|t-s|^{-\nu}\mathcal{A}(t,s)+\mathcal{B}(t,s)]v(s)ds,$$

$$(\mathcal{T}_nv)(t)=\int_0^1[|t-s|^{-\nu}Q'_{h,m}(\mathcal{A}(t,s)v(s))+Q'_{h,m}(\mathcal{B}(t,s)v(s))]ds.$$

We claim that $\mathcal{T}_n\to\mathcal{T}$ compactly in $C[0,1]$ as $n\to\infty$, i.e.,

$$\|\mathcal{T}_nv-\mathcal{T}v\|_\infty\to 0 \text{ for every } v\in C[0,1], \tag{4.6}$$

$$(v_n)\subset C[0,1], \|v_n\|_\infty\le 1 \Rightarrow (\mathcal{T}_nv_n) \text{ is relatively compact in } C[0,1]. \tag{4.7}$$

Indeed, the sets $\{\mathcal{A}(t,\cdot):0\le t\le 1\}$ and $\{\mathcal{B}(t,\cdot):0\le t\le 1\}$ are relatively compact in $C[-\delta,1+\delta]$, and by Lemma 2.3, for a fixed $v\in C[0,1]$ extended by $v(t)=v(0)$ for $-\delta\le s\le 0$, $v(t)=v(1)$ for $1\le s\le 1+\delta$, it holds that

$$\sup_{0\le t\le 1}\max_{0\le s\le 1}|\mathcal{A}(t,s)v(s)-Q'_{h,m}(\mathcal{A}(t,s)v(s))|\to 0 \text{ for } n\to\infty,$$

$$\sup_{0\le t\le 1}\max_{0\le s\le 1}|\mathcal{B}(t,s)v(s)-Q'_{h,m}(\mathcal{B}(t,s)v(s))|\to 0 \text{ for } n\to\infty.$$

This together with the equality $\|Q'_{h,m}\|=q'_m$ implies (4.6). The proof of (4.7) can be built using the Arzelà theorem.

Due to the condition $\mathcal{N}(I-T)=\{0\}$, also $\mathcal{N}(I-\mathcal{T})=\{0\}$. As is well known (see [1, 2, 7] or [18]), relations (4.6), (4.7) and $\mathcal{N}(I-\mathcal{T})=\{0\}$ imply that, for sufficiently large n, the operators $I-\mathcal{T}_n$ are invertible and the inverses are uniformly bounded:

$$\|(I-\mathcal{T}_n)^{-1}\|_{C[0,1]\to C[0,1]}\le c, \qquad n\ge n_0. \tag{4.8}$$

Let v and v_n be the solutions of (3.4) and (4.2), respectively. Then

$$v-v_n=(I-\mathcal{T}_n)^{-1}(\mathcal{T}v-\mathcal{T}_nv), \tag{4.9}$$

and due to (4.8) and (4.6), the convergence (4.3) follows.

Next we establish the uniform estimate (4.4). Assume the conditions of Theorem 1.3, $f \in C^m_\star(0,1)$, and (3.17), (3.20) hold. For the solutions u and v of (1.1) and (3.4) we have $v(t) = u(\varphi(t))$ and $u \in C^m_\star(0,1)$ by Theorem 1.3. On the basis of (2.16) and (3.19),

$$\begin{aligned}\int_{2mh}^{1-2mh} &|t-s|^{-\nu}|\mathcal{A}(t,s)v(s) - Q'_{h,m}(\mathcal{A}(t,s)v(s))|ds \\ &\le ch^m \int_{mh}^{1-mh} |t-s|^{-\nu} s^{-(1-\nu)+\delta_0}(1-s)^{-(1-\nu)+\delta_1} ds \|u\|_{C^m_\star(0,1)} \\ &\le c'h^m \|u\|_{C^m_\star(0,1)},\end{aligned}$$

where we have taken into account that for $2mh \le s \le 1-2mh$, it holds that

$$\max_{|\sigma-s|\le mh} \sigma^{-(1-\nu)+\delta_0}(1-\sigma)^{-(1-\nu)+\delta_1} \le cs^{-(1-\nu)+\delta_0}(1-s)^{-(1-\nu)+\delta_1}.$$

Further, due to (3.18)

$$\max_{0\le t\le 1, s\in[0,2mh]\cup[1-2mh,1]} |\mathcal{A}(t,s)| \le ch^{m-(1-\nu)+\delta'}, \quad \delta' = \min\{\delta_0,\delta_1\} > 0,$$

which implies

$$\begin{aligned}\left(\int_0^{2mh} + \int_{1-2mh}^1\right) &|t-s|^{-\nu}|\mathcal{A}(t,s)v(s) - Q'_{h,m}(\mathcal{A}(t,s)v(s))|ds \\ &\le (1+q'_m)ch^{m-(1-\nu)+\delta'} \left(\int_0^{2mh} + \int_{1-2mh}^1\right) |t-s|^{-\nu} ds \|v\|_\infty \\ &\le c'h^{m+\delta'}\|u\|_\infty\end{aligned}$$

and together with the previous estimate,

$$\int_0^1 |t-s|^{-\nu}|\mathcal{A}(t,s)v(s) - Q'_{h,m}(\mathcal{A}(t,s)v(s))|ds \le ch^m\|u\|_{C^m_\star(0,1)}, \quad 0 \le t \le 1.$$

With the help of (3.21) and (3.22) we obtain in a similar way that

$$\int_0^1 |\mathcal{B}(t,s)v(s) - Q'_{h,m}(\mathcal{B}(t,s)v(s))|ds \le ch^m\|u\|_{C^m_\star(0,1)}, \quad 0 \le t \le 1.$$

Exploiting also Theorem 1.3 we get

$$\|\mathcal{T}v - \mathcal{T}_n v\|_\infty \le ch^m\|u\|_{C^m_\star(0,1)} \le c'h^m\|f\|_{C^m_\star(0,1)}.$$

Together with (4.8) and (4.9) this proves (4.4).

Finally, let us prove the weighted error estimate (4.5) under conditions (3.20), (3.23) on r_0 and r_1. Let v and v_n be the solutions of (3.4) and (4.2), respectively; then $w(t) = \varphi'(t)^\nu v(t)$ and $w_n(t) = \varphi'(t)^\nu v_n(t)$ are the solutions of equations

$$w(t) = \int_0^1 [|t-s|^{-\nu}\overline{\mathcal{A}}(t,s)w(s) + \overline{\mathcal{B}}(t,s)w(s)]ds + \varphi'(t)^\nu g(t), \tag{4.10}$$

$$\begin{aligned}w_n(t) = \int_0^1 &[|t-s|^{-\nu}Q'_{h,m}(\overline{\mathcal{A}}(t,s)w_n(s)) + Q'_{h,m}(\overline{\mathcal{B}}(t,s))w_n(s)]ds \\ &+ \varphi'(t)^\nu g(t), \quad 0 \le t \le 1,\end{aligned} \tag{4.11}$$

respectively, where

$$\overline{\mathcal{A}}(t,s) = \varphi'(t)^\nu \mathcal{A}(t,s)\varphi'(s)^{-\nu} = \varphi'(t)^\nu a(\varphi(t),\varphi(s))\Phi(t,s)^{-\nu}\varphi'(s)^{1-\nu},$$
$$\overline{\mathcal{B}}(t,s) = \varphi'(t)^\nu \mathcal{B}(t,s)\varphi'(s)^{-\nu} = \varphi'(t)^\nu b(\varphi(t),\varphi(s))\varphi'(s)^{1-\nu}.$$

Denote by $\overline{\mathcal{T}}$ and $\overline{\mathcal{T}}_n$ the integral operators of (4.10) and (4.11). Arguing similarly as above it is easily seen that $\overline{\mathcal{T}}_n \to \overline{\mathcal{T}}$ compactly in $C[0,1]$; by the way, this holds even under the conditions of part (i) of the theorem, in particular, (3.13) and (3.15) guarantee the continuity of $\overline{\mathcal{A}}(t,s)$ and $\overline{\mathcal{B}}(t,s)$ on $[0,1]\times\mathbb{R}$. Hence

$$\|(I-\overline{\mathcal{T}}_n)^{-1}\|_{C[0,1]\to C[0,1]} \le c, \quad n \ge n_0, \tag{4.12}$$
$$\|w - w_n\|_\infty \le c\|\overline{\mathcal{T}}w - \overline{\mathcal{T}}_n w\|_\infty = c \max_{0\le t\le 1} \varphi'(t)^\nu |(\mathcal{T}v)(t) - (\mathcal{T}_n v)(t)|.$$

Using (3.24), (3.25), (3.21), (3.22), and Theorem 1.3, we obtain

$$\max_{0\le t\le 1} \varphi'(t)^\nu |(\mathcal{T}v)(t) - (\mathcal{T}_n v)(t)| \le ch^m \|u\|_{C^m_\star(0,1)} \le c'h^m \|f\|_{C^m_\star(0,1)},$$

which completes the proof of estimate (4.5). □

Remark 4.1. Under the conditions of Theorem 4.1(i), we have

$$\|\mathcal{T}_n\|_{C[0,1]\to C[0,1]} \le c, \|\overline{\mathcal{T}}_n\|_{C[0,1]\to C[0,1]} \le c, \qquad n \ge m. \tag{4.13}$$

Remark 4.2. Under the conditions of Theorem 4.1(ii) but using slack inequalities instead of strict ones in (3.17), (3.20), a slight modification in the proof yields

$$\|v - v_n\|_\infty \le ch^m |\log h| \|f\|_{C^m_\star(0,1)}. \tag{4.14}$$

A similar remark concerns Theorem 4.1(iii).

The numerical example in section 6 does not confirm the presence of the factor $|\log h|$ in (4.14). If it really can be dropped, the proof needs new ideas.

Remark 4.3. Assume that m is odd, $f \in C^{m+1}_\star(0,1)$, $a, b \in C^{m+1}([0,1]\times(0,1))$ satisfy (1.2) for $k+l \le m+1$, and $\mathcal{N}(I-T) = \{0\}$. Then under the conditions

$$r_0, r_1 \ge 1, \quad r_0 \ge (m+1-\nu)/(1-\nu-\lambda_0), r_1 \ge (m+1-\nu)/(1-\nu-\lambda_1),$$
$$r_0 \ge (m+1-\nu)/(1-\mu_0), r_1 \ge (m+1-\nu)/(1-\mu_1)$$

the convergence order (4.4) of method (4.2) can be improved (cf. [13]):

$$\|v - v_n\|_\infty \le ch^{m+1-\nu} \|f\|_{C^{m+1}_\star(0,1)}. \tag{4.15}$$

The outlines of the proof are as follows. Due to (2.12), $\alpha^{(p)}_{k,m} = \alpha^{(p)}_{-k,m}$. Together with the symmetry property (2.2) of B_m this implies that for a function e which if odd with respect to a point $(j+\frac{1}{2})h$ also $Q'_{h,m}e$ has the same parity property, a consequence is that $\int_{jh}^{(j+1)h}(e_m - Q'_{h,m}e_m)ds = 0$ for odd m and polynomials e_m of degree $\le m$ (note that, due to (2.9) and (2.14), $e_{m-1} - Q'_{h,m}e_{m-1} = 0$ for polynomials of degree $\le m-1$). Hence for odd m,

$$\left|\int_{jh}^{(j+1)h} (w - Q'_{h,m}w)ds\right| \le ch^{m+2} \max_{(j-m+\frac{1}{2})h\le s\le(j+m-\frac{1}{2})h} |w^{(m+1)}(s)|. \tag{4.16}$$

For $w(s) = \mathcal{A}(t,s)v(s)$, $0 < s < 1$, $0 \le t \le 1$, the conditions on r_0, r_1 yield

$$|w^{(m)}(s)| \le c\|v\|_{C^m_\star(0,1)}, \quad |w^{(m+1)}(s)| \le c[s^{-1} + (1-s)^{-1}]\|v\|_{C^{m+1}_\star(0,1)},$$

and with the help of (2.16) and (4.16) we obtain

$$\varepsilon_j := \max_{jh\le s\le (j+1)h} |w(s)-(Q'_{h,m}w)(s)| \le ch^m \|v\|_{C^m_\star(0,1)}, \quad 0\le j\le n-1,$$

$$\varepsilon'_j := \left| \int_{jh}^{(j+1)h} (w-Q'_{h,m}w)ds \right| \le ch^{m+2}[(jh)^{-1}+((n-j)h)^{-1}]\|v\|_{C^{m+1}_\star(0,1)},$$
$$j=m+1,\dots,n-m-2.$$

With $i\in\mathbb{Z}$, $0\le i\le n-1$, such that $|t-(i+\frac12)h|\le\frac{h}{2}$, we get

$$\left|\int_0^1 |t-s|^{-\nu}[w(s)-(Q'_{h,m}w)(s)]ds\right| \le \left(\sum_{j=0}^{m}+\sum_{j=n-m-1}^{n-1}\right)\varepsilon_j\int_{jh}^{(j+1)h}|t-s|^{-\nu}ds$$
$$+\sum_{j=m+1}^{n-m-2}\left\{\varepsilon_j\int_{jh}^{(j+1)h}\left||t-s|^{-\nu}-\left|\left(i+\frac12-j\right)h\right|^{-\nu}\right|ds+\varepsilon'_j\left|\left(i+\frac12-j\right)h\right|^{-\nu}\right\}$$
$$\le ch^{m+1-\nu}\|v\|_{C^{m+1}_\star(0,1)}, \quad 0\le t\le 1.$$

For $w(s)=\mathcal{B}(t,s)v(s)$ we get in a straightforward manner, as in the proof of Theorem 4.1, that $|\int_0^1(w-Q'_{h,m}w)ds|\le ch^{m+1-\nu}\|v\|_{C^{m+1}_\star(0,1)}$, and now (4.15) follows.

For even m, an inequality like (4.16) is violated, and estimate (4.4) for the method (4.2) cannot be improved; for $m=4$, a numerical confirmation can be seen from Table 6.1, column $r=9$. It is possible to modify the basic method (4.2) so that (4.15) will hold for even m; we do not go into the details here.

4.2. Matrix form of the method. With the help of (4.1) we rewrite (4.2) in the form

$$v_n(t)=\sum_{j=-m+1}^{n-1}\sum_{p\in\mathbb{Z}:|p|<m_1,0<j-p+\frac{m}{2}<n}\alpha'_{p,m}\left[\mathcal{A}\left(t,\left(j-p+\frac{m}{2}\right)h\right)\beta_j(t)\right.$$
$$\left.+\mathcal{B}\left(t,\left(j-p+\frac{m}{2}\right)h\right)\beta_j^0\right]v_n\left(\left(j-p+\frac{m}{2}\right)h\right)+g(t), \quad 0\le t\le 1, \tag{4.17}$$

where

$$\beta_j(t)=\int_0^1|t-s|^{-\nu}B_m(ns-j)ds, \quad \beta_j^0=\int_0^1 B_m(ns-j)ds;$$

we took into account that $\mathcal{A}(t,s)=0$, $\mathcal{B}(t,s)=0$ for $s\le 0$ and for $s\ge 1$. The solution v_n of (4.17) is determined by its values at the points $(k+\frac{m}{2})h$ for k satisfying $0<(k+\frac{m}{2})h<1$, that is, for $k=-m_0,\dots,n-m_1$ with m_0 and m_1 defined in (2.8), (2.15). Collocating (4.17) at $(i+\frac{m}{2})h$ and denoting

$$v_{i,n}=v_n\left(\left(i+\frac{m}{2}\right)h\right), \quad g_i=g\left(\left(i+\frac{m}{2}\right)h\right),$$
$$i=-m_0,\dots,n-m_1,$$
$$a_{i,k}=\mathcal{A}\left(\left(i+\frac{m}{2}\right)h,\left(k+\frac{m}{2}\right)h\right), \quad b_{i,k}=\mathcal{B}\left(\left(i+\frac{m}{2}\right)h, \quad \left(k+\frac{m}{2}\right)h\right),$$
$$i,k=-m_0,\dots,n-m_1,$$

we arrive at the system of linear algebraic equations

$$v_{i,n} = \sum_{j=-m+1}^{n-1} \sum_{p\in\mathbb{Z}:|p|<m_1, 0<j-p+\frac{m}{2}<n} \alpha'_{p,m}(\beta_{i,j}a_{i,j-p} + \beta_j^0 b_{i,j-p})v_{j-p,n} + g_i, \tag{4.18}$$
$$i = -m_0, \dots, n-m_1,$$

where for $i = -m_0, \dots, n-m_1$, $j = -m+1, \dots, n-1$,

$$\beta_{i,j} = \int_0^1 \left|\left(i+\frac{m}{2}\right)h - s\right|^{-\nu} B_m(ns-j)ds, \quad \beta_j^0 = \int_0^1 B_m(ns-j)ds. \tag{4.19}$$

To present (4.18) in a standard form, we change the summation ordering:

$$\sum_{j=-m+1}^{n-1} \sum_{p\in\mathbb{Z}:|p|<m_1, 0<j-p+\frac{m}{2}<n} \alpha'_{p,m}(\beta_{i,j}a_{i,j-p} + \beta_j^0 b_{i,j-p})v_{j-p,n}$$
$$= \sum_{j=-m+1}^{n-1} \sum_{k=\max\{-m_0, j-m_1+1\}}^{\min\{n-m_1, j+m_1-1\}} \alpha'_{j-k,m}(\beta_{i,j}a_{i,k} + \beta_j^0 b_{i,k})v_{k,n}$$
$$= \sum_{k=-m_0}^{n-m_1} \sum_{j=k-m_1+1}^{k+m_1-1} \alpha'_{j-k,m}(\beta_{i,j}a_{i,k} + \beta_j^0 b_{i,k})v_{k,n}$$

(the summation goes over $(j,k) \in D\cap\mathbb{Z}^2$, where $D \subset \mathbb{R}^2$ is the parallelogram restricted by the lines $k = j - m_1 + 1$, $k = j + m_1 - 1$, $k = -m_0$, $k = n - m_1$; note that $m_0 + m_1 = m$). We arrive at the following form of system (4.18):

$$v_{i,n} = \sum_{k=-m_0}^{n-m_1} \tau_{i,k}v_{k,n} + g_i, \quad i = -m_0, \dots, n-m_1, \tag{4.20}$$

where

$$\tau_{i,k} = \sum_{j=k-m_1+1}^{k+m_1-1} \alpha'_{j-k,m}(\beta_{i,j}a_{i,k} + \beta_j^0 b_{i,k}), \quad i,k = -m_0, \dots, n-m_1. \tag{4.21}$$

The dimension of system (4.20) is, respectively, $n-1$ and n for even and odd m. The computation of matrix elements (4.21) from $\alpha'_{j,m}$, $\beta_{i,j}$, β_j^0, $a_{i,k}$, $b_{i,k}$ costs approximately $3mn^2$ flops.

4.3. Quasi-interpolation extension of the discrete solution. Having found the solution $v_{i,n}$, $i = -m_0, \dots, n-m_1$, of system (4.20) we can use (4.17) to compute $v_n(t)$ for any $t \in [0,1]$. A cheaper way is to construct on every $[ih, (i+1)h]$, $i = 0, \dots, n-1$, the quasi-interpolant $\widetilde{v}_n(t)$ of degree $m-1$ using the solution of (4.20) completed by values $v_{i,n} = v_{-m_0,n}$ for $i < -m_0$ and $v_{i,n} = v_{n-m_1,n}$ for $i > n-m_1$; a slightly more accurate way is to compute $v_n(0)$ and $v_n(1)$ from (4.17) and set $v_{i,n} = v_n(0)$ for $i < -m_0$ and $v_{i,n} = v_n(1)$ for $i > n-m_1$. To maintain the convergence orders (4.4) and (4.5) for $\widetilde{v}_n$, we have to strengthen conditions on f and parameters r_0 and r_1.

THEOREM 4.2. (i) *Under the assumptions of Theorem* 4.1(i), $\|v - \widetilde{v}_n\|_\infty \to 0$ *as* $n \to \infty$.

(ii) *Under the assumptions of Theorem* 1.3, $f \in C^{m,\theta_0,\theta_1}(0,1)$ *with* $\theta_0 = \max\{\lambda_0+\nu, \mu_0\}$, $\theta_1 = \max\{\lambda_1+\nu, \mu_1\}$, (3.17), (3.20), *and* $r_0 > m$, $r_1 > m$, *it holds that*

$$\|v - \widetilde{v}_n\|_\infty \le ch^m \|f\|_{C^{m,\theta_0,\theta_1}(0,1)}. \tag{4.22}$$

(iii) *Under the assumptions of Theorem* 1.3, $f \in C^{m,\theta_0,\theta_1}(0,1)$ *as in* (ii), (3.20), (3.23), *and* $r_0 > (m+\nu)/(1+\nu)$, $r_1 > (m+\nu)/(1+\nu)$, *it holds that*

$$\max_{0\le t\le 1} \varphi'(t)^\nu |v(t) - \widetilde{v}_n(t)| \le ch^m \|f\|_{C^{m,\theta_0,\theta_1}(0,1)}. \tag{4.23}$$

Proof. Accept the assumptions of (ii). Due to (3.9) and the conditions on r_0, r_1, it holds that $v^{(j)}(0) = v^{(j)}(1) = 0$, $j = 1, \dots, m$. Extending $v(t) = v(0)$ for $t < 0$, $v(t) = v(1)$ for $t > 1$, we have $v \in C^m(\mathbb{R})$. The equality $v - \widetilde{v}_n = v - Q'_{h,m}v + Q'_{h,m}(v - v_n)$ together with (2.16), (3.9), and (4.4) implies

$$\|v - \widetilde{v}_n\|_\infty \le \|v - Q'_{h,m}v\|_\infty + q'_m \|v - v_n\|_\infty$$

$$\le ch^m \|v^{(m)}\|_\infty + ch^m \|f\|_{C^m_\star(0,1)} \le ch^m \|u\|_{C^{m,\theta_0,\theta_1}(0,1)} + ch^m \|f\|_{C^m_\star(0,1)},$$

where u is the solution of (1.1), $\|u\|_{C^{m,\theta_0,\theta_1}(0,1)} \le c\|f\|_{C^{m,\theta_0,\theta_1}(0,1)}$ by Theorem 1.3. This completes the proof of (4.22). The proof of (4.23) is similar. ∎

4.4. Modification: The product interpolation method. The considerations of sections 4.1–4.3 can be easily modified for the case of the product interpolation method defined by

$$v_n(t) = \int_0^1 [|t-s|^{-\nu} Q_{h,m}(\mathcal{A}(t,s)v_n(s)) + Q_{h,m}(\mathcal{B}(t,s)v_n(s))]ds + g(t) \tag{4.24}$$

(the spline interpolation projector $Q_{h,m}$ is used instead of the quasi-interpolation operator $Q'_{h,m}$; cf. (4.2); $\mathcal{A}(t,\cdot)v$ and $\mathcal{B}(t,\cdot)v$ are still extended from $[0,1]$ to $\mathbb{R}$ with the zero value). For $0 \le s \le 1$ and a function w defined on $\mathbb{R}$ we have (see (2.5), (2.7))

$$(Q_{h,m}w)(s) = \sum_{j=-m+1}^{n-1} \sum_{k\in\mathbb{Z}} \alpha_{j-k,m} w\left(\left(k + \frac{m}{2}\right)h\right) B_m(ns - j).$$

Since in the functions $w(s) = \mathcal{A}(t,s)v(s)$ and $w(s) = \mathcal{B}(t,s)v(s)$ we have $w(s) = 0$ for $s \le 0$, and for $s \ge 1$, the infinite sum over k reduces to the sum over $k = -m_0, \dots, n-1$, and the matrix form of method (4.24) takes the form (4.20) with (cf. (4.21))

$$\tau_{i,k} = \sum_{j=-m+1}^{n-1} \alpha_{j-k,m}(\beta_{i,j}a_{i,k} + \beta^0_j b_{i,k})$$

$$= a_{i,k} \sum_{j=-m+1}^{n-1} \alpha_{j-k,m}\beta_{i,j} + b_{i,k} \sum_{j=-m+1}^{n-1} \alpha_{j-k,m}\beta^0_j, \quad i,k = -m_0, \dots, n-m_1.$$

Now the computation of the elements of the matrix costs $O(n^3)$ flops, but using the convolution structure of the sums in the last representation form of $\tau_{i,k}$, the cost can be reduced to $O(n^2 \log n)$ flops with the help of FFT. Nevertheless, this is more complicated and slightly more expensive than in the case of the product quasi-interpolation method.

Theorem 4.1 remains valid also for method (4.24); in the proof we simply exploit Lemma 2.1 instead of Lemma 2.3.

5. Some computational details.

5.1. A numerically stable evaluation of $\Phi(t,s)$. The computation of the divided difference $\Phi(t,s) = (\varphi(t)-\varphi(s))/(t-s)$ (see (3.5) and (3.2)) for small $|t-s| \neq 0$ may cause a loss of accuracy. For $r_0, r_1 \in \mathbb{N}$, the division by $t-s$ can be performed analytically. For $0 \le s < t \le 1$ we have

$$\Phi(t,s) = \frac{1}{t-s}\int_s^t \varphi'(\sigma)d\sigma = \frac{1}{c_\star(t-s)}\int_s^t \sigma^{r_0-1}(1-\sigma)^{r_1-1}d\sigma$$

$$= \frac{1}{c_\star}\int_0^1 [(t-s)\xi+s]^{r_0-1}[(1-t)+(t-s)(1-\xi)]^{r_1-1}d\xi, \tag{5.1}$$

where we undertook the change of variables $\sigma = (t-s)\xi + s$. The last integral can be computed in a fast and stable way by an exact Gauss rule since the integrand is a polynomial of degree r_0+r_1-2 in ξ. Alternatively, applying the Newton binomial formula, we obtain the expansion

$$\Phi(t,s) = (r_0+r_1-1)!\sum_{p=0}^{r_0-1}\sum_{q=0}^{r_1-1}\frac{s^{r_0-1-p}(1-t)^{r_1-1-q}(t-s)^{p+q}}{(r_0-1-p)!(r_1-1-q)!(p+q+1)!}$$

with nonnegative terms for $0 \le s \le t \le 1$. Nevertheless, the use of this stable formula is more expensive than the use of an exact Gauss rule in (5.1). For $0 \le t < s \le 1$, the symmetry $\Phi(t,s) = \Phi(s,t)$ can be used.

5.2. Computation of the quadrature coefficients. The integrals $\beta_j(t)$ in (4.17), in particular the quadrature coefficients $\beta_{i,j}$ and β_j^0 defined in (4.19), can be evaluated on the basis of the following two lemmas.

LEMMA 5.1. *For a locally integrable function $w \in L^1_{\mathrm{loc}}(\mathbb{R})$, it holds that*

$$\int_{\mathbb{R}} w(s)B_m(ns-j)ds = h(D_h^m w^{(-m)})(jh), \quad h = 1/n, \quad j \in \mathbb{Z}, \tag{5.2}$$

where $w^{(-m)}$ is an integral function of w of order m, i.e., in the sense of distributions, $(d/ds)^m w^{(-m)}(s) = w(s)$, and $D_h^m = (D_h)^m$ is defined by

$$(D_h u)(x) = h^{-1}(u(x+h)-u(x)), \quad (D_h^m u)(x) = h^{-m}\sum_{k=0}^{m}(-1)^{m-k}\binom{m}{k}u(x+kh).$$

Proof. Integrating by parts $m-1$ times and using (2.2)–(2.4) we find that

$$\int_{\mathbb{R}} w(s)B_m(ns-j)ds = (-1)^{m-1}n^{m-1}\int_{\mathbb{R}} w^{-(m-1)}(s)B_m^{(m-1)}(ns-j)ds$$

$$= (-1)^{m-1}n^{m-1}\sum_{l=0}^{m-1}(-1)^l\binom{m-1}{l}\int_{(j+l)h}^{(j+l+1)h} w^{-(m-1)}(s)ds$$

$$= (-1)^{m-1}h^{-m+1}\sum_{l=0}^{m-1}(-1)^l\binom{m-1}{l}h(D_h w^{(-m)})((j+l)h).$$

We get (5.2) since $(-1)^{m-1}h^{-m+1}\sum_{l=0}^{m-1}(-1)^l\binom{m-1}{l}u(x+lh) = (D_h^{m-1}u)(x)$. ∎

Of course, the right-hand side of (5.2) is independent of the choice of a particular integral function $w^{(-m)}$ since D_h^m nullifies the difference of any two integral functions—those differ by a polynomial of degree $\le m-1$.

LEMMA 5.2. *For $w \in L^1(0,1)$, let $w^{(-m)}(s)$ be its integral function of order m on $[0,1]$; put $w^{(k-m)}(s) = (d/ds)^k w^{(-m)}(s)$, $0 \le s \le 1$, $k = 0, \dots, m-1$. Then*

$$\int_0^1 w(s) B_m(ns-j)ds = h(D_h^m \overline{w}^{(-m)})(jh), \quad h = 1/n, \quad j \in \mathbb{Z}, \tag{5.3}$$

where

$$\overline{w}^{(-m)}(s) = \begin{cases} \sum_{k=0}^{m-1} \frac{w^{(k-m)}(0)}{k!} s^k \text{ for } s < 0, \\ w^{(-m)}(s) \text{ for } 0 \le s \le 1, \\ \sum_{k=0}^{m-1} \frac{w^{(k-m)}(1)}{k!} (s-1)^k \text{ for } s > 1. \end{cases}$$

Proof. This immediately follows from (5.2) representing

$$\int_0^1 w(s) B_m(ns-j)ds = \int_{\mathbb{R}} \overline{w}(s) B_m(ns-j)ds,$$

where $\overline{w}$ is the extension of w by the zero value outside $(0,1)$. The integral functions of $\overline{w}$ and w can be taken equal on $[0,1]$; for $s < 0$ the integral function of $\overline{w}$ must be a polynomial of degree $m-1$, and hence the Taylor polynomial of $w^{(-m)}$ with the expansion center 0; similarly for $s > 1$. ∎

To compute $\beta_j^0 = \int_0^1 B_m(ns-j)ds$, Lemma 5.2 can be applied with $\overline{w}^{(-m)}(s) = \frac{1}{m!} s_+^m$ for $-\infty < s \le 1$. According to (5.3),

$$\beta_j^0 = h \frac{1}{m!} \triangle^m \gamma_j^0, \quad j = -m+1, \dots, n-m+1, \quad \gamma_j^0 = \begin{cases} 0, & j < 0, \\ j^m, & 0 \le j \le n, \end{cases} \tag{5.4}$$

where $\triangle^m$ is the forward difference operator of order m defined for $(\gamma_j)_{j \in \mathbb{Z}}$ by

$$\Delta \gamma_j = \gamma_{j+1} - \gamma_j, \quad \triangle^m \gamma_j = \sum_{k=0}^{m} (-1)^{m-k} \binom{m}{k} \gamma_{j+k}, \quad j \in \mathbb{Z}.$$

Actually it is sufficient to compute $\beta_j^0 = h \frac{1}{m!} \triangle^m \gamma_j^0$ by (5.4) only for $j = -m+1, \dots, -1$, since $\beta_j^0 = h$ for $0 \le j \le n-m$ and by a symmetry argument $\beta_{n-m+k}^0 = \beta_{-k}^0$, $k = 1, 2, \dots$; see (2.2).

For $w_t(s) = |t-s|^{-\nu}$, $t \in (0,1)$, an integral function $w_t^{(-m)}(s)$ on $[0,1]$ is given by

$$\overline{w}^{(-m)}(s) = w_t^{(-m)}(s) = \frac{1}{(1-\nu)\dots(m-\nu)} \begin{cases} (-1)^m (t-s)^{m-\nu}, & 0 \le s \le t, \\ (s-t)^{m-\nu}, & t \le s \le 1. \end{cases}$$

Respectively,

$$\text{for } s \le 0, \quad \overline{w}^{(-m)}(s) = \sum_{k=0}^{m-1} \frac{1}{k!} \frac{(-1)^{m-k} t^{m-k-\nu}}{(1-\nu)\dots(m-k-\nu)} s^k,$$

$$\text{for } s \ge 1, \quad \overline{w}^{(-m)}(s) = \sum_{k=0}^{m-1} \frac{1}{k!} \frac{(1-t)^{m-k-\nu}}{(1-\nu)\dots(m-k-\nu)} (s-1)^k.$$

For $\beta_{i,j} = \int_0^1 |(i+\frac{m}{2})h - s|^{-\nu} B_m(ns-j)ds$, Lemma 5.2 yields the formula

$$\beta_{i,j} = h^{1-\nu} \triangle_j^m \gamma_{i,j}, \quad i = -m_0, \dots, n-m_1, \quad j = -m+1, \dots, n-1, \tag{5.5}$$

where $\triangle^m$ is still applied to $(\gamma_{i,j})$ with respect to j and

$$\gamma_{i,j} = \begin{cases} \sum_{k=0}^{m-1} \frac{(-1)^{m-k}}{k!(1-\nu)\dots(m-k-\nu)} (i+\frac{m}{2})^{m-k-\nu} j^k, & j < 0, \\ \frac{(-1)^m}{(1-\nu)\dots(m-\nu)} (i-j+\frac{m}{2})^{m-\nu}, & 0 \le j < i+\frac{m}{2}, \\ \frac{1}{(1-\nu)\dots(m-\nu)} (j-i-\frac{m}{2})^{m-\nu}, & i+\frac{m}{2} \le j \le n, \\ \sum_{k=0}^{m-1} \frac{1}{k!(1-\nu)\dots(m-k-\nu)} (n-i-\frac{m}{2})^{m-k-\nu} (j-n)^k, & j > n. \end{cases} \tag{5.6}$$

There are some symmetries which enable us to reduce the computation cost of (5.5)–(5.6): due to (2.2), for $\widetilde{\beta}_{i,j} := \int_{\mathbb{R}} |(i+\frac{m}{2})h - s|^{-\nu} B_m(ns-j)ds$ we have $\widetilde{\beta}_{i,j} = \widetilde{\beta}_{0,|i-j|}$, $i, j \in \mathbb{Z}$, and $\beta_{i,j} = \widetilde{\beta}_{i,j} = \widetilde{\beta}_{0,|i-j|}$ for $i = -m_0, \dots, n-m_1$, $j = 0, \dots, n-m$.

One must be careful using exact formulae like (5.5)–(5.6): the differences $\triangle^m \gamma_{i,j}$ may cause a loss of accuracy in a standard floating point arithmetic. For instance, for $j - i \ge m$ we have

$$\triangle^m \left(j - i - \frac{m}{2}\right)^{m-\nu} = \left(\frac{d}{dz}\right)^m z^{m-\nu}\Big|_{z=\xi} = (1-\nu)\dots(m-\nu)\xi^{-\nu},$$

where ξ is a point from the interval $(j-i-\frac{m}{2}, j-i+\frac{m}{2})$; thus $\triangle^m (j-i-\frac{m}{2})^{m-\nu}$ is approximately $(j-i)^m/[(1-\nu)\dots(m-\nu)]$ times smaller than $(j-i-\frac{m}{2})^{m-\nu}$ itself. To avoid the loss of accuracy, $\gamma_{i,j}$ and their differences should be presented with sufficiently long mantissas. A simple rule is as follows: in cases of single-precision computations, the 7 decimal digits of $\triangle^m \gamma_{i,j}$ are correct if $\gamma_{i,j}$ and their differences are computed with double precision and $n^m \le 10^7 \cdot [(1-\nu)\dots(m-\nu)]$; in cases of double-precision computations, the 15 decimal digits of $\triangle^m \gamma_{i,j}$ are correct if $\gamma_{i,j}$ and their differences are computed with quadruple precision and

$$n^m \le 10^{15} \cdot [(1-\nu)\dots(m-\nu)]. \tag{5.7}$$

Actually, condition (5.7) can be somewhat relaxed, since usually we do not need maximally high precision of $\beta_{i,j}$.

Forgetting exact formulae, $\beta_{i,j}$ can be computed in the framework of a standard arithmetic approximately using suitable quadratures, with a given accuracy; this is more laborious than the use of (5.5)–(5.6). Exact formulae for the quadrature coefficient seem to be a delicate problem also in other methods of Nyström type for weakly singular integral equations. For instance, in [9] an unstable recurrence formula is proposed and successfully used for the computations of the quadrature coefficients in a Gauss-type quadrature.

5.3. Solving the system. Due to (4.8) and (4.13), the condition number of the matrix $(\delta_{i,k} - \tau_{i,k})_{i,k=-m_0}^{n-m_1}$ of system (4.20) is bounded uniformly in n; therefore standard methods are expected to work well when solving (4.20). Gauss elimination with its $O(n^3)$ operations can be recommended for moderate n. For large n, iteration methods with stopping when the discrepancy achieves a value δn^{-r}, $\delta > 0$, $r \ge m$, are preferable. The two-grid iteration method with a fixed coarse level [2] is of complexity $O(n^2 \log n)$ flops; with a suitable enlarging strategy for the dimension of the coarse level, the complexity can be reduced to $O(n^2)$ flops (cf. [20]); here n^2 is the cost of one

matrix to vector multiplication. The complexity of GMRES is $o(n^2 \log n)$ flops due to (4.6), (4.7) (see [19]). In our numerical computations treated in section 6, rarely more than 20 GMRES iterations were needed to achieve the discrepancy level 10^{-14}–10^{-16}.

5.4. Approximate solution of (1.1). The solutions of (1.1) and (3.4) are in the relation $v(t) = u(\varphi(t))$, or $u(x) = v(\varphi^{-1}(x))$, where $\varphi^{-1} : [0,1] \to [0,1]$ is the inverse function of φ defined in (3.2)/(3.3). Having solved the system (4.20), we find that $v_{i,n} = v_n((i + \frac{m}{2})h)$ are approximations to $u(x_{i,n})$ at $x_{i,n} = \varphi((i + \frac{m}{2})h)$, $0 < (i + \frac{m}{2})h < 1$, and a local polynomial interpolation of degree $m-1$ can be used to obtain an approximation for $u(x)$ between the knots. A more precise way is to determine $t = \varphi^{-1}(x)$ and put $\tilde{u}_n(x) = \widetilde{v}_n(\varphi^{-1}(x))$; see section 4.3. Under the conditions of Theorem 4.2(ii), we have the uniform error bound

$$\max_{0\le x\le 1} |u(x) - \tilde{u}_n(x)| = \max_{0\le t\le 1} |v(t) - \widetilde{v}_n(t)| \le ch^m \|f\|_{C^{m,\theta_0,\theta_1}(0,1)};$$

under the conditions of Theorem 4.2(iii) we have the weighted error bound

$$\begin{aligned}&\max_{0\le x\le 1} x^{\nu(r_0-1)/r_0}(1-x)^{\nu(r_1-1)/r_1}|u(x) - \tilde{u}_n(x)|\\ &\le c' \max_{0\le t\le 1} \varphi'(t)^{\nu}|v(t) - \widetilde{v}_n(t)| \le ch^m \|f\|_{C^{m,\theta_0,\theta_1}(0,1)}.\end{aligned}$$

In general φ is too complicated to present a closed formula for $t = \varphi^{-1}(x)$. For given $x \in (0,1)$, $t = \varphi^{-1}(x)$ can be approximated by the Newton method,

$$t_k = t_{k-1} - (\varphi(t_{k-1}) - x)/\varphi'(t_{k-1}), \quad k = 1, 2, \dots;$$

note that according to (3.2) $\varphi'(t) = (1/c_\star)t^{r_0-1}(1-t)^{r_1-1}$. For any $x \in (0,1)$, starting from the initial guess $t_0 = (r_0 - 1)/(r_0 + r_1 - 2)$, which is the only flex point of φ for $r_0, r_1 > 1$, the iterations converge monotonically to $t = \varphi^{-1}(x)$. For x close to 0 or 1, the initial guess $t_0 = (c_\star r_0 x)^{1/r_0}$, respectively, $t_0 = 1 - (c_\star r_1(1-x))^{1/r_1}$, may be preferable.

6. Numerical example. For the testing of the algorithms we took a simple equation (1.1) with $\nu = 1/2$:

$$u(x) = \int_0^1 |x-y|^{-1/2} u(y)dy + f(x), \quad 0 \le x \le 1.$$

We put $u(x) = 1 + x^{1/2} + (1-x)^{1/2}$ to be the exact solution; it corresponds to $f(x) = 1 - \frac{\pi}{2} - 2x^{1/2} - 2(1-x)^{1/2} - x\log(1 + (1-x)^{1/2}) - (1-x)\log(1 + x^{1/2}) + \frac{1}{2}x\log x + \frac{1}{2}(1-x)\log(1-x)$. We composed system (4.20), (4.21) for $m = 3, 4, \dots, 10$, $n = 2^k$ with $k = 4, 5, \dots, 12$, and the smoothing parameters $r_0 = r_1 =: r \in \mathbb{N}$ with $2 \le r \le 2m+1$; we solved the system by GMRES. Double precision was used everywhere except in the computation of $\beta_{i,j}$ by formulae (5.5)–(5.6), where quadruple precision was involved (see section 5.2). The errors

$$\varepsilon_{m,n,r} := \max_{-m_0\le i\le n-m_1} \left| v\left(\left(i + \frac{m}{2}\right)h\right) - v_{i,n}\right|,$$

$$\overline{\varepsilon}_{m,n,r} := \max_{-m_0\le i\le n-m_1} \left[\varphi'\left(\left(i + \frac{m}{2}\right)h\right)\right]^{1/2} \left| v\left(\left(i + \frac{m}{2}\right)h\right) - v_{i,n}\right|$$

are presented in Tables 6.1 and 6.2 for $m = 4$, different n and r. The error $\varepsilon_{m,n,r}$ for $m = 6$, different r, is presented graphically on Figure 6.1 as a function of $\log_2 n$. In

Figure 6.2, the error $\varepsilon_{m,n,2m}$ is presented graphically for different m. The numerical results are in good accordance with Theorem 4.1, which in the present case ($\nu = 1/2$, $\lambda_0 = \lambda_1 = 0$, $b(x,y) \equiv 0$) claims that (i) $\varepsilon_{m,n,r} \to 0$ as $n \to \infty$ for $r > 1$; (ii) $\varepsilon_{m,n,r} = O(n^{-m})$ for $r > 2m$; (iii) $\bar{\varepsilon}_{m,n,r} = O(n^{-m})$ for $r > m + \frac{1}{2}$. We can see from Tables 6.1 and 6.2 that in reality, the best results for $m = 4$ in the uniform norm are obtained for $r = 2m = 8$, whereas in the weighted norm, the best results are obtained for $r = m + 1 = 5$; for the uniform norm, the empirical convergence order is $\varepsilon_{4,n,r} = O(n^{-4})$ for $r \geq 8$ and lower for $r \leq 7$; for the weighted norm, the empirical convergence order is $\bar{\varepsilon}_{4,n,r} = O(n^{-4})$ for $r \geq 5$ and lower for $m \leq 4$; on the other hand, the logarithmic factor of estimate (4.14) for $r = 2m = 8$ cannot be observed in the present example.

For $r > 2m$ recommended by Theorem 4.1(ii), and also for $r = 2m$, the computations appeared to be rather stable in a wide scale of n; see Figure 6.2. A side remark is that the numerical results presented on Figure 6.2 encourage the use of high order splines in computations: in the present example, already beginning from $n = 32$, the use of tenth order splines gave more precise numerical results than the use of splines of lower order.

For $m = 4$ and fixed $r \geq 2$, we can see from Table 6.1 a monotone decrease of errors $\varepsilon_{4,n,r}$ in n. For large m but r significantly smaller than $2m$, the error $\varepsilon_{m,n,r}$ starts to grow beginning from some (relatively large) $n = n_{m,r}$; see Figure 6.1 ($m = 6$). We run into difficulties trying to explain this kind of instability for small r ($r = 2$ on Figure 6.1 for $m = 6$). Condition (5.7) guaranteeing a safe use of the quadruple precision in formulae (5.5)–(5.6) is violated for $m = 6$, $n \geq 739$. Nevertheless, when the precision of the computations in (5.5)–(5.6) was increased, no essential change in the behavior of $\varepsilon_{6,n,r}$ was observed compared with Figure 6.1. Hence the instability for large m, n and small r cannot be explained by the violation of (5.7) only.

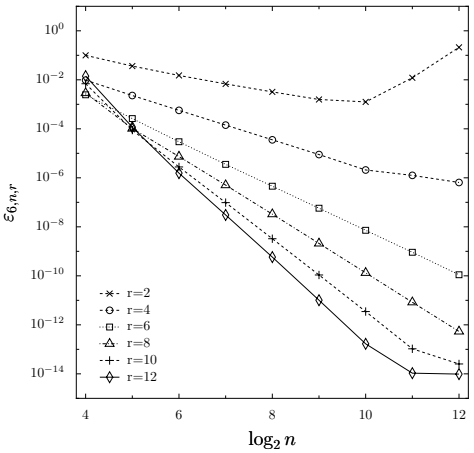

FIG. 6.1. *Errors* $\varepsilon_{6,n,r}$.

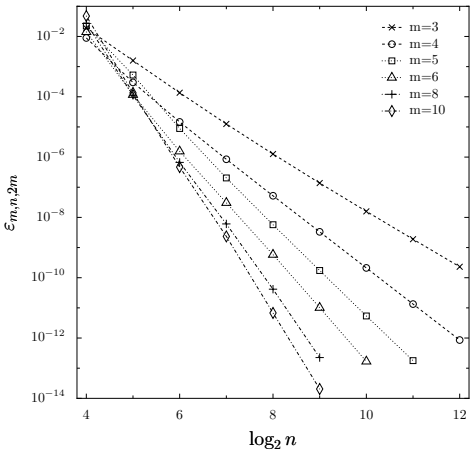

FIG. 6.2. *Errors* $\varepsilon_{m,n,2m}$.

All programs for given computations were written using the SciPy package (Scientific Tools for Python, http://www.scipy.org). For carrying out higher precision floating point arithmetic, a Python interface to a Fortran95 subroutine was used, which uses the `quadruple precision` datatype for internal calculations. As an alternative to Fortran95, we used also Python Decimal datatype for higher precision calculations. With the Decimal type there is a performance penalty compared to Fortran95 calculations. But the flexibility of specifying an arbitrary length of the mantissa in floating point calculations proved to be very helpful in finding out the sensitivity of our algorithms to precision changes.

The source code and numerical results in more detail of provided tests can be found at http://www.ut.ee/∼eero/WSIE/Fredholm/.

Further prospects. We solved the equation $\lambda u(x) = \int_0^1 |x-y|^{-\nu} u(y)du + f(x)$ numerically also for some other values of $\nu \in (0,1)$. For small and moderate ν, the method behaves as expected by Theorem 4.1. For ν close to 1, the uniform accuracy becomes lower due to great values of the smoothing parameter $r \sim m/(1-\nu)$; see Theorem 4.1(ii).

Returning to the general problem (1.1), it is possible to modify our approach towards smaller values of the smoothing parameters r_0 and r_1. In the arguments of section 4 we exploited the fact that the smoothing change of variables suppresses the coefficient function by $|t-s|^{-\nu}$ but since $v(0) \neq 0$, $v(1) \neq 0$ in general, we were not able to use the fact that also the derivatives of the solution v of (3.4) are suppressed if $f \in C^{m,\theta_0,\theta_1}(0,1)$ with $\theta_0 < 1$, $\theta_1 < 1$. The situation changes if $u(0) = u(1) = 0$ for the solution of (1.1), then also $v(0) = v(1) = 0$. The idea of the modification is to rewrite (1.1) with respect to unknowns $u(0)$, $u(1)$, and $U(x) = u(x) - u(0) - (u(1) - u(0))\psi(x)$, where ψ is a function of type (3.2), achieving $V^{(j)}(0) = V^{(j)}(1) = 0$, $j = 0, \ldots, m$, for $V(t) = U(\varphi(t))$. In the algorithm and its justification, some new problems arrive. We cannot go into details here because of the length of the paper but we will return to the question elsewhere.

Acknowledgment. The authors are grateful to the referees for the useful discussion and valuable comments that enabled them to improve some details of the paper.

NUMERICAL SOLUTIONS OF NEUTRAL STOCHASTIC FUNCTIONAL DIFFERENTIAL EQUATIONS*

FUKE WU† AND XUERONG MAO‡

Abstract. This paper examines the numerical solutions of neutral stochastic functional differential equations (NSFDEs) $d[x(t) - u(x_t)] = f(x_t)dt + g(x_t)dw(t)$, $t \geq 0$. The key contribution is to establish the strong mean square convergence theory of the Euler–Maruyama approximate solution under the local Lipschitz condition, the linear growth condition, and contractive mapping. These conditions are generally imposed to guarantee the existence and uniqueness of the true solution, so the numerical results given here are obtained under quite general conditions. Although the way of analysis borrows from [X. Mao, *LMS J. Comput. Math.*, 6 (2003), pp. 141–161], to cope with $u(x_t)$, several new techniques have been developed.

Key words. neutral stochastic functional differential equations, strong convergence, Euler–Maruyama method, local Lipschitz condition

1. Introduction.

The theory of stochastic functional differential equations (SFDEs) has received a great deal of attention in recent decades. More recently researchers have given special interest to the study of equations in which the variable delay argument occurs in the derivative of the state variable, or so-called neutral stochastic functional differential equations (NSFDEs). Many well-known theorems in SFDEs are successfully extended to NSFDEs; see, for example, [10, 13, 14, 15, 16, 18].

As is the case with deterministic neutral functional differential equations and SFDEs, most NSFDEs cannot be solved explicitly, so numerical methods become one of the most powerful techniques. A number of papers study the numerical analysis of deterministic neutral functional differential equations; see, for example, [1, 3, 5, 7, 11] and the references therein. Numerical solutions of SFDEs have also been studied extensively by many authors. Here we mention some of them, for example, [2, 4, 6, 9, 12, 16, 17].

However, little is as yet known about numerical solutions for NSFDEs although it may be seen as a combination of deterministic neutral functional differential equations and SFDEs. This paper will fill that gap.

We study the Euler–Maruyama numerical solutions of the NSFDE

$$d[x(t) - u(x_t)] = f(x_t)dt + g(x_t)dw(t), \quad t \geq 0, \tag{1.1}$$

with initial data $x_0 = \xi \in L^p_{\mathcal{F}_0}([-\tau, 0], \mathbb{R}^n)$. Here,

$$f : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^n, \quad g : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^{n\times m}, \quad u : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^n,$$

$x(t) \in \mathbb{R}^n$ for each t,

$$x_t = \{x(t+\theta) : -\tau \le \theta \le 0\} \in C([-\tau, 0]; \mathbb{R}^n),$$

and $w(t)$ is an m-dimensional Brownian motion. The initial data ξ is an $\mathcal{F}_0$-measurable $C([-\tau, 0]; \mathbb{R}^n)$-valued random variable such that $\mathbb{E}\|\xi\|^p < \infty$ for some $p \ge 2$. Our main aim is to extend the method developed by [16] and [17] to NSFDEs and study strong convergence for the Euler–Maruyama numerical approximations in the case where f and g satisfy both the local Lipschitz condition and the linear growth condition and where u is a contractive mapping. These three conditions are standard for the existence and uniqueness of the true solutions.

Although the method of analysis borrows from [16], the existence of the neutral term $u(x_t)$ essentially changes the problem, and several new techniques have been developed to cope with the difficulties which have risen from the neutral term.

In section 2, we introduce some necessary assumptions and auxiliary results, define the Euler–Maruyama method for NSFDEs, and state our main result that the approximate solutions strongly converge to the exact solution. The proof of the result is rather technical so we present several lemmas in section 3 and then complete the proof in section 4. In the final section, under the global Lipschitz condition, we reveal the order of convergence of approximate solutions.

2. The Euler–Maruyama method for NSFDEs. Throughout this paper, unless otherwise specified, we use the following notation. Let $|\cdot|$ be the Euclidean norm in $\mathbb{R}^n$. If A is a vector or matrix, its transpose is denoted by A^T. If A is a matrix, its trace norm is denoted by $|A| = \sqrt{\text{trace}(A^T A)}$. Let $\mathbb{R}_+ = [0, \infty)$, and let $\tau > 0$. Denote by $C([-\tau, 0], \mathbb{R}^n)$ the family of continuous functions from $[-\tau, 0]$ to $\mathbb{R}^n$ with the norm $\|\varphi\| = \sup_{-\tau \le \theta \le 0} |\varphi(\theta)|$.

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space with a filtration $\{\mathcal{F}_t\}_{t \ge 0}$ satisfying the usual conditions; that is, it is right continuous and increasing while $\mathcal{F}_0$ contains all P-null sets. Let $w(t) = (w_1(t), \dots, w_m(t))^T$ be an m-dimensional Brownian motion defined on the probability space. Let $p > 0$ and let $L^p_{\mathcal{F}_0}([-\tau, 0]; \mathbb{R}^n)$ be the family of $\mathcal{F}_0$-measurable $C([-\tau, 0]; \mathbb{R}^n)$-valued random variables ξ such that $\mathbb{E}\|\xi\|^p < \infty$. If $x(t)$ is an $\mathbb{R}^n$-valued stochastic process on $t \in [-\tau, \infty)$, we let $x_t = \{x(t+\theta) : -\tau \le \theta \le 0\}$ for $t \ge 0$.

Let $f : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^n$, $g : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^{n \times m}$, and $u : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^n$. In this paper we impose the following hypotheses.

Assumption 2.1 (local Lipschitz condition). For each integer $j \ge 1$, there exists a positive constant C_j such that

$$|f(\varphi) - f(\psi)|^2 \vee |g(\varphi) - g(\psi)|^2 \le C_j \|\varphi - \psi\|^2 \tag{2.1}$$

for $\varphi, \psi \in C([-\tau, 0]; \mathbb{R}^n)$ with $\|\varphi\| \vee \|\psi\| \le j$.

Assumption 2.2 (linear growth condition). There is a constant $K > 0$ such that

$$|f(\varphi)|^2 \vee |g(\varphi)|^2 \le K(1 + \|\varphi\|^2) \tag{2.2}$$

for $\varphi \in C([-\tau, 0]; \mathbb{R}^n)$.

Assumption 2.3 (contractive mapping). There exists a constant $\kappa \in (0, 1)$ such that for all $\varphi, \psi \in C([-\tau, 0]; \mathbb{R}^n)$,

$$|u(\varphi) - u(\psi)| \le \kappa \|\varphi - \psi\| \tag{2.3}$$

for $\varphi, \psi \in C([-\tau, 0]; \mathbb{R}^n)$ and $u(0) = 0$.

Consider the n-dimensional NSFDE

$$d[x(t) - u(x_t)] = f(x_t)dt + g(x_t)dw(t), \quad t \geq 0, \tag{2.4}$$

with initial data $x_0 = \xi \in L^p_{\mathcal{F}_0}([-\tau, 0]; \mathbb{R}^n)$.

We know that Assumptions 2.1, 2.2, and 2.3 are standard conditions for the existence and uniqueness of the solution of (2.4) except that we impose $u(0) = 0$. Actually, $u(0) = 0$ is also standard for the boundedness of the solution's moments (for example, see [14]).

We impose the following condition on the initial data.

Assumption 2.4. $\xi \in L^p_{\mathcal{F}_0}([-\tau, 0]; \mathbb{R}^n)$ for some $p \geq 2$, and there exists a nondecreasing function $\alpha(\cdot)$ such that

$$\mathbb{E}\Big(\sup_{-\tau \leq s \leq t \leq 0} |\xi(t) - \xi(s)|^2 \Big) \leq \alpha(t - s) \tag{2.5}$$

with the property $\alpha(s) \to 0$ as $s \to 0$.

From Mao [14, p. 211], we may therefore state the following theorem.

THEOREM 2.1. *Let $p \geq 2$. If Assumptions* 2.2–2.4 *are satisfied, then*

$$\mathbb{E}\Big(\sup_{-\tau \leq t \leq T} |x(t)|^p \Big) \leq (1 + \bar{C}\mathbb{E}\|\xi\|^p) e^{\widetilde{C}T} \tag{2.6}$$

for any $T > 0$, where

$$\widetilde{C} = \frac{2p(1+\kappa)^{p-2}}{(1-p)^p}[\sqrt{2K}(1+\kappa) + K(33p-1)] \quad \textit{and} \quad \bar{C} = \frac{1}{1-\kappa} + \frac{2(1+\kappa)^p}{(1-\kappa)^p}.$$

From now on, we will consider (2.4) on the finite time interval $[0, T]$, since our aim is to discuss the finite time convergence of the Euler–Maruyama method. Without loss of generality, we may assume that T/τ is a rational number; otherwise we may replace T by a larger number. Let the step size $\triangle \in (0, 1)$ be a fraction of τ and T, namely, $\triangle = \tau/N = T/M$ for some integers $N > \tau$ and $M > T$. The explicit discrete Euler–Maruyama approximate solution $\bar{y}(k\triangle)$, $k \geq -N$, is defined as follows:

$$\begin{cases} \bar{y}(k\triangle) = \xi(k\triangle), & -N \leq k \leq 0, \\ \bar{y}((k+1)\triangle) = \bar{y}(k\triangle) + u(\bar{y}_{k\triangle}) - u(\bar{y}_{(k-1)\triangle}) + f(\bar{y}_{k\triangle})\triangle + g(\bar{y}_{k\triangle})\triangle w_k, & \\ \qquad\qquad 0 \leq k \leq M-1, & \end{cases} \tag{2.7}$$

where $\triangle w_k = w((k+1)\triangle) - w(k\triangle)$ and $\bar{y}_{k\triangle} = \{\bar{y}_{k\triangle}(\theta) : -\tau \leq \theta \leq 0\}$ is a $C([-\tau, 0]; \mathbb{R}^n)$-valued random variable defined by

$$\begin{aligned} \bar{y}_{k\triangle}(\theta) &= \bar{y}((k+i)\triangle) + \frac{\theta - i\triangle}{\triangle}[\bar{y}((k+i+1)\triangle) - \bar{y}((k+i)\triangle)] \\ &\qquad \text{for } i\triangle \leq \theta \leq (i+1)\triangle,\ i = -N, -(N-1), \ldots, -1, \end{aligned} \tag{2.8}$$

where in order for $\bar{y}_{-\triangle}$ to be well defined, we set $\bar{y}(-(N+1)\triangle) = \xi(-N\triangle)$.

It is easy to see from (2.8) that $\bar{y}_{k\triangle}(\cdot)$ is the linear interpolation of $\bar{y}((k-N)\triangle), \ldots, \bar{y}(k\triangle)$ and (2.8) can be rewritten as

$$\bar{y}_{k\triangle}(\theta) = \frac{(i+1)\triangle - \theta}{\triangle}\bar{y}((k+i)\triangle) + \frac{\theta - i\triangle}{\triangle}\bar{y}((k+i+1)\triangle), \tag{2.9}$$

which yields

$$|\bar{y}_{k\triangle}(\theta)| \le \frac{(i+1)\triangle-\theta}{\triangle}|\bar{y}((k+i)\triangle)| + \frac{\theta-i\triangle}{\triangle}|\bar{y}((k+i+1)\triangle)|$$
$$\le |\bar{y}((k+i)\triangle)| \vee |\bar{y}((k+i+1)\triangle)|$$

because $(i+1)\triangle-\theta$ and $\theta-i\triangle \in [0,\triangle]$. We therefore have

$$\|\bar{y}_{k\triangle}\| = \max_{-N\le i\le 0}|\bar{y}((k+i)\triangle)| \quad \forall k=-1,0,1,2,\ldots,M-1. \tag{2.10}$$

It is obvious that $\|\bar{y}_{-\triangle}\| \le \|\bar{y}_0\|$.

In our analysis it will be more convenient to use continuous-time approximations. We hence introduce the $C([-\tau,0];\mathbb{R}^n)$-valued step process

$$\bar{y}_t = \sum_{k=0}^{M-2}\bar{y}_{k\triangle}1_{[k\triangle,(k+1)\triangle)}(t) + \bar{y}_{(M-1)\triangle}1_{[(M-1)\triangle,M\triangle]}(t), \tag{2.11}$$

and we define the continuous Euler–Maruyama approximate solution as follows: let $y(t)=\xi(t)$ for $-\tau\le t\le 0$, while for $t\in[k\triangle,(k+1)\triangle]$, $k=0,1,\ldots,M-1$,

$$y(t) = \xi(0) + u\Big(\bar{y}_{(k-1)\triangle} + \frac{t-k\triangle}{\triangle}(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})\Big) - u(\bar{y}_{-\triangle})$$
$$+\int_0^t f(\bar{y}_s)ds + \int_0^t g(\bar{y}_s)dw(s). \tag{2.12}$$

Clearly, (2.12) can also be written as

$$y(t) = \bar{y}(k\triangle) + u\Big(\bar{y}_{(k-1)\triangle} + \frac{t-k\triangle}{\triangle}(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})\Big) - u(\bar{y}_{(k-1)\triangle})$$
$$+\int_{k\triangle}^t f(\bar{y}_s)ds + \int_{k\triangle}^t g(\bar{y}_s)dw(s). \tag{2.13}$$

In particular, this shows that $y(k\triangle)=\bar{y}(k\triangle)$, that is, the discrete and continuous Euler–Maruyama approximate solutions coincide at the gridpoints. We know that $y(t)$ is not computable because it requires knowledge of the entire Brownian path, not just its $\triangle$-increments. However, $y(k\triangle)=\bar{y}(k\triangle)$, so the error bound for $y(t)$ will automatically imply the error bound for $\bar{y}(k\triangle)$. It is then obvious that

$$\|\bar{y}_{k\triangle}\| \le \|y_{k\triangle}\| \quad \forall k=0,1,2,\ldots,M-1. \tag{2.14}$$

Moreover, for any $t\in[0,T]$,

$$\begin{aligned}\sup_{0\le t\le T}\|\bar{y}_t\| &= \sup_{0\le k\le M-1}\|\bar{y}_{k\triangle}\|\\ &\le \sup_{0\le k\le M-1}\|y_{k\triangle}\|\\ &= \sup_{0\le k\le M-1}\sup_{-\tau\le\theta\le 0}|y(k\triangle+\theta)|\\ &\le \sup_{0\le t\le T}\sup_{-\tau\le\theta\le 0}|y(t+\theta)|\\ &\le \sup_{-\tau\le s\le T}|y(s)|,\end{aligned} \tag{2.15}$$

and letting $[t/\triangle]$ be the integer part of $t/\triangle$, then

$$\|\bar{y}_t\| = \|\bar{y}_{[t/\triangle]\triangle}\| \le \|y_{[t/\triangle]\triangle}\| \le \sup_{-\tau\le s\le t}|y(s)|. \tag{2.16}$$

These properties will be used frequently in what follows, without further explanation.

The primary aim of this paper is to establish the following strong mean square convergence theorem for the Euler–Maruyama approximations.

THEOREM 2.2. *Under Assumptions* 2.1–2.4,

$$\lim_{\triangle\to 0}\mathbb{E}\Big(\sup_{0\le t\le T}|x(t)-y(t)|^2\Big) = 0. \tag{2.17}$$

The proof of this theorem is very technical, so we present some lemmas in the next section, and then complete the proof in section 4.

3. Lemmas.

LEMMA 3.1. *Under Assumptions* 2.2–2.4, *for any* $p \ge 2$, *there exists a constant* $H(p)$ *such that*

$$\mathbb{E}\Big(\sup_{-\tau\le t\le T}|y(t)|^p\Big) \le H(p), \tag{3.1}$$

where $H(p)$ *is independent of* $\triangle$.

Proof. For $t \in [k\triangle,(k+1)\triangle]$, $k = 0,1,2,\dots,M-1$, set $\tilde{y}(t) := y(t) - u(\bar{y}_{(k-1)\triangle} + (t-k\triangle)(\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle})/\triangle)$ and

$$h(t) := \mathbb{E}\left(\sup_{-\tau\le s\le t}|y(s)|^p\right);$$

$$\tilde{h}(t) := \mathbb{E}\left(\sup_{0\le s\le t}|\tilde{y}(s)|^p\right).$$

Recall the inequality that for $p \ge 1$ and any $\varepsilon > 0$,

$$|x+y|^p \le (1+\varepsilon)^{p-1}(|x|^p + \varepsilon^{1-p}|y|^p).$$

This, together with Assumption 2.3, yields

$$\begin{aligned}|y(t)|^p &\le (1+\varepsilon)^{p-1}(|\tilde{y}(t)|^p + \varepsilon^{1-p}|u(\bar{y}_{(k-1)\triangle} + (t-k\triangle)(\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle})/\triangle)|^p)\\ &\le (1+\varepsilon)^{p-1}\Big(|\tilde{y}(t)|^p + \varepsilon^{1-p}\kappa^p\Big\|\bar{y}_{(k-1)\triangle} + \frac{t-k\triangle}{\triangle}(\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle})\Big\|^p\Big).\end{aligned}$$

By (2.9) and $\|\bar{y}_{-\triangle}\| \le \|\bar{y}_0\|$, noting $k = 0,1,2,\dots,M-1$,

$$\begin{aligned}&\Big\|\bar{y}_{(k-1)\triangle} + \frac{t-k\triangle}{\triangle}(\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle})\Big\|^p\\ &\le \Big|\frac{(k+1)\triangle - t}{\triangle}\|\bar{y}_{(k-1)\triangle}\| + \frac{t-k\triangle}{\triangle}\|\bar{y}_{k\triangle}\|\Big|^p\\ &\le \Big[\frac{(k+1)\triangle - t}{\triangle}\Big(\sup_{-\tau\le s\le t}|y(s)|\Big) + \frac{t-k\triangle}{\triangle}\Big(\sup_{-\tau\le s\le t}|y(s)|\Big)\Big]^p\\ &\le \sup_{-\tau\le s\le t}|y(s)|^p.\end{aligned}$$

Consequently,

$$|y(t)|^p \le (1+\varepsilon)^{p-1}\Big[|\tilde{y}(t)|^p + \varepsilon^{1-p}\kappa^p\Big(\sup_{-\tau\le s\le t}|y(s)|^p\Big)\Big].$$

Choose $\varepsilon = \kappa/(1-\kappa)$. Then

$$|y(t)|^p \le (1-\kappa)^{1-p}|\tilde{y}(t)|^p + \kappa\Big(\sup_{-\tau\le s\le t}|y(s)|^p\Big).$$

Hence,

$$\begin{aligned} h(t) &\le \mathbb{E}\|\xi\|^p + \mathbb{E}\Big(\sup_{0\le s\le t}|y(s)|^p\Big) \\ &\le \mathbb{E}\|\xi\|^p + \kappa h(t) + (1-\kappa)^{1-p}\tilde{h}(t), \end{aligned}$$

which implies

$$h(t) \le \frac{\mathbb{E}\|\xi\|^p}{1-\kappa} + \frac{\tilde{h}(t)}{(1-\kappa)^p}. \tag{3.2}$$

Since

$$\tilde{y}(t) = \tilde{y}(0) + \int_0^t f(\bar{y}_s)ds + \int_0^t g(\bar{y}_s)dw(s)$$

with $\tilde{y}(0) = \bar{y}(0) - u(\bar{y}_{-\triangle})$, by the Hölder inequality, we have

$$|\tilde{y}(t)|^p \le 3^{p-1}\left[|\tilde{y}(0)|^p + t^{p-1}\int_0^t |f(\bar{y}_s)|^p ds + \left|\int_0^t g(\bar{y}_s)dw(s)\right|^p\right].$$

Hence, for any $t_1 \in [0,T]$

$$\begin{aligned} \tilde{h}(t_1) \le 3^{p-1}\Bigg[&\mathbb{E}|\tilde{y}(0)|^p + T^{p-1}\mathbb{E}\int_0^{t_1}|f(\bar{y}_s)|^p ds \\ &+ \mathbb{E}\left(\sup_{0\le t\le t_1}\left|\int_0^t g(\bar{y}_s)dw(s)\right|^p\right)\Bigg]. \end{aligned} \tag{3.3}$$

By Assumption 2.3 and the fact $\|\bar{y}_{-\triangle}\| \le \|\bar{y}_0\|$, we compute that

$$\begin{aligned} \mathbb{E}|\tilde{y}(0)|^p &= \mathbb{E}|\bar{y}(0) - u(\bar{y}_{-\triangle})|^p \\ &\le \mathbb{E}(|\bar{y}(0)| + \kappa\|\bar{y}_{-\triangle}\|)^p \\ &\le \mathbb{E}(|\bar{y}(0)| + \kappa\|\bar{y}_0\|)^p \\ &\le \mathbb{E}(|\xi(0)| + \kappa\|\xi\|)^p \\ &\le (1+\kappa)^p\mathbb{E}\|\xi\|^p. \end{aligned} \tag{3.4}$$

Assumption 2.2 and the Hölder inequality give

$$\begin{aligned} \mathbb{E}\int_0^{t_1}|f(\bar{y}_s)|^p ds &\le \mathbb{E}\int_0^{t_1} K^{\frac{p}{2}}(1+\|\bar{y}_s\|^2)^{\frac{p}{2}}ds \\ &\le K^{\frac{p}{2}}2^{\frac{p-2}{2}}\mathbb{E}\int_0^{t_1}(1+\|\bar{y}_s\|^p)ds \\ &\le K^{\frac{p}{2}}2^{\frac{p-2}{2}}\left[T + \int_0^{t_1}\mathbb{E}\left(\sup_{-\tau\le t\le s}|y(t)|^p ds\right)\right]. \end{aligned} \tag{3.5}$$

Applying the Burkholder–Davis–Gundy inequality, the Hölder inequality, and Assumption 2.2 yields

$$\begin{aligned}\mathbb{E}\left(\sup_{0\le t\le t_1}\left|\int_0^t g(\bar{y}_s)dw(s)\right|^p\right) &\le C_p\mathbb{E}\left(\int_0^{t_1}|g(\bar{y}_s)|^2ds\right)^{\frac{p}{2}}\\ &\le C_pT^{\frac{p-2}{2}}\mathbb{E}\int_0^{t_1}|g(\bar{y}_s)|^pds\\ &\le C_pT^{\frac{p-2}{2}}\mathbb{E}\int_0^{t_1}K^{\frac{p}{2}}\left(1+\|\bar{y}_s\|^2\right)^{\frac{p}{2}}ds\\ &\le C_pT^{\frac{p-2}{2}}K^{\frac{p}{2}}2^{\frac{p-2}{2}}\mathbb{E}\int_0^{t_1}\left(1+\|\bar{y}_s\|^p\right)ds\\ &\le C_pT^{\frac{p-2}{2}}K^{\frac{p}{2}}2^{\frac{p-2}{2}}\left[T+\int_0^{t_1}\mathbb{E}\Big(\sup_{-\tau\le t\le s}|y(t)|^p\Big)ds\right], \qquad (3.6)\end{aligned}$$

where C_p is a constant dependent only on p. Substituting (3.4), (3.5), and (3.6) into (3.3) gives

$$\begin{aligned}\tilde{h}(t_1) \le\ & 3^{p-1}\Big[(1+\kappa)^p\mathbb{E}\|\xi\|^p+K^{\frac{p}{2}}2^{\frac{p-2}{2}}T^p+C_p(2T)^{\frac{p-2}{2}}K^{\frac{p}{2}}T\Big]\\ &+3^{p-1}\Big[K^{\frac{p}{2}}2^{\frac{p-2}{2}}T^{p-1}+C_p(2T)^{\frac{p-2}{2}}K^{\frac{p}{2}}\Big]\int_0^{t_1}\mathbb{E}\Big(\sup_{-\tau\le t\le s}|y(t)|^p\Big)ds\\ =:\ & C_1+C_2\int_0^{t_1}h(s)ds.\end{aligned}$$

Hence from (3.2), we have

$$\begin{aligned}h(t_1)&\le\frac{\mathbb{E}\|\xi\|^p}{1-\kappa}+\frac{1}{(1-\kappa)^p}\left[C_1+C_2\int_0^{t_1}h(s)ds\right]\\ &\le\frac{\mathbb{E}\|\xi\|^p}{1-\kappa}+\frac{C_1}{(1-\kappa)^p}+\frac{C_2}{(1-\kappa)^p}\int_0^{t_1}h(s)ds.\end{aligned}$$

By the Gronwall inequality we find that

$$h(T)\le\left[\frac{\mathbb{E}\|\xi\|^p}{1-\kappa}+\frac{C_1}{(1-\kappa)^p}\right]e^{\frac{C_2T}{(1-\kappa)^p}}.$$

From the expressions of C_1 and C_2, we know that they are positive constants dependent only on ξ, κ, K, p, and T but independent of $\triangle$. The required assertion must hold. □

LEMMA 3.2. *If Assumptions* 2.2–2.4 *hold, then for any integer* $l>1$,

$$\mathbb{E}\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle}\|^2\Big)\le c_1\alpha(\triangle)+\bar{c}_1(l)\triangle^{\frac{l-1}{l}}=:\gamma(\triangle), \qquad (3.7)$$

where $c_1=1/(1-\kappa)$, *and* $\bar{c}_1(l)$ *is a constant dependent on* l *but independent of* $\triangle$.

Proof. For $\theta \in [i\triangle, (i+1)\triangle]$, where $i = -N, -(N+1), \ldots, -1$, from (2.9),

$$\begin{aligned}|\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle}| &\le \frac{(i+1)\triangle - \theta}{\triangle}|\bar{y}((k+i)\triangle) - \bar{y}((k-1+i)\triangle)| \\ &\quad + \frac{\theta - i\triangle}{\triangle}|\bar{y}((k+i+1)\triangle) - \bar{y}((k+i)\triangle)| \\ &\le |\bar{y}((k+i)\triangle) - \bar{y}((k-1+i)\triangle)| \vee |\bar{y}((k+i+1)\triangle) - \bar{y}((k+i)\triangle)|,\end{aligned}$$

so

$$\|\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle}\| \le \sup_{-N\le i\le 0}|\bar{y}((k+i)\triangle) - \bar{y}((k-1+i)\triangle)|.$$

We therefore have

$$\begin{aligned}&\mathbb{E}\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle}\|^2\Big) \\ &\le \mathbb{E}\Big[\sup_{0\le k\le M-1}\Big(\sup_{-N\le i\le 0}|\bar{y}((k+i)\triangle) - \bar{y}((k-1+i)\triangle)|^2\Big)\Big] \\ &\le \mathbb{E}\Big(\sup_{-N\le k\le M-1}|\bar{y}(k\triangle) - \bar{y}((k-1)\triangle)|^2\Big). \qquad (3.8)\end{aligned}$$

When $-N \le k \le 0$, by Assumption 2.4 and $\bar{y}(-(N+1)\triangle) = \xi(-N\triangle)$,

$$\begin{aligned}\mathbb{E}\Big(\sup_{-N\le k\le 0}|\bar{y}(k\triangle) - \bar{y}((k-1)\triangle)|^2\Big) &\le \mathbb{E}\Big(\sup_{-N\le k\le 0}|\xi(k\triangle) - \xi((k-1)\triangle)|^2\Big) \\ &\le \alpha(\triangle). \qquad (3.9)\end{aligned}$$

When $1 \le k \le M-1$, from (2.7), we have

$$\bar{y}(k\triangle) - \bar{y}((k-1)\triangle) = u(\bar{y}_{(k-1)\triangle}) - u(\bar{y}_{(k-2)\triangle}) + f(\bar{y}_{(k-1)\triangle})\triangle + g(\bar{y}_{(k-1)\triangle})\triangle w_k.$$

Recall the elementary inequality, for any $x, y > 0$ and $\varepsilon \in (0,1)$,

$$(x+y)^2 \le \frac{x^2}{\varepsilon} + \frac{y^2}{1-\varepsilon}.$$

Then we have

$$\begin{aligned}&|\bar{y}(k\triangle) - \bar{y}((k-1)\triangle)|^2 \\ &\le \frac{1}{\varepsilon}|u(\bar{y}_{(k-1)\triangle}) - u(\bar{y}_{(k-2)\triangle})|^2 + \frac{1}{1-\varepsilon}|f(\bar{y}_{(k-1)\triangle})\triangle + g(\bar{y}_{(k-1)\triangle})\triangle w_k|^2 \\ &\le \frac{\kappa^2}{\varepsilon}\|\bar{y}_{(k-1)\triangle} - \bar{y}_{(k-2)\triangle}\|^2 + \frac{2}{1-\varepsilon}|f(\bar{y}_{(k-1)\triangle})|^2\triangle^2 + \frac{2}{1-\varepsilon}|g(\bar{y}_{(k-1)\triangle})\triangle w_k|^2,\end{aligned}$$

and consequently,

$$\begin{aligned}&\mathbb{E}\Big(\sup_{1\le k\le M-1}|\bar{y}(k\triangle) - \bar{y}((k-1)\triangle)|^2\Big) \\ &\le \frac{\kappa^2}{\varepsilon}\mathbb{E}\Big(\sup_{1\le k\le M-1}\|\bar{y}_{(k-1)\triangle} - \bar{y}_{(k-2)\triangle}\|^2\Big) \\ &\quad + \frac{2\triangle^2}{1-\varepsilon}\mathbb{E}\Big(\sup_{1\le k\le M-1}|f(\bar{y}_{(k-1)\triangle})|^2\Big) \\ &\quad + \frac{2}{1-\varepsilon}\mathbb{E}\Big(\sup_{1\le k\le M-1}|g(\bar{y}_{(k-1)\triangle})\triangle w_k|^2\Big). \qquad (3.10)\end{aligned}$$

We deal with these three terms separately. By (3.9),

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{1\le k\le M-1}\|\bar{y}_{(k-1)\triangle}-\bar{y}_{(k-2)\triangle}\|^2\Big)\\
&\le \mathbb{E}\Big(\sup_{1\le k\le M-1}\sup_{-N\le i\le 0}|\bar{y}((k+i-1)\triangle)-\bar{y}((k-2+i)\triangle)|^2\Big)\\
&\le \mathbb{E}\Big(\sup_{-N\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big)\\
&\le \mathbb{E}\Big(\sup_{-N\le k\le 0}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big)\\
&\quad+\mathbb{E}\Big(\sup_{1\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big)\\
&\le \alpha(\triangle)+\mathbb{E}\Big(\sup_{1\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big). \qquad (3.11)
\end{aligned}$$

Noting that $\mathbb{E}[\sup_{-\tau\le t\le T}|\bar{y}(t)|^2]\le\mathbb{E}[\sup_{-\tau\le t\le T}|y(t)|^2]\le H(2)$ (where $H(p)$ has been defined in Lemma 3.1), by Assumption 2.2 and (2.10),

$$\begin{aligned}
\mathbb{E}\Big(\sup_{1\le k\le M-1}|f(\bar{y}_{(k-1)\triangle})|^2\Big)&\le\mathbb{E}\Big(\sup_{1\le k\le M-1}K(1+\|\bar{y}_{(k-1)\triangle}\|^2)\Big)\\
&\le K+K\mathbb{E}\Big(\sup_{1\le k\le M-1}\sup_{-N\le i\le 0}|\bar{y}((k-1+i)\triangle)|^2\Big)\\
&\le K+K\mathbb{E}\Big(\sup_{-N\le k\le M-1}|\bar{y}(k\triangle)|^2\Big)\\
&\le K+K\mathbb{E}\Big(\sup_{-\tau\le t\le T}|\bar{y}(t)|^2\Big)\\
&\le K(1+H(2)). \qquad (3.12)
\end{aligned}$$

By the Hölder inequality, for any integer $l>1$,

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{1\le k\le M-1}|g(\bar{y}_{k\triangle})\triangle w_k|^2\Big)\\
&\le\mathbb{E}\Big(\sup_{1\le k\le M-1}|g(\bar{y}_{(k-1)\triangle})|^2\sup_{1\le k\le M-1}|\triangle w_k|^2\Big)\\
&\le\Big[\mathbb{E}\Big(\sup_{1\le k\le M-1}|g(\bar{y}_{(k-1)\triangle})|^{\frac{2l}{l-1}}\Big)\Big]^{\frac{l-1}{l}}\Big[\mathbb{E}\Big(\sup_{0\le k\le M-1}|\triangle w_k|^{2l}\Big)\Big]^{\frac{1}{l}}\\
&\le\Big[\mathbb{E}\Big(\sup_{0\le k\le M-1}(K(1+\|\bar{y}_{k\triangle}\|^2))^{\frac{l}{l-1}}\Big)\Big]^{\frac{l-1}{l}}\Big[\mathbb{E}\Big(\sum_{k=0}^{M-1}|\triangle w_k|^{2l}\Big)\Big]^{\frac{1}{l}}\\
&\le\Big[K^{\frac{l}{1-l}}\mathbb{E}\Big(1+\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle}\|^2\Big)\Big)^{\frac{l}{l-1}}\Big]^{\frac{l-1}{l}}\Big[\Big(\sum_{k=0}^{M-1}\mathbb{E}|\triangle w_k|^{2l}\Big)\Big]^{\frac{1}{l}}\\
&\le\Big[2^{\frac{1}{l-1}}K^{\frac{l}{1-l}}\Big(1+\mathbb{E}\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle}\|^{\frac{2l}{l-1}}\Big)\Big)\Big]^{\frac{l-1}{l}}\Big[\Big(\sum_{k=0}^{M-1}(2l-1)!!\triangle^l\Big)\Big]^{\frac{1}{l}}\\
&\le\Big[2^{\frac{1}{l-1}}K^{\frac{l}{1-l}}\Big(1+H\Big(\frac{2l}{l-1}\Big)\Big)\Big]^{\frac{l-1}{l}}[(2l-1)!!T\triangle^{l-1}]^{\frac{1}{l}}\\
&\le D(l)\triangle^{\frac{l-1}{l}}, \qquad (3.13)
\end{aligned}$$

where $(2l-1)!! = 1 \cdot 3 \cdots (2l-1)$, $D(l)$ is a constant dependent on l.

Substituting (3.11), (3.12), and (3.13) into (3.10), choosing $\varepsilon = \kappa$, and noting that $\triangle \in (0,1)$, we have

$$\begin{aligned} &\mathbb{E}\Big(\sup_{1\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big) \\ &\le \frac{\kappa}{1-\kappa}\alpha(\triangle)+\frac{2K(1+H(2))+2D(l)}{(1-\kappa)^2}\triangle^{\frac{l-1}{l}}. \end{aligned} \tag{3.14}$$

Combining (3.9) with (3.14), from (3.8) we have

$$\begin{aligned} &\mathbb{E}\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle}\|^2\Big) \\ &\le \mathbb{E}\Big(\sup_{-N\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big) \\ &\le \mathbb{E}\Big(\sup_{-N\le k\le 0}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big) \\ &\quad + \mathbb{E}\Big(\sup_{1\le k\le M-1}|\bar{y}(k\triangle)-\bar{y}((k-1)\triangle)|^2\Big) \\ &\le \frac{1}{1-\kappa}\alpha(\triangle)+\frac{2K(1+H(2))+2D(l)}{(1-\kappa)^2}\triangle^{\frac{l-1}{l}}, \end{aligned} \tag{3.15}$$

as required. □

LEMMA 3.3. *If Assumptions* 2.2–2.4 *hold,*

$$\mathbb{E}\Big(\sup_{0\le s\le T}\|y_s-\bar{y}_s\|^2\Big)\le c_2\alpha(2\triangle)+\bar{c}_2(l)\triangle^{\frac{l-1}{l}} =: \beta(\triangle), \tag{3.16}$$

where c_2 is a constant independent of l and $\triangle$, and $\bar{c}_2(l)$ is a constant dependent on l but independent of $\triangle$.

Proof. Fix any $s \in [0,T]$ and $\theta \in [-\tau, 0]$. Let $k_s \in \{0,1,2,\ldots,M-1\}$, $k_\theta \in \{-N, -N+1, \ldots, -1\}$, and $k_{s\theta} \in \{-N, -N+1, \ldots, M-1\}$ be the integers for which $s \in [k_s\triangle, (k_s+1)\triangle]$, $\theta \in [k_\theta\triangle, (k_\theta+1)\triangle]$, and $s+\theta \in [k_{s\theta}\triangle, (k_{s\theta}+1)\triangle]$, respectively. Clearly,

$$0 \le s+\theta-(k_s+k_\theta) \le 2\triangle, \tag{3.17}$$

$$k_{s\theta}-(k_s+k_\theta) \in \{0,1,2\}. \tag{3.18}$$

From (2.8),

$$\begin{aligned} \bar{y}_s &= \bar{y}_{k_s\triangle}(\theta) \\ &= \bar{y}((k_s+k_\theta)\triangle)+\frac{\theta-k_\theta\triangle}{\triangle}(\bar{y}((k_s+k_\theta+1)\triangle)-\bar{y}(k_s+k_\theta)\triangle), \end{aligned}$$

which yields

$$\begin{aligned} |y_s-\bar{y}_s| &= |y(s+\theta)-\bar{y}_{k_s\triangle}(\theta)| \\ &\le |y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|+\frac{\theta-k_\theta\triangle}{\triangle}|\bar{y}((k_s+k_\theta+1)\triangle)-\bar{y}((k_s+k_\theta)\triangle)| \\ &\le |y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|+|\bar{y}((k_s+k_\theta+1)\triangle)-\bar{y}((k_s+k_\theta)\triangle)|, \end{aligned}$$

so by (3.8) and Lemma 3.2, noting that $\bar{y}(M\triangle) = \bar{y}((M-1)\triangle)$ from (2.11),

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{0\le s\le T}\|y_s-\bar{y}_s\|^2\Big)\\
&\le 2\mathbb{E}\Big[\sup_{0\le s\le T}\Big(\sup_{-\tau\le\theta\le 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\Big]\\
&\quad+2\mathbb{E}\Big[\sup_{0\le k_s\le M-1}\Big(\sup_{-N\le k_\theta\le 0}|\bar{y}((k_s+k_\theta+1)\triangle)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\Big]\\
&\le 2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)+2\gamma(\triangle). \qquad (3.19)
\end{aligned}$$

Therefore, it is key to compute $\mathbb{E}\big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\big)$. We discuss the following four possible cases.

Case 1: $k_s+k_\theta\ge 0$. We again divide this case into three possible subcases according to $k_{s\theta}-(k_s+k_\theta)\in\{0,1,2\}$.

Subcase 1: $k_{s\theta}-(k_s+k_\theta)=0$. From (2.13)

$$\begin{aligned}
&y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)\\
&=u\Big(\bar{y}_{(k_{s\theta}-1)\triangle}+\frac{s+\theta-k_{s\theta}\triangle}{\triangle}(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\Big)-u(\bar{y}_{(k_{s\theta}-1)\triangle})\\
&\quad+\int_{k_{s\theta}\triangle}^{s+\theta}f(\bar{y}_r)dr+\int_{k_{s\theta}\triangle}^{s+\theta}g(\bar{y}_r)dw(r),
\end{aligned}$$

which yields

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\
&\le 3\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|u\Big(\bar{y}_{(k_{s\theta}-1)\triangle}+\frac{s+\theta-k_{s\theta}\triangle}{\triangle}(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\Big)\\
&\quad-u(\bar{y}_{(k_{s\theta}-1)\triangle})\Big)\Big|^2+3\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|\int_{k_{s\theta}\triangle}^{s+\theta}f(\bar{y}_r)dr\Big|^2\Big)\\
&\quad+3\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|\int_{k_{s\theta}\triangle}^{s+\theta}g(\bar{y}_r)dw(r)\Big|^2\Big). \qquad (3.20)
\end{aligned}$$

From Assumption 2.3 and Lemma 3.2, we have

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|u\Big(\bar{y}_{(k_{s\theta}-1)\triangle}\\
&\quad+\frac{s+\theta-k_{s\theta}\triangle}{\triangle}(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\Big)-u(\bar{y}_{(k_{s\theta}-1)\triangle})\Big)\Big|^2\\
&\le\kappa^2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big\|\frac{s+\theta-k_{s\theta}\triangle}{\triangle}(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\Big\|^2\Big)\\
&\le\kappa^2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\|(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\|^2\Big)\\
&\le\kappa^2\mathbb{E}\Big(\sup_{0\le k_{s\theta}\le M-1}\|(\bar{y}_{k_{s\theta}\triangle}-\bar{y}_{(k_{s\theta}-1)\triangle})\|^2\Big)\\
&\le\kappa^2\gamma(\triangle). \qquad (3.21)
\end{aligned}$$

By the Hölder inequality, Assumption 2.2, and Lemma 3.1,

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|\int_{k_{s\theta}\triangle}^{s+\theta} f(\bar{y}_r)dr\Big|^2\Big)\\
&\le \triangle\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\int_{k_{s\theta}\triangle}^{s+\theta}|f(\bar{y}_r)|^2dr\Big)\\
&\le K\triangle\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\int_{k_{s\theta}\triangle}^{s+\theta}(1+\|\bar{y}_r\|^2)dr\Big)\\
&\le K\triangle\mathbb{E}\Big[\int_0^T\Big(1+\sup_{0\le r\le T}\|\bar{y}_r\|^2\Big)dr\Big]\\
&\le K\triangle\int_0^T\Big[1+\mathbb{E}\Big(\sup_{-\tau\le t\le T}|y(t)|^2\Big)\Big]dr\\
&\le K\triangle\int_0^T[1+H(2)]dr\\
&\le KT[1+H(2)]\triangle. \qquad (3.22)
\end{aligned}$$

Setting $v=s+\theta$ and $k_v=k_{s\theta}$ and applying the Hölder inequality yield

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|\int_{k_{s\theta}\triangle}^{s+\theta} g(\bar{y}_r)dw(r)\Big|^2\Big)\\
&\quad=\mathbb{E}\Big(\sup_{0\le v\le T,0\le k_v\le M-1}|g(\bar{y}_{k_v\triangle})(w(v)-w(k_v\triangle))|^2\Big)\\
&\quad\le\Big[\mathbb{E}\Big(\sup_{0\le v\le T,0\le k_v\le M-1}|g(\bar{y}_{k_v\triangle})|^{\frac{2l}{l-1}}\Big)\Big]^{\frac{l-1}{l}}\\
&\qquad\Big[\mathbb{E}\Big(\sup_{0\le v\le T,0\le k_v\le M-1}|w(v)-w(k_v\triangle)|^{2l}\Big)\Big]^{\frac{1}{l}}.
\end{aligned}$$

The Doob martingale inequality gives

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{0\le v\le T,0\le k_v\le M-1}|w(v)-w(k_v\triangle)|^{2l}\Big)\\
&=\mathbb{E}\Big(\sup_{0\le k_v\le M-1}\Big(\sup_{k_v\triangle\le v\le(k_v+1)\triangle}|w(v)-w(k_v\triangle)|^{2l}\Big)\Big)\\
&\le\mathbb{E}\Big(\sum_{k_v=0}^{M-1}\Big(\sup_{k_v\triangle\le v\le(k_v+1)\triangle}|w(v)-w(k_v\triangle)|^{2l}\Big)\Big)\\
&=\sum_{k_v=0}^{M-1}\mathbb{E}\Big(\sup_{k_v\triangle\le v\le(k_v+1)\triangle}|w(v)-w(k_v\triangle)|^{2l}\Big)\\
&\le\Big(\frac{2l}{2l-1}\Big)^{2l}\sum_{k_v=0}^{M-1}\mathbb{E}|w((k_v+1)\triangle)-w(k_v\triangle)|^{2l}.
\end{aligned}$$

By (3.13), we therefore have

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_{s\theta}\ge 0}\Big|\int_{k_{s\theta}\triangle}^{s+\theta} g(\bar{y}_r)dw(r)\Big|^2\Big)\\
&\le \Big(\frac{2l}{2l-1}\Big)^2\Big[\mathbb{E}\Big(\sup_{0\le k_v\le M-1}|g(\bar{y}_{k_v\triangle})|^{\frac{2l}{l-1}}\Big)\Big]^{\frac{l-1}{l}}\\
&\times\Big[\sum_{k_v=0}^{M-1}\mathbb{E}|w((k_v+1)\triangle)-w(k_v\triangle)|^{2l}\Big]^{\frac{1}{l}}\\
&\le \Big(\frac{2l}{2l-1}\Big)^2 D(l)\triangle^{\frac{l-1}{l}}. \qquad (3.23)
\end{aligned}$$

Substituting (3.21), (3.22), and (3.23) into (3.20) and noting $\triangle\in(0,1)$ give

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\
&\le 3\kappa^2\gamma(\triangle)+3\Big(KT(1+H(2))+\Big(\frac{2l}{2l-1}\Big)^2 D(l)\Big)\triangle^{\frac{l-1}{l}}\\
&=: 3\kappa^2\gamma(\triangle)+c_1(l)\triangle^{\frac{l-1}{l}}. \qquad (3.24)
\end{aligned}$$

Subcase 2: $k_{s\theta}-(k_s+k_\theta)=1$. From (2.13) and (2.7),

$$\begin{aligned}
&y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)\\
&=y(k_{s\theta}\triangle)-\bar{y}((k_s+k_\theta)\triangle)+y(s+\theta)-\bar{y}(k_{s\theta}\triangle)\\
&\le u(\bar{y}_{(k_s+k_\theta)\triangle})-u(\bar{y}_{(k_s+k_\theta-1)\triangle})+f(\bar{y}_{(k_s+k_\theta)\triangle})\triangle+g(\bar{y}_{(k_s+k_\theta)\triangle})\triangle w_{k_s+k_\theta}\\
&\quad+y(s+\theta)-\bar{y}(k_{s\theta}\triangle),
\end{aligned}$$

so we have

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\
&\le 4\Big\{\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|u(\bar{y}_{(k_s+k_\theta)\triangle})-u(\bar{y}_{(k_s+k_\theta-1)\triangle})|^2\Big)\\
&\quad+\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|f(\bar{y}_{(k_s+k_\theta)\triangle})\triangle|^2\Big)\\
&\quad+\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|g(\bar{y}_{(k_s+k_\theta)\triangle})\triangle w_{k_s+k_\theta}|^2\Big)\\
&\quad+\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}(k_{s\theta}\triangle)|^2\Big)\Big\}. \qquad (3.25)
\end{aligned}$$

Since

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|u(\bar{y}_{(k_s+k_\theta)\triangle})-u(\bar{y}_{(k_s+k_\theta-1)\triangle})|^2\Big)\\
&\le\kappa^2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}\|\bar{y}_{(k_s+k_\theta)\triangle}-\bar{y}_{(k_s+k_\theta-1)\triangle}\|^2\Big)\\
&\le\kappa^2\gamma(\triangle), \qquad (3.26)
\end{aligned}$$

from (3.12), (3.13), and Subcase 1, noting that $\triangle \in (0,1)$, we have

$$\begin{aligned}&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\ &\le 4\Big\{\kappa^2\gamma(\triangle)+K[1+H(2)]\triangle^2+D(l)\triangle^{\frac{l-1}{l}}+3\kappa^2\gamma(\triangle)+c_1(l)\triangle^{\frac{l-1}{l}}\Big\}\\ &=: 16\kappa^2\gamma(\triangle)+c_2(l)\triangle^{\frac{l-1}{l}}. \qquad (3.27)\end{aligned}$$

Subcase 3: $k_{s\theta}-(k_s+k_\theta)=2$. From (2.13) and (2.7), we have

$$\begin{aligned}&y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)\\ &=y(s+\theta)-y((k_{s\theta}-1)\triangle)+y((k_{s\theta}-1)\triangle)-\bar{y}((k_s+k_\theta)\triangle),\end{aligned}$$

so from Subcase 2, we have

$$\begin{aligned}&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\ &\le 2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_{s\theta}-1)\triangle)|^2\Big)\\ &\quad+2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y((k_{s\theta}-1)\triangle)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\ &\le 2[16\kappa^2\gamma(\triangle)+c_2(l)\triangle^{\frac{l-1}{l}}]+2[\kappa^2\gamma(\triangle)+K[1+H(2)]\triangle^2+D(l)\triangle^{\frac{l-1}{l}}]\\ &=: 34\kappa^2\gamma(\triangle)+c_3(l)\triangle^{\frac{l-1}{l}}. \qquad (3.28)\end{aligned}$$

From these three subcases, we have

$$\begin{aligned}&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T,k_s+k_\theta\ge 0}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\ &\le 53\kappa^2\gamma(\triangle)+[c_1(l)+c_2(l)+c_3(l)]\triangle^{\frac{l-1}{l}}. \qquad (3.29)\end{aligned}$$

Case 2: $k_s+k_\theta=-1$ *and* $0\le s+\theta\le\triangle$. In this case, applying Assumption 2.4 and Case 1, we have

$$\begin{aligned}&\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\\ &\le 2\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}(0)|^2\Big)+2E|y(0)-y(-\triangle)|^2\\ &\le 106\kappa^2\gamma(\triangle)+2[c_1(l)+c_2(l)+c_3(l)]\triangle^{\frac{l-1}{l}}+2\alpha(\triangle). \qquad (3.30)\end{aligned}$$

Case 3: $k_s+k_\theta=-1$ *and* $-\triangle\le s+\theta\le 0$. In this case, using Assumption 2.4

$$\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\le\alpha(\triangle). \qquad (3.31)$$

Case 4: $k_s+k_\theta\le -2$. In this case, $s+\theta\le 0$, so using Assumption 2.4

$$\mathbb{E}\Big(\sup_{-\tau\le\theta\le 0,0\le s\le T}|y(s+\theta)-\bar{y}((k_s+k_\theta)\triangle)|^2\Big)\le\alpha(2\triangle). \qquad (3.32)$$

Substituting these four cases into (3.19) and noting the expression of $\gamma(\triangle)$, there exist c_2 and $\bar{c}_2(l)$ such that

$$\mathbb{E}\Big(\sup_{0\le s\le T}\|y_s-\bar{y}_s\|^2\Big)\le c_2\alpha(2\triangle)+\bar{c}_2(l)\triangle^{\frac{l-1}{l}}, \tag{3.33}$$

namely, the required assertion holds. □

4. Proof of Theorem 2.2. From Lemma 3.1 and Theorem 2.1, there exists a positive constant $\widetilde{H}$ such that

$$\mathbb{E}\Big(\sup_{-\tau\le t\le T}|x(t)|^p\Big)\vee\mathbb{E}\Big(\sup_{-\tau\le t\le T}|y(t)|^p\Big)\le\widetilde{H}. \tag{4.1}$$

Let j be a sufficient large integer. Define the stopping times

$$u_j:=\inf\{t\ge 0:\|x_t\|\ge j\},\quad v_j:=\inf\{t\ge 0:\|y_t\|\ge j\},\quad \rho_j:=u_j\wedge v_j,$$

where we set $\inf\emptyset=\infty$ as usual. Let

$$e(t):=x(t)-y(t).$$

Obviously,

$$\begin{aligned}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2\Big)&=\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2 1_{\{u_j>T,\ v_j>T\}}\Big)\\&\quad+\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2 1_{\{u_j\le T\text{ or }v_j\le T\}}\Big).\end{aligned}$$

Recall the following elementary inequality:

$$a^\gamma b^{1-\gamma}\le\gamma a+(1-\gamma)b\quad\forall a,b>0,\ \gamma\in[0,1]. \tag{4.2}$$

We thus have, for any $\delta>0$,

$$\begin{aligned}&\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2 1_{\{u_j\le T\text{ or }v_j\le T\}}\Big)\\&\quad\le\mathbb{E}\Big[\Big(\delta\sup_{\{0\le t\le T\}}|e(t)|^p\Big)^{\frac{2}{p}}\Big(\delta^{-\frac{2}{p-2}}1_{\{u_j\le T\text{ or }v_j\le T\}}\Big)^{\frac{p-2}{p}}\Big]\\&\quad\le\frac{2\delta}{p}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^p\Big)+\frac{p-2}{p\delta^{2/(p-2)}}\mathbb{P}(u_j\le T\text{ or }v_j\le T).\end{aligned}$$

Hence

$$\begin{aligned}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2\Big)&\le\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2 1_{\{\rho_j>T\}}\Big)+\frac{2\delta}{p}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^p\Big)\\&\quad+\frac{p-2}{p\delta^{2/(p-2)}}\mathbb{P}(u_j\le T\text{ or }v_j\le T).\end{aligned} \tag{4.3}$$

Now,

$$\begin{aligned}\mathbb{P}(u_j\le T)&\le\mathbb{E}\Big(1_{\{u_j\le T\}}\frac{\|x_t\|^p}{j^p}\Big)\\&\le\frac{1}{j^p}\mathbb{E}\Big(\sup_{-\tau\le t\le T}|x(t)|^p\Big)\\&\le\frac{\widetilde{H}}{j^p}.\end{aligned}$$

Similarly,

$$\mathbb{P}(v_j \le T) \le \frac{\widetilde{H}}{j^p}.$$

Thus

$$\begin{aligned}\mathbb{P}(v_j \le T \text{ or } u_j \le T) &\le \mathbb{P}(v_j \le T) + \mathbb{P}(u_j \le T)\\ &\le \frac{2\widetilde{H}}{j^p}. \end{aligned} \tag{4.4}$$

We also have

$$\begin{aligned}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^p\Big) &\le 2^{p-1}\mathbb{E}\Big(\sup_{0\le t\le T}(|x_t|^p + |y_t|^p)\Big)\\ &\le 2^p\widetilde{H}. \end{aligned} \tag{4.5}$$

Moreover,

$$\begin{aligned}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2 1_{\{\rho_j>T\}}\Big) &= \mathbb{E}\Big(\sup_{0\le t\le T}|e(t\wedge\rho_j)|^2 1_{\{\rho_j>T\}}\Big)\\ &\le \mathbb{E}\Big(\sup_{0\le t\le T}|e(t\wedge\rho_j)|^2\Big).\end{aligned}$$

Using these bounds in (4.3) yields

$$\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2\Big) \le \mathbb{E}\Big(\sup_{0\le t\le T}|e(t\wedge\rho_j)|^2\Big) + \frac{2^{p+1}\delta\widetilde{H}}{p} + \frac{2(p-2)\widetilde{H}}{p\delta^{2/(p-2)}j^p}. \tag{4.6}$$

Setting $r := t\wedge\rho_j$ and for any $\varepsilon\in(0,1)$, by the Hölder inequality, when $r\in[k\triangle,(k+1)\triangle]$, for $k=0,1,2,\dots,M-1$,

$$\begin{aligned}|e(r)|^2 &= |x(r)-y(r)|^2\\ &\le \Big|u(x_r) - u(\bar{y}_{(k-1)\triangle} + (r-k\triangle)(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})/\triangle)\\ &\quad + \int_0^r [f(x_s)-f(\bar{y}_s)]ds + \int_0^r [g(x_s)-g(\bar{y}_s)]dw(s)\Big|^2\\ &\le \frac{1}{\varepsilon}|u(x_r) - u(\bar{y}_{(k-1)\triangle} + (r-k\triangle)(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})/\triangle)|^2\\ &\quad + \frac{2}{1-\varepsilon}\Big[T\int_0^r [f(x_s)-f(\bar{y}_s)]^2ds + \Big|\int_0^r [g(x_s)-g(\bar{y}_s)]dw(s)\Big|^2\Big].\end{aligned}$$

Since

$$\begin{aligned}&\Big|u(x_r) - u\Big(\bar{y}_{(k-1)\triangle} + \frac{r-k\triangle}{\triangle}(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})\Big)\Big|^2\\ &\le \kappa^2\Big\|x_r - \bar{y}_{(k-1)\triangle} - \frac{r-k\triangle}{\triangle}(\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle})\Big\|^2\\ &\le \kappa^2\Big\||x_r-y_r| + |y_r-\bar{y}_r| + |\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle}| - \frac{r-k\triangle}{\triangle}|\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle}|\Big\|^2\\ &\le \frac{\kappa^2}{\varepsilon}\|x_r-y_r\|^2 + \frac{2\kappa^2}{1-\varepsilon}\Big(\|y_r-\bar{y}_r\|^2 + \|\bar{y}_{k\triangle}-\bar{y}_{(k-1)\triangle}\|^2\Big),\end{aligned}$$

we have

$$|e(r)|^2 \le \frac{\kappa^2}{\varepsilon^2}\|x_r - y_r\|^2 + \frac{2\kappa^2}{\varepsilon(1-\varepsilon)}(\|y_r - \bar{y}_r\|^2 + \|\bar{y}_{k\triangle} - \bar{y}_{(k-1)\triangle}\|^2)$$
$$+\frac{2}{1-\varepsilon}\Big[T\int_0^r [f(x_s) - f(\bar{y}_s)]^2 ds + \Big|\int_0^r [g(x_s) - g(\bar{y}_s)]dw(s)\Big|^2\Big].$$

Hence, for any $t_1 \in [0, T]$, by Lemmas 3.2 and 3.3,

$$\begin{aligned}
&\mathbb{E}\Big[\sup_{0\le t\le t_1}|e(t\wedge\rho_j)|^2\Big]\\
&\le \frac{\kappa^2}{\varepsilon^2}\mathbb{E}\Big(\sup_{0\le t\le t_1}\|x_{t\wedge\rho_j} - y_{t\wedge\rho_j}\|^2\Big) + \frac{2\kappa^2}{\varepsilon(1-\varepsilon)}\Big[\mathbb{E}\Big(\sup_{0\le t\le t_1}\|y_{t\wedge\rho_j} - \bar{y}_{t\wedge\rho_j}\|^2\Big)\\
&\quad + \mathbb{E}\Big(\sup_{0\le k\le M-1}\|\bar{y}_{k\triangle\wedge\rho_j} - \bar{y}_{(k-1)\triangle\wedge\rho_j}\|^2\Big)\Big]\\
&\quad + \frac{2T}{1-\varepsilon}\mathbb{E}\int_0^{t_1\wedge\rho_j}[f(x_s) - f(\bar{y}_s)]^2 ds\\
&\quad + \frac{2}{1-\varepsilon}\mathbb{E}\Big[\sup_{0\le t\le t_1}\Big|\int_0^{t\wedge\rho_j}[g(x_s) - g(\bar{y}_s)]dw(s)\Big|^2\Big]\\
&\le \frac{\kappa^2}{\varepsilon^2}\mathbb{E}\Big(\sup_{0\le t\le t_1}\|x_{t\wedge\rho_j} - y_{t\wedge\rho_j}\|^2\Big) + \frac{2\kappa^2}{\varepsilon(1-\varepsilon)}(\gamma(\triangle) + \beta(\triangle))\\
&\quad + \frac{2T}{1-\varepsilon}\mathbb{E}\int_0^{t_1\wedge\rho_j}[f(x_s) - f(\bar{y}_s)]^2 ds\\
&\quad + \frac{2}{1-\varepsilon}\mathbb{E}\Big[\sup_{0\le t\le t_1}\Big|\int_0^{t\wedge\rho_j}[g(x_s) - g(\bar{y}_s)]dw(s)\Big|^2\Big]. \qquad (4.7)
\end{aligned}$$

Since $x(t) = y(t) = \xi(t)$ when $t \in [-\tau, 0]$, we have

$$\begin{aligned}
&\mathbb{E}\Big(\sup_{0\le t\le t_1}\|x_{t\wedge\rho_j} - y_{t\wedge\rho_j}\|^2\Big)\\
&\le \mathbb{E}\Big(\sup_{-\tau\le\theta\le 0}\sup_{0\le t\le t_1}|x(t\wedge\rho_j + \theta) - y(t\wedge\rho_j + \theta)|^2\Big)\\
&\le \mathbb{E}\Big(\sup_{-\tau\le t\le t_1}|x(t\wedge\rho_j) - y(t\wedge\rho_j)|^2\Big)\\
&= \mathbb{E}\Big(\sup_{0\le t\le t_1}|x(t\wedge\rho_j) - y(t\wedge\rho_j)|^2\Big). \qquad (4.8)
\end{aligned}$$

By Assumption 2.1 and Lemma 3.3, we may compute

$$\begin{aligned}
&\mathbb{E}\int_0^{t_1\wedge\rho_j}[f(x_s) - f(\bar{y}_s)]^2 ds\\
&\le C_j\mathbb{E}\int_0^{t_1\wedge\rho_j}\|x_s - \bar{y}_s\|^2 ds\\
&\le 2C_j\mathbb{E}\int_0^{t_1\wedge\rho_j}\|x_s - y_s\|^2 ds + 2C_j\mathbb{E}\int_0^{t_1\wedge\rho_j}\|y_s - \bar{y}_s\|^2 ds
\end{aligned}$$

$$\le 2C_j\mathbb{E}\int_0^{t_1\wedge\rho_j}\sup_{-\tau\le\theta\le 0}|x(s+\theta)-y(s+\theta)|^2ds+2C_j\int_0^{t_1}\mathbb{E}\|y_s-\bar{y}_s\|^2ds$$

$$\le 2C_j\mathbb{E}\int_0^{t_1}\sup_{-\tau\le\theta\le 0}|x(s\wedge\rho_j+\theta)-y(s\wedge\rho_j+\theta)|^2ds+2C_jT\beta(\triangle)$$

$$\le 2C_j\mathbb{E}\int_0^{t_1}\sup_{-\tau\le r\le s}|x(r\wedge\rho_j)-y(r\wedge\rho_j)|^2ds+2C_jT\beta(\triangle)$$

$$= 2C_j\mathbb{E}\int_0^{t_1}\sup_{0\le r\le s}|x(r\wedge\rho_j)-y(r\wedge\rho_j)|^2ds+2C_jT\beta(\triangle). \tag{4.9}$$

By the Doob martingale inequality and Assumption 2.1,

$$\mathbb{E}\Big[\sup_{0\le t\le t_1}\Big|\int_0^{t\wedge\rho_j}[g(x_s)-g(\bar{y}_s)]dw(s)\Big|^2\Big]$$

$$\le 4\mathbb{E}\int_0^{t_1\wedge\rho_j}|g(x_s)-g(\bar{y}_s)|^2ds$$

$$\le 4C_j\mathbb{E}\int_0^{t_1\wedge\rho_j}\|x_s-\bar{y}_s\|^2ds$$

$$\le 8C_j\int_0^{t_1}\mathbb{E}\Big(\sup_{0\le r\le s}|x(r\wedge\rho_j)-y(r\wedge\rho_j)|^2\Big)ds+8C_jT\beta(\triangle). \tag{4.10}$$

Substituting (4.8), (4.9), (4.10) into (4.7) yields

$$\Big(1-\frac{\kappa^2}{\varepsilon^2}\Big)\mathbb{E}\Big[\sup_{0\le t\le t_1}|e(t\wedge\rho_j)|^2\Big]\le\frac{2\kappa^2}{\varepsilon(1-\varepsilon)}[\beta(\triangle)+\gamma(\triangle)]+\frac{4C_jT(T+4)}{1-\varepsilon}\beta(\triangle)$$

$$+\frac{4C_j(T+4)}{1-\varepsilon}\int_0^{t_1}\mathbb{E}\Big(\sup_{0\le r\le s}|e(r\wedge\rho_j)|^2\Big)ds. \tag{4.11}$$

Choosing $\varepsilon=(1+\kappa)/2$ and noting that $\kappa\in(0,1)$, we have

$$\mathbb{E}\Big(\sup_{0\le t\le t_1}|e(t\wedge\rho_j)|^2\Big)$$

$$\le\frac{8\kappa^2(1+\kappa)}{(1-\kappa)^2(1+3\kappa)}[\beta(\triangle)+\gamma(\triangle)]+\frac{8C_jT(1+\kappa)^2(T+4)}{(1-\kappa)^2(1+3\kappa)}\beta(\triangle)$$

$$+\frac{8C_j(1+\kappa)^2(T+4)}{(1-\kappa)^2(1+3\kappa)}\int_0^{t_1}\mathbb{E}\Big(\sup_{0\le s\le r}|e(s\wedge\rho_j)|^2\Big)dr$$

$$\le\frac{8}{(1-\kappa)^2}[\beta(\triangle)+\gamma(\triangle)]+\frac{16}{(1-\kappa)^2}C_jT(T+4)\beta(\triangle)$$

$$+\frac{16}{(1-\kappa)^2}C_j(T+4)\int_0^{t_1}\mathbb{E}\Big(\sup_{0\le s\le r}|e(s\wedge\rho_j)|^2\Big)dr.$$

The Gronwall inequality yields

$$\mathbb{E}\Big[\sup_{0\le t\le t_1}|e(t\wedge\rho_j)|^2\Big]\le\frac{8}{(1-\kappa)^2}[\beta(\triangle)+\gamma(\triangle)+2C_jT(T+4)\beta(\triangle)]$$

$$\times e^{\frac{16}{(1-\kappa)^2}C_jT(T+4)}. \tag{4.12}$$

By (4.6),

$$\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2\Big) \le \frac{8}{(1-\kappa)^2}[\beta(\triangle)+\gamma(\triangle)+2C_jT(T+4)\beta(\triangle)]e^{\frac{16}{(1-\kappa)^2}C_jT(T+4)}$$

$$+\frac{2^{p+1}\delta\widetilde{H}}{p}+\frac{2(p-2)\widetilde{H}}{p\delta^{2/(p-2)}j^p}. \tag{4.13}$$

Given any $\epsilon>0$, we can now choose δ sufficiently small such that $2^{p+1}\delta\widetilde{H}/p\le\epsilon/3$, then choose j sufficiently large such that

$$\frac{2(p-2)\widetilde{H}}{p\delta^{2/(p-2)}j^p}<\frac{\epsilon}{3},$$

and finally choose $\triangle$ so small that

$$\frac{8}{(1-\kappa)^2}[\beta(\triangle)+\gamma(\triangle)+2C_jT(T+4)\beta(\triangle)]e^{\frac{16}{(1-\kappa)^2}C_jT(T+4)}<\frac{\epsilon}{3}$$

and thus $\mathbb{E}(\sup_{0\le t\le T}|e(t)|^2)\le\epsilon$, as required. □

Remark. It should be pointed out that much simpler proofs of Lemmas 3.2 and 3.3 can be obtained by choosing $l=2$ if we only want to prove Theorem 2.2. The reason why we want to control the stochastic term by $c_1(l)\Delta^{\frac{l-1}{l}}$ for any $l>1$ in section 3 is for the use in the next section, where we will show the order of the strong convergence.

5. Order of convergence under the global Lipschitz condition. Theorem 2.2 shows that under Assumptions 2.1–2.4 the Euler–Maruyama approximate solutions strongly converge to the true solution. However, this theorem does not give the order of the convergence. In this section we reveal the order of the convergence, but here we need to replace the local Lipschitz condition by the global Lipschitz condition. To be more precise, we state the assumption as follows.

Assumption 5.1 (global Lipschitz condition). There exists a constant C such that for all $\varphi,\psi\in C([-\tau,0];\mathbb{R}^n)$ and $t\in[0,T]$

$$|f(\varphi)-f(\psi)|^2\vee|g(\varphi)-g(\psi)|^2\le C\|\varphi-\psi\|^2. \tag{5.1}$$

It is easy to see from the global Lipschitz condition that for any $\varphi\in C([-\tau,0];\mathbb{R}^n)$,

$$|f(\varphi)|^2\vee|f(\psi)|^2\le 2(|f(0)|^2\vee|f(0)|^2)+C\|\varphi\|^2. \tag{5.2}$$

In other words, the global Lipschitz condition implies a linear growth condition with the growth coefficient

$$K=2[|f(0)|^2\vee|g(0)|^2\vee C].$$

In addition, we need to slightly strengthen Assumption 2.4 on the initial data.

Assumption 5.2. $\xi\in L^p_{\mathcal{F}_0}([-\tau,0];\mathbb{R}^n)$ for some $p\ge2$, and there exists a positive constant λ such that

$$\mathbb{E}\Big(\sup_{-\tau\le s\le t\le0}|\xi(t)-\xi(s)|^2\Big)\le\lambda(t-s). \tag{5.3}$$

We can state another theorem which reveals the order of the convergence.

THEOREM 5.1. *Under Assumptions* 5.1, 5.2, *and* 2.3, *for any positive constant* $\varepsilon \in (0,1)$,

$$\mathbb{E}\Big(\sup_{0\le t\le T}|x(t)-y(t)|^2\Big) \le O(\triangle^{1-\varepsilon}). \tag{5.4}$$

Proof. Since $\alpha(\triangle)$ may be replaced by $\lambda\triangle$, from Lemmas 3.2 and 3.3, there exists constants $\tilde{c}_1(l)$ and $\tilde{c}_2(l)$ such that $\beta(\triangle) \le \tilde{c}_1(l)\triangle^{\frac{l-1}{l}}$ and $\gamma(\triangle) \le \tilde{c}_2(l)\triangle^{\frac{l-1}{l}}$. Here we do not need to define the stopping times u_j and v_j; we may repeat the proof in section 4 and directly compute

$$\begin{aligned}\mathbb{E}\Big(\sup_{0\le t\le T}|e(t)|^2\Big) \le{}& \frac{8}{(1-\kappa)^2}[\tilde{c}_1(l)+\tilde{c}_2(l)+2\tilde{c}_1(l)CT(T+4)]\\ &\times e^{\frac{16CT(T+4)}{(1-\kappa)^2}}\triangle^{\frac{l-1}{l}}.\end{aligned} \tag{5.5}$$

Choosing $l \ge 1/\varepsilon$ yields the required assertion. ∎

Remark. Let us give some closing comments. Theorem 5.1 reveals that the order of convergence in mean square is close to 1, although the order of the strong convergence in mean square for the Euler–Maruyama scheme applied to both SDEs and SFDEs is 1 (see [8, 16]). Noting that $\tilde{c}_i(l)(i=1,2)$ appeared in (5.5) will tend to infinity as $l \to \infty$, we cannot simply let $l \to \infty$ to show that the order of the convergence is 1. It remains open whether the order of the convergence is 1 in the case of NSFDEs.

We would also like to point out that although we concentrate on the convergence in mean square (namely, in L^2), our methods can easily be extended to establish the strong convergence in L^p for any $p \ge 2$. In particular, under the global Lipschitz condition, we can show that the order of the strong convergence in L^p is $p/2-\varepsilon$ for any $\varepsilon > 0$.

Acknowledgments. The authors would like to thank the Chinese Scholarship Council for its financial support. They also wish to thank the referees for their detailed comments and helpful suggestions.

ENERGY-CONSERVING ALGORITHMS FOR A COROTATIONAL FORMULATION*

J. SALOMON†, A. A. WEISS†, AND B. I. WOHLMUTH†

Abstract. Standard nonlinear schemes for the the simulation of elastodynamic problems have several shortcomings when considering high-speed rotations. To tackle these problems, we use a corotational framework and a corresponding specific linearization to design new energy-conserving numerical schemes. In the two-dimensional case, an algorithm preserving also angular momentum is presented. The existence of a solution for the fully discrete setting of this algorithm is established. Numerical results illustrate the flexibility and efficiency of the proposed algorithms.

Key words. elastodynamic, corotational formulation, energy-conservative schemes, large displacements, small strains

DOI. 10.1137/060669863

1. Introduction.

The time discretization of elastodynamic problems involving large rotations and translations is a well-known challenge in the simulation of continuum mechanics. Usually, geometrically nonlinear strain measures such as Green–Lagrange strains are applied to tackle this kind of problem. The resulting nonlinear equation requires iterative solvers which can be very costly, for example when considering high-speed rotation in combination with large time steps. Moreover, such methods show unsatisfying numerical results in these cases as the global motion is not reproduced correctly and spurious oscillations can be observed.

In order to accelerate the computations, one can use the framework of linear elasticity, i.e., linearize the evolution equation with respect to parameters associated with the displacements of the body. However, this kind of linearization does not show satisfying results for rotating bodies. In particular, rigid body rotations wrongly contribute to the elastic energy as the small deformation assumption is not fulfilled anymore.

As a remedy, the motion can be split into a rigid body motion and a purely elastic effective deformation. This idea was initially introduced in [10] to trace the global motion of elastic bodies in the context of aircraft and spacecraft dynamics. Then, the approach was put in an abstract framework by Fraejis de Veubeke [20], where different criteria were presented to guarantee the uniqueness of the decomposition. Nowadays, this idea is often used by the engineering community where it is referred to as "corotational formulation." In this paper, we use this splitting to carry out the linearization with respect to the effective displacements. To this end, we make use of the Fraejis de Veubeke's criterion and choose the corotational decomposition that minimizes the L^2-norm of the effective displacements. The well-posedness of the associated system has been proved recently in [23, 24].

The problem of handling large rotations in the Lagrangian kinematic description of continuum mechanics has spawned several publications, e.g., [1, 2, 3, 25]. The application of the splitting of the deformation in combination with finite elements was introduced by Wempner [37] and Belytschko and Hsieh [7]. In the engineering literature, the term "corotational finite elements" was established for this method starting with [5, 6] where the splitting was used for each element, resulting in additional degrees of freedom per element. Some developments of this approach were presented in [17, 18, 34, 36]. The method was improved by defining a corotated frame per element [8, 9]; see also the overview [27]. Crisfield [12, 13] developed the concept of consistent linearization in the corotational formulation. Nour-Omid and Rankin [26], Rankin and Brognan [32], and Rankin and Nour-Omid [33] finally invented the element-independent corotational formulation, where projectors were used to separate the total deformation. Recently, the corotational formulation has been used for control and regulation [4, 28], sensitivity analysis [29, 30, 31], and modern solution techniques for large-scale simulations [15, 16]. For a more exhaustive overview of the development of the corotational formulation, we refer the reader to [19]. However, the design of suitable time integration methods for the corotational framework is still an open question; see topic E of section 7 in [19].

An important property of a suitable time discretization is the conservation of energy and angular momentum. For standard schemes, one can proceed using the discrete energy momentum method by Simo and Tarnow; see [35] or similar variants, e.g., [22]. This method has also been successfully adapted to the corotational framework for special finite element models; see [14, 21]. However, conservation of the angular momentum is not always guaranteed and the effect of linearizations with respect to effective deformations has not been considered so far.

In this paper, we show how the linearization induced by a corotational formulation enables us to design a new energy-conserving time discretization of elastodynamic problems in two and three dimensions. In two dimensions, one of our algorithms also preserves the angular momentum. The existence of a solution for the fully discrete setting is established in this case. In the other cases, the angular momentum is asymptotically preserved and a priori estimates are obtained. These new algorithms are compared to standard algorithms used in the simulation of elastodynamics involving large rigid body motion.

Our new schemes are quite attractive from the computational point of view and show high accuracy in the case of large rigid body motions. Moreover, the approach can be easily extended to nonlinear strain measures and nonlinear material laws. Numerical simulations indicate that the resulting algorithms are almost as efficient as the linearized version.

Though most of the concepts presented in this paper hold for both two and three dimensions, we focus on the two-dimensional (2D) case for simplicity. However, the necessary adaptations to the three-dimensional (3D) case are presented together with a 3D version of one of our algorithms.

The rest of the paper is organized as follows. In section 2, we derive the 2D model and present the continuous linearized system of equations describing the evolution of the system. We state two time-discretized energy conservative algorithms in section 3. In section 4, the space discretization on a constrained space and the existence of a solution is discussed. In section 5, we extend one of our algorithms to the 3D case. Finally, in section 6, we show the efficiency and flexibility of our approach by means of various numerical tests.

2. Problem setting. Throughout this paper, we use the notation

$$\dot{a}(x,t) := \frac{\partial}{\partial t} a(x,t), \quad \ddot{a}(x,t) := \frac{\partial^2}{\partial t^2} a(x,t).$$

Given a matrix A, we denote by $A^\top$ its transposed and by $\operatorname{tr}(A)$ its trace. The identity matrix of $\mathbb{R}^2$ is denoted by I and R_θ represents the rotation of θ, $R_\theta := \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$. The matrix Π is defined by $\Pi := R_{\frac{\pi}{2}} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ and $A : B := \operatorname{tr}(A^\top B)$ is the usual matrix scalar product. We note that using this notation the derivative of the rotation matrix reads $\frac{d}{d\theta} R_\theta = \Pi R_\theta$.

2.1. Nonlinear evolution equation. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with a piecewise sufficiently smooth boundary $\Gamma := \partial\Omega$ describing an elastic body with mass density $\rho(x)$. The coordinate system is chosen such that the center of gravity has the coordinates $(0,0)$, i.e., $\int_\Omega \rho x = 0$. The body is subject to some volume forces $f(x,t)$ and boundary tractions $g(x,t)$. Let $\varphi : \Omega \times [0,T] \to \mathbb{R}^2$ be the deformation mapping. In the fully nonlinear setting, the evolution of φ is described by the weak form of the equilibrium condition [11],

$$\int_\Omega \rho \ddot{\varphi} \cdot \eta + \int_\Omega \frac{\partial}{\partial E} W\big(E(d)\big) : F^\top \nabla \eta = \int_\Omega f \cdot \eta + \int_\Gamma g \cdot \eta, \tag{2.1}$$

where η is a function in $V := [H^1(\Omega)]^2$, $d := \varphi - x$, and $F := \nabla\varphi = I + \nabla d$ is the deformation gradient. The so-called Green–Lagrange strain is given by

$$E(d) := \frac{1}{2}(\nabla d + \nabla d^\top + \nabla d^\top \nabla d). \tag{2.2}$$

We assume a Saint Venant–Kirchhoff material model where the stored energy $W\big(E(d)\big)$ is calculated from

$$W\big(E(d)\big) := \frac{\lambda}{2} \left(\operatorname{tr}\big(E(d)\big)\right)^2 + \mu \operatorname{tr}\big(E(d)^2\big),$$

with Lamé parameters λ and μ. For this linear material model, the second Piola–Kirchhoff stress tensor $\Sigma(d) := \frac{\partial}{\partial E} W\big(E(d)\big)$ reads

$$\Sigma(d) = 2\mu E(d) + \lambda \operatorname{tr} E(d) I.$$

Energy- and momentum-conserving time integration schemes for this setting are well-known; see, e.g., [35]. However, when considering high-speed rotation in combination with large timesteps, these standard time integration schemes show poor accuracy: In this case, the rotation speed is not reproduced correctly which results in a wrong solution; see section 6.1.

2.2. Corotational decomposition of the motion. As a remedy, the corotational formulation proposes to work with effective displacements in smaller spaces by removing the large rigid body component of the displacements involved in the elastic term of (2.1). The deformation is decomposed as follows [24]:

$$\varphi(x,t) = \tau(t) + R_{\theta(t)}\big(x + u(x,t)\big). \tag{2.3}$$

In this equation, $\tau(t) \in \mathbb{R}^2$ describes the rigid body translation of the body and R_θ its rigid body rotation. After this change of variable, the effective displacements are described by u. An important property of the decomposition (2.3) is that

$$E\big(d\big) = E\big(u\big), \tag{2.4}$$

which shows that the nonlinear model correctly cancels the rigid body motion appearing in φ. In order to define a unique triple (τ, θ, u) and to work with small effective displacements, we consider the decomposition that minimizes the weighted L^2-norm of u, $\int_\Omega \rho u^2$; see [20]. A straightforward computation shows that if $\int_\Omega \rho(x+u)\cdot x \neq 0$, the minimization condition for u is equivalent to (see [23, 24])

$$\int_\Omega \rho u = 0, \quad \int_\Omega \rho u \cdot \Pi x = 0. \tag{2.5}$$

We note that the first condition results from the translation and the second condition from the rotation term. Thus, we are looking for the effective displacements u in the linear space $X := X^{\mathrm{trans}} \cap X^{\mathrm{rot}}$ defined by

$$X^{\mathrm{trans}} := \left\{ u \in V;\ \int_\Omega \rho u = 0 \right\}, \quad X^{\mathrm{rot}} := \left\{ u \in V;\ \int_\Omega \rho u \cdot \Pi x = 0 \right\}.$$

Let us now consider the effects of this change of variable on (2.1).
We start with the elastic term of (2.1). Defining $\hat{F} := I + \nabla u$, we have, thanks to (2.4),

$$\int_\Omega \frac{\partial}{\partial E} W\big(E(d)\big) : F^\top \nabla \eta = \int_\Omega \frac{\partial}{\partial E} W\big(E(u)\big) : \hat{F}^\top R_\theta^\top \nabla \eta = \int_\Omega \Sigma(u) : \hat{F}^\top R_\theta^\top \nabla \eta. \tag{2.6}$$

The inertial term of (2.1) can also be rewritten in this new setting. To this end, we define the relative velocity by

$$s(x,t) := R_{\theta(t)}^\top \big(\dot{\varphi}(x,t) - \dot{\tau}(t)\big) = \dot{u}(x,t) + \dot{\theta}(t)\Pi\big(x + u(x,t)\big). \tag{2.7}$$

The acceleration term can then be expressed by

$$\ddot{\varphi}(x,t) = \ddot{\tau}(t) + R_{\theta(t)} \left(\dot{s}(x,t) + \dot{\theta}(t)\Pi s(x,t) \right). \tag{2.8}$$

Using this representation of $\ddot{\varphi}$ and reducing the test space to X, (2.1) now reads

$$\int_\Omega \rho \left(\dot{s} + \dot{\theta}\Pi s \right) \cdot v + \int_\Omega \Sigma(u) : \hat{F}^\top \nabla v = B_\theta(v) \quad \forall v \in X, \tag{2.9}$$

where we have set $v = R_\theta^\top \eta$ and

$$B_\theta(v) := \int_\Omega f \cdot R_\theta v + \int_\Gamma g \cdot R_\theta v. \tag{2.10}$$

We note that the term $\int_\Omega \ddot{\tau} \cdot R_\theta v$ cancels because $R_\theta v \in X^{\mathrm{trans}}$. To compensate this reduction of the test space, additional constraints have to be imposed which are then used to determine the correct values of θ and τ. Thus, in addition to (2.9), we require that the linear and angular momentum are preserved. To obtain the corresponding conditions, we formally test (2.9) with $v^1_{\mathrm{trans}} = R_\theta^\top (0,1)^\top$, $v^2_{\mathrm{trans}} = R_\theta^\top (1,0)^\top$, and $v_{\mathrm{rot}} = \Pi(x+u)$, respectively, to get the linear and angular momentum equations. Using $u \in X^{\mathrm{trans}}$, this gives the conservation of the linear momentum,

$$\mathcal{M}\ddot{\tau} = \int_\Omega f + \int_\Gamma g, \tag{2.11}$$

and the conservation of the angular momentum,

$$\dot{\mathcal{J}} = B_\theta(\Pi(x+u)), \tag{2.12}$$

where $\mathcal{M}$ and $\mathcal{J}$ are defined by

$$\mathcal{M} := \int_\Omega \rho, \quad \mathcal{J} := \int_\Omega \rho s \cdot \Pi(x+u).$$

2.3. Linearization of the elastic term. In order to accelerate the computation or when considering numerical methods to solve (2.9), some additional linearization can be introduced. For small effective displacements u, the strain relationship can be linearized. Using the following approximation of (2.2):

$$E(u) \approx \varepsilon(u) := \frac{1}{2}(\nabla u + \nabla u^\top),$$

and $\hat{F} \approx I$, the equilibrium equation (2.9) becomes linear with respect to u,

$$\int_\Omega \rho \left(\dot{s} + \dot{\theta}\Pi s\right) \cdot v + \int_\Omega \sigma(u) : \nabla v = B_\theta(v), \tag{2.13}$$

where $\sigma(u) := 2\mu\varepsilon(u) + \lambda \operatorname{tr} \varepsilon(u) I$.

We will consider the nonlinear models (2.1) and (2.9) as a reference to measure the efficiency of our algorithms.

Let us now introduce the space Y defined by

$$Y := \left\{ u \in X;\ \int_\Omega \rho(x+u) \cdot x > 0 \right\}.$$

In a recent paper [23] (see also [24]), Grandmont, Maday, and Metier have obtained the following existence result concerning the system (2.11)–(2.13).

THEOREM 2.1. *Let τ_0, $\dot{\tau}_0$ be given in $\mathbb{R}^2$, θ_0, $\dot{\theta}_0$ be real numbers, $u_0 \in Y, \dot{u}_0 \in L^2(\Omega)$, $f \in L^2_{loc}(0,+\infty; L^2(\Omega))$, and $g \in H^1_{loc}(0,+\infty; H^{-\frac{1}{2}}(\Gamma)) \cap L^2_{loc}(0,+\infty; L^1(\Gamma))$. There exists $T^\star > 0$ such that for all $T < T^\star$ there exists a unique triplet (τ, θ, u) with $\tau \in H^2(0,T)$, $\theta \in H^2(0,T)$, $u \in H^2(0,T; (H^1(\Omega))') \cap W^{1,\infty}(0,T; L^2(\Omega)) \cap L^\infty(0,T; H^1(\Omega))$, and $u \in \mathcal{C}^0([0,T]; Y)$ satisfying*

$$\begin{cases} \mathcal{M}\ddot{\tau} = \displaystyle\int_\Omega f + \int_\Gamma g \text{ in } L^2(0,T), \\ \dot{\mathcal{J}} = B_\theta(\Pi(x+u)) \text{ in } \mathcal{D}'(0,T), \\ \forall v \in X, \displaystyle\int_\Omega \rho \left(\dot{s} + \dot{\theta}\Pi s\right) \cdot v + \sigma(u) : \varepsilon(v) = B_\theta(v) \text{ in } \mathcal{D}'(0,T), \end{cases} \tag{2.14}$$

where s is defined by (2.7) together with $\tau(0) = \tau_0$, $\dot{\tau}(0) = \dot{\tau}_0$, $\theta(0) = \theta_0$, $\dot{\theta}(0) = \dot{\theta}_0$, $u(0) = u_0$, $\dot{u}(0) = \dot{u}_0$.

Moreover, the following alternative holds:

- $T^\star = +\infty$ *or*
- $\lim_{t \to T^\star} \int_\Omega \rho(x+u) \cdot x = 0$.

3. Energy conservative algorithms. We now present our energy conservative algorithms which are based on two different time discretizations of (2.14). The first one guarantees the conservation of the energy, but not of the angular momentum. Next, an alternative scheme is presented that preserves both quantities. We briefly outline the strategies we have followed to design our algorithms. Denoting by $\frac{d}{dt}$ the time derivation operator, we find in terms of (2.7) and (2.8),

$$R_\theta^\top(\ddot{\varphi}-\ddot{\tau}) = \left(\frac{d}{dt}+\dot{\theta}\Pi\right)s \tag{3.1}$$

$$= \left(\frac{d}{dt}+\dot{\theta}\Pi\right)^2(x+u)$$

$$= \ddot{u}+\Pi\left(\frac{d}{dt}(\dot{\theta}u)+\dot{\theta}\dot{u}\right)-(\dot{\theta})^2(x+u). \tag{3.2}$$

The first algorithm is now obtained by discretizing each term of (3.2). In the second algorithm, we first discretize $s = (\frac{d}{dt}+\dot{\theta}\Pi)(x+u)$ (see (3.16)) and then discretize $R_\theta^\top(\ddot{\varphi}-\ddot{\tau})$ via (3.1) (see the first term of (3.15)).

3.1. Midpoint time discretization and discrete setting. Let us denote the timestep by Δt and the time index by n with $t_n := n\Delta t$. We use a midpoint time discretization which has the property

$$\dot{a}_{n+1/2}b_{n+1/2}+a_{n+1/2}\dot{b}_{n+1/2} = [\dot{ab}]_{n+1/2}, \tag{3.3}$$

where we have used the following notations for a generic time-discretized quantity $\star$:

$$\star_{n+1/2} := \frac{\star_{n+1}+\star_n}{2}, \quad \dot{\star}_{n+1/2} := \frac{\star_{n+1}-\star_n}{\Delta t}. \tag{3.4}$$

Let us also define the total energy of the linearized system at time t_n by

$$\mathcal{E}_n := \frac{1}{2}\mathcal{M}\dot{\tau}_n^2+\frac{1}{2}\int_\Omega \rho s_n^2+\frac{1}{2}\int_\Omega \sigma(u_n):\varepsilon(u_n). \tag{3.5}$$

The angular momentum is given by

$$\mathcal{J}_n := \int_\Omega \rho s_n\cdot\Pi(x+u_n). \tag{3.6}$$

Here s_n is a time discretization of (2.7), depending on the algorithm under consideration.

Note that without linearization of the strain term, the energy corresponding to (2.9) is defined by

$$\mathcal{E}_n^{nl} := \frac{1}{2}\mathcal{M}\dot{\tau}_n^2+\frac{1}{2}\int_\Omega \rho s_n^2+\frac{1}{2}\int_\Omega \Sigma(u_n):E(u_n), \tag{3.7}$$

which coincides with (3.5) when neglecting terms of second order with respect to ∇u_n. Finally, we discretize B_θ at time $t_{n+1/2}$ by

$$B_{n+1/2}(v) := \int_\Omega f_{n+1/2}\cdot R_{\theta_{n+1/2}}v+\int_\Gamma g_{n+1/2}\cdot R_{\theta_{n+1/2}}v.$$

3.2. Algorithm I. A time discretization of (2.14) can be done in terms of (3.2). Special care has to be taken about the energy conservation property. To this end, we choose suitable approximations, for example $(\dot\theta(t_{n+1/2}))^2 \approx \dot\theta_n\dot\theta_{n+1}$.

Algorithm I then reads: Let τ_0, $\dot\tau_0$, θ_0, $\dot\theta_0$, u_0, as well as the external forces $(f_{n+1/2})_{n\in\mathbb{N}}$ and $(g_{n+1/2})_{n\in\mathbb{N}}$ be given, and suppose that $\tau_n, \dot\tau_n, \theta_n, \dot\theta_n$ and $u_n, \dot u_n \in X$ have already been computed. The derivation of $\tau_{n+1}, \dot\tau_{n+1}$, $\theta_{n+1}, \dot\theta_{n+1}$ and u_{n+1}, $\dot u_{n+1} \in X$ is carried out by solving

$$\mathcal{M}\ddot\tau_{n+1/2} = \int_\Omega f_{n+1/2} + \int_\Gamma g_{n+1/2}, \tag{3.8}$$

$$\begin{aligned}\frac{1}{\Delta t}\left(\int_\Omega \rho\dot\theta_{n+1}(x+u_{n+1})^2 - \int_\Omega \rho\dot\theta_n(x+u_n)^2\right) + \int_\Omega \rho\Pi\frac{\dot\theta_{n+1}u_{n+1}+\dot\theta_n u_n}{2\dot\theta_{n+1/2}}\cdot\ddot u_{n+1/2}\\ = B_{n+1/2}(\Pi(x+u_{n+1/2})),\end{aligned} \tag{3.9}$$

$$\begin{aligned}\int_\Omega \rho\left(\ddot u_{n+1/2} + \Pi\frac{\dot\theta_{n+1}u_{n+1}-\dot\theta_n u_n}{\Delta t} + \Pi\dot\theta_{n+1/2}\dot u_{n+1/2} - \dot\theta_n\dot\theta_{n+1}(x+u_{n+1/2})\right)\cdot v\\ + \int_\Omega \sigma(u_{n+1/2}):\varepsilon(v) = B_{n+1/2}(v) \quad \forall v\in X.\end{aligned} \tag{3.10}$$

Equations (3.8)–(3.10) correspond to the three equations of (2.14). We refer the reader to section 4 for details about how to guarantee that $u_{n+1} \in X$.

We note that using the discretized relative velocity

$$s_n := \dot u_n + \dot\theta_n\Pi(x+u_n), \tag{3.11}$$

and the fact that $u_n, \dot u_n \in X$, the angular momentum $\mathcal{J}_n$ can be written as

$$\mathcal{J}_n = \int_\Omega \rho s_n\cdot\Pi(x+u_n) = \dot\theta_n\int_\Omega \rho(x+u_n)^2 + \int_\Omega \rho\dot u_n\cdot\Pi u_n.$$

This quantity is not preserved exactly by Algorithm I because of the third term of the left-hand side of (3.9). It is, however, possible to specify the local order with respect to Δt. Indeed, we have

$$\mathcal{J}_{n+1} - \mathcal{J}_n - \Delta t B_{n+1/2}\big(\Pi(x+u_{n+1/2})\big) = \frac{\Delta t^2}{4}\frac{\ddot\theta_{n+1/2}}{\dot\theta_{n+1/2}}\Pi\dot u_{n+1/2}\cdot\ddot u_{n+1/2}. \tag{3.12}$$

Although the momentum is asymptotically preserved if Δt tends to zero, we observe that local oscillations occur; see Figure 6.11. This motivates the introduction of Algorithm II.

3.3. Algorithm II. We now describe a time discretization of (2.14) that preserves both the energy and the angular momentum.

Let τ_0, $\dot\tau_0$, θ_0, u_0, s_0, the external forces $(f_{n+1/2})_{n\in\mathbb{N}}$, and $(g_{n+1/2})_{n\in\mathbb{N}}$ be given, and suppose that τ_n, $\dot\tau_n$, θ_n, $u_n \in X$ and s_n have already been computed. The derivation of $\tau_{n+1}, \dot\tau_{n+1}$, θ_{n+1}, $u_{n+1} \in X$ and $s_{n+1} \in V$ is carried out by solving

$$\mathcal{M}\ddot\tau_{n+1/2} = \int_\Omega f_{n+1/2} + \int_\Gamma g_{n+1/2}, \tag{3.13}$$

$$\dot{\mathcal{J}}_{n+1/2} = B_{n+1/2}\big(\Pi(x+u_{n+1/2})\big), \tag{3.14}$$

$$G(\dot s_{n+1/2}, s_{n+1/2}, \dot\theta_{n+1/2}, u_{n+1/2}; v) = B_{n+1/2}(v) \quad \forall v\in X, \tag{3.15}$$

with

$$G(\dot{s}, s, \dot{\theta}, u; v) := \int_\Omega \rho(\dot{s} + \dot{\theta}\Pi s) \cdot v + \int_\Omega \sigma(u) : \varepsilon(v)$$

and

$$s_{n+1/2} := \dot{u}_{n+1/2} + \dot{\theta}_{n+1/2}\Pi\big(x + u_{n+1/2}\big). \tag{3.16}$$

Equations (3.13)–(3.15) correspond to the three equations of (2.14). Equation (3.14) guarantees that the angular momentum is preserved by this algorithm.

Remark. We note that the time discretization of the auxiliary variable s is done at the timestep n (see (3.11)) in Algorithm I and at the staggered timestep $(n+1/2)$ (see (3.16)) in Algorithm II. Moreover, given a parameter $\star$ and denoting by $\star^I$ and $\star^{II}$ its time discretizations in Algorithms I and II, respectively, we have that

$$s^I_{n+1/2} = s^{II}_{n+1/2} + \frac{\Delta t^2}{4}\ddot{\theta}^{II}_{n+1/2}\Pi\dot{u}^{II}_{n+1/2}.$$

3.4. Energy conservation. Let us state the main property of our algorithms.

THEOREM 3.1. *Algorithms* I *and* II *defined by* (3.8)–(3.10) *and* (3.13)–(3.15), *respectively, guarantee the energy conservation in the sense that*

$$\mathcal{E}_{n+1} - \mathcal{E}_n = \Delta t\Big(\int_\Omega f_{n+1/2} \cdot \dot{\varphi}_{n+1/2} + \int_\Gamma g_{n+1/2} \cdot \dot{\varphi}_{n+1/2}\Big).$$

Here, $\mathcal{E}_n$ is the total energy defined by (3.5) *where s is defined by* (3.11) *when considering Algorithm* I *and by* (3.16) *when considering Algorithm* II. *The time discretization of $\dot{\varphi}$ is done by*

$$\dot{\varphi}_{n+1/2} := \dot{\tau}_{n+1/2} + R_{\theta_{n+1/2}} s_{n+1/2}.$$

Proof. We give only the proof for the case of Algorithm II, since the one corresponding to Algorithm I can be obtained in a similar way.

Testing (3.15) with $v = \dot{u}_{n+1/2}$, we obtain

$$\int_\Omega \rho(\dot{s}_{n+1/2} + \dot{\theta}_{n+1/2}\Pi s_{n+1/2}) \cdot \dot{u}_{n+1/2} + \int_\Omega \sigma(u_{n+1/2}) : \varepsilon(\dot{u}_{n+1/2}) = B_{n+1/2}(\dot{u}_{n+1/2}). \tag{3.17}$$

On the other hand, using (3.3), (3.14) reads

$$\int_\Omega \rho\dot{s}_{n+1/2} \cdot \Pi(x + u_{n+1/2}) + \int_\Omega \rho s_{n+1/2} \cdot \Pi\dot{u}_{n+1/2} = B_{n+1/2}\big(\Pi(x + u_{n+1/2})\big). \tag{3.18}$$

Multiplying (3.18) by $\Delta t\dot{\theta}_{n+1/2}$ and (3.17) by Δt and adding the two resulting equations, we get by means of (3.16),

$$\begin{aligned}\Delta t \int_\Omega \rho\dot{s}_{n+1/2} \cdot \big(\dot{u}_{n+1/2} + \dot{\theta}_{n+1/2}\Pi(x + u_{n+1/2})\big) + \Delta t \int_\Omega \sigma(u_{n+1/2}) : \varepsilon(\dot{u}_{n+1/2}) \\ = \frac{1}{2}\left(\int_\Omega \rho s^2_{n+1} + \sigma(u_{n+1}) : \varepsilon(u_{n+1}) - \int_\Omega \rho s^2_n + \sigma(u_n) : \varepsilon(u_n)\right),\end{aligned}$$

and thus

(3.19)

$$\frac{1}{2}\left(\int_\Omega \rho s_{n+1}^2 + \sigma(u_{n+1}) : \varepsilon(u_{n+1}) - \int_\Omega \rho s_n^2 + \sigma(u_n) : \varepsilon(u_n)\right) = \Delta t B_{n+1/2}(s_{n+1/2}).$$

Using (3.13), we end up with

$$\frac{1}{2}\mathcal{M}\dot{\tau}_{n+1}^2 - \frac{1}{2}\mathcal{M}\dot{\tau}_n^2 = \Delta t\left(\int_\Omega f_{n+1/2}\cdot\dot{\tau}_{n+1/2} + \int_\Gamma g_{n+1/2}\cdot\dot{\tau}_{n+1/2}\right),$$

which yields the energy conservation in combination with (3.19). ∎

In contrast to Algorithm I(see (3.12)), Algorithm II preserves the angular momentum; thanks to (3.14), we have

$$\mathcal{J}_{n+1} - \mathcal{J}_n - \Delta t B_{n+1/2}\big(\Pi(x+u_{n+1/2})\big) = 0. \tag{3.20}$$

4. Space discretization. In this section, we present a suitable space discretization for the time-discretized systems. We focus on (3.15), although the same method can be used for the discretization of (3.10). The space X motivates the use of a Galerkin method based on the spectral decomposition of the operator $-\mathrm{div}(\sigma(\cdot))$. Indeed, we note that X is spanned by the eigenvectors with nonzero eigenvalue and is orthogonal (in the sense of the $L^2(\Omega)$ scalar product) on the kernel of this operator.

Unfortunately, finite elements do not fit into this setting. We observe that the conditions (2.5) are not satisfied by nodal finite element basis functions. The orthogonal projection of these basis functions onto the space X leads to a nonlocal support of the finite element basis and additional computational costs. We therefore use a Lagrange multiplier approach to guarantee (2.5) and state the problem in a saddle point framework. For this fully discretized setting, we show the existence of a solution of (3.13)–(3.15).

4.1. Finite element approximation of the space X. We assume that the domain Ω is resolved by a mesh consisting of quadrilaterals and/or triangles. We use a conforming finite element space of lowest order, denoting the nodal basis functions by ϕ_i and the finite element space by V_h. The mass matrix is referred to by M, $M_{ij} := \int_\Omega \rho\phi_i\cdot\phi_j$, and the stiffness matrix for linear elasticity by S, $S_{ij} := \int_\Omega \sigma(\phi_i) : \varepsilon(\phi_j)$. The subspace X_h of X is defined by $X_h := X \cap V_h$.

To guarantee that $u \in V_h$ is also in X_h, i.e., satisfies (2.5), we introduce two Lagrange multipliers $\alpha \in \mathbb{R}$ and $\beta \in \mathbb{R}^2$ and rewrite (3.15) as

$$\begin{aligned} G(\dot{s}_{n+1/2}, s_{n+1/2}, \dot{\theta}_{n+1/2}, u_{n+1/2}; v) + \alpha\int_\Omega \rho v\cdot\Pi x + \int_\Omega \rho\beta\cdot v &= B_{n+1/2}(v)\ \forall v\in V_h,\\ \int_\Omega \rho u_{n+1/2}\cdot\Pi x &= 0,\\ \int_\Omega \rho u_{n+1/2} &= 0. \end{aligned} \tag{4.1}$$

The Lagrange multiplier β can be eliminated by static condensation as follows. First, we recall that $s_n, u_n, u_{n+1/2} \in X^{\mathrm{trans}}$, implying $\int_\Omega \rho\Pi u_{n+1/2} = \Pi\int_\Omega \rho u_{n+1/2} = 0$. Therefore $\Pi u_{n+1/2} \in X^{\mathrm{trans}}$ and thus $s_{n+1/2}, \dot{s}_{n+1/2} \in X^{\mathrm{trans}}$. Using a constant

$v \in V_h$, we have $\varepsilon(v) = 0$ and therefore $G(\dot{s}_{n+1/2}, s_{n+1/2}, \dot{\theta}_{n+1/2}, u_{n+1/2}; v) = 0$. We use $v^1 = (1,0)^\top$ and $v^2 = (0,1)^\top$, respectively, in (4.1) and finally obtain

$$\beta = \frac{1}{\mathcal{M}} \left(\int_\Omega R^\top_{\theta_{n+1/2}} f_{n+1/2} + \int_\Gamma R^\top_{\theta_{n+1/2}} g_{n+1/2} \right) = R^\top_{\theta_{n+1/2}} \ddot{\tau}_{n+1/2}. \tag{4.2}$$

Inserting (4.2) in (4.1) gives the following system:

$$\begin{aligned} G(\dot{s}_{n+1/2}, s_{n+1/2}, \dot{\theta}_{n+1/2}, u_{n+1/2}; v) + \alpha \int_\Omega \rho v \cdot \Pi x = \tilde{B}_{n+1/2}(v) \quad \forall v \in V_h, \\ \int_\Omega \rho u_{n+1/2} \cdot \Pi x = 0, \end{aligned} \tag{4.3}$$

where $\tilde{B}_{n+1/2}$ is defined by

$$\tilde{B}_{n+1/2}(v) := B_{n+1/2}(v) - \int_\Omega \rho R^\top_{\theta_{n+1/2}} \ddot{\tau}_{n+1/2} \cdot v.$$

We note that the first line of (4.3) ensures $\int_\Omega \rho u_{n+1/2} = 0$, i.e., $u_{n+1/2} \in X^{\text{trans}}$.

We rewrite (4.3) in terms of $u_{n+1/2}$ and obtain the following linear system for the vector of nodal values:

$$\left(\begin{array}{c|c} \tilde{G}(\theta_{n+1} - \theta_n, \Delta t) & M\Pi x \\ \hline (M\Pi x)^\top & 0 \end{array} \right) \cdot \left(\begin{array}{c} u_{n+1/2} \\ \hline \alpha_{n+1/2} \end{array} \right) = \left(\begin{array}{c} \tilde{c}_{n+1/2}(\theta_{n+1} - \theta_n, \Delta t) \\ \hline 0 \end{array} \right), \tag{4.4}$$

where

- $\tilde{G}(\delta, \Delta t) := M\big(2I + \delta\Pi\big)^2 + \Delta t^2 S$,
- $\tilde{c}_{n+1/2}(\delta, \Delta t) := M\big(2I + \delta\Pi\big)(2u_n - \delta\Pi x) + 2M\Delta t s_n + \Delta t^2 \tilde{B}_{n+1/2}$.

We note that we follow the widely applied abuse of notation; i.e., the symbols u_n, $u_{n+1/2}$, s_n, and $\tilde{B}_{n+1/2}$ denote the function or the vector of coefficients of the finite element representation, depending on the situation. We also keep the notation "$\cdot$" for the scalar product in what follows.

Equation (3.14) now reads

$$h(\theta_{n+1} - \theta_n, \Delta t) = 0, \tag{4.5}$$

with

$$\begin{aligned} h(\delta, \Delta t) :&= 4\delta(x + u_{n+1/2}) \cdot M(x + u_{n+1/2}) \\ &\quad + \left(-\delta M(x + u_n) + 2\Delta t M \Pi s_n + \Delta t^2 \Pi R^\top_{\theta_n + \delta/2} \tilde{B}_{n+1/2} \right) \cdot (x + u_{n+1/2}), \end{aligned}$$

where $u_{n+1/2}$ is the solution of (4.4) corresponding to $\theta_{n+1} - \theta_n = \delta$.

4.2. Existence of a solution for the fully discretized algorithm. This section is devoted to the existence of a solution of the fully discretized system associated with Algorithm II.

THEOREM 4.1. *Given $\mathcal{E}_{max} > 0$, $B_{max} > 0$, and $\nu > 0$, suppose that at time t_n we have $\mathcal{E}_n \le \mathcal{E}_{max}$, $\|\tilde{B}_{n+1/2}\| \le B_{max}$, where $\|\cdot\|$ is a given norm on V_h and*

$$\nu \le x \cdot M(x + u_n). \tag{4.6}$$

Then there exists $\Delta t^* > 0$ depending on $\mathcal{E}_{max}$, B_{max}, and ν such that, given $\Delta t \leq \Delta t^*$, τ_n, $\dot{\tau}_n$, θ_n, u_n, and s_n, as well as the external forces $f_{n+1/2}$ and $g_{n+1/2}$, there exists $\theta_{n+1} \in \mathbb{R}$ satisfying (4.5) (with $u_{n+1/2}$ the corresponding solution of (4.4)).
Moreover, there exist $\delta^+(\Delta t)$, $\delta^-(\Delta t)$ such that

- $\lim_{\Delta t \to 0} \delta^+(\Delta t) = 2$,
- $\lim_{\Delta t \to 0} \delta^-(\Delta t) = -2$,
- $\theta_{n+1} \in [\theta_n + \delta^-(\Delta t), \theta_n + \delta^+(\Delta t)]$.

Proof. Given $\Delta t > 0$, $\eta \in]0,1[$, and $\delta \in L := [-2-\eta, 2+\eta]$, we denote by $u(\delta, \Delta t) := u_{n+1/2}$ the solution of (4.4) corresponding to $\theta_{n+1} - \theta_n = \delta$. Since $\tilde{G}(\delta, 0)$ is invertible for $\delta \in L$, there exists Δt_0 (depending only on S) such that $\tilde{G}(\delta, \Delta t)$ is invertible on $L \times [0, \Delta t_0]$. Then, let us define $q(\delta, \Delta t)$ by

$$q(\delta, \Delta t) := \Pi x \cdot \tilde{G}(\delta, \Delta t)^{-1} \Pi x.$$

The inversion of (4.4) provides

$$u(\delta, \Delta t) = \tilde{G}(\delta, \Delta t)^{-1} \left(\tilde{c}_{n+1/2}(\delta, \Delta t) - \frac{1}{q(\delta, \Delta t)} \Big((\Pi x) \cdot \tilde{G}(\delta, \Delta t)^{-1} \tilde{c}_{n+1/2}(\delta, \Delta t) \Big) \Pi x \right).$$

By means of (4.6), we get for $\delta \neq 0$,

$$(\Pi x) \cdot \tilde{G}(\delta, 0)^{-1} \tilde{c}_{n+1/2}(\delta, 0) = -\frac{2\delta}{(4+\delta^2)^2} x \cdot M(x + u_n) \neq 0.$$

There exists $\Delta t_0'$ depending on $\mathcal{E}_{max}$, B_{max}, and ν such that

$$\forall (\delta, \Delta t) \in \{[-2-\eta, -2+\eta] \cup [2-\eta, 2+\eta]\} \times [0, \Delta t_0'],$$
$$(\Pi x) \cdot \tilde{G}(\delta, \Delta t)^{-1} \tilde{c}_{n+1/2}(\delta, \Delta t) \neq 0. \tag{4.7}$$

Let us focus now on the behavior of $q(\cdot, \cdot)$ on $\{[-2-\eta, -2+\eta] \cup [2-\eta, 2+\eta]\} \times [0, \Delta t_0']$. We have

$$q(\delta, 0) = \frac{4 - \delta^2}{(4+\delta^2)^2} x \cdot Mx,$$

such that $q(-2, 0) = q(2, 0) = 0$ and $q(\delta, 0) \neq 0$ for $\delta \neq \pm 2$. Moreover, since

$$\frac{\partial q}{\partial \delta}(\pm 2, 0) = \mp \frac{1}{16} x \cdot Mx \neq 0,$$

the implicit function theorem proves the existence of $\Delta t_0''$ (depending only on S) and two functions δ^+ and δ^- defined on $[0, \Delta t_0'']$ such that

$$\forall \Delta t \in [0, \Delta t_0''], \qquad q\big(\delta^+(\Delta t), \Delta t\big) = 0, \ q\big(\delta^-(\Delta t), \Delta t\big) = 0,$$
$$\lim_{\Delta t \to 0} \delta^-(\Delta t) = -2, \ \lim_{\Delta t \to 0} \delta^+(\Delta t) = 2.$$

We have then proved the existence of two roots of $\delta \mapsto q(\delta, \Delta t)$ in L for all $\Delta t \leq \Delta t_0''$. By decreasing $\Delta t_0''$, these two roots can be guaranteed to be unique: indeed, suppose that there exists a sequence $(\Delta t_n)_{n \in \mathbb{N}}$ of $[0, \Delta t_0'']$ converging towards 0 and $(r_n)_{n \in \mathbb{N}}$ a sequence of roots of $h(\cdot, \Delta t_n)$ such that

$$\forall n \in \mathbb{N}, \quad r_n \neq \delta^+(\Delta t_n), \ r_n \neq \delta^-(\Delta t_n).$$

Since L is compact, we can assume that $(r_n)_{n\in\mathbb{N}}$ is convergent. By continuity of $q(\cdot,\cdot)$, the possible limits are -2 and 2. Suppose, for example, that

$$\lim_{n\to+\infty} r_n = 2;$$

then

$$\lim_{n\to\infty} \frac{q\big(\delta^+(\Delta t_n),\Delta t_n\big) - q(r_n,\Delta t_n)}{\delta^+(\Delta t_n) - r_n} = 0 = \frac{\partial q}{\partial \delta}(2,0) \neq 0,$$

which gives a contradiction. The case $\lim_{n\to+\infty} r_n = -2$ is treated similarly.

Thanks to (4.7), we obtain that for $\Delta t \leq \Delta t^* := \min(\Delta t_0, \Delta t_0', \Delta t_0'')$, the function $\phi : \delta \mapsto u(\delta,\Delta t)\cdot Mu(\delta,\Delta t)$ satisfies

- ϕ is continuous on $L - \{\delta^-(\Delta t), \delta^+(\Delta t)\}$,
- $\lim_{\delta\to\delta^-(\Delta t)} \phi(\delta) = \lim_{\delta\to\delta^+(\Delta t)} \phi(\delta) = +\infty$.

Since $h(\delta,\Delta t) = 4\delta\phi(\delta) + a_{n+1/2}(\delta).u(\delta,\Delta t) + b_{n+1/2}(\delta)$, where $a_{n+1/2}$ and $b_{n+1/2}$ are bounded on L, the existence of θ_{n+1} follows. □

Remark. Note that the hypothesis (4.6) is the discretized version of the one of Theorem 2.1 and relies on the fact that the model is valid only for motions close to the rigid body motion, whereas the hypothesis on the parameters B_{max} and $\mathcal{E}_{max}$ stem from the discretization.

5. Extension to the 3D case. This section is devoted to the extension of Algorithm II to the 3D case. Here the rotation is parameterized by a vector. As a consequence, Algorithm I cannot be extended to three dimensions since it strongly relies on the scalar nature of the angular parameter; see, e.g., (3.9).

The subset Ω is now a domain in $\mathbb{R}^3$. We denote by $\times$ the cross product defined by

$$\begin{pmatrix} a \\ b \\ c \end{pmatrix} \times \begin{pmatrix} a' \\ b' \\ c' \end{pmatrix} := \begin{pmatrix} bc' - b'c \\ a'c - ac' \\ ab' - a'b \end{pmatrix}.$$

5.1. Parameterization of 3D rotations. The major problem met when extending Algorithm II to three dimensions is to parameterize the rotation corresponding to the previous R_θ. We choose to describe it by using the Euler angles and refer the reader to Appendix A of [19] for a review on other parameterizations. We remark that the representation of a rotation with respect to Euler angles is not unique. Given $\theta \in \mathbb{R}$, let us introduce the rotation matrices R^1_θ, R^2_θ, and R^3_θ given by

$$R^1_\theta := \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{pmatrix},\ R^2_\theta := \begin{pmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{pmatrix},$$

$$R^3_\theta := \begin{pmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

We also define for $i = 1,2,3$ the matrices $\Pi^i := \frac{1}{2}\big(R^i_{\frac{\pi}{2}} - R^i_{-\frac{\pi}{2}}\big)$.

Consider now $\boldsymbol{\theta} = (\theta_1,\theta_2,\theta_3) \in \mathbb{R}^3$. We can express a general 3D rotation matrix $R_{\boldsymbol{\theta}}$ as follows:

$$R_{\boldsymbol{\theta}} := R^1_{\theta_1} R^2_{\theta_2} R^3_{\theta_3}.$$

For $\boldsymbol{\theta}$ depending on the time variable t, the derivative of $R_{\boldsymbol{\theta}}$ reads

$$\dot{R}_{\boldsymbol{\theta}} = R_{\boldsymbol{\theta}} \Theta^{\boldsymbol{\theta}}(t),$$

where $\Theta^{\boldsymbol{\theta}}(t)$ is the skew-symmetric matrix defined by

(5.1)
$$\Theta^{\boldsymbol{\theta}}(t) := \dot{\theta}_1(t)(R^3_{\theta_3(t)})^\top (R^2_{\theta_2(t)})^\top \Pi^1 R^3_{\theta_3(t)} R^2_{\theta_2(t)} + \dot{\theta}_2(t)(R^3_{\theta_3(t)})^\top \Pi^2 R^3_{\theta_3(t)} + \dot{\theta}_3(t)\Pi^3.$$

Note that $\Theta^{\boldsymbol{\theta}}(t)$ depends on both $\boldsymbol{\theta}(t)$ and $\dot{\boldsymbol{\theta}}(t)$.

5.2. Corotational model. Before considering the system of evolution equations, we introduce the space $\widetilde{X} = \widetilde{X}^{\mathrm{trans}} \cap \widetilde{X}^{\mathrm{rot}}$, defined by

$$\widetilde{X}^{\mathrm{trans}} := \left\{ u \in \widetilde{V};\ \int_\Omega \rho u = 0 \right\}, \quad \widetilde{X}^{\mathrm{rot}} := \left\{ u \in \widetilde{V};\ \int_\Omega \rho u \times x = 0 \right\},$$

where $\widetilde{V} := [H^1(\Omega)]^3$.

Let us now look at the time derivatives of the deformation φ. As for the 2D case, we decompose φ into

$$\varphi(x,t) = \tau(t) + R_{\boldsymbol{\theta}}(t)(x + u(x,t)),$$

with $\tau(t) \in \mathbb{R}^3$ and $u \in \widetilde{X}$.

Introducing the relative velocity s defined by

$$s(x,t) := \dot{u}(x,t) + \Theta^{\boldsymbol{\theta}}(t)\big(x + u(x,t)\big),$$

we obtain

$$\dot{\varphi}(x,t) = \dot{\tau}(t) + R_{\boldsymbol{\theta}(t)} s(x,t)$$

and

$$\ddot{\varphi}(x,t) = \ddot{\tau}(t) + R_{\boldsymbol{\theta}(t)} \Big(\dot{s}(x,t) + \Theta^{\boldsymbol{\theta}}(t) s(x,t) \Big).$$

The angular momentum is given by

$$\mathcal{J} := R_{\boldsymbol{\theta}} \int_\Omega \rho s \times (x + u).$$

Note that, in contrast to the 2D case, we have to keep the rotation $R_{\boldsymbol{\theta}}$ in this definition, since $\int_\Omega \rho s \times (x+u)$ cannot be collinear to the axis of the rotation. This fact motivates the introduction of the relative angular momentum m defined by

$$m := \int_\Omega \rho s \times (x + u).$$

In terms of m, the time derivative of $\mathcal{J}$ reads

$$\dot{\mathcal{J}} = R_{\boldsymbol{\theta}} \big(\dot{m} + \Theta^{\boldsymbol{\theta}} m \big).$$

The dynamics of our system can be described by the following three equations:

$$\mathcal{M}\ddot{\tau} = \int_\Omega f + \int_\Gamma g,$$

$$\dot{m} + \Theta^{\boldsymbol{\theta}} m = \int_\Omega R_{\boldsymbol{\theta}}^\top f \times (x + u) + \int_\Gamma R_{\boldsymbol{\theta}}^\top g \times (x + u),$$

and

$$\int_\Omega \rho(\dot s + \Theta^{\boldsymbol\theta} s)\cdot v + \int_\Omega \sigma(u):\varepsilon(v) = B_{\boldsymbol\theta}(v)\ \forall v \in \widetilde X,$$

where

$$B_{\boldsymbol\theta}(v) := \int_\Omega f\cdot R_{\boldsymbol\theta} v + \int_\Gamma g\cdot R_{\boldsymbol\theta} v.$$

5.3. 3D Algorithm. We are now able to extend Algorithm II to the 3D case. We keep the notation corresponding to the midpoint time discretization; see (3.4).

Let τ_0, $\dot\tau_0$, $\boldsymbol\theta_0$, u_0, s_0, as well as the external forces $(f_{n+1/2})_{n\in\mathbb N}$ and $(g_{n+1/2})_{n\in\mathbb N}$ be given, and suppose that τ_n, $\dot\tau_n$, $\boldsymbol\theta_n$, $u_n \in \widetilde X$, and s_n have already been computed. The derivation of $\tau_{n+1}, \dot\tau_{n+1}$, $\boldsymbol\theta_{n+1}$, $u_{n+1} \in \widetilde X$ and $s_{n+1} \in \widetilde V$ is carried out by the resolution of

$$\mathcal M\ddot\tau_{n+1/2} = \int_\Omega f_{n+1/2} + \int_\Gamma g_{n+1/2}, \tag{5.2}$$

$$\begin{aligned} K(\dot m_{n+1/2}, m_{n+1/2}, \dot{\boldsymbol\theta}_{n+1/2}, \boldsymbol\theta_{n+1/2}) = {}& \int_\Omega R^\top_{\boldsymbol\theta_{n+1/2}} f_{n+1/2}\times(x+u_{n+1/2}) \\ & + \int_\Gamma R^\top_{\boldsymbol\theta_{n+1/2}} g_{n+1/2}\times(x+u_{n+1/2}), \end{aligned} \tag{5.3}$$

(5.4)

$$G(\dot s_{n+1/2}, s_{n+1/2}, \dot{\boldsymbol\theta}_{n+1/2}, \boldsymbol\theta_{n+1/2}, u_{n+1/2}; v) = B_{n+1/2}(v) \qquad \forall v \in \widetilde X,$$

with

$$\begin{aligned} K(\dot m, m, \dot{\boldsymbol\theta}, \boldsymbol\theta) &:= \dot m + \Theta^{\boldsymbol\theta} m, \\ G(\dot s, s, \dot{\boldsymbol\theta}, \boldsymbol\theta, u; v) &:= \int_\Omega \rho(\dot s + \Theta^{\boldsymbol\theta} s)\cdot v + \int_\Omega \sigma(u):\varepsilon(v), \\ B_{n+1/2}(v) &:= \int_\Omega f_{n+1/2}\cdot R_{\boldsymbol\theta_{n+1/2}} v + \int_\Gamma g_{n+1/2}\cdot R_{\boldsymbol\theta_{n+1/2}} v, \end{aligned}$$

and

(5.5)

$$m_{n+1/2} := \int_\Omega \rho s_{n+1/2}\times\big(x+u_{n+1/2}\big), \qquad s_{n+1/2} := \dot u_{n+1/2} + \Theta^{\boldsymbol\theta}_{n+1/2}\big(x+u_{n+1/2}\big).$$

Here, $\Theta^{\boldsymbol\theta}_{n+1/2}$ is the time discretization of $\Theta^{\boldsymbol\theta}(t_{n+1/2})$ computed with $\boldsymbol\theta_{n+1/2}$ and $\dot{\boldsymbol\theta}_{n+1/2}$ by (5.1).

5.4. Angular momentum and energy conservation. The energy conservation of the 3D Algorithm can be established as in the 2D case. However, regarding the angular momentum, we only get a weaker conservation property, namely that the norm of the angular momentum vector is preserved.

THEOREM 5.1. *The 3D Algorithm defined by* (5.2)–(5.4) *guarantees the energy conservation in the sense that*

$$\mathcal E_{n+1} - \mathcal E_n = \Delta t\Big(\int_\Omega f_{n+1/2}\cdot\dot\varphi_{n+1/2} + \int_\Gamma g_{n+1/2}\cdot\dot\varphi_{n+1/2}\Big),$$

where $\mathcal{E}_n$ is the total energy defined by (3.5). *The time discretization of $\dot{\varphi}$ is done by*

$$\dot{\varphi}_{n+1/2} := \dot{\tau}_{n+1/2} + R_{\boldsymbol{\theta}_{n+1/2}} s_{n+1/2},$$

with $s_{n+1/2}$ as given in (5.5).

The proof of Theorem 5.1 can be obtained by following the one of Theorem 3.1. Note that we do not have exact angular momentum conservation since $\dot{\mathcal{J}}$ cannot be written as an explicit variation of a time discretization of $\mathcal{J}$ between two timesteps. As for Algorithm I in two dimensions, it is however possible to specify the local order with respect to Δt. Defining the time-discretized angular momentum $\mathcal{J}$ by

$$\mathcal{J}_n := R_{\boldsymbol{\theta}_n} m_n,$$

where $\boldsymbol{\theta}_n, u_n$, and s_n are computed by the 3D Algorithm, it can be shown that there exists $C_{n+1/2}$, depending only on $\dot{\boldsymbol{\theta}}_{n+1/2}$, such that

$$\Big\| \mathcal{J}_{n+1} - \mathcal{J}_n - \Delta t \Big(\int_\Omega f_{n+1/2} \times R_{\boldsymbol{\theta}_{n+1/2}}(x + u_{n+1/2}) + \int_\Gamma g_{n+1/2} \times R_{\boldsymbol{\theta}_{n+1/2}}(x + u_{n+1/2}) \Big) \Big\| \le C_{n+1/2} \Delta t^2,$$

where $\|\cdot\|$ is a norm in $\mathbb{R}^3$. Moreover, the norm of the angular momentum is preserved in the following sense:

$$\mathcal{J}_{n+1}^2 - \mathcal{J}_n^2 = 2\Delta t \Big(\int_\Omega f_{n+1/2} \times R_{\boldsymbol{\theta}_{n+1/2}}(x + u_{n+1/2}) \cdot R_{\boldsymbol{\theta}_{n+1/2}} m_{n+1/2} + \int_\Gamma g_{n+1/2} \times R_{\boldsymbol{\theta}_{n+1/2}}(x + u_{n+1/2}) \cdot R_{\boldsymbol{\theta}_{n+1/2}} m_{n+1/2} \Big).$$

6. Numerical examples. In this section, we present some numerical examples which show the flexibility and efficiency of our method. We start with several 2D examples based on the linear Saint Venant–Kirchhoff material model, which are numerically studied using the energy- and momentum-conserving algorithm (Algorithm II). Then, we apply our corotational scheme to a nonlinear material law. At the end, we present a 3D example.

In our 2D examples, we compare the two corotational formulations (with and without the linearization of strains introduced in section 2.3) with the standard nonlinear formulation, where the linearization is not possible due to the rotation. In what follows, we call these three formulations "corotational linear," "corotational nonlinear," and "(standard) nonlinear," where "nonlinear" is always referred to using the nonlinearized Green–Lagrange strains (2.2). We remark that in the corotational nonlinear setting, two nonlinearities occur: the nonlinearity to determine the correct rotation angle and the nonlinearity in the stiffness term. For the nonlinear formulations, we use an energy-conserving time discretization as introduced, e.g., in [35].

To compare the results, we compute from the solution φ_n of the standard nonlinear setting in a postprocessing step the translation τ_n and the rotation angle θ_n such that the minimization condition (2.5) is fulfilled, i.e.,

$$\tau_n := \int_\Omega \rho \varphi_n, \quad \int_\Omega \rho R_{\theta_n}^\top (\varphi_n - \tau_n) \cdot \Pi x = 0.$$

We then set $\dot{\tau}_{n+1/2} = \frac{\tau_{n+1}-\tau_n}{\Delta t}$ and $\dot{\theta}_{n+1/2} = \frac{\theta_{n+1}-\theta_n}{\Delta t}$. The energy for the standard nonlinear formulation is computed by

$$\frac{1}{2}\int_\Omega \rho\dot{\varphi}_n^2 + \frac{1}{2}\int_\Omega \Sigma(d_n) : E(d_n),$$

with $d_n := \varphi_n - x$, whereas the angular momentum is given by

$$\int_\Omega \rho\dot{\varphi}_n \cdot \Pi\varphi_n.$$

For the corotational formulations, the energies are computed by (3.5) and (3.7), respectively, and the angular momentum by (3.6).

As initial deformations, we use either $u_0 = 0$, i.e., $\varphi_0 = x$, or $u_0 = u_{\rm rot}(\dot{\theta}_0)$ and $\varphi_0 = \varphi_{\rm rot}(\dot{\theta}_0)$, respectively, where $u_{\rm rot}$, $\varphi_{\rm rot}$ are the effective displacements and deformations of a body rotating with a given constant angular speed $\dot{\theta}_0$.

We obtain $u_{\rm rot}(\dot{\theta}_0)$ for the linearized setting by solving the system

$$-(\dot{\theta}_0)^2 M(x + u_{\rm rot}) + S u_{\rm rot} = 0. \tag{6.1}$$

We note that multiplying (6.1) by Πx gives $M u_{\rm rot} \cdot \Pi x = 0$ and thus $u_{\rm rot} \in X_h$.

For the nonlinearized strains, $\varphi_{\rm rot}(\dot{\theta}_0)$ is given by the solution of

$$-(\dot{\theta}_0)^2 M\varphi_{\rm rot} + S(\varphi_{\rm rot} - x) = 0. \tag{6.2}$$

Here, $S(\cdot)$ denotes the discretized nonlinear elasticity operator.

The nonlinear equation (4.5) is solved for our examples using a Newton scheme. We note that the derivative $\frac{d}{d\theta}u_{n+1/2}$ can be computed by solving the system (4.4) with a modified right-hand side. For the corotational nonlinear setting, we do not use a full Newton scheme to resolve both nonlinearities but a nested iteration scheme leading here to an inner iteration where the tangential matrix can be computed in the same way as in the standard nonlinear setting. Restricting the number of inner iterations (also called inexact solving), we get an efficient solver that is easy to implement.

6.1. Examples using the standard nonlinear setting. We start with two examples demonstrating the effect of large timesteps when using the standard nonlinear setting to simulate high-speed rotating bodies; see Figure 6.1. First, we simulate a rigid body motion with a constant rotation speed of 20; for details see Example 1 later. Here we see that the larger the stepwidth is, the worse the rotational speed is approximated. Second (see Example 3), a rigid body motion with high-speed elastic oscillations is depicted. These high-speed oscillations cannot be resolved for large timesteps. Yet, it turns out that the standard nonlinear setting with energy- and momentum-conserving time integration scheme not only reproduces a wrong mean value of the rotational speed but also artificially increases the oscillation.

6.2. Example 1: Rotating beam. We consider a beam that is rotating with a constant speed. The domain Ω is given by $[-0.5, 0.5] \times [-0.05, 0.05]$ (see Figure 6.2), and the material parameters are given by $E = 1.62 \cdot 10^5$, $\nu = 0.2$, and $\rho = 1.0$.

We assume no boundary and no volume forces, i.e., $g = 0$ and $f = 0$. As initial rotation speed, we use $\dot{\theta}_0 = 20$. For the corotational setting, we use the initial effective displacement $u_0 = u_{\rm rot}(\dot{\theta}_0)$ and $u_0 = \varphi_{\rm rot}(\dot{\theta}_0) - x$ for the linear and nonlinear strain

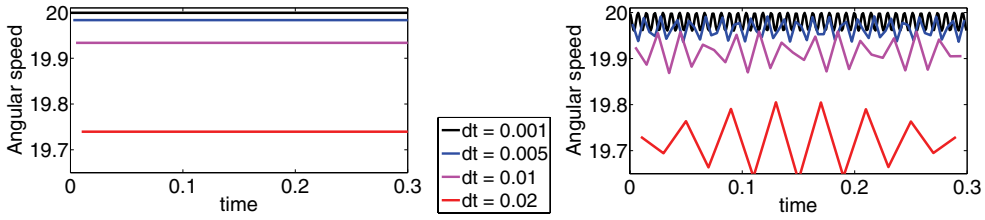

FIG. 6.1. *Calculated rotation speed using standard time discretization. Left: rigid body motion. Right: rotation plus oscillation.*

FIG. 6.2. *Example* 1. *Left: grid. Middle: initial condition for corotational formulation. Right: initial condition for nonlinear formulation (displacement with factor* 200, *effective stress).*

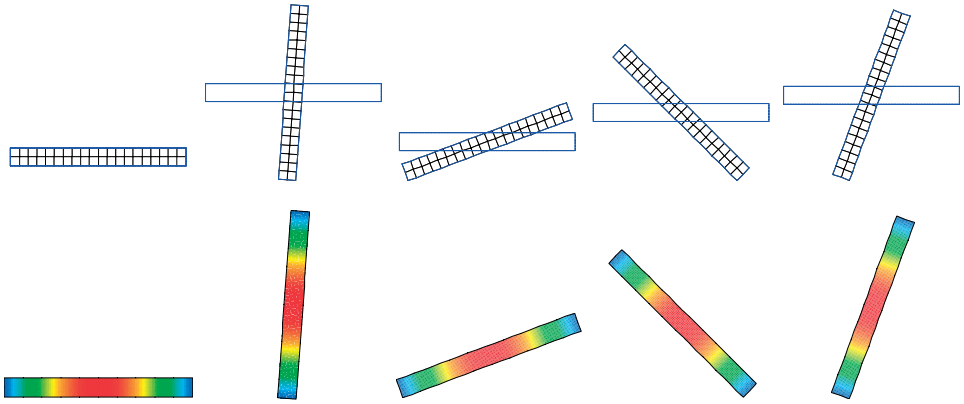

FIG. 6.3. *Example* 1. *Deformed mesh and effective stress (corotational linear) at time* $t = 0, 0.1, 0.2, 0.3, 0.4$.

setting, respectively, and set $s_0 = \dot{\theta}_0 \Pi(x + u_0)$, $\theta_0 = 0$. $\dot{\tau}_0 = (1,1)^\top$, $\tau_0 = (0,0)^\top$. With these initial conditions, it is easy to verify that the solution of (3.13)–(3.15) is given by $\theta_n = n\Delta t \dot{\theta}_0$, $\dot{\theta}_n = \dot{\theta}_0$, $\tau_n = n\Delta t \dot{\tau}_0$, $\dot{\tau}_n = \dot{\tau}_0$, $u_n = u_0$, $s_n = s_0$. The solution at various timesteps is given in Figure 6.3.

For the standard nonlinear setting, we set $\varphi_0 = \varphi_{\mathrm{rot}}(\dot{\theta}_0)$ and $\dot{\varphi}_0 = \dot{\theta}_0 \Pi \varphi_0$. As timesteps we use $\Delta t = 0.05, 0.01, 0.001$. We note that in our corotational formulations the solution is independent of the choice of Δt. Moreover, only one Newton iteration is needed if the iteration is started with θ_{n+1} such that $\dot{\theta}_{n+1/2} = \dot{\theta}_n$ which is the correct solution. This holds for both corotational formulations with and without linearized strain. For the standard nonlinear setting, we observe an increasing number of Newton steps with increasing Δt; see Figure 6.4. Moreover, it turns out that for large Δt the nonlinear approach is not able to handle the rotation correctly resulting in a wrong rotational speed.

6.3. Example 2: Rotation of a soft disc with no initial deformation. In this example, we consider a soft rotating disc, given by a circle with radius $r = 1.0$

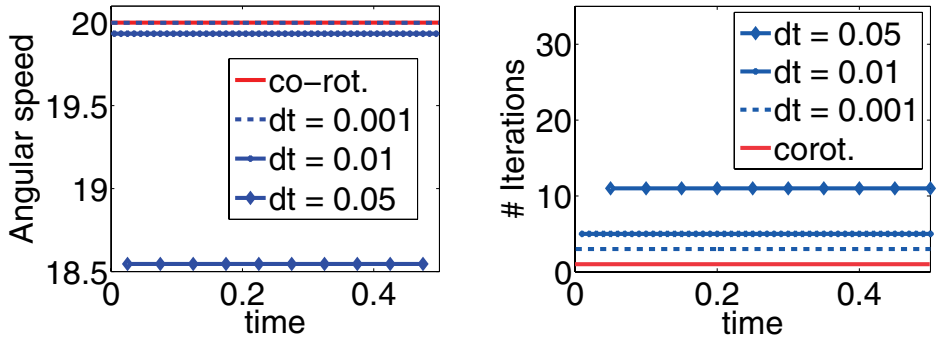

FIG. 6.4. *Example* 1. *Computed angular speed and number of iterations, both corotational formulations vs. nonlinear approach with different timesteps.*

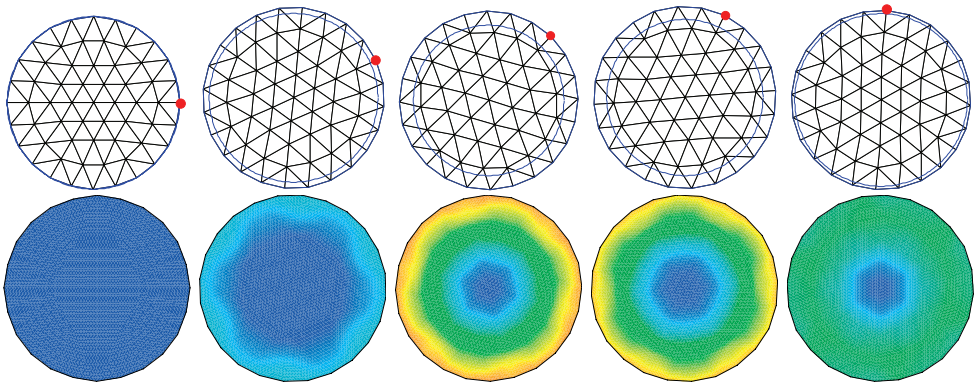

FIG. 6.5. *Example* 2. *Deformed mesh and effective stress (corotational linear) at time* t_n, $n = 0, 5, 10, 15, 20$.

and the material parameters $E = 500$, $\nu = 0.2$, and $\rho = 1.0$. We assume no boundary and volume forces and use the timestep $\Delta t = 0.001$. As initial conditions for the corotational settings, we use $\dot{\theta}_0 = 20$ and assume no initial displacements, therefore $u_0 = 0$. The initial speed is given by $s_0 = \dot{\theta}_0 \Pi x$ and the initial rotation angle by $\theta_0 = 0$. For the standard nonlinear setting, we have $\varphi_0 = x$, $\dot{\varphi}_0 = \dot{\theta}_0 \Pi x$. We assume zero translation, i.e., $\tau = (0,0)^\top$, $\dot{\tau} = (0,0)^\top$.

In Figure 6.5, the solution of the corotational linear setting at various times is shown. The calculated angular speed for the corotational and standard nonlinear approaches is depicted in Figure 6.6. We observe that the corotational linear approach fails to resolve the frequency of the solution. This is due to the linearized strain which leads to a wrong approximation of the elastic term for large deformations. However, the corotational nonlinear setting perfectly reproduces the results obtained by the standard nonlinear setting. When comparing the energies and angular momenta for the three formulations (Figure 6.7), we see that all settings yield conservation of these quantities.

In Figure 6.8, the necessary Newton steps per timestep for the standard nonlinear and the two corotational settings are shown. For $\Delta t = 0.01$ we see that the standard nonlinear setting even performs somewhat better than the corotational formulations. In a second test, we increase the stepwidth to $\Delta t = 0.1$. Here, a comparable

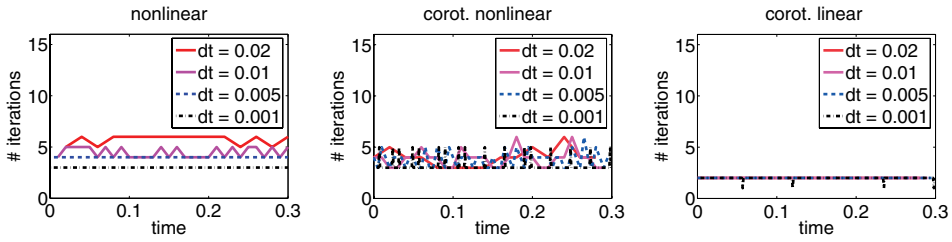

FIG. 6.9. *Example* 3. *Number of Newton iterations comparing standard nonlinear with corotational settings.*

performance is obtained for all three schemes.

6.4. Example 3: Rotation of a hard disc with no initial deformation. Now, we consider a rotating hard disc given by a circle with radius $r = 1.0$ and the material parameters $E = 1.62 \cdot 10^5$, $\nu = 0.2$, and $\rho = 1.0$. We use the same initial and boundary conditions as in the previous example and the timesteps $\Delta t = 0.001, 0.005, 0.01, 0.02$.

In Figure 6.9, the necessary Newton steps per timestep for the three formulations are shown. One can see that for small timesteps all settings perform quite well. For larger timesteps, however, the number of iterations using the standard nonlinear approach increases while the corotational formulations stay at low iteration numbers. When comparing the corotational linear with the corotational nonlinear setting, we can clearly see that in this example the linearization enhances the performance, which is expectable because the very stiff body is close to a rigid body motion.

The angular speed $\dot{\theta}$ obtained by the three settings is depicted in Figure 6.10. We see that for large timesteps the time integration scheme is no longer able to handle the oscillations correctly. Moreover, the standard nonlinear approach gives a wrong average rotation speed. This points out the fact that the standard time integration scheme with a large timestep is not able to handle the rotation correctly even when using the nonlinear strain relationship. Here, the corotational approach yields a good approximation of the angular speed for both strain-displacement relationships.

In Figure 6.11, we compare the angular momentum for the two different algorithms presented in this paper. While Algorithm II preserves the angular momentum, we see a small oscillation when using Algorithm I.

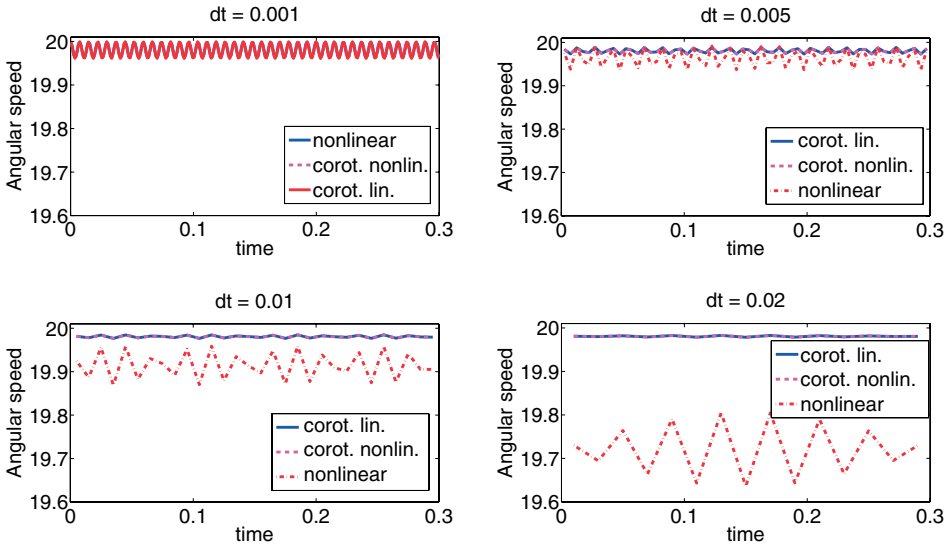

FIG. 6.10. *Example* 3. *Angular speed for nonlinear and corotational settings with different* Δt.

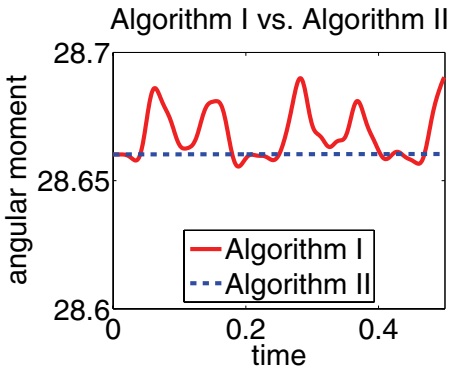

FIG. 6.11. *Example* 3. *Angular momentum using Algorithms* I *and* II.

6.5. Example 4: Rotation of a beam under surface traction. We consider a rotating beam under surface traction. For such rotational problems, boundary forces normal or perpendicular to the rotated configuration are quite common. This leads to a boundary force $g = R_\theta g_{\text{rel}}$, where g_{rel} is the boundary force relative to the rotated configuration and θ is the actual rotation angle that can be defined, for example, by (2.5). This setting causes extra difficulties when solving with standard time integration schemes as the right-hand side depends on the actual solution. However, in the corotational framework, this type of boundary condition can be modeled in a natural way and moreover gives a right-hand side that is independent of the actual rotation.

We use the same setting and initial conditions as in Example 1 and a timestep of $\Delta t = 0.01$. Here, the surface traction is given by $g_{\text{rel}} = (0, -20)^\top$ on the right boundary and $g_{\text{rel}} = (0, 20)^\top$ on the left boundary. On the top and bottom, we assume no surface traction. The rotation angle and angular speed using the corotational linear framework are depicted on the left of Figure 6.12, and the energy and angular

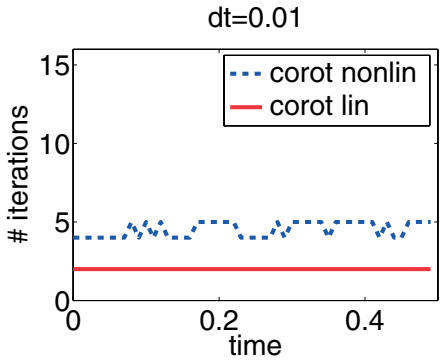

FIG. 6.14. *Example* 4. *Number of iterations.*

momentum are shown on the right. In Figure 6.13, the effective displacement u is plotted at various timesteps. We note that for this example the number of necessary Newton iterations is two for all timesteps; see Figure 6.14. Computing the same setting with the corotational nonlinear scheme leads to iteration numbers between 4 and 5 without improving the results.

6.6. Example 5: Nonlinear material law. In this example, we apply our corotational formulation to a nonlinear material law. We use the Mooney–Rivlin material model with $E = 500$, $\nu = 0.2$, and $c_m = \frac{1}{11}$. The computational domain and initial conditions are the same as in Examples 2 and 3, i.e., a circle with initial speed 20 and no initial displacements. Again, we use a stepwidth of $\Delta t = 0.001$. To achieve energy conservation, we use the method of Gonzalez [22]. The results for the rotation angle and angular speed comparing the standard nonlinear scheme with the corotational nonlinear schemes are given in Figure 6.15. Comparing with the linear

Saint Venant–Kirchhoff material model used in Example 2, we see that the body is artificially hardened by the linearization in the material law. Good agreement of the angular speed is achieved for the two schemes. This can also be observed in the energy plots. However, in contrast to our new corotational scheme, the standard nonlinear scheme does not preserve the angular momentum; see Figure 6.15. The number of iterations per timestep is compared in Figure 6.16 for stepwidths $\Delta t = 0.001$ and $\Delta t = 0.01$. Here, both schemes yield similar iteration numbers with the standard nonlinear scheme performing somewhat better.

6.7. Example 6: Rotation of a 3D cube. In our last example, we apply our algorithm to a 3D problem. We model a rotating cube with constant rotation axis $(1, 1, 1)^\top$. We note that for this kind of rotation, R can be represented in terms of just one rotation angle. Moreover, the angular momentum is exactly preserved in this example as the algorithm preserves the norm of the angular momentum. The domain is given by $[0, 1] \times [0, 1] \times [0, 1]$ and the material parameters by $E = 1.62 \cdot 10^4$, $\nu = 0.2$, and $\rho = 1.0$. We use $\Delta t = 0.001$, an initial angular speed of 20, and zero initial effective displacement. The deformed mesh at various timesteps is presented in Figure 6.17. As the cube is not rotationally symmetric with respect to the rotation

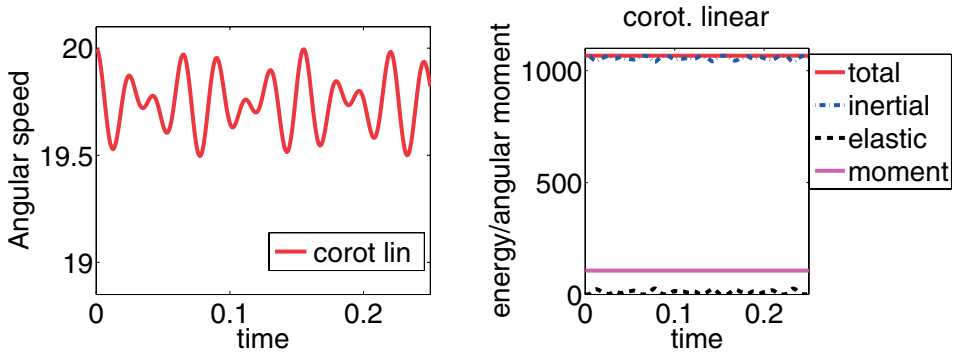

FIG. 6.18. *Example* 6. *Left*: *angular speed. Right*: *energy and angular momentum.*

axis, we do not get the periodic behavior as in the 2D examples; see Figure 6.18. However, the energy and angular momentum are still preserved.

NONCONFORMING, ANISOTROPIC, RECTANGULAR FINITE ELEMENTS OF ARBITRARY ORDER FOR THE STOKES PROBLEM*

THOMAS APEL† AND GUNAR MATTHIES‡

Abstract. The numerical solution of the Stokes problem is analyzed for four families of rectangular, nonconforming finite elements of arbitrary order. While two of them become unstable as the maximum aspect ratio of the finite elements increases, the other two remain stable. A complete convergence analysis is given for these two families on two-level triangulations with isotropic rectangular macroelements and certain anisotropic refinement strategies within the macros.

Key words. nonconforming finite elements, anisotropic meshes, consistency error, inf-sup condition

1. Introduction.

We consider the stationary Stokes problem

$$\begin{aligned} -\triangle \boldsymbol{u} + \nabla p &= \boldsymbol{f} && \text{in } \Omega, \\ \operatorname{div} \boldsymbol{u} &= 0 && \text{in } \Omega, \\ \boldsymbol{u} &= \boldsymbol{0} && \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

in a two-dimensional domain Ω. For the discretization of (1.1), one has to make the fundamental decision of choosing either a continuous or a discontinuous pressure approximation. We advocate the latter due to a better mass conservation on the element level. Furthermore, coupled multigrid solvers work in general better for discontinuous pressure spaces [16, 17]. Moreover, one has to distinguish between conforming and nonconforming velocity spaces. Since the degrees of freedom in two-dimensional nonconforming methods are edge-oriented, these methods are advantageous for parallel implementation due to missing cross-point communication.

Well-known examples for low order nonconforming discretizations of (1.1) can be found in [8, 11, 13]. Families of nonconforming triangular elements of arbitrarily high polynomial order were given in [22, 23] where only in [22] the application to the Stokes problem was considered. Three families of quadrilateral elements and a family of hexahedral elements were derived recently in [21]. They generalize the well-known rotated Q_1 element [24].

The spaces for approximating the velocity and the pressure in Stokes and Navier–Stokes problems cannot be chosen independently but have to satisfy the discrete inf-sup stability condition. The solution of the Navier–Stokes problem includes in general layer phenomena. To capture this anisotropic behavior, one usually employs adequately refined anisotropic meshes. The small element size in one direction is used to compensate for large derivatives in this direction. It is essential in such

applications that the constant in the discrete inf-sup condition does not degenerate for an increasing aspect ratio of the elements. We refer the reader to [5] for the state of the art in about 2002. However, the above-mentioned families were until now not investigated concerning their behavior on meshes which contain elements with a large aspect ratio. In this paper, we focus on anisotropic meshes and analyze the properties of the three quadrilateral families of [21] and a further new family which generalizes the first order element developed in [4]. All considered elements are parametric. The first mentioned three families generalize the parametric rotated Q_1 element, which itself is not inf-sup stable on anisotropic meshes. Although we investigate families of arbitrary polynomial degree, we focus on an h-version of the finite element method, which means that the dependence of the constants on the polynomial degree is not elaborated.

The paper is organized as follows. We start with basic notation in section 2. All four considered families will be introduced in section 3. The numerical results which are obtained by using these families on isotropic meshes differ only slightly. However, a numerical study on selected anisotropic meshes shows that for two families the constant in the inf-sup condition degenerates to zero as the aspect ratio increases. We succeeded in analyzing the remaining two families and present interpolation error estimates, the proof of the inf-sup condition, and an estimate of the consistency error in sections 5, 6, and 7, respectively. Since the proofs are technical, we summarize our results in section 4.

2. Notation. Let Ω be a bounded domain in $\mathbb{R}^2$. For a one- or two-dimensional domain $G \subset \Omega$ we will use the Sobolev spaces $W^{m,p}(G)$ with norm $\|\cdot\|_{m,p,G}$ and semi-norm $|\cdot|_{m,p,G}$, where the last index will be omitted if $G = \Omega$. We write in the case $p = 2$, as usual, $H^m(G) := W^{m,2}(G)$, and we omit the index p in the norms. Note further that $L^p(G) := W^{0,p}(G)$. The vector-valued version of all spaces will be denoted by the corresponding bold-face letter. The inner product in $L^2(G)$ and its vector-valued and tensor-valued versions will be denoted by $(\cdot,\cdot)_G$. For a one-dimensional manifold $F \subset \partial G$, the inner product in $L^2(F)$ and its vector-valued versions are written as $\langle\cdot,\cdot\rangle_F$.

Let $\boldsymbol{X} := \boldsymbol{H}^1_0(\Omega)$ and $M := L^2_0(\Omega) = \{v \in L^2(\Omega) : (v,1) = 0\}$. A weak formulation of (1.1) reads as follows: Find $(\boldsymbol{u}, p) \in \boldsymbol{X} \times M$ such that

$$\begin{aligned} a(\boldsymbol{u},\boldsymbol{v}) - b(\boldsymbol{v},p) &= (\boldsymbol{f},\boldsymbol{v}) \qquad \forall \boldsymbol{v} \in \boldsymbol{X}, \\ b(\boldsymbol{u},q) &= 0 \qquad \forall q \in M, \end{aligned} \tag{2.1}$$

where

$$a(\boldsymbol{u},\boldsymbol{v}) := (\nabla\boldsymbol{u}, \nabla\boldsymbol{v}), \qquad b(\boldsymbol{v},q) := (\operatorname{div}\boldsymbol{v}, q).$$

Let $\{\mathcal{T}_h\}$ be a family of admissible triangulations of Ω into rectangular elements. For a domain $G \subset \mathbb{R}^d$, $d = 1, 2$, let $P_k(G)$ denote the space of polynomials of degree less than or equal to k. For discretizing the pressure, we will use the space

$$M_h := \{p \in L^2_0(\Omega) : p|_K \in P_{r-1}(K)\, \forall K \in \mathcal{T}_h\}$$

of generally discontinuous, piecewise polynomials of degree less than or equal to $r-1$. The velocity will be approximated by a nonconforming finite element space $\boldsymbol{X}_h := X_h^2$. The detailed definition for several choices of X_h will be given in section 3.

Since the bilinear forms a and b are not defined for general functions from $\boldsymbol{X}_h$, we introduce the bilinear forms a_h and b_h by

$$a_h(\boldsymbol{u}_h, \boldsymbol{v}_h) := \sum_{K \in \mathcal{T}_h} (\nabla \boldsymbol{u}_h, \nabla \boldsymbol{v}_h)_K, \qquad b_h(\boldsymbol{v}_h, q_h) := \sum_{K \in \mathcal{T}_h} (\operatorname{div} \boldsymbol{v}_h, q_h)_K,$$

which coincide for regular arguments with a and b, i.e., $a_h(\boldsymbol{u}, \boldsymbol{v}) = a(\boldsymbol{u}, \boldsymbol{v})$ for $\boldsymbol{u}, \boldsymbol{v} \in \boldsymbol{X}$ and $b_h(\boldsymbol{v}, q) = b(\boldsymbol{v}, q)$ for $\boldsymbol{v} \in \boldsymbol{X}$, $q \in M$. Furthermore, we define

$$|v_h|_{1,h} := \left(\sum_{K \in \mathcal{T}_h} |v_h|_{1,K}^2 \right)^{1/2},$$

which will be a norm on X_h; see (3.2) for the definition of X_h. The discretized Stokes problem reads as follows: Find $(\boldsymbol{u}_h, p_h) \in \boldsymbol{X}_h \times M_h$ such that

$$\begin{aligned} a_h(\boldsymbol{u}_h, \boldsymbol{v}_h) - b_h(\boldsymbol{v}_h, p_h) &= (\boldsymbol{f}, \boldsymbol{v}_h) \qquad && \forall \boldsymbol{v}_h \in \boldsymbol{X}_h, \\ b_h(\boldsymbol{u}_h, q_h) &= 0 && \forall q_h \in M_h. \end{aligned} \tag{2.2}$$

We define for the spaces $\boldsymbol{X}_h$ and M_h the quantity

$$\beta_h := \inf_{q_h \in M_h} \sup_{\boldsymbol{v}_h \in \boldsymbol{X}_h} \frac{b_h(\boldsymbol{v}_h, q_h)}{|\boldsymbol{v}|_{1,h} \, \|q_h\|_0}. \tag{2.3}$$

The positivity of β_h ensures that (2.2) is uniquely solvable. Moreover, the inverse of β_h enters the estimate of the discretization error; see [8, sect. II.2.2]. Since we are interested in anisotropic discretizations, the quantity β_h should be bounded away from zero not only for h tending to zero but also for an increasing aspect ratio. We call this the inf-sup condition, and we shall see that it is not generally satisfied.

Within this paper, we will frequently use the notation $x \lesssim y$ for the case that $x \leq C\, y$ holds true where C is a positive constant which is independent of the mesh parameters, i.e., independent of the mesh size h and the aspect ratio.

3. Families of finite elements. For a nonnegative integer k, we denote by L_k the kth one-dimensional Legendre polynomial normalized such that $L_k(1) = 1$. Let

$$\delta_k := \int_{-1}^{1} L_k^2(t)\, dt = \frac{2}{2k+1}, \qquad k \geq 0.$$

The Legendre polynomials are orthogonal, i.e.,

$$\int_{-1}^{1} L_i(t) L_j(t)\, dt = \delta_{ij} \delta_i,$$

where δ_{ij} denotes the Kronecker delta. The integrated Legendre polynomials $\widehat{L}_k$ which are defined by

$$\widehat{L}_k(t) := \int_{-1}^{t} L_k(s)\, ds$$

are related to the Legendre polynomials by

$$\widehat{L}_k(t) = \begin{cases} \frac{\delta_k}{2}\big(L_{k+1}(t) - L_{k-1}(t)\big), & k \geq 1, \\ L_1(t) + L_0(t), & k = 0. \end{cases} \tag{3.1}$$

For defining the nonconforming finite element space, we will use the triple notation in the sense of Ciarlet [9]. Let $(\widehat{K}, \widehat{V}, \widehat{\mathcal{N}})$ be a finite element on the reference cell $\widehat{K}$. All quantities which are connected to the reference element will be indicated by a hat. Note that as an exception both the Legendre polynomials L_k and the integrated Legendre polynomials $\widehat{L}_k$ are always defined on reference interval $[-1, 1]$. Let $F_K := \widehat{K} \to K$ be the affine transformation which maps $\widehat{K}$ onto K. Then, the function space $V(K)$ on K is defined by

$$V(K) := \big\{ v = \hat{v} \circ F_K^{-1} \,:\, \hat{v} \in \widehat{V} \big\}.$$

Using the notation $\mathcal{S}_h^i$ and $\mathcal{S}_h^b$ for the set of interior and boundary edges of $\mathcal{T}_h$, the global scalar finite element space X_h is given by

$$\begin{aligned} X_h := \Big\{ & v \in L^2(\Omega) \,:\, v|_K \in V(K)\, \forall K \in \mathcal{T}_h,\ \langle q, [v]_E \rangle_E = 0\, \forall q \in P_{r-1}(E), \forall E \in \mathcal{S}_h^i, \\ & \langle q, v \rangle_E = 0\, \forall q \in P_{r-1}(E), \forall E \in \mathcal{S}_h^b \Big\}. \end{aligned} \tag{3.2}$$

As usual, $[v]_E$ denotes the jump of the function v across the edge E. The vector-valued finite element space $\boldsymbol{X}_h$ consists of X_h in each component.

Now, we will define several finite elements on the reference cell $\widehat{K} = (-1, 1)^2$. We introduce the nodal functionals

$$\widehat{N}_{ij}(\hat{v}) := \frac{1}{\delta_i \delta_j} \int_{-1}^{1} \int_{-1}^{1} \hat{v}(\hat{x}_1, \hat{x}_2)\, L_i(\hat{x}_1) L_j(\hat{x}_2)\, d\hat{x}_2\, d\hat{x}_1, \qquad i, j \geq 0,$$

and, for nonnegative integers k,

$$\widehat{N}_{k,-}(\hat{v}) := \frac{1}{\delta_k} \int_{-1}^{1} \hat{v}(\hat{x}_1, -1)\, L_k(\hat{x}_1)\, d\hat{x}_1, \qquad \widehat{N}_{k,+}(\hat{v}) := \frac{1}{\delta_k} \int_{-1}^{1} \hat{v}(\hat{x}_1, +1)\, L_k(\hat{x}_1)\, d\hat{x}_1,$$

$$\widehat{N}_{-,k}(\hat{v}) := \frac{1}{\delta_k} \int_{-1}^{1} \hat{v}(-1, \hat{x}_2)\, L_k(\hat{x}_2)\, d\hat{x}_2, \qquad \widehat{N}_{+,k}(\hat{v}) := \frac{1}{\delta_k} \int_{-1}^{1} \hat{v}(+1, \hat{x}_2)\, L_k(\hat{x}_2)\, d\hat{x}_2.$$

For a fixed integer $r \geq 1$, the set $\widehat{\mathcal{N}}_r$ of nodal functionals is given by

$$\widehat{\mathcal{N}}_r := \big\{ \widehat{N}_{ij} \,:\, 0 \leq i + j \leq r - 2 \big\} \cup \big\{ \widehat{N}_{k,-}, \widehat{N}_{k,+}, \widehat{N}_{-,k}, \widehat{N}_{+,k} \,:\, k = 0, \ldots, r - 1 \big\}. \tag{3.3}$$

Now, we look for suitable function spaces $\widehat{V}_r \supset P_r(\widehat{K})$ with the property that the set $\widehat{\mathcal{N}}_r$ of nodal functionals is unisolvent with respect to the space $\widehat{V}_r$. The following four choices for $\widehat{V}_r$ fulfill these conditions. An illustration of these families for $r = 11$ is given in Figure 3.1 where the grey boxes indicate the space $P_r(\widehat{K})$, the dark boxes stand for further functions of form $L_i(\hat{x}_1) L_j(\hat{x}_2)$, and if a pair of bright boxes is connected by an arc, then only the difference of the involved functions belongs to the space $\widehat{V}_r$.

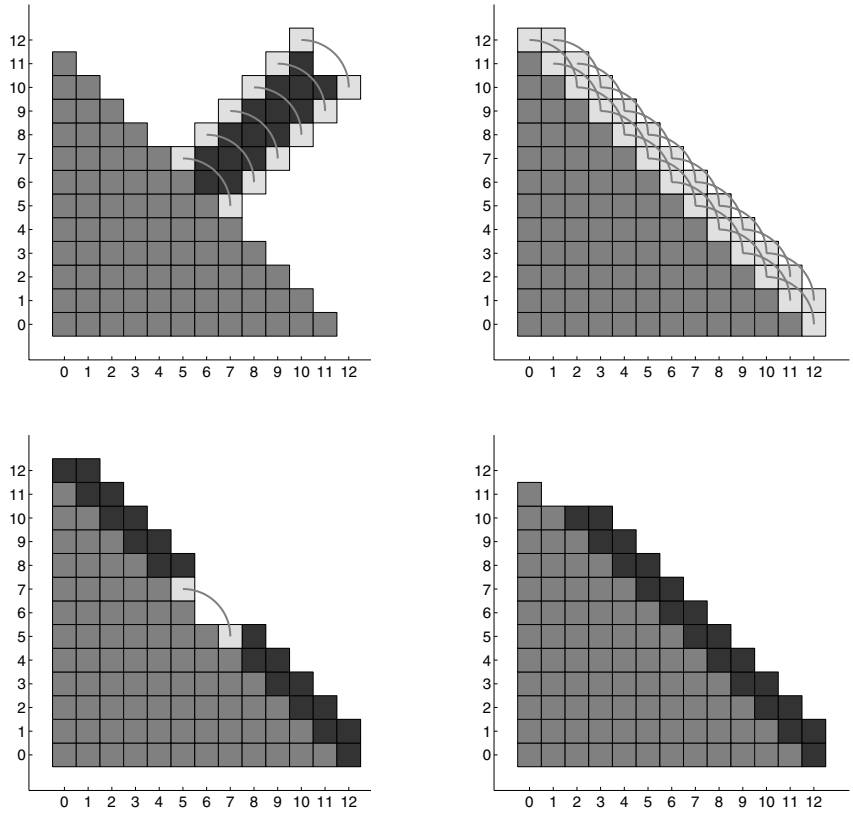

FIG. 3.1. *Illustration of the function spaces* $\widehat{V}_{11}^{\nu}$ *for* $\nu = 1, \ldots, 4$, *from top left to bottom right.*

A first choice was given in Example 5 in [14]. We set

$$\widehat{V}_r^1 := P_r(\widehat{K}) \oplus \widehat{R}_r \oplus \widehat{S}_r, \tag{3.4}$$

where

$$\widehat{R}_r := \begin{cases} \operatorname{span}\Big\{ L_{i+1}(\hat{x}_1)L_i(\hat{x}_2),\ L_i(\hat{x}_1)L_{i+1}(\hat{x}_2) \\ \qquad L_{i+2}(\hat{x}_1)L_i(\hat{x}_2) - L_i(\hat{x}_1)L_{i+2}(\hat{x}_2),\ :\ i = r/2 \Big\}, & r \text{ even}, \\ \operatorname{span}\Big\{ L_{i+2}(\hat{x}_1)L_i(\hat{x}_2) - L_i(\hat{x}_1)L_{i+2}(\hat{x}_2)\ :\ i = (r-1)/2 \Big\}, & r \text{ odd}, \end{cases}$$

and

$$\widehat{S}_r := \operatorname{span}\Big\{ L_i(\hat{x}_1)L_i(\hat{x}_2),\ L_{i+1}(\hat{x}_1)L_i(\hat{x}_2),\ L_i(\hat{x}_1)L_{i+1}(\hat{x}_2), \\ L_{i+2}(\hat{x}_1)L_i(\hat{x}_2) - L_i(\hat{x}_1)L_{i+2}(\hat{x}_2)\ :\ r/2 < i \le r-1 \Big\}.$$

A second variant which is given by

(3.5)
$$\widehat{V}_r^2 := P_r(\widehat{K}) \oplus \operatorname{span}\Big\{ L_{i+2}(\hat{x}_1)L_{r-1-i}(\hat{x}_2) - L_i(\hat{x}_1)L_{r+1-i}(\hat{x}_2)\ ,\ i=0,\dots,r-1 \Big\}$$
$$\oplus \operatorname{span}\Big\{ L_{i+2}(\hat{x}_1)L_{r-i}(\hat{x}_2) - L_i(\hat{x}_1)L_{r+2-i}(\hat{x}_2)\ ,\ i=1,\dots,r-1 \Big\}$$

was introduced in [21]. The following third version can also be found there:

(3.6)
$$\begin{aligned}\widehat{V}_r^3 :=& P_r(\widehat{K}) \\ &\oplus \operatorname{span}\Big\{ L_i(\hat{x}_1)L_{r+1-i}(\hat{x}_2),\ L_{r+1-i}(\hat{x}_1)L_i(\hat{x}_2)\ ,\ i=0,\dots,\lfloor r/2\rfloor-1 \Big\} \\ &\oplus \operatorname{span}\Big\{ L_i(\hat{x}_1)L_{r+2-i}(\hat{x}_2),\ L_{r+2-i}(\hat{x}_1)L_i(\hat{x}_2)\ ,\ i=1,\dots,\lfloor (r+1)/2\rfloor-1 \Big\} \\ &\oplus \operatorname{span}\Big\{ L_{\lfloor r/2\rfloor+2}(\hat{x}_1)L_{\lfloor r/2\rfloor}(\hat{x}_2) - L_{\lfloor r/2\rfloor}(\hat{x}_1)L_{\lfloor r/2\rfloor+2}(\hat{x}_2) \Big\},\end{aligned}$$

where $\lfloor s\rfloor$ is the largest integer which is less than or equal to s. Note that all these spaces generalize the parametric rotated Q_1 element, i.e., $\widehat{V}_1^1 = \widehat{V}_1^2 = \widehat{V}_1^3 = Q_1^{\mathrm{rot}}$. Finally, we introduce a new family,

(3.7)
$$\begin{aligned}\widehat{V}_r^4 := P_r(\widehat{K}) &\oplus \operatorname{span}\big\{ L_{r+1-i}(\hat{x}_1)L_i(\hat{x}_2),\ i=0,\dots,r-1 \big\} \\ &\oplus \operatorname{span}\big\{ L_{r+2-i}(\hat{x}_1)L_i(\hat{x}_2),\ i=1,\dots,r-1 \big\},\end{aligned}$$

which recovers for $r=1$ the space introduced in [4]. Note that this space is not symmetric with respect to $\hat{x}_1$ and $\hat{x}_2$. It is adapted to anisotropic elements which are elongated in the $\hat{x}_1$-direction. If the anisotropic element is stretched in the $\hat{x}_2$-direction, the roles of $\hat{x}_1$ and $\hat{x}_2$ must be exchanged in the definition of $\widehat{V}_r^4$. For isotropic elements one can use both variants or one of the families $\widehat{V}_r^\nu$, $\nu=1,2,3$.

All four families are unisolvent with respect to the set $\widehat{\mathcal{N}}_r$ of nodal functionals defined in (3.3). The proof for $\widehat{V}_r^1$ can be found in [14]. The unisolvence results for $\widehat{V}_r^2$ and $\widehat{V}_r^3$ are given in [21]. The proof for the family $\widehat{V}_r^4$ will be given in the appendix; see Lemma A.1 on page 1888.

Note that $\widehat{V}_r^\nu \subset \widehat{V}_{r+1}^\nu$, $\nu=1,2,3,4$, holds true, but the resulting nonconforming finite element spaces X_h are nonnested since a higher value of r also requires a higher order of consistency; see the definition (3.2) of X_h.

In order to assess these families of elements, we present the results of numerical tests performed with the finite element package MooNMD [18]. Table 3.1 shows that the results for different elements of the same order are comparable on isotropic meshes. The presented results were obtained on a uniform 64×64-decomposition of the unit square. The right-hand side and the boundary conditions were chosen such that

$$u(x,y) = \begin{pmatrix} \sin(x)\sin(y) \\ \cos(x)\cos(y) \end{pmatrix}, \qquad p(x,y) = 2\cos(x)\sin(y) - p_0$$

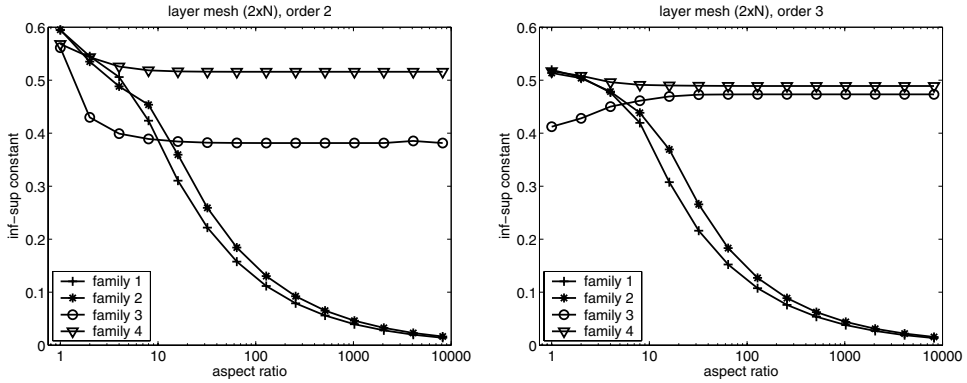

FIG. 3.2. *Plot of β_h against the aspect ratio for a family of layer meshes. Left: $r = 2$. Right: $r = 3$.*

is the given solution of (2.1), where the constant p_0 is determined by $p \in L_0^2(\Omega)$. The given orders were calculated from the data on the 64×64 mesh and the next coarser 32×32 mesh. All convergence rates are optimal.

We display in Figure 3.2 the inf-sup constants β_h for the finite element spaces $(\boldsymbol{X}_h, M_h)$ defined via $\widehat{V}_r^\nu$, $r = 2, 3$, $\nu = 1, 2, 3, 4$, on a family of meshes with increasing aspect ratio. These rectangular $2 \times N$ meshes are defined by their nodes (x_i, y_j), $x_i = i/2$, $i = 0, 1, 2$, $y_j = j/N$, $j = 0, \ldots, N$, yielding the aspect ratio $N/2$ for all elements. We see that the inf-sup constant β_h tends to zero for the families with $\nu = 1, 2$. This means that these families are not suited when anisotropic meshes are employed. For $\nu = 3, 4$, however, the inf-sup constant β_h remains bounded away from zero on a quite large level. Therefore, we will investigate these two families further.

Since we will not focus on a p-version of the finite element method, the dependence of all constants on the parameter r is not elaborated within this paper. For $\nu = 3, 4$, we define by

$$\widehat{N}(\widehat{I}^\nu \hat{v}) = \widehat{N}(\hat{v}) \qquad \forall \widehat{N} \in \widehat{\mathcal{N}}$$

the canonical interpolation operators $\widehat{I}^\nu$ which map onto $\widehat{V}^\nu$. Note that these interpolation operators are well defined for all functions which belong to $W^{1,1}(\widehat{K})$. The global interpolant I_h^ν is defined elementwise as usual via $\big(I_h^\nu u\big)|_K = \big(\widehat{I}^\nu (u|_K \circ F_K)\big) \circ F_K^{-1}$. Since the edge functionals from $\widehat{\mathcal{N}}$ are transformed into functionals which are

associated with the edges of $\mathcal{T}_h$, the elementwise defined interpolation operators I_h^ν, $\nu = 3, 4$, map into the corresponding nonconforming space X_h. The vector-valued interpolation operators $\boldsymbol{I}_h^\nu : \boldsymbol{X} \to \boldsymbol{X}_h$, where $\boldsymbol{X}_h$ is based on $\widehat{V}^\nu$, $\nu = 3, 4$, are defined componentwise.

4. Main results. We will investigate in the remaining part of this paper the families 3 and 4, where we succeed to prove, on special meshes, the fulfillment of the inf-sup condition and estimates for the interpolation error and the consistency error. These three properties result in the final discretization error estimate of order r. Since the proofs are quite lengthy, we summarize the results in this section. The proofs of Theorems 4.1–4.4 are given in sections 5–7.

The first ingredient is an anisotropic local interpolation error estimate on an element K which is a rectangle with edge sizes $h_{K,1}$ and $h_{K,2}$. We assume that K is elongated in the x_1-direction; i.e., $h_{K,1} \geq h_{K,2}$. We abbreviate $\partial_1 := \partial/\partial x_1$, $\partial_2 := \partial/\partial x_2$, $\hat{\partial}_1 := \partial/\partial \hat{x}_1$, $\hat{\partial}_2 := \partial/\partial \hat{x}_2$, and we use the multi-index notation with $\alpha = (\alpha_1, \alpha_2)$, $\alpha_1, \alpha_2 \geq 0$, $|\alpha| = \alpha_1 + \alpha_2$, $D^\alpha = \partial_1^{\alpha_1} \partial_2^{\alpha_2}$, and $h_K^\alpha = h_{K,1}^{\alpha_1} h_{K,2}^{\alpha_2}$.

THEOREM 4.1 (interpolation of smooth functions). *Let $u \in W^{\ell,p}(K)$, where $\ell \in \mathbb{N}$, $2 \leq \ell \leq r+1$, $p \in [1, \infty]$. Fix $m \in \{0, 1\}$ and $q \in [1, \infty]$ such that $W^{\ell-m,p}(K) \hookrightarrow L^q(K)$. Then, the anisotropic interpolation error estimate*

$$|u - I_h^\nu u|_{m,q,K} \lesssim |K|^{1/q-1/p} \sum_{|\alpha|=\ell-m} h_K^\alpha |D^\alpha u|_{m,p,K}, \quad \nu = 3, 4,$$

holds true.

Although the interpolation operators I_h^ν, $\nu = 3, 4$, are well defined for functions from $W^{1,1}(K)$, the anisotropic interpolation error estimate holds only for functions from $W^{2,1}(K)$ if $r \geq 2$. The reason is that we need traces of derivatives in the proof; see also Example 5.5. Note that for $r = 1$ and $\ell = 1$, the anisotropic interpolation error estimate holds for I_h^4 (see [3, Corollary 1]) but not for I_h^3 (see [6]), since the parametric version is considered here.

Interpolation error estimates for regular functions are needed for the estimation of the best approximation error. However, for the proof of the fulfillment of the inf-sup condition, one needs an interpolation estimate for H^1-functions. Fortunately, the regularity assumption $u \in W^{2,1}(K)$ in Theorem 4.1 can be weakened if functions which vanish on the short sides of K are considered. To this end, we introduce the function space

$$W_E^{1,p}(K) := \big\{ v \in W^{1,p}(K) \,:\, v|_{E_{-,*}} = v|_{E_{+,*}} = 0 \big\}, \tag{4.1}$$

where we denote by $E_{-,*}$ and $E_{+,*}$ the edges on the left-hand and right-hand sides of the element K, respectively; see Figure 4.1. The anisotropic interpolation error estimate on $W_E^{1,p}(K)$ is stated in the following theorem.

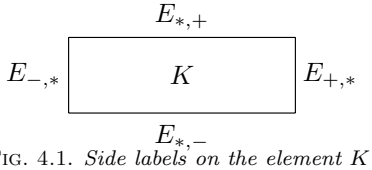

FIG. 4.1. *Side labels on the element K.*

THEOREM 4.2 (interpolation of nonsmooth functions). *Let $u \in W_E^{1,p}(K)$, $p \in [1, \infty]$. Fix $m \in \{0, 1\}$ and $q \in [1, \infty]$ such that $W^{1-m,p}(K) \hookrightarrow L^q(K)$. Then, the*

anisotropic interpolation error estimate

$$|u - I_h^\nu u|_{m,q,K} \lesssim |K|^{1/q-1/p} \sum_{|\alpha|=1-m} h^\alpha |D^\alpha u|_{m,p,K}, \quad \nu = 3, 4,$$

holds true.

To be able to use this result for checking the inf-sup condition, we employ the macroelement technique from [7]; see also [13, sect. II.1.4]. To this end, let $\mathcal{T}_H$ be an admissible macrotriangulation of Ω into isotropic rectangular macroelements Q:

$$\overline{\Omega} = \bigcup_{Q \in \mathcal{T}_H} \overline{Q}.$$

The finally used triangulation $\mathcal{T}_h$ is obtained from $\mathcal{T}_H$ by applying local refinement strategies to the macroelements Q in such a way that $\mathcal{T}_h$ is admissible. In particular, here we investigate boundary layer and corner patches which are defined in what follows. Other patches can be included provided a local inf-sup condition, as given by Lemmas 6.2 and 6.3, holds.

Let $Q = (x_-, x_+) \times (y_-, y_+)$ be a patch, and let $\tau_x = \{(x_{i-1}, x_i), i = 1, \dots, n\}$ and $\tau_y = \{(y_{j-1}, y_j), j = 1, \dots, m\}$ be decompositions of (x_-, x_+) and (y_-, y_+) into subintervals, respectively. In this way, the tensor-product triangulation $\tau_x \times \tau_y$ of Q is induced. If τ_x is the trivial decomposition of (x_-, x_+) into one interval, then the obtained patch is called a boundary layer patch. If $m = n$, $x_0 = x_-$, $y_0 = y_-$, $x_i = x_- + (x_+ - x_-)\sigma^{n-i}$, $i = 1, \dots, n$, and $y_j = y_- + (y_+ - y_-)\sigma^{n-j}$, $j = 1, \dots, n$, with a parameter $\sigma \in (0, 1)$, then the resulting patch is called a corner patch. Typical boundary layer and corner patches are shown in Figure 4.2. Note that the trivial decomposition of Q into one cell is allowed. The constants σ and n may vary from patch to patch. It is required only that the global mesh $\mathcal{T}_h$ is admissible.

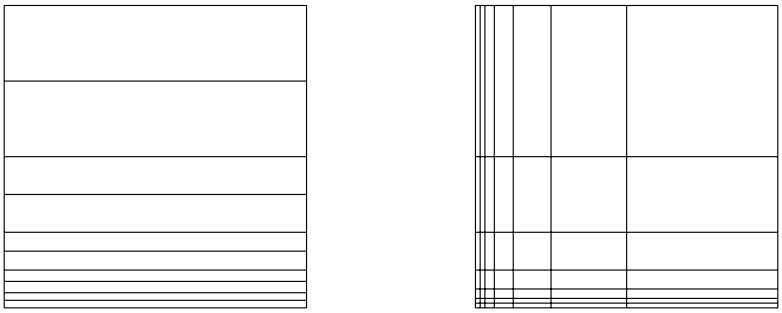

FIG. 4.2. *Typical boundary layer (left) and corner patches (right).*

THEOREM 4.3 (inf-sup condition). *Let $\mathcal{T}_h$ be a triangulation of Ω as described above and consider $\mathbf{X}_h$ based on $\widehat{V}_r^3$ or $\widehat{V}_r^4$ with $r \geq 3$. Then, there exists a constant $\beta > 0$ such that $\beta_h \geq \beta$. Like all constants in this paper, β is independent of the mesh parameter h and the maximal aspect ratio.*

Our method of proof works for all polynomial degrees $r \geq 3$ but not for $r = 2$. Since some numerical tests with $r = 2$ showed stability, the validity of a uniform inf-sup condition must be considered open for this case.

The consistency error is estimated in the following theorem.

THEOREM 4.4 (consistency error). *Let $\boldsymbol{u} \in \boldsymbol{X} \cap \boldsymbol{H}^{r+1}(\Omega)$ and $p \in M \cap H^r(\Omega)$ be the solution of (2.1). Then, the consistency error estimate*

$$\sup_{\boldsymbol{v}_h \in \boldsymbol{X}_h} \frac{|a_h(\boldsymbol{u},\boldsymbol{v}_h) - b_h(\boldsymbol{v}_h,p) - (\boldsymbol{f},\boldsymbol{v}_h)|}{|\boldsymbol{v}_h|_{1,h}}$$

$$\lesssim \left(\sum_{K\in\mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \left(\|D^\alpha(\partial_1 u_1 - p)\|_{0,K}^2 + \|D^\alpha \partial_1 u_2\|_{0,K}^2 \right) \right)^{1/2}$$

$$+ \left(\sum_{K\in\mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \|D^\alpha \boldsymbol{f}\|_{0,K}^2 \right)^{1/2}$$

holds true. As is the case above, the space $\mathbf{X}_h$ is based on $\widehat{V}_r^3$ or $\widehat{V}_r^4$.

Now, we can formulate our main result.

THEOREM 4.5 (discretization error estimate). *Let $(\boldsymbol{u},p) \in \boldsymbol{X} \times M$ and $(\boldsymbol{u}_h,p_h) \in \boldsymbol{X}_h \times M_h$ be the solutions of (2.1) and (2.2), respectively. The space $\mathbf{X}_h$ is based on $\widehat{V}_r^3$ or $\widehat{V}_r^4$ with $r \geq 3$. Then, the discretization error is estimated by*

$$|\boldsymbol{u}-\boldsymbol{u}_h|_{1,h} + \|p-p_h\|_0 \lesssim \left(\sum_{K\in\mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \left(|D^\alpha \boldsymbol{u}|_{1,K}^2 + \|D^\alpha p\|_{0,K}^2 \right) \right)^{1/2}$$

$$+ \left(\sum_{K\in\mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \|D^\alpha \boldsymbol{f}\|_{0,K}^2 \right)^{1/2}$$

provided that $\boldsymbol{u} \in \boldsymbol{H}^{r+1}(\Omega)$, $p \in H^r(\Omega)$, and $\boldsymbol{f} \in \boldsymbol{H}^{r-1}(\Omega)$.

Proof. Under the assumption that the uniform inf-sup condition $\beta_h \geq \beta > 0$ is valid, Proposition II.2.16 of [8] gives

$$|\boldsymbol{u}-\boldsymbol{u}_h|_{1,h} + \|p-p_h\|_0 \lesssim \inf_{\boldsymbol{v}_h \in \boldsymbol{X}_h} |\boldsymbol{u}-\boldsymbol{v}_h|_{1,h} + \inf_{q_h \in M_h} \|p-q_h\|_0$$

$$+ \sup_{\boldsymbol{v}_h \in \boldsymbol{X}_h} \frac{|a_h(\boldsymbol{u},\boldsymbol{v}_h) - b_h(\boldsymbol{v}_h,p) - (\boldsymbol{f},\boldsymbol{v}_h)|}{|\boldsymbol{v}_h|_{1,h}}.$$

The estimate for the error of the best approximation is obtained by combining the local estimates from Theorem 4.1. The consistency term is estimated in Theorem 4.4. The assertion is concluded by observing that parts of the right-hand side of the consistency error estimate can be bounded by best approximation terms. ∎

Note that the estimate is standard in the sense that we have a method of order r for $\boldsymbol{u} \in \boldsymbol{H}^{r+1}(\Omega)$, $p \in H^r(\Omega)$, and $\boldsymbol{f} \in \boldsymbol{H}^{r-1}$. The advantage is that we can compensate large derivatives of $\boldsymbol{u}$ and p in the x_2-direction by choosing small values for $h_{K,2}$.

5. Proof of the interpolation error estimates. Estimates for $\|u - I_h u\|_{0,q,K}$ and $\|\partial_1(u - I_h u)\|_{0,q,K}$ can be proved in the standard way since the element K is assumed to be stretched in the x_1-direction. Even nonsmooth functions $u \in W^{1,p}(K)$ can be treated by this approach.

LEMMA 5.1. *Let $u \in W^{\ell,p}(K)$, where $\ell \in \mathbb{N}$, $1 \le \ell \le r+1$, $p \in [1,\infty]$. Fix $m \in \{0,1\}$ and $q \in [1,\infty]$ such that $W^{\ell-m,p}(K) \hookrightarrow L^q(K)$. Then, the anisotropic interpolation error estimate*

$$\|\partial_1^m(u - I_h^\nu u)\|_{0,q,K} \lesssim |K|^{1/q-1/p} \sum_{|\alpha|=\ell-m} h_K^\alpha |D^\alpha u|_{m,p,K}, \quad \nu = 3,4,$$

holds true.

Proof. We prove the estimate first on the reference element $\widehat{K}$. Since the interpolation operator $\widehat{I}^\nu$ preserves polynomials of degree r and since $\widehat{I}^\nu : W^{\ell,p}(\widehat{K}) \to W^{m,q}(\widehat{K})$ is a bounded operator, we have for all $\hat{w} \in P_{\ell-1}(\widehat{K}) \subset P_r(\widehat{K}) \subset \widehat{V}_r^\nu$

$$\|\hat{\partial}_1^m(\hat{u} - \widehat{I}^\nu \hat{u})\|_{0,q,\widehat{K}} = \|\hat{\partial}_1^m(\hat{u} - \hat{w}) - \hat{\partial}_1^m \widehat{I}^\nu(\hat{u} - \hat{w})\|_{0,q,\widehat{K}} \lesssim \|\hat{u} - \hat{w}\|_{\ell,p,\widehat{K}}.$$

By using the Deny–Lions lemma, we obtain

$$\|\hat{\partial}_1^m(\hat{u} - \widehat{I}^\nu \hat{u})\|_{0,q,\widehat{K}} \lesssim |\hat{u}|_{\ell,p,\widehat{K}}.$$

The assertion is proved by transforming this estimate from $\widehat{K}$ to K by using $h_{K,2} \le h_{K,1}$. ∎

The challenge is the proof for $\|\partial_2(u - I_h^\nu u)\|_{0,q,K}$; see [2, Ex. 2.1]. Due to [2, Lemma 2.2], we succeed if we find a set $\widehat{\mathcal{F}}_r$ of $\dim \hat{\partial}_2 \widehat{V}_r^\nu$ linear functionals such that

$$\widehat{F} \in \big(W^{\ell-1,p}(\widehat{K})\big)' \quad \forall \widehat{F} \in \widehat{\mathcal{F}}_r, \tag{5.1}$$

$$\widehat{F}\big(\hat{\partial}_2(\hat{u} - \widehat{I}^\nu \hat{u})\big) = 0 \quad \forall \widehat{F} \in \widehat{\mathcal{F}}_r, \quad \forall \hat{u} \in W^{\ell,p}(\widehat{K}), \tag{5.2}$$

$$\hat{v} \in \hat{\partial}_2 \widehat{V}_r^\nu \quad \text{and} \quad \widehat{F}(\hat{v}) = 0 \quad \forall \widehat{F} \in \widehat{\mathcal{F}}_r \quad \Rightarrow \quad \hat{v} \equiv 0. \tag{5.3}$$

To this end, we define the set

$$\begin{aligned} \widehat{\mathcal{F}}_r := \big\{\widehat{F}_{i,*} \,:\, i = 0,\dots,r-1\big\} \cup \big\{\widehat{F}_{ij} \,:\, 0 \le i+j \le r-2\big\} \\ \cup \big\{\widehat{F}_{+,i}, \widehat{F}_{-,i} \,:\, i = 1,\dots,r-1\big\} \end{aligned} \tag{5.4}$$

with

$$\widehat{F}_{i,*}(\hat{v}) := \frac{1}{\delta_i \delta_0} \int_{-1}^1 \int_{-1}^1 L_i(\hat{x}_1) L_0(\hat{x}_2) \hat{v}(\hat{x}_1, \hat{x}_2)\, d\hat{x}_1\, d\hat{x}_2,$$

$$\widehat{F}_{ij}(\hat{v}) := \frac{2}{\delta_i \delta_j} \int_{-1}^1 \int_{-1}^1 L_i(\hat{x}_1) \widehat{L}_j(\hat{x}_2) \hat{v}(\hat{x}_1, \hat{x}_2)\, d\hat{x}_1\, d\hat{x}_2,$$

$$\widehat{F}_{+,i}(\hat{v}) := \frac{2}{\delta_i} \int_{-1}^1 \widehat{L}_i(\hat{x}_2) \hat{v}(+1, \hat{x}_2)\, d\hat{x}_2,$$

$$\widehat{F}_{-,i}(\hat{v}) := \frac{2}{\delta_i} \int_{-1}^1 \widehat{L}_i(\hat{x}_2) \hat{v}(-1, \hat{x}_2)\, d\hat{x}_2.$$

One easily checks that both the dimension of $\hat{\partial}_2 \widehat{V}_r^\nu$, $\nu = 3,4$, and the number of functionals in $\widehat{\mathcal{F}}_r$ are equal to $r^2/2 + 5r/2 - 2$. It remains to prove that the set $\widehat{\mathcal{F}}_r$

satisfies the properties (5.1)–(5.3). We start with the unisolvence property (5.3) which needs the most complex proof, done for $\widehat{V}_r^4$ and $\widehat{V}_r^3$ separately.

LEMMA 5.2. *The set $\widehat{\mathcal{F}}_r$ of functionals is unisolvent on $\hat{\partial}_2\widehat{V}_r^4$.*

Proof. The definition of $\widehat{V}_r^4$ gives immediately

$$\begin{aligned}\hat{\partial}_2\widehat{V}_r^4 = P_{r-1}(\widehat{K}) &\oplus \operatorname{span}\big\{L_{r-i}(\hat{x}_1)L_i(\hat{x}_2),\ i=0,\dots,r-2\big\}\\ &\oplus \operatorname{span}\big\{L_{r+1-i}(\hat{x}_1)L_i(\hat{x}_2),\ i=0,\dots,r-2\big\}.\end{aligned} \tag{5.5}$$

We will show that $\hat{v}\in\hat{\partial}_2\widehat{V}_r$ and $\widehat{F}(\hat{v})=0$ for all $\widehat{F}\in\widehat{\mathcal{F}}_r$ give $\hat{v}\equiv 0$. To this end, a general element $\hat{v}\in\hat{\partial}_2\widehat{V}_r$ is written as

$$\hat{v} = \sum_{0\le i+j\le r-1}\alpha_{ij}L_i(\hat{x}_1)L_j(\hat{x}_2) + \sum_{i=0}^{r-2}\beta_i L_{r-i}(\hat{x}_1)L_i(\hat{x}_2) + \sum_{i=0}^{r-2}\gamma_i L_{r+1-i}(\hat{x}_1)L_i(\hat{x}_2).$$

Applying $\widehat{F}_{n,*}$ to $\hat{v}$ and using the orthogonality of the Legendre polynomials it follows that

$$0=\widehat{F}_{n,*}(\hat{v})=\alpha_{n0},\qquad n=0,\dots,r-1. \tag{5.6}$$

Hence, the function $\hat{v}$ can be written as

$$\hat{v} = \sum_{i=0}^{r-2}\sum_{j=1}^{r-1-i}\alpha_{ij}L_i(\hat{x}_1)L_j(\hat{x}_2) + \sum_{i=0}^{r-2}\beta_i L_{r-i}(\hat{x}_1)L_i(\hat{x}_2) + \sum_{i=0}^{r-2}\gamma_i L_{r+1-i}(\hat{x}_1)L_i(\hat{x}_2).$$

Applying $\widehat{F}_{m,0}$, $m=0,\dots,r-2$, and using the orthogonality of the Legendre polynomials together with $2/\delta_0=1$ result in

$$\begin{aligned}0=\widehat{F}_{m,0}(\hat{v}) = &\sum_{i=0}^{r-2}\sum_{j=1}^{r-1-i}\alpha_{ij}\delta_{im}(\delta_{j1}\delta_1+\delta_{j0}\delta_0) + \sum_{i=0}^{r-2}\beta_i\delta_{m,r-i}(\delta_{i1}\delta_1+\delta_{i0}\delta_0)\\ &+\sum_{i=0}^{r-2}\gamma_i\delta_{m,r+1-i}(\delta_{i1}\delta_1+\delta_{i0}\delta_0) = \alpha_{m1}\delta_1\end{aligned} \tag{5.7}$$

since all other terms vanish due to the range of i and j in the various sums. Hence, $\alpha_{m1}=0$ for $m=0,\dots,r-2$. Now, we apply $\widehat{F}_{mn}$ for $n\ge 1$, i.e., for $n=1,\dots,r-2$, $m=0,\dots,r-2-n$. Applying relation (3.1) between Legendre polynomials and integrated Legendre polynomials, we obtain

$$\begin{aligned}0=\widehat{F}_{mn}(\hat{v}) = &\sum_{i=0}^{r-2}\sum_{j=2}^{r-1-i}\alpha_{ij}\delta_{im}(\delta_{j,n+1}\delta_{n+1}+\delta_{j,n-1}\delta_{n-1})\\ &+\sum_{i=0}^{r-2}\beta_i\delta_{m,r-i}(\delta_{i,n+1}\delta_{n+1}+\delta_{i,n-1}\delta_{n-1})\\ &+\sum_{i=0}^{r-2}\gamma_i\delta_{m,r+1-i}(\delta_{i,n+1}\delta_{n+1}+\delta_{i,n-1}\delta_{n-1}),\end{aligned}$$

where again the orthogonality of the Legendre polynomials was used. The first double sum can be simplified, and the sums with β_i and γ_i are again zero due to $m+n \le r-2$. Thus, the equations become

$$0 = \alpha_{m,n+1}\delta_{n+1} - \alpha_{m,n-1}\delta_{n-1}.$$

For $n = 1$ one gets $\alpha_{m2} = 0$, $m = 0, \dots, r-3$, since $\alpha_{m0} = 0$. By induction we obtain with (5.6) and (5.7)

$$\alpha_{ij} = 0, \qquad 0 \le i + j \le r - 1.$$

Hence, we have

$$\hat{v} = \sum_{i=0}^{r-2} \Big(\beta_i L_{r-i}(\hat{x}_1) + \gamma_i L_{r+1-i}(\hat{x}_1)\Big) L_i(\hat{x}_2).$$

Using $\widehat{F}_{+,n}(\hat{v}) = 0$ and $\widehat{F}_{-,n}(\hat{v}) = 0$, $n = 1, \dots, r-1$, we get

$$0 = \sum_{i=0}^{r-2} \Big(\beta_i (+1)^{r-i} + \gamma_i (+1)^{r+1-i}\Big)\big(\delta_{n+1,i}\delta_{n+1} - \delta_{n-1,i}\delta_{n-1}\big),$$

$$0 = \sum_{i=0}^{r-2} \Big(\beta_i (-1)^{r-i} + \gamma_i (-1)^{r+1-i}\Big)\big(\delta_{n+1,i}\delta_{n+1} - \delta_{n-1,i}\delta_{n-1}\big).$$

These equations reduce in the cases $n = r-1$ and $n = r-2$ to

$$\beta_{r-2} + \gamma_{r-2} = 0, \qquad \beta_{r-2} - \gamma_{r-2} = 0,$$

$$\beta_{r-3} + \gamma_{r-3} = 0, \qquad \beta_{r-3} - \gamma_{r-3} = 0;$$

i.e., we get

$$\beta_{r-2} = \gamma_{r-2} = \beta_{r-3} = \gamma_{r-3} = 0.$$

Using this result, we get by induction on $n = r-3, \dots, 1$ the final result

$$\beta_i = \gamma_i = 0, \qquad i = 0, \dots, r-2.$$

This means that $\hat{v} \equiv 0$. ∎

LEMMA 5.3. *The set $\widehat{\mathcal{F}}_r$ of functionals is unisolvent on $\hat{\partial}_2 \widehat{V}_r^3$.*

Proof. In order to get an expression for $\hat{\partial}_2 \widehat{V}_r^3$, we have to consider the difference term carefully. Setting

$$k := \lfloor r/2 \rfloor \tag{5.8}$$

and using the differentiated version of (3.1), we obtain

$$\begin{aligned}
&\frac{\partial}{\partial \hat{x}_2}\big(L_{k+2}(\hat{x}_1)L_k(\hat{x}_2) - L_k(\hat{x}_1)L_{k+2}(\hat{x}_2)\big) \\
&\quad = L_{k+2}(\hat{x}_1)\left[L'_{k-2}(\hat{x}_2) + \frac{2}{\delta_{k-1}} L_{k-1}(\hat{x}_2)\right] - L_k(\hat{x}_1)\left[L'_k(\hat{x}_2) + \frac{2}{\delta_{k+1}} L_{k+1}(\hat{x}_2)\right] \\
&\quad = \frac{2}{\delta_{k+1}}\left[\frac{\delta_{k+1}}{\delta_{k-1}} L_{k+2}(\hat{x}_1)L_{k-1}(\hat{x}_2) - L_k(\hat{x}_1)L_{k+1}(\hat{x}_2)\right] + q_{r-1}
\end{aligned}$$

with $q_{r-1} \in P_{r-1}(\widehat{K})$. Hence, the space $\hat{\partial}_2 \widehat{V}_r^3$ can be written as

(5.9)

$$\begin{aligned}\hat{\partial}_2 \widehat{V}_r^3 = {} & P_{r-1}(\widehat{K}) \\ & \oplus \operatorname{span}\Big\{ L_{r-i}(\hat{x}_1) L_i(\hat{x}_2), L_{r+1-i}(\hat{x}_1) L_i \,:\, i = 0, \dots, k-2 \text{ or } i = k+2, \dots, r \Big\} \\ & \oplus \operatorname{span}\left\{ \frac{\delta_{k+1}}{\delta_{k-1}} L_{k+2}(\hat{x}_1) L_{k-1}(\hat{x}_2) - L_k(\hat{x}_1) L_{k+1}(\hat{x}_2) \right\} \\ & \oplus \operatorname{span}\Big\{ L_m(\hat{x}_1) L_n(\hat{x}_2) \Big\},\end{aligned}$$

where k is defined in (5.8) and

$$(m,n) := \begin{cases} (k+3, k-1) & \text{for } r \text{ odd}, \\ (k-1, k+1) & \text{for } r \text{ even}. \end{cases} \tag{5.10}$$

As usual, we will show that $\hat{v} \in \hat{\partial}_2 \widehat{V}_r^3$ with $\widehat{F}(\hat{v}) = 0$ for all $\widehat{F} \in \widehat{\mathcal{F}}_r$ results in $\hat{v} \equiv 0$. In order to do so, we write $\hat{v}$ as a linear combination of the basis functions given in (5.9) and the Legendre basis of $P_{r-1}(\widehat{K})$. Proceeding as in the beginning of the proof of Lemma 5.2, we get that all coefficients for functions from $P_{r-1}(\widehat{K})$ vanish. Hence, the function $\hat{v}$ can be represented as

$$\begin{aligned}\hat{v} = {} & \sum_{i=0}^{k-2} \Big(\beta_i L_{r-i}(\hat{x}_1) L_i(\hat{x}_2) + \gamma_i L_{r+1-i}(\hat{x}_1) L_i(\hat{x}_2) \Big) \\ & + \sum_{i=k+2}^{r} \Big(\beta_i L_{r-i}(\hat{x}_1) L_i(\hat{x}_2) + \gamma_i L_{r+1-i}(\hat{x}_1) L_i(\hat{x}_2) \Big) \\ & + \mu \left(\frac{\delta_{k+1}}{\delta_{k-1}} L_{k+2}(\hat{x}_1) L_{k-1}(\hat{x}_2) - L_k(\hat{x}_1) L_{k+1}(\hat{x}_2) \right) \\ & + \vartheta L_m(\hat{x}_1) L_n(\hat{x}_2)\end{aligned}$$

with k from (5.8) and m, n from (5.10). Now, the cases of odd and even r have to be distinguished. Let r be even. Applying the nodal functionals $\widehat{F}_{\pm,k}$, we obtain

$$\begin{aligned} 0 = \widehat{F}_{\pm,k}(\hat{v}) = {} & \mu \frac{\delta_{k+1}}{\delta_{k-1}} \int_{-1}^{1} (\pm 1)^{k+2} L_{k-1}(\hat{x}_2) \big(L_{k+1}(\hat{x}_2) - L_{k-1}(\hat{x}_2) \big) \, d\hat{x}_2 \\ & - \mu \int_{-1}^{1} (\pm 1)^{k} L_{k+1}(\hat{x}_2) \big(L_{k+1}(\hat{x}_2) - L_{k-1}(\hat{x}_2) \big) \, d\hat{x}_2 \\ & + \vartheta \int_{-1}^{1} (\pm 1)^{k-1} L_{k+1}(\hat{x}_2) \big(L_{k+1}(\hat{x}_2) - L_{k-1}(\hat{x}_2) \big) \, d\hat{x}_2 \\ = {} & (\pm 1)^k \left[\frac{\delta_{k+1}}{\delta_{k-1}} (-\delta_{k-1}) \mu - \delta_{k+1} \mu + (\pm 1) \delta_{k+1} \vartheta \right] \end{aligned}$$

by again using the orthogonality of the Legendre polynomials. Hence, we get

$$0 = -2\mu + \vartheta, \qquad 0 = -2\mu - \vartheta,$$

which immediately give $\mu = \vartheta = 0$. We obtain in a similar way that $\mu = \vartheta = 0$ also for odd r. For showing that the coefficients β_i and γ_i will vanish, we proceed as in the end of the proof of Lemma 5.2. Here, we apply $\widehat{F}_{\pm,\ell}$ for $\ell = k+1, \dots, r-1$ and $\ell = k-1, \dots, 0$. Finally, we end up with $\hat{v} \equiv 0$ since all coefficients vanish. ∎

We are now prepared to prove the anisotropic interpolation error estimate for $\partial_2(u - I_h^\nu u)$, $\nu = 3, 4$. We start with the case of smooth functions $u \in W^{\ell,p}(K)$, $\ell \geq 2$.

LEMMA 5.4. *Let $u \in W^{\ell,p}(K)$, where $\ell \in \mathbb{N}$, $2 \leq \ell \leq r+1$, $p \in [1, \infty]$. Fix $q \in [1, \infty]$ such that $W^{\ell-1,p}(K) \hookrightarrow L^q(K)$. Then, the anisotropic interpolation error estimate*

$$\|\partial_2(u - I_h^\nu u)\|_{0,q,K} \lesssim |K|^{1/q-1/p} \sum_{|\alpha|=\ell-1} h_K^\alpha |D^\alpha u|_{1,p,K}, \quad \nu = 3, 4,$$

holds true.

Proof. We prove first an estimate on the reference element $\widehat{K}$. In order to be able to apply [2, Lemma 2.2], it remains to show that the functionals $\widehat{F} \in \widehat{\mathcal{F}}_r$ satisfy the properties (5.1) and (5.2) since the property (5.3) was already proved in Lemmas 5.2 and 5.3.

Property (5.1) is satisfied since $\ell - 1 \geq 1$ and all functionals are well defined for $\hat{u} \in W^{1,1}(\widehat{K})$. We note here that weaker functions cannot be used since their trace on an edge of $\widehat{K}$ must be integrable. This is the reason for the assumption $\ell \geq 2$.

Property (5.2) can also be proved simultaneously for both $\widehat{V}_r^3$ and $\widehat{V}_r^4$ since the set of nodal functionals $\widehat{\mathcal{N}}$ is the same. We have

$$\begin{aligned}
\widehat{F}_{i,*}\big(\hat{\partial}_2(\hat{u} - \widehat{I}^\nu \hat{u})\big) &= \frac{1}{\delta_i \delta_0} \int_{-1}^{1} \int_{-1}^{1} L_i(\hat{x}_1) L_0(\hat{x}_2) \hat{\partial}_2\big(\hat{u} - \widehat{I}^\nu \hat{u}\big)(\hat{x}_1, \hat{x}_2)\, d\hat{x}_1\, d\hat{x}_2 \\
&= \frac{1}{\delta_i \delta_0} \int_{-1}^{1} L_i(\hat{x}_1)\big(\hat{u} - \widehat{I}^\nu \hat{u}\big)(\hat{x}_1, +1)\, d\hat{x}_1 \\
&\qquad - \frac{1}{\delta_i \delta_0} \int_{-1}^{1} L_i(\hat{x}_1)\big(\hat{u} - \widehat{I}^\nu \hat{u}\big)(\hat{x}_1, -1)\, d\hat{x}_1 \\
&= \frac{1}{\delta_0}\big(\widehat{N}_{i,+}(\hat{u} - \widehat{I}^\nu \hat{u}) - \widehat{N}_{i,-}(\hat{u} - \widehat{I}^\nu \hat{u})\big) = 0, \qquad i = 0, \dots, r-1, \\
\widehat{F}_{\pm,i}\big(\hat{\partial}_2(\hat{u} - \widehat{I}^\nu \hat{u})\big) &= \frac{2}{\delta_i} \int_{-1}^{1} \widehat{L}_i(\hat{x}_2) \hat{\partial}_2\big(\hat{u} - \widehat{I}^\nu \hat{u}\big)(\pm 1, \hat{x}_2)\, d\hat{x}_2 \\
&= -\frac{2}{\delta_i} \int_{-1}^{1} L_i(\hat{x}_2)\big(\hat{u} - \widehat{I}^\nu \hat{u}\big)(\pm 1, \hat{x}_2)\, d\hat{x}_2 \\
&= \widehat{N}_{\pm,i}\big(\hat{u} - \widehat{I}^\nu \hat{u}\big) = 0, \qquad i = 1, \dots, r-1,
\end{aligned}$$

$$\begin{aligned}\widehat{F}_{ij}\big(\hat\partial_2(\hat u-\widehat I^\nu\hat u)\big) &= \frac{2}{\delta_i\delta_j}\int_{-1}^1 L_i(\hat x_1)\int_{-1}^1 \widehat L_j(\hat x_2)\hat\partial_2\big(\hat u-\widehat I^\nu\hat u\big)(\hat x_1,\hat x_2)\,d\hat x_2\,d\hat x_1\\ &= \delta_{j0}\frac{2}{\delta_i\delta_0}\int_{-1}^1 L_i(\hat x_1)\widehat L_0(+1)\big(\hat u-\widehat I^\nu\hat u\big)(\hat x_1,1)\,d\hat x_1\\ &\quad -\frac{2}{\delta_i\delta_j}\int_{-1}^1 L_i(\hat x_1)\int_{-1}^1 L_j(\hat x_2)\big(\hat u-\widehat I^\nu\hat u\big)(\hat x_1,\hat x_2)\,d\hat x_2\,d\hat x_1\\ &= 2\delta_{j0}\widehat N_{i,+}\big(\hat u-\widehat I^\nu\hat u\big)-2\widehat N_{ij}\big(\hat u-\widehat I^\nu\hat u\big)=0,\qquad 0\le i+j\le r-2.\end{aligned}$$

Consequently, Lemma 2.2 of [2] delivers

$$\|\hat\partial_2(\hat u-\widehat I^\nu\hat u)\|_{0,q,\widehat K}\lesssim|\hat\partial_2\hat u|_{\ell-1,p,\widehat K}. \tag{5.11}$$

Note that the condition $\hat u\in C(\widehat K)$ in [2, Lemma 2.2] is not needed here but only for Lagrangian finite elements. The transformation of (5.11) from $\widehat K$ to K gives

$$\begin{aligned}\|\partial_2(u-I_h^\nu u)\|_{0,q,K}&\lesssim|K|^{1/q-1/p}\sum_{|\alpha|=\ell-1}h_K^\alpha\|D^\alpha\partial_2 u\|_{0,p,K}\\ &\lesssim|K|^{1/q-1/p}\sum_{|\alpha|=\ell-1}h_K^\alpha|D^\alpha u|_{1,p,K}.\end{aligned}$$

This is the desired estimate. ∎

Example 5.5. We show that the assumption $\ell\ge 2$ in Lemma 5.4 is essential. The validity of

$$\|\partial_2(u-I_h^\nu u)\|_{0,q,K}\lesssim|K|^{1/q-1/p}|u|_{1,p,K}$$

is equivalent to

$$\|\hat\partial_2(\hat u-\widehat I^\nu\hat u)\|_{0,q,\widehat K}\lesssim\|\hat\partial_2\hat u\|_{0,p,\widehat K}; \tag{5.12}$$

compare this with [2, Example 2.1]. In order to show that estimate (5.12) is not valid, we adapt Example 2.3 of [2] and consider the sequence of functions

$$\hat u_\varepsilon(\hat x_1,\hat x_2):=\hat x_2\cdot\min\left\{1,\varepsilon\left|\ln\frac{\hat x_1+1}{2}\right|\right\},\quad \varepsilon\to+0.$$

The limit function is defined pointwise by

$$\hat u_0(\hat x_1,\hat x_2):=\lim_{\varepsilon\to0}\hat u_\varepsilon(\hat x_1,\hat x_2)=\begin{cases}\hat x_2 & \text{for } \hat x_1=-1,\\ 0 & \text{for } \hat x_1>-1.\end{cases}$$

Since, for $p<\infty$,

$$\lim_{\varepsilon\to0}\|\hat\partial_2\hat u_\varepsilon\|_{0,p,\widehat K}=0\quad\text{and}\quad\lim_{\varepsilon\to0}\|\hat\partial_2(\hat u_\varepsilon-\widehat I^\nu\hat u_\varepsilon)\|_{0,q,\widehat K}=\|\hat\partial_2\widehat I^\nu\hat u_0\|_{0,q,\widehat K}=C>0,$$

the estimate (5.12) cannot hold.

The last equality is proved by contradiction: If $\|\hat\partial_2\widehat I^\nu\hat u_0\|_{0,q,\widehat K}=0$, then $I^\nu\hat u_0=:\hat v(\hat x_1)$ is polynomial in $\hat x_1$, and $(\hat u_0-\widehat I^\nu\hat u_0)(-1,\hat x_2)=\hat x_2-\hat v(-1)$ is a nonvanishing first

order polynomial in $\hat{x}_2$. On the other hand, we obtain from the definition of $\widehat{I}^\nu$ that this polynomial is orthogonal to all polynomials of order $r-1$. This is not possible for a nonvanishing first order polynomial if $r \geq 2$.

In order to prove an anisotropic interpolation error estimate for nonsmooth functions $u \in W^{1,p}(K)$, we have to deal with the difficulty that $\widehat{F}_{-,i}$ and $\widehat{F}_{+,i}$, $i = 1, \ldots, r-1$, are in general not defined for functions $\hat{v} \in L^p(\widehat{K})$. The alternative is to consider functions from $W^{1,p}_E(K)$ which vanish on $E_{-,*}$ and $E_{+,*}$; see (4.1).

LEMMA 5.6. *Let $u \in W^{1,p}_E(K)$ defined in (4.1), $p, q \in [1, \infty]$, $q \leq p$. Then, the estimate*

$$\|\partial_2(u - I_h^\nu u)\|_{0,q,K} \lesssim |K|^{1/q-1/p} |\partial_2 u|_{0,p,K}, \quad \nu = 3, 4,$$

holds true.

Proof. We start with an estimate on the reference element $\widehat{K}$. We have with respect to (5.3) and (5.4) the following equivalence of norms on the space $\hat{\partial}_2 \widehat{V}_r^\nu$, $\nu = 3, 4$:

$$\|\hat{\partial}_2 \widehat{I}^\nu \hat{u}\|_{0,q,\widehat{K}} \lesssim \sum_{0 \leq i+j \leq r-2} |\widehat{F}_{ij}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})| + \sum_{i=0}^{r-1} |\widehat{F}_{i,*}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})|$$
$$+ \sum_{i=1}^{r-1} |\widehat{F}_{+,i}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})| + \sum_{i=1}^{r-1} |\widehat{F}_{+,i}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})|.$$

For the functionals $\widehat{F}_{ij}$ and $\widehat{F}_{i,*}$, we use their property (5.2) and their boundedness for functions from $L^1(\widehat{K})$:

$$|\widehat{F}_{ij}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})| = |\widehat{F}_{ij}(\hat{\partial}_2 \hat{u})| \lesssim \|\hat{\partial}_2 \hat{u}\|_{0,p,\widehat{K}}, \quad 0 \leq i+j \leq r-2,$$

$$|\widehat{F}_{i,*}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})| = |\widehat{F}_{i,*}(\hat{\partial}_2 \hat{u})| \lesssim \|\hat{\partial}_2 \hat{u}\|_{0,p,\widehat{K}}, \quad i = 0, \ldots, r-1.$$

Moreover, we integrate by parts for the functionals $\widehat{F}_{\pm,i}$ and employ $\widehat{L}_i(\pm 1) = 0$ for $i \geq 1$ to obtain

$$\left|\widehat{F}_{\pm,i}(\hat{\partial}_2 \widehat{I}^\nu \hat{u})\right| = \frac{2}{\delta_i} \left| \int_{-1}^{1} \widehat{L}_i(\hat{x}_2)(\hat{\partial}_2 \widehat{I}^\nu \hat{u})(\pm 1, \hat{x}_2)\, d\hat{x}_2 \right| = \frac{2}{\delta_i} \left| \int_{-1}^{1} L_i(\hat{x}_2) \widehat{I}^\nu \hat{u}(\pm 1, \hat{x}_2)\, d\hat{x}_2 \right|$$
$$= \left|\widehat{N}_{\pm,i}(\widehat{I}^\nu \hat{u})\right| = \left|\widehat{N}_{\pm,i}(\hat{u})\right| = 0.$$

Therefore, we can conclude

$$\|\hat{\partial}_2 \widehat{I}^\nu \hat{u}\|_{0,q,\widehat{K}} \lesssim \|\hat{\partial}_2 \hat{u}\|_{0,p,\widehat{K}},$$

$$\|\hat{\partial}_2 (\hat{u} - \widehat{I}^\nu \hat{u})\|_{0,q,\widehat{K}} \lesssim \|\hat{\partial}_2 \hat{u}\|_{0,p,\widehat{K}},$$

where we have used $\|\cdot\|_{0,q,\widehat{K}} \lesssim \|\cdot\|_{0,p,\widehat{K}}$ for $q \leq p$. The assertion of the lemma is proved by transforming this estimate from $\widehat{K}$ to K. ∎

Lemmas 5.1 and 5.4 yield Theorem 4.1, whereas Lemmas 5.1 and 5.6 give Theorem 4.2.

6. Checking the inf-sup condition. For showing that the inf-sup condition holds true, we will use the macroelement technique introduced in [7]; see also [13, sect. II.1.4]. As already described in section 4, the domain Ω is decomposed into isotropic rectangular macroelements Q such that

$$\overline{\Omega} = \bigcup_{Q\in\mathcal{T}_H} \overline{Q}.$$

On the macroelements Q from this macrotriangulation $\mathcal{T}_H$, we define subspaces of $\boldsymbol{X}_h$ and Q_h in the following way:

$$\boldsymbol{X}_h(Q) := \bigl\{\boldsymbol{v} \,:\, \boldsymbol{v}\in\boldsymbol{X}_h,\, \boldsymbol{v}\equiv\boldsymbol{0} \text{ in } \Omega\setminus\overline{Q}\bigr\},$$

$$M_h(Q) := \bigl\{q|_Q : q\in M_h\bigr\} \cap L^2_0(Q).$$

Furthermore, let

$$\overline{M}_h := \bigl\{q\in L^2_0(\Omega) \,:\, q|_Q = \text{const}\ \forall Q\in\mathcal{T}_H\bigr\}$$

be the space of piecewise constant functions with respect to the macrotriangulation $\mathcal{T}_H$. Now, we can give the uniform local inf-sup condition

$$\exists\beta_\ell>0\ \forall Q\in\mathcal{T}_H \,:\, \inf_{q_h\in M_h(Q)} \sup_{\boldsymbol{v}_h\in\boldsymbol{X}_h(Q)} \frac{b_h(\boldsymbol{v}_h,q_h)}{|\boldsymbol{v}_h|_{1,h}\,\|q_h\|_{0,Q}} \geq \beta_\ell.$$

Adapting the results from [7] to the nonconforming case, we can state the following lemma.

LEMMA 6.1. *Let the local inf-sup condition be fulfilled with a constant β_ℓ which is independent of the number of macroelements and the mesh size h. Furthermore, we assume that there exists a subspace $\overline{\boldsymbol{X}}_h$ of $\boldsymbol{X}_h$ such that $(\overline{\boldsymbol{X}}_h,\overline{M}_h)$ satisfies an inf-sup condition with a constant $\overline{\beta}>0$ which does not depend on h. Then, there exists a constant $\beta>0$ independent of h such that $(\boldsymbol{X}_h,M_h)$ is inf-sup stable with the constant β.*

Proof. For conforming finite elements, the proof can be found in [7] and [13, sect. II.1.4]. For the adaptation of the idea to nonconforming finite elements, we refer the reader to [10, 19, 20]. ∎

A careful inspection of the macroelement techniques shows that the global inf-sup constant is independent of all mesh parameters if the constants β_ℓ and $\overline{\beta}$ are independent of the mesh parameters.

For our purposes, we will use for $\overline{\boldsymbol{X}}_h$ the space of continuous functions v_H with $v_H|_Q \in Q'_2(Q)$ (serendipity elements) for all $Q\in\mathcal{T}_H$. Note that this space is a subspace of $\boldsymbol{X}_h$ for $r\geq 3$ and forms together with $\overline{M}_h$ an inf-sup stable pair. Hence, it remains to show that the local inf-sup condition will be satisfied on boundary layer patches and corner patches. Let us start with boundary layer patches.

LEMMA 6.2. *Let Q be a boundary layer patch. Then, there exists a constant $\beta>0$ independent of the aspect ratio of the elements such that*

$$\beta_h := \inf_{q_h\in M_h(Q)} \sup_{\boldsymbol{v}_h\in\boldsymbol{X}_h(Q)} \frac{b_h(\boldsymbol{v}_h,q_h)}{|\boldsymbol{v}|_{1,Q}\,\|q_h\|_{0,Q}} > \beta \tag{6.1}$$

holds true provided $r\geq 2$.

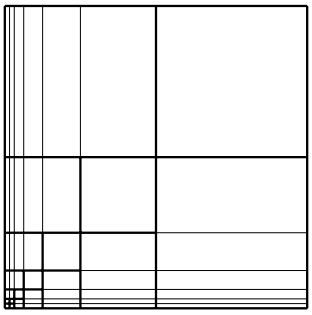

FIG. 6.1. *Corner patch with macrotriangulation.*

Proof. Due to Fortin [12], the fulfillment of the inf-sup condition on a macroelement Q is equivalent to the existence of an interpolation operator $\boldsymbol{i}_Q : \boldsymbol{H}_0^1(Q) \to \boldsymbol{X}_h$ which has the following properties:

$$b_h(\boldsymbol{i}_Q \boldsymbol{v}, q_h) = b_h(\boldsymbol{v}, q_h) \qquad \forall q_h \in M_h(Q),\ \boldsymbol{v} \in \boldsymbol{H}_0^1(Q), \tag{6.2}$$

$$|\boldsymbol{i}_Q \boldsymbol{v}|_{1,h} \lesssim |\boldsymbol{v}|_1 \qquad \forall \boldsymbol{v} \in \boldsymbol{H}_0^1(Q). \tag{6.3}$$

We can choose in the considered situation the natural interpolation operator $\boldsymbol{I}^\nu$, $\nu = 3, 4$, for $\boldsymbol{i}_Q$. The condition (6.3) follows directly from the interpolation error estimate given in Theorem 4.2 for the case $m = 1$, $p = 2$. The condition (6.2) is a consequence of the natural interpolation operator which is defined via the nodal functionals from $\widehat{\mathcal{N}}_r$. Indeed, we have

$$\begin{aligned} b_h(\boldsymbol{I}^\nu \boldsymbol{v}, q_h) &= \sum_{K \subset Q} (\operatorname{div} \boldsymbol{I}^\nu \boldsymbol{v}, q_h)_K \\ &= \sum_{K \subset Q} \big[-(\boldsymbol{I}^\nu \boldsymbol{v}, \nabla q_h)_K + \langle \boldsymbol{n}^K \cdot \boldsymbol{I}^\nu \boldsymbol{v}, q_h \rangle_{\partial K} \big] \\ &= \sum_{K \subset Q} \big[-(\boldsymbol{v}, \nabla q_h)_K + \langle \boldsymbol{n}^K \cdot \boldsymbol{v}, q_h \rangle_{\partial K} \big] \\ &= \sum_{K \subset Q} (\operatorname{div} \boldsymbol{v}, q_h)_K = b_h(\boldsymbol{v}, q_h), \end{aligned}$$

where we have used that $\nabla q_h|_K \in \boldsymbol{P}_{r-2}(K)$ and $q_h|_E \in P_{r-1}(E)$ for all edges $E \in \partial K$. Since both conditions (6.2) and (6.3) are fulfilled and the constant in (6.3) is independent of all mesh parameters, we conclude that the local inf-sup condition is satisfied with a constant which does not depend on the mesh parameters. ∎

LEMMA 6.3. *Let Q be a corner patch. Then there exists a constant $\beta > 0$ independent of the aspect ratio of the elements such that* (6.1) *holds true provided $r \geq 3$.*

Proof. The corner patch Q can be considered as a macrotriangulation $\Delta = \{K\}$ with hanging nodes where the macros K are boundary layer patches. This is illustrated in Figure 6.1 by using lines with different widths. Furthermore, we denote by $\widehat{\Delta} = \{\widehat{K}\}$ the affine image of Δ on $\widehat{Q} = (0,1)^2$. Schötzau, Schwab, and Stenberg [25, sect. 4.2] considered on each $\widehat{K} \in \widehat{\Delta}$ the velocity space

$$L^1(\widehat{K}) := Q_1(\widehat{K})^2 \oplus \operatorname{span}\big\{\hat{b}_1 \hat{\boldsymbol{n}}_1, \ldots, \hat{b}_4 \hat{\boldsymbol{n}}_4\big\},$$

where $\hat{\boldsymbol{n}}_i$ is the outward normal on the ith edge of $\widehat{K}$ and $\hat{b}_i \in Q_2'(\widehat{K})$ is the corresponding edge bubble function, $i = 1, \ldots, 4$. Moreover, they defined the spaces

$$L_0^{1,1}(\widehat{\Delta}) := \bigl\{\hat{\boldsymbol{u}} \in H_0^1(\widehat{Q})^2 : \hat{\boldsymbol{u}}|_{\widehat{K}} \in L^1(\widehat{K})\ \forall \widehat{K} \in \widehat{\Delta}\bigr\},$$

$$S_0^{0,0}(\widehat{\Delta}) := \bigl\{\hat{p} \in L_0^2(\widehat{Q}) : \hat{p}|_{\widehat{K}} \in P_0(\widehat{K})\ \forall \widehat{K} \in \widehat{\Delta}\bigr\}$$

and proved inf-sup stability for this pair [25, Theorem 4.9]. The inf-sup constant depends just on the grading factor σ. The stability for the pair $\bigl(L_0^{1,1}(\Delta), S_0^{0,0}(\Delta)\bigr)$ is obtained by scaling. Since $L^1(\widehat{K}) \subset Q_2'(\widehat{K})^2$, we also have stability for the pair of spaces which is defined on the basis of (Q_2', P_0). This result can also be derived by a closer look at the proofs of Heuveline and Schieweck [15], who investigated the (Q_2, P_0) pair on meshes with hanging nodes.

Since $Q_2'(\widehat{K}) \subset \widehat{V}_r^3, \widehat{V}_r^4$ for $r \geq 3$ and due to the stability on boundary layer patches as proved in Lemma 6.2, we can conclude the assertion of Lemma 6.3 by the macroelement technique. ∎

Numerical tests for the case $r = 2$ have shown that all four families are stable on corner patches with $\sigma = \frac{1}{2}$. Nevertheless, our method of proof does not work for $r = 2$. Therefore, the validity of a uniform inf-sup condition must be considered open for this case.

Now, we can finish this section with the following proof.

Proof of Theorem 4.3. Since we have shown all necessary ingredients for the macroelement technique, the stated inf-sup condition holds true with a constant which is independent of the mesh parameter, aspect ratio, and mesh size. ∎

7. Proof of the consistency error estimate. For proving the estimate of the consistency error, we start with an estimate for an auxiliary problem.

LEMMA 7.1. *For arbitrary $\boldsymbol{\eta} \in \boldsymbol{H}^r(\Omega)$ and $g = -\operatorname{div}\boldsymbol{\eta}$, the estimate*

$$\sup_{v_h \in X_h} \frac{(\boldsymbol{\eta}, \nabla v_h)_h - (g, v_h)}{|v_h|_{1,h}} \lesssim \left(\sum_{K \in \mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \|D^\alpha \boldsymbol{\eta}\|_{0,K}^2 \right)^{1/2} + \left(\sum_{K \in \mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \|D^\alpha g\|_{0,K}^2 \right)^{1/2}$$

holds true where

$$(\boldsymbol{\eta}, \nabla v_h)_h := \sum_{K \in \mathcal{T}_h} (\boldsymbol{\eta}, \nabla v_h)_K.$$

Proof. By using $g = -\operatorname{div}\boldsymbol{\eta}$ and integration by parts, we can rewrite the numerator as

$$(\boldsymbol{\eta}, \nabla v_h)_h - (g, v_h) = \sum_{K \in \mathcal{T}_h} \langle \boldsymbol{\eta} \cdot \boldsymbol{n}_K, v_h \rangle_{\partial K} = T_1 + T_2$$

with

$$T_1 = \sum_{K \in \mathcal{T}_h} \sum_{E \in \mathcal{E}_S(K)} \int_E \boldsymbol{\eta} \cdot \boldsymbol{n}\, v_h \, d\gamma, \qquad T_2 = \sum_{K \in \mathcal{T}_h} \sum_{E \in \mathcal{E}_L(K)} \int_E \boldsymbol{\eta} \cdot \boldsymbol{n}\, v_h \, d\gamma,$$

where $\mathcal{E}_L(K)$ and $\mathcal{E}_S(K)$ denote the sets of long and short edges of K, respectively. Let us further assume that the long edges are parallel to the x_1-direction while the short edges are parallel to the x_2-direction. This gives that $n_2 = 0$ on short edges and $n_1 = 0$ on long edges. Hence, T_1 and T_2 simplify to

$$T_1 = \sum_{E\in\mathcal{E}_S} \int_E \eta_1 n_1^E [v_h]_E \, d\gamma, \qquad T_2 = \sum_{E\in\mathcal{E}_L} \int_E \eta_2 n_2^E [v_h]_E \, d\gamma.$$

Here, $\mathcal{E}_L$ and $\mathcal{E}_S$ are the global sets of long and short edges, respectively. Let Π denote the special interpolation operator into the space of continuous Q_{r-1} elements defined in [13, p. 108]. Due to the definition of X_h, the jump $[v_h]_E$ is orthogonal to all polynomials of degree $r-1$. Hence, we obtain

$$T_1 = \sum_{E\in\mathcal{E}_S} \int_E (\eta_1 - \Pi\eta_1) n_1^E [v_h]_E \, d\gamma, \qquad T_2 = \sum_{E\in\mathcal{E}_L} \int_E (\eta_2 - \Pi\eta_2) n_2^E [v_h]_E \, d\gamma$$

since the normal vectors are constant on the edges. Using the Gaussian theorem and the product rule, we get

$$\begin{aligned} T_1 &= \sum_{K\in\mathcal{T}_h} \int_K \partial_1 \big[(\eta_1 - \Pi\eta_1) v_h\big] \, dx \\ &= \sum_{K\in\mathcal{T}_h} \int_K \partial_1(\eta_1 - \Pi\eta_1) v_h \, dx + \sum_{K\in\mathcal{T}_h} \int_K (\eta_1 - \Pi\eta_1) \partial_1 v_h \, dx, \\ T_2 &= \sum_{K\in\mathcal{T}_h} \int_K \partial_2 \big[(\eta_2 - \Pi\eta_2) v_h\big] \, dx \\ &= \sum_{K\in\mathcal{T}_h} \int_K \partial_2(\eta_2 - \Pi\eta_2) v_h \, dx + \sum_{K\in\mathcal{T}_h} \int_K (\eta_2 - \Pi\eta_2) \partial_2 v_h \, dx. \end{aligned}$$

Due to the choice of the special interpolation operator Π, we have

$$\int_K \partial_i(\eta_i - \Pi\eta_i) \, dx = 0.$$

Hence, we get

$$\begin{aligned} T_1 &= \sum_{K\in\mathcal{T}_h} \int_K \partial_1(\eta_1 - \Pi\eta_1)(v_h - v_h^K) \, dx + \sum_{K\in\mathcal{T}_h} \int_K (\eta_1 - \Pi\eta_1) \partial_1 v_h \, dx, \\ T_2 &= \sum_{K\in\mathcal{T}_h} \int_K \partial_2(\eta_2 - \Pi\eta_2)(v_h - v_h^K) \, dx + \sum_{K\in\mathcal{T}_h} \int_K (\eta_2 - \Pi\eta_2) \partial_2 v_h \, dx, \end{aligned}$$

where v_h^K is the integral mean of v_h on the cell K. The interpolation operator Π fulfills

$$\|\partial_i(w - \Pi w)\|_{0,K} \lesssim \sum_{|\alpha|=r-1} h_K^\alpha \|D^\alpha \partial_i w\|_{0,K}, \qquad \|w - \Pi w\|_{0,K} \lesssim \sum_{|\alpha|=r} h_K^\alpha \|D^\alpha w\|_{0,K}$$

provided that $w \in H^r(K)$; see [1, 26]. We end up with

$$|T_1| \lesssim \left[\left(\sum_{K\in\mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \|D^\alpha \partial_1 \eta_1\|_{0,K}^2 \right)^{1/2} + \left(\sum_{K\in\mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \|D^\alpha \eta_1\|_{0,K}^2 \right)^{1/2} \right] |v_h|_{1,h},$$

$$|T_2| \lesssim \left[\left(\sum_{K\in\mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \|D^\alpha \partial_2 \eta_2\|_{0,K}^2 \right)^{1/2} + \left(\sum_{K\in\mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \|D^\alpha \eta_2\|_{0,K}^2 \right)^{1/2} \right] |v_h|_{1,h},$$

where the Cauchy–Schwarz inequality was used. The desired estimate is obtained by using $\partial_2\eta_2 = -g - \partial_1\eta_1$. ∎

We finish this section with the following proof.

Proof of Theorem 4.4. The proof is accomplished by applying Lemma 7.1 to

$$\boldsymbol{\eta}^{(1)} = \begin{pmatrix} \partial_1 u_1 \\ \partial_2 u_1 \end{pmatrix}, \quad g^{(1)} = f_1 - \partial_1 p, \quad \text{and} \quad \boldsymbol{\eta}^{(2)} = \begin{pmatrix} \partial_1 u_2 \\ \partial_2 u_2 - p \end{pmatrix}, \quad g^{(2)} = f_2.$$

This choice leads to

$$\begin{aligned} &|a_h(\boldsymbol{u},\boldsymbol{v}_h) - b_h(\boldsymbol{v}_h,p) - (\boldsymbol{f},\boldsymbol{v}_h)| \\ &\quad = \left|(\boldsymbol{\eta}^{(1)},\nabla v_{h,1})_h - (g^{(1)},v_{h,1}) + (\boldsymbol{\eta}^{(2)},\nabla v_{h,2})_h - (g^{(2)},v_{h,2})\right| \\ &\quad \lesssim \left(\sum_{K\in\mathcal{T}_h} \sum_{|\alpha|=r} h_K^{2\alpha} \left(|D^\alpha \boldsymbol{u}|_{1,K}^2 + \|D^\alpha p\|_{0,K}^2 \right) \right)^{1/2} |\boldsymbol{v}_h|_{1,h} \\ &\qquad + \left(\sum_{K\in\mathcal{T}_h} h_{K,1}^2 \sum_{|\alpha|=r-1} h_K^{2\alpha} \left(\|D^\alpha \boldsymbol{f}\|_{0,K}^2 + \|D^\alpha \partial_1 p\|_{0,K}^2 \right) \right)^{1/2} |\boldsymbol{v}_h|_{1,h}. \end{aligned}$$

The pressure terms in the last row are part of those in the second last row. This finishes the proof. ∎

Appendix. Unisolvence. This appendix contains the proof of the unisolvence results for $\widehat{V}_r^4$.

LEMMA A.1. *The set $\widehat{\mathcal{N}}_r$ is unisolvent on $\widehat{V}_r^4$.*

Proof. We have to show that $\hat{v} \in \widehat{V}_r^4$ and $\widehat{N}(\hat{v}) = 0$ for all $\widehat{N} \in \widehat{\mathcal{N}}_r$ results in $\hat{v} \equiv 0$. To this end, we represent an arbitrary function $\hat{v} \in \widehat{V}_r^4$ in the form

(A.1)
$$\hat{v} = \sum_{0\le i+j\le r} \alpha_{ij} L_i(\hat{x}_1) L_j(\hat{x}_2) + \sum_{i=0}^{r-1} \beta_i L_{r+1-i}(\hat{x}_1) L_i(\hat{x}_2) + \sum_{i=1}^{r-1} \gamma_i L_{r+2-i}(\hat{x}_1) L_i(\hat{x}_2).$$

The orthogonality of the Legendre polynomials gives

$$0 = \widehat{N}_{mn}(\hat{v}) = \alpha_{mn}, \qquad 0 \le m + n \le r - 2.$$

Hence, we have

$$\hat{v} = \sum_{i=0}^{r-1} \alpha_{r-1-i,i} L_{r-1-i}(\hat{x}_1) L_i(\hat{x}_2) + \sum_{i=0}^{r} \alpha_{r-i,i} L_{r-i}(\hat{x}_1) L_i(\hat{x}_2)$$
$$+ \sum_{i=0}^{r-1} \beta_i L_{r+1-i}(\hat{x}_1) L_i(\hat{x}_2) + \sum_{i=1}^{r-1} \gamma_i L_{r+2-i}(\hat{x}_1) L_i(\hat{x}_2).$$

The application of $\widehat{N}_{-,n}$ and $\widehat{N}_{+,n}$, $0 \le n \le r-1$, results in

$$0 = \alpha_{r-1-n,n} + \alpha_{r-n,n} + \beta_n + \gamma_n, \qquad n = 0, \dots, r-1, \tag{A.2}$$

$$0 = \alpha_{r-1-n,n} - \alpha_{r-n,n} + \beta_n - \gamma_n, \qquad n = 0, \dots, r-1, \tag{A.3}$$

where again the orthogonality of the Legendre polynomials is used. The parameter $\gamma_0 = 0$ is introduced for the convenience of notation. The sum and the difference of (A.2) and (A.3) give

$$0 = \alpha_{r-1-n,n} + \beta_n, \qquad n = 0, \dots, r-1, \tag{A.4}$$

$$0 = \alpha_{r-n,n} + \gamma_n, \qquad n = 0, \dots, r-1, \tag{A.5}$$

respectively. If we apply $\widehat{N}_{m,-}$ and $\widehat{N}_{m,+}$, $m = 0, \dots, r-1$, then we get

$$0 = \alpha_{m,r-1-m} - \alpha_{m,r-m} + \beta_{r+1-m} - \gamma_{r+2-m}, \qquad m = 0, \dots, r-1, \tag{A.6}$$

$$0 = \alpha_{m,r-1-m} + \alpha_{m,r-m} + \beta_{r+1-m} + \gamma_{r+2-m}, \qquad m = 0, \dots, r-1, \tag{A.7}$$

where we set $\beta_r = \beta_{r+1} = 0$ and $\gamma_r = \gamma_{r+1} = \gamma_{r+2} = 0$. Taking the sum and the difference of (A.6) and (A.7), we obtain

$$0 = \alpha_{m,r-1-m} + \beta_{r+1-m}, \qquad m = 0, \dots, r-1, \tag{A.8}$$

$$0 = \alpha_{m,r-m} + \gamma_{r+2-m}, \qquad m = 0, \dots, r-1, \tag{A.9}$$

respectively. Using (A.4) for n and (A.8) for $m = r - 1 - n$, we obtain

$$\alpha_{r-1-n,n} + \beta_n = 0 = \alpha_{r-1-n,n} + \beta_{n+2}, \qquad n = 0, \dots, r-1.$$

Hence, we get $\beta_n = \beta_{n+2}, n = 0, \dots, r-1$. We conclude with $\beta_r = \beta_{r+1} = 0$ that

$$\beta_n = 0, \qquad n = 0, \dots, r-1,$$

and with (A.4)

$$\alpha_{r-1-n,n} = 0, \qquad n = 0, \dots, r-1.$$

For $n = 1, \dots, r-1$, we obtain from (A.5) for n and from (A.9) for $m = r - n$

$$\alpha_{r-n,n} + \gamma_n = 0 = \alpha_{r-n,n} + \gamma_{n+2}, \qquad n = 1, \dots, r-1.$$

Hence, we have $\gamma_n = \gamma_{n+2}, n = 1, \ldots, r-1$. Together with $\gamma_r = \gamma_{r+1} = 0$, we end up with

$$\gamma_n = 0, \qquad n = 1, \ldots, r-1.$$

Putting this into (A.5), we get

$$\alpha_{r-n,n} = 0, \qquad n = 1, \ldots, r-1.$$

It remains to consider $\alpha_{r,0}$ and $\alpha_{0,r}$. From (A.5) for $n = 0$ we get $\alpha_{r,0} = 0$ since $\gamma_0 = 0$. Setting $m = 0$ in (A.9) results in $\alpha_{0,r} = 0$ due to $\gamma_{r+2} = 0$. Finally, we have seen that all coefficients in the representation (A.1) vanish. Hence, $\hat{v} \equiv 0$, and the set of nodal functionals $\widehat{\mathcal{N}}_r$ is unisolvent on $\widehat{V}_r^4$. □

ON USING APPROXIMATE FINITE DIFFERENCES IN MATRIX-FREE NEWTON–KRYLOV METHODS*

PETER N. BROWN†, HOMER F. WALKER‡, REBECCA WASYK‡, AND CAROL S. WOODWARD†

Abstract. A Newton–Krylov method is an implementation of Newton's method in which a Krylov subspace method is used to solve approximately the linear systems that characterize steps of Newton's method. Newton–Krylov methods are often implemented in "matrix-free" form, in which the Jacobian-vector products required by the Krylov solver are approximated by finite differences. Here we consider using approximate function values in these finite differences. We first formulate a finite-difference Arnoldi process that uses approximate function values. We then outline a Newton–Krylov method that uses an implementation of the GMRES or Arnoldi method based on this process, and we develop a local convergence analysis for it, giving sufficient conditions on the approximate function values for desirable local convergence properties to hold. We conclude with numerical experiments involving particular function-value approximations suitable for nonlinear diffusion problems. For this case, conditions are given for meeting the convergence assumptions for both lagging and linearizing the nonlinearity in the function evaluation.

Key words. matrix-free Newton–Krylov methods, Newton–GMRES methods, Newton–Arnoldi methods, Newton's method, Krylov subspace methods, GMRES method, Arnoldi method

1. Introduction.

The problem of interest is to determine $u_* \in \mathbb{R}^n$ satisfying a system of nonlinear equations

$$F(u_*) = 0, \tag{1.1}$$

where $F : \mathbb{R}^n \to \mathbb{R}^n$ is continuously differentiable. A classical algorithm for approximately solving (1.1) is *Newton's method*, which, at a current approximate solution u, generates a next approximate solution $u + s$ through a step s that satisfies the linear *Newton equation*

$$F'(u)s = -F(u). \tag{1.2}$$

Our interest here is in *Newton–Krylov methods* (cf. [2], [11], [12], [15]), in which *Krylov subspace methods* are used to solve (1.2) approximately. An extensive introduction to Krylov subspace methods is beyond the scope of this paper; we touch on only the most relevant aspects here and refer the reader to [8], [9], [18], [19] for full treatments.

A Krylov subspace method applied to a general linear system $Ax = b$, $A \in \mathbb{R}^{n\times n}$ invertible, begins with an initial approximate solution x_0 and, at the jth iteration, determines $x_j = x_0 + z_j$ through a correction z_j in the jth *Krylov subspace*

$$\mathcal{K}_j \equiv \text{span}\,\{r_0, Ar_0, \ldots, A^{j-1}r_0\}, \tag{1.3}$$

where $r_0 = b - Ax_0$. Specific methods are determined by the choice of $z_j \in \mathcal{K}_j$.

We focus here on two Krylov subspace methods: the *generalized minimal residual method* (GMRES) [16], in which each z_j is chosen to minimize the residual norm over all corrections in $\mathcal{K}_j$, and the *Arnoldi method* (also known as the *full orthogonalization method*) [17], in which each z_j is chosen to make the residual orthogonal to $\mathcal{K}_j$, if that is possible. (We consider these methods in only their basic forms and do not consider "restarted" or "truncated" variants.) These have in common that their iterates are generated directly from the *Arnoldi process* [1], which we review in section 2.1.

In the Newton–Krylov context, a particular advantage of the most widely used Krylov subspace methods, including the GMRES and Arnoldi methods, is that they require only products of F' with vectors for their implementation. Thus they allow "matrix-free" Newton–Krylov formulations (cf. [12]), in which these products are evaluated or approximated without creating or storing F'. Perhaps the most popular way of approximating these products is with a first-order forward difference

$$F'(u)v \approx \frac{F(u+\sigma v) - F(u)}{\sigma}, \tag{1.4}$$

where σ is an appropriately chosen difference step.

Each approximation (1.4) requires a new F-evaluation. If F-evaluations are expensive or if many iterations of the Krylov solver are required, then the aggregate cost of these evaluations over all Krylov iterations may be undesirably high. In this case, it is natural to consider using an inexpensive approximation of $F(u+\sigma v)$ in (1.4), if one is available.

In the following, we explore this possibility. Our goal is to lay out a framework that will provide guidelines for using such approximations, specifically to outline conditions on such approximations that lead to desirable convergence properties of the resulting Newton–Krylov methods. Although we consider only the GMRES and Arnoldi methods here, it is our expectation that the results will provide useful guidance when other Krylov subspace methods are used as well.

In section 2, we first describe the approximations of F that we allow in difference quotients and formulate a finite-difference Arnoldi process that uses them. We then outline a Newton–Krylov method that uses GMRES or Arnoldi implementations based on this process, and we develop a local convergence analysis for it. In section 3, we discuss numerical experiments involving two illustrative approximations of F that are appropriate for a broad class of nonlinear diffusion problems. We also show how these approximations can be chosen to satisfy the convergence assumptions in section 2. We offer a summary discussion and conclusions in section 4.

This work builds on and extends work of [3]. We assume throughout that F is continuously differentiable on domains of interest and, for convenience, that $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$ are the Euclidean norm and inner-product on $\mathbb{R}^n$, respectively. (All results can be easily extended to the case of an arbitrary inner-product norm on $\mathbb{R}^n$.) For $u \in \mathbb{R}^n$ and $\delta > 0$, we denote $B(u,\delta) \equiv \{v \in \mathbb{R}^n : \|v-u\| < \delta\}$. We implicitly assume that arithmetic is exact and do not consider errors due to rounding in finite-precision arithmetic.

2. The approximate finite-difference framework. We assume that there is a function $\tilde{F} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ such that $\tilde{F}(u,u) = F(u)$ for all $u \in \mathbb{R}^n$. The presumption is that, in an application of interest, one can determine $\tilde{F}$ so that, for each u and w near u, evaluating $\tilde{F}(u,w)$ is preferred over evaluating $F(w)$. Thus, in lieu of (1.4), we consider approximations of the form

$$F'(u)v \approx \frac{\tilde{F}(u, u+\sigma v) - F(u)}{\sigma}. \tag{2.1}$$

We make further assumptions on $\tilde{F}$ after outlining in section 2.1 a version of the Arnoldi process that uses these approximations.

2.1. The approximate finite-difference Arnoldi process. We begin by recalling the usual Arnoldi process for a general linear system $Ax = b$, $A \in \mathbb{R}^{n\times n}$ invertible, and initial $x_0 \in \mathbb{R}^n$.

ALGORITHM 2.1: ARNOLDI PROCESS

GIVEN x_0, SET $r_0 = b - Ax_0$.

IF $r_0 = 0$, STOP; OTHERWISE SET $v_1 = r_0/\|r_0\|$.

FOR $j = 1, 2, \ldots,$ DO:

SET $w_j = Av_j - \sum_{i=1}^{j} h_{ij} v_i$, WHERE $h_{ij} = \langle Av_j, v_i \rangle$.

IF $h_{j+1,j} \equiv \|w_j\| = 0$, STOP; OTHERWISE, SET

$v_{j+1} = w_j/h_{j+1,j}$ AND CONTINUE.

If $r_0 \neq 0$, then the process terminates at step $j > 0$ if and only if $h_{j+1,j} = 0$, which occurs if and only if $\mathcal{K}_j$ is an invariant subspace of A. Thus the process must terminate for some $j \leq n$. For each j up to termination, $\{v_i\}_{i=1,\ldots,j}$ constitutes an orthonormal basis of $\mathcal{K}_j$. After j steps, particular products of the process are the matrices $V_j \equiv (v_1, \ldots, v_j)$ and upper-Hessenberg

$$H_j \equiv \begin{pmatrix} h_{11} & \cdots & h_{1j} \\ h_{21} & \cdots & h_{2j} \\ & \ddots & \vdots \\ & & h_{j+1,j} \end{pmatrix}.$$

The relationship between V_j and H_j is characterized by

$$AV_j = \begin{cases} V_{j+1}H_j & \text{if } h_{j+1,j} \neq 0, \\ V_j \bar{H}_j & \text{if } h_{j+1,j} = 0, \end{cases}$$

where $\bar{H}_j$ is obtained from H_j by deleting the $(j+1)$st row.

The iterates of the GMRES and Arnoldi methods applied to $Ax = b$ are uniquely determined by the matrices V_j and H_j. In the case of the GMRES method, an approximate solution is defined at each iteration; in the case of the Arnoldi method, an approximate solution may not be defined at every iteration, depending on A and b. However, for both methods, with A invertible, the approximate solution is defined and equal to the exact solution at some step if and only if Algorithm 2.1 terminates at that step. In both methods, the approximate solution is computed only upon termination. During the intermediate iterations, the value of the residual norm is maintained recursively without computing the approximate solution, and termination is based on this value, which we refer to below as the *recursive residual norm*.

To formulate our approximate finite-difference Arnoldi process, we consider a Jacobian system

$$F'(u)x = c \tag{2.2}$$

and outline a process analogous to Algorithm 2.1 that uses approximations of the form (2.1). In this, we use "~" to denote approximate counterparts of quantities in Algorithm 2.1 that are derived from $\tilde{F}$.

ALGORITHM 2.2: APPROXIMATE FINITE-DIFFERENCE ARNOLDI PROCESS

GIVEN x_0, SET $q_0 = \frac{\tilde{F}(u,u+\sigma_0 x_0)-F(u)}{\sigma_0}$ AND $\tilde{r}_0 = c - q_0$.
IF $\tilde{r}_0 = 0$, STOP; OTHERWISE, SET $\tilde{v}_1 = \tilde{r}_0/\|\tilde{r}_0\|$.
FOR $j = 1, 2, \ldots,$ DO:
SET $q_j = \frac{\tilde{F}(u,u+\sigma_j \tilde{v}_j)-F(u)}{\sigma_j}$ AND $\tilde{w}_j = q_j - \sum_{i=1}^{j} \tilde{h}_{ij}\tilde{v}_i$,
WHERE $\tilde{h}_{ij} = \langle q_j, \tilde{v}_i \rangle$.
IF $\tilde{h}_{j+1,j} \equiv \|\tilde{w}_j\| = 0$, STOP; OTHERWISE, SET
$\tilde{v}_{j+1} = \tilde{w}_j/\tilde{h}_{j+1,j}$ AND CONTINUE.

If $\tilde{r}_0 \neq 0$, then the process terminates at step $j > 0$ if and only if $\tilde{h}_{j+1,j} = 0$. For each j up to termination, $\{\tilde{v}_i\}_{i=1,\ldots,j}$ is an orthonormal set; hence, termination must occur for some $j \leq n$.

The GMRES and Arnoldi methods applied to (2.2) can be based on Algorithm 2.2 in an obvious way. In particular, for each j, we define $\tilde{V}_j \equiv (\tilde{v}_1, \ldots, \tilde{v}_j)$ and upper-Hessenberg

$$\tilde{H}_j \equiv \begin{pmatrix} \tilde{h}_{11} & \cdots & \tilde{h}_{1j} \\ \tilde{h}_{21} & \cdots & \tilde{h}_{2j} \\ & \ddots & \vdots \\ & & \tilde{h}_{j+1,j} \end{pmatrix}.$$

Then, like their counterparts V_j and H_j produced by Algorithm 2.1, the matrices $\tilde{V}_j$ and $\tilde{H}_j$ uniquely determine the iterates of the GMRES and Arnoldi methods based on Algorithm 2.2. As before, the GMRES approximate solution is defined at every iteration, but the Arnoldi approximate solution may not be.

We further define

$$\begin{aligned} e_0 &\equiv q_0 - F'(u)x_0, \\ e_i &\equiv q_i - F'(u)\tilde{v}_i, \quad i = 1, \ldots, j. \end{aligned} \tag{2.3}$$

With the orthonormality of $\{\tilde{v}_i\}_{i=1,\ldots,j}$, one easily verifies that

$$\{F'(u) + e_i \tilde{v}_i^T\}\tilde{v}_i = q_i, \quad i = 1, \ldots, j,$$

and, therefore,

$$\{F'(u) + E_j\}\tilde{V}_j = (q_1, \ldots, q_j) = \begin{cases} \tilde{V}_{j+1}\tilde{H}_j & \text{if } \tilde{h}_{j+1,j} \neq 0, \\ \tilde{V}_j \bar{\tilde{H}}_j & \text{if } \tilde{h}_{j+1,j} = 0, \end{cases} \tag{2.4}$$

where

$$E_j \equiv (e_1, \ldots, e_j)\tilde{V}_j^T \tag{2.5}$$

and $\bar{\tilde{H}}_j \in \mathbb{R}^{j \times j}$ is obtained from $\tilde{H}_j$ by deleting the $(j+1)$st row.

In view of (2.3)–(2.5), the following theorem is immediate.

THEOREM 2.3. *Suppose that, for some $j \in \{1, \ldots, n\}$, $\tilde{V}_j$ and $\tilde{H}_j$ have been produced by j steps of Algorithm 2.2 with an initial x_0. Then $\tilde{V}_j$ and $\tilde{H}_j$ are the same*

as, respectively, V_j and H_j produced by j steps of Algorithm 2.1 *with the same initial x_0 and with $A = F'(u) + E_j$ and $b = c - e_0 + E_j x_0$, where E_j and e_0 are defined by* (2.3) *and* (2.5).

Proof. In Algorithm 2.2, one has $\tilde{v}_1 = \tilde{r}_0/\|\tilde{r}_0\|$ and, with (2.3),

$$\tilde{r}_0 = c - q_0 = c - e_0 + E_j x_0 - (F'(u) + E_j)\, x_0.$$

The theorem follows from this and (2.4). ∎

COROLLARY 2.4. *Suppose that, for some $j \in \{1, \ldots, n\}$, the GMRES or Arnoldi method based on Algorithm* 2.2 *has been applied to* (2.2) *for j steps. If $F'(u) + E_j$ is invertible, then the approximate solution determined at step j by the method (if defined) is the same as the approximate solution of the perturbed system*

$$\{F'(u) + E_j\}x = c - e_0 + E_j x_0 \tag{2.6}$$

determined at step j by the same method based on Algorithm 2.1. *The approximate solution at step j is defined and is the exact solution of* (2.6) *if and only if Algorithm* 2.2 *terminates at step j.*

2.2. A local convergence analysis. Newton–Krylov methods are usually implemented as *inexact Newton methods* [5], in which the Newton equation (1.2) is replaced with an *inexact Newton condition*

$$\|F(u) + F'(u)s\| \le \eta\|F(u)\|, \tag{2.7}$$

where $\eta \in [0, 1)$. In a Newton–Krylov implementation, (2.7) normally provides a criterion for terminating the Krylov iterations: one first chooses $\eta \in [0, 1)$ and then applies the Krylov solver to (1.2) until (2.7) holds. Used in this way, η is often called a *forcing term* (cf. [7]). In the seminal paper [5], it is shown that the local convergence of inexact Newton methods is determined by the forcing terms.

In the context of interest here, the Krylov solver is the GMRES or Arnoldi method based on Algorithm 2.2, and the approximate solution it produces is actually that of the perturbed linear system (2.6) with $c = -F(u)$. Thus an accurate evaluation of the linear residual norm $\|F(u) + F'(u)s\|$ is very likely to be undesirably expensive or unavailable. If this is the case, then (2.7) cannot be used directly for terminating the Krylov iterations. A likely course is to replace $\|F(u) + F'(u)s\|$ in (2.7) by the recursive residual norm maintained by the Krylov solver. This leads to the following algorithm.

ALGORITHM 2.5: APPROXIMATE FINITE-DIFFERENCE GMRES/ARNOLDI NEWTON–KRYLOV METHOD

SUPPOSE THAT u_0 IS GIVEN.

FOR $k = 0, 1, \ldots,$ DO:

CHOOSE $\eta_k \in [0, 1)$ AND APPLY THE GMRES OR ARNOLDI METHOD BASED ON ALGORITHM 2.2 TO $F'(u_k)s = -F(u_k)$ TO OBTAIN AN APPROXIMATE SOLUTION s_k FOR WHICH THE RECURSIVE RESIDUAL NORM IS LESS THAN OR EQUAL TO $\eta_k\|F(u_k)\|$.

SET $u_{k+1} = u_k + s_k$.

In the remainder of this subsection, we develop a local convergence analysis for Algorithm 2.5. This culminates in our main result (Theorem 2.12) to the effect that, near a solution of (1.2) at which the Jacobian is invertible, Algorithm 2.5 does not break down and enjoys desirable convergence properties if the difference steps are chosen sufficiently small and the forcing terms are chosen appropriately.

We begin with Lemma 2.6 below, which shows that, if the recursive residual norm satisfies a specified inexact Newton condition, then the actual residual norm satisfies a related inexact Newton condition. This lemma is a perturbation result based on Corollary 2.4. With $c = -F(u)$, the perturbed linear system (2.6) can be viewed as a specific instance of a more general perturbed linear system considered by Catinas in [4]. Perturbation results are given in [4] that are somewhat similar in spirit to Lemma 2.6 but are not as directly suited to our purposes.

For convenience in Lemma 2.6 and that which follows, we regard the initial residual norm as the recursive residual norm at step zero. Throughout the discussion, e_0 and E_j for $j > 0$ are defined by (2.3) and (2.5), with x_0 the initial approximate solution in the Krylov solver and with $c = -F(u)$ in Algorithm 2.2.

LEMMA 2.6. *Suppose that $\eta \in [0, 1)$ is given and that the GMRES or Arnoldi method based on Algorithm* 2.2 *is applied to* (1.2) *until, for some $j \in \{0, \ldots, n\}$, the recursive residual norm is less than or equal to $\eta\|F(u)\|$ at step j. Let s denote the approximate solution of* (1.2) *obtained by the method at step j. If $j = 0$, or if $j > 0$ and $F'(u) + E_j$ is invertible, then*

$$\|F(u) + F'(u)s\| \le \tilde{\eta}\|F(u)\|, \tag{2.8}$$

where

$$\tilde{\eta} \equiv \begin{cases} \eta + \dfrac{\|e_0\|}{\|F(u)\|} & \text{if } j = 0, \\ \eta + (1+\eta)\|E_j(F'(u)+E_j)^{-1}\| & \\ \qquad + \left[1 + \|E_j(F'(u)+E_j)^{-1}\|\right] \dfrac{\|e_0 - E_j\, x_0\|}{\|F(u)\|} & \text{if } j > 0. \end{cases} \tag{2.9}$$

Remark. If the initial approximate solution x_0 in the GMRES or Arnoldi method is zero, as is usually the case in Newton–Krylov methods, then $e_0 = 0$ and (2.9) reduces to

$$\tilde{\eta} \equiv \begin{cases} \eta & \text{if } j = 0, \\ \eta + (1+\eta)\|E_j(F'(u)+E_j)^{-1}\| & \text{if } j > 0. \end{cases} \tag{2.10}$$

Proof. If $j = 0$, then $s = x_0$ in Algorithm 2.2, and, with q_0 as in Algorithm 2.2, we have

$$\begin{aligned} \|F(u) + F'(u)s\| &\le \|F(u) + q_0\| + \|F'(u)s - q_0\| \\ &\le \eta\|F(u)\| + \|e_0\| \\ &= \left(\eta + \frac{\|e_0\|}{\|F(u)\|}\right)\|F(u)\|. \end{aligned}$$

If $j > 0$, then, by using Corollary 2.4 with $c = -F(u)$, we have

$$\begin{aligned} \|F(u) + F'(u)s\| &\le \|F(u) + e_0 - E_j\, x_0 + (F'(u) + E_j)\, s\| \\ &\qquad + \|E_j\, s\| + \|e_0 - E_j\, x_0\| \\ &\le \eta\|F(u)\| + \|E_j(F'(u)+E_j)^{-1}\| \cdot \|(F'(u) + E_j)\, s\| \\ &\qquad + \|e_0 - E_j\, x_0\|. \end{aligned} \tag{2.11}$$

Writing

$$(F'(u)+E_j)s = -F(u) - e_0 + E_j x_0 + r, \quad \|r\| \le \eta\|F(u)\|,$$

one verifies that

$$\begin{aligned}\|(F'(u)+E_j)s\| &\le (1+\eta)\|F(u)\| + \|e_0 - E_j\, x_0\| \\ &= \left(1+\eta+\frac{\|e_0 - E_j\, x_0\|}{\|F(u)\|}\right)\|F(u)\|.\end{aligned}$$

Substituting this in (2.11) and rearranging gives

$$\begin{aligned}\|F(u)+F'(u)s\| &\le \left\{\eta + \|E_j(F'(u)+E_j)^{-1}\|\cdot\left(1+\eta+\frac{\|e_0 - E_j\, x_0\|}{\|F(u)\|}\right)\right. \\ &\qquad \left. + \frac{\|e_0 - E_j\, x_0\|}{\|F(u)\|}\right\}\|F(u)\| \\ &= \left\{\eta + (1+\eta)\|E_j(F'(u)+E_j)^{-1}\|\right. \\ &\qquad \left. + \left[1+\|E_j(F'(u)+E_j)^{-1}\|\right]\frac{\|e_0 - E_j\, x_0\|}{\|F(u)\|}\right\}\|F(u)\|. \qquad \square\end{aligned}$$

We now formulate the first of two additional assumptions on $\tilde{F}$ and establish Lemma 2.8 and Corollary 2.9 below, which will be helpful in developing our local convergence results and also in justifying the assumptions in Lemma 2.6 near a solution of (1.2) at which the Jacobian is invertible.

Assumption 2.7. There exists $\Omega \subseteq \mathbb{R}^n$ such that

$$\omega(\sigma) \equiv \sup_{u\in\Omega,\ \|v\|\le 1}\left\|\frac{\tilde{F}(u,u+\sigma v)-F(u)}{\sigma} - F'(u)v\right\| \tag{2.12}$$

satisfies $\omega_* \equiv \limsup_{\sigma\to 0}\omega(\sigma) < \infty$.

The role of Assumption 2.7 in that which follows is to ensure that approximations of the form (2.1) are uniformly accurate when σ is appropriately small. We note that, if this assumption holds with $\omega_* = 0$, then the Frechet derivative $\tilde{F}_w(u,w) \equiv \frac{\partial \tilde{F}(u,w)}{\partial w}$ exists for $u \in \Omega$ and $w = u$ and, moreover, $\tilde{F}_w(u,u) = F'(u)$ for $u \in \Omega$.

LEMMA 2.8. *Suppose that Assumption* 2.7 *holds and that* $u_* \in \Omega$ *is such that* $F'(u_*)$ *is invertible and*

$$n\|F'(u_*)^{-1}\|\omega_* < 1/2. \tag{2.13}$$

Then, for any ϵ *such that*

$$\frac{n\|F'(u_*)^{-1}\|\omega_*}{1-n\|F'(u_*)^{-1}\|\omega_*} < \epsilon < 1, \tag{2.14}$$

there exist $\delta > 0$ *and* $\sigma_* > 0$ *such that if* $u \in B(u_*,\delta)$ *and, for some* $j \in \{1,\dots,n\}$, *Algorithm* 2.2 *has been applied with* $0 < |\sigma_i| \le \sigma_*$ *for* $i = 1, \dots, j$, *then* $F'(u)+E_j$ *is invertible, and*

$$\|E_j(F'(u)+E_j)^{-1}\| \le \epsilon. \tag{2.15}$$

Moreover, there is a λ independent of j and u for which

$$\|E_j(F'(u)+E_j)^{-1}\| \le \lambda \max_{1\le i\le j}\omega(\sigma_i)\,. \tag{2.16}$$

Proof. Since F is continuously differentiable and $F'(u_*)$ is invertible, there exists $\delta>0$ such that $B(u_*,\delta)\subset\Omega$, $F'(u)$ is invertible whenever $u\in B(u_*,\delta)$, and $\sup_{u\in B(u_*,\delta)}\|F'(u)^{-1}\|<\infty$. Moreover, in view of (2.13) and (2.14), we can choose δ and $\sigma_*>0$ sufficiently small to have $n\|F'(u)^{-1}\|\omega(\sigma)\le 1/2$ and

$$\frac{n\|F'(u)^{-1}\|\omega(\sigma)}{1-n\|F'(u)^{-1}\|\omega(\sigma)}\le\epsilon \tag{2.17}$$

whenever $u\in B(u_*,\delta)$ and $0<|\sigma|\le\sigma_*$. Note that, for $0<|\sigma|\le\sigma_*$, (2.17) implies that

$$\omega(\sigma)\le\frac{\epsilon}{(1+\epsilon)n\|F'(u)^{-1}\|}. \tag{2.18}$$

Suppose that $u\in B(u_*,\delta)$ and that Algorithm 2.2 has been applied with $0<|\sigma_i|\le\sigma_*$ for $i=1,\ldots,j$. Then

$$\begin{aligned}\|E_j\| &= \max_{\|v\|=1}\|E_jv\| = \max_{\|v\|=1}\|(e_1,\ldots,e_j)\tilde V_j^Tv\|\\ &= \max_{\|v\|=1}\left\|\sum_{i=1}^j\langle\tilde v_i,v\rangle\,e_i\right\| \le \max_{\|v\|=1}\sum_{i=1}^j|\,\langle\tilde v_i,v\rangle\,|\,\|e_i\|\\ &\le \textstyle\sum_{i=1}^j\|e_i\|\end{aligned} \tag{2.19}$$

since $|\,\langle\tilde v_i,v\rangle\,|\le\|\tilde v_i\|\,\|v\|=1$. Since

$$\|e_i\| = \|q_i-F'(u)\tilde v_i\| = \left\|\frac{\tilde F(u,u+\sigma_i\tilde v_i)-F(u)}{\sigma_i}-F'(u)\tilde v_i\right\|\le\omega(\sigma_i)$$

for each i, it follows from (2.19) and (2.18) that

$$\|E_j\|\le j\max_{1\le i\le j}\omega(\sigma_i)\le n\max_{1\le i\le j}\omega(\sigma_i)\le\frac{\epsilon}{(1+\epsilon)\|F'(u)^{-1}\|}. \tag{2.20}$$

From (2.20), we have

$$\|E_jF'(u)^{-1}\|\le\|E_j\|\,\|F'(u)^{-1}\|\le\frac{\epsilon}{1+\epsilon}<1, \tag{2.21}$$

and it follows by using well-known arguments (see, e.g., [6, Thm. 3.1.4]) that $I+E_jF'(u)^{-1}$ is invertible and

$$\left\|\left(I+E_jF'(u)^{-1}\right)^{-1}\right\|\le\frac{1}{1-\epsilon/(1+\epsilon)}=1+\epsilon. \tag{2.22}$$

Consequently, $F'(u)+E_j=(I+E_jF'(u)^{-1})F'(u)$ is invertible, and

$$\begin{aligned}\left\|E_j(F'(u)+E_j)^{-1}\right\| &= \left\|E_jF'(u)^{-1}\left(I+E_jF'(u)^{-1}\right)^{-1}\right\|\\ &\le \|E_jF'(u)^{-1}\|\,\|\left(I+E_jF'(u)^{-1}\right)^{-1}\|\\ &\le \frac{\epsilon}{1+\epsilon}\cdot(1+\epsilon)=\epsilon\,.\end{aligned} \tag{2.23}$$

To complete the proof, one easily verifies from the inequalities in (2.18)–(2.23) that

$$\|E_j(F'(u)+E_j)^{-1}\| \le n \max_{1\le i\le j} \omega(\sigma_i)\, \|F'(u)^{-1}\|\, (1+\epsilon)\,.$$

It follows that (2.16) holds with $\lambda = n \sup_{u\in B(u_*,\delta)} \|F'(u)^{-1}\|\,(1+\epsilon)$. ∎

COROLLARY 2.9. *Suppose that Assumption* 2.7 *holds and that* $u_* \in \Omega$ *is such that* $F'(u_*)$ *is invertible and* $F'(u_*)^{-1}$ *satisfies* (2.13). *Then there exist* $\delta > 0$ *and* $\sigma_* > 0$ *such that if* $u \in B(u_*, \delta)$ *and the GMRES or Arnoldi method based on Algorithm* 2.2 *is applied to* (1.2) *with* $0 < |\sigma_j| \le \sigma_*$ *for each* j, *then for some* $j \in \{0, \dots, n\}$ *the approximate solution obtained by the method at step* j *is defined and the recursive residual norm is zero. In particular, given any* $\eta \in [0, 1)$, *the method determines at some step an approximate solution for which the recursive residual norm is less than or equal to* $\eta\|F(u)\|$.

Proof. Suppose that the GMRES or Arnoldi method based on Algorithm 2.2 is applied to (1.2). If $\tilde{r}_0 = 0$, then there is nothing to prove. If $\tilde{r}_0 \neq 0$, then Algorithm 2.2 terminates for some $j \in \{1, \dots, n\}$. By Lemma 2.8, there exist $\delta > 0$ and $\sigma_* > 0$ such that if $u \in B(u_*, \delta)$ and $0 < |\sigma_i| \le \sigma_*$ for $i = 1, \dots, j$, then $F'(u) + E_j$ is invertible. Consequently, assuming $u \in B(u_*, \delta)$ and $0 < |\sigma_i| \le \sigma_*$ for $i = 1, \dots, j$, one has from Corollary 2.4 that the approximate solution determined by the method at step j is defined and is the exact solution of the perturbed system

$$\{F'(u) + E_j\}x = -F(u) - e_0 + E_j x_0. \tag{2.24}$$

Since the recursive residual norm is the norm of the residual of (2.24), it follows that the recursive residual norm is zero. ∎

We use the following somewhat specialized assumption of Hölder continuity of $\tilde{F}_w$. For a general definition of Hölder continuity, see, e.g., [14, section 3.1.9].

Assumption 2.10. With Ω as in Assumption 2.7, there is a $\delta_\Omega > 0$ such that $\tilde{F}_w(u, u+v)$ exists for all $u \in \Omega$ and all v with $\|v\| \le \delta_\Omega$. Moreover, there exist γ and $p \in (0, 1]$ such that

$$\|\tilde{F}_w(u, u+v) - \tilde{F}_w(u, u)\| \le \gamma \|v\|^p$$

for all $u \in \Omega$ and all v with $\|v\| \le \delta_\Omega$.

LEMMA 2.11. *Suppose that Assumption* 2.7 *holds with* $\omega_* = 0$ *and that Assumption* 2.10 *also holds. Then* $\omega(\sigma)$ *given by* (2.12) *satisfies*

$$\omega(\sigma) \le \mu\, |\sigma|^p \tag{2.25}$$

for sufficiently small $|\sigma|$ *and* $\mu = \gamma(\delta_\Omega)^{1+p}/(1+p)$.

Proof. Assume for convenience that $\sigma > 0$. (The proof requires only trivial changes when $\sigma < 0$.) By recalling that $\omega_* = 0$ implies $F'(u) = \tilde{F}_w(u, u)$ and adapting familiar reasoning (see, e.g., [14, section 3.2.12]), we have for $u \in \Omega$, $\|v\| \le \delta_\Omega$, and

sufficiently small $\sigma > 0$ that

$$\begin{aligned}\|\tilde{F}(u, u+\sigma v) - F(u) - \sigma F'(u)v\| &= \left\| \left\{ \int_0^\sigma [\tilde{F}_w(u, u+\tau v) - \tilde{F}_w(u,u)]\, d\tau \right\} v \right\| \\ &\le \left\{ \int_0^\sigma \|\tilde{F}_w(u, u+\tau v) - \tilde{F}_w(u,u)\|\, d\tau \right\} \|v\| \\ &\le \left\{ \int_0^\sigma \gamma \tau^p\, d\tau \right\} \|v\|^{1+p} \\ &= \frac{\gamma}{1+p}\sigma^{1+p}\|v\|^{1+p} \le \frac{\gamma(\delta_\Omega)^{1+p}}{1+p}\sigma^{1+p},\end{aligned}$$

which immediately yields (2.25). ∎

The theorem below is our local convergence result for Algorithm 2.5. It can be viewed as a counterpart of Theorems 2.3 and 3.3 of [5], which are used in its proof. For definitions of the types of convergence referred to in the theorem, see, e.g., [6]. For convenience, we denote by σ_{jk} the jth difference step used by the GMRES or Arnoldi method at the kth iteration of Algorithm 2.5. We also assume that, at each iteration of Algorithm 2.5, the GMRES or Arnoldi method begins with the zero initial approximate solution, and, therefore, the applicable perturbation result from Lemma 2.6 is (2.8) followed by (2.10) rather than (2.9).

THEOREM 2.12. *Suppose that Assumption* 2.7 *holds and that $u_* \in \Omega$ is such that $F(u_*) = 0$, $F'(u_*)$ is invertible, and $n\|F'(u_*)^{-1}\|\omega_* < 1/2$. Then for any t_* and η_* such that*

$$\mu_* \equiv \frac{n\|F'(u_*)^{-1}\|\omega_*}{1 - n\|F'(u_*)^{-1}\|\omega_*} < t_* < 1 \quad \text{and} \quad 0 \le \eta_* < \frac{t_* - \mu_*}{1+\mu_*}, \tag{2.26}$$

there exist $\delta_* > 0$ and $\sigma_* > 0$ such that if $u_0 \in B(u_*, \delta_*)$, $0 \le \eta_k \le \eta_*$ for each k, and $0 < |\sigma_{jk}| \le \sigma_*$ for each j and k, then Algorithm 2.5 *produces $\{u_k\}_{k=0,1,\ldots}$ that converges to u_* with*

$$\|u_{k+1} - u_*\|_* \le t_*\|u_k - u_*\|_* \tag{2.27}$$

for each k, where $\|v\|_* \equiv \|F'(u_*)v\|$ for $v \in \mathbb{R}^n$. Additionally, if $\omega_* = 0$ and if $\eta_k \to 0$ and $\max_j |\sigma_{jk}| \to 0$ as $k \to \infty$, then the convergence is q-superlinear. If Assumption 2.10 *also holds, F' is Hölder continuous with exponent p at u_*, and $\eta_k = O(\|F(u_k)\|^p)$ and $\max_j |\sigma_{jk}| = O(\|F(u_k)\|)$ as $k \to \infty$, then the convergence is of q-order $1+p$.*

Proof. Suppose that t_* and η_* satisfy (2.26). Let ϵ be such that $\mu_* < \epsilon < t_*$ and $\eta_* < (t_* - \epsilon)/(1+\epsilon)$. Note that $\eta_{\max} \equiv \eta_* + (1+\eta_*)\epsilon < t_*$. By [5, Thm. 2.3], there is a $\delta_* > 0$ such that any sequence $\{u_k\}_{k=0,1,\ldots}$ for which $u_0 \in B(u_*, \delta_*)$ and

$$\left.\begin{aligned} u_{k+1} &= u_k + s_k \\ \|F(u_k) + F'(u_k)s_k\| &\le \eta_{\max}\|F(u_k)\| \end{aligned}\right\} \quad k = 0, 1, \ldots$$

satisfies (2.27) for each k and converges to u_*.

Let $\delta > 0$ and $\sigma_* > 0$ be chosen so that the conclusions of Lemma 2.8 and Corollary 2.9 hold. Let M be such that

$$\frac{1}{M}\|v\| \le \|v\|_* \le M\|v\|$$

for all $v \in \mathbb{R}^n$. By taking δ_* smaller if necessary, assume that $M^2\delta_* < \delta$. Suppose that Algorithm 2.5 is applied with $u_0 \in B(u_*, \delta_*)$, $0 \le \eta_k \le \eta_*$ for all k, and $0 < |\sigma_{jk}| \le \sigma_*$ for all j and k. If, for some $k \ge 0$, the algorithm has determined $\{u_j\}_{j=0,\dots,k} \subseteq B(u_*, \delta)$, then, at step k of the algorithm, it follows from Corollary 2.9 that the GMRES or Arnoldi method based on Algorithm 2.2 determines at some iteration an approximate solution s_k for which the recursive residual norm is less than or equal to $\eta_k \|F(u_k)\|$. Then u_{k+1} is defined. Moreover, with Lemmas 2.8 and 2.6, we have, by using (2.8)–(2.10) and (2.15), that

$$\|F(u_k) + F'(u_k)s_k\| \le [\eta_k + (1+\eta_k)\epsilon]\, \|F(u_k)\| \le \eta_{\max}\|F(u_k)\|,$$

and we can apply (2.27) to obtain

$$\begin{aligned} \|u_{k+1} - u_*\| &\le M\|u_{k+1} - u_*\|_* \le M t_*^{k+1}\|u_0 - u_*\|_* \\ &\le M^2 t_*^{k+1}\|u_0 - u_*\| < M^2\delta_* < \delta. \end{aligned}$$

It follows inductively that Algorithm 2.2 produces $\{u_k\}_{k=0,1,\dots} \subseteq B(u_*, \delta)$ that converges to u_*, with (2.27) holding for each k.

Assuming $u_0 \in B(u_*, \delta_*)$, we also have from (2.8)–(2.10) and (2.16) that

$$\|F(u_k) + F'(u_k)s_k\| \le [\eta_k + (1+\eta_k)\,\lambda \max_j \omega(\sigma_{jk})]\, \|F(u_k)\| \tag{2.28}$$

for each k, where λ is independent of k. Consequently, if $\omega_* \equiv \lim_{\sigma\to 0}\omega(\sigma) = 0$ and if $\eta_k \to 0$ and $\max_j |\sigma_{jk}| \to 0$ as $k \to \infty$, then it follows from [5, Thm. 3.3] that $\{u_k\}_{k=0,1,\dots}$ converges to u_* q-superlinearly. If Assumption 2.10 also holds, then (2.28) and (2.25) yield

$$\|F(u_k) + F'(u_k)s_k\| \le [\eta_k + (1+\eta_k)\,\lambda\,\mu\,(\max_j |\sigma_{jk}|)^p]\, \|F(u_k)\|\,,$$

where μ is independent of k. It follows from [5, Thm. 3.3] that, if $\eta_k = O(\|F(u_k)\|^p)$ and $\max_j |\sigma_{jk}| = O(\|F(u_k)\|)$ as $k \to \infty$, then the convergence is of q-order $1+p$. ∎

Remark. The framework and analysis given above cover the case in which $F = F_1 + F_2$, where F_1 and F_2 are differentiable and such that, for each u and v, $F_1'(u)v$ can be readily evaluated but $F_2'(u)v$ must be approximated with a finite difference.[1] Indeed, setting $\tilde{F}(u, w) \equiv F_1(u) + F_1'(u)(w-u) + F_2(w)$, we obtain

$$\frac{\tilde{F}(u, u+\sigma v) - F(u)}{\sigma} = F_1'(u)v + \frac{F_2(u+\sigma v) - F_2(u)}{\sigma}.$$

Then Assumption 2.7 becomes

$$\omega_* \equiv \sup_{u\in\Omega,\ \|v\|\le 1} \left\| \frac{F_2(u+\sigma v) - F_2(u)}{\sigma} - F_2'(u)v \right\| < \infty,$$

and Assumption 2.10 becomes an assumption of Hölder continuity of $F_2'(u)$. With this understanding, it is straightforward to apply Corollary 2.9 and Theorem 2.12.

3. Numerical experiments. In this section we first describe the test problems considered. We then focus on two possible choices for $\tilde{F}$ and analyze to what degree they satisfy Assumptions 2.7 and 2.10. Finally, we present numerical results obtained with these choices on the test problems.

[1] This case can also be addressed with a modest extension of the results in [3].

TABLE 1
Test cases.

Test case	$D(u)$
1	$\sqrt{u^2+u+1}$
2	$\frac{1}{\sqrt{u^2+u+1}}$
3	$u^{3/5}e^u$
4	$K\sqrt{S(u)}[1-(1-S(u)^{\frac{1}{\mu}})^{\mu}]^2$, where $S(u)=(1+\lvert\alpha u\rvert^{\nu})^{-\mu}$ and K,α,μ,ν are constants

3.1. Test problems. The test problems are of the form

$$\mathcal{F}(u) \equiv \nabla \cdot D(u)\nabla u - g(u) + f = 0. \tag{3.1}$$

This class of nonlinear diffusion problems arises in many applications, such as flow through porous media, radiation transport, phase transition, biochemistry, and dynamics of biological groups. In our experiments, we considered these problems on square domains in $\mathbb{R}^2$ with homogeneous Dirichlet boundary conditions.

We are motivated by circumstances in which g-evaluations are inexpensive, but D-evaluations are relatively costly, and less expensive approximations may be desirable. In our experiments, we considered four choices for D, labeled test cases 1–4 in Table 1. For cases 1–3, we chose $g(u) \equiv u^2$. In case 4, we used $g(u) \equiv 0$. Except in test case 4, we took the domain to be $[0,1] \times [0,1]$ and chose f so that the solution of (3.1) was $u_c(x,y) \equiv cx(1-x)y(1-y)$, with $c = 1$, 2, 5, and 10. Choosing f in this way allowed us to determine success or failure with certainty and also to exercise some control over the magnitude of the solution and its derivatives. Test case 4 was inspired by a formulation of Richards's equation describing fluid flow in unsaturated porous media that appeared in [13]. In this case, the domain was $[0, \frac{1}{2}] \times [0, \frac{1}{2}]$ and f was chosen so that the solution was $u_c(x,y) \equiv \frac{c}{4}x(1-2x)y(1-2y) + \beta$, where $\beta > 0$ is a small constant chosen to avoid singularities ($\beta = \frac{1}{16}$ in the experiments reported here) and again $c = 1$, 2, 5, and 10.

In our tests, (3.1) was discretized by using central differences on an $m \times m$ grid of regularly spaced interior points with grid spacing $h = 1/(m+1)$ in test cases 1–3 and $h = 1/2(m+1)$ in test case 4. The resulting system of equations is

$$\begin{aligned} F_{i,j}(u) \equiv \frac{1}{h^2}\Bigg[& D\left(\frac{u_{i+1,j}+u_{i,j}}{2}\right)(u_{i+1,j}-u_{i,j}) - D\left(\frac{u_{i,j}+u_{i-1,j}}{2}\right)(u_{i,j}-u_{i-1,j}) \\ & + D\left(\frac{u_{i,j+1}+u_{i,j}}{2}\right)(u_{i,j+1}-u_{i,j}) - D\left(\frac{u_{i,j}+u_{i,j-1}}{2}\right)(u_{i,j}-u_{i,j-1})\Bigg] \\ & - g(u_{i,j}) + f(x_i,y_j) = 0 \end{aligned} \tag{3.2}$$

for $1 \le i \le m$ and $1 \le j \le m$, where (x_i, y_j) denotes the ijth grid point and $u_{i,j}$ denotes the approximate solution there. (The boundary conditions give $u_{0,j} = u_{m+1,j} = u_{i,0} = u_{i,m+1} = 0$.) We denote this system by $F(u) = 0$, where, for convenience, u denotes the vector of $u_{i,j}$'s as well as the solution of (3.1).

3.2. Choices of $\tilde{F}$. In our experiments, we considered two illustrative choices of $\tilde{F}$ based on our motivating assumption that D-evaluations are significantly more expensive than g-evaluations. (Other choices of $\tilde{F}$ are possible; see the remark at

the end of this subsection.) We refer to these choices as the "lagged" and "linear" approximations of F and denote them by $\tilde{F}^{\mathrm{Lag}}(u,w)$ and $\tilde{F}^{\mathrm{Lin}}(u,w)$, respectively. These correspond to the respective approximations

$$\tilde{\mathcal{F}}^{\mathrm{Lag}}(u,w) \equiv \nabla \cdot D(u)\nabla w - g(w) + f$$

and

$$\tilde{\mathcal{F}}^{\mathrm{Lin}}(u,w) \equiv \nabla \cdot [D(u) + D'(u)(w-u)]\nabla w - g(w) + f$$

of $\mathcal{F}$ in the continuous problem (3.1). They are defined by respective ijth components

$$\begin{aligned}
&\tilde{F}^{\mathrm{Lag}}_{i,j}(u,w) \\
&\quad \equiv \frac{1}{h^2}\left[D\left(\frac{u_{i+1,j}+u_{i,j}}{2}\right)(w_{i+1,j}-w_{i,j}) - D\left(\frac{u_{i,j}+u_{i-1,j}}{2}\right)(w_{i,j}-w_{i-1,j})\right. \\
&\qquad \left. + D\left(\frac{u_{i,j+1}+u_{i,j}}{2}\right)(w_{i,j+1}-w_{i,j}) - D\left(\frac{u_{i,j}+u_{i,j-1}}{2}\right)(w_{i,j}-w_{i,j-1})\right] \\
&\qquad - g(w_{i,j}) + f(x_i,y_j),
\end{aligned} \tag{3.3}$$

$$\begin{aligned}
&\tilde{F}^{\mathrm{Lin}}_{i,j}(u,w) \\
&\quad \equiv \frac{1}{h^2}\left\{\left[D\left(\frac{u_{i+1,j}+u_{i,j}}{2}\right) + \frac{1}{2}D'\left(\frac{u_{i+1,j}+u_{i,j}}{2}\right)(w_{i+1,j}+w_{i,j}-u_{i+1,j}-u_{i,j})\right]\right. \\
&\qquad \cdot (w_{i+1,j}-w_{i,j}) \\
&\qquad - \left[D\left(\frac{u_{i,j}+u_{i-1,j}}{2}\right) + \frac{1}{2}D'\left(\frac{u_{i,j}+u_{i-1,j}}{2}\right)(w_{i,j}+w_{i-1,j}-u_{i,j}-u_{i-1,j})\right] \\
&\qquad \cdot (w_{i,j}-w_{i-1,j}) \\
&\qquad + \left[D\left(\frac{u_{i,j+1}+u_{i,j}}{2}\right) + \frac{1}{2}D'\left(\frac{u_{i,j+1}+u_{i,j}}{2}\right)(w_{i,j+1}+w_{i,j}-u_{i,j+1}-u_{i,j})\right] \\
&\qquad \cdot (w_{i,j+1}-w_{i,j}) \\
&\qquad - \left[D\left(\frac{u_{i,j}+u_{i,j-1}}{2}\right) + \frac{1}{2}D'\left(\frac{u_{i,j}+u_{i,j-1}}{2}\right)(w_{i,j}+w_{i,j-1}-u_{i,j}-u_{i,j-1})\right] \\
&\qquad \left. \cdot (w_{i,j}-w_{i,j-1})\right\} - g(w_{i,j}) + f(x_i,y_j).
\end{aligned} \tag{3.4}$$

It is clear that both $\tilde{F}^{\mathrm{Lag}}(u,w)$ and $\tilde{F}^{\mathrm{Lin}}(u,w)$ satisfy $\tilde{F}(u,u) = F(u)$. To apply the theoretical results obtained in the previous section, we must determine whether they also satisfy Assumptions 2.7 and 2.10. To facilitate verifying these assumptions, we note that the discrete problem (3.2) is a particular case of the model problem

$$F(u) \equiv A(u)u - b(u) + c = 0, \tag{3.5}$$

where $u \in \mathbb{R}^n$, $A(u) \in \mathbb{R}^{n\times n}$ has continuously differentiable entries $a_{ij}(u)$, and $b(u) \in \mathbb{R}^n$ has continuously differentiable components $b_i(u)$. For this model problem, we have that

$$F'(u)v = A(u)v + [A'(u)v]u - b'(u)v,$$

where $[A'(u)v] \in \mathbb{R}^{n\times n}$ has entries $[A'(u)v]_{ij} = \nabla a_{ij}(u)^T v$ and $\nabla a_{ij}(u)$ denotes the gradient of $a_{ij}(u)$ with respect to u. We define

$$\tilde{F}^{\text{Lag}}(u,w) \equiv A(u)w - b(w) + c, \tag{3.6}$$

$$\tilde{F}^{\text{Lin}}(u,w) \equiv (A(u) + [A'(u)(w-u)])\, w - b(w) + c. \tag{3.7}$$

We show the following results for problem (3.5) and the approximations (3.6)–(3.7).

THEOREM 3.1. *Let F, $\tilde{F}^{\text{Lag}}$, and $\tilde{F}^{\text{Lin}}$ be defined by* (3.5)–(3.7). *Then*

$$\frac{\tilde{F}^{\text{Lag}}(u,u+\sigma v) - F(u)}{\sigma} - F'(u)v = -[A'(u)v]u - \left[\frac{b(u+\sigma v) - b(u)}{\sigma} - b'(u)v\right] \tag{3.8}$$

and

$$\frac{\tilde{F}^{\text{Lin}}(u,u+\sigma v) - F(u)}{\sigma} - F'(u)v = \sigma[A'(u)v]v - \left[\frac{b(u+\sigma v) - b(u)}{\sigma} - b'(u)v\right]. \tag{3.9}$$

If, in addition, there exists an $\Omega \subseteq \mathbb{R}^n$ such that, for all $u \in \Omega$, $|\partial a_{ij}(u)/\partial u_k| \le C_1 < \infty$ and $|\partial b_i(u)/\partial u_j| \le C_2 < \infty$ for all $i,j,k \in \{1,\dots,n\}$ and some constants C_1 and C_2, then both $\tilde{F}^{\text{Lag}}$ and $\tilde{F}^{\text{Lin}}$ satisfy Assumption 2.7 *with $\omega_*^{\text{Lag}} < \infty$ for $\tilde{F}^{\text{Lag}}$ and $\omega_*^{\text{Lin}} = 0$ for $\tilde{F}^{\text{Lin}}$.*

Proof. The proof follows by substituting the definitions of the lagged and linear approximations into the above expressions and then deleting appropriate terms. ∎

THEOREM 3.2. *Let the assumptions regarding $\tilde{F}^{\text{Lin}}$ in Theorem* 3.1 *hold. In addition, assume that there exist γ and $p \in (0,1]$ such that*

$$\|b'(u+v) - b'(u)\| \le \gamma \|v\|^p$$

for all $u \in \Omega$ and all v, with $\|v\| \le \delta_\Omega$. Then Assumption 2.10 *holds for $\tilde{F}^{\text{Lin}}$ with the same value of p.*

Proof. We first show that, for any v,

$$\tilde{F}^{\text{Lin}}_w(u,w)v = A(u)v + [A'(u)(w-u)]v + [A'(u)v]w - b'(w)v.$$

We have

$$\begin{aligned}
&\sigma^{-1}\left[\tilde{F}^{\text{Lin}}(u,w+\sigma v) - \tilde{F}^{\text{Lin}}(u,w)\right] \\
&\quad = \sigma^{-1}\left[(A(u) + [A'(u)(w+\sigma v - u)])(w+\sigma v) - (A(u) + [A'(u)(w-u)])w\right] \\
&\qquad - \sigma^{-1}\left[b(w+\sigma v) - b(w)\right] \\
&\quad = A(u)v + [A'(u)(w-u)]v + [A'(u)v](w+\sigma v) - \sigma^{-1}\left[b(w+\sigma v) - b(w)\right].
\end{aligned}$$

Letting $\sigma \to 0$ gives the result. Next, for any vector $\hat{v}$

$$\begin{aligned}
&\tilde{F}^{\text{Lin}}_w(u,u+v)\hat{v} - F'(u)\hat{v} \\
&\qquad = A(u)\hat{v} + [A'(u)v]\hat{v} + [A'(u)\hat{v}](u+v) - b'(u+v)\hat{v} \\
&\qquad\quad - A(u)\hat{v} - [A'(u)\hat{v}]u + b'(u)\hat{v} \\
&\qquad = [A'(u)v]\hat{v} + [A'(u)\hat{v}]v - (b'(u+v) - b'(u))\hat{v}.
\end{aligned}$$

Letting $\|\cdot\|_F$ denote the Frobenius norm on $\mathbb{R}^{n\times n}$, we have

$$\|[A'(u)v]\|_F = \left(\sum_{i,j=1}^n (\nabla a_{ij}(u)^T v)^2\right)^{1/2} \le \|v\| \left(\sum_{i,j=1}^n \|\nabla a_{ij}(u)\|^2\right)^{1/2} \le K \cdot \|v\|$$

for some constant K since $|\partial a_{ij}(u)/\partial u_k| \le C_1 < \infty$ for all $i, j, k = 1, \ldots, n$. Thus,

$$\begin{aligned}\|\tilde{F}_w^{\mathrm{Lin}}(u, u+v)\hat{v} - F'(u)\hat{v}\| &\le 2K \cdot \|v\| \cdot \|\hat{v}\| + \|b'(u+v) - b'(u)\| \cdot \|\hat{v}\| \\ &\le 2K \cdot \|v\| \cdot \|\hat{v}\| + \gamma\|v\|^p \cdot \|\hat{v}\| \\ &= \left(2K\delta_\Omega^{1-p} + \gamma\right)\|v\|^p \cdot \|\hat{v}\|\end{aligned}$$

for any vector $\hat{v}$. Therefore,

$$\|\tilde{F}_w^{\mathrm{Lin}}(u, u+v) - F'(u)\| \le \left(2K\delta_\Omega^{1-p} + \gamma\right)\|v\|^p$$

for all $u \in \Omega$ and all v with $\|v\| \le \delta_\Omega$, which completes the proof. □

For the discrete problem (3.2), a short computation reveals that $\tilde{F}^{\mathrm{Lag}}$ and $\tilde{F}^{\mathrm{Lin}}$ given by (3.3) and (3.5) both satisfy the assumptions of Theorem 3.1 if there exists a convex set Ω such that $|D'(u)|$ and $|g'(u)|$ are uniformly bounded for $u \in \Omega$. Additionally, $\tilde{F}^{\mathrm{Lin}}$ satisfies the assumptions of Theorem 3.2 if $g'(u)$ is Hölder continuous in Ω. Thus, under these mild assumptions, the local convergence results in section 2.2 can be applied to these two cases.

We note that using $\tilde{F} = \tilde{F}^{\mathrm{Lag}}$ given by (3.3) requires minimal new calculations at each step of the linear solve in Algorithm 2.5. Indeed, each step requires only one g-evaluation at each grid point in addition to a very modest amount of arithmetic, since the necessary D- and f-values are already available. Thus, the computational effort required to implement $\tilde{F}^{\mathrm{Lag}}$ is so small that the time savings may be considerable for problems for which convergence can be achieved with this approximation.

Using $\tilde{F} = \tilde{F}^{\mathrm{Lin}}$ given by (3.5) in Algorithm 2.5 requires evaluating D' at points intermediate to the grid points, which may be problematic if D'-evaluations are expensive or unavailable. However, this needs to be done only once at the outset of each linear solve and, in many applications, may be no more difficult than evaluating D at those points. Once the necessary D'-values have been computed, each step of the linear solve requires the same g-evaluations as $\tilde{F}^{\mathrm{Lag}}$ together with a somewhat greater but still very modest amount of arithmetic.

Remark. One of the referees suggested an alternative to (3.7) in defining $\tilde{F}^{\mathrm{Lin}}$ for the model problem (3.5), viz.,

$$\tilde{F}^{\mathrm{Lin}}(u, w) = A(u)w + [A'(u)(w-u)]u - b(w) + c. \tag{3.10}$$

This has the error term

$$\frac{\tilde{F}^{\mathrm{Lin}}(u, u+\sigma v) - F(u)}{\sigma} - F'(u)v = -\left[\frac{b(u+\sigma v) - b(u)}{\sigma} - b'(u)v\right],$$

which is slightly simpler than (3.9). Implementing this $\tilde{F}^{\mathrm{Lin}}$ on the discrete problem (3.2) has essentially the same cost as implementing $\tilde{F}^{\mathrm{Lin}}$ given by (3.7). With this $\tilde{F}^{\mathrm{Lin}}$, the analysis in section 2.2 can be applied as in the remark at the end of section 2.2 by writing F in (3.5) as $F = F_1 + F_2$, where $F_1(u) \equiv A(u)u$ and $F_2(u) \equiv -b(u) + c$. Then (3.10) becomes

$$\tilde{F}^{\mathrm{Lin}}(u, w) = F_1(u) + F_1'(u)(w-u) + F_2(w),$$

and Assumptions 2.7 and 2.10 become assumptions on F_2 and, hence, on b as in the remark at the end of section 2.2.

Key to abbreviations.

Abbreviation	Meaning
NEQ	Number of equations (unknowns)
NNI	Number of nonlinear iterations
NLI	Number of linear iterations

3.3. Numerical results. In our numerical experiments, the test problems described above were treated by applying the KINSOL Newton–Krylov code from the SUNDIALS suite [10]; see [10] for details of the algorithm not specified here. KINSOL was applied in matrix-free mode with modifications to allow the approximation (2.1) with $\tilde{F} = \tilde{F}^{\mathrm{Lag}}$ and $\tilde{F} = \tilde{F}^{\mathrm{Lin}}$ to be used in place of (1.4). The linear solver used was GMRES with a banded block-diagonal preconditioner provided by SUNDIALS using finite differences of F-values; see [10]. The linear and nonlinear solver specifications were as follows: the maximum number of GMRES iterations allowed was 100, with no restarts; each forcing term η_k was the constant 10^{-3}; the nonlinear iterations terminated successfully if $\|F(u_k)\| \leq 10^{-8}$. These tight tolerances were chosen to bring out performance differences resulting from the different choices of $\tilde{F}$. Additionally, failure was declared if either the number of nonlinear iterations exceeded 200 or $\|s_k\| \leq 10^{-13}$; however, these failure modes were not observed in our tests.

All runs were done on the ASC Frost machine at Lawrence Livermore National Laboratory, an IBM SP parallel platform running the AIX operating system with 1088 375 MHz processors grouped into 16-processor nodes. In each of our runs, the spatial domain was subdivided into a $p \times p$ array of square subdomains having an equal number of grid points, and the grid points in each subdomain were mapped to one processor.

In test cases 1–3, the domain was divided into 400×400 zones yielding $160,000$ unknowns. In test case 4, a smaller problem was also considered, in which the domain was divided into 200×200 zones yielding 40,000 unknowns. In all cases, the grid was adjusted so that the number of grid points per subdomain (and processor) was always 10,000. Thus, for the 160,000-unknown problems, 16 processors were used, and four were used for the smaller test case 4 problem.

The results of our runs are given in the tables below. A key to the abbreviations used in these tables is provided in Table 2. In Tables 3–6, "None" refers to using no approximation, i.e., using (1.4); "Linear" and "Lagged" refer to using $\tilde{F} = \tilde{F}^{\mathrm{Lag}}$ and $\tilde{F} = \tilde{F}^{\mathrm{Lin}}$, respectively, in (2.1). Run times are given in seconds, and each normalized run time is calculated by dividing the run time by that obtained by using no approximation.

3.3.1. Case 1: $D(u) = \sqrt{u^2 + u + 1}$. This choice for D is the least expensive to evaluate of all of those we experimented with, and so we expected the time savings using the approximations $\tilde{F}^{\mathrm{Lag}}$ and $\tilde{F}^{\mathrm{Lin}}$ to be less significant than in the other test problems. Recall that the problem was posed so that the exact solution was $u_c(x, y) = cx(1-x)y(1-y)$. Here we took $c = 10$ with the initial approximate solution $u_0 \equiv c$. (No significant additional information was gained in this case by considering the other values of c.) The results are given in Table 3. There were no unsuccessful runs in this case.

As expected, since D is not very expensive to evaluate, using the approximations $\tilde{F}^{\mathrm{Lag}}$ and $\tilde{F}^{\mathrm{Lin}}$ did not significantly reduce computational time. In fact, the lagged approximation required more GMRES iterations and, consequently, more run time than

TABLE 3

	Linear	7	343	30.8	0.91
	Lagged	10	566	47.2	1.40

the two alternatives, apparently because of less compatibility between the approximate Jacobian-vector products obtained with $\tilde{F}^{\mathrm{Lag}}$ and the preconditioner provided by SUNDIALS using exact F-values. Consistent with the theory, there is very close agreement between the numbers of nonlinear and linear iterations obtained by using $\tilde{F}^{\mathrm{Lin}}$ and those obtained by using no approximation.

3.3.2. Case 2: $D(u) = \frac{1}{\sqrt{u^2+u+1}}$. This choice for D is only slightly more expensive to evaluate than the choice in Case 1; however, there are some notable differences in the computational results. For $c = 1$ and $c = 2$, we took $u_0 \equiv c$ as in Case 1. However, for $c = 5$ and $c = 10$, we took $u_0 \equiv 1$; this was necessary in order to obtain convergence to the solution, even when no approximation was used. With these choices of u_0, all runs were successful. The results are shown in Table 4.

This choice for D is interesting because the results with the lagged approximation $\tilde{F}^{\mathrm{Lag}}$ show sensitivity to the value of c. As c gets larger, the lagged approximation becomes less accurate, and, as a result, its performance degrades. The results obtained by using the linear approximation $\tilde{F}^{\mathrm{Lin}}$ are similar to those in Case 1. Again we note very close agreement between the numbers of linear and nonlinear iterations obtained by using $\tilde{F}^{\mathrm{Lin}}$ and those obtained by using no approximation.

3.3.3. Case 3: $D(u) = u^{\frac{3}{5}}e^u$. This choice for D entails the largest values of $D'(u)$ at the solutions $u_c(x, y) = cx(1 - x)y(1 - y)$, and so we expected differences in the effectiveness of $\tilde{F}^{\mathrm{Lag}}$ and $\tilde{F}^{\mathrm{Lin}}$ as approximations in (2.1) to be significant and to become increasingly pronounced as c increases. We took the initial approximate solution to be $u_0 \equiv c$ for each value of c. With this u_0, there were two failures when $\tilde{F}^{\mathrm{Lag}}$ was used. The results are given in Table 5.

TABLE 5
Case 3: $D(u) = u^{\frac{3}{5}} e^u$.

	Linear	16	598	81.5	0.79
	Lagged	33	2374	273.6	2.65
2.0	None	17	645	110.0	1.00
	Linear	17	632	85.1	0.77
	Lagged	35	2503	287.0	2.61
5.0	None	19	771	124.8	1.00
	Linear	19	782	98.0	0.79
	Lagged	-	-	-	-
10.0	None	23	1201	199.2	1.00
	Linear	23	1199	152.4	0.77
	Lagged	-	-	-	-

The results in Table 5 are consistent with our expectations. The lagged approximation resulted in failures of the method and greatly increased run times when it did not fail. (The failures resulted from GMRES failing to produce the requested residual norm reduction within the allowable 100 iterations.) In contrast, the linear approximation led to success in every case and to significant reductions in run times. For all values of c, as seen in the previous cases, there is very close agreement between the numbers of linear and nonlinear iterations obtained by using $\tilde{F}^{\mathrm{Lin}}$ and those obtained by using no approximation.

3.3.4. Case 4: $D(u) = K\sqrt{S(u)}[1 - (1 - S(u)^{\frac{1}{\mu}})^{\mu}]^2$. This problem is the most realistic of all of those considered here, and, of all of the choices for D, this is the most expensive to evaluate. The problem is related to a formulation of Richards's equation, which is often used for modeling fluid flows in unsaturated porous media. Here we chose values of the parameters appropriate for groundwater flow in an unsaturated dune sand (see [13] and the references therein), as follows: $K = 5.040$, $\alpha = 5.470$, $\nu = 4.264$, and $\mu = \frac{\nu-1}{\nu}$. In each test case, we began with $u_0 \equiv \beta = \frac{1}{16}$, for which all runs were successful. Results are given in Table 6.

As in the previous cases, there is very close agreement between the numbers of linear and nonlinear iterations obtained by using the linear approximation and those obtained by using no approximation. For the linear approximation, the greater runtime reductions on the larger problems are notable and likely reflect the benefit of amortizing the cost of evaluating D' over larger numbers of GMRES iterations per inexact Newton step. While not as effective as the linear approximation, the lagged approximation, for all values of c except 10, also resulted in significantly reduced run times, with greater reductions on the larger problems, which required many more GMRES iterations per inexact Newton step than the smaller problems.

4. Summary and conclusions. We have considered Newton–Krylov methods for solving (1.1) in which the matrix-vector products required by the Krylov solver are approximated by finite differences of the form (2.1) involving an approximating function $\tilde{F} \approx F$. The particular Krylov subspace methods considered are the GMRES and Arnoldi methods, which are based on the Arnoldi process (Algorithm 2.1); however, the developments here should also be helpful when other Krylov subspace methods are of interest.

In Algorithm 2.2, we formulate an Arnoldi process that uses approximate finite differences of the form (2.1) on a Jacobian system (2.2), and we consider the GMRES and Arnoldi methods applied to (2.2) that are based on this process. In Theorem 2.3 and Corollary 2.4, it is shown that an approximate solution of (2.2) determined at some step of the GMRES or Arnoldi method based on Algorithm 2.2 is the same as the approximate solution of the perturbed system (2.6) obtained at the same step of the method based on Algorithm 2.1.

In Algorithm 2.5, we outline a Newton–Krylov method that uses the GMRES or Arnoldi method based on Algorithm 2.2. Our main result for Algorithm 2.5 is Theorem 2.12, which can be viewed as a counterpart of results in [5, Thms. 2.3 and 3.3]. This theorem asserts that, under Assumption 2.7 on the approximating function $\tilde{F}$ as well as mild assumptions on F, the iterates produced by Algorithm 2.5 converge to a solution locally and q-linearly in a certain norm, provided the forcing terms are uniformly bounded below one and the difference steps are uniformly sufficiently small. If the forcing terms and difference steps approach zero, then the convergence is q-superlinear. If Assumption 2.10 on $\tilde{F}$ also holds, then the convergence is of q-order $1 + p$, where $p \in (0, 1]$ is the exponent of Hölder continuity in Assumption 2.10.

In section 3, we report on numerical experiments with two illustrative choices of $\tilde{F}$ that are suitable for a broad class of nonlinear diffusion problems. One of these choices, the "linear" approximation $\tilde{F}^{\mathrm{Lin}}$ satisfies the assumptions of Theorem 2.12 under mild conditions and, therefore, has a sound theoretical basis. In our tests, this choice yielded run times that were always less than those obtained by using exact values

of F, with greater run-time reductions observed for problems with more expensive F-evaluations. Additionally, in all test cases, this choice resulted in numbers of linear and nonlinear iterations that were very close to those obtained by using exact values of F. Thus this choice promises to be both robust and helpful in improving efficiency in many nonlinear diffusion problems, especially those in which F-evaluations are expensive. However, its implementation may be problematic in some applications (see section 3.2). Our other choice, the "lagged" approximation $\tilde{F}^{\mathrm{Lag}}$, does not normally satisfy the assumptions of Theorem 2.12; however, it is relatively easy and inexpensive to apply. It improved efficiency in some of our tests, especially in Case 2 (see Table 4); however, it was inefficient in other tests and suffered failures in Case 3 (see Table 5). Thus this choice should be kept in mind for ease of application and potential for improving efficiency but should not be counted on for improvement in all problems.

RENORMALIZED MESHFREE SCHEMES I: CONSISTENCY, STABILITY, AND HYBRID METHODS FOR CONSERVATION LAWS*

NATHALIE LANSON† AND JEAN-PAUL VILA‡

Abstract. This paper is devoted to the study of a new kind of meshfree scheme based on a new class of meshfree derivatives: the renormalized meshfree derivatives, which improve the consistency of the original weighted particle methods. The weak renormalized meshfree scheme, built from the weak formulation of general conservation laws, turns out to be L^2 stable under some geometrical conditions on the distribution of particles and some regularity conditions of the transport field. A time discretization is then performed by analogy with finite volume methods, and the L^1, L^∞, and BV stabilities of the obtained time discretized scheme are studied. From the same analogy with finite volume methods, a hybrid particle scheme is built using the Godunov method and is numerically compared to the weak renormalized scheme.

1. Introduction.

We focus on conservation laws of type

$$\begin{cases} L_a(u) + \operatorname{div}(F(u,x,t)) = S(u,x,t), \quad t \in \mathbb{R}_+,\ x \in \mathbb{R}^d, \\ u(x,0) = u_0(x), \end{cases} \tag{1}$$

where L_a is the transport operator defined as $L_a(u) = \frac{\partial u}{\partial t} + \operatorname{div}(a(x,t) \otimes u)$, a the transport field $a = (a^\alpha)_{\alpha=1}^d$, $a^\alpha : \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}$, and $u \in \mathbb{R}^p$ is the exact solution of the problem. We denote $u_0 \in \mathbb{R}^p$ to be the initial condition. The flux $F = (F^\alpha)_{\alpha=1}^d$, composed of d vectors $F^\alpha \in \mathbb{R}^p$, and the source term $S = (S^l)_{l=1}^p$ are as follows: $F^\alpha : \mathbb{R}^p \times \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}^p\ \forall \alpha = 1, \dots, d$ and $S : \mathbb{R}^p \times \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}^p$.

Many numerical schemes aimed at solving this problem already exist and can be classified as mesh-based or meshfree methods. The main advantage of meshfree methods lies in their ability to handle complex situations such as extremely large deformation of bodies, impact problems, treatment of discontinuities as in multiphases flows, or free surface flows. Mathematical analysis of weighted particle methods [14] pointed out the lack of consistency of these methods. We focus on the renormalization, a recent tool introduced in [13, 7], which seems to give accurate results and increases the consistency of weighted particle methods. According to the literature [4] this tool, although very attractive for applications, seems to make the global conservativity of the original method disappear. In this paper, this drawback is alleviated by introducing a new class of meshfree approximation of derivatives, the renormalized meshfree derivatives. We propose to use this new class of derivatives for the

approximation of the weak formulation of conservation laws (see [17, 2]) to build and study the conservative weak renormalized meshfree scheme.

We will start by recalling some basic principles of particle approximation, and we will build the new class of meshfree approximate derivatives and study their consistency. The end of the second section is devoted to the construction and the computational study of a time continuous scheme based on the weak formulation of (1): the weak renormalized meshfree scheme. In section 3, we study the L^2 stability property of the time continuous weak renormalized meshfree scheme and give some geometrical conditions necessary for stability to be achieved. We verify these geometrical conditions in the case of a regular transport field and a regular initial distribution of particles. Section 4 is devoted to the construction and stability study of a time discretized weak renormalized scheme. We will apply the obtained scheme to general scalar conservation laws and give L^∞, L^1, and BV stability results. Finally, in section 5, we apply the analogy made with finite volumes in section 4 to develop another type of renormalized meshfree method: *the renormalized hybrid particle method*. This new method is applied to Euler equations, and comparisons with the weak renormalized meshfree scheme are given in the case of free surface flows.

2. Renormalized particle approximation.

2.1. Basic principles of particle approximation. We consider a regular vector field a and introduce a system of Lagrangian coordinates (ξ, t). Let us take a set of moving particles P, with coordinates $x_j(t)$ $\forall j \in P$, volumes $\Omega_j(t)$ which represent a volume surrounding the particle j at time t (see the example in Figure 1(a)), and weights $w_j(t)$, such that $w_j(t) = \text{measure}(\Omega_j(t))$. The *characteristic distance* between particles is denoted $h(t)$ and represents the order of magnitude of the distances between particles at time t (see Figure 1(a)). h depends on the time t since the particles are moving. Indeed, consider $h_j(t)$ the minimum of the distances between a particle j and its immediate neighbors. The characteristic distance $h(t)$ is then defined as the maximum of the $h_j(t)$. The particles are moved along the characteristic curves of the field a and the weights are modified in order to take the deformations of the system into account:

$$\begin{aligned} &\frac{dx_j}{dt} = a(x_j, t), && \text{with } x_j(0) = \xi_j, \\ &\frac{dw_j(t)}{dt} = w_j(t)\text{div}(a(x_j, t)), && \text{with } w_j(0) = w_j^0. \end{aligned} \tag{2}$$

We consider that the vector field is regular enough, such that at any time t: $\mathbb{R}^d = \cup_{j\in P}\Omega_j(t)$. In the following, in order to simplify the notation, the time dependency will not be explicitly written.

The particle approximation of a function f is defined as

$$\Pi^h f(x) = \sum_{j\in P} w_j\, f(x_j)\, \delta(x - x_j). \tag{3}$$

In order to deal with derivatives, the particle weighted approximation $\Pi^h_\varepsilon f$ of a function f is defined as in (3), where the delta functions are approximated by the regularizing kernels $\zeta_\varepsilon(x - x_j)$, with ε the length of its compact support, also called the *smoothing length*. Such kernel functions ζ_ε are defined by

$$\zeta_\varepsilon(x - x_j) = \frac{1}{\varepsilon^d}\zeta\left(\frac{\|x - x_j\|}{\varepsilon}\right), \tag{4}$$

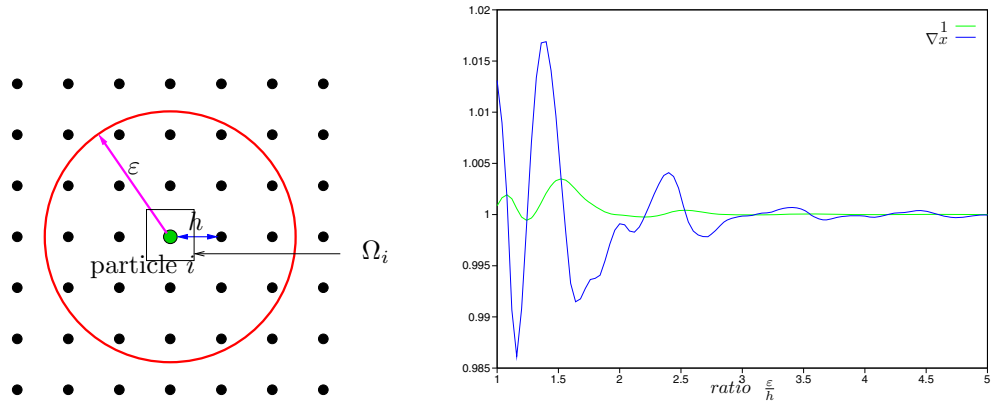

FIG. 1. *Geometry of the particle set and smoothed particle approximation.*

where the function ζ is a positive function with compact support. For instance, in the case of a cubic B-spline (see [11]), support$(\zeta) \subset [0,2]$ and ζ is given by

$$\zeta(r) = C \times \begin{cases} 1 - \frac{3}{2}r^2 + \frac{3}{4}r^3 & \text{if } 0 \le r \le 1, \\ \frac{1}{4}(2-r)^3 & \text{if } 1 \le r \le 2, \end{cases} \tag{5}$$

where $C = \frac{2}{3}$ for $d = 1$, $\frac{10}{7\pi}$ for $d = 2$, $\frac{1}{\pi}$ for $d = 3$.

The smoothing length varies in time and space according to

$$\frac{d\varepsilon}{dt} = \frac{\varepsilon}{d}\mathrm{div}a, \tag{6}$$

where d is again the dimension of the domain. The initial value of $\varepsilon(x,0)$ is computed using the initial characteristic length $h(0)$. If the particle are initially equidistributed, we take $\varepsilon(x,0) = Ch(0)\ \forall x$, where the coefficient C is chosen so that each particle has enough interaction with its surrounding neighboring particles.

We will suppose that the smoothing length stays bounded (this is true if a is regular enough). In section 3.2 we will take $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d)$:

$$\exists C, \varepsilon_0 \text{ constant such that } \forall x, t \quad \varepsilon_0 \le \varepsilon \le C\varepsilon_0. \tag{7}$$

When ε is computed from (6), the C depends on the transport field a.

The weighted particle approximation of derivatives is then given by the operator

$$D^{\varepsilon}_{\alpha,h} f(x) = \sum_{j \in P} w_j\, f(x_j)\, D_\alpha \zeta_\varepsilon(x - x_j). \tag{8}$$

Consider now that the approximation (8) is taken at $x = x_i$; then ε defines the set of particles that have a contribution to the calculation of $D^{\varepsilon}_{\alpha,h} f(x_i)$ as shown in Figure 1(a). This set of particles, referred to as the *neighborhood* of the particle i, will be denoted V_i in the following:

$$V_i = \{ j \in P \text{ s.t. } ||x_i - x_j|| \le \varepsilon \}. \tag{9}$$

It is shown in [14] that the approximation of derivatives depends on $\frac{h}{\varepsilon}$. This ratio $\frac{h}{\varepsilon}$ has to tend to zero in order to get convergence, which is not the case for numerical applications. Figure 1(b) represents the accuracy of the approximation of two functions, 1 and ∇x, on a regular grid in 2 dimensions of space, using the smoothed particle approximation (8), for different values of the ratio $\frac{\varepsilon}{h}$. One can see that, in two dimensions, a good value is $\varepsilon = 1.2h$. This value is different depending on the dimension of the space we work in. Within computations, however, the distribution of particles is no longer regular and it becomes difficult to ensure the consistency of the method.

2.2. A new class of meshfree approximation of derivatives. In order to alleviate the smooth particle methods' lack of consistency, we introduce the class of renormalized meshfree derivatives. We will consider a general kernel μ instead of $D_\alpha \zeta_\varepsilon$, as the renormalization applies to any kernel with compact support. Suppose that the approximation of the derivatives is given by

$$D^{\varepsilon}_{\alpha,h} f(x) = \sum_{j \in P} w_j \, f(x_j) \mu^\alpha(x, x_j) \quad \forall \alpha = 1, \dots, d, \tag{10}$$

where $\mu = \mu(x, y)$ is a vector-valued function with spherical compact support, of radius $\varepsilon = \varepsilon(x, y)$:

$$\mu(x, y) = 0 \quad \text{for } ||x - y|| \geq \varepsilon(x, y), \tag{11}$$

and ε satisfies (7). The following lemma can be proved.

LEMMA 2.1. *Under the hypotheses* (7), (11) *and the scaling hypothesis*

$$\exists C \text{ constant such that } ||\mu(x, y)|| \leq \frac{C}{\varepsilon_0^{d+1}} \quad \forall x, y \tag{12}$$

there exists $C > 0$ *(depending on the constants in* (7) *and* (12)*) such that* $\forall x, t$

$$\sum_{j \in P} w_j ||\mu(x, x_j)|| \leq \frac{C}{\varepsilon_0}. \tag{13}$$

The general renormalized meshfree derivatives of a function with respect to x^α, $\alpha \in \{1 \cdots d\}$, is given by

$$D_{\alpha,h} f(x) = \sum_{j \in P} w_j \left(f(x_j) - f(x)\right) \, A^\alpha(x, x_j), \tag{14}$$

where $A^\alpha(x, x_j)$ is an element of the vector $A(x, x_j)$ that we choose equal to

$$A(x, x_j) = B(x).\mu(x, x_j). \tag{15}$$

The *renormalization matrix* $B(x)$ allows us to achieve the consistency we are seeking.

The discrete operator of (14) and its adjoint are given by the following $\forall \alpha = 1, \dots, d$:

$$D_{\alpha,h} f(x_i) = \sum_{j \in P} w_j (f(x_j) - f(x_i)) A^\alpha_{ij}, D^*_{\alpha,h} f(x_i) = \sum_{j \in P} w_j (f(x_i) A^\alpha_{ij} - f(x_j) A^\alpha_{ji}). \tag{16}$$

Remark 2.2. In (16), when we consider $\mu(x, y) = \nabla \zeta(x, y)$, the vectors A_{ij} are defined by $A_{ij} := B_i . \nabla \zeta_{ij}$, which clearly reduces to the standard particle weighted approximation of derivatives if we take $B_i = B(x_i) = \mathbb{1}$.

The renormalization matrices $B_i = B(x_i)\ \forall i \in P$ are computed in order to get

$$D_h f = Df \quad \forall f \in \mathbb{P}^1(\mathbb{R}^d), \tag{17}$$

where $\mathbb{P}^1(\mathbb{R}^d)$ is the space of polynomials of $\mathbb{R}^d$ of order 1. The definition of $B_i\ \forall i \in P$ that satisfies the condition (17) is given in the following proposition.

PROPOSITION 2.3. *The condition* (17) *is satisfied if and only if* $B_i = (E_i)^{-1}$ *with*

$$E_i^{\alpha\beta} = \sum_{j\in P} w_j (x_j^\beta - x_i^\beta)\, \mu_{ij}^\alpha \quad \forall (\alpha,\beta) \in \{1,\dots,d\}^2, \tag{18}$$

where $\mu_{ij} = \mu(x_i, x_j)$*, and* μ *is the general kernel function used in* (10).

We can now prove the following error estimate.

PROPOSITION 2.4. *Suppose that the matrix* $E(x)$ *defined in* (18) *is invertible* $\forall x$*. Then, under the hypotheses* (7), (11), (12)*, there exists* $C > 0$ *such that* $\forall \varphi \in W^{2,\infty}(\mathbb{R}^d)$*, the renormalized meshfree derivatives* (14) *computed with* (18) *satisfy*

$$\|D_h\varphi(x) - D\varphi(x)\| \le C\varepsilon_0 \|B(x)\| \|D^2\varphi\|_\infty,$$

where D^2 *denotes the matrix of the second order derivatives of* φ*.*

Proof. Let us start from a Taylor series expansion:

$$\varphi_j - \varphi(x) = D\varphi(x).(x_j - x) + \overbrace{\frac{1}{2}\int_0^1 (1-s)(x_j - x).D^2\varphi(x - s(x_j - x)).(x_j - x)ds}^{R_j(\varphi)}.$$

We deduce that

$$D\varphi(x) - D_h\varphi(x) = \overbrace{D\varphi(x) - \sum_{j\in P} D\varphi(x).(x_j - x)B(x)\mu(x,x_j)}^{I} + \sum_{j\in P} w_j R_j(\varphi) B(x)\mu(x,x_j).$$

Using Proposition 2.3, we verify that

$$\begin{aligned} I^\alpha &= D_\alpha\varphi(x) - \sum_{\gamma,\beta=1}^d D_\gamma\varphi(x) B(x)^{\alpha\beta} \sum_{j\in P} (x_j^\gamma - x^\gamma)\mu^\beta(x,x_j) \\ &= D_\alpha\varphi(x) - \sum_{\gamma,\beta=1}^d \delta^{\alpha,\gamma} D_\gamma\varphi(x) = 0. \end{aligned}$$

It remains to estimate the term $\sum_{j\in P} w_j R_j(\varphi) B(x)\mu(x,x_j)$. Knowing that $\mu(x,x_j) = 0$ when $||x_j - x|| \ge C\varepsilon_0$, and using Lemma 2.1, we get

$$||D\varphi(x) - D_h\varphi(x)|| \le \frac{C\varepsilon_0^2}{2} ||D^2\varphi||_\infty |||B(x)||| \frac{C}{2\varepsilon_0} \le C\varepsilon_0 |||B(x)|||\ ||D^2\varphi||_\infty. \qquad \square$$

It turns out that the approximation depends now solely on the parameter ε_0, while the ratio h/ε_0 must tend to zero for classical weighted particles approximation.

The kernel is taken spherical in order to have $\nabla\zeta_{ij} = -\nabla\zeta_{ji}$. To simplify the

scheme and for local conservation, we choose $B_{ij} = \frac{B_i+B_j}{2}$ instead of B_i, so that $A_{ij} = -A_{ji}$. We can also prove that Proposition 2.4 also holds in the following case.

PROPOSITION 2.5. *Under the same hypothesis as in Proposition* 2.4 *and if the condition*

$$\forall (i,j) \text{ such that } ||x_j - x_i|| \leq C\varepsilon \Rightarrow B_j = B_i + O(\varepsilon) \tag{19}$$

is satisfied, then the L^∞ *error estimate of the operator* D_h *with* $A_{ij} = \frac{B_i+B_j}{2}\mu_{ij} = -A_{ji}$ *holds:*

$$||D_h\varphi(x) - D\varphi(x)|| \leq C\varepsilon_0 ||B(x)|| \ (||D^2\varphi||_\infty + ||D\varphi||_\infty). \tag{20}$$

The principle of the proof is the same as for Proposition 2.4, and it is left to the reader.

Hypotheses (7), (11), (12) are related to the choice of the shape function $\mu(x)$ and the variations of $\varepsilon(x)$. The important assumption in Proposition 2.4 is that the matrices $E(x)$ must be invertible $\forall x$. We will prove in section 3.2 that this is satisfied when the ratio $\frac{\varepsilon}{h}$ is of order 1, the transport field is $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$, and the particles are initially equidistributed.

2.3. The time continuous weak renormalized meshfree scheme. We consider the general conservation law (1). In order to deal with nonlinear hyperbolic conservation laws and the computation of discontinuous solutions, it is necessary to introduce the notion of a weak solution of (1): $\forall \varphi \in (\mathcal{C}_c^2(\mathbb{R}^d \times \mathbb{R}_+^*))^p$

$$\int_{\mathbb{R}^d \times \mathbb{R}^+} (u(x,t)L_a^*(\varphi) + F(u,x,t).\nabla(\varphi) + S(u,x,t)\varphi)\, dxdt = 0, \tag{21}$$

where $-L_a^*$ is the adjoint operator of L_a defined as $L_a^*(\varphi) = \frac{\partial \varphi}{\partial t} + \sum_{\alpha=1}^d a^\alpha \frac{\partial \varphi}{\partial x^\alpha}$.

We replace the integration over space in (21) by the discrete scalar product $(.,.)_h$ defined as $(\varphi, \Phi)_h = \sum_i w_i \varphi_i \Phi_i$ and the derivative $\nabla(\varphi)$ by its approximation $D_h\varphi$. We then get the following system, whose solution is denoted by u^h:

$$\int_{\mathbb{R}_+} \left[\left(u^h(.,t), L_a^*(\varphi)\right)_h + \sum_{\alpha=1}^d \left(F^\alpha(u^h,.,t), D_{\alpha,h}\varphi\right)_h + \left(S(u^h,.,t),\varphi\right)_h \right] dt = 0. \tag{22}$$

Let us choose $u^h(x,t) = u_i^h(t)\ \forall x \in \Omega_i$. Making an integration by parts with respect to t, we find that (22) is true if and only if

$$\begin{cases} \text{(i)} \quad \dfrac{d}{dt}x_i = a(x_i,t), & x_i(0) = \xi_i, \\ \text{(ii)} \quad \dfrac{d}{dt}w_i = \text{div } (a(x_i,t))w_i, & w_i(0) = w_i^0, \\ \text{(iii)} \quad \dfrac{d}{dt}(w_i u_i^h) + w_i \displaystyle\sum_{\alpha=1}^d D_{\alpha,h}^*(F^\alpha)(u_i^h, x_i, t) = w_i S(u_i^h, x_i, t), & u_i^h(0) = u^0(\xi_i), \end{cases} \tag{23}$$

where $x_i = x_i(t)$, $u_i^h = u_i^h(t)$, and $w_i = w_i(t)$.

Remark 2.6. It is possible to build a strong scheme by simply replacing the derivative operator in (1) by the approximation operator $D_{\alpha,h}$ (14). We will not discuss this scheme in this paper, but it is studied in [8].

2.4. Application to Euler equations. Euler equations read as follows:

$$\begin{cases} \dfrac{\partial \rho}{\partial t} + \operatorname{div}(\rho \vec{v}) = 0, \\ \dfrac{\partial \rho \vec{v}}{\partial t} + \operatorname{div}(\rho \vec{v} \otimes \vec{v}) + \vec{\nabla} p = 0, \\ \dfrac{\partial E}{\partial t} + \operatorname{div}(\vec{v}(E+p)) = 0, \end{cases}$$

where ρ is the density, $\vec{v}$ the velocity (the transport field), E the total energy, and $p = p(\rho, u)$ the pressure. The total energy E is given by $E = \rho(u + \frac{1}{2}\|\vec{v}\|^2)$ with u the specific internal energy.

Euler equations can be rewritten as a conservation law. Applying the weak renormalized scheme (23), we get

$$\begin{cases} \dfrac{d}{dt} m_i = \dfrac{d}{dt}(w_i \rho_i) = 0, \\ \dfrac{d}{dt} v_i = -\displaystyle\sum_{j \in P} \frac{m_j}{\rho_i \rho_j}(p_i + p_j) A_{ij} - \sum_{j \in P} m_j \pi_{ij} A_{ij}, \\ \dfrac{d}{dt} u_i = \displaystyle\sum_{j \in P} \frac{m_j}{\rho_i \rho_j} p_j (v_i - v_j) A_{ij} + \frac{1}{2} \sum_{j \in P} \pi_{ij} (v_i - v_j) A_{ij}, \end{cases} \tag{24}$$

where we have chosen $A_{ij} = -A_{ji}$ as explained in Proposition 2.5. As we will show in section 4.1, when using an Euler explicit type of time discretization, one must add a numerical viscosity, which we have denoted π_{ij} in the above equations. For now, we will use the classical Von Neumann–Richtmeyer numerical viscosity (see [11] for instance). It remains to compute the density ρ and the smoothing length ε, as we want to move ε according to the distortion of the domain (see (6)) in order to keep a good number of neighbors per particle. We use

$$\frac{d}{dt}\rho_i = -\left(\rho \sum_{\alpha=1,\dots,d} D_h^\alpha v \right)_i = -\rho_i \sum_{j \in P} \frac{m_j}{\rho_j}(v_j - v_i) A_{ij}, \tag{25}$$

$$\frac{d}{dt}\varepsilon_i = \frac{1}{d}\left(\varepsilon \sum_{\alpha=1,\dots,d} D_h^\alpha v \right)_i = \frac{1}{d}\varepsilon_i \sum_{j \in P} \frac{m_j}{\rho_j}(v_j - v_i) A_{ij}. \tag{26}$$

Let us notice that the time-continuous scheme (24) satisfies the following properties: conservation of momentum (impulse and angular), conservation of total energy, second law of thermodynamics: $T_i \frac{ds_i}{dt} \geq 0$ (T = temperature, s = entropy).

Let us now present some numerical results that will demonstrate the efficiency of the renormalized method compared to the classical weighted particle methods. Consider the case of a one-dimensional implosion problem. The initial conditions are $\rho = 1$, $v = 1$, $p = 1$ in the domain $-1 \leq x \leq 0$ and $\rho = 1$, $v = -1$, $p = 1$ in the domain $0 \leq x \leq 1$. We used ghost particles to compute the wall boundary conditions at each end of the line of particles. The exact solution is composed of two shock waves, with a pressure plateau of $p_e = 2.92665$. We compare the results obtained from the classical SPH (smooth particle hydrodynamics) weighted particle scheme (based on the weak formulation of the conservation law as well) and the weak renormalized scheme. Both schemes have been implemented using the cubic B-spline (5) and with

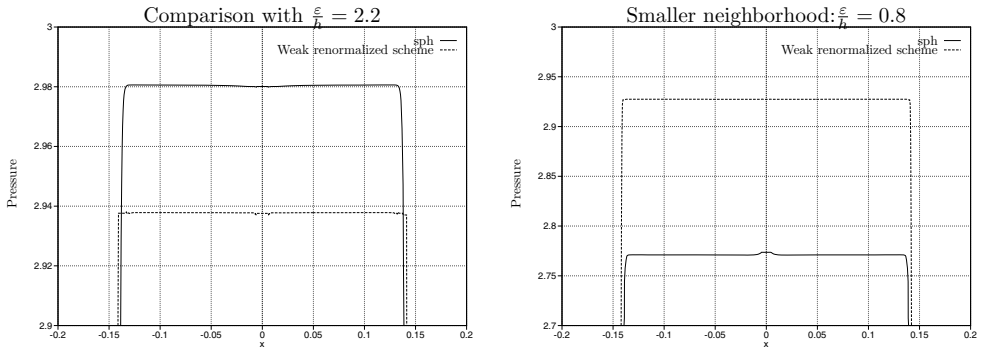

FIG. 2. *Comparison between SPH and weak renormalized schemes.*

two different values of the initial ratio $\frac{\varepsilon}{h}$: $\frac{\varepsilon}{h} = 2.2$, which is the optimal value of this ratio for a one-dimensional problem, and $\frac{\varepsilon}{h} = 0.8$. As explained earlier, ε will be computed according to (26), so that the number of neighbors for each particle will remain roughly the same within the computation. Our aim is not only to prove the efficiency of the renormalized method, but also to investigate the possibility of reducing the neighborhood of each particle to a minimum number of particles (for a one-dimensional problem, 2 particles) in order to reduce the computation time (as the computation time is directly linked to the number of neighbors per particles in a meshfree code). The results are given in Figure 2. The pressure plateaus obtained with the SPH scheme are $p = 2.984$ for $\frac{\varepsilon}{h} = 2.2$ and 2.780 for $\frac{\varepsilon}{h} = 0.8$. As for the weak renormalized scheme, we get $p = 2.934$ for $\frac{\varepsilon}{h} = 2.2$ and $p = 2.928$ for $\frac{\varepsilon}{h} = 0.8$. It is clear the weak renormalized scheme gives better results than the classical SPH weighted particle scheme, even in the case $\frac{\varepsilon}{h} = 2.2$, where the behavior of the classical SPH weighted particle scheme is supposed to be optimum. We refer to [2] for more numerical results and comparisons.

3. L^2 stability of the time continuous weak renormalized meshfree scheme. In this section, we will study the L^2 stability of the time continuous weak renormalized meshfree scheme (23) through the special case of Friedrichs systems. Let us consider the case where the physical problem admits a regular transport field $a = (a^\alpha)_{\alpha=1}^d$. Friedrichs systems are then written as

$$\begin{aligned} &\frac{\partial u}{\partial t} + \sum_{\alpha=1}^{d} D_\alpha(a^\alpha u) + \sum_{\alpha=1}^{d} D_\alpha(\tilde{\mathcal{F}}^\alpha u) + B_0 u = S \quad \forall (t,x) \in [0,T] \times \mathbb{R}^d, \\ &u(0,x) = u_0(x) \quad \forall x \in \mathbb{R}^d, \end{aligned} \tag{27}$$

where $u : [0,T] \times \mathbb{R}^d \to \mathbb{R}^p$ is the solution of the system, u_0 the initial condition $u_0 : \mathbb{R}^d \to \mathbb{R}^p$, S and B_0 the parameters of the source term such that $S : [0,T] \times \mathbb{R}^d \to \mathbb{R}^p$, $B_0 : [0,T] \times \mathbb{R}^d \to \mathcal{L}(\mathbb{R}^p)$, and $\tilde{\mathcal{F}}^\alpha$, $\alpha = 1, \ldots, d$, the flux matrices $\tilde{\mathcal{F}}^\alpha : [0,T] \times \mathbb{R}^d \to \mathcal{L}(\mathbb{R}^p)$ $\forall \alpha \in \{1, \ldots, d\}$, which are supposed symmetric. Applying (23) to the set of equations (27), one gets

$$\begin{cases} \dfrac{d}{dt} x_i = a_i, \quad x_i(0) = \xi_i, & \dfrac{d}{dt} w_i = w_i \mathrm{div}\,(a_i), \quad w_i(0) = w_i, \\ \dfrac{d}{dt}(w_i u_i^h) + w_i \displaystyle\sum_{\alpha=1}^{d} D^*_{\alpha,h}(\tilde{\mathcal{F}}^\alpha u^h)_i + w_i B_{0,i} u_i^h = w_i S_i, \quad u_i^h(0) = u^0(\xi_i), \end{cases} \tag{28}$$

where $x_i = x_i(t)$, $w_i = w_i(t)$, $a_i = a(x_i,t)$, $u_i^h = u^h(x_i,t)$, $S_i = S(x_i,t)$, $B_{0,i} = B_0(x_i,t)$, and $(\tilde{\mathcal{F}}^\alpha u^h)_i = (\tilde{\mathcal{F}}^\alpha u^h)(x_i,t) = \tilde{\mathcal{F}}^\alpha(x_i,t)u_i^h$.

3.1. L^2 stability analysis. We prove the following result, which is a key point for the stability analysis.

PROPOSITION 3.1. *Suppose that the shape vector A_{ij} satisfies the following: $\exists C$ s.t.*

$$\text{(i)} \quad \sup_{i\in P}\sum_{j\in P} w_j||A_{ij}|| \le \frac{C}{\varepsilon_0}, \tag{29a}$$

$$\text{(ii)} \quad \sup_{i\in P}||\sum_{j\in P} w_j A_{ij}|| \le C, \tag{29b}$$

$$\text{(iii)} \quad \sup_{i\in P}||A_{ij}+A_{ji}|| \le \frac{C}{\varepsilon_0^d}. \tag{29c}$$

Then, under the hypotheses (7), (11), *$\exists C$ such that $\forall\varphi\in(L^2(\mathbb{R}^d))^m$, $\forall\alpha\in\{1,\dots,d\}$, and for all regular symmetric matrices M^1, M^2 satisfying $M^1M^2 = M^2M^1$, we have*

$$\left|\left(M^2\varphi, D_{\alpha,h}(M^1\varphi)\right)_h\right| = \left|\left(M^1\varphi, D^*_{\alpha,h}(M^2\varphi)\right)_h\right| \le C||\varphi||_h^2\ , \tag{30}$$

where C depends on M^1, M^2 and their first order derivatives.

Proof. Let us first define the quantities S_1 and S_2:

$$\left(M^1\varphi, D_h^{\alpha,*}(M^2\varphi)\right)_h = \sum_{i,j} w_iw_j\left((M_i^1\varphi_i, M_i^2\varphi_i)A_{ij}^\alpha - (M_i^1\varphi_i, M_j^2\varphi_j)A_{ji}^\alpha\right) = S_1+S_2.$$

We will estimate S_1 and S_2 separately.

Term S_1.

$$||S_1|| = \sum_i w_i(M_i^1\varphi_i, M_i^2\varphi_i)\left(\sum_j w_jA_{ij}^\alpha\right). \tag{31}$$

Using the conditions (29b), one deduces (with $||M||_\infty = \sup_x|||M(x)||||$)

$$||S_1|| \le C||M^1M^2||_\infty\sum_i w_i||\varphi_i||^2 \le C||M^1M^2||_\infty||\varphi||_h^2. \tag{32}$$

Term S_2. Since M^1 and M^2 are symmetric, we have $S_2 = \frac{1}{2}(S_{21}+S_{22})$:

$$S_{21} = \sum_{i,j} w_iw_j(\varphi_i, (M_i^2M_j^1 - M_i^1M_j^2).\varphi_j)A_{ji}^\alpha, \tag{33}$$

$$S_{22} = \sum_{i,j} w_iw_j(\varphi_i, (M_i^2M_j^1).\varphi_j)(A_{ij}^\alpha + A_{ji}^\alpha). \tag{34}$$

From $M_i^2M_j^1 - M_i^1M_j^2 = (M_i^2-M_j^2)M_j^1 + (M_j^1-M_i^1)M_j^2$, and the hypotheses (7), (11), we obtain the following from the regularity of the matrices M^1 and M^2:

$$|||M_i^2M_j^1 - M_i^1M_j^2||| \le C_{\varepsilon_0}(||M^2||_\infty||DM^1||_\infty + ||M^1||_\infty||DM^2||_\infty)\varepsilon_0 \le C_2\varepsilon_0,$$

where DM represents the derivatives of the matrix M. We deduce

(35)
$$||S_{21}|| \leq C_2\varepsilon_0 \sum_{i,j} w_i w_j ||\varphi_j||\ ||\varphi_i||\ ||A_{ij}|| \leq C_2 \frac{\varepsilon_0}{2} \sum_{i,j} w_i w_j (||\varphi_j||^2 + ||\varphi_i||^2)||A_{ij}||$$
$$\leq C_2 \frac{\varepsilon_0}{2} \sum_i w_i ||\varphi_i||^2 \left(\sum_j w_j (||A_{ij}|| + ||A_{ji}||) \right).$$

Using (29a), it is found that $\varepsilon_0 \sum_{j\in P} w_j ||A_{ij}||$ is uniformly bounded. Arguing that $\sum_{j\in P} = O(\frac{\varepsilon_0^d}{h^d})$ and using (29c), we get

$$\sum_{j\in P} w_j ||A_{ij} + A_{ji}|| \leq C. \tag{36}$$

As a consequence, we also get that $\varepsilon_0 \sum_{j\in P} w_j ||A_{ji}|| \leq C$. It follows that

$$||S_{21}|| \leq (||M^2||_\infty ||DM^1||_\infty + ||M^1||_\infty ||DM^2||_\infty) C ||\varphi||_h^2. \tag{37}$$

We then find an upper bound of the term S_{22} from the condition (29c):

(38)
$$||S_{22}|| \leq \frac{||M^2||_\infty ||M^1||_\infty}{2} \sum_{i,j} w_i w_j (||\varphi_i||^2 + ||\varphi_j||^2)||A_{ij} + A_{ji}||$$
$$\leq ||M^2||_\infty ||M^1||_\infty C ||\varphi||_h^2.$$

The proof is achieved by combining (32), (37), and (38). ∎

Remark 3.2. The conditions (i) and (ii) are consequences of hypotheses (7), (11), (12), Lemma 2.1, and the invertibility of the matrices $E(x)$. The last condition (iii) is important for ensuring the L^2 stability. The validity of these three hypotheses will be established in section 3.2.

We can now prove the main stability result for the time continuous scheme.

THEOREM 3.3. *Consider the same hypothesis as Proposition* 3.1*, and also suppose that* $\tilde{\mathcal{F}}^\alpha$, $\alpha = 1, \ldots, d$, *and* a *are in* $L^\infty(\mathbb{R}_+; W^{1,\infty}(\mathbb{R}^d))$, S *and* B_0 *are in* $L^\infty(\mathbb{R}_+ \times \mathbb{R}^d)$, *and* $u_0 \in L^\infty(\mathbb{R}^d)$. *Then the solution of the time continuous weak renormalized scheme applied to the Friedrichs system* (28) *is bounded in* $C(0, T; (L^2(\mathbb{R}^d))^p)$.

Proof. Let us differentiate $||u^h||_h^2 = \sum_{i\in P} w_i u_i^2$ with respect to time t:

$$\frac{d}{dt}(||u^h||_h^2) = 2 \sum_{i\in P} u_i^h . \frac{d}{dt}(w_i u_i^h) - \sum_{i\in P} w_i ||u_i^h||^2 \mathrm{div} a_i.$$

Using the ODE of the scheme (28), we get

$$\frac{d}{dt}(||u^h||_h^2) = -2 \sum_{\alpha=1}^d (u^h, D_{\alpha,h}(\tilde{\mathcal{F}}^\alpha . u^h))_h - (u^h, u^h \mathrm{div} a)_h + 2(u^h, B_0 u^h + S)_h.$$

We thus obtain (using Proposition 3.1)

$$\frac{d}{dt}(||u^h||_h^2) \leq (2C + ||\mathrm{div} a||_\infty + 2||B_0||_\infty)||u^h||_h^2 + ||u^h||_h^2 + ||S||_h^2 \leq C_1 ||u^h||_h^2 + C_2.$$

A direct integration gives

$$||u^h(., t)||_h^2 \leq ||u^h(., 0)||_h^2 \exp(C_1 t) + \frac{C_2}{C_1}(\exp(C_1 t) - 1).$$

The L^2 stability follows. ∎

From this stability result, we can prove the following convergence theorem.

THEOREM 3.4. *Let u^h be an approximate solution to* (27) *computed with the weak renormalized scheme* (28)*. Under the same assumptions as Theorem* 3.3*, u^h weakly converges towards the exact solution u of* (27) *in $L^2(0,T;(L^2(R^d))^p)$.*

Proof. We proved stability in Theorem 3.3; it remains to prove consistency. If consistency can be proved for a general conservation law, it would then also be true for Friedrichs systems. We want to prove that if u^h computed from the scheme (23) converges towards a function $\bar{u}$ as ε_0 and $h \to 0$, then $\bar{u}$ is a weak solution of (1), thus satisfying (21). From the construction of the scheme (23), it is clear that $\bar{u}$ satisfies the following: $\forall \varphi \in C_c^2(\mathbb{R}^d \times \mathbb{R}^{+,*})$

$$\int_{\mathbb{R}^+} \left[(\bar{u}(.,t), L_a^*(\varphi))_h + \sum_{\alpha=1}^{d} (F^\alpha(\bar{u},.,t), D_{\alpha,h}\varphi)_h + (S(\bar{u},.,t),\varphi)_h \right] dt = 0. \tag{39}$$

The discrete scalar product $(\varphi,\Phi)_h = \sum_i w_i \varphi_i \Phi_i$ used to develop the weak renormalized scheme (23) tends towards the scalar product in $L^2(\mathbb{R}^d)$ when h tends to 0. From Propositions 2.4 and 2.5, we know that $D_{\alpha,h}\varphi \to_{\varepsilon_0 \to 0} D_\alpha \varphi$. Applying the Lebesgue theorem, we establish that $\bar{u}$ satisfies (21), and thus is a weak solution of (1). ∎

Remark 3.5. The convergence of the weak renormalized scheme applied to Friedrichs systems, and discretized in time, towards a physically relevant solution is proved in [9]. A convergence rate is also given.

3.2. Geometrical interpretation. In the previous subsection, we established a set of conditions that the kernels A_{ij} must satisfy in order to obtain the L^2 stability for linear systems of PDEs. We will now discuss the validity of these conditions for a chosen regularizing kernel μ. Let us consider the following regularizing function:

$$\mu_{ij} = \mu(x_i,x_j) = \frac{1}{\varepsilon_{ij}^{d+2}} r_{ij}\theta_{ij}, \tag{40}$$

where $r_{ij} = x_j - x_i$ and $\theta_{ij} = \theta(x_i,x_j)$, with θ a function with compact support. In this paper, we will consider the function θ that classically appears in the smoothed particle approximation, with variable smoothing length:

$$\theta_{ij} = \frac{\varepsilon_{ij}}{||r_{ij}||} \zeta' \left(\frac{||r_{ij}||}{\varepsilon_{ij}} \right), \tag{41}$$

where ζ is, for instance, the cubic B-spline (5).

Remark 3.6. We chose a symmetric variable smoothing length $\varepsilon_{ij} = \frac{\varepsilon_i + \varepsilon_j}{2}$. One could also choose ε_i or ε_j instead of ε_{ij} in (41). The results proved in the following still hold for these two other choices.

The inverses E_i of the renormalization matrices B_i are rewritten as

$$E_i^{\alpha\beta}(t) = \sum_{j \in P} w_j \frac{r_{ij}^\alpha r_{ji}^\beta}{\varepsilon_{ij}^{d+2}} \theta_{ij}, \quad (\alpha,\beta) \in 1,\dots,d^2. \tag{42}$$

We will also use the following notation:

$$\Delta_i^h(t) = \sum_{j \in P} w_j \frac{r_{ji}}{\varepsilon_{ij}^{d+2}} \theta_{ij}. \tag{43}$$

We will in the following give three results that will identify some geometrical conditions under which (29) are satisfied. The following proposition gives a first set of sufficient conditions that ensure that (29) and (19) are satisfied.

PROPOSITION 3.7. *Suppose that* (7) *is satisfied, and that*

$$\text{(i)}\quad E_i \text{ is uniformly invertible}, \tag{44a}$$

$$\text{(ii)}\quad \sup_{i\in P} ||\Delta_i^h(t)|| = O(1), \tag{44b}$$

$$\text{(iii)}\quad \sup_{i\in P, j\in V_i} ||E_i - E_j|| = O(\varepsilon_0); \tag{44c}$$

then the inequalities (29) *and the condition* (19) *are verified:*

(A_1) (i) $\Rightarrow ||B(.)||_\infty \le C \Rightarrow$ (29a),
(A_2) (i) *and* (ii) $\Rightarrow$ (29b),
(A_3) (i) *and* (iii) $\Rightarrow$ (29c),
(A_4) (i) *and* (iii) $\Rightarrow$ (19).

Proof.

(A_1) (44a) $\Rightarrow ||B(.)||_\infty \le C$ is obvious.
Hypothesis (7) on ε being satisfied, and given the definition of μ (40), (41), one can use Lemma 2.1 and obtain (29a):

$$\sup_{i\in P}\sum_{j\in P} w_j||A_{ij}|| \le \sup_{i\in P}\sum_{j\in V_i} w_j||B_i||\ ||\mu_{ij}|| \le \frac{C}{\varepsilon_0}.$$

Using $\frac{B_i+B_j}{2}$ instead of B_i gives the same result.

(A_2) $\sum_{j\in P} w_j A_{ij} = \sum_{j\in P} w_j B_i.\mu_{ij} = B_i.(\sum_{j\in P} w_j\mu_{ij})$. Hypotheses (44a) and (44b) allow us to conclude the following: $||\sum_{j\in P} w_j A_{ij}|| \le ||B_i||\ ||\sum_{j\in P} w_j\mu_{ij}|| \le C$. If one uses $\frac{B_i+B_j}{2}$ instead of B_i in the definition of the kernel A_{ij}, one has to use hypothesis (19), which is proved as assertion A_4.

(A_3) From the definition of μ_{ij}, we have $\mu_{ij} + \mu_{ji} = \frac{1}{\varepsilon_{ij}^{d+2}} r_{ij}(\theta_{ij} - \theta_{ji}) = 0$. Considering $A_{ij} + A_{ji} = B_j.(E_j - E_i).A_{ij} + B_j.(\mu_{ji} + \mu_{ij})$, we obtain

$$||A_{ij} + A_{ji}|| \le ||B_j||\ ||E_j - E_i||\ ||A_{ij}|| + ||B_j||\ ||\mu_{ji} + \mu_{ij}||,$$

which can be upper bounded from (44a), (44c):

$$||A_{ij} + A_{ji}|| \le C\varepsilon_0||A_{ij}|| \le C\varepsilon_0||B_i||\ ||\mu_{ij}|| = O\left(\frac{1}{\varepsilon_0^d}\right).$$

If we use $\frac{B_i+B_j}{2}$ instead of B_i, (29c) is automatically satisfied.

(A_4) (44c) implies that $E_j = E_i + O(\varepsilon_0)$. Considering (44a), we deduce (19). ∎

Let us now check that the conditions (44) are satisfied for the chosen function θ. Since ε varies, we introduce a bounded function $\kappa(x,t)$ such that $\varepsilon_{ij} = \kappa_{ij}\varepsilon_0 = \frac{\kappa_i+\kappa_j}{2}\varepsilon_0$, where $\kappa_i = \kappa(x_i,t)$. Hypothesis (7) becomes

$$0 \le \kappa_{ij} \le C \quad \forall i,j \in P. \tag{45}$$

Let us now introduce the matrix of the Lagrangian coordinates DX and the Jacobian of the transformation J:

$$DX(\xi,t) = \left(\frac{\partial x^\alpha}{\partial \xi^\beta}(\xi,t)\right)_{\alpha,\beta=1,d}, \quad J(\xi,t) = \det(DX(\xi,t)). \tag{46}$$

Using these elements, we have the following Taylor series expansion:

$$\begin{aligned} &r_{ij} = DX_i.\xi_{ij} + O(\varepsilon_0^2), \qquad w_j = w_j^0(J_i + O(\varepsilon_0)), \\ &J_j = J_i + O(\varepsilon_0), \quad \kappa_{ij} = \kappa_i + \frac{\nabla\kappa_i}{2}.DX_i.\xi_{ij} + O(\varepsilon_0^2), \end{aligned} \tag{47}$$

where $\xi_{ij} = \xi_j - \xi_i$, $DX_i = DX(\xi_i, t)$, and $J_i = J(\xi_i, t)$. Let us denote

$$\nu = \frac{\xi}{\varepsilon_0}. \tag{48}$$

Introducing the Taylor series (47) into the definitions (42) and (43), we get

$$\Delta_i^h(t) = J_i DX_i.\tilde{\Delta}_i^h(t) + O(1), \quad E_i(t) = J_i DX_i.\tilde{E}_i(t).DX_i^T + O(\varepsilon_0), \tag{49}$$

with

$$\tilde{\Delta}_i^h(t) = \frac{1}{\varepsilon_0}\sum_{j\in P} b_{ij}(t)\nu_{ji}, \quad \tilde{E}_i^{\alpha\beta}(t) = \sum_{j\in P} b_{ij}(t)\nu_{ij}^\alpha\nu_{ji}^\beta, \quad b_{ij}(t) = w_j^0\frac{\theta_{ij}(t)}{(\kappa_{ij})^{d+2}\varepsilon_0^d}. \tag{50}$$

From these expansions, we can prove the following result.

PROPOSITION 3.8. *Suppose that the transport field $a(x,t)$ is regular, $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$, and that $b_{ij}(t)$ and ν_{ij} defined by* (50) *and* (48) *satisfy the following:*

(51a) (i) *for $d \geq 2$, no particle initially has its neighbors on the same line;*

(51b) (ii) $\displaystyle\sum_{j\in P} b_{ij}(t)\nu_{ij} = O(\varepsilon_0)$;

(51c) (iii) $\displaystyle\sum_{j\in P} b_{ij}(t)\nu_{ij}^\alpha\nu_{ij}^\beta - C_0(t,\xi_i)\delta^{\alpha\beta} = O(\varepsilon_0)$,

where $C_0(t,\xi)$ is bounded with respect to t and Lipschitz with respect to ξ. Then the conditions (44) *of Proposition* 3.7 *are satisfied.*

Proof.

Condition (44a). From its definition (41), θ is positive, which implies that the elements $b_{ij}(t)$ are positive. Consider Λ in the following quadratic form:

$$\Lambda_i(x) = \frac{1}{2}\sum_{\alpha,\beta\in\{1,\dots,d\}}\sum_{j\in V_i} x^\alpha x^\beta b_{ij}(t)\nu_{ij}^\alpha\nu_{ij}^\beta,$$

where V_i is the set defined in (9).

We clearly have $\tilde{E}_i(t) = -D_2\Lambda_i(x)$. $\tilde{E}_i(t)$ is thus the Hessian matrix of the quadratic form Λ_i. If Λ_i is uniformly strictly convex, then $\tilde{E}_i(t)$ is symmetric negative definite and consequently uniformly invertible. Due to the definition of θ $A_{ij} \geq 0$ $\forall i,j \in P$, the quadratic form can be rewritten as

$$\Lambda_i(x) = \frac{1}{2}\sum_{j\in V_i} b_{ij}(t)\left(\sum_{\alpha\in\{1,\dots,d\}} x^\alpha\nu_{ij}^\alpha\right)^2 = \frac{1}{2}\sum_{j\in V_i} b_{ij}(t)|x.\nu_{ij}|^2 \geq b_{*,i}||x||^2,$$

where $b_{*,i} = \inf_{y;||y||=1}\frac{1}{2}\sum_{j\in V_i} b_{ij}(t)|y.\nu_{ij}|^2$. The quantities $b_{*,i}$ must be different from 0 in order to have Λ strictly convex. When working in a space of dimension

$d \geq 2$, if all the particle neighbors of i are initially on the same straight line, it suffices to take y orthogonal to this straight line to get $b_{*,i} = 0$, as we would then have $|y.\nu_{ij}| = 0\ \forall j \in V_i$. Consequently, we must impose a condition on the initial distribution of particles, so that no particle will have all its neighbors on the same straight line (condition (51a)).

Condition (44b). We have $\Delta_i^h(t) = J_i DX_i.\tilde{\Delta}_i^h(t) + O(1)$. From (51b), and considering the regularity of the transport field, we have

$$||J_i DX_i.\tilde{\Delta}_i^h(t)|| \leq C||J||_{L^\infty(P)}||DX||_{L^\infty(P)}$$

and we deduce (44b).

Condition (44c). Let us write

$$\begin{aligned} E_i - E_j &= J_i DX_i.\tilde{E}_i.DX_i^T - J_j DX_j.\tilde{E}_j.DX_j^T + O(\varepsilon_0) \\ &= (J_i DX_i - J_j DX_j).\tilde{E}_i.DX_i^T + J_j DX_j.\tilde{E}_i.(DX_i - DX_j)^T \\ &\quad + J_j DX_j.(\tilde{E}_i - \tilde{E}_j).DX_j^T + O(\varepsilon_0). \end{aligned}$$

Using the hypothesis of regularity of the transport field a, we prove

$$||J_i - J_j||_{L^\infty(P)} \leq C||\xi_j - \xi_i||,$$

$$||DX_i - DX_j||_{L^\infty(P)} \leq C||\xi_j - \xi_i||.$$

From (51c), we deduce $||\tilde{E}_i||_{L^\infty(P)} \leq C$ and $||\tilde{E}_i - \tilde{E}_j||_{L^\infty(P)} \leq C\varepsilon_0$. Knowing that $j \in V_i$, we deduce $||\xi_j - \xi_i|| \leq C\varepsilon_0$ and consequently (44c). ∎

We now identify a special initial geometry of the distribution of particles sufficient to satisfy the conditions (51).

PROPOSITION 3.9. *Suppose that the particles are initially distributed on a regular net of characteristic length h:*

$$\text{(52)} \qquad \begin{cases} P = \mathbb{Z}^d = \{j = (j_1, \ldots, j_d), \quad j_l \in \mathbb{Z}, \quad l \in \{1, \ldots, d\}\}, \\ x_j = (x_{j_1}^1, \ldots, x_{j_d}^d), \qquad x_{j_l}^l = j_l h. \end{cases}$$

Suppose also that the transport field $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$ and the smoothing length coefficient $\kappa \in \mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+)$. Then the conditions (51) *are satisfied.*

Proof. Since the particles are equidistributed according to (52), we will consider in the following $\Omega_i(0) = \Pi_{\alpha=1}^d [(i_\alpha - \frac{1}{2})h, (i_\alpha + \frac{1}{2})h]$ such that $w_i^0 = h^d$.

Condition (51b). Since we have considered a regular initial distribution of particles (52), for every particle j, there exists a particle $s(j)$ symmetric of j with respect to i. This particle $s(j)$ satisfies $\nu_{ij} + \nu_{is(j)} = 0$, and we have

$$\sum_{j \in P} b_{ij}(t)\nu_{ij} = \frac{1}{2} \sum_{j \in P} (b_{ij}(t) - b_{is(j)}(t))\nu_{ij}.$$

Using the Taylor series expansions (47), together with the definition (41) of θ, and considering only the terms of order ε_0, we get

$$\begin{aligned} b_{ij}(t) &= \left(\frac{h}{\varepsilon_0}\right)^d \frac{1}{\kappa_i^{d+2}} \left(||DX_i.\nu_{ij}||^{-1} \zeta' \left(\left\| \frac{DX_i.\nu_{ij}}{\kappa_i} \right\| \right) + O(\varepsilon_0) \right) \\ &= \left(\frac{h}{\varepsilon_0}\right)^d \frac{1}{\kappa_i^{d+2}} \left(||DX_i.\nu_{is(j)}||^{-1} \zeta' \left(\frac{||DX_i.\nu_{is(j)}||}{\kappa_i} \right) + O(\varepsilon_0) \right) = b_{is(j)}(t) + O(\varepsilon_0), \end{aligned}$$

and condition (51b) follows.

Condition (51c). Let us study the cases $\alpha = \beta$ and $\alpha \neq \beta$ separately.

For $d \geq 2$ and $\alpha \neq \beta$, from the initial distribution of particles (52), for all particles j there exists a symmetric particle $s^{\alpha\beta}(j)$ with respect to i that satisfies $\nu_{ij}^{\alpha} + \nu_{is^{\alpha\beta}(j)}^{\alpha} = 0$ and $\nu_{ij}^{\beta} = \nu_{is^{\alpha\beta}(j)}^{\beta}$, such that

$$\sum_{j\in P} b_{ij}(t)\nu_{ij}^{\alpha}\nu_{ij}^{\beta} = \frac{1}{2}\sum_{j\in P}(b_{ij}(t) - b_{is^{\alpha\beta}(j)}(t))\nu_{ij}^{\alpha}\nu_{ij}^{\beta}.$$

Using the Taylor series expansion (47), we get

$$\sum_{j\in P} b_{ij}(t)\nu_{ij}^{\alpha}\nu_{ij}^{\beta} = \sum_{j\in P}\left(\frac{h}{\varepsilon_0}\right)^{d} O(\varepsilon_0) = O(\varepsilon_0). \tag{53}$$

Thus, in the case $\alpha \neq \beta$, the condition (51c) is satisfied.

For case $\alpha = \beta$, $d \geq 1$, let us take

$$\sum_{j\in P} b_{ij}(t)\nu_{ij}^{\alpha}\nu_{ij}^{\alpha} = \left(\frac{h}{\varepsilon_0}\right)^{d}\sum_{j\in P}\frac{1}{\kappa_{ij}^{d+2}}\theta_{ij}(t)(\nu_{ij}^{\alpha})^2 = C_0(t,\xi_i).$$

Combining the two cases, we obtain

$$\sum_{j\in P} b_{ij}(t)\nu_{ij}^{\alpha}\nu_{ij}^{\beta} = C_0(t,\xi_i)\delta^{\alpha\beta} + O(\varepsilon_0).$$

It remains to make sure that $C_0(t,\xi)$ is Lipschitz with respect to ξ. Using the Taylor expansions (47), we prove that

$$C_0(\xi_i,t) = \left(\frac{h}{\varepsilon_0}\right)^{d}\frac{1}{\kappa_i^{d+1}}\sum_{j\in P}\frac{1}{||DX_i.\nu_{ij}||}\zeta'\left(\frac{||DX_i.\nu_{ij}||}{\kappa_i}\right)(\nu_{ij}^{\alpha})^2 + O(\varepsilon_0).$$

From the regularity of the transport field a and of the function κ, we can prove $C_0(\xi_i,t) = C_0(\xi_k,t) + O(\xi_i - \xi_k) + O(\varepsilon_0)$. □

In this section, we proved that if the transport field and the smoothing length are regular enough, and if the initial distribution of particles is regular, the time continuous scheme will be L^2 stable. The smoothing length regularity is clearly linked to the transport fields' regularity when using (6) to compute ε. We also established that the existence of the renormalization matrix at each particle $i \in P$ depends on whether the neighborhood of i is on one line. The case where the neighbors are on one line (or close to a line) corresponds to the case of a very flat element in finite element methods. However, the possibility of varying the smoothing length ε allows us to increase the neighborhood in order to avoid these situations.

Although the regularity $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$ is required in our proofs, the numerical study in section 2.4 clearly shows that even when the transport field is initially not regular, the weak renormalized code gives accurate results. In practice, we do not require $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$.

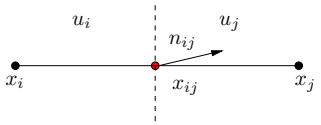

FIG. 3. *Interaction between two particles.*

4. On the L^∞ and BV stabilities of the time discretized weak renormalized meshfree scheme.

4.1. Time discretization: Analogy with finite volume. Our aim is to discretize the numerical scheme (23). Using an explicit Euler-like scheme leads to an unstable scheme. One means of stabilizing it is to introduce some numerical viscosity by analogy with finite volume schemes. Thus, let n_{ij} be the normal vector $n_{ij} = \frac{A_{ij}}{||A_{ij}||}$, and let us consider the interaction between two particles i and j as shown in Figure 3.

Consider the Riemann problem at the interface of position $x_{ij} = \frac{x_i+x_j}{2}$ in the unidimensional direction n_{ij}:

$$\frac{\partial v}{\partial t} + \frac{\partial}{\partial x}(F(v, x_{ij}, t).n_{ij}) = 0, \quad v(x, t^n) = \begin{cases} u_j^{h,n} \text{ if } x > x_{ij}, \\ u_i^{h,n} \text{ if } x < x_{ij}. \end{cases} \tag{54}$$

Let us introduce a numerical flux $g(n_{ij}, u_i^h, u_j^h)$ in order to define a numerical scheme representing the interaction between i and j. The numerical flux $g(n, u, v)$, analogous to a finite volume flux, includes the numerical viscosity. We suppose that this flux belongs to the E-scheme flux class (see [12, 15]) and satisfies

$$\text{(i)} \quad g(n, u, u) = F(u, x, t).n, \quad \text{(ii)} \quad g(n, u, v) = -g(-n, v, u). \tag{55}$$

The numerical viscosity is then defined as

$$Q(n_{ij}, u_i^h, u_j^h) = \frac{F(u_i^h, x_{ij}, t).n_{ij} - 2g(n_{ij}, u_i^h, u_j^h) + F(u_j^h, x_{ij}, t).n_{ij}}{u_j^h - u_i^h}. \tag{56}$$

Let us now introduce the contribution of particle j on particle i, which we denote by $u_i^{h,n+1,j}$ (with $F_{i,ij}^n = F(u_i^{h,n}, x_{ij}, t^n)$ and $Q_{ij}^n = Q(n_{ij}, u_i^{h,n}, u_j^{h,n})$):

$$\begin{aligned} u_i^{h,n+1,j} &= u_i^{h,n} - \frac{\Delta t}{\overline{\Delta x}_i^n} \overbrace{\left(\frac{F_{j,ij}^n - F_{i,ij}^n}{2}.n_{ij} + Q_{ij}^n (u_i^{h,n} - u_j^{h,n}) \right)}^{C_{ij}^n} \\ &= u_i^{h,n} - \frac{\Delta t}{\overline{\Delta x}_i^n} \left(g(n_{ij}, u_i^{h,n}, u_j^{h,n}) - F_{i,ij}^n \right), \end{aligned} \tag{57}$$

where C_{ij}^n is the incremental coefficient and

$$\overline{\Delta x}_i^n = \frac{1}{2\sum_{l\in P} w_l^n ||A_{il}^n||}, \tag{58}$$

and is clearly equivalent to a space step as $\sum_{l\in P} w_l^n ||A_{il}^n|| = O(\frac{1}{\varepsilon_0})$. Indeed, it can be viewed as a mean distance separating i from its neighbors. In (58), we use the notation $A_{ij}^n = A_{ij}(t^n)$, since it is clear from the definition of A_{ij} that it depends on

the time variable, since x_i and x_j depend on the time. When referring to the γth component of the vector A_{ij}^n, we will write $A_{ij}^{n,\gamma}$.

Let us denote

$$\alpha_{ij}^n = \frac{w_j^n ||A_{ij}^n||}{\sum_{l\in P} w_l^n ||A_{il}^n||}. \tag{59}$$

From a convex combination of these single contributions, we get $\tilde{u^h}_i^{n+1}$:

$$\tilde{u^h}_i^{n+1} = \sum_{j\in P} \alpha_{ij}^n u_i^{h,n+1,j} - 2\Delta t \sum_{j\in P} w_j^n F_{i,ij}^n A_{ij}^n + \Delta t S_i^n, \tag{60}$$

where $S_i^n = S(u_i^{h,n}, x_i, t^n)$. The convex combination $\tilde{u^h}_i^{n+1}$ corresponds to an explicit Euler time discretized scheme, where the convection part is not taken into account. Taking the convection into account, we get the time discretized scheme, with constant time step Δt:

$$\left\{ \begin{array}{l} \tilde{u^h}_i^{n+1} = \displaystyle\sum_{j\in P} \alpha_{ij}^n u_i^{h,n+1,j} - 2\Delta t \sum_{j\in P} w_j^n F_{i,ij}^n A_{ij}^n + \Delta t S_i^n \\ \qquad\qquad = u_i^{h,n} - \Delta t \left(\mathrm{div}_h^* F_{i,ij}^n + \displaystyle\sum_{j\in P} w_j^n Q_{ij}^n ||A_{ij}^n|| - S_i^n \right), \\ \dfrac{w_i^{n+1}}{w_i^n} u_i^{h,n+1} = \tilde{u^h}_i^{n+1}. \end{array} \right. \tag{61}$$

Remark 4.1. We choose a constant time step in order to simplify the notation. The stability results still hold for a variable time step.

Finally, the expression of $u_i^{h,n+1,j}$ (57) allows us to give a CFL condition:

$$\sup_{\substack{|u|,\,|v| \le C(T,\,||u_0||_\infty) \\ i,\,j\,\in\,P,\ n\Delta t \le T}} \frac{\Delta t}{\overline{\Delta x}_i} |Q(n_{ij}, u, v)| \le 1 - \beta, \quad 0 < \beta < 1. \tag{62}$$

4.2. L^∞ and BV stability results. We will consider the following regularities on F, S, and a:

$$\begin{array}{l} a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d, \ \ F \in (\mathcal{C}^2(\mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+))^d, \\ F(0,.,.), D_\beta F(0,.,.) \in (L^1(\mathbb{R}^d \times \mathbb{R}_+))^d, \ \ \beta = 1, \ldots, d, \\ S \in C^1(\mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+), \ \ S(0,.,.) \in L^1(\mathbb{R}^d \times \mathbb{R}_+). \end{array} \tag{63}$$

Since we will introduce here some stability results with functional norms, let us introduce the function $u^h(x,t)$ associated with the scheme (61):

$$\left\{ \begin{array}{ll} u^h(x,t) = u^h(x_i^{n+1}, t^{n+1}) & \text{if } \ t \in]t^n, t^{n+1}], \ x \in \Omega_i^{n+1} \text{ with } \ n \ge 1, \\ u^h(x,t) = u^h(x_i^0, 0) & \text{if } \ t \in [t^0, t^1], \ x \in \Omega_i^0. \end{array} \right. \tag{64}$$

We first give the L^∞ and L^1 properties.

PROPOSITION 4.2. *Let u^h be the resulting function of the scheme* (61), (64). *Let us assume that a, S, and F satisfy* (63) *and the initial condition $u_0 \in L^\infty(\mathbb{R}^d) \cap L^1(\mathbb{R}^d)$. We also suppose that the coefficients A_{ij}^n satisfy* (29) *$\forall i \in P$, $\forall j \in P$, and*

for all time t^n. Then $\forall T > 0$, there are two constants $C_\infty(T, F, S, a, ||u_0||_\infty)$ and $C_1(T, F, S, a, ||u_0||_\infty, ||u_0||_1)$ such that if the time step Δt satisfies the CFL condition (62)*, we have the following $\forall t \leq T$:*

$$||u^h(.,t)||_{L^\infty(\mathbb{R}^d)} \leq C_\infty(T, F, S, a, ||u_0||_{L^\infty(\mathbb{R}^d)}), \tag{65}$$

$$||u^h(.,t)||_{L^1(\mathbb{R}^d)} \leq C_1(T, F, S, a, ||u_0||_{L^\infty(\mathbb{R}^d)}, ||u_0||_{L^1(\mathbb{R}^d)}). \tag{66}$$

Proof. The proof is based on the study of SPH [3]. However, some differences occur in the estimates, and the proof is given in [8, pp. 202–203]. ∎

We now focus on the a priori BV estimate.

PROPOSITION 4.3. *Let us suppose that $u_0 \in L^\infty(\mathbb{R}^d) \cap L^1(\mathbb{R}^d)$. Then, under the same assumptions as in Proposition* 4.2*, $\forall T > 0$, there exists a positive constant $C_{est}(T, F, S, a, u_0)$ such that the following inequality holds:*

$$\sum_{\substack{(i,j) \in P^2 \\ n;\, n\Delta t \leq T}} \Delta t w_i^n w_j^n \frac{\Delta t}{\overline{\Delta x_i}} |C_{ij}^n|^2 |u_i^{h,n} - u_j^{h,n}|^2 |A_{ij}^n| \leq C_{est}, \tag{67}$$

where $\overline{\Delta x_i}$ is defined by (58) *and $C_{ij}^n = C(n_{ij}, u_i^h, u_j^h)$ is the incremental coefficient* (57)*. Furthermore, if the particles belong to a bounded domain $\Omega \in \mathbb{R}^d$, then there exists a constant $C_{BV}(u_0, F, S, a, T, \Omega)$ such that*

$$\sum_{\substack{i \in P;\, x_i \in \Omega \\ n;\, t^n \leq T}} \Delta t w_i^n |u_i^{h,n+1} - u_i^{h,n}| \leq C_{BV}(\sqrt{h} + h). \tag{68}$$

Proof. In order to prove (67), we use the local energy estimate in [1], and (68) is deduced from inequality (67), together with the regularity of the transport field a. The proof is standard and is given in [8, p. 203]. ∎

Results from this section are used to prove the convergence of the weak renormalized meshfree scheme applied to the scalar nonlinear conservation law in [10].

5. Comparison with hybrid finite volume schemes.

5.1. Basic principle. In subsection 4.1, we explained how the time discretized weak renormalized scheme can be built from a finite volume interpretation. The same process allows us to define another type of renormalized scheme, directly based on finite volume Godunov methods: *the hybrid renormalized finite volume schemes*. The basic principle is to use the definition (55) of the numerical flux $g(n, u, v)$ in order to redefine the time continuous scheme. It remains to define the fluxes $g(n_{ij}, u_i^h, u_j^h)$. As explained in the following subsection, we use a Godunov-type method, where the fluxes at each cell interface are computed from solving a Riemann problem of type (54) at each interface. For the computation, we will not be able to use the actual computed transport field, but instead we will have to introduce a smoother transport field to move the particles. This approach is connected with the notion of arbitrary Lagrange Euler approximation and is also in some sense a generalization of ideas developed in [6].

Higher order version of the method. In the field of particle methods a classical tool for increasing accuracy is for increasing the smoothness of the kernel and making its momentum equal to zero. This approach has been used in SPH calculations, for example, by using a "super Gaussian" kernel. The increase of accuracy by modifying

the kernel introduces some instability due to the nonpositiveness of the kernel. Thus, we propose a different method based upon the well-known MUSCL schemes developed by Van Leer [16] for finite difference schemes, and extended more recently to finite volume methods (see, e.g., [1] for a mathematical analysis). The idea is to account for information given by $\nabla^h(u)$ (where $\nabla^h(u)$ is the approximate gradient operator computed with (14)) to compute a numerical flux which increases the accuracy of the method: we replace the flux $g(n_{ij}, u_i, u_j)$ which approximates the flux of the conservation law (54) located at x_{ij} by $g(\boldsymbol{n}_{ij}, u_{ij}, u_{ji})$. u_{ij} is an approximation of u at x_{ij} given by a first order Taylor expansion from the point x_i: $u_{ij} = u_i + \nabla^h(u)_i.(x_{ij} - x_i)$. It is well known in the field of MUSCL finite difference schemes that such an approximation leads to unstable schemes unless we introduce a limitation of the derivative $\nabla^h(u)_i$. We propose to start from the value $\nabla^h(u^\alpha)_i = \sum_{j\in P} w_j \left(u_j^\alpha - u_i^\alpha\right) \boldsymbol{A}_{ij}$, and then make a loop over all the neighboring particles such that each component of the gradient is reduced in a way that for all neighboring particles j

$$\begin{cases} u_{ij}^\alpha - u_i^\alpha = \lambda_{ij}^\alpha (u_j^\alpha - u_i^\alpha), \\ \text{with } 0 \le \lambda_{ij}^\alpha \le 1, \end{cases}$$

where the interface values at x_{ij} have been computed according to $u_{ij}^\alpha = u_i^\alpha + \nabla^h(u^\alpha)_i.(x_{ij} - x_i)$. In the scalar case it can be proven that the method is L^∞ stable and convergent with suitable assumptions on the numerical flux.

5.2. Application to Euler equations: Use of Riemann solvers. Consider a regular transport field $a(x,t)$ and the following conservative form of Euler equations in two dimensions (for simplicity):

$$L_a(u) + \sum_{\alpha=1,d} \frac{\partial}{\partial x^\alpha}(F_E^\alpha(u) - a^\alpha u) = 0,$$

where the fluxes F_E^α are given by

$$\text{(i)} \quad F_E^1(u) = \begin{pmatrix} \rho v^1 \\ p + \rho (v^1)^2 \\ \rho v^1 v^2 \\ v^1 (p+E) \end{pmatrix}, \qquad \text{(ii)} \quad F_E^2(u) = \begin{pmatrix} \rho v^2 \\ \rho v^1 v^2 \\ p + \rho (v^2)^2 \\ v^2 (p+E) \end{pmatrix}.$$

We thus have to solve between each particle i and j the Riemann problem

$$\text{(69)} \qquad \begin{cases} \dfrac{\partial}{\partial t}(u) + \dfrac{\partial}{\partial x}((F_E(u).\boldsymbol{n}_{ij} - a(x_{ij},t).\boldsymbol{n}_{ij} u)) = 0, \\ u(x,0) = \begin{cases} u_i & \text{if } x < x_{ij}, \\ u_j & \text{if } x > x_{ij}. \end{cases} \end{cases}$$

A reasonable choice for the flux $g_E(n_{ij}, u_i, u_j)$ of the Godunov scheme associated with our smooth particle approximation is

$$\begin{cases} \lambda_{ij}^a = a(x_{ij},t).\boldsymbol{n}_{ij}, \\ u_{ij}(\lambda_{ij}^a) = u_E(\lambda_{ij}^a; u_i, u_j), \\ G_E(u_i, u_j) = F_E(u_{ij}(\lambda_{ij}^a)) - a(x_{ij},t) \otimes u_{ij}(\lambda_{ij}^a), \\ g_E(\boldsymbol{n}_{ij}, u_i, u_j) = G_E(u_i, u_j).\boldsymbol{n}_{ij}. \end{cases}$$

The resulting particle approximation is given by

$$\frac{d}{dt}(x_i) = a(x_i,t), \qquad \frac{d}{dt}(w_i) = w_i \mathrm{div}(a(x_i,t)),$$
$$\frac{d}{dt}(w_i u_i) + w_i \sum_{j\in P} w_j 2G_E(u_i,u_j)\boldsymbol{A}_{ij} = 0, \qquad u_i(0) = u^0(\xi_i).$$

The detailed equations for mass, momentum, and total energy conservation are

$$\left\{ \begin{array}{l} \dfrac{d}{dt}(w_i\rho_i) + w_i \displaystyle\sum_{j\in P} w_j 2\rho^a_{E,ij}(v^a_{E,ij} - a(x_{ij},t)).\boldsymbol{A}_{ij} = 0, \\ \dfrac{d}{dt}(w_i\rho_i v_i) + w_i \displaystyle\sum_{j\in P} w_j 2\left[\rho^a_{E,ij} v^a_{E,ij} \otimes (v^a_{E,ij} - a(x_{ij},t)) + p^a_{E,ij}\right].\boldsymbol{A}_{ij} = 0, \\ \dfrac{d}{dt}(w_i\rho_i E_i) + w_i \displaystyle\sum_{j\in P} w_j 2 \ \left[E^a_{E,ij}(v^a_{E,ij} - a(x_{ij},t)) + p^a_{E,ij} v^a_{E,ij}\right].\boldsymbol{A}_{ij} = 0, \end{array} \right. \tag{70}$$

where $(\rho^a_{E,ij}, \rho^a_{E,ij} v^a_{E,ij}, E^a_{E,ij})^T = u_{ij}(\lambda^a_{ij})$.

Remark 5.1. Even if we take the transport field equal to the velocity of the particles, $m_i = w_i\rho_i$ does not stay constant as in the renormalized method developed in the previous sections. Although we lose this nice property of the method, we keep global conservation of mass, momentum, and energy. We also expect more robustness since we have better convergence results in the scalar case (see [1, 10]).

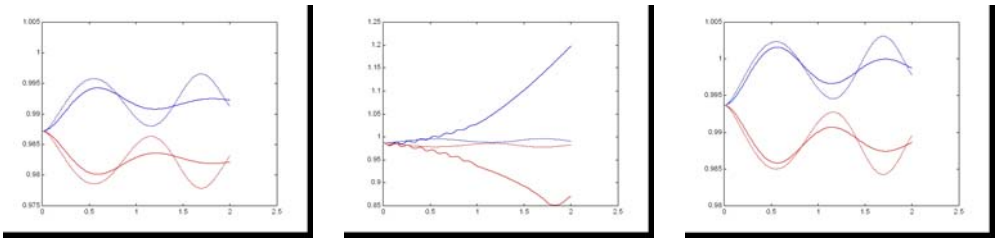
5.3. Applications to free surface flow. We present here some results concerning the simulation of incompressible free surface flows such as those that can arise in sloshing of satellite tanks or launcher tanks. All the computations are performed with an artificial compressibility of the water. Practically we use a linear pressure law, with a sound velocity chosen such that the effective Mach number of the flow is less than 0.1.

5.3.1. A linear regime test case. We first present a test case in two-dimensional plane geometry in the linear regime. We have a two-dimensional tank filled with water, with length $L = 1.0$ m and height $H = 1.0$ m. At time $t = 0$ s the water is at rest with a hydrostatic pressure. We suddenly impose a horizontal acceleration $g = 0.0981$. The characteristic Froude number of the surface waves is $F = 0.001$. In Figure 4 we present successively the computed (full line) and exact position (dotted line) of the water-free surface on the two sides of the tank. In Case 1 we use a 40×40 initial distribution of particles and the hybrid renormalized Godunov–MUSCL (70) scheme, in Case 2 the meshfree weak renormalized scheme (numerical viscosity $\alpha = 0.5, \beta = 1.0$) with 40×40 particles, and in Case 3 the hybrid renormalized Godunov–MUSCL with 80×80 particles.

The weak renormalized scheme with artificial viscosity is not able to reasonably compute this solution, due to the sensitivity of the result to small perturbations (in practice the displacement of any particle is less than 1/100 of the average distance between any particles). It is almost ill conditioned for the SPH Lagrangian-type scheme. Our new method offers the possibility to perform such a computation.

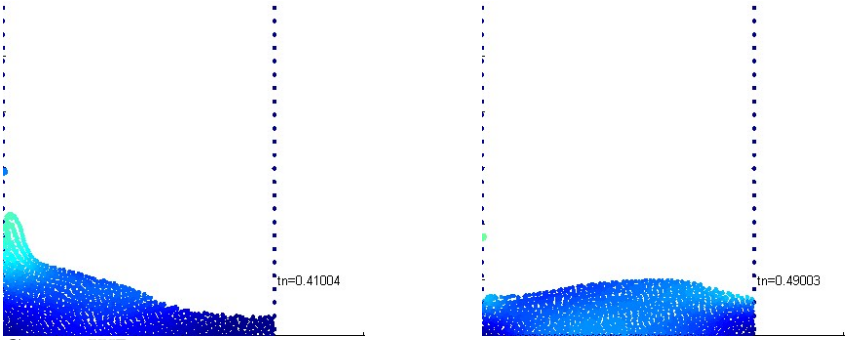
5.3.2. Effect of dissipation in a dam break type problem. We now study the evolution of water in a two-dimensional tank of width $L = 0.15$ m. The water is initially located in a "dam" of height 0.15 m and width 0.05 m. The inner wall is removed at $t = 0$ s.

In Cases 1 and 2 of Figure 5 we use an initial set of 20×60 particles. In Case 3, we use 40×120 particles. In Cases 2 and 3 we use our hybrid renormalized

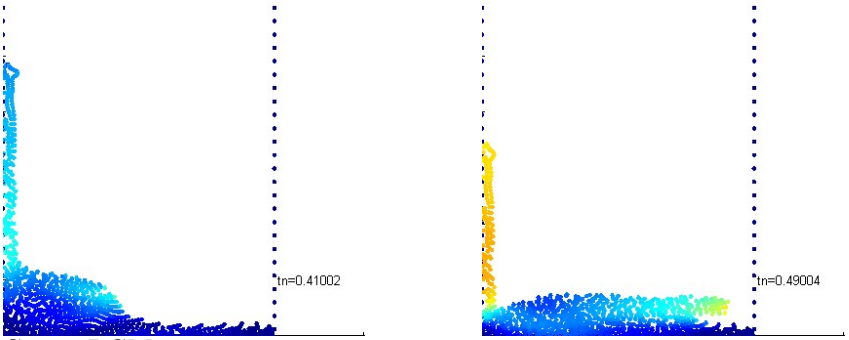


Case 1 Case 2 Case 3

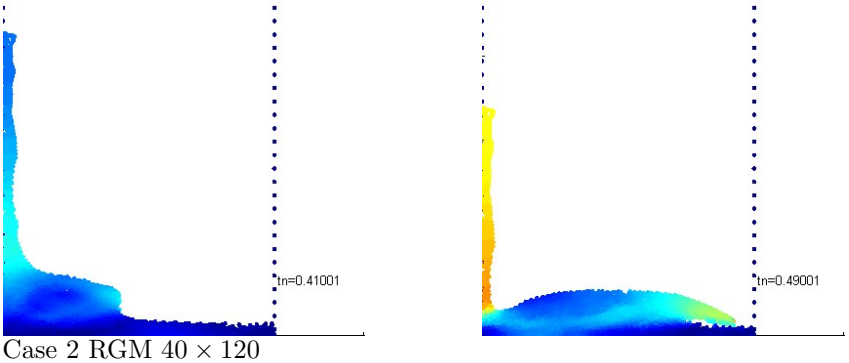
FIG. 4. *Two-dimensional tank of water in linear regime.*



Case 1 WR 20×60



Case 2 RGM 20×60



Case 2 RGM 40×120

FIG. 5. *Dam breaking problem.*

Godunov–MUSCL (RGM) scheme (70), while in Case 1 we use the weak renormalized (WR) scheme (numerical viscosity $\alpha = 0.5, \beta = 1.0$). Clearly the weak renormalized scheme (Case 1) suffers from a great dissipation effect. Comparison of Cases 2 and 3 proves that even with the thicker mesh the renormalized Godunov–MUSCL scheme gives accurate results.

6. Conclusions. We introduced a new class of meshfree derivatives (16) that is more consistent, and we derived the weak renormalized scheme (23) to approach the solution of a general conservation law (1). We established that the time continuous version of this scheme is L^2 stable under the regularity condition on the transport field $a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d$ and for a regular initial distribution of particles. We also gave L^∞ and L^1 stability results as well as a BV estimate for the solution of the scheme. These results of stability will be essential in the study of convergence (see [10]). The time discretization was performed by analogy with finite volume methods and the concept of E-schemes. The same analogy allowed us to build another type of scheme, based on the renormalization as well, but including more of the Godunov finite volume approach. The hybrid renormalized particle scheme shows great potential, as the numerical results established that it behaves better than the weak renormalized scheme (subsection 5.3), which already gives much better results than classical weighted particle methods, as shown in subsection 2.4.

RENORMALIZED MESHFREE SCHEMES II: CONVERGENCE FOR SCALAR CONSERVATION LAWS*

NATHALIE LANSON† AND JEAN-PAUL VILA‡

Abstract. We establish a convergence rate of the renormalized meshfree numerical scheme applied to scalar conservation laws. Renormalization is a tool introduced in order to eliminate the smoothed particle hydrodynamics (SPH) lack of consistency. A conservative scheme, the weak renormalized scheme, is derived from the general conservation laws weak formulation and is time discretized by using finite volume techniques. Because of the new form of the derivative approximation, the convergence proof of the classical SPH method cannot be applied. Thus, we use a Kruskov technique to obtain an L^1 norm comparison between the approximate solution and the solution of a regularized conservation law, the pseudoviscous problem.

Key words. meshfree methods, smoothed particle hydrodynamics, renormalization, weak scheme, pseudoviscosity, Kruskov–Kuznetsov entropy method, convergence rate

1. Introduction.

We focus on scalar conservation laws:

$$\begin{cases} L_a(u) + \operatorname{div}(F(u,x,t)) = S(u,x,t), \quad t \in \mathbb{R}_+,\ x \in \mathbb{R}^d\ , \\ u(x,0) = u_0(x)\ , \end{cases} \tag{1}$$

where L_a is the transport operator defined as $L_a(u) = \frac{\partial u}{\partial t} + \operatorname{div}(a(x,t)u)$, where a is the transport field $a = (a^\alpha)_{\alpha=1}^d$, $a^\alpha : \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}$, and $u \in \mathbb{R}$ is the exact solution of the problem. $u_0 \in \mathbb{R}$ is the initial condition. The flux $F = (F^\alpha)_{\alpha=1}^d$ and the source term S are $\mathbb{R}$-valued functions: $F : \mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}$ and $S : \mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+ \to \mathbb{R}$.

The aim of the present paper is to analyze the convergence of the weak renormalized meshfree scheme developed in [10] for the scalar conservation law (1). We consider the following hypothesis on the transport vector field a, the flux F^α, $\alpha = 1, \dots, d$, the source term S, and the initial condition u_0:

$$\begin{aligned} &u_0 \in L^\infty(\mathbb{R}^d) \cap BV_{loc}(\mathbb{R}^d), \qquad a \in (\mathcal{C}^2(\mathbb{R}^d \times \mathbb{R}_+))^d, \\ &F^\alpha \in \mathcal{C}^2(\mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+), F^\alpha(0,.,.), D_\beta F^\alpha(0,.,.) \in L^1(\mathbb{R}^d \times \mathbb{R}_+), \\ &S \in C^1(\mathbb{R} \times \mathbb{R}^d \times \mathbb{R}_+), S(0,.,.) \in L^1(\mathbb{R}^d \times \mathbb{R}_+). \end{aligned} \tag{2}$$

These regularity conditions are the same as the one required for the stability analysis of the weak renormalized scheme developed in [10].

The existence and uniqueness of the weak entropy solution $u \in L^\infty(\mathbb{R}^d \times \mathbb{R}_+)$ of the problem (1) was proved by Kruszkov in [7]. These solutions satisfy the following

entropy inequality: $\forall \varphi \geq 0 \in C_c^1(\mathbb{R}^d \times \mathbb{R}_+)$, $\forall c \in \mathbb{R}$

$$
\begin{aligned}
&\int_{\mathbb{R}^d \times \mathbb{R}_+} |u-c| L_a^*(\varphi) + H_c(u,x,t).\nabla_x \varphi dx dt \\
&- \int_{\mathbb{R}^d \times \mathbb{R}_+} sign(u-c)(c\mathrm{div}(a) + \mathrm{div}(F(c,x,t)) - S(u,x,t))\varphi dx dt \\
&+ \int_{\mathbb{R}^d} |u-c|\varphi(x,0) dx \geq 0,
\end{aligned} \tag{3}
$$

where $H_c(u,x,t) = sign(u-c)(F(u,x,t)-F(c,x,t))$ and L_a^* is the transposed operator of L_a and the only physically relevant weak solution. Our aim is to prove that the weak renormalized meshfree scheme developed in [10] converges towards such a solution.

The paper is organized as follows. In section 2, the renormalization principles are briefly recalled, and the time discretized weak renormalized meshfree scheme for conservation laws is given. Some stability results proved in [10] are restated in the end of section 2. In section 3, the classical smoothed particle hydrodynamics (SPH) convergence proof is briefly reviewed, and its inapplicability to the weak renormalized meshfree scheme is explained. In order to prove the convergence, we then introduce a regularized Kruskov entropy function and the pseudoviscous problem associated to the conservation law needed to handle the adjoint operator of the renormalized meshfree derivatives. The organization of the convergence proof for the weak renormalized meshfree numerical scheme is then given. The pseudoviscous problem and its properties are studied in section 4, with an emphasis on building an L^∞ estimate of the second order derivative of the pseudoviscous solution. In section 5, entropy inequalities, using the specific regularized Kruskov entropy, are built for both the solution of the numerical scheme and the solution of the pseudoviscous problem. These two entropy inequalities are compared in section 6. Finally, the main convergence result is given section 7. In order to make the proof clearer, the definitions of the remainders and their estimates are given in Appendices A and B, as well as some quadrature results. The reader can also find a table of symbols at the end of Appendix C.

2. Renormalized particle approximation.

2.1. Basic principles. Consider a set of moving particles P, with coordinates $x_j(t)$, $\forall j \in P$, volumes $\Omega_j(t)$, and weights $w_j(t)$, as explained in [10]. The particle position and weights are moved and are calculated according to:

$$
\begin{aligned}
&\frac{dx_j}{dt} = a(x_j,t), && \text{with } x_j(0) = \xi_j, \\
&\frac{dw_j(t)}{dt} = \mathrm{div}(a(x_j,t))w_j(t), && \text{with } w_j(0) = w_j^0.
\end{aligned} \tag{4}
$$

We consider that the vector field is regular enough such that at any time t: $\mathbb{R}^d = \cup_{j\in P}\Omega_j(t)$, where $\Omega_j(t)$ are distinct volumes of measure $w_j(t)$. In the following the time dependence of x_i and w_i, $\forall i \in P$, will not be explicitly written.

As explained in [10], the *renormalized meshfree derivatives* is introduced to alleviate the lack of consistency of the original particle method. The renormalized meshfree derivatives $D_{\alpha,h}$, $\alpha = 1,\ldots,d$, are given by:

$$
D_{\alpha,h} f(x) = \sum_{j\in P} w_j \left(f(x_j) - f(x)\right)\ A^\alpha(x,x_j), \tag{5}
$$

where the vector is chosen equal to:

$$A(x,x_j)=\frac{B(x)+B(x_j)}{2}.\mu(x,x_j). \tag{6}$$

The regularizing kernel $\mu(x,y)$ has compact support of radius $\varepsilon(x,y)=\frac{\varepsilon(x)+\varepsilon(y)}{2}$, where the smoothing length ε varies in both space and time following $\frac{d\varepsilon}{dt}=\frac{\varepsilon}{d}\mathrm{div}a$ and satisfies $\exists C$ and ε_0 such that, $\forall x,t,\varepsilon_0\leq\varepsilon\leq C\varepsilon_0$. In [10], we saw that, by computing $B_i=B(x_i)$, $\forall i\in P$, as follows:

$$E_i^{\alpha\beta}=\sum_{j\in P}w_j(x_j^\beta-x_i^\beta)\,\mu^\alpha(x_i,x_j),\forall(\alpha,\beta)\in\{1,\dots,d\}^2,\qquad B_i=(E_i)^{-1}, \tag{7}$$

we obtain that the error estimate of the renormalized meshfree derivatives (5) is

$$\forall\varphi\in W^{2,\infty}(\mathbb{R}^d),\quad \|D_h\varphi(x)-D\varphi(x)\|\leq C\varepsilon_0\|B(x)\|\|D^2\varphi\|_\infty, \tag{8}$$

as soon as $B(x)$ is uniformly bounded. We proved in [10] that $B(x)$ is uniformly bounded under the condition that $a\in\mathcal{C}^2(\mathbb{R}_+\times\mathbb{R}^d)$ for a regular initial distribution of particles.

2.2. The weak renormalized meshfree scheme. The construction of the weak renormalized meshfree scheme is given in [10]. It is derived from the weak formulation of (1) together with the use of the approximate derivatives (5). A time discretization is performed in analogy with finite volume methods. The time discretized weak renormalized meshfree scheme:

$$\begin{cases}\tilde{u^h}_i^{n+1}=u_i^{h,n}-\Delta t\left(\mathrm{div}_h^*F_{i,ij}^n+\displaystyle\sum_{j\in P}w_j^nQ_{ij}^n||A_{ij}^n||-\Delta tS_i^n\right),\\[2ex] \dfrac{w_i^{n+1}}{w_i^n}u_i^{h,n+1}=\tilde{u^h}_i^{n+1},\end{cases} \tag{9}$$

where $S_i^n=S(u_i^{h,n},x_i,t^n)$, $Q_{ij}^n=Q(n_{ij},u_i^{h,n},u_j^{h,n})$, is a numerical viscosity, that is assumed to be the numerical viscosity of an E-scheme (see [12, 14]). The numerical viscosity is added in analogy with finite volume methods to stabilize the numerical scheme. The operator $\mathrm{div}_h^*F_{i,ij}^n$ is the transposed operator of the renormalized approximation of the divergence and is defined by:

$$\mathrm{div}_h^*F(u_i^h,x_{ij},t)=\sum_{j\in P}w_j(F(u_i^h,x_{ij},t))+F(u_j^h,x_{ij},t)\dot{A}_{ij}), \tag{10}$$

where $x_{ij}=\frac{x_i+x_j}{2}$. This scheme has a CFL type of stability condition:

$$\sup_{\substack{|u|,\,|v|\,\leq\,C(T,\,||u_0||_\infty)\\ i,\,j\,\in\,P,\ n\Delta t\,\leq\,T}}\frac{\Delta t}{\overline{\Delta x_i}}|Q(n_{ij},u,v)|\leq 1-\beta,\quad 0<\beta<1, \tag{11}$$

where

$$\overline{\Delta x_i}^n=\frac{1}{2\sum_{l\in P}w_l^n||A_{il}^n||} \tag{12}$$

can be viewed as a mean distance separating i from its neighbors. Finally, let us introduce the function $u^h(x,t)$ associated with the scheme (9):

$$\left\{\begin{array}{ll} u^h(x,t) = u^h(x_i^{n+1}, t^{n+1}) & \text{if } t \in]t^n, t^{n+1}],\ x \in \Omega_i^{n+1},\ \text{with } n \geq 1, \\ u^h(x,t) = u^h(x_i^0, 0) & \text{if } t \in [t^0, t^1],\ x \in \Omega_i^0. \end{array}\right. \tag{13}$$

We proved in [10] that this scheme is L_∞, L_1, and BV stable (see Propositions 4.5 and 4.6 of [10]), under the condition that

$$\begin{array}{l} \text{(i) } \sup\limits_{i\in P} \sum\limits_{j\in P} w_j^n ||A_{ij}^n|| \leq \dfrac{C}{\varepsilon_0}, \quad \text{(ii) } \sup\limits_{i\in P} \left\| \sum\limits_{j\in P} w_j^n A_{ij}^n \right\| \leq C, \\ \text{(iii) } \sup\limits_{i\in P} ||A_{ij}^n + A_{ji}^n|| \leq \dfrac{C}{\varepsilon_0^d}. \end{array} \tag{14}$$

It was shown in [10] that the vectors A_{ij}^n satisfy those conditions if $a \in \mathcal{C}^2(\mathbb{R}_+ \times \mathbb{R}^d)$, for a regular initial distribution of particles.

3. First elements on the convergence analysis.

3.1. Methodology and its justification. In the case of classical SPH for nonlinear scalar conservation laws, the convergence proof (see [2]) uses the notion of measure-valued solutions. In the frame of SPH, it is sufficient to prove that, for all convex functions η, the approximate solution of the SPH scheme u^h satisfies (with the definition of (16)):

$$\begin{array}{l} \displaystyle\int_{\mathbb{R}^d\times\mathbb{R}_+} \eta(u^h) L_a^*(\varphi) + H(u^h,x,t)\nabla_x\varphi dxdt \\ \displaystyle + \int_{\mathbb{R}^d\times\mathbb{R}_+} \sum_{\alpha=1}^d \left(D_\alpha H^\alpha(u^h,x,t) - \eta'(u^h) D_\alpha F^\alpha(u^h,x,t) \right) \varphi dxdt \\ \displaystyle + \int_{\mathbb{R}^d\times\mathbb{R}_+} \left(\eta'(u^h) S(u^h,x,t) - (\eta(u^h) - \eta'(u^h)u^h)\mathrm{div}(a) \right) \varphi dxdt \\ \displaystyle + \int_{\mathbb{R}^d} \eta(u_0)\varphi(x,0)dx \geq 0\ . \end{array} \tag{15}$$

Having the adjoint operator of approximation of the divergence tending strongly towards the exact divergence $\mathrm{div}_x F$ is crucial within the convergence proof. Unfortunately, our transposed operator (10) does not satisfy this requirement, and we cannot apply the proof developed in [2] to our scheme. We will use a Kruskov–Kuznetsov-like method, similar to the work in [15, 3, 4, 5]. However, another difficulty arises: The term $sign(u^h - c)\mathrm{div}_{h,x}^* F^\alpha(c,x,t)$, when using Kruskov entropy, appears in the entropy inequality of the approximate solution. Since our renormalized meshfree derivative adjoint operator $\mathrm{div}_{h,x}^*$ does not tend strongly toward div_x, the term $sign(u^h - c)\mathrm{div}_{h,x}^* F^\alpha(c,x,t)$ can only weakly tend to $sign(u^h - c)\mathrm{div}_x F^\alpha(c,x,t)$. Consequently, one needs some regularity on $sign(u^h - c)$. The first step is to regularize the sign function (see Definition 3.1). Second, the approximate solution u^h is not regular enough, and neither is the exact solution u ($W^{2,\infty}$ is required). We introduce the pseudoviscous problem (section 4), and we will show that the solution of the pseudoviscous problem u^ϵ has enough regularity to make possible the handling of such a term as $sign(u^\epsilon - c)\mathrm{div}_{h,x}^* F^\alpha(c,x,t)$. Thus, we build an entropy inequality for the pseudoviscous solution u^ϵ (26), that we can compare to the entropy inequality of the approximate solution u^h (24).

3.2. Entropy and regularized Kruskov entropy functions.

(16) Let H be the flux associated to the entropy η, such that $\partial_u H = \eta'(u)\partial_u F$,

where F is the flux of the conservation law (1) with $p = 1$.

The numerical entropy flux h_e satisfying $h_e(n, u, u) = H(u, x, t).n$ is defined by:

$$h_e(n_{ij}, u_i^h, u_j^h) = \frac{(H(u_i^h, x_{ij}, t) + H(u_j^h, x_{ij}, t)).n_{ij}}{2} - Q^\eta(n_{ij}, u_i^h, u_j^h). \tag{17}$$

As explained earlier, we take a $\mathcal{C}^2$ regularization of the Kruskov entropy.

DEFINITION 3.1. *The regularized function* $(\eta_\delta)'(u) = sign_\delta(u - c)$ *is defined by:*

$$sign_\delta(u-c) = \begin{cases} -1 & \text{if } u - c \le -\delta, \\ \frac{15}{8\delta}(u-c) - \frac{5}{4\delta^3}(u-c)^3 + \frac{3}{8\delta^5}(u-c)^5 & \text{if } u - c \in]-\delta;\delta[, \\ 1 & \text{if } u - c \ge \delta, \end{cases} \tag{18}$$

and the associated flux entropy H *is given by:*

$$\begin{aligned} H_\delta(u,x,t) &= \int_c^u sign_\delta(v-c)\partial_v F(v,x,t)dv = H_\delta^c(u,x,t) + \Psi_\delta^c(u,x,t), \\ H_\delta^c(u,x,t) &= sign_\delta(u-c)(F(u,x,t)-F(c,x,t)), \\ \Psi_\delta^c(u,x,t) &= \int_c^u (sign_\delta(u-c)-sign_\delta(v-c))\partial_v F(v,x,t)dv. \end{aligned} \tag{19}$$

These definitions satisfy the following results.

LEMMA 3.2. *Definitions* (18) *and* (19) *imply that*

$$\big||u|^\delta - |u|\big| \le C\delta, \tag{20}$$

$$||\Psi_\delta^c(u,x,t)|| \le C_\Psi(u)\delta, \quad |\mathrm{div}_x \Psi_\delta^c(u,x,t)| \le C'_\Psi(u)\delta, \tag{21}$$

where $C_\Psi(u) = \sup_{v\in[c,u]} |\partial_u F(v,x,t)|$ *and* $C'_\Psi(u) = \sup_{v\in[c,u]} |\mathrm{div}_x \partial_u F(v,x,t)|$,

$$\begin{aligned} &sign_\delta(u-c)F(u,x,t) - H_\delta^c(u,x,t) = sign_\delta(u-c)F(c,x,t), \\ &sign_\delta(u-c)\mathrm{div}_x F(u,x,t) - \mathrm{div}_x H_\delta^c(u,x,t) = sign_\delta(u-c)\mathrm{div}_x F(c,x,t), \end{aligned} \tag{22}$$

and the following inequalities: $\forall$*compact* $Q \in \mathbb{R}^d \times \mathbb{R}_+$

$$\begin{aligned} &||H_\delta(u,.,.)||_{L^\infty(Q)} \le ||u-c||_\infty ||sign_\delta||_\infty ||\partial_u F(u,.,.)||_{L^\infty(Q)}, \\ &||\mathrm{div}_x H_\delta(u,.,.)||_{L^\infty(Q)} \le ||u-c||_\infty ||sign_\delta||_\infty ||\mathrm{div}_x \partial_u F(u,.,.)||_{L^\infty(Q)}, \\ &||H_\delta^c(u,.,.)||_{L^\infty(Q)} \le 2||sign_\delta||_\infty ||F(u,.,.)||_{L^\infty(Q)}, \\ &||\mathrm{div}_x H_\delta^c(u,.,.)||_{L^\infty(Q)} \le 2||sign_\delta||_\infty ||\mathrm{div}_x F(u,.,.)||_{L^\infty(Q)}, \\ &||\partial_t H_\delta^c(u,.,.)||_{L^\infty(Q)} \le 2||sign_\delta||_\infty ||\partial_t F(u,.,.)||_{L^\infty(Q)}. \end{aligned} \tag{23}$$

Proof. The only nontrivial part is to prove the estimates (21). The proof is given in [9, page 161]. ∎

3.3. Organization of the convergence proof.

1. We prove in section 5.1 that the solution u^h of the scheme (9), (13) satisfies:

(24)
$$\underbrace{\int_{\mathbb{R}_+\times\mathbb{R}^d} |u^h(x,t)-c|^\delta L_a^*(\varphi)dxdt}_{\text{(a)}} + \underbrace{\int_{\mathbb{R}_+\times\mathbb{R}^d} H_\delta^c(u^h(x,t),x,t).\nabla\varphi dxdt}_{\text{(b)}}$$
$$\underbrace{-\int_{\mathbb{R}_+\times\mathbb{R}^d} (u^h(x,t)sign_\delta(u^h(x,t)-c)-|u^h(x,t)-c|^\delta)\mathrm{div}a(x,t)\varphi dxdt}_{\text{(c)}}$$
$$\underbrace{+\int_{\mathbb{R}_+\times\mathbb{R}^d} sign_\delta(u^h(x,t)-c)S(u^h(x,t),x,t)\varphi dxdt}_{\text{(d)}} + \underbrace{\int_{\mathbb{R}^d} |u^h(x,0)-c|^\delta\varphi dx}_{\text{(e)}}$$
$$\underbrace{-\int_{\mathbb{R}_+\times\mathbb{R}^d} sign_\delta(u^h(x,t)-c)\overline{\mathrm{div}_h^*}F(c,x,t)\varphi dxdt}_{\text{(f)}} \geq \langle\mu_h,\varphi\rangle,$$

(25) where $\mu_h \to 0$ and
$$\overline{\mathrm{div}_h^*}F(c,x,t) = \mathrm{div}_h^*F(c,x_i,t^n) \text{ for } x\in\Omega_i^n, t\in]t^n,t^{n+1}].$$

2. The term $\mathrm{div}_{h,x}^*(F(c,x,t))$ tends only weakly towards $\mathrm{div}_x(F(c,x,t))$. Thus, we have to transform the entropy equation satisfied by the exact solution of problem (1) in order to get a similar term $\mathrm{div}_{h,x}^*F$. Then another problem arises: Considering the assumptions (2) on F, a, S, and u_0, our exact solution is not regular enough to handle this transformation. Indeed, the error estimate on the renormalized meshfree derivatives implies that u should be $W^{2,\infty}$. Thus, we introduce the *pseudoviscous solution* u^ϵ in section 4, give its properties, and deduce the L^∞ estimate of its second order derivatives.
3. We prove in section 5.2 that the pseudoviscous solution u^ϵ satisfies:

(26)
$$\underbrace{\int_{\mathbb{R}_+\times\mathbb{R}^d} |u^\epsilon(y,s)-c|^\delta L_a^*(\varphi)dyds}_{\text{(a')}} + \underbrace{\int_{\mathbb{R}_+\times\mathbb{R}^d} H_\delta^c(u^\epsilon(y,s),y,s).\nabla\varphi dyds}_{\text{(b')}}$$
$$\underbrace{-\int_{\mathbb{R}_+\times\mathbb{R}^d} (u^\epsilon(y,s)sign_\delta(u^\epsilon(y,s)-c)-|u^\epsilon(y,s)-c|^\delta)\mathrm{div}a(y,s)\varphi dyds}_{\text{(c')}}$$
$$\underbrace{+\int_{\mathbb{R}_+\times\mathbb{R}^d} sign_\delta(u^\epsilon(y,s)-c)S(u^\epsilon(y,s),y,s)\varphi dyds}_{\text{(d')}} + \underbrace{\int_{\mathbb{R}^d} \eta_\delta(u_0^\epsilon-c)\varphi dy}_{\text{(e')}}$$
$$\underbrace{-\int_{\mathbb{R}_+\times\mathbb{R}^d} \varphi sign_\delta(u^\epsilon(y,s)-c)\overline{\mathrm{div}_h^*}F(c,y,s)dyds}_{\text{(f')}} \geq \langle\nu_\epsilon,\varphi\rangle,$$

where ν_ϵ is a measure term tending to zero.
4. In section 6 we sum the inequality (24), integrated over (s,y) with $c=u(y,s)$, and the inequality (26), integrated over (t,x) with $c=u^h(x,t)$. The chosen

test function $\varphi = \varphi(x, y, s, t)$ (Definition 6.1) together with the error estimate given in Appendix A leads to the L^1 error estimate between u^ϵ and u^h. By using the convergence properties of u^ϵ, we get the L^1 convergence of the approximate solution u^h towards the exact solution u (Theorem 7.1).

4. Pseudoviscous solution and its properties. The pseudoviscous problem is given by (with $\epsilon > 0$):

$$\left\{ \begin{array}{l} \dfrac{\partial u^\epsilon}{\partial s} + \mathrm{div} F(u^\epsilon, y, s) = \epsilon \Delta u^\epsilon + S(u^\epsilon, y, s), \\ u^\epsilon(0, .) = u^{\epsilon,0}, \end{array} \right. \tag{27}$$

where $u^{\epsilon,0} = u_0 * \zeta_\epsilon$; ζ_ϵ is a regularizing kernel. Note that the flux F includes the transport term a. We use this convention to simplify the notations in this section.

4.1. Estimates on u^ϵ. *Note: In the following $TV(v)$ represents the total variation of a function v.*

This problem has been studied in [6] for a space- and time-dependent flux and in [11] for a flux and a source term depending on u, x, and t. Lemmas 4.13 and 2.9 and Theorem 2.29 of [13] are summed up below.

LEMMA 4.1. *If $u_0 \in L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d) \cap BV(\mathbb{R}^d)$, then the solution of (27) satisfies: $\exists C$ and $C(Q)$ (Q compact subset of $\mathbb{R}^d \times \mathbb{R}_+$) independent of ϵ such that*

$$||u^\epsilon(., s)||_{L^\infty(\mathbb{R}^d)} \leq ||u^{0,\epsilon}||_{L^\infty(\mathbb{R}^d)},\ ||u^\epsilon(., s)||_{L^1(\mathbb{R}^d)} \leq ||u^{0,\epsilon}||_{L^1(\mathbb{R}^d)} + C\ TV(u_0),$$
$$||\nabla u^\epsilon(., s)||_{L^1(\mathbb{R}^d)} \leq TV(u_0),\ ||\partial_t u^\epsilon(., s)||_{L^1(\mathbb{R}^d)} \leq C\ TV(u_0),\ ||\nabla u^\epsilon||_{L^2(Q)} \leq \frac{C(Q)}{(\epsilon)^{\frac{1}{2}}}.$$

By using the ideas developed in [13, 11], one can also prove the following.

LEMMA 4.2. *Under the assumption that $u_0 \in L^1(\mathbb{R}^d) \cup L^\infty(\mathbb{R}^d) \cup BV(\mathbb{R}^d)$, there exists a constant $C'(Q)$ (independ of ϵ) such that u^ϵ satisfies:*

$$||D^2 u^\epsilon||_{L^\infty(Q)} \leq \frac{C'(Q)}{\epsilon^{\frac{5}{2}}}. \tag{28}$$

Proof. In the following, $u^\varepsilon_\alpha = \frac{\partial u^\varepsilon}{\partial x^\alpha}$. First differentiate the parabolic equation (27) with respect to x^α, and then integrate the resulting equation by parts over space, with the test function $\varphi = u^\epsilon_\alpha \chi^2$, where χ is a function with compact support $Q \subset \mathbb{R}^+ \times \mathbb{R}^d$ and such that $\chi = 1\ \forall (x, t) \in Q$ and $\chi = 0$ if distance$((t, x), Q) > 1$. Since $(u^\epsilon_\alpha \chi)^2(T)$ is positive, we have:

$$\int_Q |\epsilon^{\frac{1}{2}} \nabla (u^\epsilon_\alpha \chi)|^2 dx dt \leq \sum_{k=1}^{8} I_k, \text{ with}$$

$$I_1 = \left| \int_Q \frac{\partial}{\partial u^2} F^\beta(u^\epsilon, x, t) u^\epsilon_\beta (u^\epsilon_\alpha)^2 \chi^2 dx dt \right|, \qquad I_4 = \left| \int_Q (u^\epsilon_\alpha)^2 \chi \frac{\partial \chi}{\partial t} dx dt \right|,$$

$$I_2 = \left| \int_Q \frac{\partial}{\partial u} F^\beta(u^\epsilon, x, t) u^\epsilon_{\beta\alpha} u^\epsilon_\alpha \chi^2 dx dt \right|, \qquad I_5 = \epsilon \left| \int_Q (u^\epsilon_\alpha)^2 |\nabla \chi|^2 dx dt \right|,$$

$$I_3 = \left| \int_Q \frac{\partial^2}{\partial x^\beta \partial x^\alpha} F^\beta(u^\epsilon, x, t) u^\epsilon_\alpha \chi^2 dx dt \right|, \qquad I_6 = \left| \int_Q \frac{\partial}{\partial x^\alpha} S(u^\epsilon, x, t) u^\epsilon_\alpha \chi^2 dx dt \right|,$$

$$I_7 = \left| \int_Q \frac{\partial}{\partial u} S(u^\epsilon, x, t) (u^\epsilon_\alpha)^2 \chi^2 dx dt \right|, \qquad I_8 = \int_{\mathbb{R}^d} (u^\epsilon_\alpha \chi)^2(0) dx.$$

Integrals I_k, $k=3,\dots,7$, are bounded from the hypothesis (2) on the flux F and the source term S and from the estimates of Lemma 4.1:

$$
\begin{aligned}
&I_3 \leq \sup_{v;|v|\leq C(u_0)} \left\{ \frac{\partial^2}{\partial x^\beta \partial x^\alpha} F^\beta(u^\epsilon,.,.)||_{L^\infty(Q)} \right\} TV(u_0),\\
&I_4 \leq \frac{C(Q)}{\sqrt{\epsilon}}, \quad I_5 \leq \frac{C(Q)}{\sqrt{\epsilon}},\\
&I_6 \leq \sup_{v;|v|\leq C(u_0)} \left\{ \left\| \frac{\partial}{\partial x^\alpha} S(v,.,.) \right\|_{L^\infty(Q)} \right\} TV(u_0),\\
&I_7 \leq \sup_{v;|v|\leq C(u_0)} \{||\partial_v S(v,.,.)||_{L^\infty(Q)}\} \frac{C(Q)}{\sqrt{\epsilon}}.
\end{aligned}
\tag{29}
$$

The second integral is bounded by using the Cauchy–Schwartz inequality:

$$
I_2 \leq \sup_{v;|v|\leq C(u_0)} \{||\partial_v F(v,.,.)||_{L^\infty(Q)}\} ||u^\epsilon_{\alpha\beta}||_{L^2(Q)} ||u^\epsilon_\alpha||_{L^2(Q)}. \tag{30}
$$

The first integral is estimated by using an integration by parts and estimates (4.1):

(31)

$$
\begin{aligned}
I_1 &\leq \sup_{v;|v|\leq C(u_0)} \{||\partial_u^2 F(v,.,.)||_{L^\infty(Q)}\} \int_Q |u^\epsilon_\beta| (u^\epsilon_\alpha)^2 \chi^2 dxdt\\
&\leq C(F,u_0) \sup_t ||u^\epsilon(.,t)||_{L^\infty(\mathbb{R}^d)} \left(||u^\epsilon_{\beta\alpha}||_{L^2(Q)} ||u^\epsilon_\alpha||_{L^2(Q)} + ||u^\epsilon_\beta||_{L^2(Q)} ||u^\epsilon_{\alpha\alpha}||_{L^2(Q)} \right.\\
&\qquad \left. +2||u^\epsilon_\beta||_{L^2(Q)} ||u^\epsilon_\alpha||_{L^2(Q)} \right),\\
&\leq C(F,S,u_0,Q) \left(\frac{||u^\epsilon_{x_j x_i}||_{L^2(Q)}}{\sqrt{\epsilon}} + \frac{||u^\epsilon_{x_i x_i}||_{L^2(Q)}}{\sqrt{\epsilon}} + \frac{1}{\epsilon} \right).
\end{aligned}
$$

Finally, integral I_8 is bounded by using Lemma 4.6 of [13], which proves that $||u^\epsilon(0,.)||_{L^\infty(\mathbb{R}^d)} \leq ||u_0||_{L^\infty(\mathbb{R}^d)}$ and $||\Delta u^\epsilon(0,.)||_{L^1(\mathbb{R}^d)} \leq \frac{C}{\varepsilon} TV(u_0)$. Consequently, we have:

$$
\begin{aligned}
I_8 &= \int_{\mathbb{R}^d} (u^\epsilon_\alpha(0,x))^2 \chi(0,x)^2 dx \leq \int_{\mathbb{R}^d} (u^\epsilon_\alpha(0,x))^2 dx\\
&\leq \left| \int_{\mathbb{R}^d} u^\epsilon(0,x) u^\epsilon_{\alpha\alpha}(0,x) dx \right| \leq \frac{C}{\epsilon} TV(u_0) ||u_0||_{L^\infty(\mathbb{R}^d)} \leq \frac{C(u_0)}{\epsilon}.
\end{aligned}
$$

The upper bounds of the integrals I_k, $k=1,\dots,8$, lead to:

$$
\begin{aligned}
&\epsilon ||D^2 u^\epsilon||^2_{L^2(Q)} \leq C(F,S,u_0,Q) \left(1 + \frac{1}{\epsilon} + \frac{1}{\sqrt{\epsilon}} + \frac{1}{\epsilon} + \frac{1}{\sqrt{\epsilon}} ||D^2 u^\epsilon||_{L^2(Q)} \right)\\
&\Rightarrow ||D^2 u^\epsilon||_{L^2(Q)} \leq \frac{C(F,S,u_0,Q)}{\epsilon^{\frac{3}{2}}}.
\end{aligned}
\tag{32}
$$

$$
\text{Let us use the Sobolev injection } ||D^2 u^\epsilon||_{L^\infty(\Omega)} \leq C ||D^2 u^\epsilon||_{H^1(\Omega)} \ \forall \Omega. \tag{33}
$$

We now have to estimate the L^2 norm of $D^3 u^\epsilon$. This is achieved by rederiving the proof above, starting by differentiating (27) a second time with respect to x_γ, and using the test function $\varphi = u_{x_\gamma x_\alpha} \chi^2$. We then prove that

$$
||D^3 u^\epsilon||_{L^2(Q)} \leq \frac{C(F,S,u_0,Q)}{\epsilon^{\frac{5}{2}}}. \tag{34}
$$

One deduces (28) from the above inequality, together with the Sobolev injection (33) (we keep only the dependence in Q in the constant C' for simplicity). ∎

4.2. Convergence of the pseudoviscous solution. We recall here a classical result, established by Kuznetsov [8].

THEOREM 4.3 (Kuznetsov). *$\exists C > 0$ such that, if $u_0 \in BV(\mathbb{R}^d)$ and if $u(0) = u^\epsilon(0) = u_0$, then*

$$||u^\epsilon(.,s) - u(.,s)||_1 \leq C\sqrt{\epsilon s}\ TV(u_0). \tag{35}$$

5. Kruzkov entropy inequalities for approximate and pseudoviscous solutions.

5.1. Entropy inequality for the approximate solution.

PROPOSITION 5.1. *Let us suppose that assumptions* (2) *are satisfied, and let u^h be the solution of* (9), (13). *Then u^h verifies the continuous entropy inequality* (24).

Proof.

- *Construction of a first inequality for a general entropy η*: The following result is proved in [14] and [1]: If g is the flux of an E-scheme consistent with (1) (with $p = 1$), and if the CFL is satisfied: $\lambda Q(n,u,v) \leq 1$, then there exists a convex entropy flux η such that:

$$\begin{aligned}\eta(u - \lambda(g(n,u,v) - F(u,x,t).n)) - \eta(u) + \lambda[h_e(n,u,v)\\ -H(u,x,t).n] \leq 0.\end{aligned} \tag{36}$$

η is a convex function, and thus $\eta(u+v) \leq \eta(u) + v\eta'(u+v)$; consequently:

$$\begin{aligned}\eta(\tilde{u^h}_i^{n+1}) \leq \eta\left(\sum_{j\in P} \alpha_{ij}^n u^{h,n+1,j}\right) - \Delta t\eta'(\tilde{u^h}_i^{n+1}) \sum_{j\in P} w_j^n (F_{i,ij}^n - F_i^n).A_{ij}^n\\ + \Delta t\eta'(\tilde{u^h}_i^{n+1})S_i^n,\end{aligned}$$

where $u_i^{h,n+1,j}$ is defined section 4.1 of [10], $\alpha_{ij}^n = \frac{w_j^n||A_{ij}^n||}{\sum_{l\in P} w_l^n||A_{il}^n||}$, $F_{i,ij}^n = F(u_i^{h,n}, x_{ij}, t^n)$, $F_i^n = F(u_i^{h,n}, x_i, t^n)$, and $S_i^n = S(u_i^{h,n}, x_i, t^n)$. By using Jensen's inequality (since $\sum_{j\in P} \alpha_{ij}^n = 1$), and applying (36) to $u_i^{h,n+1,j}$, with $\lambda = \frac{\Delta t}{\overline{\Delta x_i^n}}$ ($\overline{\Delta x_i^n}$ defined in (12)), we get:

$$\begin{aligned}\eta(\tilde{u^h}_i^{n+1}) + 2\Delta t \sum_{j\in P} w_j^n (h_{e,ij}^n - H_{i,ij}^n.n_{ij})||A_{ij}^n|| \leq \eta(u_i^{h,n})\\ - \eta'(\tilde{u^h}_i^{n+1})\Delta t \sum_{j\in P} w_j^n (F_{i,ij}^n - F_i^n).A_{ij}^n + \Delta t\eta'(\tilde{u^h}_i^{n+1})S_i^n,\end{aligned}$$

where $H_{i,ij}^n = H(u_i^{h,n}, x_{ij}, t^n)$ and $h_{e,ij}^n = h_e(n_{ij}, u_i^{h,n}, u_j^{h,n})$. After using the definition of the numerical flux h_e (17), we multiply the above inequality by a test function $(-\varphi)$, with $\varphi \geq 0$, and sum over all particles and time steps. By transposing the adjoint derivatives approximate operator on H to φ, one finally gets, by using the notation $(\Phi, \varphi)_h^n$ for the l^2 scalar product

$\sum_{i\in P} w_i^n \Phi_i^n \varphi_i^n$:

$$
\begin{aligned}
&- \sum_{n\geq 0} \Delta t \left\{ \overbrace{\left(\frac{\eta(\tilde{u^h}^{n+1}) - \eta(u^{h,n})}{\Delta t}, \varphi^n \right)_h^n}^{I_1} - (H^n, D\varphi^n)_h^n \right\} \\
&\geq -2\Delta t \sum_i w_i^n \varphi_i^n \sum_{j\in P} w_j^n (H_{i,ij}^n - \eta'(\tilde{u^h}_i^{n+1}) F_{i,ij}^n).A_{ij}^n \\
&- \sum_{n\geq 0} \Delta t \left(\eta'(\tilde{u^h}^{n+1}) S^n, \varphi^n \right)_h^n + R_{11}^h(\varphi) + R_{12}^h(\varphi) + R_{13}^h(\varphi),
\end{aligned} \tag{37}
$$

where $R_{11}^h(\varphi)$, $R_{12}^h(\varphi)$, and $R_{13}^h(\varphi)$ are defined in (72a).
In the following, we will use the results below, deduced from (4) and (9):

$$
\begin{aligned}
&w_i^{n+1} = w_i^n + \Delta t \mathrm{div} a_i^n w_i^n, \\
&\eta(\tilde{u^h}_i^{n+1}) \leq \eta(u_i^{h,n+1}) + u_i^{h,n+1} \Delta t \mathrm{div} a_i^n \eta'(\tilde{u^h}_i^{n+1}), \\
&\eta(u_i^{h,n+1}) \leq \eta(\tilde{u^h}_i^{n+1}) + \eta'(u_i^{h,n+1}) \left(u_i^{h,n+1} - \tilde{u^h}_i^{n+1} \right).
\end{aligned} \tag{38}
$$

Suppose that φ has a compact support in $\mathbb{R}_+ \times \mathbb{R}^d$ and $\varphi(T,.) = 0$. By dividing the sum and making a discrete integration by parts, one obtains:

$$
\begin{aligned}
I_1 = &\overbrace{- \sum_{n\geq 0} \sum_{i\in P} (w_i^n \eta(\tilde{u^h}_i^{n+1}) - w_i^{n+1} \eta(u_i^{h,n+1})) \varphi_i^n}^{I_{11}} \\
&+ \sum_{n\geq 0} \sum_{i\in P} w_i^{n+1} \eta(u_i^{h,n+1}) (\varphi_i^{n+1} - \varphi_i^n) + \sum_{i\in P} w_i \eta(u_i^{h,0}) \varphi_i^0.
\end{aligned} \tag{39}
$$

From (38), we have:

$$
\begin{aligned}
I_{11} &\leq \sum_{n\geq 0} \sum_{i\in P} \left((w_i^{n+1} - w_i^n) \eta(u_i^{h,n+1}) - \eta'(u_i^{h,n+1}) u_i^{h,n+1} (w_i^{n+1} - w_i^n) \right) \varphi_i^n \\
&\leq \sum_{n\geq 0} \Delta t \sum_{i\in P} w_i^n \left(\eta(u_i^{h,n+1}) - \eta'(u_i^{h,n+1}) u_i^{h,n+1} \right) \mathrm{div} a_i^n \varphi_i^n.
\end{aligned} \tag{40}
$$

By using (40) and (39) in (37), one gets $\forall \eta, H$, and $\forall \varphi$ regular with compact support:

$$
\begin{aligned}
&\sum_{n\geq 0} \Delta t \left(\eta(u^{h,n+1}), \frac{(\varphi^{n+1} - \varphi^n)}{\Delta t} \right)_h^{n+1} + \sum_{n\geq 0} \Delta t (H(u^{h,n}, ., t^n), \nabla \varphi^n)_h^n \\
&+ \sum_{n\geq 0} \Delta t ((\eta(u^{h,n+1}) - \eta'(u^{h,n+1}) u^{h,n+1}) \mathrm{div} a^n, \varphi^n)_h^n + \left(\eta(u^{h,0}), \varphi^0 \right)_h^0 \\
&- 2\Delta t \sum_i \varphi_i^n \sum_{j\in P} w_j^n (H_{i,ij}^n - \eta'(\tilde{u^h}_i^{n+1}) F_{i,ij}^n).A_{ij}^n \\
&+ \sum_{n\geq 0} \Delta t (\eta'(\tilde{u^h}^{n+1}) S(u^{h,n}, ., t^n), \varphi^n)_h^n \geq R_1^h(\varphi),
\end{aligned} \tag{41}
$$

where R_1^h is defined in (72a), with $H = H_\delta$ and $\eta = \eta_\delta$.

- *Application of Kruszkov entropy*: Let us replace the entropy η by the regularized Kruszkov entropy $|.|^\delta$ and the entropy flux H by $H^c_\delta + \Psi^c_\delta$ (see Definition 3.1) in (41). We then obtain R^h_2 (72b) (linked to the introduction of Ψ^c_δ). By using equality (22), one gets:

$$\begin{aligned} &- 2\Delta t \sum_i \varphi^n_i \sum_{j\in P} w^n_j (H^{c,n}_{\delta,i,ij} - sign_\delta(u^{h,n+1}_i) F^n_{i,ij}).A^n_{ij} \\ &= 2\sum_n \Delta t \sum_i w^n_i sign_\delta(u^{h,n+1}_i)\varphi^n_i \sum_j w^n_j F(c, x_{ij}, t^n) A^n_{ij}, \end{aligned}$$

that we transform into $\mathrm{div}^{h,*}_x F(c, x_i, t^n)$ using $R^h_3(\varphi)$ defined in (72c).
In order to fit with the definition of u_h (13), we change all dependencies in $u^{h,n}$ or $\tilde{u^h}^{n+1}$ into $u^{h,n+1}$, and, with the definition (72d) of $R^h_4(\varphi)$, we get:
(42)

$$\begin{aligned} &\sum_{n\geq 0} \Delta t \left(|u^{h,n+1} - c|^\delta, \frac{(\varphi^{n+1} - \varphi^n)}{\Delta t} \right)^{n+1}_h + \sum_{n\geq 0} \Delta t (H^c_\delta(u^{h,n+1}, ., t^n), \nabla\varphi^n)^n_h \\ &+ \sum_{n\geq 0} \Delta t ((|u^{h,n+1} - c|^\delta - sign_\delta(u^{h,n+1} - c) u^{h,n+1}) \mathrm{div} a^n, \varphi^n)^n_h \\ &- \sum_{n\geq 0} \Delta t (sign_\delta(u^{h,n+1} - c) \mathrm{div}^{h,*}_x F(c, ., t^n), \varphi^n)^n_h + \left(|u^{h,0} - c|^\delta, \varphi^0\right)^0_h \\ &+ \sum_{n\geq 0} \Delta t \left(sign_\delta(u^{h,n+1} - c) S(u^{h,n+1}, ., t^n), \varphi^n\right)^n_h \geq \sum_{k=1}^4 R^h_k(\varphi). \end{aligned}$$

- *Continuous entropy inequality for the scheme*: We finally obtain (24) by introducing $R^h_5(\varphi)$ (see (72e)), representing the transition between discrete sums and continuous integrals with $\langle \mu_h, \varphi\rangle = \sum_{k=1}^5 R^h_k(\varphi)$. ∎

5.2. Entropy inequality for pseudoviscous solution.

PROPOSITION 5.2. *Let us suppose that assumptions* (2) *are satisfied, and let* u^ϵ *be the solution of* (27). *Then* u^ϵ *verifies the continuous entropy inequality* (26).

Proof. Let η be a convex function and H the associated entropy flux. We multiply (27) by $\eta'(u^\epsilon)$ and integrate over t and x. The term resulting from the perturbation is then transformed as follows:

$$\begin{aligned} -\epsilon \int_{\mathbb{R}_+\times\mathbb{R}^d} \eta'(u^\epsilon)\Delta u^\epsilon \varphi dyds &= -\epsilon \int_{\mathbb{R}_+\times\mathbb{R}^d} \nabla(\eta'(u^\epsilon)\nabla u^\epsilon)\varphi dxdt \\ &\quad + \epsilon \int_{\mathbb{R}_+\times\mathbb{R}^d} \eta''(u^\epsilon)(\nabla u^\epsilon)^2 \varphi dyds. \end{aligned}$$

Since η is a convex function, $\eta''(u^\epsilon) \geq 0$, the second term on the right-hand side of the above equality is positive, and we deduce the entropy inequality for u^ϵ:

$$\begin{aligned} &\int_{\mathbb{R}_+\times\mathbb{R}^d} \eta(u^\epsilon(y,s)) \frac{d\varphi}{dt} - (u^\epsilon(y,s)\eta'(u^\epsilon(y,s)) - \eta(u^\epsilon(y,s))) \mathrm{div} a(y,s)\varphi \\ &\qquad + H(u^\epsilon(y,s), y, s).\nabla\varphi - \eta'(u^\epsilon(y,s)) \mathrm{div}_y F(u^\epsilon(y,s), y, s)\varphi \\ &\qquad + \eta'(u^\epsilon(y,s)) S(u^\epsilon(y,s), y, s)\varphi - \epsilon\eta'(u^\epsilon(y,s))\nabla u^\epsilon(y,s).\nabla\varphi dyds \\ &+ \int_{\mathbb{R}^d} \eta(u^\epsilon_0)\varphi dy \geq 0. \end{aligned} \tag{43}$$

We apply $\eta(u) = |u-c|^\delta$ (see Definition 3.1) in (43) to get $R_1^\epsilon(\varphi)$ defined in (94a). By considering $H = H_\delta^c + \Psi_\delta^c$, we introduce the remainder $R_2^\epsilon(\varphi)$ defined in (94b). It remains to transform the term including the adjoint approximate operator of div$F$ into a term including the derivative of $\varphi sign_\delta(u^\epsilon)$. This is achieved by considering $R_3^\epsilon(\varphi)$ defined in (94c). We finally get (26) with $\langle \nu_\epsilon, \varphi \rangle = \sum_{k=1}^3 R_k^\epsilon(\varphi)$. ∎

6. Comparison of the two entropy inequalities. We present the test function that allows us to compare inequalities (24) and (26) and establish the comparison result that will lead to the proof of the main result.

6.1. Definition and properties of the test function. The test function depends on x, y, s, and t and must be with compact support with respect to x and t. Our aim is to have (s,y) tending to (t,x). Thus we use some approximations of the delta function with smoothing length γ.

DEFINITION 6.1. *The test function φ is equal to:*

$$\varphi(x,y,t,s) = \psi(t,x)\zeta^\gamma(t-s)\bar{\zeta}^\gamma(x-y), \tag{44}$$

where

$$\zeta^\gamma(x-y) = \frac{1}{\gamma^d}\zeta\left(\frac{||x-y||}{\gamma}\right) \quad \bar{\zeta}^\gamma(t-s) = \frac{1}{\gamma}\bar{\zeta}\left(\frac{|t-s|}{\gamma}\right), \tag{45}$$

$$\psi(t,x) = \begin{cases} e^{C_\psi t}\rho(|x|^\delta + \omega t)\frac{T-t}{T} & \text{if } x \in \mathbb{R}^d, t \in [0,T], \\ 0 & \text{if } x \in \mathbb{R}^d, t \geq T. \end{cases} \tag{46}$$

The positive functions $\zeta \in C_c^\infty(\mathbb{R}^d)$ and $\bar{\zeta} \in C_c^\infty(\mathbb{R})$ are with compact support such that Supp$(\bar{\zeta}) \subset [-1,0]$ and Supp$(\zeta) \subset [-1,1]$, and

$$\int_{\mathbb{R}^d} \zeta(||x||)dx = 1, \quad \int_{\mathbb{R}_+} \bar{\zeta}(t)dt = 1. \tag{47}$$

The function ρ in (46) *has the following properties:*

$$\begin{cases} \rho(r) = 1 \text{ if } r \in [0,R], \\ \rho(r) = 0 \text{ if } r \in [R+1, +\infty[, \\ \rho'(r) \leq 0 \ \forall r \in \mathbb{R}_+. \end{cases} \tag{48}$$

We first remark that $\varphi(x,y,t,0) = 0$, since $\zeta^\gamma(t-0) = 0$ for all $t \geq 0$, and that ρ goes to zero smoothly. Also, the derivatives of functions ζ^γ and $\bar{\zeta}^\gamma$ satisfy $\nabla_x \zeta^\gamma(x-y) = -\nabla_y \zeta^\gamma(x-y)$ and $\partial_t \bar{\zeta}^\gamma(t-s) = -\partial_s \bar{\zeta}^\gamma(t-s)$. This definition of φ ensures that φ has a compact support: $(x,t) \in Q$ and $(y,s) \in \tilde{Q}$, where Q and $\tilde{Q}$ are defined by

$$Q = \Omega \times [0,T] \text{ and } \tilde{Q} = \tilde{\Omega} \times [0, T+\gamma], \ \tilde{\Omega} = \text{extension of } \Omega \text{ by a width } \gamma. \tag{49}$$

The upper bounds of the L^∞ norm of some derivatives of ψ and φ will be needed later to estimate the remainders. They can be found in [9, page 190, equation (6.134) for φ and page 172, equation (6.89) for ψ].

6.2. Comparison of the entropy inequalities. We take $c = u(y,s)$ (resp., $c = u^h(x,t)$) in the entropy inequality for u^h (24) (resp., u^ϵ (26)) and integrate over

y and s (resp., x and t). By summing the two resulting inequalities and considering the definition of H_c^δ (19), (24)+(26) becomes:

$$\begin{aligned}
(\mathrm{a})+(\mathrm{a}') &= \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|^\delta \psi_t(t,x)\zeta^\gamma(x-y)\zeta^\gamma(t-s)dxdydtds \\
&\quad + \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|^\delta (a(x,t)-a(y,s)) \\
&\qquad \cdot \psi(t,x)\nabla_x\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds \qquad (50)\\
&\quad + \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|^\delta a(x,t) \\
&\qquad \cdot \nabla_x\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds \\
&= T_1+T_2+T_3, \\
(\mathrm{b})+(\mathrm{b}') &= \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(F(u^h(x,t),x,t)-F(u^\epsilon(y,s),x,t)\right) \\
&\quad \cdot \nabla_x\psi(t,x)\zeta^\gamma(x-y)\zeta^\gamma(t-s)dxdydtds + \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t) \\
&\quad - u^\epsilon(y,s))\left((F(u^h(x,t),x,t)-F(u^h(x,t),y,s))+(F(u^\epsilon(y,s),y,s)\right. \qquad (51)\\
&\quad \left. - F(u^\epsilon(y,s),x,t))\right).\psi(t,x)\nabla_x\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt \\
&= T_4+T_5, \\
(\mathrm{c})+(\mathrm{c}') &= \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|^\delta(\mathrm{div}a(y,s)+\mathrm{div}a(x,t)) \\
&\qquad \cdot \psi(t,x)\zeta^\gamma(x-y)\zeta^\gamma(t-s)dxdydtds \\
&\quad - \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(u^h(x,t)\mathrm{div}a(x,t)\right. \qquad (52)\\
&\qquad \left. -u^\epsilon(y,s)\mathrm{div}a(y,s)\right)\psi(t,x)\zeta^\gamma(x-y)\zeta^\gamma(t-s)dxdydtds \\
&= T_6-T_7, \\
(\mathrm{f})+(\mathrm{f}') &= -\int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t)-u^\epsilon(y,s))(\overline{\mathrm{div}_x^{h,*}}F(u^\epsilon(y,s),x,t) \qquad (53)\\
&\qquad -\overline{\mathrm{div}_y^{h,*}}F(u^h(x,t),y,s))\varphi(x,y,t,s)dxdydtds = -T_8, \\
(\mathrm{d})+(\mathrm{d}') &= -\int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t)-u^\epsilon(y,s))(S(u^h(x,t),x,t) \qquad (54)\\
&\qquad -S(u^\epsilon(y,s),y,s))\varphi(x,y,t,s)dxdydtds = T_9,
\end{aligned}$$

and

$$(\mathrm{e})+(\mathrm{e}') = \int_{\Omega\times\tilde{Q}} |u^h(x,0)-u^\epsilon(y,s)|^\delta\psi(x,0)\zeta^\gamma(x-y)\zeta^\gamma(s)dxdyds = T_{10}. \qquad (55)$$

By considering that $\varphi(x,y,t,0)=0$, we get:

$$\sum_{i=1}^{10} T_i \geq \int_{(\mathbb{R}^+\times\mathbb{R}^d)} \langle\mu_h,\varphi(.,y,.,s)\rangle dyds + \int_{(\mathbb{R}^+\times\mathbb{R}^d)} \langle\nu_\epsilon,\varphi(x,.,t,.)\rangle dxdt. \qquad (56)$$

Inequality (56) is the basis to prove the following lemma.

LEMMA 6.2. *Let u^h be the solution of the scheme* (9), (13) *and u^ϵ the solution of the pseudoviscous equation* (27)*, and then the following inequality holds:*

(57)
$$\int_{(\mathbb{R}_+\times\mathbb{R}^d)^2} \big(|u^h(x,t)-u^\epsilon(y,s)|\partial_t\psi(t,x) + sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(F(u^h(x,t),x,t)-F(u^\epsilon(y,s),x,t)\right).\nabla_x\psi(t,x)\big) \cdot\zeta^\gamma(x-y)\zeta^\gamma(t-s)dxdydtds + \int_{\Omega\times\tilde{Q}} |u^h(x,0)-u^\epsilon(y,s)|\psi(0,x)\zeta^\gamma(x-y)\zeta^\gamma(s)dxdyds \geq T_{L^1}(\varphi)+\langle\lambda_1,\varphi\rangle + \int_{\tilde{Q}}\langle\mu_h,\varphi(.,y,.,s)\rangle dyds + \int_Q\langle\nu_\epsilon,\varphi(x,.,t,.)\rangle dxdt,$$

where μ_h and ν_ϵ are, respectively, defined in (72) *and* (94)*, and $\langle\lambda_1,\varphi\rangle=\sum_{k=1}^8 R_k^c(\varphi)$, where $R_k^c(\varphi), k=1,\dots,8$, are given in* (104)*. The term $T_{L^1}(\varphi)$ represents all elements which can be bounded by $||u^h-u^\epsilon||_L^1(\Omega\times[0,T])$ and is defined in* (118)*.*

Proof. Each term T_k, $k=1,\dots,10$, from inequality (56) not including derivatives of ψ is transformed in order to get terms either tending to 0 or upper bounded by $||u^h-u^\epsilon||_{L^1}$. The fourth term T_4 is kept unchanged. We use the characteristic function χ such that χ_V is equal to 1 on V and 0 elsewhere, where V is a subspace of $\mathbb{R}$ or $\mathbb{R}^d$. The subspaces Q and $\tilde{Q}$ were defined in (49).

- *Term T_1*: The transformation of T_1 concerns only the regularization of $|.|$

$$T_1 = \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|\psi_t(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt + R_1^c(\varphi), \tag{58}$$

  where $R_1^c(\varphi)$ is defined in (104a).
- *Term T_2*: By using the regularity (2) on a, the inequality $|v|^\delta\leq|v|$ (from Definition (3.1)), and the compact supports of ζ and $\bar{\zeta}$ (see (45)), one gets:

$$|T_2|\leq(||Da||_{L^\infty(\tilde{Q})}+||\partial_t a||_{L^\infty(\tilde{Q})})||\nabla\zeta^\gamma||_\infty||\bar{\zeta}^\gamma||_\infty\gamma \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|\ |\psi(t,x)|\chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dydsdxdt.$$

  By considering

$$\int_{\tilde{Q}}\chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dyds=\gamma^{d+1}, \tag{59}$$

  let us transform the integral in the following way:

$$\int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|\ |\psi(t,x)|\chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dydsdxdt = \gamma^{d+1}\int_Q|u^h(x,t)-u^\epsilon(x,t)|\ |\psi(t,x)|dxdt + \int_{Q\times\tilde{Q}}|u^\epsilon(x,t)-u^\epsilon(y,s)|\ |\psi(t,x)|\chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dydsdxdt.$$

By using the definition of $R^{c,L^1}(\psi)$ given in (104k), we deduce that

$$|T_2| \leq C(u_0,T,\Omega,F,S)\left(\int_Q |u^h(x,t)-u^\epsilon(x,t)|\ |\psi(t,x)|dxdt + R^{c,L^1}(\psi)\right). \tag{60}$$

- *Term* T_3: We proceed as for the term T_1: With $R_2^c(\psi)$ defined in (104b),

$$T_3 = \int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|a(x,t).\nabla\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt + R_2^c(\varphi).$$

- *Term* T_5: By using hypothesis (2) on F, one can use Taylor's formula on $F(u^h(x,t),a,b) - F(u^\epsilon(y,s),a,b)$ for $(a,b)=(x,t)$ or (y,s). We get:

$$\begin{aligned} T_5 = \int_{Q\times\tilde{Q}}\int_0^1 sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(\partial_1 F(u^\epsilon(y,s)+\theta(u^h(x,t)\right. \\ - u^\epsilon(y,s)),x,t) - \partial_1 F(u^\epsilon(y,s)+\theta(u^h(x,t) \\ \left. - u^\epsilon(y,s)),y,s)\right)(u^\epsilon(y,s)-u^h(x,t)) \\ \cdot \psi(t,x)\nabla_x\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtdsd\theta. \end{aligned}$$

Let us bound T_5 as follows:

$$\begin{aligned} |T_5| \leq ||sign_\delta||_{L^\infty(\mathbb{R})}\int_{Q\times\tilde{Q}} \{\sup_{c\in\mathbb{R}} |\partial_1 F(c,x,t)-\partial_1 F(c,y,s)|\} \\ \cdot |u^\epsilon(y,s)-u^h(x,t)|\ |\psi(t,x)|\ |\nabla_x\zeta^\gamma(x-y)|\bar{\zeta}^\gamma(t-s)dxdydtds. \end{aligned}$$

By using the regularity hypothesis on F and proceeding as for T_2, there exists $C(u_0,F,S,a,T)$ such that:

$$|T_5| \leq C(u_0,F,S,a,T)\left(\int_Q |u^\epsilon(x,t)-u^h(x,t)|\ |\psi(t,x)|dxdt + R^{c,L^1}(\psi)\right), \tag{61}$$

with $R^{c,L^1}(\psi)$ defined in (104k).

- *Term* T_6: We write $T_6 = T_6' + R_3^c(\varphi) + R_4^c(\varphi)$, where $R_3^c(\varphi)$, $R_4^c(\varphi)$, and T_6' are defined in (104c), (104d), and (118c), respectively, and T_6' satisfies (as for the term T_2):

$$|T_6'| \leq C(u_0,F,S,a,T)\left(\int_Q |u^\epsilon(x,t)-u^h(x,t)|\ |\psi(t,x)|dxdt + R^{c,L^1}(\psi)\right). \tag{62}$$

- *Term* T_7: We write $T_7 = T_7' + R_5^c(\Psi)$, where $R_5^c(\varphi)$ and T_7' are defined in (104e) and (118d), respectively, and T_7' satisfies (as for the term T_2):

$$|T_7'| \leq C(u_0,F,S,a,T)\left(\int_Q |u^\epsilon(x,t)-u^h(x,t)|\ |\psi(t,x)|dxdt + R^{c,L^1}(\psi)\right). \tag{63}$$

- *Term T_8*: We write $T_8 = T_8' + R_6^c$, where $R_6^c(\varphi)$ and T_8' are defined in (104f) and (118e), respectively.
  Concerning T_8', let us use the regularity of F with its first variable:

$$\underline{T_8'} \leq \left(\sup_{v,|v|\leq C(u_0)} ||\partial_1 F(v,.,.)||_{L^\infty(\tilde{Q})} + \sup_{v,|v|\leq C(u_0)} ||\nabla \partial_1 F(v,.,.)||_{L^\infty(\tilde{Q})} \right)$$
$$\cdot ||sign_\delta'||_\infty \int_{Q\times\tilde{Q}} |\varphi(x,y,t,s)|\ |u^\epsilon(y,s) - u^h(x,t)| dxdyds dt \tag{64}$$
$$\leq C(u_0,F,S,a,T,\Omega) \left(\int_Q |u^\epsilon(x,t) - u^h(x,t)| \psi(t,x) dxdt + R^{c,L^1}(\psi) \right).$$

- *Term T_9*: We set $T_9 = T_9' + R_7^c(\varphi)$, where $R_7^c(\varphi)$ and T_9' are defined in (104g) and (118f), respectively. From the hypothesis (2) on the source term S, one prove that

$$|T_9'| \leq ||sign_\delta||_\infty \sup_{c;||c||\leq C} \{ ||\partial_u S(c,.,.)||_{L^\infty(\tilde{(}Q))} \} \tag{65}$$
$$\cdot \int_{Q\times\tilde{Q}} |u^\epsilon(y,s) - u^h(x,t)| \psi(t,x) \zeta^\gamma(x-y) \bar{\zeta}^\gamma(t-s) dxdydtds$$
$$\leq C(u_0,F,S,a,T) \left(\textstyle\int_Q |u^\epsilon(x,t) - u^h(x,t)|\ |\psi(t,x)| dxdt + R^{c,L^1}(\psi) \right).$$

- *Term T_{10}*: We set $T_{10} = T_{10}' + R_8^c(\varphi)$, where $R_8^c(\varphi)$ is defined in (104h), and $T_{10}' = \int_{\tilde{Q}\times\Omega} |u^h(x,0) - u^\epsilon(x,0)| \zeta^\gamma(x-y) \bar{\zeta}^\gamma(s) dyds \psi(x,0) dx$ and satisfies:

$$|T_{10}'| \leq C(u_0,T,\Omega,F,a,S) \int_\Omega |u^h(x,0) - u^\epsilon(x,0)| \psi(x,0) dx. \tag{66}$$

- *Conclusion*: From the above transformations, we obtain inequality (57), with $\langle \lambda_1, \varphi \rangle = \sum_{k=1}^8 R_k^c(\varphi)$, and T_{L^1} defined in (118), bounded by $||u^h - u^\epsilon||_{L^1}$: $\exists C_{L^1}(u_0,F,S,a,T,\Omega)$ such that

$$\boxed{|T_{L^1}(\varphi)| \leq C_{L^1} \left(\int_Q |u^h(x,t) - u^\epsilon(x,t)|\ |\psi(x,t)| dxdt + R^{c,L^1}(\psi) \right).} \tag{67}$$
□

6.3. Gronwall formula. From Lemma 6.2, we deduce the following proposition.

PROPOSITION 6.3. *Let u^h be the solution of the scheme* (9), (13) *and u^ϵ the solution of problem* (27) *with S, F, a, and u_0 satisfying* (2). *Then, with the definition* (44) *and* (49) *for $\varphi(x,y,t,s)$, Q, and $\tilde{Q}$, we have for all compact E in $\mathbb{R}^d \times \mathbb{R}_+$:*

$$\int_E |u^h(x,t) - u^\epsilon(x,t)| dxdt \leq \int_\Omega |u^h(x,0) - u^\epsilon(x,0)| dx + T \int_{\tilde{Q}} \langle \mu_h, \varphi(.,y,.,s) \rangle dyds$$
$$+ T \int_Q \langle \nu_\epsilon, \varphi(x,.,t,.) \rangle dxdt + T \langle \lambda, \varphi \rangle, \tag{68}$$

where μ_h, ν_ϵ, and λ are defined in (72), (94), *and* (104), *respectively.*

Proof. By using the definition of ψ (46), the left-hand side of (57) (called I) reads:

$$\begin{aligned}
I = &\int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)| C_\psi e^{C_\psi t}\rho(|x|^\delta+\omega t)\frac{T-t}{T}\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt\\
&-\int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)| e^{C_\psi t}\rho(|x|^\delta+\omega t)\frac{1}{T}\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt\\
&+\int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)| e^{C_\psi t}\omega\rho'(|x|^\delta+\omega t)\frac{T-t}{T}\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt\\
&+\int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(F(u^h(x,t),x,t)-F(u^\epsilon(y,s),x,t)\right)\\
&\cdot e^{C_\psi t}\vec{sign}_\delta(x)\rho'(|x|^\delta+\omega t)\frac{T-t}{T}\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt.
\end{aligned}$$

From hypothesis (2), we have $|F(\tilde{u},x,t)-F(u,x,t)|\le D_F^1|\tilde{u}-u|$. By taking $\omega=D_F^1$ and using $\bar{\zeta}\ge 0$, $\zeta\ge 0$, $\rho'\le 0$, and $||sign_\delta||_\infty\le 1$, we get:

$$\begin{aligned}
&\int_{Q\times\tilde{Q}} e^{C_\psi t}\rho'(|x|^\delta+D_F^1 t)\frac{T-t}{T}\zeta^\gamma(x-y)\zeta^\gamma(t-s)\left(D_F^1|u^h(x,t)-u^\epsilon(y,s)|\right.\\
&\left.+\,sign(u^h(x,t)-u^\epsilon(y,s))\left(F(u^h(x,t),x,t)-F(u^\epsilon(y,s),x,t)\right).\vec{sign}_\delta(x)\right)dxdydsdt\le 0.
\end{aligned}$$

From the upper bound of $T_{L^1}(\varphi)$ (67), one gets:

$$\begin{aligned}
&\int_Q |u^h(x,t)-u^\epsilon(x,t)| e^{C_\psi t}\rho(|x|^\delta+D_F^1 t)\frac{1}{T}dxdt\\
&\le \int_Q |u^h(x,t)-u^\epsilon(x,t)| C_\psi e^{C_\psi t}\rho(|x|^\delta+\omega t)\frac{T-t}{T}dxdt\\
&+\int_\Omega |u^h(x,0)-u^\epsilon(x,0)|\rho(|x|^\delta)dx + C_{L^1}\int_Q |u^h(x,t)-u^\epsilon(x,t)| e^{C_\psi t}\rho(|x|^\delta+D_F^1 t)\\
&\quad\cdot\frac{T-t}{T}\Big|dxdt+\langle\lambda,\varphi\rangle+\int_{\tilde{Q}}\langle\mu_h,\varphi(.,y,.,s)\rangle dyds\\
&\quad+\int_Q\langle\nu_\epsilon,\varphi(x,.,t,.)\rangle dxdt,
\end{aligned}$$

where we take $\langle\lambda,\varphi\rangle=\langle\lambda_1,\varphi\rangle+R_9^c(\varphi)+R_{10}^c(\varphi)+R^{c,L^1}(\psi)$, R_9^c and R_{10}^c being defined in (104i) and (104j), respectively.

Take $C_\psi=-C_{L^1}(u_0,F,S,a,T,\Omega)$. It remains that

(69)
$$\begin{aligned}
\int_Q |u^h(x,t)-u^\epsilon(x,t)| e^{C_\psi t}\rho(|x|^\delta+\omega t)\frac{1}{T}dxdt &\le \int_\Omega |u^h(x,0)-u^\epsilon(x,0)|\ \rho(|x|^\delta)\ dx\\
&+\langle\lambda,\varphi\rangle+\int_{\tilde{Q}}\langle\mu_h,\varphi(.,y,.,s)\rangle dyds+\int_Q\langle\nu,\varphi(x,.,t,.)\rangle dxdt.
\end{aligned}$$

The integration domain with respect to t being $0\le t\le T$ and the constant C_ψ being negative, we have $e^{C_\psi T}\ge e^{C_\psi t}$. Moreover, if we consider any subspace $E\in\cup_{0\le t\le T}(B(0,R-\omega t)\times\{t\})$, the function ρ is equal to 1 when $(x,t)\in E$, and we get:

$$\int_E |u^h(x,t)-u^\epsilon(x,t)|dxdt\le\frac{1}{e^{(C_\psi T)}}\int_E |u^h(x,t)-u^\epsilon(x,t)| e^{C_\psi t}\rho(|x|^\delta+\omega t)dxdt. \tag{70}$$

By combining this equation with (69), one gets the result of Proposition 6.3. ∎

7. Main result.

THEOREM 7.1. *Let us assume that a, F, S, and u_0 satisfy the hypothesis* (2)*, that the time step satisfies the CFL condition* (11)*, and that the ratio $\frac{\varepsilon}{h} = \mathcal{O}(1)$. Suppose that the shape vectors A_{ij}^n verify the conditions* (14) *and the Lipschitz condition:*

$$\left| \sum_{j \in P} w_j^n A_{ij}^n - \sum_{j \in P} w_j^m A_{kj}^m \right| \leq C(|t^m - t^n| + |\xi_i - \xi_k| + O(\varepsilon_0)).$$
