HOMOGENIZATION OF PARABOLIC EQUATIONS WITH A CONTINUUM OF SPACE AND TIME SCALES*

HOUMAN OWHADI† AND LEI ZHANG‡

Abstract. This paper addresses the issue of the homogenization of linear divergence form parabolic operators in situations where no ergodicity and no scale separation in time or space are available. Namely, we consider divergence form linear parabolic operators in $\Omega \subset \mathbb{R}^n$ with $L^\infty(\Omega \times (0,T))$-coefficients. It appears that the inverse operator maps the unit ball of $L^2(\Omega \times (0,T))$ into a space of functions which at small (time and space) scales are close in H^1 norm to a functional space of dimension n. It follows that once one has solved these equations at least n times it is possible to homogenize them both in space and in time, reducing the number of operation counts necessary to obtain further solutions. In practice we show under a Cordes-type condition that the first order time derivatives and second order space derivatives of the solution of these operators with respect to caloric coordinates are in L^2 (instead of H^{-1} with Euclidean coordinates). If the medium is time-independent, then it is sufficient to solve n times the associated elliptic equation in order to homogenize the parabolic equation.

Key words. multiscale problem, compensation, homogenization, upscaling, compression

1. Introduction and main results.

Let Ω be a bounded and convex domain of class C^2 of $\mathbb{R}^n$. Let $T > 0$. Consider the following parabolic PDE:

$$\begin{cases} \partial_t u = \operatorname{div}\big(a(x,t)\nabla u(x,t)\big) + g \quad \text{in} \quad \Omega \times (0,T), \\ u(x,t) = 0 \quad \text{for} \quad (x,t) \in \big(\partial\Omega \times (0,T)\big) \cup \big(\Omega \times \{t=0\}\big). \end{cases} \tag{1.1}$$

Write $\Omega_T := \Omega \times (0,T)$. g is a function in $L^2(\Omega_T)$. $(x,t) \to a(x,t)$ is a mapping from Ω_T into the space of symmetric positive definite matrices with entries in $L^\infty(\Omega_T)$. Assume a to be uniformly elliptic on the closure of Ω_T. This paper addresses the issue of the homogenization of (1.1) in space and time in situations where scale separation and ergodicity at small scales are not available (see [16], [43], [4] for an introduction to classical homogenization theory).

We will introduce in subsection 1.1 theorems establishing under Cordes-type conditions the increase of regularity of solutions of (1.1) when derivatives are taken with respect to caloric coordinates instead of Euclidean coordinates. In subsections 1.2 and 1.3 these results will be used to homogenize (1.1) in space and in time. More precisely, assume a to be written on a fine tessellation with N degrees of freedom. If a is time-independent, then by solving n times an elliptic boundary value problem associated to (1.1) (at a cost of $O(N(\ln N)^{n+3})$ operations, using the hierarchical matrix method [11] or in $O(N)$ operations using iterative methods (see [76], [77]) it

is possible to approximate the solutions of (1.1) by solving an homogenized operator with N^α degrees of freedom ($\alpha < 1$, $\alpha = 0.2$, for instance) or with a fixed number M of degrees of freedom (numerical experiments given at the end of this paper have been conducted with $N = 16641$ and $M = 9$). Therefore, in the case of time-independent a, it is possible to reduce the number of operations even if we solve the problem (1.1) only once by using large time steps. If a is also characterized by a continuum of time scales, then the method presented here does not reduce the number of operation counts necessary to solve (1.1) only one time. However, if one needs to solve (1.1) K ($K > n$) times (with different right-hand sides), then by solving (1.1) n times it is possible to obtain an approximation of the solutions of (1.1) by solving an homogenized (in space and time) parabolic equation written on a coarse tessellation with coarse time steps. From a broader point of view, this paper suggests that, when one is trying to solve the linear problem $Ax = y$ with many different y (where A is a matrix associated to a divergence form operator), one should never compute A^{-1}.

In [60] the authors have addressed the issue of the homogenization of divergence form elliptic equations with a continuum of space scales; however, this paper is not a technical extension of the previous one. Indeed the presence of temporal scales adds strong difficulties through the fact that for parabolic equations finite element methods are no longer optimal. The main difference when the coefficients are rough in both space and time lies in the fact that we have to introduce time-dependent elements and use dual methods for controlling the numerical homogenization errors instead of simply relying on the increased regularity. Furthermore the numerical scheme has to be implicit in time.

Numerical results given in section 3 show that the method can be implemented and work in practice. The idea to use a change of coordinates for a finite element method for divergence form elliptic equations with rough coefficients can be traced back to the work of Babuška et al. [9, 8] (in dimension two with coefficients depending only on one parameter). The idea to use a global change of coordinates to homogenize transport equations is currently being implemented in the industry and has been shown to give accurate results when local methods fail. For instance, we refer to [75], [74] for reservoir modeling in geophysics; in this situation the porosity of the medium is time-independent, and one has to solve an elliptic equation only at $t = 0$ to upscale the transport equations. Observe also that using an implicit method to solve divergence form parabolic equations with time-independent rough coefficients implies solving an elliptic problem at each time step. The method presented in this paper implies that these elliptic problems can be solved with an "homogenized" operator leading to a sharp improvement of the computational cost.

Although we use the term "homogenization" in this paper for lack of a better word, the method presented in this paper is more general than homogenization. Homogenization is typically associated with the limit points of a sequence of operators. Here we are speaking of a fixed operator.

1.1. Compensation phenomenon. Let F be the solution of the following parabolic equation:

$$\begin{cases} \partial_t F = \operatorname{div}\big(a(x,t)\nabla F(x,t)\big) \quad \text{in} \quad \Omega_T, \\ F(x,t) = x \quad \text{for} \quad (x,t) \in \big(\partial\Omega \times (0,T)\big), \\ \operatorname{div}\big(a(x,0)\nabla F(x,0)\big) = 0 \quad \text{in} \quad \Omega. \end{cases} \tag{1.2}$$

By (1.2) we mean that $F := (F_1, \dots, F_n)$ is a n-dimensional vector field such that each of its entries satisfies

$$\begin{cases} \partial_t F_i = \operatorname{div}\big(a(x,t)\nabla F_i(x,t)\big) & \text{in} \quad \Omega_T, \\ F_i(x,t) = x_i & \text{for} \quad (x,t) \in \big(\partial\Omega \times (0,T)\big), \\ \operatorname{div}\big(a(x,0)\nabla F_i(x,0)\big) = 0 & \text{in} \quad \Omega. \end{cases} \tag{1.3}$$

In the literature F is also called a caloric coordinate associated to (1.1). Observe that if a is time-independent, then F is the solution of an elliptic boundary value problem.

Definition 1.1. *Write*

$$\sigma := {}^t\nabla F a \nabla F. \tag{1.4}$$

Write β_σ as the Cordes parameter associated to σ defined by

$$\beta_\sigma := \operatorname{esssup}_{(x,t)\in\Omega_T} \left(n - \frac{\big(\operatorname{Trace}[\sigma]\big)^2}{\operatorname{Trace}[{}^t\sigma\sigma]} \right). \tag{1.5}$$

Observe that since

$$\beta_\sigma = \operatorname{esssup}_{(x,t)\in\Omega_T} \left(n - \frac{\big(\sum_{i=1}^n \lambda_{i,\sigma(x,t)}\big)^2}{\sum_{i=1}^n \lambda_{i,\sigma(x,t)}^2} \right), \tag{1.6}$$

where $(\lambda_{i,M})$ denotes the eigenvalues of M, β_σ is a measure of the anisotropy of σ. The greater β_σ is, the more anisotropic σ is, and $\beta_\sigma = 0$ corresponds to an isotropic σ.

1.1.1. Time-independent medium. In this subsection we assume that a does not depend on time t. Write for $p \geq 2$, $W_D^{2,p}$ (D for Dirichlet boundary condition) the Banach space $W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$. Equip $W_D^{2,p}(\Omega)$ with the norm

$$\|v\|^p_{W_D^{2,p}(\Omega)} := \int_\Omega \left(\sum_{i,j} (\partial_i \partial_j v)^2 \right)^{\frac{p}{2}}. \tag{1.7}$$

Equip the space $L^p(0,T,W_D^{2,p}(\Omega))$ with the norm

$$\|v\|^p_{L^p(0,T,W_D^{2,p}(\Omega))} = \int_0^T \int_\Omega \left(\sum_{i,j} (\partial_i \partial_j v)^2 \right)^{\frac{p}{2}} dx\, dt. \tag{1.8}$$

Theorem 1.1. *Assume that $\partial_t a \equiv 0$, $g \in L^2(\Omega_T)$, Ω is convex, $\beta_\sigma < 1$, and $(\operatorname{Trace}[\sigma])^{\frac{n}{4}-1} \in L^\infty(\Omega)$; then $u \circ F^{-1} \in L^2(0,T,W_D^{2,2}(\Omega))$ and*

$$\|u \circ F^{-1}\|_{L^2(0,T,W_D^{2,2}(\Omega))} \leq \frac{C}{1-\beta_\sigma^{\frac{1}{2}}} \|g\|_{L^2(\Omega_T)}. \tag{1.9}$$

Remark 1.1. The constant C can be written

$$C = \frac{C_n}{(\lambda_{\min}(a))^{\frac{n}{4}}} \big\| (\operatorname{Trace}[\sigma])^{\frac{n}{4}-1} \big\|_{L^\infty(\Omega)}.$$

Throughout this paper, we write

$$\lambda_{\min}(a) := \inf_{(x,t)\in\Omega_T} \inf_{l\in\mathbb{R}^n, |l|=1} {}^t l.a(x,t).l. \tag{1.10}$$

All of the results are stated in a finite time interval [0, T]. T is just any given finite time, and it is easy to observe that if $\|g\|_{L^2(\Omega_\infty)} < \infty$, then one can take $T = \infty$.

Remark 1.2. According to Theorem 1.1 although the second order derivatives of u with respect to Euclidean coordinates are only in $L^2(0, T, H^{-1}(\Omega))$, they are in $L^2(\Omega_T)$ with respect to harmonic coordinates. The proof of that theorem (given in subsection 2.1.1) lies on the fact $u \circ F^{-1}$ satisfies nondivergence form parabolic equations, and the solutions of these equations are known to have a higher regularity under a Cordes-type condition on the coefficients and under a convexity assumption on the domain. One can obtain a similar result without the convexity assumption on the domain (Theorem 2.6), but the Cordes-type condition on the coefficients would have to be stronger.

Remark 1.3. Observe that if a is time-independent, then F and σ are time-independent, and F is the solution of the following elliptic problem:

$$\begin{cases} \operatorname{div} a\nabla F = 0 \quad \text{in} \quad \Omega, \\ F(x) = x \quad \text{on} \quad \partial\Omega. \end{cases} \tag{1.11}$$

In dimension one F is trivially a homeomorphism. In dimension two this property follows from the convexity of the domain [3] (even with $a_{i,j} \in L^\infty(\Omega)$), [6] (one can also deduce from [6] that for $n = 2$, if a is smooth, then the conditions $\beta_\sigma < 1$ and $(\text{Trace}[\sigma])^{-1} \in L^\infty(\Omega)$ are satisfied). In dimension three and higher F can be nonbijective even if a is smooth; we refer to [6], [22]. However in dimension three the assumption $(\text{Trace}[\sigma])^{\frac{n}{4}-1} \in L^\infty(\Omega_T)$ implies that F is a homeomorphism. If $n \geq 4$, we need to assume that F is a homeomorphism to prove the theorem.

Remark 1.4. In fact the condition $(\text{Trace}(\sigma))^{-1} \in L^p(\Omega_T)$, for $p < \infty$ depending on n, is sufficient to obtain Theorem 1.1 and the following compensation theorems. For the sake of clarity this paper has been restricted to $(\text{Trace}(\sigma))^{-1} \in L^\infty(\Omega_T)$.

Remark 1.5. Write

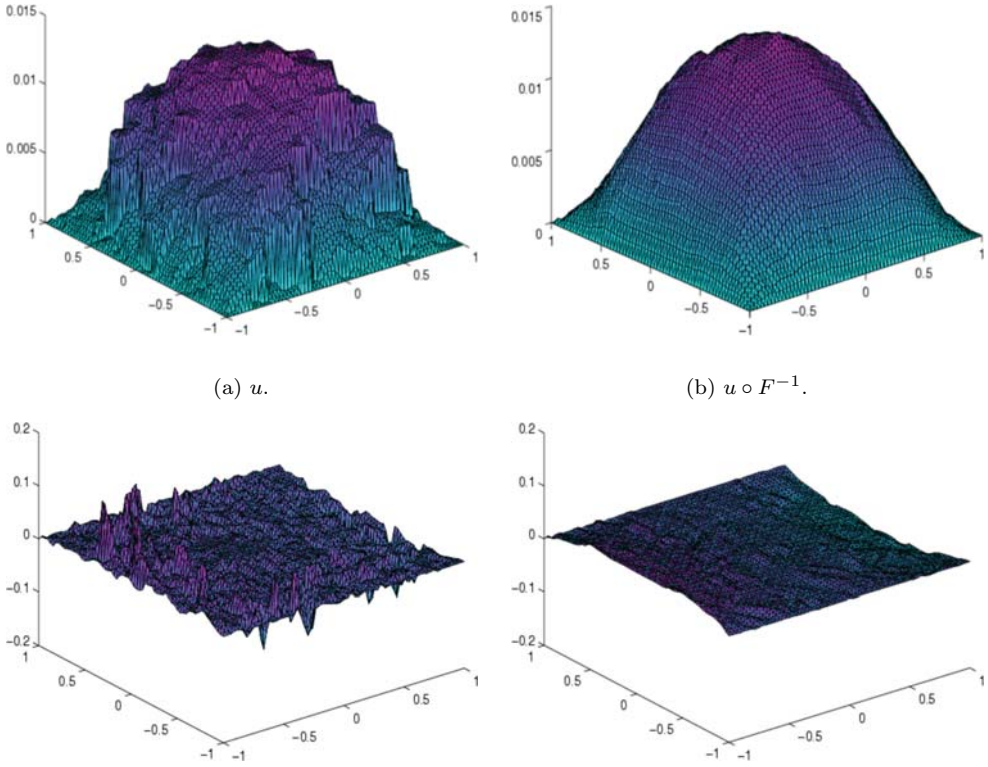
$$\mu_\sigma := \text{esssup}_{\Omega_T} \frac{\lambda_{\max}(\sigma)}{\lambda_{\min}(\sigma)}. \tag{1.12}$$

It is easy to check that μ_σ is bounded by an increasing function of $(1 - \beta_\sigma)^{-1}$, and in dimension two $\beta_\sigma < 1$ is equivalent to $\mu_\sigma < \infty$.

Remark 1.6. Theorem 1.1 has been called the compensation phenomenon because the composition by F^{-1} increases the regularity of $u \in L^2(0, T, H^1_0(\Omega))$. The choice of this name has been motivated by Murat and Tartar's work on H-convergence [54] which is also based on a regularization property called compensated compactness or the div-curl lemma introduced in the 1970s by Murat and Tartar [53], [70] (we also refer to [26] for refinements of the div-curl lemma).

The compensation phenomena presented in this subsection can be observed numerically. We consider the time-independent site percolation, and the value of a is set to be equal to 1 or 100 with probability 1/2 on each triangle of a fine mesh characterized by 16641 nodes and 32768 triangles. (1.1) has been solved numerically on that mesh with $g = 1$. u, $u \circ F^{-1}$, $\partial_x u$, and $\partial x(u \circ F^{-1})$ are plotted at time $t = 1$ in Figure 1.1.

It is easy to check that if $a = e(x)S(t)$, where e, is a time-independent symmetric uniformly elliptic matrix with $L^\infty(\Omega)$ entries and S is a smooth uniformly positive function, then the results given in this subsection and the homogenization schemes of subsection 1.2 remain valid with the time-independent harmonic coordinates associated to e, i.e., solution of $-\operatorname{div} e\nabla F = 0$.



(a) u. (b) $u \circ F^{-1}$.

(c) $\partial_x u$. (d) $\partial_x (u \circ F^{-1})$.

FIG. 1.1. *u, $u \circ F^{-1}$, $\partial_x u$, and $\partial_x (u \circ F^{-1})$ at time $t = 1$ for the time-independent site percolating medium.*

1.1.2. Medium with a continuum of time scales. In this subsection the entries of a are merely in $L^\infty(\Omega_T)$. We need to introduce the following Cordes-type condition.

CONDITION 1.1. *We say that Condition* 1.1 *is satisfied if and only if there exists $\delta \in (0, \infty)$ and $\epsilon > 0$ such that*

$$\operatorname{esssup}_{\Omega_T} \frac{\delta^2 \operatorname{Trace}[{}^t\sigma\sigma] + 1}{\left(\delta \operatorname{Trace}[\sigma] + 1\right)^2} \leq \frac{1}{n + \epsilon}. \tag{1.13}$$

Remark 1.7. This remark is due to Gyrya and Berlyand. Equation (1.13) can be written in terms of the Cordes parameter by

$$\operatorname{esssup}_{\Omega_T} \left\{ n - \frac{\left(\operatorname{Trace}(\sigma) + \delta^{-1}\right)^2}{\operatorname{Trace}(\sigma^t\sigma) + \delta^{-2}} \right\} \leq -\varepsilon. \tag{1.14}$$

An alternative way of interpreting the Cordes-type condition is by rewriting (1.14) as follows:

$$\beta_{\hat{\sigma}(\delta)} = \operatorname{esssup}_{\Omega_T} \left\{ (n+1) - \frac{\left(\operatorname{Trace}(\sigma) + \delta^{-1}\right)^2}{\operatorname{Trace}(\sigma^t\sigma) + \delta^{-2}} \right\} \leq 1 - \varepsilon, \tag{1.15}$$

where

$$\hat{\sigma}(\delta) = \begin{bmatrix} \delta^{-1} & 0 & \dots & 0 \\ 0 & & & \\ \vdots & & \sigma & \\ 0 & & & \end{bmatrix}.$$

Write

$$z_\sigma := \operatorname{esssup}_{\Omega_T} n \frac{\operatorname{Trace}[{}^t\sigma\sigma]}{(\operatorname{Trace}[\sigma])^2}. \tag{1.16}$$

Observe that z_σ is a measure of anisotropy of σ, in particular, $1 \leq z_\sigma \leq n$ and $z_\sigma = 1$ if σ is isotropic. Write

$$y_\sigma := \|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)} \left\|(\operatorname{Trace}[\sigma])^{-1}\right\|_{L^\infty(\Omega_T)}. \tag{1.17}$$

PROPOSITION 1.1. *If* $\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)} < \infty$ *and* $\left\|(\operatorname{Trace}[\sigma])^{-1}\right\|_{L^\infty(\Omega_T)} < \infty$, *then Condition* 1.1 *is satisfied with*

$$\delta := n \left\|(\operatorname{Trace}[\sigma])^{-1}\right\|_{L^\infty(\Omega_T)} \tag{1.18}$$

and with $\epsilon := \frac{2ny_\sigma - n}{2ny_\sigma^2}$ *provided that* $z_\sigma \leq 1 + \frac{\epsilon}{n}$.

Remark 1.8. Observe that in dimension one $z_\sigma = 1$, and thus for $n = 1$ Condition 1.1 is satisfied if $\operatorname{Trace}[\sigma] \in L^\infty(\Omega_T)$ and $(\operatorname{Trace}[\sigma])^{-1} \in L^\infty(\Omega_T)$.

We have the following compensation theorem for a time-dependent medium.

THEOREM 1.2. *Assume that* Ω *is convex, and Condition* 1.1 *is satisfied, then* $u \circ F^{-1} \in L^2(0, T, W_D^{2,2}(\Omega))$, $\partial_t(u \circ F^{-1}) \in L^2(\Omega_T)$, *and*

$$\|u \circ F^{-1}\|_{L^2(0,T,W_D^{2,2}(\Omega))} + \|\partial_t(u \circ F^{-1})\|_{L^2(\Omega_T)} \leq C\|g\|_{L^2(\Omega_T)}, \tag{1.19}$$

where C *depends on* Ω, n, δ, *and* ϵ.

Remark 1.9. According to Theorem 1.2 although the second order space derivatives and first order time derivatives of u with respect to Euclidean coordinates are only in $L^2(0, T, H^{-1}(\Omega))$, they are in $L^2(\Omega_T)$ with respect to caloric coordinates. As in the time-independent, the proof (given in subsection 2.1.2) lies on the fact that $u \circ F^{-1}$ satisfies a nondivergence form parabolic equation.

The compensation phenomena can be observed numerically. We consider in dimension $n = 2$

$$a(x, y, t) = \frac{1}{6}\left(\sum_{i=1}^{5} \frac{1.1 + \sin(2\pi x'/\epsilon_i)}{1.1 + \sin(2\pi y'/\epsilon_i)} + \sin(4x'^2 y'^2) + 1\right), \tag{1.20}$$

with $x' = x + \sqrt{2}t$, $y' = y - \sqrt{2}t$, $\epsilon_1 = \frac{1}{5}$, $\epsilon_2 = \frac{1}{13}$, $\epsilon_3 = \frac{1}{17}$, $\epsilon_4 = \frac{1}{31}$, and $\epsilon_5 = \frac{1}{65}$. This medium has been plotted in Figure 1.2 at time 0 (observe that $\lambda_{\max}(a)/\lambda_{\min}(a) \sim 100$).

Equation (1.1) has been solved numerically on that mesh with $g \equiv 1$ on the fine mesh with 16641 nodes and 32768 triangles. Figure 1.3 shows $\partial_x u$ and $\partial_x(u \circ F^{-1})$ at time 0.3. In Figures 1.4 and 1.5, the value of x_0 is set to $x_0 := (0.75, -0.25)$, and the curves $t \to u(x_0, t), u \circ F^{-1}(x_0, t), \nabla u(x_0, t)$, and $\nabla u \circ F^{-1}(x_0, t)$ are plotted from $t = 0$ to $t = 0.3$.

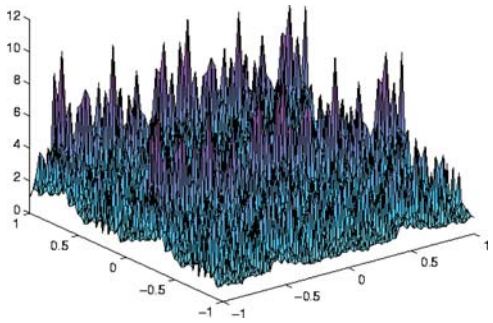


FIG. 1.2. *a at time* 0.

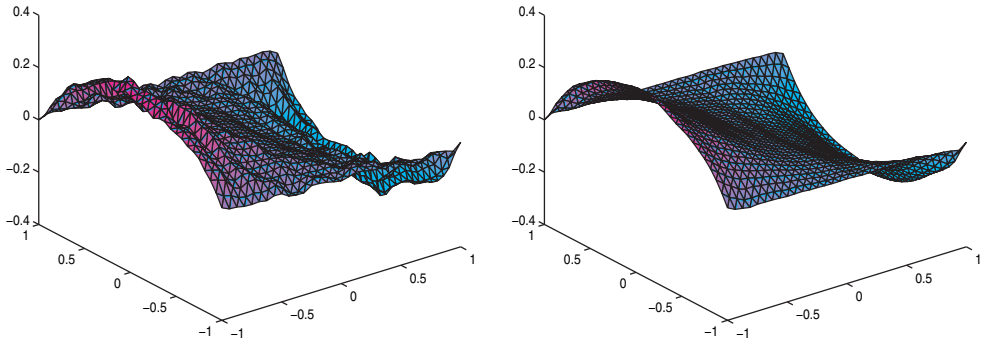
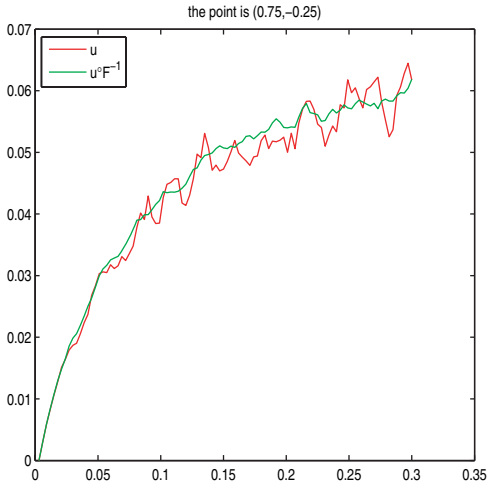


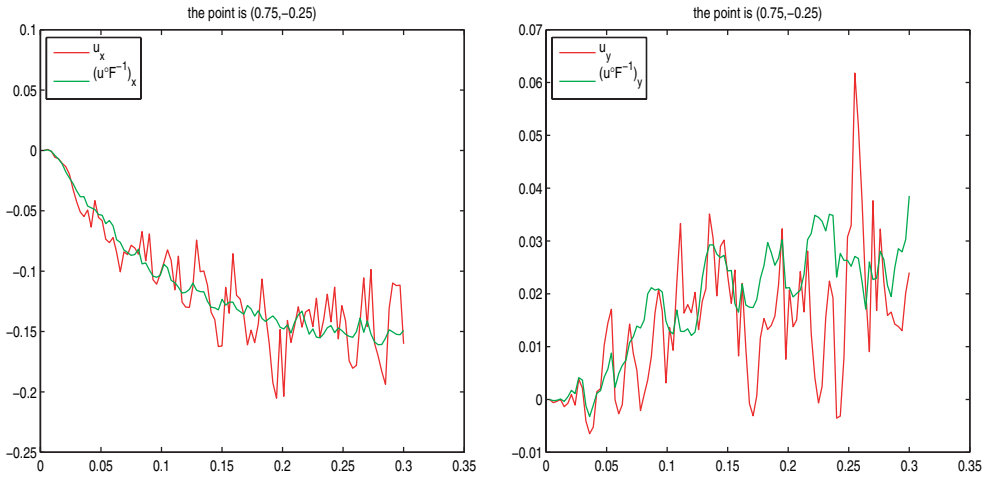
(a) $\partial_x u$. (b) $\partial_x (u \circ F^{-1})$.

FIG. 1.3. *$\partial_x u$ and $\partial_x (u \circ F^{-1})$ at time $t = 0.3$ for the multiscale trigonometric time-dependent medium.*



(a) u and $u \circ F^{-1}$.

FIG. 1.4. *$t \to u(x_0, t), u \circ F^{-1}(x_0, t)$ from $t = 0$ to $t = 0.3$, with $x_0 := (0.75, -0.25)$.*



(a) $\partial_x u$ and $\partial_x(u \circ F^{-1})$. (b) $\partial_y u$ and $\partial_y(u \circ F^{-1})$.

FIG. 1.5. $t \to \nabla u(x_0,t), \nabla u \circ F^{-1}(x_0,t)$ *from* $t=0$ *to* $t=0.3$, *with* $x_0 := (0.75,-0.25)$.

1.2. Numerical homogenization in space. Let X^h be a finite-dimensional subspace of $H_0^1(\Omega) \cap W^{1,\infty}(\Omega)$ ($W^{1,\infty}$ is the usual space of uniformly Lipschitz continuous functions) with the following approximation property: There exists a constant C_X such that for all $f \in W_D^{2,2}(\Omega)$

$$\inf_{v \in X^h} \|f - v\|_{H_0^1(\Omega)} \leq C_X h \|f\|_{W_D^{2,2}(\Omega)}. \tag{1.21}$$

It is known and easy to check that the set of piecewise linear functions on a triangulation of Ω satisfies condition (1.21) provided that the length of the edges of the triangles are bounded by h (C_X in (1.21) being given by the aspect ratio of the triangles).

For media characterized by a continuum of time scales we will consider twice differentiable elements satisfying the following usual inverse inequalities (see section 1.7 of [30]): For $v \in X^h$,

$$\|v\|_{W_D^{2,2}(\Omega)} \leq C_X h^{-1} \|v\|_{H_0^1(\Omega)}. \tag{1.22}$$

and

$$\|v\|_{H_0^1(\Omega)} \leq C_X h^{-1} \|v\|_{L^2(\Omega)}. \tag{1.23}$$

In this paper we will use splines to ensure that condition (1.22) is satisfied (observe that it requires the quasi uniformity of the (coarse) mesh, i.e., a bound on the aspect ratio of the (coarse) triangles).

For $t \in (0,T)$ let us define

$$V_h(t) := \{\varphi \circ F(x,t) \,:\, \varphi \in X^h\}. \tag{1.24}$$

Write $L^2(0,T;H_0^1(\Omega))$, the usual Sobolev space associated to the norm

$$\|v\|^2_{L^2(0,T;H_0^1(\Omega))} := \int_0^T \|v(.,t)\|^2_{H_0^1(\Omega)}\, dt. \tag{1.25}$$

Define Y_T^h, the subspace of $L^2(0,T;H_0^1(\Omega))$, as

$$Y_T^h := \{v \in L^2\big(0,T;H_0^1(\Omega)\big) : v(x,t) \in V_h(t)\ \forall t \in [0,T]\}. \tag{1.26}$$

Write u_h, the solution in Y_T^h of the following system of ordinary differential equations:

$$\begin{cases} (\psi, \partial_t u_h)_{L^2(\Omega)} + a[\psi, u_h] = (\psi, g)_{L^2(\Omega)} & \text{for all } t \in (0,T) \text{ and } \psi \in V_h(t), \\ u_h(x,0) = 0. \end{cases} \tag{1.27}$$

Write

$$a[v,w] := \int_\Omega {}^t\nabla v(x,t) a(x,t) \nabla w(x,t)\, dx. \tag{1.28}$$

1.2.1. Time-independent domain. We have the following theorem.

THEOREM 1.3. *Assume that $\partial_t a \equiv 0$, Ω is convex, $\beta_\sigma < 1$, and $(\mathrm{Trace}[\sigma])^{-1} \in L^\infty(\Omega_T)$; then*

$$\big\|(u-u_h)(.,T)\big\|_{L^2(\Omega)} + \big\|u-u_h\big\|_{L^2(0,T;H_0^1(\Omega))} \leq Ch\|g\|_{L^2(\Omega_T)}. \tag{1.29}$$

Remark 1.10. The constant C depends on C_X, n, Ω, $\lambda_{\min}(a)$, and $\|(\mathrm{Trace}[\sigma])^{-1}\|_{L^\infty(\Omega_T)}$. If $n \geq 5$, it also depends on $\|\,\mathrm{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$, and if $n = 1$, it also depends on $\lambda_{\max}(a)$.

1.2.2. Medium with a continuum of time scales.

THEOREM 1.4. *Assume that Ω is convex, and Condition* 1.1 *is satisfied; then*

$$\big\|(u-u_h)(T)\big\|_{L^2(\Omega)} + \big\|u-u_h\big\|_{L^2(0,T,H_0^1(\Omega))} \leq Ch\|g\|_{L^2(\Omega_T)}. \tag{1.30}$$

Remark 1.11. The constant C depends on C_X, n, Ω, δ, ϵ, $\lambda_{\min}(a)$, and $\lambda_{\max}(a)$.

The system of ordinary differential equations (1.27) is still characterized by a continuum of time scales in situations where the entries of a merely belong to $L^\infty(\Omega_T)$. They need to be discretized (homogenized) in time in order to be solved numerically. This will be the object of the next subsection. Loosely speaking, although (1.1) is associated to a fine tessellation and fine time steps, it is possible to approximate its operator on a coarse tessellation with coarse time steps.

1.3. Numerical homogenization in space and time. Let $M \in \mathbb{N}$, and $\{t_n = n\frac{T}{M}\}_{0\leq n\leq M}$ is a discretization of $[0,T]$. Assume (φ_i) is a basis of X^h. Write Z_T^h, the subspace of Y_T^h, such that

$$Z_T^h = \Big\{ w \in Y_T^h : w(x,t) = \sum_i c_i(t)\varphi_i\big(F(x,t)\big),\ c_i(t) \text{ are constants on } (t_n, t_{n+1}] \Big\}. \tag{1.31}$$

Write U_T^h, the subspace of Y_T^h, such that

$$U_T^h = \left\{ \psi \in Y_T^h : \psi(x,t) = \sum_i d_i\varphi_i\big(F(x,t)\big),\ d_i \text{ are constants on } [0,T] \right\}. \tag{1.32}$$

For $w \in Y_T^h$, define $w_n \in U_T^h$ by

$$w_n(x,t) := \sum_i c_i(t_n)\varphi_i(F(x,t)). \tag{1.33}$$

Write v, the solution in Z_T^h of the following system of implicit weak formulation (such that $v(x,0)\equiv 0$): For $n\in\{0,\dots,M-1\}$ and $\psi\in V$,

$$\begin{aligned}\big(\psi(t_{n+1}),v_{n+1}(t_{n+1})\big)_{L^2(\Omega)} =&\big(\psi(t_n),v_n(t_n)\big)_{L^2(\Omega)}\\ &+\int_{t_n}^{t_{n+1}}\Big(\big(\partial_t\psi(t),v_{n+1}(t)\big)_{L^2(\Omega)}\\ &-a\big[\psi(t),v_{n+1}(t)\big]+\big(\psi(t),g(t)\big)_{L^2(\Omega)}\Big)\,dt.\end{aligned}\tag{1.34}$$

The following theorem shows the stability of the implicit scheme (1.34).

THEOREM 1.5. *Let $v\in Z_T$ be the solution of* (1.34)*. We have*

$$\big\|v(T)\big\|_{L^2(\Omega)}+\|v\|_{L^2(0,T,H_0^1(\Omega))}\leq C\|g\|_{L^2(\Omega_T)}.\tag{1.35}$$

Remark 1.12. The constant C depends on n, Ω, and $\lambda_{\min}(a)$.

The following theorem gives an error bound on the accuracy of time discretization scheme (1.34) when a does not depend on time.

THEOREM 1.6. *Let $v\in Z_T$ be the solution of* (1.34) *and u_h be the solution of* (1.27)*. Assume that $\partial_t a\equiv 0$. We have*

$$\begin{aligned}\big\|(u_h-v)(T)\big\|_{L^2(\Omega)}+&\|u_h-v\|_{L^2(0,T,H_0^1(\Omega))}\leq C|\Delta t|\\ &\Big(\|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))}+\big\|g(.,0)\big\|_{L^2(\Omega)}\Big).\end{aligned}\tag{1.36}$$

Remark 1.13. The constant C depends on n, Ω, and $\lambda_{\min}(a)$.

Remark 1.14. Observe that the combination of Theorem 1.6 with Theorem 1.3 leads to the following inequality:

$$\begin{aligned}\big\|(u-u_h)(.,T)\big\|_{L^2(\Omega)}+\big\|u-u_h\big\|_{L^2(0,T;H_0^1(\Omega))}&\leq C(h+\Delta t)\\ \Big(\|g\|_{L^2(\Omega_T)}+\|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))}+\big\|g(.,0)\big\|_{L^2(\Omega)}\Big).&\end{aligned}\tag{1.37}$$

Hence the accuracy of the method is controlled by $\max(h,\Delta t)$.

The following theorem gives an error bound on the accuracy of the time discretization scheme (1.34) when a has no bounded time derivatives.

THEOREM 1.7. *Assume that Ω is convex, and Condition* 1.1 *is satisfied. Let $v\in Z_T$ be the solution of* (1.34) *and u_h be the solution of* (1.27)*, and we have*

$$\big\|(u_h-v)(T)\big\|_{L^2(\Omega)}+\|u_h-v\|_{L^2(0,T,H_0^1(\Omega))}\leq C\frac{|\Delta t|}{h}\|g\|_{L^2(\Omega_T)},\tag{1.38}$$

where C depends on Ω, n, δ, ϵ, $\lambda_{\min}(a)$, and $\lambda_{\max}(a)$.

Remark 1.15. Observe that the accuracy of the time discretization scheme (1.34) requires that $|\Delta t|<<h$ when a has no bounded time derivatives. Indeed the combination of Theorem 1.7 with (1.30) leads to the following inequality:

$$\begin{aligned}\big\|(u-u_h)(.,T)\big\|_{L^2(\Omega)}+\big\|u-u_h\big\|_{L^2(0,T;H_0^1(\Omega))}&\leq C\left(h+\frac{\Delta t}{h}\right)\\ &\|g\|_{L^2(\Omega_T)}.\end{aligned}\tag{1.39}$$

Hence the accuracy of the method is controlled by h if one chooses $\Delta t\sim h^2$. The fact that one must chose $\Delta t\sim h^2$ for optimal accuracy is a standard phenomenon for parabolic equations, and we refer to [48] for a reminder.

We refer to section 3 for numerical experiments.

1.4. Remarks on caloric coordinates F. In numerical simulations a is given as mapping from a fine mesh triangulation Ω into the set of positive definite symmetric matrices. In other words (in the time-independent case, for instance), a is a constant matrix in each triangle of a given fine mesh. In the time-dependent case on each fine mesh triangle a is a step function from $[0,T]$ into the set of positive definite symmetric matrices.

The caloric coordinates F have been computed on the same fine triangulation of Ω associated to a through a standard finite element method.

The homogenization results given above assume an underlying continuous medium and that F is a function on that continuous medium. As has been mentioned in [60] the proofs given in this paper can be extended to the case where the underlying medium is discrete. Indeed the core of those proofs is based on Theorems 2.1 and 2.2, which are straightforward adaptations of Theorem 1.2.1 of [52], and those theorems can be extended to the discrete case.

A similar issue lies in the fact that a may be a mapping from the continuous medium Ω. In that case the equation solved in practice is not (1.1) but a discretization of (1.1) associated to a discretization of a over a fine mesh triangulation of Ω. The control of the error between the solution of (1.1) and the discrete counterpart of (1.1) is standard.

1.5. Literature and further remarks. For early works on homogenization with random mixing coefficients we refer to [62], [45], [61], [64], [78], [46], [47], [37]. Papanicolaou, Stroock, and Varadhan [63] have considered a two-component Markov process $(x(t), y(t))$, where $y(t)$ is rapidly varying (and is not assumed to be ergodic in dimension one) and enters in the coefficients of the stochastic process driving $x(t)$. They have studied the convergence properties of $x(t)$ as the fluctuations of $y(t)$ becomes more rapid using the martingale approach to diffusion, developed by Stroock and Varadhan [67], [66], [69], [68].

Methods dealing with problems involving multiple scales are numerous and not limited to the ones cited in this paper. As an example of a different approach, we refer to [2], where the concept of Young measure on micropatterns is introduced to study variational problems leading to multiple small scales involving a small parameter.

The numerical homogenization method implemented in this paper is a finite element method. The idea of using oscillating test functions can be tracked back to the work of Murat and Tartar on homogenization and H-convergence; we refer in particular to [71] and [54]. Those papers also contain convergence proofs for the finite element method in an abstract setting for a sequence of H-converging elliptic operators (recall that the framework of H-convergence is independent from ergodicity or scale separation assumptions and is based on the compactness of any sequence of solutions of $-\operatorname{div} a_\epsilon \nabla u_\epsilon = g$, with uniformly bounded and elliptic conductivities a_ϵ; we also refer to the initial work of Spagnolo [65] for G-convergence).

The numerical implementation and practical application of oscillating test functions in numerical finite element homogenization have been called multiscale finite element methods and have been studied by several authors [8], [29], [55], [41], [40], [35], [39], [5]. The work of Hou and Wu [41] has been a large source of inspiration in numerical applications (particularly for reservoir modeling in geophysics; we refer to [74], [49], [1], [75] for recent developments) since it was leading to a coarse scale operator while keeping the fine scale structures of the solutions. The construction of the base functions is decoupled from element to element, leading to a scheme adapted to parallel computers. A proof of the convergence of the method is given in periodic

settings when the size of the heterogeneities is smaller than the grid size, and an oversampling technique is proposed to remove the so-called cell resonance error [42] when the size of the heterogeneities is comparable to the grid size.

Allaire and Brizzi [5] have introduced the composition rule in the formulation of a multiscale finite element and observed that a multiscale finite element method with higher order Lagrange polynomials would have a better accuracy. In fact, Babuska et al. introduced a so-called change of variable technique in the general setting of the partition of unity method using a p-version of finite elements. In [8], a special class of second order elliptic problems with essentially one-dimensional rough coefficients $a(x,y)=a(x)$ was considered. In [56], [57], conformal mapping was used to map the rough solution to a smoother function for elliptic problems in two dimensions with corners or interfaces.

In [60], we proved that if u is the solution of the divergence form elliptic equation

$$\begin{cases} -\operatorname{div}\big(a(x)\nabla u(x)\big)=g \quad \text{in} \quad \Omega,\\ u=0 \quad \text{in} \quad \partial\Omega, \end{cases} \tag{1.40}$$

and F are caloric coordinates defined by

$$\begin{cases} \operatorname{div} a\nabla F=0 \quad \text{in} \quad \Omega,\\ F(x)=x \quad \text{on} \quad \partial\Omega, \end{cases} \tag{1.41}$$

then, under the Cordes-type condition $\beta_\sigma<1$ on σ given by (1.4), one has for some $p>2$

$$\|u\circ F^{-1}\|_{W^{2,p}(\Omega)}\leq C\|g\|_{L^p(\Omega)}. \tag{1.42}$$

It has been deduced from this compensation phenomenon that numerical homogenization methods based on oscillating finite elements can converge in the presence of a continuum of scales if one uses global caloric coordinates to obtain the test functions instead of solutions of a local cell problem [60]. In dimension three and higher it has been known since the work of Fenchenko and Khruslov [34], [44] that the homogenization of divergence form elliptic operators $-\operatorname{div} a_\epsilon\nabla u_\epsilon=g$ can lead to a nonlocal homogenized operator if the sequence of matrices a_ϵ is uniformly elliptic but with entries uniformly bounded only in $L^1(\Omega)$. From a numerical point of view these nonlocal effects imply that a nonlocal numerical homogenization method cannot be avoided to obtain accuracy. Hence in [60], it is shown that the accuracy of local methods depends on the aspect ratio of the triangles of the tessellation with respect to caloric coordinates (which is not the case if one uses nonlocal finite elements; we refer to [60] for further discussions on the apparition of nonlocal effects in numerical homogenization). Recently Briane has shown [21] that this nonlocal effect is absent in dimension two in the H-convergence setting.

The phenomenon is similar here; however, observe that, if one has solved the initial parabolic equation at least n times and those solutions are (locally) linearly independent, it is also possible to use them as new coordinates for numerical homogenization. Observe that in dimension higher than three the caloric coordinates are not always invertible; an idea to bypass this difficulty could be either to choose the change of coordinates locally and adaptively or to enrich the coordinates by writing down the initial equations as degenerate equations in a space of higher dimension [72]; these points have not been explored. For divergence form elliptic equations, recall that fast methods based on hierarchical matrices are available [14], [13], [12], [10], [11] for solving

(1.40) and (1.41) in $O\big(N(\ln N)^{n+3}\big)$ operations (or in $O(N)$ operations using iterative methods (see [76], [77]), N being the number of interior nodes of the fine mesh).

The issue of numerical homogenization partial differential equations with heterogeneous coefficients has received a great deal of attention, and many methods have been proposed. A few of them are cited below.

- multiscale finite volume methods [50];
- heterogeneous multiscale methods [28], [24];
- wavelet-based homogenization [38], [27], [25], [17], [7], [19];
- residual-free bubble methods [20];
- discontinuous enrichment methods [33], [32];
- partition of unity methods [36];
- energy-minimizing multigrid methods [73].

Following [60], it is possible to implement a finite volume method based on the compensation theorems given in this paper. The elements given in this paper contain the fine scale structure of F, and has been done in [60], and it is possible to approximate the initial parabolic operator by a homogenized parabolic operator associated to the coarse mesh (the test functions in this case would be piecewise linear on the coarse mesh, and the approximation error associated to the homogenized operator would depend on the aspect ratio of the triangles of the coarse mesh in the metric induced by F).

In this paper a has been assumed to be bounded and uniformly elliptic. Without these assumptions the diffusion associated to a homogenized operator can be anomalously slow [15], [58] or fast (superdiffusive) [59]. If a has an unbounded skew symmetric component, the homogenization of (1.1) can give rise to a degenerate operator [59].

2. Proofs.

2.1. Compensation.

2.1.1. Time-independent medium: Proof of Theorem 1.1. We will need the following lemmas. Let $\mathcal{A}_T$ be the bilinear form on $L^2\big(0,T;H_0^1(\Omega)\big)$ defined by

$$\mathcal{A}_T[v,w] := \int_0^T a[v,w](t)\,dt, \tag{2.1}$$

where

$$a[v,u](t) := \int_\Omega {}^t\nabla v(x,t)a(x,t)\nabla u(x,t)\,dx. \tag{2.2}$$

We write $\mathcal{A}_T[u] := \mathcal{A}_T[u,u]$. The following lemmas are standard energy estimates, and we refer to [31, section 7.1.2] for a reminder.

LEMMA 2.1. *We have*

$$\big\|u(.,T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[u] \leq \frac{C_{n,\Omega}}{\lambda_{\min}(a)}\|g\|^2_{L^2(\Omega_T)}. \tag{2.3}$$

LEMMA 2.2. *Assume $\partial_t a \equiv 0$, and we have*

$$\big\|\partial_t u\big\|^2_{L^2(\Omega_T)} + a\big[u(.,T)\big] \leq \big\|g\big\|^2_{L^2(\Omega_T)}. \tag{2.4}$$

LEMMA 2.3. *Assume $\partial_t a \equiv 0$, and we have*

$$\big\|\partial_t u(.,T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[\partial_t u] \leq \frac{C_{n,\Omega}}{\lambda_{\min}(a)}\|\partial_t g\|^2_{L^2(0,T,H^{-1}(\Omega))} + \big\|g(.,0)\big\|^2_{L^2(\Omega)}. \tag{2.5}$$

We now need a variation of Campanato's result [23] on nondivergence form elliptic operators. Let us write for a symmetric matrix M

$$\nu_M := \frac{\mathrm{Trace}(M)}{\mathrm{Trace}({}^tMM)}. \tag{2.6}$$

We consider the following Dirichlet problem:

$$L_M v = f, \tag{2.7}$$

with $L_M := \sum_{i,j=1}^n M_{ij}(x)\partial_i\partial_j$. The following Theorems 2.1 and 2.2 are straightforward adaptations of Theorem 1.2.1 of [52]. They are proven in [52] under the assumption that M is bounded and elliptic. It is easy to check that the conditions $\beta_M < 1$ and $\nu_M \in L^\infty(\Omega)$ are sufficient for the validity of those theorems. We refer to [60] for that adaptation.

THEOREM 2.1. *Assume that $\beta_M < 1$, $\nu_M \in L^\infty(\Omega)$, and Ω is convex. Then if $f \in L^2(\Omega)$, the Dirichlet problem* (2.7) *has a unique solution satisfying*

$$\|v\|_{W_D^{2,2}(\Omega)} \leq \frac{C}{1-\beta_M^{\frac{1}{2}}}\|\nu_M f\|_{L^2(\Omega)}. \tag{2.8}$$

Remark 2.1. β_M is the Cordes parameter associated to M.

THEOREM 2.2. *Assume that $\beta_M < 1$, $\nu_M \in L^\infty(\Omega)$, and Ω is convex. Then there exists a real number $p_0 > 2$ depending only on n, Ω, and β_M such that for each $f \in L^p(\Omega)$, $2 \leq p < p_0$, the Dirichlet problem* (2.7) *has a unique solution satisfying*

$$\|v\|_{W_D^{2,p}(\Omega)} \leq \frac{C_{n,\Omega,p}}{1-\beta_M^{\frac{1}{2}}}\|\nu_M f\|_{L^p(\Omega)}. \tag{2.9}$$

Let us now prove the compensation theorems. Choose

$$M := \frac{\sigma}{|\det(\nabla F)|^{\frac{1}{2}}} \circ F^{-1}. \tag{2.10}$$

It is easy to check that $\beta_\sigma < 1$ implies that F is a homeomorphism from Ω onto Ω, and thus (2.10) is well defined. Moreover observe that $\beta_M = \beta_\sigma$ and

$$\|\nu_M\|^2_{L^\infty(\Omega_T)} \leq \frac{C_n}{(\lambda_{\min}(a))^{\frac{n}{2}}}\big\|(\mathrm{Trace}[\sigma])^{\frac{n}{4}-1}\big\|^2_{L^\infty(\Omega_T)}. \tag{2.11}$$

Fix $t \in [0,T]$. Choose

$$f := \frac{(\partial_t u - g)}{|\det(\nabla F)|^{\frac{1}{2}}} \circ F^{-1}. \tag{2.12}$$

Observe that by the change of variable $y = F(x)$ one obtains that, if $\partial_t a \equiv 0$ (which implies that F is time-independent), $\partial_t u \in L^2(\Omega)$, and $g(.,t) \in L^2(\Omega)$, $f \in L^2(\Omega)$ and

$$\|f\|_{L^2(\Omega)} \leq \|\partial_t u\|_{L^2(\Omega)} + \|g\|_{L^2(\Omega)}. \tag{2.13}$$

It follows from Theorem 2.1 that there exists a unique $v \in W_D^{2,2}(\Omega)$ satisfying

$$\|v\|^2_{W_D^{2,2}(\Omega)} \leq \frac{C\|\nu_M\|^2_{L^\infty(\Omega_T)}}{(1-\beta_\sigma^{\frac{1}{2}})^2}\big(\|\partial_t u\|^2_{L^2(\Omega)} + \|g\|^2_{L^2(\Omega)}\big) \tag{2.14}$$

and the following equation:

$$\partial_t \hat{u}(y,t) = \sum_{i,j} \big(\sigma(F^{-1}(y,t),t)\big)_{i,j} \partial_i \partial_j v(y,t) + \hat{g}(y,t). \tag{2.15}$$

We use the notation $\hat{g} := g \circ F^{-1}$ and $\hat{u} := u \circ F^{-1}$. Using the change of variable $y = F(x)$ and using the property $\operatorname{div} a\nabla F = 0$ when $\partial_t a \equiv 0$, we obtain that (2.15) can be written

$$\partial_t u = \operatorname{div}\big(a\nabla(v \circ F)\big) + g. \tag{2.16}$$

If $\partial_t u \in L^2(\Omega)$ and $g(.,t) \in L^2(\Omega)$, we can use the uniqueness property of the solution of the divergence form elliptic Dirichlet problem

$$\operatorname{div}\big(a\nabla w\big) = \partial_t u - g \tag{2.17}$$

to obtain that $v \circ F = u$. Assume that $g \in L^2(\Omega_T)$ and $\partial_t u \in L^2(\Omega_T)$. It follows that, for $t \in [0,T] - B$, $g(.,t) \in L^2(\Omega)$ and $\partial_t u(.,t) \in L^2(\Omega)$, where B is a subset of $[0,T]$ of 0-Lebesgue measure. It follows from the previous arguments that, on $[0,T] - B$, $u \circ F^{-1}(.,t) \in W_D^{2,2}(\Omega)$ and satisfies

$$\|u \circ F^{-1}(.,t)\|^2_{W_D^{2,2}(\Omega)} \leq \frac{C\|\nu_M\|^2_{L^\infty(\Omega_T)}}{(1-\beta_\sigma^{\frac{1}{2}})^2}\big(\|\partial_t u(.,t)\|^2_{L^2(\Omega)} + \|g(.,t)\|^2_{L^2(\Omega)}\big). \tag{2.18}$$

Integrating (2.18) with respect to time we obtain that $u \circ F^{-1} \in L^2(0,T,W_D^{2,2}(\Omega))$ and that

$$\|u \circ F^{-1}\|^2_{L^2(0,T,W_D^{2,2}(\Omega))} \leq \frac{C\|\nu_M\|^2_{L^\infty(\Omega_T)}}{(1-\beta_\sigma^{\frac{1}{2}})^2}\big(\|\partial_t u\|^2_{L^2(\Omega_T)} + \|g\|^2_{L^2(\Omega_T)}\big). \tag{2.19}$$

Thus using Lemma 2.2 we have obtained Theorem 1.1.

In situations where $g \in L^\infty(0,T,L^2(\Omega))$, $\partial_t g \in L^2(0,T,H^{-1}(\Omega))$, or $g \in L^p(\Omega_T)$, with $p > 2$, one can obtain a higher regularity for $u \circ F^{-1}$. This is the object of the following theorems.

THEOREM 2.3. *Assume that Ω is convex, $g \in L^\infty(0,T,L^2(\Omega))$, $\partial_t g \in L^2(0,T,H^{-1}(\Omega))$, $\partial_t a \equiv 0$, $\beta_\sigma < 1$, and $(\operatorname{Trace}[\sigma])^{\frac{n}{4}-1} \in L^\infty(\Omega_T)$; then for all $t \in [0,T]$, $u \circ F^{-1}(.,t) \in W_D^{2,2}(\Omega)$ and*

$$\|u \circ F^{-1}(.,t)\|_{W_D^{2,2}(\Omega)} \leq \frac{C}{1-\beta_\sigma^{\frac{1}{2}}}\Big(\big\|g\big\|_{L^\infty(0,T,L^2(\Omega))} + \|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))}\Big). \tag{2.20}$$

Remark 2.2. The constant C can be written

$$C = \frac{C_{n,\Omega}}{(\lambda_{\min}(a))^{\frac{n}{4}}}\big\|(\operatorname{Trace}[\sigma])^{\frac{n}{4}-1}\big\|_{L^\infty(\Omega_T)}\left(1 + \frac{1}{\lambda_{\min}(a)}\right)^{\frac{1}{2}}.$$

THEOREM 2.4. *Assume that Ω is convex, $g(.,0) \in L^2(\Omega)$, $\partial_t g \in L^2(0,T,H^{-1}(\Omega))$, $g \in L^p(\Omega_T)$, $\partial_t a \equiv 0$, $\beta_\sigma < 1$, and $(\operatorname{Trace}[\sigma])^{\frac{n}{4}-1} \in L^\infty(\Omega_T)$; then there exists a real number $p_0 > 2$ depending only on n, Ω, and β_σ such that for each p such that $2 \leq p < p_0$ one has*

$$\begin{aligned}\|u \circ F^{-1}\|_{L^p(0,T,W_D^{2,p}(\Omega))} \leq & \frac{C}{1-\beta_\sigma^{\frac{1}{2}}}\big(\|g\|_{L^p(\Omega_T)} \\ & + \big\|g(.,0)\big\|_{L^2(\Omega)} + \|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))}\big).\end{aligned} \tag{2.21}$$

Remark 2.3. The constant C can be written

$$C = \frac{C_{n,\Omega,p}}{(\lambda_{\min}(a))^{\frac{n}{4}}} \left\| (\mathrm{Trace}[\sigma])^{\frac{n}{4}-1} \right\|_{L^\infty(\Omega_T)} \left(1 + \frac{1}{\lambda_{\min}(a)}\right)^{\frac{1}{2}}.$$

Write

$$\|v\|_{C^\gamma(\Omega)} := \sup_{x,y\in\Omega, x\neq y} \frac{|v(x)-v(y)|}{|x-y|^\gamma}. \tag{2.22}$$

THEOREM 2.5. *Assume that $n \leq 2$, Ω is convex, $g(.,0) \in L^2(\Omega)$, $\partial_t g \in L^2(0, T, H^{-1}(\Omega))$, $g \in L^p(\Omega_T)$, $\partial_t a \equiv 0$, $\beta_\sigma < 1$, $(\mathrm{Trace}[\sigma])^{-1} \in L^\infty(\Omega_T)$, and $g \in L^2[0,T; L^{p^*}(\Omega)]$, with $2 < p^*$. Then there exists $p \in (2, p^*]$ and $\gamma(p) > 0$ such that*

$$\left(\int_0^T \left\| \nabla(u \circ F^{-1})(.,t) \right\|^2_{C^\gamma(\Omega)} dt \right)^{\frac{1}{2}} \leq \frac{C}{1-\beta_\sigma^{\frac{1}{2}}} \big(\|g\|_{L^p(\Omega_T)} + \left\| g(.,0) \right\|_{L^2(\Omega)} + \|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))} \big). \tag{2.23}$$

Remark 2.4. The constant C in (2.23) depends on n, p, Ω, $\lambda_{\min}(a)$, and $\|(\mathrm{Trace}(\sigma))^{-1}\|_{L^\infty(\Omega_T)}$. It is easy to check that if $n = 1$, then the theorem is valid with $\gamma = 1/2$.

Using Lemma 2.3 we can prove Theorem 2.3.

Let us now prove Theorem 2.4. Assume that there exists $q_0 > 2$ such that, for $2 \leq p < q_0$, $\partial_t u \in L^p(\Omega_T)$ and $g \in L^p(\Omega_T)$. Let us now apply Theorem 2.2 with $p < \min(p_0, q_0)$, M given by (2.10), and f given by (2.12). It follows that, for $t \in [0,T] - B$ (where B is a subset of $[0,T]$ of 0-Lebesgue measure), $g(.,t) \in L^p(\Omega)$ and $\partial_t u(.,t) \in L^p(\Omega)$. We deduce from Theorem 2.2 and the argumentation related to (2.17) that, on $[0,T] - B$, $u \circ F^{-1}(.,t) \in W_D^{2,p}(\Omega)$ and

$$\|u \circ F^{-1}(.,t)\|^p_{W_D^{2,p}(\Omega)} \leq \frac{C_{n,p,\Omega} \|\nu_M\|^p_{L^\infty(\Omega_T)}}{(1-\beta_\sigma^{\frac{1}{2}})^p} \big(\|\partial_t u(.,t)\|^p_{L^p(\Omega)} + \|g(.,t)\|^p_{L^p(\Omega)} \big). \tag{2.24}$$

Integrating (2.24) with respect to time, we have $u \circ F^{-1} \in L^p(0,T,W_D^{2,p}(\Omega))$ and

$$\|u \circ F^{-1}\|_{L^p(0,T,W_D^{2,p}(\Omega))} \leq \frac{C_{n,p,\Omega} \|\nu_M\|_{L^\infty(\Omega_T)}}{1-\beta_\sigma^{\frac{1}{2}}} \big(\|\partial_t u\|_{L^p(\Omega_T)} + \|g\|_{L^p(\Omega_T)} \big). \tag{2.25}$$

It remains to show that, under the assumptions of Theorem 2.4, $\partial_t u \in L^p(\Omega_T)$.

In order to bound $\left\|\partial_t u(.,t)\right\|_{L^p(\Omega)}$ we use general Sobolev inequalities (chapter 5.6 of [31]).

- If $n \geq 3$, write $p^* = 2n/(n-2)$. We have for $2 < p \leq p^*$

$$\left(\int_\Omega (\partial_t u)^p \, dx \right)^{\frac{2}{p}} \leq C_{n,\Omega} \left(\int_\Omega (\partial_t u)^{p^*} \, dx \right)^{\frac{2}{p^*}}, \tag{2.26}$$

and thus, using the Gagliardo–Nirenberg–Sobolev inequality,

$$\left(\int_\Omega (\partial_t u)^p \, dx \right)^{\frac{2}{p}} \leq C_{n,p,\Omega} \frac{1}{\lambda_{\min}(a)} a[\partial_t u]. \tag{2.27}$$

- If $n = 2$, we write, for $(x_1, x_2, x_3) \in \Omega \times (0,1)$, $v(x_1, x_2, x_3) := \partial_t u(x_1, x_2)$. Using the Gagliardo–Nirenberg–Sobolev inequality in dimension three we obtain that for $2 < p \leq 6$

$$\left(\int_\Omega (\partial_t u)^p \, dx \right)^{\frac{2}{p}} \leq C_{n,p,\Omega} \int_\Omega (\nabla \partial_t u)^2 \, dx, \tag{2.28}$$

  which leads us to (2.27).
- If $n = 1$, then using Morrey's inequality we obtain that, with $\gamma := 1/2$,

$$\|\partial_t u\|^2_{C^{0,\gamma}(\Omega)} \leq C_\Omega \frac{1}{\lambda_{\min}(a)} a[\partial_t u]. \tag{2.29}$$

We conclude the proof of Theorem 2.4 by using Lemma 2.3.

We deduce Theorem 2.5 from Morrey's inequality and Theorem 2.4.

Hölder continuity for $n \geq 3$ or nonconvexity of Ω. In this paragraph we will not assume Ω to be convex. Let $N^{p,\lambda}(\Omega)$ $(1 < p < \infty,\ 0 < \lambda < n)$ be the weighted Morrey space formed by the functions $v : \Omega \to \mathbb{R}$ such that $\|v\|_{N^{p,\lambda}(\Omega)} < \infty$, with

$$\|v\|_{N^{p,\lambda}(\Omega)} := \sup_{x_0 \in \Omega} \left(\int_\Omega |x - x_0|^{-\lambda} |v(x)|^p \right)^{\frac{1}{p}}. \tag{2.30}$$

To obtain the Hölder continuity of $u \circ F^{-1}$ in dimension $n \geq 3$ we use Corollary 4.1 of [51]. We give the result of Leonardi below in a form adapted to our context. Consider the Dirichlet problem (2.7). We write $W^{2,p,\lambda}(\Omega)$, the functions in $W^{2,p}_D(\Omega)$, such that their second order derivatives belong to $N^{p,\lambda}(\Omega)$.

THEOREM 2.6. *There exist a constant $C^* = C^*(n, p, \lambda, \partial\Omega) > 0$ such that if $\beta_M < C^*$ and $f \in N^{p,\lambda}(\Omega)$, then the Dirichlet problem (2.7) has a unique solution in $W^{2,p,\lambda} \cap W^{1,p}_0(\Omega)$. Moreover, if $0 < \lambda < n < p$, then $\nabla v \in C^\alpha(\Omega)$, with $\alpha = 1 - n/p$ and*

$$\|\nabla v\|_{C^\alpha(\Omega)} \leq \frac{C}{\lambda_{\min}(M)} \|f\|_{N^{p,\lambda}(\Omega)}, \tag{2.31}$$

where $C = C(n, p, \lambda, \partial\Omega)$.

Now we have the compensation theorem in the nonconvex case.

THEOREM 2.7. *Assume $n \geq 2$ and $\partial_t a \equiv 0$. Let $p > 2$. There exists a constant $C^* = C^*(n, \partial\Omega) > 0$, a real number $\gamma > 0$, depending only on n, Ω, and p such that if $\beta_\sigma < C^*$, then*

$$\left(\int_0^T \left\| \nabla (u \circ F^{-1})(., t) \right\|^2_{C^\gamma(\Omega)} dt \right)^{\frac{1}{2}} \leq C \big(\|g\|_{L^p(\Omega_T)} + \|g(., 0)\|_{L^2(\Omega)} + \|\partial_t g\|_{L^2(0,T,H^{-1}(\Omega))} \big). \tag{2.32}$$

Remark 2.5. The constant C in (2.32) depends on n, γ, Ω, C^*, $\lambda_{\min}(a)$, and $\left\| (\mathrm{Trace}(\sigma))^{\frac{n}{2p}-1} \right\|_{L^\infty(\Omega_T)}$.

Remark 2.6. Compared with the convex case, we have to assume F is an automorphism. Theorem 2.7 shows that convexity is not needed, but without convexity the Cordes-type assumption $\beta_\sigma < C^*$ is stronger than $\beta_\sigma < 1$.

The proof of Theorem 2.7 is an application of Theorem 2.6. We just need to observe that from the Hölder inequality we have for $0 < \epsilon < 0.5$

$$\|f\|_{N^{p,\epsilon}(\Omega)} \leq C_{n,p,\Omega,\epsilon} \|f\|_{L^{p(1+\epsilon)}(\Omega)}. \tag{2.33}$$

From this point the proof is similar to the proof of Theorem 2.4.

2.1.2. Medium with a continuum of time scales: Proof of Theorem 1.2. We will need Theorems 1.6.2 and 1.6.3 of [52]. For the sake of completeness we will recall those theorems below in a version adapted to our framework. Consider the following parabolic problem:

$$\partial_t v = \sum_{i,j=1}^{n} M_{ij}(x)\partial_i\partial_j v + f. \tag{2.34}$$

We assume M to be symmetric bounded and elliptic and $v = 0$ at $t = 0$ and on the boundary $\partial\Omega$. Write

$$\eta_M := \sup_{x\in\Omega_T} \frac{\mathrm{Trace}[{}^tMM] + 1}{\big(\mathrm{Trace}[M] + 1\big)^2} \tag{2.35}$$

and

$$\alpha_M := \sup_{x\in\Omega_T} \frac{\mathrm{Trace}[M] + 1}{\mathrm{Trace}[{}^tMM] + 1}. \tag{2.36}$$

Write for $p \geq 2$

$$S_p(\Omega_T) := \Big\{ v \in L^p\big(0, T, W_D^{2,p}(\Omega)\big); \partial_t v \in L^p(\Omega_T); v(.,0) \equiv 0 \Big\} \tag{2.37}$$

and

$$\|v\|^p_{S_p(\Omega_T)} := \int_{\Omega_T} \left(\sum_{i,j} (\partial_i\partial_j v)^2 + (\partial_t v)^2 \right)^{\frac{p}{2}} dy\, dt. \tag{2.38}$$

THEOREM 2.8. *Assume Ω to be convex and that there exists $\epsilon \in (0,1)$ such that $\eta_M \leq 1/(n+\epsilon)$; then for each $f \in L^2(\Omega_T)$ the Cauchy–Dirichlet problem* (2.34) *admits a unique solution in $S_2(\Omega_T)$ which satisfies the bound*

$$\|v\|_{S_2(\Omega_T)} \leq \frac{\alpha_M}{1 - \sqrt{1-\epsilon}} \|f\|_{L^2(\Omega_T)}. \tag{2.39}$$

THEOREM 2.9. *Assume Ω to be convex and that there exists $\epsilon \in (0,1)$ such that $\eta_M \leq 1/(n+\epsilon)$; then there exists a number $p_0 > 2$ depending on Ω, n, ϵ such that for each $f \in L^p(\Omega_T)$ the Cauchy–Dirichlet problem* (2.34) *admits a unique solution in $S_p(\Omega_T)$ which satisfies the bound*

$$\|v\|_{S_p(\Omega_T)} \leq C_p \frac{\alpha_M}{1 - \sqrt{1-\epsilon}} \|f\|_{L^p(\Omega_T)}. \tag{2.40}$$

Remark 2.7. In fact Theorem 1.6.3 of [52] is written with $1 - C(p)\sqrt{1-\epsilon}$ in the denominator of (2.40), but it is easy to modify it to obtain (2.40) by lowering the value of p_0 and changing the value of C_p.

Let $\delta > 0$. Let us now prove Proposition 1.1. Write $x = \mathrm{Trace}[\sigma]$ and $z = n\frac{\mathrm{Trace}[{}^t\sigma\sigma]}{(\mathrm{Trace}[\sigma])^2}$ (observe that $1 \leq z \leq n$). It is easy to check that Condition 1.1 can be written

$$-\delta^2 x^2 \left(\frac{\epsilon + n}{n} z - 1 \right) + 2x\delta - (n + \epsilon - 1) \geq 0. \tag{2.41}$$

Choose $\delta = n\big\|(\mathrm{Trace}[\sigma])^{-1}\big\|_{L^\infty(\Omega_T)}$. Observing that $\delta x \geq n$ and $\delta x = n y_\sigma$ it is easy to conclude the proof of Proposition 1.1. Similarly one obtains the following lemma by straightforward computation from (2.41).

LEMMA 2.4. *Assume that Condition* 1.1 *is satisfied; then* $\mu_\sigma < C(n, \epsilon, \delta)$

$$\big\|(\mathrm{Trace}[\sigma])^{-1}\big\|_{L^\infty(\Omega_T)} \leq C(n, \epsilon, \delta) \tag{2.42}$$

and

$$\big\|\,\mathrm{Trace}[\sigma]\big\|_{L^\infty(\Omega_T)} \leq C(n, \epsilon, \delta). \tag{2.43}$$

Let us now apply Theorem 2.8 on $[0, T/\delta]$ with

$$M := \delta\sigma \circ F^{-1}(y, \delta t) \tag{2.44}$$

and

$$f := \delta(g \circ F^{-1})(y, \delta t). \tag{2.45}$$

Observe that if Condition 1.1 is satisfied, then F is a homeomorphism and M is well-defined, bounded, and elliptic. Moreover $\eta_M < \infty$ and $\alpha_M < \infty$ since

$$\mathrm{esssup}_{\Omega_{\frac{T}{\delta}}} \frac{\mathrm{Trace}[{}^t M M] + 1}{\big(\,\mathrm{Trace}[M] + 1\big)^2} = \mathrm{esssup}_{\Omega_T} \frac{\delta^2\,\mathrm{Trace}[{}^t\sigma\sigma] + 1}{\big(\delta\,\mathrm{Trace}[\sigma] + 1\big)^2}\,. \tag{2.46}$$

It follows that the following equation admits a unique solution in $S_2(\Omega_{\frac{T}{\delta}})$:

$$\partial_t w(y,t) = \sum_{i,j} M_{i,j}(y,t)\partial_i\partial_j w(y,t) + k(y,t), \tag{2.47}$$

with $k(y,t) = \delta\hat{g}(y, \delta t)$. We also have

$$\int_0^{\frac{T}{\delta}} \int_\Omega \left((\partial_t w)^2 + \sum_{i,j} (\partial_i\partial_j w)^2 \right) dy\, dt \leq \frac{C}{(1 - \sqrt{1-\epsilon})^2} \|f\|_{L^2(\Omega_{\frac{T}{\delta}})}. \tag{2.48}$$

Using the change of variables $t \to \delta t$ and writing

$$w(y,t) := v(y, \delta t), \tag{2.49}$$

we obtain that v satisfies the following equation on Ω_T:

$$\partial_t v(y,t) = \sum_{i,j} \big(\sigma(F^{-1}(y,t), t)\big)_{i,j} \partial_i\partial_j v(y,t) + \hat{g}(y,t). \tag{2.50}$$

Using the change of variable $y = F(x)$ and observing that $\partial_t F = \mathrm{div}\, a\nabla F$, we obtain that $v \circ F$ satisfies

$$\partial_t(v \circ F) = \mathrm{div}\,\big(a\nabla(v \circ F)\big) + g. \tag{2.51}$$

It follows from the uniqueness of the solution of (2.51) that $u = v \circ F$. In resume we have obtained Theorem 1.2 (we use Lemma 2.4 to control the constants).

Similarly we obtain the following theorems in situations where $g \in L^p(\Omega_T)$, with $p > 2$.

THEOREM 2.10. *Assume that Ω is convex and Condition 1.1 is satisfied; then there exists a number $p_0 > 2$ depending on n, Ω, ϵ such that, for $p \in (2, p_0)$, $u \circ F^{-1} \in L^p(0, T, W_D^{2,p}(\Omega))$, $\partial_t(u \circ F^{-1}) \in L^p(\Omega_T)$, and*

$$\|u \circ F^{-1}\|_{L^p(0,T,W_D^{2,p}(\Omega))} + \|\partial_t(u \circ F^{-1})\|_{L^p(\Omega_T)} \leq C\|g\|_{L^p(\Omega_T)}, \tag{2.52}$$

where C depends on Ω, n, δ, and ϵ.

THEOREM 2.11. *Assume that Ω is convex and Condition 1.1 is satisfied; then there exists a number $\alpha_0 > 2$ depending on n, Ω, ϵ, p such that, for $\alpha \in (0, \alpha_0)$, $\nabla(u \circ F^{-1}) \in L^2(0, T, C^\alpha(\Omega))$ and*

$$\|\nabla(u \circ F^{-1})\|_{L^2(0,T,C^\alpha(\Omega))} \leq C\|g\|_{L^p(\Omega_T)}, \tag{2.53}$$

where C depends on Ω, δ, n, and ϵ.

The proof of Theorem 2.10 is similar and based on Theorem 2.9. The proof of Theorem 2.11 follows from Theorem 2.10 and Morrey's inequality.

2.2. Convergence of the numerical homogenization. Write $\mathcal{R}_h$, the projection operator mapping $L^2\big(0, T; H_0^1(\Omega)\big)$ onto Y_T^h defined by: For all $v \in Y_T^h$

$$\mathcal{A}_T[v, u - \mathcal{R}_h u] = 0. \tag{2.54}$$

Write $\rho := u - \mathcal{R}_h u$ and $\theta := \mathcal{R}_h u - u_h$. By a standard energy estimate, we have the following lemmas without proof.

LEMMA 2.5.

$$\frac{1}{2}\big\|(u - u_h)(T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[u - u_h] = \int_{\Omega_T} \rho\partial_t(u - u_h) + \mathcal{A}_T[\rho, u - u_h]. \tag{2.55}$$

Proof. Subtracting (1.1) (integrated against ψ) and (1.27) we obtain that

$$\big(\psi, \partial_t(u - u_h)\big) + a[\psi, u - u_h] = 0 \quad \text{for all } \psi \in V_h(t). \tag{2.56}$$

Integrating by parts with respect to time we deduce that

$$\big(\psi, (u - u_h)(., t)\big) + a[\psi, u - u_h] = \int_{\Omega_t} \partial_t\psi(u - u_h). \tag{2.57}$$

Taking $\psi = \theta$ in (2.57) we deduce that

$$\begin{aligned}\big\|(u - u_h)(., t)\big\|^2_{L^2(\Omega)} + \mathcal{A}_t[u - u_h] = \int_{\Omega_t} \partial_t\theta(u - u_h) + \big(\rho, (u - u_h)(., t)\big) \\ + \mathcal{A}_t[\rho, u - u_h].\end{aligned} \tag{2.58}$$

Observing that

$$\begin{aligned}\int_0^t \big(\partial_t\theta, u - u_h\big) + \big(\rho, (u - u_h)(., t)\big) =& \frac{1}{2}\big\|(u - u_h)(., t)\big\|^2_{L^2(\Omega)} \\ &+ \int_0^t (\rho, \partial_t(u - u_h))\end{aligned} \tag{2.59}$$

we deduce the lemma. ∎

2.2.1. Time-independent medium: Proof of Theorem 1.3.

LEMMA 2.6.

$$\begin{aligned}\big\|(u-u_h)(T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[u-u_h] \le 2\Big(&\|\rho\|_{L^2(\Omega_T)}\|\partial_t u - \partial_t u_h\|_{L^2(\Omega_T)} \\ &+ \mathcal{A}_T[\rho]\Big).\end{aligned} \tag{2.60}$$

Proof. Lemma 2.6 is a straightforward consequence of Lemma 2.5 and Cauchy–Schwartz and Minkowski inequalities. □

Similar to Lemmas 2.1 and 2.2, we have the following energy estimate for u_h.

LEMMA 2.7. *Assume $\partial_t a \equiv 0$, and we have*

$$\big\|u_h(.,T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[u_h] \le \frac{C_{n,\Omega}}{\lambda_{\min}(a)}\|g\|^2_{L^2(\Omega_T)}. \tag{2.61}$$

LEMMA 2.8. *Assume $\partial_t a \equiv 0$, and we have*

$$\big\|\partial_t u_h\big\|^2_{L^2(\Omega_T)} + a\big[u_h(.,T)\big] \le \big\|g\big\|^2_{L^2(\Omega_T)}. \tag{2.62}$$

Let $t \in [0,T]$ and $v \in H^1_0(\Omega)$, and we will write $\mathcal{R}_{h,t}v(.,t)$, the solution of

$$\int_\Omega {}^t\nabla\psi a(x,t)(\psi, v - \mathcal{R}_{h,t}v)\,dx = 0 \quad \text{for all } \psi \in V_h(t). \tag{2.63}$$

We will need the following lemma.

LEMMA 2.9. *Assume the mapping $x \to F(x,t)$ to be invertible, and then for $v \in H^1_0(\Omega)$ we have*

- *for $n = 1$,*

$$\big(a[v - \mathcal{R}_{h,t}v]\big)^{\frac{1}{2}} \le C_X h\|v \circ F^{-1}(.,t)\|_{W^{2,2}_D}\|a\nabla F\|^{\frac{1}{2}}_{L^\infty(\Omega_T)}; \tag{2.64}$$

- *for $n \ge 2$,*

$$\begin{aligned}\big(a[v - \mathcal{R}_{h,t}v]\big)^{\frac{1}{2}} \le &C_X h\|v \circ F^{-1}(.,t)\|_{W^{2,2}_D} \\ &\times C_n\mu_\sigma^{\frac{n-1}{4}}\big\|(\mathrm{Trace}[\sigma])^{-1}\big\|^{\frac{n-2}{4}}_{L^\infty(\Omega_T)}.\end{aligned} \tag{2.65}$$

Remark 2.8. Recall that μ_σ is given by (1.12), and it is easy to check that μ_σ is bounded by an increasing function of $(1-\beta_\sigma)^{-1}$.

Proof. Using the change of coordinates $y = F(x,t)$ we obtain that (we write $\hat{v} := v \circ F^{-1}$)

$$a[v] = Q[\hat{v}], \tag{2.66}$$

with

$$\mathcal{Q}[w] := \int_\Omega {}^t\nabla w(y,t)Q(y,t)\nabla w(y,t)\,dy \tag{2.67}$$

and

$$Q(y,t) := \frac{\sigma}{\det(\nabla F)} \circ F^{-1}. \tag{2.68}$$

Using the definition of $\mathcal{R}_{h,t}v$ we obtain that

$$\mathcal{Q}[\hat{v} - \widehat{\mathcal{R}_{h,t}v}] = \inf_{\varphi \in X^h} \mathcal{Q}[\hat{v} - \varphi]. \tag{2.69}$$

Using property (1.21) we obtain that

$$\mathcal{Q}[\hat{v} - \widehat{\mathcal{R}_{h,t}v}] \leq \lambda_{\max}(Q) C_X^2 h^2 \|\hat{v}\|^2_{W_D^{2,2}(T)}. \tag{2.70}$$

It is easy to obtain that

- for $n = 1$,

$$\lambda_{\max}(Q) \leq \|a \nabla F\|_{L^\infty(\Omega_T)}; \tag{2.71}$$

- for $n \geq 2$,

$$\lambda_{\max}(Q) \leq C_n \mu_\sigma^{\frac{n-1}{2}} \big\| (\mathrm{Trace}[\sigma])^{-1} \big\|^{\frac{n}{2}-1}_{L^\infty(\Omega_T)}. \tag{2.72}$$

□

LEMMA 2.10. *Assume that $\partial_t a \equiv 0$, Ω is convex, $\beta_\sigma < 1$, and $(\mathrm{Trace}[\sigma])^{-1} \in L^\infty(\Omega_T)$, and then*

$$\mathcal{A}_T[\rho] \leq C h^2 \|g\|^2_{L^2(\Omega_T)}. \tag{2.73}$$

Remark 2.9. The constant C depends on C_X, n, Ω, $\lambda_{\min}(a)$, and $\|(\mathrm{Trace}[\sigma])^{-1}\|_{L^\infty(\Omega_T)}$. If $n \geq 5$ it also depends on $\|\mathrm{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$, and if $n = 1$ it also depends on $\lambda_{\max}(a)$.

Proof. The proof is a straightforward application of Lemma 2.9 and Theorem 1.1. Observe that in dimension one $a \nabla F = (\int_\Omega a^{-1})^{-1}$. □

LEMMA 2.11. *Assume that $\partial_t a \equiv 0$, Ω is convex, $\beta_\sigma < 1$, and $(\mathrm{Trace}[\sigma])^{-1} \in L^\infty(\Omega_T)$, and then*

$$\|\rho\|_{L^2(\Omega_T)} \leq C h^2 \|g\|_{L^2(\Omega_T)}. \tag{2.74}$$

Remark 2.10. The constant C depends on C_X, n, Ω, $\lambda_{\min}(a)$, and $\|(\mathrm{Trace}[\sigma])^{-1}\|_{L^\infty(\Omega_T)}$. If $n \geq 5$ it also depends on $\|\mathrm{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$, and if $n = 1$ it also depends on $\lambda_{\max}(a)$.

Proof. The proof follows from standard duality techniques (see, for instance, Theorem 5.7.6 of [18]). We choose $v \in L^2(0, T, H^1_0(\Omega))$ to be the solution of the following linear problem: For all $w \in L^2(0, T, H^1_0(\Omega))$

$$A_T[w, v] = (w, \rho)_{L^2(\Omega_T)}. \tag{2.75}$$

Choosing $w = \rho$ in (2.75) we deduce that

$$\|\rho\|^2_{L^2(\Omega_T))} = \mathcal{A}_T[\rho, v - \mathcal{R}_{h,t}v]. \tag{2.76}$$

Using the Cauchy–Schwartz inequality we deduce that

$$\|\rho\|^2_{L^2(\Omega_T)} \leq \big(\mathcal{A}_T[\rho]\big)^{\frac{1}{2}} \big(\mathcal{A}_T[v - \mathcal{R}_{h,t}v]\big)^{\frac{1}{2}}. \tag{2.77}$$

Using Theorem 1.1 we obtain that

$$\|\hat{v}\|_{L^2(0,T,W_D^{2,2}(\Omega))} \leq C \|\rho\|_{L^2(\Omega_T)}. \tag{2.78}$$

Using Lemma 2.9 we obtain that

$$\big(\mathcal{A}_T[v-\mathcal{R}_{h,t}v]\big)^{\frac12}\le Ch\|\rho\|_{L^2(\Omega_T)}. \tag{2.79}$$

It follows that

$$\|\rho\|_{L^2(\Omega_T)}\le Ch\big(\mathcal{A}_T[\rho]\big)^{\frac12}. \tag{2.80}$$

We deduce the lemma by applying Lemma 2.10 to bound $A_T[\rho]$. ∎

The proof of Theorem 1.3 is a straightforward application of Lemmas 2.2, 2.6, 2.8, 2.10, and 2.11.

2.2.2. Medium with a continuum of time scales: Proof of Theorem 1.4. In this subsection we will assume that the finite elements are in $H^2(\Omega)\cap H^1_0(\Omega)$ and satisfy inverse inequality (1.22).

Lemma 2.12.

$$\begin{aligned}\frac12\big\|(u-u_h)(t)\big\|^2_{L^2(\Omega)}+\mathcal{A}_t[u-u_h]=\int_{\Omega_t}\frac{\hat\rho}{|\det\nabla F|\circ F^{-1}}\\ \left(\hat g+\sum_{i,j=1}^n\sigma_{i,j}\circ F^{-1}\partial_i\partial_j\hat u_h-\partial_t\hat u_h\right).\end{aligned} \tag{2.81}$$

Proof. Consider (2.55). We have

$$\int_{\Omega_t}\rho\partial_t(u-u_h)=\int_{\Omega_t}\frac{\hat\rho}{|\det\nabla F|\circ F^{-1}}\partial_t(\hat u-\hat u_h)+\int_{\Omega_t}\rho\partial_tF(\nabla F)^{-1}\nabla(u-u_h). \tag{2.82}$$

Using (1.2) we obtain that

$$\int_{\Omega_t}\rho\partial_tF(\nabla F)^{-1}\nabla(u-u_h)=-\mathcal{A}_t[\rho,u-u_h]-\sum_{i,j=1}^n\int_{\Omega_t}\hat\rho Q_{i,j}\partial_i\partial_j(\hat u-\hat u_h). \tag{2.83}$$ ∎

Lemma 2.13.

$$\left\|\frac{\partial_t\hat u_h}{|\det(\nabla F)|^{\frac12}\circ F^{-1}}\right\|_{L^2(\Omega_T)}\le 2\|g\|_{L^2(\Omega_T)}+C\|\hat u_h\|_{L^2(0,T,W^{2,2}_D(\Omega))}, \tag{2.84}$$

where the constant C depends on n, $\lambda_{\max}(a)$, $\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$, and μ_σ.

Proof. Using the change of variable $y=F(x,t)$ in (1.27) we obtain that for all $\varphi\in X^h$

$$\begin{cases}(\varphi,\frac{\partial_t\hat u_h}{|\det(\nabla F)|\circ F^{-1}})_{L^2(\Omega)}= & \sum_{i,j=1}^n\int_\Omega(\varphi,Q_{i,j}\partial_i\partial_j\hat u_h)_{L^2(\Omega)}\\ & +(\varphi,\frac{\hat g}{|\det(\nabla F)|\circ F^{-1}})_{L^2(\Omega)},\\ \hat u_h(x,0)=0.\end{cases} \tag{2.85}$$

Recall that Q is given by (2.68). We choose $\varphi=\partial_t\hat u$ and observe that

$$\frac{\sigma}{|\det\nabla F|^{\frac12}}=\frac{\sigma}{|\det\sigma|^{\frac14}}|\det a|^{\frac14}. \tag{2.86}$$

Thus

$$\left\|\frac{\sigma}{|\det\nabla F|^{\frac12}}\right\|\le C\big(n,\lambda_{\max}(a),\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)},\mu_\sigma\big). \tag{2.87}$$

We deduce the lemma by the Minkowski inequality. ∎

Combining Lemmas 2.12 and 2.13 we obtain the following lemma.

LEMMA 2.14.

$$\frac{1}{2}\big\|(u-u_h)(T)\big\|^2_{L^2(\Omega)} + \mathcal{A}_T[u-u_h] \leq \|\rho\|_{L^2(\Omega_T)}\Big(\|g\|_{L^2(\Omega_T)} + C\|\hat{u}_h\|_{L^2(0,T,W_D^{2,2}(\Omega))}\Big), \tag{2.88}$$

where the constant C depends on n, $\lambda_{\max}(a)$, $\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$, and μ_σ.

LEMMA 2.15. *Assume that Ω is convex and Condition 1.1 is satisfied; then*

$$\|\rho\|_{L^2(\Omega_T)} \leq Ch^2\|g\|_{L^2(\Omega_T)}. \tag{2.89}$$

Remark 2.11. The constant C depends on C_X, n, Ω, δ, ϵ, $\lambda_{\min}(a)$, and $\lambda_{\max}(a)$.

Proof. The proof is similar to the proof of Lemma 2.11. As in the proof of Lemma 2.11 we choose $v \in L^2(0,T,H_0^1(\Omega))$ to be the solution of the following linear problem: For all $w \in L^2(0,T,H_0^1(\Omega))$

$$A_T[w,v] = (w,\rho)_{L^2(\Omega_T)}. \tag{2.90}$$

Choosing $w = \rho$ in (2.90) we deduce that

$$\|\rho\|^2_{L^2(\Omega_T))} = \mathcal{A}_T[\rho, v - \mathcal{R}_{h,t}v]. \tag{2.91}$$

Using the Cauchy–Schwartz inequality we deduce that

$$\|\rho\|^2_{L^2(\Omega_T)} \leq \big(\mathcal{A}_T[\rho]\big)^{\frac{1}{2}}\big(\mathcal{A}_T[v-\mathcal{R}_{h,t}v]\big)^{\frac{1}{2}}. \tag{2.92}$$

Using Theorem 1.2 we obtain that

$$\|\hat{v}\|_{L^2(0,T,W_D^{2,2}(\Omega))} \leq C\|\rho\|_{L^2(\Omega_T)}. \tag{2.93}$$

Using Lemma 2.9 we obtain that

$$\big(\mathcal{A}_T[v-\mathcal{R}_{h,t}v]\big)^{\frac{1}{2}} \leq Ch\|\rho\|_{L^2(\Omega_T)}. \tag{2.94}$$

It follows that

$$\|\rho\|_{L^2(\Omega)} \leq Ch\big(\mathcal{A}_T[\rho]\big)^{\frac{1}{2}}. \tag{2.95}$$

We deduce the lemma by applying Lemma 2.9 and Theorem 1.2 to bound $A_T[\rho]$. ∎

LEMMA 2.16. *Assume that Ω is convex and that* $\operatorname{Trace}[\sigma] \in L^\infty(\Omega_T)$.

$$\|\hat{u}_h\|_{L^2(0,T,W_D^{2,2}(\Omega))} \leq \frac{C}{h}\|g\|_{L^2(\Omega_T)}. \tag{2.96}$$

Remark 2.12. The constant C depends on C_X, n, Ω, $\lambda_{\min}(a)$, $\lambda_{\max}(a)$, and $\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$.

Proof. Using the inverse inequality (1.22) of the finite elements we obtain that

$$\|\hat{u}_h\|_{L^2(0,T,W_D^{2,2}(\Omega))} \leq \frac{C_X}{h}\|\nabla\hat{u}_h\|_{L^2(0,T,W_D^{2,2}(\Omega))}. \tag{2.97}$$

Using the change of variables $y = F(x)$ we obtain that

$$\|\nabla\hat{u}_h\|^2_{L^2(0,T,W_D^{2,2}(\Omega))} \leq C\mathcal{A}_T[u_h], \tag{2.98}$$

where C depends on n, $\lambda_{\min}(a)$, and $\|\operatorname{Trace}[\sigma]\|_{L^\infty(\Omega_T)}$. We deduce the lemma by using Lemma 2.7. ∎

The proof of Theorem 1.4 is a straightforward application of Lemmas 2.14, 2.15, and 2.16.

2.2.3. Numerical homogenization in time and space: Proof of Theorems 1.5–1.7. We use the notation of subsection 1.3. First we will prove Theorem 1.5; let us observe that the numerical scheme associated to (1.34) is stable. Indeed choosing $\psi = v_{n+1}$ one gets

$$\begin{aligned}\big|v_{n+1}(t_{n+1})\big|^2_{L^2(\Omega)} &= \big(v_{n+1}(t_n), v_n(t_n)\big)_{L^2(\Omega)} \\ &\quad + \frac{1}{2}\big(\big|v_{n+1}(t_{n+1})\big|^2_{L^2(\Omega)} - \big|v_{n+1}(t_n)\big|^2_{L^2(\Omega)}\big) \\ &\quad - \int_{t_n}^{t_{n+1}} \Big(a\big[v_{n+1}(t)\big] + \big(v_{n+1}(t), g(t)\big)_{L^2(\Omega)}\Big)\, dt.\end{aligned} \tag{2.99}$$

It follows by the Cauchy–Schwartz inequality that

$$\begin{aligned}\frac{1}{2}\big|v_{n+1}(t_{n+1})\big|^2_{L^2(\Omega)} \le &\frac{1}{2}\big|v_n(t_n)\big|^2_{L^2(\Omega)} \\ &- \int_{t_n}^{t_{n+1}} \Big(a\big[v_{n+1}(t)\big] + \big(v_{n+1}(t), g(t)\big)_{L^2(\Omega)}\Big)\, dt.\end{aligned} \tag{2.100}$$

Hence using Poincaré and Minkowski inequalities one obtains that

$$\begin{aligned}\big|v_{n+1}(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[v_{n+1}(t)\big]\, dt \le &\big|v_n(t_n)\big|^2_{L^2(\Omega)} \\ &+ \frac{C_{n,\Omega}}{\lambda_{\min}(a)} \int_{t_n}^{t_{n+1}} \big|g(t)\big|^2_{L^2(\Omega)}\, dt,\end{aligned} \tag{2.101}$$

which implies Theorem 1.5 and the stability of the scheme.

Integrating (1.27) with respect to time we obtain that, for $\psi \in U_T^h$,

$$\begin{aligned}\big(\psi(t_{n+1}), u_h(t_{n+1})\big)_{L^2(\Omega)} = &\big(\psi(t_n), u_h(t_n)\big)_{L^2(\Omega)} \\ &+ \int_{t_n}^{t_{n+1}} \Big(\big(\partial_t\psi(t), u_h(t)\big)_{L^2(\Omega)} \\ &- a\big[\psi(t), u_h(t)\big] + \big(\psi(t), g(t)\big)_{L^2(\Omega)}\Big)\, dt.\end{aligned} \tag{2.102}$$

Let us write (u^i) the coordinates of u_h associated to the basis $(\varphi_i \circ F)$, i.e.,

$$u_h(x,t) := \sum_i u^i(t)\varphi_i(F(x,t)), \tag{2.103}$$

and define

$$u_n(x,t) := \sum_i u^i(t_n)\varphi_i(F(x,t)). \tag{2.104}$$

Subtracting (2.102) and (1.34) we obtain that, for $\psi \in Z_T$,

$$\begin{aligned}\big(\psi(t_{n+1}), (u_{n+1} - v_{n+1})(t_{n+1})\big)_{L^2(\Omega)} = &\big(\psi(t_n), (u_n - v_n)(t_n)\big)_{L^2(\Omega)} \\ &+ \int_{t_n}^{t_{n+1}} \Big(\big(\partial_t\psi(t), (u_h - v_{n+1})(t)\big)_{L^2(\Omega)} \\ &- a\big[\psi(t), (u_h - v_{n+1})(t)\big]\Big)\, dt.\end{aligned} \tag{2.105}$$

Choosing $\psi = u_{n+1} - v_{n+1}$ we deduce using the Cauchy–Schwartz inequality that

$$\begin{aligned}
&\frac{1}{2}\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt \\
&\quad\le \frac{1}{2}\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} \Big(\big(\partial_t(u_{n+1}-v_{n+1})(t),(u_h-u_{n+1})(t)\big)_{L^2(\Omega)} \\
&\quad - a\big[(u_{n+1}-v_{n+1})(t),(u_h-u_{n+1})(t)\big]\Big)\,dt.
\end{aligned} \tag{2.106}$$

Time-independent medium. Observe that if the medium is time-independent, then (2.106) can be written

$$\begin{aligned}
&\frac{1}{2}\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt \\
&\quad\le \frac{1}{2}\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)} - \int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t),(u_h-u_{n+1})(t)\big]\,dt,
\end{aligned} \tag{2.107}$$

which leads us to

$$\begin{aligned}
&\frac{1}{2}\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt \\
&\quad\le \frac{1}{2}\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)} \\
&\quad + \int_{t_n}^{t_{n+1}}\int_{t_n}^{t_{n+1}} 1(t<s)\,a\big[(u_{n+1}-v_{n+1})(t),\partial_s u_h(s)\big]\,ds\,dt.
\end{aligned} \tag{2.108}$$

Write $\Delta t := t_{n+1} - t_n$. Using the Minkowski inequality we obtain that

$$\begin{aligned}
a\big[(u_{n+1}-v_{n+1})(t),\partial_s u_h(s)\big] \le \frac{1}{2\Delta t} a\big[(u_{n+1}-v_{n+1})(t)\big] \\
+ \frac{1}{2}\Delta t a\big[\partial_s u_h(s)\big].
\end{aligned} \tag{2.109}$$

It follows from (2.108) that

$$\begin{aligned}
&\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt \\
&\le \big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)} + |\Delta t|^2 \int_{t_n}^{t_{n+1}} a\big[\partial_s u_h(s)\big]\,ds.
\end{aligned} \tag{2.110}$$

Observing that

$$\begin{aligned}
\int_{t_n}^{t_{n+1}} a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt \ge 0.5\int_{t_n}^{t_{n+1}} a\big[(u_h-v_{n+1})(t)\big]\,dt \\
- \int_{t_n}^{t_{n+1}} a\big[(u_h-u_{n+1})(t)\big]\,dt
\end{aligned} \tag{2.111}$$

and

$$\int_{t_n}^{t_{n+1}} a\big[(u_h - u_{n+1})(t)\big]\,dt \le |\Delta t|^2 \int_{t_n}^{t_{n+1}} a\big[\partial_s u_h(s)\big]\,ds, \tag{2.112}$$

we obtain that

$$\begin{aligned} &\big|(u_{n+1} - v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + 0.5 \int_{t_n}^{t_{n+1}} a\big[(u_h - v_{n+1})(t)\big]\,dt \\ &\le \big|(u_n - v_n)(t_n)\big|^2_{L^2(\Omega)} + \frac{3}{2}|\Delta t|^2 \int_{t_n}^{t_{n+1}} a\big[\partial_s u_h(s)\big]\,ds. \end{aligned} \tag{2.113}$$

In conclusion we have obtained the following lemma.

LEMMA 2.17. *Let $v \in Z_T$ be the solution of* (1.34). *We have*

$$\big\|(u_h - v)(T)\big\|^2_{L^2(\Omega)} + \int_0^T a\big[(u_h - v)(t)\big]\,dt \le 3|\Delta t|^2 \int_0^T a\big[\partial_s u_h(s)\big]\,ds. \tag{2.114}$$

Combining Lemma 2.3 with Lemma 2.17 we obtain Theorem 1.6.

Time-dependent medium. Observe that

$$\partial_t (u_{n+1} - v_{n+1}) = \partial_t F (\nabla F)^{-1} \nabla (u_{n+1} - v_{n+1}).$$

It follows after writing $\partial_t F = \operatorname{div} a \nabla F$, integration by parts, and using the change of variables $y = F(x,t)$ in (2.106) that

$$\begin{aligned} &\frac{1}{2}\big|(u_{n+1} - v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1} - v_{n+1})(t)\big]\,dt \\ &\le \frac{1}{2}\big|(u_n - v_n)(t_n)\big|^2_{L^2(\Omega)} - 2\int_{t_n}^{t_{n+1}} a\big[(u_{n+1} - v_{n+1})(t), (u_h - u_{n+1})(t)\big]\,dt \\ &- \sum_{i,j} \int_{t_n}^{t_{n+1}} \int_\Omega (\hat{u}_h - \hat{u}_{n+1}) Q_{i,j} \partial_i \partial_j (\hat{u}_{n+1} - \hat{v}_{n+1})\,dt\,dy. \end{aligned} \tag{2.115}$$

Hence using the Minkowski inequality we obtain that

$$\begin{aligned} &\big|(u_{n+1} - v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)} + \int_{t_n}^{t_{n+1}} a\big[(u_{n+1} - v_{n+1})(t)\big]\,dt \\ &\le \big|(u_n - v_n)(t_n)\big|^2_{L^2(\Omega)} + 4\int_{t_n}^{t_{n+1}} a\big[(u_h - u_{n+1})(t)\big]\,dt \\ &- 2\sum_{i,j} \int_{t_n}^{t_{n+1}} \int_\Omega (\hat{u}_h - \hat{u}_{n+1}) Q_{i,j} \partial_i \partial_j (\hat{u}_{n+1} - \hat{v}_{n+1})\,dt\,dy. \end{aligned} \tag{2.116}$$

Using the Minkowski inequality we obtain that

$$\begin{aligned}\Big|\sum_{i,j}\int_{t_n}^{t_{n+1}}\int_\Omega(\hat u_h-\hat u_{n+1})Q_{i,j}\partial_i\partial_j(\hat u_{n+1}-\hat v_{n+1})\,dt\,dy\Big|&\\ \le C_An^2\int_{t_n}^{t_{n+1}}\int_\Omega|\hat u_h-\hat u_{n+1}|^2\,dt\,dy&\\ +\frac{\lambda_{\max}(Q)}{C_A}\int_{t_n}^{t_{n+1}}\sum_{i,j}\int_\Omega|\partial_i\partial_j(\hat u_{n+1}-\hat v_{n+1})|^2\,dt\,dy.&\end{aligned}\tag{2.117}$$

Using the inverse inequality (1.22) and the change of variable $y=F(x)$ we obtain that

$$\begin{aligned}\int_{t_n}^{t_{n+1}}\sum_{i,j}\int_\Omega|\partial_i\partial_j(\hat u_{n+1}-\hat v_{n+1})|^2\,dt\,dy\le\frac{C_X}{h^2\lambda_{\min}(Q)}&\\ \int_{t_n}^{t_{n+1}}a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt.&\end{aligned}\tag{2.118}$$

In resume, choosing $C_A=\frac{4C_X\lambda_{\max}(Q)}{h^2\lambda_{\min}(Q)}$ we have obtained that

$$\begin{aligned}\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)}+0.5\int_{t_n}^{t_{n+1}}a\big[(u_{n+1}-v_{n+1})(t)\big]\,dt&\\ \le\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)}+8\int_{t_n}^{t_{n+1}}a\big[(u_h-u_{n+1})(t)\big]\,dt&\\ +\frac{8C_X\lambda_{\max}(Q)}{h^2\lambda_{\min}(Q)}n^2\int_{t_n}^{t_{n+1}}\int_\Omega|\hat u_h-\hat u_{n+1}|^2\,dt\,dy.&\end{aligned}\tag{2.119}$$

A computation similar to the one leading to (2.109) gives us

$$\begin{aligned}\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)}+\frac14\int_{t_n}^{t_{n+1}}a\big[(u_h-v_{n+1})(t)\big]\,dt&\\ \le\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)}+9\int_{t_n}^{t_{n+1}}a\big[(u_h-u_{n+1})(t)\big]\,dt&\\ +\frac{8C_X\lambda_{\max}(Q)}{h^2\lambda_{\min}(Q)}n^2\int_{t_n}^{t_{n+1}}\int_\Omega|\hat u_h-\hat u_{n+1}|^2\,dt\,dy.&\end{aligned}\tag{2.120}$$

Moreover using the change of variables $F(x)=y$ and the inverse inequality (1.23) we obtain that

$$\int_{t_n}^{t_{n+1}}a\big[(u_h-u_{n+1})(t)\big]\,dt\le\frac{C_X\lambda_{\max}(Q)}{h^2}\int_{t_n}^{t_{n+1}}\int_\Omega|\hat u_h-\hat u_{n+1}|^2\,dt\,dy.\tag{2.121}$$

Let us also observe that

$$\int_{t_n}^{t_{n+1}}\int_\Omega|\hat u_h-\hat u_{n+1}|^2\,dt\,dy\le|\Delta t|^2\int_{t_n}^{t_{n+1}}\int_\Omega|\partial_t\hat u_h|^2\,dt\,dy.\tag{2.122}$$

It follows that

$$\begin{aligned}&\big|(u_{n+1}-v_{n+1})(t_{n+1})\big|^2_{L^2(\Omega)}+\frac{1}{4}\int_{t_n}^{t_{n+1}} a\big[(u_h-v_{n+1})(t)\big]\,dt\\&\le\big|(u_n-v_n)(t_n)\big|^2_{L^2(\Omega)}+C_B\frac{|\Delta t|^2}{h^2}\int_{t_n}^{t_{n+1}}\int_\Omega|\partial_t\hat{u}_h|^2\,dt\,dy,\end{aligned}\tag{2.123}$$

with

$$C_B=C_nC_X\lambda_{\max}(Q)\left(1+\frac{1}{\lambda_{\min}(Q)}\right).\tag{2.124}$$

We deduce that

$$\big\|(u_h-v)(T)\big\|^2_{L^2(\Omega)}+\frac{1}{4}\int_0^T a\big[(u_h-v)(t)\big]\,dt\le C_B\frac{|\Delta t|^2}{h^2}\int_{\Omega_T}|\partial_t\hat{u}_h|^2\,dt\,dy.\tag{2.125}$$

Using Lemma 2.4 to control C_B and combining (2.125) with Theorem 1.2 we obtain Theorem 1.7.

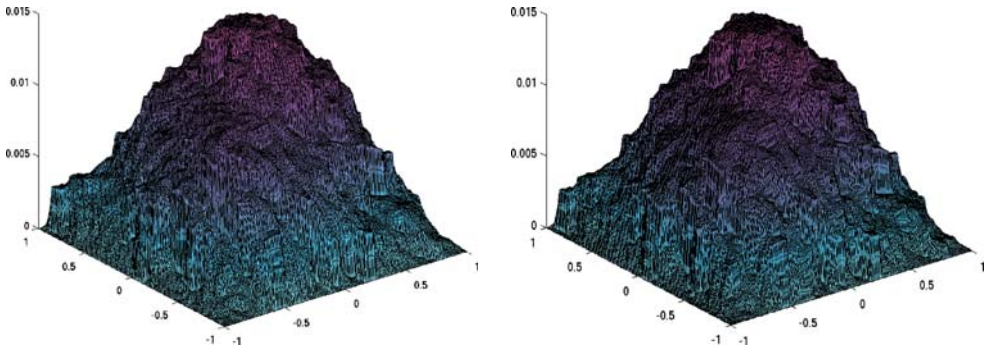
3. Numerical experiments. The purpose of this section is to give several illustrations of the implementation and performance of the numerical method. The computational domain is the unit square in dimension two. Equation (1.1) is solved on a fine tessellation characterized by 16129 interior nodes (degrees of freedom).

Three different coarse tessellations with 9, 49, and 225 degrees of freedoms are considered.

The parabolic operator associated to (1.1) has been homogenized onto these coarse meshes using the method presented in subsection 1.3. We have chosen splines to be the space X^h in subsection 1.2.

3.1. Time-independent examples.

Example 3.1 (time-independent site percolation). In this example we consider the site-percolating medium. a is set to be equal to 1 or 100 with probability 1/2 on each triangle of a fine mesh. (1.1) has been solved with $g=1$ and $g=\sin(2.4x-1.8y+2\pi t)$. Figure 3.1 shows u computed on 16641 interior nodes and u_h computed on 9 interior nodes in the case $g=1$ at time 1. The fine mesh and coarse mesh errors are given in Table 3.1.



(a) u. (b) u_h.

3.2. Time-dependent examples. In the following examples we consider media characterized by a continuum of time scales.

Example 3.2 (Time-dependent multiscale trigonometric). In this example a is given by (1.20). Although the number of fine time steps to solve (1.1) is 2663, only 134 coarse time steps have been used to solve the homogenized equation. Hence if one also takes into account homogenization in space, the compression factor is of the order of 35000 for the coarse mesh with 9 interior nodes.

Figure 3.2 shows the curves of $t \to a(x_0, t)$ and $t \to F(x_0, t)$ for a given $x_0 \in \Omega$ and the coarse and fine mesh relative to L^2 and H^1 errors with respect to time. The initial increase of the relative error is due to the initial value $u(x, 0) \equiv 0$.

The coarse and fine meshes errors at $t = 0.1$ are given in Table 3.1 for $g = 1$. The errors at $t = 0.1$ are given for $g = \sin(2.4x - 1.8y + 2\pi t)$.

Example 3.3 (Time-dependent random fractal). In this case, a is given by a product of discontinuous functions oscillating randomly at different scales: $a(x, t) = a_1(x, t)a_2(x, t) \dots a_n(x, t)$ and $a_i(x, t) = c_{pq}$ for $x \in [\frac{p}{2^i}, \frac{p+1}{2^i}) \times [\frac{q}{2^i}, \frac{q+1}{2^i})$ in the time interval $0.1 \times [\frac{k}{4^i}, \frac{k+1}{4^i})$. c_{pq} is uniformly random in $[\frac{1}{\gamma}, \gamma]$, $n = 6$, and $\gamma = 0.7$. In this example, we have $\frac{\lambda_{\max}(a)}{\lambda_{\min}(a)} = 160.3295$. The number of fine time steps is 3482, and the number of coarse time steps is 175.

a and the map (F_1, F_2) are drawn in Figure 3.3. L^2 and H^1 errors are given in Figure 3.4. Coarse and fine mesh errors at $t = 0.1$ are given in Table 3.1. We have chosen $g = 1$ in this numerical experiment, and one obtains similar results by choosing $g = \sin(2.4x - 1.8y + 2\pi t)$.

CONVERGENCE ANALYSIS OF FINITE VOLUME SCHEME FOR NONLINEAR TENSOR ANISOTROPIC DIFFUSION IN IMAGE PROCESSING*

OLGA DRBLÍKOVÁ† AND KAROL MIKULA†

Abstract. In this article we design the semiimplicit finite volume scheme for coherence enhancing diffusion in image processing and prove its convergence to the weak solution of the problem. The finite volume methods are natural tools for image processing applications since they use piecewise constant representation of approximate solutions similarly to the structure of digital images. They have been successfully applied in image processing, e.g., for solving the Perona–Malik equation or curvature-driven level set equations, where the nonlinearities are represented by a scalar function dependent on a solution gradient. Design of suitable finite volume schemes for tensor diffusion is a nontrivial task here we present the first such scheme with a convergence proof for the practical nonlinear model used in coherence-enhancing image smoothing. We provide basic information about this type of nonlinear diffusion including a construction of its diffusion tensor, and we derive a semiimplicit finite volume scheme for this nonlinear model with the help of covolume mesh. This method is well known as the diamond-cell method owing to the choice of covolume as a diamond-shaped polygon. Further, we prove a convergence of a discrete solution given by our scheme to the weak solution of the problem. The proof is based on Kolmogorov's compactness theorem and a bounding of a gradient in the tangential direction by using a gradient in the normal direction. Finally computational results illustrated in figures are discussed.

1. Introduction.

Nonlinear diffusion models are widely used nowadays in many practical tasks of image processing. In this paper we deal with the numerical solution of the model of tensor nonlinear anisotropic diffusion introduced by Weickert (see [23, 24, 22]) in the following form:

$$\frac{\partial u}{\partial t} - \nabla \cdot (D\nabla u) = 0 \qquad \text{in } Q_T \equiv I \times \Omega, \tag{1.1}$$

$$u(x,0) = u_0(x) \quad \text{in } \Omega, \tag{1.2}$$

$$(D\nabla u) \cdot \mathbf{n} = 0 \qquad \text{on } I \times \partial\Omega, \tag{1.3}$$

where D is a matrix depending on the eigenvalues and eigenvectors of the so-called (regularized) structure tensor, $u_0 \in L^2(\Omega)$, and $\mathbf{n}$ is the outer normal unit vector to $\partial\Omega$. Such a model is useful in any situation, where strong smoothing is desirable in a preferred direction and a low smoothing is expected in the perpendicular direction, e.g., for images with interrupted coherence of structures. To that goal the matrix

$$J_0(\nabla u_{\tilde{t}}) = \nabla u_{\tilde{t}} \otimes \nabla u_{\tilde{t}} = \nabla u_{\tilde{t}} \nabla u_{\tilde{t}}^T, \tag{1.4}$$

where

$$u_{\tilde{t}}(x,t) = (G_{\tilde{t}} * u(\cdot,t))(x) \qquad (\tilde{t} > 0) \tag{1.5}$$

is used. The matrix J_0 is symmetric and positive semidefinite, and its eigenvectors are parallel and orthogonal to $\nabla u_{\tilde{t}}$, respectively. We can average J_0 by applying another convolution with Gaussian G_ρ and define

$$J_\rho(\nabla u_{\tilde{t}}) = G_\rho * (\nabla u_{\tilde{t}} \otimes \nabla u_{\tilde{t}}) \qquad (\rho > 0). \tag{1.6}$$

In computer vision the matrix $J_\rho = \left(\begin{smallmatrix} a & b \\ b & c \end{smallmatrix}\right)$ is known as a structure tensor, interest operator, or second moment matrix (see [9]). It is again symmetric and positive semidefinite, and its eigenvalues are given by

$$\mu_{1,2} = \frac{1}{2}\left(a + c \pm \sqrt{(a-c)^2 + 4b^2}\right), \qquad \mu_1 \geq \mu_2. \tag{1.7}$$

Since the eigenvalues integrate the variation of the gray values within a neighborhood of size $O(\rho)$, they describe the average contrast in the eigendirections v and w.

With the help of the eigenvalues of J_ρ we can obtain useful information on the coherence. The expression $(\mu_1 - \mu_2)^2$ is large for anisotropic structures and tends to zero for isotropic structures; constant areas are characterized by $\mu_1 = \mu_2 = 0$, straight edges by $\mu_1 \gg \mu_2 = 0$, and corners by $\mu_1 \geq \mu_2 \gg 0$.

The corresponding orthogonal set of eigenvectors (v, w) to eigenvalues (μ_1, μ_2) is given by

$$\begin{aligned} &v = (v_1, v_2), && w = (w_1, w_2), \\ &v_1 = 2b, && v_2 = c - a + \sqrt{(a-c)^2 + 4b^2}, \\ &w \perp v, && w_1 = -v_2, \qquad w_2 = v_1. \end{aligned} \tag{1.8}$$

The orientation of the eigenvector w which corresponds to the smaller eigenvalue μ_2 is called coherence orientation. This orientation has the lowest fluctuations.

One can use the above-mentioned structure tensor information in a construction of specific nonlinear diffusion filter [23, 24, 22]. The idea of the tensor nonlinear diffusion filtering is as follows. We get a processed version $u(x,t)$ of an original image $u_0(x)$ with a scale parameter $t \geq 0$ as the solution of mathematical model (1.1)–(1.3), where matrix D depends on solution u, satisfies smoothness, symmetry, and uniform positive definiteness properties, and steers a filtering process such that diffusion is strong along the coherence direction w and increases with the coherence $(\mu_1 - \mu_2)^2$. To that goal D must possess the same eigenvectors v and w as the structure tensor $J_\rho(\nabla u_{\tilde{t}})$, and we choose the eigenvalues of D as

$$\begin{aligned} &\kappa_1 = \alpha, \quad \alpha \in (0,1),\ \alpha \ll 1, \\ &\kappa_2 = \begin{cases} \alpha & \text{if } \mu_1 = \mu_2, \\ \alpha + (1-\alpha)\exp\left(\frac{-C}{(\mu_1-\mu_2)^2}\right),\ C > 0 & \text{otherwise.} \end{cases} \end{aligned} \tag{1.9}$$

The matrix D then has the following form:

$$D = ABA^{-1}, \tag{1.10}$$

where $A = \left(\begin{smallmatrix} v_1 & -v_2 \\ v_2 & v_1 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} \kappa_1 & 0 \\ 0 & \kappa_2 \end{smallmatrix}\right)$. The exponential function is used in (1.9) because it ensures that the smoothness of the structure tensor carries over to the

diffusion tensor and that κ_2 does not exceed 1. The positive parameter α guarantees that the process never stops. Even if $(\mu_1-\mu_2)^2$ tends to zero so the structure becomes isotropic, there still remains some small linear diffusion with diffusivity $\alpha > 0$. Such α is a regularization parameter, which keeps the diffusion tensor uniformly positive definite. C has the role of a threshold parameter. If $(\mu_1 - \mu_2)^2 \gg C$, then $\kappa_2 \approx 1$, and, in contrast, if $(\mu_1 - \mu_2)^2 \ll C$, then $\kappa_2 \approx \alpha$. Due to the convolutions in (1.5) and (1.6), the elements of matrix D are C^∞ functions. Such a model is a nontrivial extension of the regularized Perona–Malik equation [17, 1, 15], and, as well as further PDEs employing tensor diffusion, it is used in many practical image processing applications; see, e.g., [23, 24, 22, 6, 13, 19, 18]. In section 5 of this paper we also illustrate its usefulness by smoothing and segmenting the cell membrane images obtained by a confocal microscope. We show that after application of the nonlinear tensor anisotropic diffusion using our numerical scheme the coherent structures are attenuated. If such improved edge information is used in the so-called subjective surface segmentation method [20, 16, 2], the cell boundaries are correctly segmented.

There are only a few purely finite volume methods designed and studied from the numerical analysis point of view for solving tensor diffusion problems; see, e.g., [3, 4, 5, 26] devoted to discretization of the elliptic operators. On the other hand, finite volume schemes for nonlinear parabolic problems as arising in image analysis are natural since they use piecewise constant representation of approximate solutions similarly to the structure of digital images. Finite and complementary volume schemes have been used successively in image processing for solving the Perona–Malik equation and its generalizations (see, e.g., [15, 11, 12, 10, 7, 21]) and for solving the generalized curvature-driven level set equations (see, e.g., [8, 16, 2]) where the nonlinearities are represented by a scalar function dependent on a solution gradient. Here we present the first finite volume scheme with a convergence proof for the highly nonlinear anisotropic tensor diffusion model arising in coherence-enhancing image smoothing.

The next section is devoted to derivation of our numerical scheme, in section 3 we study the existence and uniqueness of discrete solutions, section 4 contains our convergence proof, and finally, in section 5, we discuss numerical experiments.

2. Finite volume scheme for nonlinear tensor anisotropic diffusion. The aim of this section is to derive our computational method. Let the image be represented by $n_1 \times n_2$ pixels (finite volumes) such that it looks like a mesh with n_1 rows and n_2 columns. Let $\Omega = (0, n_1 h)\times(0, n_2 h)$, h is a pixel size, and let the image $u(x)$ be given by a bounded mapping $u : \Omega \to R$. The filtering process is considered in a time interval $I = [0, T]$. Let $0 = t_0 \le t_1 \le \cdots \le t_{N_{max}} = T$ denote the time discretization, with $t_n = t_{n-1} + k$, where k is the length of a discrete time step. In our scheme we will look for u^n, an approximation of solution at time t_n, for every $n = 1, \ldots, N_{max}$. As usual in finite volume methods, we integrate (1.1) over finite volume K, then provide a semiimplicit time discretization, and use a divergence theorem to get

$$\frac{u_K^n - u_K^{n-1}}{k} m(K) - \sum_{\sigma \in \mathcal{E}_K \cap \mathcal{E}_{int}} \int_\sigma (D^{n-1} \nabla u^n) \cdot \mathbf{n}_{K,\sigma} ds = 0, \tag{2.1}$$

where u_K^n, $K \in \mathcal{T}_h$, represents the mean value of u^n on K. $\mathcal{T}_h$ is an admissible finite volume mesh (see [4]), and further quantities and notations are described as follows: $m(K)$ is the measure of the finite volume K with boundary ∂K, and $\sigma_{KL} = K \cap L = K|L$ is an edge of the finite volume K, where $L \in \mathcal{T}_h$ is an adjacent finite volume to K such that $m(K \cap L) \neq 0$. Due to simplifying notation, we use σ instead of

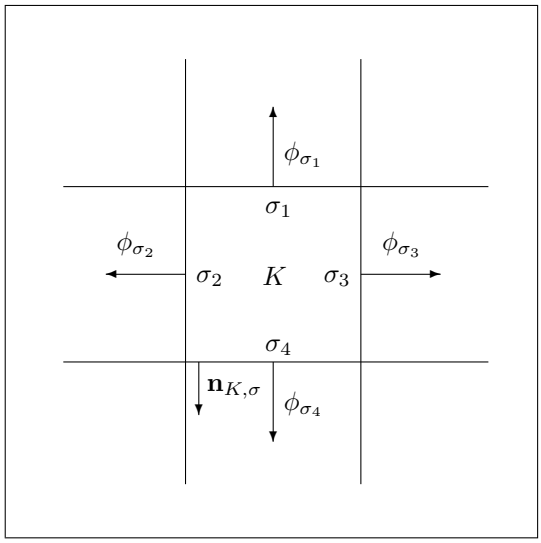

FIG. 2.1. *A detail of a finite volume mesh—a finite volume K, its boundaries σ_i, $i = 1, 2, 3, 4$, and the fluxes outward to a finite volume K.*

σ_{KL} at several places if no confusion can appear. $\mathcal{E}_K$ is a set of edges such that $\partial K = \bigcup_{\sigma\in\mathcal{E}_K} \sigma$ and $\mathcal{E} = \bigcup_{K\in\mathcal{T}_h} \mathcal{E}_K$. The set of boundary edges is denoted by $\mathcal{E}_{ext}$, that is, $\mathcal{E}_{ext} = \mathcal{E} \cap \partial\Omega$, and let $\mathcal{E}_{int} = \mathcal{E} \setminus \mathcal{E}_{ext}$. Υ is the set of pairs of adjacent finite volumes, defined by $\Upsilon = \{(K, L) \in \mathcal{T}_h^2,\ K \neq L,\ m(K|L) \neq 0\}$, and $\mathbf{n}_{K,\sigma}$ is the normal unit vector to σ outward to K. See Figure 2.1.

Let us define our discrete numerical solution by

$$u_{h,k}(x,t) = \sum_{n=0}^{N_{max}} \sum_{K\in\mathcal{T}_h} u_K^n \chi\{x \in K\}\chi\{t_{n-1} < t \le t_n\}, \tag{2.2}$$

where the function $\chi(A)$ is defined as

$$\chi_{\{A\}} = \begin{cases} 1 & \text{if A is true,} \\ 0 & \text{elsewhere.} \end{cases} \tag{2.3}$$

The extension of the function (2.2) outside Ω is given first by its periodic mirror reflection in $\Omega_{\tilde{t}}$, where $\tilde{t}$ is the width of the smoothing kernel:

$$\Omega_{\tilde{t}} = \Omega \cup B_{\tilde{t}}(x), \quad x \in \partial\Omega, \tag{2.4}$$

$B_{\tilde{t}}(x)$ is a ball centered at x with radius $\tilde{t}$, and then we extend this periodic mirror reflection by 0 outside $\Omega_{\tilde{t}}$ and denote it by $\tilde{u}_{h,k}$.

In our scheme we will start computation by defining initial values

$$u_K^0 = \frac{1}{m(K)} \int_K u_0(x)dx, \quad K \in \mathcal{T}_h \tag{2.5}$$

and letting $u_{h,k}^n(x) = \sum_{K\in\mathcal{T}_h} u_K^n \chi\{x \in K\}$ denote a finite volume approximation at the nth time step. In order to get the scheme we write (2.1) in the form $\frac{u_K^n - u_K^{n-1}}{k} - \frac{1}{m(K)} \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{int}} \phi_\sigma^n(u_{h,k}^n) m(\sigma) = 0$, where $m(\sigma)$ is the measure of edge σ and $\phi_\sigma^n(u_{h,k}^n)$

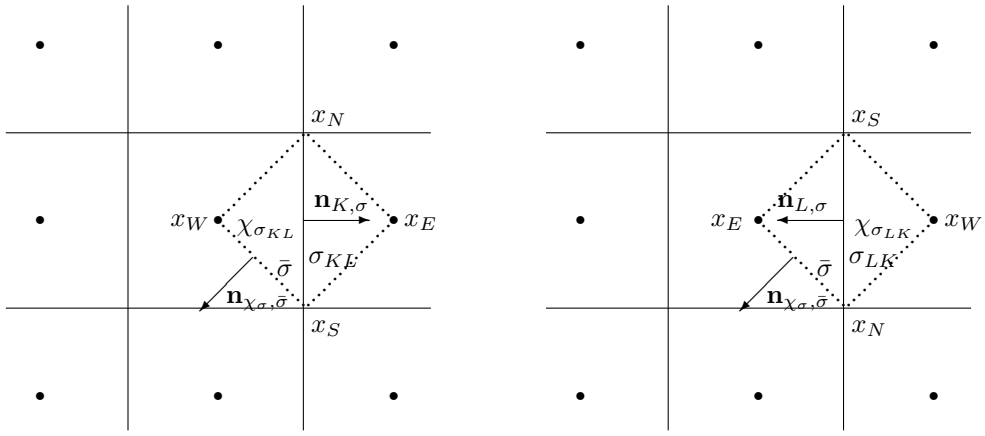

FIG. 2.2. *A detail of a mesh. The covolumes associated to edges $\sigma = \sigma_{KL}$ (left) and $\sigma = \sigma_{LK}$ (right).*

denotes an approximation of the exact averaged flux $\frac{1}{m(\sigma)}\int_\sigma (D^{n-1}\nabla u^n)\cdot\ \mathbf{n}_{K,\sigma}ds$ for any K and $\sigma \in \mathcal{E}_K$.

We construct $\phi^n_\sigma(u^n_{h,k})$ with the help of a covolume mesh (see, e.g., [3]). The covolume χ_σ associated to σ is constructed around each edge by joining end points of this edge and midpoints of finite volumes which are common to this edge; see Figure 2.2. We denote the end points of an edge $\bar{\sigma} \subset \partial\chi_\sigma$ by $N_1(\bar{\sigma})$ and $N_2(\bar{\sigma})$ and let $\mathbf{n}_{\chi_\sigma,\bar{\sigma}}$ be the normal unit vector to $\bar{\sigma}$ outward to χ_σ. In order to approximate diffusion flux, using the divergence theorem, we first derive an approximation of the averaged gradient on χ_σ, namely, $\frac{1}{m(\chi_\sigma)}\int_{\chi_\sigma}\nabla u^n dx = \frac{1}{m(\chi_\sigma)}\int_{\partial\chi_\sigma} u^n\mathbf{n}_{\chi_\sigma,\bar{\sigma}}ds$, and then we approximate it by $p^n_\sigma(u) = \frac{1}{m(\chi_\sigma)}\sum_{\bar{\sigma}\in\partial\chi_\sigma}\frac{1}{2}(u^n_{N_1(\bar{\sigma})} + u^n_{N_2(\bar{\sigma})})m(\bar{\sigma})\mathbf{n}_{\chi_\sigma,\bar{\sigma}}$. Let the values at x_E and x_W be taken as u_E and u_W, and let the values u_S and u_N at the vertices x_N and x_S be computed as the arithmetic mean of u_K, where K are finite volumes which are common to this vertex.

Since our mesh is uniform and squared, we can use the following relations: $m(\chi_\sigma) = \frac{h^2}{2}$ and $m(\bar{\sigma}) = \frac{\sqrt{2}}{2}h$, and after a short calculation we are ready to write

$$p^n_\sigma(u) = \frac{u^n_E - u^n_W}{h}\mathbf{n}_{K,\sigma} + \frac{u^n_N - u^n_S}{h}\mathbf{t}_{K,\sigma}, \tag{2.6}$$

where $\mathbf{t}_{K,\sigma}$ is a unit vector parallel to σ such that $(x_N - x_S)\cdot\mathbf{t}_{K,\sigma} > 0$. Although such u^n_N, u^n_W, u^n_E, and u^n_S correspond to a particular edge σ, and so we should denote them by $u^n_{N_\sigma}$, $u^n_{W_\sigma}$, $u^n_{E_\sigma}$, and $u^n_{S_\sigma}$, respectively, in (2.6), we will use the above simplified notations. By replacing the exact gradient ∇u^n by the numerical gradient $p^n_\sigma(u)$ in the approximation of $\phi^n_\sigma(u^n_{h,k})$, we get the numerical flux in the form

$$\phi^n_\sigma(u^n_{h,k}) = (D_\sigma p^n_\sigma(u))\cdot\mathbf{n}_{K,\sigma}, \tag{2.7}$$

where $D_\sigma = D^{n-1}_\sigma = \left(\begin{smallmatrix}\bar{\lambda}_\sigma & \bar{\beta}_\sigma\\ \bar{\beta}_\sigma & \bar{\nu}_\sigma\end{smallmatrix}\right)$ is an approximation of the mean value of matrix D along σ evaluated at the previous time step. To that goal we take $u^{n-1}_{h,k}$ for constructing the structure and diffusion tensor and evaluate them at x_{KL}, where x_{KL} is a point of $\sigma_{KL} = K|L$ intersecting the segment $x_K x_L$. From an implementation point of view, the structure and then diffusion tensor evaluation can be done in two ways.

Either we can replace gradients of u appearing in structure tensor by their numerical approximation $p_\sigma^n(u)$ and then smooth them by weighted average (convolution), or we can evaluate $\nabla G_{\tilde{t}} * u_{h,k}^{n-1}$ using weights given by $\nabla G_{\tilde{t}}$ applied to discrete piecewise constant values of $u_{h,k}^{n-1}$ as convolution realization. In the latter way we do not introduce additional approximation into the scheme, and in the part devoted to convergence analysis we use the latter approach, although both are realizable computationally.

It is important to note that in (2.7) we always consider the matrix D_σ written in the basis $(\mathbf{n}_{K,\sigma}, \mathbf{t}_{K,\sigma})$; cf. [3]. Although it may look artificial, it will simplify further considerations. In practice it means that (cf. Figure 2.1) if the matrix D is given in standard basis on edge σ by $\left(\begin{smallmatrix}\lambda_\sigma & \beta_\sigma\\ \beta_\sigma & \nu_\sigma\end{smallmatrix}\right)$, then $D_\sigma = \left(\begin{smallmatrix}\lambda_\sigma & \beta_\sigma\\ \beta_\sigma & \nu_\sigma\end{smallmatrix}\right)$, i.e., $\bar{\lambda}_\sigma = \lambda_\sigma$, $\bar{\beta}_\sigma = \beta_\sigma$, $\bar{\nu}_\sigma = \nu_\sigma$ for the two edges $\sigma = \sigma_2$ and σ_3. On the other hand, $D_\sigma = \left(\begin{smallmatrix}\nu_\sigma & -\beta_\sigma\\ -\beta_\sigma & \lambda_\sigma\end{smallmatrix}\right)$, i.e., $\bar{\lambda}_\sigma = \nu_\sigma$, $\bar{\beta}_\sigma = -\beta_\sigma$, $\bar{\nu}_\sigma = \lambda_\sigma$ for other two edges $\sigma = \sigma_1$ and σ_4. By using such a matrix representation, the definition (2.7) can be written in this compact form

$$\phi_\sigma^n(u_{h,k}^n) = \left[\begin{pmatrix}\bar{\lambda}_\sigma & \bar{\beta}_\sigma\\ \bar{\beta}_\sigma & \bar{\nu}_\sigma\end{pmatrix}\begin{pmatrix}\frac{u_E^n - u_W^n}{h}\\ \frac{u_N^n - u_S^n}{h}\end{pmatrix}\right]\cdot\begin{pmatrix}1\\0\end{pmatrix} = \bar{\lambda}_\sigma\frac{u_E^n - u_W^n}{h} + \bar{\beta}_\sigma\frac{u_N^n - u_S^n}{h}, \tag{2.8}$$

since in the basis $(\mathbf{n}_{K,\sigma}, \mathbf{t}_{K,\sigma})$ the formula (2.6) can be written for each edge as

$$p_\sigma^n(u) = \begin{pmatrix}\frac{u_E^n - u_W^n}{h}\\ \frac{u_N^n - u_S^n}{h}\end{pmatrix} \tag{2.9}$$

and $\mathbf{n}_{K,\sigma}$ is equal to $\binom{1}{0}$ in the basis $(\mathbf{n}_{K,\sigma}, \mathbf{t}_{K,\sigma})$ for each edge σ. Because of the convolutions in (1.5) and (1.6), the elements of matrix D_σ are C^∞ functions.

Finally, let us summarize our *semiimplicit finite volume scheme*:

$$\frac{u_K^n - u_K^{n-1}}{k} - \frac{1}{m(K)}\sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{int}}\phi_\sigma^n(u_{h,k}^n)m(\sigma) = 0, \tag{2.10}$$

where

$$\phi_\sigma^n(u_{h,k}^n) = \bar{\lambda}_\sigma\frac{u_E^n - u_W^n}{h} + \bar{\beta}_\sigma\frac{u_N^n - u_S^n}{h}. \tag{2.11}$$

3. Existence and uniqueness of the solution to the discrete scheme. In order to fulfill the main goal of this section, to prove the existence and uniqueness of u_K^n, $K\in\mathcal{T}_h$, we estimate the expressions $u_N^n - u_S^n$ by means of $u_E^n - u_W^n$ for all edges σ. To that goal we use mainly the results of [3] in our situation. Let us note that, due to simplification of notation, we do not use upper index n in what follows, and at some places we relate u_E and u_W to particular edge σ using u_{E_σ}, u_{W_σ}, etc. In the following we denote by C_i constants which may depend on the properties of the diffusion tensor.

DEFINITION 3.1. *Let P_σ be the set of all edges δ perpendicular to σ (see Figure* 3.1 *for two illustrative situations when $\sigma = \sigma_{WE}$ and $\sigma = \sigma_{EW}$), which have a common vertex with σ and fulfill the following conditions: $x_{E_\delta} - x_{W_\delta} > 0$ if $x_{N_\sigma} - x_{S_\sigma} > 0$ and $x_{E_\delta} - x_{W_\delta} < 0$ if $x_{N_\sigma} - x_{S_\sigma} < 0$. Let us note that $x_{W_\sigma} = x_{W_\delta}^1 = x_{E_\delta}^3$ for $\sigma = \sigma_{WE}$, $x_{E_\sigma} = x_{W_\delta}^2 = x_{E_\delta}^4$ for $\sigma = \sigma_{WE}$, $x_{W_\sigma} = x_{E_\delta}^2 = x_{W_\delta}^4$ for $\sigma = \sigma_{EW}$, and $x_{E_\sigma} = x_{E_\delta}^1 = x_{W_\delta}^3$ for $\sigma = \sigma_{EW}$.*

Using definitions given in the previous section we can write

$$u_N - u_S = \frac{1}{4}\left[(u_E^1 - u_W^1) + (u_E^3 - u_W^3) + (u_E^2 - u_W^2) + (u_E^4 - u_W^4)\right], \tag{3.1}$$

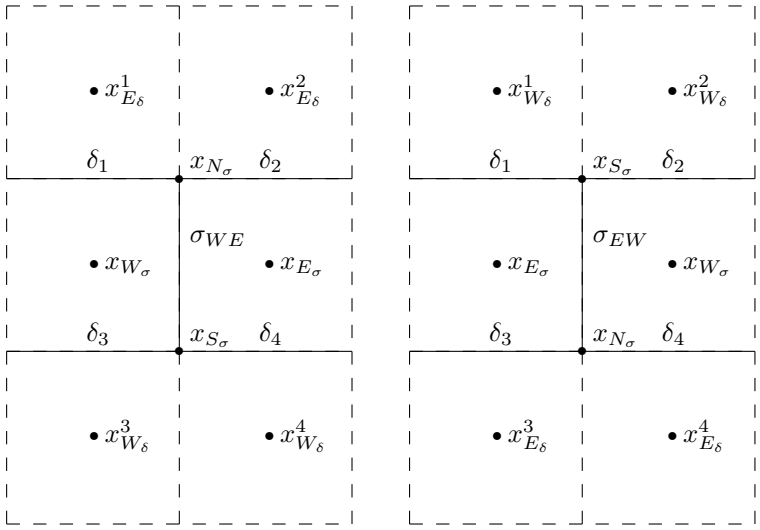

FIG. 3.1. *Left: An edge σ_{WE} and edges δ_1, δ_2, δ_3, $\delta_4 \in P_{\sigma_{WE}}$. Right: An edge σ_{EW} and edges δ_1, δ_2, δ_3, $\delta_4 \in P_{\sigma_{EW}}$.*

where $u^1_E = u_{E_{\delta_1}}$ and $u^1_W = u_{W_{\delta_1}}$ correspond to edge δ_1 and similarly u^2_E, u^2_W, u^3_E, u^3_W, u^4_E, and u^4_W correspond to edges δ_2, δ_3 and δ_4. Applying the inequality $(a+b)^2 \le 2a^2 + 2b^2$ we have

$$(u_{N_\sigma} - u_{S_\sigma})^2 \le \sum_{\delta \in P_\sigma \cap \mathcal{E}_{int}} \frac{1}{4}(u_{E_\delta} - u_{W_\delta})^2. \tag{3.2}$$

Multiplying (3.2) by $(\frac{\bar\beta_\sigma}{\bar\lambda_\sigma})^2 \frac{\bar\lambda_\sigma}{h^2}$ and summing for all $\sigma \in \mathcal{E}_{int}$ (by σ we mean σ_{WE}) we obtain

$$\sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{\bar\beta_\sigma}{\bar\lambda_\sigma}\right)^2 \left(\frac{u_{N_\sigma} - u_{S_\sigma}}{h}\right)^2 \bar\lambda_\sigma \le \sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{\bar\beta_\sigma}{\bar\lambda_\sigma}\right)^2 \sum_{\delta \in P_\sigma \cap \mathcal{E}_{int}} \frac{1}{4} \left(\frac{u_{E_\delta} - u_{W_\delta}}{h}\right)^2 \bar\lambda_\sigma. \tag{3.3}$$

Then we swap the two sums on the right-hand side of (3.3) to get

$$\sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{\bar\beta_\sigma}{\bar\lambda_\sigma}\right)^2 \left(\frac{u_{N_\sigma} - u_{S_\sigma}}{h}\right)^2 \bar\lambda_\sigma \le \sum_{\delta \in \mathcal{E}_{int}} \gamma_\delta \left(\frac{u_{E_\delta} - u_{W_\delta}}{h}\right)^2 \bar\lambda_\delta, \tag{3.4}$$

where

$$\gamma_\delta = \sum_{\sigma \in P_\delta \cap \mathcal{E}_{int}} \frac{1}{4} \left(\frac{\bar\beta_\sigma}{\bar\lambda_\sigma}\right)^2 \frac{\bar\lambda_\sigma}{\bar\lambda_\delta}. \tag{3.5}$$

Let us consider the matrix $\left(\begin{smallmatrix} \bar\lambda_{\sigma^\perp} & \bar\beta_{\sigma^\perp} \\ \bar\beta_{\sigma^\perp} & \bar\nu_{\sigma^\perp} \end{smallmatrix}\right)$, which is the matrix D written in the basis $(\mathbf{t}_{K,\sigma}, -\mathbf{n}_{K,\sigma})$ on edge σ. Due to the smoothness of D we get

$$\bar\lambda_\sigma = \bar\nu_{\sigma^\perp} = \bar\nu_\delta(1 + O(h)) = \bar\lambda_{\delta^\perp}(1 + O(h)), \quad \delta \in P_\sigma, \tag{3.6}$$

$$\bar\beta_\sigma = -\bar\beta_{\sigma^\perp} = -\bar\beta_\delta(1 + O(h)) = \bar\beta_{\delta^\perp}(1 + O(h)), \quad \delta \in P_\sigma, \tag{3.7}$$

$$\bar\nu_\sigma = \bar\lambda_{\sigma^\perp} = \bar\lambda_\delta(1 + O(h)) = \bar\nu_{\delta^\perp}(1 + O(h)), \quad \delta \in P_\sigma. \tag{3.8}$$

By applying (3.6)–(3.8) in (3.5) and using $\frac{1}{1-Ch} \leq 1 + (C + 2C^2 h)h$ for h sufficiently small ($h \leq \frac{1}{2C}$), we have

$$\gamma_\delta \leq \sum_{\sigma \in P_\delta \cap \mathcal{E}_{int}} \frac{1}{4} \left(\frac{\bar{\beta}_{\delta^\perp}}{\bar{\lambda}_{\delta^\perp}} \right)^2 \frac{\bar{\lambda}_{\delta^\perp}}{\bar{\lambda}_\delta} (1 + O(h)) = \left(\frac{\bar{\beta}_{\delta^\perp}}{\bar{\lambda}_{\delta^\perp}} \right)^2 \frac{\bar{\lambda}_{\delta^\perp}}{\bar{\lambda}_\delta} (1 + O(h)).$$

By using the positive definiteness of the diffusion tensor written in a standard basis as $\begin{pmatrix} \lambda_\delta & \beta_\delta \\ \beta_\delta & \nu_\delta \end{pmatrix}$, we obtain for its determinant

$$\lambda_\delta \nu_\delta - \beta_\delta^2 > 0. \tag{3.9}$$

Now we have two possibilities for γ_δ. Let δ be an arbitrary edge in the mesh parallel to σ_3 (see Figure 2.1). Then $\gamma_\delta \leq (\frac{-\beta_\delta}{\nu_\delta})^2 \frac{\nu_\delta}{\lambda_\delta}(1 + O(h)) = \frac{(\beta_\delta)^2}{\lambda_\delta \nu_\delta}(1 + O(h)) < 1$ for h sufficiently small due to (3.9). Similarly, if δ is any edge oriented perpendicularly to σ_3, we have $\gamma_\delta \leq (\frac{\beta_\delta}{\lambda_\delta})^2 \frac{\lambda_\delta}{\nu_\delta}(1 + O(h)) = \frac{(\beta_\delta)^2}{\lambda_\delta \nu_\delta}(1 + O(h)) < 1$ for h sufficiently small. Thus, due to the fact that $\lambda_\sigma \geq C > 0$ and $\nu_\sigma \geq C > 0$, we obtain $0 \leq \gamma_\delta < 1$ for h sufficiently small. Since this condition is fulfilled for each edge δ, we can rewrite (3.4) as

$$\sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{\bar{\beta}_\sigma}{\bar{\lambda}_\sigma} \right)^2 \left(\frac{u_N - u_S}{h} \right)^2 \bar{\lambda}_\sigma \leq \gamma \sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{u_E - u_W}{h} \right)^2 \bar{\lambda}_\sigma, \tag{3.10}$$

where $0 \leq \gamma < 1, \quad \gamma = \max_{\sigma \in \mathcal{E}} \gamma_\sigma$.

Let us now introduce the space of piecewise constant functions associated to our mesh and discrete H^1 norm for this space. This discrete norm will be used to obtain some estimates on the approximate solution given by the finite volume scheme.

DEFINITION 3.2. *Let Ω be an open bounded polygonal subset of R^2. Let $\mathcal{T}_h$ be an admissible finite volume mesh (see [4]). We define $\mathcal{P}_0(\mathcal{T}_h)$ as the set of functions from Ω to R which are constant over each finite volume K of the mesh $\mathcal{T}_h$.*

DEFINITION 3.3. *Let Ω be an open bounded polygonal subset of R^2. For $u \in \mathcal{P}_0(\mathcal{T}_h)$ we define*

$$|u^n_{h,k}|_{1,\mathcal{T}_h} = \left(\sum_{(K,L) \in \Upsilon} \frac{(u_L - u_K)^2}{d_{K,L}} m(\sigma) \right)^{\frac{1}{2}}, \tag{3.11}$$

where $d_{K,L}$ is the Euclidean distance between x_K and x_L.

Remark that (3.11) can be rewritten for our uniform mesh into the following form:

$$|u^n_{h,k}|_{1,\mathcal{T}_h} = \left(2 \sum_{\sigma \in \mathcal{E}_{int}} \left(\frac{u_E - u_W}{h} \right)^2 m(\chi_\sigma) \right)^{\frac{1}{2}}, \tag{3.12}$$

where $\sigma = \sigma_{WE}$. Let us define a discrete operator $\mathcal{L}_h$ by

$$\mathcal{L}_h(u^n_{h,k}) = u^n_K m(K) - k \sum_{\sigma \in \mathcal{E}_K \cap \mathcal{E}_{int}} \phi^n_\sigma(u^n_{h,k}) m(\sigma).$$

Then solution $u^n_{h,k} \in \mathcal{P}_0(\mathcal{T}_h)$ of our scheme at time t_n is given by

$$\mathcal{L}_h(u^n_{h,k}) = f_{h,k}(u^{n-1}_{h,k}), \tag{3.13}$$

where $f_{h,k}(u_{h,k}^{n-1}) = u_K^{n-1} m(K)$, $K \in \mathcal{T}_h$, and u_K^{n-1} is the value of the piecewise constant function $u_{h,k}^{n-1}$ in K. This equality is a linear system of N equations with N unknowns u_K^n, $K \in \mathcal{T}_h$, $N = card(\mathcal{T}_h)$.

Multiplying $\mathcal{L}_h(u_{h,k})$ by u_K^n, summing over K, and splitting into parts A and B leads to

$$\sum_{K\in\mathcal{T}_h} \mathcal{L}_h(u_{h,k}^n) u_K^n = A + B, \tag{3.14}$$

with

$$A = \sum_{K\in\mathcal{T}_h} (u_K^n)^2 m(K) = ||u_{h,k}^n||^2_{L^2(\Omega)} \tag{3.15}$$

and

$$B = k \sum_{K\in\mathcal{T}_h} u_K^n \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{int}} -\phi_\sigma^n(u_{h,k}^n) m(\sigma).$$

The above expression can be written in the following form:

$$\begin{aligned} B &= k \sum_{W\in\mathcal{T}_h} u_W^n \sum_{\sigma\in\mathcal{E}_W\cap\mathcal{E}_{int}} -\phi_\sigma^n(u_{h,k}^n) m(\sigma) \\ &= \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} \phi_\sigma^n(u_{h,k}^n) \frac{u_E - u_W}{h} 2m(\chi_\sigma) = Q(u_{h,k}^n) \end{aligned} \tag{3.16}$$

owing to property $\phi_\sigma^n(u_{h,k}^n) = \phi_{\sigma_{WE}}^n(u_{h,k}^n) = -\phi_{\sigma_{EW}}^n(u_{h,k}^n)$. Since $\phi_\sigma^n(u_{h,k}^n) = 0$ for $\sigma \in \mathcal{E}_{ext}$, we can extend the sum in (3.16) and write

$$Q(u_{h,k}^n) = \frac{k}{2} \sum_{\sigma\in\mathcal{E}} (D_\sigma p_\sigma^\star) \cdot p_\sigma 2m(\chi_\sigma) = k(D_h p_h^\star, p_h)_{L^2(\Omega)}$$

where $p_\sigma^\star = \frac{u_E - u_W}{h} \mathbf{n}_{W,\sigma}$ for $\sigma = \sigma_{WE}$ is the normal component of the gradient and $D_h, p_h, p_h^\star$ are piecewise constant functions with values extended from σ to χ_σ. Further, we use the following inequality:

$$(D_h p_h^\star, p_h)_{L^2(\Omega)} \geq (D_h p_h^\star, p_h^\star)_{L^2(\Omega)} - |(D_h p_h^\star, p_h - p_h^\star)_{L^2(\Omega)}|. \tag{3.17}$$

It is clear that $(D_h p_h^\star, p_h^\star)_{L^2(\Omega)} = \sum_{\sigma\in\mathcal{E}} \bar{\lambda}_\sigma \left(\frac{u_E - u_W}{h}\right)^2 m(\chi_\sigma)$, due to the fact that $u_E - u_W = 0$ for $\sigma \in \mathcal{E}_{ext}$ thanks to reflexion of $u_{h,k}$ in $\Omega_{\tilde{t}}$ (see the previous section). Applying Young's inequality in the second term on the right-hand side of (3.17) leads to

$$\begin{aligned} |(D_h p_h^\star, p_h - p_h^\star)_{L^2(\Omega)}| &= \left| \sum_{\sigma\in\mathcal{E}} \bar{\beta}_\sigma \frac{u_E - u_W}{h} \frac{u_N - u_S}{h} m(\chi_\sigma) \right| \\ &\leq \sum_{\sigma\in\mathcal{E}_{int}} \frac{1}{2} \left[\left(\frac{u_E - u_W}{h}\right)^2 + \left(\frac{\bar{\beta}_\sigma}{\bar{\lambda}_\sigma}\right)^2 \left(\frac{u_N - u_S}{h}\right)^2 \right] \bar{\lambda}_\sigma m(\chi_\sigma), \end{aligned} \tag{3.18}$$

since $\phi_\sigma^n(u_{h,k}^n) = 0$ for $\sigma \in \mathcal{E}_{ext}$. By using inequalities (3.10) we get

$$\begin{aligned} |(D_h p_h^\star, p_h - p_h^\star)_{L^2(\Omega)}| &\leq \frac{1+\gamma}{2} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma \left(\frac{u_E - u_W}{h}\right)^2 m(\chi_\sigma) \\ &= \frac{1+\gamma}{2} (D_h p_h^\star, p_h^\star)_{L^2(\Omega)}. \end{aligned} \tag{3.19}$$

Using (3.12), it in turn implies

$$Q(u_{h,k}^n) \geq \left(1 - \frac{1+\gamma}{2}\right) k (Dp_h^\star, p_h^\star)_{L^2(\Omega)} \geq \bar{\lambda}_{\min} \frac{1-\gamma}{2} \frac{k}{2} |u_{h,k}^n|_{1,\mathcal{T}_h}^2, \tag{3.20}$$

where $\bar{\lambda}_{\min} = \inf_{\sigma \in \mathcal{E}} \bar{\lambda}_\sigma \geq C > 0$. By applying (3.15), (3.16), and (3.20) in (3.14), we get for h sufficiently small and any $u_{h,k}^n \in \mathcal{P}_0(\mathcal{T}_h)$ that

$$\sum_{K \in \mathcal{T}_h} \mathcal{L}_h(u_{h,k}^n) u_K^n \geq \alpha \left(|u_{h,k}^n|_{1,\mathcal{T}_h}^2 + ||u_{h,k}^n||_{L^2(\Omega)}^2 \right),$$

with $\alpha = \min\left(\bar{\lambda}_{\min}(1-\gamma)\frac{k}{4}, 1\right)$.

THEOREM 3.4. *For h sufficiently small, there exists a unique solution $u_{h,k}^n$ given by the scheme* (2.10)–(2.11) *at any discrete time step t_n.*

Proof. Assume that u_K, $K \in \mathcal{T}_h$, satisfy the linear system (3.13), and let the right-hand side of (3.13) be equal to 0. Then

$$\alpha \left(|u_{h,k}^n|_{1,\mathcal{T}_h}^2 + ||u_{h,k}^n||_{L^2(\Omega)}^2 \right) \leq \sum_{K \in \mathcal{T}_h} \mathcal{L}_h(u_{h,k}^n) u_K^n = \sum_{K \in \mathcal{T}_h} f_{h,k}(u_{h,k}^{n-1}) u_K^n = 0. \tag{3.21}$$

Due to relation (3.21) and the strict positivity of α we know that $u_K^n = 0$ for all $K \in \mathcal{T}_h$. It means that the kernel of the linear transformation represented by the matrix of the system (3.13) contains only $\bar{0}$ vector, which implies that the matrix is regular. Thus it also implies that there exists a unique solution for any right-hand side. ∎

4. Convergence of the scheme to the weak solution.

DEFINITION 4.1. *The weak solution of the problem* (1.1)–(1.3) *is a function $u \in L^2(0,T;H^1(\Omega))$ which satisfies the identity*

$$\int_0^T \int_\Omega u \frac{\partial \varphi}{\partial t}(x,t) dx dt + \int_\Omega u_0(x)\varphi(x,0) dx - \int_0^T \int_\Omega (D\nabla u) \cdot \nabla \varphi dx dt = 0 \ \forall \varphi \in \Psi, \tag{4.1}$$

where $\Psi = \{\varphi \in C^{2,1}(\overline{\Omega} \times [0,T]), (D\nabla\varphi) \cdot \overrightarrow{n} = 0 \text{ on } \partial\Omega \times (0,T), \varphi(.,T) = 0\}$.

Remark 1. The existence and uniqueness of the weak solution and extremum principle for the model (1.1)–(1.3) are given in [24]. The proofs are based on theory built in [1].

In the proof of convergence we will use a strategy based on the application of Kolmogorov's compactness criterion in L^2 which gives the relative compactness of the approximate solutions given by the scheme refining the space and time discretization step. By using relative compactness we can choose a convergent subsequence which in the limit gives the weak solution. In order to use Kolmogorov's compactness criterion we shall prove the following four lemmas.

LEMMA 4.2 (uniform boundedness). *There exists a positive constant C such that*

$$\|u_{h,k}\|_{L^2(Q_T)} \leq C. \tag{4.2}$$

LEMMA 4.3 (time translate estimate). *For any $s \in (0,T)$ there exists a positive constant C such that*

$$\int_{\Omega \times (0,T-s)} \left(u_{h,k}(x,t+s) - u_{h,k}(x,t)\right)^2 dx dt \leq Cs. \tag{4.3}$$

LEMMA 4.4 (space translate estimate I). *There exists a positive constant C such that*

$$\int_{\Omega_\xi \times (0,T)} \left(u_{h,k}(x+\xi,t) - u_{h,k}(x,t)\right)^2 dx dt \leq C|\xi|(|\xi| + 2h) \tag{4.4}$$

for any vector $\xi \in R^d$, where $\Omega_\xi = \{x \in \Omega, [x, x+\xi] \in \Omega\}$.

LEMMA 4.5 (space translate estimate II). *There exists a positive constant C such that*

$$\int_{\Omega\times(0,T)} \left(u_{h,k}\left(x+\xi,t\right)-u_{h,k}\left(x,t\right)\right)^2 dxdt \le C\left|\xi\right| \tag{4.5}$$

for any vector $\xi \in R^d$.

To prove (4.2)–(4.5) we will use the following a priori estimates.

LEMMA 4.6. *The scheme* (2.10)–(2.11) *leads to the following estimates. For h sufficiently small, there exists a positive constant C which does not depend on h,k such that*

$$\max_{0\le n\le N_{\max}} \sum_{K\in\mathcal{T}_h} \left(u_K^n\right)^2 m(K) \le C, \tag{4.6}$$

$$\sum_{n=1}^{N_{\max}} k \sum_{(K,L)\in\Upsilon} \frac{\left(u_K^n-u_L^n\right)^2}{d_{K,L}} m\left(\sigma\right) \le C, \tag{4.7}$$

$$\sum_{n=1}^{N_{\max}} \sum_{K\in\mathcal{T}_h} \left(u_K^n-u_K^{n-1}\right)^2 m\left(K\right) \le C. \tag{4.8}$$

Proof. We multiply (2.10) by u_K^n, sum it over $K\in\mathcal{T}_h$ and over $n=1,\dots,m<N_{max}$, and use the property $(a-b)a=\frac{1}{2}a^2-\frac{1}{2}b^2+\frac{1}{2}(a-b)^2$ to obtain

$$\begin{aligned}&\frac{1}{2}\sum_{K\in\mathcal{T}_h}(u_K^m)^2m(K)+\frac{1}{2}\sum_{n=1}^{m}\sum_{K\in\mathcal{T}_h}(u_K^n-u_K^{n-1})^2m(K)\\ &-\sum_{n=1}^{m}k\sum_{K\in\mathcal{T}_h}u_K^n\sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{int}}\phi_\sigma^n(u_{h,k}^n)m(\sigma)=\frac{1}{2}\sum_{K\in\mathcal{T}_h}(u_K^0)^2m(K).\end{aligned} \tag{4.9}$$

Then by using (3.16) and (3.20) we have

$$\begin{aligned}&\frac{1}{2}\sum_{K\in\mathcal{T}_h}(u_K^m)^2m(K)+\frac{1}{2}\sum_{n=1}^{m}\sum_{K\in\mathcal{T}_h}(u_K^n-u_K^{n-1})^2m(K)\\ &+\bar{\alpha}\sum_{n=1}^{m}k|u_{h,k}^n|_{1,\mathcal{T}_h}^2\le\frac{1}{2}\sum_{K\in\mathcal{T}_h}(u_K^0)^2m(K),\end{aligned} \tag{4.10}$$

with positive constant $\bar{\alpha}=\bar{\lambda}_{\min}\frac{1-\gamma}{4}$. Since $u_0\in L^2(\Omega)$, the right-hand side is bounded by a positive constant C. By using the first term of (4.10) we get a priori estimate (4.6), and from the second term of (4.10) we get a priori estimate (4.8). From the strict positiveness of $\bar{\alpha}$ in the third term of (4.10) and from definition (3.11), we obtain a priori estimate (4.7). ∎

Proof of Lemma 4.2. It follows from the first $L^2(\Omega)$—a priori estimate (4.6). ∎

Proof of Lemma 4.3. First, for fixed $s\in(0,T)$, we define function

$$f(t)=\int_\Omega \left(u_{h,k}\left(x,t+s\right)-u_{h,k}\left(x,t\right)\right)^2 dx.$$

By using the fact that $u_{h,k}$ is a piecewise constant function, we get

$$f(t)=\sum_{K\in\mathcal{T}_h}\left(u_K^{n_{t+s}}-u_K^{n_t}\right)^2 m\left(K\right), \tag{4.11}$$

with $n_t = \lceil \frac{t}{k} \rceil$ and $n_{t+s} = \lceil \frac{t+s}{k} \rceil$, where $\lceil \cdot \rceil$ means the upper integer part of a positive real number. We rearrange (4.11) to obtain

$$f(t) = \sum_{K\in\mathcal{T}_h} \left(u_K^{n_{t+s}} - u_K^{n_t}\right) \sum_{t\le(n+1)k<t+s} \left(u_K^n - u_K^{n-1}\right) m\left(K\right). \tag{4.12}$$

By using the scheme (2.10)–(2.11) in (4.12) (replacing K by W) we get

$$f(t) = \sum_{t\le(n+1)k<t+s} k \sum_{W\in\mathcal{T}_h} \left(\left(u_W^{n_{t+s}} - u_W^{n_t}\right) \sum_{\sigma\in\mathcal{E}_W\cap\mathcal{E}_{int}} \bar{\lambda}_\sigma (u_E^n - u_W^n) + \bar{\beta}_\sigma (u_N^n - u_S^n) \right), \tag{4.13}$$

and due to conservativity of numerical fluxes (antisymmetry of term $\bar{\lambda}_\sigma(u_E^n - u_W^n) + \bar{\beta}_\sigma(u_N^n - u_S^n)$) we have

$$\begin{aligned} f(t) = \sum_{t\le(n+1)k<t+s} \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} & \left(u_W^{n_{t+s}} - u_W^{n_t} - u_E^{n_{t+s}} + u_E^{n_t}\right) \\ & \left(\bar{\lambda}_\sigma(u_E^n - u_W^n) + \bar{\beta}_\sigma(u_N^n - u_S^n)\right). \end{aligned} \tag{4.14}$$

Using Young's inequality leads to the relation

$$\begin{aligned} f(t) \le & \sum_{t\le(n+1)k<t+s} \frac{k}{4} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma (u_W^{n_{t+s}} - u_W^{n_t} - u_E^{n_{t+s}} + u_E^{n_t})^2 \\ & + \sum_{t\le(n+1)k<t+s} \frac{k}{4} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma \left((u_E^n - u_W^n) + \frac{\bar{\beta}_\sigma}{\bar{\lambda}_\sigma} (u_N^n - u_S^n) \right)^2, \end{aligned} \tag{4.15}$$

where the right-hand side can be further estimated and we get

$$f(t) \le f_1(t) + f_2(t) + f_3(t) + f_4(t), \tag{4.16}$$

$$f_1(t) = \sum_{t\le(n+1)k<t+s} \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma \left(u_E^{n_t} - u_W^{n_t}\right)^2, \tag{4.17}$$

$$f_2(t) = \sum_{t\le(n+1)k<t+s} \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma \left(u_E^{n_{t+s}} - u_W^{n_{t+s}}\right)^2, \tag{4.18}$$

$$f_3(t) = \sum_{t\le(n+1)k<t+s} \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma (u_E^n - u_W^n)^2, \tag{4.19}$$

$$f_4(t) = \sum_{t\le(n+1)k<t+s} \frac{k}{2} \sum_{\sigma\in\mathcal{E}_{int}} \bar{\lambda}_\sigma \left(\frac{\bar{\beta}_\sigma}{\bar{\lambda}_\sigma}\right)^2 (u_N^n - u_S^n)^2. \tag{4.20}$$

Next we integrate (4.16) in time interval $(0, T-s)$, and by replacing $\sum_{\sigma\in\mathcal{E}_{int}}$ by $\sum_{(K,L)\in\Upsilon}$ (the edge $\sigma \in \mathcal{E}_K$ is an intersection of K and its adjacent finite volume L) we get an estimate of the first integral term

$$\int_0^{T-s} f_1(t)dt = \int_0^{T-s} \frac{k}{2} \sum_{(K,L)\in\Upsilon} \bar{\lambda}_\sigma \left(u_L^{n_t} - u_K^{n_t}\right)^2 \sum_{n\in\mathbf{N}} \chi_{\{t\le(n+1)k<t+s\}} dt. \tag{4.21}$$

We substitute the integral over $(0, T-s)$ by the sum of time step intervals and use the property $\chi_{\{t\le(n+1)k<t+s\}} = \chi_{\{(n+1)k-s<t\le(n+1)k\}}$ to obtain

$$\int_0^{T-s} f_1(t)dt \le \sum_{n_t=0}^{N_{\max}-1} \frac{k}{2} \sum_{(K,L)\in\Upsilon} \bar{\lambda}_\sigma \left(u_L^{n_t} - u_K^{n_t}\right)^2 \int_{n_t k}^{(n_t+1)k} \sum_{n\in\mathbf{N^o}} \chi_{\{(n+1)k-s<t\le(n+1)k\}} dt. \tag{4.22}$$

Since $\int_{n_t k}^{(n_t+1)k} \sum_{n\in\mathbf{N^o}} \chi_{\{(n+1)k-s<t\le(n+1)k\}} dt = s$, and $m(\sigma) = d_{K,L}$ for our uniform mesh, the relation (4.22) leads to

$$\int_0^{T-s} f_1(t)dt \le s \sum_{n_t=0}^{N_{\max}} \frac{k}{2} \sum_{(K,L)\in\Upsilon} \frac{m(\sigma)}{d_{K,L}} \bar{\lambda}_\sigma \left(u_L^{n_t} - u_K^{n_t}\right)^2. \tag{4.23}$$

The next step is to prove the following relation:

$$0 < C_1 \le \bar{\lambda}_\sigma \le C_2 < \infty \ \text{ for all } \ \sigma \in \mathcal{E}. \tag{4.24}$$

Let K be any fixed finite volume. Since at any time step the matrix $D_\sigma = \left(\begin{smallmatrix} \bar{\lambda}_\sigma & \bar{\beta}_\sigma \\ \bar{\beta}_\sigma & \bar{\nu}_\sigma \end{smallmatrix}\right)$ is uniformly (strictly) positive definite, $\bar{\lambda}_\sigma \ge C_3 > 0$ and $\bar{\nu}_\sigma \ge C_4 > 0$ for all σ. The structure tensor evaluated numerically at point x_{KL} is given by

$$J_\rho\left(\nabla u_{h,k}^{n-1}{}_{\tilde{t}}\right)(x_{KL}) = G_\rho * \begin{pmatrix} A & B \\ B & C \end{pmatrix}, \tag{4.25}$$

where

$$A = \left(\left(\frac{\partial G_{\tilde{t}}}{\partial x} * \tilde{u}_{h,k}^{n-1}\right)(x_{KL})\right)^2, \quad C = \left(\left(\frac{\partial G_{\tilde{t}}}{\partial y} * \tilde{u}_{h,k}^{n-1}\right)(x_{KL})\right)^2, \tag{4.26}$$

$$B = \left(\frac{\partial G_{\tilde{t}}}{\partial x} * \tilde{u}_{h,k}^{n-1}\right)(x_{KL}) \left(\frac{\partial G_{\tilde{t}}}{\partial y} * \tilde{u}_{h,k}^{n-1}\right)(x_{KL}). \tag{4.27}$$

By using Young's inequality, a priori estimate (4.6), and the definition of extension $\tilde{u}_{h,k}^n$ (see (2.4)), we subsequently get for $i = 1, 2$ ($x_1 = x, x_2 = y$)

$$\begin{aligned} \left|\left(\frac{\partial}{\partial x_i} G_{\tilde{t}} * \tilde{u}_{h,k}^n\right)(x_{KL})\right| &\le \int_{R^d} \left|\frac{\partial}{\partial x_i} G_{\tilde{t}}(x_{KL} - \xi)\tilde{u}_{h,k}^n(\xi)\right| d\xi \\ &\le \frac{1}{2}\int_{R^d} \left|\frac{\partial}{\partial x_i} G_{\tilde{t}}(x_{KL} - \xi)\right|^2 d\xi + \frac{1}{2}\int_{R^d} |\tilde{u}_{h,k}^n(\xi)|^2 d\xi \le C_{\tilde{t}} \\ &\quad + C_5 \int_{\Omega_{\tilde{t}}} |\tilde{u}_{h,k}^n(\xi)|^2 d\xi \le C_{\tilde{t}} + C_5 \sum_{K\in\mathcal{T}_h} \left(u_K^n\right)^2 m(K) \le C_6. \end{aligned} \tag{4.28}$$

By inspecting relations (1.6)–(1.10) we may observe that if the elements of matrix J_ρ are finite, then also the elements of matrix D_σ are finite, which gives (4.24). By applying (4.24) and (4.7) in (4.23), we get $\int_0^{T-s} f_1(t)dt \le Cs$. By using similar approach as in [15] and relation (3.10), all further integrals can be estimated in the same way, which ends the proof. □

Proof of Lemma 4.4. Let us define $\xi_{K,L} = \frac{\xi}{|\xi|}.n_{K,\sigma}$ for all $(K, L) \in \Upsilon$ and let for all $x \in \Omega_\xi$

$$E(x, K, L) = \begin{cases} 1 & \text{if } [x, x+\xi] \text{ intersects } \sigma = \sigma_{KL},\ K \text{ and } L;\ \text{and } \xi_{K,L} > 0 \\ 0 & \text{otherwise.} \end{cases}$$

For any $t \in (0,T)$ there exists $n \in N$ which satisfies $(n-1)k < t \leq nk$. Then for almost all $x \in \Omega_\xi$ we can see that

$$u_{h,k}(x+\xi,t) - u_{h,k}(x,t) = u^n_{K(x+\xi)} - u^n_{K(x)} = \sum_{(K,L)\in\Upsilon} E(x,K,L)\,(u^n_L - u^n_K),$$

where $K(x)$ denotes the volume $K \in \mathcal{T}_h$, where $x \in K$. By using these notations we get the proof in similar lines as in [15]—proof of Lemma 3.2. □

Proof of Lemma 4.5. In this proof, for simplicity, let us consider that $\Omega_{\tilde{t}} = \Omega$; i.e., we extend $u_{h,k}$ outside Ω by 0. The results which are obtained below can be straightforwardly adjusted to the situation with reflexion to $\Omega_{\tilde{t}}$; the derivation is just technically more complicated, and for details we refer to [10]. Let us define the set

$$\mathcal{E}_{ext} = \{\varpi, \text{ such that there exists } K \in \mathcal{T}_h,\ \varpi \subset \partial K \cap \partial\Omega\}$$

and let $u_\varpi := u_K$, where $K \in \mathcal{T}_h,\ \varpi \subset \partial K \cap \partial\Omega$. Since now for $x \in \Omega - \Omega_\xi$ the point $x+\xi$ can be outside Ω, we see that

$$\begin{aligned} &u_{h,k}(x+\xi,t) - u_{h,k}(x,t) \\ &= \sum_{(K,L)\in\Upsilon} E(x,K,L)\,(u^n_L - u^n_K) - \sum_{\varpi\in\mathcal{E}_{ext}} \chi([x,x+\xi]\cap\varpi)\,u^n_\varpi. \end{aligned} \tag{4.29}$$

By using the Cauchy–Schwarz and Young inequalities we obtain

$$\begin{aligned} &(u_{h,k}(x+\xi,t) - u_{h,k}(x,t))^2 \\ &\leq 2\left(\sum_{(K,L)\in\Upsilon} E(x,p,q)\,\xi_{K,L}d_{K,L}\right)\left(\sum_{(K,L)\in\Upsilon} E(x,K,L)\,\frac{(u^n_L - u^n_K)^2}{\xi_{K,L}d_{K,L}}\right) \\ &\quad + 2\sum_{\varpi\in\mathcal{E}_{ext}} \chi([x,x+\xi]\cap\varpi)\,(u^n_\varpi)^2, \end{aligned} \tag{4.30}$$

$$\begin{aligned} &\int_{\Omega\times(0,T)} (u_{h,k}(x+\xi,t) - u_{h,k}(x,t))^2\,dxdt \\ &\leq (2h+|\xi|)\,|\xi|\,C + 2\sum_{n=0}^{N_{\max}} k\int_\Omega \sum_{\varpi\in\mathcal{E}_{ext}} \chi([x,x+\xi]\cap\varpi)\,(u^n_\varpi)^2\,dxdt, \end{aligned} \tag{4.31}$$

which can be written as

$$\begin{aligned} &\int_{\Omega\times(0,T)} (u_{h,k}(x+\xi,t) - u_{h,k}(x,t))^2\,dxdt \\ &\leq (2h+|\xi|)\,|\xi|\,C + 2\,|\xi| \sum_{n=0}^{N_{\max}} k \sum_{\varpi\in\mathcal{E}_{ext}} (u^n_\varpi)^2\,m(\varpi). \end{aligned} \tag{4.32}$$

For the last term in (4.32) we use the trace inequality given in [4].

LEMMA 4.7. *Let Ω be an open bounded polygonal connected subset of R^d. Let $\overline{\gamma}(u_{h,k})$ be defined by $\overline{\gamma}(u_{h,k}) = u_\varpi$ a.e. for the $(d-1)-$Lebesgue measure on $\varpi \in \mathcal{E}_{ext}$. Then there exists positive C depending only on Ω such that*

$$\left\|\overline{\gamma}\left(u^n_{h,k}\right)\right\|_{L^2(\partial\Omega)} \leq C\left(\left|u^n_{h,k}\right|_{1,\mathcal{T}_h} + \left\|u^n_{h,k}\right\|_{L^2(\Omega)}\right).$$

By using the trace operator $\overline{\gamma}(u_{h,k}) = u_{\varpi}$ we can write

$$\begin{aligned}&\int_{\Omega\times(0,T)} \left(u_{h,k}(x+\xi,t) - u_{h,k}(x,t)\right)^2 dxdt\\ &\leq (2h+|\xi|)\,|\xi|\,C + 2\,|\xi| \sum_{n=0}^{N_{\max}} k \left\|\overline{\gamma}\left(u_{h,k}^n\right)\right\|^2_{L^2(\partial\Omega)} \end{aligned} \tag{4.33}$$

and applying the trace inequality implies that

$$\begin{aligned}&\int_{\Omega\times(0,T)} \left(u_{h,k}(x+\xi,t) - u_{h,k}(x,t)\right)^2 dxdt\\ &\leq (2h+|\xi|)\,|\xi|\,C + 4C\,|\xi| \sum_{n=0}^{N_{\max}} k\Big(\left|u_{h,k}^n\right|^2_{1,\mathcal{T}_h} + \left\|u_{h,k}^n\right\|^2_{L^2(\Omega)}\Big). \end{aligned} \tag{4.34}$$

Then using a priori estimates (4.6) and (4.7) ends the proof. □

Lemmas 4.2, 4.5, and 4.3 guarantee that sequence $u_{h,k}$ is relatively compact in $L^2(Q_T)$, which implies following convergence result.

LEMMA 4.8. *There exists $u \in L^2(Q_T)$ such that $u_{h,k} \to u$ in $L^2(Q_T)$ as $h,k \to 0$ in the sense of subsequences.*

For the sake of simplicity, we denote the subsequence converging to u again by $u_{h,k}$, and we are going to prove that its limit u is the weak solution of (1.1)–(1.3) in the sense of Definition 4.1.

To that goal, let $\varphi \in \Psi$ be given, and multiply the scheme (2.10) by $\varphi(x_K, t_n)$. Then we sum it over all $K \in \mathcal{T}_h$ and for $n = 1, \ldots, N_{\max}$ to get

$$\begin{aligned}&\sum_{n=1}^{N_{\max}} k \sum_{K\in\mathcal{T}_h} \frac{\left(u_K^n - u_K^{n-1}\right)}{k} \varphi(x_K, t_{n-1})\, m(K)\\ &= \sum_{n=1}^{N_{\max}} k \sum_{K\in\mathcal{T}_h} \varphi(x_K, t_{n-1}) \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{int}} \phi^n_{\sigma_{KL}}(u^n_{h,k}) m(\sigma). \end{aligned} \tag{4.35}$$

In order to have a structure similar to the weak solution identity (4.1), we rearrange (4.35) by using a discrete integration by parts and gathering the sums over $K \in \mathcal{T}_h$ and $\sigma \in \mathcal{E}_K \cap \mathcal{E}_{int}$, and we get

$$\begin{aligned}&\sum_{n=1}^{N_{\max}} k \sum_{K\in\mathcal{T}_h} u_K^n \frac{\varphi(x_K,t_n) - \varphi(x_K,t_{n-1})}{k} m(K) + \sum_{K\in\mathcal{T}_h} u_K^0 \varphi(x_K,0)\, m(K)\\ &-\frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \phi^n_\sigma(u^n_{h,k}) m(\sigma)\left(\varphi(x_L,t_{n-1}) - \varphi(x_K,t_{n-1})\right) = 0. \end{aligned} \tag{4.36}$$

In the same way as in [15] we can prove that

$$\sum_{n=1}^{N_{\max}} k \sum_{K\in\mathcal{T}_h} u_K^n \frac{\varphi(x_K,t_n) - \varphi(x_K,t_{n-1})}{k} m(K) \to \int_0^T \int_\Omega u \frac{\partial\varphi}{\partial t}(x,t)\, dxdt, \tag{4.37}$$

$$\sum_{K\in\mathcal{T}_h} u_K^0 \varphi(x_K,0)\, m(K) \to \int_\Omega u_0(x)\,\varphi(x,0)\, dx \tag{4.38}$$

as $h, k \to 0$ for all $\varphi \in \Psi$. The main point in proving convergence of the scheme is to get that

$$\frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \phi_\sigma^n(u_{h,k}^n) m(\sigma)\left(\varphi\left(x_L, t_{n-1}\right) - \varphi\left(x_K, t_{n-1}\right)\right)$$
$$\to \int_0^T \int_\Omega -\nabla\cdot\left(D\nabla\varphi\right) u dx dt \tag{4.39}$$

as $h, k \to 0$ for all $\varphi \in \Psi$. By using then the space translate estimate (4.4) we know (see, e.g., [4] or [14]) that the limit function u is in the space $L^2((0,T), H^1)$, so we can use Green's theorem, and by applying the boundary conditions we have

$$\int_0^T \int_\Omega -\nabla\cdot\left(D\nabla\varphi\right) u dx dt = \int_0^T \int_\Omega \left(D\nabla\varphi\right)\cdot\nabla u dx dt.$$

Proving (4.39) thus leads to overall convergence of the scheme to the weak solution in the sense of (4.1). To deal with (4.39) we rewrite it and then split into the sum of five terms

$$\frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} \phi_\sigma^n(u_{h,k}^n) m(\sigma)\left(\varphi\left(x_E, t_{n-1}\right) - \varphi\left(x_W, t_{n-1}\right)\right)$$
$$+ \int_0^T \int_\Omega \nabla\cdot\left(D\nabla\varphi(x,t)\right) u(x,t) dx dt = \sum_{i=1}^{5} T_i, \tag{4.40}$$

where

$$T_1 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} \big[(D_\sigma p_\sigma(u))\cdot\mathbf{n}_{W,\sigma}(\varphi_E^{n-1} - \varphi_W^{n-1})$$
$$- (u_E^n - u_W^n)(D_\sigma p_\sigma(\varphi^{n-1}))\cdot\mathbf{n}_{W,\sigma}\big] m(\sigma),$$
$$T_2 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} (u_E^n - u_W^n) m(\sigma)\big[(D_\sigma p_\sigma(\varphi^{n-1}))$$
$$\cdot\mathbf{n}_{W,\sigma} - (D_\sigma\nabla\varphi(x_{WE}, t_{n-1}))\cdot\mathbf{n}_{W,\sigma}\big],$$
$$T_3 = \frac{1}{2}\sum_{n=1}^{N_{\max}} \sum_{(W,E)\in\Upsilon} (u_E^n - u_W^n)\left(m(\sigma) k (D_\sigma\nabla\varphi(x_{WE}, t_{n-1}))\right.$$
$$\left.\cdot\mathbf{n}_{W,\sigma} - \int_{t_{n-1}}^{t_n}\int_\sigma (D_\sigma\nabla\varphi(s,t))\cdot\mathbf{n}_{W,\sigma} ds dt\right),$$
$$T_4 = \frac{1}{2}\sum_{n=1}^{N_{\max}} \sum_{(W,E)\in\Upsilon} (u_E^n - u_W^n)\int_{t_{n-1}}^{t_n}\int_\sigma ((D_\sigma - D)\nabla\varphi(s,t))\cdot\mathbf{n}_{W,\sigma} ds dt,$$
$$T_5 = \int_0^T \int_\Omega \nabla\cdot\left(D\nabla\varphi(x,t)\right)\left(u(x,t) - u_{h,k}(x,t)\right) dx dt,$$

where $\varphi_W^{n-1} = \varphi(x_W, t_{n-1})$, $\varphi_E^{n-1} = \varphi(x_E, t_{n-1})$, and $\varphi^{n-1} = \varphi(x, t_{n-1})$. Since

$$\begin{aligned}
&\frac{1}{2}\sum_{n=1}^{N_{\max}}\sum_{(W,E)\in\Upsilon}(u_E^n - u_W^n)\int_{t_{n-1}}^{t_n}\int_\sigma (D\nabla\varphi(s,t))\cdot\mathbf{n}_{W,\sigma}dsdt\\
&= -\sum_{n=1}^{N_{\max}}\sum_{W\in\mathcal{T}_h} u_W^n\int_{t_{n-1}}^{t_n}\sum_{\sigma\in\mathcal{E}_W}\int_\sigma (D\nabla\varphi(s,t))\cdot\mathbf{n}_{W,\sigma}dsdt\\
&= -\sum_{n=1}^{N_{\max}}\sum_{W\in\mathcal{T}_h} u_W^n\int_{t_{n-1}}^{t_n}\int_W \nabla\cdot(D\nabla\varphi(x,t))dxdt\\
&= -\int_0^T\int_\Omega \nabla\cdot(D\nabla\varphi(x,t))u_{h,k}(x,t)dxdt,
\end{aligned}$$

one can see correspondence of terms in T_4 and T_5. First, let us deal with T_1 and rewrite it using (2.7)–(2.8) into the form

$$\begin{aligned}
T_1 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} \big([\bar\lambda_\sigma(u_E^n - u_W^n) + \bar\beta_\sigma(u_N^n - u_S^n)](\varphi_E^{n-1} - \varphi_W^{n-1})\\
- (u_E^n - u_W^n)[\bar\lambda_\sigma(\varphi_E^{n-1} - \varphi_W^{n-1}) + \bar\beta_\sigma(\varphi_N^{n-1} - \varphi_S^{n-1})]\big),
\end{aligned}$$

which can be easily simplified to

$$T_1 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon}[\bar\beta_\sigma(u_N^n - u_S^n)(\varphi_E^{n-1} - \varphi_W^{n-1}) - \bar\beta_\sigma(u_E^n - u_W^n)(\varphi_N^{n-1} - \varphi_S^{n-1})]. \tag{4.41}$$

By applying (3.1) for u and similarly for φ we get

$$\begin{aligned}
T_1 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon}\sum_{i=1}^{4}\Bigg[&\frac{\bar\beta_\sigma}{4}(\varphi_{E_\sigma} - \varphi_{W_\sigma})(u_{E_{\delta_i}} - u_{W_{\delta_i}})\\
&-\frac{\bar\beta_\sigma}{4}(u_{E_\sigma} - u_{W_\sigma})(\varphi_{E_{\delta_i}} - \varphi_{W_{\delta_i}})(1+O(h))\Bigg],
\end{aligned} \tag{4.42}$$

where we omit time indexes due to simplification; for graphical explanation of notations see Figures 3.1 and 4.1. For each term with positive sign in (4.42) one can find a corresponding term in the group of terms with negative signs ($\bar\beta_\sigma$ corresponds to some $\bar\beta_\delta$). We denote these couples by $T_{\sigma\delta}$. For example, for $\sigma = \sigma_{WE}$ and δ as plotted in Figure 4.1 (left) we can write the couple as follows:

$$\begin{aligned}
T_{\sigma_{WE}\delta} &= \frac{\bar\beta_{\sigma_{WE}}}{4}(\varphi^{n-1}_{E_{\sigma_{WE}}} - \varphi^{n-1}_{W_{\sigma_{WE}}})(u^n_{E_\delta} - u^n_{W_\delta})\\
&- \frac{\bar\beta_\delta}{4}(\varphi^{n-1}_{E_{\sigma_{EW}}} - \varphi^{n-1}_{W_{\sigma_{EW}}})(u^n_{E_\delta} - u^n_{W_\delta})(1+O(h))\\
= \frac{\bar\beta_{\sigma_{WE}}}{4}&(\varphi^{n-1}_{E_{\sigma_{WE}}} - \varphi^{n-1}_{W_{\sigma_{WE}}})(u^n_{E_\delta} v - u^n_{W_\delta}) - \frac{\bar\beta_\delta}{4}(\varphi^{n-1}_{W_{\sigma_{WE}}} - \varphi^{n-1}_{E_{\sigma_{WE}}})(u^n_{E_\delta} - u^n_{W_\delta})(1+O(h))
\end{aligned}$$

because $\bar\beta_{\sigma_{WE}} = \bar\beta_{\sigma_{EW}}$, $\varphi^{n-1}_{E_{\sigma_{WE}}} = \varphi^{n-1}_{W_{\sigma_{EW}}}$, and $\varphi^{n-1}_{W_{\sigma_{WE}}} = \varphi^{n-1}_{E_{\sigma_{EW}}}$; see Figure 4.1 (right). Using the previous expression for every $\sigma = \sigma_{WE}$ yields

$$\begin{aligned}
T_{\sigma\delta} &= \left[\frac{\bar\beta_\sigma}{4} + \left(-\frac{\bar\beta_\sigma}{4}(1+O(h))\right)\right](\varphi^{n-1}_{E_\sigma} - \varphi^{n-1}_{W_\sigma})(u^n_{E_\delta} - u^n_{W_\delta})\\
&= \frac{\bar\beta_\sigma}{4}O(h)(\varphi^{n-1}_{E_\sigma} - \varphi^{n-1}_{W_\sigma})(u^n_{E_\delta} - u^n_{W_\delta}).
\end{aligned} \tag{4.43}$$

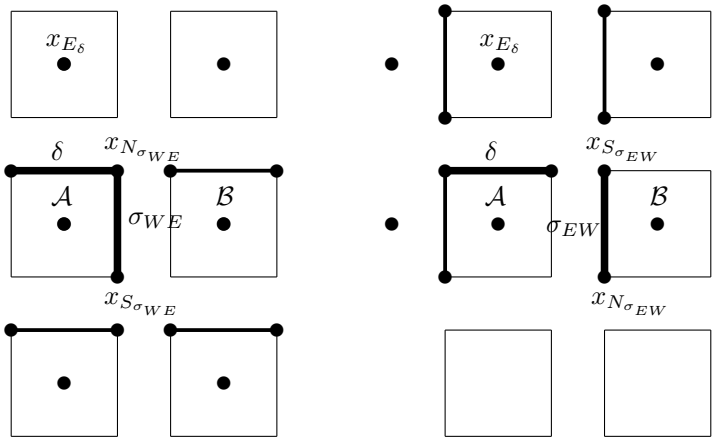

FIG. 4.1. *Left: The edge $\sigma = \sigma_{WE}$ and one $\delta \in P_\sigma$. Right: The same edge δ and one corresponding $\sigma = \sigma_{EW} \in P_\delta$. The thickest lines represent one particular couple $T_{\sigma\delta}$ in* (4.42)*, which vanishes up to the $O(h)$ term. $\mathcal{A} = x_{W_{\sigma_{WE}}} = x_{E_{\sigma_{EW}}} = x_{W_\delta}$, $\mathcal{B} = x_{E_{\sigma_{WE}}} = x_{W_{\sigma_{EW}}}$.*

Then T_1 can be estimated as follows:

$$|T_1| \le C_1 h \left| \sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \sum_{\delta\in P_\sigma\cap\mathcal{E}_{int}} (\varphi_{E_\sigma}^{n-1} - \varphi_{W_\sigma}^{n-1})(u_{E_\delta}^n - u_{W_\delta}^n) \right|,$$

with positive constant C_1 due to the fact that $\bar{\beta}_\sigma$ for each edge of mesh is finite (see (4.24)). By the Cauchy–Schwarz inequality we have

$$|T_1| \le C_2 h \left(\sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \sum_{\delta\in P_\sigma\cap\mathcal{E}_{int}} (\varphi_{E_\sigma}^{n-1} - \varphi_{W_\sigma}^{n-1})^2 \right)^{\frac{1}{2}} \left(\sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \sum_{\delta\in P_\sigma\cap\mathcal{E}_{int}} (u_{E_\delta}^n - u_{W_\delta}^n)^2 \right)^{\frac{1}{2}}. \tag{4.44}$$

It comes from the regularity of φ that there exists a positive constant C_3 such that $(\varphi_{E_\sigma}^{n-1} - \varphi_{W_\sigma}^{n-1})^2 \le C_3 h^2$. Thanks to geometrical arguments, we know that

$$\sum_{\sigma\in\mathcal{E}_{int}} d_{WE} m(\sigma) \le C_4 |\Omega|, \tag{4.45}$$

which straightforwardly gives for our uniform square mesh $\sum_{\sigma\in\mathcal{E}_{int}} h^2 \le C_4|\Omega|$. The above-mentioned facts lead to

$$\left(\sum_{n=1}^{N_{\max}} k \sum_{\sigma\in\mathcal{E}_{int}} \sum_{\delta\in P_\sigma\cap\mathcal{E}_{int}} (\varphi_{E_\sigma}^{n-1} - \varphi_{W_\sigma}^{n-1})^2 \right) \le C_5 T|\Omega|,$$

which together with a priori estimate (4.7) gives that $|T_1| \le C_6 h$, which implies

$$|T_1| \to 0 \text{ as } h, k \to 0. \tag{4.46}$$

Term T_2 can be written as $T_2 = \frac{1}{2}\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon}(u_E^n - u_W^n)m(\sigma)T_{2WE}$, where

$$T_{2WE} = \bar{\lambda}_\sigma \frac{\varphi_E^{n-1} - \varphi_W^{n-1}}{h} + \bar{\beta}_\sigma \frac{\varphi_N^{n-1} - \varphi_S^{n-1}}{h} - \bar{\lambda}_\sigma \left(\varphi_{WE}^{n-1}\right)_x - \bar{\beta}_\sigma \left(\varphi_{WE}^{n-1}\right)_y$$

and $\binom{(\varphi_{WE}^{n-1})_x}{(\varphi_{WE}^{n-1})_y} = \nabla\varphi(x_{WE}, t_{n-1})$ in the basis $(\mathbf{n}_{W,\sigma}, \mathbf{t}_{W,\sigma})$. Since $\varphi \in C^{2,1}\left(\overline{\Omega}\times[0,T]\right)$, there exist positive constants C_7 and C_8 such that

$$\left|\frac{\varphi_E^{n-1} - \varphi_W^{n-1}}{h} - \left(\varphi_{WE}^{n-1}\right)_x\right| \le C_7 h, \quad \left|\frac{\varphi_N^{n-1} - \varphi_S^{n-1}}{h} - \left(\varphi_{WE}^{n-1}\right)_y\right| \le C_8 h.$$

From there and the property that elements of D_σ are finite (see (4.28)) we have $|T_{2WE}| \le C_9 h$, with a positive constant C_9, which implies

$$|T_2| \le C_{10} h \left| \sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} (u_E^n - u_W^n) m(\sigma) \right|. \tag{4.47}$$

Then we multiply the right-hand side of (4.47) by $\frac{\sqrt{d_{WE}}}{\sqrt{d_{WE}}}$ and apply the Cauchy–Schwarz inequality to obtain

$$|T_2| \le C_{10} h \left(\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} (u_E^n - u_W^n)^2 \frac{m(\sigma)}{d_{WE}} \right)^{\frac{1}{2}} \left(\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon} m(\sigma) d_{WE} \right)^{\frac{1}{2}}.$$

A priori estimate (4.7) together with (4.45) gives $|T_2| \le C_{10}(C_{11}C_4|\Omega|T)^{\frac{1}{2}} h$ and finally

$$|T_2| \to 0 \text{ as } h, k \to 0. \tag{4.48}$$

We consider the third term in the form $T_3 = \frac{1}{2}\sum_{n=1}^{N_{\max}} \sum_{(W,E)\in\Upsilon}(u_E^n - u_W^n)T_{3WE}$, where

$$T_{3WE} = m(\sigma)k(D_\sigma \nabla\varphi(x_{WE}, t_{n-1}))\cdot \mathbf{n}_{W,\sigma} - \int_{t_{n-1}}^{t_n}\int_\sigma (D_\sigma \nabla\varphi(s,t))\cdot \mathbf{n}_{W,\sigma} ds dt.$$

Due to the smoothness of φ, the mean value theorem, and the finiteness of D_σ, we have $|T_3| \le C_{12}(h+k)|\sum_{n=1}^{N_{\max}} k \sum_{(W,E)\in\Upsilon}(u_E^n - u_W^n)m(\sigma)|$, and similarly as above by using (4.7) and (4.45) we get

$$|T_3| \to 0 \text{ as } h, k \to 0. \tag{4.49}$$

Let us define the fourth term as $T_4 = \frac{1}{2}\sum_{n=1}^{N_{\max}} \sum_{(W,E)\in\Upsilon}(u_E^n - u_W^n)T_\sigma$, where T_σ is represented by the relation $T_\sigma = \int_{t_{n-1}}^{t_n}\int_\sigma (\bar{\lambda}_\sigma - \bar{\lambda})\varphi_x + (\bar{\beta}_\sigma - \bar{\beta})\varphi_y ds dt$ and $\bar{\lambda}(x,t)$ and $\bar{\beta}(x,t)$ are the elements of matrix $D(x,t)$ in the basis $(\mathbf{n}_{W,\sigma}, \mathbf{t}_{W,\sigma})$. Owing to the continuity of function $\nabla\varphi$, one can show that there exist positive constants C_{13} and C_{14} such that $|\varphi_x| \le C_{13}$ and $|\varphi_y| \le C_{14}$. By using these facts it will be sufficient to prove that

$$|\lambda_\sigma - \lambda| = |\lambda(x_{WE}, t_{n-1}) - \lambda(x,t)| \le C_{15} h, \quad x \in \sigma, \quad t \in [t_{n-1}, t_n], \tag{4.50}$$

$$|\beta_\sigma - \beta| = |\beta(x_{WE}, t_{n-1}) - \beta(x,t)| \le C_{16} h, \quad x \in \sigma, \quad t \in [t_{n-1}, t_n], \tag{4.51}$$

$$|\nu_\sigma - \nu| = |\nu(x_{WE}, t_{n-1}) - \nu(x,t)| \le C_{17} h, \quad x \in \sigma, \quad t \in [t_{n-1}, t_n] \tag{4.52}$$

for each edge $\sigma \in \mathcal{E}$. It comes from (1.10) that

$$|\lambda_\sigma - \lambda| = \left| \frac{\kappa_1 v_{1_\sigma}^2 + \kappa_{2_\sigma} v_{2_\sigma}^2}{v_{1_\sigma}^2 + v_{2_\sigma}^2} - \frac{\kappa_1 v_1^2 + \kappa_2 v_2^2}{v_1^2 + v_2^2} \right|,$$

where the terms with index σ correspond to λ_σ and the remaining terms to λ. Here κ_2 depends on μ_1 and μ_2 (see (1.9)), and μ_1 and μ_2 together with v_1 and v_2 (see (1.7) and (1.8)) depend on the elements of the structure tensor $J_\rho(\nabla u_{\tilde{t}}) = \left(\begin{smallmatrix} a & b \\ b & c \end{smallmatrix}\right)$ which is constructed by (1.5)–(1.6). Similarly, λ_σ depends on the elements of tensor $J_\rho(\nabla u_{h,k_{\tilde{t}}})(x_{KL}) = \left(\begin{smallmatrix} a_\sigma & b_\sigma \\ b_\sigma & c_\sigma \end{smallmatrix}\right)$, evaluated numerically at point x_{KL}, using values of $\tilde{u}_{h,k}$ and weights given by convolutions. Using (4.25)–(4.27) leads to

$$a_\sigma = G_\rho * \left(\frac{\partial G_{\tilde{t}}}{\partial x} * u_{h,k} \right)^2, \quad c_\sigma = G_\rho * \left(\frac{\partial G_{\tilde{t}}}{\partial y} * u_{h,k} \right)^2,$$
$$b_\sigma = G_\rho * \left[\left(\frac{\partial G_{\tilde{t}}}{\partial x} * u_{h,k} \right) \left(\frac{\partial G_{\tilde{t}}}{\partial y} * u_{h,k} \right) \right].$$

Elements of the matrix $J_\rho(\nabla u_{\tilde{t}})$ are given as follows:

$$a = G_\rho * \left(\frac{\partial G_{\tilde{t}}}{\partial x} * u \right)^2, \quad b = G_\rho * \left[\left(\frac{\partial G_{\tilde{t}}}{\partial x} * u \right) \left(\frac{\partial G_{\tilde{t}}}{\partial y} * u \right) \right], \quad c = G_\rho * \left(\frac{\partial G_{\tilde{t}}}{\partial y} * u \right)^2.$$

To prove (4.50), we use inequality $p^2 - q^2 \le |p+q||p-q|$, and then we get $a_\sigma - a \le G_\rho * (|\frac{\partial G_{\tilde{t}}}{\partial x} * (u_{h,k}+u)||\frac{\partial G_{\tilde{t}}}{\partial x} * (u_{h,k}-u)|)$. Applying (4.28), the boundedness of solution u, and Lemma 4.8 yields that $a_\sigma \to a$ as $h, k \to 0$. One can obtain convergences $c_\sigma \to c$ in the same way, just changing x to y. For b_σ and b we add and subtract $G_\rho * [(\frac{\partial G_{\tilde{t}}}{\partial x} * u)(\frac{\partial G_{\tilde{t}}}{\partial y} * u_{h,k})]$. Then we have

$$b_\sigma - b = G_\rho * \left[\left(\frac{\partial G_{\tilde{t}}}{\partial y} * u_{h,k} \right) \left(\frac{\partial G_{\tilde{t}}}{\partial x} * (u_{h,k} - u) \right) + \left(\frac{\partial G_{\tilde{t}}}{\partial x} * u \right) \left(\frac{\partial G_{\tilde{t}}}{\partial y} * (u_{h,k} - u) \right) \right],$$

and using (4.28) and Lemma 4.8 yields the result. Due to dependence of v_1, v_2, μ_1, μ_2, and κ_2 on a, b, and c, one can conclude that also $v_{1_\sigma} \to v_1$ as $h, k \to 0$ and v_{2_σ}, μ_{1_σ}, μ_{2_σ}, and κ_{2_σ} correspondingly. Then we use above-mentioned facts to get $\lambda_\sigma \to \lambda$ as $h, k \to 0$. Since $|\beta_\sigma - \beta| = |\frac{v_{1_\sigma} v_{2_\sigma} (\kappa_1 - \kappa_{2_\sigma})}{v_{1_\sigma}^2 + v_{2_\sigma}^2} - \frac{v_1 v_2 (\kappa_1 - \kappa_2)}{v_1^2 + v_2^2}|$ and $|\nu_\sigma - \nu| = |\frac{\kappa_{2_\sigma} v_{1_\sigma}^2 + \kappa_1 v_{2_\sigma}^2}{v_{1_\sigma}^2 + v_{2_\sigma}^2} - \frac{\kappa_2 v_1^2 + \kappa_1 v_2^2}{v_1^2 + v_2^2}|$, one can prove the inequalities (4.51) and (4.52) in the same way. Then by using the same technique as in estimates of T_2 and T_3 we get

$$|T_4| \to 0 \text{ as } h, k \to 0. \tag{4.53}$$

The last term is given by $T_5 = \int_0^T \int_\Omega \nabla \cdot (D \nabla \varphi(x,t)) \, (u(x,t) - u_{h,k}(x,t)) dx dt$. We use the property that $D \in C^\infty(R^{2\times 2}, R^{2\times 2})$ (see [24, p. 115]) to state that $\nabla \cdot (D \nabla \varphi(x,t)) \in L^2(Q_T)$. Then by using the strong convergence of $u_{h,k}$ to u one can see that

$$|T_5| \to 0 \text{ as } h, k \to 0. \tag{4.54}$$

Now we can state following convergence result.

THEOREM 4.9. *The sequence $u_{h,k}$ converges strongly in $L^2(Q_T)$ to the unique weak solution u of (1.1)–(1.3) as $h, k \to 0$.*

Proof. The result comes from (4.46), (4.48), (4.49), (4.53), (4.54), and the fact that the limit u of $u_{h,k}$ is in space $L^2(0,T; H^1(\Omega))$. Due to the uniqueness of the weak solution, which can be found in [24], not only the subsequence but also the sequence $u_{h,k}$ itself converges to u. ∎

5. Numerical experiments. In this section we present results of several computational examples using real two-dimensional images coming from multiphoton laser scanning microscopy. They represent the membranes and nuclei of cells in the early stages of zebrafish embryogenesis. Especially the images of membranes are well suited for processing by this type of diffusion which is documented by comparing the edge detection and cell segmentation results before and after filtering in Figures 5.1–5.4. In the experiments we use the spatial step $h = 0.01$, time step $k = 0.0001$, $C = 1$, $\alpha = 0.001$, $\tilde{t} = 0.00001$, $\rho = 0.002$. The arising linear systems are solved using Gauss–Seidel iterations. Satisfactory results were obtained after a few filtering steps, so the denoising method is really fast. In the presented experiments we do not observe any stability problems which are a usual drawback of explicit schemes; cf. [25].

The nonlinear tensor anisotropic diffusion smoothes out the noise and improves significantly the connectivity of the coherent structures. Although the filtered image seems to be more blurred compared to the original one—cf. Figure 5.1 (left top and bottom)—the enhancement of the structure connectivity and improvement of the quality of edge detection—cf. Figure (5.1 right top and bottom)—enable us to get much more precise results of segmentation algorithms based on image intensity gradient information such as the subjective surface method [20, 16, 2]. In the subjective surface method, the initial segmentation function in the form of a peak centered in the approximate centroid of the segmented object is created. Then the initial function is evolved by nonlinear PDE, it forms a shock profile during the evolution, and the segmented object is detected as an isoline of the final (numerically steady) state of the segmentation function; for details we refer to [20, 16]. Since many spurious noisy structures can be seen in the original image, which is expressed in a highly noisy edge

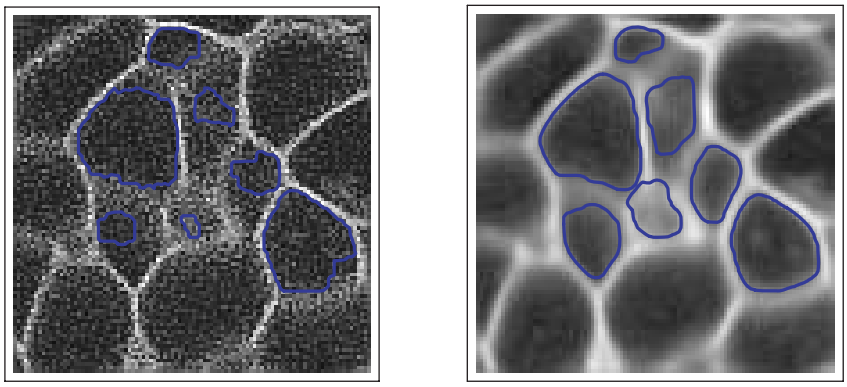

FIG. 5.2. *The results of subjective surface cell segmentation when using unfiltered and filtered images, respectively.*

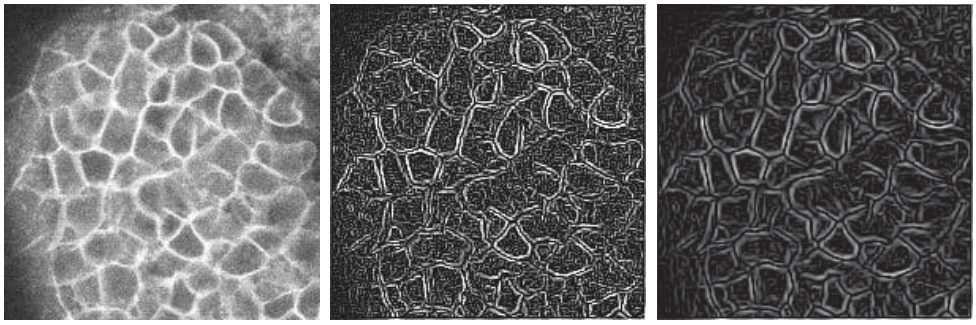

FIG. 5.3. *The image of the cell membranes (*200×200 *pixels, left), its edge detection (middle), and the edge detection for the image filtered by* 2 *diffusion steps where the strong improvement of structure coherence can be seen (right).*

detection result, the segmentation algorithm can hardly find the correct cell boundary using the noisy data. It is difficult to the chose the proper isoline when several shocks are formed in the irregular steady state which is created due to a noise in the image—cf. Figure 5.1 (left and middle top). On the other hand, using a few steps of the nonlinear tensor anisotropic diffusion, all level lines are accumulated along the

TABLE 5.1
Error in the $L_2(I, L_2(\Omega))$ norm and the EOC comparing numerical and exact solutions.

n	h	k	Error	EOC
10	0.2	0.04	$1.809572 \cdot 10^{-4}$	
20	0.1	0.01	$0.3835138 \cdot 10^{-4}$	2.2383
40	0.05	0.0025	$0.09159927 \cdot 10^{-4}$	2.06587
80	0.025	0.000625	$0.02238713 \cdot 10^{-4}$	2.03267
160	0.0125	0.00015625	$0.00495121 \cdot 10^{-4}$	2.17682

cell boundary (just one shock is created in the final state of segmentation function)—cf. Figure 5.1 (left and middle bottom), and the cell can be segmented precisely. Now it is easy to choose the isoline for the cell boundary representation, we take the average of minimal and maximal values of the final segmentation function, and in Figure 5.2 we show the segmentation results for several cells visualizing it for both unfiltered and filtered images. We use the same parameters of the subjective surface segmentation method in both cases, and one can see much more precise segmentation results after filtering.

In Figures 5.3–5.4 we show two other real images: originals (left) and edge detection results for originals (middle) and after a few steps of filtering (right). Again, one can clearly see coherence enhancement and edge detection improvement.

In the last experiment we test the experimental order of convergence (EOC) of our method. In the theoretical part we prove its convergence, and the rigorous error estimates will be an objective of a further study; cf. [7]. Here we consider function $u(x, y, t) = t\cos(\pi x)\cos(\pi y)$ which fulfills the boundary conditions in the domain $\Omega = [-1, 1]^2$ and in time interval $I = [0, 1]$. Putting this function into the model equation (1.1), without convolutions, because we do not need to smooth either the function or the structure tensor, we get the nonzero right-hand side, and we modify the scheme accordingly. We take $C = 1$ and $\alpha = 0.001$ so the diffusion matrix D has eigenvalues between α and 1 and the process is strongly anisotropic. Then we take subsequently refined grids with $M = n^2$ finite volumes, $n = 10, 20, 40, 80, 160$, and the time step $k = h^2$, and we measure errors in the $L_2(I, L_2(\Omega))$ norm, which is natural for testing the schemes for solving parabolic problems. In Table 5.1 we report the errors for different grid sizes, and we observe that the EOC of our numerical scheme is equal to 2.

6. Acknowledgments. The authors thank Dr. Nadine Peyrieras from CNRS-DEPSN, Paris, coordinator of the European project Embryomics, for providing data used in our numerical experiments. We thank also Prof. Robert Eymard for giving us a hint on how to treat the T_1 term in the convergence proof.

FINITE ELEMENT APPROXIMATIONS OF WAVE MAPS INTO SPHERES*

SÖREN BARTELS†, XIAOBING FENG‡, AND ANDREAS PROHL§

Abstract. Three fully discrete finite element methods are developed for approximating wave maps into the sphere based on two different approaches. The first method is an explicit scheme and the numerical solution satisfies the sphere-constraint exactly at every node. The second and third methods are implicit schemes which are based on a penalization approach, their numerical solutions satisfy the sphere-constraint approximately, and the quality of approximations is controlled by a small penalization parameter. Discrete energy conservation laws which mimic the underlying differential conservation law are established, and convergence of all proposed methods is proved. Computational experiments are also provided to validate the proposed methods and to present numerical evidence for possible finite-time blow-ups of the wave maps.

Key words. wave maps, penalization, finite element method, fully discrete scheme, convergence analysis

1. Introduction. Let $\mathbf{R}\times\mathbf{R}^m$ for $m\geq 1$ denote the $(m+1)$-dimensional Minkowski space endowed with the Minkowski metric $\eta=(\eta_{\alpha\beta})=\eta^{-1}=(\eta^{\alpha\beta})=\mathrm{diag}(-1,1,1,\ldots,1)$, and let $(\mathbf{N},g)$ be an n-dimensional Riemannian manifold. A map $\mathbf{u}:(t,\mathbf{x})\in\mathbf{R}\times\mathbf{R}^m\to\mathbf{u}(t,\mathbf{x})\in\mathbf{N}$ is called a *wave map* if it satisfies the *wave map equation* (cf. [20, 25])

$$\Box\mathbf{u}=A(\mathbf{u})(\partial_\alpha\mathbf{u},\partial^\alpha\mathbf{u})\perp T_{\mathbf{u}}\mathbf{N}, \tag{1.1}$$

where $\partial^\alpha\mathbf{u}=\eta^{\alpha\beta}\partial_\beta\mathbf{u}$, and $\Box$ is the d'Alembert operator, $\Box=\partial_\alpha\partial^\alpha$. Moreover, $A(\mathbf{u})(\cdot,\cdot)$ denotes the second fundamental form of the manifold $\mathbf{N}$, and $T_{\mathbf{u}}\mathbf{N}$ denotes the tangent space of $\mathbf{N}$ at $\mathbf{u}$.

It is well known (cf. [20]) that (1.1) can also be interpreted as the Euler–Lagrange equation for the Lagrangian

$$\mathcal{L}(\mathbf{u}):=\frac{1}{2}\int_{\mathbf{R}\times\mathbf{R}^m}\langle\partial_\alpha\mathbf{u},\partial^\alpha\mathbf{u}\rangle_g\,\mathrm{d}x\mathrm{d}t, \tag{1.2}$$

where all the first order derivatives of $\mathbf{u}$ take values in the tangent space $T\mathbf{N}$ of $\mathbf{N}$, that is,

$$\partial_\alpha\mathbf{u}:\mathbf{R}\times\mathbf{R}^m\to T_{\mathbf{u}}\mathbf{N},\qquad \alpha=t,x_1,x_2,\ldots,x_m.$$

The wave map equation is the simplest geometric nonlinear wave equation, thus providing a good setup for studying nonlinear wave interactions. Wave maps have many applications in physics; they arise as harmonic gauges in general relativity (cf. [10]) and as the nonlinear σ-models in particle physics (cf. [1]); under suitable hypotheses, the Einstein vacuum equations with cylindrical symmetry reduce to a wave map system on $(2+1)$-dimensional Minkowski space-time (cf. [7]). Moreover, wave maps also arise in the analysis of the more difficult hyperbolic Yang–Mills equations either as special cases or as equations for certain families of gauge transformations (cf. [11]).

In this paper we consider wave maps in the case when the target manifold $\mathbf{N}$ is an $(n-1)$-sphere, i.e., $\mathbf{N} = \mathbf{S}^{n-1} \subset \mathbf{R}^n$ $(n \geq 1)$. In this case, we have (cf. [20])

$$\begin{aligned} \Box &= \partial_t^2 - \Delta, \\ \langle \partial_\alpha \mathbf{u}, \partial^\alpha \mathbf{u} \rangle_g &= |\nabla \mathbf{u}|^2 - |\partial_t \mathbf{u}|^2, \\ A(\mathbf{u})(\partial_\alpha \mathbf{u}, \partial^\alpha \mathbf{u}) &= \big(|\,\nabla \mathbf{u}\,|^2 - |\,\partial_t \mathbf{u}\,|^2\big)\mathbf{u}, \end{aligned}$$

where $\nabla \mathbf{u} = (\partial_{x_1}, \ldots, \partial_{x_m})$, and Δ is the (spatial) Laplacian. Specifically, we shall study the following initial-boundary value problem.

Given $T > 0$ and $(\mathbf{u}_0(\mathbf{x}), \mathbf{u}_1(\mathbf{x})) \in \mathbf{S}^{n-1} \times T_{\mathbf{u}_0(\mathbf{x})}\mathbf{S}^{n-1}$ for all $\mathbf{x} \in \Omega$, find a wave map $\mathbf{u} : \mathbf{R} \times \mathbf{R}^m \to \mathbf{S}^{n-1}$ such that

$$\Box \mathbf{u} = \big(|\,\nabla \mathbf{u}\,|^2 - |\,\partial_t \mathbf{u}\,|^2\big)\mathbf{u} \qquad \text{in } \Omega_T := (0,T) \times \Omega\,, \tag{1.3}$$

$$\frac{\partial \mathbf{u}}{\partial \mathbf{n}} = 0 \qquad \text{on } \partial\Omega_T := (0,T) \times \partial\Omega\,, \tag{1.4}$$

$$\mathbf{u}(0,\cdot) = \mathbf{u}_0, \qquad \partial_t \mathbf{u}(0,\cdot) = \mathbf{u}_1 \qquad \text{in } \Omega\,, \tag{1.5}$$

where $\Omega \subset \mathbf{R}^m$ is a bounded domain. Here, $\mathbf{n}$ and $\frac{\partial \mathbf{u}}{\partial \mathbf{n}}$ denote the outward unit normal to, and the normal derivative of $\mathbf{u}$ on the boundary $\partial\Omega$, of Ω.

It is well known that the wave map equation (1.1) is *integrable* (so are many other wave equations), which implies that the solutions of (1.1) satisfy some conservation law, which is, for wave maps with the sphere target manifold (cf. [20]),

$$E\big(\partial_t \mathbf{u}(t,\cdot), \mathbf{u}(t,\cdot)\big) = E\big(\mathbf{u}_1(\cdot), \mathbf{u}_0(\cdot)\big) \qquad \forall\, t \geq 0, \tag{1.6}$$

where

$$E\big(\partial_t \mathbf{u}(t,\cdot), \mathbf{u}(t,\cdot)\big) := \frac{1}{2}\Big[\,\|\,\partial_t \mathbf{u}(t,\cdot)\,\|_{L^2}^2 + \|\,\nabla \mathbf{u}(t,\cdot)\,\|_{L^2}^2\Big]. \tag{1.7}$$

Wave map equation (1.1) has been extensively studied in the past twenty years from a theoretical point of view. It was shown that on a (1+1)-dimensional Minkowski space-time base the equation has global in time smooth solutions if the initial data are smooth. It has also been known that for $m \geq 3$ the wave maps on an $(m+1)$-dimensional Minkowski space-time base can blow up in finite time in the sense that $\lim_{t \to t^*} \|\nabla \mathbf{u}(\cdot,t)\|_{L^\infty} = \infty$ for some $t^* < \infty$. On the other hand, whether the wave map equation has global in time smooth solutions on a $(2+1)$-dimensional Minkowski space-time base remains an open problem; see Open Problems 5 and 6 in [25]. The dimension analysis identifies $(2+1)$ as the critical dimension for wave maps, and so there has been a considerable amount of interest in determining whether $(2+1)$-dimensional wave maps develop singularities in finite time for smooth initial data. Numerical experiments of [8, 17] suggest that finite-time collapses, which are identified as local concentrations of energy, may occur for the special class of spherically

equivariant wave maps in the case of large, smooth initial data with the spheres as target manifolds. For more discussions and up-to-date analytical results for wave maps, we refer the reader to the recent monograph of Shatah and Struwe [20] and the survey paper of Tataru [25].

Numerically, besides the works of [8, 17], no other results are known in the literature. However, despite the strong evidence of finite-time singularities in [8, 17], the numerical schemes proposed there are straightforward discretizations of reduced models and are not supported by rigorous numerical analysis, so unphysical numerical artifacts cannot be completely ruled out. The primary goal of this paper is to develop various finite element methods for approximating the initial-boundary value problem (1.3)–(1.5) based on two different approaches (see below and section 3). Rigorous convergence analysis will be provided, so our numerical solutions are guaranteed to converge to weak solutions of (1.3)–(1.5).

Like other well-known maps such as harmonic maps (cf. [4, 5, 22] and references therein), the main difficulty in analyzing and approximating wave maps is caused by the nonflatness of the target manifold $\mathbf{N}$, which is equivalent to imposing some (usually nonconvex) constraints on the solutions of the wave map equation, and is the reason for the nonlinearities. For example, when $\mathbf{N} = \mathbf{S}^{n-1}$, which is the focus of this paper, the constraint is $|\mathbf{u}| = 1$. Recall that the wave map equation (1.1) can be regarded as the Euler–Lagrange equation for the Lagrangian $\mathcal{L}$ defined in (1.2), interpreting this difficulty in the calculus of variation context, which means that the wave map problem is a variation problem with a holonomic constraint (cf. [16]).

The strong nonlinearity and nonconvex constraint make it very difficult to develop convergent numerical methods for (1.3)–(1.5). To the best of our knowledge, no such numerical method is known in the literature up to now. To overcome this difficulty, there are two approaches one can try. On the one hand, one may want to approximate (1.3)–(1.5) directly. To this end, one has to maintain the constraint $|\mathbf{u}| = 1$ at the discrete level, which is difficult to accomplish. Usually, a projection technique is employed for this purpose. Unfortunately, straightforward strategies do not give (discrete) energy conservation laws; consequently, the methods may not be convergent. On the other hand, one can approximate (1.3)–(1.5) indirectly. This approach often involves two steps: first, the wave map equation is penalized and the nonconvex constraint is relaxed by a singular perturbation technique; second, the penalized and nonconstrained problem is approximated by various numerical methods such as finite element, finite difference, and spectral methods. The trade-off is that one now needs to approximate singularly perturbed equations and to resolve the solutions on a very small scale introduced by the penalization parameter and to control numerical parameters according to the penalization parameter for both stability and convergence concerns.

In this paper, we shall develop numerical methods using both direct and indirect approaches. Our direct methods are inspired by the works of [2, 4, 6], where constraint-preserving finite element methods were developed respectively for the Landau–Lifshitz equation and the p-harmonic map heat flow. The direct methods are constructed based on the following equivalent reformulation of (1.3): find $\mathbf{u} : \Omega_T \to \mathbf{S}^{n-1}$ such that for all $\mathbf{w} \in C_0^\infty\big([0,T) \times \Omega, \mathbf{R}^n\big)$ with $\langle \mathbf{u}, \mathbf{w} \rangle = 0$ a.e. in Ω_T there holds

$$\int_0^T \big(\partial_t^2 \mathbf{u}, \mathbf{w}\big)\, \mathrm{d}t + \int_0^T \big(\nabla \mathbf{u}, \nabla \mathbf{w}\big)\, \mathrm{d}t = 0. \tag{1.8}$$

Our indirect methods are based on the following Ginzburg–Landau-type penalization

ansatz (cf. [20]):

$$\Box \mathbf{u}^\varepsilon + \frac{1}{\varepsilon}\big(|\,\mathbf{u}^\varepsilon\,|^2 - 1\big)\mathbf{u}^\varepsilon = 0 \qquad \text{in } \Omega_T\,, \tag{1.9}$$

$$\frac{\partial \mathbf{u}^\varepsilon}{\partial \mathbf{n}} = 0 \qquad \text{on } \partial\Omega_T\,, \tag{1.10}$$

$$\mathbf{u}^\varepsilon(0,\cdot) = \mathbf{u}_0\,, \qquad \partial_t \mathbf{u}^\varepsilon(0,\cdot) = \mathbf{u}_1 \qquad \text{in } \Omega \tag{1.11}$$

for $0 < \varepsilon << 1$. It was shown that for each $\varepsilon > 0$ the regularized problem (1.9)–(1.11) has a weak solution $\mathbf{u}^\varepsilon : \Omega_T \to \mathbf{R}^n$, which satisfies the following conservation law (hence, (1.9)–(1.11) is also integrable):

$$E\big(\partial_t \mathbf{u}^\varepsilon(t,\cdot), \mathbf{u}^\varepsilon(t,\cdot)\big) + \frac{1}{\varepsilon} F(\mathbf{u}^\varepsilon(t,\cdot)) = E\big(\mathbf{u}_1(\cdot), \mathbf{u}_0(\cdot)\big) \qquad \forall\, t \in [0,T], \tag{1.12}$$

where

$$F(\mathbf{w}) = \frac{1}{4}\int_\Omega \big(|\,\mathbf{w}\,|^2 - 1\big)^2\,\mathrm{d}\mathbf{x}. \tag{1.13}$$

Moreover, there exists a subsequence of $\{\mathbf{u}^\varepsilon\}$ which converges to a map $\mathbf{u}$, which turns out to be a weak solution of (1.3)–(1.5) as $\varepsilon \to 0^+$.

The remainder of this paper is organized as follows. In section 2 we introduce some notation and a weak formulation of (1.3)–(1.5). In section 3 we present our fully discrete finite element methods based on both direct and indirect approaches. The convergence analysis of the proposed numerical methods is given in sections 4 and 5. In section 6 we present several numerical experiment results and provide numerical evidence for finite-time (finite-energy) blow-ups of wave maps in the critical dimension $(2+1)$. Finally, we finish the paper with a few concluding remarks.

2. Preliminaries. Standard notations are adopted throughout this paper. $\langle\cdot,\cdot\rangle$ denotes the standard inner product of the Euclidean space $\mathbf{R}^m$, and $(\cdot,\cdot) := (\cdot,\cdot)_\Omega$ is the standard L^2-inner product over the domain Ω. $W^{m,p}(\Omega,\mathbf{R}^n)$ denotes the (m,p)-Sobolev space of vector-valued functions, and $\|\cdot\|_{W^{m,p}}$ denotes its norm. Note that $W^{0,p}(\Omega,\mathbf{R}^n) = L^p(\Omega,\mathbf{R}^n)$. Throughout this paper, $C > 0$ is used to denote a generic positive $(\,h,\tau,\varepsilon\,)$-independent constant which may take different values at different locations. We also introduce $\mathbf{u}_t := \partial_t \mathbf{u}, \nabla\mathbf{u} := (\partial_{x_1},\ldots,\partial_{x_m})$, and $D := (\partial_t, \nabla)$ and define the nonlinear Sobolev space

$$W^{1,2}(\Omega,\mathbf{S}^{n-1}) = \big\{\mathbf{v} \in W^{1,2}(\Omega,\mathbf{R}^n);\ \mathbf{v} \in \mathbf{S}^{n-1} \text{ a.e. in } \Omega\big\}.$$

We now give a definition of weak solutions to (1.3)–(1.5).

DEFINITION 2.1. *Given $T > 0$ and $(\,\mathbf{u}_0, \mathbf{u}_1\,) \in W^{1,2}(\Omega,\mathbf{S}^{n-1}) \times L^2(\Omega, T\mathbf{S}^{n-1})$, we call $\mathbf{u} : \Omega_T \to \mathbf{S}^{n-1}$ a weak solution of (1.3)–(1.5) if the following hold:*

1. *$D\mathbf{u} \in L^2(\Omega_T,\mathbf{R}^n)$.*
2. *$|\,\mathbf{u}\,| = 1$ a.e. in Ω_T.*
3. *Equation (1.3) holds (in wedged form) in the distributional sense; i.e., for all $\boldsymbol{\phi} \in C_0^\infty\big([0,T);\, W^{1,2}(\Omega,\mathbf{R}^n)\big)$ we have*

$$-\int_0^T \big(\mathbf{u}_t \wedge \mathbf{u}, \boldsymbol{\phi}_t\big)\,\mathrm{d}t + \int_0^T \big(\nabla\mathbf{u} \wedge \mathbf{u}, \nabla\boldsymbol{\phi}\big)\,\mathrm{d}t = \big(\mathbf{u}_1 \wedge \mathbf{u}_0, \boldsymbol{\phi}(0,\cdot)\big). \tag{2.1}$$

(4) *The initial conditions* $\mathbf{u}_0$ *and* $\mathbf{u}_1$ *are continuously attained by* $\mathbf{u}$ *and* $\mathbf{u}_t$ *in* $W^{1,2}(\Omega;\mathbf{R}^n)$ *and* $L^2(\Omega;\mathbf{R}^n)$*; i.e., there hold as* $t \to 0$

$$\mathbf{u}(t,\cdot) \to \mathbf{u}_0 \quad \textit{in } W^{1,2}(\Omega;\mathbf{R}^n), \qquad \mathbf{u}_t(t,\cdot) \to \mathbf{u}_1 \quad \textit{in } L^2(\Omega;\mathbf{R}^n).$$

(5) *The following energy inequality holds:*

$$E\big(\mathbf{u}_t(t,\cdot),\mathbf{u}(t,\cdot)\big) \le E\big(\mathbf{u}_1,\mathbf{u}_0\big) \qquad \forall\, t \in [0,T]\,. \tag{2.2}$$

Existence of weak solutions to (1.3)–(1.5) for $m \ge 1$ was proved in [19] by the Ginzburg–Landau penalization technique, and weak solutions were constructed as proper limits of $\{\mathbf{u}_\varepsilon\}$ which solve (1.9)–(1.11). Another method, which was proposed in [18], constructs weak solutions for general targets $\mathbf{N}$ as limits of convergent sequences of spatially discrete wave maps. The semidiscrete maps are direct approximations of the original wave maps and are constructed by (abstract) finite difference methods, so no penalization is involved. We remark that weak solutions to (1.3)–(1.5) are not unique in general (cf. [20]).

3. Fully discrete finite element methods.

3.1. Notation. For simplicity, let Ω be a bounded polygonal (when $m = 2$) or polyhedral (when $m = 3$) domain. Let $\mathcal{T}_h$ denote a quasiuniform triangulation of Ω into triangles or tetrahedrons with mesh-size $h > 0$ for $m = 2$ or $m = 3$, respectively. For a domain $A \subset \mathbf{R}^m$, let $\mathcal{P}(A,\mathbf{R}^n)$ stand for the set of all polynomials on A of degree ≤ 1. We define the Lagrange finite element space

$$\boldsymbol{\mathcal{V}}_h := \big\{\mathbf{w} \in C(\overline{\Omega},\mathbf{R}^n);\, \mathbf{w}|_K \in \mathcal{P}(K,\mathbf{R}^n)\ \forall\, K \in \mathcal{T}_h\big\}\,.$$

Let $\mathcal{N}_h$ denote the set of all nodes associated with the finite element space $\boldsymbol{\mathcal{V}}_h$, and let $\big\{\varphi_{\mathbf{q}_i};\, \mathbf{q}_i \in \mathcal{N}_h\big\}$ denote the nodal basis for $\boldsymbol{\mathcal{V}}_h$; we define the following nodal interpolation operator $I_h : C(\overline{\Omega},\mathbf{R}^n) \to \boldsymbol{\mathcal{V}}_h$ by

$$I_h\mathbf{w} := \sum_{\mathbf{q}_i \in \mathcal{N}_h} \mathbf{w}(\mathbf{q}_i)\varphi_{\mathbf{q}_i} \qquad \forall\, \mathbf{w} \in C(\overline{\Omega},\mathbf{R}^n).$$

For any two functions $\mathbf{v},\mathbf{w} \in C(\overline{\Omega},\mathbf{R}^n)$ we define a discrete L^2-inner product by

$$\big(\mathbf{v},\mathbf{w}\big)_h := \int_\Omega I_h\big(\langle \mathbf{v},\mathbf{w}\rangle\big)\,\mathrm{d}\mathbf{x} = \sum_{\mathbf{q}_i \in \mathcal{N}_h} \beta_{\mathbf{q}_i}\langle \mathbf{v}(\mathbf{q}_i),\mathbf{w}(\mathbf{q}_i)\rangle\,,$$

where $\beta_{\mathbf{q}_i} = \int_\Omega \varphi_{\mathbf{q}_i}\,\mathrm{d}\mathbf{x}$ for all $\mathbf{q}_i \in \mathcal{N}_h$. We also define $||\mathbf{w}||_h := (\mathbf{w},\mathbf{w})_h^{\frac12}$. It is easy to check that there hold for all $\mathbf{v}_h,\mathbf{w}_h \in \boldsymbol{\mathcal{V}}_h$

$$||\mathbf{w}_h||_{L^2} \le ||\mathbf{w}_h||_h \le (m+2)^{\frac12}||\mathbf{w}_h||_{L^2}, \tag{3.1}$$

$$\big|(\mathbf{v}_h,\mathbf{w}_h)_h - (\mathbf{v}_h,\mathbf{w}_h)\big| \le Ch\,||\mathbf{v}_h||_{L^2}\,||\nabla\mathbf{w}_h||_{L^2}. \tag{3.2}$$

Let τ_1 and τ be two (small) positive numbers, and

$$t_0 := 0,\ t_1 := \tau_1,\ t_j := t_1 + (j-1)\tau, \quad j = 1,2,\dots,J := \left[\frac{T-t_1}{\tau}\right].$$

Then $\{t_j\}$ forms a partition of the interval $[0,T]$. We introduce the following difference operators (cf. [13, 14]):

$$
\begin{aligned}
&d_t\mathbf{v}^1 := \frac{\mathbf{v}^1-\mathbf{v}^0}{\tau_1}, \qquad \delta_t\mathbf{v}^1 := \frac{\mathbf{v}^2-\mathbf{v}^0}{\tau_1+\tau},\\
&d_t\mathbf{v}^j := \frac{\mathbf{v}^j-\mathbf{v}^{j-1}}{\tau}, \quad \delta_t\mathbf{v}^j := \frac{\mathbf{v}^{j+1}-\mathbf{v}^{j-1}}{2\tau}, \quad j\geq 1,\\
&\mathbf{v}^{j\pm\frac12} := \frac{\mathbf{v}^{j\pm1}+\mathbf{v}^j}{2}, \quad \mathbf{v}^{j,\theta} := \theta\mathbf{v}^{j+1}+(1-2\theta)\mathbf{v}^j+\theta\mathbf{v}^{j-1} \qquad \forall\,\theta\in\left[0,\frac12\right].
\end{aligned}
$$

Given a sequence $\{\mathbf{w}^j\}_{1\leq j\leq J}\in \ell^\infty\big(0,J;\boldsymbol{\mathcal{V}}_h\big)$, we define the following constant and linear interpolations of the sequence in time: for every $t\in(t_{j-1},t_j]$ set

$$
\begin{aligned}
&\mathbf{w}^-(t,\cdot) := \mathbf{w}^{j-1}(\cdot)\,, && \mathbf{w}^+(t,\cdot) := \mathbf{w}^j(\cdot)\,,\\
&\overline{\mathbf{w}}(t,\cdot) := \frac12\big[\mathbf{w}^{j-1}(\cdot)+\mathbf{w}^j(\cdot)\big]\,, && \mathbf{w}(t,\cdot) := \frac{t-t_{j-1}}{\tau}\mathbf{w}^j(\cdot)+\frac{t_j-t}{\tau}\mathbf{w}^{j-1}(\cdot)\,.
\end{aligned}
$$

We note that τ needs to be replaced by τ_1 in the definition of $\mathbf{w}(t,\cdot)$ when $j=1$. It is easy to check that

$$
\|\,\mathbf{w}^\pm-\mathbf{w}\,\|+\|\,\overline{\mathbf{w}}-\mathbf{w}\,\|\leq 3\tau\,\|\,d_t\mathbf{w}\,\|. \tag{3.3}
$$

Hence, $\mathbf{w}^\pm,\overline{\mathbf{w}}$, and $\mathbf{w}$ converge simultaneously to the same limit provided that $\|\,d_t\mathbf{w}\,\|$ is bounded and one of the sequences converges. Finally, we introduce the following subsets of $\boldsymbol{\mathcal{V}}_h$:

$$
\begin{aligned}
\boldsymbol{\mathcal{M}}_h &:= \big\{\mathbf{w}\in\boldsymbol{\mathcal{V}}_h;\,|\,\mathbf{w}(\mathbf{q}_i)\,|=1\;\forall\,\mathbf{q}_i\in\mathcal{N}_h\big\}\,,\\
\boldsymbol{\mathcal{F}}_h(\boldsymbol{\chi}) &:= \big\{\mathbf{w}\in\boldsymbol{\mathcal{V}}_h;\,\langle\mathbf{w}(\mathbf{q}_i),\boldsymbol{\chi}(\mathbf{q}_i)\rangle=0\quad\forall\,\mathbf{q}_i\in\mathcal{N}_h\big\}\,,\quad \text{where } \boldsymbol{\chi}\in\boldsymbol{\mathcal{M}}_h\,.
\end{aligned}
$$

3.2. Fully discrete methods for (1.3)–(1.5). We introduce a family of fully discrete *explicit* finite element methods for (1.3)–(1.5). The starting point is the weak formulation (1.8). To discretize (1.8), the following fully discrete semi-implicit approximation of (1.8) is immediate: For $j=1\to(J-1)$, given $\hat{\mathbf{U}}^{j-1},\hat{\mathbf{U}}^j\in\boldsymbol{\mathcal{M}}_h$, find $\hat{\mathbf{U}}^{j+1}\in\boldsymbol{\mathcal{M}}_h$ such that

$$
(d_t^2\hat{\mathbf{U}}^{j+1},\mathbf{w})+(\nabla\hat{\mathbf{U}}^{j+1},\nabla\mathbf{w})=0 \qquad \forall\,\mathbf{w}\in\boldsymbol{\mathcal{F}}_h(\hat{\mathbf{U}}^j)\,, \tag{3.4}
$$

and $\hat{\mathbf{U}}^0,\hat{\mathbf{U}}^1\in\boldsymbol{\mathcal{M}}_h$, where $d_t^2\varphi^j=d_t(d_t\varphi^j)$. However, (3.4) is difficult to solve because of the nonconvex constraint on $\boldsymbol{\mathcal{M}}_h$. To overcome this difficulty, on noting $\langle\mathbf{u}_t,\mathbf{u}\rangle=0$ we may assume that $d_t\hat{\mathbf{U}}^{j+1}$ is almost an element of $\boldsymbol{\mathcal{F}}_h(\hat{\mathbf{U}}^j)$. This motivates the following explicit scheme for (1.8).

ALGORITHM 3.1.

(i) *Choose* $(\mathbf{U}^0,\mathbf{V}^0)\in\boldsymbol{\mathcal{M}}_h\times\boldsymbol{\mathcal{V}}_h$ *as a suitable approximation to* $(\mathbf{u}_0,\mathbf{u}_1)$.

(ii) *For* $j=0\to(J-1)$, *given* $(\mathbf{U}^j,\mathbf{V}^j)\in\boldsymbol{\mathcal{M}}_h\times\boldsymbol{\mathcal{V}}_h$, *find* $\mathbf{V}^{j+1}\in\boldsymbol{\mathcal{F}}_h(\mathbf{U}^j)$ *such that*

$$
(d_t\mathbf{V}^{j+1},\mathbf{w})_h=(\nabla\mathbf{U}^j,\nabla\mathbf{w}) \qquad \forall\,\mathbf{w}\in\boldsymbol{\mathcal{F}}_h(\mathbf{U}^j)\,,
$$

and define $\mathbf{U}^{j+1}\in\boldsymbol{\mathcal{M}}_h$ *by*

$$
\mathbf{U}^{j+1}(\mathbf{q}_i)=\frac{\mathbf{U}^j(\mathbf{q}_i)+\tau\mathbf{V}^{j+1}(\mathbf{q}_i)}{|\,\mathbf{U}^j(\mathbf{q}_i)+\tau\mathbf{V}^{j+1}(\mathbf{q}_i)\,|} \qquad \forall\,\mathbf{q}_i\in\mathcal{N}_h\,.
$$

Convergence analysis of Algorithm 3.1 will be given in section 4.

Remark 3.1. (a) The auxiliary function $\mathbf{V}^j$ is an approximation to $\mathbf{u}_t(t_j,\cdot)$, so the algorithm may be viewed as a mixed method which approximates $\mathbf{u}$ and $\mathbf{u}_t$ simultaneously.

(b) The last equation in the algorithm combines a discretization of $\mathbf{u}_t = \mathbf{v}$ with a projection to the sphere at the nodes.

(c) Note that owing to $\mathbf{U}^j(\mathbf{q}_i)\cdot\mathbf{V}^{j+1}(\mathbf{q}_i) = 0$ and $|\mathbf{U}^j(\mathbf{q}_i)| = 1$ for all $\mathbf{q}_i \in \mathcal{N}_h$ the projection step is well defined.

3.3. Fully discrete methods for (1.9)–(1.11). We construct two families of fully discrete *implicit* finite element methods for (1.9)–(1.11). Since the problem (1.9)–(1.11) converges to the problem (1.3)–(1.5) as $\varepsilon \to 0^+$ (cf. [20]), the methods constructed in this subsection are indirect methods for approximating the problem (1.3)–(1.5).

Because for each fixed $\varepsilon > 0$ (1.9) is a semilinear system of wave equations, a natural strategy is to adapt some of best known numerical schemes developed for the linear wave equation to the problem (1.9)–(1.11). Indeed, two families of such schemes will be considered in this subsection. The first family of schemes motivated by the work of Baker [3] are one-step implicit mixed methods in the sense of Remark 3.1 (a); the second family motivated by the work of Dupont [13] are two-step implicit methods.

Apart from the similarities of numerical methods to be given below and those developed in [3, 13], we emphasize that, in addition to the extra difficulty caused by the nonlinearity in (1.9), we also have to cope with a new scale which is due to the introduction of the penalization parameter ε. In particular, we need to make sure our numerical solutions satisfy a discrete conservation law which mimics the differential conservation law (1.12), and they are robust with respect to ε.

First, adapting the schemes of [3], we introduce the following fully discrete implicit discretization of (1.9)–(1.11).

ALGORITHM 3.2.

(i) *Choose* $(\mathbf{U}^0,\mathbf{V}^0) \in \big[\boldsymbol{\mathcal{V}}_h\big]^2$ *as a suitable approximation to* $(\,\mathbf{u}_0,\mathbf{u}_1\,)$.

(ii) *For* $j = 0 \to (J-1)$, *given* $(\mathbf{U}^j,\mathbf{V}^j) \in \big[\boldsymbol{\mathcal{V}}_h\big]^2$, *find* $(\mathbf{U}^{j+1},\mathbf{V}^{j+1}) \in \big[\boldsymbol{\mathcal{V}}_h\big]^2$ *such that for all* $(\mathbf{w},\boldsymbol{\chi}) \in [\boldsymbol{\mathcal{V}}_h]^2$

$$(d_t\mathbf{V}^{j+1},\mathbf{w})_h + (\nabla\mathbf{U}^{j+\frac12},\nabla\mathbf{w}) + \frac{1}{2\varepsilon}\big((|\,\mathbf{U}^{j+1}\,|^2 + |\,\mathbf{U}^{j}\,|^2 - 2)\mathbf{U}^{j+\frac12},\mathbf{w}\big)_h = 0\,,$$

$$(d_t\mathbf{U}^{j+1},\boldsymbol{\chi})_h = (\mathbf{V}^{j+\frac12},\boldsymbol{\chi})_h\,.$$

Next, adapting the schemes of [13], we introduce our second family of fully discrete implicit methods for (1.9)–(1.11).

ALGORITHM 3.3.

(i) *Choose* $\mathbf{U}^0,\mathbf{U}^1 \in \boldsymbol{\mathcal{V}}_h$ *as suitable approximations to* $\mathbf{u}_0$ *and* $\mathbf{u}(t_1,\cdot)$.

(ii) *For* $j = 1 \to (J-1)$, *given* $\{\mathbf{U}^i\}_{i=0}^j \subset \boldsymbol{\mathcal{V}}_h$, *find* $\mathbf{U}^{j+1} \in \boldsymbol{\mathcal{V}}_h$ *such that for all* $\mathbf{w} \in \boldsymbol{\mathcal{V}}_h$

$$(d_t^2\mathbf{U}^{j+1},\mathbf{w})_h + (\nabla\mathbf{U}^{j,\frac14},\nabla\mathbf{w}) + \frac{1}{2\varepsilon}\big((|\,\mathbf{U}^{j+\frac12}\,|^2 + |\,\mathbf{U}^{j-\frac12}\,|^2 - 2)\mathbf{U}^{j,\frac14},\mathbf{w}\big)_h = 0\,.$$

Convergence analysis of Algorithms 3.2 and 3.3 will be presented in section 5. We note that in the above equation $\mathbf{U}^{j,\frac14}$ could be replaced by $\mathbf{U}^{j,\theta}$ for any $\theta \in [0,\frac12]$. However, as pointed out in [13], although for $\theta \ge \frac14$ the analogues of the above

scheme are all absolutely stable, the time truncation error is minimized over this class at $\theta = \frac{1}{4}$, which is the main reason for the choice of $\theta = \frac{1}{4}$.

4. Convergence analysis for Algorithm 3.1. The main goal of this section is to prove that the solution sequence $\{\mathbf{U}^j\}$ of Algorithm 3.1 has a convergent subsequence whose limit is a weak solution of (1.3)–(1.5). To this end, we first need to establish some energy estimates for the solution sequence $\{\mathbf{U}^j\}$. Throughout this section we assume $\tau_1 = \tau$.

4.1. Stability. Recall that by definition every weak solution of (1.3)–(1.5) must satisfy the energy inequality (2.2). In what follows, we show that the solution sequence $\{(\mathbf{U}^j, \mathbf{V}^j)\}$ generated by Algorithm 3.1 satisfies a discrete energy inequality, which mimics (2.2), provided that the temporal mesh-size τ and the spatial mesh-size h satisfy the relation $\tau = o(h^{\frac{m+4}{3}})$. Specifically, we have the following lemma.

LEMMA 4.1. *Let $m \geq 1$ and $(\mathbf{U}^0, \mathbf{V}^0) \in \boldsymbol{\mathcal{M}}_h \times \boldsymbol{\mathcal{F}}_h(\mathbf{U}^0)$. Then, under the mesh condition $\tau = o(h^{\frac{4+m}{3}})$, the solution sequence $\{(\mathbf{U}^j, \mathbf{V}^j)\}_{j=0}^J$ of Algorithm 3.1 satisfies*

$$E_h\big(\mathbf{V}^{j+1}, \mathbf{U}^{j+1}\big) + \frac{\tau^2}{2}\sum_{\ell=0}^{j}\big[\,\|\, d_t\mathbf{V}^{\ell+1}\,\|_h^2 + \|\,\nabla d_t\mathbf{U}^{\ell+1}\,\|_{L^2}^2\big] = c_0\, E_h\big(\mathbf{V}^0, \mathbf{U}^0\big) \tag{4.1}$$

with a positive constant $c_0 = 1 + o(1)$ and where

$$E_h(\mathbf{V}^j, \mathbf{U}^j) := \frac{1}{2}\big[\,\|\,\mathbf{V}^j\,\|_h^2 + \|\,\nabla\mathbf{U}^j\,\|_{L^2}^2\,\big]. \tag{4.2}$$

Proof. Since the proof is long, we divide it into two steps.

Step 1 (auxiliary solution estimates). Setting $\mathbf{w} = \mathbf{V}^{j+1}$ in Step (ii) of Algorithm 3.1 and using the inverse inequality $\|\,\nabla\mathbf{v}_h\,\|_{L^2} \leq Ch^{-1}\|\,\mathbf{v}_h\,\|_{L^2}$ yield

$$\frac{1}{2}d_t\|\,\mathbf{V}^{j+1}\,\|_h^2 + \frac{\tau}{2}\|\,d_t\mathbf{V}^{j+1}\,\|_h^2 = -(\nabla\mathbf{U}^j, \nabla\mathbf{V}^{j+1}) \leq Ch^{-1}\,\|\,\nabla\mathbf{U}^j\,\|_{L^2}\|\,\mathbf{V}^{j+1}\,\|_{L^2}\,. \tag{4.3}$$

Next, we need to get an estimate for $d_t\|\,\nabla\mathbf{U}^{j+1}\,\|_{L^2}^2$, which in turn requires an estimate for $\|\,d_t\mathbf{U}^{j+1}\,\|_{L^2}^2$. We now derive these estimates by borrowing an argument from [2]. Let

$$\mathbf{R}^{j+1} := \mathbf{U}^{j+1} - \mathbf{U}^j - \tau\mathbf{V}^{j+1}.$$

Note that $\mathbf{R}^{j+1} \in \boldsymbol{\mathcal{V}}_h$ and $\tau^{-1}\mathbf{R}^{j+1}$ measures the discrepancy between $d_t\mathbf{U}^{j+1}$ and $\mathbf{V}^{j+1}$. By the definition of $\mathbf{U}^{j+1}$ in (ii) of Algorithm 3.1 we have

$$\begin{aligned}|\,\mathbf{R}^{j+1}(\mathbf{q}_i)\,| &= \left|\frac{\mathbf{U}^j(\mathbf{q}_i) + \tau\mathbf{V}^{j+1}(\mathbf{q}_i)}{|\,\mathbf{U}^j(\mathbf{q}_i) + \tau\mathbf{V}^{j+1}(\mathbf{q}_i)\,|} - \mathbf{U}^j(\mathbf{q}_i) - \tau\mathbf{V}^{j+1}(\mathbf{q}_i)\right| \\ &= \big|1 - \big|\mathbf{U}^j(\mathbf{q}_i) + \tau\mathbf{V}^{j+1}(\mathbf{q}_i)\big|\big| \qquad\qquad \forall\,\mathbf{q}_i \in \mathcal{N}_h.\end{aligned}$$

Since $|\,\mathbf{U}^j(\mathbf{q}_i) + \tau\mathbf{V}^{j+1}(\mathbf{q}_i)\,| = \sqrt{1 + \tau^2|\,\mathbf{V}^{j+1}(\mathbf{q}_i)\,|^2} \geq 1$, we conclude that

$$|\,\mathbf{R}^{j+1}(\mathbf{q}_i)\,| \leq \frac{\tau^2}{2}|\,\mathbf{V}^{j+1}(\mathbf{q}_i)\,|^2\,. \tag{4.4}$$

Hence,

$$\int_\Omega |\,\mathbf{R}^{j+1}\,|\,\mathrm{d}\mathbf{x} \le \int_\Omega I_h\big[|\,\mathbf{R}^{j+1}\,|\big]\,\mathrm{d}\mathbf{x} \le \frac{\tau^2}{2}\int_\Omega I_h\big[|\,\mathbf{V}^{j+1}\,|^2\big]\,\mathrm{d}\mathbf{x} \le \frac{\tau^2(m+2)}{2}\int_\Omega |\,\mathbf{V}^{j+1}\,|^2\,\mathrm{d}\mathbf{x}\,. \tag{4.5}$$

Similarly,

$$\|\,\mathbf{R}^{j+1}\,\|_{L^2}^2 \le \|\,\mathbf{R}^{j+1}\,\|_h^2 \le \frac{\tau^4}{4}\|\,\mathbf{V}^{j+1}\,\|_{L^\infty}^2\|\,\mathbf{V}^{j+1}\,\|_h^2 \le C\tau^4 h^{-m}\,\|\,\mathbf{V}^{j+1}\,\|_{L^2}^4\,;$$

thus

$$\begin{aligned}\|\,d_t\mathbf{U}^{j+1}\,\|_{L^2}^2 &\le \big[\|\,\mathbf{V}^{j+1}\,\|_{L^2} + \tau^{-1}\,\|\,\mathbf{R}^{j+1}\,\|_{L^2}\big]^2 \\ &\le \big[1 + C\tau h^{-\frac{m}{2}}\|\,\mathbf{V}^{j+1}\,\|_{L^2}\big]^2\|\,\mathbf{V}^{j+1}\,\|_{L^2}^2\,.\end{aligned} \tag{4.6}$$

Now, setting $\mathbf{w} = \mathbf{V}^{j+1} = d_t\mathbf{U}^{j+1} - \tau^{-1}\mathbf{R}^{j+1}$ in Step (ii) of Algorithm 3.1, we get

$$(d_t\mathbf{V}^{j+1}, \mathbf{V}^{j+1})_h + \big(\nabla\mathbf{U}^{j+1}, \nabla d_t\mathbf{U}^{j+1}\big) = \tau^{-1}(\nabla\mathbf{U}^j, \nabla\mathbf{R}^{j+1}) + \tau\|\,\nabla d_t\mathbf{U}^{j+1}\,\|_{L^2}^2;$$

this, an application of the inverse inequality, and (4.6) yield

$$\begin{aligned}&\frac{1}{2}d_t\|\,\mathbf{V}^{j+1}\,\|_h^2 + \frac{1}{2}d_t\|\,\nabla\mathbf{U}^{j+1}\,\|_{L^2}^2 + \frac{\tau}{2}\|\,d_t\mathbf{V}^{j+1}\,\|_h^2 + \frac{\tau}{2}\|\,\nabla d_t\mathbf{U}^{j+1}\,\|_{L^2}^2 \\ &\quad\le C\tau^{-1}h^{-2}\,\|\,\mathbf{U}^j\,\|_{L^\infty}\|\,\mathbf{R}^{j+1}\,\|_{L^1} + C\tau h^{-2}\,\|\,d_t\mathbf{U}^{j+1}\,\|_{L^2}^2 \\ &\quad\le C\tau^2 h^{-2}\,\|\,\mathbf{V}^{j+1}\,\|_h^2 + C\tau h^{-2}\,\|\,d_t\mathbf{U}^{j+1}\,\|_{L^2}^2 \\ &\quad\le C\tau h^{-2}\,\|\,\mathbf{V}^{j+1}\,\|_{L^2}^2 + C\tau h^{-2}\big[1 + \tau h^{-\frac{m}{2}}\|\,\mathbf{V}^{j+1}\,\|_{L^2}\big]^2\|\,\mathbf{V}^{j+1}\,\|_{L^2}^2\,.\end{aligned} \tag{4.7}$$

Step 2 (finishing up). We now conclude the proof by an induction argument. The assumptions on $\mathbf{u}_0$ and $\mathbf{U}^0$ imply that there exists a positive constant C_1 independent of τ and h such that $\|\,\nabla\mathbf{U}^0\,\|_{L^2} \le C_1$. Assume that $\|\,\nabla\mathbf{U}^i\,\|_{L^2} \le C_1$ for all $0 \le i \le j$; it follows from (4.3) and a discrete version of Gronwall's lemma that

$$\|\,\mathbf{V}^{j+1}\,\|_{L^2} \le \|\,\mathbf{V}^{j+1}\,\|_h \le Ch^{-1}\,. \tag{4.8}$$

If we use this result in (4.7), together with the mesh condition, we have existence of another $C_2 = C_2(T) > 0$, such that $\tau h^{-2}\tau^2 h^{-m}\,\|\,\mathbf{V}^{j+1}\,\|_{L^2}^2 \le C_2$. The discrete version of Gronwall's lemma then yields ($h \to 0$)

$$E_h\big(\mathbf{V}^{j+1}, \mathbf{U}^{j+1}\big) + \frac{\tau^2}{2}\sum_{\ell=0}^{j}\big[\|\,d_t\mathbf{V}^{\ell+1}\,\|_h^2 + \|\,\nabla d_t\mathbf{U}^{\ell+1}\,\|_{L^2}^2\big] \le \big(1 + o(1)\big)\,E_h\big(\mathbf{V}^0, \mathbf{U}^0\big).$$

Hence, by induction (4.1) holds for all $j = 0, 1, \ldots, J$. The proof is complete. ∎

The following corollary follows immediately from Lemma 4.1 and (4.6).

COROLLARY 4.2. *The solution sequence* $\{\mathbf{U}^j\}$ *of Algorithm* 3.1 *also satisfies*

$$\|\,d_t\mathbf{U}^{j+1}\,\|_{L^2} \le C\,, \qquad j = 0, 1, \ldots, J\,. \tag{4.9}$$

4.2. Convergence. To establish the convergence of Algorithm 3.1, we first need some preparations. Let $(\mathbf{U}^+_{\tau,h}, \mathbf{U}^-_{\tau,h}, \overline{\mathbf{U}}_{\tau,h}, \mathbf{U}_{\tau,h})$ and $(\mathbf{V}^+_{\tau,h}, \mathbf{V}^-_{\tau,h}, \overline{\mathbf{V}}_{\tau,h}, \mathbf{V}_{\tau,h})$ denote their respective constant and linear interpolations in time of the solution sequences $\{\mathbf{U}^j\}$ and $\{\mathbf{V}^j\}$ of Algorithm 3.1 as defined in section 3.1. However, for notational brevity, most of the time we omit subindices τ, h in this subsection and use $(\mathbf{U}^+, \mathbf{U}^-, \overline{\mathbf{U}}, \mathbf{U})$ and $(\mathbf{V}^+, \mathbf{V}^-, \overline{\mathbf{V}}, \mathbf{V})$ to stand for $(\mathbf{U}^+_{\tau,h}, \mathbf{U}^-_{\tau,h}, \overline{\mathbf{U}}_{\tau,h}, \mathbf{U}_{\tau,h})$ and $(\mathbf{V}^+_{\tau,h}, \mathbf{V}^-_{\tau,h}, \overline{\mathbf{V}}_{\tau,h}, \mathbf{V}_{\tau,h})$, respectively.

We first derive the following reformulation of Algorithm 3.1.

LEMMA 4.3. *Suppose that the assumptions of Lemma* 4.1 *are valid. There holds for all* $\mathbf{w} \in C_0^\infty\big([0,T); \boldsymbol{\mathcal{F}}_h(\mathbf{U}^-)\big)$

$$
\begin{aligned}
(4.10)\quad & \left| \int_0^T \big[-(\mathbf{U}_t, \mathbf{w}_t) + (\nabla \mathbf{U}, \nabla \mathbf{w}) \big] \, \mathrm{d}t + \big(\mathbf{V}^0, \mathbf{w}(0,\cdot) \big) \right| \\
& \qquad \le (C\tau h^{-\frac{m}{2}} + h) \left[\int_0^T \| \mathbf{w}_t \|_{L^2}^2 + \| \nabla \mathbf{w}_t \|_{L^2}^2 \, \mathrm{d}t + \| \nabla \mathbf{w}(0,\cdot) \|_{L^2}^2 \right]^{\frac{1}{2}} \\
& \qquad\qquad + \left| \int_0^T (\mathbf{V} - \mathbf{V}^+, \mathbf{w}_t) \, \mathrm{d}t \right| + \left| \int_0^T (\nabla [\mathbf{U} - \mathbf{U}^-], \nabla \mathbf{w}) \, \mathrm{d}t \right| .
\end{aligned}
$$

Proof. Using the new notation we rewrite Step (ii) in Algorithm 3.1 as

$$
\int_0^T \big[(\mathbf{V}_t, \mathbf{w})_h + (\nabla \mathbf{U}^-, \nabla \mathbf{w}) \big] \, \mathrm{d}t = 0 .
$$

Integrating by parts in t in the first term yields

$$
\int_0^T \big[-(\mathbf{V}, \mathbf{w}_t)_h + \big(\nabla \mathbf{U}^-, \nabla \mathbf{w} \big) \big] \, \mathrm{d}t + \big(\mathbf{V}^0, \mathbf{w}(0,\cdot) \big)_h = 0;
$$

this and the relation $\mathbf{V}^+ = \mathbf{U}_t - \tau^{-1} \mathbf{R}^+$ imply that

$$
\begin{aligned}
(4.11)\quad & - \int_0^T \big[-(\mathbf{U}_t, \mathbf{w}_t) + (\nabla \mathbf{U}, \nabla \mathbf{w}) \big] \, \mathrm{d}t - \big(\mathbf{V}^0, \mathbf{w}(0,\cdot) \big) \\
& \qquad = \int_0^T \big[(\mathbf{V}, \mathbf{w}_t) - (\mathbf{V}, \mathbf{w}_t)_h \big] \, \mathrm{d}t + \big(\mathbf{V}^0, \mathbf{w}(0,\cdot) \big)_h - \big(\mathbf{V}^0, \mathbf{w}(0,\cdot) \big) \\
& \qquad\qquad + \int_0^T \big[\tau^{-1} (\mathbf{R}^+, \mathbf{w}_t) + (\mathbf{V}^+ - \mathbf{V}, \mathbf{w}_t) + \big(\nabla [\mathbf{U}^- - \mathbf{U}], \nabla \mathbf{w} \big) \big] \, \mathrm{d}t .
\end{aligned}
$$

By (4.1) and the inequality after (4.5) we have

$$
\int_0^T \| \mathbf{R}^+ \|_{L^2}^2 \, \mathrm{d}t \le C \tau^4 h^{-m} .
$$

Finally, the assertion (4.10) follows from (4.11), (4.9), and (3.2). ∎

We are ready to state and prove the first main convergence theorem of this paper.

THEOREM 4.4. *Let* $T > 0$, *and* $\big(\mathbf{u}_0, \mathbf{u}_1\big) \in W^{1,2}(\Omega, \mathbf{S}^{n-1}) \times L^2(\Omega, T\mathbf{S}^{n-1})$. *Suppose that* $\big(\mathbf{U}^0, \mathbf{V}^0\big) \in \boldsymbol{\mathcal{M}}_h \times \boldsymbol{\mathcal{F}}_h(\mathbf{U}^0)$ *satisfies* $\mathbf{U}^0 \to \mathbf{u}_0$ *strongly in* $W^{1,2}(\Omega, \mathbf{R}^n)$, *and* $\mathbf{V}^0 \to \mathbf{u}_1$ *strongly in* $L^2(\Omega, \mathbf{R}^n)$ *as* $h \to 0$. *Let* $\tau = o(h^{\frac{4+m}{3}})$. *Then there exist a map*

$\mathbf{u} \in L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big) \cap W^{1,\infty}\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)$ *and a subsequence of solutions* $\{\mathbf{U}_{\tau,h}\}$ *(denoted by the same notation) of Algorithm* 3.1 *such that as* $h \to 0$

$$\begin{aligned} \mathbf{U}_{\tau,h} &\overset{*}{\rightharpoonup} \mathbf{u} \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)\,, \\ (\mathbf{U}_{\tau,h})_t &\rightharpoonup \mathbf{u}_t \quad \text{in } L^2(\Omega_T,\mathbf{R}^n)\,. \end{aligned}$$

Moreover, $\mathbf{u}$ *is a weak solution of* (1.3)–(1.5).

Proof. It follows from Lemma 4.1 that under the above mesh relation, there exist a map $\mathbf{u} \in W^{1,\infty}\big(0,T;L^2(\Omega,\mathbf{R}^n)\big) \cap L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)$ and a subsequence of $\{\mathbf{U} = \mathbf{U}_{\tau,h}\}$ (denoted by the same notation) such that as $h \to 0$

$$\begin{aligned} \mathbf{U}, \mathbf{U}^-, \mathbf{U}^+ &\overset{*}{\rightharpoonup} \mathbf{u} \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)\,, \\ &\to \mathbf{u} \quad \text{in } L^2(\Omega_T,\mathbf{R}^n), \end{aligned} \tag{4.12}$$

$$\mathbf{U}_t \overset{*}{\rightharpoonup} \mathbf{u}_t \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)\,. \tag{4.13}$$

Moreover, taking $h \to 0$ in (4.1) immediately shows that $\mathbf{u}$ satisfies the energy inequality in item (5) of Definition 2.1. Furthermore, from the inequality

$$\| \,|\,\mathbf{U}^+(t,\cdot)\,|^2 - 1\,\|_{L^2} \le Ch\,\|\,\nabla\mathbf{U}^+\,\|_{L^2} \qquad \forall\, t \in [0,T]$$

we conclude that $|\,\mathbf{u}\,| = 1$ a.e. in Ω_T.

Given $\boldsymbol{\phi} \in C_0^\infty\big([0,T);C^\infty(\Omega,\mathbf{R}^n)\big)$ let $\mathbf{w}_h = I_h\big(\mathbf{U}\wedge\boldsymbol{\phi}\big)$. By the properties of the interpolation operator I_h we get (cf. [9, 12])

$$\begin{aligned} &\| \left(I_h(\mathbf{U}\wedge\boldsymbol{\phi}) - \mathbf{U}\wedge\boldsymbol{\phi}\right)_t \|_{L^2}^2 \\ &\le Ch^4 \sum_{K\in\mathcal{T}_h} \Big(\| \nabla^2(\mathbf{U}_t\wedge\boldsymbol{\phi}) \|_{L^2(K)}^2 + \| \nabla^2(\mathbf{U}\wedge\boldsymbol{\phi}_t) \|_{L^2(K)}^2 \Big) \\ &\le Ch^4 \left[\| \,|\mathbf{U}_t|\,|\nabla^2\boldsymbol{\phi}|\, \|_{L^2}^2 + \| \,|\nabla\mathbf{U}_t|\,|\nabla\boldsymbol{\phi}|\, \|_{L^2}^2 + \| \nabla^2\boldsymbol{\phi}_t \|_{L^2}^2 + \| \,|\nabla\mathbf{U}|\,|\nabla\boldsymbol{\phi}_t|\, \|_{L^2}^2 \right] \\ &\le Ch^4 \left[\| \boldsymbol{\phi} \|_{W^{2,\infty}}^2 + h^{-2}\,\| \mathbf{U}_t \|_{L^2}^2 \| \nabla\boldsymbol{\phi} \|_{L^\infty}^2 + \| \boldsymbol{\phi}_t \|_{W^{2,\infty}}^2 \right]. \end{aligned}$$

This implies that $(\mathbf{w}_h - \mathbf{U}\wedge\boldsymbol{\phi})_t \to 0$ in $L^\infty\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)$. Hence, as $h \to 0$, using $\mathbf{U}_t \cdot \big(\mathbf{U}_t\wedge\boldsymbol{\phi}\big) = 0$ and (4.12) and (4.13),

$$\begin{aligned} &\int_{\Omega_T} \langle \mathbf{U}_t, (\mathbf{w}_h)_t \rangle \,\mathrm{d}x\mathrm{d}t \\ &\quad = \int_{\Omega_T} \langle \mathbf{U}_t, \left(I_h(\mathbf{U}\wedge\boldsymbol{\phi}) - \mathbf{U}\wedge\boldsymbol{\phi}\right)_t \rangle \,\mathrm{d}x\mathrm{d}t + \int_{\Omega_T} \langle \mathbf{U}_t, \mathbf{U}\wedge\boldsymbol{\phi}_t \rangle \,\mathrm{d}x\mathrm{d}t \\ &\quad \to \int_{\Omega_T} \langle \mathbf{u}_t, \mathbf{u}\wedge\boldsymbol{\phi}_t \rangle \,\mathrm{d}x\mathrm{d}t\,. \end{aligned} \tag{4.14}$$

Similarly, we can show

$$\| \nabla\big[I_h(\mathbf{U}\wedge\boldsymbol{\phi}) - \mathbf{U}\wedge\boldsymbol{\phi}\big] \|_{L^2}^2 \le Ch^2 \left[\| \boldsymbol{\phi} \|_{W^{2,2}}^2 + \| \nabla\mathbf{U} \|_{L^2}^2 \| \nabla\boldsymbol{\phi} \|_{L^\infty}^2 \right].$$

On noting the vector identity $\langle \nabla\mathbf{z}, \nabla\mathbf{z}\wedge\boldsymbol{\phi} \rangle = \langle \nabla\mathbf{z}, \mathbf{z}\wedge\nabla\boldsymbol{\phi} \rangle$, from (4.12) and (4.13) we conclude that as $h \to 0$

$$\begin{aligned} &\int_{\Omega_T} \langle \nabla\mathbf{U}, \nabla\mathbf{w}_h \rangle \,\mathrm{d}\mathbf{x}\mathrm{d}t \\ &\quad = \int_{\Omega_T} \langle \nabla\mathbf{U}, \nabla\big[I_h(\mathbf{U}\wedge\boldsymbol{\phi}) - \mathbf{U}\wedge\boldsymbol{\phi}\big] \rangle \,\mathrm{d}\mathbf{x}\mathrm{d}t + \int_{\Omega_T} \langle \nabla\mathbf{U}, (\mathbf{U}\wedge\nabla\boldsymbol{\phi}) \rangle \,\mathrm{d}\mathbf{x}\mathrm{d}t \\ &\quad \to \int_{\Omega_T} \langle \nabla\mathbf{u}, \mathbf{u}\wedge\nabla\boldsymbol{\phi} \rangle \,\mathrm{d}\mathbf{x}\mathrm{d}t\,. \end{aligned} \tag{4.15}$$

Straightforward calculations show that

$$\left|\int_0^T (\mathbf{V}-\mathbf{V}^+,\mathbf{w}_t)\,\mathrm{d}t\right| \le C\tau^{\frac12}\left(\tau\int_0^T ||\mathbf{V}_t||_{L^2}^2\,\mathrm{d}t\right)^{\frac12}\left(\int_0^T ||\mathbf{w}_t||_{L^2}^2\,\mathrm{d}t\right)^{\frac12}.$$

Similarly, we can bound the last term in (4.10) and benefit from the estimates for $\tau\int_0^T ||\mathbf{V}_t||_{L^2}^2\,\mathrm{d}t$ and $\tau\int_0^T ||\nabla\mathbf{U}_t||_{L^2}^2\,\mathrm{d}t$ of Lemma 4.1. Letting $h\to 0$ in (4.10) and using (4.14) and (4.15) then give (2.1).

In order to verify item (4) of Definition 2.1, we adopt an argument from [20, p. 92]. $\mathbf{u}_0=\lim_{t\to0}\lim_{\tau,h\to0}\mathbf{U}(t,\cdot)$ in $L^2(\Omega,\mathbf{R}^n)$ follows immediately from (5.7). It remains to verify $\mathbf{U}_t(t,\cdot)\to\mathbf{u}_1$ in $L^2(\Omega,\mathbf{R}^n)$ as $t\to0$. To this end, multiply $\Box\mathbf{u}\wedge\mathbf{u}=0$ with $\mathbf{w}\in C_0^\infty\big([0,T);C^\infty(\Omega,\mathbf{R}^n)\big)$, integrate by parts on Ω_T, and then subtract the resulting equation from (4.10); together with Lemma 4.3 and (5.7), (5.8), as well as assumptions on $(\mathbf{U}^0,\mathbf{V}^0)$, we find for the limit $\tau,h\to0$,

$$\big((\mathbf{u}_t(0,\cdot)-\mathbf{u}_1)\wedge\mathbf{u}_0,\mathbf{w}\big)=0\qquad\forall\,\mathbf{w}\in C_0^\infty\big([0,T);C^\infty(\Omega,\mathbf{R}^n)\big)\,.$$

On noting that $\langle\mathbf{u}_1(\mathbf{x}),\mathbf{u}_0(\mathbf{x})\rangle=\langle\mathbf{u}_t(0,\mathbf{x}),\mathbf{u}_0(\mathbf{x})\rangle=0$ for a.e. $\mathbf{x}\in\Omega$, it follows from the vector identity $\mathbf{v}=\langle\mathbf{u},\mathbf{v}\rangle\mathbf{u}-\mathbf{u}\wedge(\mathbf{u}\wedge\mathbf{v})$ with $\mathbf{v}=\mathbf{u}_t(0,\cdot)-\mathbf{u}_1$ that $\mathbf{u}_t(t,\cdot)\rightharpoonup\mathbf{u}_1$ in $L^2(\Omega,\mathbf{R}^n)$ as $t\to0$.

We also need to show that $\mathbf{u}_t(t,\cdot)\to\mathbf{u}_1$ in $L^2(\Omega,\mathbf{R}^n)$ as $t\to0$. By weak lower semicontinuity of the L^2-norm and Fatou's lemma

$$\|\,D\mathbf{u}(t,\cdot)\,\|_{L^2}\le\liminf_{\tau,h\to0}\|\,D\mathbf{U}(t,\cdot)\,\|_{L^2},\qquad t\ge0\,.$$

Hence, for all $t\ge0$, by (3.2), Lemma 4.1, and the assumptions on initial data,

$$\begin{aligned}E\big(\mathbf{u}_t(t,\cdot),\mathbf{u}(t,\cdot)\big)&\le\liminf_{\tau,h\to0}E\big(\mathbf{U}_t(t,\cdot),\mathbf{U}(t,\cdot)\big)\\&=\liminf_{\tau,h\to0}E_h\big(\mathbf{U}_t(t,\cdot),\mathbf{U}(t,\cdot)\big)\le E\big(\mathbf{u}_1,\mathbf{u}_0\big)\,.\end{aligned}$$

Therefore,

$$\limsup_{t\to0}\|\,\mathbf{u}_t(t,\cdot)\,\|_{L^2}\le\|\,\mathbf{u}_1\,\|_{L^2}\,,\quad\limsup_{t\to0}\|\,\nabla\mathbf{u}(t,\cdot)\,\|_{L^2}\le\|\,\nabla\mathbf{u}_0\,\|_{L^2}\,,$$

and the weak convergence $\mathbf{u}_t(t,\cdot)\rightharpoonup\mathbf{u}_1(\cdot)$ in $L^2(\Omega,\mathbf{R}^n)$ and $\nabla\mathbf{u}(t,\cdot)\rightharpoonup\nabla\mathbf{u}_0(\cdot)$ in $L^2(\Omega)$ imply strong convergence $\mathbf{u}_t(t,\cdot)\to\mathbf{u}_1(\cdot)$ and $\nabla\mathbf{u}(t,\cdot)\to\nabla\mathbf{u}_0(\cdot)$ in $L^2(\Omega,\mathbf{R}^{mn})$ as $t\to0$. Consequently, $\mathbf{u}:\Omega_T\to\mathbf{R}^n$ attains prescribed initial data continuously in $W^{1,2}(\Omega,\mathbf{R}^n)\times L^2(\Omega,\mathbf{R}^n)$.

Since all requirements of Definition 2.1 are verified, the map $\mathbf{u}:\Omega_T\to\mathbf{R}^n$ is a weak solution to (1.3)–(1.5). The proof is complete. □

As a by-product, the above convergence result provides an alternative (to the one given in [20]) proof of existence of weak solutions to (1.3)–(1.5).

5. Convergence analysis for Algorithms 3.2 and 3.3. The goal of this section is to prove that the solution sequences $\{\mathbf{U}^j\}$ of Algorithms 3.2 and 3.3 converge uniformly in ε, and the limits of both sequences are weak solutions of (1.9)–(1.11).

5.1. Stability of Algorithms 3.2 and 3.3. Let $E_h(\cdot,\cdot)$ be the same as in (4.2), and define

$$F_h(\mathbf{U}^j) = \frac{1}{4}\| \,|\, \mathbf{U}^j \,|^2 - 1 \,\|_h^2.$$

The following lemma establishes a discrete conservation law for Algorithm 3.2, which mimics the differential conservation law (1.12).

LEMMA 5.1. *For $\varepsilon > 0$, let $\tau_1 = \tau$ and $\big(\mathbf{U}^0, \mathbf{V}^0\big) \in [\boldsymbol{\mathcal{V}}_h]^2$. Then the solution sequence $\{(\mathbf{U}^j, \mathbf{V}^j)\}$ generated by Algorithm 3.2 satisfies for $j = 0 \to (J-1)$*

$$E_h\big(\mathbf{V}^{j+1}, \mathbf{U}^{j+1}\big) + \frac{1}{\varepsilon} F_h(\mathbf{U}^{j+1}) = E_h\big(\mathbf{V}^0, \mathbf{U}^0\big) + \frac{1}{\varepsilon} F_h(\mathbf{U}^0)\,. \tag{5.1}$$

Moreover, if $\mathbf{U}^0 \in \boldsymbol{\mathcal{M}}_h$, then $F_h(\mathbf{U}^0) = 0$, and

$$\| \,d_t \mathbf{U}^{j+1} \,\|_h^2 \le 2E_h(\mathbf{V}^0, \mathbf{U}^0). \tag{5.2}$$

Proof. Taking test functions $(\mathbf{w}, \boldsymbol{\chi}) = (d_t\mathbf{U}^{j+1}, d_t\mathbf{V}^{j+1})$ in (ii) of Algorithm 3.2 and using binomial formulas, we obtain

$$\begin{aligned}
&(d_t\mathbf{V}^{j+1}, d_t\mathbf{U}^{j+1})_h + \frac{1}{2} d_t \| \,\nabla \mathbf{U}^{j+1} \,\|_{L^2}^2 + \frac{1}{\varepsilon} d_t F_h(\mathbf{U}^{j+1}) = 0\,,\\
&(d_t\mathbf{U}^{j+1}, d_t\mathbf{V}^{j+1})_h = \frac{1}{2} d_t \| \,\mathbf{V}^{j+1} \,\|_h^2\,.
\end{aligned}$$

Subtracting the second equation from the first one and summing up the resulting equation over the index from 1 to j gives (5.1).

Alternatively, taking $\boldsymbol{\chi} = d_t\mathbf{U}^{j+1}$ as a test function in the second equation of (ii) of Algorithm 3.2, it follows from (5.1) and the fact $F_h(\mathbf{U}^0) = 0$ if $\mathbf{U}^0 \in \boldsymbol{\mathcal{M}}_h$ that

$$\| \,d_t\mathbf{U}^{j+1} \,\|_h^2 \le \| \,\mathbf{V}^{j+\frac{1}{2}} \,\|_h^2 \le \frac{1}{2} \| \,\mathbf{V}^{j+1} \,\|_h^2 + \frac{1}{2} \| \,\mathbf{V}^{j} \,\|_h^2 \le 2E_h(\mathbf{V}^0, \mathbf{U}^0)\,.$$

The proof is complete. ∎

Likewise, we now prove that Algorithm 3.3 also satisfies a discrete conservation law which mimics the differential conservation law (1.12).

LEMMA 5.2. *Let $\varepsilon > 0, m \ge 1$, and $\big(\mathbf{U}^0, \mathbf{U}^1\big) \in [\boldsymbol{\mathcal{V}}_h]^2$. Then the solution sequence $\{\mathbf{U}^j\}$ generated by Algorithm 3.3 satisfies for $j = 1 \to (J-1)$*

$$E_h\big(d_t\mathbf{U}^{j+1}, \mathbf{U}^{j+\frac{1}{2}}\big) + \frac{1}{\varepsilon} F_h(\mathbf{U}^{j+\frac{1}{2}}) = E_h\big(d_t\mathbf{U}^{1}, \mathbf{U}^{\frac{1}{2}}\big) + \frac{1}{\varepsilon} F_h(\mathbf{U}^{\frac{1}{2}})\,. \tag{5.3}$$

Proof. Choose $\mathbf{w} = \delta_t\mathbf{U}^j$ in (ii) of Algorithm 3.3, and use the identities (cf. [14])

$$\delta_t\mathbf{U}^j = d_t\mathbf{U}^{j+\frac{1}{2}} = \frac{1}{2}\big(\,d_t\mathbf{U}^{j+1} + d_t\mathbf{U}^{j}\,\big), \qquad \mathbf{U}^{j,\frac{1}{4}} = \frac{1}{2}\big(\,\mathbf{U}^{j+\frac{1}{2}} + \mathbf{U}^{j-\frac{1}{2}}\,\big)$$

and binomial formulas to simplify the resulting equation. Assertion (5.3) follows easily from summing up the equation over the index from 1 to j. ∎

We remark that the existence of solutions to Algorithms 3.2 and 3.3 now follows from the discrete conservation laws (5.1) and (5.3), respectively, and an application of the Brouwer fixed point theorem.

5.2. Convergence of Algorithm 3.2. The same notation as that in section 4.2 will be used in this subsection. The following lemma prepares us to prove the convergence of Algorithm 3.2.

LEMMA 5.3. *In addition to the assumptions of Lemma* 5.1*, we assume* $\mathbf{U}^0 \in \boldsymbol{\mathcal{M}}_h$*; then for all* $\mathbf{w} \in C_0^\infty([0,T);\boldsymbol{\mathcal{V}}_h)$ *there holds*

$$
\begin{aligned}
(5.4)\quad &\left|\int_0^T \Big[-(\mathbf{U}_t,\mathbf{w}_t)+(\nabla\mathbf{U},\nabla\mathbf{w})+\frac{1}{\varepsilon}\big([|\,\mathbf{U}\,|^2-1]\mathbf{U},\mathbf{w}\big)\Big]\,\mathrm{d}t+\big(\mathbf{V}^0,\mathbf{w}(0,\cdot)\big)\right| \\
&\qquad\le C\,\left[h+\frac{\tau+h}{\varepsilon}\right]\left\{\int_0^T\big(\|\,\nabla\mathbf{w}\,\|_{L^2}^2+\|\,\nabla\mathbf{w}_t\,\|_{L^2}^2\big)\mathrm{d}t+\|\,\nabla\mathbf{w}(0,\cdot)\,\|_{L^2}^2\right\}^{\frac12} \\
&\qquad\qquad+\left|\int_0^T(\mathbf{V}-\overline{\mathbf{V}},\mathbf{w}_t)_h\,\mathrm{d}t\right|+\left|\int_0^T\big(\nabla[\mathbf{U}-\overline{\mathbf{U}}],\nabla\mathbf{w}\big)\,\mathrm{d}t\right|.
\end{aligned}
$$

Proof. Using the new notation and integration by parts, the equations in (ii) of Algorithm 3.2 can be rewritten as follows:

$$
\begin{aligned}
(5.5)\quad &\int_0^T\left\{-(\mathbf{V},\mathbf{w}_t)_h+(\nabla\overline{\mathbf{U}},\nabla\mathbf{w})+\frac{1}{2\varepsilon}\big([\,|\,\mathbf{U}^-\,|^2+|\,\mathbf{U}^+\,|^2-2]\overline{\mathbf{U}},\mathbf{w}\big)_h\right\}\mathrm{d}t \\
&\qquad\qquad=-\big(\mathbf{V}^0,\mathbf{w}(0,\cdot)\big)_h\,, \\
(5.6)\quad &\int_0^T(\mathbf{U}_t-\overline{\mathbf{V}},\mathbf{w})_h\,\mathrm{d}t=0\,.
\end{aligned}
$$

Using the second equation, we restate terms in the first equation as follows:

$$
\begin{aligned}
\int_0^T(\mathbf{V},\mathbf{w}_t)_h\,\mathrm{d}t&=\int_0^T(\mathbf{U}_t,\mathbf{w}_t)\,\mathrm{d}t-\int_0^T\big[(\mathbf{U}_t,\mathbf{w}_t)-(\mathbf{U}_t,\mathbf{w}_t)_h\big]\,\mathrm{d}t \\
&\qquad+\int_0^T\big(\mathbf{V}-\overline{\mathbf{V}},\mathbf{w}_t\big)_h\,\mathrm{d}t\,, \\
\int_0^T(\nabla\overline{\mathbf{U}},\nabla\mathbf{w})\,\mathrm{d}t&=\int_0^T(\nabla\mathbf{U},\nabla\mathbf{w})\,\mathrm{d}t-\int_0^T\big(\nabla[\mathbf{U}-\overline{\mathbf{U}}],\nabla\mathbf{w}\big)\,\mathrm{d}t\,, \\
\frac{1}{2\varepsilon}\int_0^T\big([\,|\,\mathbf{U}^-\,|^2+|\,\mathbf{U}^+\,|^2-2]\overline{\mathbf{U}},\mathbf{w}\big)_h\,\mathrm{d}t&-\frac{1}{\varepsilon}\int_0^T\big([|\,\mathbf{U}\,|^2-1]\mathbf{U},\mathbf{w}\big)\,\mathrm{d}t \\
&=-\frac{1}{\varepsilon}\int_0^T\Big\{\big([|\,\mathbf{U}\,|^2-1]\mathbf{U},\mathbf{w}\big)-\big([|\,\mathbf{U}\,|^2-1]\mathbf{U},\mathbf{w}\big)_h\Big\}\,\mathrm{d}t \\
&\qquad-\frac{1}{2\varepsilon}\int_0^T\big([2|\,\mathbf{U}\,|^2-|\,\mathbf{U}^-\,|^2-|\,\mathbf{U}^+\,|^2]\mathbf{U},\mathbf{w}\big)_h\,\mathrm{d}t \\
&\qquad-\frac{1}{2\varepsilon}\int_0^T\big([\,|\,\mathbf{U}^-\,|^2+|\,\mathbf{U}^+\,|^2-2](\mathbf{U}-\overline{\mathbf{U}}),\mathbf{w}\big)_h\,\mathrm{d}t\,.
\end{aligned}
$$

It follows from (3.2), the L^p-stability of I_h, and an inverse inequality that

$$\Big|\int_0^T \big[(\mathbf{V},\mathbf{w}_t)_h - (\mathbf{U}_t,\mathbf{w}_t)\big]\,\mathrm{d}t\Big| \le Ch\int_0^T \|\,\mathbf{U}_t\,\|_{L^2}\,\|\,\nabla\mathbf{w}_t\,\|_{L^2}\,\mathrm{d}t + \Big|\int_0^T (\mathbf{V}-\overline{\mathbf{V}},\mathbf{w}_t)_h\Big|,$$

$$\Big|\frac{1}{2\varepsilon}\int_0^T \Big\{\big([\,|\,\mathbf{U}^-\,|^2+|\,\mathbf{U}^+\,|^2-2]\overline{\mathbf{U}},\mathbf{w}\big)_h - 2\big([\,|\,\mathbf{U}\,|^2-1]\mathbf{U},\mathbf{w}\big)\Big\}\mathrm{d}t\Big|$$

$$\le \frac{C}{\varepsilon}\int_0^T \Big\{h\|\,I_h([\,|\,\mathbf{U}\,|^2-1]\mathbf{U})\,\|_{L^2}\|\,\nabla\mathbf{w}\,\|_{L^2} + h\|\,\nabla\big([\,|\,\mathbf{U}\,|^2-1]\mathbf{U}\big)\,\|_{L^1}\|\,\mathbf{w}\,\|_{L^\infty}$$

$$+\tau\,\|\,\mathbf{U}_t\,\|_{L^2}\|\,\mathbf{U}\,\|_{L^4}^2\|\,\mathbf{w}\,\|_{L^\infty} + \frac{\tau}{2}\,\|\,\mathbf{U}_t\,\|_{L^2}\|\,I_h(|\,\mathbf{U}^-\,|^2+|\,\mathbf{U}^+\,|^2-2)\,\|_{L^2}\|\,\mathbf{w}\,\|_{L^\infty}\Big\}\,\mathrm{d}t\,.$$

The assertion of the lemma now follows from combining the above estimates and appealing to Lemma 5.1. ∎

We are ready to state and prove the second main convergence theorem of this paper.

THEOREM 5.4. *Let $\varepsilon>0, m\ge 1, \tau_1=\tau$, and $\big(\mathbf{u}_0,\mathbf{u}_1\big)\in W^{1,2}(\Omega,\mathbf{S}^{n-1})\times L^2(\Omega,T\mathbf{S}^{n-1})$. Suppose that $\big(\mathbf{U}^0,\mathbf{V}^0\big)\in\boldsymbol{\mathcal{M}}_h\times\boldsymbol{\mathcal{V}}_h$ satisfies $\mathbf{U}^0\to\mathbf{u}_0$ strongly in $W^{1,2}(\Omega,\mathbf{R}^n)$ and $\mathbf{V}^0\to\mathbf{u}_1$ strongly in $L^2(\Omega,\mathbf{R}^n)$ as $h\to 0$. Then there exist a map $\mathbf{u}^\varepsilon\in L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)\cap W^{1,\infty}\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)$ and a subsequence of the solution sequence $\{\mathbf{U}_{\varepsilon,\tau,h}\}$ (denoted by the same notation) of Algorithm 3.2 such that as $\tau,h\to 0$*

$$\begin{aligned}\mathbf{U}_{\varepsilon,\tau,h} &\overset{*}{\rightharpoonup} \mathbf{u}^\varepsilon \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)\,,\\ (\mathbf{U}_{\varepsilon,\tau,h})_t &\overset{*}{\rightharpoonup} \mathbf{u}_t^\varepsilon \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)\end{aligned}$$

uniformly in ε. Moreover, $\mathbf{u}^\varepsilon$ is a weak solution of (1.9)–(1.11). Hence, $\mathbf{u}:=\lim_{\varepsilon\to 0}\lim_{\tau,h\to 0}\mathbf{U}_{\varepsilon,\tau,h}$ exists and is a weak solution of (1.3)–(1.5), by [20].

Proof. It follows from Lemma 5.1 that there exist $\mathbf{u}^\varepsilon\in W^{1,\infty}\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)\cap L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)$ and a subsequence of $\{\mathbf{U}=\mathbf{U}_{\varepsilon,\tau,h}\}$ (denoted by the same notation) such that as $\tau,h\to 0$

$$\begin{aligned}\mathbf{U},\mathbf{U}^-,\mathbf{U}^+,\overline{\mathbf{U}} &\overset{*}{\rightharpoonup} \mathbf{u}^\varepsilon \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big)\,, \qquad (5.7)\\ &\to \mathbf{u}^\varepsilon \quad \text{in } L^2(\Omega_T,\mathbf{R}^n)\,,\\ \mathbf{U}_t &\overset{*}{\rightharpoonup} \mathbf{u}_t^\varepsilon \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)\,, \qquad (5.8)\end{aligned}$$

all uniformly in ε. For a.a. $\mathbf{x}\in\Omega$ and all $j=0,1,\dots,J-1$ there holds $\int_{t_j}^{t_{j+1}}(\mathbf{V}-\overline{\mathbf{V}})(\mathbf{x},t)\,\mathrm{d}t=0$; hence we can subtract the temporal average

$$\overline{\mathbf{w}}_t(x)=(1/\tau)\int_{t_j}^{t_{j+1}}\mathbf{w}_t(\mathbf{x},t)\,\mathrm{d}t$$

of w. Then by a Poincaré estimate we have

$$\begin{aligned}\left|\int_0^T(\mathbf{V}-\overline{\mathbf{V}},\mathbf{w}_t)\,\mathrm{d}t\right| &= \left|\int_0^T(\mathbf{V}-\overline{\mathbf{V}},\mathbf{w}_t-\overline{\mathbf{w}}_t)\,\mathrm{d}t\right|\\ &\le C\tau\left(\int_0^T||\mathbf{V}-\overline{\mathbf{V}}||_{L^2}^2\,\mathrm{d}t\right)^{1/2}\left(\int_0^T||\mathbf{w}_{tt}||_{L^2}^2\,\mathrm{d}t\right)^{1/2},\end{aligned}$$

and this tends to zero for $h,\tau \to 0$. Similarly, we can bound the last term in (5.4). Therefore, for any $\boldsymbol{\phi} \in C_0^\infty\big(\Omega_T, \mathbf{R}^n\big)$, let $\mathbf{w} = I_h\boldsymbol{\phi}$; using (5.1), (5.2), and the above inequality we can easily pass to the limit in (5.4) by setting $\tau, h \to 0$, and hence conclude that $\mathbf{u}^\varepsilon$ satisfies (1.9)–(1.11) in the distributional sense.

We now show that initial data are continuously taken for $t \to 0$ by the argument used at the end of the proof of Theorem 4.4. Since $\{D\mathbf{U}\}_{k,h}$ is bounded in $L^2(\Omega_T, \mathbf{R}^n)$, we have $\mathbf{U} \to \mathbf{u}^\varepsilon$ in $C^0\big(0,T; L^2(\Omega, \mathbf{R}^n)\big)$ as $\tau, h \to 0$; hence, $\mathbf{u}^\varepsilon : \Omega_T \to \mathbf{R}^n$ assumes data $\mathbf{u}_0 : \Omega \to \mathbf{R}^n$ continuously in $L^2(\Omega; \mathbf{R}^n)$. Multiply (1.9) with $\mathbf{w} \in C_0^\infty\big([0,T); C^\infty(\Omega, \mathbf{R}^n)\big)$, integrate by parts on Ω_T, and then subtract the resulting equation from (5.4); together with Lemma 5.3 and (5.7), (5.8), as well as the assumptions on the initial data $\mathbf{U}^0, \mathbf{V}^0$, we find that $\mathbf{u}_t^\varepsilon(t,\cdot) \rightharpoonup \mathbf{u}_1(\cdot)$ weakly in $L^2(\Omega, \mathbf{R}^n)$ as $t \to 0$. Moreover, by weak lower semicontinuity of the L^2-norm and Fatou's lemma we have

$$\| D\mathbf{u}^\varepsilon(t,\cdot) \|_{L^2} \le \liminf_{\tau,h\to 0} \| D\mathbf{U}(t,\cdot) \|_{L^2}\,, \quad F\big(\mathbf{u}^\varepsilon(t,\cdot)\big) \le \liminf_{\tau,h\to 0} F\big(\mathbf{U}(t,\cdot)\big).$$

Hence, for all $t \ge 0$, by (3.1), Lemma 5.1, and the assumptions on initial data,

$$\begin{aligned} E\big(\mathbf{u}_t^\varepsilon(t,\cdot), \mathbf{u}^\varepsilon(t,\cdot)\big) + \frac{1}{\varepsilon} F\big(\mathbf{u}^\varepsilon(t,\cdot)\big) &\le \liminf_{\tau,h\to 0} \left[E\big(\mathbf{U}_t(t,\cdot), \mathbf{U}(t,\cdot)\big) + \frac{1}{\varepsilon} F\big(\mathbf{U}(t,\cdot)\big) \right] \\ &\le \liminf_{\tau,h\to 0} \left[E_h\big(\mathbf{U}_t(t,\cdot), \mathbf{U}(t,\cdot)\big) + \frac{1}{\varepsilon} F_h\big(\mathbf{U}(t,\cdot)\big) \right] \\ &\le E\big(\mathbf{u}_1, \mathbf{u}_0\big)\,. \end{aligned}$$

Therefore,

$$\limsup_{t\to 0} \| \mathbf{u}_t^\varepsilon(t,\cdot) \|_{L^2} \le \| \mathbf{u}_1 \|_{L^2}\,, \quad \limsup_{t\to 0} \| \nabla\mathbf{u}^\varepsilon(t,\cdot) \|_{L^2} \le \| \nabla\mathbf{u}_0 \|_{L^2},$$

and weak convergence $\mathbf{u}_t^\varepsilon(t,\cdot) \rightharpoonup \mathbf{u}_1(\cdot)$ in $L^2(\Omega, \mathbf{R}^n)$ and $\nabla\mathbf{u}^\varepsilon(t,\cdot) \rightharpoonup \nabla\mathbf{u}_0(\cdot)$ in $L^2(\Omega)$ imply strong convergence $\mathbf{u}_t^\varepsilon(t,\cdot) \to \mathbf{u}_1(\cdot)$ and $\nabla\mathbf{u}^\varepsilon(t,\cdot) \to \nabla\mathbf{u}_0(\cdot)$ in $L^2(\Omega, \mathbf{R}^{mn})$ as $t \to 0$. Hence, $\mathbf{u}^\varepsilon : \Omega \to \mathbf{R}^n$ attains prescribed initial data continuously in $W^{1,2}(\Omega, \mathbf{R}^n) \times L^2(\Omega, \mathbf{R}^n)$ and is a weak solution of (1.9)–(1.11) in the sense of [20, Definition 5.1]. ∎

5.3. Convergence of Algorithm 3.3. Let $\{\mathbf{U}^j\}$ be the solution sequence generated by Algorithm 3.3, and define for $j = 1 \to J$

$$\mathbf{V}^j := d_t\mathbf{U}^j = \frac{1}{\tau}\big(\,\mathbf{U}^j - \mathbf{U}^{j-1}\,\big), \qquad \mathbf{Z}^j := \mathbf{U}^{j-\frac{1}{2}} = \frac{1}{2}\big(\,\mathbf{U}^{j-1} + \mathbf{U}^j\,\big).$$

We note that τ needs to be replaced by τ_1 in the definition of $\mathbf{V}^j$ when $j = 1$. Let $\mathbf{U}^+, \mathbf{U}^-, \overline{\mathbf{U}}, \mathbf{U}$ (respectively, $\mathbf{V}^+, \mathbf{V}^-, \overline{\mathbf{V}}, \mathbf{V}$ and $\mathbf{Z}^+, \mathbf{Z}^-, \overline{\mathbf{Z}}, \mathbf{Z}$) be the constant and linear interpolations of $\{\mathbf{U}^j\}$ (respectively, $\{\mathbf{V}^j\}$ and $\{\mathbf{Z}^j\}$) in time as defined in section 3.1.

Using the new notation the equation in (ii) of Algorithm 3.3 can be rewritten as for any $\mathbf{w} \in \boldsymbol{\mathcal{V}}_h$

$$\begin{aligned} &(d_t\mathbf{V}^{j+1}, \mathbf{w})_h + \big(\nabla\mathbf{Z}^{j+\frac{1}{2}}, \nabla\mathbf{w}\big) + \frac{1}{2\varepsilon}\big([\,|\mathbf{Z}^j|^2 + |\mathbf{Z}^{j+1}|^2 - 2]\mathbf{Z}^{j+\frac{1}{2}}, \mathbf{w}\big)_h = 0, \\ &(d_t\mathbf{U}^{j+1} - \mathbf{V}^{j+1}, \mathbf{w})_h = 0, \end{aligned}$$

or, equivalently, for any $\mathbf{w} \in C_0^\infty([0,T);\boldsymbol{\mathcal{V}}_h)$

$$\int_0^T \left\{ -(\mathbf{V},\mathbf{w}_t)_h + \big(\nabla\overline{\mathbf{Z}},\nabla\mathbf{w}\big) + \frac{1}{2\varepsilon}\big([\,|\mathbf{Z}^+|^2+|\mathbf{Z}^-|^2-2]\overline{\mathbf{Z}},\mathbf{w}\big)_h \right\} \mathrm{d}t = \big(\mathbf{V}^0,\mathbf{w}(0,\cdot)\big)_h, \tag{5.9}$$

$$\int_0^T (\mathbf{U}_t - \mathbf{V}^+,\mathbf{w})_h \,\mathrm{d}t = 0. \tag{5.10}$$

Comparing (5.9)–(5.10) with (5.5)–(5.6), we see that (5.9) can be obtained from (5.5) by replacing $\mathbf{Z}$ by $\mathbf{U}$, and (5.10) from (5.6) by replacing $\mathbf{V}^+$ by $\overline{\mathbf{V}}$. Moreover, the discrete conservation law (5.3) provides the same energy estimates for $(\mathbf{Z},\mathbf{V})$ here as those enjoyed by $(\mathbf{U},\mathbf{V})$ in subsection 5.2 as a result of the discrete conservation law (5.1). Hence, on noting $\mathbf{U}^j = \mathbf{Z}^j - \tau\mathbf{V}^j$ for Algorithm 3.3 and the inequality (3.3), by repeating the proof of Lemma 5.3 we easily get the following lemma.

LEMMA 5.5. *Let $\{\mathbf{U}^j\}$ be the solution sequence of Algorithm* 3.3 *and $\mathbf{V}^+,\mathbf{V},\mathbf{Z}^+$, $\mathbf{Z}^-$, and $\overline{\mathbf{Z}}$ be defined as above. In addition to the assumptions of Lemma* 5.2*, we assume $(\mathbf{U}^0,\mathbf{U}^1) \in [\boldsymbol{\mathcal{M}}_h]^2$ such that $E_h(d_t\mathbf{U}^1,\mathbf{U}^{\frac12}) + \frac{1}{\varepsilon}F_h(\mathbf{U}^{\frac12}) \le C$; then for all $\mathbf{w} \in C_0^\infty([0,T);\boldsymbol{\mathcal{V}}_h)$, there holds*

$$\begin{aligned}
&\left| \int_0^T \left[-(\mathbf{U}_t,\mathbf{w}_t) + (\nabla\mathbf{Z},\nabla\mathbf{w}) + \frac{1}{\varepsilon}\big([\,|\,\mathbf{Z}\,|^2-1]\mathbf{Z},\mathbf{w}\big)\right] \mathrm{d}t + \big(\mathbf{V}^0,\mathbf{w}(0,\cdot)\big)\right| \\
&\qquad \le C\left[h + \frac{\tau+h}{\varepsilon}\right]\left\{ \int_0^T \big(\|\,\nabla\mathbf{w}\,\|_{L^2}^2 + \|\,\nabla\mathbf{w}_t\,\|_{L^2}^2\big)\mathrm{d}t + \|\,\nabla\mathbf{w}(0,\cdot)\,\|_{L^2}^2 \right\}^{\frac12} \\
&\qquad\qquad + \left| \int_0^T (\mathbf{V}-\mathbf{V}^+,\mathbf{w}_t)_h \,\mathrm{d}t \right| + \left| \int_0^T \big(\nabla[\mathbf{Z}-\overline{\mathbf{Z}}],\nabla\mathbf{w}\big)\,\mathrm{d}t \right|.
\end{aligned} \tag{5.11}$$

We now state and show the third main convergence theorem of this paper.

THEOREM 5.6. *Let $\varepsilon > 0, m \ge 1$, and $\big(\mathbf{u}_0,\mathbf{u}_1\big) \in W^{1,2}(\Omega,\mathbf{S}^{n-1}) \times L^2(\Omega,T\mathbf{S}^{n-1})$. In addition to the assumptions of Lemma* 5.5*, suppose $\big(\mathbf{U}^0,\mathbf{U}^1\big) \in [\boldsymbol{\mathcal{M}}_h]^2$ satisfies $\mathbf{U}^0 \to \mathbf{u}_0$ strongly in $W^{1,2}(\Omega,\mathbf{R}^n)$ and $d_t\mathbf{U}^1 \to \mathbf{u}_1$ strongly in $L^2(\Omega,\mathbf{R}^n)$ as $\tau_1, h \to 0$. Then there exist a map $\mathbf{u}^\varepsilon \in L^\infty\big(0,T;W^{1,2}(\Omega,\,\mathbf{R}^n)\big) \cap W^{1,\infty}\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)$ and a subsequence of the solution sequence $\{\mathbf{U}_{\varepsilon,\tau,h}\}$ (denoted by the same notation) of Algorithm* 3.3 *such that as $\tau, h \to 0$*

$$\begin{aligned}
\mathbf{U}_{\varepsilon,\tau,h} &\overset{*}{\rightharpoonup} \mathbf{u}^\varepsilon \quad \text{in } L^\infty\big(0,T;W^{1,2}(\Omega,\mathbf{R}^n)\big), \\
(\mathbf{U}_{\varepsilon,\tau,h})_t &\overset{*}{\rightharpoonup} \mathbf{u}_t^\varepsilon \quad \text{in } L^\infty\big(0,T;L^2(\Omega,\mathbf{R}^n)\big)
\end{aligned}$$

uniformly in ε. Moreover, $\mathbf{u}^\varepsilon$ is a weak solution of (1.9)–(1.11)*. Hence, $\mathbf{u} := \lim_{\varepsilon\to0}\lim_{\tau,h\to0}\mathbf{U}_{\varepsilon,\tau,h}$ exists and is a weak solution of* (1.3)–(1.5) *by* [20].

Proof. The proof is essentially the same as that of Theorem 5.4. A slight complication is that after extracting convergent subsequences of $\{\mathbf{U}\}$, $\{\mathbf{Z}\}$, and $\{\mathbf{V}\}$ (which is possible thanks to the discrete energy law (5.3)) and passing to the limit in (5.11), we now need to relate the three limiting functions $\mathbf{u}^\varepsilon, \mathbf{z}^\varepsilon$, and $\mathbf{v}^\varepsilon$ to each other.

To this end, first, on noting identity $\mathbf{U}^j = \mathbf{Z}^j - \tau\mathbf{V}^j$ (or equivalently, $\mathbf{U}^+ = \mathbf{Z}^+ - \tau\mathbf{V}^+$) and inequality (3.3), we conclude that $\mathbf{U}^+$, $\mathbf{Z}^+$, and $\mathbf{Z}$ must converge to the same limit. Hence, $\mathbf{u}^\varepsilon = \mathbf{z}^\varepsilon$. Next, it follows from identity $\mathbf{V}^j = d_t\mathbf{U}^j$ (or equivalently, $\mathbf{V}^+ = \mathbf{U}_t$) and inequality (3.3) that $\mathbf{v}^\varepsilon = \mathbf{u}_t^\varepsilon$. The proof is complete. ∎

Remark 5.1. (a) The use of Algorithm 3.3 requires choosing suitable starting values $\mathbf{U}^0$ and $\mathbf{U}^1$. It is easy to see that $\mathbf{U}^0$ can be constructed straightforwardly as the interpolation or the L^2-projection of $\mathbf{u}_0$. On the other hand, the choice of $\mathbf{U}^1$ is less obvious since U^1 must satisfy (i) $d_t\mathbf{U}^1 \to \mathbf{u}_1$ strongly in $L^2(\Omega,\mathbf{R}^n)$ as $\tau_1, h \to 0$, and (ii) $\frac{1}{\varepsilon}F_h(\mathbf{U}^{\frac{1}{2}}) \le C$. To this end, let $\mathbf{V}^0$ be the interpolation or the L^2-projection of $\mathbf{u}_1$, and define $\mathbf{U}^1 := \mathbf{U}^0 + \tau_1\mathbf{V}^0$. Clearly, requirement (i) is fulfilled. Since $\mathbf{U}^{\frac{1}{2}} = \mathbf{U}^0 + \frac{\tau_1}{2}\mathbf{V}^0$, then $|\mathbf{U}^{\frac{1}{2}}| = 1 + O(\tau_1)$ and $\frac{1}{\varepsilon}F_h(\mathbf{U}^{\frac{1}{2}}) = O(\frac{\tau_1^2}{\varepsilon})$. Hence, requirement (ii) is fulfilled provided that $\tau_1 = O(\varepsilon^{\frac{1}{2}})$. We also note that if $\mathbf{u}_0 \cdot \mathbf{u}_1 = 0$, $\mathbf{V}^0$ above can be chosen such that $\mathbf{U}^0 \cdot \mathbf{V}^0 = 0$; in this case we have $\frac{1}{\varepsilon}F_h(\mathbf{U}^{\frac{1}{2}}) \le C$ provided that $\tau_1 = O(\varepsilon^{\frac{1}{4}})$.

(b) It is interesting to note that Algorithm 3.3 is stable (and converges) uniformly in ε provided that $\tau_1 = O(\varepsilon^{\frac{1}{2}})$, which means that the *first time step* must be chosen very small. On the other hand, no restriction is imposed on h and the later time step τ for stability. Hence, as expected, the algorithm is absolutely stable.

6. Numerical experiments. Besides local existence results, the only global result is a unique smooth solution for all times, provided that the initial energy is sufficiently small [20]. In order to obtain global existence without the assumption of small energy, it would be sufficient to show that the energy cannot concentrate at the hypothetical singularity. Similar to [8], our results for the same initial data show a concentration effect in the case of large initial data at a finite time $T > 0$. All of our numerical results were obtained with MATLAB using the direct linear solver provided by MATLAB's backslash operator. Constraints were included through Lagrange multipliers, and the assembly of matrices was realized in C.

6.1. Consistent discretization versus penalized approximation. In our first numerical experiment we report the performance of Algorithms 3.1 and 3.2 on an example that leads to large gradients. In particular, we follow [6] and employ, for $\mathbf{x} = \big(x_1, x_2\big) \in \mathbf{R}^2$, $r := |\mathbf{x}|$, and $a(r) := (1-2r)^4$, the pair of initial data

$$\mathbf{u}_0(\mathbf{x}) := \begin{cases} \big(0,0,-1\big) & \text{for } r \ge 1/2, \\ \big(2x_1a, 2x_2a, a^2 - r^2\big)/\big(a^2+r^2\big) & \text{for } r \le 1/2, \end{cases} \qquad \mathbf{u}_1(\mathbf{x}) := \mathbf{0}.$$

The vector field $\mathbf{u}_0$ wraps about the unit sphere once and is therefore expected to lead to large gradients. We use a uniform triangulation of $\Omega = (-1/2, 1/2)^2$ into 2048 triangles which are squares halved along the direction $(1,1)$ and with maximal diameter $h = \sqrt{2}\,2^{-5}$. The time-step size that we use is $\tau = h^{2.1}$, where the additional power 0.1 is motivated by the condition $\tau = o(h^2)$. The upper plot in Figure 1 displays the $W^{1,\infty}$ seminorm

$$|\mathbf{U}(t)|_{1,\infty} = ||\nabla\mathbf{U}(t)||_{L^\infty(\Omega)}$$

as a function of $t \in [0,2]$ and with $\mathbf{U}$ obtained from Algorithm 3.1 (indicated as "consistent") and Algorithm 3.2 for various choices of ε. In addition, we display in the lower plot of Figure 1 the discrete energies

$$E_h\big(\mathbf{U}(t)\big) = E_h\big(\mathbf{V}^+(t), \mathbf{U}^+(t)\big)$$

and

$$E_h^\varepsilon\big(\mathbf{U}(t)\big) = E_h\big(\mathbf{V}^+(t), \mathbf{U}^+(t)\big) + \frac{1}{\varepsilon}F_h\big(\mathbf{U}^+(t)\big)$$

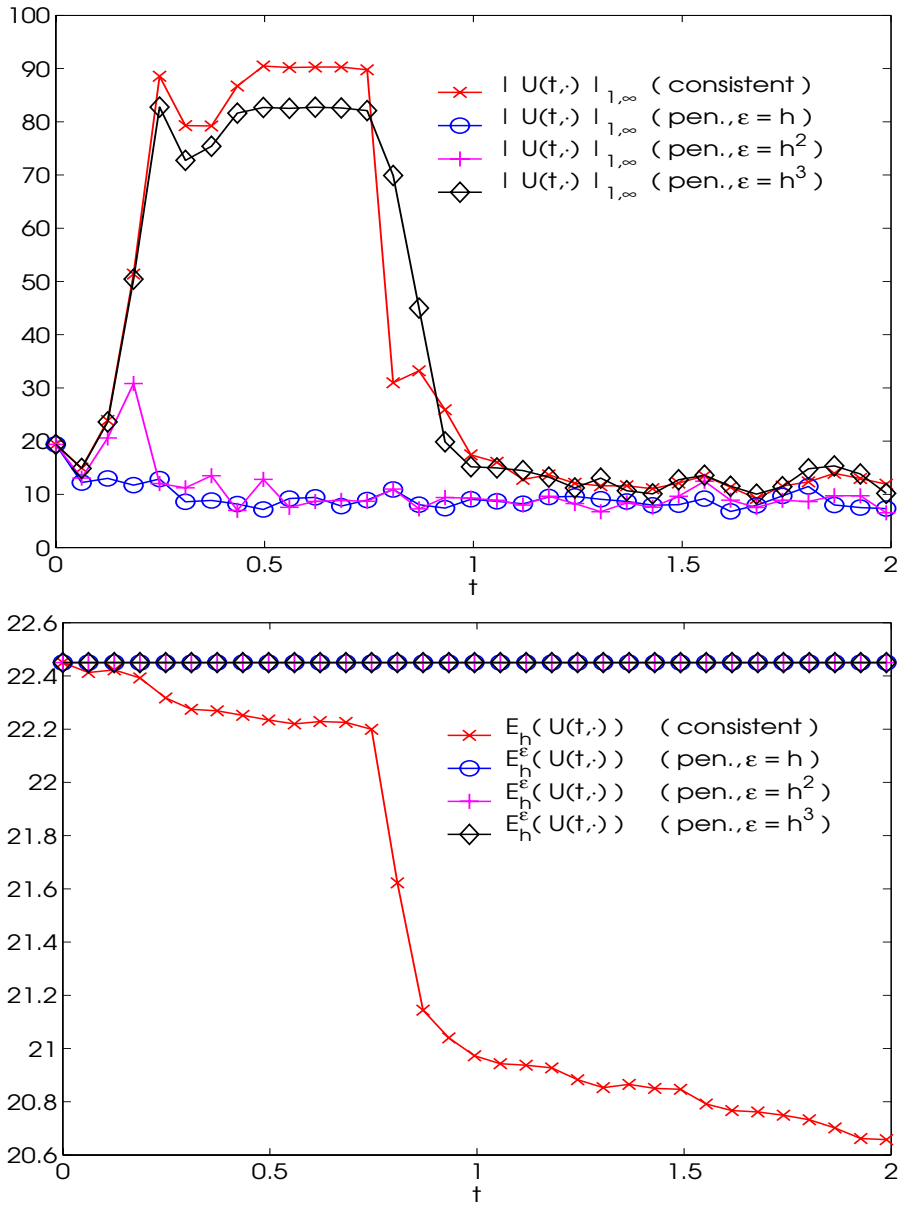

FIG. 1. *$W^{1,\infty}$ seminorm (upper plot) and discrete energy (lower plot) as functions of $t \in [0,2]$ for approximations obtained with Algorithms* 3.1 *and* 3.2 *for various choices of ε. The plots for the results obtained with the penalization method almost coincide in the lower plot.*

for the approximate solutions obtained with Algorithm 3.1 and Algorithm 3.2, respectively. We observe that the $W^{1,\infty}$ seminorm attains its maximum value

$$\max_{\mathbf{W}\in\boldsymbol{\mathcal{V}}_h;\,\forall \mathbf{q}_i\in\mathcal{N}_h,\,|\mathbf{W}(\mathbf{q}_i)|=1} ||\nabla \mathbf{W}||_{L^\infty(\Omega)} = 2^{6.5} \approx 90.51$$

among functions $\mathbf{W} \in \boldsymbol{\mathcal{V}}_h$ that satisfy $|\mathbf{W}(\mathbf{q}_i)| = 1$ for all nodes $\mathbf{q}_i \in \mathcal{N}_h$ for the solution obtained with Algorithm 3.1 at $t \approx 0.25$. Its energy $E_h\big(\mathbf{U}(t)\big)$ slightly de-

creases at the time of blow-up; however, the fact that it is not increasing indicates the robustness of our direct method. The numerical results differ significantly when the approximation is obtained with Algorithm 3.2 and when different values for ε are used. While the energies E_h^ε obtained with the unconstrained method appear to be constant, we observe that even for the extremely small choice $\varepsilon = h^3$ the $W^{1,\infty}$ seminorm of the numerical approximation remains bounded away from the maximum value. We note that such a choice of ε is critical since Lemma 5.3 suggests that convergence of the numerical approximations obtained by Algorithm 3.2 can be expected only if $\tau, h = o(\varepsilon)$. Nevertheless, it seems that the results obtained with the penalization approach those obtained with Algorithm 3.1 when ε becomes small.

6.2. Numerical evidence for finite-time blow-up and occurrence of singular solutions. Even though Algorithms 3.1 and 3.2 are mathematically equivalent in the sense that they both provide subsequences that converge weakly to a solution of the wave map equation, we believe that Algorithm 3.1 is better suited to studying the occurrence of singularities since the corresponding topological effects are not diffused as in the regularized (penalized) approximation scheme of Algorithm 3.2. The two plots in Figure 2 display the behavior of numerical solutions obtained with Algorithm 3.1 for decreasing mesh-sizes and with the initial data described above. As in the previous subsection we employed uniform triangulations of $\Omega = (-1/2, 1/2)^2$ into squares halved along the direction $(1, 1)$. The time-step size was defined through $\tau = h^{2.1}$ for $h = \sqrt{2}\,2^{-5}$, $\sqrt{2}\,2^{-6}$, $\sqrt{2}\,2^{-7}$ corresponding to a sequence of triangulations with 2048, 8192, and 32768 triangles, respectively. Figure 2 shows that for each triangulation the maximal $W^{1,\infty}$ seminorm is attained. This indicates that an existing exact solution for the choice of our initial data has unbounded $W^{1,\infty}$ norm, i.e., is a singular solution, but we stress that this behavior might change for sufficiently small mesh-sizes. This so-called finite-time blow-up behavior occurs in our example when the solution at the origin points in a direction different from all the surrounding vectors. We illustrate this behavior in Figures 3 and 4, where the first two components of the vector field $\mathbf{U}(t, \mathbf{x})$ for the nodes $\mathbf{q}_i \in (-1/4, 1/4)^2 \cap \mathcal{N}_h$ and the vectors in a neighborhood of the origin are shown, respectively, for the solution obtained with the triangulation that consists of 2048 triangles. After a small period of large (maximal) gradients, the vector at the origin changes its direction. This change of direction may be unstable and mesh-dependent. It is not clear to the authors whether such an effect also occurs in the continuous situation. We note that in this experiment it was not possible to recover the initial data by reversing time. The results in the following subsection indicate that the quantitative behavior does not change significantly when other triangulations with more symmetry are used.

6.3. Effect of symmetric/asymmetric triangulations. In order to obtain a better understanding of the mechanism that forces the vector at the origin to change its direction after the occurrence of a maximal $W^{1,\infty}$ norm, we applied Algorithm 3.1 to the initial data given above for different spatial triangulations of comparable mesh-size. The four different triangulations we used are displayed in Figure 5. The first one (upper left plot) is obtained from four uniform refinements of a coarse triangulation $\mathcal{T}_0$ of $\Omega = (-1/2, 1/2)$ into two triangles. The next triangulation (upper right plot) resulted from four uniform refinements of that coarse triangulation of Ω that is obtained from dividing Ω into four similar triangles by dividing it along its diagonals. The third triangulation shown (lower left plot) is obtained from the previous one by a random perturbation of those nodes that do not belong to the boundary $\partial\Omega$ by a value smaller than $h/10$ in each direction. Finally, we also employed an approximation of

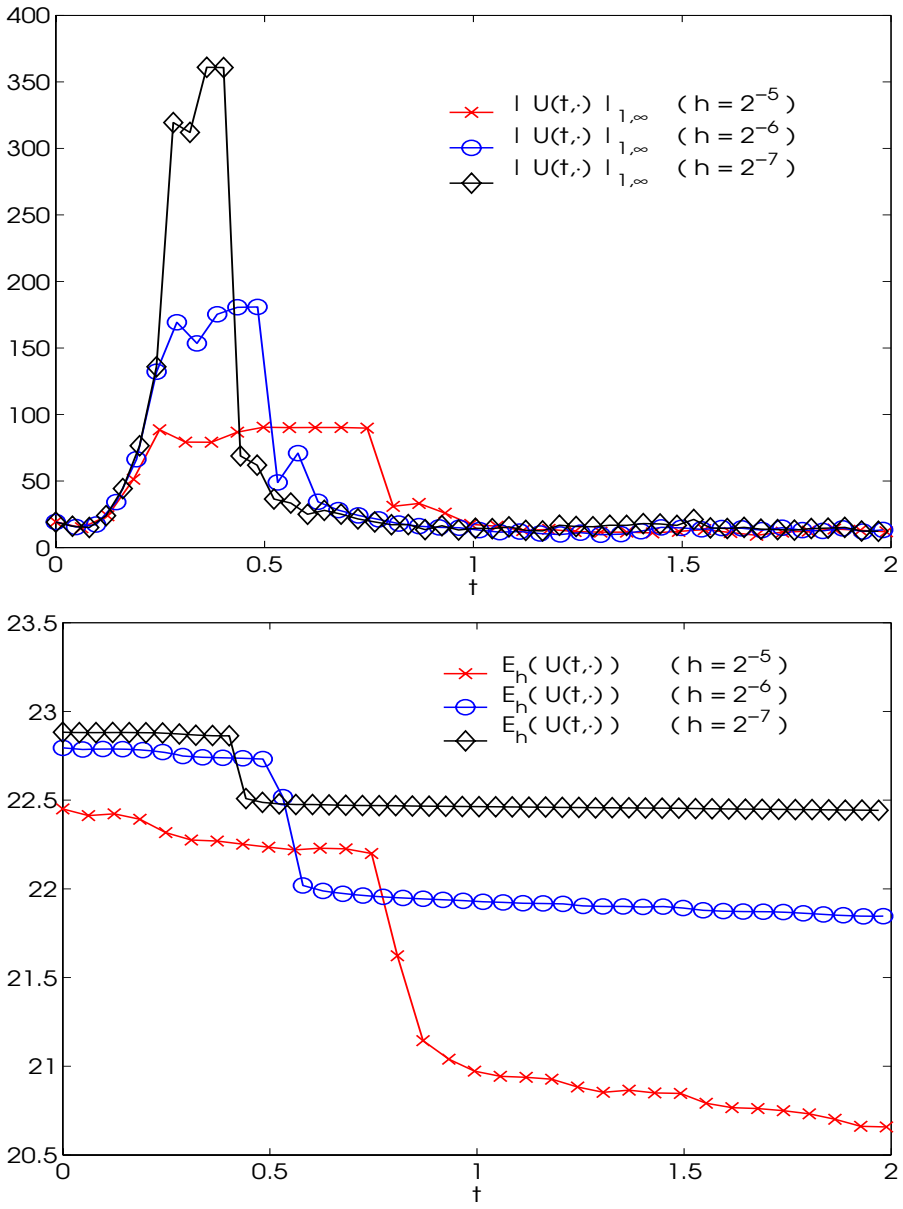

FIG. 2. *$W^{1,\infty}$ seminorm (upper plot) and discrete energy (lower plot) as functions of $t \in [0,2]$ for approximations obtained with Algorithm* 3.1 *on refining triangulations.*

the disk $\Omega = \{\mathbf{x} \in \mathbf{R}^2 : |\mathbf{x}| \leq 1/2\}$; cf. the last triangulation in Figure 5 (lower right plot). Figure 6 displays the $W^{1,\infty}$ seminorms of the numerical approximations using the four different triangulations. The results differ mostly after the occurrence of discrete blow-up, and we expect that this mesh-dependence reflects a loss of stability and a possibility of nonuniqueness of exact solutions. However, we observe that before the occurrence of maximal gradients, quantitatively the behavior of the numerical approximations does not change significantly when more symmetry is introduced in

the grid or when symmetry is entirely destroyed by perturbing the positions of the vertices. We thus believe that our Algorithm 3.1 provides an accurate approximation of the exact solution and is capable of detecting singularities in a reliable way.

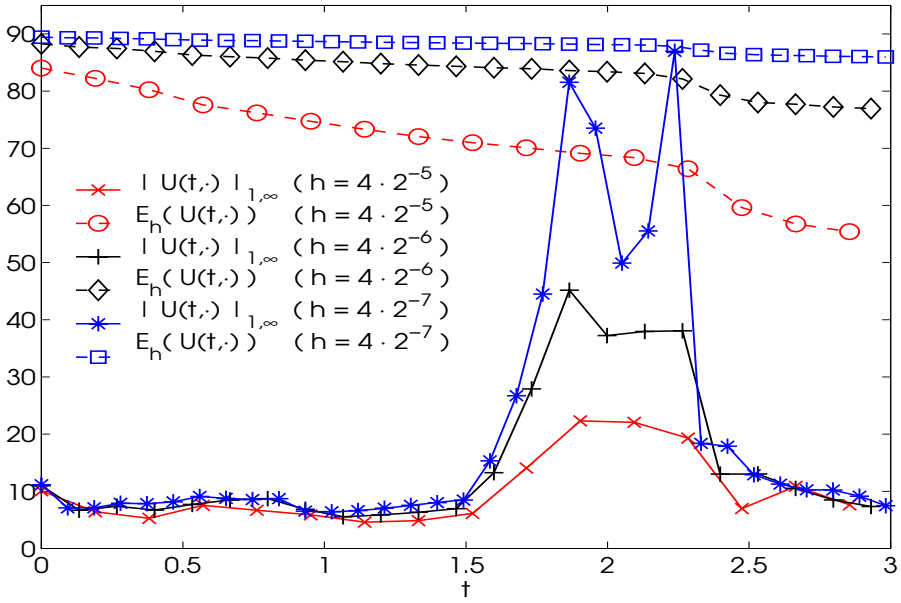

FIG. 7. *$W^{1,\infty}$ seminorm and discrete energy as functions of $t \in [0,3]$ for approximations obtained with Algorithms 3.1 for equivariant initial data on refining triangulations.*

6.4. Equivariant initial data. In our last series of experiments we follow the work of [8] and employ equivariant initial data defined by

$$\mathbf{u}_0(r,\theta) = \begin{pmatrix} \sin\chi(r,\theta)\,\sin\theta \\ \sin\chi(r,\theta)\,\cos\theta \\ \cos\chi(r,\theta) \end{pmatrix}, \qquad \mathbf{u}_1(r,\theta) \equiv 0,$$

where (r,θ) denotes polar coordinates in $\mathbf{R}^2$ and $\chi(r,\theta) = (r^3/4)\exp(-(4(r-2)/10)^4)$. We ran Algorithm 3.1 with these initial data on uniform triangulations of $\Omega = (-2,2)^2$ with 2048, 8192, and 32768 triangles. Figure 7 displays the $W^{1,\infty}$ seminorms and the energy as functions of $t \in [0,3]$ obtained with the three different triangulations. As in [8] we observe finite-time blow-up. We remark that in [8] the results were obtained by reducing the problem to a one-dimensional model that guarantees that the solution remains an equivariant map for all times. Here, this is not included as a constraint in the approximation scheme. Nevertheless, the sequence of snapshots of the numerical solution shown in Figure 8 for $t \approx 0, 2, 4, \ldots, 10$ indicates that this is true for our numerical solution. In particular, the vector at the origin does not change its direction on triangulations that obey certain symmetry properties. In Figure 9 we display the third component of the solution at the origin as a function of $t \in [0,10]$, i.e., the real number $\mathbf{U}^{(3)}(t,\mathbf{0})$, for the numerical solution obtained on the different triangulations described above (scaled by a factor of 4 for this experiment) and indicated in Figure 9 (for simplicity, we did not perturb the vertex located at the origin). For the unperturbed triangulations the solution vector at the origin does not change for $t \in (0,10)$, while for the perturbed triangulation the vector changes its direction for a small period of time when the blow-up occurs. These results are in good agreement with theoretical predictions stating that for equivariant data the vector at the origin remains constant [24]. Finally, we remark that in this experiment

(on the nonsymmetric, unperturbed triangulation) it was possible to reverse time and to reproduce the initial data.

LOWER ORDER RECTANGULAR NONCONFORMING MIXED FINITE ELEMENTS FOR PLANE ELASTICITY*

JUN HU† AND ZHONG-CI SHI‡

Abstract. In this paper, we present two stable rectangular nonconforming mixed finite element methods for the equations of linear elasticity in two space dimensions which produce direct approximations for the stress and displacement. In the first method, the normal stress space of the matrix-valued stress space is taken as the second order rotated Brezzi–Douglas–Fortin–Marini element space [F. Brezzi and M. Fortin, *Mixed and Hybrid Finite Element Methods*, Springer-Verlag, New York, 1991], the enriched nonconforming rotated Q_1 element [Q. Lin, L. Tobiska, and A. H. Zhou, *IMA J. Numer. Anal.*, 25 (2005), pp. 160–181] is taken for the shear stress, and the lowest order Raviart–Thomas element space [P. A. Raviart and J. M. Thomas, in *Mathematical Aspects of the Finite Element Method*, Lecture Notes in Math. 606, Springer-Verlag, New York, 1977, pp. 292–315] is employed to approximate the vector displacement field. The second method is obtained from the first one through dropping the interior degrees of the normal stress on each element. A first order convergence rate is obtained for both the stress and the displacement for these methods based on the superconvergence of the enriched nonconforming rotated Q_1 element.

1. Introduction.

We consider the finite element approximation of a stress-displacement system derived from the Hellinger–Reissner variational principle for the plane linear elasticity, which reads: Given $f \in L^2(\Omega, \mathbb{R}^2)$ find $(\sigma, u) \in H(\mathrm{div}, \Omega, \mathbb{S}) \times L^2(\Omega, \mathbb{R}^2)$ with

$$(A\sigma, \tau)_{L^2(\Omega)} + (\mathrm{div}\,\tau, u)_{L^2(\Omega)} = 0,$$

$$(\mathrm{div}\,\sigma, v)_{L^2(\Omega)} = (f, v)_{L^2(\Omega)}$$

for any $(\tau, v) \in H(\mathrm{div}, \Omega, \mathbb{S}) \times L^2(\Omega, \mathbb{R}^2)$. Here and throughout this paper, the compliance tensor $A(x) : \mathbb{S} \to \mathbb{S}$ is bounded and symmetric positive definite uniformly for $x \in \Omega$ with $\mathbb{S} := \mathbb{R}^{2\times 2}_{\mathrm{sym}}$ the set of symmetric tensors. The space $H(\mathrm{div}, \Omega, \mathbb{S})$ is defined as

$$H(\mathrm{div}, \Omega, \mathbb{S}) := \{\tau \in L^2(\Omega, \mathbb{S}) \text{ and } \mathrm{div}\,\tau \in L^2(\Omega, \mathbb{R}^2)\}$$

equipped with the norm

$$\|\tau\|^2_{H(\mathrm{div},\Omega)} := \|\tau\|^2_{L^2(\Omega)} + \|\mathrm{div}\,\tau\|^2_{L^2(\Omega)}.$$

Because of the symmetry requirement imposed on the discrete matrix stress spaces and the usual stable conditions for the discrete stress spaces and vector displacement spaces from the theory of mixed finite element methods [4], it becomes very difficult to construct simple mixed elements. As D. N. Arnold pointed out, in his plenary address to the 2002 International Congress of Mathematicians, four decades of searching for mixed finite elements for elasticity did not yield any stable elements with polynomial shape functions. In recent years, there has been some progress in this direction. In [2], a family of stable conforming triangular elements are presented with the simplest and lowest order element taking 21 stress and 3 displacement degrees of freedom on each triangle. In order to keep the conformity, the vertex degrees of freedom are in particular employed in those methods. To avoid the complex of conforming mixed element and also vertex degrees of freedom, they proposed a first order nonconforming triangular mixed element with 12 degrees of freedom for the stress and 3 degrees of freedom for the displacement [3]. The conforming rectangular mixed elements are proposed and analyzed in [1] with the lowest order element needing 45 stress and 12 displacement degrees of freedom. In a recent paper [12], a nonconforming mixed finite element based on rectangular meshes is proposed with 19 stress and 6 displacement degrees of freedom on each element.

In this paper, we present two first order nonconforming rectangular mixed elements. In the first method, it takes 15 stress and 4 displacement degrees of freedom on each rectangle. The total degrees of freedom is $3|E|+7|K|$ with $|E|$ the number of edges and $|K|$ the number of elements of the partition $\mathcal{T}_h$. More precisely, we use the second order rotated Brezzi–Douglas–Fortin–Marini (hereafter BDFM) element space [4] to approximate the normal stress of the matrix stress field, the enriched nonconforming rotated Q_1 element [9] is taken for the shear stress, and the lowest order Raviart–Thomas (hereafter RT) element space [11] with 4 degrees on each element is taken for the displacement space. The second element is obtained from the first one by dropping the interior degrees of freedom of both diagonal components on each element and keeping the vector displacement space. Therefore, the total degrees of freedom becomes $3|E|+5|K|$. We stress that it is the simplest element so far. Based on the superconvergence, we analyze and obtain the optimal error estimate, i.e., the first order convergence rate. We also show that the discrete analogue of the following exact sequence:

(1.1)
$$0 \longrightarrow P_1(\Omega) \xrightarrow{\subset} C^\infty(\Omega) \xrightarrow{J} C^\infty(\Omega,\mathbb{S}) \xrightarrow{\mathrm{div}} C^\infty(\Omega,\mathbb{R}^2) \longrightarrow 0$$

holds for both elements with the enriched and original nonconforming Adini elements, respectively. Here, and throughout this paper, the Airy stress function corresponding to a scalar field q reads

$$Jq := \begin{pmatrix} \frac{\partial^2 q}{\partial y^2} & -\frac{\partial^2 q}{\partial x \partial y} \\ -\frac{\partial^2 q}{\partial x \partial y} & \frac{\partial^2 q}{\partial x^2} \end{pmatrix}.$$

This paper is organized as follows. In the following two sections, we shall present the new mixed elements and analyze their properties including the well-posedness. In section 4, we prove the discrete analogue of (1.1) for both elements. The error analysis will be investigated in section 5.

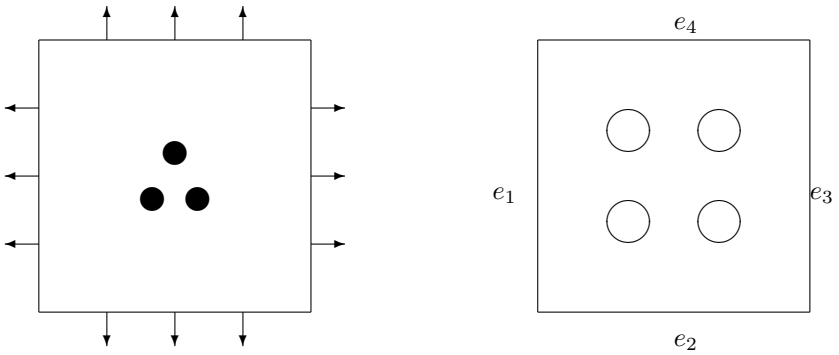

FIG. 1. *Element diagram for the stress and displacement.*

2. Nonconforming mixed finite element approximation. For approximating problem (1.1) by the finite element method, we introduce a rectangular triangulation $\mathcal{T}_h$ of the rectangular domain Ω; the regularity of the mesh $\mathcal{T}_h$ is assumed in the sense of Ciarlet [5] such that $\bigcup_{K\in\mathcal{T}_h} K = \bar{\Omega}$, two distinct elements K and K' in $\mathcal{T}_h$ are either disjoint or share the common edge e or a common vertex. Let $\mathcal{E}$ denote the set of all edges in $\mathcal{T}_h$ with $\mathcal{E}_{K,V}$ the two vertical edges of $K \in \mathcal{T}_h$ and $\mathcal{E}_{K,H}$ the two horizontal edges. Given any edge $e \in \mathcal{E}$ we assign one fixed unit normal n with (n_1, n_2) its components; we also let $t = (-n_2, n_1)$ denote the tangential vector.

For each $K \in \mathcal{T}_h$, we introduce the following affine invertible transformation:

$$F_K : \hat{K} \to K, \quad x = \frac{h_{x,K}}{2}\xi + x_{0,K}, \quad y = \frac{h_{y,K}}{2}\eta + y_{0,K}$$

with the center $(x_{0,K}, y_{0,K})$, the horizontal and vertical edge lengths $h_{x,K}$ and $h_{y,K}$, respectively, and the reference element $\hat{K} = [-1, 1]^2$. Given any integer k, let $P_k(\omega)$ denote the space of polynomials over ω of total degrees not greater than k.

The key idea in the designing of mixed finite elements for the elasticity is to construct the polynomial space pair (Σ_K, V_k) with the following conditions.

(A1) $\operatorname{div}\Sigma_K \subset V_K$.

(A2) There exists a bounded interpolation operator $\Pi_K : H^1(K, \mathbb{S}) \to \Sigma_K$ with the following commuting diagram property:

$$\operatorname{div}\Pi_K\sigma = P_K \operatorname{div}\sigma \quad \forall\sigma \in H^1(K, \mathbb{S})$$

with P_K the projection operator from $L^2(K, \mathbb{R}^2)$ to V_K.

These two conditions in turn ensure that there exists a unique critical point and provide a good approximation of the true solution.

On the element K, we choose the following RT element space [11] as the displacement space:

$$V_K := \begin{pmatrix} a + by \\ c + dx \end{pmatrix}.$$

As depicted in Figure 1, we define the space for the stress as

$$\Sigma_K^0 := \begin{pmatrix} P_2^1(K) & P_2^2(K) \\ P_2^2(K) & P_2^3(K) \end{pmatrix}_S, \tag{2.1}$$

the space of symmetric fields $\sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix} \in \mathbb{S}$ such that $\sigma_{11} \in P_2^1(K)$, $\sigma_{12} = \sigma_{21} \in P_2^2(K)$, and $\sigma_{22} \in P_2^3(K)$. Here

$$P_2^1(K) := \operatorname{span}\{1, x, y, xy, y^2\},$$

$$P_2^2(K) := \operatorname{span}\{1, x, y, x^2, y^2\},$$

$$P_2^3(K) := \operatorname{span}\{1, x, y, xy, x^2\}.$$

A straightforward investigation gives that the dimension of Σ_K^0 is 15.

Remark 2.1. Note that the normal stress space $(P_2^1(K), P_2^3(K))$ is the second order rotated BDFM element space for second order elliptic problems [4], and the shear space $P_2^2(K)$ is the enriched nonconforming rotated Q_1 element space [9].

The degrees of freedom for Σ_K^0 follow

- the moments of degrees 0 and 1 on the four edges of K for $\sigma n \cdot n$,
- the moments of degree 0 on the four edges of K for $\sigma n \cdot t$,
- the moment of degree 0 on K for σ_{12},
- the values of $\int_K (y - y_{0,K})^2 \sigma_{11} dxdy$ and $\int_K (x - x_{0,K})^2 \sigma_{22} dxdy$.

LEMMA 2.2. *If the* 15 *degrees of freedom vanish for some* $\sigma \in \Sigma_K^0$, *then* $\sigma = 0$.

Proof. The existence and uniqueness for the component $\sigma_{12} = \sigma_{21}$ follow directly from [9]; we consider only those for σ_{11} and σ_{22}. Without loss of generality, we prove them on the reference element $\hat{K}$. In this case, σ_{11} can be written as

$$\sigma_{11} = a_0 + a_1\xi + a_2\eta + a_3\xi\eta + a_4\eta^2$$

with some interpolation constants a_i, $i = 0, \ldots, 4$. Since $\int_{e \in \mathcal{E}_{\hat{K},V}} \sigma_{11} q d\eta = 0$ for any $q \in P_1(e)$, we can obtain by a direct calculation that

$$a_0 - a_1 + \frac{1}{3}a_4 = 0, \quad a_2 - a_3 = 0,$$

$$a_0 + a_1 + \frac{1}{3}a_4 = 0, \quad a_2 + a_3 = 0,$$

$$\frac{1}{3}a_0 + \frac{1}{5}a_4 = 0,$$

which yield $\sigma_{11} = 0$. A similar argument gives $\sigma_{22} = 0$. ∎

Dropping the interior degrees of σ_{11} and σ_{22}, we can get one subspace of Σ_K^0 as follows:

$$\Sigma_K^1 := \begin{pmatrix} Q_1(K) & P_2^2(K) \\ P_2^2(K) & Q_1(K) \end{pmatrix}_S,$$

the space of symmetric fields $\sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix} \in \mathbb{S}$ such that $\sigma_{11} \in Q_1(K)$, $\sigma_{12} = \sigma_{21} \in P_2^2(K)$, and $\sigma_{22} \in Q_1(K)$. See Figure 2. Therefore, the dimension of Σ_K^1 is 13. Here

$$Q_1(K) := \operatorname{span}\{1, x, y, xy\}.$$

The degrees of freedom for Σ_K^1 follow

- the moments of degrees 0 and 1 on the four edges of K for $\sigma n \cdot n$,
- the moments of degree 0 on the four edges of K for $\sigma n \cdot t$,

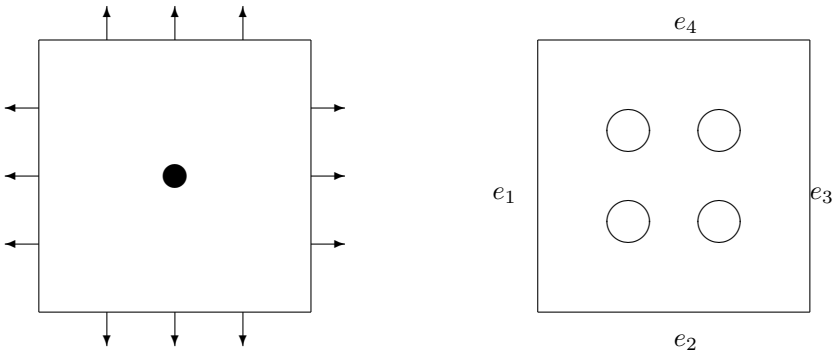

FIG. 2. *Element diagram for the stress and displacement.*

- the moment of degree 0 on K for σ_{12}.

A similar argument of Lemma 2.2 shows the following.

LEMMA 2.3. *If the* 13 *degrees of freedom vanish for some* $\sigma \in \Sigma_K^0$, *then* $\sigma = 0$.

For $i = 0, 1$, define the discrete spaces for the stress and displacement as, respectively,

$$\Sigma_h^i := \left\{ \sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix} \in L^2(\Omega, \mathbb{S}), \sigma|_K \in \Sigma_K^i \text{ and the moments of degrees 0 and 1 on all the internal edges are continuous for } \sigma n \cdot n, \text{ and the moments of degree 0 on all the internal edges are continuous for } \sigma n \cdot t, \forall K \right\},$$

$$V_h := \{v \in L^2(\Omega, \mathbb{R}^2), v|_K \in V_K, \forall K\}.$$

LEMMA 2.4. *For* Σ_h^1, *we note from the definition that* σ_{11} *is continuous on interior vertical edges,* σ_{22} *continuous on interior horizontal edges, and* $\sigma_{12} = \sigma_{21}$ *continuous in the averaging sense on all interior edges.*

Proof. The proof immediately follows from the definitions. ∎

Remark 2.5. It follows from Lemma 2.4 that Σ_h^1 is conforming-nonconforming elements with $\Sigma_h^1 \not\subseteq H(\mathrm{div}, \Omega, \mathbb{S})$, which is a very good feature.

Since $\Sigma_h^i \not\subseteq H(\mathrm{div}, \Omega, \mathbb{S})$ with $i = 0, 1$, we denote by div_h the divergence operator defined elementwise with respect to $\mathcal{T}_h$, i.e.,

$$\mathrm{div}_h \tau|_K = \mathrm{div}(\tau|_K) \quad \text{for any } \tau \in \Sigma_h^i,\ i = 0, 1.$$

With these preparations, our nonconforming mixed element methods can be stated as follows: Find $(\sigma_h, u_h) \in \Sigma_h^i \times V_h$ such that

$$\begin{aligned} (A\sigma_h, \tau)_{L^2(\Omega)} + (\mathrm{div}_h \tau, u_h)_{L^2(\Omega)} &= 0, \\ (\mathrm{div}_h \sigma_h, v)_{L^2(\Omega)} &= (f, v)_{L^2(\Omega)} \end{aligned} \tag{2.2}$$

for any $(\tau, v) \in \Sigma_h^i \times V_h$ with $i = 0, 1$.

3. Well-posedness of the discrete problem. In this section, we consider the well-posedness of the discrete problem (2.2) for $i = 0, 1$, which in turn hangs on the following two assumptions.

1. K-ellipticity. There exists a constant $C > 0$ independent of the meshsize such that
$$(A\tau, \tau)_{L^2(\Omega)} \geq C\|\tau\|^2_{H(\mathrm{div}_h,\Omega)}$$
for any
$$\tau \in Z_h^i := \{\tau \in \Sigma_h^i | (\mathrm{div}_h\, \tau, v) = 0 \quad \forall v \in V_h\}.$$
2. Discrete B-B condition. There exists a positive constant C independent of the meshsize with
$$\sup_{\tau\in\Sigma_h^i} \frac{(\mathrm{div}_h\, \tau, v)}{\|\tau\|_{H(\mathrm{div}_h,\Omega)}} \geq C\|v\|_{L^2(\Omega)} \quad \text{for any } v \in V_h.$$

We first consider Σ_h^1, and to this end, we define for any $\sigma = \begin{pmatrix}\sigma_{11} & \sigma_{12}\\ \sigma_{21} & \sigma_{22}\end{pmatrix}$ the interpolation $\Pi_h^1\sigma \in \Sigma_h^1$ with

$$\int_e \Pi_h^1\sigma n \cdot nvds = \int_e \sigma n \cdot nvds \quad \text{for any edge } e \text{ and for any } v \in P_1(e),$$

$$\int_e \Pi_h^1\sigma n \cdot tds = \int_e \sigma n \cdot tds \quad \text{for any edge } e,$$

$$\int_K (\Pi_h^1\sigma)_{12}dxdy = \int_K \sigma_{12}dxdy \quad \text{for any } K \in \mathcal{T}_h.$$

It is not difficult to see that Π_h^1 is well defined. We infer from the definition of the interpolation operator Π_h^1 that

$$(\mathrm{div}_h(\sigma - \Pi_h^1\sigma), w_h)_{L^2(\Omega)} = 0 \quad \text{for any } w_h \in V_h.$$

In fact, an integration by parts yields that

$$(\mathrm{div}_h(\sigma - \Pi_h^1\sigma), w_h)_{L^2(\Omega)} = \sum_{K\in\mathcal{T}_h}\sum_{e\subset\partial K}\int_e (\sigma - \Pi_h^1\sigma)n_e \cdot w_h ds = 0. \tag{3.1}$$

Let B denote the Jacobian matrix for the affine mapping F_K introduced in section 2. Given $\hat{\tau} : \hat{K} \to \mathbb{S}$, define $\tau : K \to \mathbb{S}$ by the matrix Piola transformation,

$$\tau(x, y) = B\hat{\tau}(\xi, \eta)B^T \tag{3.2}$$

with $(x, y) = F_K(\xi, \eta)$. A direct calculation yields that

$$\mathrm{div}\,\tau = B\,\mathrm{div}\,\hat{\tau}. \tag{3.3}$$

It follows that $\tau \in H(\mathrm{div}, K, \mathbb{S})$ if and only if $\hat{\tau} \in H(\mathrm{div}, \hat{K}, \mathbb{S})$. Since B is a diagonal matrix, one claims that $\tau \in \Sigma_K^i$ with $i = 0, 1$ if and only if $\hat{\tau} \in \Sigma_{\hat{K}}^i$.

Let $\Pi_K^1 : H(\mathrm{div}, K, \mathbb{S}) \to \Sigma_K^1$ denote the restriction of Π_h^1 onto a single rectangle. We assert that

$$\Pi_K^1\tau = B\Pi_{\hat{K}}^1\hat{\tau}B^T. \tag{3.4}$$

Indeed, $n = \hat{n}$ and $B^T n = \|B^T n\|\hat{n}$; this leads to

$$\int_e B\Pi^1_{\hat{K}}\hat{\tau}B^T n \cdot n v ds = \frac{|e|}{2} B \int_{\hat{e}} (\Pi^1_{\hat{K}}\hat{\tau})B^T\hat{n} \cdot \hat{n}\hat{v}d\hat{s} = \frac{|e|}{2}\|B^T n\| B \int_{\hat{e}} \Pi^1_{\hat{K}}\hat{\tau}\hat{n} \cdot \hat{n}\hat{v}d\hat{s}$$

$$= \frac{|e|}{2}\|B^T n\| B \int_{\hat{e}} \hat{\tau}\hat{n} \cdot \hat{n}\hat{v}d\hat{s} = \int_e \tau n \cdot n v ds$$

for any edges and for any $v \in P_1(e)$. Therefore, we have the following properties for the finite element method in consideration.

LEMMA 3.1. *It holds that*

(1) $\operatorname{div}_h \Pi^1_h \sigma = P_h \operatorname{div}\sigma$, $\|\Pi^1_h\sigma\|_{L^2(\Omega)} \le C\|\sigma\|_{H^1(\Omega)}$ *for any* $\sigma \in H^1(\Omega, \mathbb{S})$, *where* $P_h : L^2(\Omega, \mathbb{R}^2) \to V_h$ *denotes the* L^2 *projection;*

(2) $\operatorname{div}_h \Sigma^1_h = V_h$.

Proof. It follows from (3.1) that $\operatorname{div}_h \Pi^1_h\sigma = P_h \operatorname{div}\sigma$. Since $\Pi^1_{\hat{K}}$ is bounded from $H^1(\hat{K}, \mathbb{S})$ to $L^2(\hat{K}, \mathbb{S})$, a scaling argument using (3.4) proves that

$$\|\Pi^2_K\tau\|_{L^2(K)} \le C(\|\tau\|_{L^2(K)} + h\|\tau\|_{H^1(K)}). \tag{3.5}$$

Summing over the elements shows (1).

It is immediate that $\operatorname{div}_h \Sigma^1_h \subset V_h$; we now prove the converse. Indeed, for any $v \in V_h$, there exists $\tau \in H^1(\Omega, \mathbb{S})$ such that

$$\operatorname{div}\tau = v, \|\tau\|_{H^1(\Omega)} \le C\|v\|_{L^2(\Omega)}.$$

With this choice we have $\Pi^1_h\tau \in \Sigma^1_h$, $\operatorname{div}\Pi^1_h\tau = P_h \operatorname{div}\tau = P_h v = v$, which proves that $V_h \subset \operatorname{div}_h \Sigma^1_h$. ∎

THEOREM 3.2. *K-ellipticity and the discrete B-B conditions hold uniformly in the meshsize; therefore problem* (2.2) *admits a unique solution* $(\sigma_h, u_h) \in \Sigma^1_h \times V_h$.

Proof. It follows from (2) of Lemma 3.1 that $\operatorname{div}_h \tau = 0$ for all $\tau \in Z^1_h$, which implies the K-ellipticity.

It remains to show the discrete B-B condition. For any $v \in V_h$, there exists $\tau \in H^1(\Omega, \mathbb{S})$ such that

$$\operatorname{div}\tau = v, \|\tau\|_{H^1(\Omega)} \le C_0\|v\|_{L^2(\Omega)}.$$

With this choice we have $\Pi^1_h\tau \in \Sigma^1_h$, $\operatorname{div}\Pi^1_h\tau = P_h \operatorname{div}\tau = P_h v = v$. This leads to

$$(\operatorname{div}_h \Pi^1_h\tau, v)_{L^2(\Omega)} = (P_h \operatorname{div}\tau, v)_{L^2(\Omega)} = (P_h v, v)_{L^2(\Omega)} \ge 1/C_0\|v\|_{L^2(\Omega)}\|\tau\|_{H^1(\Omega)}.$$

Thanks to (1) of Lemma 3.1, we conclude that

$$(\operatorname{div}_h \Pi^1_h\tau, v)_{L^2(\Omega)} \ge C\|\Pi^1_h\tau\|_{H(\operatorname{div}_h,\Omega)}\|v\|_{L^2(\Omega)},$$

which yields the desired result. ∎

Remark 3.3. One can define a similar interpolation operator Π^0_h for the space Σ^0_h. Moreover, Lemma 3.1 and Theorem 3.2 hold equally for the space pair (Σ^0_h, V_h).

4. The discrete exact sequence of differential complex. In this section, we investigate the relations between the elements in section 2 and some nonconforming elements for the fourth order elliptic problems. We show the discrete exact sequence of differential complex for Σ^0_h and Σ^1_h.

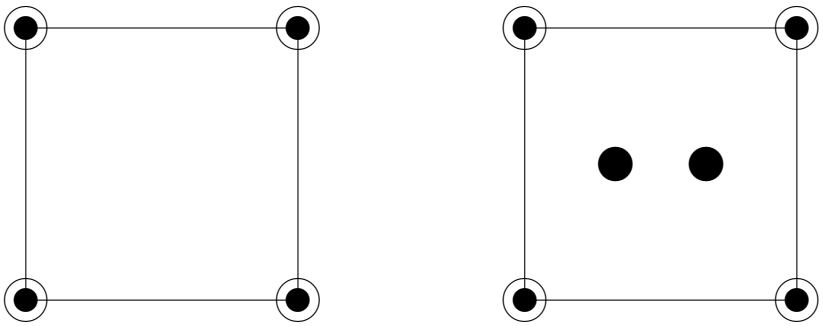

FIG. 3. *The Adini element and enriched Adini element.*

The second element Σ_h^1 is closely related to the nonconforming Adini element (see Figure 3) for the fourth order elliptic problems. In fact, the piecewise divergence-free elements in Σ_h^1 can be explicitly obtained from the Adini element on each element K. We show this observation in the following. For any $K \in \mathcal{T}_h$, the Adini element with dimension 12 reads as

$$AD(K) := P_3(K) \oplus \text{span}\{x^3y, y^3x\}.$$

Any element q in $AD(K)$ can be uniquely determined by the values of q and the two first order derivatives of q at each vertex (12 degrees of freedom). The associated finite element space AD_h is a subspace of $H^1(\Omega)$, but not a subspace of $H^2(\Omega)$ due to the discontinuity of the normal derivatives. However, the normal derivatives are weak continuous since they are continuous at nodes of the partition $\mathcal{T}_h$.

LEMMA 4.1. *It holds that*

$$J_h q \in \Sigma_h^1 \quad \textit{and} \quad \text{div}_h\, J_h q = 0 \quad \forall q \in AD_h.$$

Proof. Let J_K and q_K denote the restriction of J_h and q on K, respectively; then it is immediate that

$$J_K q_K \in \Sigma_K^1.$$

Therefore, we need only to prove that $J_h q$ satisfies the continuous conditions for the space Σ_h^1. For any vertical edge e with $n = (\pm 1, 0)$ and two endpoints V_1 and V_2, we have

$$\begin{aligned}\int_e \frac{\partial_h^2 q}{\partial y^2} v dy &= -\int_e \frac{\partial q}{\partial y}\frac{dv}{dy} dy + \left(\frac{\partial q}{\partial y} v\right)(V_2) - \left(\frac{\partial q}{\partial y} v\right)(V_1) \\ &= -\left(q\frac{dv}{dy}\right)(V_2) + \left(q\frac{dv}{dy}\right)(V_1) + \left(\frac{\partial q}{\partial y} v\right)(V_2) - \left(\frac{\partial q}{\partial y} v\right)(V_1)\end{aligned}$$

for any $v \in P_1(e)$. This, together with the definition of the Adini element space, shows the continuity of $\frac{\partial_h^2 q}{\partial y^2}$. The same argument and result hold equally for $\frac{\partial_h^2 q}{\partial x^2}$. It remains to prove that $\frac{\partial_h^2 q}{\partial y \partial x} = \frac{\partial_h^2 q}{\partial x \partial y}$ is continuous in the average sense on all interior

edges. In fact,

$$\int_e \frac{\partial_h^2 q}{\partial y \partial x} dy = \frac{\partial q}{\partial x}(V_2) - \frac{\partial q}{\partial x}(V_1) \tag{4.1}$$

for any vertical edge e. The corresponding continuity follows from that of the Adini element. The second assertion of $\mathrm{div}_h\, J_h q = 0$ is obvious. □

Define the interpolation $I_h^1 q \in AD_h$ for any $C^2(\Omega)$ by requiring that the values of $I_h^1 q$ and the first order derivatives of $I_h^1 q$ at vertexes all be equal to the corresponding values of q.

LEMMA 4.2. *There holds the commutativity property*

$$J_h I_h^1 q = \Pi_h^1 J q \quad \forall q \in C^2(\Omega).$$

Proof. Since $J_h I_h^1 q \in \Sigma_h^1$ and $\Pi_h^1 J q \in \Sigma_h^1$, we need only to establish the following identities:

$$\int_e (J_h I_h^1 q) n \cdot n v ds = \int_e J q n \cdot n v ds, \quad v \in P_1(e)\ \forall \text{ edges } e,$$

$$\int_e (J_h I_h^1 q) n \cdot t ds = \int_e J q n \cdot t ds \quad \forall \text{ edges } e,$$

$$\int_K \frac{\partial_h^2 I_h^1 q}{\partial x \partial y} dx dy = \int_K \frac{\partial^2 q}{\partial x \partial y} dx dy \quad \forall \text{ elements } K.$$

By the symmetry, we show only the case where $n = (1, 0)$ for the first and second identities in the following. As before, let V_1 and V_2 denote the bottom and top endpoints of e. Integrating by parts twice and taking into account that v is linear on e, the left-hand side of the first identity becomes

$$\int_e \frac{\partial_h^2 I_h^1 q}{\partial y^2} v dy = \left(\frac{\partial I_h^1 q}{\partial y} v\right)(V_2) - \left(\frac{\partial I_h^1 q}{\partial y} v\right)(V_1) - \left(I_h^1 q \frac{dv}{dy}\right)(V_2) + \left(I_h^1 q \frac{dv}{dy}\right)(V_1).$$

The right-hand side of the first identity becomes

$$\int_e \frac{\partial^2 q}{\partial y^2} v dy = \left(\frac{\partial q}{\partial y} v\right)(V_2) - \left(\frac{\partial q}{\partial y} v\right)(V_1) - \left(q \frac{dv}{dy}\right)(V_2) + \left(q \frac{dv}{dy}\right)(V_1).$$

These two identities and the definition of I_h^1 prove the first identity. The proof of the second identity is a direct consequence of the integration by parts with the definition of I_h^1. Now we establish the third identity. An integration by parts leads to

$$\begin{aligned}\int_K \frac{\partial_h^2 I_h^1 q}{\partial x \partial y} dx dy &= \int_{e_3} \frac{\partial I_h^1 q}{\partial y} dy - \int_{e_1} \frac{\partial I_h^1 q}{\partial y} dy \\ &= (I_h^1 q)(V_2^{e_3}) - (I_h^1 q)(V_1^{e_3}) - (I_h^1 q)(V_2^{e_1}) + (I_h^1 q)(V_1^{e_1}),\end{aligned}$$

$$\int_K \frac{\partial^2 q}{\partial x \partial y} dx dy = q(V_2^{e_3}) - q(V_1^{e_3}) - q(V_2^{e_1}) + q(V_1^{e_1}).$$

An application of the definition of I_h^1 completes the proof. □

With the aforementioned commutativity property, we have the following commuting diagram with exact rows:

$$\begin{array}{ccccccccccc}
0 & \longrightarrow & P_1(\Omega) & \xrightarrow{\subset} & C^\infty(\Omega) & \xrightarrow{J} & C^\infty(\Omega,\mathbb{S}) & \xrightarrow{\mathrm{div}} & C^\infty(\Omega,\mathbb{R}^2) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle id} & & \downarrow{\scriptstyle I_h^1} & & \downarrow{\scriptstyle \Pi_h^1} & & \downarrow{\scriptstyle P_h} & & \\
0 & \longrightarrow & P_1(\Omega) & \xrightarrow{\subset} & AD_h & \xrightarrow{J_h} & \Sigma_h^1 & \xrightarrow{\mathrm{div}_h} & V_h & \longrightarrow & 0
\end{array}$$

To obtain the analogue for the first element space Σ_h^0, we define the following enriched Adini element:

$$EAD(K) := P_3(K) \oplus \mathrm{span}\{x^3y, y^3x, x^4, y^4\}.$$

Any element q in $EAD(K)$ can be uniquely determined by

- the values of q and the two first order derivatives of q at each node (12 degrees of freedom),
- the values of $\int_K (x - x_{0,K})^2 \frac{\partial_h^2 I_h^0 q}{\partial x^2} dxdy$ and $\int_K (y - y_{0,K})^2 \frac{\partial_h^2 I_h^0 q}{\partial y^2} dxdy$ (two degrees of freedom).

A variant of the argument for Lemma 4.1 shows the following.

LEMMA 4.3. *It holds that*

$$J_h q \in \Sigma_h^0 \quad \textit{and} \quad \mathrm{div}_h J_h q = 0 \quad \forall q \in EAD_h.$$

Define the interpolation $I_h^0 q \in EAD_h$ for any $C^2(\Omega)$ by requiring that the values of $I_h^0 q$, the first order derivatives of $I_h^0 q$ at vertexes, $\int_K (x - x_{0,K})^2 \frac{\partial_h^2 I_h^0 q}{\partial x^2} dxdy$, $\int_K (y - y_{0,K})^2 \frac{\partial_h^2 I_h^0 q}{\partial y^2} dxdy$, all be equal to the corresponding values of q.

LEMMA 4.4. *There holds the commutativity property*

$$J_h I_h^0 q = \Pi_h^0 J q \quad \forall q \in C^2(\Omega).$$

Proof. Thanks to the proof of Lemma 4.2, the proof of Lemma 4.4 is the direct consequence of the definitions of I_h^0 and Π_h^0. ∎

Therefore, we have the following commuting diagram with exact rows:

$$\begin{array}{ccccccccccc}
0 & \longrightarrow & P_1(\Omega) & \xrightarrow{\subset} & C^\infty(\Omega) & \xrightarrow{J} & C^\infty(\Omega,\mathbb{S}) & \xrightarrow{\mathrm{div}} & C^\infty(\Omega,\mathbb{R}^2) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle id} & & \downarrow{\scriptstyle I_h^0} & & \downarrow{\scriptstyle \Pi_h^0} & & \downarrow{\scriptstyle P_h} & & \\
0 & \longrightarrow & P_1(\Omega) & \xrightarrow{\subset} & EAD_h & \xrightarrow{J_h} & \Sigma_h^0 & \xrightarrow{\mathrm{div}_h} & V_h & \longrightarrow & 0
\end{array}$$

5. Error analysis. This section presents the error analysis for the methods in consideration. We first collect the following error estimates for the interpolation operators Π_h^i, with $i = 0, 1$, and P_h, which can be shown using the standard scaling arguments and the properties of Π_h^i, $i = 0, 1$:

$$\|\Pi_h^i \tau - \tau\|_{L^2(\Omega)} \le Ch^m \|\tau\|_{H^m(\Omega)}, \qquad m = 1, 2,\ i = 0, 1, \tag{5.1}$$

$$\|\,\mathrm{div}_h \Pi_h^i \tau - \mathrm{div}\,\tau\|_{L^2(\Omega)} \le Ch \|\,\mathrm{div}\,\tau\|_{H^1(\Omega)}, \qquad i = 0, 1, \tag{5.2}$$

$$\|P_h v - v\|_{L^2(\Omega)} \le Ch \|v\|_{H^1(\Omega)}. \tag{5.3}$$

For the analysis, we need some further result concerning the superconvergence for the enriched nonconforming rotated Q_1 element which reads

$$NR_h := \{v \in L^2(\Omega), v|_K \in P_2^2(K) \text{ for any } K \in \mathcal{T}_h, \text{ and } v \text{ is continuous in the averaging sense on all the interior edges of } \mathcal{T}_h\}.$$

Given $\tau \in \Sigma_h^0$, it follows from the definition of Σ_h^0 that $\tau_{12} \in NR_h$.

LEMMA 5.1. *It holds for any $u \in H^2(\Omega, \mathbb{R}^2) \cap H_0^1(\Omega, \mathbb{R}^2)$ that*

$$\sum_{K\in\mathcal{T}_h} \int_{\partial K} u \cdot nv ds \le Ch^2 \|u\|_{H^2(\Omega)} |v|_{1,h} \quad \forall v \in NR_h,$$

where $n = (n_1, n_2)$ is the outer normal vector to ∂K. The broken seminorm $|\cdot|_{1,h}$ is defined as

$$|v|_{1,h}^2 := \sum_{K\in\mathcal{T}_h} \|\nabla v\|_{L^2(K)}^2.$$

Proof. For this rectangular case, a similar proof can be found in [10, 8, 6, 7, 9]. For the convenience of readers, we sketch the proof here. With $\mathcal{J}_e v = \frac{1}{|e|}\int_e v ds$ for any $v \in L^2(e)$, we have

$$\sum_{K\in\mathcal{T}_h} \int_{\partial K} u \cdot nv ds = \sum_{K\in\mathcal{T}_h} \sum_{e\subset\partial K} \int_e (u - \mathcal{J}_e u) \cdot n(v - \mathcal{J}_e v) ds$$

$$= \sum_{K\in\mathcal{T}_h} \sum_{i=1}^4 \int_{e_i} (u - \mathcal{J}_{e_i} u) \cdot n(v - \mathcal{J}_{e_i} v) ds = \sum_{K\in\mathcal{T}_h} \sum_{i=1}^4 I_K^i.$$

Let $(n_{1,1}, n_{2,1})$ (resp., $(n_{1,3}, n_{2,3})$) be the unit normal vector to e_1 (resp., e_3); we have

$$I_K^1 + I_K^3 = \int_{e_1} (u_1 - \mathcal{J}_{e_1} u_1) \times (v - \mathcal{J}_{e_1} v) n_{1,1} ds + \int_{e_3} (u_1 - \mathcal{J}_{e_3} u_1) \times (v - \mathcal{J}_{e_3} v) n_{1,3} ds$$

$$= -\frac{|e_1|}{2} \int_{-1}^1 (\widehat{u}_1(-1,\eta) - \widehat{\mathcal{J}_{e_1} u_1}) \times (\hat{v}(-1,\eta) - \widehat{\mathcal{J}_{e_1} v}) d\eta$$

$$+ \frac{|e_3|}{2} \int_{-1}^1 (\widehat{u}_1(1,\eta) - \widehat{\mathcal{J}_{e_3} u_1}) \times (\hat{v}(1,\eta) - \widehat{\mathcal{J}_{e_3} v}) d\eta.$$

Because $|\hat{e}_1| = |\hat{e}_3| = 2$,

$$\widehat{\mathcal{J}_{e_1} u_1} = \frac{1}{|\hat{e_1}|} \int_{-1}^1 \widehat{u}_1(-1,t) dt, \quad \widehat{\mathcal{J}_{e_3} u_1} = \frac{1}{|\hat{e_3}|} \int_{-1}^1 \widehat{u}_1(1,t) dt.$$

Note that

$$\hat{v}(-1,\eta) - \mathcal{J}_{\hat{e}_1} \hat{v} = \hat{v}(1,\eta) - \mathcal{J}_{\hat{e}_3} \hat{v}$$

and $\frac{\partial}{\partial\eta}\hat{v}(\xi,\eta) = c_0 + c_1\eta$ with c_0 and c_1 constant; then we derive

$$I_K^1 + I_K^3$$

$$= \frac{|e_1|}{8} \int_{-1}^1 \left\{ \int_{-1}^1 \int_t^\eta \int_{-1}^1 \frac{\partial^2}{\partial s \partial z} \widehat{u}_1(s,z) ds dz dt \right\} \times \left\{ \int_{-1}^1 \int_t^\eta \frac{\partial}{\partial z} \hat{v}(1,z) dz dt \right\} d\eta$$

$$\le Ch |\widehat{u}_1|_{H^2(\hat{K})} |\hat{v}|_{H^1(\hat{K})} \le Ch^2 |u_1|_{H^2(K)} |v|_{H^1(K)}.$$

Similarly,

$$I_K^2 + I_K^4 \le Ch^2 |u_2|_{H^2(K)} |v|_{H^1(K)}.$$

The summation over elements then completes the proof. ∎

THEOREM 5.2. *Let $(\sigma, u) \in H(\mathrm{div}, \Omega, \mathbb{S}) \times L^2(\Omega, \mathbb{R})$ be the unique solution to problem (1.1) and let $(\sigma_h, u_h) \in \Sigma_h^i \times V_h$ be the unique solution to problem (2.2) with the discrete space pairs $\Sigma_h^i \times V_h$, $i = 0, 1$, defined in section 2. Then*

$$\|\sigma - \sigma_h\|_{H(\mathrm{div}_h, \Omega)} + \|u - u_h\|_{L^2(\Omega)} \le Ch(\|u\|_{H^2(\Omega)} + \|\,\mathrm{div}\,\sigma\|_{H^1(\Omega)}). \tag{5.4}$$

Proof. Define

$$Z_f^i := \{\tau \in \Sigma_h^i | (\mathrm{div}_h\,\sigma, v) = (f, v) \quad \forall v \in V_h\}, \qquad i = 0, 1. \tag{5.5}$$

For any $\tau \in Z_f^i$, we have $\sigma_h - \tau \in Z_h^i$. It follows from the K-ellipticity (see Theorem 3.2 and Remark 3.3) and from $(\mathrm{div}_h(\sigma_h - \tau), v_h)_{L^2(\Omega)} = 0$ for any $v_h \in V_h$ that

$$\begin{aligned} C\|\sigma_h - \tau\|^2_{H(\mathrm{div}_h, \Omega)} &\le (A(\sigma_h - \tau), \sigma_h - \tau)_{L^2(\Omega)} \\ &= (A(\sigma_h - \sigma + \sigma - \tau), \sigma_h - \tau)_{L^2(\Omega)} \\ &= (A(\sigma_h - \sigma), \sigma_h - \tau)_{L^2(\Omega)} + (A(\sigma - \tau), \sigma_h - \tau)_{L^2(\Omega)} \\ &= (A(\sigma - \tau), \sigma_h - \tau)_{L^2(\Omega)} - (A\sigma, \sigma_h - \tau)_{L^2(\Omega)} \\ &\quad - (\mathrm{div}_h(\sigma_h - \tau), u)_{L^2(\Omega)} + (\mathrm{div}_h(\sigma_h - \tau), u - P_h u). \end{aligned}$$

Using $\epsilon(u) = A\sigma$ with $\epsilon(u) = 1/2(\nabla u + \nabla u^T)$ for the exact solution $u \in H_0^1(\Omega, \mathbb{R}^2)$ and Hölder's inequality, we obtain

$$\begin{aligned} \|\sigma_h - r\|_{H(\mathrm{div}_h, \Omega)} &\le C \inf_{\tau \in Z_f^i} \|\sigma - \tau\|_{L^2(\Omega)} \\ &\quad + C \sup_{\tau \in \Sigma_h^i} \frac{(\epsilon(u), \tau)_{L^2(\Omega)} + (\mathrm{div}_h\,\tau, u)_{L^2(\Omega)} + (\mathrm{div}_h\,\tau, P_h u - u)_{L^2(\Omega)}}{\|\tau\|_{H(\mathrm{div}_h, \Omega)}}. \end{aligned} \tag{5.6}$$

It follows from Lemma 3.1 (resp., Remark 3.3) that $\Pi_h^i \sigma \in Z_f^i$, which leads to

$$\inf_{\tau \in Z_f^i} \|\sigma - \tau\|_{L^2(\Omega)} \le Ch^m \|\sigma\|_{H^m(\Omega)}, \quad m = 1, 2.$$

Since $(\mathrm{div}_h\,\tau, P_h u - u)_{L^2(\Omega)} = 0$, we now focus on the second term in (5.6), which measures the nonconformity of Σ_h^i. An elementwise integration by parts yields

$$\begin{aligned} (\epsilon(u), \tau)_{L^2(\Omega)} + (\mathrm{div}_h\,\tau, u)_{L^2(\Omega)} &= \sum_{K \in \mathcal{T}_h} \sum_{e \subset \partial K} \int_e \tau n \cdot u ds \\ &= \sum_{K \in \mathcal{T}_h} \left(\sum_{e \in \mathcal{E}_{K,V}} \int_e (\tau_{11} u_1 + \tau_{21} u_2) n_1 ds + \sum_{e \in \mathcal{E}_{K,H}} \int_e (\tau_{12} u_1 + \tau_{22} u_2) n_2 ds \right). \end{aligned} \tag{5.7}$$

It follows from the definition of Σ_h^i that the moments of degree 0 and 1 of τ_{11} are continuous on vertical edges, the moments of degree 0 and 1 of τ_{22} are continuous on horizontal edges, and $\tau_{12}=\tau_{21}\in NR_h$. These with $u\in H_0^1(\Omega,\mathbb{R}^2)$ lead to

$$\begin{aligned}(\epsilon(u),\tau)_{L^2(\Omega)}+(\operatorname{div}_h\tau,u)_{L^2(\Omega)}=&\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,V}}\int_e(\tau_{21}-\Pi_0^e\tau_{21})(u_2-\Pi_0^e u_2)n_1ds\\&+\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,H}}\int_e(\tau_{12}-\Pi_0^e\tau_{12})(u_1-\Pi_0^e u_1)n_2ds\\&+\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,V}}\int_e(\tau_{11}-\Pi_1^e\tau_{11})(u_1-\Pi_1^e u_1)n_1ds\\&+\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,H}}\int_e(\tau_{22}-\Pi_1^e\tau_{22})(u_2-\Pi_1^e u_2)n_2ds.\end{aligned}$$

Here, Π_1^e denotes the projection operator from $L^2(e)$ to $P_1(e)$. It follows from Lemma 5.1 that

$$\begin{aligned}&\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,V}}\int_e(\tau_{21}-\Pi_0^e\tau_{21})(u_2-\Pi_0^e u_2)n_1ds\\&\quad+\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,H}}\int_e(\tau_{12}-\Pi_0^e\tau_{12})(u_1-\Pi_0^e u_1)n_2ds\\&\le Ch^2|\tau_{12}|_{1,h}|u|_{H^2(\Omega)}.\end{aligned}$$

In view of the approximation of Π_1^e and the trace theorem,

$$\begin{aligned}&\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,V}}\int_e(\tau_{11}-\Pi_1^e\tau_{11})(u_1-\Pi_1^e u_1)n_1ds\\&\qquad\le Ch^2|\tau_{11}|_{1,h}|u_1|_{H^2(\Omega)},\\&\sum_{K\in\mathcal{T}_h}\sum_{e\in\mathcal{E}_{K,H}}\int_e(\tau_{22}-\Pi_1^e\tau_{22})(u_2-\Pi_1^e u_2)n_2ds\\&\qquad\le Ch^2|\tau_{22}|_{1,h}|u_2|_{H^2(\Omega)}.\end{aligned}$$

A combination of the aforementioned three inequalities leads to

$$(\epsilon(u),\tau)_{L^2(\Omega)}+(\operatorname{div}_h\tau,u)_{L^2(\Omega)}\le Ch^2|\tau|_{1,h}|u|_{H^2(\Omega)}. \tag{5.8}$$

Taking into account the approximation property of P_h and using the inverse estimate, we get

$$\|\sigma_h-\sigma\|_{H(\operatorname{div}_h,\Omega)}\le Ch(\|u\|_{H^2}+\|\operatorname{div}\sigma\|_{H^1(\Omega)}). \tag{5.9}$$

We turn to the error estimate for u_h. In view of the discrete B-B condition (see Theorem 3.2 and Remark 3.3), we have for any $v \in V_h$ that

$$\begin{aligned} C\|u_h - v\|_{L^2(\Omega)} &\le \sup_{\tau\in\Sigma_h^i} \frac{(\operatorname{div}_h \tau, u_h - v)_{L^2(\Omega)}}{\|\tau\|_{H(\operatorname{div}_h,\Omega)}} \\ &\le \frac{(\operatorname{div}_h \tau, u_h - u)_{L^2(\Omega)}}{\|\tau\|_{H(\operatorname{div}_h,\Omega)}} + \inf_{v\in V_h} \|u - v\|_{L^2(\Omega)} \\ &\le C\big(\|\sigma_h - \sigma\|_{L^2(\Omega)} + \inf_{v\in V_h} \|u - v\|_{L^2(\Omega)}\big) \\ &\quad + \sup_{\tau\in\Sigma_h^i} \frac{(\epsilon(u), \tau)_{L^2(\Omega)} + (\operatorname{div}_h \tau, u)_{L^2(\Omega)}}{\|\tau\|_{H(\operatorname{div},\Omega)}} \\ &\le Ch(\|u\|_{H^2(\Omega)} + \|\operatorname{div}\sigma\|_{H^1(\Omega)}). \end{aligned} \tag{5.10}$$

An application of the triangle inequality with $v = P_h u$ gives

$$\|u - u_h\|_{L^2(\Omega)} \le Ch(\|u\|_{H^2(\Omega)} + \|\operatorname{div}\sigma\|_{H^1(\Omega)}). \qquad \square \tag{5.11}$$

Remark 5.3. With a minor modification of the above proof, one can show that

$$\|\sigma - \sigma_h\|_{L^2(\Omega)} \le Ch\|u\|_{H^2(\Omega)}, \tag{5.12}$$

$$\|\operatorname{div}\sigma - \operatorname{div}_h \sigma_h\|_{L^2(\Omega)} \le Ch\|\operatorname{div}\sigma\|_{H^1(\Omega)}, \tag{5.13}$$

$$\|u - u_h\|_{L^2(\Omega)} \le Ch\|u\|_{H^2(\Omega)}. \tag{5.14}$$

Remark 5.4. Note that for the quadrilateral mesh, the discrete space Σ_h cannot be defined from the space $\Sigma_{\hat{K}}$ on the reference element $\hat{K}$ through the usual Piola transformation. Therefore, it has to be directly defined on the present element $K \in \mathcal{T}_h$. The rectangular methods of this paper cannot be directly extended to the more general quadrilateral mesh. To get the quadrilateral versions of them, we need to enrich the shear stress space to $Q_2(K)\backslash\{x^2y^2\} \oplus \{x^3y - y^3x\}$ from [12]. In the first method, then the degrees of freedom become the moments of degrees 0 and 1 of τn on each edge and the average of τ on each element K. For the rectangular mesh, this results in a variant of the method proposed in [12]. The second method is obtained from the first one by dropping out the bubble functions in the normal stress, which goes to another variant of the method in [12] for a rectangular mesh. The displacement space V_h is the same as that in section 2. In addition, to get the stability, one can follow the idea of [12] to employ the modified energy norm $\|\tau\|_{L^2(\Omega)} + \|P_h \operatorname{div}_h \tau\|_{L^2(\Omega)}$ for $\tau \in \Sigma_h$ instead.

Remark 5.5. After the submission of this paper, we found that the second element (Σ_h^1, V_h) is independently proposed in [13]. The analysis therein is based on the superconvergence of the consistency term for $\tau \in Z_h^1$. However, the regularity $u \in (H^3(\Omega))^2$ is required in the proof of this superconvergence (see the proof of Lemmas 5.1 and 4.3 of [13]). In this paper, we get more practical results with the regularity $u \in (H^2(\Omega) \cap H_0^1(\Omega))^2$ (see Lemma 5.1 and (5.12)). We also stress that the analysis of [13] cannot be generalized to the more general quadrilateral mesh either.

STRANG SPLITTING FOR THE TIME-DEPENDENT SCHRÖDINGER EQUATION ON SPARSE GRIDS*

V. GRADINARU†

Abstract. The time-dependent Schrödinger equation is discretized in space by a sparse grid pseudospectral method. The Strang splitting for the resulting evolutionary problem features first or second order convergence in time, depending on the smoothness of the potential and of the initial data. In contrast to the full grid case, where the frequency domain is the working place, the proof of the sufficient conditions for the convergence is done in the space realm.

Key words. trigonometric interpolation, sparse grids, Strang splitting, Schrödinger equation

1. Introduction.

Problems in high dimensional spaces represent one of the big challenges today. The standard method of solving the Schrödinger equation uses a representation of the Hamiltonian and of the wave-functions in appropriate product bases [8]. It is sobering that the required computational resources grow exponentially with the number of particles. Sparse grids are an attempt to lessen this curse of dimensionality. Sometimes called hyperbolic cross approximation, they gained increasing attention since their introduction not only for the efficient approximations of smooth functions [10, 4, 11, 36, 32, 34] but also for the solution of PDEs [45, 6, 7]. The recent survey paper on sparse grids [7] contains detailed references. The crucial idea of the sparse grid schemes is to drop certain insignificant contributions of the hierarchical representations of functions. Provided that the solutions are smooth, a tremendously reduced number of unknowns yields almost the same asymptotic rates of approximation as for standard grids.

Spectral methods are well suited for solving PDEs to high accuracy on simple domains and for smooth data. The extension of the sparse grid techniques to the spectral methods comes about by means of Fourier polynomials with harmonics from the hyperbolic cross [23]. Based on the Fourier transform on sparse grids [20, 4] many common pseudospectral methods (such as those based on Chebyshev and Legendre polynomials) arise on sparse grids in the same way as Fourier methods [29, 35]. Applied to various elliptic, parabolic, and hyperbolic problems, the sparse grid collocation method evidenced a trade of efficiency for robustness [23]. The order of convergence depends on the smoothness of the solution as well as on the initial and boundary conditions.

Problems from quantum mechanics were early on a target of the sparse grids methods [21]. The combination technique on sparse grids [18, 30, 28] is used for the six-dimensional eigenvalue problem resulting from the Born–Oppenheimer approximation of the helium atom in [14]. Limitations of this approach are the impossibility to compute eigenvalues from the higher end of the spectrum and the lack of adaptivity. Recently, cutting-edge work on the electronic Schrödinger equation showed surprising

smoothness properties of their solutions [41, 42, 43], a fact that can help to break the complexity barriers using antisymmetrized sparse grid functions [17, 44].

The time-dependent setting of the quantum molecular problems is different, since we are faced with an initial value problem. In the Born–Oppenheimer approximation, the original problem is split into an electronic part and a nuclear part. The latter involves only the nuclei evolving in a smooth potential [37, 19]. Here, we tackle the time-dependent Schrödinger equation (TDSE) that appears in quantum molecular dynamics for nuclei [40]:

$$\begin{aligned} i\frac{\partial u}{\partial t} &= -\Delta u + Vu \quad \text{for } \mathbf{x} \in \Omega \text{ and } t > 0, \\ u(\mathbf{x}, 0) &= g(\mathbf{x}) \qquad\quad \text{for } \mathbf{x} \in \Omega, \end{aligned} \tag{1.1}$$

where the smooth potential $V : \mathbb{R}^d \to \mathbb{R}$ is 2π-periodic in each coordinate and the boundary conditions are periodic. In this setting, the pseudospectral method together with a Strang splitting for the time scheme are appropriate for the numerical solution [22]. However, the standard Fourier discretization of the space needs a full grid and hence confronts us with the curse of dimensionality. This limits the classical approach to dimensions $d \leq 3$; see [3]. Theoretically, the trigonometric polynomials on sparse grids permit a space discretization in higher dimensional cases. The context of the collocation method allows us to avoid the difficulties that the sparse grid schemes usually have in the presence of variable coefficients [1]. Let us note that we do not have at our disposal the symmetry conditions imposed by the Pauli principle, as we do not expect the nuclei of a molecule to be identical. Hence we are not able to really break the curse of dimensionality, as done for the electronic Schrödinger equation [17, pp. 41–44] but only to lessen it to some extent. Here, we study the sparse grid spectral collocation in space combined with the Strang splitting in time. First, we interpolate the initial data by Fourier polynomials on the sparse grid of a fixed resolution n. Then, we propagate the wave-function in time by means of a Strang splitting scheme. This is a widely used numerical approach to the linear initial value problem

$$u' = (A + B)u, \quad u(0) = u_0.$$

Also known as the symmetric operator splitting, the time iteration

$$u^{m+1} = e^{\frac{1}{2}\tau B} e^{\tau A} e^{\frac{1}{2}\tau B} u^m$$

determines recursively approximations u^m to $u(m\tau)$. The space discretization is reflected in the actual operators A and B. In [22], the analysis of the Strang splitting in the presence of unbounded operators was performed in an abstract setting. The resulting sufficient conditions are in the form of commutator bounds. The challenge in the sparse grid context is to prove such commutator bounds that hold uniformly with respect to the resolution. This is the central result of the paper. We show global error bounds ensuring order one, or, for smoother data, order two convergence in time. We impose high regularity assumptions for the initial data and the potential, and the simulations show that they are necessary. In the adiabatic case, one can prove that, away from the gap, the potential is analytic [19, 37]. Applications of such smooth potentials may be found in [26, 2] and [31, page 552].

We begin by resuming the trigonometric interpolation on sparse grids in the spirit of [20]. Then, we present several approximation estimates in Korobov spaces. Together with some direct and inverse inequalities, these estimates play a central role

in the convergence proofs. Next, we show that the interpolation error in the corresponding Korobov space transfers to the solution of the space-discretized problem, as is expected in collocation pseudospectral methods [9]. But for the convergence of the time scheme, commutator bounds for the involved unbounded operators are needed [22]. In the full grid case the proof may be done in the frequency domain by arguments relying on the aliasing formula. Lacking the corresponding tool for the Fourier coefficients of the sparse grid interpolator, we show that the commutator lemmas hold in the space domain. Here, the main ingredients are furnished by the decay of the space-residuals as established in the approximation estimates. In the last section, we resume the convergence results and the dependence on the smoothness of the potential and the initial data. We present numerical experiments in small dimensional cases. This makes possible a comparison to the full grid approach, because similar computations are then easy to perform. The focus is on the time convergence rates and on the influence of the smoothness of the initial data and of the potential. Algorithmic and convergence issues in the space discretization together with examples in higher dimensional cases are the matter of a separate paper [15].

2. Trigonometric interpolation on sparse grids. Spectral collocation methods work usually on tensor product grids [38, 13]. This is the prerequisite for a sparse grid approach as well, because it allows the reduction to the one-dimensional case. The mainstay of a sparse grid interpolation is a hierarchical multilevel representation of functions [7, 16]. We follow the approach of Hallatschek [20] for the design of the hierarchical trigonometrical basis.

We begin with the one-dimensional case discretizing the space domain $[-\pi, \pi]$ by

$$G_n := \{x_{nk} := 2\pi\, k2^{-n} \text{ for } k \in G'_n\}\,,$$

where G'_n is the discrete frequency domain

$$G'_n = \{1 - 2^{n-1}, \ldots, 2^{n-1}\}$$

for levels $n \geq 1$. For $n = 0$ we consider $G'_0 = \{0\}$.

The *nodal trigonometric representation* of a smooth function u is

$$\mathcal{I}_n u(x) := u_n(x) := \sum_{k \in G'_n} c_{nk} e^{i\,kx}\,,$$

with the *nodal Fourier coefficients* given by

$$c_{nk} := \frac{1}{2^n} \sum_{x \in G_n} u(x) e^{-i\,kx}\,.$$

For the manipulation of the indices it is useful to define the set

$$I_n := \begin{cases} \{0\} & \text{if } n = 0, \\ \{2^{n-1}, \ldots, 2^n - 1\} & \text{if } n \geq 1 \end{cases}$$

and the function

$$\sigma(q) := \begin{cases} -q/2 & \text{if } q \text{ is even}, \\ (q+1)/2 & \text{if } q \text{ is odd}. \end{cases}$$

It is then easy to see that $\sigma(I_{n+1}) = G'_{n+1} \setminus G'_n$ corresponds to the new nodes when gradually refining the grid from G_n to G_{n+1}. Let us change the order of summation according to σ:

$$u_n(x) = \sum_{q=0}^{2^n-1} c_{n\sigma(q)}\beta_{nq}(x) = \sum_{q=0}^{2^n-1} \tilde{c}_{nq}\beta_{nq}(x)\,,$$

where $\beta_{nq}$is the re-indexed exponential function:

$$\beta_{nq}(x) := \begin{cases} e^{-i\,\frac{q}{2}x} & \text{if } q \text{ is even,} \\ e^{i\,\frac{q+1}{2}x} & \text{if } q \text{ is odd.} \end{cases}$$

Note that the shape of β_{nq} does not depend explicitly on the level n but only on the index q. The meaning of n is to remind us that the range of the index q is allowed to vary: $\{0, \ldots, 2^n - 1\}$. The information gain when increasing the *resolution* n by one may then be written as

$$\begin{aligned} u_{n+1} - u_n = & \sum_{q \in I_{n+1}} \tilde{c}_{n+1\,q}(\beta_{n+1\,q} - \beta_{n+1\,2^{n+1}-q-1}) \\ & + \sum_{q=0}^{2^n-1} (\tilde{c}_{n+1\,2^{n+1}-q-1} + \tilde{c}_{n+1\,q} - \tilde{c}_{nq})\beta_{nq}\,. \end{aligned}$$

It interpolates at the new points $\sigma(I_{n+1})$, whereas it is zero at the old grid points G_n. Simple manipulations show that the coefficients of the second sum are zero:

$$\tilde{c}_{n+1\,2^{n+1}-q-1} + \tilde{c}_{n+1\,q} - \tilde{c}_{nq} = 0.$$

This yields to the definition of the *hierarchical trigonometrical basis* functions

$$\chi_{nq} := \beta_{nq} - \beta_{n\,2^n-q-1} \text{ for } q \in I_n, n \geq 1,$$

which have the property that they vanish at the grid points of level $n-1$:

$$\chi_{nq}(x) = 0 \text{ for all } x \in G_{n-1}.$$

In contrast to β_{nq}, the behavior of the hierarchical basis function is determined by q and n. We arrive at the *hierarchical representation* of the trigonometrical interpolator

$$\mathcal{I}_n u(x) = \tilde{c}_{00}\beta_{00}(x) + \sum_{l=1}^{n}\sum_{q\in I_l} \tilde{c}_{lq}\chi_{lq} = \sum_{l=0}^{n}\sum_{q\in I_l} d_{lq}\chi_{lq}\,,$$

where $d_{lq} := \tilde{c}_{lq} = c_{n\sigma(q)}$ and $\chi_{00} := \beta_{00}$. Recall the significance of c_{lk}: they are the discrete Fourier coefficients when *discretizing at the level* l. The aliasing formula for $c_{l\sigma(q)}$ gives a representation for the *hierarchical Fourier coefficients* d_{lq}:

$$d_{lq} = c_{l\sigma(q)} = \sum_{m\in\mathbb{Z}} \widehat{u}(\sigma(q) + m2^l),$$

where $\widehat{u}$ is the (continuous) Fourier transform of u: $\widehat{u}(k) = \int_{-\pi}^{\pi} e^{-ikx}u(x)dx$. One can switch from the nodal to the hierarchical coefficients and backward by simple recursive algorithms [20].

Now, we move to the higher dimensional case: $\Omega := [-\pi, \pi]^d$, $d \geq 2$. Writing $\mathbf{n} = (n_1, \ldots, n_d) \in \mathbb{N}^d$ for the *level*, and $\mathbf{k} = (k_1, \ldots, k_d) \in \mathbb{Z}^d$ for the index, the *full grid in space domain* is

$$G_{\mathbf{n}} := \{x_{\mathbf{nk}}, \text{ with } x_{n_s k_s} := 2\pi\, k_s 2^{-n_s}, \text{ for } k_s \in G'_{n_s}\}.$$

The *full grid in frequency domain* is the set of index vectors at level $\mathbf{n}$:

$$G'_{\mathbf{n}} = \{\boldsymbol{\omega}_{\mathbf{nk}} := \mathbf{k} \text{ for } k_s \in G'_{n_s}, s = 1, \ldots, d\}.$$

The *nodal trigonometric interpolation* of a function u on the full grid $G_{\mathbf{n}}$ reads

$$\mathcal{I}^{\text{full}}_{\mathbf{n}} u(\mathbf{x}) := u_{\mathbf{n}}(\mathbf{x}) := \sum_{\mathbf{k} \in G'_{\mathbf{n}}} c_{\mathbf{nk}} e^{i\, \mathbf{k}\cdot\mathbf{x}}, \tag{2.1}$$

with the *nodal Fourier coefficients*

$$c_{\mathbf{nk}} := \frac{1}{2^{|\mathbf{n}|_1}} \sum_{\mathbf{x} \in G_{\mathbf{n}}} u(\mathbf{x}) e^{-i\, \mathbf{k}\cdot\mathbf{x}},$$

where $|\mathbf{n}|_1 := n_1 + \cdots + n_d$. The tensor product allows us to perform the transformation to the hierarchical basis in each direction:

$$\mathcal{I}^{\text{full}}_{\mathbf{n}} u(\mathbf{x}) = u_{\mathbf{n}}(\mathbf{x}) = \sum_{|\mathbf{l}|_\infty \leq n} \sum_{\mathbf{q} \in I_{\mathbf{l}}} d_{\mathbf{lq}} \chi_{\mathbf{lq}}(\mathbf{x}), \tag{2.2}$$

where $|\mathbf{l}|_\infty = \max\{l_s, s = 1, \ldots, d\}$, the basis functions are constructed by tensor product $\chi_{\mathbf{lq}}(\mathbf{x}) := \prod_{s=1}^d \chi_{l_s q_s}(x_s)$, and $I_{\mathbf{l}} = I_{l_1} \times \cdots \times I_{l_d}$.

Denote $\mathbf{k} := \sigma(\mathbf{q}) := (\sigma(q_1), \ldots, \sigma(q_d))$. Due to the aliasing formula, we have for the *hierarchical Fourier coefficients*

$$d_{\mathbf{lq}} = c_{\mathbf{l}\,\sigma(\mathbf{q})} = c_{\mathbf{lk}} = \sum_{\mathbf{m} \in \mathbb{Z}^d} \widehat{u}(k_1 + m_1 2^{l_1}, \ldots, k_d + m_d 2^{l_d})\,. \tag{2.3}$$

The classical *sparse grid* in the space domain is

$$S_n := \{\mathbf{x}_{\mathbf{l}\,\sigma(\mathbf{q})}, \text{ where } |\mathbf{l}|_1 \leq n, \text{ and } \mathbf{q} \in I_{\mathbf{l}}\}$$

and in the frequency domain is

$$S'_n := \{\boldsymbol{\omega}_{\mathbf{l}\,\sigma(\mathbf{q})} := \sigma(\mathbf{q}), \text{ where } |\mathbf{l}|_1 \leq n, \text{ and } \mathbf{q} \in I_{\mathbf{l}}\}.$$

We display them in Figure 2.1 at the particular resolution $n = 4$ in two dimensions.

The thought behind these definitions is that the hierarchical coefficients $d_{\mathbf{lq}}$ furnish significant information only if $|\mathbf{l}|_1 \leq n$, as long as u is sufficiently smooth. In this case, it is enough to consider the trigonometric interpolation only on the sparse grid:

$$\mathcal{I}_n u(\mathbf{x}) := \sum_{|\mathbf{l}|_1 \leq n} \sum_{\mathbf{q} \in I_{\mathbf{l}}} d_{\mathbf{lq}} \chi_{\mathbf{lq}}(\mathbf{x})\,. \tag{2.4}$$

From this hierarchical representation one can switch to the nodal one,

$$\mathcal{I}_n u(\mathbf{x}) = u_n(\mathbf{x}) = \sum_{\boldsymbol{\omega} \in S'_n} a_{\boldsymbol{\omega}} e^{i\, \boldsymbol{\omega}\cdot\mathbf{x}}\,, \tag{2.5}$$

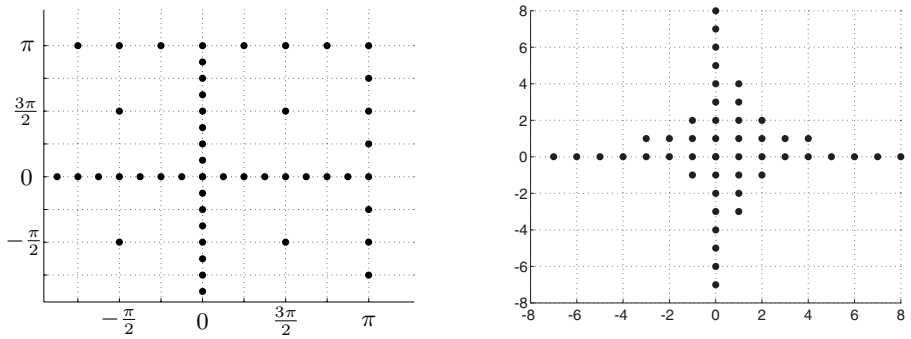

FIG. 2.1. *Sparse grids at resolution $n = 4$: in space (S_4) and in frequency (S_4').*

by recursively carrying out the inverse of the hierarchical transform [20]. Note that the obtained sparse grid Fourier coefficients $a_{\boldsymbol{\omega}}$ are not equal to the corresponding full grid Fourier coefficients $c_{\mathbf{nk}}$. For fixed d and large n, the number of function evaluations is

$$\#S_n = \frac{n^{d-1}2^n}{2^{d-1}(d-1)!} + O(n^{d-2}2^n)\,.$$

Accordingly, Hallatschek [20] showed that the complexity of the direct and reverse computations for fixed d and large n is

$$\frac{Cn^d 2^n}{2^{d-1}(d-1)!} + O(n^{d-1}2^n),$$

with some constant C; this is significantly cheaper than the work needed in the full grid approach, which requires $Cdn2^{nd}$ operations. However, it would be misleading to think that the curse of dimensionality is broken, because we still have an exponential dependence on d. This is typical for the sparse grid approach, where the curse of dimensionality can be circumvented only to some extent by restricting the class of functions under consideration [7].

3. Approximation estimates in Korobov spaces. Let us focus on the required smoothness of u and the corresponding interpolation error. Sobolev spaces of functions defined on a hypercube and having dominant mixed derivatives represent a common place of the sparse grid theory. Endowed with weights moderating the behavior of periodic functions with respect to successive variables, these so-called Korobov spaces make the approximation problem tractable [27, 39]. They reflect the blessing of dimensionality [12, 7]. Here, we stick to the *Korobov space* K^α consisting of complex-valued L^2-functions defined on Ω that are periodic in each variable with period 2π and that have finite $\|\cdot\|_\alpha$-norm:

$$\|u\|_\alpha^2 := \sum_{\mathbf{k}\in\mathbb{Z}^d} |\widetilde{k}_1 \cdot \dots \cdot \widetilde{k}_d|^{2\alpha} |\widehat{u}(\mathbf{k})|^2\,, \tag{3.1}$$

where $\widetilde{k} = 1$ if $k = 0$ and $\widetilde{k} = k$ otherwise. An equivalent norm results if we set $\widetilde{k} = \sqrt{1+k^2}$. This is useful in the proof of some inequalities involving Korobov spaces of different exponent α.

LEMMA 3.1 (direct inequalities). *Provided that u is in $K^{\alpha+2}$ or, respectively, in $K^{\alpha+2\zeta}$ with $\zeta > 0$, it holds that*

$$\|\Delta u\|_\alpha \le d\,\|u\|_{\alpha+2}\,,$$
$$\big\|(I-\Delta)^\zeta u\big\|_\alpha \le (2d)^\zeta\,\|u\|_{\alpha+2\zeta}\,.$$

Proof. In order to familiarize the reader with the Fourier techniques used in the paper, let us prove the direct inequalities explicitly. The involved norms are

$$\|\Delta u\|_\alpha^2 = \sum_{\mathbf{k}\in\mathbb{Z}^d} (\widetilde{k}_1^2+\cdots+\widetilde{k}_d^2)^2 |\widetilde{k}_1\cdot\dots\cdot\widetilde{k}_d|^{2\alpha} |\widehat{u}(\mathbf{k})|^2\,,$$
$$\big\|(I-\Delta)^\zeta u\big\|_\alpha = \sum_{\mathbf{k}\in\mathbb{Z}^d} (1+\widetilde{k}_1^2+\cdots+\widetilde{k}_d^2)^{2\zeta} |\widetilde{k}_1\cdot\dots\cdot\widetilde{k}_d|^{2\alpha} |\widehat{u}(\mathbf{k})|^2\,,$$
$$\|u\|_{\alpha+2\zeta} = \sum_{\mathbf{k}\in\mathbb{Z}^d} (\widetilde{k}_1^2\cdot\dots\cdot\widetilde{k}_d^2)^{2\zeta} |\widetilde{k}_1\cdot\dots\cdot\widetilde{k}_d|^{2\alpha} |\widehat{u}(\mathbf{k})|^2\,,$$

and hence the proof reduces to the trivial inequalities

$$\widetilde{k}_1^2+\cdots+\widetilde{k}_d^2 \le d\widetilde{k}_1^2\cdot\dots\cdot\widetilde{k}_d^2\,,$$
$$1+\widetilde{k}_1^2+\cdots+\widetilde{k}_d^2 \le 2d\widetilde{k}_1^2\cdot\dots\cdot\widetilde{k}_d^2\,. \qquad \square$$

LEMMA 3.2 (inverse inequality). *Take $r > 0$ and $\zeta > dr/2$. If u is sufficiently smooth, then*

$$\|u\|_{\alpha+r} \le C(d,r)\big\|(I-\Delta)^\zeta u\big\|_\alpha\,. \tag{3.2}$$

Proof. Writing the expressions of these norms with $\widetilde{k} = \sqrt{1+k^2}$, we see that we have to find some exponent ζ and a constant C such that $|\widetilde{k}_1\cdot\dots\cdot\widetilde{k}_d|^{2r} \le C(1+k_1^2+\dots k_d^2)^{2\zeta}$. Using the mean inequality

$$\sqrt[d]{\widetilde{k}_1^2\cdot\dots\cdot\widetilde{k}_d^2} \le \frac{\widetilde{k}_1^2+\cdots+\widetilde{k}_d^2}{d},$$

it is easy to see that each exponent $\zeta > dr/2$ gives the result. $\square$

In the following, we just omit $\widetilde{\ }$, the meaning being clear from the context. The scalar product

$$\langle u,v\rangle_\alpha := \sum_{\mathbf{k}\in\mathbb{Z}^d} |k_1\cdot\dots\cdot k_d|^{2\alpha}\widehat{u}(\mathbf{k})\overline{\widehat{v}(\mathbf{k})} \tag{3.3}$$

makes K^α a Hilbert space that is compactly embedded in $L^2(\Omega)$ for $\alpha > 0$. Moreover, for $\alpha > \frac{1}{2}$, it is a reproducing kernel Hilbert space and an algebra [27]:

$$\|uv\|_\alpha \le C(d,\alpha)\,\|u\|_\alpha\|v\|_\alpha\,. \tag{3.4}$$

Using the reasoning of the proof from [27] that K^α is an algebra, one can show that, for appropriately smooth u and v, it holds for $\alpha > 1/2$ that

$$\|\Delta(uv)\|_\alpha \le C(d,\alpha)\ \left(\|u\|_\alpha\|\Delta v\|_\alpha + \|v\|_\alpha\|\Delta u\|_\alpha\right)\,,$$
$$\big\|\Delta^2(uv)\big\|_\alpha \le C(d,\alpha)\ \left(\|u\|_\alpha\big\|\Delta^2 v\big\|_\alpha + \|v\|_\alpha\big\|\Delta^2 u\big\|_\alpha\right)\,,$$
$$\|(I-\Delta)^a(uv)\|_\alpha \le C(d,\alpha)\ \left(\|u\|_\alpha\|(I-\Delta)^a v\|_\alpha + \|v\|_\alpha\|(I-\Delta)^a u\|_\alpha\right)\,.$$

The direct inequalities (Lemma 3.1) give then upper bounds only in terms of different K^α-norms.

LEMMA 3.3. *If u and v are sufficiently smooth, we have*

$$\|\Delta(uv)\|_\alpha \le C(d,\alpha)\ \|u\|_{\alpha+2}\|v\|_{\alpha+2}\,, \tag{3.5}$$

$$\left\|\Delta^2(uv)\right\|_\alpha \le C(d,\alpha)\ \|u\|_{\alpha+4}\|v\|_{\alpha+4}\,, \tag{3.6}$$

$$\left\|(I-\Delta)^\zeta(uv)\right\|_\alpha \le C(d,\alpha)\ \|u\|_{\alpha+2\zeta}\|v\|_{\alpha+2\zeta}\,. \tag{3.7}$$

Note that in the definitions (3.1) and (3.3) the factor 2 in front of α is added for cosmetic reasons that will become clear in what follows. Keep in mind that the case $\alpha = 0$ embodies the L^2-space.

Let the sparse grid interpolation operator (2.4) act on K^α. The representation of the hierarchical Fourier coefficients in d dimensions (2.3) and the Cauchy–Schwarz inequality give for u in K^α

$$|d_{\mathbf{lq}}| \le \|u\|_\alpha \left(\sum_{\mathbf{m}\in\mathbb{Z}^d}\prod_{s=1}^{d}|k_s+m_s2^{l_s}|^{-2\alpha}\right)^{1/2}.$$

We focus on the last sum. Remember that the range of $\mathbf{k}=\sigma(\mathbf{q})$ depends on the level $\mathbf{l}$: for $l_s \ge 2$, we have $2^{l_s-2} \le |k_s| \le 2^{l_s-1}$. Thereby, the one-dimensional sum may be bounded for $\alpha > \frac{1}{2}$ by $(1+\frac{1}{\alpha-\frac{1}{2}})|k_s|^{-2\alpha}$, which is true even for $l_s = 1$ or $l_s = 0$. Hence

$$|d_{\mathbf{lq}}| \le \|u\|_\alpha \left(1+\frac{1}{\alpha-\frac{1}{2}}\right)^{d/2} |k_1\cdot\dots\cdot k_d|^{-\alpha}\,.$$

This brings us to the estimation of the hierarchical Fourier coefficients of a function u belonging to the Korobov space K^α with $\alpha > \frac{1}{2}$:

$$|d_{\mathbf{lq}}| \le \left(1+\frac{1}{\alpha-\frac{1}{2}}\right)^{d/2} 2^{(2d-|\mathbf{l}|_1)\alpha}\|u\|_\alpha.$$

The usual method for the derivation of the interpolation error on sparse grids passes across the hierarchical surpluses

$$\mathcal{H}_\mathbf{l}u(\mathbf{x}) := \sum_{\mathbf{q}\in I_\mathbf{l}} d_{\mathbf{lq}}\chi_{\mathbf{lq}}(\mathbf{x}),$$

because

$$\mathcal{I}_\mathbf{n} = \sum_{|\mathbf{l}|_\infty\le n}\mathcal{H}_\mathbf{l}\,,\quad \mathcal{I}_n = \sum_{|\mathbf{l}|_1\le n}\mathcal{H}_\mathbf{l}\,,\ \text{and}\quad \|\mathcal{I}_n u - u\| \le \sum_{|\mathbf{l}|_1>n}\|\mathcal{H}_\mathbf{l}u\|$$

for suitable norm $\|\cdot\|$. For instance, in the L^2-norm, the hierarchical contributions are estimated by means of the previously obtained bounds for the hierarchical Fourier coefficients

$$\|\mathcal{H}_\mathbf{l}u\|_{L^2(\Omega)} \le \sum_{\mathbf{q}\in I_\mathbf{l}}|d_{\mathbf{lq}}|\cdot\|\chi_{\mathbf{lq}}\|_{L^2(\Omega)} \le \sqrt{2}^d\sum_{\mathbf{q}\in I_\mathbf{l}}|d_{\mathbf{lq}}| \le C'(d,\alpha)\ \cdot 2^{|\mathbf{l}|_1(1-\alpha)}\|u\|_\alpha,$$

because $\|\chi_{\mathbf{lq}}\|_{L^2(\Omega)} = \sqrt{2}$, with the constant $C'(d,\alpha)$ not depending on n but exponentially in d:

$$C'(d,\alpha) = 2^{d\alpha} 2^{d(\alpha-\frac{1}{2})} \left(1 + \frac{1}{\alpha - \frac{1}{2}}\right)^{d/2}.$$

This yields the following bound for the L^2-norm of the interpolation error:

$$\|\mathcal{I}_n u - u\|_{L^2(\Omega)} \leq C(d,\alpha)\ (n+1)^{d-1} 2^{(1-\alpha)n} \|u\|_\alpha,$$

with the constant (with respect to n)

$$C(d,\alpha) = C'(d,\alpha) \cdot S_{\alpha,d},$$

with $S_{\alpha,d} = \sum_{r=1}^{\infty} r^{d-1} 2^{(1-\alpha)r}$. This constant suggests that even for small dimensions d, we need a high resolution n in order to get a reasonable approximation of a high frequency function. Note that $S(\alpha,d) \approx 2^{-\alpha}$ for large α and fixed d, while $S(\alpha,d) \approx e^d$ for fixed α. Hence, if u belongs to the Korobov space K^α with $\alpha > 1$, we achieve the usual convergence for the sparse grid schemes.

The method of finding a bound for the interpolation error may be also applied in the case of the K^β-norm:

$$\|\mathcal{H}_{\mathbf{l}} u\|_\beta \leq \sqrt{2}^d \cdot 2^{(|\mathbf{l}|_1 - d)\beta} \cdot C \cdot 2^{(2d - |\mathbf{l}|_1)\alpha} \|u\|_\alpha,$$

because $\|\chi_{\mathbf{lq}}\|_\beta \leq \sqrt{2} \cdot 2^{(|l|_1 - d)\beta}$. This shows convergence in the K^β-norm; if $\alpha - \beta > 1$,

$$\|\mathcal{I}_n u - u\|_\beta \leq C(d,\alpha,\beta)(n+1)^{d-1} 2^{(1-(\alpha-\beta))n} \|u\|_\alpha,$$

with $C(d,\alpha,\beta) = C'(d,\alpha-\beta) \cdot S(\alpha-\beta,d)$. As the involved constants C are all of the same kind, we often write just C and keep in mind their exponential dependence on d.

PROPOSITION 3.4. *If $u \in K^{\alpha+1+\gamma}$ with $\gamma > 0$, then there is a constant $C = C(d,\alpha,\alpha+1+\gamma)$ such that*

$$\|\mathcal{I}_n u - u\|_\alpha \leq C\ (n+1)^{d-1} 2^{-\gamma n} \|u\|_{\alpha+1+\gamma}.$$

The lack of an aliasing formula in the sparse grid case requires that we impose the condition of more smoothness of the function to interpolate u. The same reason inspires us to make use of the next three propositions regarding the decay of the error $\mathcal{I}_n u - u$ under the action of the operators Δ, Δ^2, and $(I-\Delta)^\zeta$. They are necessary in the derivation of the commutator bounds in section 5.

We begin with the case of Δ. A short calculation shows that $\|\chi''_{lq}\|_\beta \leq \sqrt{2} \cdot 2^{(l-1)(2+\beta)}$. This helps to compute the bound of the hierarchical contributions

$$|d_{\mathbf{lq}}| \cdot \|\Delta \chi_{\mathbf{lq}}\|_\beta \leq C(d,\alpha,\beta)\ 2^{(\beta-\alpha)|\mathbf{l}|_1} \sum_{s=1}^{d} 4^{l_s},$$

which add together giving as previously

$$\begin{aligned}\|\Delta(\mathcal{I}_n u - u)\|_\beta &\leq C(d,\alpha,\beta) \sum_{|\mathbf{l}|_1 > n} 2^{|\mathbf{l}|_1} 2^{(\beta-\alpha)|\mathbf{l}|_1} \sum_{s=1}^{d} 4^{l_s} \\ &\leq C \sum_{m=n+1}^{\infty} 2^{(1-(\alpha-\beta))m} \sum_{|\mathbf{l}|_1 = m} 4^{l_1}.\end{aligned}$$

The last sum is a particular case of the expression

$$S_m(r,d) = \sum_{|\mathbf{l}|_1=m} 4^{l_1+\cdots+l_r}.$$

By backward induction on the rank r with $1 \le r \le d$, it can be shown as in [16] that

$$S_m(r,d) \le \left(\frac{4}{3}\right)^{d-r} 4^m \binom{m+r-1}{r-1},$$

which finally yields for $r = 1$

$$\|\Delta(\mathcal{I}_n u - u)\|_\beta \le C(d,\alpha,\beta)\ 2^{(3-(\alpha-\beta))n}\|u\|_\alpha$$

if $\alpha - \beta > 3$. This results in the following proposition.

PROPOSITION 3.5. *If $u \in K^{\alpha+3+\gamma}$ with a $\gamma > 0$, then there is a constant $C = C(d,\alpha,\gamma)$ such that*

$$\|\Delta(\mathcal{I}_n u - u)\|_\alpha \le C\ 2^{-\gamma n}\|u\|_{\alpha+3+\gamma}.$$

Similar but long manipulations show that

$$\begin{aligned}\left\|\Delta^2(\mathcal{I}_n u - u)\right\|_\beta &\le C \sum_{m=n+1}^{\infty} 2^{(1-(\alpha-\beta))m} S_m(2,d)\\ &\le C\ (n+2)2^{(3-(\alpha-\beta))(n+1)}\|u\|_\alpha\end{aligned}$$

if $\alpha - \beta > 3$. This results in the following proposition.

PROPOSITION 3.6. *If $u \in K^{\alpha+3+\gamma}$ with a $\gamma > 0$, then there is a constant $C = C(d,\alpha,\gamma)$ such that*

$$\left\|\Delta^2(\mathcal{I}_n u - u)\right\|_\alpha \le C\ (n+2)2^{-\gamma n}\|u\|_{\alpha+3+\gamma}.$$

More care is needed in the treatment of $(I-\Delta)^\zeta$. As we cannot explicitly compute the local contributions $\left\|(I-\Delta)^\zeta \chi_{\mathbf{lq}}\right\|_\beta$, we have to use an upper bound

$$\left\|(I-\Delta)^\zeta \chi_{\mathbf{lq}}\right\|_\beta \le C\ 2^{\beta|\mathbf{l}|_1}(1 + 4^{l_1} + \ldots 4^{l_d})^\zeta$$

that furnishes

$$\left\|(I-\Delta)^\zeta(\mathcal{I}_n u - u)\right\|_\beta \le C\ (n+1)^{d-1}2^{(1+2\zeta-(\alpha-\beta))n}\|u\|_\alpha.$$

PROPOSITION 3.7. *For $\zeta \ge 0$ and $\gamma > 0$ given, there is a constant $C = C(d,\alpha,\gamma,\zeta)$ such that for all $u \in K^{\alpha+1+2\zeta+\gamma}$ it holds that*

$$\left\|(I-\Delta)^\zeta(\mathcal{I}_n u - u)\right\|_\alpha \le C\ (n+1)^{d-1}2^{-\gamma n}\|u\|_{\alpha+1+2\zeta+\gamma}.$$

Let us remark that the Korobov spaces and usual Sobolev spaces are connected by the trivial embeddings

$$H^s \subset K^s \subset H^{s/d} \text{ for } s \ge 0,$$

and the operator $(I-\Delta)^\zeta$ is a lift operator (bijection) between H^α and $H^{\alpha+\zeta}$ (see [33]). Hence, the approximation estimates of this section are not surprising. Putting them this way, the upper estimates for Δ^2 reduce to upper estimates for $(I-\Delta)$. Moreover, let us note that the error estimates for the interpolation operator $\mathcal{I}_n$ are closely related to the d-blended Boolean approximation techniques [10, 4, 11, 32, 34].

4. Discretization of the TDSE. We put to use the previously described interpolation operator for the discretization of the TDSE (1.1). Following the reasoning of [22], we first perform the space discretization by the pseudospectral method. Here, we look for a trigonometric polynomial on the sparse grid,

$$u_n(\mathbf{x}) = \sum_{|\mathbf{l}|_1 \leq n} \sum_{\mathbf{q} \in I_\mathbf{l}} d_{\mathbf{lq}}(t) \chi_{\mathbf{lq}}(\mathbf{x}) = \sum_{\boldsymbol{\omega} \in S'_n} a_{\boldsymbol{\omega}}(t) e^{i\,\boldsymbol{\omega}\cdot\mathbf{x}},$$

such that (1.1) is satisfied at the sparse grid points $\mathbf{x} \in S_n$:

$$\begin{aligned} i\frac{\partial u}{\partial t}(\mathbf{x},t) &= -\Delta u(\mathbf{x},t) + V(\mathbf{x})u(\mathbf{x},t) \quad && \text{for } \mathbf{x} \in S_n \text{ and } t > 0, \\ u(\mathbf{x},0) &= g(\mathbf{x}) && \text{for } \mathbf{x} \in S_n. \end{aligned}$$

Let $\mathbb{V}_n = \operatorname{span}\{e^{i\,\boldsymbol{\omega}\cdot\mathbf{x}}, \boldsymbol{\omega} \in S'_n\}$. We regard the operator $\mathcal{I}_n$ as the composition of the restriction $\mathcal{R}_n$ of the functions in K^α to the sparse grid points and the operator $\mathcal{Q}_n$ that constructs the sparse grid interpolation $u_n \in \mathbb{V}_n$:

$$K^\alpha \xrightarrow{\mathcal{R}_n} \mathbb{C}^{\#S_n} \xrightarrow{\mathcal{Q}_n} \mathbb{V}_n \text{ and } \mathcal{I}_n = \mathcal{Q}_n\mathcal{R}_n.$$

The space-discretized problem is then as follows: find $u_n \in \mathbb{V}_n$ such that

$$\begin{aligned} i\frac{\partial u_n}{\partial t} &= -\Delta u_n + \mathcal{Q}_n \operatorname{diag}(\mathcal{R}_n V)\mathcal{R}_n u_n \quad && \text{for } \mathbf{x} \in \Omega \text{ and } t > 0, \\ u(\mathbf{x},0) &= \mathcal{I}_n g(\mathbf{x}) && \text{for } \mathbf{x} \in \Omega\,. \end{aligned} \tag{4.1}$$

The potential V acts here via the operator B_n:

$$B_n u_n = \mathcal{Q}_n \operatorname{diag}(\mathcal{R}_n V)\mathcal{R}_n u_n = \mathcal{Q}_n\mathcal{R}_n(V u_n) = \mathcal{I}_n(V u_n)\,. \tag{4.2}$$

By the Fourier transform and the variation of constants formula, smooth initial condition g and potential V induce a smooth solution u. The restrictions that we actually set on V result from the sufficient conditions for the convergence of the time scheme below and will be revealed in the next section.

Denote $\mathcal{V}_n := \operatorname{diag}[(V(\mathbf{x}))_{\mathbf{x}\in S_n}]$ and $\mathcal{F}_n$ the discrete Fourier transform on the sparse grid S_n. Setting $\widehat{u}_n := (a_{\boldsymbol{\omega}})_{\boldsymbol{\omega}\in S'_n}$ as the vector of Fourier coefficients, (4.1) is equivalent to

$$\begin{aligned} i\widehat{u}'_n &= \mathcal{D}_n^2\widehat{u}_n + \mathcal{W}_n\widehat{u}_n \quad && \text{for } t > 0, \\ \widehat{u}_n(0) &= \widehat{g}, \end{aligned} \tag{4.3}$$

where $\mathcal{D}_n = \operatorname{diag}[(|\boldsymbol{\omega}|_2^2)_{\boldsymbol{\omega}\in S'_n}]$, with the l^2-norm $|\mathbf{k}|_2^2 = k_1^2 + \cdots + k_d^2$, the operator $\mathcal{W}_n = \mathcal{F}_n\mathcal{V}_n\mathcal{F}_n^{-1}$, and $\widehat{g} = \mathcal{F}_n g$.

We show now that the interpolation error for $u \in K^\alpha$ transfers to the error of the space-discretized problem, as is usual in collocation pseudospectral methods [9]. Denoting the error $e_n = u_n - \mathcal{I}_n u$ and the defect $d_n = \Delta(\mathcal{I}_n u) - \mathcal{I}_n(\Delta u)$, we get the equation in space domain,

$$i\frac{\partial e_n}{\partial t} = -\Delta e_n + \mathcal{I}_n(V e_n) + d_n \quad \text{for } \Omega \text{ and } t > 0,$$

and in frequency domain,

$$i\frac{d\widehat{e}_n}{dt} = \mathcal{D}_n^2\widehat{e}_n + \mathcal{W}_n\widehat{e}_n + \widehat{d}_n \quad \text{for } t > 0.$$

We focus on $\|e_n\|_\alpha$, the L^2-convergence arising for $\alpha = 0$. The counterpart in the frequency domain of the K^α-norm is the discrete norm $\|\widehat{u}\|_\alpha = \|u\|_\alpha$, arising from the scalar product $\langle \widehat{u}, \widehat{v}\rangle_\alpha = \langle u, v\rangle_\alpha$. In contrast to the full grid case, $\mathcal{F}_n$ is not orthogonal, so $\mathcal{W}_n$ is not symmetric, such that the standard arguments used in the full grid or in the Galerkin approach are not applicable. We have

$$\|\widehat{e}_n(t)\|_\alpha \frac{d}{dt}\|\widehat{e}_n(t)\|_\alpha \le \|\widehat{e}_n(t)\|_\alpha \cdot \left\|\mathcal{W}_n\widehat{e}_n + \widehat{d}_n(t)\right\|_\alpha .$$

A work-around involves the condition number of the Fourier transform on the sparse grid $c = \|\mathcal{F}_n\|_\alpha \left\|\mathcal{F}_n^{-1}\right\|_\alpha$, the upper bound B of the potential, and the Gronwall lemma:

$$\|e_n(t)\|_\alpha = \|\widehat{e}_n(t)\|_\alpha \le e^{Bct}\left(\|\widehat{e}_n(0)\|_\alpha + \int_0^t \left(1 + e^{-Bcs}\right)\|d_n(s)\|_\alpha ds\right).$$

The initial error for $g \in K^\alpha$ is given by Proposition 3.4:

$$\|\widehat{e}_n(0)\|_\alpha = \|g - \mathcal{I}_n g\|_\alpha \le C(d,\alpha)\ (n+1)^{d-1}2^{-\gamma n}\|g\|_{\alpha+1+\gamma}.$$

Concerning the defect, Proposition 3.5 intervenes as

$$\begin{aligned}\|d_n(t)\|_\alpha &\le \|\Delta(\mathcal{I}_n u(t) - u(t))\|_\alpha + \|\mathcal{I}_n(\Delta u(t)) - \Delta u(t)\|_\alpha \\ &\le C\ 2^{-\gamma n}\|u(t)\|_{\alpha+3+\gamma} + C\ (n+1)^{d-1}2^{-\gamma n}\|\Delta u(t)\|_{\alpha+1+\gamma}\end{aligned}$$

if u lies in $K^{\alpha+3+\gamma}$. We obtain K^α-convergence of u_n to u of order $O((n+1)^{d-1}2^{-\gamma n})$.

PROPOSITION 4.1. *Let the potential V and the initial condition g be so smooth that the solution u of the continuous Schrödinger equation* (1.1) *is in $K^{\alpha+3+\gamma}$. Then the solution u_n of the space-discretized problem* (4.1) *converges to u :*

$$\begin{aligned}\|u_n(t) - u(t)\|_\alpha \le e^{Bct}C\ (n+1)^{d-1}2^{-\gamma n}&\left(\|g\|_{\alpha+1+\gamma} + \int_0^t \left(1 + e^{-Bcs}\right)\|u(s)\|_{\alpha+2+\gamma}ds\right) \\ &+ C\ 2^{-\gamma n}\int_0^t \left(1 + e^{-Bcs}\right)\|u(s)\|_{\alpha+3+\gamma}ds\,.\end{aligned}$$

Note that the pessimistic factor e^{Bct} is not reflected in our numerical simulations. For the time discretization of the obtained system we carry out the Strang splitting. Over a time step τ, the differential system is solved approximately by computing recursively $\widehat{u}_n^m = (a_{\boldsymbol{\omega}})_{\boldsymbol{\omega}\in S_n'}^m$ via

$$\widehat{u}_n^{m+1} = e^{-\frac{i}{2}\tau\mathcal{W}_n}e^{-i\tau\mathcal{D}_n^2}e^{-\frac{i}{2}\tau\mathcal{W}_n}\widehat{u}_n^m\,,$$

where the action of $e^{-\frac{i}{2}\tau\mathcal{W}_n} = \mathcal{F}_n\,\mathrm{diag}[(e^{-\frac{i}{2}\tau\mathcal{V}(\mathbf{x})})_{\mathbf{x}\in S_n}]\mathcal{F}_n^{-1}$ is inexpensive to compute. This leads to the algorithm for the solution u_n^m that is discrete both in time and space. Note that, in contrast to the full grid case, $\mathcal{F}_n$ is not unitary; hence we do not expect the conservation of the L^2-norm. However, we have seen that the pseudospectral method on sparse grids furnishes a good approximation; hence the computed L^2-norm is nearly 1 and renorming is harmless.

For the convergence analysis of the time scheme, we need commutator lemmas [22]. While complicated, one can carry out the proof in the full grid case using the last formulation on the frequency domain (4.3). This method fails in the sparse grid case, since we do not have an aliasing formula for the Fourier coefficients $a_{\boldsymbol{\omega}}$. Moreover,

the hierarchical trigonometric basis functions $\chi_{\mathbf{lq}}$ are not orthogonal, and hence, the representation (2.3) of the hierarchical Fourier coefficients is not useful here. We are therefore constrained to study the convergence of the Strang splitting in the space domain:

$$u_n^{m+1} = e^{-\frac{i}{2}\tau B_n} e^{i\tau\Delta} e^{-\frac{i}{2}\tau B_n} u_n \,. \tag{4.4}$$

This is the subject of the next sections.

5. Commutator bounds. The local error of the Strang splitting is analyzed in an abstract setting in [22], where sufficient conditions in the presence of unbounded operators are derived, together with an application to the one-dimensional Schrödinger equation. Written in our context of the sparse grid discretization (4.1), the main ingredient for proving the first order convergence of the time scheme is the following commutator lemma. Remember from the equality (4.2) the action of the discrete potential $B_n u_n = \mathcal{Q}_n \operatorname{diag}(\mathcal{R}_n V)\mathcal{R}_n u_n = \mathcal{I}_n(V u_n)$. Denote $A = I - \Delta$ and the commutator $[A, B_n] = AB_n - B_n A = [-\Delta, B_n]$. Fix $\alpha \geq 0$ and $\gamma > 0$.

LEMMA 5.1. *For a smooth potential $V \in K^{\alpha+3+\gamma}$, the commutator bound*

$$\|[A, B_n]u_n\|_\alpha \leq C(d,\alpha) \left\|A^\zeta u_n\right\|_\alpha$$

holds with the constants $C(d,\alpha)$ and $\zeta > d(1 + \frac{1}{2} + \frac{\gamma}{2})$ independent of the level n and $u_n \in K^{\alpha+3+\gamma}$.

Proof. Obviously

$$[A, B_n]u_n = -\Delta\mathcal{I}_n(V u_n) + \mathcal{I}_n(V\Delta u_n)\,.$$

Denoting $v := V u_n \in K^\alpha$ and $w := V\Delta u_n \in K^\alpha$, the focus moves on $\|\Delta\mathcal{I}_n v\|_\alpha$ and $\|\mathcal{I}_n w\|_\alpha$. The bound of the interpolation error from Proposition 3.4 gives for $\gamma > 0$

$$\|\mathcal{I}_n w\|_\alpha \leq \|w\|_\alpha + C\,(n+1)^{d-1} 2^{-\gamma n} \|w\|_{\alpha+1+\gamma}.$$

For a sufficiently large $n \geq n_0(d,\alpha,\gamma)$ we obtain by the algebra property of the Korobov space (3.4)

$$\|\mathcal{I}_n w\|_\alpha \leq C\,\|V\|_\alpha \cdot \|\Delta u_n\|_\alpha + C\,\|V\|_{\alpha+1+\gamma} \cdot \|\Delta u_n\|_{\alpha+1+\gamma}\,.$$

Analogously, using Proposition 3.5 and inequality (3.5), we get

$$\|\Delta\mathcal{I}_n v\|_\alpha \leq C\,\|V\|_{\alpha+2} \cdot \|u_n\|_{\alpha+2} + C\,\|V\|_{\alpha+3+\gamma} \cdot \|u_n\|_{\alpha+3+\gamma}.$$

The first part of Lemma 3.1 and the monotony in α of the Korobov norm yield

$$\|[A, B_n]u_n\|_\alpha \leq C\,\|u_n\|_{\alpha+3+\gamma}.$$

This is the moment for the inverse inequality (3.2) to come into play, providing an exponent $\zeta > d(1 + \frac{1}{2} + \frac{\gamma}{2})$. ∎

Let us move now to the question of second order convergence of the time scheme. We split the corresponding sufficient condition into the following two lemmas.

LEMMA 5.2. *For a smooth potential $V \in K^{\alpha+5+\gamma}$, the commutator bound*

$$\|[A, [A, B_n]]u_n\|_\alpha \leq C(d,\alpha) \left\|A^\xi u_n\right\|_\alpha$$

holds with the constants $C(d,\alpha)$ and $\xi > d(2+\frac{1}{2}+\frac{\gamma}{2})$ independent of the level n and $u_n \in K^{\alpha+5+\gamma}$.

Proof. The double commutator is

$$[A,[A,B_n]]u_n = \Delta^2 B_n u_n - 2\Delta B_n \Delta u_n + B_n \Delta^2 u_n,$$

and therefore, by (4.2), the right-hand side is bounded by

$$\|[A,[A,B_n]]u_n\|_\alpha \le \left\|\Delta^2 \mathcal{I}_n(Vu_n)\right\|_\alpha + 2\|\Delta \mathcal{I}_n(V\Delta u_n)\|_\alpha + \left\|\mathcal{I}_n(V\cdot\Delta^2 u_n)\right\|_\alpha .$$

As in the proof of the previous lemma for $\mathcal{I}_n w$, we have

$$\left\|\mathcal{I}_n(V\cdot\Delta^2 u_n)\right\|_\alpha \le C\,\|V\|_\alpha \left\|\Delta^2 u_n\right\|_\alpha + C\,\|V\|_{\alpha+1+\gamma}\left\|\Delta^2 u_n\right\|_{\alpha+1+\gamma},$$

and hence, by the first part of Lemma 3.1,

$$\left\|\mathcal{I}_n(V\cdot\Delta^2 u_n)\right\|_\alpha \le C\,\|u_n\|_{\alpha+5+\gamma}.$$

Proposition 3.5 and inequality (3.5), together with the first part of Lemma 3.1, give an upper bound for the middle term

$$2\|\Delta \mathcal{I}_n(V\Delta u_n)\|_\alpha \le C\,\|V\|_{\alpha+2}\|u_n\|_{\alpha+4} + C\,\|V\|_{\alpha+3+\gamma}\|u_n\|_{\alpha+5+\gamma}.$$

Concerning the first term, we need Proposition 3.6, inequality (3.6), and the first part of Lemma 3.1 in order to obtain

$$\left\|\Delta^2 \mathcal{I}_n(Vu_n)\right\|_\alpha \le C\,\|V\|_{\alpha+4}\|u_n\|_{\alpha+4} + C\,\|V\|_{\alpha+3+\gamma}\|u_n\|_{\alpha+3+\gamma}.$$

All together, an upper bound for the left-hand side is given by $\|u_n\|_{\alpha+5+\gamma}$. As in the previous proof, the inverse inequality (3.2) shows that ξ should be chosen greater than $d(2+\frac{1}{2}+\frac{\gamma}{2})$. Note that we employed only $K^{\alpha+4+\gamma}$ smoothness of V, but more regularity of the potential (and the initial data) is required in order to have a solution $u_n \in K^{\alpha+5+\gamma}$. □

LEMMA 5.3. *Given $\zeta \ge 0$ and the potential $V \in K^{\alpha+1+2\zeta+\gamma}$, there is an exponent $\xi \ge \zeta$ such that the commutator bound*

$$\left\|[(-A)^\zeta, B_n]u_n\right\|_\alpha \le C\,\left\|(-A)^\xi u_n\right\|_\alpha$$

holds with the constant C independent of the level n and $u_n \in K^{\alpha+1+2\zeta+\gamma}$.

Proof. With $v = Vu_n$ and $w = VA^\zeta u_n$, we have

$$\left\|[(-A)^\zeta, B_n]u_n\right\|_\alpha \le \left\|A^\zeta \mathcal{I}_n v\right\|_\alpha + \|\mathcal{I}_n w\|_\alpha .$$

The convergence result from Proposition 3.4 for w produces a majoration of the last term

$$\|\mathcal{I}_n w\|_\alpha \le C\,\left(\|V\|_\alpha \left\|A^\zeta u_n\right\|_\alpha + \|V\|_{\alpha+1+\gamma}\left\|A^\zeta u_n\right\|_{\alpha+1+\gamma}\right);$$

that is, by the second part of Lemma 3.1,

$$\|\mathcal{I}_n w\|_\alpha \le C\,\|u\|_{\alpha+2\zeta+1+\gamma}.$$

We employ Proposition 3.7 and inequality (3.7) for the first term:

$$\left\|A^\zeta \mathcal{I}_n v\right\|_\alpha \le C\,\left(\|V\|_{\alpha+2\zeta}\|u_n\|_{\alpha+2\zeta} + \|V\|_{\alpha+1+2\zeta+\gamma}\|u_n\|_{\alpha+1+2\zeta+\gamma}\right).$$

Consequently, an upper bound of the left-hand side $\left\|[(-A)^\zeta, B_n]u_n\right\|_\alpha$ is $\|u_n\|_\beta$, with $\beta = \alpha+1+2\zeta+\gamma$. The inverse inequality (3.2) leads then to the choice $\xi \ge d\zeta + d(\frac{1}{2}+\frac{\gamma}{2})$. □

6. Convergence results. The previous lemmas gather into the convergence result, which is ensured by Theorem 2.1 and the immediately following remark from [22]. Let us quote it in full. Let A be the generator of a strongly continuous semigroup e^{tA} on a Banach space X and B a bounded linear operator on X.

THEOREM 6.1.

(a) *Under the condition*

$$\|[A,B]v\| \le c_1\|(-A)^\alpha v\| \text{ for all } v$$

with $\alpha > 0$, *we have*

$$\left\|e^{\frac{1}{2}\tau B}e^{\tau A}e^{\frac{1}{2}\tau B}v - e^{\tau(A+B)}v\right\| \le C_1\tau^2\|(-A)^\alpha v\| \text{ for all } v$$

with C_1 *depending only on* c_1 *and* $\|B\|$.

(b) *If we additionally have that*

$$\|[A,[A,B]]v\| \le c_2\left\|(-A)^\beta v\right\| \text{ for all } v,$$
$$\|[(-A)^\alpha,B]v\| \le c_1\left\|(-A)^\beta v\right\| \text{ for all } v$$

with $\beta \ge \alpha$, *then*

$$\left\|e^{\frac{1}{2}\tau B}e^{\tau A}e^{\frac{1}{2}\tau B}v - e^{\tau(A+B)}v\right\| \le C_2\tau^3\|(-A)^\alpha v\| \text{ for all } v$$

with C_2 *depending only on* c_1, c_2, *and* $\|B\|$.

The local bounds ensured by the previous lemmas yield the following global error bounds for the Strang splitting.

THEOREM 6.2. *Under the conditions of Lemma* 5.1 *and, respectively, of Lemmas* 5.2 *and* 5.3, *the following global error bounds of orders* 1 *and* 2 *hold for the Strang splitting* (4.4) *at time* $t = m\tau$:

$$\|u_n^m - u_n(t)\|_\alpha \le \tau C_1 t \max_{0\le s\le t}\left\|A^\zeta u_n(s)\right\|_\alpha,$$
$$\|u_n^m - u_n(t)\|_\alpha \le \tau^2 C_1 t \max_{0\le s\le t}\left\|A^\xi u_n(s)\right\|_\alpha.$$

It remains only to find a majoration of $\left\|A^\zeta u_n(t)\right\|_\alpha$ in terms of the initial data g and the potential V. In the continuous case, the formula of variation of constants together with the Gronwall lemma and inequality (3.7) yield

$$\left\|A^\zeta u(t)\right\|_\alpha \le \sqrt{2}\left\|A^\zeta g\right\|_\alpha e^{Ct^2\|V\|_\alpha^2} \tag{6.1}$$

and

$$\|u(t)\|_\alpha \le \sqrt{2}\|g\|_\alpha e^{Ct^2\|V\|_\alpha^2}. \tag{6.2}$$

The triangle inequality

$$\left\|A^\zeta u_n(t)\right\|_\alpha \le \left\|A^\zeta u_n(t) - A^\zeta u(t)\right\|_\alpha + \left\|A^\zeta u(t)\right\|_\alpha \tag{6.3}$$

reduces the question to the evaluation of the error $e_n = u_n - u$ in the norm induced by the operator A^ζ on K^α:

$$\|e_n\|_{\zeta,\alpha} := \left\|A^\zeta e_n\right\|_\alpha.$$

Analogously to the method in the proof of Proposition 4.1, we have

$$\|e_n(t)\|_{\zeta,\alpha} \leq e^{Bct}\left(\|e_n(0)\|_{\zeta,\alpha} + \int_0^t \left(1+e^{-Bc}\right)\|d_n(s)\|_{\zeta,\alpha} ds\right).$$

The initial error is provided by Proposition 3.7:

$$\|e_n(0)\|_{\zeta,\alpha} = \left\|A^{\zeta}(\mathcal{I}_n g - g)\right\|_{\alpha} \leq C\,(n+1)^{d-1}2^{-\gamma n}\|g\|_{\alpha+1+2\zeta+\gamma}.$$

We endeavor now to bound the defect d_n:

$$\begin{aligned}\|d_n(s)\|_{\zeta,\alpha} &= \left\|A^{\zeta}(\Delta\mathcal{I}_n u - \mathcal{I}_n\Delta u)\right\|_{\alpha}\\ &\leq \|\Delta(\mathcal{I}_n u - u)\|_{\zeta,\alpha} + \|\mathcal{I}_n(\Delta u) - \Delta u\|_{\zeta,\alpha}.\end{aligned}$$

The last term is known from Proposition 3.7:

$$\|\mathcal{I}_n(\Delta u) - \Delta u\|_{\zeta,\alpha} \leq C\,(n+1)^{d-1}2^{-\gamma n}\|\Delta u\|_{\alpha+1+2\zeta+\gamma}.$$

Remember that $A = I - \Delta$, and so the triangle inequality gives for the first term

$$\left\|A^{\zeta}(\Delta(\mathcal{I}_n u - u))\right\|_{\alpha} \leq \left\|A^{\zeta+1}(\mathcal{I}_n u - u)\right\|_{\alpha} + \left\|A^{\zeta}(\mathcal{I}_n u - u)\right\|_{\alpha},$$

and again Proposition 3.7 yields

$$\|\Delta(\mathcal{I}_n u - u)\|_{\zeta,\alpha} \leq C\,(n+1)^{d-1}2^{-\gamma n}\|u\|_{\alpha+3+2\zeta+\gamma}.$$

We obtain the upper bound for the defect

$$\|d_n(s)\|_{\zeta,\alpha} \leq C\,(n+1)^{d-1}2^{-\gamma n}\|u\|_{\alpha+3+2\zeta+\gamma},$$

with another constant C. Thereupon, the error is bounded by

$$\|e_n(t)\|_{\zeta,\alpha} \leq e^{Bct}C\,(n+1)^{d-1}2^{-\gamma n}\left(\|g\|_{\alpha+1+2\zeta+\gamma} + \int_0^t (1+e^{-Bcs})\|u(s)\|_{\alpha+3+2\zeta+\gamma} ds\right).$$

The last inequality, together with (6.3), (6.2) for $K^{\alpha+3+2\zeta+\gamma}$, and (6.1) produces a bound for $\left\|A^{\zeta}u_n(t)\right\|_{\alpha}$ only in terms of the initial data g and the potential V.

Note that the necessary smoothness increases with the dimension d because of the conditions set on ζ and ξ in the commutator bounds lemmas.

We now turn our attention to simulation results. The concrete implementation issues and the approximation properties are investigated numerically in [15]. Consider now the Schrödinger equation with the small parameter $\epsilon = 0.1$ or $\epsilon = 0.01$:

$$\begin{aligned} i\epsilon\frac{\partial u}{\partial t} &= -\tfrac{1}{2}\epsilon^2\Delta u + Vu \quad && \text{for } \mathbf{x}\in\Omega \text{ and } t>0,\\ u(\mathbf{x},0) &= g(\mathbf{x}) && \text{for } \mathbf{x}\in\Omega. \end{aligned} \tag{6.4}$$

We are concerned here by the time-convergence rate for different smoothness conditions. We consider a smooth potential, a harmonic potential, and a hat function potential:

$$V_1(\mathbf{x}) = \prod_{s=1}^{d}(1-\cos(x_s)), \quad V_2(\mathbf{x}) = \frac{1}{2}\sum_{s=1}^{d}(x_s-\pi)^2, \quad V_3(\mathbf{x}) = \prod_{s=1}^{d}\left(1-\frac{|x_s|}{\pi}\right).$$

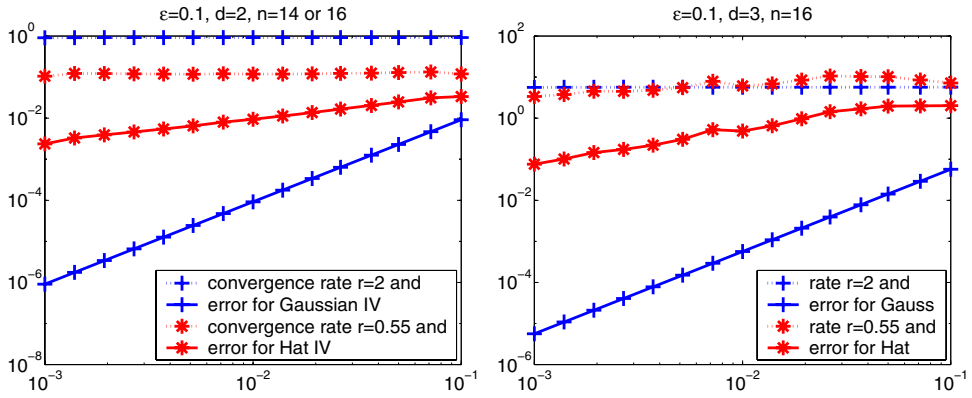

FIG. 6.1. *Error against time step for* $\epsilon = 0.1$*: Smooth potential.*

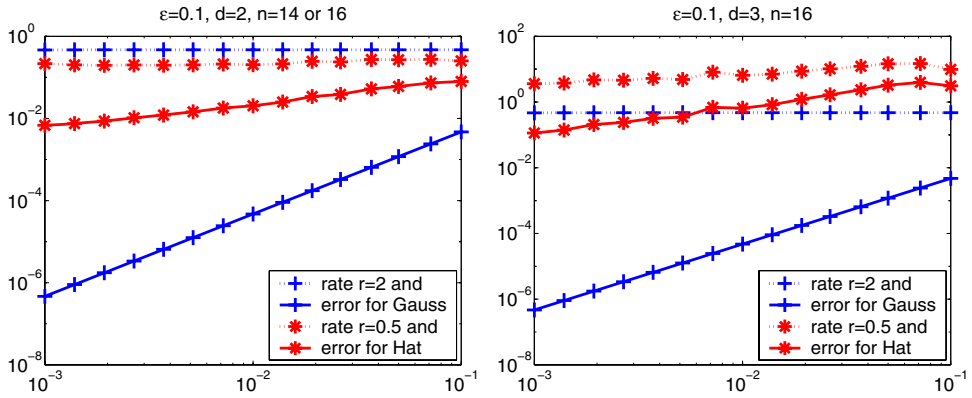

FIG. 6.2. *Error against time step for* $\epsilon = 0.1$*: Harmonic potential.*

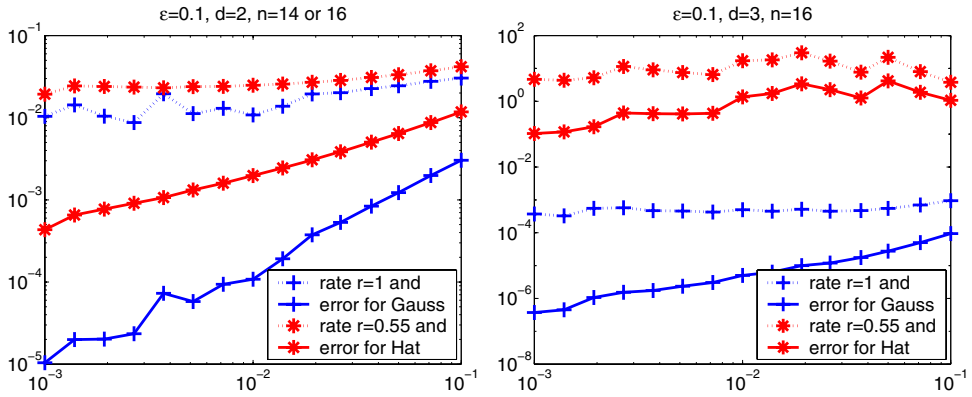

FIG. 6.3. *Error against time step for* $\epsilon = 0.1$*: Hat potential.*

The initial value is either the Gaussian

$$g(\mathbf{x}) = \left(\frac{2}{\pi\epsilon}\right)^{d/4} \exp\left(-\frac{\left(x_1 - \frac{3\pi}{2}\right)^2 + \sum_{s=2}^{d}(x_s - \pi)^2}{\epsilon}\right)$$

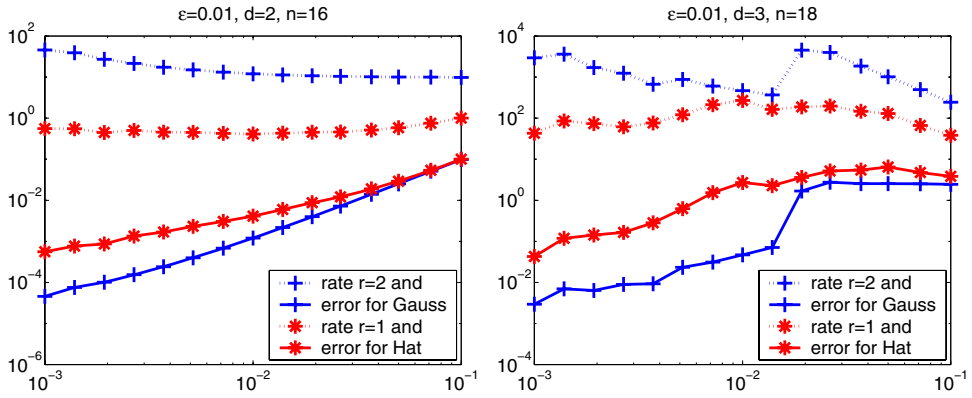

FIG. 6.4. *Error against time step for* $\epsilon = 0.01$*: Smooth potential.*

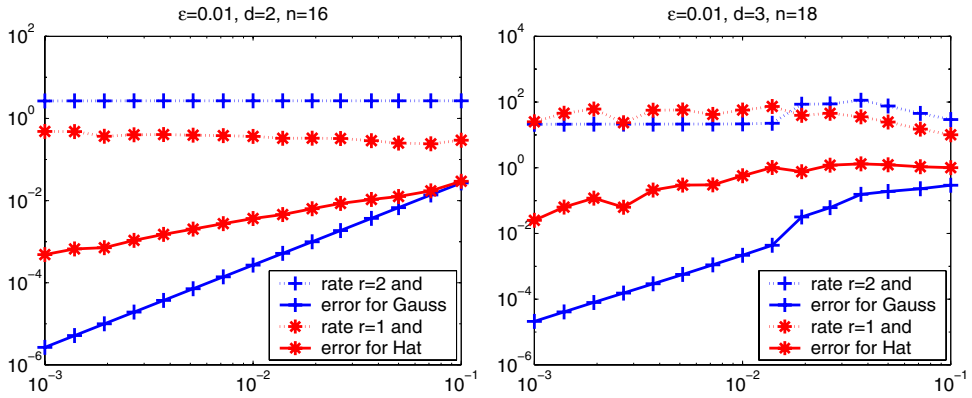

FIG. 6.5. *Error against time step for* $\epsilon = 0.01$*: Harmonic potential.*

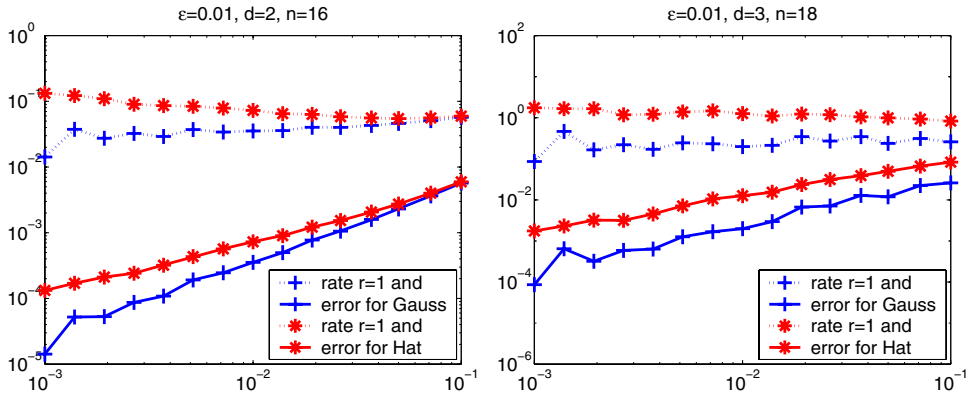

FIG. 6.6. *Error against time step for* $\epsilon = 0.01$*: Hat potential.*

or the hat function

$$h(\mathbf{x}) = \left(\frac{3}{\pi\sqrt{\epsilon}}\right)^{d/2} \cdot \left(1 - \left(\frac{2}{\pi\sqrt{\epsilon}}\right)\left|x_1 - \frac{3\pi}{2}\right|\right) \cdot \prod_{s=2}^{d}\left(1 - \left(\frac{2}{\pi\sqrt{\epsilon}}\right)\left|x_s - \frac{\pi}{2}\right|\right).$$

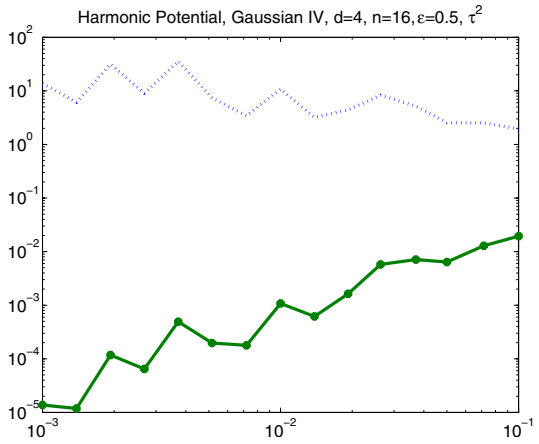

FIG. 6.7. *Error and convergence rate $r = 2$ against time step in four dimensions.*

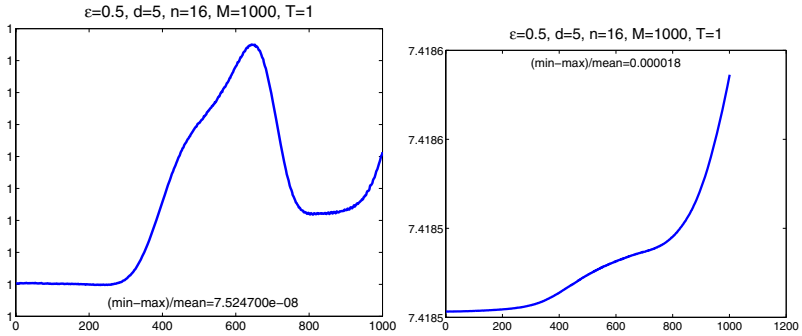

FIG. 6.8. *Time evolution of the norm and the energy for $d = 5$.*

Figures 6.1–6.7 show the norms $\left\|\widehat{u}_n^m - \widehat{u}_n^M\right\|_0$ at $t = m\tau = 1$ for $M = 10^4$ against different step sizes. The dashed lines indicate the errors divided by τ^r, with the convergence rate r. An aliasing error in the initial data may arise as an effect of multiple scales (that is, ϵ is small) or because of a too sparse grid in a high dimensional space. We try to avoid the aliasing in the interpolation of the initial values by adapting the resolution n to the dimension d and by reducing the computational domain Ω to a smaller expected domain. This results in the loss of smoothness of the potential V_1 at the ends of the interval and hence in the deterioration of the time convergence rate, as we can see in Figure 6.4. In the case of the harmonic oscillator on $[-\pi, \pi]^4$ with $\epsilon = 0.5$, the smoothness assumption does not hold on the boundary; this results in a slight deterioration of the convergence rate as shown in Figure 6.7. The improvement in the smoothness of the potential directly influences the numerical solution. The smoothness is inherent to this approach. At the same time, the accuracy is affected by the greater aliasing effect of the higher dimensions or of the smaller parameter ϵ. This is not surprising, since fixed domain truncation methods do not work well in a multiscaling context (see [5, Chapter 17]), and the sparse grids cannot cure this difficulty. For high resolutions of the space discretization we observed numerically the conservation of the L^2-norm for long times T (see Figure 6.8). This is expected if the convergence assumptions are fulfilled. What is remarkable is that the energy norm

$\langle u_n, (V - \frac{1}{2}\epsilon\Delta)u_n\rangle$ is almost conserved along the time iteration, too [15]. In the full grid case, the proof of the conservation properties resides on the orthogonality of the Fourier transform operator [22], a fact lacking here.

The exponential dependence on the dimension of the constants together with the need of a small parameter ϵ for relevant applications hamper us in using this technique on high dimensional problems. We may report simulations with norm conservation until dimension 5 and level 16.

7. Conclusion. Joined to the Strang splitting, the sparse grid discretization of the TDSE makes possible a good numerical solution in spaces of dimension up to 5. We proved first and second order convergence (in time) results under suitable smoothness assumptions. The method displays the typical efficiency of the approximations based on sparse grids. This paves the way for applications in computational chemistry such as conical crossings [24, 25]. A separate paper [15] addresses the concrete algorithmic details and more elaborate simulation results in higher dimensional spaces.

Acknowledgments. I am grateful to Christian Lubich for patient discussions on the Strang splitting and the commutator lemmas. I thank the referees for their very valuable comments and suggestions.

L^∞- AND L^2-ERROR ESTIMATES FOR A FINITE VOLUME APPROXIMATION OF LINEAR ADVECTION*

BENOIT MERLET†

Abstract. We study the convergence of the upwind finite volume scheme applied to the linear advection equation with a Lipschitz divergence-free speed in $\mathbf{R}^d$. We prove an $h^{1/2-\varepsilon}$-error estimate in the $L^\infty(\mathbf{R}^d \times [0,T])$-norm for Lipschitz initial data. The expected optimal result is an $h^{1/2}$-error estimate. In a second part, we also prove an $h^{1/2}$-error estimate in the $L^\infty(0,T;L^2(\mathbf{R}^d))$-norm for initial data in $H^1(\mathbf{R}^d)$.

Key words. scalar conservation laws, advection equation, finite volume method, error estimate

1. Introduction.

We consider here the numerical approximation by the explicit upwind finite volume (FV) scheme of the following general nonlinear hyperbolic scalar problem in d-dimensional space,

$$\left\{\begin{array}{rcccl} u_t + \operatorname{div}(Vf(u)) & = & 0 & \text{on} & \mathbf{R}_x^d \times \mathbf{R}_{+t}, \\ u(x,0) & = & u_0(x) & \text{on} & \mathbf{R}^d, \end{array}\right. \tag{1.1}$$

where the vector field V is a Lipschitz function of x and t with values in $\mathbf{R}^d$ and is divergence free.

FV schemes are widely used for the numerical approximation of such equations and more generally of conservative hyperbolic systems. They have several good behaviors: they can handle general meshes, they have a compact numerical stencil, they conserve the quantity $\int_{\mathbf{R}^d} u$, and under some hypothesis (CFL condition) they have stability properties. Moreover, in general, the solutions to (1.1) are not unique, and, again under some hypothesis concerning the time step and the regularity of the mesh, FV schemes do converge towards the physical (entropic) solution when the mesh size h tends to 0.

FV methods are also used to approximate convection-diffusion systems—see, e.g., [8, 9] for error estimates. In general the diffusion term provides energy estimates, the situation is more difficult if in some regions of the domain, the solution is derived by the convection terms. In this case, techniques developed for hyperbolic problems may be useful—see [10, 14] and the references therein.

However, the convergence theory for FV schemes applied to (1.1) is far from being complete. The first result is due to Kuznecov [11], who proved an $h^{1/2}$-error estimate in the $L^\infty(0,T;L^1_x)$-norm for BV data and a family of structured Cartesian meshes of mesh size h tending to 0. The method of Kuznecov has been extended to the case of nonregular Cartesian meshes or almost Cartesian meshes (see [3]). This method has also been extended to a family of unstructured uniformly regular meshes, but in this last case only an $h^{1/4}$-convergence rate is obtained (see Cockburn, Coquel,

†Université Paris Nord - Institut Galilée, LAGA (Laboratoire d'Analyse, Géométrie, et Applications), Avenue J. B. Clément, 93430 Villetaneuse, France (merlet@math.univ-paris13.fr).

and LeFloch [2], Vila [15], and Eymard, Gallouët, and Herbin [7]). We emphasize that for BV initial data, numerical experiments show that the error behaves like $h^{1/2}$ regardless of whether the family of meshes is structured.

Remark 1.1. If the exact solution is more regular, the error may behave like h or even h^2. This supraconvergence has been linked to geometric properties of the meshes—see [1] and the references therein.

In this paper, we focus on the advection equation (i.e., the linear case, (1.1) with $f(u) := u$) with $W^{1,p}$ initial data. Even in this case, it is more difficult to establish convergence results than in the setting of finite difference (FD) methods. Indeed, in general, FV schemes are not consistent in the FD classical sense and Lax's theorem cannot be used. From numerical experiments and existing results on uniform Cartesian meshes, we expect an $h^{1/2}$ convergence rate in the $L^\infty(0,T;L^p_x)$-norm (provided that the CFL condition is satisfied and that the meshes are uniformly regular—see the condition (1.6) below).

In [12] the author and Vovelle proved this result for $p = 1$ (BV data) under a strict CFL condition in the general case and under a sharp CFL condition when the speed does not depend on the time variable.

In [5] Després showed the result in the case $p = 2$ under a strict CFL condition and for a constant speed. His proof is based on the study of the dissipation of the consistency error by the scheme and on a generalization of the Lax theorem. The lack of consistency of the scheme is compensated by the particular structure of the consistency error.

We also refer the reader to Vila and Villedieu [16], who proved (under a strict CFL condition) an $h^{1/2}$-error estimate in the L^2_{loc} space-time norm for the FV approximation of Friedrichs hyperbolic systems with H^1 data—the linear advection equation appears to be a particular case of these systems. Their proof is based on energy estimates and on the weak consistency of the scheme in the dual of H^1_{loc}.

The case $p > 2$ has been attacked by Després. In particular, in [6] an $h^{1/4-\varepsilon}$-estimate is obtained in the L^∞-norm for Lipschitz data.

Here, we study the case $2 \le p \le \infty$. For $p = 2$, we obtain the expected result under a strict CFL condition—Theorem 1.8. The ingredients of the proof are essentially contained in [12]: the conservation of the L^2-energy of the exact solution and energy estimates for the approximate solution coming from the dissipative properties of the scheme.

In the case $p = +\infty$, we prove an $h^{1/2-\varepsilon}$-error estimate in the L^∞-norm for Lipschitz data under a strict CFL condition—Theorem 1.6. In the proof, the fact that the scheme is consistent of order 1 for the dual norm of the BV seminorm is crucial—see section 2.3 for a precise description. This result is again the consequence of the structure of the consistency error: the size of the error is $\mathcal{O}(1)$, but the integral of this error on any finite union of cells ω is controlled by the measure of the boundary of ω times h—and not only by the measure of ω.

Remark 1.2. In general, in the nonlinear setting of (1.1), the flow is not continuous with respect to the $L^p(\mathbf{R}^d)$-norm when $p > 1$. Thus the extension of Theorems 1.6 and 1.8 to nonlinear problems does not seem relevant. Moreover, in this paper (and also in [12]) the linearity hypothesis is strongly used in several places. Nevertheless, in the case $p = 1$, one may hope proving error estimates for nonlinear problems via kinetic formulation of conservation laws. In this theory, (1.1) is replaced by a family of linear equations coupled by nonlinear constraints (see [13] for a result in this direction).

The proof of Theorem 1.6 may be sketched as follows. By duality, we are led to prove Theorem 1.7 concerning the behavior of the FV approximation when the initial data is a probability measure concentrated on one cell. Namely, if K_0 is this cell, the initial condition is $u_0 := 1/|K_0|\,\mathbf{1}_{K_0}$. Let u be the exact solution to the advection equation associated with this initial condition and let $\boldsymbol{u}$ be the corresponding FV approximation. Roughly speaking, Theorem 1.7 says that the following estimate holds:

$$\int_{\mathbf{R}^d\times\mathbf{R}^d} \|x-y\| u(x,T)\boldsymbol{u}(y,T)dxdy \leq Ch^{1/2-\varepsilon}. \tag{1.2}$$

For simplicity, assume that the speed is constant: $V(x,s)=\mathbf{V}$; in this case the exact solution is given by $u(\cdot,t) = 1/_{|K_0|}\,\mathbf{1}_{K_0+\mathbf{V}t}$. Letting $x_0\in K_0$ and $R>0$, we define $\Omega_R(t) := \{x : \|x-x_0-\mathbf{V}t\|\geq R\}$. The exact solution $u(\cdot,t)$ is concentrated in an h-neighborhood of $x_0+\mathbf{V}t$. So, in order to get (1.2), we have to prove that for $R\geq Ch^{1/2-\varepsilon}$, the quantity $\int_{\Omega_R(t)}\boldsymbol{u}(\cdot,t)$ remains small for $0<t\leq T$. For $k\geq 0$, we set $R_k := kh^{1/2}$ and $\omega_k(t) := \Omega_{R_k}(t)$. We will prove that when k tends to $+\infty$ the quantity $\int_{\omega_k(t)\setminus\omega_{k+1}(t)}\boldsymbol{u}(\cdot,t)$ decreases fast.

Via the Cauchy–Schwarz inequality, we are led to study the L^2-energy, $Q_k(t) := \int_{\omega_k(t)}\boldsymbol{u}^2(\cdot,t)$. At time 0, $Q_k(0)=0$. Next, the evolution of Q_k is driven by two phenomenons:

(1) the dissipation of the scheme decreases the energy and provides energy estimates,

(2) a source term located on the boundary of $\omega_k(t)$ may increase the energy.

We use the energy identity of section 2.2 and the weak consistency result of section 2.3 to prove (recursively on k) that $Q_k(t)$ is bounded by $t^k h^{-d}/k!$. In fact, in the proof, the characteristic functions of the sets $\omega_k(t)$ are replaced by smooth cutoff functions in the neighborhood of ∞.

The rest of the paper is organized as follows. First we supplement this introduction by describing the linear advection problem (section 1.1), the explicit upwind FV scheme (section 1.2), and the main results of the paper (section 1.3).

Section 2 is devoted to the proof of Theorems 1.6 and 1.7. In section 2.1, we prove by duality that Theorem 1.6 ensues from Theorem 1.7. In section 2.2, we establish an identity satisfied by the $L^2(\Psi^2 d\lambda(x))$-energy of the numerical solution—in the applications the weight Ψ^2 will be a cutoff function in the neighborhood of ∞. In section 2.3 we prove that the implicit in time downwind FV scheme is consistent of order 1 in a weak sense. Applying the results of sections 2.2 and 2.3, we prove in section 2.4 that if two solutions of the advection equation Ψ, $\overline{\Psi}$ satisfy $0\leq\Psi\leq 1$ and $\mathbf{1}_{|\operatorname{supp}\Psi}\leq\overline{\Psi}$, the growth of the $L^2(\Psi^2 d\lambda(x))$-energy of the numerical solution between times 0 and T is controlled by its $L^2(\overline{\Psi}^2 d\lambda(x)dt)$-energy. Finally, in section 2.5, we build a decreasing sequence of cutoff functions, we apply recursively the result of section 2.4 and we end the proof of Theorem 1.7.

Theorem 1.8 is proved in section 3. In section 3.1, we recall that the FV approximation satisfies the weak formulation of the advection equation up to an error term, we prove an energy inequality, and we give some technical results concerning some projections of the exact solution on the mesh. In section 3.2 we derive successive estimates yielding Theorem 1.8.

1.1. The linear advection equation. We consider the linear advection problem in $\mathbf{R}^d$,

$$\begin{cases} u_t + \operatorname{div}(Vu) = 0, & x \in \mathbf{R}^d, t \in \mathbf{R}_+, \\ u(x,0) = u_0(x), & x \in \mathbf{R}^d, \end{cases} \tag{1.3}$$

where we suppose that $V \in W^{1,\infty}(\mathbf{R}^d \times \mathbf{R}_+, \mathbf{R}^d)$ satisfies

$$\operatorname{div} V(\cdot,t) = 0 \qquad \forall t \in \mathbf{R}_+. \tag{1.4}$$

The problem (1.3) is well-posed in $L^1_{loc}(\mathbf{R}^d)$. Let us recall the following classical result (see Theorem 1 in [12] for a sketch of the proof).

THEOREM 1.1. *For every $u_0 \in L^1_{loc}(\mathbf{R}^d)$, the problem (1.3) has a unique weak solution u, in the sense that $u \in L^1_{loc}(\mathbf{R}_+ \times \mathbf{R}^d)$ is such that, for every compactly supported test function $\phi \in W^{1,\infty}(\mathbf{R}^d \times \mathbf{R}_+)$,*

$$\int_{\mathbf{R}_+} \int_{\mathbf{R}^d} u(\phi_t + V \cdot \nabla \phi) dx dt + \int_{\mathbf{R}^d} u_0(x)\, \phi(x,0) dx = 0. \tag{1.5}$$

This solution is given by the characteristic formula

$$u(x,t) = u_0(X(x,t)) \qquad \forall (x,t) \in \mathbf{R}^d \times \mathbf{R}_+$$

with X defined by $X(\cdot,t) := Y(\cdot,t)^{-1}$, where then Y solves the Cauchy problem $\partial_t Y(x,t) = V(Y(x,t),t)$; $Y(x,0) = x$.

Moreover, for every $t \geq 0$, $X(\cdot,t) : \mathbf{R}^d \to \mathbf{R}^d$ is one to one and onto, and the map X belongs to $W^{1,\infty}_{loc}(\mathbf{R}^d \times \mathbf{R}_+, \mathbf{R}^d)$. More precisely, for every $T \geq 0$, $X - Id_{\mathbf{R}^d_x}$ and $Y - Id_{\mathbf{R}^d_x}$ belong to $W^{1,\infty}(\mathbf{R}^d \times [0,T])$ and there exists $C_0 \geq 1$ depending only on T, $\|V\|_{W^{1,\infty}}$, and d such that $\forall x \in \mathbf{R}^d$, $\forall t \in [0,T]$,

$$\|X(x,t) - x\| \leq C_0\, t, \qquad \|\nabla X(x,t)\| \leq C_0, \qquad \|\partial_t X(x,t)\| \leq C_0,$$

$$\|Y(x,t) - x\| \leq C_0\, t, \qquad \|\nabla Y(x,t)\| \leq C_0, \qquad \|\partial_t Y(x,t)\| \leq C_0.$$

Finally, for every $t \geq 0$, $X(\cdot,t)$ preserves the Lebesgue measure λ on $\mathbf{R}^d$, i.e.,

$$\lambda(X(E,t)) = \lambda(E) \qquad \text{for every Borel subset } E \text{ of } \mathbf{R}^d.$$

For $t \geq 0$, the map $u_0 \mapsto u(\cdot,t)$ acts on $W^{1,\infty}(\mathbf{R}^d)$ as a continuous linear operator and if $u_0 \in W^{1,\infty}(\mathbf{R}^d)$, then $t \mapsto u(\cdot,t)$ is locally Lipschitz from $\mathbf{R}_+$ to $L^\infty(\mathbf{R}^d)$. More precisely, the characteristic formula yields the following.

COROLLARY 1.2. *Let $0 \leq t \leq T$, there exists a constant C_0 depending on $\|V\|_{W^{1,\infty}}$ and T such that if $u_0 \in W^{1,p}(\mathbf{R}^d)$, for some $1 \leq p \leq \infty$, then*

$$\|u(\cdot,s) - u(\cdot,t)\|_{L^p} \leq C_0 \|\nabla u_0\|_{L^p} |s-t|, \qquad 0 \leq s,t \leq T,$$

$$\|\nabla u(\cdot,t)\|_{L^p} \leq C_0 \|\nabla u_0\|_{L^p}, \qquad 0 \leq t \leq T.$$

1.2. FV scheme. The FV scheme which approximates (1.3) is defined on a mesh $\mathcal{T}$ which is a family of closed connected polygonal subsets with disjoint interiors covering $\mathbf{R}^d$; the time half-line is meshed by regular cells of size $\delta t > 0$. We also assume that the partition $\mathcal{T}$ satisfies the following properties: the common interface of two control volumes is included in a hyperplane of $\mathbf{R}^d$ and

$$\text{there exists } \alpha > 0 \text{ such that } \begin{cases} \alpha h^d \le |K|, \\ |\partial K| \le \alpha^{-1} h^{d-1} \quad \forall K \in \mathcal{T}, \end{cases} \tag{1.6}$$

where h is the size of the mesh: $h := \sup\{diam(K),\, K \in \mathcal{T}\}$, $|K|$ is the d-dimensional Lebesgue measure of K, and $|\partial K|$ is the $(d-1)$-dimensional Lebesgue measure of ∂K. If K and L are two control volumes having a common edge, we say that L is a neighbor of K and denote (quite abusively) $L \in \partial K$. We also denote by $K \vert L$ the common edge and by $\mathbf{n}_{KL}$ the unit normal to $K \vert L$ pointing outward from K. We set

$$V_{KL}^n := \frac{1}{\delta t} \int_{n\delta t}^{(n+1)\delta t} \int_{K \vert L} V \cdot \mathbf{n}_{KL}.$$

We denote by $K_n := K \times [n\delta t, (n+1)\delta t)$ a generic space-time cell and by $\mathcal{M} := \mathcal{T} \times \mathbf{N}$ the space-time mesh. The sets ∂K_n^-, ∂K_n^+ are defined by

$$\partial K_n^- := \{L \in \partial K, V_{KL}^n < 0\}, \qquad \partial K_n^+ := \{L \in \partial K, V_{KL}^n \ge 0\}.$$

In the same way we set $K \vert L_n := K \vert L \times [n\delta t, (n+1)\delta t)$.

We will assume that a strict CFL condition is satisfied:

$$\sum_{L \in \partial K_n^-} \delta t |V_{KL}^n| \le (1-\xi)|K| \qquad \forall K_n \in \mathcal{M} \text{ for some } 1 \ge \xi > 0. \tag{1.7}$$

Moreover, in order to avoid the occurrence of terms with factor $\delta t/h$ in our estimates, we add to (1.7) the following condition: there exists $c_0 \ge 0$ such that

$$\delta t \le c_0 h. \tag{1.8}$$

Remark 1.3. In general, (1.7) does not imply (1.8). Indeed, if for every nonnegative integer q, we have $\int_q^{q+1} V(\cdot, s)\, ds \equiv 0$, then the CFL condition (1.7) is satisfied with $\delta t = 1$.

The upwind FV method with explicit time discretization is defined by the following set of equations:

$$u_K^0 := \frac{1}{|K|} \int_K u_0(x)\, dx \qquad \forall K \in \mathcal{T}, \tag{1.9}$$

$$u_K^{n+1} := u_K^n + \frac{\delta t}{|K|} \sum_{L \in \partial K_n^-} -V_{KL}^n (u_L^n - u_K^n) \qquad \forall K_n \in \mathcal{M}. \tag{1.10}$$

We then denote by $\boldsymbol{u}$ the approximate solution of (1.3) defined by the FV scheme,

$$\boldsymbol{u}(\cdot, t) := u_K^n \quad \text{a.e. in K for every } t \in [n\delta t, (n+1)\delta t); \quad K_n \in \mathcal{M}. \tag{1.11}$$

Classical results. The divergence-free assumption (1.4) leads to the following identity.

LEMMA 1.3. *Under the hypothesis* (1.4) *on the divergence of* V, *one has*

$$\sum_{L\in\partial K} V_{KL}^n = \sum_{L\in\partial K_n^-} V_{KL}^n + \sum_{L\in\partial K_n^+} V_{KL}^n = 0 \qquad \forall\, K_n \in \mathcal{M}.$$

Under the CFL condition (1.7) the FV scheme is order preserving.

PROPOSITION 1.4. *Under condition* (1.7), *the linear application* $\mathcal{L} : (u_K^n) \mapsto (u_K^{n+1})$ *defined by* (1.10) *is order preserving and stable for the* L^∞*-norm.*

Proof. Equation (1.10) gives

$$u_K^{n+1} = \left(1 - \sum_{L\in\partial K_n^-} \frac{-V_{KL}^n \delta t}{|K|}\right) u_K^n + \sum_{L\in\partial K_n^-} \frac{-V_{KL}^n \delta t}{|K|} u_L^n;$$

i.e., under (1.7), u_K^{n+1} is a convex combination of $u_K^n, (u_L^n)_{L\in\partial K_n^-}$. The stability result follows from $\mathcal{L}(1) = 1$. ∎

From Lemma 1.3 it is not difficult to see that the quantity $\sum_{K\in\mathcal{T}} |K| u_K^n$ is conserved. By the Crandall–Tartar lemma [4], this fact and Proposition 1.4 imply the following.

PROPOSITION 1.5. *Under condition* (1.7), *the scheme* $\mathcal{L} : (u_K^n) \mapsto (u_K^{n+1})$ *is stable for the* L^1*-norm*,

$$\sum_{K\in\mathcal{T}} |K||u_K^{n+1}| \le \sum_{K\in\mathcal{T}} |K||u_K^n| \qquad \forall n \ge 0.$$

Interpolating between L^1*- and* L^∞*-stabilities, the scheme is stable for* L^p*-norms*, $1 < p < \infty$.

1.3. Main results. We now assume that $V \in W^{1,\infty}(\mathbf{R}^d \times \mathbf{R}_+, \mathbf{R}^d)$ satisfies (1.4), that $\mathcal{T}$ is a mesh of size $h > 0$ satisfying conditions (1.6), and that the time step $\delta t > 0$ satisfies the CFL conditions (1.7) and (1.8). We fix a time $T \ge \delta t$ and we assume that there exists an integer $N \ge 0$ such that $T = (N+1)\delta t$.

In what follows, given an initial condition $u_0 \in L^1_{loc}(\mathbf{R}^d)$, the function $u \in C(\mathbf{R}_+, L^1_{loc}(\mathbf{R}^d))$ denotes the exact solution to (1.3) and $\boldsymbol{u}$ its numerical approximation obtained by the upwind FV method (1.9)–(1.11). In the results and in the proofs, $C_0 \ge 1$ is the constant introduced in Theorem 1.1 and Corollary 1.2; this constant depends only on T, $\|V\|_{W^{1,\infty}}$, and d. The letter C denotes various constants which are nondecreasing functions of α^{-1}, c_0, $\|V\|_{W^{1,\infty}}$, and d but do not depend on h, δt, ξ, u_0, or T.

We have the following error estimate for Lipschitz data.

THEOREM 1.6. *Under a strict CFL condition* ($\xi > 0$), *there exists* $h_\star > 0$ *depending only on* C_0, ξ, T, *and* c_0 *such that if* $h \le h_\star$, *we have for every* $u_0 \in W^{1,\infty}(\mathbf{R}^d)$,

$$\|\boldsymbol{u}(\cdot,T) - u(\cdot,T)\|_{L^\infty} \le C C_0^2\, \xi^{-1/2} \|\nabla u_0\|_{L^\infty} T^{1/2} h^{1/2} \Gamma^{-1}(C_0^2 \xi^{-1} T h^{-1}),$$

where $\Gamma^{-1} : [1, +\infty) \to [2, +\infty)$ *is the inverse Euler* Γ *function—in particular* $\Gamma^{-1}(n!) = n + 1$.

This result will be the consequence of the following theorem.

THEOREM 1.7. *Let $K_0 \in \mathcal{T}$, $x_0 \in K_0$, and $u_0 := 1/|K_0|\,\mathbf{1}_{K_0}$; then under a strict CFL condition, for $h \le h_\star$, as above, we have*

$$\int_{\mathbf{R}^d} \|x - Y(x_0,T)\|\,\boldsymbol{u}(x,T)dx \le CC_0^2\xi^{-1/2}T^{1/2}h^{1/2}\Gamma^{-1}(C_0^2\xi^{-1}Th^{-1}).$$

Remark 1.4. The dependency on T in Theorems 1.6 and 1.7 is not interesting in the general case since C_0 depends on T. But in the case where the speed is independent of x: $V(x,t) := \mathbf{V}(t)$, we have $X(x,t) = x - \int_0^t \mathbf{V}(s)ds$ and we can choose $C_0 = \|\mathbf{V}\|_\infty$ in Theorem 1.1. This is also valid for Theorem 1.8 below.

Remark 1.5. The function Γ^{-1} is very slowly increasing (for example, $\Gamma^{-1}(R) = o(\ln R)$) but we do not obtain an $h^{1/2}$-estimate. Proving this result (or exhibiting a counterexample) remains an open problem.

In this L^2 setting, we need an additional assumption on the mesh: there is no small interface:

$$\alpha h^{d-1} \le |K|L| \qquad \forall K \in \mathcal{T},\ L \in \partial K. \tag{1.12}$$

THEOREM 1.8. *Assume that* (1.6), (1.12), (1.7), *and* (1.8) *hold. Then for every u_0 in $H^1(\mathbf{R}^d)$, we have*

$$\begin{aligned}
&\|u(\cdot,T) - \boldsymbol{u}(\cdot,T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot,0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot,T)\|_{L^2}^2 \\
&\qquad \le C(1+C_0^2)\xi^{-1}\,\|u_0\|_{H^1}^2\,Th + C\|u_0\|_{H^1}^2h^2, \\
&\mathcal{F}(\boldsymbol{u},T) \le C(1+C_0^2)\xi^{-2}\,\|u_0\|_{H^1}^2\,Th + C\|u_0\|_{H^1}^2h^2,
\end{aligned}$$

with

$$\mathcal{F}(\boldsymbol{u},T) := \sum_{n=0}^{N}\sum_{K\in\mathcal{T}} |K||u_K^{n+1} - u_K^n|^2 + \sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} \delta t|V_{KL}^n|\,|u_L^n - u_K^n|^2.$$

Remark 1.6. Let us decompose the approximate solution $\boldsymbol{u}(\cdot,T)$ into collinear and orthogonal parts with respect to $u(\cdot,T)$: we write $\boldsymbol{u}(\cdot,T) = \lambda u(\cdot,T) + v(\cdot,T)$ with $\lambda \in \mathbf{R}$ and $v \in L^2(\mathbf{R}^d)$ such that $\int_{\mathbf{R}^d} u(\cdot,T)v = 0$.

We will see in the following that the L^2-norm of the discrete solution is nonincreasing. Since the L^2-energy of the exact solution is conserved, we deduce that $|\lambda| \le 1$. From the first estimate of Theorem 1.8 we have $0 \le \|u(\cdot,T)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot,T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot,T) - u(\cdot,T)\|_{L^2}^2 \le \mathcal{O}(h)$, so

$$0 \ \le\ \left[(1-\lambda)^2 + (1-\lambda^2)\right]\|u(\cdot,T)\|_{L^2}^2 + \|v\|_{L^2}^2 \ \le\ \mathcal{O}(h).$$

Thus, $\lambda = 1 + \mathcal{O}(h)$ and $\|v\|_{L^2} = \mathcal{O}(h^{1/2})$. The main part of the error is orthogonal to $u(\cdot,T)$.

Remark 1.7. Using the technique of [12], we may prove that in the case of a constant speed $V(x,t) = \mathbf{V}$, the result also holds under a sharp CFL condition. If moreover the speed V is constant, then assumption (1.12) is not necessary—see Remark 3.2.

Remark 1.8. The conditions (1.6), (1.12) on the mesh are not stringent. They are satisfied in practice by every efficient mesh generator.

Conventions and notations. If (X,μ) is a measurable set with finite (positive) measure and $\phi \in L^1(X)$, we denote the mean value of ϕ over X by

$$\langle \phi \rangle_X := \fint_X \phi d\mu := \frac{1}{\mu(X)} \int_X \phi d\mu.$$

The characteristic function of a set X is denoted by $\mathbf{1}_X$.

For $R>0$, $B(R)$ denotes the open ball centered at 0 with radius R in $\mathbf{R}^d$.

In what follows, we will use several functions in $L^1_{loc}(\mathbf{R}^d \times \mathbf{R}_+)$ which are almost everywhere constant on each space-time cell K_n. We will use the following convention: when $(\phi_{K_n})_{K_n \in \mathcal{M}}$ is a family of real numbers, then the bold type letter $\boldsymbol{\phi}$ denotes the function $\boldsymbol{\phi} := \sum_{K \in \mathcal{M}} \phi_K^n \mathbf{1}_{K_n}$. When ϕ belongs to $C(\mathbf{R}^d \times \mathbf{R}_+, \mathbf{R})$, then, for $K_n \in \mathcal{M}$, $\phi_K^n := \langle \phi(\cdot, n\delta t) \rangle_K$ denotes the mean value of ϕ on K at time $n\delta t$ and in this case $\boldsymbol{\phi} = \sum_{K \in \mathcal{M}} \langle \phi(\cdot, n\delta t) \rangle_K \mathbf{1}_{K_n}$. This last convention holds for any letter φ but u (u is always the exact solution to (1.3) and $\boldsymbol{u}$ its FV approximation).

For every $K_n \in \mathcal{M}$, we set $V_K^n := -\sum_{L \in \partial K_n^-} V_{KL}^n = \sum_{L \in \partial K_n^+} V_{KL}^n$ and for every $t \geq 0$,

$$\mathcal{M}_t := \{K_n \in \mathcal{M} \ : \ 0 \leq n < t/\delta t\},$$

in particular, for $T = (N+1)\delta t$, $\mathcal{M}_T = \{K_n \ : \ K \in \mathcal{T}, 0 \leq n \leq N\}$.

Let $(\varphi_K^n)_{K_n \in \mathcal{M}}$ be a bounded family of real numbers. We define an energy associated with the weight $\boldsymbol{\varphi}$ and the FV solution $\boldsymbol{u}$,

$$\mathcal{E}(\boldsymbol{\varphi}, \boldsymbol{u}, t) := \sum_{K_n \in \mathcal{M}_t} \varphi_K^{n+1} e_K^n(\boldsymbol{u}),$$

where

$$e_K^n(\boldsymbol{u}) := \sum_{L \in \partial K_n^-} \left(1 - \frac{V_K^n \delta t}{|K|}\right) |V_{KL}^n| \delta t |u_L^n - u_K^n|^2 + \frac{1}{2} \sum_{L,M \in \partial K_n^-} \frac{V_{KL}^n V_{KM}^n \delta t^2}{|K|} |u_M^n - u_L^n|^2.$$

In section 3, we will write $\mathcal{E}(\boldsymbol{u}, t)$ for $\mathcal{E}(\mathbf{1}, \boldsymbol{u}, t)$.

We also define the local consistency error $Q_K^n(\boldsymbol{\Psi})$ of the implicit-in-time downwind FV scheme associated with (1.3) applied to a function $\Psi \in W^{1,\infty}(\mathbf{R}^d \times \mathbf{R}_+)$,

$$Q_K^n(\boldsymbol{\Psi}) := \frac{\Psi_K^{n+1} - \Psi_K^n}{\delta t} + \sum_{L \in \partial K_n^+} \frac{V_{KL}^n}{|K|} \left(\Psi_L^{n+1} - \Psi_K^{n+1}\right) \qquad \forall K_n \in \mathcal{M}.$$

2. Proof of Theorems 1.6 and 1.7.

2.1. Proof of Theorem 1.6. In this section, $u_0 \in W^{1,\infty}(\mathbf{R}^d)$. We have to estimate the quantity

$$\|\boldsymbol{u}(\cdot, T) - u(\cdot, T)\|_\infty = \sup_{K_0 \in \mathcal{T}} \sup_{x_0 \in K_0} \left| u_{K_0}^{N+1} - u(x_0, T) \right|.$$

Let $x_0 \in \mathbf{R}^d$ and let $K_0 \in \mathcal{T}$ such that $x_0 \in K_0$. Next, set $\boldsymbol{v}^0 := 1/|K_0| \, \mathbf{1}_{K_0}$ and define recursively for $K \in \mathcal{T}$ and $0 \leq n \leq N$,

$$v_K^{n+1} = v_K^n + \frac{\delta t}{|K|} \sum_{L \in \partial K_{N-n}^+} V_{KL}^{N-n} (v_L^n - v_K^n). \tag{2.1}$$

Since $u_{K_0}^{N+1} = \sum_{K\in\mathcal{T}} |K|\, u_K^{N+1} v_K^0$, (1.10) and repeated discrete integrations by parts yield

$$u_{K_0}^{N+1} = \sum_{K\in\mathcal{T}} \left(|K|\, u_K^N v_K^0 - \sum_{L\in\partial K_N^-} \delta t V_{KL}^N (u_L^N - u_K^N) v_K^0 \right) = \sum_{K\in\mathcal{T}} |K|\, u_K^N v_K^1$$

$$= \cdots = \sum_{K\in\mathcal{T}} |K|\, u_K^0 v_K^{N+1}.$$

Notice that the scheme (2.1) is the FV scheme with explicit time discretization associated with the dual continuous problem $v_t(x,t) + \operatorname{div}\{-V(x,T-t)v(x,t)\} = 0$ for $(x,t) \in \mathbf{R}^d \times \mathbf{R}_+$; $v(x,0) = \boldsymbol{v}^0(x)$ for $x \in \mathbf{R}^d$ whose solution at time T is $v(x,T) = \boldsymbol{v}^0(Y(x,T))$.

From the monotony and the L^1-stability of the scheme (2.1), we have $v_K^{N+1} \geq 0$ for every $K \in \mathcal{T}$ and $\sum_{K\in\mathcal{T}} |K| v_K^{N+1} = 1$; thus for every $x_0 \in K_0$, we have

$$\begin{aligned} \left| u_{K_0}^{N+1} - u(x_0,T) \right| &\leq \sum_{K\in\mathcal{T}} |K|\, |u_K^0 - u(x_0,T)| v_K^{N+1} \\ &= \sum_{K\in\mathcal{T}} |K|\, |u_K^0 - u_0(X(x_0,T))|\, v_K^{N+1} \\ &\leq \|\nabla u_0\|_\infty \left(\int_{\mathbf{R}^d} \|x - X(x_0,T)\| \boldsymbol{v}(x,T) dx + h \right), \end{aligned}$$

and therefore Theorem 1.6 is the consequence of Theorem 1.7 applied to the dual problem. □

Remark 2.1. In general, the dual problem associated with (1.3) is

$$\begin{cases} v_t + V(\cdot, T-\cdot)\cdot\nabla v = 0, & x \in \mathbf{R}^d, t \in [0,T], \\ v(x,0) = v_0(x), & x \in \mathbf{R}^d, \end{cases}$$

but since $\operatorname{div} V = 0$, we have $V\cdot\nabla v = \operatorname{div}(Vv)$ and the dual and original problems are similar.

2.2. Energy estimates. We now turn to the proof of Theorem 1.7. We begin by proving an energy identity.

LEMMA 2.1. *Let $u_0 \in L^2(\mathbf{R}^d)$, and let $(\varphi_K^n)_{K_n\in\mathcal{M}}$ be a family of real numbers. Then, for every $t \geq 0$,*

$$\int_{\mathbf{R}^d} \boldsymbol{u}^2(x,t)\, \boldsymbol{\varphi}(x,t) dx - \int_{\mathbf{R}^d} \boldsymbol{u}^2(x,0)\, \boldsymbol{\varphi}(x,0) dx + \mathcal{E}(\boldsymbol{\varphi}, \boldsymbol{u}, t)$$

$$= - \sum_{K_n\in\mathcal{M}_t} |K| \delta t (u_K^n)^2 Q_K^n(\boldsymbol{\varphi}).$$

Proof. We assume, without loss of generality, that $t = (n_0+1)\delta t$ for some $n_0 \in \mathbf{N}$. Let $n \geq 0$; we consider the quantity

$$e^n := \sum_{K\in\mathcal{T}} |K| \varphi_K^{n+1} (u_K^{n+1})^2 - \sum_{K\in\mathcal{T}} |K| \varphi_K^n (u_K^n)^2 \;=:\; A - B. \tag{2.2}$$

Using (1.10), we get

$$A = \sum_{K\in\mathcal{T}} |K|\varphi_K^{n+1} \left(\sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n u_L^n \right)^2, \tag{2.3}$$

where, for $K_n \in \mathcal{M}$, we have set $\mathcal{V}_n^-(K) := \{L \in \partial K_n^-\} \cup \{K\}$,

$$a_{KK}^n := 1 - V_K^n \delta t/|K|, \qquad \text{and for } L \in \partial K_n^-, \quad a_{KL}^n := -V_{KL}^n \delta t/|K|.$$

Next, using Lemma 1.3, we rewrite B as

$$B = \sum_{K\in\mathcal{T}} \left(|K| - V_K^n \delta t\right) \varphi_K^n (u_K^n)^2 - \sum_{K\in\mathcal{T}} \sum_{L\in\partial K_n^+} V_{LK}^n \delta t \varphi_K^n (u_K^n)^2.$$

In the last sum, we swap the indexes K and L to get

$$\begin{aligned} B &= \sum_{K\in\mathcal{T}} \left(|K| - V_K^n \delta t\right) \varphi_K^n (u_K^n)^2 + \sum_{K\in\mathcal{T}} \sum_{L\in\partial K_n^-} -V_{KL}^n \delta t \varphi_L^n (u_L^n)^2 \\ &= \sum_{K\in\mathcal{T}} |K| \sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n \varphi_L^n (u_L^n)^2 \\ &= \sum_{K\in\mathcal{T}} |K|\varphi_K^{n+1} \sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n (u_L^n)^2 + \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{V}_n^-(K)} |K| a_{KL}^n (\varphi_L^n - \varphi_K^{n+1})(u_L^n)^2. \end{aligned} \tag{2.4}$$

Thus, plugging (2.3) and (2.4) into (2.2), we get $e^n = \mathrm{I} + \mathrm{II}$, with

$$\mathrm{I} := \sum_{K\in\mathcal{T}} |K|\varphi_K^{n+1} \left\{ \left(\sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n u_L^n \right)^2 - \sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n (u_L^n)^2 \right\},$$

$$\mathrm{II} := \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{V}_n^-(K)} |K| a_{KL}^n (\varphi_K^{n+1} - \varphi_L^n)(u_L^n)^2.$$

For every $K_n \in \mathcal{M}$, using the identity $\sum_{M\in\mathcal{V}_n^-(K)} a_{KM}^n = 1$, an easy computation yields

$$\left(\sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n u_L^n \right)^2 - \sum_{L\in\mathcal{V}_n^-(K)} a_{KL}^n (u_L^n)^2 = -\frac{1}{2} \sum_{L,M\in\mathcal{V}_n^-(K)} a_{KL}^n a_{KM}^n (u_L^n - u_M^n)^2.$$

Thus, replacing the terms a_{KL}^n by their definitions and summing on $K \in \mathcal{T}$, we get

$$\mathrm{I} = -\sum_{K\in\mathcal{T}} \varphi_K^{n+1} e_K^n(\boldsymbol{u}).$$

Now, rearranging the terms in II, we compute

$$\mathrm{II} = \sum_{K\in\mathcal{T}} |K|\delta t (u_K^n)^2 \left\{ \frac{\varphi_K^{n+1} - \varphi_K^n}{\delta t} + \sum_{L\in\partial K_n^+} \frac{V_{KL}^n \delta t}{|K|} \left(\varphi_L^{n+1} - \varphi_K^{n+1}\right) \right\}.$$

Summing these two equations and then summing on $0 \le n \le n_0$, the lemma is proved. ∎

2.3. Weak consistency. In this section, the integer $0 \le n \le N$ is fixed. Let $(v_K)_{K\in\mathcal{T}}$ be a family of real numbers and set $\boldsymbol{v} := \sum_K v_K \mathbf{1}_K$; then let us define the weighted total variation of $\boldsymbol{v}$ with respect to the family $(V^n_{KL})_{K,L\in\mathcal{T}}$ by

$$\|\boldsymbol{v}\|_{V^n-TV} := \sum_{K\in\mathcal{T}} \sum_{L\in\partial K_n^-} |V^n_{KL}||v_K - v_L|.$$

Now for $\eta \in \mathbf{R}$, we define $\omega(\boldsymbol{v},\eta)$ to be the union of cells K such that $v_K < \eta < 0$ or $0 < \eta < v_K$ and we consider the level set decomposition $\boldsymbol{v}(x) = \int_{\mathbf{R}} \operatorname{sgn}(\eta)\, \mathbf{1}_{\omega(\boldsymbol{v},\eta)} d\eta$. When $\omega \subset \mathbf{R}^d$ is a finite union of elements of $\mathcal{T}$, we have $\|\mathbf{1}_\omega\|_{V^n-TV} = \frac{1}{2}\sum_{K|L\subset\partial\omega} |V^n_{KL}|$, and it is not difficult to see that

$$\|\boldsymbol{v}\|_{V^n-TV} = \int_{\mathbf{R}} \|\mathbf{1}_{\omega(\boldsymbol{v},\eta)}\|_{V^n-TV} d\eta.$$

This suggests the following definition. Let $(w_K)_{K\in\mathcal{T}} \subset \mathbf{R}$ and $\boldsymbol{w} := \sum_{K\in\mathcal{T}} w_K \mathbf{1}_K$. We set

$$\|\boldsymbol{w}\|'_{V^n-TV} := \sup_\omega \frac{\left|\int_\omega w(x)dx\right|}{\|\mathbf{1}_\omega\|_{V^n-TV}},$$

where the supremum is taken over all subsets $\omega \subset \mathbf{R}^d$ such that ω is a finite union of elements of $\mathcal{T}$. We do not prove that $\|\cdot\|'_{V^n-TV}$ is the dual norm associated with $\|\cdot\|_{V^n-TV}$. We will only need the following lemma, which is a direct consequence of the two last identities.

LEMMA 2.2. *Let $\boldsymbol{v}$, $\boldsymbol{w}$ be as above such that $\|\boldsymbol{v}\|_{V^n-TV} < \infty$ and $\|\boldsymbol{w}\|'_{V^n-TV} < \infty$. Then*

$$\int_{\mathbf{R}^d} \boldsymbol{v}(x)\boldsymbol{w}(x)dx = \sum_{K\in\mathcal{T}} |K| v_K w_K \le \|\boldsymbol{v}\|_{V^n-TV} \|\boldsymbol{w}\|'_{V^n-TV}.$$

We now prove the following consistency result for the implicit downwind FV scheme.

LEMMA 2.3. *Let $\Psi_0 \in W^{1,\infty}(\mathbf{R}^d)$. For $(x,t) \in \mathbf{R}^d \times [0,T]$, set $\Psi(x,t) := \Psi_0(X(x,t))$ and $\boldsymbol{Q}^n(\Psi) := \sum_{K\in\mathcal{T}} Q^n_K(\boldsymbol{\Psi})\mathbf{1}_{K_n}$. There exists $R^m_K(\Psi)$, $K_m \in \mathcal{M}$, such that for $n \le N$, $\boldsymbol{R}^n(\Psi) := \sum_{K\in\mathcal{T}} R^n_K(\Psi)\mathbf{1}_{K_n}$ and $\boldsymbol{S}^n(\Psi) := \boldsymbol{Q}^n(\Psi) - \boldsymbol{R}^n(\Psi)$ satisfy*

$$\|\boldsymbol{R}^n(\Psi)\|_\infty \le CC_0 \left(\|\nabla V\|_\infty + \|\partial_t V\|_\infty\right) \|\nabla\Psi_0\|_\infty h,$$

$$\|\boldsymbol{S}^n(\Psi)\|'_{V^n-TV} \le CC_0 \|V\|_\infty \|\nabla\Psi_0\|_\infty h.$$

Proof. For $K_m \in \mathcal{M}$, let us denote by Ψ^m_K the mean value of Ψ on K at time $m\delta t$: $\Psi^m_K = \langle \Psi(\cdot, m\delta t)\rangle_K$. Let $K \in \mathcal{T}$; since Ψ solves $\partial_t\Psi + \operatorname{div}(V\Psi) = 0$ on $\mathbf{R}^d \times \mathbf{R}_+$, we have

$$\frac{\Psi^{n+1}_K - \Psi^n_K}{\delta t} = \frac{1}{|K|\delta t}\int_{K_n} \partial_t\Psi(x,s)dxds$$

$$= -\frac{1}{|K|\delta t} \sum_{L\in\partial K} \int_{K|L_n} \Psi(x,s)V(x,s)\cdot\boldsymbol{n}_{KL}dxds.$$

For $K_m \in \mathcal{M}$, we set

$$R_K^m(\Psi) := \frac{1}{|K|\delta t} \sum_{L\in\partial K} \int_{K\vert L_m} \Psi(x,s)\Big\{\langle V\cdot \boldsymbol{n}_{KL}\rangle_{K\vert L_m} - V(x,s)\cdot \boldsymbol{n}_{KL}\Big\}dxds.$$

Since we have $\int_{K\vert L_m}\{\langle V\cdot \boldsymbol{n}_{KL}\rangle_{K\vert L_m} - V(x,s)\cdot \boldsymbol{n}_{KL}\}dxds = 0$ for every space-time edge $K\vert L_m$, we may replace $\Psi(x,s)$ by $\Psi(x,s) - \langle\Psi\rangle_{K\vert L_m}$ in the above equation. Then, for every $K\in\mathcal{T}$,

$$\begin{aligned}
|R_K^n(\Psi)| &\le \frac{1}{|K|\delta t}\sum_{L\in\partial K}\Bigg|\int_{K\vert L_n}\Big\{\Psi(x,s)-\langle\Psi\rangle_{K\vert L_n}\Big\}\\
&\qquad\qquad \times\Big\{V(x,s)\cdot\boldsymbol{n}_{KL} - \langle V\cdot\boldsymbol{n}_{KL}\rangle_{K\vert L_n}\Big\}dxds\Bigg|\\
&\le \frac{|\partial K|}{|K|}\big(\|\nabla\Psi\|_{L^\infty(\mathbf{R}^d\times[0,T])}h + \|\partial_t\Psi\|_{L^\infty(\mathbf{R}^d\times[0,T])}\delta t\big)\\
&\quad\times\big(\|\nabla V\|_\infty h + \|\partial_t V\|_\infty\delta t\big).
\end{aligned}$$

The regularity of the mesh (1.6) leads to $|\partial K|/|K| \le \alpha^{-2}h^{-1}$, and using the bounds on $\|\nabla X\|$ and $\|\partial_t X\|$ of Theorem 1.1 and the CFL condition (1.8), we get the first part of the lemma.

Next, since $V_{KL}^n = |K\vert L|\langle V\cdot\boldsymbol{n}_{KL}\rangle_{K\vert L_n}$, we have

$$\frac{\Psi_K^{n+1}-\Psi_K^n}{\delta t} - R_K^n = -\sum_{L\in\partial K}\frac{V_{KL}^n}{|K|}\langle\Psi\rangle_{K\vert L_n},$$

and using the identity of Lemma 1.3,

$$\begin{aligned}
&Q_K^n(\boldsymbol{\Psi}) - R_K^n(\Psi)\\
&\quad= -\sum_{L\in\partial K}\frac{V_{KL}^n}{|K|}\langle\Psi\rangle_{K\vert L_n} + \sum_{L\in\partial K_n^+}\frac{V_{KL}^n}{|K|}\big(\Psi_L^{n+1}-\Psi_K^{n+1}\big)\\
&\quad= \frac{1}{|K|}\left(\sum_{L\in\partial K_n^+} V_{KL}^n(\Psi_L^{n+1}-\langle\Psi\rangle_{K\vert L_n}) + \sum_{L\in\partial K_n^-} V_{KL}^n(\Psi_K^{n+1}-\langle\Psi\rangle_{K\vert L_n})\right).
\end{aligned}$$

Letting $\omega = \cup_{K\in I_\omega}K$ be a finite union of elements of $\mathcal{T}$, we have

$$\int_\omega \boldsymbol{S}^n(\Psi) = \sum_{K\in I_\omega}|K|(Q_K^n(\boldsymbol{\Psi}) - R_K^n(\Psi)).$$

If the cells K, L with $L\in\partial K_n^+$ are such that K and L belong to I_ω, then the edge $K\vert L$ has two contributions in the sum above: $V_{KL}^n(\Psi_L^{n+1}-\langle\Psi\rangle_{K\vert L_n})$ (due to $K\in I_\omega$, $L\in\partial K_n^+$) and $V_{LK}^n(\Psi_L^{n+1}-\langle\Psi\rangle_{L\vert K_n})$ (due to $L\in I_\omega$, $K\in\partial L_n^-$). These contributions cancel each other. Thus, if $\partial\omega^+$ (resp., $\partial\omega^-$) denotes the set $\{K\vert L,\, K\in I_\omega, L\in\partial K_n^+\setminus I_\omega\}$ (resp., $\{K\vert L,\, K\in I_\omega, L\in\partial K_n^-\setminus I_\omega\}$), we have

$$\int_\omega \boldsymbol{S}^n(\Psi) = \sum_{K\vert L\in\partial\omega^+} V_{KL}^n(\Psi_L^{n+1}-\langle\Psi\rangle_{K\vert L_n}) + \sum_{K\vert L\in\partial\omega^-} V_{KL}^n(\Psi_K^{n+1}-\langle\Psi\rangle_{K\vert L_n}),$$

and from the definition of $\|\cdot\|_{V^n-WTV}$, we get

$$\left|\int_\omega \boldsymbol{S}^n(\Psi)\right| \le \left(\frac{1}{2}\sum_{K\,|\,L\subset\partial\omega}|V_{KL}|\right)\left(\|\nabla\Psi\|_{L^\infty(\mathbf{R}^d\times[0,T])}h + \|\partial_t\Psi\|_{L^\infty(\mathbf{R}^d\times[0,T])}\delta t\right)$$

$$\le \|\mathbf{1}_\omega\|_{V^n-WTV}C_0(1+c_0)\|\nabla\Psi_0\|_\infty h,$$

which is the desired estimate. □

2.4. Key estimate. We use the results of sections 2.2 and 2.3 to estimate the growth of $\int_{\mathbf{R}}^d \boldsymbol{u}^2(x,t)\boldsymbol{\Psi}^2(x,t)dx$, when ψ is a cutoff function.

LEMMA 2.4. *Let Ψ_0, $\overline{\Psi}_0 \in W^{1,\infty}(\mathbf{R}^d)$ such that $0 \le \Psi_0 \le \overline{\Psi}_0 \le 1$. For $(x,t) \in \mathbf{R}^d \times \mathbf{R}_+$, let us define $\Psi(x,t) := \Psi_0(X(x,t))$ and $\overline{\Psi}(x,t) := \overline{\Psi}_0(X(x,t))$. Assume that $\overline{\Psi}_0 \equiv 1$ on $\operatorname{supp}\Psi_0 + B(0, C_0(2+c_0)h) = \{x \in \mathbf{R}^d \ : \ \Psi_{0|B(x,C_0(1+c_0)h)} \not\equiv 0\}$. Then, for every $0 \le t \le T$,*

$$\int_{\mathbf{R}^d} \boldsymbol{u}^2(\cdot,t)\,\boldsymbol{\Psi}^2(\cdot,t) \;-\; \int_{\mathbf{R}^d} u_0^2\,\boldsymbol{\Psi}^2(\cdot,0)$$

$$\le \left\{C_{1,\star}\|\nabla\Psi_0\|_\infty^2\, h + C_{2,\star}\|\nabla\Psi_0\|_\infty\, h\right\}\int_0^t\int_{R^d}\overline{\boldsymbol{\Psi}}^2\,\boldsymbol{u}^2$$

with $C_{1,\star} = CC_0^2\xi^{-1}$ and $C_{2,\star} = CC_0$.

Proof. Let $0 \le t \le T$; if $t < \delta t$, the left-hand side vanishes and there is nothing to prove. So we assume that there exists $n_0 \ge 0$ such that $(n_0+1)\delta t \le t < (n_0+2)\delta t$; since the left-hand side does not depend on t for $(n_0+1)\delta t \le t < (n_0+2)\delta t$ and the right-hand side is nondecreasing, we may assume that $t = (n_0+1)\delta t$. In this case $\mathcal{M}_t = \{K_n \in \mathcal{M} \ : \ 0 \le n \le n_0\}$.

Now, let $K \in \mathcal{M}$ and $0 \le n \le n_0+1$ such that $\Psi_K^n \ne 0$. There exists $x \in K$ such that $\Psi(x, n\delta t) \ne 0$; thus $\Psi_0(X(x,n\delta t)) \ne 0$. Let $z \in \mathbf{R}^d$ and $0 \le m \le N+1$ such that $|z-x| \le 2h$ and $|n-m| \le 1$. From the estimates on ∇X and $\partial_t X$ of Theorem 1.1, we have $\|X(x,n\delta t) - X(z,m\delta t)\| \le C_0(2h+\delta t) \le C_0(2+c_0)h$; thus $\overline{\Psi}(z,s) = \overline{\Psi}_0(X(z,s)) = 1$. We conclude that for every $K_n, L_m \in \mathcal{M}$ such that $0 \le n, m \le n_0+1$, we have

$$\left(L \in \partial K \cup \{K\}, \quad |m-n| \le 1, \quad \Psi_K^n > 0\right) \implies \overline{\Psi}_L^m = 1. \tag{2.5}$$

Let us write the identity of Lemma 2.1, with $\boldsymbol{\varphi} = \boldsymbol{\Psi}^2$:

$$\mathrm{I} := \int_{\mathbf{R}^d} \boldsymbol{u}^2(\cdot,t)\,\boldsymbol{\Psi}^2(\cdot,t) - \int_{\mathbf{R}^d} u_0^2\,\boldsymbol{\Psi}^2(\cdot,0) + \mathcal{E}(\boldsymbol{\Psi}^2,\boldsymbol{u},t) \tag{2.6}$$

$$= -\sum_{K_n\in\mathcal{M}_t} |K|\,\delta t (u_K^n)^2 Q_K^n(\boldsymbol{\Psi}^2).$$

Let $K_n \in \mathcal{M}$; a direct computation yields

$$Q_K^n(\boldsymbol{\Psi}^2) = 2\Psi_K^{n+1}Q_K^n(\boldsymbol{\Psi}) - \frac{(\Psi_K^{n+1}-\Psi_K^n)^2}{\delta t} + \sum_{L\in\partial K_n^+}\frac{V_{KL}^n}{|K|}(\Psi_L^{n+1}-\Psi_K^{n+1})^2.$$

We then have

$$\text{I} \le \sum_{K_n\in\mathcal{M}_t} |K|(u_K^n)^2(\Psi_K^{n+1}-\Psi_K^n)^2 - 2\sum_{K_n\in\mathcal{M}_t}\delta t|K|\Psi_K^{n+1}(u_K^n)^2 Q_K^n(\boldsymbol{\Psi}) \tag{2.7}$$

$$=: A - 2\sum_{n=0}^{n_0}\delta t B_n.$$

First, from the estimate on $\partial_t X$ of Theorem 1.1, we have $|\Psi_K^{n+1}-\Psi_K^n| \le C_0\|\nabla\Psi_0\|_\infty\delta t \le C_0c_0\|\nabla\Psi_0\|_\infty h$ for every $K_n\in\mathcal{M}_t$. Using (2.5), we deduce that

$$A \le CC_0^2\|\nabla\Psi_0\|_\infty^2\, h\sum_{K_n\in\mathcal{M}_t}|K|\,\delta t(u_K^n)^2(\overline{\Psi}_K^n)^2 \tag{2.8}$$

$$= CC_0^2\|\nabla\Psi_0\|_\infty^2\, h\int_0^t\int_{R^d}\overline{\boldsymbol{\Psi}}^2\,\boldsymbol{u}^2.$$

Next, let us fix $0\le n\le n_0$. With the notation of Lemma 2.3, we have

$$B_n = \sum_{K\in\mathcal{T}}|K|\Psi_K^{n+1}(u_K^n)^2R_K^n(\Psi) + \sum_{K\in\mathcal{T}}|K|\Psi_K^{n+1}(u_K^n)^2S_K^n(\Psi) \tag{2.9}$$

$$=: B_n^1 + B_n^2,$$

where $\|\boldsymbol{R}^n(\Psi)\|_\infty \le CC_0\|\nabla\Psi_0\|_\infty\, h$ and $\|\boldsymbol{S}^n(\Psi)\|'_{V^n-TV} \le CC_0\|\nabla\Psi_0\|_\infty h$. Thus,

$$\left|B_n^1\right| \le CC_0\|\nabla\Psi_0\|_\infty\, h\int_{\mathbf{R}^d}\overline{\boldsymbol{\Psi}}^2\,\boldsymbol{u}^2(\cdot,n\delta t). \tag{2.10}$$

Next, using Lemma 2.2 with $\boldsymbol{v}_K^n = \Psi_K^{n+1}(u_K^n)^2$, for $K\in\mathcal{T}$ and $\boldsymbol{w} = \boldsymbol{S}^n(\Psi)$, we get

(2.11)

$$\left|B_n^2\right| \le CC_0\|\nabla\Psi_0\|_\infty h\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-}|V_{KL}^n|\,\left|\Psi_K^{n+1}(u_K^n)^2 - \Psi_L^{n+1}(u_L^n)^2\right|$$

$$\le CC_0\|\nabla\Psi_0\|_\infty\, h\left(\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-}|V_{KL}^n|\left|\Psi_L^{n+1}-\Psi_K^{n+1}\right|(u_L^n)^2\right.$$

$$\left. + \sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-}|V_{KL}^n|\,\Psi_K^{n+1}\left|(u_K^n)^2-(u_L^n)^2\right|\right)$$

$$=: CC_0\|\nabla\Psi_0\|_\infty\, h\,(C_n+D_n).$$

From (2.5), the estimate on $\|\nabla X\|$ of Theorem 1.1, and (1.6), we bound C_n by

$$C_n \le \sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-}(\|V\|_\infty\,|K\shortmid L|)\,(C_0\|\nabla\Psi_0\|_\infty 2h)\,(u_L^n)^2(\overline{\Psi}_L^n)^2$$

$$= 2C_0\|\nabla\Psi_0\|_\infty\|V\|_\infty\sum_{K\in\mathcal{T}}\left(\sum_{L\in\partial K_n^+}|K\shortmid L|h\right)(u_K^n)^2(\overline{\Psi}_K^n)^2$$

$$\le 2C_0\|\nabla\Psi_0\|_\infty\|V\|_\infty\alpha^{-2}\sum_{K\in\mathcal{T}}|K|(u_K^n)^2\left(\overline{\Psi}_K^n\right)^2,$$

and finally,

$$C_n \le CC_0\|\nabla\Psi_0\|_\infty \int_{\mathbf{R}^d} \boldsymbol{u}^2\overline{\boldsymbol{\Psi}}^2(\cdot, n\delta t). \tag{2.12}$$

Writing

$$\begin{aligned}\Psi_K^{n+1}\left|(u_K^n)^2-(u_L^n)^2\right| &= \left|\Psi_K^{n+1}(u_K^n-u_L^n)(u_K^n+u_L^n)\right| \\ &\le \left|\Psi_K^{n+1}(u_K^n-u_L^n)\right| \times \left(\left|\overline{\Psi}_K^{n+1}u_K^n\right| + \left|\overline{\Psi}_L^{n+1}u_L^n\right|\right)\end{aligned}$$

and using the Cauchy–Schwarz inequality, we bound D_n by

$$\begin{aligned} D_n &\le \left(\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} |V_{KL}^n|\,|u_K^n-u_L^n|^2\,(\Psi_K^{n+1})^2\right)^{1/2} \\ &\quad\times\left(2\sum_{K\in\mathcal{T}}\sum_{L\in\partial K} |V_{KL}^n|\,|u_K^n|^2\left(\overline{\Psi_K}^{n+1}\right)^2\right)^{1/2} \\ &\le \delta t^{-1/2}\left(\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t\,|u_L^n-u_K^n|^2(\Psi_K^{n+1})^2\right)^{1/2} \\ &\quad\times\|V\|_\infty^{1/2}\alpha^{-1}h^{-1/2}\left(2\sum_{K\in\mathcal{T}}|K|(u_K^n)^2\left(\overline{\Psi}_K^n\right)^2\right)^{1/2} \\ &\le Ch^{-1/2}\delta t^{-1/2}\left(\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t\,|u_L^n-u_K^n|^2(\Psi_K^{n+1})^2\right)^{1/2} \\ &\quad\times\left(\int_{\mathbf{R}^d}\boldsymbol{u}^2\overline{\boldsymbol{\Psi}}^2(\cdot,n\delta t)\right)^{1/2}. \end{aligned} \tag{2.13}$$

Collecting (2.9)–(2.13), we get

$$\begin{aligned}|B_n| &\le CC_0\|\nabla\Psi_0\|_\infty h^{1/2}(C_0\|\nabla\Psi_0\|_\infty h^{1/2}+Ch^{1/2})\int_{\mathbf{R}^d}\boldsymbol{u}^2\overline{\boldsymbol{\Psi}}^2(\cdot,n\delta t) \\ &\quad+CC_0\|\nabla\Psi_0\|_\infty\, h^{1/2}\delta t^{-1/2}\left(\sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t\,|u_L^n-u_K^n|^2(\Psi_K^{n+1})^2\right)^{1/2} \\ &\quad\times\left(\int_{\mathbf{R}^d}\boldsymbol{u}^2\overline{\boldsymbol{\Psi}}^2(\cdot,n\delta t)\right)^{1/2}.\end{aligned} \tag{2.14}$$

Plugging (2.14) and (2.8) into (2.7) and using again the Cauchy–Schwarz inequality yield

$$\mathrm{I} \le CC_0\|\nabla\Psi_0\|_\infty h^{1/2}(C_0\|\nabla\Psi_0\|_\infty h^{1/2} + Ch^{1/2}) \int_0^t \int_{R^d} \overline{\mathbf{\Psi}}^2\, \boldsymbol{u}^2 \tag{2.15}$$

$$+CC_0\|\nabla\Psi_0\|_\infty\, h^{1/2} \left(\sum_{K_n\in\mathcal{M}_t} \sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t\, |u_L^n - u_K^n|^2 (\Psi_K^{n+1})^2 \right)^{1/2}$$

$$\times \left(\int_0^t \int_{R^d} \overline{\mathbf{\Psi}}^2\, \boldsymbol{u}^2 \right)^{1/2}.$$

To end the proof, we introduce the following lemma.

LEMMA 2.5. *For every $t \ge 0$, we have*

$$\sum_{K_n\in\mathcal{M}_t} \sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t\, |u_L^n - u_K^n|^2 (\Psi_K^{n+1})^2 \le \xi^{-1}\mathcal{E}(\mathbf{\Psi}^2, \boldsymbol{u}, t).$$

Proof. It is sufficient to prove that, for every $K_n \in \mathcal{M}$, we have $1 \le \xi^{-1}(1 - V_K^n\delta t/|K|)$ which is a direct consequence of the CFL condition (1.7). ∎

Plugging (2.15) into (2.6) and using Lemma 2.5 and then Young's inequality ($ab \le \varepsilon a^2/2 + \varepsilon^{-1}b^2/2$) to absorb the term $\mathcal{E}(\mathbf{\Psi^2}, \boldsymbol{u}, t)$ in the left-hand side of (2.6), we obtain Lemma 2.4. ∎

2.5. Cutoff functions. Let $K_0 \in \mathcal{T}$, $x_0 \in K_0$ and define $u_0 := 1/|K_0|\,\mathbf{1}_{K_0}$. Without loss of generality, we assume that $x_0 = 0$.

With the notation of Lemma 2.4, we set

$$\sigma := 3C_{1,\star}^{1/2}T^{1/2}. \tag{2.16}$$

Let $\Psi_{0,0}$ be the constant function equal to 1 on $\mathbf{R}^d$, and for $k \ge 1$, let $\Psi_{k,0} \in W^{1,\infty}(\mathbf{R}^d, [0,1])$ be the unique cutoff function satisfying

$$\Psi_{k,0}\left(B(k+1/2)\sigma h^{1/2}\right) = \{0\}, \qquad \Psi_{k,0}\left(\mathbf{R}^d \setminus B((k+1)\sigma h^{1/2})\right) = \{1\},$$
$$\|\nabla\Psi_{k,0}\|_\infty \le \sigma^{-1}h^{-1/2}.$$

Then for $k \ge 0$ and $(x,t) \in \mathbf{R}^d \times \mathbf{R}_+$, set $\Psi_k(x,t) := \Psi_{k,0}(X(x,t))$.

We want to apply Lemma 2.4 with $(\Psi, \overline{\Psi}) = (\Psi_k, \Psi_{k-1})$, $k \ge 1$. The required hypothesis on the support of Ψ_k reads $C_0(2+c_0)h \le \sigma\, h^{1/2}/2$ and is true for $h \le h_{1,\star}$ small enough. Moreover, for $h \le h_{2,\star}$, we have $\int_{\mathbf{R}^d} u_0^2\, \mathbf{\Psi}_k^2(\cdot,0) = 0$, for $k \ge 1$, and from (2.16), for $h \le h_{3,\star}$, we have $4C_{1,\star}/\sigma^2 + 2C_{2,\star}h^{1/2}/\sigma \le T^{-1}$. We now assume $h \le h_\star := \min(h_{1,\star}, h_{2,\star}, h_{3,\star})$.

So, applying the lemma with $(\Psi, \overline{\Psi}) = (\Psi_k, \Psi_{k-1})$, we get

$$\int_{\mathbf{R}^d} \boldsymbol{u}^2(\cdot,t)\, \mathbf{\Psi}_k^2(\cdot,t) \le T^{-1} \int_0^t \int_{R^d} \boldsymbol{u}^2\, \mathbf{\Psi}_{k-1}^2, \qquad 0 \le t \le T, \quad k \ge 1.$$

Now, for $k = 0$, the L^2-stability of the scheme and (1.6) yield $\int_{\mathbf{R}^d} \boldsymbol{u}^2(\cdot,t)\, \mathbf{\Psi}_0^2(\cdot,t) \le \int_{\mathbf{R}^d} u_0^2 = 1/|K_0| \le \alpha^{-1}h^{-d}$ for every $t \ge 0$, and we obtain, recursively,

$$\int_{\mathbf{R}^d} \boldsymbol{u}^2(\cdot,t)\, \mathbf{\Psi}_k^2(\cdot,t) \le \alpha^{-1}\frac{(t/T)^k}{k!}h^{-d}, \qquad 0 \le t \le T,\ k \ge 0. \tag{2.17}$$

Let k_0 be a positive integer. Let $x \in \mathbf{R}^d$ such that $\|x\| \geq k_0\, \sigma h^{1/2}$, and k denotes the integer satisfying $k\sigma h^{1/2} \leq \|x\| < (k+1)\sigma h^{1/2}$. From the definition of $(\Psi_{j,0})_{j\geq 0}$, we have $(1 - \Psi_{k+1,0}(x))\, \Psi_{k-1,0}(x) = 1$ and since $\|x\| \leq (k+1)\sigma h^{1/2}$, we get

$$\|x\| \leq \sigma h^{1/2} \sum_{k\geq k_0} (k+1)\Psi_{k-1,0}(x)\,(1 - \Psi_{k+1,0}(x))\,.$$

So, for every $x \in \mathbf{R}^d$,

$$\|x\| \leq \sigma h^{1/2} \left(k_0 \mathbf{1}_{B(k_0\sigma h^{1/2})}(x) + \sum_{k\geq k_0} (k+1)\,(\Psi_{k-1,0}\,(1 - \Psi_{k+1,0}))\,(x) \right).$$

From the estimate on $\|\nabla Y\|$ of Theorem 1.1, we have $\|x - Y(0,T)\| \leq C_0 \|X(x,T)\|$. Thus,

$$\begin{aligned} &\|x - Y(0,T)\| \\ &\leq C_0 \sigma h^{1/2} \left(k_0 \mathbf{1}_{B(k_0\sigma h^{1/2})}(X(x,T)) + \sum_{k\geq k_0} (k+1)(\Psi_{k-1}\,(1 - \Psi_{k+1}))\,(x,T) \right). \end{aligned}$$

Multiplying by $\boldsymbol{u}(x,T)$ and integrating on $\mathbf{R}^d$, we get

$$\begin{aligned} \int_{\mathbf{R}^d} \|x - Y(0,T)\|\, \boldsymbol{u}(x,T)dx &\leq C_0\sigma h^{1/2} k_0 \int_{\mathbf{R}^d} \mathbf{1}_{B(\sigma h^{1/2})}(X(x,T))\, \boldsymbol{u}(x,T)dx \\ &+ C_0\sigma h^{1/2} \sum_{k\geq k_0} (k+1) \int_{R^d} (\boldsymbol{u}\, \Psi_{k-1}\,(1 - \Psi_{k+1}))\,(x,T)dx \\ &=:\ C_0\sigma h^{1/2} k_0\ A + C_0\sigma h^{1/2} \sum_{k\geq k_0} (k+1)\, B_k. \end{aligned} \tag{2.18}$$

From the monotony and conservation properties of (1.3), we have

$$A \leq 1. \tag{2.19}$$

For the terms B_k, we use the Cauchy–Schwarz inequality and (2.17). For every $k \geq 2$, we have

$$\begin{aligned} B_k &\leq \int_{R^d} (\boldsymbol{u}\Psi_{k-1}\,(1 - \Psi_{k+1}))\,(\cdot,T) \\ &\leq \left(\lambda \left\{ \mathrm{supp}\left(\Psi_{k-1}\,(1 - \Psi_{k+1}) \right)(\cdot,T) \right\} \right)^{1/2} \left(\int_{\mathbf{R}^d} \left(\boldsymbol{u}^2\, \Psi_{k-1}^2 \right)(\cdot,T) \right)^{1/2} \\ &\leq C\sigma^{d/2}(k+2)^{d/2} h^{d/4} \left(\int_{\mathbf{R}^d} \left(\boldsymbol{u}^2\, \boldsymbol{\Psi}_{k-2}^2 \right)(\cdot,T) \right)^{1/2} \\ &\leq C\sigma^{d/2}(k+2)^{d/2} h^{-d/4} ((k-2)!)^{-1/2}. \end{aligned} \tag{2.20}$$

Thus, (2.18)–(2.20) lead to

$$\int_{\mathbf{R}^d} \|x - Y(x_0,T)\| \boldsymbol{u}(x,T) dt$$

$$\leq CC_0 \sigma h^{1/2} \left(k_0 + \sigma^{d/2} h^{-d/4} \sum_{k \geq k_0} (k+2)^{(d-1)/2} ((k-2)!)^{-1/2} \right).$$

Clearly, $\sum_{k\geq k_0}(k+2)^{(d-1)/2}((k-2)!)^{-1/2} \overset{\infty}{\approx} ((k_0-d-1)!)^{-1/2} = (\Gamma(k_0-d))^{-1/2}$. Choosing k_0 to be the first integer such that $\sigma^d h^{-d/2}(\Gamma(k_0-d))^{-1} \leq 1$, we have

$$\int_{\mathbf{R}^d} \|x - Y(x_0,T)\| \boldsymbol{u}(x,T) dx \leq CC_0 \sigma h^{1/2}(k_0+1) \ \leq \ CC_0^2 \xi^{-1/2} T^{1/2} h^{1/2}(k_0+1).$$

And since $k_0 + 1 \leq \Gamma^{-1}(\sigma^d h^{-d/2}) + d + 2 \leq C\Gamma^{-1}(C_0^2 \xi^{-1} T h^{-1})$, Theorem 1.7 is proved. □

3. Proof of Theorem 1.8. In this section $u_0 \in L^2(\mathbf{R}^d)$. The function $u \in C(\mathbf{R}_+, L^2(\mathbf{R}^d))$ is the exact solution to (1.3) and $\boldsymbol{u}$ is the numerical approximation given by the scheme (1.9)–(1.11). We assume that (1.6) and the CFL conditions (1.7), (1.8) are satisfied with $\xi > 0$.

3.1. Weak formulation and technical results. The next lemma says that $\boldsymbol{u}$ satisfies the weak formulation (1.5) up to an error term, related to the consistency error of the scheme.

LEMMA 3.1 (Lemma 3.1 in [12]). *For every compactly supported test function $\phi \in W^{1,\infty}(\mathbf{R}^d \times \mathbf{R}_+)$, we have*

$$\int_{\mathbf{R}_+} \int_{\mathbf{R}^d} \boldsymbol{u}(\phi_t + V \cdot \nabla \phi) + \int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,0)\phi(\cdot,0) = \mu(\phi) + \nu(\phi), \tag{3.1}$$

$$\mu(\phi) := \sum_{K_n \in \mathcal{M}} |K| (u_K^{n+1} - u_K^n)(\langle \phi \rangle_{K_n} - \langle \phi \rangle_K((n+1)\delta t)), \tag{3.2}$$

$$\nu(\phi) := \sum_{K_n \in \mathcal{M}} \sum_{L \in \partial K_n^-} \delta t (u_L^n - u_K^n)(V_{KL}^n \langle \phi \rangle_{K_n} - |K|L| \langle V \cdot \mathbf{n}\, \phi \rangle_{K|L_n}), \tag{3.3}$$

where $\langle \phi \rangle_{K|L_n} := \fint_{K|L_n} \phi V \cdot \mathbf{n}_{KL}$.

Remark 3.1. This equality is similar to the entropy inequality used in the Kuznecov method (see, e.g., [7]). Here, the initial problem (1.3) is linear and the notion of entropy is useless.

Proof. We develop the first term of the inequality and perform a discrete integration by parts,

$$\int_0^\infty \int_{\mathbf{R}^d} \boldsymbol{u}(\phi_t + V\cdot\nabla\phi)dxdt = \sum_{K_n\in\mathcal{M}} |K|\delta t\, u_K^n \fint_{K_n} (\phi_t + V\cdot\nabla\phi)dxdt \tag{3.4}$$

$$= \sum_{K_n\in\mathcal{M}} u_K^n \left(|K|\Big(\langle\phi\rangle_K((n+1)\delta t) - \langle\phi\rangle_K(n\delta t)\Big) + \sum_{L\in\partial K} \delta t|K\vert L|\langle V\cdot\mathbf{n}\,\phi\rangle_{KL}^n \right)$$

$$= \sum_{K_n\in\mathcal{M}} \left(|K|(u_K^n - u_K^{n+1})\langle\phi\rangle_K((n+1)\delta t) + \sum_{L\in\partial K} \delta t|K\vert L|\langle V\cdot\mathbf{n}\,\phi\rangle_{K\vert L_n} u_K^n \right)$$

$$- \sum_{K_n\in\mathcal{M}} |K|\delta t u_K^0\langle\phi\rangle_K(0).$$

The last sum is equal to $\int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,0)\phi(\cdot,0)$. Rearranging the terms in the second sum and using the identity $\langle V\cdot\mathbf{n}\,\phi\rangle_{K\vert L_n} + \langle V\cdot\mathbf{n}\,\phi\rangle_{LK_n} = 0$, we compute, for every $n\geq 0$,

$$\sum_{K\in\mathcal{T}}\sum_{L\in\partial K} |K\vert L|\langle V\cdot\mathbf{n}\,\phi\rangle_{K\vert L_n} u_K^n = \sum_{K\in\mathcal{T}}\sum_{L\in\partial K_n^-} |K\vert L|\langle V\cdot\mathbf{n}\,\phi\rangle_{K\vert L_n}(u_K^n - u_L^n).$$

Plugging this identity and (1.10) into (3.4), we obtain (3.1)–(3.3). ∎

LEMMA 3.2. *Assume that the CFL condition* (1.7) *is satisfied with* $\xi\in(0,1)$; *then*

$$\mathcal{F}(\boldsymbol{u},T) \;\leq\; C\xi^{-1}\left(\|\boldsymbol{u}(\cdot,0)\|_{L^2(\mathbf{R}^d)}^2 - \|\boldsymbol{u}(\cdot,T)\|_{L^2(\mathbf{R}^d)}^2 \right).$$

Proof. From (1.10) and the Cauchy–Schwarz inequality, we have, for every $K_n\in\mathcal{M}$,

$$|K||u_K^{n+1} - u_K^n|^2 \leq \left(\sum_{L\in\partial K_n^-} \frac{|V_{KL}^n|\delta t}{|K|} \right) \sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t|u_L^n - u_K^n|^2.$$

Due to the CFL condition (1.7), we have $\sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t \leq |K|$; consequently, summing the preceding inequality on $K_n\in\mathcal{M}_T$, we obtain

$$\mathcal{F}(\boldsymbol{u},T) \leq 2\sum_{K_n\in\mathcal{M}_t}\sum_{L\in\partial K_n^-} |V_{KL}^n|\delta t|u_L^n - u_K^n|^2,$$

and we conclude by Lemma 2.1 applied with $\boldsymbol{\phi}=1$ and $t=T$. ∎

By continuity in H^1 of the L^2-projection on the space of functions which are constant with respect to the mesh $\mathcal{T}$, we have the following lemma.

LEMMA 3.3. *There exists* $c\geq 0$, *depending only on* d, *such that for every* $u_0\in H^1(\mathbf{R}^d)$,

$$\sum_{K\in\mathcal{T},\, L\in K_0^-} |K\vert L|\,|u_L^0 - u_K^0|^2 \leq c\alpha^{-4}\,\|\nabla u_0\|_{L^2}^2 h,$$

$$\|\boldsymbol{u}(\cdot,0) - u_0\|_{L^2} \leq c\alpha^{-1/2}\,\|\nabla u_0\|_{L^2} h.$$

Proof. Let $K \in \mathcal{T}$, $L \in \partial K$. We have

$$|u_K^0 - u_L^0| \leq \frac{1}{|K|\,|L|} \int_{K\times L} |u_0(x) - u_0(y)| dxdy.$$

Now from $|u_0(x) - u_0(y)| \leq \|x-y\| \int_0^1 |\nabla u_0((1-t)x + ty)| dt$, we have

$$|u_K^0 - u_L^0|^2 \leq \frac{1}{|K|\,|L|} \int_{K\times L} \|x-y\|^2 \int_0^1 |\nabla u_0((1-t)x+ty)|^2 dtdxdy$$

$$\leq \frac{4h^2}{|K|\,|L|} \int_{K\times L} \int_0^1 |\nabla u_0((1-t)x+ty)|^2 dtdxdy.$$

We perform the change of variables of Jacobian determinant $(-1)^d$, $(x,y,t) \mapsto (z = (1-t)x + ty, w = x - y, t = t)$, to obtain

$$|u_K^0 - u_L^0|^2 \leq \frac{4h^2}{|K|\,|L|} \int_{B(x_K,2h)} |\nabla u_0(z)|^2 \left(\int_0^1 \int_{\mathbf{R}^d} g(z,w,t) dwdt \right) dz,$$

where we have chosen $x_K \in K$ and where $g(z,w,t) = 1$ if $z + tw \in K$ and $z - (1-t)w \in L$, and $g(z,w,t) = 0$ otherwise. For $(z,t) \in B(x_K, 2h) \times [0,1]$, we have $\int_{\mathbf{R}^d} g(z,w,t) dw \leq 2^d |K|$ if $t \geq 1/2$ and $\int_{\mathbf{R}^d} g(z,w,t) dw \leq 2^d |L|$ if $t < 1/2$. Finally, we get

$$|u_K^0 - u_L^0|^2 \leq \frac{2^{d+2} h^2 \max(|K|,|L|)}{|K|\,|L|} \int_{B(x_K,2h)} |\nabla u_0(z)|^2 dz, \tag{3.5}$$

and the first inequality of (1.6) yields

$$|u_K^0 - u_L^0|^2 \leq 2^{d+2} h^{2-d} \alpha^{-1} \int_{B(x_K,2h)} |\nabla u_0(z)|^2 dz.$$

Multiplying by $|K|L|$, summing on $L \in \partial K$, and using the second part of (1.6), we get

$$\sum_{L\in\partial K} |K|L|\, |u_K^0 - u_L^0|^2 \leq M(K) 2^{d+1} h \alpha^{-2} \int_{B(x_K,2h)} |\nabla u_0(z)|^2 dz,$$

where $M(K)$ is the cardinal of $\{L : L \in \partial K\}$. From (1.6), we have

$$M(K)\alpha h^d \leq |\cup_{L\in\partial K} L| \leq |B(x_K, 3h)|, \tag{3.6}$$

and $M(K) \leq c\alpha^{-1}$. Summing on $K \in \mathcal{T}$, we obtain

$$\sum_{K\,,\,L\in\partial K} |K|L|\, |u_K^0 - u_L^0|^2 \leq ch\alpha^{-3} \int_{\mathbf{R}^d} |\nabla u_0(z)|^2 N(z) dz,$$

where $N(z)$ is the cardinal of $\{K : d(x_K, z) \leq 2h\}$. The integer $N(z)$ satisfies an inequality similar to (3.6) and so is bounded by $c\alpha^{-1}$. This leads to the first inequality of the lemma.

We now sketch the proof of the second inequality. Let $K \in \mathcal{T}$. Performing the computations and change of variables leading to (3.5) in the proof of the first part, we get successively

$$\begin{aligned}\int_K |\boldsymbol{u}(\cdot,0) - u_0|^2 &\le \frac{1}{|K|}\int_{K\times K} (u_0(x) - u_0(y))^2\,dx\,dy \\ &\le \frac{h^2}{|K|}\int_{K\times K}\int_0^1 |\nabla u_0((1-t)x+ty)|^2\,dt\,dx\,dy \\ &\le 2^d h^2 \int_{B(x_k,h)} |\nabla u_0(z)|^2.\end{aligned}$$

Summing on $K \in \mathcal{T}$ and using the fact that the cardinal of the set $\{K : d(K,z) \le h\}$ is bounded by $c\alpha^{-1}$, we get the second estimate. □

In what follows, we will need some estimates on the differences between u and its mean values on cells or on edges. They are contained in the next lemma. The three estimates are based on the trace theorem for H^1-functions. For (3.9), the conditions (1.6) are not sufficient, and we need hypothesis (1.12) to avoid the blowup of the constant in the trace theorem.

LEMMA 3.4. *Assume that* (1.6) *is satisfied. Then, for every* $u_0 \in H^1(\mathbf{R}^d)$ *we have*

$$\sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t|K|L|\,(\langle u\rangle_{K_n} - \langle u\rangle_{K|L_n})^2 \le CC_0^2\|\nabla u_0\|_{L^2}^2 Th, \tag{3.7}$$

$$\sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t|K|L| \left(\fint_{K|L_n}\fint_{n\delta t}^{(n+1)\delta t} |u(x,s)-u(x,t)|dsdtdx\right)^2 \le CC_0^2\|\nabla u_0\|_{L^2}^2 T\delta t. \tag{3.8}$$

If, moreover, assumption (1.12) *is satisfied, then*

$$\sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t|K|L| \left(\fint_{K|L_n}\fint_{K|L} |u(x,t)-u(y,t)|\,dxdydt\right)^2 \le CC_0^2\|\nabla u_0\|_{L^2}^2 Th. \tag{3.9}$$

Proof. We prove (3.7), (3.8), and (3.9) successively.

Let $K_n \in \mathcal{M}_T$, and let $L \in \partial K_n^-$. Let us fix $x_K \in K$ and $t \in [n\delta t, (n+1)\delta t)$. As in the proof of (3.5) in Lemma 3.3 (with L replaced by $B(x_K, 2h)$), we have

$$\left|\fint_K u(\cdot,t) - \fint_{B(x_K,2h)} u(\cdot,t)\right|^2 \le Ch^{2-d}\int_{B(x_K,2h)} |\nabla u(\cdot,t)|^2. \tag{3.10}$$

On the other hand, let P be the hyperplane containing $K|L$. We compute

$$\left(\fint_{K|L} u(\cdot,t) - \fint_{B(x_K,2h)} u(\cdot,t)\right)^2 \tag{3.11}$$

$$\leq \fint_{K|L} \left(u(x,t) - \fint_{B(x_K,2h)} u(y,t)\,dy\right)^2 dx$$

$$\leq \frac{1}{|K|L|}\int_{P\cap B(x_K,2h)} \left(u(x,t) - \fint_{B(x_K,2h)} u(y,t)\,dy\right)^2 dx$$

$$\leq\ C\frac{h}{|K|L|}\int_{B(x_K,2h)} |\nabla u(\cdot,t)|^2.$$

The last inequality is obtained by rescaling the following standard result. □

LEMMA 3.5. *Let $w \in H^1(B_{\mathbf{R}^d}(0,2))$ such that $\int_{B(0,2)} w = 0$, and let Q be a hyperplane such that $d(Q,0) \leq 1$; then the trace γ of w on $Q \cap B(0,2)$ satisfies $\|\gamma\|_{L^2} \leq C\|\nabla w\|_{L^2}$.*

Summing (3.10) and (3.11), integrating on $[n\delta t,(n+1)\delta t)$, and using (1.6), we get

$$\delta t|K|L|\left(\langle u\rangle_{K_n} - \langle u\rangle_{K|L_n}\right)^2 \leq C\int_{B(x_K,2h)\times[n\delta t,(n+1)\delta t)} |\nabla u|^2\ h.$$

Summing on $L \in \partial K_n^-$ and $K_n \in \mathcal{M}_T$ and using the fact that the cardinals of the sets $\{K\ :\ d(K,z) \leq 2h\}$ are uniformly bounded (see the proof of Lemma 3.3), we find that the left-hand side of (3.7) is bounded by $C\int_{\mathbf{R}^d\times[0,T]} |\nabla u|^2\, h$. We conclude by the second estimate of Corollary 1.2.

Before proving (3.8) and (3.9) we recall the definition of an $H^{1/2}$-seminorm. Let B be a ball in $\mathbf{R}^q$ centered at x_0, let P be an affine subspace of dimension $q-1$ containing x_0, and let $v \in H^1(B,\mathbf{R})$. Then γ, the trace of v on P, satisfies

$$|\gamma|^2_{H^{1/2}(B\cap P)} := \int_{(B\cap P)^2} \frac{|\gamma(x)-\gamma(y)|^2}{\|x-y\|^q} dxdy \leq C\int_B |\nabla v|^2. \tag{3.12}$$

Let $K_n \in \mathcal{M}_T$ and $L \in \partial K_n^-$. Let x_{KL} be any element of $K|L$ so that $K|L \subset B(x_{KL},h)$. We introduce new Cartesian coordinates: letting P be the affine subspace containing $K|L$, we define $(x'_1,\dots,x'_d)$ such that $x' \in P \Leftrightarrow x'_d = 0$ and we define $K|L'$ to be the set such that $x' \in K|L \Leftrightarrow (x'_d = 0$ and $\bar{x}' = (x'_1,\dots,x'_{d-1}) \in K|L')$.

From the Cauchy–Schwarz inequality, we have for every $\bar{x}' \in K|L'$

$$\left(\fint_{n\delta t}^{(n+1)\delta t}\fint_{n\delta t}^{(n+1)\delta t} |u((\bar{x}',0),s) - u((\bar{x}',0),t)|dsdt\right)^2$$

$$\leq \delta t^2 \fint_{n\delta t}^{(n+1)\delta t}\fint_{n\delta t}^{(n+1)\delta t} \frac{|u((\bar{x}',0),s) - u((\bar{x}',0),t)|^2}{|s-t|^2}\,dsdt$$

$$\leq C\int_0^{\delta t}\int_{n\delta t}^{(n+1)\delta t} |\partial_{x'_d} u((\bar{x}',x'_d),s)|^2 + |\partial_t u((\bar{x}',x'_d),s)|^2 ds\,dx'_d.$$

The last inequality comes from the trace theorem (3.12) applied with $q = 2$ and $P = \{x'_d = 0\}$ to the family of functions $(x'_d, s) \mapsto u((\bar{x}', x'_d), s)$. Integrating on $K|L'$ and using Jensen's inequality and the CFL condition $\delta t \le c_0 h$, we obtain

$$\left(\fint_{n\delta t}^{(n+1)\delta t} \fint_{K|L_n} |u(x,s) - u(u,t)| ds dt dx \right)^2 \le C \int_{n\delta t}^{(n+1)\delta t} \int_{B(x_{KL},(1+c_0)h)} |\nabla u|^2 + |\partial_t u|^2.$$

Multiplying by $\delta t |K|L|$ and summing on L, K_n, (3.8) follows from Corollary 1.2 and the fact that the cardinal of the neighbors of K is uniformly bounded.

We assume assumption (1.12) is satisfied. Let $K_n \in \mathcal{M}_T$, $L \in \partial K_n^-$, and $t \in [n\delta t, (n+1)\delta t]$. We denote again by P the affine subspace containing $K|L$ and $x_{KL} \in K|L$. From the Cauchy–Schwarz inequality, we have

$$\left(\fint_{(K|L)^2} |u(x,t) - u(y,t)| dx dy \right)^2 \le h^d \fint_{(K|L)^2} \frac{|u(x,t) - u(y,t)|^2}{\|x-y\|^d} dx dy,$$

and from the trace theorem (3.12),

$$\left(\fint_{(K|L)^2} |u(x,t) - u(y,t)| dx dy \right)^2 \le C \frac{h^d}{|K|L|^2} \int_{B(x_{KL},h)} |\nabla u(z,t)|^2 dz.$$

Integrating on $[n\delta t, (n+1)\delta t)$ and using Jensen's inequality and assumption (1.12) yield

$$\delta t |K|L| \left(\fint_{K|L_n} \fint_{K|L} |u(x,t) - u(y,t)| \, dx dy dt \right)^2 \le C \int_{B(x_{KL},h)} |\nabla u(z,t)|^2 dz \, \delta t \, h.$$

Summing on $L \in \partial K_n^-$ and $K_n \in \mathcal{M}_T$, the second inequality of Corollary 1.2 yields (3.9). □

3.2. End of the proof. We now assume that $u_0 \in H^1(\mathbf{R}^d)$ and end the proof of Theorem 1.8. Let us notice that from the L^2-stability of the scheme and of the evolution problem (1.3), it is sufficient to prove Theorem 1.8 for $u_0 \in C_c^\infty(\mathbf{R}^d)$ and conclude by density of such functions in $H^1(\mathbf{R}^d)$. In this case, the formula $u(x,t) = u_0(X(x,t))$ and the definition of X imply that $u \in W^{1,\infty}(\mathbf{R}^d \times [0, T+\delta t])$ and is compactly supported.

From now on, $u_0 \in C_c^\infty(\mathbf{R}^d)$. We want to apply the weak formulations (1.5) and (3.1) to a test function ϕ defined by $\phi(x,t) := \psi(t) u(x,t)$, for $x \in \mathbf{R}^d$, $s \ge 0$, with $\psi := \mathbf{1}_{[0,T]}$. Since the function $\mathbf{1}_{[0,T]}$ is not Lipschitz, we have to introduce a mollifying sequence to approximate ψ.

Let $(\psi_q)_{q \ge 1}$ be a sequence of $C^\infty(\mathbf{R}_+)$ functions satisfying $\psi_q \equiv 1$ on $[0,T]$, $\psi_q \equiv 0$ on $[T + \frac{\delta t}{q}, +\infty)$ and $0 \ge \psi_q' \ge \frac{-2q}{\delta t}$. We set $\phi_q(x,t) := u(x,t)\psi_q(t)$ for every $(x,t) \in \mathbf{R}^d \times \mathbf{R}_+$ and $q \ge 1$. Since u solves (1.3) and $\operatorname{div} V \equiv 0$, we have $\partial_t u + V \cdot \nabla u = \partial_t u + \operatorname{div}(Vu) = 0$ on $\mathbf{R}^d \times \mathbf{R}_+$. Thus, the weak formulation (3.1) reads

$$\int_T^{T+\delta t} \left(\int_{\mathbf{R}^d} \boldsymbol{u}(x,t) u(x,t) dx \right) \psi_q'(t) dt + \int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,0) u(\cdot,0) = \mu(\phi^q) + \nu(\phi^q).$$

The sequence of Radon measures $(\psi_q'(t)dt)_q$ converges to $-\delta_T$, so the first term of the left-hand side converges to $-\int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,T)u(\cdot,T)$. Clearly, for every $K_n \in \mathcal{M}$ and $L \in \partial K_n^-$, we have $(\langle\phi_q\rangle_K)_q \to \langle\phi\rangle_{K_n}$, $(\langle V\cdot\mathbf{n}\phi_q\rangle_{K|L_n})_q \to \langle V\cdot\mathbf{n}\phi\rangle_{K|L_n}$ and $(\langle\phi_q\rangle_K(n\delta t))_q \to \langle\phi\rangle_K(n\delta t)$. Thus, passing to the limit on q, we get

$$-\int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,T)u(\cdot,T) + \int_{\mathbf{R}^d} \boldsymbol{u}(\cdot,0)u(\cdot,0) = \mu(\psi u) + \nu(\psi u).$$

Similarly, we obtain from (1.5) (or more directly from the conservation of λ by the flow) that

$$-\int_{\mathbf{R}^d} u(\cdot,T)^2 + \int_{\mathbf{R}^d} u(\cdot,0)^2 = 0.$$

Subtracting these equalities, we get

$$\int_{\mathbf{R}^d} ((u-\boldsymbol{u})u)(\cdot,T) - \int_{\mathbf{R}^d} ((u-\boldsymbol{u})u)(\cdot,0) = \mu(\psi u) + \nu(\psi u).$$

Using the identity $(a-b)a = [(a-b)^2]/2 + [a^2-b^2]/2$, we obtain

$$\begin{aligned}&\|(u-\boldsymbol{u})(\cdot,T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot,0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot,T)\|_{L^2}^2\\ &\quad= 2\mu(\psi u) + 2\nu(\psi u) + \|(u-\boldsymbol{u})(\cdot,0)\|_{L^2}^2 + \left(\|u(\cdot,0)\|_{L^2}^2 - \|u(\cdot,T)\|_{L^2}^2\right).\end{aligned}$$

The last term vanishes and Lemma 3.3 implies $\|(u-\boldsymbol{u})(\cdot,0)\|_{L^2}^2 \le C\|\nabla u_0\|_{L^2}^2 h^2$. Thus we have

$$\begin{aligned}&\|(u-\boldsymbol{u})(\cdot,T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot,0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot,T)\|_{L^2}^2\\ &\qquad\le 2\mu(\psi u) + 2\nu(\psi u) + C\|\nabla u_0\|_{L^2}^2 h^2.\end{aligned} \tag{3.13}$$

(a) We first estimate the term $\mu(\psi u)$ in (3.13). From the definition (3.2) of μ and the Cauchy–Schwarz inequality, we get

$$|\mu(\psi u)| \le \mathcal{F}(\boldsymbol{u},T)^{1/2}\left(\sum_{K_n\in\mathcal{M}_T} |K|\,|\langle u\rangle_{K_n} - \langle u\rangle_K((n+1)\delta t)|^2\right)^{1/2}.$$

By Jensen's inequality, we have

$$|\langle u\rangle_{K_n} - \langle u\rangle_K((n+1)\delta t)|^2 \le \langle |u-u((n+1)\delta t,\cdot)|^2\rangle_{K_n},$$

and by the first estimate of Corollary 1.2 we get

$$|\mu(\psi u)| \le C_0\mathcal{F}(\boldsymbol{u},T)^{1/2}\|\nabla u_0\|_{L^2}\,T^{1/2}\delta t^{1/2}. \tag{3.14}$$

(b) We now turn to the term $\nu(\psi u)$ in (3.13). Let us write

$$\begin{aligned}\nu(\psi u) &= \sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t(u_L^n - u_K^n)(V_{KL}^n\langle u\rangle_{K_n} - |K|L|\langle V\cdot\mathbf{n}\,u\rangle_{K|L_n})\\ &= \mathrm{I} + \mathrm{II},\end{aligned} \tag{3.15}$$

with

$$\mathrm{I} := \sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t(u_L^n - u_K^n)V_{KL}^n \left(\langle u\rangle_{K_n} - \fint_{K|L_n} u\right),$$

$$\mathrm{II} := \sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-} \delta t(u_L^n - u_K^n)|K|L|\fint_{K|L_n}\left(-u + \fint_{K|L_n} u\right) V\cdot\mathbf{n}_{KL}.$$

From the Cauchy–Schwarz inequality, we deduce

$$|\mathrm{I}| \le \mathcal{F}(\boldsymbol{u},T)^{1/2}\left(\sum_{K_n\in\mathcal{M}_T}\sum_{L\in\partial K_n^-}\delta t|V_{KL}^n|\left(\langle u\rangle_{K_n} - \fint_{K|L_n} u\right)^2\right)^{1/2},$$

and since $|V_{KL}^n| \le \|V\|_\infty |K|L|$, (3.7) yields

$$|\mathrm{I}| \le CC_0\mathcal{F}(\boldsymbol{u},T)^{1/2}\|\nabla u_0\|_{L^2}T^{1/2}h^{1/2}. \tag{3.16}$$

We now estimate II. We split the integral in space and time differences,

$$\begin{aligned}\fint_{K|L_n}\left(-u + \fint_{K|L_n} u\right) V\cdot\mathbf{n}_{KL} &= \fint_{K|L_n}\fint_{K|L_n}(u(y,t)-u(x,s))V(x,s)\cdot\mathbf{n}_{KL}\,dxdrdyds\\ &=: A + B,\end{aligned} \tag{3.17}$$

with

$$A := \fint_{K|L_n}\fint_{n\delta t}^{(n+1)\delta t}(u(y,s)-u(x,s))V(x,s)\cdot\mathbf{n}_{KL},$$

$$B := \fint_{K|L_n}\fint_{K|L_n}(u(y,t)-u(y,s))V(x,s)\cdot\mathbf{n}_{KL}.$$

Since $\fint_{n\delta t}^{(n+1)\delta t}\fint_{n\delta t}^{(n+1)\delta t}(u(y,t)-u(y,s))drds = 0$, we have

$$\begin{aligned}|B| = \Bigg|\fint_{K|L_n}\fint_{K|L_n}&(u(y,s)-u(y,t))\\ &\times\left(V(x,s)\cdot\mathbf{n}_{KL} - \fint_{n\delta t}^{(n+1)\delta t} V(x,\cdot)\cdot\mathbf{n}_{KL}\right)dxdydrds\Bigg|\\ &\le C\delta t\fint_{K|L_n}\fint_{n\delta t}^{(n+1)\delta t}|u(y,s)-u(y,t)|dydrds.\end{aligned} \tag{3.18}$$

Similarly, $|A| \le Ch\fint_{K|L_n}\fint_{K|L}|u(x,s)-u(y,s)|$. Plugging this estimate and (3.18)

into (3.17) and using the Cauchy–Schwarz inequality, we get

$$
\begin{aligned}
|\mathrm{II}|^2 \le Ch & \left(\sum_{K_n \in \mathcal{M}_T,\, L \in \partial K_n^-} \delta t\, h^d |u_L^n - u_K^n|^2 \right) \\
& \times \left(\sum_{K_n \in \mathcal{M}_T,\, L \in \partial K_n^-} \delta t |K|L| \left(\fint_{K|L_n} \fint_{K|L} |u(x,t) - u(y,t)| \right)^2 \right) \\
& + C\delta t \left(\sum_{K_n \in \mathcal{M}_T,\, L \in \partial K_n^-} \delta t^2 |K|L| |u_L^n - u_K^n|^2 \right) \\
& \times \left(\sum_{K_n \in \mathcal{M}_T,\, L \in \partial K_n^-} \delta t |K|L| \left(\fint_{K|L_n} \fint_{n\delta t}^{(n+1)\delta t} |u(x,s) - u(x,t)| \right)^2 \right) \\
=: & \, ChA_1B_1 + C\delta t A_2 B_2.
\end{aligned}
$$

Using the L^2-stability of the scheme and assumption (1.6), we find that A_1 and A_2 are bounded by $CT\|u_0\|_{L^2}^2$. We use (3.9) and (3.8), respectively, to estimate B_1 and B_2 and obtain

$$
|\mathrm{II}| \le CC_0 \|\nabla u_0\|_{L^2} \|u_0\|_{L^2} Th. \tag{3.19}
$$

Remark 3.2. When V is constant, II vanishes, so (3.9) and then (1.12) are not needed.

Plugging (3.16) and (3.19) into (3.15) and then (3.15) and (3.14) into (3.13) (and using $\delta t \le c_0 h$), we get

$$
\begin{aligned}
& \|(u - \boldsymbol{u})(\cdot, T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot, 0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot, T)\|_{L^2}^2 \\
& \quad \le \; CC_0 \left(\|u_0\|_{H^1}^2 Th + \|u_0\|_{H^1} \mathcal{F}(\boldsymbol{u}, T)^{1/2} T^{1/2} h^{1/2} \right) + C\|u_0\|_{H^1}^2 h^2.
\end{aligned}
$$

And from Lemma 3.2,

$$
\begin{aligned}
& \|(u - \boldsymbol{u})(\cdot, T)\|_{L^2}^2 + \|\boldsymbol{u}(\cdot, 0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot, T)\|_{L^2}^2 \\
& \quad \le \; CC_0 \left(\|u_0\|_{H^1}^2 Th + \xi^{-1/2} \|u_0\|_{H^1} \left(\|\boldsymbol{u}(\cdot, 0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot, T)\|_{L^2}^2 \right)^{1/2} T^{1/2} h^{1/2} \right) \\
& \qquad + C\|u_0\|_{H^1}^2 h^2.
\end{aligned}
$$

We then use the Young inequality $ab \le \frac{1}{2}a^2 + \frac{1}{2}b^2$ with

$$
a = (CC_0)^{-1/2} \left(\|\boldsymbol{u}(\cdot, 0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot, T)\|_{L^2}^2 \right)^{1/2}, \qquad b = (CC_0)^{1/2} \xi^{-1/2} \|u_0\|_{H^1} T^{1/2} h^{1/2}
$$

to derive

$$
\begin{aligned}
& \|(u - \boldsymbol{u})(\cdot, T)\|_{L^2}^2 + \frac{1}{2} \left(\|\boldsymbol{u}(\cdot, 0)\|_{L^2}^2 - \|\boldsymbol{u}(\cdot, T)\|_{L^2}^2 \right) \\
& \qquad \le C(1 + C_0^2)\, \xi^{-1} \|u_0\|_{H^1}^2 Th + C\|u_0\|_{H^1}^2 h^2,
\end{aligned}
$$

which yields the first estimate of Theorem 1.8 and, by Lemma 3.2, the second estimate. ∎

CONVERGENCE OF TIME-AVERAGED STATISTICS OF FINITE ELEMENT APPROXIMATIONS OF THE NAVIER–STOKES EQUATIONS*

V. JOHN†, W. LAYTON‡, AND C. C. MANICA‡

Abstract. When discussing numerical solutions of the Navier–Stokes equations, especially when turbulent flows are concerned, there are at least two questions that can be raised. *What is meaningful to compute? How to determine the fidelity of the computed solution with respect to the true solution?* This paper takes a step towards the answer of these questions for turbulent flows. We consider long-time averages of weak solutions of the Navier–Stokes equations, rather than strong solutions. We present error estimates for the time-averaged energy dissipation rate, drag and lift, most of them under the assumption of small Reynolds/generalized Grashof number. For shear flows, we address the question of fidelity of the computed solution with respect to the true solution, in view of Kolmogorov's energy cascade theory.

1. Introduction.

The motion of an incompressible Newtonian fluid is governed by the incompressible Navier–Stokes equations. A fundamental problem of fluid motion is turbulence and a fundamental problem in the Navier–Stokes equations is uniqueness of weak solutions in the general case of no assumed extra regularity or small data. The Leray conjecture [20] states that these two problems are connected: the lack of uniqueness of weak solutions (which he called "turbulent solutions") is not an artifact of imperfect mathematical techniques, but it reflects fundamental physical mechanisms of turbulence.

The numerical analysis of turbulent flows is caught between the gaps in the physical understanding of turbulence and those in the mathematical foundations of the Navier–Stokes equations. For example, smooth strong solutions are not expected while, if the uniqueness of the weak solution is unknown, bounding the error in a numerical simulation is currently not possible without assuming extra regularity on the solution, or without assuming both the initial data u_0 and the body force $f(x,t)$ to be very small.

On the other hand, computational simulations are carried out and statistics of computed fluid velocities and pressures often reflect rather accurately statistics of physical flows even in the absence of mathematical justification for this accuracy. Further, statistics (by which we shall mean long-time averages) are often smooth, behaving deterministically (often in accordance with the Kolmogorov theory [18]) in both numerical simulations and physical experiments. From this situation, a challenge for the numerical analysis of fluid motion arises: develop a rigorous understanding

of how statistics computed from numerical simulations reflect those for the unknown solution of the Navier–Stokes equations.

The incompressible Navier–Stokes equations (with homogeneous Dirichlet boundary conditions) are given by

$$\begin{aligned} u_t + u \cdot \nabla u - \nu \Delta u + \nabla p &= f \quad && \text{in } \Omega \times (0, \infty), \\ \nabla \cdot u &= 0 \quad && \text{in } \Omega \times [0, \infty), \\ u(x, 0) &= u_0 \quad && \text{in } \Omega, \\ u &= 0 \quad && \text{on } \Gamma \times [0, \infty). \end{aligned} \tag{1.1}$$

Here, Ω denotes a bounded and regular flow domain in $\mathbb{R}^d$, $d = 2, 3$, $\Gamma = \partial\Omega$ is the boundary of Ω, $u(x,t)$, $p(x,t)$ are the fluid velocity and pressure, ν is the kinematic viscosity, $f(x,t) \in L^\infty(0,\infty; L^2(\Omega)^d)$ are the body forces, and $u_0 \in L^2(\Omega)^d$ is a weakly divergence-free initial condition. The Reynolds number is defined by $Re = LU/\nu$, where the constants L and U are, respectively, a reference large-scale length and velocity. From the point of view of applications, the three-dimensional case is the important one. This case is mathematically much more challenging than the two-dimensional one, too.

We will study statistics related to the energy dissipation rate and the total kinetic energy of the flow. The energy dissipation rate per unit volume of the flow at time t is given by

$$\varepsilon(u) := \frac{\nu}{|\,\Omega\,|} \| \nabla u(\cdot, t) \|^2,$$

where $|\,\Omega\,|$ is the volume of Ω and $\|\cdot\|$ denotes the $L^2(\Omega)$-norm, and its total kinetic energy per unit volume is

$$k(u) := \frac{1}{2|\,\Omega\,|} \| u(\cdot, t) \|^2.$$

The time average $\langle q \rangle$ of a quantity q is defined by

$$\langle q \rangle = \limsup_{T \to \infty} \frac{1}{T} \int_0^T q(t)\, dt. \tag{1.2}$$

Consequently, the time average of the energy dissipation rate is

$$\langle \varepsilon(u) \rangle = \limsup_{T \to \infty} \frac{1}{T} \int_0^T \varepsilon(u)\, dt = \frac{\nu}{|\,\Omega\,|} \limsup_{T \to \infty} \frac{1}{T} \int_0^T \|\nabla u\|^2 = \frac{\nu}{|\,\Omega\,|} \langle \|\nabla u\|^2 \rangle,$$

and the time average of the kinetic energy is

$$\langle k(u) \rangle = \frac{1}{2|\,\Omega\,|} \limsup_{T \to \infty} \frac{1}{T} \int_0^T \| u \|^2\, dt = \frac{1}{2|\,\Omega\,|} \langle \| u \|^2 \rangle.$$

In practical simulations of turbulent flows, it is typical to compute time-averaged flow statistics, which are then matched against benchmark averages; see, e.g., [2, 17, 15, 16, 21, 5]. However, there is very little numerical analysis in support of this approach. Of course, if the error in certain norms of the velocity and the pressure is provably optimal over $0 \le t < \infty$, then time averages involving these norms are

convergent with optimal rates as well. But, the practical case is complementary: time averages seem to be predictable even when the dynamic flow behavior over bounded time intervals is irregular. This is the case we aim to study. However, a complete analysis seems to be still beyond the present mathematical tools.

In section 3.1, the case of large data is studied and estimates for the L^2-norm of the time-averaged error of the pressure (Theorem 3.1) and the time-averaged energy dissipation rate (Theorem 3.2) are given. Then, in section 3.2, we consider the case of arbitrary initial data u_0 and asymptotically small body forces (small generalized Grashof number) which converge to a stationary limit $f^*(x) = \lim_{t\to\infty} f(x,t)$. Let (u^h, p^h) be a finite element approximation of the velocity field and the pressure and assume that $f^*(x)$ satisfies a small data condition. Let u^* be the solution of the stationary Navier–Stokes equations with body force f^*. We show that

$$\langle \varepsilon(u - u^*)\rangle = 0, \quad \langle \varepsilon(u^h - u^{*\,h})\rangle = 0,$$

and we prove (Theorem 3.3) an error estimate which shows that the problem of estimating $\langle \varepsilon(u - u^h)\rangle$ reduces to the one of estimating $\|\nabla(u^* - u^{*\,h})\|^2$. Then the error goes to zero optimally as the mesh width $h \to 0$. This result is plausible because the possible irregularities caused by large initial data are washed out by the time averaging.

Section 4 studies the flow through a channel around a body. Under the assumption of bounded growth of the kinetic energy (in the case of inhomogeneous inflow boundary conditions), we give estimates for the time-averaged drag and lift coefficients on an immersed body (Theorem 4.1). It is shown that the assumption holds true if the inflow boundary conditions are sufficiently small.

In section 5, we consider the complementary situation of a flow driven by a large and persistent boundary condition. We are not (yet) able to perform a complete error analysis in this case. However, following the important work of Constantin and Doering [4] in the continuous case, we show that, provided the first mesh line in the finite element mesh is within $O(1/Re)$ of the moving wall which drives the flow, the computed time-averaged energy dissipation rate for the shear flow scales as predicted for the continuous flow by the Kolmogorov theory (Theorem 5.1):

$$\langle \varepsilon(u^h)\rangle \quad \leq \quad C\,\frac{U^3}{L}.$$

This restriction on the mesh size arises from mathematical analysis of constructible background flows in finite element spaces and their subsequent analysis. However, it is in accordance with an entirely different observation of the thickness of time-averaged turbulent boundary layers [24].

2. Mathematical preliminaries. Throughout the paper, we use the standard notations $L^p(\Omega)$, $W^{k,p}(\Omega)$, $H^k(\Omega) = W^{k,2}(\Omega)$ for the Lebesgue and Sobolev spaces, respectively. The inner product in the space $L^2(\Omega)$, $L^2(\Omega)^d$, and $L^2(\Omega)^{d\times d}$ will be denoted by $(\cdot,\cdot)$ and its norm by $\|\cdot\|$. Norms in Sobolev spaces $H^k, k > 0$, are denoted by $\|\cdot\|_k$. The symbol C stands for generic constants independent of the viscosity ν and the mesh size h.

The velocity at a given time t is sought in the space

$$\mathbb{X} = H_0^1(\Omega)^d = \{v \in L^2(\Omega)^d : \nabla v \in L^2(\Omega)^{d\times d} \quad \text{and} \quad v = 0 \ \text{ on } \ \Gamma\},$$

equipped with the norm $\|v\|_{\mathbb{X}} = \|\nabla v\|$. The norm of the dual space $\mathbb{X}^*$ of $\mathbb{X}$ is denoted by $\|\cdot\|_{-1}$. The pressure at time t is sought in the space

$$\mathbb{Q} = L_0^2(\Omega) = \left\{ q : \, q \in L^2(\Omega) \, , \int_\Omega q \, dx = 0 \right\}.$$

In addition, the space of weakly divergence-free functions is denoted by

$$\mathbb{V} = \{ v \in \mathbb{X} : (\nabla \cdot v, q) = 0 \; \forall \; q \in \mathbb{Q} \}.$$

For Y being a Banach space and for $0 < T < \infty$, the space $L^p(0,T;Y)$ with $1 \leq p < \infty$ (and the usual modification if $p = \infty$) consists of all functions $v : [0,\infty) \to Y$ for which

$$\int_0^T \| \, v(t) \, \|_Y^p \, dt < \infty.$$

Define the trilinear forms on $\mathbb{X} \times \mathbb{X} \times \mathbb{X}$:

$$b(u,v,w) = \int_\Omega u \cdot \nabla v \cdot w \, dx \qquad \text{and} \qquad b_s(u,v,w) = \frac{1}{2} b(u,v,w) - \frac{1}{2} b(u,w,v).$$

Note that the convective form and the skew-symmetric form are equal for $u \in \mathbb{V}$: $b(u,v,w) = b_s(u,v,w)$.

LEMMA 2.1. *Let $\Omega \subset \mathbb{R}^d, d = 2$ or 3. Then there exists a constant $C = C(\Omega) < \infty$ such that*

$$b(u,v,w) \leq C \| \, \nabla u \, \| \, \| \, \nabla v \, \| \, \| \, \nabla w \, \| \qquad \forall \; u,v,w \in \mathbb{X}. \tag{2.1}$$

If $d = 3$, this can be improved to

$$b(u,v,w) \leq C \sqrt{\| \, u \, \| \, \| \, \nabla u \, \|} \, \| \, \nabla v \, \| \, \| \, \nabla w \, \| \qquad \forall \; u,v,w \in \mathbb{X}, \tag{2.2}$$

or, respectively, to

$$b(u,v,w) \leq C \| \, \nabla u \, \| \, \| \, \nabla v \, \| \, \sqrt{\| \, w \, \| \, \| \, \nabla w \, \|} \qquad \forall \; u,v,w \in \mathbb{X}. \tag{2.3}$$

Proof. Hölder's inequality and Sobolev imbedding theorems give

$$|b(u,v,w)| \leq \|u\|_{L^3} \|\nabla v\|_{L^2} \|w\|_{L^6} \leq C \|u\|_{1/2} \|v\|_1 \|w\|_1.$$

Estimate (2.2) is obtained now by applying the interpolation inequality between $L^2(\Omega)$ and $H^1(\Omega)$ (see Adams [1]),

$$\|u\|_{1/2} \leq C \|u\|^{1/2} \|u\|_1^{1/2},$$

and Poincaré's inequality. Similarly, (2.3) follows from

$$b(u,v,w) \leq C \|u\|_1 \|v\|_1 \|w\|_{1/2}.$$

The proof of (2.1) uses, after the application of Hölder's inequality, the imbedding $H^1(\Omega) \subset L^3(\Omega)$. ∎

Estimates for the skew-symmetric form $b_s(\cdot,\cdot,\cdot)$ can be derived directly from (2.1)–(2.3). The norms of the trilinear forms $b_s(\cdot,\cdot,\cdot) : \mathbb{X} \to \mathbb{R}$ and of the restriction $b_s(\cdot,\cdot,\cdot) : \mathbb{V} \to \mathbb{R}$ are denoted by

(2.4)
$$M = \sup_{u,v,w\in\mathbb{X}} \frac{b_s(u,v,w)}{\|\nabla u\|\,\|\nabla v\|\,\|\nabla w\|} < \infty \text{ and } N = \sup_{u,v,w\in\mathbb{V}} \frac{b_s(u,v,w)}{\|\nabla u\|\,\|\nabla v\|\,\|\nabla w\|} < \infty.$$

We will consider in this paper finite element approximations of (1.1). Throughout the paper, we shall assume that the velocity-pressure finite element spaces $\mathbb{X}^h \subset \mathbb{X}$ and $\mathbb{Q}^h \subset \mathbb{Q}$ are conforming, have approximation properties typical of finite element spaces commonly in use, and satisfy the discrete inf-sup condition,

$$\inf_{q^h\in\mathbb{Q}^h} \sup_{v^h\in\mathbb{X}^h} \frac{(q^h,\, \nabla\cdot v^h)}{\|\nabla v^h\|\,\|q^h\|} \geq \beta^h > 0, \tag{2.5}$$

where β^h is bounded away from zero uniformly in h. The space of discretely divergence-free functions is defined by

$$\mathbb{V}^h = \{v^h \in \mathbb{X}^h : (q^h,\, \nabla\cdot v^h) = 0 \quad \forall\, q^h \in \mathbb{Q}^h\}.$$

For examples of such spaces see, e.g., Gunzburger [13], Brezzi and Fortin [3], and Girault and Raviart [11].

Norms of the trilinear form $b_s(\cdot,\cdot,\cdot)$ restricted to $\mathbb{X}^h$ and $\mathbb{V}^h$, respectively, are defined in the same way as in (2.4), leading to corresponding constants M^h and N^h. Note that $M \geq M^h, N^h, N$ and that $N^h \to N$ as $h \to 0$ (see [11]) and by the same argument $M^h \to M$.

2.1. The continuous-in-time finite element discretization. Consider the standard finite element discretization of the Navier–Stokes equations. The semidiscrete (continuous-in-time) finite element approximations $u^h = u^h(\cdot,t)$ and $p^h = p^h(\cdot,t)$ are the maps $u^h : [\,0,\infty\,) \to \mathbb{X}^h$, $p^h : (\,0,\infty\,) \to \mathbb{Q}^h$ satisfying

$$(u_t^h, v^h) + \nu(\nabla u^h, \nabla v^h) + b_s(u^h, u^h, v^h) - (p^h, \nabla\cdot v^h) = (f, v^h) \quad \forall\, v^h \in \mathbb{X}^h, \tag{2.6}$$

$$(\nabla\cdot u^h, q^h) = 0 \quad \forall\, q^h \in \mathbb{Q}^h, \tag{2.7}$$

$$(u^h(\cdot,0) - u_0, v^h) = 0 \quad \forall\, v^h \in \mathbb{X}^h. \tag{2.8}$$

Under the inf-sup condition (2.5), this is equivalent to: find $u^h : [\,0,\infty\,) \to \mathbb{V}^h$ satisfying

$$(u_t^h, v^h) + \nu(\nabla u^h, \nabla v^h) + b_s(u^h, u^h, v^h) = (f, v^h) \quad \forall\, v^h \in \mathbb{V}^h, \tag{2.9}$$

$$(u^h(\cdot,0) - u_0, v^h) = 0 \quad \forall\, v^h \in \mathbb{V}^h.$$

2.2. The associated equilibrium problem. In the case that $f(x,t) \to f^*(x)$ in $H^{-1}(\Omega)$ as $t \to \infty$, we can associate with (1.1) the following equilibrium problem: find $u^*(x)$, $p^*(x)$ satisfying

$$\begin{aligned} -\nu\Delta u^* + u^*\cdot\nabla u^* + \nabla p^* &= f^* \quad \text{in } \Omega, \\ \nabla\cdot u^* &= 0 \quad \text{in } \Omega, \\ u^* &= 0 \quad \text{on } \Gamma, \\ \int_\Omega p^*\, dx &= 0. \end{aligned} \tag{2.10}$$

The variational formulation of the equilibrium problem is as follows: Find $u^* \in \mathbb{X}$ and $p^* \in \mathbb{Q}$ such that

$$\nu(\nabla u^*, \nabla v) + b_s(u^*, u^*, v) - (p^*, \nabla \cdot v) = (f^*, v) \quad \forall\, v \in \mathbb{X}, \tag{2.11}$$
$$(\nabla \cdot u^*, q) = 0 \quad \forall\, q \in \mathbb{Q},$$

or, equivalently, find $u^* \in \mathbb{V}$ such that

$$\nu(\nabla u^*, \nabla v) + b_s(u^*, u^*, v) = (f^*, v) \qquad \forall\, v \in \mathbb{V}. \tag{2.12}$$

A finite element approximation $(u^{*\,h}, p^{*\,h})$ is given by the solution of

$$\nu(\nabla u^{*\,h}, \nabla v^h) + b_s(u^{*\,h}, u^{*\,h}, v^h) - (p^{*\,h}, \nabla \cdot v^h) = (f^*, v^h) \quad \forall\, v^h \in \mathbb{X}^h, \tag{2.13}$$
$$(\nabla \cdot u^{*\,h}, q^h) = 0 \quad \forall\, q^h \in \mathbb{Q}^h.$$

In $\mathbb{V}^h$ this becomes: find $u^{*\,h} \in \mathbb{V}^h$ such that

$$\nu(\nabla u^{*\,h}, \nabla v^h) + b_s(u^{*\,h}, u^{*\,h}, v^h) = (f^*, v^h) \qquad \forall\, v^h \in \mathbb{V}^h. \tag{2.14}$$

It is known that solutions of the equilibrium problem are nonsingular for small data, generically nonsingular for large data, and optimally approximated by $u^{*\,h}$ when nonsingular; see [12]. Setting $v = u^*$ in (2.11) and $v^h = u^{*h}$ in (2.13), it is easy to check the a priori bounds

$$\| \nabla u^* \| \le \nu^{-1} \| f^* \|_{-1}, \qquad \| \nabla u^{*\,h} \| \le \nu^{-1} \| f^* \|_{-1}. \tag{2.15}$$

Both bounds can be sharpened slightly by replacing $\| f^* \|_{-1}$ with the dual norms of $\mathbb{V}$ or $\mathbb{V}^h$, respectively.

It is known that if the problem data is small enough, concretely if

$$N\nu^{-2} \| f^* \|_{-1} < 1,$$

then u^* is unique. If additionally $f(x,t) \equiv f^*(x)$, then $u(x,t) \to u^*(x)$ in $L^2(\Omega)^d$ exponentially fast as $t \to \infty$ and (u^h, p^h) approximates (u, p) optimally; see [11, 19, 13].

2.3. Weak solutions of the Navier–Stokes equations. The problem of turbulence is perhaps intimately connected with questions about weak solutions versus strong solutions of the Navier–Stokes equations. It is well known that weak solutions exist but it is not known if they are unique. (Thus, different methods of proving existence might possibly lead to different solutions.) A strong solution is generally defined as a weak solution which has enough extra regularity to ensure global uniqueness, i.e., which fulfills Serrin's condition [25]. In $\mathbb{R}^3$, it is unknown if strong solutions exist for all time; see [10, 26]. But if a strong solution exists, it is unique. Strong solutions might conceivably describe all fluid motion. However, in at least one conjecture about turbulence the case of strong solutions is associated with laminar flow.

For clearness of notation, we will give the definition of a weak and a strong solution, following [10].

DEFINITION 2.1. *Let*

1. $\mathbf{D}_T = \left\{ v \in C^\infty(\Omega \times [0,T])^d \ : \ v(t) \in C_0^\infty(\Omega)^d \text{ for each } t \right\}$,
2. $\mathcal{D} = \left\{ \psi \in C_0^\infty(\Omega)^d \ : \nabla \cdot \psi = 0 \text{ in } \Omega \right\}$,
3. $H(\Omega) = \left\{ v \in L^2(\Omega)^d : \nabla \cdot v = 0 \text{ and } v \cdot \hat{n} = 0 \text{ on } \Gamma \right\}$, *where* $\hat{n}$ *is the unit outer normal on* Γ,

4. $\mathcal{D}_T = \{\ \phi(x,t) \in C^\infty(\Omega \times [0,T])^d : \phi(x,t) \in \mathcal{D}$ *for each* t, $0 \le t \le T\}$.

Let $u_0 \in H(\Omega)$, $f \in L^2(0,T;L^2(\Omega)^d)$. *A measurable function* $u(x,t) : \Omega \times [0,T] \to \mathbb{R}^d$ *is a weak solution of the Navier–Stokes equations if for all* $T > 0$

1. $u \in L^2(0,T;\mathbb{V}) \cap L^\infty(0,T;H(\Omega))$,
2. u *satisfies the integral relation*

$$(u(T),\phi(T)) - \int_0^T \left[\left(u, \frac{\partial\,\phi}{\partial\,t}\right) - \nu\,(\nabla\,u, \nabla\,\phi) - b(u,u,\phi)\right]\,dt = (u(0),\phi(0)) + \int_0^T (f,\phi)\,dt$$

for all $\phi \in \mathcal{D}_T$, *which is equivalent to*

$$\frac{d}{dt}(u,v) + \nu(\nabla u, \nabla v) + b(u,u,v) - (f,v) = 0$$

for all $v \in \mathbb{V}$,

3. u *is a strong solution if* u *is a weak solution and* $u \in L^\infty(0,T;\mathbb{V})$ *for any* $T > 0$.

We note that if Ω is a bounded domain with Γ satisfying a cone condition, then it is known that, given a weak solution u, there exists a pressure $p(x,t) \in L^\infty(0,T;L^2_0(\Omega))$ (see, e.g., [10, Remark 2.5]) satisfying

$$(u(T),\phi(T)) - \int_0^T \left[\left(u, \frac{\partial\phi}{\partial t}\right) - \nu\,(\nabla u, \nabla\phi) - b(u,u,\phi) + (p, \nabla\cdot\phi)\right]\,dt$$

$$= (u(0),\phi(0)) + \int_0^T (f,\phi)\,dt \qquad \forall\ \phi \in \mathbf{D}_T. \tag{2.16}$$

This is equivalent to

$$\frac{d}{dt}(u,v) + \nu\,(\nabla u, \nabla v) + b(u,u,v) - (p, \nabla\cdot v) = (f,v) \qquad \forall\ v \in \mathbb{X}. \tag{2.17}$$

It is well known (see [10]) that weak solutions satisfy the energy inequality: for any $t \in [0,T]$,

$$\frac{1}{2}\|\,u(T)\,\|^2 + \nu\int_0^T \|\,\nabla\,u(t)\,\|^2\,dt \le \frac{1}{2}\|\,u_0\,\|^2 + \int_0^T (u(t), f(t))\,dt. \tag{2.18}$$

Strong solutions satisfy even an energy equality, i.e., (2.18) with "$\le$" replaced by "=".

LEMMA 2.2. *Let* (u,p) *be a weak solution of the Navier–Stokes equations, let* (u^h,p^h) *be its finite element approximation defined by* (2.6)–(2.8), *and let* $e = u - u^h$. *Then, for any* C^1 *map* $v^h : [0,T] \to \mathbb{X}^h$, $q^h : (0,T] \to \mathbb{Q}^h$ *(for each* T, $0 < T < \infty$*),*

$$(e(T), v^h(T)) - \int_0^T \left[\left(e, \frac{\partial v^h}{\partial t}\right) - \nu(\nabla e, \nabla v^h) - b_s(u,u,v^h) + b_s(u^h,u^h,v^h)\right.$$

$$\left. + (p - p^h, \nabla\cdot v^h) + (\nabla\cdot e, q^h)\right]\,dt = (e(0), v^h(0)), \tag{2.19}$$

which is equivalent to

$$\frac{d}{dt}(e, v^h) - \left(e, \frac{\partial v^h}{\partial t}\right) + \nu\,(\nabla e, \nabla v^h) + b_s(u, u, v^h) \tag{2.20}$$

$$-b_s(u^h, u^h, v^h) - (p - p^h, \nabla \cdot v^h) = 0,$$

$$(\nabla \cdot e, q^h) = 0.$$

Proof. We shall prove (2.20). The connection between (2.20) and (2.19) is the same as that between (2.16) and (2.17). The second equation in (2.20) follows immediately from $u \in \mathbb{V}$ and (2.8).

First, note that both statements of the lemma follow by subtraction if the term with the time derivative of the test function is well defined, i.e., provided (2.16) can be shown to hold for $\phi \in C^1(0,T;\mathbb{X}^h)$ or (2.17) can be shown for $v \in C^1(0,T;\mathbb{X}^h)$ (since $\mathbb{X}^h \subset \mathbb{X}$). We show the latter.

Since $\mathbb{X}^h \subset \mathbb{X}$, (2.17) holds for all $v := \tilde{v}^h(x) \in \mathbb{X}^h$. Next, let $A(t)$ be a $C^1(0,T)$ function. Multiplication of (2.17) by $A(t)$ and using

$$A(t)\frac{d}{dt}(u, \tilde{v}^h) = \frac{d}{dt}(u, A(t)\tilde{v}^h) - (u, A'(t)\tilde{v}^h)$$

give that u and p satisfy

$$\frac{d}{dt}(u, \tilde{v}^h) - \left(u, \frac{\partial \tilde{v}^h}{\partial t}\right) + \nu\,(\nabla u, \nabla \tilde{v}^h) + b_s(u, u, \tilde{v}^h) - (p, \nabla \cdot \tilde{v}^h) = (f, \tilde{v}^h)$$

with $v^h = v^h(x,t) = A(t)\tilde{v}^h(x)$. The same equation can be derived from (2.6) for (u^h, p^h). Subtracting gives (2.20) for any v^h of the form $v^h = v^h(x,t) = A(t)\tilde{v}^h(x)$.

Since (2.20) is linear in v^h, it also follows for any v^h which is a finite linear combination of such functions,

$$v^h(x,t) = \sum_{i=1}^{N} A_i(t)\tilde{v}_i^h(x).$$

Picking $\tilde{v}_i^h(x)$ to be a basis for $\mathbb{X}^h$ completes the proof. ∎

2.4. Preliminaries on the time-averaging operator. Define the temporal mean value by

$$\langle q \rangle_T = \frac{1}{T}\int_0^T q(t)\,dt.$$

By properties of integrals, $|\langle q \rangle_T| \leq \langle |q| \rangle_T$, and similarly for any function $q(t,x)$, where $\|\cdot\|$ is a spacial norm of $q(t,x)$,

$$\|\langle q \rangle_T\| \leq \langle \|q\| \rangle_T. \tag{2.21}$$

Let $u \in L^p(\Omega)$, $v \in L^q(\Omega)$ with $p^{-1} + q^{-1} = 1$, $p, q \in [1, \infty]$. Using Hölder's

inequality for Lebesgue spaces, one can show a Hölder inequality of the form

$$|\langle (u,v)\rangle_T| \le \frac{1}{T}\int_0^T |(u,v)|\,dt \le \frac{1}{T}\int_0^T \|u\|_{L^p}\|v\|_{L^q}\,dt$$

$$\le \left(\frac{1}{T}\int_0^T \|u\|_{L^p}^p\,dt\right)^{1/p}\left(\frac{1}{T}\int_0^T \|v\|_{L^q}^q\,dt\right)^{1/q}$$

$$= \langle \|u\|_{L^p}^p\rangle_T^{1/p}\langle \|v\|_{L^q}^q\rangle_T^{1/q}. \tag{2.22}$$

With the same arguments, one obtains, for $u \in H_0^1(\Omega)$ and $v \in H^{-1}(\Omega)$,

$$|\langle (u,v)\rangle_T| \;\le\; \langle \|\nabla u\|_{L^2}^2\rangle_T^{1/2}\langle \|v\|_{H^{-1}}^2\rangle_T^{1/2}. \tag{2.23}$$

The time-averaging operator $\langle\cdot\rangle$ defined in (1.2) is just $\langle\cdot\rangle = \limsup_{T\to\infty}\langle\cdot\rangle_T$. One of the subtleties of this definition is that the limit superior is not additive. For example, let $\{a_n\}$ and $\{b_n\}$ be sequences in $\mathbb{R}$. Then

$$\limsup_{n\to\infty}(a_n + b_n) \le \limsup_{n\to\infty} a_n + \limsup_{n\to\infty} b_n, \tag{2.24}$$

$$|\limsup_{n\to\infty} a_n| \le \limsup_{n\to\infty} |a_n|, \tag{2.25}$$

$$\limsup_{n\to\infty}(a_n\, b_n) \le \limsup_{n\to\infty} a_n \limsup_{n\to\infty} b_n \quad \text{if } a_n,\, b_n \ge 0\,\forall\, n, \tag{2.26}$$

$$\limsup_{n\to\infty}(c\, a_n) = c \limsup_{n\to\infty} a_n \quad \text{for } c \ge 0, \tag{2.27}$$

$$\limsup_{n\to\infty} a_n \le \limsup_{n\to\infty} b_n \quad \text{if } a_n \le b_n\,\forall\, n, \tag{2.28}$$

$$\limsup_{n\to\infty}(a_n)^p = (\limsup_{n\to\infty} a_n)^p \quad \text{if } a_n \ge 0\,\forall\, n \text{ and } p > 0. \tag{2.29}$$

Note that equality holds in (2.24) if one of the limits on the right-hand side exists.

From these properties, it follows that

$$|\langle q\rangle| \le \langle |\,q\,|\rangle, \tag{2.30}$$

$$\|\langle q\rangle\| \le \langle \|\,q\,\|\rangle, \tag{2.31}$$

$$|\langle (u,v)\rangle| \le \langle \|u\|_{L^p}^p\rangle^{1/p}\langle \|v\|_{L^q}^q\rangle^{1/q}, \tag{2.32}$$

$$|\langle (u,v)\rangle| \le \langle \|\nabla u\|^2\rangle^{1/2}\langle \|v\|_{-1}^2\rangle^{1/2} \tag{2.33}$$

if the right-hand sides of these inequalities are well defined.

3. Analysis of the time-averaged velocity, pressure, and energy dissipation. First, in section 3.1, the case of arbitrary data fulfilling the conditions of Definition 2.1 is considered. In this case, estimates for the L^2-norm of the time-averaged error of the pressure, $\limsup_{T\to\infty}\|\langle p - p^h\rangle_T\|$ (Theorem 3.1), and the time-averaged energy dissipation rate, $\langle\varepsilon(u-u^h)\rangle$ (Theorem 3.2), are proven. Section 3.2 considers the case of a small body force (but large initial data) such that the solution of the Navier–Stokes equations tends to the solution of the steady state Navier–Stokes equations. It will be shown that in this case the time average of the energy dissipation rate of the error $\langle\varepsilon(u-u^h)\rangle$ will be bounded by the energy dissipation rate of the error of the steady state problem (Theorem 3.3).

3.1. The case of large data.

LEMMA 3.1. *Let u be a weak solution to the Navier–Stokes equations (obtained by the Leray–Hopf construction). If $f \in L^\infty(0,\infty;H^{-1}(\Omega)^d)$, then $\| u \|$ is uniformly bounded,*

$$\frac{1}{2}\| u(T) \|^2 \leq e^{-\nu C_{PF}^{-2} T}\| u(0) \|^2 + \frac{C_{PF}^2}{\nu^2}\| f \|^2_{L^\infty(0,\infty;H^{-1})}, \tag{3.1}$$

where C_{PF} is the Poincaré–Friedrich constant of Ω, and consequently

$$\lim_{T\to\infty} \frac{1}{T}\| u(T) \|^2 = 0.$$

Proof. Let V_N be the span of eigenfunctions of the Stokes operator. The Leray–Hopf construction of weak solutions gives a sequence $\{u_N\}$ in $\mathbb{V}_N$ satisfying

$$(u_{N,t}, v) + \nu(\nabla u_N, \nabla v) + b(u_N, u_N, v) = (f, v) \quad \forall\, v \in \mathbb{V}_N, \tag{3.2}$$

with a subsequence $\{u_{N_j}\}$ such that u_{N_j} converges to a weak solution u strongly in $L^2(0,T;H(\Omega)^d)$ and weakly in $L^2(0,T;\mathbb{V})$.

Setting $v = u_N$ in (3.2) and using the Cauchy–Schwarz and the Young inequalities, followed by the Poincaré–Friedrich inequality, we have

$$\frac{d}{dt}\| u_N(t) \|^2 + \nu C_{PF}^{-2}\| u_N(t) \|^2 \leq \frac{1}{\nu}\| f(t) \|^2_{-1}.$$

Using the integrating factor $e^{\nu C_{PF}^{-2} t}$, we obtain a differential inequality which can be integrated on $(0,T)$, yielding

$$\| u_N(T) \|^2 \leq e^{-\nu C_{PF}^{-2} T}\| u_N(0) \|^2 + \frac{C_{PF}^2}{\nu^2}\| f \|^2_{L^\infty(0,\infty;H^{-1})}.$$

This shows the uniform boundedness of $\| u_N(T) \|$. Taking the limit of both sides, using a weak convergence argument (which is standard for the Navier–Stokes equations and which we show in detail in the proof of Lemma 3.4) and letting $N \to \infty$, we recover (3.1). The second claim now follows from the first one. ∎

LEMMA 3.2. *Let $f \in L^\infty(0,\infty;H^{-1}(\Omega)^d)$ and let u^h satisfy* (2.9). *Then $\| u^h \|$ is uniformly bounded and consequently*

$$\lim_{T\to\infty} \frac{1}{T}\| u^h(T) \|^2 = 0 \qquad \textit{and} \qquad \lim_{T\to\infty} \frac{1}{T}\| (u - u^h)(T) \|^2 = 0.$$

Proof. Take $v^h = u^h$ in (2.9) (a step not possible in the continuous case of Lemma 3.1) and proceeding as in the proof of Lemma 3.1, we prove a similar uniform bound for $\| u^h \|$. This proves the first statement and the bound on $\| u - u^h \|$ follows by the triangle inequality and Lemma 3.1. ∎

We next consider time averages.

LEMMA 3.3. *Let u be a weak solution of the Navier–Stokes equations satisfying the energy inequality* (2.18). *Then*

$$\langle \varepsilon(u) \rangle \;\leq\; \limsup_{T\to\infty} \frac{1}{|\,\Omega\,|\,T} \int_0^T (\,f, u\,)\, dt = \frac{1}{|\,\Omega\,|}\langle (f,u) \rangle. \tag{3.3}$$

If u satisfies the energy equality, then the above inequality can be replaced by equality. Further, if $f \in L^\infty(0,T;H^{-1}(\Omega)^d) \cap L^2(0,T;L^2(\Omega)^d)$ for every $0 < T < \infty$, then

$$\langle \varepsilon(u) \rangle \;\leq\; \frac{1}{\nu |\,\Omega\,|} \langle \| f \|_{-1}^2 \rangle \;\leq\; \frac{1}{\nu |\,\Omega\,|} \| f \|_{L^\infty(0,\infty;H^{-1})}^2. \tag{3.4}$$

The semidiscrete finite element approximation u^h of u satisfies (3.3) *and* (3.4), *with u replaced by u^h, and with equality in* (3.3).

Proof. Since u satisfies the energy inequality (2.18), we have

$$\frac{1}{2T} \frac{1}{|\,\Omega\,|} \| u(T) \|^2 + \frac{1}{T} \int_0^T \frac{\nu}{|\,\Omega\,|} \| \nabla u(t) \|^2 \, dt \leq \frac{1}{2T} \frac{1}{|\,\Omega\,|} \| u_0 \|^2 + \frac{1}{T|\,\Omega\,|} \int_0^T (f,u) \, dt.$$

Since $\frac{1}{2T} \| u(T) \|^2 \to 0$ by Lemma 3.1 and $\frac{1}{2T} \| u_0 \|^2 \to 0$ as $T \to \infty$, we obtain (3.3). If we use as a starting point the energy equality, the equal sign will be preserved.

For proving (3.4), we apply inequality (2.33) and Young's inequality to (3.3)

$$\begin{aligned} \langle \varepsilon(u) \rangle &\leq \frac{\nu}{2|\,\Omega\,|} \langle \| \nabla u \|^2 \rangle + \frac{1}{2\nu|\,\Omega\,|} \langle \| f \|_{-1}^2 \rangle \\ &\leq \frac{1}{2} \langle \varepsilon(u) \rangle + \frac{1}{2\nu|\,\Omega\,|} \| f \|_{L^\infty(0,\infty;H^{-1})}^2. \end{aligned}$$

In the semidiscrete case, take u^h as a test function in (2.6). This gives

$$\frac{1}{2} \frac{d}{dt} \| u^h(t) \|^2 + \nu \| \nabla u^h(t) \|^2 = (u^h(t), f(t)).$$

Integration in $(0,T)$ shows that u^h fulfills an energy equality. Now, the arguments to derive the estimates of the form (3.3) and (3.4) for u^h are the same as in the continuous case. ∎

Remark 3.1.

1. Let $f \in L^\infty(0,T;H^{-1}(\Omega)^d) \cap L^2(0,T;L^2(\Omega)^d)$ for every $0 < T < \infty$; then one obtains from the triangle inequality that $\langle \varepsilon(u - u^h) \rangle$ is bounded by the data of the problem

$$|\langle \varepsilon(u - u^h) \rangle| \leq \frac{2}{\nu |\,\Omega\,|} \| f \|_{L^\infty(0,\infty;H^{-1})}^2.$$

2. From the Poincaré–Friedrichs inequality it follows that

$$\langle k(v) \rangle \leq \frac{C_{PF}^2}{2\nu} \langle \varepsilon(v) \rangle$$

for all $v \in \mathbb{X}$. Thus, all estimates of Lemma 3.3 as well as the first part of this remark carry over to the time average of the kinetic energy.

Next, we consider the time-averaged errors. It is important to note that there is a difference between $\| \langle \nabla(u - u^h) \rangle \|$ and $\langle \| \nabla(u - u^h) \| \rangle$; the second term is an upper bound for the first one, by (2.31). Experience with turbulent flows suggests that $\langle \nabla u \rangle$ might be smooth (and thus approximable). Thus, ideally we would like estimates for the first term, $\| \langle \nabla(u - u^h) \rangle \|$. In the case of the error in the pressure, we are able to prove such a bound.

THEOREM 3.1. *Let* $f \in L^\infty(0,\infty;H^{-1}(\Omega)^d) \cap L^2(0,T;L^2(\Omega)^d)$ *and let* $(\mathbb{X}^h,\mathbb{Q}^h)$ *satisfy the discrete inf-sup condition* (2.5); *then*

$$\limsup_{T\to\infty} \|\langle p-p^h\rangle_T\| \le \frac{\nu}{\beta^h}\left(1+\frac{2M}{\nu^2}\|f\|_{L^\infty(0,\infty;H^{-1})}\right)\langle\|\nabla(u-u^h)\|^2\rangle^{1/2} + \left(1+\frac{\sqrt{d}}{\beta^h}\right)\inf_{q^h\in\mathbb{Q}^h}\limsup_{T\to\infty}\|\langle p-q^h\rangle_T\|.$$

Proof. A straightforward calculation, using (2.7), shows that (2.19) is equivalent to

$$-\int_0^T (p^h-q^h,\nabla\cdot v^h)\,dt = (e(T),v^h(T)) - (e(0),v^h(0))$$

$$-\int_0^T \left[\left(e,\frac{\partial v^h}{\partial t}\right) - \nu(\nabla e,\nabla v^h) - b_s(u,e,v^h) - b_s(e,u^h,v^h) + (p-q^h,\nabla\cdot v^h)\right]dt$$

for all $(v^h,q^h)\in\mathbb{X}^h\times\mathbb{Q}^h$. Since the velocity finite element functions are continuous in $\overline{\Omega}$, all terms are well defined. Let $v^h = v^h(x)$. Division by T gives

$$\begin{aligned}(\langle q^h-p^h\rangle_T,\nabla\cdot v^h) = {}& \frac{1}{T}(e(T),v^h) - \frac{1}{T}(e(0),v^h) + \nu\,(\langle\nabla e\rangle_T,\nabla v^h)\\ &+\langle b_s(u,e,v^h)\rangle_T + \langle b_s(e,u^h,v^h)\rangle_T\\ &-(\langle p-q^h\rangle_T,\nabla\cdot v^h).\end{aligned} \tag{3.5}$$

For estimating (3.5), we use that v^h does not depend on time, (2.4), and $\|\nabla\cdot v^h\| \le \sqrt{d}\,\|\nabla v^h\|$ to obtain

$$\begin{aligned}\left|(\langle q^h-p^h\rangle_T,\nabla\cdot v^h)\right| \le {}& \frac{C_{PF}}{T}\|e(T)\|\,\|\nabla v^h\| + \frac{C_{PF}}{T}\|e(0)\|\,\|\nabla v^h\|\\ &+\nu\,\|\langle\nabla e\rangle_T\|\,\|\nabla v^h\| + M\langle\|\nabla u\|\,\|\nabla e\|\rangle_T\|\nabla v^h\|\\ &+M\langle\|\nabla e\|\,\|\nabla u^h\|\rangle_T\|\nabla v^h\|\\ &+\sqrt{d}\,\|\langle p-q^h\rangle_T\|\,\|\nabla v^h\|.\end{aligned}$$

Dividing by $\|\nabla v^h\|$ and applying the discrete inf-sup condition (2.5) and (2.21) to the left-hand side of this inequality leads to

$$\begin{aligned}\beta^h\|\langle q^h-p^h\rangle_T\| \le {}& \frac{C_{PF}}{T}\|e(T)\| + \frac{C_{PF}}{T}\|e(0)\| + \nu\,\|\langle\nabla e\rangle_T\|\\ &+M\langle\|\nabla u\|\,\|\nabla e\|\rangle_T + M\langle\|\nabla e\|\,\|\nabla u^h\|\rangle_T\\ &+\sqrt{d}\,\|\langle p-q^h\rangle_T\|.\end{aligned}$$

The terms on the right-hand side are estimated by (2.21) and an estimate similar to (2.22), resulting in

$$\begin{aligned}\beta^h\|\langle q^h-p^h\rangle_T\| \le {}& \frac{C_{PF}}{T}\|e(T)\| + \frac{C_{PF}}{T}\|e(0)\|\\ &+(\nu + M\langle\|\nabla u\|^2\rangle_T^{1/2} + M\langle\|\nabla u^h\|^2\rangle_T^{1/2})\langle\|\nabla e\|^2\rangle_T^{1/2}\\ &+\sqrt{d}\,\|\langle p-q^h\rangle_T\|.\end{aligned}$$

The triangle inequality implies that

$$\|\langle p - p^h\rangle_T\| \le \frac{C_{PF}}{\beta^h T}\|\, e(T)\,\| + \frac{C_{PF}}{\beta^h T}\|\, e(0)\,\|$$

$$+\frac{1}{\beta^h}\left(\nu + M\langle\|\,\nabla u\,\|^2\rangle_T^{1/2} + M\langle\|\,\nabla u^h\,\|^2\rangle_T^{1/2}\right)\langle\|\,\nabla e\,\|^2\rangle_T^{1/2}$$

$$+\left(1+\frac{\sqrt{d}}{\beta^h}\right)\,\|\langle p - q^h\rangle_T\|.$$

Taking lim sup as $T \to \infty$ on both sides of the inequality and using Lemmas 3.1 and 3.2, together with properties of lim sup, give

$$\limsup_{T\to\infty}\|\langle p - p^h\rangle_T\|$$

$$\le \frac{1}{\beta^h}(\nu + M\langle\|\,\nabla u\,\|^2\rangle^{1/2} + M\langle\|\,\nabla u^h\,\|^2\rangle^{1/2})\langle\|\,\nabla e\,\|^2\rangle^{1/2}$$

$$+\left(1+\frac{\sqrt{d}}{\beta^h}\right)\,\limsup_{T\to\infty}\|\langle p - q^h\rangle_T\|.$$

The norms of the weak and the discrete solution can be estimated with the results of Lemma 3.3. The proof concludes by taking the infimum over $q^h \in \mathbb{Q}^h$. ∎

COROLLARY 3.1. *If the assumptions of Theorem* 3.1 *hold true, then*

$$\|\langle p - p^h\rangle\| \le \frac{\nu}{\beta^h}\left(1+\frac{2M}{\nu^2}\|f\|_{L^\infty(0,\infty;H^{-1})}\right)\langle\,\|\,\nabla(u-u^h)\|^2\,\rangle^{1/2}$$

$$+\left(1+\frac{\sqrt{d}}{\beta^h}\right)\,\inf_{q^h\in\mathbb{Q}^h}\,\limsup_{T\to\infty}\|\langle p - q^h\rangle_T\|.$$

Proof. The lower bound on the left-hand side is a consequence of (2.25). ∎

The key idea in the above proofs was to restrict $v^h \in \mathbb{V}^h$ to be time independent. Then, time averaging can be applied and brought inside upon the pressure error directly. It is interesting that the equations of motion give a different realization of the time-averaged error for the velocity and pressure ($\langle\|\,\nabla(u-u^h)\,\|\rangle$ versus $\|\langle p-p^h\rangle\|$). This appears also in the time-averaged lift and drag error estimates in Theorem 4.1. At this point, we do not know if this distinction has other deeper causes or implications.

We next turn to the error inequalities for the time-averaged error of the energy dissipation rate $\langle\varepsilon(u-u^h)\rangle$.

THEOREM 3.2. *Let* $Y = L^2(0,\infty;H^1(\Omega)^d)\cap L^\infty(0,\infty;\mathbb{V}^h)$ *and assume* $u_t \in L^1(0,T;\mathbb{X}^*)$ *for every* $0 < T < \infty$. *Then the time-averaged error of the energy*

dissipation rate satisfies the following inequalities:

$$\begin{aligned}\langle\varepsilon(u-u^h)\rangle \le \inf_{\tilde{u}\in Y}\Big[& C\big(\langle\varepsilon(u-\tilde{u})\rangle + \nu^{-1}\langle\|\,(u-\tilde{u})_t\,\|_{-1}^2\rangle\big)\\ & + \frac{2}{|\Omega|}\Big(\langle\,|\,b_s(u,u-u^h,u-\tilde{u})\,|\rangle + \langle|\,b_s(u-u^h,u,u-\tilde{u})\,|\rangle\\ & + \langle|\,b_s(u-u^h,u-u^h,u-\tilde{u})\,|\,\rangle\Big)\Big]\\ & + C\inf_{q^h\in\mathbb{Q}^h}\Big[\nu^{-1}\langle\|\,p-q^h\,\|^2\rangle\Big] + \frac{2}{|\Omega|}\langle|\,b_s(u-u^h,u,u-u^h)\,|\rangle\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}\langle\varepsilon(u-u^h)\rangle \le C\inf_{\tilde{u}\in Y}\Big[& \langle\varepsilon(u-\tilde{u})\rangle + \nu^{-1}\langle\|\,(u-\tilde{u})_t\,\|_{-1}^2\rangle\\ & + \nu^{-3}\langle\|\,u-u^h\,\|^{2/3}\|\,\nabla u\,\|^{4/3}\|\,\nabla(u-\tilde{u})\,\|^{4/3}\rangle\\ & + \nu^{-3}\langle\|\,u-u^h\,\|^2\|\,\nabla(u-\tilde{u})\,\|^4\rangle\\ & + \nu^{-1}\langle\|u\,\|\,\|\,\nabla u\,\|\,\|\,\nabla\,(u-\tilde{u})\,\|^2\rangle\Big]\\ & + C\inf_{q^h\in\mathbb{Q}^h}\Big[\nu^{-1}\langle\|\,p-q^h\,\|^2\rangle\Big] + C\nu^{-3}\langle\|\,\nabla u\,\|^4\|\,u-u^h\,\|^2\rangle.\end{aligned} \tag{3.7}$$

Remark 3.2. Estimate (3.7) is not closed in the sense that $\langle\varepsilon(u-u^h)\rangle$ is not estimated only by approximation errors $u-\tilde{u}$ but also by the last term. For this term, we cannot provide an estimate under the assumptions of Theorem 3.2. However, if $\|\,\nabla u\,\|$ is uniformly bounded in time, $\|\,\nabla u\,\| \in L^\infty(0,\infty;L^2(\Omega)^{d\times d})$, then these estimates can be closed provided $\langle\|\,e\,\|^2\rangle \le Ch^\alpha\langle\|\,\nabla e\,\|^2\rangle$ for some $\alpha>0$ and provided h is small enough,

$$\begin{aligned}\nu^{-3}\langle\|\,\nabla u\,\|^4\|\,u-u^h\,\|^2\rangle &\le \nu^{-3}\|\nabla u\|_{L^\infty(0,\infty;L^2)}\langle\|\,u-u^h\,\|^2\rangle \le Ch^\alpha\langle\|\nabla e\|^2\rangle\\ &\le (1-\beta)\langle\varepsilon(u-u^h)\rangle\end{aligned}$$

with $\beta\in(0,1)$ if h is sufficiently small. Now, the term can be absorbed by the left-hand side. However, the assumption on the regularity of u is again the case when pointwise accuracy in time is reasonable to expect rather than accuracy in time-averaged statistics. Thus, the problem of closing the circle in the velocity error equation for the time-averaged statistics seems to catch at the same point as in the standard error analysis.

We shall see, in section 3.2, that in at least one case the circle of analysis is closable. In more general cases, we believe the problem is due to the fact that we are estimating $\langle\|\,\nabla(u-u^h)\,\|^2\rangle$ rather than $\|\langle\nabla(u-u^h)\rangle\|^2$. Of course, an estimate for the latter term follows immediately from (2.31) and (3.7), but it is most probably not optimal.

Proof. The weak solution obtained by the Leray–Hopf construction satisfies

$$(u_t,v^h)+\nu(\nabla u,\nabla v^h)+b_s(u,u,v^h)-(p,\nabla\cdot v^h)=(f,v^h)\qquad \forall\, v^h\in L^\infty(0,T;\mathbb{X}^h)$$

as in the proof of Lemma 3.1. A similar equation holds for u^h. Subtraction and the fact that $(q^h, \nabla \cdot v^h) = 0$ for $q^h \in \mathbb{Q}^h$ give an equation for the error $e = u - u^h$:

$$(e_t, v^h) + \nu(\nabla e, \nabla v^h) + b_s(u, u, v^h) - b_s(u^h, u^h, v^h)$$

$$-(p - q^h, \nabla \cdot v^h) = 0 \quad \forall\, v^h \in L^\infty(0, T; \mathbb{V}^h),$$

where $q^h \in \mathbb{Q}^h$ is arbitrary.

Let $\tilde{u}$ be an interpolant of u with $\tilde{u} \in L^2(0, \infty; H^1(\Omega)^d) \cap L^\infty(0, \infty; \mathbb{V}^h)$ and write $e = \eta - \phi^h$, where $\eta = u - \tilde{u}$ and $\phi^h = u^h - \tilde{u}$. Adding

$$-b_s(e, e, e) + b_s(u, u^h, \phi^h) - b_s(u, u^h, \phi^h),$$

where the first term vanishes, we get with $v^h = \phi^h$

$$\frac{1}{2}\frac{d}{dt}\| \phi^h \|^2 + \nu \| \nabla \phi^h \|^2 = (\eta_t, \phi^h) + \nu(\nabla \eta, \nabla \phi^h) - (p - q^h, \nabla \cdot \phi^h)$$

$$+ b_s(e, u, \eta) - b_s(e, e, \eta) - b_s(e, u, e) + b_s(u, e, \eta).$$

Time-averaging this equation and observing that $\| \phi^h \|$ is uniformly bounded in time (since $\| u^h \|$ is bounded and $\tilde{u} \in L^\infty(0, \infty; L^2(\Omega)^d)$), we have

$$\langle \varepsilon(\phi^h) \rangle \le \frac{1}{|\Omega|}\Big[|\langle\, (\eta_t, \phi^h)\,\rangle| + |\langle \nu\,(\nabla \eta, \nabla \phi^h)\,\rangle| + |\langle\, (p - q^h, \nabla \cdot \phi^h)\,\rangle|$$

$$+ |\langle\, b_s(e, u, \eta)\,\rangle| + |\langle\, b_s(e, e, \eta)\,\rangle| + |\langle\, b_s(e, u, e)\,\rangle|$$

$$+ |\langle\, b_s(u, e, \eta)\,\rangle|\Big].$$

Inequalities (2.30), (2.32), (2.33), and Young's inequality give

$$\langle \varepsilon(\phi^h) \rangle \le C\Big[\nu^{-1}\langle \| \eta_t \|_{-1}^2 \rangle + \langle \varepsilon(\eta) \rangle + \nu^{-1}\langle \| p - q^h \|^2 \rangle\Big]$$

$$+ \frac{2}{|\Omega|}\Big[\langle |\, b_s(e, u, \eta)\,| \rangle + \langle |\, b_s(e, e, \eta)\,| \rangle + \langle |\, b_s(e, u, e)\,| \rangle$$

$$+ \langle |\, b_s(u, e, \eta)\,| \rangle\Big].$$

Now, (3.6) follows from the triangle inequality.

For proving (3.7), we use the following bounds on the trilinear forms, which can

be derived from Lemma 2.1, together with Young's inequality:

$$\begin{aligned}
\langle |\, b_s(e,u,e)\,| \rangle &\le C\,\langle \|\,\nabla u\,\|\,\|\,e\,\|^{1/2}\,\|\,\nabla e\,\|^{3/2}\rangle \\
&\le \frac{\nu}{16}\langle \|\,\nabla e\,\|^2\rangle + C\,\nu^{-3}\langle \|\,\nabla u\,\|^4\,\|\,e\,\|^2\rangle, \\
\langle |\, b_s(e,e,\eta)\,| \rangle &\le C\,\langle \|\,e\,\|^{1/2}\,\|\,\nabla e\,\|^{3/2}\,\|\,\nabla \eta\,\|\rangle \\
&\le \frac{\nu}{16}\langle \|\,\nabla e\,\|^2\rangle + C\,\nu^{-3}\langle \|\,e\,\|^2\,\|\,\nabla \eta\,\|^4\rangle, \\
\langle |\, b_s(e,u,\eta)\,| \rangle &\le C\,\langle \|\,e\,\|^{1/2}\,\|\,\nabla e\,\|^{1/2}\,\|\,\nabla u\,\|\|\,\nabla \eta\,\|\rangle \\
&\le \frac{\nu}{16}\langle \|\,\nabla e\,\|^2\rangle + C\,\nu^{-3}\langle \|\,e\,\|^{2/3}\,\|\,\nabla u\,\|^{4/3}\,\|\,\nabla \eta\,\|^{4/3}\rangle, \\
\langle |\, b_s(u,e,\eta)\,| \rangle &\le C\,\langle \|\,u\,\|^{1/2}\|\,\nabla\, u\,\|^{1/2}\|\,\nabla\, e\,\|\,\|\,\nabla \eta\,\|\rangle \\
&\le \frac{\nu}{16}\langle \|\,\nabla e\,\|^2\rangle + C\langle \nu^{-1}\|u\,\|\,\|\,\nabla u\,\|\,\|\,\nabla\,\eta\,\|^2\rangle.
\end{aligned}$$

Inserting these estimates into (3.6) proves (3.7). ∎

Remark 3.3. Alternative estimates of the trilinear terms in the proof are possible. Using (2.4), one obtains for $\langle |\, b_s(e,u,\eta)\,| \rangle$ the term $\nu^{-1}\langle \|\nabla u\|^2 \|\nabla \eta\|^2\rangle$ which stays on the right-hand side of the estimate (instead of the term

$$\nu^{-3}\langle \|\,u - u^h\,\|^{2/3}\|\,\nabla u\,\|^{4/3}\|\,\nabla \eta\,\|^{4/3}\rangle).$$

The dependency of the alternative term on ν is more favorable, however assuming $\|\nabla \eta\| = \mathcal{O}(h^k)$ and $\|\,u - u^h\,\| = \mathcal{O}(h^{k+\alpha})$, $\alpha > 0$, the order of convergence for the term in estimate (3.7) is higher.

3.2. The case of large u_0 and small $f^*(x)$. There is at least one interesting case in which the error equations for the time-averaged velocity error, $\langle \varepsilon(u - u^h)\rangle$, can be closed: the case of large initial condition u_0 and asymptotically small body force $f(x,t)$. In this subsection, we assume

$$f(x,t) \in L^\infty(0,\infty; H^{-1}(\Omega)^d), \qquad f(x,t) \to f^*(x) \text{ as } t \to \infty,$$

and

$$\nu^{-2} M\,\|\,f^*\,\|_{-1} =: \alpha < 1.$$

In this case, time averaging will eventually wash out the irregularities caused by the large initial condition. We show that this is indeed the case. To shorten the presentation, we shall simplify the condition on f to

$$f(x,t) \equiv f^*(x) \qquad \text{with} \qquad \nu^{-2} M\,\|\,f^*\,\|_{-1} = \alpha < 1. \tag{3.8}$$

This small data (or small Reynolds number) condition can also be formulated as a small generalized Grashof number condition. By a scaling argument, we find that there are constants M_0, M_1, and M_2 depending on the geometry of Ω, but not on $L = diam(\Omega)$, such that $M = M_0\, L^{2-d/2}$, and for $f^*(x) \in C^0(\Omega)$, $\|\,f^*\,\|_{-1} =$

$M_1 L^{1+d/2}$ and $\| f^* \| = M_2 L^{d/2}$. This implies that $\| f^* \|_{-1} = \frac{M_1}{M_2} L \| f^* \|$, so that (3.8) is equivalent to

$$C\, G_r < 1,$$

where G_r is the Grashof number, defined in [7] as

$$G_r = \frac{L^{3-d/2}}{\nu^2} \| f^* \|.$$

LEMMA 3.4. *Let u be a weak solution to the Navier–Stokes equations obtained by the Leray–Hopf construction and suppose* (3.8) *holds. Then*

$$\langle \varepsilon(u - u^*) \rangle = 0,$$

where u^* is the solution of the equilibrium Navier–Stokes equations (2.10).

Proof. Let V_N be the span of eigenfunctions of the Stokes operator. The Leray–Hopf construction gives a sequence $\{u_N\}$ in V_N satisfying

$$(u_{N,t}, v) + \nu(\nabla u_N, \nabla v) + b(u_N, u_N, v) = (f, v) \quad \forall\, v \in V_N, \tag{3.9}$$

with a subsequence $\{u_{N_j}\}$ in V_N converging to a weak solution u, as $N_j \to \infty$, strongly in $L^2(0,T;H(\Omega))$ and weakly in $L^2(0,T;\mathbb{V})$. Let $u_N^* \in V_N$ be the Galerkin projection of u^* in V_N. Then u_N^* satisfies

$$\nu(\nabla u_N^*, \nabla v) + b(u_N^*, u_N^*, v) = (f, v) \quad \forall\, v \in V_N, \tag{3.10}$$

and $u_N^* \to u^*$ in $\mathbb{X}$ and $\mathbb{V}$ as $N \to \infty$.

Set $\phi_N = u_N(x,t) - u_N^*(x)$ and subtract (3.10) from (3.9) to get

$$(\phi_{N,t}, v) + \nu(\nabla \phi_N, \nabla v) + b(u_N, u_N, v) - b(u_N^*, u_N^*, v) = 0 \qquad \forall\, v \in V_N.$$

Let $v = \phi_N$, add and subtract $b(u_N, u_N^*, v)$, and integrate from 0 to T to get

$$\frac{1}{2}\|\phi_N(T)\|^2 + \int_0^T \nu \|\nabla \phi_N\|^2\, dt = \frac{1}{2}\|\phi_N(0)\|^2 - \int_0^T b(\phi_N, u_N^*, \phi_N)\, dt.$$

Setting $v = u_N^*$ in (3.10) gives immediately the a priori bound $\|\nabla u_N^*\| \le \nu^{-1}\|f\|_{-1}$. Using this bound, the bound (2.4) on the trilinear form and the small data assumption (3.8) give

$$\frac{1}{2}\|\phi_N(T)\|^2 + (1-\alpha)\nu \int_0^T \|\nabla \phi_N\|^2\, dt \le \frac{1}{2}\|\phi_N(0)\|^2.$$

Thus, dropping the first term leads to

$$\int_0^T \nu \| \nabla \phi_N \|^2\, dt \le \frac{1}{2(1-\alpha)} \| \phi_N(0) \|^2. \tag{3.11}$$

Using classical properties of weak limits, we have

$$\liminf_{N\to\infty} \left(\int_0^T \| \nabla \phi_N \|^2\, dt \right) \ge \int_0^T \| \nabla \phi \|^2\, dt$$

with $\phi = u - u^*$. Therefore, taking the limit inferior on both sides of (3.11) gives

$$\int_0^T \nu \| \nabla \phi \|^2 \, dt \leq \frac{1}{2(1-\alpha)} \| \phi(0) \|^2.$$

Dividing by $T|\Omega|$ and taking the limit superior as $T \to \infty$ proves the result. ∎

The next lemma is needed to prove the desired error estimate on $\langle \varepsilon(u - u^h) \rangle$ given in Theorem 3.3.

LEMMA 3.5. *Assume that* (3.8) *holds. Then*

$$\langle \varepsilon(u^h - u^{*\,h}) \rangle = 0.$$

Proof. The proof works in the same way as that of Lemma 3.4. It is based on subtracting (2.9) and (2.14). ∎

Remark 3.4. By the Poincaré–Friedrichs inequality, the statements of Lemmas 3.4 and 3.5 hold for the kinetic energy as well.

THEOREM 3.3. *Suppose that the assumptions of Lemmas* 3.4 *and* 3.5 *hold. Then*

$$\langle \varepsilon(u - u^h) \rangle \;\; \leq \;\; 3 \; \varepsilon(u^* - u^{*\,h}). \tag{3.12}$$

Proof. The triangle inequality gives

$$\|\nabla(u - u^h)\|^2 \leq 3 \left(\|\nabla(u - u^*)\|^2 + \|\nabla(u^* - u^{*\,h})\|^2 + \|\nabla(u^{*\,h} - u^h)\|^2 \right).$$

Hence, we get

$$\langle \varepsilon(u - u^h) \rangle \leq 3 \left(\langle \varepsilon(u - u^*) \rangle + \varepsilon(u^* - u^{*\,h}) + \langle \varepsilon(u^{*\,h} - u^h) \rangle \right).$$

The first and the third terms on the right-hand side vanish by Lemmas 3.4 and Lemma 3.5, respectively. ∎

The statement of Theorem 3.3 says that the problem of estimating $\langle \varepsilon(u - u^h) \rangle$ reduces to the one of estimating $\|\nabla(u^* - u^{*\,h})\|^2$. Standard finite element error estimates thus immediately imply that $\langle \varepsilon(u - u^h) \rangle$ is optimal.

COROLLARY 3.2. *Suppose that the assumptions of Lemmas* 3.4 *and* 3.5 *hold and that* $(\mathbb{X}^h, \mathbb{Q}^h)$ *satisfies the inf-sup condition* (2.5). *Then*

$$\langle \varepsilon(u - u^h) \rangle \leq C \left[\inf_{v^h \in \mathbb{X}^h} \nu \| \nabla(u^* - v^h) \|^2 + \inf_{q^h \in \mathbb{Q}^h} \nu^{-1} \| p^* - q^h \|^2 \right].$$

Proof. This follows by inserting the error estimates for $\| \nabla(u^* - u^{*\,h}) \|$ from [11] into the right-hand side of (3.12). ∎

Concerning the time-averaged error in the pressure, we have the following corollary. It is a direct consequence of Corollary 3.1.

COROLLARY 3.3. *Let the assumptions of Theorem* 3.1 *and Lemmas* 3.4 *and* 3.5 *be fulfilled. Then*

$$\| \langle p - p^h \rangle \| \leq \frac{3\sqrt{3}\nu}{\beta^h} \| \nabla(u^* - u^{*\,h}) \| + \left(1 + \frac{\sqrt{d}}{\beta^h} \right) \inf_{q^h \in \mathbb{Q}^h} \limsup_{T \to \infty} \| \langle p - q^h \rangle_T \|.$$

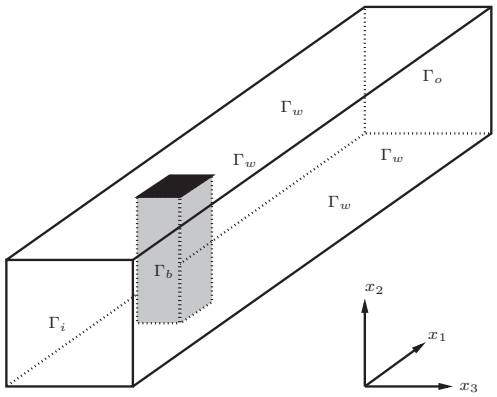

FIG. 1. *A channel with a body.*

4. Drag and lift. Consider the flow around a body in a channel with flow region Ω and boundary Γ, which consists of Γ_b (boundary of the body) and $\Gamma_c = \Gamma_i \cup \Gamma_o \cup \Gamma_w$ (where Γ_i, Γ_o correspond to the inflow and outflow and Γ_w correspond to the walls); see Figure 1 for an example.

Define

$$\sigma = -p\,\mathbb{I} + 2\,\mu\,\nabla^s u,$$

where ∇^s indicates the symmetric part of the operator ∇, and μ the dynamic viscosity. Then, we consider the Navier–Stokes equations written in the form

$$\begin{aligned} \rho(u_t + u\cdot\nabla u) &= \nabla\cdot\sigma + f && \text{in } \Omega\times(0,T],\\ \nabla\cdot u &= 0 && \text{in } \Omega\times[0,T],\\ u &= g && \text{on } \Gamma\times[0,T],\\ u(x,0) &= u_0(x) && \text{in } \Omega, \end{aligned} \tag{4.1}$$

satisfying the compatibility condition $\int_\Gamma g\cdot\hat{n}\,dS = 0$, where $\hat{n}$ is the outward pointing unit normal to Γ_b. We assume $g = 0$ on $\Gamma_w \cup \Gamma_b$.

We introduce the spaces

$$\mathbb{X}_g = \left\{ v \in H^1(\Omega)^d : v|_\Gamma = g \right\}, \quad \mathbb{X}_0 = H_0^1(\Omega)^d.$$

A weak formulation of (4.1) reads as follows: Find $u : [0,T] \to \mathbb{X}_g$ and $p : (0,T] \to \mathbb{Q}$ such that

$$\rho\,(u_t, v) + 2\,\mu(\nabla^s u, \nabla^s v) + \rho\,b(u,u,v) - (p, \nabla\cdot v) + (\nabla\cdot u, q) = (f, v) \qquad \forall (v,q) \in \mathbb{X}_0\times\mathbb{Q}. \tag{4.2}$$

We assume that the asymptotic growth of the kinetic energy of the solutions of (4.2) is bounded by

$$\limsup_{T\to\infty} \frac{1}{T} k(u(T)) = 0. \tag{4.3}$$

In particular, assumption (4.3) is valid if the solutions of (4.2) have bounded kinetic

energy.[1]

Drag and lift are defined by

$$D = -\int_{\Gamma_b} \hat{e}_1 \cdot \sigma \cdot \hat{n}\, d\gamma, \qquad L = -\int_{\Gamma_b} \hat{e}_2 \cdot \sigma \cdot \hat{n}\, d\gamma,$$

respectively, where $\hat{e}_i$ is the unit vector in the ith direction. We assume that $+\hat{e}_1$ is the direction of motion and $-\hat{e}_2$ is the direction of gravity. We note that if (u, p) are sufficiently regular and $v \in L^\infty(0, T; H^1(\Omega)^d)$ with $v = 0$ on Γ_c, then we have

$$\frac{1}{T}\int_0^T \int_{\Gamma_b} v \cdot \sigma \cdot \hat{n}\, d\gamma\, dt$$

$$= \frac{1}{T}\int_0^T \Big[\rho\,(u_t, v) + 2\,\nu(\nabla^s u, \nabla^s v) + \rho\, b(u, u, v) - (p, \nabla \cdot v) - (f, v)\Big]\, dt. \tag{4.4}$$

Whenever the right-hand side of (4.4) is well defined, it can be taken as the definition of the force on the immersed body, i.e., the left-hand side of (4.4). We will use this definition under the following regularity assumptions on (u, p):

$$u \in L^1(0, T; H^1(\Omega)^d) \cap \mathbb{X}_g, \quad u_t \in L^1(0, T; H^{-1}(\Omega)^d), \quad p \in L^1(0, T; L^2(\Omega)).$$

Choosing in (4.4) a function v satisfying $v = -\hat{e}_1$ on Γ_b gives a formula for the drag and $v = -\hat{e}_2$ gives a formula for the lift.

THEOREM 4.1. *Let the force on the immersed body be well defined by* (4.4), *let the kinetic energy of the solutions of* (4.2) *be bounded by* (4.3), *and let a similar bound be valid for the kinetic energy of the finite element approximation* u^h. *Then, the time-averaged drag and lift can be estimated as*

$$|\langle D - D^h \rangle|, |\langle L - L^h \rangle|$$

$$\leq C\Big[(\mu + M\rho\langle\|\nabla u\|^2 + \|\nabla u^h\|^2\rangle^{1/2})\langle\|\nabla (u - u^h)\|^2\rangle^{1/2}$$

$$+ \limsup_{T\to\infty} \|\langle p - p^h\rangle_T\|\Big]. \tag{4.5}$$

Proof. We present here a proof for the drag estimate. With the same arguments follows the estimate for the lift, according to an appropriate choice of v.

Let $v \in H^2(\Omega)^d$ be a time-independent vector field satisfying $v = -\hat{e}_1$ on Γ_b and $v = 0$ on Γ_c. From (4.4) it follows that

$$\int_0^T D\, dt = \int_0^T \Big[\rho\,(u_t, v) + 2\,\mu(\nabla^s u, \nabla^s v) + \rho\, b(u, u, v) - (p, \nabla v) - (f, v)\Big]\, dt.$$

Let $i_h v$ be a finite element interpolant to v such that $i_h v = -\hat{e}_1$ on Γ_b. In particular, we have $v, i_h v \in L^\infty(0, T; H^1(\Omega)^d)$. Then,

$$\int_0^T \Big[D - D^h\Big]\, dt = \int_0^T \Big[\rho\,(u_t, v) + 2\,\mu(\nabla^s u, \nabla^s v) + \rho\, b(u, u, v)$$

$$- (p, \nabla \cdot v) - (f, v) - \rho\,(u_t^h, i_h v) - 2\,\mu(\nabla^s u^h, \nabla^s i_h v)$$

$$-\rho\, b_s(u^h, u^h, i_h v) + (p^h, \nabla \cdot i_h v) + (f, i_h v)\Big]\, dt.$$

[1] This is known for geometries, such as simply connected $\partial\Omega$, which admit a Hopf extension of the boundary condition into Ω. It is unknown, for instance, if $\partial\Omega = \cup\Gamma_j$ is multiply connected and $\int_{\Gamma_j} g\, d\gamma = 0$, but $\int_{\Gamma_j} g\, d\gamma \neq 0$ for some connected component; see Theorem 4.1, p. 33, of Galdi [9].

Adding and subtracting terms and using $b(u,u,v) = b_s(u,u,v)$, this becomes

$$\begin{aligned}\int_0^T \Big[D - D^h\Big]\,dt = \int_0^T \Big[&\rho\,(u_t, v - i_h v) + \rho\,((u-u^h)_t, i_h v) + 2\,\mu(\nabla^s u, \nabla^s (v - i^h v))\\ &+ 2\,\mu(\nabla^s (u-u^h), \nabla^s\, i_h v) + \rho\, b_s(u,u,v-i_h v) + \rho\, b_s(u,u,i_h v)\\ &- \rho\, b_s(u^h,u^h,i_h v) - (p, \nabla\cdot(v - i_h v))\\ &- (p-p^h, \nabla\cdot i_h v) - (f, v - i_h v)\Big]\,dt. \qquad (4.6)\end{aligned}$$

Observe now that the term containing $(f, v - i_h v)$ in (4.6) can be rewritten by multiplying (4.1) by $v - i_h v$ and integrating:

$$(f, v-i_h v) = \rho\,(u_t, v-i_h v) + 2\,\mu(\nabla^s u, \nabla^s\,(v-i_h v)) + \rho\, b_s(u,u,v-i_h v) - (p, \nabla\cdot(v-i_h v)). \qquad (4.7)$$

Hence, combining (4.6) and (4.7) gives

$$\begin{aligned}\int_0^T \Big[D - D^h\Big]\,dt = \int_0^T \Big[&\rho\,((u-u^h)_t, i_h v) + 2\,\mu(\nabla^s\,(u-u^h), \nabla^s i^h v)\\ &+\rho\, b_s(u,u,i_h v) - \rho\, b_s(u^h,u^h,i_h v) + (p-p^h, \nabla\cdot i_h v)\Big]\,dt. \qquad (4.8)\end{aligned}$$

Let $e = u - u^h$ and divide each term in (4.8) by T. The first term on the right-hand side yields, with the time independence of $i_h v$,

$$\frac{1}{T}(e(T) - e(0), i_h v) \le \frac{C_{PF}}{T}\,(\|e(T)\| + \|e(0)\|)\,\|\nabla i_h v\|.$$

Note that the Poincaré–Friedrich inequality can be applied since $i_h v = 0$ on Γ_c. Now, by (2.22) and $\|\nabla^s v\| \le \|\nabla v\|$ for all $v \in H^1(\Omega)^d$, we obtain

$$\langle(\nabla^s e, \nabla^s\, i_h v)\rangle_T \;\le\; \langle\|\nabla e\|^2\rangle_T^{1/2}\,\|\nabla\, i_h v\|.$$

Next, the nonlinear terms are estimated by (2.4), (2.22), and Young's inequality:

$$\begin{aligned}\langle b_s(u,u,i_h v) - b_s(u^h,u^h,i_h v)\rangle_T &= \langle b_s(u,e,i_h v) + b_s(e,u^h,i_h v)\rangle_T\\ &\le M\langle(\|\nabla u\| + \|\nabla u^h\|)\|\nabla e\|\|\nabla i_h v\|\rangle_T\\ &\le M\|\nabla i_h v\|\langle(\|\nabla u\| + \|\nabla u^h\|)^2\rangle_T^{1/2}\langle\|\nabla e\|^2\rangle_T^{1/2}\\ &\le 2M\|\nabla i_h v\|\langle\|\nabla u\|^2 + \|\nabla u^h\|^2\rangle_T^{1/2}\langle\|\nabla e\|^2\rangle_T^{1/2}.\end{aligned}$$

For the pressure term, we obtain, with the time independence of $i_h v$ and the Cauchy–Schwarz inequality,

$$\langle(p-p^h, \nabla\cdot i_h v)\rangle_T = (\langle p-p^h\rangle_T, \nabla\cdot i_h v) \le \sqrt{d}\,\|\langle p-p^h\rangle_T\|\,\|\nabla\, i_h v\|.$$

Putting everything together, (4.8) becomes

$$\begin{aligned}|\langle D - D^h\rangle_T| \le \rho\frac{C_{PF}}{T}\,&(\|e(T)\| + \|e(0)\|)\,\|\nabla i_h v\|\\ &+(2\mu + 2M\rho\langle\|\nabla u\|^2 + \|\nabla u^h\|^2\rangle_T^{1/2})\,\langle\|\nabla\, e\|^2\rangle_T^{1/2}\,\|\nabla\, i_h v\|\\ &+\sqrt{d}\,\|\langle p-p^h\rangle_T\|\,\|\nabla\, i_h v\|.\end{aligned}$$

Taking the lim sup on both sides of the inequality, using (4.3) and the same property for u^h, and (2.26) give

$$\begin{aligned}
&\limsup_{T\to\infty} |\langle D - D^h \rangle_T| \\
&\qquad \le (2\mu + 2M\rho\langle \|\nabla u\|^2 + \|\nabla u^h\|^2\rangle^{1/2}) \langle \| \nabla e \|^2\rangle^{1/2} \| \nabla i_h v \| \\
&\qquad\quad + \sqrt{d} \limsup_{T\to\infty} \|\langle p - p^h\rangle_T\| \| \nabla i_h v \|.
\end{aligned}$$

Finally, applying (2.25) to the left-hand side of the estimate and $\| \nabla i_h v \| \le 2\| v \|_2 = C$ give the statement of theorem. ∎

The constant C in the estimate of Theorem 4.1 depends on the $H^2(\Omega)^d$-norm of the test function v and the size of Ω by the Poincaré–Friedrich constant.

In the last part of the proof of Theorem 4.1, the assumption on the boundedness of the growth of the kinetic energy is used. The boundedness of the kinetic energy has already been proven for the case $g = 0$ on Γ; see Lemmas 3.1 and 3.2. Thus, the statement of Theorem 4.1 applies for this case, and the respective bounds of Lemmas 3.1 and 3.2 can be inserted into (4.5).

The assumptions on g can be extended to sufficiently small Dirichlet data. We consider for simplicity of presentation the case when g does not depend on time. Let G be the Hopf extension of the boundary condition g to Ω, i.e., $G \in H^1(\Omega)^d$, $\nabla\cdot G = 0$, $G_t = 0$, and define $\tilde{u} = u - G$. Then $\tilde{u} \in \mathbb{V}$ and this function satisfies

$$\begin{aligned}
\rho(\tilde{u}_t + \tilde{u}\cdot\nabla\tilde{u}) &= \nabla\cdot\tilde{\sigma} + f + 2\mu\nabla\cdot\nabla^s G + \rho G\cdot\nabla G + \rho G \\
&\quad \cdot\nabla\tilde{u} + \rho\tilde{u}\cdot\nabla G \qquad \text{in } \Omega\times(0,T], \\
\nabla\cdot\tilde{u} &= 0 \qquad \text{in } \Omega\times[0,T], \\
\tilde{u} &= 0 \qquad \text{on } \Gamma\times[0,T], \\
\tilde{u}(x,0) &= (u_0 - G)(x) \qquad \text{in } \Omega,
\end{aligned} \tag{4.9}$$

where $\tilde{\sigma} = -\tilde{p}\,\mathbb{I} + 2\,\mu\,\nabla^s\tilde{u}$. Denote $\tilde{f} = f + 2\mu\nabla\cdot\nabla^s G + \rho G\cdot\nabla G$. Transforming (4.9) in the usual way to a variational formulation using $\tilde{u}$ as a test function, and applying the estimate for the dual pairing, Korn's inequality ($\|\nabla\tilde{u}\| \le C_{\text{Korn}}\|\nabla^s\tilde{u}\|$) and Young's inequality give

$$\frac{\rho}{2}\frac{d}{dt}\|\tilde{u}\|^2 + \frac{3\mu}{2}\|\nabla^s\tilde{u}\|^2 \le \frac{C}{\mu}\|\tilde{f}\|_{-1}^2 + \rho C_{\text{Korn}}^2\|\nabla^s\tilde{u}\|^2\|G\|_1. \tag{4.10}$$

If G is sufficiently small, for instance if

$$\rho C_{\text{Korn}}^2\|G\|_1 < \mu, \tag{4.11}$$

the last term on the right-hand side of (4.10) can be absorbed into the left-hand side and the boundedness of the kinetic energy of $\tilde{u}$ is obtained by integrating (4.10) on $(0,T)$. The kinetic energy of u is bounded by using the triangle inequality and the fact that $\|G\|$ is a constant. In the discrete case, by subtracting an interpolant of G^h from u^h and using a similar argument, one obtains this property for u^h. Thus for small G, the assumption of Theorem 4.1 of bounded kinetic energy holds.

COROLLARY 4.1. *Let the force on the immersed body be well defined by* (4.4), *let* $\tilde{f} = f + 2\mu\nabla\cdot\nabla^s G + \rho G\cdot\nabla G \in L^2(0,T;H^{-1}(\Omega))$, *and let the smallness condition*

(4.11) *on the inflow be fulfilled. Then, the time-averaged drag and lift can be estimated by* (4.5).

Remark 4.1. The estimate in Corollary 4.1 is not closed (the same problem as in Theorem 3.1) due to the term $\langle \| \nabla (u - u^h) \|^2 \rangle$ in (4.5). Closing this estimate requires the investigation (beyond the scope of this paper) of (4.9), which has additional terms in comparison with the Navier–Stokes equations. It is very likely that a small data assumption on $\tilde{f}$ (like in section 3.2) has to be used.

Note that the condition (4.11) can be reformulated with the Poincaré–Friedrichs inequality since G vanishes on $\Gamma_w \cup \Gamma_b$.

5. Persistent shear flows. We have seen in the previous sections that, provided that both the portion of the persistent body force driving the flow and the (nonhomogeneous) Dirichlet data are small, statistics, such as the time-averaged energy dissipation rate (or drag and lift), can be accurately predicted by a flow simulation. This accuracy holds quite generally without any further assumptions on u_0, ν, and *Re* typically needed to prove accuracy over bounded time intervals.

The case when the persistent forces driving the flow are not small is much more difficult. We shall prove in this section that the analogous estimate of the time-averaged energy dissipation rate is physically reasonable under a condition on the finite element mesh near the walls. Briefly, we consider the finite element approximation to the following shear flow problem: let $\Omega = [0, L]^3$, and find (u, p) satisfying

$$\begin{aligned} \frac{\partial u}{\partial t} + u \cdot \nabla u - \nu \Delta u + \nabla p &= 0 && \text{in } \Omega \times (0, T], \\ \nabla \cdot u &= 0 && \text{in } \Omega \times [0, T], \\ u &= u_0 && \text{at } t = 0, \\ u(x_1, x_2, x_3, t) &= \phi(x_3) && \text{for } x_3 \in \{0, L\}, \end{aligned}$$

where

$$\phi(x_3) = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \text{ if } x_3 = 0 \quad \text{and} \quad \phi(x_3) = \begin{pmatrix} U \\ 0 \\ 0 \end{pmatrix} \text{ if } x_3 = L,$$

and periodic boundary conditions in the x_1, x_2 directions; see Figure 2.

In this problem, the persistent force driving the flow is clearly the motion of the top wall and the time-averaged energy dissipation rate must balance the drag exerted by the walls on the fluid. For such problems, the Richardson–Kolmogorov energy

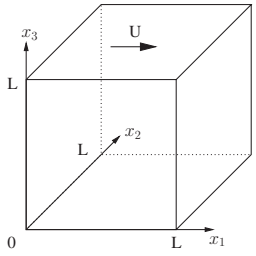

FIG. 2. *The shear flow problem.*

cascade predicts quite simply[2] that

$$\langle \varepsilon(u) \rangle \approx \frac{U^3}{L}$$

independently of ν and Re, respectively. Remarkably, the upper estimate has also been proven for weak solutions of the Navier–Stokes equations in full generality,

$$\langle \varepsilon(u) \rangle \leq C \frac{U^3}{L}$$

by Constantin and Doering [4] and Wang [27]; see also Doering and Foias [6]. Herein, we show in essence that provided the first mesh line of the finite element space is within $O(1/Re)$ of the top wall, then

$$\langle \varepsilon(u^h) \rangle \leq C \frac{U^3}{L};$$

i.e., the computed energy dissipation has the correct mathematical and physical scaling. This result depends on the precise construction of a discrete background flow. The mesh condition is necessary for the construction. Since the proof adapts the ideas of [27], we expect that a similar analysis would hold for other variational methods as well.

Let

$$\begin{aligned}
\mathbb{X} = \{ & v \in H^1(\Omega)^d \ : \ v(x_1, x_2, x_3, t) = v(x_1 + L, x_2, x_3, t) \text{ for } x_1 \in \Gamma, \\
& v(x_1, x_2, x_3, t) = v(x_1, x_2 + L, x_3, t) \text{ for } x_2 \in \Gamma, \\
& v(x_1, x_2, x_3, t) = \phi(x_3) \text{ for } x_3 \in \Gamma \}, \\
\mathbb{X}_0 = \{ & v \in H^1(\Omega)^d \ : \ v(x_1, x_2, x_3, t) = v(x_1 + L, x_2, x_3, t) \text{ for } x_1 \in \Gamma, \\
& v(x_1, x_2, x_3, t) = v(x_1, x_2 + L, x_3, t) \text{ for } x_2 \in \Gamma, \\
& v(x_1, x_2, x_3, t) = 0 \text{ for } x_3 \in \Gamma \}, \\
\mathbb{Q} = & L_0^2(\Omega)
\end{aligned}$$

and denote the corresponding conforming finite element spaces with a superscript h. We assume that the finite element space for the velocity contains linears, which is usually the case for conforming velocity finite element spaces. The finite element problem reads as follows: find $u^h : [0, T] \to \mathbb{X}^h$, $p^h : (0, T] \to \mathbb{Q}^h$ such that

$$\begin{aligned}
(u_t^h, v^h) + \nu(\nabla u^h, \nabla v^h) + b_s(u^h, u^h, v^h) - (p^h, \nabla \cdot v^h) = 0 \quad & \forall\, v^h \in \mathbb{X}_0^h, \\
(\nabla \cdot u^h, q^h) = 0 \quad & \forall\, q^h \in \mathbb{Q}^h, \\
(u^h(x, 0) - u_0(x), v^h) = 0 \quad & \forall\, v^h \in \mathbb{X}_0^h.
\end{aligned} \tag{5.1}$$

[2]Briefly, the largest coherent structures are associated with the motion of the upper wall. They thus have length scale L and characteristic velocity U. Their local Reynolds number is thus $(\frac{U\,L}{\nu} (= Re))$ and the viscous dissipation is negligible on them. These break up into smaller eddies (velocity u, length l, $Re\,(l) = \frac{u\,(l)\,l}{\nu}$) until $Re\,(l)$ is small enough for viscous dissipation to drive their kinetic energy to zero exponentially fast. Since viscous dissipation is negligible through this cascade, the energy dissipation rate is related then to the power input to the largest scales at the first step in the cascade. These largest eddies have energy $\frac{1}{2}U^2$ and time scale $\tau = \frac{L}{U}$ so the rate of energy transfer is $O(\frac{U^2}{\tau}) = O(\frac{U^3}{L})$.

Consider the background flow (an extension of the boundary condition ϕ to the interior of Ω) given by

$$\tilde{\phi}(x_3) = \begin{cases} 0 & \text{if } x_3 \in [0, L - \gamma L], \\ \frac{U}{\gamma L}(x_3 - (L - \gamma L)) & \text{if } x_3 \in [L - \gamma L, L], \end{cases}$$

and define

$$\Phi = \begin{bmatrix} \tilde{\phi}(x_3) \\ 0 \\ 0 \end{bmatrix},$$

where γ is a positive number, referred to as the "boundary layer thickness." For $\gamma \in (0, 1)$ this function is piecewise linear, continuous, and satisfies the boundary conditions. Straightforward calculations give

$$\| \Phi \|_{L^\infty} = U, \tag{5.2}$$

$$\| \nabla \Phi \|_{L^\infty} = \frac{U}{\gamma L}, \tag{5.3}$$

$$\begin{aligned} \| \Phi \|^2 &= L^2 \int_0^L | \tilde{\phi}(x_3) |^2 dx_3 \\ &= L^2 \int_{L-\gamma L}^L \frac{U^2}{(\gamma L)^2} (x_3 - (L - \gamma L))^2 dx_3 = \frac{U^2 \gamma L^3}{3}, \end{aligned} \tag{5.4}$$

$$\| \nabla \Phi \|^2 = \frac{U^2 L}{\gamma}. \tag{5.5}$$

For completeness, we include a short proof of the scaling of the constant in the Poincaré–Friedrichs inequality that will be helpful in the proof of the next theorem.

LEMMA 5.1. *Let $\mathcal{O}_{\gamma L} = \{(x_1, x_2, x_3) \in \Omega : L - \gamma L \le x_3 \le L\}$ be the region close to the upper boundary (where the background flow Φ does not vanish). Then*

$$\| u^h - \Phi \|_{L^2(\mathcal{O}_{\gamma L})} \le \gamma L \| \nabla (u^h - \Phi) \|_{L^2(\mathcal{O}_{\gamma L})}. \tag{5.6}$$

Proof. First, let v be a C^1 function on $\mathcal{O}_{\gamma L}$ that vanishes for $x_3 = L$. Then, componentwise ($i = 1, 2, 3$), we have

$$v_i(x_1, x_2, x_3) = v_i(x_1, x_2, L) - \int_{x_3}^L \frac{dv_i}{d\xi_3}(x_1, x_2, \xi_3) \, d\xi_3.$$

Observing that $v_i(x_1, x_2, L) = 0$, squaring both sides, and using the Cauchy–Schwarz inequality, we get

$$v_i^2(x_1, x_2, x_3) \le \gamma L \int_{L-\gamma L}^L \left(\frac{dv_i}{d\xi_3}(x_1, x_2, \xi_3) \right)^2 d\xi_3.$$

Integrating both sides with respect to x_3 gives

$$\int_{L-\gamma L}^L v_i^2(x_1, x_2, x_3) \, dx_3 \le (\gamma L)^2 \int_{L-\gamma L}^L \left(\frac{dv_i}{d\xi_3}(x_1, x_2, \xi_3) \right)^2 d\xi_3.$$

Then, integrating with respect to x_1 and x_2 and summing from $i = 1$ to 3, we obtain

$$\| v \|^2_{\mathcal{O}_{\gamma L}} \leq (\gamma L)^2 \| \nabla v \|^2_{\mathcal{O}_{\gamma L}},$$

which proves the lemma in the case of a C^1 function. The case $v \in \mathbb{X}^h \subset H^1(\Omega)$ follows by density. Finally, just take $v = u^h - \Phi$. ∎

THEOREM 5.1. *Let*

$$\gamma = \frac{1}{C_\gamma \, Re}, \quad \textit{where} \quad Re = \frac{U\,L}{\nu}, \quad C_\gamma \geq 5, \tag{5.7}$$

selected such that Φ belongs to the finite element space. Then, the time-averaged energy dissipation rate of the finite element velocity satisfies

$$\langle \varepsilon(u^h) \rangle \quad \leq C \, \frac{U^3}{L},$$

where $C = C(C_\gamma)$.

Proof. We take $v^h = u^h - \Phi$ (this is possible due to the choice of γ) in (5.1) to get

$$(u^h_t, u^h) - (u^h_t, \Phi) + \nu \| \nabla u^h \|^2 - \nu \, (\nabla \, u^h, \nabla \, \Phi) - b_s(u^h, u^h, \Phi) = 0 \tag{5.8}$$

since $b_s(\cdot, \cdot, \cdot)$ is skew-symmetric and Φ is divergence free.

Observing that $(u^h_t, \Phi) = \frac{d}{d\,t}(u^h, \Phi)$, since $\frac{d\,\Phi}{d\,t} = 0$, we rewrite (5.8) as

$$\frac{1}{2} \frac{d}{d\,t} \| u^h \|^2 + \nu \| \nabla u^h \|^2 = \frac{d}{d\,t}(u^h, \Phi) + b_s(u^h, u^h, \Phi) + \nu \, (\nabla \, u^h, \nabla \, \Phi)$$

and integrate in time to get

$$\begin{aligned} &\frac{1}{2} \| u^h(T) \|^2 - \frac{1}{2} \| u^h(0) \|^2 + \nu \int_0^T \| \nabla u^h \|^2 \, d\,t \\ &= (u^h(T), \Phi) - (u^h(0), \Phi) + \int_0^T b_s(u^h, u^h, \Phi) \, d\,t + \nu \int_0^T (\nabla \, u^h, \nabla \, \Phi) \, d\,t. \end{aligned} \tag{5.9}$$

We need to estimate each term on the right-hand side of (5.9). For that, we use (5.2)–(5.5) to derive upper bounds for the following terms:

$$(u^h(T), \Phi) \leq \frac{1}{2} \| u^h(T) \|^2 + \frac{1}{2} \| \Phi \|^2 = \frac{1}{2} \| u^h(T) \|^2 + \frac{1}{6} U^2 \gamma L^3,$$

$$(u^h(0), \Phi) \leq \| u^h(0) \| \, \| \Phi \| = \sqrt{\frac{\gamma}{3}} U L^{3/2} \| u^h(0) \|,$$

$$\begin{aligned} \nu \int_0^T (\nabla \, u^h, \nabla \, \Phi) \, d\,t &\leq \frac{\nu}{2} \int_0^T \| \nabla u^h \|^2 \, d\,t + \frac{\nu}{2} \int_0^T \| \nabla \, \Phi \|^2 \, d\,t \\ &= \frac{\nu}{2} \int_0^T \| \nabla u^h \|^2 \, d\,t + \frac{\nu}{2\,\gamma} L \, U^2 \, T. \end{aligned}$$

For the nonlinear term, we add and subtract terms, and use the fact that $b_s(\cdot,\cdot,\cdot)$ is skew-symmetric to write

$$\begin{aligned} b_s(u^h,u^h,\Phi) &= b_s(u^h-\Phi,u^h-\Phi,\Phi)+b_s(\Phi,u^h-\Phi,\Phi)\\ &= \frac{1}{2}b(u^h-\Phi,u^h-\Phi,\Phi)-\frac{1}{2}b(u^h-\Phi,\Phi,u^h-\Phi)\\ &\quad +\frac{1}{2}b(\Phi,u^h-\Phi,\Phi)-\frac{1}{2}b(\Phi,\Phi,u^h-\Phi). \end{aligned} \tag{5.10}$$

We use Lemma 5.1 together with (5.2)–(5.5) to analyze the terms in (5.10). In all cases, integration is restricted to $\mathcal{O}_{\gamma L}$ since $\mathrm{supp}(\Phi)=\overline{\mathcal{O}}_{\gamma L}$:

$$\begin{aligned} b(u^h-\Phi,u^h-\Phi,\Phi) &\le \|\Phi\|_{L^\infty(\mathcal{O}_{\gamma L})}\|\nabla(u^h-\Phi)\|_{L^2(\mathcal{O}_{\gamma L})}\|u^h-\Phi\|_{L^2(\mathcal{O}_{\gamma L})}\\ &\le U\gamma L\|\nabla(u^h-\Phi)\|^2_{L^2(\mathcal{O}_{\gamma L})}\\ &\le 2U\gamma L\|\nabla u^h\|^2+2U^3L^2,\\ b(u^h-\Phi,\Phi,u^h-\Phi) &\le \|\nabla\Phi\|_{L^\infty(\mathcal{O}_{\gamma L})}\|u^h-\Phi\|^2_{L^2(\mathcal{O}_{\gamma L})}\\ &\le U\gamma L\|\nabla(u^h-\Phi)\|^2\\ &\le 2U\gamma L\|\nabla u^h\|^2+2U^3L^2,\\ b(\Phi,u^h-\Phi,\Phi) &\le \|\Phi\|_{L^\infty(\mathcal{O}_{\gamma L})}\|\Phi\|_{L^2(\mathcal{O}_{\gamma L})}\|\nabla(u^h-\Phi)\|_{L^2(\mathcal{O}_{\gamma L})}\\ &\le U\left(\frac{1}{3}U^2\gamma L^3\right)^{1/2}\|\nabla u^h\|+U\left(\frac{1}{3}U^2\gamma L^3\right)^{1/2}\left(\frac{U^2L}{\gamma}\right)^{1/2}\\ &\le \frac{1}{2}U\gamma L\|\nabla u^h\|^2+\frac{5}{6}U^3L^2,\\ b(\Phi,\Phi,u^h-\Phi) &\le \|\Phi\|_{L^\infty(\mathcal{O}_{\gamma L})}\|\nabla\Phi\|_{L^2(\mathcal{O}_{\gamma L})}\|u^h-\Phi\|_{L^2(\mathcal{O}_{\gamma L})}\\ &\le U\gamma L\left(\frac{U^2L}{\gamma}\right)^{1/2}\|\nabla u^h\|+U\gamma L\left(\frac{U^2L}{\gamma}\right)^{1/2}\left(\frac{U^2L}{\gamma}\right)^{1/2}\\ &\le \frac{1}{2}U\gamma L\|\nabla u^h\|^2+\frac{3}{2}U^3L^2. \end{aligned}$$

Inserting these estimates into (5.10) gives

$$|b_s(u^h,u^h,\Phi)|\le\frac{5}{2}U\gamma L\|\nabla u^h\|^2+\frac{19}{6}U^3L^2.$$

Hence, estimate (5.9) becomes

$$\begin{aligned} \nu\int_0^T\|\nabla u^h\|^2\,dt &\le \frac{1}{6}U^2\gamma L^3+\frac{1}{2}\|u^h(0)\|^2+\sqrt{\frac{\gamma}{3}}UL^{3/2}\|u^h(0)\|+\frac{\nu}{2}\int_0^T\|\nabla u^h\|^2\,dt\\ &\quad +\frac{\nu}{2\gamma}LU^2T+\frac{5}{2}\gamma LU\int_0^T\|\nabla u^h\|^2\,dt+\frac{19}{6}U^3L^2T. \end{aligned}$$

Dividing by T, taking lim sup as $T \to \infty$, and using $|\Omega| = L^3$ lead to

$$L^3 \left(\frac{1}{2} - \frac{5}{2} \frac{L \gamma U}{\nu} \right) \langle \varepsilon(u^h) \rangle \leq \frac{\nu}{2\gamma} L U^2 + \frac{19}{6} U^3 L^2.$$

Inserting (5.7) on both sides of this estimate proves the theorem. ∎

6. Summary and outlook. There are many important and interesting questions concerning the computational approximation of statistics in different flow settings. We studied the simple yet interesting case of internal flow, for instance, for small data (Reynolds number, body force) but large initial condition. In this setting, we proved convergence of the time-averaged energy dissipation rate in three dimensions without assuming that the solution is a strong, smooth, and unique solution, or the initial data is smooth. We then analyzed the convergence of time-averaged drag and lift coefficients. The crucial assumption of the general theory, a certain control on the kinetic energy, was proven for sufficiently small inflow boundary conditions. Lastly, we considered a simple case of shear flow and showed that the statistics of the computed solutions scale as predicted by the Kolmogorov theory.

One next step could be to consider discretization in time and approximate infinite time averaging by finite time averaging [8]. Our long-term goal is to develop a theory paralleling and inspired by the theory of shadowing in approximation of dynamical systems [23, 22, 14]. Are the computed statistics the exact statistics of a perturbed flow? Answering this numerical analysis question is fundamental for turbulent flow simulation.

Acknowledgment. The authors would like to thank the referees for their careful analysis of this manuscript and their important suggestions.

RIGOROUS ERROR BOUNDS FOR THE OPTIMAL VALUE IN SEMIDEFINITE PROGRAMMING*

CHRISTIAN JANSSON†, DENIS CHAYKIN‡, AND CHRISTIAN KEIL†

Abstract. A wide variety of problems in global optimization, combinatorial optimization, as well as systems and control theory can be solved by using linear and semidefinite programming. Sometimes, due to the use of floating point arithmetic in combination with ill-conditioning and degeneracy, erroneous results may be produced. The purpose of this article is to show how rigorous error bounds for the optimal value can be computed by carefully postprocessing the output of a linear or semidefinite programming solver. It turns out that in many cases the computational costs for postprocessing are small compared to the effort required by the solver. Numerical results are presented including problems from the SDPLIB and the NETLIB LP library; these libraries contain many ill-conditioned and real-life problems.

1. Introduction.

We consider the *(primal) semidefinite program* in block diagonal form

$$p^* := \min \sum_{j=1}^{n} \langle C_j, X_j \rangle \quad \text{s.t.} \quad \sum_{j=1}^{n} \langle A_{ij}, X_j \rangle = b_i \quad \text{for } i = 1, \ldots, m, \qquad X_j \succeq 0 \quad \text{for } j = 1, \ldots, n, \tag{1.1}$$

where C_j, A_{ij}, and X_j are symmetric $s_j \times s_j$ matrices, $b \in \mathbb{R}^m$, and

$$\langle C, X \rangle = \text{ trace } (C^T X) \tag{1.2}$$

denotes the *inner product* for the set of symmetric matrices. Moreover, $\succeq$ is the *Löwner partial order*; that is, $X \succeq Y$ iff $X - Y$ is positive semidefinite. In the case $n = 1$ we suppress the index j and write shortly C, X, A_i, and s for the dimension.

If $s_j = 1$ for $j = 1, \ldots, n$ (i.e., C_j, A_{ij}, and X_j are real numbers), then (1.1) defines the standard linear programming problem. Hence, semidefinite programming is an extension of linear programming.

The *Lagrangian dual* of (1.1) is

$$d^* := \max b^T y \quad \text{s.t.} \quad \sum_{i=1}^{m} y_i A_{ij} \preceq C_j \quad \text{for } j = 1, \ldots, n, \tag{1.3}$$

where $y \in \mathbb{R}^m$. The constraints $\sum_{i=1}^{m} y_i A_{ij} \preceq C_j$ are called *linear matrix inequalities (LMIs)*. We use the convention that $p^* = -\infty$ if (1.1) is unbounded and $p^* = \infty$ if (1.1) is infeasible. The analogous convention is used for (1.3).

The duality theory is similar to linear programming, but more subtle. The programs satisfy the *weak duality* condition

$$d^* \le p^*, \tag{1.4}$$

but strong duality requires, in contrast to linear programming, additional conditions (see, for example, Nemirovski [32], Ramana, Tunçel, and Wolkowicz [39], and Vandenberghe and Boyd [49]).

THEOREM 1.1 (strong duality theorem).

(a) *If* (1.1) *is strictly feasible (i.e., there exist feasible positive definite matrices* X_j *for* $j = 1, \dots, n$*) and* p^* *is finite, then* $p^* = d^*$ *and the dual supremum is attained.*

(b) *If* (1.3) *is strictly feasible (i.e., there exists some* $y \in \mathbb{R}^m$ *such that* $C_j - \sum_{i=1}^m y_i A_{ij}$ *are positive definite for* $j = 1, \dots, n$*) and* d^* *is finite, then* $p^* = d^*$ *and the primal infimum is attained.*

In general, one of the problems (1.1) and (1.3) may have optimal solutions while its dual is infeasible, or the duality gap may be positive at optimality. The strict feasibility assumptions in Theorem 1.1 are called *Slater's constraint qualifications.*

Semidefinite programming and LMI methods are documented by many applications and a number of survey papers (see, for example, Skelton and Iwasaki [45], Balakrishnan and Feron [3], and Vandenberghe and Boyd [49]). Applications include global optimization problems, optimal state space realizations, robust controller design, integer programming problems, as well as eigenvalue problems in the form of minimizing the largest, or minimizing the sum of the first few largest eigenvalues of a symmetric matrix X subject to linear constraints on X.

Semidefinite programs can be solved in polynomial time if an a priori bound for the size of their solution is known (see Grötschel, Lovász, and Schrijver [12]). This is a consequence of the ellipsoid method for convex programming. The ellipsoid method has not proven practical, and interior point methods turned out to be the methods of choice in semidefinite programming.

Conventionally, algorithms assume that the input data are given exactly, and they use floating point arithmetic for computing an approximate solution. Occasionally, wrong results may be produced, not solely but especially for ill-conditioned and ill-posed problems in the sense defined by Renegar [40]. He defines the condition number as the scale-invariant reciprocal of the smallest data perturbation that will render the perturbed data instance either primal or dual infeasible. It is set to ∞ if the distance to primal or dual infeasibility is 0, and in this case the problem is called ill-posed. Examples where commercial solvers fail to solve linear optimization problems can be found in Neumaier and Shcherbina [37] and in [17]. It cannot be answered how frequently such failures occur. Ill-conditioning is, however, frequently observed. In a paper by Ordóñez and Freund [38] it is stated that 71% of the LP instances in the NETLIB Linear Programming Library [33] are ill-posed; i.e., the problems have an infinite condition number. Recently, Freund, Ordóñez, and Toh [9] solved 85 out of the 92 problems of the SDPLIB [5] with SDPT3 [47] and investigated the interior-point iteration counts with respect to different measures for semidefinite programming problems. They omitted the four infeasible problems and three very large problems where SDPT3 ran out of memory. Of the remaining 85 problems they have shown 32 to be ill-posed.

As pointed out in Neumaier and Shcherbina [37], ill-conditioning is also likely to take place in combinatorial optimization when branch-and-cut procedures sequentially

generate linear or semidefinite programming relaxations. Therefore, the computation of rigorous error bounds, which take account of all rounding errors and of small errors in the input data, is valuable in practice.

The primary purpose of this paper is to show that by properly postprocessing the output of a semidefinite or linear solver, rigorous error bounds for the optimal value can be obtained. Moreover, existence of optimal solutions can be proved, or a certificate of infeasibility can be given. The input data are allowed to vary within small intervals. Our numerical experience with the NETLIB LP library and the SDPLIB demonstrates that, roughly speaking, rigorous lower and upper error bounds for the optimal value are computed even for ill-conditioned and degenerate problems. The quality of the error bounds depends on the quality of the computed approximations and the distances to dual and primal infeasibility. By comparing these bounds, one knows whether the computed results are good.

The presented results can be viewed as a further development of similar methods for linear programming (Neumaier and Shcherbina [37] and Jansson [17]) and convex programming [16].

The paper is organized as follows. Section 2 contains notation. In section 3 an algorithm for computing a rigorous lower bound of the global minimum value is considered, and in section 4 a rigorous upper bound of the optimal value, together with a certificate of existence of optimal solutions, is presented. In section 5 we show how these rigorous bounds can be used for obtaining certificates of infeasibility. Section 6 contains numerical results and some remarks on other software packages. Finally, in section 7 some conclusions are given.

2. Notation, interval arithmetic. Throughout this paper we use the following notation. We denote by $\mathbb{R}$, $\mathbb{R}^n$, $\mathbb{R}^n_+$, and $\mathbb{R}^{m\times n}$ the sets of real numbers, real vectors, real nonnegative vectors, and real $m \times n$ matrices, respectively. Comparisons $\leq$, absolute value $|\cdot|$, min, max, inf, and sup are used entrywise for vectors and matrices. The identity matrix is denoted by I_d.

For a symmetric matrix A the eigenvalues are sorted nonincreasingly: $\lambda_{\max}(A) = \lambda_1(A) \geq \lambda_2(A) \geq \cdots \geq \lambda_{\min}(A)$.

For $\mu \in \mathbb{R}$ the operator

$$\operatorname{svec}(A, \mu) := (A_{11}, \mu A_{21}, \ldots, \mu A_{n1}, A_{22}, \mu A_{32}, \ldots, \mu A_{nn-1}, A_{nn})^T \tag{2.1}$$

transforms symmetric $n \times n$ matrices into $((n+1)n/2)$-dimensional vectors with the property that the inner product of two symmetric matrices A, B is

$$\langle A, B\rangle = \operatorname{svec}(A, 2)^T \operatorname{svec}(B, 1) = \operatorname{svec}(A, \sqrt{2})^T \operatorname{svec}(B, \sqrt{2}), \tag{2.2}$$

and $\operatorname{svec}(A, \sqrt{2})$ is the customary svec operator. We prefer the first representation of the inner product, since this avoids conversion errors of the input data of semidefinite programs in its vector representation form. The inverse operator of svec is denoted by $\operatorname{smat}(a, \mu)$ where a is the vector representation (2.1).

For block matrices with blocks A_j for $j = 1, \ldots, n$, we define the concatenated vector

$$\operatorname{svec}((A_j), \mu) := (\operatorname{svec}(A_1, \mu); \ldots; \operatorname{svec}(A_n, \mu)). \tag{2.3}$$

We require only some elementary facts about interval arithmetic, which are described here. There are a number of textbooks on interval arithmetic and self-validating

methods that we highly recommend to readers. These include Alefeld and Herzberger [1], Moore [31], and Neumaier [34, 35].

If $\mathbb{V}$ is one of the spaces $\mathbb{R}$, $\mathbb{R}^n$, or $\mathbb{R}^{m\times n}$, and $\underline{v}, \overline{v} \in \mathbb{V}$, then the box

$$\mathbf{v} := [\underline{v}, \overline{v}] := \{v \in \mathbb{V} : \ \underline{v} \le v \le \overline{v}\} \tag{2.4}$$

is called an *interval quantity* in $\mathbb{IV}$ with *lower bound* $\underline{v}$ and *upper bound* $\overline{v}$. In particular, $\mathbb{IR}$, $\mathbb{IR}^n$, and $\mathbb{IR}^{m\times n}$ denote the set of real intervals $\mathbf{a} = [\underline{a}, \overline{a}]$, the set of real interval vectors $\mathbf{x} = [\underline{x}, \overline{x}]$, and the set of real interval matrices $\mathbf{A} = [\underline{A}, \overline{A}]$, respectively. The real operations $A \circ B$ with $\circ \in \{+, -, \cdot, /\}$ between real numbers, real vectors, and real matrices can be generalized to *interval operations*. The result $\mathbf{A} \circ \mathbf{B}$ of an interval operation is defined as the interval hull of all possible real results, that is,

$$\mathbf{A} \circ \mathbf{B} := \cap\{\mathbf{C} \in \mathbb{IV} : \ A \circ B \in \mathbf{C} \quad \text{for all} \quad A \in \mathbf{A}, B \in \mathbf{B}\}. \tag{2.5}$$

All interval operations can be easily executed by working appropriately with the lower and upper bounds of the interval quantities. For example, in the simple case of addition, we obtain

$$\mathbf{A} + \mathbf{B} = [\underline{A} + \underline{B}, \overline{A} + \overline{B}]. \tag{2.6}$$

Interval multiplications and divisions require a distinction of cases. Similarly all operations (2.5) between interval vectors and interval matrices can be executed. For example the i, j component of the product of two interval matrices $\mathbf{C}, \mathbf{X} \in \mathbb{IR}^{n\times n}$ is

$$(\mathbf{CX})_{ij} = \sum_{k=1}^{n} \mathbf{C}_{ik}\mathbf{X}_{kj}, \tag{2.7}$$

and the inner product is

$$\langle \mathbf{C}, \mathbf{X} \rangle = \ \text{trace}\ (\mathbf{C}^T\mathbf{X}) = \sum_{i,j=1}^{n} \mathbf{C}_{ij}\mathbf{X}_{ij}. \tag{2.8}$$

For interval quantities $\mathbf{A}, \mathbf{B} \in \mathbb{IV}$ we define

$$\text{mid}\mathbf{A} := (\underline{A} + \overline{A})/2 \quad \text{as the } \textit{midpoint}, \tag{2.9}$$

$$\text{rad}\mathbf{A} := (\overline{A} - \underline{A})/2 \quad \text{as the } \textit{radius}, \tag{2.10}$$

$$|\mathbf{A}| := \max\{|A| : \ A \in \mathbf{A}\} \quad \text{as the } \textit{absolute value}, \tag{2.11}$$

$$\mathbf{A}^+ := \max\{0, \overline{A}\}, \tag{2.12}$$

$$\mathbf{A}^- := \min\{0, \underline{A}\}. \tag{2.13}$$

Moreover, the comparison in $\mathbb{IV}$ is defined by

$$\mathbf{A} \le \mathbf{B} \quad \text{iff} \quad \overline{A} \le \underline{B},$$

and other relations are defined analogously. Real quantities v are embedded in the interval quantities by identifying $v = \mathbf{v} = [v, v]$.

We call $\mathbf{A} \in \mathbb{IR}^{n\times n}$ *symmetric* if $\mathbf{A}_{ij} = \mathbf{A}_{ji}$ for all i, j, and $\mathbf{A}$ is called positive semidefinite if all $A \in \mathbf{A}$ have this property.

For linear systems of equations with inexact input data, the aim frequently is to compute an interval vector $\mathbf{x} \in \mathbb{IR}^n$ containing the *solution set*

$$\Sigma(\mathbf{A}, \mathbf{b}) := \{x \in \mathbb{R}^n : Ax = b \text{ for some } (A, b) \in (\mathbf{A}, \mathbf{b})\}, \tag{2.14}$$

where $\mathbf{A} \in \mathbb{IR}^{n\times n}$ and $\mathbf{b} \in \mathbb{IR}^n$. This is an NP-hard problem, but there are several methods that compute enclosures $\mathbf{x}$. A precise description of such methods, required assumptions, and approximation properties can be found, for example, in Neumaier [34]. Roughly speaking, it turns out that for interval matrices with $\|I_d - R\mathbf{A}\| < 1$ (R is an approximate inverse of the midpoint mid$\mathbf{A}$), there are several methods which compute an enclosure $\mathbf{x}$ with $O(n^3)$ operations. The radius rad$\mathbf{x}$ decreases linearly with decreasing radii rad$\mathbf{A}$ and rad$\mathbf{b}$. For the computation of enclosures in the case of large-scale linear systems the reader is referred to Rump [42].

In interval arithmetic several methods for computing rigorous bounds for all or some eigenvalues of interval matrices were developed. Some important references are Floudas [7], Mayer [30], Neumaier [36], and Rump [42, 43].

3. Rigorous lower bound. In many applications some or all input data are uncertain. We model these uncertainties by intervals. In the case of semidefinite programming we assume that symmetric interval matrices $\mathbf{C}_j, \mathbf{A}_{ij} \in \mathbb{IR}^{s_j\times s_j}$, $i = 1, \ldots, m$, $j = 1, \ldots, n$, and an interval vector $\mathbf{b} \in \mathbb{IR}^m$ are given. This yields a family of semidefinite programs (1.1), where the input data $P = (A, b, C)$ are allowed to vary within interval bounds $\mathbf{P} := (\mathbf{A}, \mathbf{b}, \mathbf{C})$.

In order to indicate the dependency on the input data, we sometimes write $p^*(P)$, $d^*(P)$, $X^*(P)$, etc.

First, we state a lemma proving a lower bound for the inner product of two symmetric matrices.

LEMMA 3.1. *Let D, X be symmetric matrices of dimension s that satisfy*

$$\underline{d} \le \lambda_{\min}(D), \quad 0 \le \lambda_{\min}(X), \quad \textit{and} \quad \lambda_{\max}(X) \le \overline{x}. \tag{3.1}$$

Then

$$\langle D, X\rangle \ge s \cdot \underline{d}^- \cdot \overline{x}, \tag{3.2}$$

where $\underline{d}^- := \min\{0, \underline{d}\}$.

Proof. Let D have the eigenvalue decomposition

$$D = Q\Lambda(D)Q^T, \quad QQ^T = I_d,$$

where $\Lambda(D)$ is the diagonal matrix with eigenvalues of D on the diagonal. Then

$$\begin{aligned}\langle D, X\rangle &= \operatorname{trace}(Q\Lambda(D)Q^T X)\\ &= \operatorname{trace}(\Lambda(D)Q^T XQ)\\ &= \sum_{k=1}^{s} \lambda_k(D)Q(:,k)^T XQ(:,k).\end{aligned}$$

Because of (3.1), we have $0 \le Q(:,k)^T XQ(:,k) \le \overline{x}$ yielding

$$\langle D, X\rangle \ge \sum_{k=1}^{s} \lambda_k(D)^- \cdot \overline{x} \ge s \cdot \underline{d}^- \cdot \overline{x}. \qquad \square$$

We are now ready to prove a rigorous lower bound for the optimal value p^*.

THEOREM 3.2. *Let* $\mathbf{P}$ *define a family of semidefinite programs* (1.1) *with input data* $P \in \mathbf{P}$, *let* $\tilde{y} \in \mathbb{R}^m$, *set*

$$\mathbf{D}_j := \mathbf{C}_j - \sum_{i=1}^{m} \tilde{y}_i \mathbf{A}_{ij} \quad \text{for } j = 1, \ldots, n, \tag{3.3}$$

and suppose that

$$\underline{d}_j \le \lambda_{\min}(\mathbf{D}_j) \quad \text{for } j = 1, \ldots, n. \tag{3.4}$$

Assume further that upper bounds for the maximal eigenvalues of the primal feasible solutions of (1.1)

$$\lambda_{\max}(X_j) \le \overline{x}_j \quad \text{for } j = 1, \ldots, n \tag{3.5}$$

are known, where $\overline{x}_j$ *may be infinite. If*

$$\underline{d}_j \ge 0 \quad \text{for } \overline{x}_j = +\infty, \tag{3.6}$$

then for every $P \in \mathbf{P}$ *the inequality*

$$p^*(P) \ge \inf \left\{ \mathbf{b}^T \tilde{y} + \sum_{j=1}^{n} s_j \cdot \underline{d}_j^- \cdot \overline{x}_j \right\} \tag{3.7}$$

is satisfied, and the right-hand side of (3.7) *is finite.*[1] *Moreover, for every* $P \in \mathbf{P}$ *and every* j *with* $\underline{d}_j \ge 0$ *the LMI*

$$\sum_{i=1}^{m} y_i A_{ij} - C_j \preceq 0$$

is feasible with $y := \tilde{y}$.

Proof. Let $P = (A, b, C) \in \mathbf{P}$ be chosen fixed, and let $X_j = X_j(P)$ be primal feasible for P and $j = 1, \ldots, n$. Let

$$D_j = C_j - \sum_{i=1}^{n} \tilde{y}_i A_{ij} \quad \text{for } j = 1, \ldots, n;$$

then

$$\sum_{j=1}^{n} \langle C_j, X_j \rangle - b^T \tilde{y} = \sum_{j=1}^{n} \langle D_j, X_j \rangle.$$

Since $D_j \in \mathbf{D}_j$, Lemma 3.1 implies

$$\sum_{j=1}^{n} \langle D_j, X_j \rangle \ge \sum_{j=1}^{n} s_j \cdot \underline{d}_j^- \cdot \overline{x}_j,$$

[1] Notice that $\mathbf{b}^T y$ is an interval operation yielding an interval for the expression in the braces in (3.7). Hence, the infimum denotes the lower bound of this interval. This notation applies also for the supremum and subsequently.

which proves the inequality (3.7), and the assumption (3.6) yields a finite right-hand side. The last statement is an immediate consequence of $D_j \in \mathbf{D}_j$ and $\lambda_{\min}(D_j) \geq \underline{d}_j \geq 0$. ∎

Observe that $\tilde{y}$ is dual feasible provided $\underline{d}_j \geq 0$ for $j = 1, \ldots, n$. Hence in this case, (3.7) yields the lower bound $\inf\{\mathbf{b}^T \tilde{y}\}$ for the dual optimal value $d^*(P)$ for every $P \in \mathbf{P}$.

In order to judge the quality of the lower bound (3.7), we assume that

(i) exact input data $P = \mathbf{P}$ are given,
(ii) $D = \mathbf{D}$ is computed exactly, and
(iii) Slater's constraint qualifications (cf. section 1) are fulfilled.

Moreover, let $\tilde{y}$ be the optimal solution of the dual problem (1.2), and let $\underline{d}_j = \lambda_{\min}(D)$ for $j = 1, \ldots, n$. Then $\underline{d}_j \geq 0$ for $j = 1, \ldots, n$, and

$$p^*(P) = d^*(P) = b^T \tilde{y}.$$

Hence, no overestimation occurs, and it follows that the quality of this lower bound mainly depends on the quality of the $\underline{d}_j$ and on the computed approximation $\tilde{y}$.

An immediate consequence of Theorem 3.2 is the following error bound for linear programming problems:

$$p^* := \min c^T x \quad \text{s.t. } Ax = b, x \geq 0, \tag{3.8}$$

which is proved in [17], and in [37] for finite bounds $\overline{x}_j$. The input data are $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$, $c \in \mathbb{R}^n$, and $P = (A, b, c) \in \mathbb{R}^{m \times n + m + n}$.

COROLLARY 3.1. *Let* $\mathbf{P} = (\mathbf{A}, \mathbf{b}, \mathbf{c}) \in \mathbb{IR}^{m \times n + m + n}$, $\tilde{y} \in \mathbb{R}^m$, *and let*

$$\mathbf{d} := \mathbf{c} - \mathbf{A}^T \tilde{y}. \tag{3.9}$$

Assume further that upper bounds of the primal feasible solutions

$$x_j \leq \overline{x}_j \quad \textit{for } j = 1, \ldots, n$$

are known for all $P \in \mathbf{P}$, *which may also be infinite. If*

$$\mathbf{d}_j \geq 0 \quad \textit{for } \overline{x}_j = +\infty, \tag{3.10}$$

then for every $P \in \mathbf{P}$ *the optimal value* $p^*(P)$ *satisfies the inequality*

$$p^*(P) \geq \inf \left\{ \mathbf{b}^T \tilde{y} + \sum_{j=1}^{n} \mathbf{d}_j^- \cdot \overline{x}_j \right\}. \tag{3.11}$$

Proof. Apply Theorem 3.2 to the semidefinite program where the symmetric matrices A_{ij}, C_j, and X_j are one dimensional. ∎

Next, we describe an algorithm for computing a lower bound of the optimal value, which is based on Theorem 3.2. We assume that an approximate dual optimal solution $\tilde{y} \in \mathbb{R}^m$ of the midpoint problem $\operatorname{mid} \mathbf{P}$ is known. If condition (3.6) is fulfilled, the only work is to compute the right-hand side of (3.7). Otherwise, the idea is to perturb all constraints which violate condition (3.6); that is, we solve a perturbed midpoint problem $P = (\operatorname{mid} \mathbf{A}, \operatorname{mid} \mathbf{b}, C(\varepsilon))$ with

$$C_j(\varepsilon) = \operatorname{mid} \mathbf{C}_j - \varepsilon_j I_d, \varepsilon_j = \begin{cases} > 0 & \text{if } \underline{d}_j < 0 \text{ and } \overline{x}_j = +\infty, \\ 0 & \text{otherwise.} \end{cases} \tag{3.12}$$

Then the dual optimal solution $y(\varepsilon)$ satisfies the constraints

$$\operatorname{mid} \mathbf{C}_j - \sum_{i=1}^{m} y_i(\varepsilon) \operatorname{mid} \mathbf{A}_{ij} \succeq \varepsilon_j I_d.$$

Hence, the minimal eigenvalues of the new defect

$$\mathbf{D}_j(\varepsilon) := \mathbf{C}_j - \sum_{i=1}^{m} y_i(\varepsilon) \mathbf{A}_{ij}$$

will increase. Choosing ε_j very large may imply dual infeasibility, choosing $\varepsilon_j > 0$ too small may not be sufficient for satisfying (3.6). Our current trade-off is to solve repeatedly perturbed programs until either condition (3.6) is satisfied or the dual is infeasible. The details are given in Algorithm 1. This algorithm requires interval arithmetic (or at least the monotonic rounding operations) for computing the defect matrices $\mathbf{D}$, an algorithm for computing rigorous lower bounds $\underline{d}_j$, and a semidefinite solver for computing approximate solutions of the perturbed problems.

The algorithm terminates during the first iteration in step 3 if all simple bounds $\overline{x}_j$ are finite or all $\underline{d}_j$ are nonnegative. In this case the computational costs are $O(m \cdot \sum_{j=1}^{n} s_j^2)$ for computing the $\mathbf{D}_j$'s, the lower bounds $\underline{d}_j$ require $O(\sum_{j=1}^{n} s_j^3)$ operations, and the bound $\underline{p}^*$ needs $O(m+n)$ operations. Hence the costs are negligible compared to the costs for approximately solving a semidefinite program.

In other cases, however, the computational costs may increase because perturbed semidefinite programs must be solved until either condition (3.6) is satisfied, the semidefinite programming solver indicates dual infeasibility of the perturbed problem, or the maximal number of iterations $l_{\max}$ is reached.

Several modifications of this algorithm are possible and may yield improvements. Here we have considered a simple choice of perturbations: In each step we add to ε_j the negative defects $-\underline{d}_j$ multiplied by a factor 2^{k_j}, where k_j counts the number of iterations that violated the inequality $\underline{d}_j \geq 0$.

In applications we recommend to use infinite bounds $\overline{x}_j$ instead of unreasonable large bounds, because otherwise the sum in (3.7) may yield an unnecessary overestimation.

If the upper bounds $\overline{x}_j = +\infty$ for $j = 1, \ldots, n$ and Algorithm 1 delivers a finite lower bound $\underline{p}^*$, then the lower eigenvalue bounds $\underline{d}_j$ must be nonnegative. This proves dual feasibility, and if $\underline{d}_j$ is positive for $j = 1, \ldots, n$, strict dual feasibility is verified.

4. Rigorous upper bound. In this section we investigate the computation of a rigorous upper bound for the optimal value of a semidefinite program together with a certificate of existence of primal feasible solutions. The basic idea is to compute interval matrices $\mathbf{X}_j$ for $j = 1, \ldots, n$ that contain a primal feasible solution for every semidefinite program $P \in \mathbf{P}$. The desirable characteristics of the matrices $\mathbf{X}_j$ are given in the next theorem.

THEOREM 4.1. *Let* $\mathbf{P}$ *define a family of semidefinite programs* (1.1), *and suppose that there exist interval matrices* $\mathbf{X}_j$ *for* $j = 1, \ldots, n$ *such that*

$$\begin{aligned} &\forall b \in \mathbf{b}, \forall A_{ij} \in \mathbf{A}_{ij}, i = 1, \ldots, m, j = 1, \ldots, n, \\ &\exists \text{ symmetric } X_j \in \mathbf{X}_j : \sum_{j=1}^{n} \langle A_{ij}, X_j \rangle = b_i, \end{aligned} \tag{4.1}$$

ALGORITHM 1. *Rigorous lower bound*

given: real or interval input data $\mathbf{P} = (\mathbf{A}, \mathbf{b}, \mathbf{c})$,
upper bounds $\overline{x}_j$ for $j = 1, \ldots, n$,
approximate dual optimal solution $\tilde{y}$ for $\operatorname{mid} \mathbf{P}$,
$\underline{p}^* := -\infty$,
ε, k are n-dimensional zero vectors,
maximal numbers of iterations $l_{\max}$,
$l := 0$.

while perturbed problem $P(\varepsilon)$ is dual feasible **and** $l \le l_{\max}$

1. Compute $\mathbf{D}_j = \mathbf{C}_j - \sum_{i=1}^{m} \tilde{y}_i \mathbf{A}_{ij}$, $j = 1, \ldots, n$.
2. Compute rigorous lower bounds $\underline{d}_j \le \lambda_{\min}(\mathbf{D}_j)$ for $j = 1, \ldots, n$.
3. **If** $\underline{d}_j \ge 0$ for every j with $\overline{x}_j = +\infty$ **then** compute

$$\underline{p}^* = \inf \left\{ \mathbf{b}^T \tilde{y} + \sum_{j=1}^{n} s_j \cdot \underline{d}_j^- \cdot \overline{x}_j \right\},$$

STOP.

4. Compute for $j = 1, \ldots, n$

$$k_j := \begin{cases} k_j + 1 & \text{if } \underline{d}_j < 0 \text{ and } \overline{x}_j = +\infty, \\ k_j & \text{otherwise,} \end{cases}$$

$$\varepsilon_j := \begin{cases} -2^{k_j} \underline{d}_j + \varepsilon_j & \text{if } \underline{d}_j < 0 \text{ and } \overline{x}_j = +\infty, \\ \varepsilon_j & \text{otherwise.} \end{cases}$$

5. Solve the perturbed midpoint problem $P(\varepsilon) = (\operatorname{mid} \mathbf{A}, \operatorname{mid} \mathbf{b}, C(\varepsilon))$, where $C_j(\varepsilon) = \operatorname{mid} \mathbf{C}_j - \varepsilon_j I_d$ for $j = 1, \ldots, n$, and set $\tilde{y} := \tilde{y}(\varepsilon)$ (approximate dual optimal solution).
6. $l := l + 1$.

end

and for $j = 1, \ldots, n$

$$X_j \succeq 0 \quad \textit{for all symmetric } X_j \in \mathbf{X}_j. \tag{4.2}$$

Then, the optimal value is bounded from above by

$$p^*(P) \le \sup \left\{ \sum_{j=1}^{n} \langle \mathbf{C}_j, \mathbf{X}_j \rangle \right\}. \tag{4.3}$$

Moreover, if all symmetric $X_j \in \mathbf{X}_j$ *are positive definite and* $p^*(P)$ *is bounded from below, then* $p^*(P) = d^*(P)$ *for every* $P \in \mathbf{P}$ *(no duality gap) and the dual supremum is attained.*

Proof. Let $P \in \mathbf{P}$ be a fixed chosen problem. Then the conditions (4.1) and (4.2) imply that there exists a primal feasible solution $X_j = X_j(P)$ for $j = 1, \ldots, n$. Hence, $\sum_{j=1}^{n} \langle C_j, X_j \rangle \ge p^*(P)$, and the inclusion property (2.5) yields (4.3). If all $X_j \in \mathbf{X}_j$

are positive definite, then (4.1) and (4.2) imply the existence of strictly primal feasible solutions, and hence Theorem 1.1 shows that the dual optimal solution is attained and strong duality holds. □

By weak duality the upper bound in (4.3) is also an upper bound of the dual optimal value. Moreover, if all $X_j \in \mathbf{X}_j$ are positive definite, then the strong duality theorem (Theorem 1.1) implies that the right-hand side of (3.7) is also a lower bound of the dual optimal value for all $P \in \mathbf{P}$. Hence, in this case it is not necessary to assume $\underline{d}_j \geq 0$ for $j = 1, \ldots, n$.

In the following, we describe an algorithm for computing this rigorous upper bound. This algorithm must find appropriate interval matrices $\mathbf{X}_j$ and verify the conditions (4.1) and (4.2). We discuss these items below.

To make sure that the upper bound (4.3) is close to the optimal value, the interval matrices $\mathbf{X}_j$ must be close to optimality. In general, the complementary slackness relations yield rank-deficient matrices, which are not positive definite. Therefore, we solve the slightly perturbed midpoint problem

$$\min \sum_{j=1}^{n} \langle C_j, X_j \rangle \quad \text{s.t.} \quad \sum_{j=1}^{n} \langle A_{ij}, X_j \rangle = b_i \quad \text{for } i = 1, \ldots, m, \tag{4.4}$$
$$X_j \succeq \varepsilon_j \cdot I_d \quad \text{for } j = 1, \ldots, n,$$

where ε_j is positive and the input data $(A, b, c) = \operatorname{mid} \mathbf{P}$. Then for small ε_j the optimal solution $(X_j(\varepsilon_j))$ is positive definite and close to the optimal solution of the midpoint problem.

In the following we show how we can construct an appropriate interval matrix $(\mathbf{X}_j)$ by using an approximate optimal solution $(X_j(\varepsilon_j))$ of (4.4).

The semidefinite program (1.1) can be written in the equivalent vector representation form,

$$\min c^T x \quad \text{s.t.} \quad A^{\text{mat}} x = b, X_j \succeq 0 \text{ for } j = 1, \ldots, n, \tag{4.5}$$

where

$$c := \operatorname{svec}((C_j), 2), \tag{4.6}$$

$$x := \operatorname{svec}((X_j), 1), \tag{4.7}$$

and the ith row of the $m \times \sum_{j=1}^{n} \frac{s_j(s_j+1)}{2}$ matrix A^{mat} is defined by

$$A^{\text{mat}}(i, :) = \operatorname{svec}((A_{ij})_{j=1}^{n}, 2). \tag{4.8}$$

If interval input data $\mathbf{P}$ are given, then we denote by $\mathbf{A}^{\text{mat}}$, $\mathbf{b}$, and $\mathbf{c}$ the corresponding interval quantities. Thus condition (4.1) is equivalent to

$$\forall b \in \mathbf{b}, \forall A^{\text{mat}} \in \mathbf{A}^{\text{mat}} \exists x \in \mathbf{x} \text{ such that } A^{\text{mat}} x = b, \tag{4.9}$$

which is an underdetermined system of linear equations with interval input data. Given an approximate optimal solution $(X_j(\varepsilon_j))_{j=1}^{n}$, it is straightforward to solve such a system.

We start by assuming that the $m \times m$ submatrix $\operatorname{mid} \mathbf{A}_I^{\text{mat}}$ with the m columns $\operatorname{mid} \mathbf{A}^{\text{mat}}(:, \beta_i)$ is nonsingular, where the index set $I := \{\beta_1, \ldots, \beta_m\}$. Let N denote

all indices of columns of $\operatorname{mid}\mathbf{A}^{\mathrm{mat}}$ which are not in I, let $\mathbf{A}_N^{\mathrm{mat}}$ be the matrix with columns corresponding to the indices of N, and let $\tilde{x} = \operatorname{svec}((X_j(\varepsilon_j)), 1)$. In our algorithm we choose the index set I by performing an LU decomposition on $(\operatorname{mid}\mathbf{A}^{\mathrm{mat}})^T$ and assembling the computed pivot columns to A_I^{mat}. Now we fix the variables $\tilde{x}_N$ and compute with some verification method for interval linear systems an enclosure $\mathbf{x}_I$ of the solution set

$$\Sigma_I := \left\{ x_I \in \mathbb{R}^m : A_I^{\mathrm{mat}} x_I = b - \sum_{\gamma \in N} A_N^{\mathrm{mat}} \tilde{x}_N, A \in \mathbf{A}^{\mathrm{mat}}, b \in \mathbf{b} \right\}. \tag{4.10}$$

Then $\mathbf{x} := (\mathbf{x}_I; \tilde{x}_N)$ fulfills (4.9), and therefore $(\mathbf{X}_j) := \operatorname{smat}(\mathbf{x}, 1)$ satisfies condition (4.1). Condition (4.2) must be verified by some method for computing a rigorous lower bound for the smallest eigenvalue of a symmetric interval matrix.

Algorithm 2 contains the details for computing a rigorous upper bound for the optimal value and for proving existence of primal feasible solutions. The algorithm needs verified solvers for interval linear systems and eigenvalue problems, and a semidefinite solver for computing approximations of the perturbed problems.

If Algorithm 2 delivers a finite upper bound $\overline{p}^*$, then the lower eigenvalue bounds $\underline{\lambda}_j$ must be nonnegative. If $\underline{\lambda}_j > 0$ for $j = 1, \ldots, n$, then strict primal feasibility is verified.

Krawczyk [27] was the first who solved nondegenerate interval linear programming problems by using the technique of fixing appropriate variables (the nonbasic variables) and solving a remaining quadratic interval linear system for the basic variables. In [15] this technique was used to compute enclosures of all optimal vertices in the degenerate case. Hansen [13] used this technique in order to prove existence of a feasible point for nonlinear equations within a bounded box. It was further modified and investigated numerically by Kearfott [20], and is also described in his book [19].

5. Certificate of infeasibility. In branch and bound algorithms a subproblem is discarded if the local nonlinear solver detects infeasibility. Occasionally local solvers do not find feasible solutions of a subproblem, although they exist (see, for example, the comments for use of SDPT3). A consequence is that the global minimum solutions may be cut off.

To avoid this disadvantage we can apply the algorithms for computing rigorous bounds described in the previous sections to a phase I problem in order to verify infeasibility for primal and dual semidefinite problems. In the literature there are several variations of the phase I method. It is common, however, that the auxiliary objective function describes the infeasibility in the sense that the problem has no feasible solutions, provided the optimal value is greater than zero. The latter property can be verified by the algorithms of the previous sections.

Another approach is based on certificates of infeasibility. For linear programs with bounded variables rigorous certificates of infeasibility are described in Neumaier and Shcherbina [37]. For infeasible semidefinite problems often (but not every time) certificates of infeasibility exposed by improving rays can be obtained (see also the discussion in Todd [46]).

The primal problem (1.1) has a primal improving ray if there exists a block-diagonal matrix (X_j) such that for all $i = 1, \ldots, m$ and $j = 1, \ldots, n$

$$X_j \succeq 0, \quad \sum_{j=1}^{n} \langle A_{ij}, X_j \rangle = 0, \quad \text{and} \quad \sum_{j=1}^{n} \langle C_j, X_j \rangle < 0. \tag{5.1}$$

ALGORITHM 2. *Rigorous upper bound, certificate of feasibility*

given: real or interval input data $\mathbf{P} = (\mathbf{A}, \mathbf{b}, \mathbf{c})$,
approximate primal optimal solution $(\tilde{X}_j)_{j=1}^n$ of the midpoint problem,
$\overline{p}^* := \infty$,
ε, k are n-dimensional zero vectors,
maximal number of iterations $l_{\max}$,
$l := 0$.

Choose an index set I such that the submatrix $\operatorname{mid} \mathbf{A}_I^{\mathrm{mat}}$ is (at least numerically) nonsingular (for example, by performing an LU decomposition on $(\operatorname{mid} \mathbf{A}^{\mathrm{mat}})^T$).

if there is no nonsingular submatrix **then STOP**.

while perturbed problem $P(\varepsilon)$ is primal feasible **and** $l \le l_{\max}$

1. Compute an enclosure $\mathbf{x}_I$ of the solution set Σ_I (4.10), and set $\mathbf{x} := (\mathbf{x}_I; \tilde{x}_N)$.
2. Set $(\mathbf{X}_j) = \operatorname{smat}(\mathbf{x}, 1)$, and compute rigorous bounds
$$\underline{\lambda}_j \le \lambda_{\min}(\mathbf{X}_j) \quad \text{for } j = 1, \ldots, n.$$
3. **if** $\underline{\lambda}_j \ge 0$ for $j = 1, \ldots, n$ **then** compute
$$\overline{p}^* = \sup\{\mathbf{c}^T \mathbf{x}\},$$
STOP.
4. Compute for $j = 1, \ldots, n$
$$k_j := \begin{cases} k_j + 1 & \text{if } \underline{\lambda}_j < 0, \\ k_j & \text{otherwise,} \end{cases}$$
$$\varepsilon_j := \begin{cases} -2^{k_j} \underline{\lambda}_j + \varepsilon_j & \text{if } \underline{\lambda}_j < 0, \\ \varepsilon_j & \text{otherwise.} \end{cases}$$
5. Solve the perturbed problem (4.4), set $\tilde{X}_j := \tilde{X}_j(\varepsilon)$ for $j = 1, \ldots, n$ (approximate primal optimal solution), and set $\tilde{x} := \operatorname{svec}((\tilde{X}_j), 1)$.
6. $l := l + 1$.

end

It is well known and straightforward to show that the existence of a primal improving ray implies dual infeasibility. If interval input data $\mathbf{P}$ are given, and for the midpoint problem of $\mathbf{P}$ an approximate primal improving ray is known, then we can try to verify dual infeasibility for all problems with $P \in \mathbf{P}$ by using a similar approach as in the previous section. We assume that the semidefinite solver has computed an approximate primal improving ray $(\tilde{X}_j)$ for the midpoint problem. Let $\beta \approx \sum_{j=1}^n \langle \operatorname{mid} \mathbf{C}_j, \tilde{X}_j \rangle$ be approximately calculated and assume that $\beta < 0$. Notice that for positive β the conditions (5.1) are in general not satisfied. Now, analogously to the previous section, we can compute enclosures $(\mathbf{X}_j)$ such that for every $A_{ij} \in \mathbf{A}_{ij}$ and for every $C_j \in \mathbf{C}_j$ there exist solutions $X_j \in \mathbf{X}_j$ of the underdetermined linear system

$$\sum_{j=1}^n \langle A_{ij}, X_j \rangle = 0 \quad \text{for } i = 1, \ldots, m, \qquad \sum_{j=1}^n \langle C_j, X_j \rangle = \beta. \tag{5.2}$$

If an enclosure $(\mathbf{X}_j)$ is computed and if all minimal eigenvalues $\lambda_{min}(\mathbf{X}_j)$ are nonnegative, then, because $\beta < 0$, it follows that for every $P \in \mathbf{P}$ there exists $X_j \in \mathbf{X}_j$ for $j = 1, \ldots, n$ such that (5.1) is satisfied. Therefore, all problems with $P \in \mathbf{P}$ are dual infeasible, and the block matrices $(\mathbf{X}_j)$ contain the primal improving rays.

The dual problem (1.3) has a dual improving ray if there is a vector $y \in \mathbb{R}^m$ such that

$$\sum_{i=1}^{m} y_i A_{ij} \preceq 0 \quad \text{for } j = 1, \ldots, n, \quad \text{and} \quad b^T y > 0. \tag{5.3}$$

The existence of a dual improving ray implies primal infeasibility. If interval input data $\mathbf{P}$ are given and for some problem $P \in \mathbf{P}$ an approximate dual improving ray $\tilde{y}$ is known, then we can try to verify primal infeasibility for all problems with $P \in \mathbf{P}$ as follows: First we compute by using interval arithmetic upper bounds of the maximal eigenvalues of $\sum_{i=1}^{m} \tilde{y}_i \mathbf{A}_{ij}$ for $j = 1, \ldots, n$. If these upper bounds are nonpositive and if $\mathbf{b}^T \tilde{y} > 0$, then $\tilde{y}$ is a dual improving ray for all $P \in \mathbf{P}$. Hence, $\tilde{y}$ is a rigorous certificate of primal infeasibility for all $P \in \mathbf{P}$.

6. Numerical results. In this section, we present some numerical experiments for semidefinite and linear programming problems. The results for the semidefinite programming problems were obtained by using VSDP [14], a MATLAB software package for verified semidefinite programming. This package uses the toolbox INTLAB [44] and allows interval input data. For all experiments we used the default values of the solver.

First we consider a semidefinite program of small size,

$$\begin{aligned}
\min \quad & \left\langle \begin{pmatrix} 0 & \frac{1}{2} & 0 \\ \frac{1}{2} & \delta & 0 \\ 0 & 0 & \delta \end{pmatrix}, X \right\rangle \\
\text{s.t.} \quad & \left\langle \begin{pmatrix} 0 & -\frac{1}{2} & 0 \\ -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, X \right\rangle = 1, \\
& \left\langle \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, X \right\rangle = \varepsilon, \\
& \left\langle \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, X \right\rangle = 0, \\
& \left\langle \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, X \right\rangle = 0, \\
& X \succeq 0.
\end{aligned}$$

TABLE 6.1
Approximations $\tilde{p}^*$, $\tilde{d}^*$ and rigorous bounds $\overline{p}^*$, $\underline{p}^*$.

10^{-4}	-10^{-4}	−5.9323	−1.0361	−7	−5.9324	$-\infty$

The Lagrangian dual is

$$d^* = \max y_1 + \varepsilon y_2 \quad \text{s.t.} \quad Y := C - \sum_{i=1}^{4} A_{i1} y_i$$
$$= \begin{pmatrix} -y_2 & \frac{1+y_1}{2} & -y_3 \\ \frac{1+y_1}{2} & \delta & -y_4 \\ -y_3 & -y_4 & \delta \end{pmatrix} \succeq 0.$$

The linear constraints of the primal problem imply

$$X = \begin{pmatrix} \varepsilon & -1 & 0 \\ -1 & X_{22} & 0 \\ 0 & 0 & X_{33} \end{pmatrix},$$

and X is positive semidefinite iff $X_{22} \geq 0$, $X_{33} \geq 0$, and $\varepsilon \cdot X_{22} - (-1)^2 \geq 0$. Hence, for $\varepsilon \leq 0$, the problem is primal infeasible and $p^* = +\infty$. The dual problem is infeasible for $\delta < 0$ with $d^* = -\infty$.

For $\varepsilon = 0$ and $\delta = 0$ we obtain a duality gap with $p^* = +\infty$ and $d^* = -1$, and the problem is ill-posed. For $\varepsilon > 0$ and $\delta > 0$ Slater's constraint qualifications are satisfied and the optimal value of $p^* = d^* = -1 + \delta/\varepsilon$.

Numerical results for different values of ε and δ are summarized in Table 6.1. The termination code $tc = 0$ in SDPT3 means normal termination without warning, whereas $tc = -7$ indicates primal infeasibility. In the following, $\tilde{p}^*$ and $\tilde{d}^*$ denote the computed approximations of the primal and dual optimal value, respectively.

We see that SDPT3 is not backward stable, since in five cases $\tilde{p}^* < \tilde{d}^*$, violating the weak duality. This example demonstrates that the measures for termination and accepting an approximation are not appropriate for ill-conditioned or ill-posed problems. The rigorous bounds $\overline{p}^*$ and $\underline{p}^*$ recognize difficult problems much better and overestimate the optimal value only slightly, and this overestimation depends on the quality of the computed approximations. The bounds are infinite if the problem is infeasible or very ill-conditioned. For larger values $\varepsilon > 0$ and $\delta > 0$ the approximations and the rigorous bounds are almost identical, and are not displayed here.

In the following, we describe the numerical results on problems from the SDPLIB collection of Borchers [5]. In summary, VSDP could compute (by using SDPT3 as approximate solver), for all 85 problems discussed in [9], a rigorous lower bound of the optimal value and verify the existence of strictly dual feasible solutions which implies a zero duality gap. A finite rigorous upper bound could be computed for all well-posed problems with the exception of `hinf8`, which is ill-conditioned. For the 32 ill-posed problems VSDP has computed $\overline{p}^* = +\infty$, which reflects that the distance

to the next primal infeasible problem is zero as well as the infinite condition number. Detailed numerical results can be found in the tables contained in the appendix. We measure the accuracy by the quantity

$$\mu(a,b) := \frac{a-b}{\max\{1.0, (|a|+|b|)/2\}}.$$

Notice that we do not use the absolute value of $a-b$. Hence, a negative sign implies that $a < b$. Table A.1 contains the rigorous upper bound $\overline{p}^*$, the rigorous lower bound $\underline{p}^*$, the rigorous error $\mu(\overline{p}^*, \underline{p}^*)$, and the approximate duality gap $\mu(\tilde{p}^*, \tilde{d}^*)$. We have set $\mu(\overline{p}^*, \underline{p}^*) = NaN$ if the upper bound $\overline{p}^*$ is infinite. Table A.2 contains the termination code tc given by SDPT3 and the time t in seconds for computing the approximations. The times for computing the rigorous lower and upper bounds are $\underline{t}$ and $\overline{t}$, respectively.

Some major characteristics of our numerical results for the SDPLIB are as follows: The median of the time ratio for computing the rigorous lower bound and the approximations is $\mathrm{med}(\underline{t}/t) = 0.045$ and $\mathrm{med}(\overline{t}/t) = 2.4$. The median of the guaranteed accuracy $\mu(\overline{p}^*, \underline{p}^*)$ for the problems with finite condition number is $4.9 \cdot 10^{-7}$. We have used the median here because there are some outliers.

For the SDPLIB problems, SDPT3 (with default values) gave 7 warnings, and 2 warnings were given for well-posed problems. Hence, no warnings were given for 27 ill-posed problems with zero distance to primal infeasibility. In other words, there is no correlation between warnings and the difficulty of the problem. At least for this test set our rigorous bounds reflect the difficulty of the problems much better, and they provide safety, especially in the case where algorithms subsequently call other algorithms, as is done for example in branch-and-bound methods. In our opinion the usefulness of a warning is dubious if for ill-posed problems normal termination occurs. In contrast, VSDP shows a strong correlation between the rigorous bounds and the difficulty of the problem. Moreover, the negative signs of $\mu(\tilde{p}^*, \tilde{d}^*)$ show that the approximations do not satisfy weak duality. Therefore they are not backward stable; i.e., they are not exact solutions of slightly perturbed problems.

One of the largest problems which could be solved by VSDP is `thetaG51`, where the number of constraints is $m = 6910$, $n = 1$ and the dimension of the primal Solution X_1 is $s_1 = 1001$ (implying 501501 variables). For this problem SDPT3 gave the message out of memory, and we used SDPA [10] as approximate solver. The rigorous lower and upper bounds computed by VSDP are $\underline{p}^* = -3.4900 \cdot 10^2$, $\overline{p}^* = -3.4406 \cdot 10^2$, respectively. The guaranteed relative accuracy is only 0.014, which may be sufficient in several applications, but it is insufficient from a numerical point of view. The times in seconds for computing the approximations, the lower bounds, and the upper bounds of the optimal value are $t = 3687.95$, $\underline{t} = 45.17$, and $\overline{t} = 6592.52$, respectively. Existence of optimal solutions and strong duality is proved. For the 11 instances, `control1` to `control11`, the guaranteed relative accuracies are also low, ranging from $1.21 \cdot 10^{-4}$ to $5.93 \cdot 10^{-2}$.

The aim in designing VSDP was to write the programs in a convenient form, appropriate also for students. For example, the user can specify the block-diagonal structure in the more natural way of cell arrays. Operations such as extracting selected elements of a matrix or the operations `vsvec` (rounding-error-free vectorization operator) and `vsmat` (corresponding rounding-error-free inverse operator) are written in MATLAB [29]. This causes a loss of efficiency. At present a C++ implementation of these error bounds using the interval library PROFIL/BIAS [25] is in process [6].

We already have a C++ implementation of the rigorous bounds for the special case of linear programming called Lurupa [21]. Here we present a summary of our numerical results for the NETLIB suite of linear programming problems [33]. For details we refer the reader to [23]. The NETLIB collection contains problems with up to 15695 variables and 16675 constraints. They originate from various applications, for example forestry, flap settings on aircraft, and staff scheduling. In order to compare the results, we initially chose the set of problems that Ordóñez and Freund [38] have computed condition numbers for. Removing problems *DEGEN*3 and *PILOT* because the approximate solver failed to solve these within 24 hours, the final test set included 87 problems. We applied our algorithm to the original problems without preprocessing. As Fourer and Gay [8] observed, preprocessing can change the state of an LP from feasible to infeasible and vice versa.

Roughly speaking, a finite bound can be computed iff the corresponding distance to infeasibility is greater than 0. For 76 problems a finite lower bound could be computed with a median accuracy of $\operatorname{med}(\mu(\underline{p}^*, \tilde{p}^*)) = 2.2 \cdot 10^{-8}$ and a median time ratio of $\operatorname{med}(\underline{t}/t) = 0.5$. For 35 problems the algorithm yielded a finite upper bound with $\operatorname{med}(\mu(\overline{p}^*, \tilde{p}^*)) = 8.0 \cdot 10^{-9}$ and $\operatorname{med}(\overline{t}/t) = 5.3$. For 32 problems finite rigorous lower and upper bounds could be computed with $\operatorname{med}(\mu(\overline{p}^*, \underline{p}^*)) = 5.6 \cdot 10^{-8}$. Taking into account the approximate solver's default stopping tolerance of 10^{-9}, the guaranteed accuracy for the NETLIB LP suite is reasonable. The upper bound is more expensive, since linear systems have to be solved rigorously.

To our knowledge no other software packages compute rigorous results for semidefinite programs. There are several packages that compute verified results for optimization problems where the objective and the constraints are defined by smooth algebraic expressions. The most widely known solvers for global optimization that use interval arithmetic are probably GlobSol [18], Numerica [48], and COSY [4] (on inquiry we did not receive a copy of COSY). They do not permit the nonsmooth semidefinite constraints. But they can be used to solve linear programming problems (a special, smooth case of semidefinite programming) rigorously. Packages for verified constraint programming, like ICOS [28] and RealPaver [11], can also be used to compute rigorous results for an LP by adding bounds on the objective function to the set of constraints. Specifically dedicated to verified linear programming are solvers using a rational arithmetic. Examples are QSopt_ex [2], exlp [24], and, to a limited extent, perPlex [26]. The latter one only verifies the optimality of a given basis.

We want to see how these packages compare for the special case of linear programming. For this purpose we generate dense test problems with a method similar to the one described by Rosen and Suzuki [41]. Setting a timeout of one hour on each solver run, we then determine the largest problem size that the packages can solve. First we have a look at the packages that do not exploit the linear structure in the test problems. GlobSol, Numerica, and RealPaver fail to solve the test problems if the number of variables and constraints exceeds 10. ICOS solves the problems within one hour with up to 100 variables and constraints. Now looking at the packages taking account of the linear structure, we see that these succeed for larger problems. QSopt_ex, exlp, and perPlex solve problems with 200 variables and constraints. Lurupa does not fail until the dimension exceeds 1500. For larger dimensions it turns out that it already takes more than one hour to compute the initial approximate solution. The verification part needs only a fraction of this time. Our algorithm, however, produces rigorous bounds for the optimal value and for feasible solutions close to optimality; enclosures of optimal solutions are not computed. Elaborate numerical results can be

found in [22].

7. Conclusions. The computation of rigorous error bounds for linear or semidefinite optimization problems can be viewed as a carefully postprocessing tool that uses only approximate solutions computed by an LP or SDP solver. The numerical results show that such rigorous error bounds can be computed even for problems of large size.

Appendix. Results from the SDPLIB.

THE POSTPROCESSED MIXED FINITE-ELEMENT METHOD FOR THE NAVIER–STOKES EQUATIONS: REFINED ERROR BOUNDS*

JAVIER DE FRUTOS†, BOSCO GARCÍA-ARCHILLA‡, AND JULIA NOVO§

Abstract. A postprocessing technique for mixed finite-element methods for the incompressible Navier–Stokes equations is analyzed. The postprocess, which amounts to solving a (linear) Stokes problem, is shown to increase the order of convergence of the method to which it is applied by one unit (times the logarithm of the mesh diameter). In proving the error bounds, some superconvergence results are also obtained. Contrary to previous analysis of the postprocessing technique, in the present paper we take into account the loss of regularity suffered by the solutions of the Navier–Stokes equations at the initial time in the absence of nonlocal compatibility conditions of the data. As in [H. G. Heywood and R. Rannacher, *SIAM J. Numer. Anal.*, 25 (1988), pp. 489–512], where the same hypothesis is assumed, no better than fifth-order convergence is achieved.

Key words. Navier–Stokes equations, mixed finite-element methods, optimal regularity, error estimates

1. Introduction.

It is well known that, no matter how regular the data are, solutions of the Navier–Stokes equations cannot be assumed to have more than second-order spatial derivatives bounded in L^2 up to initial time $t = 0$, since this requires the data to satisfy nonlocal compatibility conditions unlikely to be fulfilled in practical situations [36], [37]. Therefore, error analysis of numerical methods for the Navier–Stokes equations is more meaningful if this fact is taken into account. This is the case of the present paper, where we analyze a postprocessing technique that improves the errors of mixed finite-element (MFE) methods for the Navier–Stokes equations from $O(h^r)$ to $O(h^{r+1}\,|\log(h)|)$, where h is the mesh size.

This postprocessing technique was first developed for spectral methods in [26], [27], in connection with approximate inertial manifolds [14], [15]. Later it was extended to methods based on Chebyshev and Legendre polynomials [16], spectral-element methods [18], and finite-element methods [28], [19], together with being applied in the study of nonlinear shell vibrations [43]. Also, it has been effectively applied to reduce the order of practical engineering problems modeled by nonlinear differential systems [46], [45].

More recently, the postprocessing technique has also been developed for MFE methods for the Navier–Stokes equations in [4], [6], but for solutions more regular up to $t = 0$ than what can be realistically assumed in practice, and this allows the

above-mentioned improvement of the error for $r \geq 2$. In the present paper, however, due to the loss of regularity at $t = 0$, no better than $O(h^5 |\log(h)|)$ error bounds are proved, a limitation similar to that already found in [37] for MFE methods. On the other hand, as in [6], although for simplicity we concentrate on Hood–Taylor [39] elements, the postprocessing technique can be easily adapted to other kinds of mixed LBB-stable elements.

We analyze the postprocessing technique for the incompressible Navier–Stokes equations

$$\begin{aligned} u_t - \Delta u + (u \cdot \nabla)u + \nabla p &= f, \\ \operatorname{div}(u) &= 0, \end{aligned} \tag{1.1}$$

in a bounded domain $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ with a smooth boundary subject to homogeneous Dirichlet boundary conditions $u = 0$ on $\partial\Omega$. In (1.1), u is the velocity field, p the pressure, and f a given force field. We assume that the fluid density and viscosity have been normalized by an adequate change of scale in space and time.

The postprocessing technique to approximate up to time $T > 0$ the solution u and p corresponding to a given initial condition

$$u(\cdot, 0) = u_0 \tag{1.2}$$

is as follows. Compute first standard MFE approximations u_h and p_h to the velocity and pressure, respectively, by integrating in time the corresponding discretization of (1.1)–(1.2). Then compute MFE approximations $\tilde{u}_h$ and $\tilde{p}_h$ to the solution $\tilde{u}$ and $\tilde{p}$ of the following Stokes problem:

$$\left.\begin{aligned} -\Delta\tilde{u} + \nabla\tilde{p} = f - \tfrac{d}{dt}u_h - (u_h \cdot \nabla)u_h \\ \operatorname{div}(\tilde{u}) = 0 \end{aligned}\right\} \quad \text{in } \Omega, \qquad \tilde{u} = 0, \quad \text{on } \partial\Omega. \tag{1.3}$$

The MFE on this postprocessing step can be either the same-order Hood–Taylor element over a finer grid or a higher-order Hood–Taylor element over the same grid. Observe that, since the MFE approximations u_h and p_h do not depend on $\tilde{u}$ and $\tilde{p}$ or their approximations $\tilde{u}_h$ and $\tilde{p}_h$, these may be computed only when needed. If this happens only at the final time $t = T$, then an $O(h^{r+1} |\log(h)|)$ error is obtained at the cost of an $O(h^r)$ one, since only a single Stokes problem such as (1.3) is solved with the enhanced MFE method, and this is done when the time integration is completed.

The method studied in the present paper can be seen as a two-level method, where the postprocessed (or fine-mesh) approximations $\tilde{u}_h$ and $\tilde{p}_h$ are an improvement of the previously computed (coarse-mesh) approximations u_h and p_h. Recent research on two-level finite-element methods for the transient Navier–Stokes equations can be found in [30], [31], [32], [44] (see also [34], [33], [40], [42] for spectral discretizations), where the full nonlinear problem is dealt with on the coarse mesh, and a linear problem is solved on the fine mesh. Let us mention that, whereas in the present paper we are concerned with higher-order methods, in [30], [31], [32], [44] only low-order methods are dealt with. Also, in the present paper, computations on the finer grid are done only at the final time $t = T$ (or at those time levels where more accuracy is wanted), whereas in the previous works computations on the finer grids are carried out from $t = 0$ to $t = T$. It must be mentioned though, as opposed to [2], that the coarse-grid

component computation in [30], [31], [32], [44] is fully decoupled from that on the fine grid.

Although in the present paper we concentrate on the spatial discretization, practical computations are affected by the errors induced by the time discretization. Numerical experiments in [6], [16], [19], [17], [26], [28] have repeatedly shown, for the different discretizations considered, that the increase in accuracy and convergence rate predicted by the theory is also seen in practice (provided errors arising from the time discretization are kept sufficiently small). Nevertheless, in the present paper we give an explanation of this fact; that is, the gain in (spatial) accuracy in the postprocessing step takes place independently of errors arising from the temporal discretization being present or not. Similar results are obtained in [47] for finite-element methods of degree 3 or larger for reaction-diffusion problems when integrated by the implicit Euler method.

To prove our error estimates, we need to prove first some superconvergence results. These are not with respect to the Stokes projection (as in [17], [6], [4]) but with respect to the solution of a certain linear evolution problem. In this process, we also obtain error bounds for the pressure that improve those originally proved in [37, Theorem 3.1] by a factor of $t^{1/2}$.

Finally, we remark that in recent works [20], [21], [22] the postprocessing technique has shown itself useful in obtaining efficient a posteriori error estimators for partial differential equations of evolution, a field which is remarkably less developed than that of steady problems. The application of the postprocessing technique to a posteriori error estimates for the Navier–Stokes equations using the results obtained in the present paper will be the subject of future research.

The rest of the paper is as follows. In section 2 we introduce the notation and some standard material. In section 3 we comment on how to approximate the Stokes problem of the postprocessing step. Section 4 is devoted to the superconvergence analysis of the MFE approximation. In section 5 error bounds of the postprocessed approximation are obtained. Finally, we make some remarks on postprocessing when time discretization is taken into account.

2. Preliminaries and notations. We will assume that Ω is a bounded domain in $\mathbb{R}^d$, $d = 2, 3$, not necessarily convex, of class $\mathcal{C}^m$, for $m \geq 3$, and we consider the Hilbert spaces

$$H = \{u \in \left(L^2(\Omega)\right)^d \mid \operatorname{div}(u) = 0,\ u \cdot n_{|_{\partial\Omega}} = 0\},$$

$$V = \{u \in \left(H_0^1(\Omega)\right)^d \mid \operatorname{div}(u) = 0\},$$

endowed with the inner product of $L^2(\Omega)^d$ and $H_0^1(\Omega)^d$, respectively. For $l \geq 0$ integer and $1 \leq q \leq \infty$, we consider the standard Sobolev spaces $W^{l,q}(\Omega)^d$ of functions with derivatives up to order l in $L^q(\Omega)$, and $H^l(\Omega)^d = W^{l,2}(\Omega)^d$. We will denote by $\|\cdot\|_l$ the norm in $H^l(\Omega)^d$, and $\|\cdot\|_{-l}$ will represent the norm of its dual space. We consider also the quotient spaces $H^l(\Omega)/\mathbb{R}$ with norm $\|p\|_{H^l/\mathbb{R}} = \inf\{\|p + c\|_l \mid c \in \mathbb{R}\}$.

Let us recall the following Sobolev's imbeddings [1]: For $q \in [1, \infty)$, there exists a constant $C = C(\Omega, q)$ such that

$$\|v\|_{L^{q'}(\Omega)^d} \leq C\|v\|_{W^{s,q}(\Omega)^d}, \quad \frac{1}{q'} \geq \frac{1}{q} - \frac{s}{d} > 0, \quad q < \infty, \quad v \in W^{s,q}(\Omega)^d. \tag{2.1}$$

For $q' = \infty$, (2.1) holds with $\frac{1}{q} < \frac{s}{d}$.

Let $\Pi : L^2(\Omega)^d \longrightarrow H$ be the $L^2(\Omega)^d$ projection onto H. We denote by A the Stokes operator on Ω:

$$A : \mathcal{D}(A) \subset H \longrightarrow H, \quad A = -\Pi\Delta, \quad \mathcal{D}(A) = H^2(\Omega)^d \cap V.$$

Applying Leray's projector to (1.1), the equations can be written in the form

$$u_t + Au + B(u,u) = \Pi f \qquad \text{in } \Omega,$$

where $B(u,v) = \Pi(u\cdot\nabla)v$ for u, v in $H_0^1(\Omega)^d$.

We shall use the trilinear form $b(\cdot,\cdot,\cdot)$ defined by

$$b(u,v,w) = (F(u,v),w) \quad \forall u,v,w \in H_0^1(\Omega)^d,$$

where

$$F(u,v) = (u\cdot\nabla)v + \frac{1}{2}(\nabla\cdot u)v \quad \forall u,v \in H_0^1(\Omega)^d.$$

It is straightforward to verify that b enjoys the skew-symmetry property

$$b(u,v,w) = -b(u,w,v) \quad \forall u,v,w \in H_0^1(\Omega)^d. \tag{2.2}$$

Let us observe that $B(u,v) = \Pi F(u,v)$ for $u \in V$, $v \in H_0^1(\Omega)^d$.

We shall assume that

$$\|u(t)\|_1 \le M_1, \quad \|u(t)\|_2 \le M_2, \qquad 0 \le t \le T,$$

and, for $k \ge 2$ integer,

$$\sup_{0\le t\le T} \left\|\partial_t^{\lfloor k/2\rfloor} f\right\|_{k-1-2\lfloor k/2\rfloor} + \sum_{j=0}^{\lfloor (k-2)/2\rfloor} \sup_{0\le t\le T} \left\|\partial_t^j f\right\|_{k-2j-2} < +\infty,$$

so that, according to Theorems 2.4 and 2.5 in [36], there exist positive constants M_k and K_k such that for $k \ge 2$

$$\|u(t)\|_k + \|u_t(t)\|_{k-2} + \|p(t)\|_{H^{k-1}/\mathbb{R}} \le M_k \tau(t)^{1-k/2} \tag{2.3}$$

and for $k \ge 3$

$$\int_0^t \sigma_{k-3}(s)\big(\,\|u(s)\|_k^2 + \|u_s(s)\|_{k-2}^2 + \|p(s)\|_{H^{k-1}/\mathbb{R}}^2 + \|p_s(s)\|_{H^{k-3}/\mathbb{R}}^2\big)\,ds \le K_k^2, \tag{2.4}$$

where $\tau(t) = \min(t,1)$ and $\sigma_n = e^{-\alpha(t-s)}\tau^n(s)$ for some $\alpha > 0$. Observe that, for $t \le T < \infty$, we can take $\tau(t) = t$ and $\sigma_n(s) = s^n$. For simplicity, we will take these values of τ and σ_n. We note that no further than $k \le 6$ will be needed in the present paper.

Let $\mathcal{T}_h = (\tau_i^h, \phi_i^h)_{i\in I_h}$, $h > 0$, be a family of partitions of suitable domains Ω_h, where h is the maximum diameter of the elements $\tau_i^h \in \mathcal{T}_h$ and ϕ_i^h are the mappings of the reference simplex τ_0 onto τ_i^h. We restrict ourselves to quasi-uniform and regular meshes $\mathcal{T}_h$.

Let $r \ge 3$, and we consider the finite-element spaces

$$S_{h,r} = \big\{\chi_h \in \mathcal{C}(\overline{\Omega}_h)\,|\,\chi_h|_{\tau_i^h}\circ\phi_i^h \in P^{r-1}(\tau_0)\big\} \subset H^1(\Omega_h),$$

$$S_{h,r}^0 = \big\{\chi_h \in \mathcal{C}(\overline{\Omega}_h)\,|\,\chi_h|_{\tau_i^h}\circ\phi_i^h \in P^{r-1}(\tau_0),\ \chi_h(x) = 0\ \forall\, x \in \partial\Omega_h\big\} \subset H_0^1(\Omega_h),$$

where $P^{r-1}(\tau_0)$ denotes the space of polynomials of degree at most $r-1$ on τ_0. Since we are assuming that the meshes are quasi-uniform, the following inverse inequality holds for each $v_h \in (S^0_{h,r})^d$ (see, e.g., [9, Theorem 3.2.6])

$$\|v_h\|_{W^{m,q}(\tau)^d} \leq Ch^{l-m-d(\frac{1}{q'}-\frac{1}{q})}\|v_h\|_{W^{l,q'}(\tau)^d}, \tag{2.5}$$

where $0 \leq l \leq m \leq 1$, $1 \leq q' \leq q \leq \infty$, and τ is an element in the partition $\mathcal{T}_h$.

We shall denote by $(X_{h,r}, Q_{h,r-1})$ the so-called Hood–Taylor element, where

$$X_{h,r} = \left(S^0_{h,r}\right)^d, \quad Q_{h,r-1} = S_{h,r-1} \cap L^2(\Omega_h)/\mathbb{R}, \qquad r \geq 3.$$

For this mixed element a uniform inf-sup condition is satisfied (see [8]); that is, there exists a constant $\beta > 0$ independent of the mesh grid size h such that

$$\inf_{q_h \in Q_{h,r-1}} \sup_{v_h \in X_{h,r}} \frac{(q_h, \nabla \cdot v_h)}{\|v_h\|_1 \|q_h\|_{L^2/\mathbb{R}}} \geq \beta. \tag{2.6}$$

The approximate velocity belongs to the discretely divergence-free space

$$V_{h,r} = X_{h,r} \cap \left\{ \chi_h \in H^1_0(\Omega_h) \mid (q_h, \nabla \cdot \chi_h) = 0 \quad \forall q_h \in Q_{h,r-1} \right\}.$$

We observe that, for the Hood–Taylor element, $V_{h,r}$ is not a subspace of V.

Let $\Pi_h : L^2(\Omega)^d \longrightarrow V_{h,r}$ be the discrete Leray's projection defined by

$$(\Pi_h u, \chi_h) = (u, \chi_h) \quad \forall \chi_h \in V_{h,r}.$$

We will use the following well known bounds

$$\|(I - \Pi_h)u\|_j \leq Ch^{l-j} \|u\|_l, \qquad 1 \leq l \leq r, \quad j = 0, 1, \tag{2.7}$$

and, also, since we are assuming that Ω is at least $\mathcal{C}^2$.

$$\left\|A^{-m/2}\Pi(I - \Pi_h)u\right\|_0 \leq Ch^{l+\min(m,r-2)} \|u\|_l, \qquad 1 \leq l \leq r, \quad m = 1, 2, \tag{2.8}$$

We will denote by $A_h : V_{h,r} \to V_{h,r}$ the discrete Stokes operator defined by

$$(\nabla v_h, \nabla \phi_h) = (A_h v_h, \phi_h) = \left(A_h^{1/2} v_h, A_h^{1/2} \phi_h\right) \qquad \forall v_h, \phi_h \in V_{h,r}.$$

Let $\mathcal{A}$ denote either $\mathcal{A} = A$ or $\mathcal{A} = A_h$. Notice that both are positive self-adjoint operators with compact resolvent in H and V_h, respectively. Let us consider then for $\alpha \in \mathbb{R}$ and $t > 0$ the operators $\mathcal{A}^\alpha$ and $e^{-t\mathcal{A}}$, which are easily defined by means of the spectral properties of $\mathcal{A}$ (see, e.g., [10, p. 33], [24]). An easy calculation shows that

$$\|\mathcal{A}^\alpha e^{-t\mathcal{A}}\|_0 \leq (\alpha e^{-1})^\alpha t^{-\alpha}, \qquad \alpha \geq 0, \ t > 0, \tag{2.9}$$

where, here and in what follows, $\|\cdot\|_0$ when applied to an operator denotes the associated operator norm. Also, using the change of variables $\tau = s/t$, it is easy to show that

$$\int_0^t s^{-1/2} \left\|A_h^{1/2} e^{-(t-s)A_h}\right\|_0 ds \leq \frac{1}{\sqrt{2e}} B\left(\frac{1}{2}, \frac{1}{2}\right), \tag{2.10}$$

where B is the Beta function (see, e.g., [12]).

Let $(u,p) \in (H^2(\Omega)^d \cap V) \times (H^1(\Omega)/\mathbb{R})$ be the solution of a Stokes problem with right-hand side g, and we will denote by $S_h(u) \in V_{h,r}$ the so-called Stokes projection defined by (see [37])

$$(\nabla S_h(u), \nabla \chi_h) = (\nabla u, \nabla \chi_h) - (p, \nabla \cdot \chi_h) = (g, \chi_h) \quad \forall \chi_h \in V_{h,r}.$$

We will also consider the above definition of $S_h(u)$ written in mixed form: Find $(s_h, q_h) \in (X_h, Q_h)$ such that

$$(\nabla s_h, \nabla \phi_h) + (\nabla q_h, \phi_h) = (g, \phi_h) \quad \forall \phi_h \in X_h, \tag{2.11}$$

$$(\nabla \cdot s_h, \psi_h) = 0 \quad \forall \psi_h \in Q_h. \tag{2.12}$$

Obviously, $s_h = S_h(u)$. The following bound holds for $2 \le l \le r$:

$$\|u - s_h\|_0 + h\|u - s_h\|_1 \le Ch^l \left(\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}} \right). \tag{2.13}$$

The proof of (2.13) for $\Omega = \Omega_h$ can be found in [37]. For the general case superparametric approximation at the boundary is assumed [5]. Under the same conditions, the bound for the pressure is [29]

$$\|p - q_h\|_{L^2/\mathbb{R}} \le C_\beta h^{l-1} \left(\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}} \right), \tag{2.14}$$

where the constant C_β depends on the constant β in the inf-sup condition (2.6).

We will assume that the domain Ω is of class $\mathcal{C}^r$, so that standard bounds for the Stokes problem [5], [25] imply that

$$\left\| A^{-1} \Pi g \right\|_{2+j} \le \|g\|_j, \qquad -1 \le j \le r-2. \tag{2.15}$$

Then, using standard duality arguments and (2.13), it is easy to show that

$$\|u - s_h\|_{-m} \le Ch^{l+\min(m, r-2)} (\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}}), \quad m = 1, 2. \tag{2.16}$$

In what follows we will apply the above estimates to the particular case in which (u,p) is the solution of the Navier–Stokes problem (1.1)–(1.2). In that case s_h is the discrete velocity in problem (2.11)–(2.12) with $g = f - u_t - (u \cdot \nabla u)$. Note that the temporal variable t appears here merely as a parameter, and then, taking the time derivative, the error bounds (2.13), (2.16) can also be applied to the time derivative of s_h changing u, p by u_t, p_t.

Since we are assuming that Ω is of class $\mathcal{C}^r$ and $r \ge 3$, from (2.13) and standard bounds for the Stokes problem [5], [25], we deduce that

$$\|(A^{-1}\Pi - A_h^{-1}\Pi_h) f\|_j \le Ch^{2-j} \|f\|_0 \quad \forall f \in L^2(\Omega)^d, \quad j = 0, 1, \tag{2.17}$$

$$\|(A^{-1}\Pi - A_h^{-1}\Pi_h) f\|_1 \le Ch^2 \|f\|_1 \quad \forall f \in H^1(\Omega)^d. \tag{2.18}$$

In our analysis we shall frequently use the following relations for $f \in L^2(\Omega)^d$:

$$\|A_h^{-s/2} \Pi_h f\|_0 \le Ch^s \|f\|_0 + \|A^{-s/2} \Pi f\|_0, \quad s = 1, 2, \tag{2.19}$$

$$\|A^{-s/2} \Pi f\|_0 \le Ch^s \|f\|_0 + \|A_h^{-s/2} \Pi_h f\|_0, \quad s = 1, 2, \tag{2.20}$$

which are a consequence of (2.17) and the fact that for $v \in V$ and $v_h \in V_{h,r}$ we have $\|\nabla v\|_0 = \|A^{1/2}v\|_0$ and $\|\nabla v_h\|_0 = \|A_h^{1/2}v_h\|_0$. Notice also that, since $(A_h^{-1/2}\Pi_h f, v_h) = (f, A_h^{-1/2}v_h)$, for all $v_h \in V_{h,r}$, it follows that

$$\|A_h^{-1/2}\Pi_h f\|_0 \le C\|f\|_{-1}. \tag{2.21}$$

Finally, we will use the following inequality whose proof can be obtained by applying [36, Lemma 4.4]:

$$\|v_h\|_\infty \le C\,\|A_h v_h\|_0 \quad \forall v_h \in V_{h,r}. \tag{2.22}$$

Remark 2.1. We remark that our analysis applies also to any pair of LBB-stable mixed finite elements satisfying (2.7), (2.13), and especially (2.16). This is the case, for example, of the Crouzeix–Raviart element when $r \ge 3$ [11], [29]. In the case of low-order LBB-stable elements, the analysis is much simpler; see Remark 4.2 below. However, since to simplify the analysis we make use of several results from [6] which are stated and proved for Hood–Taylor elements, we will restrict ourselves to these elements in the present paper.

3. The postprocessed method. The postprocessing technique can be seen as a two-level method. In the first level, the mixed finite-element approximation to (1.1)–(1.2) for a given partition $\mathcal{T}_h$ of Ω_h is computed. That is, given $u_h(0) = \Pi_h(u_0)$, we compute $u_h(t) \in X_{h,r}$ and $p_h(t) \in Q_{h,r-1}$, $t \in (0,T]$, satisfying

$$(\dot u_h, \phi_h) + (\nabla u_h, \nabla \phi_h) + b(u_h, u_h, \phi_h) + (\nabla p_h, \phi_h) = (f, \phi_h) \quad \forall\, \phi_h \in X_{h,r}, \tag{3.1}$$

$$(\nabla \cdot u_h, \psi_h) = 0 \qquad \forall\, \psi_h \in Q_{h,r-1}. \tag{3.2}$$

In the second level, the discrete velocity and pressure $(u_h(t), p_h(t))$ are postprocessed by solving the following discrete Stokes problem: Find $(\tilde u_h(t), \tilde p_h(t)) \in (\widetilde X, \widetilde Q)$ satisfying

$$\big(\nabla \tilde u_h(t), \nabla \tilde\phi\big) + \big(\nabla \tilde p_h(t), \tilde\phi\big) = (f, \tilde\phi) - b(u_h(t), u_h(t), \tilde\phi) - (\dot u_h(t), \tilde\phi) \quad \forall\, \tilde\phi \in \widetilde X, \tag{3.3}$$

$$\big(\nabla \cdot \tilde u_h(t), \tilde\psi\big) = 0 \quad \forall\, \tilde\psi \in \widetilde Q, \tag{3.4}$$

where $(\widetilde X, \widetilde Q)$, is either

(a) the same-order Hood–Taylor element over a finer grid (that is, for $h' < h$, we choose $(\widetilde X, \widetilde Q) = (X_{h',r}, Q_{h',r-1})$), or

(b) a higher-order Hood–Taylor element over the same grid. In this case we choose $(\widetilde X, \widetilde Q) = (X_{h,r+1}, Q_{h,r})$.

In both cases, we will denote by $\widetilde V$ the corresponding discretely divergence-free space that can be either $\widetilde V = V_{h',r}$ or $\widetilde V = V_{h,r+1}$ depending on the selection of the postprocessing space. The discrete orthogonal projection into $\widetilde V$ will be denoted by $\widetilde\Pi_h$, and we will represent by $\widetilde A_h$ the discrete Stokes operator acting on functions in $\widetilde V$.

We remark that in (3.3)–(3.4) the time variable appears merely as a parameter. Thus, in practice, $(\tilde u_h, \tilde p_h)$ may be computed only for those $t \in (0,T]$ where improved accuracy is desired, which are usually a small set of selected times. Nevertheless, here we obtain error estimates for $t \in (0,T]$ since this adds no further difficulty.

Section 5 is devoted to the analysis of convergence of the postprocessed MFE method. In Theorems 5.2 and 5.3 the rate of convergence of the postprocessed method

is obtained. We notice that the order of approximation is optimal with respect to the pair $(\widetilde{X}, \widetilde{Q})$ in which the standard MFE approximation is postprocessed. Comparing with the (optimal) rate of convergence of the MFE method (see Corollaries 4.8, 4.16, and 4.19), we deduce that in case b an increase in the rate of convergence of one unit is achieved. Similar conclusions can be reached in case a by taking h' small enough.

The analysis of the postprocessed method will be done in two steps. We will first obtain superconvergence bounds for the MFE approximation in Theorems 4.7, 4.15, and 4.18 with respect to an auxiliary approximation to be introduced in section 4.1. In Theorems 4.7 and 4.15 we deal with the velocity, for the quadratic and cubic approximations, respectively, and with the pressure in Theorem 4.18. In the second step, the errors bounds of the postprocessed approximation are given in Theorem 5.2 for the velocity and in Theorem 5.3 for the pressure.

4. Analysis of the MFE approximation.

4.1. An auxiliary approximation. For a u and p solution of (1.1)–(1.2) let us consider the approximations $v_h : [0,T] \longrightarrow X_{h,r}$ and $g_h : [0,T] \longrightarrow Q_{h,r-1}$, respectively, solutions of

$$(\dot{v}_h, \phi_h) + (\nabla v_h, \nabla \phi_h) + (\nabla g_h, \phi_h) = (f, \phi_h) - b(u, u, \phi_h) \quad \forall \phi_h \in X_{h,r}, \tag{4.1}$$

$$(\nabla \cdot v_h, \psi_h) = 0 \qquad \forall\, \psi_h \in Q_{h,r-1}, \tag{4.2}$$

with initial condition $v_h(0) = \Pi_h u_0$.

Let us observe that the MFE approximation u_h and the recently defined v_h satisfy

$$\dot{u}_h + A_h u_h + B_h(u_h, u_h) = \Pi_h f, \qquad u_h(0) = \Pi_h u_0, \tag{4.3}$$

$$\dot{v}_h + A_h v_h + B_h(u, u) = \Pi_h f, \qquad v_h(0) = \Pi_h u_0, \tag{4.4}$$

respectively, where $B_h(u,v) = \Pi_h F(u,v)$. Then $e_h = v_h - u_h$ satisfies

$$\dot{e}_h + A_h e_h = B_h(u_h, u_h) - B_h(u, u), \qquad e_h(0). \tag{4.5}$$

We will also use the following notation:

$$z_h = \Pi_h u - v_h, \qquad \theta_h = \Pi_h u - s_h.$$

It is easy to show then that

$$\dot{z}_h + A_h z_h = A_h \theta_h, \quad z_h(0) = 0. \tag{4.6}$$

Some technical lemmas are stated in this section. For the convenience of the reader, we will reproduce here the following two lemmas from [6].

LEMMA 4.1. *Let $v \in (H^2(\Omega))^d \cap V$. Then there exists a constant $K = K(\|v\|_2)$ such that for all $w \in H_0^1(\Omega)^d$ we have that*

$$\left\|A^{-1}\Pi[F(v,v) - F(w,w)]\right\|_0 \leq K\big(\|v-w\|_{-1} + \|v-w\|_1 \|v-w\|_0\big). \tag{4.7}$$

LEMMA 4.2. *For any $f \in C([0,T]; L^2(\Omega)^d)$, the following estimate holds for all $t \in [0,T]$:*

$$\int_0^t \left\|A_h e^{-(t-s)A_h} \Pi_h f(s)\right\|_0 ds \leq C|\log(h)| \max_{0\leq t\leq T} \|f(t)\|_0.$$

LEMMA 4.3 (estimates for z_h). *Let (u,p) be the solution of (1.1)–(1.2). Then there exists a positive constant C such that the error $z_h = \Pi_h u - v_h$ of the discrete velocity v_h defined by (4.4) satisfies the following bounds:*

$$\|A_h^{-j/2} z_h\|_0 \le Ch^{2+j}, \qquad j = 0,1,2, \qquad r \ge 3, \tag{4.8}$$

$$\|A_h^{(-1+j)/2} z_h\|_0 \le \frac{C}{t^{1/2}} h^{4-j}, \qquad j = -1,0,1, \qquad r \ge 4, \tag{4.9}$$

$$\|A_h^{(-1+j)/2} z_h\|_0 \le \frac{C}{t^{1/2}} h^{4-j}, \qquad j = 0,1,2, \qquad r \ge 3, \tag{4.10}$$

$$\|A_h^{(-1+j)/2} z_h\|_0 \le \frac{C}{t} h^{5-j}, \qquad j = 0,1,2, \qquad r \ge 4, \tag{4.11}$$

$$\int_0^t \|z_h(s)\|_j^2 \, ds \le Ch^{6-2j}, \qquad j = 0,1, \qquad r \ge 3. \tag{4.12}$$

Proof. From (4.6) it follows that

$$z_h(t) = \int_0^t e^{-A_h(t-s)} A_h \theta_h(s) \, ds. \tag{4.13}$$

If we multiply both sides of this equation by A_h^{-1}, then using (2.10), (2.8), and (2.16) we have

$$\|A_h^{-1} z_h\|_0 \le CB\left(\frac{1}{2}, \frac{1}{2}\right) \max_{0\le s\le t} s^{1/2} \|A_h^{-1/2}\theta_h(s)\|_0 \le Ch^4 \max_{0\le s\le t} s^{1/2} \|u(s)\|_3,$$

which, applying estimates (2.3), proves (4.8) for the case $j = 2$. Since $\|A_h^{-1/2} z_h\|_0 \le Ch^{-1}\|A_h^{-1} z_h\|_0$ and $\|z_h\|_0 \le Ch^{-2}\|A_h^{-1} z_h\|_0$, the cases $j = 1$ and $j = 0$ are readily deduced, and then (4.8) is concluded.

We will now prove (4.9). Multiplying (4.6) by $t^{1/2} A_h^{-1/2}$, it is easy to see that $y_h = t^{1/2} A_h^{-1/2} z_h$ satisfies

$$\dot{y}_h + A_h y_h = t^{1/2} A_h^{1/2} \theta_h + (2t)^{-1/2} A_h^{-1/2} z_h,$$

so that we have

$$y_h(t) = \int_0^t e^{-A_h(t-s)} s^{1/2} A_h^{1/2} \theta_h(s) \, ds + \frac{1}{2} \int_0^t e^{-A_h(t-s)} s^{-1/2} A_h^{-1/2} z_h \, ds. \tag{4.14}$$

Then, using (2.10), (2.8), and (2.16), it follows that

$$\begin{aligned} t^{1/2}\|A_h^{-1} z_h\|_0 &\le CB\left(\frac{1}{2}, \frac{1}{2}\right)\left(\max_{0\le s\le t} s\|A_h^{-1/2}\theta_h\|_0 + \max_{0\le s\le t} \|A_h^{-3/2} z_h\|_0\right) \\ &\le C\left(M_4 h^5 + \max_{0\le s\le t} \|A_h^{-3/2} z_h\|_0\right). \end{aligned}$$

In order to estimate the last term on the right-hand side above, we multiple both sides of (4.13) by $A_h^{-3/2}$, so that using (2.10), (2.8), and (2.16) we obtain

$$\|A_h^{-3/2} z_h\|_0 \le CB\left(\frac{1}{2}, \frac{1}{2}\right) \max_{0\le s\le t} s^{1/2} \|A_h^{-1}\theta_h(s)\|_0 \le Ch^5 M_3,$$

and then (4.9) is proved in the case $j=-1$, from which, using the same arguments as with (4.8), the cases $j=0,1$ are inferred.

We will now prove (4.10) and (4.11) for the case $j=0$. As before, the cases $j=1$ and $j=2$ follow immediately. For $y_h(t)=tA_h^{-1/2}z_h(t)$, it is easy to see that

$$y_h(t)=\int_0^t e^{-A_h(t-s)}sA_h^{1/2}\theta_h(s)\,ds+\int_0^t e^{-A_h(t-s)}A_h^{-1/2}z_h(s)\,ds,$$

so that, integrating by parts, we have

$$\begin{aligned}y_h(t)&=tA_h^{-1/2}\theta_h(t)-\int_0^t e^{-A_h(t-s)}A_h^{-1/2}\big(\theta_h(s)+s\dot\theta_h(s)\big)\,ds\\&\quad+\int_0^t e^{-A_h(t-s)}A_h^{-1/2}z_h(s)\,ds.\end{aligned}\tag{4.15}$$

We deal first with (4.10). For the last term on the right-hand side above, by writing $e^{-A_h(t-s)}A_h^{-1/2}z_h(s)=A_h^{1/2}e^{-A_h(t-s)}A_h^{-1}z_h(s)$, then, thanks to (2.9) and (4.8), it follows that

$$\left\|\int_0^t e^{-A_h(t-s)}A_h^{-1/2}z_h(s)\,ds\right\|_0\le Ct^{1/2}\max_{0\le s\le t}\|A_h^{-1}z_h(s)\|_0\le Ct^{1/2}h^4.\tag{4.16}$$

For the second term on the right-hand side of (4.15), we start by writing $e^{-A_h(t-s)}=e^{-A_h(t-s)}s^{-1/2}s^{1/2}$, and then, since, trivially, $\|s^{-1/2}e^{-A_h(t-s)}\|_0\le s^{-1/2}$, we have

$$\begin{aligned}&\left\|\int_0^t e^{-A_h(t-s)}A_h^{-1/2}(\theta_h(s)+s\dot\theta_h(s))\,ds\right\|_0\\&\quad\le 2t^{1/2}\max_{0\le s\le t}s^{1/2}\big(\|A_h^{-1/2}(\theta_h(s)+s\dot\theta_h(s))\|_0\big)\\&\quad\le Ct^{1/2}h^4\max_{0\le s\le t}s^{1/2}\big(\|u(s)\|_3+s\,\|u_s(s)\|_3\big)\le Ct^{1/2}h^4(M_3+M_5),\end{aligned}\tag{4.17}$$

where in the last inequality we have applied (2.8) and (2.16). The same argument shows that the first term on the right-hand side of (4.15) can be bounded by $Ct^{1/2}h^4M_3$, which together with (4.16) and (4.17) finishes the proof of (4.10).

In order to prove (4.11), we go back to (4.15). Using (2.10) to estimate both integrals on the right-hand side of (4.15), we may write

$$\begin{aligned}\|y_h(t)\|_0&\le t\big\|A_h^{-1/2}\theta_h(t)\big\|_0\\&\quad+CB\left(\frac12,\frac12\right)\Big(\max_{0\le s\le t}s^{1/2}\big\|A_h^{-1}(\theta_h(s)+s\dot\theta_h(s))\big\|_0+\max_{0\le s\le t}s^{1/2}\|A_h^{-1}z_h(s)\|_0\Big),\end{aligned}$$

so that, thanks to (2.8), (2.16), and (4.9), it follows that (4.11) holds for $j=0$.

It only remains to prove (4.12) in the case $j=0$ (the case $j=1$ is deduced by applying inverse inequality (2.5)). From (4.6) we get

$$(A_h^{-1}\dot z_h,z_h)+(z_h,z_h)=(\theta_h,z_h).$$

Then

$$\frac{d}{dt}\|A_h^{-1/2}z_h\|_0^2 + \|z_h\|_0^2 \le \|\theta_h\|_0^2.$$

Finally, by integrating with respect to t and applying (2.7) and (2.13) we obtain

$$\int_0^t \|z_h(s)\|_0^2\, ds \le \int_0^t \|\theta_h(s)\|_0^2\, ds \le h^6 \int_0^t \|u(s)\|_3^2\, ds \le K_3^2 h^6,$$

which finishes the proof. ∎

4.2. Superconvergence for the velocity: $r = 3$. We need several auxiliary lemmas before proving Theorem 4.7. We start with the continuity of the nonlinear term in several different norms.

LEMMA 4.4. *For each $\alpha > 0$ there exists a constant $K > 0$ depending on α and M_2 such that, for every $w_h^1(\cdot), w_h^2(\cdot) \in V_{h,r}$ satisfying the threshold condition*

$$\|u(t) - w_h^1(t)\|_j \le \alpha h^{2-j}, \quad \|u(t) - w_h^2(t)\|_j \le \alpha h^{2-j}, \quad j = 0, 1,\ t \in [0, T], \tag{4.18}$$

the following bounds hold:

$$\|F(w_h^1, w_h^1) - F(w_h^2, w_h^2)\|_0 \le K \|w_h^1 - w_h^2\|_1, \tag{4.19}$$

$$\|F(w_h^1, w_h^1) - F(w_h^2, w_h^2))\|_{-1} \le K \|w_h^1 - w_h^2\|_0, \tag{4.20}$$

$$\|B_h(w_h^1, w_h^1) - B_h(w_h^2, w_h^2)\|_0 \le K \|w_h^1 - w_h^2\|_1, \tag{4.21}$$

$$\|A_h^{-1/2}(B_h(w_h^1, w_h^1) - B_h(w_h^2, w_h^2))\|_0 \le K \|w_h^1 - w_h^2\|_0, \tag{4.22}$$

$$\|A_h^{-1}(B_h(w_h^1, w_h^1) - B_h(w_h^2, w_h^2))\|_0 \le K\|A_h^{-1/2}(w_h^1 - w_h^2)\|_0. \tag{4.23}$$

Proof. The bounds (4.19) and (4.20) are obtained by arguing exactly as in the proof of [6, Lemma 3.1]. Using the stability of Π_h and (2.21), the proofs of (4.21) and (4.22) are easily deduced from (4.19) and (4.20).

Finally, let us prove (4.23). Let us write $w_h = w_h^1 - w_h^2$. Taking into account that

$$h^2\|w_h\|_1 \le C\|A_h^{-1/2}w_h\|_0 \tag{4.24}$$

and using (2.19) and (4.21), it follows that

$$\begin{aligned}\|A_h^{-1}(B_h(w_h^1, w_h^1) - B_h(w_h^2, w_h^2))\|_0 \le{}& \|A^{-1}\Pi(F(w_h^1, w_h^1) - F(w_h^2, w_h^2))\|_0 \\ &+ C\|A_h^{-1/2}w_h\|_0.\end{aligned} \tag{4.25}$$

We now estimate the first term on the right-hand side above by duality, since

$$\|A^{-1}\Pi(F(w_h^1, w_h^1) - F(w_h^2, w_h^2))\|_0 \le \max_{\phi\in H, \phi\neq 0} \frac{|(F(w_h^1, w_h^1) - F(w_h^2, w_h^2), A^{-1}\phi)|}{\|\phi\|_0}.$$

For this purpose, using the skew-symmetry property of b, we write

$$\begin{aligned}(F(w_h^1, w_h^1) - F(w_h^2, w_h^2), A^{-1}\phi) &= b(w_h, w_h^2, A^{-1}\phi) + b(w_h^1, w_h, A^{-1}\phi) \\ &= b(w_h, u(t), A^{-1}\phi) - b(u(t), A^{-1}\phi, w_h) \\ &\quad + b(w_h, A^{-1}\phi, u(t) - w_h^2) + b(u(t) - w_h^1, A^{-1}\phi, w_h).\end{aligned} \tag{4.26}$$

We now notice that $|b(w_h, A^{-1}\phi, u(t) - w_h^2)| \le C \|w_h\|_1 \|\phi\|_0 \|u(t) - w_h^2\|_0$, so that, thanks to (4.24) and (4.18), we have

$$\left|b(w_h, A^{-1}\phi, u(t) - w_h^2)\right| \le C \|w_h\|_1 h^2 \|\phi\|_0 \le C\left\|A_h^{-1/2} w_h\right\|_0 \|\phi\|_0 .$$

Similarly, $|b(u(t) - w_h^1, A^{-1}\phi, w_h)| \le C \|w_h\|_0 \|\phi\|_0 \|u(t) - w_h^1\|_1$. Since $h\|w_h\|_0 \le C\|A_h^{-1/2} w_h\|_0$, it follows that

$$\left|b(u(t) - w_h^1, A^{-1}\phi, w_h)\right| \le Ch \|w_h\|_0 \|\phi\|_0 \le C\left\|A_h^{-1/2} w_h\right\|_0 \|\phi\|_0 ,$$

so that from (4.26) we get

$$\begin{aligned}\left|(F(w_h^1, w_h^1) - F(w_h^2, w_h^2), A^{-1}\phi)\right| \le& \left|b(w_h, u(t), A^{-1}\phi)\right| + \left|b(u(t), A^{-1}\phi, w_h)\right| \\ &+ C\left\|A_h^{-1/2} w_h\right\|_0 \|\phi\|_0 .\end{aligned} \tag{4.27}$$

Finally, since by applying the divergence theorem we have

$$b(w_h, u(t), A^{-1}\phi) = (w_h, \nabla u(t) \cdot A^{-1}\phi) - \frac{1}{2}(w_h, \nabla(u(t) \cdot A^{-1}\phi)),$$

it follows that

$$\left|b(w_h, u(t), A^{-1}\phi)\right| \le C \|w_h\|_{-1} \left(\left\|\nabla u(t) \cdot A^{-1}\phi\right\|_1 + \left\|\nabla(A^{-1}\phi \cdot u(t))\right\|_1\right), \tag{4.28}$$

$$\left|b(u(t), A^{-1}\phi, w_h)\right| \le C \|w_h\|_{-1} \left(\left\|(u(t) \cdot \nabla)A^{-1}\phi\right\|_1 + \left\|(\nabla \cdot u(t))A^{-1}\phi\right\|_1\right). \tag{4.29}$$

Since

$$\begin{aligned}\left\|\nabla u \cdot A^{-1}\phi\right\|_1 &\le C\left(\|u\|_2 \left\|A^{-1}\phi\right\|_{L^\infty} + \|u\|_{W^{1,4}} \left\|A^{-1}\phi\right\|_{W^{1,4}}\right) \\ &\le C \|u\|_2 \left\|A^{-1}\phi\right\|_2 \le C\|u\|_2\|\phi\|_0,\end{aligned}$$

arguing similarly with the rest of the terms on the right-hand side of (4.28)–(4.29), from (4.25) and (4.27) the proof is easily finished. ∎

Remark 4.1. In what follows we will apply Lemma 4.4 to functions $w_h^1 = v_h$, satisfying (4.4), and $w_h^2 = u_h$, satisfying (4.3). Let us now check that the threshold condition (4.18) is satisfied. We first observe that $\|v_h - u\|_0 \le \|z_h\|_0 + \|u - \Pi_h u\|_0$ so that by applying (4.8) and (2.7) we get $\|v_h - u\|_0 \le Ch^2$, and then v_h satisfies (4.18). For the bound $\|u - u_h\|_0 \le Ch^2$, we refer the reader to [36, Theorem 3.1].

LEMMA 4.5. *Let (u, p) be the solution of* (1.1)–(1.2). *Then there exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *satisfies*

$$\|A_h^{-1}(B_h(v_h(t), v_h(t)) - B_h(u(t), u(t)))\|_0 \le \frac{C}{t^{(r-2)/2}} h^{r+1}, \quad t \in (0, T], \quad r = 3, 4.$$

Proof. Let us write $\rho_h = B_h(v_h, v_h) - B_h(u, u)$. By applying (2.19) we have

$$\|A_h^{-1}\rho_h\|_0 \le Ch^2 \|F(v_h, v_h) - F(u, u)\|_0 + \|A^{-1}\Pi(F(v_h, v_h) - F(u, u))\|_0.$$

Using then (4.19) from Lemmas 4.4 and 4.1 we get

$$\|A_h^{-1}\rho_h\|_0 \le Ch^2 \|v_h - u\|_1 + C(\|v_h - u\|_1 \|v_h - u\|_0 + C\|v_h - u\|_{-1}).$$

Applying now the standard bounds for Π_h (see (2.7), (2.8)) together with the estimates (4.8), (4.10) for z_h in Lemma 4.3 when $r = 3$ and (4.11), (4.8) when $r = 4$, the conclusion is reached. ∎

LEMMA 4.6. *Let (u, p) be the solution of* (1.1)–(1.2). *Then there exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *and the Hood–Taylor element approximation to u, u_h, satisfy the following bound:*

$$\|A_h^{-1/2}(v_h(t) - u_h(t))\|_0 \le Ch^4, \quad r \ge 3, \quad t \in (0, T].$$

Proof. Let us consider $y_h(t) = A_h^{-1/2} e_h(t)$ and $\rho_h = B_h(v_h, v_h) - B_h(u, u)$. From (4.5) it follows that

$$y_h(t) = \int_0^t e^{-(t-s)A_h} A_h^{-1/2} \big(B_h(u_h, u_h) - B_h(v_h, v_h)\big)\, ds + \int_0^t e^{-(t-s)A_h} A_h^{-1/2} \rho_h(s)\, ds.$$

Applying (2.9) and (4.23) we have that

$$\|y_h(t)\|_0 \le \int_0^t \frac{C}{\sqrt{t-s}} \|y_h(s)\|_0 \, ds + \left\| \int_0^t e^{-(t-s)A_h} A_h^{-1/2} \rho_h(s)\, ds \right\|_0,$$

so that a generalized Gronwall lemma [35, pp. 188–189] allows us to write

$$\max_{0 \le t \le T} \|y_h(t)\|_0 \le C \max_{0 \le t \le T} \left\| \int_0^t e^{-(t-s)A_h} A_h^{-1/2} \rho_h(s)\, ds \right\|_0.$$

Using (2.10) we obtain

$$\max_{0 \le t \le T} \|y_h(t)\|_0 \le CB\left(\frac{1}{2}, \frac{1}{2}\right) \max_{0 \le s \le T} s^{1/2} \big\| A_h^{-1} \big(B_h(v_h(s), v_h(s)) - B_h(u(s), u(s))\big) \big\|_0,$$

where, by applying Lemma 4.5 with $r = 3$, the proof is finished. ∎

THEOREM 4.7 (superconvergence for the velocity). *Let (u, p) be the solution of* (1.1)–(1.2). *There exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *and the Hood–Taylor element approximation to u, u_h, satisfy the following bound:*

$$\|v_h(t) - u_h(t)\|_j \le \frac{C}{t^{1/2}} |\log(h)| h^{4-j}, \quad t \in (0, T], \quad j = 0, 1, \quad r \ge 3. \tag{4.30}$$

Proof. We prove the error bound for the L^2 norm, from which the bound in the H^1 norm is readily obtained by applying the inverse inequality (2.5). Let us consider $y_h(t) = t^{1/2} e_h(t)$. An easy calculation shows that

$$\dot{y}_h + A_h y_h + t^{1/2}(B_h(v_h, v_h) - B_h(u_h, u_h)) = t^{1/2} \rho_h + \frac{1}{2t^{1/2}} e_h,$$

where $\rho_h = B_h(v_h, v_h) - B_h(u, u)$, and, thus,

$$y_h(t) = \int_0^t e^{-A_h(t-s)} s^{1/2} (B_h(u_h, u_h) - B_h(v_h, v_h))\, ds + \int_0^t e^{-A_h(t-s)} \left(s^{1/2} \rho_h + \frac{1}{2s^{1/2}} e_h \right) ds.$$

For the first term on the right-hand side above, using (2.9) and (4.22) we have

$$\left\| \int_0^t e^{-A_h(t-s)} s^{1/2} (B_h(u_h,u_h) - B_h(v_h,v_h))\, ds \right\|_0 \leq C \int_0^t \frac{\|y_h\|_0}{\sqrt{t-s}}\, ds,$$

so that by applying a generalized Gronwall lemma [35, pp. 188–189], it follows that

$$\max_{0\leq t\leq T} \|y_h(t)\|_0$$
$$\leq C\left(\max_{0\leq t\leq T} \left\| \int_0^t e^{-A_h(t-s)} s^{1/2} \rho_h\, ds \right\|_0 + \max_{0\leq t\leq T} \left\| \int_0^t e^{-A_h(t-s)} \frac{e_h}{s^{1/2}}\, ds \right\|_0 \right).$$

Applying now Lemma 4.2 and (2.10) we have

$$\max_{0\leq t\leq T} \|y_h(t)\|_0$$
$$\leq C|\log(h)| \max_{0\leq s\leq T} \left\| s^{1/2} A_h^{-1} \rho_h(s) \right\|_0 + CB\left(\frac{1}{2},\frac{1}{2}\right) \max_{0\leq s\leq T} \left\| A_h^{-1/2} e_h(s) \right\|_0,$$

where Lemmas 4.5 and 4.6 finish the proof. ∎

COROLLARY 4.8. *Let (u,p) be the solution of* (1.1)–(1.2). *Then, for $r \geq 3$, there exists a positive constant C such that the Hood–Taylor element approximation to u, u_h, satisfies the following bound for $j = 0, 1$:*

$$\|u_h(t) - u(t)\|_j \leq \frac{C}{t^{1/2}} h^{3-j}, \quad t \in (0,T].$$

Proof. By rewriting $u - u_h = (u - \Pi_h u) + (\Pi_h u - v_h) + (v_h - u_h)$, rewriting $u - u_h = (u - \Pi_h u) + (\Pi_h u - v_h) + (v_h - u_h)$, and applying (2.7), Lemma 4.3, and Theorem 4.7, the corollary is proved. ∎

Remark 4.2. Notice that by applying Lemma 4.2 to (4.13), for the z_h solution of (4.6), we obtain

$$\|z_h(t)\|_0 \leq C M_2 h^2 |\log(h)|. \tag{4.31}$$

With this estimate and a much simpler analysis than the previous one, it is possible to prove superconvergence results in the H^1 norm for low-order LBB-stable pairs of mixed finite-element methods, such as the so-called mini element [3]. More precisely, for the e_h solution of (4.5), the following bound holds:

$$\max_{0\leq t\leq T} \|e_h(t)\|_1 \leq C |\log(h)|^2 h^2,$$

with C depending only on M_2.

4.3. Superconvergence for the velocity: $r = 4$. As before, several auxiliary lemmas are needed before Theorem 4.15. We start with a generalized Gronwall lemma.

LEMMA 4.9. *If u is a nonnegative function, continuous in $[0,T]$ and satisfying*

$$u(t) \leq u_0 + \beta \int_0^t \left(\frac{1}{(t-s)^{1/2}} + \frac{1}{s^{1/2}} \right) u(s)\, ds, \qquad 0 \leq t < T,$$

for some $u_0 > 0$ and $\beta > 0$, then

$$u(t) \leq E_{1/2}(2\beta(\pi t)^{1/2}) u_0, \qquad 0 \leq t < T,$$

where $E_\alpha(z)$ denotes the Mittag–Leffler function (see 4.36 *below).*

Proof. Let us consider the operator

$$Eu(t) = \beta \int_0^t \left(\frac{1}{(t-s)^{1/2}} + \frac{1}{s^{1/2}} \right) u(s)\, ds, \qquad 0 \le t < T.$$

We notice that

$$u(t) \le u_0 + Eu(t) \le u_0 + Eu_0 + E^2 u(t) \le (1 + E + \cdots + E^n)u_0 + E^{n+1}u(t). \tag{4.32}$$

We have that

$$Eu_0 = 4\beta t^{1/2} u_0 = (2 + B(1/2, 1))(\beta t^{1/2})u_0,$$

where $B(x, y)$ denotes the Beta function (see, e.g., [12]). We also notice that

$$\begin{aligned} E^2 u_0 &= 4\beta^2 u_0 \int_0^t \left(\frac{1}{(t-s)^{1/2}} + \frac{1}{s^{1/2}} \right) s^{1/2}\, ds \\ &= 4\beta^2 u_0 \left(t + \int_0^t \frac{s^{1/2}}{(t-s)^{1/2}}\, ds \right). \end{aligned}$$

Now taking into account that, by means of the change of variables, $s = tx$ we have

$$\int_0^t \frac{s^{1/2}}{(t-s)^{1/2}}\, ds = t \int_0^1 \frac{x^{1/2}}{(1-x)^{1/2}}\, dx = tB(1/2, 3/2),$$

and, thus,

$$E^2 u_0 = 4(1 + B(1/2, 3/2))\left(\beta t^{1/2}\right)^2 u_0 = \left(\prod_{l=1}^{2} \left(\frac{2}{l} + B\left(\frac{1}{2}, \frac{l+1}{2} \right) \right) \right) \left(\beta t^{1/2}\right)^2 u_0.$$

Assume that for $j = 2, \ldots, n$

$$E^j u_0 = \left(\prod_{l=1}^{j} \left(\frac{2}{l} + B\left(\frac{1}{2}, \frac{l+1}{2} \right) \right) \right) (\beta t^{1/2})^j, \tag{4.33}$$

Let us compute $E^{n+1}u_0$. Since $E^{n+1}u_0 = EE^n u_0$, we have

$$E^{n+1}u_0 = \beta^{n+1} u_0 \left(\prod_{l=1}^{n} \left(\frac{2}{l} + B\left(\frac{1}{2}, \frac{l+1}{2} \right) \right) \right) \int_0^t \left(\frac{1}{(t-s)^{1/2}} + \frac{1}{s^{1/2}} \right) s^{n/2}\, ds.$$

But

$$\int_0^t \left(\frac{s^{n/2}}{(t-s)^{1/2}} + s^{(n-1)/2} \right) ds = \frac{2}{n+1} t^{(n+1)/2} + \int_0^t \frac{s^{n/2}}{(t-s)^{1/2}}\, ds,$$

and, using again the change of variables $s = tx$,

$$\int_0^t \frac{s^{n/2}}{(t-s)^{1/2}}\, ds = t^{(n+1)/2} \int_0^1 \frac{x^{n/2}}{(1-x)^{1/2}}\, ds = t^{(n+1)/2} B\left(\frac{1}{2}, \frac{n}{2} + 1 \right),$$

and since $\frac{n}{2} + 1 = \frac{(n+1)+1}{2}$, it follows that (4.33) also holds for $j = n + 1$.

Since, on the one hand

$$B\left(\frac{1}{2},\frac{n+1}{2}\right)=\Gamma\left(\frac{1}{2}\right)\frac{\Gamma(\frac{n}{2}+\frac{1}{2})}{\Gamma(\frac{n}{2}+1)}, \tag{4.34}$$

where $\Gamma(z)$ denotes the Gamma function, and on the other hand (see, e.g., [12, 6.1.47])

$$1=\lim_{z\to\infty} z^{1/2}\frac{\Gamma(z)}{\Gamma(z+1/2)},$$

we have that

$$E^{n+1}u(t)\le E^{n+1}\left\|u\right\|_{L^\infty(0,T)}\to 0 \qquad \text{as } n\to\infty.$$

Thus, from (4.32) and (4.33) it follows that

$$u(t)\le u_0\sum_{n=0}^{\infty} c_n\big(\beta t^{1/2}\big)^n, \qquad 0\le t\le T, \tag{4.35}$$

where

$$c_0=1, \qquad \frac{c_n}{c_{n-1}}=\frac{2}{n}+B\left(\frac{1}{2},\frac{n+1}{2}\right), \quad n=1,3,\dots .$$

Furthermore, on the one hand, for $n=1$ we have $2/n=B(\frac{1}{2},\frac{n+1}{2})=2$, and, on the other hand, since for $x\in(0,1)$ we have $1/\sqrt{x(1-x)}\ge 2$, it follows that, for $n\ge 2$,

$$B\left(\frac{1}{2},\frac{n+1}{2}\right)=\int_0^1\frac{x^{(n-1)/2}}{\sqrt{1-x}}\,dx=\int_0^1\frac{x^{n/2}}{\sqrt{x(1-x)}}\,dx\ge 2\int_0^1 x^{n/2}\,dx=\frac{4}{n+2}\ge\frac{2}{n},$$

so that by $c_n/c_{n-1}\le 2B(\frac{1}{2},\frac{n+1}{2})$ for $n=1,2,\dots$. Thus, if we set $k_0=2\Gamma(1/2)=2\sqrt{\pi}$, then in view of (4.34) we have $c_n\le k_0\Gamma(\frac{n}{2}+\frac{1}{2})\Gamma(\frac{n}{2}+1)^{-1}c_{n-1}$, that is,

$$c_n\le k_0\frac{\Gamma(\frac{n}{2}+\frac{1}{2})}{\Gamma(\frac{n}{2}+1)}c_{n-1}\le k_0^2\frac{\Gamma(\frac{n}{2}+\frac{1}{2})}{\Gamma(\frac{n}{2}+1)}\frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n}{2}+\frac{1}{2})}c_{n-2}=k_0^2\frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n}{2}+1)}c_{n-2},$$

so that by iterating this process we have

$$c_n\le\frac{k_0^n}{\Gamma(\frac{n}{2}+1)}c_0, \qquad n=1,2,\dots .$$

Then from (4.35) it follows that

$$u(t)\le u_0\sum_{n=0}^{\infty}\frac{\big(\beta k_0 t^{1/2}\big)^n}{\Gamma(\frac{n}{2}+1)}=E_{1/2}(\beta k_0 t^{1/2})u_0,$$

where $E_\alpha(z)$ is the Mittag–Leffler function

$$E_\alpha(z)=\sum_{n=0}^{\infty}\frac{z^n}{\Gamma(n\alpha+1)}. \tag{4.36}$$ □

LEMMA 4.10. *Let $v,w\in H_0^1(\Omega)\cap H^3(\Omega)$, and let $g\in H_0^1(\Omega)$, satisfying*

$$(\nabla\cdot\ g,\chi_h)=0, \qquad \forall\chi_h\in Q_{h,r-1}, \quad r\ge 4. \tag{4.37}$$

Then there exists a positive constant C such that the following bounds hold:

$$|b(v,w,g)| \le C\big(\|A^{-1}\Pi g\|_0 + h^2\|g\|_0\big)\big(\|(v\cdot\nabla)w\|_2 + \|(\nabla\cdot v)w\|_2\big), \tag{4.38}$$

$$|b(g,w,v)| \le C\big(\|A^{-1}\Pi g\|_0 + h^2\|g\|_0\big)\|\nabla w\cdot v\|_2 + Ch^2\|g\|_0\|\nabla v\cdot w\|_2. \tag{4.39}$$

Proof. We will first prove the following result whose proof is similar to that of Lemma 3.11 in [6]. Let $v \in H_0^1(\Omega)^d$, satisfying $(\nabla\cdot v,\chi_h) = 0$ for all $\chi_h \in Q_{h,r-1}$. Then for $f \in H_0^1(\Omega)^d \cap H^s(\Omega)^d$ the following bound holds:

$$|(v,f)| \le \big(\|A^{-s/2}\Pi v\|_0 + Ch^s\|v\|_0\big)\|f\|_s, \qquad s = 1,2. \tag{4.40}$$

To prove (4.40) we decompose

$$f = \Pi f + (I-\Pi)f = \Pi f + \nabla q$$

for some $q \in H^{s+1}$. Since Leray's projector Π is continuous from $H_0^1(\Omega)\cap H^s(\Omega)$ onto H^s, we have

$$\|\Pi f\|_s \le C\|f\|_s, \qquad \|q\|_{H^{s+1}/\mathbb{R}} \le C\|f\|_s \tag{4.41}$$

for some positive constant C. Thus,

$$(v,f) = (v,\Pi f) + (v,\nabla q) = (A^{-s/2}\Pi v, A^{s/2}\Pi f) + (v,\nabla q). \tag{4.42}$$

Since, for any $\chi_h \in Q_{h,r-1}$, $|(v,\nabla q)| = |(v,\nabla(q-\chi_h))|$, by taking χ_h as the interpolant of q in $Q_{h,r-1}$, from (4.41) and (4.42) it follows that

$$|(v,f)| \le Ch^s\|v\|\|f\|_s + \big|(A^{-s/2}\Pi v, A^{s/2}\Pi f)\big|.$$

Finally, since $\|A^{s/2}\Pi f\|_0 \le C\|\Pi f\|_s \le C'\|f\|_s$, (4.40) follows.

Notice now that (4.38) is a direct consequence of (4.40). For the second bound, the same argument shows that $((g\cdot\nabla)w,v)) = (g,\nabla w\cdot v)$ can be bounded by the first term on the right-hand side of (4.39). Now by using the divergence theorem and (4.37) we have

$$\big((\nabla\cdot g)w,v\big) = -\big(g,\nabla(w\cdot v)\big) = -\big(g,\nabla(w\cdot v-\chi_h)\big) \qquad \forall\chi_h \in Q_{h,r-1}.$$

Taking χ_h as the interpolant of $(w\cdot v)$ in $Q_{h,r-1}$ and taking into account that $\nabla(w\cdot v) = \nabla w\cdot v + \nabla v\cdot w$, the proof is easily concluded. ∎

LEMMA 4.11. *There exists a positive constant C such that for any $\phi_h \in V_{h,r}$ the following bound holds for $\psi_h(t) = e^{-tA_h}A_h^{-1}\phi_h$ and $\Psi(t) = e^{-tA}A^{-1}\Pi\phi_h$:*

$$\|\Psi(t) - \psi_h(t)\|_1 \le \frac{Ch^2}{t^{1/2}}\|\phi_h\|_0, \quad t > 0. \tag{4.43}$$

Proof. Let us first observe that, since $\Psi_t = -A\Psi$, then, thanks to (2.9) and (2.15), for $t > 0$ we have

$$\|\Psi(t)\|_{2+j} \le C\|\Psi_t(t)\|_j \le Ct^{-j/2}\|\phi_h\|_0, \qquad j = 0,1, \tag{4.44}$$

$$\|\Psi_{tt}(t)\|_0 \le Ct^{-1}\|\phi_h\|_0. \tag{4.45}$$

We set $\varphi_h(t) = e^{-tA_h}\Pi_h A^{-1}\Pi\phi_h$. We decompose $\psi_h - \Psi = (\psi_h - \varphi_h) + (\varphi_h - \Psi)$, and we will bound the two terms on the right-hand side separately. For the first one, taking into account that $\psi_h(t)-\varphi_h(t) = e^{-tA_h}\Pi_h(A_h^{-1}\Pi_h - A^{-1}\Pi)\phi_h$, and using (2.9) and (2.17), we have

$$\|\psi_h(t) - \varphi_h(t)\|_1 \le \frac{C}{t^{1/2}}\left\|(A_h^{-1}\Pi_h - A^{-1}\Pi)\phi_h\right\|_0 \le \frac{Ch^2}{t^{1/2}}\|\phi_h\|_0.$$

In order to bound $\varphi_h - \Psi$, we write $\varphi_h - \Psi = \varphi_h - \Pi_h\Psi + (I-\Pi_h)\Psi$, so that, in view of (2.7) and (4.44) we only have to estimate $\varphi_h - \Pi_h\Psi$. For this purpose, on the one hand, we have $\dot\varphi_h + A_h\varphi_h = 0$. On other hand, since $\Psi_t = -A\Psi$, we have

$$\Pi_h\Psi_t + A_h\Pi_h\Psi = \Pi_h\Psi_t - A_h\Pi_h A^{-1}\Psi_t = A_h(A_h^{-1}\Pi_h - \Pi_h A^{-1})\Psi_t,$$

so that for $\epsilon_h = \varphi_h - \Pi_h\Psi$ and $\rho_h = (A_h^{-1}\Pi_h - \Pi_h A^{-1})\Psi_t$ we have

$$\dot\epsilon_h + A_h\epsilon_h = A_h\rho_h,$$

an equation which is similar to (4.6). Thus, arguing as in the proof of (4.8) we have

$$\|\epsilon_h(t)\|_0 \le C\max_{0\le s\le t} s^{1/2}\left\|A_h^{1/2}\rho_h(s)\right\|_0 \le Ch^2\left\|\phi_h\right\|_0, \tag{4.46}$$

where, in the last inequality, we have applied (2.7), (2.18), and the case $j=1$ in (4.44). Furthermore, since for $y_h(t) = A_h^{1/2}t^{1/2}\epsilon_h(t)$ it is easy to see that

$$y_h(t) = \int_0^t e^{-A_h(t-s)}s^{1/2}A_h^{3/2}\rho_h(s)\,ds + \frac{1}{2}\int_0^t e^{-A_h(t-s)}s^{-1/2}A_h^{1/2}\epsilon_h(s)\,ds,$$

so that by integrating by parts in the first integral above and using (2.10) we have

$$\|y_h(t)\|_0 \le t^{1/2}\|\rho_h(t)\|_1 + CB\left(\frac{1}{2},\frac{1}{2}\right)\left(\max_{0\le s\le t}\left\|\frac{1}{2}\rho_h(s) + s\dot\rho_h(s)\right\|_0 + \max_{0\le s\le t}\|\epsilon_h(s)\|_0\right).$$

The first and the last terms on the right-hand side above are already bounded in (4.46), whereas the second term, applying (2.7), (2.17), and (4.44)–(4.45), can also be bounded by $Ch^2\|\phi_h\|_0$, which completes the proof. ∎

LEMMA 4.12. *Let (u,p) be the solution of (1.1)–(1.2). There exists a constant $C>0$ such that for any $g\in H_0^1(\Omega)^d$ and $\phi_h\in V_{h,r}$ the following bounds hold for $\psi_h(t) = e^{-tA_h}A_h^{-1}\phi_h$, $\Psi(t) = e^{-tA}A^{-1}\Pi\phi_h$, and $0<s<t\le T$:*

$$|b(g,u(s),\psi_h(t-s))| \le |b(g,u(s),\Psi(t-s))| + C\frac{M_2}{\sqrt{t-s}}h^2\|g\|_0\|\phi_h\|_0, \tag{4.47}$$

$$|b(u(s),\psi_h(t-s),g)| \le |b(u(s),\Psi(t-s),g)| + C\frac{M_2}{\sqrt{t-s}}h^2\|g\|_0\|\phi_h\|_0. \tag{4.48}$$

Proof. We will prove only (4.47) since (4.48) can be proved by reasoning similarly. Also, we will drop the dependence on s and $t-s$. We first observe that

$$b(g,u,\psi_h) = b(g,u,\Psi) + b(g,u,\psi_h - \Psi).$$

On the one hand, we have

$$|((g\cdot\nabla)u,\psi_h - \Psi)| \le C\|g\|_0\|\nabla u\|_{L^4(\Omega)}\|\psi_h - \Psi\|_{L^4(\Omega)},$$

so that by using (2.1) and (4.43) it follows that

$$|((g\cdot\nabla)u,\psi_h-\Psi)|\le CM_2\,\|g\|_0\,\|\psi_h-\Psi\|_1\le C\frac{M_2}{\sqrt{t-s}}h^2\,\|g\|_0\,\|\phi_h\|_0\,. \tag{4.49}$$

On the other hand, since $((\nabla\cdot g)u,\psi_h-\Psi)=-(g,\nabla(u\cdot(\psi_h-\Psi)))$, we have

$$\|((\nabla\cdot g)u,(\psi_h-\Psi))\|_0\le C\,\|g\|_0\,\big(\|\nabla u\|_{L^4}\,\|\psi_h-\Psi\|_{L^4}+\|u\|_{L^\infty}\,\|\nabla(\psi_h-\Psi)\|_0\big).$$

Applying again (2.1) and (4.43) we get

$$\|((\nabla\cdot g)u,(\psi_h-\Psi))\|_0\le CM_2\,\|g\|_0\,\|\psi_h-\Psi\|_1\le C\frac{M_2}{\sqrt{t-s}}h^2\,\|g\|_0\,\|\phi_h\|_0\,,$$

which together with (4.49) allow us to conclude (4.47). ∎

LEMMA 4.13. *Let (u,p) be the solution of (1.1)–(1.2). There exists a positive constant C such that, for $r\ge 4$ and $0<s<t\le T$, the discrete velocity v_h defined by (4.4) and the Hood–Taylor element approximation to u, u_h, satisfy the following bound:*

$$\begin{aligned}&\big\|e^{-A_h(t-s)}A_h^{-1}\big(B_h(u_h(s),u_h(s))-B_h(v_h(s),v_h(s))\big)\big\|_0\\&\qquad\le C\left(\frac{1}{\sqrt{t-s}}+\frac{1}{\sqrt{s}}\right)\big\|A_h^{-1}\big(u_h(s)-v_h(s)\big)\big\|_0.\end{aligned}\tag{4.50}$$

Proof. We write $\rho_h=B_h(u_h(s),u_h(s))-B_h(v_h(s),v_h(s))$. We will bound the norm of $e^{-A_h(t-s)}A_h^{-1}\rho_h$ by duality. As usual, we will omit the dependence on s whenever this does not cause confusion. For $\phi_h\in V_{h,r}$ we set $\psi_h=e^{-A_h(t-s)}A_h^{-1}\phi_h$, so that

$$\big\|e^{-A_h(t-s)}A_h^{-1}\rho_h\big\|_0=\max_{\phi_h\in V_{h,r}\phi_h\ne 0}\frac{\big|(\rho_h,\psi_h)\big|}{\|\phi_h\|_0}.$$

We have

$$(\rho_h,\psi_h)=-b(e_h,\psi_h,u_h)-b(v_h,\psi_h,e_h),\tag{4.51}$$

where we recall that $e_h=v_h-u_h$. For the second term on the right-hand side of (4.51) we have

$$|b(v_h,\psi_h,e_h)|\le|b(u,\psi_h,e_h)|+|b(v_h-u,\psi_h,e_h)|$$

and

$$|b(v_h-u,\psi_h,e_h)|\le\|v_h-u\|_0\,\|\nabla\psi_h\|_\infty\,\|e_h\|_0+\|\nabla\cdot(v_h-u)\|_0\,\|\psi_h\|_\infty\,\|e_h\|_0\,.$$

Applying (2.5) and (2.22) we have $\|\nabla\psi_h\|_\infty\le Ch^{-1}\,\|\psi_h\|_\infty\le Ch^{-1}\,\|\phi_h\|_0$. Also, since $(v_h-u)=z_h+(\Pi_hu-u)$, by taking into account (2.7) and Lemma 4.3 we get

$$|b(v_h,\psi_h,e_h)|\le|b(u,\psi_h,e_h)|+\frac{CM_4}{s^{1/2}}h^2\,\|e_h\|_0\,\|\phi_h\|_0\,.\tag{4.52}$$

Similarly,

$$|b(e_h,\psi_h,u_h)|\le|b(e_h,\psi_h,u)|+|b(e_h,\psi_h,u_h-u)|\,,$$

and

$$|b(e_h,\psi_h,u_h-u)| \le \left(\|e_h\|_0 \|u_h-u\|_1 + \|e_h\|_1 \|u_h-u\|_0\right) \|\psi_h\|_\infty .$$

Since by virtue of (2.5) we have $\|e_h\|_1 \le Ch^{-1}\|e_h\|_0$, by applying Corollary 4.8 we get

$$|b(e_h,\psi_h,u_h)| \le |b(e_h,\psi_h,u)| + \frac{C}{s^{1/2}} h^2 \|e_h\|_0 \|\phi_h\|_0 . \tag{4.53}$$

Thus, from (4.51), (4.52), and (4.53) and, since

$$h^2\|e_h\|_0 \le C\|A_h^{-1}e_h\|_0, \tag{4.54}$$

it follows that

$$|(\rho_h,\psi_h)| \le |b(e_h,\psi_h,u)| + |b(u,\psi_h,e_h)| + \frac{C}{\sqrt{s}} \left\|A_h^{-1}e_h\right\|_0 \|\phi_h\|_0 . \tag{4.55}$$

Next, we apply Lemma 4.12 to get

$$\begin{aligned} |(\rho_h,\psi_h)| &\le |b(e_h,\Psi(t-s),u)| + |b(u,\Psi(t-s),e_h)| \\ &\quad + \left(\frac{C}{\sqrt{t-s}} + \frac{C}{\sqrt{s}}\right) \left\|A_h^{-1}e_h\right\|_0 \|\phi\|_0 . \end{aligned} \tag{4.56}$$

Now we apply Lemma 4.10 to the first two terms on the right-hand side of (4.56), with g replaced by e_h and v by u. Let us first observe that, using (2.20) and (4.54), we have $\|A^{-1}\Pi e_h\|_0 + h^2\|e_h\|_0 \le C\|A_h^{-1}e_h\|_0$, so that in order to finish the proof we only have to bound $\|(u\cdot\nabla)\Psi\|_2$, $\|\nabla\Psi\cdot u\|_2$, and $\|\nabla u\cdot\Psi\|_2$ (recall that $(\nabla\cdot u)=0$).

Since

$$\|(u\cdot\nabla)\Psi\|_2 \le \|u\|_2 \|\nabla\Psi\|_\infty + \|u\|_{W^{1,4}} \|\Psi\|_{W^{2,4}} + \|u\|_\infty \|\Psi\|_3 ,$$

taking into account that $\|\Psi\|_3 \le Ct^{-1/2}\|\phi_h\|_0$ and applying standard Sobolev inequalities (2.1) we obtain

$$\|(u(s)\cdot\nabla)\Psi(t-s)\|_2 \le \frac{CM_2}{\sqrt{t-s}} \|\phi_h\|_0 . \tag{4.57}$$

Arguing similarly we get

$$\|\nabla\Psi(t-s)\cdot u(s)\|_2 \le \frac{CM_2}{\sqrt{t-s}} \|\phi_h\|_0 . \tag{4.58}$$

Finally, since

$$\|\nabla u\cdot\Psi\|_2 \le \|\nabla u\|_{L^4} \|\Psi\|_{W^{2,4}} + \|\nabla u\|_1 \|\Psi\|_{W^{1,\infty}} + \|\nabla u\|_2 \|\Psi\|_\infty ,$$

taking into account that $\|\Psi\|_2 \le C\|\phi_h\|_0$ and using (2.1) again, we deduce

$$\begin{aligned} \|\nabla u(s)\cdot\Psi(t-s)\|_2 &\le C\left(\frac{M_2}{\sqrt{t-s}} + \|u(s)\|_3\right) \|\phi_h\|_0 \\ &\le C\left(\frac{M_2}{\sqrt{t-s}} + \frac{M_3}{\sqrt{s}}\right) \|\phi_h\|_0 . \end{aligned} \tag{4.59}$$

Thus, inequalities (4.57), (4.58), and (4.59), together with (4.56) and Lemma 4.10, allow us to conclude the proof. ∎

LEMMA 4.14. *Let (u,p) be the solution of* (1.1)–(1.2). *There exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *and the Hood–Taylor element approximation to u, u_h, satisfy the following bound for $r \geq 4$:*

$$\|A_h^{-1}(v_h(t) - u_h(t))\|_0 \leq Ch^5, \quad t \in (0,T].$$

Proof. Let us consider $y_h(t) = A_h^{-1}e_h(t)$ and $\rho_h = B_h(v_h,v_h) - B_h(u,u)$. From (4.5) we get

$$y_h(t) = \int_0^t e^{-(t-s)A_h} A_h^{-1}\big(B_h(u_h,u_h) - B_h(v_h,v_h)\big)\,ds + \int_0^t e^{-(t-s)A_h}A_h^{-1}\rho_h(s)\,ds.$$

Thanks to Lemma 4.13 we obtain

$$\|y_h(t)\|_0 \leq C\int_0^t \left(\frac{1}{\sqrt{t-s}} + \frac{1}{\sqrt{s}}\right)\|y_h(t)\|_0 + \left\|\int_0^t e^{-(t-s)A_h}A_h^{-1}\rho_h(s)\,ds\right\|_0,$$

so that by applying Lemma 4.9, we only have to show that

$$\max_{0\leq t\leq T}\left\|\int_0^t e^{-A_h(t-s)}A_h^{-1}\rho_h(s)\,ds\right\|_0 \leq Ch^5. \tag{4.60}$$

For this purpose, we will first estimate $e^{-A_h(t-s)}A_h^{-1}\rho_h(s)$ by duality. Let us take $\phi_h \in V_{h,r}$ and set $\psi_h = e^{-A_h(t-s)}A_h^{-1}\phi_h$ and $z = u - v_h$, so that we have

$$(\rho_h,\psi_h) = b(z,u,\psi_h) + b(u,z,\psi_h) - b(z,z,\psi_h). \tag{4.61}$$

For the third term on the right-hand side above, by applying (2.22), we have

$$\big|b(z,z,\psi)\big| \leq C\,\|z\|_0\,\|z\|_1\,\|\psi_h\|_{L^\infty} \leq C\,\|z\|_0\,\|z\|_1\,\|\phi_h\|_0\,.$$

For the other two terms on the right-hand side of (4.61), Lemma 4.12 shows that

$$|b(z,u,\psi_h) + b(u,z,\psi_h)| \leq |b(z,\Psi(t-s),u)| + |b(u,\Psi(t-s),z)| + \frac{CM_2}{\sqrt{t-s}}h^2\,\|z\|_0\,\|\phi\|_0\,,$$

where, as in Lemma 4.12, $\Psi(t) = e^{-At}A^{-1}\Pi\phi_h$. Furthermore, by applying Lemma 4.10 to the first two terms on the right-hand side above, we have

$$|b(z,\Psi(t-s),u)| + |b(u,\Psi(t-s),z)| \leq Ch^2\,\|z\|_0\,\|\nabla u\cdot\Psi\|_2$$
$$+C\big(\|A^{-1}\Pi z\|_0 + h^2\,\|z\|_0\big)\big(\|(u\cdot\nabla)\Psi\|_2 + \|\nabla\Psi\cdot u\|_2\big).$$

Recalling the bounds of $\|(u\cdot\nabla)\Psi\|_2$, $\|\nabla\Psi\cdot u\|_2$ and $\|\nabla u\cdot\Psi\|_2$ in (4.57)–(4.59) we reach

$$\left\|e^{-(t-s)A_h}\rho_h(s)\right\|_0 \leq C\big(\|z\|_1 + h^2\,\|u\|_3\big)\,\|z\|_0 + \frac{CM_2}{\sqrt{t-s}}\big(h^2\,\|z\|_0 + \|A^{-1}\Pi z\|_0\big). \tag{4.62}$$

By applying Hölder's inequality, writing $z = (u - \Pi_h u) + z_h$, and using (2.7) and (4.12) we get

$$\int_0^t \left(\|z(s)\|_1 + h^2 \|u(s)\|_3\right) \|z(s)\|_0 \, ds \le Ch^5. \tag{4.63}$$

Using again (2.7) together with (4.9) we obtain $s^{1/2}\|z(s)\|_0 \le Ch^3$, and then

$$\int_0^t \frac{M_2}{\sqrt{t-s}} h^2 \|z(s)\|_0 \, ds \le CB\left(\frac{1}{2}, \frac{1}{2}\right) h^5. \tag{4.64}$$

Finally, as a consequence of (2.8) and (2.20) we have

$$\left\|A^{-1}\Pi z\right\|_0 \le \left\|A^{-1}\Pi z_h\right\|_0 + \left\|A^{-1}\Pi(I-\Pi_h)u\right\|_0 \le \left\|A_h^{-1} z_h\right\|_0 + C\left(h^2 \|z_h\|_0 + \|u\|_3 h^5\right),$$

so that using (4.9) again we get $s^{1/2}\|A^{-1}\Pi z(s)\|_0 \le Ch^5$, and then

$$\int_0^t \frac{M_2}{\sqrt{t-s}} \|A^{-1}\Pi z(s)\|_0 \, ds \le CB\left(\frac{1}{2}, \frac{1}{2}\right) h^5. \tag{4.65}$$

Now (4.60) follows from (4.62), (4.63), (4.64), and (4.65). ∎

THEOREM 4.15. *Let (u,p) be the solution of* (1.1)–(1.2). *There exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *and the Hood–Taylor element approximation to u, u_h, satisfy the following bound:*

$$\|v_h(t) - u_h(t)\|_j \le \frac{C}{t} |\log(h)| h^{5-j}, \quad t \in (0,T], \quad j = 0, 1, \quad r \ge 4. \tag{4.66}$$

Proof. We prove the error bound for the L^2 norm from which the H^1 norm bound is obtained by applying inverse inequality (2.5). We consider $y_h(t) = te_h(t)$. By arguing similarly as in Theorem 4.7 we have

$$\max_{0\le t\le T} \|y_h(t)\|_0 \le C\left(\max_{0\le s\le T} \left\|sA_h^{-1}\rho_h(s)\right\|_0 |\log(h)| + \max_{0\le s\le T} \left\|A_h^{-1}e_h(s)\right\|_0 |\log(h)|\right).$$

To conclude the estimate we apply Lemmas 4.5 and 4.14 to the first and second terms on the right-hand side above, respectively. ∎

COROLLARY 4.16. *Let (u,p) be the solution of* (1.1)–(1.2), *and let u_h be the Hood–Taylor element approximation to u. Then, for $r \ge 4$, there exists a positive constant C such that the following bound holds for $j = 0, 1$:*

$$\|u_h(t) - u(t)\|_j \le \frac{C}{t} h^{4-j}, \quad t \in (0,T].$$

Proof. The proof is obtained by reasoning as in Corollary 4.8 using Theorem 4.15 instead of Theorem 4.7. ∎

4.4. Superconvergence for the pressure. We begin with some error estimates for the time derivative of $v_h - u_h$.

LEMMA 4.17. *Let (u,p) be the solution of* (1.1)–(1.2). *Then there exists a positive constant C such that the discrete velocity v_h defined by* (4.4) *and the Hood–Taylor*

element approximation to u, u_h, satisfy the following bounds:

$$\|\dot{v}_h(t) - \dot{u}_h(t)\|_0 \leq \frac{C}{t^{s/2}} |\log(h)| h^{1+s}, \quad t \in (0,T], \tag{4.67}$$

$$\|\dot{v}_h(t) - \dot{u}_h(t)\|_{-1} \leq \frac{C}{t^{s/2}} |\log(h)| h^{2+s}, \quad t \in (0,T], \tag{4.68}$$

$$\|A^{-1}\Pi(\dot{v}_h(t) - \dot{u}_h(t))\|_0 \leq \frac{C}{t^{s/2}} |\log(h)| h^{3+s}, \quad t \in (0,T], \tag{4.69}$$

where $s = 1$ in the case $r = 3$ and $s = 2$ in the case $r = 4$.

Proof. Let us first observe that

$$\dot{e}_h = -A_h e_h + B_h(u_h, u_h) - B_h(u,u),$$

where we recall that $e_h = v_h - u_h$ Then by using (4.21) we get

$$\|\dot{e}_h\|_0 \leq Ch^{-1}\|e_h\|_1 + \|u_h - u\|_1.$$

Applying now Theorems 4.7 and 4.15 and Corollaries 4.8 and 4.16 to bound the first and second terms on the right-hand side above, we conclude (4.67).

In order to bound $\|\dot{e}_h\|_{-1} \leq C\|A_h^{-1/2}\dot{e}_h\|_0$ we observe that

$$\|A_h^{-1/2}\dot{e}_h\|_0 \leq \|A_h^{1/2}e_h\|_0 + \|A_h^{-1/2}(B_h(u_h,u_h) - B_h(u,u))\|_0,$$

so that by applying (4.22) from Lemma 4.4 we get

$$\|A_h^{-1/2}\dot{e}_h\|_0 \leq C\|e_h\|_1 + C\|u - u_h\|_0,$$

and (4.68) is reached by applying again Theorems 4.7 and 4.15 and Corollaries 4.8 and (4.16).

We now prove (4.69). By using (2.20) and Lemma 4.1 we obtain

$$\begin{aligned}
\|A^{-1}\Pi\dot{e}_h\|_0 &\leq \|A^{-1}\Pi A_h e_h\|_0 + \|A^{-1}\Pi(B_h(u_h,u_h) - B_h(u,u))\|_0 \\
&\leq C(h^2\|A_h e_h\|_0 + \|A_h^{-1}A_h e_h\|_0) + K(\|u - u_h\|_{-1} + \|u_h - u\|_0\|u_h - u\|_1) \\
&\leq C\|e_h\|_0 + K(\|e_h\|_{-1} + \|v_h - u\|_{-1} + \|u_h - u\|_0\|u_h - u\|_1).
\end{aligned}$$

To finish the proof we notice that $\|e_h\|_{-1} \leq C\|e_h\|_0$, and then we apply Theorems 4.7 and 4.15 and Corollaries 4.8 and 4.16 together with Lemma 4.3. ∎

THEOREM 4.18 (superconvergence for the pressure). *Let (u,p) be the solution of (1.1)–(1.2). Then, for $r = 3,4$, there exists a positive constant C such that the discrete pressure g_h defined by (4.1) and the Hood–Taylor element approximation to p, p_h, satisfy the following bound:*

$$\|p_h(t) - g_h(t)\|_{L^2/\mathbb{R}} \leq \frac{C}{t^{(r-2)/2}} h^r \left|\log(h)\right|, \qquad t \in (0,T].$$

Proof. By subtracting (3.1) from (4.1), we obtain for the difference $g_h - p_h$

$$(g_h - p_h, \nabla\cdot\phi_h) = (\nabla e_h, \nabla\phi_h) + (F(u,u) - F(u_h,u_h), \phi_h) + (\dot{e}_h, \phi_h)$$

for all $\phi_h \in X_{h,r}$. Using the inf-sup condition (2.6),

$$\beta\|g_h - p_h\|_{L^2/\mathbb{R}} \leq \|e_h\|_1 + \|F(u,u) - F(u_h,u_h)\|_{-1} + \|\dot{e}_h\|_{-1}.$$

By applying Theorems 4.7 and 4.15, (4.20), and (4.68) we obtain

$$\beta\|g_h - p_h\|_{L^2/\mathbb{R}} \leq \frac{C}{t^{(r-2)/2}} h^r |\log(h)| + C\|u - u_h\|_0.$$

Finally, by using Corollaries 4.8 and 4.16, the conclusion is reached. ∎

COROLLARY 4.19. *Let (u,p) be the solution of (1.1)–(1.2). Then, for $r = 3,4$, there exists a positive constant C such that the Hood–Taylor element approximation to p, p_h, satisfies the following bound:*

$$\|p_h(t) - p(t)\|_{L^2/\mathbb{R}} \leq \frac{C}{t^{(r-2)/2}} h^{r-1}, \qquad t \in (0,T]. \tag{4.70}$$

Proof. Let g_h be the discrete pressure defined by (4.1). We decompose

$$\|p_h - p\|_{L^2/\mathbb{R}} \leq \|p_h - g_h\|_{L^2/\mathbb{R}} + \|g_h - p\|_{L^2/\mathbb{R}}$$

and apply Theorem 4.18 to bound the first term on the right-hand side above. To bound the second one we decompose $\|g_h - p\|_{L^2/\mathbb{R}} \leq \|g_h - q_h\|_{L^2/\mathbb{R}} + \|q_h - p\|_{L^2/\mathbb{R}}$, where q_h is that in (2.11). Using (2.14) it only remains to bound the first term above. By taking into account that

$$(u_t, \phi_h) + (\nabla s_h, \nabla\phi_h) + b(u,u,\phi_h) + (\nabla q_h, \phi_h) = (f,\phi_h) \quad \forall \phi_h \in X_{h,r},$$

$$(\dot{v}_h, \phi_h) + (\nabla v_h, \nabla\phi_h) + b(u,u,\phi_h) + (\nabla g_h, \phi_h) = (f,\phi_h) \quad \forall \phi_h \in X_{h,r},$$

and arguing as in the proof of Theorem 4.18, we deduce that

$$\|g_h - q_h\|_{L^2/\mathbb{R}} \leq C\|v_h - s_h\|_1 + \|\dot{v}_h - u_t\|_{-1}.$$

To bound the first term we decompose $\|v_h - s_h\|_1 \leq \|z_h\|_1 + \|\Pi_h u - u\|_1 + \|s_h - u\|_1$ and then apply Lemma 4.3, (2.7), and (2.13). To bound the second one, by using (2.8) we get

$$\|\dot{v}_h - u_t\|_{-1} \leq \|\dot{z}_h\|_{-1} + \|\Pi_h u_t - u_t\|_{-1} \leq \|\dot{z}_h\|_{-1} + Ch^{r-1}\|u_t\|_{r-2}.$$

Finally, since $\|\dot{z}_h\|_{-1} \leq C\|A_h^{-1/2}\dot{z}_h\|_0$, by using (4.6) we get

$$\|\dot{z}_h\|_{-1} \leq C\|z_h\|_1 + \|\theta_h\|_1,$$

and we conclude by applying Lemma 4.3, (2.7), and (2.13). ∎

Remark 4.3. We want to point out that the error bounds for the Galerkin approximation to the velocity in Corollaries 4.8 and 4.16 are analogous to those obtained in [37, Theorem 3.1]. If we compare the error bound for the pressure in Corollary 4.19 with that of [37, Theorem 3.1], we can observe that the singular behavior of pressure estimate (4.70) as t tends to zero behaves like $t^{-(r-2)/2}$ improving the estimate in [37, Theorem 3.1] that behaves like $t^{-(r-1)/2}$. Recently, in [7] improved convergence of order $O(t^{(-1/4)-\delta})$ for any $\delta > 0$ is shown for the approximation to the velocity using quadratic elements. Error estimates for the pressure are not considered in [7].

5. Analysis of the postprocessed method. We require some error estimates for the time derivative that we now prove.

LEMMA 5.1. *Let (u,p) be the solution of (1.1)–(1.2). There exists a positive constant C such that the Hood–Taylor element approximation to u, u_h, satisfies the following bounds:*

$$\|u_t - \dot{u}_h(t)\|_0 \le \frac{C}{t^{(l+1)/2}} h^{1+l} \left|\log(h)\right|, \quad t \in (0,T], \tag{5.1}$$

$$\|u_t - \dot{u}_h(t)\|_{-1} \le \frac{C}{t^{(l+1)/2}} h^{2+l} \left|\log(h)\right|, \quad t \in (0,T], \tag{5.2}$$

$$\|A^{-1}\Pi(u_t - \dot{u}_h(t))\|_0 \le \frac{C}{t^{(l+1)/2}} h^{3+l} \left|\log(h)\right|, \quad t \in (0,T], \tag{5.3}$$

where $l = 1$ in the case $r = 3$ and $l = 2$ in the case $r = 4$.

Proof. By writing

$$u_t - \dot{u}_h = (u_t - \Pi_h u_t) + (\Pi_h u_t - \dot{v}_h) + (\dot{v}_h - \dot{u}_h) = (u_t - \Pi_h u_t) + \dot{z}_h + \dot{e}_h$$

and applying (2.7) and (2.8) to bound the first term and Lemma 4.17 for the third one, we only need to bound the different norms of $\dot{z}_h$. Since the norms $\|A_h^{-1/2}\dot{z}_h\|_0$ and $\|\dot{z}_h\|_{-1}$ are equivalent and since in view of (2.20) $\|A^{-1}\Pi\dot{z}_h\|_0$ can be bounded in terms of $\|\dot{z}_h\|_0$ and $\|A_h^{-1}\dot{z}_h\|_0$, we only have to bound $\|A_h^{-k/2}\dot{z}_h\|_0$ for $k = 0,1,2$. For this purpose, we will argue as in the proof of (4.10). We notice that $\ddot{z}_h + A_h\dot{z}_h = A_h\dot{\theta}_h$, and if we let j be $j = (1+l)/2$ for $y_h = t^j A_h^{-1}\dot{z}_h$, we have $\dot{y}_h + A_h y_h = t^j\dot{\theta}_h + jt^{j-1}A_h^{-1}\dot{z}_h$, so that

$$A_h^{-1}t^j\dot{z}_h(t) = \int_0^t e^{-A_h(t-s)}s^j\dot{\theta}_h(s)\,ds + j\int_0^t e^{-A_h(t-s)}A_h^{-1}s^{j-1}\dot{z}_h(s)\,ds.$$

By applying (2.10) to both integrals we obtain

$$\left\|A_h^{-1}t^j\dot{z}_h(t)\right\|_0 \le CB\left(\frac{1}{2},\frac{1}{2}\right) \left(\max_{0\le s\le t} s^{j+1/2}\left\|A_h^{-1/2}\dot{\theta}_h(s)\right\|_0 + j\max_{0\le s\le t} s^{j-1/2}\left\|A_h^{-3/2}\dot{z}_h(s)\right\|_0\right).$$

Now, on the one hand, we have that (2.16) and (2.8) are valid if u, s_h, and p are replaced by their time derivatives. On the other hand, we have that $A_h^{-3/2}\dot{z}_h = A_h^{-1/2}\theta_h - A_h^{-1/2}z_h$, so that in view of (2.16), (2.8), (4.10), and (4.11) the proof of (5.3) is easily finished. Taking into account that $\left\|A_h^{k/2}\right\|_0 \le Ch^{-k}$ for $k = 1,2$, then (5.1) and (5.2) follow. ∎

THEOREM 5.2. *Let (u,p) be the solution of (1.1)–(1.2). There exists a positive constant C such that the postprocessed MFE approximation to u, $\tilde{u}_h$, satisfies the following bounds for $j = 0,1$:*

(i) *If the postprocessing element is $(\widetilde{X},\widetilde{Q}) = (X_{h',r}, Q_{h',r-1})$, then*

$$\|u(t) - \tilde{u}_h(t)\|_j \le \frac{C}{t^{1/2}}(h')^{3-j} + \frac{C}{t}h^{4-j}|\log(h)|, \quad t \in (0,T],\ r \ge 3, \tag{5.4}$$

$$\|u(t) - \tilde{u}_h(t)\|_j \le \frac{C}{t}(h')^{4-j} + \frac{C}{t^{3/2}}h^{5-j}|\log(h)|, \quad t \in (0,T],\ r \ge 4; \tag{5.5}$$

(ii) *if the postprocessing element is* $(\widetilde{X},\widetilde{Q}) = (X_{h,r+1}, Q_{h,r})$*, then*

$$\|u(t)-\tilde{u}_h(t)\|_j \le \frac{C}{t}h^{4-j}|\log(h)|, \quad t\in(0,T],\ r\ge 3, \tag{5.6}$$

$$\|u(t)-\tilde{u}_h(t)\|_j \le \frac{C}{t^{3/2}}h^{5-j}|\log(h)|, \quad t\in(0,T],\ r\ge 4. \tag{5.7}$$

Proof. The proof follows the same steps as [6, Theorem 3.14]. Let $\widetilde{S}_h(u(t))\in\widetilde{V}$ be the Stokes projection of the solution of (1.1)–(1.2) at time t. We decompose $\|u(t)-\tilde{u}_h(t)\|_l \le \|u(t)-\widetilde{S}_h(u(t))\|_l + \|\widetilde{S}_h(u(t))-\tilde{u}_h(t)\|_l$, $l=0,1$. We apply (2.13) to bound the first term, so that we will concentrate now on the second. It is easy to obtain

$$\|\tilde{u}_h(t)-\widetilde{S}_h(u(t))\|_1 \le C\|F(u(t),u(t))-F(u_h(t),u_h(t))\|_{-1} + C\|u_t(t)-\dot{u}_h(t)\|_{-1}.$$

For the first term above we apply (4.20) and Corollaries 4.8 and 4.16 to obtain

$$\|F(u(t),u(t))-F(u_h(t),u_h(t))\|_{-1} \le C\|u(t)-u_h(t)\|_0 \le \frac{C}{t^{(r-1)/2}}h^r.$$

The second term is already bounded in (5.2). Then the proof for the H^1 norm is complete. We next deal with the estimate in the L^2 norm. We first observe that

$$\widetilde{A}_h(\tilde{u}_h(t)-\widetilde{S}_h(u(t))) = \widetilde{\Pi}_h(F(u(t),u(t))-F(u_h(t),u_h(t))) + \widetilde{\Pi}_h(u_t(t)-\dot{u}_h(t)).$$

Then, by applying $\widetilde{A}_h^{-1}$ to both sides of the above equation, we obtain

$$\|\tilde{u}_h-\widetilde{S}_h(u)\|_0 \le \|\widetilde{A}_h^{-1}\widetilde{\Pi}_h(F(u(t),u(t))-F(u_h(t),u_h(t)))\|_0 + \|\widetilde{A}_h^{-1}\widetilde{\Pi}_h(u_t(t)-\dot{u}_h(t))\|_0.$$

As regards the nonlinear term, by taking into account (2.19) and applying Lemma 4.1 and (4.19) we get

$$\begin{aligned}&\|\widetilde{A}_h^{-1}\widetilde{\Pi}_h(F(u,u)-F(u_h,u_h))\|_0\\ &\qquad\le C\tilde{h}^2\|u-u_h\|_1 + C(\|u-u_h\|_{-1}+\|u-u_h\|_0\|u-u_h\|_1).\end{aligned}$$

The estimates for the L^2 and H^1 norms of the errors of the Galerkin approximation to the velocity are granted by Corollaries 4.8 and 4.16. As regards the estimate in the H^{-1} norm, we use the decomposition $\|u-u_h\|_{-1} \le \|u-\Pi_h u\|_{-1} + \|z_h\|_{-1} + \|v_h-u_h\|_0$ and apply (2.8) together with Lemma 4.3 and Theorems 4.7 and 4.15. Finally, to bound $\|\widetilde{A}_h^{-1}\widetilde{\Pi}_h(u_t(t)-\dot{u}_h(t))\|_0$ we apply (2.19) again and then use estimates (5.1) and (5.3) from Lemma 5.1. ∎

THEOREM 5.3. *Let* (u,p) *be the solution of* (1.1)–(1.2)*. There exists a positive constant* C *such that the postprocessed MFE approximation to* p*,* $\tilde{p}_h$*, satisfies the following bounds:*

(i) *If the postprocessing element is* $(\widetilde{X},\widetilde{Q}) = (X_{h',r}, Q_{h',r-1})$*, then*

$$\|p(t)-\tilde{p}_h(t)\|_{L^2/\mathbb{R}} \le \frac{C}{t^{(r-2)/2}}(h')^{r-1} + \frac{C}{t^{(r-1)/2}}h^r|\log(h)|, \quad t\in(0,T];$$

(ii) *if the postprocessing element is* $(\widetilde{X},\widetilde{Q}) = (X_{h,r+1}, Q_{h,r})$*, then*

$$\|p(t)-\tilde{p}_h(t)\|_{L^2/\mathbb{R}} \le \frac{C}{t^{(r-1)/2}}h^r|\log(h)|, \quad t\in(0,T]. \tag{5.8}$$

Proof. The proof is reached by reasoning as in [6, Theorem 3.15]. Let us denote by $\tilde{q}_h(t)$ the approximation to the pressure $p(t)$ such that $(\widetilde{S}_h(u(t)), \tilde{q}_h(t)) \in (\widetilde{X}, \widetilde{Q})$ solves (2.11)–(2.12) with $g = f - u_t - u \cdot \nabla u$. Then we use the decomposition

$$\|p(t) - \tilde{p}_h(t)\|_{L^2/\mathbb{R}} \leq \|p(t) - \tilde{q}_h(t)\|_{L^2/\mathbb{R}} + \|\tilde{q}_h(t) - \tilde{p}_h(t)\|_{L^2/\mathbb{R}}.$$

The first term is estimated by applying (2.14). Let us now bound the second term. Using the inf-sup condition (2.6) it is easy to deduce that

$$\beta\|\tilde{p}_h - \tilde{q}_h\|_{L^2/\mathbb{R}} \leq \|\tilde{u}_h - \widetilde{S}_h(u)\|_1 + \|F(u_h, u_h) - F(u, u)\|_{-1} + \|u_h - u_t\|_{-1}.$$

By applying Theorem 5.2 to bound the first term, (4.20) together with Corollaries 4.8 and 4.16 for the second, and (5.2) for the third, the conclusion is reached. ∎

6. Remarks on fully discrete postprocessing. In practice, the finite-element approximations u_h and p_h, being solutions of system (3.1)–(3.2), can rarely be computed analytically, and one has to compute approximations $u_h^{(n)} \approx u_h(t_n)$ and $p_h^{(n)} \approx p_h(t_n)$ on some time levels $0 = t_0 < t_1 \ldots < t_N = T$ by means of a time integrator. Consequently, instead of the postprocessed approximations $\tilde{u}_h(t_n)$ and $\tilde{p}_h(t_n)$, one obtains $\tilde{u}_h^{(n)}$ and $\tilde{p}_h^{(n)}$ as solutions of

$$\left(\nabla\tilde{u}_h^{(n)}, \nabla\tilde{\phi}\right) + \left(\nabla\tilde{p}_h^{(n)}, \tilde{\phi}\right) = (f, \tilde{\phi}) - b(u_h^{(n)}, u_h^{(n)}, \tilde{\phi}) - (d_t u_h^{(n)}, \tilde{\phi}) \quad \forall\, \tilde{\phi} \in \widetilde{X}, \tag{6.1}$$

$$\left(\nabla \cdot \tilde{u}_h^{(n)}, \tilde{\psi}\right) = 0 \quad \forall\, \tilde{\psi} \in \widetilde{Q}, \tag{6.2}$$

where $(\widetilde{X}, \widetilde{Q})$ is as in (3.3)–(3.4), and $d_t u_h^{(n)}$ is an approximation to $\dot{u}_h(t_n)$ computed in terms of as many values $u_h^{(n-j)}$, $j = 0, 1, \ldots, N - n$, as needed. Recent research in [22] suggests

$$d_t u^{(n)} = \Pi_h f - A_h u_h^{(n)} - B_h(u_h^{(n)}, u_h^{(n)}) \tag{6.3}$$

as a convenient and adequate approximation.

Notice then that the error $u(t_n) - \tilde{u}_h^{(n)}$ can be expressed as $u(t_n) - \tilde{u}_h^{(n)} = (u(t_n) - \tilde{u}_h(t_n)) + (\tilde{u}_h(t_n) - \tilde{u}_n^{(n)})$. The first term on the right-hand side is the spatial discretization error which we have analyzed in the previous sections. The second one is the error arising from temporal discretization that will be analyzed now.

Let us denote by $e_h^{(n)} = u_h(t_n) - u_h^{(n)}$ and $\tilde{e}_h^{(n)} = \tilde{u}_h(t_n) - \tilde{u}_h^{(n)}$ the errors induced by the temporal discretization in the Galerkin and postprocessed approximations, respectively. We estimate here $\tilde{e}_h^{(n)}$ in terms of $e_h^{(n)}$, which depends on the particular time integrator used to approximate the solution of (3.1)–(3.2). Estimates of $e_h^{(n)}$ (when $t_n = nk$, $n = 0, 1, \ldots, N = T/k$) for the Crank–Nicolson method can be found in [38], with $O(t_n^{-1}k^2)$ and $O(t_n^{-1}k)$ estimates in the L^2 and H^1 norms, respectively, (see also [31]). For the second-order backward differentiation formula (BDF), similar estimates are obtained in [13] (for the limit case $h \to 0$), with a $k^{1/2}$ improvement in the H^1 estimate with respect to that in [38]. Also, from results in [41], it is straightforward to obtain $O(k)$ estimates in both the L^2 and the H^1 norms for the implicit Euler method. Notice that all of these estimates together with the boundedness of $\|u_h(t)\|_1$, $0 \leq t \leq T$, and h sufficiently small [37] imply that $\|u_h^{(n)}\|_1$ is bounded for $0 \leq n \leq N$ and h sufficiently small. Further estimates for other integrators are outside the scope of the present paper.

From (6.3) it follows that

$$\dot{u}_h(t_n) - d_t u_h^{(n)} = -A_h e_h^{(n)} + \Pi_h\big(F(u_h^{(n)}, u_h^{(n)}) - F(u_h(t_n), u_h(t_n))\big), \tag{6.4}$$

so that by subtracting (6.1) from (3.3) we get

$$\widetilde{A}_h \tilde{e}_h^{(n)} = (\widetilde{\Pi}_h - \Pi_h)\big(F(u_h^{(n)}, u_h^{(n)}) - F(u_h(t_n), u_h(t_n))\big) - \widetilde{\Pi}_h A_h e_h^{(n)}.$$

On the one hand, we may write $\widetilde{A}_h^{-1}\widetilde{\Pi}_h A_h e_h^{(n)} = e_h^{(n)} + \big(\widetilde{A}_h^{-1}\widetilde{\Pi}_h - A_h^{-1}\big)A_h e_h^{(n)}$, so that by using (2.17) we get

$$\|\tilde{A}_h^{-1}\tilde{\Pi}_h A_h e_h^{(n)}\|_j \le \|e_h^{(n)}\|_j + Ch^{2-j}\|A_h e_h^{(n)}\|_0, \quad j = 0, 1.$$

On the other hand, a simple duality argument and (2.17) show that $\|\widetilde{A}_h^{-1}(\widetilde{\Pi}_h - \Pi_h)f\|_j \le Ch^{2-j}\,\|f\|_0$ for $f \in L^2(\Omega)^d$, $j = 0, 1$, so that first applying this inequality to $f = F(u_h^{(n)}, u_h^{(n)}) - F(u_h(t_n), u_h(t_n))$ and then well-known inequalities (e.g., equation [38, (3.7)]), we conclude that

$$\big\|\tilde{e}_h^{(n)}\big\|_j \le \big\|e_h^{(n)}\big\|_j + Ch^{2-j}\Big(\big\|e_h^{(n)}\big\|_1 + \big\|A_h e_h^{(n)}\big\|_0\Big), \tag{6.5}$$

where the constant C depends on $\|u_n^{(n)}\|_1$ (which, as mentioned before, is bounded for h sufficiently small) and on $\|A_h u_h(t_n)\|_0$, which can be easily seen to be bounded for $0 \le t \le T$ and h sufficiently small. Taking into account that $h^{2-j}\big\|A_h e_h^{(n)}\big\|_0 \le C\|e_h^{(n)}\|_j$, we conclude that the temporal error $\tilde{e}_h^{(n)}$ of the fully discrete postprocessed method is proportional to temporal error $e_h^{(n)}$ of the mixed finite-element approximation. Furthermore, for the second-order BDF formula, besides the estimates in [13], in [23] we obtain $O(t_n^{-3/2}k^2)$ and $O(t_n^{-2}k^2)$ estimates for $\|e_h^{(n)}\|_1$ and $\|A_h e_h^{(n)}\|_0$, respectively, so that, in view of (6.5), the two errors $\tilde{e}_h^{(n)}$ and $e_h^{(n)}$ are asymptotically equivalent as $h \to 0$.

Finally, for the pressure, arguing as in the proof of Theorem 5.3 and using the same arguments we have used for $\tilde{e}_h^{(n)}$, one can easily show that also

$$\big\|\tilde{p}_h(t_n) - \tilde{p}_h^{(n)}\big\|_{L^2/\mathbb{R}} \le C\big\|e_h^{(n)}\big\|_1.$$

UNIFORM l^1 BEHAVIOR FOR TIME DISCRETIZATION OF A VOLTERRA EQUATION WITH COMPLETELY MONOTONIC KERNEL II: CONVERGENCE*

XU DA†

Abstract. A previous work on the time discretization for the solution of a Volterra equation with completely monotonic convolution kernel is extended. The considered time discretization method comes from Part I [X. Da, *IMA J. Numer. Anal.*, 22 (2002), pp. 133–151], where the backward Euler is combined with order one convolution quadrature approximating the integral. In the present paper, the convergence properties of the discretization in time are given in the $l_t^1(0,\infty;H)\bigcap l_t^\infty(0,\infty;H)$ norm.

Key words. Volterra equation, completely monotonic kernel, time discretization, convolution quadrature, uniform ℓ^1 behavior, convergence

DOI. 10.1137/060668699

1. Introduction.

We continue our study, begun in Part I [3], for the discretization in time of the solution of the homogeneous linear equation

$$u_t + \int_0^t \beta(t-s)\, A\, u\,(s)\, ds = 0 \quad \text{for } t > 0, \tag{1.1}$$

$$u(0) = u_0 \in H,$$

where $u_t = \partial \mathrm{u}/\partial \mathrm{t}$ and A is a self-adjoint positive definite linear operator defined on a dense subspace $\mathcal{D}(A)$ of the real Hilbert space H, with a complete eigensystem $\{\lambda_m, \varphi_m\}_{m=1}^\infty$. The real-valued kernel $\beta(t)$ satisfies

$$\beta \in L^1(0,1),\ \beta \text{ is completely monotonic on } (0,\infty), \text{ and} \tag{1.2}$$

$$0 \le \beta(\infty) < \beta(0^+) \le \infty.$$

Following Part I, we discretize (1.1) by means of a backward Euler time difference approximation of the derivative, combined with order one convolution quadrature approximating the integral in the sense of Lubich [13]. Thus we choose a fixed time step $k > 0$, and let $t_n = n\,k$ for $n \ge 0$. This yields a numerical solution $U^n \approx u(t_n)$ satisfying

$$\overline{\partial}\, U^n + \sum_{j=1}^{n} \beta_{n-j}(k)\, A\, U^j = 0 \quad \text{for } n \ge 1, \tag{1.3}$$

$$U^0 = u_0,$$

where $\overline{\partial} U^n := (U^n - U^{n-1})/k$, and the convolution quadrature weights $\beta_j(k)$ are the coefficients of the power series

$$\widehat{\beta}\left(\frac{1-z}{k}\right) = \sum_{j=0}^{\infty} \beta_j(k)\, z^j.$$

Here $\widehat{\beta}(s)$ is the Laplace transform of the kernel function β, which is

$$\widehat{\beta}(s) = \int_0^{\infty} \beta(t)\, e^{-st}\, dt.$$

Part I established the stability in the norm $l_t^1(0,\infty;H) \bigcap l_t^{\infty}(0,\infty;H)$ for the discretized problem (1.3) by using the theory of Hardy spaces [4] and Laplace transform methods considered by Hannsgen and Wheeler [9]. Our present purpose is to study the convergence properties in the same norm for the problem (1.3). We shall prove the following theorem.

THEOREM 1. *Let $\beta(t)$ satisfy* (1.2). *Then we have, for the solutions of* (1.3) *and* (1.1) *and for k sufficiently small,*

$$k \sum_{n=1}^{\infty} \|U^n - u(t_n)\| \le C\, k\, |\log k|\, \|u_0\|_6, \tag{1.4}$$

where C is a positive constant independent of $u(t)$ and k, $\|.\|$ denotes the norm in H, and $\|v\|_\nu = \|A^{\nu/2} v\|$ denotes the norm in the space $\dot{H}^\nu = D(A^{\nu/2})$.

We recall some results concerning the asymptotic behavior of the solution of problem (1.1). Let $u(t,\lambda)$ denote the solution of the real equation

$$\frac{d\,u(t,\lambda)}{d\,t} + \lambda \int_0^t \beta(t-s)\, u(s,\lambda)\, ds = 0, \quad u(0,\lambda) = 1, \tag{1.5}$$

with parameter λ ($\lambda_1 \le \lambda < \infty,\ 0 \le t < \infty$).

Carr and Hannsgen give sufficient conditions in order that

$$\text{(i)} \quad \int_0^{\infty} \sup_{\lambda \ge \lambda_1} |u(t,\lambda)|\, dt < \infty, \text{ and} \tag{1.6}$$

$$\text{(ii)} \quad \int_0^{\infty} \sup_{\lambda \ge \lambda_1} |u'(t,\lambda)\, \lambda^{-1/2}| dt < \infty \qquad \left(' = \frac{d}{dt}\right)$$

hold (see [1, 2]). In particular, (1.6) holds when $\beta(t)$ satisfies

$$\beta(t) \in L^1_{loc}[0,\infty) \quad \text{is nonnegative, nonincreasing,} \tag{1.7}$$

$$\text{convex and} \quad 0 \le \beta(\infty) < \beta(0^+) \le \infty,$$

and

$$-\beta' \text{ is convex on } (0,\infty). \tag{1.8}$$

Also it is a result, from the proof of [1, Thm. 2.2] or [2, Thm. 2.3], with $\beta(t)$ as (1.7) and (1.8), that

$$\int_0^{\infty} \sup_{\lambda \ge \lambda_1} |u''(t,\lambda)\, \lambda^{-2}| dt < \infty. \tag{1.9}$$

We note that the completely monotonic kernel (1.2) satisfies (1.7) and (1.8).

The asymptotic analysis of problem (1.5) has been a very active field over the past several decades, and there are numerous very ingenious results; see, for example, the ones just stated and those of [7, 6, 9, 8, 5, 10, 11, 12, 18]. Hannsgen and Wheeler considered the completely monotonic kernel in [7, 6, 8]. Further, in [9] they studied the more general problem for (1.1) with certain families of completely monotonic kernels. Noren [18] extended their results and gave the sufficient conditions concerning the kernel $\beta(t)$ in order that

$$\int_0^\infty \sup_{\lambda\geq\lambda_1} |u''(t,\lambda)\ \lambda^{-1}|dt\ <\infty. \tag{1.10}$$

Now we state a condition from [18, Thm. 2.5].

Assume that (1.7) and (1.8) are satisfied, and in addition

$$\int_0^1 (-\log\ t)\,\beta(t)\,dt\ <\ \infty, \tag{1.11}$$

and there exist constants $c_1,\ c_2>0$ such that

$$c_1\,\tau\,A_1(\tau^{-1})\leq\ B(\tau^{-1})\leq\ c_2\,\tau\,A_1(\tau^{-1}),\qquad \rho/2\leq\ \tau, \tag{1.12}$$

where $A(\tau^{-1})$ and $A_1(\tau^{-1})$ are defined by

$$A(\tau^{-1})\ =\ \int_0^{\tau^{-1}}\beta(t)\,dt,\quad A_1(\tau^{-1})\ =\ \int_0^{\tau^{-1}} t\,\beta(t)\,dt\qquad(\tau>0),$$

and $\rho=\omega(\lambda_0)>0$ (see (2.4) below),

$$B(\tau^{-1})\ =\ \int_0^{\tau^{-1}} -t\,\beta'(t)\,dt\qquad(\tau>0).$$

Then (1.10) holds.

From [1] we know that the formula

$$u(t)\ =\ \sum_{j=1}^{\infty} u(t,\lambda_j)\ (u_0,\varphi_j)\ \varphi_j \tag{1.13}$$

gives a solution of (1.1) in the Hilbert space H. With

$$\|u(t)\|\ \leq\ \sup_{\lambda_1\leq\lambda<\infty}|u(t,\lambda)|\ \|u_0\|, \tag{1.14}$$

and using (1.6)(i), it follows that

$$\int_0^\infty \|u(t)\|dt\ \leq\ C\|u_0\|. \tag{1.15}$$

Similarly, the conditions (1.6)(ii), (1.9), and (1.10) imply that, respectively,

$$\int_0^\infty \|u'(t)\|dt\ \leq\ C\|u_0\|_1, \tag{1.16}$$

$$\int_0^\infty \|u''(t)\|dt\ \leq\ C\|u_0\|_4, \tag{1.17}$$

$$\int_0^\infty \|u''(t)\|dt\ \leq\ C\|u_0\|_2. \tag{1.18}$$

The numerical analogue of (1.5) follows such that, for $\lambda > 0$, assume that the real sequence $\{U^n(\lambda)\}$ is the solution

$$\frac{U^n(\lambda) \;-\; U^{n-1}(\lambda)}{k} \;+\; \lambda \sum_{j=1}^{n} \beta_{n-j}(k)\, U^j(\lambda) \;=\; 0, \qquad n \;\geq\; 1, \tag{1.19}$$

$$U^0(\lambda) \;=\; 1.$$

It is easy to see that the solution of (1.3) can be represented as

$$U^n \;=\; \sum_{j=1}^{\infty} U^n(\lambda_j)\, (u_0, \varphi_j)\, \varphi_j; \tag{1.20}$$

this is a discretized analogue of (1.13). We shall establish the following two additional l_t^∞ estimates.

THEOREM 2. *Let the conditions of Theorem* 1 *be in force. Then, for k sufficiently small,*

$$\|U^n - u(t_n)\| \;\leq\; C\, k\, |\log k|\, \|u_0\|_6 \;\; \textit{for } n \geq 0. \tag{1.21}$$

The proof will be given in section 3.

From Theorem 2 we get, with $0 \leq t_m \leq 1$,

$$k \sum_{n=1}^{m} \|U^n - u(t_n)\| \;\leq\; C\, k\, |\log k|\, \|u_0\|_6. \tag{1.22}$$

The error estimate (1.21) is a long time l_t^∞ error bound and contains a factor of the logarithm. This may be removed by imposing additional conditions on the kernel, for example, (1.11) (see Remark 3.2 below). Another is a long time l_t^∞ error estimate away from 0, given in the following theorem.

THEOREM 3. *If $\beta(t)$ satisfies* (1.2), *then for the solutions of* (1.3) *and* (1.1), *and for k sufficiently small, with $t_{n-2} > 0$,*

$$\|U^n - u(t_n)\| \;\leq\; C\, k\, t_{n-2}^{-2}\, \|u_0\|_6 \quad \textit{for } t_{n-2} > 0. \tag{1.23}$$

The proof will be given in section 4.

We show that Theorems 2 and 3 imply the conclusions of Theorem 1. In fact, with $t_{m-2} > 0$, we can deduce estimate

$$k \sum_{n=m}^{\infty} \|U^n - u(t_n)\| \;\leq\; C\, k\, \|u_0\|_6. \tag{1.24}$$

Formulas (1.22) and (1.24) gives us the conclusion of Theorem 1. We have shown that Theorem 1 is a consequence of Theorems 2 and 3, which we will prove in sections 3 and 4, respectively.

Formulas (1.21) and (1.23) are similar to those in [16, 17] for the classical weakly singular kernel $\beta(t) = t^{-\alpha}$ $(0 < \alpha < 1)$ [16] and the exponential decay kernel [17]; it is known that these types of kernels satisfy (1.2).

Comparing [15] and [14], Theorem 3 is similar to Theorem 2.1 of [15] for a scalar function, and (1.22) is similar to Theorem 3.3 of [14] (see also the references therein)

for a scalar function. Thus, Theorems 2 and 3 extend the results of [14] and [15] for a scalar function to a function in an infinite-dimensional Hilbert space H, where it is a solution of (1.1).

In sections 3 and 4 we shall use different techniques in [14, 15] to obtain the proofs of Theorems 2 and 3, respectively. [14, Theorem 3.3] is a shorter time error estimate, and [15, Theorem 2.1] contains a long time error bound. We do not know whether the results from those used in [14, 15] could be used to extend or simplify the proofs of Theorems 2 and 3, but they might be worth looking at as a next step.

A completely monotonic function on $(0,\infty)$ can be represented (see [20]) by the Stieltjes integral

$$\beta(t) \;=\; \int_0^\infty e^{-xt}\, d\,\alpha(x) \quad \text{for} \;\; t>0, \tag{1.25}$$

where $\alpha(0)=0$, α is nondecreasing, and $\alpha(x)=\alpha(x^-)$ for $0<x<\infty$. The conditions in (1.2) are equivalent, respectively, to

$$\int_0^\infty \frac{1-e^{-x}}{x}\, d\,\alpha(x) \;<\; \infty, \tag{1.26}$$

$$\alpha(0^+) \;<\; \alpha(\infty) \;=\; \beta(0^+). \tag{1.27}$$

Define

$$\phi(\sigma,\tau)=\int_0^\infty \frac{(x+\sigma)d\alpha(x)}{(x+\sigma)^2+\tau^2}, \;\; \theta(\sigma,\tau)=\int_0^\infty \frac{d\alpha(x)}{(x+\sigma)^2+\tau^2} \quad (\sigma+i\,\tau \;\notin\; (-\infty,0]),$$

$$D(s;\lambda)=D(\sigma+i\tau;\lambda)=\frac{s}{\lambda}+\widehat{\beta}(s)=\frac{\sigma+i\tau}{\lambda}+\widehat{\beta}(\sigma+i\tau),$$

$$\phi(\tau)=\phi(0,\tau), \qquad \theta(\tau)=\theta(0,\tau) \qquad (0 \;<\; \tau \;<\infty).$$

Note that

$$\begin{aligned}\phi(\sigma,\tau) \;-\; i\,\tau\,\theta(\sigma,\tau) \;&=\; \int_0^\infty \frac{d\alpha(x)}{x+\sigma+i\tau} \qquad (\sigma+i\,\tau \;\notin\; (-\infty,0])\\ &=\; \int_0^\infty e^{-t\,(\sigma+i\tau)}\,\beta(t)\,dt \qquad (\sigma>0).\end{aligned}$$

Then the Fourier transform of $\beta(t)$ is

$$\widetilde{\beta}(\tau)=\int_0^\infty e^{-i\,\tau\,t}\beta(t)\,dt=\int_0^\infty \frac{d\alpha(x)}{x+i\,\tau}=\widehat{\beta}(i\,\tau)=\phi(\tau)-i\,\tau\,\theta(\tau), \quad \tau\neq 0, \tag{1.28}$$

and (see [1, Thm. 2.2 and Cor. 2.1])

$$\limsup_{\tau\to\infty} \frac{\theta(\tau)}{\phi(\tau)} \;<\; \infty. \tag{1.29}$$

We note that (1.29) is a necessary condition in order that (1.6)(i) holds [1, Thm. 2.2 (iii)]. Also, using the definition of $\theta(\tau)$, we see that $\theta(\tau)$ is nonnegative, continuously differentiable, and strictly decreasing on R^+.

The result of Theorem 1 needs more restrictive conditions on the initial data u_0. $A^3 u_0 \in H$ is not desirable from a practical point of view. If we add the conditions on the kernel $\beta(t)$, for example,

$$\limsup_{\tau\to\infty} \frac{\tau\theta(\tau)}{\phi(\tau)} < \infty, \tag{1.30}$$

then we have the following improved estimate.

COROLLARY 1. *Let $\beta(t)$ satisfy* (1.2) *and* (1.30). *Then for the solutions of* (1.3) *and* (1.1) *and for k sufficiently small, we have that*

$$k \sum_{n=1}^{\infty} \|U^n - u(t_n)\| \le C\, k\, |\log k|\, \|u_0\|_4. \tag{1.31}$$

The proof will be given at the end of section 5.

On the reader's part we assume some familiarity with the introduction to Part I. Further material from Part I will be explicitly referenced where it is required.

From the conditions given by Noren [18] and by a comparison between (1.17) and (1.18), we can conjecture that the regularity requirements on the initial data may be reduced to that, a sharper case given by McLean and Thomée [17, Thm. 4.2]. They considered an exponential decay kernel and obtained the exponential decay error bounds in the norm $l_t^\infty(0,\infty;H)$ based on the same time discretization scheme. These error bounds imply the estimate (1.32) below. The completely monotonic kernel (1.2) does not have exponential decay. As examples, consider the following three kernels all satisfying (1.2) but neither (A1) nor (A2) of [17]: (i) $\beta(t) = (1+t)^{-1}$, (ii) $\beta(t) = t^{-1/2}$, (iii) $\beta(t) = t^{-1/2}[\log(t+3)]^{-1}$. Thus one cannot apply McLean and Thomée's [17] results in the present case. Note that the exponential decay kernels given by [17] are completely monotonic as well and satisfy (1.2); in particular, the exponential kernel $\beta(t) = e^{-t}$ satisfies (1.2), (1.11), and $\beta(0^+) = 1 < \infty$. Thus, for this type of kernel Theorem 1 holds and from [18, Thm. 2.5(a)] (1.10) holds, but Corollary 1 cannot follow because it does not satisfy (1.30) (see [3]). Lubich, Sloan, and Thomée [16] considered the classical weakly singular kernel $\beta(t) = t^{-\alpha}$ $(0 < \alpha < 1)$ and obtained an $l_t^\infty(0,\infty;H)$ estimate for nonsmooth data and positive time. An easy calculation shows that it satisfies (1.2), (1.11), and (1.12), as well as (1.30), but neither (A1) nor (A2) of [17]. With this class of kernels, (1.10) holds, and in a forthcoming paper we shall investigate in detail how to reduce the spatial regularity requirement on the initial data in the estimate (1.31), and on the contrary increase the regularity requirement in Theorem 3.2 of [16]] to derive a sharper l^1 estimate (1.32) below. Seeking sufficient and necessary conditions in order that (1.31) hold when the spatial regularity is reduced further, from $A^2 u_0 \in H$ to $Au_0 \in H$, requires further investigation. We guess that the conditions which yield that (1.10) holds guarantee that (1.32) below holds.

We close the introduction with the following.

Conjecture. If $\beta(t)$ satisfies (1.2), (1.11), and (1.12), then for the solutions of (1.3) and (1.1), and for k sufficiently small, we have that

$$k \sum_{n=1}^{\infty} \|U^n - u(t_n)\| \le C\, k\, \|u_0\|_2. \tag{1.32}$$

2. Preliminaries. We collect here some known results concerning $\phi, \theta, u(t,\lambda)$. Except where noted, only (1.7) is assumed to hold. In the papers cited, some of

the inequalities are proved for the case where $\beta(\infty) = 0$; the extension to our more general situation is straightforward.

Under the assumptions (1.7) and (1.8), by [1, (4.36)] we have the formula

$$u(t,\lambda) = \mathrm{Re}\,[\lambda^{-1}u_1(t) + \lambda^{-2}u_2(t) + \lambda^{-3}u_3(t) + u_4(t,\lambda) + u_5(t,\lambda) + u_6(t,\lambda)], \tag{2.1}$$

where

$$u_1(t) = \frac{1}{\pi\, t}\int_0^{\varepsilon} e^{i\theta\, t}\,\frac{\widehat{\beta}'(i\theta)\,d\theta}{[\widehat{\beta}(i\theta)]^2}, \tag{2.2}$$

$$u_2(t) = \frac{1}{\pi\, t}\int_0^{\varepsilon} e^{i\theta\, t}\,\frac{1}{[\widehat{\beta}(i\theta)]^2}\left(1 - \frac{2\,i\theta\widehat{\beta}'(i\theta)}{\widehat{\beta}(i\theta)}\right) d\theta,$$

$$u_3(t) = -\frac{1}{\pi\, t}\int_0^{\varepsilon} e^{i\theta\, t}\,\frac{2\,i\theta\,d\theta}{[\widehat{\beta}(i\theta)]^3},$$

$$u_4(t,\lambda) = \frac{1}{\pi\, t\,\lambda^3}\int_0^{\varepsilon} e^{i\theta\, t}\,\frac{(i\theta)^2\,D_s(i\theta;\lambda)}{[\widehat{\beta}(i\theta)]^2\,D(i\theta;\lambda)}\left(\frac{2}{\widehat{\beta}(i\theta)} + \frac{1}{D(i\theta;\lambda)}\right) d\theta,$$

$$u_5(t,\lambda) = \frac{1}{\pi\, t\,\lambda}\int_{\varepsilon}^{\frac{\pi}{k}} e^{i\theta\, t}\,\frac{D_s(i\theta;\lambda)}{[D(i\theta;\lambda)]^2}\,d\theta,$$

$$u_6(t,\lambda) = \frac{1}{\pi\, t\,\lambda}\int_{\frac{\pi}{k}}^{\infty} e^{i\theta\, t}\,\frac{D_s(i\theta;\lambda)}{[D(i\theta;\lambda)]^2}\,d\theta.$$

By [5], $\infty \geq \lim_{\tau\to 0^+}|\widetilde{\beta}(\tau)| = \int_0^{\infty}\beta(t)dt > 0$, so there exists an $\varepsilon > 0$ such that

$$|\widetilde{\beta}(\tau)| > 2\tau \qquad (0 < \tau \leq \varepsilon). \tag{2.3}$$

As in [1] (see also [3]), we can define an increasing function $\omega(\lambda) : [\lambda_0,\infty) \to [2\varepsilon,\infty)$ (here $\lambda_0 \geq 1$ and sufficiently large) with $\omega(\lambda) \to \infty\,(\lambda\to\infty)$ and

$$\theta(\omega(\lambda)) = \frac{1}{\lambda} \qquad (\lambda_0 \leq \lambda < \infty). \tag{2.4}$$

We extend ω to $[\lambda_1,\infty)$ if necessary by defining $\omega(\lambda) = 2\varepsilon$ $(\lambda_1 \leq \lambda \leq \lambda_0)$.

From [1, (4.24)] and [2, (2.10) and (2.11)], there exist positive constants c and C such that

$$c\,\lambda^{1/2} \leq \omega(\lambda) \leq C\,\lambda \quad (\lambda_1 \leq \lambda). \tag{2.5}$$

By [1, Lem. 4.1 and 5.2] and [2, Lem. 5.2] (see also [19]), $\phi(\tau)$ is continuously

differentiable on R^+, and there exists a positive constant C such that

$$\frac{1}{2\sqrt{2}}\,A(\tau^{-1}) \,\le\, |\widetilde{\beta}(\tau)| \,\le\, 4\,A(\tau^{-1}) \qquad (\tau \,>\, 0), \tag{2.6}$$

$$\frac{1}{5}\,A_1(\tau^{-1}) \,\le\, \theta(\tau) \,\le\, 12\,A_1(\tau^{-1}) \qquad (\tau \,>\, 0), \tag{2.7}$$

$$|\widetilde{\beta}'(\tau)| \,\le\, 40\,A_1(\tau^{-1}) \qquad (\tau \,>\, 0), \tag{2.8}$$

$$|D(i\tau;\lambda)| \,\ge\, C\,(\tau\theta(\tau) \,+\, |\widetilde{\beta}(\tau)|) \qquad \left(\varepsilon \le \tau \le \frac{\omega(\lambda)}{2}\right), \tag{2.9}$$

$$|D(i\tau;\lambda)|^2 \,\ge\, C\,\left(\phi^2(\tau) \,+\, \left(\frac{\tau-\omega}{\lambda}\right)^2\right) \qquad (\tau \ge \varepsilon). \tag{2.10}$$

By [1, Lem. 5.1], (1.8) implies that

$$|\widetilde{\beta}''(\tau)| \,\le\, 6000\int_0^{\frac{1}{\tau}} t^2\,\beta(t)\,dt \qquad (\tau \,>\, 0). \tag{2.11}$$

We recall an estimate of Shea and Wainger [19, (1.21)], namely,

$$\int_0^{\varepsilon} \frac{A_1(\tau^{-1})}{A^2(\tau^{-1})}\,d\tau \,<\, \infty. \tag{2.12}$$

Finally, we remark that

$$\phi(\tau) \,>\, 0, \qquad \tau \,>\, 0, \tag{2.13}$$

except for certain piecewise linear kernels β for which $\phi(\tau)$ vanishes on a sequence tending to infinity [5, Lem. 4]. This fact, together with (2.7), implies that (2.13) holds whenever $\limsup_{\tau\to\infty} \frac{\theta(\tau)}{\phi(\tau)} < \infty$. Note that (2.1) holds with (2.13) instead of (1.8).

3. Proof of Theorem 2. From now on, unless noted otherwise, we assume that (1.2) holds. Let ε denote an appropriately small positive constant, independent of k, n, and let C denote a positive constant which depends only on ε; λ_1, the value of C, may change from line to line. We introduce the notation

$$\sigma \,=\, \sigma(k,\theta) \,=\, \frac{1-\cos\,k\theta}{k}, \quad \tau \,=\, \tau(k,\theta) \,=\, \frac{\sin\,k\theta}{k},$$

$$s \,=\, s(k,\theta) \,=\, \sigma + \,i\,\tau \,=\, \frac{1-e^{-i\,k\theta}}{k}.$$

Multiplying (1.19) by z^n, and then summing from $n = 1$ to infinity, we find that

$$\widetilde{U}(z,\lambda) \,=\, U^1(\lambda)\,z \,+\, U^2(\lambda)\,z^2 \,+\cdots+\, U^n(\lambda)\,z^n \,+\cdots$$

satisfies

$$\widetilde{U}(z,\lambda) \,=\, \frac{z}{k}\,\frac{1}{\left(\frac{1-z}{k}\right) \,+\, \lambda\,\widehat{\beta}\left(\frac{1-z}{k}\right)} \,=\, \frac{z}{k}\,\widehat{u}\left(\frac{1-z}{k},\lambda\right), \tag{3.1}$$

where $\widehat{u}(s,\lambda)$ is the Laplace transform of the solution of problem (1.5).

Set $V^n(\lambda) = U^n(\lambda) - 1$. Then the generating function

$$\widetilde{V}(z,\lambda) \;=\; \sum_{n=0}^{\infty} V^n(\lambda)\, z^n$$

obeys the relation

$$\widetilde{V}(z,\lambda) \;=\; \frac{z}{k}\,\widehat{K}\left(\frac{1-z}{k},\lambda\right), \tag{3.2}$$

with

$$\widehat{K}(s,\lambda) \;=\; -\;\frac{\widehat{\beta}(s)}{s\,D(s;\lambda)}.$$

This function is analytic at $z=0$, so that $\widetilde{V}(z,\lambda)$ has a positive radius of convergence, and hence, for ρ sufficiently small,

$$\begin{aligned} V^n(\lambda) \;&=\; \frac{1}{2\pi\, i}\int_{|\zeta|=\rho} \zeta^{-n-1}\,\widetilde{V}(\zeta,\lambda)\,d\zeta \\ &=\; \frac{k^{-1}}{2\pi\, i}\int_{|\zeta|=\rho} \zeta^{-n}\,\widehat{K}\left(\frac{1-\zeta}{k},\lambda\right)\,d\zeta. \end{aligned} \tag{3.3}$$

We now change variables $\zeta = e^{-kz}$ and deform the resulting contour

$$\left\{z = k^{-1}\,\log(1/\rho) \;+\; i\,y; |y| \le\; \frac{\pi}{k}\right\}$$

to

$$\Gamma_k = \left\{z = i\tau, |\tau| \le\; \frac{\pi}{k}\right\}$$

(note that $\widehat{K}\big(\frac{1-e^{-z\,k}}{k};\lambda\big)$ is analytic in $\prod^+ = \{z:\ \operatorname{Re} z \;\ge\; 0,\ z \neq 0\}$ and the contributions from the line segments on $\operatorname{Im} z = \pm\frac{\pi}{k}$ cancel by periodicity), and we get

$$V^n(\lambda) \;=\; \operatorname{Re}\left\{\frac{1}{\pi}\int_0^{\frac{\pi}{k}}\; e^{i\theta\, t_{n-1}}\,\widehat{K}\left(\frac{1-e^{-i\,\theta\,k}}{k},\lambda\right)\,d\theta\right\}. \tag{3.4}$$

On the other hand, if we let $v(t,\lambda) = u(t,\lambda) - 1$, then its Laplace transform is

$$\widehat{v}(z,\lambda) \;=\; \widehat{u}(z,\lambda) \;-\; \frac{1}{z} \;=\; \widehat{K}(z,\lambda).$$

Thus, by applying the Laplace inversion formula, since $\widehat{K}(z,\lambda)$ is analytic in $\prod^+$,

$$v(t_n,\lambda) \;=\; \operatorname{Re}\left\{\frac{1}{\pi}\;\int_0^{\infty}\; e^{i\theta\, t_n}\;\widehat{K}(i\theta,\lambda)\,d\theta\right\}. \tag{3.5}$$

Subtracting (3.5) from (3.4), we obtain

$$\begin{aligned} U^n(\lambda) \;-\; u(t_n,\lambda) \;=\; \frac{1}{\pi}\operatorname{Re}\{&V_1^n(\lambda) \;-\; v_1(t_n,\lambda) \;+\; V_2^n(\lambda) \;-\; v_2(t_n,\lambda) \\ &+\; V_3^n(\lambda) \;-\; v_3(t_n,\lambda) \;-\; v_4(t_n,\lambda)\}, \end{aligned} \tag{3.6}$$

where

$$V_1^n(\lambda) - v_1(t_n,\lambda) = E_{1,1}^n(\lambda) + E_{1,2}^n(\lambda) \tag{3.7}$$
$$= \int_0^{\varepsilon} e^{i\theta\, t_{n-1}}\,(1 - e^{i\theta\, k})\,\widehat{K}(i\theta,\lambda)\,d\theta$$
$$+ \int_0^{\varepsilon} e^{i\theta\, t_{n-1}}\,(\widehat{K}(s,\lambda) - \widehat{K}(i\theta,\lambda))\,d\theta,$$

$$V_2^n(\lambda) - v_2(t_n,\lambda) = E_{2,1}^n(\lambda) + E_{2,2}^n(\lambda) \tag{3.8}$$
$$= \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_{n-1}}\,(1 - e^{i\theta\, k})\,\widehat{K}(i\theta,\lambda)\,d\theta$$
$$+ \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_{n-1}}\,(\widehat{K}(s,\lambda) - \widehat{K}(i\theta,\lambda))\,d\theta,$$

$$V_3^n(\lambda) - v_3(t_n,\lambda) = \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_{n-1}}\,\widehat{K}(s,\lambda)\,d\theta \tag{3.9}$$
$$- \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_n}\,\widehat{K}(i\theta,\lambda)\,d\theta,$$

$$v_4(t_n,\lambda) = \int_{\frac{\pi}{k}}^{\infty} e^{i\theta\, t_n}\,\widehat{K}(i\theta,\lambda)\,d\theta. \tag{3.10}$$

If $\beta(\infty) > 0$, then (2.6) shows that

$$|\widetilde{\beta}(\tau)| \le C\,\tau^{-1} \qquad (0 < \tau \le \varepsilon),$$

and (2.13) gives us

$$|D(i\tau;\lambda)| \ge \max\left\{\phi(\tau),\ \frac{\beta(\infty)-\tau^2}{\tau}\right\} \ge \frac{C}{\tau},\quad 0<\tau\le\varepsilon. \tag{3.11}$$

Thus,

$$\int_0^{\varepsilon} \frac{|\widetilde{\beta}(\tau)|}{|D(i\tau;\lambda)|}\,d\tau \le C. \tag{3.12}$$

On the other hand, if $\beta(\infty) = 0$, then (2.6) implies that $|\widetilde{\beta}(\tau)| \le 4\,A(\tau^{-1})$ and

$$|D(i\tau;\lambda)| \ge \max\left\{2^{-3/2}A(\tau^{-1}) - \tau,\ \phi(\tau)\right\}, \tag{3.13}$$

so (3.12) is again valid. Then a simple estimate and (3.12) lead to

$$|E_{1,1}^n(\lambda)| \le C\,k\int_0^{\varepsilon} \theta\,|\widehat{K}(i\theta,\lambda)|\,d\theta \tag{3.14}$$
$$= C\,k\int_0^{\varepsilon} \frac{|\widetilde{\beta}(\theta)|}{|D(i\theta;\lambda)|}\,d\theta \le C\,k\,.$$

We remark that (3.14) holds without the assumption (1.2), which needs only (1.7) and (2.13).

By the mean-value theorem we have that

$$|E^n_{1,2}(\lambda)| \;\le\; C\,k \int_0^\varepsilon \theta^2\,|\widehat{K}'(s_1,\lambda)|\,d\theta, \tag{3.15}$$

where $s_1 = s_1(k,\theta) = \sigma_1(k,\theta)+i\tau_1(k,\theta)$, with $0 \le \sigma_1 < \sigma(k,\theta),\ \tau(k,\theta) \le \tau_1(k,\theta) < \theta$, and

$$\widehat{K}'(s,\lambda) \;=\; -\frac{\widehat{\beta}'(s)}{s\,D(s;\lambda)} \;+\; \frac{\widehat{\beta}(s)}{s^2\,D(s;\lambda)} \;+\; \frac{\widehat{\beta}(s)\,D_s(s;\lambda)}{s\,D^2(s;\lambda)}.$$

In Part I [3, (3.8) and (3.10)] we have proved that when (1.2) holds and $0 \le \theta \le \varepsilon$,

$$c_0\,\theta \;\le\; \tau(k,\theta) \;\le\; \theta, \tag{3.16}$$

$$|D(\sigma_1+i\tau_1;\lambda)| \ge\; \frac{1}{10\sqrt{2}}\,|\widetilde{\beta}(\tau_1)| \ge\; \frac{1}{160}\,|\widetilde{\beta}(\varepsilon)|, \tag{3.17}$$

and for $\sigma_1 \ge 0,\ \tau_1 > 0$ (see [3, (3.13) and (3.14)]),

$$|\widehat{\beta}(\sigma_1+i\tau_1)| \le\; 4\,|\widetilde{\beta}(\tau_1)|, \tag{3.18}$$

$$|\widehat{\beta}'(\sigma_1+i\tau_1)| \;\le\; \theta(\tau_1), \tag{3.19}$$

with $c_0 < 1$ as close as we like to 1.

Combining these estimates, (2.6), and (2.7) yields, when $0 \le \theta \le \varepsilon$,

$$|D(\sigma_1+i\tau_1;\lambda)| \ge\; C\,|\widetilde{\beta}(\tau)|, \tag{3.20}$$

and for $\sigma_1 \ge 0,\ \tau_1 \ge \tau > 0$,

$$|\widehat{\beta}(\sigma_1+i\tau_1)| \le\; C\,|\widetilde{\beta}(\tau)|, \tag{3.21}$$

$$|\widehat{\beta}'(\sigma_1+i\tau_1)| \;\le\; C\,\theta(\tau), \tag{3.22}$$

so that, after trivial estimates, some simple computations, and using (3.20) through (3.22), (2.6), and (2.7),

$$\begin{aligned}
\int_0^\varepsilon \theta^2\,|\widehat{K}'(s_1,\lambda)|\,d\theta \;&\le\; \int_0^\varepsilon \theta^2\,\frac{|\widehat{\beta}'(s_1)|}{|s_1||D(s_1;\lambda)|}\,d\theta \\
&+\; \int_0^\varepsilon \theta^2\,\frac{|\widehat{\beta}(s_1)|}{|s_1|^2|D(s_1;\lambda)|}\,d\theta \;+\; \int_0^\varepsilon \theta^2\,\frac{|\widehat{\beta}(s_1)||D_s(s_1;\lambda)|}{|s_1||D(s_1;\lambda)|^2}\,d\theta \\
&\le\; C\left[\int_0^\varepsilon \frac{\tau\theta(\tau)}{|\widetilde{\beta}(\tau)|}\,d\tau \;+\; \int_0^\varepsilon \frac{|\widetilde{\beta}(\tau)|}{|\widetilde{\beta}(\tau)|}\,d\tau\right. \\
&+\; \left.\int_0^\varepsilon \frac{\tau\,|\widetilde{\beta}(\tau)||\lambda^{-1}+\theta(\tau)|}{|\widetilde{\beta}(\tau)|^2}\,d\tau\right] \;\le\; C.
\end{aligned} \tag{3.23}$$

Combining (3.15) and (3.23) shows

$$|E^n_{1,2}(\lambda)| \le C\,k. \tag{3.24}$$

From (3.7), (3.14), and (3.24) we obtain

$$|V^n_1(\lambda) - v_1(t_n,\lambda)| \le C\,k. \tag{3.25}$$

Next we consider the estimate of $E^n_{2,1}(\lambda)$. After trivial estimates we obtain that

$$|E^n_{2,1}(\lambda)| \le C\,k \int_\varepsilon^{\frac{\varepsilon}{k}} \frac{|\widetilde{\beta}(\theta)|}{D(i\theta;\lambda)|}\,d\theta. \tag{3.26}$$

In order to bound the integral of (3.26) we split it into five cases according to the position relation of ω and $\frac{\varepsilon}{k}$. We use the estimates of (2.9) and (2.10) for lower bounds on $|D(i\theta;\lambda)|$. Inequality (2.6) will give upper bounds on the numerators.

For the remainder of the proof, the estimates (1.27) and (2.4)–(2.8) will be exploited throughout without explicit mention.

Case 1. If $\omega+\varepsilon < \frac{\varepsilon}{k}$, then (2.9) and (2.10) imply

$$\begin{aligned}\int_\varepsilon^{\frac{\varepsilon}{k}} \frac{|\widetilde{\beta}(\theta)|}{D(i\theta;\lambda)|}\,d\theta &= \int_\varepsilon^{\frac{\omega}{2}} + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} + \int_{\omega-\varepsilon}^{\omega+\varepsilon} + \int_{\omega+\varepsilon}^{\frac{\varepsilon}{k}}. \\ &\le C\left(\int_\varepsilon^{\frac{\omega}{2}} d\tau + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} \frac{\lambda}{|\tau-\omega|}\,d\tau + \int_{\omega-\varepsilon}^{\omega+\varepsilon} \frac{1}{\phi(\tau)}\,d\tau\right. \\ &\quad \left. + \lambda\int_{\omega+\varepsilon}^{\frac{\varepsilon}{k}} \frac{|\widehat{\beta}(i\,\tau)|}{|\tau-\omega|}\,d\tau\right) \\ &\le C\,(\lambda + \lambda^2 + \lambda\,|\log k|).\end{aligned} \tag{3.27}$$

Case 2. If $\omega < \frac{\varepsilon}{k} \le \omega+\varepsilon$, then, again using (2.9) and (2.10), we obtain

$$\begin{aligned}\int_\varepsilon^{\frac{\varepsilon}{k}} \frac{|\widetilde{\beta}(\theta)|}{D(i\theta;\lambda)|}\,d\theta &= \int_\varepsilon^{\frac{\omega}{2}} + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} + \int_{\omega-\varepsilon}^{\omega+\varepsilon}. \\ &\le C\left(\int_\varepsilon^{\frac{\omega}{2}} d\tau + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} \frac{\lambda}{|\tau-\omega|}\,d\tau + \int_{\omega-\varepsilon}^{\omega+\varepsilon} \frac{1}{\phi(\tau)}\,d\tau\right) \\ &\le C\,(\lambda + \lambda^2).\end{aligned} \tag{3.28}$$

Case 3. If $\omega-\varepsilon < \frac{\varepsilon}{k} \le \omega$ or $\frac{\omega}{2} < \frac{\varepsilon}{k} \le \omega-\varepsilon$ or $\frac{\varepsilon}{k} \le \frac{\omega}{2}$, then we have

$$\int_\varepsilon^{\frac{\varepsilon}{k}} \frac{|\widetilde{\beta}(\theta)|}{D(i\theta;\lambda)|}\,d\theta \le C\,(\lambda+\lambda^2). \tag{3.29}$$

For example, when $\omega-\varepsilon < \frac{\varepsilon}{k} \le \omega$, by (2.9) and (2.10)

$$\begin{aligned}\int_\varepsilon^{\frac{\varepsilon}{k}} \frac{|\widetilde{\beta}(\theta)|}{D(i\theta;\lambda)|}\,d\theta &= \int_\varepsilon^{\frac{\omega}{2}} + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} + \int_{\omega-\varepsilon}^{\omega}. \\ &\le C\left(\int_\varepsilon^{\frac{\omega}{2}} d\tau + \int_{\frac{\omega}{2}}^{\omega-\varepsilon} \frac{\lambda}{|\tau-\omega|}\,d\tau + \int_{\omega-\varepsilon}^{\omega} \frac{1}{\phi(\tau)}\,d\tau\right) \\ &\le C\,(\lambda + \lambda^2).\end{aligned} \tag{3.30}$$

Together the above five estimates yield

$$|E^n_{2,1}(\lambda)| \le C\,k\lambda^2|\log k|. \tag{3.31}$$

Now we turn to the estimate of $E^n_{2,2}(\lambda)$. First, applying the mean-value theorem we have

$$|E^n_{2,2}(\lambda)| \le C\,k\int_\varepsilon^{\frac{\varepsilon}{k}} \theta^2|\widehat{K}'(s_1,\lambda)|d\theta. \tag{3.32}$$

Then, comparing (3.32) with (3.15) and (3.23), we find that the integrand of (3.32) has the same form as these, so that

$$\begin{aligned}\int_\varepsilon^{\frac{\varepsilon}{k}} \theta^2|\widehat{K}'(s_1,\lambda)|d\theta \le C\,\Bigg(&\int_{c_0\varepsilon}^{\frac{\varepsilon}{k}} \tau^2\frac{|\widehat{\beta}'(s_1)|}{|s_1|\,|D(s_1;\lambda)|}\,d\tau\\ &+\int_{c_0\varepsilon}^{\frac{\varepsilon}{k}} \tau^2\frac{|\widehat{\beta}(s_1)|}{|s_1|^2\,|D(s_1;\lambda)|}\,d\tau+\int_{c_0\varepsilon}^{\frac{\varepsilon}{k}} \tau^2\frac{|\widehat{\beta}(s_1)|\,|D_s(s_1;\lambda)|}{|s_1|\,|D(s_1;\lambda)|^2}\,d\tau\Bigg),\end{aligned} \tag{3.33}$$

where c_0 is given by (3.34) below.

Here we have to bound the various terms on the right-hand side. For this purpose we recall from Part I [3, (3.22), (2.10), (3.23), and (3.24)] that, in the case $\varepsilon \le \theta \le \frac{\varepsilon}{k}$,

$$c_0\theta \le \tau(k,\theta) \le \theta, \tag{3.34}$$

$$|D(s_1;\lambda)| \ge \phi(\sigma_1,\tau_1) \ge C\,\phi(\tau_1), \tag{3.35}$$

$$|D(s_1;\lambda)| \ge C\left(\tau_1\,\theta(\tau_1) + A(\tau_1^{-1})\right), \quad \tau \in \left[c_0\varepsilon, \frac{c_0\omega}{2}\right] \cap \left[c_0\varepsilon, \frac{c_0\varepsilon}{k}\right], \tag{3.36}$$

$$|D(s_1;\lambda)| \ge C\frac{|\tau_1-\omega|}{\lambda}, \ \ \omega < \frac{\omega}{1-\widetilde{\varepsilon}} \le \tau, \ \ \widetilde{\varepsilon} \le \frac{1}{2}. \tag{3.37}$$

where $c_0 < 1$ can be chosen arbitrarily close to 1.

Also, using the definition of $\phi(\tau)$ in the introduction, we have that, when $\varepsilon \le \theta \le \frac{\varepsilon}{k}$,

$$\begin{aligned}|\phi(\tau)-\phi(\tau_1)| &= \left|\int_0^\infty \frac{x(\tau_1+\tau)(\tau_1-\tau)}{(x^2+\tau^2)(x^2+\tau_1^2)}\,d\alpha(x)\right|\\ &\le C\int_0^\infty \frac{x\theta(\theta-\tau)}{(x^2+\tau^2)\theta^2}\,d\alpha(x) \le C\,\varepsilon_1\,\phi(\tau),\end{aligned} \tag{3.38}$$

with $\left|\frac{\sin k\theta}{k\theta}-1\right| \le \varepsilon_1$ appropriately small.

Thus, these estimates, along with (2.6) and (2.7), give us, for $\varepsilon \le \theta \le \frac{\varepsilon}{k}$,

$$|D(s_1;\lambda)| \ge C\,\phi(\tau), \tag{3.39}$$

$$|D(s_1;\lambda)| \ge C\left(\tau\,\theta(\tau) + A(\tau^{-1})\right), \quad \tau \in \left[c_0\varepsilon, \frac{c_0\omega}{2}\right] \cap \left[c_0\varepsilon, \frac{c_0\varepsilon}{k}\right], \tag{3.40}$$

$$|D(s_1;\lambda)| \ge C\frac{|\tau-\omega|}{\lambda}, \ \ \omega < \frac{\omega}{1-\widetilde{\varepsilon}} \le \tau, \ \ \widetilde{\varepsilon} \le \frac{1}{2}. \tag{3.41}$$

In order to obtain a similar bound on (3.33), we split it into three cases. The estimates (3.21) and (3.22) will be used for estimates of the numerators. Inequalities (3.39)–(3.41) will give lower bounds on $|D(s_1;\lambda)|$, but in the proof below these estimates will be mentioned without going into detail.

When $2\,\omega < \frac{\varepsilon}{k}$,

$$\int_{\varepsilon}^{\frac{\varepsilon}{k}} \theta^2\,|\widehat{K}'(s_1,\lambda)|\,d\theta \;\le\; \left[\int_{c_0\varepsilon}^{\frac{c_0\omega}{2}} + \int_{\frac{c_0\omega}{2}}^{2\omega} + \int_{2\omega}^{\frac{\varepsilon}{k}}\ .\right] \tag{3.42}$$

$$\le\; C\left(\int_{c_0\,\varepsilon}^{\frac{c_0\omega}{2}} \left(1+\frac{\lambda^{-1}}{\theta(\tau)}\right)\,d\tau + \int_{\frac{c_0\omega}{2}}^{2\omega}\left(\frac{1}{\phi(\tau)}+\frac{\tau\,\lambda^{-1}}{\phi^2(\tau)}\right)\,d\tau\right.$$

$$\left. +\lambda\int_{2\omega}^{\frac{\varepsilon}{k}} \frac{|\widehat{\beta}(i\,\tau)|}{\tau-\omega}d\tau\right)$$

$$\le\; C\,(\lambda\;+\;\lambda^2\;+\;\lambda^3\;+\;\lambda\,|\log k|),$$

where we have used (see [1, (6.8)])

$$\theta(\tau)\;\le\; C\,\lambda^{-1},\qquad \tau\ge\;\frac{c_0\omega}{2}, \tag{3.43}$$

and an easily obtained inequality

$$|\widetilde{\beta}(\tau)|\le\;4\int_0^{\frac{1}{\tau}}\beta(t)\,dt \tag{3.44}$$

$$\le\;4\int_0^{\frac{1}{\varepsilon_0}}\beta(t)\,dt\;=\;C(\varepsilon_0)\,,\qquad \tau\ge\varepsilon_0.$$

When $\frac{\omega}{2}\le\;\frac{\varepsilon}{k}\le\;2\omega$,

$$\int_{\varepsilon}^{\frac{\varepsilon}{k}}\theta^2\,|\widehat{K}'(s_1,\lambda)|\,d\theta\le\left[\int_{c_0\varepsilon}^{\frac{c_0\omega}{2}}+\int_{\frac{c_0\omega}{2}}^{2\omega}\ .\right] \tag{3.45}$$

$$\le\;C\left(\int_{c_0\,\varepsilon}^{\frac{c_0\omega}{2}}\left(1\;+\;\frac{\lambda^{-1}}{\theta(\tau)}\right)\,d\tau\;+\;\int_{\frac{c_0\omega}{2}}^{2\omega}\left(\frac{1}{\phi(\tau)}\;+\;\frac{\tau\,\lambda^{-1}}{\phi^2(\tau)}\right)\,d\tau\;\right)$$

$$\le\;C\,(\lambda\;+\;\lambda^2\;+\;\lambda^3\;).$$

When $\frac{\varepsilon}{k}<\frac{\omega}{2}$,

$$\int_{\varepsilon}^{\frac{\varepsilon}{k}}\theta^2\,|\widehat{K}'(s_1,\lambda)|\,d\theta\le\left[\int_{c_0\varepsilon}^{\frac{c_0\omega}{2}}+\int_{\frac{c_0\omega}{2}}^{\frac{\omega}{2}}\ .\right] \tag{3.46}$$

$$\le\;C\left(\int_{c_0\,\varepsilon}^{\frac{c_0\omega}{2}}\left(1\;+\;\frac{\lambda^{-1}}{\theta(\tau)}\right)\,d\tau\;+\;\int_{\frac{c_0\omega}{2}}^{\frac{\omega}{2}}\left(\frac{1}{\phi(\tau)}\;+\;\frac{\tau\,\lambda^{-1}}{\phi^2(\tau)}\right)\,d\tau\;\right)$$

$$\le\;C\,(\lambda\;+\;\lambda^2\;+\;\lambda^3\;).$$

Together these three estimates and (3.32), (3.33) show that

$$|E^n_{2,2}(\lambda)| \;\le\; C\,k\,|\log\,k|\,\lambda^3. \tag{3.47}$$

Combining (3.31) and (3.47) we have obtained that

$$|V^n_2(\lambda) \;-\; v_2(t_n,\lambda)| \;\le\; C\,k\,|\log\,k|\;\lambda^3. \tag{3.48}$$

For the estimate of $V^n_3(\lambda)$ we recall from Part I [3, (3.18) and (3.19)] that when $\frac{\varepsilon}{k} \le \theta \le \frac{\pi}{k}$,

$$\sigma(k,\theta) \;\ge\; \frac{1-\cos\,\varepsilon}{k} = \frac{C(\varepsilon)}{k}, \;\; |D(\sigma+i\tau;\lambda)| \ge \;\frac{\sigma}{\lambda} \ge \;\frac{C(\varepsilon)}{k\lambda}, \tag{3.49}$$

and for $\sigma \ge 0$,

$$|\widehat{\beta}(\sigma+i\tau)| \le \int_0^\infty \;\frac{d\alpha(x)}{x+\sigma} = \widehat{\beta}(\sigma). \tag{3.50}$$

We use (3.49) and (3.50) to obtain

$$\begin{aligned} |V^n_3(\lambda)| \;&\le\; \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} \;|\widehat{K}(s,\lambda)|\;d\theta \\ &\le C\,k\int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} \;\frac{|\widehat{\beta}(\sigma)|\lambda}{\sigma}\;d\theta \;\le\; C\,k\int_0^{\frac{k}{c(\varepsilon)}} \;\beta(t)\;dt\;\lambda. \end{aligned} \tag{3.51}$$

Finally, we will derive an estimate on

$$|v_3(t_n,\lambda)| \;+\; |v_4(t_n,\lambda)| \;\le\; \int_{\frac{\varepsilon}{k}}^\infty \;|\widehat{K}(i\theta,\lambda)|\;d\theta. \tag{3.52}$$

In the case $2\omega < \frac{\varepsilon}{k}$,

$$\begin{aligned} \int_{\frac{\varepsilon}{k}}^\infty \;|\widehat{K}(i\theta,\lambda)|\;d\theta \;&\le\; \int_{\frac{\varepsilon}{k}}^\infty \;\frac{\lambda|\widehat{\beta}(i\theta)|}{\theta|\theta-\omega|}\;d\theta \\ &\le\; C\,k\,\lambda\int_0^{\frac{k}{\varepsilon}} \;\beta(t)\;dt. \end{aligned} \tag{3.53}$$

In the case $\omega < \frac{\varepsilon}{k} \le\; 2\omega$ or $\frac{\omega}{2} \le\; \frac{\varepsilon}{k} \le\; \omega$,

$$\begin{aligned} \int_{\frac{\varepsilon}{k}}^\infty \;|\widehat{K}(i\theta,\lambda)|\;d\theta \;&\le\; \int_0^{\frac{k}{\varepsilon}} \;\beta(t)\;dt\;\left(\frac{k}{\varepsilon}\int_{\frac{\varepsilon}{k}}^{2\omega} \;\frac{d\theta}{\phi(\theta)} \;+\; \int_{2\omega}^\infty \frac{\lambda\,d\theta}{\theta(\theta-\omega)}\right) \\ &\le\; C\,k\,\lambda^2\int_0^{\frac{k}{\varepsilon}} \;\beta(t)\;dt. \end{aligned} \tag{3.54}$$

In the case $\frac{\varepsilon}{k} < \frac{\omega}{2}$,

$$\int_{\frac{\varepsilon}{k}}^\infty \;|\widehat{K}(i\theta,\lambda)|\;d\theta \;\le\; \int_{\frac{\varepsilon}{k}}^{\frac{\omega}{2}} \;.\; +\; \int_{\frac{\omega}{2}}^{2\omega} \;.\; +\; \int_{2\omega}^\infty \;.\; \le\; C\,k\int_0^{\frac{k}{\varepsilon}} \;\beta(t)\;dt\;(\lambda+\lambda^2). \tag{3.55}$$

Taken together with (3.53)–(3.55), this shows that

$$\int_{\frac{\varepsilon}{k}}^{\infty} |\widehat{K}(i\theta,\lambda)|\, d\theta \;\le\; C\,k\,\lambda^2 \int_0^{\frac{k}{\varepsilon}} \beta(t)\, dt. \tag{3.56}$$

Using (3.6)–(3.10), (3.25), (3.48), (3.51), (3.52), and (3.56), and combining (1.13) and (1.20), we have completed the proof of Theorem 2.

Remark 3.1. If adding the condition (1.30), then we can show that

$$|E^n_{2,2}(\lambda)| \;\le\; C\,k\,(\lambda+\lambda^2+\lambda\,|\log k|), \tag{3.47$'$}$$

and hence, we have the improved estimate

$$\|U^n - u(t_n)\| \;\le\; C\,k\,|\log k|\;\|u_0\|_4 \qquad \text{for } n \ge 0. \tag{3.57}$$

Remark 3.2. We guess that a thorough analysis may remove the factor $|\log k|$ from (1.21). On the other hand if we add the conditions (1.11) on the kernel $\beta(t)$, then we have that, in the case $\omega+\varepsilon < \frac{\varepsilon}{k}$,

$$\int_{\omega+\varepsilon}^{\frac{\varepsilon}{k}} \frac{|\widehat{\beta}(i\,\tau)|}{|\tau-\omega|}\, d\tau \;\le\; C, \tag{3.58}$$

and when $2\,\omega < \frac{\varepsilon}{k}$,

$$\int_{2\,\omega}^{\frac{\varepsilon}{k}} \frac{|\widehat{\beta}(i\,\tau)|}{|\tau-\omega|}\, d\tau \;\le\; C, \tag{3.59}$$

so that we obtain the desired estimate

$$\|U^n \;-\; u(t_n)\| \;\le\; C\;k\;\|u_0\|_6 \;\text{ for } n \ge 0. \tag{3.60}$$

4. Proof of Theorem 3. To prove Theorem 3 we need the expressions of (2.1) and (2.2) for the solution of (1.5). Similarly, we recall from [3, (4.7) and (4.8)] that for the solution of (1.19),

$$U^n(\lambda) \;=\; \mathrm{Re}\,[\lambda^{-1}U^n_1 \;+\; \lambda^{-2}U^n_2 \;+\; \lambda^{-3}U^n_3 \;+\; U^n_4(\lambda) \;+\; U^n_5(\lambda)\,], \tag{4.1}$$

where

$$\begin{aligned}
U^n_1 \;&=\; \frac{1}{\pi\,t_{n-1}} \int_0^{\varepsilon} e^{i\theta\,t_{n-2}}\, \frac{\widehat{\beta}'(s)\,d\theta}{[\widehat{\beta}(s)]^2}, \\
U^n_2 \;&=\; \frac{1}{\pi\,t_{n-1}} \int_0^{\varepsilon} e^{i\theta\,t_{n-2}}\, \frac{1}{[\widehat{\beta}(s)]^2} \left(1 \;-\; \frac{2\,s\widehat{\beta}'(s)}{\widehat{\beta}(s)}\right) d\theta, \\
U^n_3 \;&=\; -\;\frac{1}{\pi\,t_{n-1}} \int_0^{\varepsilon} e^{i\theta\,t_{n-2}}\, \frac{2\,s\,d\theta}{[\widehat{\beta}(s)]^3}, \\
U^n_4(\lambda) \;&=\; \frac{1}{\pi\,t_{n-1}\lambda^3} \int_0^{\varepsilon} e^{i\theta\,t_{n-2}}\, \frac{s^2\,D_s(s;\lambda)}{[\widehat{\beta}(s)]^2\,D(s;\lambda)} \left(\frac{2}{\widehat{\beta}(s)} \;+\; \frac{1}{D(s;\lambda)}\right) d\theta, \\
U^n_5(\lambda) \;&=\; \frac{1}{\pi\,t_{n-1}\,\lambda} \int_{\varepsilon}^{\frac{\pi}{k}} e^{i\theta\,t_{n-2}}\, \frac{D_s(s;\lambda)}{[D(s;\lambda)]^2}\, d\theta.
\end{aligned} \tag{4.2}$$

By subtracting (2.1) from (4.1) we can write

(4.3)
$$U^n(\lambda) - u(t_n,\lambda) \;=\; \mathrm{Re}\{\lambda^{-1}(U_1^n - u_1(t_n)) \;+\; \lambda^{-2}(U_2^n - u_2(t_n))$$
$$+\; \lambda^{-3}(U_3^n - u_3(t_n)) \;+\; (U_4^n(\lambda) - u_4(t_n,\lambda)) \;+\; (U_5^n(\lambda) - u_5(t_n,\lambda)) - u_6(t_n,\lambda)\}.$$

We shall estimate the above various terms. The estimates (1.29) and (2.4)–(2.12) will be used throughout without explicit mention.

Estimate 1.

$$|U_1^n \;-\; u_1(t_n)| \;\le\; C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.4}$$

Write $U_1^n - u_1(t_n) \;=\; e_{1,1}^n + e_{1,2}^n + e_{1,3}^n$, where

$$e_{1,1}^n \;=\; \frac{1}{\pi\, t_{n-1}} \int_0^{\varepsilon} e^{i\theta\, t_{n-2}} \left[\widehat{K}_1(s) \;-\; \widehat{K}_1(i\theta)\right] d\theta, \tag{4.5}$$

$$e_{1,2}^n \;=\; \frac{1}{\pi\, t_{n-1}} \int_0^{\varepsilon} e^{i\theta\, t_{n-2}} (1 \;-\; e^{2i\theta\, k})\, \widehat{K}_1(i\theta)\, d\theta, \tag{4.6}$$

$$e_{1,3}^n \;=\; \frac{1}{\pi} \left(\frac{1}{t_{n-1}} \;-\; \frac{1}{t_n}\right) \int_0^{\varepsilon} e^{i\theta\, t_n}\, \widehat{K}_1(i\theta)\, d\theta, \tag{4.7}$$

$$\widehat{K}_1(s) \;=\; \frac{\widehat{\beta}'(s)}{[\widehat{\beta}(s)]^2}.$$

Evidently, in view of (2.12),

$$|e_{1,3}^n| \;\le\; C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.8}$$

Integrate by parts in (4.6) to bring out another factor of t_{n-2}^{-1},

$$e_{1,2}^n = \frac{1}{i\,\pi\, t_{n-1}\, t_{n-2}}\, e^{i\theta\, t_{n-2}} \left(1 \;-\; e^{2i\theta\, k}\right) \widehat{K}_1(i\theta)\Big|_{\theta=0}^{\theta=\varepsilon} \tag{4.9}$$
$$+\; \frac{2\,k}{\pi\, t_{n-1}\, t_{n-2}} \int_0^{\varepsilon} e^{i\theta\, t_n}\, \widehat{K}_1(i\theta)\, d\theta$$
$$-\; \frac{1}{i\,\pi\, t_{n-1}\, t_{n-2}} \int_0^{\varepsilon} e^{i\theta\, t_{n-2}} \left(1 \;-\; e^{2i\theta\, k}\right) \widehat{K}_1'(i\theta)\, d\theta,$$

where

$$\widehat{K}_1'(s) \;=\; \frac{\widehat{\beta}''(s)}{\widehat{\beta}^2(s)} \;-\; \frac{2[\widehat{\beta}'(s)]^2}{\widehat{\beta}^3(s)}.$$

After some estimates we have

$$|e_{1,2}^n| \;\le\; C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0), \tag{4.10}$$

for example, from (2.11), (2.6), (2.8), and (2.12) we see that

$$\int_0^{\varepsilon} \theta|\widehat{K}_1'(i\theta)|d\theta \le C\int_0^{\varepsilon}\left[\frac{\theta|\widetilde{\beta}''(\theta)|}{|\widetilde{\beta}(\theta)|^2} + \frac{\theta|\widetilde{\beta}'(\theta)|^2}{|\widetilde{\beta}(\theta)|^3}\right]d\theta \tag{4.11}$$

$$\le \int_0^{\varepsilon}\frac{A_1(\theta^{-1})}{A^2(\theta^{-1})}\,d\theta < \infty.$$

For $e_{1,1}^n$, again using integration by parts gives us

$$|e_{1,1}^n| \le \left|\frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\,e^{i\theta\,t_{n-2}}\,\left(\widehat{K}_1(s) - \widehat{K}_1(i\theta)\right)\right|_{\theta=0}^{\theta=\varepsilon} \tag{4.12}$$

$$+\left|\frac{1}{\pi\,t_{n-1}\,t_{n-2}}\int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\,\left(\widehat{K}_1'(s) - \widehat{K}_1'(i\theta)\right)\,d\theta\right|$$

$$+\left|\frac{1}{\pi\,t_{n-1}\,t_{n-2}}\int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\,(1-e^{i\theta\,k})\,\widehat{K}_1'(i\theta)\,d\theta\right|$$

$$= e_{1,1,1}^n + e_{1,1,2}^n + e_{1,1,3}^n.$$

Clearly, (4.11) shows

$$e_{1,1,3}^n \le C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.13}$$

By the mean-value theorem we obtain

$$|\widehat{K}_1(s) - \widehat{K}_1(i\theta)| \le C\,k\,\theta^2\,|\widehat{K}_1'(s_1)|, \tag{4.14}$$

where s_1 is given as in the form of (3.15).

We recall from [3, (5.3) and (5.4)] that, for $0 < \theta \le \varepsilon,\ \tau \le \tau_1 \le \theta$,

$$|\widehat{\beta}(s_1)| \ge C\,|\widetilde{\beta}(\tau_1)| \ge C\,|\widetilde{\beta}(\tau)|, \tag{4.15}$$

and for $\sigma_1 \ge 0,\ \tau_1 > 0$,

$$|\widehat{\beta}''(s_1)| \le \frac{2}{\tau_1}\,\theta(\tau_1), \tag{4.16}$$

which implies that, for $\sigma_1 \ge 0,\ \tau_1 \ge \tau > 0$,

$$|\widehat{\beta}''(s_1)| \le C\,\tau^{-1}\,\theta(\tau). \tag{4.17}$$

Returning to (4.14), using the estimate of (4.15) for lower bounds on $|\widehat{\beta}(s_1)|$, and of (3.22) and (4.17) for upper bounds on the numerators, we obtain, for $0 \le \theta \le \varepsilon$,

$$\theta^2\,|\widehat{K}_1'(s_1)| \le C,$$

which is

$$|\widehat{K}_1(s) - \widehat{K}_1(i\theta)| \le C\,k. \tag{4.18}$$

Similarly, we have

$$|\widehat{K}_1'(s) \;-\; \widehat{K}_1'(i\theta)| \;\le\; C\,k\,\theta^2\;|\widehat{K}_1''(s_1)|, \tag{4.19}$$

where

$$\widehat{K}_1''(s) = \frac{\widehat{\beta}'''(s)}{\widehat{\beta}^2(s)} \;-\; \frac{6\widehat{\beta}'(s)\widehat{\beta}''(s)}{\widehat{\beta}^3(s)} \;+\; \frac{6[\widehat{\beta}'(s)]^3}{\widehat{\beta}^4(s)}.$$

However, for $\sigma_1 \ge 0,\ \tau_1 \ge \tau > 0$, we have

$$|s_1\widehat{\beta}'''(s_1)| \le 6\int_0^\infty \frac{d\alpha(x)}{|x+s_1|^3} \le \frac{6}{\tau_1}\theta(\tau_1) \le C\tau^{-1}\theta(\tau). \tag{4.20}$$

Using this estimate, along with (4.15), (4.17), and (3.22), we obtain

$$|\widehat{K}_1'(s) \;-\; \widehat{K}_1'(i\theta)| \;\le\; C\,k\frac{|\widetilde{\beta}'(\tau)|}{|\widetilde{\beta}(\tau)|^2}. \tag{4.21}$$

It then follows from (2.12) and (4.12) that

$$e^n_{1,1,2} \le C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.22}$$

Combining (4.12), (4.13), (4.18), and (4.22), we obtain

$$|e^n_{1,1}| \le C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.23}$$

Together the three estimates (4.8), (4.10), and (4.23) complete the proof of Estimate 1.

Estimate 2.

$$|U_2^n \;-\; u_2(t_n)| \le C\,k\,t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{4.24}$$

Also, integrating by parts on U_2^n and $u_2(t_n)$, we write $U_2^n - u_2(t_n) = e^n_{2,1} + e^n_{2,2}$, where

$$e^n_{2,1} \;=\; \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\;e^{i\theta\,t_{n-2}}\;\widehat{K}_{2,1}(s)\Big|_{\theta=0}^{\theta=\varepsilon} \;-\; \frac{1}{i\pi\,t_n^2}\;e^{i\theta\,t_n}\;\widehat{K}_{2,1}(i\theta)\Big|_{\theta=0}^{\theta=\varepsilon}$$

and

$$e^n_{2,2} \;=\; \frac{2}{\pi\,t_{n-1}t_{n-2}}\int_0^\varepsilon e^{i\theta\,t_{n-3}}\,\widehat{K}_{2,2}(s)\,d\theta \;-\; \frac{2}{\pi\,t_n^2}\int_0^\varepsilon e^{i\theta\,t_n}\widehat{K}_{2,2}(i\theta)\,d\theta,$$

$$\widehat{K}_{2,1}(s) \;=\; \frac{1}{[\widehat{\beta}(s)]^2}\left(1 - \frac{2\,s\widehat{\beta}'(s)}{\widehat{\beta}(s)}\right),$$

$$\widehat{K}_{2,2}(s) \;=\; \frac{\widehat{\beta}'(s)}{[\widehat{\beta}(s)]^3}\left(1 - \frac{2\,s\widehat{\beta}'(s)}{\widehat{\beta}(s)}\right) \;+\; \frac{\widehat{\beta}'(s) + s\widehat{\beta}''(s)}{[\widehat{\beta}(s)]^3} - \frac{s[\widehat{\beta}'(s)]^2}{[\widehat{\beta}(s)]^4}.$$

Furthermore, by simple computations we have

$$
\begin{aligned}
|e^n_{2,1}| &\le e^n_{2,1,1} \;+\; e^n_{2,1,2} \;+\; e^n_{2,1,3} \;+\; e^n_{2,1,4} \qquad (4.25)\\
&= \left| \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\; e^{i\theta\,t_{n-2}}\; \Big(\widehat{K}_{2,1}(s) \;-\; \widehat{K}_{2,1}(i\theta)\Big) \right|^{\theta=\varepsilon}_{\theta=0} \\
&\quad + \left| \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\; e^{\theta\,t_{n-2}}\; \big(1 \;-\; e^{2i\theta\,k}\big)\, \widehat{K}_{2,1}(i\theta) \right|^{\theta=\varepsilon}_{\theta=0} \\
&\quad + \left| \frac{1}{i\,\pi\,t_{n-1}} \left(\frac{1}{t_{n-2}} \;-\; \frac{1}{t_n}\right) e^{i\theta\,t_n}\; \widehat{K}_{2,1}(i\theta) \right|^{\theta=\varepsilon}_{\theta=0} \\
&\quad + \left| \frac{1}{i\,\pi\,t_n} \left(\frac{1}{t_{n-1}} \;-\; \frac{1}{t_n}\right) e^{i\theta\,t_n}\; \widehat{K}_{2,1}(i\theta) \right|^{\theta=\varepsilon}_{\theta=0}
\end{aligned}
$$

and

$$
\begin{aligned}
|e^n_{2,2}| &\le \left| \frac{2}{\pi\,t_{n-1}t_{n-2}} \int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\; \Big(\widehat{K}_{2,2}(s) \;-\; \widehat{K}_{2,2}(i\theta)\Big)\; d\theta \;\right| \qquad (4.26)\\
&\quad + \left| \frac{2}{\pi\,t_{n-1}t_{n-2}} \int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\; \big(1 \;-\; e^{3\,i\theta\,k}\big)\; \widehat{K}_{2,2}(i\theta)\; d\theta \;\right| \\
&\quad + \left| \frac{2}{\pi\,t_{n-1}} \left(\frac{1}{t_{n-2}} \;-\; \frac{1}{t_n}\right) \int_0^{\varepsilon} e^{i\theta\,t_n}\; \widehat{K}_{2,2}(i\theta)\; d\theta \;\right| \\
&\quad + \left| \frac{2}{\pi\,t_n} \left(\frac{1}{t_{n-1}} \;-\; \frac{1}{t_n}\right) \int_0^{\varepsilon} e^{i\theta\,t_n}\; \widehat{K}_{2,2}(i\theta)\; d\theta \;\right| \\
&= e^n_{2,2,1} \;+\; e^n_{2,2,2} \;+\; e^n_{2,2,3} \;+\; e^n_{2,2,4}.
\end{aligned}
$$

It is now a clear matter that

$$
e^n_{2,1,2} \;+\; e^n_{2,1,3} \;+\; e^n_{2,1,4} \;\le\; C\,k\,t^{-2}_{n-2}\,, \qquad (4.27)
$$

$$
\begin{aligned}
&e^n_{2,2,2} \;+\; e^n_{2,2,3} \;+\; e^n_{2,2,4} \qquad (4.28)\\
&\le\; C\,k\,t^{-2}_{n-2} \left(1 + \int_0^{\varepsilon} \frac{|\widetilde{\beta}'(\theta)|}{|\widetilde{\beta}(\theta)|^2}\, d\theta\right) \;\le\; C\,k\,t^{-2}_{n-2}.
\end{aligned}
$$

For $e^n_{2,1,1}$ and $e^n_{2,2,1}$ we first use the mean-value theorem to obtain

$$
|\widehat{K}_{2,1}(s) - \widehat{K}_{2,1}(i\theta)| \;\le\; C\,k\,\theta^2 |\widehat{K}'_{2,1}(s_1)|, \qquad (4.29)
$$

$$
|\widehat{K}_{2,2}(s) - \widehat{K}_{2,2}(i\theta)| \;\le\; C\,k\,\theta^2 |\widehat{K}'_{2,2}(s_1)|, \qquad (4.30)
$$

with

$$\widehat{K}'_{2,1}(s) = -\frac{4\widehat{\beta}'(s)}{\widehat{\beta}^3(s)} - \frac{2\,s\widehat{\beta}''(s)}{\widehat{\beta}^3(s)} + \frac{6\,s[\widehat{\beta}'(s)]^2}{\widehat{\beta}^4(s)},$$

$$\widehat{K}'_{2,2}(s) = \frac{3\widehat{\beta}''(s)}{\widehat{\beta}^3(s)} - \frac{9\,[\widehat{\beta}'(s)]^2}{\widehat{\beta}^4(s)} + \frac{s\,\widehat{\beta}'''(s)}{\widehat{\beta}^3(s)}$$

$$- \frac{9\,s\widehat{\beta}'(s)\widehat{\beta}''(s)}{\widehat{\beta}^4(s)} + \frac{12\,s[\widehat{\beta}'(s)]^3}{\widehat{\beta}^5(s)}.$$

From (3.22), (4.15), (4.17) we have that, for $0 \le \theta \le \varepsilon$,

$$\theta^2\,|\widehat{K}'_{2,1}(s_1)| \le C; \tag{4.31}$$

in other words

$$e^n_{2,1,1} \le C\,k\,t^{-2}_{n-2}. \tag{4.32}$$

Taken together with (4.25) and (4.27), this shows that

$$|e^n_{2,1}| \le C\,k\,t^{-2}_{n-2}. \tag{4.33}$$

Similarly, from (4.15), (4.17), (3.22), and (4.20) we see that

$$\theta^2\,|\widehat{K}'_{2,2}(s_1)| \le C, \tag{4.34}$$

and it follows that

$$e^n_{2,2,1} \le C\,k\,t^{-2}_{n-2}. \tag{4.35}$$

Combining (4.26), (4.28), and (4.35) we now have established the estimate

$$|e^n_{2,2}| \le C\,k\,t^{-2}_{n-2}. \tag{4.36}$$

This completes the proof of Estimate 2.

We now state and prove two more estimates needed to deduce the bounds for the third and fourth terms on the right-hand side of (4.3).

Estimate 3.

$$|U^n_3 - u_3(t_n)| \le C\,k\,t^{-2}_{n-2} \quad (t_{n-2} > 0). \tag{4.37}$$

We argue similarly to the proof of Estimate 2. Let $U^n_3 - u_3(t_n) = e^n_{3,1} + e^n_{3,2}$, where

$$e^n_{3,1} = -\left\{ \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\, e^{i\theta\,t_{n-2}}\, \widehat{K}_{3,1}(s)\,|_{\theta=\varepsilon} - \frac{1}{i\pi\,t_n^2}\, e^{i\theta\,t_n}\, \widehat{K}_{3,1}(i\theta)\,|_{\theta=\varepsilon} \right\}$$

and

$$e^n_{3,2} = \frac{2}{\pi\,t_{n-1}t_{n-2}} \int_0^\varepsilon e^{i\theta\,t_{n-3}}\, \widehat{K}_{3,2}(s)\,d\theta - \frac{2}{\pi\,t_n^2} \int_0^\varepsilon e^{i\theta\,t_n}\, \widehat{K}_{3,2}(i\theta)\,d\theta,$$

$$\widehat{K}_{3,1}(s) = \frac{2\,s}{[\widehat{\beta}(s)]^3},$$

$$\widehat{K}_{3,2}(s) = \frac{1}{[\widehat{\beta}(s)]^3} - \frac{3\,s\,\widehat{\beta}'(s)}{[\widehat{\beta}(s)]^4}.$$

Similarly, we have

$$|e^n_{3,1}| \le \left| \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\; e^{i\theta\,t_{n-2}}\; \left(\widehat{K}_{3,1}(s) \;-\; \widehat{K}_{3,1}(i\theta) \right) \Big|_{\theta=\varepsilon} \right| \tag{4.38}$$

$$+ \left| \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}}\; e^{i\theta\,t_{n-2}}\; \left(1 \;-\; e^{2i\theta\,k}\right) \widehat{K}_{3,1}(i\theta) \Big|_{\theta=\varepsilon} \right|$$

$$+ \left| \frac{1}{i\,\pi\,t_{n-1}} \left(\frac{1}{t_{n-2}} \;-\; \frac{1}{t_n} \right)\; e^{i\theta\,t_n}\; \widehat{K}_{3,1}(i\theta) \Big|_{\theta=\varepsilon} \right|$$

$$+ \left| \frac{1}{i\,\pi\,t_n} \left(\frac{1}{t_{n-1}} \;-\; \frac{1}{t_n} \right)\; e^{i\theta\,t_n}\; \widehat{K}_{3,1}(i\theta) \Big|_{\theta=\varepsilon} \right|$$

and

$$|e^n_{3,2}| \le \left| \frac{2}{\pi\,t_{n-1}t_{n-2}} \int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\; \left(\widehat{K}_{3,2}(s) \;-\; \widehat{K}_{3,2}(i\theta) \right)\; d\theta \;\right| \tag{4.39}$$

$$+ \left| \frac{2}{\pi\,t_{n-1}t_{n-2}} \int_0^{\varepsilon} e^{i\theta\,t_{n-3}}\; \left(1 \;-\; e^{3\,i\theta\,k}\right)\; \widehat{K}_{3,2}(i\theta)\; d\theta \;\right|$$

$$+ \left| \frac{2}{\pi\,t_{n-1}} \left(\frac{1}{t_{n-2}} \;-\; \frac{1}{t_n} \right) \int_0^{\varepsilon} e^{i\theta\,t_n}\; \widehat{K}_{3,2}(i\theta)\; d\theta \;\right|$$

$$+ \left| \frac{2}{\pi\,t_n} \left(\frac{1}{t_{n-1}} \;-\; \frac{1}{t_n} \right) \int_0^{\varepsilon} e^{i\theta\,t_n}\; \widehat{K}_{3,2}(i\theta)\; d\theta \;\right|.$$

An analogous argument can be used to obtain the proof of Estimate 3.

Estimate 4.

$$|U^n_4(\lambda) - u_4(t_n,\lambda)| \;\le\; C\,k\,t^{-2}_{n-2}\,\lambda^{-3} \qquad (t_{n-2} > 0). \tag{4.40}$$

We first integrate by parts on $U^n_4(\lambda)$ and $u_4(t_n,\lambda)$ in order to bring out another factor of t^{-1}_{n-2} and t^{-1}_n, respectively. This gives us $U^n_4(\lambda) - u_4(t_n,\lambda) = e^n_{4,1}(\lambda) + e^n_{4,2}(\lambda)$, where

$$e^n_{4,1}(\lambda) \;=\; \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}\lambda^3}\; e^{i\theta\,t_{n-2}}\; \widehat{K}_{4,1}(s;\lambda) \Big|_{\theta=\varepsilon}$$

$$-\; \frac{1}{i\pi\,t^2_n\lambda^3}\; e^{i\theta\,t_n}\; \widehat{K}_{4,1}(i\theta;\lambda) \Big|_{\theta=\varepsilon}$$

and

$$\begin{aligned} e^n_{4,2}(\lambda) &= -\left\{ \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda^3} \int_0^\varepsilon e^{i\theta\, t_{n-3}}\, \widehat{K}_{4,2}(s;\lambda)\, d\theta \right. \\ &\quad \left. - \frac{1}{\pi\, t_n^2\lambda^3} \int_0^\varepsilon e^{i\theta\, t_n} \widehat{K}_{4,2}(i\theta;\lambda)\, d\theta \right\}, \\ \widehat{K}_{4,1}(s;\lambda) &= \frac{s^2 D_s(s;\lambda)}{[\widehat{\beta}(s)]^2 D(s;\lambda)} \left(\frac{2}{\widehat{\beta}(s)} + \frac{1}{D(s;\lambda)} \right), \\ \widehat{K}_{4,2}(s;\lambda) &= \frac{2\, s\, D_s(s;\lambda) + s^2\widehat{\beta}''(s)}{[\widehat{\beta}(s)]^2 D(s;\lambda)} \left(\frac{2}{\widehat{\beta}(s)} + \frac{1}{D(s;\lambda)} \right) \\ &\quad - \frac{s^2\, D_s(s;\lambda)}{[\widehat{\beta}(s)]^2\, D(s;\lambda)} \left(\frac{6\widehat{\beta}'(s)}{[\widehat{\beta}(s)]^2} + \frac{4\,\widehat{\beta}'(s) + 2\,\lambda^{-1}}{\widehat{\beta}(s)\, D(s;\lambda)} + \frac{2D_s(s;\lambda)}{D^2(s;\lambda)} \right). \end{aligned}$$

Arguing similarly to (4.38) and (4.39), we have that

$$\begin{aligned} |e^n_{4,1}| \le & \left| \frac{1}{i\,\pi\, t_{n-1}\, t_{n-2}\lambda^3}\, e^{i\theta\, t_{n-2}} \left(\widehat{K}_{4,1}(s;\lambda) - \widehat{K}_{4,1}(i\theta;\lambda) \right) \Big|_{\theta=\varepsilon} \right| \\ & + \left| \frac{1}{i\,\pi\, t_{n-1}\, t_{n-2}\lambda^3}\, e^{i\theta\, t_{n-2}} \left(1 - e^{2i\theta\, k}\right) \widehat{K}_{4,1}(i\theta;\lambda) \Big|_{\theta=\varepsilon} \right| \\ & + \left| \frac{1}{i\,\pi\, t_{n-1}\,\lambda^3} \left(\frac{1}{t_{n-2}} - \frac{1}{t_n} \right) e^{i\theta\, t_n}\, \widehat{K}_{4,1}(i\theta;\lambda) \Big|_{\theta=\varepsilon} \right| \\ & + \left| \frac{1}{i\,\pi\, t_n\,\lambda^3} \left(\frac{1}{t_{n-1}} - \frac{1}{t_n} \right) e^{i\theta\, t_n}\, \widehat{K}_{4,1}(i\theta;\lambda) \Big|_{\theta=\varepsilon} \right| \end{aligned} \tag{4.41}$$

and

$$\begin{aligned} |e^n_{4,2}| \le & \left| \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda^3} \int_0^\varepsilon e^{i\theta\, t_{n-3}} \left(\widehat{K}_{4,2}(s;\lambda) - \widehat{K}_{4,2}(i\theta;\lambda) \right) d\theta \right| \\ & + \left| \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda^3} \int_0^\varepsilon e^{i\theta\, t_{n-3}} \left(1 - e^{3\,i\theta\, k}\right) \widehat{K}_{4,2}(i\theta;\lambda)\, d\theta \right| \\ & + \left| \frac{1}{\pi\, t_{n-1}\lambda^3} \left(\frac{1}{t_{n-2}} - \frac{1}{t_n} \right) \int_0^\varepsilon e^{i\theta\, t_n}\, \widehat{K}_{4,2}(i\theta;\lambda)\, d\theta \right| \\ & + \left| \frac{1}{\pi\, t_n\lambda^3} \left(\frac{1}{t_{n-1}} - \frac{1}{t_n} \right) \int_0^\varepsilon e^{i\theta\, t_n}\, \widehat{K}_{4,2}(i\theta;\lambda)\, d\theta \right|. \end{aligned} \tag{4.42}$$

It is easily seen that the second and fourth terms of (4.41) and (4.42) are bounded by $C\, k\, t_{n-2}^{-2}\lambda^{-3}$, respectively. For the first term of (4.41) and (4.42), we apply the mean-value theorem, then use the estimates of (3.22), (4.17), and (4.20) for upper bounds on the numerators, and of (3.20) and (4.15) for lower bounds on $|\widehat{\beta}(s_1)|$ and $|D(s_1;\lambda)|$. Therefore we deduce the proof of Estimate 4.

Now integrate by parts on $U_5^n(\lambda)$, $u_5(t_n,\lambda)$, and $u_6(t_n,\lambda)$ to obtain

$$U_5^n(\lambda) \;-\; u_5(t_n,\lambda) \;=\; e_{5,1}^n(\lambda) \;+\; e_{5,2}^n(\lambda) \;+\; e_{5,3}^n(\lambda), \tag{4.43}$$

where

$$\begin{aligned}
e_{5,1}^n(\lambda) &= \frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}\lambda}\; e^{i\theta\,t_{n-2}}\;\widehat{K}_{5,1}(s;\lambda)\Big|_{\theta=\frac{\pi}{k}} \\
&\quad - \frac{1}{i\pi\,t_n^2\lambda}\; e^{i\theta\,t_n}\;\widehat{K}_{5,1}(i\theta;\lambda)\Big|_{\theta=\frac{\pi}{k}}, \\
e_{5,2}^n(\lambda) &= -\Big\{\frac{1}{i\,\pi\,t_{n-1}\,t_{n-2}\lambda}\; e^{i\theta\,t_{n-2}}\,\widehat{K}_{5,1}(s;\lambda)\Big|_{\theta=\varepsilon} \\
&\quad - \frac{1}{i\pi\,t_n^2\lambda}\; e^{i\theta\,t_n}\;\widehat{K}_{5,1}(i\theta;\lambda)\Big|_{\theta=\varepsilon}\Big\}, \\
e_{5,3}^n(\lambda) &= -\Big\{\frac{1}{\pi\,t_{n-1}t_{n-2}\lambda}\int_\varepsilon^{\frac{\pi}{k}}\; e^{i\theta\,t_{n-3}}\;\widehat{K}_{5,2}(s;\lambda)\;d\theta \\
&\quad - \frac{1}{\pi\,t_n^2\lambda}\int_\varepsilon^{\frac{\pi}{k}}\; e^{i\theta\,t_n}\,\widehat{K}_{5,2}(i\theta;\lambda)\,d\theta\Big\}, \\
\widehat{K}_{5,1}(s;\lambda) &= \frac{D_s(s;\lambda)}{[D(s;\lambda)]^2}, \\
\widehat{K}_{5,2}(s;\lambda) &= \frac{\widehat{\beta}''(s)}{D^2(s;\lambda)} \;-\; \frac{2\,D_s^2(s;\lambda)}{D^3(s;\lambda)},
\end{aligned}$$

and

$$\begin{aligned}
-u_6(t_n,\lambda) &= e_{6,1}^n(\lambda) \;+\; e_{6,2}^n(\lambda) \\
&= \frac{1}{i\pi\,t_n^2\lambda}\; e^{i\theta\,t_n}\;\widehat{K}_{5,1}(i\theta;\lambda)\Big|_{\theta=\frac{\pi}{k}} \\
&\quad + \frac{1}{\pi\,t_n^2\lambda}\int_{\frac{\pi}{k}}^{\infty}\; e^{i\theta\,t_n}\,\widehat{K}_{5,2}(i\theta;\lambda)\,d\theta.
\end{aligned} \tag{4.44}$$

A similar argument can be applied to show that for $t_{n-2} > 0$,

$$|e_{5,2}^n(\lambda)| \;\le\; C\,k\,\lambda^{-1}t_{n-2}^{-2}. \tag{4.45}$$

We recall as well that (see [3, (5.7)]),

$$\frac{|D_s(\frac{2}{k};\lambda)|}{|D(\frac{2}{k};\lambda)|^2} \;\le\; \frac{k^2\lambda}{4} \;+\; \frac{\frac{k}{2}\widehat{\beta}(\frac{2}{k})k\lambda}{2\phi(\frac{2}{k},0)} \;\le\; \frac{k^2\lambda}{2}, \tag{4.46}$$

which yields

$$|e_{5,1}^n(\lambda) \;+\; e_{6,1}^n(\lambda)| \;\le\; C\,k^2t_{n-2}^{-2}. \tag{4.47}$$

In section 5 we will show that

$$|e^n_{5,3}(\lambda)| \le C\,k\,\lambda^3 t_{n-2}^{-2} \quad (t_{n-2}>0), \tag{4.48}$$

$$|e^n_{6,2}(\lambda)| \le C\,k^2\,\lambda^2 t_n^{-2} \quad (t_n>0). \tag{4.49}$$

Referring to (4.3), (4.4), (4.24), (4.37), (4.40), and (4.43)–(4.45), along with the estimates (4.47)–(4.49), we obtain the proof of Theorem 3.

5. Proof of (4.48) and (4.49). In order to obtain a similar estimate on $e^n_{5,3}(\lambda)$ we put that $e^n_{5,3}(\lambda) = e^n_{5,3,1}(\lambda) + e^n_{5,3,2}(\lambda)$, where

$$e^n_{5,3,1}(\lambda) = -\left\{ \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda} \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_{n-3}}\, \widehat{K}_{5,2}(s;\lambda)\, d\theta \right. \tag{5.1}$$

$$\left. - \frac{1}{\pi\, t_n^2\lambda} \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_n} \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right\},$$

$$e^n_{5,3,2}(\lambda) = -\left\{ \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda} \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_{n-3}}\, \widehat{K}_{5,2}(s;\lambda)\, d\theta \right. \tag{5.2}$$

$$\left. - \frac{1}{\pi\, t_n^2\lambda} \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_n} \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right\}.$$

We argue as in (4.41) to obtain

$$\begin{aligned} |e^n_{5,3,1}(\lambda)| \le{}& \left| \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda} \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_{n-3}} \left(\widehat{K}_{5,2}(s;\lambda) - \widehat{K}_{5,2}(i\theta;\lambda) \right) d\theta \right| \\ &+ \left| \frac{1}{\pi\, t_{n-1}t_{n-2}\lambda} \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_{n-3}} \left(1 - e^{3\,i\theta\, k}\right) \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right| \\ &+ \left| \frac{1}{\pi\, t_{n-1}\lambda} \left(\frac{1}{t_{n-2}} - \frac{1}{t_n} \right) \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_n} \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right| \\ &+ \left| \frac{1}{\pi\, t_n\lambda} \left(\frac{1}{t_{n-1}} - \frac{1}{t_n} \right) \int_{\varepsilon}^{\frac{\varepsilon}{k}} e^{i\theta\, t_n} \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right| \\ ={}& e^n_{5,3,1,1}(\lambda) + e^n_{5,3,1,2}(\lambda) + e^n_{5,3,1,3}(\lambda) + e^n_{5,3,1,4}(\lambda). \end{aligned} \tag{5.3}$$

By the same computations we see that

$$
\begin{aligned}
(5.4)\quad e^n_{5,3,1,2}(\lambda) \;&\le\; C\,k\,t_{n-2}^{-2}\,\lambda^{-1}\int_{\varepsilon}^{\frac{\varepsilon}{k}}\theta\,|\widehat{K}_{5,2}(i\theta;\lambda)|\,d\theta\\
&\le\; C\,k\,t_{n-2}^{-2}\,\lambda^{-1}\int_{\varepsilon}^{\frac{\varepsilon}{k}}\tau\left(\left|\frac{\widehat{\beta}''(i\tau)}{D^2(i\tau;\lambda)}\right| \;+\; \left|\frac{D_S^2(i\tau;\lambda)}{D^3(i\tau;\lambda)}\right|\right)d\tau\\
&\le\; C\,k\,t_{n-2}^{-2}\,\lambda^{-1}\left\{\int_{\varepsilon}^{\frac{\omega}{2}}\frac{\lambda^{-2}+\theta^2(\tau)}{\tau^2\theta^3(\tau)}\,d\tau+\int_{\frac{\omega}{2}}^{\omega-\varepsilon}\left(\frac{\lambda}{|\tau-\omega|^2}+\frac{\tau\lambda}{|\tau-\omega|^3}\right)d\tau\right.\\
&+\left.\int_{\omega-\varepsilon}^{\omega+\varepsilon}\left(\frac{\lambda^{-1}}{\phi^2(\tau)}+\frac{\tau\lambda^{-2}}{\phi^3(\tau)}\right)d\tau+\int_{\omega+\varepsilon}^{\infty}\left(\frac{\lambda}{|\tau-\omega|^2}+\frac{\tau\lambda}{|\tau-\omega|^3}\right)d\tau\right\}\\
&\le\; C\,k\,t_{n-2}^{-2}\,\lambda.
\end{aligned}
$$

Similarly, we have that

$$
(5.5)\qquad e^n_{5,3,1,3}(\lambda) \;+\; e^n_{5,3,1,4}(\lambda) \;\le\; C\,k\,t_{n-2}^{-3}\,\lambda;
$$

for example, for $t_{n-2}>0$,

$$
\begin{aligned}
(5.6)\quad e^n_{5,3,1,3}(\lambda) \;&\le\; C\,k\,t_{n-2}^{-3}\,\lambda^{-1}\int_{\varepsilon}^{\frac{\varepsilon}{k}}|\widehat{K}_{5,2}(i\theta;\lambda)|\,d\theta\\
&\le\; C\,k\,t_{n-2}^{-3}\,\lambda^{-1}\int_{\varepsilon}^{\frac{\varepsilon}{k}}\left(\left|\frac{\widehat{\beta}''(i\tau)}{D^2(i\tau;\lambda)}\right| \;+\; \left|\frac{D_S^2(i\tau;\lambda)}{D^3(i\tau;\lambda)}\right|\right)d\tau\\
&\le\; C\,k\,t_{n-2}^{-3}\,\lambda^{-1}\left\{\int_{\varepsilon}^{\frac{\omega}{2}}\frac{\lambda^{-2}+\theta^2(\tau)}{\tau^3\theta^3(\tau)}\,d\tau+\int_{\frac{\omega}{2}}^{\omega-\varepsilon}\left(\frac{\lambda}{\tau\,|\tau-\omega|^2}+\frac{\lambda}{|\tau-\omega|^3}\right)d\tau\right.\\
&+\left.\int_{\omega-\varepsilon}^{\omega+\varepsilon}\left(\frac{\lambda^{-1}}{\tau\,\phi^2(\tau)}+\frac{\lambda^{-2}}{\phi^3(\tau)}\right)d\tau+\int_{\omega+\varepsilon}^{\infty}\left(\frac{\lambda}{\tau\,|\tau-\omega|^2}+\frac{\lambda}{|\tau-\omega|^3}\right)d\tau\right\}\\
&\le\; C\,k\,t_{n-2}^{-3}\,\lambda.
\end{aligned}
$$

Also, by the mean-value theorem we now have

$$
(5.7)\qquad e^n_{5,3,1,1}(\lambda)\;\le\; C\,k\,t_{n-2}^{-2}\lambda^{-1}\int_{\varepsilon}^{\frac{\varepsilon}{k}}\theta^2|\widehat{K}'_{5,2}(s_1;\lambda)|\,d\theta,
$$

where

$$
\widehat{K}'_{5,2}(s;\lambda) \;=\; \frac{\widehat{\beta}'''(s)}{D^2(s;\lambda)} \;-\; \frac{6\,\widehat{\beta}''(s)\,D_S(s;\lambda)}{D^3(s;\lambda)} \;+\; \frac{6\,D_S^3(s;\lambda)}{D^4(s;\lambda)}.
$$

From (3.22), (4.17), (4.20), and (3.39)–(3.41) we find that

(5.8)
$$\int_{\varepsilon}^{\frac{\varepsilon}{k}} \theta^2 |\widehat{K}'_{5,2}(s_1;\lambda)|\, d\theta \;\le\; C \int_{c_0\varepsilon}^{\frac{\varepsilon}{k}} \tau^2 |\widehat{K}'_{5,2}(s_1;\lambda)|\, d\tau$$
$$\le C \left(\int_{c_0\varepsilon}^{\frac{c_0\omega}{2}} \;+\; \int_{\frac{c_0\omega}{2}}^{2\omega} \;+\; \int_{2\omega}^{\infty} \tau^2 \;\left(\left| \frac{\widehat{\beta}'''(s_1)}{D^2(s_1;\lambda)} \right| \right.\right.$$
$$+ \;\left| \frac{\widehat{\beta}''(s_1)\, D_s(s_1;\lambda)}{D^3(s_1;\lambda)} \right| \;+\; \left.\left| \frac{D_s^3(s_1;\lambda)}{D^4(s_1;\lambda)} \right| \right) \, d\tau \Bigg)$$
$$\le\; C \Bigg\{ \int_{c_0\varepsilon}^{\frac{c_0\omega}{2}} \frac{\lambda^{-3} + \lambda^{-1}\theta^2(\tau) + \theta^3(\tau)}{\tau^2\theta^4(\tau)}\, d\tau + \int_{\frac{c_0\omega}{2}}^{2\omega} \left(\frac{\lambda^{-1}}{\phi^2(\tau)} + \frac{\tau\lambda^{-2}}{\phi^3(\tau)} + \frac{\tau^2\lambda^{-3}}{\phi^4(\tau)} \right) \, d\tau$$
$$+ \;\int_{2\omega}^{\infty} \left(\frac{\lambda}{|\tau-\omega|^2} + \frac{\tau\lambda}{|\tau-\omega|^3} + \frac{\tau^2\lambda}{|\tau-\omega|^4} \right) \, d\tau \Bigg\} \;\le\; C\,\lambda^4.$$

Combining (5.7) and (5.8) yields

$$e^n_{5,3,1,1}(\lambda) \;\le\; C\,k\,\lambda^3 t_{n-2}^{-2}. \tag{5.9}$$

Together the estimates (5.1) and (5.3)–(5.9) yield

$$|e^n_{5,3,1}(\lambda)| \le C\,k\,\lambda^3 t_{n-2}^{-2} \qquad (t_{n-2} > 0). \tag{5.10}$$

Next we turn to $e^n_{5,3,2}(\lambda)$. We know from [3, (5.12) and (5.13)] that

$$\lambda^{-1} \int_{\frac{\varepsilon}{k}}^{\frac{\pi-\varepsilon\,k}{k}} \left(\frac{|\widehat{\beta}''(s)|}{|D(s;\lambda)|^2} + \frac{|D_s^2(s;\lambda)|}{|D(s;\lambda)|^3} \right) \, d\theta \;\le\; C\,k^2 \tag{5.11}$$

and

$$\lambda^{-1} \int_{\frac{\pi-\varepsilon\,k}{k}}^{\frac{\pi}{k}} \left(\frac{|\widehat{\beta}''(s)|}{|D(s;\lambda)|^2} + \frac{|D_s^2(s;\lambda)|}{|D(s;\lambda)|^3} \right) \, d\theta \;\le\; C\,k^2. \tag{5.12}$$

We use (5.11) and (5.12) to obtain

$$\left| \frac{1}{\pi\, t_{n-1} t_{n-2} \lambda} \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_{n-3}}\, \widehat{K}_{5,2}(s;\lambda)\, d\theta \right| \;\le\; C\,k^2\, t_{n-2}^{-2}\,. \tag{5.13}$$

It remains to establish an estimate on

$$\left| \frac{1}{\pi\, t_n^2 \lambda} \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_n}\, \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right| \tag{5.14}$$
$$\le\; \frac{1}{\pi\, t_n^2 \lambda} \int_{\frac{\varepsilon}{k}}^{\infty} \left(\left| \frac{\widehat{\beta}''(i\tau)}{D^2(i\tau;\lambda)} \right| \;+\; \left| \frac{D_s^2(i\tau;\lambda)}{D^3(i\tau;\lambda)} \right| \right) \, d\tau \;=\; \overline{e}^n_{5,3,2}(\lambda).$$

If $2\omega \le \frac{\varepsilon}{k}$, then $\frac{1}{\varepsilon - k\omega} \le \frac{2}{\varepsilon}$, and we have

$$\overline{e}^n_{5,3,2}(\lambda) \;\le\; C\, t_n^{-2} \left(\frac{k}{\varepsilon} \int_{\frac{\varepsilon}{k}}^{\infty} \frac{d\tau}{(\tau-\omega)^2} \;+\; \int_{\frac{\varepsilon}{k}}^{\infty} \frac{d\tau}{(\tau-\omega)^3} \right) \le\; C\, \frac{k^2 t_n^{-2}}{\varepsilon^2}. \tag{5.15}$$

If $\omega + \varepsilon \le \frac{\varepsilon}{k} < 2\omega$, then $\lambda^{-1} < \frac{2k}{\varepsilon}$, and arguing similarly to (5.15),

$$\overline{e}^n_{5,3,2}(\lambda) \;\le\; C\, t_n^{-2} \left(\int_{\frac{\varepsilon}{k}}^{\infty} \frac{d\tau}{\tau(\tau-\omega)^2} \;+\; \int_{\frac{\varepsilon}{k}}^{\infty} \frac{d\tau}{(\tau-\omega)^3} \right) \le\; C\, \frac{k^2 t_n^{-2} \lambda^2}{\varepsilon^4}. \tag{5.16}$$

If $\omega \le \frac{\varepsilon}{k} < \omega + \varepsilon < 2\omega$, then $\lambda^{-1} \le \frac{2k}{\varepsilon}$, and

$$\begin{aligned} \overline{e}^n_{5,3,2}(\lambda) \;\le\; C\, t_n^{-2} \lambda^{-1} \int_{\frac{\varepsilon}{k}}^{\omega+\varepsilon} \left(\frac{\lambda^{-1}}{\tau \phi^2(\tau)} \;+\; \frac{\lambda^{-2}}{\phi^3(\tau)} \right) d\tau \\ + C\, t_n^{-2} \int_{\omega+\varepsilon}^{\infty} \left(\frac{1}{\tau(\tau-\omega)^2} \;+\; \frac{1}{(\tau-\omega)^3} \right) d\tau \;\le\; C\, k^2 \lambda^2\, \frac{t_n^{-2}}{\varepsilon^4}. \end{aligned} \tag{5.17}$$

If $\omega - \varepsilon \le \frac{\varepsilon}{k} < \omega$, then $\lambda^{-1} < \frac{k}{\varepsilon}$, and

$$\overline{e}^n_{5,3,2}(\lambda) \;\le\; C\, t_n^{-2} \lambda^{-1} \left(\int_{\frac{\varepsilon}{k}}^{\omega+\varepsilon} . \;+\; \int_{\omega+\varepsilon}^{\infty} . \right) \;\le\; C\, k^2 \lambda^2\, \frac{t_n^{-2}}{\varepsilon^4}. \tag{5.18}$$

If $\frac{\omega}{2} \le \frac{\varepsilon}{k} < \omega - \varepsilon$, or $\frac{\varepsilon}{k} < \frac{\omega}{2}$, similar arguments apply to obtain

$$\overline{e}^n_{5,3,2}(\lambda) \;\le\; C t_n^{-2}\, k^2 \;\lambda^2. \tag{5.19}$$

Using (5.15)–(5.19) it follows that

$$\left| \frac{1}{\pi\, t_n^2 \lambda} \int_{\frac{\varepsilon}{k}}^{\frac{\pi}{k}} e^{i\theta\, t_n}\, \widehat{K}_{5,2}(i\theta;\lambda)\, d\theta \right| \;\le\; C\, k^2 \lambda^2\, t_n^{-2}, \tag{5.20}$$

and together with (5.13) show that

$$|e^n_{5,3,2}(\lambda)| \;\le\; C\, k^2 \lambda^2\, t_{n-2}^{-2} \quad (t_{n-2} > 0). \tag{5.21}$$

Together, (5.10), (5.21) give us

$$|e^n_{5,\,3}(\lambda)| \;\le\; C\, k\, \lambda^3\, t_{n-2}^{-2}, \tag{5.22}$$

which is (4.48).

Repeating the proof of (5.20) we now have

$$|e^n_{6,2}(\lambda)| \;\le\; C\, k^2 \lambda^2 t_n^{-2} \quad (t_n > 0), \tag{5.23}$$

which is (4.49).

Remark 5.1. Under the additional condition (1.30) on the kernel $\beta(t)$, we have that

$$e^n_{5,3,1,1}(\lambda) \;\le\; C\, k\, t_{n-2}^{-2}\; \lambda^2, \tag{5.9$'$}$$

and along with the proof of Theorem 3, this implies that

$$k \sum_{n=m}^{\infty} \|U^n \;-\; u(t_n)\| \;\le\; C\, k\, \|u_0\|_4 \quad (t_{m-2} > 0). \tag{5.24}$$

Combining Remarks 3.1 and 5.1 completes the proof of Corollary 1.

ANALYSIS OF THE MULTISCALE FINITE ELEMENT METHOD FOR NONLINEAR AND RANDOM HOMOGENIZATION PROBLEMS*

ZHANGXIN CHEN† AND TATYANA Y. SAVCHUK‡

Abstract. In this paper we study the convergence of the multiscale finite element method for nonlinear and random homogenization problems. Error estimates similar to those for linear homogenization problems are obtained here.

Key words. multiscale problem, multiscale finite element method, finite element, nonlinear problems, random problems, oversampling technique, convergence, stability, error estimate

1. Introduction. Hou and Wu [16] introduced the multiscale finite element method for numerical solution of multiscale problems that are described by partial differential equations with highly oscillatory coefficients. The main idea of this method is to incorporate the microscale information of a multiscale differential problem into finite element basis functions. It is through these modified bases and finite element formulations that the effect of microscales on macroscales can be correctly captured.

The convergence analysis of the method was given in [17] for a two-scale linear homogenization problem with periodic coefficients. It was proven that the multiscale finite element solution converges to the homogenized solution as $h,\ \epsilon \to 0$, where h is the mesh size and ϵ is the small scale in the solution. The analysis also indicated that a resonance error exists between the grid scale and the scales of the homogenization problem. This is a common feature in some numerical upscaling techniques. This error represents a mismatch between the local construction of the multiscale basis functions and the global nature of the continuous problem. An oversampling technique was analyzed in [13] to reduce the resonance error. The idea of this technique is to construct the local basis functions over a domain with size larger than h to reduce the boundary layer effect present in the first order corrector of the local solution.

A convergence analysis of the multiscale finite element method and its oversampled version for nonlinear problems was recently given by Efendiev [11] and Efendiev, Hou, and Ginting [12], and error estimates were obtained for monotone operators (see the next section). These monotone operators do not cover the nonlinear problem studied here, which is a natural extension of the usual linear homogenization problems with highly oscillatory coefficients [5, 16, 17]. The primary goal of this paper is to derive error estimates for the nonlinear problem under consideration. We show that error estimates similar to those for linear homogenization problems hold

for this problem as well. We also indicate how to extend this error analysis to random homogenization problems.

The present analysis is based on an equivalent formulation for the multiscale finite element method recently introduced by Chen [5], which utilizes standard basis functions of finite element spaces but modifies the bilinear (quadratic) form in the finite element formulation of the underlying multiscale problems. This new formulation captures the macroscale structure of the solution of a differential multiscale problem through the modification of this bilinear form. It is a general approach that can handle a large variety of differential problems, periodic or nonperiodic, linear or nonlinear, and stationary or dynamic, as shown here. A similar idea using the operator approach was employed by Arbogast [1].

The paper is organized as follows. In the next section we present a continuous two-scale nonlinear problem, the multiscale finite element method, and existing error estimates. Existence and uniqueness of a multiscale finite element solution is shown in the third section. An improved error analysis is given in the fourth section. An oversampling technique for the nonlinear problem is presented in the fifth section, and a simple reconstruction trick to retrieve the microscopic information is described in the sixth section. Finally, an extension to a random homogenization problem is given in the seventh section. As a general remark, the generic constant $C > 0$ (with or without a subscript) is assumed to be independent of the mesh size h and the microscale ϵ throughout this paper.

2. Existing error estimates for nonlinear problems. Let Ω be a bounded domain in $\mathbb{R}^d$, $1 \le d \le 3$, with Lipschitz boundary Γ. For a subdomain $D \subset \Omega$, each integer $m \ge 0$, and each real number $1 \le p \le \infty$, $W^{m,p}(D)$ indicates the usual Sobolev space of real functions that have all their weak derivatives of order up to m in the Lebesgue space $L^p(D)$. The norm and seminorm of $W^{m,p}(D)$ are denoted by $\|\cdot\|_{m,p,D}$ and $|\cdot|_{m,p,D}$, respectively. When $p = 2$, $W^{m,p}(D)$ is written as $H^m(D)$ with the norm $\|\cdot\|_{m,D}$ and the seminorm $|\cdot|_{m,D}$. We also use the space

$$W_0^{1,p}(D) = \{v \in W^{1,p}(D) : v|_{\partial D} = 0\}, \qquad p > 1.$$

Again, when $p = 2$, it is written as $H_0^1(D)$.

We consider the nonlinear problem

$$\begin{aligned} -\nabla \cdot \left(a_\epsilon \nabla u^\epsilon\right) &= f \qquad \text{in } \Omega, \\ u^\epsilon &= 0 \qquad \text{on } \Gamma, \end{aligned} \tag{2.1}$$

where $a_\epsilon = a(x, x/\epsilon, u^\epsilon)$ depends on the solution u^ϵ. In problem (2.1), the multiscale feature is reflected in the oscillatory nature of the coefficient a_ϵ for $\epsilon \ll 1$, which represents the microscale.

We assume that the coefficient $a(x, y, z)$ is equicontinuous in z uniformly with respect to x and y and periodic in y with period $I = [0, 1]^d$. Furthermore, it satisfies

$$a_*|\zeta|^2 \le \sum_{i,j=1}^{d} a_{ij}(x, y, q)\zeta_i\zeta_j \le a^*|\zeta|^2 \qquad \forall x \in \Omega,\ y,\ \zeta \in \mathbb{R}^d,\ q \in \mathbb{R}, \tag{2.2}$$

for some positive constants a_* and a^*. Under such assumptions, the solution u^ϵ of problem (2.1) converges weakly in $\mathcal{U} = W_0^{1,p}(\Omega)$ $(p > 1)$ to the solution of the homogenized equation [3]

$$\begin{aligned} -\nabla \cdot \left(\mathcal{A}(x, U_0)\nabla U_0\right) &= f \qquad \text{in } \Omega, \\ U_0 &= 0 \qquad \text{on } \Gamma, \end{aligned} \tag{2.3}$$

where the homogenized matrix $\mathcal{A} = (\mathcal{A}_{ij})$ is

$$\mathcal{A}_{ij}(x,q) = \frac{1}{|I|}\int_I \left(a_{ij}(x,y,q) + \sum_{k=1}^{d} \left(a_{ik}\frac{\partial \chi^j}{\partial y_k} \right)(x,y,q) \right) dy \qquad \forall q \in \mathbb{R},$$

and χ^j satisfies, with a periodic boundary condition in y,

$$\begin{aligned} -\nabla_y \cdot \left(a(x,y,q)\nabla_y \chi^j \right) &= \sum_{i=1}^{d} \frac{\partial}{\partial y_i} a_{ij}(x,y,q), \qquad && y \in I, \\ \int_I \chi^j(x,y,q)\, dy &= 0, && q \in \mathbb{R}. \end{aligned} \tag{2.4}$$

The variational form of (2.3) reads as follows: Find $U_0 \in \mathcal{U}$ such that

$$A(U_0, v) \equiv (\mathcal{A}(x, U_0)\nabla U_0, \nabla v) = (f, v) \qquad \forall v \in \mathcal{U}. \tag{2.5}$$

For $h > 0$, let T_h be a regular, quasi-uniform macroscale triangulation of Ω [4, 7] into simplices, where the mesh size h resolves the variations of Ω, f, and the slow variable of a_ϵ. Associated with T_h, let $\mathcal{U}_h \subset \mathcal{U}$ be the finite element space of piecewise linear functions over simplices so that for any $v \in \mathcal{U} \cap H^2(\Omega)$, there exists a $v_h \in \mathcal{U}_h$ satisfying the approximation property

$$\|v - v_h\|_{0,\Omega} + h\|v - v_h\|_{1,\Omega} \le Ch^2 |v|_{l,\Omega}. \tag{2.6}$$

For any $v \in \mathcal{U}_h$, we define its local solution $R_T(v) \in H^1(T)$, $T \in T_h$, by

$$\begin{aligned} (a(x, x/\epsilon, v)\nabla R_T(v), \nabla w)_T &= 0 \qquad && \forall w \in H_0^1(T), \\ R_T(v) &= v && \text{on } \partial T. \end{aligned} \tag{2.7}$$

The global operator R is then given by

$$R(v)|_T = R_T(v) \qquad \forall v \in \mathcal{U}_h,\ T \in T_h.$$

It is easy to see that $R(v) \in \mathcal{U}$, $v \in \mathcal{U}_h$. Note that the local problem (2.7) is linear. In the case without ambiguity in the context, the subscript T in R will be omitted.

Define

$$A_h(v,w) = \big(a(x, x/\epsilon, v)\nabla R(v), \nabla R(w)\big), \qquad v,\ w \in \mathcal{U}_h.$$

The multiscale finite element method (MsFEM) for (2.1) is as follows: Find $u_h \in \mathcal{U}_h$ such that

$$A_h(u_h, v) = (f, v) \qquad \forall v \in \mathcal{U}_h. \tag{2.8}$$

Note that the major difference between (2.8) and the standard Galerkin finite element method lies in the modification of the bilinear form, which needs the solution of local problems (2.7). It is through these local problems and the finite element formulation that the effect of microscales on macroscales can be correctly captured. Since these local problems are independent of each other, they can be solved in parallel.

For a linear counterpart of problem (2.1) where the coefficient $a_\epsilon = a(x, x/\epsilon)$ does not depend on the solution u^ϵ, the following error estimate was obtained for method (2.8) [5, 17]:

$$
\begin{aligned}
|u^\epsilon - R(u_h)|_{1,\Omega} &\le C\left\{(h+\epsilon)\|f\|_{0,\Omega} + \sqrt{\frac{\epsilon}{h}}\,|U_0|_{1,\infty,\Omega}\right\},\\
\|u^\epsilon - R(u_h)\|_{0,\Omega} &\le C\left\{(h^2+\epsilon)\|f\|_{0,\Omega} + \sqrt{\frac{\epsilon}{h}}\,|U_0|_{1,\infty,\Omega}\right\},
\end{aligned}
\tag{2.9}
$$

provided that $U_0 \in H^2(\Omega) \cap W^{1,\infty}(\Omega)$.

Recently, Efendiev, Hou, and Ginting [12] studied convergence of the MsFEM for a nonlinear problem analogous to (2.1):

$$
-\nabla \cdot a(x, u^\epsilon, \nabla u^\epsilon) = f. \tag{2.10}
$$

Under the assumptions that $a(x, u^\epsilon, \nabla u^\epsilon) = a(x/\epsilon, \nabla u^\epsilon)$ and

$$
\begin{aligned}
&|a(x,\xi)| \le C|\xi|^{p-1},\\
&(a(x,\xi_1) - a(x,\xi_2), \xi_1 - \xi_2) \ge C|\xi_1 - \xi_2|^p,\\
&(a(x,\xi),\xi) \ge C|\xi|^p,\\
&|a(x,\xi_1) - a(x,\xi_2)| \le CH(\xi_1,\xi_2,p-1-s)|\xi_1 - \xi_2|^s,
\end{aligned}
$$

where $s > 0$ and $p > 1$, the following error estimate was derived (see [12, Theorem 3.2]):

$$
\|u - u_h\|^p_{1,p,\Omega} \le C\left(\left(\frac{\epsilon}{h}\right)^{\frac{s}{(p-1)(p-s)}} + \left(\frac{\epsilon}{h}\right)^{\frac{p}{p-1}} + h^{\frac{p}{p-1}}\right). \tag{2.11}
$$

Obviously, the assumptions made on a_ϵ exclude the nonlinear problem (2.1). The convergence result in [12] was obtained for the general nonlinear case (2.10); however, there is no explicit convergence for the case considered in this paper because of very weak assumptions made in the way the coefficients depend on u^ϵ. The aim of this paper is to obtain error estimates for the MsFEM (2.8). In particular, we will derive error estimates similar to (2.9) under much weaker assumptions on the coefficient a_ϵ in (2.1). The error analysis is inspired by E [9] and E, Ming, and Zhang [10] for the heterogeneous multiscale method.

3. Existence and uniqueness of a solution. It is known that the error analysis of the MsFEM for the case $h < \epsilon$ is different from that for the case $h > \epsilon$. In the former case, the MsFEM has error estimates similar to those for the traditional finite element method [5, 17]. It is the latter case that is of interest and is being investigated in this paper. The argument below requires that $\epsilon > 0$ be sufficiently small.

Introduce the linearized differential operator at U_0

$$
L(U_0)v = -\nabla \cdot (\mathcal{A}(x, U_0)\nabla v + v\ \mathcal{A}_p(x, U_0)\nabla U_0)\,, \qquad v \in H^1(\Omega),
$$

and the corresponding bilinear form

$$
\hat{A}(U_0; v, w) = (\mathcal{A}(x, U_0)\nabla v, \nabla w) + (v\mathcal{A}_p(x, U_0)\nabla U_0, \nabla w) \qquad \forall v,\ w \in H^1(\Omega),
$$

where $\mathcal{A}_p(x,u) = \nabla_u \mathcal{A}(x,u)$. We assume that this linearized operator is an isomorphism from $H^1_0(\Omega)$ to $H^{-1}(\Omega)$, and so U_0 is an isolated solution of (2.5) and there is

$h_0 > 0$ such that for $0 < h < h_0$ [19],

$$\sup_{w \in \mathcal{U}_h} \frac{\hat{A}(U_0; v, w)}{\|w\|_{1,\Omega}} \geq C_0 \|v\|_{1,\Omega} \qquad \forall v \in \mathcal{U}_h, \tag{3.1}$$

where $C_0 > 0$ is independent of h.

For any $v, v_h, w \in \mathcal{U}$, we define

$$\mathcal{R}(v, v_h, w) = A(v_h, w) - A(v, w) - \hat{A}(v; v_h - v, w).$$

If $v, v_h \in \mathcal{U}$ satisfy $\|v\|_{1,\infty,\Omega} + \|v_h\|_{1,\infty,\Omega} \leq M$, then it follows from [20] that

$$|\mathcal{R}(v, v_h, w)| \leq C(M) \left(\|e_h\|_{0,2p}^2 + \|e_h \nabla e_h\|_{0,p} \right) \|\nabla w\|_{0,q}, \qquad e_h = v - v_h, \ \frac{1}{p} + \frac{1}{q} = 1. \tag{3.2}$$

It follows from the definition of $\mathcal{R}$ and (2.5) that $u_h \in \mathcal{U}_h$ is the solution of (2.8) if and only if

$$\hat{A}(U_0; U_0 - u_h, w) = \mathcal{R}(U_0, u_h, w) + A_h(u_h, w) - A(u_h, w) \qquad \forall w \in \mathcal{U}_h. \tag{3.3}$$

Define

$$E(v, w) = A_h(v, w) - A(v, w) \qquad \forall v, \ w \in \mathcal{U}_h,$$

and

$$\overline{E} = \max_{v \in \mathcal{U}_h \cap W^{1,\infty}(\Omega), w \in \mathcal{U}_h} \frac{|E(v, w)|}{\|v\|_{1,\Omega} \|w\|_{1,\Omega}}.$$

The following equivalence will be used [5]:

$$C_1' |v|_{1,T} \leq |R_T(v)|_{1,T} \leq C_2' |v|_{1,T} \qquad \forall T \in T_h, \ v \in \mathcal{U}_h. \tag{3.4}$$

To prove existence and uniqueness of a solution to (2.8), we introduce the projection of U_0 into $\mathcal{U}_h$ through the linearized bilinear form $\hat{A}$:

$$\hat{A}(U_0; P_h U_0, v) = \hat{A}(U_0; U_0, v) \qquad \forall v \in \mathcal{U}_h. \tag{3.5}$$

It follows from (3.1) that $P_h U_0$ exists and is unique for $0 < h < h_0$, and it satisfies [8]

$$\|U_0 - P_h U_0\|_{1,\infty,\Omega} \leq Ch, \quad \|U_0 - P_h U_0\|_{1,\Omega} \leq Ch \tag{3.6}$$

if $U_0 \in W^{2,\infty}(\Omega)$. When $U_0 \in W^{2,p}(\Omega)$ $(p > d)$, it holds that

$$\|U_0 - P_h U_0\|_{1,\infty,\Omega} \leq Ch^{1-d/p}. \tag{3.7}$$

Finally, for a given $x \in \Omega$, we define the discrete Green function $G_h^x \in \mathcal{U}_h$ by

$$\hat{A}(U_0; v, G_h^x) = \partial v(x) \qquad \forall v \in \mathcal{U}_h, \tag{3.8}$$

where ∂v indicates any of the partial derivatives $\partial v / \partial x_i$ $(i = 1, 2, \ldots, d)$. This function satisfies

$$\|G_h^x\|_{1,1,\Omega} \leq C |\ln h|. \tag{3.9}$$

THEOREM 3.1. *Assume that L is an isomorphism from $H_0^1(\Omega)$ to $H^{-1}(\Omega)$ and $U_0 \in \mathcal{U} \cap W^{2,p}(\Omega)$ with $p > d$. In addition, assume that $\overline{E}$ is bounded and there are constants C_1 and h_1 such that for $0 < h \le h_1$,*

$$\overline{E}^{1/2} |\ln h| \le C_1. \tag{3.10}$$

Then problem (2.8) *has a solution u_h satisfying*

$$\begin{aligned} &\|u_h - P_h U_0\|_{1,\infty,\Omega} \le \overline{E}^{1/2} + h^{1-d/p}, \\ &\|u_h - U_0\|_{1,\infty,\Omega} \le C\left(\overline{E}^{1/2} + h^{1-d/p}\right). \end{aligned} \tag{3.11}$$

Furthermore, if, for all $v_1, v_2 \in \mathcal{U}_h \cap W^{1,\infty}(\Omega)$ and $w \in \mathcal{U}_h$ with $\|v_1\|_{1,\infty,\Omega} + \|v_2\|_{1,\infty,\Omega} \le M$, there is a constant $\zeta_0(M)$, with $0 < \zeta_0 < 1$, such that

$$|E(v_1, w) - E(v_2, w)| \le \zeta_0(M) \|v_1 - v_2\|_{1,\Omega} \|w\|_{1,\Omega}, \tag{3.12}$$

then this solution u_h is locally unique.

Proof. We define the nonlinear mapping $\mathcal{L} : \mathcal{U}_h \to \mathcal{U}_h$ by

$$\hat{A}(U_0; \mathcal{L}(v), w) = \hat{A}(U_0; U_0, w) - \mathcal{R}(U_0, v, w) + A(v, w) - A_h(v, w) \qquad \forall w \in \mathcal{U}_h.$$

This mapping is continuous using (3.1) and (3.2). We also define the set

$$B = \left\{ v \in \mathcal{U}_h : \|v - P_h U_0\|_{1,\infty,\Omega} \le \overline{E}^{1/2} + h^{1-d/p} \right\}.$$

Note that, by (3.5),

$$\hat{A}(U_0; \mathcal{L}(v) - P_h U_0, w) = -\mathcal{R}(U_0, v, w) + A(v, w) - A_h(v, w) \qquad \forall w \in \mathcal{U}_h.$$

Choosing $w = G_h^x$ in this equation and applying (3.2), (3.7), (3.9), and (3.10), we see that, with $v \in B$ and $\|v\|_{1,\infty,\Omega} \le M$,

$$\begin{aligned} \|\mathcal{L}(v) - P_h U_0\|_{1,\infty,\Omega} &\le C(M) \left(\|U_0 - v\|_{1,\infty,\Omega}^2 + \overline{E} \right) |\ln h| \\ &\le C(M) \left(\|U_0 - P_h U_0\|_{1,\infty,\Omega}^2 + \|P_h U_0 - v\|_{1,\infty,\Omega}^2 + \overline{E} \right) |\ln h| \\ &\le C(M) \left(h^{2-2d/p} + \overline{E} \right) |\ln h|. \end{aligned}$$

Because $v \in B$ and $\overline{E}$ is bounded (e.g., $\overline{E} \le \mathcal{C}_1$), we see that

$$\begin{aligned} \|v\|_{1,\infty,\Omega} &\le \|v - P_h U_0\|_{1,\infty,\Omega} + \|P_h U_0\|_{1,\infty,\Omega} \\ &\le \overline{E}^{1/2} + C(U_0) \le \mathcal{C}_1^{1/2} + C(U_0) \equiv \mathcal{C}_0. \end{aligned} \tag{3.13}$$

Combining these two inequalities, we have

$$\|\mathcal{L}(v) - P_h U_0\|_{1,\infty,\Omega} \le C(\mathcal{C}_0) \left(h^{2-2d/p} + \overline{E} \right) |\ln h|.$$

Defining $C_1 = 1/C(\mathcal{C}_0)$, it follows from (3.10) that

$$\|\mathcal{L}(v) - P_h U_0\|_{1,\infty,\Omega} \le \overline{E}^{1/2} + C(\mathcal{C}_0) h^{2-2d/p} |\ln h|.$$

Thus there is a constant h_2 such that for $0 < h \le h_2$, we obtain

$$\|\mathcal{L}(v) - P_h U_0\|_{1,\infty,\Omega} \le \overline{E}^{1/2} + h^{1-d/p}.$$

Set $h_1 = \min(h_0, h_2)$. Then, for $0 < h \le h_1$, we see that $\mathcal{L}(B) \subset B$. The Brouwer fixed point theorem means that there is a $u_h \in B$ such that $\mathcal{L}(u_h) = u_h$.

To prove the uniqueness, let u_h^1 and u_h^2 be two solutions of (2.8). Then it follows from (3.3) that

$$\begin{aligned}\hat{A}(U_0; u_h^2 - u_h^1, w) &= \hat{A}(U_0; U_0 - u_h^1, w) - \hat{A}(U_0; U_0 - u_h^2, w)\\ &= \mathcal{R}(U_0, u_h^1, w) - \mathcal{R}(U_0, u_h^2, w) + E(u_h^1, w) - E(u_h^2, w).\end{aligned} \tag{3.14}$$

Because both u_h^1 and u_h^2 are in the set B, it follows from (3.13) that $\|u_h^1\|_{1,\infty,\Omega} + \|u_h^2\|_{1,\infty,\Omega} \le 2\mathcal{C}_0$, which, together with (3.1), (3.12), (3.14), and Poincaré's inequality, implies that

$$\|u_h^1 - u_h^2\|_{1,\Omega} \le \zeta_0(2\mathcal{C}_0)\|u_h^1 - u_h^2\|_{1,\Omega}.$$

Since $\zeta_0 < 1$ via assumption, then $u_h^1 = u_h^2$. Therefore, the solution u_h is locally unique. ∎

4. Improved error estimates for nonlinear problems. The main result in this section is stated in the next theorem. The multiscale finite element solution u_h used below refers to the one that satisfies the conditions in Theorem 3.1. To avoid unnecessary techniques, we perform an error analysis when system (2.7) is replaced by

$$\begin{aligned}&(a(x_T, x/\epsilon, v(x_T))\nabla R_T(v), \nabla w)_T = 0 \qquad && \forall w \in H_0^1(T),\\ &R_T(v) = v && \text{on } \partial T,\end{aligned} \tag{4.1}$$

where x_T is any point in $T \in T_h$ (e.g., the barycenter of T).

THEOREM 4.1. *Let U_0 and u_h be the solutions of* (2.5) *and* (2.8), *respectively, and $U_0 \in W^{2,\infty}(\Omega)$. Then there is $h_0 > 0$ such that for $0 < h < h_0$,*

$$\|U_0 - u_h\|_{1,\Omega} \le C\left(h + \sqrt{\frac{\epsilon}{h}}\right), \quad \|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \sqrt{\frac{\epsilon}{h}}\right)|\ln h|, \tag{4.2}$$

provided that ϵ/h is sufficiently small.

This theorem can be shown by combining the next two propositions.

PROPOSITION 4.2. *In addition to the assumptions of Theorem* 3.1, *let $U_0 \in W^{2,\infty}(\Omega)$. Then there are constants C_2 (see the proof below) and $h_0 > 0$ such that if $C_1 < C_2$ and $0 < h < h_0$, then*

$$\|U_0 - u_h\|_{1,\Omega} \le C\left(h + \overline{E}\right), \quad \|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \overline{E}\right)|\ln h|. \tag{4.3}$$

PROPOSITION 4.3. *Under the assumptions of Theorem* 4.1, *if $\sqrt{\epsilon/h}|\ln h|$ is sufficiently small, then conditions* (3.10) *and* (3.12) *hold. Moreover,*

$$\overline{E} \le C\sqrt{\frac{\epsilon}{h}}. \tag{4.4}$$

Proof of Proposition 4.2. Taking $w = P_h U_0 - u_h$ in (3.3) and using (3.1), (3.2), and (3.6), we see that

$$\|P_h U_0 - u_h\|_{1,\Omega} \le C\left(\|U_0 - u_h\|_{1,4,\Omega}^2 + \overline{E} + h\right). \tag{4.5}$$

Applying an interpolation inequality, we have

$$\|U_0 - u_h\|_{1,4,\Omega}^2 \le \|U_0 - u_h\|_{1,\Omega}\|U_0 - u_h\|_{1,\infty,\Omega}, \tag{4.6}$$

which, together with (3.6) and (3.13), yields

$$\|P_hU_0 - u_h\|_{1,\Omega} \le C_3\left(\overline{E}^{1/2} + h^{1-d/p}\right)\|P_hU_0 - u_h\|_{1,\Omega} + C\left(h + \overline{E}\right).$$

Choosing $w = G_h^x$ in (3.3) and using (3.2), (3.6), and (3.9), we have

$$\begin{aligned}\|P_hU_0 - u_h\|_{1,\infty,\Omega} \le{}& C_4(\overline{E} + h)|\ln h|\|P_hU_0 - u_h\|_{1,\infty,\Omega}\\ &+ C\left(\|U_0 - u_h\|_{1,\infty,\Omega}^2 + \overline{E} + h\right)|\ln h|.\end{aligned}$$

From (3.6), (3.7), and (3.10) it follows that

$$\begin{aligned}\|P_hU_0 - u_h\|_{1,\infty,\Omega} \le{}& C_4(\overline{E}^{1/2} + h^{1-d/p})|\ln h|\|P_hU_0 - u_h\|_{1,\infty,\Omega}\\ &+ C\left(\overline{E} + h\right)|\ln h|.\end{aligned}$$

Now, we set

$$C_2 = \min\left(\frac{|\ln h|}{2C_3}, \frac{1}{2C_4}\right)$$

and choose h_0 such that $\overline{E}^{1/2}|\ln h| \le C_2$. With these two choices, we obtain

$$\begin{aligned}&\|P_hU_0 - u_h\|_{1,\Omega} \le C\left(\overline{E} + h\right),\\ &\|P_hU_0 - u_h\|_{1,\infty,\Omega} \le C\left(\overline{E} + h\right)|\ln h|,\end{aligned}$$

which, together with (3.6), gives the desired result. □

Proposition 4.3 can be proven from the next three lemmas.

LEMMA 4.4. *For $v, w \in \mathcal{U}_h$, we have*

$$|R(v) - R(w)|_{1,T} \le C\left(\|v - w\|_{0,\infty,T}\left[|v|_{1,T} + |w|_{1,T}\right] + |v - w|_{1,T}\right), \quad T \in T_h. \tag{4.7}$$

Proof. It follows from (2.2) and (4.1) that

$$\begin{aligned}C|R(v) - R(w)|_{1,T}^2 \le{}& \left(a\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\nabla[R(v) - R(w)], \nabla[R(v) - R(w)]\right)_T\\ \equiv{}& J_1 + J_2,\end{aligned} \tag{4.8}$$

where

$$\begin{aligned}J_1 &= \left(a\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\nabla R(v) - a\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\nabla R(w), \nabla(v - w)\right)_T,\\ J_2 &= -\left(\left[a\left(x_T, \frac{x}{\epsilon}, v(x_T)\right) - a\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\right]\nabla R(w), \nabla[R(v) - R(w)]\right)_T.\end{aligned}$$

Note that

$$\begin{aligned}J_1 = {}& \left(\left[a\left(x_T, \frac{x}{\epsilon}, v(x_T)\right) - a\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\right]\nabla R(v), \nabla(v - w)\right)_T\\ &+ \left(a\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\nabla[R(v) - R(w)], \nabla(v - w)\right)_T.\end{aligned}$$

As a result, using (2.2), we bound J_1 and J_2 as follows:

$$|J_1| \le C\left(\|v-w\|_{0,\infty,T}|R(v)|_{1,T} + |R(v)-R(w)|_{1,T}\right)|v-w|_{1,T},$$
$$|J_2| \le C\|v-w\|_{0,\infty,T}|R(w)|_{1,T}|R(v)-R(w)|_{1,T}.$$

Substituting these two bounds for J_1 and J_2 into (4.8) and using (3.4) implies the desired result (4.7). □

For $v, w \in \mathcal{U}_h$, we define

$$Q(v) = v(x) + \epsilon \sum_{k=1}^{d} \chi^k\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\frac{\partial v}{\partial x_k}(x),$$
$$Q(w) = w(x) + \epsilon \sum_{k=1}^{d} \chi^k\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\frac{\partial w}{\partial x_k}(x).$$

Set $\theta_\epsilon(v) = R(v) - Q(v)$ and $\theta_\epsilon(w) = R(w) - Q(w)$. Note that

$$\begin{aligned} -\nabla\cdot\left(a\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\nabla\theta_\epsilon(v)\right) &= 0 \qquad \text{in } T,\\ \theta_\epsilon(v) &= -\epsilon\sum_{k=1}^{d}\chi^k\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\frac{\partial v}{\partial x_k} \qquad \text{on } \partial T, \end{aligned} \tag{4.9}$$

and an analogous definition can be given for $\theta_\epsilon(w)$. These two quantities satisfy [5, 17]

$$|\theta_\epsilon(v)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}\,|v|_{1,T}, \quad |\theta_\epsilon(w)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}\,|w|_{1,T}, \tag{4.10}$$

which hold because ∇v and ∇w are piecewise constant.

LEMMA 4.5. *For $v, w \in \mathcal{U}_h$, we have*

$$|\theta_\epsilon(v) - \theta_\epsilon(w)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}\left(\|v-w\|_{0,\infty,T}\left[|v|_{1,T}+|w|_{1,T}\right] + |v-w|_{1,T}\right), \quad T \in T_h. \tag{4.11}$$

Proof. Let $\xi_\epsilon \in C_0^\infty(T)$, $0 \le \xi_\epsilon \le 1$, be a cut-off function in T such that $\xi_\epsilon = 1$ outside a ϵ-neighborhood of the boundary ∂T and $|\nabla\xi_\epsilon| \le C\epsilon^{-1}$ with C independent of ϵ and T. Define, for $v \in \mathcal{U}_h$,

$$\varphi_\epsilon(v) = \theta_\epsilon(v) + \epsilon\sum_{k=1}^{d}\chi^k\left(x_T, \frac{x}{\epsilon}, v(x_T)\right)\frac{\partial v}{\partial x_k}(1-\xi_\epsilon),$$

and a similar meaning can be given for $\varphi_\epsilon(w)$, $w \in \mathcal{U}_h$. Calculations show that

$$\begin{aligned} &C|\varphi_\epsilon(v) - \varphi_\epsilon(w)|_{1,T}\\ &\quad\le \max_{x\in T}|a\big(x_T, x/\epsilon, v(x_T)\big) - a\big(x_T, x/\epsilon, w(x_T)\big)|\left(|\varphi_\epsilon(v)-\theta_\epsilon(v)|_{1,T} + |\varphi_\epsilon(w)|_{1,T}\right)\\ &\qquad + \max_{x\in T}|a\big(x_T, x/\epsilon, w(x_T)\big)|\;|\varphi_\epsilon(v)-\theta_\epsilon(v)-\varphi_\epsilon(w)+\theta_\epsilon(w)|_{1,T} \end{aligned}$$

and

$$|\varphi_\epsilon(v)-\theta_\epsilon(v)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}|v|_{1,T}, \quad |\varphi_\epsilon(w)-\theta_\epsilon(w)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}|w|_{1,T}.$$

Also, using (4.10), we see that

$$|\varphi_\epsilon(w)|_{1,T} \le |\varphi_\epsilon(w) - \theta_\epsilon(w)|_{1,T} + |\theta_\epsilon(w)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}|w|_{1,T}.$$

Observe that

$$\begin{aligned}
&\varphi_\epsilon(v) - \theta_\epsilon(v) - \varphi_\epsilon(w) + \theta_\epsilon(w) \\
&\quad = \epsilon \sum_{k=1}^{d} \left(\chi^k\left(x_T, \frac{x}{\epsilon}, v(x_T)\right) - \chi^k\left(x_T, \frac{x}{\epsilon}, w(x_T)\right)\right) \frac{\partial v}{\partial x_k}(1-\xi_\epsilon) \\
&\qquad + \epsilon \sum_{k=1}^{d} \chi^k\left(x_T, \frac{x}{\epsilon}, w(x_T)\right) \frac{\partial (v-w)}{\partial x_k}(1-\xi_\epsilon).
\end{aligned}$$

Consequently, by the continuity of $\{\chi^k\}_{k=1}^d$, we see that

$$|\varphi_\epsilon(v) - \theta_\epsilon(v) - \varphi_\epsilon(w) + \theta_\epsilon(w)|_{1,T} \le C\sqrt{\frac{\epsilon}{h}}\left(\|v-w\|_{0,\infty,T}|v|_{1,T} + |v-w|_{1,T}\right).$$

Combining these inequalities gives the desired result (4.11). ∎

The next lemma indicates that $E(\cdot,\cdot)$ has certain continuity with respect to its first argument.

LEMMA 4.6. *For $v_1, v_2, w \in \mathcal{U}_h$ satisfying $\|v_1\|_{1,\infty,\Omega} + \|v_2\|_{1,\infty,\Omega} \le M$, we have*

$$|E(v_1,w) - E(v_2,w)| \le C(M)\sqrt{\frac{\epsilon}{h}}\|v_1 - v_2\|_{1,\Omega}|w|_{1,\Omega}, \quad T \in T_h. \tag{4.12}$$

Proof. Define $l = [h/\epsilon]$, and let $I_{l\epsilon}$ be the cube of size $l\epsilon$ at x_T. By the definition of $R(v_1)$ and the relation that $R(v_1) = \theta_\epsilon(v_1) + Q(v_1)$, we see that

$$\begin{aligned}
\big(a\big(x_T, x/\epsilon, v_1(x_T)\big)\nabla R(v_1), \nabla R(w)\big)_T &= \big(a\big(x_T, x/\epsilon, v_1(x_T)\big)\nabla R(v_1), \nabla w\big)_T \\
&= \big(a\big(x_T, x/\epsilon, v_1(x_T)\big)\nabla [\theta_\epsilon(v_1) + Q(v_1)], \nabla w\big)_T.
\end{aligned}$$

Also, note that

$$\frac{1}{|I_{l\epsilon}|}\left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla Q(v_1), \nabla w\right)_{I_{l\epsilon}} = \nabla w \cdot \mathcal{A}\big(x_T, v_1(x_T)\big)\nabla v_1.$$

Then $E(v_1,w) - E(v_2,w)$ can be split as follows:

$$E(v_1,w) - E(v_2,w) = \sum_{T\in T_h} \left(E(v_1,w) - E(v_2,w)\right)|_T = \sum_{T\in T_h}(J_3 + J_4), \tag{4.13}$$

where

$$\begin{aligned}
J_3 &= \left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla\theta_\epsilon(v_1) - a\left(x_T, \frac{x}{\epsilon}, v_2(x_T)\right)\nabla\theta_\epsilon(v_2), \nabla w\right)_T, \\
J_4 &= \left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla Q(v_1), \nabla w\right)_T \\
&\quad - \frac{|T|}{|I_{l\epsilon}|}\left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla Q(v_1), \nabla w\right)_{I_{l\epsilon}} \\
&\quad - \left(a\left(x_T, \frac{x}{\epsilon}, v_2(x_T)\right)\nabla Q(v_2), \nabla w\right)_T \\
&\quad - \frac{|T|}{|I_{l\epsilon}|}\left(a\left(x_T, \frac{x}{\epsilon}, v_2(x_T)\right)\nabla Q(v_2), \nabla w\right)_{I_{l\epsilon}}.
\end{aligned}$$

It follows from Lemma 4.5 that

$$|J_3| \le C\sqrt{\frac{\epsilon}{h}}\big(\|v_1 - v_2\|_{0,\infty,T}\,[|v_1|_{1,T} + |v_2|_{1,T}] + |v_1 - v_2|_{1,T}\big)|w|_{1,T}. \tag{4.14}$$

The term J_4 can be rewritten as follows:

$$\begin{aligned} J_4 = &-\left(\frac{|T|}{|l\epsilon|^d} - 1\right)\left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla Q(v_1) - a\left(x_T, \frac{x}{\epsilon}, v_2(x_T)\right)\nabla Q(v_2), \nabla w\right)_T \\ &+ \frac{|T|}{|l\epsilon|^d}\left(a\left(x_T, \frac{x}{\epsilon}, v_1(x_T)\right)\nabla Q(v_1) - a\left(x_T, \frac{x}{\epsilon}, v_2(x_T)\right)\nabla Q(v_2), \nabla w\right)_{T\setminus I_{l\epsilon}}. \end{aligned}$$

Then it can be bounded by

$$|J_4| \le C\frac{\epsilon}{h}\left(\|v_1 - v_2\|_{0,\infty,T}\,[|v_1|_{1,T} + |v_2|_{1,T}] + |v_1 - v_2|_{1,T}\right)|w|_{1,T}. \tag{4.15}$$

Applying an inverse inequality, we see that

$$\begin{aligned} \|v_1 - v_2\|_{0,\infty,T}|v_1|_{1,T} &\le Ch_T^{-d/2}\|v_1 - v_2\|_{0,T}h_T^{d/2}\|v_1\|_{1,\infty,T} \\ &= C\|v_1 - v_2\|_{0,T}\|v_1\|_{1,\infty,T}, \end{aligned} \tag{4.16}$$

since $\nabla v_1|_T$ is a constant. A similar result holds for $\|v_1 - v_2\|_{0,\infty,T}|v_2|_{1,T}$. Substituting (4.14)–(4.16) into (4.13) implies the desired result. ∎

Proof of Proposition 4.3. Taking $v_2 = 0$ in (4.12) generates (4.4). Also, if $\sqrt{\epsilon/h}|\ln h|$ is sufficiently small, $\overline{E}^{1/2}|\ln h|$ can be made smaller than any given threshold, and so (3.10) holds. Finally, choose $\zeta_0(M) = C(M)\sqrt{\epsilon/h}$. Then if $\sqrt{\epsilon/h}|\ln h|$ is sufficiently small, $\zeta_0(M) < 1$, and thus (3.12) is verified. ∎

5. An oversampling technique. Note that estimates (4.2) deteriorate when ϵ is of the same order as the mesh size h. This phenomenon reveals a "resonance error" between the grid scale h and the scale ϵ of the continuous problem (2.1). This resonance is due to a mismatch between the local solution of (2.7) and the global solution of (2.1) on the boundary of each $T \in T_h$, which produces a boundary layer. Since this layer is thin, we can sample in a (local) domain with size larger than h and utilize only the interior sampled information. In this manner, the influence of the boundary layer in the larger domain can be greatly reduced. In this section, we extend an oversampling technique for linear problems [13, 16] to the nonlinear problem (2.1) in order to reduce the resonance error in (4.2).

For each $T \in T_h$, we indicate by $S(T)$ a macroelement which contains T and satisfies the following condition: There are positive constants C_3 and C_4, independent of h and ϵ, such that $h_S \le C_3 h_T$ and $\operatorname{dist}(\partial S, \partial T) \ge C_4 h_T$. For each $v \in \mathcal{U}_h(T)$, we extend it to $\mathcal{U}_h(S)$ as follows. Let $\{\phi_i^T\}_1^{d+1}$ and $\{\psi_i^S\}_1^{d+1}$ be the respective bases of $\mathcal{U}_h(T)$ and $\mathcal{U}_h(S)$. Set

$$v|_T = \sum_{i=1}^{d+1} c_i^T \phi_i^T, \quad \phi_i^T = \sum_{j=1}^{d+1} c_{ij}^T \psi_j^S|_T.$$

Then we define $\widehat{v} \in \mathcal{U}_h(S)$ by

$$\widehat{v} = \sum_{i,j=1}^{d+1} c_i^T c_{ij}^T \psi_j^S.$$

Now, for any $v \in \mathcal{U}_h$, we define $R_S(v) \in H^1(S)$, $T \subset S$, $T \in T_h$, by

$$\begin{aligned} &(a(x, x/\epsilon, \widehat{v})\nabla R_S(v), \nabla w)_S = 0 \qquad && \forall w \in H_0^1(S), \\ &R_S(v) = \widehat{v} && \text{on } \partial S. \end{aligned} \tag{5.1}$$

The global operator R is defined by

$$R(v)|_T = R_S(v)|_T \qquad \forall v \in \mathcal{U}_h,\ T \in T_h.$$

The oversampled MsFEM for (2.1) is to seek $u_h \in \mathcal{U}_h$ such that

$$\sum_{T \in T_h} \left(a(x, x/\epsilon, u_h)\nabla R_{S(T)}(u_h), \nabla R_{S(T)}(v)\right)_T = (f, v) \qquad \forall v \in \mathcal{U}_h. \tag{5.2}$$

The existence and uniqueness of a solution to (5.2) can be shown in Theorem 3.1. Furthermore, combining the error analysis in the previous section and that for the oversampled MsFEM for linear problems given in [5, 13], the following improved error estimates can be shown as in Theorem 4.1.

THEOREM 5.1. *Let U_0 and u_h be the solutions of* (2.5) *and* (5.2)*, respectively, and $U_0 \in W^{2,\infty}(\Omega)$. Then there is $h_0 > 0$ such that for $0 < h < h_0$,*

$$\|U_0 - u_h\|_{1,\Omega} \le C\left(h + \frac{\epsilon}{h}\right), \quad \|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \frac{\epsilon}{h}\right)|\ln h|, \tag{5.3}$$

provided that ϵ/h is sufficiently small.

Note that while these estimates improve those in (5.15), resonance persists.

6. Approximation to u^ϵ. Theorems 4.1 and 5.1 show that the multiscale finite element solution u_h of (2.8) is a good approximation of the macroscopic solution U_0. We now consider an approximation to the solution u^ϵ of (2.1).

Define $R(u_h)$ as the solution of (4.1) with v replaced by u_h:

$$\begin{aligned} &(a(x_T, x/\epsilon, u_h(x_T))\nabla R_T(u_h), \nabla w)_T = 0 \qquad && \forall w \in H_0^1(T), \\ &R_T(v) = u_h && \text{on } \partial T. \end{aligned} \tag{6.1}$$

Applying (2.4), $R_T(u_h)$ satisfies

$$\nabla R_T(u_h) = \nabla u_h + \sum_{k=1}^{d} \nabla_y \chi^k \left(x_T, \frac{x}{\epsilon}, u_h(x_T)\right) \frac{\partial u_h}{\partial x_k} + \nabla \theta_\epsilon(u_h), \qquad T \in T_h. \tag{6.2}$$

Also, define the first order approximation of u_1^ϵ by

$$u_1^\epsilon = U_0 + \epsilon \sum_{k=1}^{d} \chi^k \left(x, \frac{x}{\epsilon}, U_0(x)\right) \frac{\partial U_0}{\partial x_k}.$$

Clearly,

$$\nabla u_1^\epsilon = \nabla U_0 + \sum_{k=1}^{d} \left\{ \left(\epsilon \nabla \chi^k + \nabla_y \chi^k\right) \frac{\partial U_0}{\partial x_k} + \epsilon \frac{\partial \chi^k}{\partial U_0} \frac{\partial U_0}{\partial x_k} \nabla U_0 + \epsilon \chi^k \nabla \frac{\partial U_0}{\partial x_k} \right\}. \tag{6.3}$$

Combining (6.2) and (6.3) gives

(6.4)
$$|u_1^\epsilon - R(u_h)|_{1,T} \le C\left(|U_0 - u_h|_{1,T} + \epsilon\left[\|U_0\|_{2,T} + \|U_0\|_{1,4,T}^2\right]\right) + |\theta_\epsilon(u_h)|_{1,T}$$
$$+ \left\|\sum_{k=1}^d \left[\nabla_y \chi^k\left(x_T, \frac{x}{\epsilon}, u_h(x_T)\right) - \nabla_y \chi^k\left(x, \frac{x}{\epsilon}, U_0(x)\right)\right]\frac{\partial U_0}{\partial x_k}\right\|_{0,T}$$
$$\le C\Big\{|U_0 - u_h|_{1,T} + |U_0 - u_h|_{1,\infty,T}|U_0|_{1,T} + |\theta_\epsilon(u_h)|_{1,T}$$
$$+ (\epsilon + h)\left(\|U_0\|_{2,T} + \|U_0\|_{1,4,T}^2 + |U_0|_{1,\infty,T}|U_0|_{1,T}\right)\Big\}.$$

A classical estimate for $u^\epsilon - u_1^\epsilon$ [2, 3, 22] gives

$$\|u^\epsilon - u_1^\epsilon\|_{1,\Omega} \le C\sqrt{\epsilon}. \tag{6.5}$$

Finally, combining (4.2), (4.10), (6.4), and (6.5), we obtain the next theorem.

THEOREM 6.1. *Let u^ϵ be the solution of* (2.1), *$R(u_h)$ be defined by* (6.1), *and $U_0 \in W^{2,\infty}(\Omega)$. Then there is $h_0 > 0$ such that for $0 < h < h_0$,*

$$|u^\epsilon - R(u_h)|_{1,\Omega} \le C\left(h + \sqrt{\epsilon} + \sqrt{\frac{\epsilon}{h}}\right)|\ln h|, \tag{6.6}$$

provided that ϵ/h is sufficiently small.

Note that estimate (6.6) is similar to (2.9) obtained for a linear counterpart of (2.1). The oversampling technique discussed in the previous section can also be applied to (6.1).

7. A random homogenization problem. In the previous sections we have assumed that the coefficient a_ϵ in (2.1) is periodic. In many problems such as in porous media flows [6], this coefficient is often random. In this section we extend the multiscale finite element analysis performed for the nonlinear problem (2.1) to a multiscale problem with a random coefficient.

Let (D, F, P) be a probability space and $a(y,\omega) = \big(a_{ij}(y,\omega)\big)$ be a random field, $y \in \mathbb{R}^d$, $\omega \in D$, whose statistics is invariant under integer shifts. Furthermore, let a satisfy the uniform ellipticity condition (2.2); i.e.,

$$a_*|\zeta|^2 \le \sum_{i,j=1}^d a_{ij}(y,\omega)\zeta_i\zeta_j \le a^*|\zeta|^2 \qquad \forall \omega \in D,\ y,\ \zeta \in \mathbb{R}^d, \tag{7.1}$$

for some positive constants a_* and a^*. Problem (2.1) now takes the form

$$\begin{aligned} -\nabla\cdot\big(a(x/\epsilon,\omega)\nabla u^\epsilon\big) &= f \qquad \text{in } \Omega,\\ u^\epsilon &= 0 \qquad \text{on } \Gamma. \end{aligned} \tag{7.2}$$

7.1. Homogenization results. We collect some homogenization results for problem (7.2), following [21]. As in (2.4), let χ^j satisfy [18]

$$-\nabla_y\cdot\big(a(y,\omega)\nabla_y\chi^j\big) = \sum_{i=1}^d \frac{\partial}{\partial y_i}a_{ij}(y,\omega), \tag{7.3}$$

and $\nabla\chi^j$ is assumed to be stationary under integer shifts. χ^j is generally not stationary.

Define the average operator with respect to the measure P (mathematical expectation)

$$\langle v \rangle = \mathbb{E} \int_{[0,1]^d} v(y)\ dy.$$

Also, define

$$[v]_m \equiv [v; m] = \frac{1}{m^d} \int_{[0,m]^d} v(y)\ dy.$$

The homogenized coefficient $\mathcal{A}$ is given by

$$\mathcal{A} = \langle a(\mathcal{I} + \nabla\chi) \rangle\,, \tag{7.4}$$

where $\mathcal{I}$ is the identity matrix and $\chi = (\chi^1, \chi^2, \ldots, \chi^d)^T$.

For any $\rho > 0$, we consider the auxiliary problem

$$-\nabla_y \cdot (a(y,\omega)\nabla_y u) + \rho u = \sum_{i=1}^{d} \frac{\partial g_i}{\partial y_i}, \tag{7.5}$$

where

$$g_i \in \{v : \langle v^2 \rangle \le G^2\}, \qquad i = 1, 2, \ldots, d,$$

with v a random field whose statistics is stationary under integer shifts.

For each fixed realization of $\{a(y,\cdot)\}$, let η_x be the diffusion process generated by $-\nabla_y \cdot (a(y,\omega)\nabla_y)$ and starting from x at $t = 0$, and let M_x be the expectation with respect to η_x. Set

$$\Gamma(s) = \int_0^s e^{-\rho\tau} \sum_{i=1}^{d} \frac{\partial g_i}{\partial y_i}\big(\eta(\tau)\big)\ d\tau.$$

It is known [14] that the solution of problem (7.5) is

$$u_\rho(x) = M_x \Gamma(\infty).$$

Lemmas 7.1–7.3 and 7.5 below can be found in [21] and Lemma 7.4 in [10]. Note that the homogenization results in [21] may be overestimated because they are based on the Green function estimates that are not required for the computation of effective coefficients. Because of this, the convergence result here may be overestimated as well.

LEMMA 7.1. *For the solution u_ρ of (7.5), there are constants $C > 0$, independent of ρ, such that*

$$\begin{aligned} &\langle |\nabla u_\rho|^2 \rangle + \rho \langle u_\rho^2 \rangle \le C \langle |g|^2 \rangle\,, \\ &\left\langle \left(M_x \Gamma(\infty)\right)^2 \right\rangle^{1/2} \le \frac{CG^2}{\rho}, \\ &\left\langle M_x \left(\Gamma(\infty) - \Gamma(s)\right)^2 \right\rangle \le \frac{CG^2}{\rho} e^{-2s\rho}, \end{aligned} \tag{7.6}$$

where $g = (g_1, g_2, \ldots, g_d)^T$.

Due to the presence of the lower order term ρu, the Green function associated with the differential operator $-\nabla_y \cdot (a(y,\omega)\nabla_y) + \rho$ in the left-hand side of (7.5) decays exponentially with a rate of order $\mathcal{O}(\sqrt{\rho})$. To be specific, define

$$B_\rho = \left\{ x \in \mathbb{R}^d : \|x\|_\infty \le \rho^{-\frac{1}{2}|\ln \rho^{-1}|^{1/2}} \right\},$$

where $\|x\|_\infty = \max\{|x_i|, i = 1, 2, \ldots, d\}$.

LEMMA 7.2. *Let t be the first exit time of B_ρ starting at $x \in B_\rho$, and define $\hat{u}_\rho(x) = M_x \Gamma(t)$. Then, if ρ is small enough,*

$$\mathbb{E} \int_{\|x\|_\infty \le 10} |u_\rho(x) - \hat{u}_\rho(x)|^2 \, dx \le C G^2 e^{-C|\ln \rho^{-1}|^2},$$
$$\mathbb{E} \int_{\|x\|_\infty \le 1} |\nabla u_\rho(x) - \nabla \hat{u}_\rho(x)|^2 \, dx \le C G^2 e^{-C|\ln \rho^{-1}|^2}.$$

LEMMA 7.3. *Let $\{a^1, g^1\}$ and $\{a^2, g^2\}$ be two sets of data satisfying*

$$\{a^1(y), g^1(y)\} = \{a^2(y), g^2(y)\}, \qquad y \notin B,$$

where $B \subset \mathbb{R}^d$ is a domain, and u_ρ^1 and u_ρ^2 be the respective solutions of (7.5) *associated with $\{a^1, g^1\}$ and $\{a^2, g^2\}$. Then*

$$\int_{\mathbb{R}^d} |u_\rho^1(x) - u_\rho^2(x)|^2 \, dx \le \frac{C}{\rho} \int_{\mathbb{R}^d} \left(G^2 + |\nabla u_\rho^1(x)|^2 \right) I_B(x) \, dx,$$

where I_B is the indicator function of B.

For a subdomain $B \subset \mathbb{R}^d$, denote by $\Phi(B)$ the σ-algebra generated by the parameters $\{a(y,\omega) : y \in B\}$. Let ζ_1 and ζ_2 be two random variables that are measurable with respect to $\Phi(B_1)$ and $\Phi(B_2)$, respectively. We will use the exponential decay condition

$$|\mathbb{E}(\zeta_1 \zeta_2) - \mathbb{E}(\zeta_1)\mathbb{E}(\zeta_2)| \le e^{-C \operatorname{dist}(B_1, B_2)} \sqrt{\mathbb{E}\zeta_1^2} \sqrt{\mathbb{E}\zeta_2^2}. \tag{7.7}$$

This type of exponential decay condition is often used for geostatistical models [15].

LEMMA 7.4. *Under condition* (7.7), *we have*

$$\mathbb{E}\,[u_\rho; m]^2 \le C \left(\frac{G^2}{\rho} \left(\frac{|\ln \rho^{-1}|^2}{\rho^{1/2} m} \right) + e^{-C|\ln \rho^{-1}|^2} \right).$$

LEMMA 7.5. *Let $\chi_\rho = \left(\chi_\rho^1, \chi_\rho^2, \ldots, \chi_\rho^d\right)^T$, where χ_ρ^i is the solution of* (7.5) *with*

$$g = (a_{i1}, a_{i2}, \ldots, a_{id})^T.$$

Under condition (7.7), *for any $0 < \lambda < 1/2$, we have*

$$|\mathcal{A} - \langle a(\mathcal{I} + \nabla \chi_\rho) \rangle| \le C \rho^{(d-2-2\lambda)/(4+d)},$$

where $|\cdot|$ represents a matrix norm.

7.2. The MsFEM. Note that the definition of the MsFEM (2.8) does not utilize any periodicity or macroscopic model. Thus, in the random case it can be defined in the same manner as in the periodic case. That is, for any $v \in \mathcal{U}_h$, we define its local solution $R_T(v) \in H^1(T)$, $T \in T_h$, by

$$\begin{aligned} &(a_\epsilon \nabla R_T(v), \nabla w)_T = 0 \qquad && \forall w \in H_0^1(T), \\ &R_T(v) = v && \text{on } \partial T. \end{aligned} \tag{7.8}$$

Define

$$A_h(v,w) = \sum_{T \in T_h} \left(a_\epsilon \nabla R_T(v), \nabla R_T(w)\right)_T, \qquad v,\ w \in \mathcal{U}_h.$$

Then the MsFEM for (7.2) is as follows: Find $u_h \in \mathcal{U}_h$ such that

$$A_h(u_h, v) = (f, v) \qquad \forall v \in \mathcal{U}_h. \tag{7.9}$$

THEOREM 7.6. *Let U_0 and u_h be the respective solutions of* (2.5) *and* (7.9)*, where the homogenized coefficient $\mathcal{A}$ is now given by* (7.4)*, and $U_0 \in W^{2,\infty}(\Omega)$. Then, under condition* (7.7)*, we have*

$$\begin{aligned} &\mathbb{E}\ \|U_0 - u_h\|_{1,\Omega} \le C\left(h + \left(\frac{\epsilon}{h}\right)^\kappa\right), \\ &\mathbb{E}\ \|U_0 - u_h\|_{0,\Omega} \le C\left(h^2 + \left(\frac{\epsilon}{h}\right)^\kappa\right), \\ &\mathbb{E}\ \|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \left(\frac{\epsilon}{h}\right)^\kappa\right) |\ln h|, \end{aligned} \tag{7.10}$$

where

$$\kappa = \begin{cases} \dfrac{6 - 12\lambda}{25 - 8\lambda} & \text{if } d = 3, \\ \dfrac{1}{2} & \text{if } d = 1 \end{cases}$$

for any $0 < \lambda < 1/2$.

Note that the case $d = 2$ remains open. This theorem can be proven by combining the next two propositions. As in the nonlinear case in the third section, define

$$\overline{E} = \max_{v,w \in \mathcal{U}_h} \frac{|A_h(v,w) - A(v,w)|}{|v|_{1,\Omega}|w|_{1,\Omega}}.$$

PROPOSITION 7.7. *Let U_0 and u_h be the respective solutions of* (2.5) *and* (7.9)*, and let $U_0 \in W^{2,\infty}(\Omega)$. Then*

$$\begin{aligned} &\|U_0 - u_h\|_{1,\Omega} \le C\left(h + \overline{E}\right), \\ &\|U_0 - u_h\|_{0,\Omega} \le C\left(h^2 + \overline{E}\right). \end{aligned} \tag{7.11}$$

Furthermore, if there is a constant C_5 such that $\overline{E}|\ln h| < C_5$, then there is a constant h_0 such that for any $0 < h < h_0$,

$$\|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \overline{E}\right)|\ln h|. \tag{7.12}$$

PROPOSITION 7.8. *Under condition* (7.7)*, we have*

$$\mathbb{E}\overline{E} \le C\left(\frac{\epsilon}{h}\right)^{\kappa}, \tag{7.13}$$

where κ *is defined as in Theorem* 7.6.

As in (3.8), for a given $x \in \Omega$, we define the Green function $G^x \in H_0^1(\Omega)$ and its discrete counterpart $G_h^x \in \mathcal{U}_h$ by

$$\begin{aligned} A(G^x, v) &= \partial v(x) \qquad \forall v \in H_0^1(\Omega), \\ A(G_h^x, v) &= \partial v(x) \qquad \forall v \in \mathcal{U}_h. \end{aligned} \tag{7.14}$$

They satisfy

$$\|G^x - G_h^x\|_{1,1,\Omega} \le C, \quad \|G_h^x\|_{1,1,\Omega} \le C|\ln h|. \tag{7.15}$$

Below P_h indicates the standard Lagrange interpolation operator from $H_0^1(\Omega)$ into $\mathcal{U}_h$.

Proof of Proposition 7.7. It follows from the first Strang lemma [7] that

$$\|U_0 - u_h\|_{1,\Omega} \le C \inf_{v\in\mathcal{U}_h}\left(\|U_0 - v\|_{1,\Omega} + \sup_{w\in\mathcal{U}_h}\frac{|A(v,w) - A_h(v,w)|}{\|w\|_{1,\Omega}}\right).$$

Taking $v = P_h U_0$ and using the definition of $\overline{E}$ implies the first inequality in (7.11). The second inequality in (7.11) follows from a standard duality argument [4, 7].

To prove (7.12), using (7.14), we see that

$$\begin{aligned} \partial(U_0 - u_h)(x) &= A(G^x, U_0 - P_h U_0) + A(G^x, P_h U_0 - u_h) \\ &= A(G^x - G_h^x, U_0 - P_h U_0) + A(G_h^x, U_0 - u_h) \\ &= A(G^x - G_h^x, U_0 - P_h U_0) + A_h(u_h, G_h^x) - A(u_h, G_h^x) \\ &= A(G^x - G_h^x, U_0 - P_h U_0) + (A_h(P_h U_0, G_h^x) - A(P_h U_0, G_h^x)) \\ &\quad + (A_h(u_h - P_h U_0, G_h^x) - A(u_h - P_h U_0, G_h^x)), \end{aligned}$$

which, together with (7.15), gives

$$\begin{aligned} \|U_0 - u_h\|_{1,\infty,\Omega} \le C\|U_0 - P_h U_0\|_{1,\infty,\Omega} &+ |A_h(P_h U_0, G_h^x) - A(P_h U_0, G_h^x)| \\ &+ |A_h(u_h - P_h U_0, G_h^x) - A(u_h - P_h U_0, G_h^x)|. \end{aligned} \tag{7.16}$$

Applying (7.15) again and an inverse inequality, we have

$$|A_h(P_h U_0, G_h^x) - A(P_h U_0, G_h^x)| \le C\overline{E}|\ln h|\|U_0\|_{2,\infty,\Omega}. \tag{7.17}$$

A similar argument yields

$$\begin{aligned} &|A_h(u_h - P_h U_0, G_h^x) - A(u_h - P_h U_0, G_h^x)| \\ &\quad \le C\overline{E}|\ln h|\left(\|U_0 - u_h\|_{1,\infty,\Omega} + h\|U_0\|_{2,\infty,\Omega}\right). \end{aligned} \tag{7.18}$$

Substituting (7.17) and (7.18) into (7.16) implies that

$$\|U_0 - u_h\|_{1,\infty,\Omega} \le C\left(h + \overline{E}|\ln h| + \overline{E}|\ln h|\|U_0 - u_h\|_{1,\infty,\Omega}\right). \tag{7.19}$$

If $\overline{E}|\ln h| < C_5 = 1/(2C)$, the desired result (7.12) follows from (7.19). ∎

Proof of Proposition 7.8. Let $m = h/(2\epsilon)$, and let χ_m^j be the solution of (7.3) on $[0,m]^d$, with the boundary condition $\chi_m^j = 0$ on $\partial[0,m]^d$. Set $\chi_m = (\chi_m^1, \chi_m^2, \ldots, \chi_m^d)^T$. u_ρ^m can be similarly defined using (7.5). Then it follows from the definition of $\overline{E}$ that

$$\overline{E} = |\mathcal{A} - [a(\mathcal{I} + \nabla\chi_m)]_m| \le C(F_1 + F_2 + F_3), \tag{7.20}$$

where

$$\begin{aligned} F_1 &= |\mathcal{A} - [a(\mathcal{I} + \nabla u_\rho)]_m|, \\ F_2 &= |[a(\mathcal{I} + \nabla u_\rho) - a(\mathcal{I} + \nabla u_\rho^m)]_m|, \\ F_2 &= |[a\nabla(u_\rho^m - \chi_m)]_m|. \end{aligned}$$

Note that

$$F_1 = |\mathcal{A} - \langle a(\mathcal{I} + \nabla u_\rho)\rangle + [\varphi]_m|,$$

where $\varphi = \langle a(\mathcal{I} + \nabla u_\rho)\rangle - a(\mathcal{I} + \nabla u_\rho)$. It follows [21] that

$$\mathbb{E}|[\varphi]_m| \le \sqrt{\mathbb{E}[\varphi]_m^2} \le C\left(\frac{|\ln\rho^{-1}|^2}{\rho^{1/2}m}\right)^{d/2},$$

which, together with Lemma 7.5, gives

$$\mathbb{E}F_1 \le C\left(G\rho^{(d-2-2\lambda)/(4+d)} + \left(\frac{|\ln\rho^{-1}|^2}{\rho^{1/2}m}\right)^{d/2}\right). \tag{7.21}$$

Let t_m be the first exit time of the domain $[0,2m]^d$. Then $u_\rho^{2m} = M_x\Gamma(t_m)$, and for any $s > 0$,

$$\begin{aligned} |u_\rho - u_\rho^{2m}| &= \left|M_x\big(\Gamma(\infty) - \Gamma(t_m)\big)\right| \\ &\le M_x\left\{|\Gamma(\infty)| + |\Gamma(t_m)| : t_m \le s\right\} \\ &\quad + M_x\left\{e^{-s\rho}M_{\rho(s)}|\Gamma(\infty) - \Gamma(t_m)| : t_m > s\right\} \\ &\le C\left(M_x\left((\Gamma(\infty))^2 + (\Gamma(t_m))^2\right)\right)^{1/2}\left(P_x\{t_m \le s\}^{1/2} + e^{-s\rho}\right). \end{aligned}$$

Because $P_x\{t_m \le s\} \le e^{-Cm^2/s}$, we see that

$$\mathbb{E}\left[|u_\rho - u_\rho^{2m}|^2\right]_{2m} \le \frac{CG^2}{\rho}\left(e^{-Cm^2/s} + e^{-s\rho}\right)^2,$$

whose optimization in s gives

$$\mathbb{E}\left[|u_\rho - u_\rho^{2m}|^2\right]_{2m} \le \frac{CG^4}{\rho^2}e^{-Cm\rho^{1/2}}.$$

Now, it follows from standard interior estimates that

$$\begin{aligned} \mathbb{E}F_2 &\le C\left(\mathbb{E}\left[|\nabla(u_\rho - u_\rho^m)|^2\right]_m\right)^{1/2} \le \frac{C}{m}\left(\mathbb{E}\left[|u_\rho - u_\rho^{2m}|^2\right]_{2m}\right)^{1/2} \\ &\le \frac{CG^2}{m\rho}e^{-Cm\rho^{1/2}}. \end{aligned} \tag{7.22}$$

Also, in an argument similar to that for F_1, we have

$$\mathbb{E}F_3 \le C\left(G^2\rho^{(d-2-2\lambda)/(4+d)} + \left(\frac{|\ln\rho^{-1}|^2}{\rho^{1/2}m}\right)^{d/2}\right). \tag{7.23}$$

Finally, substituting (7.21)–(7.23) into (7.20) generates

$$\mathbb{E}\overline{E} \le C\left(G^2\rho^{(d-2-2\lambda)/(4+d)} + \left(\frac{|\ln\rho^{-1}|^2}{\rho^{1/2}m}\right)^{d/2} + \frac{G^2}{m\rho}e^{-Cm\rho^{1/2}}\right).$$

Optimizing in ρ with respect to the first two terms of this inequality, we see that

$$\rho_o = m^{-(2d)/(d+4\beta)},$$

where $\beta = (d-2-2\lambda)/(d+4)$. Consequently, we obtain

$$\mathbb{E}\overline{E} \le C\left(\frac{|\ln m|^d}{m^\kappa} + \frac{G^2}{m\rho_0}e^{-Cm\rho_0^{1/2}}\right) \le C\frac{|\ln m|^d}{m^\kappa}, \tag{7.24}$$

where

$$\kappa = \frac{d/2}{1+\frac{d(d+4)/4}{d-2-2\lambda}}, \quad 0<\lambda<\frac{1}{2}.$$

Absorbing the factor $|\ln m|^d$ into m^κ in (7.24) yields the desired result (7.13) for $d=3$.

For $d=1$, a direct evaluation gives

$$\mathbb{E}\overline{E}^2 \le \frac{C}{m},$$

where C is independent of m, which yields (7.13) with $\kappa = 1/2$. ∎

Acknowledgment. The authors would like to thank the referees for their comments that led to great improvements in content.

SPECTRUM OF THE JACOBI TAU APPROXIMATION FOR THE SECOND DERIVATIVE OPERATOR*

MARIOS CHARALAMBIDES† AND FABIAN WALEFFE‡

Abstract. It is proved that the eigenvalues of the Jacobi tau method for the second derivative operator with Dirichlet boundary conditions are real, negative, and distinct for a range of the Jacobi parameters. Special emphasis is placed on the symmetric case of the Gegenbauer tau method where the range of parameters included in the theorems can be merged and characteristic polynomials given by successive order approximations interlace. This includes the common Chebyshev and Legendre tau and Galerkin methods.

Key words. Jacobi polynomials, Gegenbauer polynomials, stable polynomials, positive pairs, zeros of polynomials, spectral methods

DOI. 10.1137/060665907

1. Introduction.

Constructing polynomial approximations to solutions of differential equations is the basic ingredient of most numerical methods. Approximations based on orthogonal polynomials have been widely used (e.g., [2], [3], [9]) because their rate of convergence is faster than algebraic for arbitrary boundary conditions when the solution is smooth. The purpose of this paper is to give a rigorous proof that the spectrum of the Jacobi tau approximation is real, negative, and distinct for the second order operator with Dirichlet boundary conditions. The Jacobi tau class of *spectral methods* includes the common Chebyshev and Legendre tau and Galerkin formulations, as demonstrated below. The general method of proof is similar to that used by Gottlieb and Lustman [7], [8] to prove such results for the Chebyshev collocation operator. However, we argue in Appendix B that Gottlieb and Lustman's proof for the collocation operator is not complete.

The spectrum of the Jacobi tau approximation for the first order operator has been considered elsewhere [5]. Here, we consider polynomial approximations to the eigenvalue problem

$$\frac{d^2u}{dx^2} = \lambda u, \qquad -1 < x < 1, \qquad \text{with} \qquad u(\pm 1) = 0. \tag{1.1}$$

The spectrum of Jacobi polynomial approximations to this eigenvalue problem is directly relevant to numerical simulations of the diffusion equation $u_t = u_{xx}$ which is itself a building block for numerical solution of various other problems including the Stokes and Navier–Stokes equations (e.g., [3, section 5.1], [13]).

The second order problem (1.1) is a self-adjoint, negative definite Sturm–Liouville differential eigenproblem, so its eigenvalues λ are real, negative, and distinct. The

eigenmodes separate into even modes $\cos\sqrt{|\lambda|}\,x$ with $\lambda = -(2k-1)^2\pi^2/4$ and odd modes $\sin\sqrt{|\lambda|}\,x$ with $\lambda = -k^2\pi^2$ for $k = 1, 2, 3, \ldots$.

If $u_n(x)$ is a polynomial approximation of degree n to (1.1), then $u_n(x)$ satisfies the differential equation

$$\lambda u_n(x) - D^2 u_n(x) = R_n(x), \tag{1.2}$$

where the *residual* $R_n(x)$ is a polynomial of degree n in x and $D = d/dx$. We can invert this relation to express the polynomial approximation $u_n(x)$ in terms of the residual $R_n(x)$ [8]:

$$u_n(x) = \mu \sum_{k=0}^{[n/2]} \mu^k D^{2k} R_n(x), \tag{1.3}$$

where $\mu = 1/\lambda$ and $[n/2]$ denotes the greatest integer less than or equal to $n/2$. We can assume that $\lambda \neq 0$ because $\lambda = 0$ with $u_n(\pm 1) = 0$ necessarily corresponds to the trivial solution $u_n(x) = 0$, for all x in $[-1, 1]$, as shown below. The inversion (1.3) follows from formal application of the geometric (Neumann) series for $(1 - \mu D^2)^{-1} = \sum_{k=0}^{\infty} \mu^k D^{2k}$ which terminates since $R_n(x)$ is a polynomial.

Spectral methods fit in the general framework of the *method of weighted residuals* [3]. In the *tau* method [3, section 10.4.2], the polynomial approximation $u_n(x)$ is determined from the boundary conditions $u_n(\pm 1) = 0$ and the requirement that $R_n(x)$ is orthogonal to all polynomials $p_{n-2}(x)$ of degree $n-2$ or less with respect to a weight function $W(x) \geq 0$ in the interval $(-1, 1)$:

$$\int_{-1}^{1} R_n(x) p_{n-2}(x) W(x) dx = 0. \tag{1.4}$$

For the Jacobi weight function $W_{\alpha,\beta}(x) = (1-x)^\alpha (1+x)^\beta$, the residual (1.2) can be written as

$$R_n(x) = \tau_0 \lambda\, P_n^{(\alpha,\beta)}(x) + \tau_1 \lambda\, P_{n-1}^{(\alpha,\beta)}(x) \tag{1.5}$$

for some x-independent coefficients τ_0 and τ_1, where $P_n^{(\alpha,\beta)}(x)$ is the Jacobi polynomial of degree n (see Appendix A). This follows from orthogonality of the Jacobi polynomials in $-1 < x < 1$ with respect to the Jacobi weight $W_{\alpha,\beta}(x)$ which implies orthogonality of the Jacobi polynomial of degree k to *any* polynomial of degree $k-1$ or less with respect to that weight function. Jacobi polynomials are the most general class of polynomial solutions of a Sturm–Liouville eigenproblem that is singular at ± 1 as required for faster than algebraic convergence [3, sections 9.2.2 and 9.6.1]. It is now easy to verify from (1.2) and (1.5) that if $\lambda = 0$, then $D^2 u_n(x) = R_n(x) = 0$ for all x in $(-1, 1)$, but the boundary conditions $u_n(\pm 1) = 0$ would then require that $u_n(x) = 0$ for all x in $[-1, 1]$. Therefore we can assume that $\lambda \neq 0$.

In the *Galerkin* approach, $u_n(x)$ is determined from the boundary conditions $u_n(\pm 1) = 0$ and orthogonality of the residual $R_n(x)$ to all polynomials of degree n that vanish at $x = \pm 1$, with respect to a weight function $W(x) \geq 0$. In other words, the *test functions* are in the same space (polynomials of degree n) as the trial functions, and they satisfy the same boundary conditions. Such polynomials can be written in the form $(1 - x^2) p_{n-2}(x)$, where $p_{n-2}(x)$ is an arbitrary polynomial of degree $n-2$, and the Galerkin equations can be written as

$$\int_{-1}^{1} R_n(x)(1 - x^2) p_{n-2}(x) W(x) dx = 0. \tag{1.6}$$

For the Jacobi weight $W(x) = W_{\alpha,\beta}(x) = (1-x)^\alpha(1+x)^\beta$, the Galerkin method is therefore equivalent to the tau method for the weight $W_{\alpha+1,\beta+1}(x)$, and the residual controlled by (1.6) has the form

$$R_n(x) = \tau_0 \lambda\, P_n^{(\alpha+1,\beta+1)}(x) + \tau_1 \lambda\, P_{n-1}^{(\alpha+1,\beta+1)}(x). \tag{1.7}$$

This residual can be written in terms of the derivatives of $P_{n+1}^{(\alpha,\beta)}(x)$ and $P_n^{(\alpha,\beta)}(x)$ using (A.4), but the key point is that since we consider a range of parameters α and β, the Jacobi tau method (1.4) also includes some Jacobi–Galerkin methods (1.6).

Characteristic polynomials for the eigenvalues $\mu = 1/\lambda$ are derived in section 2 from the explicit expression (1.3) for $u_n(x)$ in terms of the residual $R_n(x)$ specified by (1.5) and (1.7). The zeros of these characteristic polynomials are shown to be real, negative, and distinct in section 3, and the results are extended to Neumann and Dirichlet–Neumann boundary conditions. We conclude in section 4 with a brief discussion of further results involving recurrence relations for the characteristic polynomials in the Gegenbauer case and equivalence of these recurrences with an integration formulation. Those results are available in an extended online version of our article [4].

2. Characteristic polynomials.

2.1. Jacobi tau method. Substituting (1.5) into (1.3), the Jacobi tau approximation can be written explicitly in terms of the yet undetermined constants τ_0, τ_1 and the eigenvalue $\mu = 1/\lambda$ as

$$u_n(x) = \tau_0 \sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(x) + \tau_1 \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(x). \tag{2.1}$$

The boundary conditions $u_n(\pm 1) = 0$ then yield the characteristic equations

$$\begin{cases} \tau_0 \displaystyle\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(1) + \tau_1 \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(1) = 0, \\ \tau_0 \displaystyle\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(-1) + \tau_1 \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(-1) = 0. \end{cases} \tag{2.2}$$

This system has a nontrivial solution $(\tau_0, \tau_1) \neq (0,0)$ if and only if

$$\left(\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(1) \right) \left(\sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\beta,\alpha)}(1) \right) + \left(\sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(1) \right) \left(\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\beta,\alpha)}(1) \right) = 0, \tag{2.3}$$

where we have used the symmetry $P_n^{(\alpha,\beta)}(-1) = (-1)^n P_n^{(\beta,\alpha)}(1)$ [1, eq. (22.4.1)], [11, eq. (1.5.2)]. This is the characteristic equation for the eigenvalue μ.

2.2. Gegenbauer tau method. Gegenbauer (a.k.a. ultraspherical) polynomials $G_n^{(\gamma)}(x)$ are the class of Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$ with equal indices $\alpha = \beta = \gamma - 1/2$. The Gegenbauer polynomials are even in x for n even and odd for n odd [1, eq. (22.4.2)]. Chebyshev and Legendre polynomials are Gegenbauer polynomials with $\gamma = 0$ and $1/2$, respectively. We use a nonstandard normalization for Gegenbauer polynomials, denoted $G_n^{(\gamma)}(x)$ and defined in (A.6), since the standard normalization $C_n^{(\gamma)}(x)$ is singular in the Chebyshev case.

The symmetry of the differential equation (1.1) and of the Gegenbauer polynomials allows decoupling of the discrete problem into even and odd solutions. This parity reduction leads to simpler residuals and simpler forms for the corresponding characteristic polynomials. The residual (1.4) in the parity-separated Gegenbauer case contains only one term,

$$R_n(x) = \tau_0 \lambda\, G_n^{(\gamma)}(x), \tag{2.4}$$

where $G_n^{(\gamma)}(x)$ is the nth Gegenbauer polynomial and n is even for even solutions and odd for odd solutions. Substituting (2.4) into (1.3) provides the Gegenbauer tau approximation to (1.1) in terms of an undetermined constant τ_0 and the eigenvalue $\mu = 1/\lambda$:

$$u_n(x) = \tau_0 \sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} G_n^{(\gamma)}(x). \tag{2.5}$$

The boundary conditions $u_n(\pm 1) = 0$ lead to the characteristic polynomial equation

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} G_n^{(\gamma)}(1) = 0, \tag{2.6}$$

since by symmetry $G_n^{(\gamma)}(-1) = (-1)^n G_n^{(\gamma)}(1)$ and the two boundary conditions give the same equation.

3. Zeros of characteristic polynomials.

3.1. Stable polynomials and the Hermite–Biehler theorem. The general approach to proving that the eigenvalues are real, negative, and distinct is to construct a *stable* real polynomial $p(z)$ and then use the Hermite–Biehler theorem to deduce that the polynomials $\Omega_1(\mu)$ and $\Omega_2(\mu)$ such that $p(z) = \Omega_1(z^2) + z\Omega_2(z^2)$ have real, negative, and distinct zeros that interlace.

DEFINITION 3.1. *A real polynomial, $p(z)$, is stable (a.k.a.* Hurwitz*) if all its zeros lie in the open left half-plane, i.e., their real part is strictly less than zero, $\Re z < 0$.*

DEFINITION 3.2. *Two real polynomials $\Omega_1(\mu)$ and $\Omega_2(\mu)$ of degree n and $n-1$ (or n), respectively, form a positive pair if* (a) *the roots $\mu_1, \ldots, \mu_n$ of Ω_1 and $\mu'_1, \ldots, \mu'_{n-1}$ (or $\mu'_1, \ldots, \mu'_n$) of Ω_2 are real, negative, and distinct;* (b) *the roots strictly interlace (or alternate) as follows: $\mu_1 < \mu'_1 < \cdots < \mu'_{n-1} < \mu_n < 0$ (or $\mu'_1 < \mu_1 < \cdots < \mu'_n < \mu_n < 0$);* (c) *the highest coefficients of $\Omega_1(\mu)$ and $\Omega_2(\mu)$ are of like sign.*

THEOREM 3.3 (Hermite–Biehler). *A real polynomial $p(z) = \Omega_1(z^2) + z\Omega_2(z^2)$ is stable if and only if $\Omega_1(\mu)$ and $\Omega_2(\mu)$ form a positive pair.*

The Hermite–Biehler theorem (e.g., [11, p. 197], [10]) states that the even and odd parts of stable polynomials form positive pairs. This supplies us with a very

strong tool to prove reality and negativity of the roots of certain polynomials. We will also need the following lemmas about positive pairs [11, p. 198], [12, section 2].

LEMMA 3.4. *Any nontrivial real linear combination of two polynomials that form a positive pair has real roots.*

LEMMA 3.5. *Let $P(\mu)$ and $Q(\mu)$ be real standard polynomials (i.e., the leading coefficient is positive) with only nonpositive zeros. Then $P(\mu)$ interlaces (or alternates) $Q(\mu)$ (in the sense of Definition* 3.2 *but not strictly) if and only if for all $A > 0$ both $Q(\mu) + AP(\mu)$ and $Q(\mu) + A\mu P(\mu)$ have only nonpositive zeros.*

The polynomials P and Q of Theorem 3.5 do not necessarily form a *positive pair* since they are allowed to have common and/or multiple roots. We call this set of polynomials a *quasi-positive pair.*

LEMMA 3.6 (see [8, Lemma 3.4]). *If $\Omega_1(\mu), \Omega_2(\mu)$ and $\Theta_1(\mu), \Theta_2(\mu)$ are two positive pairs, then the zeros of $H(\mu) = \Omega_1(\mu)\Theta_2(\mu) + \Omega_2(\mu)\Theta_1(\mu)$ are real, negative, and distinct.*

Gottlieb and Lustman [8] used the Hermite–Biehler theorem to prove that the spectrum of the Chebyshev collocation operator for the heat equation is real, negative, and distinct for a variety of homogeneous boundary conditions. The basic strategy is to show that the characteristic polynomials for that method are the even or odd parts of a stable polynomial. Our results extend their strategy to a class of Jacobi and Gegenbauer tau methods that includes Chebyshev and Legendre tau and Galerkin formulations. Although the general approach is similar to that of Gottlieb [7] and Gottlieb and Lustman [8], the extension is technically nontrivial, and there are differences and some corrections. Their work is discussed in more detail in Appendix B, where we argue that their proof of stability for the collocation operator is not complete.

3.2. Important stable polynomials and positive pairs. Here we prove stability of certain real polynomials whose even and odd parts are directly related to the characteristic polynomials derived in section 2 for the Jacobi tau method.

THEOREM 3.7. *Let $P_n^{(\alpha,\beta)}(x)$ denote the Jacobi polynomial of degree n, where $n \geq 2$. If $-1 < \alpha \leq 1$ and $\beta > -1$, then the zeros of the polynomial*

$$\Phi_n(z) := \sum_{k=0}^{n} z^k \, D^k P_n^{(\alpha,\beta)}(1) \tag{3.1}$$

lie in the left half-plane; that is, $\Phi_n(z)$ is a stable polynomial.

The proof of this theorem is in [5] together with a discussion of its relation to zeros of Bessel polynomials. The next two theorems give generalizations of that result that are needed for this paper.

THEOREM 3.8. *Let $P_n^{(\alpha,\beta)}(x)$ denote the Jacobi polynomial of degree n with $n \geq 3$; then the polynomial*

$$\Phi_n^{(1)}(z) := \sum_{k=0}^{n} z^k \, D^k P_n^{(\alpha,\beta)}(1) + A \sum_{k=0}^{n-1} z^k \, D^k P_{n-1}^{(\alpha,\beta)}(1) \tag{3.2}$$

is stable for every $A \geq 0$ when $-1 < \alpha \leq 0$ and $\beta > -1$.

THEOREM 3.9. *Let $P_n^{(\alpha,\beta)}(x)$ denote the Jacobi polynomial of degree n with $n \geq 3$; then the polynomial*

$$\Phi_n^{(2)}(z) := \sum_{k=0}^{n} z^k \, D^k P_n^{(\alpha,\beta)}(1) + Az^2 \sum_{k=0}^{n-1} z^k \, D^k P_{n-1}^{(\alpha,\beta)}(1) \tag{3.3}$$

is stable for every $A \geq 0$ *when* $-1 < \alpha \leq 1$ *and* $\beta > -1$.

The proofs of these theorems are technical and are given in Appendix A. Our next theorem combines all the above theorems to get an important result.

THEOREM 3.10. *Let* $n \geq 3$*; then the polynomials*

$$\Omega_n^{(\alpha,\beta)}(\mu) := \sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(1), \quad \Omega_{n-1}^{(\alpha,\beta)}(\mu) := \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(1) \tag{3.4}$$

form a positive pair if $-1 < \alpha, \beta \leq 0$ *or* $0 < \alpha, \beta \leq 1$.

Remark 1. It was shown in [5] that these polynomials have real, negative, and distinct roots for $-1 < \alpha \leq 1$ and $-1 < \beta$. The important addition of Theorem 3.10 is that the roots of these polynomials interlace, as was conjectured in [5].

Proof. Applying the Hermite–Biehler theorem to the stable polynomials of Theorem 3.7 for a given n and also for $n - 1 \geq 2$ proves that the polynomials $\Omega_n^{(\alpha,\beta)}(\mu)$ and $\Omega_{n-1}^{(\alpha,\beta)}(\mu)$ have real, negative, and distinct roots for $-1 < \alpha, \beta \leq 1$ (notice that we can interchange α and β). Applying the Hermite–Biehler theorem to the stable polynomials of Theorems 3.8 and 3.9 shows that the polynomials

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(1) + A \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(1) = \Omega_n^{(\alpha,\beta)}(\mu) + A\Omega_{n-1}^{(\alpha,\beta)}(\mu), \tag{3.5}$$

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha,\beta)}(1) + A\mu \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha,\beta)}(1) = \Omega_n^{(\alpha,\beta)}(\mu) + A\mu\Omega_{n-1}^{(\alpha,\beta)}(\mu) \tag{3.6}$$

have real, negative, and distinct roots for all $A > 0$ and $-1 < \alpha, \beta \leq 0$. These results provide sufficient information to apply Lemma 3.5 to deduce that the set of polynomials $(\Omega_n^{(\alpha,\beta)}(\mu), \Omega_{n-1}^{(\alpha,\beta)}(\mu))$ form quasi-positive pairs for $-1 < \alpha, \beta \leq 0$.

To show that these polynomials form a positive pair, recall that both $\Omega_n^{(\alpha,\beta)}(\mu)$ and $\Omega_{n-1}^{(\alpha,\beta)}(\mu)$ have real, negative, and distinct roots by Theorem 3.7. Thus it remains to show that they have no common roots. To do so, assume that μ is a common root. Then $P_1(\mu) = \Omega_n^{(\alpha,\beta)}(\mu) + A\Omega_{n-1}^{(\alpha,\beta)}(\mu) = 0$, and $P_2(\mu) = \Omega_n^{(\alpha,\beta)}(\mu) + A\mu\Omega_{n-1}^{(\alpha,\beta)}(\mu) = 0$. Since $D\Omega_n^{(\alpha,\beta)}(\mu) \neq 0$ and $D\Omega_{n-1}^{(\alpha,\beta)}(\mu) \neq 0$ (both Ω_n and Ω_{n-1} do not have a double root), set $A = -\frac{D\Omega_n^{(\alpha,\beta)}(\mu)}{D\Omega_{n-1}^{(\alpha,\beta)}(\mu)}$ or $A = -\frac{D\Omega_n^{(\alpha,\beta)}(\mu)}{\mu D\Omega_{n-1}^{(\alpha,\beta)}(\mu)}$, whichever one is positive (one of the two must be since μ is negative). But this will imply that $DP_1(\mu) = 0$ and $DP_2(\mu) = 0$, respectively, which is a contradiction since $P_1(\mu)$ and $P_2(\mu)$ have simple zeros. For the second range of parameters, replace n with $n + 1$ in Theorems 3.8 and 3.9 and apply the Hermite–Biehler theorem. This gives that the polynomials

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k+1} P_{n+1}^{(\alpha,\beta)}(1) + A \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k+1} P_n^{(\alpha,\beta)}(1), \tag{3.7}$$

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k+1} P_{n+1}^{(\alpha,\beta)}(1) + A\mu \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k+1} P_n^{(\alpha,\beta)}(1) \tag{3.8}$$

also have real, negative, and distinct roots. Using (A.4), these polynomials transform into

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha+1,\beta+1)}(1) + A' \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha+1,\beta+1)}(1), \tag{3.9}$$

$$\sum_{k=0}^{[\frac{n}{2}]} \mu^k D^{2k} P_n^{(\alpha+1,\beta+1)}(1) + A'\mu \sum_{k=0}^{[\frac{n-1}{2}]} \mu^k D^{2k} P_{n-1}^{(\alpha+1,\beta+1)}(1). \tag{3.10}$$

The new polynomials have real, negative, and distinct roots for all $A' > 0$, where $A' = \frac{n+\alpha+\beta}{n+1+\alpha+\beta} A$, and thus the second range $0 < \alpha, \beta \leq 1$ follows from the first by a simple change of variables. ∎

3.3. Eigenvalues of the Gegenbauer and Jacobi tau methods. The previous subsection provides all necessary information needed for proving reality and negativity of the eigenvalues. First consider the Gegenbauer case.

THEOREM 3.11. *The eigenvalues of the Gegenbauer tau discretization of the second order operator with Dirichlet boundary conditions, problem* (1.1)*, are real, negative, and distinct for* $-1/2 < \gamma \leq 5/2$*. Also, eigenvalues given by successive order approximations (i.e.,* $n-1$ *and* n*) interlace.*

Proof. The eigenvalues are the roots of (2.6). The theorem follows directly from Theorem 3.10 since $\alpha = \beta = \gamma - 1/2$ in the Gegenbauer case and the two ranges for the indices (α, β) merge into the single range $-1/2 < \gamma \leq 5/2$. ∎

Remark 2. The results of Theorem 3.11 are sharp in the sense that well-conditioned numerical calculations give some complex conjugate pairs of eigenvalues for $\gamma > 5/2$ and Gegenbauer integration diverges in general for $\gamma \leq -1/2$.

Remark 3. As pointed out in the introduction, the Galerkin method with weight function $W_{\alpha,\beta}(x)$ for problem (1.1) is equivalent to the tau method with weight function $W_{\alpha+1,\beta+1}(x)$. For the Gegenbauer case, the Galerkin method with weight function $W_\gamma(x)$ is equivalent to the tau method with weight function $W_{\gamma+1}(x)$. Thus, a direct consequence of Theorem 3.11 is that the eigenvalues of the Gegenbauer–Galerkin method are real, negative, and distinct for $-1/2 < \gamma \leq 3/2$. Again, eigenvalues given by successive order approximations interlace.

Remark 4. Theorem 3.11 includes the Chebyshev and Legendre polynomials. For $\gamma = 0$, we have $T_n(x) = nG_n^{(0)}(x)$, where $T_n(x)$ denotes the nth Chebyshev polynomial of the first kind [11, p. 19]. Thus the theorem implies that the Chebyshev tau method has real, negative, and distinct eigenvalues that interlace for successive order approximations. For $\gamma = 1/2$ we have $G_n^{(1/2)}(x) = P_n(x)$, where $P_n(x)$ is the nth Legendre polynomial and for $\gamma = 1$ we have that $U_n(x) = 2G_n^{(1)}(x)$, where $U_n(x)$ is the Chebyshev polynomial of second kind. Therefore, the same result holds for both the Legendre tau and the Chebyshev tau of second kind method. Furthermore, in the Galerkin case (see Remark 3), the Galerkin–Chebyshev, the Galerkin–Legendre, and the Galerkin–Chebyshev of the second kind methods have real, negative, and distinct eigenvalues as well.

For the Jacobi case we have the following theorem.

THEOREM 3.12. *The eigenvalues of the Jacobi tau discretization of the second order operator with Dirichlet boundary conditions, problem* (1.1)*, are real, negative, and distinct if* $-1 < \alpha, \beta \leq 0$ *or* $0 < \alpha, \beta \leq 1$.

Proof. By Theorem 3.10 the polynomials $(\Omega_n^{(\alpha,\beta)}(\mu), \Omega_{n-1}^{(\alpha,\beta)}(\mu))$ form a positive pair for $-1 < \alpha, \beta \leq 0$ and $0 < \alpha, \beta \leq 1$. Interchanging the indices α, β, the same result holds for $(\Omega_n^{(\beta,\alpha)}(\mu), \Omega_{n-1}^{(\beta,\alpha)}(\mu))$. Application of Lemma 3.6 to these sets of positive pairs gives that the polynomial

$$B_n^{(\alpha,\beta)}(\mu) = \Omega_n^{(\alpha,\beta)}(\mu)\Omega_{n-1}^{(\beta,\alpha)}(\mu) + \Omega_n^{(\beta,\alpha)}(\mu)\Omega_{n-1}^{(\alpha,\beta)}(\mu) \tag{3.11}$$

has real, negative, and distinct roots. Equation (2.3) shows that $B_n^{(\alpha,\beta)}(\mu)$ is the characteristic polynomial for the Jacobi tau method. ∎

This paper focuses on the second order problem with Dirichlet boundary conditions. Naturally, questions arise about the equivalent results for different boundary conditions. The next remarks give some answers to those questions.

Remark 5. Consider problem (1.1) with Neumann boundary conditions, i.e., $\lambda u - D^2u = 0$ with $Du(\pm 1) = 0$. The Jacobi tau method gives $\lambda u - D^2u = \tau_0 P_n^{(\alpha,\beta)}(x) + \tau_1 P_{n-1}^{(\alpha,\beta)}(x)$. Notice that $\lambda = 0$ is an eigenvalue since $u = constant$ is a solution. For $\lambda \neq 0$, differentiate the last equation to get $\lambda Du - D^3u = \tau_0 DP_n^{(\alpha,\beta)}(x) + \tau_1 DP_{n-1}^{(\alpha,\beta)}(x)$ with $Du(\pm 1) = 0$. Now set $v = Du$; with the use of (A.4) the equation transforms to $\lambda v - D^2v = \tau_0' P_{n-1}^{(\alpha+1,\beta+1)}(x) + \tau_1' P_{n-2}^{(\alpha+1,\beta+1)}(x)$ with $v(\pm 1) = 0$. This is the Jacobi tau approximation of second kind, i.e., $(\alpha, \beta) \to (\alpha + 1, \beta + 1)$ for problem (1.1), and by Theorem 3.12 it has real, negative, and distinct eigenvalues for $-1 < \alpha, \beta \leq 0$.

Remark 6. Consider problem (1.1) with boundary conditions $u(-1) = 0$ and $Du(1) = 0$. Using equations (2.1) and (A.4) and following the ideas of subsection 2.1, the characteristic polynomial in this case is $B_n^{(\alpha,\beta)}(\mu) = k_{n-1}\Omega_n^{(\beta,\alpha)}(\mu)\Omega_{n-2}^{(\alpha+1,\beta+1)}(\mu) + k_n\Omega_{n-1}^{(\beta,\alpha)}(\mu)\Omega_{n-1}^{(\alpha+1,\beta+1)}(\mu)$, where $k_n = \frac{1}{2}(n + \alpha + \beta + 1)$. Since the polynomials $(\Omega_n^{(\beta,\alpha)}(\mu), \Omega_{n-1}^{(\beta,\alpha)}(\mu))$ and $(k_n\Omega_{n-1}^{(\alpha+1,\beta+1)}(\mu), k_{n-1}\Omega_{n-2}^{(\alpha+1,\beta+1)}(\mu))$ form positive pairs for $-1 < \alpha, \beta \leq 0$, by Theorem 3.6 the roots of $B_n^{(\alpha,\beta)}(\mu)$ are real, negative, and distinct for $-1 < \alpha, \beta \leq 0$.

An alternative implementation is to rescale the domain to $[-1, 0]$ with the Neuman boundary condition $Du(0) = 0$ and to use only the even Gegenbauer polynomials with a Gegenbauer tau approach on the entire domain $[-1, 1]$ and boundary conditions $u(\pm 1) = 0$ since such polynomials automatically satisfy $Du(0) = 0$.

4. Conclusions. We have proved that the eigenvalues of the Jacobi tau method for the second derivative operator with Dirichlet boundary conditions are real, negative, and distinct for ranges of the Jacobi indices α and β. These ranges include tau methods with Chebyshev and Legendre polynomials of the first and second kinds. Chebyshev and Legendre–Galerkin formulations are included as well, but collocation methods are not. Although our work owes much to earlier work by Gottlieb and Lustman [7, 8], we have raised doubts about the completeness of their proof for the Chebyshev collocation operator.

Special emphasis has been placed on the symmetric case of the Gegenbauer tau method where the range of parameters included in the theorems can be extended and characteristic polynomials given by successive order approximations interlace. The interlacing proof is between successive even and odd approximations [5, Conjecture 1], not between successive even or odd approximations, although we believe the latter is true as well [5, Conjecture 2].

In an extended version of this paper posted online [4], the characteristic polynomials (2.6) of both even and odd Gegenbauer tau approximations are shown to satisfy three term recurrences *plus* a constant term. That constant vanishes for the

Legendre tau and Galerkin methods ($\gamma = 1/2$ and $\gamma = 3/2$). Hence for those cases the characteristic polynomials are new classes of orthogonal polynomials, and their roots interlace; that is, the roots of successive even or odd Legendre tau or Galerkin approximations interlace. It is also shown in [4] that the integration formulation of spectral tau methods leads directly to the same tridiagonal plus one row matrices as those arising from the characteristic polynomial recurrences. These recurrences and integration formulation are perfectly conditioned, and some numerical results up to approximations of degree 2000 together with a MATLAB code are provided.

In a forthcoming paper we apply similar methods to the simplified Stokes eigenvalue problem $D^4u = \lambda D^2u$ with $u(\pm1) = Du(\pm1) = 0$ and rigorously identify classes of spectral methods that are free of spurious eigenvalues.

Appendix A. Proofs of Theorems 3.8 and 3.9.

We recall some properties of the Jacobi polynomials that are used in the proofs of Theorems 3.8 and 3.9.

A.1. Jacobi. The Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$ [11, eq. (1.5.2)] are suitably standardized orthogonal polynomials with weight function $W_{\alpha,\beta}(x) = (1-x)^\alpha(1+x)^\beta$. They satisfy the orthogonality relation

$$\int_{-1}^{1}(1-x)^\alpha(1+x)^\beta\, P_m^{(\alpha,\beta)}P_n^{(\alpha,\beta)}\,dx = \begin{cases} 0, & m \neq n, \\ h_n^{\alpha,\beta}, & m = n, \end{cases} \tag{A.1}$$

where $h_n^{\alpha,\beta} > 0$ is given in [11, eq. (1.5.5)]. Orthogonal polynomials satisfy a three term recurrence relation; for the Jacobi polynomials this reads as

$$\begin{aligned} 2(n+1)(n+\alpha+\beta+1)(2n+\alpha+\beta)P_{n+1}^{(\alpha,\beta)}(x) \\ = \big((2n+\alpha+\beta+1)(\alpha^2-\beta^2) + (2n+\alpha+\beta)_3\, x\big)\, P_n^{(\alpha,\beta)}(x) \\ - 2(n+\alpha)(n+\beta)(2n+\alpha+\beta+2)P_{n-1}^{(\alpha,\beta)}(x), \end{aligned} \tag{A.2}$$

where $(2n+\alpha+\beta)_3 = (2n+\alpha+\beta)(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)$. To ease the notation in our calculations we write the recurrence relation in the form

$$a_{1,n}P_{n+1}^{(\alpha,\beta)}(x) = (a_{2,n} + a_{3,n}x)P_n^{(\alpha,\beta)}(x) - a_{4,n}P_{n-1}^{(\alpha,\beta)}(x). \tag{A.3}$$

Two other useful relations involving derivatives of Jacobi polynomials [6] are

$$\frac{d}{dx}P_n^{(\alpha,\beta)}(x) = \frac{1}{2}(n+\alpha+\beta+1)P_{n-1}^{(\alpha+1,\beta+1)}(x) \tag{A.4}$$

and

$$\frac{d}{dx}P_{n+1}^{(\alpha,\beta)}(x) = B_nP_n^{(\alpha,\beta)}(x) + p_{n-1}(x) \tag{A.5}$$

with $B_n = \frac{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)}{2(n+\alpha+\beta+1)}$ and $p_{n-1}(x)$ a polynomial of degree $n-1$.

A.2. Gegenbauer. The Gegenbauer (a.k.a. ultraspherical) polynomials $C_n^{(\gamma)}(x)$, $\gamma > -1/2$, of degree n are the Jacobi polynomials with $\alpha = \beta = \gamma - 1/2$, up to normalization [1, eq. (22.5.20)]. Since the standard normalization [1, eq. (22.3.4)] is singular for the Chebyshev case $\gamma = 0$, we use a nonstandard normalization denoted by $G_n^{(\gamma)}(x)$ that includes the Chebyshev polynomials but preserves the simplicity of the Gegenbauer recurrences. Our normalization is defined as

$$G_0^{(\gamma)}(x) := 1, \qquad G_n^{(\gamma)}(x) := \frac{C_n^{(\gamma)}(x)}{2\gamma}, \quad n \geq 1. \tag{A.6}$$

A.3. Theorem 3.8.

Proof. For $A = 0$ the theorem reduces to Theorem 3.7. Now fix $A > 0$ but otherwise arbitrary. Let

$$f_n(x;z) = \sum_{k=0}^{n} z^k D^k P_n^{(\alpha,\beta)}(x) + A \sum_{k=0}^{n-1} z^k D^k P_{n-1}^{(\alpha,\beta)}(x) \tag{A.7}$$

with z such that $f_n(1;z) = 0$ and $D := d/dx$. Then $f_n(x;z)$ satisfies the following differential equation:

$$\left(f_n - P_n^{(\alpha,\beta)} - AP_{n-1}^{(\alpha,\beta)}\right) = z\frac{df_n}{dx}. \tag{A.8}$$

Multiplying by $\frac{df_n^*(x;z)}{dx}(1+x)$, integrating from -1 to 1 in the Jacobi norm, and adding the conjugate, we obtain

$$\int_{-1}^{1} \frac{d|f_n|^2}{dx}(1+x)W_{\alpha,\beta}dx - \int_{-1}^{1}\left(\frac{df_n}{dx} + \frac{df_n^*}{dx}\right)(1+x)P_n^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx \tag{A.9}$$

$$-A\int_{-1}^{1}\left(\frac{df_n}{dx} + \frac{df_n^*}{dx}\right)(1+x)P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx = (z+z^*)\int_{-1}^{1}\left|\frac{df_n}{dx}\right|^2(1+x)W_{\alpha,\beta}dx.$$

For the first term of equation (A.9), integration by parts yields

$$\int_{-1}^{1} \frac{d|f_n|^2}{dx}(1+x)W_{\alpha,\beta}dx = -\int_{-1}^{1}|f_n|^2\frac{W_{\alpha,\beta}}{(1-x)}\left(\beta+1-\alpha-(\beta+1+\alpha)x\right)dx. \tag{A.10}$$

For $\beta > -1$ and $\alpha \le 0$ the factor $\beta + 1 - \alpha - (\beta + 1 + \alpha)x$ is nonnegative for all $x \in [-1, 1]$. The second term of (A.9) can be expanded as

$$\begin{aligned}\int_{-1}^{1}\left(\frac{df_n}{dx} + \frac{df_n^*}{dx}\right)(1+x)P_n^{(\alpha,\beta)}W_{\alpha,\beta}dx &= 2\int_{-1}^{1} xDP_n^{(\alpha,\beta)}P_n^{(\alpha,\beta)}W_{\alpha,\beta}dx \\ &= 2B_{n-1}\int_{-1}^{1} xP_{n-1}^{(\alpha,\beta)}P_n^{(\alpha,\beta)}W_{\alpha,\beta}dx \\ &= \frac{2B_{n-1}a_{1,n-1}}{a_{3,n-1}}\int_{-1}^{1}\left(P_n^{(\alpha,\beta)}\right)^2 W_{\alpha,\beta}dx \\ &= \frac{2B_{n-1}a_{1,n-1}}{a_{3,n-1}}h_n^{\alpha,\beta},\end{aligned} \tag{A.11}$$

where we have used expression (A.5), the Jacobi recurrence relation (A.3), and orthogonality of $P_n^{(\alpha,\beta)}(x)$ to all polynomials of degree less than n with respect to the

Jacobi weight $W_{\alpha,\beta}(x)$. Similarly, the third term of (A.9) can be calculated as

(A.12)
$$\begin{aligned}
&\int_{-1}^{1}\left(\frac{df_n}{dx}+\frac{df_n^*}{dx}\right)(1+x)P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx\\
&=2\int_{-1}^{1}(1+x)DP_n^{(\alpha,\beta)}P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx+(z+z^*)\int_{-1}^{1}xD^2P_n^{(\alpha,\beta)}P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx\\
&\quad+2A\int_{-1}^{1}xDP_{n-1}^{(\alpha,\beta)}P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx\\
&=2B_{n-1}\int_{-1}^{1}\left(P_{n-1}^{(\alpha,\beta)}\right)^2W_{\alpha,\beta}dx+2B_{n-1}\int_{-1}^{1}x\left(P_{n-1}^{(\alpha,\beta)}\right)^2W_{\alpha,\beta}dx\\
&\quad+(z+z^*)B_{n-1}B_{n-2}\int_{-1}^{1}xP_{N-2}^{(\alpha,\beta)}P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx\\
&\quad+2AB_{n-2}\int_{-1}^{1}xP_{N-2}^{(\alpha,\beta)}P_{n-1}^{(\alpha,\beta)}W_{\alpha,\beta}dx\\
&=2B_{n-1}h_{n-1}^{\alpha,\beta}-2\frac{a_{2,n-1}}{a_{3,n-1}}B_{n-1}h_{n-1}^{\alpha,\beta}+(z+z^*)\frac{a_{1,n-2}}{a_{3,n-2}}B_{n-1}B_{n-2}h_{n-1}^{\alpha,\beta}\\
&\quad+2A\frac{a_{1,n-2}}{a_{3,n-2}}B_{n-2}h_{n-1}^{\alpha,\beta}.
\end{aligned}$$

Substituting these expressions back into (A.9) yields

$$\begin{aligned}
&-\left[\int_{-1}^{1}|f_n|^2\frac{W_{\alpha,\beta}}{(1-x)}(\beta+1-\alpha-(\beta+1+\alpha)x)dx+\frac{2B_{n-1}a_{1,n-1}}{a_{3,n-1}}h_n^{\alpha,\beta}\right.\\
&\qquad\left.+2A\left(\left(1-\frac{a_{2,n-1}}{a_{3,n-1}}\right)B_{n-1}+A\frac{a_{1,n-2}}{a_{3,n-2}}B_{n-2}\right)h_{n-1}^{\alpha,\beta}\right]\\
&\qquad=(z+z^*)\left[\int_{-1}^{1}\left|\frac{df_n}{dx}\right|^2(1+x)W_{\alpha,\beta}dx+A\frac{a_{1,n-2}}{a_{3,n-2}}B_{n-1}B_{n-2}h_{n-1}^{\alpha,\beta}\right].
\end{aligned}\tag{A.13}$$

Since $1>\frac{a_{2,n-1}}{a_{3,n-1}}$, it follows that the left-hand side is negative and $\Re(z)<0$, which ensures stability. ∎

A.4. Theorem 3.9.

Proof. For $A=0$ the theorem reduces again to Theorem 3.7. Now fix $A>0$. Let

$$f_n(x;z)=\sum_{k=0}^{n}z^kD^kP_n^{(\alpha,\beta)}(x)+Az^2\sum_{k=0}^{n-1}z^kD^kP_{n-1}^{(\alpha,\beta)}(x)\tag{A.14}$$

with $f_n(1;z)=0$. Then $f_n(x;z)$ satisfies the differential equation

$$\frac{1}{z}\left(f_n-P_n^{(\alpha,\beta)}-Az^2P_{n-1}^{(\alpha,\beta)}\right)=\frac{df_n}{dx}.\tag{A.15}$$

Multiplying by $f_n^*(x;z)\frac{(1+x)}{(1-x)}$, integrating from -1 to 1, and adding the conjugate yields

$$\left(\frac{1}{z}+\frac{1}{z^*}\right)\int_{-1}^{1}|f_n|^2\frac{(1+x)}{(1-x)}W_{\alpha,\beta}dx-\frac{1}{z}\int_{-1}^{1}f_n^*\frac{(1+x)}{(1-x)}P_n^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx \tag{A.16}$$

$$-\frac{1}{z^*}\int_{-1}^{1}f_n\frac{(1+x)}{(1-x)}P_n^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx-Az\int_{-1}^{1}f_n^*\frac{(1+x)}{(1-x)}P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx$$

$$-Az^*\int_{-1}^{1}f_n\frac{(1+x)}{(1-x)}P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx\;=\int_{-1}^{1}\frac{d|f_n|^2}{dx}\frac{(1+x)}{(1-x)}W_{\alpha,\beta}dx.$$

Integration by parts on the first term gives

$$\int_{-1}^{1}\frac{d|f_n|^2}{dx}(1+x)W_{\alpha,\beta}dx=-\int_{-1}^{1}|f_n|^2\frac{W_{\alpha,\beta}}{(1-x)^2}\left(\beta-\alpha+2-(\beta+\alpha)x\right)dx. \tag{A.17}$$

For $\beta>-1$ and $\alpha\le 1$ the factor $\beta-\alpha+2-(\beta+\alpha)x$ is nonnegative for all $x\in[-1,1]$. For the other terms on the left-hand side of (A.16), recall that $f_n(1;z)=0$ and write

$$f_n=(1-x)\sum_{k=0}^{n-1}c_kP_k^{(\alpha,\beta)}(x). \tag{A.18}$$

Then

$$\int_{-1}^{1}\frac{(1+x)}{(1-x)}f_n^*P_n^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx=\int_{-1}^{1}c_{n-1}^*xP_{n-1}^{(\alpha,\beta)}(x)P_n^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx \tag{A.19}$$

$$=c_{n-1}^*\frac{a_{1,n-1}}{a_{3,n-1}}\int_{-1}^{1}\left(P_n^{(\alpha,\beta)}(x)\right)^2W_{\alpha,\beta}dx=c_{n-1}^*\frac{a_{1,n-1}}{a_{3,n-1}}h_n^{\alpha,\beta}.$$

Also

$$\int_{-1}^{1}\frac{(1+x)}{(1-x)}f_n^*P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx \tag{A.20}$$

$$=\int_{-1}^{1}c_{n-1}^*(1+x)P_{n-1}^{(\alpha,\beta)}(x)P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx+\int_{-1}^{1}c_{n-2}^*xP_{n-2}^{(\alpha,\beta)}(x)P_{n-1}^{(\alpha,\beta)}(x)W_{\alpha,\beta}dx$$

$$=c_{n-1}^*\int_{-1}^{1}\left(P_{n-1}^{(\alpha,\beta)}(x)\right)^2W_{\alpha,\beta}dx-c_{n-1}^*\frac{a_{2,n-1}}{a_{3,n-1}}\int_{-1}^{1}\left(P_{n-1}^{(\alpha,\beta)}(x)\right)^2W_{\alpha,\beta}dx$$

$$+c_{n-2}^*\frac{a_{1,n-2}}{a_{3,n-2}}\int_{-1}^{1}\left(P_{n-1}^{(\alpha,\beta)}(x)\right)^2W_{\alpha,\beta}dx$$

$$=\left(c_{n-1}^*\left[1-\frac{a_{2,n-1}}{a_{3,n-1}}\right]+c_{n-2}^*\frac{a_{1,n-2}}{a_{3,n-2}}\right)h_{n-1}^{\alpha,\beta}.$$

Explicit values of c_{n-1} and c_{n-2} follow from (A.18):

$$
\begin{aligned}
f_n &= (1-x)\sum_{k=0}^{n-1} c_k P_k^{(\alpha,\beta)}(x) \\
&= c_{n-1}P_{n-1}^{(\alpha,\beta)}(x) - c_{n-1}xP_{n-1}^{(\alpha,\beta)}(x) - c_{n-2}xP_{n-2}^{(\alpha,\beta)}(x) + O(n-2) \\
&= -c_{n-1}\frac{a_{1,n-1}}{a_{3,n-1}}P_n^{(\alpha,\beta)}(x) \\
&\quad + \left(c_{n-1}\left[1+\frac{a_{2,n-1}}{a_{3,n-1}}\right] - c_{n-2}\frac{a_{1,n-2}}{a_{3,n-2}}\right)P_{n-1}^{(\alpha,\beta)}(x) + O(n-2).
\end{aligned} \tag{A.21}
$$

Now from (A.14),

$$
\begin{aligned}
f_n &= P_n^{(\alpha,\beta)}(x) + zDP_n^{(\alpha,\beta)}(x) + Az^2P_{n-1}^{(\alpha,\beta)}(x) + O(n-2) \\
&= P_n^{(\alpha,\beta)}(x) + B_{n-1}zP_{n-1}^{(\alpha,\beta)}(x) + Az^2P_{n-1}^{(\alpha,\beta)}(x) + O(n-2).
\end{aligned} \tag{A.22}
$$

Comparing these two expressions for f_n gives

$$
c_{n-1} = -\frac{a_{3,n-1}}{a_{1,n-1}}, \qquad c_{n-2} = \frac{a_{3,n-2}}{a_{1,n-2}}\left(-\frac{a_{2,n-1}}{a_{1,n-1}} - \frac{a_{3,n-1}}{a_{1,n-1}} - B_{n-1}z - Az^2\right). \tag{A.23}
$$

Substituting all these results back into (A.16) yields

$$
\begin{aligned}
&\left(\frac{1}{z}+\frac{1}{z^*}\right)\left[\int_{-1}^{1}|f_n|^2\frac{(1+x)}{(1-x)}W_{\alpha,\beta}dx + h_n^{\alpha,\beta}\right] + 2A(z+z^*)\frac{a_{3,n-1}}{a_{1,n-1}}h_{n-1}^{\alpha,\beta} \\
&+ 2AB_{n-1}|z|^2h_{n-1}^{\alpha,\beta} + (z+z^*)A^2|z|^2h_{n-1}^{\alpha,\beta} = -\int_{-1}^{1}|f_n|^2\frac{(\alpha-\beta+2-(\alpha+\beta)x)}{(1-x)^2}W_{\alpha,\beta}dx
\end{aligned} \tag{A.24}
$$

or, after rearranging some of the terms,

$$
\begin{aligned}
&(z+z^*)\left(\frac{1}{|z|^2}\left[\int_{-1}^{1}|f_n|^2\frac{(1+x)}{(1-x)}W_{\alpha,\beta}dx + h_n^{\alpha,\beta}\right] + \left(2A\frac{a_{3,n-1}}{a_{1,n-1}} + A^2|z|^2\right)h_{n-1}^{\alpha,\beta}\right) \\
&\qquad = -\int_{-1}^{1}|f_n|^2\frac{(\beta-\alpha+2-(\beta+\alpha)x)}{(1-x)^2}W_{\alpha,\beta}dx - 2AB_{n-1}|z|^2h_{n-1}^{\alpha,\beta}.
\end{aligned} \tag{A.25}
$$

The right-hand side is negative, so this implies that $\Re(z) < 0$. ∎

Appendix B. On stability for collocation.

Gottlieb and Lustman [8] focus on the Chebyshev collocation method where $u_n(x)$ is determined from the boundary conditions $u_n(\pm1) = 0$ and vanishing of the residual $R_n(x_j) = 0$ at $x_j = \cos j\pi/n$, $j = 1, \ldots, n-1$. The collocation residual has the form [8, eq. (4.5)] $R_n(x) = (A+Bx)DT_n(x)$, where $T_n(x)$ is the Chebyshev polynomial of degree n. Substituting into (1.3) leads to the characteristic polynomial as in section 2. Gottlieb and Lustman consider [8, eqs. (4.11), (4.12)]

$$
f_n(x;z) = \sum_{k=0}^{n-1} z^{k+1}D^{k+1}T_n(x) \quad \text{and} \quad g_n(x;z) = \sum_{k=0}^{n} z^{k+1}D^k\left(xDT_n(x)\right). \tag{B.1}
$$

To prove that $f_n(1;z)$ is stable, they first note that $f_n(x;z)$ satisfies $z^{-1}f_n - Df_n = DT_n$ and then consider $w_n(x,t;z) = e^{t/z}f_n(x;z)$ with the boundary condition $w_n(1,t;z) = e^{t/z}f_n(1;z) = 0$. That w_n satisfies the PDE

$$\partial_t w_n - \partial_x w_n = e^{t/z} DT_n(x). \tag{B.2}$$

Gottlieb and Lustman state *"In* [7] *it has been shown that w_n decays in time and therefore that $\Re(z) < 0$."* Presumably, this refers to the stability result [7, eq. (3.18)] for the polynomial approximation $v_n(x,t) = \sum_{k=0}^{n-1} d_k(t)T_k(x)$ to $\partial_t v - \partial_x v = 0$ with $v(1,t) = 0$ obtained by imposing $v_n(1,t) = 0$ and collocating at $x_j = \cos j\pi/n$, $j = 1,\dots,n-1$. The approximation $v_n(x,t)$ satisfies [7, eq. (3.11b)]

$$\partial_t v_n - \partial_x v_n = \tau_2(t)\, DT_n(x) \quad \text{with} \quad v_n(1,t) = 0. \tag{B.3}$$

Gottlieb shows stability of $v_n(x,t)$ by evaluating (B.3) at the interior point x_j where $DT_n(x_j) = 0$, multiplying by $(1+x_j)v_n(x_j,t)w_j$, and summing over $j = 1,\dots,n-1$, where $w_j > 0$ are the Chebyshev Gauss–Lobatto weights (Gottlieb's lemma [7, eq. (3.14)] is not necessary; one can directly use [7, eq. (3.15)] as done here). This yields

$$\begin{aligned} \frac{d}{dt}\sum_{j=1}^{n-1}(1+x_j)v_n^2(x_j,t)w_j &= \sum_{j=1}^{n-1}(1+x_j)v_n(x_j,t)\partial_x v_n(x_j,t)\, w_j \\ &= \int_{-1}^{1}(1+x)v_n\partial_x v_n \frac{dx}{\sqrt{1-x^2}} = \cdots \le 0. \end{aligned} \tag{B.4}$$

The last equality holds because v_n is of degree $n-1$ in x, so $(1+x)v_n\partial_x v_n$ is of degree $2n-2$ and vanishes at $x = \pm 1$; thus Gauss–Lobatto integration with $n-1$ interior points is exact. The integral can be calculated by parts to show that it is ≤ 0 and deduce stability since each term in the sum on the left-hand side is nonnegative.

That this result implies stability of w_n in (B.2) is not quite correct since v_n is assumed to be real, while $w_n(t,x;z)$ is complex since z is complex. However, this is a minor issue that is easily fixed. Our proof in [5] (Theorem 3.7 above) generalizes this result to a class of Jacobi polynomials without going back to a PDE such as (B.2) and without using Gauss integration.

For the proof of stability of $g_n(1;z)$, Gottlieb and Lustman simply state that *"a similar argument holds"* [8, eq. (4.12)], but we do not think it is that simple. Gottlieb [7] makes a similar claim that the stability of another approximation $u_n(x,t)$ which satisfies [7, eq. (3.11a)]

$$\partial_t u_n - \partial_x u_n = \tau_1(t)(1+x)DT_n(x) \quad \text{with} \quad u_n(1,t) = 0 \tag{B.5}$$

follows directly from the stability of (B.3) [7, eq. (3.11b)], but that does not seem correct since $\tau_1(t)$ and $\tau_2(t)$ are different functions of t. The Gauss integration procedure (B.4) does not work here since u_n is of degree n; thus $(1+x)u_n\partial_x u_n$ is of degree $2n$ and Gauss–Lobatto integration is not exact.

Gottlieb states another direct relation [7, eq. (3.8)] between $u_n(x,t)$ and $v_n(x,t)$, but that, too, does not seem correct. While it is true that one can write

$$u_n(x_j,t) = \sum_{k=0}^{n} a_k(t)T_k(x_j) = \sum_{k=0}^{n-1}\tilde{d}_k(t)T_k(x_j) \tag{B.6}$$

for $x_j = \cos j\pi/n$, $j = 0, \dots, n-1$, with $d_k = a_k + (-1)^{n-1} 2a_n (-1)^k / c_k$ [7, (3.8)], where $c_0 = c_n = 2$, $c_k = 1$ for $0 \neq k \neq n$, there is no reason why those $\tilde{d}_k(t)$ coefficients would be identical to the corresponding coefficients for $v_n(x_j, t)$ since $u_n(x_j, t)$ and $v_n(x_j, t)$ are distinct solutions determined by different sets of equations.[1] Hence, it appears that there is currently no proof of the stability of [7, eqs. (3.6), (3.11a)] and [8, eq. (4.12)], therefore invalidating Gottlieb and Lustman's proof that the eigenvalues of the Chebyshev collocation operator are real, negative, and distinct [8].

Acknowledgment. The authors thank Jue Wang for several helpful calculations in the early stages of this work.

[1] The reduction in (B.6) follows from the Chebyshev expansion of $(1-x)DT_n(x)$ which vanishes at all $x_j = \cos j\pi/n$, $j = 0, \dots, n-1$. One obtains $(1-x)DT_n(x) = \sum_{k=0}^{n} \frac{2}{nc_k}(-1)^k DT_n(-1)T_k(x)$ by Chebyshev transform (e.g., [7, eqs. (3.2), (3.3)]), from which one can express $T_n(x_j)$ as a combination of $T_k(x_j)$ for $j, k = 0, \dots, n-1$.

THREE-SCALE FINITE ELEMENT DISCRETIZATIONS FOR QUANTUM EIGENVALUE PROBLEMS*

XIAOYING DAI† AND AIHUI ZHOU‡

Abstract. Based on globally and locally coupled discretizations, some three-scale finite element schemes are proposed in this paper for a class of quantum eigenvalue problems. It is shown that the solution of a quantum eigenvalue problem on a fine grid may be reduced to the solution of an eigenvalue problem on a relatively coarse grid, and the solutions of linear algebraic systems on a globally mesoscopic grid and the locally fine grid, and the resulting solution is still very satisfactory.

Key words. eigenvalue, finite element, ground state energy, local computation, three-scale, quantum chemistry

DOI. 10.1137/06067780X

1. Introduction.

It is significant to obtain the ground state energies in the electronic structure study. In modern electronic structure computations, the ground state energies are usually obtained from the Kohn–Sham equations [7, 19, 25]. Since Kohn–Sham equations are nonlinear eigenvalue systems in three dimensions, an iteration procedure must be involved. More precisely, the central computation in solving Kohn–Sham equations is the repeated solution of the following type of singular eigenvalue problem, posed on a convex polyhedral domain $\Omega \subset \mathbb{R}^3$:

$$\begin{cases} -\Delta u + Vu = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $V = V_{ne} + V_0$ is some (density-dependent) effective potential that has finite singular points:

$$V_{ne}(x) = -\sum_{q=1}^{N_{atom}} \frac{Z_q}{|x - r_q|}$$

and V_0 is the remainder of the effective potential with $r_q \in \Omega$ and $Z_q \in (0, \infty)(q = 1, 2, \ldots, N_{atom})$ (see section 4). Because of the singularity of the potential V, the eigenvectors of (1.1) vary very rapidly near the singular points but diffuse further away (cf., e.g., [7]). Thus it is important to design some efficient approximation scheme for solving such a linear singular eigenvalue problem at each iteration step.

As the finite element method is one of the most effective numerical methods, we shall consider using the finite element scheme to discretize such linear singular eigenvalue problems. Indeed, a significant strength of the finite element method lies in its ability to place adaptive/local refinements in regions where the desired functions vary rapidly while treating the distant zones with a coarser description. We refer the reader to [7, 26, 32] and the references cited therein for the application of the finite element method to electronic structure computations. In this paper, we will propose some new techniques for finite element eigenvalue approximations and then apply these new techniques to ground state energy computations. These techniques are based on our understanding of local behaviors of finite element solutions to some (linear) elliptic problems. By using these techniques, the computational complexity can be resolved through some globally and locally coupled discretizations that can be carried out in parallel. The main idea of our new algorithms is to use a relatively coarse finite element to approximate the low frequency of the solution and then to use some linear algebraic systems to correct the residual (which contains mostly high frequencies) in some globally and locally fine finite element spaces. With these new proposed schemes, solving an elliptic eigenvalue problem will not be much more difficult than the global and local solutions of some standard elliptic boundary value problems. Our schemes are some iterative approaches, which are related to those in [10, 20, 38, 39]. The schemes in the current work, however, are proposed for solving singular eigenvalue problems and based on globally and locally coupled discretizations on different finite element grids with different scales.

The main philosophy behind this paper is that we should treat different phenomena by different tools that are usually posed in different scale settings (cf. [37, 41]). In multigrid approaches, this kind of idea is used to devise iterative methods for solving a given eigenvalue discretization scheme (see, e.g., [7, 8, 12, 16, 21, 24, 35] and the references cited therein); while in our approach, we try to use this idea for designing discretization schemes for quantum eigenvalue problems, which are known to be singular.

Let us now give a little more detailed but informal description of the main ideas in this paper. Let $S_0^H(\Omega), S_0^k(\Omega)$, and $S_0^h(\Omega)$, satisfying $S_0^H(\Omega) \subset S_0^k(\Omega) \subset S_0^h(\Omega) \subset H_0^1(\Omega)$, be three finite element spaces which consist of piecewise polynomials of degree less than or equal to r associated with a coarse grid $T^H(\Omega)$ of mesh size H, a mesoscopic grid $T^k(\Omega)$ of mesh size k, and a fine grid $T^h(\Omega)$ of mesh size h, respectively. If the singular points are located in some subdomain, say $D \subset \Omega$, we may employ the following algorithm to discretize (1.1) to obtain eigenpair approximations (see section 3):

1. Solve an eigenvalue problem on a globally coarse grid (see Figure 1.1 for the two-dimensional version): find $(\lambda_H, u_H) \in S_0^H(\Omega) \times \mathbb{R}$ satisfying $\|u_H\|_{L^2(\Omega)} = 1$ and

$$\int_\Omega (\nabla u_H \cdot \nabla v + V u_H v) = \lambda_H \int_\Omega u_H v \quad \forall v \in S_0^H(\Omega).$$

2. Solve a linear boundary value problem on a globally mesoscopic grid (see Figure 1.2 for the two-dimensional version): find $u^k \in S_0^k(\Omega)$ satisfying

$$\int_\Omega \left(\nabla u^k \cdot \nabla v + V u^k v\right) = \lambda_H \int_\Omega u_H v \quad \forall v \in S_0^k(\Omega).$$

3. Solve a linear boundary value problem on a locally fine grid (see Figure 1.3

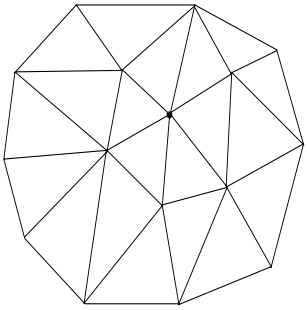

FIG. 1.1. *A coarse grid.*

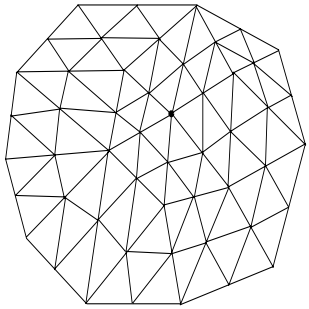

FIG. 1.2. *A mesoscopic grid.*

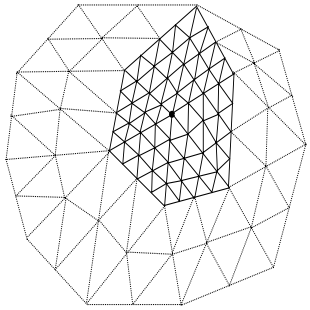

FIG. 1.3. *A locally fine grid.*

for the two-dimensional version): find $e_h \in S_0^h(\Omega_0)$ satisfying

$$\int_{\Omega_0} (\nabla e_h \cdot \nabla v + V e_h v)$$

$$= \lambda_H \int_{\Omega_0} u_H v - \int_{\Omega_0} \left(\nabla u^k \cdot \nabla v + V u^k v\right) \quad \forall v \in S_0^h(\Omega_0).$$

4. Set

$$u^{k,h} = \begin{cases} u^k + e_h & \text{on } \bar{\Omega}_0, \\ u^k & \text{in } \Omega \setminus \bar{\Omega}_0 \end{cases}$$

and

$$\lambda^{k,h} = \frac{\displaystyle\int_\Omega \left(|\nabla u^{k,h}|^2 + V|u^{k,h}|^2\right)}{\displaystyle\int_\Omega |u^{k,h}|^2},$$

where $D \subset\subset \Omega_0$, which means that $D \subset \Omega_0$ and dist $(\partial D \setminus \partial\Omega, \partial\Omega_0 \setminus \partial\Omega) > 0$.

In this algorithm, we use step 1 to handle the nonlinearity (note that the eigenvalue problem is nonlinear). To damp out the singularity (which contains mostly high frequencies), we set up step 3. And we apply step 2 to improve the accuracy of approximation. If, for example, λ_H is the first eigenvalue of the problem at the first step, then under some reasonable assumption we can establish the following results (see section 3):

$$\|u - u^{k,h}\|_{H^1(\Omega)} = \mathcal{O}(h^{r+s-1} + k^r + H^{r+s+\theta-1}) \tag{1.2}$$

and

$$\left|\lambda - \lambda^{k,h}\right| = \mathcal{O}(h^{2r+2s-2} + k^{2r} + H^{2r+2s+2\theta-2}), \tag{1.3}$$

where $s \in [0, 1)$ depends on the local regularity of the exact eigenvector associated with the first eigenvalue λ of (1.1) (more precisely, $u \in H_0^1(\Omega) \cap H^{r+s}(\Omega) \cap H^{r+1}(\Omega \setminus \bar{D})$), and $\theta \in (0, 1]$ depends on s and the regularity of Ω.

This is a very satisfactory result since we may choose $H \gg k \gg h$. As a consequence, for example, we can then design the following local and parallel scheme:

first, solve the eigenvalue problem on a globally coarse grid $T^H(\Omega)$, then solve a linear boundary value problem on a globally mesoscopic grid $T^k(\Omega)$ and some linear boundary value problems on a collection of nonoverlapped subdomains on locally fine grids $T^h(\Omega_j)$ in parallel, and, finally, compute some Rayleigh quotient to obtain a new eigenvalue approximation $\lambda^{k,h}$ which satisfies (1.3) (see section 3).

It is seen that, with this new scheme, the computational complexity is significantly reduced. More precisely, we can largely resolve the computational complexity and keep the same approximation accuracy as that of solving the eigenvalue problem in the globally fine grid. The theoretical tool for motivating this idea is the local error estimates for finite element approximations developed in [37, 39] (see also section 2.2). It is shown by numerical examples that this new scheme is a potentially efficient approach to solving quantum eigenvalue problems (see section 4). To apply the three-scale discretization schemes for ground state energies, which are of nonlinear eigenvalue problems, we need to employ a so-called self-consistent approach [7, 19, 32]. In our computations, a Broyden-type quasi-Newton method [34] will be used.

The rest of the paper is organized as follows. In the next section, we shall describe some basic notation and the finite element approximations to a class of linear second order elliptic boundary value and eigenvalue problems, including some local properties of finite element solutions discovered and studied in [37, 39]. Based on the local properties of finite element solutions and certain globally and locally coupled discretizations, some three-scale discretization schemes for linear eigenvalue approximations are devised and analyzed in section 3. Combining with the self-consistent approach, in section 4, the corresponding three-scale discretization schemes are constructed for Kohn–Sham equations. It is shown by the numerical experiments that our schemes are very efficient in electronic structure computations. Finally, some concluding remarks are given.

2. Preliminaries. In this section, we shall describe some basic notation and the standard finite element discretizations for a class of linear second order elliptic boundary value and eigenvalue problems.

Let Ω be a bounded domain in $\mathbb{R}^d (d \geq 1)$. We shall use the standard notation for Sobolev spaces $W^{s,p}(\Omega)$ and their associated norms and seminorms; see, e.g., [1, 11]. For $p = 2$, we denote $H^s(\Omega) = W^{s,2}(\Omega)$ and $H_0^1(\Omega) = \{v \in H^1(\Omega) : v\mid_{\partial\Omega} = 0\}$, where $v\mid_{\partial\Omega} = 0$ is in the sense of trace, $\|\cdot\|_{s,\Omega} = \|\cdot\|_{s,2,\Omega}$ and $\|\cdot\|_{\Omega} = \|\cdot\|_{0,2,\Omega}$. (In some places in this paper, $\|\cdot\|_{s,2,\Omega}$ should be viewed as piecewise defined if necessary.) The space $H^{-1}(\Omega)$, the dual of $H_0^1(\Omega)$, will also be used.

For $D \subset G \subset \Omega$, we use the notation $D \subset\subset G$ to mean that $\mathrm{dist}(\partial D \setminus \partial\Omega, \partial G \setminus \partial\Omega) > 0$ (see Figure 2.1 for two-dimensional cases). For simplicity, we assume that Ω and its subdomain (if any) involved in this paper are polytopic. Note that any $w \in H_0^1(\Omega_0)$ can be naturally extended to be a function in $H_0^1(\Omega)$ with zero outside of Ω_0 when $\Omega_0 \subset \Omega$; thus we shall state this fact by the slightly abused notation $H_0^1(\Omega_0) \subset H_0^1(\Omega)$.

Throughout this paper, we shall use the letter C (with or without subscripts) to denote a generic positive constant which may stand for different values at its different occurrences. For convenience, the symbol $\lesssim$ will be used in this paper. The notation that $x_1 \lesssim y_1$ means that $x_1 \leq Cy_1$ for some positive constant C that is independent of mesh parameters.

Assume that $T^h(\Omega) = \{\tau\}$ is a mesh of Ω with mesh-size function $h(x)$ whose value is the diameter h_τ of the element τ containing x. One basic assumption on the mesh is that it is not exceedingly overrefined locally; namely, we have the following.

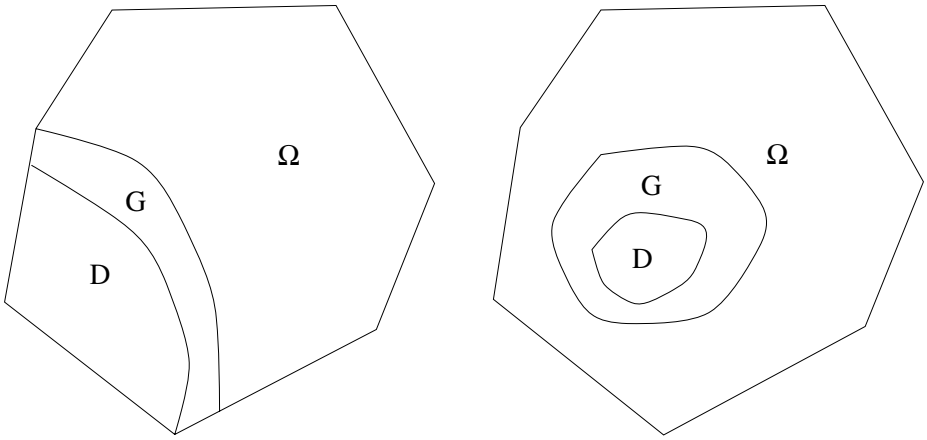

FIG. 2.1. *Subdomains.*

A.0. There exists $\nu \geq 1$ such that

$$h_{\Omega}^{\nu} \lesssim h(x), \quad x \in \Omega, \tag{2.1}$$

where $h_{\Omega} = \max_{x\in\Omega} h(x)$ is the (largest) mesh size of $T^h(\Omega)$.

This is apparently a very mild assumption from the theoretical point of view. Sometimes, we will drop the subscript in h_{Ω} to h for the mesh size on a domain that is clear from the context.

Let $T^h(\Omega)$ consist of shape-regular simplices and define $S^h(\Omega)(\equiv S^{h,r}(\Omega))$ to be a space of continuous functions on Ω such that for $v \in S^h(\Omega), v$ restricted to each τ is a polynomial of total degree $\leq r$, namely

$$S^h(\Omega) = \{v \in C(\bar{\Omega}) : v\,|_{\tau} \in P_{\tau}^r \quad \forall \tau \in T^h(\Omega)\}, \tag{2.2}$$

where P_{τ}^r is the space of polynomials of degree not greater than a positive integer r. Set $S_0^h(\Omega) = S^h(\Omega) \cap H_0^1(\Omega)$. These are Lagrange finite element spaces, and we refer the reader to [37] (see also [28, 29]) for their basic properties that will be used in our analysis.

Given $G \subset \Omega$, we define $S^h(G)$ and $T^h(G)$ to be the restriction of $S^h(\Omega)$ and $T^h(\Omega)$ to G, respectively, and

$$S_h^0(G) = \{v \in S^h(\Omega) : \text{supp } v \subset\subset G\}.$$

For any $G \subset \Omega$ mentioned in this paper, we assume that it aligns with $T^h(\Omega)$ when necessary.

2.1. A linear elliptic boundary value problem. In this subsection, we shall present some basic properties of a second order elliptic boundary value problem and its finite element approximations, which will be used in this paper.

Let $(\cdot,\cdot)$ be the standard inner product of $L^2(\Omega)$ and

$$a(u,v) = \int_{\Omega} \sum_{i,j=1}^{d} a_{ij} \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_j} + cuv,$$

where (a_{ij}) is symmetric with $a_{ij} \in L^\infty(\Omega)(i,j = 1,2,\ldots,d)$ and c is some real function such that $a(\cdot,\cdot)$ is a bounded bilinear form in $H_0^1(\Omega)$ and

$$\|w\|_{1,\Omega}^2 - C^{-1}\|w\|_{0,\Omega}^2 \lesssim a(w,w) \quad \forall w \in H_0^1(\Omega)$$

holds for some positive constant C.

Consider the homogeneous boundary value problem

$$\begin{cases} Lu = f \ \text{ in } \ \Omega, \\ u = 0 \ \text{ on } \ \partial\Omega, \end{cases} \tag{2.3}$$

where L is a linear second order elliptic operator:

$$Lu = -\sum_{i,j=1}^{d} \frac{\partial}{\partial x_j}\left(a_{ij}\frac{\partial u}{\partial x_i}\right) + cu.$$

The weak form of (2.3) is as follows: Find $u \equiv L^{-1}f \in H_0^1(\Omega)$ such that

$$a(u,v) = (f,v) \quad \forall v \in H_0^1(\Omega). \tag{2.4}$$

Our basic assumption is that (2.4) is well posed; namely, (2.4) is uniquely solvable for any $f \in H^{-1}(\Omega)$. We have (cf. [15]) the following estimate for the regularity of the solution of (2.3) or (2.4): $u \in H_0^1(\Omega) \cap H^{1+\gamma}(\Omega)$ and

$$\|u\|_{1+\gamma,\Omega} \lesssim \|f\|_{-1+\gamma,\Omega} \tag{2.5}$$

for some $\gamma \in (0,1]$ depending on Ω and the coefficients of L.

For some $G \subset \Omega$, we need the following assumption.

R(G). For any $f \in L^2(G)$, there exists a $u \in H_0^1(G) \cap H^{1+\gamma}(G)$ satisfying

$$a(v,u) = (f,v) \quad \forall v \in H_0^1(G)$$

and

$$\|u\|_{1+\gamma,G} \lesssim \|f\|_{-1+\gamma,G}.$$

Define a Galerkin projection $P_h : H_0^1(\Omega) \mapsto S_0^h(\Omega)$ by

$$a(u - P_h u, v) = 0 \quad \forall v \in S_0^h(\Omega) \tag{2.6}$$

and apparently

$$\|P_h u\|_{1,\Omega} \lesssim \|u\|_{1,\Omega} \quad \forall u \in H_0^1(\Omega). \tag{2.7}$$

From (2.7), various global a priori error estimates for finite element approximation $P_h u$ to u can be obtained from the approximate properties of the finite element space $S^h(\Omega)$ (cf. [11, 37]).

Now we introduce the following quantity:

$$\rho_\Omega(h) = \sup_{f \in L^2(\Omega), \|f\|_{0,\Omega}=1} \inf_{v \in S_0^h(\Omega)} \|L^{-1}f - v\|_{1,\Omega}.$$

Then (see, e.g., [37]) $\rho_\Omega(h) \to 0$ as $h_\Omega \to 0$ and

$$\rho_\Omega(h) \lesssim h_\Omega^\gamma. \tag{2.8}$$

Similarly, if Assumption R(G) holds, we can define $\rho_G(h)$ well, too.

The following results can be found in [37] (cf. also [5, 30, 38]).

PROPOSITION 2.1.

$$\|(I - P_h)L^{-1}f\|_{1,\Omega} \lesssim \rho_\Omega(h)\|f\|_{0,\Omega} \quad \forall f \in L^2(\Omega) \tag{2.9}$$

and

$$\|u - P_h u\|_{0,\Omega} \lesssim \rho_\Omega(h)\|u - P_h u\|_{1,\Omega} \quad \forall u \in H_0^1(\Omega). \tag{2.10}$$

Local error estimates for finite element approximations can also be obtained (see, e.g., [11, 28, 29, 37]). For instance, we have the following a priori error estimate (see [37] for details), which will be employed in our discussions.

PROPOSITION 2.2. *Suppose that* $D \subset\subset \Omega_0$.

(i) *If* $f \in H^{-1}(\Omega)$ *and* $w \in S^h(\Omega_0)$ *satisfies*

$$a(w, v) = f(v) \quad \forall v \in S_h^0(\Omega_0), \tag{2.11}$$

then

$$\|w\|_{1,D} \lesssim \|w\|_{0,\Omega_0} + \|f\|_{-1,\Omega_0}. \tag{2.12}$$

(ii) *If* $u \in H_0^1(\Omega)$, *then*

$$\|u - P_h u\|_{1,D} \lesssim \inf_{v \in S_0^h(\Omega)} \|u - v\|_{1,\Omega_0} + \rho_\Omega(h)\|u - P_h u\|_{1,\Omega}. \tag{2.13}$$

2.2. A linear elliptic eigenvalue problem. A number λ is called an eigenvalue of the form $a(\cdot,\cdot)$ relative to the form $(\cdot,\cdot)$ if there is a nonzero vector $u \in H_0^1(\Omega)$, called an associated eigenvector, satisfying

$$a(u, v) = \lambda(u, v) \quad \forall v \in H_0^1(\Omega). \tag{2.14}$$

It is known that (2.14) has a countable sequence of real eigenvalues

$$\lambda_1 < \lambda_2 \le \lambda_3 \le \cdots$$

and the corresponding eigenvectors

$$u_1, u_2, u_3, \ldots,$$

which can be assumed to satisfy

$$(u_i, u_j) = \delta_{ij}, \quad i, j = 1, 2, \ldots.$$

In the sequence $\{\lambda_j\}$, the λ_j's are repeated according to geometric multiplicity.

The following straightforward property of eigenvalue and eigenvector is useful (see, e.g., [5, 6] or [38]).

PROPOSITION 2.3. *Let* (λ, u) *be an eigenpair of* (2.14). *For any* $w \in H_0^1(\Omega) \setminus \{0\}$,

$$\frac{a(w,w)}{(w,w)} - \lambda = \frac{a(w-u,w-u)}{(w,w)} - \lambda \frac{(w-u,w-u)}{(w,w)}. \tag{2.15}$$

A standard finite element scheme for (2.14) is the following: find a pair of (λ_h, u_h), where λ_h is a number and $0 \neq u_h \in S_0^h(\Omega)$, satisfying

$$a(u_h, v) = \lambda_h (u_h, v) \quad \forall v \in S_0^h(\Omega), \tag{2.16}$$

and use λ_h and u_h as approximations to λ and u (as $h \to 0$), respectively. One sees that (2.16) has a finite sequence of eigenvalues

$$\lambda_{1,h} < \lambda_{2,h} \leq \cdots \leq \lambda_{n_h,h}, \quad n_h = \dim\, S_0^h(\Omega),$$

and the corresponding eigenvectors

$$u_{1,h}, u_{2,h}, \ldots, u_{n_h,h},$$

which can be assumed to satisfy

$$(u_{i,h}, u_{j,h}) = \delta_{ij}, \quad i,j = 1,2,\ldots.$$

Set

$$M(\lambda_i) = \{w \in H_0^1(\Omega) : w \text{ is an eigenvector of (2.14) corresponding to } \lambda_i\}$$

and

$$\delta_h(\lambda_i) = \sup_{w \in M(\lambda_i), \|w\|_{0,\Omega}=1} \inf_{v \in S_0^h(\Omega)} \|w - v\|_{1,\Omega}.$$

The following results are standard and can be found in the literature (see, e.g., [5, 6, 10] or [38]).

PROPOSITION 2.4. (i) *For any eigenvector* $u_{i,h}$ *of* (2.16) $(i = 1,2,\ldots,n_h)$ *with* $\|u_{i,h}\|_{0,\Omega} = 1$, *there is an eigenvector* u^i *of* (2.14) *corresponding to* λ_i *satisfying* $\|u^i\|_{0,\Omega} = 1$ *and*

$$\|u^i - u_{i,h}\|_{1,\Omega} \leq C_i \delta_h(\lambda_i). \tag{2.17}$$

Moreover,

$$\|u^i - u_{i,h}\|_{0,\Omega} \leq C_i \rho_\Omega(h) \|u^i - u_{i,h}\|_{1,\Omega}. \tag{2.18}$$

(ii) *For eigenvalues,*

$$\lambda_i \leq \lambda_{i,h} \leq \lambda_i + C_i \delta_h^2(\lambda_i), \quad i = 1,2,\ldots,n_h. \tag{2.19}$$

Here C_i *is some positive constant depending on* i *but not on the mesh parameter* h.

For the eigenvectors, there is a local a priori estimate which was presented in [39].

THEOREM 2.5. *If* $D \subset\subset \Omega_0$, *then*

$$\|u^i - u_{i,h}\|_{1,D} \lesssim \inf_{v \in S_0^h(\Omega)} \|u^i - v\|_{1,\Omega_0} + \lambda_{i,h} - \lambda_i + \lambda_i \rho_\Omega(h) \|u^i - u_{i,h}\|_{1,\Omega}. \tag{2.20}$$

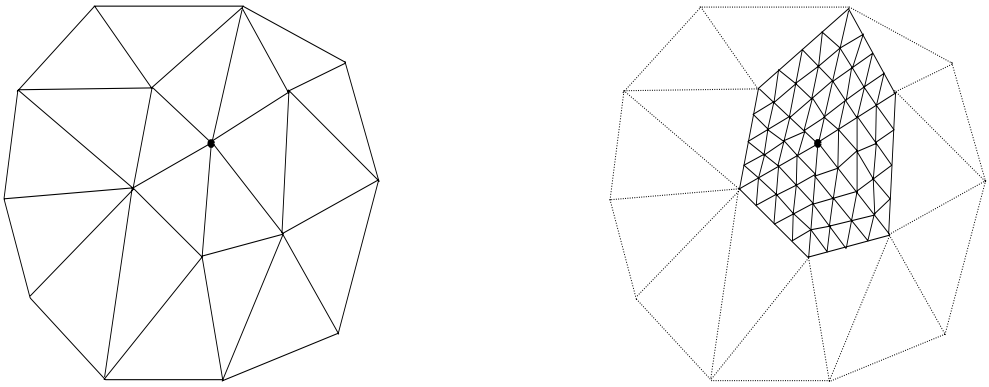

FIG. 3.1. *Localization.*

3. Discretization schemes for linear eigenvalue problems. In this section we shall present and analyze a three-scale discretization scheme for solving linear elliptic eigenvalue problems, based on some global and local corrections on different grids that are of different scales. The parallel version of the three-scale scheme is proposed, too. The schemes are motivated by the observation that for a solution of some elliptic problem, low frequency components can be approximated well on a relatively coarse grid and high frequency ones can be computed on some globally mesoscopic grid and locally fine grids. Although these schemes are theoretically interesting in their own right for linear eigenvalue problems, our main motivation is to use them to devise efficient and accurate numerical methods for quantum eigenvalue problems; see section 4.

Let $T^H(\Omega)$ be a shape-regular grid of size $H \in (0,1)$, $D \subset \Omega$ be a subdomain which contains a singular point, and Ω_0 be a slightly larger subdomain containing D (namely $D \subset\subset \Omega_0$). Let $h \ll H$ and a highly locally refined grid $T^h(\Omega_0)$ be obtained from $T^H(\Omega)$; see Figure 3.1. Let $S_0^H(\Omega)(\equiv S_0^{H,r}(\Omega))$ denote the finite element space which consists of piecewise polynomials of degree less than or equal to r associated with $T^H(\Omega)$. In our discussion, we shall use an auxiliary fine grid, say $T^h(\Omega)$, that is globally defined. Associated with $T^h(\Omega)$, the finite element space $S_0^h(\Omega)(\equiv S_0^{h,r}(\Omega))$ which consists of piecewise polynomials of degree less than or equal to r is then defined. One basic assumption for this auxiliary fine finite element space is that it should coincide with the locally fine finite element space in the subdomain of interest. To improve the efficiency, we also need to apply the third finite element space $S_0^k(\Omega)(\equiv S_0^{k,r}(\Omega))$ which consists of piecewise polynomials of degree less than or equal to r associated with a shape-regular grid $T^k(\Omega)$ of a mesoscopic size k. All these spaces satisfy $S_0^H(\Omega) \subset S_0^k(\Omega) \subset S_0^h(\Omega) \subset H_0^1(\Omega)$.

We consider the approximation of any eigenvalue λ of (2.14). Here and hereafter we let λ_H be the finite element eigenvalue of (2.16) corresponding to $S_0^H(\Omega)$ and satisfying

$$|\lambda_H - \lambda| \lesssim \delta_H(\lambda). \tag{3.1}$$

3.1. A two-scale discretization. Before we propose and analyze the three-scale discretization scheme, we shall discuss a simpler scheme—a so-called two-scale discretization scheme. The two-scale discretization scheme we shall now present can be used to obtain an approximate solution mostly by a local computation. The main

idea is that the more global component of a finite element eigenvector may be obtained in a relatively coarse finite element space, and the rest of the computation can then be localized using a locally fine finite element discretization. This scheme may be viewed as a postprocessing of the standard finite element discretization when the eigenvectors are known to be oscillating in some local domain.

A prototype of our two-scale discretization, which is mainly a local computational scheme, is stated as follows.

ALGORITHM A0.

1. *Solve an eigenvalue problem on a globally coarse grid: find* $(\lambda_H, u_H) \in S_0^H(\Omega) \times \mathbb{R}$ *satisfying* $\|u_H\|_{0,\Omega} = 1$ *and*

$$a(u_H, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^H(\Omega).$$

2. *Solve a linear boundary value problem on a locally fine grid: find* $e_h \in S_0^h(\Omega_0)$ *satisfying*

$$a(e^h, v) = \lambda_H(u_H, v) - a(u_H, v) \quad \forall v \in S_0^h(\Omega_0).$$

3. *Set*

$$u^h = \begin{cases} u_H + e^h & \text{on } \bar{\Omega}_0, \\ u_H & \text{in } \Omega \setminus \bar{\Omega}_0 \end{cases}$$

and

$$\lambda^h = \frac{a(u^h, u^h)}{\| u^h \|_{0,\Omega}^2}.$$

It is seen from Proposition 2.4 that associated with the eigenvector u_H obtained by step 1 in Algorithm A0, there exists an exact eigenvector u of (2.14) satisfying $\|u\|_{0,\Omega} = 1$ and

$$\|u - u_H\|_{1,\Omega} \lesssim \delta_H(\lambda), \quad \|u - u_H\|_{0,\Omega} \lesssim \rho_\Omega(H)\delta_H(\lambda). \tag{3.2}$$

LEMMA 3.1. *Let* $\sigma \in \{H, k, h\}$ *and* $G \subset \Omega$. *If* $M(\lambda) \subset H^{r+s}(G)(0 \le s \le 1)$, *then*

$$\sup_{w \in M(\lambda), \|w\|_{0,\Omega}=1} \inf_{v \in S_0^\sigma(G)} \|w - v\|_{1,G} \lesssim \sigma^{r+s-1}. \tag{3.3}$$

In particular, if $M(\lambda) \subset H^{r+s}(\Omega)(0 \le s \le 1)$, *then*

$$|\lambda - \lambda_H| \lesssim H^{2r+2s-2}, \quad \|u - u_H\|_{1,\Omega} \lesssim H^{r+s-1}, \quad \|u - u_H\|_{0,\Omega} \lesssim H^{\gamma+r+s-1} \tag{3.4}$$

and

$$\|u - P_\sigma u\|_{1,\Omega} \lesssim \sigma^{r+s-1}, \quad \|u - P_\sigma u\|_{0,\Omega} \lesssim \sigma^{\gamma+r+s-1}. \tag{3.5}$$

Proof. Since Riesz–Schauder theory implies that $\dim M(\lambda) < \infty$, we immediately have

$$\sup_{w \in M(\lambda), \|w\|_{0,\Omega}=1} \|w\|_{r+s,G} < \infty,$$

from which we get (3.3). This completes the proof. ∎

In the following discussion, we assume that (λ, u) is the exact eigenpair of (2.14) satisfying (3.1), (3.2), and $M(\lambda) \subset H^{r+s}(\Omega)(1 < r+s$ and $0 \le s < 1)$. For simplicity, we set $\theta = \min(\gamma, r+s-1)$. Obviously, $\theta \in (0,1]$.

THEOREM 3.2. *Assume that u^h is obtained by Algorithm* A0 *and assumption $R(\Omega_0)$ holds. If $M(\lambda) \subset H_0^1(\Omega) \cap H^{r+s}(\Omega) \cap H^{r+1}(\Omega \setminus \bar{D})(1 < r+s$ and $0 \le s < 1)$, then*

$$\|u - u^h\|_{1,\Omega} \lesssim h^{r+s-1} + H^r + H^{r+s+\theta-1} \tag{3.6}$$

and

$$|\lambda - \lambda^h| \lesssim h^{2r+2s-2} + H^{2r} + H^{2r+2s+2\theta-2}. \tag{3.7}$$

Proof. Because of Lemma 3.1 and Proposition 2.3 it is sufficient to prove that

$$\|P_h u - u^h\|_{1,\Omega} \lesssim H^r + H^{r+s+\theta-1}. \tag{3.8}$$

We divide the proof of (3.8) into four steps. Let $G \subset \Omega$ satisfy $D \subset\subset G \subset\subset \Omega_0$. Due to the triangle inequality

$$\|P_h u - u^h\|_{1,\Omega} \lesssim \|P_h u - u^h\|_{1,D} + \|P_h u - u^h\|_{1,G\setminus\bar{D}} + \|P_h u - u^h\|_{1,\Omega\setminus\bar{G}},$$

we shall estimate $\|P_h u - u^h\|_{1,D}$, $\|P_h u - u^h\|_{1,G\setminus\bar{D}}$, and $\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}}$, respectively.

First, we proceed to estimate $\|P_h u - u^h\|_{1,D}$. Note that the following equation can be derived from the construction of Algorithm A0:

$$a(u^h - P_h u, v) = \lambda_H(u_H, v) - \lambda(u, v) \quad \forall v \in S_0^h(\Omega_0). \tag{3.9}$$

Hence, from the identity

$$\lambda_H(u_H, v) - \lambda(u, v) = (\lambda_H - \lambda)(u, v) + \lambda_H(u_H - u, v) \ \ \forall v \in H_0^1(\Omega), \tag{3.10}$$

we obtain

$$a(u^h - P_h u, v) = (\lambda_H - \lambda)(u, v) + \lambda_H(u_H - u, v) \quad \forall v \in S_0^h(\Omega_0). \tag{3.11}$$

Since $S_h^0(\Omega_0) \subset S_0^h(\Omega)$, the estimation

$$\|P_h u - u^h\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0} + \|u^h - P_h u\|_{0,\Omega_0}$$

or

$$\|P_h u - u^h\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0} + \|u - P_h u\|_{0,\Omega_0} + \|e_h\|_{0,\Omega_0}$$

can be obtained from (3.11) and Proposition 2.2.

We now need to estimate $\|e^h\|_{0,\Omega_0}$ by using the Aubin–Nitsche duality argument. Given any $\phi \in L^2(\Omega_0)$, there exists $w \in H_0^1(\Omega_0)$ such that

$$a(v, w) = (\phi, v) \quad \forall v \in H_0^1(\Omega_0). \tag{3.12}$$

Let $w_h^0 \in S_0^h(\Omega_0)$ and $w_H^0 \in S_0^H(\Omega_0)$ satisfy

$$a(v, w_h^0) = a(v, w) \quad \forall v \in S_0^h(\Omega_0), \tag{3.13}$$

$$a(v, w_H^0) = a(v, w) \quad \forall v \in S_0^H(\Omega_0). \tag{3.14}$$

Then, Proposition 2.1 implies

$$\|w - w_h^0\|_{1,\Omega_0} \lesssim h^\gamma \|\phi\|_{0,\Omega_0}, \quad \|w - w_H^0\|_{1,\Omega_0} \lesssim H^\gamma \|\phi\|_{0,\Omega_0}.$$

It follows from the definitions of w, e_h, and w_h^0 that

$$\begin{aligned}(e^h, \phi) &= a(e^h, w) = a(e^h, w_h^0) = a(u^h - u_H, w_h^0)\\ &= a(P_h u - u_H, w_h^0) + a(u^h, w_h^0) - a(P_h u, w_h^0)\\ &= a(P_h u - u_H, w_h^0) + \lambda_H(u_H, w_h^0) - \lambda(u, w_h^0).\end{aligned}$$

Thus, we obtain

$$\begin{aligned}(e^h, \phi) &= a(P_h u - u_H, w_h^0 - w) + a(P_h u - u_H, w - w_H^0)\\ &\quad + a(P_h u - u_H, w_H^0) + \lambda_H(u_H, w_h^0) - \lambda(u, w_h^0)\\ &= a(P_h u - u_H, w_h^0 - w) + a(P_h u - u_H, w - w_H^0) + \lambda(u, w_H^0)\\ &\quad - \lambda_H(u_H, w_H^0) + \lambda_H(u_H, w_h^0) - \lambda(u, w_h^0).\end{aligned}$$

By some further simple operations, we then arrive at

$$\begin{aligned}(e^h, \phi) &= a(P_h u - u_H, w_h^0 - w) + a(P_h u - u_H, w - w_H^0)\\ &\quad + \lambda(u, w_H^0 - w_h^0) - \lambda_H(u_H, w_H^0 - w_h^0)\\ &= a(P_h u - u_H, w_h^0 - w) + a(P_h u - u_H, w - w_H^0)\\ &\quad + (\lambda - \lambda_H)(u, w_H^0 - w_h^0) + \lambda_H(u - u_H, w_H^0 - w_h^0).\end{aligned}$$

As a result, we get the estimation for any $\phi \in L^2(\Omega)$ that

$$|(e^h, \phi)| \lesssim (H^\gamma \|P_h u - u_H\|_{1,\Omega} + |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0}) \|\phi\|_{0,\Omega_0},$$

which implies

$$\|e^h\|_{0,\Omega_0} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0} + H^\gamma \|P_h u - u_H\|_{1,\Omega}. \tag{3.15}$$

Therefore

$$\|P_h u - u^h\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + \|u - P_h u\|_{0,\Omega} + H^\gamma \|P_h u - u_H\|_{1,\Omega},$$

which together with Lemma 3.1 yields

$$\|P_h u - u^h\|_{1,D} \lesssim H^{r+s+\theta-1}. \tag{3.16}$$

Second, we turn to estimate $\|P_h u - u^h\|_{1,G\setminus\bar{D}}$. Note that $(G \setminus \bar{D}) \subset\subset \Omega_0$; hence the estimation

$$\|P_h u - u^h\|_{1,G\setminus\bar{D}} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + \|u - P_h u\|_{0,\Omega} + H^\gamma \|P_h u - u_H\|_{1,\Omega}$$

can be derived from (3.9) and Proposition 2.2, too. Consequently, we have

$$\|P_h u - u^h\|_{1,G\setminus\bar{D}} \lesssim H^{r+s+\theta-1}. \tag{3.17}$$

Third, let us investigate $\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}}$. It is seen from the construction of Algorithm A0 that

$$\|P_h u - u^h\|_{1,\Omega\setminus\bar{\Omega}_0} = \|P_h u - u_H\|_{1,\Omega\setminus\bar{\Omega}_0},$$

and we may estimate $\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}}$ as follows:

$$\begin{aligned}\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}} &\le \|P_h u - u_H\|_{1,\Omega\setminus\bar{\Omega}_0} + \|P_h u - u_H\|_{1,\Omega_0\setminus\bar{G}} + \|e^h\|_{1,\Omega_0\setminus\bar{G}}\\ &\lesssim \|P_h u - u_H\|_{1,\Omega\setminus\bar{G}} + \|e^h\|_{1,\Omega_0\setminus\bar{G}}. \qquad (3.18)\end{aligned}$$

To analyze $\|e^h\|_{1,\Omega_0\setminus\bar{G}}$, we need the following equation:

$$a(e^h, v) = \lambda_H(u_H, v) - \lambda(u, v) - a(u_H - u, v) \quad \forall v \in S_0^h(\Omega_0), \qquad (3.19)$$

which is nothing but a variant of (3.9). Thus, from (3.10) and Proposition 2.2, we obtain

$$\|e^h\|_{1,\Omega_0\setminus\bar{G}} \lesssim \|e^h\|_{0,\Omega_0\setminus\bar{F}} + |\lambda - \lambda_H| + \|u - u_H\|_{1,\Omega_0\setminus\bar{F}}, \qquad (3.20)$$

where $F \subset \Omega$ satisfies $D \subset\subset F \subset\subset G$. Combining (3.18) and (3.20), we have

$$\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}} \lesssim \|P_h u - u_H\|_{1,\Omega\setminus\bar{G}} + \|e^h\|_{0,\Omega_0\setminus\bar{F}} + |\lambda - \lambda_H| + \|u - u_H\|_{1,\Omega_0\setminus\bar{F}}$$

or

$$\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}} \lesssim \|e^h\|_{0,\Omega_0} + |\lambda - \lambda_H| + \|u - u_H\|_{1,\Omega\setminus\bar{F}} + \|P_h u - u\|_{1,\Omega\setminus\bar{F}}. \qquad (3.21)$$

Note that $(\Omega \setminus \bar{F}) \subset\subset (\Omega \setminus \bar{D})$, and we may estimate by using Proposition 2.2 and Theorem 2.5 that

$$\begin{aligned}&\|u - P_h u\|_{1,\Omega\setminus\bar{F}} + \|u - u_H\|_{1,\Omega\setminus\bar{F}}\\ &\lesssim \inf_{v\in S_0^h(\Omega)} \|u - v\|_{1,\Omega\setminus\bar{D}} + \rho_\Omega(h)\|u - P_h u\|_{1,\Omega}\\ &\quad + \inf_{v\in S_0^H(\Omega)} \|u - v\|_{1,\Omega\setminus\bar{D}} + |\lambda - \lambda_H| + \rho_\Omega(H)\|u - u_H\|_{1,\Omega}\\ &\lesssim \inf_{v\in S_0^H(\Omega)} \|u - v\|_{1,\Omega\setminus\bar{D}} + |\lambda - \lambda_H| + \rho_\Omega(H)\|u - u_H\|_{1,\Omega} + \rho_\Omega(h)\|u - P_h u\|_{1,\Omega},\end{aligned}$$

which, together with (3.15), (3.21), and Lemma 3.1, leads to

$$\|P_h u - u^h\|_{1,\Omega\setminus\bar{G}} \lesssim H^r + H^{r+s+\theta-1}. \qquad (3.22)$$

Finally, the desired result then follows from (3.22), (3.16), and (3.17). ∎

3.2. A three-scale discretization. It is shown by the analysis above and the numerics in section 4 that the two-scale scheme may not be very efficient. It will be shown in this subsection that the efficiency can be improved if one more scale discretization is coupled. Let $T^k(\Omega)$ be a refined mesoscopic shape-regular grid (from $T^H(\Omega)$) and $T^h(\Omega_0)$ a locally refined grid (from $T^k(\Omega)$) that satisfy $h \ll k \ll H$; see Figure 3.2.

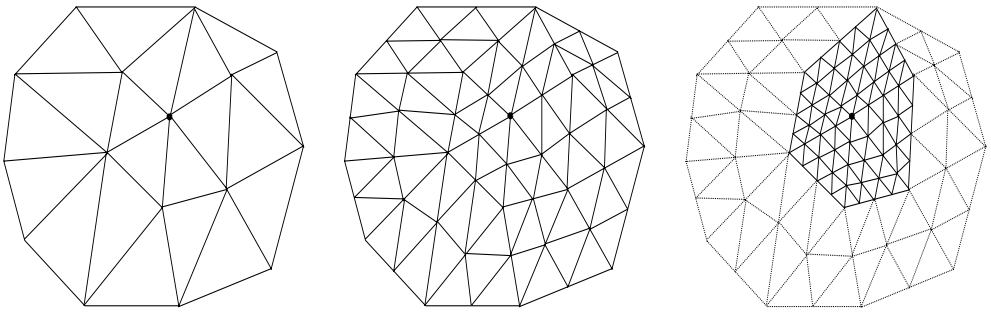

FIG. 3.2. *Globally mesoscopic grid + locally fine grid.*

ALGORITHM B0.

1. *Solve* (2.14) *on a globally coarse grid: find* $(\lambda_H, u_H) \in S_0^H(\Omega) \times \mathbb{R}$ *satisfying* $\|u_H\|_{0,\Omega} = 1$ *and*

$$a(u_H, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^H(\Omega).$$

2. *Solve a linear boundary value problem on a globally mesoscopic grid: find* $u^k \in S_0^k(\Omega)$ *satisfying*

$$a(u^k, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^k(\Omega).$$

3. *Solve a linear boundary value problem on a locally fine gird: find* $e^h \in S_0^h(\Omega_0)$ *satisfying*

$$a(e^h, v) = \lambda_H(u_H, v) - a(u^k, v) \quad \forall v \in S_0^h(\Omega_0).$$

4. *Set*

$$u^{k,h} = \begin{cases} u^k + e^h & \text{on } \bar{\Omega}_0, \\ u^k & \text{in } \Omega \setminus \bar{\Omega}_0 \end{cases}$$

and

$$\lambda^{k,h} = \frac{a(u^{k,h}, u^{k,h})}{\|u^{k,h}\|_{0,\Omega}^2}.$$

The above algorithm is in a way an improvement of the relevant scheme proposed in [20, 38] when the eigenvectors are oscillating in some local domain.

THEOREM 3.3. *Assume that* $u^{k,h}$ *is obtained by Algorithm* B0 *and assumption* $R(\Omega_0)$ *holds. If* $M(\lambda) \subset H_0^1(\Omega) \cap H^{r+s}(\Omega) \cap H^{r+1}(\Omega \setminus \bar{D})(1 < r + s$ *and* $0 \le s < 1)$*, then*

$$\|u - u^{k,h}\|_{1,\Omega} \lesssim h^{r+s-1} + k^r + H^{r+s+\theta-1}$$

and

$$|\lambda - \lambda^{k,h}| \lesssim h^{2r+2s-2} + k^{2r} + H^{2r+2s+2\theta-2}.$$

Proof. Following the proof of Theorem 3.2, we choose $G \subset \Omega$ satisfying $D \subset\subset G \subset\subset \Omega_0$. Since $\|P_h u - u^{k,h}\|_{1,\Omega}$ is bounded by

$$\|P_h u - u^{k,h}\|_{1,D} + \|P_h u - u^{k,h}\|_{1,G\setminus\bar{D}} + \|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}},$$

we need only estimate $\|P_h u - u^{k,h}\|_{1,D}$, $\|P_h u - u^{k,h}\|_{1,G\setminus\bar{D}}$, and $\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}}$, respectively. For these goals, we take $F \subset \Omega$ such that $D \subset\subset F \subset\subset G \subset\subset \Omega_0$.

First of all, from the equation

$$a(P_k u - u^k, v) = \lambda(u, v) - \lambda_H(u_H, v) \quad \forall v \in S_0^k(\Omega),$$

we have

$$\|P_k u - u^k\|_{1,\Omega} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega}, \tag{3.23}$$

which will be used in the following analysis.

To estimate $\|P_h u - u^{k,h}\|_{1,D}$, we need the identity

$$a(u^{k,h} - P_h u, v) = \lambda_H(u_H, v) - \lambda(u, v) \quad \forall v \in S_0^h(\Omega_0), \tag{3.24}$$

which comes from the construction of Algorithm B0. It is seen that the estimation

$$\|P_h u - u^{k,h}\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0} + \|P_h u - u^{k,h}\|_{0,\Omega_0} \tag{3.25}$$

can be derived from (3.10), (3.24), and Proposition 2.2. Due to the definition of $u^{k,h}$, we may estimate $\|P_h u - u^{k,h}\|_{0,\Omega_0}$ as follows:

$$\begin{aligned}\|P_h u - u^{k,h}\|_{0,\Omega_0} &\le \|P_h u - u^k\|_{0,\Omega_0} + \|e^h\|_{0,\Omega_0} \\ &\le \|P_h u - P_k u\|_{0,\Omega_0} + \|P_k u - u^k\|_{0,\Omega_0} + \|e^h\|_{0,\Omega_0}.\end{aligned}$$

Thus combining (3.23) and (3.25), we obtain

$$\|P_h u - u^{k,h}\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + \|P_h u - P_k u\|_{0,\Omega} + \|e^h\|_{0,\Omega_0}. \tag{3.26}$$

Now we are going to estimate $\|e^h\|_{0,\Omega_0}$ by using the Aubin–Nitsche duality argument. Given any $\phi \in L^2(\Omega_0)$, there exists $w \in H_0^1(\Omega_0)$ satisfying (3.12). Let $w_h^0 \in S_0^h(\Omega_0)$ and $w_H^0 \in S_0^H(\Omega_0)$ be the solutions of (3.13) and (3.14), respectively. Similar to that in the proof of Theorem 3.2, it follows from the definitions of w, e_h, and w_h^0 that

$$\begin{aligned}(e^h, \phi) = {} & a(P_h u - u^k, w_h^0 - w) + a(P_h u - u^k, w - w_H^0) \\ & + (\lambda - \lambda_H)(u, w_H^0 - w_h^0) + \lambda_H(u - u_H, w_H^0 - w_h^0).\end{aligned}$$

As a result, we get the estimation for any $\phi \in L^2(\Omega)$ that

$$|(e^h, \phi)| \lesssim (H^\gamma \|P_h u - u^k\|_{1,\Omega} + |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega})\|\phi\|_{0,\Omega_0},$$

which leads to

$$\|e^h\|_{0,\Omega_0} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + H^\gamma \|P_h u - u^k\|_{1,\Omega}.$$

Hence taking (3.23) and the triangle inequality

$$\|P_h u - u^k\|_{1,\Omega} \le \|P_h u - P_k u\|_{1,\Omega} + \|P_k u - u^k\|_{1,\Omega}$$

into account, we then obtain

$$\|e^h\|_{0,\Omega_0} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + H^\gamma \|P_h u - P_k u\|_{1,\Omega}. \tag{3.27}$$

It is not difficult to see that the estimation

$$\|P_h u - P_k u\|_{0,\Omega} \lesssim H^{\gamma} \|P_h u - P_k u\|_{1,\Omega}$$

can also be derived from the Aubin–Nitsche duality argument. Therefore we have

$$\|P_h u - u^{k,h}\|_{1,D} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + H^{\gamma} \|P_h u - P_k u\|_{1,\Omega},$$

which together with Lemma 3.1 and (3.23) implies

$$\|P_h u - u^{k,h}\|_{1,D} \lesssim H^{r+s+\theta-1}. \tag{3.28}$$

Similarly, the estimation

$$\|P_h u - u^{k,h}\|_{1,G\setminus\bar{D}} \lesssim H^{r+s+\theta-1} \tag{3.29}$$

can be obtained from $(G \setminus \bar{D}) \subset\subset \Omega_0$ and Proposition 2.2, too.

The remainder is to analyze $\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}}$. From the construction of Algorithm B0, we see that

$$\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{\Omega}_0} = \|P_h u - u^{k}\|_{1,\Omega\setminus\bar{\Omega}_0},$$

which leads to

$$\begin{aligned}\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} &\le \|P_h u - u^{k}\|_{1,\Omega\setminus\bar{\Omega}_0} + \|P_h u - u^{k}\|_{1,\Omega_0\setminus\bar{G}} + \|e^h\|_{1,\Omega_0\setminus\bar{G}} \\ &\lesssim \|P_h u - u^{k}\|_{1,\Omega\setminus\bar{G}} + \|e^h\|_{1,\Omega_0\setminus\bar{G}}.\end{aligned}$$

Hence we have

$$\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} \lesssim \|P_h u - u\|_{1,\Omega\setminus\bar{G}} + \|u - u^{k}\|_{1,\Omega\setminus\bar{G}} + \|e^h\|_{1,\Omega_0\setminus\bar{G}}. \tag{3.30}$$

Note that the estimation

$$\|e^h\|_{1,\Omega_0\setminus\bar{G}} \lesssim \|e^h\|_{0,\Omega_0\setminus\bar{F}} + |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega_0} + \|u^k - u\|_{1,\Omega_0\setminus\bar{F}} \tag{3.31}$$

can be derived from Proposition 2.2, (3.10), and

$$a(e^h, v) = \lambda_H(u_H, v) - \lambda(u, v) - a(u^k - u, v) \quad \forall v \in S_0^h(\Omega_0); \tag{3.32}$$

we then arrive at

$$\begin{aligned}\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} \lesssim{}& \|e^h\|_{0,\Omega_0} + |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} \\ &+ \|P_h u - u\|_{1,\Omega\setminus\bar{F}} + \|u^k - u\|_{1,\Omega\setminus\bar{F}}.\end{aligned} \tag{3.33}$$

Thanks to (3.23) and the triangle inequality

$$\|u^k - u\|_{1,\Omega\setminus\bar{F}} \le \|u - P_k u\|_{1,\Omega\setminus\bar{F}} + \|P_k u - u^k\|_{1,\Omega\setminus\bar{F}},$$

we get

$$\|u^k - u\|_{1,\Omega\setminus\bar{F}} \le \|u - P_k u\|_{1,\Omega\setminus\bar{F}} + |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega}.$$

Thus combining (3.27) and (3.33), we conclude that

$$\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} \lesssim |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + H^\gamma \|P_h u - P_k u\|_{1,\Omega} + \|u - P_h u\|_{1,\Omega\setminus\bar{F}} + \|u - P_k u\|_{1,\Omega\setminus\bar{F}}. \tag{3.34}$$

Since $(\Omega \setminus \bar{F}) \subset\subset (\Omega \setminus \bar{D})$, we obtain from Proposition 2.2 that

$$\begin{aligned}\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} \lesssim\ & |\lambda - \lambda_H| + \|u - u_H\|_{0,\Omega} + H^\gamma \|P_h u - P_k u\|_{1,\Omega} \\ & + \inf_{v\in S_0^h(\Omega)} \|u - v\|_{1,\Omega\setminus\bar{D}} + \rho_\Omega(h)\|u - P_h u\|_{1,\Omega} \\ & + \inf_{v\in S_0^k(\Omega)} \|u - v\|_{1,\Omega\setminus\bar{D}} + \rho_\Omega(k)\|u - P_k u\|_{1,\Omega},\end{aligned}$$

which together with Lemma 3.1 yields

$$\|P_h u - u^{k,h}\|_{1,\Omega\setminus\bar{G}} \lesssim k^r + H^{r+s+\theta-1}. \tag{3.35}$$

Combining (3.35), (3.28), (3.29), and Lemma 3.1, finally, we complete the proof. □

3.3. Parallel algorithms. For eigenvalue problems having at least two isolated singular points, such as the Kohn–Sham equation of a system that contains more than two atoms, we can use the parallel versions of the algorithms designed above. Let n represent the number of isolated singular points. For each singular point, we choose a subdomain D_j containing it and then enlarge each D_j to Ω_j, and all these Ω_j satisfy that $\Omega_i \bigcap \Omega_j = \emptyset$ if $i \neq j(\ i, j = 1, \ldots, n)$; see Figure 3.3. Based on Algorithms A0 and B0, we have the following two parallel algorithms.

Algorithm A.

1. *Solve* (2.14) *on a globally coarse grid: find* $(\lambda_H, u_H) \in S_0^H(\Omega) \times \mathbb{R}$ *satisfying* $\|u_H\|_{0,\Omega} = 1$ *and*

$$a(u_H, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^H(\Omega).$$

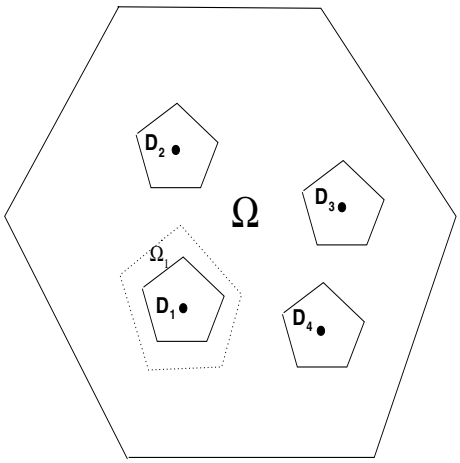

Fig. 3.3. *Localization.*

2. *Solve linear boundary value problems on locally fine grids in parallel: find* $e_h^j \in S_0^h(\Omega_j)(j = 1, 2, \ldots, n)$ *satisfying*

$$a(e_j^h, v) = \lambda_H(u_H, v) - a(u_H, v) \quad \forall v \in S_0^h(\Omega_j).$$

3. *Set*

$$u^h = \begin{cases} u_H + e_j^h & \text{on } \bar{\Omega}_j,\ j = 1, 2, \ldots, n, \\ u_H & \text{in } \Omega \backslash \left(\bigcup_{j=1}^n \bar{\Omega}_j \right) \end{cases}$$

and

$$\lambda^h = \frac{a(u^h, u^h)}{\|u^h\|_{0,\Omega}^2}.$$

Note that the assumption $\bigcup_{j=1}^n \bar{\Omega}_j = \bar{\Omega}$ is not required; hence Algorithm A is different from that in [39]. As a result, the local computational subdomains $\Omega_j (j = 1, 2, \ldots, n)$ may be much smaller. From the proof of Theorem 3.2, for this algorithm, we apparently have the following result.

THEOREM 3.4. *Assume that* u^h *is obtained by Algorithm* A *and assumption* $R(\Omega_j)$ *holds for* $j = 1, 2, \ldots, n$. *If* $u \in H_0^1(\Omega) \cap H^{r+s}(\Omega) \cap H^{r+1}(\Omega \setminus (\bigcup_{j=1}^n \bar{D}_j))(1 < r + s$ *and* $0 \le s < 1)$, *then*

$$\|u - u^h\|_{1,\Omega} \lesssim h^{r+s-1} + H^r + H^{r+s+\theta-1}$$

and

$$|\lambda - \lambda^h| \lesssim h^{2r+2s-2} + H^{2r} + H^{2r+2s+2\theta-2}.$$

ALGORITHM B.

1. *Solve* (2.14) *on a globally coarse grid: find* $(\lambda_H, u_H) \in S_0^H(\Omega) \times \mathbb{R}$ *satisfying* $\|u_H\|_{0,\Omega} = 1$ *and*

$$a(u_H, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^H(\Omega).$$

2. *Solve a linear boundary value problem on a globally mesoscopic grid: find* $u^k \in S_0^k(\Omega)$ *satisfying*

$$a(u^k, v) = \lambda_H(u_H, v) \quad \forall v \in S_0^k(\Omega).$$

3. *Solve linear boundary value problems on locally fine grids in parallel: find* $e_j^h \in S_0^h(\Omega_j)(j = 1, 2, \ldots, n)$ *satisfying*

$$a(e_j^h, v) = \lambda_H(u_H, v) - a(u^k, v) \quad \forall v \in S_0^h(\Omega_j).$$

4. *Set*

$$u^{k,h} = \begin{cases} u^k + e_j^h & \text{on } \bar{\Omega}_j,\ j = 1, 2, \ldots, n, \\ u^k & \text{in } \Omega \backslash \left(\bigcup_{j=1}^n \bar{\Omega}_j \right) \end{cases}$$

and

$$\lambda^{k,h} = \frac{a(u^{k,h}, u^{k,h})}{\|u^{k,h}\|_{0,\Omega}^2}.$$

It should be mentioned that step 2 in Algorithm B can be localized and carried out in parallel, too (cf. [37]). For Algorithm B, we also have the following result.

THEOREM 3.5. *Assume that $u^{k,h}$ is obtained by Algorithm* B *and assumption $R(\Omega_j)$ holds for $j = 1, 2, \ldots, n$. If $u \in H_0^1(\Omega) \cap H^{r+s}(\Omega) \cap H^{r+1}(\Omega \backslash (\bigcup_{j=1}^n \bar{D}_j))(1 < r + s$ and $0 \le s < 1)$, then*

$$\|u - u^{k,h}\|_{1,\Omega} \lesssim h^{r+s-1} + k^r + H^{r+s+\theta-1}$$

and

$$|\lambda - \lambda^{k,h}| \lesssim h^{2r+2s-2} + k^{2r} + H^{2r+2s+2\theta-2}.$$

4. Discretization schemes for quantum eigenvalue problems. In this section, we shall construct some multiscale finite element discretization schemes for electronic structure computations and apply the schemes to obtain the ground state energies for several typical atomic and molecular systems. It is shown by our numerical experiments that the three-scale discretization schemes are very efficient and recommended to quantum eigenvalue computations.

4.1. Linearization of the Kohn–Sham equation. Modern electronic structure computations are usually based on the following Kohn–Sham equation (see, e.g., [7, 19, 25]):

$$\left(-\frac{1}{2}\Delta + V_{ne}(x) + V_H(\rho) + V_{xc}(\rho)\right) u_i = \lambda_i u_i \quad \text{in } \mathbb{R}^3 \tag{4.1}$$

with $\int_{\mathbb{R}^3} |u_i|^2 dx = 1 (i = 1, 2, \ldots, N)$, where the first term $-\frac{1}{2}\Delta u_i$ is the kinetic energy of the system, the second term $V_{ne}(x)$ is the potential of the electron-ion attraction,

$$V_{ne}(x) = -\sum_{q=1}^{N_{atom}} \frac{Z_q}{|x - r_q|},$$

the third term $V_H(\rho)$ is the Hartree approximation of the Coulomb potential of the system

$$V_H(\rho) = \int_{\mathbb{R}^3} \frac{\rho(y)}{|x - y|} dy,$$

the last term $V_{xc}(\rho)$ is the exchange-correlation potential, $\rho(x) = \sum_{i=1}^N |u_i(x)|^2$ is the electron density of the ground state of the system, N_{atom} is the total number of the atoms, Z_q is the electron number of the qth atom, r_q is the position of the qth atom, and N is the number of the electrons. Usually, $V_H(\rho)$ is obtained from solving the Poisson equation:

$$-\Delta V_H(\rho) = 4\pi\rho(x). \tag{4.2}$$

The most important thing for the molecular system, as we see, is the total energy of the ground state:

$$E_{total} = \sum_{i=1}^N \lambda_i - \frac{1}{2}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{\rho(x)\rho(y)dxdy}{|x - y|} + E_{xc}(\rho) - \int_{\mathbb{R}^3} \rho(x)V_{xc}(\rho)dx$$

$$+ \frac{1}{2} \sum_{p,q=1, p\neq q}^{N_{atom}} \frac{Z_p Z_q}{|r_p - r_q|},$$

where $E_{xc}(\rho)$ is the exchange-correlation energy, and $\lambda_i (i = 1, 2, \ldots, N)$ are the eigenvalues of (4.1). Since the Kohn–Sham equations (4.1) are nonlinear eigenvalue systems, we need to linearize and solve them iteratively, which is called the self-consistent approach [7, 19, 27, 32]. In our computations, a Broyden-type quasi-Newton method [34] will be used. The self-consistent iteration is described as follows.

SELF-CONSISTENT ITERATION.

1. Given an initial $\rho_{in}(x)$ by superposing atomic charge densities, obtain $V_{xc}(\rho_{in})$ and $V_H(\rho_{in})$.
2. Compute

$$V^{eff}(\rho_{in}) = V_{ne}(x) + V_H(\rho_{in}) + V_{xc}(\rho_{in})$$

and solve

$$\left(-\frac{1}{2}\Delta + V^{eff}(\rho_{in})\right) u_i = \lambda_i u_i \quad \text{in } \mathbb{R}^3 \tag{4.3}$$

with $\int_{\mathbb{R}^3} |u_i|^2 dx = 1 (i = 1, 2, \ldots, N)$.

3. Set $\rho_{out}(x) = \sum_{i=1}^{N} |u_i(x)|^2$.
4. Obtain $\rho_{in}^{new}(x)$ by "mixing" density with a Broyden-type quasi-Newton approach.
5. If self-consistent, stop; else repeat from step 2.

It is noted that the electron density ρ of the ground state of the system exponentially decays (see, e.g., [2, 14, 33]). Consequently, the central computation in solving the Kohn–Sham equations becomes the repeated solution of the linear eigenvalue problems (4.3) when $\mathbb{R}^3$ is replaced by some bounded domain $\Omega \subset \mathbb{R}^3$. We apply the multiscale finite element discretization schemes designed in section 3 to solve the linear eigenvalue problems (4.3).

4.2. Discretization schemes based on adaptive grids. Because of the singular potentials, we consider applying piecewise linear finite elements to solve (4.3). As we see, it is expensive to solve three-dimensional problems by using uniform grids, while it is much cheaper by using adaptive grids when accurate approximate solutions are required (cf. Tables 4.1–4.7). Thus, in our quantum eigenvalue computations, we will employ adaptive grids instead of uniform grids. The globally coarse grids we will use are some adaptive finite element grids, which are constructed from the bisection approaches [4] and the error indicators

$$\eta_\tau = \eta_{\tau,G} = \|A^{-1/2}(G_h u_h - A\nabla u_h)\|_{0,\tau}^2, \quad \tau \in T^h(\Omega),$$

where

$$A = \begin{pmatrix} 1/2 & 0 & 0 \\ 0 & 1/2 & 0 \\ 0 & 0 & 1/2 \end{pmatrix}$$

and the locally averaging operator $G_h : S_0^h(\Omega) \to S^h(\Omega) \times S^h(\Omega)$ is defined by (see, e.g., [40, 42])

$$G_h v = \sum_{z \in \partial^2 T^h} (A\nabla v)_z \phi_z, \qquad (A\nabla v)_z = \sum_{j=1}^{J_z} \alpha_z^j (A(z)\nabla v)_{\tau_z^j} \quad \forall v \in S_0^h(\Omega)$$

with $\bigcup_{j=1}^{J_z} \tau_z^j = \omega_z$, $\sum_{j=1}^{J_z} \alpha_z^j = 1$, $\omega_z = \bigcup_{z\in\bar{\tau},\tau\in T^h(\Omega)} \tau$, $\alpha_z^j \geq 0$ (for instance, $\alpha_z^j = \frac{1}{J_z}$, $\alpha_z^j = \frac{|\tau_z^j|}{|\omega_z|}$), and J_z is the number of elements containing z (see, e.g., [22]). While in the step of correction, the mesoscopic grid and the fine grid are obtained from the globally coarse grids directly by using some tetrahedral bisection strategy.

Remark 4.1. It should be pointed out that Assumption A.0 rules out most adaptively refined grids. However, the adaptive grids obtained from the bisection approach [4] satisfy Assumption A.0 if the initial grid, on which the bisection approach is posed, is fine enough. Indeed, let $T^{h_0}(\Omega)$ be the initial grid of size $h_0 \in (0,1)$ and $T^h(\Omega)$ be an adaptive grid of size h constructed from the bisection approach. Then there exists a positive integer m such that the finest size of elements in $T^h(\Omega)$ is $\mathcal{O}(h_0/2^m)$. Consequently, Assumption A.0 is satisfied when $\nu \geq 1 - \frac{m\ln 2}{\ln h_0}$.

We will use three types of algorithms to solve (4.3). The first one, which is denoted by Algorithm I, is the algorithm proposed in [39] for linear finite element eigenvalues: solve an eigenvalue problem in the linear finite element space associated with a relatively coarse grid and then find the correction by solving some Poisson boundary value problems over locally refined grids in parallel when there is more than one atom (the union of the subdomains is a partition of the whole domain); or it is the algorithm, which was studied in [38] in a general setting, presented in [20] for linear finite element eigenvalues: solve an eigenvalue problem in the linear finite element space associated with a relatively coarse grid and find the solution of the Poisson boundary value problem over a global refined grid when there is only one atom.

The second one, which is denoted by Algorithm II, is Algorithm A described in section 3: solve an eigenvalue problem in the globally coarse grid space and then find the correction by solving some Poisson boundary value problems over locally refined grids in parallel if there is more than one atom (the union of the subdomains may not be the exact whole domain); or it is Algorithm A0 described in section 3: solve an eigenvalue problem in the globally coarse grid space and then find the correction by solving some Poisson boundary value problem over a locally refined grid when there is only one atom.

The third one, which is denoted by Algorithm III, is Algorithm B described in section 3: solve an eigenvalue problem in the globally coarse grid space, then solve the Poisson boundary value problem in a globally mesoscopic grid, and, finally, find the correction by solving some Poisson boundary value problems in locally fine grids in parallel if there is more than one atom (the union of the subdomains may not be the exact whole domain); or it is Algorithm B0 described in section 3: solve an eigenvalue problem in the globally coarse grid space, then solve the Poisson boundary value problem in a globally mesoscopic grid, and, finally, find the correction by solving some Poisson boundary value problem in a locally fine grid when there is only one atom.

4.3. Numerical examples. In this subsection, we will report our numerical results of the ground state energies of the following typical atoms and molecules: hydrogen atom (H), helium atom (He), hydrogen molecule (H_2), and lithium hydride (LiH). The first two atoms are the simplest ones. While the diatomic hydrogen molecule H_2 is the most common molecule in space and the presence of H_2 also has important consequences regarding the origin of the universe and interpretation of the cosmological redshift [23], the molecule LiH is the simplest stable metallic hydride, and it is increasingly being studied as a potential storage agent for solid-state hydro-

gen storage with recent trials suggesting that it can exhibit the maximum reversible hydrogen capacity ever achieved in metal hydrides [3]. It is also believed that LiH molecules have played a crucial role in the early universe. The numerical examples were carried out on an SGI Origin 3800 in the State Key Laboratory of Scientific and Engineering Computing, Chinese Academy of Sciences.

Example 1. Consider the Kohn–Sham equation for hydrogen atoms:

$$\left(-\frac{1}{2}\Delta - \frac{1}{|x|}\right) u = \lambda u \quad \text{in } \mathbb{R}^3 \tag{4.4}$$

with $\int_{\mathbb{R}^3} |u|^2 dx = 1$. The first eigenvalue of (4.4), i.e., the total energy of the ground state for the hydrogen atom, is $\lambda = -0.5$.

In our computation for the total energy of the ground state, we solve the following eigenvalue problem by using one processor: find $(\lambda, u) \in H_0^1(\Omega) \times \mathbb{R}$ such that $\int_\Omega |u|^2 dx = 1$ and

$$\begin{cases} \left(-\frac{1}{2}\Delta - \frac{1}{|x|}\right) u = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{4.5}$$

where $\Omega = (-6.4, 6.4)^3$. We choose $\Omega_0 = (-3.2, 3.2)^3$.

The numerical results obtained from the uniform grids are presented in Tables 4.1–4.3, while the numerical results obtained from the adaptive grids are presented in Tables 4.5–4.7. And the numerical results obtained from the standard discretization scheme on adaptive grids are reported in Table 4.4. Here and hereafter, we will use the following notation in our tables:

N_c : the number of degrees of freedom for solving the eigenvalue problem without any correction.

N_f: the total number of degrees of freedom for solving the boundary value problems for corrections.

λ_c: the numerical eigenvalue without any correction.

λ^h (or $\lambda^{k,h}$): the eigenvalue approximation obtained from the Rayleigh quotient.

* *We are not able to carry out the computation on the fine grid correction on our SGI O*3800 *because the number of degrees of freedom is too large. The CPU time is that of getting the numerical solution on the coarse grid.*

It is shown by Tables 4.1–4.3 that, on uniform grids, Algorithms III and II are more efficient than Algorithm I, and the approximation accuracy of Algorithm III is better than that of Algorithm II, which coincide with the theory obtained in section 3. However, it is seen from comparing Tables 4.1–4.3 with Tables 4.5–4.7, respectively, that it is much cheaper to use adaptive grids than to use uniform grids to get numerical

approximations. As a result, it is sufficient to show and discuss the numerical results for other examples on adaptive grids only.

Next we turn to discussing the numerical results obtained by our schemes on adaptive grids. First, it is seen from Tables 4.4–4.7 that our correction procedures are efficient. Second, it is observed from Tables 4.5 and 4.6 that when the scale of the coarse grids is the same, the time cost of Algorithm II is much less than that of Algorithm I, while the accuracy of Algorithm II is a little less than that of Algorithm I.

12343	−4.938080e-01	1.238395e-02	652885	−4.989565e-01	2.087074e-03	8.119487e+02

It should be noted that instead of a global boundary value problem, a local boundary value problem is solved in the step of correction; hence many more large-scale problems can be solved by Algorithm II than by Algorithm I. Third, thanks to Algorithm III, in which an additional correction is carried out over a global mesoscopic grid, the approximation accuracy can be improved. Different from Algorithm I, in Algorithm III, two small-scale boundary value problems, instead of a large-scale boundary value problem, are solved. As a result, for instance, it is seen from Tables 4.5 and 4.7 that the CPU times using Algorithm III are less than those of Algorithm I while keeping the same approximation accuracy. Consequently, Algorithm III is the first choice among the three algorithms taking into account both the computational complexity and the accuracy.

Example 2. Consider the Kohn–Sham equation for helium atoms:

$$\left(-\frac{1}{2}\Delta - \frac{2}{|x|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right) u = \lambda u \quad \text{in } \mathbb{R}^3 \tag{4.6}$$

with $\int_{\mathbb{R}^3} |u|^2 = 1$, where $\rho = 2|u|$. In our computation for the total energy of the ground state, we solve the following nonlinear eigenvalue problem by using one processor: find $(\lambda, u) \in H_0^1(\Omega) \times \mathbb{R}$ such that $\int_\Omega |u|^2 dx = 1$ and

$$\begin{cases} \left(-\frac{1}{2}\Delta - \frac{2}{|x|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right) u = \lambda u \text{ in } \Omega, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad u = 0 \quad \text{on } \partial\Omega, \end{cases} \tag{4.7}$$

where $\Omega = (-10.0, 10.0)^3$. In computation, we choose $V_{xc}(\rho) = -\frac{3}{2}\alpha(\frac{3}{\pi}\rho)^{\frac{1}{3}}$, where $\alpha = 0.77298$. The local computation subdomain $\Omega_0 = (-5.0, 5.0)^3$.

The relevant numerical results in the literature are provided in Table 4.8. The exact total energy of the ground state may be viewed as -2.90 (cf. [9, 31]). Our numerical results are reported in Tables 4.9–4.11. It is shown that our results are good enough, and Algorithms II and III are better than Algorithm I taking into account both the computational complexity and the accuracy.

Because there is only one singular point in Examples 1 and 2, we use only one processor to solve them, which results in the advantage of Algorithms II and III not being very apparent. In the following two examples, however, because there are two isolated singularity points, we solve them by using two processors in parallel: first, we solve an eigenvalue problem in a globally coarse grid (and a boundary value problem in a globally refined grid); then we solve two boundary value problems in locally refined grids in parallel. It is seen that the time cost of Algorithms II and III is much less than that of Algorithm I, while the corresponding accuracy is comparable with

that of Algorithm I. Taking into account both the computational complexity and the accuracy, Algorithms II and III are better than Algorithm I. And Algorithm III is recommended if more accurate approximations are required.

Example 3. Consider the Kohn–Sham equation of diatomic hydrogen molecules:

$$\left(-\frac{1}{2}\Delta - \frac{1}{|x-r_1|} - \frac{1}{|x-r_2|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right)u = \lambda u \ \text{ in } \mathbb{R}^3 \tag{4.8}$$

with $\int_{\mathbb{R}^3} |u|^2 = 1$, where $\rho = 2|u|$, $r_j (j = 1, 2)$ are the positions of the two hydrogen atoms. Here we choose $r_1 = (-0.70, 0, 0), r_2 = (0.70, 0, 0)$. In our computation for the total energy of the ground state, we use two processors to solve the following nonlinear eigenvalue problem: find $(\lambda, u) \in H_0^1(\Omega) \times \mathbb{R}$ such that $\int_\Omega |u|^2 dx = 1$ and

$$\begin{cases} \left(-\frac{1}{2}\Delta - \frac{1}{|x-r_1|} - \frac{1}{|x-r_2|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right)u = \lambda u \ \text{ in } \Omega, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad u = 0 \ \text{ on } \partial\Omega, \end{cases} \tag{4.9}$$

where $\Omega = (-10.0, 10.0)^3$. Here we choose V_{xc} as follows (see [27]):

$$V_{xc}(\rho) = \begin{cases} \frac{\kappa}{1+\beta_1\sqrt{r_s}+\beta_2 r_s}\frac{1+\frac{7}{6}\beta_1\sqrt{r_s}+\frac{4}{3}\beta_2 r_s}{1+\beta_1\sqrt{r_s}+\beta_2 r_s} - (\frac{9}{4\pi^2})^{\frac{1}{3}}\frac{1}{r_s} & \text{if } r_s \geq 1, \\ \xi\ln(r_s) + \zeta - \frac{1}{3}\xi + \frac{2}{3}\eta r_s \ln(r_s) + \frac{1}{3}(2\mu - \eta)r_s - (\frac{9}{4\pi^2})^{\frac{1}{3}}\frac{1}{r_s} & \text{if } r_s < 1, \end{cases}$$

where $r_s = (\frac{3}{4\pi\rho})^{\frac{1}{3}}$, $\kappa = -0.1423$, $\beta_1 = 1.0529$, $\beta_2 = 0.3334$, $\xi = 0.0311$, $\zeta = -0.048$, $\eta = 0.0020$, and $\mu = -0.0116$. The local subdomains in Algorithms II and III are $\Omega_1 = (-5.0, 0) \times (-5.0, 5.0)^2$ and $\Omega_2 = (0, 5.0) \times (-5.0, 5.0)^2$.

The experimental value for the ground state energy and the equilibrium bond distance of H_2 are −1.1746 a.u. and 1.40 a.u., respectively [17]. Some numerical results in literature [13] are listed in Table 4.12. Our numerical results are reported in Tables 4.13–4.15. Compared with that of [13], our results are good enough, too.

Example 4. Consider the Kohn–Sham equations for LiH molecules:

$$\left(-\frac{1}{2}\Delta - \frac{3}{|x-r_1|} - \frac{1}{|x-r_2|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right)u_i = \lambda_i u_i \ \text{ in } \mathbb{R}^3 \tag{4.10}$$

with $\int_{\mathbb{R}^3} |u_i|^2 = 1 (i = 1, 2)$, where $\rho = 2(|u_1|^2 + |u_2|^2)$, $r_j (j = 1, 2)$ are the positions of the lithium atom and the hydrogen atom, respectively. Here we choose $r_1 = (-1.0075, 0, 0)$ and $r_2 = (2.0075, 0, 0)$.

In our computation for the total energy of the ground state, we use two processors to solve the following nonlinear eigenvalue problem: find $(\lambda_i, u_i) \in H_0^1(\Omega)\times\mathbb{R}(i = 1, 2)$

such that $\int_\Omega |u_i|^2 dx = 1$ and

$$\text{(4.11)}\quad \begin{cases} \left(-\frac{1}{2}\Delta - \frac{3}{|x-r_1|} - \frac{1}{|x-r_2|} + \int \frac{\rho(y)}{|x-y|}dy + V_{xc}\right) u_i = \lambda_i u_i \ \text{ in } \Omega, \\ u_i = 0 \ \text{ on } \partial\Omega, \end{cases}$$

where $\Omega = (-40.0, 40.0)^3$. In computation, we choose V_{xc} as that of Example 3 and the local subdomains in Algorithms II and III to be $\Omega_1 = (-20.0, 0) \times (-20.0, 20.0)^2$ and $\Omega_2 = (0, 20.0) \times (-20.0, 20.0)^2$.

For a fixed LiH bondlength 3.015 a.u., the experimental value of the ground state energy of LiH is -8.0705 a.u. and one numerical result in literature is -7.9891 a.u. [3]. Some other numerical results of LiH can also be found in [18], in which the energy of the ground state of LiH is -7.987352237 a.u. Our numerical results are reported in Tables 4.16–4.18. It is seen that our results are more agreeable with the experimental value than those of [3] and [18].

5. Concluding remarks. In this paper, we have proposed some three-scale finite element discretization schemes for a class of elliptic eigenvalue problems and especially applied these new schemes to several typical electronic structure computations successfully. We believe that these kinds of computational approaches are powerful techniques in obtaining accurate and efficient approximations for large-scale eigenvalue problems. Indeed, to apply these approaches to complex quantum chemistry computations is our ongoing project. For such applications to complex quantum chemistry computations, however, there are many practical issues, including the implementation details for local density approximations and pseudopotentials, that need to be addressed. We will present our progresses in our forthcoming papers.

Acknowledgments. The authors would like to thank the referees for their valuable comments and suggestions that have improved the presentation of this paper and Prof. X. Gong, Dr. L. Shen, and Mr. D. Zhang for stimulating discussions and fruitful cooperation on electronic structure computations that have motivated the topic in this paper.

LIE SYMMETRY PRESERVATION AND SHOCK-CAPTURING METHODS*

ZHENG RAN†

Abstract. It is known that some traditional shock-capturing schemes, including Godunov- or Roe-type schemes, generate downstream oscillatory wave patterns that cannot be effectively dampened by the dissipation methods they provide. The theme of this paper is to understand the formation and behavior at these upstream/downstream patterns from the point view of the symmetry inherent in the PDE. This paper investigates symmetry breaking and spatial oscillations in finite difference solutions for the inviscid Burgers and one-dimensional Navier–Stokes shock equations using the Lax–Wendroff, TVD, and nonoscillatory, nonfree parameter dissipative schemes. Symmetry breaking is considered as a candidate for the inherent cause of the nonphysical oscillations in the vicinity of the shock.

Key words. difference scheme, symmetry, shock-capturing method

1. Introduction.

The past four decades have seen tremendous progress in the development of numerical methods for solving the equations governing the unsteady flow of an inviscid, adiabatic ideal gas, that is, the Euler equations [1, 2, 3, 4, 5]. The goal of shock-capturing methods is to capture discontinuities in solutions to these equations automatically, without explicitly tracking them. Discontinuities must then be smeared over one or more grid cells. Success requires that the method implicitly incorporates the correct jump conditions, reduces smearing to a minimum, and does not introduce nonphysical oscillations near the discontinuities. High-resolution finite difference/volume methods based on Riemann solutions often perform well and are simple to implement. There are several circumstances where even first order schemes (such as the Godunov method and the Roe scheme) may produce inferior results [6]. One known example is the computation of slow-moving shocks. Several references have reported the difficulty of computing slow-moving shocks, where first order Godunov- or Roe-type methods produce spurious long wave oscillations behind the shock [7, 8, 9]. These eventually ruin the downstream solution. A full understanding of the nature of this kind of numerical phenomenon is still lacking. Regardless of definition, spurious oscillations and overshoots are the most common symptoms of numerical instability. In one natural interpretation, these numerical phenomena are due to nonlinear stability. Linear stability theory has a strong history, dating back to the late 1940s, but the study of nonlinear stability is far newer. Starting with papers by Boris and Book [10] and van Leer [11], nonlinear stability theory has developed over roughly the past thirty years. Perhaps the best known nonlinear stability condition is the total variation diminishing (TVD) condition, suggested by Harten in 1983 [2]. A review of this can be found in [12]. This paper addresses the interesting problem of nonlinear instability from a new point of view. Before moving on, it should be noted that the Euler equations and most scalar conservation laws are highly nonlinear.

Numerical approximations for these should contain at least as much nonlinearity as the governing equations. Most modern numerical methods add their own nonlinearity, making them highly nonlinear even for linear governing equations. Unfortunately, in general, there are still many unresolved issues in nonlinear stability theory. There are two primary drawbacks in the existing theoretical development: heuristics and one-dimensional analysis. Indeed, both of these reflect the difficulties presented by high nonlinearity. It is hoped that Lie symmetry analysis can be used to throw some light on this subject.

Symmetry has always played an important role in mechanics, from the fundamental formulation of basic principles to concrete application [13, 14, 15]. Applications of symmetry groups to numerical analysis are given extensive treatment by Shokin [16] and Dorodnistyn [17]. For gas dynamics, the noninvariance relative to Galileo transformation of a difference scheme which approximates the equations results in nonphysical fluctuations, which was remarked in the 1960s (Harlow 1964).[1] In 1970 Yanenko and Shokin [18] developed a method of differential approximations for the study of the group properties of difference schemes for hyperbolic systems of equations. They used the first differential approximation to perform a group analysis. The study of symmetry in difference equations is a much more recent phenomenon than for differential equations. Early work in this direction performed by Maeda [19] concentrates on transformations acting only on dependent variables. A more recent series of papers was devoted to the Lie point symmetries of differential difference equations on fixed regular lattices [20]. A different approach was developed mainly for linear or linearizable difference equations and involved transformations acting on more than one point of the lattice [21, 22]. The symmetries considered in this approach are really generalized; however, they reduce to point symmetries at the continuous limit. A more general class of generalized symmetries has also been investigated for difference equations, and differential-difference equations on fixed regular lattices [23, 24]. A further approach to investigating symmetries in discrete equations was originally suggested by Dorodnitsyn and collaborators [25, 26]. The main aim of this series of papers is to make differential equations discrete while preserving their Lie point symmetries. Symmetries of ordinary and partial difference schemes on lattices that are a prior given, but are allowed to transform under point transformations, were studied in [27, 28, 29]. In a series of lectures, presented at the CIMPA Winter School on Discrete Integrability Systems in February 2003, Winternitz [30] gave a useful review of the application of Lie point symmetries, and their generalizations, to the study of difference equations. The overall theme could be called "continuous symmetries of discrete equations."

Three important questions on numerical analysis, especially important for shock-capturing methods are discussed from the point of view of group theory below. They are

(1) the group classification of the Lax–Wendroff scheme,

(2) symmetry and Harten's entropy enforcement condition,

(3) the role of symmetry in various aspects of a proper manipulation of the coefficients of the third order derivative ν_3 in the nonoscillatory, nonfree parameter dissipative (NND) scheme.

The structure of this paper is as follows. First, the theory of symmetries of differential equations is very briefly discussed, by way of a theoretical introduction in section 2. The group classification of the nonlinear wave equations is discussed in section 3. The following three sections are devoted to a complete development of

[1] Thanks to the referee's information.

the Lie symmetry analysis method proposed here and its application to three special cases of interest. The final section contains concluding remarks.

2. Mathematical preliminaries. All of the problems addressed here can be described by a general system of nonlinear differential equations of the nth order

$$\Delta_\nu \left(x, u^{(n)}\right) = 0, \tag{2.1}$$

where $\nu = 1, \ldots, l$, and $x = \left(x^1, \ldots, x^p\right) \in X$ are independent variables, $u = \left(u^1, \ldots, u^q\right) \in U$ are dependent variables, and $\Delta_\nu(x, u^{(n)}) = (\Delta_1(x, u^{(n)}), \ldots, \Delta_l(x, u^{(n)}))$ is a smoothing function that depends on x, u, and derivatives of u up to order n with respect to $x^1, \ldots, x^p$. If we define a jet space $X \times U^{(n)}$ as a space whose coordinates are independent variables, dependent variables, and derivatives of dependent variables up to order n, then Δ is a smoothing mapping

$$\Delta : X \times U^{(n)} \to R^l. \tag{2.2}$$

Before studying the symmetries of difference schemes, let us very briefly review the theory of symmetries for differential equations. For all details, proofs, and further information we refer to the many excellent books on the subject, e.g., [13, 14, 15]. Here we follow the style of [13], but the Lie symmetry description is made concise by emphasizing the significant points and results. In order to provide the reader with a relatively quick and painless introduction to Lie symmetry theory, some important concepts must be introduced.

The main tool used in Lie group theory and working with transformation groups is "infinitesimal transformation." In order to present this, we need first to develop the concept of a vector field on a manifold. We begin with a discussion of tangent vectors. Suppose C is a smooth curve on a manifold M, parameterized by

$$\phi : I \to M, \tag{2.3}$$

where I is a subinterval of R. In local coordinates $x = \left(x^1, \ldots, x^p\right)$, C is given by p smoothing functions

$$\phi(\varepsilon) = \left(\phi^1(\varepsilon), \ldots, \phi^p(\varepsilon)\right) \tag{2.4}$$

of the real variable ε. At each point $x = \phi(\varepsilon)$ of C the curve has a tangent vector, namely, the derivative

$$\dot{\phi} = \frac{d\phi}{d\varepsilon} = \left(\frac{d\phi^1}{d\varepsilon}, \ldots, \frac{d\phi^p}{d\varepsilon}\right). \tag{2.5}$$

In order to distinguish between tangent vectors and local coordinate expressions for a point on the manifold, we adopt the notation

$$V = \frac{d\phi}{d\varepsilon} = \frac{d\phi^1}{d\varepsilon} \cdot \frac{\partial}{\partial x^1} + \cdots + \frac{d\phi^p}{d\varepsilon} \cdot \frac{\partial}{\partial x^p} \tag{2.6}$$

for the vector tangential to C at $x = \phi(\varepsilon)$. The collection of all tangent vectors to all possible curves passing through a given point x in M is called the tangent space to M at x and is denoted by TM. A vector field V on M assigns a tangent vector $V \in TM$ to each point $x \in M$, with V varying smoothly from point to point. In local coordinates, a vector field has the form

$$V = \xi^1(x) \cdot \frac{\partial}{\partial x^1} + \cdots + \xi^p(x) \cdot \frac{\partial}{\partial x^p}, \tag{2.7}$$

where each $\xi^i(x)$ is a smoothing function of x.

If V is a vector field, we denote the parameterized maximal integral curve passing through x in M by $\Psi(\varepsilon, x)$ and call Ψ the flow generated by V. Thus for each x in M, and ε in some interval I_x containing 0, $\Psi(\varepsilon, x)$ is a point on the integral curve passing through x in M. The flow of a vector field has the basic properties

$$\Psi(\delta, \Psi(\varepsilon, x)) = \Psi(\delta + \varepsilon, x) \tag{2.8}$$

for all $\delta, \varepsilon \in R$ such that both sides of equation are defined:

$$\Psi(0, x) = x, \tag{2.9}$$

and

$$\frac{d}{d\varepsilon}\Psi(\varepsilon, x) = V \tag{2.10}$$

for all ε where defined. We see that the flow generated by a vector field is the same as a local group action of the Lie group on the manifold M, often called a "one-parameter group of transformations." The vector field V is called the infinitesimal generator of the action since, by Taylor's theorem, in local coordinates

$$\Psi(\varepsilon, x) = x + \varepsilon\xi(x) + O\left(\varepsilon^2\right), \tag{2.11}$$

where $\xi = \left(\xi^1, \ldots, \xi^p\right)$ are the coefficients of V. The orbits of the one-parameter group action are the maximal integral curves of the vector field V.

Definition 1. *A symmetry group of* (2.1) *is a one-parameter group of transformations G, acting on $X \times U$, such that if $u = f(x)$ is an arbitrary solution of* (2.1) *and $g_\varepsilon \in G$, then $g_\varepsilon \cdot f(x)$ is also a solution of* (2.1).

The infinitesimal generator of a symmetry group is called an infinitesimal symmetry. Infinitesimal generators are used to formulate the conditions for a group G to make it a symmetry group. Working with infinitesimal generators is simple. First we define a prolongation of a vector field. The symmetry group of a system of differential equations is the largest local group of transformations acting on the independent and dependent variables of the system such that it can transform one system solution to another. The main goal of Lie symmetry theory is to determine a useful, systematic, computational method that explicitly determines the symmetry group of any given system of differential equations. The search for the symmetry algebra L of a system of differential equations is best formulated in terms of vector fields acting on the space $X \times U$ of independent and dependent variables. The vector field tells us how the variables x, u transform. We also need to know how the derivatives, that is, $u_x, u_{xx}, \ldots$, transform. This is given by the prolongation of the vector field V. Combining these, we have [13, p. 110, Theorem 2.36] the following.

Theorem 1. *Let*

$$V = \sum_{i=1}^{p} \xi^i(x, u)\,\partial_{x^i} + \sum_{a=1}^{q} \eta_a(x, u)\,\partial_{u^a}$$

be a vector defined on an open subset $M \subset X \times U$. The nth prolongation of the original vector field is the vector field:

$$pr^{(n)}V = V + \sum_{a=1}^{q} \sum_{J}^{\eta_a^J} \left(x, u^{(n)}\right) \frac{\partial}{\partial u_J^a}$$

defined on the corresponding jet space $M^{(n)} \subset X \times U^{(n)}$. *The second summation here is over all (unordered) multiindices* $J = (j_1, j_2, \ldots, j_k)$, *with* $1 \leq j_k \leq p$, $1 \leq k \leq n$. *The coefficient functions* ϕ_a^J *of* $pr^{(n)}V$ *are given by the following formula:*

$$\eta_a^J \left(x, u^{(n)}\right) = D_J \left(\eta_a - \sum_{i=1}^{p} \xi^i u_i^a\right) + \sum_{i=1}^{p} \xi^i u_{J,i}^a,$$

where $u_i^a = \frac{\partial u^a}{\partial x^i}$, $u_{J,i}^a = \frac{\partial u_J^a}{\partial x^i}$, *and* D_J *is the total derivative of* η *with respect to* x^j.

In the following analysis, we deal only with one-dimensional scalar differential equations that are assumed to be differentiable up to the necessary order.

Consider the special case where $p = 2, q = 1$ in the prolongation formula, so that we are looking at a partial differential equation involving the function $u = f(x,t)$. A general vector field on $X \times U \cong R^2 \times R$ then takes the form [13, p. 114]:

$$V = \xi(x,t,u)\frac{\partial}{\partial x} + \tau(x,t,u)\frac{\partial}{\partial t} + \eta(x,t,u)\frac{\partial}{\partial u}. \tag{2.12}$$

The first prolongation of V is the vector field:

$$pr^{(1)}V = V + [\eta_x]\frac{\partial}{\partial u_x} + [\eta_t]\frac{\partial}{\partial u_t}, \tag{2.13}$$

where

$$[\eta_x] = \eta_x + (\eta_u - \xi_x)u_x - \tau_x u_t - \xi_u u_x^2 - \tau_u u_x u_t$$

and

$$[\eta_t] = \eta_t + (\eta_u - \tau_t)u_t - \xi_t u_x - \tau_u u_t^2 - \xi_u u_x u_t.$$

The subscripts on η, ξ, τ denote partial derivatives. Similarly,

$$pr^{(2)}V = pr^{(1)}V + [\eta_{xx}]\frac{\partial}{\partial u_{xx}} + [\eta_{xt}]\frac{\partial}{\partial u_{xt}} + [\eta_{tt}]\frac{\partial}{\partial u_{tt}}, \tag{2.14}$$

where

$$\begin{aligned}
&[\eta_{xx}] = \eta_{xx} + (2\eta_{xu} - \xi_{xx})u_x - \tau_{xx}u_t + (\eta_{uu} - 2\xi_{xu})u_x^2 - 2\tau_{xu}u_x u_t - \xi_{uu}u_x^3 \\
&-\tau_{uu}u_x^2 u_t + (\eta_u - 2\xi_x)u_{xx} - 2\tau_x u_{xt} - 3\xi_u u_{xx}u_x - \tau_u u_{xx}u_t - 2\tau_u u_{xt}u_t, \\
&[\eta_{xt}] = \eta_{xt} + (\eta_{xu} - \tau_{tx})u_t + (\eta_{tu} - \xi_{tx})u_x - \tau_{xu}u_t^2 + (\eta_{uu} - \xi_{xu} - \tau_{ut})u_x u_t \\
&-\xi_{tu}u_x^2 - \tau_{uu}u_x u_t^2 - \xi_{uu}u_t u_x^2 - \tau_x u_{tt} + (\eta_u - \xi_x - \tau_t)u_{xt} - \xi_t u_{xx} - 2\tau_u u_t u_{xt} \\
&-2\xi_u u_x u_{xt} - \tau_u u_x u_{tt} - \xi_u u_t u_{xx}, \\
&[\eta_{tt}] = \eta_{tt} + (2\eta_{tu} - \tau_{tt})u_t - \xi_{tt}u_x + (\eta_{uu} - 2\tau_{tu})u_t^2 - 2\xi_{tu}u_x u_t - \tau_{uu}u_x^3 \\
&-\tau_{uu}u_t^2 u_x + (\eta_u - 2\tau_t)u_{tt} - 2\xi_t u_{xt} - 3\tau_u u_{tt}u_t - \xi_u u_{tt}u_x - 2\xi_u u_{xt}u_t.
\end{aligned}$$

From here on the analysis of difference equations concerns only modified equations from the third prolongation of the vector field. From work in computational fluid dynamics, we know that the right-hand side of the modified equation is written entirely in terms of x derivatives. So investigation can be limited to the terms of the spatial derivatives in the following analysis. The coefficients of the various monomials in the third order partial derivatives of u are given in the following:

$$pr^{(3)}V = pr^{(2)}V + [\eta_{xxx}]\frac{\partial}{\partial u_{xxx}} + [\eta_{xxt}]\frac{\partial}{\partial u_{xxt}} + [\eta_{xtt}]\frac{\partial}{\partial u_{xtt}} + [\eta_{ttt}]\frac{\partial}{\partial u_{ttt}}, \tag{2.15}$$

where

$$
\begin{aligned}
[\eta_{xxx}] &= \eta_{xxx} + (3\eta_{xxu} - \xi_{xxx})u_x - \tau_{xxx}u_t + 3(\eta_{xuu} - \xi_{xxu})u_x^2 - 3\tau_{xxu}u_xu_t \\
&+(\eta_{uuu} - 3\xi_{xuu})(u_x)^3 + 3(\eta_{xu} - \xi_{xx})u_{xx} - 3\tau_{xx}u_{xt} - 3\tau_{xuu}(u_x)^2u_t \\
&+3(\eta_{uu} - 3\xi_{xu})u_xu_{xx} - 3\tau_{xu}u_tu_{xx} - 6\tau_{xu}u_{xt}u_x - 3\tau_xu_{xxt} + (\eta_u - 3\xi_x)u_{xxx} \\
&-\xi_{xxx}(u_x)^4 - 6\xi_{uu}(u_x)^2u_{xx} - 3\tau_{uu}(u_x)^2u_{xt} - \tau_{uuu}(u_x)^3u_t - 3\xi_u(u_{xx})^2 \\
&-3\tau_uu_{xxt}u_x - 3\tau_uu_{xt}u_{xx} - 3\tau_{uu}u_{xx}u_xu_t - 4\xi_uu_{xxx}u_x - \tau_uu_{xxx}u_t.
\end{aligned}
$$

Suppose we are given an nth order system of differential equations or, equivalently, a subvariety of the jet space $M^{(n)} \subset X \times U^{(n)}$. A symmetry group of this system is a local transformation G acting on $M \subset X \times U$ which transforms solutions of the system to other solutions. We can reduce the important infinitesimals condition for a group G to be a symmetry group of a given system of differential equations. The following theorem [13, p. 104, Theorem 2.31] provides the infinitesimal conditions for a group G to be a symmetry group.

THEOREM 2. *Suppose*

$$\Delta_\nu\left(x, u^{(n)}\right) = 0, \quad \nu = 1, 2, \ldots, l,$$

is a system of differential equations of maximal rank defined over $M \subset X \times U$. If G is a local group of transformations acting on M, and

$$pr^{(n)}V \circ \left[\Delta_\nu\left(x, u^{(n)}\right)\right] = 0, \quad \nu = 1, 2, \ldots, l,$$

whenever

$$\Delta_\nu\left(x, u^{(n)}\right) = 0,$$

for every infinitesimal generator V of G, then G is a symmetry group of the system.

In the following sections, this theorem is used to deduce explicitly different infinitesimal conditions for specific problems. It must be remembered, however, that, in all cases, though only the scalar differential problem is being discussed, Δ_ν is still used to denote different differential equations.

3. The group classification of the nonlinear wave equations. The main prototype equation here is the inviscid Burgers equation. Its mathematical properties are very clear, and its group classification can be obtained from previous work. In 1981 Ames, Lohner, and Adams [34] (also see [14, p. 194]) considered the nonlinear wave equation:

$$u_{tt} = \left(c^2(u)\,u_x\right)_x, \tag{3.1}$$

where $c(u) \neq \text{const}$. Viewing this in terms of infinitesimal generators reveals that the group classification of (3.1) is

a. $c(u)$ arbitrary:

$$V_1 = \partial_x, \tag{3.2}$$

$$V_2 = \partial_t, \tag{3.3}$$

$$V_3 = x\partial_x + t\partial_t. \tag{3.4}$$

b. $c(u) = A(u+B)^C$, where A, B, C are arbitrary constants:

$$V_1, V_2, V_3, \tag{3.5}$$

$$V_4 = Cx\partial_x + (u+B)\partial_u. \tag{3.6}$$

c. $c(u) = A(u+B)^{-2}$, where A, B are arbitrary constants:

$$V_1, V_2, V_3, V_4(C=-2), \tag{3.7}$$

$$V_5 = t^2\partial_t + t(u+B)\partial_u. \tag{3.8}$$

d. $c(u) = A(u+B)^{-\frac{2}{3}}$, where A, B are arbitrary constants:

$$V_1, V_2, V_3, V_4\left(C=-\frac{2}{3}\right), \tag{3.9}$$

$$V_5 = x^2\partial_x - 3x(u+B)\partial_u. \tag{3.10}$$

For the inviscid Burgers equation:

$$u_t + uu_x = 0. \tag{3.11}$$

This equation can be rewritten as:

$$u_{tt} = \left(u^2 u_x\right)_x. \tag{3.12}$$

The corresponding wave velocity is then:

$$c(u) = u, \tag{3.13}$$

with the corresponding classification coefficients:

$$A = 1, \tag{3.14}$$

$$B = 0, \tag{3.15}$$

$$C = 1. \tag{3.16}$$

This indicates that there are four spans in the infinitesimal symmetry group of nonlinear wave equation vector fields:

$$V_1 = \partial_x, \tag{3.17}$$

$$V_2 = \partial_t, \tag{3.18}$$

$$V_3 = x\partial_x + t\partial_t, \tag{3.19}$$

$$V_4 = x\partial_x + u\partial_u. \tag{3.20}$$

The prolongation formula up to the third order can then be listed as follows:

$$pr^{(2)}V_1 = \partial_x, \tag{3.21}$$

$$pr^{(2)}V_2 = \partial_t, \tag{3.22}$$

$$pr^{(2)}V_3 = x\partial_x + t\partial_t - u_x\partial_{u_x} - u_t\partial_{u_t} - 2u_{xx}\partial_{u_{xx}} - 2u_{xt}\partial_{u_{xt}} - 2u_{tt}\partial_{u_{tt}}, \tag{3.23}$$

$$pr^{(2)}V_4 = x\partial_x + u\partial_u + u_t\partial_{u_t} - u_{xx}\partial_{u_{xx}} + u_{tt}\partial_{u_{tt}}, \tag{3.24}$$

$$pr^{(3)}V_3 = pr^{(2)}V_3 - 3u_{xxx}\partial_{u_{xxx}}, \tag{3.25}$$

$$pr^{(3)}V_4 = x\partial_x + u\partial_u + u_t\partial_{u_t} - u_{xx}\partial_{u_{xx}} + u_{tt}\partial_{u_{tt}}. \tag{3.26}$$

4. The group classification of the Lax–Wendroff scheme.

4.1. The Lax–Wendroff scheme. In this paper a rigorous systematic approach for the group classification of the Lax–Wendroff scheme is developed. To achieve this the difference approximations to the scalar conservation law

$$u_t + f(u)_x = 0 \tag{4.1}$$

require study. The equation in (4.1) is the simplest one-dimensional nonlinear model exhibiting behavior typical of the equations of inviscid fluid dynamics. The Lax–Wendroff difference approximation to (4.1) is defined by

$$\frac{u_j^{n+1} - u_j^n}{\Delta t} + \frac{f(u_{j+1}^n) - f(u_{j-1}^n)}{2\Delta x} = \frac{1}{2}\Delta t \frac{a_{j+\frac{1}{2}}^2(u_{j+1}^n - u_j^n) - a_{j-\frac{1}{2}}^2(u_j^n - u_{j-1}^n)}{\Delta x^2}, \tag{4.2}$$

where

$$\begin{aligned} u_j^n &= u\left(n\Delta t, j\Delta x\right), \\ a(u) &= \frac{\partial f\left(u\right)}{\partial u}, \\ a_{j+\frac{1}{2}} &= a\left(u_{j+\frac{1}{2}}^n\right), \\ u_{j+\frac{1}{2}}^n &= \frac{1}{2}(u_{j+1}^n + u_j^n). \end{aligned}$$

It is well known that the Lax–Wendroff scheme was designed to have the following desirable computational features [31, 32]: conservation of form; to have a three-point scheme; second order accuracy on smooth solutions. Numerical spikes and downstream oscillations are generated in the vicinity of the shock.

4.2. The modified differential equation of Lax–Wendroff scheme. Majda and Osher [32, eq. 1.5] have produced the modification equation:

$$\begin{aligned} u_t = -(f(u))_x + \frac{h^2}{6}\big[&-(f(u))_{xxx} + \lambda^2([a'(u)((f(u))_x)^2]_x \\ &+[a(u)[a(u)(f(u))_x]_x]_x)\big]. \end{aligned} \tag{4.3}$$

Some remarks are essential here:

1. The modified equation retains the conservation law form.

2. Even though the modified equation has been derived by assuming that the exact solution of (4.1) is smooth, numerical evidence indicates that, for shock solutions of (4.1), solution of the difference equation in (4.2) more closely mimics the solution of a modified equation in (4.3) than solutions of the original equation in (4.1).

Setting $f(u) = \frac{1}{2}u^2$, and performing some mechanical calculations, we arrive at the model differential equation for the Lax–Wendroff scheme [32, eq. 1.7]

$$\Delta_1 = u_t + uu_x + RHS = 0, \tag{4.4}$$

where

$$RHS = -h^2\left[\frac{u}{6}(\lambda^2u^2-1)u_{xxx} + \lambda^2uu_x^3 + \frac{1}{4}(3\lambda^2u^2-1)(2u_xu_{xx})\right],$$

$$h = \Delta x, \quad \lambda = \frac{\Delta t}{\Delta x}.$$

4.3. Group invariants of the Lax–Wendroff scheme. Before beginning the group analysis, some detailed but mechanical calculations must be performed:

$$d_1 = \partial_x \circ \Delta_1 = 0, \tag{4.5}$$

$$d_2 = \partial_t \circ \Delta_1 = 0, \tag{4.6}$$

$$d_3 = \partial_u \circ \Delta_1 = u_x - h^2\left[\frac{1}{6}\left(3\lambda^2u^2-1\right)u_{xxx} + \lambda^2u_x^3 + 3\lambda^2uu_xu_{xx}\right], \tag{4.7}$$

$$d_4 = \partial_{u_x} \circ \Delta_1 = u - h^2\left[3\lambda^2uu_x^2 + \frac{1}{2}\left(3\lambda^2u^2-1\right)u_{xx}\right], \tag{4.8}$$

$$d_5 = \partial_{u_t} \circ \Delta_1 = 1, \tag{4.9}$$

$$d_6 = \partial_{u_{xx}} \circ \Delta_1 = -h^2\left[\frac{1}{2}\left(3\lambda^2u^2-1\right)u_x\right], \tag{4.10}$$

$$d_7 = \partial_{u_{xt}} \circ \Delta_1 = 0, \tag{4.11}$$

$$d_8 = \partial_{u_{tt}} \circ \Delta_1 = 0, \tag{4.12}$$

$$d_9 = \partial_{u_{xxx}} \circ \Delta_1 = -h^2\left[\frac{1}{6}\left(\lambda^2u^3-u\right)\right]. \tag{4.13}$$

According to Theorem 2, the system of equations admits a space of operators with the basis V_3 (3.19) if and only if the following equations are satisfied:

$$\Delta_1 = 0, \tag{4.14}$$

$$pr^{(3)}V_3 \circ \Delta_1 = 0, \tag{4.15}$$

From (4.15), we have

$$-u_xd_4 - u_td_5 - 2u_{xx}d_6 - 3u_{xxx}d_9 = 0. \tag{4.16}$$

Expressing the functions $d_l, l = 1, \ldots, 9$, leads to a system of equations equivalent to:

$$\begin{aligned} &-u_x\left\{u - h^2\left[3\lambda^2 u u_x^2 + \frac{1}{2}\left(3\lambda^2 u^2 - 1\right)u_{xx}\right]\right\} - u_t \\ &- 2u_{xx}\left\{-h^2\left[\frac{1}{2}\left(3\lambda^2 u^2 - 1\right)u_x\right]\right\} \\ &- 3u_{xxx}\left\{-h^2\left[\frac{1}{6}\left(\lambda^2 u^3 - u\right)\right]\right\} = 0. \end{aligned} \tag{4.17}$$

Performing some mechanical calculations, we arrive at

$$u_{xxx} = \frac{3}{u}\frac{u_x}{\left(1 - \lambda^2 u^2\right)}\left[(3\lambda^2 u^2 - 1)u_{xx} + 2\lambda^2 u u_x^2\right]. \tag{4.18}$$

The right-hand side of the group invariant equation is written entirely in terms of x derivatives. Under the condition that λ is a small parameter, (4.18) can be recast into

$$u_{xxx} \approx -\frac{3}{u}u_x u_{xx}. \tag{4.19}$$

From the theory of gas dynamics we known that, for the Navier–Stokes shock, there are some inherent constraints among the spatial derivatives: $u_x, u_{xx}, u_{xxx}, \ldots$. In the following tables, the theoretical and group invariant conditions are compared, revealing a conflict.

Analysis at the upstream from the shock:

	u	u_x	u_{xx}	u_{xxx}
Theoretical solution	> 0	< 0	< 0	> 0
Lax–Wendroff scheme	> 0	< 0	< 0	< 0

Obviously, there is a conflict upstream from the shock. The signature of the third spatial derivative from group theory is inconsistent with the theoretical results, showing that this is the result of a lack of invariance in the similarity transformation upstream from the shock.

Analysis downstream from the shock:

	u	u_x	u_{xx}	u_{xxx}
Theoretical solution	> 0	< 0	> 0	> 0
Lax–Wendroff scheme	> 0	< 0	> 0	> 0

There is no conflict downstream from the shock, and the signature of the third spatial derivative from group theory is consistent with the theoretical results. The invariance of the similarity transformation is preserved upstream from the shock.

These group analysis results are consistent with previous numerical results produced by the Lax–Wendroff scheme [31, 33]. They exhibit some level of momentum spikes and postshock oscillations, while the group invariant conditions are broken in this region.

By using the same analysis, we finally obtain an exact group invariant equation for V_4

$$u_{xxx} = -\frac{3}{u}u_x u_{xx}. \tag{4.20}$$

Other results are the same as those for group analysis on the basis of V_3. Some remarks should be made here:

1. Based on the analysis above, we can see that the origin of the spurious wave oscillations behind the shock has some inherent connection with the lack of symmetry. Obviously, there is a conflict upstream from the shock as the signature of the third spatial derivative from group theory is not consistent with the theoretical results. This is a result of the lack of invariance of the similarity transformation upstream from the shock. The Lax–Wendroff scheme exhibits some level of momentum spikes and postshock oscillations, but the group invariant conditions are broken in this region.
2. In the above analysis (4.19), it is assumed that λ is a small parameter. This condition is met in many cases, but this is not generally applicable. It appears that, in general, modification equations do not admit similarity transformations for both cases.

5. Symmetry and Harten's entropy enforcement condition. The approach to development of the shock-capturing methods TVD and essentially nonoscillatory shock-capturing method (ENO) has been primarily mathematical. Most of these schemes do not directly consider the physical reasons for oscillation production in the numerical solutions. It is well known that Harten [2] has proved that some conditions must be met for the coefficient of numerical viscosity, in order for the TVD property to hold, but the general formula of these coefficients cannot be obtained from Harten's analysis. In his celebrated paper [2], he simply presented a heuristic analysis and provided the entropy enforcement formula. In this section, we will address the coefficient of numerical viscosity from the point of view of symmetry.

5.1. TVD scheme and its modified equation. This section studies the difference approximations to the scalar conservation law and discusses numerical approximations to weak solutions of (4.1), which are obtained by $(2k+1)$-point explicit schemes in conservation form:

$$v_j^{n+1} = v_j^n - \lambda\left(\bar{f}_{j+\frac{1}{2}}^n - \bar{f}_{j-\frac{1}{2}}^n\right), \tag{5.1}$$

where

$$\bar{f}_{j+\frac{1}{2}}^n = f\left(v_{j-k+1}^n, \ldots, v_{j+k}^n\right).$$

Here $v_j^n = v\left(j\Delta x, n\Delta t\right)$, and $\bar{f}$ is a numerical flux function. The numerical flux function must be consistent with the flux $f(u)$ in the following sense:

$$\bar{f}(u, \ldots, u) = f(u). \tag{5.2}$$

Let us consider a general three-point finite difference scheme in conservation form with a numerical flux $\bar{f}$ of the form [2, eq. 3.1a]

$$\bar{f}\left(v_j, v_{j+1}\right) = \frac{1}{2}\left[f\left(v_j\right) + f\left(v_{j+1}\right) - \frac{1}{\lambda}Q\left(\lambda\bar{a}_{j+\frac{1}{2}}\right)\Delta_{j+\frac{1}{2}}v\right], \tag{5.3}$$

where

$$\bar{a}_{j+\frac{1}{2}} = \frac{f\left(v_{j+1}\right) - f\left(v_j\right)}{\Delta_{j+\frac{1}{2}}v} \text{ when } \Delta_{j+\frac{1}{2}}v \neq 0,$$

TABLE 5.1
The coefficients of numerical viscosity for different conservation schemes.

Scheme	$Q(x)$
Lax–Friedrichs	$Q(x) = \frac{1}{\lambda}$
Lax–Wendroff	$Q(x) = x^2$
Roe	$Q(x) = \|x\|$
Harten	$Q(x) = \begin{cases} \|x\|, \|x\| \geq \epsilon \\ \frac{x^2+\epsilon^2}{2\epsilon}, \|x\| \leq \epsilon \end{cases}$
Boris–Book	$Q(x) = x^2 + \frac{1}{4}$

$$\bar{a}_{j+\frac{1}{2}} = a\left(v_j\right) \text{ when } \Delta_{j+\frac{1}{2}} v = 0.$$

Here $Q\left(x\right)$ is a function, which is often referred to as the coefficient of numerical viscosity. The modified equation of scheme (5.3), i.e., the equation that it approximates to second order accuracy, is

$$u_t + f\left(u\right)_x = \frac{\Delta t}{2\lambda^2}\left\{\left[Q\left(\nu\right) - \nu^2\right] u_x\right\}_x, \tag{5.4}$$

where

$$\lambda = \frac{\Delta t}{\Delta x},$$
$$\nu = \lambda a\left(u\right).$$

In Table 5.1, some typical coefficients of numerical viscosity are presented, including Harten's formula.

5.2. Group invariants of the TVD scheme. In this section, the modified equation is used instead of the first differential approximation, and the conditions under which a modified equation admits all groups of transformations allowed by the inviscid Burgers equation are formulated.

Setting $f(u) = \frac{1}{2}u^2$, we rewrite the modified equation as

$$u_t + uu_x = \left[D(u)u_x\right]_x, \tag{5.5}$$

where

$$D(u) = \frac{\Delta t}{2\lambda^2}\left[Q(\nu) - \nu^2\right].$$

Hence,

$$\Delta_2 = u_t + uu_x - D'(u)u_x^2 - D(u)u_{xx} = 0. \tag{5.6}$$

Using the same mathematical manipulation presented in section 4, we can obtain two different group invariant conditions as follows:

$$D'(u)u_x^2 + D(u)u_{xx} = 0, \tag{5.7}$$

$$\left[D'(u) - uD''(u)\right]u_x^2 + \left[2D(u) - uD'(u)\right]u_{xx} = 0. \tag{5.8}$$

Equations (5.7) and (5.8) consist of a homogeneous equation system about variables u_x^2, u_{xx}. The nondegenerate conditions for these variables are

$$\begin{vmatrix} D'(u) & D(u) \\ D'(u) - uD''(u) & 2D(u) - uD'(u) \end{vmatrix} = uD(u)D''(u) + D(u)D'(u) - uD'^2(u) = 0. \tag{5.9}$$

This is a nonlinear equation of variable u; the function is $D(u)$. The solution of this equation is

$$D(u) = D_0 u^a, \tag{5.10}$$

where D_0, a are constant parameters.

According to Harten's definition [2, eq. 3.15b], we have

$$Q(\nu) = \nu^2 + \frac{2\lambda^2}{\Delta t} D(u). \tag{5.11}$$

For the present problem,

$$\nu = \lambda u. \tag{5.12}$$

Using the group invariant condition (5.10), we have

$$Q(\nu) = \nu^2 + \frac{2\lambda^2}{\Delta t} D_0 u^a \tag{5.13}$$

or

$$Q(\nu) = \nu^2 + \frac{2\lambda^2}{\Delta t} D_0 \lambda^{-a} \nu^a. \tag{5.13'}$$

In order to obtain a universal formula the coefficients in it must be dimensionalless parameters. Δx and Δt denote, as usual, the dimensions of length and time, respectively. It is clear that D_0 can be rewritten as

$$D_0 = \hat{\varepsilon} (\Delta x)^b (\Delta t)^c, \tag{5.14}$$

where $\hat{\varepsilon}$ is a dimensionless parameter; meanwhile b, c are the exponents that must be chosen.

Finally, we have

$$Q(\nu) = \nu^2 + 2\hat{\varepsilon} \nu^a. \tag{5.15}$$

These dimensional exponents must be met:

$$\begin{aligned} Q_0 &= (\Delta x)^b (\Delta t)^c (\Delta t)^{-1} (\Delta t)^{2-a} (\Delta x)^{a-2} \\ &= (\Delta x)^{a+b-2} (\Delta t)^{c-a+1}. \end{aligned} \tag{5.16}$$

Hence:

$$a + b - 2 = 0, \tag{5.17}$$

$$c - a + 1 = 0. \tag{5.18}$$

That is,

$$b = 2 - a, \tag{5.19}$$

$$c = a - 1. \tag{5.20}$$

These exponents form the universal formula of the coefficients of numerical viscosity, inheriting the symmetries of the PDE. Different schemes could be deduced depending upon the choice of the parameter a.

Another dissipation condition reads as:

$$Q(0) > 0. \tag{5.21}$$

So, the choice of the parameter a is

$$a = 0. \tag{5.22}$$

Finally, we have a definition of the coefficients of numerical viscosity, deduced from the symmetries:

$$Q(x) = x^2 + 2\hat{\varepsilon}. \tag{5.23}$$

THEOREM 3. *If we let $Q(x)$ in (5.3) satisfy the equality*

$$Q(x) = x^2 + 2\hat{\varepsilon},$$

where $\hat{\varepsilon} > 0$ is a dimensionless constant, then the finite different scheme

$$\hat{f}_{j+\frac{1}{2}} = \frac{1}{2}\left[f(u_j^n) + f(u_{j+1}^n) - \frac{1}{\lambda}Q(\lambda \bar{a}_{j+\frac{1}{2}}^n)(u_{j+1}^n - u_j^n)\right]$$

satisfies all of the group invariant conditions of the nonlinear wave equation.

6. The reexploration of the spatial oscillations in finite difference solutions for Navier–Stokes shocks. In the calculation of complex flow fields containing shock waves, much attention has been paid to the shock capturing method [1, 2, 3, 4, 5, 6, 7, 8, 9]. In order to capture shock waves smoothly without spurious data near or in the shock region, the development of high-resolution nonoscillatory dissipative schemes containing no free parameters has been much emphasized. These include TVD schemes and ENO schemes. In [4, 36], Zhang found that, with a linearized analysis of one-dimensional Navier–Stokes equations and a proper manipulation of the coefficients of third order derivative ν_3, the spurious oscillation both upstream and downstream from shocks can be totally suppressed. The choice of ν_3 must be in accordance with the second law of thermodynamics. The numerical experiments with nonlinear Navier–Stokes equations confirm that conclusions reached through linearized analysis are valid in general. The importance of the role played by ν_3 has not been previously recognized [35]. While it has been usually thought that the third order dispersion terms in modified differential equations would not play an essential role in a linear problem, e.g., in stability analysis, etc., they do contribute through nonlinear interactions to the unwanted wave structure and even lead to chaos, if they are not properly treated. Based on the above physical concepts, Zhang suggested the celebrated NND schemes that have been applied to the numerical simulation of Navier–Stokes equations with some success [4, 35].

It is well known that, in application, Navier–Stokes equations are unsteady and nonlinear. The validity of the above linearized analysis is an open question. Difficulty in nonlinear analysis is primarily caused by the nonlinearity inherent in the Navier–Stokes equations, in particular the mechanism that allows the formation of shocks. The theme of this section is to emphasize the role of symmetry in various aspects of a proper manipulation of the coefficients of third order derivative ν_3.

6.1. The model equation and its symmetries. To avoid complicated mathematics, let us consider only the one-dimensional Navier–Stokes shock equation [36]:

$$\rho u_t + \frac{\gamma+1}{2\gamma}\rho_\infty u_\infty \left(1 - \frac{u_2 u_\infty}{u^2}\right) u_x = \frac{4}{3}(\mu u_x)_x, \tag{6.1}$$

where ρ is the mass per unit volume, u is the velocity, t is time, x is the spatial coordinate, γ is the specific heat ratio, and μ is dynamic viscosity.

Here

$$\rho = \frac{\rho_\infty u_\infty}{u},$$
$$\frac{\mu}{\mu_\infty} = \left(\frac{h}{h_\infty}\right)^n,$$
$$h = \frac{1}{2}u_\infty^2\left(1 + \frac{2}{\gamma-1}\frac{1}{M_\infty^2}\right) - \frac{1}{2}u^2.$$

For the propagating shock problem the Dirichlet boundary conditions for u are required up- and downstream from the shock. These are

$$u = u_\infty, \qquad x \to -\infty,$$
$$u_2 = \frac{\gamma-1}{\gamma+1}\left(1 + \frac{2}{\gamma-1}\frac{1}{M_\infty^2}\right) u_\infty. \tag{6.2}$$

The system of equations (6.1) admits a space of operators with the basis:

1. translation in time $V_1 = \partial_t$,
2. translation in a space coordinate $V_2 = \partial_x$,
3. Galileo transformation $V_3 = t\partial_x + \partial_u$,
4. similarity transformation $V_4 = x\partial_x + t\partial_t$,

together with the prolongation vectors as follows, only showing the spatial partial derivatives of u:

$$pr^{(3)}V_1 = \partial_t, \tag{6.3}$$

$$pr^{(3)}V_2 = \partial_x, \tag{6.4}$$

$$pr^{(3)}V_3 = t\partial_x + \partial_u - u_x\partial_{u_t}, \tag{6.5}$$

$$pr^{(3)}V_4 = x\partial_x + t\partial_t - u_x\partial_{u_x} - u_t\partial_{u_t} - 2u_{xx}\partial_{u_{xx}} - 3u_{xxx}\partial_{u_{xxx}}. \tag{6.6}$$

6.2. The modified equation and its symmetries. It can be stated that, generally when the leading term of the truncation error is the third order derivative, the modified equation of the above one-dimensional Navier–Stokes shock is

$$\rho u_t + \frac{\gamma+1}{2\gamma}\rho_\infty u_\infty \left(1 - \frac{u_2 u_\infty}{u^2}\right) u_x = \frac{4}{3}(\mu u_x)_x - (\nu_3 u_{xx})_x. \tag{6.7}$$

The physical viscid coefficient will be taken as constant wherever convenient, and the modified equation could be written as follows:

$$\Delta_3 = u_t + \frac{\gamma+1}{2\gamma}\left(u - \frac{u_2 u_\infty}{u}\right)u_x - \frac{\nu}{\rho_\infty u_\infty}uu_{xx} + \frac{\nu_3}{\rho_\infty u_\infty}uu_{xxx} = 0. \tag{6.8}$$

By using the same mathematical manipulation presented in section 4, we can obtain two different group invariance conditions listed as follows:

(1) For the invariants of the Galileo transformation, the group invariance condition reads

$$\nu_3 u_{xxx} = \nu u_{xx} + \rho_\infty u_\infty \left(\frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{u_2 u_\infty}{u^2}\right)u_x. \tag{6.9}$$

(2) For the invariants of the similarity transformation, the group invariance condition reads:

$$\nu_3 u_{xxx} = \frac{1}{2}\nu u_{xx}. \tag{6.10}$$

6.3. The choice of ν_3 in accordance with the group invariants. First, considering the invariants of the similarity transformation, the corresponding signature of ν_3 can be calculated as follows.

Equation (6.10) can be recast into

$$\nu_3 = \frac{\nu}{2}\cdot\frac{u_{xx}}{u_{xxx}}. \tag{6.11}$$

Hence, we have

$$signature\,[\nu_3] = signature\,[u_{xx}] \times signature\,[u_{xxx}]\,. \tag{6.12}$$

From (6.12), we have

$$\nu_3 < 0 \tag{6.13}$$

in the upstream region, while

$$\nu_3 > 0 \tag{6.14}$$

in the downstream region.

ν_3 is chosen using the similarity invariance analysis developed above. Now it is obvious that, if we can keep $\nu_3 < 0$ upstream and $\nu_3 > 0$ downstream, the invariants of the similarity transformation condition can be met. This result is equivalent to the former linearized result.

6.4. The Galileo invariants. The invariants of the Galileo transformation are more complex than those of the similarity transformations. In general conditions, there is not a simple relation for the choice of ν_3. In this situation, it is thought that the invariants of the similarity transformations are met, and those for the Galileo transformation are not. Here we focus only on the region near the shock. In this region, we have

$$\frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{u_2 u_\infty}{u^2} \approx \frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{u_2}{u_\infty}. \tag{6.15}$$

The speed of shock propagation is the governing parameter for this problem. For a given speed of shock propagation, the boundary value of u_2 is obtained from the Rankine–Hugoniot relation:

$$\frac{u_2}{u_\infty} = \frac{\gamma-1}{\gamma+1}\left(1+\frac{2}{\gamma-1}\frac{1}{M_\infty^2}\right). \tag{6.16}$$

Hence,

$$\begin{aligned}\frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{u_2 u_\infty}{u^2} &\approx \frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{u_2}{u_\infty}\\ &= \frac{\gamma-1}{2\gamma} - \frac{\gamma+1}{2\gamma}\frac{\gamma-1}{\gamma+1}\left(1+\frac{2}{\gamma-1}\frac{1}{M_\infty^2}\right)\\ &= \frac{\gamma-1}{2\gamma} - \frac{\gamma-1}{2\gamma} - \frac{1}{\gamma M_\infty^2}\\ &= -\frac{1}{\gamma M_\infty^2}.\end{aligned} \tag{6.17}$$

The Galileo invariants can be written in compact form as:

$$\nu_3 u_{xxx} = \nu u_{xx} - \frac{1}{\gamma M_\infty^2}\rho_\infty u_\infty u_x. \tag{6.18}$$

If $M_\infty >> 1$, then the choice of ν_3 is the same as that of the similarity transformation. But, for the case $M_\infty << 1$,

$$\nu_3 u_{xxx} = -\frac{1}{\gamma M_\infty^2}\rho_\infty u_\infty u_x. \tag{6.19}$$

The Galileo invariants are not met up- or downstream.

From the above consideration, we known that for fast shock propagation the choice of ν_3 based on the linearized analysis is valid under unsteady, nonlinear conditions, but for slow shock propagation, the Galileo invariants are not met in some cases.

It should be remarked that:

> A NND scheme has been suggested based on linear analysis, which has good stability characteristics and convergence. Through the preliminary numerical calculations, confidence was gained in the use of the NND schemes. The principle by which the coefficients of the third order derivatives are chosen is still based on the linearized conclusion. Under unsteady, nonlinear conditions, the validity of this linear conclusion is an open question. The use of symmetries helps us to reach a new conclusion and demonstrate that the linear conclusion is met with the similarity invariants but not met with the Galileo invariants in the general case.

7. Conclusions. It is known that the numerical solutions calculated by finite difference schemes are always associated with numerical dissipation and dispersion. Such errors can lead to undesirable numerical effects, especially for shock capturing. This paper uses a Lie symmetry analysis method to investigate some noteworthy properties of several difference schemes for nonlinear equations. We have demonstrated that the loss of properties of invariance from a modification equation, which conserve the main properties of its difference scheme, can serve as the cause of nonphysical

oscillations that are capable of eventually completely destroying a numerical solution. Further, this points to symmetry breaking as the inherent cause of nonphysical oscillation in the vicinity of shock. Each of these results is vital to the further development of the application of Lie symmetry to the study of shock-capturing methods.

It should be pointed out that the conclusions presented in this paper have preliminary character and demand further study.

Acknowledgments. I appreciate the numerous corrections and very useful comments of the referees. Special thanks to the referee who provided valuable information about the history of this research.

ALTERNATING DIRECTION IMPLICIT ORTHOGONAL SPLINE COLLOCATION METHODS FOR AN EVOLUTION EQUATION WITH A POSITIVE-TYPE MEMORY TERM*

AMIYA KUMAR PANI†, GRAEME FAIRWEATHER‡, AND RYAN I. FERNANDES§

Abstract. New numerical techniques are presented for the solution of a class of linear partial integro-differential equations (PIDEs) with a positive-type memory term in the unit square. In these methods, orthogonal spline collocation (OSC) is used for the spatial discretization, and, for the time stepping, new alternating direction implicit (ADI) methods based on the backward Euler, the Crank–Nicolson, and the second order BDF methods combined with judiciously chosen quadrature rules are considered. The ADI OSC methods are proved to be of optimal accuracy in time and in the L^2 norm in space. Numerical results confirm the predicted convergence rates and also exhibit optimal accuracy in the L^∞ and H^1norms and superconvergence phenomena.

Key words. evolution equation with positive-type memory term, alternating direction implicit method, orthogonal spline collocation, backward Euler method, Crank–Nicolson method, second order backward differentiation formula method, quadrature rules, optimal order convergence.

1. Introduction.

We formulate and analyze alternating direction implicit (ADI) time-stepping schemes combined with an orthogonal spline collocation (OSC) spatial discretization for solving the evolution equation with a positive-type memory term

$$u_t = \int_0^t a(t-s)\Delta u(s)\,ds + f(x,y,t), \quad (x,y,t) \in \Omega_T \equiv \Omega \times (0,T], \tag{1.1}$$

subject to the initial and boundary conditions

$$u(x,y,0) = u_0(x,y), \quad (x,y) \in \Omega, \tag{1.2}$$

$$u(x,y,t) = 0, \quad (x,y,t) \in \partial\Omega \times (0,T], \tag{1.3}$$

respectively, where Δ is the two-dimensional Laplacian, $\Omega = (0,1)\times(0,1)$ with boundary $\partial\Omega$, and $u_0(x,y)$ and $f(x,y,t)$ are given functions. The kernel a is assumed to be smooth for $t \geq 0$ and to satisfy

$$(-1)^j a^{(j)}(t) \geq 0, \quad t > 0, \quad j = 0,1,2. \tag{1.4}$$

It follows from [18] that the kernel a is positive definite in the sense that, for all $T > 0$,

$$\int_0^T v(s)\left(\int_0^s a(s-\tau)v(\tau)\,d\tau\right) ds \geq 0 \quad \forall v \in C([0,T]).$$

Equations of the type (1.1) and nonlinear versions of it arise in viscoelasticity and heat conduction in materials with memory; see, for example, [12, 13, 21].

Various numerical methods have been developed for the solution of (1.1) for both smooth and nonsmooth kernels. For the one-dimensional form of (1.1) with a weakly singular kernel, Sanz-Serna [22] employed a spectral method, while a finite difference scheme is used in [11] to discretize the spatial variable. Methods based on an OSC spatial discretization combined with various time-stepping schemes for (1.1) are formulated in [7] and optimal error estimates derived. For a one-dimensional problem, a modified spline collocation method is also considered. In [24], the Laplace transform is used in time with OSC in space. For details of more recent work on the use of transforms for the time discretization, see [16] and the review in [23], which includes a preview of [14]. In [15, 17], finite element Galerkin methods combined with constant and variable time-stepping schemes for (1.1) with both smooth and nonsmooth kernels are discussed. In [19], an H^1-Galerkin mixed finite element method is formulated and analyzed. For a review of earlier work involving finite element methods for solving (1.1), see [4].

In this paper, we approximate the solution u of (1.1)–(1.3) using OSC with C^1 piecewise polynomials of arbitrary degree $r \geq 3$ in each space variable for the spatial discretization. Then the resulting systems of integro-differential equations in the time variable are discretized using ADI versions of the backward Euler method (section 3), the Crank–Nicolson method (section 4), and the second order backward differentiation formula (BDF) scheme (section 5), each combined with a judiciously chosen quadrature rule. For each method, we examine the existence and uniqueness of the OSC approximation, and derive optimal order error estimates in the L^2 norm at each time step, assuming that the solution u of (1.1)–(1.3) is sufficiently smooth. (For a discussion of regularity results under various assumptions on the kernel a and the data, see [15].) In section 6, we present numerical results obtained using the ADI Crank–Nicolson OSC method and the second order ADI BDF OSC scheme with tensor products of piecewise Hermite cubics. These results not only confirm the predicted convergence rates but also exhibit optimal accuracy in the L^∞ and H^1norms and superconvergence phenomena invariably observed in numerical experiments involving OSC methods but as yet unproved. In section 2, we introduce notation and basic lemmas used in the paper. A survey of orthogonal spline collocation methods for partial differential equations and partial integro-differential equations is given in [2]. Recent advances in the development and analysis of ADI OSC methods for parabolic and hyperbolic problems can be found in [3].

2. Preliminaries. Set $I = (0, 1)$, and let $\delta_x = \{x_i\}_{i=0}^{N_x}$ and $\delta_y = \{y_j\}_{j=0}^{N_y}$ be two partitions of $\bar{I}$ such that

$$0 = x_0 < x_1 < \cdots < x_{N_x - 1} < x_{N_x} = 1, \qquad 0 = y_0 < y_1 < \cdots < y_{N_y - 1} < y_{N_y} = 1.$$

Assume that the partition $\delta = \delta_x \otimes \delta_y$ of Ω is quasi-uniform. Let

$$I_i^x = (x_{i-1}, x_i), \quad I_j^y = (y_{j-1}, y_j), \quad I_{ij} = I_i^x \times I_j^y,$$
$$h_i^x = x_i - x_{i-1}, \quad h_j^y = y_j - y_{j-1}$$

for $1 \leq i \leq N_x$, $1 \leq j \leq N_y$, and set

$$h = \max\left(\max_i h_i^x, \max_j h_j^y\right).$$

Let $\mathcal{M}_r(\delta_x)$ be the spaces of piecewise polynomials of degree $\leq r$ defined by

$$\mathcal{M}_r(\delta_x) = \{v \in C^1([0,1]) : v|_{I_i^x} \in P_r,\ 1 \leq i \leq N_x, v(0) = v(1) = 0\},$$

where P_r denotes the set of polynomials of degree $\leq r$. Let $\mathcal{M}_r(\delta_y)$ be defined similarly, and set

$$\mathcal{M}_r(\delta) = \mathcal{M}_r(\delta_x) \otimes \mathcal{M}_r(\delta_y).$$

Then $\dim(\mathcal{M}_r(\delta)) = (r-1)^2 N_x N_y$.

Let $\{\lambda_\ell\}_{\ell=1}^{r-1}$ and $\{\gamma_\ell\}_{\ell=1}^{r-1}$ be the nodes and weights, respectively, of the $(r-1)$-point Gauss quadrature rule on I. Let

$$\mathcal{G}_x = \{\xi_p^x\}_{p=1}^{M_x} \quad \text{and} \quad \mathcal{G}_y = \{\xi_q^y\}_{q=1}^{M_y},$$

where $M_x = (r-1)N_x$ and $M_y = (r-1)N_y$, be the sets of Gauss points in the x- and y-directions, respectively, where

$$\xi_{i,\ell}^x = x_{i-1} + h_i^x \lambda_\ell, \qquad \xi_{j,\ell}^y = y_{j-1} + h_j^y \lambda_\ell$$

for $1 \leq i \leq N_x,\ 1 \leq j \leq N_y,\ 1 \leq \ell \leq r-1$. Let

$$\mathcal{G}_r = \{\xi = (\xi^x, \xi^y) : \xi^x \in \mathcal{G}_x, \xi^y \in \mathcal{G}_y\}$$

be the set of Gauss points in Ω.

For V and W defined on $\mathcal{G}_r$, let $\langle V, W\rangle_x$, $\langle V, W\rangle_y$, $\langle V, W\rangle$, and $|V|_h$ be defined by

$$\langle V, W\rangle_x(y) = \sum_{i=1}^{N_x} h_i^x \sum_{k=1}^{r-1} \gamma_k (VW)(\xi_{i,k}^x, y), \qquad y \in \bar{I}, \tag{2.1}$$

$$\langle V, W\rangle_y(x) = \sum_{j=1}^{N_y} h_j^y \sum_{l=1}^{r-1} \gamma_l (VW)(x, \xi_{j,l}^y), \qquad x \in \bar{I}, \tag{2.2}$$

$$\langle V, W\rangle = \sum_{i=1}^{N_x} \sum_{j=1}^{N_y} h_i^x h_j^y \sum_{k=1}^{r-1} \sum_{l=1}^{r-1} \gamma_k \gamma_l (VW)(\xi_{i,k}^x, \xi_{j,l}^y), \tag{2.3}$$

and

$$|V|_h = \langle V, V\rangle^{\frac{1}{2}}. \tag{2.4}$$

Let $L^p(\Omega)$, $1 \leq p < \infty$, denote the Banach space with norm $\|\cdot\|_{L^p}$, where

$$\|v\|_{L^p} = \left(\int_\Omega |v|^p dxdy\right)^{1/p}, \qquad \|v\|_{L^\infty} = \sup_\Omega |v|.$$

With m a nonnegative integer, let $H^m(\Omega)$ denote the Sobolev space with norm

$$\|v\|_{H^m} = \left(\sum_{l=0}^{m} \sum_{i+j=l} \left\| \frac{\partial^{i+j} v}{\partial x^i \partial y^j} \right\|_{L^2}^2\right)^{1/2}.$$

If X is a normed space with norm $\|\cdot\|_X$, then we define $L^p(X)$ by

$$L^p(X) = \{v : v(\cdot\,,t) \in X,\ t \in [0,T];\ \|v\|_{L^p(X)} < \infty\},$$

where

$$\|v\|_{L^p(X)} = \left(\int_0^T \|v\|_X^p dt\right)^{1/p}, \qquad \|v\|_{L^\infty(X)} = \sup_{0\le t\le T} \|v\|_X.$$

We assume that $\{t_n\}_{n=0}^J$ is a uniform partition of $[0,T]$ such that $t_n = nk$, $k = T/J$, and we introduce the following notation:

$$V^n(\cdot\,) = V(\cdot\,,t_n), \qquad 0 \le n \le J,$$

$$\partial_t V^n = \frac{V^n - V^{n-1}}{k}, \quad V^{n-\frac{1}{2}} = \frac{1}{2}\left[V^n + V^{n-1}\right], \qquad 1 \le n \le J.$$

Also, we denote by C a generic positive constant that is independent of h and k.

In the error analysis, we use the differentiable map $W : [0,T] \to \mathcal{M}_r(\delta)$ defined by

$$\Delta(u - W) = 0 \quad \text{on } \mathcal{G} \times [0,T], \tag{2.5}$$

where u is the solution of (1.1)–(1.3). The following estimates of $u - W$ and its time derivatives are well known [10, 20].

LEMMA 2.1. *If $\partial^\ell u/\partial t^\ell \in L^p(H^{r+3-j})$, $\ell = 0,1$, $j = 0,1$, $p = 2,\infty$, then there exists a constant C, independent of h, such that*

$$\left\|\frac{\partial^\ell (u - W)}{\partial t^\ell}\right\|_{H^j} \le Ch^{r+1-j}\left\|\frac{\partial^\ell u}{\partial t^\ell}\right\|_{H^{r+3-j}}, \quad j = 0,1, \quad \ell = 0,1. \tag{2.6}$$

3. The backward Euler ADI OSC method. Using the composite right rectangle rule,

$$q_n(\phi) = k\sum_{j=1}^n a_{n-j}\phi^j \approx \int_0^{t_n} a(t_n - s)\phi(s)ds, \tag{3.1}$$

we define the backward Euler OSC method for the solution of (1.1) by

$$\partial_t U^n = k\sum_{j=1}^n a_{n-j}\Delta U^j + f^n \quad \text{on } \mathcal{G}, \quad n = 1,\dots,J, \tag{3.2}$$

with given U^0; see [7]. With $E^n = U^n - U^{n-1}$, we may rewrite (3.2) as

$$\begin{aligned} E^n - k^2 a_0 \Delta E^n &= k^2 \sum_{j=1}^{n-1} a_{n-j}\Delta U^j + k^2 a_0 \Delta U^{n-1} + kf^n \quad \text{on } \mathcal{G} \\ &\equiv F^n, \quad n = 1,\dots,J. \end{aligned} \tag{3.3}$$

If we add the term

$$a_0^2 k^4 \frac{\partial^4 E^n}{\partial x^2 \partial y^2}$$

to the left-hand side of (3.3), we obtain the backward Euler ADI OSC method

$$\left[1 - a_0k^2\Delta + a_0^2k^4\frac{\partial^4}{\partial x^2\partial y^2}\right]E^n = F^n \quad \text{on } \mathcal{G}, \quad n = 1, \ldots, J. \tag{3.4}$$

A unique feature of this method, and of the ADI methods of sections 4 and 5, is the use of a term from the quadrature rule in its formulation.

We now rewrite (3.4) in a more familiar ADI form. To this end, let $\{\phi_i\}_{i=1}^{M_x}$ and $\{\psi_j\}_{j=1}^{M_y}$ be bases for $\mathcal{M}_r(\delta_x)$ and $\mathcal{M}_r(\delta_y)$, respectively, set

$$U^n(x,y) = \sum_{i=1}^{M_x}\sum_{j=1}^{M_y}\alpha_{ij}^{(n)}\phi_i(x)\psi_j(y),$$

and let

$$\boldsymbol{\alpha}^{(n)} = [\alpha_{11}^{(n)}, \alpha_{12}^{(n)}, \ldots, \alpha_{1M_y}^{(n)}, \alpha_{21}^{(n)}, \ldots, \alpha_{M_xM_y}^{(n)}]^T.$$

Define

$$\begin{aligned} &A_x = \left(a_{ij}^x\right)_{i,j=1}^{M_x}, \quad a_{ij}^x = -\phi_j''(\xi_i^x), \quad B_x = \left(b_{ij}^x\right)_{i,j=1}^{M_x}, \quad b_{ij}^x = \phi_j(\xi_i^x), \\ &A_y = \left(a_{ij}^y\right)_{i,j=1}^{M_y}, \quad a_{ij}^y = -\psi_j''(\xi_i^y), \quad B_y = \left(b_{ij}^y\right)_{i,j=1}^{M_y}, \quad b_{ij}^y = \psi_j(\xi_i^y), \end{aligned} \tag{3.5}$$

and

$$\mathbf{F}^{(n)} = [F^n(\xi_1^x,\xi_1^y), F^n(\xi_1^x,\xi_2^y), \ldots, F^n(\xi_1^x,\xi_{M_y}^y), F^n(\xi_2^x,\xi_1^y), \ldots, F^n(\xi_{M_x}^x,\xi_{M_y}^y)].$$

Then (3.4) becomes

$$\left[B_x\otimes B_y + a_0k^2(A_x\otimes B_y + B_x\otimes A_y) + a_0^2k^4A_x\otimes A_y\right](\boldsymbol{\alpha}^{(n)} - \boldsymbol{\alpha}^{(n-1)}) = \mathbf{F}^{(n)},$$

or, with $\boldsymbol{\nu}^{(n)} = \boldsymbol{\alpha}^{(n)} - \boldsymbol{\alpha}^{(n-1)}$,

$$\left[(B_x + k^2a_0A_x)\otimes I_{M_y}\right]\left[I_{M_x}\otimes(B_y + k^2a_0A_y)\right]\boldsymbol{\nu}^{(n)} = \mathbf{F}^{(n)}, \tag{3.6}$$

where $\otimes$ denotes the matrix tensor product,[1] and I_{M_x} and I_{M_y} are unit matrices of orders M_x and M_y, respectively. Introducing the auxiliary vector $\hat{\boldsymbol{\nu}}^{(n)}$, (3.6) is equivalent to

$$\begin{aligned} &\left[(B_x + k^2a_0A_x)\otimes I_{M_y}\right]\hat{\boldsymbol{\nu}}^{(n)} = \mathbf{F}^{(n)}, \\ &\left[I_{M_x}\otimes(B_y + k^2a_0A_y)\right]\boldsymbol{\nu}^{(n)} = \hat{\boldsymbol{\nu}}^{(n)}. \end{aligned} \tag{3.7}$$

Thus we determine $\boldsymbol{\nu}^{(n)}$ by solving two sets of independent one-dimensional problems, first

$$(B_x + a_0k^2A_x)\hat{\boldsymbol{\nu}}_j^{(n)} = \mathbf{F}_j^{(n)}, \quad j = 1, \ldots, M_y, \tag{3.8}$$

[1]If the matrix $A = (a_{i,j})$ is $M_A \times N_A$ and B is $M_B \times N_B$, then the matrix $A \otimes B$ is the $M_AM_B \times N_AN_B$ block matrix whose (i,j) block is $a_{i,j}B$.

in the x-direction, where

$$\mathbf{v}_j = [v_{1j}, v_{2j}, \ldots, v_{M_x j}]^T,$$

followed by

$$(B_y + a_0 k^2 A_y)\boldsymbol{\nu}_i^{(n)} = \hat{\boldsymbol{\nu}}_i^{(n)}, \quad i = 1, \ldots, M_x, \tag{3.9}$$

in the y-direction, where

$$\mathbf{v}_i = [v_{i1}, v_{i2}, \ldots, v_{iM_y}]^T.$$

Then

$$\boldsymbol{\alpha}^{(n)} = \boldsymbol{\alpha}^{(n-1)} + \boldsymbol{\nu}^{(n)}.$$

Since $a_0 \geq 0$, the matrices $B_x + k^2 a_0 A_x$ and $B_y + k^2 a_0 A_y$ are nonsingular [5]. Hence, there exists a unique backward Euler ADI OSC approximation. With standard choices of bases for $\mathcal{M}_r(\delta_x)$ and $\mathcal{M}_r(\delta_y)$, the linear systems (3.8) and (3.9) are almost block diagonal and can be solved efficiently using Gauss elimination-based algorithms [8].

An optimal order L^2 error estimate for the backward Euler ADI OSC approximation is given in the following theorem.

THEOREM 3.1. *Let u and $\{U_n\}_{n=0}^J$ denote the solutions of* (1.1)–(1.3) *and* (3.4)*, respectively. Assume that $a \in C^1([0,T])$ and satisfies* (1.4)*. Then*

$$\|u(t_J) - U^J\|_{L^2} \leq C\Bigg([h^{r+1} + k^4 h^{r-1}]\|u\|_{L^\infty(H^{r+3})} + [h^{r+1} + k^4 h^{r-3}]\|u_t\|_{L^1(H^{r+3})}$$
$$+ k\left[\|\Delta u\|_{L^1(L^\infty)} + \|\Delta u_t\|_{L^1(L^\infty)} + \|u_{tt}\|_{L^1(L^\infty)}\right] + k^4 \left\| \frac{\partial^4 u_t}{\partial x^2 \partial y^2} \right\|_{L^1(L^\infty)} \Bigg),$$

provided U^0 is chosen so that

$$\|u_0 - U^0\|_{L^2} \leq C h^{r+1} \|u_0\|_{H^{r+1}}. \tag{3.10}$$

Proof. Let $\zeta^n = U^n - W^n$ and $\eta^n = u^n - W^n$, where W is defined by (2.5). Then

$$u^n - U^n = \eta^n - \zeta^n.$$

Since bounds on η^n are known from Lemma 2.1, it is sufficient to bound ζ^n and then use the triangle inequality to bound $u^n - U^n$.

First note that (3.4) can be written as

$$\partial_t U^n + a_0^2 k^4 \frac{\partial^4 [\partial_t U^n]}{\partial x^2 \partial y^2} = k \sum_{j=1}^n a_{n-j} \Delta U^j + f^n \quad \text{on } \mathcal{G}, \quad n = 1, \ldots, J, \tag{3.11}$$

which is equivalent to

$$\langle \partial_t U^n, v \rangle + \left\langle a_0^2 k^4 \frac{\partial^4 [\partial_t U^n]}{\partial x^2 \partial y^2}, v \right\rangle = k \sum_{j=1}^n a_{n-j} \langle \Delta U^j, v \rangle + \langle f^n, v \rangle, \quad v \in \mathcal{M}_r(\delta). \tag{3.12}$$

Also,

$$\langle \partial_t u^n, v\rangle + \left\langle a_0^2 k^4 \frac{\partial^4[\partial_t u^n]}{\partial x^2 \partial y^2}, v \right\rangle = \langle q_n(\Delta u), v\rangle + \langle f^n, v\rangle + \left\langle (\partial_t u^n - u_t^n) + a_0^2 k^4 \frac{\partial^4[\partial_t u^n]}{\partial x^2 \partial y^2} - \varepsilon_n(\Delta u), v \right\rangle, \quad v \in \mathcal{M}_r(\delta), \tag{3.13}$$

where ε_n is the quadrature error associated with the quadrature rule (3.1), that is,

$$\varepsilon_n(\phi) = q_n(\phi) - \int_0^{t_n} a(t_n - s)\phi(s)ds. \tag{3.14}$$

Then, using (3.12), (3.13), and (2.5) and choosing $v = \zeta^n$, we obtain

$$\langle \partial_t \zeta^n, \zeta^n\rangle + a_0^2 k^4 \left\langle \frac{\partial^4[\partial_t \zeta^n]}{\partial x^2 \partial y^2}, \zeta^n \right\rangle + k \sum_{j=1}^{n} a_{n-j} \left\langle -\Delta \zeta^j, \zeta^n \right\rangle = \left\langle \sigma^n, \zeta^n \right\rangle, \tag{3.15}$$

where $\sigma^n = \sigma_1^n + \sigma_2^n + \sigma_3^n + \sigma_4^n$ with

$$\sigma_1^n = u_t(t_n) - \partial_t u(t_n), \quad \sigma_2^n = -\varepsilon_n(\Delta u), \quad \sigma_3^n = \partial_t \eta^n,$$

and

$$\sigma_4^n = a_0^2 k^4 \frac{\partial^4}{\partial x^2 \partial y^2}[\partial_t \eta^n - \partial_t u(t_n)].$$

Then

$$\langle \partial_t \zeta^n, \zeta^n\rangle \geq \frac{1}{2}\partial_t |\zeta^n|_h^2, \tag{3.16}$$

and

$$\left\langle \frac{\partial^4[\partial_t \zeta^n]}{\partial x^2 \partial y^2}, \zeta^n \right\rangle \geq \frac{1}{2}\partial_t \left\langle \frac{\partial^4 \zeta^n}{\partial x^2 \partial y^2}, \zeta^n \right\rangle. \tag{3.17}$$

If we substitute (3.16) and (3.17) into (3.15), apply the Cauchy–Schwarz inequality to the right-hand-side term, multiply both sides by $2k$, and then sum the resulting expression from $n = 1$ to $n = m$, $1 \leq m \leq J$, we obtain

$$|\zeta^m|_h^2 + a_0^2 k^4 \left\langle \frac{\partial^4 \zeta^m}{\partial x^2 \partial y^2}, \zeta^m \right\rangle + 2k^2 \sum_{n=1}^{m} \sum_{j=1}^{n} a_{n-j} \left\langle -\Delta \zeta^j, \zeta^n \right\rangle \leq |\zeta^0|_h^2 + a_0^2 k^4 \left\langle \frac{\partial^4 \zeta^0}{\partial x^2 \partial y^2}, \zeta^0 \right\rangle + 2k \sum_{n=1}^{m} |\sigma^n|_h |\zeta^n|_h. \tag{3.18}$$

Now, from [9, Lemma 3.4],

$$a_0^2 k^4 \left\langle \frac{\partial^4 \zeta^m}{\partial x^2 \partial y^2}, \zeta^m \right\rangle \geq a_0^2 k^4 \left\| \frac{\partial^2 \zeta^m}{\partial x \partial y} \right\|_{L^2}^2 \geq 0, \quad 1 \leq m \leq J. \tag{3.19}$$

Then if $a \in C([0,T])$ and satisfies (1.4), it follows from [7, Lemma 3.5] that the quadrature rule (3.1) is positive, that is,

$$k \sum_{n=1}^{m} q_n(\phi)\phi^n = k^2 \sum_{n=1}^{m} \sum_{j=1}^{n} a_{n-j} \phi^j \phi^n \geq 0, \quad 1 \leq m \leq J. \tag{3.20}$$

Thus, from [7, Lemma 3.3] and (3.20), it follows that

$$2k^2 \sum_{n=1}^{m} \sum_{j=1}^{n} a_{n-j} \left\langle -\Delta \zeta^j, \zeta^n \right\rangle \geq 0, \quad 1 \leq m \leq J. \tag{3.21}$$

We bound the second term on the right-hand side of (3.18) using the inequality

$$\left\langle \frac{\partial^4 \zeta^0}{\partial x^2 \partial y^2}, \zeta^0 \right\rangle \leq C \|\zeta^0\|_{H^1}^2, \tag{3.22}$$

which is proved in the following way. If we choose a tensor product basis for $\mathcal{M}_r(\delta)$, it suffices to consider the case where $\zeta^0(x,y) = \zeta_1^0(x)\zeta_2^0(y)$. Then, using [5, Lemma 3.1],

$$\left\langle \frac{\partial^4 \zeta^0}{\partial x^2 \partial y^2}, \zeta^0 \right\rangle = \left\langle \frac{\partial^2 \zeta_1^0}{\partial x^2}, \zeta_1^0 \right\rangle_x \left\langle \frac{\partial^2 \zeta_2^0}{\partial y^2}, \zeta_2^0 \right\rangle_y \leq C \|\zeta^0\|_{H^1}^2,$$

as required. Using the inverse inequality [9, equation (2.4b)] and the equivalence of the norms $\|\cdot\|_{L^2}$ and $|\cdot|_h$ on $\mathcal{M}_r(\delta)$ proved in [20], we then obtain

$$a_0^2 k^4 \left\langle \frac{\partial^4 \zeta^0}{\partial x^2 \partial y^2}, \zeta^0 \right\rangle \leq C k^4 h^{-1} \|\zeta^0\|_{H^1} |\zeta^0|_h. \tag{3.23}$$

From (3.18)–(3.23), we obtain

$$\begin{aligned} |\zeta^m|_h^2 &\leq C \left(|\zeta^0|_h^2 + k^4 h^{-1} \|\zeta^0\|_{H^1} |\zeta^0|_h + k \sum_{n=1}^{m} |\sigma^n|_h |\zeta^n|_h \right) \\ &\leq C \left(|\zeta^0|_h + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{m} |\sigma^n|_h \right) |\zeta^N|_h, \end{aligned}$$

where

$$|\zeta^N|_h = \max_{0 \leq m \leq J} |\zeta^m|_h.$$

Hence

$$|\zeta^N|_h^2 \leq C \left(|\zeta^0|_h + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{J} |\sigma^n|_h \right) |\zeta^N|_h,$$

from which it follows that

$$|\zeta^J|_h \leq |\zeta^N|_h \leq C \left(|\zeta^0|_h + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{J} |\sigma^n|_h \right),$$

and

$$\|\zeta^J\|_{L^2} \leq C \left(\|\zeta^0\|_{L^2} + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{N} |\sigma^n|_h \right), \tag{3.24}$$

on using the equivalence of the norms $\|\cdot\|_{L^2}$ and $|\cdot|_h$ on $\mathcal{M}_r(\delta)$. Since, from (3.10) and (2.6),

$$\|\zeta^0\|_{H^j} \leq \|U^0 - u_0\|_{H^j} + \|u_0 - W^0\|_{H^j} \leq C h^{r+1-j} \|u_0\|_{H^{r+3}},$$

the first and second terms on the right-hand side of (3.24) are bounded by

$$\|\zeta^0\|_{L^2} + k^4 h^{-1} \|\zeta^0\|_{H^1} \le C \left(h^{r+1} + k^4 h^{r-1}\right) \|u_0\|_{H^{r+3}}. \tag{3.25}$$

It remains to estimate the last term on the right-hand side of (3.24). To estimate σ_1^n, we use Taylor's theorem with integral remainder to obtain

$$k \sum_{n=1}^{J} |\sigma_1^n|_h \le Ck \int_0^T \|u_{tt}\|_{L^\infty}\, ds. \tag{3.26}$$

If $a \in C^1([0,T])$, then

$$|\varepsilon_n(\phi)| \le Ck \int_0^{t_n} \left| \frac{\partial}{\partial s}[a(t_n - s)\phi(s)] \right| ds \le Ck \int_0^{t_n} \left(\|\phi\|_{L^\infty} + \|\phi_t\|_{L^\infty}\right) ds, \tag{3.27}$$

from which it follows that

$$|\sigma_2^n|_h = |\varepsilon_n(\Delta u)|_h \le Ck \int_0^{t_n} \left(\|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty}\right) ds,$$

and

$$k \sum_{n=1}^{J} |\sigma_2^n|_h \le Ck \int_0^T \left[\|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty}\right] ds. \tag{3.28}$$

Since

$$\partial_t \eta^n = \frac{1}{k} \int_{t_{n-1}}^{t_n} \eta_t(s)\, ds,$$

we obtain

$$\begin{aligned} k \sum_{n=1}^{J} |\sigma_3^n|_h \le \int_0^T |\eta_t|_h &\le Ch^2 \int_0^T \sum_{i=1}^{N_x} \sum_{j=1}^{N_y} \|\eta_t\|_{L^\infty(I_{ij})}\, ds \\ &\le Ch^{r+1} \int_0^T \|u_t\|_{H^{r+3}}\, ds \end{aligned} \tag{3.29}$$

on using Lemmas 3.1 and 3.2 in [9]. Similarly,

$$k \sum_{n=1}^{J} \left| \frac{\partial^4 [\partial_t \eta^n]}{\partial x^2 \partial y^2} \right|_h \le Ch^{r-3} \int_0^T \|u_t\|_{H^{r+3}}\, ds,$$

and

$$k \sum_{n=1}^{J} \left| \frac{\partial^4 [\partial_t u^n]}{\partial x^2 \partial y^2} \right|_h \le \int_0^T \left| \frac{\partial^4 [u_t]}{\partial x^2 \partial y^2} \right|_h ds \le \int_0^T \left\| \frac{\partial^4 u_t}{\partial x^2 \partial y^2} \right\|_{L^\infty} ds.$$

Thus we obtain

$$k \sum_{n=1}^{J} |\sigma_4^n|_h \le Ck^4 \int_0^T \left(h^{r-3} \|u_t\|_{H^{r+3}} + \left\| \frac{\partial^4 u_t}{\partial x^2 \partial y^2} \right\|_{L^\infty} \right) ds. \tag{3.30}$$

On substituting (3.25)–(3.30) into (3.24), we obtain

$$\|\zeta^J\|_{L^2} \le C \left(\left[h^{r+1} + k^4 h^{r-1}\right] \|u_0\|_{H^{r+3}} + \left[h^{r+1} + k^4 h^{r-3}\right] \int_0^T \|u_t\|_{H^{r+3}}\, ds \right.$$
$$\left. + k \int_0^T \left[\|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty} + \|u_{tt}\|_{L^\infty}\right] ds + k^4 \int_0^T \left\| \frac{\partial^4 u_t}{\partial x^2 \partial y^2} \right\|_{L^\infty} ds \right). \tag{3.31}$$

Now we use the triangle inequality, (3.31), and Lemma 2.1 to complete the proof. ∎

4. The ADI Crank–Nicolson OSC method. In order to obtain higher order accuracy in time, we now consider a method in which the time discretization is done using a Crank–Nicolson-type approach. This method comprises

$$\partial_t U^n = q_{n-1/2}(-\Delta U) + f(t_{n-1/2}) \text{ on } \mathcal{G}, \quad n = 1, \ldots, J, \tag{4.1}$$

where $q_{n-1/2}(\phi)$, a variant of the composite midpoint quadrature rule, is defined by

$$q_{n-1/2}(\phi) = k \sum_{j=1}^{n-1} a(t_{n-1/2} - t_{j-1/2}) \phi^{j-1/2} + \frac{k}{2} a_0 \phi^{n-1/2}$$
$$= k \sum_{j=1}^{n-1} a_{n-j} \phi^{j-1/2} + \frac{k}{2} a_0 \phi^{n-1/2} \approx \int_0^{t_{n-1/2}} a(t_{n-1/2} - s) \phi(s) ds, \tag{4.2}$$

with

$$\phi^{j-1/2} = (\phi^j + \phi^{j-1})/2, \quad j = 1, \ldots, n.$$

Using [17, Lemma 2.1], it is easy to check that the quadrature rule (4.2) is positive; that is, for all ϕ, and $1 \le m \le J$,

$$k \sum_{n=1}^{m} q_{n-1/2}(\phi) \phi^{n-1/2} = k^2 \sum_{n=1}^{m} \left(\sum_{j=1}^{n-1} a_{n-j} \phi^{j-1/2} + \frac{1}{2} a_0 \phi^{n-1/2} \right) \phi^{n-1/2} \ge 0. \tag{4.3}$$

If $E^n = U^n - U^{n-1}$, then (4.1) can be written as

$$E^n - \frac{k^2}{4} a_0 \Delta E^n = F^n \quad \text{on } \mathcal{G}, \quad n = 1, \ldots, J, \tag{4.4}$$

where

$$F^n = k f_{n-1/2} + k^2 \sum_{j=1}^{n-1} a_{n-j} \Delta U^{j-1/2} + \frac{k^2}{2} a_0 \Delta U^{n-1}.$$

If we add the term

$$\frac{k^4}{16} a_0^2 \frac{\partial^4 E^n}{\partial x^2 \partial y^2}$$

to the left-hand side of (4.4), we obtain the ADI Crank–Nicolson OSC method

$$\left[1 - \frac{k^2}{4} a_0 \Delta + \frac{k^4}{16} a_0^2 \frac{\partial^4}{\partial x^2 \partial y^2}\right] E^n = F^n \quad \text{on } \mathcal{G}, \quad n = 1, \ldots, J. \tag{4.5}$$

Thus, using the notation of section 3, we may write (4.5) in the form (3.7) with k^2 replaced by $k^2/4$.

We denote the error associated with the quadrature rule (4.2) by $\varepsilon_{n-1/2}(\phi)$ with

$$\varepsilon_{n-1/2}(\phi) = q_{n-1/2}(\phi) - \int_0^{t_{n-1/2}} a(t_n - s)\phi(s)\, ds.$$

If $a \in C^2([0,T])$, then, for $0 \le t_n \le T$,

$$|\varepsilon_{n-1/2}(\phi)| \le C\left(k\int_{t_{n-1}}^{t_{n-1/2}} [|\phi| + |\phi'|]\, ds + k^2 \sum_{j=1}^{n-1} \int_{t_{j-1}}^{t_j} [|\phi| + |\phi'| + |\phi''|]\, ds\right). \tag{4.6}$$

THEOREM 4.1. *Let u and $\{U_n\}_{n=0}^J$ denote the solutions of* (1.1)–(1.3) *and* (4.5)*, respectively. Assume that $a \in C^2[0,T]$ and satisfies* (1.4)*. Then*

$$\begin{aligned}\|u(t_J) - U^J\|_{L^2} \le C\Big(&[h^{r+1} + k^4 h^{r-1}]\|u\|_{L^\infty(H^{r+3})} + [h^{r+1} + k^4 h^{r-3}]\|u_t\|_{L^1(H^{r+3})} \\ &+ k^2\left[\|\Delta u\|_{L^1(L^\infty)} + \|\Delta u_t\|_{L^1(L^\infty)} + \|\Delta u_{tt}\|_{L^1(L^\infty)} + \|u_{ttt}\|_{L^1(L^\infty)}\right] \\ &+ k^4 \left\|\frac{\partial^4 u_t}{\partial x^2 \partial y^2}\right\|_{L^1(L^\infty)}\Big),\end{aligned}$$

provided U^0 is chosen so that (3.10) *is satisfied.*

Proof. From (4.5), we obtain

$$\partial_t U^n + \frac{k^4}{16} a_0^2 \frac{\partial^4[\partial_t U^n]}{\partial x^2 \partial y^2} + q_{n-1/2}(-\Delta U) = f_{n-1/2} \quad \text{on } \mathcal{G}, \quad n = 1, \ldots, J,$$

which is equivalent to

$$\left\langle \partial_t U^n + \frac{k^4}{16} a_0^2 \frac{\partial^4[\partial_t U^n]}{\partial x^2 \partial y^2}, v \right\rangle + \left\langle q_{n-1/2}(-\Delta U), v\right\rangle = \left\langle f_{n-1/2}, v\right\rangle, \quad v \in \mathcal{M}_r(\delta).$$

With $\zeta^n = U^n - W^n$ and $\eta^n = u^n - W^n$ as before, we have

$$\langle \partial_t \zeta^n, v\rangle + \frac{k^4}{16} a_0^2 \left\langle \frac{\partial^4 \partial_t \zeta^n}{\partial x^2 \partial y^2}, v\right\rangle + \left\langle q_{n-1/2}(-\Delta\zeta), v\right\rangle = \left\langle \sigma^{n-1/2}, v\right\rangle, \tag{4.7}$$

where $\sigma^{n-1/2} = \sigma_1^{n-1/2} + \sigma_2^{n-1/2} + \sigma_3^{n-1/2} + \sigma_4^{n-1/2}$ with

$$\sigma_1^{n-1/2} = u_t(t_{n-1/2}) - \partial_t u^n, \quad \sigma_2^{n-1/2} = -\varepsilon_{n-1/2}(\Delta u), \quad \sigma_3^{n-1/2} = \partial_t \eta_n,$$

and

$$\sigma_4^{n-1/2} = \frac{k^4}{16} a_0^2 \frac{\partial^4[\partial_t \eta^n - \partial_t u^n]}{\partial x^2 \partial y^2}.$$

Choose $v = \zeta^{n-1/2}$ in (4.7). Then

$$\left\langle \partial_t \zeta^n, \zeta^{n-1/2}\right\rangle = \frac{1}{2}\partial_t \left\langle \zeta^n, \zeta^n\right\rangle,$$

and

$$\left\langle \frac{\partial^4 \partial_t \zeta^n}{\partial x^2 \partial y^2}, \zeta^{n-1/2} \right\rangle = \frac{1}{2} \partial_t \left\langle \frac{\partial^4 \zeta^n}{\partial x^2 \partial y^2}, \zeta^n \right\rangle.$$

On substituting these expressions into (4.7), we multiply the resulting equation by $2k$ and then sum from $n = 1, \ldots, m$, $1 \le m \le J$, to obtain

$$\begin{aligned} (4.8) \qquad & |\zeta^m|_h^2 + a_0^2 \frac{k^4}{16} \left\langle \frac{\partial^4 \zeta^m}{\partial x^2 \partial y^2}, \zeta^m \right\rangle + 2k \sum_{n=1}^{m} \left\langle q_{n-1/2}(-\Delta\zeta), \zeta^{n-1/2} \right\rangle \\ & \le |\zeta^0|_h^2 + a_0^2 \frac{k^4}{16} \left\langle \frac{\partial^4 \zeta^0}{\partial x^2 \partial y^2}, \zeta^0 \right\rangle + 2k \sum_{n=1}^{m} |\sigma^{n-1/2}|_h \left(|\zeta^n|_h + |\zeta^{n-1}|_h \right). \end{aligned}$$

Using [9, equation (3.7)] and the positivity property (4.3), it can be shown that

$$\sum_{n=1}^{m} \left\langle q_{n-1/2}(-\Delta\zeta), \zeta^{n-1/2} \right\rangle \ge 0.$$

The second term on the left-hand side of (4.8) is nonnegative from (3.19), and the second term on the right-hand side is bounded as in (3.23). Then we obtain

$$|\zeta^m|_h^2 \le C \left(|\zeta^0|_h^2 + k^4 h^{-1} \|\zeta^0\|_{H^1} |\zeta^0|_h + k \sum_{n=1}^{m} |\sigma^{n-1/2}|_h \left[|\zeta^n|_h + |\zeta^{n-1}|_h \right] \right).$$

With

$$|\zeta^N|_h = \max_{0 \le m \le J} |\zeta^m|_h,$$

we obtain

$$|\zeta^N|_h^2 \le C \left(|\zeta^0|_h + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{J} |\sigma^{n-1/2}|_h \right) |\zeta^N|_h,$$

and hence

$$(4.9) \qquad |\zeta^J|_h \le |\zeta^N|_h \le C \left(|\zeta^0|_h + k^4 h^{-1} \|\zeta^0\|_{H^1} + k \sum_{n=1}^{J} |\sigma^{n-1/2}|_h \right).$$

As in (3.25), the first two terms on the right-hand side of (4.9) are bounded by

$$(4.10) \qquad C \left(h^{r+1} + k^4 h^{r-1} \right) \|u_0\|_{H^{r+3}}.$$

Thus, it remains to estimate the last term on the right-hand side of (4.9). Using Taylor's theorem with integral remainder, we obtain

$$(4.11) \qquad k \sum_{n=1}^{J} |\sigma_1^{n-1/2}|_h \le C k^2 \int_0^T \|u_{ttt}\|_{L^\infty} \, ds.$$

Then we use the quadrature error (4.6) to obtain

$$\begin{aligned} |\varepsilon_{n-1/2}(\Delta u)|_h \le C \Bigg(& k \int_{t_{n-1}}^{t_{n-1/2}} \left[\|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty} \right] ds \\ & + k^2 \sum_{j=1}^{n-1} \int_{t_{j-1}}^{t_j} \left[\|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty} + \|\Delta u_{tt}\|_{L^\infty} \right] ds \Bigg), \end{aligned}$$

and hence

$$k\sum_{n=1}^{J}|\sigma_2^{n-1/2}|_h \le Ck^2\int_0^T \left(\|\Delta u\|_{L^\infty}+\|\Delta u_t\|_{L^\infty}+\|\Delta u_{tt}\|_{L^\infty}\right)\,ds. \tag{4.12}$$

The terms involving $\sigma_3^{n-1/2}$ and $\sigma_4^{n-1/2}$ are bounded as in (3.29) and (3.30), respectively. If we substitute these bounds, (4.10)–(4.12), into (4.9) and use the equivalence of the norms $\|\cdot\|_{L^2}$ and $|\cdot|_h$ on $\mathcal{M}_r(\delta)$, we obtain

$$\begin{aligned}\|\zeta^J\|_{L^2} \le C\Bigg(&\left[h^{r+1}+k^4h^{r-1}\right]\|u_0\|_{H^{r+3}}+\left[h^{r+1}+k^4h^{r-3}\right]\int_0^T\|u_t\|_{H^{r+3}}\,ds\\ &+k^2\int_0^T\left[\|\Delta u\|_{L^\infty}+\|\Delta u_t\|_{L^\infty}+\|\Delta u_{tt}\|_{L^\infty}+\|u_{ttt}\|_{L^\infty}\right]ds\\ &+k^4\int_0^T\left\|\frac{\partial^4 u_t}{\partial x^2\partial y^2}\right\|_{L^\infty}ds\Bigg).\end{aligned} \tag{4.13}$$

The triangle inequality, Lemma 2.1, and (4.13) then yield the desired result. ∎

5. The second order ADI BDF OSC scheme. First we define the trapezoidal rule

$$q_n(\phi)=\sum_{j=0}^{n}\omega_{nj}\phi^j \approx \int_0^{t_n} a(t_n-s)\phi(s)\,ds,$$

where $w_{nn}=\frac{1}{2}ka_0$, $w_{n0}=\frac{1}{2}ka_n$, and $w_{nj}=ka_{n-j}, 1\le j\le n-1$. If $a\in C([0,T])$ and (1.4) holds, then the quadrature rule $q_n(\phi)$ is ω_0-positive [15]; that is,

$$k\sum_{n=1}^{m}q_n(\phi)\phi^n \ge -\omega_0(\phi^0)^2, \quad 1\le m\le J, \tag{5.1}$$

where $\omega_0=k^2a_0/4$. Further, if $a\in C^2([0,T])$, then

$$|\varepsilon_n(\phi)|\le Ck^2\int_0^{t_n}\left|\frac{\partial^2}{\partial s^2}[a(t_n-s)\phi(s)]\right|ds, \quad 0\le t_n\le T, \tag{5.2}$$

where

$$\varepsilon_n(\phi)=q_n(\phi)-\int_0^{t_n}a(t_n-s)\phi(s)ds.$$

The second order BDF OSC scheme for the solution of (1.1)–(1.3) consists of determining $\{U^n\}_{n=0}^J$ satisfying

$$\begin{aligned}&\partial_t U^1=q_1(\Delta U)+f^1 \quad \text{on } \mathcal{G},\\ &D_tU^n=q_n(\Delta U)+f^n \quad \text{on } \mathcal{G}, \qquad n=2,\dots,J,\end{aligned} \tag{5.3}$$

where

$$D_t\phi^n=\frac{3\phi^n-4\phi^{n-1}+\phi^{n-2}}{2k}=\frac{3}{2}\partial_t\phi^n-\frac{1}{2}\partial_t\phi^{n-1},$$

and U^0 satisfies (3.10). The second order ADI BDF OSC scheme then takes the form

$$\partial_t U^1 - \omega_{11}\Delta U^1 + k^2\omega_{11}^2 \frac{\partial^4[\partial_t U^1]}{\partial x^2 \partial y^2} = \omega_{10}\Delta U^0 + f^1, \tag{5.4}$$

$$\begin{aligned}\partial_t U^n - \frac{2}{3}\omega_{nn}\Delta U^n + \frac{4}{9}k^2\omega_{nn}^2 \frac{\partial^4[\partial_t U^n]}{\partial x^2 \partial y^2} \\ = \frac{1}{3}\partial_t U^{n-1} + \frac{2}{3}f^n + \frac{2}{3}\sum_{j=0}^{n-1}\omega_{nj}\Delta U^j, \quad n = 2, \dots, J,\end{aligned} \tag{5.5}$$

or

$$\begin{aligned}&\partial_t U^1 + k^2\omega_{11}^2 \frac{\partial^4[\partial_t U^1]}{\partial x^2 \partial y^2} = q_1(\Delta U) + f^1 \quad \text{on } \mathcal{G}, \\ &D_t U^n + \frac{2}{3}k^2\omega_{nn}^2 \frac{\partial^4[\partial_t U^n]}{\partial x^2 \partial y^2} = q_n(\Delta U) + f^n \quad \text{on } \mathcal{G}, \qquad n = 2, \dots, J.\end{aligned} \tag{5.6}$$

THEOREM 5.1. *Let u and $\{U_n\}_{n=0}^J$ denote the solutions of* (1.1)–(1.3) *and* (5.6), *respectively. Assume that $a \in C^2([0,T])$ and satisfies* (1.4). *Then*

$$\begin{aligned}\|u(t_J) - U^J\|_{L^2} \le C\Bigg(&\left[h^{r+1} + kh^r\right]\|u\|_{L^\infty(H^{r+3})} + \left[h^{r+1} + k^4h^{r-3}\right]\|u_t\|_{L^1(H^{r+3})} \\ &+ k^2\left[\|u_{tt}\|_{L^\infty(L^\infty)} + \|u_{ttt}\|_{L^1(L^\infty)} + \|\Delta u\|_{L^1(L^\infty)} + \|\Delta u_t\|_{L^1(L^\infty)} + \|\Delta u_{tt}\|_{L^1(L^\infty)}\right] \\ &+ k^4\left\|\frac{\partial^4 u_t}{\partial x^2 \partial y^2}\right\|_{L^1(L^\infty)}\Bigg),\end{aligned}$$

provided U^0 is chosen so that (3.10) *is satisfied.*

Proof. As before, we write

$$u(t_n) - U^n = [u(t_n) - W^n] - [U^n - W^n] = \eta^n - \zeta^n$$

and estimate ζ^n. Following the approach of earlier sections, it is easy to see that, for $n = 2, \dots, J$,

$$\langle D_t\zeta^n, \zeta^n\rangle + \frac{2}{3}k^2\omega_{nn}^2\left\langle \frac{\partial^4[\partial_t\zeta^n]}{\partial x^2\partial y^2}, \zeta^n\right\rangle + \langle q_n(-\Delta\zeta), \zeta^n\rangle = \langle \sigma^n, \zeta^n\rangle, \tag{5.7}$$

where $\sigma^n = \sigma_1^n + \sigma_2^n + \sigma_3^n + \sigma_4^n$ with

$$\sigma_1^n = u_t(t_n) - D_t u(t_n), \quad \sigma_2^n = -\varepsilon_n(\Delta u), \quad \sigma_3^n = \frac{2}{3}D_t\eta^n,$$

and

$$\sigma_4^n = \frac{2}{3}k^2\omega_{nn}^2\frac{\partial^4}{\partial x^2\partial y^2}[\partial_t\eta^n - \partial_t u(t_n)].$$

Also, for $n = 1$,

$$\left\langle \partial_t\zeta^1, \zeta^1\right\rangle + k^2\omega_{11}^2\left\langle \frac{\partial^4[\partial_t\zeta^1]}{\partial x^2\partial y^2}, \zeta^1\right\rangle + \left\langle q_1(-\Delta\zeta), \zeta^1\right\rangle = \left\langle \sigma^1, \zeta^1\right\rangle, \tag{5.8}$$

where $\sigma^1 = \sigma_1^1 + \sigma_2^1 + \sigma_3^1 + \sigma_4^1$ with

$$\sigma_1^1 = u_t(t_1) - \partial_t u(t_1), \quad \sigma_2^1 = -\varepsilon_1(\Delta u), \quad \sigma_3^1 = \partial_t \eta^1,$$

and

$$\sigma_4^1 = k^2\omega_{11}^2 \frac{\partial^4}{\partial x^2 \partial y^2}[\partial_t \eta^1 - \partial_t u(t_1)].$$

Then on summing (5.7) for $n = 2$ to $n = m$, $1 \le m \le J$, adding (5.8), and multiplying the resulting equation by k,

$$k\left\langle \partial_t \zeta^1, \zeta^1 \right\rangle + k\sum_{n=2}^{m} \langle D_t \zeta^n, \zeta^n \rangle + \frac{k^5}{6} a_0^2 \sum_{n=2}^{m} \left\langle \frac{\partial^4[\partial_t \zeta^n]}{\partial x^2 \partial y^2}, \zeta^n \right\rangle + \frac{k^5}{4} a_0^2 \left\langle \frac{\partial^4[\partial_t \zeta^1]}{\partial x^2 \partial y^2}, \zeta^1 \right\rangle + k\sum_{n=1}^{m} \langle q^n(-\Delta\zeta), \zeta^n \rangle = k\sum_{n=1}^{m} \langle \sigma^n, \zeta^n \rangle . \tag{5.9}$$

With $\delta_k U^n = U^n - U^{n-k},\ k = 1, 2$, we have

$$kD_t \zeta^n = \frac{3}{2}\zeta^n - 2\zeta^{n-1} + \frac{1}{2}\zeta^{n-2} = 2\delta_1 \zeta^n - \frac{1}{2}\delta_2 \zeta^n,$$

and

$$2\langle \delta_k \zeta^n, \zeta^n \rangle = \delta_k |\zeta^n|_h^2 + |\delta_k \zeta^n|_h^2.$$

Using these results, we have

$$k\sum_{n=2}^{m} \langle D_t \zeta^n, \zeta^n \rangle = \sum_{n=2}^{m} \left(\delta_1 |\zeta^n|_h^2 - \frac{1}{4}\delta_2 |\zeta^n|_h^2 \right) + \sum_{n=2}^{m} \left(|\delta_1 \zeta^n|_h^2 - \frac{1}{4}|\delta_2 \zeta^n|_h^2 \right). \tag{5.10}$$

The first term on the right-hand side of (5.10) becomes

$$\sum_{n=2}^{m} \left(\delta_1 |\zeta^n|_h^2 - \frac{1}{4}\delta_2 |\zeta^n|_h^2 \right) = \frac{3}{4}|\zeta^m|_h^2 - \frac{1}{4}|\zeta^{m-1}|_h^2 - \frac{3}{4}|\zeta^1|_h^2 + \frac{1}{4}|\zeta^0|_h^2. \tag{5.11}$$

Since $\delta_2 \zeta^n = \delta_1 \zeta^n + \delta_1 \zeta^{n-1}$ and $(a+b)^2 \le 2(a^2 + b^2), a, b \in \mathcal{R}$, we bound the second term on the right-hand side of (5.10) in the following way:

$$\begin{aligned} \sum_{n=2}^{m} \left(|\delta_1 \zeta^n|_h^2 - \frac{1}{4}|\delta_2 \zeta^n|_h^2 \right) &\ge \sum_{n=2}^{m} \left(|\delta_1 \zeta^n|_h^2 - \frac{1}{4}\left[|\delta_1 \zeta^n|_h + |\delta_1 \zeta^{n-1}|_h^2 \right]^2 \right) \\ &\ge \sum_{n=2}^{m} \left(|\delta_1 \zeta^n|_h^2 - \frac{1}{2}\left[|\delta_1 \zeta^n|_h^2 + |\delta_1 \zeta^{n-1}|_h \right]^2 \right) \\ &= \frac{1}{2}\sum_{n=2}^{m} \left(|\delta_1 \zeta^n|_h^2 - |\delta_1 \zeta^{n-1}|_h^2 \right) \\ &= \frac{1}{2}\left(|\delta_1 \zeta^m|_h^2 - |\delta_1 \zeta^1|_h^2 \right). \end{aligned} \tag{5.12}$$

Also,

$$k\left\langle \partial_t \zeta^1, \zeta^1 \right\rangle = \frac{1}{2}\left[|\zeta^1|_h^2 - |\zeta^0|_h^2 + |\delta_1 \zeta^1|_h^2 \right]. \tag{5.13}$$

Combining (5.10)–(5.13), we obtain

$$
\begin{aligned}
(5.14)\qquad & k\left\langle \partial_t\zeta^1,\zeta^1\right\rangle + k\sum_{n=2}^{m}\left\langle D_t\zeta^n,\zeta^n\right\rangle \geq \frac{1}{2}\left[|\zeta^1|_h^2-|\zeta^0|_h^2+|\delta_1\zeta^1|_h^2\right]\\
&+\left(\frac{3}{4}|\zeta^m|_h^2-\frac{1}{4}|\zeta^{m-1}|_h^2-\frac{3}{4}|\zeta^1|_h^2+\frac{1}{4}|\zeta^0|_h^2\right)+\frac{1}{2}\left(|\delta_1\zeta^m|_h^2-|\delta_1\zeta^1|_h^2\right)\\
&\geq \frac{3}{4}|\zeta^m|_h^2-\frac{1}{4}\left(|\zeta^{m-1}|_h^2+|\zeta^1|_h^2+|\zeta^0|_h^2\right).
\end{aligned}
$$

Now, on using [9, equation (6.37)] and (5.1),

$$
\begin{aligned}
(5.15)\qquad k\sum_{n=1}^{m}\left\langle q^n(-\Delta\zeta),\zeta^n\right\rangle &= k\sum_{n=1}^{m}\sum_{j=0}^{n}\omega_{nj}\left\langle -\Delta\zeta^j,\zeta^n\right\rangle\\
&\geq -\omega_0^2\left\langle -\Delta\zeta^0,\zeta^0\right\rangle \geq -Ck^4\left\|\zeta^0\right\|_{H^1}^2,
\end{aligned}
$$

since $\omega_0 = k^2a_0/4$ and, from [9, Lemma 3.2],

$$\left\langle -\Delta\zeta^0,\zeta^0\right\rangle \leq C\|\zeta^0\|_{H^1}^2.$$

Multiplying (5.9) by 4/3 and using (3.17), (5.14), and (5.15), we obtain

$$
\begin{aligned}
(5.16)\qquad & |\zeta^m|_h^2+\frac{k^4}{9}a_0^2\left\langle\frac{\partial^4\zeta^m}{\partial x^2\partial y^2},\zeta^m\right\rangle+\frac{k^4}{18}a_0^2\left\langle\frac{\partial^4\zeta^1}{\partial x^2\partial y^2},\zeta^1\right\rangle\\
&\leq \frac{1}{3}\left[|\zeta^{m-1}|_h^2+|\zeta^1|_h^2+|\zeta^0|_h^2\right]\\
&\quad+\frac{4}{3}k\sum_{n=1}^{m}|\sigma^n|_h\,|\zeta^n|_h+Ck^4\|\zeta^0\|_{H^1}^2+\frac{k^4}{6}a_0^2\left\langle\frac{\partial^4\zeta^0}{\partial x^2\partial y^2},\zeta^0\right\rangle.
\end{aligned}
$$

The second and third terms on the left-hand side are positive from (3.19). Setting

$$|\zeta^N|_h=\max_{0\leq m\leq J}|\zeta^m|_h,$$

we have

$$
\begin{aligned}
(5.17)\qquad |\zeta^N|_h^2 &\leq \frac{1}{3}|\zeta^N|_h^2+\frac{1}{3}\left[|\zeta^1|_h+|\zeta^0|_h+4k\sum_{n=1}^{J}|\sigma^n|_h\right]|\zeta^N|_h\\
&\quad+Ck^4\|\zeta^0\|_{H_1}^2+\frac{k^4}{6}a_0^2\left\langle\frac{\partial^4\zeta^0}{\partial x^2\partial y^2},\zeta^0\right\rangle.
\end{aligned}
$$

Thus, using (3.22), we obtain

$$
\begin{aligned}
(5.18)\quad |\zeta^N|_h^2 &\leq \left(\frac{1}{2}\left[|\zeta^1|_h+|\zeta^0|_h+4k\sum_{n=1}^{J}|\sigma^n|_h\right]\right)|\zeta^N|_h+Ck^4\|\zeta^0\|_{H^1}^2\\
&\leq \frac{1}{2}\left(\frac{1}{2}\left[|\zeta^1|_h+|\zeta^0|_h+4k\sum_{n=1}^{J}|\sigma^n|_h\right]\right)^2+Ck^4\|\zeta^0\|_{H^1}^2+\frac{1}{2}|\zeta^N|_h^2,
\end{aligned}
$$

so that

$$(5.19)\qquad |\zeta^J|_h\leq|\zeta^N|_h\leq\frac{1}{2}\left(|\zeta^1|_h+|\zeta^0|_h\right)+2k\sum_{n=1}^{J}|\sigma^n|_h+Ck^2\|\zeta^0\|_{H^1}.$$

From (5.8),

$$\left\langle \zeta^1-\zeta^0,\zeta^1\right\rangle+\frac{k^4}{4}a_0^2\left\langle \frac{\partial^4(\zeta^1-\zeta^0)}{\partial x^2\partial y^2},\zeta^1\right\rangle+k\left\langle q_1(-\Delta\zeta^1),\zeta^1\right\rangle=k\left\langle \sigma^1,\zeta^1\right\rangle.$$

Using (3.16) and (3.17) in the first and second terms, respectively, and bounding the third term as in (5.15), we obtain

$$|\zeta^1|_h^2\le C\left(|\zeta^0|_h^2+k^4\left\langle \frac{\partial^4\zeta^0}{\partial x^2\partial y^2},\zeta^0\right\rangle+k^4\|\zeta^0\|_{H^1}^2+k^2|\sigma^1|_h^2\right).$$

Thus, using (3.22),

$$|\zeta^1|_h\le C\left(|\zeta^0|_h+k^2\|\zeta^0\|_{H^1}+k|\sigma^1|_h\right).$$

On substitution into (5.19), it follows that

$$|\zeta^J|_h\le C\left(|\zeta^0|_h+k^2\|\zeta^0\|_{H^1}+Ck\sum_{n=1}^{J}|\sigma^n|_h\right). \tag{5.20}$$

To complete the proof, we estimate the term

$$k\sum_{n=1}^{J}|\sigma^n|_h.$$

First,

$$k\sum_{n=2}^{J}|\sigma_1^n|_h\le Ck^2\int_k^T\|u_{ttt}\|_{L^\infty}\,ds,$$

and

$$k|\sigma_1^1|_h\le Ck\int_0^k\|u_{tt}\|_{L^\infty}\,ds.$$

Since $a\in C^2([0,T])$, we obtain

$$k\sum_{n=1}^{J}|\sigma_2^n|_h\le Ck^2\int_0^T\left[\|\Delta u\|_{L^\infty}+\|\Delta u_t\|_{L^\infty}+\|\Delta u_{tt}\|_{L^\infty}\right]ds.$$

Following the argument in (3.29), we have

$$k\sum_{n=2}^{J}|\sigma_3^n|_h\le Ch^{r+1}\int_k^T\|u_t\|_{H^{r+3}}\,ds,$$

and

$$k|\sigma_3^1|_h\le Ch^{r+1}\int_0^k\|u_t\|_{H^{r+3}}\,ds.$$

The term

$$k\sum_{n=1}^{J}|\sigma_4^n|_h$$

is bounded as in (3.30). Thus, substituting into (5.20) and using the equivalence of the norms $\|\cdot\|_{L^2}$ and $|\cdot|_h$ on $\mathcal{M}_r(\delta)$, we obtain

$$\|\zeta^J\|_{L^2} \le C\left(\left[h^{r+1}+kh^r\right]\|u_0\|_{H^{r+3}} + \left[h^{r+1}+k^4h^{r-3}\right]\int_0^T \|u_t\|_{H^{r+3}}\,ds \right. \tag{5.21}$$
$$+ k\int_0^k \|u_{tt}\|_{L^\infty}\,ds + k^2\int_0^T \left[\|u_{ttt}\|_{L^\infty} + \|\Delta u\|_{L^\infty} + \|\Delta u_t\|_{L^\infty} + \|\Delta u_{tt}\|_{L^\infty}\right] ds$$
$$\left. + k^4\int_0^T \left\|\frac{\partial^4 u_t}{\partial x^2\partial y^2}\right\|_{L^\infty}\right).$$

An application of the triangle inequality with Lemma 2.1 and (5.21) completes the proof. ∎

6. Numerical results. We present numerical results obtained using the ADI Crank–Nicolson OSC scheme (4.5) and the second order ADI BDF OSC scheme (5.4)–(5.5). In our test problem, the kernel $a(t) = e^{-t}$ and the forcing function $f(x, y, t)$ is chosen so that

$$u(x, y, t) = e^{xy+t}xy(x-1)(y-1)$$

is the exact solution of the partial integro-differential equation (PIDE) problem.

In the implementation of the ADI methods, we use the space of tensor products of piecewise Hermite cubics, $\mathcal{M}_3(\delta)$, with standard value and scaled slope basis functions defined on uniform partitions $\{x_i\}_{i=0}^{N_x^{(l)}} = \{y_j\}_{j=0}^{N_y^{(l)}}$ of $[0, 1]$ with $N_x^{(l)} = N_y^{(l)} = N_l$; see [6]. We present spatial errors in various norms and the corresponding convergence rates determined by the formula

$$\text{Convergence rate} \approx \frac{\log(\varepsilon_l/\varepsilon_{l+1})}{\log(h_l/h_{l+1})},$$

where the stepsize $h_l = 1/N_l$ and ε_l is the norm of the error with $h = h_l$.

The initial condition can be approximated using either the Gauss or the Hermite interpolant of u_0; the results presented were obtained using the Gauss interpolant. We select $k_l = h_l^2$ ($J_l = N_l^2$) to verify the second order accuracy in t and fourth order accuracy in space for both methods.

The results for the ADI Crank–Nicolson OSC method and the second order ADI BDF OSC scheme are presented in Tables 6.1–6.3 and Tables 6.4–6.6, respectively, at $T = 1$. Specifically, the L^∞ and L^2 errors and the corresponding rates of convergence for the respective schemes are shown in Tables 6.1 and 6.4.

In Tables 6.2 and 6.5, the L^∞ errors in u_x and u_y, the H^1 errors, and the corresponding rates of convergence for the two schemes are given. The L^∞ errors are estimated by taking the maximum error at 10 by 10 points in each subrectangle $[x_{i-1}, x_i] \times [y_{j-1}, y_j]$. Finally, in Tables 6.3 and 6.6, the maximum absolute value errors in u, u_x, and u_y at the partition nodes together with the corresponding rates of convergence for the two schemes are presented.

The numerical results shown in Tables 6.1 and 6.3 indicate that the rate of convergence corresponding to the L^2 error is consistent with the theory for the two schemes (cf. Theorems 4.1 and 5.1), where we have taken $k = h^2$. One would also expect the rate of convergence using the H^1 error to be 3 for both schemes. This can be observed in the last columns of Tables 6.2 and 6.5.

20	0.550–06	4.001	0.324–05	3.990	0.324–05	3.990

For each scheme, the rates of convergence in u, u_x, and u_y when using the L^∞ error are $4, 3$, and 3, respectively (cf. Tables 6.1 and 6.4 and 6.2 and 6.5).

The results in Tables 6.3 and 6.6 demonstrate that, for each scheme, the phenomenon of superconvergence is observed; that is, the rates of convergence in the maximum norm error at the nodes in u_x and u_y are approximately 4 in each case.

It should be noted that, throughout, the errors in both methods are very similar.

7. Concluding remarks. We have formulated and analyzed ADI OSC methods for the solution of a PIDE with a positive-type memory term under smoothness conditions which yield optimal error estimates. The analysis in the case of nonsmooth problems is a topic for future study. Numerical results support the analysis and also exhibit optimal convergence and superconvergence phenomena not proved in the present paper. In fact, while superconvergence is frequently observed in numerical implementations of OSC methods, very little analysis has been produced to justify it; see, for example, [1].

In this paper, the problem is linear, and the spatial domain is assumed to be the unit square. Using the approach of [3], it may be possible to extend the present ADI methods to nonlinear equations in rectangular polygons.

EXPONENTIALLY CONVERGENT DUHAMEL-LIKE ALGORITHMS FOR DIFFERENTIAL EQUATIONS WITH AN OPERATOR COEFFICIENT POSSESSING A VARIABLE DOMAIN IN A BANACH SPACE*

T. YU. BOHONOVA†, I. P. GAVRILYUK‡, V. L. MAKAROV§, AND V. VASYLYK§

Abstract. A suitable abstract setting of an initial value problem for the first order operator differential equation is introduced for the case when both the unbounded operator coefficient and its domain can depend on the differentiation variable t. A new exponentially convergent algorithm is proposed. The algorithm is based on a generalization of the Duhamel integral for vector-valued functions. The Duhamel-like technique makes it possible to translate the initial problem to an integral equation and then approximate it with exponential accuracy. The theoretical results are illustrated by examples associated with the heat transfer boundary value problems.

Key words. first order differential equations in Banach space, operator coefficient with a variable domain, Duhamel's integral, operator exponential, exponentially convergent algorithms

1. Introduction.

This paper deals with a special class of parabolic partial differential equations with time-dependent boundary conditions in an abstract setting, which are associated with the first order differential equation in a Banach space X

$$\frac{du(t)}{dt} + A(t)u(t) = f(t), \quad u(0) = u_0. \tag{1.1}$$

Here t is a real variable, the unknown function $u(t)$ and the given function $f(t)$ take values in X, and $A(t)$ is a given function whose values are densely defined, closed linear operators in X with domains $D(A,t)$ depending on the parameter t.

In some special cases it is possible to translate problem (1.1) to an operator differential equation, in which operator coefficient $\tilde{A}$ possesses domain $D(\tilde{A})$ independent of t. For example, let us consider the problem

$$\begin{aligned} &\frac{\partial u(x,t)}{\partial t} = \frac{\partial^2 u}{\partial x^2} + f(x,t), \\ &u_x(0,t) - \alpha(t)u(0,t) = \phi_1(t), \quad u_x(1,t) + \beta(t)u(1,t) = \phi_2(t), \\ &u(x,0) = u_0(x), \end{aligned} \tag{1.2}$$

where f, α, β, ϕ_1, ϕ_2, and u_0 are given smooth functions. This problem belongs to

class (1.1). The operator coefficient A is as follows:

(1.3)
$$D(A,t) = \{u(x) \in H^2(0,1) :\ u'(0) - \alpha(t)u(0) = \phi_1(t),\ u'(1) + \beta(t)u(1) = \phi_2(t)\},$$
$$Au = -u''(x) \quad \forall u \in D(A,t).$$

Substitution of (compare with [17])

$$u(x,t) = e^{r(x,t)}v(x,t) \tag{1.4}$$

with function $r(x,t)$ satisfying

$$r_x(0,t) + \alpha(t) = 0, \quad r_x(1,t) - \beta(t) = 0 \tag{1.5}$$

(one can, for example, choose $r(x,t) = -\alpha(t)\cdot x + \frac{1}{2}[\alpha(t) + \beta(t)]\cdot x^2$) transforms (1.2) into

(1.6)
$$\frac{\partial v(x,t)}{\partial t} = \frac{\partial^2 v}{\partial x^2} + 2r_x(x,t)\frac{\partial v}{\partial x} + (r_{xx} - r_t)v + e^{-r(x,t)}f(x,t),$$
$$v_x(0,t) = e^{-r(0,t)}\phi_1(t), \quad v_x(1,t) = e^{-r(0,t)}\phi_2(t),$$
$$v(x,0) = e^{-r(x,0)}u_0(x).$$

The new operator coefficient $\tilde{A}(t)$ is defined by

(1.7)
$$D(\tilde{A},t) = \{v(x) \in H^2(0,1) :\ v'(0) = e^{-r(0,t)}\phi_1(t),\ v'(1) = e^{-r(1,t)}\phi_2(t)\},$$
$$-\tilde{A}(t)u = v''(x) + 2r_x(x,t)v' + (r_{xx} - r_t)v \quad \forall v \in D(\tilde{A},t).$$

The operator coefficient $\tilde{A}$ becomes more complicated and is not more self-adjoint. However, in the homogeneous case $\phi_1(t) \equiv 0,\ \phi_2(t) \equiv 0$ due to substitution (1.4) we obtain a bounded operator $R(t)$ as the multiplicative operator $R(t) = e^{r(x,t)}$ such that the operator $\tilde{A}(t) = [R(t)]^{-1}AR(t)$ possesses the domain independent of t. Under this and some other assumptions it was shown in [17, 16] that the initial value problem (1.2) has a unique solution. Unfortunately there is not a constructive way to find such an operator $R(t)$ in the general case.

The variable domain of an operator can be described by a separate equation, and then we have an abstract problem of the kind

(1.8)
$$\frac{du(t)}{dt} = A(t)u(t), \quad 0 \le s \le t \le T,$$
$$L(t)u(t) = \Phi(t)u(t) + f(t), \quad 0 \le s \le t \le T,$$
$$u(s) = u_0$$

instead of (1.1). Here $L(t)$ and $\Phi(t)$ are some linear operators defined on the boundary of the spatial domain, and the second equation represents an abstract model of the time-dependent boundary condition. An existence and uniqueness result for this problem was proven in [5]. Incorporating the boundary condition into the definition of the operator coefficient of the first equation, one obtains problem (1.1).

The literature concerning discretizations of such problems in an abstract setting is rather limited (see, e.g., [25], where the Euler difference approximation of the first accuracy order for problem (1.1) with the time-dependent domain was considered, and the references therein). The classical Duhamel integral together with discretization of high accuracy order for the two-dimensional heat equation with the time-dependent inhomogeneous Dirichlet boundary condition was proposed in [13]. It is clear that the discretization (with respect to t) is more complicated than in the case of a t-independent domain $D(A)$, since the inclusion $y_k = y(t_k) \in D(A, t_k)$ of the approximate solution y_k at each discretization point t_k should be additionally checked and guaranteed.

In the present paper we consider the problem

$$\begin{aligned} &\frac{du(t)}{dt} + A(t)u(t) = f(t), \\ &\partial_1 u(t) + \partial_0(t)u(t) = g(t), \\ &u(0) = u_0, \end{aligned} \tag{1.9}$$

where $u(t)$ is the unknown function $u : (0,T) \to D(A) \subset X$ with values in a Banach space X, $f(t)$ is a given measurable function $f : (0,T) \to X$ from $L_q(0,T;X)$ with the norm $\|f\| = \{\int_0^T \|f\|_X^q dt\}^{1/q}$, $A(t) : D(A) \in X$ is a densely defined, closed linear operator in X with a time-independent domain $D(A)$, $g : (0,T) \to Y$ is a given function from $L_q(0,T;Y)$ with values in some other Banach space Y, and $\partial_1 : D(A) \to Y$ (independent of t!), $\partial_0(t) : D(A) \to Y$ (can depend on t!) are linear operators. In applications the second equation above is just the time-dependent boundary condition with appropriate operators ∂_1, ∂_0 acting on the boundary of the spatial domain (see section 6 for examples). For this reason we call this equation an abstract (time-dependent) boundary condition.

Incorporating the boundary condition into the definition of the operator coefficient in the first equation, we get a problem of the type (1.1) with a variable domain. The difficulties of the discretization of problems of this form were mentioned above and were well discussed in [25]. The separation of this condition in (1.9) will allow us below to use an abstract Duhamel-like technique in order to reduce the problem to another one including operators with t-independent domains.

The goal of the present paper is threefold. First, we want to generalize the classical Duhamel integral technique for abstract differential equation (1.9) pursuing a t-independent domain of the operators for the transformed statement. Second, we use this technique for reduction of problem (1.9) to a "boundary" integral equation in the case of t-independent operator coefficient A or to a system of boundary integral equations in the case $A = A(t)$. Finally, there is the task of constructing a temporal discretization (i.e., the discretization in t) of these equations with an exponential convergence order.

The boundary integral equations appearing in the framework of the second task deal with integrals over a simple t-interval, and the integrands are the values of some operators (boundary operators) defined on the boundary of the spatial domain. The studied integral equations differ dramatically from those in the boundary integral/boundary element method. The reason is that the last ones include integrals over a boundary of the spatial domain (see, e.g., [31] and the references therein).

The third aim has as a consequence algorithms of low complexity. Exponentially convergent algorithms were proposed recently for various problems. In [7, 8, 9, 10,

11, 14, 15], such algorithms based on the Dunford–Cauchy integral representation and on the Sinc-quadratures were proposed for parabolic and elliptic solution operators, the Silvester operator equation, the inverse of an elliptic operator, and other operator-valued functions. The paper [21] deals with exponentially convergent algorithms for parabolic partial differential equations based on the Runge–Kutta methods. In [23, 22] exponentially convergent algorithms for inverting Laplace transforms were proposed and justified. But to the authors' best knowledge there are no exponentially convergent temporal discretizations for problems of type (1.1) and (1.9) in the literature.

The paper is organized as follows. In section 2 we start from the case of an operator coefficient A independent of the parameter t. Using the Duhamel-like integral and the operator exponential we reduce problem (1.9) to an abstract boundary integral equation. Using the fixed point iteration we show in section 3 that this integral equation is uniquely solvable and that the iteration sequence converges to the exact solution with the factorial convergence rate. The general case of an operator coefficient $A(t)$ depending on the parameter t is considered in section 4. The Duhamel-like technique allows us to reduce problem (1.9) to a system of two boundary integral equations. In section 4 we introduce a prediscretization of this system. The prediscretization is based on the piecewise constant approximation of the operators involved. By a factorially convergent fixed point iteration we prove the existence and uniqueness result for the system of boundary integral equations. Then, using the piecewise constant prediscretization, the Chebyshev interpolation for unknown functions involved, and the collocation, we derive in section 5 a discretization of the boundary integral equations. The main theorem of this section shows an almost (i.e., within a polynomial factor) exponential convergence of the discretization for analytical input data. In sections 6 and 7 we give some examples of parabolic partial differential equations with time-dependent coefficients and boundary conditions which illustrate our theoretical assumptions and confirm the main results. Section 7 presents a numerical example illustrating the efficiency of our temporal discretization.

2. Duhamel-like technique for the first order differential equations in Banach space. In this section we consider a particular case of problem (1.9),

$$\begin{aligned} &\frac{du(t)}{dt} + Au(t) = f(t), \\ &\partial_1 u(t) + \partial_0(t)u(t) = g(t), \quad u(0) = u_0, \end{aligned} \tag{2.1}$$

where the operator A and its domain $D(A)$ in some Banach space X are independent of t, $f(t)$ is a given measurable function $f : (0,T) \to X$ from the space $L_q(0,T;X)$ with the norm $\|f\| = \{\int_0^T \|f\|_X^q dt\}^{1/q}$, $g : (0,T) \to Y$ is a given function from $L_q(0,T;Y)$ with values in some other Banach space Y, and $\partial_1 : D(A) \to Y$ (independent of t!), $\partial_0(t) : D(A) \to Y$ (can depend on t!) are linear operators.

We represent the solution in the form

$$u(t) = w(t) + v(t), \tag{2.2}$$

with v and w satisfying

$$\begin{aligned} &\frac{dv}{dt} + Av = f(t), \\ &\partial_1 v = 0, \quad v(0) = u_0 \end{aligned} \tag{2.3}$$

and

$$\begin{aligned} &\frac{dw(t)}{dt} + Aw = 0, \\ &\partial_1 w(t) = -\partial_0(t)u(t) + g(t), \\ &w(0) = 0, \end{aligned} \tag{2.4}$$

respectively. Introducing the operator $A^{(1)} : D(A^{(1)}) \to X$ independent of t and defined by

$$\begin{aligned} &D(A^{(1)}) = \{u \in D(A) : \partial_1 u = 0\}, \\ &A^{(1)}u = Au \quad \forall u \in D(A^{(1)}), \end{aligned} \tag{2.5}$$

we can rewrite problem (2.3) also in the form

$$\begin{aligned} &\frac{dv}{dt} + A^{(1)}v = f(t), \\ &v(0) = u_0. \end{aligned} \tag{2.6}$$

We suppose that the operator A is such that the operator $A^{(1)}$ is strongly positive [1, 12, 15] (m-sectorial in the sense of [6]); i.e., there exist a positive constant M_R and a fixed $\theta \in [0, \pi/2)$ such that on the rays from the origin building a sector $\Sigma_\theta = \{z \in \mathbb{C} : |\arg(z)| \le \theta\}$ and outside this sector, the following resolvent estimate holds:

$$\|(zI - A^{(1)})^{-1}\| \le \frac{M_R}{1 + |z|}. \tag{2.7}$$

Then under some assumptions with respect to $f(t)$ the solution of (2.6) can be represented by [26]

$$v(t) = e^{-A^{(1)}t}u_0 + \int_0^t e^{-A^{(1)}(t-\tau)}f(\tau)d\tau. \tag{2.8}$$

Note that problem (2.6) with a strongly positive operator $A^{(1)}$ can also be solved numerically by the recently proposed exponentially convergent algorithm from [15].

Returning to problem (2.4) we introduce the auxiliary function $W(\lambda, t)$ by

$$\begin{aligned} &\frac{\partial W(\lambda,t)}{\partial t} + AW(\lambda,t) = 0, \\ &\partial_1 W(\lambda,t) = -\partial_0(\lambda)u(\lambda) + g(\lambda), \\ &W(\lambda,0) = 0, \end{aligned} \tag{2.9}$$

where the abstract boundary condition is now independent of t. The next result gives a representation of the solution of problem (2.4) through the function W by the so-called Duhamel integral.

THEOREM 2.1. *The solution of problem* (2.4) *with a* t*-dependent boundary condition can be represented through the solution of problem* (2.9) *with a* t*-independent boundary condition by the following Duhamel integral:*

$$w(t) = \frac{d}{dt}\int_0^t W(\lambda, t-\lambda)d\lambda = \int_0^t \frac{\partial}{\partial t}W(\lambda, t-\lambda)d\lambda. \tag{2.10}$$

Proof. Let us show that the function (2.10) in fact satisfies (2.4) (compare with the classical representation by Duhamel's integral [13, 27]).

Actually, the initial condition $w(0) = 0$ obviously holds true. Due to the first representation in (2.10) and (2.9) we have

$$\begin{aligned}\partial_1 w(t) &= \frac{d}{dt}\int_0^t \partial_1 W(\lambda, t-\lambda)d\lambda = \frac{d}{dt}\int_0^t [-\partial_0(\lambda)u(\lambda) + g(\lambda)]d\lambda \\ &= -\partial_0(t)u(t) + g(t);\end{aligned} \tag{2.11}$$

i.e., the boundary condition $\partial_1 w(t) = -\partial_0(t)u(t) + g(t)$ is also fulfilled. Due to the second representation in (2.10) we obtain

$$\begin{aligned}&\frac{dw(t)}{dt} + Aw(t) = \frac{d}{dt}\int_0^t \frac{\partial}{\partial t}W(\lambda, t-\lambda)d\lambda + Aw(t) \\ &= \frac{\partial}{\partial t}W(\lambda, t-\lambda)\Big|_{\lambda=t} + \int_0^t \frac{\partial^2}{\partial t^2}W(\lambda, t-\lambda)d\lambda + \int_0^t \frac{\partial}{\partial t}AW(\lambda, t-\lambda)d\lambda \\ &= -AW(\lambda, t-\lambda)|_{\lambda=t} + \int_0^t \frac{\partial}{\partial t}\left[\frac{\partial}{\partial t}W(\lambda, t-\lambda) + AW(\lambda, t-\lambda)\right]d\lambda = 0;\end{aligned} \tag{2.12}$$

i.e., the first equation in (2.4) holds true, which completes the proof. □

In order to make the boundary condition in (2.9) homogeneous and independent of t, we introduce the operator $B : Y \to D(A)$ by

$$\begin{aligned}A(By) &= 0, \\ \partial_1 By &= y;\end{aligned} \tag{2.13}$$

i.e., $\partial_1 B$ is a projector on Y.

Remark 2.2. In order to show the existence of the operator B, we set $By = v$. Then the problem (2.13) is equivalent to the problem

$$Av = 0,$$

$$\partial_1 v = y.$$

We assume that there exists an operator $E : Y \to D(A)$ such that $\partial_1 Ey = y$ (compare with $E(t)$ from [25]). The existence of this operator for an elliptic operator A is proven in [30, section 5.4, Theorem 5.4.5]. Let us introduce $v_1 = v - Ey \in D(A)$, and then

$$Av_1 = -AEy,$$

$$\partial_1 v_1 = 0.$$

Taking into account (2.5) we have the problem

$$A^{(1)}v_1 = -AEy,$$

which has a solution since operator $A^{(1)}$ is strongly positive. Thus, we have

$$B = (I - [A^{(1)}]^{-1}A)E.$$

Given operator B we change the dependent variable by

$$W(\lambda,t)=B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]+W_1(\lambda,t). \tag{2.14}$$

For the new dependent variable we have the problem

$$\begin{aligned}&\frac{\partial W_1(\lambda,t)}{\partial t}+AW_1(\lambda,t)=0,\\ &\partial_1 W_1(\lambda,t)=0,\\ &W_1(\lambda,0)=-B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]\end{aligned} \tag{2.15}$$

or, equivalently,

$$\begin{aligned}&\frac{\partial W_1(\lambda,t)}{\partial t}+A^{(1)}W_1(\lambda,t)=0,\\ &W_1(\lambda,0)=-B[-\partial_0(\lambda)u(\lambda)+g(\lambda)].\end{aligned} \tag{2.16}$$

Using the operator exponential, the solution of this problem can be given in the form

$$W_1(\lambda,t)=-e^{-A^{(1)}t}B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]. \tag{2.17}$$

Now taking into account the substitution (2.14) and the last representation, we obtain

$$W(\lambda,t)=-[e^{-A^{(1)}t}-I]B[-\partial_0(\lambda)u(\lambda)+g(\lambda)], \tag{2.18}$$

where $I:X\to X$ is the identity operator. Due to relations (2.2), (2.10), and (2.18) we arrive at the representation

$$\begin{aligned}u(t)&=v(t)+\frac{\partial}{\partial t}\int_0^t W(\lambda,t-\lambda)d\lambda\\ &=v(t)-\int_0^t\frac{\partial}{\partial t}\left\{e^{-A^{(1)}(t-\lambda)}B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]\right\}d\lambda\end{aligned} \tag{2.19}$$

and further the following boundary integral equation:

$$\partial_0(t)u(t)=\partial_0(t)v(t)-\partial_0(t)\int_0^t\frac{\partial}{\partial t}\left\{e^{-A^{(1)}(t-\lambda)}B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]\right\}d\lambda. \tag{2.20}$$

The last equation can also be written in the form

$$\partial_0(t)u(t)=\partial_0(t)v(t)+\partial_0(t)\int_0^t A^{(1)}e^{-A^{(1)}(t-\lambda)}B[-\partial_0(\lambda)u(\lambda)+g(\lambda)]d\lambda. \tag{2.21}$$

After determining $\partial_0(t)u(t)$ from (2.21), we can find the solution of problem (2.1) by (2.8), (2.19) using the exponentially convergent algorithms for the operator exponential from [15, 10].

Let us introduce the operator-valued kernel $K(t-\tau)=A^{(1)}e^{-A^{(1)}(t-\tau)}B$, the functions $\theta(t)=\partial_0(t)u(t)$ and $F(t)=\partial_0(t)v(t)+\partial_0(t)\int_0^t A^{(1)}e^{-A^{(1)}(t-\lambda)}Bg(\lambda)d\lambda$, and the operator $V:L_q(0,T;D(A))\to L_q(0,T;Y)$ defined by

$$V(t)y(\cdot)=\partial_0(t)\int_0^t K(t-\lambda)y(\lambda)d\lambda. \tag{2.22}$$

Then (2.20) can be written in the fixed point iteration form

$$\theta(t) = V(t)\theta(\cdot) + F(t). \tag{2.23}$$

3. Existence and uniqueness of the solution of the integral equation. In order to prove the existence and uniqueness result for the equivalent equations (2.20), (2.21), and (2.23), we make the following hypotheses (see section 6 for examples):

(A1) There exists a positive constant c such that

$$\|\partial_0(t)\|_{X\to Y} \le c \quad \forall t \in [0,T] \tag{3.1}$$

(compare with H1 from [25]).

(A2) For some $p \ge 1$ it holds that

$$\left[\int_0^t \|A^{(1)}e^{-A^{(1)}(t-\lambda)}B\|^p_{Y\to X}d\lambda\right]^{1/p} \le c \quad \forall t \in [0,T]. \tag{3.2}$$

(A3) The function

$$\begin{aligned} F(t) &= \partial_0(t)v(t) - \partial_0(t)\int_0^t \frac{\partial}{\partial t}e^{-A^{(1)}(t-\lambda)}Bg(\lambda)d\lambda \\ &= \partial_0(t)v(t) + \partial_0(t)\int_0^t A^{(1)}e^{-A^{(1)}(t-\lambda)}Bg(\lambda)d\lambda : (0,T)\to Y \end{aligned} \tag{3.3}$$

belongs to the Banach space $L_q(0,T;Y)$ and

$$\|F\|_{L_q(0,T;Y)} = \left\{\int_0^T \|F(\tau)\|^q_Y d\tau\right\}^{1/q} \le c, \tag{3.4}$$

where q is such that $\frac{1}{p}+\frac{1}{q}=1$ for p defined in (A2).

Let us define the sequences

$$\begin{aligned} \theta_j(t) &= V(t)\theta_{j-1}(\cdot) + F(t), \\ \delta_j(t) &= \theta_j(t) - \theta^*(t), \end{aligned} \tag{3.5}$$

where $\theta^*(t)$ is the exact solution of (2.23).

Now we are in a position to prove the following result.

THEOREM 3.1. *Let conditions* (A1)–(A3) *be fulfilled; then* (2.20) *(or, equivalently,* (2.21), (2.23)) *possesses the unique solution* $\theta^*(t) \in L_q(0,T;Y)$. *This solution is the limit of the sequence* $\{\theta_j(t)\}$ *from* (3.5) *with the factorial convergence, i.e., with the estimate*

$$\|\delta_j(t)\|_{L_q(0,T;Y)} = \|\theta_j(t)-\theta^*(t)\|_{L_q(0,T;Y)} \le \left(\frac{c^{2jq}T^n}{j!}\right)^{1/q}\|\theta_0(t)-\theta^*(t)\|_{L_q(0,T;Y)}. \tag{3.6}$$

For the solution $\theta^*(t) = \partial_0(t)u(t)$ *the following stability estimate holds:*

$$\int_0^t \|\partial_0(\tau)u(\tau)\|^q_Y d\tau \le 2^{q/p}\int_0^t \|F(\tau)\|^q_Y e^{2^{q/p}c^{2q}(t-\tau)}d\tau. \tag{3.7}$$

For the proof of the theorem see Appendix A.

Given the solution $\theta^*(t) = \partial_0(t)u(t)$ of integral equation (2.20), problem (2.1) takes the form

$$\begin{aligned} &\frac{du(t)}{dt} + Au(t) = f(t), \\ &\partial_1 u(t) = g_1(t), \quad u(0) = u_0, \end{aligned} \tag{3.8}$$

with a known function $g_1(t) = \theta^*(t) + g(t)$, and its solution is given by (see (2.19))

$$u(t) = v(t) + \int_0^t \frac{\partial}{\partial t} \left\{ e^{-A^{(1)}(t-\lambda)} B g_1(\lambda) \right\} d\lambda \tag{3.9}$$

and can also be computed with exponential accuracy by algorithms from [15, 10].

4. Generalization to a parameter-dependent operator. Existence and uniqueness result. Let $(X, \|\cdot\|), (\mathcal{W}, \|\cdot\|_{\mathcal{W}}), (Y, \|\cdot\|_Y)$ be three Banach spaces and $\mathcal{W} \subset X$. For each $t \in [0, T]$ we are given a densely defined closed linear unbounded operator $A(t) : \mathcal{W} \to X$ and linear bounded operator $\partial_0(t) : \mathcal{W} \to Y$. We suppose that the domain $D(A(t)) = D(A) \subset \mathcal{W}$ is independent of t.

Let us consider the problem

$$\begin{aligned} &\frac{du(t)}{dt} + A(t)u(t) = f(t), \\ &\partial_1 u(t) + \partial_0(t)u(t) = g(t), \quad t \in (0, T], \\ &u(0) = u_0, \end{aligned} \tag{4.1}$$

where u_0 is a given vector, $f(t)$ is a given vector-valued function, and the operator $\partial_0(t)$ is the product of two operators

$$\partial_0(t) = \mu(t)\partial_0, \tag{4.2}$$

with $\partial_0 : D(A) \to Y$, $\mu(t) : Y \to Y$. We suppose that problem (4.1) possesses a unique solution $u(t)$ for all $t \in (0, T)$ for input data f, g, u_0 from some set including the elements $f = 0, g = 0, u_0 = 0$.

We choose a mesh $\omega_n = \{t_k,\ k = 1, \ldots, n\}$ of n various points on $[0, T]$ and set

$$\begin{aligned} &\overline{A}(t) = A_k = A(t_k), \quad t \in (t_{k-1}, t_k], \\ &\overline{\mu}(t) = \mu_k = \mu(t_k), \quad t \in (t_{k-1}, t_k]. \end{aligned} \tag{4.3}$$

On each subinterval $(t_{k-1}, t_k]$ we define the operator $A_k^{(2)}$ with a t-independent domain by

$$\begin{aligned} &D(A_k^{(2)}) = \{u \in D(A) :\ \partial_1 u + \mu_k \partial_0 u = 0\}, \\ &A_k^{(2)} u = A_k u \quad \forall u \in D(A_k^{(2)}) \end{aligned} \tag{4.4}$$

and the operator $B_k^{(1)} : Y \to D(A)$ by

$$\begin{aligned} &A_k(B_k^{(1)} y) = 0, \\ &(\partial_1 + \mu_k \partial_0) B_k^{(1)} y = y. \end{aligned} \tag{4.5}$$

For all $t \in [0, T)$ we define the operators

$$\begin{aligned} &A^{(2)}(t) = A_k^{(2)}, \quad t \in (t_{k-1}, t_k], \\ &B^{(1)}(t) = B_k^{(1)}, \quad t \in (t_{k-1}, t_k], \quad \forall k = 1, \ldots, n \end{aligned} \tag{4.6}$$

(the existence of $B_k^{(1)}$ can be shown analogously to the existence of B from section 2).

Further, we accept the following hypotheses (see section 6 for examples):

(B1) We suppose the operator $A^{(2)}(t)$ to be strongly positive (see (2.7)).

This assumption implies that there exist a positive constant c and a fixed κ such that (see, e.g., [6, p. 103])

$$\|[A^{(2)}(t)]^{\kappa} e^{-sA^{(2)}(t)}\| \le cs^{-\kappa}, \quad s > 0, \quad \kappa > 0. \tag{4.7}$$

(B2) There exists a real positive ω such that

$$\|e^{-sA^{(2)}(t)}\| \le e^{-\omega s} \quad \forall s, t \in [0, T] \tag{4.8}$$

(see [26, Corollary 3.8, p. 12] for corresponding assumptions on $A(t)$).

We also assume that the following conditions hold:

(B3)

$$\|[A^{(2)}(t) - A^{(2)}(s)][A^{(2)}(t)]^{-\gamma}\| \le c|t - s| \quad \forall t, s, \ 0 \le \gamma \le 1; \tag{4.9}$$

(B4)

$$\|[A^{(2)}(t)]^{\beta}[A^{(2)}(s)]^{-\beta} - I\| \le c|t - s| \quad \forall t, s \in [0, T], \quad \beta \in (0, 1). \tag{4.10}$$

(B5) The operator $\mu(t)\partial_0$ satisfies the following conditions:

$$\begin{aligned} &\|\mu(t) - \mu(t')\|_{Y \to Y} \le M|t - t'|, \\ &\|\partial_0\|_{X \to Y} \le c. \end{aligned} \tag{4.11}$$

(B6) For some $p \ge 1$ and $\gamma \ge 0$ there holds

$$\left[\int_0^t \|[A^{(2)}(\eta)]^{1+\gamma} e^{-A^{(2)}(\eta)(t-\lambda)} B^{(1)}(\eta)\|_{Y \to X}^p d\lambda\right]^{1/p} \le c \quad \forall t, \ \eta \in [0, T]. \tag{4.12}$$

Let us rewrite problem (4.1) in the equivalent form (so-called prediscretization)

$$\begin{aligned} &\frac{du}{dt} + \overline{A}(t)u = [\overline{A}(t) - A(t)]u(t) + f(t), \\ &[\partial_1 + \overline{\mu}(t)\partial_0]u(t) = -[\mu(t) - \overline{\mu}(t)]\partial_0 u(t) + g(t), \quad t \in [0, T], \\ &u(0) = u_0. \end{aligned} \tag{4.13}$$

Note that now all operators on the left-hand side of these equations are constant on each subinterval and piecewise constant on the whole interval $[0, T)$.

From (4.13) analogously to (2.19), (2.21) we deduce

(4.14)

$$u(t) = e^{-A_k^{(2)}(t-t_{k-1})}u(t_{k-1}) + \int_{t_{k-1}}^{t} e^{-A_k^{(2)}(t-\tau)}\{-[A(\tau)-A_k]u(\tau)+f(\tau)\}\,d\tau$$

$$+ \int_{t_{k-1}}^{t} A_k^{(2)} e^{-A_k^{(2)}(t-\lambda)} B_k^{(1)}\{-[\mu(\lambda)-\mu_k]\partial_0 u(\lambda)+g(\lambda)\}d\lambda,$$

$$\partial_0 u(t) = \partial_0 e^{-A_k^{(2)}(t-t_{k-1})}u(t_{k-1})$$

$$+ \partial_0 \int_{t_{k-1}}^{t} e^{-A_k^{(2)}(t-\tau)}\{-[A(\tau)-A_k]u(\tau)+f(\tau)\}\,d\tau$$

$$+ \partial_0 \int_{t_{k-1}}^{t} A_k^{(2)} e^{-A_k^{(2)}(t-\lambda)} B_k^{(1)}\{-[\mu(\lambda)-\mu_k]\partial_0 u(\lambda)+g(\lambda)\}d\lambda,$$

$$t \in [t_{k-1}, t_k], \quad k = 1, \dots, n.$$

Thus, with the Duhamel-like technique we have obtained the system of two integral equations with respect to the unknown functions $u(t)$ and $\partial_0 u(t)$ which is equivalent to (4.1). This system is the starting point for our further investigations and for the numerical algorithm.

In order to prove the existence and uniqueness result it is sufficient to choose in the framework above $n = 1,\ t_0 = 0,\ t_1 = T,\ \overline{A}(t) = A(0) = A$, and $\overline{\mu}(t) = \mu(T)$. In addition, we introduce the vectors

$$\mathcal{U}(t) = \begin{pmatrix} u(t) \\ \theta(t) \end{pmatrix}, \quad \mathcal{U}_n(t) = \begin{pmatrix} u_n(t) \\ \theta_n(t) \end{pmatrix}, \quad \mathcal{F} = \begin{pmatrix} F_1(t) \\ F_2(t) \end{pmatrix} \tag{4.15}$$

and the matrices

(4.16)

$$\mathcal{K}(t,\tau) = \begin{pmatrix} K_{11}(t,\tau) & K_{12}(t,\tau) \\ K_{21}(t,\tau) & K_{22}(t,\tau) \end{pmatrix}, \quad \mathcal{D} = \begin{pmatrix} I & 0 \\ 0 & \partial_0 \end{pmatrix}, \quad \mathcal{E}_\gamma = \begin{pmatrix} [A^{(2)}]^\gamma & 0 \\ 0 & I \end{pmatrix},$$

with

(4.17)

$$K_{11}(t,\tau) = K_{21}(t,\tau) = -e^{-A^{(2)}(t-\tau)}[A(\tau)-A],$$

$$K_{12}(t,\tau) = K_{22}(t,\tau) = -A^{(2)}e^{-A^{(2)}(t-\tau)}B^{(1)}(t)[\mu_k-\mu(\tau)],$$

$$F_1(t) = e^{-A^{(2)}t}u_0 + \int_0^t e^{-A^{(2)}(t-\tau)}f(\tau)d\tau$$

$$+ \operatorname{int}_0^t A^{(2)}e^{-A^{(2)}(t-\lambda)}B^{(1)}g(\lambda)d\lambda, \quad F_2(t) = \partial_0 F_1(t).$$

We also introduce the space $\mathcal{Y}$ of vectors $\mathcal{U} = (u,v)^T$ with the norm

$$\|\mathcal{U}\|_{\mathcal{Y}} = \max\{\|u\|_{L_q(0,T;D([A^{(2)}]^\gamma))}, \|v\|_{L_q(0,T;Y)}\}, \tag{4.18}$$

and we equip the space of matrices $\mathcal{K}(t,\tau)$ from (4.16) with the matrix norm

$$\|\mathcal{K}\|_\infty = \max\{\|K_{1,1}\|_{X\to X} + \|K_{1,2}\|_{Y\to X}, \|K_{2,1}\|_{X\to X} + \|K_{2,2}\|_{Y\to X}\}, \tag{4.19}$$

which is consistent with the vector norm (4.18). Now the system (4.14) with $k = 1,\ t_0 = 0, t_1 = T$ can be written in the form

$$\mathcal{U}(t) = \mathcal{D}\int_0^t \mathcal{K}(t,\tau)\mathcal{U}(\tau)d\tau + \mathcal{F}(t). \tag{4.20}$$

The fixed point iteration for the system (4.20) is given by

$$\mathcal{U}_{j+1}(t) = \mathcal{D}\int_0^t \mathcal{K}(t,\tau)\mathcal{U}_j(\tau)d\tau + \mathcal{F}(t), \quad j = 0, 1, \ldots, \quad \mathcal{U}_0(t) = 0. \tag{4.21}$$

Since the operators $\mathcal{E}_\gamma$ and $\mathcal{D}(t)$ commute, we get from (4.21) that

$$\mathcal{U}_{\gamma,j+1}(t) = \mathcal{D}\int_0^t \mathcal{E}_\gamma\mathcal{K}(t,\tau)\mathcal{E}_\gamma^{-1}\mathcal{U}_{\gamma,j}(\tau)d\tau + \mathcal{F}_\gamma(t), \quad j = 0, 1, \ldots, \quad \mathcal{U}_0(t) = 0, \tag{4.22}$$

where $\mathcal{U}_{\gamma,j}(t) = \mathcal{E}_\gamma\mathcal{U}_j(t)$ and $\mathcal{F}_\gamma(t) = \mathcal{E}_\gamma\mathcal{F}(t)$.

Now we are in a position to formulate the following result (the proof is completely analogous to the one of Theorem 3.1 and is given in Appendix B).

THEOREM 4.1. *Let us assume that the conditions* (B1)–(B6) *are fulfilled; then the system of equations* (4.14) *possesses the unique solution* $\mathcal{U}^*_\gamma(t)$ *in* $\mathcal{Y}$. *This solution is the limit of the sequence* $\mathcal{U}_{\gamma,j}(t)$ *from* (4.22) *with the factorial convergence characterized by the estimate*

$$\|\mathcal{U}_{\gamma,j}(t) - \mathcal{U}^*_\gamma(t)\|_{\mathcal{Y}} \le \left(\frac{c^{2jq}T^j}{j!}\right)^{1/q} \|\mathcal{U}_{\gamma,0}(t) - \mathcal{U}^*_\gamma(t)\|_{\mathcal{Y}}. \tag{4.23}$$

For the solution $\mathcal{U}^*_\gamma(t)$ *the following stability estimate holds:*

$$\int_0^t \|\mathcal{U}^*_\gamma(\tau)\|^q_{\mathcal{Y}} d\tau \le 2^{q/p}\int_0^t \|\mathcal{F}(\tau)\|^q_{\mathcal{Y}} e^{2^{q/p}c^{2q}(t-\tau)}d\tau. \tag{4.24}$$

5. Numerical algorithm. In order to construct a discrete approximation of (4.14) we use the Chebyshev interpolation on the interval $[-1, 1]$ (if it is not the case one can reduce the problem (4.1) to this interval by the variable transform $t = 2t'/T - 1,\ t \in [-1, 1],\ t' \in [0, T]$). We choose a mesh $\omega_n = \{t_k = -\cos\frac{(2k-1)\pi}{2n}, k = 1, \ldots, n\}$ on $[-1, 1]$ of n zeros of Chebyshev orthogonal polynomial $T_n(t)$ and set $\tau_k = t_k - t_{k-1}$. It is well known that (see [28, Chapter 6, Theorem 6.11.12], [29, p. 123])

$$t_{\nu+1} - t_\nu < \frac{\pi}{n}, \quad \nu = 1, \ldots, n,$$

$$\tau = \tau_{max} = \max_{1\le k\le n}\tau_k < \frac{\pi}{n}. \tag{5.1}$$

Let

$$P_{n-1}(t; u) = P_{n-1}u = \sum_{j=1}^n u(t_j)L_{j,n-1}(t),$$

$$P_{n-1}(t; \partial_0 u) = P_{n-1}(\partial_0 u) = \sum_{j=1}^n \partial_0 u(t_j)L_{j,n-1}(t) \tag{5.2}$$

be the Lagrange interpolation polynomials for $u(t)$ and $\partial_0 u(t)$ on the mesh ω_n, where $L_{j,n-1} = \frac{T_n(t)}{T_n'(t_j)(t-t_j)}$, $j = 1, \dots, n$, are the Lagrange fundamental polynomials. For a given vector $v = (v_1, \dots, v_n)$ we introduce the interpolation polynomial

$$P_{n-1}(t; v) = P_{n-1} y = \sum_{j=1}^{n} v_j L_{j,n-1}(t), \tag{5.3}$$

so that $P_{n-1}(t_j; v) = v_j$, $j = 1, 2, \dots, n$. Let $x = (x_1, x_2, \dots, x_n)$ and $y = (y_1, y_2, \dots, y_n)$ be the approximating vectors for $U = (u(t_1), u(t_2), \dots, u(t_n))$ and $\partial U = (\partial_0 u(t_1), \partial_0 u(t_2), \dots, \partial_0 u(t_n))$, respectively; i.e., x_k approximates $u(t_k)$, and y_k approximates $\partial_0 u(t_k)$. Substituting $P_{n-1}(\eta; x)$ for $u(\eta)$ and $P_{n-1}(\eta; y)$ for $\partial_0 u(\lambda)$ and then setting $t = t_k$ in (4.14), we arrive at the following system of linear equations with respect to the unknown elements x_k, y_k:

$$\begin{aligned} x_k &= e^{-A_k^{(2)}\tau_k} x_{k-1} + \sum_{j=1}^{n} \alpha_{kj} x_j + \sum_{j=1}^{n} \beta_{kj} y_j + \phi_k, \\ y_k &= \partial_0 e^{-A_k^{(2)}\tau_k} x_{k-1} + \partial_0 \sum_{j=1}^{n} \alpha_{kj} x_j + \partial_0 \sum_{j=1}^{n} \beta_{kj} y_j + \partial_0 \phi_k, \\ k &= 1, \dots, n, \quad x_0 = u_0, \quad y_0 = \partial_0 u_0, \end{aligned} \tag{5.4}$$

which represents our algorithm. Here we use the notation

$$\begin{aligned} \alpha_{kj} &= \int_{t_{k-1}}^{t_k} e^{-A_k^{(2)}(t_k-\eta)} [A_k - A(\eta)] L_{j,n-1}(\eta) d\eta, \\ \beta_{kj} &= \int_{t_{k-1}}^{t_k} A_k^{(2)} e^{-A_k^{(2)}(t_k-\lambda)} B_k^{(1)} [\mu(\lambda) - \mu_k] L_{j,n-1}(\lambda) d\lambda, \\ \phi_k &= \int_{t_{k-1}}^{t_k} e^{-A_k^{(2)}(t_k-\eta)} f(\eta) d\eta + \int_{t_{k-1}}^{t_k} A_k^{(2)} e^{-A_k^{(2)}(t_k-\lambda)} B_k^{(1)} g(\lambda) d\lambda. \end{aligned} \tag{5.5}$$

Further, for the sake of simplicity we analyze this algorithm for the particular case of problem (4.1), where operator $A(t)$ is independent on t, i.e., $A(t) \equiv A$. In this case we have $\alpha_{kj} = 0$, and system (5.4) takes the form

$$\begin{aligned} x_k &= e^{-A_k^{(2)}\tau_k} x_{k-1} + \sum_{j=1}^{n} \beta_{kj} y_j + \phi_k, \\ y_k &= \partial_0 e^{-A_k^{(2)}\tau_k} x_{k-1} + \partial_0 \sum_{j=1}^{n} \beta_{kj} y_j + \partial_0 \phi_k, \\ k &= 1, \dots, n, \quad x_0 = u_0, \quad y_0 = \partial_0 u_0. \end{aligned} \tag{5.6}$$

Remark 5.1. Under the assumption that $f(t), \mu(t), g(t)$ are polynomials, the calculation of the operators β_{kj} and the elements ϕ_k can be reduced to the calculation of integrals of the kind $I_s = \int_{t_{k-1}}^{t_k} e^{-A_k^{(2)}(t_k-\lambda)} \lambda^s d\lambda$, which can be found by a simple recurrence algorithm: $I_l = -l[A_k^{(2)}]^{-1} I_{l-1} + [A_k^{(2)}]^{-1}(t_k^l I - t_{k-1}^l e^{-A_k^{(2)}\tau_k})$, $l = 1, 2, \dots, s$,

$I_0 = [A_k^{(2)}]^{-1}(I - e^{-A_k^{(2)}\tau_k})$, where the operator exponentials can be computed by the exponentially convergent algorithm from [15].

For the errors $z_x = (z_{x,1}, \dots, z_{x,n})$, $z_y = (z_{y,1}, \dots, z_{y,n})$, with $z_{x,k} = u(t_k) - x_k$ and $z_{y,k} = \partial_0 u(t_k) - y_k$, we have the relations

$$
\begin{aligned}
&z_{x,k} = e^{-A_k\tau_k} z_{x,k-1} + \sum_{j=1}^{n} \beta_{kj} z_{y,j} + \psi_{y,k},\\
&z_{y,k} = \partial_0 e^{-A_k\tau_k} z_{y,k-1} + \partial_0 \sum_{j=1}^{n} \beta_{kj} z_{y,j} + \partial_0 \psi_{y,k},\\
&k = 1, \dots, n, \quad z_{x,0} = 0, \quad z_{y,0} = 0,
\end{aligned}
\tag{5.7}
$$

where

$$
\psi_{y,k} = \int_{t_{k-1}}^{t_k} A_k^{(2)} e^{-A_k^{(2)}(t_k-\eta)} B_k^{(1)} [\mu_k - \mu(\eta)][\partial_0 u(\eta) - P_n(\eta; \partial_0 u)] d\eta. \tag{5.8}
$$

In order to represent algorithm (5.4) in a block-matrix form, we introduce the matrix

$$
S = \{s_{i,k}\}_{i,k=1}^{n} = \begin{pmatrix}
E_X & 0 & 0 & \cdot & \cdot & \cdot & 0 & 0 \\
-e^{-A_2^{(2)}\tau_2} & E_X & 0 & \cdot & \cdot & \cdot & 0 & 0 \\
0 & -e^{-A_3^{(2)}\tau_3} & E_X & \cdot & \cdot & \cdot & 0 & 0 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
0 & 0 & 0 & \cdot & \cdot & \cdot & -e^{-A_n^{(2)}\tau_n} & E_X
\end{pmatrix}, \tag{5.9}
$$

with E_X being the identity operator in X, the matrix $D = \{\beta_{k,j}\}_{k,j=1}^{n}$, and the vectors

$$
x = \begin{pmatrix} x_1 \\ \cdot \\ \cdot \\ \cdot \\ x_n \end{pmatrix}, \quad
f_x = \begin{pmatrix} \phi_1 \\ \cdot \\ \cdot \\ \cdot \\ \phi_n \end{pmatrix}, \quad
\tilde{f}_x = \begin{pmatrix} e^{-A_1^{(2)}\tau_1} u_0 \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{pmatrix}, \quad
\psi_y = \begin{pmatrix} \psi_{y,1} \\ \cdot \\ \cdot \\ \cdot \\ \psi_{y,n} \end{pmatrix},
$$

$$
f_y = \begin{pmatrix} \partial_0\phi_1 \\ \cdot \\ \cdot \\ \cdot \\ \partial_0\phi_n \end{pmatrix}, \quad
\tilde{f}_y = \begin{pmatrix} \partial_0 e^{-A_1^{(2)}\tau_1} u_0 \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{pmatrix}, \quad
\psi_y^{(0)} = \begin{pmatrix} \partial_0\psi_{y,1} \\ \cdot \\ \cdot \\ \cdot \\ \partial_0\psi_{y,n} \end{pmatrix}. \tag{5.10}
$$

It is easy to see that for the (left) inverse

$$S^{-1} = \begin{pmatrix} E_X & 0 & \cdots & 0 & 0 \\ s_1 & E_X & \cdots & 0 & 0 \\ s_2 s_1 & s_2 & \cdots & 0 & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ s_{n-1} \cdots s_1 & s_{n-1} \cdots s_2 & \cdots & s_{n-1} & E_X \end{pmatrix}, \tag{5.11}$$

where $s_k = -e^{-A^{(2)}_{k+1}\tau_{k+1}}$, it holds that

$$S^{-1}S = \begin{pmatrix} E_X & 0 & \cdots & 0 \\ 0 & E_X & \cdots & 0 \\ \cdot & \cdot & \cdots & \cdot \\ 0 & 0 & \cdots & E_X \end{pmatrix}. \tag{5.12}$$

Remark 5.2. Using results of [15, 10, 11] one can get a parallel and sparse approximation with an exponential convergence rate of the operator exponentials contained in S^{-1} and as a consequence a parallel and sparse approximation of S^{-1}.

The first and second equations of (5.4) can be written in the matrix form as

$$\begin{aligned} Sx &= Dy + f_x + \tilde{f}_x, \\ y &= \Lambda[(I_X - S)x + Dy + f_x + \tilde{f}_x], \end{aligned} \tag{5.13}$$

where

$$\Lambda = \operatorname{diag}[\partial_0, \ldots, \partial_0], \quad I_X = \operatorname{diag}(E_X, \ldots, E_X). \tag{5.14}$$

The errors z_x, z_y satisfy the equations

$$\begin{aligned} Sz_x &= Dz_y + \psi_y, \\ z_y &= \Lambda\left[(I_X - S)z_x + Dz_y + \psi_y\right]. \end{aligned} \tag{5.15}$$

From the second equation in (5.13) and the second equation in (5.15) we obtain

$$\begin{aligned} [I_Y - \Lambda D]y &= \Lambda[(I_X - S)x + f_x + \tilde{f}_x], \\ [I_Y - \Lambda D]z_y &= \Lambda[(I_X - S)z_x + \psi_y], \end{aligned} \tag{5.16}$$

where $I_Y = \operatorname{diag}(E_Y, \ldots, E_Y)$ and E_Y is the identity operator in Y.

For a vector $v = (v_1, v_2, \ldots, v_n)^T$ and a block operator matrix $A = \{a_{ij}\}_{i,j=1}^n$, we introduce the vector norm

$$|||v||| \equiv |||v|||_\infty = \max_{1 \le k \le n} \|v_k\| \tag{5.17}$$

and the consistent matrix norm

$$|||A||| \equiv |||A|||_\infty = \max_{1 \le i \le n} \sum_{j=1}^{n} \|a_{i,j}\|. \tag{5.18}$$

For further analysis we need the following auxiliary result.

LEMMA 5.3. *Under assumptions* (B1)–(B6) *the following estimates hold true:*

$$
\begin{aligned}
&|||S^{-1}||| \le n,\\
&|||D||| \le cn^{-(1+1/q)} \ln n, \quad 1/p + 1/q = 1,\\
&|||\Lambda||| \le c,
\end{aligned}
\tag{5.19}
$$

with a positive constant c independent of n.

Proof. The assumption (B2) yields

$$
|||S^{-1}||| \le 1 + e^{-\omega\tau} + \cdots + e^{-\omega\tau(n-1)} \le n. \tag{5.20}
$$

For the matrix D we have from (4.12)

$$
\begin{aligned}
|||D||| &\le \max_{1\le k\le n} \sum_{j=1}^{n} \|\beta_{kj}\|\\
&= \max_{1\le k\le n} \sum_{j=1}^{n} \left\| \int_{t_{k-1}}^{t_k} A_k^{(2)} e^{-A_k^{(2)}(t_k-\tau)} B_k^{(1)} [\mu(t_k) - \mu(\tau)] L_{j,n-1}(\tau) d\tau \right\|\\
&\le \max_{1\le k\le n} \int_{t_{k-1}}^{t_k} \|A_k^{(2)} e^{-A_k^{(2)}(t_k-\tau)} B_k^{(1)}\| \|\mu(t_k) - \mu(\tau)\| \sum_{j=1}^{n} |L_{j,n-1}(\tau)| d\tau\\
&\le c\Lambda_n (t_k - t_{k-1}) \int_{t_{k-1}}^{t_k} \|A_k^{(2)} e^{-A_k^{(2)}(t_k-\tau)} B_k^{(1)}\| d\tau \le cn^{-(1+1/q)} \ln n,
\end{aligned}
\tag{5.21}
$$

where $\Lambda_n = \max_{-1\le\tau\le 1} \sum_{j=1}^{n} |L_{j,n-1}(\tau)|$ is the Lebesgue constant related to the Chebyshev interpolation nodes.

The last estimate is a simple consequence of assumption (B5). The lemma is proved. ∎

Due to (5.19) for n large enough there exists the inverse $(I_Y - \Lambda D)^{-1}$, which is bounded by a constant c independent of n; i.e.,

$$
|||(I_Y - \Lambda D)^{-1}||| \le c. \tag{5.22}
$$

Therefore, we obtain from (5.16)

$$
\begin{aligned}
y &= [I_Y - \Lambda D]^{-1} \Lambda \left[(I_X - S)x + f_x + \tilde{f}_x \right],\\
z_y &= [I_Y - \Lambda D]^{-1} \Lambda \left[(I_X - S) z_x + \psi_y \right].
\end{aligned}
\tag{5.23}
$$

Substituting these expressions into the first equation in (5.13) and (5.15), respectively, we obtain

$$
\begin{aligned}
Gx &= Q(f_x + \tilde{f}_x),\\
Gz_x &= Q\psi_y,
\end{aligned}
\tag{5.24}
$$

where

$$
\begin{aligned}
G &= S - D[I_Y - \Lambda D]^{-1} \Lambda (I_X - S),\\
Q &= D[I_Y - \Lambda D]^{-1} \Lambda + I_X.
\end{aligned}
\tag{5.25}
$$

The next lemma presents estimates for G^{-1} and Q.

LEMMA 5.4. *Under assumptions of Lemma* 5.3 *there exists* G^{-1}, *and there holds*

$$\begin{aligned} |||G^{-1}||| &\le cn, \\ |||Q||| &\le c \end{aligned} \tag{5.26}$$

with some constant independent on n.

Proof. We represent $G = S[I_X - G_1]$ with $G_1 = S^{-1}D[I_Y - \Lambda D]^{-1}\Lambda(I_X - S)$ and estimate $|||G_1|||$. We have

$$|||G_1||| \le |||S^{-1}||| \cdot |||D||| \cdot |||(I_Y - \Lambda D)^{-1}||| \cdot |||\Lambda||| \cdot |||I_X - S|||, \tag{5.27}$$

and now Lemma 5.3 implies that

$$|||G_1||| \le n\, n^{-(1+1/q)} c \ln n = c\frac{\ln n}{n^{1/q}}. \tag{5.28}$$

This estimate guarantees the existence of the bounded inverse operator $(I_X - G_1)^{-1}$, which together with the estimate $|||S^{-1}||| \le n$ proves the first assertion of the lemma. The second assertion is evident. The proof is complete. □

This lemma and (5.24) imply the following stability estimates:

$$\begin{aligned} |||x||| &\le cn|||f_x + \tilde{f}_x|||, \\ |||z_x||| &\le cn|||\tilde{\psi}_y|||. \end{aligned} \tag{5.29}$$

Substituting estimates (5.29) into (5.23) and taking into account the estimates $|||I_X - S||| \le c$, $|||\Lambda||| \le c$ as well as (5.22), we obtain

$$\begin{aligned} |||y||| &\le cn|||f_x + \tilde{f}_x|||, \\ |||z_y||| &\le cn|||\psi_y|||. \end{aligned} \tag{5.30}$$

Remark 5.5. We have reduced the interval length to $T = 2$, but in general the constants c involved depend on the interval length T.

Let Π_{n-1} be the set of all polynomials in t with vector coefficients of degree less than or equal to $n - 1$. In complete analogy with [2, 28, 29], the following Lebesgue inequality for vector-valued functions can be proved:

$$\|u(\eta) - P_{n-1}(\eta; u)\|_{C[-1,1]} \equiv \max_{\eta\in[-1,1]} \|u(\eta) - P_{n-1}(\eta; u)\| \le (1 + \Lambda_n)E_n(u), \tag{5.31}$$

with the error of the best approximation of u by polynomials of degree not greater than $n - 1$

$$E_n(u) = \inf_{p\in\Pi_{n-1}} \max_{\eta\in[-1,1]} \|u(\eta) - p(\eta)\|. \tag{5.32}$$

Now we can go to the main result of this section.

THEOREM 5.6. *Let the assumptions of Lemma* 5.3 *hold; then there exists a positive constant* c *such that*

1. *for n large enough it holds that*

$$|||z_x||| \le cn^{-1/q} \cdot \ln n \cdot E_n(\partial_0 u),$$
$$|||z_y||| \le cn^{-1/q} \cdot \ln n \cdot E_n(\partial_0 u), \tag{5.33}$$

where u is the solution of (4.1);

2. *the first equation in* (5.24) *can be written in the form*

$$x = G_1 x + S^{-1} Q(f_x + \tilde{f}_x) \tag{5.34}$$

and can be solved by the fixed point iteration

$$x^{(k+1)} = G_1 x^{(k)} + S^{-1} Q(f_x + \tilde{f}_x), \quad k = 0, 1, \ldots; \quad x^{(0)} \text{ is arbitrary} \tag{5.35}$$

with the convergence rate of a geometrical progression with the denominator $q \le c\frac{\ln n}{n^{1/q}} < 1$ for n large enough.

Proof. Using (B6) the norm of ψ_y can be estimated in the following way:

$$\begin{aligned} |||\psi_y||| &= \max_{1\le k\le n} \left| \int_{t_{k-1}}^{t_k} A_k^{(2)} e^{-A_k^{(2)}(t_k-\eta)} B_k^{(1)} [\mu_k - \mu(\eta)]\,[\theta(\eta) - P_n(\eta;\theta)] d\eta \right| \\ &\le c\|\theta(\cdot) - P_n(\cdot;\theta)\|_{C[-1,1]} \max_{1\le k\le n} (t_k - t_{k-1})^{1+1/q} \\ &\le cn^{-(1+1/q)}(1+\Lambda_n) E_n(\theta) \le cn^{-(1+1/q)} \cdot \ln n \cdot E_n(\theta). \end{aligned} \tag{5.36}$$

Now the first assertion of the theorem follows from (5.29) and (5.30) and the second one from (5.28). ∎

Remark 5.7. Assuming that the vector-valued functions $\partial_0 u(t)$ can be analytically extended from the interval $[-1, 1]$ into the domain $\mathcal{D}_\rho$ enveloped by the so-called Bernstein regularity ellipse $\mathcal{E}_\rho = \mathcal{E}_\rho(B)$ (with the foci at $z = \pm 1$ and the sum of semiaxes equal to $\rho > 1$),

$$\begin{aligned} \mathcal{E}_\rho &= \left\{ z \in \mathbb{C} : z = \frac{1}{2}\left(\rho e^{i\varphi} + \frac{1}{\rho} e^{-i\phi}\right) \right\} \\ &= \left\{ (x,y) : \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,\ a = \frac{1}{2}\left(\rho + \frac{1}{\rho}\right),\ b = \frac{1}{2}\left(\rho - \frac{1}{\rho}\right) \right\}, \end{aligned}$$

we obtain for the value of the best polynomial approximation [3, 15]

$$E_n(\partial_0 u) \le \frac{\rho^{-n}}{1-\rho} \sup_{z\in D_\rho} \|\partial_0 u(z)\|, \tag{5.37}$$

which together with (5.33) yields the exponential convergence rate with the estimates (5.33).

Remark 5.8. For an elliptic operator A and for its discrete counterpart A_h (say, A_h is the finite element method/finite difference stiffness matrix corresponding to A), it holds that (see, e.g., [6])

$$\|(zI - A)^{-1}\|_{X\to X} \le \frac{1}{|z| \sin(\theta_1 - \theta)} \quad \forall z \in \mathbb{C} :\ \theta_1 \le |\arg z| \le \pi \tag{5.38}$$

for any $\theta_1 \in (\theta, \pi)$, where $\cos\theta = \delta_0/C$; i.e., both are strongly positive in the sense of (2.7). Replacing A by A_h in (4.1) and then applying the temporal discretization described above, we arrive at the full discretization of problem (2.1). Since the bound (5.38) on the matrix resolvent of A_h is valid uniformly in the mesh size h, the full error is the sum of the temporal and the spatial errors which can be controlled independently from each other.

6. Examples. In this section we show that many applied parabolic problems with a time-dependent boundary condition can be fitted into our abstract framework. Our aim here is to illustrate the assumptions accepted in sections 3 and 4.

A special example of the problem from the class (1.1) is

$$\begin{aligned} &\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + f(x,t), \\ &u(0,t) = 0, \quad \frac{\partial u(1,t)}{\partial x} + b(t)u(1,t) = g(t), \\ &u(x,0) = u_0(x), \end{aligned} \tag{6.1}$$

where the operator $A : D(A) \in X \to X,\ X = L_q(0,1)$, is defined by

$$\begin{aligned} &D(A) = \{v \in W_q^2(0,1) : v(0) = 0\}, \\ &Av = -\frac{\partial^2 v}{\partial x^2}, \end{aligned} \tag{6.2}$$

the operators $\partial_1 : D(A) \to Y$ and $\partial_0(t) : D(A) \to Y$, $Y = \mathbb{R}$ are defined by

$$\begin{aligned} &\partial_1 u = \left.\frac{\partial u(x,t)}{\partial x}\right|_{x=1}, \\ &\partial_0(t)u = b(t) \cdot u(x,t)|_{x=1}, \end{aligned} \tag{6.3}$$

and $g(t) \in L_q(0,T;Y) = L_q(0,T)$.

We represent the solution of (6.1) in the form (compare with (2.3), (2.4))

$$u(x,t) = w(x,t) + v(x,t), \tag{6.4}$$

where the function $v(x,t)$ is the solution of the problem

$$\begin{aligned} &\frac{\partial v}{\partial t} = \frac{\partial^2 v}{\partial x^2} + f(x,t), \\ &v(0,t) = 0, \quad \frac{\partial v(1,t)}{\partial x} = 0, \\ &v(x,0) = u_0(x) \end{aligned} \tag{6.5}$$

and the function $w(x,t)$ satisfies

$$\begin{aligned} &\frac{\partial w}{\partial t} = \frac{\partial^2 w}{\partial x^2}, \\ &w(0,t) = 0, \quad \frac{\partial w(1,t)}{\partial x} = -b(t)u(1,t) + g(t), \\ &w(x,0) = 0. \end{aligned} \tag{6.6}$$

Introducing the operator $A^{(1)} : D(A^{(1)}) \to X$ defined by

$$\begin{aligned} &D(A^{(1)}) = \{u \in W_q^2(0,1) :\ u(0) = 0,\ u'(1) = 0\} = \{u \in D(A) : u'(1) = 0\}, \\ &A^{(1)}u = -\frac{d^2u}{dx^2} \quad \forall u \in D(A^{(1)}) \end{aligned} \tag{6.7}$$

(see (2.5) for an abstract setting), we can also write problem (6.5) in the form

$$\begin{aligned} &\frac{dv}{dt} + A^{(1)}v = f(t), \\ &v(0) = u_0, \end{aligned} \tag{6.8}$$

with the solution

$$v(t) = e^{-A^{(1)}t}u_0 + \int_0^t e^{-A^{(1)}(t-\tau)}f(\tau)d\tau. \tag{6.9}$$

In order to solve the problem (6.6) we use Duhamel's integral. We introduce the auxiliary function $W(x, \lambda, t)$ satisfying the following equations (compare with (2.10)):

$$\begin{aligned} &\frac{\partial W(x,\lambda,t)}{\partial t} = \frac{\partial^2 W(x,\lambda,t)}{\partial x^2}, \\ &W(0,\lambda,t) = 0, \quad \frac{\partial W(1,\lambda,t)}{\partial x} = -b(\lambda)u(1,\lambda) + g(\lambda), \\ &W(x,\lambda,0) = 0 \end{aligned} \tag{6.10}$$

with time-independent boundary conditions. Then the solution of problem (6.6) is given by (see Theorem 2.1)

$$w(x,t) = \int_0^t \frac{\partial}{\partial t} W(x,\lambda,t-\lambda)d\lambda. \tag{6.11}$$

Using this representation one can obtain an integral equation with respect to $u(1,t)$. Actually, we have

$$\begin{aligned} w(1,t) = u(1,t) - v(1,t) &= \frac{\partial}{\partial t}\int_0^t W(1,\lambda,t-\lambda)d\lambda \\ &= \int_0^t \frac{\partial}{\partial t} W(1,\lambda,t-\lambda)d\lambda. \end{aligned} \tag{6.12}$$

The substitution

$$W(x,\lambda,t) = B[-b(\lambda)u(1,\lambda) + g(\lambda)] + W_1(x,\lambda,t) \tag{6.13}$$

implies the following problem with homogeneous boundary conditions for $W_1(x, \lambda, t)$:

$$\begin{aligned} &\frac{\partial W_1(x,\lambda,t)}{\partial t} = \frac{\partial^2 W_1(x,\lambda,t)}{\partial x^2}, \\ &W_1(0,\lambda,t) = 0, \quad \frac{\partial W_1(1,\lambda,t)}{\partial x} = 0, \\ &W_1(x,\lambda,0) = -B[-b(\lambda)u(1,\lambda) + g(\lambda)], \end{aligned} \tag{6.14}$$

where the operator B is given by

$$B[-b(\lambda)u(1,\lambda)+g(\lambda)] = x[-b(\lambda)u(1,\lambda)+g(\lambda)]. \tag{6.15}$$

By separation of variables we get the solution of this problem explicitly in the form

$$\begin{aligned} W_1(x,\lambda,t) &= -2[-b(\lambda)u(1,\lambda)+g(\lambda)] \\ &\quad \cdot \sum_{n=1}^{\infty}(-1)^{n+1}\left[\frac{2}{(2n-1)\pi}\right]^2 e^{-[\pi(2n-1)/2]^2 t}\sin\left[\frac{\pi}{2}(2n-1)x\right]. \end{aligned} \tag{6.16}$$

Due to (6.15) the boundary integral equation (2.20) (or, equivalently, (2.23)) for the example problem (6.1) takes the form

$$\begin{aligned} b(t)u(1,t) &= b(t)v(1,t) + b(t)\int_0^t \frac{\partial}{\partial t}W_1(1,\lambda,t-\lambda)d\lambda \\ &= b(t)v(1,t) - b(t)\int_0^t K(t-\lambda)g(\lambda)d\lambda + b(t)\int_0^t K(t-\lambda)b(\lambda)u(1,\lambda)d\lambda, \end{aligned} \tag{6.17}$$

with

$$K(t) = 2\sum_{n=1}^{\infty} e^{-[\pi(2n-1)/2]^2 t}. \tag{6.18}$$

Remark 6.1. Note that in this particular case we can represent the integrand through the kernel $K(t-\lambda)$ analytically. In the general case one can use the exponentially convergent algorithm for the operator exponential in (2.21) like the one from [15].

Let us illustrate Theorem 3.1 for the example problem (6.1). It is easy to see that the condition (A1) is fulfilled provided that

$$|b(t)| \le c \quad \forall t \in [0,T]. \tag{6.19}$$

Let us show that there exists p for which the assumption (A2) holds. Actually, we have

$$\begin{aligned} \int_0^t \|A^{(1)}e^{-A^{(1)}(t-\lambda)}B\|_{Y\to X}^p d\lambda &= \int_0^t [K(t-\lambda)]^p\, d\lambda \\ &= \int_0^t \left[2\sum_{n=1}^{\infty} e^{-(\frac{\pi(2n-1)}{2})^2(t-\lambda)}\right]^p d\lambda. \end{aligned} \tag{6.20}$$

Using the Hölder inequality, the kernel $K(t-\lambda)$ can be estimated by

$$\begin{aligned} K(t-\lambda) &= 2\sum_{n=1}^{\infty} e^{-(\frac{\pi(2n-1)}{2})^2(t-\lambda)} \\ &= 2\sum_{n=1}^{\infty}(2n-1)^{\alpha}e^{-(\frac{\pi(2n-1)}{2})^2(t-\lambda)}\frac{1}{(2n-1)^{\alpha}} \\ &\le 2\left\{\sum_{n=1}^{\infty}(2n-1)^{p\alpha}e^{-p(\frac{\pi(2n-1)}{2})^2(t-\lambda)}\right\}^{1/p}\cdot\left\{\sum_{n=1}^{\infty}\frac{1}{(2n-1)^{q\alpha}}\right\}^{1/q}, \end{aligned} \tag{6.21}$$

where $\frac{1}{p}+\frac{1}{q}=1$.

Substituting this inequality into (6.20), we obtain

$$\int_0^t [K(t-\lambda)]^p d\lambda \le \frac{2^{p+1}}{p\pi^2}\left\{\sum_{n=1}^{\infty}\frac{1}{(2n-1)^{q\alpha}}\right\}^{p/q}$$

$$\cdot\sum_{n=1}^{\infty}\frac{1}{(2n-1)^{2-p\alpha}}\left[1-e^{-p(\frac{\pi(2n-1)}{2})^2 t}\right] \tag{6.22}$$

$$\le \frac{2^{p+1}}{p\pi^2}\left\{\sum_{n=1}^{\infty}\frac{1}{(2n-1)^{q\alpha}}\right\}^{p/q}\cdot\sum_{n=1}^{\infty}\frac{1}{(2n-1)^{2-p\alpha}}.$$

The series are bounded by a constant c if

$$\begin{cases} q\alpha>1, \\ 2-p\alpha>1, \end{cases} \tag{6.23}$$

or $\frac{1}{q}<\alpha<\frac{1}{p}$. Thus, we can choose an arbitrary $p\in[1,2)$, and then $\frac{1}{q}=1-\frac{1}{p}$ and the choice of an arbitrary α from the interval $(1-\frac{1}{p},\frac{1}{p})$ provide that the assumption (A2) holds.

The assumption (A3) for the example problem (6.1) reads as

$$\left\{\int_0^T\left|b(t)v(1,t)-b(t)\int_0^t K(t-\lambda)g(\lambda)d\lambda\right|^q dt\right\}^{1/q}\le c. \tag{6.24}$$

Since $K(t-\cdot)\in L_p(0,T)$, this inequality holds provided that

$$g(t)\in L_q(0,T),\quad v(1,t)\in L_q(0,T). \tag{6.25}$$

Due to the estimate

$$\left(\int_0^T |v(1,t)|^q dt\right)^{1/q}=\left(\int_0^T\left|\int_0^1\frac{\partial v(x,t)}{\partial x}dx\right|^q dt\right)^{1/q}$$

$$\le\left(\int_0^T\int_0^1\left|\frac{\partial v(x,t)}{\partial x}\right|^q dxdt\right)^{1/q}, \tag{6.26}$$

the condition $v(1,t)\in L_q(0,T)$ is fulfilled if the last integral exists. The corresponding sufficient conditions on the input data $f(x,t),\ u_0(x)$ of the problem (6.1) can be found in [26, 20].

Given the solution of (6.17) (which can be found numerically by algorithm (5.4) consisting in this case of the second equation only), the problem (6.1) takes the form

$$\frac{du}{dt}+Au=f(t),$$

$$u(0)=u_0,\quad \partial_1 u=g_1(t), \tag{6.27}$$

with a known function $g_1(t) = g(t) - \partial_0(t)u(t)$. Using the representation by Duhamel's integral (6.11) we have

$$u(t) = v(t) - \int_0^t A^{(1)} e^{-A^{(1)}(t-\lambda)} B g_1(\lambda) d\lambda. \tag{6.28}$$

Now let us show that the assumptions (B1)–(B6) hold for the following model problem from the class (1.1):

$$\begin{aligned} &\frac{\partial u(x,t)}{\partial t} = \frac{\partial^2 u}{\partial x^2} - q(x,t)u + f(x,t), \\ &u(0,t) = 0, \quad \frac{\partial u(1,t)}{\partial x} + b(t)u(1,t) = g(t), \\ &u(x,0) = u_0(x). \end{aligned} \tag{6.29}$$

The results of [20, section 4, paragraph 9, p. 388] yield that this problem possesses the unique solution $u \in W_q^{2,1}(Q_T)$ provided that $q(x,t),\ f(x,t) \in L_q(Q_T),\ Q_T = (0,1) \times (0,T),\ g(t) \in W_q^{1-1/(2q)}(0,T),\ b(t) \in W_q^{1/2}(0,T),\ u_0 \in W_q^{2-\frac{2}{q}}(0,1),\ q > 3/2$, and some compatibility conditions for initial and boundary conditions are fulfilled.

Here the operator $A(t) : D(A) \in X \to X,\ X = L_q(0,1)$, is defined by

$$\begin{aligned} &D(A(t)) = \{v \in W_q^2(0,1) : v(0) = 0\}, \\ &A(t)v = -\frac{d^2 v(x)}{dx^2} + q(x,t)v(x), \end{aligned} \tag{6.30}$$

the operators $\partial_1 : D(A) \to Y$ and $\partial_0(t) : D(A) \to Y$, $Y = \mathbb{R}$ are defined by

$$\begin{aligned} &\partial_1 u = \left.\frac{\partial u(x,t)}{\partial x}\right|_{x=1}, \\ &\partial_0(t)u = b(t) \cdot u(x,t)|_{x=1}, \end{aligned} \tag{6.31}$$

and $g(t) \in L_q(0,T;Y) = L_q(0,T)$. We suppose that the function $b(t)$ satisfies condition (6.19), so that our assumption (B5) is fulfilled.

The piecewise constant operator $A^{(2)}(t)$ from (4.6) is defined on each subinterval $[t_{k-1}, t_k]$ by

$$D(A^{(2)}(t)) = \{v \in W_q^2(0,1) : v(0) = 0, \quad v'(1) + \mu_k v(1) = 0\}, \quad \mu_k = b(t_k),$$

$$A_k v = -\frac{d^2 v(x)}{dx^2} + q(x,t_k)v(x)$$

and the operator $B_k^{(1)}$ by

$$B_k^{(1)} z = \frac{x}{\mu_k + 1} z, \quad z \in Y.$$

Assumptions (B1)–(B2) are fulfilled due to results from [6], and assumptions (B3)–(B4) are obviously fulfilled, too. It remains to check assumption (B6). Let

$(\lambda_j^{(k)}, e_j^{(k)})$, $j = 1, 2, \ldots$, be the system of eigenpairs of $A^{(2)}(t), t \in [t_{k-1}, t_k]$. Then we have

$$\int_0^t \|[A^{(2)}]^{1+\gamma} e^{-A^{(2)}(t-\lambda)} B^{(1)}\|_{Y\to X}^p d\lambda = \sum_{k=1}^n \int_{t_{k-1}}^{t_k} \left[K_\gamma^{(k)}(t-\lambda)\right]^p d\lambda, \tag{6.32}$$

where

$$K_\gamma^{(k)}(t-\lambda) = \sum_{j=1}^\infty [\lambda_j^{(k)}]^\gamma e^{-\lambda_j^{(k)}(t-\lambda)}. \tag{6.33}$$

Using the well-known asymptotic $c_L j^2 \le \lambda_j \le c_U j^2$ (see, e.g, [24]) and Hölder's inequality, the kernel $K_\gamma^{(k)}(t-\lambda)$ can be estimated in the following way:

(6.34)

$$\begin{aligned} K_\gamma^{(k)}(t-\lambda) &= \sum_{j=1}^\infty \left(\lambda_j^{(k)}\right)^\gamma e^{-\lambda_j^{(k)}(t-\lambda)} \le c_U^\gamma \sum_{j=1}^\infty j^{2\gamma} e^{-c_L j^2 (t-\lambda)} \\ &= c_U^\gamma \sum_{n=1}^\infty j^{2\gamma+\alpha} e^{-c_L j^2(t-\lambda)} \frac{1}{j^\alpha} \\ &\le c_U^\gamma \left\{\sum_{j=1}^\infty j^{p(\alpha+2\gamma)} e^{-pc_L j^2(t-\lambda)}\right\}^{1/p} \cdot \left\{\sum_{j=1}^\infty \frac{1}{j^{q\alpha}}\right\}^{1/q}, \quad \frac{1}{p}+\frac{1}{q} = 1. \end{aligned}$$

Substituting this inequality into (6.32) we obtain

(6.35)

$$\begin{aligned} &\sum_{k=1}^n \int_{t_{k-1}}^{t_k} [K_\gamma^{(k)}(t-\lambda)]^p d\lambda \le \sum_{k=1}^n c_U^\gamma \int_{t_{k-1}}^{t_k} \sum_{j=1}^\infty j^{p(\alpha+2\gamma)} e^{-pc_L j^2(t-\lambda)} d\lambda \cdot \left\{\sum_{j=1}^\infty \frac{1}{j^{q\alpha}}\right\}^{p/q} \\ &= c_U^\gamma \sum_{j=1}^\infty j^{p(\alpha+2\gamma)} (pc_L j^2)^{-1} \left[1 - e^{-pc_L j^2 t}\right] \cdot \left\{\sum_{j=1}^\infty \frac{1}{j^{q\alpha}}\right\}^{p/q} \\ &\le \frac{c_U^\gamma}{pc_L} \sum_{j=1}^\infty \frac{1}{j^{2-p(\alpha+2\gamma)}} \cdot \left\{\sum_{j=1}^\infty \frac{1}{j^{q\alpha}}\right\}^{p/q}. \end{aligned}$$

The series remains bounded if

$$\begin{cases} q\alpha > 1, \\ 2 - p(\alpha + 2\gamma) > 1, \end{cases} \tag{6.36}$$

or $\frac{1}{q} < \alpha < \frac{1}{p} - 2\gamma$. Thus, we can choose an arbitrary $p \in [1, 2)$; then $\frac{1}{q} = 1 - \frac{1}{p}$ and the assumption (B6) holds with an arbitrary γ from the interval $[0, \frac{1}{p} - \frac{1}{2})$.

7. Numerical example. In this section we show that the algorithm (5.4) possesses the exponential convergence with respect to the temporal discretization parameter n predicted by Theorem 5.6. In order to eliminate the influence of other errors (the spatial error, the error of approximation of the operator exponential and of the integrals in (5.5)), we calculate the coefficients of the algorithm (5.6) exactly using the computer algebra tool Maple.

We consider the model problem (6.1) with

$$u_0(x) = \frac{4\sqrt{2}}{\pi}\sin\frac{\pi}{4}x, \quad b(t) = \frac{\pi}{4}\exp\left(\frac{\pi^2}{16}t\right), \quad g(t) = 1 + \exp\left(-\frac{\pi^2}{16}t\right),$$

for which algorithm (5.4) consists of the second equation only, where $\alpha_{kj} = 0$.

The exact solution of this problem is

$$u(x,t) = \exp\left(-\frac{\pi^2}{16}t\right)\frac{4\sqrt{2}}{\pi}\sin\frac{\pi}{4}x.$$

For the function $v(x,t)$ from (6.5) we have the following problem:

$$\begin{aligned} &\frac{\partial v(x,t)}{\partial t} = \frac{\partial^2 v(x,t)}{\partial x^2}, \quad v(0,t) = 0, \quad \frac{\partial v(1,t)}{\partial x} = 0, \\ &v(x,0) = \frac{4\sqrt{2}}{\pi}\sin\frac{\pi}{4}x. \end{aligned} \tag{7.1}$$

It is easy to check that

$$v(x,t) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}32}{\pi^2(4k-1)(4k-3)} e^{-\left(\frac{\pi(2k-1)}{2}\right)^2 t}\sin\Big(\frac{\pi}{2}(2k-1)x\Big). \tag{7.2}$$

Equation (6.17) (compare also with (6.16), (6.22)) reads as follows:

$$\begin{aligned} u(1,t) &= v(1,t) + 2\int_0^t \left[1 + e^{\frac{-\pi^2}{16}\tau}\right]\sum_{k=1}^{\infty} e^{-\left(\frac{\pi(2k-1)}{2}\right)^2(t-\tau)}d\tau \\ &\quad -2\int_0^t \frac{\pi}{4}e^{\frac{\pi^2}{16}\tau}u(1,\tau)\sum_{k=1}^{\infty} e^{-\left(\frac{\pi(2k-1)}{2}\right)^2(t-\tau)}d\tau \\ &= f(t) - \frac{\pi}{2}\int_0^t e^{\frac{\pi^2}{16}\tau}u(1,\tau)\sum_{k=1}^{\infty} e^{-\left(\frac{\pi(2k-1)}{2}\right)^2(t-\tau)}d\tau, \end{aligned} \tag{7.3}$$

with

$$\begin{aligned} f(t) &= v(1,t) - 2\sum_{k=1}^{\infty} e^{-\left(\frac{\pi(2k-1)}{2}\right)^2 t}\left[\frac{1}{\left(\frac{\pi(2k-1)}{2}\right)^2} + \frac{1}{\left(\frac{\pi(2k-1)}{2}\right)^2 - \frac{\pi^2}{16}}\right] + 1 + \frac{4}{\pi}e^{-\frac{\pi^2}{16}t} \\ &= -\frac{8}{\pi^2}\sum_{k=1}^{\infty}\frac{e^{-\left(\frac{\pi(2k-1)}{2}\right)^2 t}}{(2k-1)^2} + 1 + \frac{4}{\pi}e^{-\frac{\pi^2}{16}t}. \end{aligned}$$

In order to reduce the problem to the interval $[-1,1]$ we change the variable t in (7.3) by

$$t=\frac{s+1}{2}T,\quad s\in[-1,1];\quad \tau=\frac{\xi+1}{2}T,\quad \xi\in[-1,s];\quad d\tau=\frac{T}{2}d\xi$$

and obtain

$$u\left(1,\frac{s+1}{2}T\right)=f\left(\frac{s+1}{2}T\right)-\frac{\pi T}{4}\sum_{k=1}^{\infty}\int_{-1}^{s}e^{\frac{\pi^2}{16}\frac{\xi+1}{2}T}u\left(1,\frac{\xi+1}{2}T\right)e^{-\left(\frac{\pi(2k-1)}{2}\right)^2\frac{T}{2}(s-\xi)}d\xi.$$

Note that this equation is, in fact, the explicit form of the operator equation (6.22) with an explicitly calculated integrand including the operator exponential.

Substituting the corresponding interpolation polynomials and collocating the obtained equation at the points

$$s_l=\cos\left[\frac{2l-1}{2n}\pi\right],\quad l=\overline{1,n},$$

analogously as in (5.6), we arrive at a system of linear algebraic equations with respect to $y_j\approx u(1,t_j)$, where the calculation of the values β_{kj} and $\partial_0\phi_k$ is reduced to the calculation of integrals of the type $\int_{-1}^{s}e^{-a(s-\tau)}\tau^n d\tau$ and can be performed exactly. The computations were provided in Maple 9. For the cases of $n=2,3,4,8$ we used Digits=20', whereas for the case $n=16$ we used Digits=40'. The results of the computation presented in Tables 7.1–7.4 confirm our theory above.

Appendix A. Proof of Theorem 3.1. Using the Hölder inequality and assumptions (A1)–(A3) we have

(A.1)

$$\left(\int_0^t \|V^j(\tau_1)s(\cdot)\|^q d\tau_1\right)^{1/q} = \left(\int_0^t \left\|\partial_0(\tau_1)\int_0^{\tau_1} K(\tau_1-\tau_2)V^{j-1}(\tau_2)s(\cdot)d\tau_2\right\|^q d\tau_1\right)^{1/q}$$

$$\le c\left(\int_0^t \left(\int_0^{\tau_1} \|K(\tau_1-\tau_2)\|\cdot\|V^{j-1}(\tau_2)s(\cdot)\|d\tau_2\right)^q d\tau_1\right)^{1/q}$$

$$\le c\left(\int_0^t \left(\int_0^{\tau_1} \|K(\tau_1-\tau_2)\|^p d\tau_2\right)^{q/p}\cdot\int_0^{\tau_1}\|V^{j-1}(\tau_2)s(\cdot)\|^q d\tau_2 d\tau_1\right)^{1/q}$$

$$\le c^2\left(\int_0^t\int_0^{\tau_1}\|V^{j-1}(\tau_2)s(\cdot)\|^q d\tau_2 d\tau_1\right)^{1/q} \le \cdots$$

$$\le c^{2j}\left(\int_0^t\int_0^{\tau_1}\cdots\int_0^{\tau_j}\|s(\tau_{j+1})\|^q d\tau_{j+1}\ldots d\tau_2 d\tau_1\right)^{1/q}$$

$$\le c^{2j}\left(\int_0^t\int_0^{\tau_1}\cdots\int_0^{\tau_{j-1}} d\tau_j\ldots d\tau_2 d\tau_1\right)^{1/q}\left(\int_0^t\|s(\tau_{j+1})\|^q d\tau_{j+1}\right)^{1/q}$$

$$\le c^{2j}\left(\frac{t^j}{j!}\right)^{1/q}\left(\int_0^t\|s(\tau_{j+1})\|^q d\tau_{j+1}\right)^{1/q} \qquad \forall s(t)\in L_q(0,T;Y),$$

which means that the spectral radius of the operator $V : L_q(0,T;Y) \to L_q(0,T;Y)$ is equal to zero. The general theory of the Volterra integral equations (see, for example, [18, 19] and section 2) yields the existence and uniqueness of the solution of (2.20).

Applying the Hölder inequality to the equation

$$\delta_j(t) = \partial_0(t)\int_0^t K(t-\lambda)\delta_{j-1}(\lambda)d\lambda \tag{A.2}$$

analogously as above, we deduce that

(A.3)
$$\left(\int_0^t \|\delta_j(\tau_1)\|^q d\tau_1\right)^{1/q}$$
$$\leq c^2\left(\int_0^t\int_0^{\tau_1}\|\delta_{j-1}(\tau_2)\|^q d\tau_2 d\tau_1\right)^{1/q} \leq \cdots \leq c^{2j}\left(\frac{t^j}{j!}\right)^{1/q}\left(\int_0^t \|\delta_0(\tau_{j+1})\|^q d\tau_{j+1}\right)^{1/q},$$

from which the factorial convergence (3.6) follows.

Further, let us prove the stability of the solution of (2.20) with respect to the right-hand side.

Using the Hölder inequality for integrals we obtain

(A.4)
$$\left(\int_0^t \|\partial_0(\tau)u(\tau)\|_Y^q d\tau\right)^{1/q} \leq \left(\int_0^t \|F(\tau)\|_Y^q d\tau\right)^{1/q}$$
$$+\left\{\int_0^t\left\|\partial_0(\tau)\int_0^\tau A^{(1)}e^{-A^{(1)}(\tau-\lambda)}B\partial_0(\lambda)u(\lambda)d\lambda\right\|_Y^q d\tau\right\}^{1/q} \leq \left(\int_0^t \|F(\tau)\|_Y^q d\tau\right)^{1/q}$$
$$+\left\{\int_0^t \|\partial_0(\tau)\|^q\left(\int_0^\tau \|A^{(1)}e^{-A^{(1)}(\tau-\lambda)}B\|_{Y\to X}\|\partial_0(\lambda)u(\lambda)\|_Y d\lambda\right)^q d\tau\right\}^{1/q}.$$

Applying condition (3.1) to the last summand and then again the Hölder inequality, we arrive at the estimate

(A.5)
$$\left(\int_0^t \|\partial_0(\tau)u(\tau)\|_Y^q d\tau\right)^{1/q} \leq \left(\int_0^t \|F(\tau)\|_Y^q d\tau\right)^{1/q}$$
$$+c\left\{\int_0^t\left(\int_0^\tau \|A^{(1)}e^{-A^{(1)}(\tau-\lambda)}B\|_{Y\to X}^p d\lambda\right)^{q/p}\int_0^\tau \|\partial_0(\lambda)u(\lambda)\|_Y^q d\lambda d\tau\right\}^{1/q}.$$

Due to (3.2) we further obtain

(A.6)
$$\left(\int_0^t \|\partial_0(\tau)u(\tau)\|_Y^q d\tau\right)^{1/q} \leq \left(\int_0^t \|F(\tau)\|_Y^q d\tau\right)^{1/q}$$
$$+c^2\left\{\int_0^t\int_0^\tau \|\partial_0(\lambda)u(\lambda)\|_Y^q d\lambda d\tau\right\}^{1/q}.$$

The well-known inequality $(a+b)^q \leq 2^{q/p}(a^q+b^q)$ and the last estimate imply

(A.7)
$$\int_0^t \|\partial_0(\tau)u(\tau)\|_Y^q d\tau \leq 2^{q/p}\left[\int_0^t \|F(\tau)\|_Y^q d\tau\right.$$
$$\left.+c^{2q}\int_0^t\int_0^\tau \|\partial_0(\lambda)u(\lambda)\|_Y^q d\lambda d\tau\right].$$

Now the Gronwall lemma [4, 3] yields (3.7).

The proof is complete. ∎

Appendix B. Proof of Theorem 4.1.

Let us introduce the linear operator $\mathcal{V}(t)$ by

$$\mathcal{V}(t)\mathcal{U}(\cdot) = \mathcal{D}(t)\int_0^t \mathcal{E}_\gamma \mathcal{K}(t,\tau)\mathcal{E}_\gamma^{-1}\mathcal{U}(\tau)d\tau. \tag{B.1}$$

Using assumptions (B1) and (B3) we get the following for the element $[\mathcal{E}_\gamma \mathcal{K}\mathcal{E}_\gamma^{-1}]_{1,1}$ of the matrix $\mathcal{E}_\gamma \mathcal{K}\mathcal{E}_\gamma^{-1}$ with the indexes $(1,1)$:

$$\left\| \left[\mathcal{E}_\gamma \mathcal{K}(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{1,1} \right\| = \left\| \left[A^{(2)}\right]^\gamma e^{-A^{(2)}(\tau_1-\tau_2)} \left[A(\tau_2)-A\right] \left[A^{(2)}\right]^{-\gamma} \right\|$$

$$\le \left\| \left[A^{(2)}\right]^\gamma e^{-A^{(2)}(\tau_1-\tau_2)} \right\| \left\| [A(\tau_2)-A] \left[A^{(2)}\right]^{-\gamma} \right\| \le c^2(\tau_1-\tau_2)^{-\gamma}(T-\tau_2).$$

This estimate implies

$$\begin{aligned} &\int_0^{\tau_1} \| \left[\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{1,1} \|^p d\tau_2 \le c^{2p}\int_0^{\tau_1} (\tau_1-\tau_2)^{-\gamma p}(T-\tau_2)^p d\tau_2 \\ &\le c^{2p}\tau_1^{1-\gamma p}T^p \int_0^1 (1-\eta)^{-\gamma p} d\eta = c^{2p}\tau_1^{1-\gamma p}\frac{T^p}{1-\gamma p} \le C^p, \end{aligned} \tag{B.2}$$

with some new constant C. This expression remains bounded for $\gamma p \in [0,1)$.

Assumption (B6) implies

$$\begin{aligned} &\left(\int_0^{\tau_1} \| \left[\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{1,2} \|^p d\tau_2\right)^{1/p} \\ &= \left(\int_0^{\tau_1} \left\| \left[A^{(2)}\right]^{\gamma+1} e^{-A^{(2)}(\tau_1-\tau_2)} B^{(1)} \right\|^p d\tau_2\right)^{1/p} \le C, \\ &\left(\int_0^{\tau_1} \| \left[\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{2,2} \|^p d\tau_2\right)^{1/p} \\ &= \left(\int_0^{\tau_1} \|A^{(2)} e^{-A^{(2)}(\tau_1-\tau_2)} B^{(1)}\|^p d\tau_2\right)^{1/p} \le C. \end{aligned} \tag{B.3}$$

Using (B2) and (B3) we have

$$\begin{aligned} &\left(\int_0^{\tau_1} \| \left[\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{2,1} \|^p d\tau_2\right)^{1/p} \\ &= \left(\int_0^{\tau_1} \left\| e^{-A^{(2)}(\tau_1-\tau_2)} \left[A(\tau_2)-A\right] \left[A^{(2)}\right]^{-\gamma} \right\|^p d\tau_2\right)^{1/p} \\ &\le \left(\int_0^{\tau_1} \left\| [A(\tau_2)-A] \left[A^{(2)}\right]^{-\gamma} \right\|^p d\tau_2\right)^{1/p} \le c\left(\int_0^{\tau_1} (T-\tau_2)^p d\tau_2\right)^{1/p} \le C. \end{aligned} \tag{B.4}$$

Therefore

$$\|\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\|_\infty \le 2\max_{i,j}\|\left[\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\right]_{i,j}\| \le C. \tag{B.5}$$

Assumption (B5) yields

$$\|\mathcal{D}(\tau_1)\|_1 \le \max\{1, \|\partial_0(\tau)\|\} \le C. \tag{B.6}$$

Now using estimates (B.5) and (B.6) we get for the nth power of the operator $\mathcal{V}(t)$

(B.7)

$$\begin{aligned}
&\left(\int_0^t \|\mathcal{V}^j(\tau_1)s(\cdot)\|^q d\tau_1\right)^{1/q} \\
&= \left(\int_0^t \left\|\mathcal{D}(\tau_1)\int_0^{\tau_1}\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\mathcal{V}^{j-1}(\tau_2)s(\cdot)d\tau_2\right\|^q d\tau_1\right)^{1/q} \\
&\le \left(\int_0^t \|\mathcal{D}(\tau_1)\|_\infty^q \left(\int_0^{\tau_1}\|\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\mathcal{V}^{j-1}(\tau_2)s(\cdot)\|_\infty d\tau_2\right)^q d\tau_1\right)^{1/q} \\
&\le C\left(\int_0^t \left(\int_0^{\tau_1}\|\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\|_\infty\|\mathcal{V}^{j-1}(\tau_2)s(\cdot)\|_\infty d\tau_2\right)^q d\tau_1\right)^{1/q} \\
&\le C\left(\int_0^t \left(\int_0^{\tau_1}\|\mathcal{E}_\gamma K(\tau_1,\tau_2)\mathcal{E}_\gamma^{-1}\|_\infty^p d\tau_2\right)^{q/p}\cdot\int_0^{\tau_1}\|\mathcal{V}^{j-1}(\tau_2)s(\cdot)\|_\infty^q d\tau_2 d\tau_1\right)^{1/q} \\
&\le C^2\left(\int_0^t\int_0^{\tau_1}\|\mathcal{V}^{j-1}(\tau_2)s(\cdot)\|_\infty^q d\tau_2 d\tau_1\right)^{1/q} \le \cdots \\
&\le C^{2j}\left(\int_0^t\int_0^{\tau_1}\cdots\int_0^{\tau_j}\|s(\tau_{j+1})\|_\infty^q d\tau_{j+1}\ldots d\tau_2 d\tau_1\right)^{1/q} \\
&\le C^{2j}\left(\int_0^t\int_0^{\tau_1}\cdots\int_0^{\tau_{j-1}} d\tau_j\ldots d\tau_2 d\tau_1\right)^{1/q}\left(\int_0^t\|s(\tau_{j+1})\|_\infty^q d\tau_{j+1}\right)^{1/q} \\
&\le C^{2j}\left(\frac{t^j}{j!}\right)^{1/q}\left(\int_0^t\|s(\tau_{j+1})\|_\infty^q d\tau_{j+1}\right)^{1/q} \qquad \forall s(t)\in\mathcal{Y}.
\end{aligned}$$

For the difference

$$\Delta_j(t) = \mathcal{U}_j(t) - \mathcal{U}^*(t)$$

between the jth iteration and the exact solution, we have the equation

$$\Delta_j(t) = \mathcal{D}(t)\int_0^t \mathcal{E}_\gamma K(t,\tau)\mathcal{E}_\gamma^{-1}\Delta_{j-1}(\tau)d\tau. \tag{B.8}$$

Applying the Hölder inequality analogously as above, we get

$$\begin{aligned}
&\left(\int_0^t \|\Delta_j(\tau_1)\|_\infty^q d\tau_1\right)^{1/q} \\
&\le c^2 \left(\int_0^t \int_0^{\tau_1} \|\Delta_{j-1}(\tau_2)\|_\infty^q d\tau_2 d\tau_1\right)^{1/q} \le \cdots \\
&\le c^{2j} \left(\frac{t^j}{j!}\right)^{1/q} \left(\int_0^t \|\Delta_0(\tau_{j+1})\|_\infty^q d\tau_{j+1}\right)^{1/q},
\end{aligned} \tag{B.9}$$

from which the factorial convergence (4.23) follows.

Finally, let us prove the stability of the solution of (4.19) with respect to the right-hand side.

Using the Hölder inequality for integrals we obtain

$$\begin{aligned}
\left(\int_0^t \|\mathcal{U}_\gamma(\tau)\|_\infty^q d\tau\right)^{1/q} &\le \left(\int_0^t \|\mathcal{F}(\tau)\|_\infty^q d\tau\right)^{1/q} \\
&+ \left\{\int_0^t \left\|\mathcal{D}(\tau_1) \int_0^{\tau_1} \mathcal{E}_\gamma K(\tau_1,\tau_2) \mathcal{E}_\gamma^{-1} \mathcal{U}_\gamma(\tau_2) d\tau_2\right\|_\infty^q d\tau_1\right\}^{1/q}.
\end{aligned}$$

Using estimates as above we obtain

$$\left(\int_0^t \|\mathcal{U}_\gamma(\tau)\|_\infty^q d\tau\right)^{1/q} \le c^2 \left(\int_0^t \int_0^{\tau_1} \|\mathcal{U}_\gamma(\tau_2)\|_\infty^q d\tau_2 d\tau_1\right)^{1/q} + \left(\int_0^t \|\mathcal{F}(\tau)\|_\infty^q d\tau\right)^{1/q}.$$

This estimate together with the inequality $(a+b)^q \le 2^{q/p}(a^q + b^q)$ implies

$$\int_0^t \|\mathcal{U}_\gamma(\tau)\|_\infty^q d\tau \le 2^{q/p} \left[c^{2q} \int_0^t \int_0^{\tau_1} \|\mathcal{U}_\gamma(\tau_2)\|_\infty^q d\tau_2 d\tau_1 + \int_0^t \|\mathcal{F}(\tau)\|_\infty^q d\tau\right]. \tag{B.10}$$

Now, the Gronwall lemma yields (4.24).

The proof is complete. □

MODIFIED NODAL CUBIC SPLINE COLLOCATION FOR POISSON'S EQUATION†

ABEER ALI ABUSHAMA‡ AND BERNARD BIALECKI†

Abstract. We present a new modified nodal cubic spline collocation scheme for solving the Dirichlet problem for Poisson's equation on the unit square. We prove existence and uniqueness of a solution of the scheme and show how the solution can be computed on an $(N+1)\times(N+1)$ uniform partition of the square with cost $O(N^2\log N)$ using a direct fast Fourier transform method. Using two comparison functions, we derive an optimal fourth order error bound in the continuous maximum norm. We compare our scheme with other modified nodal cubic spline collocation schemes; in particular, the one proposed by Houstis, Vavalis, and Rice in [*SIAM J. Numer. Anal.*, 25 (1988), pp. 54–74]. We believe that our paper gives the first correct convergence analysis of a modified nodal cubic spline collocation for solving partial differential equations.

1. Introduction.

De Boor [7] proved that classical nodal cubic spline collocation for solving two-point boundary value problems is only second order accurate and no better. For two-point boundary value problems, Archer [2] and, independently, Daniel and Swartz [6] developed a modified nodal cubic spline collocation (MNCSC) scheme which is fourth order accurate. The approximate solution in this scheme satisfies higher-order perturbations of the ordinary differential equation at the partition nodes. Based on the method of [2] and [6], Houstis, Vavalis, and Rice [8] derived a fourth order MNCSC scheme for solving elliptic boundary value problems on rectangles. For the Helmholtz equation, a direct fast Fourier transform (FFT) algorithm for solving this scheme was proposed recently in [3].

In this paper, we consider the Dirichlet boundary value problem for Poisson's equation

$$\Delta u = f \text{ in } \Omega, \qquad u = 0 \text{ on } \partial\Omega, \tag{1.1}$$

where Δ denotes the Laplacian, $\Omega = (0,1)\times(0,1)$, and $\partial\Omega$ is the boundary of Ω. Let $\rho_x = \{x_i\}_{i=0}^{N+1}$ be a uniform partition of $[0,1]$ in the x-direction such that $x_i = ih$, $i = 0,\dots,N+1$, where $h = 1/(N+1)$. For the sake of simplicity, we assume that a uniform partition $\rho_y = \{y_j\}_{i=0}^{N+1}$ of $[0,1]$ in the y-direction is such that $y_j = x_j$. Let S_3 be the space of cubic splines defined by

$$S_3 = \{v \in C^2[0,1] : v|_{[x_{i-1},x_i]} \in P_3, i = 1,\dots,N+1\},$$

where P_3 denotes the set of all polynomials of degree ≤ 3, and let

$$S^D = \{v \in S_3 : v(0) = v(1) = 0\}.$$

‡Department of Mathematical and Computer Sciences, Colorado School of Mines, Golden, CO 80401-1887 (ashamaa@gmail.com, bbialeck@mines.edu).

Our MNCSC scheme for solving (1.1) is formulated as follows: Find $u_h \in S^D \otimes S^D$ such that

$$\Delta u_h(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i,y_j) = f(x_i,y_j) - \frac{h^2}{12}\Delta f(x_i,y_j), \quad i,j = 0,\dots,N+1. \tag{1.2}$$

The scheme (1.2) is motivated by the fourth order finite difference method for (1.1); see, for example, equation (7) in section 4.5 of [9]. Using $u_h = u = 0$ on $\partial\Omega$ and (1.1), we see that (1.2) is equivalent to

$$2D_x^2 D_y^2 u_h(x_i,y_j) = \Delta f(x_i,y_j), \quad i,j = 0, N+1, \tag{1.3}$$

$$D_x^2 u_h(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i,y_j) = f(x_i,y_j) - \frac{h^2}{12}\Delta f(x_i,y_j), \quad i = 0, N+1, \quad j = 1,\dots,N, \tag{1.4}$$

$$D_y^2 u_h(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i,y_j) = f(x_i,y_j) - \frac{h^2}{12}\Delta f(x_i,y_j), \quad i = 1,\dots,N, \quad j = 0, N+1, \tag{1.5}$$

$$\Delta u_h(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i,y_j) = f(x_i,y_j) - \frac{h^2}{12}\Delta f(x_i,y_j), \quad i,j = 1,\dots,N. \tag{1.6}$$

The scheme (4.2)–(4.4) of [8] for (1.1) is: Find $u_h \in S^D \otimes S^D$ satisfying (1.3) and

$$D_x^2 u_h(x_i,y_j) = f(x_i,y_j), \quad i = 0, N+1, \quad j = 1,\dots,N, \tag{1.7}$$

$$D_y^2 u_h(x_i,y_j) = f(x_i,y_j), \quad i = 1,\dots,N, \quad j = 0, N+1, \tag{1.8}$$

$$(L_x + L_y) u_h(x_i,y_j) = f(x_i,y_j), \quad i,j = 1,\dots,N, \tag{1.9}$$

where, for $i,j = 1,\dots,N$,

$$L_x v(x_i,y_j) = \frac{1}{12}\left[D_x^2 v(x_{i-1},y_j) + 10 D_x^2 v(x_i,y_j) + D_x^2 v(x_{i+1},y_j)\right], \tag{1.10}$$

$$L_y v(x_i,y_j) = \frac{1}{12}\left[D_y^2 v(x_i,y_{j-1}) + 10 D_y^2 v(x_i,y_j) + D_y^2 v(x_i,y_{j+1})\right].$$

Our scheme and that of [8] are identical at the corners of $\overline{\Omega}$. However, they are different at the remaining partition nodes. While (1.4)–(1.6) involve perturbations of both the left- and right-hand sides, (1.9) involves a perturbation of the left-hand side only. Numerical results show that our scheme exhibits superconvergence phenomena while that of [8] does not.

An outline of this paper is as follows. We give preliminaries in section 2. The matrix-vector form of our scheme, an existence and uniqueness proof of its solution, and a direct FFT algorithm for solving the scheme are presented in section 3. In section 4, using two comparison functions, we derive a fourth order error bound in the continuous maximum norm. In section 5, we give convergence analysis of the scheme in [4] that consists of (1.3)–(1.5) and (1.9). We also explain why convergence analysis of the scheme (1.3) and (1.7)–(1.9), given in [8], is incorrect. This is why, we believe, our paper gives the first correct convergence analysis of MNCSC for solving partial differential equations. Section 6 includes numerical results obtained using our scheme.

2. Preliminaries. We extend the uniform partition $\rho_x = \{x_i\}_{i=0}^{N+1}$ outside of $[0,1]$ using $x_i = ih, i = -3,-2,-1,N+2,N+3,N+4$, and introduce $I_i = [x_{i-1}, x_i]$, $i = -2,\dots,N+4$. Let $\{B_m\}_{m=-1}^{N+2}$ be the basis for S_3 defined by

$$B_m(x) = \begin{cases} g_1[(x - x_{m-2})/h], & x \in I_{m-1}, \\ g_2[(x - x_{m-1})/h], & x \in I_m, \\ g_2[(x_{m+1} - x)/h], & x \in I_{m+1}, \\ g_1[(x_{m+2} - x)/h], & x \in I_{m+2}, \\ 0 & \text{otherwise}, \end{cases} \tag{2.1}$$

where

$$g_1(x) = x^3, \qquad g_2(x) = 1 + 3x + 3x^2 - 3x^3. \tag{2.2}$$

The basis functions are such that, for $m = 0,\dots,N+1$,

$$\begin{array}{lll} B_{m-1}(x_m) = 1, & B_m(x_m) = 4, & B_{m+1}(x_m) = 1, \\ B''_{m-1}(x_m) = 6/h^2, & B''_m(x_m) = -12/h^2, & B''_{m+1}(x_m) = 6/h^2. \end{array} \tag{2.3}$$

Let $\{B_m^D\}_{m=0}^{N+1}$ be the basis for S^D defined by

$$\begin{array}{l} B_0^D = B_0 - 4B_{-1}, \qquad B_1^D = B_1 - B_{-1}, \\ B_m^D = B_m, \quad m = 2,\dots,N-1, \\ B_N^D = B_N - B_{N+2}, \qquad B_{N+1}^D = B_{N+1} - 4B_{N+2}. \end{array} \tag{2.4}$$

It follows from (2.3) that

$$\begin{array}{lll} B_0^D(x_1) = 1, & B_1^D(x_1) = 4, & B_1^D(x_2) = 1, \\ B_N^D(x_{N-1}) = 1, & B_N^D(x_N) = 4, & B_{N+1}^D(x_N) = 1, \end{array} \tag{2.5}$$

$$\begin{array}{lll} \left[B_0^D\right]''(x_0) = -36/h^2, & \left[B_1^D\right]''(x_0) = 0, & \\ \left[B_0^D\right]''(x_1) = 6/h^2, & \left[B_1^D\right]''(x_1) = -12/h^2, & \left[B_1^D\right]''(x_2) = 6/h^2, \\ \left[B_N^D\right]''(x_{N-1}) = 6/h^2, & \left[B_N^D\right]''(x_N) = -12/h^2, & \left[B_{N+1}^D\right]''(x_N) = 6/h^2, \\ \left[B_N^D\right]''(x_{N+1}) = 0, & \left[B_{N+1}^D\right]''(x_{N+1}) = -36/h^2. & \end{array} \tag{2.6}$$

It also follows from (2.5), (2.6), (2.4), and (2.3) that, for $i = 1,\dots,N$,

$$B_m^D(x_i) - \frac{h^2}{6}[B_m^D]''(x_i) = \begin{cases} 6, & m = i, \\ 0, & m \neq i, \end{cases} \qquad m = 0,\dots,N+1. \tag{2.7}$$

Throughout this paper, C denotes a generic positive constant that is independent of u and h.

LEMMA 2.1. *$\{B_m^D\}_{m=0}^{N+1}$ of (2.4) satisfy $\max_{x\in[0,1]}|B_m^D(x)| \le C, m = 0,\dots,N+1$.*

Proof. For each fixed $m = -1,\dots,N+2$, using $I_i = [x_{i-1}, x_i]$ and $x_i = ih$, we have

$$\begin{array}{llll} 0 \le (x - x_{m-2})/h \le 1, & x \in I_{m-1}, & 0 \le (x - x_{m-1})/h \le 1, & x \in I_m, \\ 0 \le (x_{m+1} - x)/h \le 1, & x \in I_{m+1}, & 0 \le (x_{m+2} - x)/h \le 1, & x \in I_{m+2}. \end{array} \tag{2.8}$$

Equations (2.2) and (2.8) give

$$\begin{array}{llll} |g_1[(x - x_{m-2})/h]| \le 1, & x \in I_{m-1}, & |g_2[(x - x_{m-1})/h]| \le 7, & x \in I_m, \\ |g_2[(x_{m+1} - x)/h]| \le 7, & x \in I_{m+1}, & |g_1[(x_{m+2} - x)/h]| \le 1, & x \in I_{m+2}. \end{array} \tag{2.9}$$

Using (2.1) and (2.9), we see that $\max_{x\in[0,1]}|B_m(x)| \le C, m = -1, \dots, N+2$. Hence the required inequality follows from (2.4), which implies that each B_m^D is a linear combination of at most two of the functions $\{B_n\}_{n=-1}^{N+2}$. ∎

For $\{B_m^D\}_{m=0}^{N+1}$ of (2.4), we introduce $N \times N$ matrices A and B defined by

$$A = (a_{i,m})_{i,m=1}^{N}, \quad a_{i,m} = [B_m^D]''(x_i), \quad B = (b_{j,n})_{j,n=1}^{N}, \quad b_{j,n} = B_n^D(y_j). \tag{2.10}$$

It follows from (2.4), (2.3), (2.5), and (2.6) that

$$A = 6h^{-2}T, \qquad B = T + 6I, \tag{2.11}$$

where I is the identity matrix and the $N \times N$ matrix T is given by

$$T = \begin{bmatrix} -2 & 1 & & & \\ 1 & -2 & 1 & & \\ & \ddots & \ddots & \ddots & \\ & & 1 & -2 & 1 \\ & & & 1 & -2 \end{bmatrix}. \tag{2.12}$$

LEMMA 2.2. *If $B[u_1, \dots, u_N]^T = [v_1, \dots, v_N]^T$, where B is defined in* (2.10), *then* $\max_{1\le i\le N}|u_i| \le C \max_{1\le i\le N}|v_i|$.

Proof. It follows from (2.10), (2.11), and (2.12) that $|b_{i,i}| - \sum_{i\ne j}|b_{i,j}| \ge 2$, $i = 1, \dots, N$. Hence the required result follows, for example, from the discussion on page 21 in [1]. ∎

In what follows, $[u_{1,1}, \dots, u_{N,N}]^T$ is the short notation for

$$[u_{1,1}, \dots, u_{1,N}, u_{2,1}, \dots, u_{2,N}, \dots, u_{N,1}, \dots, u_{N,N}]^T.$$

LEMMA 2.3. *If $\mathbf{u} = [u_{1,1}, \dots, u_{N,N}]^T$ and $\mathbf{v} = [v_{1,1}, \dots, v_{N,N}]^T$ are such that $(B\otimes B)\mathbf{u} = \mathbf{v}$, where B is defined in* (2.10), *then* $\max_{1\le i,j\le N}|u_{i,j}| \le C \max_{1\le i,j\le N}|v_{i,j}|$.

Proof. Since $B \otimes B = (B \otimes I)(I \otimes B)$, we have

$$\mathbf{v} = (B \otimes I)\mathbf{w}, \qquad \mathbf{w} = (I \otimes B)\mathbf{u}. \tag{2.13}$$

Using (2.13) and Lemma 2.2, we obtain

$$\max_{1\le i,j\le N}|u_{i,j}| \le C \max_{1\le i,j\le N}|w_{i,j}|, \quad \max_{1\le i,j\le N}|w_{i,j}| \le C \max_{1\le i,j\le N}|v_{i,j}|,$$

which imply the required inequality. ∎

It is well known (see Theorem 4.5.2 of [10]) that for T of (2.12), we have

$$QTQ = \Lambda, \qquad QQ = I, \tag{2.14}$$

where the $N \times N$ matrices Λ and Q are given by

$$\Lambda = \operatorname{diag}(\lambda_i)_{i=1}^{N}, \qquad \lambda_i = -4\sin^2\frac{i\pi}{2(N+1)}, \tag{2.15}$$

$$Q = (q_{i,j})_{i,j=1}^{N}, \quad q_{i,j} = \left(\frac{2}{N+1}\right)^{1/2} \sin\frac{ij\pi}{N+1}. \tag{2.16}$$

LEMMA 2.4. *If* $\mathbf{v} = [v_{1,1}, \ldots, v_{N,N}]^T$ *and* $\mathbf{w} = [w_{1,1}, \ldots, w_{N,N}]^T$ *are such that*

$$\left[\frac{T}{h^2} \otimes I + I \otimes \frac{T}{h^2} + \frac{h^2}{6}\left(\frac{T}{h^2} \otimes \frac{T}{h^2}\right)\right] \mathbf{v} = \mathbf{w}, \tag{2.17}$$

where T *is the matrix defined in* (2.12)*, then* $\max_{1\le i,j\le N} v_{i,j}^2 \le Ch^2 \sum_{i=1}^N \sum_{j=1}^N w_{i,j}^2$.

Proof. The matrix in (2.17) arises in the fourth order finite difference method for (1.1). Hence the desired result follows, for example, from the last unnumbered equation on page 296 in [9]. □

Finally, we observe that the matrix-vector form of

$$\phi_{i,j} = \sum_{m=1}^{N} c_{i,m}^{(1)} \sum_{n=1}^{N} c_{j,n}^{(2)} \psi_{m,n}, \qquad i,j = 1, \ldots, N, \tag{2.18}$$

is

$$\boldsymbol{\phi} = (C_1 \otimes C_2)\boldsymbol{\psi}, \tag{2.19}$$

where $C_1 = \left(c_{i,m}^{(1)}\right)_{i,m=1}^{N}$, $C_2 = \left(c_{j,n}^{(2)}\right)_{j,n=1}^{N}$, and

$$\boldsymbol{\phi} = [\phi_{1,1}, \ldots, \phi_{N,N}]^T, \qquad \boldsymbol{\psi} = [\psi_{1,1}, \ldots, , \psi_{N,N}]^T.$$

3. Matrix-vector form of scheme. Since $\dim(S^D \otimes S^D) = (N+2)^2$, the scheme (1.3)–(1.6) involves $(N+2)^2$ equations in $(N+2)^2$ unknowns. Using the basis $\{B_m^D\}_{m=0}^{N+1}$ of (2.4) for the space S^D, we have

$$u_h(x,y) = \sum_{m=0}^{N+1} \sum_{n=0}^{N+1} u_{m,n} B_m^D(x) B_n^D(y). \tag{3.1}$$

Substituting (3.1) into (1.3), we obtain

$$2 \sum_{m=0}^{N+1} \sum_{n=0}^{N+1} u_{m,n} [B_m^D]''(x_i)[B_n^D]''(y_j) = \Delta f(x_i, y_j), \qquad i,j = 0, N+1. \tag{3.2}$$

Using (2.6), we conclude that (3.2) gives

$$u_{i,j} = \frac{h^4}{2592} \Delta f(x_i, y_j), \qquad i,j = 0, N+1. \tag{3.3}$$

Substituting (3.1) into (1.4), we obtain

$$\begin{aligned} &\sum_{m=0}^{N+1} \sum_{n=0}^{N+1} u_{m,n} [B_m^D]''(x_i) \left(B_n^D(y_j) - \frac{h^2}{6}[B_n^D]''(y_j)\right) \\ &\quad = f(x_i, y_j) - \frac{h^2}{12} \Delta f(x_i, y_j), \qquad i = 0, N+1, \quad j = 1, \ldots, N. \end{aligned} \tag{3.4}$$

Using (2.6) and (2.7), we see that (3.4) gives

$$u_{i,j} = -\frac{h^2}{216} f(x_i, y_j) + \frac{h^4}{2592} \Delta f(x_i, y_j), \quad i = 0, N+1, \quad j = 1, \ldots, N. \tag{3.5}$$

Using (3.5) and symmetry with respect to x and y, we conclude that (1.5) gives

$$u_{i,j} = -\frac{h^2}{216} f(x_i, y_j) + \frac{h^4}{2592} \Delta f(x_i, y_j), \quad i = 1, \ldots, N, \quad j = 0, N+1. \tag{3.6}$$

Substituting (3.1) into (1.6), we obtain

$$\begin{aligned} \sum_{m=0}^{N+1} \sum_{n=0}^{N+1} u_{m,n} \left([B_m^D]''(x_i) B_n^D(y_j) + \left[B_m^D(x_i) - \frac{h^2}{6} [B_m^D]''(x_i) \right] [B_n^D]''(y_j) \right) \\ = f(x_i, y_j) - \frac{h^2}{12} \Delta f(x_i, y_j), \quad i, j = 1, \ldots, N. \end{aligned} \tag{3.7}$$

Moving the terms involving $\{u_{m,n}\}_{n=0}^{N+1}$, $m = 0, N+1$, $\{u_{m,n}\}_{m=1}^{N}$, $n = 0, N+1$, to the right-hand side of (3.7), we get

$$\begin{aligned} \sum_{m=1}^{N} \sum_{n=1}^{N} u_{m,n} \left([B_m^D]''(x_i) B_n^D(y_j) + \left[B_m^D(x_i) - \frac{h^2}{6} [B_m^D]''(x_i) \right] [B_n^D]''(y_j) \right) \\ = p_{i,j}, \quad i, j = 1, \ldots, N, \end{aligned} \tag{3.8}$$

where

$$\begin{aligned} p_{i,j} &= f(x_i, y_j) - \frac{h^2}{12} \Delta f(x_i, y_j) \\ &- \sum_{m=0,N+1} \sum_{n=0}^{N+1} u_{m,n} \left([B_m^D]''(x_i) B_n^D(y_j) + \left[B_m^D(x_i) - \frac{h^2}{6} [B_m^D]''(x_i) \right] [B_n^D]''(y_j) \right) \\ &- \sum_{m=1}^{N} \sum_{n=0,N+1} u_{m,n} \left([B_m^D]''(x_i) B_n^D(y_j) + \left[B_m^D(x_i) - \frac{h^2}{6} [B_m^D]''(x_i) \right] [B_n^D]''(y_j) \right). \end{aligned}$$

Using (2.18)–(2.19), we write (3.8) as

$$\left[A \otimes B + \left(B - \frac{h^2}{6} A \right) \otimes A \right] \mathbf{u} = \mathbf{p}, \tag{3.9}$$

where $\mathbf{u} = [u_{1,1}, \ldots, u_{N,N}]^T$, $\mathbf{p} = [p_{1,1}, \ldots, p_{N,N}]^T$, and A, B are defined in (2.10). Using (2.11), we see that

$$A \otimes B + \left(B - \frac{h^2}{6} A \right) \otimes A = \frac{6}{h^2} \left[6T \otimes I + (6I + T) \otimes T \right],$$

and hence the system (3.9) simplifies to

$$6h^{-2} \left[6T \otimes I + (6I + T) \otimes T \right] \mathbf{u} = \mathbf{p}. \tag{3.10}$$

We are now ready to prove the existence and uniqueness of u_h in $S^D \otimes S^D$ which satisfies (1.3)–(1.6).

THEOREM 3.1. *There exists unique u_h in $S^D \otimes S^D$ satisfying* (1.3)–(1.6).

Proof. Since the number of equations in (1.3)–(1.6) is equal to the number of unknowns, we assume that the right-hand side in (1.3)–(1.6) is zero, and show that $u_h = 0$ is the only solution of the resulting scheme. Using (3.1), (3.3), (3.5), and (3.6), we have

$$u_{m,n} = 0, \quad m = 0, N+1, n = 0, \ldots, N+1, \quad m = 1, \ldots, N, n = 0, N+1. \tag{3.11}$$

Clearly

$$6h^{-2}[6T \otimes I + (6I+T) \otimes T] = 36\left[\frac{T}{h^2} \otimes I + I \otimes \frac{T}{h^2} + \frac{h^2}{6}\left(\frac{T}{h^2} \otimes \frac{T}{h^2}\right)\right]. \tag{3.12}$$

Hence it follows from (3.10) with $\mathbf{p}$ replaced by $\mathbf{0}$, (3.12), and Lemma 2.4 that

$$u_{m,n} = 0, \qquad m,n = 1,\ldots,N. \tag{3.13}$$

Equations (3.1), (3.11), and (3.13) give $u_h = 0$. □

Using Q of (2.16), we see that (3.10) is equivalent to

$$6h^{-2}(Q \otimes I)\,[6T \otimes I + (6I+T) \otimes T]\,(Q \otimes I)(Q^{-1} \otimes I)\mathbf{u} = (Q \otimes I)\mathbf{p}. \tag{3.14}$$

Introducing $\mathbf{u}' = (Q^{-1} \otimes I)\mathbf{u}$ and $\mathbf{p}' = (Q \otimes I)\mathbf{p}$, and using (3.14) and (2.14), we obtain

$$6h^{-2}\,[6\Lambda \otimes I + (6I+\Lambda) \otimes T]\mathbf{u}' = \mathbf{p}', \tag{3.15}$$

where Λ is defined in (2.15). The system (3.15) reduces to the N independent systems

$$6h^{-2}\,[6\lambda_i I + (6+\lambda_i)T]\mathbf{u}_i' = \mathbf{p}_i', \qquad i = 1,\ldots,N, \tag{3.16}$$

where $\mathbf{u}_i' = [u_{i,1}',\ldots,u_{i,N}']^T$, $\mathbf{p}_i' = [p_{i,1}',\ldots,p_{i,N}']^T$, $i = 1,\ldots,N$.

We have the following algorithm for solving (3.10):

Step 1. Compute $\mathbf{p}' = (Q \otimes I)\mathbf{p}$.
Step 2. Solve the N systems in (3.16).
Step 3. Compute $\mathbf{u} = (Q \otimes I)\mathbf{u}'$.

It follows from (2.16) and section 4.4.5 in [10] that the cost of performing Steps 1 and 3 is $2.5N^2 \log_2 N$ each. In Step 2, the systems are tridiagonal, so this step is performed at a cost $O(N^2)$. Thus the total cost of the algorithm is $5N^2 \log_2 N + O(N^2)$.

4. Convergence analysis. In what follows, $C(u)$ denotes a generic positive constant that is independent of h, but depends on u.

Our goal is to show that if u in $C^6(\overline{\Omega})$ and u_h in $S^D \otimes S^D$ are the solutions of (1.1) and (1.3)–(1.6), respectively, then

$$\|u - u_h\|_{C(\overline{\Omega})} \le C(u)h^4, \tag{4.1}$$

where $\|g\|_{C(\overline{\Omega})} = \max_{x\in\overline{\Omega}} |g(x)|$ for g in $C(\overline{\Omega})$.

To prove (4.1), for u in $C^4(\overline{\Omega})$, we introduce two comparison functions, the spline interpolants S and Z in $S^D \otimes S^D$ of u defined, respectively, by

$$D_x^2 D_y^2 S(x_i,y_j) = D_x^2 D_y^2 u(x_i,y_j), \qquad i,j = 0,N+1, \tag{4.2}$$

$$\begin{aligned} D_x^2 S(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 S(x_i,y_j) &= D_x^2 u(x_i,y_j) - \frac{h^2}{12} D_x^4 u(x_i,y_j) \\ -\frac{h^2}{6} D_x^2 D_y^2 u(x_i,y_j), &\qquad i = 0,N+1, \quad j = 1,\ldots,N, \end{aligned} \tag{4.3}$$

$$\begin{aligned} D_y^2 S(x_i,y_j) - \frac{h^2}{6} D_x^2 D_y^2 S(x_i,y_j) &= D_y^2 u(x_i,y_j) - \frac{h^2}{12} D_y^4 u(x_i,y_j) \\ -\frac{h^2}{6} D_x^2 D_y^2 u(x_i,y_j), &\qquad i = 1,\ldots,N, \quad j = 0,N+1, \end{aligned} \tag{4.4}$$

$$S(x_i, y_j) = u(x_i, y_j), \quad i, j = 1, \ldots, N, \tag{4.5}$$

and

$$D_x^2 D_y^2 Z(x_i, y_j) = D_x^2 D_y^2 u(x_i, y_j), \quad i, j = 0, N+1, \tag{4.6}$$

$$D_x^2 Z(x_i, y_j) = D_x^2 u(x_i, y_j), \quad i = 0, N+1, \quad j = 1, \ldots, N, \tag{4.7}$$

$$D_y^2 Z(x_i, y_j) = D_y^2 u(x_i, y_j), \quad i = 1, \ldots, N, \quad j = 0, N+1, \tag{4.8}$$

$$Z(x_i, y_j) = u(x_i, y_j), \quad i, j = 1, \ldots, N. \tag{4.9}$$

It follows from (1.1) that

$$f = D_x^2 u + D_y^2 u, \quad \Delta f = D_x^4 u + D_y^4 u + 2 D_x^2 D_y^2 u. \tag{4.10}$$

Hence, using $u = 0$ on $\partial\Omega$, we see that (1.3)–(1.5) reduce, respectively, to

$$D_x^2 D_y^2 u_h(x_i, y_j) = D_x^2 D_y^2 u(x_i, y_j), \quad i, j = 0, N+1, \tag{4.11}$$

$$\begin{aligned} D_x^2 u_h(x_i, y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i, y_j) &= D_x^2 u(x_i, y_j) - \frac{h^2}{12} D_x^4 u(x_i, y_j) \\ -\frac{h^2}{6} D_x^2 D_y^2 u(x_i, y_j), &\quad i = 0, N+1, \quad j = 1, \ldots, N, \end{aligned} \tag{4.12}$$

$$\begin{aligned} D_y^2 u_h(x_i, y_j) - \frac{h^2}{6} D_x^2 D_y^2 u_h(x_i, y_j) &= D_y^2 u(x_i, y_j) - \frac{h^2}{12} D_y^4 u(x_i, y_j) \\ -\frac{h^2}{6} D_x^2 D_y^2 u(x_i, y_j), &\quad i = 1, \ldots, N, \quad j = 0, N+1. \end{aligned} \tag{4.13}$$

Comparing (4.11)–(4.13) and (4.2)–(4.4), we see that u_h and S are defined in the same way for $i = 0, N+1, j = 0, \ldots, N+1$, and $i = 1, \ldots, N$, $j = 0, N+1$. On the other hand, (4.6)–(4.8) are a simplified, tensor product version of (4.2)–(4.4).

The triangle inequality gives

$$\|u - u_h\|_{C(\overline{\Omega})} \le \|u - Z\|_{C(\overline{\Omega})} + \|Z - S\|_{C(\overline{\Omega})} + \|S - u_h\|_{C(\overline{\Omega})}. \tag{4.14}$$

In what follows, we bound the three terms on the right-hand side of (4.14).

4.1. Bounding $\|u - Z\|_{C(\overline{\Omega})}$. We need the following results.

LEMMA 4.1. *Let the interpolant $I_x v$ in S_3 of v in $C^2[0,1]$ be defined by*

$$(I_x v)''(x_i) = v''(x_i), \quad i = 0, N+1, \qquad I_x v(x_i) = v(x_i), \quad i = 0, \ldots, N+1. \tag{4.15}$$

Then

$$\max_{x \in [0,1]} |v(x) - I_x v(x)| \le C \max_{x \in [0,1]} |v''(x)| h^2. \tag{4.16}$$

If $v \in C^4[0,1]$, then

$$\max_{x \in [0,1]} |v(x) - I_x v(x)| \le C \max_{x \in [0,1]} |v^{(4)}(x)| h^4. \tag{4.17}$$

Proof. First, we prove (4.16). Using the discussion on page 404 in [5], we have

$$I_x v(x) = v(x_i) + B_i(x - x_i) + C_i(x - x_i)^2 + D_i(x - x_i)^3, \quad x \in [x_i, x_{i+1}], \tag{4.18}$$

for $i = 0, \ldots, N$, where

$$B_i = -\frac{h}{6} r_{i+1} - \frac{h}{3} r_i + \frac{1}{h}\left[v(x_{i+1}) - v(x_i)\right], \quad C_i = \frac{r_i}{2}, \quad D_i = \frac{1}{6h}\left(r_{i+1} - r_i\right), \tag{4.19}$$

and $r_i = (I_x v)''(x_i)$. Equations (4.18) and (4.19) give

$$\begin{aligned} I_x v(x) - v(x) = A_i(x) &- \frac{h}{6} r_{i+1}(x - x_i) - \frac{h}{3} r_i (x - x_i) + \frac{r_i}{2}(x - x_i)^2 \\ &+ \frac{1}{6h}(r_{i+1} - r_i)(x - x_i)^3, \quad x \in [x_i, x_{i+1}], \end{aligned} \tag{4.20}$$

where

$$A_i(x) = v(x_i) - v(x) + \frac{v(x_{i+1}) - v(x_i)}{h}(x - x_i), \quad x \in [x_i, x_{i+1}]. \tag{4.21}$$

Using (4.20) and the triangle inequality, we obtain, for $x \in [x_i, x_{i+1}]$,

$$|I_x v(x) - v(x)| \le |A_i(x)| + h^2 \left(|r_i| + \frac{1}{3}|r_{i+1}|\right) \le |A_i(x)| + \frac{4}{3} h^2 \max_{0 \le i \le N+1} |r_i|. \tag{4.22}$$

We introduce

$$E = (e_{i,j})_{i,j=0}^{N+1} = \begin{bmatrix} 1 & & & & & \\ 1 & 4 & 1 & & & \\ & \ddots & \ddots & \ddots & & \\ & & 1 & 4 & 1 & \\ & & & & 1 & \end{bmatrix}, \qquad \begin{aligned} \mathbf{r} &= [r_0, \ldots, r_{N+1}]^T, \\ \mathbf{p} &= [p_0, \ldots, p_{N+1}]^T, \end{aligned}$$

where

$$p_i = \begin{cases} v''(x_i), & i = 0, N+1, \\ h^{-2}[v(x_{i-1}) - 2v(x_i) + v(x_{i+1})], & i = 1, \ldots, N. \end{cases} \tag{4.23}$$

It follows from the discussion on pages 400 and 401 in [5] that $E\mathbf{r} = \mathbf{p}$. Since $|e_{i,i}| - \sum_{i \ne j} |e_{i,j}| \ge 1$, $i, j = 0, \ldots, N+1$, the discussion on page 21 in [1] implies that

$$\max_{0 \le i \le N+1} |r_i| \le C \max_{0 \le i \le N+1} |p_i|. \tag{4.24}$$

Using Taylor's theorem, we obtain

$$|v(x_{i-1}) - 2v(x_i) + v(x_{i+1})| \le C h^2 \max_{x \in [0,1]} |v''(x)|, \quad i = 1, \ldots, N. \tag{4.25}$$

It follows from (4.24), (4.23), and (4.25) that

$$\max_{0 \le i \le N+1} |r_i| \le C \max_{x \in [0,1]} |v''(x)|. \tag{4.26}$$

Using Taylor's theorem to expand $v(x)$, $x \in [x_i, x_{i+1}]$, around x_i, we have

$$v(x) = v(x_i) + (x - x_i)v'(x_i) + \frac{(x - x_i)^2}{2}v''(\xi_{i,x}), \qquad x_i \le \xi_{i,x} \le x. \tag{4.27}$$

Using (4.21), (4.27), and the triangle inequality, we obtain, for $x \in [x_i, x_{i+1}]$,

$$|A_i(x)| = \left| \frac{(x - x_i)^2}{2}v''(\xi_{i,x}) - \frac{h}{2}(x - x_i)v''(\xi_{i,x_{i+1}}) \right| \le h^2 \max_{x\in[0,1]} |v''(x)|. \tag{4.28}$$

Inequality (4.16) follows from (4.22), (4.26), and (4.28).

A proof of (4.17) is given in the proof of Theorem 2.3.4 in [1]. □

LEMMA 4.2. *If $u \in C^4(\overline{\Omega})$, Z in $S^D \otimes S^D$ is defined by* (4.6)–(4.9), *and $I_x u$ and $I_y u$ are defined in* (4.15), *then for (x, y) in $\overline{\Omega}$, we have*

$$Z(x, y) = I_x(I_y u)(x, y), \qquad D_x^2(I_y u)(x, y) = I_y(D_x^2 u)(x, y). \tag{4.29}$$

Proof. Let $\{C_i\}_{i=0}^{N+3}$ be the basis for S_3 such that

$$\begin{aligned}
&C_i(x_j) = \delta_{ij}, \qquad i, j = 0, \dots, N+1,\\
&C_i''(x_j) = 0, \qquad i = 0, \dots, N+1, \quad j = 0, N+1,\\
&C_{N+2}(x_j) = C_{N+3}(x_j) = 0, \qquad j = 0, \dots, N+1,\\
&C_{N+2}''(x_0) = C_{N+3}''(x_{N+1}) = 1, \qquad C_{N+2}''(x_{N+1}) = C_{N+3}''(x_0) = 0,
\end{aligned} \tag{4.30}$$

where δ_{ij} is the Kronecker delta. Using (4.15) and (4.30), we have for $(x, y) \in \overline{\Omega}$,

$$\begin{aligned}
&I_x(I_y u)(x, y)\\
&= I_x\left[\sum_{j=0}^{N+1} u(x, y_j)C_j(y) + D_y^2 u(x, y_0)C_{N+2}(y) + D_y^2 u(x, y_{N+1})C_{N+3}(y)\right]\\
&= \sum_{i=0}^{N+1}\left[\sum_{j=0}^{N+1} u(x_i, y_j)C_j(y) + D_y^2 u(x_i, y_0)C_{N+2}(y) + D_y^2 u(x_i, y_{N+1})C_{N+3}(y)\right] C_i(x)\\
&+\left[\sum_{j=0}^{N+1} D_x^2 u(x_0, y_j)C_j(y) + D_x^2 D_y^2 u(x_0, y_0)C_{N+2}(y)\right.\\
&\left.+D_x^2 D_y^2 u(x_0, y_{N+1})C_{N+3}(y)\right] C_{N+2}(x) + \left[\sum_{j=0}^{N+1} D_x^2 u(x_{N+1}, y_j)C_j(y)\right.\\
&\left.+D_x^2 D_y^2 u(x_{N+1}, y_0)C_{N+2}(y) + D_x^2 D_y^2 u(x_{N+1}, y_{N+1})C_{N+3}(y)\right] C_{N+3}(x).
\end{aligned}$$

Since $u = 0$ on $\partial\Omega$, all terms involving $C_0(x)$, $C_{N+1}(x)$, $C_0(y)$, $C_{N+1}(y)$ drop out which implies that $I_x(I_y u) \in S^D \otimes S^D$. Using (4.30), we verify that $I_x(I_y u)$ satisfies (4.6)–(4.9), that is, (4.6)–(4.9) hold with $I_x(I_y u)$ in place of Z. Hence, the uniqueness

of the interpolant Z implies the first equation in (4.29). To prove the second equation in (4.29), we use (4.15) and (4.30) to see that for $(x, y) \in \overline{\Omega}$,

$$
\begin{aligned}
&I_y(D_x^2 u)(x,y)\\
&= \sum_{j=0}^{N+1} D_x^2 u(x,y_j)C_j(y) + D_x^2 D_y^2 u(x,y_0)C_{N+2}(y) + D_x^2 D_y^2 u(x,y_{N+1})C_{N+3}(y)\\
&= D_x^2\left[\sum_{j=0}^{N+1} u(x,y_j)C_j(y) + D_y^2 u(x,y_0)C_{N+2}(y) + D_y^2 u(x,y_{N+1})C_{N+3}(y)\right]\\
&= D_x^2(I_y u)(x,y). \qquad \square
\end{aligned}
$$

THEOREM 4.1. *If $u \in C^4(\overline{\Omega})$ and Z in $S^D \otimes S^D$ is defined by* (4.6)–(4.9)*, then* $\|u - Z\|_{C(\overline{\Omega})} \le C(u)h^4$.

Proof. Using (4.29) and the triangle inequality, we have

$$
\begin{aligned}
\|u - Z\|_{C(\overline{\Omega})} \le\ & \|u - I_x u\|_{C(\overline{\Omega})} + \|I_x(u - I_y u) - (u - I_y u)\|_{C(\overline{\Omega})}\\
&+ \|u - I_y u\|_{C(\overline{\Omega})}.
\end{aligned} \tag{4.31}
$$

For any fixed y in $[0,1]$, $I_x u(\cdot, y)$ is the cubic spline interpolant of $u(\cdot, y)$. Using this, symmetry with respect to x and y, and (4.17), we have

$$
\|u - I_x u\|_{C(\overline{\Omega})} \le C(u)h^4, \qquad \|u - I_y u\|_{C(\overline{\Omega})} \le C(u)h^4. \tag{4.32}
$$

For any fixed y in $[0,1]$, $I_x(u - I_y u)(\cdot, y)$ is the cubic spline interpolant of $(u - I_y u)(\cdot, y)$. Hence it follows from (4.16) that

$$
\|I_x(u - I_y u) - (u - I_y u)\|_{C(\overline{\Omega})} \le C\|D_x^2(u - I_y u)\|_{C(\overline{\Omega})} h^2. \tag{4.33}
$$

Using (4.29) and(4.16), we obtain

$$
\|D_x^2(u - I_y u)\|_{C(\overline{\Omega})} = \|D_x^2 u - I_y(D_x^2 u)\|_{C(\overline{\Omega})} \le C\|D_x^2 D_y^2 u\|_{C(\overline{\Omega})} h^2. \tag{4.34}
$$

Combining (4.33) and (4.34), we have

$$
\|I_x(u - I_y u) - (u - I_y u)\|_{C(\overline{\Omega})} \le C(u)h^4. \tag{4.35}
$$

The desired inequality now follows from (4.31), (4.32), and (4.35). $\square$

4.2. Bounding $\|S - Z\|_{C(\overline{\Omega})}$. We prove the following result.

THEOREM 4.2. *If $u \in C^4(\overline{\Omega})$ and S, Z in $S^D \otimes S^D$ are defined by* (4.2)–(4.5) *and* (4.6)–(4.9)*, respectively, then* $\|S - Z\|_{C(\overline{\Omega})} \le C(u)h^4$.

Proof. Clearly,

$$
S(x,y) = \sum_{m=0}^{N+1}\sum_{n=0}^{N+1} s_{m,n} B_m^D(x) B_n^D(y), \quad Z(x,y) = \sum_{m=0}^{N+1}\sum_{n=0}^{N+1} z_{m,n} B_m^D(x) B_n^D(y). \tag{4.36}
$$

Using (4.2), (4.6), and following the derivation of (3.3) from (1.3), we obtain

$$
s_{m,n} = z_{m,n}, \qquad m, n = 0, N+1. \tag{4.37}
$$

Using (4.7), we have

$$D_x^2(S-Z)(x_0,y_j) = D_x^2 S(x_0,y_j) - D_x^2 u(x_0,y_j), \quad j=1,\dots,N. \tag{4.38}$$

It follows from (4.36), (4.37), and (2.6) that

$$D_x^2(S-Z)(x_0,y_j) = -36h^{-2}\sum_{n=1}^{N}(s_{0,n}-z_{0,n})B_n^D(y_j), \quad j=1,\dots,N. \tag{4.39}$$

Using (4.36), (2.6), (2.4), (2.3), and (2.5), we obtain, for $j=1,\dots,N$, that

$$D_x^2 S(x_0,y_j) = -36h^{-2}\sum_{n=0}^{N+1} s_{0,n}B_n^D(y_j) = -36h^{-2}(s_{0,j-1}+4s_{0,j}+s_{0,j+1}). \tag{4.40}$$

Substituting (4.39) and (4.40) into (4.38), and multiplying through by $-h^2/36$, we have

$$\sum_{n=1}^{N}(s_{0,n}-z_{0,n})B_n^D(y_j) = s_{0,j-1}+4s_{0,j}+s_{0,j+1}+\frac{h^2}{36}D_x^2u(x_0,y_j) \tag{4.41}$$

for $j=1,\dots,N$. Using (4.2), (4.3), and following the derivations of (3.3) from (1.3) and (3.5) from (1.4), we obtain

$$s_{0,j} = \frac{h^4}{1296}D_x^2D_y^2u(x_0,y_j), \quad j=0,N+1, \tag{4.42}$$

and

$$s_{0,j} = -\frac{h^2}{216}\left[D_x^2u(x_0,y_j) - \frac{h^2}{12}D_x^4u(x_0,y_j) - \frac{h^2}{6}D_x^2D_y^2u(x_0,y_j)\right] \tag{4.43}$$

for $j=1,\dots,N$. Since $u=0$ on $\partial\Omega$, (4.42) is the same as (4.43) with $j=0,N+1$. This observation and (4.43) imply that for $j=1,\dots,N$, we have

$$s_{0,j\pm1} = -\frac{h^2}{216}\left[D_x^2u(x_0,y_{j\pm1}) - \frac{h^2}{12}D_x^4u(x_0,y_{j\pm1}) - \frac{h^2}{6}D_x^2D_y^2u(x_0,y_{j\pm1})\right]. \tag{4.44}$$

Taylor's theorem gives

$$D_x^2u(x_0,y_{j\pm1}) = D_x^2u(x_0,y_j) \pm hD_x^2D_yu(x_0,y_j) + \frac{h^2}{2}D_x^2D_y^2u(x_0,\xi_j^{\pm}), \tag{4.45}$$

where $y_{j-1}\le\xi_j^-\le y_j$, $y_j\le\xi_j^+\le y_{j+1}$. Using (4.44), (4.43), and (4.45), we obtain

$$\left|s_{0,j-1}+4s_{0,j}+s_{0,j+1}+\frac{h^2}{36}D_x^2u(x_0,y_j)\right| \le C(u)h^4, \quad j=1,\dots,N. \tag{4.46}$$

It follows from (4.46) that (4.41) is a system in $\{s_{0,n}-z_{0,n}\}_{n=1}^N$ with the matrix B defined in(2.10) and with each entry on the right-hand side bounded in absolute value by $C(u)h^4$. Hence, Lemma 2.2 implies

$$\max_{1\le n\le N}|s_{0,n}-z_{0,n}| \le C(u)h^4. \tag{4.47}$$

Using (4.47) and symmetry with respect to x and y, we also have

$$\begin{aligned} &\max_{1\le n\le N}|s_{N+1,n}-z_{N+1,n}|\le C(u)h^4,\\ &\max_{1\le m\le N}|s_{m,n}-z_{m,n}|\le C(u)h^4, \qquad n=0,N+1. \end{aligned} \tag{4.48}$$

Using (4.5) and (4.9), we have $(S-Z)(x_i,y_j)=0$, $i,j=1,\dots,N$, which, by (4.36) and (4.37), can be written as

$$\sum_{m=1}^{N}\sum_{n=1}^{N}(s_{m,n}-z_{m,n})B_m^D(x_i)B_n^D(y_j)=d_{i,j}, \qquad i,j=1,\dots N, \tag{4.49}$$

where

$$d_{i,j}=\left(\sum_{m=0,N+1}\sum_{n=1}^{N}+\sum_{m=1}^{N}\sum_{n=0,N+1}\right)(z_{m,n}-s_{m,n})B_m^D(x_i)B_n^D(y_j).$$

Since for any fixed i,j, each of the above double sums reduces to at most three terms, using the triangle inequality, (4.47), (4.48), and Lemma 2.1, we obtain

$$|d_{i,j}|\le C(u)h^4, \qquad i,j=1,\dots,N. \tag{4.50}$$

It follows from (2.18)–(2.19) that (4.49) is a system in $\{s_{m,n}-z_{m,n}\}_{m,n=1}^{N}$ with the matrix $B\otimes B$, where B is defined in (2.10). Hence, (4.50), Lemma 2.3, (4.47), and (4.48) give

$$|s_{m,n}-z_{m,n}|\le C(u)h^4, \qquad m,n=0,\dots,N+1. \tag{4.51}$$

Since $S-Z$ is continuous on $\overline{\Omega}$, there is (x_*,y_*) in $\overline{\Omega}$ such that

$$\|S-Z\|_{C(\overline{\Omega})}=|(S-Z)(x_*,y_*)|.$$

Hence, (4.36) and the triangle inequality imply

$$\|S-Z\|_{C(\overline{\Omega})}\le\sum_{m=0}^{N+1}\sum_{n=0}^{N+1}|s_{m,n}-z_{m,n}||B_m^D(x_*)||B_n^D(y_*)|.$$

Since the above double sum reduces to at most nine terms, the required inequality follows from (4.51) and Lemma 2.1. ∎

4.3. Bounding $\|S-u_h\|_{C(\overline{\Omega})}$ and $\|u-u_h\|_{C(\overline{\Omega})}$. To bound $\|S-u_h\|_{C(\overline{\Omega})}$, we need two additional lemmas.

LEMMA 4.3. *If $u\in C^6(\overline{\Omega})$ and S in $S^D\otimes S^D$ is defined by (4.2)–(4.5), then for $i=0,N+1$, $j=1,\dots,N$,*

$$\left|D_x^2D_y^2S(x_i,y_j)-D_x^2D_y^2u(x_i,y_j)\right|\le C(u)h^2, \tag{4.52}$$

$$\left|D_x^2S(x_i,y_j)-D_x^2u(x_i,y_j)+\frac{h^2}{12}D_x^4u(x_i,y_j)\right|\le C(u)h^4. \tag{4.53}$$

Proof. We prove (4.52) for $i = 0$; for $i = N + 1$, (4.52) follows by symmetry with respect to x. Using (4.36), we obtain

$$D_x^2 D_y^2 S(x_0, y_j) = \sum_{m=0}^{N+1} \sum_{n=0}^{N+1} s_{m,n} \left[B_m^D\right]''(x_0) \left[B_n^D\right]''(y_j), \qquad j = 1, \ldots, N,$$

and hence (2.4), (2.3), and (2.6) imply

$$D_x^2 D_y^2 S(x_0, y_j) = -216h^{-4}(s_{0,j-1} - 2s_{0,j} + s_{0,j+1}), \quad j = 1, \ldots, N. \tag{4.54}$$

Equations (4.54), (4.43), and (4.44) give, for $j = 1, \ldots, N$,

$$\begin{aligned} &D_x^2 D_y^2 S(x_0, y_j) - D_x^2 D_y^2 u(x_0, y_j) = -D_x^2 D_y^2 u(x_0, y_j) \\ &+h^{-2}\left[D_x^2 u(x_0, y_{j-1}) - 2D_x^2 u(x_0, y_j) + D_x^2 u(x_0, y_{j+1})\right] \\ &-\frac{1}{12}\left[D_x^4 u(x_0, y_{j-1}) - 2D_x^4 u(x_0, y_j) + D_x^4 u(x_0, y_{j+1})\right] \\ &-\frac{1}{6}\left[D_x^2 D_y^2 u(x_0, y_{j-1}) - 2D_x^2 D_y^2 u(x_0, y_j) + D_x^2 D_y^2 u(x_0, y_{j+1})\right]. \end{aligned} \tag{4.55}$$

Using Taylor's theorem, we obtain

$$\begin{aligned} D_x^2 u(x_0, y_{j\pm1}) = D_x^2 u(x_0, y_j) \pm hD_x^2 D_y u(x_0, y_j) + \frac{h^2}{2} D_x^2 D_y^2 u(x_0, y_j) \\ \pm \frac{h^3}{3!} D_x^2 D_y^3 u(x_0, y_j) + \frac{h^4}{4!} D_x^2 D_y^4 u(x_0, \xi_j^{\pm}), \end{aligned} \tag{4.56}$$

$$D_x^4 u(x_0, y_{j\pm1}) = D_x^4 u(x_0, y_j) \pm hD_x^4 D_y u(x_0, y_j) + \frac{h^2}{2} D_x^4 D_y^2 u(x_0, \eta_j^{\pm}), \tag{4.57}$$

$$D_x^2 D_y^2 u(x_0, y_{j\pm1}) = D_x^2 D_y^2 u(x_0, y_j) \pm hD_x^2 D_y^3 u(x_0, y_j) + \frac{h^2}{2} D_x^2 D_y^4 u(x_0, \kappa_j^{\pm}), \tag{4.58}$$

where $y_{j-1} \le \xi_j^-, \eta_j^-, \kappa_j^- \le y_j$, $y_j \le \xi_j^+, \eta_j^+, \kappa_j^+ \le y_{j+1}$. Equations (4.56)–(4.58) give

$$\begin{aligned} \left|h^{-2}\left[D_x^2 u(x_0, y_{j-1}) - 2D_x^2 u(x_0, y_j) + D_x^2 u(x_0, y_{j+1})\right] - D_x^2 D_y^2 u(x_0, y_j)\right| \le C(u)h^2, \\ \left|D_x^4 u(x_0, y_{j-1}) - 2D_x^4 u(x_0, y_j) + D_x^4 u(x_0, y_{j+1})\right| \le C(u)h^2, \\ \left|D_x^2 D_y^2 u(x_0, y_{j-1}) - 2D_x^2 D_y^2 u(x_0, y_j) + D_x^2 D_y^2 u(x_0, y_{j+1})\right| \le C(u)h^2, \end{aligned}$$

and hence (4.52) for $i = 0$ follows from (4.55) and the triangle inequality. Using (4.3) and (4.52), we obtain (4.53). ∎

LEMMA 4.4. *If $u \in C^6(\overline{\Omega})$ and S in $S^D \otimes S^D$ is defined by* (4.2)–(4.5)*, then, for $i, j = 1, \ldots, N$, we have*

$$\left|D_x^2 S(x_i, y_j) - D_x^2 u(x_i, y_j) + \frac{h^2}{12} D_x^4 u(x_i, y_j)\right| \le C(u)h^4, \tag{4.59}$$

$$\left|D_y^2 S(x_i, y_j) - D_y^2 u(x_i, y_j) + \frac{h^2}{12} D_y^4 u(x_i, y_j)\right| \le C(u)h^4, \tag{4.60}$$

$$|D_x^2 D_y^2 S(x_i, y_j) - D_x^2 D_y^2 u(x_i, y_j)| \le C(u)h^2. \tag{4.61}$$

Proof. First, we prove (4.59). For $i = 0, \ldots, N+1$, $j = 1, \ldots, N$, we introduce

$$d_{i,j} = D_x^2 S(x_i, y_j) - \left[D_x^2 u(x_i, y_j) - \frac{h^2}{12} D_x^4 u(x_i, y_j) \right]. \tag{4.62}$$

Then

$$d_{i-1,j} + 4d_{i,j} + d_{i+1,j} = \phi_{i,j} - \psi_{i,j}, \qquad i, j = 1, \ldots, N, \tag{4.63}$$

where

$$\begin{aligned} \phi_{i,j} &= D_x^2 S(x_{i-1}, y_j) + 4D_x^2 S(x_i, y_j) + D_x^2 S(x_{i+1}, y_j) \\ &\quad - 6 \left[D_x^2 u(x_i, y_j) + \frac{h^2}{12} D_x^4 u(x_i, y_j) \right], \end{aligned} \tag{4.64}$$

$$\begin{aligned} \psi_{i,j} &= D_x^2 u(x_{i-1}, y_j) - \frac{h^2}{12} D_x^4 u(x_{i-1}, y_j) + 4 \left[D_x^2 u(x_i, y_j) - \frac{h^2}{12} D_x^4 u(x_i, y_j) \right] \\ &\quad + D_x^2 u(x_{i+1}, y_j) - \frac{h^2}{12} D_x^4 u(x_{i+1}, y_j) - 6 \left[D_x^2 u(x_i, y_j) + \frac{h^2}{12} D_x^4 u(x_i, y_j) \right] \\ &= D_x^2 u(x_{i-1}, y_j) - 2D_x^2 u(x_i, y_j) + D_x^2 u(x_{i+1}, y_j) \\ &\quad - \frac{h^2}{12} \left[D_x^4 u(x_{i-1}, y_j) + 10 D_x^4 u(x_i, y_j) + D_x^4 u(x_{i+1}, y_j) \right]. \end{aligned} \tag{4.65}$$

Since $S(\cdot, y_j) \in S_3$, (2.1.7) in [1], (4.5), and $S = u = 0$ on $\partial\Omega$, imply that

$$\begin{aligned} &D_x^2 S(x_{i-1}, y_j) + 4D_x^2 S(x_i, y_j) + D_x^2 S(x_{i+1}, y_j) \\ &= 6h^{-2} \left[u(x_{i-1}, y_j) - 2u(x_i, y_j) + u(x_{i+1}, y_j) \right], \quad i, j = 1, \ldots, N. \end{aligned} \tag{4.66}$$

Using Taylor's theorem, we obtain

$$\begin{aligned} u(x_{i\pm1}, y_j) &= u(x_i, y_j) \pm h D_x u(x_i, y_j) + \frac{h^2}{2} D_x^2 u(x_i, y_j) \pm \frac{h^3}{3!} D_x^3 u(x_i, y_j) \\ &\quad + \frac{h^4}{4!} D_x^4 u(x_i, y_j) \pm \frac{h^5}{5!} D_x^5 u(x_i, y_j) + \frac{h^6}{6!} D_x^6 u(\xi_i^{\pm}, y_j), \end{aligned}$$

where $x_{i-1} \le \xi_i^- \le x_i$, $x_i \le \xi_i^+ \le x_{i+1}$, and hence

$$\begin{aligned} &\Big| h^{-2} \left[u(x_{i-1}, y_j) - 2u(x_i, y_j) + u(x_{i+1}, y_j) \right] \\ &\quad - \left[D_x^2 u(x_i, y_j) + \frac{h^2}{12} D_x^4 u(x_i, y_j) \right] \Big| \le C(u)h^4, \quad i, j = 1, \ldots, N. \end{aligned} \tag{4.67}$$

Using (4.64), (4.66), and (4.67), we obtain

$$|\phi_{i,j}| \le C(u)h^4, \quad i, j = 1, \ldots, N. \tag{4.68}$$

Using Taylor's theorem, we obtain

$$\begin{aligned} D_x^2 u(x_{i\pm1}, y_j) &= D_x^2 u(x_i, y_j) \pm h D_x^3 u(x_i, y_j) + \frac{h^2}{2} D_x^4 u(x_i, y_j) \\ &\quad \pm \frac{h^3}{3!} D_x^5 u(x_i, y_j) + \frac{h^4}{4!} D_x^6 u(\xi_i^{\pm}, y_j), \\ D_x^4 u(x_{i\pm1}, y_j) &= D_x^4 u(x_i, y_j) \pm h D_x^5 u(x_i, y_j) + \frac{h^2}{2} D_x^6 u(\eta_i^{\pm}, y_j), \end{aligned}$$

where $x_{i-1} \le \xi_i^-, \eta_i^- \le x_i$, $x_i \le \xi_i^+, \eta_i^+ \le x_{i+1}$, and hence (4.65) gives

$$|\psi_{i,j}| \le C(u)h^4, \quad i,j = 1,\dots,N. \tag{4.69}$$

Using (4.62) and (4.53), we have

$$|d_{i,j}| \le C(u)h^4, \quad i = 0, N+1, \quad j = 1,\dots,N. \tag{4.70}$$

It follows from (4.68)–(4.70) that moving $d_{0,j}$ and $d_{N+1,j}$ to the right-hand side of (4.63), we obtain, for each $j = 1,\dots,N$, a system in $\{d_{i,j}\}_{i=1}^N$ with the matrix B of (2.10)–(2.12), and with each entry on the right-hand side bounded in absolute value by $C(u)h^4$. Hence (4.59) follows from (4.62) and Lemma 2.2, and (4.60) follows from (4.59) by symmetry with respect to x and y.

Next we prove (4.61). Since $S(x,\cdot) \in S_3$ for $x \in [0,1]$, (2.1.7) in [1] gives

$$\begin{aligned} &D_y^2 S(x,y_{j-1}) + 4D_y^2 S(x,y_j) + D_y^2 S(x,y_{j+1}) \\ &= 6h^{-2}\left[S(x,y_{j-1}) - 2S(x,y_j) + S(x,y_{j+1})\right], \quad j = 1,\dots,N, \quad x \in [0,1]. \end{aligned} \tag{4.71}$$

Differentiating (4.71) twice with respect to x, we obtain, for $j = 1,\dots,N$, $x \in [0,1]$,

$$\begin{aligned} &D_x^2 D_y^2 S(x,y_{j-1}) + 4D_x^2 D_y^2 S(x,y_j) + D_x^2 D_y^2 S(x,y_{j+1}) \\ &= 6h^{-2}\left[D_x^2 S(x,y_{j-1}) - 2D_x^2 S(x,y_j) + D_x^2 S(x,y_{j+1})\right]. \end{aligned} \tag{4.72}$$

Using (4.72) with $x = x_{i-1}, x_i, x_{i+1}$, we obtain, for $i,j = 1,\dots,N$,

$$\begin{aligned} &D_x^2 D_y^2 S(x_{i-1},y_{j-1}) + 4D_x^2 D_y^2 S(x_{i-1},y_j) + D_x^2 D_y^2 S(x_{i-1},y_{j+1}) \\ &= 6h^{-2}\left[D_x^2 S(x_{i-1},y_{j-1}) - 2D_x^2 S(x_{i-1},y_j) + D_x^2 S(x_{i-1},y_{j+1})\right], \end{aligned} \tag{4.73}$$

$$\begin{aligned} &D_x^2 D_y^2 S(x_i,y_{j-1}) + 4D_x^2 D_y^2 S(x_i,y_j) + D_x^2 D_y^2 S(x_i,y_{j+1}) \\ &= 6h^{-2}\left[D_x^2 S(x_i,y_{j-1}) - 2D_x^2 S(x_i,y_j) + D_x^2 S(x_i,y_{j+1})\right], \end{aligned} \tag{4.74}$$

$$\begin{aligned} &D_x^2 D_y^2 S(x_{i+1},y_{j-1}) + 4D_x^2 D_y^2 S(x_{i+1},y_j) + D_x^2 D_y^2 S(x_{i+1},y_{j+1}) \\ &= 6h^{-2}\left[D_x^2 S(x_{i+1},y_{j-1}) - 2D_x^2 S(x_{i+1},y_j) + D_x^2 S(x_{i+1},y_{j+1})\right]. \end{aligned} \tag{4.75}$$

Adding (4.73), (4.75), and (4.74) multiplied through by 4, and using (4.66) and $S = u = 0$ on $\partial\Omega$, we obtain

$$\begin{aligned} &D_x^2 D_y^2 S(x_{i-1},y_{j-1}) + 4D_x^2 D_y^2 S(x_{i-1},y_j) + D_x^2 D_y^2 S(x_{i-1},y_{j+1}) \\ &+4D_x^2 D_y^2 S(x_i,y_{j-1}) + 16D_x^2 D_y^2 S(x_i,y_j) + 4D_x^2 D_y^2 S(x_i,y_{j+1}) \\ &+D_x^2 D_y^2 S(x_{i+1},y_{j-1}) + 4D_x^2 D_y^2 S(x_{i+1},y_j) + D_x^2 D_y^2 S(x_{i+1},y_{j+1}) \\ &= 36h^{-4}\alpha_{i,j}, \quad i,j = 1,\dots,N, \end{aligned} \tag{4.76}$$

where

$$\begin{aligned} \alpha_{i,j} = {} & u(x_{i-1},y_{j-1}) - 2u(x_i,y_{j-1}) + u(x_{i+1},y_{j-1}) \\ & -2u(x_{i-1},y_j) + 4u(x_i,y_j) - 2u(x_{i+1},y_j) \\ & +u(x_{i-1},y_{j+1}) - 2u(x_i,y_{j+1}) + u(x_{i+1},y_{j+1}). \end{aligned} \tag{4.77}$$

Using (4.77) and the discussion on pages 290–292 in [9], we have

$$\left|h^{-4}\alpha_{i,j} - D_x^2 D_y^2 u(x_i,y_j)\right| \le C(u)h^2, \quad i,j = 1,\dots,N. \tag{4.78}$$

Equation (4.76) is equivalent to

$$\begin{aligned}
&D_x^2D_y^2(S-u)(x_{i-1},y_{j-1})+4D_x^2D_y^2(S-u)(x_{i-1},y_j)\\
&+D_x^2D_y^2(S-u)(x_{i-1},y_{j+1})+4D_x^2D_y^2(S-u)(x_i,y_{j-1})\\
&+16D_x^2D_y^2(S-u)(x_i,y_j)+4D_x^2D_y^2(S-u)(x_i,y_{j+1})\\
&+D_x^2D_y^2(S-u)(x_{i+1},y_{j-1})+4D_x^2D_y^2(S-u)(x_{i+1},y_j)\\
&+D_x^2D_y^2(S-u)(x_{i+1},y_{j+1})=36h^{-4}\alpha_{i,j}-\beta_{i,j},\qquad i,j=1,\dots,N,
\end{aligned}\tag{4.79}$$

where

$$\begin{aligned}
\beta_{i,j}=\ &D_x^2D_y^2u(x_{i-1},y_{j-1})+4D_x^2D_y^2u(x_{i-1},y_j)+D_x^2D_y^2u(x_{i-1},y_{j+1})\\
&+4D_x^2D_y^2u(x_i,y_{j-1})+16D_x^2D_y^2u(x_i,y_j)+4D_x^2D_y^2u(x_i,y_{j+1})\\
&+D_x^2D_y^2u(x_{i+1},y_{j-1})+4D_x^2D_y^2u(x_{i+1},y_j)+D_x^2D_y^2u(x_{i+1},y_{j+1}).
\end{aligned}\tag{4.80}$$

Using Taylor's theorem, we obtain

$$\begin{aligned}
D_x^2D_y^2u(x_{i-1},y_{j\pm1})&=D_x^2D_y^2u(x_i,y_j)-hD_x^3D_y^2u(x_i,y_j)\pm hD_x^2D_y^3D_yu(x_i,y_j)+\epsilon_{i,j}^{\pm},\\
D_x^2D_y^2u(x_{i+1},y_{j\pm1})&=D_x^2D_y^2u(x_i,y_j)+hD_x^3D_y^2u(x_i,y_j)\pm hD_x^2D_y^3D_yu(x_i,y_j)+\sigma_{i,j}^{\pm},\\
D_x^2D_y^2u(x_i,y_{j\pm1})&=D_x^2D_y^2u(x_i,y_j)\pm hD_x^2D_y^3u(x_i,y_j)+\mu_{i,j}^{\pm},\\
D_x^2D_y^2u(x_{i\pm1},y_j)&=D_x^2D_y^2u(x_i,y_j)\pm hD_x^3D_y^2u(x_i,y_j)+\nu_{i,j}^{\pm},
\end{aligned}$$

where $|\epsilon_{i,j}^{\pm}|$, $|\sigma_{i,j}^{\pm}|$, $|\mu_{i,j}^{\pm}|$, $|\nu_{i,j}^{\pm}|\le C(u)h^2$, $i,j=1,\dots,N$, and hence (4.80) gives

$$\left|\beta_{i,j}-36D_x^2D_y^2u(x_i,y_j)\right|\le C(u)h^2,\qquad i,j=1,\dots,N.\tag{4.81}$$

It follows from (4.78) and (4.81) that the right-hand side of (4.79) is bounded in absolute value by $C(u)h^2$. Using (4.2) and moving terms involving

$$D_x^2D_y^2(S-u)(x_i,y_j),\quad i=0,N+1,j=1,\dots,N,\quad i=1,\dots,N,j=0,N+1,$$

to the right-hand side of (4.79), we obtain a system in $\{D_x^2D_y^2(S-u)(x_i,y_j)\}_{i,j=1}^N$ with the matrix $B\otimes B$, where B is given in (2.10)–(2.12). By (4.52) and symmetry with respect to x and y, each entry on the right-hand side in this system is bounded in absolute value by $C(u)h^2$. Therefore, (4.61) follows from Lemma 2.3. ∎

THEOREM 4.3. *If $u\in C^6(\overline{\Omega})$ and u_h and S in $S^D\otimes S^D$ are defined by* (1.3)–(1.6) *and* (4.2)–(4.5)*, respectively, then $\|S-u_h\|_{C(\overline{\Omega})}\le C(u)h^4$.*

Proof. Clearly, u_h and S are given by the formulas in (3.1) and (4.36), respectively. Using (4.2)–(4.4), (4.11)–(4.13), and following the derivations of (3.3) from (1.3), (3.5) from (1.4), and (3.6) from (1.5), we conclude that

$$s_{m,n}=u_{m,n},\quad m=0,N+1,n=0,\dots,N+1,\quad m=1,\dots,N,n=0,N+1.\tag{4.82}$$

We define $\{w_{i,j}\}_{i,j=1}^N$ by

$$\Delta(S-u_h)(x_i,y_j)-\frac{h^2}{6}D_x^2D_y^2(S-u_h)(x_i,y_j)=w_{i,j},\quad i,j=1,\dots,N.\tag{4.83}$$

Using (4.83), (1.6), and (4.10), we obtain

$$\begin{aligned}
w_{i,j}=\ &D_x^2S(x_i,y_j)+D_y^2S(x_i,y_j)-\frac{h^2}{6}D_x^2D_y^2S(x_i,y_j)\\
&-D_x^2u(x_i,y_j)-D_y^2u(x_i,y_j)+\frac{h^2}{12}\left[D_x^4u(x_i,y_j)+D_y^4u(x_i,y_j)+2D_x^2D_y^2u(x_i,y_j)\right],
\end{aligned}$$

and hence (4.59)–(4.61) and the triangle inequality imply that

$$|w_{i,j}| \le C(u)h^4, \quad i,j = 1,\dots,N. \tag{4.84}$$

Introducing $\mathbf{v} = [s_{1,1} - u_{1,1},\dots,s_{N,N} - u_{N,N}]^T$, $\mathbf{w} = [w_{1,1},\dots,w_{N,N}]^T$, using (4.83), (3.1), (4.36), (4.82), and following the derivation of (3.10) from (1.6), we obtain

$$6h^{-2}\left[6T \otimes I + (6I + T) \otimes T\right]\mathbf{v} = \mathbf{w}. \tag{4.85}$$

Since $h = 1/(N+1)$, (4.84) gives $h^2\sum_{i,j=1}^{N} w_{i,j}^2 \le C^2(u)h^8$, and hence (4.85), (3.12), and Lemma 2.4 imply that

$$\max_{1\le m,n\le N} |s_{m,n} - u_{m,n}| \le C(u)h^4, \quad m,n = 1,\dots,N. \tag{4.86}$$

Since $S - u_h$ is continuous on $\overline{\Omega}$, there is (x_*, y_*) in $\overline{\Omega}$ such that

$$\|S - u_h\|_{C(\overline{\Omega})} = |(S - u_h)(x_*, y_*)|.$$

Hence, (3.1), (4.36), (4.82), and the triangle inequality give

$$\|S - u_h\|_{C(\overline{\Omega})} \le \sum_{m=1}^{N}\sum_{n=1}^{N} |s_{m,n} - u_{m,n}||B_m^D(x_*)||B_n^D(y_*)|.$$

Since the above double sum reduces to at most nine terms, the desired result follows from (4.86) and Lemma 2.1. □

THEOREM 4.4. *If u in $C^6(\overline{\Omega})$ and u_h in $S^D \otimes S^D$ are the solutions of* (1.1) *and* (1.3)–(1.6)*, respectively, then* $\|u - u_h\|_{C(\overline{\Omega})} \le C(u)h^4$.

Proof. The required inequality follows from (4.14) and Theorems 4.1, 4.2, and 4.3. □

5. Other schemes. Consider the scheme for solving (1.1) formulated as follows: Find $u_h \in S^D \otimes S^D$ satisfying (1.3)–(1.5) and (1.9). This scheme is essentially the same as the scheme (4.1)–(4.3) in [4], except that (1.5) is replaced in [4] with

$$\frac{1}{12}[13D_y^2u_h(x_i,y_j) - 2D_y^2u_h(x_i,y_{j+1}) + D_y^2u_h(x_i,y_{j+2})] = f(x_i,y_j), \quad j = 0,$$

$$\frac{1}{12}[D_y^2u_h(x_i,y_{j-2}) - 2D_y^2u_h(x_i,y_{j-1}) + 13D_y^2u_h(x_i,y_j)] = f(x_i,y_j), \quad j = N+1,$$

where $i = 1,\dots,N$. It follows from (3.1), the discussion in section 3, and (2.9) of [4] that the matrix-vector form of (1.3)–(1.5) and (1.9) is

$$(A \otimes B + B \otimes A)\mathbf{u} = \mathbf{p}, \tag{5.1}$$

where $\mathbf{u} = [u_{1,1},\dots,u_{N,N}]^T$, $\mathbf{p} = [p_{1,1},\dots,p_{N,N}]^T$,

$$p_{i,j} = f(x_i,y_j) - \sum_{m=0,N+1}\sum_{n=0}^{N+1} u_{m,n}\left[L_xB_m^D(x_i)B_n^D(y_j) + B_m^D(x_i)L_yB_m^D(y_j)\right]$$
$$-\sum_{m=1}^{N}\sum_{n=0,N+1} u_{m,n}\left[L_xB_m^D(x_i)B_n^D(y_j) + B_m^D(x_i)L_yB_n^D(y_j)\right],$$

$\{u_{i,j}\}_{j=0}^{N+1}$, $i = 0, N+1$, $\{u_{i,j}\}_{i=1}^{N}$, $j = 0, N+1$, are given in (3.3), (3.5), (3.6),

$$A = \frac{1}{2h^2}(T^2 + 12T), \quad B = T + 6I, \tag{5.2}$$

and T is defined in (2.12).

LEMMA 5.1. *Assume A, B are as in* (5.2) *and* $\mathbf{v} = [v_{1,1}, \ldots, v_{N,N}]^T$, $\mathbf{w} = [w_{1,1}, \ldots, w_{N,N}]^T$ *are such that* $(A \otimes B + B \otimes A)\mathbf{v} = \mathbf{w}$. *Then*

$$\max_{1 \le i,j \le N} v_{i,j}^2 \le Ch^2 \sum_{i=1}^{N} \sum_{j=1}^{N} w_{i,j}^2.$$

Proof. It follows from (5.2) that

$$\begin{aligned} A \otimes B + B \otimes A &= \frac{1}{2h^2}(T^2 \otimes T) + \frac{3}{h^2}(T^2 \otimes I) + \frac{6}{h^2}(T \otimes T) + \frac{36}{h^2}(T \otimes I) \\ &+ \frac{1}{2h^2}(T \otimes T^2) + \frac{3}{h^2}(I \otimes T^2) + \frac{6}{h^2}(T \otimes T) + \frac{36}{h^2}(I \otimes T) = 36[r(T) + s(T)], \end{aligned} \tag{5.3}$$

where for an $N \times N$ matrix P,

$$r(P) = h^{-2}(P \otimes I + I \otimes P), \tag{5.4}$$

$$s(P) = \frac{1}{3h^2}(P \otimes P) + \frac{1}{72h^2}\left(P^2 \otimes P + P \otimes P^2\right) + \frac{1}{12h^2}\left(P^2 \otimes I + I \otimes P^2\right). \tag{5.5}$$

First, we will show that

$$([r(T) + s(T)]\mathbf{z}, \mathbf{z}) \le \frac{2}{9}(r(T)\mathbf{z}, \mathbf{z}), \qquad \mathbf{z} \in R^{N^2}, \tag{5.6}$$

where $(\cdot, \cdot)$ is the standard inner product in R^{N^2}. It follows from (2.14) and $Q^T = Q$ for Q of (2.16) that

$$(r(T)\mathbf{z}, \mathbf{z}) = ([Q \otimes Q]r(\Lambda)[Q \otimes Q]\mathbf{z}, \mathbf{z}) = (r(\Lambda)[Q \otimes Q]\mathbf{z}, [Q \otimes Q]\mathbf{z}),$$

$$(s(T)\mathbf{z}, \mathbf{z}) = ([Q \otimes Q]s(\Lambda)[Q \otimes Q]\mathbf{z}, \mathbf{z}) = (s(\Lambda)[Q \otimes Q]\mathbf{z}, [Q \otimes Q]\mathbf{z}),$$

where Λ is given in (2.15). Hence (5.6) is equivalent to

$$([r(\Lambda) + s(\Lambda)]\mathbf{z}, \mathbf{z}) \le \frac{2}{9}(r(\Lambda)\mathbf{z}, \mathbf{z}), \qquad \mathbf{z} \in R^{N^2},$$

which, by (5.4), (5.5), and (2.15), is in turn equivalent to

$$g(\lambda_i, \lambda_j) \le 0, \qquad i, j = 1, \ldots, N, \tag{5.7}$$

where

$$g(x, y) = \frac{7}{9}(x + y) + \frac{1}{3}xy + \frac{1}{72}(x^2 y + xy^2) + \frac{1}{12}(x^2 + y^2).$$

It follows from (2.15) that $-4 \le \lambda_i \le 0$, $i = 1, \ldots, N$. Hence, (5.7) follows from

$$g(x, y) \le 0, \qquad x, y \in [-4, 0],$$

which is established using elementary calculus.

The matrices $r(T)$ and $s(T)$ are symmetric, $r(T)s(T) = s(T)r(T)$, and $-r(T)$ is positive definite. Hence, (5.6) and the considerations 6) on page 135 in [9] imply that

$$\|r(T)\mathbf{z}\|_2 \le \frac{9}{2}\|[r(T)+s(T)]\mathbf{z}\|_2, \qquad \mathbf{z} \in R^{N^2}, \tag{5.8}$$

where $\|\cdot\|_2$ is the two vector norm. It is known (see, for example, the embedding theorem on page 281 in [9]) that

$$\max_{1\le i,j\le N} z_{i,j}^2 \le \frac{1}{4}h^2\|r(T)\mathbf{z}\|_2^2, \qquad \mathbf{z} = [z_{1,1},\dots,z_{N,N}]^T \in R^{N^2}. \tag{5.9}$$

Hence the desired result follows from (5.9), (5.8), and (5.3). □

THEOREM 5.1. *If $u \in C^6(\overline{\Omega})$ and u_h and S are defined by* (1.3)–(1.5) *and* (1.9)*, and* (4.2)–(4.5)*, respectively, then $\|S-u_h\|_{C(\overline{\Omega})} \le C(u)h^4$.*

Proof. Following the proof of Theorem 4.3, we define $\{w_{i,j}\}_{i,j=1}^N$ by

$$(L_x+L_y)(S-u_h)(x_i,y_j) = w_{i,j}, \quad i,j = 1,\dots,N. \tag{5.10}$$

Using (5.10), (1.9), and (1.1), we obtain

$$w_{i,j} = L_xS(x_i,y_j) - D_x^2u(x_i,y_j) + L_yS(x_i,y_j) - D_y^2u(x_i,y_j).$$

Equations (1.10), (4.59), and (4.53) give, for $i,j = 1,\dots,N$,

$$\begin{aligned}
&L_xS(x_i,y_j) - D_x^2u(x_i,y_j) = D_x^2S(x_i,y_j) - D_x^2u(x_i,y_j)\\
&+\frac{1}{12}[D_x^2S(x_{i-1},y_j) - 2D_x^2S(x_i,y_j) + D_x^2S(x_{i+1},y_j)]\\
&= -\frac{h^2}{12}D_x^4u(x_i,y_j) + \frac{1}{12}[D_x^2u(x_{i-1},y_j) - 2D_x^2u(x_i,y_j) + D_x^2u(x_{i+1},y_j)]\\
&-\frac{h^2}{144}[D_x^4u(x_{i-1},y_j) - 2D_x^4u(x_i,y_j) + D_x^4u(x_{i+1},y_j)] + \epsilon_{i,j},
\end{aligned}$$

where $|\epsilon_{i,j}| \le C(u)h^4$, $i,j = 1,\dots,N$. Hence Taylor's theorem and similar considerations for $L_yS(x_i,y_j) - D_y^2u(x_i,y_j)$ show that (4.84) holds. It follows from (3.1), (4.36), and (4.82) that the matrix-vector form of (5.10) is

$$(A\otimes B + B\otimes A)\mathbf{v} = \mathbf{w},$$

where A, B are as in (5.2), $\mathbf{v} = [s_{1,1}-u_{1,1},\dots,s_{N,N}-u_{N,N}]^T$, $\mathbf{w} = [w_{1,1},\dots,w_{N,N}]^T$. Hence Lemma 5.1 implies (4.86) and the desired result follows from the proof of Theorem 4.3. □

THEOREM 5.2. *If u in $C^6(\overline{\Omega})$ and u_h in $S^D\otimes S^D$ are the solutions of* (1.1)*, and* (1.3)–(1.5) *and* (1.9)*, respectively, then*

$$\|u-u_h\|_{C(\overline{\Omega})} \le C(u)h^4. \tag{5.11}$$

Proof. The required inequality follows from (4.14) and Theorems 4.1, 4.2, and 5.1. □

It is claimed in Theorem 4.1 of [8] that for the scheme (1.3) and (1.7)–(1.9), one has (5.11) provided that $u \in C^6(\overline{\Omega})$. The proof of this claim in [8] is based on using Z

defined in (4.6)–(4.9) as a comparison function. It is claimed, for example, in Lemma 2.1 of [8] that Z has properties (4.59) and (4.60), that is, (4.59) and (4.60) hold with Z in place of S. Unfortunately, numerical examples indicate that such property does not hold even in the one-dimensional case. Specifically, for $u(x) = x(x-1)e^x$ and $Z \in S^D$ such that

$$Z(x_i) = u(x_i), \quad i = 1, \ldots, N, \qquad Z''(x_i) = u''(x_i), \quad i = 0, N+1,$$

we only have

$$\max_{1 \le i \le N} \left| Z''(x_i) - u''(x_i) + \frac{h^2}{12} u^{(4)}(x_i) \right| = Ch^2$$

and not better. It should be noted that the convergence analysis of [6] for two-point boundary value problems involves the comparison function $S \in S^D$ defined by

$$S(x_i) = u(x_i), \quad i = 1, \ldots, N, \qquad S''(x_i) = u''(x_i) - \frac{h^2}{12} u^{(4)}(x_i), \quad i = 0, N+1,$$

which, in part, was motivation for the definition (4.2)–(4.5). The convergence analysis of the scheme (4.2)–(4.4) in [8] remains an open problem. We believe that such analysis may require proving stability not only with respect to the right-hand side but also with respect to the boundary conditions.

6. Numerical results. We used scheme (1.3)–(1.6) and the algorithm in section 3 to solve a test problem (1.1). The computations were carried out in double precision. We determined the nodal and global errors using the formulas

$$\|w\|_h = \max_{0 \le i,j \le N+1} |w(x_i, y_j)|, \qquad \|w\|_{C(\overline{\Omega})} \approx \max_{0 \le i,j \le 501} |w(t_i, t_j)|,$$

where $t_i = i/501$, $i = 1, \ldots, 501$. Convergence rates were determined using the formula

$$\text{rate} = \frac{\log(e_{N/2}/e_N)}{\log[(N+1)/(N/2+1)]},$$

where e_N is the error corresponding to the partition $\rho_x \times \rho_y$.

We took f in (1.1) corresponding to the exact solution

$$u(x, y) = 3e^{xy}(x^2 - x)(y^2 - y).$$

We see from the results in Tables 1 and 2 that the scheme (1.3)–(1.6) produces fourth order accuracy for u in both the discrete and the continuous maximum norms. We also observe superconvergence phenomena since the derivative approximations at the partition nodes are of order four.

$\mathcal{Y}$-SCALE REGULARIZATION*

HERBERT EGGER†

Abstract. Many inverse problems are ill-posed in the sense that their solution is unstable with respect to data perturbations, and hence *regularization methods* have to be used for their stable solution. Two possible drawbacks of standard regularization methods are (a) saturation, i.e., only suboptimal approximations can be found for smooth solutions—this is the case, e.g., for Tikhonov regularization; (b) numerical effort, e.g., the large number of iterations of methods like Landweber iteration. A framework that allows us to overcome both effects at least for certain classes of inverse problems is regularization in Hilbert scales, where a solution is searched in a scale of spaces (Hilbert scale), but convergence is achieved in the original space. Regularization methods in Hilbert scales can be viewed as modified (preconditioned) versions of standard methods. In order to make the advantages of the Hilbert scale approach applicable to a new class of problems, we propose to use a scale of spaces over the image space instead. This results in a new family of methods which we call $\mathcal{Y}$*-scale regularization*, and whose (optimal) convergence properties are analyzed. One of the key steps in the analysis is the formulation of an adequate a posteriori stopping rule and the proof of optimal convergence rates. The theoretical results are illustrated in several numerical examples.

Key words. inverse problems, regularization, Hilbert scales, preconditioning

1. Introduction.

We consider the solution of linear inverse problems of the form

$$Tx = y^\delta, \tag{1.1}$$

where $T \in L(\mathcal{X}, \mathcal{Y})$ is a linear bounded injective operator between Hilbert spaces $\mathcal{X}$ and $\mathcal{Y}$; without loss of generality we assume $\|T\| \le 1$. Such problems arise in a variety of applications; cf., e.g., [2, 3, 5, 8, 15] and the references therein. In practice, one tries to reconstruct the solution from perturbed measurements y^δ, and we assume that at least a bound on the data error

$$\|y - y^\delta\| \le \delta \tag{1.2}$$

is available, where $y = Tx^\dagger \in \mathcal{R}(T)$ denotes the unperturbed data corresponding to the *true* solution $x^\dagger$. It is well known (cf., e.g., [8, 11]) that in case $\mathcal{R}(T)$ is not closed in $\mathcal{Y}$, problem (1.1) is *ill-posed*, i.e., (1.1) might not admit a unique solution, and more severely, a solution is usually unstable with respect to data noise $y - y^\delta$. In order to construct a stable approximate solution of (1.1) we apply *regularization* methods of the form

$$x_\alpha^\delta := R_\alpha y^\delta := g_\alpha(T^*T)T^*y^\delta, \tag{1.3}$$

generated by a family of piecewise continuous (filter-) functions $\{g_\alpha\}_{\alpha \in \mathcal{R}_+}$ with the property $g_\alpha(\lambda) \to 1/\lambda$ as $\alpha \to 0$ pointwise for all $\lambda > 0$. For a convergence (rate)

analysis in case of perturbed data, the following assumptions are usually made; cf. [8]:

$$\sup_{0\le\lambda\le 1} |g_\alpha(\lambda)| \le c_* \alpha^{-1}, \tag{1.4}$$

$$\sup_{0\le\lambda\le 1} \lambda^\mu |r_\alpha(\lambda)| \le c_\mu \alpha^\mu, \qquad 0 \le \mu \le \mu_0, \tag{1.5}$$

where $r_\alpha(\lambda) := 1 - \lambda g_\alpha(\lambda)$, and c_μ, c_* are positive constants independent of $\alpha \in \mathbb{R}_+$. A maximal constant μ_0 for which (1.5) holds is called *qualification* of the method. In case of iterative regularization methods, we use the notation $g_k = g_\alpha$ and replace α in (1.4), (1.5) by adequate functions of k. If g_k is a polynomial, then condition (1.4) already follows from (1.5) by Markov's inequality.

For illustration and later reference, we mention some important examples of regularization methods of the form (1.3).

1. *Tikhonov regularization* [9, 32]. The approximate solutions are defined by

   $$x_\alpha^\delta = (T^*T + \alpha)^{-1} T^* y^\delta. \tag{1.6}$$

   Here, g_α is defined by $g_\alpha(\lambda) := (\lambda + \alpha)^{-1}$, and (1.5) holds for all $\mu \le 1$; i.e., the qualification of Tikhonov regularization is $\mu_0 = 1$.
2. *Landweber iteration* [13, 18]. The approximations x_k^δ are defined by the iteration

   $$x_{k+1}^\delta = x_k^\delta + T^*(y^\delta - T x_k^\delta), \qquad x_0^\delta = 0.$$

   Landweber iteration has the form (1.3) with $g_k(\lambda) = \sum_{i=0}^{k-1}(1-\lambda)^i$ and $r_k(\lambda) = (1-\lambda)^k$, respectively, and satisfies (1.5) for all $\mu \ge 0$ with α replaced by $\frac{1}{k}$ and $g_\alpha = g_k$.
3. *The ν-methods by Brakhage* [4, 12]. Semi-iterative methods whose residual polynomials r_k form an orthogonal sequence with respect to some positive weight function satisfy a three-term recurrence, which also carries over to the iterates; i.e., there exist sequences μ_k and ω_k such that

   $$x_k^\delta = x_{k-1}^\delta + \mu_k(x_{k-1}^\delta - x_{k-2}^\delta) + \omega_k T^*(y^\delta - T x_{k-1}^\delta), \quad k \ge 1,$$

   with $x_0^\delta = x_{-1}^\delta = x_0$. The choice $\mu_1 = 0$, $\omega_1 = (4\nu+2)/(4\nu+1)$, and

   $$\mu_k = \frac{(k-1)(2k-3)(2k+2\nu-1)}{(k+2\nu-1)(2k+4\nu-1)(2k+2\nu-3)},$$
   $$\omega_k = 4\frac{(2k+2\nu-1)(k+\nu-1)}{(k+2\nu-1)(2k+2\nu-1)}, \qquad k > 1,$$

   yields the ν-methods by Brakhage. Each ν-method satisfies (1.5) with α replaced by $\frac{1}{k^2}$ for $0 \le \mu \le \nu$.

Under condition (1.4) the regularized solutions x_α^δ converge to $x^\dagger$ with $\delta \to 0$ if $\alpha \to 0$ such that $\delta^2/\alpha \to 0$. In general, this convergence will be arbitrarily slow [28], and convergence rates can be obtained if and only if the true solution satisfies certain smoothness requirements, so-called *source conditions*. For

$$x^\dagger \in \mathcal{R}((T^*T)^\mu), \tag{1.7}$$

for some $\mu \le \mu_0$, the estimate

$$\|x_\alpha^\delta - x^\dagger\| = O(\delta^{\frac{2\mu}{2\mu+1}}) \tag{1.8}$$

can be obtained for the parameter choice

$$\alpha = \alpha(\delta) \sim \delta^{\frac{2}{2\mu+1}}, \tag{1.9}$$

and one can show that the rate (1.8) is optimal under this source condition. Such a source condition is not only sufficient but also (almost) necessary in order to obtain convergence at a rate (1.8); cf., e.g., [8]. While in general, the meaning of (1.7) is difficult to understand, sufficient conditions for validity of (1.7) can be given for certain problems by a problem adapted analysis; cf. [10] for a nonlinear problem in parameter identification of a differential operator; see Assumption 3.1 below.

If the source condition (1.7) holds for some $\mu > \mu_0$, still only a rate of $\delta^{\frac{2\mu_0}{2\mu_0+1}}$ can be expected; this phenomenon is called *saturation*. Tikhonov regularization, for instance, does not provide a better rate than $\delta^{\frac{2}{3}}$, while for Landweber iteration the rate may be arbitrarily close to δ if μ is sufficiently large. For an iterative method like Landweber iteration the number of iterations yielding optimal convergence rates is $n_* = O(\delta^{-\frac{2}{2\mu+1}})$ by (1.9); i.e., for small μ (nonsmooth solution $x^\dagger$) one has $n_* \sim O(\delta^{-2})$. Hence, for $\delta = 10^{-3}$ one would need about 10^6 iterations to stay within the regime of optimal convergence.

One way to overcome saturation and/or reduce the number of iterations and to relate the source condition (1.7) to standard differentiability assumptions, is provided by *regularization in Hilbert scales* introduced by Natterer [23] for Tikhonov regularization, and later analyzed for more general regularization methods in [8, 16, 30] and also for nonlinear problems [26, 27, 31]. We will recall the definition of a Hilbert scale and the most important results on regularization in Hilbert scales in section 2. The general idea is the following: We assume that the smoothing properties of the operator T can be characterized in terms of a simple, e.g., differential, operator L. The standard analysis of regularization in Hilbert scales is then based on the condition

$$\underline{m}\|y\| \le \|L^a T^* y\| \le \overline{m}\|y\| \qquad \text{for all} \quad y \in \mathcal{Y} \tag{1.10}$$

for some a, $\underline{m}$, $\overline{m} > 0$. For illustration we give a short example.

Example 1.1. Let $T : L_2(0,1) \to L_2(0,1)$ denote the solution operator to

$$-q\,y'' = x \quad \text{in} \quad [0,1]; \quad u(0) = u(1) = 0, \tag{1.11}$$

i.e., $Tx = y$. We assume that $q \in L_2(0,1)$ satisfies $0 < q_0 \le q \le q_1$ for some positive constants q_0, $q_1 \in \mathbb{R}$. One can show that $\mathcal{R}(T) = H^2(0,1) \cap H_0^1(0,1)$, and by the closed range theorem T is a homeomorphism between the spaces $L_2(0,1)$ and $H^2(0,1) \cap H_0^1(0,1)$.

Now let $L : \mathcal{D}(L) = H^2(0,1) \cap H_0^1(0,1) \to L_2(0,1)$ be defined by $Lx = -x''$. Since L is self-adjoint and positive definite, one can define fractional powers of L; then $\|x\|_s := \|L^s x\|$ are the natural norms on a scale of (Sobolev) spaces (cf. Definition 2.1). If q is sufficiently smooth, e.g., $q \in H^2(0,1)$, then (1.10) holds for $a = 1$.

Instead of (1.3) the regularized solutions can now be defined by the modified method

$$x_\alpha^\delta := g_\alpha(L^{-2s}T^*T)L^{-2s}T^*y^\delta, \qquad s \ge -a/2. \tag{1.12}$$

As shown in [8, 23, 30], saturation effects of a method g_α due to finite qualification μ_0 can be overcome by choosing $s > 0$ in (1.12); in this case L^{-2s} is smoothing. Conversely, for $s < 0$ the operator L^{-2s} acts as a preconditioner, and in this way

iterative regularization methods can be accelerated; cf. [6, 7]. Note that for $s < 0$ the right inequality in (1.10) is already needed to ensure well-definedness of the method (1.12).

Condition (1.10) characterizes the smoothing properties of the operator T^* in terms of the operator L, respectively, the scale of spaces over the preimage space $\mathcal{X}$ generated by it. Regularization in Hilbert scales is applicable if the range of T^* consists of sufficiently smooth functions. Note that in Example 1.1 condition (1.10) cannot hold for any $a \geq 1/4$ if q has jumps. Nevertheless, the condition

$$\underline{m}\|x\| \leq \|L^a T x\| \leq \overline{m}\|x\| \qquad \text{for all} \quad x \in L_2(0,1) \tag{1.13}$$

holds with $a = 1$ also for nonsmooth parameters q. In view of (1.13) one might call T smoothing like two times integration, while (1.10) would only suggest smoothing properties like integration of power $1/2$ at most. Similar examples, where (1.13) characterizes the smoothing properties of T more precisely than (1.10), arise from integral operators $(Tx)(s) := \int k(s,t)x(t)dt$ with kernels $k(s,t)$ that are differentiable with respect to s but not with respect to t; see section 5 for a detailed example.

In this paper, we analyze the solution of the inverse problem (1.1) by modified regularization methods of the form

$$x_\alpha^\delta := g_\alpha(T^* L^{-2s} T) T^* L^{-2s} y^\delta, \qquad s \geq -a/2, \tag{1.14}$$

under condition (1.13) or relaxed versions of it. In this way, the advantages of Hilbert scale regularization—overcoming saturation by choosing $s > 0$, respectively, by preconditioning by setting $s < 0$—can be made accessible for a new class of problems. Note that for methods (1.14) the operator L acts on the image space $\mathcal{Y}$ and generates a scale of spaces over $\mathcal{Y}$. For this reason we call the methods of the form (1.14) *$\mathcal{Y}$-scale regularization*.

The outline of the paper is as follows. We start by recalling the basic results on regularization in Hilbert scales. In section 3, we discuss regularization methods of the form (1.14) and derive the main error estimates. Section 4 contains the analysis of $\mathcal{Y}$-scale regularization methods under relaxed assumptions with some emphasis on the preconditioning of iterative regularization methods and the design of an order optimal a posteriori stopping rule. We conclude with presenting several examples and numerical tests illustrating the theoretical results.

2. Regularization in Hilbert scales. Before we quote the most important results concerning regularization in Hilbert scales, we shortly recall the definition of a Hilbert scale; see [17] or [8, section 8.4] for details.

DEFINITION 2.1. *Let L be a densely defined, unbounded, self-adjoint, and strictly positive operator in a Hilbert space $\mathcal{Z}$, and let $\mathcal{M} := \bigcap_{k=0}^\infty D(L^k)$. By $\mathcal{Z}_s$ we denote the completion of $\mathcal{M}$ with respect to the norm $\|z\|_s := \|L^s z\|_{\mathcal{Z}}$; $(\mathcal{Z}_s)_{s\in\mathbb{R}}$ is called a Hilbert scale (induced by L).*

Note that obviously $\|z\|_0 = \|z\|_{\mathcal{Z}}$. Two implications of this construction are that $\mathcal{Z}_{-s} = \mathcal{Z}_s'$ and that the following interpolation inequality holds, cf., e.g., [8, section 8.4]:

$$\|z\|_r \leq \|z\|_q^{\frac{s-r}{s-q}} \|z\|_s^{\frac{r-q}{s-q}} \tag{2.1}$$

for $-\infty < q < r < s < \infty$ and $z \in \mathcal{Z}_s$.

Remark 2.2. Like in Example 1.1, L is chosen to be a (simple) differential operator in most situations and the spaces $\mathcal{Z}_s$ coincide with standard Sobolev spaces for a

certain range of values of s. Note that the Sobolev spaces H^s do not form a Hilbert scale in general; cf. [25]. Fractional powers of L can then be efficiently implemented by Fourier transform or multilevel techniques.

Another choice of L always yielding (1.10) with $a = 1$ is $L := (T^*T)^{-\frac{1}{2}}$. At least for preconditioning, e.g., for $s = -a/2$, such a choice is, however, impractical since applying $(T^*T)^{-\frac{1}{2}}$ in (1.12) or (1.14) is at least as difficult as solving the original problem (1.1). If T is self-adjoint, then $L^{-2s} = (T^*T)^{-\frac{1}{2}}$ can be applied without any effort by skipping the terms $L^{-2s}T^* = I$, and the method (1.3) simplifies to

$$x_\alpha^\delta = g_\alpha(T)\, y^\delta,$$

which would be the default formulation of a regularization method for symmetric problems.

The standard assumption for regularization in Hilbert scales is the following norm equivalence condition:

$$\underline{m}\,\|x\|_{-a} \le \|Tx\| \le \overline{m}\,\|x\|_{-a} \tag{2.2}$$

for some $\underline{m}$, $\overline{m}$, $a > 0$. This condition is equivalent to (1.10) (cf. [7]; a similar result is derived in Proposition 3.3). If $x^\dagger \in \mathcal{X}_u$ for some $0 < u \le a + 2s$ and the operator T satisfies (2.2), then the regularization method (1.12) yields order optimal convergence rates

$$\|x_{\alpha_*}^\delta - x^\dagger\| = O(\delta^{\frac{u}{a+u}}) \qquad \text{for} \qquad \alpha_* \sim \delta^{\frac{2(a+s)}{a+u}}; \tag{2.3}$$

cf. [8, 30]. By setting $u = 2a\mu$, one can see that the rate (2.3) coincides with the standard results (1.8), and since the rate holds for $u \le a + 2s$, saturation can be overcome by choosing s sufficiently large. Note that under assumption (2.2) the source condition $x^\dagger \in \mathcal{X}_u$ is equivalent to $x^\dagger \in \mathcal{R}((T^*T)^{\frac{u}{2a}})$ for $u \le a$.

A different view on regularization in Hilbert scale has been taken in [6, 7]: If an iterative regularization method is used for the solution of (1.1), then (2.3) yields that the number of iterations needed to obtain the optimal convergence rates increases with s. Thus, from a numerical point of view (in particular for nonsmooth solutions) it is advantageous to choose s as small as possible, eventually $s < 0$. In this case the operator L^{-2s} in (1.12) acts as a preconditioner, and by setting $s = -a/2$, the number of iterations needed to guarantee the optimal rates (2.3) can be reduced to the square root, e.g., $n(\delta) = O(\delta^{-\frac{a}{a+u}})$ for Landweber iteration. Additionally, the analysis can be carried out under the weaker condition

$$\|Tx\| \le \overline{m}\|x\|_{-a}, \quad \text{respectively,} \quad \|T^*y\|_a \le \overline{m}\|y\|_{\mathcal{Y}}, \tag{2.4}$$

which allows us to apply the approach for a significantly wider class of problems.

THEOREM 2.3 (cf. Theorem 1 in [7]). *Let condition* (2.4) *hold,* g_α *satisfy* (1.4), (1.5), *and* $-a/2 \le s \le 0$. *Assume that* $x^\dagger$ *satisfies the source condition*

$$x^\dagger = L^{-s}(B^*B)^{\frac{u}{2(a+s)}}\, w, \qquad B := TL^{-s}, \tag{2.5}$$

for some $w \in \mathcal{X}$, *and let* x_k^δ *be defined by* (1.12). *Then the rate* (2.3) *holds.*

If the stronger condition (1.10) is valid, then the source condition (2.5) is $u \le a+2s$ equivalent to $x^\dagger \in \mathcal{X}_u$ usually used in regularization in Hilbert scales; cf. [6, 7] for a detailed discussion. We turn now to the analysis of $\mathcal{Y}$-scale regularization methods and prove the convergence rates (2.3) for methods (1.14) under condition (1.13).

3. $\mathcal{Y}$-scale regularization. Let $\{\mathcal{Y}_s\}_{s\in\mathbb{R}}$ be a Hilbert scale induced by some densely defined self-adjoint strictly positive operator $L : \mathcal{D}(L) \subset \mathcal{Y} \to \mathcal{Y}$ (cf. Definition 2.1), and let $\|\cdot\|_r$ denote the norm of $\mathcal{Y}_r$, i.e., $\|y\|_r = \|L^r y\|$. In what follows we require that the operator T satisfies the following assumption.

Assumption 3.1. There exist positive real constants $\underline{m}$, $\overline{m}$, and a such that

$$\underline{m}\|x\| \le \|Tx\|_a \le \overline{m}\|x\| \tag{3.1}$$

holds uniformly for all $x \in X$.

Note that Assumption 3.1 already implies infectivity of the operator T. For the stable solution of the inverse problem (1.1) we consider modified regularization methods of the form

$$x_\alpha^\delta := g_\alpha(T^*L^{-2s}T)T^*L^{-2s}y^\delta = g_\alpha(B^*B)B^*L^{-s}y^\delta \qquad \text{with} \quad B := L^{-s}T. \tag{3.2}$$

Here and below we assume that the functions g_α satisfy the standard assumptions (1.4), (1.5); $s \in \mathbb{R}$ will be specified later. Throughout, A^* denotes the adjoint of a linear operator A with respect to the spaces $\mathcal{X}$ and $\mathcal{Y}$. Under Assumption 3.1, the operator B is bounded as operator from $\mathcal{X}$ to $\mathcal{Y}$ for $s \ge -a$. Without loss of generality, we will assume $\|B\| \le 1$, which can always be achieved by proper scaling.

Remark 3.2. Problem (1.1) is equivalent to

$$Bx = L^{-s}y^\delta, \tag{3.3}$$

where B has to be understood as an operator between $\mathcal{X}$ and $\mathcal{Y}$, respectively, T in (1.1) as an operator from $\mathcal{X}$ to $\mathcal{Y}_s$. Note that T^*L^{-2s} is the adjoint of T with respect to these spaces. The $\mathcal{Y}$-scale method (3.2) hence corresponds to applying the regularization method defined by g_α to the solution of (3.3). Note that in case $s < 0$, the right-hand side $L^{-s}y^\delta$ may not be an element of $\mathcal{Y}$. In any case the noise level estimate (1.2) is not given in the appropriate norm if $s \ne 0$.

For the subsequent error analysis, we need some preliminary results.

PROPOSITION 3.3. *Assumption* 3.1 *is equivalent to*

$$\underline{m}\|y\|_{-a} \le \|T^*y\| \le \overline{m}\|y\|_{-a}. \tag{3.4}$$

Proof. First assume that (3.1) holds, let $y \in \mathcal{Y}$, and observe that

$$\sup_{y\in\mathcal{Y}} \frac{\|T^*y\|}{\|y\|_{-a}} = \sup_{y\in\mathcal{Y}} \sup_{x\in\mathcal{X}} \frac{\langle T^*y, x\rangle}{\|x\|\|y\|_{-a}} = \sup_{x\in\mathcal{X}} \sup_{y\in\mathcal{Y}} \frac{\langle y, Tx\rangle}{\|x\|\|y\|_{-a}} \le \sup_{x\in\mathcal{X}} \frac{\|Tx\|}{\|x\|} \le \overline{m}.$$

Hence, T^* is extendable as a bounded linear operator to $\mathcal{Y}_{-a}$. The result then follows similar to the above by noting that

$$\sup_{y\in\mathcal{Y}_{-a}} \frac{\|T^*y\|}{\|y\|_{-a}} = \sup_{x\in\mathcal{X}} \frac{\|Tx\|}{\|x\|}.$$

The other implication follows similarly. ∎

PROPOSITION 3.4. *Let Assumption* 3.1 *hold and let* $s \ge -a$. *Then for* $|\nu| \le 1$

$$\underline{c}(\nu)\|y\|_{-\nu(a+s)} \le \|(BB^*)^{\frac{\nu}{2}}y\| \le \overline{c}(\nu)\|y\|_{-\nu(a+s)}$$

holds for $y \in \mathcal{D}((BB^*)^{\frac{\nu}{2}})$ *with* $\underline{c}(\nu) = \min(\underline{m}^\nu, \overline{m}^\nu)$ *and* $\overline{c}(\nu) = \max(\underline{m}^\nu, \overline{m}^\nu)$. *Moreover,*

$$\mathcal{D}((BB^*)^{-\frac{\nu}{2}}) = \mathcal{R}((BB^*)^{\frac{\nu}{2}}) = \mathcal{Y}_{\nu(a+s)},$$

where in the case $\nu > 0$, $(BB^*)^{\frac{\nu}{2}}$ is identified with its extension to $\mathcal{Y}$.

Proof. The result follows by the inequality of Heinz; see, e.g., [8, Corollary 8.22] for details. ∎

It is well known that in order to obtain convergence rates, the true solution $x^\dagger$ has to satisfy some smoothness assumptions; cf. [28]. As will become clear from our analysis the appropriate source condition for $\mathcal{Y}$-scale regularization has to be stated in terms of the operator B (see also Remark 3.2 and Theorem 2.3).

Assumption 3.5 (source condition). Let $s > -a$. There exist a real number $u > 0$ and an element $w \in \mathcal{X}$ such that

$$x^\dagger = (B^*B)^{\frac{u}{2(a+s)}} w. \tag{3.5}$$

The total error $\|x_\alpha^\delta - x^\dagger\|$ can be decomposed into the two main components, namely, the *approximation error* $\|x_\alpha - x^\dagger\|$ and the *propagated data error* $\|x_\alpha^\delta - x_\alpha\|$, where x_α denotes the approximate solution defined by (3.2) with y^δ replaced by the correct data $y = Tx^\dagger$. We will now derive estimates for the two error components in terms of α and δ.

THEOREM 3.6. *Let Assumption* 3.1 *hold, let y^δ satisfy* (1.2)*, and let x_α^δ, x_α be defined by the $\mathcal{Y}$-scale method* (3.2) *with some $s \geq -a/2$. Furthermore, let g_α satisfy* (1.4), (1.5) *for some $\mu_0 > 0$ and let $x^\dagger$ satisfy Assumption* 3.5 *for $u \leq 2(a+s)\mu_0$. Then the following a priori estimates hold:*

$$\|x_\alpha - x^\dagger\| \leq C_1\, \alpha^{\frac{u}{2(a+s)}} \|w\|, \tag{3.6}$$

$$\|x_\alpha^\delta - x_\alpha\| \leq C_2\, \alpha^{-\frac{a}{2(a+s)}}\, \delta, \tag{3.7}$$

where C_1, C_2 denote generic constants depending only on c_μ, c_*, $\underline{m}$, and $\overline{m}$. As a consequence

$$\|x^\dagger - x_{\alpha_*}^\delta\| = O(\delta^{\frac{u}{a+u}}) \qquad \text{for} \quad \alpha_* \sim \delta^{\frac{2(a+s)}{a+u}}. \tag{3.8}$$

Proof. We start by estimating the approximation error by using (1.5) and (3.5),

$$s\|x_\alpha^\delta - x^\dagger\| = \|g_\alpha(B^*B)B^*L^{-s}y - x^\dagger\| \tag{3.9}$$

$$= \|r_\alpha(B^*B)(B^*B)^{\frac{u}{2(a+s)}} w\| \tag{3.10}$$

$$\leq c_{\frac{u}{2(a+s)}}\, \alpha^{\frac{u}{2(a+s)}} \|w\|. \tag{3.11}$$

Now consider the propagated data error. By Proposition 3.4 we have $\mathcal{R}(L^{-s}) = \mathcal{Y}_s = \mathcal{R}((BB^*)^{\frac{s}{2(a+s)}})$, hence

$$x_\alpha^\delta - x_\alpha = g_\alpha(B^*B)B^*L^{-s}(y^\delta - y) = g_\alpha(B^*B)B^*(BB^*)^{\frac{s}{2(a+s)}} v$$

for some $v_\delta \in \mathcal{Y}$ with $\|v_\delta\| \leq c_1\|y - y^\delta\|$. Thus, we can further estimate

$$\|x_\alpha^\delta - x_\alpha\| = \|g_\alpha(B^*B)B^*(BB^*)^{\frac{s}{2(a+s)}} v_\delta\| \tag{3.12}$$

$$\leq c_2\, \|g_\alpha(B^*B)(B^*B)^{\frac{a+2s}{2(a+s)}}\| \|y - y^\delta\| \tag{3.13}$$

$$\leq c_3\, \alpha^{-\frac{a}{2(a+s)}}\, \delta, \tag{3.14}$$

where for the last estimate we utilized that

$$\sup_{\lambda \in [0,1]} |g_\alpha(\lambda)\lambda^\mu| \leq C_\mu\, \alpha^{\mu-1}, \qquad 0 \leq \mu \leq 1,$$

which follows readily from (1.4) and (1.5). Equation (3.8) is implied by (3.6) and (3.7). ∎

Remark 3.7. In contrast to standard regularization in Hilbert scales, the source condition (3.5) cannot be interpreted in terms of the spaces $\mathcal{Y}_r$ directly. However, the following interpretation is possible. Define z by $x = B^*z$. Then problem (1.1) is equivalent to

$$BB^*z = L^{-s}y^\delta, \qquad x = B^*z.$$

The source condition (3.5) can be restated for z by noting

$$B^*z^\delta = x^\dagger = (B^*B)^{\frac{u}{2(a+s)}}w = B^*(BB^*)^{\frac{u-a-s}{2(a+s)}}v,$$

hence $z^\delta \in \mathcal{R}((BB^*)^{\frac{u-a-s}{2(a+s)}}) = \mathcal{Y}_{u-a-s}$. The last identity is valid only for $u \le a+s$. A similar restriction also holds for standard regularization in Hilbert scales, where the the source condition $x^\dagger \in \mathcal{X}_u$ guarantees optimal convergence rates only for $u \le a+2s$; cf. [8, Remark 8.24]. Finally, let Assumption 3.1 hold and let $x^\dagger$ satisfy a standard source condition $x^\dagger = T^*w$ for some $w \in \mathcal{Y}$. Then we obtain by Proposition 3.4 that

$$x^\dagger = T^*w = B^*L^sw = B^*(BB^*)^{-\frac{s}{2(a+s)}}\tilde{w} = (B^*B)^{\frac{a}{2(a+s)}}\hat{w}$$

holds for some $\hat{w} \in \mathcal{X}$ with $\|\hat{w}\|_{\mathcal{X}} \sim \|w\|_{\mathcal{Y}}$. Hence by the inequality of Heinz we at least have $\mathcal{R}((T^*T)^\mu) = \mathcal{R}((B^*B)^{\frac{\mu a}{a+s}})$ for $0 \le \mu \le \frac{1}{2}$.

Since in practice the smoothness of the solution $x^\dagger$ is not known a priori, an optimal parameter choice (3.8) is not possible in general. Therefore, we next consider an a posteriori parameter selection criterion based on the discrepancy principle (cf. [8, 22]), i.e.,

$$\alpha_* := \sup\{\alpha : \|Tx_\alpha^\delta - y^\delta\| \le \tau\delta\}. \tag{3.15}$$

The advantage of such a criterion is that it requires no a priori information about the smoothness of $x^\dagger$. Moreover, the residual $r_k^\delta := Tx_k^\delta - y^\delta$ usually has to be calculated anyway, in particular for iterative regularization methods.

THEOREM 3.8. *Let the assumptions of Theorem* 3.6 *hold and let* $\alpha_* = \alpha_*(\delta)$ *be determined by the discrepancy principle* (3.15). *Then the rates* (3.8) *hold for* $0 < u \le 2(a+s)\mu_0 - a$.

Proof. We have to estimate the residual $\|Tx_\alpha^\delta - y^\delta\|$,

$$s\|Tx_\alpha^\delta - y^\delta\| = \|L^s(Bg_\alpha(B^*B)B^* - I)L^{-s}y^\delta\| \tag{3.16}$$

$$\le c_1\,\|r_\alpha(BB^*)B(B^*B)^{\frac{u-s}{2(a+s)}}\|\|w\| + c_2\,\delta \tag{3.17}$$

$$\le c_{\frac{u+a}{2(a+s)}}\,\alpha^{\frac{u+a}{2(a+s)}}\|w\| + c_2\,\delta, \tag{3.18}$$

where we used (1.5) and $u \le 2(a+s)\mu_0 - a$. Hence,

$$\alpha_* \ge C\,\delta^{\frac{2(a+s)}{a+u}} \tag{3.19}$$

as long as $\tau > c_2$, which yields a sufficient bound for the propagated data error by (3.7). It remains to consider the approximation error. First note that we have

$$\|T(x_{\alpha_*} - x^\dagger)\| \le \|Tx_{\alpha_*}^\delta - y^\delta\| + \|T(x_{\alpha_*} - x_{\alpha_*}^\delta)\| + \delta \le C\,\delta.$$

It then follows by the interpolation inequality and (3.5) that

$$\|x_{\alpha_*} - x^\dagger\| \le c_3 \|T(x_{\alpha_*} - x^\dagger)\|^{\frac{u}{a+u}} \|w\|^{\frac{a}{a+u}} \le c_4 \delta^{\frac{u}{a+u}} \|w\|^{\frac{a}{a+u}},$$

which completes the proof. ∎

Remark 3.9. For $s = 0$ the above results coincide with the standard regularization theory by noting that $u = 2a\mu$. The restriction $u \le 2(a+s)\mu_0 - a$ in Theorem 3.8 then amounts to $\mu \le \mu_0 - 1/2$, which is the well-known saturation for the discrepancy principle. As for regularization in Hilbert scales, saturation effects of the applied method can be overcome by choosing s large enough.

4. $\mathcal{Y}$-scale regularization under relaxed assumptions—preconditioning. Probably the most severe drawback of $\mathcal{Y}$-scale regularization as presented in the previous section is the restrictive assumptions (3.1) (corresponding to (1.10) for standard regularization in Hilbert scales). As we will show now, most of the results remain valid if only one of the estimates in (3.1) is available. We will treat in detail the case where the right inequality holds and $s \le 0$ has to be chosen; the corresponding results for the other inequality and the choice $s \ge 0$ are indicated in remarks. As can be seen from (3.8), the (optimal) regularization parameter α_* can be increased by choosing $s < 0$. For an iterative regularization method $g_\alpha = g_n$, this means that the corresponding stopping index decreases by setting $s < 0$. This motivates calling the operator L^{-2s} in (1.14) a preconditioner. In order to stay with the notation of the previous section, we continue to consider general regularization methods g_α and mention some implications for iterative regularization methods in separate remarks.

Preconditioning of iterative regularization methods in Hilbert scales has been investigated in [6, 7] under the standard assumption (1.10) and under weaker conditions. Here, we are using scales of spaces over $\mathcal{Y}$ and the assumption (4.1). The derivation of the convergence results of the following sections therefore requires different reasoning and a more sophisticated a posteriori stopping rule.

Let L and $\mathcal{Y}_s$ be defined as above. Throughout this section we require the following assumption.

Assumption 4.1. T is injective and there exists a positive real constant a such that

$$\|Tx\|_a \le \|x\| \tag{4.1}$$

holds uniformly for all $x \in X$.

Unlike (3.1), where the injectivity of the operator T was implied by the left estimate, it has to be assumed here additionally. Similarly as in the previous section we have the following equivalent characterization of Assumption 4.1.

PROPOSITION 4.2. *Assumption* 4.1 *is equivalent to* T *being injective and*

$$\|T^* y\| \le \|y\|_{-a} \qquad \text{for all } y \in \mathcal{Y}_{-a}. \tag{4.2}$$

Proof. Let x, y, $\hat{y} \ne 0$. Assumption 4.1 can be restated as

$$\begin{aligned} 1 &\ge \sup_{x \in \mathcal{X}} \frac{\|L^a T x\|}{\|x\|} = \sup_{x \in \mathcal{X}} \sup_{y \in \mathcal{Y}} \frac{\langle Tx, L^a y\rangle}{\|x\|\|y\|} \\ &= \sup_{\hat{y} \in \mathcal{Y}_{-a}} \sup_{x \in \mathcal{X}} \frac{\langle x, T^* \hat{y}\rangle}{\|x\| \|\hat{y}\|_{-a}} = \sup_{\hat{y} \in \mathcal{Y}_{-a}} \frac{\|T^* \hat{y}\|}{\|\hat{y}\|_{-a}}. \end{aligned}$$

The other implication follows in the same way. ∎

Due to the relaxed assumption (4.1), Proposition 3.4 is no longer valid in its general form. Instead, only the following weaker implications hold.

PROPOSITION 4.3. *Let Assumption* 4.1 *hold, and let* $B = L^{-s}T$ *for some* $s \geq -a$ *with* $\|B\| \leq 1$. *Then the estimates*

$$\|(BB^*)^{\frac{\nu}{2}} y\| \leq \|y\|_{-\nu(a+s)} \qquad \text{for all } y \in \mathcal{Y}_{-\nu(a+s)} \subset \mathcal{R}((BB^*)^{-\frac{\nu}{2}}), \tag{4.3}$$

$$\|(BB^*)^{-\frac{\nu}{2}} y\| \geq \|y\|_{\nu(a+s)} \qquad \text{for all } y \in \mathcal{R}((BB^*)^{\frac{\nu}{2}}) \subset \mathcal{Y}_{\nu(a+s)} \tag{4.4}$$

hold for $0 \leq \nu \leq 1$.

Proof. The results follow from the inequality of Heinz and the standard results on Hilbert scales; see [8, section 8.5] for details. ∎

Assumption 4.1 and Proposition 4.3 are sufficient to prove the following a priori error estimates corresponding to those of Theorem 3.6.

THEOREM 4.4. *Let* $-a/2 \leq s \leq 0$ *and let Assumption* 4.1 *hold. Additionally, let* g_α, $x^\dagger$, y^δ *satisfy the assumptions of Theorem* 3.6. *Then* (3.6), (3.7), *and* (3.8) *hold.*

Proof. The estimate for the approximation error $x_\alpha^\delta - x^\dagger$ follows as in the proof of Theorem 3.6. Now observe that $L^{-s}(y^\delta - y) \in \mathcal{R}(L^{-s}) = \mathcal{Y}_s \subset \mathcal{R}((BB^*)^{\frac{s}{2(a+s)}})$ is implied by (4.3) since $s \leq 0$. Hence, also the estimate for the propagated data error follows as in Theorem 3.6. ∎

Remark 4.5. In case $s \geq 0$, condition (4.1) has to be replaced by

$$\|x\| \leq \|Tx\|_{\tilde{a}}. \tag{4.5}$$

Proposition 4.3 then holds with opposite inclusions and the analogue of Theorem 4.4 follows with obvious modifications. Again, similarly as in the proof of Theorem 3.6, there exists a $v_\delta \in \mathcal{Y}$ such that $L^{-s}(y - y^\delta) = (BB^*)^{\frac{s}{2(\tilde{a}+s)}} v_\delta$, since for $s \geq 0$ and under condition (4.5),

$$\mathcal{R}(L^{-s}) = \mathcal{Y}_s \subset \mathcal{R}((BB^*)^{\frac{s}{2(\tilde{a}+s)}})$$

follows from the analogue of Proposition 4.3 for this case.

4.1. A posteriori parameter choice. The result of Theorem 4.4 is not of great use per se, since it would require exact knowledge of the smoothness of the solution $x^\dagger$. We will therefore consider a posteriori parameter choice rules in the following.

A discrepancy principle. In contrast to the results of the previous section, the discrepancy principle (3.15) does not provide parameters that guarantee optimal convergence rates if only Assumption 4.1 is used. To see this, let us estimate the residual

$$\|Tx_\alpha^\delta - y^\delta\| = \|L^s(Bg_\alpha(B^*B)B^* - I)L^{-s}y^\delta\| \tag{4.6}$$

$$\begin{aligned} &\leq \|L^s r_\alpha(BB^*)B(B^*B)^{\frac{u}{2(a+s)}} w\| \\ &\qquad + \|L^s g_\alpha(BB^*)BB^*L^{-s}(y^\delta - y)\| + \|y^\delta - y\| \end{aligned} \tag{4.7}$$

$$\leq c_1 \alpha^{\frac{u+a+s}{2(a+s)}} + c_2 \alpha^{\frac{s}{2(a+s)}} \delta \tag{4.8}$$

for some positive constants c_1 and c_2. A careful inspection of the proof of Theorem 3.8 reveals that the second term may disturb the convergence of the residual $Tx_\alpha^\delta - y^\delta$; i.e., one cannot guarantee that $\inf\{\|Tx_\alpha^\delta - y^\delta\| : \alpha > 0\} \leq \tau\delta$ holds for any τ (independent of δ and y^δ) and for all possible data y^δ. Hence, the discrepancy principle (3.15) might not yield a parameter α_* at all. A partial result can, however, be found for the following modified criterion: Let α_{max} be defined by

$$\alpha_{max} := \sup\{\alpha : \|Tx_\alpha^\delta - y^\delta\| \leq \tau\delta\alpha^{\frac{s}{2(a+s)}}\} \tag{4.9}$$

for some appropriate $\tau > 1$. We can estimate α_{max} from below by

$$\tau\delta\alpha_{max}^{\frac{s}{2(a+s)}} \le \|Tx_\alpha^\delta - y^\delta\| \le c_1\,\alpha^{\frac{u+a+s}{2(a+s)}} + c_2\,\alpha^{\frac{s}{2(a+s)}}\delta$$

for all $\alpha > \alpha_{max}$. Hence, assuming that $\tau > c_2$, we obtain with an appropriate constant $\overline{C} > 0$ that

$$\alpha_{max} \ge \overline{C}\delta^{\frac{2(a+s)}{a+u}}. \tag{4.10}$$

In view of Theorems 3.6 and 3.8, a parameter choice $\alpha_* = \alpha_{max}$ cannot provide optimal convergence rates in general, but at least the following suboptimal result holds.

PROPOSITION 4.6. *Let the iterative method* (1.14) *be stopped at* $\alpha_* = \alpha_{max}$. *Then the following (suboptimal) rate holds:*

$$\|x_\alpha^\delta - x^\dagger\| = O\left(\delta^{\frac{u+\frac{us}{2(a+s)(a+u)}}{a+u}}\right). \tag{4.11}$$

Proof. In the same manner as (4.6) one obtains that

$$\|Tx_\alpha - y\| \le \alpha^{\frac{s}{2(a+s)}}\delta.$$

The result then follows similarly as in the proof of Theorem 3.8. ∎

Remark 4.7. For $s = 0$ the rate (4.11) coincides with the optimal rate $O(\delta^{\frac{u}{a+u}})$. If $s < 0$, the convergence rate observed for this parameter choice is not optimal; e.g., for $s = -a/2$, (4.11) yields

$$\|x_\alpha^\delta - x^\dagger\| = O(\delta^{\frac{u}{2(a+u)}}),$$

which is only half of the optimal rate (3.8). We only mention that even if the standard discrepancy principle (3.15) provides a parameter, i.e., if there exists an α such that $\|Tx_\alpha^\delta - y^\delta\| \le \tau\delta$, such a choice will in general only yield suboptimal rates similar to (4.11).

We will show next how optimal rates can be restored.

A Lepskij principle. In view of Theorem 3.6, α_{max} is a reasonable upper bound for appropriate parameters yielding optimal convergence rates. On the other hand, according to Theorem 3.6 optimal rates are always obtained for the choice

$$\alpha_* = \alpha_{opt} := \overline{C}\delta^{\frac{2(a+s)}{a+u}} \ge \overline{C}\delta^{\frac{2(a+s)}{a}} =: \alpha_{min} \tag{4.12}$$

with $\overline{C}$ as in (4.10). Hence, α_{min} may serve as a reasonable lower bound for interesting regularization parameters. A specific parameter yielding optimal convergence rates can be found in the range $[\alpha_{min}, \alpha_{max}]$ by means of the Lepskij principle (cf. [19, 21]); we use here a formulation similar to the one presented in [1].

Let α_{min}, α_{max} be determined according to (4.9), (4.12), and let α_n be defined by $\alpha_n := q^n \cdot \alpha_{max}$ for some $0 < q < 1$. We define the set $\mathcal{M}$ (of admissible parameters) by

$$\mathcal{M} := \left\{ \alpha_n \in [\alpha_{min}, \alpha_{max}] : \begin{array}{l} \|x_{\alpha_n}^\delta - x_{\alpha_m}^\delta\| \le 4C\alpha_n^{-\frac{a}{2(a+s)}}\delta \\ \text{for all } m = n+1, \dots, N \end{array} \right\}, \tag{4.13}$$

where N is the largest integer such that $\alpha_N > \alpha_{min}$, and C is a generic constant such that

$$\max\{\|x_\alpha^\delta - x_\alpha\|, \|x_\alpha - x^\dagger\|\} \le C\alpha^{-\frac{a}{2(a+s)}}\delta \qquad \text{for all} \quad \alpha \le \alpha_{opt}. \tag{4.14}$$

Note that by the error estimates (3.6), (3.7), such a constant can be chosen depending on (a bound on) $\|w\|$, but without knowledge of u or α_{opt}. As appropriate parameter, we select

$$\alpha_* := \begin{cases} \max \mathcal{M} & \text{if } \mathcal{M} \neq \emptyset, \\ \alpha_N & \text{else.} \end{cases} \tag{4.15}$$

THEOREM 4.8. *Let the assumptions of Theorem* 4.4 *be satisfied and let* α_* *be defined by* (4.15). *Then the rate*

$$\|x_{\alpha_*} - x^\dagger\| = O(\delta^{\frac{u}{a+u}}) \tag{4.16}$$

holds.

Proof. By the definition of α_{opt} we have $\alpha_{opt} \in [\alpha_{min}, \alpha_{max}]$. Additionally, it follows from the error estimates (3.6), (3.7), and (4.14) that $\alpha_* \ge \alpha_{opt}$. Hence, we obtain together with (4.13) that

$$\|x_{\alpha_*}^\delta - x^\dagger\| \le \|x_{\alpha_{opt}}^\delta - x^\dagger\| + \|x_{\alpha_*}^\delta - x_{\alpha_{opt}}^\delta\| = O(\delta^{\frac{u}{a+u}}). \qquad \square$$

Remark 4.9. A disadvantage of the Lepskij principle is that its realization requires a higher computational effort than the standard discrepancy principle (3.15). Note that the construction of the set $\mathcal{M}$ requires us to generate solutions for a wide range of regularization parameters. Additionally, at least some solutions $x_{\alpha_n}^\delta$ have to be stored in order to check the conditions for the construction of $\mathcal{M}$. By using the upper bound α_{max} on admissible parameters, the number of solutions $x_{\alpha_n}^\delta$ which have to be stored can be reduced significantly; note that usually one chooses $\alpha_{max} \sim 1$. Additionally, the $\mathcal{Y}$-scale approach allows us to choose the smallest regularization parameter α_{min} relatively large, e.g., $\alpha_{min} \sim \delta$ for $s = -a/2$, whereas one would need $\alpha_{min} \sim \delta^2$ without preconditioning; cf. [1, 21].

Remark 4.10. The results derived for general regularization methods (1.3) hold with obvious modifications also for iterative regularization methods. If the strong condition (3.1) holds and $s = -a/2$, Theorem 3.8 yields optimal convergence rates when the method is stopped at iteration k_* defined by the discrepancy principle

$$\|Tx_{k_*}^\delta - y^\delta\| \le \tau\delta < \|Tx_k^\delta - y^\delta\| \qquad \text{for all} \quad k < k_*.$$

As can be seen from (3.8), respectively, (2.3), the number of iterations needed to get the optimal rates (2.3) can be reduced to about the square root by proper preconditioning ($s = -a/2$).

Under the weaker assumption (4.1), and with $s = -a/2$, one has to perform $k_{max} := 1/\alpha_{min} \sim \delta^{-1}$ iterations in order to apply the Lepskij principle (4.15). Note that if $x^\dagger$ is not very smooth, i.e., if μ in (1.9) is small, which is the case we are interested in, then one would expect $k_* = O(\delta^{\frac{2}{2\mu+1}}) \sim O(\delta^{-2})$ iterations for (the standard version of) Landweber iteration. Hence also in this case, the number of iterations can be reduced to about the square root by preconditioning.

Remark 4.11. If instead of Assumption 4.1 condition (4.5) holds and $s \ge 0$, then the results concerning the discrepancy principle are slightly different from

those presented here; e.g., the standard discrepancy principle (3.15) can be used to determine α_{max}. However, as in the case $s \le 0$, a choice $\alpha_* = \alpha_{max}$ does not yield optimal convergence rates in general. The result for the Lepskij principle follows as above with obvious modification. For $s \ge 0$ and if iterative regularization methods are applied, the number of iterations will be increased by application of L^{-2s}, which in case $s \ge 0$ is a smoothing operator. Such choice seems to be disadvantageous from a numerical point of view, at least for iterative methods.

We only mention that if a condition (4.5) holds for some $\tilde{a} \ge a$ additionally to (4.1) (cf. Example 5.2), then some of the previous results can be strengthened. In particular, for $\tilde{a} = a$, the results of section 3 apply.

5. Examples and numerical tests. In this section we verify Assumption 3.1, respectively, Assumption 4.1, for several examples and present the results of the numerical tests illustrating the theoretical results.

Example 5.1 (Radon transform). Let $f \in C_0^\infty(\Omega^n)$ for some compact domain $\Omega^n \subset \mathbb{R}^n$, $n \ge 2$. The Radon transform defined by

$$Rf(\omega, s) = \int_{x\cdot\omega=s} f(x)dx$$

is important in many applications, e.g., in computerized tomography, and has been studied extensively in the literature. The following very general stability estimate holds; cf. [24, 29]:

$$c(\gamma, n)\|f\|_{H_0^\gamma(\Omega^n)} \le \|Rf\|_{H^{\gamma+(n-1)/2}(Z)} \le C(\gamma, n)\|f\|_{H_0^\gamma(\Omega^n)}, \tag{5.1}$$

where Z denotes the unit cylinder in $\mathbb{R}^n$, and

$$\|g\|_{H^{\gamma+(n-1)/2}(Z)} := \int_{S^{n-1}} \int_{\mathbb{R}} (1+\sigma^2)^\gamma |\hat{g}(\theta, \sigma)|^2 d\sigma\, d\theta.$$

Here, the Fourier transform is only taken with respect to the second variable. Due to (5.1) with $\alpha = 0$, the results of section 3 are applicable with $Ly(\theta, s) = -\partial_{ss} y(\theta, s) + y(\theta, s)$; fractional powers of the operator L can be realized efficiently by Fourier transform.

Example 5.2 (an integral equation allowing a lower bound). Consider the Fredholm integral equation $Tx = y$ with operator $T : L_2(0,1) \to L_2(0,1)$ defined by

$$Tx(s) = \int_0^1 k(s,t)dt \quad \text{with} \quad k(s,t) = \sqrt{t} \begin{cases} s(1-t), & 0 \le s < t \le 1, \\ t(1-s), & 0 \le t \le s \le 1. \end{cases}$$

Since $k(s,t) \in L_2([0,1]^2)$, it follows that T is compact and $Tx = y$ is ill-posed. With

$$(Tx)(s) = (1-s)\int_0^s t^{3/2} x(t)dt + s\int_s^1 t^{1/2}(1-t)x(t)dt$$

we get $(Tx)(0) = (Tx)(1) = 0$. By twice differentiation we obtain that

$$(Tx)''(s) = -s^{1/2}x(s),$$

which yields

$$\mathcal{R}(T) = \{y \in H^2(0,1) \cap H_0^1(0,1) : s^{-1/2} y''(s) \in L_2(0,1)\}.$$

We utilize the Hilbert scale induced by the operator L defined by

$$L^s y := \sum_{n=1}^{\infty} (n\pi)^s \langle x, x_n \rangle y_n \qquad \text{with} \quad y_n := \sqrt{2}\sin(n\pi\cdot), \tag{5.2}$$

i.e., $L^2 x = -x''$ and $\mathcal{Y}_2 = H^2(0,1) \cap H_0^1(0,1)$. This choice yields $\mathcal{R}(T) \subsetneq \mathcal{Y}_2$ and $\mathcal{R}(T) \supset \mathcal{Y}_{2.5} = \{y \in H^{2.5}(0,1) \cap H_0^1(0,1) : \rho^{-1/2} y'' \in L_2(0,1)\}$ with $\rho(t) = t(1-t)$. By Theorem 11.7 in [20], we get

$$\underline{m}\,\|x\| \le \|Tx\|_{2.5} \quad \text{and} \quad \|Tx\|_2 \le \overline{m}\,\|x\|$$

for some positive constants $\underline{m}$, $\overline{m}$, and the results of section 4 can be applied.

Next we compare Landweber iteration and the ν-methods by Brakhage [4, 12] for the numerical solution of $Tx = y$. As parameter choice strategy we use the Lepskij principle (4.15). We shortly describe how this stopping rule is implemented for Landweber iteration: As soon as the modified discrepancy principle (4.9) is satisfied, we set $\mathcal{M}_x := \{k_{min}\}$, where k_{min} plays the role of α_{max} in (4.9). Note that we store the iterates x_k^δ rather than the iteration indices k. At each iteration $k_n := 2^n \cdot k_{min}$, $n \in \mathbb{N}$, we add the element $x_{k_n}^\delta$ to the set $\mathcal{M}_x$ and check if the condition

$$\|x_{k_n}^\delta - x_{k_m}^\delta\| \le 4C k_n^{\frac{a}{2(a+s)}}\,\delta \tag{5.3}$$

holds for all $x_{k_n}^\delta$, $x_{k_m}^\delta$ in the set $\mathcal{M}_x$ with $m > n$. If (5.3) does not hold for some n, we eliminate all elements $x_{k_m}^\delta$ with $m < n$. This procedure is continued until the final iteration k_N is reached, where N is the largest integer such that $k_N < k_{max} = C\delta^{-1}$. As stopping index k_* we then choose the smallest k_n with x_{k_n} in $\mathcal{M}_x$.

For a concrete numerical test, we set $x^\dagger(s) = \operatorname{sign}(1-2s)$. With $a = 2$, $s = -1$, and the above choice of a Hilbert scale, we have

$$x^\dagger \in \mathcal{R}(B^*B)^{\frac{u}{2(a+s)}} = \left\{ x \in \mathcal{Y}_2 : \frac{1}{\sqrt{s}} \left(\frac{x}{\sqrt{s}} \right)'' \in L_2(0,1) \right\}$$

for $0 \le u < 1$. The correct data $y = Tx^\dagger$ are perturbed by uniformly distributed random noise such that $\|y - y^\delta\| = \delta$ for several values of δ. In a first test, we compare the performance of the discrepancy principle and the Lepskij rule suggested in the previous section: we set $\delta = 0.002$, $\tau = 1.1$ and plot the two error components (approximation error and propagated data error) for Landweber iteration with preconditioning ($s = -a/2$) in Figure 5.1. The optimal stopping index, i.e., the one where the total error $\|x_k^\delta - x^\dagger)\|$ attains its minimum, is 230, whereas the standard discrepancy principle stops only after 469 iterations; cf. (4.6) and Remark 4.9. The Lepskij principle (4.15) with $C = 0.25$ yields $k_* = 96$. The corresponding errors $e_k = \|x_k^\delta - x^\dagger\|$ are $e_{230} = 0.26$, $e_{469} = 0.30$, and $e_{96} = 0.27$.

In a second test, we illustrate the effect of preconditioning and list the iteration numbers and errors for several values of δ obtained for Landweber iteration and the ν-methods by Brakhage [4, 12] with and without preconditioning in Table 5.1. Note that the numerical effort for an iteration step is about the same for all methods and consists of application of T and T^*. The preconditioned iteration requires further application of a differential operator, which is cheap in comparison with application of the integral operator T.

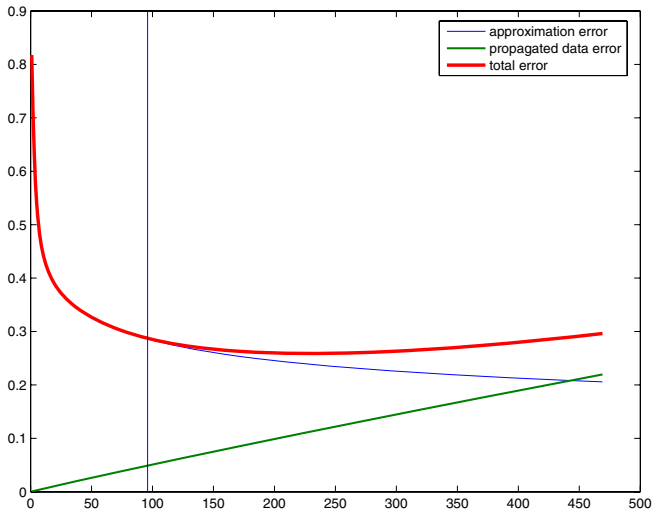

FIG. 5.1. *Approximation error, propagated data error, and total error, Example* 5.2*, with* $\delta = 0.002$*,* $\tau = 1.1$*, and iterates obtained by the preconditioned Landweber iteration. The vertical line denotes the actual stopping index* n_* *determined by the Lepskij rule.*

TABLE 5.1
Iteration numbers and relative errors for Landweber iteration (lw), the ν*-method with* $\nu = 2$*, and the preconditioned versions, Example* 5.2*.*

δ	$k_*^{(lw)}$	$e_{k_*}^{(lw)}$	$k_*^{(hslw)}$	$e_{k_*}^{(hslw)}$	$k_*^{(nu)}$	$e_{k_*}^{(nu)}$	$k_*^{(hsnu)}$	$e_{k_*}^{(hsnu)}$
0.02	46	0.4299	20	0.4244	13	0.4099	9	0.4078
0.01	177	0.3920	38	0.3655	21	0.3655	12	0.3634
0.005	819	0.3307	81	0.3312	43	0.3333	18	0.3300
0.002	3488	0.2690	166	0.2704	112	0.2587	29	0.2589

The corresponding convergence rates are $e_{k_*} = \|x_{k_*}^\delta - x^\dagger\| = O(\delta^{0.18})$ for all iterations. The iteration numbers behave like $k_*^{(lw)} \sim \delta^{-1.7}$, $k_*^{(nu)} \sim \delta^{-0.87}$ for the standard Landweber iteration and the ν-method. In both cases the stopping indices can be reduced to the square root by preconditioning, i.e., $k_*^{(hslw)} \sim \delta^{-0.90}$ and $k_*^{(hsnu)} \sim \delta^{-0.48}$.

The following two examples shall serve as models for inverse problems governed by partial differential equations. Note that in two dimensions or three dimensions, an assembly of the full operator is usually impossible for reasonable discretization levels, and even the application of the operator T which involves the solution of the governing equation may be rather expensive. Thus such problems will usually be solved by some iterative method, and the number of iterations should be kept as small as possible. As we will illustrate, this can effectively be achieved by preconditioning in $\mathcal{Y}$-scales.

Example 5.3 (source reconstruction). Let $\Omega \subset \mathbb{R}^n$, $n = 2, 3$, be a bounded convex domain and let $T : L_2(\Omega) \to L_2(\Omega)$ be defined by $Tf = u$ where u satisfies

$$-q\Delta u + cu = f, \qquad u\big|_{\partial\Omega} = 0,$$

and c, $q \in L_2(\Omega)$ are known functions bounded from below by some constants $\underline{c} \geq 0$,

TABLE 5.2

δ	$k_*^{(lw)}$	$e_{k_*}^{(lw)}$	$k_*^{(hslw)}$	$e_{k_*}^{(hslw)}$	$k_*^{(nu)}$	$e_{k_*}^{(nu)}$	$k_*^{(hsnu)}$	$e_{k_*}^{(hsnu)}$
0.02	424	0.451	34	0.587	55	0.456	14	0.538
0.01	1639	0.374	52	0.445	116	0.375	18	0.425
0.005	4723	0.307	91	0.359	192	0.310	26	0.355
0.0025	12794	0.251	161	0.282	321	0.253	33	0.275

$\underline{q} > 0$. We consider the $\mathcal{Y}$-scale induced by

$$L^2 : \mathcal{D}(L^2) \subset L_2(\Omega) \to L_2(\Omega) \quad \text{with} \quad L^2 u = -\Delta u,$$

and domain $\mathcal{D}(L^2) = H^2(\Omega) \cap H_0^1(\Omega) =: \mathcal{Y}_2$. It follows from standard regularity results for elliptic equations that the solution u satisfies $u \in \mathcal{Y}_2$, i.e., $\mathcal{R}(T) \subset \mathcal{Y}_2$. Moreover, if q is additionally bounded from above, then also the opposite inclusion holds; i.e., Assumption 3.1 is valid with $a = 2$.

For a numerical test, we consider $\Omega = (0,1)^2$, $q = 2 + \text{sign}(1-2x)$, $c = 1$. Let the true solution be defined by $f^\dagger = \text{sign}(1-2y)$ and choose $s = -a/2 = -1$. In view of Theorem 3.8, we can apply the standard discrepancy principle for this example. The results of the numerical tests are listed in Table 5.2.

Example 5.4 (exponentially ill-posed problems). As a final example we consider the backward heat equation as a model problem for exponentially ill-posed problems: Let $T : L_2(0,1) \to L_2(0,1)$ defined by $(Tg)(x) = y(x) := u(x,\bar{t})$ with some $\bar{t} > 0$ and

$$-u_t + q u_{xx} = 0, \qquad u(0,t) = u(1,t) = 0, \qquad u(x,0) = g.$$

The solution of this equation has the Fourier expansion

$$u(x,\bar{t};g) = \sum_{n=1}^{\infty} \exp(-q\bar{t}\pi^2 n^2)\langle g, y_n\rangle y_n$$

with the basis functions y_n as in Example 5.2. Let L^s be defined by (5.2). Then we have

$$\|Tg\|_r \le c(r)\|g\| \qquad \text{for all} \quad r \in \mathbb{R};$$

thus Assumption 4.1 can be satisfied for arbitrary a (up to scaling by a constant).

For a numerical test, we let $q = 0.01$, set $s = -2$ for preconditioning, and try to reconstruct the initial condition

$$g^\dagger = 2x - \text{sign}(2x-1) - 1$$

from measurements of u at time $\bar{t} = 1$.

Since the problem under consideration is exponentially ill-posed, only logarithmic convergence rates can be expected; cf. [14]. The solution of all considered methods look almost identical. Note that for this problem, our theory does not actually imply smaller stopping indices of the discrepancy principle for the preconditioned methods. However, as can be seen from Table 5.3, the number of iterations is reduced significantly for finite noise levels $\delta > 0$; cf. also [7] for a discussion of this phenomenon.

FINITE ELEMENT APPROXIMATION OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS DRIVEN BY POISSON RANDOM MEASURES OF JUMP TYPE*

ERIKA HAUSENBLAS†

Abstract. The paper deals with stochastic partial differential equations driven by Poisson random measures of jump type and their numerical approximation. We investigate the accuracy of space and time approximation. As space approximation we consider finite elements and as time approximation the implicit Euler scheme.

Key words. stochastic evolution equations, stochastic partial differential equations, numerical approximation, time discretization, space discretization, Poisson random measure

AMS subject classifications. 60H15, 60H35, 65C30, 35R30

DOI. 10.1137/050654141

1. Introduction.

Our point of interest is the numerical approximation solutions of stochastic partial differential equations (SPDEs) of the following type:

$$\begin{cases} du(t,\xi) = \frac{\partial^2}{\partial \xi^2} u(t-,\xi)\, dt + f(u(t-,\xi),\xi)\, dt \\ \qquad\qquad + \int_{\zeta\in\mathbb{R}} g(u(t-,\xi),\xi;\zeta)\, \tilde{\eta}(d\zeta,\xi,dt),\ \xi\in\mathcal{O},\ 0<t<\infty, \\ u(0,\xi) = u_0(\xi), \end{cases} \tag{1.1}$$

where $f : \mathbb{R}\times\mathcal{O}\to\mathbb{R}$ and $g : \mathbb{R}\times\mathbb{R}\to\mathbb{R}$ are global Lipschitz continuous functions and η is a space time Poisson random measure of impulsive type (see, e.g., Saint Loubert Bié [SLB98] or Peszat and Zabczyk [PZ07]).

Non-Gaussian random processes play an increasing rôle in modeling stochastic dynamical systems. Typical examples of non-Gaussian stochastic processes are Lévy processes and processes arising by Poisson random measures. In neurophysiology the driving noise of the cable equation is basically impulsive, e.g., of a Poisson type (see Walsh [Wal86, Chapter 3])—or, on the other hand, Woyczyński describes in [Woy01] a number of phenomena from fluid mechanics, solid state physics, polymer chemistry, economic science, etc., for which non-Gaussian Lévy processes can be used as their mathematical model in describing the related stochastic behavior. Thus, from the point of view of applications one might feel that the restriction to Gaussian noise is unsatisfactory; to handle such cases one can replace the Gaussian noise by a Poisson random measure.

Concerning the numerical approximation of SPDEs driven by Wiener noise, several works already exist. Just to mention a few (see, e.g., Gyöngy [Gyö99, Gyö98]), Hausenblas [Hau03, Hau02], Kloeden and Shott [KS01], Printems [Pri01a, Pri01b], Shardlow [Sha99], and Yoo [Yoo00]. Finite element approximation of SPDEs driven by Wiener space time white noise were considered by Allen, Novosel, and Zhang

[ANZ98], Cardon-Weber and Millet [CWM04], Germani and Piccioni [GP88], Gyöngy [Gyö99, Gyö98], Gyöngy and Millet [GM05], Millet and Morien [MM05], Walsh [Wal05], and Yan [Yan05]. The numerical approximation of finite-dimensional SDEs driven by Poisson random measures is the topic of, e.g., the work of Gardoń [Gar04], Kuznetsov [Kuz01], Protter and Talay [PT97], or Rubenthaler [Rub03]. But the numerical approximation of SPDEs driven by Poisson random measures is barely investigated, and, in the cases known to the author, processes of finite variation are considered, e.g., by Kouritzin, Long, and Sun [KLS03] and Kouritzin and Long [KL02]. If the driving process is of infinite variation, there exists only some works about existence and uniqueness, e.g., Albeverio, Wu, and Zhang [AWZ98], Hausenblas [Hau05, Hau06], and Kallianpur and Xiong [KX87, KX96]. Applebaum and Wu [AW00] and Saint Loubert Bié [SLB98] considered SPDEs with space time Lévy noise.

First, we discretize the SPDE spatially by the finite element method, obtaining a system of high-dimensional SDEs that can be solved by the implicit Euler scheme. The noise will be approximated by using the projection onto finite elements.

2. Preliminaries. Let $\mathcal{O} \subset \mathbb{R}^d$ be a convex polygon, $1 < p \leq 2$, and A be a uniformly elliptic, dissipative, second order partial differential operator with either Dirichlet or Neumann boundary conditions. In particular, let $A : D(A) \subset L^p(\mathcal{O}) \to L^p(\mathcal{O})$ be the realization of

$$\begin{aligned} \mathcal{L} &= \mathcal{L}(x, D) \\ &= -\sum_{i,j=1}^{2} \frac{\partial}{\partial x_i} a_{i,j}(x) \frac{\partial}{\partial x_j} + \sum_{i=1}^{2} b_i(x) \frac{\partial}{\partial x_i} + c(x), \end{aligned} \tag{2.1}$$

with either

$$u = 0 \quad \text{on} \quad \partial\mathcal{O} \times (0, \infty)$$

or

$$\frac{\partial u}{\partial n_L} + \sigma u = 0,$$

where $\frac{\partial u}{\partial n_L}$ denotes the differentiation along the outer normal unit vector n on $\mathcal{O}$. We assume that $a_{ij} \in C^2(\mathcal{O})$, $1 \leq i, j \leq d$, strictly bounded away from zero, and $\sigma \in C^2(\mathcal{O})$.

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space. Let $\eta : \mathcal{B}(\mathbb{R}) \hat{\times} \mathcal{B}(\mathcal{O}) \hat{\times} \mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ be a Poisson random measure over $(\Omega, \mathcal{F}, \mathbb{P})$ with intensity[1] $\iota = \lambda \hat{\times} \nu$, $\nu \in \mathcal{L}(\mathbb{R}) := \{\sigma : \mathcal{B}(\mathbb{R}) \to \mathbb{R}^+, \sigma \text{ is a Lévy measure}\}$, γ be the compensator, and $\tilde{\eta} = \eta - \gamma$. Let $(\mathcal{F}_t)_{t \geq 0}$ be the natural filtration induced by η.

Our point of interest is solutions of SPDEs of the following form:

$$\begin{cases} du(t, \xi) = Au(t, \xi)\, dt + f(u(t-, \xi), \xi)\, dt \\ \qquad\qquad + \int_{\zeta \in \mathbb{R}} g(u(t-, \xi), \xi; \zeta)\, \tilde{\eta}(d\zeta, \xi, dt), \ \xi \in \mathcal{O}, \ t > 0, \\ u(0, \xi) = u_0(\xi), \quad \xi \in \mathcal{O}, \end{cases} \tag{2.2}$$

where $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ are globally Lipschitz continuous functions. By a mild solution of (1.1) we understand a process u such that

[1] λ denotes the Lebesgue measure.

- u satisfies the integral equation

$$u(t,\xi) = \int_{\mathcal{O}} G_t(\zeta,\xi)u_0(\zeta)\,d\zeta + \int_{0+}^{t}\int_{\mathcal{O}} G_{t-s}(\zeta,\xi)f(u(s-,\zeta,\zeta))\,d\zeta\,ds + \int_{0+}^{t}\int_{\zeta\in\mathcal{O}}\int_{z\in\mathbb{R}} G_{t-s}(\zeta,\xi)g(u(s-,\zeta),\zeta;z)\,\eta(dz,d\zeta,ds),\ \text{a.s.},\quad t\geq 0,$$

  where $G = \{G_t(\cdot,\star), 0 < t < \infty\}$ is the Green kernel associated with $\frac{\partial}{\partial t} + \mathcal{L}$ and the boundary conditions specified above;
- for all $\phi \in C_b^\infty(\mathcal{O})$, the $\mathbb{R}$-valued process $t \mapsto \langle u(t), \phi\rangle$ is adapted and cádlág.

It is shown in Saint Loubert Bié [SLB98] or Hausenblas [Hau05, Example 2.3] that if $p < \frac{2}{d} + 1$, then there exists a unique solution of problem (1.1) such that $u \in L^p(\Omega; L^p(\mathcal{O}))$.

Our point of interest is the numerical approximation of the solution of (1.1). First, we introduce the space discretization by finite elements, and second we introduce the time discretization, i.e., the Euler scheme.

2.1. Space discretization. The space discretization is done by finite elements. For the definition for a finite element, we follow the book of Brenner and Scott [BS02].

DEFINITION 2.1. *Let*

- $K \subset \mathbb{R}^d$ *be a bounded closed set with nonempty interior and piecewise smooth boundary (the* element domain*);*
- $\mathcal{P}$ *be a finite-dimensional space of functions on* K *(the space of* shape functions*); and*
- $\mathcal{N} = \{N_1, \ldots, N_k\}$ *be a basis for* $\mathcal{P}'$ *(the set of* nodal variables*).*

Then $(K, \mathcal{P}, \mathcal{N})$ *is called a* finite element*. Moreover, we denote by* $diam(K) = \max_{x,y\in K} |x-y|_{\mathbb{R}^d}$ *the diameter of* K*.*

DEFINITION 2.2. *A set* K *is* star-shaped with respect to B*, if for all* $x \in K$ *the closed convex hull of* $\{x\} \cup B$ *is a subset of* K*.*

DEFINITION 2.3. *Suppose* K *has diameter* d *and is star-shaped with respect to a ball. Let* $\rho_{max} = \sup\{\rho : K \text{ is star-shaped with respect to a ball of radius } \rho\}$*. Then the* chunkiness parameter *of* K *is defined by*

$$\gamma := \frac{d}{\rho_{max}}.$$

Moreover, we denote by P_m the set of all polynomials in d variables of degree less than or equal to m.

DEFINITION 2.4 (compare the assumptions of Theorem 4.4.4 in [BS02]). *We assume that a finite element satisfies the* standard conditions for some l and m*, iff*

- K *is star-shaped with respect to some ball,*
- $P_{m-1} \subset \mathcal{P} \subset W_\infty^m(\mathcal{O})$*,*
- $\mathcal{N} \subset (C^l(\bar{K}))'$*.*

DEFINITION 2.5. *Let* $(K, \mathcal{P}, \mathcal{N})$ *be a finite element. The basis* $\{\phi_1, \ldots, \phi_k\}$ *of* $\mathcal{P}$ *dual to* $\mathcal{N}$ *is called the* nodal basis *of* $\mathcal{P}$*.*

DEFINITION 2.6. *Given a finite element* $(K, \mathcal{P}, \mathcal{N})$*, let the set* $\{\phi_1, \ldots, \phi_k\} \subset \mathcal{P}$ *be the basis dual to* $\mathcal{N}$*. If* v *is a function for which all* $N_i \in \mathcal{N}$*,* $i = 1, \ldots, k$*, are defined, then we define the* local interpolant *by*

$$\mathcal{I}_K v := \sum_{i=1}^{k} v(N_i)\phi_i.$$

DEFINITION 2.7. *A* subdivision *of a domain $\mathcal{O}$ is a finite collection of element domains $\{K_i, i = 1, \dots k\}$ such that*

- $\int K_i \cap \int K_j = \emptyset$ *if* $i \neq j$ *and*
- $\cup K_i = \mathcal{O}$.

Remark 2.1. The nodal basis of a subdivision $\{K_i, i = 1, \dots k\}$ induces a Voronoi decomposition $\{J_i; i = 1, \dots, k\}$ of $\mathcal{O}$ by

$$J_i := \left\{ \xi \in \mathcal{O},\ |\xi - N_i| \leq \min_{1 \leq i \leq k} \{|\xi - N_j|\} \right\}.$$

DEFINITION 2.8. *Suppose that $\mathcal{O}$ is a polyhedral domain with subdivision $\mathcal{T}$. Assume that each element domain K in the subdivision is equipped with some type of shape functions $\mathcal{P}$ and nodal variables $\mathcal{N}$ such that $(K, \mathcal{P}, \mathcal{N})$ forms a finite element. Let m be the order of the highest partial derivatives involved in the nodal variables. For $f \in C^m(\bar{\mathcal{O}})$, the* global interpolant *is defined by*

$$\mathcal{I}_{\mathcal{T}} f \Big|_{K_i} = \mathcal{I}_{K_i} f$$

for all $K_i \in \mathcal{T}$.

Example 2.1. Let $H = L^2([0,1])$. Let $\{x_i := \frac{i}{N}, i = 1, \dots, N-1\}$ be the set of grid points. For $0 \leq i \leq N$ let ϕ_i be a pyramid function, i.e., a function, which takes value 1 at the grid point $\frac{i}{N}$, vanishes at the other grid points, and is linear between the grid points. For $i = 1, \dots, N-1$, a finite element $(K_i, \mathcal{N}_i, \mathcal{P}_i)$ consists of the interval $[\frac{i-1}{N}, \frac{i}{N}]$, the nodal variables $N_i : \mathcal{C}^0([0,1]) \ni v \mapsto v(x_i) \in \mathbb{R}$, the shape functions $\phi_i|_{K_i}$ and $\phi_{i-1}|_{K_i}$, and $J_i = [\frac{i-1}{N} + \frac{1}{2N}, \frac{i}{N} + \frac{1}{2N}]$.

We can now define a family of subdivisions $\mathcal{F}_h$, $h = N_h^{-1}$. For each subdivision $\mathcal{T}_h$, let $\mathcal{V}_h$ the linear hull of the shape functions, i.e., the linear hull of $\{\phi_i\}_{i=1}^{N_h - 1}$. For any $v \in C([0,1])$, the global interpolant is given by

$$\mathcal{I}_h(v) = \sum_{i=1}^{N_h} N_i^h(v) \phi_i.$$

DEFINITION 2.9. *We call a family of subdivisions $\{\mathcal{T}_h, 0 < h \leq 1\}$* nondegenerate *if the chunkiness parameter is uniformly bounded for all $T \in \{\mathcal{T}_h\}$ and all $h \in (0,1]$.*

Let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions of a polyhedral domain $\mathcal{O}$ in $\mathbb{R}^d$, consisting of k_h finite elements of reference type $(K, \mathcal{P}, \mathcal{N})$. We assume that the parameter h corresponds to the maximal diameter of the finite elements, i.e., $h = \max\{1 \leq i \leq k_h \mid \operatorname{diam}(K_i)\}$. Let $\{\phi_1^h, \dots, \phi_{k_h}^h\}$ be the set of shape functions and $\{N_1^h, \dots, N_{k_h}^h\}$ be the set of nodal variables. We denote by $\mathcal{V}_h$ the linear hull of the shape functions and $\mathcal{V}_h'$ its dual. The semidiscrete problem corresponding to (2.2) is to find the process $u_h = \{u_h(t) \in \mathbb{R}^{k_h}, 0 \leq t < \infty\}$

$$\text{(2.3)} \qquad \begin{cases} du_h(t) = \mathcal{A}_h u_h(t)\, dt f_h(u_h(t-))\, dt \\ \qquad\qquad + \int_{i \in \{1, \dots, k_h\}} \int_{\zeta \in \mathbb{R}} g_h(u_h(t-), i, \zeta)\, \tilde{\eta}_h(d\zeta, di, dt),\ t > 0, \\ u(0) = (\langle u_0, N_1 \rangle, \dots, \langle u_0, N_{k_h} \rangle) \in \mathbb{R}^{k_h} \end{cases}$$

where $\mathcal{A}_h : \mathcal{V}_h \to \mathcal{V}_h$ is the discrete analogue of A defined by

$$\text{(2.4)} \qquad \langle \mathcal{A}_h \phi, \chi \rangle = \langle A\phi, \chi \rangle \quad \forall \phi, \chi \in \mathcal{V}_h,$$

and $\tilde{\eta}_h : \mathcal{B}(\mathbb{R})\hat{\times}\mathcal{P}(\{1,\dots,k_h\})\hat{\times}\mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ is the compensated Poisson random measure with intensity ι_h given by

$$\mathcal{B}(\mathbb{R}) \times \mathcal{B}(\{1,\dots,k_h\}) \ni (A,B) \mapsto \iota_h((A,B)) := \cup_{i\in B}\lambda(J_i^h)\,\nu(A) \in \mathbb{R}^+.$$

Moreover, $f_h : \mathcal{V}_h \to \mathcal{V}_h$ and $g_h : \mathcal{V}_h \times \{1,\dots k_h\} \times \mathbb{R} \to \mathcal{V}_h$ are given by

$$\mathcal{V}_h \ni v \mapsto f_h(v) := \sum_{i=1}^{k_h} f(v(N_i), N_i)\phi_i^h \in \mathcal{V}_h$$

and

$$\mathcal{V}_h \times \{1,\dots k_h\} \times \mathbb{R} \ni (v,i,\zeta) \mapsto g_h(v,i,\zeta) = g(v(N_i), N_i;\zeta)\, c_i^h\ \phi_i^h \in \mathcal{V}_h,$$

where $c_i^h := \left[\int_{\mathcal{O}} \phi_i^h(\xi)\, d\xi\right]^{-1}$.

Remark 2.2. The Poisson random measure $\tilde{\eta}_h$ can also be written as a sum of k_h independent Poisson random measures (see, e.g., [Lin86, Proposition 5.3.2]). To be precise, let $\tilde{\eta}_h^i : \mathcal{B}(\mathbb{R})\hat{\times}\mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ be pairwise independent compensated Poisson random measures with intensity $\nu^i = \lambda(J_i^h)\,\nu$. Then we have for some $A \in \mathcal{B}(\{1,\dots,k_h\})$ and $B \in \mathcal{B}(\mathbb{R})$, $\nu(B) < \infty$,

$$\int_{i\in A}\int_{\xi\in B} \iota_h(di,d\xi) \overset{\mathrm{d}}{=} \sum_{i=1}^{k_h} 1_A(i)\lambda(J_i^h)\int_B \nu^i(d\xi).$$

In particular, we have for all $\mathcal{V}_h$-valued $\mathcal{F}_t$-adapted and cádlág processes $u = \{u(t), 0 \le t < \infty\}$

$$\int_0^t \int_{\{1,\dots,k_h\}} \int_{\zeta\in\mathbb{R}} g_h(u(s-),di,\zeta)\ \tilde{\eta}_h(di,d\zeta,ds) \overset{\mathrm{d}}{=} \sum_{i=1}^{k_h}\int_0^t\int_{\zeta\in\mathbb{R}} g_h(u(s-),i,\zeta)\tilde{\eta}_h^i(d\zeta,ds).$$

2.2. Time discretization. One usually prefers to discretize simultaneously in time and space. Thus, let τ_h be the time step size corresponding to the subdivision $\mathcal{T}_h$. One popular way for time discretization is to use the *implicit Euler scheme*, i.e.,

$$\frac{u_h(t+\tau_h)-u_h(t)}{\tau_h} + \mathcal{A}_h u_h(t+\tau_h) \approx f_h(u_h(t)) + \int_t^{t+\tau_h}\int_{z\in\mathbb{R}^{k_h}} g_h(u_h(t);z)\tilde{\eta}_h(dz,dt).$$

So, if v_h^m denotes the approximation of $u_h(m\tau_h)$, then

$$\begin{cases} v_h^{m+1} = (1-\tau_h A_h)^{-1}\left[v_h^m + \tau_h f_h(m\tau_h, v_h^m) + \xi_h^m(u_h(m\tau_h))\right], \\ v_h^0 = P_h u_0, \end{cases} \tag{2.5}$$

where we denote by $\xi_h^m(u_h(m\tau_h))$ the k_h dimensional random variable

$$\int_{m\tau_h}^{(m+1)\tau_h}\int_{\zeta\in\mathbb{R}^{k_h}} g_h(u_h(m\tau_h);\zeta)\ \tilde{\eta}_h(dz;ds). \tag{2.6}$$

The approximation at time $t = \tau_h m$, $m \in \mathbb{N}$, is given by

$$\hat{u}_h(m\tau) := \mathcal{I}_h v_h^m. \tag{2.7}$$

The solution is defined by linear interpolation; let $t \in (m\tau_h, (m+1)\tau_h)$; we define $v_h(t)$ by $v_h(t) = v_h^m$ and

$$\hat{u}_h(t) := \mathcal{I}_h\, v_h(t), \quad m\tau_h < t < (m+1)\tau_h.$$

Since the implicit Euler scheme is unconditionally stable, no stability conditions arise. Now we can state our main result.

THEOREM 2.1. *Let $\mathcal{O}$ be a polyhedral domain and A be a uniformly elliptic, second order differential operator given in* (2.1) *with Dirichlet or Neumann boundary conditions.*

For a fixed p, $1 \le p \le 2$, let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge 0}, P)$ be the usual filtration and

$$\eta : \mathcal{O} \times \mathbb{R} \times \mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$$

be a Poisson random measure of jump type with intensity $\iota := \lambda \times \nu$, where ν belongs to the set of p-integrable Lévy measures on $\mathbb{R}$.

We assume that the functions $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \bar{\mathcal{O}} \times \mathbb{R} \to \mathbb{R}$ are globally Lipschitz and g linear in the third variable. Moreover, we assume that the initial condition u_0 belongs to $L^p(\mathcal{O})$.

The space is approximated by a nondegenerate family of subdivisions $\{\mathcal{T}_h, 0 < h \le 1\}$ of finite elements, satisfying the conditions described in section 2.1. *Moreover, the reference element is supposed to be a standard element for $l \ge 0$ and $m = 2$. Let v_n^k, $k \in \mathbb{N}$, be the approximation of* (2.2) *given by* (2.7). *Then for all $N \in \mathbb{N}$, for all α such that*

$$\alpha < \frac{2}{p} - d + \frac{d}{p},$$

and for all δ_1, δ_2, and δ_3, with

$$\delta_1 = 2 + \frac{d}{2} - \frac{d}{p}, \quad \delta_2 < \frac{2}{p} - d + \frac{d}{p}, \text{ and } \delta_3 < \left(\frac{2}{p} - d + \frac{d}{p}\right)\left(2 + \frac{d}{2} - \frac{d}{p}\right),$$

there exist constants C_0, C_1, C_2, and C_3 depending on p, f, and g such that for all $0 < h \le 1$ the following estimate holds for $0 < k \le N$:

$$\left[\mathbb{E}\ \left\|u(k\tau_h) - v_h^k\right\|_{L^p(\mathcal{O})}^p\right]^{\frac{1}{p}} \le \frac{C_0}{\epsilon}\,\tau^\alpha + \frac{C_1}{(k\tau_h)^{\frac{1}{p}}}\,h^{\delta_1} + \frac{C_2}{\epsilon_2}\,h^{\delta_2} + \frac{C_3}{\epsilon_3}\,h^{\delta_3},$$

where $\epsilon_1 = \frac{2}{p} - d + \frac{d}{p} - \alpha$, $\epsilon_2 = \frac{2}{p} - d + \frac{d}{p} - \delta_2$ and $\epsilon_3 = \frac{2}{p} - d + \frac{d}{p} - \frac{\delta_3}{\delta_1}$,

In [Hau05, Example 2.3] we treated (2.2) by means of $L^p(\mathcal{O})$ spaces. But finite elements are designed for Hilbert spaces. In particular, the approximation of the operator A is given by the inner product (see problem 3.4), and usually the error estimates of the corresponding semigroups are given in $L^2(\mathcal{O})$ or $H^1(\mathcal{O})$ (see Theorem 3.3). Since the $L^p(\mathcal{O})$ spaces were essential in [Hau05]—on which this paper relies—we had to express the error estimates of the corresponding semigroups in $L^p(\mathcal{O})$ spaces. We have done this in Theorem 3.4. Therefore, the entity $2 + \frac{d}{2} - \frac{d}{p}$ appears.

Fix $p \in [1,2]$. Let E be a separable M-type p Banach space and Z be a Banach space. Let A be an operator generating a compact and analytic semigroup, $\nu \in \mathcal{L}(Z)$, $\tilde{\eta}$ be a compensated Poisson random measure on Z with intensity ν, and $G : E \to L(Z,E)$ be a mapping such that there exist some $\gamma < \frac{2}{p}$ and $C < \infty$, with

$$\int_Z \left| (-A)^{-\frac{\gamma}{2}} \left(G(u,z) - G(v,z) \right) \right|_E^p \nu(dz) \leq C \, |u-v|_E^p. \tag{2.8}$$

Then, by [Hau05], there exists a unique solution to the equation

$$\begin{cases} du(t) = (Au(t-)) \; dt + \int_Z g(u(t-);z) \tilde{\eta}(dz;dt), \\ u(0) = u_0. \end{cases} \tag{2.9}$$

In [Hau05, Example 2.3], the space time Poissonian noise was represented as a functional-valued Poisson random measure taking values in the Besov space $B_p^{\frac{d}{p}-d}(\mathcal{O})$. Let $\nu \in \mathcal{L}(E)$ and $1 \leq p \leq 2$. Let $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ be Lipschitz continuous in the following sense: There exists some constant $C < \infty$ such that

$$\int_{\mathcal{O}} \int_{\mathbb{R}} |g(x,\xi,\zeta) - g(y,\xi,\zeta)|^p \nu(d\zeta) d\xi \leq C |x-y|^p, \quad x,y \in \mathbb{R}. \tag{2.10}$$

Thus, if

$$\frac{d}{p} - d < \frac{2}{p},$$

then the Nemytskij operator G of g, defined in (3.20), satisfies by Proposition A.1 the Lipschitz condition (2.8). The remaining difference

$$\frac{2}{p} - d + \frac{d}{p}$$

is used for estimating the error of the approximation. Therefore, the entity $\frac{2}{p} - d + \frac{d}{p}$ appears.

Again, let $\nu \in \mathcal{L}(E)$, $1 \leq p_0 \leq 2$ and $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ be Lipschitz continuous satisfying (2.10), with $p = p_0$. Moreover, let $f = 0$. Then, if

$$\frac{2}{p_0} - d + \frac{d}{p_0} > 0, \tag{2.11}$$

problem (1.1) has a unique solution such that $u \in L^p(\Omega; L^p(\mathcal{O}))$ for all $p \in [p_0, p_1)$, where $p_1 = \frac{2}{d} + 1$ (compare [Hau05, Example 2.3]). Moreover, the assumptions of Theorem 2.1 are fulfilled for all $p \in [p_0, p_1)$, and we can choose any $p \in [p_0, p_1)$ such that $\min(\delta_1, \delta_2, \delta_3)$ is maximal. If

$$2 + \frac{d}{2} - \frac{d}{p_1} < 0,$$

then no convergence is given by Theorem 2.1.

3. Finite elements—a short account. In the existing literature several error bounds for the approximation by finite elements can be found. In this section, we will cite the estimates which are necessary to prove our main result.

In this chapter, let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions of a polyhedral domain $\mathcal{O}$ in $\mathbb{R}^d$, consisting of k_h finite elements of reference type $(K, \mathcal{S}, \mathcal{N})$ satisfying the standard conditions for some m and l. We assume that the parameter h corresponds to the maximal diameter of the finite elements, i.e., $h = \max\{1 \leq i \leq N \mid \operatorname{diam}(K_i)\}$. Moreover, we assume throughout this section, that $(K, \mathcal{P}, \mathcal{N})$ satisfies the standard conditions for some l and m.

Let $\{\phi_1^h, \dots, \phi_{k_h}^h\}$ be the set of shape functions and $\{N_1^h, \dots, N_k^h\}$ be the set of nodal variables. By $\bar{\mathcal{N}}$ we denote the set of nodal variables which are inner points. We denote by $\mathcal{V}_h$ the linear hull of the shape functions and by $\mathcal{V}_h'$ its dual.

The quality of approximation is given by the following Bramble–Hilbert (Raviart–Ciarlet) inequality.

THEOREM 3.1 (see, e.g., Brenner and Scott [BS02, Corollary 4.4.24]). *Assume that the conditions above are satisfied. Suppose* $1 \leq p \leq \infty$ *and either* $m - l - \frac{d}{p} > 0$ *when* $p > 1$ *or* $m - l - d \geq 0$ *when* $p = 1$. *Then there exists a positive constant* C *depending on the reference element,* m, l, d, p, *and the chunkiness parameter such that for* $0 \leq s \leq m$

$$\left(\sum_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_p^s(T)}^p \right)^{\frac{1}{p}} \leq C\, h^{m-s}\, \|v\|_{W_p^m(\mathcal{O})}$$

for all $v \in W_p^m(\mathcal{O})$, *where the left-hand side should be interpreted, in the case where* $p = \infty$, *as* $\max_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_\infty^s(\mathcal{O})}$. *For* $0 \leq s \leq l$,

$$\max_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_\infty^s(\mathcal{O})} \leq C\, h^{m-s-\frac{d}{p}}\, \|v\|_{W_p^m(\mathcal{O})} \quad \forall v \in W_p^m(\mathcal{O}).$$

Since the space $\mathcal{V}_h$ is finite-dimensional, all norms which can be defined in $\mathcal{V}_h$ are equivalent. The purpose of the inverse inequalities is to specify how the equivalent constants depend on the parameter h.

THEOREM 3.2 (Brenner and Scott [BS02, Theorem 4.5.11]). *Assume that the conditions above are satisfied, and let* p, q, *and* l *be given constants such that* $1 \leq p \leq \infty$, $1 \leq q \leq \infty$, $0 \leq m \leq l$, *and* $\phi_i^h \in W_p^l(\mathcal{O}) \cap W_q^m(\mathcal{O})$ *for* $i = 1, \dots, k_h$. *Then there exists a positive constant* C *depending on the reference element,* d, m, p, *and* q *such that*

$$\left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_p^l(T)}^p \right]^{\frac{1}{p}} \leq C\, h^{m-l+\min(0, \frac{d}{p} - \frac{d}{q})} \left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_q^m(T)}^q \right]^{\frac{1}{q}}$$

for all $v \in \mathcal{V}_h$. *When* $p = \infty$, *then* $[\sum_{T \in \mathcal{T}_h} \|v\|_{W_p^s(T)}^p]^{\frac{1}{p}}$ *is interpreted as* $\max_{T \in \mathcal{T}_h} \|v\|_{W_\infty^l(T)}^q$.

COROLLARY 3.1. *Under the conditions above, there exists a positive constant* C *depending on the reference element such that we have for all* $1 > \delta \geq 0$

$$\left[\sum_{T \in \mathcal{T}_h} \|v\|_{L_p(T)}^p \right]^{\frac{1}{p}} \leq C\, h^{-\delta+\min(0, \frac{d}{p} - \frac{d}{q})} \left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_q^{-\delta}(T)}^q \right]^{\frac{1}{q}}$$

for all $v \in \mathcal{V}_h$.

Proof. The proof is done similarly to the proof of Theorem 3.2 (see Brenner and Scott [BS02, Theorem 4.5.11]). Let $(\hat{K}, \hat{\mathcal{P}}, \hat{\mathcal{N}})$ be a finite element of reference type satisfying the standard conditions for m and l with $\operatorname{diam}(\hat{K}) = 1$ and $(K, \mathcal{P}, \mathcal{N})$ be a finite element of the family of subdivisions with $\operatorname{diam}(K) = h_K$. Since the subdivision is nondegenerate, a transformation exists, having the form

$$T_K : \hat{K} \ni \hat{x} \mapsto J_K \hat{x} + b_K \in K,$$

where $J_K \in \mathbb{R}^d \times \mathbb{R}^d$ being invertible and $b_K \in \mathbb{R}^d$ (see Proposition 4.4.11 in [BS02]). Let $\hat{v} : \hat{K} \to \mathbb{R}$ be an arbitrary function and $v : K \to \mathbb{R}$ be defined by

$$K \ni x \mapsto v(x) := \hat{v}(J_K^{-1} x) \in \mathbb{R}.$$

Then substitution gives

$$|v|_{L^p(K)} = \det(J_K)^{\frac{1}{p}} |\hat{v}|_{L^p(\hat{K})} = C\, h_K^{\frac{d}{p}} |\hat{v}|_{L^p(\hat{K})}, \quad 0 < h_K \le 1,$$

and

$$|v|_{L^\infty(K)} = |\hat{v}|_{L^\infty(\hat{K})}, \quad 0 < h_K \le 1.$$

Similarly there exists a constant $C > 0$ such that we have for all $0 < h_K \le 1$

$$|v|_{W_p^j(K)} = C\, \det(J_K)^{\frac{1}{p}} h_K^{-j} |\hat{v}|_{W_p^j(\hat{K})} = C\, h_K^{\frac{d}{p}-j} |\hat{v}|_{W_p^j(\hat{K})}$$

and

$$|v|_{W_\infty^j(K)} = C\, h_K^{-j} |\hat{v}|_{W_\infty^j(\hat{K})} = C\, h_K^{-j} |\hat{v}|_{W_\infty^j(\hat{K})}.$$

Duality arguments give for q conjugate to p and for all $0 < h_K \le 1$

$$\begin{aligned} |v|_{W_p^{-j}(K)} &= \sup_{w \in W_q^j(K)} \frac{\langle v, w \rangle}{|w|_{W_q^j(K)}} \le C \sup_{\hat{w} \in W_q^j(\hat{K})} \frac{\det(J_K) \langle \hat{v}, \hat{w} \rangle}{h_K^{\frac{d}{q}-j} |\hat{w}|_{W_q^j(\hat{K})}} \\ &= C\, h_K^{d(1-\frac{1}{q})+j} \sup_{\hat{w} \in W_q^j(K)} \frac{\langle \hat{v}, \hat{w} \rangle}{|\hat{w}|_{W_q^j(K)}} \le C\, h_K^{\frac{d}{p}+j} |\hat{v}|_{W_p^{-j}(\hat{K})}. \end{aligned} \tag{3.1}$$

Since $\hat{\mathcal{P}}$ is finite-dimensional, all norms are equivalent, and there exists a constant $\hat{C}$ such that

$$|\hat{v}|_{L^p(\hat{K})} \le \hat{C}\, |\hat{v}|_{W_q^{-\gamma}(\hat{K})} \quad \forall v \in \mathcal{P}.$$

Therefore (3.1) and interpolation arguments imply for $\gamma > 0$ that

$$h_K^{-\frac{d}{p}} |v|_{L^p(K)} \le C\, h_K^{-\frac{d}{q}-\gamma} |v|_{W_q^{-\gamma}(K)} \quad \forall v \in \mathcal{P},\ 0 < h_K \le 1.$$

Let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions. Then, by taking the sum, one can show by the same arguments as in Theorem 4.5.11 in [BS02], that, if the family of subdivisions is nondegenerate, the assertion of Corollary 3.1 holds. ∎

3.1. Approximation of the operator. We can associate with the operator $(A, D(A))$ the Gelfand triple (V, H, V'), where $V \hookrightarrow H = H' \hookrightarrow V'$ densely. In fact, $V = D(-A)^{\frac{1}{2}}$ and V' its dual. In our case, where $(A, D(A))$ is a second order differential operator with boundary conditions, we have $V = H^1(\mathcal{O})$ if the boundary condition involves first order derivatives and $V = H_0^1(\mathcal{O})$ if the homogeneous Dirichlet condition is specified on the whole boundary. Now the operator $A : V \to V'$ defines a bilinear form on H by

$$a(u, v) := \langle Au, v\rangle, \quad u, v \in V.$$

The corresponding symmetric variational problem is posed as follows. Suppose that the following three conditions are valid:

$$\text{(3.2)} \qquad \begin{cases} (1) & (H, \langle\cdot,\cdot\rangle) \text{ is a Hilbert space.} \\ (2) & V \text{ is a (closed) subspace of } H. \\ (3) & a(\cdot,\cdot) \text{ is a } \textit{bounded, symmetric} \text{ bilinear form} \\ & \text{that is } \textit{coercive} \text{ on } V. \end{cases}$$

Then the *symmetric variational* problem is the following:

$$\text{(3.3)} \qquad \begin{cases} \text{For a given } F \in V', \text{ find } u \in V \text{ such that} \\ \quad a(u, v) = F(v) \quad \forall v \in V. \end{cases}$$

Given the family of nondegenerate subdivisions $\mathcal{T}_h$ of a polyhedral domain $\mathcal{O}$, the *Ritz–Galerkin approximation* of problem (3.3) is the following:

$$\text{(3.4)} \qquad \begin{cases} \text{For a given } F \in \mathcal{V}_h', \text{ find } u_h \in \mathcal{V}_h \text{ such that} \\ \quad a(u_h, v) = F(v) \quad \forall v \in \mathcal{V}_h. \end{cases}$$

Assume that u solves problem (3.3) and u_h solves problem (3.4). Then we can find the following estimates on $u - u_h$ depending on F. By means of the inequality above and duality arguments, one can verify bounds of the difference $u - u_h$ in $H^1(\mathcal{O})$ and $L^2(\mathcal{O})$. In particular, one can show that, if the family of subdivisions $\{\mathcal{T}_h, 0 < h \leq 1\}$ satisfies the assumptions of Theorem 3.1 with $m = 2$, $l \geq 0$ and $p = 2$, then

$$\text{(3.5)} \qquad \inf_{v \in \mathcal{V}_h} \|u - v\|_{H^1(\mathcal{O})} \leq C\, h\, \|u\|_{H^2(\mathcal{O})} \quad \forall u \in H^2(\mathcal{O}), \quad 0 < h \leq 1,$$

is valid, and therefore (for more details, see Theorem 5.4.8 in [BS02])

$$\text{(3.6)} \qquad \|u - u_h\|_{L^2(\mathcal{O})} \leq Ch^2 \|u\|_{H^2(\mathcal{O})} \leq Ch^2 \|F\|_{L^2(\mathcal{O})}, \quad 0 < h \leq 1.$$

Finally, by using duality arguments, one can show that there exists a $h_0 > 0$ such that (see Theorem 5.8.3 in [BS02])

$$\text{(3.7)} \qquad \|u - u_h\|_{H^{2,-\gamma}(\mathcal{O})} \leq Ch^{\gamma+1} \|u - u_h\|_{H^1(\mathcal{O})} \leq Ch^{2+\gamma} \|F\|_{L^2(\mathcal{O})}, \quad 0 < h \leq 1.$$

Since our problem (2.2) is well-posed in $L^p(\mathcal{O})$, the error bounds of the difference have to be transferred to $L^p(\mathcal{O})$ or $W^p_{-\gamma}(\mathcal{O})$, $\gamma > d - \frac{d}{p}$, $p \in (1, 2]$.

COROLLARY 3.2. *Assume that* (3.5) *holds. Then, under the conditions above, there exist positive constants* C *and* h_0 *such that for all* $h \le h_0$ *there is a unique solution to problem* (3.4) *satisfying*

$$\|u - u_h\|_{L^p(\mathcal{O})} \le Ch^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{L^p(\mathcal{O})}, \quad 0 < h \le 1,$$

and for $\gamma \in (0,1)$

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le Ch^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{W^p_{-\gamma}(\mathcal{O})}, \quad 0 < h \le 1.$$

Proof. Since $p \le 2$ and O is bounded we can infer that

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C \ \|u - u_h\|_{L^2(\mathcal{O})}.$$

The estimate (3.6) gives

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C\, h^2 \|F\|_{L^2(\mathcal{O})}.$$

Theorem 3.2 leads to

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C\, h^{2+\frac{d}{2}-\frac{d}{p}} \|F\|_{L^p(\mathcal{O})}.$$

Similarly, we get

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C \ \|u - u_h\|_{W^2_{-\gamma}(\mathcal{O})}.$$

Estimate (3.7) gives

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C\, h^{2+\gamma} \|F\|_{L^2(\mathcal{O})}.$$

Next, we apply negative norm estimates. In particular, Theorem 3.2 leads to

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C\, h^{2+\frac{d}{2}-\frac{d}{p}} \|F\|_{W^p_{-\gamma}(\mathcal{O})}. \qquad \square$$

3.2. Approximation of the semigroup. The approximation $\mathcal{A}_h : \mathcal{V}_h \to \mathcal{V}_h'$ of the operator A is given by the induced bilinear form on $\mathcal{V}_h$. In particular, for any $u \in \mathcal{V}_h$ we define $\mathcal{A}_h u$ by

$$\langle \mathcal{A}_h u, v\rangle := a(u,v), \quad v \in \mathcal{V}_h. \tag{3.8}$$

The semidiscrete approximation of the solution u to the abstract Cauchy problem

$$\begin{cases} \frac{d}{dt}u(t) + Au(t) = 0, & t > 0, \\ u(0) = u_0 \end{cases} \tag{3.9}$$

is the function $u_h : [0,\infty) \to \mathcal{V}_h$, determined by the following condition: For all $v \in \mathcal{V}_h$ we have

$$\begin{cases} \frac{d}{dt}\langle u_h(t), v\rangle + a(u_h(t), v) = 0, \ t > 0, \\ \langle u_h(0), v\rangle = \langle u_0, v\rangle. \end{cases} \tag{3.10}$$

In use of the operator $\mathcal{A}_h$, relation (3.10) is written as

$$\frac{du_h(t)}{dt} + \mathcal{A}_h u_h(t) = 0, \quad t > 0.$$

Let $\mathcal{H}_h$ be the space $\mathcal{V}_h$ equipped with the topology induced from H. Let $\mathcal{R}_h : H \to \mathcal{H}_h$ be the Ritz projection. Recall that the linear operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ is defined by (3.8). Let $\mathcal{R}_h : V \to \mathcal{V}_h$ be the *Ritz operator* defined through

$$a(R_h u, v_h) = a(u, v) \quad \forall u \in \mathcal{V}_h \text{ and } u \in V.$$

By the Lax–Milgram theorem, it can be shown that the Ritz operator is well-defined, i.e., that the element $R_h u$ exists and is unique. Theorem 1.1 of [FSS01] shows that the operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ generates an analytic semigroup on $\mathcal{H}_h$ independently of h. To be precise, there exist some $\theta \in (0, \pi)$ and some $M \geq 1$ such that $\mathbb{C} \setminus \Sigma_\theta \subset \rho(\mathcal{A}_h)$, where $\rho(\mathcal{A}_h)$ denotes the resolvent set of $\mathcal{A}_h$ and

$$\Sigma_\theta := \{z \in \mathcal{C}, 0 \leq |\arg(z)| \leq \theta\}.$$

The semidiscrete approximation admits the error estimate of optimal order for $t > 0$.

THEOREM 3.3 ([FSS01, Theorem 2.1]). *Given $u_0 \in H$, let u and u_h be the solutions of* (3.9) *and* (3.10)*, respectively. Then we have*

$$\|u(t) - u_h(t)\|_{L^2(\mathcal{O})} + h \|u(t) - u_h(t)\|_{H^1(\mathcal{O})} \leq C\, h^2 t^{-1} \|u_0\|_{L^2(\mathcal{O})}, \quad t > 0,\ 0 < h \leq 1.$$

Similarly to the Proof of Theorem 3.3 one can find error estimates in L^p spaces.

THEOREM 3.4. *Given $u_0 \in H$, let u and u_h be the solutions of* (3.9) *and* (3.10)*, respectively. Then we have for $1 \leq p \leq 2$ and $0 \leq \gamma < 1$*

$$\|u(t) - u_h(t)\|_{W^{p,-\gamma}(\mathcal{O})} \leq C\, h^{2-\frac{d}{p}+\frac{d}{2}} t^{-1} \|u_0\|_{W^{p,-\gamma}(\mathcal{O})}, \quad t > 0,\ 0 < h \leq 1.$$

Proof. The proof of Theorem 3.4 is similar to the proof of Theorem 3.3, i.e., Theorem 2.1 in [FSS01]. Assume that u solves problem (3.3) with $F = u_0$ and u_h solves problem (3.4) with $F = \mathcal{I}_h u_0$. In Corollary 3.2 we have shown that there exists estimates of the error in L^p spaces. In particular, we have

$$\|u - u_h\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{L^p(\mathcal{O})}.$$

Since $u = A^{-1}u_0$ and $\mathcal{A}_h^{-1}\mathcal{I}_h u_0$, we can write

$$\left\|A^{-1}u_0 - \mathcal{A}_h^{-1}\mathcal{I}_h u_0\right\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{L^p(\mathcal{O})}.$$

Next, since for all $\lambda_0, \lambda \in \rho(A) \cap \rho(\mathcal{A}_h)$ we have

$$\begin{aligned}(\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1} - (\lambda - A)^{-1} &= \left(1 + (\lambda - \lambda_0)(\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right) \\ &\times \left((\lambda_0\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h - (\lambda_0 - A)^{-1}\right) \times (\lambda_0 - A)(\lambda_0 - A)^{-1}, \end{aligned} \tag{3.11}$$

we can conclude that the following estimates:

$$\left\|(\lambda I - A)^{-1} u_0 - (\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h u_0\right\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{L^p(\mathcal{O})} \tag{3.12}$$

and for $\gamma \in (0, 1)$

$$\left\|(\lambda I - A)^{-1} u_0 - (\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h u_0\right\|_{W^p_{-\gamma}(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{W^p_{-\gamma}(\mathcal{O})} \tag{3.13}$$

are valid for all $\lambda \in \rho(A) \cap \rho(\mathcal{A}_h)$. The proof of Theorem 3.3 relies on the fact that we can represent the semigroup in terms of the resolvent. By comparing to [FSS01, page 58], or to [Paz83, Theorem 1.7.7], we have

$$\|u(t) - u_h(t)\mathcal{I}_h\| \leq \frac{1}{2\pi} \int_\Gamma \left|e^{-tz}\right| \cdot \left\| \left[(\lambda I - A)^{-1} - (\lambda \mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right] u_0 \right\| \, dz, \tag{3.14}$$

where Γ is the boundary of $\Sigma_{\theta_1} = \{z, 0 \leq |\arg(z)| \leq \theta_1\}$, for $\theta_1 \in (\theta, \frac{\pi}{2})$ coming from $\infty e^{i\theta_1}$, passing through the origin and going out to $\infty e^{-i\theta_1}$. Using estimate (3.6) and taking into account the calculations in (3.11) gives

$$\begin{aligned} &\left\| \left[(\lambda I - A)^{-1} - (\lambda \mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right] u_0 \right\|_{L^2(\mathcal{O})} \\ &\qquad \leq C\, h^m \left\|u_0\right\|_{L^2(\mathcal{O})}, \quad u_0 \in L^2(\mathcal{O}). \end{aligned} \tag{3.15}$$

By substituting estimate (3.15) into (3.14), Theorem 3.3 can be shown. Similarly, by substituting estimate (3.12) into (3.14) one gets

$$\begin{aligned} &\|u(t) - u_h(t)\mathcal{I}_h\|_{L^p(\mathcal{O})} \leq \frac{C}{2\pi}\, h^{2-\frac{d}{p}+\frac{d}{2}}\ \|u_0\|_{L^p(\mathcal{O})} \int_\Gamma \left|e^{-tz}\right| \, dz \\ &\leq C\, h^{2-\frac{d}{p}+\frac{d}{2}}\ \|u_0\|_{L^p(\mathcal{O})} \int_0^\infty e^{-tr\cos(\theta_1)}\, dr \leq C\, h^{2-\frac{d}{p}+\frac{d}{2}}\ t^{-1}\ \|u_0\|_{L^p(\mathcal{O})}. \end{aligned}$$

The case $\gamma = 0$ of Theorem 3.4 follows. To show Theorem 3.4 for $\gamma > 0$ one can use the same computations, but one has to substitute estimate (3.13) instead of (3.12) into (3.14). □

3.3. Mesh-dependent norms. For $x \in \mathcal{V}_h$, one can define the mesh-dependent inner product

$$\langle v, w\rangle_h := h^d \sum_{i=1}^{k_h} N_i^h(v) N_i^h(w)$$

and the norm

$$\|v\|^2_{L^2_h(\mathcal{O})} := \langle v, v\rangle = h^d \sum_{i=1}^{k_h} v(N_i^h)^2.$$

It can be shown that there exist some constants c and C such that we have for all $h \in (0, 1)$ (see Lemma 6.2.7 of [BS02])

$$c\|v\|_{L^2(\mathcal{O})} \leq \|v\|_{L^2_h(\mathcal{O})} \leq C\|v\|_{L^2(\mathcal{O})} \quad \forall v \in \mathcal{V}_h.$$

Since the natural spaces for SPDEs driven by Poisson random measure are L^p spaces, we will also define mesh-dependent L^p spaces; i.e., for $0 < h \leq 1$ and $v \in \mathcal{V}_h$ we define

$$\|v\|_{L^p_h(\mathcal{O})} := \left(h^d \sum_{i=1}^{k_h} \left|N_i^h(v)\right|^p \right)^{\frac{1}{p}}$$

and

$$L^p_h(\mathcal{O}) := \{v \in \mathcal{V}_h, \|v\|_{L^p_h(\mathcal{O})} < \infty\}.$$

Similarly to the case where $p = 2$, one can show that there exist some constants c and C such that we have for all h with $0 < h \leq 1$

$$c\|v\|_{L^p(\mathcal{O})} \leq \|v\|_{L^p_h(\mathcal{O})} \leq C\|v\|_{L^p(\mathcal{O})} \quad \forall v \in \mathcal{V}_h \cap L^p(\mathcal{O}). \tag{3.16}$$

Remark 3.1. It follows from the nondegeneracy assumptions of the subdivisions that there exist some constants c and C such that

$$c\, h^d \leq k_h \leq Ch^d, \quad 0 < h < 1.$$

Theorem 1.1 of [FSS01] shows that the operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ generates an analytic semigroup on $\mathcal{H}_h$ with parameter M and ω independent of h. To be precise, there exist some $\theta \in (0, \pi)$ and some $M \geq 1$ such that $\mathcal{C} \setminus \Sigma_\theta \subset \rho(\mathcal{A}_h)$, where $\rho(\mathcal{A}_h)$ denotes the resolvent set of operator $\mathcal{A}_h$ and

$$\Sigma_\theta := \{z \in \mathcal{C}, 0 \leq |\arg(z)| \leq \theta\}.$$

Let X be a Banach space and $A : X \to X$ be a operator generating an analytic semigroup on X. Since the constants M, ω, and C in

$$\left\|e^{-tA}u\right\|_X \leq M\, e^{\omega t}\, \|u\|_X$$

and

$$\left\|Ae^{-tA}u\right\|_X \leq \frac{C}{t}\, e^{\omega t}\, \|u\|_X$$

depend on the resolvent set, in particular, on the angle θ which includes the numerical range, we can conclude that there exist some constants C_1 and C_2 such that

$$\left\|e^{-t\mathcal{A}_h}u\right\|_{L^p_h(\mathcal{O})} \leq C_1\, \|u\|_{L^p_h(\mathcal{O})} \quad \forall v \in L^p_h(\mathcal{O}), \quad 0 < h \leq 1, \tag{3.17}$$

and

$$\left\|Ae^{-t\mathcal{A}_h}u\right\|_{L^p_h(\mathcal{O})} \leq \frac{C_2}{t}\, \|u\|_{L^p_h(\mathcal{O})} \quad \forall v \in L^p_h(\mathcal{O}), \quad 0 < h \leq 1. \tag{3.18}$$

For more details, see [Paz83, Theorem 2.5.2] and [FSS01].

3.4. The mass and stiffness matrix. In this section we will investigate properties of the mass and stiffness matrix. Let $\mathcal{O}$ be a polyhedron in $\mathbb{R}^d$ and $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions, where the reference finite element $(\hat{K}, \hat{\mathcal{P}}, \hat{\mathcal{N}})$ satisfies the standard conditions for $m = l = 1$.

The mass matrix $\mathbf{M}_h$ of a subdivision is given by $\mathbf{M}_h = ((m^h_{i,j}))^{k_h}_{i,j=1}$, where

$$m^h_{i,j} := \langle \phi^h_i, \phi^h_j \rangle, \quad 1 \leq i, j \leq k_h.$$

Since the shape functions are locally defined, there exists a number m such that for all $h \in (0, 1)$ there exists a set $\mathcal{C}_h \subset \mathbb{N}^{k_h} \times \mathbb{N}^{k_h}$ such that

$$\operatorname{supp}(\phi^h_i) \cap \operatorname{supp}(\phi^h_j) = \emptyset \quad \forall (i, j) \not\subset \mathcal{C}_h, \quad 0 < h \leq 1,$$

and

$$|(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h| \leq m, \quad 0 < h \leq 1.$$

Remark 3.2. The mass matrix is given by Theorem 9.8, page 387 in Ern and Guermond [EG04]. The left-hand side is given by

$$\langle \mathcal{A}_h \phi_l^h, \phi_j^h \rangle = \langle \nabla \phi_i^h, \nabla \phi_j^h \rangle.$$

Since $\{\mathcal{T}_h, 0 < h \leq 1\}$ is a uniformly bounded family of subdivisions, we have

$$\langle \nabla \phi_l^h, \nabla \phi_j^h \rangle = \begin{cases} c\, h^{d-2}, & \text{if } (i,j) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere.} \end{cases}$$

Fix some i, $1 \leq i \leq k_h$. Our point of interest is $\mathcal{A}_h^{-1}\phi_i$. Let $u_i = \mathcal{A}_h^{-1}\phi_i$. Then

$$\langle \mathcal{A}_h u_i, \phi_j^h \rangle = \langle \phi_i^h, \phi_j^h \rangle, \quad j = 1, \ldots, k_h.$$

Since $u_i \in \mathcal{V}_h$, there exists $u_{i1}, \ldots, u_{ik_h} \in \mathbb{R}$ such that

$$u_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h.$$

Therefore,

$$\langle \mathcal{A}_h u_i, \phi_j^h \rangle = \sum_{l=1}^{k_h} u_{il} \langle \mathcal{A}_h \phi_l^h, \phi_j^h \rangle = \langle \phi_i^h, \phi_j^h \rangle$$

and by Remark 3.2

$$u_{il} = \begin{cases} c\, h^2, & \text{if } (i,j) \subset C, \\ 0, & \text{elsewhere.} \end{cases} \tag{3.19}$$

3.5. Approximation of the noise. The space time Poissonian noise of jump type is given by a Poisson random measure

$$\eta : \mathcal{B}(\mathcal{O}) \times \mathcal{B}(\mathbb{R}) \times \mathcal{B}([0,\infty)) \to \mathbb{R}^+$$

with intensity $\lambda \times \nu$, where ν is a Lévy measure over $\mathbb{R}$, such that

$$\int_{\mathbb{R}} |z|^p \, \nu(dz) < \infty.$$

The function

$$g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$$

is Lipschitz continuous with Nemytskij operator

$$L^p(\mathcal{O}) \times \mathbb{R} \ni (u,z) \mapsto G(u;z) = g(u(\cdot);\cdot;z) \in L^p(\mathcal{O}), \tag{3.20}$$

where $g(u(\cdot);\cdot;z)(\xi) := g(u(\xi);\xi;z)$. In [Hau05] we have seen that the space time Poissonian noise can be described by a Banach-valued Poisson random measure. In particular, let $Z = B_{p,\infty}^{\frac{d}{p}-d}(\mathcal{O})$ and U be the unit sphere in Z. Let χ be defined by

$$\mathcal{O} \ni \xi \mapsto \chi(\xi) := c\, \delta_\xi \in Z,$$

where $c = |\delta_\xi|_Z^{-1}$. The intensity ι of the Z-valued Poisson random measure is given by

$$\mathcal{B}(Z) \ni B \mapsto \iota(B) := \int_{\zeta\in\mathbb{R}} \int_{x\in U} 1_B(\zeta x)\sigma(dx)\nu(d\zeta) \in \mathbb{R}^+,$$

where $\sigma(A) := \lambda(\chi^{-1}(A \cap \chi(\mathcal{O})))$, $A \in \mathcal{B}(Z)$. By inserting the definition above into the definition of the Besov space, one gets by Proposition A.1

$$\begin{aligned}\int_{z\in Z} |G(u,z) - G(v,z)|_Z^p \iota(dz) &= \int_{\xi\in\mathcal{O}} \int_{\zeta\in\mathbb{R}} |g(u(\xi),\xi;\zeta) - g(v(\xi),\xi;\zeta)|^p \,\nu(d\zeta)\,d\xi \\ &\le C\,|u-v|^p_{L^p(\mathcal{O})}, \quad u,v \in C_b^0(\mathcal{O}).\end{aligned}$$

Extension to $L^p(\mathcal{O})$ leads to the Lipschitz property (2.10) of G. The approximation can be similarly interpreted. First, the Lebesgue measure is approximated by λ_h defined by

$$\mathcal{B}\left(\{1,2,\dots,k_h\}\right) \ni A \mapsto \lambda_h(A) := \sum_{i=1}^{k_h} \lambda(J_i^h) 1_A(i) \in \mathbb{R}^+.$$

Now the approximation $\iota_h : \mathcal{B}(\{1,\dots,k_h\}) \times \mathcal{B}(\mathbb{R}) \to \mathbb{R}^+$ of the intensity ι is defined by

$$\{1,\dots,k_h\} \times \mathcal{B}(\mathbb{R}) \ni (A,B) \mapsto \iota_h(A,B) := \sum_{i=1}^{k_h} 1_A(i)\lambda_h(\{i\}) \int_{\zeta\in\mathbb{R}} \nu(d\zeta) \in \mathbb{R}^+.$$

The approximated Nemytiskij operator G_h is defined by

$$\mathcal{V}_h \times \{1,\dots,k_h\} \times \mathcal{B}(\mathbb{R}) \ni (u,i,\zeta) \mapsto G_h(u,i,\zeta) := g(u(N_i^h), N_i^h;\zeta)\, c_i^h \phi_i^h.$$

Similarly to the above we can show the following proposition.

PROPOSITION 3.1. *There exists some $C > 0$ such that for any $h > 0$ and for any $\gamma > \frac{1}{2}(d - \frac{d}{p})$ and $\delta < 2\gamma - d - \frac{d}{p}$ the following inequality holds for all $u_h, v_h \in \mathcal{V}_h$:*

$$\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \le C\, h^{d\delta p} \left\|u_h - v_h\right\|^p_{L^p(\mathcal{O})}.$$

Proof. Let $u, v \in \mathcal{V}_h$. Then we have

$$\begin{aligned}&\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \\ &= \mathbb{E}\left\|\sum_{i=1}^{k_h} \int_{\mathbb{R}} (-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,\zeta) - G_h(v_h,\zeta)\right] \mu_i^h(d\zeta,ds)\right\|^p_{L^p(\mathcal{O})},\end{aligned}$$

where μ_i^h, $i = 1,\dots,k_h$, are independent Poisson random measures with intensity $\lambda_h(i)\nu$. The generalized Burkholder inequality gives

$$\begin{aligned}&\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \\ &\le \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[g(u_h(N_j^h),N_j^h;\zeta) - g(v_h(N_j^h),N_j^h;\zeta)\right] c_j^h\phi_j^h\right\|^p_{L^p(\mathcal{O})} \lambda(J_j^h)\nu(d\zeta).\end{aligned}$$

Since $g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta) \in \mathbb{R}$ and $\mathcal{A}_h$ is linear, we can continue

$$\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz) \le \sum_{j=1}^{k_h} \int_{\mathbb{R}}$$

$$\left\|\left[g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right](-\mathcal{A}_h)^{-\gamma} c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta).$$

Since the family of subdivisions is nondegenerate, we have $\left\|\phi_j^h\right\|_{L^p(\mathcal{O})}^p \sim h^{\frac{d}{p}}$, $c_j^h \sim h^{-d}$, and $\lambda(J_j^h) \sim h^d$. Therefore, by using also Remark 3.2, we get

$$\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz)$$

$$\le C \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \left\|(-\mathcal{A}_h)^{-\gamma} c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta)$$

$$\le C\, h^{\gamma 2} \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \left\|c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta)$$

$$\le C\, h^{\gamma 2 - dp + d} \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \lambda(J_j^h)\nu(d\zeta).$$

According to the Lipschitz condition of g we have

$$\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz)$$

$$\le C\, h^{\gamma 2 - dp + d} \sum_{j=1}^{k_h} h^d \left|u_h(N_j^h) - v_h(N_j^h)\right|^p.$$

The equivalence between $L^p(\mathcal{O})$ and $L_h^p(\mathcal{O})$ gives the assertion. ∎

In order to calculate the error induced by the approximation of the Poisson random measure, we have to express the measure ι_h in terms of ι.

PROPOSITION 3.2. *There exists some $C > 0$ such that for any $h > 0$ and for any $\gamma > \frac{1}{2}(d - \frac{d}{p})$ and $\delta < 2\gamma - d - \frac{d}{p}$ the following inequality holds for all $u_h \in \mathcal{V}_h$:*

$$\int_Z \left\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u,z)\right\|_{L^p(\mathcal{O})}^p (\iota - \iota_h)(dz) \le C\, h^{d\delta p}\left(1 + \|u_h\|_{L^p(\mathcal{O})}^p\right).$$

Remark 3.3. In our calculation we use the fact that for $\gamma > d - \frac{d}{p}$ in $W^{p,-\gamma}(\mathcal{O})$ the noise vanishes for $h \to 0$. But, by plugging the difference $\iota - \iota_h$ into the definition of Z, one can show directly that the approximated noise converges to the functional-valued representation of the space time Poissonian noise in Z.

Proof. Embedding Z_h into Z by $i \mapsto c_i^h \phi_i^h$ leads to

$$\begin{aligned}
&\int_Z \left\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u,z)\right\|^p_{L^p(\mathcal{O})}\ (\iota-\iota_h)(dz) \le \int_{\xi\in\mathcal{O}}\int_{\zeta\in\mathbb{R}} \\
&\quad \left\|(-\mathcal{A}_h)^{-\gamma}\left[\mathcal{I}_h G(u,z)\delta_\xi - \sum_{j=1}^{k_h} 1_{J_j^h}(\xi) g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|^p_{L^p(\mathcal{O})} d\zeta\ d\xi \\
&\le \sum_{i=1}^{k_h}\int_{\xi\in J_i^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right.\right. \\
&\qquad\qquad \left.\left. - \sum_{j=1}^{k_h} 1_{J_j^h}(\xi) g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|^p_{L^p(\mathcal{O})} d\zeta\ d\xi \\
&\le \sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right]\right\|^p_{L^p(\mathcal{O})} d\zeta\ d\xi \\
&+ \sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|^p_{L^p(\mathcal{O})}\ d\zeta\ d\xi \\
&=: S_1 + S_2.
\end{aligned}$$

By Corollary 3.1 we obtain

$$S_1 \le h^{-\delta p}\sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right]\right\|^p_{Z} d\zeta\ d\xi.$$

Inequality (A.1) leads to

$$S_1 \le C\ h^{-\delta p}\sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\right]\right\|^p_{L^p(J_j^h)} d\zeta.$$

Since there exists a constant m such that $|\{i \mid \sup\phi_i^h \cap J_j^h \neq \emptyset\}| \le m$ for all $i,j = 1,\dots,k_h$ and $h>0$, and $\sum_{i=1}^{k_h}\phi_i^h(\xi) = 1$, we can infer by Remark 3.2 that

$$\begin{aligned}
S_1 &\le C\ h^{(2\gamma-\delta)p}\sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|\sum_{l,\sup\phi_l^h\cap J_j^h\neq\emptyset} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\right\|^p_{L^p(J_j^h)} d\zeta \\
&\le C\ h^{(2\gamma-\delta)p}\ m\ \sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|g(u(N_j^h),N_j^h,\zeta)\phi_j^h\right\|^p_{L^p(\mathcal{O})}\ d\zeta.
\end{aligned}$$

By the linearity of g and the equivalence of $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ we get

$$S_1 \le C\ h^{(2\gamma-\delta)p} m\ \left(1 + \sum_{j=1}^{k_h} h^d\ \left|u(N_j^h)\right|^p\right) \le h^{(2\gamma-\delta)p}\ m\ \left(1 + |u|^p_{L^p(\mathcal{O})}\right).$$

By applying Remark 3.19 we get for S_2

$$\begin{aligned}
S_2 &\le \sum_{j=1}^{k_h} \lambda(J_j^h) \int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma} g(u(N_j^h), N_j^h, \zeta) c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p} \sum_{j=1}^{k_h} \lambda(J_j^h) \int_{\zeta\in\mathbb{R}} \left\|g(u(N_j^h), N_j^h, \zeta) c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p - dp} \sum_{j=1}^{k_h} \lambda(J_j^h) h^d \int_{\zeta\in\mathbb{R}} \left|g(u(N_j^h), N_j^h, \zeta)\right| \left\|\phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p - dp + d} \sum_{j=1}^{k_h} \lambda(J_j^h) h^d \int_{\zeta\in\mathbb{R}} \left|g(u(N_j^h), N_j^h, \zeta)\right| \, d\zeta \,.
\end{aligned}$$

The linearity of g and the equivalence of $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ give

$$S_2 \le C\, h^{2\gamma p - dp + d} \left(1 + \|u\|_{L^p(\mathcal{O})}^p\right). \qquad \square$$

4. Stability of the finite element approximation. In this section we shall investigate the stability of the approximation by finite elements. Since the semidiscrete problem (2.3) is finite-dimensional, for all $0 < h \le 1$ there exists a unique solution $u_h = \{u_h(t) \in \mathbb{R}^{k_h}, 0 \le t < \infty\}$ (see, e.g., Theorem 8 of [Pro04]). In this section we show that the family of unique solution $\{u_h, 0 < h \le 1\}$ is uniformly bounded.

THEOREM 4.1. *Let $u_h = \{u_h(t), 0 \le t < \infty\}$ be a solution to problem (2.3). Then, under the conditions of Theorem 2.1, for all $p \in (1, 2]$, with $p < \frac{2}{d} + 1$, and for all $T > 0$ there exists some constant such that*

$$\sup_{0\le t\le T} \mathbb{E}\, \|u_h(t)\|_{L^p(\mathcal{O})}^p \le C, \quad 0 < h \le 1.$$

Proof. First, we show that there exist some $q < \infty$ and some constants C_1 and C_2 such that

$$(\mathbb{E}\|u_h(t)\|^p)^q \le C_1 + C_2 \int_0^t (\mathbb{E}\, \|u_h(s)\|^p)^q \, ds, \quad t > 0 \text{ and } 0 < h \le 1.$$

The Gronwall lemma yields the assertion. The variation of constant formula gives

$$\begin{aligned}
u_h(t) = e^{-t\mathcal{A}_h} u_h(0) &+ \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \\
&+ \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i\in\mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}_h^i(d\zeta_i; ds), \quad t > 0.
\end{aligned}$$

Taking the expectation leads to

$$\begin{aligned}
\mathbb{E}\, \|u_h(t)\|_{L^p(\mathcal{O}}^p &\le C_p \left\|e^{-t\mathcal{A}_h}\, u_h(0)\right\|_{L^p(\mathcal{O})}^p \\
&+ C_p \mathbb{E} \left\| \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \right\|_{L^p(\mathcal{O})}^p \\
&+ C_p \mathbb{E} \left\| \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i\in\mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}_h^i(d\zeta_i; ds) \right\|_{L^p}^p \\
&=: S_1 + S_2 + S_3.
\end{aligned}$$

If $u_0 \in L^p(\mathcal{O})$, then the first entity S_1 is finite. The second entity can be calculated directly. The Minkowski inequality gives

$$\begin{aligned} S_2 &= \mathbb{E} \left\| \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \right\|^p_{L^p(\mathcal{O})} \\ &\leq \mathbb{E} \left(\int_0^t \left\| e^{-(t-s)\mathcal{A}_h} f_h(u_h(s)) \right\|_{L^p(\mathcal{O})} ds \right)^p. \end{aligned}$$

In section 3.2 we have seen that there exist $\omega \in \mathbb{R}$, $M \geq 1$, and $\theta \in (0, \pi)$ such that for all $h \in (0,1)$ the operator $\mathcal{A}_h$ generates an analytic semigroup of (ω, M, θ) on $L^p_h(\mathcal{O})$ and the inequality (3.17) holds. In section 3.3 we have seen that there exist some constants c and C such that for all $0 < h \leq 1$ we have (see (3.16))

$$c \|w\|_{L^p(\mathcal{O})} \leq \|w_h\|_{L^p_h(\mathcal{O})} \leq C \|w\|_{L^p(\mathcal{O})}, \quad w \in \mathcal{V}_h \tag{4.1}$$

where

$$\|w\|_{L^p_h(\mathcal{O})} := h^d \sum_{i=1}^{k_h} |w_h(N_i)|^p, \quad w \in \mathcal{V}_h.$$

Therefore, a constant $C < \infty$ exists such that for all $0 < h \leq 1$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L^p(\mathcal{O})} \leq C \|v\|_{L^p(\mathcal{O})}, \quad v \in L^p(\mathcal{O}) \cap \mathcal{V}_h. \tag{4.2}$$

Thus,

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \|f_h(u_h(s))\|_{L^p(\mathcal{O})}\, ds \right)^p.$$

Again by (4.1) we can infer that

$$S_2 \ \leq C\, \mathbb{E} \left(\int_0^t \|f(u_h(s))\|_{L^p_h(\mathcal{O})}\, ds \right)^p.$$

By the globally Lipschitz property of f it follows that

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \left(1 + \|u_h(s)\|_{L^p_h(\mathcal{O})} \right) ds \right)^p.$$

Again by (4.1) we get

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \left(1 + \|u_h(s)\|_{L^p(\mathcal{O})} \right) ds \right)^p.$$

The Hölder inequality leads to

$$S_2 \leq C\, t^p \left(1 + \sup_{0 \leq s \leq t} \mathbb{E} \|u_h(s)\|^p_{L^p(\mathcal{O})} \right).$$

Next, we estimate the term

$$S_3 = \mathbb{E} \left\| \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i \in \mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}^i_h(d\zeta_i; ds) \right\|^p_{L^p(\mathcal{O})}.$$

Since $L^p(\mathcal{O})$ is of M-type p, we can infer by Proposition 3.3 in [Hau05]

$$S_3 \leq \mathbb{E} \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i; \zeta_i) \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

In section 3.2 we have seen that there exist $\omega \in \mathbb{R}$, $M \geq 1$, and $\theta \in (0, \pi)$ such that for all $h \in (0,1)$ the operator $\mathcal{A}_h$ generates an analytic semigroup of (ω, M, θ) on $L^p(\mathcal{O})$. In particular (3.18) holds; i.e., there exists a constant $C < \infty$ such that for all $h > 0$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L_h^p(\mathcal{O})} \leq \frac{C}{t} \|v\|_{L_h^p(\mathcal{O})}, \quad v \in L_h^p(\mathcal{O}). \tag{4.3}$$

Because of inequality (4.3), and since the norms in $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ are equivalent, we have for all $\gamma < \frac{1}{p}$

$$S_3 \leq \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| \mathcal{A}_h^{-\gamma} g_h(u_h(s); i, \zeta_i) \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

Since $g_h(u_h(s); i, \zeta) = N_i(G(u_h(s); \zeta_i))\phi_i$ and since $\mathcal{A}_h$ is linear, we get

$$S_3 \leq \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| N_i(G(u_h(s); \zeta_i)) \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

The Hölder inequality gives

$$\begin{aligned} S_3 \leq & \int_0^t \frac{1}{k_h} \\ & \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| N_i(G(u_h(s); \zeta_i)) \right\|_{L^p(\mathcal{O})}^p \left\| \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^\infty(\mathcal{O})}^p \nu(d\zeta_i)\, ds. \end{aligned} \tag{4.4}$$

Moreover, by (3.19) we know that for any $i = 1, \ldots, k_h$ we have

$$\mathcal{A}_h^{-\gamma} \phi_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h,$$

where

$$u_{il} = \begin{cases} c\, h^{2\gamma}, & \text{if } (i,l) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere,} \end{cases}$$

and there exists some constant m_0 such that for any i and $0 < h < 1$

$$\left| \{(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h \right| \leq m_0. \tag{4.5}$$

Therefore, we have

$$\left\| \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^\infty(\mathcal{O})} \leq m_0 h^{2\gamma}. \tag{4.6}$$

By substituting (4.6) in (4.4) we obtain

$$S_3 \leq \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)$$
$$(t-s)^{-\gamma p}\, m_0\, h^{2\gamma p} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta)\right\|^p_{L^p(\mathcal{O})}\, \nu(d\zeta_i)\, ds. \tag{4.7}$$

The inverse inequality given in Corollary 3.1 gives for all $\delta > d - \frac{d}{p}$

$$\begin{aligned} S_3 &\leq \int_0^t C \sum_{i=1}^{k_h} \lambda(J_i^h) \\ &\quad (t-s)^{-\gamma p}\, h^{2\gamma p-\delta p} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta_i)\right\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \nu(d\zeta)\, ds \\ &\leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \int_{\zeta_i\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta)\right\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \nu(d\zeta)\, ds, \end{aligned}$$

which gives

$$S_3 \leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \int_{\zeta_i\in\mathbb{R}} \mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\, \nu(d\zeta)\, ds.$$

The mapping g is linear in the last variable and globally Lipschitz in the first variable. Thus we can infer that

$$S_3 \leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \left(1 + \mathbb{E}\left|u_h(s,N_i^h)\right|^p\right)\, ds.$$

By the equivalence of the $L^p_h(\mathcal{O})$ and $L^p(\mathcal{O})$ norms we infer that

$$S_3 \leq C \int_0^t (t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \left(1 + \mathbb{E}\left|u_h(s)\right|^p_{L^p(\mathcal{O})}\right)\, ds.$$

Let q be so large that $\gamma p < 1 - \frac{1}{q}$. Since there exists a $\delta > d - \frac{d}{p}$ such that $2\gamma - \delta > 0$, the Hölder inequality gives

$$\left(\mathbb{E}\left|S_3\right|\right)^q \leq c(t) \int_0^t \left(1 + \mathbb{E}\left|u_h(s)\right|^p_{L^p(\mathcal{O})}\right)^q\, ds.$$

Summing up leads to the assertion. □

5. Proof of the main result. The error of the time discretization follows from Theorem 3.1 of [HM06a]. By the Lipschitz continuity of f and g we infer that

$$\int_{z\in Z} \|G(u;z)\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \iota(dz) \leq C\|u\|^p_{L^p(\mathcal{O})}, \quad u \in L^p(\mathcal{O}),$$

and

$$\|F(u)\|_{L^p(\mathcal{O})} \leq C\|u\|_{L^p(\mathcal{O})}, \quad u \in L^p(\mathcal{O}).$$

Thus, Theorem 3.1 of [HM06a] gives the order of convergence in time for $\alpha < \frac{2}{p} - d + \frac{d}{p}$. Here we investigate the accuracy of the space discretization, i.e., the difference $\Delta(t) = u(t) - u_h(t)\mathcal{I}_h$ at time t. To show the assertion, we will show that for a certain $q < \infty$ there exist constants C_1, C_2, and C_3 such that for all $0 < h \le 1$

$$\begin{aligned} &\left(\mathbb{E}\,\|\Delta(t)\|^p_{L^p(\mathcal{O})}\right)^q \\ &\le \frac{C_1}{t^q}\, h^{pq\delta_1} + C_2\, h^{pq\delta_2} + C_3\, h^{pq\delta_3} + C_4 \int_0^t \left(\mathbb{E}\,\|\Delta(t)\|^p_{L^p(\mathcal{O})}\right)^q ds \end{aligned} \tag{5.1}$$

where δ_1, δ_2, and δ_3 are the constants specified in Theorem 2.1. Now the second part of the assertion of Theorem 2.1 follows by an extension of Grownwall's lemma which is a simple consequence of Exercise 3, page 190 in [Hen81] and the proof of which is omitted.

LEMMA 5.1 (Gronwall-type lemma). *Suppose that $\alpha > 0$ and $c_1, c_2, c_3 > 0$. Assume that $u : \mathbb{R}^+ \to \mathbb{R}^+$ is a measurable function such that the function $t \mapsto t^{1-\alpha}u(t)$ is locally integrable on $\mathbb{R}^+$ and a.s. on $\mathbb{R}^+$,*

$$u(t) \le c_1 t^{\alpha-1} + c_2 + c_3 \int_0^t u(s)\, ds.$$

Then, a.s. on $\mathbb{R}^+$,

$$u(t) \le \left(c_1 t^{\alpha-1}\Gamma(\alpha) + c_2\right) \sum_{m=0}^{\infty} \frac{[c_3 t]^m}{\Gamma(m+\alpha)}.$$

To show the second part of Theorem 2.1, we will show the following: Let q and γ be two real numbers such that

$$d - \frac{d}{p} < \gamma < 2p \quad \text{and} \quad \frac{\gamma p}{2} < 1 - \frac{1}{q} \tag{5.2}$$

are satisfied. Then under the conditions of Theorem 2.1 for all δ_1, δ_2, and δ_3, with

$$\delta_1 = 2 - \frac{d}{p} + \frac{d}{2}, \quad \delta_2 < \frac{2}{p} - d + \frac{d}{p}, \text{ and } \delta_3 < \left(\frac{2}{p} - d + \frac{d}{p}\right)\left(2 + \frac{d}{2} - \frac{d}{p}\right),$$

there exist constants C_1, C_2, and C_3 depending on p, f, g, δ_1, δ_2, and δ_3 such that for all $0 < h \le 1$ inequality (5.1) holds.

Proof. By using the variation of constants formula, i.e.,

$$\begin{aligned} u(t) = e^{-At}u_0 &+ \int_0^t e^{-A(t-s)} f(u(s-))\, ds \\ &+ \int_{0^+}^t \int_Z e^{-A(t-s)} g(u(s-); z)\eta(ds; dz) \end{aligned}$$

and

$$\begin{aligned} u_h(t) = e^{-\mathcal{A}_h t}u_0 &+ \int_0^t e^{-\mathcal{A}_h(t-s)} f(u(s-))\, ds \\ &+ \int_{0^+}^t \int_Z e^{-\mathcal{A}_h(t-s)} g u(s-); z)\eta(ds; dz), \end{aligned}$$

we obtain

$$u(t) - u_h(t) = \sum_{i=1}^{6} I_{ni}(t), \tag{5.3}$$

where

$$\begin{aligned}
I_0(t) &= \left(e^{-At} - e^{-\mathcal{A}_h t}\right) u_0,\\
I_1(t) &= \int_{0+}^{t} \left(e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right) f(u(s))\, ds,\\
I_2(t) &= \int_{0+}^{t} e^{-\mathcal{A}_h(t-s)} \left(\mathcal{I}_h f(u(s)) - f_h(u_h(s))\right)\, ds,\\
I_3(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)} \left(g(u(s);z) - g(u_h(s);z)\right)\, \tilde{\eta}(ds;dz),\\
I_4(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)} \left(I - \mathcal{I}_h\right) g(u_h(s);z)\, \tilde{\eta}(ds;dz),\\
I_5(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)}\mathcal{I}_h g(u_h(s);z)\, \tilde{\eta}(ds;dz)\\
&\quad - \int_{0+}^{t}\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}} e^{-A(t-s)} g_h(u_h(s);i;\zeta)\, \tilde{\eta}_h^i(ds,d\zeta),\\
I_6(t) &= \int_{0+}^{t}\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left(e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\right) g_h(u_h(s);i;\zeta)\, \tilde{\eta}_h^i(ds;d\zeta).
\end{aligned}$$

By substituting (5.3), we get

$$\mathbb{E}\left[\|\Delta(t)\|^p\right] \leq C \cdot \sum_{i=0}^{4} \mathbb{E}\left[\|I_i(t)\|^p\right].$$

To give an estimate of $\mathbb{E}\left[\|I_0(t)\|^p\right]$, we apply Theorem 3.1. Thus, we get

$$\mathbb{E}\left[\|I_0(t)\|^p\right] \leq \frac{C}{t}\, h^{p\left(2-\frac{d}{p}+\frac{d}{2}\right)}\, \|u_0\|^p_{L^p(\mathcal{O})}. \tag{5.4}$$

The next entity we have to estimate is

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})} \leq \mathbb{E}\left(\int_{0+}^{t} \left\|e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h f(u(s))\right\|_{L^p(\mathcal{O})}\, ds\right)^p.$$

In Theorem 3.4, the factor t^{-1} appears on the right-hand side. Thus, fix $\gamma < 1$, take into account

$$\left\|e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))} \leq C,$$

and apply Theorem 3.4. Thus, we get

$$\begin{aligned}
&\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\\
&\le C\,\left(\int_{0+}^{t}\left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C\,\Big(\int_{0+}^{t}\left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|^{\gamma}_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\\
&\quad\times\left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|^{1-\gamma}_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\Big)^p\\
&\le C\,h^{\gamma(2-\frac{d}{p}+\frac{d}{2})p}\,\left(\int_{0+}^{t}(t-s)^{-\gamma}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C(\gamma)\,h^{\gamma(2-\frac{d}{p}+\frac{d}{2})p}\sup_{0\le t\le T}\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,,
\end{aligned}$$

where

$$C(\gamma)=\frac{C'}{1-\gamma}.$$

The Lipschitz property of f gives

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\le C\,h^{p(2-\frac{d}{p}+\frac{d}{2})\gamma}\,\left(1+\sup_{0\le s\le t}\mathbb{E}\,\|u(s)\|^p_{L^p(\mathcal{O})}\right).$$

Since $u\in L^p(\Omega;L^p(\mathcal{O}))$, there exists some C such that

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\le C\,h^{p(2-\frac{d}{p}+\frac{d}{2})\gamma},\quad 0<h<1. \tag{5.5}$$

In section 3.3 we have shown that $\mathcal{A}_h$ generates a semigroup in $L^p_h(\mathcal{O})$. Thus, by the Minkowski inequality (4.2) and by the equivalence of the norms in $L^p(\mathcal{O})$ and $L^p_h(\mathcal{O})$, i.e., (3.16), we can write

$$\begin{aligned}
\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}&\le\mathbb{E}\left(\int_{0+}^{t}\|\mathcal{I}_hf(u(s))-f_h(u_h(s))\|_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C\,\mathbb{E}\left(\int_{0+}^{t}\|\mathcal{I}_hf(u(s))-f_h(u_h(s))\|_{L^p_h(\mathcal{O})}\,ds\right)^p.
\end{aligned}$$

The mapping f is Lipschitz continuous, and therefore

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\left(\int_{0+}^{t}\|\mathcal{I}_hu(s)-u_h(s)\|_{L^p_h(\mathcal{O})}\,ds\right)^p.$$

Again, by the equivalence of the norms in $L^p(\mathcal{O})$ and $L^p_h(\mathcal{O})$, we can infer that

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\left(\int_{0+}^{t}\|u(s)-u_h(s)\|_{L^p(\mathcal{O})}\,ds\right)^p.$$

The Hölder inequality gives

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\int_{0+}^{t}\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\,ds. \tag{5.6}$$

Next, we handle the third term. The generalized Burkholder inequality (compare Proposition 3.3 in [Hau05]) gives

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z \mathbb{E}\left\|e^{-A(t-s)}\left(g(u(s);z)-g(u_h(s);z)\right)\right\|^p_{L^p(\mathcal{O})}\,\iota(dz)\,ds.$$

The operator A generates an analytic semigroup in $L^p(\mathcal{O})$ (see, e.g., Theorem 7.3.5 in [Paz83]). Therefore, for each $\rho>0$ there exists some constant $C<\infty$ such that

$$\left\|e^{-(t-s)A}Av\right\|_{W_p^{-\rho}(\mathcal{O})} \leq \frac{C}{t^{\frac{\rho}{2}}}\,\|v\|_{L^p(\mathcal{O})}\,, \quad v\in L^p(\mathcal{O}). \tag{5.7}$$

Thus, we can infer for any $\gamma>0$ that

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|g(u(s);z)-g(u_h(s);z)\|^p_{W_p^{-\gamma}(\mathcal{O})}\,\iota(dz)\,ds.$$

By Sobolev inequalities for any $\gamma > d-\frac{d}{p}$ we have $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously. Therefore,

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|(g(u(s);z)-g(u_h(s);z))\|^p_Z\,\iota(dz)\,ds.$$

The Lipschitz property of g yields

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\,ds.$$

If γ satisfies (5.2), then $\frac{\gamma p}{2} < 1-\frac{1}{q}$, and we can infer by the Hölder inequality that

$$\left(\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})}\right)^q \leq c(t)\int_0^t \left(\mathbb{E}\,\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\right)^q ds. \tag{5.8}$$

Similarly by Proposition 3.2 in [Hau05] we get for the fourth term

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z \mathbb{E}\left\|e^{-A(t-s)}\left(I-\mathcal{I}_h\right)g(u_h(s);z)\right\|^p_{L^p(\mathcal{O})}\,\nu(dz)\,ds.$$

By the smoothing property of A, i.e., (5.7), and since $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously for all $\gamma > d-\frac{d}{p}$, we obtain for any $\rho < \frac{2}{p}-d+\frac{d}{p}$

$$\begin{aligned}
&\mathbb{E}\,\|I_4(t)\|^p_{L^p}\\
&\leq \int_{0+}^t (t-s)^{-\frac{p}{2}\left(\rho+d-\frac{d}{p}\right)} \int_Z \mathbb{E}\left\|A^{-\rho}\left(I-\mathcal{I}_h\right)G(u_h(s);z)\right\|^p_Z\,\iota(dz)\,ds\\
&\leq \int_{0+}^t (t-s)^{-\frac{p}{2}\left(\rho+d-\frac{d}{p}\right)} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|A^{-\rho}\left(I-\mathcal{I}_h\right)g(u_h(s),\cdot,\zeta)\right\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)\,ds,
\end{aligned}$$

where G is defined in (3.20). Theorem 3.1 leads to

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \leq C(t)\,h^{p\rho}\sup_{0\leq s\leq t}\int_{\zeta\in\mathbb{R}}\mathbb{E}\,\|g(u_h(s),\cdot;\zeta)\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)$$

and the Lipschitz properties of g to

$$\mathbb{E}\,\|I_4(t)\|_{L^p}^p \le C(t)\,h^{p\rho}\,\left(1+\sup_{0\le s\le t}\mathbb{E}\,\|u_h(s)\|_{L^p(\mathcal{O})}^p\right).$$

By Proposition 4.1 there exists some constant $C<\infty$ such that

$$\sup_{0\le s\le t}\mathbb{E}\,\|u_h(s)\|_{L^p(\mathcal{O})}^p \le C,\quad h>0.$$

Thus, we can infer that there exists some constant $C'<\infty$ such that

$$\mathbb{E}\,\|I_4(t)\|_{L^p(\mathcal{O})}^p \le C'\,h^{p\rho},\quad 0\le t\le T. \tag{5.9}$$

The Burkholder inequality leads for any $\frac{1}{2}(d-\frac{d}{p})<\gamma<\frac{1}{p}$ to

$$\begin{aligned}
&\mathbb{E}\,\|I_5(t)\|_{L^p(\mathcal{O})}^p\\
&\le \int_0^t\int_Z \left\|(-\mathcal{A}_h)^{\gamma}e^{-A(t-s)}(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_hG(u(t),z)\right\|_{L^p(\mathcal{O})}^p\,(\iota-\iota_h)(dz)\\
&\le \int_0^t (t-s)^{-\gamma p}\,dt\times\sup_{0\le t\le T}\int_Z \left\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_hG(u(t),z)\right\|_{L^p(\mathcal{O})}^p\,(\iota-\iota_h)(dz).
\end{aligned}$$

Proposition 3.2 gives for any $0\le\delta<\frac{1}{p}-\frac{1}{2}(d-\frac{d}{p})$

$$\mathbb{E}\,\|I_5(t)\|_{L^p(\mathcal{O})}^p \le C\,\frac{h^{\delta p}}{p\gamma-1}. \tag{5.10}$$

Next, we have to calculate the entity I_6. The Fubini theorem and the generalized Burkholder inequality give

$$\begin{aligned}
\mathbb{E}\,\|I_6(t)\|^p &= \mathbb{E}\left\|\int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\left(e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\right)g_h(u_h(s);i,\zeta)\,\tilde{\eta}_h^i(ds;dz)\right\|_{L^p(\mathcal{O})}^p\\
&\le \mathbb{E}\int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\left\|\left(e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\right)g_h(u_h(s);i,\zeta)\right\|_{L^p(\mathcal{O})}^p\,\nu^i(d\zeta)\,ds\\
&\le \int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\mathbb{E}\Big\|\Big(e^{-\frac{1}{2}A(t-s)}\\
&\qquad -e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\Big)e^{-\frac{1}{2}A(t-s)}g_h(u_h(s);i,\zeta)\Big\|_{L^p(\mathcal{O})}^p\,\nu^i(d\zeta)\,ds\\
&+ \int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\mathbb{E}\Big\|e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\Big(e^{-\frac{1}{2}A(t-s)}\\
&\qquad -e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\Big)g_h(u_h(s);i,\zeta)\Big\|_{L^p(\mathcal{O})}^p\,\nu^i(d\zeta)\,ds\\
&:= I_{61}+I_{62}.
\end{aligned}$$

First, in Theorem 3.4 we have shown that

$$\left\|\left[e^{-\frac{1}{2}A(t-s)}-e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\right]u\right\|_{L^p}\le\frac{C}{t}\,h^{2+\frac{d}{2}-\frac{d}{p}}\|u\|_{L^p(\mathcal{O})}\ \forall u\in L^p(\mathcal{O}). \tag{5.11}$$

Let us recall estimate (3.17). There exists a constant $C<\infty$ such that for all $h>0$ and $v\in L^p_h(\mathcal{O})\cap\mathcal{V}_h$

$$\left\|e^{-(t-s)\mathcal{A}_h}v\right\|_{L^p_h}\leq C\left\|v\right\|_{L^p_h},\quad v\in L^p_h.$$

Moreover, the norms in $L^p_h(\mathcal{O})$ and in $L^p(\mathcal{O})$ are equivalent (see (3.16)). Therefore

$$\left\|e^{-(t-s)\mathcal{A}_h}v\right\|_{L^p_h}\leq C\left\|v\right\|_{L^p(\mathcal{O})},\quad v\in L^p_h(\mathcal{O}).$$

Thus, we can infer for any $\gamma\in(0,1)$ that

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\\&\times\int_{0+}^t(t-s)^{-\frac{\gamma p}{2}}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|e^{-\frac{1}{2}A(t-s)}g_h(u_h(s);i,\zeta)\right\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)\,ds\end{aligned}$$

holds. The operator A generates an analytic semigroup in $L^p(\mathcal{O})$. Therefore, for each $\rho>0$ there exists some constant $C<\infty$ such that

$$\left\|e^{-tA}Av\right\|_{L^p(\mathcal{O})}\leq\frac{C}{t^{\frac{\rho}{2}}}\left\|v\right\|_{W_p^{-\rho}(\mathcal{O})},\quad v\in W_p^{-\rho}(\mathcal{O}),\ t>0. \tag{5.12}$$

Inequality (5.12) leads for all $\rho\geq0$, with $p(\gamma+\rho)<2$, to

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\\&\quad\times\int_{0+}^t(t-s)^{-\frac{p}{2}(\gamma+\rho)}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{W_p^{-\rho}(\mathcal{O})}\,\nu(d\zeta)\,ds\\&\leq C(\gamma,\rho)\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{W_p^{-\rho}(\mathcal{O})}\,\nu(d\zeta),\end{aligned}$$

where

$$C(\gamma,\rho)=\frac{C'}{2-p(\gamma+\rho)}.$$

By Sobolev inequalities, we know that $L^1(\mathcal{O})\hookrightarrow W_p^{-\rho}(\mathcal{O})$ continuously. Thus we obtain

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{L^1(\mathcal{O})}\,\nu(d\zeta)\\&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\left\|c_i^h\phi_i^h\right\|^p_{L^1(\mathcal{O})}\,\nu(d\zeta)\\&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\,\nu(d\zeta).\end{aligned}$$

Since g is Lipschitz continuous and linear in the third variable, we get

$$I_{61}\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\left(1+\mathbb{E}\left\|u_h(s,N_i^h)\right\|^p_{L^p_h}\right)\,ds.$$

In section 3.3 we have seen that there exist some constants c and C such that for all $0 < h < 1$ we have (see (3.16))

$$c \left\| w \right\|_{L^p(\mathcal{O})} \leq h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \left\| w_h \right\|_{L_h^p} \leq C \left\| w \right\|_{L^p(\mathcal{O})}, \quad w \in \mathcal{V}_h.$$

Thus, by taking into account Remark 3.1 we can write

$$I_{61} \leq Ct^{1-p(\gamma+\rho)} h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \sup_{0\leq s\leq t} \left(1 + \mathbb{E} \left\| u_h(s) \right\|_{L^p(\mathcal{O})}^p\right).$$

Since $\mathbb{E} \left\| u_h(s) \right\|_{L^p(\mathcal{O})}^p$ is bounded, there exists a constant $C < \infty$ such that

$$I_{61} \leq Ct^{1-p(\gamma+\rho)} h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}. \tag{5.13}$$

Next, we have to handle the term I_{62}. Because of (3.18) and (3.16), there exists a constant $C < \infty$ such that for all $0 < h \leq 1$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L^p(\mathcal{O})} \leq \frac{C}{t} \left\| v \right\|_{L^p(\mathcal{O})}, \quad v \in L^p(\mathcal{O}). \tag{5.14}$$

Because of inequality (5.14), we have for all $0 < \delta < \frac{1}{p}$

$$\begin{aligned} I_{62} \leq & \int_0^t (t-s)^{-\delta p} \sum_{i=1}^{k_h} \lambda(J_i^h) \\ & \int_{\zeta\in\mathbb{R}} \mathbb{E} \left\| (-\mathcal{A}_h)^{-\delta} \left(\mathcal{I}_h e^{-\frac{1}{2}A(t-s)} - e^{-\frac{1}{2}\mathcal{A}_h(t-s)} \right) g_h(u_h(s); i, \zeta) \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta)\, ds. \end{aligned} \tag{5.15}$$

In Remark 3.1 we have shown that there exist some constants c and C such that $h^d \leq ck_h \leq h^d$. By (3.19) we know that for any $i = 1, \ldots, k_h$ we have

$$(-\mathcal{A}_h)^{-\delta} \phi_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h, \tag{5.16}$$

where

$$u_{il} = \begin{cases} c\, h^{2\delta}, & \text{if } (i,l) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere.} \end{cases}$$

Moreover, there exists some constant m_0 such that for any i and $0 < h < 1$

$$\left| \{(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h\} \right| \leq m_0.$$

By substituting (5.16) in (5.15) we obtain

$$\begin{aligned} I_{62} \leq & h^{2\delta p} \int_0^t (t-s)^{-\delta p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \\ & \int_{\zeta\in\mathbb{R}} \mathbb{E} \left\| \left(\mathcal{I}_h e^{-\frac{1}{2}A(t-s)} - e^{-\frac{1}{2}\mathcal{A}_h(t-s)} \right) g_h(u_h(s); i, \zeta) \right\|_{L^p(\mathcal{O})}^p \nu^i(d\zeta)\, ds. \end{aligned}$$

By applying Theorem 3.4 we can infer that for any $\gamma \in (01)$, we have

$$I_{62} \leq C\, h^{p\delta+p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\gamma)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \int_{\zeta\in\mathbb{R}} \mathbb{E}\Big\| g_h(u_h(s);i,\zeta)\Big\|^p_{L^p(\mathcal{O})}\, \nu(d\zeta)\, ds,$$

where $\rho = \gamma/(2-\frac{d}{p}+\frac{d}{2})$. By Theorem 3.1 and since $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously, we get for any $\rho > d - \frac{d}{p}$

$$I_{62} \leq C\, h^{p(\delta-\rho)+p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \int_{\zeta\in\mathbb{R}} \mathbb{E}\Big\| g_h(u_h(s);i,\zeta)\Big\|^p_{Z}\, \nu(d\zeta)\, ds.$$

Provided that $\delta \geq \rho$ we can omit the first term in the exponent of h. The mapping g is linear in the last variable and globally Lipschitz in the first. Thus we can infer that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \left(1+\mathbb{E}\left|u_h(s,N_i^h)\right|^p\right) ds.$$

By Remark 3.1 it follows that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} h^d \left(1+\mathbb{E}\left|u_h(s,N_i^h)\right|^p\right) ds,$$

and by (3.16)

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} \left(1+\mathbb{E}\,\|u_h(s)\|^p_{L^p(\mathcal{O})}\right) ds.$$

The Hölder inequality leads to

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\, C(t) \left(1+\sup_{0\leq s\leq t} \mathbb{E}\,\|u_h(s)\|^p_{L^p(\mathcal{O})}\right)$$

and Theorem 4.1 that there exists a constant C such that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}, \quad 0 < h \leq 1. \tag{5.17}$$

Collecting together (5.4), (5.5), (5.6), (5.8), (5.9), (5.10), (5.13), and (5.17) gives the assertion. ∎

6. Discussions and conclusions. The next step is to confirm the theory described in this paper by numerical experiments. One of the problems which arises here is that, if the intensity of the Poisson random measure is given, the distribution is known only in a few cases. Therefore, it is difficult to find a benchmark where the solution is known analytically and to compare the numerical result with the exact solution.

Moreover, because of this problem, the distribution of the random variables $\xi_h^m(\cdot)$, $m \in \mathbb{N}$, appearing in (2.6), is not given a priori. Different approaches exist to solve this problem; e.g., Rubenthaler [Rub03] cut off the jumps, which are smaller than a certain threshold, calculated the time of the first jump, and applied the Euler scheme until the time of the first jump. Then he simulated a random variable according to the distribution of size of the jump, with the condition that the jump is larger than the threshold. This step is repeated until the time T is reached.

In [HM06a, HM06b] we approximated the intensity by a simple function. In fact, first we cut off the small jumps by setting $\nu_h(B) = 0$ for a neighborhood B of the origin, and then we approximated ν_h by a simple function ν_h^n. To be precise, let $\tilde{\eta}_h^n$ be the real-valued compensated Poisson random measure given by the intensity ν_h^n. Now for any $x \in \mathbb{R}$ the random variable

$$\int_{m\tau_h}^{(m+1)\tau_h} \int_{\zeta \in \mathbb{R}^{k_h}} g(x;\zeta)\, \tilde{\eta}_h^n(dz;ds)$$

can be simulated directly by the sum of N independent random variables with distribution $\frac{1}{\nu_h^n(\mathbb{R})}\nu_h^n$, where N is exponentially distributed with parameter $\nu_h^n(\mathbb{R})$.

By taking into account that the small jumps are cut off, one may ask if the perturbation of the small jumps can be approximated by, e.g., a Wiener process. This has been done, e.g., by Kallianpur and Xiong [KX95]. Since we are in Banach spaces of M-type p, $1 \le p \le 2$, the convergence of a simple random walk is not necessarily given. One alternative is to choose another scaling, which we also consider in [HM06b].

Appendix A. Besov spaces and their properties. An introduction to Besov spaces is given by Runst and Sickel [RS96]. We are interested is the continuity of the mapping G described in (3.20). To be precise, we prove the following result.

PROPOSITION A.1. *If $f \in \mathcal{S}(\mathbb{R}^d)$, then for each $a \in \mathbb{R}^d$ the Schwartz distribution $f\delta_a$ belongs to the Besov space $B_{p,\infty}^{\frac{d}{p}-d}(\mathbb{R}^d)$, and moreover there exists a constant $C = C(d,p)$ independent of f such that*

$$\int_{\mathbb{R}^d} |f\delta_a|^p_{B_{p,\infty}^{\frac{d}{p}-d}(\mathbb{R}^d)}\, da = |f|^p_{L^p(\mathbb{R}^d)}\,.$$

Thus, there exists a unique bounded linear map $\Lambda : L^p(\mathbb{R}^d) \to L^p(\mathbb{R}^d, B_{p,\infty}^{\frac{n}{p}-n}(\mathbb{R}^d))$ such that $[\Lambda(f)](a) = f\delta_a$, $f \in \mathcal{S}(\mathbb{R}^d)$, $a \in \mathbb{R}^d$. Moreover, for any $s \ge 0$ there exists some constant C such that

$$\int_{\mathbb{R}^d} |f\delta_a|^p_{B_{p,\infty}^{\frac{d}{p}-d-s}(\mathbb{R}^d)}\, da \le C\ |f|^p_{W_p^{-s}(\mathbb{R}^d)}\,.$$

In the following we denote the value of $\Lambda(f)$ at a, where $f \in L^p(\mathbb{R}^d)$ by $f\delta_a$. Let us recall the definition of the Besov spaces as given in [RS96, Definition 2, pages 7–8]. First we choose a function $\psi \in \mathcal{S}(\mathbb{R}^d)$ such that $0 \le \psi(x) \le 1$, $x \in \mathbb{R}^d$, and

$$\psi(x) = \begin{cases} 1, & \text{if} \quad |x| \le 1, \\ 0 & \text{if} \quad |x| \ge \frac{3}{2}. \end{cases}$$

Then put

$$\begin{cases} \phi_0(x) = \psi(x),\ x \in \mathbb{R}^d, \\ \phi_1(x) = \psi(\frac{x}{2}) - \psi(x),\ x \in \mathbb{R}^d, \\ \phi_j(x) = \phi_1(2^{-j+1}x),\ x \in \mathbb{R}^d, \quad j = 2,3,\ldots. \end{cases}$$

With the choice of $\phi = \{\phi_j\}_{j=0}^{\infty}$ as above and $\mathcal{F}$ and $\mathcal{F}^{-1}$ being the Fourier and the inverse Fourier transformations, respectively, (acting in the space $\mathcal{S}'(\mathbb{R}^d)$ of Schwartz distributions), we have the following definition.

DEFINITION A.1. *Let $s \in \mathbb{R}$, $0 < p \leq \infty$, and $0 < q \leq \infty$. If $0 < q < \infty$ and $f \in \mathcal{S}'(\mathbb{R}^d)$, we put*

$$|f|_{B^s_{p,q}} = \left(\sum_{j=0}^{\infty} 2^{sjq} \left| \mathcal{F}^{-1} \left[\phi_j \mathcal{F} f \right] \right|_{L^p}^q \right)^{\frac{1}{q}},$$
$$|f|_{B^s_{p,\infty}} = \sup_{j \in \mathbb{N}} 2^{sj} \left| \mathcal{F}^{-1} \left[\phi_j \mathcal{F} f \right] \right|_{L^p}.$$

We denote by $B^s_{p,q}(\mathbb{R}^d)$ the space of all $f \in \mathcal{S}'(\mathbb{R}^d)$ for which $|f|_{B^s_{p,q}}$ is finite.

LEMMA A.2. *If $h \in \mathcal{S}(\mathbb{R}^d)$, $h \in \mathcal{S}(\mathbb{R}^d)$, and $a \in \mathbb{R}^d$, then*

$$|(h\delta_a) * g|_{L^p(\mathbb{R}^d)} = |h(a)||g|_{L^p(\mathbb{R}^d)}.$$

Proof. Let us recall that $h\delta_b \in \mathcal{S}'(\mathbb{R}^d)$ assigns to a function $g \in \mathcal{S}(\mathbb{R}^d)$ a value $\delta_a(hg) = h(a)g(a)$. Since by the definition of the convolution of a distribution with a test function

$$[(h\delta_a) * g](x) = (h\delta_a)(\tau_x \check{g}) = h(a)(\tau_x \check{g})(a) = h(a)\check{g}(a - x) = h(a)g(x - a),\ x \in \mathbb{R}^d,$$

we have

$$\begin{aligned} |(h\delta_a) * g|^p_{L^p(\mathbb{R}^d)} &= \int_{\mathbb{R}^d} |g(x - a)h(a)|^p \, dx \\ &= |h(a)|^p \int_{\mathbb{R}^d} |g(x)|^p \, dx = |h(a)|^p \ |g|^p_{L^p(\mathbb{R}^d)}. \end{aligned}$$

∎

LEMMA A.3. *If $\varphi \in \mathcal{S}(\mathbb{R}^d)$, $\lambda > 0$, and $g(x) := \varphi(\lambda x)$, $x \in \mathbb{R}^d$, then*

$$|\mathcal{F}^{-1} g|_{L^p(\mathbb{R}^d)} = \lambda^{d(\frac{1}{p} - 1)} |\mathcal{F}^{-1} \varphi|_{L^p(\mathbb{R}^d)}.$$

Proof. The proof follows with simple calculations. ∎

Proof of Proposition A.1. Obviously it is enough to prove the first part of the proposition. We will use the definition of the Fourier transform as in [RS96]. In particular, with $\langle \cdot, \cdot \rangle$ being the scalar product in $\mathbb{R}^d$, we put

$$(\mathcal{F} f)(\xi) := (2\pi)^{-d/2} \int_{\mathbb{R}^d} e^{-i\langle x, \xi \rangle} f(x) \, dx,\ \xi \in \mathbb{R}^d,\ f \in \mathcal{S}(\mathbb{R}^d).$$

Let us fix $f \in \mathcal{S}(\mathbb{R}^d)$. Since $\mathcal{F}^{-1}(\varphi u) = (2\pi)^{-d/2}(\mathcal{F}^{-1}\varphi) * (\mathcal{F}^{-1} u)$, $\varphi \in \mathcal{S}$, $u \in \mathcal{S}'$, we infer that, for $j \in \mathbb{N}^*$,

$$\begin{aligned} |\mathcal{F}^{-1}[\varphi_j \mathcal{F}(f\delta_a)]|_{L^p(\mathbb{R}^d)} &= (2\pi)^{-d/2} |(\mathcal{F}^{-1}\varphi_j) * (f\delta_a)|_{L^p(\mathbb{R}^d)} \\ &= (2\pi)^{-d/2} |f(a)| \mathcal{F}^{-1}\varphi_j|_{L^p(\mathbb{R}^d)} \\ &= (2\pi)^{-d/2} 2^{d(\frac{1}{p} - 1)} 2^{-jd(\frac{1}{p} - 1)} |f(a)| |\mathcal{F}^{-1}\varphi_1|_{L^p(\mathbb{R}^d)}. \end{aligned}$$

Hence, $f\delta_a$ belongs to the Besov space $B^{d(\frac{1}{p} - 1)}_{p,\infty}(\mathbb{R}^d)$ as requested, and the equality (A.1) follows immediately. In order to show (A.1) note that

$$\|f\|_{B^{s+\gamma}_{p,\infty}(\mathbb{R}^d)} = \|I(s) f\|_{B^{\gamma}_{p,\infty}(\mathbb{R}^d)},$$

where $I(s) = \mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}$. Next,

$$\begin{aligned}
&\left\|\mathcal{F}^{-1}\left(\varphi_j\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right)\right\|_{L^p(\mathbb{R}^d)}\\
&\le \left\|\mathcal{F}^{-1}\varphi_j \star \mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^p(\mathbb{R}^d)}\\
&\le \left\|\mathcal{F}^{-1}\varphi_j\right\|_{L^p(\mathbb{R}^d)}\left\|\mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^1(\mathbb{R}^d)}.
\end{aligned}$$

Moreover,

$$\begin{aligned}
&\left\|\mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^1(\mathbb{R}^d)}\\
&= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\left(1+\xi^2\right)^{\frac{s}{2}}\int_{\mathbb{R}^d} e^{-i\langle a,\xi\rangle}f(a)\,d\xi\,da\right|\,dy\\
&\quad= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\left(1+\xi^2\right)^{\frac{s}{2}} e^{-i\langle a,\xi\rangle}f(a)\,da\,d\xi\right|\,dy\\
&= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right](\xi)\,d\xi\right|dy = \int_{\mathbb{R}^d}\left(\mathcal{F}^{-1}\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right]\right)(y)\,dy\\
&\le \left\|\mathcal{F}^{-1}\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right]\right\|_{L^1(\mathbb{R}^d)} = \left\|(I+\Delta)^{\frac{s}{2}}f\right\|_{L^1(\mathbb{R}^d)} = \|f\|_{W_p^s(\mathbb{R}^d)}.
\end{aligned}$$

In summary, one can show that for any $s\in\mathbb{R}$ there exists some C such that

$$\left\|\int_{\mathbb{R}^d} f\delta_a\,da\right\|_{B_p^{s+\frac{d}{p}-d}(\mathbb{R}^d)} \le C\,\|f\|_{W_p^s(\mathbb{R}^d)}, \quad f\in C_b^0(\mathbb{R}^d).$$

Since the operator $I(s)$ is positive for $s\le 0$, it follows that

$$\int_{\mathbb{R}^d}\|f\delta_a\|_{B_p^{s+\frac{d}{p}-d}(\mathbb{R}^d)}\,da \le C\,\|f\|_{W_p^s(\mathbb{R}^d)}, \quad f\in C_b^0(\mathbb{R}^d),\ \ f\ge 0.$$

Theorem 5.1.2 in [BL76] gives inequality (A.1). □

FINITE ELEMENT APPROXIMATION OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS DRIVEN BY POISSON RANDOM MEASURES OF JUMP TYPE*

ERIKA HAUSENBLAS†

Abstract. The paper deals with stochastic partial differential equations driven by Poisson random measures of jump type and their numerical approximation. We investigate the accuracy of space and time approximation. As space approximation we consider finite elements and as time approximation the implicit Euler scheme.

Key words. stochastic evolution equations, stochastic partial differential equations, numerical approximation, time discretization, space discretization, Poisson random measure

AMS subject classifications. 60H15, 60H35, 65C30, 35R30

DOI. 10.1137/050654141

1. Introduction.

Our point of interest is the numerical approximation solutions of stochastic partial differential equations (SPDEs) of the following type:

$$\begin{cases} du(t,\xi) = \frac{\partial^2}{\partial \xi^2} u(t-,\xi)\, dt + f(u(t-,\xi),\xi)\, dt \\ \qquad\qquad + \int_{\zeta\in\mathbb{R}} g(u(t-,\xi),\xi;\zeta)\, \tilde{\eta}(d\zeta,\xi,dt),\ \xi\in\mathcal{O},\ 0<t<\infty, \\ u(0,\xi) = u_0(\xi), \end{cases} \tag{1.1}$$

where $f : \mathbb{R}\times\mathcal{O}\to\mathbb{R}$ and $g : \mathbb{R}\times\mathbb{R}\to\mathbb{R}$ are global Lipschitz continuous functions and η is a space time Poisson random measure of impulsive type (see, e.g., Saint Loubert Bié [SLB98] or Peszat and Zabczyk [PZ07]).

Non-Gaussian random processes play an increasing rôle in modeling stochastic dynamical systems. Typical examples of non-Gaussian stochastic processes are Lévy processes and processes arising by Poisson random measures. In neurophysiology the driving noise of the cable equation is basically impulsive, e.g., of a Poisson type (see Walsh [Wal86, Chapter 3])—or, on the other hand, Woyczyński describes in [Woy01] a number of phenomena from fluid mechanics, solid state physics, polymer chemistry, economic science, etc., for which non-Gaussian Lévy processes can be used as their mathematical model in describing the related stochastic behavior. Thus, from the point of view of applications one might feel that the restriction to Gaussian noise is unsatisfactory; to handle such cases one can replace the Gaussian noise by a Poisson random measure.

Concerning the numerical approximation of SPDEs driven by Wiener noise, several works already exist. Just to mention a few (see, e.g., Gyöngy [Gyö99, Gyö98]), Hausenblas [Hau03, Hau02], Kloeden and Shott [KS01], Printems [Pri01a, Pri01b], Shardlow [Sha99], and Yoo [Yoo00]. Finite element approximation of SPDEs driven by Wiener space time white noise were considered by Allen, Novosel, and Zhang

[ANZ98], Cardon-Weber and Millet [CWM04], Germani and Piccioni [GP88], Gyöngy [Gyö99, Gyö98], Gyöngy and Millet [GM05], Millet and Morien [MM05], Walsh [Wal05], and Yan [Yan05]. The numerical approximation of finite-dimensional SDEs driven by Poisson random measures is the topic of, e.g., the work of Gardoń [Gar04], Kuznetsov [Kuz01], Protter and Talay [PT97], or Rubenthaler [Rub03]. But the numerical approximation of SPDEs driven by Poisson random measures is barely investigated, and, in the cases known to the author, processes of finite variation are considered, e.g., by Kouritzin, Long, and Sun [KLS03] and Kouritzin and Long [KL02]. If the driving process is of infinite variation, there exists only some works about existence and uniqueness, e.g., Albeverio, Wu, and Zhang [AWZ98], Hausenblas [Hau05, Hau06], and Kallianpur and Xiong [KX87, KX96]. Applebaum and Wu [AW00] and Saint Loubert Bié [SLB98] considered SPDEs with space time Lévy noise.

First, we discretize the SPDE spatially by the finite element method, obtaining a system of high-dimensional SDEs that can be solved by the implicit Euler scheme. The noise will be approximated by using the projection onto finite elements.

2. Preliminaries. Let $\mathcal{O} \subset \mathbb{R}^d$ be a convex polygon, $1 < p \leq 2$, and A be a uniformly elliptic, dissipative, second order partial differential operator with either Dirichlet or Neumann boundary conditions. In particular, let $A : D(A) \subset L^p(\mathcal{O}) \to L^p(\mathcal{O})$ be the realization of

$$\begin{aligned} \mathcal{L} &= \mathcal{L}(x, D) \\ &= -\sum_{i,j=1}^{2} \frac{\partial}{\partial x_i} a_{i,j}(x) \frac{\partial}{\partial x_j} + \sum_{i=1}^{2} b_i(x) \frac{\partial}{\partial x_i} + c(x), \end{aligned} \tag{2.1}$$

with either

$$u = 0 \quad \text{on} \quad \partial\mathcal{O} \times (0, \infty)$$

or

$$\frac{\partial u}{\partial n_L} + \sigma u = 0,$$

where $\frac{\partial u}{\partial n_L}$ denotes the differentiation along the outer normal unit vector n on $\mathcal{O}$. We assume that $a_{ij} \in C^2(\mathcal{O})$, $1 \leq i, j \leq d$, strictly bounded away from zero, and $\sigma \in C^2(\mathcal{O})$.

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space. Let $\eta : \mathcal{B}(\mathbb{R}) \hat{\times} \mathcal{B}(\mathcal{O}) \hat{\times} \mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ be a Poisson random measure over $(\Omega, \mathcal{F}, \mathbb{P})$ with intensity[1] $\iota = \lambda \hat{\times} \nu$, $\nu \in \mathcal{L}(\mathbb{R}) := \{\sigma : \mathcal{B}(\mathbb{R}) \to \mathbb{R}^+, \sigma \text{ is a Lévy measure}\}$, γ be the compensator, and $\tilde{\eta} = \eta - \gamma$. Let $(\mathcal{F}_t)_{t \geq 0}$ be the natural filtration induced by η.

Our point of interest is solutions of SPDEs of the following form:

$$\begin{cases} du(t, \xi) = Au(t, \xi)\, dt + f(u(t-, \xi), \xi)\, dt \\ \qquad\qquad + \int_{\zeta \in \mathbb{R}} g(u(t-, \xi), \xi; \zeta)\, \tilde{\eta}(d\zeta, \xi, dt), \ \xi \in \mathcal{O}, \ t > 0, \\ u(0, \xi) = u_0(\xi), \quad \xi \in \mathcal{O}, \end{cases} \tag{2.2}$$

where $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ are globally Lipschitz continuous functions. By a mild solution of (1.1) we understand a process u such that

[1] λ denotes the Lebesgue measure.

- u satisfies the integral equation

$$u(t,\xi) = \int_{\mathcal{O}} G_t(\zeta,\xi)u_0(\zeta)\,d\zeta + \int_{0+}^{t}\int_{\mathcal{O}} G_{t-s}(\zeta,\xi)f(u(s-,\zeta,\zeta))\,d\zeta\,ds + \int_{0+}^{t}\int_{\zeta\in\mathcal{O}}\int_{z\in\mathbb{R}} G_{t-s}(\zeta,\xi)g(u(s-,\zeta),\zeta;z)\,\eta(dz,d\zeta,ds),\ \text{a.s.},\quad t\geq 0,$$

  where $G = \{G_t(\cdot,\star), 0 < t < \infty\}$ is the Green kernel associated with $\frac{\partial}{\partial t} + \mathcal{L}$ and the boundary conditions specified above;
- for all $\phi \in C_b^\infty(\mathcal{O})$, the $\mathbb{R}$-valued process $t \mapsto \langle u(t), \phi\rangle$ is adapted and cádlág.

It is shown in Saint Loubert Bié [SLB98] or Hausenblas [Hau05, Example 2.3] that if $p < \frac{2}{d} + 1$, then there exists a unique solution of problem (1.1) such that $u \in L^p(\Omega; L^p(\mathcal{O}))$.

Our point of interest is the numerical approximation of the solution of (1.1). First, we introduce the space discretization by finite elements, and second we introduce the time discretization, i.e., the Euler scheme.

2.1. Space discretization. The space discretization is done by finite elements. For the definition for a finite element, we follow the book of Brenner and Scott [BS02].

DEFINITION 2.1. *Let*

- $K \subset \mathbb{R}^d$ *be a bounded closed set with nonempty interior and piecewise smooth boundary (the* element domain*);*
- $\mathcal{P}$ *be a finite-dimensional space of functions on* K *(the space of* shape functions*); and*
- $\mathcal{N} = \{N_1, \ldots, N_k\}$ *be a basis for* $\mathcal{P}'$ *(the set of* nodal variables*).*

Then $(K, \mathcal{P}, \mathcal{N})$ *is called a* finite element*. Moreover, we denote by* $diam(K) = \max_{x,y\in K} |x-y|_{\mathbb{R}^d}$ *the diameter of* K*.*

DEFINITION 2.2. *A set* K *is* star-shaped with respect to B*, if for all* $x \in K$ *the closed convex hull of* $\{x\} \cup B$ *is a subset of* K*.*

DEFINITION 2.3. *Suppose* K *has diameter* d *and is star-shaped with respect to a ball. Let* $\rho_{max} = \sup\{\rho : K \text{ is star-shaped with respect to a ball of radius } \rho\}$*. Then the* chunkiness parameter *of* K *is defined by*

$$\gamma := \frac{d}{\rho_{max}}.$$

Moreover, we denote by P_m the set of all polynomials in d variables of degree less than or equal to m.

DEFINITION 2.4 (compare the assumptions of Theorem 4.4.4 in [BS02]). *We assume that a finite element satisfies the* standard conditions for some l and m*, iff*

- K *is star-shaped with respect to some ball,*
- $P_{m-1} \subset \mathcal{P} \subset W_\infty^m(\mathcal{O})$*,*
- $\mathcal{N} \subset (C^l(\bar{K}))'$*.*

DEFINITION 2.5. *Let* $(K, \mathcal{P}, \mathcal{N})$ *be a finite element. The basis* $\{\phi_1, \ldots, \phi_k\}$ *of* $\mathcal{P}$ *dual to* $\mathcal{N}$ *is called the* nodal basis *of* $\mathcal{P}$*.*

DEFINITION 2.6. *Given a finite element* $(K, \mathcal{P}, \mathcal{N})$*, let the set* $\{\phi_1, \ldots, \phi_k\} \subset \mathcal{P}$ *be the basis dual to* $\mathcal{N}$*. If* v *is a function for which all* $N_i \in \mathcal{N}$*,* $i = 1, \ldots, k$*, are defined, then we define the* local interpolant *by*

$$\mathcal{I}_K v := \sum_{i=1}^{k} v(N_i)\phi_i.$$

DEFINITION 2.7. *A* subdivision *of a domain $\mathcal{O}$ is a finite collection of element domains $\{K_i, i = 1, \dots k\}$ such that*

- $\int K_i \cap \int K_j = \emptyset$ *if* $i \neq j$ *and*
- $\cup K_i = \mathcal{O}$.

Remark 2.1. The nodal basis of a subdivision $\{K_i, i = 1, \dots k\}$ induces a Voronoi decomposition $\{J_i; i = 1, \dots, k\}$ of $\mathcal{O}$ by

$$J_i := \left\{ \xi \in \mathcal{O},\ |\xi - N_i| \leq \min_{1 \leq i \leq k} \{|\xi - N_j|\} \right\}.$$

DEFINITION 2.8. *Suppose that $\mathcal{O}$ is a polyhedral domain with subdivision $\mathcal{T}$. Assume that each element domain K in the subdivision is equipped with some type of shape functions $\mathcal{P}$ and nodal variables $\mathcal{N}$ such that $(K, \mathcal{P}, \mathcal{N})$ forms a finite element. Let m be the order of the highest partial derivatives involved in the nodal variables. For $f \in C^m(\bar{\mathcal{O}})$, the* global interpolant *is defined by*

$$\mathcal{I}_{\mathcal{T}} f \Big|_{K_i} = \mathcal{I}_{K_i} f$$

for all $K_i \in \mathcal{T}$.

Example 2.1. Let $H = L^2([0,1])$. Let $\{x_i := \frac{i}{N}, i = 1, \dots, N-1\}$ be the set of grid points. For $0 \leq i \leq N$ let ϕ_i be a pyramid function, i.e., a function, which takes value 1 at the grid point $\frac{i}{N}$, vanishes at the other grid points, and is linear between the grid points. For $i = 1, \dots, N-1$, a finite element $(K_i, \mathcal{N}_i, \mathcal{P}_i)$ consists of the interval $[\frac{i-1}{N}, \frac{i}{N}]$, the nodal variables $N_i : \mathcal{C}^0([0,1]) \ni v \mapsto v(x_i) \in \mathbb{R}$, the shape functions $\phi_i|_{K_i}$ and $\phi_{i-1}|_{K_i}$, and $J_i = [\frac{i-1}{N} + \frac{1}{2N}, \frac{i}{N} + \frac{1}{2N}]$.

We can now define a family of subdivisions $\mathcal{F}_h$, $h = N_h^{-1}$. For each subdivision $\mathcal{T}_h$, let $\mathcal{V}_h$ the linear hull of the shape functions, i.e., the linear hull of $\{\phi_i\}_{i=1}^{N_h - 1}$. For any $v \in C([0,1])$, the global interpolant is given by

$$\mathcal{I}_h(v) = \sum_{i=1}^{N_h} N_i^h(v) \phi_i.$$

DEFINITION 2.9. *We call a family of subdivisions $\{\mathcal{T}_h, 0 < h \leq 1\}$* nondegenerate *if the chunkiness parameter is uniformly bounded for all $T \in \{\mathcal{T}_h\}$ and all $h \in (0,1]$.*

Let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions of a polyhedral domain $\mathcal{O}$ in $\mathbb{R}^d$, consisting of k_h finite elements of reference type $(K, \mathcal{P}, \mathcal{N})$. We assume that the parameter h corresponds to the maximal diameter of the finite elements, i.e., $h = \max\{1 \leq i \leq k_h \mid \operatorname{diam}(K_i)\}$. Let $\{\phi_1^h, \dots, \phi_{k_h}^h\}$ be the set of shape functions and $\{N_1^h, \dots, N_{k_h}^h\}$ be the set of nodal variables. We denote by $\mathcal{V}_h$ the linear hull of the shape functions and $\mathcal{V}_h'$ its dual. The semidiscrete problem corresponding to (2.2) is to find the process $u_h = \{u_h(t) \in \mathbb{R}^{k_h}, 0 \leq t < \infty\}$

$$\begin{cases} du_h(t) = \mathcal{A}_h u_h(t)\, dt f_h(u_h(t-))\, dt \\ \qquad\qquad + \int_{i \in \{1, \dots, k_h\}} \int_{\zeta \in \mathbb{R}} g_h(u_h(t-), i, \zeta)\, \tilde{\eta}_h(d\zeta, di, dt),\ t > 0, \\ \qquad u(0) = (\langle u_0, N_1 \rangle, \dots, \langle u_0, N_{k_h} \rangle) \in \mathbb{R}^{k_h} \end{cases} \tag{2.3}$$

where $\mathcal{A}_h : \mathcal{V}_h \to \mathcal{V}_h$ is the discrete analogue of A defined by

$$\langle \mathcal{A}_h \phi, \chi \rangle = \langle A\phi, \chi \rangle \quad \forall \phi, \chi \in \mathcal{V}_h, \tag{2.4}$$

and $\tilde{\eta}_h : \mathcal{B}(\mathbb{R})\hat{\times}\mathcal{P}(\{1,\dots,k_h\})\hat{\times}\mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ is the compensated Poisson random measure with intensity ι_h given by

$$\mathcal{B}(\mathbb{R}) \times \mathcal{B}(\{1,\dots,k_h\}) \ni (A,B) \mapsto \iota_h((A,B)) := \cup_{i\in B}\lambda(J_i^h)\,\nu(A) \in \mathbb{R}^+.$$

Moreover, $f_h : \mathcal{V}_h \to \mathcal{V}_h$ and $g_h : \mathcal{V}_h \times \{1,\dots k_h\} \times \mathbb{R} \to \mathcal{V}_h$ are given by

$$\mathcal{V}_h \ni v \mapsto f_h(v) := \sum_{i=1}^{k_h} f(v(N_i), N_i)\phi_i^h \in \mathcal{V}_h$$

and

$$\mathcal{V}_h \times \{1,\dots k_h\} \times \mathbb{R} \ni (v,i,\zeta) \mapsto g_h(v,i,\zeta) = g(v(N_i), N_i;\zeta)\, c_i^h\ \phi_i^h \in \mathcal{V}_h,$$

where $c_i^h := \left[\int_{\mathcal{O}} \phi_i^h(\xi)\, d\xi\right]^{-1}$.

Remark 2.2. The Poisson random measure $\tilde{\eta}_h$ can also be written as a sum of k_h independent Poisson random measures (see, e.g., [Lin86, Proposition 5.3.2]). To be precise, let $\tilde{\eta}_h^i : \mathcal{B}(\mathbb{R})\hat{\times}\mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$ be pairwise independent compensated Poisson random measures with intensity $\nu^i = \lambda(J_i^h)\,\nu$. Then we have for some $A \in \mathcal{B}(\{1,\dots,k_h\})$ and $B \in \mathcal{B}(\mathbb{R})$, $\nu(B) < \infty$,

$$\int_{i\in A}\int_{\xi\in B} \iota_h(di,d\xi) \overset{\mathrm{d}}{=} \sum_{i=1}^{k_h} 1_A(i)\lambda(J_i^h)\int_B \nu^i(d\xi).$$

In particular, we have for all $\mathcal{V}_h$-valued $\mathcal{F}_t$-adapted and cádlág processes $u = \{u(t), 0 \le t < \infty\}$

$$\int_0^t \int_{\{1,\dots,k_h\}} \int_{\zeta\in\mathbb{R}} g_h(u(s-),di,\zeta)\ \tilde{\eta}_h(di,d\zeta,ds) \overset{\mathrm{d}}{=} \sum_{i=1}^{k_h}\int_0^t\int_{\zeta\in\mathbb{R}} g_h(u(s-),i,\zeta)\tilde{\eta}_h^i(d\zeta,ds).$$

2.2. Time discretization. One usually prefers to discretize simultaneously in time and space. Thus, let τ_h be the time step size corresponding to the subdivision $\mathcal{T}_h$. One popular way for time discretization is to use the *implicit Euler scheme*, i.e.,

$$\frac{u_h(t+\tau_h)-u_h(t)}{\tau_h} + \mathcal{A}_h u_h(t+\tau_h) \approx f_h(u_h(t)) + \int_t^{t+\tau_h}\int_{z\in\mathbb{R}^{k_h}} g_h(u_h(t);z)\tilde{\eta}_h(dz,dt).$$

So, if v_h^m denotes the approximation of $u_h(m\tau_h)$, then

$$\begin{cases} v_h^{m+1} = (1-\tau_h A_h)^{-1}\left[v_h^m + \tau_h f_h(m\tau_h, v_h^m) + \xi_h^m(u_h(m\tau_h))\right], \\ v_h^0 = P_h u_0, \end{cases} \tag{2.5}$$

where we denote by $\xi_h^m(u_h(m\tau_h))$ the k_h dimensional random variable

$$\int_{m\tau_h}^{(m+1)\tau_h}\int_{\zeta\in\mathbb{R}^{k_h}} g_h(u_h(m\tau_h);\zeta)\,\tilde{\eta}_h(dz;ds). \tag{2.6}$$

The approximation at time $t = \tau_h m$, $m \in \mathbb{N}$, is given by

$$\hat{u}_h(m\tau) := \mathcal{I}_h v_h^m. \tag{2.7}$$

The solution is defined by linear interpolation; let $t \in (m\tau_h, (m+1)\tau_h)$; we define $v_h(t)$ by $v_h(t) = v_h^m$ and

$$\hat{u}_h(t) := \mathcal{I}_h\, v_h(t), \quad m\tau_h < t < (m+1)\tau_h.$$

Since the implicit Euler scheme is unconditionally stable, no stability conditions arise. Now we can state our main result.

THEOREM 2.1. *Let $\mathcal{O}$ be a polyhedral domain and A be a uniformly elliptic, second order differential operator given in* (2.1) *with Dirichlet or Neumann boundary conditions.*

For a fixed p, $1 \le p \le 2$, let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge 0}, P)$ be the usual filtration and

$$\eta : \mathcal{O} \times \mathbb{R} \times \mathcal{B}(\mathbb{R}^+) \to \mathbb{R}^+$$

be a Poisson random measure of jump type with intensity $\iota := \lambda \times \nu$, where ν belongs to the set of p-integrable Lévy measures on $\mathbb{R}$.

We assume that the functions $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \bar{\mathcal{O}} \times \mathbb{R} \to \mathbb{R}$ are globally Lipschitz and g linear in the third variable. Moreover, we assume that the initial condition u_0 belongs to $L^p(\mathcal{O})$.

The space is approximated by a nondegenerate family of subdivisions $\{\mathcal{T}_h, 0 < h \le 1\}$ of finite elements, satisfying the conditions described in section 2.1. *Moreover, the reference element is supposed to be a standard element for $l \ge 0$ and $m = 2$. Let v_n^k, $k \in \mathbb{N}$, be the approximation of* (2.2) *given by* (2.7). *Then for all $N \in \mathbb{N}$, for all α such that*

$$\alpha < \frac{2}{p} - d + \frac{d}{p},$$

and for all δ_1, δ_2, and δ_3, with

$$\delta_1 = 2 + \frac{d}{2} - \frac{d}{p}, \quad \delta_2 < \frac{2}{p} - d + \frac{d}{p}, \text{ and } \delta_3 < \left(\frac{2}{p} - d + \frac{d}{p}\right)\left(2 + \frac{d}{2} - \frac{d}{p}\right),$$

there exist constants C_0, C_1, C_2, and C_3 depending on p, f, and g such that for all $0 < h \le 1$ the following estimate holds for $0 < k \le N$:

$$\left[\mathbb{E}\ \left\|u(k\tau_h) - v_h^k\right\|_{L^p(\mathcal{O})}^p\right]^{\frac{1}{p}} \le \frac{C_0}{\epsilon}\,\tau^\alpha + \frac{C_1}{(k\tau_h)^{\frac{1}{p}}}\,h^{\delta_1} + \frac{C_2}{\epsilon_2}\,h^{\delta_2} + \frac{C_3}{\epsilon_3}\,h^{\delta_3},$$

where $\epsilon_1 = \frac{2}{p} - d + \frac{d}{p} - \alpha$, $\epsilon_2 = \frac{2}{p} - d + \frac{d}{p} - \delta_2$ and $\epsilon_3 = \frac{2}{p} - d + \frac{d}{p} - \frac{\delta_3}{\delta_1}$,

In [Hau05, Example 2.3] we treated (2.2) by means of $L^p(\mathcal{O})$ spaces. But finite elements are designed for Hilbert spaces. In particular, the approximation of the operator A is given by the inner product (see problem 3.4), and usually the error estimates of the corresponding semigroups are given in $L^2(\mathcal{O})$ or $H^1(\mathcal{O})$ (see Theorem 3.3). Since the $L^p(\mathcal{O})$ spaces were essential in [Hau05]—on which this paper relies—we had to express the error estimates of the corresponding semigroups in $L^p(\mathcal{O})$ spaces. We have done this in Theorem 3.4. Therefore, the entity $2 + \frac{d}{2} - \frac{d}{p}$ appears.

Fix $p \in [1,2]$. Let E be a separable M-type p Banach space and Z be a Banach space. Let A be an operator generating a compact and analytic semigroup, $\nu \in \mathcal{L}(Z)$, $\tilde{\eta}$ be a compensated Poisson random measure on Z with intensity ν, and $G : E \to L(Z,E)$ be a mapping such that there exist some $\gamma < \frac{2}{p}$ and $C < \infty$, with

$$\int_Z \left| (-A)^{-\frac{\gamma}{2}} \left(G(u,z) - G(v,z) \right) \right|_E^p \nu(dz) \leq C \, |u-v|_E^p. \tag{2.8}$$

Then, by [Hau05], there exists a unique solution to the equation

$$\begin{cases} du(t) = (Au(t-)) \; dt + \int_Z g(u(t-);z) \tilde{\eta}(dz;dt), \\ u(0) = u_0. \end{cases} \tag{2.9}$$

In [Hau05, Example 2.3], the space time Poissonian noise was represented as a functional-valued Poisson random measure taking values in the Besov space $B_p^{\frac{d}{p}-d}(\mathcal{O})$. Let $\nu \in \mathcal{L}(E)$ and $1 \leq p \leq 2$. Let $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ be Lipschitz continuous in the following sense: There exists some constant $C < \infty$ such that

$$\int_{\mathcal{O}} \int_{\mathbb{R}} |g(x,\xi,\zeta) - g(y,\xi,\zeta)|^p \nu(d\zeta) d\xi \leq C |x-y|^p, \quad x,y \in \mathbb{R}. \tag{2.10}$$

Thus, if

$$\frac{d}{p} - d < \frac{2}{p},$$

then the Nemytskij operator G of g, defined in (3.20), satisfies by Proposition A.1 the Lipschitz condition (2.8). The remaining difference

$$\frac{2}{p} - d + \frac{d}{p}$$

is used for estimating the error of the approximation. Therefore, the entity $\frac{2}{p} - d + \frac{d}{p}$ appears.

Again, let $\nu \in \mathcal{L}(E)$, $1 \leq p_0 \leq 2$ and $g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$ be Lipschitz continuous satisfying (2.10), with $p = p_0$. Moreover, let $f = 0$. Then, if

$$\frac{2}{p_0} - d + \frac{d}{p_0} > 0, \tag{2.11}$$

problem (1.1) has a unique solution such that $u \in L^p(\Omega; L^p(\mathcal{O}))$ for all $p \in [p_0, p_1)$, where $p_1 = \frac{2}{d} + 1$ (compare [Hau05, Example 2.3]). Moreover, the assumptions of Theorem 2.1 are fulfilled for all $p \in [p_0, p_1)$, and we can choose any $p \in [p_0, p_1)$ such that $\min(\delta_1, \delta_2, \delta_3)$ is maximal. If

$$2 + \frac{d}{2} - \frac{d}{p_1} < 0,$$

then no convergence is given by Theorem 2.1.

3. Finite elements—a short account. In the existing literature several error bounds for the approximation by finite elements can be found. In this section, we will cite the estimates which are necessary to prove our main result.

In this chapter, let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions of a polyhedral domain $\mathcal{O}$ in $\mathbb{R}^d$, consisting of k_h finite elements of reference type $(K, \mathcal{S}, \mathcal{N})$ satisfying the standard conditions for some m and l. We assume that the parameter h corresponds to the maximal diameter of the finite elements, i.e., $h = \max\{1 \leq i \leq N \mid \operatorname{diam}(K_i)\}$. Moreover, we assume throughout this section, that $(K, \mathcal{P}, \mathcal{N})$ satisfies the standard conditions for some l and m.

Let $\{\phi_1^h, \dots, \phi_{k_h}^h\}$ be the set of shape functions and $\{N_1^h, \dots, N_k^h\}$ be the set of nodal variables. By $\bar{\mathcal{N}}$ we denote the set of nodal variables which are inner points. We denote by $\mathcal{V}_h$ the linear hull of the shape functions and by $\mathcal{V}_h'$ its dual.

The quality of approximation is given by the following Bramble–Hilbert (Raviart–Ciarlet) inequality.

THEOREM 3.1 (see, e.g., Brenner and Scott [BS02, Corollary 4.4.24]). *Assume that the conditions above are satisfied. Suppose* $1 \leq p \leq \infty$ *and either* $m - l - \frac{d}{p} > 0$ *when* $p > 1$ *or* $m - l - d \geq 0$ *when* $p = 1$. *Then there exists a positive constant* C *depending on the reference element,* m, l, d, p, *and the chunkiness parameter such that for* $0 \leq s \leq m$

$$\left(\sum_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_p^s(T)}^p \right)^{\frac{1}{p}} \leq C\, h^{m-s}\, \|v\|_{W_p^m(\mathcal{O})}$$

for all $v \in W_p^m(\mathcal{O})$, *where the left-hand side should be interpreted, in the case where* $p = \infty$, *as* $\max_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_\infty^s(\mathcal{O})}$. *For* $0 \leq s \leq l$,

$$\max_{T \in \mathcal{T}_h} \|v - \mathcal{I}_h v\|_{W_\infty^s(\mathcal{O})} \leq C\, h^{m-s-\frac{d}{p}}\, \|v\|_{W_p^m(\mathcal{O})} \quad \forall v \in W_p^m(\mathcal{O}).$$

Since the space $\mathcal{V}_h$ is finite-dimensional, all norms which can be defined in $\mathcal{V}_h$ are equivalent. The purpose of the inverse inequalities is to specify how the equivalent constants depend on the parameter h.

THEOREM 3.2 (Brenner and Scott [BS02, Theorem 4.5.11]). *Assume that the conditions above are satisfied, and let* p, q, *and* l *be given constants such that* $1 \leq p \leq \infty$, $1 \leq q \leq \infty$, $0 \leq m \leq l$, *and* $\phi_i^h \in W_p^l(\mathcal{O}) \cap W_q^m(\mathcal{O})$ *for* $i = 1, \dots, k_h$. *Then there exists a positive constant* C *depending on the reference element,* d, m, p, *and* q *such that*

$$\left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_p^l(T)}^p \right]^{\frac{1}{p}} \leq C\, h^{m-l+\min(0, \frac{d}{p} - \frac{d}{q})} \left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_q^m(T)}^q \right]^{\frac{1}{q}}$$

for all $v \in \mathcal{V}_h$. *When* $p = \infty$, *then* $[\sum_{T \in \mathcal{T}_h} \|v\|_{W_p^s(T)}^p]^{\frac{1}{p}}$ *is interpreted as* $\max_{T \in \mathcal{T}_h} \|v\|_{W_\infty^l(T)}^q$.

COROLLARY 3.1. *Under the conditions above, there exists a positive constant* C *depending on the reference element such that we have for all* $1 > \delta \geq 0$

$$\left[\sum_{T \in \mathcal{T}_h} \|v\|_{L_p(T)}^p \right]^{\frac{1}{p}} \leq C\, h^{-\delta+\min(0, \frac{d}{p} - \frac{d}{q})} \left[\sum_{T \in \mathcal{T}_h} \|v\|_{W_q^{-\delta}(T)}^q \right]^{\frac{1}{q}}$$

for all $v \in \mathcal{V}_h$.

Proof. The proof is done similarly to the proof of Theorem 3.2 (see Brenner and Scott [BS02, Theorem 4.5.11]). Let $(\hat{K}, \hat{\mathcal{P}}, \hat{\mathcal{N}})$ be a finite element of reference type satisfying the standard conditions for m and l with $\operatorname{diam}(\hat{K}) = 1$ and $(K, \mathcal{P}, \mathcal{N})$ be a finite element of the family of subdivisions with $\operatorname{diam}(K) = h_K$. Since the subdivision is nondegenerate, a transformation exists, having the form

$$T_K : \hat{K} \ni \hat{x} \mapsto J_K \hat{x} + b_K \in K,$$

where $J_K \in \mathbb{R}^d \times \mathbb{R}^d$ being invertible and $b_K \in \mathbb{R}^d$ (see Proposition 4.4.11 in [BS02]). Let $\hat{v} : \hat{K} \to \mathbb{R}$ be an arbitrary function and $v : K \to \mathbb{R}$ be defined by

$$K \ni x \mapsto v(x) := \hat{v}(J_K^{-1} x) \in \mathbb{R}.$$

Then substitution gives

$$|v|_{L^p(K)} = \det(J_K)^{\frac{1}{p}} |\hat{v}|_{L^p(\hat{K})} = C\, h_K^{\frac{d}{p}} |\hat{v}|_{L^p(\hat{K})}, \quad 0 < h_K \le 1,$$

and

$$|v|_{L^\infty(K)} = |\hat{v}|_{L^\infty(\hat{K})}, \quad 0 < h_K \le 1.$$

Similarly there exists a constant $C > 0$ such that we have for all $0 < h_K \le 1$

$$|v|_{W_p^j(K)} = C\, \det(J_K)^{\frac{1}{p}} h_K^{-j} |\hat{v}|_{W_p^j(\hat{K})} = C\, h_K^{\frac{d}{p}-j} |\hat{v}|_{W_p^j(\hat{K})}$$

and

$$|v|_{W_\infty^j(K)} = C\, h_K^{-j} |\hat{v}|_{W_\infty^j(\hat{K})} = C\, h_K^{-j} |\hat{v}|_{W_\infty^j(\hat{K})}.$$

Duality arguments give for q conjugate to p and for all $0 < h_K \le 1$

$$\begin{aligned} |v|_{W_p^{-j}(K)} &= \sup_{w \in W_q^j(K)} \frac{\langle v, w \rangle}{|w|_{W_q^j(K)}} \le C \sup_{\hat{w} \in W_q^j(\hat{K})} \frac{\det(J_K) \langle \hat{v}, \hat{w} \rangle}{h_K^{\frac{d}{q}-j} |\hat{w}|_{W_q^j(\hat{K})}} \\ &= C\, h_K^{d(1-\frac{1}{q})+j} \sup_{\hat{w} \in W_q^j(K)} \frac{\langle \hat{v}, \hat{w} \rangle}{|\hat{w}|_{W_q^j(K)}} \le C\, h_K^{\frac{d}{p}+j} |\hat{v}|_{W_p^{-j}(\hat{K})}. \end{aligned} \tag{3.1}$$

Since $\hat{\mathcal{P}}$ is finite-dimensional, all norms are equivalent, and there exists a constant $\hat{C}$ such that

$$|\hat{v}|_{L^p(\hat{K})} \le \hat{C}\, |\hat{v}|_{W_q^{-\gamma}(\hat{K})} \quad \forall v \in \mathcal{P}.$$

Therefore (3.1) and interpolation arguments imply for $\gamma > 0$ that

$$h_K^{-\frac{d}{p}} |v|_{L^p(K)} \le C\, h_K^{-\frac{d}{q}-\gamma} |v|_{W_q^{-\gamma}(K)} \quad \forall v \in \mathcal{P},\ 0 < h_K \le 1.$$

Let $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions. Then, by taking the sum, one can show by the same arguments as in Theorem 4.5.11 in [BS02], that, if the family of subdivisions is nondegenerate, the assertion of Corollary 3.1 holds. □

3.1. Approximation of the operator. We can associate with the operator $(A, D(A))$ the Gelfand triple (V, H, V'), where $V \hookrightarrow H = H' \hookrightarrow V'$ densely. In fact, $V = D(-A)^{\frac{1}{2}}$ and V' its dual. In our case, where $(A, D(A))$ is a second order differential operator with boundary conditions, we have $V = H^1(\mathcal{O})$ if the boundary condition involves first order derivatives and $V = H_0^1(\mathcal{O})$ if the homogeneous Dirichlet condition is specified on the whole boundary. Now the operator $A : V \to V'$ defines a bilinear form on H by

$$a(u, v) := \langle Au, v\rangle, \quad u, v \in V.$$

The corresponding symmetric variational problem is posed as follows. Suppose that the following three conditions are valid:

$$\text{(3.2)} \qquad \begin{cases} (1) & (H, \langle\cdot,\cdot\rangle) \text{ is a Hilbert space.} \\ (2) & V \text{ is a (closed) subspace of } H. \\ (3) & a(\cdot,\cdot) \text{ is a } \textit{bounded, symmetric} \text{ bilinear form} \\ & \text{that is } \textit{coercive} \text{ on } V. \end{cases}$$

Then the *symmetric variational* problem is the following:

$$\text{(3.3)} \qquad \begin{cases} \text{For a given } F \in V', \text{ find } u \in V \text{ such that} \\ \quad a(u, v) = F(v) \quad \forall v \in V. \end{cases}$$

Given the family of nondegenerate subdivisions $\mathcal{T}_h$ of a polyhedral domain $\mathcal{O}$, the *Ritz–Galerkin approximation* of problem (3.3) is the following:

$$\text{(3.4)} \qquad \begin{cases} \text{For a given } F \in \mathcal{V}_h', \text{ find } u_h \in \mathcal{V}_h \text{ such that} \\ \quad a(u_h, v) = F(v) \quad \forall v \in \mathcal{V}_h. \end{cases}$$

Assume that u solves problem (3.3) and u_h solves problem (3.4). Then we can find the following estimates on $u - u_h$ depending on F. By means of the inequality above and duality arguments, one can verify bounds of the difference $u - u_h$ in $H^1(\mathcal{O})$ and $L^2(\mathcal{O})$. In particular, one can show that, if the family of subdivisions $\{\mathcal{T}_h, 0 < h \leq 1\}$ satisfies the assumptions of Theorem 3.1 with $m = 2$, $l \geq 0$ and $p = 2$, then

$$\text{(3.5)} \qquad \inf_{v \in \mathcal{V}_h} \|u - v\|_{H^1(\mathcal{O})} \leq C\, h\, \|u\|_{H^2(\mathcal{O})} \quad \forall u \in H^2(\mathcal{O}), \quad 0 < h \leq 1,$$

is valid, and therefore (for more details, see Theorem 5.4.8 in [BS02])

$$\text{(3.6)} \qquad \|u - u_h\|_{L^2(\mathcal{O})} \leq Ch^2 \|u\|_{H^2(\mathcal{O})} \leq Ch^2 \|F\|_{L^2(\mathcal{O})}, \quad 0 < h \leq 1.$$

Finally, by using duality arguments, one can show that there exists a $h_0 > 0$ such that (see Theorem 5.8.3 in [BS02])

$$\text{(3.7)} \qquad \|u - u_h\|_{H^{2,-\gamma}(\mathcal{O})} \leq Ch^{\gamma+1} \|u - u_h\|_{H^1(\mathcal{O})} \leq Ch^{2+\gamma} \|F\|_{L^2(\mathcal{O})}, \quad 0 < h \leq 1.$$

Since our problem (2.2) is well-posed in $L^p(\mathcal{O})$, the error bounds of the difference have to be transferred to $L^p(\mathcal{O})$ or $W^p_{-\gamma}(\mathcal{O})$, $\gamma > d - \frac{d}{p}$, $p \in (1, 2]$.

COROLLARY 3.2. *Assume that* (3.5) *holds. Then, under the conditions above, there exist positive constants* C *and* h_0 *such that for all* $h \le h_0$ *there is a unique solution to problem* (3.4) *satisfying*

$$\|u - u_h\|_{L^p(\mathcal{O})} \le Ch^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{L^p(\mathcal{O})}, \quad 0 < h \le 1,$$

and for $\gamma \in (0,1)$

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le Ch^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{W^p_{-\gamma}(\mathcal{O})}, \quad 0 < h \le 1.$$

Proof. Since $p \le 2$ and O is bounded we can infer that

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C \ \|u - u_h\|_{L^2(\mathcal{O})}.$$

The estimate (3.6) gives

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C\, h^2 \|F\|_{L^2(\mathcal{O})}.$$

Theorem 3.2 leads to

$$\|u - u_h\|_{L^p(\mathcal{O})} \le C\, h^{2+\frac{d}{2}-\frac{d}{p}} \|F\|_{L^p(\mathcal{O})}.$$

Similarly, we get

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C \ \|u - u_h\|_{W^2_{-\gamma}(\mathcal{O})}.$$

Estimate (3.7) gives

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C\, h^{2+\gamma} \|F\|_{L^2(\mathcal{O})}.$$

Next, we apply negative norm estimates. In particular, Theorem 3.2 leads to

$$\|u - u_h\|_{W^p_{-\gamma}(\mathcal{O})} \le C\, h^{2+\frac{d}{2}-\frac{d}{p}} \|F\|_{W^p_{-\gamma}(\mathcal{O})}. \qquad \square$$

3.2. Approximation of the semigroup. The approximation $\mathcal{A}_h : \mathcal{V}_h \to \mathcal{V}_h'$ of the operator A is given by the induced bilinear form on $\mathcal{V}_h$. In particular, for any $u \in \mathcal{V}_h$ we define $\mathcal{A}_h u$ by

$$\langle \mathcal{A}_h u, v\rangle := a(u,v), \quad v \in \mathcal{V}_h. \tag{3.8}$$

The semidiscrete approximation of the solution u to the abstract Cauchy problem

$$\begin{cases} \frac{d}{dt}u(t) + Au(t) = 0, & t > 0, \\ u(0) = u_0 \end{cases} \tag{3.9}$$

is the function $u_h : [0,\infty) \to \mathcal{V}_h$, determined by the following condition: For all $v \in \mathcal{V}_h$ we have

$$\begin{cases} \frac{d}{dt}\langle u_h(t), v\rangle + a(u_h(t), v) = 0, \ t > 0, \\ \langle u_h(0), v\rangle = \langle u_0, v\rangle. \end{cases} \tag{3.10}$$

In use of the operator $\mathcal{A}_h$, relation (3.10) is written as

$$\frac{du_h(t)}{dt} + \mathcal{A}_h u_h(t) = 0, \quad t > 0.$$

Let $\mathcal{H}_h$ be the space $\mathcal{V}_h$ equipped with the topology induced from H. Let $\mathcal{R}_h : H \to \mathcal{H}_h$ be the Ritz projection. Recall that the linear operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ is defined by (3.8). Let $\mathcal{R}_h : V \to \mathcal{V}_h$ be the *Ritz operator* defined through

$$a(R_h u, v_h) = a(u, v) \quad \forall u \in \mathcal{V}_h \text{ and } u \in V.$$

By the Lax–Milgram theorem, it can be shown that the Ritz operator is well-defined, i.e., that the element $R_h u$ exists and is unique. Theorem 1.1 of [FSS01] shows that the operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ generates an analytic semigroup on $\mathcal{H}_h$ independently of h. To be precise, there exist some $\theta \in (0, \pi)$ and some $M \geq 1$ such that $\mathbb{C} \setminus \Sigma_\theta \subset \rho(\mathcal{A}_h)$, where $\rho(\mathcal{A}_h)$ denotes the resolvent set of $\mathcal{A}_h$ and

$$\Sigma_\theta := \{z \in \mathcal{C}, 0 \leq |\arg(z)| \leq \theta\}.$$

The semidiscrete approximation admits the error estimate of optimal order for $t > 0$.

THEOREM 3.3 ([FSS01, Theorem 2.1]). *Given $u_0 \in H$, let u and u_h be the solutions of* (3.9) *and* (3.10)*, respectively. Then we have*

$$\|u(t) - u_h(t)\|_{L^2(\mathcal{O})} + h \|u(t) - u_h(t)\|_{H^1(\mathcal{O})} \leq C\, h^2 t^{-1} \|u_0\|_{L^2(\mathcal{O})}, \quad t > 0,\ 0 < h \leq 1.$$

Similarly to the Proof of Theorem 3.3 one can find error estimates in L^p spaces.

THEOREM 3.4. *Given $u_0 \in H$, let u and u_h be the solutions of* (3.9) *and* (3.10)*, respectively. Then we have for $1 \leq p \leq 2$ and $0 \leq \gamma < 1$*

$$\|u(t) - u_h(t)\|_{W^{p,-\gamma}(\mathcal{O})} \leq C\, h^{2-\frac{d}{p}+\frac{d}{2}} t^{-1} \|u_0\|_{W^{p,-\gamma}(\mathcal{O})}, \quad t > 0,\ 0 < h \leq 1.$$

Proof. The proof of Theorem 3.4 is similar to the proof of Theorem 3.3, i.e., Theorem 2.1 in [FSS01]. Assume that u solves problem (3.3) with $F = u_0$ and u_h solves problem (3.4) with $F = \mathcal{I}_h u_0$. In Corollary 3.2 we have shown that there exists estimates of the error in L^p spaces. In particular, we have

$$\|u - u_h\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|F\|_{L^p(\mathcal{O})}.$$

Since $u = A^{-1}u_0$ and $\mathcal{A}_h^{-1}\mathcal{I}_h u_0$, we can write

$$\left\|A^{-1}u_0 - \mathcal{A}_h^{-1}\mathcal{I}_h u_0\right\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{L^p(\mathcal{O})}.$$

Next, since for all $\lambda_0, \lambda \in \rho(A) \cap \rho(\mathcal{A}_h)$ we have

$$\begin{aligned}(\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1} - (\lambda - A)^{-1} &= \left(1 + (\lambda - \lambda_0)(\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right) \\ &\times \left((\lambda_0\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h - (\lambda_0 - A)^{-1}\right) \times (\lambda_0 - A)(\lambda_0 - A)^{-1}, \end{aligned} \tag{3.11}$$

we can conclude that the following estimates:

$$\left\|(\lambda I - A)^{-1} u_0 - (\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h u_0\right\|_{L^p(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{L^p(\mathcal{O})} \tag{3.12}$$

and for $\gamma \in (0, 1)$

$$\left\|(\lambda I - A)^{-1} u_0 - (\lambda\mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h u_0\right\|_{W^p_{-\gamma}(\mathcal{O})} \leq C h^{2-\frac{d}{p}+\frac{d}{2}} \|u_0\|_{W^p_{-\gamma}(\mathcal{O})} \tag{3.13}$$

are valid for all $\lambda \in \rho(A) \cap \rho(\mathcal{A}_h)$. The proof of Theorem 3.3 relies on the fact that we can represent the semigroup in terms of the resolvent. By comparing to [FSS01, page 58], or to [Paz83, Theorem 1.7.7], we have

$$\|u(t) - u_h(t)\mathcal{I}_h\| \leq \frac{1}{2\pi} \int_\Gamma \left|e^{-tz}\right| \cdot \left\| \left[(\lambda I - A)^{-1} - (\lambda \mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right] u_0 \right\| \, dz, \tag{3.14}$$

where Γ is the boundary of $\Sigma_{\theta_1} = \{z, 0 \leq |\arg(z)| \leq \theta_1\}$, for $\theta_1 \in (\theta, \frac{\pi}{2})$ coming from $\infty e^{i\theta_1}$, passing through the origin and going out to $\infty e^{-i\theta_1}$. Using estimate (3.6) and taking into account the calculations in (3.11) gives

$$\begin{aligned} &\left\| \left[(\lambda I - A)^{-1} - (\lambda \mathcal{I}_h - \mathcal{A}_h)^{-1}\mathcal{I}_h\right] u_0 \right\|_{L^2(\mathcal{O})} \\ &\qquad \leq C\, h^m \left\|u_0\right\|_{L^2(\mathcal{O})}, \quad u_0 \in L^2(\mathcal{O}). \end{aligned} \tag{3.15}$$

By substituting estimate (3.15) into (3.14), Theorem 3.3 can be shown. Similarly, by substituting estimate (3.12) into (3.14) one gets

$$\begin{aligned} &\|u(t) - u_h(t)\mathcal{I}_h\|_{L^p(\mathcal{O})} \leq \frac{C}{2\pi}\, h^{2-\frac{d}{p}+\frac{d}{2}}\ \|u_0\|_{L^p(\mathcal{O})} \int_\Gamma \left|e^{-tz}\right| \, dz \\ &\leq C\, h^{2-\frac{d}{p}+\frac{d}{2}}\ \|u_0\|_{L^p(\mathcal{O})} \int_0^\infty e^{-tr\cos(\theta_1)}\, dr \leq C\, h^{2-\frac{d}{p}+\frac{d}{2}}\ t^{-1}\ \|u_0\|_{L^p(\mathcal{O})}. \end{aligned}$$

The case $\gamma = 0$ of Theorem 3.4 follows. To show Theorem 3.4 for $\gamma > 0$ one can use the same computations, but one has to substitute estimate (3.13) instead of (3.12) into (3.14). □

3.3. Mesh-dependent norms. For $x \in \mathcal{V}_h$, one can define the mesh-dependent inner product

$$\langle v, w\rangle_h := h^d \sum_{i=1}^{k_h} N_i^h(v) N_i^h(w)$$

and the norm

$$\|v\|^2_{L^2_h(\mathcal{O})} := \langle v, v\rangle = h^d \sum_{i=1}^{k_h} v(N_i^h)^2.$$

It can be shown that there exist some constants c and C such that we have for all $h \in (0, 1)$ (see Lemma 6.2.7 of [BS02])

$$c\|v\|_{L^2(\mathcal{O})} \leq \|v\|_{L^2_h(\mathcal{O})} \leq C\|v\|_{L^2(\mathcal{O})} \quad \forall v \in \mathcal{V}_h.$$

Since the natural spaces for SPDEs driven by Poisson random measure are L^p spaces, we will also define mesh-dependent L^p spaces; i.e., for $0 < h \leq 1$ and $v \in \mathcal{V}_h$ we define

$$\|v\|_{L^p_h(\mathcal{O})} := \left(h^d \sum_{i=1}^{k_h} \left|N_i^h(v)\right|^p \right)^{\frac{1}{p}}$$

and

$$L^p_h(\mathcal{O}) := \{v \in \mathcal{V}_h, \|v\|_{L^p_h(\mathcal{O})} < \infty\}.$$

Similarly to the case where $p = 2$, one can show that there exist some constants c and C such that we have for all h with $0 < h \leq 1$

$$c\|v\|_{L^p(\mathcal{O})} \leq \|v\|_{L^p_h(\mathcal{O})} \leq C\|v\|_{L^p(\mathcal{O})} \quad \forall v \in \mathcal{V}_h \cap L^p(\mathcal{O}). \tag{3.16}$$

Remark 3.1. It follows from the nondegeneracy assumptions of the subdivisions that there exist some constants c and C such that

$$c\, h^d \leq k_h \leq Ch^d, \quad 0 < h < 1.$$

Theorem 1.1 of [FSS01] shows that the operator $\mathcal{A}_h : \mathcal{H}_h \to \mathcal{H}_h$ generates an analytic semigroup on $\mathcal{H}_h$ with parameter M and ω independent of h. To be precise, there exist some $\theta \in (0, \pi)$ and some $M \geq 1$ such that $\mathcal{C} \setminus \Sigma_\theta \subset \rho(\mathcal{A}_h)$, where $\rho(\mathcal{A}_h)$ denotes the resolvent set of operator $\mathcal{A}_h$ and

$$\Sigma_\theta := \{z \in \mathcal{C}, 0 \leq |\arg(z)| \leq \theta\}.$$

Let X be a Banach space and $A : X \to X$ be a operator generating an analytic semigroup on X. Since the constants M, ω, and C in

$$\left\|e^{-tA}u\right\|_X \leq M\, e^{\omega t}\, \|u\|_X$$

and

$$\left\|Ae^{-tA}u\right\|_X \leq \frac{C}{t}\, e^{\omega t}\, \|u\|_X$$

depend on the resolvent set, in particular, on the angle θ which includes the numerical range, we can conclude that there exist some constants C_1 and C_2 such that

$$\left\|e^{-t\mathcal{A}_h}u\right\|_{L^p_h(\mathcal{O})} \leq C_1\, \|u\|_{L^p_h(\mathcal{O})} \quad \forall v \in L^p_h(\mathcal{O}), \quad 0 < h \leq 1, \tag{3.17}$$

and

$$\left\|Ae^{-t\mathcal{A}_h}u\right\|_{L^p_h(\mathcal{O})} \leq \frac{C_2}{t}\, \|u\|_{L^p_h(\mathcal{O})} \quad \forall v \in L^p_h(\mathcal{O}), \quad 0 < h \leq 1. \tag{3.18}$$

For more details, see [Paz83, Theorem 2.5.2] and [FSS01].

3.4. The mass and stiffness matrix. In this section we will investigate properties of the mass and stiffness matrix. Let $\mathcal{O}$ be a polyhedron in $\mathbb{R}^d$ and $\{\mathcal{T}_h, 0 < h \leq 1\}$ be a nondegenerate family of subdivisions, where the reference finite element $(\hat{K}, \hat{\mathcal{P}}, \hat{\mathcal{N}})$ satisfies the standard conditions for $m = l = 1$.

The mass matrix $\mathbf{M}_h$ of a subdivision is given by $\mathbf{M}_h = ((m^h_{i,j}))^{k_h}_{i,j=1}$, where

$$m^h_{i,j} := \langle \phi^h_i, \phi^h_j \rangle, \quad 1 \leq i, j \leq k_h.$$

Since the shape functions are locally defined, there exists a number m such that for all $h \in (0, 1)$ there exists a set $\mathcal{C}_h \subset \mathbb{N}^{k_h} \times \mathbb{N}^{k_h}$ such that

$$\operatorname{supp}(\phi^h_i) \cap \operatorname{supp}(\phi^h_j) = \emptyset \quad \forall (i, j) \not\subset \mathcal{C}_h, \quad 0 < h \leq 1,$$

and

$$|(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h| \leq m, \quad 0 < h \leq 1.$$

Remark 3.2. The mass matrix is given by Theorem 9.8, page 387 in Ern and Guermond [EG04]. The left-hand side is given by

$$\langle \mathcal{A}_h \phi_l^h, \phi_j^h \rangle = \langle \nabla \phi_i^h, \nabla \phi_j^h \rangle.$$

Since $\{\mathcal{T}_h, 0 < h \leq 1\}$ is a uniformly bounded family of subdivisions, we have

$$\langle \nabla \phi_l^h, \nabla \phi_j^h \rangle = \begin{cases} c\, h^{d-2}, & \text{if } (i,j) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere.} \end{cases}$$

Fix some i, $1 \leq i \leq k_h$. Our point of interest is $\mathcal{A}_h^{-1}\phi_i$. Let $u_i = \mathcal{A}_h^{-1}\phi_i$. Then

$$\langle \mathcal{A}_h u_i, \phi_j^h \rangle = \langle \phi_i^h, \phi_j^h \rangle, \quad j = 1, \ldots, k_h.$$

Since $u_i \in \mathcal{V}_h$, there exists $u_{i1}, \ldots, u_{ik_h} \in \mathbb{R}$ such that

$$u_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h.$$

Therefore,

$$\langle \mathcal{A}_h u_i, \phi_j^h \rangle = \sum_{l=1}^{k_h} u_{il} \langle \mathcal{A}_h \phi_l^h, \phi_j^h \rangle = \langle \phi_i^h, \phi_j^h \rangle$$

and by Remark 3.2

$$u_{il} = \begin{cases} c\, h^2, & \text{if } (i,j) \subset C, \\ 0, & \text{elsewhere.} \end{cases} \tag{3.19}$$

3.5. Approximation of the noise. The space time Poissonian noise of jump type is given by a Poisson random measure

$$\eta : \mathcal{B}(\mathcal{O}) \times \mathcal{B}(\mathbb{R}) \times \mathcal{B}([0,\infty)) \to \mathbb{R}^+$$

with intensity $\lambda \times \nu$, where ν is a Lévy measure over $\mathbb{R}$, such that

$$\int_{\mathbb{R}} |z|^p \, \nu(dz) < \infty.$$

The function

$$g : \mathbb{R} \times \mathcal{O} \times \mathbb{R} \to \mathbb{R}$$

is Lipschitz continuous with Nemytskij operator

$$L^p(\mathcal{O}) \times \mathbb{R} \ni (u,z) \mapsto G(u;z) = g(u(\cdot);\cdot;z) \in L^p(\mathcal{O}), \tag{3.20}$$

where $g(u(\cdot);\cdot;z)(\xi) := g(u(\xi);\xi;z)$. In [Hau05] we have seen that the space time Poissonian noise can be described by a Banach-valued Poisson random measure. In particular, let $Z = B_{p,\infty}^{\frac{d}{p}-d}(\mathcal{O})$ and U be the unit sphere in Z. Let χ be defined by

$$\mathcal{O} \ni \xi \mapsto \chi(\xi) := c\, \delta_\xi \in Z,$$

where $c = |\delta_\xi|_Z^{-1}$. The intensity ι of the Z-valued Poisson random measure is given by

$$\mathcal{B}(Z) \ni B \mapsto \iota(B) := \int_{\zeta\in\mathbb{R}} \int_{x\in U} 1_B(\zeta x)\sigma(dx)\nu(d\zeta) \in \mathbb{R}^+,$$

where $\sigma(A) := \lambda(\chi^{-1}(A \cap \chi(\mathcal{O})))$, $A \in \mathcal{B}(Z)$. By inserting the definition above into the definition of the Besov space, one gets by Proposition A.1

$$\begin{aligned}\int_{z\in Z} |G(u,z) - G(v,z)|_Z^p \iota(dz) &= \int_{\xi\in\mathcal{O}} \int_{\zeta\in\mathbb{R}} |g(u(\xi),\xi;\zeta) - g(v(\xi),\xi;\zeta)|^p \,\nu(d\zeta)\,d\xi \\ &\le C\,|u-v|^p_{L^p(\mathcal{O})}, \quad u,v \in C_b^0(\mathcal{O}).\end{aligned}$$

Extension to $L^p(\mathcal{O})$ leads to the Lipschitz property (2.10) of G. The approximation can be similarly interpreted. First, the Lebesgue measure is approximated by λ_h defined by

$$\mathcal{B}\left(\{1,2,\dots,k_h\}\right) \ni A \mapsto \lambda_h(A) := \sum_{i=1}^{k_h} \lambda(J_i^h) 1_A(i) \in \mathbb{R}^+.$$

Now the approximation $\iota_h : \mathcal{B}(\{1,\dots,k_h\}) \times \mathcal{B}(\mathbb{R}) \to \mathbb{R}^+$ of the intensity ι is defined by

$$\{1,\dots,k_h\} \times \mathcal{B}(\mathbb{R}) \ni (A,B) \mapsto \iota_h(A,B) := \sum_{i=1}^{k_h} 1_A(i)\lambda_h(\{i\}) \int_{\zeta\in\mathbb{R}} \nu(d\zeta) \in \mathbb{R}^+.$$

The approximated Nemytiskij operator G_h is defined by

$$\mathcal{V}_h \times \{1,\dots,k_h\} \times \mathcal{B}(\mathbb{R}) \ni (u,i,\zeta) \mapsto G_h(u,i,\zeta) := g(u(N_i^h), N_i^h;\zeta)\, c_i^h \phi_i^h.$$

Similarly to the above we can show the following proposition.

PROPOSITION 3.1. *There exists some $C > 0$ such that for any $h > 0$ and for any $\gamma > \frac{1}{2}(d - \frac{d}{p})$ and $\delta < 2\gamma - d - \frac{d}{p}$ the following inequality holds for all $u_h, v_h \in \mathcal{V}_h$:*

$$\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \le C\, h^{d\delta p} \left\|u_h - v_h\right\|^p_{L^p(\mathcal{O})}.$$

Proof. Let $u, v \in \mathcal{V}_h$. Then we have

$$\begin{aligned}&\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \\ &= \mathbb{E}\left\|\sum_{i=1}^{k_h} \int_{\mathbb{R}} (-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,\zeta) - G_h(v_h,\zeta)\right] \mu_i^h(d\zeta,ds)\right\|^p_{L^p(\mathcal{O})},\end{aligned}$$

where μ_i^h, $i = 1,\dots,k_h$, are independent Poisson random measures with intensity $\lambda_h(i)\nu$. The generalized Burkholder inequality gives

$$\begin{aligned}&\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|^p_{L^p(\mathcal{O})} \iota_h(dz) \\ &\le \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[g(u_h(N_j^h),N_j^h;\zeta) - g(v_h(N_j^h),N_j^h;\zeta)\right] c_j^h\phi_j^h\right\|^p_{L^p(\mathcal{O})} \lambda(J_j^h)\nu(d\zeta).\end{aligned}$$

Since $g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta) \in \mathbb{R}$ and $\mathcal{A}_h$ is linear, we can continue

$$\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz) \le \sum_{j=1}^{k_h} \int_{\mathbb{R}}$$

$$\left\|\left[g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right](-\mathcal{A}_h)^{-\gamma} c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta).$$

Since the family of subdivisions is nondegenerate, we have $\left\|\phi_j^h\right\|_{L^p(\mathcal{O})}^p \sim h^{\frac{d}{p}}$, $c_j^h \sim h^{-d}$, and $\lambda(J_j^h) \sim h^d$. Therefore, by using also Remark 3.2, we get

$$\begin{aligned}
&\int_{z\in Z_h} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz)\\
&\le C \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \left\|(-\mathcal{A}_h)^{-\gamma} c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta)\\
&\le C\, h^{\gamma 2} \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \left\|c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \lambda(J_j^h)\nu(d\zeta)\\
&\le C\, h^{\gamma 2 - dp + d} \sum_{j=1}^{k_h} \int_{\mathbb{R}} \left|g(u_h(N_j^h), N_j^h; \zeta) - g(v_h(N_j^h), N_j^h; \zeta)\right|^p \lambda(J_j^h)\nu(d\zeta).
\end{aligned}$$

According to the Lipschitz condition of g we have

$$\begin{aligned}
&\int_{z\in Z} \left\|(-\mathcal{A}_h)^{-\gamma}\left[G_h(u_h,z) - G_h(v_h,z)\right]\right\|_{L^p(\mathcal{O})}^p \iota_h(dz)\\
&\qquad \le C\, h^{\gamma 2 - dp + d} \sum_{j=1}^{k_h} h^d \left|u_h(N_j^h) - v_h(N_j^h)\right|^p.
\end{aligned}$$

The equivalence between $L^p(\mathcal{O})$ and $L_h^p(\mathcal{O})$ gives the assertion. ∎

In order to calculate the error induced by the approximation of the Poisson random measure, we have to express the measure ι_h in terms of ι.

PROPOSITION 3.2. *There exists some $C > 0$ such that for any $h > 0$ and for any $\gamma > \frac{1}{2}(d - \frac{d}{p})$ and $\delta < 2\gamma - d - \frac{d}{p}$ the following inequality holds for all $u_h \in \mathcal{V}_h$:*

$$\int_Z \left\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u,z)\right\|_{L^p(\mathcal{O})}^p (\iota - \iota_h)(dz) \le C\, h^{d\delta p}\left(1 + \|u_h\|_{L^p(\mathcal{O})}^p\right).$$

Remark 3.3. In our calculation we use the fact that for $\gamma > d - \frac{d}{p}$ in $W^{p,-\gamma}(\mathcal{O})$ the noise vanishes for $h \to 0$. But, by plugging the difference $\iota - \iota_h$ into the definition of Z, one can show directly that the approximated noise converges to the functional-valued representation of the space time Poissonian noise in Z.

Proof. Embedding Z_h into Z by $i \mapsto c_i^h \phi_i^h$ leads to

$$\begin{aligned}
&\int_Z \left\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u,z)\right\|_{L^p(\mathcal{O})}^p \ (\iota-\iota_h)(dz) \leq \int_{\xi\in\mathcal{O}}\int_{\zeta\in\mathbb{R}} \\
&\quad \left\|(-\mathcal{A}_h)^{-\gamma}\left[\mathcal{I}_h G(u,z)\delta_\xi - \sum_{j=1}^{k_h} 1_{J_j^h}(\xi) g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|_{L^p(\mathcal{O})}^p d\zeta\ d\xi \\
&\leq \sum_{i=1}^{k_h}\int_{\xi\in J_i^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right.\right. \\
&\qquad\qquad \left.\left. - \sum_{j=1}^{k_h} 1_{J_j^h}(\xi) g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|_{L^p(\mathcal{O})}^p d\zeta\ d\xi \\
&\leq \sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right]\right\|_{L^p(\mathcal{O})}^p d\zeta\ d\xi \\
&+ \sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[g(u(N_j^h),N_j^h,\zeta)c_j^h\phi_j^h\right]\right\|_{L^p(\mathcal{O})}^p d\zeta\ d\xi \\
&=: S_1 + S_2.
\end{aligned}$$

By Corollary 3.1 we obtain

$$S_1 \leq h^{-\delta p}\sum_{j=1}^{k_h}\int_{\xi\in J_j^h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\delta_\xi\right]\right\|_Z^p d\zeta\ d\xi.$$

Inequality (A.1) leads to

$$S_1 \leq C\ h^{-\delta p}\sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma}\left[\sum_{l=1}^{k_h} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\right]\right\|_{L^p(J_j^h)}^p d\zeta.$$

Since there exists a constant m such that $|\{i \mid \sup\phi_i^h \cap J_j^h \neq \emptyset\}| \leq m$ for all $i,j = 1,\dots,k_h$ and $h>0$, and $\sum_{i=1}^{k_h}\phi_i^h(\xi) = 1$, we can infer by Remark 3.2 that

$$\begin{aligned}
S_1 &\leq C\ h^{(2\gamma-\delta)p}\sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|\sum_{l,\sup\phi_l^h\cap J_j^h\neq\emptyset} g(u(N_l^h),N_l^h,\zeta)\phi_l^h\right\|_{L^p(J_j^h)}^p d\zeta \\
&\leq C\ h^{(2\gamma-\delta)p}\ m\ \sum_{j=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left\|g(u(N_j^h),N_j^h,\zeta)\phi_j^h\right\|_{L^p(\mathcal{O})}^p d\zeta.
\end{aligned}$$

By the linearity of g and the equivalence of $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ we get

$$S_1 \leq C\ h^{(2\gamma-\delta)p} m\ \left(1 + \sum_{j=1}^{k_h} h^d\ \left|u(N_j^h)\right|^p\right) \leq h^{(2\gamma-\delta)p}\ m\ \left(1 + |u|_{L^p(\mathcal{O})}^p\right).$$

By applying Remark 3.19 we get for S_2

$$\begin{aligned}
S_2 &\le \sum_{j=1}^{k_h} \lambda(J_j^h) \int_{\zeta\in\mathbb{R}} \left\|(-\mathcal{A}_h)^{-\gamma} g(u(N_j^h), N_j^h, \zeta) c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p} \sum_{j=1}^{k_h} \lambda(J_j^h) \int_{\zeta\in\mathbb{R}} \left\|g(u(N_j^h), N_j^h, \zeta) c_j^h \phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p - dp} \sum_{j=1}^{k_h} \lambda(J_j^h) h^d \int_{\zeta\in\mathbb{R}} \left|g(u(N_j^h), N_j^h, \zeta)\right| \left\|\phi_j^h\right\|_{L^p(\mathcal{O})}^p \, d\zeta \\
&\le C\, h^{2\gamma p - dp + d} \sum_{j=1}^{k_h} \lambda(J_j^h) h^d \int_{\zeta\in\mathbb{R}} \left|g(u(N_j^h), N_j^h, \zeta)\right| \, d\zeta \,.
\end{aligned}$$

The linearity of g and the equivalence of $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ give

$$S_2 \le C\, h^{2\gamma p - dp + d} \left(1 + \|u\|_{L^p(\mathcal{O})}^p\right). \qquad \square$$

4. Stability of the finite element approximation. In this section we shall investigate the stability of the approximation by finite elements. Since the semidiscrete problem (2.3) is finite-dimensional, for all $0 < h \le 1$ there exists a unique solution $u_h = \{u_h(t) \in \mathbb{R}^{k_h}, 0 \le t < \infty\}$ (see, e.g., Theorem 8 of [Pro04]). In this section we show that the family of unique solution $\{u_h, 0 < h \le 1\}$ is uniformly bounded.

THEOREM 4.1. *Let $u_h = \{u_h(t), 0 \le t < \infty\}$ be a solution to problem (2.3). Then, under the conditions of Theorem 2.1, for all $p \in (1, 2]$, with $p < \frac{2}{d} + 1$, and for all $T > 0$ there exists some constant such that*

$$\sup_{0\le t\le T} \mathbb{E}\, \|u_h(t)\|_{L^p(\mathcal{O})}^p \le C, \quad 0 < h \le 1.$$

Proof. First, we show that there exist some $q < \infty$ and some constants C_1 and C_2 such that

$$(\mathbb{E}\|u_h(t)\|^p)^q \le C_1 + C_2 \int_0^t (\mathbb{E}\, \|u_h(s)\|^p)^q \, ds, \quad t > 0 \text{ and } 0 < h \le 1.$$

The Gronwall lemma yields the assertion. The variation of constant formula gives

$$\begin{aligned}
u_h(t) = e^{-t\mathcal{A}_h} u_h(0) &+ \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \\
&+ \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i\in\mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}_h^i(d\zeta_i; ds), \quad t > 0.
\end{aligned}$$

Taking the expectation leads to

$$\begin{aligned}
\mathbb{E}\, \|u_h(t)\|_{L^p(\mathcal{O}}^p &\le C_p \left\|e^{-t\mathcal{A}_h}\, u_h(0)\right\|_{L^p(\mathcal{O})}^p \\
&+ C_p \mathbb{E} \left\| \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \right\|_{L^p(\mathcal{O})}^p \\
&+ C_p \mathbb{E} \left\| \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i\in\mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}_h^i(d\zeta_i; ds) \right\|_{L^p}^p \\
&=: S_1 + S_2 + S_3.
\end{aligned}$$

If $u_0 \in L^p(\mathcal{O})$, then the first entity S_1 is finite. The second entity can be calculated directly. The Minkowski inequality gives

$$\begin{aligned} S_2 &= \mathbb{E} \left\| \int_0^t e^{-(t-s)\mathcal{A}_h} f_h(u_h(s))\, ds \right\|^p_{L^p(\mathcal{O})} \\ &\leq \mathbb{E} \left(\int_0^t \left\| e^{-(t-s)\mathcal{A}_h} f_h(u_h(s)) \right\|_{L^p(\mathcal{O})} ds \right)^p. \end{aligned}$$

In section 3.2 we have seen that there exist $\omega \in \mathbb{R}$, $M \geq 1$, and $\theta \in (0, \pi)$ such that for all $h \in (0,1)$ the operator $\mathcal{A}_h$ generates an analytic semigroup of (ω, M, θ) on $L^p_h(\mathcal{O})$ and the inequality (3.17) holds. In section 3.3 we have seen that there exist some constants c and C such that for all $0 < h \leq 1$ we have (see (3.16))

$$c \|w\|_{L^p(\mathcal{O})} \leq \|w_h\|_{L^p_h(\mathcal{O})} \leq C \|w\|_{L^p(\mathcal{O})}, \quad w \in \mathcal{V}_h \tag{4.1}$$

where

$$\|w\|_{L^p_h(\mathcal{O})} := h^d \sum_{i=1}^{k_h} |w_h(N_i)|^p, \quad w \in \mathcal{V}_h.$$

Therefore, a constant $C < \infty$ exists such that for all $0 < h \leq 1$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L^p(\mathcal{O})} \leq C \|v\|_{L^p(\mathcal{O})}, \quad v \in L^p(\mathcal{O}) \cap \mathcal{V}_h. \tag{4.2}$$

Thus,

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \|f_h(u_h(s))\|_{L^p(\mathcal{O})}\, ds \right)^p.$$

Again by (4.1) we can infer that

$$S_2 \ \leq C\, \mathbb{E} \left(\int_0^t \|f(u_h(s))\|_{L^p_h(\mathcal{O})}\, ds \right)^p.$$

By the globally Lipschitz property of f it follows that

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \left(1 + \|u_h(s)\|_{L^p_h(\mathcal{O})} \right) ds \right)^p.$$

Again by (4.1) we get

$$S_2 \leq C\, \mathbb{E} \left(\int_0^t \left(1 + \|u_h(s)\|_{L^p(\mathcal{O})} \right) ds \right)^p.$$

The Hölder inequality leads to

$$S_2 \leq C\, t^p \left(1 + \sup_{0 \leq s \leq t} \mathbb{E} \|u_h(s)\|^p_{L^p(\mathcal{O})} \right).$$

Next, we estimate the term

$$S_3 = \mathbb{E} \left\| \int_0^t \sum_{i=1}^{k_h} \int_{\zeta_i \in \mathbb{R}} e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i, \zeta_i)\, \tilde{\eta}^i_h(d\zeta_i; ds) \right\|^p_{L^p(\mathcal{O})}.$$

Since $L^p(\mathcal{O})$ is of M-type p, we can infer by Proposition 3.3 in [Hau05]

$$S_3 \leq \mathbb{E} \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| e^{-(t-s)\mathcal{A}_h} g_h(u_h(s); i; \zeta_i) \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

In section 3.2 we have seen that there exist $\omega \in \mathbb{R}$, $M \geq 1$, and $\theta \in (0, \pi)$ such that for all $h \in (0,1)$ the operator $\mathcal{A}_h$ generates an analytic semigroup of (ω, M, θ) on $L^p(\mathcal{O})$. In particular (3.18) holds; i.e., there exists a constant $C < \infty$ such that for all $h > 0$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L_h^p(\mathcal{O})} \leq \frac{C}{t} \|v\|_{L_h^p(\mathcal{O})}, \quad v \in L_h^p(\mathcal{O}). \tag{4.3}$$

Because of inequality (4.3), and since the norms in $L_h^p(\mathcal{O})$ and $L^p(\mathcal{O})$ are equivalent, we have for all $\gamma < \frac{1}{p}$

$$S_3 \leq \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| \mathcal{A}_h^{-\gamma} g_h(u_h(s); i, \zeta_i) \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

Since $g_h(u_h(s); i, \zeta) = N_i(G(u_h(s); \zeta_i))\phi_i$ and since $\mathcal{A}_h$ is linear, we get

$$S_3 \leq \int_0^t \frac{1}{k_h} \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| N_i(G(u_h(s); \zeta_i)) \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^p(\mathcal{O})}^p \nu(d\zeta_i)\, ds.$$

The Hölder inequality gives

$$\begin{aligned} S_3 \leq & \int_0^t \frac{1}{k_h} \\ & \sum_{i=1}^{k_h} (t-s)^{-\gamma p} \int_{\zeta_i \in \mathbb{R}} \mathbb{E} \left\| N_i(G(u_h(s); \zeta_i)) \right\|_{L^p(\mathcal{O})}^p \left\| \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^\infty(\mathcal{O})}^p \nu(d\zeta_i)\, ds. \end{aligned} \tag{4.4}$$

Moreover, by (3.19) we know that for any $i = 1, \ldots, k_h$ we have

$$\mathcal{A}_h^{-\gamma} \phi_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h,$$

where

$$u_{il} = \begin{cases} c\, h^{2\gamma}, & \text{if } (i,l) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere,} \end{cases}$$

and there exists some constant m_0 such that for any i and $0 < h < 1$

$$\left| \{(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h \right| \leq m_0. \tag{4.5}$$

Therefore, we have

$$\left\| \mathcal{A}_h^{-\gamma} \phi_i \right\|_{L^\infty(\mathcal{O})} \leq m_0 h^{2\gamma}. \tag{4.6}$$

By substituting (4.6) in (4.4) we obtain

$$S_3 \leq \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)$$
$$(t-s)^{-\gamma p}\, m_0\, h^{2\gamma p} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta)\right\|^p_{L^p(\mathcal{O})}\, \nu(d\zeta_i)\, ds. \tag{4.7}$$

The inverse inequality given in Corollary 3.1 gives for all $\delta > d - \frac{d}{p}$

$$\begin{aligned} S_3 &\leq \int_0^t C \sum_{i=1}^{k_h} \lambda(J_i^h) \\ &\quad (t-s)^{-\gamma p}\, h^{2\gamma p-\delta p} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta_i)\right\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \nu(d\zeta)\, ds \\ &\leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \int_{\zeta_i\in\mathbb{R}} \mathbb{E}\left\|g(u_h(s,N_i^h),N_i^h;\zeta)\right\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \nu(d\zeta)\, ds, \end{aligned}$$

which gives

$$S_3 \leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \int_{\zeta_i\in\mathbb{R}} \mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\, \nu(d\zeta)\, ds.$$

The mapping g is linear in the last variable and globally Lipschitz in the first variable. Thus we can infer that

$$S_3 \leq C \int_0^t \sum_{i=1}^{k_h} \lambda(J_i^h)(t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \left(1 + \mathbb{E}\left|u_h(s,N_i^h)\right|^p\right)\, ds.$$

By the equivalence of the $L^p_h(\mathcal{O})$ and $L^p(\mathcal{O})$ norms we infer that

$$S_3 \leq C \int_0^t (t-s)^{-\gamma p}\, h^{(2\gamma-\delta)p} \left(1 + \mathbb{E}\left|u_h(s)\right|^p_{L^p(\mathcal{O})}\right)\, ds.$$

Let q be so large that $\gamma p < 1 - \frac{1}{q}$. Since there exists a $\delta > d - \frac{d}{p}$ such that $2\gamma - \delta > 0$, the Hölder inequality gives

$$\left(\mathbb{E}\left|S_3\right|\right)^q \leq c(t) \int_0^t \left(1 + \mathbb{E}\left|u_h(s)\right|^p_{L^p(\mathcal{O})}\right)^q\, ds.$$

Summing up leads to the assertion. □

5. Proof of the main result. The error of the time discretization follows from Theorem 3.1 of [HM06a]. By the Lipschitz continuity of f and g we infer that

$$\int_{z\in Z} \|G(u;z)\|^p_{B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O})}\, \iota(dz) \leq C\|u\|^p_{L^p(\mathcal{O})}, \quad u \in L^p(\mathcal{O}),$$

and

$$\|F(u)\|_{L^p(\mathcal{O})} \leq C\|u\|_{L^p(\mathcal{O})}, \quad u \in L^p(\mathcal{O}).$$

Thus, Theorem 3.1 of [HM06a] gives the order of convergence in time for $\alpha < \frac{2}{p} - d + \frac{d}{p}$. Here we investigate the accuracy of the space discretization, i.e., the difference $\Delta(t) = u(t) - u_h(t)\mathcal{I}_h$ at time t. To show the assertion, we will show that for a certain $q < \infty$ there exist constants C_1, C_2, and C_3 such that for all $0 < h \le 1$

$$\begin{aligned} &\left(\mathbb{E}\,\|\Delta(t)\|^p_{L^p(\mathcal{O})}\right)^q \\ &\le \frac{C_1}{t^q}\, h^{pq\delta_1} + C_2\, h^{pq\delta_2} + C_3\, h^{pq\delta_3} + C_4 \int_0^t \left(\mathbb{E}\,\|\Delta(t)\|^p_{L^p(\mathcal{O})}\right)^q ds \end{aligned} \tag{5.1}$$

where δ_1, δ_2, and δ_3 are the constants specified in Theorem 2.1. Now the second part of the assertion of Theorem 2.1 follows by an extension of Grownwall's lemma which is a simple consequence of Exercise 3, page 190 in [Hen81] and the proof of which is omitted.

LEMMA 5.1 (Gronwall-type lemma). *Suppose that $\alpha > 0$ and $c_1, c_2, c_3 > 0$. Assume that $u : \mathbb{R}^+ \to \mathbb{R}^+$ is a measurable function such that the function $t \mapsto t^{1-\alpha}u(t)$ is locally integrable on $\mathbb{R}^+$ and a.s. on $\mathbb{R}^+$,*

$$u(t) \le c_1 t^{\alpha-1} + c_2 + c_3 \int_0^t u(s)\, ds.$$

Then, a.s. on $\mathbb{R}^+$,

$$u(t) \le \left(c_1 t^{\alpha-1}\Gamma(\alpha) + c_2\right) \sum_{m=0}^{\infty} \frac{[c_3 t]^m}{\Gamma(m+\alpha)}.$$

To show the second part of Theorem 2.1, we will show the following: Let q and γ be two real numbers such that

$$d - \frac{d}{p} < \gamma < 2p \quad \text{and} \quad \frac{\gamma p}{2} < 1 - \frac{1}{q} \tag{5.2}$$

are satisfied. Then under the conditions of Theorem 2.1 for all δ_1, δ_2, and δ_3, with

$$\delta_1 = 2 - \frac{d}{p} + \frac{d}{2}, \quad \delta_2 < \frac{2}{p} - d + \frac{d}{p}, \text{ and } \delta_3 < \left(\frac{2}{p} - d + \frac{d}{p}\right)\left(2 + \frac{d}{2} - \frac{d}{p}\right),$$

there exist constants C_1, C_2, and C_3 depending on p, f, g, δ_1, δ_2, and δ_3 such that for all $0 < h \le 1$ inequality (5.1) holds.

Proof. By using the variation of constants formula, i.e.,

$$\begin{aligned} u(t) = e^{-At}u_0 &+ \int_0^t e^{-A(t-s)} f(u(s-))\, ds \\ &+ \int_{0^+}^t \int_Z e^{-A(t-s)} g(u(s-); z)\eta(ds; dz) \end{aligned}$$

and

$$\begin{aligned} u_h(t) = e^{-\mathcal{A}_h t}u_0 &+ \int_0^t e^{-\mathcal{A}_h(t-s)} f(u(s-))\, ds \\ &+ \int_{0^+}^t \int_Z e^{-\mathcal{A}_h(t-s)} g u(s-); z)\eta(ds; dz), \end{aligned}$$

we obtain

$$u(t) - u_h(t) = \sum_{i=1}^{6} I_{ni}(t), \tag{5.3}$$

where

$$\begin{aligned}
I_0(t) &= \left(e^{-At} - e^{-\mathcal{A}_h t}\right) u_0,\\
I_1(t) &= \int_{0+}^{t} \left(e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right) f(u(s))\, ds,\\
I_2(t) &= \int_{0+}^{t} e^{-\mathcal{A}_h(t-s)} \left(\mathcal{I}_h f(u(s)) - f_h(u_h(s))\right)\, ds,\\
I_3(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)} \left(g(u(s);z) - g(u_h(s);z)\right)\, \tilde{\eta}(ds;dz),\\
I_4(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)} \left(I - \mathcal{I}_h\right) g(u_h(s);z)\, \tilde{\eta}(ds;dz),\\
I_5(t) &= \int_{0+}^{t}\int_{Z} e^{-A(t-s)}\mathcal{I}_h g(u_h(s);z)\, \tilde{\eta}(ds;dz)\\
&\quad - \int_{0+}^{t}\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}} e^{-A(t-s)} g_h(u_h(s);i;\zeta)\, \tilde{\eta}_h^i(ds,d\zeta),\\
I_6(t) &= \int_{0+}^{t}\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}} \left(e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\right) g_h(u_h(s);i;\zeta)\, \tilde{\eta}_h^i(ds;d\zeta).
\end{aligned}$$

By substituting (5.3), we get

$$\mathbb{E}\left[\|\Delta(t)\|^p\right] \leq C \cdot \sum_{i=0}^{4} \mathbb{E}\left[\|I_i(t)\|^p\right].$$

To give an estimate of $\mathbb{E}\left[\|I_0(t)\|^p\right]$, we apply Theorem 3.1. Thus, we get

$$\mathbb{E}\left[\|I_0(t)\|^p\right] \leq \frac{C}{t}\, h^{p\left(2-\frac{d}{p}+\frac{d}{2}\right)}\, \|u_0\|^p_{L^p(\mathcal{O})}. \tag{5.4}$$

The next entity we have to estimate is

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})} \leq \mathbb{E}\left(\int_{0+}^{t} \left\|e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h f(u(s))\right\|_{L^p(\mathcal{O})}\, ds\right)^p.$$

In Theorem 3.4, the factor t^{-1} appears on the right-hand side. Thus, fix $\gamma < 1$, take into account

$$\left\|e^{-A(t-s)} - e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))} \leq C,$$

and apply Theorem 3.4. Thus, we get

$$\begin{aligned}
&\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\\
&\le C\,\left(\int_{0+}^t \left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C\,\Big(\int_{0+}^t \left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|^{\gamma}_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\\
&\quad\times\left\|e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\mathcal{I}_h\right\|^{1-\gamma}_{L(L^p(\mathcal{O}),L^p(\mathcal{O}))}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\Big)^p\\
&\le C\,h^{\gamma(2-\frac{d}{p}+\frac{d}{2})p}\,\left(\int_{0+}^t (t-s)^{-\gamma}\,\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C(\gamma)\,h^{\gamma(2-\frac{d}{p}+\frac{d}{2})p}\sup_{0\le t\le T}\mathbb{E}\,\|f(u(s))\|^p_{L^p(\mathcal{O})}\,,
\end{aligned}$$

where

$$C(\gamma)=\frac{C'}{1-\gamma}.$$

The Lipschitz property of f gives

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\le C\,h^{p(2-\frac{d}{p}+\frac{d}{2})\gamma}\,\left(1+\sup_{0\le s\le t}\mathbb{E}\,\|u(s)\|^p_{L^p(\mathcal{O})}\right).$$

Since $u\in L^p(\Omega;L^p(\mathcal{O}))$, there exists some C such that

$$\mathbb{E}\,\|I_1(t)\|^p_{L^p(\mathcal{O})}\le C\,h^{p(2-\frac{d}{p}+\frac{d}{2})\gamma},\quad 0<h<1. \tag{5.5}$$

In section 3.3 we have shown that $\mathcal{A}_h$ generates a semigroup in $L^p_h(\mathcal{O})$. Thus, by the Minkowski inequality (4.2) and by the equivalence of the norms in $L^p(\mathcal{O})$ and $L^p_h(\mathcal{O})$, i.e., (3.16), we can write

$$\begin{aligned}
\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}&\le\mathbb{E}\left(\int_{0+}^t\|\mathcal{I}_hf(u(s))-f_h(u_h(s))\|_{L^p(\mathcal{O})}\,ds\right)^p\\
&\le C\,\mathbb{E}\left(\int_{0+}^t\|\mathcal{I}_hf(u(s))-f_h(u_h(s))\|_{L^p_h(\mathcal{O})}\,ds\right)^p.
\end{aligned}$$

The mapping f is Lipschitz continuous, and therefore

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\left(\int_{0+}^t\|\mathcal{I}_hu(s)-u_h(s)\|_{L^p_h(\mathcal{O})}\,ds\right)^p.$$

Again, by the equivalence of the norms in $L^p(\mathcal{O})$ and $L^p_h(\mathcal{O})$, we can infer that

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\left(\int_{0+}^t\|u(s)-u_h(s)\|_{L^p(\mathcal{O})}\,ds\right)^p.$$

The Hölder inequality gives

$$\mathbb{E}\,\|I_2(t)\|^p_{L^p(\mathcal{O})}\le C\,\mathbb{E}\int_{0+}^t\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\,ds. \tag{5.6}$$

Next, we handle the third term. The generalized Burkholder inequality (compare Proposition 3.3 in [Hau05]) gives

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z \mathbb{E}\left\|e^{-A(t-s)}\left(g(u(s);z)-g(u_h(s);z)\right)\right\|^p_{L^p(\mathcal{O})}\,\iota(dz)\,ds.$$

The operator A generates an analytic semigroup in $L^p(\mathcal{O})$ (see, e.g., Theorem 7.3.5 in [Paz83]). Therefore, for each $\rho>0$ there exists some constant $C<\infty$ such that

$$\left\|e^{-(t-s)A}Av\right\|_{W_p^{-\rho}(\mathcal{O})} \leq \frac{C}{t^{\frac{\rho}{2}}}\,\|v\|_{L^p(\mathcal{O})}\,,\quad v\in L^p(\mathcal{O}). \tag{5.7}$$

Thus, we can infer for any $\gamma>0$ that

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|g(u(s);z)-g(u_h(s);z)\|^p_{W_p^{-\gamma}(\mathcal{O})}\,\iota(dz)\,ds.$$

By Sobolev inequalities for any $\gamma > d-\frac{d}{p}$ we have $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously. Therefore,

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|(g(u(s);z)-g(u_h(s);z))\|^p_Z\,\iota(dz)\,ds.$$

The Lipschitz property of g leads to

$$\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t (t-s)^{-\frac{\gamma p}{2}}\,\mathbb{E}\,\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\,ds.$$

If γ satisfies (5.2), then $\frac{\gamma p}{2} < 1-\frac{1}{q}$, and we can infer by the Hölder inequality that

$$\left(\mathbb{E}\,\|I_3(t)\|^p_{L^p(\mathcal{O})}\right)^q \leq c(t)\int_0^t \left(\mathbb{E}\,\|u(s)-u_h(s)\|^p_{L^p(\mathcal{O})}\right)^q ds. \tag{5.8}$$

By arguments similar to those used in Proposition 3.2 in [Hau05] we get for the fourth term

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \leq \int_{0+}^t \int_Z \mathbb{E}\left\|e^{-A(t-s)}\left(I-\mathcal{I}_h\right)g(u_h(s);z)\right\|^p_{L^p(\mathcal{O})}\,\nu(dz)\,ds.$$

By the smoothing property of A, i.e., (5.7), and since $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously for all $\gamma > d-\frac{d}{p}$, we obtain for any $\rho < \frac{2}{p}-d+\frac{d}{p}$

$$\begin{aligned}
&\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})}\\
&\leq \int_{0+}^t (t-s)^{-\frac{p}{2}\left(\rho+d-\frac{d}{p}\right)} \int_Z \mathbb{E}\left\|A^{-\rho}\left(I-\mathcal{I}_h\right)G(u_h(s);z)\right\|^p_Z\,\iota(dz)\,ds\\
&\leq \int_{0+}^t (t-s)^{-\frac{p}{2}\left(\rho+d-\frac{d}{p}\right)} \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\|A^{-\rho}\left(I-\mathcal{I}_h\right)g(u_h(s),\cdot,\zeta)\right\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)\,ds,
\end{aligned}$$

where G is defined in (3.20). Theorem 3.1 leads to

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \leq C(t)\,h^{p\rho}\sup_{0\leq s\leq t}\int_{\zeta\in\mathbb{R}}\mathbb{E}\,\|g(u_h(s),\cdot;\zeta)\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)$$

and the Lipschitz property of g to

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \le C(t)\,h^{p\rho}\,\Big(1+\sup_{0\le s\le t}\mathbb{E}\,\|u_h(s)\|^p_{L^p(\mathcal{O})}\Big).$$

By Proposition 4.1 there exists some constant $C<\infty$ such that

$$\sup_{0\le s\le t}\mathbb{E}\,\|u_h(s)\|^p_{L^p(\mathcal{O})} \le C, \quad h>0.$$

Thus, we can infer that there exists some constant $C'<\infty$ such that

$$\mathbb{E}\,\|I_4(t)\|^p_{L^p(\mathcal{O})} \le C'\,h^{p\rho}, \quad 0\le t\le T. \tag{5.9}$$

The Burkholder inequality leads for any $\frac{1}{2}(d-\frac{d}{p})<\gamma<\frac{1}{p}$ to

$$\begin{aligned}
&\mathbb{E}\,\|I_5(t)\|^p_{L^p(\mathcal{O})}\\
&\le \int_0^t\int_Z \Big\|(-\mathcal{A}_h)^{\gamma}e^{-A(t-s)}(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u(t),z)\Big\|^p_{L^p(\mathcal{O})}\ (\iota-\iota_h)(dz)\\
&\le \int_0^t (t-s)^{-\gamma p}\,dt \times \sup_{0\le t\le T}\int_Z \big\|(-\mathcal{A}_h)^{-\gamma}\mathcal{I}_h G(u(t),z)\big\|^p_{L^p(\mathcal{O})}\ (\iota-\iota_h)(dz).
\end{aligned}$$

Proposition 3.2 gives for any $0\le\delta<\frac{1}{p}-\frac{1}{2}(d-\frac{d}{p})$

$$\mathbb{E}\,\|I_5(t)\|^p_{L^p(\mathcal{O})} \le C\,\frac{h^{\delta p}}{p\gamma-1}. \tag{5.10}$$

Next, we have to calculate the entity I_6. The Fubini theorem and the generalized Burkholder inequality give

$$\begin{aligned}
\mathbb{E}\,\|I_6(t)\|^p_{L^p(\mathcal{O})} &= \mathbb{E}\left\|\int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\Big(e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\Big)\,g_h(u_h(s);i,\zeta)\,\tilde{\eta}^i_h(ds;dz)\right\|^p_{L^p(\mathcal{O})}\\
&\le \mathbb{E}\int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\Big\|\Big(e^{-A(t-s)}-e^{-\mathcal{A}_h(t-s)}\Big)\,g_h(u_h(s);i,\zeta)\Big\|^p_{L^p(\mathcal{O})}\,\nu^i(d\zeta)\,ds\\
&\le \int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\mathbb{E}\Big\|\Big(e^{-\frac{1}{2}A(t-s)}\\
&\qquad -e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\Big)e^{-\frac{1}{2}A(t-s)}g_h(u_h(s);i,\zeta)\Big\|^p_{L^p(\mathcal{O})}\,\nu^i(d\zeta)\,ds\\
&+ \int_{0+}^t\sum_{i=1}^{k_h}\int_{\zeta\in\mathbb{R}}\mathbb{E}\Big\|e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\Big(e^{-\frac{1}{2}A(t-s)}\\
&\qquad -e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\Big)g_h(u_h(s);i,\zeta)\Big\|^p_{L^p(\mathcal{O})}\,\nu^i(d\zeta)\,ds\\
&:= I_{61}+I_{62}.
\end{aligned}$$

First, in Theorem 3.4 we have shown that

$$\Big\|\Big[e^{-\frac{1}{2}A(t-s)}-e^{-\frac{1}{2}\mathcal{A}_h(t-s)}\mathcal{I}_h\Big]\,u\Big\|_{L^p(\mathcal{O})} \le \frac{C}{t}\,h^{2+\frac{d}{2}-\frac{d}{p}}\|u\|_{L^p(\mathcal{O})}\ \forall u\in L^p(\mathcal{O}). \tag{5.11}$$

Let us recall estimate (3.17). There exists a constant $C<\infty$ such that for all $h>0$ and $v\in L^p_h(\mathcal{O})\cap\mathcal{V}_h$

$$\left\|e^{-(t-s)\mathcal{A}_h}v\right\|_{L^p_h}\leq C\left\|v\right\|_{L^p_h},\quad v\in L^p_h.$$

Moreover, the norms in $L^p_h(\mathcal{O})$ and in $L^p(\mathcal{O})$ are equivalent (see (3.16)). Therefore

$$\left\|e^{-(t-s)\mathcal{A}_h}v\right\|_{L^p_h}\leq C\left\|v\right\|_{L^p(\mathcal{O})},\quad v\in L^p_h(\mathcal{O}).$$

Thus, we can infer for any $\gamma\in(0,1)$ that

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\\&\times\int_{0+}^t(t-s)^{-\frac{\gamma p}{2}}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|e^{-\frac{1}{2}A(t-s)}g_h(u_h(s);i,\zeta)\right\|^p_{L^p(\mathcal{O})}\,\nu(d\zeta)\,ds\end{aligned}$$

holds. The operator A generates an analytic semigroup in $L^p(\mathcal{O})$. Therefore, for each $\rho>0$ there exists some constant $C<\infty$ such that

$$\left\|e^{-tA}Av\right\|_{L^p(\mathcal{O})}\leq\frac{C}{t^{\frac{\rho}{2}}}\left\|v\right\|_{W_p^{-\rho}(\mathcal{O})},\quad v\in W_p^{-\rho}(\mathcal{O}),\ t>0.\tag{5.12}$$

Inequality (5.12) leads for all $\rho\geq0$, with $p(\gamma+\rho)<2$, to

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\\&\quad\times\int_{0+}^t(t-s)^{-\frac{p}{2}(\gamma+\rho)}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{W_p^{-\rho}(\mathcal{O})}\,\nu(d\zeta)\,ds\\&\leq C(\gamma,\rho)\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{W_p^{-\rho}(\mathcal{O})}\,\nu(d\zeta),\end{aligned}$$

where

$$C(\gamma,\rho)=\frac{C'}{2-p(\gamma+\rho)}.$$

By Sobolev inequalities, we know that $L^1(\mathcal{O})\hookrightarrow W_p^{-\rho}(\mathcal{O})$ continuously. Thus we obtain

$$\begin{aligned}I_{61}&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left\|g_h(u_h(s);i,\zeta)\right\|^p_{L^1(\mathcal{O})}\,\nu(d\zeta)\\&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\left\|c_i^h\phi_i^h\right\|^p_{L^1(\mathcal{O})}\,\nu(d\zeta)\\&\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\int_{\zeta\in\mathbb{R}}\mathbb{E}\left|g(u_h(s,N_i^h),N_i^h;\zeta)\right|^p\,\nu(d\zeta).\end{aligned}$$

Since g is Lipschitz continuous and linear in the third variable, we get

$$I_{61}\leq C\,h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\sup_{0\leq s\leq t}\sum_{i=1}^{k_h}\lambda(J_i^h)\left(1+\mathbb{E}\left\|u_h(s,N_i^h)\right\|^p_{L^p_h}\right)\,ds.$$

In section 3.3 we have seen that there exist some constants c and C such that for all $0 < h < 1$ we have (see (3.16))

$$c \|w\|_{L^p(\mathcal{O})} \leq h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \|w_h\|_{L_h^p} \leq C \|w\|_{L^p(\mathcal{O})}, \quad w \in \mathcal{V}_h.$$

Thus, by taking into account Remark 3.1 we can write

$$I_{61} \leq Ct^{1-p(\gamma+\rho)} h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \sup_{0\leq s\leq t} \left(1 + \mathbb{E}\|u_h(s)\|^p_{L^p(\mathcal{O})}\right).$$

Since $\mathbb{E}\|u_h(s)\|^p_{L^p(\mathcal{O})}$ is bounded, there exists a constant $C < \infty$ such that

$$I_{61} \leq Ct^{1-p(\gamma+\rho)} h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}. \tag{5.13}$$

Next, we have to handle the term I_{62}. Because of (3.18) and (3.16), there exists a constant $C < \infty$ such that for all $0 < h \leq 1$

$$\left\| e^{-(t-s)\mathcal{A}_h} \mathcal{A}_h v \right\|_{L^p(\mathcal{O})} \leq \frac{C}{t} \|v\|_{L^p(\mathcal{O})}, \quad v \in L^p(\mathcal{O}). \tag{5.14}$$

Because of inequality (5.14), we have for all $0 < \delta < \frac{1}{p}$

$$\begin{aligned} I_{62} \leq & \int_0^t (t-s)^{-\delta p} \sum_{i=1}^{k_h} \lambda(J_i^h) \\ & \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\| (-\mathcal{A}_h)^{-\delta} \left(\mathcal{I}_h e^{-\frac{1}{2}A(t-s)} - e^{-\frac{1}{2}\mathcal{A}_h(t-s)} \right) g_h(u_h(s); i, \zeta) \right\|^p_{L^p(\mathcal{O})} \nu(d\zeta)\, ds. \end{aligned} \tag{5.15}$$

In Remark 3.1 we have shown that there exist some constants c and C such that $h^d \leq ck_h \leq h^d$. By (3.19) we know that for any $i = 1, \ldots, k_h$ we have

$$(-\mathcal{A}_h)^{-\delta} \phi_i = \sum_{l=1}^{k_h} u_{il} \phi_l^h, \tag{5.16}$$

where

$$u_{il} = \begin{cases} c\, h^{2\delta}, & \text{if } (i,l) \subset \mathcal{C}_h, \\ 0, & \text{elsewhere.} \end{cases}$$

Moreover, there exists some constant m_0 such that for any i and $0 < h < 1$

$$\left| \{(i, \mathbb{N}^{k_h}) \cap \mathcal{C}_h\} \right| \leq m_0.$$

By substituting (5.16) in (5.15) we obtain

$$\begin{aligned} I_{62} \leq & h^{2\delta p} \int_0^t (t-s)^{-\delta p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \\ & \int_{\zeta\in\mathbb{R}} \mathbb{E}\left\| \left(\mathcal{I}_h e^{-\frac{1}{2}A(t-s)} - e^{-\frac{1}{2}\mathcal{A}_h(t-s)} \right) g_h(u_h(s); i, \zeta) \right\|^p_{L^p(\mathcal{O})} \nu^i(d\zeta)\, ds. \end{aligned}$$

By applying Theorem 3.4 we can infer that for any $\gamma \in (01)$, we have

$$I_{62} \leq C\, h^{p\delta+p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\gamma)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \int_{\zeta\in\mathbb{R}} \mathbb{E}\Big\| g_h(u_h(s);i,\zeta)\Big\|_{L^p(\mathcal{O})}^p \nu(d\zeta)\, ds,$$

where $\rho = \gamma/(2-\frac{d}{p}+\frac{d}{2})$. By Theorem 3.1 and since $Z = B^{\frac{d}{p}-d}_{p,\infty}(\mathcal{O}) \hookrightarrow W_p^{-\gamma}(\mathcal{O})$ continuously, we get for any $\rho > d - \frac{d}{p}$

$$I_{62} \leq C\, h^{p(\delta-\rho)+p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \int_{\zeta\in\mathbb{R}} \mathbb{E}\Big\| g_h(u_h(s);i,\zeta)\Big\|_{Z}^p \nu(d\zeta)\, ds.$$

Provided that $\delta \geq \rho$ we can omit the first term in the exponent of h. The mapping g is linear in the last variable and globally Lipschitz in the first. Thus we can infer that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} \lambda(J_i^h) \left(1+\mathbb{E}\left|u_h(s,N_i^h)\right|^p\right) ds.$$

By Remark 3.1 it follows that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} m_0 \sum_{i=1}^{k_h} h^d \left(1+\mathbb{E}\left|u_h(s,N_i^h)\right|^p\right) ds,$$

and by (3.16)

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})} \int_0^t (t-s)^{-(\delta+\rho)p} \left(1+\mathbb{E}\,\|u_h(s)\|_{L^p(\mathcal{O})}^p\right) ds.$$

The Hölder inequality leads to

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}\, C(t) \left(1+\sup_{0\leq s\leq t} \mathbb{E}\,\|u_h(s)\|_{L^p(\mathcal{O})}^p\right)$$

and Theorem 4.1 that there exists a constant C such that

$$I_{62} \leq C\, h^{p\gamma(2+\frac{d}{2}-\frac{d}{p})}, \quad 0 < h \leq 1. \tag{5.17}$$

Collecting together (5.4), (5.5), (5.6), (5.8), (5.9), (5.10), (5.13), and (5.17) gives the assertion. ∎

6. Discussions and conclusions. The next step is to confirm the theory described in this paper by numerical experiments. One of the problems which arises here is that, if the intensity of the Poisson random measure is given, the distribution is known only in a few cases. Therefore, it is difficult to find a benchmark where the solution is known analytically and to compare the numerical result with the exact solution.

Moreover, because of this problem, the distribution of the random variables $\xi_h^m(\cdot)$, $m \in \mathbb{N}$, appearing in (2.6), is not given a priori. Different approaches exist to solve this problem; e.g., Rubenthaler [Rub03] cut off the jumps, which are smaller than a certain threshold, calculated the time of the first jump, and applied the Euler scheme until the time of the first jump. Then he simulated a random variable according to the distribution of size of the jump, with the condition that the jump is larger than the threshold. This step is repeated until the time T is reached.

In [HM06a, HM06b] we approximated the intensity by a discrete distribution. In fact, first we cut off the small jumps by setting $\nu_h(B) = 0$ for a neighborhood B of the origin, and then we approximated ν_h by a discrete distribution ν_h^n. To be precise, let $\tilde{\eta}_h^n$ be the real-valued compensated Poisson random measure given by the intensity ν_h^n. Now for any $x \in \mathbb{R}$ the random variable

$$\int_{m\tau_h}^{(m+1)\tau_h} \int_{\zeta \in \mathbb{R}^{k_h}} g(x;\zeta)\, \tilde{\eta}_h^n(dz;ds)$$

can be simulated directly by the sum of N independent random variables with distribution $\frac{1}{\nu_h^n(\mathbb{R})}\nu_h^n$, where N is exponentially distributed with parameter $\nu_h^n(\mathbb{R})$.

By taking into account that the small jumps are cut off, one may ask if the perturbation of the small jumps can be approximated by, e.g., a Wiener process. This has been done, e.g., by Kallianpur and Xiong [KX95]. Since we are in Banach spaces of M-type p, $1 \le p \le 2$, the convergence of a simple random walk is not necessarily given. One alternative is to choose another scaling, which we also consider in [HM06b].

Appendix A. Besov spaces and their properties. An introduction to Besov spaces is given by Runst and Sickel [RS96]. We are interested is the continuity of the mapping G described in (3.20). To be precise, we prove the following result.

PROPOSITION A.1. *If $f \in \mathcal{S}(\mathbb{R}^d)$, then for each $a \in \mathbb{R}^d$ the Schwartz distribution $f\delta_a$ belongs to the Besov space $B_{p,\infty}^{\frac{d}{p}-d}(\mathbb{R}^d)$, and moreover there exists a constant $C = C(d,p)$ independent of f such that*

$$\int_{\mathbb{R}^d} |f\delta_a|^p_{B_{p,\infty}^{\frac{d}{p}-d}(\mathbb{R}^d)}\, da = |f|^p_{L^p(\mathbb{R}^d)}\,.$$

Thus, there exists a unique bounded linear map $\Lambda : L^p(\mathbb{R}^d) \to L^p(\mathbb{R}^d, B_{p,\infty}^{\frac{n}{p}-n}(\mathbb{R}^d))$ such that $[\Lambda(f)](a) = f\delta_a$, $f \in \mathcal{S}(\mathbb{R}^d)$, $a \in \mathbb{R}^d$. Moreover, for any $s \ge 0$ there exists some constant C such that

$$\int_{\mathbb{R}^d} |f\delta_a|^p_{B_{p,\infty}^{\frac{d}{p}-d-s}(\mathbb{R}^d)}\, da \le C\ |f|^p_{W_p^{-s}(\mathbb{R}^d)}\,.$$

In the following we denote the value of $\Lambda(f)$ at a, where $f \in L^p(\mathbb{R}^d)$ by $f\delta_a$. Let us recall the definition of the Besov spaces as given in [RS96, Definition 2, pages 7–8]. First we choose a function $\psi \in \mathcal{S}(\mathbb{R}^d)$ such that $0 \le \psi(x) \le 1$, $x \in \mathbb{R}^d$, and

$$\psi(x) = \begin{cases} 1, & \text{if} \quad |x| \le 1, \\ 0 & \text{if} \quad |x| \ge \frac{3}{2}. \end{cases}$$

Then put

$$\begin{cases} \phi_0(x) = \psi(x),\ x \in \mathbb{R}^d, \\ \phi_1(x) = \psi(\frac{x}{2}) - \psi(x),\ x \in \mathbb{R}^d, \\ \phi_j(x) = \phi_1(2^{-j+1}x),\ x \in \mathbb{R}^d, \quad j = 2,3,\ldots. \end{cases}$$

With the choice of $\phi = \{\phi_j\}_{j=0}^{\infty}$ as above and $\mathcal{F}$ and $\mathcal{F}^{-1}$ being the Fourier and the inverse Fourier transformations, respectively, (acting in the space $\mathcal{S}'(\mathbb{R}^d)$ of Schwartz distributions), we have the following definition.

DEFINITION A.1. *Let $s \in \mathbb{R}$, $0 < p \leq \infty$, and $0 < q \leq \infty$. If $0 < q < \infty$ and $f \in \mathcal{S}'(\mathbb{R}^d)$, we put*

$$|f|_{B^s_{p,q}} = \left(\sum_{j=0}^{\infty} 2^{sjq} \left| \mathcal{F}^{-1} \left[\phi_j \mathcal{F} f \right] \right|_{L^p}^q \right)^{\frac{1}{q}},$$
$$|f|_{B^s_{p,\infty}} = \sup_{j \in \mathbb{N}} 2^{sj} \left| \mathcal{F}^{-1} \left[\phi_j \mathcal{F} f \right] \right|_{L^p}.$$

We denote by $B^s_{p,q}(\mathbb{R}^d)$ the space of all $f \in \mathcal{S}'(\mathbb{R}^d)$ for which $|f|_{B^s_{p,q}}$ is finite.

LEMMA A.2. *If $h \in \mathcal{S}(\mathbb{R}^d)$, $h \in \mathcal{S}(\mathbb{R}^d)$, and $a \in \mathbb{R}^d$, then*

$$|(h\delta_a) * g|_{L^p(\mathbb{R}^d)} = |h(a)||g|_{L^p(\mathbb{R}^d)}.$$

Proof. Let us recall that $h\delta_b \in \mathcal{S}'(\mathbb{R}^d)$ assigns to a function $g \in \mathcal{S}(\mathbb{R}^d)$ a value $\delta_a(hg) = h(a)g(a)$. Since by the definition of the convolution of a distribution with a test function

$$[(h\delta_a) * g](x) = (h\delta_a)(\tau_x \check{g}) = h(a)(\tau_x \check{g})(a) = h(a)\check{g}(a - x) = h(a)g(x - a),\ x \in \mathbb{R}^d,$$

we have

$$\begin{aligned} |(h\delta_a) * g|^p_{L^p(\mathbb{R}^d)} &= \int_{\mathbb{R}^d} |g(x - a)h(a)|^p \, dx \\ &= |h(a)|^p \int_{\mathbb{R}^d} |g(x)|^p \, dx = |h(a)|^p \ |g|^p_{L^p(\mathbb{R}^d)}. \end{aligned}$$ ∎

LEMMA A.3. *If $\varphi \in \mathcal{S}(\mathbb{R}^d)$, $\lambda > 0$, and $g(x) := \varphi(\lambda x)$, $x \in \mathbb{R}^d$, then*

$$|\mathcal{F}^{-1} g|_{L^p(\mathbb{R}^d)} = \lambda^{d(\frac{1}{p} - 1)} |\mathcal{F}^{-1} \varphi|_{L^p(\mathbb{R}^d)}.$$

Proof. The proof follows with simple calculations. ∎

Proof of Proposition A.1. Obviously it is enough to prove the first part of the proposition. We will use the definition of the Fourier transform as in [RS96]. In particular, with $\langle \cdot, \cdot \rangle$ being the scalar product in $\mathbb{R}^d$, we put

$$(\mathcal{F} f)(\xi) := (2\pi)^{-d/2} \int_{\mathbb{R}^d} e^{-i\langle x, \xi \rangle} f(x) \, dx,\ \xi \in \mathbb{R}^d,\ f \in \mathcal{S}(\mathbb{R}^d).$$

Let us fix $f \in \mathcal{S}(\mathbb{R}^d)$. Since $\mathcal{F}^{-1}(\varphi u) = (2\pi)^{-d/2}(\mathcal{F}^{-1}\varphi) * (\mathcal{F}^{-1} u)$, $\varphi \in \mathcal{S}$, $u \in \mathcal{S}'$, we infer that, for $j \in \mathbb{N}^*$,

$$\begin{aligned} |\mathcal{F}^{-1}[\varphi_j \mathcal{F}(f\delta_a)]|_{L^p(\mathbb{R}^d)} &= (2\pi)^{-d/2} |(\mathcal{F}^{-1}\varphi_j) * (f\delta_a)|_{L^p(\mathbb{R}^d)} \\ &= (2\pi)^{-d/2} |f(a)| \mathcal{F}^{-1}\varphi_j|_{L^p(\mathbb{R}^d)} \\ &= (2\pi)^{-d/2} 2^{d(\frac{1}{p} - 1)} 2^{-jd(\frac{1}{p} - 1)} |f(a)| |\mathcal{F}^{-1}\varphi_1|_{L^p(\mathbb{R}^d)}. \end{aligned}$$

Hence, $f\delta_a$ belongs to the Besov space $B^{d(\frac{1}{p} - 1)}_{p,\infty}(\mathbb{R}^d)$ as requested, and the equality (A.1) follows immediately. In order to show (A.1) note that

$$\|f\|_{B^{s+\gamma}_{p,\infty}(\mathbb{R}^d)} = \|I(s) f\|_{B^{\gamma}_{p,\infty}(\mathbb{R}^d)},$$

where $I(s) = \mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}$. Next,

$$\begin{aligned}
&\left\|\mathcal{F}^{-1}\left(\varphi_j\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right)\right\|_{L^p(\mathbb{R}^d)}\\
&\le \left\|\mathcal{F}^{-1}\varphi_j \star \mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^p(\mathbb{R}^d)}\\
&\le \left\|\mathcal{F}^{-1}\varphi_j\right\|_{L^p(\mathbb{R}^d)}\left\|\mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^1(\mathbb{R}^d)}.
\end{aligned}$$

Moreover,

$$\begin{aligned}
&\left\|\mathcal{F}^{-1}\left(1+\xi^2\right)^{\frac{s}{2}}\mathcal{F}\left(\int_{\mathbb{R}^d}\delta_a f\,da\right)\right\|_{L^1(\mathbb{R}^d)}\\
&= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\left(1+\xi^2\right)^{\frac{s}{2}}\int_{\mathbb{R}^d} e^{-i\langle a,\xi\rangle}f(a)\,d\xi\,da\right|\,dy\\
&\quad= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\left(1+\xi^2\right)^{\frac{s}{2}} e^{-i\langle a,\xi\rangle}f(a)\,da\,d\xi\right|\,dy\\
&= \int_{\mathbb{R}^d}\left|\int_{\mathbb{R}^d} e^{i\langle y,\xi\rangle}\,\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right](\xi)\,d\xi\right|dy = \int_{\mathbb{R}^d}\left(\mathcal{F}^{-1}\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right]\right)(y)\,dy\\
&\le \left\|\mathcal{F}^{-1}\mathcal{F}\left[(I+\Delta)^{\frac{s}{2}}f\right]\right\|_{L^1(\mathbb{R}^d)} = \left\|(I+\Delta)^{\frac{s}{2}}f\right\|_{L^1(\mathbb{R}^d)} = \|f\|_{W_p^s(\mathbb{R}^d)}.
\end{aligned}$$

In summary, one can show that for any $s\in\mathbb{R}$ there exists some C such that

$$\left\|\int_{\mathbb{R}^d} f\delta_a\,da\right\|_{B_p^{s+\frac{d}{p}-d}(\mathbb{R}^d)} \le C\,\|f\|_{W_p^s(\mathbb{R}^d)}, \quad f\in C_b^0(\mathbb{R}^d).$$

Since the operator $I(s)$ is positive for $s\le 0$, it follows that

$$\int_{\mathbb{R}^d}\|f\delta_a\|_{B_p^{s+\frac{d}{p}-d}(\mathbb{R}^d)}\,da \le C\,\|f\|_{W_p^s(\mathbb{R}^d)}, \quad f\in C_b^0(\mathbb{R}^d),\ \ f\ge 0.$$

Theorem 5.1.2 in [BL76] gives inequality (A.1). □

IMMERSED-INTERFACE FINITE-ELEMENT METHODS FOR ELLIPTIC INTERFACE PROBLEMS WITH NONHOMOGENEOUS JUMP CONDITIONS*

YAN GONG†, BO LI‡, AND ZHILIN LI§

Abstract. In this work, a class of new finite-element methods, called *immersed-interface finite-element methods,* is developed to solve elliptic interface problems with nonhomogeneous jump conditions. Simple non–body-fitted meshes are used. A single function that satisfies the same nonhomogeneous jump conditions is constructed using a level-set representation of the interface. With such a function, the discontinuities across the interface in the solution and flux are removed, and an equivalent elliptic interface problem with homogeneous jump conditions is formulated. Special finite-element basis functions are constructed for nodal points near the interface to satisfy the homogeneous jump conditions. Error analysis and numerical tests are presented to demonstrate that such methods have an optimal convergence rate. These methods are designed as an efficient component of the finite-element level-set methodology for fast simulation of interface dynamics that does not require remeshing.

Key words. elliptic interface problems, nonhomogeneous jump conditions, immersed-interface finite-element method, level-set functions, error estimates

1. Introduction.

We consider numerical solution of the elliptic interface problem

$$-\nabla\cdot\beta^-\nabla u = f \qquad \text{in } \Omega^-, \tag{1.1}$$

$$-\nabla\cdot\beta^+\nabla u = f \qquad \text{in } \Omega^+, \tag{1.2}$$

$$[u]_\Gamma = w, \tag{1.3}$$

$$\left[\beta\frac{\partial u}{\partial n}\right]_\Gamma = Q, \tag{1.4}$$

$$u = g \qquad \text{on } \partial\Omega. \tag{1.5}$$

Here, $\Omega \subset \mathbb{R}^2$ is a bounded domain with its boundary $\partial\Omega$. Both Ω^- and Ω^+ are subdomains of Ω such that $\Omega^- \cap \Omega^+ = \emptyset$ and $\overline{\Omega^-} \cup \overline{\Omega^+} = \overline{\Omega}$, where an overline denotes the

closure; see Figure 1.1 for an illustration. For simplicity, we assume that $\overline{\Omega^-} \cap \partial\Omega = \emptyset$. We denote $\Gamma = \overline{\Omega^-} \cap \overline{\Omega^+}$ and call it the *interface* separating Ω^- and Ω^+. We shall assume that Γ is sufficiently smooth. We also denote by n the unit vector normal to Γ pointing from Ω^- to Ω^+, or the unit exterior normal to $\partial\Omega$, and by $\partial/\partial n$ or ∂_n the corresponding normal derivative.

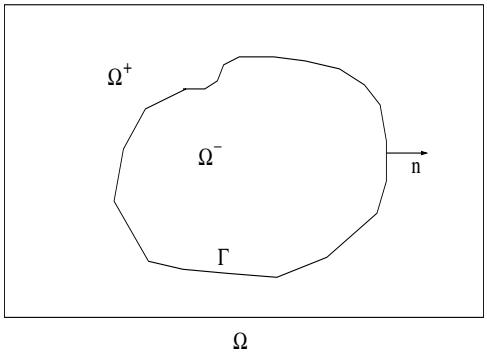

FIG. 1.1. *The geometry of an elliptic interface problem.*

All the functions β, $f : \Omega \to \mathbb{R}$, w, $Q : \Gamma \to \mathbb{R}$, and $g : \partial\Omega \to \mathbb{R}$ are given. As usual, for any function $\xi : \Omega \to \mathbb{R}$, we denote the restrictions of ξ on Ω^- and Ω^+ by

$$\xi^- = \xi|_{\Omega^-} \qquad \text{and} \qquad \xi^+ = \xi|_{\Omega^+},$$

respectively, and we denote by

$$[\xi]_\Gamma(x) = \lim_{y \to x, y \in \Omega^+} \xi^+(y) - \lim_{y \to x, y \in \Omega^-} \xi^-(y)$$

the jump of ξ across the interface Γ at $x \in \Gamma$, when the unique limiting values on Γ of ξ from both sides of Γ exist. We assume that β^- and β^+ are smooth and bounded on Ω^- and Ω^+, respectively,

$$\beta(x) \geq \beta_0 \qquad \forall x \in \Omega, \tag{1.6}$$

for some constant $\beta_0 > 0$, $f \in L^2(\Omega)$, all w, Q, and g are smooth and bounded.

Equations (1.3) and (1.4) are nonhomogeneous interface or jump conditions. Elliptic interface problems (1.1)–(1.5) with such jump conditions arise in many areas. For example, in a Burton–Cabrera–Frank-type model for epitaxial growth of thin films, the adatom (adsorbed atom) density that solves the diffusion equation on terraces, and the corresponding flux, can have jumps across interfaces that represent atomic steps [3, 5, 6]. Another example is that the reaction potential of electrostatics of a solvation energy satisfies a nonhomogeneous jump condition for the flux [13].

If the jump conditions are homogeneous, i.e., $w = 0$ and $Q = 0$ on Γ (cf. (1.3) and (1.4)), then the problem (1.1)–(1.5) is equivalent to that of finding $u \in H^1(\Omega)$ with $u = g$ on $\partial\Omega$ such that

$$\int_\Omega \beta \nabla u \cdot \nabla v \, dx = \int_\Omega f v \, dx \qquad \forall v \in H_0^1(\Omega).$$

In general, we can extend the nonhomogeneous jump $w : \Gamma \to \mathbb{R}$ to a piecewise smooth function $\hat{w} : \Omega \to \mathbb{R}$ such that

$$[\hat{w}]_\Gamma = w \qquad \text{and} \qquad \hat{w} = g \quad \text{on } \partial\Omega.$$

Then, the problem (1.1)–(1.5) is equivalent to the problem for $u = q + \hat{w}$ with $q \in H_0^1(\Omega)$ uniquely determined by

$$\int_\Omega \beta \nabla q \cdot \nabla v \, dx = \int_\Omega f v \, dx - \int_\Gamma Q v \, ds - \int_\Omega \beta \nabla \hat{w} \cdot \nabla v \, dx \qquad \forall v \in H_0^1(\Omega). \tag{1.7}$$

In a standard body-fitted finite-element method for solving the problem in the weak formulation (1.7), the interface is covered by a low dimensional finite-element mesh, and the extension of $w : \Gamma \to \mathbb{R}$ to $\hat{w} : \Omega \to \mathbb{R}$ can be made by finite-element approximations.

In this work, we develop a class of finite-element methods based on non–body-fitted finite-element meshes to solve the elliptic interface problem (1.1)–(1.5). Such a method has the following distinguished features.

(a) A fixed finite-element mesh that allows the interface to cut through edges of elements is used.
(b) Both the jumps $w : \Gamma \to \mathbb{R}$ and $Q : \Gamma \to \mathbb{R}$ are extended locally by a single function using a level-set representation of the interface Γ. The extensions are necessary to transfer the original problem to a new one with homogeneous jump conditions so that the immersed finite-element methods developed in [18] can be applied. The new methods make it possible to maintain second order accuracy on the elements near the interface; see sections 2 and 5.
(c) Special finite-element basis functions for nodal points near the interface are constructed to satisfy the homogeneous jump conditions; see section 4.
(d) The resulting linear system of discretization is symmetric positive definite.
(e) Optimal convergence rates, the same as those for a body-fitted finite-element method, are achieved; see section 3 for basic error estimates and section 6 for numerical results on such convergence properties.

Our methods incorporate the finite-element discretization into the framework of an immersed-interface method for interface problems, and we therefore call them *immersed-interface finite-element methods.* The basic idea of an immersed-interface method is to incorporate the jump conditions in constructing basis functions. In a finite-difference immersed-interface method, the jump conditions are enforced through finite-difference equations on grid points near the interface. In our immersed-interface finite-element methods, the jump conditions are enforced through the construction of special finite-element basis functions that satisfy the homogeneous interface conditions. Clearly, such basis functions depend on the interface location and the jump w. Some of the related work can be found in [7, 12].

The development of our methods is strongly motivated by the need for a fast and accurate solver of elliptic interface problems that is required in each time step in a long-time level-set simulation of interface dynamics without remeshing. Such simulation has been a powerful numerical approach in understanding material properties, biological processes, and many other important phenomena in science and engineering [20, 21, 22].

The finite-element spaces constructed in this paper are conforming ones that contain piecewise P_1 polynomials. The interpolation error is therefore of second order. If the solution to the elliptic interface problem is piecewise smooth, or, more precisely, $u^\pm \in C^2(\overline{\Omega^\pm})$, which is true for many applications, then the standard convergence results are true for our finite-element methods. This means that our finite-element solution is first order accurate in the H^1 norm and second order accurate in the L^2 norm. In this work, we construct only some two-dimensional linear and quadratic

triangular immersed-interface finite elements. However, our framework described here can be used for high order immersed-interface finite elements and for more general elliptic interface problems in two and three space dimensions.

We use the zero level set of a Lipschitz continuous function particularly, a good approximation of the signed distance function, to represent the interface Γ. For such a level-set function, the interface can cut the interface only once between two grid lines. The resolution of the interface Γ is determined by the level-set function. We note that there are plenty of discussions in the literature about how to construct the level-set function for an interface Γ; see, e.g., [20, 22]. If the interface is complicated in reference to a mesh, then it may not be resolved well by the level-set function. Consequently, the finite-element solution obtained from our method may not resolve all the fine details of the solution. A finer mesh is then needed to resolve the geometry and the solution.

Our work combines the development of a new formulation of underlying problems, construction of new elements, basic error estimates, and numerical experiments. The analysis in our work focuses on two parts: one is the algorithm of removing source singularities, and the other is the interpolation error estimate for some of the immersed-interface finite-element approximations. We have not tried to deal in this paper with the analysis of other errors, such as those of the approximation of the interface Γ by Γ_h, numerical quadrature, round-off errors, etc.

In section 2, we present a new weak formulation of the elliptic interface problem (1.1)–(1.5) with a special treatment of nonhomogeneous jump conditions. In section 3, we describe the framework of our immersed-interface finite-element methods and provide basic error estimates. In section 4, we construct several linear or quadratic immersed-interface finite-element spaces and obtain their corresponding interpolation errors. In section 5, we give some details of implementation of our methods. In section 6, we present numerical results. Finally, in section 7, we draw conclusions.

2. Weak formulation. We first review the level-set representation of the interface Γ which is assumed to be smooth. Let $\varphi : \Omega \to \mathbb{R}$ be a continuous function that satisfies

$$\varphi(x) \begin{cases} < 0 & \text{if } x \in \Omega^-, \\ = 0 & \text{if } x \in \Gamma, \\ > 0 & \text{if } x \in \Omega^+. \end{cases} \tag{2.1}$$

We call such a function $\varphi : \Omega \to \mathbb{R}$ a *level-set function* that represents the interface Γ. For $\rho > 0$, we denote the ρ-neighborhood of Γ in Ω by

$$N(\Gamma, \rho) = \{x \in \Omega : \text{dist}\,(x, \Gamma) < \rho\},$$

where $\text{dist}\,(x, \Gamma)$ is the distance from x to Γ. We assume that there exists $\rho_0 > 0$ such that $\overline{N(\Gamma, \rho_0)} \subset \Omega$, and

$$\varphi \text{ is smooth and } |\nabla\varphi| > 0 \text{ in } N(\Gamma, \rho_0). \tag{2.2}$$

We note that the unit normal n to Γ, pointing from Ω^- to Ω^+, is given by

$$n = \frac{\nabla\varphi}{|\nabla\varphi|}. \tag{2.3}$$

The signed distance function

$$\varphi(x) = \begin{cases} -\operatorname{dist}(x,\Gamma) & \text{if } x \in \Omega^-, \\ 0 & \text{if } x \in \Gamma, \\ +\operatorname{dist}(x,\Gamma) & \text{if } x \in \Omega^+ \end{cases}$$

is a typical level-set function that satisfies our assumptions.

We now turn to the description of our treatment of nonhomogeneous jump conditions. We first need the following lemma.

LEMMA 2.1. *Let $\rho > 0$ be small enough. Then, for any $x \in N(\Gamma,\rho)$, there exists a unique $\hat{x} \in \Gamma$ such that*

$$|x - \hat{x}| = dist(x,\Gamma). \tag{2.4}$$

Moreover,

$$\frac{x-\hat{x}}{|x-\hat{x}|} = \begin{cases} -n(\hat{x}) & \text{if } x \in \Omega^-, \\ +n(\hat{x}) & \text{if } x \in \Omega^+, \end{cases} \tag{2.5}$$

where $n(\hat{x})$ is the unit normal to Γ at $\hat{x}$, pointing from Ω^- to Ω^+.

Proof. Without loss of generality, let us assume that, in a local Cartesian coordinate system, $x = (0,0)$ is the origin, and the interface nearby is a graph of a smooth function $\eta = \eta(s)$ that is nonzero for any s in a certain range. The distance from the origin to any point $(s,\eta(s))$ on the interface is then given by $\sqrt{I(s)} < \rho$ with

$$I(s) = s^2 + [\eta(s)]^2.$$

Setting $I'(s) = 0$, we get $\eta'(s) = -s/\eta(s)$. This implies (2.5), since $(-1,\eta'(s))$ is parallel to the normal at $(s,\eta(s))$. Moreover,

$$I''(s) = 2 + 2[\eta'(s)]^2 + 2\eta(s)\eta''(s)$$

is positive, since $I(s)$, and hence $\eta(s)$, is small enough, whenever $\rho > 0$ is small enough. Thus, there exists a unique s that minimizes $I(s)$. This implies the existence and uniqueness of $\hat{x}$ that satisfies (2.4). ∎

In what follows, we fix $\rho_0 > 0$ as in (2.2). We let $\rho \in \mathbb{R}$ be given as in the above lemma and assume that $0 < \rho < \rho_0$. We define $w_\rho : \Omega \to \mathbb{R}$ and $Q_\rho : \Omega \to \mathbb{R}$ to be the extensions of $w : \Gamma \to \mathbb{R}$ and $Q : \Gamma \to \mathbb{R}$, respectively, that satisfy the following.

E1. Both w_ρ and Q_ρ are smooth on $\overline{\Omega}$.

E2. $w_\rho(x) = w(\hat{x})$ and $Q_\rho(x) = Q(\hat{x})$ for any $x \in N(\Gamma,\rho)$, where $\hat{x}$ is defined as in Lemma 2.1.

E3. $w_\rho(x) = g(x)$ for any $x \in \partial\Omega$, and $Q_\rho(x) = 0$ for any $x \in \Omega \setminus N(\Gamma,\rho)$.

To see the existence of w_ρ, we first apply Lemma 2.1 to define a function, say, w_1, by $w_1(x) = w(\hat{x})$ for any $x \in N(\Gamma,2\rho)$ for $\rho > 0$ small enough, and $w_1 = 0$ elsewhere in Ω. Using the lifting operator [2, 11], there exists a smooth function, say, w_2, on Ω such that the restriction of w_2 on $\partial\Omega$ is g. (The smoothness depends on that of $\partial\Omega$.) Now, assume that $N(\Gamma,2\rho)$ and $A := N(\partial\Omega,\varepsilon) = \{x \in \Omega : \operatorname{dist}(x,\partial\Omega) < \varepsilon\}$ are disjoint for some small $\varepsilon > 0$. Then, by applying mollifiers to $w_1 + \chi_A w_2$, we obtain the desired w_ρ. The existence of Q_ρ is seen similarly.

We define $u_\rho : \Omega \to \mathbb{R}$ by

$$u_\rho(x) = \chi_{\Omega^+}(x)\left(w_\rho(x) + \frac{Q_\rho(x)}{\beta^+(x)}\frac{\varphi(x)}{|\nabla\varphi(x)|}\right) \qquad \forall x \in \Omega, \tag{2.6}$$

where χ_{Ω^+} is the characteristic function of Ω^+. Note by E3 that $Q_\rho = 0$ outside $N(\Gamma, \rho_0)$ in which φ may not be smooth. Thus, implicitly, the second term in u_ρ is defined to be 0 outside $N(\Gamma, \rho_0)$.

The following statement summarizes some useful properties of $u_\rho : \Omega \to \mathbb{R}$.

LEMMA 2.2. *Both u_ρ^- and u_ρ^+ are smooth on Ω^- and Ω^+, respectively. Moreover, $u_\rho = g$ on $\partial\Omega$, and*

$$[u_\rho]_\Gamma = w, \qquad \left[\beta\frac{\partial u_\rho}{\partial n}\right]_\Gamma = Q.$$

Proof. Since β^+ is smooth and bounded on Ω^+, it follows from (1.6), E1, and (2.2) that u_ρ^+ is smooth on Ω^+. Obviously, $u_\rho^- = 0$ is smooth on Ω^-. By E3, $u_\rho = g$ on $\partial\Omega$. By (2.1) and E2,

$$[u_\rho]_\Gamma = u_\rho^+ - u_\rho^- = w.$$

Now, fix $x \in \Gamma$. It follows from Lemma 2.1 and E2 that $\partial_n w_\rho = 0$. Moreover, $\varphi(x) = 0$ by (2.1). Therefore, for any $x \in \Gamma$, we obtain by E2, (2.6), (2.3), and the fact that $\varphi(x) = 0$ that

$$\begin{aligned}
\left[\beta(x)\frac{\partial u_\rho(x)}{\partial n}\right]_\Gamma &= \beta^+(x)\frac{\partial u_\rho^+(x)}{\partial n} \\
&= \beta^+(x)\frac{\partial w_\rho(x)}{\partial n} + \beta^+(x)\frac{\partial}{\partial n}\left(\frac{Q_\rho(x)}{\beta^+(x)|\nabla\varphi(x)|}\right)\varphi(x) + \frac{Q_\rho(x)}{|\nabla\varphi(x)|}\frac{\partial\varphi(x)}{\partial n} \\
&= Q(x)\frac{n(x)\cdot\nabla\varphi(x)}{|\nabla\varphi|(x)} \\
&= Q(x).
\end{aligned}$$

The proof is completed. ∎

THEOREM 2.3. *There exists a unique $q \in H_0^1(\Omega)$ such that*

$$\int_\Omega \beta\nabla q\cdot\nabla v\,dx = \int_\Omega fv\,dx - \int_\Gamma Qv\,ds - \int_{\Omega^+}\beta^+\nabla u_\rho\cdot\nabla v\,dx \qquad \forall v \in H_0^1(\Omega). \tag{2.7}$$

This is equivalent to

$$\int_\Omega \beta\nabla q\cdot\nabla v\,dx = \int_\Omega fv\,dx + \int_{\Omega^+}(\nabla\cdot\beta^+\nabla u_\rho)\,v\,dx \qquad \forall v \in H_0^1(\Omega). \tag{2.8}$$

Moreover, $u = q + u_\rho$ solves the problem (1.1)–(1.5). In particular, $q \in H_0^1(\Omega)$ satisfies the homogeneous jump conditions

$$[q]_\Gamma = 0 \qquad \text{and} \qquad \left[\beta\frac{\partial q}{\partial n}\right]_\Gamma = 0. \tag{2.9}$$

Proof. Note that the line integral in (2.7) defines a continuous, linear functional on $H_0^1(\Omega)$. The existence and uniqueness of $q \in H_0^1(\Omega)$ satisfying (2.7) follow therefore

from the Lax–Milgram theorem. By integration by parts, (2.6), and Lemma 2.2, we imply that (2.7) and (2.8) are equivalent.

Choosing $v \in H_0^1(\Omega)$ with $\operatorname{supp} v \subset \Omega^-$ and $\operatorname{supp} v \subset \Omega^+$, respectively, applying the regularity theory of elliptic problems, we obtain from (2.7) that $u = q + u_\rho$ satisfies (1.1) and (1.2). The jump condition (1.3) follows from Lemma 2.2. Now, integrating by parts, we obtain by (1.1), (1.2), (2.6), and (2.7) that

$$\int_\Gamma \left(\left[\beta \frac{\partial u}{\partial n} \right]_\Gamma - Q \right) v \, ds = 0 \qquad \forall v \in H_0^1(\Omega).$$

This leads to (1.4). Clearly, the function $u = q + u_\rho$ satisfies (1.5).

Finally, since $q = u - u_\rho$, we have

$$[q]_\Gamma = [u]_\Gamma - [u_\rho]_\Gamma = w - w = 0$$

from (1.3) and Lemma 2.2. We also have

$$\left[\beta \frac{\partial q}{\partial n} \right]_\Gamma = \left[\beta \frac{\partial u}{\partial n} \right]_\Gamma - \left[\beta \frac{\partial u_\rho}{\partial n} \right]_\Gamma = Q - Q = 0$$

from (1.4) and Lemma 2.2. ∎

3. Immersed-interface finite-element approximations. In this section, we first state practically reasonable assumptions on how the interface can cut edges of elements in a finite-element mesh. We then define immersed-interface finite-element approximations of our underlying problem formulated in Theorem 2.3. Finally, we give rigorous error estimates for our method.

Let $\mathcal{T}_h$ be a finite-element mesh with mesh size h that covers $\overline{\Omega}$. We assume that the elements in $\mathcal{T}_h$ are all triangles. For simplicity, we shall assume that Ω is a convex polygonal domain and the mesh covers $\overline{\Omega}$ exactly. Standard finite-element techniques can be applied to treat a curved boundary without affecting our approximation properties. We remark that in practice the computational domain Ω can often be chosen as a rectangular domain with sides parallel to the coordinate axes; and the finite-element mesh can be uniform.

We call an element $T \in \mathcal{T}_h$ an *interface element* if $\Gamma \cap \operatorname{int} T \neq \emptyset$. Note that an element is a noninterface element if one of its edges is part of the interface. We assume, for any interface element $T \in \mathcal{T}_h$, that the set $\Gamma \cap \partial T$ consists of exactly two points that are on different edges of T.

We define an immersed-interface finite-element space V_h with respect to the mesh $\mathcal{T}_h$ to be a finitely dimensional subspace of $L^2(\Omega)$ that consists of all the linear combinations of the corresponding basis functions $\phi_1, \ldots, \phi_N$ for some integer $N \geq 1$:

$$V_h = \operatorname{span}\{\phi_1, \ldots, \phi_N\}. \tag{3.1}$$

The basis functions are the usual finite-element basis functions on a noninterface element and are piecewise polynomials on each interface element that is determined by the element and the interface Γ. All the basis functions satisfy the homogeneous jump conditions for both the function and flux. Moreover, there exists an interpolation operator from some functional space to V_h that enjoys the usual approximation properties.

To be more precise, we define a *conforming immersed-interface finite-element* space V_h for the approximation of a second order elliptic interface problem to be a subspace of $H^1(\Omega)$ that satisfies the following properties.

FE1. All the functions in V_h restricted onto the union of all noninterface elements form a usual finite-element space of piecewise polynomials of degree $\le k$ for some integer $k \ge 1$, such as a P_k-type Lagrange finite-element space when $\mathcal{T}_h$ is a triangular mesh, or a Q_k- or Q'_k-type Lagrange finite-element space when $\mathcal{T}_h$ is a quadrilateral mesh [4, 8]. On each interface element $T \in \mathcal{T}_h$, all functions in V_h are piecewise polynomials. The support of each basis function is a union of a few elements.

FE2. All the basis functions, and hence all the functions in V_h, satisfy the homogeneous jump conditions

$$[v_h]_{\Gamma_h} = 0 \quad \text{and} \quad \left[\beta(\hat{x})\frac{\partial v_h}{\partial n}\right]_{\Gamma_h} = 0 \qquad \forall v_h \in V_h, \tag{3.2}$$

where Γ_h denotes the union of line segments approximating the interface Γ, and the normal derivatives of $v_h \in V_h$ from each side of the interface are assumed to exist; $\hat{x}$ is the orthogonal projection on the interface of the midpoint of Γ_h within the triangle.[1] Note that $\left[\beta(\hat{x})\frac{\partial v_h}{\partial n}\right]_{\Gamma_h} = \beta^+(\hat{x})\frac{\partial v_h^+}{\partial n} - \beta^-(\hat{x})\frac{\partial v_h^-}{\partial n}$.

FE3. There exists an interpolation operator $I_h : D(\Omega) \to V_h$ such that

$$\|I_h v - v\|_{H^1(\Omega)} \le C h^{\sigma(k)} \|v\|_{H^{k+1}(\Omega\setminus\Gamma)} \qquad \forall v \in D(\Omega), \tag{3.3}$$

where $D(\Omega) \subset H^1(\Omega)$ is an infinite-dimensional space of functions that are smooth and bounded on both Ω^- and Ω^+, respectively, $\bar{k}$ is a constant such that $0 < \sigma(k) \le k$, and $C > 0$ denotes a generic constant independent of h and v.

The homogeneous jump condition for $v_h \in V_h$ in (3.2) is a consequence of the fact that $V_h \subset H^1(\Omega)$. Often the interpolation error in FE3 can be the same as usual, i.e., $\bar{k} = k$. But, it can be slightly worse due to the approximation of Γ by Γ_h.

We can similarly define a *nonconforming immersed-interface finite-element* space $V_h \subset L^\infty(\Omega)$ with $V_h \not\subset H^1(\Omega)$. For a nonconforming immersed-interface finite-element space V_h that is used to solve our underlying problem with the boundary condition (1.5), we also need to assume that a discrete Poincaré inequality,

$$\|v_h\|^2_{L^2(\Omega)} \le C \sum_{T\in T_h} \|\nabla v_h\|^2_{L^2(T\setminus\Gamma_h)} \qquad \forall v_h \in V_h,$$

is satisfied. Several examples of conforming and nonconforming, linear or quadratic, immersed-interface finite elements will be presented in the next section.

We consider now immersed-interface finite-element approximations of the solution $q \in H^1_0(\Omega)$ defined by (2.7). Let $u_\rho : \Omega \to \mathbb{R}$ be as given in (2.6) for some $\rho > 0$ small enough. Now let $V_h \subset H^1_0(\Omega)$ be a conforming immersed-interface finite-element space of piecewise polynomials of degree $\le k$ as in FE1–FE3 that accounts for the boundary condition (1.5). To be precise, we assume in our analysis below that the domain of the interpolation operator I_h is

$$D(\Omega) = \left\{ v \in H^1_0(\Omega) : v^- \in H^{k+1}(\Omega^-) \cap C(\overline{\Omega^-}) \text{ and } v^+ \in H^{k+1}(\Omega^+) \cap C(\overline{\Omega^+}) \right\}.$$

[1] Alternatively, we can approximate $\beta^\pm(\hat{x})$ using $\beta^\pm(\hat{X})$, where $\hat{X} \in \Gamma \cap \mathcal{T}_h$ is any point on the interface and in the triangle.

THEOREM 3.1. *There exists a unique $q_h \in V_h$ such that*

$$\int_\Omega \beta \nabla q_h \cdot \nabla v_h \, dx = \int_\Omega f v_h \, dx + \int_{\Omega^+} (\nabla \cdot \beta^+ \nabla u_\rho) \, v_h \, dx \qquad \forall v \in V_h. \tag{3.4}$$

Moreover, if the solution $q \in H_0^1(\Omega)$ of (2.7) satisfies that $q^- \in H^{k+1}(\Omega^-) \cap C(\overline{\Omega^-})$ and $q^+ \in H^{k+1}(\Omega^+) \cap C(\overline{\Omega^+})$, then

$$\|q - q_h\|_{H^1(\Omega)} \le C h^{\sigma(k)} \|q\|_{H^{k+1}(\Omega \backslash \Gamma)}, \tag{3.5}$$

$$\|q - q_h\|_{L^2(\Omega)} \le C h^{\sigma(k)+\sigma(1)} \|q\|_{H^{k+1}(\Omega \backslash \Gamma)}, \tag{3.6}$$

where $\sigma(k)$ is defined in FE3 *and $C > 0$ is a constant independent of h and q.*

Proof. Since $V_h \subset H_0^1(\Omega)$, the existence and uniqueness of $q_h \in V_h$ satisfying (3.4) follow from the Lax–Milgram theorem. Moreover, by (2.8), which is equivalent to (2.7) by Theorem 2.3, and (3.4), we obtain

$$\int_\Omega \beta \nabla (q - q_h) \cdot \nabla v_h \, dx = 0 \qquad \forall v_h \in V_h. \tag{3.7}$$

The error estimate (3.5) can be obtained by a standard argument using a Poincaré inequality, the ellipticity indicated by (1.6), the error equation (3.7), and the interpolation error estimate (3.3); see [4, 8].

To obtain the L^2 error estimate (3.6), we use the standard dual argument (cf., e.g., [4, 8]) with slight modification taking care of the lack of global regularity of a solution. Let $r \in H_0^1(\Omega)$ be the unique function satisfying

$$\int_\Omega \beta \nabla r \cdot \nabla v \, dx = \int_\Omega (q - q_h) v \, dx \qquad \forall v \in H_0^1(\Omega). \tag{3.8}$$

Since β^- and β^+ are smooth and bounded in Ω^- and Ω^+, respectively, we see that $r^- \in H^2(\Omega)$ and $r^+ \in H^2(\Omega)$. Moreover, it follows from (3.8) that $[\beta \partial_n r]_\Gamma = 0$. Therefore, we have (cf. Theorem 2.1 in [7]) that

$$\|r^\pm\|_{H^2(\Omega^\pm)} \le C \|q - q_h\|_{L^2(\Omega)}. \tag{3.9}$$

Setting $v = q - q_h \in H_0^1(\Omega)$ in (3.8), we have by (3.8), (3.7) with $v_n = I_h r$, the Cauchy–Schwarz inequality, (3.3) with $k = 1$, (3.5), and (3.9) that

$$\begin{aligned}
\|q - q_h\|_{L^2(\Omega)}^2 &= \int_\Omega \beta \nabla r \cdot \nabla (q - q_h) \, dx \\
&= \int_\Omega \beta \nabla (r - I_h r) \cdot \nabla (q - q_h) \, dx \\
&\le C \|r - I_h r\|_{H^1(\Omega)} \|q - q_h\|_{H^1(\Omega)} \\
&\le C h^{\sigma(k)+\sigma(1)} \|r\|_{H^2(\Omega \backslash \Gamma)} \|q\|_{H^{k+1}(\Omega \backslash \Gamma)} \\
&\le C h^{\sigma(k)+\sigma(1)} \|q\|_{H^{k+1}(\Omega \backslash \Gamma)} \|q - q_h\|_{L^2(\Omega)},
\end{aligned}$$

leading to (3.6). ∎

We remark that the removal of both jumps w and Q using a single function leads to finite-element equation (3.4) which does not involve line integrals as in (2.7). This much simplifies numerical implementation.

4. Construction of basis functions. We now describe how to construct some new classes of triangular immersed-interface finite-element basis functions that satisfy the homogeneous jump conditions.

Let $z_1, \ldots, z_N$ be all the vertices of triangular elements in the mesh $\mathcal{T}_h$. We define our linear or quadratic linear immersed-interface finite-element basis functions ϕ_i associated with z_i $(i = 1, \ldots, N)$ to be functions on Ω that satisfy the following properties.

B1. Each ϕ_i $(1 \le i \le N)$ is linear on a noninterface element and is piecewise linear or quadratic on an interface element.

B2. $\phi_i(z_j) = \delta_{ij}$ for $i, j = 1, \ldots, N$, where $\delta_{ij} = 1$ if $i = j$ and 0 if $i \ne j$.

B3. All ϕ_i $(1 \le i \le N)$ satisfy the approximate homogeneous jump conditions

$$[\phi_i]_{\Gamma_h} = 0, \qquad \left[\beta(\hat{x})\frac{\partial \phi_i}{\partial n}\right]_{\Gamma_h} = 0.$$

The corresponding finite-element space V_h is given by (3.1).

We call a vertex an *irregular vertex* or *irregular node* if it is a vertex of an interface element and a *regular vertex* or *regular node* otherwise. For a regular node z_i, we define ϕ_i to be the usual conforming linear finite-element basis function associated with z_i, i.e., $\phi_i \in C(\overline{\Omega}) \cap H_0^1(\Omega)$, ϕ_i is a linear polynomial on each element $T \in \mathcal{T}_h$, and $\phi_i(z_j) = \delta_{ij}$ for $j = 1, \ldots, N$.

For an irregular node z_i, we construct the corresponding basis function by modifying the usual linear finite-element basis function to satisfy the properties B1–B3. We need only to construct a local basis (or shape) function on an interface element for an irregular node.

4.1. A nonconforming linear element. This nonconforming immersed-interface finite element was first constructed in [18]; see also [12]. We briefly review it, since it will be used to construct our new linear and quadratic elements.

Fix an interface element $T \in \mathcal{T}_h$; cf. Figure 4.1. As in the common practice, we approximate the interface in T, $\Gamma \cap T$, by a line segment connecting the intersections of the interface and the edges of the triangle T. This line segment is $\overline{DE}$ in Figure 4.1. The line segment divides T into two parts T^+ and T^-, one triangular and the other quadrilateral. Note that there is a small region T_r in T,

$$T_r = T - \Omega^+ \cap T^+ - \Omega^- \cap T^-,$$

whose area is of order $O(h^3)$.

We now consider the element T in Figure 4.1 as a reference interface element T and define local basis functions for each vertex of T. The local basis function for a general interface element in the mesh $\mathcal{T}_h$ can be defined through the usual affine transformation. We denote

$$T = \{(x_1, x_2) : 0 \le x_1 \le h, \quad 0 \le x_2 \le hx_1 + x_2 \le h\}$$

and assume that the coordinates at A, B, C, D, and E are

$$(0, h), \quad (0, 0), \quad (h, 0), \quad (0, y_1), \quad (h - y_2, y_2),$$

respectively; cf. Figure 4.1.

Each of the three local basis functions corresponding to the nodes A, B, or C takes value 1 at one node and 0 at the other two. Once the values at nodes A, B, and

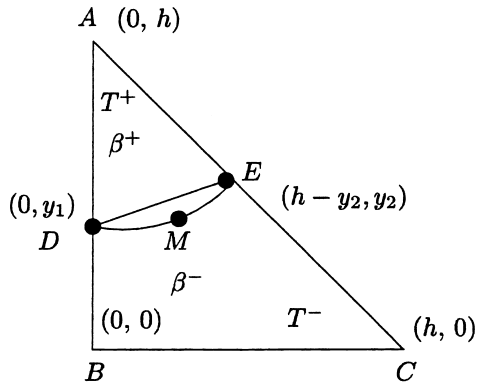

FIG. 4.1. *A typical interface element $T = \triangle ABC$. The arc DME is the part of the interface Γ in T. It is approximated by the line segment $\overline{DE}$. $T^+ = \triangle ADE$, $T^- = T - T^+$, and T_r is the region enclosed by the $\overline{DE}$ and the arc DME.*

C are specified, a local nonconforming finite-element basis function ϕ for this interface triangle is determined by

$$\phi(x) = \begin{cases} \phi^+(x) = a_0 + a_1 x_1 + a_2(x_2 - h) & \text{if } x = (x_1, x_2) \in T^+, \\ \phi^-(x) = b_0 + b_1 x_1 + b_2 x_2 & \text{if } x = (x_1, x_2) \in T^-. \end{cases} \tag{4.1}$$

The coefficients a_i and b_i $(i = 0, 1, 2)$ are determined by the conditions (cf. [18])

$$\phi^+(D) = \phi^-(D), \quad \phi^+(E) = \phi^-(E), \quad \beta^+ \frac{\partial \phi}{\partial n}^+ = \beta^- \frac{\partial \phi}{\partial n}^-, \tag{4.2}$$

where n is the unit normal direction of the line segment $\overline{DE}$. It is shown in [18] that this function ϕ is uniquely determined. Note that basis functions defined in this way can be discontinuous across edges of interface elements. So, this defines a nonconforming finite element.

4.2. A conforming linear element. This conforming element was proposed in [18]. Both error estimates and numerical experiments in [18] show that the corresponding interpolation errors that can depend on an angle condition are of second order, which is optimal [18].

Let $T = \Delta ABC$ be an interface element; cf. Figure 4.2. As before, we assume that the interface meets edges of this element at D and E. To construct a local basis function that is globally continuous, we extend the previously defined basis function at the same node (vertex) to one more triangle along the interface (cf. Figure 4.2 (b)). We require that the local basis functions in two adjacent interface elements, such as ΔABC and ΔAFB, take the same value at the interface point on their common edge, such as the point D. This will achieve the global continuity of a basis function associated with an irregular node.

We construct a local basis function ϕ by assigning its values at the vertices A, B, C, F, and I, respectively. This construction consists of the following five steps.

P1. Use the values at the nodes A, B, C, F, and I to construct the three nonconforming finite-element basis functions defined as in subsection 4.1 on the elements ΔABC, ΔAFB, and ΔACI, respectively.

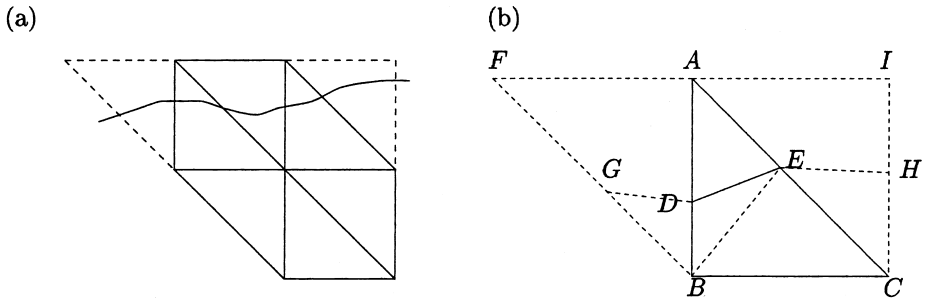

FIG. 4.2. (a) *The support of a local basis function.* (b) *A diagram for the construction of a local basis function on* $\triangle ABC$.

P2. Set the value at D as the average of the values at D of the nonconforming piecewise linear basis functions defined on ΔABC and ΔAFB constructed in P1.

P3. Similarly, set the value at E as the average of values at E of the nonconforming piecewise linear basis functions defined on the elements ΔABC and ΔACI constructed in P1.

P4. Partition the element ΔABC into three subtriangles by an auxiliary line, say, line segment $\overline{BE}$, or $\overline{DC}$. We choose the auxiliary line in such a way that at least one of angles (or complimentary angles if the angle is more than $\pi/4$) is bigger than or equal to $\pi/2$.

P5. Define the basis function to be the piecewise linear function in the three subtriangles determined by the values at the points A, B, C, D, and E.

For this type of conforming finite-element space and homogeneous jump conditions, i.e., $w = 0$ and $Q = 0$, we have the following error estimates of the interpolation function:

$$\|I_h u - u\|_\infty \le Ch^2 \|D^2 u\|_{\infty, \Omega \setminus (\cup T_r)}, \tag{4.3}$$

$$\|I_h u - u\|_{H^1(\Omega)} \le Ch \|D^2 u\|_{\infty, \Omega \setminus (\cup T_r)}, \tag{4.4}$$

assuming that $\beta(x)$ is a piecewise constant and the solution is piecewise smooth in Ω^- and Ω^+, where $C > 0$ is a generic constant independent of h and $\cup T_r$ is the region of mismatched regions between Γ and Γ_h; see [18] for the proof.

4.3. A conforming quadratic element. We now construct a conforming quadratic element. As before, the basis functions associated with regular nodes are the standard conforming linear finite-element basis functions. But, the basis functions associated with irregular nodes are piecewise quadratic. All the basis functions are globally continuous. The idea is to average the tangential derivatives in the construction in subsection 4.2. Referring the reader to Figure 4.2, we describe this procedure as follows.

P1. Use the values at the nodes A, B, C, F, and I to construct the three nonconforming linear finite-element basis functions defined in subsection 4.1 on the elements ΔABC, ΔAFB, and ΔACI, respectively.

P2. Set the value at D as the average of the values at D of the nonconforming linear finite-element basis functions defined ΔABC and ΔAFB constructed in P1. Assign the tangential derivative at D along AD to be the average of the values of the tangential derivatives (along AD) of the nonconforming

linear finite-element basis functions on ΔABC and ΔAFB constructed in P1. Similarly, assign the tangential derivative at D along DB as the average of the values of the tangential derivatives (along DB) of the nonconforming finite-element basis functions on ΔABC and ΔAFB constructed in P1.

P3. Repeat to set the value at E as the average of values at E of the nonconforming linear finite-element basis functions defined on the elements ΔABC and ΔACI in P1. Also assign the tangential derivatives along AE and EC as the average of those from the nonconforming finite-element basis functions along the same edge.

P4. Partition the element ΔABC into three subtriangles by an auxiliary line. We choose the auxiliary line in such a way that at least one of the angles (or complimentary angles if the angle is bigger than $\pi/4$) is bigger than or equal to $\pi/2$. In Figure 4.2, for example, the angles are $\angle EDB$, $\angle DEB$, and $\angle EBD$, where the complimentary angle of $\angle EDB$ is bigger than $\pi/4$.

P5. Assign the tangential derivatives along DE and BE exactly the same (no average) as those from the nonconforming finite-element basis functions.

P6. Set the values of the tangential derivatives along BE and BC exactly the same as those from the nonconforming finite-element basis function on ΔABC.

P7. Define the basis function ψ_i to be the piecewise quadratic function in the three subtriangles determined by the values at the points A, B, C, D, and E, respectively, and the tangential derivatives from each side of the triangles; see Figure 4.3 for an illustration.

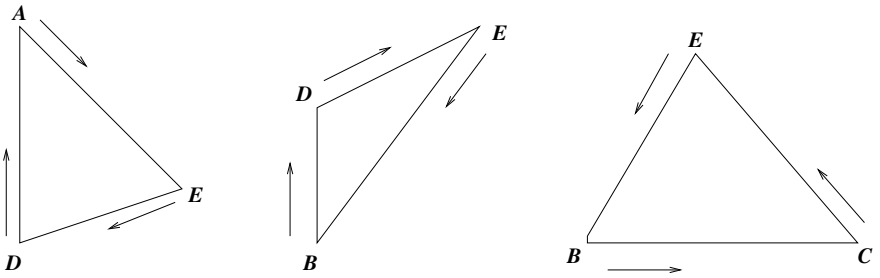

FIG. 4.3. *Three triangles on which piecewise continuous quadratic functions can be determined. The symbol "⟶" indicates a tangential derivative.*

We now give an error estimate for the interpolation error of this element for a given piecewise smooth function v. We first show that a quadratic function on a triangle is uniquely determined by its values at the three vertices and its tangential derivatives along the three sides at some particular points.

LEMMA 4.1. *Referring to the geometry in Figure* 4.4, *there is a unique quadratic polynomial*

$$I_h v(x,y) = v_A + a_{10}x + a_{01}y + a_{20}x^2 + a_{11}xy + a_{02}y^2 \tag{4.5}$$

that interpolates the values of v_A, v_D, and v_E, and three tangential derivatives v'_{AE}, v'_{AD}, and v'_{ED} defined at the three vertices A, E, and D, respectively.

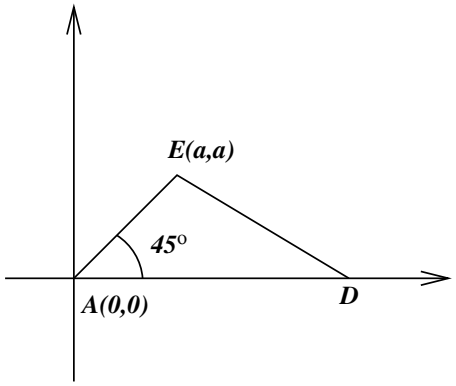

FIG. 4.4. *An illustration of determining the quadratic interpolation function.*

Proof. Using the undetermined coefficient method, we find the unique expression of the coefficients[2]

$$a_{10} = \frac{\tilde{h}v'_{AD} + 2v_D - 2v_A}{\tilde{h}},$$

$$a_{01} = -\frac{\tilde{h}v'_{AD} - \sqrt{2}v'_{AE}\tilde{h} + 2v_D - 2v_A}{\tilde{h}},$$

$$a_{20} = -\frac{\tilde{h}v'_{AD} + v_D - v_A}{\tilde{h}^2},$$

$$a_{11} = -\frac{-2\tilde{h}\alpha v'_{AD} - 2\alpha v_D + 2\alpha v_A + \tilde{h}^2 v'_{AD} + 2\tilde{h}v_D}{\tilde{h}^2\alpha}$$
$$- \frac{\sqrt{\tilde{h}^2 - 2\tilde{h}\alpha + 2\alpha^2}v'_{ED}\tilde{h} + \tilde{h}\alpha\sqrt{2}v'_{AE} - 2\tilde{h}v_E}{\tilde{h}^2\alpha},$$

$$a_{02} = \frac{\tilde{h}^2 v'_{AD}\alpha + 2\tilde{h}\alpha v_D - \tilde{h}^2\alpha\sqrt{2}v'_{AE} - \tilde{h}v'_{AD}\alpha^2 - \alpha^2 v_D + \alpha^2 v_A}{\tilde{h}^2\alpha^2}$$
$$+ \frac{v_E\tilde{h}^2 - v_A\tilde{h}^2 + \sqrt{\tilde{h}^2 - 2\tilde{h}\alpha + 2\alpha^2}v'_{ED}\tilde{h}\alpha + \tilde{h}\alpha^2\sqrt{2}v'_{AE} - 2v_E\tilde{h}\alpha}{\tilde{h}^2\alpha^2},$$

where $\tilde{h}$ is the distance from A to D, and the coordinates at E are (α, α). ∎

There are two steps in obtaining the interpolation error. First, the values of the quadratic function according to our algorithm at vertices either are directly copied from the conforming linear basis function (at the vertices of the right triangles) or are the average of values of the conforming linear basis function from the two adjacent triangles. Therefore, those values are $O(h^2)$ perturbations to v from the reference [18]. Similarly, the values of the tangential derivatives are $O(h)$ perturbations to that of v. Second, from the above reasoning, we can conclude that the values at the mid-points of each side of the triangle are $O(h^2)$ perturbations to v. Since the quadratic function can also be uniquely determined from its values at vertices and the three midpoints

[2]We use Maple to get the coefficients.

and it is insensitive to perturbations of those values (see [14]), we conclude that the interpolation function is an $O(h^2)$ perturbation to $v(x)$ in the entire triangle.

The second part of the argument is a direct consequence of the interpolation error estimate for the standard conforming P_2 finite element. The first part of the argument is a consequence of the following result.

LEMMA 4.2. *Let $a, b \in \mathbb{R}$ with $h := b - a > 0$. Let $v \in C^1[a, b]$. Then, there exists a unique quadratic polynomial p such that $p(a) = v(a)$, $p(b) = v(b)$, and $p'(a) = v'(a)$. Moreover, if v is smooth, then*

$$\|v - p\|_{L^\infty}(a, b) \le Ch^3,$$

$$\|v' - p'\|_{L^\infty}(a, b) \le Ch^2,$$

where $C > 0$ is a constant independent of h.

Proof. Note that any quadratic polynomial q can be written as

$$q(x) = q(a) + q'(a)(x - a) + \frac{q(b) - q(a) - q'(a)(b - a)}{(b - a)^2}(x - a)^2.$$

Therefore, the unique quadratic polynomial that interpolates $v(a)$, $v(b)$, and $v'(a)$ is given by

$$p(x) = v(a) + v'(a)(x - a) + \frac{v(b) - v(a) - v'(a)(b - a)}{(b - a)^2}(x - a)^2.$$

Now an application of the Bramble–Hilbert lemma [8] concludes the proof. ∎

The lemma is still true if we replace $p'(a)$ by $p'(b)$.

By the lemma, we see that if $p(a) = v(a) + O(h^2)$, $p(b) = v(b) + O(h^2)$, and $p'(a) = v'(a) + O(h)$, then $|v(x) - p(x)| = O(h^2)$ and $|v'(x) - p'(x)| = O(h)$ in the entire interval $[a, b]$ including the midpoint.

With the same local angle constraint given in [18] (e.g., at least one angle or complementary angle is larger than or equal to $\pi/4$), we have the following error estimates for the interpolation.

PROPOSITION 4.3. *Assume that $w = Q = 0$, $\beta(x)$ is a piecewise constant, and the solution u is piecewise C^2, i.e., $u^\pm \in C(\overline{\Omega^\pm})$. Then the following error estimates hold:*

$$\|I_h u - u\|_\infty \le Ch^2 \|D^2 u\|_{\infty, \Omega \setminus \sum T_r}, \tag{4.6}$$

$$\|I_h u - u\|_{H^1(\Omega)} \le Ch \|D^2 u\|_{\infty, \Omega \setminus \sum T_r}. \tag{4.7}$$

For the conforming linear finite-element space, the proof is given in [18]. So we just need to discuss the conforming quadratic finite-element space. The proof of the first inequality is straightforward, as has been discussed above. The proof of the second inequality is quite technical and tedious with different geometric configurations. This proof, though, is quite similar to that for the nonconforming immersed finite-element method (cf. [18]); we give only a sketch here. Taking the geometry in Figure 4.4 as an example, we have analytic expression of the interpolation function given in Lemma 4.1 in terms of its values and the tangential derivatives (averaging those of the nonconforming interpolation function). From the analytic expression of the

interpolation, it is easy to get $\|\nabla I_h u - \nabla I_h \tilde{u}\|_\infty \le Ch$, where $I_h\tilde{u}$ is any quadratic function when we perturb v_A, v_D, and v_E by $O(h^2)$, and v'_{AD}, v'_{AE}, and v'_{ED} by $O(h)$.

Our numerical tests reported in section 6 confirm such an estimate for the interpolation error. Note that, while the error bounds for the linear and quadratic basis functions are the same, numerical examples of our test problems show that the quadratic one behaves better numerically. Since the quadratic basis function is a conforming one, we can conclude that the finite-element solution is first order in the H^1 norm from the standard finite element theory.

Remark 1. Consider a uniform triangular mesh. For both conforming linear and conforming quadratic elements, the basis function ϕ_i associated with the ith node is nonzero only on the six surrounding triangular elements if the interface does not cut through any of these triangles. Otherwise, the support of a basis function includes two more triangular elements along the direction of the interface if the interface cuts through any of the surrounding triangle. A corresponding finite-difference scheme, however, generally has a nonstandard nine-point stencil.

Remark 2. If the coefficient β is continuous across the interface, i.e., $[\beta]_\Gamma = 0$, then both the linear and quadratic basis functions become the standard linear basis functions.

5. Implementation. In this section, we give details about the numerical extension of the jumps w and Q, the assembly of the stiffness matrix and load vector, and the evaluation of certain integrals on part of an interface element.

5.1. Numerical extension of the jumps w and Q. We use a Gaussian quadrature to compute the stiffness matrix and the load vector in each triangle $\triangle ADE$, $\triangle DEB$, and $\triangle BEC$ in Figure 4.2. Let x be such a Gaussian point which is close to the interface. We need to extend the jumps w and Q to this Gaussian point by the definition of w_ρ and Q_ρ given in E2 and E3 in section 2. This is done in two steps. The first step is to find an approximation of the orthogonal projection $\hat{x}$ of x on the interface Γ; see Lemma 2.1. The second step is to define the extensions of w and Q at x as $w(\hat{x})$ and $Q(\hat{x})$, respectively.

The orthogonal projection can be approximated by

$$\hat{x} = x + \alpha p,$$

where

$$p = \begin{bmatrix} \varphi_x(x) \\ \varphi_y(x) \end{bmatrix}.$$

Here, a subscript denotes a partial derivative. The scalar α is determined from the following quadratic equation:

$$\varphi(x) + (\nabla\varphi(x)\cdot p)\,\alpha + \frac{1}{2}\left(p^T \mathrm{He}(\varphi(x))\, p\right)\,\alpha^2 = 0,$$

where

$$p^T \mathrm{He}(\varphi)\, p = \varphi_x^2\,\varphi_{xx} + 2\,\varphi_x\varphi_y\varphi_{xy} + \varphi_y^2\,\varphi_{yy}.$$

The sign of α is chosen to be opposite that of $\varphi(x)$. If the underlying mesh is uniform, formulated from a Cartesian grid, then, the partial derivatives $\nabla\varphi(x)$ and the Hessian

matrix $\mathrm{He}(\varphi)$ can be computed at x using the standard centered five-point finite-difference formula. Using the method above, the computed projections have third order accuracy.

Note that in our implementation, we use the orthogonal projections $\hat{x} \in \Gamma$. It is also possible to use the orthogonal projections $\hat{x} \in \Gamma_h$. The difference in the finite-element solution using the two different implementations is small since the area of the mismatched region $\sum T_r$ is small. If the level set function is the signed distance function, or a good approximation of the signed distance function, then the error in approximating $\hat{x}$ would be $O(h^3)$; see [19]. We also refer the reader to [9,10] for some of the recent discussions on computing orthogonal projections.

Note that when one uses a finite number of piecewise linear basis functions $\phi_h' s \in V_h$ to seek the finite-element solution, we have introduced an error in substituting $V = H^1(\Omega)$ by V_h which is often $O(h^2)$. Other approximating errors, such as numerical integration, approximating orthogonal projections, have little effect on the finite-element solutions as long as they are higher order terms of h^3.

In practice, we need only to extend both jumps w and Q to $N(\Gamma, 2h)$, the $2h$ neighborhood of the interface Γ. This is described in (5.4), where the last two terms are identical but differ by a sign for noninterface triangles.

5.2. Assembly of stiffness matrix and load vector. On noninterface elements where the interface does not cut through, we can use the standard way in computing the contribution to the stiffness matrix and the load vector. On interface elements where the interface cuts through, we need to modify the load vector (the right-hand side); but the computation for the stiffness matrix remains the same as in the case of homogeneous jump conditions.

To fix this idea, let us focus on the quadratic conforming element (cf. subsection 4.3). We rewrite the finite-element equation (3.4) in terms of $u_h = q_h + u_\rho$:

(5.1)
$$\int_\Omega \beta \nabla u_h \cdot \nabla v_h \, dx = \int_\Omega f \, v_h \, dx + \int_\Omega \beta \nabla u_\rho \cdot \nabla v_h \, dx + \int_\Omega H(\varphi) \, \nabla \cdot (\beta \nabla \tilde{u}_\rho) \, v_h \, dx \qquad \forall v_h \in V_h,$$

where H is the Heaviside function and $\tilde{u}_\rho$ is given by

$$\tilde{u}_\rho(x) = w_\rho(x) + \frac{Q_\rho(x)}{\beta^+(x)} \frac{\varphi(x)}{|\nabla \varphi(x)|}, \qquad x \in \Omega. \tag{5.2}$$

Note that $\tilde{u}_\rho$ is smooth in a neighborhood of Γ and that $u_\rho = \chi_{\Omega^+} \tilde{u}_\rho$ and its corresponding flux have nonhomogeneous jumps across the interface.

Let $\{\phi_j(x)\}$ be the basis functions of the modified conforming finite-element space. Then, we define

(5.3)
$$u_h(x) = \begin{cases} \displaystyle\sum_j \alpha_j \phi_j(x) & \text{if } x \text{ belongs to a noninterface triangle,} \\ \displaystyle\sum_j \alpha_j \phi_j(x) + \sum_j u_\rho(x_j) \phi_j(x) & \text{otherwise,} \end{cases}$$

where $\phi_j(x)$ is the jth basis function centered at x_j. The left-hand side is exactly the same as in the case of the homogeneous jump condition. The entries of the stiffness matrix are

$$a_{ij} = \int_\Omega \beta \nabla \phi_i \cdot \nabla \phi_j \, dx.$$

Only the right-hand side of the system of equation needs to be modified for certain triangles near the interface.

At a noninterface triangle that is entirely in Ω^-, the last two terms of integration over the triangle are zero, since $H(\varphi(x)) = 0$ and $u_\rho = 0$. The situation is a little more complicated for triangles in Ω^+. If all the nonzero basis functions over a triangle in Ω^+ have no support from interface triangles, then the last two terms in (5.1) are canceled out. To see this, let T_k be such a triangle, and let ϕ_l be such a basis function with Ω_l being its support. We have

$$\begin{aligned}
&\int_{\Omega_l} \beta \nabla u_\rho \cdot \nabla \phi_l \, dx + \int_{\Omega_l} H(\varphi) \, \nabla \cdot (\beta \nabla \tilde{u}_\rho) \, \phi_l \, dx \\
&\qquad = \int_{\Omega_l} \beta \nabla u_\rho \cdot \nabla \phi_l \, dx + \int_{\Omega_l} \nabla \cdot (\beta \nabla \tilde{u}_\rho) \, \phi_l \, dx \\
&\qquad = \int_{\Omega_l} \beta \nabla u_\rho \cdot \nabla \phi_l \, dx + \int_{\partial \Omega_l} \frac{\partial \tilde{u}_\rho}{\partial n} \phi_l \, ds - \int_{\Omega_l} \beta \nabla \tilde{u}_\rho \cdot \nabla \phi_l \, dx = 0,
\end{aligned}$$

since $\tilde{u}_\rho = u_\rho$ and $\phi_l = 0$ along $\partial \Omega_l$. In other words, the total contribution of the line integral along the boundary of each triangle summed up to be zero. The right-hand side of the load vector can be summarized as

$$F_i = \begin{cases} \displaystyle\int_{\Omega_i} f \phi_i \, dx & \text{if } \Omega^s(\phi_i) \cap \Gamma = \emptyset, \\ \displaystyle\int_{\Omega_i} f \phi_i \, dx + \int_{\Omega^s} H(\varphi) \nabla \cdot (\beta \nabla \tilde{u}_\rho) \, \phi_i \, dx & \\ \qquad \displaystyle + \sum_j u_\rho(x_j) \int_{\Omega_i} \beta \nabla \phi_i \cdot \nabla \phi_j \, dx & \text{otherwise,} \end{cases} \tag{5.4}$$

where $\Omega^s(\phi_i)$ is the support of ϕ_i.

5.3. Evaluation of $\int_{\Omega^s} H(\varphi) \nabla \cdot (\beta \nabla \tilde{u_\rho}) \, \phi_i \, dx$. Take Figure 4.1 as an example. There are two ways to evaluate the integral. One way is to use

$$\int_{T_j} H(\varphi) \nabla \cdot (\beta \nabla \tilde{u}_\rho) \, \phi_i \, dx = \int_{\partial \triangle ADE} \beta \, \frac{\partial \tilde{u}_\rho}{\partial n} \, \phi \, ds - \int_{\triangle ADE} \nabla \tilde{u}_\rho \cdot \nabla \phi \, dx. \tag{5.5}$$

The line integral is evaluated using a Gaussian quadrature formula or some other numerical quadrature.

The second approach is to evaluate the double integral directly over the triangle using a quadrature formula, say, the four-point formula [14]. The coefficient β is approximated by a constant in the triangle. In order to evaluate the values of the integrand at a given point x, we first find a square $[x_i, x_{i+1}] \times [y_j, y_{j+1}]$ that contains the point x. The Laplacian at the vertices $(x_{i\pm1}, y_{j\pm1})$ is computed using the standard three-point central finite difference formula. Finally, the Laplacian at the point x is interpolated using the bilinear interpolation; see [17].

6. Numerical results. We report two examples of numerical calculations using our conforming quadratic immersed-interface finite-element method. In each of the calculations, we used ITPACK [23] to solve the resulting linear system of equations.

Example 1. *Homogeneous jump conditions.* This example is from [18]. We consider the problem (1.1)–(1.5) with $\Omega = (-1,1)\times(-1,1)$, Γ being the circle centered at point $(0,0)$ with radius $R = 0.5$, $\beta^- = 1$, and $\beta^+ = 100$. The source term $f(x,y)$ and the Dirichlet boundary data $u_0(x,y)$ are calculated from the exact solution $u(x,y)$:

$$u(x,y) = \begin{cases} \dfrac{r^3}{\beta^-} & \text{if } r \le R, \\ \dfrac{r^3}{\beta^+} + \left(\dfrac{1}{\beta^-} - \dfrac{1}{\beta^+}\right) R^3 & \text{otherwise,} \end{cases}$$

where $r = \sqrt{x^2+y^2}$. The exact solution satisfies the homogeneous jump conditions.

In Table 6.1 (a), we show a grid refinement analysis of our computations. The first column $E_N = \|u - u_h\|_\infty$ is the error of the finite-element solution measured in the L^∞ norm, and the second column is the estimate of the order of accuracy using the formula

$$\text{order} = \frac{\log\left(\|E_N\|_\infty / \|E_{2N}\|_\infty\right)}{\log 2}.$$

The sixth and eighth columns are defined as

$$e_{x,\infty} = \left\| \frac{\partial u}{\partial x} - \frac{\partial I_h u}{\partial x} \right\|_{\Omega',\infty}, \qquad e_{y,\infty} = \left\| \frac{\partial u}{\partial y} - \frac{\partial I_h u}{\partial y} \right\|_{\Omega',\infty},$$

respectively. We see clearly the second order accuracy. The fourth to the last columns are the interpolation errors. We see that the interpolation errors are of second order and its derivatives are of first order. These are optimal.

In Table 6.1 (b), we show the results and comparison of the finite-element solution in L^∞, L^2, and H^1 norms. We see second order convergence in L^∞ and L^2 norms and first order in the H^1 norm as expected.

Example 2. *A complicated interface and nonhomogeneous jump conditions.* We consider the problem (1.1)–(1.5) with $\Omega = (-1,1)\times(-1,1)$ and the interface Γ being the zero level set of the function

$$\varphi(x,y) = \sqrt{x^2+y^2} - 0.1\sin(5\theta - \pi/5) - 0.5,$$

where $\tan\theta = x/y$ and $0 \le \theta \le 2\pi$; see Figure 6.1 for the geometry. The function β is defined by

$$\beta(x,y) = \begin{cases} x^2+y^2+1 & \text{if } (x,y) \in \Omega^-, \\ b & \text{otherwise,} \end{cases}$$

where $b > 0$ is a parameter. The function f is defined by

$$f(x,y) = \begin{cases} -4\left(2x^2+2y^2+1\right) & \text{if } (x,y) \in \Omega^-, \\ 2\sin x\cos y & \text{otherwise.} \end{cases}$$

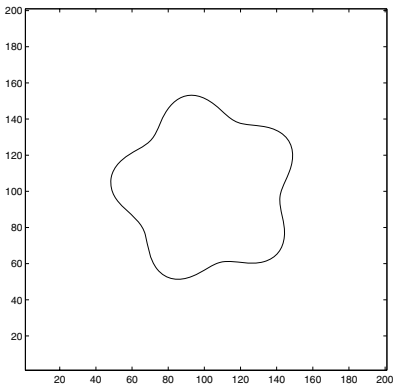

FIG. 6.1. *The domain and the interface for Example* 2.

Both β and f have nonzero jumps across the interface Γ. The exact solution is

$$u(x,y) = \begin{cases} x^2 + y^2 & \text{if}(x,y) \in \Omega^-, \\ \dfrac{1}{b}\left(\sin x \cos y + \log\sqrt{x^2+y^2}\right) & \text{otherwise.} \end{cases}$$

Notice that both the solution u and the normal flux $\beta\partial_n u$ have nonzero jumps across the interface Γ.

We remark that the solution behavior depends on the magnitude of the parameter b. If b is large, then the solution is close to a piecewise quadratic function. If b is small, then the jumps of the solution and its normal flux across the interface are very large. Numerically, this gives rise to difficulties in achieving optimal convergence

properties [1,16]. We test our method for various b and analyze the computed results.

In Table 6.2, we show a grid refinement analysis for $b = 100$. We see clearly the second order accuracy in L^∞ and L^2 norms and first order accuracy in the H^1 norm.

TABLE 6.2

A grid refinement analysis for Example 2 *with* $b = 100$*, where* p_i *are the approximated convergence order and the norms that involve the partial derivatives. Second order accuracy in* L^∞ *norm is observed.*

N	$\|u-u_h\|_\infty/\|u\|_\infty$	p_1	$\|u-u_h\|_{L^2}$	p_2	$\|u-u_h\|_{H^1}$	p_3
32	1.1995×10^{-1}		1.6705×10^{-2}		3.9175×10^{-1}	
64	2.4397×10^{-2}	2.30	1.8542×10^{-3}	3.17	1.9551×10^{-1}	1.00
128	5.3913×10^{-3}	2.18	3.2668×10^{-4}	2.51	9.8144×10^{-2}	0.99
256	1.1218×10^{-3}	2.27	5.1452×10^{-5}	2.66	4.9894×10^{-2}	0.94
512	2.7480×10^{-4}	2.03	9.4668×10^{-6}	2.44	2.5310×10^{-2}	0.98

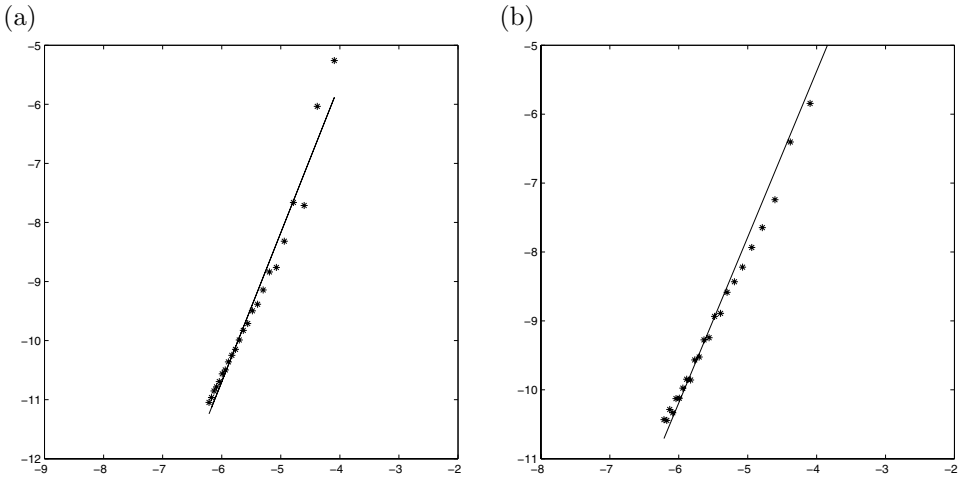

FIG. 6.2. *The linear regression analysis in the* L^∞ *norm in* log-log *scale with the mesh varying according to* $N = 40 + 20k$*,* $k = 0, 1, \ldots, 23$*.* (a) $b = 1$*; the slope (convergence order) is* 2.8122*.* (b) $b = 0.1$*; the slope is* 2.4061*.*

Where b gets smaller, the jumps in the solution and flux get larger. For interface problems, the errors obtained from non–body-fitted meshes usually do not decrease monotonically as we refine the mesh; see, for example, [15]. For small b, it is thus more realistic to find the asymptotic convergence rate as the slope of the line fitting of the experimental data $(\log(h_i), \log(E_i))$.

In Figure 6.2, we show the linear regression analysis for $b = 1$ and $b = 0.1$ for the computed finite-element solution. For these two cases, the convergence orders are 2.8122 and 2.4061. As the mesh gets finer, the linear regression analyses (by deleting the results from coarse meshes) get closer to number two, indicating a second order accuracy. In Figure 6.3, we also show the linear regression analysis in the L^2 and H^1 norms. The convergence orders are 1.9906 and 0.9135, respectively.

Figure 6.4 shows the result for $b = 0.01$ that is quite small, and hence there is a large ratio in the coefficient from both sides of the interface. The convergence order from the sample meshes ranging from 40 to 500 with 10 increments is 1.8875; see Figure 6.4(a). But as the mesh gets finer, the linear regression analyses done by cutting the results from coarse meshes get closer to number two, again indicating a second order accuracy. Figure 6.4(b) shows the convergence order to be 1.9811.

7. Conclusions. We have developed a class of immersed-interface finite-element methods for solving elliptic interface problems with *nonhomogeneous jump conditions*. These methods consist of three parts:

(a) a weak formulation of the problem in which the nonhomogeneous jump conditions are removed by using the level-set representation of the interface;
(b) construction of immersed-interface finite-element basis functions for irregular nodes that satisfy the homogeneous jump conditions; and
(c) several techniques of numerical implementation for the resulting finite-element equations.

Our methods have several advantages. For instance, they result in symmetric positive definite systems of linear equations. Moreover, they can be used with the level-set method for fast simulations of interface dynamics. Our basic error analysis and numerical tests demonstrate that such methods have optimal convergence properties.

THE CROUZEIX–RAVIART FE ON NONMATCHING GRIDS WITH AN APPROXIMATE MORTAR CONDITION*

TALAL RAHMAN†, PETTER BJØRSTAD‡, AND XUEJUN XU§

Abstract. A new approximate mortar condition is proposed for the lowest order Crouzeix–Raviart finite element on nonmatching grids, which uses only the nodal values on the interface for the calculation of the mortar projection. This approach allows for improved and more flexible algorithms compared to those for the standard mortar condition where nodal values in the interior of a subdomain, those closest to a mortar side of the subdomain, are also required in the calculation.

Key words. Crouzeix–Raviart finite element, nonmatching grids, mortar condition, additive Schwarz

1. Introduction. The general concept of the mortar technique was originally introduced by Bernardi, Maday, and Patera in [3], which provides a useful tool for coupling different discretization schemes. In recent years, the approach has largely been applied to nonmatching grids for the design of algorithms which are very well suited for parallel implementation and which can easily handle complicated geometries and heterogeneous materials. In order to ensure that the overall discretization makes sense, an optimal coupling between the meshes is required. In a standard mortar technique, this condition is realized by applying the condition of weak continuity on the solution, called the mortar condition, saying that the jump of the solution along the interface between two meshes is orthogonal to some suitable test space. The mortar technique has been extensively studied by many authors. A saddle point formulation for the mortar technique was studied in [2]. Later, an extension to three dimensions was introduced in [1]. Further analysis and extensions of the mortar technique can be found in [5, 9, 15, 21, 23, 24, 10] and the references therein.

In this paper, we are interested in the application of the mortar technique on nonmatching grids, where in each subgrid, the nonconforming P1 or the lowest order Crouzeix–Raviart (CR) finite element [13] is used for the discretization. The first analysis of the mortar technique for such an element was given by Marcinkowski in [15]. In the event of applying the mortar condition, it is necessary to know the function on the interface. For the conforming P1 finite element, it is enough to know the nodal values along the interface. However, for the nonconforming P1 finite element (the lowest order CR finite element), where the degrees of freedom are associated

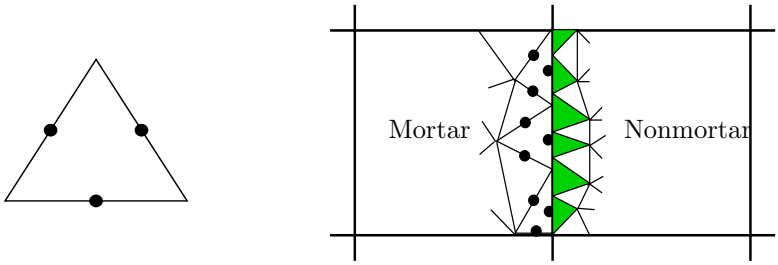

FIG. 1.1. *The lowest order CR finite element (left) and two nonmatching grids (right). CR basis functions associated with the nodes on the mortar side, denoted by dots (in the interior) and semidots (on the mortar side of the interface), have nonzero support on the nonmortar side, denoted by shaded triangles.*

with the edge midpoints, the function on the interface depends on the nodal values corresponding to interface nodes and some subdomain interior nodes lying closest to the interface; see [15] and Figure 1.1 for an illustration.

A variant of the mortar technique has recently been proposed in [17], where the standard mortar condition [15] has been modified so that the method will use only the nodal values on the interface. However, the error estimate as given in [17] requires the mesh sizes to be of the same order. In this paper, we improve this situation by modifying the mortar condition a step further, giving us an error estimate which is free from any such requirement on the mesh sizes.

The motivation to replace the standard mortar condition with an approximate mortar condition which uses nodal values only on the interface lies in the fact that the new approach will facilitate the design of improved and less intricate algorithms for the CR finite element on nonmatching grids. As we know, there already exists a number of algorithms for the conforming P1 mortar finite element, many of which, particularly the domain decomposition algorithms, can be extended to the CR mortar finite element; see, for instance, [15, 19]. In order to be able to readily extend an algorithm for the conforming P1 mortar finite element to the CR mortar finite element, it is desirable that the latter uses similar geometrical information as the former, for instance, using nodal values only on the interface for the mortar condition. An important application of the approximate mortar condition is the solution of elliptic problems with discontinuous coefficients using, for instance, parallel domain decomposition algorithms of the nonoverlapping type. Since, in the CR standard mortar case, basis functions corresponding to some interior nodes of a subdomain may have nonzero support on the neighboring subdomain, special care with respect to those nodes is required in defining the nonoverlapping subspaces in the algorithm; cf. [16, 19]. This results in a more intricate code as compared to the code in the approximate mortar case. In fact, the algorithm is affected even further; the stiffness matrices corresponding to subspaces living on the interfaces lose their block diagonal structure, which is natural in the approximate mortar approach; cf. [19]. It is also important to note that, in the application of the mortar condition for the CR finite element, the matrix on the nonmortar side, called the slave matrix, is a diagonal matrix. An application of the standard mortar condition simply destroys the advantage of having a diagonal slave matrix in the design of any effective algorithms. Another important application of the approximate mortar condition, which seems now obvious, is the construction of the intergrid transfer operator which is a vital and already an intricate part of a multilevel or multigrid algorithm; cf. [25, 18]. In the analysis of all such algorithms (those mentioned

here are for two-dimensional problems), one hardly notices the difference between using the standard and the approximate mortar conditions. However, the difference is significant in the implementation, especially for three-dimensional problems where the interfaces are no longer straight lines but planes. An analysis of a three-dimensional extension of the CR approximate mortar finite element method is already in progress.

The concept of using an approximate mortar condition has started to receive more and more attention. Recently, an additive Schwarz preconditioner for an approximate CR mortar finite element has been used to precondition the standard CR mortar finite element; see [16]. Approximate constraint has also been used in other contexts; see [4], for instance, where approximate constraint was indeed necessary for coupling the wavelet and the finite element.

The paper is organized as follows. In section 2, a detailed description of the new approximate mortar condition is given, and the corresponding discrete problem is then formulated. The analysis of the new approach is found in section 3, and a brief discussion of the implementation is given in section 5. For the purpose of experimenting, in section 4, we also propose an additive Schwarz preconditioner for the new approximate CR mortar finite element. Numerical results supporting our theory are presented in the final section.

2. The discrete problem. Let $\Omega \subset R^2$ be a bounded, simply connected polygonal domain, partitioned into a collection of nonoverlapping polygonal subdomains, $\Omega_i, i = 1, N$. We consider the following problem: Find $u^* \in H_0^1(\Omega)$ such that

$$a(u^*, v) = f(v), \quad v \in H_0^1(\Omega), \tag{2.1}$$

where

$$a(u,v) = \sum_{i=1}^{N} \int_{\Omega_i} \nabla u \cdot \nabla v \; dx \quad \text{and} \quad f(v) = \sum_{i=1}^{N} \int_{\Omega_i} fv \; dx.$$

We consider the subdomains to be geometrically conforming. With each subdomain Ω_i, we associate a quasi-uniform triangulation $\mathcal{T}_h(\Omega_i)$ of mesh size h_i. The resulting triangulation can be nonmatching across subdomain interfaces.

Let $X_{h_i}(\Omega_i)$ (or simply $X_h(\Omega_i)$) be the nonconforming P1 (CR) finite element space defined on a shape regular triangulation $\mathcal{T}_{h_i}(\Omega_i)$ (or simply $\mathcal{T}_h(\Omega_i)$) of Ω_i, consisting of functions which are piecewise linear in each triangle $\tau \in \mathcal{T}_h(\Omega_i)$, continuous at the interior edge midpoints of Ω_{ih}^{CR}, and vanishing at the edge midpoints of $\partial\Omega_{ih}^{CR} \cap \partial\Omega$ lying on the boundary $\partial\Omega$. We use a subscript for h only when we need to differentiate the discretization of one domain from the other. Let $X_h^0(\Omega_i) \subset X_h(\Omega_i)$ be the space of functions whose values at $\partial\Omega_{ih}^{CR}$ are equal to zero. Here, Ω_{ih}^{CR} and $\partial\Omega_{ih}^{CR}$ represent the sets of edge midpoints, i.e., the nonconforming P1 (CR) nodal points, of Ω_i and $\partial\Omega_i$, respectively. Note that $\overline{\Omega}_{ih}^{CR} = \Omega_{ih}^{CR} \cup \partial\Omega_{ih}^{CR}$ and $\Omega_{ih}^{CR} \cap \partial\Omega_{ih}^{CR}$ is an empty set. Without the superscript CR, the sets represent the corresponding sets of triangle vertices, i.e., the P1 conforming nodal points. Using $X_h(\Omega_i)$, we define the product space X_h on the whole domain as

$$X_h(\Omega) = X_h(\Omega_1) \times X_h(\Omega_2) \ldots \times X_h(\Omega_N).$$

Let Γ_{ij} be an open edge common to Ω_i and Ω_j, i.e., $\overline{\Gamma}_{ij} = \overline{\Omega}_i \cap \overline{\Omega}_j$. Note that each interface Γ_{ij} inherits two different discretizations from its two sides, $\mathcal{T}_{h_i}(\gamma_{ij})$ and $\mathcal{T}_{h_j}(\gamma_{ij})$. We select one side of Γ_{ij} as the master side, called the mortar, and the other

side as the slave side, called the nonmortar. We define the skeleton $\mathcal{S} = (\cup\partial\Omega_i) \setminus \partial\Omega$ of the decomposition as follows:

$$\overline{\mathcal{S}} = \bigcup_m \overline{\gamma}_m, \quad \text{with } \gamma_m \cap \gamma_n = \emptyset \ \text{ if } \ m \neq n,$$

where each γ_m denotes an open mortar edge. We write γ_m as $\gamma_{m(i)}$, if it is an edge of Ω_i, i.e., $\gamma_{m(i)} \subset \partial\Omega_i$. Let $\delta_m = \delta_{m(j)} \subset \partial\Omega_j$ be the corresponding open nonmortar edge of Ω_j that occupies the same geometrical space as $\gamma_{m(i)}$, i.e., $\gamma_{m(i)} = \Gamma_{ij} = \delta_{m(j)}$ (see Figure 2.1 for an illustration).

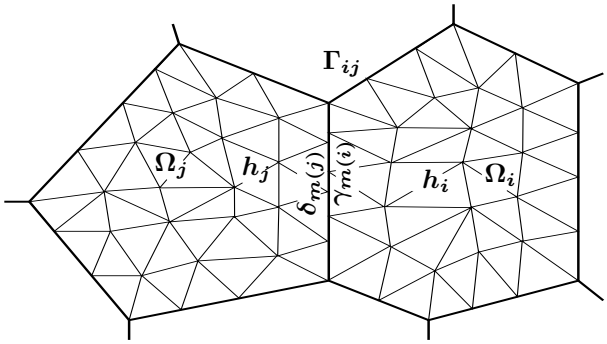

FIG. 2.1. *Illustrating a mortar side ($\gamma_{m(i)}$) and the corresponding nonmortar side ($\delta_{m(j)}$) of a subdomain interface (Γ_{ij}) with nonmatching meshes on both sides.*

Since the triangulations on Ω_i and Ω_j do not match on their common interface Γ_{ij}, the functions in $X_h(\Omega)$ are discontinuous on the set $\gamma^{CR}_{m(i)h}$ or $\delta^{CR}_{m(j)h}$ of edge midpoints on Γ_{ij}. In other words, $X_{h_i}(\gamma_{m(i)}) = X_{h_i}(\Omega_i)|_{\gamma_{m(i)}}$ differ from $X_{h_j}(\delta_{m(j)}) = X_{h_j}(\Omega_j)|_{\delta_{m(j)}}$ at those points. A weak continuity condition, called the mortar condition, is therefore imposed. Let $u_h \in X_h$, where $u_h = \{u_i\}_{i=1}^N$. A function $u_h \in X_h$ satisfies the mortar condition on $\delta_{m(j)} = \Gamma_{ij} = \gamma_{m(i)}$ if

$$Q_m J_m u_i = Q_m u_j, \tag{2.2}$$

where J_m is an interpolation operator to be defined below, and Q_m is the L^2-projection operator $Q_m : L^2(\Gamma_{ij}) \to M^{h_j}(\delta_{m(j)})$ defined as

$$(Q_m u, \psi)_{L^2(\delta_{m(j)})} = (u, \psi)_{L^2(\delta_{m(j)})} \qquad \forall \psi \in M^{h_j}(\delta_{m(j)}), \tag{2.3}$$

where $M^{h_j}(\delta_{m(j)}) \subset L^2(\Gamma_{ij})$ is the test space of functions which are piecewise constant on the triangulation of $\delta_{m(j)}$, and $(\cdot,\cdot)_{L^2(\delta_{m(j)})}$ denotes the L^2 inner product on $L^2(\delta_{m(j)})$. We remark that in the original mortar method (cf. [15]) the operator J_m is simply the identity operator.

Let $P^1(\tau)$ be the space of linear functions on a triangle $\tau \in \mathcal{T}_h(\Omega_i)$, uniquely determined by their values at the vertices. Denote by $Z_h(\Omega_i) = \Pi_{\tau\in\mathcal{T}_h(\Omega_i)} P^1(\tau)$ the space of piecewise linear functions defined on the triangulation $\mathcal{T}_h(\Omega_i)$. Let $\mathcal{T}_{\frac{h}{2}}(\Omega_i)$ be the triangulation associated with the Ω_i, which is obtained as a result of dividing the edges of $\mathcal{T}_h(\Omega_i)$. Denote by $Y_{\frac{h}{2}}(\Omega_i)$ the conforming space of piecewise linear and continuous functions on the triangulation $\mathcal{T}_{\frac{h}{2}}(\Omega_i)$. The functions of this space are

defined by their values at the set $\overline{\Omega}_{i\frac{h}{2}}$ of all edge endpoints of $\mathcal{T}_{\frac{h}{2}}(\Omega_i)$. Let $Y^0_{\frac{h}{2}}(\Omega_i) \subset Y_{\frac{h}{2}}(\Omega_i)$ be the space of functions whose values at $x \in \partial\Omega_{i\frac{h}{2}}$ are equal to zero. It is easy to see that $\overline{\Omega}_{i\frac{h}{2}} = \overline{\Omega}^{CR}_{ih} \cup \overline{\Omega}_{ih}$.

Let $\mathcal{E}$ denote an edge (a triangle edge) or an edge segment. The midpoint and the left and right endpoints of each edge (or edge segment) $\mathcal{E}$ are denoted by $x^{\mathcal{E}}_m$, $x^{\mathcal{E}}_l$, and $x^{\mathcal{E}}_r$, respectively. The length of $\mathcal{E}$ is denoted by $h_{\mathcal{E}}$.

We now define the operator $J_m : X_h(\gamma_m) \to Z_h(\gamma_m)$. It is based on the definition of another interpolation operator $I_m : X_h(\gamma_m) \to Y_{\frac{h}{2}}(\gamma_m)$; see Definition 2.1.

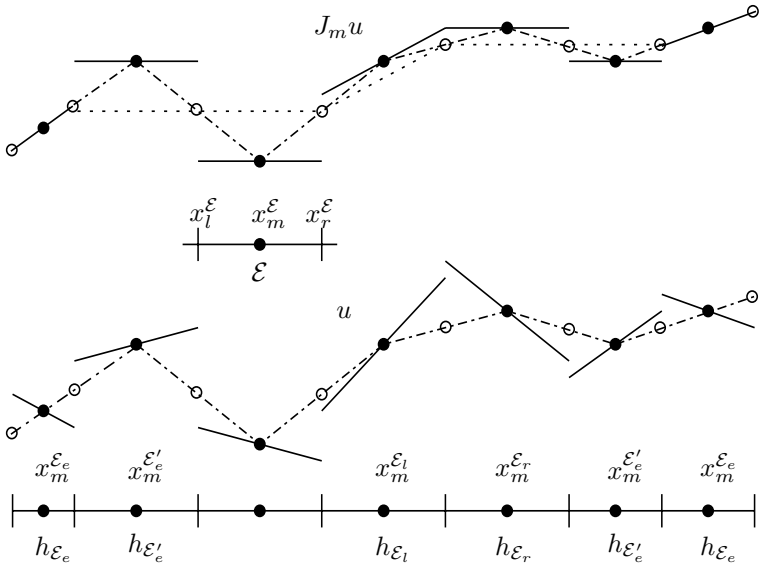

FIG. 2.2. *Illustrating the interpolation operator J_m. Here $u \in X_h(\gamma_m)$ is a (discontinuous) piecewise linear function shown (using solid lines) in the lower figure. The dashed-dotted lines (in both the upper and lower figures) correspond to $I_m u$; cf. Definition* 2.1. *The solid lines in the upper figure correspond to $J_m u$; cf. Definition* 2.2.

DEFINITION 2.1. *For $u \in X_h(\gamma_m)$, $I_m u \in Y_{\frac{h}{2}}(\gamma_m)$ is defined by the nodal values as*

$$I_m u(x) = \begin{cases} u(x), & x \in \gamma^{CR}_{mh}, \\ \frac{h_{\mathcal{E}_r}}{h_{\mathcal{E}_l}+h_{\mathcal{E}_r}} u(x^{\mathcal{E}_l}_m) + \frac{h_{\mathcal{E}_l}}{h_{\mathcal{E}_l}+h_{\mathcal{E}_r}} u(x^{\mathcal{E}_r}_m), & x \in \gamma_{mh}, \\ u(x^{\mathcal{E}_e}_m) + \frac{h_{\mathcal{E}_e}}{h_{\mathcal{E}_e}+h_{\mathcal{E}'_e}} \left(u(x^{\mathcal{E}_e}_m) - u(x^{\mathcal{E}'_e}_m) \right), & x \in \partial\gamma_{mh}. \end{cases}$$

Here, $\mathcal{E}_l$ and $\mathcal{E}_r$ are the left and the right neighboring edges of $x \in \gamma_{mh}$, respectively. $\mathcal{E}_e$ represents a triangle edge of $\mathcal{T}_h(\gamma_m)$, touching $\partial\gamma_m$, and $\mathcal{E}'_e$ is the corresponding neighboring edge.

The interpolation is done basically by first joining the neighboring edge midpoints using straight lines, and then simply extending the two end straight lines toward the end of the mortar γ_m; see Figure 2.2. The operator J_m can now be defined using I_m.

DEFINITION 2.2. *For $u \in X_h(\gamma_m)$, $J_m u \in Z_h(\gamma_m)$ is a piecewise linear function on the edges, $\{\mathcal{E}\}$, of γ_m, defined by its values at the two endpoints, $x^{\mathcal{E}}_l \in \overline{\gamma}_{mh}$ and*

$x_r^{\mathcal{E}} \in \overline{\gamma}_{mh}$, *of each such edge* $\mathcal{E}$. *If* $\mathcal{E}$ *is an interior edge of* γ_m, *then*

$$J_m u(x) = \begin{cases} u(x_m^{\mathcal{E}}) + \frac{1}{2}\left\{I_m u(x_l^{\mathcal{E}}) - I_m u(x_r^{\mathcal{E}})\right\}, & x = x_l^{\mathcal{E}}, \\ u(x_m^{\mathcal{E}}) + \frac{1}{2}\left\{I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}})\right\}, & x = x_r^{\mathcal{E}}. \end{cases}$$

It is easy to see that, if $\mathcal{E}$ *is a boundary edge of* γ_m, *then* $J_m u(x) = I_m u(x)$ *for* $x = x_l^{\mathcal{E}}, x_r^{\mathcal{E}}$.

As seen from Figure 2.2; for each edge $\mathcal{E}$ with edge midpoint $x_m^{\mathcal{E}}$, the straight line $J_m u$ passes through $u(x_m^{\mathcal{E}})$; in other words, $J_m u(x_m^{\mathcal{E}}) = I_m u(x_m^{\mathcal{E}}) = u(x_m^{\mathcal{E}})$. It is not difficult to see that the operator J_m preserves all linear functions on the mortar.

Let $V_h \subset X_h$ be the subspace of functions which satisfy the mortar condition for all $\delta_m \subset \mathcal{S}$. Since functions of V_h are not continuous, for $u, v \in X_h$, we use the broken bilinear form $a_h(\cdot,\cdot)$ defined by

$$a_h(u,v) = \sum_{i=1}^{N} a_i(u,v) = \sum_{\tau \in \mathcal{T}_h(\Omega_i)} \int_\tau \nabla u \cdot \nabla v \, dx$$

and the corresponding broken H^1 seminorm $|u|^2_{H^1_h(\Omega_i)} = \sum_{\tau \in \mathcal{T}_h(\Omega_i)} |u|^2_{H^1(\tau)}$. The discrete problem takes the following form: Find $u_h^* = \{u_i\}_{i=1}^N \in V_h$ such that

$$a_h(u_h^*, v_h) = f(v_h) \quad \forall v_h \in V_h. \tag{2.4}$$

In our analysis, we will be using the subspace $H^{\frac{1}{2}}_{oo}(\delta_m)$ which is defined as consisting of functions $v \in H^{\frac{1}{2}}(\delta_m)$ such that their trivial extensions by zero to all of $\partial\Omega_j$ belong to the space $H^{\frac{1}{2}}(\partial\Omega_j)$; cf. [14]. The corresponding norm $\|\cdot\|_{H^{\frac{1}{2}}_{oo}(\delta_m)}$ is defined as

$$\| v \|_{H^{\frac{1}{2}}_{oo}(\delta_m)} = \inf_{w \in H^1_{0,\partial\Omega_j \setminus \delta_m}(\Omega_j), w|_{\delta_m} = v} \| v \|_{H^1(\Omega_j)},$$

where $H^1_{0,\delta}$ is the closure in H^1 of all C^∞ functions vanishing on δ.

3. Analysis. Since, by construction, both $u \in X_h(\gamma_m)$ and $J_m u \in Z_h(\gamma_m)$ are linear on any edge $\mathcal{E}$ belonging to an interface γ_m, and they have the same value at the edge midpoint $x_m^{\mathcal{E}}$, their integral averages over the edge are the same; in other words, $\frac{1}{|\mathcal{E}|}\int_{\mathcal{E}} J_m u \, dx = \frac{1}{|\mathcal{E}|}\int_{\mathcal{E}} u \, dx$. This we will see is essential for our analysis.

DEFINITION 3.1. *For any interior edge* $\mathcal{E} \subset \gamma_m$, *where* γ_m *is a subdomain interface, such that* $\mathcal{E}$ *is not touching the boundary* $\partial\gamma_m$, *we call* $B_{\mathcal{E}}$ *the set of all triangles* τ *such that* $\partial\tau \cap \mathcal{E} \neq \emptyset$, *that is, all triangles touching* $\mathcal{E}$; *see Figure* 3.1 *(middle). If* $\mathcal{E}$ *is a boundary edge of* γ_m *(see Figure* 3.1 *(left)), then* $B_{\mathcal{E}}$ *is the set of all triangles touching* $\mathcal{E}$ *excluding the ones touching only at the endpoint* $\partial\mathcal{E} \cap \partial\gamma_m$ *of* $\mathcal{E}$. *We call* $B_{\mathcal{E}_i\mathcal{E}_j}$ *the set of triangles* τ *connecting the two triangle edges* $\mathcal{E}_i$ *and* $\mathcal{E}_j$ *(see Figure* 3.1 *(right)) in such a way that* $\partial\tau \cap \mathcal{E} \neq \emptyset$, *where* $\mathcal{E} = (x_m^{\mathcal{E}_i}, x_m^{\mathcal{E}_j})$ *is the straight line joining the two edge midpoints* $x_m^{\mathcal{E}_i}$ *and* $x_m^{\mathcal{E}_j}$.

Using the continuity of the function u at edge midpoints and the discrete equivalence of the H^1-seminorm, it is easy to see that, for any two neighboring edges $\mathcal{E}_i$ and $\mathcal{E}_j$ with $\partial\mathcal{E}_i \cap \partial\mathcal{E}_j \neq \emptyset$,

$$\left(u(x_m^{\mathcal{E}_i}) - u(x_m^{\mathcal{E}_j})\right)^2 \leq c \sum_{\tau \in B_{\mathcal{E}_i\mathcal{E}_j}} |u|^2_{H^1(\tau)}, \tag{3.1}$$

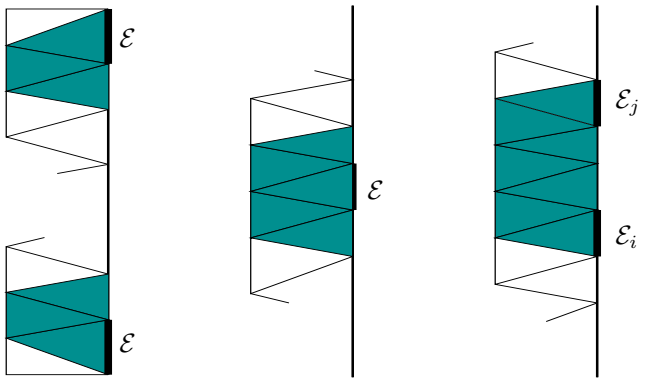

FIG. 3.1. *Shaded areas representing $B_{\mathcal{E}}$ (left and middle) and $B_{\mathcal{E}_i\mathcal{E}_j}$ (right).*

where the sum is taken over the elements of the set $B_{\mathcal{E}_i\mathcal{E}_j}$.

Now, we follow the definition of I_m; cf. Definition 2.1. If $\mathcal{E}$ is an interior edge of γ_m, then a simple calculation yields

$$I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) = \left[\frac{h_{\mathcal{E}}}{h_{\mathcal{E}} + h_{\mathcal{E}_r}} \left\{ u(x_m^{\mathcal{E}_r}) - u(x_m^{\mathcal{E}}) \right\} + \frac{h_{\mathcal{E}}}{h_{\mathcal{E}} + h_{\mathcal{E}_l}} \left\{ u(x_m^{\mathcal{E}}) - u(x_m^{\mathcal{E}_l}) \right\} \right],$$

where $\mathcal{E}_l$ and $\mathcal{E}_r$ are, respectively, the left and right neighboring edges of $\mathcal{E}$. If $\mathcal{E}$ is the right boundary edge of γ_m, then we have the special case

$$I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) = \frac{2h_{\mathcal{E}}}{h_{\mathcal{E}} + h_{\mathcal{E}_l}} \left\{ u(x_m^{\mathcal{E}}) - u(x_m^{\mathcal{E}_l}) \right\},$$

and, similarly, if $\mathcal{E}$ is the left boundary edge of γ_m, then

$$I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) = \frac{2h_{\mathcal{E}}}{h_{\mathcal{E}} + h_{\mathcal{E}_r}} \left\{ u(x_m^{\mathcal{E}_r}) - u(x_m^{\mathcal{E}}) \right\}.$$

Hence, by applying (3.1), we get

$$(I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}))^2 \;\le\; c \sum_{\tau \in B_{\mathcal{E}}} |u|^2_{H^1(\tau)} \tag{3.2}$$

for each edge $\mathcal{E} \subset \gamma_m$, where the sum is taken over the elements of the set $B_{\mathcal{E}}$. Note that $B_{\mathcal{E}}$ equals either $B_{\mathcal{E}\mathcal{E}_l}$ or $B_{\mathcal{E}\mathcal{E}_r}$ if $\mathcal{E}$ is a boundary edge and equals $B_{\mathcal{E}\mathcal{E}_l} \cup B_{\mathcal{E}\mathcal{E}_r}$ if $\mathcal{E}$ is an interior edge.

Now we follow the definition of J_m; cf. Definition 2.2. For any edge $\mathcal{E} \subset \gamma_m$, the following is true:

$$J_m u(x_r^{\mathcal{E}}) - u(x_m^{\mathcal{E}}) = -\left(J_m u(x_l^{\mathcal{E}}) - u(x_m^{\mathcal{E}}) \right) = \frac{1}{2} \left[I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) \right].$$

If $x \in \mathcal{E}$ is a point lying on the right of $x_m^{\mathcal{E}}$, then

$$J_m u(x) - u(x_m^{\mathcal{E}}) = \frac{\operatorname{dist}(x, x_m^{\mathcal{E}})}{h_{\mathcal{E}}} \left[I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) \right],$$

or, if it is lying on the left of $x_m^{\mathcal{E}}$, then

$$J_m u(x) - u(x_m^{\mathcal{E}}) = -\frac{\operatorname{dist}(x, x_m^{\mathcal{E}})}{h_{\mathcal{E}}} \left[I_m u(x_r^{\mathcal{E}}) - I_m u(x_l^{\mathcal{E}}) \right],$$

where $\operatorname{dist}(x, x_m^{\mathcal{E}})$ is the distance between the points x and $x_m^{\mathcal{E}}$. If $x^{\mathcal{E}}$ is a point anywhere on the edge $\mathcal{E}$, then by applying (3.2), we get

$$(J_m u(x^{\mathcal{E}}) - u(x_m^{\mathcal{E}}))^2 \ \le \ c \sum_{\tau \in B_{\mathcal{E}}} |u|^2_{H^1(\tau)} \tag{3.3}$$

for edge $\mathcal{E} \subset \gamma_m$, where the sum is taken over the elements of the set $B_{\mathcal{E}}$.

The properties of J_m can be stated in the following lemmas.

LEMMA 3.2. *For $u_i \in X_h(\Omega_i)$, and each $\mathcal{E} \subset \gamma_m$, we have*

$$\| u_i - J_m u_i \|^2_{L^2(\mathcal{E})} \le c h_i \sum_{\tau \in B_{\mathcal{E}}} |u_i|^2_{H^1(\tau)}$$

and

$$\| u_i - J_m u_i \|^2_{L^2(\gamma_{m(i)})} \le c h_i |u_i|^2_{H^1_h(\Omega_i)}.$$

Proof. Let $\overline{(u_i)}_{\mathcal{E}}$ denote the average of u_i over the edge $\mathcal{E}$; that is, $\overline{(u_i)}_{\mathcal{E}} = \frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} u_i \, dx$. From the trace and the Poincaré inequalities and (3.3), we get

$$\begin{aligned}
&\| u_i - J_m u_i \|^2_{L^2(\mathcal{E})} \\
&\quad \le 2 \| u_i - \overline{(u_i)}_{\mathcal{E}} \|^2_{L^2(\mathcal{E})} + 2 \| J_m u_i - \overline{(u_i)}_{\mathcal{E}} \|^2_{L^2(\mathcal{E})} \\
&\quad \le c h_i |u_i|^2_{H^1(\tau_{\mathcal{E}})} + c h_i \sum_{x = x_r^{\mathcal{E}}, x_m^{\mathcal{E}}, x_l^{\mathcal{E}}} (J_m u_i(x) - u_i(x_m^{\mathcal{E}}))^2 \\
&\quad \le c h_i |u_i|^2_{H^1(\tau_{\mathcal{E}})} + c h_i \sum_{\tau \in B_{\mathcal{E}}} |u_i|^2_{H^1(\tau)} \\
&\quad \le c h_i \sum_{\tau \in B_{\mathcal{E}}} |u_i|^2_{H^1(\tau)}.
\end{aligned}$$

The second inequality follows immediately from the first one by taking the sum over the triangle edges $\mathcal{E}$ of $\gamma_{m(i)}$. ∎

The next lemma is crucial for the analysis. The factor $h_j^{1/2}$ in its estimate is essential for our estimate of the consistency error. In the first part of its proof, we will need the operator $\mathcal{M}_i : X_h(\Omega_i) \to Y_{\frac{h}{2}}(\Omega_i)$ (cf. [20]): for $u \in X_h(\Omega_i)$,

$$\mathcal{M}_i u(x) = \begin{cases} u(x), & x \in \overline{\Omega}_{ih}^{CR}, \\ \frac{1}{n_x} \sum_{\tau \in B_x} u|_\tau(x), & x \in \Omega_{ih}, \\ \frac{h_{\mathcal{E}_l}}{h_{\mathcal{E}_l} + h_{\mathcal{E}_r}} u(x_m^{\mathcal{E}_l}) + \frac{h_{\mathcal{E}_r}}{h_{\mathcal{E}_l} + h_{\mathcal{E}_r}} u(x_m^{\mathcal{E}_r}), & x \in \partial\Omega_{ih}. \end{cases}$$

Here, B_x is the set of all triangles of $\mathcal{T}_h(\Omega_i)$ sharing the vertex x, and n_x is the number of such elements. The following are the properties of $\mathcal{M}_i$ which we will use:

$$\| u - \mathcal{M}_i u \|^2_{L^2(\mathcal{E})} \le c h_i \sum_{\tau \in \hat{B}_{\mathcal{E}}} |u_i|^2_{H^1(\tau)} \quad \text{and} \quad |\mathcal{M}_i u_i|^2_{H^1(\Omega_i)} \le c |u_i|^2_{H^1(\Omega_i)}. \tag{3.4}$$

In the first inequality above, $\mathcal{E}$ is an edge of $\partial\Omega_i$, where $\hat{B}_{\mathcal{E}}$ is the set of all triangles τ touching $\mathcal{E}$. We remark here that the number of triangles touching any vertex in a subdomain is bounded independently of the mesh size. The first estimate of (3.4) can be proved in a similar way as the proof of the first estimate in Lemma 3.2, and so we omit the proof here. For the proof of the second estimate we refer the reader to [20].

LEMMA 3.3. *For $u_i \in X_h(\Omega_i)$, we have*

$$\| J_m u_i - Q_m J_m u_i \|_{L^2(\gamma_{m(i)})} \leq c h_j^{1/2} |u_i|_{H_h^1(\Omega_i)}. \tag{3.5}$$

Proof. We partition γ_m into a collection of nonoverlapping subintervals or edge segments, $\mathcal{E}_o$, which are intersections between the edges from the mortar side and the edges from the nonmortar side. For simplicity we assume that each $\mathcal{E}_o$, shown as a thick line segment in Figures 3.2–3.3 (left pictures), corresponds to a complete edge. For the case where $\mathcal{E}_o$ may not be a complete edge but rather an edge segment shown as a thick line segment in Figures 3.2–3.3 (right pictures), the analyses are similar and will contribute only to the constant c. For the proof of the present lemma, we consider separately the two different cases of the mesh sizes: the mesh on the mortar side is finer than the mesh on the nonmortar side (Case A), and vice versa (Case B). The general case where the mesh on the mortar side may be finer than the mesh on the nonmortar side at some region along the interface and coarser in the other region can be formed as a combination of the two cases.

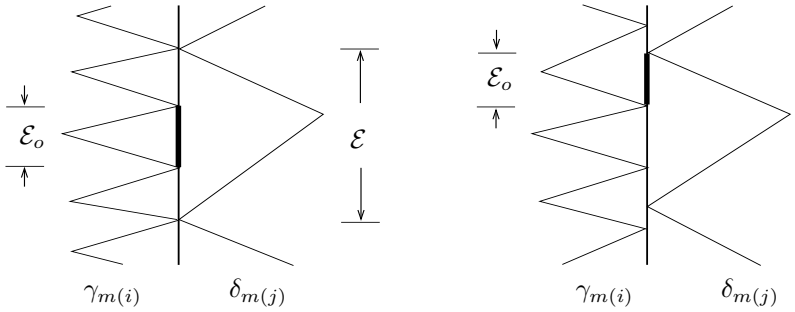

FIG. 3.2. *Illustrating $h_i < h_j$.*

Case A. Let $\mathcal{E} \subset \delta_{m(j)}$ and $\mathcal{E}_o \subset \gamma_{m(i)}$, where $\mathcal{E}_o \subset \mathcal{E}$ such that $h_{\mathcal{E}_o} \leq h_{\mathcal{E}}$; cf. Figure 3.2. Now, by the triangle inequality and the L^2 stability of the projection operator Q_m, we can write

$$\begin{aligned} &\| J_m u_i - Q_m J_m u_i \|^2_{L^2(\gamma_{m(i)})} \\ &\quad \leq c \Big\{ \| J_m u_i - u_i \|^2_{L^2(\gamma_{m(i)})} + \| u_i - Q_m u_i \|^2_{L^2(\gamma_{m(i)})} \\ &\qquad + \| Q_m(u_i - J_m u_i) \|^2_{L^2(\gamma_{m(i)})} \Big\} \\ &\quad \leq c \Big\{ \sum_{\mathcal{E} \subset \delta_{m(j)}} \| u_i - J_m u_i \|^2_{L^2(\mathcal{E})} + \| u_i - Q_m u_i \|^2_{L^2(\gamma_{m(i)})} \Big\}. \end{aligned} \tag{3.6}$$

Owing to the same L^2 stability, the second term above can further be estimated as the following:

$$\| u_i - Q_m u_i \|^2_{L^2(\gamma_{m(i)})}$$

$$\leq c\Big\{ \sum_{\mathcal{E}\subset\delta_{m(j)}} \| u_i - \mathcal{M}_i u_i \|^2_{L^2(\mathcal{E})} + \| \mathcal{M}_i u_i - Q_m \mathcal{M}_i u_i \|^2_{L^2(\gamma_{m(i)})} \Big\}.$$

Using Lemma 3.2 and the first estimate of (3.4) for each edge $\mathcal{E}_o \subset \mathcal{E}$, adding their contributions, and finally noting that $h_{\mathcal{E}_o} \leq h_{\mathcal{E}}$, the terms $\| u_i - J_m u_i \|^2_{L^2(\mathcal{E})}$ and $\| u_i - \mathcal{M}_i u_i \|^2_{L^2(\mathcal{E})}$ can be estimated as $ch_j \sum_{\tau\in B_{\mathcal{E}}} |u_i|^2_{H^1(\tau)}$ and $ch_j \sum_{\tau\in \hat{B}_{\mathcal{E}}} |u_i|^2_{H^1(\tau)}$, respectively. Now summing over $\mathcal{E} \subset \delta_{m(j)}$, in each case, we get the bound equal to $ch_j|u_i|^2_{H^1_h(\Omega_i)}$. What remains now is to estimate the term $\| \mathcal{M}_i u_i - Q_m \mathcal{M}_i u_i \|_{L^2(\gamma_{m(i)})}$. To do so, we first note that (cf. [1])

$$\| \mathcal{M}_i u_i - Q_m \mathcal{M}_i u_i \|^2_{L^2(\mathcal{E})} \leq ch_j |\mathcal{M}_i u_i|^2_{H^{\frac{1}{2}}(\mathcal{E})}.$$

Now, by adding together the estimates over $\mathcal{E} \subset \delta_{m(j)}$, using the trace inequality $|\mathcal{M}_i u_i|_{H^{\frac{1}{2}}(\gamma_{m(i)})} \leq c|\mathcal{M}_i u_i|_{H^1(\Omega_i)}$, and finally applying the second estimate of (3.4) we again get the bound $ch_j|u_i|^2_{H^1_h(\Omega_i)}$. Replacing the three estimates into (3.6) proves the lemma for the present case.

Case B. Let $\mathcal{E} \subset \gamma_{m(i)}$ and $\mathcal{E}_o \subset \delta_{m(j)}$, and $\mathcal{E}_o \subset \mathcal{E}$ such that $h_{\mathcal{E}_o} \leq h_{\mathcal{E}}$; cf. Figure 3.3. We note that the function $J_m u_i - Q_m J_m u_i$ is linear over $\mathcal{E}_o$. Now,

$$\begin{aligned}
&\| J_m u_i - Q_m J_m u_i \|^2_{L^2(\delta_{m(j)})} \\
&\quad = \sum_{\mathcal{E}_o\subset\delta_{m(j)}} \| J_m u_i - Q_m J_m u_i \|^2_{L^2(\mathcal{E}_o)} \\
&\quad \leq c \sum_{\mathcal{E}_o\subset\delta_{m(j)}} h_{\mathcal{E}_o} \sum_{x=x_l^{\mathcal{E}_o}, x_m^{\mathcal{E}_o}, x_r^{\mathcal{E}_o}} (J_m u_i(x) - Q_m J_m u_i(x))^2.
\end{aligned}$$

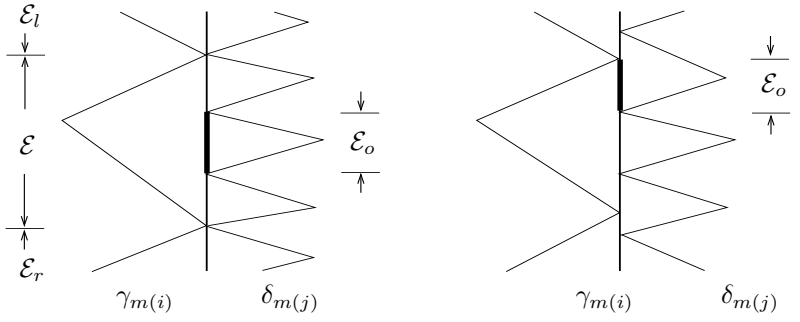

FIG. 3.3. *Illustrating* $h_j < h_i$.

On the edge $\mathcal{E}_o$, $Q_m J_m u_i$ is a constant equal to $J_m u_i(x_m^{\mathcal{E}_o})$. The difference $(J_m u_i(x) - Q_m J_m u_i(x))$ is zero at $x = x_m^{\mathcal{E}_o}$, and at $x = x_l^{\mathcal{E}_o}$ and $x_r^{\mathcal{E}_o}$ it can be written as

$$\begin{aligned}
J_m u_i(x_l^{\mathcal{E}_o}) - Q_m J_m u_i(x_l^{\mathcal{E}_o}) &= -\left(J_m u_i(x_r^{\mathcal{E}_o}) - Q_m J_m u_i(x_r^{\mathcal{E}_o})\right) \\
&= -\left\{ \frac{1}{h_{\mathcal{E}}} \left(I_m u_i(x_r^{\mathcal{E}}) - I_m u_i(x_l^{\mathcal{E}})\right) \right\} \frac{h_{\mathcal{E}_o}}{2},
\end{aligned}$$

where the term inside the curly brackets represents the slope of $J_m u_i$ or, equivalently, of $I_m u_i$, along the mortar. Hence, for $x = x_l^{\mathcal{E}_o}$ and $x_r^{\mathcal{E}_o}$, it follows from (3.2) that

$$(J_m u_i(x) - Q_m J_m u_i(x))^2 \le c \left(\frac{h_{\mathcal{E}_o}}{h_{\mathcal{E}}}\right)^2 \left(I_m u_i(x_r^{\mathcal{E}}) - I_m u_i(x_l^{\mathcal{E}})\right)^2$$

$$\le c \left(\frac{h_j}{h_i}\right)^2 \sum_{\tau \subset B_{\mathcal{E}}} |u_i|^2_{H^1(\tau)},$$

where the sum is taken over the set $B_{\mathcal{E}}$ of triangles along the mortar side, those touching the edge $\mathcal{E}$. The number of occurrences of the above sum in the final calculation is $\approx h_i/h_j$. This results in an h_j in the final calculation, since $h_{\mathcal{E}_o}(\frac{h_j}{h_i})^2 \frac{h_i}{h_j} \le h_j$ due to $\frac{h_j}{h_i} \le 1$. Hence, we arrive at

$$\| J_m u_i - Q_m J_m u_i \|^2_{L^2(\gamma_{m(i)})} \le c h_j |u_i|^2_{H^1_h(\Omega_i)}.$$

The lemma thus holds for both cases. For the general case where both Cases A and B exist along the interface $\gamma_{m(i)} = \delta_{m(j)}$, we simply need to take an appropriate combination of the estimates, that is, the estimates on $\mathcal{E}$ from Case A and the estimates on $\mathcal{E}_o$ from Case B, to show that the lemma holds. ∎

In the following, we briefly introduce some special operators from [15, 20] which we will need for our analysis. Let $\Pi_m : L^2(\delta_m(j)) \to Y_h^0(\delta_{m(j)})$, where $Y_h^0(\delta_{m(j)})$ is the set of continuous and piecewise linear functions on $\delta_{m(j)}$, defined uniquely by their values at $x \in \delta^{CR}_{m(j)h}$, and taking zero values at the boundary. $\Pi_m u$ on $\delta_{m(j)}$ is defined as follows (cf. [15]):

$$\Pi_m u(x) = Q_m u(x) \quad \forall x \in \delta^{CR}_{m(j)h}.$$

From the definition of Q_m (cf. (2.3)), it follows that $Q_m(Q_m u)(x) = (Q_m u)(x)$ for $x \in \delta^{CR}_{m(j)h}$, giving $(\Pi_m(Q_m u))(x) = (Q_m(Q_m u))(x) = Q_m u(x) = \Pi_m u(x)$ for all $x \in \delta^{CR}_{m(j)h}$. Hence, on $\overline{\delta}_m(j)$,

$$\Pi_m u = \Pi_m(Q_m u). \tag{3.7}$$

The stability of Π_m is stated in the following lemma; see [15] for proof.

LEMMA 3.4. *For* $u \in H^{\frac{1}{2}}_{oo}(\delta_{m(j)})$,

$$\| \Pi_m u \|_{H^{\frac{1}{2}}_{oo}(\delta_{m(j)})} \le c \| u \|_{H^{\frac{1}{2}}_{oo}(\delta_{m(j)})},$$

and for $u \in L^2(\delta_{m(j)})$,

$$\| \Pi_m u \|_{L^2(\delta_{m(j)})} \le c \| u \|_{L^2(\delta_{m(j)})}.$$

In the following, we define the two discrete harmonic extension operators, $\mathcal{H}_h^{CR} : X_h(\partial\Omega_j) \to X_h(\Omega_j)$ and $\mathcal{H}_{\frac{h}{2}} : Y_{\frac{h}{2}}(\partial\Omega_j) \to Y_{\frac{h}{2}}(\Omega_j)$, corresponding to the nonconforming P1 functions and the conforming P1 functions, respectively. For $u \in X_h(\partial\Omega_j)$, $\mathcal{H}_h^{CR} u \in X_h(\Omega_j)$ is the solution of

$$a_h(\mathcal{H}_h^{CR} u, v) = 0 \quad \forall v \in X_h^0(\Omega_j), \tag{3.8}$$

where $\mathcal{H}_h^{CR} u(x) = u(x)$ for $x \in \partial\Omega^{CR}_{jh}$. Similarly, for $u \in Y_{\frac{h}{2}}(\partial\Omega_j)$, $\mathcal{H}^{CR}_{\frac{h}{2}} u \in X_h(\Omega_j)$ is the solution of

$$a_j(\mathcal{H}_{\frac{h}{2}} u, v) = 0 \quad \forall v \in Y^0_{\frac{h}{2}}(\Omega_j), \tag{3.9}$$

where $\mathcal{H}_{\frac{h}{2}} u(x) = u(x)$ for $x \in \partial\Omega_{jh}$.

We state another useful operator, $\mathcal{M}_j^+ : Y_{\frac{h}{2}}(\Omega_j) \to X_h(\Omega_j)$ (cf. [20]), which is defined as follows: for $u \in Y_{\frac{h}{2}}(\Omega_j)$,

$$\mathcal{M}_j^+ u(x) = u(x) \quad \forall x \in \Omega_{jh}^{CR}.$$

For any $u \in Y_{\frac{h}{2}}(\Omega_j)$, the following holds (cf. [20]):

$$|\mathcal{M}_j^+ u|_{H_h^1(\Omega_j)} \le c|u|_{H_h^1(\Omega_j)}. \tag{3.10}$$

In the next lemma we estimate the H_h^1-seminorm over a subdomain by the $H_{oo}^{\frac{1}{2}}$-norm on a nonmortar side of the subdomain.

LEMMA 3.5. *Let $u \in X_h(\Omega_j)$ be a discrete harmonic function in Ω_j, in the sense of* (3.8)*, with $u = 0$ at $x \in \partial\Omega_{jh}^{CR} \setminus \delta_{m(j)h}^{CR}$. Then*

$$|u|_{H_h^1(\Omega_j)} \le c \parallel \Pi_m u \parallel_{H_{oo}^{\frac{1}{2}}(\delta_{m(j)})}. \tag{3.11}$$

Proof.

$$\begin{aligned} |u|_{H_h^1(\Omega_j)} &\le c|\mathcal{M}_j^+ \mathcal{H}_{\frac{h}{2}} E_m \Pi_m u|_{H_h^1(\Omega_j)} \\ &\le c|\mathcal{H}_{\frac{h}{2}} E_m \Pi_m u|_{H_h^1(\Omega_j)} \\ &\le c \parallel \Pi_m u \parallel_{H_{oo}^{\frac{1}{2}}(\delta_{m(j)})}. \end{aligned}$$

The first inequality follows from the fact that u is itself discrete harmonic and therefore has the minimal energy over all functions whose boundary values at $x \in \partial\Omega_{jh}^{CR}$ are the same as those of u. The second inequality follows from (3.10), and the third inequality follows from the property of a conforming discrete harmonic function; cf. [7]. E_m is the zero extension operator from $L^2(\delta_{m(j)})$ to $L^2(\partial\Omega_j)$. ∎

THEOREM 3.6 (error). *Let $u \in H^2(\Omega)$ and $u_h \in V_h$ be the exact solution of* (2.1) *and* (2.4)*, respectively. Then*

$$|u - u_h|_{H_h^1(\Omega)} \le c \left(\sum_{k=1}^{N} h_k^2 |u|_{H^2(\Omega_k)}^2 \right)^{\frac{1}{2}}. \tag{3.12}$$

The proof follows from the second Strang lemma (cf. [12]),

$$\begin{aligned} |u - u_h|_{H_h^1(\Omega)} \le c \inf_{v \in V_h} |u - v|_{H_h^1(\Omega)} \\ + \sup_{w \in V_h} \sum_{k=1}^{N} \sum_{\tau \in \mathcal{T}_h(\Omega_k)} \int_{\partial\tau} \frac{\partial u}{\partial \eta} \frac{w}{|w|}_{H_h^1(\Omega)} ds, \end{aligned} \tag{3.13}$$

and Lemmas 3.7 and 3.8.

LEMMA 3.7 (consistency error). *Let $u \in H^2(\Omega)$ be the exact solution of* (2.1)*. Then for any $w = \{w_k\} \in V_h$,*

$$\sum_{k=1}^{N} \sum_{\tau \in \mathcal{T}_h(\Omega_k)} \int_{\partial\tau} \frac{\partial u}{\partial \eta} \frac{w}{|w|}_{H_h^1(\Omega)} ds \le c \left(\sum_{k=1}^{N} h_k^2 |u|_{H^2(\Omega_k)}^2 \right)^{1/2}. \tag{3.14}$$

Proof. Note that

$$\sum_{k=1}^{N} \sum_{\tau \in \mathcal{T}_h(\Omega_k)} \int_{\partial\tau} \frac{\partial u}{\partial \eta} w_k \, ds = \sum_{\tau \in \mathcal{T}_h(\Omega_k),\ \mathcal{E} \subset (\partial\tau \setminus \mathcal{S})} \int_{\mathcal{E}} \frac{\partial u}{\partial \eta} [w] \, ds + \sum_{\Gamma_{ij} \subset \mathcal{S}} \int_{\Gamma_{ij}} \frac{\partial u}{\partial \eta} [w] \, ds.$$

Using Lemmas 8.3.7 and 8.3.9 of [12], for the interior and boundary edges, respectively, one can estimate the first term as follows:

$$\sum_{\tau \in \mathcal{T}_h(\Omega_k),\ \mathcal{E} \subset (\partial\tau \setminus \mathcal{S})} \int_{\mathcal{E}} \frac{\partial u}{\partial \eta} [w] \, ds \leq c \left(\sum_{k=1}^{N} h_k^2 |u|^2_{H^2(\Omega_k)} \right)^{1/2} |w|_{H_h^1(\Omega)}.$$

In the following, we estimate the second term.

Let $[w] = w_i - w_j$ be the jump across Γ_{ij}, where $\gamma_{m(i)} = \Gamma_{ij} = \delta_{m(j)}$. Let $\alpha = \{\alpha_{\mathcal{E}}\}_{\mathcal{E} \subset \gamma_{m(i)}}$ be the piecewise constant function on $\gamma_{m(i)}$, where $\alpha_{\mathcal{E}} = \frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} \frac{\partial u}{\partial \eta_{\mathcal{E}}} \, d\sigma$ for each triangle edge $\mathcal{E} \subset \gamma_{m(i)}$. Similarly, we define the piecewise constant function on $\delta_{m(j)}$ as $\beta = \{\beta_{\mathcal{E}}\}_{\mathcal{E} \subset \delta_{m(j)}}$, where $\beta_{\mathcal{E}} = \frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} \frac{\partial u}{\partial \eta_{\mathcal{E}}} \, d\sigma$ for each triangle edge $\mathcal{E} \subset \delta_{m(j)}$. We get immediately the two relations

$$\int_{\gamma_{m(i)}} \alpha (w_i - J_m w_i) \, d\sigma = 0$$

and

$$\int_{\delta_{m(j)}} \beta (J_m w_i - w_j) \, d\sigma = 0.$$

The first one follows from the fact that $\frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} J_m w_i \, dx = \frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} w_i \, dx$ by construction, for each $\mathcal{E} \subset \gamma_{m(i)}$, and the second one is due to the mortar condition, giving, for each $\mathcal{E} \subset \delta_{m(j)}$, that $w_j(x_m^{\mathcal{E}}) = \frac{1}{|\mathcal{E}|} \int_{\mathcal{E}} J_m w_i \, dx$. Now, using these relations, we get

$$\begin{aligned}
\int_{\Gamma_{ij}} \frac{\partial u}{\partial \eta} [w] \, d\sigma &\leq \left| \int_{\gamma_{m(i)}} \left(\frac{\partial u}{\partial \eta} - \alpha \right) (w_i - J_m w_i) \, d\sigma \right| \\
&\quad + \left| \int_{\delta_{m(j)}} \left(\frac{\partial u}{\partial \eta} - \beta \right) (J_m w_i - w_j) \, d\sigma \right| \\
&\leq \left\| \frac{\partial u}{\partial \eta} - \alpha \right\|_{L^2(\gamma_{m(i)})} \| w_i - J_m w_i \|_{L^2(\gamma_{m(i)})} \\
&\quad + \left\| \frac{\partial u}{\partial \eta} - \beta \right\|_{L^2(\delta_{m(j)})} \| J_m w_i - w_j \|_{L^2(\delta_{m(j)})}.
\end{aligned}$$

We have

$$\left\| \frac{\partial u}{\partial \eta} - \alpha \right\|^2_{L^2(\gamma_{m(i)})} = \sum_{\mathcal{E} \subset \gamma_{m(i)}} \left\| \frac{\partial u}{\partial \eta} - \alpha_{\mathcal{E}} \right\|^2_{L^2(\mathcal{E})}$$

$$\leq c \sum_{\mathcal{E} \subset \gamma_{m(i)}} h_{\mathcal{E}} \left| \frac{\partial u}{\partial \eta_{\mathcal{E}}} \right|^2_{H^1(\tau_{\mathcal{E}})}$$

$$\leq c h_i |u|^2_{H^2(\Omega_i)},$$

where the last sum is taken over the triangles $\tau_{\mathcal{E}} \in \mathcal{T}_h(\Omega_i)$—those having $\mathcal{E} \subset \gamma_{m(i)}$ as one of their edges. Similarly,

$$\left\| \frac{\partial u}{\partial \eta} - \beta \right\|^2_{L^2(\delta_{m(j)})} \leq c h_j |u|^2_{H^2(\Omega_j)}.$$

Also, it follows from Lemma 3.2 that

$$\|w_i - J_m w_i\|^2_{L^2(\gamma_{m(i)})} \leq c h_i |w_i|^2_{H^1_h(\Omega_i)}.$$

Now, using the mortar condition $Q_m J_m w_i = Q_m w_j$ and Lemma 3.3, we get

$$\begin{aligned} \| J_m w_i - w_j \|^2_{L^2(\delta_{m(j)})} &\leq 2 \| J_m w_i - Q_m J_m w_i \|^2_{L^2(\delta_{m(j)})} \\ &\quad + 2 \| Q_m w_j - w_j \|^2_{L^2(\delta_{m(j)})} \\ &\leq c \left(h_j |w_i|^2_{H^1_h(\Omega_i)} + h_j |w_j|^2_{H^1_h(\Omega_j)} \right). \end{aligned}$$

Finally,

$$\begin{aligned} \int_{\Gamma_{ij}} \frac{\partial u}{\partial \eta} [w] \, d\sigma &\leq c \left[h_i |u|_{H^2(\Omega_i)} |w_i|_{H^1(\Omega_i)} \right. \\ &\quad \left. + h_j |u|_{H^2(\Omega_j)} (|w_i|_{H^1_h(\Omega_i)} + |w_j|_{H^1_h(\Omega_j)}) \right]. \end{aligned}$$

Now, summing over the interfaces $\Gamma_{ij} \subset \mathcal{S}$, and using the Cauchy–Schwarz inequality, $|\sum_i (a_i b_i)| \leq (\sum_i a_i^2)^{\frac{1}{2}} (\sum_i b_i^2)^{\frac{1}{2}}$, we get the proof. ∎

LEMMA 3.8 (approximation error). *For any function $u \in H^1_0(\Omega)$, with $u_{|\Omega_k} \in H^2(\Omega_k)$, we have*

$$\inf_{v \in V_h} |u - v|_{H^1_h(\Omega)} \leq c \left(\sum_{k=1}^{N} h_k^2 |u|^2_{H^2(\Omega_k)} \right)^{1/2}. \tag{3.15}$$

Proof. Let I_h be the conforming P1-interpolant of u on $\mathcal{T}_h(\Omega_k)$ for $k = 1, \ldots N$, and define $\tilde{v} = I_h u = \{\tilde{v}_k\}_{k=1,\ldots,N} \in X_h$. We note that $\tilde{v}$ does not satisfy the mortar condition, and so $\tilde{v} \notin V_h$. Let $v = \tilde{v} + w$, where $w = \{w_k\}_{k=1,\ldots,N} \in X_h$, and $w_k = \sum_{\delta_{m(k)} \subset \partial\Omega_k} w_{m(k)} \in X_h(\Omega_k)$. The function $w_{m(k)} \in X_h(\Omega_k)$ is defined as follows:

$$w_{m(k)}(x) = \begin{cases} Q_m(J_m \tilde{v}_l - \tilde{v}_k)(x), & x \in \delta^{CR}_{m(k)h}, \\ 0, & x \in \partial\Omega^{CR}_{kh} \setminus \delta^{CR}_{m(k)h}, \\ \text{discrete harmonic (cf. 3.8)}, & x \in \Omega^{CR}_{kh}. \end{cases}$$

It is easy to see that $v \in V_h$:

$$\begin{aligned}|u-v|^2_{H^1_h(\Omega_k)} &\le |u-\tilde{v}_k|^2_{H^1(\Omega_k)} + |w_k|^2_{H^1_h(\Omega_k)} \\ &\le ch_k^2|u|^2_{H^2(\Omega_k)} + \sum_{\delta_{m(k)}\subset\partial\Omega_k} |w_{m(k)}|^2_{H^1_h(\Omega_k)}.\end{aligned}$$

Here we have used $|u - I_h u|_{H^1(\Omega_k)} \le ch_k|u|_{H^2(\Omega_k)}$ from the Bramble–Hilbert lemma. Now using Lemma 3.5 and (3.7), we have

$$\begin{aligned}&|w_{m(k)}|^2_{H^1_h(\Omega_k)} \\ &\le \| \Pi_m(J_m\tilde{v}_l - \tilde{v}_k) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})} \\ &\le \| \Pi_m(J_m\tilde{v}_l - \tilde{v}_l) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})} + \| \Pi_m(\tilde{v}_l - \tilde{v}_k) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})}.\end{aligned}$$

From [15], we can bound the second term as

$$\| \Pi_m(\tilde{v}_l - \tilde{v}_k) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})} \le c\left(h_l^2|u|^2_{H^2(\Omega_l)} + h_k^2|u|^2_{H^2(\Omega_k)}\right).$$

For the second term we use a trace inequality to have

$$\begin{aligned}\| \Pi_m(J_m\tilde{v}_l - \tilde{v}_l) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})} &\le ch_l^{-1} \| \Pi_m(J_m\tilde{v}_l - \tilde{v}_l) \|^2_{L^2(\delta_{m(k)})} \\ &\le ch_l^{-1} \| J_m\tilde{v}_l - \tilde{v}_l \|^2_{L^2(\gamma_{m(l)})} \\ &= ch_l^{-1} \sum_{\mathcal{E}\subset\gamma_{m(l)}} \| J_m\tilde{v}_l - \tilde{v}_l \|^2_{L^2(\mathcal{E})} \\ &\le ch_l^{-1} \sum_{\mathcal{E}\subset\gamma_{m(l)}} h_l \sum_{\tau\in B_\mathcal{E}} |\tilde{v}_l|^2_{H^1(\tau)}.\end{aligned}$$

For each $\mathcal{E} \subset \gamma_{m(l)}$, define Q^2u inside $B_\mathcal{E}$, where Q^2u is the averaged Taylor polynomial of order 2 of u as defined in Chapter 4 of [12]. We note that $(J_m I_h u - I_h u) = J_m I_h(u - Q^2u) - I_h(u - Q^2u)$ on $\mathcal{E}$, and hence using the Bramble–Hilbert lemma, we have (cf. [12])

$$\begin{aligned}\| J_m\tilde{v}_l - \tilde{v}_l \|^2_{L^2(\mathcal{E})} &\le ch_l \sum_{\tau\in B_\mathcal{E}} |I_h(u - Q^2u)|^2_{H^1(\tau)} \\ &\le ch_l \sum_{\tau\in B_\mathcal{E}} |u - Q^2u|^2_{H^1(\tau)} \\ &\le ch_l^3 \sum_{\tau\in B_\mathcal{E}} |u|^2_{H^2(\tau)}.\end{aligned}$$

Hence,

$$\| \Pi_m(J_m\tilde{v}_l - \tilde{v}_l) \|^2_{H^{\frac{1}{2}}_{oo}(\delta_{m(k)})} \le ch_l^2|u|^2_{H^2(\Omega_l)}. \qquad \square$$

Theorem 3.6 gives an estimate for the error in the finite element solution in the broken H^1-seminorm. In the following we remark on the L^2-norm estimate of the error, which can be obtained using the same arguments as is in [11] for the conforming P1 finite element. Using (3.14), (3.15), and a duality technique in Lemma III.1.4 of [8], we can get the estimate

$$\|u - u_h\|_{L^2(\Omega)} \leq ch^2 |u|_{H^2(\Omega)},$$

where $h = \max_k h_k$. A careful manipulation of the estimates will yield the following estimate:

$$\|u - u_h\|_{L^2(\Omega)} \leq Ch \left(\sum_{k=1}^{N} h_k^2 |u|^2_{H^2(\Omega_k)^2} \right)^{\frac{1}{2}},$$

which explicitly includes the mesh sizes of the subdomains. However, the factor h appearing in the estimate is due to the use of the global regularity assumption: $|u|_{H^2(\Omega)} \leq c\|f\|_{L^2(\Omega)}$.

4. An additive Schwarz method. Recently, an additive Schwarz method for the CR mortar finite element, which uses the standard mortar condition, has been proposed in [19]. A P1 mortar finite element version of the method can be found in [6]. In this section, we propose a similar method for our discrete problem (2.4), which is formed as a natural extension of the original method from the standard mortar case to the new approximate mortar case. This is done by a simple adjustment in the definition of the subspaces involved in the decomposition of the discrete space, so that the subspaces adapt naturally to the new situation. In the standard mortar case, we recall from the definition of the subspaces that part of the subdomain interior nodes, that is, the set of edge midpoints lying closest to a mortar side, were treated as if they were on the mortar side; in other words, the mortar side became thicker. Note that due to the new mortar condition we do not require this arrangement.

So, following the general framework for additive Schwarz methods (cf. [22]), we can decompose V_h as $V_h = V^{\mathcal{S}} + V^0 + \sum_{i=1}^{N} V^i$. For $i = 1, \ldots, N$, V^i is the restriction of V_h to Ω_i, with functions vanishing at subdomain boundary edge midpoints $\partial\Omega_{ih}^{CR}$ as well as on the remaining subdomains.

$V^{\mathcal{S}}$ is the space of functions given by their values on the skeleton edge midpoints $\mathcal{S}_h^{CR} = \bigcup_{\gamma_m} \gamma_{mh}^{CR}$, $V^{\mathcal{S}} = \{v \in V_h : v(x) = 0,\ x \in \overline{\Omega}_h^{CR} \setminus \mathcal{S}_h^{CR}\}$. We assume that there are no corner triangles, that is, triangles having more than one edge on a subdomain boundary. It is then easy to see that the corresponding stiffness matrix is a block diagonal matrix with each block being associated to one mortar side only.

The coarse space V^0 is a special space having a dimension equal to the number of subdomains. It is defined using the function $\chi_i \in X_h(\Omega_i)$ associated with the subdomain Ω_i. χ_i is defined by its nodal values as $\chi_i(x) = 1/\sum_j \rho_j(x)$ at $x \in \overline{\Omega}_{ih}^{CR}$, where the sum is taken over the subdomains Ω_j to which x belongs, and $\rho_j = 1$ for all j. Note that the ρ_j's may represent physical parameters with jumps across interfaces; see [19]. V^0 is given as the span of its basis functions, $\Phi_i, i = 1, \ldots, N$,

i.e., $V^0 = span\{\Phi_i : i = 1, \ldots, N\}$, where Φ_i associated with Ω_i is defined as

$$\Phi_i(x) = \begin{cases} 1, & x \in \Omega_{ih}^{CR}, \\ \rho_i \chi_i(x), & x \in \gamma_{m(i)h}^{CR}, \\ \rho_i Q_m(J_m \chi_j)(x), & x \in \delta_{m(i)h}^{CR},\ \delta_{m(i)} = \gamma_{m(j)}, \\ \rho_i Q_m(J_m \chi_i)(x), & x \in \delta_{m(j)h}^{CR},\ \delta_{m(j)} = \gamma_{m(i)}, \\ \rho_i \chi_j(x), & x \in \gamma_{m(j)h}^{CR},\ \gamma_{m(j)} = \delta_{m(i)}, \\ 0, & x \in \partial\Omega_{ih}^{CR} \cap \partial\Omega, \end{cases} \tag{4.1}$$

and $\Phi_i(x) = 0$ at all other x in $\overline{\Omega}_h^{CR}$. We use exact bilinear forms for all our subproblems. The projection-like operators $T^i : V_h \to V^i$ are defined in the standard way; i.e., for $i \in \{\mathcal{S}, 0, \ldots, N\}$ and $u \in V_h$, $T^i u \in V^i$ is the solution of $a_h(T^i u, v) = a_h(u, v)$, $v \in V^i$. Let $T = T^{\mathcal{S}} + T^0 + T^1 + \cdots + T^N$. The problem (2.4) is now replaced by an equivalent system (cf. [22]),

$$Tu_h^* = g, \tag{4.2}$$

where $g = T^{\mathcal{S}} u_h^* + \sum_{i=0}^N T^i u_h^*$. Let c and C represent constants independent of the mesh sizes $h = \inf_i h_i$ and $H = \max_i H_i$. Then the following theorem holds.

THEOREM 4.1. *For all $u \in V_h$,*

$$c\frac{h}{H} a_h(u, u) \le a_h(Tu, u) \le C a_h(u, u). \tag{4.3}$$

The theorem can be shown in the same way as the proof in [19], which uses the general theory for Schwarz methods; cf. [22]. It follows from the theorem that the condition number of the operator T grows as $\frac{H}{h}$.

5. Implementation issues. The best way to understand how to implement the method is to look into the matrix representation of the method. When it comes to implementation, the mortar method of this paper differs from the one in [17] mainly in the mortar condition. We consider therefore only the mortar condition and present its matrix representation here. For the rest we refer to the matrix formulation section of [17].

For each mortar γ_m, let $\{\mathcal{E}_k : \mathcal{E}_k \in \mathcal{T}_h(\gamma_m)\}_{k=1,\ldots,n}$ and $\{\mathcal{E}_o : \mathcal{E}_o \in \mathcal{T}_h(\delta_m)\}_{o=1,\ldots,p}$ be the sets of n and p triangle edges along the mortar and the corresponding nonmortar sides, respectively. Let $\mathbf{J}_m$ be the matrix representation of the interpolation operator $J_m : X_h(\gamma_m) \to Z_h(\gamma_m)$ in the sense that if $\mathbf{u}_{\gamma_m}$ is the vector containing the values of the function $u \in X_h$ at the nodes of γ_{mh}^{CR}, that is, the set of edge midpoints of $\mathcal{T}_h(\gamma_m)$, then $\mathbf{J}_m \mathbf{u}_{\gamma_m}$ will return the values of the function $J_m u$ at the edge left and right endpoints $\overline{\gamma}_{mh}^{LR} = \{x : x = x_l^{\mathcal{E}_k}, x_r^{\mathcal{E}_k}, \mathcal{E}_k \in \mathcal{T}_h(\gamma_m)\}$. We note that $\overline{\gamma}_{mh}^{LR}$ contains edge endpoints which geometrically occupy the same space as those of $\overline{\gamma}_{mh}$. In the set $\overline{\gamma}_{mh}^{LR}$, each edge endpoint in the interior of γ_m occurs twice, once as the left endpoint of an edge and once as the right endpoint of the neighboring edge, or vice versa (the superscript "LR" stands for "left and right"). Let $\mathbf{I}_m$ be the matrix representation of the interpolation operator $I_m : X_h(\gamma_m) \to Y_{\frac{h}{2}}(\gamma_m)$ in the following sense. Let $\mathbf{u}_{\gamma_m}$ be the same vector as above; then $\mathbf{I}_m \mathbf{u}_{\gamma_m}$ will be the vector containing the values of the function $I_m u$ at the nodes of $\overline{\gamma}_{m\frac{h}{2}}$, that is, the set of edge endpoints of $\mathcal{T}_{\frac{h}{2}}(\gamma_m)$. Note that $\overline{\gamma}_{m\frac{h}{2}}$ is also the set of edge endpoints and edge midpoints of $\mathcal{T}_h(\gamma_m)$. Let h_k be

the length of the edge $\mathcal{E}_k$; then

$$\mathbf{I}_m = \begin{bmatrix} \frac{2h_1+h_2}{h_1+h_2} & -\frac{h_1}{h_1+h_2} & & & & & \\ 1 & & & & & & \\ \frac{h_2}{h_1+h_2} & \frac{h_1}{h_1+h_2} & & & & & \\ & 1 & & & & & \\ & \frac{h_3}{h_2+h_3} & * & & & & \\ & & * & & & & \\ & & * & \frac{h_{n-2}}{h_{n-2}+h_{n-1}} & & & \\ & & & 1 & & & \\ & & & \frac{h_n}{h_{n-1}+h_n} & \frac{h_{n-1}}{h_{n-1}+h_n} & & \\ & & & & 1 & & \\ & & & -\frac{h_n}{h_{n-1}+h_n} & \frac{h_{n-1}+2h_n}{h_{n-1}+h_n} & & \end{bmatrix}.$$

We follow Definition 2.2 and introduce an intermediate matrix $\mathbf{K}_m$ so that we have

$$\mathbf{J}_m = \mathbf{K}_m \mathbf{I}_m.$$

$\mathbf{K}_m$ is a block matrix consisting of n rectangular blocks, each corresponding to an edge $\mathcal{E}_k \in \mathcal{T}_h(\gamma_m)$ and being equal to the following 2×3 rectangular matrix:

$$\begin{bmatrix} \frac{1}{2} & 1 & -\frac{1}{2} \\ -\frac{1}{2} & 1 & \frac{1}{2} \end{bmatrix}.$$

The columns of this rectangular matrix correspond to the left endpoint $x_l^{\mathcal{E}_k}$, the midpoint $x_m^{\mathcal{E}_k}$, and the right endpoint $x_r^{\mathcal{E}_k}$ of the edge $\mathcal{E}_k$, respectively, and the rows correspond to the endpoints $x_l^{\mathcal{E}_k}$ and $x_r^{\mathcal{E}_k}$ of the edge $\mathcal{E}_k$, respectively. Consequently, the columns of $\mathbf{K}_m$ correspond to the set $\overline{\gamma}_{m\frac{h}{2}}$, while the rows correspond to the set $\overline{\gamma}_{mh}^{LR}$. We remark that the extra work involved in our algorithm, compared to the one presented in [17], is associated with the application of $\mathbf{K_m}$.

Let φ_k and φ_l be the standard CR basis functions associated with the edge midpoints $x_m^{\mathcal{E}_k} \in \gamma_{mh}^{CR}$ ($\mathcal{E}_k \in \mathcal{T}_h(\gamma_m)$) and $x_m^{\mathcal{E}_l} \in \delta_{mh}^{CR}$ ($\mathcal{E}_l \in \mathcal{T}_h(\delta_m)$), respectively. Let ψ_o be the basis function of the $M^h(\delta_m)$ associated with the edge midpoint $x_m^{\mathcal{E}_o}$ ($\mathcal{E}_o \in \mathcal{T}_h(\delta_m)$), defined as $\psi_o = 1$ in $\mathcal{E}_o$ and zero otherwise. Finally, let ξ_q be the basis function of $P^1(\mathcal{E}_q)$, associated with one of the edge endpoints $x_l^{\mathcal{E}_q}$ (left) and $x_r^{\mathcal{E}_q}$ (right).

Define the master matrix as $\mathbf{M}_{\gamma_m} = \left\{(J_m\varphi_k, \psi_o)_{L^2(\delta_m)}\right\}$ and the corresponding slave matrix as $\mathbf{S}_{\delta_m} = \left\{(\varphi_l, \psi_o)_{L^2(\delta_m)}\right\}$, where $x_m^{\mathcal{E}_k} \in \gamma_{mh}^{CR}$ and $x_m^{\mathcal{E}_l}, x_m^{\mathcal{E}_o} \in \delta_{mh}^{CR}$. Now, let $\mathbf{u}_{\gamma_m}$ be the vector defined as above, and let $\mathbf{u}_{\delta_m}$ be the corresponding vector containing the values of the function $u \in X_h$ at the edge midpoints δ_{mh}^{CR}; then

$$\mathbf{S}_{\delta_m}\mathbf{u}_{\delta_m} = \mathbf{M}_{\gamma_m}\mathbf{u}_{\gamma_m} = \mathbf{N}_{\gamma_m}\mathbf{K}_m\mathbf{I}_m\mathbf{u}_{\gamma_m}$$

is the matrix (discrete) representation of the mortar condition, where the supporting master matrix $\mathbf{N}_{\gamma_m} = \left\{(\xi_q, \psi_o)_{L^2(\delta_m)}\right\}$ with $x_l^{\mathcal{E}_q}, x_r^{\mathcal{E}_q} \in \overline{\gamma}_{mh}^{LR}$, and $x_m^{\mathcal{E}_o} \in \delta_{mh}^{CR}$. We note that $\mathbf{S}_{\delta_m}$ is a diagonal matrix containing the lengths of the triangle edges $\mathcal{E}_o \in \mathcal{T}_h(\delta_m)$ along the nonmortar side as entries.

6. Numerical results. The numerical results are presented here. We consider our model problem on a unit square domain with the function $f = 2\pi^2 \sin(\pi x)\sin(\pi y)$ and homogeneous Dirichlet boundary condition. The exact solution u equals the function $\sin(\pi x)\sin(\pi y)$. For all our experiments, as a general rule, we decompose the domain into a $d \times d = d^2$ number of square subdomains (subregions) and then uniformly triangulate each subdomain. In order to get nonmatching grids across all interfaces, each pair of subdomains sharing an interface are triangulated using a fixed $2m^2$ and $2n^2$ number of right angle triangles, where m is different from n. Note that the number d is inversely proportional to the subdomain size H, whereas the numbers m and n are proportional to $\frac{H}{h}$, the ratio between the subdomain size and the mesh size h. All sides of a subdomain are chosen to be either mortar or nonmortar. For comparison, we consider both the standard mortar condition of [15] and the new approximate mortar condition of the present paper for the lowest order CR finite element for solving the boundary value problem. The two resulting algebraic systems, which differ from each other due to different mortar conditions, are then solved using the conjugate gradient (CG) method.

TABLE 6.1

L^2-norm (error_{L^2}) and H^1_h-seminorm (error_{H^1}) of the error, using the standard and the approximate mortar conditions for the lower order CR finite element on 3×3 nonmatching grids.

		Standard CR Mortar		Approximate CR Mortar	
$\{m, n\}$	# dofs	error_{L^2}	$\text{error}_{H^1_h}$	error_{L^2}	error_{H1}
$\{07, 05\}$	1009	2.023e-3	5.815e-2	1.982e-3	5.858e-2
$\{14, 10\}$	4088	5.019e-4	2.905e-2	4.970e-4	2.916e-2
$\{28, 20\}$	16456	1.249e-4	1.454e-2	1.243e-4	1.456e-2
$\{56, 40\}$	66032	3.116e-5	7.272e-3	3.109e-5	7.278e-3

In our first experiment, we look at the accuracy of the computed solution u_h for the approximate mortar condition and compare it with that for the standard mortar condition. The L^2-norm and the H^1_h-seminorm of the error $u - u_h$ for different mesh sizes are calculated and shown in Table 6.1. As we can see from the table, the errors in both mortar cases are very close, and they vary as h^2 in the L^2-norm and as h in the H^1_h-seminorm, which is in accordance with the theory.

In our next experiment, we study the convergence behavior of their corresponding additive Schwarz methods; those are the method proposed for the approximate mortar condition in section 4 and the method proposed for the standard mortar condition in [19]. The additive Schwarz methods are used as preconditioners for the CG method for their respective algebraic systems. The condition number estimates and the number of iterations required to reduce the discrete L^2-norm of the residual by a factor of 10^{-6} are shown in the Table 6.2. As seen from the table, the condition number estimates as well as the iteration counts remain bounded for fixed $\frac{H}{h}$ ratio, which is as predicted by the theory. Again, the condition number estimates in both mortar cases are very close; however, the approximate mortar case seems to require slightly fewer iterations for the same tolerance.

We conclude by saying that both approaches, the standard mortar and the proposed approximate mortar, exhibit very similar numerical behavior. The approximate mortar approach, however, has the advantage that the mortar condition uses only the

TABLE 6.2
Condition number estimates and iteration counts using the standard and the approximate mortar conditions for the lower order CR finite element. $\frac{H}{h}$ *is fixed with* $m = 07$ *and* $n = 05$.

OPTIMAL PANEL-CLUSTERING IN THE PRESENCE OF ANISOTROPIC MESH REFINEMENT*

I. G. GRAHAM†, L. GRASEDYCK‡, W. HACKBUSCH‡, AND S. A. SAUTER§

Abstract. In this paper we consider the numerical solution of discrete boundary integral equations on polyhedral surfaces in three dimensions. When the solution contains typical edge singularities, highly stretched meshes are preferred to uniform meshes, since they reduce the number of degrees of freedom needed to obtain a fixed accuracy. The classical panel-clustering method can still be applied in the presence of such highly stretched meshes. However, we will show that the savings in computation time and storage become suboptimal because the nearfield matrix arising in the panel-clustering algorithm is no longer as sparse as it is in the case of uniform meshes. Hence, a natural question arises as to whether a new enhanced panel-clustering algorithm can be designed which performs efficiently even in the presence of highly stretched meshes. The main result of this paper is to formulate such an enhanced version of the panel-clustering algorithm. The key features of the algorithm are (i) the employment of partial analytic integration in the direction of stretching, yielding a new kernel function on a one-dimensional manifold where the influence of high aspect ratios in the stretched elements is removed, and (ii) the introduction of a generalized admissibility condition with respect to the partially integrated kernel, which ensures that certain stretched clusters which are inadmissible in the classical sense now become admissible. In the context of a model problem, we prove that our algorithm yields an accurate (up to the discretization error) matrix-vector multiplication which requires $\mathcal{O}(Nlog^k N)$ operations, where N is the number of degrees of freedom and k is small and independent of the aspect ratio. The generalized admissibility condition can be viewed as an addition to the classical method which may be useful in general when stretched meshes are present. We also have performed a numerical experiment which shows that the sparsity of the nearfield matrix for the enhanced panel-clustering method is not negatively affected by stretched elements, and the method will perform optimally.

Key words. boundary elements, panel-clustering, anisotropic meshes, matrix compression

1. Introduction.

The boundary integral method is a well-known method for solving several important classes of boundary-value problems. Since boundary integral operators are nonlocal, their straightforward discretization via the boundary element method (BEM) leads to dense linear systems, which, for large applications, have to be solved iteratively. The storage requirement and the cost of a matrix-vector multiplication scale quadratically with the number of unknowns N, and this is a major bottleneck in the solution process.

The panel-clustering algorithm [19, 18, 20, 27, 28, 3, 4] employs separable polynomial expansions of the kernel function in the far field (i.e., for matrix entries corresponding to well separated pairs of freedoms) to obtain an approximate matrix for which the complexity of storage and matrix-vector multiplication is $O(N \log^\kappa N)$, for

moderate κ, but for which the asymptotic accuracy of the resulting numerical solution (as the mesh is refined) remains unchanged.

To perform a thorough analysis of the panel-clustering algorithm we are required to address both the stability/consistency of the approximation and the complexity of the resulting matrix-vector multiplication. For quasi-uniform meshes this analysis can be found, e.g., in [19, 20, 29]. For more general classes of meshes, including certain degenerate meshes, a stability/consistency analysis was recently given in [11]. However, the complexity analysis has so far not been extended beyond the quasi-uniform case.

In this paper we focus on a class of degenerate meshes which are typically used in connection with the h-version of the Galerkin boundary element method on domains with nonsmooth boundaries. Because the solution being sought features anisotropic edge singularities, it can be shown (cf. [23, 8]) that meshes which are *algebraically graded* towards edges and corners allow a much better approximation of the solution than quasi-uniform meshes. These graded meshes are neither quasi-uniform nor shape-regular: Elements which are near edges but away from corners have an aspect ratio which tends to infinity as $N \to \infty$. Unfortunately, for such meshes, the standard panel-clustering algorithm will have suboptimal complexity, due to the fact that the near field becomes too large in the vicinity of the stretched elements. (This is explained in sections 5 and 7 below and was also the subject of previous unpublished work [10].) An alternative way to treat edge and corner singularities is the use of singular functions in the test and trial spaces of a Galerkin discretization which reflect the characteristic behavior of the solution [30, 22]. However, for complicated three-dimensional domains, the proper design of these functions, their implementation, and their numerical integration is far from trivial, and we will not investigate this method here.

In this paper we present a new version of the panel-clustering method which does not suffer from this defect. In order for the fundamental idea to be made clear, we will present the algorithm for general operators of order $> 1/2$ on polyhedra, discretised with piecewise constant elements. To keep the paper at reasonable length, the proofs will be limited to the case of the single layer potential for the Laplace operator. However, we also indicate throughout how the method and, in principle, the proofs can be extended to more general situations which are encountered in practical applications. The results of this paper complement those in [12], where the conditioning of Galerkin matrices on anisotropic meshes is analyzed, along with simple preconditioners which remove ill-conditioning due to the anisotropy. The fast multipole method (FMM) [26, 16] is closely related to the classical panel-clustering method. However, the generalization of the FMM to a version where the complexity is independent of an anisotropic mesh grading seems not to be straightforward and—to our best knowledge—not available in the literature. We remark that in addition to panel-clustering and FMM, other fast methods for realising discretizations of boundary integral operators can be based on Fourier methods; see, e.g., [1, 25].

The paper is organized as follows. In section 2, we briefly review the boundary integral equations, the graded meshes, and corresponding boundary element spaces having optimal approximation property. In section 3, we introduce the new (generalized) version of the panel-clustering method for stretched meshes and the algorithms for its efficient realization. The key idea is the introduction of a generalized admissibility condition which is based on the partial analytic integration of the kernel function on stretched elements in the direction parallel to the nearest edge. Here we make the (natural) assumption that the degenerate elements are parallel to the edge in

question. Section 4 is devoted to the error analysis of the generalized panel-clustering approximation. Specifically we show that the approximate system yields a solution which satisfies the same asymptotic error estimate as the true Galerkin solution. In section 5, we will show that the complexity of the new panel-clustering algorithm is of order $N \log^{\kappa} N$ for moderate κ. We will also show that the *standard* panel-clustering method for the stretched meshes considered here has complexity $N^{1+\delta}$, where $\delta \in (0, 1/2)$ and depends on the grading of the mesh. (In an extreme case, δ approaches $1/2$.) In section 6, explicit representations are presented for the partially integrated kernel function which is employed in section 3, along with the properties of the partially integrated kernel which are required for the proofs in sections 4 and 5. Numerical experiments are reported in section 7.

2. Boundary elements on anisotropically refined meshes. Let Γ be the surface of a closed bounded Lipschitz polyhedron in $\mathbb{R}^3$. Linear elliptic boundary-value problems with constant coefficients in the domain interior or exterior to Γ may be reformulated as boundary integral equations

$$(\lambda I + \mathcal{K})u(\mathbf{x}) := \lambda u(\mathbf{x}) + \int_{\Gamma} k(\mathbf{x}, \mathbf{y}) u(\mathbf{y}) ds_{\mathbf{y}} = f(\mathbf{x}), \quad \mathbf{x} \in \Gamma, \tag{2.1}$$

where $\lambda \in \mathbb{R}$, k is a known kernel function, and f is a known right-hand side. We will assume (as is true in very many cases) that for some $\mu \in \mathbb{R}$ the corresponding weak form,

$$\text{Find } u \in H^{\mu}(\Gamma) \quad \text{s.t. } a(u, v) := ((\lambda I + \mathcal{K})u, v) = (f, v) \quad \text{for all } v \in H^{\mu}(\Gamma), \tag{2.2}$$

constitutes a well-posed variational principle in the Sobolev space $H^{\mu}(\Gamma)$. (In some cases the energy space must be chosen as a suitable closed subspace of $H^{\mu}(\Gamma)$.) The continuous extension of the $L^2(\Gamma)$-scalar product $(\cdot, \cdot)$ to the duality pairing $H^{-\mu}(\Gamma) \times H^{\mu}(\Gamma)$ in (2.2) is again denoted by $(\cdot, \cdot)$. Typical examples include all the standard boundary integral formulations of Laplace's equation and the Helmholtz equation (see, e.g., [21, 29]). While the algorithm which we discuss in this paper is applicable to general boundary integral equations, we will present proofs for the following particular case.

Example 2.1. The Laplace single layer integral equation is of the form (2.1) with $\lambda = 0$ and $k(\mathbf{x}, \mathbf{y}) = 1/(4\pi \|\mathbf{x} - \mathbf{y}\|)$. The formulation (2.2) holds with $\mu = -1/2$, and the corresponding bilinear form is symmetric, bounded, and coercive in $H^{-1/2}(\Gamma)$.

To approximate (2.2) we assume that we have a mesh $\mathcal{T}$ of elements (here called *panels*) $\tau \in \mathcal{T}$. Each panel may be a triangle or quadrilateral and is assumed to be the image of a unit triangle or quadrilateral under an affine map. On this mesh we can introduce a space of piecewise polynomial functions $\mathcal{S} \subset H^{\mu}(\Gamma)$. The Galerkin method then seeks an approximate solution $U \in \mathcal{S}$ by solving

$$a(U, V) = (f, V) \qquad \text{for all } V \in \mathcal{S}. \tag{2.3}$$

Suppose $\mathbf{u}$ is the vector of coefficients of U with respect to a basis $\{\phi_i : i \in \mathcal{I}\}$, for some index set $\mathcal{I}$ with cardinality N. Then we have to solve the $N \times N$ linear system

$$(\lambda M + K)\mathbf{u} = \mathbf{f}, \tag{2.4}$$

with $M_{i,j} = (\phi_i, \phi_j)$, $K_{i,j} = (\mathcal{K}\phi_j, \phi_i)$, and $f_i = (f, \phi_i)$. The panel-clustering algorithm is used to approximate the dense matrix K. To be more precise, the panel-clustering is best thought of, *not* as an approximation of the *matrix entries* of K but as a data-sparse representation of the associated linear operator $K : \mathbb{R}^{\mathcal{I}} \to \mathbb{R}^{\mathcal{I}}$.

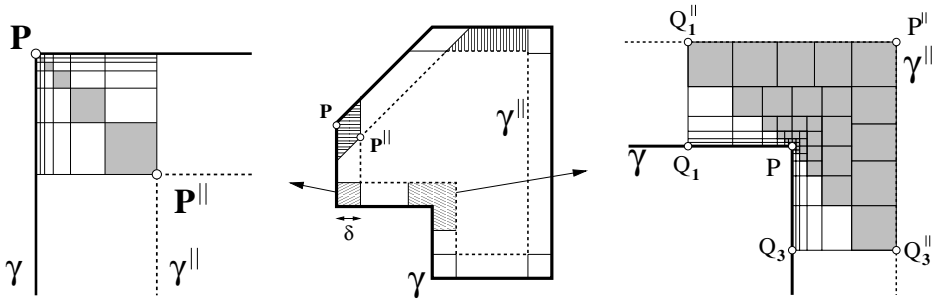

FIG. 2.1. *The face* Γ *(middle) is partitioned into segments with convex corners (left), concave corners (right), and the segments parallel to* γ *in between. Grey panels are shape-regular.*

It is well known (cf. [23, 29]) that the exact solution u exhibits a characteristic singular behavior in the *normal direction* near edges of Γ and in the *radial direction* near corners of Γ. Moreover, u is smooth in the interior of the plane faces of Γ and also in the *tangential* direction relative to the edges. This suggests that it may be advantageous to employ graded meshes whose elements have the following properties (as the meshes are refined): (i) they become increasingly small in the normal direction near the edges but are larger in the tangential direction, (ii) they become (uniformly) small when lying close to corners, and (iii) they are quasi-uniform when bounded away from the corners and edges.

We briefly describe the construction of suitable meshes. In general we are considering polyhedral surfaces, but without loss of generality we can explain the meshing algorithm by restricting to the case when Γ is a single planar polygon, with polygonal boundary $\gamma = \partial\Gamma$. For sufficiently small $\delta > 0$ we insert a polygon $\gamma^{\|}$ into Γ which is parallel to γ and has distance δ from γ (cf. Figure 2.1(middle)).[1] The portion of Γ between γ and $\gamma^{\|}$ we call "the δ-strip." We assume that δ is sufficiently small, so that for any vertex P in γ there exists a corresponding vertex $P^{\|}$ in $\gamma^{\|}$.

If P is a convex vertex of Γ, we extend both segments of $\gamma^{\|}$ which meet at $P^{\|}$ so that they hit γ.

If P is a concave vertex of Γ, we insert two lines into the δ-strip which are orthogonal to γ and a distance δ along γ from P.

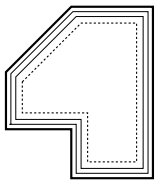
If δ is chosen sufficiently small, this procedure subdivides Γ into (i) rhombus-shaped regions of the δ-strip near convex corners, (ii) L-shaped regions of the δ-strip near concave corners, (iii) trapezia-shaped regions near edges but away from corners, and (iv) a polygonal inner region bounded by $\gamma^{\|}$.

The mesh on Γ depends on two parameters: $N \in \mathbb{N}$ (the number of elements in Γ) and $g \geq 1$ (the grading parameter which determines the concentration of panels towards edges). We shall study the convergence and complexity of our method as $N \to \infty$, with g fixed (although, in general, g may depend on the integral equation being solved, the polynomial degree of the elements, and the angles at the corners of Γ). Since some part of the mesh on Γ will be defined using tensor product constructions, we also introduce a coordinatewise discretization parameter $n \in \mathbb{N}$ such that $N \sim n^2$. The maximum mesh diameter will be proportional to n^{-1}.

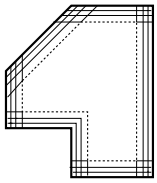
We will use the symbol "$\lesssim$" to compare two quantities $A \lesssim B$ if there exists a constant $C > 0$ which is independent of N such that $A \leq CB$.

[1] To be more precise, for each segment γ_i in γ there is a corresponding segment $\gamma_i^{\|}$ in $\gamma^{\|}$ so that the infinite lines through γ_i and $\gamma_i^{\|}$ are parallel and are a distance δ apart.

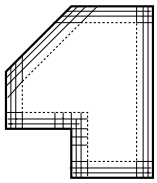
ALGORITHM 2.2 (construction of the mesh). *The meshing is applied to the four different types of region separately after the introduction of the δ-strip.*



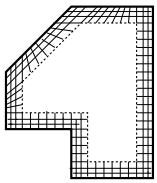
Step 1: *Edge-parallel mesh lines. For $n \in \mathbb{N}$, insert further polygons $\gamma_\ell^{\parallel}$, $1 \le \ell \le n-1$, into Γ which are parallel to γ and have distance $\delta\,(\ell/n)^g$ from γ. For any vertex P_ℓ of γ, there exists a corresponding vertex $P_\ell^{\parallel}$ in $\gamma_\ell^{\parallel}$.*



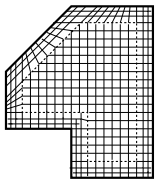
Step 2: *Rectangular meshes on rhombi near convex vertices. The straight line segments which meet at each $P_\ell^{\parallel}$ are prolonged until they hit γ. This produces a locally rectangular (non–shape-regular) mesh on each near-vertex rhombus which is graded towards the outer edges of the rhombus (cf. Figure* 2.1*(left)). The panels on the diagonal (towards the corner) are congruent to the near-vertex rhombus; i.e., they are shape-regular.*



Step 3: *Rectangular meshes on L-shaped regions at concave corners. We consider an L-shaped region as in Figure* 2.1*(right). In the two triangles $Q_1PQ_1^{\parallel}$ and $PQ_3Q_3^{\parallel}$ we use the same mesh as in a convex corner: graded towards the corner. Elements on the two lines $Q_1^{\parallel}P$ and $Q_3^{\parallel}P$ are then shape-regular. In the remaining part of the L-shaped region we use a shape-regular mesh that can be either conforming or nonconforming. We show the nonconforming case in Figure* 2.1*(right).*



Step 4: *Quadrilateral meshes on near-edge trapezia. Consider a near-edge trapezium with vertices $ABCD$ so that $\overline{AB} \subset \gamma$ and $\overline{CD} \subset \gamma^{\parallel}$. Subdivide $\overline{AB}$ into n equidistant segments and $\overline{CD}$ into n equidistant segments, and connect the opposite grid points in $\overline{AB}$ with those in $\overline{CD}$ by lines.*



Step 5: *Refinement of the inner region. The inner region is finally partitioned with a quasi-uniform mesh consisting of triangles and quadrilaterals of diameter $O\left(n^{-1}\right)$ such that the mesh points on $\gamma^{\parallel}$ already defined above coincide with the mesh points of the inner mesh at $\gamma^{\parallel}$. The quadrilaterals can be subdivided into triangles if required.*

Remark 2.3. The insertion of the lines as described in Algorithm 2.2, Step 4, subdivides the trapezium with vertices A, B, C, D into n smaller trapezia which we call *containers*. Each container Q consists of n parallel panels and has one and only one edge which lies in γ (namely, the edge $\overline{AB}$). The extension of this edge to an infinite line is called base line and denoted by γ_Q.

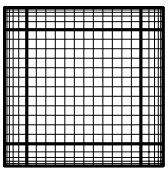
Since we will need it later, we now give the following explicit example.

Example 2.4. Let $\Gamma = [0,1] \times [0,1]$, and define the rectangular mesh:

$$\mathcal{T} := \{[p_{i-1}, p_i] \times [p_{j-1}, p_j] \ : \ i,j = 1, \dots, 3n\}, \text{ where}$$

$$p_i := \begin{cases} \delta(\frac{i}{n})^g, & 0 \le i \le n, \\ \delta + (1-2\delta)(\frac{i-n}{n}), & n \le i \le 2n, \\ 1 - \delta(\frac{3n-i}{n})^g, & 2n \le i \le 3n, \end{cases} \quad \text{and}$$

$$\delta := 1/(g+2).$$



(The inner square $\gamma^{\|}$ is denoted by the thick lines in the figure.)

Recalling that $N \sim n^2$, we see that near edges but away from corners we have degenerate elements with length $\sim N^{-1/2}$ and width $\sim \rho_\tau \sim N^{-g/2}$, i.e., aspect ratio growing with $N^{(g-1)/2}$ as $N \to \infty$. The reason for the specific choice of δ is that it ensures that adjacent elements on each side of any one of the thick lines have approximately the same sizes (as $N \to \infty$).

Now let $\mathcal{S}$ denote the space of piecewise constant functions with respect to the mesh on Γ. The analysis of the use of such graded meshes for approximating boundary integral equations on polyhedra can be found, for example, in [23, 24, 8, 9, 13]. In particular (see, e.g., [9, Theorem 1.4]) it is known that the Galerkin solution $U \in \mathcal{S}$ (see (2.3)) to the model problem in Example 2.1 on a Lipschitz polyhedral surface (for sufficiently smooth data f) satisfies

$$\|u - U\|_{H^{-1/2}(\Gamma)} \lesssim N^{-3/4} \qquad \text{when } g > 3. \tag{2.5}$$

Note that (2.5) constitutes an optimal estimate in terms of number of degrees of freedom N, since in the case of quasi-uniform meshes on smooth surfaces we expect $O(h^{3/2})$ convergence in the $H^{-1/2}$ norm, and the mesh diameter $h \sim N^{-1/2}$. Suboptimal convergence is attained for $1 \le g \le 3$. (This result also extends to some higher order elements [23].)

The central problem which we are concerned with in this paper is the construction of a data-sparse representation of the dense stiffness matrix K appearing in (2.4) which has optimal complexity but for which the convergence rates (2.5) are preserved.

We note in passing that as well as having a fast matrix-vector multiplication, the number of iterations required by an iterative method is of key importance for the speed of the method. It is known that anisotropic mesh refinement can produce considerable ill-conditioning. This can be substantially reduced by scaling the linear equations appropriately [12]. Additional preconditioning techniques involving approximate inverses such as the $\mathcal{H}$-matrix techniques [15, 14] or SPAI techniques [5] can be applied in addition.

3. Panel-clustering for graded meshes. The basic idea of the panel-clustering algorithm is to approximate the kernel k in (2.1) by a (short) separable expansion when $\mathbf{x}$ and $\mathbf{y}$ belong to sufficiently well separated sets. We briefly recall the essential ingredients of the panel-clustering method before we explain the modifications for stretched meshes.

From now on, the mesh $\mathcal{T}$ on Γ will be written $\mathcal{T} = \{\tau_i : i \in \mathcal{I}\}$, where $\mathcal{I}$ is a suitable index set. For each i, let ξ_i denote the incenter (center of the largest inscribed circle), let h_i denote the diameter, and let ρ_i denote the diameter of the largest inscribed circle in the panel τ_i.

3.1. Classical panel-clustering (isotropic admissibility).

DEFINITION 3.1 (cluster). *A cluster t is a subset of $\mathcal{I}$. If t is a cluster, the corresponding subdomain of Γ is $\Gamma_t := \bigcup_{i \in t} \tau_i$.*

The clusters are collected in a hierarchical cluster tree $T_{\mathcal{I}}$.

DEFINITION 3.2 (cluster tree). *A tree $T_{\mathcal{I}}$ is a cluster tree if the following conditions are satisfied:*

1. *The nodes in $T_{\mathcal{I}}$ are clusters.*
2. *The root of $T_{\mathcal{I}}$ is $\mathcal{I}$.*
3. *The leaves of $T_{\mathcal{I}}$ are denoted by $\mathcal{L}(T_{\mathcal{I}})$, and the tree hierarchy is given by a father/son relation: For each interior node $t \in T_{\mathcal{I}} \setminus \mathcal{L}(T_{\mathcal{I}})$, the set of sons of*

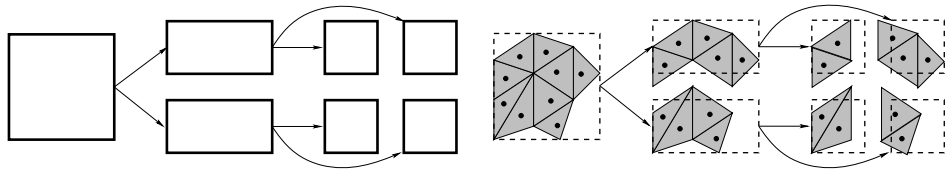


FIG. 3.1. *Left: Tree of regular boxes $\tilde{\mathcal{B}}$ obtained by bisection. Right: Tree of corresponding clusters $t = t(\tilde{\mathcal{B}})$. The black dots mark the corresponding incenters ξ_i of the panels $\tau_i \in \mathcal{T}$.*

t, $\mathrm{sons}(t)$, is the minimal subset in $\mathcal{T}_{\mathcal{I}} \setminus \{t\}$ such that

$$t = \dot{\bigcup_{s \in \mathrm{sons}(t)}} s$$

holds. Conversely, the father of any $s \in \mathrm{sons}(t)$ is t.

The standard (geometrically regular) construction of the cluster tree $T_{\mathcal{I}}$ is as follows. Choose a bounding box

$$\tilde{\mathcal{B}} := [a_1, b_1) \times [a_2, b_2) \times [a_3, b_3) \supset \Gamma.$$

Then subdivide $\tilde{\mathcal{B}}$ by bisecting a longest side, thus obtaining two sons $\tilde{\mathcal{B}}_1, \tilde{\mathcal{B}}_2$, e.g.,

$$\tilde{\mathcal{B}}_1 = [a_1, b_1') \times [a_2, b_2) \times [a_3, b_3), \quad \tilde{\mathcal{B}}_2 = [a_1', b_1) \times [a_2, b_2) \times [a_3, b_3),$$

where $a_1' = b_1' := (a_1 + b_1)/2$. Finally, applying the same bisection process recursively, starting with $\tilde{\mathcal{B}}_1$ and $\tilde{\mathcal{B}}_2$, yields an infinite tree T_{box} with root $\tilde{\mathcal{B}}$. Letting $\tilde{\mathcal{B}}_j$ denote a typical box in this tree, we can define a corresponding cluster by (cf. Figure 3.1)

$$t(\tilde{\mathcal{B}}_j) := \{i \in \mathcal{I} \mid \xi_i \in \tilde{\mathcal{B}}_j\}.$$

This yields an infinite cluster tree with root $t(\tilde{\mathcal{B}})$. We construct a finite cluster tree by deleting (not constructing) sons of clusters below a minimal cardinality $n_{\min}$, e.g., $n_{\min} := 8$. The cardinality of the cluster tree for the meshes introduced in section 2, as well as the complexity of its construction, will be estimated in section 5. (Note that for the special case that Γ is a flat polygon we may choose $\tilde{\mathcal{B}}$ as a two-dimensional bounding box.)

For a cluster, $t \subset \mathcal{I}$, let $\mathcal{B}_t$ denote the minimal bounding box (of the type from above) of Γ_t.

Conventionally, in order to obtain the approximation of the matrix K in (2.4), the kernel function k is approximated on $\Gamma_t \times \Gamma_s$, where (t, s) is a pair of clusters which satisfy the following condition.

DEFINITION 3.3 (isotropic admissibility condition). *Choose an isotropic admissibility parameter $\eta^{\mathrm{iso}} > 0$. A pair of clusters $(t, s) \in T_{\mathcal{I}} \times T_{\mathcal{I}}$ is isotropically (η^{iso}-) admissible if*

$$\max\{\mathrm{diam}\mathcal{B}_t,\ \mathrm{diam}\mathcal{B}_s\} \leq \eta^{\mathrm{iso}}\ \mathrm{dist}(\mathcal{B}_t,\ \mathcal{B}_s). \tag{3.1}$$

The standard choice for the parameter in (3.1) is $\eta^{\mathrm{iso}} := 3$.

The admissibility condition (3.1) allows us to define a nonoverlapping partition of $\mathcal{I} \times \mathcal{I}$ into admissible pairs of clusters (called block clusters) and nonadmissible pairs of (small) clusters. This partition is formed by the leaves of the block cluster tree $T^{\mathrm{iso}}_{\mathcal{I} \times \mathcal{I}}$, which we now define.

DEFINITION 3.4 (block cluster tree $T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}}$). *Let $T_{\mathcal{I}}$ be a cluster tree. Then the block cluster tree $T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}}$ based on the isotropic admissibility condition* (3.1) *is defined by the root $(\mathcal{I},\mathcal{I})$ and the father-son relation for $\mathbf{b}=(t,s)\in T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}}$:*

$$\operatorname{sons}(\mathbf{b}) := \begin{cases} \emptyset & \text{if } (t,s) \text{ is isotropically } \eta^{\mathrm{iso}}\text{-admissible,} \\ \operatorname{sons}(t)\times\operatorname{sons}(s) & \text{otherwise.} \end{cases}$$

The practical construction of the block cluster tree $T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}}$ from the root to the leaves is straightforward (cf. [19, 20]). The leaves $\mathcal{L}(T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}})$ consist of two different types of block clusters,

$$\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}} := \{\mathbf{b}\in\mathcal{L}(T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}}) \,:\, \mathbf{b} \text{ is isotropically } \eta^{\mathrm{iso}}\text{-admissible }\}, \quad \mathcal{L}^{\mathrm{iso}}_{\mathrm{near}} := \mathcal{L}(T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}})\backslash\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}.$$

These are known as the nearfield block clusters ($\mathcal{L}^{\mathrm{iso}}_{\mathrm{near}}$) and the farfield block clusters ($\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}$). For each block cluster $\mathbf{b}=(t,s)$ we denote the corresponding domain by $\Gamma_{\mathbf{b}} := \Gamma_t\times\Gamma_s$. The set of all subdomains $P^{\mathrm{iso}} = \{\Gamma_{\mathbf{b}} \mid \mathbf{b}\in\mathcal{L}(T^{\mathrm{iso}}_{\mathcal{I}\times\mathcal{I}})\}$ is a partition of the tensor surface $\Gamma\times\Gamma$. The partition P^{iso} consists of two different types of subdomains, the farfield $P^{\mathrm{iso}}_{\mathrm{far}}$ and the nearfield $P^{\mathrm{iso}}_{\mathrm{near}}$:

$$P^{\mathrm{iso}}_{\mathrm{far}} := \left\{\Gamma_{\mathbf{b}} \,:\, \mathbf{b}\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}\right\}, \quad P^{\mathrm{iso}}_{\mathrm{near}} := P^{\mathrm{iso}}\setminus P^{\mathrm{iso}}_{\mathrm{far}}.$$

On each admissible block $\Gamma_{\mathbf{b}}\in P^{\mathrm{iso}}_{\mathrm{far}}$ the kernel function k is approximated by a degenerate expansion of the form

$$\tilde{k}_{\mathbf{b}}(\mathbf{x},\mathbf{y}) = \sum_{\nu=1}^{M} \Phi_{\mathbf{b},\nu}(\mathbf{x})\Psi_{\mathbf{b},\nu}(\mathbf{y}), \qquad (\mathbf{x},\mathbf{y})\in\Gamma_t\times\Gamma_s. \tag{3.2}$$

Remark 3.5. For the kernel function of the single layer potential for the Laplace problem, allowable expansion functions in (3.2) include, e.g., polynomial interpolation, multipole expansions, and Taylor expansion. One can show (for the proofs we refer the reader to, e.g., [29, 2]) that, for sufficiently small η^{iso}, there exist constants $0<\sigma<1$ (depending on η^{iso}) and $0<C<\infty$ with the following property: For all isotropically admissible blocks $\mathbf{b}=(t,s)\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}$ the Taylor expansion, Chebyshev interpolation, or multipole expansion of order m satisfies

$$\left|k(\mathbf{x},\mathbf{y}) - \tilde{k}_{\mathbf{b}}(\mathbf{x},\mathbf{y})\right| \;\le\; C\sigma^m \left(\operatorname{dist}(\mathcal{B}_t,\mathcal{B}_s)\right)^{-1} \quad \text{for all } (\mathbf{x},\mathbf{y})\in\Gamma_t\times\Gamma_s. \tag{3.3}$$

The number of terms M in (3.2) depends on m through $M(m) = m^q$ for some $q\in\{2,3\}$. For example, if the kernel $k(\mathbf{x},\mathbf{y})$ is interpolated (with respect to $\mathbf{y}$) using polynomials of degree m in each of the three coordinate directions, then there are $M=(m+1)^3$ terms in (3.2).

For interpolation and multipole expansions, (3.2) can be generalized so that the expansion functions depend only on the clusters and not on the blocks.

In the following, we briefly will sketch the algorithmic realization in the case of the Laplace single layer potential in Example 2.1 discretized by the Galerkin BEM with piecewise constant boundary elements.

For $\mathbf{b}=(t,s)\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}$ we define the matrices known as the "farfield coefficients" by

$$L^{\mathbf{b}}_{i,\nu} := \int_{\tau_i} \Phi_{\mathbf{b},\nu}(\mathbf{x})ds_{\mathbf{x}}, \quad R^{\mathbf{b}}_{\nu,j} := \int_{\tau_j} \Psi_{\mathbf{b},\nu}(\mathbf{y})ds_{\mathbf{y}}, \quad i\in t,\ j\in s,\ \nu\in\{1,\dots,M\},$$

and the nearfield matrix $\mathbf{V}^{\mathrm{near}}$ with entries

$$\mathbf{V}^{\mathrm{near}}_{i,j} := \begin{cases} \int_{\tau_i\times\tau_j} k(\mathbf{x},\mathbf{y})ds_{\mathbf{x}}ds_{\mathbf{y}} & \text{if } i\in t, j\in s, (t,s)\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{near}},\\ 0 & \text{otherwise.}\end{cases}$$

The number of columns of $L^{\mathbf{b}}$ and the number of rows of $R^{\mathbf{b}}$ is equal to M. We have in mind that M will be small compared to N (typically $M\sim\log^q N$ for some $q\in\{2,3\}$). For the Laplace single layer potential on the screen (Example 2.1) $M\sim\log^2 N$ (see [2]).

The bilinear form

$$a(U,V)=\int_{\Gamma\times\Gamma} k(\mathbf{x},\mathbf{y})U(\mathbf{x})V(\mathbf{y})ds_{\mathbf{x}}ds_{\mathbf{y}} \qquad \text{for all } U,V\in S$$

is split into the blockwise bilinear forms

$$a(U,V)=\sum_{\mathbf{b}\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{near}}\cup\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}} \underbrace{\int_{\Gamma_{\mathbf{b}}} k(\mathbf{x},\mathbf{y})U(\mathbf{x})V(\mathbf{y})ds_{\mathbf{x}}ds_{\mathbf{y}}}_{=:a_{\mathbf{b}}(U,V)}.$$

The panel-clustering approximation $\tilde{a}(U,V)$ of the bilinear form $a(U,V)$ is then obtained by replacing the blockwise bilinear form $a_{\mathbf{b}}(U,V)$ in the farfield blocks $\mathbf{b}=(t,s)\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}$ by

$$\begin{aligned}\tilde{a}_{\mathbf{b}}(U,V) &:= \int_{\Gamma_{\mathbf{b}}} \tilde{k}_{\mathbf{b}}(\mathbf{x},\mathbf{y})V(\mathbf{x})U(\mathbf{y})ds_{\mathbf{x}}ds_{\mathbf{y}}\\ &= \sum_{\nu=1}^{M}\int_{\Gamma_{\mathbf{b}}} \Phi_{\mathbf{b},\nu}(\mathbf{x})\Psi_{\mathbf{b},\nu}(\mathbf{y})V(\mathbf{x})U(\mathbf{y})ds_{\mathbf{x}}ds_{\mathbf{y}}\\ &= \sum_{i\in t}\sum_{j\in s}\left(L^{\mathbf{b}}R^{\mathbf{b}}\right)_{i,j} V(\xi_i)U(\xi_j). \qquad (3.4)\end{aligned}$$

The final equality follows because here we have restricted our analysis to piecewise constant elements.

The nearfield matrix $\mathbf{V}^{\mathrm{near}}$ contains all contributions from the nearfield blocks $\mathbf{b}\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{near}}$. It is sparse since $P^{\mathrm{iso}}_{\mathrm{near}}$ covers only a small part of the tensor surface $\Gamma\times\Gamma$. The farfield coefficients $L^{\mathbf{b}}$ and $R^{\mathbf{b}}$ for blocks $\mathbf{b}\in\mathcal{L}^{\mathrm{iso}}_{\mathrm{far}}$ can be computed by standard quadrature techniques, since the degenerate expansion functions are smooth in the far field. They contain only $M(\#t+\#s)$ entries instead of the $\#t\#s$ entries of the full block $t\times s$.

In [11], the stability and convergence of the standard panel-clustering method is analyzed for general classes of meshes, including the stretched meshes discussed in section 2. It is shown there that the mesh degeneracy does not affect the accuracy of the approximation. However, it turns out that the standard algorithm is not optimal in terms of complexity, as the following example shows.

Example 3.6. Consider the Laplace single layer equation from Example 2.1, and consider piecewise constant elements on the meshes on the unit square in Example 2.4. In order to obtain optimal convergence rates we have to choose $g>3$ (see (2.5)).

We fix an arbitrary index $n+1\le i\le 2n$. All panels $\tau_{i,j}:=[p_{i-1},p_i]\times[p_{j-1},p_j]$ satisfy

$$p_i-p_{i-1}=(1-2\delta)n^{-1}=\left(\frac{g}{g+2}\right)n^{-1}>\frac{3}{5}n^{-1}.$$

On the other hand, for all indices $j = 1, \ldots, n^{1-1/g} + 1$ we have

$$p_{j-1} = \delta(j-1)^g n^{-g} \leq \delta n^{g-1} n^{-g} \leq \frac{1}{5} n^{-1} < \frac{3}{5} n^{-1},$$

so that for all $j, \ell \in J := \{1, \ldots, n^{1-1/g} + 1\}$

$$\operatorname{dist}(\tau_{i,j}, \tau_{i,\ell}) < \frac{3}{5} n^{-1}.$$

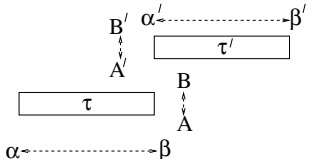
Thus any pair of clusters (t, s), where both t and s contain a panel $\tau_{i,j}$ with $j \in J$, cannot be isotropically admissible when the parameter η^{iso} is chosen such that $\eta^{iso} \leq 1$. Therefore, in the rows of the matrix K corresponding to the indices $\{(i,j) \mid i = n+1, \ldots, 2n,\ j \in J\}$ there are at least $\#J = n^{1-1/g}$ nearfield entries that must be computed and stored. There are $n^{2-1/g}$ such rows, and so we have to store at least $n^{3-2/g} = \mathcal{O}(N^{3/2-1/g})$ entries; i.e., the (storage) complexity of conventional panel-clustering is at least this. As g increases, the complexity approaches $\mathcal{O}(N^{3/2})$.

3.2. Anisotropic admissibility. The reason for the suboptimal performance of the panel-clustering method for stretched meshes is the isotropic admissibility condition. The near field of the long thin elements which lie close to edges of Γ becomes too large.

This problem is overcome by a modified panel-clustering algorithm which will be presented next.

3.2.1. The case of the screen. To illustrate the underlying idea we first consider the screen domain Γ from Example 2.4. Let two panels parallel to the x-axis be of the form

(3.5)



$$\begin{aligned} \tau &= (\alpha, \beta) \times (A, B), \\ \tau' &= (\alpha', \beta') \times (A', B'), \end{aligned}$$

with $\alpha < \beta$, $\alpha' < \beta'$, $A < B < A' < B'$.

Suppose also that

(3.6)

$$\max\{\operatorname{diam}(\tau), \operatorname{diam}(\tau')\} \geq \max\{\beta - \alpha, \beta' - \alpha'\} > \eta^{\text{iso}}(A' - B) = \eta^{\text{iso}} \operatorname{dist}(\tau, \tau'),$$

but at the same time

$$\max\{B - A, B' - A'\} \leq \eta^{\text{iso}} (A' - B). \tag{3.7}$$

Clearly (3.6) indicates that this pair of panels is inadmissible in the sense of condition (3.1). The problem is that the long sides (with length $\beta - \alpha$ and $\beta' - \alpha'$) are much longer than the distance between the elements. On the other hand, if somehow the lengths of the long sides could be ignored, then these elements would become admissible by virtue of (3.7). The essence of our new method is the observation that, provided the elements are parallel, analytic partial integration may be performed, leading to a new admissibility criterion which admits pairs satisfying (3.7) but not (3.1).

Continuing with the example (3.5), assuming U and V are piecewise constant functions and using the notation $\mathbf{x} = (x_1, x_2), \mathbf{y} = (y_1, y_2)$, we obtain

$$\begin{aligned} \int_\tau \int_{\tau'} k(\mathbf{x}, \mathbf{y}) V(\mathbf{x}) U(\mathbf{y}) \mathrm{d}\mathbf{x} \mathrm{d}\mathbf{y} &= V(\xi) U(\xi') \int_A^B \int_{A'}^{B'} \int_\alpha^\beta \int_{\alpha'}^{\beta'} k((x_1, x_2), (y_1, y_2)) \mathrm{d}\mathbf{x} \mathrm{d}\mathbf{y} \\ &= V(\xi) U(\xi') \int_A^B \int_{A'}^{B'} k^{\text{ad}}(x_2, y_2) \mathrm{d}y_2 \mathrm{d}x_2, \end{aligned}$$

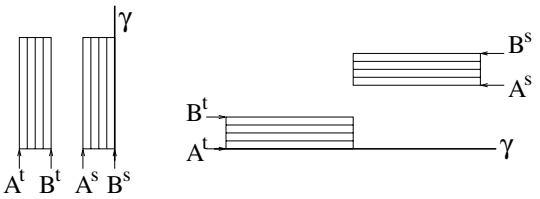


FIG. 3.2. *Examples of pairs (t,s) of anisotropically admissible clusters.*

where ξ and ξ' are the incenters of τ, τ' and $k^{\mathrm{ad}}(x_2,y_2) := \int_\alpha^\beta \int_{\alpha'}^{\beta'} k((x_1,x_2),(y_1,y_2))\mathrm{d}y_1\mathrm{d}x_1$ is the antiderivative of k. We will show that the twofold integration over the *long* directions (α,β), (α',β') leads to a kernel function $k^{\mathrm{ad}} : (A,B)\times(A',B') \to \mathbb{R}$ which is admissible for the one-dimensional intervals (A,B), (A',B') via the one-dimensional admissibility condition (3.7).

The idea can be carried over to pairs of clusters (instead of pairs of panels), provided they fulfil the following anisotropic admissibility condition.

DEFINITION 3.7 (anisotropic admissibility condition for the screen). *Choose $\eta^{\mathrm{aniso}} > 0$. A pair of clusters $(t,s) \in T_{\mathcal{I}} \times T_{\mathcal{I}}$ is anisotropically (η^{aniso}-) admissible if all panels τ_i, $i \in t$, and τ_j, $j \in s$, are of the form (in some suitable coordinate system; cf. Figure* 3.2*)*

$$\tau_i = (A_i^t, B_i^t)\times(\alpha^t,\beta^t), \quad \tau_j = (A_j^s, B_j^s)\times(\alpha^s,\beta^s), \tag{3.8}$$

or

$$\tau_i = (\alpha^t,\beta^t)\times(A_i^t, B_i^t), \quad \tau_j = (\alpha^s,\beta^s)\times(A_j^s, B_j^s) \tag{3.9}$$

and

$$\max\{|B^t - A^t|, |B^s - A^s|\} \;\le\; \eta^{\mathrm{aniso}}\,\mathrm{dist}(\mathcal{B}_t,\mathcal{B}_s), \tag{3.10}$$

where $A^t := \min\{A_i^t : i \in t\}$, $B^t := \max\{B_i^t : i \in t\}$, and A^s, B^s are defined analogously.

Let t and s, $\mathbf{b} := (t,s)$, be two clusters with corresponding panels of the form (3.8) or (3.9). The evaluation of the blockwise bilinear form $a_{\mathbf{b}}(U,V)$ for two piecewise constant finite element functions U and V can be written in the form

$$\begin{aligned} a_{\mathbf{b}}(U,V) &= \int_{\Gamma_{\mathbf{b}}} k(\mathbf{x},\mathbf{y})V(\mathbf{x})U(\mathbf{y})\mathrm{d}x\mathrm{d}y \\ &= \int_{\alpha^t}^{\beta^t}\int_{\alpha^s}^{\beta^s} \sum_{i\in t}\sum_{j\in s}\int_{A_i^t}^{B_i^t}\int_{A_j^s}^{B_j^s} V(x_1,x_2)U(y_1,y_2)k((x_1,x_2),(y_1,y_2))\mathrm{d}\mathbf{x}\mathrm{d}\mathbf{y} \\ &= \sum_{i\in t}\sum_{j\in s} V(\xi_i)U(\xi_j)\int_{A_i^t}^{B_i^t}\int_{A_j^s}^{B_j^s} k_{\mathbf{b}}^{\mathrm{ad}}(x_2,y_2)\mathrm{d}y_2\mathrm{d}x_2, \end{aligned}$$

where $k_{\mathbf{b}}^{\mathrm{ad}}$, as before, is the antiderivative of k,

$$k_{\mathbf{b}}^{\mathrm{ad}}(x_2,y_2) = \int_{\alpha^t}^{\beta^t}\int_{\alpha^s}^{\beta^s} k((x_1,x_2),(y_1,y_2))\mathrm{d}y_1\mathrm{d}x_1. \tag{3.11}$$

In section 4 we will prove that for an anisotropically admissible block $\mathbf{b} = (t, s)$ the integrated kernel $k_{\mathbf{b}}^{\mathrm{ad}}$ can be approximated by a degenerate kernel $\tilde{k}_{\mathbf{b}}^{\mathrm{ad}}$ of the form

$$\tilde{k}_{\mathbf{b}}^{\mathrm{ad}}(x_2, y_2) = \sum_{\nu=1}^{m} \Phi_{\mathbf{b},\nu}(x_2)\Psi_{\mathbf{b},\nu}(y_2). \tag{3.12}$$

The bilinear form $a_{\mathbf{b}}(U, V)$ is then approximated by

$$\begin{aligned}
\tilde{a}_{\mathbf{b}}(U,V) &:= \sum_{i\in t}\sum_{j\in s} V(\xi_i)\, U(\xi_j) \int_{A_i^t}^{B_i^t} \int_{A_j^s}^{B_j^s} \sum_{\nu=1}^{m} \Phi_{\mathbf{b},\nu}(x_2)\Psi_{\mathbf{b},\nu}(y_2)\mathrm{d}y_2\mathrm{d}x_2 \\
&= \sum_{i\in t}\sum_{j\in s} V(\xi_i)\, U(\xi_j) \sum_{\nu=1}^{m} \underbrace{\int_{A_i^t}^{B_i^t} \Phi_{\mathbf{b},\nu}(x_2)\mathrm{d}x_2}_{=:L_{i,\nu}^{\mathbf{b}}} \underbrace{\int_{A_j^s}^{B_j^s} \Psi_{\mathbf{b},\nu}(y_2)\mathrm{d}y_2}_{=:R_{\nu,j}^{\mathbf{b}}} \\
&= \sum_{i\in t}\sum_{j\in s} (L^{\mathbf{b}}R^{\mathbf{b}})_{i,j} V(\xi_i)U(\xi_j), \qquad (3.13)
\end{aligned}$$

where $L^{\mathbf{b}} \in \mathbb{R}^{\#t\times m}$ and $R^{\mathbf{b}} \in \mathbb{R}^{m\times \#s}$. Since it will turn out that m can be chosen proportional to $\log(N)$, the storage and matrix by vector complexity is $\mathcal{O}(\log(N)(\#t+\#s))$ instead of the quadratic complexity for the standard representation.

Combining the isotropic and anisotropic admissibilities, we arrive at a final block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ described as follows.

DEFINITION 3.8 (block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$). *Let $T_{\mathcal{I}}$ be a cluster tree. Then the block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ based on the admissibility conditions* (3.1), (3.10) *is defined by the root $(\mathcal{I},\mathcal{I})$ and the father-son relation for $\mathbf{b} = (t, s) \in T_{\mathcal{I}\times\mathcal{I}}$:*

$$\mathrm{sons}\,(\mathbf{b}) := \begin{cases} \emptyset & \text{if } (t,s) \text{ is isotropically or anisotropically admissible,} \\ \mathrm{sons}(t)\times\mathrm{sons}(s) & \text{otherwise.} \end{cases}$$

The leaves $\mathbf{b} \in \mathcal{L}(T_{\mathcal{I}\times\mathcal{I}})$ of the block cluster tree form a partition of $\mathcal{I}\times\mathcal{I}$, and the corresponding domains $\Gamma_{\mathbf{b}}$ yield a partition of the tensor surface $\Gamma\times\Gamma$. In contrast to the isotropic case discussed in Definition 3.4, three different types of blocks will appear in this case:

- $\mathcal{L}_{\mathrm{far}}^{II} := \{\mathbf{b} \in \mathcal{L}(T_{\mathcal{I}\times\mathcal{I}}) : \mathbf{b}$ is anisotropically, but not isotropically, admissible$\}$. These blocks allow an approximation by $\tilde{a}_{\mathbf{b}}$ given in (3.13) and involve the integrated kernel $\tilde{k}_{\mathbf{b}}^{\mathrm{ad}}$.
- $\mathcal{L}_{\mathrm{far}}^{I} := \{\mathbf{b} \in \mathcal{L}(T_{\mathcal{I}\times\mathcal{I}}) : \mathbf{b}$ is isotropically admissible$\}$. These are treated by the standard techniques (3.4).
- $\mathcal{L}_{\mathrm{near}} := \mathcal{L}(T_{\mathcal{I}\times\mathcal{I}})\backslash\mathcal{L}_{\mathrm{far}}$, $\quad \mathcal{L}_{\mathrm{far}} := \mathcal{L}_{\mathrm{far}}^{II} \cup \mathcal{L}_{\mathrm{far}}^{I}$. For these blocks we use the original bilinear form $a_{\mathbf{b}}$.

For the block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ we will prove in section 5 that the nearfield matrix $\mathbf{V}^{\mathrm{near}}$ corresponding to entries from nearfield blocks $\mathbf{b} \in \mathcal{L}_{\mathrm{near}}$ is sparse (i.e., $\mathcal{O}(N)$ entries). This means that the generalized panel-clustering approximation

$$\tilde{a}(U,V) := \sum_{\mathbf{b}\in\mathcal{L}_{\mathrm{near}}} a_{\mathbf{b}}(U,V) + \sum_{\mathbf{b}\in\mathcal{L}_{\mathrm{far}}} \tilde{a}_{\mathbf{b}}(U,V) \tag{3.14}$$

can be evaluated in $\mathcal{O}(N\log(N)M)$ operations, where $M \approx \log^2 N$. In section 4 we prove the consistency of the panel-clustering approximation, i.e., that the complexity of $\mathcal{O}(N\log^3 N)$ is attained without damaging the accuracy of the underlying boundary element method.

3.2.2. The case of a polyhedral surface. The anisotropic admissibility condition (Definition 3.7) can be extended to the case of polyhedral surfaces Γ which are composed of faces with polygonal boundaries. Recall the definition of the containers Q and their base line γ_Q as in Remark 2.3.

DEFINITION 3.9 (anisotropic admissibility condition for polyhedral surfaces). *A pair of clusters (t,s) is anisotropically admissible with respect to $\gamma \in \mathcal{E}$ if there exist containers Q_t, Q_s with the same base line $\gamma_{Q_t} = \gamma_{Q_s}$ such that*

$$\Gamma_t \subset Q_t \quad \textit{and} \quad \Gamma_s \subset Q_s$$

and

$$\max\{H_t, H_s\} \;\leq\; \eta^{\mathrm{aniso}} \;\operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s),$$

where for $i = s, t$

$$H_i := \sup_{\mathbf{x},\mathbf{y}\in\Gamma_i} \{\|\mathbf{x}-\mathbf{y}\| : (\mathbf{x}-\mathbf{y}) \perp (\gamma_{Q_i})\}.$$

Analogously to the screen case, the integration parallel to $\gamma_{Q_s} = \gamma_{Q_i}$ is carried out analytically, leading again to an antiderivative of the kernel function which can be approximated efficiently by panel-clustering with respect to the remaining (orthogonal) variables.

To be more precise, let (t,s) be a pair of clusters which is anisotropically admissible. Let Q_t, Q_s denote the containers for t, s which have the common base line $\gamma_Q = \gamma_{Q_t} = \gamma_{Q_s}$. Note that Q_t and Q_s may be subsets on the same face of Γ or subsets of two adjoining faces of Γ. We choose a local coordinate system such that the x_1-axis points in the direction of γ_Q and t lies in the (x_1,x_2)-plane. Because of the meshing algorithm, we have

$$t = \left\{(x_1,x_2,0)^\intercal \in \mathbb{R}^3 \mid A_t \leq x_2 \leq B_t \text{ and } \alpha_t(x_2) \leq x_1 \leq \beta_t(x_2)\right\}, \tag{3.15}$$

where $A_t < B_t$ are constants and α_t, β_t are affine functions which satisfy $\alpha_t(x_2) < \beta_t(x_2)$ for all $A_t \leq x_2 \leq B_t$. Analogously s is described by

$$s = \{(w_1, w_2\cos\varphi, w_2\sin\varphi)^\intercal \mid A_s \leq w_2 \leq B_s \text{ and } \alpha_s(w_2) \leq w_1 \leq \beta_s(w_2)\}.$$

Again, $A_s < B_s$ are constants, and α_s, β_s are affine functions which satisfy $\alpha_s(w_2) < \beta_s(w_2)$. The angle $\varphi \in [0, 2\pi[$ is fixed and denotes the angle between Γ_t and Γ_s. The antiderivative of the kernel function is then defined (analogously to (3.11)) by

$$k^{\mathrm{ad}}_{\mathbf{b}}(x_2,y_2) := \int_{\alpha_s(y_2)}^{\beta_s(y_2)} \int_{\alpha_t(x_2)}^{\beta_t(x_2)} k(\chi_t(x_1,x_2), \chi_s(w_1,y_2))\, dx_1 dw_1, \tag{3.16}$$

where χ_t, χ_s denote a unitary transformation of the two-dimensional coordinate systems to the surface panels.

An illustration of a pair of admissible clusters in this case is given in Figure 3.3.

The panel-clustering method for anisotropic elements uses an approximation of $k^{\mathrm{ad}}_{\mathbf{b}}$ by a degenerate expansion $\tilde{k}^{\mathrm{ad}}_{\mathbf{b}}$ of the form

$$\tilde{k}^{\mathrm{ad}}_{\mathbf{b}}(x_2,y_2) = \sum_{\nu=1}^{m} \Phi_{\mathbf{b},\nu}(x_2)\, \Psi_{\mathbf{b},\nu}(y_2). \tag{3.17}$$

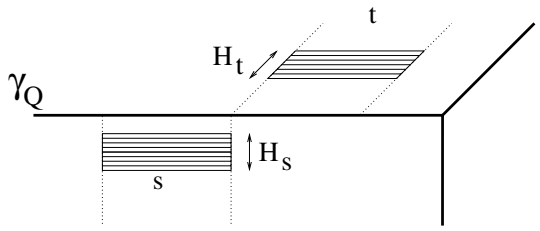

FIG. 3.3. *A pair of admissible clusters* (t, s).

The following assumption states that the approximation $\tilde{k}_{\mathbf{b}}^{\mathrm{ad}}$ converges exponentially towards $k_{\mathbf{b}}^{\mathrm{ad}}$.

ASSUMPTION 3.10. *Let k denote the kernel of the single layer operator, and let $k_{\mathbf{b}}^{\mathrm{ad}}$ be as in* (3.16). *For sufficiently small η^{aniso}, there exist constants $0 < \delta < 1$ (depending on η^{aniso}) and $0 < C < \infty$ with the following property: For all anisotropically admissible blocks $\mathbf{b} = (t, s) \in \mathcal{L}_{\mathrm{far}}^{\mathrm{aniso}}$ there exists a family of degenerate expansions $\tilde{k}_{\mathbf{b}}^{\mathrm{ad}}(\cdot, \cdot)$ depending on a parameter $m \in \mathbb{N}$ of the form* (3.17) *with*

$$\left| k_{\mathbf{b}}^{\mathrm{ad}}(\mathbf{x}, \mathbf{y}) - \tilde{k}_{\mathbf{b}}^{\mathrm{ad}}(\mathbf{x}, \mathbf{y}) \right| \leq C m^2 \delta^m \qquad \text{for all } (\mathbf{x}, \mathbf{y}) \in \Gamma_t \times \Gamma_s. \tag{3.18}$$

Remark 3.11. The proof of (3.18) in the case of the screen problem is given in Theorem 6.4, while the general case can be analyzed along the same lines.

Remark 3.12. Higher order elements can also be treated by anisotropic panel-clustering, provided we write the basis functions as a sum of products of the form $\psi(x_1)\phi(x_2)$, with x_1 being the coordinate in the direction orthogonal to the base line γ_Q.

Along the edges of the surface Γ it usually happens that stretched elements from two different containers (meeting at the edge) are contained in the same cluster t. In this situation, we will consider a pair (t, s) admissible even if this is only true for the two subsets of t coming from each of the two containers.

DEFINITION 3.13 (generalized anisotropic admissibility condition). *Let C_{cl} be a given constant (cf. section 5, typically $C_{\mathrm{cl}} = 2$). A pair of clusters (t, s) is (generalized) anisotropically admissible if there exists a partition*

$$t = \dot{\bigcup_{i=1,\ldots,C_{\mathrm{cl}}}} t_i, \qquad s = \dot{\bigcup_{j=1,\ldots,C_{\mathrm{cl}}}} s_j$$

such that each pair (t_i, s_j) is anisotropically admissible as defined in Definition 3.9.

The generalized anisotropic admissibility is in accordance with Assumption 3.10, because after the subdivision into $C_{\mathrm{cl}} \times C_{\mathrm{cl}}$ subblocks one can apply the one-dimensional expansion as in (3.17) for the arising subblocks.

4. Error analysis. In this section, we will prove the consistency and stability of the generalized panel-clustering algorithm for the single layer potential equation from Example 2.1 discretized by piecewise constant elements on the stretched meshes defined in Algorithm 2.2. In [11] the consistency and stability of the standard panel-clustering method for such meshes was proved. Thus the results here are a generalization of those, with particular emphasis on the approximations on the anisotropic blocks. The error analysis will be based on the second Strang lemma, which we

briefly recall. Let $\tilde{a} : \mathcal{S} \times \mathcal{S} \to \mathbb{R}$ denote the bilinear form corresponding to the panel-clustering approximation (3.14). The corresponding approximate Galerkin method is to seek $\tilde{U} \in \mathcal{S}$ such that

$$\tilde{a}(\tilde{U}, V) = (g, V). \tag{4.1}$$

The following theorem follows from [7] (see in particular [11, Lemma 4.2, equation (4.24)]).

THEOREM 4.1. *Assume that there exists a continuous function $\mu : \mathbb{R}_+ \to \mathbb{R}_+$ with $\mu(N) \to 0$ as $N \to \infty$ such that, for all $V, W \in \mathcal{S}$,*

(i) $|a(V,W) - \tilde{a}(V,W)| \lesssim \mu(N)\|V\|_{H^{-1/2}(\Gamma)}\|W\|_{H^{-1/2}(\Gamma)}$,

(ii) $|a(V,W) - \tilde{a}(V,W)| \lesssim N^{-3/4}\|V\|_{L^2(\Gamma)}\ \|W\|_{H^{-1/2}(\Gamma)}$.

Then, for N sufficiently large, a unique solution $\tilde{U} \in \mathcal{S}$ of (4.1) exists and satisfies

$$\left\|u - \tilde{U}\right\|_{H^{-1/2}(\Gamma)} \lesssim N^{-1/4} \inf_{Z \in \mathcal{S}} \|u - Z\|_{L^2(\Gamma)} + N^{-3/4}\|u\|_{L^2(\Gamma)}.$$

The fact that $u \in L^2(\Gamma)$ follows from [6, Theorem 3]. Now it is shown in [23, Satz 3.7] that a suitable choice of g can be made which ensures that $\inf_{Z\in\mathcal{S}} \|u - Z\|_{L^2(\Gamma)} = N^{-1/2}$, and so in this case we obtain the estimate

$$\left\|u - \tilde{U}\right\|_{H^{-1/2}(\Gamma)} \lesssim N^{-3/4}. \tag{4.2}$$

In the remaining part of this section, we will prove that the bilinear form $\tilde{a}(\cdot,\cdot)$ satisfies the assumptions (i) and (ii) of Theorem 4.1. To reduce technicalities we assume for the following that the boundary element mesh $\mathcal{T}$ is conforming; i.e., the intersection $\overline{\tau} \cap \overline{\sigma}$ of any two nonidentical panels $\tau, \sigma \in \mathcal{T}$ is either empty or a common vertex or a common edge. This can be easily achieved by performing an appropriate closure of the mesh for the L-shaped regions in Algorithm 2.2, Step 3. Furthermore, we assume that all panels are convex and the interior angles are bounded above by a constant $\alpha_{\max} < \pi$. We introduce a positive-valued continuous function ρ as follows. For each panel τ, let ρ_τ denote the diameter of the largest inscribed disc. Let $\widehat{S}$ denote the unit triangle with vertices $(0,0)$, $(1,0)$, $(0,1)$, and let $\widehat{Q} := (0,1)^2$ denote the unit square. For each $\tau \in \mathcal{T}$, if τ is a triangle, let $\chi_\tau : \widehat{S} \to \tau$ denote an affine bijection, and if τ is a quadrilateral, let $\chi_\tau : \widehat{Q} \to \tau$ denote a bijection which is affine in each variable. Then ρ is defined by requiring the following:

- For all panels $\tau : \rho \circ \chi_\tau$ is $\begin{cases} \text{affine} & \text{if } \tau \text{ is a triangle,} \\ \text{affine in each variable} & \text{if } \tau \text{ is a quadrilateral.} \end{cases}$
- For all panel vertices $\mathbf{x}_p : \rho(\mathbf{x}_p) = \max\{\rho_\tau : \mathbf{x}_p \in \overline{\tau}\}$.

We use the function ρ in the proof of the following result.

THEOREM 4.2. *Assume that we are solving the single layer potential equation in Example 2.1 on a Lipschitz polyhedral surface Γ, meshed as in Algorithm 2.2, and choose $g = 3 + \epsilon$, where $\epsilon > 0$ is any small number. Let σ be as in Remark 3.5, and let Assumption 3.10 be satisfied for some $0 < \delta < 1$. Choose the orders m of the panel-clustering according to*

$$m = \left\lceil \frac{(2+\epsilon)\ \log N}{|\log \sigma|} \right\rceil \quad \textit{for the isotropic panel-clustering,} \tag{4.3}$$

$$m = \left\lceil \frac{(5/2+\epsilon)\ \log N}{|\log \delta|} \right\rceil \quad \textit{for the anisotropic panel-clustering,} \tag{4.4}$$

where $\lceil x \rceil$ *denotes the smallest integer* z *with* $z \geq x$. *Then the assumptions* (i) *and* (ii) *of Theorem* 4.1 *hold.*

Proof. For a block $\mathbf{b} \in \mathcal{L}^I_{\text{far}}$, let $\tilde{k}_{\mathbf{b}}$ denote the approximation as in (3.4), and let $\varepsilon_{\mathbf{b}} := k - \tilde{k}_{\mathbf{b}}$ denote the corresponding error. For a block $\mathbf{b} \in \mathcal{L}^{II}_{\text{far}}$, the partially integrated kernel function is denoted by $k^{\text{ad}}_{\mathbf{b}}$ (cf. 3.16) and the approximation by $\tilde{k}^{\text{ad}}_{\mathbf{b}}$ (cf. (3.12)). The corresponding error is denoted by $\varepsilon^{\text{ad}}_{\mathbf{b}} = k^{\text{ad}}_{\mathbf{b}} - \tilde{k}^{\text{ad}}_{\mathbf{b}}$. Thus

$$\begin{aligned} |a(U,V) - \tilde{a}(U,V)| &\leq \sum_{\mathbf{b}\in\mathcal{L}^I_{\text{far}}} \int_{\mathbf{b}} |\varepsilon_{\mathbf{b}}(\mathbf{x},\mathbf{y})|\,|U(\mathbf{x})|\,|V(\mathbf{y})|\,ds_{\mathbf{x}}ds_{\mathbf{y}} \\ &\quad + \sum_{\mathbf{b}\in\mathcal{L}^{II}_{\text{far}}} \int_{A^t}^{B^t} \int_{A^s}^{B^s} \left|\varepsilon^{\text{ad}}_{\mathbf{b}}(x_2,y_2)\right|\,|U(x_2)|\,|V(y_2)|\,dx_2dy_2 \\ &=: E^I(U,V) + E^{II}(U,V), \end{aligned} \tag{4.5}$$

where for all $\mathbf{b} = (s,t) \in \mathcal{L}^{II}_{\text{far}}$ and $(i,j) \in (s,t)$ we have set

$$\begin{aligned} U(x_2) &:= U(\xi_i) \qquad \text{for all } x_2 : (x_1,x_2) \in \tau_i, \\ V(y_2) &:= V(\xi_j) \qquad \text{for all } y_2 : (y_1,y_2) \in \tau_j. \end{aligned}$$

In the definition of E^{II} we have assumed the scenario and notation as in (3.9), i.e., $\mathbf{b} = (t,s)$, with

$$\Gamma_t = \bigcup\nolimits_{i=1}^{\#t} \tau_i, \quad \text{with } \tau_i = (\alpha^t,\beta^t)\times(A^t_i,B^t_i),\ h_i = \beta^t - \alpha^t,\ \rho_i = B^t_i - A^t_i, \tag{4.6}$$

and the analogous definition of Γ_s.

We first turn to the estimate of E^I and proceed as in [11]. From Assumption 3.5 and the fact that $\theta = 1$, we obtain

$$\begin{aligned} E^I(U,V) &\lesssim \sigma^m \sum_{(t,s)\in\mathcal{L}^I_{\text{far}}} \int_{\Gamma_t\times\Gamma_s} \frac{1}{\operatorname{dist}(\mathcal{B}_t,\mathcal{B}_s)} |U(\mathbf{x})||V(\mathbf{y})| ds_{\mathbf{y}}ds_{\mathbf{x}} \\ &= \sigma^m \sum_{(t,s)\in\mathcal{L}^I_{\text{far}}} \frac{1}{\operatorname{dist}(\mathcal{B}_t,\mathcal{B}_s)} \int_{\Gamma_t} |U(\mathbf{x})| ds_{\mathbf{x}} \int_{\Gamma_s} |V(\mathbf{y})| ds_{\mathbf{y}}. \end{aligned}$$

Since (t,s) is an isotropically admissible pair, from (3.3), we have

$$\operatorname{dist}(\mathcal{B}_t,\mathcal{B}_s)^{-1} \ \leq\ \eta^{iso} \max(\operatorname{diam}\mathcal{B}_t, \operatorname{diam}\mathcal{B}_s)^{-1} \leq \eta^{iso} h_i^{-1} \quad \text{for all } i \in t.$$

So, using the fact that the sets $\{\Gamma_t \times \Gamma_s : (t,s) \in \mathcal{L}^I_{\text{far}}\}$ are pairwise disjoint (and also $|\tau_i| \leq h_i^2$), we have

$$\begin{aligned} E^I(U,V) &\lesssim \eta^{iso}\sigma^m \sum_{i\in\mathcal{I}} \sum_{j\in\mathcal{I}} h_i^{-1} \|U\|_{L^1(\tau_i)} \|V\|_{L^1(\tau_j)} \\ &\leq \eta^{iso}\sigma^m \sum_{i\in\mathcal{I}} \sum_{j\in\mathcal{I}} h_j\ \|U\|_{L^2(\tau_i)} \|V\|_{L^2(\tau_j)}. \end{aligned}$$

Now, for any $\theta \in [0,1/2]$, using $h_j \lesssim N^{-1/2}$ and $\rho_j \gtrsim N^{-g/2}$, we obtain

$$\begin{aligned} E^I(U,V) &\lesssim \eta^{iso}\sigma^m N^{-1/2} \sum_{i\in\mathcal{I}} \sum_{j\in\mathcal{I}} \rho_i^{-\theta} \|\rho^\theta U\|_{L^2(\tau_i)} \rho_j^{-1/2} \|\rho^{1/2} V\|_{L^2(\tau_j)} \\ &\lesssim \eta^{iso}\sigma^m N^{-1/2} N^{g\theta/2} N^{g/4} \sum_{i\in\mathcal{I}} \|\rho^\theta U\|_{L^2(\tau_i)} \sum_{j\in\mathcal{I}} \|\rho^{1/2} V\|_{L^2(\tau_j)}. \end{aligned}$$

Hence, using the Cauchy–Schwarz inequality and then the inverse estimates in [11, Theorem 3.6], we have

$$\begin{aligned} E^I(U,V) &\leq \eta^{iso}\sigma^m N^{-1/2} N^{g\theta/2} N^{g/4} N \|\rho^\theta U\|_{L^2(\Gamma)} \|\rho^{1/2} V\|_{L^2(\Gamma)} \\ &\leq \eta^{iso}\sigma^m N^{1/2+g\theta/2+g/4} \|U\|_{H^{-\theta}(\Gamma)} \|V\|_{H^{-1/2}(\Gamma)}. \end{aligned}$$

The required estimate for $E^I(U,V)$ follows by observing that by taking m as given in (4.3) and with $g = 3+\epsilon$,

$$\sigma^m N^{1/2+g\theta/2+g/4} \lesssim \begin{cases} N^{-3(1+\epsilon)/4} & \text{if } \theta = 0, \\ N^{-\epsilon/2} & \text{if } \theta = 1/2. \end{cases}$$

In order to estimate $E^{II}(U,V)$, take a typical block $\mathbf{b} = (t,s)$ in $\mathcal{L}^{II}_{\text{far}}$ and assume the notation as in (4.6). Assumption 3.10 implies

$$\left|\varepsilon^{\text{ad}}_{\mathbf{b}}(x_2,y_2)\right| \lesssim m^2\delta^m.$$

Hence

$$E^{II}(U,V) \lesssim m^2\delta^m \sum_{\mathbf{b}=(t,s)\in\mathcal{L}^{II}_{\text{far}}} \int_{A^t} |U(x_2)|dx_2 \int_{A^s} |V(x_2)|dx_2. \tag{4.7}$$

Moreover, for any $\theta \in [0,1/2]$

$$\begin{aligned} \int_{A^t} |U(x_2)|dx_2 &= \sum_{i\in t} \int_{A^t_i} |U(x_2)|dx_2 \lesssim \sum_{i\in t} \rho_i^{1/2} \left\{ \int_{A^t_i} |U(x_2)|^2 dx_2 \right\}^{1/2} \\ &\lesssim \sum_{i\in t} \rho_i^{1/2-\theta} h_i^{-1/2} \|\rho^\theta U\|_{L^2(\tau_i)}. \end{aligned}$$

Since $\rho_i \leq h_i$ and $1/2-\theta \geq 0$, we have $\rho_i^{1/2-\theta} h_i^{-1/2} \lesssim h_i^{-\theta} \lesssim N^{g\theta/2}$, and so

$$\int_{A^t} |U(x_2)|dx_2 \lesssim N^{g\theta/2} \sum_{i\in t} \|\rho^\theta U\|_{L^2(\tau_i)}. \tag{4.8}$$

Hence combining (4.7) and (4.8) and using the Cauchy–Schwarz inequality, we get

$$\begin{aligned} E^{II}(U,V) &\lesssim m^2\delta^m N^{(g\theta/2+g/4)} \sum_{i\in\mathcal{I}} \|\rho^\theta U\|_{L^2(\tau_i)} \sum_{j\in\mathcal{I}} \|\rho^{1/2} V\|_{L^2(\tau_j)} \\ &\lesssim m^2\delta^m N^{(g\theta/2+g/4+1)} \|\rho^\theta U\|_{L^2(\Gamma)} \|\rho^{1/2} V\|_{L^2(\Gamma)}. \end{aligned}$$

Then, making use of [11, Theorem 3.6], we have

$$E^{II}(U,V) \lesssim m^2\delta^m N^{g\theta/2+g/4+1} \|U\|_{H^{-\theta}(\Gamma)} \|V\|_{H^{-1/2}(\Gamma)}. \tag{4.9}$$

Now if we choose m as in (4.4), it follows that

$$\delta^m N^{g\theta/2+g/4+1} \lesssim \begin{cases} N^{-3/4(1+\epsilon)}, & \theta = 0, \\ N^{-\epsilon/2}, & \theta = 1/2, \end{cases}$$

and so the required estimates for E^{II} follow. ∎

5. Complexity analysis. In this section we analyze the complexity of the storage requirements and of the matrix-vector multiplication for our new version of the panel-clustering algorithm. First we introduce a measure of the sparsity of the block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$.

DEFINITION 5.1 (sparsity). *The sparsity of a block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ based on a cluster tree $T_{\mathcal{I}}$ is characterized by the quantity*

$$C_{\mathrm{sp}} := \max\left\{\max_{s\in T_{\mathcal{I}}} \#\{t\in T_{\mathcal{I}} \mid s\times t\in T_{\mathcal{I}\times\mathcal{I}}\},\ \max_{t\in T_{\mathcal{I}}} \#\{s\in T_{\mathcal{I}} \mid s\times t\in T_{\mathcal{I}\times\mathcal{I}}\}\right\}.$$

The importance of C_{sp} was discussed in [15]. In the case of shape-regular meshes and with cluster trees created using standard bisection algorithms, using the isotropic admissibility condition (3.1), it was shown in [15, Lemma 4.5] that C_{sp} is bounded independently of N (the number of degrees of freedom in the mesh). Here we shall extend this result to the anisotropic case. Before we do this, we will state the complexity bounds for the storage and matrix-vector product of the panel-clustering approximation $\tilde{a}(U,V)$ of the bilinear form $a(U,V)$ based on the measure C_{sp} and the depth p of the cluster tree. Both quantities will be bounded in Theorem 5.11 under quite general conditions, which are fulfilled for the screen mesh from Example 2.4.

THEOREM 5.2 (storage and matrix by vector complexity). *Let $T := T_{\mathcal{I}\times\mathcal{I}}$ be a block cluster tree with sparsity C_{sp} and depth $p\geq 1$. Let m be the (maximal) interpolation order used for the interpolation of the kernel function in isotropically or anisotropically admissible blocks. Then the storage requirements $N_{\mathrm{St}}(T,m)$ and the matrix by vector complexity $N_{\tilde{a}(U,V)}(T,m)$ for the panel-clustering approximation* (3.13) *are bounded by*

$$N_{\mathrm{St}}(T,m) = \mathcal{O}(C_{\mathrm{sp}}m^2p\#\mathcal{I}), \qquad N_{\tilde{a}(U,V)}(T,m)\sim N_{\mathrm{St}}(T,m).$$

In particular for the screen mesh from Example 2.4*, we have $pm^2\#\mathcal{I} = \mathcal{O}(gN\log^3 N)$.*

Proof. (a) For each block $(t,s)\in\mathcal{L}_{\mathrm{near}}$ we have to store the entries V_{ij}^{near} for all $(i,j)\in t\times s$. The construction of the block cluster tree ensures that either t or s is a leaf of $T_{\mathcal{I}}$, i.e., $\#t\leq n_{\min}$ or $\#s\leq n_{\min}$, so that at most $n_{\min}(\#t+\#s)$ entries have to be stored.

(b) For each block $\mathbf{b}=(t,s)\in\mathcal{L}_{\mathrm{far}}$ we have to store the entries $L_{i,\nu}^{\mathbf{b}}$ and $R_{\nu,j}^{\mathbf{b}}$ for all $i\in t, j\in s, \nu\in M$, where $M=\{1,\ldots,m\}$ for anisotropically admissible blocks and $M=\{1,\ldots,m^q\}$ (q from Remark 3.5) for isotropically admissible blocks. In total we can bound the number of entries to be stored for the block $\mathbf{b}$ by $m^q(\#t+\#s)$.

(c) Due to (a) and (b) the storage complexity for each block $\mathbf{b}\in\mathcal{L}(T_{\mathcal{I}\times\mathcal{I}})$ is bounded by $\max\{n_{\min},m^q\}(\#t+\#s)$. We conclude

$$\begin{aligned}
N_{\mathrm{St}}(T,m) &\leq \sum_{(t,s)\in\mathcal{L}(T_{\mathcal{I}\times\mathcal{I}})} \max\{n_{\min},m^q\}(\#t+\#s)\\
&\leq \sum_{t\in T_{\mathcal{I}}}\sum_{(t,s)\in T_{\mathcal{I}\times\mathcal{I}}} \max\{n_{\min},m^q\}\#t + \sum_{s\in T_{\mathcal{I}}}\sum_{(t,s)\in T_{\mathcal{I}\times\mathcal{I}}} \max\{n_{\min},m^q\}\#s\\
&\leq 2C_{\mathrm{sp}}\max\{n_{\min},m^q\}\sum_{t\in T_{\mathcal{I}}}\#t\\
&\overset{[15,\ \mathrm{R.1.10}]}{\leq} 2C_{\mathrm{sp}}\max\{n_{\min},m^q\}(p+1)\#\mathcal{I} = \mathcal{O}(C_{\mathrm{sp}}m^qp\#\mathcal{I}).
\end{aligned}$$

(d) The matrix by vector complexity is proportional to the storage complexity because every stored entry of V^{near}, $L^{\mathbf{b}}$, and $R^{\mathbf{b}}$ is accessed exactly once when computing a matrix-vector product. ∎

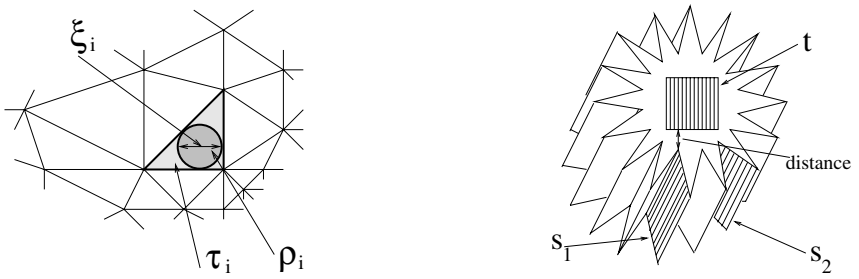

FIG. 5.1. *Left: In the inscribed circle around the incenter ξ_i there lies no other incenter $\xi_j, j \neq i$, i.e., $C_{\rm ov} = 1$. Right: The cluster t is surrounded by many clusters of the type of s_1, s_2 with very small distance to t.*

COROLLARY 5.3 (complexity for the cluster tree construction). *A cluster tree $T_{\mathcal{I}}$ of depth $p \geq 1$ has at most $\#T_{\mathcal{I}} = \mathcal{O}(p\#\mathcal{I})$ nodes. The complexity for the standard construction (so-called geometrically regular clustering) as introduced in section* 3.1 *is $\mathcal{O}(p\#\mathcal{I})$.*

Proof. Using [15, Remark 1.10], we obtain $\#\mathcal{L}(T_{\mathcal{I}}) \leq \#\mathcal{I}$, so that the property $t = \dot{\bigcup}_{s \in \mathrm{sons}(t)} s$ for interior nodes yields $\#T_{\mathcal{I}} = \mathcal{O}(p\#\mathcal{I})$. In the standard construction of the cluster tree $T_{\mathcal{I}}$ we compute the boxes $\tilde{\mathcal{B}}_1, \tilde{\mathcal{B}}_2$ for each node t in $\mathcal{O}(1)$ and determine for each point $(\xi_i)_{i \in t}$ the box to which it belongs, in total $\mathcal{O}(\#t)$ operations. Due to [15, Remark 1.10] the sum over all $t \in T_{\mathcal{I}}$ is $\mathcal{O}(p\#\mathcal{I})$. ∎

For the following bound on the sparsity measure $C_{\rm sp}$ we will now introduce some mesh-dependent quantities. The first of them is the quantity C_{ov} defined below. This quantifies the maximal number of nearby panels.

DEFINITION 5.4. *We define (cf. Figure* 5.1*)*

$$C_{\rm ov} := \max_{i \in \mathcal{I}} \#\left\{ j \in \mathcal{I} \mid \mathrm{dist}(\xi_i, \xi_j) \leq \rho_i/2 \right\},$$

where ρ_i is the diameter of the largest inscribed circle in τ_i and ξ_i, ξ_j are the incenters of τ_i, τ_j, respectively.

In many cases, and in particular for the screen mesh from Example 2.4, we have $C_{\rm ov} = 1$. In general (e.g., for highly folded surfaces) $C_{\rm ov} > 1$ might hold.

Next we want to characterize the alignment (in the sense of (3.8), (3.9), or (3.15)) of stretched panels. A situation where the constants in the complexity estimates might become large is depicted in Figure 5.1: The cluster t containing stretched panels is surrounded by a large number C of clusters $s_1, \ldots, s_C$ that also contain stretched panels. The clusters s_i are pairwise unaligned (the union of any two of those clusters would not fulfil the requirements of the anisotropic admissibility condition). In the following we want to consider the neighborhood of a panel.

DEFINITION 5.5. *Let $C_{\rm str} > 2 + 3\eta^{\rm iso}$. We define the neighborhood of a panel τ_i, $i \in \mathcal{I}$, by*

$$N_{str}(\tau_i) := \{ j \in \mathcal{I} \mid \mathrm{dist}(\tau_j, \tau_i) < C_{\rm str} (\eta^{\rm iso})^{-1} \max\{\mathrm{diam}(\tau_i), \mathrm{diam}(\tau_j)\}.$$

A partition of the form $N_{str}(\tau_i) = \dot{\cup}_{\nu=1}^{C} N_{str}^{\nu}(\tau_i)$ is an alignment-classification of $N_{str}(\tau_i)$, if for all $\nu = 1, \ldots, C$ the set $N_{str}^{\nu}(\tau_i)$ is aligned, i.e., of the form (3.8), (3.9), *or* (3.15).

ASSUMPTION 5.6. *We assume that for any panel τ_i, $i \in \mathcal{I}$, with $h_i > C_{\rm aniso}\, \rho_i$ there exists an alignment-classification of $N_{str}(\tau_i)$ with not more than $C_{\rm cl}$ classes,*

where $C_{\rm cl}$ depends on the given mesh but is bounded independently of i, the grading parameter g, and the number of unknowns N.

Remark 5.7. For the screen mesh the number of classes is $C_{\rm cl} = \mathcal{O}(C_{\rm str}/\eta^{\rm iso})$ independent of $C_{\rm aniso}$.

The following three auxiliary lemmata are needed to prove the final theorem of this section, Theorem 5.11.

LEMMA 5.8. *Let $t \in T_{\mathcal{I}}$ be a cluster of cardinality $\#t > C_{\rm ov}$. If the diameter of the minimal bounding box $\mathcal{B}_t$ is larger than the diameter of the regular box $\tilde{\mathcal{B}}_t$ (cf. section* 3.1*, Figure* 3.1*) of the cluster tree, i.e.,*

$$\operatorname{diam}(\mathcal{B}_t) = C\operatorname{diam}(\tilde{\mathcal{B}}_t), \quad C > 1,$$

then there exists an index $i \in t$ such that

$$h_i \geq (C-1)/C\operatorname{diam}(\mathcal{B}_t) \qquad \text{and} \qquad h_i > \frac{1}{2}(C-1)\rho_i.$$

Proof. Let $\operatorname{diam}(\mathcal{B}_t) = C\operatorname{diam}(\tilde{\mathcal{B}}_t)$. Then there exists at least one panel τ_i with centroid $\xi_i \in \tilde{\mathcal{B}}_t$ and a point $\zeta \in \tau_i \cap \partial\mathcal{B}_t$ with $\operatorname{dist}(\zeta, \tilde{\mathcal{B}}_t) \geq (C-1)/2\operatorname{diam}(\tilde{\mathcal{B}}_t)$. We conclude $h_i \geq 2|\zeta - \xi_i| \geq (C-1)\operatorname{diam}(\tilde{\mathcal{B}}_t) = (C-1)/C\operatorname{diam}(\mathcal{B}_t)$. Assume that $h_i \leq (C-1)\rho_i/2$. Then $\rho_i \geq 2h_i/(C-1) \geq 2\operatorname{diam}(\mathcal{B}_t)/C = 2\operatorname{diam}(\tilde{\mathcal{B}}_t)$, so that $|\xi_i - \xi_j| \leq \rho_i/2$ holds for all $j \in t$. Due to the assumption $\#t > C_{\rm ov}$, this is not possible. ∎

LEMMA 5.9. *Let $t, s \in T_{\mathcal{I}}$ be two clusters of cardinality $\#t > C_{\rm ov}, \#s > C_{\rm ov}$ that are not isotropically admissible: $\eta^{\rm iso}\operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s) < \max\{\operatorname{diam}(\mathcal{B}_t), \operatorname{diam}(\mathcal{B}_s)\}$. Let $\operatorname{diam}(\mathcal{B}_t) = C\operatorname{diam}(\tilde{\mathcal{B}}_t)$ or $\operatorname{diam}(\mathcal{B}_s) = C\operatorname{diam}(\tilde{\mathcal{B}}_s)$ for some $C \geq C_{\rm str}/(C_{\rm str} - 1 - 2\eta^{\rm iso})$ and $\operatorname{diam}(\tilde{\mathcal{B}}_t) = \operatorname{diam}(\tilde{\mathcal{B}}_s)$. Then one of the following two cases is true:*

1. *$\exists i \in t : s \subset N_{str}(\tau_i)$ and $h_i \geq \frac{1}{2}(C-1)\rho_i$, or*
2. *$\exists j \in s : t \subset N_{str}(\tau_j)$ and $h_j \geq \frac{1}{2}(C-1)\rho_j$.*

Proof. Case 1. Let $\operatorname{diam}(\mathcal{B}_t) = C\operatorname{diam}(\tilde{\mathcal{B}}_t)$ and $\operatorname{diam}(\mathcal{B}_t) \geq \operatorname{diam}(\mathcal{B}_s)$. According to Lemma 5.8 there exists $i \in t$ such that $h_i \geq \frac{1}{2}(C-1)\rho_i$ and $h_i \geq \frac{C-1}{C}\operatorname{diam}(\mathcal{B}_t)$. We can now bound the distance of τ_i to any $\tau_j, j \in s$, by

$$\begin{aligned}\operatorname{dist}(\tau_i, \tau_j) &\leq \operatorname{diam}(\mathcal{B}_t) + \operatorname{diam}(\mathcal{B}_s) + \operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s) \;\leq\; (2 + (\eta^{\rm iso})^{-1})\operatorname{diam}(\mathcal{B}_t) \\ &\leq \frac{C}{C-1}(2 + (\eta^{\rm iso})^{-1})h_i \;=\; \frac{C}{C-1}(1 + 2\eta^{\rm iso})(\eta^{\rm iso})^{-1}h_i \;\leq\; C_{\rm str}(\eta^{\rm iso})^{-1}h_i.\end{aligned}$$

According to Definition 5.5, $j \in N_{str}(\tau_i)$; i.e., $s \subset N_{str}(\tau_i)$.

Case 2. Let $\operatorname{diam}(\mathcal{B}_s) = C\operatorname{diam}(\tilde{\mathcal{B}}_s)$ and $\operatorname{diam}(\mathcal{B}_s) \geq \operatorname{diam}(\mathcal{B}_t)$. Analogously to case 1 we have $t \subset N_{str}(\tau_j)$ for some $j \in s$ and $h_j \geq \frac{1}{2}(C-1)\rho_j$. ∎

LEMMA 5.10. *Let $t, s_1, \ldots, s_\ell \in T_{\mathcal{I}}$ be clusters of cardinality $\#t > C_{\rm ov}, \#s_i > C_{\rm ov}$ that are not isotropically admissible and $\max\{\operatorname{diam}(\mathcal{B}_{s_i}), \operatorname{diam}(\mathcal{B}_t)\} \geq C\operatorname{diam}(\tilde{\mathcal{B}}_{s_i}) = \operatorname{diam}(\tilde{\mathcal{B}}_t)$, where $C := max\{2C_{\rm aniso} + 1, C_{\rm str}/(C_{\rm str} - 2 - 3\eta^{\rm iso})\}$. Then there exists $i \in t \cup_{i=1}^{\ell} s_i$ such that $t \cup_{i=1}^{\ell} s_i \subset N_{str}(\tau_i)$ and the panel τ_i is stretched in the sense $h_i > C_{\rm aniso}\rho_i$ required in Assumption* 5.6.

Proof. Let s_j denote the cluster with maximal diameter $\operatorname{diam}(\mathcal{B}_{s_j})$ among the $s_1, \ldots, s_\ell, t$. Due to Lemma 5.9 there is an element $i \in s_j$ with $\operatorname{diam}(\mathcal{B}_{s_j}) \leq \frac{C}{C-1}\operatorname{diam}(\tau_i)$. For any element $\nu \in s \in \{t, s_1, \ldots, s_\ell\}$ we can bound

$$\begin{aligned}\operatorname{dist}(\tau_i, \tau_\nu) &\leq \operatorname{diam}(\mathcal{B}_{s_j}) + \operatorname{dist}(\mathcal{B}_{s_j}, \mathcal{B}_t)\operatorname{diam}(\mathcal{B}_t) + \operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s) + \operatorname{diam}(\mathcal{B}_s) \\ &\leq (3 + 2(\eta^{\rm iso})^{-1})\operatorname{diam}(\mathcal{B}_{s_j}) \;\leq\; (3 + 2(\eta^{\rm iso})^{-1})\frac{C}{C-1}\operatorname{diam}(\tau_i) \\ &\leq (\eta^{\rm iso})^{-1}C_{\rm str}\operatorname{diam}(\tau_i),\end{aligned}$$

i.e., $\nu \in N_{str}(\tau_i)$. Lemma 5.9 gives the bound for h_i. ∎

For the following theorem we use the notation level(t) for the distance of a cluster $t \in T_{\mathcal{I}}$ to the root. The construction of the block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ ensures that for any block cluster (t, s) there holds level(t) = level(s), and the corresponding boxes $\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_s$ used for the clustering are identical up to translation.

THEOREM 5.11. *Let $T := T_{\mathcal{I}\times\mathcal{I}}$ be the block cluster tree constructed in section* 3.1 *from the cluster tree $T_{\mathcal{I}}$, where $n_{\min} \geq C_{\rm ov}$; i.e., a cluster with not more than $C_{\rm ov}$ elements is not further subdivided. We assume that $N^{-g} \lesssim |\xi_i - \xi_j|$. Under Assumption* 5.6 *the following statements hold:*

(a) *The depth of the tree is bounded by*

$$\operatorname{depth}(T) = \mathcal{O}(g \log N).$$

(b) *The sparsity constant is bounded (independently of the mesh parameters g and N) by*

$$C_{\rm sp} = \mathcal{O}(1).$$

Proof. (a) Let $t \in T_{\mathcal{I}}$ be a nonleaf node and ℓ the level of t. We denote the box corresponding to t by $\tilde{\mathcal{B}}_t$, where due to the construction, $\operatorname{diam}(\tilde{\mathcal{B}}_t) \sim 2^{-\ell/d}$. Since t is a nonleaf node, the size of t is at least $\#t > 1$. Let $i \neq j \in t$ be two different indices. Due to the assumed bound $N^{-g} \lesssim |\xi_i - \xi_j|$ we have $N^{-g} \lesssim \operatorname{diam}(\tilde{\mathcal{B}}_t) \lesssim \sqrt{d}2^{-\ell/d}$ so that $\ell \lesssim g \log N$ follows.

(b) We exploit the structure of the regular subdivision of the box $\tilde{\mathcal{B}} = [a_1, b_1) \times [a_2, b_2) \times [a_3, b_3)$ used for the clustering in section 3.1.

1. Let $t \in T_{\mathcal{I}}$ be a node with level$(t) = \ell$ and $\#t > C_{\rm ov}$. We count the number of clusters s with level$(t) = \ell$ and $\#s > C_{\rm ov}$ that are *not admissible* to t. Let

$$C := \max\{2C_{\rm aniso} + 1, C_{\rm str}/(C_{\rm str} - 2 - 3\eta^{\rm iso})\}.$$

Case (1). $\operatorname{diam}(\mathcal{B}_t) \leq C\operatorname{diam}(\tilde{\mathcal{B}}_t)$ and $\operatorname{diam}(\mathcal{B}_s) \leq C\operatorname{diam}(\tilde{\mathcal{B}}_s)$. Since (t, s) is not admissible, the relation

$$\begin{aligned}\operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s) &\leq (\eta^{\rm iso})^{-1} \max\{\operatorname{diam}(\mathcal{B}_t), \operatorname{diam}(\mathcal{B}_s)\} \\ &\leq (\eta^{\rm iso})^{-1} C \max\{\operatorname{diam}(\tilde{\mathcal{B}}_t), \operatorname{diam}(\tilde{\mathcal{B}}_s)\} \;=\; C(\eta^{\rm iso})^{-1}\operatorname{diam}(\tilde{\mathcal{B}}_t)\end{aligned}$$

is valid. On the other hand,

$$\begin{aligned}\operatorname{dist}(\mathcal{B}_t, \mathcal{B}_s) &\geq \operatorname{dist}(\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_s) - (\operatorname{diam}(\mathcal{B}_t) + \operatorname{diam}(\mathcal{B}_s))/2 \\ &\geq \operatorname{dist}(\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_s) - C\operatorname{diam}(\tilde{\mathcal{B}}_t),\end{aligned}$$

i.e., $\operatorname{dist}(\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_s) \leq C(1 + (\eta^{\rm iso})^{-1})\operatorname{diam}(\tilde{\mathcal{B}}_t)$.
Now the distance of the regular boxes $\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_s$ can be measured in layers around t (cf. Figure 5.2): There are 3^d boxes touching $\tilde{\mathcal{B}}_t$. By induction it follows that all boxes $\tilde{\mathcal{B}}_r$ with $\operatorname{dist}(\tilde{\mathcal{B}}_t, \tilde{\mathcal{B}}_r) \leq p\operatorname{diam}(\tilde{\mathcal{B}}_t)/(2\sqrt{d})$ are contained in the first p layers, which are at most $(2p + 1)^d$ boxes.
For $p \geq 2\sqrt{d}C(1 + (\eta^{\rm iso})^{-1})$ the box $\tilde{\mathcal{B}}_s$ is included in the first p layers; i.e., s is one of the $(2p + 1)^d = \mathcal{O}(1)$ clusters of the first p layers.

Case (2). Either $\operatorname{diam}(\mathcal{B}_t) > C\operatorname{diam}(\tilde{\mathcal{B}}_t)$ or $\operatorname{diam}(\mathcal{B}_s) > C\operatorname{diam}(\tilde{\mathcal{B}}_s)$. Lemma 5.10 shows that there exists an index i such that t and all clusters s (with the above property) (isotropically) inadmissible to t are contained

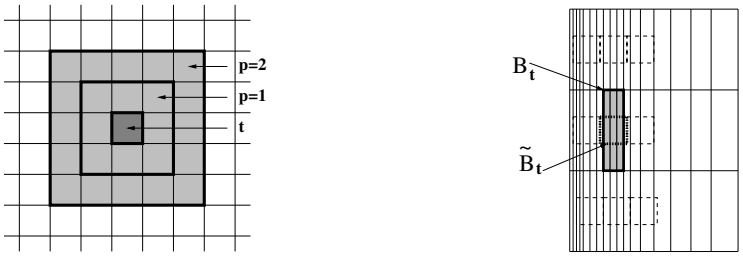

FIG. 5.2. *Left: The first two layers $p = 1$ and $p = 2$ around the box $\tilde{\mathcal{B}}_t$ of t. The first layer consists of 9 boxes, the second one of 25 boxes (it includes the first). Right: A cluster t with box $\tilde{\mathcal{B}}_t$ that is much smaller than the bounding box $\mathcal{B}_t$ of Γ_t. The dashed boxes $\tilde{\mathcal{B}}_s$ correspond to nonempty clusters s.*

in $N_{str}(\tau_i)$ and that τ_i is stretched in the sense $h_i > C_{\mathrm{aniso}}\rho_i$. Assumption 5.6 says that we can find an alignment-classification of $N_{str}(\tau_i)$ with $C_{\mathrm{cl}} = \mathcal{O}(1)$ classes. In each class, the one-dimensional anisotropic admissibility (3.15) applies. In this situation at most $\mathcal{O}((\eta^{\mathrm{ansio}})^{-1})$ clusters s form an inadmissible pair (t, s).

2. As a consequence of 1, the number of nodes $s \in T_{\mathcal{I}}$ (with $\mathrm{level}(s) = \mathrm{level}(t)$, $\#s > C_{\mathrm{ov}}$ and $\#t > C_{\mathrm{ov}}$) not admissible to t is bounded by $\mathcal{O}(1)$.
3. Let $t' \in T_{\mathcal{I}}$ be arbitrary. If t' is the root of $T_{\mathcal{I}}$, then there is exactly one cluster on the same level, namely, t'. Therefore a sparsity constant $C_{\mathrm{sp}} \geq 1$ would be sufficient. If t' is not the root, then the father cluster t of t' fulfils $\#t > n_{\min} \geq C_{\mathrm{ov}}$. Due to 2 we conclude that there are at most $\mathcal{O}(1)$ clusters $s \in T_{\mathcal{I}}$ with $s \times t \in T_{\mathcal{I}\times\mathcal{I}}$, so that there are at most $\mathcal{O}(1)$ clusters $s' \in T_{\mathcal{I}}$ with $s' \times t' \in T_{\mathcal{I}\times\mathcal{I}}$. This is the desired bound for C_{sp}. ∎

The previous theorem gives a rigorous proof that the sparsity constant is independent of N or the geometry and behaves like $\mathcal{O}(1)$ for fixed $\eta^{\mathrm{iso}}, \eta^{\mathrm{aniso}}$ from the admissibility condition and fixed constants $C_{\mathrm{ov}}, C_{\mathrm{str}}, C_{\mathrm{aniso}}, C_{\mathrm{cl}}$ describing the geometry and mesh. For the screen mesh with $\eta^{\mathrm{iso}} = \eta^{\mathrm{aniso}} = 1$ the constants $C_{\mathrm{ov}} := 1$, $C_{\mathrm{str}} := 6$, $C_{\mathrm{aniso}} := 2$, and $C_{\mathrm{cl}} := 12$ fulfil all the requirements.

6. Exact integration.

6.1. The partially integrated kernel: Simple case. In this section we investigate the analytical properties of the partially integrated kernel k^{ad} defined in (3.11). We show that the Assumption 3.10 holds true in the case of the Laplace single layer potential kernel in Example 2.1. Thus we are concerned with the function

$$k^{\mathrm{ad}}_{\mathbf{b}}(x, y) = \frac{1}{4\pi} \int_{\alpha^t}^{\beta^t} \int_{\alpha^s}^{\beta^s} ((y_1 - x_1)^2 + (y - x)^2)^{-1/2} \mathrm{d}y_1 \mathrm{d}x_1. \tag{6.1}$$

A suitable analytic formula is given in the following lemma.

LEMMA 6.1. *For any $x, y \in \mathbb{R}$,*

$$\begin{aligned} k^{\mathrm{ad}}_{\mathbf{b}}(x, y) = {} & \kappa(\alpha^s - \beta^t, x - y) + \kappa(\beta^s - \alpha^t, x - y) \\ & - \kappa(\alpha^s - \alpha^t, x - y) - \kappa(\beta^s - \beta^t, x - y), \end{aligned} \tag{6.2}$$

where

$$\kappa(\xi, z) := \frac{1}{4\pi} \left[\sqrt{\xi^2 + z^2} - \xi \ln \left(\xi + \sqrt{\xi^2 + z^2} \right) \right]. \tag{6.3}$$

Proof. The assertion follows by using

$$\frac{\partial \kappa\,(\xi,z)}{\partial \xi} = -\frac{\ln\left(\xi+\sqrt{z^2+\xi^2}\right)}{4\pi} \quad \text{and} \quad \frac{\partial^2 \kappa\,(\xi,z)}{\partial \xi^2} = -\frac{1}{4\pi\sqrt{z^2+\xi^2}}$$

and some obvious substitutions. □

(Note that this lemma could be generalized to the case of higher order basis functions, in which case an additional polynomial factor appears in (6.1); cf. [17]. The treatment of more general kernel functions such as the kernel for the double layer potential can be treated in the same way because analytic formulae for the antiderivatives with respect to the (x_1, y_1)-coordinates are available.)

Our next result obtains bounds for the derivatives with respect to x of a typical term from the right-hand side of (6.2).

LEMMA 6.2. *There exists an absolute constant C such that*

$$\left|\left\{\frac{\partial^j \kappa}{\partial z^j}\right\}(\xi,z)\right| \;\le\; C\; j!\;|\xi|\;\left(\frac{2}{\sqrt{\xi^2+z^2}}\right)^j \quad \textit{for all} \quad j \ge 1,\ldots$$

for all $\xi, z \in \mathbb{R}$ with $(\xi, z) \neq (0,0)$. (The factor 2 on the right-hand side can be replaced by 1 by a more refined analysis.)

Proof. First consider fixed $\xi \neq 0$, and write $\kappa(\xi,z) = (f(\xi,z) - g(\xi,z))\,/\,(4\pi)$, where

$$f\,(\xi,z) := \sqrt{\xi^2+z^2} \quad \text{and} \quad g(\xi,z) := \xi \ln\left(\xi + f\,(\xi,z)\right).$$

To bound the derivatives of f, note first that $\{\partial^j f/\partial z^j\}\,(\xi,z) = \xi^{1-j}\,\hat{f}^{(j)}\,(z/\xi)$, where $\hat{f}(z) := \sqrt{1+z^2}$. Then for any $z \in \mathbb{R}$, let $\mathcal{D}_z$ denote the disc centered on z with radius $\frac{\sqrt{1+z^2}}{2}$, and let $\mathcal{C}_z$ denote its boundary. Since $\hat{f}$ is analytic in $\mathcal{D}_z$, Cauchy's integral formula yields

$$\frac{1}{j!}\hat{f}^{(j)}\,(z) = \frac{1}{2\pi i}\oint_{\mathcal{C}_z} \frac{\hat{f}\,(t)}{(t-z)^{j+1}}\,dt. \tag{6.4}$$

Elementary but somewhat tedious arguments lead to the estimates

$$\frac{3}{8}\sqrt{1+z^2} \;\le\; \left|\hat{f}\,(t)\right| \;\le\; \frac{\sqrt{13}}{2}\sqrt{1+z^2} \quad \text{for } t \in \mathcal{C}_z, \tag{6.5}$$

and using this in (6.4) yields

$$\left|f^{(j)}\,(z)\right| \;\le\; \frac{\sqrt{13}}{4}\; j!\; 2^{j+1}\; \left\{\sqrt{\xi^2+z^2}\right\}^{1-j}. \tag{6.6}$$

To estimate the derivatives of g, let $\hat{g}\,(z) := \ln(1+\hat{f}\,(z))$, and observe that, for $j \ge 1$, $\left\{\partial^j g/\partial z^j\right\}(\xi,z) = \xi^{1-j}\hat{g}^{(j)}\,(z/\xi)$. Now, to estimate $\hat{g}^{(j)}$ for $j \ge 1$, we shall apply (6.4) with $\hat{f}$ replaced by $\hat{g}'$. To do this note that, for $t \in \mathcal{C}_z$,

$$|\hat{g}'\,(t)| = \left|\left(\frac{t}{\hat{f}\,(t)}\right)\left(\frac{1}{1+\hat{f}\,(t)}\right)\right| \;\le\; \frac{|t-z|+|z|}{|\hat{f}(t)|}\frac{1}{|1+\hat{f}\,(t)\,|} \;\le\; \frac{4}{|1+\hat{f}\,(t)\,|}$$

(where the last inequality follows from (6.5)). Since $\operatorname{Re}\hat{f}(t) > 0$ for all $t \in \mathcal{C}_z$, we have $|1+\hat{f}(t)| \geq |\hat{f}(t)|$ and hence (using also the left-hand side of (6.5))

$$|\hat{g}'(t)| \;\leq\; \frac{4}{|f(t)|} \;\leq\; \frac{32}{3\sqrt{1+z^2}}\,.$$

Using this in (6.4), with $\hat{f}$ replaced by $\hat{g}'$, we obtain, for $j \geq 1$,

$$\left|\hat{g}^{(j)}(z)\right| \;\leq\; \frac{32}{3}\;(j-1)!\;2^{j-1}\;\left\{\sqrt{1+z^2}\right\}^{-j}.$$

For the original function g this implies

$$\left|\left\{\frac{\partial^j g}{\partial z^j}\right\}(\xi,z)\right| \;\leq\; \frac{32}{3}\;(j-1)!\;2^{j-1}\;|\xi|\;\left\{\sqrt{\xi^2+z^2}\right\}^{-j} \quad \text{for} \quad j \geq 1. \tag{6.7}$$

The required result for $\xi \neq 0$ now follows on collection of (6.6) and (6.7). The result for $\xi = 0$ is trivial since then $\kappa(0,z) = |z|$. ∎

The bounds proved in Lemma 6.2 can now be used to bound the error in polynomial approximation of κ.

LEMMA 6.3. *Let $-\infty < a < b < \infty$, and suppose $y \notin [a,b]$. Then, for any $\xi \in \mathbb{R}$ and any $m \geq 1$, the function $\kappa(\xi, \cdot - y)$ can be interpolated on $[a,b]$ by an mth order Chebyshev polynomial $\tilde{\kappa}(\xi, \cdot - y)$ with error bounded by*

$$\|\kappa(\xi,\cdot-y) - \tilde{\kappa}(\xi,\cdot-y)\|_{L^\infty([a,b])} \;\leq\; C|\xi|\,(m+1)^2\,(1+\eta)\left(1+\frac{1}{\eta}\right)^{-m-1},$$

where C is an absolute constant and $\eta = \frac{b-a}{\operatorname{dist}(y,I)}$.

Proof. We apply [2, Theorem 3.2], where the constants C_u, γ_u appearing there are estimated using Lemma 6.2. ∎

THEOREM 6.4. *Let $([\alpha^t,\beta^t]\times[A,B],\ [\alpha^s,\beta^s]\times[A',B'])$ be the domain corresponding to an η^{aniso}-admissible block cluster with respect to* (3.10)*. The integrated kernel $k^{\text{ad}}_{\mathbf{b}} : [A,B]\times[A',B'] \to \mathbb{R}$ (see* (3.11)*) can be approximated by an mth order Chebyshev interpolation $\tilde{k}^{\text{ad}}_{\mathbf{b}}$ with error bounded by*

$$|k^{\text{ad}}_{\mathbf{b}} - \tilde{k}^{\text{ad}}_{\mathbf{b}}|_{[A,B]\times[A',B'],\infty} \;\lesssim (m+1)^2(1+\eta^{\text{aniso}})\left(1+\frac{1}{\eta^{\text{aniso}}}\right)^{-m-1}.$$

Proof. From Lemma 6.3 we get a bound on the interpolation error for each of the four functions on the right-hand side of (6.2). Each of the functions is of the form considered in in Lemma 6.3, where the parameter $\xi \in \{\beta^t-\alpha^s, \beta^t-\beta^s, \alpha^t-\alpha^s, \alpha^t-\beta^s\}$. We can trivially bound $|\xi| \leq \operatorname{diam}\Gamma$. Hence, the assertion is a direct consequence of Lemma 6.3. ∎

6.2. General polyhedral domains. The key idea of the anisotropic panel-clustering relies on the analytic integration of pairs of stretched panels. In the previous section, the relevant antiderivatives of the kernel function have been developed and analyzed for the special case of the screen mesh and piecewise constant shape functions.

In this section, we will present the antiderivatives of the kernel function for general polyhedral domains. We restrict our analysis to piecewise constant elements in order not to overload this paper with technicalities. The generalization to higher order

elements is straightforward because the antiderivatives of the kernel function can be computed analytically also for this case and the resulting integrated kernel has analyticity properties analogous to those for piecewise constant elements.

We consider pairs of panels which are trapezias of the following form. By a suitable translation and rotation of the coordinate system we may assume that one panel has the form

$$t = \left\{(x_1, x_2, 0) \in \mathbb{R}^3 \mid A_t \leq x_2 \leq B_t \text{ and } \alpha_t(x_2) \leq x_1 \leq \beta_t(x_2)\right\},$$

where $0 \leq A_t < B_t$ are constants and α_t, β_t are affine functions which satisfy $\alpha_t(x_2) < \beta_t(x_2)$ for all $0 \leq x_2 \leq B_t$ and $\alpha_t(0) = 0$. The second trapezia is described by

$$s = \left\{(w_1, w_2\cos\varphi, w_2\sin\varphi)^\intercal \mid A_s \leq w_2 \leq B_s \wedge \alpha_s(w_2) \leq w_1 \leq \beta_s(w_2)\right\}.$$

Again, $0 \leq A_s < B_s$ are constants, and α_s, β_s are affine functions which satisfy $\alpha_s(w_2) < \beta_2(w_2)$ for all $0 \leq w_2 \leq B_S$. The compatibility conditions are $\alpha_s(0) = \alpha_t(0) = 0$ and $\beta_s(0) = \beta_t(0)$. The angle $\varphi \in [0, 2\pi[$ is fixed and denotes the angle between t and s with respect to the x_1-axes. The antiderivative of the single layer kernel is given by

$$k_{\mathbf{b}}^{\mathrm{ad}}(x_2, y_2) = \frac{1}{4\pi}\int_{\alpha_s(y_2)}^{\beta_s(y_2)}\int_{\alpha_t(x_2)}^{\beta_t(x_2)} \frac{1}{\sqrt{(x_1 - w_1)^2 + z^2}}\mathrm{d}x_1\mathrm{d}w_1,$$

where $z = z(x_2, y_2) = \sqrt{(x_2 - y_2\cos\varphi)^2 + (y_2\sin\varphi)^2}$. Explicit calculations yield (cf. Lemma 6.1)

$$k_{\mathbf{b}}^{\mathrm{ad}}(x_2, y_2) = \kappa_{\mathbf{b}}(z, d)\big|_{d=\alpha_s(y_2)-\alpha_t(x_2)}^{\alpha_s(y_2)-\beta_t(x_2)} - \kappa_{\mathbf{b}}(z, d)\big|_{d=\beta_s(y_2)-\alpha_t(x_2)}^{\beta_s(y_2)-\beta_t(x_2)}, \tag{6.8}$$

where $\kappa_{\mathbf{b}}$ is as in Lemma 6.1.

Remark 6.5. The qualitative analysis of $k_{\mathbf{b}}^{\mathrm{ad}}$ can be developed along the same lines as for the screen problem. However, the analysis is more subtle since we can assume neither $B_s < A_t$ nor $B_t < A_s$ and the integration bounds in (6.8) have to be taken into account.

7. Numerical experiments. In this section we consider the model problem from Example 2.4 for three different grading parameters $g \in \{1, 3, 5\}$ and an increasing number N of panels, where $N = 9n^2$. We construct the cluster tree $T_{\mathcal{I}}$ by geometrically regular clustering as was introduced in section 3.1, with minimal size $n_{\min} = 4$. The block cluster tree $T_{\mathcal{I}\times\mathcal{I}}$ and corresponding matrix partition is based either on the isotropic admissibility alone or, additionally, on the anisotropic admissibility condition, both with parameters $\eta^{\mathrm{iso}} = \eta^{\mathrm{aniso}} = 3$. For the isotropic admissibility condition we expect the number of nearfield entries to be at least $N^{3/2-1/g}$; cf. Example 3.6.

In the first numerical test we use the isotropic admissibility condition and a blockwise rank of $k = 1$ for all farfield blocks (for a larger rank $k > 1$ one has to multiply the respective numbers in the column "Far" in Table 7.1 by k). We measure the storage requirements in kilobytes per degree of freedom, separately for the nearfield part (isotropically inadmissible leaves of the block cluster tree) and the farfield part (isotropically admissible leaves of the block cluster tree). In Table 7.1 the results are reported along with the sparsity constant C_{sp} (cf. Definition 5.1) from the

(theoretical) complexity estimates. The column "Near" contains the nearfield storage requirements in kilobytes per degree of freedom, and the column "Far" the respective farfield storage requirements. We observe an increase of the nearfield part and the unboundedness of the sparsity constant C_{sp} for $g > 1$ as $n \to \infty$. Since the columns "Far" grow with $O(\log N)$, this shows that the farfield part of the representation is growing with $O(N \log N)$.

TABLE 7.1
Matrix storage requirements using isotropic admissibility.

	$g=1$			$g=3$			$g=5$		
n	Near	Far	C_{sp}	Near	Far	C_{sp}	Near	Far	C_{sp}
100	0.6	1.7	24	0.7	1.6	30	1.0	1.5	30
200	0.6	2.0	24	0.8	2.0	30	1.3	1.9	30
400	0.6	2.3	24	0.8	2.3	36	1.7	2.2	42
800	0.6	2.6	24	1.0	2.6	48	2.4	2.4	66
1600	0.6	2.9	24	1.1	2.8	72	3.3	2.7	120

For the second numerical test we employ the combined isotropic and anisotropic admissibility conditions and measure the storage requirements in kilobyte per degree of freedom, separately for the nearfield part (isotropically and anisotropically inadmissible leaves of the block cluster tree) and the farfield part (isotropically or anisotropically admissible leaves of the block cluster tree). The results in Table 7.2 confirm the theoretical estimates that the storage requirements are $\mathcal{O}(N \log N)$ and the sparsity constant C_{sp} remains bounded, independently of g and N.

TABLE 7.2
Matrix storage requirements using isotropic and anisotropic admissibility.

	$g=1$			$g=3$			$g=5$		
n	Near	Far	C_{sp}	Near	Far	C_{sp}	Near	Far	C_{sp}
100	0.6	1.7	24	0.6	1.7	30	0.8	1.7	30
200	0.6	2.0	24	0.6	2.0	30	0.7	2.1	30

CONVERGENCE ANALYSIS FOR THE NUMERICAL BOUNDARY CORRECTOR FOR ELLIPTIC EQUATIONS WITH RAPIDLY OSCILLATING COEFFICIENTS*

MARCUS SARKIS‡ AND HENRIQUE VERSIEUX†

Abstract. We develop the convergence analysis of a numerical scheme for approximating the solution of the elliptic problem $L_\epsilon u_\epsilon = -\frac{\partial}{\partial x_i} a_{ij}(x/\epsilon)\frac{\partial}{\partial x_j} u_\epsilon = f$ in $\Omega, u_\epsilon = 0$ on $\partial\Omega$, where $a(y) = (a_{ij}(y))$ is a periodic symmetric positive definite matrix and $\Omega = (0,1)^2$. The major goal of the numerical scheme is to capture the ϵ-scale of the oscillations of the solution u_ϵ on a mesh size $h > \epsilon$ (or $h >> \epsilon$). The numerical scheme is based on asymptotic expansions, constructive boundary corrector, and finite element approximations. New a priori error estimates are established for the asymptotic expansions and for the constructive boundary correctors under weak assumptions on the regularity of the problem. These estimates permit to establish sharp finite element error estimates and to consider composite materials applications. Depending on the regularity of the problem, we establish for the numerical scheme a priori error estimates of $O(h^2 + \epsilon^{3/2} + \epsilon h)$ on the L^2-norm, and $O(h + \epsilon^{1+\hat{\delta}})$ for the broken H^1-norm where $\hat{\delta} \in (-\frac{1}{4}, 0]$.

1. Introduction.

This paper develops the convergence analysis of the numerical scheme proposed in [46] to approximate the solution of the following problem:

$$L_\epsilon u_\epsilon = -\frac{\partial}{\partial x_i}\left(a_{ij}(x/\epsilon)\frac{\partial}{\partial x_j} u_\epsilon\right) = f \ \text{ in } \ \Omega, \quad u_\epsilon = 0 \ \text{ on } \ \partial\Omega. \tag{1.1}$$

Here, ϵ is a small scale and $a(y) = (a_{ij}(y))$ is a periodic symmetric positive definite matrix with period $Y = (0,1)^2$, and $\Omega = (0,1)^2$. We assume that $a_{ij} \in L^\infty_{\text{per}}(Y)$, i.e., a_{ij} is Y-periodic and $a_{ij} \in L^\infty(\mathbb{R}^2)$, and that there exists a positive constant γ_a such that $\gamma_a \|\xi\|^2 \le a_{ij}(y)\xi_i\xi_j$ for all $\xi \in \mathbb{R}^2$ and $y \in Y$. Throughout the text we consider the Einstein summation convention, i.e., repeated indices indicate summation, and domains are always considered open.

We note that standard finite element methods do not yield good numerical approximations when the mesh size $h > \epsilon$; see [27]. To overcome this, new numerical methods have been recently proposed for solving the problem (1.1) such as the multiscale finite element methods [22, 26, 4, 15, 23], the residual-free bubble function methods [14, 6, 5, 39, 13], and the generalized FEM for homogenization problems [40]. There are also related methods for the case in which the homogenized equation is not known; see the heterogeneous multiscale method [18, 19, 1, 20, 21]. The numerical method considered here, as opposed to the methods in [6, 26, 39, 4, 14], is

based strongly on the asymptotic expansion of u_ϵ. We also explore the periodicity of the matrix a to obtain a very efficient numerical method for approximating u_ϵ.

A theoretical tool commonly used to treat this problem is homogenization theory [8, 9, 10, 11, 16, 28, 37] where, for instance, a first order term expansion for u_ϵ plus a boundary corrector term are considered. Based on such theory, [45, 46] propose numerical schemes to approximate such terms. These numerical methods were designed to work with a mesh size $h > \epsilon$ (or $h >> \epsilon$); however, they also work for the case $h < \epsilon$. In [45] is presented a numerical algorithm for the case in which the domain Ω is a rectangular region, while [46] generalizes the method to the case where the domain Ω is a convex polygon with rational boundary normals.

The convergence analysis for the numerical method is performed in two parts. In the first part we estimate the error between u_ϵ and $u_0 + \epsilon u_1 + \epsilon\phi_\epsilon$ in L^2- and H^1-norms, where ϕ_ϵ is a constructive approximation for the boundary corrector term θ_ϵ; see [3, 35, 36]. To estimate this error, we first estimate the error between u_ϵ and $u_0+\epsilon u_1+\epsilon\theta_\epsilon$ on the H^1- and L^2-norms (see Propositions 3.1 and 3.4) and then estimate the error between ϕ_ϵ and θ_ϵ; see Propositions 3.2 and 3.3. Propositions 3.1 and 3.4 extend some results of [3, 35] using fewer regularity requirements. More specifically, Proposition 3.1 gives the same error estimate of Theorem 2.2 in [3]; however, here we assume $u_0 \in W^{2,p}(\Omega)$ and $\chi^j \in W^{1,q}_{per}(\Omega)$ for $1/p + 1/q \leq 1/2$ and for Lipschitz domains $\Omega \subset \mathbb{R}^{2,3}$, while in Theorem 2.2 in [3] it is assumed that $u_0 \in W^{2,\infty}(\Omega)$ and $\chi^j \in H^1_{per}(Y)$ for Lipschitz domains $\Omega \subset \mathbb{R}^d$, d a natural number. We also note that Propositions 3.1 and 3.4 generalize, respectively, Propositions 2.1 and 2.3 of [35]. In Proposition 3.1, we assume that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{2,p}(\Omega)$, and $\chi^j \in W^{1,q}_{per}(\Omega)$ for $1/p + 1/q \leq 1/2$, and $\Omega \subset \mathbb{R}^{2,3}$ is a Lipschitz domain, while in Proposition 2.1 in [35] it is assumed that $a_{ij} \in C^{1,\beta}_{per}(Y)$, $u_0 \in H^2(\Omega)$, and $\Omega \subset \mathbb{R}^2$ is a smooth domain. Proposition 3.4 assumes that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{3,p}(\Omega)$, χ^j and $\chi^{ij} \in W^{1,q}_{per}(\Omega)$ for $1/p + 1/q \leq 1/2$, $\Omega \subset \mathbb{R}^{2,3}$ is a Lipschitz domain, while Proposition 2.3 in [35] assumes that $a_{ij} \in C^{1,\beta}_{per}(Y)$, $u_0 \in H^3(\Omega)$, and $\Omega \subset \mathbb{R}^2$ is smooth. The importance of considering a theory that handles the case $a_{ij} \in L^\infty_{per}(Y)$ comes from applications to composite materials where the coefficients a_{ij} are often piecewise constants; see also Theorem 1.1 in [31] which gives conditions on the discontinuities of the functions a_{ij} so that χ^j and $\chi^{ij} \in W^{1,\infty}_{per}(Y)$. We also observe that Proposition 2.1 in [35] is used in the convergence analysis of the numerical methods presented in [22, 27, 39], and therefore, the analysis presented here can be used to extend the analysis of these numerical methods with fewer regularity requirements on a, u_0, or Ω. To the best of our knowledge, Propositions 3.2 and 3.3 have not been considered in the literature; however, a technique developed in [35] is used in part of the proof of Proposition 3.2.

In the second part of this paper we develop the finite element analysis to estimate the a priori error estimates due to the finite element approximations. One difficulty lies in the fact that we need a discrete approximation for $\partial_\eta u_0$ to define the Dirichlet boundary condition for the discrete boundary corrector problem; If u_0^h is a finite element approximation for u_0, then $\partial_\eta u_0^h$ does not necessarily belong to $H^{1/2}(\partial\Omega)$, i.e., the space required to define the boundary corrector terms. To overcome this, we introduce a Lagrange multiplier space to approximate $\partial_\eta u_0$ and to develop error estimates between $\partial_\eta u_0$ and its discrete approximation μ_h using fractional-order Sobolev norms. The Lagrange multiplier plays an important role in obtaining convergence rates under weak assumptions on the regularity of u_0 and χ^j.

We now introduce some norms and semi-norms. Let $B \subset \mathbb{R}^{2,3}$ be a Lipschitz

domain and define

$$\|v\|_{m,\infty,B} = \max_{|\alpha|\le m}\left\{\text{ess. sup}_{x\in B}|\partial^\alpha v(x)|\right\} \quad \text{and} \quad |v|_{m,\infty,B} = \max_{|\alpha|=m}\left\{\text{ess. sup}_{x\in B}|\partial^\alpha v(x)|\right\},$$

and for $1 \le q < \infty$

$$\|v\|_{m,q,B} = \left(\int_B \sum_{|\alpha|\le m} |D^\alpha v|^q dx\right)^{1/q} \quad \text{and} \quad |v|_{m,q,B} = \left(\int_B \sum_{|\alpha|=m} |D^\alpha v|^q dx\right)^{1/q}.$$

We also define the nonconforming norms related to a partition $\mathcal{T}_h = K_1, K_2, \ldots, K_N$ of B by

$$\|v\|_{m,h} = \sqrt{\sum_{K_j\in\mathcal{T}_h} \|v\|^2_{H^m(K_j)}}.$$

Throughout this paper when we do not make reference to the domain B or to the norm q, it is because $B = \Omega$ or $q = 2$, respectively. In what follows c denotes a generic constant independent of ϵ and mesh parameters.

This paper is organized as follows: we devote section 2 to introducing the asymptotic expansion of u_ϵ and to describing the continuous approximation for the boundary corrector terms; in section 3 we develop the main results and proofs associated to error estimates due to the asymptotic expansion approximation. In section 4 we consider the numerical algorithm introduced in [46] for the case $\Omega = (0,1)^2$, while in section 5 we analyze the discretization errors due to the finite element approximation. In section 6 we test numerically the numerical schemes, and in section 7 we make some conclusions.

2. Periodic homogenization and asymptotic expansions.

2.1. Asymptotic expansions.

Consider the following ansatz:

$$u_\epsilon(x) = u_0(x, x/\epsilon) + \epsilon u_1(x, x/\epsilon) + \epsilon^2 u_2(x, x/\epsilon) + \cdots, \tag{2.1}$$

where the functions $u_j(x, y)$ are Y periodic in y. Using (2.1) in (1.1) and matching the terms with the same order in ϵ, one may define functions u_j such that $u_0(x, x/\epsilon) + \epsilon u_1(x, x/\epsilon) + \epsilon^2 u_2(x, x/\epsilon)$ approximates u_ϵ as

$$\|u_\epsilon(x) - u_0(x, x/\epsilon) - \epsilon u_1(x, x/\epsilon)\|_1 \le c\epsilon^{1/2}\|u_0\|_{2,\infty},$$

where $u_0 \in C^2(\Omega)$ and $\chi^j \in W^{1,\infty}(Y)$, and the constant c depends only on a, χ^j, and $\Omega \subset \mathbb{R}^{2,3}$ a Lipschitz domain. These terms are defined in detail below; for more details, including the proof of the above inequality, see [11, 28].

Let $\chi^j \in H^1_{\text{per}}(Y)$, i.e., $\chi^j \in H^1_{loc}(\mathbb{R}^{2,3})$ and Y-periodic, be the weak solution with zero average over Y of

$$\nabla_y \cdot a(y)\nabla_y \chi^j = \nabla_y \cdot a(y)\nabla_y y_j = \frac{\partial}{\partial y_i} a_{ij}(y), \tag{2.2}$$

and define the matrix

$$A_{ij} = \frac{1}{|Y|}\int_Y a_{lm}(y)\frac{\partial}{\partial y_l}(y_i - \chi^i)\frac{\partial}{\partial y_m}(y_j - \chi^j)dy. \tag{2.3}$$

It is easy to check that the matrix A is symmetric positive definite. Define $u_0 \in H_0^1(\Omega)$ as the weak solution of

$$-\nabla.A\nabla u_0 = f \ \text{ in } \ \Omega, \qquad u_0 = 0 \ \text{ on } \ \partial\Omega, \tag{2.4}$$

and let

$$u_1\left(x, \frac{x}{\epsilon}\right) = -\chi^j\left(\frac{x}{\epsilon}\right)\frac{\partial u_0}{\partial x_j}(x). \tag{2.5}$$

Note that $u_0 + \epsilon u_1$ does not satisfy the zero Dirichlet boundary condition on $\partial\Omega$. To overcome this, the boundary corrector term $\theta_\epsilon \in H^1(\Omega)$ is introduced and defined as the solution of

$$-\nabla \cdot a(x/\epsilon)\nabla\theta_\epsilon = 0 \ \text{ in } \ \Omega, \qquad \theta_\epsilon = -u_1\left(x, \frac{x}{\epsilon}\right) \ \text{ on } \ \partial\Omega. \tag{2.6}$$

Hence, we have that $u_0 + \epsilon u_1 + \epsilon\theta_\epsilon \in H_0^1(\Omega)$. Propositions 3.1 and 3.4 provide error estimates between u_ϵ and $u_0 + \epsilon u_1 + \epsilon\theta_\epsilon$ in the norms $\|\cdot\|_1$ and $\|\cdot\|_0$, respectively.

We also define the term u_2 (see (2.8)), which is used in the proof of Proposition 3.4. Set

$$b_{ij} = -a_{ij} + a_{im}\frac{\partial\chi^j}{\partial y_m} + \frac{\partial}{\partial y_m}(a_{mi}\chi^j)$$

and observe that $\overline{b}_{ij} = A_{ij}$, where $\overline{b}_{ij} = \int_Y b_{ij}dy$. Define $\chi^{ij} \in H^1_{per}(Y)$ as the weak solution with zero average over Y of

$$\nabla_y \cdot a\nabla_y\chi^{ij} = b_{ij} - \overline{b}_{ij}, \tag{2.7}$$

and let

$$u_2\left(x, \frac{x}{\epsilon}\right) = -\chi^{ij}\left(\frac{x}{\epsilon}\right)\frac{\partial^2 u_0}{\partial x_i \partial x_j}(x). \tag{2.8}$$

Note that $u_0 + \epsilon u_1 + \epsilon\theta_\epsilon + \epsilon^2 u_2$ does not satisfy the zero Dirichlet boundary condition on $\partial\Omega$ and to overcome this the boundary corrector term $\varphi_\epsilon \in H^1(\Omega)$ is introduced as the weak solution of

$$-\nabla \cdot a(x/\epsilon)\nabla\varphi_\epsilon = 0 \ \text{ in } \Omega, \ \text{ and } \ \varphi_\epsilon(x) = -u_2(x, x/\epsilon) \ \text{ on } \ \partial\Omega. \tag{2.9}$$

2.2. The boundary corrector terms. When dealing with constructive boundary corrector terms, we assume that $\Omega = (0,1)^2$, although the same theory holds for the case $\Omega = \prod_{i=1}^2 (a_i, b_i)$, $a_i < b_i \in \mathbb{R}$, or convex polygon or polyhedron domains with rational boundary normals; see [46, 44].

The coefficients $a_{ij}(x/\epsilon)$ and the Dirichlet boundary data $-u_1(x, \frac{x}{\epsilon})$ in (2.6) are highly oscillatory; thus it is not a trivial problem to obtain a good discrete approximation for θ_ϵ. We consider an analytical approximation for θ_ϵ, denoted by ϕ_ϵ, which satisfies the oscillating boundary condition and is suitable for numerical approximation; see [3, 35]. Analytical and numerical approximations for φ_ϵ will not be considered in this paper.

Denote η as the unity outward normal vector to $\partial\Omega$ and let $\partial_\eta u_0$ be the unity outward normal derivative of u_0 on $\partial\Omega$. In order to define the approximation ϕ_ϵ for θ_ϵ, we first introduce a decomposition for $\theta_\epsilon = \tilde{\theta}_\epsilon + \bar{\theta}_\epsilon$ as

$$-\nabla \cdot a(x/\epsilon)\nabla\tilde{\theta}_\epsilon = 0 \ \text{ in } \ \Omega, \quad \tilde{\theta}_\epsilon = \left(\chi^j\left(\frac{x}{\epsilon}\right)\eta_j - \chi^*\right)\partial_\eta u_0 \ \text{ on } \ \partial\Omega \tag{2.10}$$

and

$$-\nabla \cdot a(x/\epsilon)\nabla \bar{\theta}_\epsilon = 0 \ \text{ in } \ \Omega, \qquad \bar{\theta}_\epsilon = \chi^* \partial_\eta u_0 \ \text{ on } \ \partial\Omega, \tag{2.11}$$

where $\chi^*|_{\Gamma_k} = \chi_k^*$, $k \in \{e, w, n, s\}$, are properly chosen constants defined in subsection 2.2.1, and $\Gamma_e = \{1\} \times [0,1]$, $\Gamma_w = \{0\} \times [0,1]$, $\Gamma_n = [0,1] \times \{1\}$, and $\Gamma_s = [0,1] \times \{0\}$ are the edges of the domain $\Omega = (0,1)^2$. In Remark 2.1 we show that $\chi^* \partial_\eta u_0$ and $\chi^j(\frac{x}{\epsilon})\eta_j \partial_\eta u_0$ belong to $H^{1/2}(\partial\Omega)$; therefore, problems (2.10) and (2.11) are well posed. Later in this section we define the functions $\tilde{\phi}_\epsilon$ and $\bar{\phi}_\epsilon$, which are the approximations for $\tilde{\theta}_\epsilon$ and $\bar{\theta}_\epsilon$, respectively, and define $\phi_\epsilon = \tilde{\phi}_\epsilon + \bar{\phi}_\epsilon$.

Remark 2.1. Let $\Omega \subset \mathbb{R}^2$ be a convex polygon and assume $u_0 \in H^2(\Omega) \cap H_0^1(\Omega)$. We have by Theorem A.2 in [38] that $\partial_\eta u_0|_{\Gamma_k} \in H_{00}^{1/2}(\Gamma_k)$ and $\|\partial_\eta u_0\|_{H_{00}^{1/2}(\Gamma_k)} \leq c\|u_0\|_2$; therefore,

$$\|\chi^* \partial_\eta u_0\|_{H^{1/2}(\partial\Omega)} \leq c \max_k |\chi_k^*| \|u_0\|_2,$$

where $|\chi_k^*|$ can be bounded by $c \max_j \|\chi^j\|_{1,2,Y}$; see the proof of Lemma 4.4 in [3]. Note also that $u_1(x, \frac{x}{\epsilon}) = -\chi^j\left(\frac{x}{\epsilon}\right)\frac{\partial u_0}{\partial x_j}(x)$ and $\frac{\partial u_1}{\partial x_l} = -(\frac{\partial \chi^j}{\partial x_l})\frac{\partial u_0}{\partial x_j} - \chi^j(\frac{\partial^2 u_0}{\partial x_l \partial x_j})$. If we assume $u_0 \in W^{2,p}(\Omega)$ and $\chi^j \in W_{per}^{1,q}(Y)$ for $\frac{1}{p} + \frac{1}{q} \leq \frac{1}{2}$, $2 \leq p, q \leq \infty$, then $u_1 \in H^1(\Omega)$. In addition, using $u_0 \in H_0^1(\Omega)$ and density arguments we also have $u_1|_{\Gamma_k} \in H_{00}^{1/2}(\Gamma_k)$.

2.2.1. Calculating the constants χ_k^*. We now define properly the constants χ_k^* in order to make the function $\tilde{\phi}_\epsilon$ decay exponentially to zero away from the boundary $\partial\Omega$ and to satisfy the Dirichlet boundary condition $\tilde{\phi}_\epsilon(x) = -u_1(x, \frac{x}{\epsilon}) - \chi^* \partial_\eta u_0(x)$ for $x \in \partial\Omega$.

For $k \in \{e, w, n, s\}$ let $G_k = I_k^1 \times I_k^2$, where $I_e^1 = I_n^2 = (-\infty, 0)$, $I_e^2 = I_w^2 = (0,1)$, $I_w^1 = I_s^2 = (0, \infty)$, and $I_n^1 = I_s^1 = (0,1)$. Associated to each side Γ_k of Ω define the function v_k as the solution of

$$\begin{aligned} &-\nabla_y \cdot a(y_1, y_2)\nabla_y v_k = 0 \ \text{ in } \ G_k, \\ &\text{and } \ \partial_{y_i} v_n \exp(\gamma(-1)^{m_k} y_{n_k}) \in L^2(G_k), \quad i = 1, 2, \end{aligned}$$

where $n_k = 1$ if $k \in \{e, w\}$, $n_k = 2$ if $k \in \{s, n\}$, $m_k = 1$ if $k \in \{e, n\}$, and $m_k = 2$ if $k \in \{w, s\}$. For each $k \in \{e, w, s, n\}$ we impose the following boundary conditions:

$$\begin{aligned} &v_e(0, y_2) = \chi^1(1/\epsilon, y_2) \ \text{ for } 0 < y_2 < 1, && v_w(0, y_2) = -\chi^1(0, y_2) \ \text{ for } 0 < y_2 < 1, \\ &v_e(y_1, \cdot) \ \ [0,1]\text{-periodic for } -\infty < y_1 < 0, && v_w(y_1, \cdot) \ \ [0,1]\text{-periodic for } 0 < y_1 < \infty, \\ &v_n(y_1, 0) = \chi^2(y_1, 1/\epsilon) \ \text{ for } \ 0 < y_1 < 1, && v_s(y_1, 0) = -\chi^2(y_1, 0) \ \text{ for } \ 0 < y_1 < 1, \\ &v_n(\cdot, y_2) \ \ [0,1]\text{-periodic for } -\infty < y_2 < 0, && v_s(\cdot, y_2) \ \ [0,1]\text{-periodic for } 0 < y_2 < \infty. \end{aligned}$$

These boundary layer problems have been studied by several authors; see [30, 32, 28, 35]. Theorem 10.1 in section 10.4 in [32] guarantees existence and uniqueness of v_k and χ_k^*.

2.2.2. Approximating $\tilde{\theta}_\epsilon$. We note by Remark 2.1 that $(u_1(x, \frac{x}{\epsilon}) - \chi^* \partial_\eta u_0)|_{\Gamma_k} \in H_{00}^{1/2}(\Gamma_k)$. Thus, we can split $\tilde{\theta}_\epsilon = \sum_{k \in \{e,w,n,s\}} \tilde{\theta}_\epsilon^k$, where

$$L_\epsilon \tilde{\theta}_\epsilon^k = 0 \ \text{ in } \ \Omega, \quad \text{and} \quad \tilde{\theta}_\epsilon^k = \begin{cases} -u_1(x, \frac{x}{\epsilon}) - \chi_k^* \partial_\eta u_0 & \text{on } \ \Gamma_k, \\ 0 & \text{on } \ \partial\Omega \setminus \Gamma_k. \end{cases} \tag{2.12}$$

We propose to approximate $\tilde{\theta}_\epsilon^k$ by

$$\tilde{\phi}_\epsilon^k(x_1,x_2) = \varphi_k(x_1,x_2)\left(v_k\left(\frac{x-\delta_k}{\epsilon}\right) - \chi_k^*\right)\frac{\partial u_0}{\partial x_{i_k}}(x_1,x_2), \tag{2.13}$$

where $\delta_e = (1,0)$, $\delta_n = (0,1)$, $\delta_w = (0,0)$, and $\delta_s = (0,0)$. The cutting-off functions φ_k are nonnegative smooth functions satisfying $\varphi_k(x_1,x_2) = \varphi_k(x_1)$ for $k \in \{e,w\}$, $\varphi_k(x_1,x_2) = \varphi_k(x_2)$ for $k \in \{n,s\}$, and

$$\varphi_e(s) = \varphi_n(s) = \begin{cases} 1 & \text{if } s \in [2/3,1], \\ 0 & \text{if } s \in [0,1/3], \end{cases} \qquad \varphi_w(s) = \varphi_s(s) = \begin{cases} 0 & \text{if } s \in [2/3,1], \\ -1 & \text{if } s \in [0,1/3]. \end{cases}$$

Therefore,

$$\tilde{\phi}_\epsilon = \sum_{k\in\{e,w,n,s\}} \tilde{\phi}_\epsilon^k \tag{2.14}$$

approximates $\tilde{\theta}_\epsilon$ with $\tilde{\phi}_\epsilon = \tilde{\theta}_\epsilon$ on the boundary of Ω.

2.2.3. Approximating $\bar{\theta}_\epsilon$. The boundary condition imposed on (2.11) does not depend on ϵ. An effective approximation for $\bar{\theta}_\epsilon$ is given by $\bar{\phi} \in H^1(\Omega)$, the weak solution of

$$-\nabla \cdot A\nabla\bar{\phi} = 0 \ \text{ in } \ \Omega, \qquad \bar{\phi} = \chi^* \partial_\eta u_0 \ \text{ on } \ \partial\Omega, \tag{2.15}$$

where Remark 2.1 guarantees the well posedness of this problem.

2.2.4. Approximating u_ϵ. We finally define the analytical approximation for u_ϵ as $u_0 + \epsilon u_1 + \epsilon\phi_\epsilon$, where

$$\phi_\epsilon = \tilde{\phi}_\epsilon + \bar{\phi}. \tag{2.16}$$

Note that $\phi_\epsilon|_{\partial\Omega} = \theta_\epsilon|_{\partial\Omega}$; therefore, $u_0 + \epsilon u_1 + \epsilon\phi_\epsilon = 0$ on $\partial\Omega$.

3. Convergence results of asymptotic expansions. We now prove the propositions that are used in the proofs of Theorems 3.1 and 3.2.

Proposition 3.1 generalizes Theorem 2.2 in [3]. Here we assume that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{2,p}(\Omega)$, and $\chi^j \in W^{1,q}_{per}(\Omega)$ for $1/p + 1/q \le 1/2$, while Theorem 2.2 in [3] assumes that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{2,\infty}(\Omega)$, and $\chi^j \in H^1_{per}(\Omega)$. Proposition 3.1 also generalizes Proposition 2.1 in [35], where it is assumed that $a_{ij} \in C^{1,\beta}_{per}(Y)$, $u_0 \in H^2(\Omega)$, and $\Omega \subset \mathbb{R}^2$ is a smooth domain. We also refer the reader to Theorem 1.1 in [31] for results associated to sufficient conditions on a_{ij} in order to have $\chi^j \in W^{1,\infty}_{per}(Y)$.

PROPOSITION 3.1. *Let $\Omega \subset \mathbb{R}^d$, $d = 2,3$, be a bounded domain with a Lipschitz boundary. Let u_ϵ be the solution of the problem* (1.1) *and u_0, u_1, and θ_ϵ be defined by* (2.4), (2.5), *and* (2.6), *respectively. Assume $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{2,p}(\Omega)$, and $\chi^j \in W^{1,q}_{per}(Y)$ for $1/p + 1/q \le 1/2$, $2 \le p,q \le \infty$. Then there exists a constant c, independent of u_0, χ^j, and ϵ, such that*

$$\|u_\epsilon(\cdot) - u_0(\cdot) - \epsilon u_1(\cdot,\cdot/\epsilon) - \epsilon\theta_\epsilon(\cdot)\|_1 \le c\epsilon \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}. \tag{3.1}$$

In addition, if $p,q > d$, then

$$\|u_\epsilon - u_0\|_0 \le c\epsilon \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}. \tag{3.2}$$

Proof. Define

$$v_0(x,y) = a(y)\nabla_x u_0(x) + a(y)\nabla_y u_1(x,y) = a(y)(\nabla_y y_j - \nabla_y \chi^j(y))\frac{\partial u_0}{\partial x_j}(x). \tag{3.3}$$

From the definition of χ^j (see (2.2)) we have

$$\int_Y \left(a(y)(e_j - \nabla_y \chi^j(y)) - Ae_j\right)\nabla_y \phi(y)dy = 0 \ \ \forall\, \phi \in H^1_{per}(Y).$$

Since the vector $a(y)(e_j - \nabla_y \chi^j(y)) - Ae_j$ is Y periodic and has zero average entries over Y, then the Lemma 3.1 guarantees the existence of a $\phi_j(y) \in H^1_{per}(Y)$ with zero average over Y and such that

$$a(y)(\nabla_y y_j - \nabla_y \chi^j(y)) - Ae_j = -curl_y \phi_j(y). \tag{3.4}$$

Let

$$\phi(x,y) = \phi_j(y)\frac{\partial u_0}{\partial x_j}(x). \tag{3.5}$$

For the case $d = 2$ define

$$\begin{aligned} v_1(x,y) &= -curl_x \phi(x,y) \\ &= \begin{pmatrix} -\phi_j(y)\frac{\partial^2 u_0}{\partial x_2 \partial x_j}(x) \\ \phi_j(y)\frac{\partial^2 u_0}{\partial x_1 \partial x_j}(x) \end{pmatrix}, \end{aligned}$$

and note that $|curl_y \phi_j|_{0,q} = |\phi_j|_{1,q}$. Since $\chi^j \in W^{1,q}_{per}(Y)$ and ϕ_j have zero average over Y, we apply a Poincaré inequality to obtain

$$\|\phi_j\|_{1,q,Y} \le c|curl_y \phi_j|_{0,q,Y} \le c(\|\chi^1\|_{1,q,Y} + \|\chi^2\|_{1,q,Y}).$$

For the case $d = 3$, the Remark 3.11 in [24] guarantees the existence of $\phi_j \in W^{1,q}_{per}(Y)^3$. Since $\chi^j \in W^{1,q}_{per}(Y)$ and $u_0 \in W^{2,p}(\Omega)$ for $1/p + 1/q \le 1/2$, we obtain $v_1(x, x/\epsilon) \in L^2(\Omega)$ and is estimated by $\|v_1\|_0 \le c\sum_{j=1}^d \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}, d = 2, 3$. Moreover, by Lemma 3.1, we have

$$\nabla_x \cdot v_1(x,y) = 0, \tag{3.6}$$

and using elementary calculations we obtain

$$\begin{aligned} \nabla_y \cdot v_1(x,y) &= \nabla_y \cdot curl_x\left(\phi_j(y)\partial_{x_j} u_0(x)\right) \\ &= -\nabla_x \cdot curl_y\left(\phi_j(y)\partial_{x_j} u_0(x)\right) \\ &= -\nabla_x \cdot v_0(x,y) - f. \end{aligned} \tag{3.7}$$

Let

$$z_\epsilon(x) = u_\epsilon(x) - u_0(x) - \epsilon u_1(x, x/\epsilon)$$

and

$$\eta_\epsilon(x) = a(x/\epsilon)\nabla u_\epsilon(x) - v_0(x, x/\epsilon) - \epsilon v_1(x, x/\epsilon). \tag{3.8}$$

We have

$$\begin{aligned}
&a(x/\epsilon)\nabla z_\epsilon(x) - \eta_\epsilon(x)\\
&\quad = a(x/\epsilon)\nabla u_\epsilon(x) - a(x/\epsilon)\nabla_x u_0(x) - \epsilon a(x/\epsilon)\nabla_x u_1(x, x/\epsilon)\\
&\qquad - a(x/\epsilon)\nabla_y u_1(x, x/\epsilon) - a(x/\epsilon)\nabla u_\epsilon(x) + v_0(x, x/\epsilon) + \epsilon v_1(x, x/\epsilon)\\
&\quad = \epsilon(v_1(x, x/\epsilon) - a(x/\epsilon)\nabla_x u_1(x, x/\epsilon)),
\end{aligned}$$

and using the notation $a^\epsilon(x) = a(x/\epsilon)$ we obtain

$$\|a^\epsilon \nabla z_\epsilon - \eta_\epsilon\|_0 \leq \epsilon \|v_1(\cdot, \cdot/\epsilon) - a^\epsilon(\cdot)\nabla_x u_1(\cdot, \cdot/\epsilon)\|_0. \tag{3.9}$$

Given $g \in L^2(\Omega)$, let $w_\epsilon \in H_0^1(\Omega)$ be the solution of

$$\int_\Omega a(x/\epsilon)\nabla w_\epsilon(x)\nabla\psi(x)dx = \int_\Omega g(x)\psi(x)dx \quad \forall \psi \in H_0^1(\Omega). \tag{3.10}$$

Hence, using (2.6), we obtain

$$\begin{aligned}
\int_\Omega g(z_\epsilon - \epsilon\theta_\epsilon)dx &= \int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla(z_\epsilon - \epsilon\theta_\epsilon)dx,\\
\int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla z_\epsilon dx - \epsilon \int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla \theta_\epsilon dx &= \int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla z_\epsilon dx. \qquad (3.11)
\end{aligned}$$

Now observe that

$$\int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla z_\epsilon dx = \int_\Omega \nabla w_\epsilon \cdot (a^\epsilon \nabla z_\epsilon - \eta_\epsilon)dx + \int_\Omega \eta_\epsilon \cdot \nabla w_\epsilon dx. \tag{3.12}$$

In order to estimate the second term on the right-hand side of (3.12) we apply the definition of η_ϵ (see (3.8)) to obtain

$$\begin{aligned}
\int_\Omega \eta_\epsilon \cdot \nabla w_\epsilon dx &= \int_\Omega (a(x/\epsilon)\nabla u_\epsilon(x) - v_0(x, x/\epsilon) - \epsilon v_1(x, x/\epsilon)) \cdot \nabla w_\epsilon(x)dx\\
&= \int_\Omega f w_\epsilon dx - \int_\Omega (v_0(x, x/\epsilon) - \epsilon v_1(x, x/\epsilon)) \cdot \nabla w_\epsilon(x)dx. \qquad (3.13)
\end{aligned}$$

We note that

$$\begin{aligned}
\int_\Omega v_1(x, x/\epsilon) \cdot \nabla w_\epsilon(x)dx &= \int_\Omega \nabla \cdot v_1(x, x/\epsilon) w_\epsilon(x)dx\\
= \int_\Omega (\nabla_x + 1/\epsilon \nabla_y) \cdot v_1(x, y)|_{(y=x/\epsilon)} w_\epsilon(x)dx &= -\frac{1}{\epsilon}\int_\Omega (\nabla_x \cdot v_0 + f) w_\epsilon dx, \qquad (3.14)
\end{aligned}$$

where we have used (3.6) and (3.7) to obtain (3.14). Using the definition of v_0 (see (3.3)) we have

$$\int_\Omega v_0(x, x/\epsilon) \cdot \nabla w_\epsilon(x)dx = \int_\Omega a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon))\frac{\partial u_0}{\partial x_j}(x) \cdot \nabla w_\epsilon(x)dx,$$

and by the chain rule we obtain

$$\begin{aligned}
\int_\Omega v_0(x, x/\epsilon) \cdot \nabla w_\epsilon dx &= \int_\Omega a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon)) \cdot \nabla \left(\frac{\partial u_0}{\partial x_j} w_\epsilon(x)\right) dx\\
&\quad - \int_\Omega a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon)) \cdot \left(w_\epsilon \nabla \frac{\partial u_0}{\partial x_j}(x)\right) dx. \qquad (3.15)
\end{aligned}$$

In this paragraph we evaluate the first term on the right-hand side of (3.15). Let $(\frac{\epsilon}{3}Y_i)_{i=1,\dots,i_m}$ be a finite set of translated cells of $\frac{\epsilon}{3}Y$, covering $\overline{\Omega}$, and consider a partition of unity ρ_i, such that $\text{supp}\rho_i \subset \frac{2\epsilon}{3}Y_i$, where $\frac{2\epsilon}{3}Y_i$ denotes the cell $\frac{2\epsilon}{3}Y$ centered at $\frac{\epsilon}{3}Y_i$. We note that

$$\text{supp}(\rho_i w_\epsilon) \subset \frac{2\epsilon}{3}Y_i \cap \overline{\Omega} \subset \epsilon Y_i. \tag{3.16}$$

Thus,

$$\begin{aligned}&\int_\Omega a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon)) \cdot \nabla \left(\frac{\partial u_0}{\partial x_j} w_\epsilon(x)\right) dx \\ &= \sum_{i=1:i_m} \int_{\epsilon Y_i} a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon)) \cdot \nabla \left(\rho_i \frac{\partial u_0}{\partial x_j} w_\epsilon(x)\right) dx = 0.\end{aligned} \tag{3.17}$$

Here we have used that for Lipschitz domains, the function u_0 defined in (2.4) has a stable extension to $W^{2,p}(\mathbb{R}^d)$ (see [43]) which we have also denoted by u_0. We also note that from (3.16) it follows that the function $\rho_i \partial_{x_j} u_0 w_\epsilon$ is well defined and vanishes outside of Ω. In addition, since $1/p + 1/q \le 1/2$, we have $\rho_i \partial_{x_j} u_0 w_\epsilon \in W^{1,q'}(\mathbb{R}^d)$ for $1/q' = 1 - 1/q$. In addition, $\chi^j \in W^{1,q}_{per}(Y)$ and (2.2) imply that

$$\int_Y a_{lm}(y) \partial_{y_l}(\chi^j - y_j) \partial_{y_m} \psi = 0 \quad \forall\, \psi \in W^{1,q'}_{per}(Y).$$

Therefore, since $\rho_i \partial_{x_j} u_0 w_\epsilon$ has a compact support contained in the interior of ϵY_i (see (3.16)) then $\rho_i \partial_{x_j} u_0 w_\epsilon \in W^{1,q'}_{per}(\epsilon Y_i)$ and (3.17) follows.

For the second term on the right-hand side of (3.15), we use the definition of v_0 (see (3.3)) and $1/p + 1/q \le 1/2$ to obtain

$$-\int_\Omega a(x/\epsilon)(e_j - \nabla_y \chi^j(x/\epsilon)) \cdot \left(w_\epsilon \nabla \frac{\partial u_0}{\partial x_j}(x)\right) dx = -\int_\Omega \nabla_x \cdot v_0(x, x/\epsilon) w_\epsilon(x) dx.$$

Hence,

$$\int_\Omega v_0(x, x/\epsilon) \cdot \nabla w_\epsilon(x) dx = -\int_\Omega \nabla_x \cdot v_0(x, x/\epsilon) w_\epsilon(x) dx. \tag{3.18}$$

From (3.13), (3.14), and (3.18) we obtain

$$\int_\Omega \eta_\epsilon \cdot \nabla w_\epsilon dx = 0,$$

and from (3.12)

$$\int_\Omega a^\epsilon \nabla w_\epsilon \cdot \nabla z_\epsilon dx = \int_\Omega (a^\epsilon \nabla z_\epsilon - \eta_\epsilon) \cdot \nabla w_\epsilon dx. \tag{3.19}$$

Also from (3.11) and (3.19) we have

$$\begin{aligned}\left|\int_\Omega g(z_\epsilon - \epsilon\theta_\epsilon) dx\right| &\le c \|a^\epsilon \nabla z_\epsilon - \eta_\epsilon\|_0 \|w_\epsilon\|_1 \\ &\le \epsilon \|v_1(\cdot, \cdot/\epsilon) - a^\epsilon \nabla_x u_1(\cdot, \cdot/\epsilon)\|_0 \|g\|_{-1} \quad \text{by (3.9).}\end{aligned}$$

Dividing by $\|g\|_{-1}$ and taking the supremum for $g \neq 0$, the estimate (3.1) follows since

$$\|z_\epsilon(x) - \epsilon\theta_\epsilon\|_1 \leq c\epsilon\|v_1(\cdot,\cdot/\epsilon) - a^\epsilon \nabla_x u_1(\cdot,\cdot/\epsilon)\|_0 \leq c\epsilon \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}.$$

We now prove the estimate (3.2). The proof is based on the maximum principle; see also [7] for a proof based on L^p boundary data. Since $u_0 \in W^{2,p}(\Omega)$ and $p > d$, we have $\partial_{x_i} u_0 \in C(\Omega)$, and since $\chi^j \in W^{1,q}_{per}(Y)$ and $q > d$, we obtain $\chi^j \in C(Y)$; see (2.5) and (2.6). Using a Sobolev embedding theorem we obtain

$$\|u_1\|_{0,\infty,\partial\Omega} \leq c \max_j \|\chi^j\|_{0,\infty,Y}\|u_0\|_{1,\infty} \leq c \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p},$$

and using the maximum principle in [42], we have

$$\|\theta_\epsilon\|_0 \leq c\|\theta_\epsilon\|_{0,\infty,\partial\Omega} = c\|u_1\|_{0,\infty,\partial\Omega} \leq c \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}. \tag{3.20}$$

The estimate (3.2) follows from (3.20) and (3.1). ∎

The following remark is used in the proof of Proposition 3.5.

Remark 3.1. *Assume that the solution u_0 of*

$$-\nabla.A\nabla u_0 = f \quad in \quad \Omega, \qquad u_0 = g \quad on \quad \partial\Omega$$

belongs to $W^{2,p}(\Omega)$. Also let $u_\epsilon \in H^1(\Omega)$ be the weak solution of

$$L_\epsilon u_\epsilon = f \quad in \quad \Omega, \quad u_\epsilon = g \quad on \quad \partial\Omega.$$

Then it is easy to see that Proposition 3.1 *extends immediately to the nonhomogeneous Dirichlet boundary condition case.*

Proposition 3.2 estimates the H^1-norm of $\tilde{\theta}_\epsilon - \tilde{\phi}_\epsilon$ in terms of a parameter r; see Remark 3.2 for the discussion on r. Proposition 3.2 is also used in the proof of Theorems 3.1 and 3.2.

PROPOSITION 3.2. *Let $\Omega = (0,1)^2$ be the unit square. Let u_0, $\tilde{\theta}_\epsilon$, and $\tilde{\phi}_\epsilon$ be defined by* (2.4), (2.10), *and* (2.14), *respectively. Assume that $a_{ij} \in L^\infty_{per}(Y)$ and $u_0 \in W^{2,p}(\Omega)$. Let the functions v_k be defined as in subsection* 2.2.1. *Assume that $\exp(-\gamma y_1)\nabla v_e \in L^{\tilde{q}}(G_e)$ and $\exp(-\gamma y_1)(v_e - \chi^*_e) \in L^{\tilde{q}}(G_e)$ and that similar conditions also hold for the other functions v_k, $k \in \{w,n,s\}$. Let l be defined by $\frac{1}{p} + \frac{1}{\tilde{q}} + \frac{1}{l} = 1$, $1 \leq p, \tilde{q} \leq \infty$. Let r be any number such that $r > 2$. Then, there is positive constant $c = c(\gamma, l, r)$ and $\delta = \delta(p,l,r) = -\frac{1}{p} + \frac{1}{lr}$ such that*

$$\begin{aligned}\|\tilde{\theta}_\epsilon - \tilde{\phi}_\epsilon\|_1 \leq c\epsilon^\delta \max_k \big(&\|\exp(-\gamma y\cdot\eta^k)\nabla v_k\|_{0,\tilde{q},G_k} \\ &+ \|\exp(-\gamma y\cdot\eta^k)v_k - \chi^*_k\|_{1,\tilde{q},G_k}\big)\,\|u_0\|_{2,p}.\end{aligned}$$

In addition, when $p, q = \infty$, then $\delta = \frac{1}{2}$. Also, when $\frac{3}{p} + \frac{1}{\tilde{q}} < 1$, then there exists an $r > 2$ such that $\delta > 0$. Lastly, when $\frac{1}{p} + \frac{1}{\tilde{q}} < \frac{1}{2}$, then there exists an $r > 2$ such that $\delta > -\frac{1}{p} + \frac{1}{4}$.

Proof. By definition

$$\|\tilde{\theta}_\epsilon - \tilde{\phi}_\epsilon\|_1 \leq \sum_{k\in\{e,w,n,s\}} \|\tilde{\theta}^k_\epsilon - \tilde{\phi}^k_\epsilon\|_1.$$

Consider the case $k = e$; the other cases are treated similarly. Denote $a^\epsilon(x) = a(x/\epsilon)$, let $v_e^\epsilon(x) = v_e(\frac{x_1-1}{\epsilon}, \frac{x_2}{\epsilon})$, and take $g \in H_0^1(\Omega)$. Then applying the definition of $\tilde{\phi}_\epsilon^e$ and $\tilde{\theta}^e$ (see (2.13) and (2.12), respectively) we obtain

$$\int_\Omega a^\epsilon \nabla(\tilde{\theta}_\epsilon^e - \tilde{\phi}_\epsilon^e)\cdot\nabla g dx = \int_\Omega -a^\epsilon\nabla\left((v_e^\epsilon - \chi_e^*)\varphi_e\frac{\partial u_0}{\partial x_1}\right)\cdot\nabla g dx$$

$$= -\int_\Omega\left(\varphi_e\frac{\partial u_0}{\partial x_1}a^\epsilon\nabla v_e^\epsilon\right)\cdot\nabla g dx - \int_\Omega\left((v_e^\epsilon-\chi_e^*)a^\epsilon\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}\right)\right)\cdot\nabla g dx. \tag{3.21}$$

We note that due to the Sobolev embedding Theorem 5.4 in [2], the integrals above are well defined. For estimating the first term on the right-hand side of (3.21) we let

$$\int_\Omega\left(\varphi_e\frac{\partial u_0}{\partial x_1}a^\epsilon\nabla v_e^\epsilon\right)\cdot\nabla g dx$$

$$= \int_\Omega a^\epsilon\nabla v_e^\epsilon\cdot\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}g\right)dx - \int_\Omega a^\epsilon\nabla v_e^\epsilon\cdot g\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}\right)dx. \tag{3.22}$$

We now estimate the first term of the right-hand side of (3.22). Let $I_i = \{(i-1)\epsilon/6 - \epsilon/6 < x_2 < i\epsilon/6+\epsilon/6,\}$, $i_{max} = 1+\sup_{i\in\mathbb{N}}(i3/\epsilon < 1)$, and consider a partition of unity ρ_i of Ω, subject to $(0,1)\times I_i$. Let I_i^ϵ be the interval centered in I_i with $|I_i^\epsilon| = \epsilon$. Since $\mathrm{supp}(\rho_i g)\subset[0,1]\times I_i^\epsilon$ we have

$$\int_\Omega a^\epsilon\nabla v_e^\epsilon\cdot\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}g\right)dx$$

$$= \sum_{i=0:i_{max}}\int_0^1\int_{I_i^\epsilon} a^\epsilon\nabla v_e^\epsilon\cdot\nabla\left(\rho_i\varphi_e\frac{\partial u_0}{\partial x_1}g\right)dx_2dx_1 = 0, \tag{3.23}$$

where to arrive at (3.23) we have used the definition of v_e and arguments similar to the ones given to obtain (3.17).

For estimating the second term on the right-hand side of (3.22) we apply Hölder's inequality to obtain

$$\left|\int_\Omega a^\epsilon\nabla v_e^\epsilon\cdot\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}\right)g dx\right|$$

$$\le \|a\|_\infty|\varphi_e\nabla u_0|_{1,p}\left\|\exp\left(-\gamma\frac{x_1-1}{\epsilon}\right)\nabla v_e^\epsilon\right\|_{0,\tilde{q}}\left(\frac{\epsilon}{\gamma}\right)^{1/l}\left\|(\gamma/\epsilon)^{1/l}\exp\left(\gamma\frac{x_1-1}{\epsilon}\right)g\right\|_{0,l}, \tag{3.24}$$

where $1/l = 1-1/p-1/\tilde{q}$. Taking $y_1 = (x_1-1)/\epsilon$ and $y_2 = x_2/\epsilon$, and exploring the $[0,1]$-periodicity of $v_e(y_1,\cdot)$, we have

$$\left\|\nabla(v_e^\epsilon)\exp\left(-\gamma\frac{x_1-1}{\epsilon}\right)\right\|_{0,\tilde{q}} \le \left(\left(\frac{1}{\epsilon}+1\right)\int_{-1/\epsilon}^0\int_0^1|\exp(-\gamma y_1)\nabla_y v_e|^s\epsilon^{2-\tilde{q}}dy_2dy_1\right)^{\frac{1}{\tilde{q}}}$$

$$\le c\epsilon^{(\frac{1}{\tilde{q}}-1)}\|\exp(-\gamma y_1)\nabla_y v_e\|_{0,\tilde{q},G_e}. \tag{3.25}$$

Now let $g_n \in C_0^\infty(\Omega)$ such that $g_n \to g$ in H^1, and let $I_n = (0,1)\cap|g_n| > 0$.

Using integration by parts in x_1 we obtain

$$\left\|(\gamma/\epsilon)^{1/l}\exp\left(\gamma\frac{x_1-1}{\epsilon}\right)g_n\right\|_{0,l} = \left(\int_0^1\int_{I_n}\frac{\gamma}{\epsilon}\exp\left(l\gamma\frac{x_1-1}{\epsilon}\right)|g_n|^l dx_1dx_2\right)^{1/l}$$

$$= \left(-\int_0^1\int_{I_n}\frac{1}{l}\exp\left(l\gamma\frac{x_1-1}{\epsilon}\right)\frac{\partial|g_n|^l}{\partial x_1}dx_1dx_2\right)^{1/l} \tag{3.26}$$

$$\leq c\left(\left\|\exp\left(l\gamma\frac{x_1-1}{\epsilon}\right)\right\|_{0,r}\|g_n\|^{l-1}_{0,s(l-1)}\left\|\frac{\partial g_n}{\partial x_1}\right\|_0\right)^{1/l} \tag{3.27}$$

$$\leq c(s(l-1))^{(l-1)/l}\left(\frac{\epsilon}{rl\gamma}\right)^{1/(rl)}|g_n|_1, \tag{3.28}$$

where we have used Hölder's inequality with $1/s+1/r=1/2, s<\infty$ to obtain (3.27). To obtain (3.28), we use the following inequality used in the proof of Lemma 5.10 in [2], i.e., there exists $1\leq t<2$ such that

$$\begin{aligned}\|g_n\|_{0,r(l-1)} &\leq 2^{(t-1)/t}\left(\frac{2t-t}{2-t}\right)\|g_n\|_{1,t} \quad \text{for} \quad 2t/(2-t)=s(l-1)\\ &\leq 2^{(t-1)/t}\left(\frac{2t-t}{2-t}\right)\mathrm{vol}(\Omega)^{(1/t-1/2)}\|g_n\|_1 \text{ by Theorem 2.8 in [2]}\\ &\leq c\left(\frac{2t-t}{2-t}\right)|g_n|_1 \text{ by a Poincaré inequality.}\end{aligned}$$

Hence, (3.28) follows from (3.27). Now taking the limit $n\to\infty$ in (3.28), we obtain the inequality (3.28) for g. Thus, using (3.22), (3.23), (3.24), (3.25), and (3.28), it follows that

$$\begin{aligned}\int_\Omega \varphi_e\frac{\partial u_0}{\partial x_1}a^\epsilon\nabla v_e^\epsilon\cdot\nabla g dx &\leq c(\gamma)(s(l-1))^{(l-1)/l}\epsilon^\delta\|a\|_\infty|\varphi_e\nabla u_0|_{1,p}\\ &\quad \|\exp(-\gamma y_1)\nabla v_e\|_{0,\tilde q,G_e}|g|_1,\end{aligned} \tag{3.29}$$

where $\delta=-\frac{1}{p}+\frac{1}{lr}$. When $p,\tilde q\to\infty$ and then $r\to 2$, then $(s(l-1))^{(l-1)/l}\,(\epsilon/(rl\gamma))^{1/(rl)}$ $\to \epsilon^{1/2}/(2\gamma)$. Also it is easy to see that $\frac{3}{p}+\frac{1}{\tilde q}<1$ implies that there exists $r<2$ such that $\delta=-\frac{1}{p}+\frac{1}{rl}>0$, and $\frac{1}{p}+\frac{1}{\tilde q}<\frac{1}{2}$ implies that there exists $r<2$ such that $\delta=-\frac{1}{p}+\frac{1}{rl}>-\frac{1}{4}$.

For estimating the second term on the right-hand side of (3.21), we apply Hölder's inequality to obtain

$$\begin{aligned}&\left|\int_\Omega(v_e^\epsilon-\chi_e^*)a^\epsilon\nabla\left(\varphi_e\frac{\partial u_0}{\partial x_1}\right)\cdot\nabla g dx\right|\\ &\leq\|a\|_{0,\infty}\left|\varphi_e\frac{\partial u_0}{\partial x_1}\right|_{1,p}\left\|(v_e^\epsilon-\chi_e^*)\exp\left(-\gamma\frac{x_1-1}{\epsilon}\right)\right\|_{0,\tilde q}\left\|\exp\left(\gamma\frac{x_1-1}{\epsilon}\right)\right\|_{0,l}\\ &\leq c(\gamma)\epsilon^{\frac{1}{2}-\frac{1}{p}}\|a\|_{0,\infty}\left|\varphi_e\frac{\partial u_0}{\partial x_1}\right|_{1,p}\|(v_e-\chi_e^*)\exp(-\gamma y_1)\|_{0,\tilde q,G_e}|g|_1,\end{aligned} \tag{3.30}$$

and we note that $\delta<-\frac{1}{p}+\frac{1}{2}$ since $0\leq\frac{1}{l}\leq 1$ and $2<r$.

Taking $g = \tilde{\theta}_\epsilon^e - \tilde{\phi}_\epsilon^e$ and using the ellipticity of a, we obtain

$$\begin{aligned}|\tilde{\theta}_\epsilon^e - \tilde{\phi}_\epsilon^e|^2_{H_0^1(\Omega)} &\le \gamma_a^{-1} \int_\Omega (a^\epsilon \nabla(\tilde{\theta}_\epsilon^e - \tilde{\phi}_\epsilon^e)) \cdot \nabla(\tilde{\theta}_\epsilon^e - \tilde{\phi}_\epsilon^e) dx \\ &\le c\epsilon^\delta \|a\|_{0,\infty} |\varphi_e \nabla u_0|_{1,p} \left(\|\nabla(v_e - \chi_e^*) \exp(-\gamma y_1)\|_{0,\tilde{q},G_e} \right. \\ &\quad \left. + \|(v_e - \chi_e^*)\exp(-\gamma y_1)\|_{0,\tilde{q},G_e} \right). \qquad \square\end{aligned}$$

Remark 3.2. When $r \to 2$, then $\delta(p,l,r) = \frac{1}{p} - \frac{1}{rl}$ increases to $\frac{1}{p} - \frac{1}{2l}$. We note, however, that $r \to 2$ implies that $s \to \infty$ and, therefore, the a priori constant $c(\gamma, l, r) \to \infty$ if $l \neq 1$; see the term $(s(l-1))^{(l-1)/l}(\frac{\epsilon}{r\gamma l})^{\frac{1}{rl}}$ in (3.28). The optimal choice of r (denoted by r^*) to minimize this term depends on ϵ, l, and weakly on γ. When $l \to 1$, then $r^*(l) \to 2$. Therefore, $\delta \to -\frac{1}{p} + \frac{1}{2}$. Also, it is easy to see that when $\epsilon \to 0$, then $r^* \to 2$. Hence, for the worst case, i.e., $p = 2$ and $\tilde{q} = \infty$, when ϵ is very small, then δ is very close to $-\frac{1}{4}$.

We next prove the last proposition used in the proof of Theorem 3.1. Proposition 3.3 estimates the H^1-norm of $\bar{\phi} - \bar{\theta}_\epsilon$.

PROPOSITION 3.3. *Let $\Omega = (0,1)^2$ be the unit square. Let the functions u_0, $\bar{\theta}_\epsilon$, and $\bar{\phi}$ be defined by* (2.4), (2.11), *and* (2.15), *respectively. Assume that $a_{ij} \in L^\infty_{per}(Y)$ and $u_0 \in H^2(\Omega)$. Then there exists a positive constant c, independent of ϵ, u_0, and χ^j, such that*

$$\|\bar{\phi} - \bar{\theta}_\epsilon\|_1 \le c \max_j \|\chi^j\|_{1,2,Y} \|u_0\|_2.$$

Proof. Using that $(\bar{\phi} - \bar{\theta}_\epsilon) = 0$ on $\partial\Omega$ we have

$$\begin{aligned}\int_\Omega a_{ij}^\epsilon \frac{\partial(\bar{\phi} - \bar{\theta}_\epsilon)}{\partial x_i} \frac{\partial(\bar{\phi} - \bar{\theta}_\epsilon)}{\partial x_j} dx &= \int_\Omega a_{ij}^\epsilon \frac{\partial \bar{\phi}}{\partial x_i} \frac{\partial(\bar{\phi} - \bar{\theta}_\epsilon)}{\partial x_j} dx \\ &\le \|a\|_{0,\infty,Y} \left(\int_\Omega |\nabla \bar{\phi}|^2 dx \right)^{1/2} \left(\int_\Omega |\nabla(\bar{\phi} - \bar{\theta}_\epsilon)|^2 dx \right)^{1/2},\end{aligned}$$

and from the ellipticity of a and using Remark 2.1 we obtain

$$|\bar{\phi} - \bar{\theta}_\epsilon|_1 \le \frac{\|a\|_{0,\infty,Y}}{\gamma_a} |\bar{\phi}|_1 \le \tilde{c} \frac{\|a\|_{0,\infty,Y}}{\gamma_a} \max_j \|\chi^j\|_{1,2,Y} \|u_0\|_2.$$

The proposition follows from a Poincaré inequality. $\square$

The following proposition generalizes Proposition 2.3 in [35], where it is assumed that $a_{ij} \in C^{1,\beta}_{per}(Y)$, $u_0 \in H^3(\Omega)$, and $\Omega \subset \mathbb{R}^2$ is a smooth domain.

PROPOSITION 3.4. *Let $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, be a bounded domain with a Lipschitz boundary. Let u_ϵ be the solution of the problem* (1.1), *and let χ^j, u_0, u_1, θ_ϵ, χ^{ij}, u_2, and φ_ϵ be defined by* (2.2), (2.4), (2.5), (2.6), (2.7), (2.8), *and* (2.9), *respectively. Assume that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{3,p}(\Omega)$, and χ^j and $\chi^{ij} \in W^{1,q}_{per}(Y)$ for $1/p + 1/q \le 1/2$. Then there exists a constant c independent of u_0, ϵ, χ^j, and χ^{ij} such that*

$$\begin{aligned}\|u_\epsilon(\cdot) - u_0(\cdot) - \epsilon u_1(\cdot, \cdot/\epsilon) - \epsilon\theta_\epsilon(\cdot) - \epsilon^2 u_2(\cdot, \cdot/\epsilon) - \epsilon^2 \varphi_\epsilon(\cdot)\|_1 \\ \le C\epsilon^2 \left(\max_j \|\chi^j\|_{0,q,Y} + \max_{kj} \|\chi^{kj}\|_{1,q,Y} \right) \|u_0\|_{3,p}.\end{aligned}$$

In addition, if $p, q > d$, then

$$\|u_\epsilon(\cdot) - u_0(\cdot) - \epsilon u_1(\cdot, \cdot/\epsilon) - \epsilon\theta_\epsilon(\cdot)\|_0 \le c\epsilon^2 \left(\max_j \|\chi^j\|_{0,q} + \max_{kj} \|\chi^{kj}\|_{1,q} \right) \|u_0\|_{3,p}.$$

Proof. Define the field v_1 by

$$(v_1(x,y))_k = -a_{ki}(y)\chi^j \frac{\partial^2 u_0}{\partial x_j \partial x_i}(x) + a_{kl}(y)\frac{\partial \chi^{ij}}{\partial y_l}\frac{\partial^2 u_0}{\partial x_j \partial x_i}(x); \tag{3.31}$$

then

$$a(y)\nabla_x u_1(x,y) + a(y)\nabla_y u_2(x,y) = v_1(x,y). \tag{3.32}$$

Let $q(y) = \phi(y)$, where ϕ is defined by (3.5), and let $\psi_{ij} \in W^{1,q}_{\text{per}}(Y)$ such that

$$curl_y \psi_{1j} = \tilde{\psi}_{1j} = \begin{pmatrix} -a_{11}\chi^j + a_{1l}\partial_l \chi^{1,j} - c^1_{1j} \\ -a_{21}\chi^j + a_{2l}\partial_l \chi^{1,j} - \phi^{(3)}_j - c^2_{1j} \\ -a_{31}\chi^j + a_{3l}\partial_l \chi^{1,j} + \phi^{(2)}_j - c^3_{1j} \end{pmatrix},$$

$$curl_y \psi_{2j} = \tilde{\psi}_{2j} = \begin{pmatrix} -a_{12}\chi^j + a_{1l}\partial_l \chi^{2,j} + \phi^{(3)}_j - c^1_{2j} \\ -a_{22}\chi^j + a_{2l}\partial_l \chi^{2,j} - c^2_{2j} \\ -a_{32}\chi^j + a_{3l}\partial_l \chi^{2,j} - \phi^{(1)}_j - c^3_{2j} \end{pmatrix},$$

and

$$curl_y \psi_{3j} = \tilde{\psi}_{3j} = \begin{pmatrix} -a_{13}\chi^j + a_{1l}\partial_l \chi^{3,j} - \phi^{(2)}_j - c^1_{3j} \\ -a_{23}\chi^j + a_{2l}\partial_l \chi^{3,j} + \phi^{(1)}_j - c^2_{3j} \\ -a_{33}\chi^j + a_{3l}\partial_l \chi^{3,j} - c^3_{3j} \end{pmatrix}.$$

Here the constants c^l_{ij} are chosen so that each entry of the vectors $\tilde{\psi}_{ij}$ has zero value integral over Y; for instance, $c^1_{1j} = \int_Y -a_{11}\chi^j + a_{1l}\partial_l \chi^{1,j} dy$. It is easy to check that $\nabla_y \cdot \tilde{\psi}_{kj} = 0$; hence, the existence of such functions ψ_{kj} is guaranteed by Lemma 3.1 and by Remark 3.11 in [24]. We then obtain

$$\|\psi_{kj}\|_{1,q} \leq c(\|\chi^j\|_{0,q} + \|\chi^{kj}\|_{1,q}). \tag{3.33}$$

Define

$$p(x,y) = \psi_{kj}(y)\frac{\partial^2 u_0}{\partial x_k \partial x_j}(x), \tag{3.34}$$

and let

$$v_2(x,y) = -curl_x p(x,y).$$

An elementary calculation gives

$$\nabla_y \cdot v_2 = -\nabla_x \cdot v_1, \quad \nabla_x \cdot v_2 = 0 \tag{3.35}$$

and

$$\begin{aligned} \|v_2(\cdot,\cdot/\epsilon)\|_0 &\leq c\|u_0\|_{3,p} \max_{kj} \|\psi_{kj}\|_{1,q,Y} \\ &\leq c\|u_0\|_{3,p}(\|\chi^j\|_{0,q} + \|\chi^{kj}\|_{1,q}) \quad \text{by (3.33).} \end{aligned} \tag{3.36}$$

Define

$$\psi_\epsilon(x) = u_\epsilon(x) - u_0(x) - \epsilon u_1(x, x/\epsilon) - \epsilon^2 u_2(x, x/\epsilon)$$

and

$$\xi_\epsilon(x) = a(x/\epsilon)\nabla u_\epsilon(x) - v_0(x, x/\epsilon) - \epsilon v_1(x, x/\epsilon) - \epsilon^2 v_2(x, x/\epsilon),$$

where v_0 is defined by (3.3). Then

$$\begin{aligned} a(x/\epsilon)\nabla\psi_\epsilon - \xi_\epsilon(x) &= a(x/\epsilon)\nabla u_\epsilon(x) - a(x/\epsilon)\nabla u_0(x) - \epsilon a(x/\epsilon)\nabla u_1(x, x/\epsilon) \\ &\quad -\epsilon^2 a(x/\epsilon)\nabla u_2(x, x/\epsilon) \\ &\quad -a(x/\epsilon)\nabla u_\epsilon(x) + v_0(x, x/\epsilon) + \epsilon v_1(x, x/\epsilon) + \epsilon^2 v_2(x, x/\epsilon) \\ &= -a(x/\epsilon)\nabla_x u_0(x) - \epsilon a(x/\epsilon)\nabla_x u_1(x, x/\epsilon) - a(x/\epsilon)\nabla_y u_1(x, x/\epsilon) \\ &\quad -\epsilon^2 a(x/\epsilon)\nabla_x u_2(x, x/\epsilon) - \epsilon a(x/\epsilon)\nabla_y u_2(x, x/\epsilon) \\ &\quad +v_0(x, x/\epsilon) + \epsilon v_1(x, x/\epsilon) + \epsilon^2 v_2(x, x/\epsilon) \\ &= \epsilon^2(v_2(x, x/\epsilon) - a(x/\epsilon)\nabla_x u_2(x, x/\epsilon)) \quad \text{by (3.3) and (3.32).} \end{aligned}$$

Using (3.36) and the definition of u_2 (see (2.8)) we obtain

$$\|a(x/\epsilon)\nabla\psi_\epsilon - \xi_\epsilon\|_0 \le c\epsilon^2 \|u_0\|_{3,p} \max_{kj}(\|\chi^j\|_{0,q} + \|\chi^{kj}\|_{1,q}). \tag{3.37}$$

Given $g \in L^2(\Omega)$, let $w_\epsilon \in H^1(\Omega)$ denote the solution of

$$\int_\Omega a(x/\epsilon)\nabla w_\epsilon(x)\nabla\psi(x)dx = \int_\Omega g(x)\psi(x)dx \quad \forall\psi \in H_0^1(\Omega). \tag{3.38}$$

Since $\psi_\epsilon - \epsilon\theta_\epsilon - \epsilon^2\varphi_\epsilon \in H_0^1(\Omega)$ we obtain

$$\begin{aligned} \int_\Omega g(\psi_\epsilon - \epsilon\theta_\epsilon - \epsilon^2\varphi_\epsilon)dx &= \int_\Omega a(x/\epsilon)(\nabla\psi_\epsilon - \epsilon\nabla\theta_\epsilon - \epsilon^2\nabla\varphi_\epsilon)\nabla w_\epsilon(x)dx \\ &= \int_\Omega a(x/\epsilon)\nabla\psi_\epsilon\nabla w_\epsilon(x)dx, \end{aligned} \tag{3.39}$$

where we have used the definition of θ_ϵ and φ_ϵ to obtain (3.39). We observe that

$$\int_\Omega a^\epsilon\nabla\psi_\epsilon\nabla w_\epsilon dx = \int_\Omega (a^\epsilon\nabla\psi_\epsilon - \xi_\epsilon)\cdot\nabla w_\epsilon dx + \int_\Omega \xi_\epsilon\cdot\nabla w_\epsilon dx, \tag{3.40}$$

and we estimate the second term on the right-hand side of (3.40) as follows:

$$\begin{aligned} \int_\Omega \xi_\epsilon\cdot\nabla w_\epsilon dx &= \int_\Omega (a(x/\epsilon)\nabla u_\epsilon(x) - v_0(x, x/\epsilon) - \epsilon v_1(x, x/\epsilon) \\ &\quad -\epsilon^2 v_2(x, x/\epsilon))\cdot\nabla w_\epsilon(x)dx \\ &= \int_\Omega f(x)w_\epsilon(x) + \nabla_x\cdot v_0(x, x/\epsilon)w_\epsilon(x) \\ &\quad -\epsilon v_1(x, x/\epsilon)\cdot\nabla w_\epsilon(x) + \epsilon\nabla_x v_1(x, x/\epsilon)w_\epsilon(x)dx, \end{aligned} \tag{3.41}$$

where we have used the definition of u_ϵ, (3.18), integration by parts, and (3.35) to obtain (3.41). Using (3.31) we have

$$\begin{aligned} \int_\Omega v_1(x, x/\epsilon)\cdot\nabla w_\epsilon(x) = \int_\Omega \Bigg(&-a^\epsilon_{ki}\chi^j_\epsilon \frac{\partial^2 u_0}{\partial x_j \partial x_i}(x) \\ &+ a^\epsilon_{kl}\frac{\partial\chi^{ij}_\epsilon}{\partial y_l}\frac{\partial^2 u_0}{\partial x_j\partial x_i}(x)\Bigg)\frac{\partial w_\epsilon}{\partial x_k}(x)dx. \end{aligned} \tag{3.42}$$

Considering the partition of unit ρ_i defined in the proof of Proposition 3.1, we obtain

$$\begin{aligned}
&\int_\Omega a_{kl}^\epsilon \frac{\partial \chi_\epsilon^{ij}}{\partial y_l}\frac{\partial^2 u_0}{\partial x_j \partial x_i}\frac{\partial w_\epsilon}{\partial x_k}(x)dx = \sum_1^{i_m}\int_{\epsilon Y_i} a_{kl}^\epsilon \frac{\partial \chi_\epsilon^{ij}}{\partial y_l}\rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}\frac{\partial w_\epsilon}{\partial x_k}dx \\
&= \sum_1^{i_m}\int_{\epsilon Y_i} a_{kl}^\epsilon \frac{\partial \chi_\epsilon^{ij}}{\partial y_l}\frac{\partial}{\partial x_k}\left(\rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}w_\epsilon(x)\right) - a_{kl}^\epsilon \frac{\partial \chi_\epsilon^{ij}}{\partial y_l}w_\epsilon(x)\frac{\partial}{\partial x_k}\left(\rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}\right)dx \\
&= \sum_1^{i_m}\int_{\epsilon Y_i} \epsilon^{-1}\left(a_{ij}^\epsilon - a_{ik}^\epsilon \frac{\partial \chi_\epsilon^j}{\partial_{y_k}} + A_{ij}\right)\rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}w_\epsilon \\
&\quad + a_{ki}^\epsilon \chi_\epsilon^j \left(\frac{\partial}{\partial_{x_k}}\left(\rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}(x)\right)w_\epsilon(x) + \rho_i \frac{\partial^2 u_0}{\partial x_j \partial x_i}(x)\frac{\partial w_\epsilon}{\partial_{x_k}}(x)\right)dx \\
&\quad - \int_\Omega a_{kl}\frac{\partial \chi_\epsilon^{ij}}{\partial y_l}w_\epsilon(x)\frac{\partial}{\partial x_k}\left(\frac{\partial^2 u_0}{\partial x_j \partial x_i}\right)dx \qquad (3.43) \\
&= \int_\Omega \epsilon^{-1}\left(\nabla_x v_0 \frac{\partial^2 u_0}{\partial x_j \partial x_i}(x) - f\right)w_\epsilon(x)dx \\
&\quad - \int_\Omega a_{ki}^\epsilon \chi_\epsilon^j \frac{\partial^2 u_0}{\partial x_j \partial x_i}\frac{\partial w_\epsilon}{\partial_{x_k}}(x)dx - \int_\Omega \nabla_x \cdot v_1 dx. \qquad (3.44)
\end{aligned}$$

Here, we have used the definition of χ^{ij} to arrive at (3.43). From (3.41), (3.42), and (3.44) we obtain

$$\int_\Omega \xi_\epsilon \cdot \nabla w_\epsilon(x)dx = 0,$$

and, therefore, from (3.37) and (3.40) we obtain

$$\begin{aligned}
\left|\int_\Omega g(\psi_\epsilon - \epsilon\theta_\epsilon - \epsilon^2\varphi_\epsilon)dx\right| &\le \|a^\epsilon \nabla\psi_\epsilon - \xi_\epsilon\|_0 \|w_\epsilon\|_1 \\
&\le c\epsilon^2 \|u_0\|_{3,p}(\|\chi^j\|_{0,q,Y} + \|\chi^{kj}\|_{1,q,Y})\|g\|_{-1}.
\end{aligned}$$

Dividing by g and taking the supremum over g, (3.31) follows since

$$\|u_\epsilon - u_0 - \epsilon u_1 - \epsilon\theta_\epsilon - \epsilon^2 u_2 - \epsilon^2\varphi_\epsilon\|_1 \le c\epsilon^2\|u_0\|_{3,p}\max_{kj}(\|\chi^j\|_{0,q} + \|\chi^{kj}\|_{1,q}).$$

The remainder of the proof uses the same arguments given to prove (3.2). ∎

The following proposition estimates the L^2-norm of $\bar\phi - \bar\theta_\epsilon$, and it is used in the proof of Theorem 3.2.

PROPOSITION 3.5. *Let $\Omega = (0,1)^2$ be the unit square. Let u_0, χ^j, $\bar\theta_\epsilon$, and $\bar\phi$ be defined by* (2.4), (2.2), (2.11), *and* (2.15), *respectively. Assume that $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{3,p}(\Omega)$, and $\chi^j \in W^{1,q}_{per}(Y)$ for $1/p + 1/q \le 1/2$, $2 \le p, q \le \infty$. Then we have*

$$\|\bar\theta_\epsilon - \bar\phi\|_0 \le c\epsilon \max_j \|\chi^j\|_{1,2,Y}\|u_0\|_{3,p}.$$

Proof. Using the arguments given in Remark 2.1 we have

$$\left\|\sum_k \varphi_k \chi_k^* \nabla u_0 \cdot \eta_k\right\|_{2,p} \le c\max_k |\chi_k^*|\|u_0\|_{3,p} \le c\max_j \|\chi^j\|_{1,2,Y}\|u_0\|_{3,p}, \qquad (3.45)$$

where we have used that $|\chi_k^*| \leq c \max_j \|\chi^j\|_{1,2,Y}$; see the proof of Lemma 4.4 in [3]. By assumption, $u_0 \in H_0^1(\Omega) \cap W^{3,p}(\Omega)$. Using a trace theorem and Remarks 2.1 and 5.1, we obtain that

$$\bar{\phi}_{|\partial\Omega} = \sum_k \varphi_k \chi_k^* \nabla u_0 \cdot \eta_{k|\partial\Omega}$$

belongs to $W^{2-\frac{1}{p},p}(\Gamma_k) \cap W_{00}^{1-\frac{1}{p},p}(\Gamma_k)$, $k = \{e, w, n, s\}$. Following Chapter 5 in [25], when Ω is a is a polygonal convex domain, then the problem is $W^{2,p}(\Omega)$ regular. Therefore, the solution of (2.16) belongs to $W^{2,p}(\Omega)$ and satisfies $\|\bar{\phi}\|_{2,p} \leq c \max_j \|\chi^j\|_{1,2,Y} \|u_0\|_{3,p}$. From Remark 3.1 and (3.2) we obtain

$$\|\bar{\theta}_\epsilon - \bar{\phi}\|_0 \leq c\epsilon \max_j \|\chi^j\|_{1,2,Y} \|\bar{\phi}\|_{2,p},$$

and the proposition follows. ∎

The following proposition is used in the proof of Propositions 3.1 and 3.4.

LEMMA 3.1. *A function* $\mathbf{v} \in L^2_{per}(Y)^2$, $(\mathbf{v} \in L^2_{per}(Y)^3)$ *satisfies*

$$\nabla \cdot \mathbf{v} = \mathbf{0}, \tag{3.46}$$

and $\int_Y v_i dy = 0$ *iff there exists a function* $\phi \in H^1_{per}(Y)$ $(\phi \in H^1_{per}(Y)^3)$ *such that*

$$\mathbf{v} = curl\phi. \tag{3.47}$$

Proof. The proof is similar to the proof of Theorem 3.4 in [24], where here we use discrete Fourier transforms rather than continuous Fourier transforms; see [44]. ∎

The following theorems provide error estimates between u_ϵ and $u_0 - \epsilon u_1 - \epsilon\phi_\epsilon$ on the H^1- and L^2-norms.

THEOREM 3.1. *Let* $\Omega = (0,1)^2$ *be the unit square, and let* u_ϵ *be the solution of the problem* (1.1). *Let* u_0, u_1, ϕ_ϵ *be defined by* (2.4), (2.5), *and* (2.16), *respectively. Assume* $a_{ij} \in L^\infty_{per}(Y)$, $u_0 \in W^{2,p}(\Omega)$, *and* $\chi^j \in W^{1,q}_{per}(Y)$ *for* $1/p + 1/q \leq 1/2$. *Let the functions* v_k *be defined as in subsection* 2.2.1. *Assume that* $\exp(-\gamma y_1)\nabla v_e \in L^{\tilde{q}}(G_e)$ *and* $\exp(-\gamma y_1)(v_e - \chi_e^*) \in L^{\tilde{q}}(G_e)$ *for* $\frac{1}{p} + \frac{1}{\tilde{q}} \leq \frac{1}{2}$ *and that similar conditions also hold for the other functions* v_k, $k \in \{w, n, s\}$. *Define* $\hat{\delta} = \min\{0, \delta\}$, δ *defined by Proposition* 3.2 *and Remark* 3.2. *Then there exists a constant* c *independent of* ϵ *such that*

$$\|u_\epsilon(\cdot) - u_0(\cdot) - \epsilon u_1(\cdot, \cdot/\epsilon) - \epsilon\phi_\epsilon(\cdot)\|_1 \leq c\epsilon^{1+\hat{\delta}} \|u_0\|_{2,p}.$$

In addition, if $\frac{1}{p} + \frac{1}{\tilde{q}} < \frac{1}{2}$, *then* $\hat{\delta} > -\frac{1}{p} + \frac{1}{4}$. *Also, if* $\frac{3}{p} + \frac{1}{\tilde{q}} < 1$, *then* $\hat{\delta} = 0$.

Proof. By the triangular inequality we have

$$\begin{aligned} |u_\epsilon - u_0 - \epsilon u_1 - \epsilon\phi_\epsilon|_1 \leq\ & |u_\epsilon - u_0 - \epsilon u_1 - \epsilon\theta_\epsilon|_1 \\ & + \epsilon|\tilde{\theta}_\epsilon - \tilde{\phi}_\epsilon|_1 + \epsilon|\bar{\theta}_\epsilon - \bar{\phi}|_1, \end{aligned}$$

and applying Propositions 3.1, 3.2, and 3.3 and Remark 3.2, the theorem then follows. ∎

Remark 3.3. Theorem 1 in [34] guarantees that $\chi^j \in W^{1,q}_{per}(Y)$ for all $q < \infty$. See also Theorem 1.1 in [31] for conditions on a_{ij} in order to have $\chi^j \in W^{1,\infty}_{per}(Y)$.

The following theorem gives higher error estimates when more regularity is assumed.

THEOREM 3.2. *Let $\Omega = (0,1)^2$ be the unit square, and let u_ϵ be the solution of problem (1.1). Let u_0, u_1, ϕ_ϵ be defined by (2.4), (2.5), and (2.16), respectively. Assume $u_0 \in W^{3,p}(\Omega)$, $\bar{\phi} \in W^{2,p}(\Omega)$, and χ^j and $\chi^{ij} \in W^{1,q}_{per}(Y)$ for $1/p + 1/q \leq 1/2$, $p, q > 2$. Let the functions v_k be defined as in subsection 2.2.1. Assume that $\exp(-\gamma y_1)\nabla v_e \in L^\infty(G_e)$ and $\exp(-\gamma y_1)(v_e - \chi^*_e) \in L^\infty(G_e)$ and that similar conditions also hold for the other functions v_k, $k \in \{w, n, s\}$. Then there exists a constant c independent of ϵ such that*

$$\|u_\epsilon(\cdot) - u_0(\cdot) - \epsilon u_1(\cdot, \cdot/\epsilon) - \epsilon\phi_\epsilon(\cdot)\|_0 \leq c\epsilon^{3/2}\|u_0\|_{3,p}.$$

Proof. Use a triangular inequality similar to the one used in the proof of Theorem 3.1, use a Sobolev embedding theorem to have $u_0 \in W^{2,\infty}(\Omega)$, and then apply the Propositions 3.4, 3.2, and 3.5. We obtain the factor $O(\epsilon^{3/2})$ rather than the (ϵ^2) as in Proposition 3.4 since $\|\tilde{\theta}_\epsilon - \tilde{\phi}_\epsilon\|_0$ is $O(\epsilon^{1/2})$; see Remark 3.2 and Proposition 3.2. ∎

Remark 3.4. Note that if $a_{ij} \in C^{1,\beta}_{per}(Y)$, $\beta > 0$, then from regularity theory we have $\chi^j \in C^{1,\beta}_{per}$, $v_e \in C^{1,\beta}$, and $\nabla(v_e - \chi^*_e)\exp(-\gamma y_1) \in L^\infty(G_e)$; see Theorem 15.1 in [29] and Remark 6.4 in [35]; see also Theorem 3 in [30] for related issues.

4. Finite element approximation. For sections 4 and 5 we assume that A, χ^j, v_k, and χ^* are computed exactly. We now describe the finite element approximations for u_0, u_1, $\tilde{\phi}_\epsilon$, and $\bar{\phi}$.

- Let $V^h(\Omega)$ be the P_1 or the Q_1 conforming finite element space on the mesh $\mathcal{T}_h(\Omega)$, and let $V^h_0(\Omega) = V^h(\Omega) \cap H^1_0(\Omega)$. Define $u^h_0 \in V^h_0(\Omega)$ as the solution of

$$\int_\Omega A\nabla u^h_0 \cdot \nabla v^h dx = \int_\Omega f v^h dx \quad \forall v^h \in V^h_0(\Omega). \tag{4.1}$$

- We now introduce the discrete approximation for $\partial_\eta u_0$. Note that $\partial_\eta u_0$ is used on the boundary condition imposed for problem (2.15). In order to approximate $\partial_\eta u_0$, we define $Y^h = V^h(\Omega)|_{\partial\Omega}$, $Y^h_k = Y^h|_{\Gamma_k}$, and $Y^h_{0,k} = \{\lambda^h \in Y^h_k; \lambda^h = 0 \text{ at } \partial\Gamma_k\}$. For all $\phi^h \in V^h(\Omega)$ and $\phi^h|_{\partial\Omega\setminus\Gamma_k} = 0$, let $\lambda^h_k \in Y^h_{0,k}$ be defined as the solution of

$$\int_{\Gamma_k} \lambda^h_k \phi^h d\sigma = \int_\Omega A\nabla u^h_0 \cdot \nabla\phi^h dx - \int_\Omega f\phi^h dx; \tag{4.2}$$

  see [48]. Later in Lemma 5.3 we show that λ^h_k is a good approximation for $A\nabla u_0 \cdot \eta_k$ on Γ_k; hence, we approximate $\partial_\eta u_0$ by μ^h, where

$$\mu^h|_{\Gamma_k} = \lambda^h_k / A_{l_k l_k},\ l_k = \begin{cases} 1 & \text{if} \quad k = e, w, \\ 2 & \text{if} \quad k = n, s. \end{cases} \tag{4.3}$$

- We note that we use μ^h as the approximation for $\partial_\eta u_0$ in (4.7). Therefore, in order to guarantee that the final numerical approximation for u_ϵ satisfies the zero Dirichlet boundary condition, we define the approximation for ∇u_0 as

$$\Psi^h = \nabla u^h_0 + \sum_{k\in\{e,w,n,s\}} E^h_k(\mu^h - \nabla u^h_0 \cdot \eta^k)\eta^k. \tag{4.4}$$

  Here $E^h_k(\cdot)$ denotes the trivial zero nonconforming discrete extension of $\mu^h - \nabla u^h_0 \cdot \eta^k$ in Ω. More specifically, $E^h_k(\mu^h - \nabla u^h_0 \cdot \eta^k)(z) = 0$ if z is a nodal point

of $\mathcal{T}_h(\overline{\Omega})\setminus\Gamma_k$, $E_k^h(\mu^h-\nabla u_0^h\cdot\eta^k)=\mu^h-\nabla u_0^h\cdot\eta^k$ on Γ_k, and $E_k^h(\mu^h-\nabla u_0^h\cdot\eta^k)$ inside each element $K_i\in\mathcal{T}_h(\Omega)$ belongs to $V_h(K_i):=V^h(\Omega)|_{K_i}$.

- Define

$$u_1^h(x,x/\epsilon)=-\Psi_j^h(x)\chi^j(x/\epsilon). \tag{4.5}$$

Note that this leads to a nonconforming approximation for u_1 in $\mathcal{T}_h(\Omega)$.

- Define

$$\tilde{\phi}_\epsilon^h=\sum_{k\in\{e,w,n,s\}}\tilde{\phi}_\epsilon^{k,h}, \tag{4.6}$$

where

$$\tilde{\phi}_\epsilon^{e,h}(x_1,x_2)=\varphi_e(x_1,x_2)\left(v_e\left(\frac{x_1-1}{\epsilon},\frac{x_2}{\epsilon}\right)-\chi_e^*\right)\Psi^h$$

(see (2.13) and (4.4)) and the others terms $\tilde{\phi}_\epsilon^{k,h}$ are defined similarly.

- Let $\bar{\phi}^h\in V_h(\Omega)$ be the solution of

$$\int_\Omega A\nabla\bar{\phi}^h\cdot\nabla v^h dx=0\quad\forall v^h\in V_0^h(\Omega)\quad\text{and}\quad\bar{\phi}^h=\chi^*\mu^h\ \text{ on }\ \partial\Omega. \tag{4.7}$$

The well posedness of (4.7) follows from Remark 4.1.

- Approximate ϕ_ϵ by $\phi_\epsilon^h=\tilde{\phi}_\epsilon^h+\bar{\phi}^h$ and finally define the numerical solution for (1.1) as

$$u_\epsilon^h=u_0^h+\epsilon u_1^h+\epsilon\phi_\epsilon^h. \tag{4.8}$$

Remark 4.1. By construction μ^h vanishes at the corners of Ω; therefore, $\chi^*\mu^h\in H^{1/2}(\partial\Omega)$. This implies that (4.7) is well posed. In addition, $\chi^*\mu^h\in V^h|_{\partial\Omega}$; hence, we can look for a numerical solution of (4.7) in $V^h(\Omega)$.

5. Finite element error analysis. The main results of this section are Theorems 5.1 and 5.2, which provide the a priori error estimates between the exact solution u_ϵ and its numerical approximation u_ϵ^h. Theorem 5.1 provides estimates on the a priori error estimates on the broken H^1-norm, while Theorem 5.2 provides the L_2-norm.

In this section we recall a few results on discrete Sobolev norms and spaces, prove the propositions and lemmas required in the proofs of Theorems 5.1 and 5.2, and then close the section proving Theorems 5.1 and 5.2.

5.1. Preliminaries. We first review general finite element results that are used later in this section. Let u_0 and u_0^h be the solutions of problems (2.4) and (4.1), respectively. We consider $\mathcal{P}_1$ or $\mathcal{Q}_1$ finite elements spaces for approximating u_0. We assume that the domain Ω is a convex polygon; therefore, problem (2.4) is $W^{2,p}$ regular for some $2<p$; see [25]. Standard finite element analysis provides

$$\|u_0-u_0^h\|_{1,p}\le ch\|u_0\|_{2,p}\text{ for }2\le p\le\infty, \tag{5.1}$$

$$\|u_0-u_0^h\|_{0,p}\le ch^2\|u_0\|_{2,p}\text{ for }2\le p<\infty, \tag{5.2}$$

and

$$\|u_0-u_0^h\|_{2,p,h}\le c\|u_0\|_{2,p}\text{ for }2\le p\le\infty; \tag{5.3}$$

see Corollary 7.1.12, inequality (7.5.4), and Theorem 4.4.20 in [12] to obtain (5.1), and standard duality arguments to obtain (5.2). To obtain the stability result (5.3), we first introduce the interpolation operator $\mathcal{I}^h$, i.e., the usual local pointwise interpolation $\mathcal{P}_1$ or $\mathcal{Q}_1$ in $\mathcal{T}_h(\Omega)$. Then, for each element $K \in \mathcal{T}_h(\Omega)$, we have

$$|u_0 - u_0^h|_{2,p,K} \leq |u_0 - \mathcal{I}^h u_0|_{2,p,K} + |\mathcal{I}^h u_0 - u_0^h|_{2,p,K}, \tag{5.4}$$

and using an interpolation error estimate (see Theorem 4.4.20 in [12]) we obtain

$$|u_0 - \mathcal{I}^h u_0|_{s,p,h} \leq c h^{2-s} |u_0|_{2,p,h} \text{ for } 1 \leq p \leq \infty \text{ for } 0 \leq s \leq 2. \tag{5.5}$$

Now apply an inverse inequality (see Lemma 4.5.3 in [12]) to obtain

$$|\mathcal{I}^h u_0 - u_0^h|_{2,p,K} \leq c h^{-1} \|\mathcal{I}^h u_0 - u_0^h\|_{1,p,K} \text{ for } 1 \leq p \leq \infty, \tag{5.6}$$

and hence, (5.3) follows from (5.4), (5.5), (5.6), and (5.1).

In order to estimate the L^2- and the broken H^1-norms of $u_1 - u_1^h$ (see Proposition 5.1) we apply Hölder's inequality on $u_1 - u_1^h = (\partial_{x_j} u_0 - \Psi_j^h)\chi^j$ to obtain $\|u_1 - u_1^h\|_{1,h} \leq c\|\partial_{x_j} u_0 - \Psi_j^h\|_{1,p,h}\|\chi^j\|_{1,q}$ and $\|u_1 - u_1^h\|_0 \leq c\|\partial_{x_j} u_0 - \Psi_j^h\|_{0,p}\|\chi^j\|_{0,q}$ for $\frac{1}{p} + \frac{1}{q} \leq \frac{1}{2}$. Hence, it requires estimating the error between Ψ^h and ∇u_0 on the L^p-norm and the broken $W^{1,p}$-norm; see Lemma 5.4. Lemma 5.4 requires estimating the errors between $A\nabla u_0 \cdot \eta$ and λ^h (see (4.2)) over Γ_k using fractional-order Sobolev norms.

Remark 5.1. Here, we review some facts about fractional-order Sobolev norms and spaces that are used throughout the text; see [25, 33].

Case $2 < p < \infty$. Since $W^{1-\frac{1}{p},p}(\Gamma_k) \hookrightarrow C^0(\Gamma_k)$, we define the spaces $W_{00}^{1-\frac{1}{p},p}(\Gamma_k) = \{\varphi \in W^{1-\frac{1}{p},p}(\Gamma_k);\ \varphi = 0 \text{ on } \partial\Gamma_k\}$ equipped with the norm $\|\cdot\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} = \|\cdot\|_{W^{1-\frac{1}{p},p}(\Gamma_k)}$.

Case $p = 2$. We set $W_{00}^{1-\frac{1}{p},p}(\Gamma_k) = H_{00}^{1/2}(\Gamma_k)$ equipped with the norm $\|\cdot\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} = \|\cdot\|_{H_{00}^{1/2}(\Gamma_k)}$; see [33] for the definition of $H_{00}^{1/2}(\Gamma_k)$.

Case $1 < p < 2$. We define $W_{00}^{1-\frac{1}{p},p}(\Gamma_k) = W^{1-\frac{1}{p},p}(\Gamma_k)$ equipped with the norm $\|\cdot\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} = \|\cdot\|_{W^{1-\frac{1}{p},p}(\Gamma_k)}$.

We note that for Lipschitz domains, we have that $W_{00}^{1-\frac{1}{p},p}(\Gamma_k)$ are also equivalent to $[L^p(\Gamma_k), W_0^{1,p}(\Gamma_k)]_{1-1/p,p}$, i.e., via real interpolation theory on Banach spaces; see [25]. This property is used throughout the text to establish stabilities and a priori error estimates results.

The spaces $W_{00}^{1-\frac{1}{p},p}(\Gamma_k)$ also have the following important feature. Denote by $\tilde{\varphi}$ the extension by zero to $\partial\Omega \setminus \Gamma_k$ of a given function $\varphi \in W_{00}^{1-1/p,p}(\Gamma_k)$. Then, by the trace theorem and the lift theorem, Theorem 1.5.2.3 in [25], there exists a function $\psi_\varphi \in W^{1,p}(\Omega)$ such that $\psi_\varphi|_{\partial\Omega} = \tilde{\varphi}$ and

$$c_1\|\varphi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq \|\psi_\varphi\|_{1,p} \leq c_2\|\tilde{\varphi}\|_{W^{1-\frac{1}{p},p}(\partial\Omega)} \leq c_3\|\varphi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}. \tag{5.7}$$

The dual space of $W_{00}^{1-\frac{1}{p},p}(\Gamma_k)$ is denoted by $W^{-1+\frac{1}{p},p'}(\Gamma_k)$, where $\frac{1}{p} + \frac{1}{p'} = 1$.

5.2. Finite element convergence analysis. We now prove the lemmas and propositions required to complete the proof of Theorems 5.1 and 5.2.

The following inverse inequality is required in the proofs of Lemma 5.3.

LEMMA 5.1. *Let $1 < p < \infty$ and $v^h \in Y^h_{0,k}$. Then*

$$\|v^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq ch^{-1}\|v^h\|_{W^{-1+\frac{1}{p'},p}(\Gamma_k)}. \tag{5.8}$$

Proof. Considering the inverse inequality given by Theorem 4.5.11 in [12] followed by the real interpolation method (see Proposition 12.1.5 in [12]), we have

$$\|v^h\|_{s,q,\partial\Omega} \leq ch^{-s}\|v^h\|_{0,q,\partial\Omega} \quad \forall\, v^h \in Y^h,\ 1 \leq p \leq \infty, \text{ and } 0 \leq s \leq 1. \tag{5.9}$$

Given $v^h \in Y^h_{0,k}$, let $\tilde{v}^h \in Y^h$ be the extension of v^h to $\partial\Omega \setminus \Gamma_k$ by zero. Using (5.7) and (5.9) we obtain

$$\begin{aligned}\|v^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} &\leq c\|\tilde{v}^h\|_{W^{1-\frac{1}{p},p}(\partial\Omega)} \\ &\leq ch^{-1+\frac{1}{p}}\|\tilde{v}^h\|_{L^p(\partial\Omega)} = ch^{-1+\frac{1}{p}}\|v^h\|_{L^p(\Gamma_k)}.\end{aligned} \tag{5.10}$$

Let $\mathcal{P}_{0,k}$ denote the L^2 projection on $Y^h_{0,k}$, and assume that $v^h \in Y^h_{0,k}$. Then

$$\|v^h\|_{L^p(\Gamma_k)} = \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle v^h, \phi\rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}} = \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle v^h, \mathcal{P}_{0,k}\phi\rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}}.$$

We also have by Theorem 1 in [17] that

$$\|\mathcal{P}_{0,k}\phi\|_{L^{p'}(\Gamma_k)} \leq c\|\phi\|_{L^{p'}(\Gamma_k)}, \quad 1 \leq p' \leq \infty. \tag{5.11}$$

Thus,

$$\begin{aligned}\|v^h\|_{L^p(\Gamma_k)} &\leq c \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\|v^h\|_{W^{-1+\frac{1}{p'},p}(\Gamma_k)}\|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}}{\|\mathcal{P}_{0,k}\phi\|_{L^{p'}(\Gamma_k)}} \\ &\leq ch^{-1+\frac{1}{p'}}\|v^h\|_{W^{-1+\frac{1}{p'},p}(\Gamma_k)},\end{aligned} \tag{5.12}$$

where in the last inequality we have used (5.10). Combining inequalities (5.10) and (5.12), we obtain (5.8). ∎

The following lemma provides stability and approximation results associated to $\mathcal{P}_{0,k}$, i.e., the L^2 projection on $Y^h_{0,k}$. These results are required in the proof of Lemma 5.3.

LEMMA 5.2. *Let $1 < p < \infty$ and $\mathcal{P}_{0,k} : W^{-1+\frac{1}{p},p'}(\Gamma_k) \to Y^h_{0,k}$ be the L^2 projection on $Y^h_{0,k}$. Then we have*

$$\|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq c\|\phi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \quad \forall\, \phi \in W_{00}^{1-\frac{1}{p},p}(\Gamma_k), \tag{5.13}$$

$$\|\phi - \mathcal{P}_{0,k}\phi\|_{L^p(\Gamma_k)} \leq ch^{1-\frac{1}{p}}\|\phi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \quad \forall\, \phi \in W_{00}^{1-\frac{1}{p},p}(\Gamma_k), \tag{5.14}$$

$$\|\mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)} \leq c\|\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)} \quad \forall\, \phi \in W^{-1+\frac{1}{p},p'}(\Gamma_k), \tag{5.15}$$

and

$$\|\phi - \mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)} \leq ch^{1-\frac{1}{p}}\|\phi\|_{L^{p'}(\Gamma_k)} \quad \forall\ \phi \in L^{p'}(\Gamma_k). \tag{5.16}$$

Proof of (5.13). Observe that $\mathcal{P}_{0,k} : L^p(\Gamma_k) \to Y_{0,k}^h$ is stable in L^p and $W_0^{1,p}$, $1 \leq p \leq \infty$, i.e., $\|\mathcal{P}_{0,k}\phi\|_{L^p(\Gamma_k)} \leq c\|\phi\|_{L^p(\Gamma_k)}$ for all $\phi \in L^p(\Gamma_k)$, and $\|\mathcal{P}_{0,k}\phi\|_{W^{1,p}(\Gamma_k)} \leq c\|\phi\|_{W^{1,p}(\Gamma_k)}$ for all $\phi \in W_0^{1,p}(\Gamma_k)$, respectively; see Theorems 1 and 2 in [17]. Since $W_{00}^{1-1/p,p}(\Gamma_k)$ is equivalent to $[L^p(\Gamma_k), W_0^{1,p}(\Gamma_k)]_{1-1/p,p}$, the stability of $\mathcal{P}_{0,k}$ in the norm $W_{00}^{1-1/p,p}(\Gamma_k)$ follows from the real interpolation method; see Proposition 12.1.5 in [12]. The inequality (5.13) then follows.

Proof of (5.14). Let $\mathcal{Q}^h : L^p(\Gamma_k) \to V^h(\Omega)|_{\Gamma_k}$ denote the $\mathcal{P}_1$ or $\mathcal{Q}_1$ Clement interpolation operator defined by (2.13) in [41]. Then we have

$$\begin{aligned}
\|\phi - \mathcal{P}_{0,k}\phi\|_{L^p(\Gamma_k)} &\leq \|\phi - \mathcal{Q}^h\phi\|_{L^p(\Gamma_k)} + \|\mathcal{P}_{0,k}(\phi - \mathcal{Q}^h\phi)\|_{L^p(\Gamma_k)} \\
&\leq c\|\phi - \mathcal{Q}^h\phi\|_{L^p(\Gamma_k)} \text{ by (5.11)} \\
&\leq ch^{1-\frac{1}{p}}\|\phi\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}, \qquad (5.17)
\end{aligned}$$

where to obtain (5.17) we have used Theorem 4.1 and Lemma 4.1 [41] followed by the real interpolation method.

Proofs of (5.15) *and* (5.16). These proofs follow from standard duality arguments, the properties of the L_2 projection $\mathcal{P}_{0,k}$, and estimates (5.13) and (5.14), respectively. ∎

The following lemma estimates the error between $\lambda = A\nabla u_0 \cdot \eta$ and its numerical approximation λ^h defined by (4.2). This lemma is used in the proof of Lemma 5.4.

LEMMA 5.3. *Assume that* $u_0 \in W^{2,p}(\Omega)$. *Then we have*

$$\|\lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}, \|\lambda - \lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq c\|u_0\|_{2,p} \quad \textit{for} \quad 2 \leq p < \infty, \tag{5.18}$$

$$\|\lambda - \lambda^h\|_{W^{-1+\frac{1}{p'},p}(\Gamma_k)} \leq ch\|u_0\|_{2,p} \quad \textit{for} \quad 2 \leq p < \infty, \tag{5.19}$$

and

$$\|\lambda - \lambda^h\|_{L^p(\Gamma_k)} \leq ch^{1-\frac{1}{p}}\|u_0\|_{2,p} \quad \textit{for} \quad 2 \leq p \leq \infty. \tag{5.20}$$

Proof of (5.18). From Remark 2.1 and a trace theorem we have

$$\|\lambda\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq c\|u_0\|_{2,p}. \tag{5.21}$$

In order to prove inequality (5.18) observe that

$$\|\lambda - \lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \leq \|\lambda\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} + \|\lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}, \tag{5.22}$$

and

$$\|\lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} = \sup_{\phi \in W^{-1+\frac{1}{p},p'}(\Gamma_k)} \frac{\langle \lambda^h, \phi\rangle}{\|\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)}}.$$

Since $\lambda^h \in Y^h_{0,k}$, then $\langle \lambda^h, \phi\rangle = \langle \lambda^h, \mathcal{P}_{0,k}\phi\rangle$, and using (5.15) we obtain

$$\|\lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \le c \sup_{\phi\in W^{-1+\frac{1}{p},p'}(\Gamma_k)} \frac{\langle \lambda^h, \mathcal{P}_{0,k}\phi\rangle}{\|\mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)}}. \tag{5.23}$$

Let $E : W^{-1+\frac{1}{p},p'}(\partial\Omega) \to W^{1,p'}(\Omega)$ be a stable lift extension and let $\mathcal{Q}_h$ (see [41]) be the modified Clement L_2-quasi-projection satisfying the discrete boundary condition. Then $E_h = \mathcal{Q}_h E : Y^h \to V^h(\Omega)$ (see (5.5) in [41]) satisfies

$$\|E_h g\|_{1,p'} \le c\|g\|_{W^{1-\frac{1}{p'},p'}(\partial\Omega)}$$

for $g \in Y^h$. Hence, if $g^h \in Y^h_{0,k}$ and $\tilde{g}^h$ denotes the extension of g^h by zero to $\partial\Omega \setminus \Gamma_k$, it follows that

$$\|E_h\tilde{g}^h\|_{1,p'} \le c\|g^h\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}. \tag{5.24}$$

Let $\tilde{\mathcal{P}}_{0,k}\phi$ denote the discrete extension of $\mathcal{P}_{0,k}\phi$ to $\partial\Omega \setminus \Gamma_k$ by zero. From the definition of λ^h (see (4.2)) inequalities (5.1), and (5.24), and the inverse inequality (5.8), we obtain

$$\begin{aligned}\langle \lambda^h, \mathcal{P}_{0,k}\phi\rangle &= \langle \lambda, \mathcal{P}_{0,k}\phi\rangle + \int_\Omega A\nabla(u_0^h - u_0)\cdot\nabla(E_h\tilde{\mathcal{P}}_{0,k}\phi)dx \\ &\le \|\lambda\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}\|\mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)} + ch\|u_0\|_{2,p}\|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)} \\ &\le \left(\|\lambda\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} + c\|u_0\|_{2,p}\right)\|\mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)}. \end{aligned} \tag{5.25}$$

The inequality (5.18) follows from (5.23), (5.25), (5.22), and (5.21).

Proof of (5.19). We observe that

$$\begin{aligned}\|\lambda - \lambda^h\|_{W^{-1+\frac{1}{p'},p}(\Gamma_k)} &= \sup_{\phi\in W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)} \frac{\langle \lambda - \lambda^h, \phi\rangle}{\|\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}} \\ &\le \sup_{\phi\in W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)} c\frac{\langle \lambda - \lambda^h, \mathcal{P}_{0,k}\phi\rangle}{\|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}} + \sup_{\phi\in W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)} c\frac{\langle \lambda - \lambda^h, \phi - \mathcal{P}_{0,k}\phi\rangle}{\|\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}}. \end{aligned} \tag{5.26}$$

In order to estimate the first term on the right-hand side of (5.26), we use the definition of λ and λ^h and inequality (5.24) to obtain

$$\begin{aligned}\langle \lambda - \lambda^h, \mathcal{P}_{0,k}\phi\rangle &= \int_\Omega A\nabla(u_0^h - u_0)\cdot\nabla(E_h\tilde{\mathcal{P}}_{0,k}\phi)dx \\ &\le ch\|u_0\|_{2,p}\|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}. \end{aligned} \tag{5.27}$$

For estimating the second term on the right-hand side of (5.26), we use (5.18) and (5.16) to obtain

$$\begin{aligned}\langle \lambda - \lambda^h, \phi - \mathcal{P}_{0,k}\phi\rangle &\le \|\lambda - \lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)}\|\phi - \mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)} \\ &\le ch\|u_0\|_{2,p}\|\phi\|_{W_{00}^{1-\frac{1}{p'},p'}(\Gamma_k)}, \end{aligned} \tag{5.28}$$

and inequality (5.19) follows from (5.26), (5.27), and (5.28).

Proof of (5.20).

Case $2 \leq p < \infty$. We have

$$\|\lambda - \lambda^h\|_{L^p(\Gamma_k)} \leq \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle \lambda - \lambda^h, \phi - \mathcal{P}_{0,k}\phi \rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}} + \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle \lambda - \lambda^h, \mathcal{P}_{0,k}\phi \rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}}. \tag{5.29}$$

The first term on the right-hand side of (5.29) is bounded as follows:

$$\begin{aligned} \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle \lambda - \lambda^h, \phi - \mathcal{P}_{0,k}\phi \rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}} &\leq \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\|\lambda - \lambda^h\|_{W_{00}^{1-\frac{1}{p},p}(\Gamma_k)} \|\phi - \mathcal{P}_{0,k}\phi\|_{W^{-1+\frac{1}{p},p'}(\Gamma_k)}}{\|\phi\|_{L^{p'}(\Gamma_k)}} \\ &\leq c h^{1-\frac{1}{p}} \|u_0\|_{2,p}. \end{aligned} \tag{5.30}$$

Here we have used (5.16) and (5.18) to arrive at (5.30). In order to estimate the second term on the right-hand side of (5.29) we use the definition of λ and λ^h to obtain

$$\begin{aligned} \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\langle \lambda - \lambda^h, \mathcal{P}_{0,k}\phi \rangle}{\|\phi\|_{L^{p'}(\Gamma_k)}} &\leq c \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\int_\Omega A\nabla(u_0 - u_0^h) \cdot \nabla(E_h \tilde{\mathcal{P}}_{0,k}\phi) dx}{\|\mathcal{P}_{0,k}\phi\|_{L^{p'}(\Gamma_k)}} \\ &\leq ch \sup_{\phi \in L^{p'}(\Gamma_k)} \frac{\|u_0\|_{2,p} \|\mathcal{P}_{0,k}\phi\|_{W_{00}^{1-\frac{1}{p'},p'}}}{\|\mathcal{P}_{0,k}\phi\|_{L^{p'}(\Gamma_k)}} \\ &\leq ch^{1-\frac{1}{p}} \|u_0\|_{2,p}, \text{ by (5.10)}. \end{aligned}$$

Case $p = \infty$. Let $z \in \Gamma_k$; then

$$|\lambda(z) - \lambda^h(z)| \leq |\lambda(z) - \mathcal{P}_{0,k}\lambda(z)| + |\lambda^h(z) - \mathcal{P}_{0,k}\lambda(z)|. \tag{5.31}$$

To estimate the first term on the right-hand side of (5.31), we use that the L^2 projection is stable in any L^p-norm, $1 \leq p \leq \infty$; see Lemma 3.5 in [47].

To estimate the second term on the right-hand side of (5.31) we use the techniques developed in [47]. Let $E_z \subset \Gamma_k$ denote an edge of an element $K_z \in \mathcal{T}^h(\Omega)$ such that $z \in E_z$, and define δ_z as the polynomial of degree 1 on E_z such that

$$\int_{E_z} \delta_z(s) v(s) ds = v(z) \text{ for any } v \text{ polynomial of degree 1.}$$

Regard δ_z as extended by zero to $\Gamma_k \setminus E_z$, and denote by $\tilde{\delta}_z^h \in V^h(\Omega)$ the extension by zero of $\mathcal{P}_{0,k}\delta_z$ to Ω. Then we have

$$\begin{aligned} \lambda^h(z) - \mathcal{P}_{0,k}\lambda(z) &= \int_{\Gamma_k} \mathcal{P}_{0,k}(\lambda^h - \lambda)\delta_z ds = \int_{\Gamma_k} (\lambda^h - \lambda)\mathcal{P}_{0,k}\delta_z ds \\ &= \int_\Omega A\nabla(u_0 - u_0^h) \cdot \nabla \tilde{\delta}_z^h dx, \end{aligned} \tag{5.32}$$

where we have used the definition of λ^h to obtain (5.32). From (5.1) and (5.32) it follows that

$$|\lambda^h(z) - \mathcal{P}_{0,k}\lambda(z)| \leq ch \|u_0\|_{2,\infty} \|\tilde{\delta}_z^h\|_{1,1}.$$

Using an inverse inequality followed by a discrete Sobolev inequality for trivial extensions, we have

$$\|\tilde{\delta}_z^h\|_{1,1} \le ch^{-1}\|\tilde{\delta}_z^h\|_{0,1} \le c\|\mathcal{P}_{0,k}\delta_z\|_{0,1,\Gamma_k}.$$

Finally, we use the fact that $\|\mathcal{P}_{0,k}\delta_z\|_{0,1,\Gamma_k} \le c$ (see Lemma 3.5 in [47]) to obtain (5.20). ∎

The next lemma estimates the error between ∇u_0 and its numerical approximation Ψ^h. This proposition is required in the proof of Proposition 5.1.

LEMMA 5.4. *Let u_0 and Ψ^h be defined by (2.4) and (4.4), respectively. Assume that $u_0 \in W^{2,p}(\Omega)$ for $2 \le p \le \infty$. Then*

$$\|(\nabla u_0 - \Psi^h)\cdot\nu\|_{0,p} \le ch\|u_0\|_{2,p} \quad \forall\, \nu \in \mathbb{R}^2 \text{ with } |\nu| = 1 \tag{5.33}$$

and

$$\|(\nabla u_0 - \Psi^h)\cdot\nu\|_{1,p,h} \le c\|u_0\|_{2,p} \quad \forall\, \nu \in \mathbb{R}^2 \text{ with } |\nu| = 1. \tag{5.34}$$

Proof of (5.33). From the triangular inequality we have

$$\|(\nabla u_0 - \Psi^h)\cdot\nu\|_{0,p} \le \|(\nabla u_0 - \nabla u_0^h)\cdot\nu\|_{0,p} + \|(\nabla u_0^h - \Psi^h)\cdot\nu\|_{0,p}. \tag{5.35}$$

The first term on the right-hand side of (5.35) is estimated by (5.1), while for the second term we use (4.4) to obtain

$$\|(\nabla u_0^h - \Psi^h)\cdot\nu\|_{0,p} \le c \sum_{k\in\{e,w,n,s\}} \|E_k^h(\mu^h - \nabla u_0^h\cdot\eta^k)\|_{0,p}.$$

Consider the case $k = e$ and $\mathcal{Q}_1$ conforming finite elements for approximating u_0; the other cases, i.e., $k \in \{w,n,s\}$ or $\mathcal{P}_1$ conforming finite elements, can be treated similarly. The function $E_e^h(\mu^h - \frac{\partial u_0^h}{\partial x_1})$ is piecewise linear in the x_1 direction and equal to zero for $x_1 \le 1-h$; see the definition of E_e^h in (4.4). Hence, using a discrete Sobolev inequality for trivial extensions we obtain

$$\|E_e^h(\mu^h - \nabla u_0^h\cdot\eta^k)\|_{0,p} \le h^{\frac{1}{p}} \left\|\partial_{x_1}u_0^h - \mu^h\right\|_{0,p,\Gamma_e} \quad \text{if } \ 2 \le p < \infty$$

or

$$\|E_e^h(\mu^h - \nabla u_0^h\cdot\eta^k)\|_{0,\infty} \le \left\|\partial_{x_1}u_0^h - \mu^h\right\|_{0,\infty,\Gamma_e} \quad \text{if } \ p = \infty.$$

Case $2 \le p < \infty$. The triangular inequality gives

$$\left\|\partial_{x_1}u_0^h - \mu^h\right\|_{0,p,\Gamma_e} \le \left\|\partial_{x_1}u_0^h - \partial_{x_1}u_0\right\|_{0,p,\Gamma_e} + \left\|\partial_{x_1}u_0 - \mu^h\right\|_{0,p,\Gamma_e}. \tag{5.36}$$

In order to estimate the first term on the right-hand side of (5.36), let K be an element of $\mathcal{T}_h(\Omega)$ containing an edge $E \subset \Gamma_k$. Applying a trace theorem we have

$$\begin{aligned}&\left\|\partial_{x_1}u_0^h - \partial_{x_1}u_0\right\|_{0,p,E}\\ &\qquad \le c\left(h^{-1}\left\|\partial_{x_1}u_0^h - \partial_{x_1}u_0\right\|_{0,p,K}^p + h^{p-1}\|\partial_{x_1}u_0^h - \partial_{x_1}u_0\|_{1,p,K}^p\right)^{\frac{1}{p}}.\end{aligned} \tag{5.37}$$

From (5.37), (5.1), and (5.3) we obtain

$$\left\|\partial_{x_1}u_0^h - \partial_{x_1}u_0\right\|_{0,p,\Gamma_e} \le ch^{1-\frac{1}{p}}\|u_0\|_{2,p}. \tag{5.38}$$

We now estimate the second term on the right-hand side of (5.36). Let $\lambda = A\nabla u_0 \cdot \eta$, and let λ_h and μ_h be defined by (4.2) and (4.3), respectively. Using that the tangential derivative of u_0 vanishes on $\partial\Omega$, we obtain

$$\partial_{x_1} u_0 - \mu^h = A_{11}(\lambda - \lambda^h). \tag{5.39}$$

Hence, from (5.20) we have

$$\|\partial_{x_1} u_0 - \mu^h\|_{0,p,\Gamma_e} \leq A_{11}\|\lambda - \lambda^h\|_{0,p,\Gamma_e} \leq ch^{1-\frac{1}{p}}\|u_0\|_{2,p}. \tag{5.40}$$

From (5.36), (5.38), and (5.40) we obtain

$$\|E_e(\mu^h - \nabla u_0^h \cdot \eta^e)\|_{0,p} \leq ch\|u_0\|_{2,p},$$

and thus the estimate (5.33) holds for $2 \leq p \leq \infty$.

Case $p = \infty$. We have

$$\left\|\partial_{x_1} u_0^h - \mu^h\right\|_{0,\infty,\Gamma_e} \leq \|\partial_{x_1} u_0^h - \partial_{x_1} u_0\|_{0,\infty,\Gamma_e} + \|\partial_{x_1} u_0 - \mu^h\|_{0,\infty,\Gamma_e},$$

and applying (5.1), (5.39), and (5.20) we have

$$\left\|\partial_{x_1} u_0 - \mu^h\right\|_{0,\infty,\Gamma_e} \leq ch\|u_0\|_{2,\infty}.$$

Hence, estimate (5.33) follows for $p = \infty$.

Proof of (5.34). We have

$$\begin{aligned}\|(\nabla u_0^h - \Psi^h)\cdot\nu\|_{0,p} &\leq c\|(\nabla u_0 - \Psi^h)\cdot\nu\|_{0,p} + \|(\nabla u_0 - \nabla u_0^h)\cdot\nu\|_{0,p} \\ &\leq ch\|u_0\|_{2,p} \quad \text{by (5.1) and (5.33)},\end{aligned} \tag{5.41}$$

and from an inverse inequality (see Lemma 4.5.3 in [12]) it follows that

$$\|(\nabla u_0^h - \Psi^h)\cdot\nu\|_{1,p,h} \leq c\|u_0\|_{2,p}. \tag{5.42}$$

Since

$$\|(\nabla u_0 - \Psi^h)\cdot\nu\|_{1,p,h} \leq c\left(\|(\nabla u_0^h - \nabla u_0)\cdot\nu\|_{1,p,h} + \|(\nabla u_0^h - \Psi^h)\cdot\nu\|_{1,p,h}\right),$$

we obtain (5.34) from (5.3) and (5.42). ∎

The following proposition is required in the proofs of Theorems 5.1 and 5.2.

PROPOSITION 5.1. *Let u_1 and u_1^h be defined by* (2.5) *and* (4.5)*, respectively. Assume that $u_0 \in W^{2,p}(\Omega)$ and $\chi^j \in W^{1,q}_{per}(Y)$ for $\frac{1}{p} + \frac{1}{q} \leq \frac{1}{2}$ and $2 \leq p, q \leq \infty$. Then there exists a constant c independent of ϵ and h such that*

$$|u_1 - u_1^h|_{1,h} \leq c\left(\frac{h^2}{\epsilon^2} + 1\right)^{1/2} \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p} \tag{5.43}$$

and

$$\|u_1 - u_1^h\|_0 \leq ch \max_j \|\chi^j\|_{1,q,Y}\|u_0\|_{2,p}. \tag{5.44}$$

Proof of (5.43). We have

(5.45)

$$\begin{aligned}&|u_1 - u_1^h|_{1,h}^2 \\ &\leq 2\sum_{K\in\mathcal{T}_h(\Omega)}\int_K \sum_{i\in 1,2}((\partial_{x_j} u_0 - \Psi_j^h)\partial_{x_i}\chi^j(\cdot/\epsilon))^2 + (\chi^j(\cdot/\epsilon)\cdot\partial_{x_i}(\partial_{x_j} u_0 - \Psi_j^h))^2 dx.\end{aligned}$$

For the first term on the right-hand side of (5.45) we have

$$\sum_{K\in\mathcal{T}_h(\Omega)}\int_K((\partial_{x_j}u_0-\Psi_j^h)\partial_{x_i}\chi^j(\cdot/\epsilon))^2dx \le |\partial_{x_j}u_0-\Psi_j^h|_{0,p}^2\|\partial_{x_i}\chi^j(\cdot/\epsilon)\|_{0,q}^2$$

$$\le \epsilon^{-2}|\partial_{x_j}u_0-\Psi_j^h|_{0,p}^2\|\chi^j\|_{1,q,Y}^2 \le c\epsilon^{-2}h^2\|u_0\|_{2,p}^2\|\chi^j\|_{1,q,Y}^2, \tag{5.46}$$

where we have used (5.33) to obtain (5.46).

For the second term on the right-hand side of (5.45) we use Hölder's inequality to obtain $\|\chi^j\partial_{x_i}(\partial_{x_j}u_0-\Psi_j^h)\|_0^2 \le \|\chi^j\|_{0,q}^2|\partial_{x_j}u_0-\Psi_j^h|_{1,p,h}^2$.

Proof of (5.44). This proof follows from a direct application of Hölder's inequality and the approximation error estimate (5.33). ∎

The next proposition is required in the proofs of Theorems 5.1 and 5.2.

PROPOSITION 5.2. *Let $\tilde{\phi}_\epsilon$ and $\tilde{\phi}_\epsilon^h$ be defined by* (2.14) *and* (4.6)*, respectively. Let the functions v_k be defined as in subsection* 2.2.1*. Assume that $u_0 \in W^{2,p}(\Omega)$ and $v_k \in W^{1,\tilde{q}}(G_k)$ for $\frac{1}{p}+\frac{1}{\tilde{q}} \le \frac{1}{2}$ and $2 \le p,\tilde{q} \le \infty$. Then*

$$|\tilde{\phi}_\epsilon-\tilde{\phi}_\epsilon^h|_{1,h} \le c\left(\frac{h^2}{\epsilon^2}+1\right)^{\frac{1}{2}}\max_k\|v_k\|_{1,\tilde{q},G_k}\|u_0\|_{2,p} \tag{5.47}$$

and

$$\|\tilde{\phi}_\epsilon-\tilde{\phi}_\epsilon^h\|_0 \le ch\max_k\|v_k-\chi_k^*\|_{0,\tilde{q},G_k}\|u_0\|_{2,p}. \tag{5.48}$$

Proof. From the definition of $\tilde{\phi}_\epsilon$ and $\tilde{\phi}_\epsilon^h$ we have

$$|\tilde{\phi}_\epsilon-\tilde{\phi}_\epsilon^h|_{1,h} \le \sum_{k\in\{e,w,n,s\}}|\tilde{\phi}_\epsilon^k-\tilde{\phi}_\epsilon^{k,h}|_{1,h},$$

and using the arguments similar to the ones given in the proof of Proposition 5.1, the proof follows. ∎

We now prove the last proposition used in the proof of Theorems 5.1 and 5.2.

PROPOSITION 5.3. *Let $\bar{\phi}$ and $\bar{\phi}^h$ be defined by* (2.15) *and* (4.7)*, respectively, and assume that $u_0 \in H^2(\Omega)$. Then we have*

$$\|\bar{\phi}-\bar{\phi}^h\|_1 \le c\|u_0\|_2 \tag{5.49}$$

and

$$\|\bar{\phi}-\bar{\phi}^h\|_0 \le ch\|u_0\|_2. \tag{5.50}$$

Proof of (5.49). Consider the triangular inequality

$$\|\bar{\phi}-\bar{\phi}^h\|_1 \le \|\bar{\phi}^h-\psi\|_1+\|\bar{\phi}-\psi\|_1,$$

where $\psi \in H^1(\Omega)$ is defined as the weak solution of

$$-\nabla\cdot A\nabla\psi = 0 \ \text{ in } \ \Omega \quad \text{and} \quad \psi = \chi^*\mu^h \ \text{ on } \ \partial\Omega. \tag{5.51}$$

We note that problem (5.51) is well defined since $\chi^*\mu^h \in H^{1/2}(\partial\Omega)$; see Remark 4.1. From regularity theory, (5.18), (5.39), and Remark 2.1 we have the following estimate:

$$\|\psi\|_1 \le \sum_k c\|\chi^*\mu^h\|_{H_{00}^{1/2}(\Gamma_k)} \le c\|u_0\|_2. \tag{5.52}$$

Note also that $\chi^* \mu^h$ belongs to Y^h. Hence, by using (5.52) and standard finite element analysis for conforming finite element discretizations we obtain

$$|\bar{\phi}^h - \psi|_1 \leq c \|u_0\|_2.$$

Finally, from regularity theory, (5.39), and (5.20) we obtain

$$\begin{aligned} |\bar{\phi} - \psi|_1 &\leq \|\chi^* \mu^h - \chi^* \partial_\eta u_0\|_{H^{1/2}(\partial\Omega)} \\ &\leq \sum_k \|\chi^* \mu^h - \chi^* \partial_\eta u_0\|_{H_{00}^{1/2}(\Gamma_k)} \leq c \|u_0\|_2. \end{aligned}$$

Proof of (5.50). From the triangular inequality

$$\|\bar{\phi} - \bar{\phi}^h\|_0 \leq c \|\bar{\phi} - \psi\|_0 + \|\bar{\phi}^h - \psi\|_0,$$

and from standard finite element analysis and (5.52) we obtain

$$\|\bar{\phi}^h - \psi\|_0 \leq ch \|\psi\|_1 \leq ch \|u_0\|_2.$$

Finally, from Theorem 6.1 in [38], (5.39), and (5.19) we obtain

$$\begin{aligned} \|\bar{\phi} - \psi\|_0 &\leq c \left(\sum_k \|\chi^* \partial_\eta u_0 - \chi^* \mu^h\|^2_{H^{-1/2}(\Gamma_k)} \right)^{1/2} \\ &\leq ch \|u_0\|_2 \quad \text{by (5.19).} \end{aligned}$$

∎

Finally, we prove Theorems 5.1 and 5.2.

THEOREM 5.1. *Assume the same conditions of Theorem* 3.1*, and let* u_ϵ *be defined by* (4.8)*. Then there exists a constant* c *independent of* ϵ*,* u_0*, and* h *such that*

$$|u_\epsilon - u_\epsilon^h|_{1,h} \leq c(h + \epsilon^{1+\hat{\delta}}) \|u_0\|_{2,p} \tag{5.53}$$

and

$$\|u_\epsilon - u_\epsilon^h\|_0 \leq c(h^2 + \epsilon^{1+\hat{\delta}}) \|u_0\|_{2,p}. \tag{5.54}$$

Proof. From the triangular inequality we have

$$\begin{aligned} |u_\epsilon - u_\epsilon^h|_{1,h} \leq |u_\epsilon - u_0 - u_1 - \phi_\epsilon|_1 + |u_0 - u_0^h|_1 + \epsilon |u_1 - u_1^h|_{1,h} \\ + \epsilon |\tilde{\phi}_\epsilon - \tilde{\phi}_\epsilon^h|_{1,h} + \epsilon |\bar{\phi} - \bar{\phi}^h|_1, \end{aligned}$$

and (5.53) follows from Theorem 3.1, the approximation error (5.1), and Propositions 5.1, 5.2, and 5.3. Using similar arguments and (5.2) the estimate (5.54) follows. ∎

THEOREM 5.2. *Assume the same conditions of Theorem* 3.2*, and let* u_ϵ *be defined by* (4.8)*. Then there exists a constant* c *independent of* ϵ*,* u_0*, and* h *such that*

$$\|u_\epsilon - u_\epsilon^h\|_0 \leq c(h^2 + \epsilon^{\frac{3}{2}} + \epsilon h) \|u_0\|_{3,p}.$$

Proof. Repeat the proof of Theorem 5.1 and use Theorem 3.2. ∎

6. Numerical results. The objective of this section is to compare the difference between u_ϵ and u_ϵ^h on the L^2-norm and on the broken H^1-semi-norm. We note, however, that an explicit formula for u_ϵ is not known; hence, we replace u_ϵ by a regular $\mathcal{P}_1$ conforming finite element solution of the problem (1.1) on a very fine uniform mesh of size h_f; denote this numerical solution by u_ϵ^*.

We note that we have assumed in sections 4 and 5 that the cell and boundary layer problems were solved exactly in order to define χ, A, v_k, and χ^*. In [44, 46] we have developed an accurate numerical algorithm for approximating these values and, as a result, the errors between u_ϵ^h and u_ϵ^* do not depend on whether the approximated or the exact values were used or not. We now describe how to approximate χ, A, v_k, χ^*, and $\tilde{\phi}_\epsilon$ and display only the changes that should be made in the algorithm in section 4 in order to obtain the numerical results of this section.

- Replace χ^j by the finite element solution of the problem (2.2) using a $\mathcal{P}_1$ or $\mathcal{Q}_1$ conforming finite element method on a partition $\mathcal{T}_{\hat{h}}(Y)$.
- Replace A_{ij} by $\frac{1}{|Y|}\int_Y a_{lm}(y)\frac{\partial}{\partial y_l}(y_i-\chi^i)\frac{\partial}{\partial y_m}(y_j-\chi^j)dy$; see (2.3).
- Let τ be a positive integer and $G_e^\tau = \{y \in \mathbb{R}^2;\ -\tau \le y_1 \le 0 \text{ and } 0 \le y_2 \le 1\}$. Using a $\mathcal{P}_1$ or $\mathcal{Q}_1$ conforming finite element, replace v_e by the finite element solution associated to the following problem:

$$\begin{aligned}
&-\nabla_y \cdot a(y)\nabla_y v_e = 0 \ \text{ in } \ G_e^\tau,\\
&v_e(y) = \chi^1(1/\epsilon, y_2) \ \text{ on } \ \{y \in G_e^\tau, y_1 = 0\},\\
&\partial_\eta v_e = 0 \ \text{ on } \{y \in G_e^\tau;\ y_1 = -\tau\},\\
&\text{and } v_e(y_1, 0) = v_k(y_1, 1) \ \text{ for } \ -\tau \le y_1 \le 0,
\end{aligned}$$

and replace χ_e^* by $\int_0^1 v_e(-\tau, y_2)dy_2$. We replace $\tilde{\phi}_\epsilon^e$ by

$$\tilde{\phi}_\epsilon^e(x_1,x_2) = \begin{cases} \left(v_e\left(\frac{x_1-1}{\epsilon}, \frac{x_2}{\epsilon}\right) - \chi_e^*\right)\Psi^h & \text{if } \ x_1 > 1-\epsilon\tau,\\ 0 & \text{otherwise.}\end{cases}$$

The other cases $k \in \{w, n, s\}$ are treated similarly.

In the numerical experiments we use a $\mathcal{P}_1$ conforming finite element with a uniform mesh $\hat{h} = \frac{1}{128}$ and $\tau = 2$.

For the first test of experiments we consider a smooth coefficient $a(y_1, y_2)$ case (see [26]) where

$$a(y) = \left(\frac{2+1.8\sin(2\pi y_1)}{2+1.8\cos(2\pi y_2)} + \frac{2+\sin(2\pi y_2)}{2+1.8\sin(2\pi y_1)}\right) I_{2\times 2} \ \text{ and } \ f(x) = -1.$$

Table 6.1 shows the errors between u_ϵ^* and u_ϵ^h. We see that for $\epsilon << h$ the errors are of order h^2 and h on the L^2-norm and the on broken H^1-semi-norm, respectively. We can see that when we fix h and decrease ϵ the errors then change very little. This is evidence that the dominant error is related to h, not to ϵ. Also, looking at the diagonal values of Table 6.1 we see that the numerical errors are in agreement with the theoretical convergent rates of Theorems 5.1 and 5.2.

Table 6.2 shows the level of approximation when each term of $u_\epsilon = u_0^h + \epsilon u_1^h + \epsilon\bar{\phi}^h + \epsilon\tilde{\phi}_\epsilon^h$ is taken into account separately. We can see that the numerical boundary layer treatment $\bar{\phi}^h$ is very effective on the L_2-norm rather than on the broken H^1-semi-norm. The improvement on the L^2-norm is evidence that we were able to obtain, through the proper calculation of χ^*, the L^2 asymptotic behavior of the boundary corrector θ_ϵ in the interior of the domain Ω. We also see from Table 6.2 that the

TABLE 6.1

1/64	0.0086	0.0045	0.0026

Although the convergence analysis presented here is not intended for the quasi-periodic case $a_{ij}(x, x/\epsilon)$, the numerical approximation presented here can be generalized for this case. This would be done by approximating the matrix $a(x, x/\epsilon)$ by $\sum_{K_j \in \mathcal{T}_h(\Omega)} a_j(x/\epsilon) I_{K_j}(x)$, where $a_j(x/\epsilon) = \frac{1}{|K_j|} \int_{z \in K_j} a_j(z, x/\epsilon) dz$, and I_{K_j} is the characteristic function of K_j. In such case, it is required to solve a cell problem for each element K_j.

7. Conclusions. We perform the convergence analysis for the proposed numerical method for approximating the solution of (1.1). The error estimates obtained in the numerical experiments agree with the theoretical error estimates from Theorems 5.1 and 5.2. The numerical method presented here is strongly based on the periodicity of the coefficients a_{ij} and on the construction of computable boundary correctors.

For this reason the method has relative low computational cost with optimal error convergence rates.

We generalize results in the literature for estimating the error between u_ϵ and its first and second order asymptotic expansion under weak assumptions on the regularity of the solutions of the cell problems and the homogenized equation. We also develop and analyze constructive boundary correctors. Such analysis permits us to develop finite element error estimates with very weak assumptions on the regularity of $a(y)$, including composite materials applications.

RECOVERY ALGORITHMS FOR VECTOR-VALUED DATA WITH JOINT SPARSITY CONSTRAINTS*

MASSIMO FORNASIER† AND HOLGER RAUHUT‡

Abstract. Vector-valued data appearing in concrete applications often possess sparse expansions with respect to a preassigned frame for each vector component individually. Additionally, different components may also exhibit common sparsity patterns. Recently, there were introduced sparsity measures that take into account such joint sparsity patterns, promoting coupling of nonvanishing components. These measures are typically constructed as weighted ℓ_1 norms of componentwise ℓ_q norms of frame coefficients. We show how to compute solutions of linear inverse problems with such joint sparsity regularization constraints by fast thresholded Landweber algorithms. Next we discuss the adaptive choice of suitable weights appearing in the definition of sparsity measures. The weights are interpreted as indicators of the sparsity pattern and are iteratively updated after each new application of the thresholded Landweber algorithm. The resulting two-step algorithm is interpreted as a double-minimization scheme for a suitable target functional. We show its ℓ_2-norm convergence. An implementable version of the algorithm is also formulated, and its norm convergence is proven. Numerical experiments in color image restoration are presented.

Key words. linear inverse problems, joint sparsity, thresholded Landweber iterations, curvelets, subdifferential inclusion, color image reconstruction

1. Introduction. Inverse problems.

We address the problem of recovering an element u of a Hilbert space $\mathcal{K}$ from the observed datum $g = Tu$ in the Hilbert space $\mathcal{H}$, where $T : \mathcal{K} \to \mathcal{H}$ is a bounded linear operator, possibly noninvertible or with an unbounded inverse. A simple approach to this problem is to minimize the discrepancy

$$\mathcal{T}(u) := \|Tu - g|\mathcal{H}\|^2.$$

If $\ker(T) = \{0\}$, then there exists a unique solution given by $u^* = (T^*T)^{-1}T^*g$. However, if T has an unbounded inverse, i.e., $(T^*T)^{-1}$ is unbounded, then this approach is very unstable.

Thus, if T is noninvertible or has an unbounded inverse (or an inverse with a high norm), one has to take into account further features of the expected solution. Indeed, a well-known way out is to consider the regularized problem [26]

$$u_\alpha^* := \operatorname{argmin}_{u\in\mathcal{K}} \mathcal{T}(u) + \alpha\|u|\mathcal{K}\|^2,$$

for which the corresponding solution operator $T_\alpha^\dagger : g \mapsto u_\alpha^*$ is bounded. Unfortunately, the minimal norm constraint is often not appropriate. A recent approach is

to substitute this particular constraint with a more general one

$$u_\Phi^* := \operatorname{argmin}_{u \in \mathcal{K}} \mathcal{T}(u) + \Phi(u),$$

where Φ is a suitable *sparsity measure*.

Sparse frame expansions. A *sparse representation* of an element of a Hilbert space is a series expansion with respect to orthonormal bases or a frame that has only a small number of large coefficients. Several types of signals appearing in nature admit sparse frame expansions, and thus, sparsity is a realistic assumption for a very large class of problems. For instance, images are well-represented by sparse expansions with respect to wavelets or curvelets, while for audio signals a Gabor frame is a good choice.

Sparsity has already had a long history of successes. The design of frames for sparse representations of digital signals has led to extremely efficient compression methods, such as JPEG2000 and MP3 [34]. Successively a new generation of optimal numerical schemes has been developed for the computation of sparse solutions of differential and integral equations, exploiting adaptive and greedy strategies [12, 39, 14, 15]. The use of sparsity in inverse problems for data recovery has been the most recent step of this long career of "simplifying and understanding complexity," with an enormous potential in applications [2, 17, 18, 20, 22, 21, 36, 40, 10, 13, 16]. Another field, which has gained much attention recently, is the observation that it is possible to reconstruct sparse signals from vastly incomplete information [6, 9, 23, 33, 37]. This line of research is called sparse recovery or compressed sensing.

From sparsity to joint sparsity. Most of the contributions appearing in the literature are addressed to the recovery of sparse scalar functions. Multichannel signals (i.e., vector-valued functions) appearing in concrete applications may not only possess sparse frame expansions for each channel individually, but additionally the different channels can also exhibit common sparsity patterns. Recently, new sparsity measures have been introduced that promote such coupling of the nonvanishing components through different channels [3, 30, 41]. These measures are typically constructed as *weighted* ℓ_1 norms of channel ℓ_q norms, with $q > 1$. We will use this concept for the solution of vector-valued inverse problems and combine it with another approach further promoting the coupling of sparsity patterns along channels. We note that sparse recovery of vector-valued signals was already investigated in [2], although joint sparsity was not considered in that work.

Our main results. We show how to compute solutions of linear inverse problems with joint sparsity regularization constraints by fast thresholded Landweber algorithms, similar to those presented in [17, 36, 40]. We discuss the adaptive choice of suitable *weights* appearing in the definition of the sparsity measures. The *weights* are interpreted as indicators of the sparsity pattern and are iteratively updated after each new application of the thresholded Landweber algorithm. The resulting two-step algorithm is interpreted as a double-minimization scheme for a suitable target functional. We prove that our algorithm converges to its minimizer. Since the functional is not smooth, this is done by subdifferential inclusions [38]. We prove that the thresholded Landweber algorithm, which constitutes the inner iteration of the double-minimization algorithm, converges linearly. The second step of the double-minimization has actually a simple explicit solution. Finally, we show that the full exact double-minimization scheme converges linearly, and we provide an implementable version which is also ensured to converge.

Morphological analysis of signals and sparsity patterns. The use of sparseness measures not only allows one to reconstruct a signal. At the same time it gives information about (joint) sparsity patterns which may encode morphological features of the signal. Well-known examples are the microlocal analysis properties of wavelets [31, 32] for singularity and regularity detection and the characterization of edges and curves by curvelets for natural images [8]. For instance, the weight sequences appearing in the sparsity measures we define, and interpret as indicators of the sparsity pattern, play a similar role as the discontinuity set is playing in the Mumford–Shah functional [35]. In fact, it is well known that wavelet or curvelet coefficients have high absolute values at high scales as soon as we are in the neighborhood of discontinuities. Even more illuminating and suggestive is the parallel between the sparsity measure and its indicator weights with the Ambrosio–Tortorelli [1] approximation of the Mumford–Shah functional. Here the discontinuity set is indicated by an auxiliary function, which is 1 where the image is smooth and 0 where edges and discontinuities are detected.

Joint sparsity patterns of vector-valued (i.e., multichannel) signals encode even finer properties of the morphology which do not belong only to one channel but are a common feature of all of the channels. Here the parallel is with generalizations of the Mumford–Shah functional as appearing, for example, in [5], where polyconvex functions of gradients couple discontinuity sets through different color channels of images.

Applications. We expect that our scheme can be applied in several different contexts. In this paper we limit ourselves to an application in color image reconstruction, modeling a real-world problem in art restoration. Indeed, color images have the advantage of being nontrivial multivariate and multichannel signals, exhibiting a very rich morphology and structure. In particular, discontinuities (jump sets) may appear in all of the channels at the same locations, which will be reflected in their curvelet representation (for instance). For these reasons, color images are a good model to test the effectiveness of our scheme promoting joint sparsity, also because the solution can be easily checked just by a visual analysis. Of course, the range of applicability of our approach is not limited to color image restoration. Neuroimaging (functional magnetic resonance imaging, magnetoencephalography), distributed compressed sensing [3], and several other problems with coupled vector-valued solutions are fields where we expect that our scheme can be fruitfully used. The numerical solution of differential and integral operator equations can also be addressed within this framework, and we refer, for example, to [14, 39, 15] for implementations by adaptive strategies.

Content of the paper. The paper is organized as follows. In section 2 we introduce the mathematical setting. We formulate our model of joint sparsity for multichannel signals and the corresponding functional to be minimized in order to solve a given linear inverse problem. The functional depends on two variables. The first belongs to the space of signals to be reconstructed; the second belongs to the space of sparsity indicator weights. Convexity properties of the functional are discussed. Section 3 is dedicated to the formulation of the double-minimization algorithm and to its weak convergence. The scheme is based on alternating minimizations in the first and in the second variable individually. In section 4 we discuss an efficient thresholded Landweber algorithm for the minimization with respect to the first variable. Its strong convergence is shown following the analysis in [17]. The minimization with respect to the second variable has an explicit solution, and no elaboration is needed. We provide an implementable version of the full scheme in section 5. To prove its convergence we

develop an error analysis. As a byproduct of the results in this section we show that the double-minimization scheme converges strongly. In section 6 we present an application in color image reconstruction. Numerical experiments are shown and discussed.

2. The functional.

2.1. Notation. Before starting our discussion let us briefly introduce some of the spaces we will use in the following. For some countable index set Λ we denote by $\ell_p = \ell_p(\Lambda)$, $1 \le p \le \infty$, the space of real sequences $u = (u_\lambda)_{\lambda\in\Lambda}$ with norm

$$\|u\|_p \;=\; \|u|\ell_p\| \;:=\; \left(\sum_{\lambda\in\Lambda} |u_\lambda|^p\right)^{1/p}, \quad 1 \le p < \infty,$$

and $\|u\|_\infty := \sup_{\lambda\in\Lambda} |u_\lambda|$ as usual. If (v_λ) is a sequence of positive weights, then we define the weighted spaces $\ell_{p,v} = \ell_{p,v}(\Lambda) = \{u, (u_\lambda v_\lambda) \in \ell_p(\Lambda)\}$ with norm

$$\|u\|_{p,v} \;=\; \|u|\ell_{p,v}\| \;=\; \|(u_\lambda v_\lambda)\|_p \;=\; \left(\sum_{\lambda\in\Lambda} v_\lambda^p |u_\lambda|^p)\right)^{1/p}$$

(with obvious modification for $p = \infty$). If the entries u_λ are actually vectors in a Banach space X with norm $\|\cdot\|_X$, then we denote

$$\ell_{p,v}(\Lambda, X) \;:=\; \{(u_\lambda)_{\lambda\in\Lambda}, u_\lambda \in X, (\|u_\lambda\|_X)_{\lambda\in\Lambda} \in \ell_{p,v}(\Lambda)\},$$

with norm $\|u|\ell_{p,v}(\Lambda, X)\| = \|(\|u_\lambda\|_X)_{\lambda\in\Lambda}|\ell_{p,v}(\Lambda)\|$. Usually X will be $\mathbb{R}^M$ endowed with the Euclidean norm or the M-dimensional space ℓ_q^M, i.e., $\mathbb{R}^M$ endowed with the ℓ_q norm. By $\mathbb{R}_+$ we denote the nonnegative real numbers.

2.2. Inverse problems with joint sparsity constraints. Let $\mathcal{K}$ and $\mathcal{H}_j$, $j = 1, \dots, N$, be (separable) Hilbert spaces and $A_{\ell,j} : \mathcal{K} \to \mathcal{H}_j$, $j = 1, \dots, M$, $\ell = 1, \dots, N$, some bounded linear operators. Assume we are given data $g_j \in \mathcal{H}_j$,

$$g_j \;=\; \sum_{\ell=1}^{M} A_{\ell,j} f_\ell, \quad j = 1, \dots, N.$$

Then our basic task consists in reconstructing the (unknown) elements $f_\ell \in \mathcal{K}$, $\ell = 1, \dots, M$.

In practice, it happens that the corresponding mapping from the vector (f_ℓ) to the vector (g_j) is not invertible or ill-conditioned. Moreover, the data g_j, $j = 1, \dots, N$, are often corrupted by noise. Thus, in order to deal with our reconstruction problem we have to regularize it.

Our basic assumption throughout this paper will be that the "channels" f_ℓ, $\ell = 1, \dots, M$, are correlated by means of joint sparsity patterns. Our aim is to model the joint sparsity within a regularization term. In the following we develop this idea.

For the sake of short notation we resume the data vector into

$$g \;=\; (g_j)_{j=1,\dots,N} \in \mathcal{H} := \bigoplus_{j=1}^{N} \mathcal{H}_j,$$

where the Hilbert space $\mathcal{H}$ is equipped with the usual inner product $\langle \sum_j g_j, \sum_j h_j \rangle := \sum_j \langle g_j, h_j \rangle$, with $g_j, h_j \in \mathcal{H}_j$. We also combine the operators $A_{\ell,j}$ into one operator

$$A : \bigoplus_{\ell=1}^{M} \mathcal{K} \to \mathcal{H}, \quad A(f_\ell)_{\ell=1}^M \;=\; \left(\sum_{\ell=1}^{M} A_{\ell,j} f_\ell\right)_{j=1}^{N}.$$

In order to exploit sparsity ideas we assume that we have given a suitable frame $\{\psi_\lambda : \lambda \in \Lambda\} \subset \mathcal{K}$ indexed by a countable set Λ. This means that there exist constants $C_1, C_2 > 0$ such that

$$C_1\|f\|_{\mathcal{K}}^2 \le \sum_{\lambda\in\Lambda} |\langle f, \psi_\lambda\rangle|^2 \le C_2\|f\|_{\mathcal{K}}^2 \qquad \text{for all } f \in \mathcal{K}. \tag{2.1}$$

Orthonormal bases are particular examples of frames. Frames allow for a (stable) series expansion of any $f \in \mathcal{K}$ of the form

$$f \;=\; Fu \;:=\; \sum_{\lambda\in\Lambda} u_\lambda \psi_\lambda, \tag{2.2}$$

where $u = (u_\lambda)_{\lambda\in\Lambda} \in \ell_2(\Lambda)$. The linear operator $F : \ell_2(\Lambda) \to \mathcal{K}$ is called the *synthesis map* in frame theory. It is bounded due to the frame inequality (2.1). In contrast to orthonormal bases, the coefficients u_λ need not be unique, in general. For more information on frames we refer to [11].

A main assumption here is that the f_ℓ to be reconstructed are sparse with respect to the frame $\{\psi_\lambda\}$. This means that f_ℓ can be well-approximated by a series of the form (2.2) with only a small number of nonvanishing coefficients u_λ. This can be modeled by assuming that the sequence u is contained in a (weighted) $\ell_1(\Lambda)$ space. Indeed, the minimization of the $\ell_1(\Lambda)$ norm promotes that only a few entries are nonzero. Taking, for instance, a wavelet frame and a suitable weight, the ℓ_1 constraint implies that the element to be reconstructed lies in a certain Besov space $B^s_{1,1}$; see [17].

Analogously as in [17] such considerations lead to the regularized functional

$$\begin{aligned}\mathcal{J}(u) &= \|g - Tu|\mathcal{H}\|^2 + \|u|\ell_{1,v}(\Lambda^M)\| \\ &= \sum_{j=1}^{N} \left\| g_j - \sum_{\ell=1}^{M} A_{\ell,j} F u^\ell \right\|_{\mathcal{H}_j}^2 + \sum_{\ell=1}^{M}\sum_{\lambda\in\Lambda} v_\lambda |u_\lambda^\ell|,\end{aligned} \tag{2.3}$$

which has to be minimized with respect to the vector of coefficients $u = (u_\lambda^\ell)_{\lambda\in\Lambda}^{\ell=1,\dots,M}$. The $\ell_{1,v}$ norm in this functional clearly represents the regularization term. The numbers v_λ, $\lambda \in \Lambda$, are some suitable positive weights. Once the minimizer $u = (u_\lambda^\ell)$ is determined, we obtain a reconstruction of the vectors of interest by means of $f_\ell = Fu^\ell = \sum_\lambda u_\lambda^\ell \psi_\lambda$. The algorithm in [17] can be taken to perform the minimization with respect to u.

The functional $\mathcal{J}(u)$ in the form stated, however, does not necessarily model any correlation between the vectors (channels) f_ℓ, $\ell = 1, \dots, M$. A way to incorporate such correlation is the assumption of joint sparsity; see also [30, 41]. By this we mean that the pattern of nonzero coefficients representing f_ℓ is (approximately) the same for all of the channels. In other words, for some *finite* set of indexes $\Lambda_0 \subset \Lambda$ and for all $\ell = 1, \dots, N$ there is an expansion

$$f_\ell \;\approx\; \sum_{\lambda\in\Lambda_0} u_\lambda^\ell \psi_\lambda.$$

In particular, the *same* Λ_0 can be chosen for all f_ℓ's.

We propose two approaches (that can be combined) to model joint sparsity. The first one assumes that the mixed norm

$$\|u|\ell_{1,v}(\Lambda,\ell_q^M)\| \,=\, \sum_{\lambda\in\Lambda} v_\lambda \|u_\lambda\|_q$$

of $u=(u_\lambda^\ell)$ is small. Here u_λ denotes the vector $(u_\lambda^{(\ell)})_{\ell=1}^M$ in $\mathbb{R}^M$. (Recall also that ℓ_q^M denotes $\mathbb{R}^M$ endowed with the ℓ_q norm). Here $q>1$ and, in particular, $q=2$ or $q=\infty$ represent the interesting cases, since for $q=1$ the above norm reduces to the usual weighted $\ell_{1,v}$ norm. In fact if q is large and some $|u_\lambda^\ell|$ is large, then the channel entries $|u_\lambda^{\ell'}|$ are also allowed to be large for $\ell'\neq\ell$, without increasing significantly the norm $\|u_\lambda|\ell_q^M\|$. The minimization of the above norm promotes that all entries of the "interchannel" vector u_λ may become significant, once at least one of the components $|u_\lambda^\ell|$ is large.

Introduce the operators $T_{\ell,j}=A_{\ell,j}F:\ell_2(\Lambda)\to\mathcal{H}_\ell$ and

$$T:\ell_2(\Lambda,\mathbb{R}^M)\to\mathcal{H},\quad Tu \,=\, \left(\sum_{\ell=1}^M T_{\ell,j}u^\ell\right)_{j=1}^N \,=\, \left(\sum_{\ell=1}^M A_{\ell,j}Fu^\ell\right)_{j=1}^N.$$

The above reasoning leads to the functional

$$\begin{aligned} K(u) \,=\, K_v^{(q)}(u) \,&:=\, \|Tu-g|\mathcal{H}\|^2+\|u|\ell_{1,v}(\Lambda,\ell_q^M)\| \\ &=\, \sum_{j=1}^N \left\|\sum_{\ell=1}^M T_{\ell,j}u^\ell-g_j\right\|_{\mathcal{H}_j}^2+\sum_{\lambda\in\Lambda} v_\lambda\|u_\lambda\|_q \end{aligned} \tag{2.4}$$

to be minimized with respect to u. In section 4 we will develop an iterative thresholding algorithm similar as in [17] to perform this minimization.

The second approach to support joint sparsity is to encode the joint sparsity information in some sort of indicator function. This can in fact be done by using the weight (v_λ) as a second minimization variable. To this end we add an additional term to the original functional (2.3), punishing small values of v_λ. We obtain the functional

$$J_0(u,v) \,:=\, J_{\theta,\rho,0}^{(1)}(u,v) \,:=\, \|Tu-g|\mathcal{H}\|^2+\sum_{\lambda\in\Lambda} v_\lambda\|u_\lambda\|_1+\sum_\lambda \theta_\lambda(\rho_\lambda-v_\lambda)^2$$

restricted to $v_\lambda\geq 0$. Here $(\theta_\lambda)_\lambda$ and $(\rho_\lambda)_\lambda$ are some suitable positive sequences.

Now the task is to minimize $J_0(u,v)$ jointly with respect to both u and v. (Again, once this minimizer is determined we obtain $f_\ell=Fu^\ell$). Analyzing $J_0(u,v)$ we realize that for the minimizer (u,v) we will have $v_\lambda=0$ (or close to 0) if $\|u_\lambda\|_1=\sum_{\ell=1}^M|u_\lambda^\ell|$ is large so that $v_\lambda\|u_\lambda\|_1$ becomes small. On the other hand, if $\|u_\lambda\|_1$ is small, then the term $\theta_\lambda(\rho_\lambda-v_\lambda)$ dominates and forces v_λ to be close to ρ_λ. Thus, v_λ serves indeed as an indicator of large values of $\|u_\lambda\|_1$. It has the effect that, if v_λ is chosen small due to one large u_λ^ℓ, then also the other coefficients $u_\lambda^{\ell'}$, $\ell'\neq\ell$, can be chosen large without making the functional considerably bigger.

Unfortunately, in contrast to the previous functionals, $J(u,v)$ as stated above is no longer jointly convex in (u,v) in general (although it is convex as a functional of u and of v alone). Thus, it cannot be ensured that a local minimum of the functional will be a global one, a property that is very crucial for an efficient minimization method.

To overcome this problem we may add an additional suitable quadratic term. Moreover, we can, of course, combine the second approach with the first one and use an ℓ_q norm instead of an ℓ_1 norm for the interchannel vectors u_λ. This leads to the most general form of the regularized functional considered in this paper:

$$J(u,v) = J^{(q)}_{\theta,\rho,\omega}(u,v) \tag{2.5}$$

$$:= \|Tu - g|\mathcal{H}\|^2 + \sum_{\lambda\in\Lambda} v_\lambda \|u_\lambda\|_q + \sum_{\lambda\in\Lambda} \omega_\lambda \|u_\lambda\|_2^2 + \sum_{\lambda\in\Lambda} \theta_\lambda(\rho_\lambda - v_\lambda)^2.$$

Here ω_λ is a suitably chosen sequence of positive numbers, and $1 \le q \le \infty$.

We will provide a sufficient condition depending on θ_λ and ρ_λ in the next subsection ensuring the strict joint convexity of $J(u,v)$ in (u,v). Although there is an extra term, $J(u,v)$ has similar properties as $J_0(u,v)$. In particular, v can still be seen as a sort of indicator function.

Observe that in the minimum we will always have $0 \le v_\lambda \le \rho_\lambda$. Therefore, we can assume the domain of J to be $\ell_2(\Lambda,\mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)_+$, where $\ell_{\infty,\rho^{-1}}(\Lambda)_+$ denotes the (convex) cone of all nonnegative sequences $(v_\lambda) \in \ell_{\infty,\rho^{-1}}(\Lambda)$.

Our main contribution consists in providing an algorithm for the minimization of $J(u,v)$. It consists in alternately minimizing with respect to u and with respect v. The minimization with respect to v can be done explicitly. For the minimization with respect to u we propose an efficient iterative algorithm.

We will mainly study the problem in the real-valued case. The complex-valued case can be treated with the same methods (in principle) by observing that $\mathbb{C}^M$ is isomorphic to $\mathbb{R}^{2M}$, so passing from M complex-valued channels to $2M$ real-valued channels. We note, however, that slight complications may arise from the fact that an ℓ_q norm on $\mathbb{C}^M$ is not isometric to an ℓ_q norm on $\mathbb{R}^{2M}$ if $q \ne 2$. (In particular, the thresholding operator on $\mathbb{C}^M$ for $q = \infty$ will have a different form than the one provided in the next section for the real-valued case.)

Remark. In [2] Anthoine considered a similar functional as in (2.3) for multichannel signals,

$$\mathcal{J}'_v(u) \;=\; \|Tu - g|\mathcal{H}\|^2 + \sum_{\ell=1}^{M} \sum_{\lambda\in\Lambda} v_\lambda^\ell |u_\lambda|^{p_\ell},$$

with $1 \le p_\ell \le 2$ for $\ell = 1,\dots,M$. Clearly, the generalization consists in the latter exponents p_ℓ. An algorithm for the minimization of $\mathcal{J}'$ was developed in [2]. However, Anthoine's functional does not promote joint sparsity like our functionals in (2.4) or (2.5), since the penalty term decouples with respect to the channels u^ℓ, $\ell = 1,\dots,M$.

2.3. Convexity of the functional J. At several places in the following it will be convenient to write

$$J(u,v) \;=\; \mathcal{T}(u) + \Phi^{(q)}(u,v), \tag{2.6}$$

where

$$\mathcal{T}(u) \;=\; \|Tu-g\|_{\mathcal{H}}^2 \;=\; \sum_{j=1}^{N}\left\|\sum_{\ell=1}^{M} T_{\ell,j}u^{\ell}-g_j\right\|_{\mathcal{H}_j}^2,$$

$$\begin{aligned}\Phi^{(q)}(u,v) \;&=\; \sum_{\lambda\in\Lambda} v_\lambda\|u_\lambda\|_q+\sum_{\lambda\in\Lambda}\omega_\lambda\|u_\lambda\|_2^2+\sum_{\lambda\in\Lambda}\theta_\lambda(\rho_\lambda-v_\lambda)^2\\ &=\; \|(v_\lambda\|u_\lambda\|_q)_{\lambda\in\Lambda}\|_1+\left\|u|\ell_{2,\omega^{1/2}}(\Lambda,\ell_2^M)\right\|^2+\|\rho-v|\ell_{2,\theta^{1/2}}(\Lambda)\|^2\end{aligned}$$

are the discrepancy with respect to the data and the joint sparsity measure, respectively.

Also it is useful to observe that $\Phi^{(q)}$ decouples with respect to λ, i.e.,

$$\Phi^{(q)}(u,v) \;=\; \sum_{\lambda\in\Lambda}\Phi_\lambda^{(q)}(u_\lambda,v_\lambda), \tag{2.7}$$

where

$$\begin{aligned}\Phi_\lambda^{(q)}(x,y) \;&=\; y\|x\|_q+\omega_\lambda\|x\|_2^2+\theta_\lambda(\rho_\lambda-y)^2\\ &=\; y\left(\sum_{\ell=1}^{M}|x_\ell|^q\right)^{1/q}+\omega_\lambda\sum_{\ell=1}^{M}x_\ell^2+\theta_\lambda(\rho_\lambda-y)^2,\qquad x\in\mathbb{R}^M,y\geq 0\end{aligned} \tag{2.8}$$

(with the usual modification for $q=\infty$).

In the following we give necessary and sufficient conditions for the (strict) convexity of the functional $\Phi^{(q)}$ for the most interesting cases $q=1,2,\infty$. These imply sufficient conditions for the (strict) convexity of $J=J_{\theta,\rho,\omega}^{(q)}$.

PROPOSITION 2.1. *Let $q\in\{1,2,\infty\}$. The sparsity measure $\Phi^{(q)}$ is convex if and only if $\omega_\lambda\theta_\lambda\geq\frac{\kappa_q}{4}$ for all $\lambda\in\Lambda$, where $\kappa_1=M$ and $\kappa_2=\kappa_\infty=1$. In particular, if $\omega_\lambda\theta_\lambda\geq\frac{\kappa_q}{4}$ for all $\lambda\in\Lambda$, then J is convex. In the case of a strict inequality $\omega_\lambda\theta_\lambda>\frac{\kappa_q}{4}$ we can replace "convexity" by "strict convexity" in all of these statements.*

Proof. It is easy to see that $\Phi^{(q)}$ is (strictly) convex if and only if all of the $\Phi_\lambda^{(q)}$, $\lambda\in\Lambda$, are (strictly) convex.

Let us first consider $q=1$. Observe that we can write $\Phi_\lambda^{(1)}(x,y)=\sum_{\ell=1}^{M}F_\lambda^{(1)}(x_\ell,y)$, with

$$\begin{aligned}F_\lambda^{(1)}(z,y) \;&=\; y|z|+\omega_\lambda|z|^2+M^{-1}\theta_\lambda(\rho_\lambda-y)^2\\ &=\; \left(y|z|+\omega_\lambda|z|^2+M^{-1}\theta_\lambda y^2\right)+M^{-1}\theta_\lambda\left(\rho_\lambda^2-2\rho_\lambda y\right),\quad z\in\mathbb{R},y\geq 0.\end{aligned} \tag{2.9}$$

The function in the second bracket is obviously linear and hence convex. The function in the first bracket can be written as the composition $G_\lambda\circ L$, with $L(z,y)=(|z|,y)$ and

$$G_\lambda(z,y) \;=\; yz+\omega_\lambda z^2+M^{-1}\theta_\lambda y^2 \;=\; \frac{1}{2}(z,y)\,H^{(1)}\,(z,y)^T,\qquad z,y\in\mathbb{R},$$

where

$$H^{(1)} \;=\; \begin{pmatrix}2\omega_\lambda & 1\\ 1 & 2\theta_\lambda M^{-1}\end{pmatrix}.$$

Since L is convex and has range $\mathbb{R}^2_+$, and G_λ is monotonically increasing in each coordinate on $\mathbb{R}^2_+$, it suffices to show that $G_\lambda(z,y)$ is convex if and only if $\theta_\lambda\omega_\lambda \geq M/4$; see, e.g., [4, p. 86]. The convexity of G_λ is equivalent to $H^{(1)}$ being positive semidefinite. The latter is clearly equivalent to $\theta_\lambda\omega_\lambda \geq M/4$. Strict convexity is equivalent to a strict inequality $\theta_\lambda\omega_\lambda > M/4$.

Now let $q = 2$. Observe that $\Phi^{(2)}_\lambda = F^{(2)}_\lambda \circ L^{(2)}$, where $L^{(2)} : \mathbb{R}^M \times \mathbb{R}_+ \to \mathbb{R}^2_+$, $L^{(2)}(x,y) = (\|x\|_2, y)$, and

$$F^{(2)}_\lambda(z,y) = yz + \omega_\lambda z^2 + \theta_\lambda(\rho_\lambda - y)^2 \tag{2.10}$$
$$= \frac{1}{2}(z,y)\, H^{(2)}\, (z,y)^T + \theta_\lambda(\rho_\lambda^2 - 2\rho_\lambda y), \quad z,y \in \mathbb{R},$$

with

$$H^{(2)} = \begin{pmatrix} 2\omega_\lambda & 1 \\ 1 & 2\theta_\lambda \end{pmatrix}.$$

By a similar argument as above, $\Phi^{(2)}_\lambda$ is convex if and only if $H^{(2)}$ is positive semidefinite. The latter is the case if and only if $\omega_\lambda\theta_\lambda \geq 1/4$, and a strict convexity is equivalent to a strict inequality.

Finally, let $q = \infty$. Observe that

$$\Phi^{(\infty)}_\lambda(x,y) = \max_{\ell=1,\dots,M} \left\{ y|x_\ell| + \omega_\lambda \sum_{m=1}^{M} |x_m|^2 + \theta_\lambda(\rho_\lambda - y)^2 \right\}.$$

Since $\Phi^{(\infty)}_\lambda$ is the pointwise maximum of M functions, it is sufficient (see [4, p. 80]) to investigate the (strict) convexity of each of the functions

$$f_{\lambda,\ell}(x,y) = yx_\ell + \omega_\lambda \sum_{m=1}^{M} (x_m)^2 + \theta_\lambda(\rho_\lambda - y)^2$$
$$= \frac{1}{2}(y,x)\, H^{(\infty)}_\ell\, (y,x)^T + \theta_\lambda(\rho_\lambda^2 - 2y\rho_\lambda), \quad x \in \mathbb{R}^M, y \geq 0,$$

with

$$H^{(\infty)}_\ell = \begin{pmatrix} 2\omega_\lambda & 0 & \cdots & 0 & \delta_{1,\ell} \\ 0 & 2\omega_\lambda & \cdots & 0 & \delta_{2,\ell} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 2\omega_\lambda & \delta_{M,\ell} \\ \delta_{1,\ell} & \delta_{2,\ell} & \cdots & \delta_{M,\ell} & 2\theta_\lambda \end{pmatrix}.$$

One can show by induction that

$$\det(H^{(\infty)}_\ell) = 2^{M-1}\omega_\lambda^{M-1}(4\theta_\lambda\omega_\lambda - 1).$$

Thus, $H^{(\infty)}_\ell$ is positive semidefinite if and only if $\theta_\lambda\omega_\lambda \geq 1/4$, and the convexity of $\Phi^{(q)}_\lambda$ is equivalent to the latter condition. Once again the strict convexity is equivalent to the strict inequality. □

We do not pursue the task to obtain conditions for the convexity of $\Phi^{(q)}$ and J for general $q \neq 1, 2, \infty$ but rather assume that $\Phi^{(q)}$ and hence J are always convex also in this case.

3. The minimizing algorithm and its convergence. In this section we propose and analyze an algorithm for the computation of the minimizer (u^*, v^*) of the functional $J(u,v) = J^{(q)}_{\theta,\rho,\omega}(u,v)$ defined in (2.5). The algorithm consists in alternating a minimization with respect to u and a minimization with respect to v. More formally, for an arbitrary choice $v^{(0)}$, for example, $v^{(0)} = (\rho_\lambda)_{\lambda\in\Lambda}$, we define

$$\begin{aligned} u^{(n)} &:= \arg\min_{u\in\ell_2(\Lambda,\mathbb{R}^M)} J(u, v^{(n-1)}), \\ v^{(n)} &:= \arg\min_{v\in\ell_{\infty,\rho^{-1}}(\Lambda)_+} J(u^{(n)}, v). \end{aligned} \tag{3.1}$$

The minimization of $J(u, v^{(n-1)})$ with respect to u can be done by means of the iterative thresholding algorithm that we will study in the next section. The minimizer $v^{(n)}$ of $J(u^{(n)}, v)$ for fixed $u^{(n)}$ can be computed explicitly. Indeed, it follows from elementary calculus that

$$v^{(n)}_\lambda = \begin{cases} \rho_\lambda - \frac{1}{2\theta_\lambda}\|u^{(n)}{}_\lambda\|_q & \text{if } \|u^{(n)}{}_\lambda\|_q < 2\theta_\lambda\rho_\lambda, \\ 0 & \text{otherwise.} \end{cases} \tag{3.2}$$

We have the following result about the convergence of the above algorithm.

THEOREM 3.1. *Let $1 \le q \le \infty$, and assume that $\Phi^{(q)}$ and hence J are strictly convex (see also Proposition 2.1). Moreover, we assume that $\ell_{2,\omega^{1/2}}(\Lambda,\mathbb{R}^M)$ is embedded into $\ell_2(\Lambda,\mathbb{R}^M)$, i.e., $\omega_\lambda \ge \gamma > 0$ for all $\lambda\in\Lambda$. Then the sequence $(u^{(n)}, v^{(n)})_{n\in\mathbb{N}}$ converges to the unique minimizer $(u^*, v^*) \in \ell_2(\Lambda,\mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)_+$ of J. The convergence of $u^{(n)}$ is weak in $\ell_2(\Lambda,\mathbb{R}^M)$ and that of $v^{(n)}$ holds componentwise.*

For the most interesting cases $q \in \{1, 2, \infty\}$, if in addition $\theta_\lambda\omega_\lambda \ge \sigma > \kappa_q/4$ for all $\lambda\in\Lambda$, where $\kappa_1 = M$ and $\kappa_2 = \kappa_\infty = 1$, then the convergence of $u^{(n)}$ to u^* is also strong in $\ell_2(\Lambda,\mathbb{R}^M)$ and $v^{(n)} - v^*$ converges to 0 strongly in $\ell_{2,\theta}(\Lambda)$.

The rest of the section will be spent with the proof of the weak convergence of the algorithm. The strong convergence and the full proof of the Theorem 3.1 will be established only in section 5.3 later.

3.1. Subdifferential calculus. A main tool in the analysis of nonsmooth functionals and their minima is the concept of subdifferential. Recall that, for a convex functional F on some Banach space V, its subdifferential $\partial F(x)$ at a point $x \in V$, with $F(x) < \infty$, is defined as the set

$$\partial F(x) = \{x^* \in V^*, x^*(z-x) + F(x) \le F(z) \text{ for all } z \in V\},$$

where V^* denotes the dual space of V. It is obvious from this definition that $0 \in \partial F(x)$ if and only if x is a minimizer of F. In the following, we investigate the subdifferential of J. In order to have J defined on the whole Banach space $\ell_2(\Lambda,\mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)$ rather than just for positive v_λ's (which is needed to use subdifferentials), we simply extend $J(u,v)$ by

$$J(u,v) = \infty \qquad \text{if } v_\lambda < 0 \text{ for some } \lambda\in\Lambda$$

as usual. This extension preserves convexity and does not change the minimizer.

Recall that J can be written as $J(u,v) = \mathcal{T}(u) + \Phi^{(q)}(u,v)$; see (2.6). Since both $\mathcal{T}$ and $\Phi^{(q)}$ are convex we have (see, e.g., [24, Proposition 5.6])

$$\partial J(u,v) = \partial\mathcal{T}(u) \times \{0\} + \partial\Phi^{(q)}(u,v). \tag{3.3}$$

Concerning the subdifferential of $\mathcal{T}$ we have the following result.

LEMMA 3.2. *The subdifferential of* $\mathcal{T}$ *at* $u \in \ell_2(\Lambda, \mathbb{R}^M)$ *consists of one element:*

$$\partial\mathcal{T}(u) = \{2T^*(Tu - g)\}.$$

Proof. Since $\mathcal{T}$ is convex and Gateaux-differentiable, by Proposition 5.3 [24] we have $\partial\mathcal{T}(u) = \{\mathcal{T}'(u)\}$, where its Gateaux derivative is characterized by $\langle \mathcal{T}'(u), z\rangle = \lim_{h\to 0^+} \frac{\mathcal{T}(u+hz)-\mathcal{T}(u)}{h}$ for all $z \in \ell_2(\Lambda, \mathbb{R}^M)$. It is straightforward to check that the Gateaux derivative of a functional of the type $u \to \|Tu - g\|^2$ (with linear T) at u applied on z is given by $2\langle Tu-g, Tz\rangle = 2\langle T^*(Tu-g), z\rangle$. This proves the claim. ∎

Let us now consider the subdifferential of $\partial\Phi^{(q)}(u, v)$. Recall its domain $\ell_2(\Lambda, \mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)$. Since the dual of $\ell_{\infty,\rho^{-1}}$ is a bit inconvenient to handle, we restrict the subdifferential to the predual $\ell_{1,\rho}$. This will be enough for our purposes. Moreover, recall that $\Phi^{(q)}$ decouples into a sum of functionals $\Phi_\lambda^{(q)}$ depending on only (u_λ, v_λ); see (2.7). It is straightforward to show the following lemma.

LEMMA 3.3. *The subdifferential of* $\Phi^{(q)}$ *at a point* $(u, v) \in \ell_2(\Lambda, \mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)$, *with* $\Phi^{(q)}(u, v) < \infty$, *satisfies*

$$\begin{aligned} D\Phi^{(q)}(u, v) &:= \partial\Phi^{(q)}(u, v) \cap (\ell_2(\Lambda, \mathbb{R}^M) \times \ell_{1,\rho}(\Lambda)) \\ &= \{(\xi, \eta) \in \ell_2(\Lambda, \mathbb{R}^M) \times \ell_{1,\rho}(\Lambda) : \ (\xi_\lambda, \eta_\lambda) \in \partial\Phi_\lambda^{(q)}(u_\lambda, v_\lambda) \text{ for all } \lambda \in \Lambda\}. \end{aligned}$$

We are left with investigating the subdifferential of the functional $\Phi_\lambda^{(q)}$ defined in (2.8). Similarly as J we extend it to $\mathbb{R}^M \times \mathbb{R}$ by $\Phi_\lambda^{(q)}(x, y) = \infty$ for $y < 0$.

LEMMA 3.4. *Let* $1 \le q \le \infty$. *Assume that* $\Phi_\lambda^{(q)}$ *is convex (see also Proposition* 2.1*). Then for* $(x, y) \in \mathbb{R}^M \times \mathbb{R}_+$ *we have*

$$\begin{aligned} \partial\Phi_\lambda^{(q)}(x, y) = \{(\xi, \eta) \in \mathbb{R}^M \times \mathbb{R} : \ &\xi \in y\partial\|\cdot\|_q(x) + 2\omega_\lambda x, \\ &\eta \in \|x\|_q \partial s^+(y) + 2\theta_\lambda(y - \rho_\lambda)\}, \end{aligned} \tag{3.4}$$

where $s^+(y) := y$ *for* $y \ge 0$ *and* $s^+(y) = \infty$ *for* $y < 0$. *In particular,* $\partial s^+(y) = \{1\}$ *for* $y > 0$ *and* $\partial s^+(0) = (-\infty, 1]$.

Remark. We recall that the subdifferential of the q norm on $\mathbb{R}^M$ is given as follows. If $1 < q < \infty$, then

$$\partial\|\cdot\|_q(x) = \begin{cases} B^{q'}(1) & \text{if } x = 0, \\ \left\{ \left(\frac{|x_\ell|^{q-1}\operatorname{sign}(x_\ell)}{\|x\|_q^{q-1}} \right)_{\ell=1}^M \right\} & \text{otherwise,} \end{cases}$$

where $B^{q'}(1)$ denotes the ball of radius 1 in the dual norm, i.e., in $\ell_{q'}^M$ with $1/q + 1/q' = 1$.

If $q = 1$, then

$$\partial\|\cdot\|_1(x) = \{\xi \in \mathbb{R}^M : \ \xi_\ell \in \partial|\cdot|(x_\ell), \ell = 1, \dots, M\}, \tag{3.5}$$

where $\partial|\cdot|(z) = \{\operatorname{sign}(z)\}$ if $z \neq 0$ and $\partial|\cdot|(0) = [-1, 1]$.

If $q = \infty$, then

$$\partial\|\cdot\|_\infty(x) = \begin{cases} B^1(1) & \text{if } x = 0, \\ \operatorname{conv}\{(\operatorname{sign}(x_\ell))e_\ell : |x_\ell| = \|x\|_\infty\} & \text{otherwise,} \end{cases} \tag{3.6}$$

where conv A denotes the convex hull of a set A and e_ℓ the ℓth canonical unit vector in $\mathbb{R}^M$.

Proof. Recall that

$$\Phi_\lambda^{(q)}(x,y) \;=\; s^+(y)\|x\|_q + \omega_\lambda \|x\|_2^2 + \theta_\lambda(\rho_\lambda - y)^2.$$

Let $y \geq 0$ so that $\Phi_\lambda^{(q)}(x,y)$ is finite. The subdifferential $\partial(\Phi_\lambda^{(q)})_x(x,y)$ of $\Phi^{(q)}(x,y)$ considered as a function of x alone (i.e., for fixed y) is clearly given by

$$\partial(\Phi_\lambda^{(q)})_x(x,y) \;=\; y\partial\|\cdot\|_q(x) + 2\omega_\lambda x, \tag{3.7}$$

while keeping x fixed gives

$$\partial(\Phi_\lambda^{(q)})_y(x,y) \;=\; \partial s^+(y)\|x\|_q + 2\theta_\lambda(y-\rho_\lambda).$$

This shows the inclusion "$\subset$" in (3.4). Moreover, for all of the points $(x,y) \in \mathbb{R}^M \times \mathbb{R}_+$ where $\Phi_\lambda^{(q)}$ is differentiable we even have equality in (3.4) since $\Phi_\lambda^{(q)}$ is convex, and, thus, all of the subdifferentials appearing consist of precisely one point, i.e., the usual gradient.

Let $1 < q < \infty$. Then for $x \neq 0$, $y > 0$ the differentiability assumption is clearly satisfied. For the other cases $x = 0$ or $y = 0$ we note that by convexity of $\Phi_\lambda^{(q)}$ we have (see [38, Corollary 10.11])

$$\partial(\Phi_\lambda^{(q)})_x(x,y) \;=\; \{\xi : \exists \eta \text{ such that } (\xi,\eta) \in \partial\Phi_\lambda^{(q)}(x,y)\} \tag{3.8}$$

and the corresponding relation for $\partial(\Phi_\lambda^{(q)})_y(x,y)$. Now, if $y > 0$, then $\Phi_\lambda^{(q)}(x,y)$ is differentiable with respect to y, and thus, η in the right-hand side of (3.8) is unique; indeed $\eta = \eta_0 := \frac{\partial}{\partial y}\Phi_\lambda^{(q)}(x,y)$. We conclude that for $y > 0$

$$\partial(\Phi_\lambda^{(q)})(x,y) = \{(\xi,\eta_0), \xi \in \partial(\Phi_\lambda^{(q)})_x(x,y)\}.$$

In particular this holds for $x = 0$, even for general $1 \leq q \leq \infty$. The same argument applies for the case $y = 0$ and $x \neq 0$ (and $1 < q < \infty$), which shows (3.4) in these cases. Now let $x = 0$ and $y = 0$. Then the right-hand side of (3.4) contains precisely one point, i.e., $(\xi,\eta) = (0, -2\theta_\lambda\rho_\lambda)$. Since the subdifferential $\Phi_\lambda^{(q)}(0,0)$ contains at least one point by convexity, it must coincide with (ξ,η) by the trivial inclusion $\subset$. (It is easy to check also directly that $(0,-2\theta_\lambda\rho_\lambda) \in \Phi_\lambda^{(q)}(0,0)$.) Note that this argument applies also for $q = 1, \infty$.

It remains to treat the cases $q = 1, \infty$ with $x \neq 0$ and arbitrary $y \geq 0$. Let us start with $q = 1$. In the proof of Proposition 2.1 it was noted that

$$\Phi_\lambda^{(1)}(x,y) \;=\; \sum_{\ell=1}^M F_\lambda^{(1)}(x_\ell, y),$$

with $F_\lambda^{(1)} : \mathbb{R}^2 \to \mathbb{R}$ defined in (2.9). The subdifferential of F_λ can be obtained in the same way as above (expressing, e.g., formally the modulus as a 2-norm on $\mathbb{R}^1$). For $(z,y) \in \mathbb{R} \times \mathbb{R}_+$ this yields

$$\partial F_\lambda^{(1)}(z,y) \;=\; \{(\tau,\eta) :\; \tau \in y\partial|\cdot|(z) + 2\omega_\lambda z, \eta \in |z|\partial s^+(y) + 2M^{-1}\theta_\lambda(y-\rho_\lambda)\}.$$

By convexity we have

$$\partial\Phi_\lambda^{(1)}(x,y) \;=\; \sum_{\ell=1}^{M} \Big\{ (e_\ell z_\ell, \eta) :\; (z_\ell,\eta) \in \partial F_\lambda^{(1)}(x_\ell, y) \Big\},$$

where e_ℓ denotes the ℓth unit vector in $\mathbb{R}^M$. By the explicit form of the subdifferential of the ℓ_1 norm (3.5), this gives (3.4) for $q = 1$.

Finally, let $q = \infty$. Similarly as in the proof of Proposition 2.1 we write

$$\Phi_\lambda^{(\infty)}(x,y) \;=\; \max_{\ell=1,\dots,M} F_\ell(x,y),$$

with

$$F_\ell(x,y) \;=\; y|x_\ell| + \omega_\lambda \|x\|_2^2 + \theta_\lambda(\rho_\lambda - y)^2.$$

If $x_\ell \neq 0$, then $F_\ell(x,y)$ is differentiable with respect to x and

$$\partial F_\ell(x,y) \;=\; \{(\xi,\eta) : \xi \;=\; y\,\mathrm{sign}(x_\ell) e_\ell + 2\omega_\lambda x,\; \eta \in \partial s^+(y)|x_\ell| + 2\theta_\lambda(y-\rho_\lambda)\},$$

where e_ℓ denotes the ℓth canonical unit vector in $\mathbb{R}^M$. This even holds for $y = 0$ by an analogous argument as above; see (3.8). The subdifferential of $\Phi_\lambda^{(\infty)}(x,y)$ for $x \neq 0$ is then given by (see, e.g., [38, Exercise 8.31])

$$\partial\Phi_\lambda^{(\infty)}(x,y) \;=\; \mathrm{conv}\{\partial F_\ell(x,y) : F_\ell(x,y) \;=\; \max_{m=1,\dots,M} F_m(x,y)\}.$$

Since $x \neq 0$, we have $x_\ell \neq 0$ if $|x_\ell| = \|x\|_\infty$, and the latter is the case if and only if $F_\ell(x,y) = \max_m F_m(x,y)$. Thus, we obtain

$$\begin{aligned}
&\partial\Phi_\lambda^{(\infty)}(x,y) \\
&\quad= \mathrm{conv} \bigcup_{\ell:|x_\ell|=\|x\|_\infty} \{(\xi,\eta) : \xi = y\,\mathrm{sign}(x_\ell)e_\ell + 2\omega_\lambda x, \eta \in \partial s^+(y)|x_\ell| + 2\theta_\lambda(y-\rho_\lambda)\} \\
&\quad= \{(\xi,\eta) : \xi \in \mathrm{conv}\{y\,\mathrm{sign}(x_\ell)e_\ell, |x_\ell| = \|x\|_\infty\} + 2\omega_\lambda x, \\
&\qquad \eta \in \|x\|_\infty \partial s^+(y) + 2\theta_\lambda(y-\rho_\lambda)\big\}.
\end{aligned}$$

By the characterization of the subdifferential of the ∞ norm in (3.6), we obtain the claimed equality in (3.4) for $q = \infty$ and $x \neq 0$. This finishes the proof. ∎

Combining the previous lemmas we obtain the following result.

PROPOSITION 3.5. *Let $1 \le q \le \infty$. Assume that $\Phi^{(q)}$ is convex, and let $(u,v) \in \ell_2(\Lambda,\mathbb{R}^M) \times \ell_{\infty,\rho^{-1}}(\Lambda)$ such that $\Phi^{(q)}(u,v) < \infty$. Then we have*

$$\begin{aligned}
D\Phi^{(q)}(u,v) = \{&(\xi,\eta) \in \ell_2(\Lambda,\mathbb{R}^M) \times \ell_{1,\rho}(\Lambda), \\
&\xi_\lambda \in v_\lambda \partial \|\cdot\|_q(u_\lambda) + 2\omega_\lambda u_\lambda, \\
&\eta_\lambda \in \|u_\lambda\|_q \partial s^+(v_\lambda) + 2\theta_\lambda(v_\lambda - \rho_\lambda), \lambda \in \Lambda\} \\
&\subset \partial\Phi^{(q)}(u,v)
\end{aligned} \tag{3.9}$$

and

$$\begin{aligned}
DJ(u,v) &= \partial J(u,v) \cap \big(\ell_2(\Lambda,\mathbb{R}^M) \times \ell_{1,\rho}(\Lambda)\big) \\
&= (2T^*(Tu-g),0) + D\Phi_\lambda^{(q)}(u,v) \;\subset\; \partial J(u,v).
\end{aligned}$$

3.2. Weak convergence of the double minimization. Before we actually start proving the weak convergence of the algorithm in (3.1) we recall the following definition [38].

DEFINITION 3.6. *Let V be a topological space and $\mathcal{A} = (A_n)_{n\in\mathbb{N}}$ a sequence of subsets of V. The subset $A \subseteq V$ is called the* limit of the sequence $\mathcal{A}$*, and we write $A = \lim_n A_n$, if*

$$A = \{a \in V : \exists a_n \in A_n, a = \lim_n a_n\}.$$

The following observation will be useful for us; see, e.g., [38, Proposition 8.7].

LEMMA 3.7. *Assume that Γ is a convex function on $\mathbb{R}^M$ and $(x_n) \subset \mathbb{R}^M$ a convergent sequence with limit x such that $\Gamma(x_n), \Gamma(x) < \infty$. Then the subdifferentials satisfy*

$$\lim_n \partial\Gamma(x_n) \subseteq \partial\Gamma(x).$$

In other words, the subdifferential $\partial\Gamma$ of a convex function is an outer semicontinuous set-valued function.

In the following we agree on the convention that the upper index n at $u^{(n)} \in \ell_2(\Lambda, \mathbb{R}^M)$ always denotes the nth iterate, and $u_\lambda^{(n)} \in \mathbb{R}^M$ denotes the (vector-valued) entry at λ of the nth iterate. In the following proof we will never refer to the ℓth component of the M-dimensional vector $u_\lambda^{(n)}$, so hopefully no confusion can arise. Also, we denote by $(DJ(u,v))_\lambda$ the restriction of $DJ(u,v) \subset \ell_2(\Lambda, \mathbb{R}^M) \times \ell_{1,\rho}(\Lambda)$ to the index λ. By the previous section it holds that

$$(DJ(u,v))_\lambda = (2T^*T(u-g))_\lambda, 0) + \partial\Phi_\lambda^{(q)}(u_\lambda, v_\lambda). \tag{3.10}$$

Now the proof is developed as follows. First, we recall that $(u^*, v^*) = \arg\min J(u, v)$ if and only if $0 \in \partial J(u^*, v^*)$. Next, we show that there exist weakly convergent subsequences of $(u^{(n)}, v^{(n)})$ (again denoted by $(u^{(n)}, v^{(n)})$) which converge to $(u^{(\infty)}, v^{(\infty)})$ and that

$$0 \in \lim_n DJ(u^{(n)}, v^{(n)}) \subseteq \partial J(u^{(\infty)}, v^{(\infty)}). \tag{3.11}$$

Due to the strict convexity of J we conclude that $(u^{(\infty)}, v^{(\infty)}) = (u^*, v^*)$. Now let us detail the argument.

By definition of $u^{(n)}$ and $v^{(n)}$ we have

$$\begin{aligned} &J(u^{(n)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \\ &= J(u^{(n)}, v^{(n)}) - J(u^{(n+1)}, v^{(n)}) + J(u^{(n+1)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \geq 0. \end{aligned}$$

Thus, $(J(u^{(n)}, v^{(n)}))_n$ is a nonincreasing sequence, and since $J \geq 0$ this implies that $(J(u^{(n)}, v^{(n)}))_n$ converges. Furthermore, we have

$$J(u^{(n)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \geq J(u^{(n+1)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \geq 0.$$

Observe that

$$\begin{aligned} &J(u^{(n+1)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \\ &= \sum_{\lambda\in\Lambda} \left(v_\lambda^{(n)} \|u_\lambda^{(n+1)}\|_q + \theta_\lambda (v_\lambda^{(n)} - \rho_\lambda)^2 - v_\lambda^{(n+1)} \|u_\lambda^{(n+1)}\|_q - \theta_\lambda (\rho_\lambda - v_\lambda^{(n+1)})^2 \right). \end{aligned}$$

A straightforward computation shows that the terms in the latter sum equal

$$\left(\|u_\lambda^{(n+1)}\|_q - 2\theta_\lambda(\rho_\lambda - v_\lambda^{(n+1)})\right)(v_\lambda^{(n)} - v_\lambda^{(n+1)}) + \theta_\lambda(v_\lambda^{(n)} - v_\lambda^{(n+1)})^2.$$

If $\|u_\lambda^{(n+1)}\|_q < 2\theta_\lambda\rho_\lambda$, then by (3.2) and a simple computation the first term vanishes. If $\|u_\lambda^{(n+1)}\|_q \geq 2\theta_\lambda\rho_\lambda$, then $v_\lambda^{(n+1)} = 0$ and the first term is nonnegative. Altogether, this shows that

$$J(u^{(n)}, v^{(n)}) - J(u^{(n+1)}, v^{(n+1)}) \geq \sum_{\lambda\in\Lambda} \theta_\lambda(v_\lambda^{(n)} - v_\lambda^{(n+1)})^2 \geq \theta_\lambda(v_\lambda^{(n)} - v_\lambda^{(n+1)})^2.$$

As noted above, the term on the left-hand side converges to 0, and since $\theta_\lambda > 0$ we deduce that

$$\lim_{n\to\infty} |v_\lambda^{(n)} - v_\lambda^{(n+1)}| = 0 \quad \text{for all } \lambda \in \Lambda. \tag{3.12}$$

Moreover, we have

$$J(u^{(0)}, v^{(0)}) \geq J(u^{(n)}, v^{(n)}) \geq \sum_{\lambda\in\Lambda} \omega_\lambda \|u_\lambda^{(n)}\|_2^2.$$

Therefore, $(u^{(n)})_n$ is uniformly bounded in $\ell_{2,\omega^{1/2}}(\Lambda, \mathbb{R}^M)$, and thus, there exists a subsequence $(u^{(n_k)})_k$ that converges to $u^{(\infty)} \in \ell_{2,\omega^{1/2}}(\Lambda, \mathbb{R}^M)$ weakly in both $\ell_{2,\omega^{1/2}}(\Lambda, \mathbb{R}^M)$ and $\ell_2(\Lambda, \mathbb{R}^M)$, due to our assumption $\omega_\lambda \geq \gamma > 0$ for all $\lambda \in \Lambda$. For simplicity, let us denote again $u^{(n_k)} = u^{(n)}$.

First of all, observe that weak convergence implies componentwise convergence, so that $u_\lambda^{(n)} \to u_\lambda^{(\infty)}$ and $[T^*Tu^{(n)}]_\lambda \to [T^*Tu^{(\infty)}]_\lambda$ for all $\lambda \in \Lambda$. By the explicit formula (3.2) for $v_\lambda^{(n)}$, this implies that $v^{(n)}$ converges pointwise to the limit

$$v_\lambda^{(\infty)} := \lim_n v_\lambda^{(n)} = \begin{cases} \rho_\lambda - \frac{1}{2\theta_\lambda}\|u^{(\infty)}{}_\lambda\|_q & \text{if } \|u^{(\infty)}{}_\lambda\|_q < 2\theta_\lambda\rho_\lambda, \\ 0 & \text{otherwise.} \end{cases} \tag{3.13}$$

By the definition of $u^{(n)}$ in (3.1), we have $0 \in \partial J_u(u, v^{(n)})$ (where $\partial J_u(u, v)$ denotes the subdifferential of J considered as a functional of u only). This means that

$$0 \in \left[2T^*(Tu^{(n)} - g)\right]_\lambda + v_\lambda^{(n-1)}\partial\|\cdot\|_q(u_\lambda^{(n)}) + 2\omega_\lambda u_\lambda^{(n)} \quad \text{for all } \lambda \in \Lambda$$

(see also Lemma 3.2 and (3.7)); in other words

$$0 = \left[2T^*(Tu^{(n)} - g)\right]_\lambda + v_\lambda^{(n-1)}\zeta_\lambda^{(n)} + 2\omega_\lambda u_\lambda^{(n)} \tag{3.14}$$

for a suitable $\zeta_\lambda^{(n)} \in \partial\|\cdot\|_q(u_\lambda^{(n)})$. Now let $(\xi^{(n)}, \eta^{(n)}) \in DJ(u^{(n)}, v^{(n)})$. Our goal is to show that we can choose $(\xi^{(n)}, \eta^{(n)})$ such that it converges to $(0, 0)$ as $n \to \infty$. By the definition of DJ and by (3.14), we have

$$\begin{aligned} \xi_\lambda^{(n)} &\in [2T^*(Tu^{(n)} - g)]_\lambda + v_\lambda^{(n)}\partial\|\cdot\|_q(u_\lambda^{(n)}) + 2\omega_\lambda u_\lambda^{(n)} \\ &= v_\lambda^{(n)}\partial\|\cdot\|_q(u_\lambda^{(n)}) - v_\lambda^{(n-1)}\zeta_\lambda^{(n)} \end{aligned}$$

for a suitable $\zeta_\lambda^{(n)} \in \partial\|\cdot\|_q(u_\lambda^{(n)})$. By (3.12) it is possible to choose the sequence $\xi^{(n)}$ such that $\lim_{n\to\infty} \xi_\lambda^{(n)} = 0$ for all $\lambda \in \Lambda$. From (3.13) it is straightforward to check that

$$0 \in \partial s^+(v_\lambda^{(\infty)})\|u_\lambda^{(\infty)}\|_q + 2\theta_\lambda(v_\lambda^{(\infty)} - \rho_\lambda) \quad \text{for all } \lambda \in \Lambda, \tag{3.15}$$

and similarly

$$0 \in \partial s^+(v_\lambda^{(n)})\|u_\lambda^{(n)}\|_q + 2\theta_\lambda(v_\lambda^{(n)} - \rho_\lambda).$$

Thus by the definition of $DJ(u^{(n)}, v^{(n)})$, we can choose $\eta^{(n)} = 0$ so that $\lim_n \eta_\lambda^{(n)} = 0$ for all $\lambda \in \Lambda$. Altogether we conclude that $0 \in \lim_n (DJ(u^{(n)}, v^{(n)}))_\lambda$ for all $\lambda \in \Lambda$. By the continuity of T and Lemma 3.7, we conclude that

$$\begin{aligned} 0 &\in \lim_n \left[(2(T^*T(u^{(n)} - g))_\lambda, 0) + \partial\Phi_\lambda^{(q)}(u_\lambda^{(n)}, v_\lambda^{(n)})\right] \\ &\subset (2T^*T(u^{(\infty)} - g)_\lambda, 0) + \partial\Phi_\lambda^{(q)}(u_\lambda^{(\infty)}, v_\lambda^{(\infty)}) = DJ(u^{(\infty)}, v^{(\infty)})_\lambda \end{aligned}$$

for all $\lambda \in \Lambda$. It follows that $0 \in DJ(u^{(\infty)}, v^{(\infty)}) \subset \partial J(u^{(\infty)}, v^{(\infty)})$, the latter inclusion by Proposition 3.5. Hence, by strict convexity $(u^*, v^*) = (u^{(\infty)}, v^{(\infty)})$. With this we have shown the weak convergence of the sequence $u^{(n)}$ to u^*.

To establish the strong convergence we need to develop a more detailed analysis of the minimization of J with respect to u. The next section is devoted to this end, and it will allow us to use some further tools for the full proof of Theorem 3.1 in section 5.3.

4. An iterative thresholding algorithm for the minimization with respect to u. One step of the minimization algorithm in the previous section consists in minimizing $J(u, v) = J_{\theta,\rho,\omega}^{(q)}(u, v)$ for some fixed v. Moreover, keeping v fixed is also interesting on its own—in particular, if one is interested in minimizing the functional $K = K_v^{(q)}$ defined in (4.2). Indeed, for $\omega = 0$ and $\rho = v$ we have $J_{\theta,v,0}^{(q)}(u, v) = K_v^{(q)}(u)$. As we will describe in the following this minimization task can be performed by a thresholded Landweber algorithm similar to the one analyzed by Daubechies, Defrise, and DeMol in [17].

With v fixed our task is equivalent to minimizing

$$K(u) = K_{v,\omega}^{(q)} := \|Tu - g\|_{\mathcal{H}}^2 + \Psi(u) \tag{4.1}$$

with respect to $u \in \ell_2(\Lambda, \mathbb{R}^M)$, where

$$\Psi(u) := \Psi_{v,\omega}^{(q)}(u) := \sum_{\lambda\in\Lambda} v_\lambda\|u_\lambda\|_q + \sum_{\lambda\in\Lambda} \omega_\lambda\|u_\lambda\|_2^2. \tag{4.2}$$

We assume that T is nonexpansive, i.e., $\|T\| < 1$, which can always be achieved by rescaling. Also we suppose that K is strictly convex. This is ensured if, e.g., the kernel of T is trivial or $\omega_\lambda > 0$ for all $\lambda \in \Lambda$.

We define a surrogate functional by

$$K^s(u, a) := K(u) - \|Tu - Ta\|_{\mathcal{H}}^2 + \|u - a\|_2^2 = \|Tu - g\|_{\mathcal{H}}^2 + \Psi(u) - \|Tu - Ta\|_{\mathcal{H}}^2 + \|u - a\|_2^2.$$

Since $\|T\| < 1$, K^s is also convex; see [17] for a rigorous argument. Now starting with some $u^{(0)} \in \ell_2(\Lambda, \mathbb{R}^M)$ we define a sequence $u^{(m)}$ by

$$u^{(m+1)} = \arg\min_{u\in\ell^2(\Lambda,\mathbb{R}^M)} K^s(u, u^{(m)}).$$

The minimizer of $K^s(u,a)$ (for fixed a) can be determined explicitly as follows. First, we claim that

$$\arg\min_u K^s(u,a) \;=\; U_\Psi(a + T^*(g - Ta)),$$

where the "thresholding" operator U_Ψ is defined as

$$U_\Psi(u) \;:=\; \arg\min_{z\in\ell_2(\Lambda,\mathbb{R}^M)} \|u-z\|_2^2 + \Psi(z). \tag{4.3}$$

Indeed, a direct calculation shows that

$$\begin{aligned} K^s(u,a) &= \|Tu-g\|_{\mathcal{H}}^2 - \|Tu-Ta\|_{\mathcal{H}}^2 + \|u-a\|_2^2 + \Psi(u) \\ &= \|(a+T^*(g-Ta))-u\|_2^2 + \Psi(u) \\ &\quad - \|a+T^*(g-Ta)\|_2^2 + \|g\|_{\mathcal{H}}^2 - \|Ta\|_{\mathcal{H}}^2 + \|a\|_2^2. \end{aligned}$$

Since the last terms (after $\Psi(u)$) do not depend on u, they can be discarded when minimizing with respect to u, and the above claim follows. (The same argument works also for general "sparseness measures" Ψ.) Thus, the iterative algorithm reads

$$u^{(m+1)} \;=\; U_\Psi(u^{(m)} + T^*(g - Tu^{(m)})). \tag{4.4}$$

In the following we give more details about U_Ψ and analyze the convergence of this algorithm.

4.1. The thresholding operator. Let us derive more information about U_Ψ for our specific $\Psi = \Psi_{v,\omega}^{(q)}$ in (4.2). We have the following lemma.

LEMMA 4.1. *Let $1 \le q \le \infty$. It holds that*

$$(U_{v,\omega}^{(q)}(u))_\lambda \;:=\; (U_{\Psi_{v,\omega}^{(q)}}(u))_\lambda \;=\; (1+\omega_\lambda)^{-1} S_{v_\lambda}^{(q)}(u_\lambda),$$

where

$$S_v^{(q)}(x) \;=\; \arg\min_{z\in\mathbb{R}^M} \|z-x\|_2^2 + v\|z\|_q, \quad x\in\mathbb{R}^M. \tag{4.5}$$

Furthermore, $S_v^{(q)}$ is given by

$$S_v^{(q)}(x) \;=\; x - P_{v/2}^{q'}(x), \tag{4.6}$$

where $P_{v/2}^{q'}$ denotes the orthogonal projection onto the norm ball of radius $v/2$ with respect to the dual norm of $\|\cdot\|_q$, i.e., the $\|\cdot\|_{q'}$ norm with q' denoting the dual index, $1/q + 1/q' = 1$. (The analogous result holds also if the norm $\|\cdot\|_q$ is replaced by an arbitrary norm on $\mathbb{R}^M$.)

Proof. For $\Psi_{v,\omega}$ the minimizing problem defining $U_\Psi = U_{v,\omega}^{(q)}$ decouples with respect to $\lambda\in\Lambda$. Thus, we have

$$(U_{v,\omega}^{(q)}(x))_\lambda = \arg\min_{z\in\mathbb{R}^M} \|x_\lambda - z\|_2^2 + \omega_\lambda\|z\|_2^2 + v_\lambda\|z\|_q.$$

If z minimizes the latter term, then necessarily $0 \in 2(1+\omega_\lambda)z - 2x + v_\lambda\partial\|\cdot\|_q(z)$, where $\partial\|\cdot\|_q$ denotes the subdifferential of the q norm. In other words,

$$(1+\omega_\lambda)z - x \in -\frac{v_\lambda}{2}\partial\|\cdot\|_q(z).$$

Since $\|\cdot\|_q$ is 1-homogeneous, we have $\partial\|\cdot\|_q(z) = \partial\|\cdot\|_q((1+\omega_\lambda)z)$. Setting $y = (1+\omega_\lambda)z$ gives $y - x \in -\frac{v_\lambda}{2}\partial\|\cdot\|_q(y)$, which is the above relation for $\omega_\lambda = 0$. From this we deduce the first claim.

Let us show the second claim, i.e., the explicit form of the operator $S_v^{(q)}$. We already know that if z minimizes the left-hand side of (4.5), then $x - z \in \partial\frac{v}{2}\|z\|_q$. Let $\psi(z) = \frac{v}{2}\|z\|_q$ and ψ^* be its Fenchel conjugate function defined by $\psi^*(y) = \sup_x(\langle x, y\rangle - \psi(x))$. It is well known [4, p. 93] that

$$\psi^*(y) \;=\; \chi_{B^{q'}(v/2)}(y) \;:=\; \begin{cases} 0 & \text{if } \|y\|_{q'} \le v/2, \\ \infty & \text{otherwise.} \end{cases}$$

Here $B^{q'}(v/2)$ denotes the norm ball of radius $v/2$ with respect to the dual norm of $\|\cdot\|_q$. It is a standard result (see, e.g., [38, Proposition 11.3], [24, Corollary 5.2]) that $w \in \partial\psi(y)$ if and only if $y \in \partial\psi^*(w)$ yielding $z \in \partial\psi^*(x-z)$ in our case, and hence,

$$x \in x - z + \partial\psi^*(x-z) \;=\; x - z + \partial\chi_{B^{q'}(v/2)}(x-z).$$

Now if $y \in w + \partial\chi_{B^{q'}(v/2)}(w)$, then it is straightforward to see that w must be the orthogonal projection of y onto $B^{q'}(v/2)$, i.e., $w = \arg\min_{w' \in B^{q'}(v/2)} \|w' - y\|_2$; see also [38, Example 10.2 and p. 20]. For our situation this means that $x - z = P_{v/2}^{q'}(x)$, i.e., $z = x - P_{v/2}^{q'}(x)$. This shows the second claim.

Clearly, all arguments work also for a general norm rather than the q norm. ∎

Let us give $S_v^{(q)}$ explicitly for $q = 1, 2, \infty$.

LEMMA 4.2. *Let $x \in \mathbb{R}^M$ and $v \ge 0$.*

(a) *For $q = 1$ we have $S_v^{(1)}(x) = (s_v^{(1)}(x_\ell))_{\ell=1}^M$, where for $y \in \mathbb{R}$*

$$s_v^{(1)}(y) \;=\; \begin{cases} 0 & \text{if } |y| \le \frac{v}{2}, \\ \operatorname{sign}(y)(|y| - \frac{v}{2}) & \text{otherwise.} \end{cases}$$

(b) *For $q = 2$ it holds that*

$$S_v^{(2)}(x) := \begin{cases} 0 & \text{if } \|x\|_2 \le \frac{v}{2}, \\ \frac{(\|x\|_2 - v/2)}{\|x\|_2} x & \text{otherwise.} \end{cases}$$

(c) *Let $q = \infty$. Order the entries of x by magnitude such that $|x_{i_1}| \ge |x_{i_2}| \ge \cdots \ge |x_{i_M}|$.*

1. *If $\|x\|_1 < v/2$, then $S_v^{(\infty)}(x) = 0$.*
2. *Suppose $\|x\|_1 > v/2$. If $|x_{i_2}| < |x_{i_1}| - v/2$, then choose $n = 1$. Otherwise, let $n \in \{2, \dots, M\}$ be the largest index satisfying*

$$|x_{i_n}| \;\ge\; \frac{1}{n-1}\left(\sum_{k=1}^{n-1} |x_{i_k}| - \frac{v}{2}\right). \tag{4.7}$$

Then

$$(S_v^{(\infty)}(x))_{i_j} \;=\; \frac{\operatorname{sign}(x_{i_j})}{n}\left(\sum_{k=1}^{n} |x_{i_k}| - \frac{v}{2}\right), \quad j = 1, \dots, n,$$

$$(S_v^{(\infty)}(x))_{i_j} \;=\; x_{i_j}, \quad j = n+1, \dots, M.$$

Proof. (b) The projection $P^2_{v/2}(x)$ of x onto an ℓ_2 ball of radius $v/2$ is clearly given by

$$P^2_{v/2}(x) \;=\; \begin{cases} x & \text{if } \|x\|_2 \le v/2, \\ \frac{v/2}{\|x\|_2} x & \text{otherwise.} \end{cases}$$

Since by the previous lemma $S^{(2)}_v(x) = x - P^2_{v/2}(x)$, this gives the assertion.

(a) Although this is well known, we give a simple argument. For $q = 1$ the functional in (4.5) defining $S^{(1)}$ decouples, i.e.,

$$S^{(1)}_v(x) \;=\; \arg\min_{z\in\mathbb{R}^M} \sum_{\ell=1}^{M} \left(|z_\ell - x_\ell|^2 + v|z_\ell|\right).$$

Thus, $S^{(1)}_v(x)_\ell = \arg\min_{z_\ell\in\mathbb{R}} |z_\ell - x_\ell|^2 + v|x_\ell|$ for all $\ell = 1,\dots,M$. The latter can be interpreted as the problem for $q = 2$ on $\mathbb{R}^1$, and hence, the assertion follows from (b).

(c) If $\|x\|_1 \le v/2$, then $P^1_{v/2}(x) = x$, and by the previous lemma $S^{(\infty)}_v(x) = x - P^1_{v/2}(x) = 0$. Now assume $\|x\|_1 > v/2$. Let $z = S^{(\infty)}_v(x)$. This is equivalent to 0 being contained in the subdifferential of the functional in (4.5) defining $S^{(\infty)}_v$. This means

$$2(z - x) \in -v\partial\|\cdot\|_\infty(z). \tag{4.8}$$

We recall that the subdifferential of the maximum norm is given by (3.6).

Now assume for the moment that the maximum norm of z is attained in $z_{i_1},\dots,z_{i_n}$. We will later check whether this was really the case. Further, we assume for simplicity that all of the entries $x_{i_1},\dots,x_{i_n}$ are positive. (The other cases can be carried through in the same way.) Then certainly also the numbers $z_{i_1},\dots,z_{i_n}$ are positive, because choosing them with the opposite sign would certainly increase the functional defining $S^{(\infty)}_v$. Then by (3.6) we obtain $2(z_{i_j} - x_{i_j}) = 0$ for the entries z_{i_j} not giving the maximum, i.e., $z_{i_j} = x_{i_j}, j = n+1,\dots,M$.

Moreover, if $n = 1$ (i.e., the maximum norm of z is attained at only one entry), then $2(z_{i_1} - x_{i_1}) = -v$; in other words, $z_{i_1} = x_{i_1} - v/2$. Thus, the initial hypothesis that the maximum norm of z is attained only at z_{i_1} is true if and only if the second largest entry x_{i_2} satisfies $|x_{i_2}| < |x_{i_1}| - v/2$.

So if the latter inequality is not satisfied, then the maximum norm of z is at least attained at two entries, i.e., $n \ge 2$. In this case by (3.6) the entries $z_{i_1} = z_{i_2} = \cdots = z_{i_n} = t$ satisfy

$$2t - 2x_{i_j} \;=\; -va_j, \quad j = 1,\dots,n-1,$$

$$2t - 2x_{i_n} \;=\; -v\left(1 - \sum_{k=1}^{n-1} a_k\right)$$

for some numbers $a_1,\dots,a_{n-1} \in [0,1]$ satisfying $\sum_j a_j \le 1$. This is a system of n linear equations in t and $a_1,\dots,a_{n-1}$. Writing it in matrix form, we get

$$\begin{pmatrix} 1 & v/2 & 0 & 0 & \cdots & 0 \\ 1 & 0 & v/2 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & -v/2 & -v/2 & -v/2 & \cdots & -v/2 \end{pmatrix} \begin{pmatrix} t \\ a_1 \\ \vdots \\ a_{n-1} \end{pmatrix} = \begin{pmatrix} x_{i_1} \\ \vdots \\ x_{i_{n-1}} \\ x_{i_n} - v/2 \end{pmatrix}.$$

Denoting the matrix on the left-hand side by B, a simple computation verifies that

$$B^{-1} = \frac{1}{n}\begin{pmatrix} 1 & 1 & 1 & \cdots & 1 \\ \frac{2(n-1)}{v} & -\frac{2}{v} & -\frac{2}{v} & \cdots & -\frac{2}{v} \\ -\frac{2}{v} & \frac{2(n-1)}{v} & -\frac{2}{v} & \cdots & -\frac{2}{v} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ -\frac{2}{v} & \cdots & -\frac{2}{v} & \frac{2(n-1)}{v} & -\frac{2}{v} \end{pmatrix}.$$

This gives

$$z_{i_1} = \cdots = z_{i_n} = t = \frac{1}{n}\left(\sum_{j=1}^{n} x_{i_j} - v/2\right)$$

and $a_j = \frac{2}{nv}(v/2 + (n-1)x_{i_j} - \sum_{k\in\{1,\ldots,n\}\setminus\{j\}} x_{i_k})$. Thus, all a_j are nonnegative if for all $j \in \{1,\ldots,n-1\}$

$$x_{i_j} \geq \frac{1}{n-1}\left(\sum_{k\in\{1,\ldots,n\}\setminus\{j\}} x_{i_k} - v/2\right).$$

Moreover, a simple calculation gives $\sum_{j=1}^{n-1} a_j = \frac{n-1}{n} + \frac{2}{nv}(\sum_{j=1}^{n-1} x_{i_j} - (n-1)x_{i_n})$. Thus, it holds that $1 - \sum_{j=1}^{n-1} a_j \geq 0$ if and only if

$$x_{i_n} \geq \frac{1}{n-1}\left(\sum_{j=1}^{n-1} x_{i_j} - v/2\right).$$

Therefore, the initial assumption that the maximum norm of u is attained precisely at $z_{i_1},\ldots,z_{i_n}$ can be true only if $x_{i_1},\ldots,x_{i_n}$ are the largest entries of the vector x and

$$z_{i_{n+1}} = x_{i_{n+1}} < t = \frac{1}{n}\left(\sum_{j=1}^{n} x_{i_j} - v/2\right),$$

i.e., $|x_{i_{n+1}}| < n^{-1}(\sum_{j=1}^{n} |x_{i_j}| - v/2)$. Pasting all of the pieces together shows the assertion of the lemma. □

4.2. Weak convergence. In the following we will prove that $u^{(m)}$ converges weakly and strongly to the unique minimizer of K. We first establish the weak convergence. Following the proof of Proposition 3.11 in [17], one may extract essentially three conditions on a general sparsity measure Ψ such that weak convergence is ensured. Let us collect them in the following proposition.

PROPOSITION 4.3. *Assume K is given by* (4.1) *with a general sparsity measure Ψ, and suppose K is strictly convex. Let U_Ψ be the associated "thresholding operator" given by* (4.3). *Assume that the following conditions hold:*

(1) *U_Ψ is nonexpansive; i.e., $\|U_\Psi(x) - U_\Psi(y)\|_2 \leq \|x-y\|_2$ for all $x, y \in \ell_2(\Lambda, \mathbb{R}^M)$.*

(2) *It holds that* $\|f\|_2 \le H(\Psi(f))$ *for all* $f \in \ell_2(\Lambda, \mathbb{R}^M)$ *and some monotonically increasing function* H *on* $\mathbb{R}_+$. *(This ensures that a sequence* f_n *satisfying* $\Psi(f_n) \le C$ *is bounded in* $\ell_2(\Lambda, \mathbb{R}^M)$.*)*

(3) *For all* $x, h \in \ell_2(\Lambda, \mathbb{R}^M)$ *it holds that*

$$\Psi(U_\Psi(x) + h) - \Psi(U_\Psi(x)) + 2\langle h, U_\Psi(x) - x\rangle \ge 0.$$

Then the sequence $u^{(m)}$ *defined by* (4.4) *converges weakly to the minimizer of* K *independently of the choice of* $u^{(0)}$.

Proof. First we claim that the condition in (3) implies that the surrogate functional K^s satisfies

$$K^s(u + h, a) - K^s(u, a) \ \ge \ \|h\|_2^2 \tag{4.9}$$

for $u = \arg\min_{u'} K^s(u', a) = U_\Psi(a - T^*(g - Ta))$. Indeed, set $x := a - T^*(g - Ta)$, i.e., $u = U_\Psi(x)$. Then an elementary calculation yields

$$\begin{aligned} K^s(u + h, a) - K^s(u) &= \|T(u + h) - g\|_2^2 + \Psi(u + h) - \|T(u + h) - Ta\|_2^2 + \|u \\ &\quad + h - a\|_2^2 - \|Tu - g\|_2^2 - \Psi(u) + \|Tu - Ta\|_2^2 - \|u - a\|_2^2 \\ &= 2\langle h, u - a - T^*(g - Ta)\rangle + \Psi(u + h) - \Psi(u) + \|h\|_2^2 \\ &= 2\langle h, U_\Psi(x) - x\rangle + \Psi(U_\Psi(x) + h) - \Psi(U_\Psi(x)) + \|h\|_2^2 \ge \|h\|_2^2. \end{aligned}$$

The relation in (3) was used in the last inequality.

Now with (4.9) and properties (1) and (2) one can justify that the proofs of the analogues of Theorem 3.2 until Proposition 3.11 in [17] go through completely in the same way, which finally leads to the statement of this proposition. ∎

Let us now show that for our specific choice of $\Psi = \Psi_{v,\omega}^{(q)}$ properties (1)–(3) in the previous proposition hold, and thus, $u^{(n)}$ converges weakly to a minimizer of K.

LEMMA 4.4. $U_{v,\omega}^{(q)} = U_{\Psi_{v,\omega}^{(q)}}$ *is nonexpansive.*

Proof. Clearly, the map $x \mapsto (1 + \omega_\lambda)^{-1} x$ is nonexpansive. By (4.6) we have $S_v^{(q)} = I - P_{v/2}^{q'}$. Since $P_{v/2}^{q'}$ is an orthogonal projection onto a convex set, $S_v^{(q)}$ is also nonexpansive; see, e.g., [40]. Hence, $U_{v,\omega}^{(q)}$ is nonexpansive, since on each component x_λ, $\lambda \in \Lambda$, it is a composition of nonexpansive operators. ∎

LEMMA 4.5. *If* (v_λ) *or* (ω_λ) *are bounded away from* 0, *then condition* (2) *in Proposition* 4.3 *holds.*

Proof. This follows by a standard argument. ∎

If we consider the problem of minimizing $J(u, v)$ jointly over u and v, then we certainly cannot assume that v is bounded away from 0, but in this case we require that ω_λ is bounded away from 0. (By Proposition 2.1 this is needed anyway to ensure that $J(u, v)$ is jointly convex in u and v.) In the case where we only minimize $J(u, v)$ with respect to u (i.e., when minimizing $\Psi(u)$ defined in (4.2)), we may take ω_λ arbitrary (and even $\omega_\lambda = 0$), but then we have to require a lower bound on v_λ.

Now consider the third condition in the proposition. The next lemma reduces it to the respective condition for $S_v^{(q)}$.

LEMMA 4.6. *Assume that for all* $x, h \in \mathbb{R}^M$ *it holds that*

$$v(\|S_v^{(q)}(x) + h\|_q - \|S_v^{(q)}(x)\|_q) + 2\langle h, S_v^{(q)}(x) - x\rangle \ge 0.$$

Then condition (3) *in Proposition* 4.3 *is satisfied.*

Proof. By the definition of $\Psi_{v,\omega}^{(q)}$ we need to show that for $\omega, v \geq 0$ and all $x, h \in \mathbb{R}^M$

$$\begin{aligned} & v(\|(1+\omega)^{-1}S_v^{(q)}(x)+h\|_q - \|(1+\omega)^{-1}S_v^{(q)}(x)\|_q) \\ & \quad + \omega(\|(1+\omega)^{-1}S_v^{(q)}(x)+h\|_2^2 - \|(1+\omega)^{-1}S_v^{(q)}(x)\|_2^2) \\ & \quad + 2\langle h, (1+\omega)^{-1}S_v^{(q)}(x) - x\rangle \geq 0. \end{aligned}$$

Setting $h' = (1+\omega)h$, a straightforward computation yields for the left-hand side of this inequality

$$(1+\omega)^{-1}\left[v(\|S_v^{(q)}(x)+h'\|_q - \|S_v^{(q)}(x)\|_q) + 2\langle h', S_v^{(q)}(x) - x\rangle\right]$$

$$+(1+\omega)^{-2}\omega\left[\|S_v^{(q)}(x)+h'\|_2^2 - \|S_v^{(q)}(x)\|_2^2 - 2\langle h', S_v^{(q)}(x)\rangle\right] \geq (1+\omega)^{-2}\omega\|h'\|_2^2 \geq 0.$$

This completes the proof. ∎

LEMMA 4.7. *The condition in the previous lemma holds for* $S_v^{(q)}$, $1 \leq q \leq \infty$ *(and even if the* ℓ_q *norm is replaced by a general norm on* $\mathbb{R}^M$*).*

Proof. First note that by definition (4.5) and duality we have

$$\|S_v^{(q)}(x)\|_q \;=\; (v/2)^{-1} \sup_{k \in B^{q'}(v/2)} \langle k, x - P_{v/2}^{q'}x\rangle.$$

A characterization of the orthogonal projection tells us that $\langle k - P_{v/2}^{q'}x, x - P_{v/2}^{q'}x\rangle \leq 0$ for all $k \in B^{q'}(v/2)$; see, e.g., [40, Lemma 8]. This gives

$$\begin{aligned} \|S_v^{(q)}(x)\|_q \;&=\; (v/2)^{-1} \sup_{k \in B^{q'}(v/2)} \left(\langle k - P_{v/2}^{q'}x, x - P_{v/2}^{q'}(x)\rangle + \langle P_{v/2}^{q'}(x), S_v^{(q)}(x)\rangle\right) \\ &\leq\; (v/2)^{-1}\langle P_{v/2}^{q'}(x), S_v^{(q)}(x)\rangle. \end{aligned}$$

Using once more that $S_v^{(q)}(x) - x = -P_{v/2}^{q}(x)$, we further obtain

$$\begin{aligned} & v(\|S_v^{(q)}(x)+h\|_q - \|S_v(q)(x)\|_q) + 2\langle h, S_v^{(q)}(x) - x\rangle \\ & \quad \geq v\|S_v^{(q)}(x)+h\|_q - 2\langle P_{v/2}^{q'}(x), S_v^{(q)}(x)\rangle - 2\langle P_{v/2}^{q'}(x), h\rangle \\ & \quad = v\|S_v^{(q)}(x)+h\|_q - 2\langle P_{v/2}^{q'}(x), S_v^{(q)}(x)+h\rangle \\ & \quad \geq v\|S_v^{(q)}(x)+h\|_q - 2\|P_{v/2}^{q'}x\|_{q'}\|S_v^{(q)}(x)+h\|_q \;\geq\; 0. \end{aligned}$$

Here we used that $P_{v/2}^{q'}$ is a projection onto $B^{q'}(v/2)$, so $\|P_{v/2}^{q'}x\|_{q'} \leq v/2$. This finishes the proof. ∎

To summarize we have the following result about weak convergence.

COROLLARY 4.8. *Let* $1 \leq q \leq \infty$*, and assume that* (v_λ) *or* (ω_λ) *is bounded from below. Then the sequence* $u^{(m)}$ *defined in* (4.4) *converges weakly to a minimizer of* K*, where* $\Psi = \Psi_{v,\omega}^{(q)}$ *is the sparsity measure defined in* (4.2)*. (The* q *norm in* (4.2) *can be replaced by any other norm on* $\mathbb{R}^M$*.)*

4.3. Strong convergence. The next result establishes the strong convergence.

PROPOSITION 4.9. *Let $1 \le q \le \infty$, and assume that (v_λ) or (ω_λ) are bounded away from 0. In case (v_λ) is not bounded away from 0, assume further that there is a constant $c > 0$ such that $v_\lambda < c$ for only finitely many λ. Then $u^{(m)}$ converges strongly to a minimizer of K.*

Proof. The analogues of Lemmas 3.15 and 3.17 in [17] are proven in completely the same way. It remains to justify the analogue of [17, Lemma 3.18]: If for some $a \in \ell_2(\Lambda, \mathbb{R}^M)$ and some sequence $(h^{(m)}) \subset \ell_2(\Lambda, \mathbb{R}^M)$ converging weakly to 0 it holds that $\lim_{m\to\infty} \|U^{(q)}_{v,\omega}(a+h^{(m)}) - U^{(q)}_{v,\omega}(a) - h^{(m)}\|_2 = 0$, then $\|h^{(m)}\|_2 \to 0$ for $m \to \infty$. To this end we mainly follow the argument in [17].

Let c be the constant such that $v_\lambda < c$ for $\lambda \in \Lambda_{00}$ for Λ_{00} finite. Then let Λ_{01} be a finite set such that $\sum_{\lambda\in\Lambda\setminus\Lambda_{01}} \|a_\lambda\|^2_{q'} \le \sigma^2$ for some $\sigma < c/2$. (Such a set Λ_{01} exists since $\|\cdot\|_{q'}$ and $\|\cdot\|_2$ are equivalent norms on $\mathbb{R}^M$ and by assumption $a \in \ell_2(\Lambda, \mathbb{R}^M)$.) Since $\Lambda_0 = \Lambda_{00} \cup \Lambda_{01}$ is also finite, we have $\sum_{\lambda\in\Lambda_0} \|h^{(m)}_\lambda\|^2_2 \to 0$ for $m \to \infty$ by the weak convergence of $h^{(m)}$ to 0. Thus, we are left with proving that $\sum_{\lambda\in\Lambda\setminus\Lambda_0} \|h^{(m)}_\lambda\|^2_2 \to 0$ for $m \to \infty$.

For each m we split $\Lambda_1 := \Lambda\setminus\Lambda_0$ into the subsets $\Lambda_{1,m} := \{\lambda \in \Lambda_1 : \|h^{(m)}_\lambda + a_\lambda\|_{q'} < v_\lambda/2\}$ and $\widetilde{\Lambda}_{1,m} = \Lambda_1 \setminus \Lambda_{1,m}$. If $\lambda \in \Lambda_{1,m}$, then $U^{(q)}_{v,\omega}(a+h^{(m)})_\lambda = U^{(q)}_{v,\omega}(a)_\lambda = 0$ since $\|a_\lambda + h^{(m)}_\lambda\|_{q'}, \|a_\lambda\|_{q'} \le v_\lambda/2$. Thus, $\|h^{(m)}_\lambda - U^{(q)}_{v,\omega}(a+h^{(m)})_\lambda + U^{(q)}_{v,\omega}(a)_\lambda\|^2_2 = \|h^{(m)}_\lambda\|^2_2$ and by assumption

$$\sum_{\lambda\in\Lambda_1} \|h^{(m)}_\lambda\|^2_2 \le \|h^{(m)} - U^{(q)}_{v,\omega}(a+h^{(m)}) + U^{(q)}_{v,\omega}(a)\|^2_2 \to 0 \quad \text{as } m \to \infty.$$

Now let $\lambda \in \widetilde{\Lambda}_{1,m}$. We first consider the case that $\omega_\lambda = 0$, i.e., $U^{(q)}_{v,\omega}(x)_\lambda = S^{(q)}_v(x)_\lambda$. Since $\|a_\lambda\|_{q'} \le \sigma < v_\lambda/2$, we have $S^{(q)}_v(a) = 0$, and thus,

$$\begin{aligned}
&\|h^{(m)}_\lambda - S^{(q)}_{v_\lambda}(h^{(m)}_\lambda + a_\lambda)\|_{q'} \\
&\quad = \|h^{(m)}_\lambda - (h^{(m)}_\lambda + a_\lambda) + P^{q'}_{v_\lambda/2}(h^{(m)}_\lambda + a_\lambda)\|_{q'} \\
&\quad = \|P^{q'}_{v_\lambda/2}(h^{(m)}_\lambda + a_\lambda) - a_\lambda\|_{q'} \ge \|P^{q'}_{v_\lambda/2}(h^{(m)}_\lambda + a_\lambda)\|_{q'} - \|a_\lambda\|_{q'} \\
&\quad \ge v_\lambda/2 - \sigma \ge c/2 - \sigma.
\end{aligned}$$

Here we used that $\|P^{q'}_{v_\lambda/2}(h^{(m)}_\lambda + a_\lambda)\|_{q'} = v_\lambda/2$ (because $\|h^{(m)}_\lambda + a_\lambda\|_{q'} \ge v_\lambda/2$). Since every norm on a finite-dimensional space is equivalent, there is a constant C such that

$$\|h^{(m)}_\lambda - S^{(q)}_{v_\lambda}(h^{(m)}_\lambda + a_\lambda) + S^{(q)}_{v_\lambda}(a_\lambda)\|^2_2 \ge C^2(c/2 - \sigma)^2 > 0.$$

However, since by assumption $\sum_{\lambda\in\Lambda} \|h^{(m)}_\lambda - S^{(q)}_{v_\lambda}(h^{(m)}_\lambda + a_\lambda) + S^{(q)}_{v_\lambda}(a)\|^2_2 \to 0$ as $m \to \infty$, there must exist an m_0 such that $\widetilde{\Lambda}_{1,m}$ is empty for all $m \ge m_0$.

In the case that ω_λ does not vanish, we have

$$\begin{aligned}
&\|h^{(m)}_\lambda - U^{(q)}_{v,\omega}(h^{(m)} + a)_\lambda + U^{(q)}_{v,\omega}(a)_\lambda\|_2 \\
&\quad = \|h^{(m)}_\lambda - (1+\omega_\lambda)^{-1} S^{(q)}_{v_\lambda}(h^{(m)}_\lambda + a_\lambda)\|_2 \\
&\quad = (1+\omega_\lambda)^{-1}\|(1+\omega_\lambda)h^{(m)}_\lambda - S^{(q)}_{v_\lambda}(h^{(m)}_\lambda + a_\lambda)\|_2.
\end{aligned} \tag{4.10}$$

We claim that

$$\|(1+\omega_\lambda)h_\lambda^{(m)} - S_{v_\lambda}^{(q)}(h_\lambda^{(m)}+a_\lambda)\|_2 \;\geq\; \|h_\lambda^{(m)} - S_{v_\lambda}^{(q)}(h_\lambda^{(m)}+a_\lambda)\|_2 \tag{4.11}$$

so that we can apply the argument for $\omega_\lambda = 0$ to conclude that $\widetilde{\Lambda}_{1,m}$ is empty for m sufficiently large. Let us omit for the moment all indexes λ and m for the sake of simpler notation. We have

$$\|(1+\omega)h - S_v^{(q)}(h+a)\|_2^2 - \|h - S_v^{(q)}(h+a)\|_2^2 \;=\; 2\omega\langle h, h - S_v^{(q)}(h+a)\rangle + \omega^2\|h\|_2^2 \tag{4.12}$$

and, furthermore,

$$\begin{aligned}\langle h, h - S_v^{(q)}(h+a)\rangle &= \langle h, P_{v/2}^{q'}(h+a) - a\rangle \\ &= -\langle h + a - P_{v/2}^{q'}(h+a), a - P_{v/2}^{q'}(h+a)\rangle \\ &\quad + \|a - P_{v/2}^{q'}(h+a)\|_2^2 \geq 0. \end{aligned} \tag{4.13}$$

Here we used that $a \in B^{q'}(\sigma) \subset B^{q'}(v/2)$ and the fact that $\langle k - P_{v/2}^{q'}(x), x - P_{v/2}^{q'}(x)\rangle \leq 0$ for all $k \in B^{q'}(v/2)$ and $x \in \mathbb{R}^M$. Thus, the term in (4.12) is nonnegative, and therefore our claim (4.11) holds. □

Let us shortly comment on the condition that, if v_λ is not bounded from below, there is at least some $c > 0$ such that $v_\lambda > c$ except for a finite set of indexes λ. This condition is mainly relevant when considering also a minimization over (v_λ). Then the term $\sum \theta_\lambda(\rho_\lambda - v_\lambda)^2$ in the functional $J(u,v)$ ensures that the sequence $(\rho_\lambda - v_\lambda)$ is contained in $\ell_{2,\theta^{1/2}}$. If θ_λ and ρ_λ are bounded from below, this implies that v_λ can be less than $1/2 \min_\lambda \rho_\lambda$, say, only for finitely many λ.

5. Numerical implementation and convergence analysis. The scope of this section is twofold: We want to formulate an implementable version of the double-minimization algorithm and show its strong convergence. To this end we develop an error analysis.

5.1. Numerical implementation. Let us compose the two iterative algorithms described in (3.1) and (4.4), respectively, into a unique scheme.

ALGORITHM 1. **JOINTSPARSE**

Input: Data vector $(g_j)_{j=1}^N$, initial points $u^{(0)} \in \ell_2(\Lambda, \mathbb{R}^M)$, $v^{(0)}$, with $0 \leq v_\lambda^{(0)} \leq \rho_\lambda$, number $n_{\max}$ of outer iterations, number of inner iterations L_n, $n = 1, \ldots, n_{\max}$.

Parameters: $q \in [1, \infty]$, positive weights (θ_λ), (ρ_λ), (ω_λ), with $\omega_\lambda \geq c > 0$, such that $\Phi^{(q)}$ and hence J are convex; see Proposition 2.1.

Output: Approximation (u^*, v^*) of the minimizer of $J_{\theta,\rho,\omega}^{(q)}$

$u^{(0,0)} := u^{(0)}$;

for $n := 0$ *to* $n_{\max}$ *do*

  for $m := 0$ *to* L_n *do*

    $u^{(n,m+1)} := U_{v^{(n)},\omega}^{(q)}\left(u^{(n,m)} + T^*(g - Tu^{(n,m)})\right)$;

  endfor

  $u^{(n+1,0)} := u^{(n,L_n)}$;

  $v^{(n+1)} := \left(\begin{cases} \rho_\lambda - \frac{1}{2\theta_\lambda}\|u^{(n+1,0)}{}_\lambda\|_q, & \|u^{(n+1,0)}{}_\lambda\|_q < 2\theta_\lambda\rho_\lambda, \\ 0, & \text{otherwise.} \end{cases} \right)_{\lambda\in\Lambda}$;

endfor
$u^* := u^{(n_{\max}, L_{n_{\max}})}$;
$v^* := v^{(n_{\max})}$.

We will discuss below how to choose the number of inner iterations L_n and outer iterations $n_{\max}$. Our previous analysis ensures the (weak) convergence of this scheme only if the inner loop computes exactly the minimizer of $J(u, v^{(n)})$ for fixed $v^{(n)}$, i.e., if $L_n = \infty$. Of course, this cannot be numerically realized, so we need to analyze what happens if the inner loop makes a small error in computing this minimizer. In other words, we will clarify how large we have to choose $n_{\max}$ and $L_n, n = 1, \dots, n_{\max}$, in order to ensure that we have approximately computed the minimizer (u^*, v^*) within a given error tolerance.

The role of the other parameters $\rho_\lambda, \theta_\lambda, \omega_\lambda$ are investigated in the subsequent contribution [27]. Observe further that each (inner) iteration of the above algorithm involves an application of T^*T and of the thresholding operator $U^{(q)}_{v,\omega}$. The latter can be applied rapidly. So if there is also a fast algorithm for the computation of T^*T, then each iteration can be done rapidly.

5.2. Strong convergence of JOINTSPARSE. First of all we want to establish the convergence rate of the inner loop, i.e., the iterative thresholding algorithm of the previous section.

PROPOSITION 5.1. *Assume that $\omega_\lambda \geq \gamma > 0$ for all $\lambda \in \Lambda$ (implying that $K(u) = K^{(q)}_{v,\omega}(u)$ is strictly convex) and $\|T\| < 1$. Set $\alpha := (1+\gamma)^{-1}\|I - T^*T\| < 1$. Then the iterative thresholding algorithm*

$$u^{(n,m+1)} := U^{(q)}_{v^{(n)},\omega}\left(u^{(n,m)} + T^*(g - Tu^{(n,m)})\right)$$

converges linearly:

$$\|u^{(n,\infty)} - u^{(n,m+1)}\|_2 \leq \alpha \|u^{(n,\infty)} - u^{(n,m)}\|_2. \tag{5.1}$$

Proof. Note that

$$u^{(n,\infty)} := U^{(q)}_{v^{(n)},\omega}\left(u^{(n,\infty)} + T^*(g - Tu^{(n,\infty)})\right).$$

By nonexpansiveness of $S^{(q)}_v$ (see Lemma 4.4 and its proof) we obtain

$$\begin{aligned}
&\|u^{(n,\infty)} - u^{(n,m+1)}\|_2 \\
&\quad = \left\| U^{(q)}_{v^{(n)},\omega}\left(u^{(n,\infty)}_\lambda + T^*(g - Tu^{(n,\infty)}_\lambda)\right) - U^{(q)}_{v^{(n)},\omega}\left(u^{(n,m)} + T^*(g - Tu^{(n,m)})\right)\right\|_2 \\
&\quad = \Bigg(\sum_{\lambda\in\Lambda}(1+\omega_\lambda)^{-2}\|S^{(q)}_{v_\lambda}(u^{(n,\infty)}_\lambda + T^*(g - Tu^{(n,\infty)}_\lambda)_\lambda) \\
&\qquad\quad - S^{(q)}_{v_\lambda}(u^{(n,m)} + T^*(g - Tu^{(n,m)})_\lambda)\|_2^2\Bigg)^{1/2} \\
&\quad \leq \sup_{\lambda\in\Lambda}(1+\omega_\lambda)^{-1}\|(I - T^*T)(u^{(n,\infty)} - u^{(n,m)})\|_2 \\
&\quad \leq (1+\gamma)^{-1}\|I - T^*T\|\,\|u^{(n,\infty)} - u^{(n,m)}\|_2 \\
&\quad = \alpha\|u^{(n,\infty)} - u^{(n,m)}\|_2.
\end{aligned}$$

This establishes the claim. ∎

Remark. Clearly, the error estimation in (5.1) holds also if one is interested only in analyzing the iterative thresholding algorithm from the last section (i.e., without doing the outer iteration). Then it might also be interesting to consider the case that $\omega = 0$. According to what we have proven in the previous section, the algorithm still converges provided the weight v is bounded away from zero. However, then the error estimation (5.1) has a useful meaning only if $\alpha = \|I - T^*T\| < 1$. So this applies if T^*T is boundedly invertible. For a usual inverse problem, however, we will have a noninvertible T or at least one with an unbounded inverse resulting in $\|I - T^*T\| = 1$. So in this case we know only that the algorithm converges, but an error estimate does not seem to be available.

For simplicity we restrict the following analysis to the most interesting cases $q \in \{1, 2, \infty\}$. We first need the following technical result.

LEMMA 5.2. *For $q \in \{1, 2, \infty\}$ the projection P_v^q onto the ball $B^q(v) \subset \mathbb{R}^M$ is a Lipschitz function with respect to $v \in \mathbb{R}_+$. In particular, we have*

$$\|P_v^q(x) - P_w^q(x)|\ell_2^M\| \le L|v - w| \quad \text{for all } x \in \mathbb{R}^M, \tag{5.2}$$

where $L = 1$ for $q \in \{1, 2\}$ and $L = M^{1/2}$ for $q = \infty$.

Proof. Let us start with $q = 2$. By distinguishing cases it is not difficult to show that

$$\|P_v^2(x) - P_w^2(x)|\ell_2^M\| \le |v - w|.$$

For $q = \infty$ we have $P_v^\infty(x) = (p_v^\infty(x_\ell))_{\ell=1}^M$, where for $y \in \mathbb{R}$

$$p_v^\infty(y) = \begin{cases} y & \text{if } |y| \le v, \\ y - \operatorname{sign}(y)(|y| - v) & \text{otherwise.} \end{cases}$$

Since p_v^∞ can be interpreted as a projection onto the ℓ_2 ball in dimension 1, we obtain that

$$|p_v^\infty(y) - p_w^\infty(y)| \le |v - w|,$$

and

$$\|P_v^\infty(x) - P_w^\infty(x)|\ell_2^M\| = \left(\sum_{\ell=1}^M |p_v^\infty(x_\ell) - p_w^\infty(x_\ell)|^2 \right)^{1/2} \le M^{1/2}|v - w|.$$

The case $q = 1$ requires a bit more effort. By Lemma 4.2(c) we have the following. Let x_{i_k} denote the reordering of the entries of x by magnitude as in Lemma 4.2. Let $n \in \{1, \dots, M\}$ be the largest index satisfying

$$|x_{i_n}| \ge \frac{1}{n-1} \left(\sum_{k=1}^{n-1} |x_{i_k}| - v \right).$$

Then

$$(P_v^1(x))_{i_j} = x_{i_j} - \frac{\operatorname{sign}(x_{i_j})}{n} \left(\sum_{k=1}^{n} |x_{i_k}| - v \right), \quad j = 1, \dots, n,$$

$$(P_v^1(x))_{i_j} = 0, \quad j = n+1, \dots, M.$$

Observe first that for all $x \in \mathbb{R}^M$ there exists $\varepsilon_0 > 0$ such that for all $0 < \varepsilon < \varepsilon_0$ the same $n \in \{1, \dots, M\}$ is the largest index satisfying

$$|x_{i_n}| \geq \frac{1}{n-1} \left(\sum_{k=1}^{n-1} |x_{i_k}| - (v + \varepsilon) \right).$$

For $0 < \varepsilon < \varepsilon_0$, a simple computation yields

$$\frac{(P^1_{v+\varepsilon}(x) - P^1_v(x))_{i_j}}{\varepsilon} = \begin{cases} \frac{\operatorname{sign}(x_{i_j})}{n} & \text{for } j = 1, \dots, n, \\ 0 & j = n+1, \dots, M. \end{cases}$$

This means that the map $v \to P^1_v(x)$ is right-differentiable; i.e., the limit

$$(P^1_v(x))'_+ = \lim_{\varepsilon \to 0_+} \frac{P^1_{v+\varepsilon}(x) - P^1_v(x)}{\varepsilon}$$

exists in $\mathbb{R}^M$. Moreover, it also follows that

$$\|(P^1_v(x))'_+\|_2 = \frac{1}{\sqrt{n}} \leq 1. \tag{5.3}$$

To conclude the proof we use the following standard result.

LEMMA 5.3. *Let $f : \mathbb{R} \to \mathbb{R}^M$ and $\varphi : \mathbb{R} \to \mathbb{R}$ be two continuous and right-differentiable functions such that*

$$\|f'_+(v)\| \leq \varphi'_+(v)$$

for all $v \in \mathbb{R}$. Then

$$\|f(v) - f(w)\| \leq \varphi(v) - \varphi(w) \quad \text{for all } v \geq w.$$

According to the notation of this latter lemma, let us set $f(v) = P^1_v(x)$ and $\varphi(v) = v$. Since $P^1_v(x)$ is a continuous function with respect to v (in fact this is true for any projection onto convex sets; see [38]), by (5.3) and an application of the lemma we conclude that $\|P^1_v(x) - P^1_w(x)\| \leq |v - w|$. ∎

Observe that the strict convexity of $\Phi^{(q)}(u, v)$ is equivalent to $\theta_\lambda \omega_\lambda > \kappa_q/4$; see Proposition 2.1. In the following proposition we require the slightly stronger condition that $\theta_\lambda \omega_\lambda$ is bounded strictly away from $\kappa_q/4$.

PROPOSITION 5.4. *Let $q \in \{1, 2, \infty\}$. Assume that $\theta_\lambda \omega_\lambda \geq \sigma > \kappa_q/4$ for all $\lambda \in \Lambda$, where $\kappa_1 = M$ and $\kappa_2 = \kappa_\infty = 1$, implying that $\Phi^{(q)}(u, v)$ and $J(u, v)$ are strictly convex; see Proposition* 2.1. *Moreover, let us assume that $\omega_\lambda \geq \gamma > 0$ for all $\lambda \in \Lambda$. Suppose $\|T\| < 1$ resulting in $\|I - T^*T\| \leq 1$. Set*

$$\beta := \sup_{\lambda \in \Lambda} \frac{\kappa_q}{4\theta_\lambda \omega_\lambda + 4\theta_\lambda (1 - \|I - T^*T\|)} \leq \frac{\kappa_q}{4\sigma} < 1. \tag{5.4}$$

Then for each $n \in \mathbb{N}$ one has the following error estimate:

$$\|u^{(n,\infty)} - u^* | \ell_2(\Lambda, \mathbb{R}^M)\| \leq \beta \|u^{(n,0)} - u^* | \ell_2(\Lambda, \mathbb{R}^M)\|.$$

Proof. Let us consider the nth iteration of the outer loop. We have

$$u^{(n,\infty)} = U^{(q)}_{v^{(n)}, \omega}(\underbrace{u^{(n,\infty)} + T^*(g - Tu^{(n,\infty)})}_{:= y^{(n)}}).$$

By the weak convergence of the double-minimization algorithm, the minimum solution u^* also satisfies a similar relation:

$$u^* = U^{(q)}_{v^*,\omega}(\underbrace{u^* + T^*(g - Tu^*)}_{:=y^*}).$$

Recall that $U^{(q)}_{v,\omega}(y)_\lambda := (1+\omega_\lambda)^{-1} S^{(q)}_{v_\lambda}(y_\lambda)$. By nonexpansiveness of $S^{(q)}_v$ (Lemma 4.4) we have

$$\begin{aligned}
\|u^{(n,\infty)}_\lambda - u^*_\lambda\|_2 &\le \|U^{(q)}_{v^{(n)},\omega}(y^{(n)})_\lambda - U^{(q)}_{v^{(n)},\omega}(y^*)_\lambda\|_2 + \|U^{(q)}_{v^{(n)},\omega}(y^*)_\lambda - U^{(q)}_{v^*,\omega}(y^*)_\lambda\|_2 \\
&= (1+\omega_\lambda)^{-1}\|y^{(n)}_\lambda - y^*_\lambda\|_2 + \|U^{(q)}_{v^{(n)},\omega}(y^*)_\lambda - U^{(q)}_{v^*,\omega}(y^*)_\lambda\|_2 \\
&\le (1+\omega_\lambda)^{-1}\|I - T^*T\|\,\|u^{(n,\infty)}_\lambda - u^*_\lambda\|_2 \\
&\quad + \|U^{(q)}_{v^{(n)},\omega}(y^*)_\lambda - U^{(q)}_{v^*,\omega}(y^*)_\lambda\|_2.
\end{aligned}$$

This implies

$$\begin{aligned}
\|u^{(n,\infty)}_\lambda - u^*_\lambda\|_2 &\le \left(1 - (1+\omega_\lambda)^{-1}\|I - T^*T\|\right)^{-1} \|U^{(q)}_{v^{(n)},\omega}(y^*)_\lambda - U^{(q)}_{v^*,\omega}(y^*)_\lambda\|_2 \\
&= (1 + \omega_\lambda - \|I - T^*T\|)^{-1}\,\|S_{v^{(n)}_\lambda}(y^*_\lambda) - S_{v^*_\lambda}(y^*_\lambda)\|_2.
\end{aligned}$$

Recall from Lemma 4.1 that $S^{(q)}_v(x) = x - P^{q'}_{v/2}(x)$, where $P^{q'}_{v/2}$ denotes the orthogonal projection of x onto the $\ell_{q'}$ ball of radius $v/2$. By Lemma 5.2 we have that for any $z \in \mathbb{R}^M$

$$\|S^{(q)}_{v^{(n)}_\lambda}(z) - S^{(q)}_{v^*_\lambda}(z)\|_2 = \|P^{q'}_{v^*_\lambda/2}(z) - P^{q'}_{v^{(n)}_\lambda/2}(z)\|_2 \le \frac{L}{2}|v^{(n)}_\lambda - v^*_\lambda|.$$

So $S^{(q)}_v(z)$ is also Lipschitz in v. Let us recall that

$$v^{(n)}_\lambda := \begin{cases} \rho_\lambda - \frac{1}{2\theta_\lambda}\|u^{(n,0)}_\lambda\|_q & \|u^{(n,0)}_\lambda\|_q < 2\theta_\lambda\rho_\lambda, \\ 0 & \text{otherwise} \end{cases}$$

and

$$v^*_\lambda := \begin{cases} \rho_\lambda - \frac{1}{2\theta_\lambda}\|u^*_\lambda\|_q & \|u^*_\lambda\|_q < 2\theta_\lambda\rho_\lambda, \\ 0 & \text{otherwise.} \end{cases}$$

By distinguishing cases we can show that

$$|v^{(n)}_\lambda - v^*_\lambda| \le \frac{1}{2\theta_\lambda}\left|\|u^{(n,0)}_\lambda\|_q - \|u^*_\lambda\|_q\right| \le \frac{1}{2\theta_\lambda}\|u^{(n,0)}_\lambda - u^*_\lambda\|_q \le \frac{R}{2\theta_\lambda}\|u^{(n,0)}_\lambda - u^*_\lambda\|_2,$$

where $R = 1$ for $q \in \{2,\infty\}$ and $R = M^{1/2}$ for $q = 1$. Pasting the pieces together and using $RL = \kappa_q$ yields

$$\|u^{(n,\infty)}_\lambda - u^*_\lambda\|_2 \le \frac{\kappa_q}{4\theta_\lambda\,(\omega_\lambda + 1 - \|I - T^*T\|)}\|u^{(n,0)}_\lambda - u^*_\lambda\|_2 \le \beta\|u^{(n,0)}_\lambda - u^*_\lambda\|_2.$$

Summation over $\lambda \in \Lambda$ completes the proof. □

Let us combine the previous two results to obtain the error estimation for the finite algorithm, i.e., for $L_n < \infty$.

THEOREM 5.5. *Make the same assumptions as in Propositions* 5.1 *and* 5.4. *Choose* L_n *such that*

$$\delta_n := \left(\alpha^{L_n}(1+\beta)+\beta\right) \le \delta < 1 \quad \text{for all } n \in \mathbb{N}.$$

(This is possible since $\alpha, \beta < 1$.*) Then we have linear convergence of our algorithm, i.e.,*

$$\|u^{(n,0)} - u^*\|_2 \le \delta_n \|u^{(n-1,0)} - u^*\|_2.$$

Proof. Using Propositions 5.1 and 5.4 we get

$$\begin{aligned}
\|u^{(n,0)} - u^*\|_2 &\le \|u^{(n,0)} - u^{(n-1,\infty)}\|_2 + \|u^{(n-1,\infty)} - u^*\|_2 \\
&\le \alpha^{L_{n-1}} \|u^{(n-1,0)} - u^{(n-1,\infty)}\|_2 + \beta \|u^{(n-1,0)} - u^*\|_2 \\
&\le \alpha^{L_{n-1}} \left(\|u^{(n-1,0)} - u^*\|_2 + \|u^* - u^{(n-1,\infty)}\|_2 \right) + \beta \|u^{(n-1,0)} - u^*\|_2 \\
&\le \alpha^{L_{n-1}} \left(\|u^{(n-1,0)} - u^*\|_2 + \beta \|u^{(n-1,0)} - u^*\|_2 \right) + \beta \|u^{(n-1,0)} - u^*\|_2 \\
&\le \left(\alpha^{L_{n-1}}(1+\beta)+\beta\right) \|u^{(n-1,0)} - u^*\|_2.
\end{aligned}$$

This concludes the proof. ∎

Remark. The last theorem shows that it is possible to choose the number L_n of inner iterations constant with respect to n.

5.3. Strong convergence of the double-minimization algorithm. Finally, we can establish the strong convergence of the double-minimization algorithm and conclude the full proof of Theorem 3.1.

COROLLARY 5.6. *Under the assumptions of Proposition* 5.4, *if the minimizer of* $J(u, v^{(n)})$ *for fixed* $v^{(n)}$ *could be computed exactly, i.e.,* $L_n = \infty$ *for all* $n \in \mathbb{N}$, *then the outer loop converges with exponential rate, and we have*

$$\|u^{(n)} - u^*\|_2 \le \beta^n \|u^{(0)} - u^*\|_2,$$

where we have denoted $u^{(n)} := u^{(n,\infty)}$. *Moreover, the sequence* $v^{(n)}$ *converges componentwise, and* $v^{(n)} - v^*$ *converges to* 0 *strongly in* $\ell_{2,\theta}(\Lambda)$.

Proof. The first part of the statement is a direct application of Proposition 5.4. It remains to show that $v^{(n)} - v^*$ converges to 0 strongly in $\ell_{2,\theta}(\Lambda)$. Using that all norms on $\mathbb{R}^M$ are equivalent it follows that

$$\begin{aligned}
4 \sum_{\lambda \in \Lambda} \theta_\lambda^2 |v^{(n)} - v^*|^2 &= \sum_{\lambda \in \Lambda} |\|u_\lambda^*\|_q - \|u_\lambda^{(n)}\|_q|^2 \le \sum_{\lambda \in \Lambda} \|u_\lambda^* - u_\lambda^{(n)}\|_q^2 \\
&\le C \sum_{\lambda \in \Lambda} \|u_\lambda^* - u_\lambda^{(n)}\|_2^2 = C \|u^* - u^{(n)} | \ell_2(\Lambda, \mathbb{R}^M)\|^2.
\end{aligned}$$

Thus, $v^{(n)} - v^{(\infty)}$ converges also strongly in $\ell_{2,\theta}(\Lambda)$. ∎

6. Color image reconstruction. With this section we illustrate the application of the algorithms for color image recovery. The scope is to furnish a qualitative description of the behavior of the scheme. In a subsequent work we plan to provide a finer quantitative analysis in the context of *distributed compressed sensing* [3].

We begin by illustrating an interesting real-world problem occurring in art restoration. On March 11, 1944, a group of bombs launched from an Allied airplane hit the famous Italian Eremitani's Church in Padua, destroying it together with the inestimable frescoes by Andrea Mantegna et al. contained in the Ovetari Chapel. Details on "the state of the art" can be found in [29, 28]. In 1920 a collection of high quality gray level pictures of these frescoes was made by Alinari. The only color images of the frescoes are dated to 1940, but unfortunately their quality (i.e., the intrinsic resolution of the printouts) is much lower; see Figure 6.6. Inspired by the fresco application, we model the problem of the recovery of a high-resolution color image from a low-resolution color datum and a high-resolution gray datum. We will implement the solution to the model problem as a nontrivial application of the algorithms we have presented in this paper.

6.1. Color images, curvelets, and joint sparsity. Let us assume that the color images are encoded into YIQ channels. The Y component represents the luminance information (gray level), while I and Q give the chrominance information. Of course, one may also choose a different encoding system, e.g., RGB or CMYK. Clearly, the color image $f = (f_1, f_2, f_3)$ can be represented as a 3-channel signal. In order to apply our algorithm, we need to fix a frame for which we can assume color images being jointly sparse.

It is well known that *curvelets* [8] are well suited for sparse approximations of curved singularities. A natural image can in fact be modeled as a function which is piecewise smooth except on a discontinuity set, the latter being described as the union of rectifiable curves. Moreover, there are fast algorithms available for the computation of curvelet coefficients of digital images [7].

In the following, let us assume that a color image f is encoded into a vector of curvelet coefficients $(u_\lambda^\ell)_{\lambda\in\Lambda}^{\ell=1,2,3}$. The image can be reconstructed by the synthesis formula

$$f \;=\; (Fu^\ell)_{\ell=1,2,3} := \left(\sum_{\lambda\in\Lambda} u_\lambda^\ell \psi_\lambda\right)_{\ell=1,2,3},$$

where $\{\psi_\lambda : \lambda \in \Lambda\}$ is the collection of curvelets. The index λ consists of 3 different parameters: $\lambda = (j, p, k)$, where j corresponds to scale, p to a rotation, and k to the spatial location of the curvelet ψ_λ. We do not enter into further details, especially of the discrete and numerical implementation, which one can find in [8, 7].

Let us instead observe that significant curvelet coefficients $u_\lambda = (u_\lambda^1, u_\lambda^2, u_\lambda^3)$ will appear simultaneously at the same $\lambda \in \Lambda$ for all of the channels, as soon as the corresponding curvelet overlaps with a (curved) singularity (appearing simultaneously in all of the channels) and is approximately tangent to it. This justifies the joint sparsity assumption for color images with respect to curvelets.

6.2. The model of the problem. The datum of our problem is a 3-channel signal $g = (g_1, g_2, g_3) \in \ell_2(\mathbb{Z}_{N_0}^2, \mathbb{R}^3)$, where g_i, $i = 2, 3$, are the low-resolution chrominance channels I and Q, and g_1 is the high-resolution gray channel Y. We assume that g was produced by $g = Tu$, where $u = (u^1, u^2, u^3)$ are the curvelet coefficients of the three channels of the high-resolution color image that we want to reconstruct. The

operator $T = (T_{\ell,j})_{\ell,j=1,2,3}$ can be expressed by the matrix

$$T = \begin{pmatrix} F & 0 & 0 \\ 0 & AF & 0 \\ 0 & 0 & AF \end{pmatrix}. \tag{6.1}$$

Here A is the linear operator that transforms the high-resolution image into the low-resolution image. In particular, A can be taken as a convolution operator (with a Gaussian, for instance) followed by downsampling. Eventually, we may assume a suitable scaling in order to make $\|T\| < 1$ and a different weighting of the gray channel and the I,Q channels in the discrepancy term. Since A is not invertible, the operator T is also not invertible, and the minimization of $\mathcal{T}(u)$ requires a regularization. Clearly, for this task we use the functional K defined in (2.4) or J defined in (2.5).

6.3. On the choice of the parameters. What remains to clarify is the choice of the parameters ω_λ, θ_λ, and ρ_λ. The parameter $\omega_\lambda \geq \gamma > 0$ has been introduced for the sole purpose of making J strictly convex. A large value of this parameter actually produces an image u which is significantly blurred, and no information about edges is recovered. Thus, we rather put $\omega_\lambda = \gamma = \varepsilon > 0$ small. Due to the convexity requirements (see section 2.3), we select $\theta_\lambda \sim \frac{M}{\varepsilon}$. The choice of ρ_λ requires a deeper understanding of the information encoded by the curvelet coefficients.

Indeed, in [8] it was observed that those curvelets that overlap with a discontinuity decay like $\|u_\lambda\|_q \lesssim 2^{-3/4j}$, while the others satisfy $\|u_\lambda\|_q \lesssim 2^{-3/2j}$ (where j denotes the scale). Since we want to recover joint discontinuities, we may choose $\rho_\lambda := \rho_{j,p,k} \sim 2^{-js}$, with $s \in [3/4, 3/2]$. By this choice and by (3.2) the locations λ for which $v_\lambda = 0$ will indicate a potential joint discontinuity.

Of course, this is just one possible choice of the parameters, and further information might be extracted from the joint sparsity pattern indicated by v, by the use of different parameters. We believe that a deeper study of the characterization of the morphological properties of signals encoded by frames (e.g., curvelets and wavelets) is fundamental for the right choice of these parameters. We refer to [31, 32] for deeper insights in this direction, concerning fine properties of functions encoded by the distribution of wavelet coefficients.

6.4. Numerical experiments. According to the previous subsections, we illustrate here the application of **JOINTSPARSE** for the recovery of a high-resolution color image from a low-resolution color datum and a high-resolution gray datum. In Figure 6.1 we illustrate the data of the problem. In this case the resolution of the color image has been reduced by a factor of 4 in each direction by using a Gaussian filter and a downsampling. We have conducted several experiments for different choices of $q \in \{1, 2, \infty\}$, with fixed parameters as indicated in section 6.3. We have chosen $L_n = 105$ and $n_{\max} = 1$, as well as $L_n = 7$ and $n_{\max} = 15$ (the numbers of inner and outer iterations, respectively). In the first case, only the minimization of $J(u, v^{(0)})$ with respect to u has been performed; i.e., no iterative adaptation of the joint sparsity pattern indicated by v occurred. In order to estimate the different behavior depending on the parameters above, we have evaluated at each iteration the ℓ_2 error between the reconstructed I and Q color channels and the *original* I and Q color channels. Figures 6.2 and 6.3 indicate that the error decreases for increasing values of q. This means that the increased coupling due to the q parameter is significant in order to improve the recovery. Recall that the choice $q = 1$ does not induce any coupling between channels.

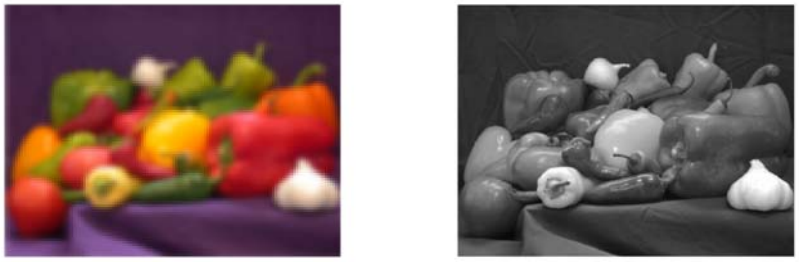

FIG. 6.1. Left: *The low-resolution color image is here presented after Gaussian filtering and downsampling. In the numerical experiments the I and Q channels are used.* Right: *The high-resolution gray level image encodes several morphological information useful to recover the high-resolution color image.*

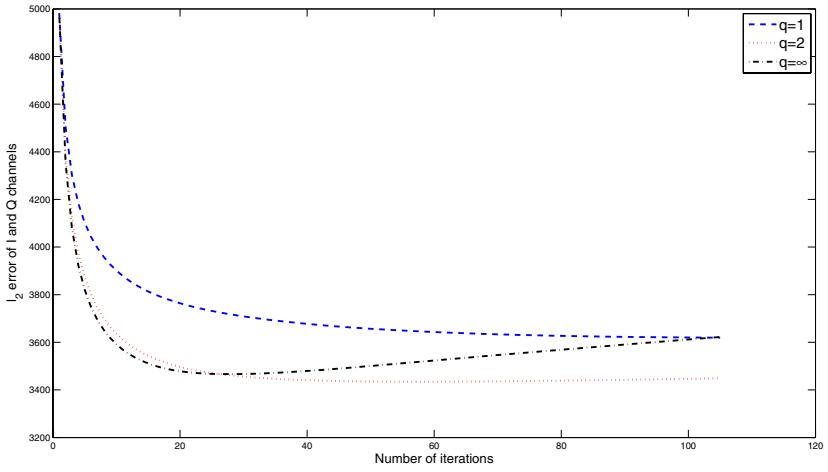

FIG. 6.2. *The ℓ_2 error between the* original color image *and the iterations of the algorithm is shown for different values of $q = 1, 2, \infty$. We have considered $L_n = 105$ and $n_{\max} = 1$ the numbers of inner and outer iterations, respectively. We have fixed here $\omega_\lambda = 0$, $\theta_\lambda = 10$, and $\rho_\lambda = 20 \times 2^{-j}$.*

This coupling effect due to $q > 1$ is even more evident in Figure 6.3, where the adaptation of the weight v occurs. The left and the central pictures in the second row of Figure 6.4 show a reduced color distortion at edges, passing from the case $q = 1$ (without coupling) to the case $q = \infty$, respectively, and consequently a better edge resolution. Nevertheless, the differences are not so remarkable. This is due to the fact that, although the functional J promotes coupling at edges, it does not necessarily enforce a significant edge enhancement. Thus, we may modify the functional by adding an additional total variation (TV) constraint on the I and Q channels:

$$J_{\mathrm{TV}}(u, v) := J(u, v) + \left(|Fu^2|_{\mathrm{TV}} + |Fu^3|_{\mathrm{TV}}\right).$$

The effect of this modification is to promote edge enhancing together with their simultaneous coupling through different channels. For the minimization of J_{TV} we use a heuristic scheme as in [25], by alternating iterations for the minimization of J and for

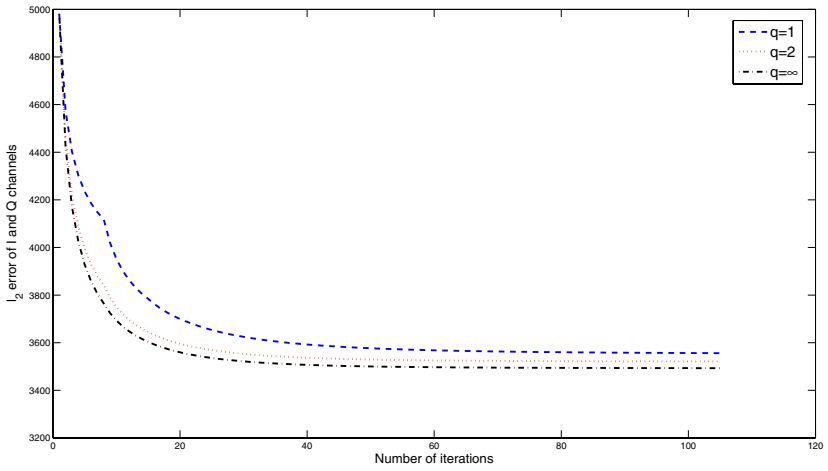

FIG. 6.3. *The ℓ_2 error between the* original color image *and the iterations of the algorithm is shown for different values of $q = 1, 2, \infty$. We have considered $L_n = 7$ and $n_{\max} = 15$ the numbers of inner and outer iterations, respectively. We have fixed here $\omega_\lambda = 1/20$, $\theta_\lambda = 10$, and $\rho_\lambda = 20 \times 2^{-j}$.*

FIG. 6.4. First row. Left: *Portion of the low-resolution color image.* Center: *Portion of the reconstructed color image by Gaussian interpolation and substitution of the Y channel with the gray level datum. Evident color artifacts appear at edges.* Right: *Portion of the original color image.* Second row. Left: *Portion of the reconstructed color image for $q = 1$, $L_n = 105$, and $n_{\max} = 1$.* Center: *Portion of the reconstructed color image for $q = \infty$, $L_n = 7$, and $n_{\max} = 15$.* Right: *Portion of the reconstructed color image for $q = \infty$, $L_n = 7$, $n_{\max} = 15$, and TV minimization.*

the minimization of $\left(|Fu^2|_{\mathrm{TV}} + |Fu^3|_{\mathrm{TV}}\right)$; compare also [19]. The corresponding results are shown in Figure 6.5, where the effect of the coupling (for the cases $q = 2, \infty$) is further enhanced. The right picture in the second row of Figure 6.4 shows the result of the reconstruction in this latter case. The edges are perfectly recovered.

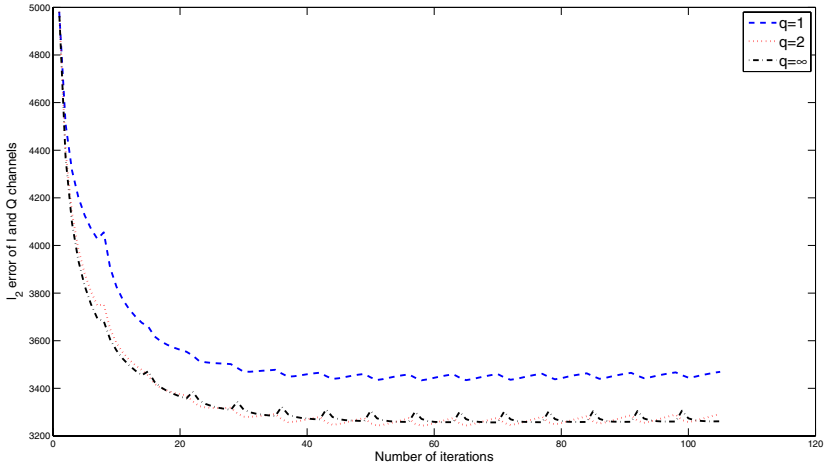

FIG. 6.5. *The ℓ_2 error between the* original color image *and the iterations of the algorithm is shown for different values of $q = 1, 2, \infty$. We have considered $L_n = 7$ and $n_{\max} = 15$ the numbers of inner and outer iterations, respectively. We have fixed here $\omega_\lambda = 1/20$, $\theta_\lambda = 10$, and $\rho_\lambda = 20 \times 2^{-j}$. Further iterations of TV minimization are added in the outer loop to enforce edge enhancing.*

FIG. 6.6. Left: *Low quality color image of the fresco dated to* 1940. Center: *High quality gray image of the fresco dated to* 1920. *Some details are not visible in the color version.* Right: *The reconstructed image after* 6 *outer iterations with* 7 *inner iterations each, for $q = \infty$. The final Y channel is substituted with the high-resolution gray level datum. The discontinuities are enhanced, and no artifact colors appear.*

These numerical experiments confirm that the use of the joint sparsity measure $\Phi^{(q)}$ associated to the curvelet representation can improve significantly the quality of the reconstructed color image. Better results are achieved by choosing $q = \infty$ and by the adaptive choice of weights as indicators of the sparsity pattern. Further improvements can be achieved by channelwise edge enhancing, e.g., via total variation minimization. An application to the real case of the art frescoes is illustrated in Figure 6.6.

7. Final remarks. 1. If the index set Λ is infinite, then T^*T is represented as a biinfinite matrix, and thus its evaluation might not be exactly numerically implementable. In a subsequent work we will consider the case $\#\Lambda = \infty$ and the treatment

of sparse (approximate) evaluations of bi-infinite matrices in order to realize fast and convergent schemes also in this situation; compare also [39, 14, 15].

2. In the subsequent paper [27] we investigated the role of the various parameters. To exploit the optimal performance of the scheme, an extensive campaign of numerical experiments should be conducted. It is also crucial to investigate the deeper relations among the parameter ρ_λ, the *multifractal analysis* as, e.g., in [31], and morphological image analysis. In particular, the parallel between the functional J and the Γ-approximation of the Mumford–Shah functional by Ambrosio and Tortorelli [1, 5] is suggestive:

$$F_\varepsilon(u,v) := \underbrace{\int_\Omega (u-g)^2 dx}_{\sim \mathcal{T}(u)} + \underbrace{\int_\Omega v^2 f(\nabla u) dx}_{\sim \sum_\lambda v_\lambda \|u\|_q} + \underbrace{\int_\Omega \varepsilon |\nabla u|^2 dx}_{\sim \sum_\lambda \omega_\lambda \|u\|_2^2}$$
$$+ \underbrace{\int_\Omega \left(\varepsilon |\nabla v|^2 + \frac{1}{4\varepsilon}(1-v)^2 \right) dx}_{\sim \sum_\lambda \theta_\lambda (\rho_\lambda - v_\lambda)^2},$$

where f is a suitable polyconvex function, e.g., $f(\nabla u) = (|\nabla u|^2 + |u_x \times u_y|) = (|\nabla u|^2 + |\mathrm{adj}_2(\nabla u)|)$, where $\mathrm{adj}_2(A)$ is the matrix of all 2×2 minors of A. The minimization of this term enforces the fact that derivatives of different channels are large only in the same directions.

3. While we were finishing this paper, we were informed by Teschke of the results in [19]. In that paper the authors consider linear inverse problems where the solution is assumed to fulfill some general 1-homogeneous convex constraint. They develop an algorithm that amounts to a projected Landweber iteration and that provides an iterative approach to the solution of this inverse problem. In particular, for the case $\omega = (\omega_\lambda)_\lambda = 0$, some of our results stated in section 4 can be reformulated in this more general setting and therefore derived from [19]. However, for $\omega \neq 0$ the sparsity measure $\Psi^{(q)}_{v,\omega}$ as in (4.2) is not 1-homogeneous, and the elaborations in section 4 are needed. Moreover, for the relevant cases $q = 1, 2, \infty$, we express explicitly the projection $P^{q'}_{v/2}$. Due to their generality, the results in [19] do not provide concrete recipes to compute such projections.

8. Conclusion. We have investigated joint sparsity measures with respect to frame expansions of vector-valued functions. These sparsity measures generalize approaches valid for scalar functions and take into account common sparsity patterns through different channels. We have analyzed linear inverse problems with joint sparsity regularization as well as their efficient numerical solution by means of a novel algorithm based on thresholded Landweber iterations. We have provided the convergence analysis for a wide range of parameters. The role of the joint sparsity measure is twofold: to tighten the characterization of solutions of interest and to extract significant morphological properties which are a common feature of all of the channels. By numerical applications in color image restoration, we have shown that joint sparsity significantly outperforms uncoupled constraints. We have presented the results of an application to a relevant real-world problem in art restoration. The wide range of applicability of our approach includes several other problems with coupled vector-valued solutions, e.g., neuroimaging and distributed compressed sensing.

Acknowledgment. Massimo Fornasier thanks NuHAG for its warm hospitality.

LINEAR CONVERGENCE OF AN ADAPTIVE FINITE ELEMENT METHOD FOR THE p-LAPLACIAN EQUATION*

LARS DIENING† AND CHRISTIAN KREUZER‡

Abstract. We study an adaptive finite element method for the p-Laplacian like PDEs using piecewise linear, continuous functions. The error is measured by means of the quasi norm of Barrett and Liu. We provide residual based error estimators without a gap between the upper and lower bound. We show linear convergence of the algorithm which is similar to the one of Morin, Nochetto, and Siebert. All results are obtained without extra marking for the oscillation.

Key words. convergence, a posteriori error estimator, p-Laplacian, quasi norms, error reduction, oscillation

DOI. 10.1137/070681508

1. Introduction.

Let Ω be a polyhedral, bounded domain in $\mathbb{R}^d$, $d \in \mathbb{N}$. We consider the following system of nonlinear structure:

$$\begin{aligned} -\operatorname{div}(\mathbf{A}(\nabla u)) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

Our considerations include in particular the case of the p-Laplacian, where

$$\mathbf{A}(\nabla u) = (\kappa + |\nabla u|)^{p-2}\, \nabla u, \tag{1.2}$$

with $1 < p < \infty$, $\kappa \geq 0$, $f \in L^{p'}(\Omega)$, and $\frac{1}{p} + \frac{1}{p'} = 1$.

The purpose of this paper is to present a linear convergence result for an adaptive finite element method (AFEM) applied to the nonlinear Laplace equation (1.1). As is common practice the AFEM consists of a loop

$$\text{SOLVE} \to \text{ESTIMATE} \to \text{MARK} \to \text{REFINE} \tag{AFEM}$$

starting from a initial triangulation of Ω. To be more specific, the finite element problem on the current mesh is solved, then the a posteriori error estimator is computed, and finally with its help elements are marked for refinement. The marking strategy resorts to *Dörfler's marking* introduced in [Dör96]. The algorithm uses piecewise linear, continuous finite elements, whereas the refinement is realized by newest vertex bisection. This produces a sequence of weak finite element solutions u_k of (1.1) in nested finite element spaces V_k.

This author's research was supported by Project C.1 of the DFG-Research-Unit "Nonlinear Partial Differential Equations": Generalized Newtonian Fluids and Electrorheological Fluids.

The main result states linear convergence of u_k to the weak solution u of (1.1). In particular, we show that there exists $\alpha \in (0,1)$, $C > 0$ with

$$\|\mathbf{F}(\nabla u_k) - \mathbf{F}(\nabla u)\|_2^2 + \operatorname{osc}_k^2(f) \leq \alpha^{2k} C,$$

where the vector field $\mathbf{F}$ arises from the vector field $\mathbf{A}$ by $\mathbf{F}(\mathbf{a}) := |\mathbf{A}(\mathbf{a})|^{\frac{1}{2}} |\mathbf{a}|^{-\frac{1}{2}} \mathbf{a}$. The L^2 norm of the error $\|\mathbf{F}(\nabla u_k) - \mathbf{F}(\nabla u)\|_2^2$ measured in terms of $\mathbf{F}$ is equivalent to the so-called *quasi norm* $\|\nabla u_k - \nabla u\|_{(p)}^2$ introduced by Barrett and Liu; cf. [BL94a, BL94b] and Remark 5. The *quasi norm* was a breakthrough in the numerical investigation of (1.1). In particular, Barrett and Liu obtained the best approximation property of the conforming, finite element solution $u_h \in V_h$ in terms of quasi norms, i.e.,

$$\|\nabla v - \nabla v_h\|_{(p)}^2 \leq c \min_{\psi_h \in V_h} \|\nabla v - \nabla \psi_h\|_{(p)}^2.$$

In [EL05] it has been proved by Ebmeyer and Liu that for piecewise linear, continuous finite elements and $p > \frac{2d}{d+2}$ the best approximation error can be estimated as

$$\min_{\psi_h \in V_h} \|\nabla v - \nabla \psi_h\|_{(p)}^2 \leq c\, h^2 \int_\Omega (\kappa + |\nabla u|)^{p-2} \left|\nabla^2 u\right|^2 dx. \tag{1.3}$$

Recently, Diening and Růžička improved these results in [DR07] to the case $p > 1$, admitting also more general finite element spaces. In particular, they showed that

$$\|\mathbf{F}(\nabla v) - \mathbf{F}(\nabla v_h)\|_2^2 \leq c \min_{\psi_h \in V_h} \|\mathbf{F}(\nabla v) - \mathbf{F}(\nabla \psi_h)\|_2^2$$

and

$$\|\mathbf{F}(\nabla v) - \mathbf{F}(\nabla \Pi_h v)\|_2^2 \leq c\, h^2 \|\nabla \mathbf{F}(\nabla u)\|_2^2, \tag{1.4}$$

where Π_h is a suitable interpolation operator, e.g., the Scott–Zhang operator. We want to mention that the right-hand sides of (1.3) and (1.4) are proportional. They express the natural regularity of a *strong* solution of (1.1) (cf. [Giu03], [BL93a], [ELS05], [Ebm05]).

The technique of quasi norms found its way into a posteriori analysis in the work of Liu and Yan [LY01, LY02]. They show that

$$c\, \eta_h^2 - C \operatorname{osc}_h^2(f) \leq \|\nabla u - \nabla u_h\|_{(p)}^2 \leq C \left(\eta_h^2 + \widetilde{\eta}^2\right)$$

for residual based estimators η_h. Numerical experiments [LY01, CK06] indicate that these new estimators are indeed sharper and lead to more efficient meshes than existing ones. However, for convergence analysis the additional term $\widetilde{\eta}^2$ causes problems, since it forms a gap between the left- and the right-hand side. In this work we are able to overcome this drawback and prove estimates avoiding $\widetilde{\eta}^2$ (see Lemma 8 and Corollary 11):

$$c\, \eta_h^2 - C \operatorname{osc}_h^2(f) \leq \|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_h)\|_2^2 \leq C\, \eta_h^2. \tag{1.5}$$

Recently a posteriori error estimators by gradient recovery have been studied in [CLY06].

Dörfler [Dör96] was the first to prove linear error reduction of (AFEM) for the linear Laplacian if the data oscillation is small enough. Later, this additional assumption has been removed by Morin, Nochetto, and Siebert in [MNS00] by additional marking for oscillation. The first convergence result for the nonlinear Laplacian is stated by Veeser [Ve02]. There residual based estimators for the $W^{1,p}$ norm are used. Since a gap appears in the power between the upper and lower estimates this prevents proving linear convergence.

The convergence results in the linear case are heavily based on Galerkin orthogonality and the Pythagorean theorem, which yield

$$|||u_h - u|||^2 = |||u_H - u|||^2 - |||u_H - u_h|||^2 \tag{1.6}$$

in the energy norm. To overcome the lack of orthogonality in the nonlinear case we proceed as follows: We prove that the energy difference of weak solutions in nested spaces $V_1 \subset V_2$ is proportional to the quasi-norm distance, i.e.,

$$\mathcal{J}(u_1) - \mathcal{J}(u_2) \sim \|\nabla u_1 - \nabla u_2\|_{(p)}^2 \sim \|\mathbf{F}(\nabla u_1) - \mathbf{F}(\nabla u_2)\|_2^2,$$

where $\mathcal{J}(u)$ is the energy functional of (1.1), $u_1 \in V_1$, and $u_2 \in V_2$; see (2.10) and Lemma 16. This property and the trivial equality

$$\mathcal{J}(u_h) - \mathcal{J}(u) = \big(\mathcal{J}(u_H) - \mathcal{J}(u)\big) - \big(\mathcal{J}(u_H) - \mathcal{J}(u_h)\big)$$

are our substitute for the orthogonality of the error (1.6).

In the linear, symmetric case it is possible to consider the reduction of the error and the oscillation independently, since the oscillation is solely dependent on the data f. Mekchay and Nochetto showed linear reduction of the sum of error and oscillation for nonsymmetric second order linear elliptic PDEs in [MN05]. In this case oscillation and error are coupled. A similar effect appears in our nonlinear setting. We introduce a new proof for error reduction, which enables us to manage without extra marking for oscillation; see Remark 14. Our proof permits us to use the fact that oscillation is dominated by the error indicator. Moreover, we prove a strict reduction of the difference of energies plus the oscillation in each step.

An essential tool in our calculations is the use of *shifted* N-functions, namely φ_a. They are closely related to the quasi norms, which are best expressed by the relation

$$\big(\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})\big) \cdot (\mathbf{a} - \mathbf{b}) \sim \big|\mathbf{F}(\mathbf{a}) - \mathbf{F}(\mathbf{b})\big|^2 \sim \varphi_{|\mathbf{a}|}(|\mathbf{a} - \mathbf{b}|)$$

for $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$. See Lemma 3 for more details. The shifted N-functions enable us to handle more general nonlinear equations than the p-Laplacian, namely the φ-Laplacian from (2.1). But most important, the shifted N-functions simplify and clarify the calculations significantly also in the case of the p-Laplacian.

2. Preliminaries. We first introduce the nonlinear Dirichlet problem. Thereby the nonlinear partial differential operator called φ-Laplacian is defined via a certain function $\varphi : \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$. The most popular case of such operators is the p-Laplacian which corresponds to the function $\varphi(t) := \int_0^t (\kappa + s)^{p-2} s \, ds$. As mentioned before, the treatment of the nonlinear Laplacian via *N-functions* simplifies and clarifies calculations. Assumptions on φ and related properties are discussed subsequently. Afterwards the weak formulation of the problem is stated along with the corresponding minimizing problem.

Let Ω be a polyhedral, bounded domain in $\mathbb{R}^d$, $d \in \mathbb{N}$. In the center of our considerations are solutions of the φ-Laplacian problem, i.e.,

$$\begin{aligned} -\operatorname{div}(\mathbf{A}(\nabla u)) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

with

$$\mathbf{A}(\nabla u) = \varphi'(|\nabla u|)\frac{\nabla u}{|\nabla u|}. \tag{2.2}$$

2.1. Assumptions on φ and resulting properties. Now we shed light on the considered function φ. To not go beyond the scope of this work we give only a short sketch of the underlying theory. The following definitions and results are standard in the theory of Orlicz functions and can be found, for example, in [RR91]. A few assertions are also proved in the appendix.

We use $c, C > 0$ (no index) as generic constants; i.e., their value may change from line to line but does not depend on the important variables. Furthermore, we write $f \sim g$ iff $c\,f \le g \le C\,f$.

A continuous function $\varphi : \mathbb{R}^{\ge 0} \to \mathbb{R}^{\ge 0}$ is said to be an *N-function* iff

- φ is continuous and convex with $\varphi(0) = 0$;
- there exists a derivative φ' of φ which is right continuous, nondecreasing, and satisfies $\varphi'(0) = 0$, $\varphi'(t) > 0$ for $t > 0$, and $\lim_{t\to\infty} \varphi'(t) = \infty$.

The N in N-function stands for *nice* function. Furthermore, φ satisfies the Δ_2-condition iff it holds that

- $\varphi(2t) \le C\,\varphi(t)$ uniformly in $t \ge 0$.

We denote the smallest such constant by $\Delta_2(\varphi)$. Since $\varphi(t) \le \varphi(2t)$ the Δ_2-condition means that $\varphi(t)$ and $\varphi(2t)$ are proportional. Note that if $\Delta_2(\varphi) < \infty$, then $\varphi(t) \sim \varphi(a\,t)$ uniformly in $t \ge 0$ for any fixed $a > 1$.

Define $(\varphi')^{-1} : \mathbb{R}^{\ge 0} \to \mathbb{R}^{\ge 0}$ as

$$(\varphi')^{-1}(t) := \sup\{u \in \mathbb{R}^{\ge 0} : \varphi'(u) \le t\}.$$

If φ' is strictly increasing, then $(\varphi')^{-1}$ is the inverse function of φ'. By the definition

$$\varphi^*(t) := \int_0^t (\varphi')^{-1}(s)\,ds$$

the so-called complementary function φ^* of φ is again an N-function and $(\varphi^*)'(t) = (\varphi')^{-1}(t)$ for $t > 0$. Note that $(\varphi^*)^* = \varphi$.

Assume that $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$. Then for all $\delta > 0$ there exists $C_\delta > 0$ (depending only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$) such that for all $s, t \ge 0$ it holds that

$$\begin{aligned} s\,t &\le C_\delta\,\varphi(s) + \delta\,\varphi^*(t), \\ s\,t &\le \delta\,\varphi(s) + C_\delta\,\varphi^*(t). \end{aligned} \tag{2.3}$$

This inequality is called Young's inequality. Moreover, for all $t > 0$ there exists $s > 0$ such that

$$s\,t = \varphi(s) + \varphi^*(t). \tag{2.4}$$

Further basic inequalities are for all $t \geq 0$

$$t \leq \varphi^{-1}(t)\,(\varphi^*)^{-1}(t) \leq 2t,$$

$$\frac{t}{2}\varphi'\Big(\frac{t}{2}\Big) \leq \varphi(t) \leq t\,\varphi'(t), \tag{2.5}$$

$$\varphi\bigg(\frac{\varphi^*(t)}{t}\bigg) \leq \varphi^*(t) \leq \varphi\bigg(\frac{2\,\varphi^*(t)}{t}\bigg).$$

Therefore, uniformly in $t \geq 0$

$$\varphi^{-1}(t)\,(\varphi^*)^{-1}(t) \sim t, \qquad \varphi(t) \sim \varphi'(t)\,t, \qquad \varphi^*\big(\varphi'(t)\big) \sim \varphi(t), \tag{2.6}$$

where the constants depend only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$.

As in [DE08, DR07] we require the following properties about our function φ.

Assumption 1. Let φ be an N-function with $\Delta_2(\varphi) < \infty$, $\Delta_2(\varphi^*) < \infty$, and $\varphi \in C^2(0,\infty)$ such that

$$\varphi'(t) \sim t\,\varphi''(t) \tag{2.7}$$

uniformly in $t \geq 0$.

It is shown in [DE08] that φ satisfies Assumption 1 iff φ^* satisfies Assumption 1. Moreover, it is shown that we have for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$

$$\begin{aligned} \big(\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})\big) \cdot (\mathbf{a} - \mathbf{b}) &\geq c\,\varphi''(|\mathbf{a}| + |\mathbf{b}|)\,|\mathbf{a} - \mathbf{b}|^2, \\ |\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})| &\leq C\,\varphi''(|\mathbf{a}| + |\mathbf{b}|)\,|\mathbf{a} - \mathbf{b}|, \end{aligned} \tag{2.8}$$

where c, C depend only on $\Delta_2(\varphi)$, $\Delta_2(\varphi)$, and the constant in (2.7).

Remark 2. The most important example of such functions is certainly the p-Laplacian. Thereby $\varphi(t) := \int_0^t (\kappa + s)^{p-2}\,s\,ds$ with $1 < p < \infty$ and $\kappa \geq 0$. This function satisfies Assumption 1. If $\kappa = 0$, then Young's inequality (2.3) coincides with the well-known classical Young inequality

$$s\,t \leq \delta \frac{1}{p} t^p + \delta^{\frac{-1}{p-1}} \frac{1}{q} s^q,$$

where $q \in (1,\infty)$ with $\frac{1}{p} + \frac{1}{q} = 1$. Moreover, with $\mathbf{A}(\mathbf{a}) = \varphi'(|\mathbf{a}|)\frac{\mathbf{a}}{|\mathbf{a}|} = (\kappa + |\mathbf{a}|)^{p-2}\mathbf{a}$ (2.8) corresponds to the well-known monotonicity and coercivity inequalities

$$\begin{aligned} \big((\kappa + |\mathbf{a}|)^{p-2}\mathbf{a} - (\kappa + |\mathbf{b}|)^{p-2}\mathbf{b}\big)(\mathbf{a} - \mathbf{b}) &\geq c\,(\kappa + |\mathbf{a}| + |\mathbf{b}|)^{p-2}\,|\mathbf{a} - \mathbf{b}|^2, \\ |(\kappa + |\mathbf{a}|)^{p-2}\mathbf{a} - (\kappa + |\mathbf{b}|)^{p-2}\mathbf{b}| &\leq C\,(\kappa + |\mathbf{a}| + |\mathbf{b}|)^{p-2}\,|\mathbf{a} - \mathbf{b}| \end{aligned}$$

for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ (see, e.g., [GM75, BL93a]).

2.2. Weak formulation of the φ-Laplacian problem and corresponding minimizing problem. We introduce the weak form of the nonlinear equation (2.1). To proceed we first have to introduce analytical background. For details we refer the reader to [RR91].

In the following the function φ will be a fixed N-function as stated in Assumption 1. By L^φ and $W^{1,\varphi}$ we denote the classical Orlicz and Sobolev–Orlicz spaces; i.e., $g \in L^\varphi$ iff $\int \varphi(|g|)\,dx < \infty$ and $g \in W^{1,\varphi}$ iff $g, \nabla g \in L^\varphi$. The norm on L^φ is

given by $\|f\|_\varphi = \inf\{\lambda > 0 : \int \varphi(f/\lambda)\,dx \le 1\}$. By $W_0^{1,\varphi}(\Omega)$ we denote the closure of $C_0^\infty(\Omega)$ in $W^{1,\varphi}(\Omega)$.

The weak formulation reads as follows: For $f \in L^{\varphi^*}(\Omega) \subset (W_0^{1,\varphi}(\Omega))^*$ find $u \in W_0^{1,\varphi}(\Omega)$ with

$$\langle \mathbf{A}(\nabla u), \nabla v\rangle = \langle f, v\rangle \qquad \text{for all } v \in W_0^{1,\varphi}(\Omega). \tag{2.9}$$

The theory of monotone operators ensures the unique existence of u. Moreover, u is the unique minimizer of the *energy functional*

$$\mathcal{J}(u) := \int_\Omega \varphi(|\nabla u|)\,dx - \int_\Omega u\,f\,dx \to \min! \tag{2.10}$$

3. A posteriori analysis. In this section we first discuss our concept of distance. In particular we introduce shifted N-functions and construct a measure of distance related to the nonlinear problem (2.1). In case of the p-Laplacian this concept is equivalent to the quasi norm introduced by Barrett and Liu [BL93a]. In the following we introduce the finite element spaces and note an interpolation inequality. In the second part of this section we construct a posteriori upper and lower bounds for the error of a finite element solution to the continuous solution. Finally, we discuss a discrete local lower bound, i.e., a lower bound for the distance between two different finite element solutions.

3.1. Concept of distance. Let φ again be a fixed N-function. We define another N-function ψ by

$$\psi'(t) := \sqrt{\varphi'(t)\,t}$$

and set for $\mathbf{a} \in \mathbb{R}^d$

$$\mathbf{F}(\mathbf{a}) := \psi'(|\mathbf{a}|)\,\frac{\mathbf{a}}{|\mathbf{a}|} = \sqrt{\varphi'(|\mathbf{a}|)\,|\mathbf{a}|}\;\frac{\mathbf{a}}{|\mathbf{a}|} = \sqrt{|\mathbf{A}(\mathbf{a})|\,|\mathbf{a}|}\,\frac{\mathbf{a}}{|\mathbf{a}|}. \tag{3.1}$$

It is shown in [DE08] that since φ satisfies Assumption 1 also ψ, ψ^*, and φ^* satisfy Assumption 1. It is also shown that as a consequence (2.8) holds with $\mathbf{A}, \varphi$ replaced by $\mathbf{F}, \psi$. In addition we introduce a family of N-function $\{\varphi_a\}_{a\ge 0}$ by

$$\frac{\varphi_a'(t)}{t} := \frac{\varphi'(a+t)}{a+t} \tag{3.2}$$

which owing to (2.7) implies that $\varphi_a''(t) \sim \varphi''(a+t)$ uniformly in $a, t \ge 0$. The functions φ_a are called *shifted* N-functions. The basic properties of φ_a are summarized in the appendix. The connection between $\mathbf{A}$, $\mathbf{F}$, and $\{\varphi_a\}_{a\ge 0}$ is best reflected in the following lemma from [DE08].

LEMMA 3. *Let φ satisfy Assumption* 1 *and let* $\mathbf{A}$ *and* $\mathbf{F}$ *be defined by* (2.2) *and* (3.1). *Then*

$$\big(\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})\big)\cdot\big(\mathbf{a}-\mathbf{b}\big) \sim \big|\mathbf{F}(\mathbf{a}) - \mathbf{F}(\mathbf{b})\big|^2 \tag{3.3a}$$

$$\sim \varphi_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|), \tag{3.3b}$$

$$\sim |\mathbf{a}-\mathbf{b}|^2\,\varphi''\big(|\mathbf{a}| + |\mathbf{b}|\big) \tag{3.3c}$$

uniformly in $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$. *If* $\varphi''(0)$ *does not exists, the expression in* (3.3c) *is continuously extended by zero for* $|\mathbf{a}| = |\mathbf{b}| = \mathbf{0}$. *Moreover,*

$$|\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})| \sim \varphi'_{|\mathbf{a}|}(|\mathbf{a} - \mathbf{b}|), \tag{3.3d}$$

$$\mathbf{A}(\mathbf{b}) \cdot \mathbf{b} \sim |\mathbf{F}(\mathbf{b})|^2 \sim \varphi(|\mathbf{b}|) \tag{3.3e}$$

uniformly in $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$.

We use the equivalences (3.3) extensively in this paper without referring.

An immediately consequence of Lemma 3 is the following corollary.

COROLLARY 4. *We have for all* $u, v \in W^{1,\varphi}(\Omega)$

$$\int_\Omega \big(\mathbf{A}(\nabla u) - \mathbf{A}(\nabla v)\big) \cdot (\nabla u - \nabla v)\, dx \sim \|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla v)\|_2^2 \sim \int_\Omega \varphi_{|\nabla u|}(|\nabla u - \nabla v|)\, dx.$$

Remark 5. In the case of the p-Laplacian, i.e., $\mathbf{A}(\nabla v) = (\kappa + |\nabla v|)^{p-2}\nabla v$ and $\varphi'(t) = (\kappa + t)^{p-2}\, t$ with $1 < p < \infty$ and $\kappa \geq 0$, we have for all $\mathbf{a} \in \mathbb{R}^d$, $t \geq 0$

$$\mathbf{F}(\mathbf{a}) := (\kappa + |\mathbf{a}|)^{\frac{p-2}{2}}\mathbf{a}, \qquad \psi'(t) := (\kappa + t)^{\frac{p-2}{2}}\, t.$$

Moreover, for the p-Laplacian all expressions in Corollary 4 are proportional to the quasi norm introduced by Barrett and Liu in [BL93a]. This follows from the relation

$$\varphi'_{|\mathbf{a}|}(t) = (\kappa + |\mathbf{a}| + t)^{p-2}t$$

and

$$\|\nabla u - \nabla v\|_{(p)}^2 = \int_\Omega (\kappa + |\nabla u| + |\nabla u - \nabla v|)^{p-2}|\nabla u - \nabla v|^2\, dx = \int_\Omega \varphi'_{|\nabla u|}(|\nabla u - \nabla v|)|\nabla u - \nabla v|\, dx \sim \int_\Omega \varphi_{|\nabla u|}(|\nabla u - \nabla v|)\, dx.$$

This ensures in the case of the p-Laplacian that all the results below can also be expressed in terms of the quasi norm.

Additionally, we need the following direct consequence of Lemma 3.

COROLLARY 6. *Let* $\mathbf{A}, \varphi, \mathbf{F}$ *be as in Lemma* 3. *Then for all* $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$

$$(\varphi_{|\mathbf{a}|})^*\big(\big|\mathbf{A}(\mathbf{a}) - \mathbf{A}(\mathbf{b})\big|\big) \sim \varphi_{|\mathbf{a}|}\big(\big|\mathbf{a} - \mathbf{b}\big|\big) \sim \big|\mathbf{F}(\mathbf{a}) - \mathbf{F}(\mathbf{b})\big|^2. \tag{3.4}$$

Proof. The second relation is contained in Lemma 3. The first relation follows from (3.3d), (2.6), and $\Delta_2(\varphi) < \infty$. ∎

3.2. Finite element spaces. Let $\mathcal{T}_H$ be a conforming triangulation of Ω consisting of closed simplices $T \in \mathcal{T}_H$. Let h_T denote the diameter of the (closed) simplex $T \in \mathcal{T}_H$ and ρ_T the maximal radius of a ball that is contained in T. The maximal quotient h_T/ρ_T with $T \in \mathcal{T}_h$ is called the *shape regularity* (chunkiness) of $\mathcal{T}_H$.

Let $V_H := V(\mathcal{T}_H)$ be the space of continuous, piecewise linear finite elements over $\mathcal{T}_H$ with boundary values zero; then $V_H \subset V$. By $u_H \in V_H$ we denote the finite element solution of (2.9) with respect to V_H, i.e.,

$$\langle \mathbf{A}(\nabla u_H), \nabla v_H\rangle = \langle f, v_H\rangle \qquad \text{for all } v_H \in V_H, \tag{3.5}$$

where $\langle f, v_H\rangle = \int_\Omega f\, v_H\, dx$. The theory of monotone operators ensures the existence of a unique solution.

We denote by Γ_H the set of interior faces (sides) of the triangulation $\mathcal{T}_H$. For $\gamma \in \Gamma_H$ we define N_γ as the set of elements sharing γ and S_γ as the union of these elements, i.e.,

$$N_\gamma := \{T_1, T_2 \in \mathcal{T}_H \,:\, T_1 \cap T_2 = \gamma\}, \qquad S_\gamma := \bigcup_{T\in N_\gamma} T.$$

For $T \in \mathcal{T}_H$ define the set of neighbors N_T and the neighborhood S_T by

$$N_T := \{T' \in \mathcal{T}_H \,:\, T' \cap T \in \Gamma_H\}, \qquad S_T := \bigcup_{T'\in N_T} T'.$$

For interpolation estimates (see (3.6)) we additionally need to define the patch Ω_T around T and the set of its elements ω_T by

$$\omega_T := \{T' \in \mathcal{T}_H \,:\, T' \cap T \neq \emptyset\}, \qquad \Omega_T := \bigcup_{T'\in\omega_T} T'.$$

For $\gamma \in \Gamma_H$ let $h_\gamma := \operatorname{diam}(\gamma)$. For $T \in \mathcal{T}_H$ it holds that $h_T \sim h_\gamma$ for each face (side) $\gamma \subset \partial T$ depending only on the shape regularity of $\mathcal{T}_H$.

Let $\Pi_H : V \to V_H$ be the Scott–Zhang interpolation operator which respects zero boundary values; see [SZ90]. Additionally Π_H satisfies $\Pi_H v_H = v_H$ for all $v_H \in V_H$. It was shown in [DR07] that for all $v \in W^{1,\varphi}(\Omega)$, $a \geq 0$, and $T \in \mathcal{T}_h$

$$\int_T \varphi_a(|v - \Pi_H v|)\, dx + \int_T \varphi_a(h_T\,|\nabla v - \nabla \Pi_H v|)\, dx \leq C \int_{\Omega_T} \varphi_a(h_T\,|\nabla v|)\, dx, \tag{3.6}$$

where C depends only on $\Delta_2(\varphi)$ and the shape regularity of $\mathcal{T}_H$.

We introduce residual based error estimators for our system (2.1). For $\gamma \in \Gamma_H$ and $T \in \mathcal{T}_H$ define the (local) *interior and the jump estimators* by

$$\eta_E^2(u_H, T) := \int_T (\varphi_{|\nabla u_H|})^*\big(h_T\,|f|\big)\, dx,$$

$$\eta_J^2(u_H, \gamma) := \int_\gamma h_\gamma \left|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\right|^2 dx,$$

where $[\![\mathbf{F}(\nabla u_H)]\!]_\gamma$ denotes the jump of $\mathbf{F}(\nabla u_H)$ over the face γ. Furthermore, we define for $T \in \mathcal{T}_H$ the (local) element based error indicators and the oscillation as

$$\begin{aligned} \eta^2(u_H, T) &:= \eta_E^2(u_H, T) + \sum_{\gamma\in\Gamma_H, \gamma\subset\partial T} \eta_J^2(u_H, \gamma), \\ \operatorname{osc}^2(u_H, T) &:= \inf_{f_T\in\mathbb{R}} \int_T (\varphi_{|\nabla u_H|})^*\big(h_T\,|f - f_T|\big)\, dx. \end{aligned} \tag{3.7}$$

For a subset $\hat{\mathcal{T}}_H \subset \mathcal{T}_H$ we define the *total error estimator* over $\hat{\mathcal{T}}_H$ by

$$\eta^2(u_k, \hat{\mathcal{T}}_H) := \sum_{T\in\hat{\mathcal{T}}_H} \eta^2(u_k, T).$$

Note that $\eta^2(u_H, \{T\}) = \eta^2(u_H, T)$, and so there is no confusion between this definition of η^2 and (3.7). Similarly, we define the *total oscillation* on subsets of $\mathcal{T}_H$.

Furthermore, we use $e_H := u - u_H$ for the difference of the solutions.

Remark 7. In the case of the p-Laplacian we can translate the above definitions of the estimators and the oscillation. For the jump estimator we obtain by Corollary 4, Lemma 22, and Remark 5

$$\begin{aligned}\eta_J^2(u_H,\gamma) &= \int_\gamma h_\gamma \left|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\right|^2 dx \sim \int_{S_\gamma} \varphi_{|\nabla u_H|}\big([\![\nabla u_H]\!]_\gamma\big)\\ &\sim \int_{S_\gamma} \big(\kappa + |\nabla u_H| + |[\![\nabla u_H]\!]_\gamma|\big)^{p-2} |[\![\nabla u_H]\!]_\gamma|\, dx.\end{aligned}$$

The element residual and the oscillation can be treated in the same way. We use Lemma 22, (2.6), and Remark 5 to obtain

$$\begin{aligned}\eta_E^2(u_H,T) &= \int_T (\varphi_{|\nabla u_H|})^*\big(h_T\,|f|\big)\,dx \sim \int_T (\varphi^*)_{\varphi'(|\nabla u_H|)}\big(h_T\,|f|\big)\,dx\\ &\sim \int_T \big(\kappa + |\nabla u_H|^{p-1} + h_T\,|f|\big)^{q-2} h_T^2\,|f|^2\,dx.\end{aligned}$$

Let f_T denote the mean value of f over T. Then the same calculations yield for the oscillation

$$\operatorname{osc}^2(u_H,T) \sim \int_T \big(\kappa + |\nabla u_H|^{p-1} + h_T\,|f - f_T|\big)^{q-2} h_T^2\,|f - f_T|^2\,dx,$$

where we have used that for any N-function ϱ with $\Delta_2(\varrho) < \infty$ it holds that

$$\inf_{f_T} \int_T \varrho(|f - f_T|)\,dx \le \int_T \varrho(|f - f_T|)\,dx \le c \inf_{f_T} \int_T \varrho(|f - f_T|)\,dx$$

with constants c depending only on $\Delta_2(\varphi)$. Thus our a posteriori estimators improve the one in [LY02].

3.3. Upper bound. To obtain the upper bound we use Lemma 3, the Galerkin orthogonality, and $\Pi_H : V \to V_H$:

$$\begin{aligned}\big\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\big\|_2^2 &\sim \big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H), \nabla(u - u_H)\big\rangle\\ &= \big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H), \nabla(e_H - \Pi_H e_H)\big\rangle.\end{aligned}$$

By integration by parts on each $T \in \mathcal{T}_h$ we get

$$\begin{aligned}&\big\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\big\|_2^2\\ &\quad\sim -\sum_{T\in\mathcal{T}_H} \int_{\partial T} \big(\mathbf{A}(\nabla u_H)\cdot\mathbf{n}\big)\big(e_H - \Pi_H e_H\big)\,dx + \big\langle f, e_H - \Pi_H e_H\big\rangle\\ &\quad= -\sum_{\gamma\in\Gamma_H} \int_\gamma [\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma \big(e_H - \Pi_H e_H\big)\,dx + \big\langle f, e_H - \Pi_H e_H\big\rangle\\ &\quad= (\mathtt{Upper}_1) + (\mathtt{Upper}_2),\end{aligned} \tag{3.8}$$

where $\mathbf{n}$ is the outer normal of ∂T. We handle the two terms jump residual ($\mathtt{Upper}_1$) and element residual ($\mathtt{Upper}_2$) separately. First we estimate

$$(\mathtt{Upper}_1) \le \sum_{\gamma\in\Gamma_H} \big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big| \int_\gamma \big|e_H - \Pi_H e_H\big|\,dx, \tag{3.9}$$

where we have used that ∇u_H is constant on each $T \in \mathcal{T}_H$. The trace theorem $W^{1,1}(S_\gamma) \hookrightarrow L^1(\gamma)$ and the $W^{1,1}$-approximability of Π_H (see [SZ90] or use (3.6) with $\varphi(t) = t$ and $a = 0$) imply that

$$\begin{aligned}\int_\gamma \big|e_H - \Pi_H e_H\big|\,dx &\le C\,h_\gamma \int_{S_\gamma} |e_H - \Pi_H e_H|\,dx + C \int_{S_\gamma} |\nabla e_H - \nabla\Pi_H e_H|\,dx\\ &\le c \sum_{T\in N_\gamma} \int_{\Omega_T} |\nabla e_h|\,dx.\end{aligned}$$

If we combine this with (3.9), then we get

$$(\mathtt{Upper}_1) \le C \sum_{\gamma\in\Gamma_H} \left(\big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big| \sum_{T\in N_\gamma} \int_{\Omega_T} \big|\nabla e_H\big|\,dx \right).$$

Now Young's inequality (2.3) for $\varphi_{|\nabla u_H|}$ on each element yields

$$(\mathtt{Upper}_1) \le \sum_{\gamma\in\Gamma_H} \sum_{T\in N_\gamma} \int_{\Omega_T} C_\delta\,(\varphi_{|\nabla u_H|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big|\big) + \delta\,\varphi_{|\nabla u_H|}\big(\big|\nabla e_H\big|\big)\,dx.$$

Due to (3.4) we have

$$(\varphi_{|\nabla u_H|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big|\big) \sim \varphi_{|\nabla u_H|}\big(\big|[\![\nabla u_H]\!]_\gamma\big|\big) \sim \big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2. \tag{3.10}$$

Note that due to shape regularity it holds that $h_{T'} \sim h_T \sim h_\gamma$ for $T' \in \omega_T$, $T \in N_\gamma$. With the help of (3.10), Lemma 3, the finite overlapping of the Ω_T, and $\#N_T = 2$ we get

$$\begin{aligned}(\mathtt{Upper}_1) &\le C_\delta\,C \sum_{\gamma\in\Gamma_H} \sum_{T\in N_\gamma} \int_{\Omega_T} \big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2\\ &\quad + \delta\,C \sum_{\gamma\in\Gamma_H} \sum_{T\in N_\gamma} \int_{\Omega_T} \big|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)\big|^2\,dx\\ &\le C_\delta\,C \sum_{\gamma\in\Gamma_H} \int_\gamma h_\gamma \big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2 \qquad (3.11)\\ &\quad + \delta\,C \sum_{\gamma\in\Gamma_H} \sum_{T\in N_\gamma} \int_{\Omega_T} \big|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)\big|^2\,dx\\ &\le C_\delta\,C \sum_{\gamma\in\Gamma_H} \eta_J^2(u_H,\gamma) + \delta\,C\,\big\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\big\|_2^2.\end{aligned}$$

We treat the element residual as follows:

$$\begin{aligned}(\mathtt{Upper}_2) &\le \sum_{T\in\mathcal{T}_H}\int_T |f|\,|e_H-\Pi_H e_H|\,dx\\ &\le \sum_{T\in\mathcal{T}_H}\int_T C_\delta\,(\varphi_{|\nabla u_H|})^*\big(h_T\,|f|\big)+\delta\,(\varphi_{|\nabla u_H|})\bigg(\frac{|e_H-\Pi_H e_H|}{h_T}\bigg)\,dx,\end{aligned}$$

where we have used Young's inequality (2.3). Since ∇u_H is constant on each $T\in\mathcal{T}_H$ we can use (3.6) to obtain

$$(\mathtt{Upper}_2)\le C_\delta\,C\sum_{T\in\mathcal{T}_H}\eta_E^2(u_H,T)+\delta\,C\sum_{T\in\mathcal{T}_H}\int_{\Omega_T}\varphi_{|\nabla u_H(T)|}(|\nabla e_H|)\,dx,$$

where we write $\nabla u_H(T)$ to indicate that the shift on the whole Ω_T depends on the value of ∇u_H on the triangle T. In order to get $\varphi_{|\nabla u_H|}(|\nabla e_H|)$ instead of $\varphi_{|\nabla u_H(T)|}(|\nabla e_H|)$ we need a *change of shift*. We apply Corollary 26 on each $T'\in\omega_T$ and get

$$\begin{aligned}(\mathtt{Upper}_2)&\le C_\delta\,C\sum_{T\in\mathcal{T}_H}\eta_E^2(u_H,T)+\delta\,C\sum_{T\in\mathcal{T}_H}\int_{\Omega_T}\varphi_{|\nabla u_H|}(|\nabla e_H|)\,dx\\ &\quad+\delta\,C\sum_{T\in\mathcal{T}_H}\sum_{T'\in\omega_T}\int_{T'}\big|\mathbf{F}(\nabla u_H(T))-\mathbf{F}(\nabla u_H(T'))\big|^2\,dx.\end{aligned}$$

Now we transform the last term. Since one can reach T' from T by passing through a finite number of faces (depending on the shape regularity of $\mathcal{T}_H$), we can estimate each $\big|\mathbf{F}(\nabla u_H(T))-\mathbf{F}(\nabla u_H(T'))\big|$ for $T'\in\omega_T$ by a sum of jumps $\big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|$ over these faces. In particular,

$$\begin{aligned}\sum_{T\in\mathcal{T}_H}\sum_{T'\in\omega_T}\int_{T'}\big|\mathbf{F}(\nabla u_H(T))-\mathbf{F}(\nabla u_H(T'))\big|^2\,dx&\sim\sum_{\gamma\in\Gamma_H}\int_{S_\gamma}\big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2\,dx\\ &\sim\sum_{\gamma\in\Gamma_H}h_\gamma\int_\gamma\big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2\,dx\;=\sum_{\gamma\in\Gamma_H}\eta_J^2(u_H,\gamma)\end{aligned}$$

using that ∇u_H is piecewise constant and $|S_\gamma|\sim h_\gamma\,|\gamma|$. Hence, with Lemma 3

$$\begin{aligned}&(\mathtt{Upper}_2)\\ &\le C_\delta\,C\sum_{T\in\mathcal{T}_H}\eta_E^2(u_H,T)+\delta\,C\sum_{T\in\mathcal{T}_H}\int_{\Omega_T}\varphi_{|\nabla u_H|}(|\nabla e_H|)\,dx+\delta\,C\sum_{\gamma\in\Gamma_H}\eta_J^2(u_H,\gamma)\\ &\le C_\delta\,C\sum_{T\in\mathcal{T}_H}\eta_E^2(u_H,T)+\delta\,C\,\big\|\mathbf{F}(\nabla u_H)-\mathbf{F}(\nabla u)\big\|_2^2+\delta\,C\sum_{\gamma\in\Gamma_H}\eta_J^2(u_H,\gamma).\end{aligned}$$

Now taking $\delta>0$ small enough we obtain from (3.8), (3.11), the last inequality, (3.7), and the fact that each side $\gamma\in\Gamma_H$ is shared by at most two elements the following lemma.

LEMMA 8 (upper bound). *For finite element solutions u_H of (3.5) it holds that*

$$\big\|\mathbf{F}(\nabla u_H)-\mathbf{F}(\nabla u)\big\|_2^2\le C\,\eta^2(u_H,\mathcal{T}_H),\tag{3.12}$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and the shape regularity of $\mathcal{T}_H$.

3.4. Lower bound. In this section we show that the error can be locally estimated from below by the error estimators. We begin with the element estimator. As is well known, for each $T \in \mathcal{T}_H$ there exists a *bubble function* $w_T \in W_0^{1,\varphi}(T)$ with $w_T \geq 0$ and

$$\int_T w_T \, dx = |T|, \qquad \|w_T\|_\infty \leq C, \qquad \|\nabla w_T\|_\infty \leq \frac{C}{h_T}, \tag{3.13}$$

where $C > 0$ depends only on the shape regularity of $\mathcal{T}_H$. Then for $s \in \mathbb{R}$

$$\big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H), \nabla(s\, w_T) \big\rangle = \langle f, s\, w_T \rangle, \tag{3.14}$$

where we have used that ∇u_H is constant on T. For $f_T \in \mathbb{R}$ by (2.4) applied to $\varphi_{|\nabla u_H|}$ there exists $s_T \in \mathbb{R}$ such that

$$s_T\,(h_T f_T) = (\varphi_{|\nabla u_H(T)|})^*(h_T|f_T|) + \varphi_{|\nabla u_H|}(|s_T|); \tag{3.15}$$

i.e., Young's inequality is sharp. We obtain with (3.15) and (3.14) taking $s = h_T s_T$

$$\begin{aligned} |T|\,(\varphi_{|\nabla u_H(T)|})^*(h_T|f_T|) + |T|\,\varphi_{|\nabla u_H(T)|}(|s_T|) &= |T|\, f_T\, h_T\, s_T \\ &= \big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H(T)), \nabla(h_T\, s_T\, w_T) \big\rangle + \langle f_T - f, h_T\, s_T\, w_T \rangle \\ &= (\mathtt{Lower}_1) + (\mathtt{Lower}_2). \end{aligned} \tag{3.16}$$

With the help of (3.13), Young's inequality (2.3), (3.4), and the fact that the integrand is constant $\varphi_{|\nabla u_H|}(|s_T|) = \varphi_{|\nabla u_H(T)|}(|s_T|)$ on T, we have

$$\begin{aligned} (\mathtt{Lower}_1) &\leq C \int_T |\mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H)|\, |s_T|\, dx \\ &\leq C_\delta\, C \int_T |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)|^2\, dx + \delta\, C\, |T|\, \varphi_{|\nabla u_H(T)|}(|s_T|). \end{aligned} \tag{3.17}$$

Similarly, with (3.13) and Young's inequality (2.3) we get

$$\begin{aligned} (\mathtt{Lower}_2) &\leq C \int_T h_T\, s_T\, |f - f_T|\, dx \\ &\leq C_\delta\, C \int_T (\varphi_{|\nabla u_H|})^*(h_T|f - f_T|)\, dx + \delta\, C|T|\, \varphi_{|\nabla u_H(T)|}(|s_T|). \end{aligned} \tag{3.18}$$

Now taking $\delta > 0$ small enough we obtain from (3.16), (3.17), and (3.18) that

$$\begin{aligned} |T|\,(\varphi_{|\nabla u_H(T)|})^*(h_T|f_T|) \leq C \int_T |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)|^2\, dx \\ + C \int_T (\varphi_{|\nabla u_H|})^*(h_T|f - f_T|)\, dx. \end{aligned} \tag{3.19}$$

Observe that by convexity of $(\varphi_{|\nabla u_H(T)|})^*$, $\Delta_2(\varphi^*), \Delta_2(\varphi) < \infty$, and Lemma 22

$$\begin{aligned} \eta_E^2(u_H, T) &= \int_T (\varphi_{|\nabla u_H|})^*(h_T|f|) \\ &\leq \int_T (\varphi_{|\nabla u_H|})^*(2h_T|f - f_T|) + (\varphi_{|\nabla u_H|})^*(2h_T|f_T|) \\ &\leq C \int_T (\varphi_{|\nabla u_H|})^*(h_T|f - f_T|)\, dx + C\,|T|\,(\varphi_{|\nabla u_H(T)|})^*(h_T|f_T|) \end{aligned}$$

with $C > 0$ depending only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$. This and (3.19) give

$$\eta_E^2(u_H,T) \le C \int_T |\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)|^2 \,dx + C \int_T (\varphi_{|\nabla u_H|})^*(h_T|f - f_T|)\,dx. \tag{3.20}$$

Taking the infimum over all $f_T \in \mathbb{R}$ proves the following assertion.

LEMMA 9. *For finite element solutions u_H of (3.5) and $T \in \mathcal{T}_h$ it holds that*

$$\eta_E^2(u_H,T) \le C\,\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\|_{L^2(T)}^2 + C\,\mathrm{osc}^2(u_H,T), \tag{3.21}$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and the shape regularity of $\mathcal{T}_H$.

Now we estimate the jump estimator. As is well known, for each $\gamma \in \Gamma_H$ there exists a *bubble function* $w_\gamma \in W_0^{1,\varphi}(S_\gamma)$ with $w_\gamma \ge 0$ and

$$\int_\gamma w_\gamma \,dx = |\gamma|, \qquad \|w_\gamma\|_\infty \le C, \qquad \|\nabla w_\gamma\|_\infty \le \frac{C}{h_\gamma}, \tag{3.22}$$

where $C > 0$ depends only on the shape regularity of $\mathcal{T}_H$. Then for $s \in \mathbb{R}$

$$\begin{aligned} \big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H), \nabla(s\,w_\gamma)\big\rangle &= \langle f, s\,w_\gamma\rangle - \int_\gamma [\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\, s\, w_\gamma \,dx \\ &= \langle f, s\,w_\gamma\rangle - |\gamma|\,[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\, s, \end{aligned} \tag{3.23}$$

where we have used partial integration and that ∇u_H is piecewise constant. Let T_0, T_1 be the two triangles sharing γ. Then by (2.4) applied to $\varphi_{|\nabla u_H(T_0)|}$ there exists $s_\gamma \in \mathbb{R}$ such that

$$[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\, s_\gamma = (\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big) + \varphi_{|\nabla u_H(T_0)|}(|s_\gamma|); \tag{3.24}$$

i.e., Young's inequality is sharp. We have chosen $|\nabla u_H(T_0)|$ as the shift, which puts T_0 into a special position, but we will see later that it is not important which of the two triangles is chosen. Let $s = \frac{|S_\gamma|}{|\gamma|} s_\gamma$ in (3.23); then we obtain with (3.24)

$$\begin{aligned} &|S_\gamma|\,(\varphi_{|\nabla u_H(T_0)|})^*\big([\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big) + |S_\gamma|\,\varphi_{|\nabla u_H(T_0)|}(|s_\gamma|) \\ &\quad = |S\gamma|\,[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\, s_\gamma \\ &\quad = -\frac{|S_\gamma|}{|\gamma|}\big\langle \mathbf{A}(\nabla u) - \mathbf{A}(\nabla u_H), \nabla(s_\gamma\, w_\gamma)\big\rangle + \frac{|S_\gamma|}{|\gamma|}\,\langle f, s_\gamma\, w_\gamma\rangle \\ &\quad = (\mathtt{Lower}_3) + (\mathtt{Lower}_4). \end{aligned} \tag{3.25}$$

Before we proceed with the estimates for $(\mathtt{Lower}_3)$ and $(\mathtt{Lower}_4)$ we simplify the term $(\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big)$. First we show that

$$\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big| \sim \varphi'_{|\nabla u_H|}\big(\big|[\![\nabla u_H]\!]_\gamma\big|\big) \sim \big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big|. \tag{3.26}$$

The last part of (3.26) is an immediate consequence of Lemma 3. If $[\![\nabla u_H]\!]_\gamma = 0$, then also $[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma = 0$ and all terms in (3.26) are zero. So we can assume that $[\![\nabla u_H]\!]_\gamma \ne 0$. Since $u_H \in C(S_\gamma)$, the tangential derivatives of u_H are continuous on γ and do not jump. Hence, $|[\![\nabla u_H]\!]_\gamma| = |[\![\nabla u_H]\!]_\gamma \cdot \mathbf{n}|$ and

$$\mathbf{n} = \pm \frac{[\![\nabla u_H]\!]_\gamma}{|[\![\nabla u_H]\!]_\gamma|}.$$

This and (3.3) imply that

$$|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma|\cdot|[\![\nabla u_H]\!]_\gamma| = \big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\cdot[\![\nabla u_H]\!]_\gamma\big| \sim \varphi_{|\nabla u_H|}(|[\![\nabla u_H]\!]_\gamma|).$$

Now (2.6) proves (3.26). Lemma 22 states that $(\varphi_{|u_H|})^*$ is an N-function with $\Delta_2((\varphi_{|u_H|})^*) < \infty$ depending solely on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$. Therefore, we get with (3.4) and (3.26)

$$\begin{aligned}(\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big) &\sim (\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)]\!]_\gamma\big|\big)\\ &\sim \big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2.\end{aligned} \tag{3.27}$$

Now it becomes clear why the preference of T_0 is not important: The expression $|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma|^2$ in (3.27) is symmetrical in T_0 and T_1 and therefore independent of the choice T_0.

We proceed with the estimate for ($\mathtt{Lower}_3$). With $|S_\gamma| \sim h_\gamma\,|\gamma|$, (3.22), Young's inequality (2.3), and (3.4) we get

$$\begin{aligned}(\mathtt{Lower}_3) &\le C\int_{S_\gamma}|\mathbf{A}(\nabla u)-\mathbf{A}(\nabla u_H)|\,|s_\gamma|\,dx\\ &\le C_\delta\,C\int_{S_\gamma}|\mathbf{F}(\nabla u)-\mathbf{F}(\nabla u_H)|^2\,dx+\delta\,C\sum_{T\in N_\gamma}|T|\,\varphi_{|\nabla u_H(T)|}(|s_\gamma|).\end{aligned} \tag{3.28}$$

With $|S_\gamma| \sim h_\gamma\,|\gamma|$, (3.22), and Young's inequality (2.3) we deduce that

($\mathtt{Lower}_4$)

$$\begin{aligned}&\le C\int_{S_\gamma}|f|\,h_\gamma\,|s_\gamma|\,dx\\ &\le C\sum_{T\in N_\gamma}\inf_{f_T\in\mathbb{R}}\int_T|f-f_T|\,h_\gamma\,|s_\gamma|+|f_T|\,h_\gamma\,|s_\gamma|\,dx\\ &\le C_\delta\,C\sum_{T\in N_\gamma}\inf_{f_T\in\mathbb{R}}\int_T(\varphi_{|\nabla u_H|})^*(h_\gamma\,|f-f_T|)\,dx+(\varphi_{|\nabla u_H|})^*(h_\gamma|f_T|)\,dx\\ &\quad+\delta\,C\sum_{T\in N_\gamma}\int_T\varphi_{|\nabla u_H|}(|s_\gamma|)\,dx\\ &\le C_\delta\,C\sum_{T\in N_\gamma}\operatorname{osc}^2(u_H,T)+C_\delta\,C\sum_{T\in N_\gamma}\eta_E^2(u_H,T)+\delta\,C\sum_{T\in N_\gamma}|T|\varphi_{|\nabla u_H(T)|}(|s_\gamma|).\end{aligned}$$

This, (3.25), (3.28), and $|T_0|, |T_1| \le |S_\gamma|$ imply that

$$\begin{aligned}&|S_\gamma|\,(\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big)+|S_\gamma|\,\varphi_{|\nabla u_H(T_0)|}(|s_\gamma|)\\ &\quad\le C_\delta\,C\int_{S_\gamma}|\mathbf{F}(\nabla u)-\mathbf{F}(\nabla u_H)|^2\,dx+C_\delta\,C\sum_{T\in N_\gamma}\operatorname{osc}^2(u_H,T)\\ &\qquad+C_\delta\,C\sum_{T\in N_\gamma}\eta_E^2(u_H,T)+\delta\,C\sum_{T\in N_\gamma}|S_\gamma|\varphi_{|\nabla u_H(T)|}(|s_\gamma|).\end{aligned}$$

For small $\delta > 0$ the summand of the last term with $T = T_0$ could be absorbed on the left-hand side, but the term with $T = T_1$ bothers us, since it has the wrong shift $|\nabla u_H(T_1)|$. With Corollary 26 and (3.27) we get rid of this term:

$$\begin{aligned}\varphi_{|\nabla u_H(T_1)|}(|s_\gamma|) &\le C\,\varphi_{|\nabla u_H(T_0)|}(|s_\gamma|) + C\,\big|[\![\mathbf{F}(\nabla u_H)]\!]_\gamma\big|^2 \\ &\le C\,\varphi_{|\nabla u_H(T_0)|}(|s_\gamma|) + C\,(\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big).\end{aligned}$$

This and (3.28) give for $\delta > 0$ small

$$\begin{aligned}&|S_\gamma|\,(\varphi_{|\nabla u_H(T_0)|})^*\big(\big|[\![\mathbf{A}(\nabla u_H)\cdot\mathbf{n}]\!]_\gamma\big|\big) \\ &\qquad\le C\,\|\mathbf{F}(\nabla u) - \mathbf{F}(\nabla u_H)\|^2_{L^2(S_\gamma)} + C\sum_{T\in N_\gamma}\operatorname{osc}^2(u_H,T) + C\sum_{T\in N_\gamma}\eta_E^2(u_H,T).\end{aligned}$$

Now an application of (3.27) and $|S_\gamma| \sim h_\gamma\,|\gamma|$ prove the following assertion.

LEMMA 10. *For finite element solutions u_H of (3.5) and $\gamma \in \Gamma_H$ it holds that*

$$\eta_J^2(u_H,\gamma) \le C\,\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\|^2_{L^2(S_\gamma)} + C\operatorname{osc}^2(u_H,N_\gamma) + C\,\eta_E^2(u_H,N_\gamma),$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and the shape regularity of $\mathcal{T}_H$.

Lemmas 9 and 10 can be combined.

COROLLARY 11. *For finite element solutions u_H of (3.5) and $T \in \mathcal{T}_H$ it holds that*

$$\eta^2(u_H,T) \le C\,\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u)\|^2_{L^2(S_T)} + C\operatorname{osc}^2(u_H,N_T), \tag{3.29}$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and the shape regularity of $\mathcal{T}_H$.

3.5. Discrete lower estimates. In the following let $\mathcal{T}_h$ be a refinement of $\mathcal{T}_H$, which is generated from $\mathcal{T}_H$ by finitely many bisections. Then $V_h := V(\mathcal{T}_h)$ and $V_H := V(\mathcal{T}_H)$ are nested, i.e., $V_H \subset V_h \subset V$. Let u_h, u_H denote the unique solution of (2.1) with respect to V_h (resp., V_H).

Our aim is to generalize Corollary 11 from $V_H \subset V$ to $V_H \subset V_h$. Therefore, we have to ensure that V_h is a sufficient refinement of V_H. In particular, we have to ensure the existence of bump functions as required in (3.13) and (3.22). We say that $T \in \mathcal{T}_H$ is *fully refined in* $\mathcal{T}_h$ if T and each of its faces contain a node in their interior. This yields the existence of a bump function $w_T \in V_h$ on T which satisfies (3.13) and bump functions $w_\gamma \in V_h$ on S_γ for all $\gamma \in \Gamma_H \cup T$ which satisfy (3.22). Thus, to obtain the local lower bound (3.29) on S_T for a certain $T \in \mathcal{T}_H$ it suffices to assume that each $T' \in N_T$ is fully refined in $\mathcal{T}_h$. With these additional assumptions we can now transfer the estimates from section 3.4 to $V_H \subset V_h$.

LEMMA 12. *If for $T \in \mathcal{T}_H$ each $T' \in N_T$ is fully refined in $\mathcal{T}_h$, then*

$$\eta^2(u_H,T) \le C\,\|\mathbf{F}(\nabla u_H) - \mathbf{F}(\nabla u_h)\|^2_{L^2(S_T)} + C\operatorname{osc}^2(u_H,N_T), \tag{3.30}$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and the shape regularity of $\mathcal{T}_H$.

4. Algorithm and convergence. Let us first state the adaptive algorithm which produces a sequence u_k of solutions in nested spaces $V_k := V(\mathcal{T}_k)$ over triangulations $\mathcal{T}_k$. We substitute the index H (resp., h) of the previous sections by the index k (resp., $k+1$) to indicate the underlying mesh. Then we introduce the concept of energy reduction and thereafter prove convergence of the algorithm.

4.1. Adaptive algorithm. We propose the following adaptive algorithm to solve (1.1).

ALGORITHM 13 (AFEM). Choose $\theta \in (0,1)$. Construct an initial triangulation $\mathcal{T}_0$ of Ω and set $k := 0$.

1. (*"Solve"*) Compute the solution $u_k \in V_k$ of problem (3.5).
2. (*"Estimate"*) Compute $\eta^2(u_k, T)$ for all $T \in \mathcal{T}_k$.
3. If $\eta^2(u_k, \mathcal{T}_k) = 0$, then STOP.
4. (*"Mark"*) Choose a subset $\mathcal{T}_k^m \subset \mathcal{T}_k$ such that
$$\eta^2(u_k, \mathcal{T}_k^m) \geq \theta^2 \eta^2(u_k, \mathcal{T}_k). \tag{4.1}$$
5. (*"Refine"*) Perform a (minimal) conforming refinement of $\mathcal{T}_k$ using newest vertex bisections to obtain $\mathcal{T}_{k+1}$ such that each element of the neighborhood $N(\mathcal{T}_k^m) := \bigcup_{T \in \mathcal{T}_k^m} N_T \subset \mathcal{T}_k$ of $\mathcal{T}_k^m$ is fully refined in $\mathcal{T}_{k+1}$. This ensures that each $T \in N(\mathcal{T}_k^m)$ as well as each of its faces contain a node of $\mathcal{T}_{k+1}$ in their interior. Increment k and go to step 1.

Remark 14. Note that our marking strategy differs from the one proposed by Morin, Nochetto, and Siebert in [MNS00]. They used separate marking steps for the error estimator and the data oscillation. In our setting this would correspond to the following strategy: Construct $\mathcal{T}_k^m$ as in step *"Mark."* Then enlarge $\mathcal{T}_k^m$ such that for $\hat{\theta} > 0$ also
$$\operatorname{osc}^2(u_k, \mathcal{T}_k^m) \geq \hat{\theta}^2 \operatorname{osc}^2(u_k, \mathcal{T}_k). \tag{4.2}$$
This requires the calculation of the oscillation in step *"Estimate."* We want to point out that by the marking strategy (*"Mark"*) our new proof of convergence overcomes the drawback of additional marking for oscillation. This reflects the practical experience that the effect of oscillation plays a minor role (see, e.g., [MNS00]). We prove the success of most adaptive strategies which disregard the issue of oscillation altogether. Since $\eta^2(u_k, T) \geq \operatorname{osc}^2(u_k, T)$, this implies that (4.1) is equivalent to
$$\eta^2(u_k, \mathcal{T}_k^m) + \operatorname{osc}^2(u_k, \mathcal{T}_k^m) \geq \overline{\theta}^2 \big(\eta^2(u_k, \mathcal{T}_k) + \operatorname{osc}^2(u_k, \mathcal{T}_k)\big) \tag{4.3}$$
with $\overline{\theta} \in (0,1)$. Based on this cognition we give a new proof to show that the combination of energy difference and oscillation is reduced in each step (see Theorem 20).

Remark 15. Note that the condition in *"Refine"* of fully refined $T \in \mathcal{T}_k^m$ can be obtained by bisecting each $T \in \mathcal{T}_k^m$ three times in two dimensions (resp., six times in three dimensions); see [MNS00]. With this property we have a reduction factor $\lambda < 1$ of element size; i.e., if $T' \in \mathcal{T}_{k+1}$ is obtained by refining $T \in \mathcal{T}_k$, it holds that $h_{T'} \leq \lambda\, h_T$. By using the method of *newest vertex bisection* the shape regularity of $(\mathcal{T}_k)$ is uniformly bounded with respect to k depending on the shape regularity of $\mathcal{T}_0$.

4.2. Energy reduction in nested spaces. Assume as before that $V_H \subset V_h \subset V$. One main ingredient of proving linear convergence in [MNS00] for the linear case is the error reduction property for the energy norm
$$|||u_h - u|||^2 = |||u_H - u|||^2 - |||u_H - u_h|||^2.$$
This is a consequence of the Galerkin orthogonality and the Pythagorean theorem, which is related to Hilbert spaces. We do not have this property in the general case of the φ-Laplacian. But there is another way to interpret this property. In the linear case it is equivalent to
$$\mathcal{J}(u_h) - \mathcal{J}(u) = \mathcal{J}(u_H) - \mathcal{J}(u) - \big(\mathcal{J}(u_H) - \mathcal{J}(u_h)\big). \tag{4.4}$$

Obviously, this equality holds also in our case. Since $V_H \subset V_h \subset V$ and the minimizing property of u, u_h, and u_H we have

$$\mathcal{J}(u) \le \mathcal{J}(u_h) \le \mathcal{J}(u_H).$$

Thus we have a reduction of energy difference. Now it remains to find a link between the energy differences and the error. This is the content of the following lemma. For $v, w \in V$ we define the energy difference by

$$\varepsilon(v,w) := \mathcal{J}(v) - \mathcal{J}(w).$$

LEMMA 16. *Let u_1, u_2 be minimizers of the energy functional $\mathcal{J}$ with respect to the $V_1 \subset V_2 \subset V$. Then*

$$\mathcal{J}(u_1) - \mathcal{J}(u_2) \sim \|\mathbf{F}(\nabla u_1) - \mathbf{F}(\nabla u_2)\|_2^2,$$

where the constants depend only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and (2.7).

Proof. Define $\Phi : \mathbb{R}^d \to \mathbb{R}$ by $\Phi(\mathbf{a}) := \varphi(|\mathbf{a}|)$; then $\mathcal{J}(u) = \int_\Omega \Phi(\nabla u)\,dx - \int_\Omega u\,f\,dx$. Let $g(t) := \mathcal{J}([u_2,u_1]_t)$ for $t \in \mathbb{R}$, where $[u_2,u_1]_t := (1-t)\,u_2 + t\,u_1$. Since u_2 is the minimizer of $\mathcal{J}$ on $V_2 \supset V_1$, we have $g'(0) = 0$. We estimate by Taylor's formula

(4.5)

$$\mathcal{J}(u_1) - \mathcal{J}(u_2) = g(1) - g(0) = \frac{1}{2}\int_0^1 g''(t)\,(1-t)\,dt$$

$$= \frac{1}{2}\sum_{k,m}\int_0^1\int_\Omega (\partial_k\partial_m\Phi)([\nabla u_2, \nabla u_1]_t)\,(\partial_k u_1 - \partial_k u_2)(\partial_m u_1 - \partial_m u_2)\,dx\,(1-t)\,dt.$$

Note that for $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$

$$\sum_{k,m}(\partial_k\partial_m\Phi)(\mathbf{a})\,b_k\,b_m = \frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}\left(|\mathbf{b}|^2 - \frac{|\mathbf{a}\cdot\mathbf{b}|}{|\mathbf{a}|^2}\right) + \varphi''(|\mathbf{a}|)\frac{|\mathbf{a}\cdot\mathbf{b}|^2}{|\mathbf{a}|^2}.$$

By Assumption 1 we have $c\,\varphi'(t) \le t\,\varphi''(t) \le C\,\varphi'(t)$ uniformly in $t \ge 0$. Therefore,

$$\sum_{k,m}(\partial_k\partial_m\Phi)(\mathbf{a})\,b_k\,b_m \le (1+C)\,\frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}|\mathbf{b}|^2$$

and

$$\sum_{k,m}(\partial_k\partial_m\Phi)(\mathbf{a})\,b_k\,b_m \ge \frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}|\mathbf{b}|^2 + (c-1)\,\frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}\frac{|\mathbf{a}\cdot\mathbf{b}|^2}{|\mathbf{a}|^2} \ge c\,\frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}|\mathbf{b}|^2.$$

In other words $\sum_{k,m}(\partial_k\partial_m\Phi)(\mathbf{a})\,b_k\,b_m \sim \frac{\varphi'(|\mathbf{a}|)}{|\mathbf{a}|}|\mathbf{b}|^2$ uniformly in $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$. Combining the last estimates with (4.5) yields

$$\mathcal{J}(u_1) - \mathcal{J}(u_2) \sim \int_0^1\int_\Omega \frac{\varphi'(|[\nabla u_2, \nabla u_1]_t|)}{|[\nabla u_2, \nabla u_1]_t|}|\nabla u_1 - \nabla u_2|^2\,dx\,(1-t)\,dt. \tag{4.6}$$

Now we cite Lemma 19 from [DE08], which states that for any $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$

$$\int_0^1 \frac{\varphi'(|[\mathbf{a},\mathbf{b}]_t|)}{|[\mathbf{a},\mathbf{b}]_t|}\,dt \sim \frac{\varphi'(|\mathbf{a}|+|\mathbf{b}|)}{|\mathbf{a}|+|\mathbf{b}|}$$

with constants depending only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$. In particular, this, (4.6), Assumption 1, and Lemma 3 give

$$\begin{aligned}\mathcal{J}(u_1)-\mathcal{J}(u_2) &\le C\int_\Omega \frac{\varphi'(|\nabla u_2|+|\nabla u_1|)}{|\nabla u_2|+|\nabla u_1|}\,|\nabla u_1-\nabla u_2|^2\,dx\\ &\le C\int_\Omega \varphi''(|\nabla u_2|+|\nabla u_1|)|\nabla u_1-\nabla u_2|^2\,dx\\ &\le C\int_\Omega |\mathbf{F}(\nabla u_1)-\mathbf{F}(\nabla u_2)|^2\,dx.\end{aligned}$$

On the other hand, (4.6), $\varphi'(t)\,t\sim\varphi(t)$ by (2.6), and Jensen's inequality give

$$\begin{aligned}\mathcal{J}(u_1)-\mathcal{J}(u_2) &\ge c\int_\Omega\int_0^1 \frac{\varphi(|[\nabla u_2,\nabla u_1]_t|)}{(|\nabla u_2|+|\nabla u_1|)^2}\,(1-t)\,dt\,|\nabla u_1-\nabla u_2|^2\,dx\\ &\ge c\int_\Omega \frac{\varphi(\int_0^1 |[\nabla u_2,\nabla u_1]_t|\,2\,(1-t)\,dt)}{(|\nabla u_2|+|\nabla u_1|)^2}\,|\nabla u_1-\nabla u_2|^2\,dx.\end{aligned}$$

Uniformly in $\mathbf{a},\mathbf{b}\in\mathbb{R}^d$ it holds that $\int_0^1 |[\mathbf{a},\mathbf{b}]_t|\,2(1-t)\,dt\sim|\mathbf{a}|+|\mathbf{b}|$, because both sides are a norm for the couple $(\mathbf{a},\mathbf{b})$. This and $\varphi''(t)\,t^2\sim\varphi(t)$ imply that

$$\mathcal{J}(u_1)-\mathcal{J}(u_2)\ge c\int_\Omega \varphi''(|\nabla u_2|+|\nabla u_1|)\,|\nabla u_1-\nabla u_2|^2\,dx.$$

Now Lemma 3 proves $\mathcal{J}(u_1)-\mathcal{J}(u_2)\ge c\int_\Omega |\mathbf{F}(\nabla u_1)-\mathbf{F}(\nabla u_2)|^2\,dx$. ∎

We recall that by Algorithm 13 for each element $T\in\mathcal{T}_k^m$ it holds that $N_T\subset N(\mathcal{T}_k^m)$. Thus each of the elements in N_T is marked for full refinement. Thus by Lemma 12 we have a discrete lower bound for each $T\in\mathcal{T}_k^m$. Summing over all sides in $\mathcal{T}_k^m$ yields together with Lemma 16 the following corollary.

COROLLARY 17. *For the sequence of finite element solutions produced by Algorithm* 13 *it holds that*

$$\eta^2(u_k,\mathcal{T}_k^m)\le C\,\varepsilon(u_k,u_{k+1})+C\,\operatorname{osc}^2(u_k,N(\mathcal{T}_k^m)),\tag{4.7}$$

where the constant C depends only on $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, (2.7), and the shape regularity of $\mathcal{T}_0$.

4.3. Convergence. To prove that Algorithm 13 produces a sequence (u_k) which converges to the weak solution u of (1.1) we need an auxiliary lemma which deals with oscillation.

LEMMA 18. *Then for the sequence of finite element solutions produced by Algorithm* 13 *there exists $\rho\in(0,1)$ such that*

$$\operatorname{osc}^2(u,\mathcal{T}_{k+1})\le\operatorname{osc}^2(u,\mathcal{T}_k)-\rho\,\operatorname{osc}^2(u,N(\mathcal{T}_k^m)),\tag{4.8}$$

with $\rho=1-\lambda$ and λ from Remark 15.

Proof. Recall that for any $T \in \mathcal{T}_k$ and any $T' \in \mathcal{T}_{k+1}$ with $T' \subset T$ we have $h_{T'} \leq h_T$. Moreover, if T is refined in $\mathcal{T}_{k+1}$, then we even have $h_{T'} \leq \lambda\, h_T$. In particular, this holds if $T \in \mathcal{T}_k^m$ since these T are fully refined in $\mathcal{T}_{k+1}$. First, for every $T \in \mathcal{T}_k$ we estimate

$$\begin{aligned}
\sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \operatorname{osc}^2(u, T') &= \sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \inf_{f_{T'} \in \mathbb{R}} \int_{T'} (\varphi_{|\nabla u|})^*(h_{T'}\, |f - f_{T'}|)\, dx \\
&\leq \sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \inf_{f_{T'} \in \mathbb{R}} \int_{T'} (\varphi_{|\nabla u|})^*(h_T\, |f - f_{T'}|)\, dx \\
&\leq \inf_{f_T \in \mathbb{R}} \int_T (\varphi_{|\nabla u|})^*(h_T\, |f - f_T|)\, dx \\
&= \operatorname{osc}^2(u, T).
\end{aligned} \tag{4.9}$$

Second, for $T \in N(\mathcal{T}_k^m)$ we have a better estimate, since all elements in $N(\mathcal{T}_k^m)$ are fully refined in $\mathcal{T}_{k+1}$. Therefore, it holds that with the convexity of N-functions

$$\begin{aligned}
\sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \operatorname{osc}^2(u, T') &= \sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \inf_{f_{T'} \in \mathbb{R}} \int_{T'} (\varphi_{|\nabla u|})^*(h_{T'}\, |f - f_{T'}|)\, dx \\
&\leq \sum_{T' \in \mathcal{T}_{k+1}, T' \subset T} \inf_{f_{T'} \in \mathbb{R}} \int_{T'} (\varphi_{|\nabla u|})^*(\lambda\, h_T\, |f - f_{T'}|)\, dx \\
&\leq \inf_{f_T \in \mathbb{R}} \int_T (\varphi_{|\nabla u|})^*(\lambda\, h_T\, |f - f_T|)\, dx \\
&\leq \lambda \operatorname{osc}^2(u, T).
\end{aligned} \tag{4.10}$$

Now (4.9) and (4.10) imply that

$$\begin{aligned}
\operatorname{osc}^2(u, \mathcal{T}_{k+1}) &\leq \operatorname{osc}^2(u, \mathcal{T}_k \setminus \mathcal{T}_k^m) + \lambda \operatorname{osc}^2(u, \mathcal{T}_k^m) \\
&= \operatorname{osc}^2(u, \mathcal{T}_k) - (1 - \lambda) \operatorname{osc}^2(u, \mathcal{T}_k^m).
\end{aligned}$$

This proves the lemma. ∎

LEMMA 19. *For the sequence of finite element solutions produced by Algorithm* 13 *it holds that*

$$\eta^2(u_k, \mathcal{T}_k) + \operatorname{osc}^2(u_k, \mathcal{T}_k) \sim \varepsilon(u_k, u) + \operatorname{osc}^2(u_k, \mathcal{T}_k) \tag{4.11a}$$

$$\sim \varepsilon(u_k, u) + \operatorname{osc}^2(u, \mathcal{T}_k). \tag{4.11b}$$

Proof. First we prove (4.11a). From Corollary 11, Lemma 16, and Lemma 8 it follows that

$$\begin{aligned}
\eta^2(u_k, \mathcal{T}_k) &\leq C\, \varepsilon(u_k, u) + C \operatorname{osc}^2(u_k, \mathcal{T}_k), \\
\varepsilon(u_k, u) &\leq C\, \eta^2(u_k, \mathcal{T}_k) + C \operatorname{osc}^2(u_k, \mathcal{T}_k),
\end{aligned}$$

which immediately implies (4.11a). With the help of Corollary 28 we can change the shift in the last term, i.e.,

$$\begin{aligned}
&\operatorname{osc}^2(u_k,\mathcal{T}_k)\\
&\quad=\sum_{T\in\mathcal{T}_k}\inf_{f_T\in\mathbb{R}}\int_T(\varphi_{|\nabla u_k|})^*(h_K\,|f-f_T|)\,dx\\
&\quad\le\sum_{T\in\mathcal{T}_k}\left(\inf_{f_T\in\mathbb{R}}C\int_T(\varphi_{|\nabla u|})^*(h_K\,|f-f_T|)\,dx+C\,|\mathbf{F}(\nabla u_k)-\mathbf{F}(\nabla u)|^2\right)\\
&\quad=C\operatorname{osc}^2(u,\mathcal{T}_k)+C\,\|\mathbf{F}(\nabla u_k)-\mathbf{F}(\nabla u)\|_2^2\le C\operatorname{osc}^2(u,\mathcal{T}_k)+C\,\varepsilon(u_k,u).
\end{aligned}\tag{4.12}$$

The same calculation with u_k and u exchanged proves

$$\operatorname{osc}^2(u,\mathcal{T}_k)\le C\operatorname{osc}^2(u_k,\mathcal{T}_k)+C\,\varepsilon_k(u_k,u).\tag{4.13}$$

Now (4.12) and (4.13) prove (4.11b). ∎

Now we are able to prove our main result.

THEOREM 20 (energy/oscillation reduction). *There exists a constant $\alpha\in(0,1)$ such that for the sequence (u_k) of finite element solutions produced by Algorithm* AFEM

$$\varepsilon(u_{k+1},u)+\operatorname{osc}^2(u,\mathcal{T}_{k+1})\le\alpha^2\big(\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)\big).\tag{4.14}$$

Here α depends only on the shape regularity of the sequence $(\mathcal{T}_k)$, $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, (2.7), and θ from the marking strategy (4.1). *In particular, for $k\in\mathbb{N}$*

$$\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)\le\alpha^{2k}\big(\varepsilon(u_0,u)+\operatorname{osc}^2(u,\mathcal{T}_0)\big).\tag{4.15}$$

Proof. We start with the energy reduction (4.4)

$$\varepsilon(u_{k+1},u)=\varepsilon(u_k,u)-\varepsilon(u_k,u_{k+1})\tag{4.16}$$

and note that by Lemma 18 we have a similar relation for oscillation; i.e.,

$$\operatorname{osc}^2(u,\mathcal{T}_{k+1})\le\operatorname{osc}^2(u,\mathcal{T}_k)-\rho\operatorname{osc}^2(u,N(\mathcal{T}_k^m))$$

for some $\rho\in(0,1)$. Summing these two terms yields

$$\begin{aligned}
&\varepsilon(u_{k+1},u)+\operatorname{osc}^2(u,\mathcal{T}_{k+1})\\
&\qquad\le\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\big(\varepsilon(u_k,u_{k+1})+\rho\operatorname{osc}^2\big(u,N(\mathcal{T}_k^m)\big)\big).
\end{aligned}\tag{4.17}$$

The main idea is to apply the discrete lower bound to $\varepsilon(u_k,u_{k+1})$, whereas the oscillation on the right-hand side of (3.30) shall be absorbed at the oscillation term in the above inequality. Since in (3.30) the oscillation appears with shift u_k, we use Corollary 28 (change of shift) as in (4.12) to obtain,

$$\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)\le(1+C_\delta)C\operatorname{osc}^2\big(u,N(\mathcal{T}_k^m)\big)+\delta\,C\,\varepsilon_k(u_k,u)$$

for $\delta>0$ and a corresponding $C_\delta\ge0$. We set $D=(1+C_\delta)>1$ and obtain, equivalently,

$$\frac{1}{C\,D}\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)-\frac{\delta}{D}\,\varepsilon(u_k,u)\le\operatorname{osc}^2\big(u,N(\mathcal{T}_k^m)\big).$$

This, (4.17), and (4.7) imply that

$$\begin{aligned}
&\varepsilon(u_{k+1},u)+\operatorname{osc}^2\big(u,\mathcal{T}_{k+1}\big)\\
&\quad\le \varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\bigg(\varepsilon(u_k,u_{k+1})+\frac{\rho}{CD}\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)-\frac{\rho\,\delta}{D}\,\varepsilon(u_k,u)\bigg)\\
&\quad\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\bigg(\varepsilon(u_k,u_{k+1})+\frac{\rho}{CD}\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)\bigg).
\end{aligned}$$

Since $D\ge 1$ and $\rho\in(0,1)$ we have $\frac{\rho}{2\,C\,D}\le 1$. Thus

$$\begin{aligned}
&\varepsilon(u_{k+1},u)+\operatorname{osc}^2(u,\mathcal{T}_{k+1})\\
&\quad\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\frac{\rho}{2\,CD}\bigg(\varepsilon(u_k,u_{k+1})+2\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)\bigg),
\end{aligned}$$

the discrete lower estimate (4.7), and $\mathcal{T}_k^m\subset N(\mathcal{T}_k^m)$ yield

$$\begin{aligned}
&\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\frac{\rho}{2\,CD}\bigg(\frac{1}{C}\,\eta^2(u_k,\mathcal{T}_k^m)+\operatorname{osc}^2\big(u_k,N(\mathcal{T}_k^m)\big)\bigg)\\
&\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\frac{\rho}{2\,CD}\bigg(\eta^2(u_k,\mathcal{T}_k^m)+\operatorname{osc}^2(u_k,\mathcal{T}_k^m)\bigg).
\end{aligned}$$

Now it remains to utilize the marking strategy. By the equivalent form (4.3) of our marking strategy *"Mark"* and (4.11) we get

$$C\,\big(\varepsilon(u_k,u)+\operatorname{osc}_k^2(u,\mathcal{T}_k)\big)\le\overline{\theta}^2\,\big(\eta^2(u_k,\mathcal{T}_k^m)+\operatorname{osc}_k^2(u_k,\mathcal{T}_k^m)\big).\tag{4.18}$$

This observation and Lemma 8 finally imply that

$$\begin{aligned}
&\varepsilon(u_{k+1},u)+\operatorname{osc}^2(u,\mathcal{T}_{k+1})\\
&\quad\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\frac{\rho\,\overline{\theta}^2}{2\,CD}\bigg(\eta^2(u_k,\mathcal{T}_k)+\operatorname{osc}^2(u,\mathcal{T}_k)\bigg)\\
&\quad\le \bigg(1+\frac{\rho\,\delta}{D}\bigg)\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)-\frac{\rho\,\overline{\theta}^2}{2\,CD}\bigg(\frac{1}{C}\,\varepsilon(u_k,u)+\operatorname{osc}^2(u,\mathcal{T}_k)\bigg)\\
&\quad\le \bigg(1+\frac{\rho\,\delta}{D}-\frac{\rho\,\overline{\theta}^2}{2\,CD}\bigg)\,\varepsilon(u_k,u)+\bigg(1-\frac{\rho\,\overline{\theta}^2}{2\,CD}\bigg)\operatorname{osc}^2(u,\mathcal{T}_k).
\end{aligned}$$

Substituting D by its definition, we set

$$\alpha^2:=\min\left\{1+\frac{\rho\,\delta}{(1+C_\delta)}-\frac{\rho\,\overline{\theta}^2}{2\,C\,(1+C_\delta)},1-\frac{\rho\,\overline{\theta}^2}{2\,C\,(1+C_\delta)}\right\}$$

and obtain the proposition for $\delta>0$ small enough. ∎

From the energy/oscillation reduction of Theorem 20 the next corollary follows with the help of Lemma 16.

COROLLARY 21 (energy/oscillation reduction). *For the sequence (u_k) of finite element solutions produced by Algorithm* AFEM *there exists constant $\alpha \in (0,1)$ such that for all $k \in \mathbb{N}$*

$$\begin{aligned} &\|\mathbf{F}(\nabla u_k) - \mathbf{F}(\nabla u)\|^2_{L^2(\Omega)} + \operatorname{osc}^2(u, \mathcal{T}_k) \\ &\qquad \le C\,\alpha^{2k}\left(\|\mathbf{F}(\nabla u_0) - \mathbf{F}(\nabla u)\|^2_{L^2(\Omega)} + \operatorname{osc}^2(u, \mathcal{T}_0)\right). \end{aligned} \tag{4.19}$$

Here α and the constants depend only on the shape regularity of $\mathcal{T}_0$, $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, (2.7), and θ from the marking strategy (4.1).

5. Appendix. In this section we summarize the properties of the *shifted* N-functions φ_a. Recall that for given N-function φ with $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$ we define φ_a as in (3.2) and $\mathbf{F}$ as in (3.1). The following results are from [DE08], and we present them here without proof. We use $C \ge 1$ as a generic constant that does solely depend on the Δ_2-constants of φ (resp., φ^*) and may change from line to line.

LEMMA 22. *Let φ be an N-function with $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$. Then for all $a \ge 0$ the functions φ_a and $(\varphi_a)^*$ are N-functions. Moreover, the families φ_a and $(\varphi_a)^*$ satisfy the Δ_2 condition uniformly in $\alpha \ge 0$, i.e., $c_0 := \sup_{a\ge 0}(\Delta_2(\varphi_a), \Delta_2((\varphi_a)^*)) < \infty$. The constant c_0 depends on φ only by $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$. Moreover,*

$$(\varphi_a)^*(t) \sim (\varphi^*)_{\varphi'(a)}(t) \tag{5.1}$$

uniformly in $a, t \ge 0$, where the constants depend only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$.

LEMMA 23. *Let φ be an N-function with $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$. Then uniformly in $\mathbf{a} \in \mathbb{R}^d$*

$$\begin{aligned} \varphi''(|\mathbf{a}| + |\mathbf{b}|)\,|\mathbf{a}-\mathbf{b}| &\sim \varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|) \sim \varphi'_{|\mathbf{b}|}(|\mathbf{a}-\mathbf{b}|), \\ \varphi''(|\mathbf{a}| + |\mathbf{b}|)\,|\mathbf{a}-\mathbf{b}|^2 &\sim \varphi_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|) \sim \varphi_{|\mathbf{b}|}(|\mathbf{a}-\mathbf{b}|), \end{aligned} \tag{5.2}$$

with constants depending only on $\Delta_2(\varphi)$ and $\Delta_2(\varphi^*)$.

LEMMA 24. *Let φ be as in Assumption* 1. *Then φ^* satisfies Assumption* 1, *too. If we define the N-function ψ by*

$$\frac{\psi'(t)}{t} := \left(\frac{\varphi'(t)}{t}\right)^{\frac{1}{2}},$$

then ψ and ψ^* satisfy Assumption 1. *Moreover, $\psi''(t) \sim \sqrt{\varphi''(t)}$ uniformly in $t > 0$. The Δ_2-constants of ψ and ψ^* and the constants of $\psi''(t) \sim \sqrt{\varphi''(t)}$ depend only on $\Delta_2(\varphi)$.*

The following lemma is proven already in [DR07], but we give a shorter proof.

LEMMA 25. *Let φ be an N-function with $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$. Then there exists $C \ge 1$, which depends only on $\Delta_2(\varphi)$ such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \ge 0$*

$$\varphi'_{|\mathbf{a}|}(t) \le C\,\varphi'_{|\mathbf{b}|}(t) + C\,\varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|). \tag{5.3}$$

Proof. Since $\varphi'_{|\mathbf{a}|}(t) \sim \varphi_{|\mathbf{a}|}(t)/t$ and $\varphi_{|\mathbf{a}|}(2t) \sim \varphi_{|\mathbf{a}|}(t)$, we have $\varphi'_{|\mathbf{a}|}(2t) \sim \varphi'_{|\mathbf{a}|}(t)$. In particular, $\varphi'_{|\mathbf{a}|}(2t) \le C\,\varphi'_{|\mathbf{a}|}(t)$ for some $C > 0$ uniformly in $t \ge 0$. All constants depend only on $\Delta_2(\varphi_{|\mathbf{a}|})$, and so by Lemma 22 the constants depend only on $\Delta_2(\varphi)$.

Case $|\mathbf{a}-\mathbf{b}| \le \frac{1}{2}\,t$. From $|\mathbf{a}-\mathbf{b}| \le \frac{1}{2}\,t$ it follows that $0 \le \frac{1}{2}(|\mathbf{b}|+t) \le |\mathbf{a}|+t \le 2(|\mathbf{b}|+t)$. Hence,

$$\varphi'_{|\mathbf{a}|}(t) = \frac{\varphi'(|\mathbf{a}|+t)}{|\mathbf{a}|+t}\,t \le \frac{\varphi'(2\,(|\mathbf{b}|+t))}{\frac{1}{2}(|\mathbf{b}|+t)}\,t \le 2\,C\,\frac{\varphi'(|\mathbf{b}|+t)}{|\mathbf{b}|+t}\,t = 2\,C\,\varphi'_{|\mathbf{b}|}(t).$$

Case $|\mathbf{a}-\mathbf{b}| \ge \frac{1}{2}\,t$. We estimate

$$\varphi'_{|\mathbf{a}|}(t) \le \varphi'_{|\mathbf{a}|}(2\,|\mathbf{a}-\mathbf{b}|) \le C\,\varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|).$$

Combining the two cases proves the lemma. ∎

COROLLARY 26 (change of shift). *Let φ be an N-function with $\Delta_2(\varphi), \Delta_2(\varphi^*) < \infty$. Then for any $\delta > 0$ there exists $C_\delta > 0$, which depends only on δ and $\Delta_2(\varphi)$ such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \ge 0$*

$$\varphi_{|\mathbf{a}|}(t) \le (1+C_\delta)C\,\varphi_{|\mathbf{b}|}(t) + \delta\,\varphi_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|). \tag{5.4}$$

If φ satisfies Assumption 1, *then for any $\delta > 0$ there exists $C_\delta > 0$, which depends only on δ, $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and* (2.7) *such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \ge 0$*

$$\varphi_{|\mathbf{a}|}(t) \le (1+C_\delta)C\,\varphi_{|\mathbf{b}|}(t) + \delta\,C\,\big|\mathbf{F}(\mathbf{a}) - \mathbf{F}(\mathbf{b})\big|^2. \tag{5.5}$$

Proof. Due to (2.7) it holds that $\varphi_{|\mathbf{a}|}(t) \sim \varphi'_{|\mathbf{a}|}(t)\,t$. Now inequality (5.4) follows by (5.3), (5.2), an application of Young's inequality (2.3), (5.2), and (2.5):

$$\begin{aligned}
\varphi_{|\mathbf{a}|}(t) &\le C\,\varphi'_{|\mathbf{a}|}(t)\,t \\
&\le C\,\varphi'_{|\mathbf{b}|}(t)\,t + C\,\varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|)\,t \\
&\le C\,\varphi'_{|\mathbf{b}|}(t)\,t + C\,\varphi'_{|\mathbf{b}|}(|\mathbf{a}-\mathbf{b}|)\,t \\
&\le C\,\varphi_{|\mathbf{b}|}(t) + C\,\delta\,(\varphi_{|\mathbf{b}|})^*\big(\varphi'_{|\mathbf{b}|}(|\mathbf{a}-\mathbf{b}|)\big) + C\,C_\delta\,\varphi_{|\mathbf{b}|}(t) \\
&\le C\,C_\delta\,\varphi_{|\mathbf{b}|}(t) + C\,\delta\,\varphi_{|\mathbf{b}|}(|\mathbf{a}-\mathbf{b}|) + C\,C_\delta\,\varphi_{|\mathbf{b}|}(t).
\end{aligned}$$

On the other hand, (5.5) follows from (5.4) with the help of Lemma 3. ∎

The following lemma is new. It generalizes the *change of shift* to complementary functions.

LEMMA 27. *If φ satisfies Assumption* 1, *then for any $\delta > 0$ there exists $C_\delta > 0$, which depends only on δ, $\Delta_2(\varphi)$, and $\Delta_2(\varphi^*)$ such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \ge 0$*

$$\big((\varphi_{|\mathbf{a}|})^*\big)'(t) \le C\,\big((\varphi_{|\mathbf{b}|})^*\big)'(t) + C\,|\mathbf{a}-\mathbf{b}|. \tag{5.6}$$

Proof. With Lemma 22, $|\mathbf{A}(\mathbf{a})| = \varphi'(|\mathbf{a}|)$, Lemma 25, Lemma 3, and $\Delta_2(\varphi) < \infty$ we estimate that

$$\begin{aligned}
\big((\varphi_{|\mathbf{a}|})^*\big)'(t) &\le C\,\big((\varphi^*)_{|\mathbf{A}(\mathbf{a})|}\big)'(t) \\
&\le C\,\big((\varphi^*)_{|\mathbf{A}(\mathbf{a})|}\big)'(t) + C\,\big((\varphi^*)_{|\mathbf{A}(\mathbf{a})|}\big)'(|\mathbf{A}(\mathbf{a})-\mathbf{A}(\mathbf{b})|) \\
&\le C\,\big((\varphi_{|\mathbf{a}|})^*\big)'(t) + C\,\big((\varphi_{|\mathbf{a}|})^*\big)'(C\,\varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|)) \\
&\le C\,\big((\varphi_{|\mathbf{a}|})^*\big)'(t) + C\,\big((\varphi_{|\mathbf{a}|})^*\big)'(\varphi'_{|\mathbf{a}|}(|\mathbf{a}-\mathbf{b}|)) \\
&= C\,\big((\varphi_{|\mathbf{a}|})^*\big)'(t) + C\,|\mathbf{a}-\mathbf{b}|.
\end{aligned}$$

This proves the lemma. ∎

COROLLARY 28 (change of shift $*$). *If φ satisfies Assumption* 1, *then for any $\delta > 0$ there exists $C_\delta > 0$, which depends only on δ, $\Delta_2(\varphi)$, and $\Delta_2(\varphi^*)$ such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \geq 0$*

$$(\varphi_{|\mathbf{a}|})^*(t) \leq (1 + C_\delta) C\, (\varphi_{|\mathbf{b}|})^*(t) + \delta\, C\, \varphi_{|\mathbf{a}|}(|\mathbf{a} - \mathbf{b}|). \tag{5.7}$$

If φ satisfies Assumption 1, *then for any $\delta > 0$ there exists $C_\delta > 0$, which depends only on δ, $\Delta_2(\varphi)$, $\Delta_2(\varphi^*)$, and* (2.7) *such that for all $\mathbf{a}, \mathbf{b} \in \mathbb{R}^d$ and $t \geq 0$*

$$(\varphi_{|\mathbf{a}|})^*(t) \leq (1 + C_\delta) C\, (\varphi_{|\mathbf{b}|})^*(t) + \delta\, C\, |\mathbf{F}(\mathbf{a}) - \mathbf{F}(\mathbf{b})|^2. \tag{5.8}$$

Proof. Due to (2.7) it holds that $(\varphi_{|a|})^*(t) \sim ((\varphi_{|a|})^*)'(t)\, t$. Now inequality (5.7) follows by (5.6), an application of Young's inequality, (2.3), (5.2), and (2.5), similarly to the proof of Corollary 26. On the other hand, (5.8) follows from (5.7) with the help of Lemma 3. ∎

CONVERGENCE OF A HIGH-ORDER SEMI-LAGRANGIAN SCHEME WITH PROPAGATION OF GRADIENTS FOR THE ONE-DIMENSIONAL VLASOV–POISSON SYSTEM*

NICOLAS BESSE†

Abstract. In this paper we give a proof of convergence of a new numerical method introduced in [N. Besse and E. Sonnendrücker, *J. Comput. Phys.*, 191 (2003), pp. 341–376] for the Vlasov equation. The numerical method is based on the semi-Lagrangian principle and the transport of the gradient of the statistical distribution function in order to get a high-order and stable reconstruction. These kinds of new schemes have been successfully implemented on unstructured meshes of four-dimensional phase space (cf. [N. Besse, *Etude mathématique et numérique de l'equation de Vlasov sur des maillages non structurés de l'espace des phases*, thèse de l'Université Louis Pasteur, Strasbourg, France, 2003; N. Besse, J. Segré, and E. Sonnendrücker, *Transport Theory Statist. Phys.*, 34 (2005), pp. 311–332]). In order to make a rigorous proof of convergence of this method and simplify the convergence analysis, we have considered the periodic one-dimensional Vlasov–Poisson system in phase space on a grid. The distribution $f(t,x,v)$ and the electric field are shown to converge to the exact solution values in H^1 norm. The rate of convergence is of $\mathcal{O}(\Delta t^2 + \frac{\Delta x^{4-|\alpha|}}{\Delta t} + \frac{\Delta v^{4-|\alpha|}}{\Delta t})$, $\alpha \in \mathbb{N}^2$, $|\alpha| \leq 1$.

Key words. Vlasov–Poisson system, semi-Lagrangian methods, high-order schemes, convergence analysis

1. Introduction.

The numerical resolution of the Vlasov equation is most of the time performed by Lagrangian methods such as particle-in-cell methods which consist of approximating the plasma by a finite number of macroparticles (see Birdsall and Langdon [10] for more details). Although this method allows us to obtain satisfying results with a small number of particles, it is well known that the numerical noise inherent to the particle method becomes too significant to allow a precise description of the tail of the distribution function, which plays an important role in charged particle beams. To remedy this problem, Eulerian methods which consist in discretizing the Vlasov equation on a mesh of phase space have been proposed. One of these methods is semi-Lagrangian methods, which have efficiently been implemented using parallel computers [15] and give considerable promise in displaying the detailed structure of distribution functions in weak densities regions.

The author extends semi-Lagrangian schemes on unstructured meshes on two-, three-, and four-dimensional phase spaces with different kinds of high-order local interpolation operators and with the possibility of having a positive and conservative method by introducing a linear combination of low-order solution and high-order solution tempered by a limiter coefficient (cf. [5]). The interpolation operator considered involves the knowledge of the gradient of the distribution function which is obtained by solving a transport problem on the gradient or by differentiating the convected solution. For more details on how we get these schemes we refer the reader to [5, 8, 9].

To simplify the convergence analysis we have considered this scheme on a uniform grid, without limiter coefficient, for the one-dimensional Vlasov–Poisson system.

Let us note that a first work on the convergence of one-dimensional particle methods is stated in [23], where Neunzert and Wick consider nonuniform initial loadings of particles asymptotically distributed with respect to initial data. Cottet and Raviart [14] present a mathematical analysis of the particle method for solving the one-dimensional Vlasov–Poisson system where uniform initial loadings of particles are considered. Then a lot of authors have studied the convergence of particle methods for the multidimensional Vlasov–Poisson system [18, 27, 28, 29]. They have also proved convergence results on random and deterministic particle methods for the Vlasov–Poisson–Fokker–Planck kinetic equations [21, 22]. Moreover Glassey and Schaeffer have done the convergence analysis of a particle method for the relativistic Vlasov–Maxwell system [20]. Schaeffer [24] has proved the convergence of a finite difference scheme for the one-dimensional Vlasov–Poisson–Fokker–Planck system, and Filbet [17] has shown the convergence of a finite volume scheme for the one-dimensional Vlasov–Poisson system. Finally the author [7] has proved the convergence of a semi-Lagrangian scheme on unstructured meshes (triangulation) of phase space in which a linear reconstruction is used, for the one-dimensional Vlasov–Poisson system. In the latter the author obtains a convergence rate in $\mathcal{O}(\Delta t^2 + h^2 + h^2/\Delta t)$ when $f \in \mathscr{C}_c^2([0,T] \times \mathbb{R}_x \times \mathbb{R}_v)$ (best convergence rate is in $\mathcal{O}(h^{4/3})$ when $\Delta t = h^{2/3}$) and a rate in $\mathcal{O}(\Delta t + h + h/\Delta t)$ when $f \in W_c^{1,\infty}([0,T] \times \mathbb{R}_x \times \mathbb{R}_v)$ (best convergence rate is in $\mathcal{O}(h^{1/2})$ when $\Delta t = h^{1/2}$).

Although a lot of papers present satisfactory numerical results using semi-Lagrangian methods [1, 2, 5, 13, 16, 25, 26], few rigorous mathematical results on convergence analysis of semi-Lagrangian methods have been stated. Despite interesting a priori estimates that have been pointed out (cf. [3, 4, 16]), a lot of work still remains to give complete and rigorous results in more general situations. The more difficult step in the convergence analysis of semi-Lagrangian methods is to obtain a stability result for the interpolation operators. If stability results in the $W^{1,\infty}$ norm seem inaccessible for high-order interpolation operators because of the Runge phenomena (artificial oscillations, whose amplitude increases with the degree of the polynomial in the case of Lagrange interpolation, appear at the edges of finite elements), a more appropriate mathematical framework is H^1 stability. If Fourier analysis tools such as Fourier series are useful for proving H^1 stability in case of grids, for unstructured meshes such as triangulation, convenient mathematical tools are lacking and have to be developed in the future. Nevertheless new results on convergence analysis of classes of high-order schemes can be found in [6].

This paper is organized as follows. In the first part we present the continuous problem. In the second part we expose the discrete problem and the numerical scheme to solve it. Then we study the convergence of our numerical scheme.

2. The continuous problem. Denoting by $f(t,x,v) \geq 0$ the distribution function of electrons in phase space (with mass normalized to one and the charge to plus one) and by $E(t,x)$ the self-consistent electric field, the adimensional Vlasov–Poisson system reads as

$$\frac{\partial f}{\partial t} + v\frac{\partial f}{\partial x} + E(t,x)\frac{\partial f}{\partial v} = 0, \tag{2.1}$$

$$\frac{dE}{dx}(t,x) = \rho(t,x) = \int_{-\infty}^{+\infty} f(t,x,v)dv - 1, \tag{2.2}$$

where x and v are independent variables. We consider a periodic plasma of period L. Hence in (2.1) and (2.2) we have $x \in [0, L]$, $v \in \mathbb{R}$, $t \geq 0$, and the functions f and E satisfy the periodic boundary conditions

$$f(t, 0, v) = f(t, L, v), \quad v \in \mathbb{R}, \quad t \geq 0, \tag{2.3}$$

and

$$E(t, 0) = E(t, L) \iff \frac{1}{L} \int_0^L \int_{-\infty}^{+\infty} f(t, x, v) dv dx = 1, \quad t \geq 0, \tag{2.4}$$

which means that the plasma is globally neutral. In order to have a well-posed problem we add to (2.1)–(2.4) a zero-mean electrostatic condition

$$\int_0^L E(t, x) dx = 0, \quad t \geq 0, \tag{2.5}$$

and an initial condition

$$f(0, x, v) = f_0(x, v), \quad x \in [0, L], \quad v \in \mathbb{R}. \tag{2.6}$$

Besides, by assuming that the electric field E is smooth enough, we can solve (2.1), (2.3), and (2.6) in the classical sense as follows. For the existence, the uniqueness, and the regularity of the solutions of the following differential system, we refer the reader to [11].

We consider the first-order differential system

$$\begin{aligned} \frac{dX}{dt}(t; s, x, v) &= V(t; s, x, v), \\ \frac{dV}{dt}(t; s, x, v) &= E(t, X(t; s, x, v)) \end{aligned} \tag{2.7}$$

and denote by $t \to (X(t; s, x, v), V(t; s, x, v))$ the characteristic curves, which are the solution of (2.7) with the initial condition

$$X(s; s, x, v) = x, \qquad V(s; s, x, v) = v. \tag{2.8}$$

Then the solution of problem (2.1), (2.6) is given by

$$f(t, x, v) = f_0(X(0; t, x, v), V(0; t, x, v)), \quad x,\ v \in \mathbb{R}, \quad t \geq 0. \tag{2.9}$$

We note that the periodicity in x of $f_0(x, v)$ and $E(t, x)$ implies the periodicity in x of $f(t, x, v)$. Moreover as

$$\left| \frac{\partial(X, V)}{\partial(x, v)} \right| = 1,$$

we get

$$\frac{1}{L} \int_0^L \int_{-\infty}^{+\infty} f(t, x, v) dv dx = \frac{1}{L} \int_0^L \int_{-\infty}^{+\infty} f_0(x, v) dv dx = 1.$$

Therefore, according to the previous considerations, an equivalent form of the Vlasov–Poisson periodic problem is to find a couple (f, E), smooth enough, periodic with respect to x, with period L, and solving (2.2), (2.7), (2.8), and (2.9).

If we introduce the electrostatic potential $\phi = \phi(t,x)$ such that $E(t,x) = -\partial_x \phi(t,x)$, and if we denote by $G = G(x,y)$ the fundamental solution of the Laplacian operator in one dimension with a periodic boundary condition, therefore we obtain

$$E(t,x) = \int_0^L K(x,y) \left(\int_{-\infty}^{+\infty} f(t,y,v) dv - 1 \right) dy,$$

where

$$K(x,y) = -\partial_x G(x,y) = \begin{cases} \left(\dfrac{y}{L} - 1 \right), & 0 \le x < y, \\ \dfrac{y}{L}, & y < x \le L. \end{cases}$$

2.1. Existence, uniqueness, and regularity of the solution of the continuous problem. In this section we recall a theorem of the existence of a classical solution for the Vlasov–Poisson system. The following theorem gives the existence, the uniqueness, and the regularity of the classical solutions, global in time, of the Vlasov–Poisson periodic system in one dimension. Let us note that a theory of weak solutions (in BV spaces) for the Vlasov equation has been recently developed in [12].

THEOREM 2.1. *Assuming $f_0 \in \mathscr{C}^1_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$ (continuously differentiable functions which are periodic with respect to x and compactly supported with respect to v), positive, periodic with respect to the variable x with period L, and $Q(0) \le R$, with $R > 0$ and $Q(t)$ defined as*

$$Q(t) = 1 + \sup \left\{ |v| : \exists x \in [0,L], \quad \tau \in [0,t] \mid f(\tau,x,v) \neq 0 \right\},$$

and

$$\frac{1}{L} \int_0^L \int_{-\infty}^{+\infty} f_0(x,v) dv dx = 1,$$

then the periodic Vlasov–Poisson system has a unique classical solution (f,E) periodic in x, with period L, for all time t in $[0,T]$, such that

$$f \in \mathscr{C}^1_b \left(0, T; \mathscr{C}^1_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v) \right),$$

$$E \in \mathscr{C}^1_b \left(0, T; \mathscr{C}^1_{b,per_x}(\mathbb{R}) \right),$$

and there exists a constant $C = C(R, f_0)$ dependent on R and f_0 such that

$$Q(T) \le CT.$$

Moreover if we assume $f_0 \in \mathscr{C}^m_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$, then $(f,E) \in \mathscr{C}^m_b(0,T;\mathscr{C}^m_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)) \times \mathscr{C}^m_b(0,T;\mathscr{C}^m_{b,per_x}(\mathbb{R}))$ for all finite time T.

Proof. For a proof we refer the reader to the treatise by Glassey [19]. □

3. The discrete problem. This section presents the description of the numerical scheme. Sections 3.1–3.3 are devoted to some notation and definitions (definitions of the interpolation operators and the transport operators in order to discretize in time and space the nonlinear transport equations, on a fixed phase-space grid). Section 3.4 resumes the algorithm in a simple way and refers the reader to the previous subsections for more details.

3.1. Interpolation operator. Let $\Omega = [0, L] \times [-R, R]$, with $R > Q(T)$, and let $\mathcal{M}_h$ be a Cartesian mesh of the phase space Ω. The grid $\mathcal{M}_h$ is given by a first increasing sequence $(x_i)_{i\in\{0,\dots,N_x\}}$ of the interval $[0, L]$ and a second increasing sequence $(v_i)_{i\in\{0,\dots,N_v\}}$ of the interval $[-R, R]$.

Let $\Delta x_i = x_{i+1} - x_i$ be the physical space set and $\Delta v_i = v_{i+1} - v_i$ be the velocity space set. In order to simplify the convergence analysis we suppose that $\Delta x_i = \Delta x$ and $\Delta v_i = \Delta v$. We call h a generic discretization parameter which stands for Δx or Δv. We define the one-dimensional Hermite interpolation operator $\mathcal{I}_h^{\mathcal{H}}$ as

$$\mathcal{I}_h^{\mathcal{H}} f(z)_{|_{[z_i, z_{i+1}]}} = f(z_i)\phi_i(z) + f(z_{i+1})\phi_{i+1}(z) + \dot{f}(z_i)\psi_i(z) + \dot{f}(z_{i+1})\psi_{i+1}(z),$$

where

$$\phi_i(z) = \frac{(z - z_{i+1})^2[(z_i - z_{i+1}) - 2(z - z_i)]}{(z_i - z_{i+1})^3}, \qquad \psi_i(z) = \frac{(z - z_i)(z - z_{i+1})^2}{(z_i - z_{i+1})^2},$$
$$\phi_{i+1}(z) = \frac{(z - z_i)^2[(z_i - z_{i+1}) + 2(z - z_{i+1})]}{(z_i - z_{i+1})^3}, \qquad \psi_{i+1}(z) = \frac{(z - z_i)^2(z - z_{i+1})}{(z_i - z_{i+1})^2},$$

and the one-dimensional Lagrange interpolation operator of degree three $\mathcal{I}_h^{\mathcal{L}}$ as

$$\mathcal{I}_h^{\mathcal{L}} f(z)_{|_{[z_i, z_{i+1}]}} = \sum_{k=i-1}^{i+2} f(z_k)\ell_k^3(z), \quad \text{where } \ell_k^3(z) = \prod_{\substack{i=k-1 \\ i\neq k}}^{i=k+2} \frac{(z - z_i)}{(z_k - z_i)}.$$

Let $\delta(y, y_i) = 1$ if $y = y_i$ and zero otherwise; then we consider $\mathcal{H}_h$ the interpolation operator defined by $\mathcal{H}_h f(x, v) = \sum_{j=0}^{N_v} \mathcal{I}_h^{\mathcal{H}} f(x, v_j)\delta(v, v_j)$ for advection in the x-direction and $\mathcal{H}_h f(x, v) = \sum_{i=0}^{N_x} \mathcal{I}_h^{\mathcal{H}} f(x_i, v)\delta(x, x_i)$ for advection in the v-direction. In the same way we define $\mathcal{L}_h$ thanks to $\mathcal{I}_h^{\mathcal{L}}$.

3.2. Transport operators. In this section we introduce some transport operators. Let $\mathbb{S}_{h,\xi}$ be the translation operator defined by $\mathbb{S}_{h,\xi} f(t, x, v) = f(t, x - h, v - \xi)$. We suppose that $t \in [t^n, t^{n+1}]$, and then we define $\mathcal{T}_1^{0,0}$, $\mathcal{T}_2^{0,0}$, $\mathcal{T}_1^{1,0}$, $\mathcal{T}_1^{0,1}$, $\mathcal{T}_2^{1,0}$, and $\mathcal{T}_2^{0,1}$ as follows:

$$\begin{aligned}
\mathcal{T}_1^{0,0} f(t, x, v) &= f(t, x - v\Delta t/2, v), \\
\mathcal{T}_2^{0,0} f(t, x, v) &= f\left(t, x, v - \Delta t E(t^{n+1/2}, x)\right), \\
\mathcal{T}_1^{1,0} f(t, x, v) &= \partial_x \mathcal{T}_1^{0,0} f(t, x, v) \\
&= \partial_x \left(f(t, x - v\Delta t/2, v)\right) = \partial_x f(t, x - v\Delta t/2, v), \\
\mathcal{T}_1^{0,1} f(t, x, v) &= \partial_v \mathcal{T}_1^{0,0} f(t, x, v) \\
&= \partial_v \left(f(t, x - v\Delta t/2, v)\right) \\
&= \partial_v f(t, x - v\Delta t/2, v) - \frac{\Delta t}{2} \partial_x f(t, x - v\Delta t/2, v), \\
\mathcal{T}_2^{1,0} f(t, x, v) &= \partial_x \mathcal{T}_2^{0,0} f(t, x, v) \\
&= \partial_x \left(f\left(t, x, v - \Delta t E(t^{n+1/2}, x)\right)\right) \\
&= \partial_x f\left(t, x, v - \Delta t E(t^{n+1/2}, x)\right) \\
&\quad - \Delta t \partial_x E\left(t^{n+1/2}, x\right) \partial_v f\left(t, x, v - \Delta t E(t^{n+1/2}, x)\right),
\end{aligned}$$

$$\begin{aligned}\mathcal{T}_2^{0,1} f(t,x,v) &= \partial_v \mathcal{T}_2^{0,0} f(t,x,v) \\ &= \partial_v \left(f\left(t,x,v-\Delta t E(t^{n+1/2},x)\right)\right) = \partial_v f\left(t,x,v-\Delta t E(t^{n+1/2},x)\right),\end{aligned}$$

where $E(t,x)$ is the solution of the Poisson problem (2.2) and (2.5). For a given couple (x_k, v_l) there exists a real $\theta_k \in]0,1[$ and an integer m with $(k+m,l) \in \mathcal{M}_h$ such that $x_k - v_l \Delta t/2 = x_{k+m} + \theta_k \Delta x$. We set

$$\begin{aligned}\phi_0(z) &= \frac{1}{h^3}(h+2z)(h-z)^2, \qquad & \phi_1(z) &= \frac{z^2}{h^3}(3h-2z), \\ \psi_0(z) &= \frac{z}{h^2}(h-z)^2, & \psi_1(z) &= \frac{z^2}{h^2}(z-h),\end{aligned}$$

where h denotes Δx or Δv. Therefore, using the notation $f_{k,l}(t) = f(t,x_k,v_l)$ and $\partial_x f_{k,l}(t) = (\partial_x f)(t,x_k,v_l)$, we define $\widetilde{\mathcal{T}}_1^{0,0}$, $\widetilde{\mathcal{T}}_1^{1,0}$, and $\widetilde{\mathcal{T}}_1^{0,1}$ as follows:

$$\begin{aligned}\left(\widetilde{\mathcal{T}}_1^{0,0} f(t)\right)_{k,l} &= \left(\mathbb{S}_{v\Delta t/2,0} \mathcal{H}_h f\right)(t,x_k,v_l) \\ &= f_{m+k,l}(t)\phi_0(\theta_k\Delta x) + f_{m+k+1,l}(t)\phi_1(\theta_k\Delta x) \\ &\quad + \partial_x f_{m+k,l}(t)\psi_0(\theta_k\Delta x) + \partial_x f_{m+k+1,l}(t)\psi_1(\theta_k\Delta x), \\ \left(\widetilde{\mathcal{T}}_1^{1,0} f(t)\right)_{k,l} &= \left(\mathbb{S}_{v\Delta t/2,0} \partial_x \mathcal{H}_h f\right)(t,x_k,v_l), \\ &= f_{m+k,l}(t)\dot{\phi}_0(\theta_k\Delta x) + f_{m+k+1,l}(t)\dot{\phi}_1(\theta_k\Delta x) \\ &\quad + \partial_x f_{m+k,l}(t)\dot{\psi}_0(\theta_k\Delta x) + \partial_x f_{m+k+1,l}(t)\dot{\psi}_1(\theta_k\Delta x), \\ \left(\widetilde{\mathcal{T}}_1^{0,1} f(t)\right)_{k,l} &= \left(\mathbb{S}_{v\Delta t/2,0} \mathcal{L}_h \partial_v f\right)(t,x_k,v_l) - \frac{\Delta t}{2}\left(\mathbb{S}_{v\Delta t/2,0} \partial_x \mathcal{H}_h f\right)(t,x_k,v_l) \\ &= \sum_{i=k-1}^{k+2} \partial_v f_{m+i,l}(t)\ell_i^3((m+i+\theta_k)\Delta x)) \\ &\quad - \frac{\Delta t}{2}\{f_{m+k,l}(t)\dot{\phi}_0(\theta_k\Delta x) + f_{m+k+1,l}(t)\dot{\phi}_1(\theta_k\Delta x) \\ &\quad + \partial_x f_{m+k,l}(t)\dot{\psi}_0(\theta_k\Delta x) + \partial_x f_{m+k+1,l}(t)\dot{\psi}_1(\theta_k\Delta x)\}.\end{aligned}$$

Here we have used the Lagrange interpolation of degree three on the gradient in order to keep high-order accuracy.

Then we introduce the following two Poisson problems:

$$\text{(P)} \qquad \left\{ \left(\frac{d}{dx} E_h^{n+1/2}\right)(x) = \int_v \widetilde{\mathcal{T}}_1^{0,0} f_h(t^n) dv - 1, \quad \int_0^L E_h^{n+1/2}(x) dx = 0 \right.$$

and

$$\text{(P}') \left\{ \left(\frac{d}{dx}\left(\frac{d}{dx} E_h^{n+1/2}\right)\right)(x) = \int_v \widetilde{\mathcal{T}}_1^{1,0} f_h(t^n) dv, \quad \int_0^L \left(\frac{d}{dx} E_h^{n+1/2}\right)(x) dx = 0. \right.$$

In order to discretize (P) and (P′) we use a finite difference formula of order four for the x-derivative and a quadrature formula of order four for the integration in v. As a

consequence we have the following two schemes:

$$(\mathrm{P}_h)\quad \begin{cases} \dfrac{1}{12\Delta x}\{8(E_h^{n+1/2}(x_{k+1})-E_h^{n+1/2}(x_{k-1}))-(E_h^{n+1/2}(x_{k+2})-E_h^{n+1/2}(x_{k-2}))\} \\ = -1+\dfrac{\Delta v}{3}\Bigg\{ \left(\widetilde{\mathcal{T}}_1^{0,0} f_h(t^n)\right)_{k,0} + \left(\widetilde{\mathcal{T}}_1^{0,0} f_h(t^n)\right)_{k,N_v} \\ +4\displaystyle\sum_{l,\mathrm{odd}} \left(\widetilde{\mathcal{T}}_1^{0,0} f_h(t^n)\right)_{k,l} + 2\sum_{l,\mathrm{even}} \left(\widetilde{\mathcal{T}}_1^{0,0} f_h(t^n)\right)_{k,l} \Bigg\}, \\ E_h^{n+1/2}(x_0)+E_h^{n+1/2}(x_{N_x})+4\displaystyle\sum_{l,\mathrm{odd}} E_h^{n+1/2}(x_l)+2\sum_{l,\mathrm{even}} E_h^{n+1/2}(x_l)=0, \end{cases}$$

$$(\mathrm{P}'_h)\quad \begin{cases} \dfrac{1}{12\Delta x}\{8(\partial_x E_h^{n+1/2}(x_{k+1})-\partial_x E_h^{n+1/2}(x_{k-1}))-(\partial_x E_h^{n+1/2}(x_{k+2}) \\ -\partial_x E_h^{n+1/2}(x_{k-2}))\} = \dfrac{\Delta v}{3}\Bigg\{ \left(\widetilde{\mathcal{T}}_1^{1,0} f_h(t^n)\right)_{k,0} + \left(\widetilde{\mathcal{T}}_1^{1,0} f_h(t^n)\right)_{k,N_v} \\ +4\displaystyle\sum_{l,\mathrm{odd}} \left(\widetilde{\mathcal{T}}_1^{1,0} f_h(t^n)\right)_{k,l} + 2\sum_{l,\mathrm{even}} \left(\widetilde{\mathcal{T}}_1^{1,0} f_h(t^n)\right)_{k,l} \Bigg\}, \\ \partial_x E_h^{n+1/2}(x_0)+\partial_x E_h^{n+1/2}(x_{N_x})+4\displaystyle\sum_{l,\mathrm{odd}} \partial_x E_h^{n+1/2}(x_l)+2\sum_{l,\mathrm{even}} \partial_x E_h^{n+1/2}(x_l)=0. \end{cases}$$

As we choose periodic boundary conditions in the x-direction we have

$$E_h^{n+1/2}(x_{l+N_x+1}) = E_h^{n+1/2}(x_l), \quad \partial_x E_h^{n+1/2}(x_{l+N_x+1}) = \partial_x E_h^{n+1/2}(x_l), \quad l\in\mathbb{Z}.$$

Finally we build $E_h^{n+1/2}(x)$ by using the Hermite interpolation operator $\mathcal{I}_h^{\mathcal{H}}$, and, with $x = x_i+\theta\Delta x$, $0\le\theta\le 1$, we get

$$\begin{aligned} E_h^{n+1/2}(x)_{|_{[x_i,x_{i+1}]}} &= E_h^{n+1/2}(x_i)\phi_0(\theta\Delta x)+E_h^{n+1/2}(x_{i+1})\phi_1(\theta\Delta x) \\ &\quad +\partial_x E_h^{n+1/2}(x_i)\psi_0(\theta\Delta x)+\partial_x E_h^{n+1/2}(x_{i+1})\psi_1(\theta\Delta x). \end{aligned}$$

For a given couple (x_k, v_l) there exists a real $\theta_l\in\,]0,1[$ and an integer m with $(k, l+m)\in\mathcal{M}_h$ such that $v_l-\Delta t E_h^{n+1/2}(x_k) = v_{l+m}+\theta_l\Delta v$. Therefore, using the notation $\partial_v f_{k,l}(t) = (\partial_v f)(t,x_k,v_l)$, we consider the transport operators $\widehat{\mathcal{T}}_2^{0,0}$, $\widehat{\mathcal{T}}_2^{1,0}$, and $\widehat{\mathcal{T}}_2^{0,1}$, defined by

$$\begin{aligned} \widehat{\mathcal{T}}_2^{0,0} f(t,x,v) &= f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right), \\ \widehat{\mathcal{T}}_2^{1,0} f(t,x,v) &= \partial_x \widehat{\mathcal{T}}_2^{0,0} f(t,x,v) \\ &= \partial_x\left(f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right)\right) \\ &= \partial_x f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right) \\ &\quad -\Delta t\partial_x E_h^{n+1/2}(x)\partial_v f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right), \\ \widehat{\mathcal{T}}_2^{0,1} f(t,x,v) &= \partial_v \widehat{\mathcal{T}}_2^{0,0} f(t,x,v) \\ &= \partial_v\left(f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right)\right) = \partial_v f\left(t,x,v-\Delta t E_h^{n+1/2}(x)\right), \end{aligned}$$

and $\widetilde{\mathcal{T}}_2^{0,0}$, $\widetilde{\mathcal{T}}_2^{1,0}$, and $\widetilde{\mathcal{T}}_2^{0,1}$, defined by

$$\begin{aligned}
\left(\widetilde{\mathcal{T}}_2^{0,0} f(t)\right)_{k,l} &= \left(\mathbb{S}_{0,\Delta t E_h} \mathcal{H}_h f\right)(t, x_k, v_l) \\
&= f_{k,m+l}(t)\phi_0(\theta_l \Delta v) + f_{k,m+l+1}(t)\phi_1(\theta_l \Delta v) \\
&\quad + \partial_v f_{k,m+l}(t)\psi_0(\theta_l \Delta v) + \partial_v f_{k,m+l+1}(t)\psi_1(\theta_l \Delta v), \\
\left(\widetilde{\mathcal{T}}_2^{1,0} f(t)\right)_{k,l} &= \left(\mathbb{S}_{0,\Delta t E_h} \mathcal{L}_h \partial_x f\right)(t, x_k, v_l) - \Delta t \partial_x E_h^{n+1/2}(x_k)\left(\mathbb{S}_{0,\Delta t E_h} \partial_v \mathcal{H}_h f\right)(t, x_k, v_l) \\
&= \sum_{i=l-1}^{l+2} \partial_x f_{k,m+i}(t) \ell_i^3((m + i + \theta_l)\Delta v) \\
&\quad - \Delta t \partial_x E_h^{n+1/2}(x_k)\{\partial_v f_{k,m+l}(t)\dot{\phi}_0(\theta_l \Delta v) + f_{k,m+l+1}(t)\dot{\phi}_1(\theta_l \Delta v) \\
&\quad + \partial_v f_{k,m+l}(t)\dot{\psi}_0(\theta_l \Delta v) + \partial_v f_{k,m+l+1}(t)\dot{\psi}_1(\theta_l \Delta v)\}, \\
\left(\widetilde{\mathcal{T}}_2^{0,1} f(t)\right)_{k,l} &= \left(\mathbb{S}_{0,\Delta t E_h} \partial_v \mathcal{H}_h f\right)(t, x_k, v_l) \\
&= f_{k,m+l}(t)\dot{\phi}_0(\theta_l \Delta v) + f_{k,m+l+1}(t)\dot{\phi}_1(\theta_l \Delta v) \\
&\quad + \partial_v f_{k,m+l}(t)\dot{\psi}_0(\theta_l \Delta v) + \partial_v f_{k,m+l+1}(t)\dot{\psi}_1(\theta_l \Delta v).
\end{aligned}$$

Let us notice that the transport operators $\widetilde{\mathcal{T}}_1^{\alpha}$ and $\widetilde{\mathcal{T}}_2^{\alpha}$ act only on a Cartesian grid function and that the operators $\mathcal{T}_1^{\alpha}$, $\mathcal{T}_2^{\alpha}$, and $\widehat{\mathcal{T}}_2^{\alpha}$ act only on functions defined in a Cartesian coordinate system. Therefore when we make the composition of these operators we must take into account this constraint. In order to be more precise we give an abstract example of the composition of such an operator. Let φ and ψ be two applications from $\mathbb{R}^2$ into $\mathbb{R}^2$:

$$\begin{array}{rcl}
\varphi : & \mathbb{R}^2 \longrightarrow \mathbb{R}^2 \\
& (x, v) \longrightarrow \varphi(x, v) = (\varphi_1(x, v), \varphi_2(x, v))
\end{array}
\quad \Big| \quad
\begin{array}{rcl}
\psi : & \mathbb{R}^2 \longrightarrow \mathbb{R}^2 \\
& (x, v) \longrightarrow \psi(x, v) \\
& \qquad = (\psi_1(x, v), \psi_2(x, v)).
\end{array}$$

Let Γ_1 and Γ_1 be two transport operators which act only on functions defined in a Cartesian coordinate system. The operators Γ_1 and Γ_2 are defined as follows:

$$\Gamma_1 f(x, v) = f(\varphi_1(x, v), \varphi_2(x, v)) \quad \text{and} \quad \Gamma_2 f(x, v) = f(\psi_1(x, v), \psi_2(x, v)).$$

Let us now compute $\Gamma_1 \circ \Gamma_2 \circ \Gamma_1 f(x, v)$. First by applying Γ_1 to f we get

$$\Gamma_1 \circ \Gamma_2 \circ \Gamma_1 f(x, v) = \Gamma_1 \circ \Gamma_2 f(\varphi_1(x, v), \varphi_2(x, v)).$$

Now the function $f(\cdot, \cdot)$ is no longer defined in a Cartesian coordinate system, but it is defined in a curvilign coordinate system given by the mapping φ. Nevertheless there exists a function g defined in the original Cartesian coordinate system (x, v) such that $g(x, v) = f(\varphi_1(x, v), \varphi_2(x, v))$. We can now apply the operator Γ_2 to g, and we obtain

$$\begin{aligned}
\Gamma_1 \circ \Gamma_2 \circ \Gamma_1 f(x, v) &= \Gamma_1 \circ \Gamma_2 g(x, v) \\
&= \Gamma_1 g(\psi_1(x, v), \psi_2(x, v)) \\
&= \Gamma_1 f(\varphi_1(\psi_1(x, v), \psi_2(x, v)), \varphi_2(\psi_1(x, v), \psi_2(x, v))).
\end{aligned}$$

Following the same argument as before, there exists a function h which is defined in the original Cartesian coordinate system (x, v) such that $h(x, v) = g(\psi_1(x, v), \psi_2(x, v))$.

Therefore we get

$$\begin{aligned}\Gamma_1\circ\Gamma_2\circ\Gamma_1 f(x,v) &= \Gamma_1\circ\Gamma_2 g(x,v) \;=\; \Gamma_1 g(\psi_1(x,v),\psi_2(x,v)) \;=\; \Gamma_1 h(x,v)\\ &= h(\varphi_1(x,v),\varphi_2(x,v))\\ &= g(\psi_1(\varphi_1(x,v),\varphi_2(x,v)),\psi_2(\varphi_1(x,v),\varphi_2(x,v)))\\ &= f\left(\varphi_1(\psi_1(\varphi_1(x,v),\varphi_2(x,v)),\psi_2(\varphi_1(x,v),\varphi_2(x,v))),\right.\\ &\qquad \left.\varphi_2(\psi_1(\varphi_1(x,v),\varphi_2(x,v)),\psi_2(\varphi_1(x,v),\varphi_2(x,v)))\right).\end{aligned}$$

3.3. Notation and definitions. In this section we introduce some notation and definitions. The grid function $f=\{f_{i,j}\}_{(i,j)\in\mathcal{M}_h}$ belongs to functional space $L^2_h(\Omega)$ if the norm $\|\cdot\|_{L^2_h(\Omega)}$ defined as

$$\|f\|_{L^2_h(\Omega)}=\left(\Delta x\Delta v\sum_{(i,j)\in\mathcal{M}_h}|f_{i,j}|^2\right)^{1/2}$$

is uniformly bounded.

Let

$$\begin{aligned}G:\quad \mathcal{M}_h &\longrightarrow \mathbb{R}^2,\\ (i,j) &\longrightarrow (G_{1_{i,j}},G_{2_{i,j}}),\end{aligned}$$

with $G_1,\ G_2\in L^2_h(\Omega)$. Then we define the norm $\|\cdot\|_{\mathbb{L}^2_h(\Omega)}$ as

$$\|G\|^2_{\mathbb{L}^2_h(\Omega)}=\|G_1\|^2_{L^2_h(\Omega)}+\|G_2\|^2_{L^2_h(\Omega)}.$$

Let $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$ be the vectors $(\mu_0,\dots,\mu_j,\dots,\mu_{N_v})$ and $(\nu_0,\dots,\nu_i,\dots,\nu_{N_x})$, with $0\le\mu_j,\nu_i\le 1$ for all $(i,j)\in[0,N_x]\times[0,N_v]$. Then we define the norm $\|\cdot\|_{L^2_h,\Delta^{\boldsymbol{\mu},\boldsymbol{\nu}}_h}$ by

$$\|f\|_{L^2_h,\Delta^{\boldsymbol{\mu},\boldsymbol{\nu}}_h}=\left(\Delta x\Delta v\sum_{(i,j)\in\mathcal{M}_h}|f_{i+\mu_j,j+\nu_i}|^2\right)^{1/2}.$$

We also define the translation operator $\tau_{\boldsymbol{\mu},\boldsymbol{\nu}}$ as follows:

$$(\tau_{\boldsymbol{\mu},\boldsymbol{\nu}}f)_{i,j}=f_{i+\mu_j,j+\nu_i}=f(x_i+\mu_j\Delta x,v_j+\nu_i\Delta v).$$

We continue by introducing the space $\ell^\infty(0,T;X)$ defined by

$$\begin{aligned}\ell^\infty(0,T;X):=\Big\{&f:\{t^0,\dots,t^M\}\to X|M\Delta t=T,\\ &||f||_{\ell^\infty(0,T;X)}=\max_{1\le n\le M}||f(t^n)||_X<\infty\Big\},\end{aligned}$$

where X denotes a functional space with norm $||.||_X$, and the norm $\|\cdot\|_{L^\infty_h}$ defined by

$$\|f\|_{L^\infty_h}=\max_{(i,j)\in\mathcal{M}_h}|f_{i,j}|.$$

We introduce now the notation

$$\mathcal{T}^\alpha,\quad \mathcal{T}\in\left\{\mathcal{T}_1,\mathcal{T}_2,\widetilde{\mathcal{T}}_1,\widetilde{\mathcal{T}}_2,\widehat{\mathcal{T}}_2\right\},$$

where $\alpha=(\alpha_1,\alpha_2)\in\{(0,0),(1,0),(0,1)\}$, with $|\alpha|=\alpha_1+\alpha_2$. In order to simplify the notation the following conventions are used:

$$\nabla\mathcal{T}=\begin{pmatrix}\mathcal{T}^{1,0}\\ \mathcal{T}^{0,1}\end{pmatrix},\qquad \partial^\alpha f\in\{\partial^{0,0}f,\partial^{1,0}f,\partial^{0,1}f\}=\{f,\partial_x f,\partial_v f\}.$$

3.4. The numerical scheme. We suppose that we know $f_h(t^n) = \left\{f_{i,j}^n, \partial_x f_{i,j}^n, \partial_v f_{i,j}^n\right\}_{(i,j)\in\mathcal{M}_h}$. Therefore the numerical scheme which allows us to go from time t^n to t^{n+1} and compute $f_h(t^{n+1}) = \left\{f_{i,j}^{n+1}, \partial_x f_{i,j}^{n+1}, \partial_v f_{i,j}^{n+1}\right\}_{(i,j)\in\mathcal{M}_h}$ can be described in four steps:

(A1) We evaluate the distribution function and its partial derivatives at time t^n at the foot of the field-free characteristics starting at $\{(x_k, v_l)\}_{(k,l)\in\mathcal{M}_h}$ at time $t^{n+1/2}$ using $\mathcal{L}_h$ and $\mathcal{H}_h$, the Lagrange and Hermite interpolation operators, respectively. Then we obtain three new grid functions: One approximates the particle distribution, and the other two approximate its gradients. These actions are described by the transport operators $\widetilde{\mathcal{T}}_1^{\alpha}$. The superscripts denote the position or velocity gradient under consideration.

(A2) The output from (A1) is integrated with respect to velocity (by a quadrature formula of order four) to provide an approximation for the density and its gradient at time $t^{n+1/2}$, which are then substituted into the Poisson equations (P_h) and (P_h') to compute the approximation of the electric field and its gradient at time $t^{n+1/2}$, respectively.

(A3) Therefore the result obtained from (A1) is evaluated at the foot of the velocity characteristic starting at $\{(x_k, v_l)\}_{(k,l)\in\mathcal{M}_h}$ at time t^{n+1} with the acceleration field found in (A2) using $\mathcal{L}_h$ and $\mathcal{H}_h$, the Lagrange and Hermite interpolation operators, respectively. Then we obtain three new grid functions: One approximates the particle distribution, and the other two approximate its gradients. These actions are described by the transport operators $\widetilde{\mathcal{T}}_2^{\alpha}$, with the superscripts denoting the appropriate gradient under consideration.

(A4) Between time $t^{n+1/2}$ and t^{n+1}, we apply step (A1) to the output from (A3). This action is described by the transport operators $\widetilde{\mathcal{T}}_1^{\alpha}$. Then we obtain $f_h(t^{n+1})$, the distribution function and its gradients at time t^{n+1}, which are the new initial data for the algorithm (A1)–(A4).

By using transport operators defined in section 3.2 the numerical scheme can be written as

$$\left(\partial^{\alpha} f_h(t^{n+1})\right)_{k,l} = \left(\widetilde{\mathcal{T}}_1^{\alpha} \circ \widetilde{\mathcal{T}}_2^{\alpha} \circ \widetilde{\mathcal{T}}_1^{\alpha} f_h(t^n)\right)_{k,l}, \quad |\alpha| \leq 1,\ k \in [0, N_x],\ l \in [0, N_v],$$

with $(\partial^{\alpha} f_h^0) = (\partial^{\alpha} f_0)_{k,l}$, $|\alpha| \leq 1$, as a discretization of the initial data f_0, $\partial^{\alpha} f_h^n(x_0 + L, v_l) = \partial^{\alpha} f_h^n(x_0, v_l)$, $|\alpha| \leq 1$, for all $l \in [0, N_v]$, the boundary condition in the x-direction, and $\partial^{\alpha} f_h^n(x, v_l) = 0$, for all $|v_l| > R$, for all $x \in [0, L]$, $|\alpha| \leq 1$, the boundary condition in the v-direction.

Let us note that the method presented in this paper belongs to the class of semi-Lagrangian methods but has the distinctive feature of using a splitting à la Strang for the operators associated to the transport of the distribution function and its gradient.

4. Convergence analysis. Let us state the convergence theorem and give the a priori error estimates.

THEOREM 4.1. *Assume that* $f \in \mathscr{C}^2(0, T; \mathscr{C}^4_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, *is positive, and is periodic with respect to the variable* x *with period* L; *then the numerical solution of the Vlasov–Poisson system* (f_h, E_h), *computed by the numerical scheme exposed in section* 3.4, *converges towards the solution* (f, E) *of the periodic Vlasov–Poisson system, and there exists a constant* $C = C(||f||_{\mathscr{C}^2(0,T;\mathscr{C}^4_b(\Omega))})$ *independent of* Δt, Δx,

and Δv *such that for* $|\alpha| \leq 1$ *we have*

$$||\partial^\alpha f - \partial^\alpha f_h||_{l^\infty\left(0,T;L^2_h(\Omega)\right)} \leq C\Bigg(\Delta t^2 + \frac{\Delta x^{4-|\alpha|} + \Delta v^{4-|\alpha|}}{\Delta t}. \\ + \frac{\left(\Delta x^4 + \Delta v^4\right)}{\Delta x^{|\alpha|}}\left(1 + \frac{\Delta x}{\Delta t} + \frac{1}{\Delta t}\right)\Bigg)$$

and

$$||\partial^\alpha E - \partial^\alpha E_h||_{l^\infty\left(0,T;L^\infty_h([0,L])\right)} \leq C\Bigg(\Delta t^2 + \Delta x^4 + \Delta v^4 + \Delta x^{4-|\alpha|} \\ + \frac{\left(\Delta x^4 + \Delta v^4\right)}{\Delta x^{|\alpha|}}\left(1 + \frac{\Delta x}{\Delta t} + \frac{1}{\Delta t}\right) \\ + \frac{\Delta x^{4-|\alpha|} + \Delta v^{4-|\alpha|}}{\Delta t}\Bigg).$$

Remark 4.2. Theorem 4.1 tells us that the convergence occurred with a rate in $\mathcal{O}(\Delta t^2 + \Delta t^{-1}(\Delta x^{4-|\alpha|} + \Delta v^{4-|\alpha|}))$, $\alpha \in \mathbb{N}^2$, $|\alpha| \leq 1$. If $f \in \mathscr{C}^1(0,T;\mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, the convergence rate will be in $\mathcal{O}(\Delta t + \Delta t^{-1}(\Delta x^{2-|\alpha|} + \Delta v^{2-|\alpha|}))$, $\alpha \in \mathbb{N}^2$, $|\alpha| \leq 1$.

Idea of the proof. We want to evaluate the global error at the time t^{n+1} in the L^2_h norm

$$\|\partial^\alpha e^{n+1}\|_{L^2_h(\Omega)} = ||\partial^\alpha f(t^{n+1}) - \partial^\alpha f_h(t^{n+1})||_{L^2_h(\Omega)}.$$

Therefore we decompose $\partial^\alpha f(t^{n+1}, x_k, v_l) - \partial^\alpha f_h(t^{n+1}, x_k, v_l)$ as follows:

$$\begin{aligned}
&\partial^\alpha f(t^{n+1}, x_k, v_l) - \partial^\alpha f_h(t^{n+1}, x_k, v_l) \\
&\qquad = \partial^\alpha f(t^{n+1}, x_k, v_l) - \left(\mathcal{T}_1^\alpha \circ \mathcal{T}_2^\alpha \circ \mathcal{T}_1^\alpha f(t^n)\right)_{k,l} && \text{(I1)} \\
&\qquad + \left(\mathcal{T}_1^\alpha \circ \mathcal{T}_2^\alpha \circ \mathcal{T}_1^\alpha f(t^n)\right)_{k,l} - \left(\mathcal{T}_1^\alpha \circ \widehat{\mathcal{T}}_2^\alpha \circ \mathcal{T}_1^\alpha f(t^n)\right)_{k,l} && \text{(I2)} \\
&\qquad + \left(\mathcal{T}_1^\alpha \circ \widehat{\mathcal{T}}_2^\alpha \circ \mathcal{T}_1^\alpha f(t^n)\right)_{k,l} - \left(\widetilde{\mathcal{T}}_1^\alpha \circ \widetilde{\mathcal{T}}_2^\alpha \circ \widetilde{\mathcal{T}}_1^\alpha f(t^n)\right)_{k,l} && \text{(I3)} \\
&\qquad + \left(\widetilde{\mathcal{T}}_1^\alpha \circ \widetilde{\mathcal{T}}_2^\alpha \circ \widetilde{\mathcal{T}}_1^\alpha (f(t^n) - f_h(t^n))\right)_{k,l}. && \text{(I4)}
\end{aligned}$$

In order to estimate $\|\partial^\alpha e^{n+1}\|_{L^2_h(\Omega)}$ we will estimate the four right-hand terms of the previous equation. These estimates are described in the following section.

A priori estimates. The following lemma gives an estimate for the term (I1), which can be viewed as a discretization error in time.

LEMMA 4.3. *Assuming that* $f \in \mathscr{C}^2_b(0,T;\mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, *then there exists a constant* C *such that for* $|\alpha| \leq 1$ *we get*

$$\left\|\partial^\alpha f(t^{n+1}) - \mathcal{T}_1^\alpha \circ \mathcal{T}_2^\alpha \circ \mathcal{T}_1^\alpha f(t^n)\right\|_{L^2_h(\Omega)} \leq C\Delta t^3.$$

Proof. On one hand we can write

$$\begin{aligned}
f(t^{n+1}, x, v) &= f(t^{n+1}, X(t^{n+1}; t^{n+1}, x, v), V(t^{n+1}; t^{n+1}, x, v)) \\
&= f(t^n, X(t^n; t^{n+1}, x, v), V(t^n; t^{n+1}, x, v)) \\
&= f(t^n, X(t^n), V(t^n))
\end{aligned}$$

and

$$\begin{aligned}\nabla f(t^{n+1},x,v) &= \begin{pmatrix} \dfrac{\partial f}{\partial x}(t^{n+1},x,v) \\ \dfrac{\partial f}{\partial v}(t^{n+1},x,v) \end{pmatrix} \\ &= \begin{pmatrix} \dfrac{\partial X}{\partial x}(t^n) & \dfrac{\partial V}{\partial x}(t^n) \\ \dfrac{\partial X}{\partial v}(t^n) & \dfrac{\partial V}{\partial v}(t^n) \end{pmatrix} \begin{pmatrix} \dfrac{\partial f}{\partial X}(t^n,X(t^n),V(t^n)) \\ \dfrac{\partial f}{\partial V}(t^n,X(t^n),V(t^n)) \end{pmatrix} \\ &= \nabla(X(t^n),V(t^n))\nabla f(t^n,X(t^n),V(t^n)).\end{aligned}$$

Now we introduce $\mathbb{T}_1$ and $\mathbb{T}_2$ defined by

$$\mathbb{T}_1 = \begin{pmatrix} \mathcal{T}_1^{0,0} \\ \mathcal{T}_1^{1,0} \\ \mathcal{T}_1^{0,1} \end{pmatrix}, \qquad \mathbb{T}_2 = \begin{pmatrix} \mathcal{T}_2^{0,0} \\ \mathcal{T}_2^{1,0} \\ \mathcal{T}_2^{0,1} \end{pmatrix}.$$

On the other hand we get

$$\begin{aligned}\mathbb{T}_1 \circ \mathbb{T}_2 \circ \mathbb{T}_1 f(t^n) &= \mathbb{T}_1 \circ \mathbb{T}_2 \circ \mathbb{T}_1 f(t^n,x,v) \\ &= \mathbb{T}_1 \circ \mathbb{T}_2 \begin{pmatrix} f(t^n,x-v\Delta t/2,v) \\ \partial_x f(t^n,x-v\Delta t/2,v) \\ \partial_v f(t^n,x-v\Delta t/2,v) - \frac{\Delta t}{2}\partial_x f(t^n,x-v\Delta t/2,v) \end{pmatrix} \\ &= \mathbb{T}_1 \begin{pmatrix} f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x)) \\ \\ \partial_x f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x)) \\ -\Delta t \partial_x E(t^{n+1/2},x) \\ \times\{\partial_v f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x)) \\ -\frac{\Delta t}{2}\partial_x f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x))\} \\ \\ \partial_v f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x)) \\ -\frac{\Delta t}{2}\partial_x f(t^n,x-v\frac{\Delta t}{2}+\frac{\Delta t^2}{2}E(t^{n+1/2},x),v-\Delta t E(t^{n+1/2},x)) \end{pmatrix} \\ &= \begin{pmatrix} f(t^n,\widetilde{X}(t^n),\widetilde{V}(t^n)) \\ \dfrac{\partial \widetilde{X}}{\partial x}(t^n)\partial_x f(t^n,\widetilde{X}(t^n),\widetilde{V}(t^n)) + \dfrac{\partial \widetilde{V}}{\partial x}(t^n)\partial_v f(t^n,\widetilde{X}(t^n),\widetilde{V}(t^n)) \\ \dfrac{\partial \widetilde{X}}{\partial v}(t^n)\partial_x f(t^n,\widetilde{X}(t^n),\widetilde{V}(t^n)) + \dfrac{\partial \widetilde{V}}{\partial v}(t^n)\partial_v f(t^n,\widetilde{X}(t^n),\widetilde{V}(t^n)) \end{pmatrix},\end{aligned}$$

where

$$\widetilde{X}(t^n) = x - v\Delta t + \frac{\Delta t^2}{2}E(t^{n+1/2},x-v\Delta t/2)$$

and

$$\widetilde{V}(t^n) = v - \Delta t E(t^{n+1/2}, x - v\Delta t/2).$$

A Taylor expansion gives

$$\begin{aligned} X(t^{n+1/2}) - (x - v\Delta t/2) &= X(t^{n+1/2}) - \left(X(t^{n+1}) - V(t^{n+1})\frac{\Delta t}{2}\right) \\ &= X(t^{n+1/2}) - \left(X(t^{n+1}) - \frac{\Delta t}{2}\dot{X}(t^{n+1})\right) \\ &= \mathcal{O}(\Delta t^2). \end{aligned} \tag{4.1}$$

By using (4.1) we get

$$\begin{aligned} V(t^n) - \widetilde{V}(t^n) &= V(t^n) - \left(V(t^{n+1}) - \Delta t E\left(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\frac{\Delta t}{2}\right)\right) \\ &= V(t^n) - \left(V(t^{n+1}) - \Delta t E\left(t^{n+1/2}, X(t^{n+1/2}) + \mathcal{O}(\Delta t^2)\right)\right) \\ &= V(t^n) - (V(t^{n+1}) - \Delta t E(t^{n+1/2}, X(t^{n+1/2})) + \mathcal{O}(\Delta t^3) \\ &= V(t^n) - V(t^{n+1}) + \Delta t \dot{V}(t^{n+1/2}) + \mathcal{O}(\Delta t^3). \end{aligned}$$

We deduce that

$$\begin{aligned} &\sup\left\{\left|\partial^\alpha V(t^n; t^{n+1}, x, v) - \partial^\alpha \widetilde{V}(t^n; t^{n+1}, x, v)\right| \mid \forall (x,v) \in [0,L]\times[-R,R],\ |\alpha| \le 1\right\} \\ &\quad \le C\Delta t^3. \end{aligned}$$

In the same way we have

$$\begin{aligned} &X(t^n) - \widetilde{X}(t^n) \\ &\quad = X(t^n) - \left(X(t^{n+1}) - \Delta t V(t^{n+1}) + \frac{\Delta t^2}{2} E\left(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\frac{\Delta t}{2}\right)\right) \\ &\quad = X(t^n) - \left(X(t^{n+1}) - \Delta t V(t^{n+1}) + \frac{\Delta t^2}{2} E(t^{n+1/2}, X(t^{n+1/2}) + \mathcal{O}(\Delta t^2))\right) \\ &\quad = X(t^n) - \left(X(t^{n+1}) - \Delta t V(t^{n+1}) + \frac{\Delta t^2}{2} E(t^{n+1/2}, X(t^{n+1/2}))\right) + \mathcal{O}(\Delta t^4) \\ &\quad = X(t^n) - \left(X(t^{n+1}) - \Delta t \dot{X}(t^{n+1}) + \frac{\Delta t^2}{2}\ddot{X}(t^{n+1/2})\right) + \mathcal{O}(\Delta t^4) \\ &\quad = X(t^n) - \left(X(t^{n+1}) - \Delta t \dot{X}(t^{n+1}) + \frac{\Delta t^2}{2}\ddot{X}(t^{n+1})\right) + \mathcal{O}(\Delta t^3). \end{aligned}$$

It follows that

$$\sup\left\{\left|\partial^\alpha X(t^n) - \partial^\alpha \widetilde{X}(t^n)\right| \mid \forall (x,v) \in [0,L]\times[-R,R],\ |\alpha| \le 1\right\} \le C\Delta t^3.$$

We note that

$$X_{k,l}(t^n) = X(t^n; t^{n+1}, x_k, v_l), \qquad V_{k,l}(t^n) = V(t^n; t^{n+1}, x_k, v_l).$$

Finally we get

$$\begin{aligned}(\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n))_{k,l} &= f(t^n, X_{k,l}(t^n) + \mathcal{O}(\Delta t^3), V_{k,l}(t^n) + \mathcal{O}(\Delta t^3)) \\ &= f(t^n, X_{k,l}(t^n), V_{k,l}(t^n)) + \nabla f(t^n, X_{k,l}(t^n), V_{k,l}(t^n)).\mathcal{O}(\Delta t^3) \\ &= f(t^{n+1}, X_{k,l}(t^{n+1}), V_{k,l}(t^{n+1})) + \nabla f(t^n, X_{k,l}(t^n), V_{k,l}(t^n)).\mathcal{O}(\Delta t^3) \\ &= f(t^{n+1}, x_k, v_l) + \nabla f(t^n, X_{k,l}(t^n), V_{k,l}(t^n)).\mathcal{O}(\Delta t^3)\end{aligned}$$

and

$$\|f(t^{n+1}) - \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n)\|_{L^2_h(\Omega)} \leq C\Delta t^3 \|\nabla f\|_{l^\infty(0,T;L^\infty(\Omega))}.$$

Moreover we have

$$\begin{aligned}&\left|\nabla f(t^{n+1}, x_k, v_l) - (\nabla\mathcal{T}_1 \circ \nabla\mathcal{T}_2 \circ \nabla\mathcal{T}_1 f(t^n))_{k,l}\right| \\ &\qquad \leq \left|\left(\nabla\widetilde{X}_{k,l}(t^n), \nabla\widetilde{V}_{k,l}(t^n)\right) - (\nabla X_{k,l}(t^n), \nabla V_{k,l}(t^n))\right| \\ &\qquad\quad \cdot \left|\nabla f\left(t^n, \widetilde{X}_{k,l}(t^n), \widetilde{V}_{k,l}(t^n)\right)\right| + |(\nabla X_{k,l}(t^n), \nabla V_{k,l}(t^n))| \\ &\qquad\quad \cdot \left|\nabla f\left(t^n, \widetilde{X}_{k,l}(t^n), \widetilde{V}_{k,l}(t^n)\right) - \nabla f\left(t^n, X_{k,l}(t^n), V_{k,l}(t^n)\right)\right|,\end{aligned}$$

so that we get

$$\begin{aligned}&\left\|\nabla f(t^{n+1}) - \nabla\mathcal{T}_1 \circ \nabla\mathcal{T}_2 \circ \nabla\mathcal{T}_1 f(t^n)\right\|_{\mathbb{L}^2_h(\Omega)} \\ &\qquad \leq C\Delta t^3 \left(\|\nabla f\|_{l^\infty(0,T;L^\infty(\Omega))} + \left\|\nabla^2 f\right\|_{l^\infty(0,T;L^\infty(\Omega))}\right),\end{aligned}$$

which ends the proof. □

We go on with a proposition which gives information on the L^2_h-stability of the interpolation operators.

PROPOSITION 4.4. *Let $\mathcal{H}_h$ and $\mathcal{L}_h$ be the interpolation operators and $\tau_{\boldsymbol{\mu},\boldsymbol{\nu}}$ the translation operator defined in section* 3.1. *Then for all functions $f \in \mathscr{C}\left(0,T;\mathscr{C}^1_b(\Omega)\right)$, we get the estimates*

$$\|\tau_{\boldsymbol{\mu},0}\mathcal{L}_h f\|_{L^2_h(\Omega)} \leq \|f\|_{L^2_h(\Omega)}, \tag{4.2}$$

$$\|\tau_{\boldsymbol{\mu},0}\mathcal{H}_h f\|_{L^2_h(\Omega)} \leq \|f\|_{L^2_h(\Omega)}, \tag{4.3}$$

$$\|\tau_{\boldsymbol{\mu},0}\partial_x\mathcal{H}_h f\|_{L^2_h(\Omega)} \leq \|\partial_x f\|_{L^2_h(\Omega)}, \tag{4.4}$$

$$\|\tau_{0,\boldsymbol{\nu}}\mathcal{L}_h f\|_{L^2_h(\Omega)} \leq \|f\|_{L^2_h(\Omega)}, \tag{4.5}$$

$$\|\tau_{0,\boldsymbol{\nu}}\mathcal{H}_h f\|_{L^2_h(\Omega)} \leq \|f\|_{L^2_h(\Omega)}, \tag{4.6}$$

$$\|\tau_{0,\boldsymbol{\nu}}\partial_v\mathcal{H}_h f\|_{L^2_h(\Omega)} \leq \|\partial_v f\|_{L^2_h(\Omega)}. \tag{4.7}$$

Proof. We give only the proof for the estimates (4.2)–(4.4), because the proof of inequalities (4.5)–(4.7) is the same.

Let us start with the estimate (4.2). We have

$$\|\tau_{\boldsymbol{\mu},0}\mathcal{L}_h f\|_{L^2_h(\Omega)} = \|\mathcal{L}_h f\|_{L^2_h,\Delta_h^{\boldsymbol{\mu},0}}.$$

Let $\boldsymbol{\omega} = (\omega_x, \omega_v)$ be a two-component vector belonging to $\mathbb{Z}^2$. $\mathbf{z}$ is an abbreviation for (x, v), and $\mathbf{k}$ is an abbreviation for (k_x, k_v). k_x (resp., k_v) takes the values $2\pi\omega_x/L$

(resp., $2\pi\omega_v/(2R)$), where ω_x and ω_v are integers. If we note that $\mathbf{N} = (N_x, N_v)$ and $\mathbf{z}_{k,l} = (x_k, v_l)$, the Fourier series decomposition of f gives

$$f_{i,j} = \frac{1}{|\Omega|^{1/2}} \sum_{|\boldsymbol{\omega}| \le \mathbf{N}/2} \widehat{f}(\boldsymbol{\omega}) e^{i\langle \mathbf{k}(\boldsymbol{\omega}), \mathbf{z}_{i,j}\rangle}.$$

Therefore we get

$$\begin{aligned}(\mathcal{L}_h f)_{i+\mu_j,j} &= \frac{1}{|\Omega|^{1/2}} \sum_{|\boldsymbol{\omega}| \le \mathbf{N}/2} \sum_{k=i-1}^{i+2} \widehat{f}(\boldsymbol{\omega}) \ell_k^3(x_i + \mu_j \Delta x) e^{i\langle \mathbf{k}(\boldsymbol{\omega}), \mathbf{z}_{k,j}\rangle} \\ &= \frac{1}{|\Omega|^{1/2}} \sum_{|\boldsymbol{\omega}| \le \mathbf{N}/2} \widehat{f}(\boldsymbol{\omega}) \varrho(\mu_j, \omega_x) e^{i\langle \mathbf{k}(\boldsymbol{\omega}), \mathbf{z}_{i-1,j}\rangle},\end{aligned}$$

where

$$\varrho(\mu_j, \omega_x) = \sum_{k=0}^{3} \ell_k^3((1+\mu_j)\Delta x) e^{ik_x(\omega_x)x_k}.$$

As a consequence we obtain

$$\begin{aligned}\|\mathcal{L}_h f\|^2_{L_h^2, \Delta_h^{\boldsymbol{\mu},0}} &= \Delta x \Delta v \sum_{i=0}^{N_x} \sum_{j=0}^{N_v} (\mathcal{L}_h f)_{i+\mu_j,j} \overline{(\mathcal{L}_h f)}_{i+\mu_j,j} \\ &= \frac{\Delta x \Delta v}{|\Omega|} \sum_{i=0}^{N_x} \sum_{j=0}^{N_v} \sum_{|\boldsymbol{\omega}| \le \mathbf{N}/2} \sum_{|\boldsymbol{\omega}'| \le \mathbf{N}/2} \widehat{f}(\boldsymbol{\omega}) \overline{\widehat{f}(\boldsymbol{\omega}')} \varrho(\mu_j, \omega_x) \overline{\varrho(\mu_j, \omega_x')} \\ &\qquad e^{-i\langle \mathbf{k}(\boldsymbol{\omega}) - \mathbf{k}(\boldsymbol{\omega}'), (1,0)\rangle} e^{i\langle \mathbf{k}(\boldsymbol{\omega}) - \mathbf{k}(\boldsymbol{\omega}'), \mathbf{z}_{i,j}\rangle}.\end{aligned}$$

Since

$$\frac{\Delta x}{|L|} \sum_{i=0}^{N_x} e^{i(k_x(\omega_x) - k_x(\omega_x'))x_i} = \delta_{\omega_x, \omega_x'},$$

we find

$$\|\mathcal{L}_h f\|^2_{L_h^2, \Delta_h^{\boldsymbol{\mu},0}} = \frac{\Delta v}{|2R|} \sum_{j=0}^{N_v} \sum_{|\boldsymbol{\omega}| \le \mathbf{N}/2} \sum_{|\omega_v'| \le N_v/2} \widehat{f}(\boldsymbol{\omega}) \overline{\widehat{f}(\omega_x, \omega_v')} |\varrho(\mu_j, \omega_x)|^2 e^{i(k_v(\omega_v) - k_v(\omega_v'))v_j}.$$

Finally as

$$\frac{\Delta v}{|2R|} \sum_{j=0}^{N_v} e^{i(k_v(\omega_v) - k_v(\omega_v'))v_j} = \delta_{\omega_v, \omega_v'},$$

we get
